Results: 46 patients with biopsy-proven NAFLD patients were enrolled from October 2016 to May 2017. Mean age and BMI were 51.2 ± 12.8 years and 27.6 ± 7.5 kg/m^2, respectively. Female was dominant (30, 63.4%) and other co-morbidities were diabetes (n = 18, 38.3%), hypertension (n = 16, 34.0%) and dyslipidemia (n = 15, 31.9%). For diagnosis of advanced fibrosis (stage 3–4), the AUROC of MRE tended to be superior (0.88; 95% CI, 0.74–0.97) comparing with TE (0.85; 95% CI, 0.72–0.95) (p = 0.532). For diagnosis of severe steatosis (stage 2–3), CAP (0.69; 95% CI, 0.51–0.83) showed lower AUROC compared with mDIXON (0.83; 95% CI, 0.67–0.93; p = 0.0.35) and MRS (0.83; 95% CI, 0.67–0.93; p = 0.109), respectively. In serum biomarker analysis, increased resistin had a significant association with severe steatosis (stage 2–3) compared to mild steatosis (stage 0–1) (OR = 1.44; 95% CI, 1.01–2.06; p = 0.04). Increased IFN-γ was associated with severe inflammation (stage 2–3) compared to mild inflammation (stage 0–1) (OR = 1.36; 95% CI, 1.01–1.83; p = 0.04). Total PAI-1 showed tendency of association with presence of NASH (OR = 1.063; 95% CI, 0.99–1.14; p = 0.07).
Conclusion: In our preliminary results, MRI (mDIXON, MRS and MRE) tended to identify more severe steatosis and fibrosis compared to TE in patients with biopsy-proven NAFLD. Serum IFN-γ was significantly associated with inflammation and serum resistin was also associated with steatosis. Non-invasive modalities using MRI and serum biomarker could be potential tools for diagnosis and classification of disease severity in patients with NAFLD.

FRI-469

Monocyte subpopulations for non-invasive diagnosis of NAFLD and NASH in a bariatric patient collective

K. Staufer[1,2], K. Scheuba[1], F. Winkler[1], M. Eilenberg[3], F. Langer[3], M. Trauner[4], C. Brostjan[1], G. Prager[3]. *[1]Medical University of Vienna, Surgical Research Laboratories, Vienna, Austria; [2]Medical University of Vienna, Department of Surgery, Division of Transplantation, Vienna, Austria; [3]Medical University of Vienna, Department of Surgery, Division of General Surgery, Vienna, Austria; [4]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria*
Email: katharina.staufer@meduniwien.ac.at

Background and Aims: Up to 80% of patients with obesity suffer from non-alcoholic fatty liver disease (NAFLD) including non-alcoholic steatohepatitis (NASH). The present study investigated inflammatory-induced changes in monocyte-subpopulations for the non-invasive diagnosis of NAFLD, as well as the differentiation of NASH and non-alcoholic fatty liver (NAFL).
Method: Patients with NAFLD scheduled for bariatric surgery between 07/2015 and 05/2017, as well as healthy controls were consecutively included. The expression profile of monocyte surface markers for the differentiation of classical (CL; CD14++ CD16-), non-classical (NC; CD14+ CD16++) and intermediate monocytes (IM; CD14++ CD16+) were investigated by flow cytometry in EDTA whole blood. According to intra-operative liver biopsy patients were stratified into NAFL and NASH and disease activity was graded based on NAFLD-activity score (NAS).
Results: In total, 80 patients (m:f = 34:46, median BMI: 43,8) und 27 healthy controls (m:f = 15:12, median BMI: 25,0) were included. Seventy-nine percent of patients suffered from NASH, 21% presented with NAFL.
The median absolute concentration of monocyte subpopulations was significantly higher in patients with NAFLD than in healthy controls. In contrast, the relative number of monocyte subpopulations showed a significant rise of IM, as well as a significant decrease in CL in patients with NAFLD, whereas NC were equal in both groups.
Patients with NASH had significantly higher absolute IM/ml, as well as a significantly lower CL/IM ratio than patients with NAFL or healthy controls.
The absolute IM concentration was the most suitable diagnostic marker for NAFLD (AUC 0.861; cut-off > 18.7; sensitivity 71%;

specificity 89%). The CL/IM ratio was the most suitable marker for the presence of NASH (AUC 0.706; cut-off < 20.1; sensitivity 71%; specificity 72%).
Conclusion: Monocyte subpopulations are suited for the non-invasive diagnosis of NAFLD and NASH. The inflammatory process within NASH seems to be reflected by a strong activation of monocytes which can be non-invasively and therefore repeatedly monitored in peripheral blood.

FRI-470
Comparing of noninvasive tests in predicting diagnosis of Nonalcoholic Steatohepatitis

C.F. Braticevici, M. Alexandru, L. Tribus, P. Razvan, P. Ana, A. Necula, U. Radu. [1]*"Carol Davila" University of Medicine and Pharmacy, University Hospital Bucharest, Gastroenterology, Romania*
Email: cfierbinteanu@yahoo.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) encompasses two sub-types of conditions with different prognosis: fatty liver (steatosis) and steatohepatitis (NASH). Many studies have highlighted that the identification of the NASH sub-group is crucial due to its higher risk for liver disease progression toward cirrhosis and end-stage liver disease. The invasive liver biopsy remains the gold standard diagnostic test for NASH. **Aim**: to evaluate and compare the efficacy and clinical utility of three non-invasive methods for identifying NASH among patients diagnosed with NAFLD.
Method: 71 patients with histological proven NAFLD were included in the study. All the patients underwent stable isotope breath tests ^{13}C Methacetin (^{13}C – MBT) and ^{13}C-Octanoate (^{13}C–OBT) for microsomal and mitochondrial liver function and acoustic radiation force impulse (ARFI) elastography, a promising method for assessing liver fibrosis in patients with chronic liver disease. The main endpoint was to evaluate the diagnostic accuracy of each test using the area under receiver operating characteristic curve (AUROC) with 95%CI referring to liver histology (SAF scoring system) as gold standard. The correlation between the non-invasive measurements and liver biopsy was tested using Spearman's coefficient
Results: Patients were divided in two groups according to the histologic characteristics: 31 patients with steatosis and 40 patients with NASH. The ability of non-invasive tests in predicting NASH according to the areas under the curve for ^{13}C - OBT, ARFI and ^{13}C – MBT was: 0.930, 0.867, 0.824 respectively. The best parameter for ^{13}C-OBT was Dose at 15 min (r = 0.625, p < 0.001), for ARFI elastography was 1.20 m/s – ten measurements average (r = 0.597, p < 0.001) and for ^{13}C-MBT was Dose at 20 min (r = –0.602, p < 0.001). ROC analysis for each test: best cutoff, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) are presented in table1.

	^{13}C-MBT	^{13}C-OBT	ARFI elastography
Sensitivity	69.5%	84.6%	76.7%
Specificity	72.9%	81.8%	83.3%
PPV	74.0%	84.6%	91.6%
NPV	69.7%	81.8%	60.0%
Cut-off	27 ^{13}C%	22 ^{13}C%	1.2 m/s
AUROC	0.824	0.930	0.867
(95%CI)	0.723–0.926	0.879–1.000	0.782–0.953

Conclusion: All the noninvasive tests used in our study are promising methods with very good accuracy (for ^{13}C-OBT) and good accuracy (for ARFI elastography and for ^{13}C-MBT) in identifying patients with NASH and may become tools in clinical practice.

FRI-471
Machine learning approaches for non-invasive ultrasound. Based quantitative assessment of liver steatosis

N.D. Lascio[1], C. Avigo[1], A. Salvati[2], N. Martini[3], M. Ragucci[4], S. Monti[5], A. Prinster[4], D. Chiappino[3], M. Mancini[4], F. Bonino[2], M. Brunetto[2], F. Faita[1]. [1]*Institute of Clinical Physiology;* [2]*University of Pisa;* [3]*Tuscany Foundation G. Monasterio;* [4]*Institute of Biostructure and Bioimages;* [5]*IRCSS Sdn*
Email: f.faita@ifc.cnr.it

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is becoming a global epidemic and is considered the most common chronic liver disease in Western countries. We propose a non-invasive and easy-to-use system based on quantitative extraction of features form ultrasound (US) hepatic images and machine learning approaches for the classification of steatosis severity.
Method: The study population included 54 subjects and was divided on the percentage of fat basis assessed by magnetic resonance spectroscopy (MRS) using previously specified cut-off values correspondent to biopsy steatosis classes S0, S1, S2 and S3 as defined in guidelines (Chalasani et al., Hepatology 55: 2005–2023, 2012). In particular, 3 classifications were performed: S0 vs S1S2S3 using a MRS cut-off of 3.12%; S0S1 vs S2S3 using a MRS cut-off of 8.77%; S0S1S2 vs S3 using a MRS cut-off of 13.69%. US images were post-processed in order to assess 5 standard parameters (hepatic-renal

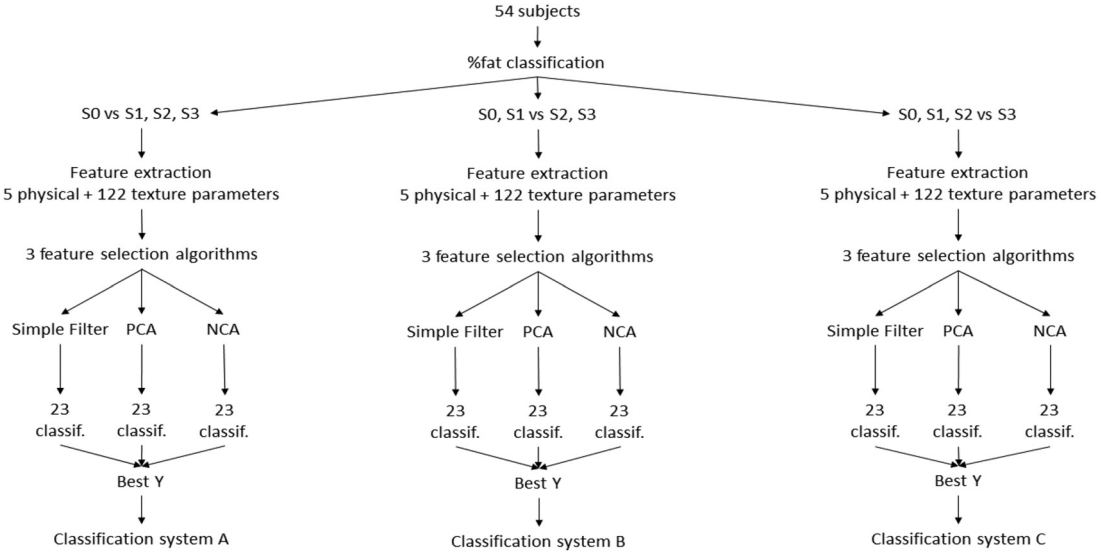

Figure 1: (abstract: FRI-471): Analysis process

ratio (HR), hepatic-portal vein ratio (HPV), attenuation rate (AR), diaphragm visualization (DV) and portal vein wall visualization (PVWvis)) and 122 indexes obtained performing texture analysis. For each MRS-based classification (S0 vs S1S2S3, S0S1 vs S2S3, S0S1S2 vs S3) 3 different algorithms of feature selection were employed (Simple Filter, Principal Component Analysis (PCA), Neighborhood component analysis (NCA)) and 23 classifiers were tested (Figure 1). The best approach for each classification was identified as that maximising the Younden Index (YI) and the area under the receiving operator characteristic (AUROC) curve was also assessed.
Results: NCA approach with Quadratic Discriminant classifier provided the best results for the classification S0 vs S1S2S3 (YI = 0.79, AUROC = 0.91), while NCA approach with Linear Discriminant classifier led to best results for the classification S0S1 vs S2S3 (YI = 0.84, AUROC = 0.99). The best results for the classification S0S1S2 vs S3 was obtained with NCA approach and the Support Vector Machine classifier (YI = 0.8, AUROC = 0.92).
Conclusion: The proposed system can represent a valid approach for quantitative steatosis assessment and could be an excellent alternative to liver biopsy.

FRI-472
Positive predictive value of a physician diagnosis of non-alcoholic steatohepatitis is low and risks high rates of unnecessary liver biopsy

A. Roskilly[1,2], J. Shearer[1,2], I. Rowe[1,2]. [1]*Leeds Institute for Data Analytics, University of Leeds, Hepatology, Leeds;* [2]*Leeds Teaching Hospitals, St James's Hospital, Leeds Liver Unit, Leeds*
Email: aroskilly@doctors.org.uk

Background and Aims Non-alcoholic fatty liver disease (NAFLD) is estimated to affect 25% of western populations and, to date, there are no licensed therapies. Non-alcoholic steatohepatitis (NASH) is its progressive subtype. Current clinical trial treatments aim to prevent progression to end-stage disease through reductions in ongoing liver injury, measured by improvements in NASH or liver fibrosis. Four agents are in phase 3 trials. Phase 2 trials which support the development of these agents provide important information about physicians' diagnosis of NASH alongside the applicability of these treatments.
The aim of this study was to understand the positive predictive value (PPV) of physician diagnosis of NASH with or without liver fibrosis in the context of clinical trial recruitment.
Method: Published phase 2 clinical trials of obeticholic acid, elafibrinor, cenicriviroc, and selonsertib were reviewed independently by two researchers. Inclusion criteria were extracted, including NASH activity (using the NAFLD activity score (NAS) and fibrosis stage. Number of individuals screened and reasons for screening failure were also noted. Where insufficient information was available, the corresponding author was contacted. The PPV was calculated for physicians' assessment of the presence of NASH and overall suitability for clinical trial entry. A subgroup analysis assessed studies that excluded individuals with stage 0 fibrosis.
Results: The four published reports contained 920 participants. The inclusion criteria for the trials showed variation. One trial required NAS ≥3, two required NAS ≥4, and one NAS ≥5. The two most recent trials required fibrosis stage ≥1. All trials excluded participants with cirrhosis. Overall, more patients were excluded than subsequently entered the studies: pooled PPV for trial eligibility 0.37 (Range 0.30–0.82). Ineligible liver histology was the most common reason for screening failure, accounting for 59% of screen failures. PPV for the identification of NASH varied from 0.46 to 0.87, with a pooled value of 0.59. Lower PPVs were observed in the two trials that excluded those with fibrosis stage 0 where the pooled PPV for the identification of NASH with fibrosis was 0.47.
Conclusion: Clinical trials for new treatments in NASH require liver biopsy for trial entry. The prediction of NASH on liver biopsy amongst physicians recruiting participants to clinical trials is poor, particularly when NASH is associated with liver fibrosis. Since these trials are done in centres with an interest in NASH it is likely that the PPV will be lower in less expert hands. In practice, in a highly prevalent disease, many individuals will be exposed to the risks of an unnecessary liver biopsy since it may not diagnose NASH and therefore impact a treatment change.

FRI-473
Screening for liver fibrosis using transient elastography by fibroscan and fibrotest in type 2 diabetic patient

J. Sandler, E. Vinnitskaya, I. Bakulin, V. Keyan, A. Polukchina, T. Chaimenova. *Moscow Clinical Scientific Center, Hepatology, moscow, Russian Federation*
Email: sandlerjulia2012@gmail.com

Background and Aims: Patients with type 2 diabetes (T2D) are at risk for non-alcoholic fatty liver disease (NAFLD) leading to advanced fibrosis, cirrhosis, and liver cancer. We examined the efficacy of a screening strategy with noninvasive fibrosis biomarkers, FibroTest and FibroMax (FT, BioPredictive, France) and transient elastography (TE, Fibroscan, Echosens, France) in patients with T2D without previous history of liver disease.
Method: We prospectively studied 104 patients without a history of liver disease seen for T2DM. The biomarker data were obtained, and patients with presumed advanced fibrosis were reinvestigated by a hepatologist using, if necessary, ultrasonography, endoscopy, or liver biopsy in order to confirm fibrosis.
Results: 104 patients were included, mean age 56.4 ± 9.5yrs. (range of 29–82), 60.6% females, mean (range) BMI 33.3 ± 5.1(22–47), 72.1% (> = 30 kg/m). According to the FibroTest biomarkers, advanced fibrosis was diagnosed in 44 out of 104 patients (42%), while the TE biomarkers confirmed the diagnosis in 45% of cases (47/104). Among of 104 patients advanced fibrosis was confirmed in 42 subjects (40%), liver cirrhosis - in 11 patients (10.6%), including 2 cases of esophageal varices, 9 cases of splenomegaly and thrombocytopenia. According to SteatoTest 66% patients had advanced steatosis (cutoff score > = 0.76) and 39.8% according to CAP (dB/m), cutoff score > = 302.0. In patients who were 50 years or older, the prevalence of confirmed advanced fibrosis was 38.5% (p-value = 0.00023 versus p-value = 0.04249). FibroTest diagnosed F4 in 10 subjects (10.4%). The comparative analysis between these results and those of the TE showed discordance in 21 cases (20.2%). The TE performed false positive diagnosis in 9 cases, while FT only in 3. At the same time, FT registered 1 case of false negative result, while TE indicated it in 4 patients. Among 44 patients with advanced fibrosis (F2-F4) according to FT normal ALT level was in 29.6% cases (p-value = 0.58267) and 45.5% (p-value = 0.00034) had normal GGT.
Conclusion: Noninvasive fibrosis biomarkers, FT and TE, might be used for the detection of advanced fibrosis in patients with T2DM. ALT and GGT are not a reliable markers to detect fibrosis.

FRI-474
Body mass index influences Controlled Attenuation Parameter (CAP) values measured with Fibroscan® M probe. When should we evaluate steatosis with the XL probe?

T. Broquetas, L. Canillas, M. Puigvehí, R. Fernández, G. Díaz, S. Coll, M.G. Retortillo, N. Cañete, X. Bessa, R.S. Lamoglia, J.A. Carrión. *Hospital del Mar, IMIM (Hospital del Mar Medical Research Institute), UAB (Universitat Autònoma de Barcelona), Liver Section, Gastroenterology Department, Barcelona, Spain*
Email: 95565@parcdesalutmar.cat

Background and Aims: The FibroScan® XL probe quantifies liver fibrosis in obese patients. Anthropometric variables should be taken into account to choose the appropriate probe. Controlled Attenuation Parameter (CAP) quantifies the degree of steatosis. Recently, CAP determination has been incorporated into the XL probe but there are no studies comparing CAP values between both probes (M and XL) in

obese patients. The aim of the study was to evaluate the correlation of CAP values with M and XL probe, in patients with BMI ≥28 kg/m².
Method: Non-randomized prospective study, evaluating all patients with chronic liver disease and BMI ≥28 kg/m^2 from April to October 2017. The measurements with the FibroScan® M and XL probe were performed the same day and by the same explorer. Clinical, anthropometric, analytical and elastographic data have been analyzed.
Results: 386 patients with BMI ≥ 28 and chronic liver disease were evaluated (37% with hepatitis C, 31% non-alcoholic fatty liver disease, 14% Hepatitis B, 18% others). Patients (n = 89) evaluated by a non-experienced explorer (<500 TE) or those without both probes (n = 116) were excluded. Thus, 181 patients assessed with both probes by an experienced explorer were included. The median (range) age was 57 (27–93), 61% were men and 52% diabetic, 37% had a BMI between 28–30, 50% between 30–35 and 13% a BMI ≥35. The skin-capsule distance (SCD) according to the BMI category was 18 (13–24) mm, 20 (11–25) mm and 22 (15–25) mm, respectively. The CAP correlation with both probes was $\rho = 0.78$ ($p < 0.001$). There were no differences between the median CAP (dB/m) values with M (275) and XL (277) probes (p = ns). However, CAP values were significantly lower with M probe (278) compare to XL probe (287) ($p = 0.014$) in patients with BMI ≥ 35 Kg/m^2, probably due to a lower distribution of fat in the cortical area of the liver.
Conclusion: Controlled Attenuation Parameter (CAP) shows a good correlation between the FibroScan® M and XL probes. However, in patients with a BMI ≥35 Kg/m^2 values with M probe underestimate the degree of steatosis, making necessary to evaluate these patients with the XL probe.

FRI-475

The easy Liver Fibrosis Test (eLIFT) avoids unnecessary specialized evaluations of liver fibrosis in NAFLD and ALD patients

B. Thomas[1], L. Adrien[1], S. Bertrais[2], P. Etienne[1], Frédéric Oberti[1,2], I.F. Hubert[1,2], P. Cales[1,2], J. Boursier[1,2]. *[1]Angers, Hepato-Gastroenterology Department, Angers University Hospital, Angers, France, Angers; [2]Angers, HIFIH Laboratory, Angers University, Angers, France, Angers, France*
Email: thomas_brou@hotmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) and alcoholic liver disease (ALD) are risk factors for cirrhosis and liver-related complications. Therefore, all NAFLD and ALD patients should theoretically undergo a non-invasive evaluation of liver fibrosis. However, the best non-invasive tests of liver fibrosis are limited by their cost and/or poor accessibility. Moreover, NAFLD and ALD patients represent a very large population, with most of them having no/mild fibrosis which would induce a majority of "unnecessary" specialized evaluations of liver fibrosis. The easy LIver Fibrosis Test (eLIFT) is a very simple fibrosis test including common parameters (age, sex, GGT, AST, platelets, prothrombin time). It has been developed to identify patients at-risk of advanced liver fibrosis who require further specialized evaluation. We aimed to evaluate whether the eLIFT helps to appropriately avoid unnecessary specialized evaluations of liver fibrosis in NAFLD and ALD patients.
Method: NAFLD and/or ALD patients referred for the first time to our centre for a non-invasive evaluation of liver fibrosis between October 2014 and March 2017 were included. Patients with other causes of chronic liver disease were excluded. FibroMeter^{VCTE} (FM^{VCTE}, which includes in a single formula the Fibroscan result and the parameters of the FibroMeter^{VIRUS}) was considered as the reference for the non-invasive evaluation of liver fibrosis (best non-invasive test in a recent large series of 1946 patients, J Hepatol 2017). As previously published, eLIFT ≥8 identified patients at-risk of advanced fibrosis.
Results: 543 patients were included: 260 NAFLD, 185 ALD and 98 NAFLD + ALD. FM^{VCTE} diagnosis was no/mild fibrosis in 55.2% of patients, advanced fibrosis in 33.1%, undetermined in 11.6%. 247/543 patients (45.5%) had eLIFT <8. Among patients with eLIFT <8, 207/247 (83.8%) had no/mild fibrosis according to FM^{VCTE}. Among the 40 remaining patients, FM^{VCTE} diagnosis was advanced fibrosis in 17 and undetermined in 23. 155 NAFLD patients had eLIFT <8 and 124 of them (80.0%) had no/mild fibrosis according to FM^{VCTE}. 59 of the 66 ALD patients with eLIFT <8 (89.4%) had no/mild fibrosis according to FM^{VCTE}, and 24 of the 26 NAFLD + ALD patients (92.3%).
Conclusion: Used as first-line test in NAFLD and ALD, the eLIFT avoids unnecessary specialized non-invasive evaluations of liver fibrosis in half of the patients referred to a tertiary centre.

FRI-476

Feasibility and utility of controlled attenuation parameter and transient elastography in the assessment of nonalcoholic fatty liver disease severity in children

A. Scott[1], M. Mansouri[1], T. Okubote[1], M. Scott[1], A. Betancourt[1], G. Mesa[1], E. Lawitz[1], F. Poordad[1], N. Alkhouri[2]. *[1]Texas Liver Institute, University of Texas (UT) Health San Antonio, San Antonio, United States; [2]Texas Liver Institute, Texas Liver Institute, San Antonio, United States*
Email: ascott@txliver.com

Background and Aims: Estimating the severity of liver steatosis by controlled attenuation parameter (CAP) and liver fibrosis by transient elastography (TE) using the Fibroscan™ machine provides a noninvasive method to establish the presence of nonalcoholic fatty liver disease (NAFLD) and assess its severity. Although the use of CAP/TE is becoming routine practice in adults, limited data exist in children with suspected NAFLD. The aim of this study was to assess the feasibility and utility of measuring CAP/TE by Fibroscan™ in a cohort of children with suspected NAFLD referred to a community gastroenterology clinic.
Method: All children seen at our clinic from May to October 2017 with suspected NAFLD (elevated ALT or fatty infiltration on ultrasonography) who had CAP/TE measured were included. Fibroscan™ was performed by an experienced operator. Standard criteria for having valid measurements were applied (IQR < 30% with ≥ 70% success rate). The severity of steatosis was evaluated by CAP: <225 db/m no steatosis, 225–250 mild, 250–300 moderate, and > 300 severe. The severity of liver stiffness/fibrosis was evaluated by TE: <7 kPa no significant fibrosis, 7–10 kPa mild or moderate, >10 kPa advanced. Clinical and laboratory parameters were collected. Chi-square test was used for statistical comparison between mild-to-moderate and severe steatosis; and presence or absence of significant fibrosis. Crude and adjusted logistic regression models were used to determine associations between patients' characteristics and CAP/TE.
Results: 44 children with suspected NAFLD were referred in the specified time period. Mean age (± SD) was 14.0 years (± 3.5). Majority were males (77%), obese (95%), and Hispanic (89%). All patients (44/44) had successful Fibroscan™ measurements but the large adult probe (XL) needed to be used in 21/44 (48%) of our patients and the regular M probe was used for the rest. All patients had CAP > 225 indicating steatosis and 50% of female and 80% of male patients had severe steatosis with CAP > 300 (Figure). On multivariable analysis, the presence of elevated AST (>48 U/l) was associated with a 9.6-fold increase in the presence of severe steatosis ($p = 0.04$), whereas the presence of positive smooth muscle antibody (SMA) was significantly protective. Evidence of fibrosis based on TE was present in 43% of children and 17% of male subjects had TE > 10 kPa indicating the potential for having advanced fibrosis. Factors associated with significant fibrosis included the presence of prediabetes, hypertension, hemoglobin level, and serum bilirubin ($p < 0.05$ for all).
Conclusion: CAP/TE provides a reliable way to confirm the diagnosis of NAFLD and assess its severity in children. Larger pediatric studies that assess the correlation with liver histology and disease progression are urgently needed.

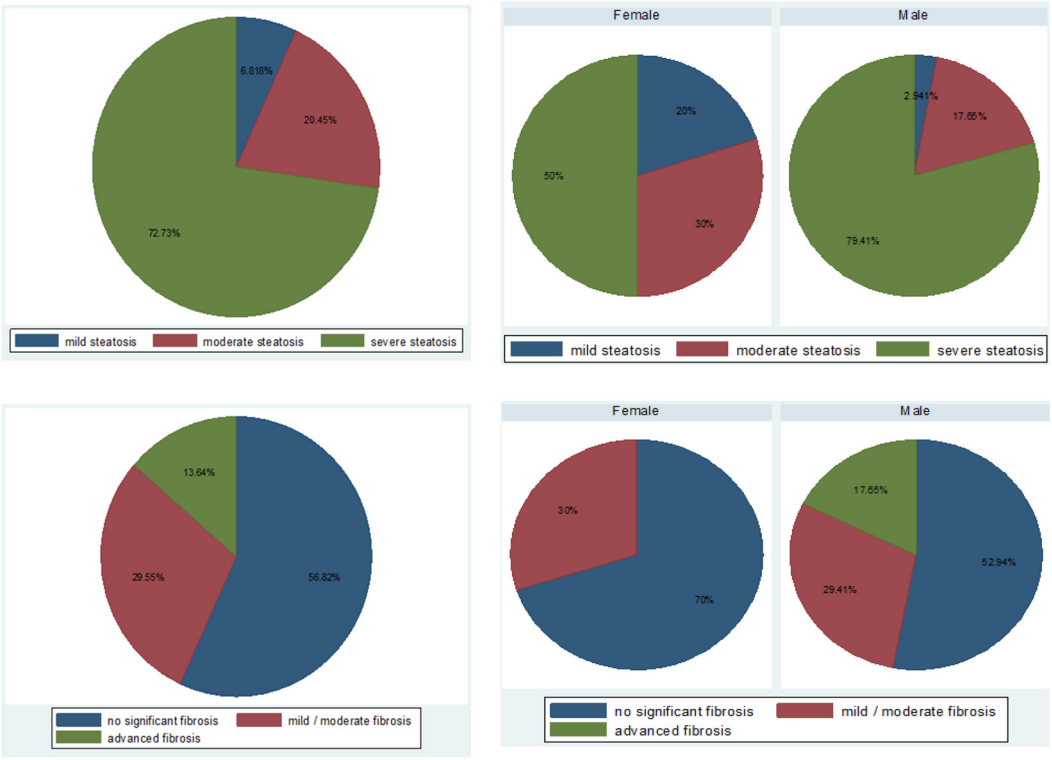

Figure 1: (abstract: FRI_476): The prevalence and severity of steatosis/fibrosis based on Fibroscan™ measurements.

Optimal cutoff value of assessing changes in intrahepatic fat amount by using the controlled attenuation parameter in a longitudinal setting

B.-K. Kang[1], D.W. Jun[2], M.M. Kim[1], S.B. Ahn[3], Y.C. Joo[4], H. Oh[2], E.C.J. Jang[5], J.H. Sohn[6], J.Y. Jeong[6], E. Kim[2]. *[1]Hanyang University School of Medicine, Radiology; [2]Hanyang University School of Medicine, Internal Medicine; [3]Eulji university college of medicine, Internal Medicine; [4]Hanyang University Graduate school of Biomedical Science and Engineering, Department of Translational Medicine; [5]Soonchunhyang University College of Medicine, Department of Occupational and Enviroment Medicine; [6]Hanyang University, College of Medicine, Guri Hospital, Internal Medicine*
Email: msbbogri@naver.com

Background and Aims: The controlled attenuation parameter (CAP) has shown a good correlation with the intrahepatic fat amount in cross-sectional studies. However, there is no study on whether the change of CAP scores can also show good correlation in a longitudinal setting. Therefore, we investigated the correlation between CAP and magnetic resonance imaging-estimated proton density fat fraction (MR PDFF) through serial examination in a longitudinal setting.
Method: Sixty-five patients with nonalcoholic fatty liver disease were evaluated with MR PDFF and transient elastography including CAP at baseline and 3 months later.
Results: CAP and MR PDFF at baseline showed a strong correlation in assessing hepatic steatosis ($r = 0.66$, $p < 0.001$). After treatment, the correlation between the change in CAP after treatment and the intrahepatic fat change (%) on MR PDFF was not satisfactory ($r = 0.37$, $p = 0.005$) in the longitudinal setting. The optimal cutoff value of the change in CAP for discriminating an improvement or an aggravation in intrahepatic fat percentage (>1% change in MR PDFF) was selected as 38 dB/m (area under the receiver operating characteristic curve = 0.559). For CAP changes >38 dB/m, the predictive value was 14/16 (87.5%), whereas for changes <38 dB/m, the predictive value was 12/41 (29.3%). Thereby, the accuracy of the method using the change in CAP was only 26/57 (46%). In addition, Cohen's kappa value was not significant ($\kappa = 0.11$, $p = 0.186$).
Conclusion: Careful interpretation of the steatosis change based on the CAP score is needed when the absolute change value is <38 dB/m in a longitudinal setting.

NAFLD: Therapy

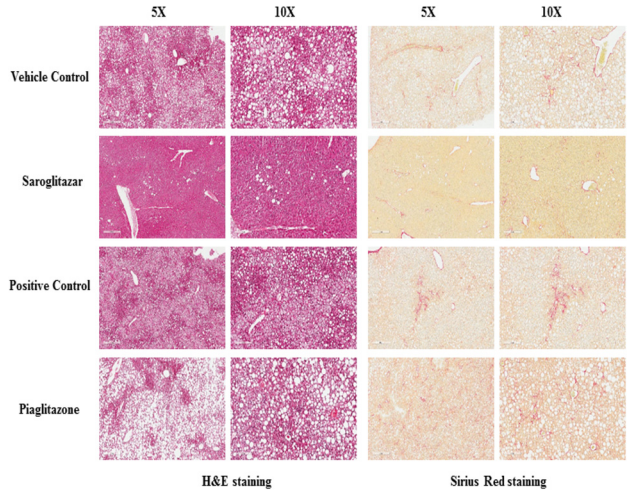
FRI-478

Saroglitazar treatment prevents NASH, eliminates hepatocyte ballooning, and significantly improves serum LFTs, lipids and insulin resistance in DIAMOND(tm) mice compared to pioglitazone benchmark

R. Caffrey[1], J. Marioneaux[1], P. Santhekadur[1], P. Bedossa[2], B. Philip[3], S. Giri[4], M. Jain[3], A. Sanyal[5]. *[1]Sanyal Biotechnology; [2]Hopital Beaujon, Anatomie Pathologique, France; [3]Zydus Cadila Healthcare, India; [4]Zydus Cadila Healthcare, Iceland; [5]Virginia Commonwealth University, Gastroenterology and Hepatology*
Email: rebecca@sanyalbio.com

Background and Aims: In this study the efficacy of the dual PPAR-α and PPAR-γ agonist Saroglitazar in preventing progression of early NASH F0 to more advanced NASH was investigated in Sanyal Biotechnology's DIAMOND™ mouse model. It has previously been demonstrated that pioglitazone attenuates measures of NASH and metabolic syndrome similarly to humans in this mouse model. We hypothesized that administration of Saroglitazar may also prevent progression of NASH. **Aims:** (1) To determine if Saroglitazar could prevent progression of NASH, (2) To compare the efficacy of Saroglitazar with benchmark pioglitazone and positive and negative natural history controls.

Method: 8 week old DIAMOND™ mice (10–12 per group) were weight randomized and placed on either normal chow/normal water (NC/NW) or Western Diet/sugar water (WD/SW) for 12 weeks. At 12 weeks on diet the WD/SW groups to progress to full metabolic syndrome with NASH F0 while NC/NW negative natural history controls remain healthy. Daily oral gavage of Saroglitazar (4 mg/kg/day), pioglitazone (30 mg/kg/day) and vehicle (water) began at 12 weeks and both dosing and diet continued for 3 months. At 24 weeks mice were necropsied and liver tissue and serum were collected. Sirius Red and H&E stained sections were made from each mouse, and scored for measures of NASH pathology. Serum LFTs, lipids, fasting insulin and glucose were measured and HOMA IR was calculated. Saroglitazar was compared to pioglitazone benchmark, vehicle control, and both Western Diet/Sugar Water (WD/SW) positive and normal chow/normal water (NC/NW) negative natural history controls.



Results: Compared to pioglitazone, Saroglitazar significantly reduced steatosis (both percent and grade), NAS score, and SAF activity score. Hepatocyte ballooning was completely eliminated in the Saroglitazar-treated group. No Saroglitazar treated mice progressed past steatosis to NASH whereas most pioglitazone and positive WD/SW controls did progress. The body weight of the Saroglitazar treatment group at end of study was significantly less than pioglitazone, vehicle control, and positive controls. Saroglitazar lowered fasting blood glucose more than pioglitazone, and lowered fasting insulin more than than all other groups. HOMA IR was improved and total serum cholesterol and triglycerides were significantly decreased in the Saroglitazar treated mice. Saroglitazar treatment successfully attenuated and even reversed some serological and pathological measures of NASH.
Conclusion: The anti-diabetic drug Saroglitazar met the primary endpoint of preventing progression of NAFLD to NASH, while simultaneously improving measures of insulin resistance and diabetes in the DIAMOND™ mouse model. This study demonstrated that Saroglitazar has significantly more beneficial effects than pioglitazone in the DIAMOND™ mice.

FRI-479
Mitochondrial uncoupler HU6 successfully treats NASH in DIAMOND mouse model

R. Caffrey[1], J. Marioneaux[1], P. Santhekadur[1], P. Bedossa[2], F. Portell[3], S. Eaton[3], J. Dennis[3], I. Onyango[3], O. Khan[3], S. Khan[3], A. Sanyal[4].
[1]Sanyal Biotechnology; [2]Hopital Beaujon, Anatomie Pathologique, Clichy, France; [3]Gencia; [4]Virginia Commonwealth University, Gastroenterology and Hepatology
Email: rebecca@sanyalbio.com

Background and Aims: The Gencia mitochondrial uncoupler compound HU6 was evaluated for utility in treating NASH in a diet-induced animal model of metabolic syndrome and NASH (DIAMOND™ mice).
Method: Mice were grouped into 5 groups: vehicle control (VC), high dose HU6 (5mg/kg), low dose HU6 (1mg/kg), WD/SW positive (PC) and NC/NW negative (NC) natural history controls. Mice were raised for 12 weeks on diet, corresponding to a baseline NASH F0 in the WD/SW groups. Treatment groups were then gavaged once daily with aqueous vehicle or drug in vehicle for 8 weeks.
Results: At necropsy, the body weight of the mice in the high dose group was significantly less than VC ($p = 0.04$), and liver weight was significantly less than the VC ($p = 0.001$) and PC ($p = 0.004$). LFTs were measured and AST, ALT, and ALP levels in the high dose group were significantly lower than in the VC ($p = 0.001$, 0.0004, and 0.0002, respectively) and PC ($p = 0.03$, 0.01, and 0.00008, respectively). Total serum cholesterol was also significantly lower in the high dose group compared to VC ($p = 0.001$). Liver tissue was embedded in FFPE blocks and slides stained with H&E and Sirius Red. Steatosis percentage and grade ($p = 0.001$ and 0.01, respectively) and ballooning ($p = 0.0000001$) were significantly lower in the high dose group compared to VC. Lobular inflammation was significantly improved in high dose group compared to PC ($p = 0.05$) and there was a strong trend to significance compared to VC and low dose group. NAS and SAF activity scores were also significantly improved in the high dose group compared to VC ($p = 0.001$, 0.0007) and PC ($p = 0.01$, 0.003). While all VC and PC mice progressed to NASH, only one mouse in the high dose group developed NASH. No significant difference in fibrosis measurements was found at this early stage of fibrosis development.
Conclusion: HU6 successfully met the primary study endpoint of treating and preventing progression of NASH. Significant improvements in body and liver weight, serum LFTs and lipids, and liver pathology were observed in the high dose group. HU6 warrants further investigation as a treatment for NASH.

FRI-480
Fibrosis stage improvement in nonalcoholic steatohepatitis: A systematic review of placebo treated participants in randomized controlled trials

A. Roskilly[1,2], E. Taylor[1,2], R.L Jones[2], I. Rowe[1,2]. *[1]Leeds Institute for Data Analytics, University of Leeds, Hepatology, Leeds, United Kingdom; [2]Leeds Teaching Hospitals, St James's Hospital, Leeds Liver Unit, Leeds, United Kingdom*
Email: aroskilly@doctors.org.uk

Background and Aims: The severity of fibrosis in patients with non-alcoholic fatty liver disease (NAFLD) is the critical determinant of liver related mortality. Consequently, improvements in liver fibrosis are being incorporated into clinical trial endpoints for new therapies for patients with non-alcoholic steatohepatitis (NASH).
The aim of this study was to estimate the proportion of patients with NASH with fibrosis improvement in timeframes relevant to ongoing trials.
Method: We undertook a systematic review of placebo controlled randomized clinical trials (RCT) with a histological endpoint including patients with NASH. Data reported were extracted and the proportion of patients with fibrosis improvement, defined as at least 1 stage improvement, were calculated per protocol. A pre-specified subgroup analysis explored fibrosis improvement in patients with fibrosis stage (F) ≥ 1 since those individuals with F0 at baseline could not improve fibrosis. The proportion and 95% confidence interval (95%CI) was calculated for each study and summarized as a pooled estimate.
Results: We identified 31 RCT of therapies for patients with NASH with a histological endpoint. Of these, 19 trials (including 898 placebo treated participants) reported the proportion of those included where fibrosis improved. In these studies, a total of 717 placebo treated participants underwent repeat liver biopsy per protocol. There was substantial variation in the proportion of participants improving fibrosis (range 0–45%, Figure). The pooled proportion

improving fibrosis in these 717 participants was 21.8% (95%CI 18.8–25.0%). 15 RCT reported fibrosis stage at baseline, and in these trials the proportion of participants with F0 was 18.8%. In a subgroup analysis excluding these participants, the pooled fibrosis improvement rate was 26.2% (95%CI 22.1–30.7%).

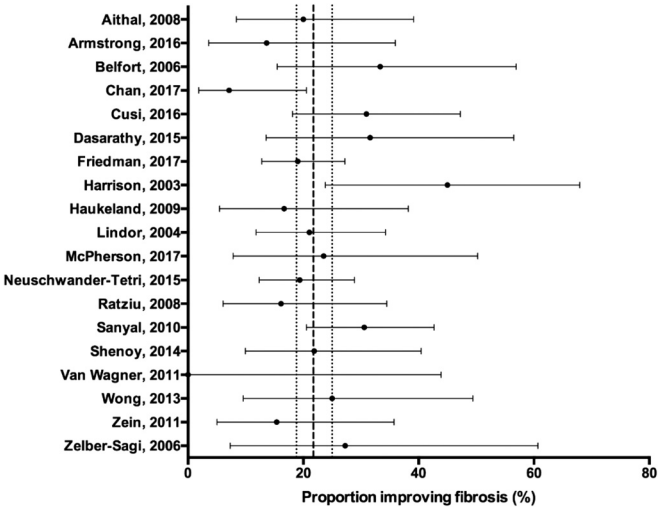


Figure 1: Proportion of placebo treated participants with NASH improving fibrosis in RCTs. Data are plotted as proportion ± 95%CI. The pooled proportion estimate and 95%CI are shown in the heavy and light dotted lines, respectively.

Conclusions: This study has important implications for current and future clinical trial design and interpretation. There is marked heterogeneity in the reported proportions of placebo treated participants with NASH improving fibrosis that requires further study. The pooled estimate for participants with F ≥ 1 at baseline improving fibrosis is 26.2%. This is consistent with previous reports of sampling variability in NASH, highlighting the deficiencies of liver biopsy to determine fibrosis endpoints in clinical trials in NASH. Validation of fibrosis stage improvement as a surrogate endpoint is an important outcome of the ongoing Phase 3 clinical trials.

FRI-481

Persistent improvement of liver function tests and health-related quality of life from an individualized exercise program in patients with histological confirmed NAFLD – the HELP study

Y. Huber[1], D. Pfirrmann[2], I. Gebhardt[1], C. Labenz[1], B. Straub[3], J. Kittner[1], M.-A. Wörns[1], P. Galle[1], P. Simon[2], Jörn Schattenberg[1].
[1]I. Department of Medicine, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany; [2]Department of Sports Medicine, Disease Prevention and Rehabilitation, Johannes Gutenberg University Mainz, Department of Sports Medicine, Disease Prevention and Rehabilitation, Mainz, Germany; [3]Institute of Pathology, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany
Email: yvonne.huber@unimedizin-mainz.de

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the fastest growing and most common cause of liver disease. The clinical spectrum of NAFLD ranges from isolated hepatic steatosis to non-alcoholic steatohepatitis (NASH), which can progress to end stage liver disease. Currently there are no approved pharmacologic therapies for NASH and lifestyle interventions are recommended. The impact of regular physical activity on the liver is poorly studied. Additionally, the capability to perform physical activity in chronic liver disease is not well explored. The aim of this prospective trial is to determine the effects of an individualized exercise program on hepatic surrogate markers and physical performance in patients with NAFLD and NASH.

Method: 44 patients with histological confirmed NAFLD were included in this prospective pilot-study (ClinicalTrials.gov Identifier: NCT 02526732). Patients underwent an independent 8-week training program consisting of combined endurance and strength exercise 3–5 times per week under qualified instruction. An online support platform with an individualized access and weekly bidirectional feedback by Email was provided. Health-related quality of life (HrQoL) as well as metabolic and liver chemistry were measured at study entry, end-of-treatment (EoT) and follow-up (FU) 12 weeks after the supervised program. An interims analysis of 35 patients is provided and the study will be completed in March 2018.
Results: At baseline the mean age was 41.2 (± 11.8) years, 68.7% of patients were male. Mean BMI was 31.0 (± 4.5)kg/m², 78% exhibited NASH determined by histology. At EoT exercise had a positive effect on body composition with a reduction in fat mass (−4.6%), while BMI changes were marginal (−0.4 kg/m²). The maximum oxygen uptakes (VO_2max) improved by 11% and physical performance increased from 136.8–152.2 Watt. AST and ALT decreased by 16.1% and 22.5% as well as ferritin levels by 20.9%. Median liver stiffness determined by Fibroscan showed a reduction from 8.4 to 6.5 kPa. During follow-up 65.4% of participants reported continued regular physical activity. Strikingly, a significant reduction of liver function test and an additional improvement of HrQoL (increase in overall score of 8.5%, $p < 0.05$) compared to the end-of-treatment were detected during FU.
Conclusion: A temporary, individualized exercise program supported by an online platform in patients with NAFLD leads to improvement in physical performance and hepatic surrogate markers even after cessation of counseling.

FRI-482

Treatment with obeticholic acid in patients with NASH does not show increased markers of liver toxicity based on evaluation of drug-induced serious hepatotoxicity

A. Sanyal[1], A. Shah[2], P. Pockros[3], R. Shringarpure[2], L. Macconell[2], D. Shapiro[2]. *[1]Virginia Commonwealth University, Richmond, United States; [2]Intercept Pharmaceuticals, Inc., San Diego, United States; [3]Scripps Clinic, La Jolla, United States*
Email: arun.sanyal@vcuhealth.org

Background and Aims: Evaluation of drug-induced serious hepatotoxicity (eDISH) is a tool used to assess and identify potential cases of drug-induced liver injury. eDISH was used to evaluate obeticholic acid (OCA) and placebo profiles in 2 double-blind, placebo-controlled studies in patients with nonalcoholic steatohepatitis (NASH). FLINT was a 72-week study, which demonstrated statistically significant improvements in hepatocellular ballooning, steatosis, lobular inflammation, and fibrosis in patients treated with OCA compared to placebo. CONTROL was a 16-week study, which showed that the addition of low-dose atorvastatin reversed OCA-associated changes in LDL-C. The objective of this analysis was to use eDISH to determine if patients with NASH treated with OCA show increased markers of liver injury or whole liver dysfunction.
Method: eDISH methodology was applied to 278 patients treated with placebo (n = 140) or 25 mg OCA (n = 138) from FLINT and 84 patients treated with placebo (n = 21), 5mg OCA (n = 20), 10 mg OCA (n = 21), or 25 mg OCA (n = 22) from CONTROL. Individual subject peak values of alanine aminotransferase (ALT) and total bilirubin throughout the double-blind treatment phase were plotted on an x–y chart as logarithm_{10} values of multiples of elevations above the upper limit of the normal reference ranges (x ULN).
Results: Overall, no OCA-treated patients were in the Hy's law quadrant (>3 × ULN for ALT and >2x ULN for total bilirubin) compared with 1 placebo-treated patient in FLINT. The proportion of patients with peak ALT and total bilirubin values in the lower left quadrant (representing normal or near normal range) was higher in OCA-treated patients compared with placebo (FLINT: 91% OCA vs 84% placebo; CONTROL: 91% OCA vs 86% placebo). 8% of OCA-treated patients from both FLINT and CONTROL presented in the Temple's

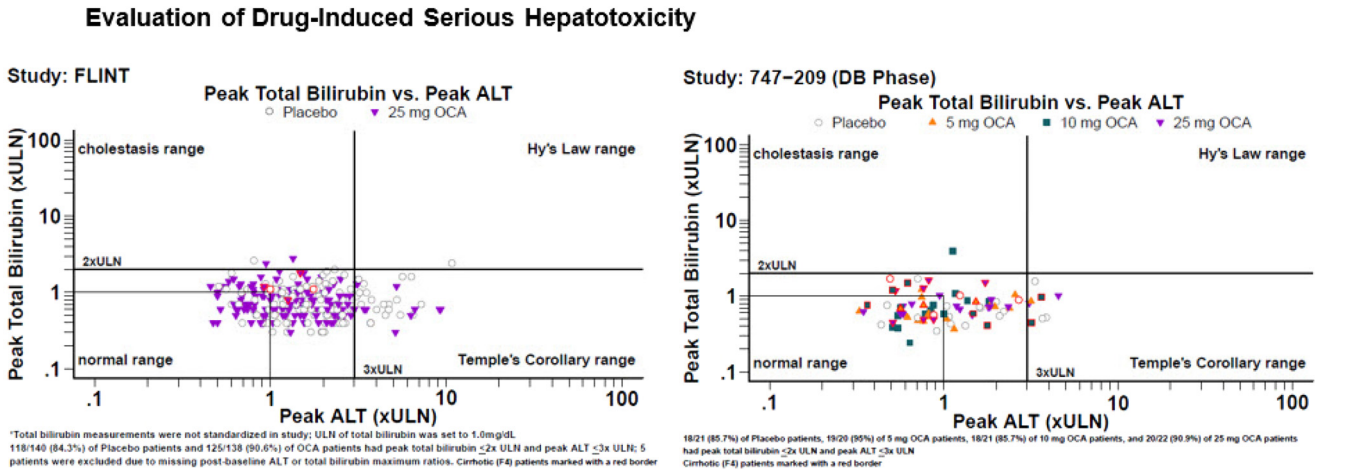

Figure 1: (abstract: FRI-482)

corollary quadrant (>3x ULN for ALT and <2x ULN for total bilirubin) vs 14% (in both studies) for the placebo-treated patients. Across both studies (n = 362), 4 patients were in the cholestasis quadrant (>2X ULN total bilirubin and <3X ULN for ALT); 1 placebo-treated patient and 3OCA-treated patients, including 1 patient with Gilbert's syndrome.

Conclusion: In these 2 placebo-controlled, double-blind NASH studies, the eDISH analysis showed no trend for liver injury with OCA at doses up to and including 25 mg.

FRI-483

The effect of semaglutide on liver enzymes in subjects with obesity and elevated alanine aminotransferase: Data from a randomised Phase 2 trial

P. Newsome[1], S. Harrison[2], Søren Rasmussen[3], T.M. Hansen[3], L.V. Gaal[4]. [1]*Queen Elizabeth Hospital, Liver Unit, Birmingham, United Kingdom;* [2]*University of Oxford, Radcliffe Dept. of Medicine, Oxford, United Kingdom;* [3]*Novo Nordisk A/S, Søborg, Denmark;* [4]*Antwerp University Hospital, Dept. of Endocrinology, Diabetology & Metabolism, Antwerp, Belgium*
Email: tmnh@novonordisk.com

Background and Aims: The glucagon-like peptide 1 analogues semaglutide and liraglutide improve glycaemic control and reduce elevated liver enzymes in subjects with type 2 diabetes (T2D), and reduce body weight in subjects with or without T2D. Histological resolution of non-alcoholic steatohepatitis has also been seen for liraglutide in subjects with or without T2D. A randomised, placebo-controlled phase 2 trial (NCT0243711) of once-daily subcutaneous semaglutide (0.05, 0.1, 0.2, 0.3, or 0.4 mg following 4-weekly escalations) in subjects with obesity without T2D, showed mean weight losses of –6.0% (0.05 mg) to –13.8% (0.4 mg) with semaglutide vs –2.3% with placebo at week 52. The effect of semaglutide on liver enzymes in subjects with elevated baseline alanine aminotransferase (ALT) was evaluated in a *post hoc* sub-analysis from this trial.

Method: Baseline fibrosis was categorised by the non-alcoholic fatty liver disease (NAFLD) fibrosis score (NFS) and Fibrosis-4 (FIB-4) score. Changes in ALT were estimated at week 52 (mixed model on log-transformed data) and semaglutide-to-placebo group ratios and 95% confidence intervals (95%CI) calculated from this model for subjects with high baseline ALT (>30U/l [male]; >19U/l [female]).

Results: Mean (range) baseline characteristics of the 957 treated subjects (35% male) were: age 47 (18–86) years, weight 111 (70–244) kg, body mass index 39 (30–80)kg/m^2, NFS–0.49 (–4.70–4.66) and FIB-4 0.72 (0.14–3.31); 52% (n = 499) had high ALT, 18% a high NFS (>0.676), and <1% a high FIB-4 (>3.25). ALT ratios (95%CI) at week 52 in those with high baseline ALT were: 0.88 (0.76–1.01; 0.05 mg); 0.94 (0.82–1.08; 0.1 mg); 0.82 (0.71–0.95; 0.2 mg); 0.79 (0.68–0.91; 0.3 mg), and 0.82 (0.70–0.95; 0.4 mg). p values were <0.01 at doses >0.1mg, unadjusted for multiple testing. ALT changes at week 52 were broadly comparable across weight loss categories from <2% to ≥10% of baseline weight. Normalization of high baseline ALT was seen at week 52 in 29% (17/58; 0.05 mg), 25% (15/59; 0.1 mg), 38% (19/50; 0.2 mg), 43% (23/54; 0.3 mg), and 46% (21/46; 0.4 mg) of subjects on semaglutide, versus 18% (14/76) of subjects on placebo.

Conclusion: In subjects with obesity and high ALT, semaglutide 0.2–0.4 mg daily reduced ALT to an extent that was broadly comparable across weight loss categories, and resulted in dose-related ALT normalization in up to 46% of subjects after 52 weeks. These data suggest a potential role for semaglutide in the treatment of NAFLD with elevated liver enzymes.

FRI-484

Effet of bariatric surgery in biopsy-proven NASH patients after 5 years

G. Lassailly[1], C. Robert[2], V. Gnemmi[3], A. Louvet[1], L. Emmanuelle[3], F. Artru[1], M. Ningarhari[1], Valérie Canva[1], S. Dharancy[1], F. Pattou[4], P. Mathurin[1]. [1]*CHRU de Lille, Service des maladies de l'appareil digestif, Lille, France;* [2]*CHRU de Lille, General & bariatric surgery, Lille, France;* [3]*CHRU de Lille, service d'anatomopathologie, Lille, France;* [4]*CHRU de Lille, General & Bariatric surgery, Lille, France*
Email: guillaume.lassailly@gmail.com

Background and Aims: Bariatric surgery induces disappearance of NASH from nearly 85% of patients and reduced the pathologic features of the disease after 1 year of follow-up. The outcome at 5 years, in NASH patients is not well established.

Method: in the Lille bariatric Cohort, 198 morbidly obese patients with biopsy-proven NASH were referred for bariatric surgery from 1994 through 2017, at the University Hospital of Lille, France (the Lille Bariatric Cohort). Clinical, biological, and histologic data were collected before, at 1 and 5 year after surgery. Primary outcome was disappearance of NASH and secondary outcomes included NAS (Nafld Activity Score) and individual score of lobular inflammation, ballooning and fibrosis. Primary and secondary outcomes and changes in parameters (continuous, ordinal, binary variables) were analyzed from baseline to 1 year and from 1 year to 5 year using the Wilcoxon signed rank tests and mantel-haenszel test.

Results: At time of analysis, about 70% of patients with NASH performed the one year liver biopsy and 31% at 5 year.
A/ At baseline, the cohort characteristics were as follow: BMI 46.8kg/m² (42.8–52.3), type 2 diabetes and dyslipidemia were present in 68% and 66% of cases respectively. Histological characteristics were: steatosis was 60% (40–75), Ballooning (1.2 ± 0.6), lobular inflammation (1.8 ± 0.7) and fibrosis (1.17 ± 1.16) (Metavir score).

B/ At 1 year after surgery, NASH disappeared in 86% of cases and all histological features improved: steatosis, (from 60 to 10%), ballooning (1.2 ± 0.6 to 0.2 ± 0.4), lobular inflammation (1.8 ± 0.7 to 0.4 ± 0.6), NAS (4.7 ± 1.3 to 1.7 ± 1.4) and fibrosis (according to Metavir) (1.6 ± 1.1 vs 0.9 ± 1.1) (For all $p < 0.001$).
C/ Comparison between 1 and 5 year: patients with disappearance of NASH at 1 year remained free of NASH at 5 years. As compared to 1 year, liver fibrosis continue to improve (0.9 ± 1 vs. 0.5 ± 0.8 $p < 0.003$). For all the other histological features of NASH, the initial improvement obtained at one year after surgery was sustained until 5 years: steatosis (10–10%), ballooning (0.17 ± 0.4 to 0.11 ± 0.3), lobular inflammation (0.36 ± 0.5 to 0.5 ± 0.5) and NAS (1.5 ± 1.1 to 1.4 ± 1.5) ($p > 0.05$ for all comparison).
The improvement of clinical features and biological parameters sustained between 1 and 5 years after surgery: BMI (37.7 ± 7 to 36.6 ± 8), AST (23 ± 8 to 26 ± 14), γ-glutamyltransferases (32 ± 23 to 41 ± 60), LDL (2.7 ± 0.9 to 2.8 ± 0.9), HDL (1.29 ± 0.29 to 1.33 ± 0.29) and mean insulin resistance index (HOMA-IR: 1.86 ± 2.6 to 1.65 ± 1.25), A1c glycated hemoglobin (6 ± 0.9 to 6 ± 0.9%) ($p > 0.05$ for each comparison).
Conclusion: Disappearance of NASH occurred in more than 80% of case after bariatric surgery. Disappearance of NASG and all histological features of NASH improvement appeared a 1 one year and sustained until 5 year. Moreover, extend of fibrosis continue to improve from 1 year to 5 year.

FRI-485
Safety, tolerability, pharmacokinetics and pharmacodynamics of a liver-targeting ACC inhibitor (PF-05221304) following single and multiple oral doses

A. Bergman[1], S.C. Gonzalez[1], S. Tarabar[2], A. Saxena[3], W. Esler[3], N. Amin[3]. *[1]Pfizer, Inc., Early Clinical Development, Cambridge, MA, United States; [2]Pfizer, Inc., Clinical Research Unit, New Haven, CT, United States; [3]Pfizer, Inc., Internal Medicine Research Unit, Cambridge, MA, United States*
Email: arthur.bergman@pfizer.com

Background and Aims: Elevated hepatic de novo lipogenesis (DNL) is a distinct characteristic of patients with nonalcoholic steatohepatitis (NASH). Pharmacologic inhibition of acetyl-CoA carboxylase (ACC), the rate limiting enzyme for DNL, has been shown to reduce hepatic steatosis in rodents and humans. PF–05221304 is a potent, selective, and reversible dual ACC 1/2 inhibitor (ACCi) designed to have asymmetric distribution to the liver. This asymmetric distribution enables potent inhibition of hepatic ACC to normalize hepatic DNL in patients with NASH, while minimizing systemic DNL inhibition.
Method: A 3-part study was conducted to evaluate (1) safety/tolerability and pharmacokinetics (PK) of single ascending doses from 1 mg to 240 mg in 2 interleaving cohorts (n = 6 active/2 placebo per dose-level), (2) safety/tolerability, PK, and pharmacodynamics (PD) of repeated, ascending doses ranging from 2 to 200 mg daily (as Q12H or QD regimens) with PK assessed on Day 7 and PD assessed on Day 14 (demonstrated by inhibition of oral fructose-stimulated hepatic DNL via ^2H_2O incorporation into triglyceride palmitate; n = 8 active/2 placebo per dose-level), and (3) effect of food on single dose PK versus fasted state in healthy adult subjects (n = 10).
Results: *Safety and tolerability*: PF-05221304 was well tolerated at all single and multiple oral doses. Upon repeated dosing, asymptomatic decline in platelet count at doses ≥60 mg/day, plus fasting and postprandial triglyceride increases at doses ≥40mg/day, were observed. *PK:* Steady state AUC (over the dosing interval) increased approximately in a dose proportional manner over the range of multiple oral doses studied. Mean terminal half-life ranged from 11 to 18 hours over the doses studied. Food had minimal effect on the plasma PK of PF-05221304. *PD:* Fructose stimulated hepatic DNL was inhibited in a dose-dependent manner with near complete DNL inhibition following 14 days of dosing at the highest doses studied.
Conclusion: In healthy subjects, well tolerated doses of PF-05221304 demonstrated robust DNL inhibition, sufficient to normalize DNL in patients with NASH, while exhibiting minimal effects on platelet count and serum triglycerides. PF-05221304 is suitable for further clinical development.

FRI-486
Regular aspirin use is not protective against advanced fibrosis in type-2 diabetics with biopsy-proven nonalcoholic fatty liver disease

A. Singh[1], F. Gosai[2], R. Lopez[1], A. Vigni[3], A. Tabbaa[4], E. Lawitz[3], F. Poordad[3], A. Scott[3], T. Okubote[3], M. Scott[3], M. Mansouri[3], N. Alkhouri[3]. *[1]Cleveland Clinic - Main Campus, Cleveland, United States; [2]Cleveland Clinic - Fairview Hospital, Cleveland, United States; [3]Texas Liver Institute, San Antonio, United States; [4]UC San Francisco, San Francisco, United States*
Email: singha4@ccf.org

Background and Aims: Patients with type 2 diabetes (T2DM) frequently use aspirin as a cardioprotective agent and are commonly affected by nonalcoholic fatty liver disease (NAFLD). Recent analysis of a nationally representative databased suggested that aspirin use was protective from advanced fibrosis based on noninvasive indices in individuals with suspected NAFLD. However, limited data exist on the association of aspirin use with histologically-proven advanced liver fibrosis (AF) in diabetics with NAFLD. The aim of this study was to assess this association in a large cohort of patients with T2DM and biopsy-proven NAFLD.
Method: All patients with T2DM who had a liver biopsy for suspected NAFLD were included. Patients with secondary causes of hepatic steatosis (excessive alcohol consumption, hepatitis C etc.) were excluded. Biopsies were assessed by an experienced pathologist and the stage of fibrosis was determined (F0-F4) with AF being F3-4. Laboratory data and use of various medications within 24 months of liver biopsies were used for the analysis. Univariable and multivariable logistic regression analyses were performed to assess any association.
Results: Our cohort consisted of 592 patients with T2DM and biopsy-proven NAFLD. The mean age at biopsy was 52.2 ± 11.7 years, 62.7% were female, 84.8% were Caucasian, 92% were overweight or obese, and the median HbA1C was 6.4% [5.7–7.5]. Sixty six percent of our

patients had no or early fibrosis (F0-2) and 34% had AF (F3-4). A total of 146 patients were on regular aspirin therapy (98% on 81 mg daily and 2% on 325 mg daily), out of which 51 patients had AF. Unadjusted odds ratio (OR) for association of aspirin use with AF was 1.04 (0.71, 1.5) (p = 0.83) and after adjusting for age, gender, race and body mass index OR was 0.77 (0.51, 1.2) (p = 0.22).
Conclusion: Aspirin use is not protective against AF in T2DM patients with NAFLD. Future studies to assess the effects of other medications commonly used in diabetics on liver fibrosis are warranted.

FRI-487
Preliminary efficacy and safety of acetyl-CoA carboxylase inhibitor GS-0976 in patients with compensated cirrhosis due to NASH

Email: rob.myers@gilead.com

Background and Aims: Elevated *de novo* lipogenesis (DNL) contributes to the pathogenesis of NASH. Acetyl-CoA carboxylase (ACC) catalyzes the first and rate-limiting step in DNL. Here, we describe the efficacy, safety, and pharmacodynamic effects of GS-0976, a liver-targeted inhibitor of ACC, in subjects with compensated cirrhosis due to NASH.
Method: In a proof-of-concept study, 10 subjects with suspected compensated cirrhosis (Child-Turcotte-Pugh [CTP]-A) due to NASH (defined by any one of biopsy, liver stiffness by magnetic resonance elastography [MRE] ≥4.67 kPa or transient elastography ≥14.0 kPa, or Fibrotest ≥0.75) received GS-0976 20 mg orally once daily for 12 weeks. Centrally-read magnetic resonance imaging-proton density fat fraction (MRI-PDFF) and MRE, and serum markers of fibrosis were measured at baseline (BL), Week 4 (W4), and Week 12 (W12). For DNL determination, heavy water (^2H_2O, 35 mL) was administered three times daily for one-week cycles prior to baseline, W4, and W12. Deuterium incorporation into palmitate was measured in fasting plasma samples by GC/MS, and mass isotopomer distribution analysis was used to calculate hepatic DNL and its inhibition by GS-0976.
Results: Compared to BL, statistically significant reductions in hepatic PDFF (median: 9.2 vs. 4.6%; p = 0.004) and serum ALT (46 vs. 32U/l; p = 0.008; Figure 1) were observed after 12 weeks of GS-0976 treatment. Reductions in PDFF were significant by W4. A ≥30% relative decline was seen in 5 subjects at W4 (50%) and 7 subjects (70%) at W12. No significant changes in MRE-stiffness or serum fibrosis markers were observed. Decreases in PDFF correlated with changes in ALT, ELF score, and PIII-NP. GS-0976 was well-tolerated; no subjects prematurely discontinued study medication. Median (IQR) fasting triglycerides increased from 147 mg/dl (105, 231) at BL to 159 mg/dl (142, 248) at W12 (p = 0.008), but other lipid parameters were unchanged. One subject had asymptomatic Grade 3 hypertriglyceridemia and responded to fibrate therapy. Data regarding the impact of GS-0976 on fasting hepatic DNL are pending.
Conclusion: In a proof-of-concept study, 12-week therapy with the liver-targeted, oral ACC inhibitor GS-0976 in subjects with compensated cirrhosis due to NASH was safe and associated with significant improvements in hepatic steatosis and serum ALT.

FRI-488
Characterization of changes in lipoprotein profiles of patients with nonalcoholic steatohepatitis treated with the acetyl-CoA carboxylase inhibitor GS-0976

P. Mantry[1], Z. Kayali[2], M. Noureddin[3], P. Ruane[4], B. Mccolgan[5], J. Tarrant[5], L. Wang[5], T. Nguyen[5], E. Harting[5], S. Djedjos[5], A. Ray[5], R. Myers[5], M. Lai[6], M. Charlton[7], E. Lawitz[8], S. Harrison[9], R. Loomba[10].

Email: rob.myers@gilead.com

Background and Aims: GS-0976 is an oral, liver-targeted inhibitor of acetyl-CoA carboxylase (ACC). In a Phase 2 trial, GS-0976 20 mg daily improved hepatic steatosis and markers of fibrosis in subjects with nonalcoholic steatohepatitis (NASH); however, increased serum triglycerides (TG) were observed in some subjects. Our aim was to further characterize lipid changes that occur with GS-0976 therapy.
Method: In a Phase 2 trial, 126 non-cirrhotic subjects with NASH were randomized to receive GS-0976 20 mg (n = 49), GS-0976 5 mg (n = 51), or placebo (n = 26) orally QD for 12 weeks (W12). This analysis focuses on subjects treated with GS-0976 20 mg QD (the efficacious dose) or placebo. In addition to standard lipids (TG, total cholesterol [TC], LDL-C, and HDL-C), lipoproteins were measured by NMR (NMR LipoProfile®, LabCorp) in fasting samples at BL, W1, W4 and W12. Changes from baseline (BL) in GS-0976-treated subjects were evaluated using Wilcoxon sign-rank tests and comparisons vs placebo using Wilcoxon rank-sum tests (all Bonferroni-adjusted).
Results: The median age was 56 years, 69% were female, 63% had diabetes, and 43% were on lipid lowering therapy at BL (37% statins, 4% fibrates, 12% other). TG elevations in subjects on GS-0976 peaked at W1 and declined thereafter (Table 1). At W12, a median (IQR) TG

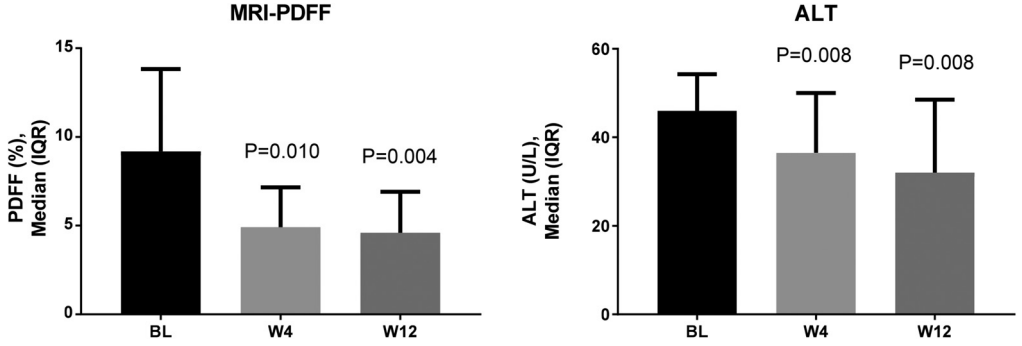

Figure 1: (abstract: FRI-487): Changes in MRI-PDFF and ALT during GS-0976 Treatment in Subjects with Compensated Cirrhosis due to NASH

increase of 14mg/dl (−6, 72) was observed among GS-0976-treated subjects compared with a reduction of 5.5 mg/dl (−24, 26) in those on placebo (p = 0.14). In subjects on GS-0976, significant increases in VLDL particles and VLDL-TG at W1 were not significant at W12. Changes at W12 in HDL-C, TC, and LDL-C were not significant in subjects on GS-0976, but TC and LDL-C declined in those on placebo. No significant changes in total HDL or LDL particles were observed in subjects on GS-0976.

Table 1: Lipid Parameters in Subjects Treated with GS-0976 20 mg Daily

Parameter	BL	W1	W4	W12
TG (mg/dl)	160 (125,201)	191 (136,290)*,†	188 (142,270)*	177 (116,277)*
VLDL-TG (nmol/l)	93 (66,133)	120 (73,236)*,†	97 (69,200)*	96 (68,175)
VLDL-P (nmol/l)	53 (36,73)	72 (39, 121)*	52 (43,90)	52 (31,93)
TC (mg/dl)	179 (152,203)	192 (162,215)†	184 (159,215)†	182 (158,220)†
LDL-C (mg/dl)	99 (82,125)	102 (72,134)	96 (72,124)	99 (71,139)†
LDL-P (umol/l)	1397 (1074,1664)	1256 (990,1558)	1365 (995,1688)	1230 (1013,1592)
HDL-C (mg/dl)	42 (35,53)	39 (33,52)*	39 (33,47)*	42 (33,50)
HDL-P (umol/l)	30 (25,37)	30 (26,36)†	30 (25,36)	30 (25,34)

Data are median (IQR).
HDL-P, total HDL particles; LDL-P, total LDL particles; VLDL-P, total VLDL particles; VLDL-TG.
*p < 0.05 for comparison with BL.
†p < 0.05 for comparison of change from BL vs. placebo.

Conclusion: TG elevations in NASH patients treated with GS-0976 are greatest during the first week of therapy and may relate to a transient increase in hepatic release of VLDL particles. Despite the increase in serum TG concentration, HDL and LDL particles did not change significantly. Longer term studies will be completed to understand the effects of GS-0976 on lipids beyond 12 weeks.

FRI-489

Pharmacokinetics, pharmacodynamics, and safety of EDP-305, in healthy and presumptive NAFLD subjects

A. Ahmad[1], K. Sanderson[1], D. Dickerson[2], N. Adda[1]. [1]*Enanta Pharmaceuticals Inc., Watertown, United States;* [2]*PRA Health Sciences, Lenexa, United States*
Email: nadda@enanta.com

Background and Aims: EDP-305 is a novel oral Farnesoid X Receptor (FXR) agonist under development for the treatment of nonalcoholic steatohepatitis (NASH) with liver fibrosis and cholestatic liver disorders.
Method: A randomized, double-blind, placebo-controlled (PBO), first-in-human study was conducted to evaluate the safety, tolerability, PK, and PD of single ascending doses (SAD) and multiple ascending doses (MAD) of EDP-305 in healthy (HV) and PN subjects (PN = presumptive NAFLD; obese with or without prediabetes or type 2 diabetes mellitus). Subjects received EDP-305/PBO as a single dose (SAD, 6 cohorts, 1–80 mg) or QD for 14 days (MAD, 12 cohorts, 0.5–20 mg), (6 active: 2 PBO/cohort) while fasting, except in the SAD food effect cohort (8 active: 2 PBO). PD measurements included plasma fibroblast growth factor 19 (FGF19) and serum 7-α-hydroxy-4-cholesten-3-one (C4).
Results: A total of 146 subjects (n = 50 in SAD; n = 96 (48 HV and 48 PN) in MAD) received at least one dose of EDP-305 or PBO. Dose proportional increases in exposure were observed, with median $t_{1/2}$ following multiple doses from 10–23 hours. Strong FXR target engagement (increased FGF-19, reduced C4) was demonstrated at EDP-305 doses as low as 2.5 mg in HV, and 0.5 mg in PN subjects. EDP-305 was generally well tolerated at all doses. No clinically significant laboratories were reported except one transient Grade 2 ALT/AST elevation in n = 1 (MAD-HV-20 mg) that led to drug discontinuation. Pruritus was 9% for EDP-305, 3% in placebo: the majority was mild or moderate and occurred at multiple doses of 20 mg, with no cases below 10 mg. No dose-related changes in lipids were observed in HV subjects at any doses; and no dose-related changes in lipids were observed in PN subjects except for reductions of total cholesterol and HDL cholesterol at the multiple 20mg dose, with no concomitant increase in LDL cholesterol.
Conclusion: EDP-305 was generally safe over a broad range of single and multiple doses with PK suitable for once daily oral dosing. Significant elevations of FGF19 and diminutions of C4 demonstrated potent activity on FXR with an opportunity to engage the pharmacological target at the lower multiple dose range of 0.5–5 mg that neither elicits adverse effects on lipids nor results in pruritus. These results support clinical evaluation of EDP-305 in patients with NASH, PBC and PSC.

FRI-490

An integrated safety analysis of phase 2 studies of BMS-986036, a PEGylated fibroblast growth factor 21 analogue for the treatment of non-alcoholic steatohepatitis

D. Halegoua-Demarzio[1], E. Charles[2], B. Tetri[3], S. Kundu[2], G. Tirucherai[2], R. Christian[2]. [1]*Thomas Jefferson University, Philadelphia, United States;* [2]*Bristol-Myers Squibb, Lawrenceville, United States;* [3]*St. Louis University, St. Louis, United States*
Email: dina.halegoua-demarzio@jefferson.edu

Background and Aims: BMS-986036 is a PEGylated analogue of human fibroblast growth factor 21 (FGF21), a key regulator of energy and lipid metabolism, and it improves steatosis, liver injury, and biomarkers of fibrosis and liver stiffness in patients (pts) with non-alcoholic steatohepatitis (NASH). This analysis evaluated the safety and tolerability of BMS-986036 in 2 randomized, placebo (PBO)-controlled phase 2 trials.
Method: Obese pts with type 2 diabetes (T2DM; MB130-002, NCT02097277; n = 120) or pts with biopsy-proven NASH (MB130-045, NCT02413372; n = 78) received treatment (tx) for 12 or 16 wks, respectively, with subcutaneous injections of once-daily (QD; 1, 5, 10, or 20 mg) or once-weekly (QW; 20 mg) BMS-986036 (n = 146) or PBO (n = 52). Safety data, including adverse events (AEs), lab parameters, drug immunogenicity, and bone mineral density (BMD) by dual-energy X-ray absorptiometry, were integrated.
Results: Baseline (BL) characteristics were comparable between the BMS-986036 and PBO groups (table). The most frequent AEs in BMS-986036–treated pts were diarrhoea and injection site bruising; most were of mild or moderate intensity. Median onset of diarrhoea was 21 d after the first dose and resolved after a median of 65 d. There were no deaths or drug-induced liver injury events. During the tx period, 2 pts receiving BMS-986036 experienced serious AEs of depression and suicide attempt, and valvular heart disease; none were tx-related. Two pts discontinued BMS-986036 due to tx-related AEs of moderate fatigue and severe injection site reaction. Anti-BMS-986036 and anti-FGF21 antibodies were detected in >50% of BMS-986036–treated pts; however, titres were generally low (<64), not associated with immune-related AEs, and stable or declining in most pts post-study. BMS-986036 tx did not result in clinically relevant changes in ECG or BMD.

BL characteristics	PBO (n = 52)	BMS-986036 (n = 146)
Men	24 (46.2)	70 (47.9)
Mean age (range), years	51.4 (23–75)	54.2 (23–75)
White	49 (94.2)	121 (82.9)
Mean BMI (range), kg/m^2	35.9 (29.4–57.4)	34.7 (25.7–47.7)
T2DM	35 (67.3)	113 (77.4)
Safety Summary		
Any AE	31 (59.6)	94 (64.4)
Tx-related AE	16 (30.8)	33 (22.6)
Serious AE	2 (3.8)	2 (1.4)
Diarrhoea	4 (7.7)	23 (15.8)
Injection site bruising	6 (11.5)	18 (12.3)

Values are n (%) unless noted

Conclusion: This integrated safety analysis of phase 2 data showed that BMS-986036 was generally safe and well tolerated, supporting further clinical trials to evaluate the safety and efficacy of BMS-986036 in the tx of NASH.

FRI-491

Improvement of liver steatosis achieved byprobiotics in patients with nonalcoholic fatty liver disease

I. Copaci, A. Franculescu, L. Micu, G. Chiriac, M. Mihaila, E.L. Iliescu. *Fundeni Clinical Institute, Department of Internal Medicine, Bucharest, Romania*
Email: laurentiumicu2000@yahoo.com

Background and Aims: Diet-induced weight loss and probiotics are associated with changes in the gut microbioma composition in humans and mice. The aim of the study was to assess the efficacy of this combination in patients with nonalcoholic fatty liver disease (NAFLD).
Method: In a prospective observational study, 92 overweight subjects (54 men, 38 women) with steatosis were recruited after excluding other etiologies. Patients were assigned a moderate caloric restriction (1200–1500 Kcal/day), with less than 30% calories from fat. Group A (40pts) received a combination of B. longum and L. rhamnosus (ZirComBi, Alfasigma), 1 sachet/day, 12 days/month for six months. Group B (52 pts) remained only on diet. Blood samples (biochemistry, HOMA-IR, cytokine levels, steatotest) were collected at entry and at months 6 and 12. All subjects underwent abdominal CT to assess visceral and subcutaneous adipose tissue area (VAT/SAT).
Results: After 12 months, baseline descriptive characteristics (weight, BMI, waist circumference) decreased significantly. Biochemical parameters that decreased significantly in group A vs group B were: GGT (32.2 ± 14 vs 43 ± 18; p = 0.01), ALT (33.8 ± 14.3 vs 59.1 ± 22.5; p = 0.05) and HOMA-IR (3 ± 0.43 vs 4.83 ± 0.65; p = 0.018). Steatotest improved significantly (0.38 ± 0.13 vs 0.68 ± 0.16; p = 0.02). Modification of cytokine levels was significant for leptin (5.9 ± 2.8 vs 13.6 ± 4.7 ng/ml; p = 0.018), adiponectin (11.6 ± 4.9 vs 7.1 ± 3.1 µg/ml; p = 0.003) and IL-6 (1.2 ± 0.3 vs 2.8 ± 2.2 pg/ml; p = 0.02). VAT/SAT did not differ significantly. Multivariate logistic regression showed the following factors related to improved steatosis: BMI < 25 kg/m^2, ALT < 42IU/l, leptin < 10.5 ng/ml, adiponectin > 8.4 µ/ml, and treatment with probiotics.
Conclusion: 1. A 6-month course of lifestyle intervention and probiotics reduces steatosis. 2. Association of probiotics significantly influences ALT, HOMA-IR, IL-6, adipocytokines and steatosis.

FRI-492

Endoscopic sleeve gastroplasty improves liver enzymes and hepatic steatosis index

R. Rosenblatt, S. Kumar, R. Schwartz, R. Sharaiha. *New York Presbyterian Hospital*
Email: RussellRosenblatt@gmail.com

Background and Aims: Increasing numbers of patients with metabolic syndrome also develop nonalcoholic fatty liver disease (NAFLD). The mainstay of treatment of NAFLD is diet and exercise for weight loss, as patients with greater than 10% of total body weight loss have improvement in hepatic steatosis and fibrosis. Some patients undergo surgical procedures for more lasting weight loss. Novel endoscopic techniques have been developed as treatment of obesity, such as endoscopic sleeve gastroplasty (ESG), which utilizes noninvasive and endoscopic suturing to reduce gastric volume. Prospective data evaluating endoscopic methods of weight loss as a safe and effective potential treatment for NASH are lacking. The aim of this study is to evaluate the impact of endoscopic sleeve gastroplasty on NAFLD using the hepatic steatosis index.
Method: Forty-eight patients undergoing endoscopic sleeve gastroplasty for obesity treatment were enrolled in this pilot study. Clinical examination, body mass index, and laboratory evaluation (e.g. liver function tests) was completed before and 6 months after ESG treatment. The hepatic steatosis index (HSI) was calculated using these indices, the patient's gender and presence of diabetes.
Results: Of the 48 patients enrolled in the pilot study, the average age was 42 and the median BMI was 38.2 and significantly decreased at 6 weeks to 32.5, p = 0.0002. The median ALT decreased from 30 to 21 (p = 0.004) while AST decreased from 24 to 21 over 6 weeks (p = 0.005). The HSI significantly decreased from 50.5 to 42.6 in 6 weeks (p = 0.02).
Conclusion: Endoscopic sleeve gastroplasty significantly reduced transaminases, body mass index, and HSI. It remains an intriguing option to improve NASH in obese patients as a less invasive option to bariatric surgery.

FRI-493

Effects of rosuvastatin and pioglitazone long therapy on NASH and coronary heart disease courses

N. Virstyuk[1], I. Vakalyuk[2], O. Virstyuk[3]. [1]*Iwano-Frankiwsk, Internal therapy, Iwano-Frankiwsk, Ukraine;* [2]*Ivano-Frankivsk National Medical University, Internal Medicine department, Ivano-Frankivsk, Ukraine;* [3]*Ivano-Frankivsk Central Clinical Hospital, neurological department, Ivano-Frankivsk, Ukraine*
Email: virstyukn@gmail.com

Background and Aims: Non-alcoholic steatohepatitis (NASH) with fibrosis have been identified as an independent cardiovascular disease (CVD) risk factor. Rosuvastatin treatment at high doses is effective in patients with CVD and nonalcoholic fatty liver disease (NAFLD). The aim of this study was to evaluate the effects of rosuvastatin at low doses and pioglitazone at low doses on NASH and Coronary Heart Disease (CHD) courses.
Method: 42 patients (pts) with stable CHD (postinfarction cardiosclerosis: myocardial infarction 1–3 years ago) and NASH were observed. General clinical examination, ECG, EchoCG, liver elastography, AST, ALT, GGT, lipids, serum C-reactive proteins (CRP), N-terminal prohormone of B-type natriuretic peptide (NT-proBNP) and type IV collagen levels were performed. 22pts have been received rosuvastatin 10mg/day for 1 year (group I), 20 NASH pts have been received rosuvastatin 10mg/day and pioglitazone 15–30 mg/day for 1 year (group II). Examination of the pts was conducted at baseline and after 1 year of treatment.
Results: After treatment, in pts of groups I and II blood circulating triglycerides (p = 0.04 vs. p = 0.006), cholesterol of low density lipoprotein (p = 0.02 vs. p = 0.007), CRP (p = 0.03 vs. p = 0.008), NT-proBNP (p = 0.04 vs. p = 0.009), type IV collagen (p = 0.06 vs. p = 0.02) levels were reduced. In group II AST, ALT, GGT levels were normalized compared with group I and were associated with a shear wave velocity decreased (p = 0.03). Liver fibrosis was decreased in 27.2% pts and remained stable in 40.9% pts, and increased in 31.9% pts of group I. In group II liver fibrosis was decreased in 60.0% pts, 35.0% pts and 5.0% pts respectively. After treatment in pts of group II improvement of the structural-functional state of the heart was observed: left ventricle mass index decreased on 6.1%; left ventricle ejection fraction increased on 8.5%; segmental left ventricular contractility increased on 10.2%. Progression of heart failure from II class NYHA to III class NYHA was in 18.6% pts (group I), vs. 5.0% pts (group II).
Conclusion: Combination of Rosuvastatin and Pioglitazone at low doses for 1 year treatment has metabolic, anti-inflammatory and antifibrotic effects in NASH patients with postinfarction cardiosclerosis and reduces progression of NASH and CHD courses.

FRI-494

Correction of intrahepatic microcirculation disorders by L-ornithine-L-aspartate at the chronic liver diseases patients

T. Ermolova[1], S. Ermolov[2]. [1]*North-Western State Medical University named after I.I.Mechnikov, Internal Medicine, St.-Petersburg, Russian Federation;* [2]*North-Western State Medical University named after I.I. Mechnikov, Therapy and Nephrology, St.-Petersburg, Russian Federation*
Email: t.v.ermolova@mail.ru

Background and Aims: The basis of initial component of increased intrahepatic vascular resistance at the chronic liver diseases are endothelial disfunction, activation of hepatic stellate cells, hyperammoniemia. In some only experimental studies in vivo and in vitro was demonstrated effect of hypoammoniemic drugs for liver microcirculation due to decrease of activity of hepatic stellate cells, portal hypertension, increase of endothelial nitric oxide synthase. Aims of our study are to estimate intrahepatic microcirculation and efficacy of hypoammoniemic L-ornithine-L-aspartate (LOLA) for correction of intrahepatic hemodinamics disorders at the chronic liver diseases patients.
Method: We investigated 78 patients with NASH and 60 chronic viral hepatitis C patients, minimal fibrosis 0–1 stage. Stage of liver fibrosis was estimated by transient elastography (FibroScan). Intrahepatic hemodinamics are determined by polyhepatography – modificated hepatic impedansometry, non-invasive method (PHG). PHG registers a blood flow in projection of zone of hepatic right, left lobes and spleen, integral body impedansography. For verification of functional disorderes induring PHG we use test with deep respiration and nitrates. Our study manifested a high degree of sensitiveness (99%) and specificity (89%) of PHG for definition of localization of hemodynamic disorders in liver (presinusoidal, sinusoidal). For correction of blood flow disorders we used hypoammoniemic drug LOLA in dosage 3 grams 3 times daily 4 weeks. Efficacy of LOLA we looked in 2 and 4 weeks via the control PHG.
Results: Analysis of PHG demonstrated, that at all patients we revealed a liver microcirculation disorders – increased blood resistance, abnormal forms and amplitude of waves in sinusoidal level (out flow zone) at the NASH patients and in presinusoidal level (in flow zone) at the viral patient. Analysis of efficacy of LOLA showed, that LOLA was effective for correction of all hepatic hemodinamic disorders. In 2 weeks of the treatment we observed normalization or improvement of the wave form, in 4 weeks – wave amplitude.
Conclusion: chronic liver diseases are characterized by disorders of intrahepatic microcirculation at different levels, depending on etiology of chronic liver diseases, even in 0–1st stage of liver fibrosis. LOLA improved liver microcirculation at the all patients.

FRI-495

The anti-fibrotic agent, tipelukast (MN-001) reduces serum triglyceride significantly in non-alcoholic steatohepatitis and non-alcoholic fatty liver disease patients with hypertriglyceridemia after 4 weeks of treatment, an interim analysis of ongoing clinical trial, MN-001-NATG-201

K. Matsuda[1,1], J. Gutierrez[2], T. Hassanein[2], Y. Iwaki[1]. [1]*MediciNova, Inc., Clinical R/D, La Jolla, United States;* [2]*Southern California Liver Centers, Coronado, United States*
Email: matsuda@medicinova.com

Background and Aims: Tipelukast (MN-001) is known as an anti-fibrotic agent (AASLD 2014). Also, it was observed that tipelukast reduced serum triglyceride levels in previous clinical studies targeting healthy volunteers and patients with chronic asthma and interstitial cystitis. In this study, we evaluated the effect of tipelukast on non-alcoholic steatohepatitis (NASH) and non-alcoholic fatty liver disease (NAFLD) patients with hypertriglyceridemia.
Method: The MN-001-NATG-201 is a multi-center, open-label study designed to evaluate the efficacy, safety, and tolerability of tipelukast (MN-001) in subjects diagnosed with NASH or NAFLD with hypertriglyceridemia. Subjects receive tipelukast 250 mg qd for the first 4 weeks and increase dosage to 250 mg bid for 8 weeks. In this study, 9 subjects who completed tipelukast (MN-001) 250 mg qd first 4 weeks treatment were analyzed. Of 9 subjects, 3 received tipelukast (MN-001) 250 bid for another 4 weeks.
Results: After 4 weeks of treatment with tipelukast (MN-001), the serum triglyceride level was significantly reduced in 8 of 9 subjects. For 8 patients who reduced their serum triglyceride after the first 4 weeks treatment, pre-treatment mean serum triglyceride was 229.1 mg/dl which was reduced to 174.7 mg/dl ($p < 0.005$). However, for a patient whose serum triglyceride level was not reduced after 4 weeks of tipelukast (MN-001) treatment, a reduction of serum triglyceride was observed after 8 weeks of treatment (24% reduction). There were no significant issues in safety and tolerability.
Conclusion: From this interim analysis, tipelukast (MN-001) significantly reduced serum triglyceride in NASH and NAFLD patients with hypertriglyceridemia, warranting continuation of this ongoing trial.

FRI-496

Lifestyle intervention is effective in treating non-alcoholic fatty liver disease in morbidly obese patients

S. Hohenester[1], C. Simon[2], D. Gerald[1], B. Gert[2], C. Rust[2]. [1]*LMU Munich, University Hospital, Department of Medicine II, Munich, Germany;* [2]*Krankenhaus Barmherzige Brüder, Department of Medicine I, Munich, Germany*
Email: simon.hohenester@med.uni-muenchen.de

Background and Aims: The prevalence of obesity-related non-alcoholic fatty liver disease (NAFLD) is rising worldwide. NAFLD may result in non-alcoholic steatohepatitis (NASH) and progress to liver cirrhosis. Weight loss is recommended to treat obesity-related NASH. Lifestyle intervention has been shown to improve NASH in a few trials, however, these focused on mild obesity, i.e. overweight patients. In contrast, real-life obesity programs typically address patients with morbid obesity. In addition, reports on the efficacy of lifestyle intervention to treat liver fibrosis are scarce. We aimed at evaluating the effect of lifestyle intervention for weight reduction on NAFLD in a real-life cohort of mostly morbidly obese patients.
Method: In this observational single center study, 152 patients underwent lifestyle intervention and were followed for 52 weeks. Measures of obesity, the metabolic syndrome and established non-invasive markers of liver steatosis, damage, and fibrosis were analyzed.
Results: In our cohort of morbidly obese patients (obesity class I, II and III in 13%, 28% and 59% of patients, respectively), treatment response in terms of weight loss was achieved in 85.1%. Dysglycemia and dyslipidemia, i.e. markers of the metabolic syndrome, greatly improved. The proportion of patients with fatty liver, as determined by the fatty liver index (FLI) dropped from 98.1% to 54.3% during follow up ($p < 0.001$). Weight loss >10% was associated with a better treatment response ($p = 0.0009$) in terms of steatosis. Prevalence of abnormal serum alanintransferase (cut-off 30U/L for females, 19U/l for males) fell from 81.0% to 50.5% ($p < 0.001$). The proportion of patients with established liver fibrosis, as determined by the NAFLD fibrosis score, dropped from 11.8% to 0% of patients ($p < 0.05$). Adiponectin correlated inversely with serum ALT ($r = -0,32$, $p < 0.05$), and adiponectin serum levels rose during follow up.
Conclusion: Lifestyle intervention was effective in improving liver steatosis, liver damage and liver fibrosis in a real-life cohort of morbidly obese patients. Improvement was most significant in patients with weight loss of >10%. While 5–7% weight loss is recommended in current guidelines to target NAFLD, >10% might be favorable in patients with morbid obesity.

Acute liver failure and drug induced liver injury

FRI-498

Tauroursodeoxycholic acid protects against valproic acid-induced sensitization to acetaminophen hepatotoxicity

Email: sandra88tn@gmail.com

Background and Aims: Drug-induced liver injury (DILI) is a potentially fatal adverse event. Although valproic acid (VPA), an anticonvulsant drug, has been shown to interact with acetaminophen (APAP), a pain reliever, the impact of this event in DILI has not been fully explored as a potential adverse drug combination. VPA-derived metabolites target mitochondria, inducing mitochondrial permeability transition and disruption of glutathione (GSH) homeostasis as a consequence of reactive metabolites produced by VPA metabolism. Moreover, APAP can cause liver necrosis and acute liver failure in case of overdose due to the generation of NAPQ1, which depletes GSH and covalently bind to mitochondrial proteins. As both drugs have been described to generate endoplasmic reticulum (ER) stress and since StARD1, a protein involved in the intramitochondrial trafficking of cholesterol, is ER stress target gene, thus our aim was to investigate the role of ER stress response in the sensitization of VPA to APAP hepatotoxicity.
Method: Fasted or fed WT mice were treated three times every 12 h with VPA (400 mg/Kg, sc) or TUDCA (250 mg/Kg, ip) followed by a single dose of APAP (300 mg/Kg, ip). Liver damage by ALT and H&E, cholesterol trafficking, GSH homeostasis and mitochondrial function was examined in these animals. Expression of StARD1, MLN64, ER stress markers and lipogenic transcription factors were examined by qPCR and WB.
Results: During fasting, APAP-induced liver injury was independent of VPA. However, in fed mice VPA + APAP treatment significantly increased serum ALT levels and induced centrilobular necrosis compared to control, VPA and APAP groups. TUDCA fully abolished the VPA + APAP hepatotoxic response, revealed by the H&E staining and the significant decrease in serum ALT release. mRNA analysis revealed an induction of StARD1 (2,5 fold) in mice treated with VPA + APAP compared to VPA and APAP treated groups, as well as an upregulation of BiP, CHOP and MLN64 at 4 and 24h after VPA + APAP treatment. TUDCA treatment prevented VPA + APAP-mediated ER stress markers and abolished StARD1 upregulation. These events mirrored the replenishment of GSH levels in mitochondria in VPA + APAP-treated mice following TUDCA administration.
Conclusion: TUDCA protects against the hepatotoxic effects of VPA-induced sensitization to APAP hepatotoxicity, thus suggesting that ER stress is an important player in the liver injury induced by the combination of VPA plus APAP.

FRI-499

s-ademetionine effectively prevents drug-induced liver injury in overweight patients with acute leukemia

I. Skrypnyk, G. Maslova. *Ukrainian Medical Stomatological Academy, Internal Medicine, Poltava, Ukraine*
Email: inskrypnyk@gmail.com

Background and Aims: Overweight patients are in high-risk group of hepatic injury on the background of acute leukemia (AL) chemotherapy. Without preventive medications the incidence of hepatotoxic reactions of varying severity in the dynamics of chemotherapy in patients with obesity can reach 70%.
The aim – to assess the effectiveness of S-ademetionine (S-AME) in the prevention of DILI in overweight patients with AL in chemotherapy dynamic.
Method: The study involved 44 overweight patients with newly diagnosed LA (34 – acute myeloid leukemia (AML), 10 – acute lymphoblastic leukemia (ALL)), ECOG I-II, aged 20–67 years, 21(47.7%) women, 23(52.3%) – men. The body mass index (BMI): 25–29.9 – in 32 (72.7%), BMI > 30 – in 12(27.2%) patients. The liver function was assessed by the activity of alanine aminotransferase (ALT), aspartate (AST) aminotransferase, alkaline phosphatase (ALP), gamma-glutamyltranspeptidase (GGT), bilirubin, total protein in the blood serum twice: at baseline and on the 56-thth day after starting induction of remission therapy, according to the ALL (prednisolone, doxorubicin, vincristin, asparaginase, cyclophosphamide, cytarabine, mercaptopurine) and AML (cytarabine, doxorubicin) treatment protocols. To assess the severity of hepatotoxic reactions the CTCAE scale was used.
Depending on the assigned treatment, the patients were divided into 2 groups: I (n = 23) – chemotherapy + S-ademetionine (S-AME) 1000 mg/day; II (n = 21) – chemotherapy.
Results: In all patients of groups I and II with overweight in the debut of AL ALT activity was increased in 1.4, AST – in 1.2 times, ALP and GGT in 1.3 times compared to the normal values ($p < 0.05$) and reached grade I level, and not significantly different from healthy people in bilirubin and total protein levels.
On the 56-th day of treatment in 6(26%) patients of group I on the background of S-AME prophylactic appointment the functional liver state violation was revealed: the increased activity of ALT in 1.5, AST – in 1.2, ALP – in 1.5, GGT – in 1.6 times compared to normal, the bilirubin and total protein levels remained in within the normal, that consistent with grade I. Hepatotoxicity was detected in 15(71.4%) patients of group II, which was characterized by the increased activity of ALT and AST in 2.7 and in 2.3 times, GGT and ALP in 2.7 and 3.2 times respectively, the level of bilirubin increased in 3.1 times, of which in 6(28.6%) patients hepatotoxic reactions were of grade I and in 9(42.9%) – of grade II level.
Conclusion: Obesity in patients with AL significantly increases the frequency and severity of hepatotoxic reactions in the dynamics of chemotherapy. Appointment of S-AME on the background of induction therapy can reduce the grade of the functional liver state injury and prevent DILI.

FRI-500

Drug exposure and risk of Acute Liver Failure leading to registration for liver Transplantation (ALFT): Results of the SALT III study in adults in France

D. Larrey[1], L. Meunier[1], G.-P. Pageaux[1], S. Maleyran[2], S. Micon[2], S. Lorrain[2], R. Lassalle[2], C. Droz@u-Bordeaux. Fr[2], N. Moore[2,3]. *[1]CHU St Eloi Montpellier, Liver and Transplant Unit, MONTPELLIER, France; [2]Bordeaux Pharmacoepi, CIC Bordeaux Cic 1401, Bordeaux, France; [3]NSERM U1219, Bordeaux, France*
Email: dom-larrey@chu-montpellier.fr

Background and Aims: Acute liver failure leading to liver transplantation (ALFT) indication is largely related to drugs (DILI), as shown by our previous SALT-I 2005–2007 and SALT-II 2008–2013 retrospective multicentre studies and the American DILI network. SALT-III study is aimed to estimate the evolution of the risk of DILI-induced ALFT in France in 2015–2016.
Method: Multicentre, prospective and retrospective, case-population study focused on adults patients registered on transplant list for ALF over 2 years (2015–2016). Data are collected in 17 liver transplant centres. Cases are classified in 2 groups: ALFT "with identified non-DILI cause" (viral, autoimmune hepatitis) and ALFT with well-identified DILI cause, cases with drug exposed ALFT and undetermined ALFT. Drug exposure within 30 days prior to index date (initial symptoms of liver disease) is investigated for all cases, whatever the cause of ALFT. The risk of drug-exposed ALFT, expressed as rate per million treatment-years (tt-yrs), will be calculated using reimbursement data of EGB (permanent random sample of the national healthcare insurance system database). This incidence rate will be compared to that of ALFT "with identified non-DILI cause" in order to identify drugs increasing the risk of ALF.
Results: To date, 119 of 148 cases ALFT cases have been adjudicated by a hepatologist group in the 17 liver transplant participating centres. Among them: 53 cases (44.5% of ALFT) have been classified as ALFT with non-DILI cause (autoimmune hepatitis n = 17 (14.3%); vascular liver injury n = 10 (8.4%); hepatitis B n = 8 (6.7%); other viruses n = 4 (3.4%); alcoholic ALF n = 6 (5.0%); mushroom intoxication n = 4 (3.4%); other causes n = 4 (3.4%) and 50 cases (42% of ALFT) related to paracetamol including 30 cases (25%) with voluntary overdosage

and 21 cases (17.6%) of accidental paracetamol-DILI; 10 cases (8.4%) exposed to drugs 30 days prior to liver injury including 4 DILI with probable causality: amoxicillin (1 case), anti-tuberculous (1 case), antiepileptics (1 case) chemotherapy (1 case) and 6 cases with possible other DILI (several concomitant drugs) and 5 cases (4.2%) not exposed to drugs 30 days prior to liver injury.
Conclusion: In France, over the years 2015–2016, the role of paracetamol in ALFT is further increasing, with a significant proportion of accidental counterpart. Other drugs account for 8.4% of ALFT. Non identified causes is significantly reduced. The results for the whole 143 patients will be available for April 2018. This study was supported by ANSM.

FRI-501

Long-term liver safety of lomitapide in patients with homozygous familial hypercholesterolemia: Three-year data from the lomitapide observational worldwide evaluation registry (LOWER)

D. Larrey[1], J. Underberg[2], C. Cannon[3], L. Makris[4], A. Jurecka[5], D. Blom[6].
[1]Hôpital Saint Eloi, Montpellier School of Medicine, Department Hépato-gastro-entérologie, Montpellier cedex 5, France; [2]NYU Medical School & NYU Center for CV Prevention, Division of General Internal Medicine, New York, United States; [3]Baim Institute for Clinical Research, Boston, United States; [4]Stathmi Inc., New Hope, United States; [5]Aegerion Pharmaceuticals, Cambridge, United States; [6]University of Cape Town, Department of Medicine, Cape Town, South Africa
Email: agnieszka.jurecka@aegerion.com

Background and Aims: Phase 3 clinical study for a microsomal triglyceride transfer protein (MTP) inhibitor, lomitapide, in the treatment of Homozygous Familial Hypercholesterolemia (HoFH) has been associated with asymptomatic transaminase elevations and liver-fat accumulation. Lomitapide prescribing information therefore carries a warning of the risk of hepatotoxicity with use, thus, lomitapide is only available through the restricted REMS Program.
Method: The Lomitapide Observational Worldwide Evaluation Registry (LOWER), is an international, multicenter, observational registry, established to prospectively assess long-term safety and efficacy of lomitapide. This analysis examines 3 years of data among patients enrolled in the registry.
Results: As of March 1, 2017, 163 patients with mean age of 52.3 years were enrolled in LOWER in the USA, EU, Taiwan and Canada. Exposure duration was up to 47.1 months, with 72.4% of patients receiving the drug for >12 months and 38% for 2–5 years. Mean dose was 10 mg (range 5 mg QOD-40 mg QD). The median time to elevated transaminases was 7.7 months. Patients were referred for additional liver-related evaluations for 21 (67.7%) patients with ALT or AST ≥3× ULN to <5× ULN and 10 (90.9%) patients with ALT or AST >5× ULN. Further, elevated transaminases >3× ULN (n = 35, 22.3%) with data following escalation resolved spontaneously or after dose reduction or drug discontinuation. There has been no case with symptomatic hepatitis. Across the 3 years of the registry, only 7 of163 (4.3%) patients had confirmed event of special interest of hepatic transaminase elevations resulting in discontinuation of lomitapide.
Conclusion: The 3-year duration of LOWER afforded the opportunity to assess the effect of chronic MTP inhibition on liver safety. Our data confirm that lomitapide is associated with frequent asymptomatic increase of transaminases, however the percentages of ALT/AST increase are less than those reported in clinical trials. The reduction of lomitapide dose or temporary interruption was associated with resolution allowing the continuation of treatment. There was no significant liver injury and no Hy's law cases.

FRI-502

Proof-of-concept of full-length genome sequencing as diagnostic tool of acute viral hepatitis

I. Ruiz[1], G. Gricourt[2], S. Fourati[1], C. Stephane[2], A.L. Bouter[2], H. Regnault[2], V. Demontant[2], Frédéric L. Gal[3], E. Gordien[3], C. Hezode[2], C. Rodriguez[2], J.-M. Pawlotsky[2]. *[1]INSERM U955, France; [2]CHU Henri Mondor, APHP; [3]Hôpitaux Universitaires de Paris Seine Saint-Denis, Site Avicenne, Bobigny, France*
Email: isaac.ruiz@me.com

Background and Aims: Acute hepatitis is a common clinical condition with serious complications such as fulminant hepatitis. The cornerstone of acute hepatitis management remains the identification of the etiological cause. Indeed, PCR or serological tests available for viral diseases are all specific for one virus making diagnosis difficult. The aim of this study was to evaluate full-length-genome sequencing (FLGS) as a diagnostic tool.
Method: "Acute hepatitis cohort" enrolled 11 patients with a causal diagnosis of acute viral hepatitis; "Hepatitis-related-virus cohort" enrolled 71 patients without acute hepatitis but with viral infections associated with hepatitis. Full medical history was recorded and acute hepatitis was diagnosed as recommended by the EASL guidelines. Samples were tested by means of an original in-house patent-protected shotgun metagenomics method using MetaMIC® process. A universal extraction (whole microbes, DNA and RNA) followed by library preparation using Total RNA and Nextera XT kit (Illumina) and sequencing with NextSeq500 (Illumina) were performed. Then, sequences were analyzed using MetaMIC software (quality, filtering, identification, genome reconstruction and comparison) for rate mutation calculation in whole viral genome (cut off at 15%).
Results: Shotgun metagenomics provided different levels of characterization of viral infections depending on their viral load: Low viral load could be only "Detected", while high viral load is associated with a "FLGS". The results are summarized in table 1. In addition, viruses not detected by routine test panels viruses not detected by routine test panels, such as human Pegivirus 1, were also detected in 3 cases.
Conclusion: FLGS by means of shotgun metagenomics using deep sequencing technology identifies all common viruses causing acute hepatitis, as well as non-common hepatitis-virus-related infections. In addition, the technique detects viruses not detected by routine test panels in diagnostic laboratories, including co-infections. Thus, we have established a FLGS technology able to blindly detect any pathogen in the context of acute hepatitis, regardless of the disease

Table 1: (abstract: FRI-501): Peak Transaminases (Peak ALT or AST by Time Period Elevation Category at Any Time Point during Analysis Windows – Full Analysis Set), Cases of Hy's Law and Hospitalizations due to LFT elevations in Phase 3 clinical study and LOWER 3 Year data

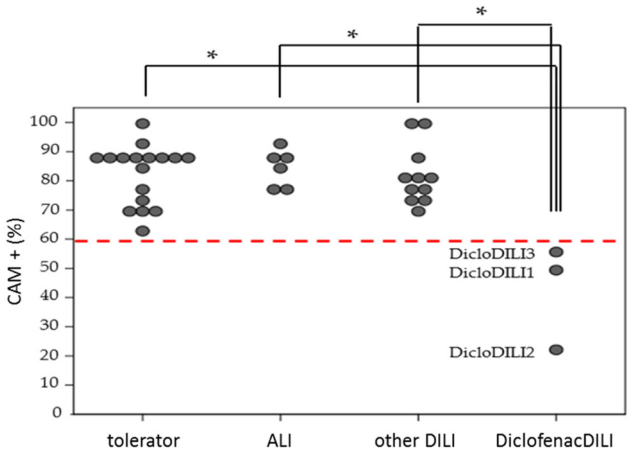
MH cells in combination with proteomics identify a potential biomarker for Drug-induced Liver Injury by Diclofenac

A. Benesic[1,2], D. Dragoi[2], G. Pichler[3,4], N. Kulak[3,4], H. Bartsch[5], A. Gerbes[6]. *[1]University Hospital Grosshadern Munich, Department of Medicine 2, Liver Centre Munich, Munich, Germany; [2]MetaHeps GmbH, Martinsried, Germany; [3]Preomics GmbH, Martinsried, Germany; [4]Max Planck Institute for Biochemistry, Department of Proteomics und signal transduction, Martinsried, Germany; [5]Institute of Pathology, Medical School Ludwig-Maximilians University Munich; [6]University Hospital Grosshadern Munich, Department of Medicine 2, Liver Centre Munich*
Email: andreas.benesic@med.uni-muenchen.de

Background and Aims: Drug-induced liver injury (DILI) is the most frequent cause of acute liver failure and the single most important reason for regulatory actions on drugs. Idiosyncratic DILI (iDILI) is not predictable by pre-clinical models and its diagnosis is very challenging. Drug causality may be impossible to determine in polymedicated patients. These difficulties in case characterization impede with efficient development of novel iDILI biomarkers. We have developed a method to diagnose or exclude iDILI using hepatocyte-like cells derived from peripheral monocytes (MH cells) which can improve causality assessment in polymedication. Aim of this study was to investigate whether proteomics analyses of patient derived MH cells allow the identification of novel specific iDILI biomarkers.

Method: MH cells were generated from 22 donors (study NCT02353455): 12 were exposed to diclofenac (3 patients who tolerated diclofenac, 4 patients who suffered iDILI by diclofenac, 2 patients with iDILI by another drug and 3 patients with acute liver injury (ALI) of non-drug cause). 10 patients without diclofenac intake were used as additional controls (3 healthy, 4 iDILI by other drugs and 3 ALI patients). MH cells were treated with diclofenac in vitro and analysis of MH cells was performed using mass spectrometry (MS)-based proteomics. From over 2700 proteins that could be quantified in MH cells derived from individual patients, we identified a cell adhesion molecule (CAM) to be specifically upregulated in Diclofenac-treated MH cells from Diclofenac-DILI patients compared to control groups.

Results: Flow cytometry of whole blood and histological staining of liver biopsies derived from additional patients diagnosed with Diclofenac-DILI and controls shoed a decrease of CAM-positive cells in blood samples of patients with Diclofenac DILI (Figure) whereas an increased CAM-signal was found in liver biopsies of these patients. These results suggest a recruitment of CAM-positive cells in the liver during iDILI by diclofenac.



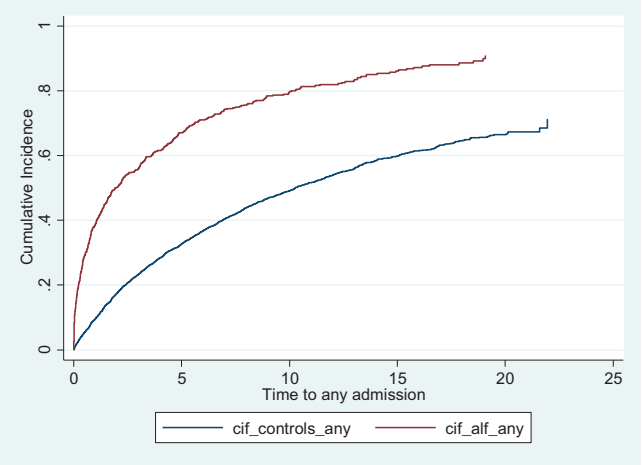
Conclusion: Proteomics analysis of these MH cells from patients with Diclofenac DILI show distinct changes in protein expression induced by diclofenac treatment. The cell adhesion molecule (CAM) as identified biomarker candidate showed distinct changes in blood samples and liver biopsies from patients with diclofenac DILI. The combination of MH cells and MS-based proteomics may present a novel tool to identify drug-specific biomarkers for iDILI.

FRI-504

Health care utilisation in spontaneous survivors of acute liver failure

M. Donnelly[1], L.J. Williams[2], B. Murray[3], C. Taylor[3], A. Springbett[3], J. Davidson[4], A. Baird[4], K. Martin[4], J. Moore[4], N. Lone[2], K.J. Simpson[4]. *[1]Royal Infirmary of Edinburgh, Hepatology, Edinburgh, United Kingdom; [2]University of Edinburgh, Centre for Population Health Sciences, Edinburgh, United Kingdom; [3]Electronic Data Research and Innovation Service, NHS Information Services Division, Edinburgh, United Kingdom; [4]Royal Infirmary of Edinburgh, Department of Hepatology and Scottish Liver Transplant Unit, Edinburgh, United Kingdom*
Email: mhairi.donnelly@nhs.net

Background and Aims: In Scotland, patients with severe acute liver injury or failure (ALF) are managed in a single centre (Scottish Liver Transplant Unit; SLTU). Patients surviving ALF without transplantation ("spontaneous survivors"; ALF-SS) are expected to return to normal health without lasting morbidity. Little research has been undertaken on the long-term morbidity and health care utilisation of ALF-SS. Our aims were to analyse health care resource use in ALF-SS compared with a matched sample of the general Scottish population.
Method: The study cohort was patients admitted to the SLTU (01/11/1992–30/12/2014) surviving to hospital discharge without transplantation. The general population control cohort was matched for year of birth, sex and postcode sector. Units of resource use were identified from the SMR01 database and costs calculated. Independent predictors of hospital readmission were identified by negative binomial multivariable regression modelling. Fine and Gray models were used in analysing time to first readmission with death as a competing risk.
Results: In ALF-SS, the cumulative incidence of first readmission was 12.6% at 30 days, 38.3% at one year, 66.9% at five years, 79.4% at 10 years and 90.9% at 20 years compared with 1.3%, 9.6%, 32.7%, 49.2% and 67.4% in the matched controls – see Figure.
The ALF-SS experienced their first readmission significantly earlier than the matched controls (mean years to any readmission: ALF-SS 5.3; matched controls 11.8: $p < 0.0001$). The adjusted relative rate (RR) of any readmission (for ALF-SS compared with matched controls) was 2.99 (RR 95% CI 2.64–3.39; $p < 0.0001$) and emergency readmissions was 4.65 (RR 95% CI 4.00–5.38; $p < 0.0001$). Total costs of readmissions in the ALF-SS were £9,316,125 with a cost of £13,536/10 person years (py) for all admissions. The cost/10py was £4366.81 in the matched controls.
Predictors of time to any readmission in the ALF-SS were: age, count of elective and emergency admissions pre SLTU admission, previous psychiatric admissions, and non-paracetamol aetiology. Predictors of time to emergency readmission were: age, count of elective and emergency admissions pre SLTU admission, Carstairs decile, non-paracetamol aetiology and bilirubin. In analysing rate of readmissions per-person year, bilirubin was a predictor of readmission, in addition to those variables reported as predictors of time to any readmission.



Cumulative incidence of any admission in ALF-SS (cif_alf_any) and matched controls (cif_controls_any) (years since hospital discharge).

Conclusion: Due to the rarity of ALF, the long-term implications of surviving ALF have not previously been recognised. We have shown that spontaneously surviving ALF is associated with increased health care utilisation. We must now begin to develop follow up protocols for ALF-SS, to reduce readmission rates and the resource use burden in this population.

FRI-505

Amatoxin poisoning in Germany – important clues for clinical practice

B. Schlevogt[1], N. Jedicke[2], H. Heinzow[1], I. Kabar[1], M. Busch[2], M.P. Manns[2], H. Schmidt[1], C. Wilms[1]. *[1]University Hospital Münster, Gastroenterology and Hepatology, Münster, Germany; [2]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany*
Email: bernhard.schlevogt@ukmuenster.de

Background and Aims: Intoxication with amatoxins is a rare but often severe cause of acute liver injury requiring even liver transplantation in some cases. As most mushroom intoxications are not related to amatoxins and therefore do not have serious consequences there is a need for early identification of those who require treatment in a transplant center due to acute liver failure. The aim of this study was to better characterise the patients at risk and to test a temporal cutoff for safe termination of laboratory follow-up after symptomatic mushroom ingestion.
Method: In a multicenter retrospective cohort study (2 tertiary referral transplant centers) 31 patients with a history of mushroom ingestion and subsequent liver injury were included from 2002 until 2017. Clinical and laboratory data was collected from chart review.
Results: Patients with amatoxin intoxication predominantly came from countries from the former USSR. A much smaller group of patients presented during the European refugee crisis in 2015 whereas only 2 patients came from Germany (Table 1). Occurrence of amatoxin poisoning was clearly seasonal as 87% of the patients presented during August and September. All patients developed gastrointestinal symptoms after a median 10h (range 2–24h) and presented at the hospital after a median 25h (range 13–104h). At initial presentation 90% of the patients already had an elevated alanine transaminase (ALT) after a median 30h (range 16–104h). The 3 initial ALT negative patients developed an increased ALT at 30h, 37h and 51h. The latter patient was excluded from further analysis because of a peak ALT reaching just 65 U/l. When taking 48h from ingestion as a cutoff for termination of the laboratory surveillance only 8 patients had their first available ALT (range 391–8293 U/l) after a longer period of time. Due to these strongly increased ALT values it is highly likely ALT would have been tested positive at the cut-off of 48h post ingestion if they had just presented earlier.

Table 1: Origin of patients with amatoxin poisoning in 2 tertiary referral transplant centers from 2002–2017

country of origin	patients
Kazakhstan	6
Russia	5
Rumania	4
Poland	2
Syria	2
Iraq	2
Germany	2
Lithuania	1
Hungary	1
Turkey	1

Conclusion: In this study we describe for the first time that people who originated in countries from the former USSR are the main population at risk for amatoxin associated liver injury. With this knowledge more targeted awareness campaigns can be launched. Very often, it is difficult for the clinician to identify the exact mushroom species in order to predict toxicity. Based on our results, we suggest that severe mushroom poisoning can be excluded safely if ALT values are still within normal range at 48h past mushroom ingestion.

FRI-506

Opal, but not MARS improves patients albumin binding function measured by Electron Spin Resonance (ESR) in a prospective multicenter trial

A. Kortgen, J. Stange, C. Sponholz, H. Schmidt, C. Wilms, H.U. Gerth, S. Mitzner, M. Dollinger, T. Hassanein
Email: jstange@ucsd.edu

Background and Aims: In patients with decompensated cirrhosis, endogenous accumulation of toxins results into overload of patient's albumin as a toxin carrier and reduction of patient's albumin binding functions measured by Dansylsarkosine binding (ABiC), a marker for bile acid binding (Klammt et al. EJGH 2007) or Electron Spin Resonance (ESR), a marker for long chain fatty acid binding (Jalan et al. Hepatology 2009). Both markers have been shown to be associated with survival. Extracorporeal albumin dialysis (ECAD) using MARS has been reported to be ineffective to improve ESR parameters in decompensated cirrhosis, indicating the reduction seen in this condition is either irreversible or insufficient removal of albumin bound toxins, or both. Open albumin dialysis (OPAL), employing new membranes and more efficient adsorbents was tested versus MARS in a multicenter randomized cross over study to test the hypothesis if these changes can be reversed by more effective ECAD.
Method: 30 subjects in 4 sites with chronic liver disease and progressive jaundice and/or hepatic encephalopathy and/or renal failure and/or pruritus were treated first randomly with OPAL or MARS and after wards crossed over to the other. Patient's albumin binding was measured by ESR using a long chain fatty acid as a marker.
Results: Subjects initiated with MARS and initiated with OPAL were comparable with respect to age, gender, baseline MELD. Detoxification Efficacy (DE) was unchanged during MARS (0.11 ± 0.07 vs. 0.11 ± 0.09; n.s.) while it was significantly increased after OPAL (0.085 ± 0.07 vs. 0.14 ± 0.09; $p < 0.05$). Binding Efficacy (DE) was unchanged during MARS (0.23 ± 0.09 vs. 0.22 ± 0.09; n.s.) while it was significantly increased after OPAL (0.2 ± 0.06 vs. 0.26 ± 0.07; $p < 0.05$).
Conclusion: These data indicate that the reduction of patient's albumin binding for long chain fatty acids is at least in part reversible provided effective adsorbents are used to remove albumin bound toxins. A prospective randomized study is planned to re-examine the consequence of improving this prognostoic marker on survival.

FRI-507

Etiology and clinical features of patients with drug-induced liver injury diagnosed by liver biopsy

G. Chen[1,2], D. Ji[1,2], C. Wang[3,4], J. Chen[3], Q. Shao[1,2], B. Li[1,2], F. Li[1,2], Z.B. Li[1], Y. Wang[3], T. Wu[3], V. Wu[3], G. Lau[5]. *[1]302 Hospital, Second Liver Cirrhosis Diagnosis and Treatment Center, Beijing, China; [2]Beijing 302-Hong Kong Humanity and Health Hepatitis C Diagnosis and Treatment Centre, Beijing, China; [3]Humanity and Health Research Center, Hong Kong, Hong Kong; [4]State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; [5]Humanity and Health Research Centre, Unit 1505, 15/F, No. 9 Queen's Road Central, Hong Kong, Hong Kong*
Email: gkklau@netvigator.com

Background and Aims: Drug-induced liver injury (DILI) is a rare adverse drug reaction and it can lead to jaundice, liver failure, or even death in some patients. Antimicrobials and herbal and dietary supplements are among the most common therapeutic classes to cause DILI in the Western world. This study aimed to investigate the etiology and clinical features of Chinese patients with DILI.
Method: A total of 194 consecutive DILI inpatients, who underwent liver biopsy in Beijing 302 hospital from January 2015 to December 2015, were enrolled in the study. The etiology, laboratory markers (alanine transaminase, aspartate aminotransferase, total bilirubin, gamma-glutamyl transferase and alkaline phosphatase), and the pathological features were analyzed retrospectively. The relationship between liver fibrosis stage and non-invasive measurements, e.g. liver stiffness measured (LSM) by FibroScan® (Echosens, Paris, France), APRI, FIB-4 and portal vein diameter were analyzed by Spearman correlation analysis.
Results: Chinese traditional medicine (TCM) was the most common cause of DILI, which accounted for 46.9% of patients, followed by acetaminophen-containing regimen (14.4%), antibiotics (9.3%), environmental toxins (4.6%), antidepressant (4.6%), dietary supplement (3.1%), lipid-lowering drugs (3.1%), chemotherapeutic agents (3.1%), and others (11.3%). Of 194 DILI patients, hepatocellular type was observed in 78 (40.2%) patients, cholestatic type in 63 (32.5%) patients, and mixed type in 53 (27.3%) patients. Histological findings showed that 70 (36.1%) patients had an acute injury, 124 (63.9%) patients had chronic damages, which composed by G0 (9.8%), G1 (19.1%), G2 (21.6%), G3 (9.8%), and G4 (3.6%) inflammation level. LSM, APRI and FIB-4 were positively correlated with liver fibrosis stage, but portal vein diameter had no relationship with liver fibrosis stage.
Conclusion: In Chinese population, almost half of DILI was induced by TCM. Liver stiffness measured by non-invasive biomarkers is correlated with grading from liver biopsy in Chinese patients with DILI.

FRI-508

Acute Liver Failure-Organ Failure (ALF-OF) score is better than King's College Hospital criteria in predicting mortality in patients with non-paracetamol-related acute liver failure (ALF)

F. Figorilli[1], A. Putignano[1], B. Agarwal[2], R. Jalan[1]. *[1]UCL Institute for Liver and Digestive Health, UCL Medical School, Royal Free Campus, Liver Failure Group, London, United Kingdom; [2]Royal Free Hospital, Royal Free Hampstead NHS Trust, University College London, Intensive Care Unit, London, United Kingdom*
Email: francesco.figorilli@gmail.com

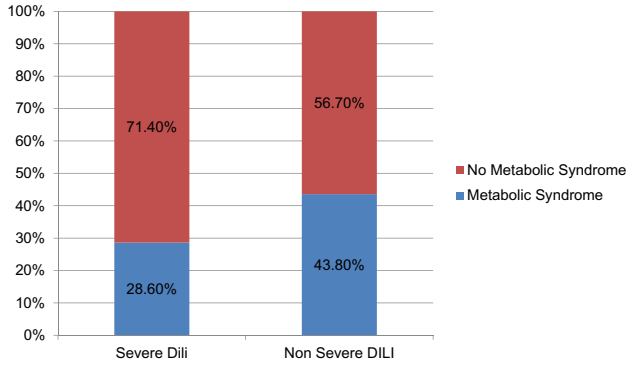
Background and Aims: ALF is a critical illness and a liver transplant (LT) is often the only life-saving treatment. King's College Hospital criteria (KCH) are currently used to identify LT potential candidates among patients with ALF of all aetiologies. Given high mortality and the organ shortage, a more sensitive score is needed. ALF-OF score is a modified version of CLIF-OF score recently created for paracetamol related-ALF. A cut-off of 4.5 has been proposed as a poor prognostic criteria. In this study we compared the new prognostic score with KCH and SOFA score to find the best predictor of free-LT survival in the context of non-paracetamol related ALF.
Method: We included all consecutive patients admitted to the intensive care unit of the Royal free Hospital between 2001–2016 with ALF not related to paracetamol overdose. Clinical and laboratory data were collected and ALF-OF, KCH and SOFA were calculated at the admission. Primary endpoint was the 3-month mortality of any cause. For each score we assessed the area under the curve (AUC), the best cut-off value, sensitivity, specificity and positive predictive value (PPV). Cox regression analysis was used to identify the best predictor of 3-month mortality.
Results: 75 patients were included: 76% fulfilled poor prognostic KCH criteria. Of them, 35 were listed for LT but 3 died while on the waiting list. The 3-month mortality among the 32 transplanted patients was 15.6%. 22 patients despite fullfiling poor prognostic criteria, did not receive LT (2 were not listed for psychiatric problems, 15 were considered too unwell for LT and 5 improved). 43/75 were not transplanted showing a 3-month mortality of 46.5%. ALF-OF had the best AUC (0.766) with 60% sensitivity and 75% PPV; it was also the best mortality predictor in the multivariate analysis ($p < 0.001$; HR 3.3; 95%CI 1.78–6.1). SOFA showed the second highest AUC (0.665) with a higher sensitivity (90%) but the lowest specificity (47.8%). KCH criteria showed the lowest AUC (0.620) with the lowest sensitivity (50%). Non-transplanted patients achieving an ALF-OF score >4.5 showed a higher 3-month mortality in Kaplan Meier analysis (56% vs

11%, p = 0.025) while no significant difference was observed according to KCH criteria (62%vs37%; p = 0.083).
Conclusion: ALF-OF score is better than KCH criteria in predicting the mortality among patients with non-paracetamol related ALF. This new score could be used to select the optimal candidates for emergency LT.

FRI-509
Drug induced liver injury – A study on the factors affecting severity and prognosis with special emphasis on metabolic syndrome

S. Narayanan, K. Devadas. *Trivandrum Medical College Thiruvananthapuram, India*
Email: sanpnr@gmail.com

Background and Aims: The factors predicting outcome in DILI has not been well understood. Of late several studies have linked DILI severity with underlying NASH as both the disorders has been linked with mitochondrial dysfunction. Objective of the study was to whether metabolic syndrome is an independent predictive factor for severity and mortality in drug induced liver injury. Secondary objective was to identify other factors influencing outcome.
Method: Severe DILI was defined as either INR > 1.5 or Ascites or hepatic encephalopathy or other organ failure.Metabolic Syndrome was defined by IDF Criteria. **Inclusion criteria:** Documented exposure to drug ingestion resulting in hepatotoxicity satisfying DILI criteria with RUCAM score 6 or more. **Exclusion Criteria:** Viral marker positivity, Decompensated cirrhosis s. USG, FBS, FLP, anthropometric measurements, BP measurement and BMI was obtained for all patients.
Results: A total of 76 patients were included in the study, out of which 28 had severe DILI. There was 7 cases of fatal DILI, out of which 3 had underlying cirrhosis. Females formed 59.2% of the cohort. Thee most common cause of DILI was ATT(27.6%), followed by CAMS (15.8%), Chemotherapeutic drugs (13.2%) and antiepileptics (13.2%). Most of the severe DILI cases were due to ATT (46.4% of all severe DILI cases). Of the 76 cases, 38.2% had metabolic syndrome. Metabolic syndrome was present in 28.6% of severe DILI cases compared to 43.8% of non severe DILI cases (P > 0.05). When ATT DILI was excluded, the proportion of Metabolic Syndrome in the severe DILI cohort rose to 44.4%. Fatty liver was seen in 39.5% of the patients. Only 14.3% of severe DILI patients had fatty liver compared to 56.3% of non severe DILI patients (p = 0.001). Of the seven cases of mortality due to DILI, two (28.5%) satisfied the criteria for metabolic Syndrome. Mean latent period was 91.9 days in the ATT group compared 27.6 days in the non ATT group. In severe DILI the mean latent period was 73.9 days compared to 28.4 days in the non severe DILI group (p < 0.05). Mean bilirubin in the DILI group was 18.8 compared to 5.7 in the non severe group. Mean ALT was 988.8 in the severe group compared to 390.8 in the non severe group.



Conclusion: Metabolic syndrome showed no correlation with the severity or mortality in DILI. Paradoxically metabolic syndrome was lower in the severe DILI group though the results were not statistically significant. The proportion of patients in the DILI cohort was higher than population prevalence.

FRI-510
Serum CXCL10, CXCL11, CXCL12 and CXCL14 chemokine patterns in patients with acute liver injury

A. Chalin[1,2], B. Lefevre[1,2], C. Devisme[1,2], V. Carrière[1,2], L. Amiot[1,2,3], M. Samson[1,2]. *[1]IRSET - U.1085 Inserm, Rennes, [2]Université de Rennes 1, Rennes, [3]Université de Rennes 1/CHU Pontchaillou de Rennes*
Email: michel.samson@univ-rennes1.fr

Background and Aims: CXCL10 (interferon ϒ-inducible protein 10 [IP-10]), CXCL11 (Human interferon inducible T cell alpha chemokine [I-TAC]), CXCL12 (stromal cell derived factor 1 [SDF-1]) and CXCL14 (breast and kidney-expressed chemokine [BRAK]) chemokines are known to be involved in recruitment, migration, activation and homing in liver diseases and have been shown to be upregulated during acute liver injury (ALI) in animal models. However, to our knowledge, no data has been reported on their expression in patients with ALI. Here, we aim to provide evidence on the presence of circulating CXCL10, CXCL11, CXCL12 and CXCL14 chemokines during human ALI to propose new biomarkers of inflammation during ALI.
Methods: The 4 chemokines were measured on sera samples from 149 patients and 36 healthy volunteers using ELISA assay. Inclusion criteria for ALI patients were ALT activity superior to 129 UI/L (or 3 × upper normal limit). Patients with acute on chronic liver injury or hepatocarcinoma were excluded or if other source of ALT activity was suspected (rhabdomyolysis, myocardial infarction …). Patients were separated into 8 groups depending on the cause of the ALI. The degree of association between two variables was assessed by Pearson's parametric test rank correlation. Comparisons of parameters between two different groups were analysed by the Student t-test.

Table: (abstract: FRI-510): Serum chemokine levels mean fold increase among the different groups of patients compared to healthy donors. (*p < 0.05, **p < 0.01, ***p < 0.001; statistical significance was determined by Student's t-test for difference in means)

	CXCL10		CXCL11		CXCL12		CXCL14	
	Mean fold increase	Significance	Mean fold increase	Significance	Mean fold increase	Significance	Mean fold increase	Significance
Ischemia reperfusion post liver graft	4.5	**	3.7	***	3.8	***	1.43	ns
Acute viral infection	11.4	***	8.1	***	3.3	***	3.8	**
Biliary	2.0	ns	1.8	*	2.1	**	−2.9	ns
Congestive hepatopathy	2.5	*	2.5	***	4.5	***	3.4	*
Toxic	3.8	*	3.1	***	5.6	***	2.4	ns
Auto-immune	9.0	***	6.6	***	3.9	***	−3.2	ns
Vascular	10.5	***	3.5	***	6.1	***	5.3	***
Obstetrical	3.4	**	6.4	***	5.0	***	−1.1	ns

Results: CXCL10 was mainly found in acute viral infection, autoimmune, vascular diseases and to a less extent in liver ischemia post graft and obstetrical aetiologies. CXCL11 and CXCL12 were strongly upregulated for all aetiologies excepted biliary diseases. CXCL14 was found only in acute viral infection and vascular aetiologies.
Conclusion: These data provide evidence on circulating CXCL10, CXCL11, CXCL12 and CXCL14 chemokines during ALI and confirm data obtained on animal models. CXCL11 and CXCL12 are the most and CXCL14 the less represented chemokines while CXCL10 shows an intermediate profile. Differential expression patterns were obtained according to ALI aetiologies suggesting a potential use of these chemokines as biomarkers of ALI.

FRI-511

The proportion of patients waitlisted for transplantation for HDS induced liver injury is increasing and differs by race

J. Odin[1], V. Kesar[2], N. Roth[1], P. Grewal[1], J. Ahmad[1]. *[1]Icahn School of Medicine at Mount Sinai, Transplantation Institute, New York, United States; [2]Lenox Hill Hospital, Department of Medicine, New York, United States*
Email: joseph.odin@mountsinai.org

Background and Aims: Cases collected by the US Drug Induced Liver Injury Network (US DILIN) have suggested that the incidence of DILI from herbal and dietary supplements (HDS) has increased in the past five to ten years and may be a growing health problem. We previously examined data on US liver transplantation recipients and found that those of Asian race were disproportionately transplanted for HDS-DILI for unknown reasons. Whether or not proportionately more Asians are waitlisted for transplant for HDS versus nonHDS induced liver injury was not determined in our original study.
Method: We searched the Organ Procurement and Transplantation Network (OPTN) database for those waitlisted for liver transplantation for "acute hepatic necrosis-drug" between January 1, 1994 and October 31, 2014. We identified patients waitlisted for transplant for HDS-DILI (n = 51) and nonHDS-DILI (n = 433), excluding DILI due to acetaminophen or "other/unknown" causes. Each group was evaluated on the basis of sex, age, race/ethnicity, and education (Table).

Table: Characteristics of Patients Waitlisted for nonHDS- versus and HDS-DILI

	NonHDS-DILI (n = 433)	HDS-DILI (n = 51)	p-value
Sex:			
Female	303 (70.0%)	37 (72.6%)	0.70
Male	130 (30.0%)	14 (27.5%)	
Age (years):			
0–29	130 (30.0%)	15 (29.4%)	0.16
30–44	118 (27.3%)	20 (39.2%)	
45–73	185 (42.7%)	16 (31.4%)	
0–39	204 (47.1%)	27 (52.9%)	0.43
40–73	229 (51.9%)	24 (47.1%)	
Median (IQR)	41 (27–54)	38 (22–52)	0.42
Race/Ethnicity:			
White	219 (50.6%)	26 (51.0%)	<0.001
Black	112 (25.9%)	3 (5.9%)	
Hispanic	65 (15.0%)	6 (11.8%)	
Asian	24 (5.5%)	13 (25.5%)	
Other	13 (3.0%)	3 (5.9%)	
Education beyond high school:[1]			
No	152 (54.5%)	15 (42.9%)	0.19
Yes	127 (45.5%)	20 (57.1%)	

Significance calculated with chi-squared tests for categorical variables and Kruskal-Wallis rank tests for continuous variables.
[1]Missing for n = 170 patients.

Results: There were no significant differences between the two groups with regard to sex, age, or educational level. Race did have a significant effect (p < 0.001). Asians were disproportionately waitlisted for transplant for HDS-DILI (25.5%) versus nonHDS-DILI (5.5%). Conversely, Blacks were disproportionately more likely to be waitlisted for nonHDS-DILI (25.9%) versus HDS-DILI (5.9%). Differences for both races were statistically significantly different on multivariate analysis. Using univariate logistic regression models, we determined that proportionately more individuals were waitlisted for transplant caused by HDS-DILI during the years 2005–2014 (14.4%) versus 1994–2004 (7.8%) (p = 0.02).

Conclusion: The proportion of patients waitlisted for liver transplantation for HDS induced liver injury is increasing and differs by race. Proportionately more Asians are being both waitlisted and transplanted for HDS-DILI compared to nonHDS-DILI. The role of cultural and genetic factors in this racial difference remains uncertain.

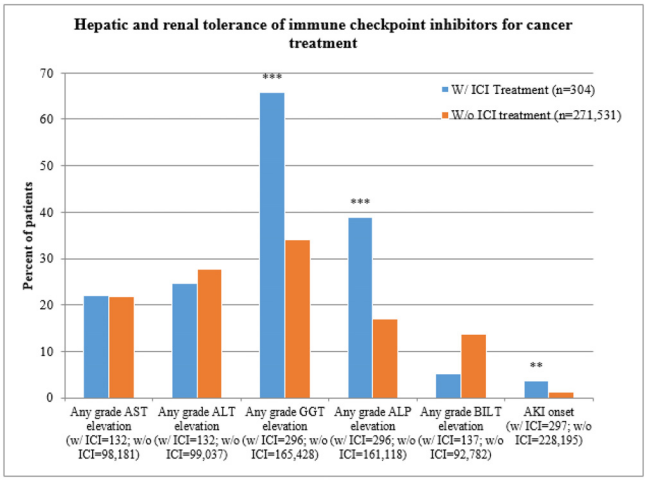
FRI-512

Hepatic and renal tolerance of immune checkpoint inhibitors for cancer treatment: A retrospective monocentric cohort study

L. Parlati[1], A.V. Pichard[1], H. Alain[2], A. Bellesoeur[3], J. Arrondeau[3], P.B. Rouquette[3], F. Goldwasser[3], N. Kramkimel[3], O. Huillard[3], J. Alexandre[3], S. Aractingi[4], J. Chapron[5], B.D. Fischer[6], M.L.B. Piat[7], R. Batista[7], R. Coriat[8], F. Helene[9], M. Cororuge[9], P. Sogni[9], P. Stanislas[9], V. Mallet[9]. *[1]Cochin University Hospital, Hepatology, Paris, France; [2]Cochin University Hospital, Biology Service; [3]Cochin University Hospital, Medical oncology; [4]Cochin University Hospital, Dermatology Service; [5]Cochin University Hospital, Pneumology Service; [6]Cochin University Hospital, Hematology Service; [7]Cochin University Hospital, Pharmacy Service; [8]Cochin University Hospital, Gastroenterology Service; [9]Cochin University Hospital, Hepatology Service*
Email: lucia.parlati85@gmail.com

Background and Aims: Immune checkpoint inhibitors (ICI), including those interfering with the CTLA-4 (ipilimumab [IPI]) and PD-1/PD-L1 axes (nivolumab [NIVO]/pembrolizumab [PEMBRO] and avelumab [AVE]/atezolizumab [ATE], respectively), will be given to a growing number of patients with cirrhosis and hepatocellular carcinoma (HCC). There is a gap of knowledge on the safety profile of these molecules.
Method: We conducted a retrospective cohort study among consecutive and non-selected adult patients (N = 271,835) with at least one blood test (median (interquartile range [IQR]) 2 [1–5] measures per patient) at Cochin University Hospital between 2010 and 2017. During the observational period, 304 (0.11%) patients received ICI treatment, including NIVO (n = 187, 61.5%), PEMBRO (n = 97, 31.9%), IPI (n = 10, 3.3%), NIVO/IPI (n = 3, 4.5%), AVE (n = 3, 1.0%), ATE (n = 3, 1.0%). Other patients served as controls.
All liver function tests and creatinine measures (N = 1,483,106) were retrieved. Severity of liver injury and acute kidney injury (AKI) were graded according to the CTCAEv4 and KDIGO guidelines, respectively. Baseline measure was first measure under ICI treatment or first measure at institution for controls. Characteristics were compared with the use of T-test, chi-square test and binary logistic regressions.
Results: ICI patients were older (median [IQR] age: 65 [55–73] versus 51 [34–67]) and preferentially of male sex (56.6% versus 41.3%). Adjusted on age and sex, ICI treatment was associated with grade 3 and 4 GGT (n = 53, 17.9%; P < 0.001) and ALP (n = 7, 2.4%; P < 0.05) elevations and not with AST, ALT, and total bilirubin elevations. AKI concerned 11 (3.7%) ICI patients (P = 0.001) (see figure). Adjusted risk (95% CI) of AKI under ICI treatment was 2.5 (1.4–4.6). Any grade of ALP elevation was associated with NIVO (P < 0.001) and PEMBRO (P < 0.001); any grade of GGT elevation was associated with IPI (P = 0.007), NIVO (P < 0.001), and PEMBRO (P < 0.001); any grade of total bilirubin elevation was associated with IPI (P = 0.020); there was a trend for ALT elevation with PEMBRO and IPI (P = 0.056); AKI was electively associated with NIVO (P < 0.001). In multivariate analysis, IPI (P < 0.001), NIVO (P < 0.001), and PEMBRO (P < 0.05) were associated with

GGT increase and IPI ($P < 0.05$) with ALP increase. The adjusted risk (95% CI) of AKI under NIVO was 3.1 (1.5–6.2).



Note: ICI: immune checkpoint inhibitor; ALT: alanine aminotransferase; AST: aspartate aminotransferase; GGT: gamma-glutamyl transferase; ALP: alkaline phosphatase; BILT: total bilirubin; AKI: acute kidney injury; w/:with; w/o: without; **P<0.01 and *** P<0.001

Conclusion: ICI treatments are associated with cholestatic liver disease and renal impairment. Adjusted on age and sex, NIVO is associated with AKI. Studies are needed to explore the clinical implications of these findings, including in cirrhotic and HCC patients who are at risk for AKI.

FRI-513
Impact of early corticosteroid treatment in patients with indeterminate acute severe hepatitis

E. Mohr[1], R. Sucher[2], T. Müller[3], T. Kaiser[4], D.M.Z. Büschenfelde[5], B. Thomas[1]. *[1]University Clinic Leipzig, Gastroenterology, Division of Hepatology, Leipzig, Germany; [2]University Clinic Leipzig, Department of Visceral- Transplant, Thoracic and Vascular Surgery, Leipzig, Germany; [3]Charite Berlin, Gastroenterology, Division of Hepatology; [4]University Clinic Leipzig, Department of Laboratory Diagnostics, Leipzig, Germany; [5]Charite Berlin, Department of Laboratory Diagnostics*
Email: elisabeth.mohr@medizin.uni-leipzig.de

Background and Aims: Discrimination of acute severe autoimmune hepatitis AS-AIH and drug induced liver injury (DILI) in patients with indeterminate acute severe hepatitis (ASH) is challenging due to insufficient clinical diagnostics for both diseases. Early corticosteroid therapy, which is not widely applied in clinical routine, may prevent the progression to acute liver failure and the need for liver transplantation. We aimed to investigate the clinical outcomes of patients with AS-AIH and DILI with particular focus on the role of corticosteroids.
Method: A retrospective analysis of data (years: 2013–2016) identified 1039 patients presenting with ASH (defined by ALT > 5 × ULN) in two German liver centers.
Results: Out of the 179 patients identified with early corticosteroid treatment 67 patients were diagnosed with AS-AIH, 52 with DILI, and 56 with other diseases, e.g. steatohepatitis, alcoholic hepatitis etc. Only 34% of the patients with AIH displayed a positive AIH score, whereas 66% showed an indeterminate (34%) or negative (32%) score. Histology confirmed AIH in only 14% of cases, whereas 86% of the liver biopsies showed findings being either only compatible (46%) or atypical (40%) for AIH. Interestingly, patients with DILI had a significant higher MELD score when compared to patients with AIH (MELD 21 range 6–40 vs. MELD 15 range 6–26 $p < 0.01$). In parallel, initial ALT values in patients with DILI (mean 1846 U/L range 356–12330 U/L) were significantly higher when compared to AIH patients (mean 1208 U/L range 304–4095 U/L $p = 0.01$) and decreased significantly faster upon corticosteroid treatment ($p < 0.01$). Hence, DILI patients required a significant shorter course of steroid therapy (mean 87 days range 3–300 vs. mean 366 days range 60–1080 ($p < 0.0001$). Moreover, steroid tapering in AIH was commonly associated with an ALT flare requiring an intensified immunosuppressive regimen, which was not detected in patients with DILI (0% ALT flares, $p < 0.001$). 1-year patient survival was 97% for AIH and 95% for DILI. In the whole cohort infection rates remained low (mild infection: 7%; severe infection: 6%). Seven patients (6%) with DILI required liver transplantation. Within the DILI cohort, they displayed significant higher MELD scores and Quick levels at time-point of admission (MELD: 30, range 23–40; Quick: 29 range 12–47, $p < 0.05$) as indicators for a severe stadium of disease. One-year transplant survival was 85%.
Conclusion: Early corticosteroid therapy is warranted in patients with acute severe hepatitis suspicious for AS-AIH or DILI and results in good response and survival rates avoiding liver transplantation.

FRI-514
Evaluation of the hepatoprotective effects of polygonum multiflorum thunb in acetaminophen induced liver injury

A. Chagnaadorj. *Mongolian National University, Department of Medicine, Ulaanbaatar, Mongolia*
Email: ch.amarzaya@mnu.edu.mn

Background and Aims: Acetaminophen (APAP-Paracetamol) is a safe and effective analgesic at therapeutic dosage, however, overdose of APAP is the principle cause of acute liver failure. Formation of toxic metabolite NAPQI is considered to be the trigger of liver injury via the rapid depletion of intracellular glutathione (GSH) and the generation of excess reactive oxygen species (ROS) that damage hepatocytes. PME is an ethanol extract derived from polygonum multiforum thunb, a traditional herbal medicine, reportedly has strong anti-oxidant, anti-inflammatory and anti-tumor properties.
Nrf2 transcription factor is a key transcription factor that regulates anti-oxidant defense mechanisms and phase II anti-oxidant defense genes. In this study, the hepatoprotective effect of the PME was evaluated using APAP induced acute liver injury model.
Aim: Our study aiming to evaluate the hepatoprotective effects of Polygonum Multiflorum Thunb in Acetaminophen induced acute liver injury.
Method: *In vivo* and *in vitro* studies were intended for prevention. We established 4 weeks old male ICR mice to induce liver injury by single dose of APAP (400mg/kg) injection. Mice were treated with PME for 3 consequtive days at daily dose of 120 mg/kg by oral gavage before APAP injection. The serum transaminases were measured and histological examinations were performed. In vitro study we used HepG2 (Human hepatocellular carcinoma) cell line and primary isolated hepatocytes. Cell viability and cell toxicity were determined by MTS and LDH assay. The number of ROS (+), ROS (-) cells were measured by flow cytometry. Nrf2 transcription factor activation was identified by immune-histochemical analysis, western blotting and mRNA expression levels of antioxidant genes such as HO-1, NQO1, GCLc, GCLm were analyzed by q-PCR in both *in vivo* and *in vitro* study.

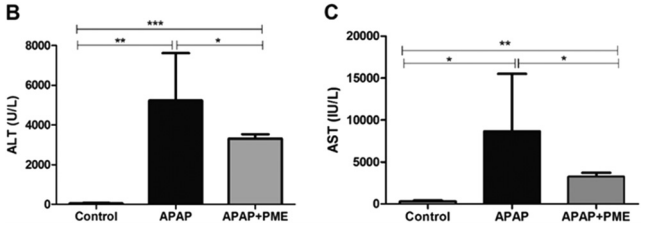


Figure 1: Pretreatment with PME protects mice from APAP induced liver injury Serum ALT (b), AST (c).

Results: PME showed no cytotoxicity and reduced APAP mediated HepG2 cell death. APAP treated cells exhibited a remarkable increase of ROS (+) cells while ROS production was diminished in PME pre-incubated cells.Treatment with PME induced Nrf2 transcription factor

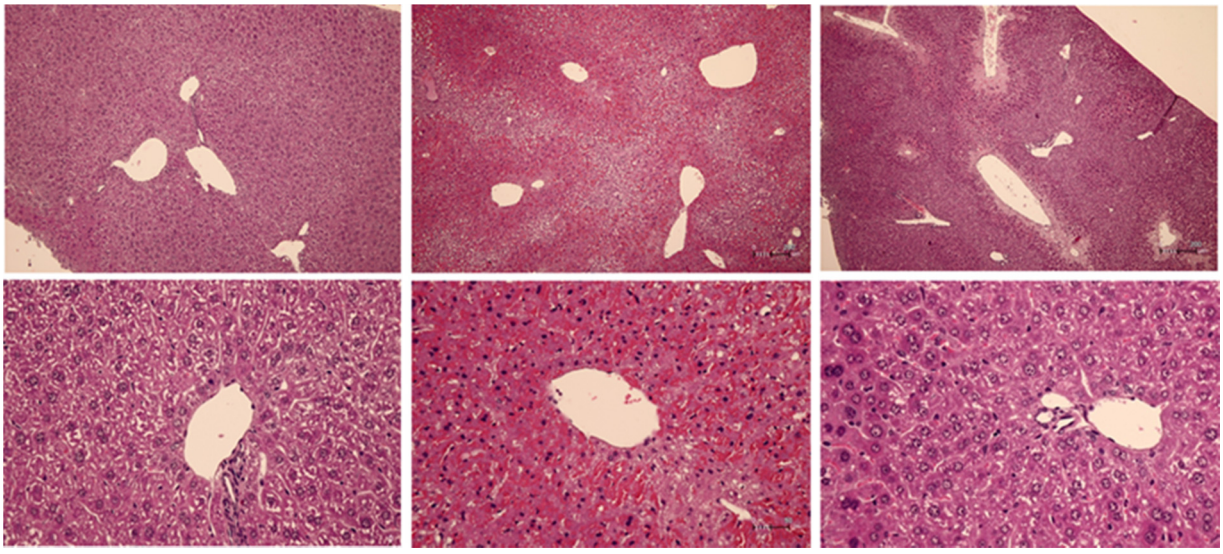

Figure 2: (abstract: FRI-514) Representative histological sections of the liver. Control (a) APAP (b) PME + APAP (c).

activation and up-regulated down-stream anti-oxidant response element genes expressions. Pre-treatment with PME induced Nrf2 nuclear translocation and protect the toxicity of overdosed-APAP induced animal death, elevation of the serum transaminases and hepatocytes damages.

Conclusion: The study had shown that the PME, ethanol extract of Polygonum Multiforum Thunb has a protective effect against APAP induced liver injury by activating Nrf2 transcription factor and it's phase II downstream antioxidant response genes. PME may be useful for prevention of oxidative stress induced acute liver injury.

FRI-515

Prophylactic use of entecavir for lymphoma patients with past HBV infection: A randomized controlled trial

W.P. Liu[1], X.B. Xiao[2], M. Xue[3], G.Q. Wang[4], X.P. Wang[5], Y.Q. Song[5], J. Zhu[5]. *[1]Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing, China; [2]Affiliated Hospital, Academy of Military Medical Sciences, Affiliated Hospital, Academy of Military Medical Sciences, China; [3]Air Force General Hospital, Air Force General Hospital, China; [4]Peking University First Hospital, Peking University First Hospital, China; [5]Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), China*

Email: dreaming2217@126.com

Background and Aims: Hepatitis B virus (HBV) reactivation may occur in lymphoma patients with past HBV infection (HBsAg-negative/anti-HBc-positive/HBV DNA-negative) as a result of treatment with chemotherapy or rituximab-containing immunotherapy. However, the cost effectiveness of antiviral prophylaxis in preventing hepatitis B virus (HBV) reactivation in lymphoma patients with past HBV infection is unclear.

Method: Lymphoma patients with past HBV infection were randomly assigned to chemotherapy alone (control) or prophylactic entecavir (ETV) before chemotherapy and up to 6 months after completion of chemotherapy. All patients underwent close virologic and biochemical surveillance. HBV DNA and alanine aminotransferase (ALT) levels were tested at baseline, before each cycle of chemotherapy, and every 3 months until 18 months after the last cycle of chemotherapy. Therapeutic ETV was used to treat patients with HBV reactivation in the control group. The primary endpoint was the incidence of HBV reactivation (appearance of HBV DNA) and HBV reactivation-related hepatitis (defined as a greater than 3-fold increase in serum ALT levels exceeding 100 IU/L).

Results: A total of 190 patients were included, 141 (74.2%) of whom were positive for anti-HBs. Rituximab-containing treatment was administered in 142 (74.7%) patients. The incidence of HBV reactivation and HBV reactivation related hepatitis were 0 (0/95) and 0 (0/95) in the prophylactic ETV group, 3.2% (3/95) and 1.1% (1/95) in the control group, respectively, but the difference had not statistical significance (*P* value were 0.246 and 1.000, respectively). Among the three patients with HBV reactivation, two were negative for anti-HBs, and one was positive. HBV reactivation-related hepatitis flare occurred in one patient who exhibited elevated ALT levels (1217 IU/L) after seven cycles of chemotherapy, resulting in premature termination of chemotherapy. Two patients experienced HBV reactivation without hepatitis flare after two cycles of chemotherapy and cessation of chemotherapy, respectively. Serum HBsAg became positive in two of the three patients with HBV reactivation. All patients with HBV reactivation recovered after therapeutic ETV treatment. No HBV-related deaths were observed during the follow-up period. Cost-effectiveness analysis showed that the cost in the prophylactic ETV group was higher than that of the control group by $160 per month. No significant difference in effectiveness was observed between the treatment groups over the follow-up period.

Conclusion: Prophylactic antiviral therapy is not a cost-effective strategy for management of lymphoma patients with past HBV infection (NCT01765231).

FRI-516

Inhibition of pyruvate dehydrogenase complex and lactate dehydrogenase for therapy of acute liver failure

R. Ferriero[1], E. Nusco[1], R.D. Cegli[1], A. Carissimo[1], G. Manco[2], N. Brunetti-Pierri[1,3]. *[1]Telethon Institute of Genetics and Medicine, Pozzuoli; [2]National Research Council, Institute of Protein Biochemistry, Naples; [3]Department of Translational Medicine, Federico II University of Naples*

Email: ferriero@tigem.it

Background and Aims: Acute liver failure is a rapidly progressive deterioration of hepatic function resulting in high mortality and morbidity. Metabolic enzymes can translocate in the nucleus to regulate histone acetylation and gene expression.

Method: Levels and activities of pyruvate dehydrogenase complex (PDHC) and lactate dehydrogenase (LDH) were evaluated in nuclear fractions of livers of mice exposed to various hepatotoxins including

CD95-Ab, acetaminophen, and α-amanitin. Whole-genome gene expression profiling by RNA-seq was performed in livers of mice with acute liver failure and analyzed by Gene Ontology Enrichment Analysis (GOEA). Efficacy of the histone acetyltransferaseinhibitor garcinoland LDH inhibitor galloflavin at improving survival and reducing liver damage was evaluated in mice injected with CD95-Ab.
Results: Levels and activities of PDHCand LDH were increased in nuclear fractions of livers of mice with acute liver failure. The increase of nuclear PDHC and LDH was associated with increased concentrations of acetyl-coA and lactate in nuclear fractions, and histone H3 hyper-acetylation. Gene expression in mouse livers with acute liver failure suggested that increased histone H3 acetylation induces the expression of genes related to response to damage. Reduced histone acetylation by the histone acetyltransferase inhibitor garcinol decreased liver damage and improved survival in mice with acute liver failure. Knock-down of PDHC or LDH improved viability in cells exposed to a pro-apoptotic stimulus. Treatment with the LDH inhibitor galloflavin that was also found to inhibit PDHC reduced hepatic necrosis, apoptosis, and expression of pro-inflammatory cytokines in mice with acute liver failure. Mice treated with galloflavin showed a dose-response increase in survival.
Conclusion: PDHC and LDH translocate to the nucleus and are targets for therapy of acute liver failure.

FRI-517
Pyrrolizidine alkaloid-induced hepatic sinusoidal obstructive syndrome: clinical characteristics, imaging signs and pathological findings

Y. Song[1], F. Liu[2], X. Rong[2], H. Guo[2], D. Xu[2]. *[1]Tongji Medical College, HUST, Union Hospital, Wuhan, China; [2]Tongji Medical College, HUST, Union Hospital, China*
Email: yuhusong@163.com

Background and Aims: One major etiology of hepatic sinusoidal obstruction syndrome (HSOS) in China is the intake of pyrrolizidine alkaloids (PA)-containing products. Since PAs-induced HSOS is a rare disease that has not been clearly characterized until now. This study investigated clinical characteristics, CT features, and pathological findings of PA-induced HSOS.
Method: This retrospective cohort study included 116 patients with PAs-induced HSOS from January 2006 to June 2016. We collected medical records of the patients, and reviewed image features of CT, and analyzed pathological findings.
Results: Common clinical manifestations of PAs-induced HSOS were abdominal distention (98.26%), ascites (100%), jaundice (53.27%), abdominal pain (36.36%). Abnormal liver function was observed in most of PAs-induced HSOS. On CT scan, common findings of PAs-induced HSOS included: ascites, hepatomegaly, gallbladder wall thickening, pleural effusion, patchy liver enhancement, and heterogeneous hypoattenuation. Most of the PAs-induced HSOS patients had low ascitic AFTP (<25 g/L) and high SAAG (≥11.0 g/L). In acute stage, pathologic features were massive sinusoidal dilatation, sinusoidal congestion, the extravasation of erythrocytes, hepatocellular necrosis, the accumulation of macrophages, the deposition of hemosiderin. In chronic stage, complete loss of pericentral hepatocytes, sinusoidal dilatation, the deposition of pigment granules were observed.
Conclusion: The PAs-induced HSOS patients displayed distinct clinical characteristics, imaging features, and pathological findings, which made a further understanding and provided evidence for the diagnosis of PA-induced HSOS.

FRI-518
Low serum hepcidin and high transferrin saturation are associated with a poor short-term survival in adults with acute liver failure

I. Spivak[1], J. Arora[2], C. Ellerbe[2], V. Durkalski-Mauldin[2], W.M. Lee[3], R. Fontana[4], P. Strnad[1]. *[1]University Hospital Aachen, Medical Clinic III, Aachen, Germany; [2]Medical University of South Carolina, Department of Public Health Sciences, Charleston, SC, United States; [3]University of Texas, UT Southwestern Medical Center at Dallas, Dallas, TX, United States; [4]University of Michigan, Ann Arbor, MI, United States*
Email: ispivak@ukaachen.de

Background and Aims: The liver is a key player in iron homeostasis through synthesis of the serum transporter transferrin and the iron hormone hepcidin. In a single-center analysis high ferritin and low transferrin levels associated with worse outcome in patients with acute liver failure (ALF). We explored associations of parameters of

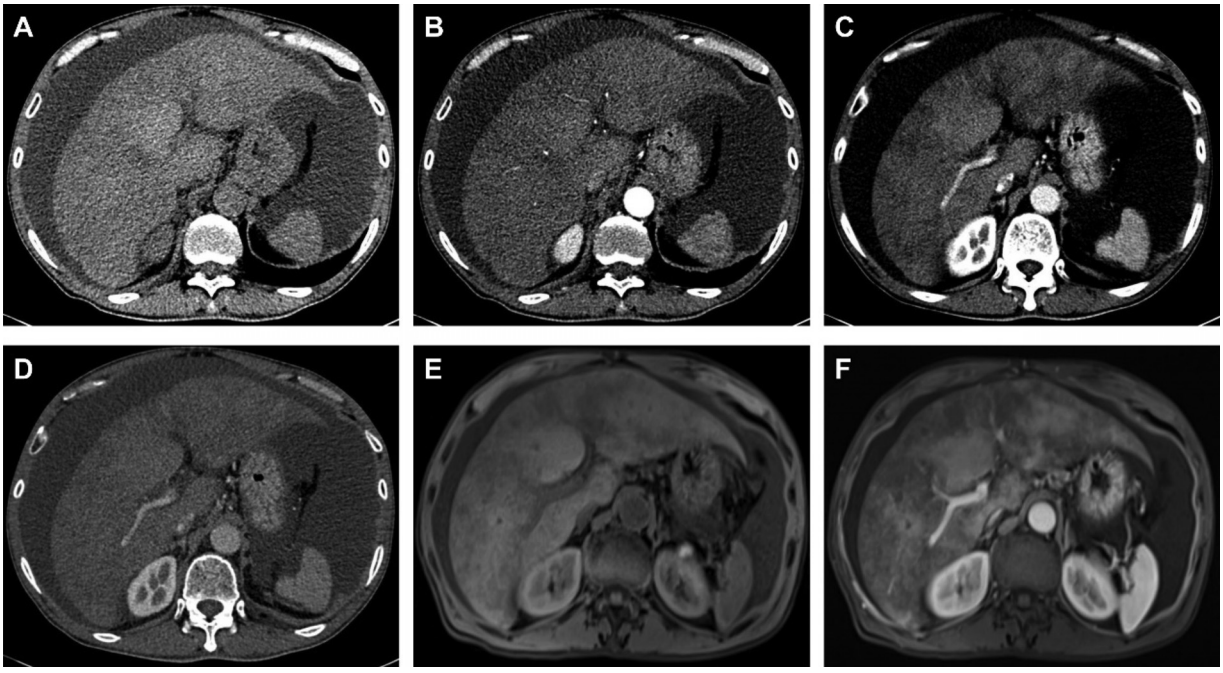

Figure 1: (abstract: FRI-517): 67-year-old man diagnosed with gynura segetum-induced HSOS received contrast-enhanced CT and MRI scan. (A–D) images of plain and contrast-enhanced CT scan; (A) plain CT scan; (B) arterial phase; (C) porta-venous phase; (D) equilibrium phases. (E–F) images of pre-contrast and portal-venous phase on dynamic contrast-enhanced MRI scan; (E) pre-contrast MRI scan; (F) portal-venous phase of MRI scan.

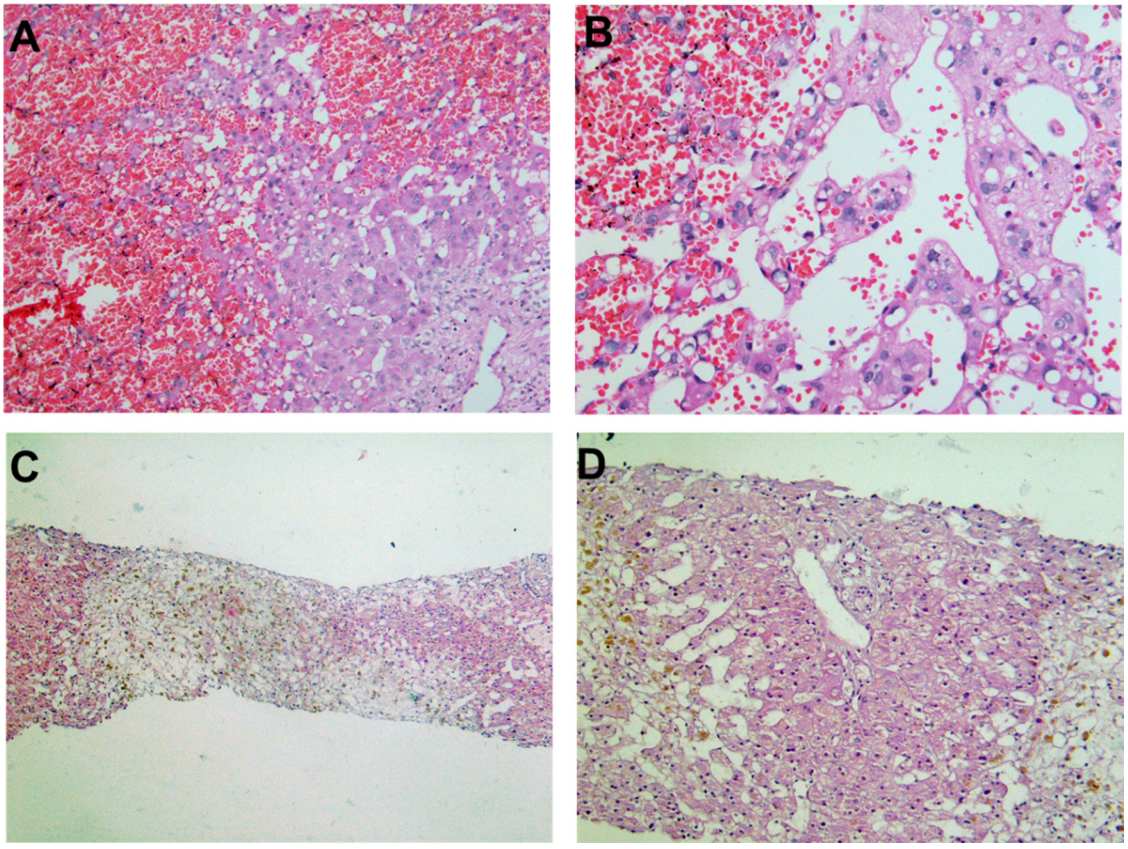

Figure 2: (abstract: FRI-517): Patients histology; (A–B): Early pathological changes of PAs-induced HSOS; (A) significant congestion around the central vein of the hepatic lobule (H&E ×200); (B) higher magnification of peri-central region which demonstrated sinusoidal congestion, sinusoidal dilatation, extravasation of erythrocytes into space of Disse and congestive necrosis of some hepatocyte (H&E ×400); (27) Histology of PAs-induced HSOS in subacute or chronic stage. (C) low power image of PAs-induced HSOS of longer duration showing complete loss of pericentral hepatocytes and sinusoidal dilatation (H&E ×100); (D) Medium power image showing the deposition of pigment granules. (H&E ×200).

iron metabolism with the etiology and outcome of adults with ALF in a multicenter retrospective study setup. We also analyzed an acetaminophen (APAP)-induced ALF mouse model.

Method: A representative subset of 121 adults with ALF enrolled in the US ALFSG had a day 1 or 2 serum sample tested for serum ferritin, transferrin, iron, and hepcidin. In mice, these parameters were measured prior to (controls) and 18 hours after injection of 500 mg/kg APAP. Outcomes at 3 weeks after enrollment were categorized as spontaneous survivor (SS) vs. death/transplantation. Univariate models of predicted survival were compared to the current ALF prognosis model.

Results: 66 patients with APAP-related and 55 patients with non-APAP-related ALF were assessed, who had a 3-week SS rate of 57.6% and 38.2%, respectively. ALF patients often displayed altered iron parameters (medians: iron 33.3 µmol/l; transferrin 186 mg/dl; transferrin saturation (TSAT) 71.8%; ferritin 2866.8 ng/ml; hepcidin 5.7 ng/ml). APAP-induced ALF presented with significantly higher ferritin, transferrin and hepcidin values than non-APAP cases ($p < 0.05$ for all). SS had lower iron levels (29.1 vs. 34.5 µmol/l; $p < 0.05$) and TSAT (60.9 vs. 79.1%; $p < 0.001$), but higher hepcidin levels (8.2 vs. 2.7 ng/ml; $p < 0.001$) and hepcidin/ferritin ratio (0.0047 vs. 0.0009; $p < 0.001$). The univariate model of log transformed hepcidin and square-root transformed hepcidin/ferritin ratio had a C-statistic of 0.727 and 0.699 respectively, whereas the current ALF prognosis model had a C-statistic of 0.852. Compared to controls, APAP-treated mice displayed lower serum hepcidin (24.3 vs. 37.8 ng/ml), a negative correlation between hepcidin and ALT ($r = –0.79$) and lower hepcidin/ferritin ratio (0.0018 vs. 0.05; $p < 0.0001$).

Conclusion: Our findings demonstrate that several serum iron parameters significantly associate with 3-week SS in ALF adults. In mice, hepcidin levels inversely correlate with the surrogate of liver injury. Preliminary results indicate that hepcidin (and hepcidin-ferritin ratio) is a promising univariate predictor of survival and may demonstrate increased prediction in the multivariate model.

FRI-519

43 candidate SNPs were not found to be associated with drug induced liver injury

L. Pang[1], W. Yang[2], K. Tan[2], F. Hou[3,4]. *[1]Peking University First Hospital, Beijing, China; [2]Department of Infectious Diseases, Beijing, China; [3]Peking University First Hospital, Department of Infectious Diseases, Beijing, China; [4]Peking University International Hospital, Department of Infectious Diseases, Beijing, China*
Email: houfqys@139.com

Background and Aims: Drug induced liver injury (DILI) is suspected to have a heritable component. With genome-wide association study and candidate gene approaches, some genetic variants were reported to have associations with DILI but few of them can be repeated or validated. The aim of this study is to investigate the asso ciation between some gene polymorphisms and DILI.

Method: 43 candidate SNPs were sequenced by Sequenom MassARRAY SNP in 144 Chinese DILI patients admitted to the Peking University First Hospital and 221 healthy controls.

Results: Three SNPs ever reported to be associated with DILI were not be validated in our study. Allele frequencies of T for rs2741045 in UGT1A9, T for rs2287622 in ABCB11 and C for rs3740065 in ABCC2 among patients and controls were 0.025 vs 0.035, 0.269 vs 0.264 and

0.367 vs 0.392 respectively (both P > 0.05). The frequencies of the T allele for rs1801133 in MTHFR and A allele for rs5747933 in PRODH were lower in patients than controls (0.538 vs 0.622, P = 0.027 and 0.120 vs 0.188, P = 0.012). The allele frequencies of other 38 SNPs in 31 genes (IL-10, CYP2C9, SLCO1B1, NEU2, NAT2, FAM65B etc.) were same in two groups.
Conclusion: We did not find any significant associations between UGT1A9, ABCB11, ABCC2 and DILI which were ever reported. The associations between MTHFR, PRODH and DILI need further studies to validate.

FRI-520
CC10 protein attenuates hepatic injury in MHV-3 induced fulminant hepatitis by inhibiting fgl2 expression on macrophages
H. Yu, H. Wang, X. Wan, J. Huang, W. Yan, D. Xi, X. Wang, Q. Ning. *Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Infectious Disease*
Email: qning@vip.sina.com

Background and Aims: Fulminant hepatitis (FH) is a serious life-threatening disease with massive necroinflammation during a short time. Macrophages are the major immune cells population for innate immune response which are considered to be central for FH initiation and progression. Fibrinogen-like protein 2 (FGL2) is a procoagulant protein that is induced substantially on macrophage upon viral infection and amplified inflammatory cascade and hepatocytes necrosis and FGL2 depletion resisted murine hepatitis virus strain 3 (MHV-3) infection. Clara cell 10KDa (CC10) protein is a secretory protein with anti-inflammatory property in the upper airway disease, however, the mechanism and pathogenic role in other disease settings are still unclear. In this study, we sought to determine the role of CC10 on FH and the regulation of CC10 on FGL2.
Method: FH was established by peritoneal injection MHV-3. The mice were received CC10 protein with tail vein injection prior to viral infection. Liver histology, fibrin deposition, necrosis and survival rate was measured. The regulatory effects of CC10 on the expression of the FGL2 gene were investigated in vitro by THP-1 cells and mouse peritoneal macrophages. DNA microarray was applied to validate the altered expression of selected genes at mRNA level.
Results: In the FH model induced by MHV-3, the survival rate increased from 0 to 12.5% in CC10 group compared with saline group. Meanwhile, the levels of ALT and AST in serum were significantly decreased and the liver damage was improved. Further more, the hepatic FGL2, TNF-α and IL-1β expression was significantly decreased combined with reduction of hepatic fibrin deposition and hepatocyte apoptosis after administration of CC10 protein. In vitro, we found that CC10 significantly inhibit the expression of FGL2 in IFN-γ treated THP-1 cells and MHV-3 infected mouse peritoneal macrophages. However, there is no direct interaction between CC10 and FGL2 as manifested by co-immunoprecipitation. Further microarray suggested that HMG-box transcription factor 1(HBP1), was significantly lower in CC10 treated THP-1 cells than that in IFN-γ primed THP-1 cells. HBP1-SiRNA treatment abrogated the inhibitory effect of CC10 on FGL2 expression in HUVEC cells.
Conclusion: CC10 protects against MHV-3 induced FH via suppression of FGL2 expression on the macrophages. Such effect may be mediated by a transcript factor HBP1.

FRI-521
Role and regulation of mitophagy by ROS in hepatic stellate cells during acute liver failure
Z. Tian, Y. He, T. Chen, Y. Zhao. *Institute of hepatology, Department of Infectious Disease, Xi'an, China*
Email: tianzen1984@163.com

Background and Aims: We previously found that acute liver failure (ALF) is accompanied by hepatic stellate cells (HSCs) activation. HSCs also integrate cytokine-mediated inflammation responses in the sinusoids and relay them to the liver parenchyma in immune-mediated hepatitis. Oxidative stress has been shown to promote

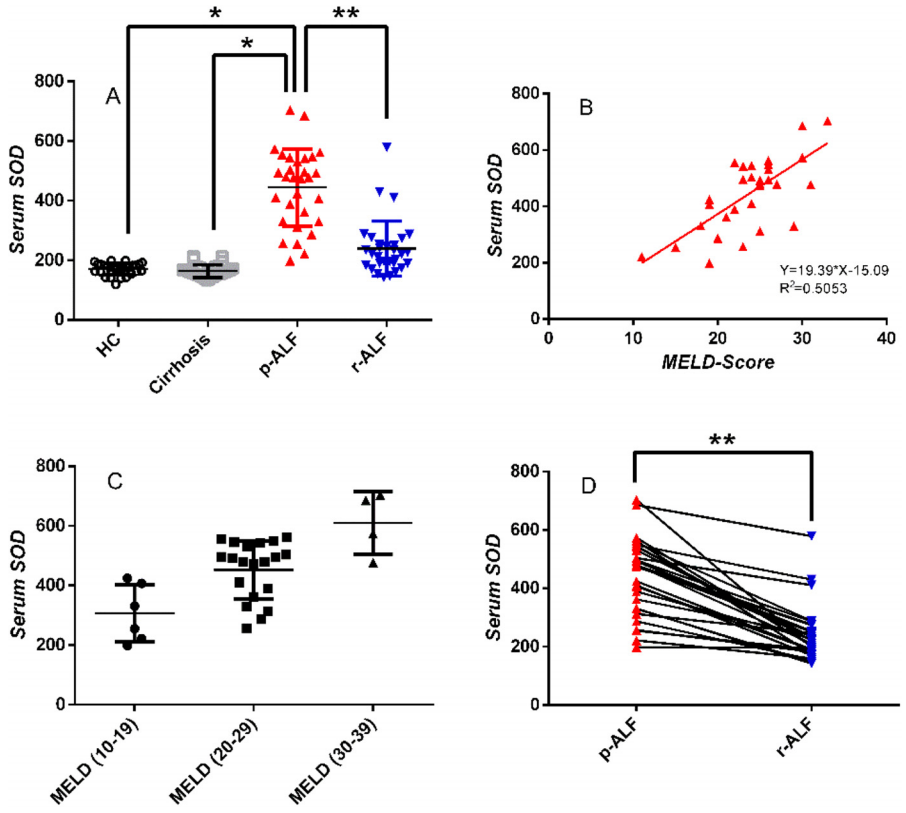

Figure 1: (abstract: FRI-521): Increased SOD level was associated with poor prognosis of ALF.

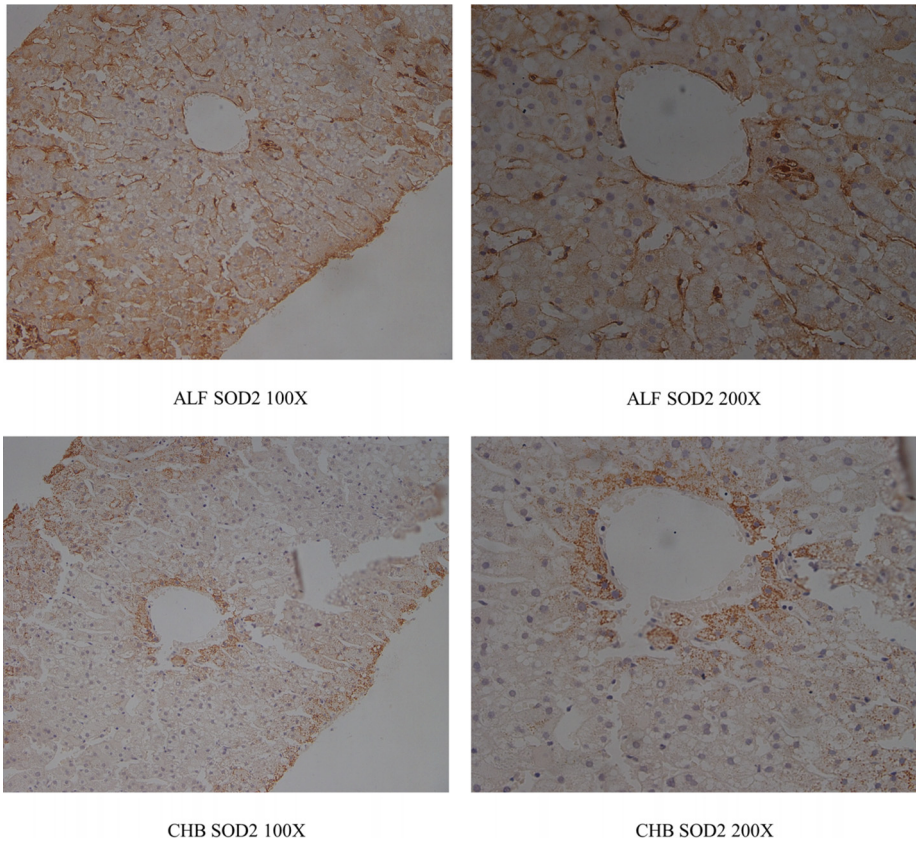

Figure 2: (abstract: FRI-521): Immunohistochemical SOD2 staining were conducted in liver tissues from patients with chronic cirrhosis (A, B) and ALF (C, D) to show SOD2 expression. Original magnification x100 or 200.

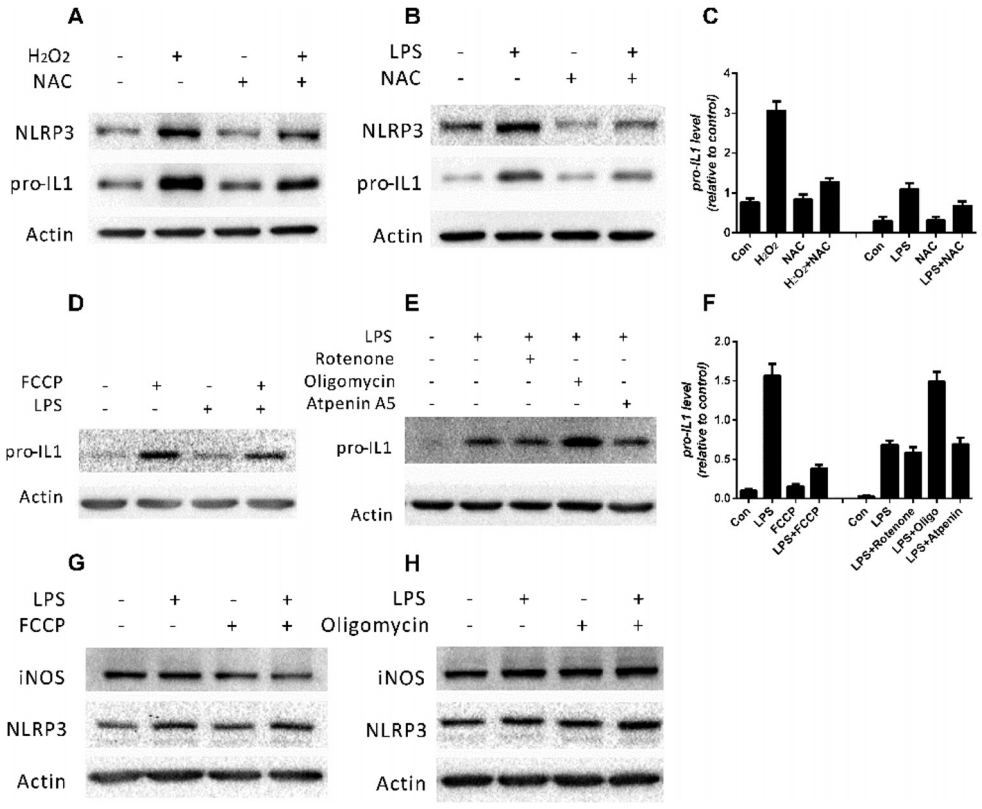

Figure 3: (abstract: FRI-521): Mitophagy rescues ROS induced inflammation in HSCs.

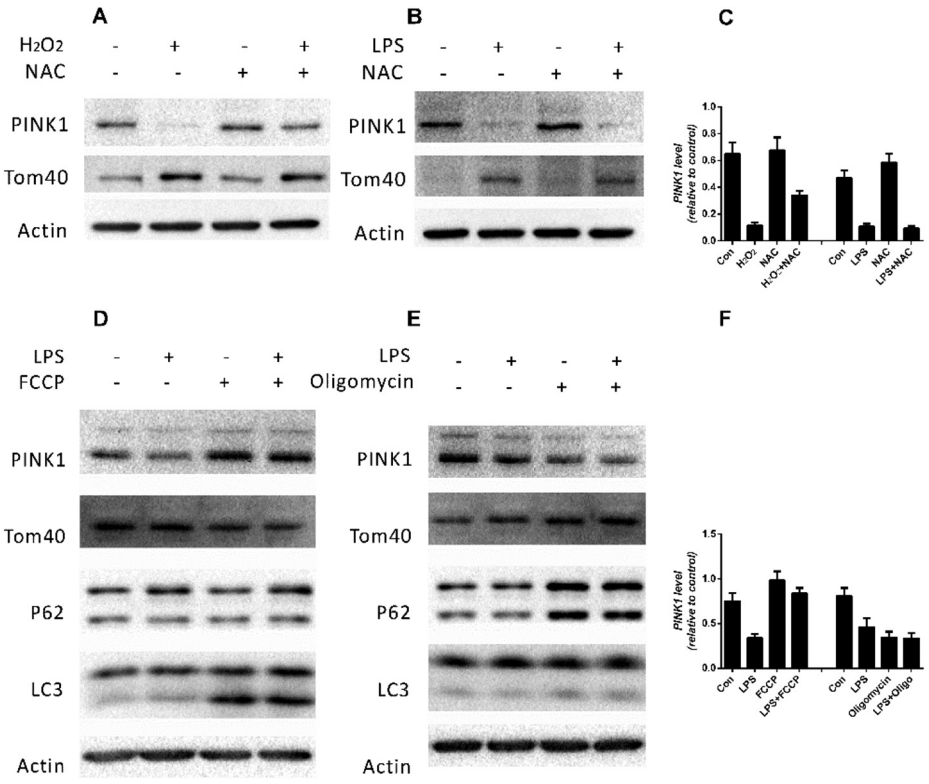

Figure 4: (abstract: FRI-521): ROS inhibits mitophagy in HSCs.

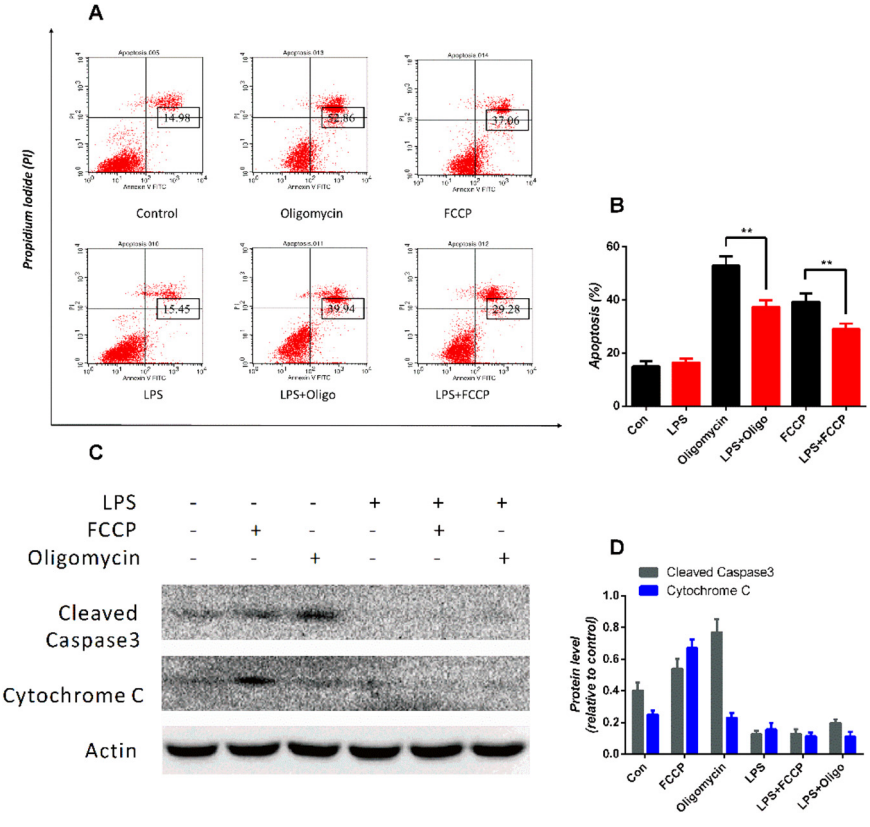

Figure 5: (abstract: FRI-521): Mitophagy but not apoptosis regulates inflammation in HSCs.

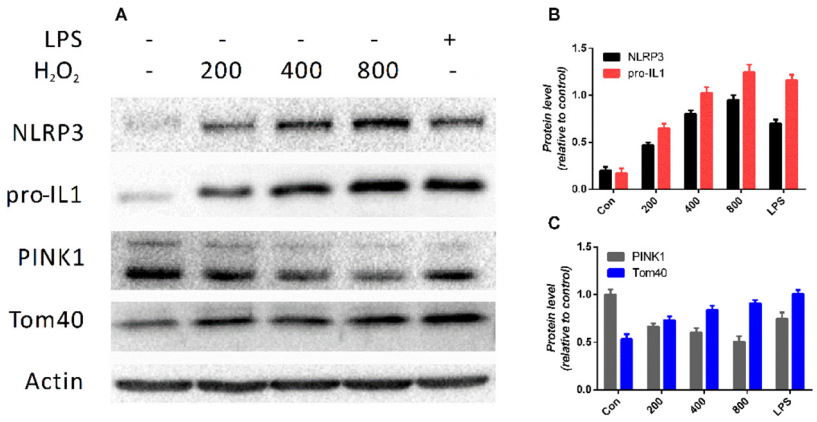

Supplementary Figure 1: (abstract: FRI-521): H_2O_2 promotes inflammation and inhibits mitophagy in a dose dependent manner.

inflammation. Whether and how oxidative stress is involved in ALF and HSCs inflammation remains unclear.

Method: ALF patients were recruited to investigate the correlation between plasma superoxide dismutase (SOD) levels and clinical features. Liver tissues were collected from chronic hepatitis patients by biopsy and from ALF patients who had undergone liver transplantation. The expression of SOD2, hepatic stellate cell activation (α-SMA) and mitophagy activity (Tom40) were investigated by immunohistochemistry. Inflammation, mitophagy and apoptosis were investigated by immunoblot analysis, confocal microscopy and flow cytometry in HSCs treated with LPS and reactive oxygen species (ROS) donors.

Results: Plasm SOD level was significantly increased in patients with ALF compared to those with cirrhosis (444.4 ± 23.58 U/mL vs 170.07 ± 3.52 U/mL, P < 0.01) and positively correlated with MELD-score (r = 0.5053, P < 0.01). In vivo observation revealed that mitophagy was inhibited in HSCs based on increased Tom40 immunostaining, and in vitro experiments demonstrated that ROS can promote inflammation via inhibition of mitophagy. Moreover, regulation of inflammation in HSCs was apoptosis independent.

Conclusion: Increased oxidative stress induced by LPS participants in promoting inflammation through mitophagy inhibition in HSCs during the process of ALF, providing a novel strategy for the treatment of patients with ALF.

FRI-522

DRESS cases included in the Spanish and Latin-American DILI registries: clinical phenotype and outcome

Email: imcaliz@uma.es

Background and Aims: Severe cutaneous adverse reactions can manifest in a wide spectrum of heterogeneous clinical presentations, including drug reaction with eosinophilia and systemic symptoms (DRESS), a severe idiosyncratic drug reaction. DRESS is characterized by presence of rash, fever, eosinophilia and/or lymphopenia, and liver injury but there is no consensus for the definition of this condition. We aimed to evaluate clinical phenotype, outcome and causative agents associated with DRESS.

Method: Dress cases were defined according to the International Registry of Severe Cutaneous Adverse Reaction (RegiSCAR). Demographics, clinical presentation and outcome were compared between DILI cases without hypersensitivity features (non-DRESS DILI) and DRESS cases included in the Spanish (n = 35/920) and Latin-American (n = 25/269) DILI registries.

Results: Sixty patients with DRESS syndrome were identified compared to 620 non-DRESS DILI cases, with a slightly higher proportion of women in the latter group (53% vs 50%). Mean age at onset was similar in both groups, 53 vs 49 years. Duration of treatment and time to onset were shorter in the DRESS cases (40 vs 107 and 35 vs 95 days, respectively) although the differences were not statistically significant. All DRESS cases presented rash (three with severe toxicoderma), 19 (33%) lymphopenia and 46 (78%) eosinophilia. Jaundice was present in 73% of DRESS patients and 64% of non-DRESS DILI patients. Positive autoantibodies were detected in 24% of non-DRESS DILI vs 9% of DRESS patients (p = 0.021). Hospitalization was higher for DRESS cases (78% vs 51%, p = 0.001). Type of liver injury differed between the groups, with cholestatic-mixed damage predominating in DRESS (58%), and hepatocellular damage (67%) in non-DRESS DILI, (p = 0.001). Severity also differed, with 14% severe and no fatal cases in DRESS and 7% severe and 5% fatal cases in non-DRESS DILI (p = 0.046). The most frequent causative drugs in the DRESS group were amoxicillin-clavulanate (7 cases), carbamazepine (7), allopurinol (5) and lamotrigine (5).

Conclusion: Compared to non-DRESS DILI, DRESS cases presented a predominance of cholestatic-mixed pattern and greater severity without mortality. Amoxicillin-clavulanate stands out as a leading cause of DRESS syndrome in the Spanish DILI Registry, while antiepileptic predominates in Latin-America, similar to previously published studies.

FRI-523

Independent cohort validation of hepatic metabolism, daily dose and comorbidities as features associated with delayed symptom onset in drug-induced liver injury

A. González-Jiménez[1], I. Medina-Caliz[1], M. Robles-Díaz[1], F. Bessone[2], N. Hernandez[3], A. Sánchez[3], M. Arrese[4], R.P. Filho[5], M. Lizarzábal[6], M. Tagle[7], M.I. Lucena[1], C. Stephens[1], R.J. Andrade[1]. [1]*UGC Aparato Digestivo y Servicio de Farmacología Clínica, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Universitario Virgen de la Victoria, Universidad de Málaga, CIBERehd, Málaga, Spain;* [2]*H Provincial del Centenario, Rosario, Argentina;* [3]*H de Clínicas, Montevideo, Uruguay;* [4]*Pontificia Universidad Católica de Chile, Santiago, Chile;* [5]*H U Prof Edgard Santos, Universidad Federal da Bahía, Salvador de Bahía, Brazil;* [6]*H U de Maracaibo, Maracaibo, Venezuela;* [7]*Clinica Anglo Americana, Lima, Peru*
Email: cstephens@uma.es

Background and Aims: Most patients with drug-induced liver injury (DILI) manifest liver injury while on drug treatments, however some patients do not manifest hepatotoxicity until after treatment completion (delayed onset). The underlying mechanism of delayed onset is unknown, but believed to be influenced by both host factors and drug properties. In a previous study of 413 Spanish DILI patients we found low hepatic metabolism, high daily dose and absence of preexisting conditions to be associated with increased risk of delayed onset in DILI (Hepatology 2015;62(S1): 504A). The aim of the current study was validate these results in an independent cohort of Latin American DILI cases.

Method: External validation of previous findings was performed using information corresponding to 188 Latin American DILI cases induced by drugs associated with at least 3 cases in the Latin American DILI Network. The cases were classified as delayed onset (DO) or no delayed onset (NDO) according to the temporal relationship between the first DILI manifestation and time of treatment cessation.

Results: Of the 188 DILI cases, 32 (17%) manifested DILI with DO and 156 (83%) NDO DILI. The drugs associated with DO were amoxicillin-clavulanate, nitrofurantoin, azithromycin and ibuprofen. Similar to the previous study, the Latin American DO cases were associated with higher daily dose treatments (mean: 1717 vs 493 mg, p = 0.001) and hepatic metabolism <50% (75% vs 13%, p = 0.0174). Drugs in BDDCS class 3 (low metabolism/high solubility) were overrepresented in DO cases (50% vs 9%, p = 0.0012). In addition, a higher proportion of NDO cases had preexisting conditions (68% vs 45%, p = 0.0484). In contrast to previous findings, eosinophilia and presence of positive autoantibody titres did not differ significantly between the two groups.

External validation of the logistic regression model previously identified with the Spanish DILI cases demonstrated that low hepatic metabolism (OR: 85.86, p = 0.0001), daily dose ≥200 mg (OR: 3.84, p = 0.0333) and absence of preexisting conditions (OR: 2.86, p = 0.0484) also had good predictive capacity of DO in the Latin American DILI cohort.

Conclusion: The current validation study confirmed results previous identified in a Spanish DILI cohort. Hence, healthier DILI patients with regards to comorbidities, taking higher daily doses of medications with low hepatic metabolism are at higher risk of manifesting DO.

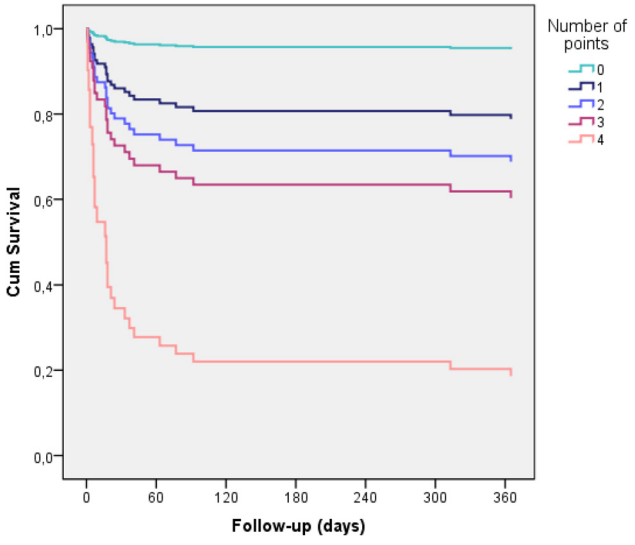
Prediction of early mortality despite liver transplantation in acute liver failure

M. Cardoso[1], R. Costa[2], E. Tsochatzis[1], D. Patch[1], J. Ryan[3], R. Westbrook[4]. [1]*Royal Free Hospital NHS Foundation Trust, Sheila Sherlock Liver Centre, London, United Kingdom;* [2]*Hospital of Braga, Gastrenterology Department, Braga, Portugal;* [3]*Royal Free London NHS Trust, UCL Institute of Liver and Digestive Health, The Royal Free Sheila Sherlock Centre, United Kingdom;* [4]*Royal Free Hospital, London, United Kingdom*
Email: marianafcardoso@gmail.com

Background and Aims: In patients with acute liver failure (ALF) who meet poor prognostic criteria correctly identifying those with a poor outcome despite LT is challenging. Previous attempts at risk stratification consider ALF and subacute liver failure (SALF) as a single entity. It is increasingly recognised that hyperacute/ALF and SALF have different phenotypes and clinical courses. We investigate predictors of mortality despite LT, in ALF and SALF as two distinct cohorts.

Method: Retrospective review of a prospectively collated database of all LT for ALF at our unit since 1990 until the present. Data on the recipient (age, gender, aetiology of ALF/SALF, clinical and laboratorial variables prior to LT), graft/ surgery (size, steatosis, cold ischemic time) and donor (age, gender, status) were collected. Patients with ALF (jaundice to encephalopathy ≤ 28 days) and SALF were studied separately. In each group, variables associated with hospital mortality (p < 0.1) in univariate analysis were included in a multivariate logistic regression.

Results: 166 patients aged ≥ 16 years were transplanted for ALF/SALF (122/44). Patients with SALF were older (44.4 vs 37.1-years, p = 0.002) and more often males (47.7% vs 31.1%, p = 0.049). Hospital survival post LT did not differ between ALF/SALF (77.0% vs 75.0%, p = .783). In ALF, predictors of hospital mortality on multivariate analysis included age ≥ 55 years (p = 0.019), serum sodium (p = 0.026), history of organ support (p = 0.051) and cold ischemic time (p = 0.006). A prognostic score was created by assigning points according to odds ratio values (age ≥ 55: 2 points; sodium < 135 mmol/L: 1 point; organ support: 1 point), which were then added. Hospital survival according to the total number of points was: 100% (0 points), 81.9% (1 point), 69.2% (2 points), 60.0% (3 points) and 20.0% (4 points). A Cox proportional hazards regression limited at 1 year showed a significant correlation between the number of points and mortality (p < 0.001) (See Figure). In SALF, only female gender (p = 0.031) and encephalopathy grade ≥ 3 (p = 0.030) were associated with decreased hospital survival on multivariate logistic regression.



Conclusion: This data highlights that in patients undergoing LT for ALF mortality despite LT can be predicted pre-operatively based on a simple scoring system. The proposed score, if validated further, could potentially avoid use of a valuable organ in patients with extremely poor predicted 1-year survival.

FRI-525

Should age be an absolute contraindication to liver transplantation in acute liver failure?

M. Cardoso[1], R. Costa[2], E. Tsochatzis[1], D. Patch[1], J. Ryan[3], R. Westbrook[4]. [1]*Royal Free Hospital NHS Foundation Trust, Sheila Sherlock Liver Centre, London, United Kingdom;* [2]*Hospital of Braga, Gastroenterology Department, Braga, Portugal;* [3]*Royal Free London NHS Trust, UCL Institute of Liver and Digestive Health, The Royal Free Sheila Sherlock Centre, United Kingdom;* [4]*Royal Free Hospital, London, United Kingdom*
Email: marianafcardoso@gmail.com

Background and Aims: Liver Transplantation (LT) for acute liver failure (ALF) has a high early mortality when compared to elective LT and utilises a significant proportion of high quality organs. Candidate selection to define those with poor outcome without LT has been extensively evaluated; however in those that meet ALF listing criteria, identifying those with a poor outcome despite LT remains challenging with little data existing to support decision making. We explore how age impacts on outcome in ALF.

Method: Retrospective review of a prospectively collated database of all LT for ALF at our unit since 1990 until the present. Data on aetiology, age, ALF (jaundice to encephalopathy ≤ 28 days) vs subacute liver failure (SALF), hospital mortality, 1-year and 5-year survival was collated.

Results: 166 patients aged ≥ 16 years were transplanted for ALF/SALF (122/44). Mean age was 39.0 ± 13.4 years and 64.5% were female. Aetiology was paracetamol in 15.7%, other drugs in 18.1%, viral in 13.3%, AIH in 13.3%, other known causes in 9.0% and indeterminate in 30.7%. In hospital, 1-year and 5-year survival in 1990–2003 and 2004–2017 were 59.0%, 57.4%, 54.1% and 86.7%, 84.0%, 79.2%, respectively (p =< 0.001, p < 0.001, p = 0.005). Mean ages at transplant for the defined time periods were 37.3 ± 13.7 vs 40.0 ± 13.1 years. Overall 104 patients were <45 years (62.7%); 41 patients were 45–55 years (24.7%); 21 patients were ≥ 55 years (12.7%). Hospital survival decreased along these age groups (81.7% vs 73.2% vs 57.1%, p = 0.045), as did 1-year (78.6% vs 74.4% vs 44.4%, p = 0.010) and 5-year survival (72.4% vs 64.3% vs 20.0%, p = 0.005), with ≥ 55 years appearing to be a more relevant cut-off. When excluding those with SALF, age ≥ 55 years was indeed associated with significantly lower hospital (41.7% in ≥55 years vs 80.9% <55 years, p = 0.006), 1-year (36.4% vs 78.6%, p = 0.005) and 5-year (0.0% vs 72.8%, p = 0.002) survival. Conversely age ≥55-years had no significant impact on hospital (77.8% vs 74.3%, p = 1.000), 1-year (57.1% vs 72.7%, p = 0.410) and 5-year survival (40.0% vs 60.9%, p = 0.624) in the 44 patients with SALF.

Conclusion: Patients greater than 55-years undergoing LT for ALF have a poor outcome with 41% surviving to hospital discharge and 0% alive at 5-years. This data suggests that in patients >55-years with ALF who meet poor prognostic criteria, LT is a poor utilization of a valuable organ resource and should not be undertaken.

miR-21 contributes to the onset and progression of liver disease through the deregulation of small intestine permeability

A.A. Santos, M.B. Afonso, P.M. Rodrigues, R.E. Castro, C.M.P. Rodrigues.
Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal
Email: afasantos@ff.ulisboa.pt

Background and Aims: The gut-liver axis influences the onset and progression of a wide variety of liver diseases. High fat, choline-deficient (HFCD) diet and common bile duct ligation (BDL) are experimental models of liver disease associated with early increased intestinal permeability, disturbed bile acid homeostasis and gut microbiota (GM) dysbiosis. Previously, we have demonstrated that oncogenic miRNA-21 (miR-21) is upregulated in experimental non-alcoholic steatohepatitis and in mice liver following BDL, mediating inflammation and fibrosis. Here we aimed to investigate the impact of whole body genetic deletion or therapeutic modulation of miR-21 in small intestine permeability as well as in the GM, which may influence miR-21 effects in the liver.
Method: Three-week old C57BL/6 mice were fed a HFCD diet or a control diet for 14 weeks. Mice were injected with antagomiR Control (Anti-C; 16 mg /kg) or antagomir-21 (Anti-miR21; 16 mg/kg) in the beginning of the study, for 3 consecutive days, and repeated each 5 weeks until the end of the experiment. In addition, 3-month old C57BL/6 wild type (WT) and miR-21 whole body knockout (KO) mice were submitted to sham or BDL surgeries for 3 days. After mice sacrifice, liver tissue and small intestine were preserved and mRNA and protein expression were analysed by qRT-PCR and immunoblotting, respectively. Serum was also collected for biochemical analysis. GM composition was evaluated by sequencing the 16S rRNA gene V3 region of the bacterial DNA present in the small intestinal lumen.
Results: BDL miR-21 KO mice showed decreased circulating levels of *hepatic enzymes*, concomitant with decreased fibrogenic gene expression in the liver, in comparison with WT mice, suggesting that miR-21 contributes to BDL-induced liver injury and fibrosis. Occludin and claudin-1 mRNA levels were decreased in small intestine of WT mice after BDL, suggesting increased permeability. Moreover, zonula occludens (ZO-1) and occludin mRNA levels were also decreased in Anti-C HFCD-fed mice. Strikingly, both genetic deletion of miR-21 and Anti-miR-21 treatment reverted mRNA levels of tight junction proteins to control. TGF-β mRNA levels increased in the small intestine of BDL miR-21 KO mice or in Anti-miR-21 HFCD-fed mice, and associated with alterations in the GM. Moreover, the GM of the WT mice became dysbiotic, with decreased *Bacteroidetes* and increased *Proteobacteria* and *Firmicutes*. In miR-21 KO mice, the GM was not affected by BDL surgery.
Conclusion: Our results indicate that miR-21 deficiency and Anti-miR-21 treatment are associated with decreased small intestine permeability after BDL or following HFCD diet, concomitant with the maintenance of GM homeostasis, which suggests miR-21 involvement in the onset and progression of liver injury by impacting on liver and small intestine targets. (Supported by PTDC/BIM-MEC/089572014 and SFRH/BPD/114924/2016).

SAT-002

Depletion of Paneth cells is associated with decreased portal hypertension and angiogenesis after partial portal vein ligation in mice

M. Hassan[1], S. Moghadamrad[1], P. Kellmann[1], C. Trentesaux[2], M. Fraudeau[3], B. Romagnolo[3], A. De Gottardi[1]. *[1]University Hosptal Bern, Department of Biomedical Research, Hepatology, Bern, Switzerland; [2]Institut Cochin, INSERM, Department of Biomedical Research, Oncogenesis of digestive epithelia, Paris, France; [3]Institut Cochin, INSERM, Department of Biomedical Research, Oncogenesis of digestive epithelia, Paris, France*
Email: andrea.degottardi@gmail.com

Background and Aims: Paneth cells may contribute to the regulation of splanchnic hemodynamics in response to microbial stimuli from intestinal flora. However, the detailed mechanistic links have not been elucidated yet. We hypothesized that conditional deletion of intestinal Paneth cells might have regulatory effects on portal hypertension and angiogenesis after partial portal vein ligation (PPVL) in mice.
Method: Math-1 Lox/LoxVilcre^{ERT2} (a tamoxifen-dependent conditional model of Paneth cell depletion) or wild type mice were injected three consecutive doses of tamoxifen and subsequently underwent PPVL or sham surgery. Portal pressure (PP) and the development of portosystemic shunts (PSS) were assessed 14 days after PPVL. Intestinal and mesenteric angiogenesis was assessed by immunohistochemistry (IHC) using anti-CD-31 and anti-Lyve-1 antibodies. Expression of genes involved in the regulation of angiogenesis was evaluated by RT2 profiler PCR array in intestinal tissue.
Results: PP was significantly attenuated in Paneth cell depleted mice compared to control mice after PPVL ($n = 7$/group, 8.78 ± 1.23 cmH_2O vs 11.75 ± 1.53 cmH_2O, respectively, $p < 0.01$). This was associated with a decrease in PSS ($n = 3$/group, $42.8\% \pm 4.6$ vs $65.3\% \pm 3.0$, $p = 0.13$). Depletion of Paneth cells also resulted in a significantly decreased density of blood and lymphatic vessels as assessed by IHC ($n = 5$, pixel ratio, $2.7\% \pm 1.9$ vs $13.9\% \pm 2.3$ $p = 0.05$ and $10.5\% \pm 2.9$ vs $29.0\% \pm 7.2$ $p = 0.03$, respectively). Quantitative gene expression measurements showed a differential expression in 69 angiogenic genes, whereby 47 proangiogenic genes including Ang-1, Angpt-1, VEGFR1&2, VEGFb, VEGFc, and Nrp1 were downregulated in Paneth cell depleted mice.
Conclusion: Portal hypertension was significantly decreased in mice lacking Paneth cells. The decreased density of blood and lymphatic vessels suggest that Paneth cell-derived factors may act on portal hypertension and angiogenesis.

A functional metagenomics investigation of cirrhotic patients highlights distinctive microbiota features involved in bacterial translocation, systemic inflammation and hepatic encephalopathy

V.D.I. Gregorio[1], V. Iebba[2], F. Guerrieri[3], M. Levrero[3], A. Gagliardi[2], F. Santangelo[2], A.P. Sobolev[4], S. Circi[4], V. Giannelli[1], L. Mannina[4], S. Schippa[5], M. Merli[1]. [1]*Sapienza University of Rome, Department of Clinical Medicine, Rome, Italy;* [2]*Public Health and Infectious Diseases Dept., Institute Pasteur Cenci Bolognetti Foundation, Sapienza University of Rome, Rome, Italy;* [3]*Center for Life NanoScience@Sapienza, Institute Italiano di Tecnologia, Rome, Italy;* [4]*Sapienza University of Rome, Department of Chemistry and Pharmaceutical Technologies, Rome, Italy;* [5]*Sapienza University of Rome, Public Health and Infectious Diseases Dept, Rome, Italy*
Email: vincenzadg@yahoo.it

Background and Aims: Cirrhotic patients had an altered intestinal motility, an impaired gut intestinal barrier and altered immune system leading to dysbiosis and possible bacterial translocation (BT). The presence of bacteria or their byproducts within bloodstream could thus play a role in systemic inflammation and hepatic encephalopathy (HE).
Method: We employed a 'functional metagenomics' and network approach aimed at describing the interrelationships of microbiota members (biopsies, feces, peripheral and portal blood samples, n = 109), and fecal metabolites, with clinical parameters of cirrhotic patients (n = 46) and controls (n = 14).
Results: Feces and biopsies showed a marked dysbiosis in cirrhotic patients, with a higher proportion of Enterobacteriaceae; Proteobacteria were also predominant in peripheral and portal blood. Functional metagenomics evidenced an impaired fecal bacterial metabolism of short chain fatty acids (SCFAs) and carbon/methane sources in LC, along with an enhanced stress-related response. Network analysis revealed a 'functional dysbiosis' in cirrhotic feces, with Bacteroides vulgatus and threonine as keystone elements. Sixteen species, mainly belonging to Proteobacteria phylum, were shared among cirrhotic peripheral and portal blood, and were functionally linked to iron metabolism. Fecal Enterobacteriaceae and trimethylamine were positively correlated to proinflammatory cytokines, while Ruminococcaceae and SCFAs exerted a protective role. Within peripheral blood and feces, definite species (Stenotrophomonas pavanii, Methylobacterium extorquens) and metabolites (methanol, threonine) were positively related to HE.
Conclusion: Cirrhotic patients harbor a 'functional dysbiosis' in feces and peripheral/portal blood, with specific keystone species and metabolites related to clinical markers of systemic inflammation and HE.

SAT-004

Novel characterization of the gut microbiome in patients with NASH and longitudinal changes associated with histological improvement

R. Loomba[1], Y. Gindin[2], O. Podlaha[2], Z. Jiang[2], E. Lawitz[3], S. Caldwell[4], S. Djedjos[2], R. Xu[2], D. Gong[2], M. Subramanian[2], R. Myers[2], M. Charlton[5], Z. Goodman[6], A.M. Diehl[7]. [1]*University of California at San Diego, Division of Gastroenterology, Department of Medicine, San Diego, United States;* [2]*Gilead Sciences, Foster City, United States;* [3]*Texas Liver Institute, University of Texas Health San Antonio, San Antonio;* [4]*University of Virginia, Falls Church, United States;* [5]*University of Chicago, Chicago, United States;* [6]*Inova Fairfax Hospital, Falls Church, United States;* [7]*Duke Clinical Research Institute, Durham, United States*
Email: stephen.djedjos@gilead.com

Background and Aims: Data comparing the normal human gut microbiome versus patients with biopsy-proven NASH, and associations between longitudinal changes in the microbiome and histologic responses, are limited. Our aims were to: (1) characterize differences in 16S bacterial DNA in the stool microbiome between patients with NASH and healthy controls; and (2) evaluate longitudinal changes in the gut microbiome of NASH patients and their associations with changes in liver histology.
Methods: Stool samples for microbiome analysis were collected from 69 subjects with biopsy-confirmed NASH (NASH CRN F2-3 fibrosis and NAS ≥5) enrolled in a 24 week Phase 2 study of selonsertib (SEL) ± simtuzumab and compared to 32 healthy controls from the Human Microbiome Project (HMP). The 16S ribosomal RNA region was sequenced on the Illumina MiSeq platform and genus level assignments were made from operational taxonomic unit (OTU) data. OTU abundance was normalized to allow for sample comparisons with p-values from student's t-test adjusted using false discovery rate correction. Microbial changes across time were summarized using multidimensional scaling where the distance between two samples is proportional to the difference in their microbial community at the genus level. Distance between each NASH sample and an average HMP profile was calculated using Euclidean distance. Treatment-related effects were assessed based on the change in distance to average HMP profile between baseline (BL) and W24.
Results: The mean age and BMI of patients with NASH and healthy controls were 54 yrs and 34.3 kg/m^2 versus 26 yrs and 24 kg/m^2. Compared with controls, stool from patients with NASH had significantly lower Bactereoidetes, and higher Firmicutes, Actinobacteria, Proteobacteria, and Verrucomicrobia (Table). Following treatment with SEL, a significant trend toward normalization of the gut microbiome was observed (p = 0.033). In addition, increases in Ruminococcaceae were significantly associated with improvement in lobular inflammation (p = 0.023). In subjects who progressed to cirrhosis (n = 5), more Fusobacteria were observed at BL compared with subjects with a ≥1-stage improvement in fibrosis (n = 21; p = 0.016).

Table: Faecal microbial composition in NASH subjects vs healthy controls.

Phylum	Median abundance in healthy controls (N = 32)	Median abundance in NASH subjects (N = 69)	p-value
Bactereoidetes	4293 (3653–5499)	1206 (158–2791)	5.74×10^{-11}
Firmicutes	2252 (1553–3582)	5768 (3669–7449)	5.58×10^{-12}
Actinobacteria	7 (2–24)	117 (42–309)	6.21×10^{-8}
Proteobacteria	97 (41–219)	145 (39–590)	2.87×10^{-5}
Verrucomicrobia	0 (0–12)	2 (0–136)	2.15×10^{-3}

Conclusion: There are significant differences in the stool microbiome of patients with NASH and fibrosis compared to healthy controls. In NASH patients treated with SEL, changes in the gut microbial pattern are associated with improvements in liver histology.

SAT-005

Iron reduction by venesection alters the gut microbiome in Haemochromatosis patients

B. Parmanand[1], M. Watson[2], V. Black[2], R. Morovat[3], E. Lund[4], J.D. Collier[2], S. Fairweather-Tait[5], A. Narbad[1], J. Cobbold[2], J. Ryan[2]. [1]*Quadram Institute Bioscience, Norwich, United Kingdom;* [2]*University of Oxford, Translational Gastroenterology Unit;* [3]*Oxford University Hospitals NHS Foundation Trust, Department of Clinical Biochemistry, Oxford, United Kingdom;* [4]*University of East Anglia, Department of Biological Sciences, Norwich;* [5]*University of East Anglia, Department of Nutrition, Norwich, United Kingdom*
Email: john.ryan@ndm.ox.ac.uk

Background and Aims: Therapeutic venesection has been the standard of care for patients with Haemochromatosis for decades. Iron depletion is associated with an improvement in liver function tests, insulin resistance, liver fibrosis, and a reduction in mortality and risk of several malignancies. The mechanisms underlying these benefits are unknown. Paradoxically, venesection promotes iron

absorption from the gut, and reduced faecal iron levels have been reported during treatment. As iron is critical to the growth and proliferation of numerous gut microbes, and excess colonic iron has been implicated in colonic inflammation and carcinogenesis, changes in faecal iron during venesection could favourably alter the gut microbiome.

Method: Patients initiating venesection for iron overload were recruited between November 2014 and June 2016. Blood and stool samples were collected baseline and 3-month intervals during treatment. Faecal iron, microbiome (16S rRNA metagenomics) and metabolomic (NMR) analyses were performed.

Results: Baseline faecal free iron levels were higher in patients with iron overload than healthy controls ($p = 0.0013$). Serum ferritin, ALT, and faecal iron levels fell significantly with iron depletion (all $p < 0.05$). Of 11 patients with paired samples, 6 had a significant reduction in faecal iron ($p = 0.017$; termed 'responders') while 5 did not ($p = 0.62$; non-responders). While no significant differences in baseline serum ferritin, age, gender or LFTs were noted between groups, significant changes in bacterial genera were only seen in responders to treatment. The genus that changed most with treatment was Faecalibacterium, which increased significantly with iron depletion ($p = 0.0084$). Indeed, levels of Faecalibacterium species are known to correlate negatively with systemic inflammatory markers, and reduced levels have been associated with IBD, obesity and NAFLD, as well as following oral iron supplementation. Similarly, significant negative correlations between Faecalibacterium levels and serum ferritin ($r = -0.41$, $p = 0.006$) and CRP ($r = -0.45$, $p = 0.013$) were seen. Significant faecal metabolomic changes were also evident, only in responders, with increased levels of faecal aspartate, glycine, methionine and tyrosine seen (all $p < 0.05$).

Conclusion: Targeted depletion of faecal iron can alter the composition and function of the gut microbiome and may represent a novel therapy for metabolic and inflammatory diseases.

SAT-006

Does the bile acid receptor TGR5 play a role in Kupffer cell response during Alcoholic Liver Disease?

M. Spatz[1,2], D. Ciocan[1,2], F. Neuza[3], D. Rainteau[3], L. Humbert[3], C. Hugot[1,2], L. Wrzosek[1,2], P. Virginie[1,2], G. Ferrere[1,2], G. Perlemuter[1,2,4], T. Tordjmann[5], A.-M.C. Doulcier[1,2]. *[1]Inflammation Chemokines and Immunopathology, INSERM, Fac. de médecine-Univ Paris-Sud, Université Paris-Saclay, Clamart, France; [2]Laboratoire d'Excellence en Recherche sur le Médicament et l'Innovation Thérapeutique (LERMIT); [3]Département de Biochimie B et LCBGM, Hôpital Saint Antoine AP-HP, Paris, France; [4]AP-HP, Hôpital Antoine Béclère, Service d'hépato-grastroentérologie, Clamart, Univ Paris-Sud, CHU Bicêtre, Kremlin-Bicêtre, France; [5]INSERM U1174, Univ Paris-Sud, Université Paris-Saclay, Orsay, France*
Email: cassard.doulcier@u-psud.fr

Background and Aims: Chronic alcohol consumption is one of the major etiological factor of chronic liver diseases in western countries. Nevertheless, among heavy drinkers, only a subset of individuals will develop liver inflammation, cirrhosis and hepatocarcinoma. Alcohol intake induces a dysbiosis and patients with severe alcoholic hepatitis, a life-threatening situation, harbour a specific configuration of the gut microbiota. The intestinal microbiota (IM) was recently identified as a major player in the mechanisms involved in alcoholic liver disease (ALD) and in the individual susceptibility to alcohol. Bile acids (BA) metabolism is dependent on IM, and BA are discriminant metabolites between alcoholic patients with or without severe liver injury. As previously described, hepatic macrophages, Kupffer cells, are involved in the inflammatory process during ALD. Therefore, we assessed the role of the BA receptor TGR5, in the inflammatory phenotype of Kupffer cells in a murine model of ALD.

Method: Wild type (WT) and TGR5-deficient mice were fed with a 5% ethanol diet for 10 days (Lieber DeCarli). Liver lesions were scored by plasma transaminases, hepatic triglycerides, histology and qPCR regarding inflammatory genes. Kupffer cells phenotype was assessed by qPCR. BA were studied in faeces, plasma and liver by mass spectrometry. Disturbances in BA metabolism were determined by qPCR regarding BA enzymes and transporters. IM composition was analysed using Illumina MiSeq technology targeting the 16S ribosomal DNA V3-V4 region and correlated to the IM composition.

Results: In WT mice, alcohol induced significant liver steatosis, with elevated plasma transaminases. Quantification by qPCR of cytokines and chemokines confirmed the inflammatory profile in the liver and specifically in isolated Kupffer cells. BA concentration in plasma, liver and faeces were modified by alcohol intake. We observed a BA overload in plasma and liver, associated with an increase in hydrophobic BA, and a decrease in faecal excretion associated with a lower expression of ileal BA transporters. In TGR5-deficient mice, alcohol diet induced more important liver steatosis and inflammatory profile than in littermate-alcohol fed mice. Kupffer cells harboured a higher inflammatory profile. Microbiota analysis showed a dysbiosis in TGR5-deficient mice, both in control and alcohol diet groups, which may at least in part contribute to the observed BA metabolism dysregulation.

Conclusion: These results showed that TGR5 deficiency worsens liver lesions in a murine model of ALD and is associated with increased Kupffer cell inflammatory phenotype and altered BA homeostasis. We will further investigate the improvement of ALD by treating mice with a TGR5 agonist.

SAT-007

Does the gut play a pivotal role in the protective effect of coffee on liver damage?

G. Mazzone[1], A. Rossi[1], P. Vitaglione[2], V. Lembo[1], G. D'argenio[1], G. Maria[3], M. Savoia[4], N. Caporaso[1], F. Morisco[5]. *[1]University of Naples Federico II, Department of Clinical Medicine and Surgery, Gastroenterology Unit, Naples, Italy; [2]University of Naples Federico II, Department of Agricultural Sciences, Portici, Italy; [3]University of Padua, Department of Medicine, Padua, Italy; [4]University of Naples Federico II, Department of Biochemistry and Medical Biotechnology, Naples, Italy; [5]Federico II University, Gastroenterology, Napoli, Italy*
Email: antonellarossi46@hotmail.it

Background and Aims: Metabolic syndrome is one of the most important health issues worldwide. Its liver phenotype is called nonalcoholic fatty liver disease (NAFLD). We have previously demonstrated that high fat diet (HFD)-induced liver damage is reverted by coffee consumption thought a reduction of fat deposition in the liver and an amelioration of antioxidant and anti-inflammatory status. Nonetheless we hypothesize that the first target organ of coffee is the gut, supporting the protective effect on the liver by modulating the gut permeability and contributing to the concept of relevant role of gut-liver link.

Method: Twenty-four C57BL/6 mice were divided into 3 groups of 8 mouse each: one group received standard diet (SD: 3.3 Kcal/g, 5% from fat), one group received HFD (5.6 Kcal/g, 58% from fat), and a third group received HFD plus decaffeinated coffee solution (HFD + Coffee) for 12 weeks. Coffee daily dosage corresponded to 6 cups of espresso coffee or 2 cups of filtered coffee for a 70 kg person. At the end of treatment, hepatic histology was examined by H&E staining. Alanine-aminotrasferase (ALT), total cholesterol levels were measured in serum samples. Gene expression of PPAR-α and LXR-α was assessed in the liver. The expression of molecular mediators of fatty acids ABCA1, ABCG1, FFAR-1 and of gut permeability Zonulin and Claudin were evaluated in duodenum and colon by RT-PCR. Cecum fecal samples were collected for triglycerides and fatty acids analysis.

Results: Mouse body weight was significantly lower in HFD + Coffee group *vs* HFD ($p < 0.003$). Coffee treatment also reduced cholesterol and ALT serum levels ($p < 0.001$ and $p < 0.05$, respectively), and ameliorated liver macrovesicular steatosis ($p < 0.001$) and ballooning degeneration ($p < 0.05$). Coffee supplementation increased the expression of PPAR-α and LXR-α in the liver and upregulated the

expression of ABCA1, ABCG1, FFAR-1, Zonulin, and Claudin in the duodenum and colon. The fecal cecum content of HFD + coffee group showed higher levels of total triglycerides and fatty acids *vs* HFD group.

Conclusion: Coffee modulates the intestinal permeability and molecular expression of fatty acids mediators increasing fat oxidation and ameliorating fatty acids efflux. Coffee by *via* of gut-liver axis exerts a beneficial effect on the liver reducing hepatic steatosis.

SAT-008

Intestinal microbiota significantly alters hepatic expression of energy metabolism genes in mice with acute cholestasis

S. Moghadamrad[1], I. Keller[2], C. Simillion[2], L. Deshanais[3], R. Bernier-Latmani[3], A. De Gottardi[1]. *[1]Berne University Hospital, BioMedical Research, Bern, Switzerland; [2]Univesity hospital of Berne, Interfaculty Bioinformatic unit, Bern, Switzerland; [3]École polytechnique fédérale de Lausanne, Environmental Microbiology Laboratory, Lausanne, Switzerland*
Email: sheida.moghadamrad@dbmr.unibe.ch

Background and Aims: We were interested in assessing the effects of intestinal microbiota on hepatic gene expression profile and plasma bile acid (BA) composition in basal conditions and in an acute cholestasis.

Method: We induced acute cholestasis in germ free (GF) and altered Schaedler flora colonized (ASF) mice by performing bile duct ligation (BDL) and we performed studies after 5 days. We evaluated gene expression profile in the liver of these mice compared to non-cholestatic control groups using next generation sequencing and pathway analysis. We also measured the plasma concentration of BA by UHPLC-HRMS analysis.

Results: We found that acute cholestasis was associated with distinct genes expression patterns mainly involved in the regulation of the immune system, oxidative processes and accumulation of extracellular matrix in both ASF and GF mice (Figure A). In addition, we observed significant differences related to the hygiene status of the mice in the expression of genes controlling the generation of precursor metabolites, energy metabolism and amino acid metabolic process pathways. In non-cholestatic mice, the absence of microbiota significantly induced or suppressed the expression level of 80 genes involved in organic acid catabolic and fatty acid metabolic processes, leukocyte migration and external side of plasma membrane (Figure B). Under basal conditions, there were no significant differences in primary BA concentrations between GF and ASF mice. The concentration of the majority of BA markedly increased after BDL in both groups without remarkable differences according to the hygiene status of the mice.

Conclusion: Intestinal microbiota significantly alters hepatic gene expression before and after acute cholestasis. Alterations observed after BDL suggest that microbial-induced differences may impact the course of cholestasis and modulate liver injury.

SAT-009

Fecal microbiota profiles as a diagnostic biomarkers in cirrhosis and hepatocellular carcinoma and the impact of life style and nutrition

Y. Lapidot[1,2], R. Nosenko[3], B. Gayshis[1], M. Likhter[1], D. Ben-Ami[1], T. Engel[1], R. Margalit[1], I. Kalisky[1], P. Weiss[1], V. Ella[1], O. Cohen-Ezra[1], Y. Davidov[4], O. Koren[3], M. Safran[1], Z.B. Ari[5]. *[1]Chaim Sheba Medical center, Liver Disease Center, Tel Hashomer, Israel; [2]Tel-Aviv University, Sackler School of Medicine, Tel-Aviv, Israel; [3]Bar-Ilan University, Safed, Faculty of Medicine, Safed, Israel; [4]Chaim Sheba Medical Center, Liver Disease Center, Ramat Gan, Israel; [5]Sheba Medical Center at Tel Hashomer, Center of Liver Diseases, Tel Aviv, Israel*
Email: michal.safran@sheba.health.gov.il

Background and Aims: Liver cirrhosis is the main predisposing risk factor for the development of hepatocellular carcinoma (HCC).

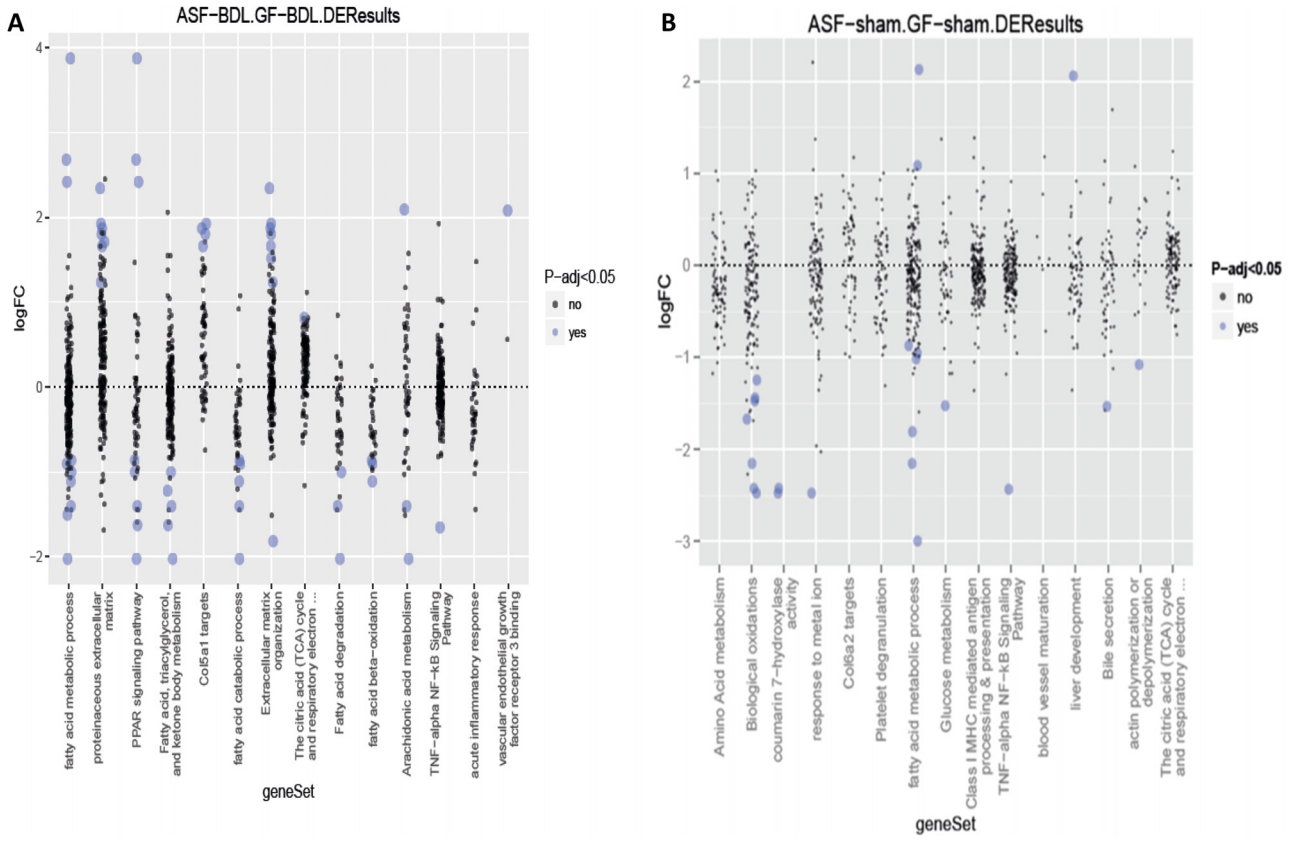

Figure: (abstract: SAT-008).

The factor(s) influencing disease progression from cirrhosis to HCC remain unknown. Gut microbiota has recently emerged as a major player in different liver diseases, however its association with HCC is still undetermined. Moreover, the association between the gut microbiota, nutrition, life style, cirrhosis and HCC was not studied previously. The aim of our study was to characterize the gut microbial signature in association with life style and nutrition of patients with cirrhosis, HCC and healthy controls.

Method: Stool samples were collected from 95 individuals (30 patients with HCC, 38 patients with cirrhosis and 27 age, gender and BMI-matched healthy volunteers,). 16S rDNA sequencing of fecal DNA was performed (MiSeq Illumina).

Results: The microbiota of patients with HCC-cirrhosis was characterized by overrepresentation of Bacteriodetes (42.3%) and lower expression of Firmecutes (46.7%) compared to healthy controls (36.1 and 52.2% respectively) and cirrhotic patients (34.2% and 50.3% respectively). However, the relative abundance of Proteobacteria in the samples of HCC-cirrhotic patients resembled the abundance of this species in patients with cirrhosis and not in healthy controls (6.1%, 6.4% and 3.8% respectively), while the relative population of the Actinocacteria in the HCC patients was closer to that of the healthy controls and not the cirrhotic patients (3.2%, 3.5% and 5.7% respectively). Nevertheless, investigating the life style and nutrition habits of HCC-cirrhosis, cirrhotic patients and the healthy controls we found that both groups of patients (HCC and cirrhosis) have very similar life style, which is different from the healthy controls. Both groups of patients reported similar dietary patterns that included high protein, low sodium and low sugar intake. On the other hand, healthy controls described consuming a low fat diet and a significantly more active lifestyle.

Conclusion: We here present the first report of the correlation between dietary habits and microbiota in liver disease patients. We have demonstrated in our study that the distribution of the fecal microbiome in HCC patients is different from both the cirrhotic patients and healthy control. This result is even more pronounced based on the results showing that both the diet and life style of HCC-cirrhosis and cirrhotic patients is very similar. Further studies are needed to confirm these findings and assess causality.

SAT-010

Gut microbes mediate liver fibrosis in chimeric mice with human hepatocytes persistently infected with hepatitis B virus

M. Sugiyama[1], T. Kanto[2], M. Masashi[1]. [1]*National Center for Global Health and Medicine, Genome Medical Sciences Project, Ichikawa;* [2]*National Center for Global Health and Medicine, Department of Liver Diseases, Ichikawa, Japan*
Email: msugiyama@hosp.ncgm.go.jp

Background and Aims: Hepatitis B virus (HBV) infection induces liver fibrosis and hepatocellular carcinomas. We previously established an in vivo model of liver fibrosis triggered by HBV infection using an uPA/SCID mouse with human hepatocytes (chimeric mouse). However, the mechanism remained unknown. Our purpose was to reveal the pathway of liver fibrosis using the chimeric mouse model.

Method: Chimeric mice were infected with HBV/C. Group A was treated with daily antibiotics cocktail (ampicillin, vancomycin, neomycin, and metronidazole), whereas Group B received normal DW for 6 months ($n = 4$ each). HBVDNA and markers in the mouse sera were determined by PCR and ELISA, respectively. The sera were determined by multiplex chemokine and cytokine assay for mouse or human. Histopathological changes in the liver were examined after the mouse dissection. The gene expression relating to liver fibrosis was determined using species-specific PCR primers in the liver specimens. The microbiome profile of mouse feces were compared between Group A and B by NGS using 16S amplicon.

Results: The serum HBVDNA level of Group A was higher than Group B ($p < 0.05$). However, Group B showed hepatic fibrosis (F1-2) 6 months post-infection, but not Group A. Alpha-SMA positive cells were stained around fibrosis in Group B. TIMP1, MMP2, and Col1a2 gene expressions were higher in Group B than Group A in the liver ($p < 0.05$ each). In particular, TLR4 expression was strongly induced in Group B ($p < 0.05$), whereas the other TLRs didn't show the significance. CD163+ monocyte cells in the liver induced the expression of the TLR4 gene in the mice with fibrosis. IL-6 gene expression was induced in mouse-derived cells. The levels of serum IL-34, IL-12, CX3CL1 and CCL25 in Group B were higher than Group A ($p < 0.05$), which were related with monocyte activity. The microbiome analysis of mouse feces determined that sixteen species of bacteria were significantly decreased in Group A, which were mainly Clostridiales.

Conclusion: These data suggested that liver fibrosis induced by HBV infection could occur by certain types of bacteria in the gut-liver axis. Especially, these pathogen could induce the activation of TLR4 pathway followed by the monocyte activation in the liver.

SAT-011

Prebiotic treatment prevents alcohol-induced liver lesions in mice with indigenous microbiota and mice with human microbiota

L. Wrzosek[1], G. Ferrere[1], D. Ciocan[1], W. Turpin[2], C. Hugot[1], P. Virginie[1], M. Spatz[1], M. Dupeux[1], F. Gaudin[1], S. Prevot[1], G. Perlemuter[1,3], A.-M. Cassard Doulcier[1]. Background and Aims: Alcoholic liver disease (ALD) is a leading cause of liver failure and mortality. In humans, severe alcoholic hepatitis is associated with key changes to intestinal microbiota (IM), which influences individual sensitivity to develop advanced ALD. In mice receiving an alcohol diet we also observed, depending on the animal facility, a difference in susceptibility to develop liver damages associated to changes in IM. Here we tested the efficiency of a prebiotic treatment in alcohol-sensitive mice to reverse dysbiosis and prevent ALD.

Method: Mice with indigenous IM (their own IM) were fed alcohol with a Lieber DeCarli (LDC) diet. First, mice were progressively adapted to the semi-liquid LDC diet, then an ethanol diet, and finally mice were fed a 5% ethanol diet for ten days. A group of mice with indigenous IM received pectin during the entire alcohol consumption period. In parallel, other groups of mice were colonized with the IM of an alcoholic patient with severe alcoholic hepatitis by fecal microbiota transplantation and then fed an alcohol diet. Once again, a group of mice with human IM received pectin during the alcohol period. Different doses of pectin were tested (from 0.4 to 6.5%). Control mice were fed a control diet containing an isocaloric amount of maltodextrin.

Results: In mice with indigenous IM and mice with human IM, ethanol induced steatosis and liver inflammation, which were associated with disruption of gut homeostasis and a modification of IM with a lower proportion of Bacteroides ($p < 0.05$) compared to control mice. We targeted IM with a prebiotic treatment (pectin) to prevent alcohol-induced liver lesions. Pectin treatment induced modifications of the IM in mice with indigenous IM and mice with human IM. Pectin treatment prevented steatosis, liver inflammation, and restored gut homeostasis in both groups of mice. Depending on the dose of pectin used, the beneficial effects of pectin were more or less pronounced.

Conclusion: Manipulation of IM with prebiotic treatment can prevent alcohol-induced liver injury. The IM should be considered as a new therapeutic target in ALD. These findings open new possibilities for treatment of human ALD through intestinal microbiota manipulation.

SAT-012

Comprehensive analysis of alcohol treatment in mouse model of acute-on-chronic liver injury

S. Furuya[1], J.A. Cichocki[2], H. Kono[1], R. Bataller[3], I. Rusyn[2]. [1]*University of Yamanashi, First Department of Surgery;* [2]*Texas A&M University, Department of Veterinary Integrative Biosciences;* [3]*University of Pittsburgh, Department of Medicine*
Email: irusyn@cvm.tamu.edu

Background and Aims: Human alcoholic hepatitis (AH) carries a high mortality rate. AH is an acute-on-chronic type of liver disease characterized by hepatic steatosis, ballooned hepatocytes, increased serum transaminases, and pericellular fibrosis, which is an important prognostic factor. Chronic alcohol consumption is accompanied by umbalance of bile acids (BAs) and intestinal dysbiosis, and the development of alcoholic liver disease requires gut-derived bacterial products. However, little is known about how alterations in the microbiome contribute to pathogenesis of alcoholic liver disease. Currently, no existing animal model of alcoholic liver disease faithfully recapitulates the pathological features of advanced forms of AH. However, little is known about how alterations in the BAs profile and the microbiome contribute to pathogenesis of alcoholic liver disease.
Method: We used adult male C57BL6/J mice were treated with 3.5-diethoxycarbonyl-1.4-dihydrocolidine (DDC) contain diet (0.05% w/w) to induce chronic liver fibrosis. Following DDC-induced fibrogenesis, ethyl alcohol (EtOH) (up to 27 g/ kg/day, up to 28 days) was administered continuously to mice via a gastric feeding tube (Tsukamoto-French surgery). Liver tissue was evaluated to characterize acute-on-chronic-alcoholic liver disease in our model. Liver total RNA was extracted for deep transcriptomic sequencing, and bacterial DNA from the feces was extracted for deep metagenomic sequencing. Targeted metabolomics assessed concentrations of BAs in the liver tissue and feces.
Results: Exposure to DDC or EtOH alone resulted in cholestasis or steatosis, respectively, as anticipated. Combined treatment with DDC and EtOH lead to an additive effect on liver injury, as evident by the development of hepatic inflammation, steatosis, and pericellular fibrosis, and by increased serum transaminase levels, compared to mice treated with either agent alone. Liver transcriptomic changes specific to combined treatment group included pathways involved in the cell cycle and DNA damage. Analyses of feces from mice revealed alcohol-associated changes to the BAs profile and microbiota, characterized by reduced conjugated BAs in liver and secondary BAs in feces.
Conclusion: Mice treated with DDC and EtOH displayed several key characteristics of human AH, including pericellular fibrosis, increased hepatic bacterial load with dysbiosis, reducing the capacity of the microbiome to synthesize secondary BAs and the proportion of Enterobacteriacae species, and especially transcriptome analysis. This model may be useful for developing therapeutics for AH.

SAT-013

The Impact of proton pump inhibitors on the intestinal microbiota in chronic hepatitis C patients

F. Wellhöner[1], N. Döscher[1], V. Marius[2], I. Plumeier[2], S. Kahl[2], A. Potthoff[1], M.P. Manns[3], P. Dietmar[2,4], H. Wedemeyer[5], M. Cornberg[1], B. Heidrich[1,2,4]. [1]*Hanover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*Helmholtz Center for Infection Research, Microbial Interactions and Prosseses Research Group, Braunschweig, Germany;* [3]*Dept. of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany;* [4]*German Center for Infection Research, Germany;* [5]*Department of Gastroenterology and Hepatology, University Clinic Essen, Essen, Germany*
Email: freya.wellhoener@stud.mh-hannover.de

Background and Aims: Proton pump inhibitors (PPI) are among the most prescribed drugs and are known to influence the intestinal microbiota. Patients with chronic liver diseases are in risk of infectious complications such as spontaneous bacterial peritonitis (SBP). Former studies on the impact of PPI use on the microbiota have been done in patients with several different liver diseases. Therefore, the aim of the present study was to elucidate the role of PPI in patients with chronic hepatitis C infection in order to exclude effects introduced by differences in the underlying liver disease.
Method: Stool samples of 141 patients with chronic hepatits C infection were analyzed. The V1-2 region of the 16S rRNA gene was amplified followed by sequencing on the Illumina MiSeq platform. Samples with less than 10,000 reads and those from patients who were taking immunosuppressives, antibiotics, oral antidiabetics, UDC, HepaMerz or Lefax were excluded. In total, 28 with and 78 without PPI intake were included. Random subsampling was performed to achieve equal numbers of reads. Alpha and beta diversity were calculated in Primer 7. Differences in relative abundances were calculated with DESeq2.
Results: Baseline characteristics of both groups were comparable. However the frequency of patients with liver cirrhosis was significantly higher in the PPI group (54% vs 32%; $p = 0.044$). In contrast to former studies no significant differences in alpha diversity were observed. Beta diversity differed significantly. However, the observed differences between both groups were only small ($R = 0.123$, $p = 0.014$). The relative abundance of 27 genera differed significantly between patients with and without PPIs. In order to exclude effects induced by the presence of liver cirrhosis we performed a second analysis for patients with (CIR) and without cirrhosis (No-CIR) separately. In CIR 28 genera differed significantly whereas in No-CIR 13 genera showed differences in relative abundance. Importantly, only the relative abundances of *Streptococcus spp.* ($p = 3.0*10^{-14}$), *Haemophilus spp.* ($p = 1.2*10^{-11}$) and *Enterobacter spp.* ($p = 3.1*10^{-8}$) were significantly increased in both groups.
Conclusion: PPIs lead to a significant change in the composition of the gut microbiota independent of the presence of liver cirrhosis. Importantly, *Streptococcus spp.* and *Enterobacter spp.* can be isolated regularly from ascitic fluid. Therefore, we recommend a careful use of PPI in patients with liver diseases in order to avoid selection of potential harmful genera.

Immunology except viral hepatitis

Paradoxically functioning onco-miR-155 and the tumor suppressor miR-194 consensus on PD-L1 immune checkpoint upregulation via MALAT-1 and XIST in hepatocellular carcinoma

S. Atwa[1], K. Hosny[2], H. Handoussa[3], H. El Tayebi[4]. [1]*Pharmaceutical Biology, Cairo, Egypt;* [2]*General Surgery, Kasr El Einy, Cairo, Egypt;* [3]*German University in Cairo, Pharmaceutical Biology, Cairo, Egypt;* [4]*Genetic Pharmacology Research Group, Pharmacology and Toxicology department, Cairo, Egypt*
Email: sara.mahmoud-atwa@guc.edu.eg

Background and Aims: Immunotherapy elicits nontoxic, systemic, long-lived anti-tumor activity. Anti-programmed death therapy has thrust the immunotherapy into spotlight. Nevertheless, programmed-cell-death-ligand-1 (PD-L1) targeted therapies are yet understudied in hepatocellular carcinoma (HCC). MicroRNAs (miRNAs) and long non-coding RNAs (lncRNAs) have emerged as eminent players in human pathophysiological processes. However, interaction between miRNAs and LncRNAs in immunotherapy is inadequately studied. Our recent data described LncRNA-XIST as an upstream regulator of PD-L1. This study aims at exploring non-coding RNAs as novel intermediaries between XIST and PD-L1 in HCC.
Method: Bioinformatics softwares were used to predict PD-L1 upstream regulatory noncoding-RNAs. Twenty HCC, cirrhotic and

healthy liver tissues were surgically resected from liver transplant patients. Ectopic miR-155 and miR-194 expression manipulation was performed in Huh-7-cells followed by extraction of total RNA using Trizol, then RT-qPCR was performed. RNU6B and Beta-2-microglobulin were house-keeping genes.
Results: miR-155 and miR-194-5p were predicted to target PD-L1, MALAT-1 and XIST. MALAT-1 and XIST were predicted to target PD-L1 mRNA. PD-L1 was detected in only 30% of HCC biopsies, however, it was absent in 100% of cirrhotic tissues and minimally detected in controls. MALAT-1 was markedly upregulated in cirrhotic (p = 0.0136) and downregulated in HCC (p = 0.043) compared to controls. XIST was significantly upregulated in HCC (p = 0.048) compared to controls. Expression of MALAT-1 was inversely correlated with both miR-155 and PD-L1 in HCC and cirrhotic tissues. In contrast to miR-194 expression that was directly associated with MALAT-1 expression in cirrhotic and HCC tissues. Ectopic expression of miR-155 in Huh-7 cells resulted in significant upregulation of XIST and PD-L1 (p = 0.0477 and P = 0.0219, respectively) and downregulation of MALAT-1 (p = 0.0053) compared to miR-155 antagonised cells and untransfected controls. Intended overexpression of miR-194 led to significant upregulation of XIST and PD-L1 (p = 0.0026 and P = 0.0209, respectively) compared to miR-194 antagonised cells and untransfected controls, however, it didn't significantly affected MALAT-1.
Conclusion: Despite the contradicting functions of the overexpressed oncomiR-155 and the downregulated tumor suppressor miR-194 in HCC, unexpectedly, both microRNAs showed the same impact on XIST and PD-L1 expression via MALAT-1 downregulation. Moreover, this study showed the sensitivity of PD-L1 expression appearance to MALAT-1 expression in HCC tissues. Therefore, our data suggests a pivotal role for MALAT-1 in the intermediation between XIST and PD-L1 and recommends additional investigation of the controversial and contradicting roles of microRNAs in the context of cancer.

SAT-015

Circulating NK cells in cirrhosis are hypofunctional, with an expanded inhibitory liver-homing CD56dimCD16+/– NK cell population

N. Kumar[1], W. Khamri[1], F. Sadiq[1], E. Triantafyllou[1], F. Lebossé[1], M. Sujit[1], A. Dhar[1], M. Thursz[1], H. Antoniades[1], S. Khakoo[2]. *[1]Imperial College London; [2]University of Southampton*
Email: n.kumar@imperial.ac.uk

Background and Aims: Natural Killer (NK) cells have vital roles in anti-pathogen responses and tumour surveillance. However, cirrhosis renders patients susceptible to sepsis and cancer. Here we aim to characterise NK cells in cirrhosis.
Method: Peripheral blood mononuclear cells (PBMCs) from healthy volunteers and cirrhotic patients (n = 20 in each group) were surface stained for markers CD161, CD16, CXCR6, and maturity (KLRG1, CD57, n = 5). Transcriptomic analysis using Nanostring technology further characterised CD56/CD16 subpopulations (Healthy, Non-alcohol Fatty Liver Disease (NAFLD) related cirrhosis, Alcohol (ALD) related cirrhosis, n = 3 in each group). Function was measured against K562 targets (PBMCs:K562,5:1) using intracellular staining for cytokines (Tumour Necrosis Factor alpha (TNFα), Interferon gamma (IFNγ)), and staining for degranulation (CD107a) as a marker of cytotoxicity.
Results: Circulating CD56dimCD16+/–NK cells are increased in proportion in cirrhosis (26.4%vs7.04; p < 0.0001), and mature cytotoxic CD56dimCD16++NK cells are reduced compared to healthy controls (67.0%vs83.9%; p = 0.003). A greater proportion of CD56dimCD16+/–NK cells express inhibitory receptor CD161 (91.1% vs 82.6%, p = 0.03) and liver homing marker CXCR6 (7.57%vs1.8%, p < 0.0001) in comparison to the CD56dimCD16++NK cells. CD57 and KLRG1, mature NK cell markers, are expressed by a smaller proportion of CD56dimCD16+/–NK cells compared to CD56dimCD16++NK cells (CD57 40.1%vs57.1%, p = 0.06; KLRG1 44.6%vs52.3%, p = 0.008), and at a lower median fluorescent intensity(MFI) (CD57 6629vs8596, p = 0.03; KLRG1 926vs1303, p = 0.09). Transcriptomic comparison of CD56dimCD16+/–NK cells between NAFLD cirrhosis and ALD cirrhosis did not demonstrate significant differences, indicating the CD56dimCD16+/–NK profile may be independent of cirrhotic aetiology. Cirrhotic CD56dimNK cells demonstrate a functional deficit with regards to cytotoxicity (reduced CD107a 52.1%vs64.5%; p = 0.008) and cytokine production (39.7%vs48.1%; p = 0.04) compared to healthy NK cells. Gene expression analysis demonstrates a reduction in Granzyme A and B within CD56dimCD16+/–NK cells, and downregulation in CCL4 expression. Cirrhotic NK cells also have a significantly lower proportion of polyfunctional CD56dim NK cells (NK able to produce IFNγ, TNFα and degranulate (14.6vs21.2, p = 0.03).
Conclusion: Here we describe an increased circulating proportion of inhibitory NK cells with attenuated responses in cirrhosis. Greater knowledge of NK cell dysfunction in cirrhosis independent of cirrhotic aetiology, can aid understanding of infection and malignancy susceptibility in cirrhosis.

SAT-016

Liver sinusoidal endothelial cells are involved in the aggravation of liver injury induced by the activated NKT cells in aged mice

H. Nakashima[1], M. Nakashima[1], M. Kinoshita[1], S. Kato[2], T. Ishikiriyama[1], S. Seki[1]. *[1]National Defense Medical College, Immunology and Microbiology, Tokorozawa Saitama, Japan; [2]National Defense Medical College, Internal Medicine, Tokorozawa Saitama*
Email: hiro1618@ndmc.ac.jp

Background and Aims: The liver non-parenchymal cells such as NK cells, NKT cells and Kupffer cells maintain the innate immune functions of the liver. We previously reported that NKT cells exert two opposite effects after alpha-galactosylceramide (a-GalCer) activation. One is upregulation of anti-tumor immunity mediated by their IFN-gamma production and NK cell activation (Nakagawa R, J Immunol, 2001). The other is hepatocyte injury induced by FasL expressing NKT cells stimulated with TNF produced by recruited macrophages (Mphgs) (Inui T, J Hepatol, 2005). Furthermore, in either aged mice or mice fed high fat and high cholesterol diet, TNF production from recruited Mphgs is up-regulated and thereby NKT cells express excessive FasL to induce severe liver injury (Nakashima H, PLOS ONE, 2013). In this study, we examined the role of liver sinusoidal endothelial cells (LSECs) in aggravation of the liver injury induced by a-GalCer in aged mice.
Method: Young (8 weeks old) and aged C57BL/6 mice (50 weeks old) were i.v. injected with a-GalCer. The levels of serum ALT and MCP-1 were compared to those in young mice. Liver injury in CCR2–/– mice was also examined. Mononuclear cells (MNCs) were harvested from the liver by collagenase digestion and intracellular MCP-1 induced by a-GalCer in CD31(+) LSECs were examined by flow-cytometric analysis (FACS). Liver injury in CCR2–/– mice was also examined.
Results: In aged mice, liver injury was much more severe than that of young mice. Infiltration of TNF producing CD11b(+) Mphgs was augmented and elevated serum TNF levels in aged mice. Intracellular FACS analysis revealed that LSECs were the main producer of MCP-1 after a-GalCer administration, suggesting that LSECs recruited Mphgs via MCP-1. Serum and intracellular MCP-1 of LSECs were elevated in aged mice. In CCR2–/– mice, recruitment of Mphgs and serum TNF were downregulated, and liver injury was ameliorated.
Conclusion: Our results indicate that LSECs produce MCP-1 and play a key role in aggravation of liver injury by recruitment of Mphgs in a-GalCer hepatitis. Not only CD45(+) immune cells but also LSECs may participate in the immune system in the liver, especially in aged mice.

M2 macrophage specfifc gene silencing in the liver using third generations mannose coated, siRNA-loaded nanohydrogel particles

L. Kaps[1], N. Leber[2], A. Yang[3], M. Giardino[3], S. Rizelli[2], M. Aslam[3], A. Mostafa[3], R. Zentel[2], D. Schuppan[3]. [1]*Institute of Translational Immunology and Research Center for Immunotherapy, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany;* [2]*Johannes Gutenberg-University of Mainz, Institutes of Organic Chemistry;* [3]*University Medical Center of the Johannes Gutenberg-University Mainz, Institute of Translational Immunology and Research Center for Immunotherapy (FZI), Germany*
Email: detlef.schuppan@unimedizin-mainz.de

Background and Aims: Efficient *in vivo* transport of active siRNA to specific liver cells remains challenging. First and second generation cationic nanohydrogel particles (NHP) are excellent oligonucleotide carriers [Kaps L et al, Adv. Healthcare Mat. 2015; J. Contr. Rel. 2016]. We designed a third generation of NHP where mannose residues are covalently linked to the surface (Man-NHP), enabling targeting of CD206 positive M2 macrophages, which are implicated in HCC and liver fibrosis progression.
Method and Results: Man-NHP composed of block copolymers (pentafluorophenyl methacrylate and tri-(ethylene glycol) methyl ether methacrylate), with diameters around 40 nm and loaded with control siRNA (scsiRNA) up to 400 nM did not show cytotoxicity for murine 3T3 fibroblasts, Raw macrophages, SVEC endothelial cells or HepG2 human hepatoma cells. Man-NHP labelled with FITC showed a preferential binding to *in vitro* polarized CD206 high M2 compared to CD206 low non-polarized M0 or M1-polarized bone-marrow derived macrophages (BMDM), as determined by FACS analysis. Man-NHP were shielded from unspecific interactions compared to non-mannose coated NHP, which exhibited high binding to macrophages regardless of their phenotype. Man-NHP loaded with siRNA to CSFR-1, an M2 macrophage specific target, yielded a robust knock-down in M2 polarized BMDM after 48 h of incubation.
After intravenous injection in mice with CCl_4-induced liver fibrosis, near infrared (NIR, CW800-dye) labeled Man-NHP loaded with Cy5-labelled scsiRNA distributed preferentially to the liver (>80%), as determined by *in vivo* and *ex vivo* NIR imaging. *Ex vivo* colocalization studies of liver single cell suspension obtained from Man-NHP-NIR/Cy5-scsiRNA treated fibrotic mice, as well as *in vivo* knockdown (vs. the myeloid specific target CSFR-1) will be presented.
Conclusion: Third generation NHP were derivatized with surface mannose residues for effective M2 macrophage targeting via the mannose receptor CD206 *in vitro* and *in vivo*. Man-NHP are a promising tool to specifically target therapeutic siRNA to fibrosis and HCC promoting M2 macrophages.

SAT-018

The pathogenic role of Stat2 in inflammation is independent of canonical interferon signaling and is mediated by TNFa

H. Heath[1], H. Kudo[2], G. Renney[3], M. Ward[3], P. Cutillas[4], R.D. Goldin[2], R. Hutchins[4], G. Foster[1], W. Alazawi[1]. Email: w.alazawi@qmul.ac.uk

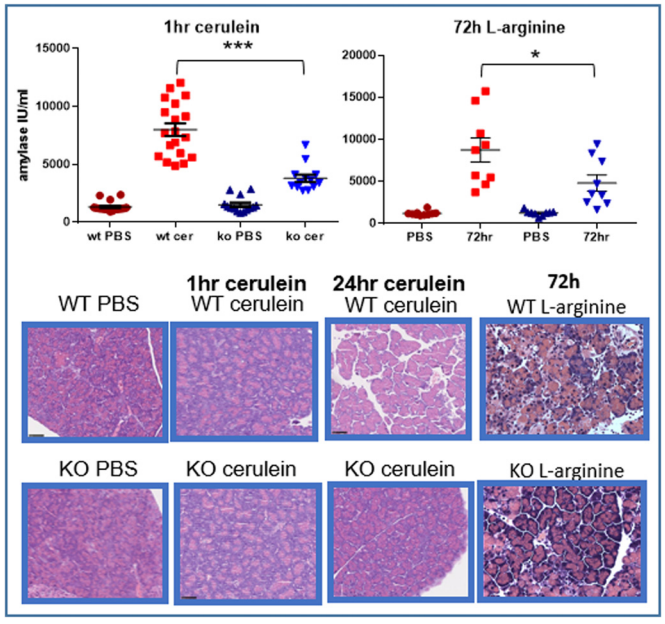
Background and Aims: Inflammatory diseases of the liver and pancreas cause much morbidity and mortality worldwide. Even in the absence of infectious agents, tissue injury causes release of damage-associated molecular patterns (DAMPs) which activate pattern recognition receptors such as toll-like receptors (TLR). Our group has previously identified Stat2 as an important mediator of TLR4-mediated inflammation that is required for appropriate cytokine production (Alazawi et al, PNAS 2013). Here we have tested the hypothesis that Stat2 loss is protective in pancreatic inflammation, and showed the mechanism by which Stat2 mediates tissue injury.
Method: Wild type (WT) and Stat2$^{-/-}$ mice were challenged with either cerulein or L-arginine by intraperitoneal injection. Pancreata and blood were harvested 1 h and 24 h after the final dose of cerulein and up to 96 h post L-arginine.
Results: Stat2$^{-/-}$ mice are protected from cerulein-induced pancreatitis and L-arginine-induced severe pancreatitis compared to WT (Figure) shown histologically, and with significantly lower serum amylase levels and inflammatory cytokine expression (including IL-6, IL-13, TNFα, CCL2 & CXCL2). Antibody-mediated blockade of type I interferon signaling in WT mice did not recapitulate the protective effects of Stat2 loss in the cerulein model.



Global protein analysis by label-free mass spectrometry on whole inflamed pancreata identified 128 phosphoproteins that were expressed differently in cerulein-treated Stat2$^{-/-}$ compared to WT mice (66 upregulated in Stat2$^{-/-}$ and 62 downregulated in Stat2$^{-/-}$). Key differences were in activating modifications of mitogen-activated protein (MAP) kinase mediators confirmed by western blot. Nuclear translocation of MAPKp38 was impaired as was NFκB p65 in Stat2$^{-/-}$ pancreatitis and in primary pancreatic cells, assessed by confocal imaging and western blot, resulting in reduced expression of inflammatory genes such as TNFα in Stat2$^{-/-}$ mice. Indeed, antibody-mediated TNFα blockade protected WT mice but had no effect in Stat2$^{-/-}$.
Conclusion: Stat2 is a mediator of acute sterile inflammation in the liver and pancreas and is required for cytokine-mediated inflammatory injury in an interferon-independent, TNFα dependent mechanism. Stat2 or other (phospho) protein mediators identified in this study are therapeutic targets for sterile inflammation.

SAT-019

AXL-expressing monocytes indicate immuneparesis and disease severity in patients with cirrhosis

Email: robert.brenig@kssg.ch

Background and Aims: Infection related complications substantially contribute to the high morbidity and mortality in advanced cirrhosis. While susceptibility to infections has been attributed to immuneparesis, precise mechanisms of the underlying pathophysiology remain elusive. TAM-receptors (Tyro-3, AXL, MERTK), expressed on monocytes, are important regulators of innate immune responses to microbial challenge. We sought to evaluate TAM-receptor expression on monocytes in patients with cirrhosis in relation to monocyte function and disease severity.
Methods: We collected blood from patients with stable early (Child A n = 33) and advanced cirrhosis (Child B n = 22; C n = 12) at the Cantonal Hospital St. Gallen and healthy controls (HC n = 15). Ex-vivo monocyte immunophenotyping including TAM-receptor expression and cytokine production (TNF-alpha; IL-6) in response to lipopolysaccharide (LPS) were assessed using flow cytometry. GAS6 was measured by ELISA. AXL was overexpressed in THP-1 cells and TNF-alpha production upon LPS assessed by ELISA.
Results: We observed a significant upregulation of AXL on monocytes of patients with cirrhosis independent of aetiology and increasing with disease severity (HC 2.1% vs. Child A 2.9% vs. B 11.8% vs. C 17.1%, Figure A). MERTK and Tyro-3 expression were low in all groups. AXL-expressing (AXL^+) monocytes were characterised by increased expression of HLA-DR, CD16, MERTK, Tyro-3, TLR4, CCR5/7 and CX3CR1. Plasma levels of AXL ligand GAS6 were elevated in cirrhosis, also increasing with disease severity. TNF-alpha and IL-6 production upon LPS by contrast were significantly lower in cirrhosis compared to HC (22.5% vs. 51.2%, p = 0.002; 43.2% vs. 74.2%, p < 0.0001) and decreased with disease severity. Interestingly, AXL^+ monocytes produced less TNF-alpha (Figure B) and IL-6. Accordingly, AXL overexpression in THP-1 cells significantly reduced LPS induced TNF-alpha production in vitro (Figure C, D). The frequency of AXL^+ monocytes correlated with markers indicating disease severity or complications: Child Pugh (r = 0.46, p = 0.0001), MELD (r = 0.41, p = 0.001), bilirubin (r = 0.3, p = 0.03), AST (r = 0.39, p = 0.004), albumin (r = –0.35, p = 0.008), grade of ascites (r = 0.31, p = 0.01), creatinine (r = 0.37, p = 0.004) and connect the number test (r = 0.75, p = 0.03). Patients who died within 1 year or developed secondary infections within 1 month expressed higher AXL levels (MFI 581 vs. 333, p = 0.03; MFI 592 vs. 318, p = 0.008).
Conclusion: We newly observed an expansion of AXL^+ immunoregulatory monocytes in patients with advanced cirrhosis. AXL expression was crucial in dampening innate immune response to microbial challenge and may merit evaluation as an immunotherapeutic target. Moreover, AXL expression was associated with disease severity, infectious complications and death indicating its potential value as prognostic marker of cirrhosis.

Paired-Cell sequencing reveals global transcriptional zonation of liver non-parencymal cells

K.B. Halpern[1], S. Itzkovitz[1], R. Shenhav[2]. *[1]Weizmann institute of Science, Israel, Rehovot, Israel; [2]Weizmann Institute of Science, Israel*
Email: kerenb@weizmann.ac.il

Background and Aims: The mammalian liver consists of millions of hexagonal-shaped lobules that are polarized by morphogens and blood-borne factors. The liver lobule is comprised of hepatocytes and

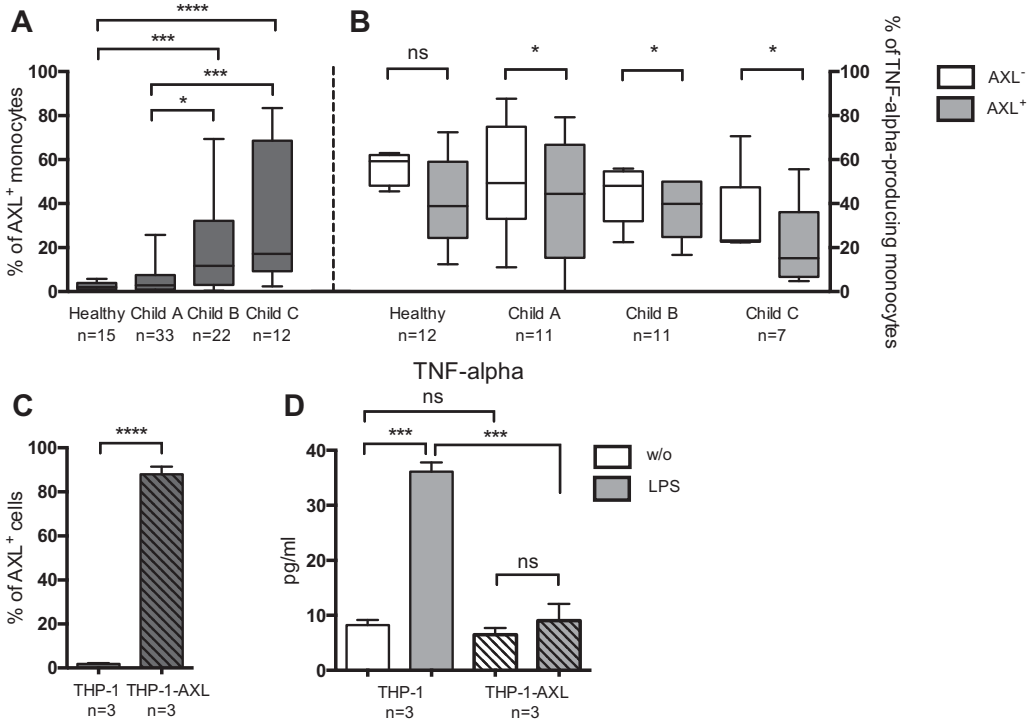

Figure: (abstract: SAT-019).

several types of non-parenchymal cells (NPCs), including endothelial cells and kupffer cells. We have recently applied spatially resolved single cell transcriptomics to reconstruct the global zonation patterns of hepatocyte genes, however it is unclear if NPCs exhibit similar spatial heterogeneity.
Method: To address this, we combined single cell RNAseq of NPCs with paired-cell sequencing of hepatocytes dissociated together with attached NPCs.
Results: We used the hepatocyte genes to infer the radial coordinate of each cell pair, yielding spatial reconstruction of NPC genes. We found a broad zonation in the expression patterns of NPCs and identified a robust expression signature for the pericentral endothelial cell niche.
Conclusion: Our approach can be used to reconstruct spatial expression maps of non-parenchymal cells in other tissues.

Secreted ectodomain of SIGLEC-9 and MCP-1 ameliorate acute liver failure in rats by altering bone marrow macrophage polarity
T. Ito[1], M. Ishigami[1], A. Yamamoto[2], Y. Ishizu[1], T. Kazuya[1], T. Honda[1], K. Hayashi[1], T. Ishikawa[1], Y. Hirooka[1], H. Goto[1]. *[1]Nagoya University Graduate School of Medicine, Department of Gastroenterology and Hepatology, Nagoya, Japan; [2]Tokushima University Graduate School, Department of Oral histology, Institute of Biomedical Science, Tokushima, Japan*
Email: tahkun56@gmail.com

Background and Aims: Acute liver failure (ALF) induces a poorly controlled inflammation, extensive hepatic destruction, and leads to multiple organ failure and sudden death. We previously reported that an intravenous administration of serum-free conditioned medium from stem cells derived from human exfoliated deciduous teeth (SHED-CM) improves the liver injury in the D-galactosamine (D-Gal)-induced rat ALF model. Furthermore, we recently revealed that a set of specific anti-inflammatory/tissue-regenerative macrophage (Mφ) inducers, monocyte chemoattractant protein-1 (MCP-1) and the secreted ectodomain of sialic acidbinding Ig-like lectin-9 (sSiglec-9), identified from SHED-CM ameliorates rat ALF. However, the detailed mechanism to activate intrahepatic Mφ by these two proteins is unclear. Therefore, we investigated the mechanism of MCP-1/sSiglec-9 treatment in this study.
Method: Rat ALF was induced by intraperitoneal injection of D-gal. 24-hours after D-Gal injection, MCP-1/sSiglec-9 with/without $CD206^{+}$Mφ-depletion reagent (mannosylated clodronate liposomes, m-Clodrosome), or PBS, was injected into the tail vein. We assessed serum transaminase levels, liver histopathology, and gene expression with real time RT-PCR. In addition, bone marrow Mφ or resident Kupffer cells of rat were isolated in vitro. Theses cells' morphologies and mRNA expression were examined, and proteins of these supernatants were measured by ELISA.
Results: We found that an intravenous injection of MCP-1/sSiglec-9 markedly decreased the AST and ALT levels ($p < 0.05$), and suppressed the hepatic inflammation and destruction. Conversely, treatment with m-Clodrosome abolished the MCP-1/sSiglec-9-mediated recovery from ALF. mRNA levels of anti-inflammatory markers, IL-10, Arginase-1, Ym-1 and TGF-β, were significantly elevated in MCP-1/sSiglec-9 group ($p < 0.01$), but not treatment with m-Clodrosome group. In addition, MCP-1/sSiglec-9 promoted M2-like differentiation of bone marrow-derived Mφ in vitro. However, these proteins had no effect on resident Kupffer cells. The CM from MCP-1/sSiglec-9-activated bone marrow-derived Mφ showed higher concentration of HGF compared with control.
Conclusion: The unique combination of MCP-1/ sSiglec-9 ameliorates rat ALF through the induction of anti-inflammatory/tissue-repairing macrophages, mainly induced from bone-marrow cells, not resident Kupffer cells.

SAT-022
Elevated programmed death ligand 2 (PDL2) in macrophages of BALB/c mice model of liver fibrosis associated with decreased CD80 and IL12 expressions
J. Amer[1], W. Basha[1], S. Hattab[2]. *[1]An Najah National University, Faculty of Medicine and Health Sciences, Nablus, Palestine; [2]An Najah National University, Faculty of Medicine and Health Sciences, Jerusalem, Palestine*
Email: j.amer@najah.edu

Background & Aims: BALB/c mice have been shown to easily induce Th2 type responses in several infection models. Certain macrophage phenotypes contribute to liver fibrosis. Upon injury the changing tissue microenvironment alters their phenotype and primes infiltrating monocytes toward pro-inflammatory macrophages. Here, we characterized changes in macrophages phenotype (M1/M2) during fibrogenesis in a mice model of liver fibrosis.
Methods: Carbon-tetrachloride (CCl_4) hepatic-fibrosis was induced in Balb/c-mice for 4 weeks through i.p injections/2x week. Along 1th to 4th weeks liver macrophages were isolated and were identified by the flow cytometry as CD45+/CD16+/CD68+. M1/M2 model of macrophage polarization was determined by CD80/CD273 (programmed death ligand 2 (PDL2)), respectively. Liver proteins were quantified for αSMA expressions by western blot and RT PCR, respectively. Livers were also assessed histologically and serum ALT levels were estimated.
Results: Hepatic fibrosis were gradually increased along 4 weeks injections of CCl_4 as indicated by serum ALT levels and αSMA expressions ($p < 0.02$) as well as H&E staining of liver necro-inflammatory lesions. These results were associated with increase in liver CD273 (M2 macrophage subpopulation) expressions (from 20.1% ± 3.1in naïve mice to 27.8% ± 3.2 in fibrotic mice; $p = 0.01$), however, no significant changes were observed between the mice groups of the different changes in fibrosis severity. On the other hand, gradual decrease in CD80 expressions (M2 macrophage subpopulation) were seen along fibrosis progressions (From 12% ± 6.2 in naïve mice to 1.97% ± 0.4 in fibrotic mice; $p < 0.02$). The overall data showed a decrease in M1/M2 macrophage ratio in BALB/c mice model of liver fibrosis indicating a reduced differentiation of M1 macrophages. These results were accompanied with inhibited expressions in M2 macrophages IFN-γ and IL-12 while high levels of TGF-β.
Conclusion: The known anti-inflammatory M2 macrophages were predominated prior and during liver injury. Although they were elevated by count during fibrosis, they secreted less IFN-γ and IL-12 which might indicate inability of differentiation of naïve T cells into Th1 cells. Our data could suggest pro-fibrotic role of M2 macrophages through their productions of TGF-β with reduced M1 pro-inflammatory macrophages.

SAT-023
WISP1: A novel key protein in acute liver damage
D. González, G. Campos, K. Rochlitz, J.G. Hengstler, P. Godoy. *IfADo-Leibniz Research Centre for Working Environment and Human Factors at the Technical University Dortmund, Toxicology, Dortmund, Germany*
Email: gonzalez@ifado.de

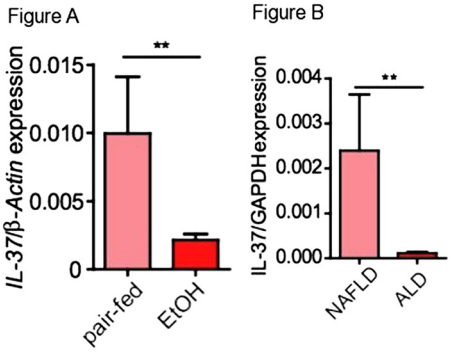
Background and Aims: Matricellular proteins from the CCN family have emerged as multitasking intermediators and have been shown to play different roles in liver pathophysiology. These highly conserved secreted proteins specifically interact with and signal through various extracellular partners, in particular integrins, which enable them to play crucial roles in various processes including development, angiogenesis, wound healing and diseases such as fibrosis and cancer. We have discovered that WISP1 (Wnt-induced secreted protein-1) also named CCN4, is induced upon intoxication and may play a protective role in liver pathophysiology. Furthermore, deletion of WISP1 leads to increased damage after acute liver injury by the hepatotoxicant CCl_4 compared with their wild type counterparts. In this context, we aim to understand how WISP1 might be

playing its hepatoprotective role studying WISP1 knock out (KO) mice.
Method: To establish the role of WISP1 in acute liver damage we used a knockout mouse model and we performed a time course after CCl_4 intoxication (460 mg/kg, i.p.) by collecting liver tissue at 30 min, 2 h, 8 h, 12 h, 18 h, and day 1. Damage was analyzed by necrotic area in hematoxylin & eosin staining and by transaminase activity. Different signal pathways were asses by western blot and the inflammatory state by real-time PCR of different cytokines and by immunostaining to detect immune cell infiltration. Re-introduction of WISP1 in KO mice was done by using a recombinant adeno-associated viral vector serotype 8. Different liver cell isolation was done using magnetic beads and macrophage depletion was performed by clodronate liposomes.
Results: Deletion of WISP1 led to a significant increase of necrotic area at d1 reaching 49% in KO vs 27% in WT mice. Importantly WT and WISP1 KO mice showed no significant differences in CYP2E1 expression, suggesting that the difference in tissue injury does not depend on alterations of CCl_4 metabolism in KO mice. Western blot analysis showed marked alterations in signal transduction pathways in liver tissue of WISP1 KO mice, with stronger activations of p-JNK at 2 h and p-STAT3 at 18 h and day 1. Furthermore, deletion of WISP1 leads to higher expression of inflammatory cytokines such us TNF and IL-6 and immune cell infiltration at 18h. Re-expression of WISP1 in WISP1 KO hepatocytes did not rescue the phenotype maybe due to the non-detectable WISP1 secretion in plasma. Liver cells isolation and WISP1 expression analysis showed a higher expression of WISP1 in liver sinusoidal endothelial cells and Kupffer cells compared to hepatocytes, supporting that hepatocytes are not the main source of WISP1 and non-parenchymal cells may play an important role in WISP1 expression-function in liver damage.
Conclusion: In conclusion, WISP1 is an interesting novel target in acute liver damage but further investigation is still need it.

SAT-024
Ethanol dampens IL-37 expression in liver tissue

F. Grabherr, G. Christoph, T. Adolph, V. Wieser, L. Mayr, M. Sangineto, S. Macheiner, A. Viveiros, H. Zoller, A. Moschen, H. Tilg. *Medical University Innsbruck, Department of Internal Medicine I, Gastroenterology, Endocrinology & Metabolism, Innsbruck, Austria*
Email: felix.grabherr@student.i-med.ac.at

Background and Aims: Hepatic inflammation is a driving force in alcoholic liver disease (ALD). Interleukin-37 (IL-37) is an anti-inflammatory member of the IL-1 family. It was described that IL-37 exerts this anti-inflammatory effects in hepatic diseases, however it is not known if IL-37 has an impact on ALD. In this study, we addressed the role of IL-37 in ALD.
Method: To address if IL-37 plays a role in the development of ALD we used IL-37 expressing transgenic mice and human recombinant IL-37 in different models of alcoholic liver disease, additionally *IL-37* expression was measured in liver samples of patients suffering from alcoholic steatohepatitis and of non-alcoholic fatty liver disease patients.



Results: IL-37 tg mice are not protected against hepatic injury and inflammation in experimental models of ALD. *IL-37* expression was suppressed in IL-37 transgenic mice (Figure A). Patients with ASH exhibited similarly reduced *IL-37* expression when compared to NAFLD patients (Fig. B). In a murine binge drinking model of ALD human recombinant IL-37 ameliorated hepatic inflammation.
Conclusion: We provide evidence for an exogenous noxae that suppresses Interleukin 37 expression which limits its anti-inflammatory effects in alcoholic liver disease.

SAT-025
Serum CXCL14 chemokine as a biomarker during murine acute and chronic hepatitis

C. Devisme, V. Carriere, V. Genet, M. Farooq, J. Le Seyec, C. Piquet-Pellorce, M. Samson. *IRSET - U.1085 Inserm, Rennes, France*
Email: michel.samson@univ-rennes1.fr

Background and Aims: Inflammation of liver is characterised by immune cells recruitment and release of chemokines. CXCL14, also called BRAK (breast and kidney cancer), is a chemokine poorly studied due to lack of knowledge of its specific receptor. In hepatic field, an up-regulation of CXCL14 mRNA has been reported in CCL4-induced liver injury in mice. However no information about the CXCL4 protein is announced. We aim to study the expression of CXCL14 protein in hepatitis developing murine models.
Method: We develop various *in vivo* models in C57Bl/6 mice: Concanavalin A-induced and murine hepatitis virus type 3 (MHV-3)-induced acute hepatitis, CCL4-induced chronic hepatitis and High Fat Diet-Induced chronic non-alcoholic steatohepatitis (NASH). Furthermore, we perform primary mouse hepatocytes (PMH) culture infected or not by MHV3 during 4 hours. ELISA, RT-qPCR, AST/ALT measurements, histology have been performed. Comparisons of parameters between two different groups were analysed by the Student t-test.
Results: Level of CXCL14 in sera of mice with acute and chronic hepatitis is increased in comparison with untreated mice. This is correlated with the increase of AST/ALT. In acute hepatitis induced by MHV3 infection, plasmatic concentration of CXCL14 is ≈10 000 pg/mL at 72 hours post-infection. Same results are observed in other acute hepatitis model as ConA administration. In chronic CCL4-induced hepatitis, serum CXCL14 concentration is ≈1000 pg/mL and remains constant during treatment. Beside, level of CXCL14 is not correlated with the progression of fibrosis, as observed by Sirius red labelling.
We found that infection of primary mouse hepatocytes by MHV3 did not induce CXCL14 mRNA expression but the lysis of MHV3 infected PMH allows a release of CXCL14 in conditioned media at 48 hours post-infection.
Conclusion: Our *in vivo* data show that CXCL14 chemokine is released in sera during acute and chronic hepatitis in mice. We show that hepatocytes could be a source of CXCL14 since virus-infected hepatocytes release CXCL14. CXCL14 is therefore a new biomarker linked to hepatitis, and could be involved in the development of the liver diseases.

SAT-026
Autophagy-related liver enzymes in chronic liver disease

G. Notas[1], D. Samonakis[2], M. Koulentaki[3], I. Voumvouraki[3], E. Kouroumalis[4]. *[1]University of Crete Medical School, Laboratory Medicine, Heraklion, Greece; [2]University Hospital of Heraklion, Dept of Gastroenterology, Heraklion, Greece; [3]University Hospital, Gastroenterology, Heraklion, Greece; [4]University of Crete Medical School, Gastroenterology, Heraklion, Greece*
Email: kouroumi@uoc.gr

Background and Aims: Autophagy, the fusion of phagosomes with lysosomes is an important mechanism in hepatic homeostasis. Abnormalities of this process are associated with liver diseases,

particularly non alcoholic steatohepatitis. Autophagy in other chronic liver diseases has not been adequately studied. Therefore the aim of the study was the quantification in liver tissue from chronic liver disease patients of the vital for normal autophagy enzyme cathepsin B1 and two lysosomal acid hydrolases, Cathepsin D and acid Lipase.

Method: We studied liver biopsy tissue from 18 patients with Primary Biliary Cholangitis (PBC) (16 females, 7 early stages I-II and 11 late stages III-IV) 34 with Alcoholic Liver Disease (14 Fatty Liver, 8 steatohepatits and 12 cirrhotics) and 13 patients with chronic viral hepatitis (CH). Controls were 5 patients with a normal liver biopsy.

Enzyme substrates were: a-N-benzoyl-DL-arginine 2-naphtylamide for cathepsin B1, 14C haemoglobin for cathepsin D and methyl umbelliferone oleate for acid lipase.

One-way Anova with Dunn post-hoc test was used for statistical analysis.

Results: Cathepsin B1 activity was significantly increased in early PBC (252 ± 65 ng/mg Protein/min^{-1}, $p < 0.01$) and reduced in late stages (70 ± 14. $p < 0.01$) compared to the normal liver (128 ± 13). It was also reduced in alcoholic steatohepatitis and cirrhosis (90 ± 12 $p < 0.05$ and 75 ± 17 $p < 0.05$ respectively) but not in CH (130 ± 45). Cathepsin D activity was increased in early PBC ($38.2 \pm 4.8.10^3$ $p < 0.001$) and less so in late stages (18.9 ± 1.4 $p < 0.05$), compared to controls (13.1 ± 2.2). It was also significantly increased in the presence of histological necroinflammation (Alcoholic hepatitis: $24.5.10^3$ dpm/mg Protein/hr^{-1}, $p < 0.01$, active alcoholic cirrhosis: 20 ± 3.6, $p < 0.05$, CH: 27.5 ± 6.8, $p < 0.01$) compared to both normal liver and inactive alcoholic cirrhosis (12.8 ± 4.5). Acid lipase activity changes paralled those of Cathepsin B1.

Conclusion: (1) A reduction of Cathepsin B1, a vital autophagic enzyme is associated with fibrosis in parallel with Acid Lipase in patients with chronic liver disease, possibly indicating a defective autophagy during the fibrotic process (2) The highly increased activity levels in early PBC might indicate an overactive autophagic process early in this autoimmune disease (3) The acid protease Cathepsin D is probably involved with the development of necroinflammation.

Email: olga.kuchuk@mssm.edu

Background and Aims: Hepatoblastoma (HB) is the most common primary liver cancer in pediatric patients. Surgery and chemotherapy are the mainstay therapies. No molecular targeted therapy is available for tumors at advanced stages. Thus, the identification of actionable drivers is an unmet medical need. Here, we aimed to identify the most prevalent targetable drivers in HB and evaluate therapeutic potential of precision therapies.

Method: Tumors and paired non-tumor (NT) tissues from 32 HB patients were profiled by RNA-seq and gene copy number (GCN) analysis to define the top disrupted signaling pathways. Levels of *IGF2* mRNA transcripts derived from adult (*P1*) or fetal (*P3*) promoters, *IGF1R,* and *H19* expression were assessed by RT-qPCR in human tissues and cell lines. Survival of HepG2 and HUH6 HB cells was tested *in vitro* in presence of xentuzumab, an anti-IGF1/2 monoclonal antibody.

Results: Transcriptomic analysis of HB samples revealed deregulation of multiple signaling networks, being protein ubiquitination, immune signaling and IGF pathway (FDR = 0.001) among the top ones. RT-qPCR confirmed overexpression of *P3* (>20 fold-change (FC), 78%) and *IGF1R* (5 FC, 41%), and down-regulation of *P1* (96%) and *H19* (78%) about 15 FC in HB vs NT ($p < 0.001$). GCN analysis showed allelic imbalance of a minimal region of 3.9Mb at 11p15 region, encoding for IGF2, H19, and imprint controlling regions, in 42% of HB. Epigenetic analysis of the remaining HB samples revealed hypermethylation of *P1* in 78% and hypomethylation of *P3* in 36% compared to NT. No changes in methylation were observed in 14% of HB vs NT. These results suggest a double mechanism of IGF signaling upregulation due to aberrant methylation of IGF2 promoters and allelic imbalance. HepG2 and HUH6 recapitulated the expression profile of HB tumors overexpressing *P3* and *IGF1R* (both >55 fold-change) and down-regulating *H19.* None of the cell lines expressed *P1.* Treatment with xentuzumab decreased viability of HepG2 and HUH6 to 66% ($p = 0.01$) and 77% (ns), respectively. Moreover, it reduced the amount of HepG2 colonies to 26% ($p < 0.0001$). At the protein level, xentuzumab blocked IGF1R phosphorylation preventing activation of the pathway without interfering with insulin receptor-metabolic effects.

Conclusion: IGF2 is overexpressed in 78% of HB tumors, either as a result of allelic imbalance or aberrant methylation. In experimental studies, targeted blocking of IGF1/2 with xentuzumab had potent antiproliferative effects on HB cells. Further *in vivo* studies are currently ongoing to assess the anti-cancer efficacy of xentuzumab.

SAT-028

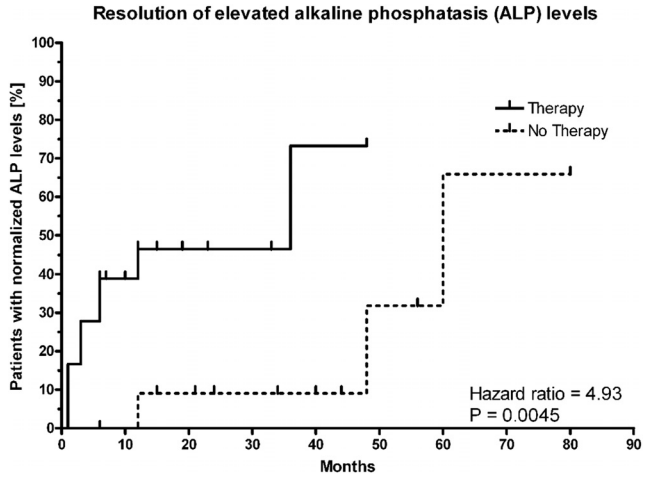
Clinical presentation, natural history and treatment of hepatic sarcoidosis: A case-series of 39 patients with histologically proven hepatic sarcoidosis

M. Wehmeyer[1], J. Lutz[1], J.S.Z. Wiesch[1], A.W. Lohse[1], C. Schramm[1,2], M. Sebode[1]. *[1]University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Martin Zeitz-Centre for Rare Diseases*
Email: m.wehmeyer@uke.de

Background and Aims: Sarcoidosis is a multisystem-disease of unknown origin with possible liver involvement. The aim of our study was to describe the natural history, effect of therapy and predictors of liver related morbidity in patients with hepatic sarcoidosis.

Method: In total, 39 patients with hepatic sarcoidosis underwent liver-biopsy between January 2009 and October 2017 at our center. Clinical and laboratory parameters at the time of biopsy were analyzed by univariate analysis to identify risk factors for hepatic fibrosis or cirrhosis. The course of the liver enzymes until October 2017 was compared between patients who received treatment for

sarcoidosis and untreated patients. The endpoint were normalized liver enzyme levels (AST, ALT, gGT, ALP) during follow-up.
Results: The mean age of patients was 44 years, 72% were male (n = 28), 46% had no fibrosis (F0; n = 18), 39% had F1 fibrosis (n = 15), 5% F2 fibrosis (n = 2) and 10% had cirrhosis (F4; n = 4). Pulmonary sarcoidosis was present in 31 patients, peritoneal and splenic sarcoidosis could be diagnosed in 7 patients, each. Patients with cirrhosis were older (mean age 62 years vs. 42 years; p < 0.001) and had a higher AST/ALT-ratio (median AST/ALT-ratio 1.24 vs. 0.67; p = 0.005) than non-cirrhotic patients. AST, ALT, gGT and ALP levels did not correlate with the degree of fibrosis. The AST/ALT-ratio (r = 0.519; n = 0.001), but not the APRI-score (r = 0.135; n = 0.413) correlated with the degree of fibrosis. Follow-up data were available of 11 patients who never received treatment, 8 patients who started treatment during follow-up and 15 patients who started treatment after biopsy. 20/23 patients received steroids ± MTX/azathioprine ± ursodeoxycholic acid (UDCA) and 3 patients where treated with UDCA alone. The median follow-up time was 22 months (no therapy; range 6-99) and 23 months (with therapy; range 6–94). 18 patients without therapy and 18 patients with therapy had an elevated ALP at baseline or before initiation of therapy (median AP 207 and 212U/l). 3 patients without therapy and 8 patients who received treatment achieved normalized ALP-levels during follow-up (p = 0.005; Figure 1).



Conclusion: Hepatic sarcoidosis can lead to fibrosis and cirrhosis in a relevant number of patients. The AST/ALT-ratio was superior to other laboratory tests to identify patients with cirrhosis. Immunosuppressive treatment may lead to a biochemical remission in a considerable proportion of patients.

SAT-029

Upregulation of miR-34c driven by JNK and FOXO3 in livers expressing mutant Z alpha1-antitrypsin

P. Piccolo[1], A. Barbato[1], F. Borel[2], P. Annunziata[1], S. Attanasio[1], R. Ferriero[1], A. Carissimo[3], S. Campione[4], L. Quagliata[5], L.M. Terracciano[5], J. Teckman[6], C. Mueller[7], N. Brunetti-Pierri[1,8].

Email: piccolo@tigem.it

Background and Aims: The deficiency of α1-antitrypsin (AATD) affects ~1 in 3,000 live births and present with lung and liver disease. The common and severe Z allele of α1-antitrypsin (ATZ) causes the protein to form polymers that are retained within the endoplasmic reticulum of hepatocytes. Accumulation of the mutant protein causes liver damage, cirrhosis, and hepatocellular carcinoma (HCC) whilst the lack of circulating α1-antitrypsin predisposes to early onset emphysema. MiRNAs play key roles in a wide range of biological processes and their expression is affected in several liver diseases. Alterations of miRNA expression have not been investigated so far in AAT liver disease. We hypothesized that miRNAs play a role in the pathogenesis of the liver disease. Moreover, the identified miRNAs may inform novel therapeutic targets and disease biomarkers.
Method: Transgenic PiZ mice have been genetically engineered to express ATZ and have been a valuable experimental model for liver disease due to AAT polymerization. In these mice we studied liver miRNA expression by next generation sequencing (NGS). In vivo ATZ silencing and Laser Controlled Microdissection (LCM) were used to correlate ATZ load with miR-34c expression. PiZ/*Jnk1*$^{-/-}$ mouse was generated to investigate miR-34c regulation by JNK/FOXO3 axis. Human liver specimens from AATD patients and controls were used to assess the clinical relevance of our findings.
Results: A comprehensive analysis of liver miRNome revealed a set of miRNAs with differential expression between control and PIZ mice expressing ATZ. Among these, miR-34c was strongly upregulated and its levels correlated with the levels of intrahepatic ATZ. Expression of miR-34c is driven by Forkhead box O3 (FOXO3) and mechanistically, we found that FOXO3 activation and miR-34c upregulation were dependent upon c-Jun N-terminal kinase (JNK) phosphorylation on Ser574 residue. FOXO3 activation was lost in HCC of mice expressing ATZ. Liver specimens from AATD patients revealed the same alterations in JNK/FOXO3/miR-34c pathway found in mice.
Conclusion: Our study unravels novel insights on the pathogenesis of liver disease and HCC due to ATZ and provides a set of clinically relevant data for the development of disease biomarkers that are highly needed for AATD.

Email: christophe.corpechot@aphp.fr

Background and Aims: Diagnostic criteria of low-phospholipid associated cholelithiasis (LPAC) syndrome have been defined from very limited populations of patients and controls (Rosmorduc et al. 2003). These criteria mostly rely on the recurrence of biliary pain after cholecystectomy while surgery could be avoided if diagnosis was made earlier. Furthermore, they were originally established to predict ABCB4 alteration that is absent in more than half of patients. At last, the prevalence of the syndrome is unknown. Our primary aim was therefore to refine the diagnostic criteria of LPAC syndrome from

large populations of patients and controls, regardless of ABCB4 status. Our secondary aim was to estimate the frequency of the syndrome among patients with symptomatic cholelithiasis.
Method: This retrospective case-control study included all patients diagnosed with LPAC syndrome based on original criteria in 4 French centers (one referral center and 3 general hospitals). Patients who underwent cholecystectomy for classical gallstone disease in a general hospital served as controls. A multivariate logistic regression model adjusted on age, sex, body mass index, and metabolic syndrome was used to identify the variables independently associated with LPAC syndrome. A diagnostic score was developed and validated. Patients were compared according to ABCB4 mutation status. Frequency of LPAC syndrome was estimated based on the number of all patients cholecystectomized for gallstones during the same period.
Results: 512 adult patients (306 cases, 206 controls) were included. In addition to the 3 previously established criteria (age at first symptoms <40; recurrence of symptoms after cholecystectomy; ultrasound signs of intrahepatic microlithiasis), 2 new criteria were identified: (1) features suggestive of common bile duct lithiasis, (2) lack of cholecystitis evidence. The new score had a high diagnostic performance (c-statistic: 0.99). ABCB4 mutation was present in 43% of LPAC patients. These patients had an increased risk of intrahepatic cholestasis of pregnancy (ICP; 34% vs. 17%), chronic elevation of GGT (33% vs. 14%) and transaminases (16% vs. 8%), history suggestive of common bile duct lithiasis (80% vs. 68%), and personal or familial history of primary liver cancer (6% vs. 1%). One (1.5%) out of 68 controls who had an expert ultrasound focused on signs of intrahepatic microlithiasis showed typical features of LPAC syndrome. In line with this, the frequency of LPAC syndrome within all patients with symptomatic cholelithiasis varied from 0.5% to 1.9%.
Conclusion: Common bile duct stone in young patients with no prior history of cholecystectomy should suggest LPAC syndrome. LPAC patients with ABCB4 alteration seem more exposed to the risk of ICP, chronic cholestasis, and personal or familial primary liver cancer. LPAC syndrome represents about 1% of patients with symptomatic cholelithiasis.

SAT-032

Role of alpha-1 antitrypsin genotypes in the progression of adult liver disease

Background and Aims: Alpha-1 antitrypsin deficiency (A1AD) is an autosomal codominant disease associated with an increased risk of liver and lung disease in adults. The association between liver disease and homozygosity for the mutant Z allele (PiZZ) is well-established, however, the contribution of other genotypes to the pathogenesis of adult liver disease is unclear. We aimed to assess the prevalence of liver fibrosis in different A1AD genotypes, including rare variants.
Method: Multicenter cross-sectional case-control study, including adult A1AD patients treated in pneumology departments of four Portuguese academic and one non-academic centers. Data pertaining pulmonary function and imaging were retrospectively collected. Clinical, biochemical, and liver stiffness (LS) measured by transient elastography (TE, Fibroscan) data were prospectively collected at time of enrollment. Significant liver fibrosis was defined by LS values ≥7.0 kPa. Patients with concomitant liver diseases were excluded. Controls were recruited within a prospective epidemiological study in the general adult population.
Results: 142 cases and 200 controls were included. Our study comprised 47 PiZZ, as well as 76 PiZ heterozygotes (38 MZ, 34 SZ, 3 MheerlenZ, 1 ZQ0s), 10 PiS (5 SS, 5 MS), and 9 PiMmalton or PiMpalermo carriers. Cases and controls did not differ in terms of age, BMI, alcohol consumption, serum lipid levels, or CAP. Cases had significantly higher serum levels of ALT, AST and GGT ($p < 0.0001$) compared to controls. CAP values were higher in A1AD patients but the difference did not attain statistical significance ($p = 0.114$).
LS was 5.2 ± 1.5 kPa in controls and 6.0 ± 4.1 kPa in A1AD ($p = 0.046$) being highest in PiZZ (7.3 ± 5.3 kPa) and PiZ heterozygotes (5.7 ± 3.6 kPa). Liver fibrosis was detected in 20% (29/142) of patients. The genotype-specific prevalence was: PiZZ 34%(16/47), PiZ- 16%(12/76), while none of the PiS carriers had significant liver fibrosis. Among patients with rare A1AD variants, one PiMmalton/PiMmalton had significant liver fibrosis. Liver fibrosis was statistically significantly associated with lower alpha-1 antitrypsin ($p < 0.0001$) and higher total cholesterol ($p = 0.024$). Importantly, only 18% (26/142) of patients with liver fibrosis had abnormal liver tests.

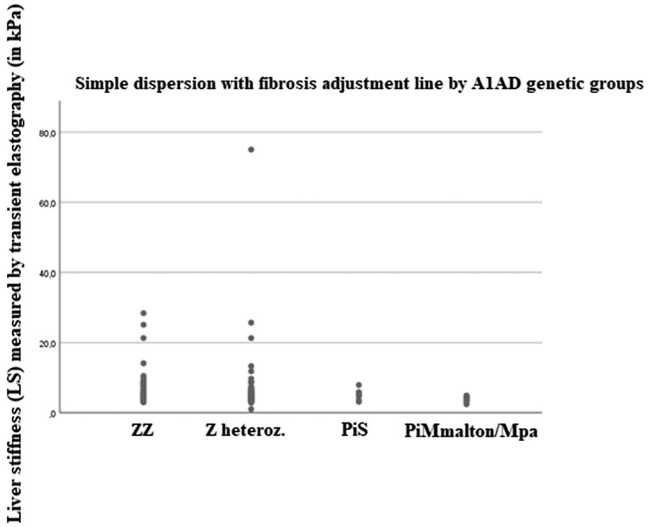

Figure 1: Liver fibrosis by alpha-1 antitrypsin deficiency genetic group.

Conclusion: Akin to PiZZ, PiZ heterozygoty is associated with liver fibrosis development. Moreover, our results suggest that rare A1AD variants may also promote liver fibrogenesis. Routine laboratory tests are not predictive of significant liver fibrosis, highlighting the need for non-invasive methods such as TE in patients with A1AD.

SAT-033

Genetic ablation of CHOP decreases hepatic accumulation of mutant Z alpha1-antitrypsin

S. Attanasio[1], R. Castello[2], N. Pastore[2], P. Piccolo[1], N. Brunetti-Pierri[1,3].
[1]*Telethon Institute of Genetics and Medicine, Pozzuoli (NA), Italy, Molecular therapy, Pozzuoli (NA);* [2]*Telethon Institute of Genetics and Medicine, Pozzuoli (NA), Italy, Scientific Office, Pozzuoli (NA), Italy;* [3]*University of Naples "Federico II", Department of Translational Medicine, Napoli, Italy*
Email: s.attanasio@tigem.it

Background and Aims: Alpha1-antitrypsin deficiency (AATD) is one of the most common genetic disorders resulting in lung and liver diseases. The vast majority of patients carry the Z mutation in the serine protease inhibitor 1A (*SERPINA1*) gene that results in a single glutamic acid to lysine substitution at amino acid position 342. The mutant Z alpha1-antitrypsin (ATZ) accumulates in the endoplasmic reticulum (ER) of hepatocytes resulting in liver disease that is a prototype of conformational disorder due to protein misfolding and protein aggregation. Although ATZ accumulation causes ER stress, the role of unfolded protein response (UPR) has been controversial in the last years. The aim of this study is to investigate the role of the transcription factor CHOP in the pathogenesis of liver disease due to ATZ accumulation.
Method: We used as mouse model the transgenic PiZ mice, genetically engineered to express the human ATZ. We generated PiZ/*Chop*$^{-/-}$ mouse and we investigated ATZ levels by ELISA, periodic acid–Schiff diastase-resistant (PAS-D) staining, immunofluorescence and qPCR.
Results: By expression array profiling of livers of PiZ mice, we previously found upregulation of genes associated with response to unfolded proteins, ER nuclear signaling pathway, and response to protein stimulus. Among the differentially expressed genes, we focused on *Chop* that was significantly upregulated in both mouse and human livers expressing ATZ. To investigate the role of CHOP in ATZ-induced liver damage, we crossed PiZ with *Chop*$^{-/-}$ mice to generate PiZ/*Chop*$^{-/-}$ mice. PiZ/*Chop*$^{-/-}$ mice exhibited marked reduction of PAS-D-positive globules compared to PiZ/*Chop*$^{+/+}$ control mice. *SERPINA1* mRNA levels in livers of PiZ/*Chop*$^{-/-}$ mice were also significantly reduced compared to PiZ controls suggesting that CHOP induces ATZ accumulation by increasing *SERPINA1* transcription.
Conclusion: The transcription factor CHOP has been involved in the pathogenesis of several liver disorders but not in hepatic disease induced by ATZ. The results of this study suggest that the CHOP is an important player in the disease pathogenesis and is a therapeutic target for correction of the liver disease due to ATZ expression.

Etiology of splanchnic vein thrombosis in 812 chinese patients from a single center

J. Fan[1], Q. Wang[1], H. Chen[1], J. Niu[1], B. Luo[1], J. Yuan[1], C. He[1], W. Bai[1], W. Guo[1], J. Tie[1], K. Li[1], X. Yuan[1], T. Yu[1], Z. Wang[1], Y. Zhu[1], N. Han[1], X. Li[1], Y. Lv[1], H. Liu[1], E. Wang[1], D. Xia[1], L. Liu[1], L. Zuo[1], Z. Yin[1], D. Fan[2], G. Han[1].
[1]*National Clinical Research Center for Digestive Disease and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Liver Disease and Digestive Interventional Radiology, Xi'an;* [2]*National Clinical Research Center for Digestive Disease and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, State Key laboratory of Cancer Biology, Xi'an, China*
Email: hangh@fmmu.edu.cn

Background and Aims: In western countries, both inherited and acquired prothrombotic factors for splanchnic vein thrombosis (SVT), including Budd-Chiari syndrome (BCS) and portal vein system thrombosis (PVT), have been identified. These prothrombotic factors include factor V Leiden (FVL) mutation, prothrombin G20210A mutation, inherited antithrombin deficiency, inherited protein C or S deficiency, myeloproliferative neoplasms (MPNs), paroxysmal nocturnal haemoglobinuria (PNH), antiphospholipid syndrome (APS), etc, of which MPNs are the leading cause with a prevalence ranging between 20%–50%. However, the data regarding aetiological distribution in Chinese SVT patients are extremely limited. The aim of this observational study is to investigate the risk factors in chinese SVT patients systematically.
Method: Between July 1999 and July 2017, 985 patients with a diagnosis of non-malignant and non-cirrhotic PVT or primary BCS were consecutively admitted to our department. Since March 2012, all of these patients who were consecutively admitted to our department or regularly followed up were invited to participate in our study to evaluate the prothrombotic factors.
Results: A total of 812 patients with SVT were enrolled including 394 with PVT and 418 with BCS. Hepatic vein (HV)-type, combined-type and inferior vena cava (IVC)-type were involved in 114 (27%), 191 (46%) and 113 (27%) of these 418 patients with BCS. Among all of the 812 patients with SVT, FVL or prothrombin gene G20210A mutation, MPL mutation, JAK2 exon12 mutation, PNH and Systemic disorders were rarely observed and their prevalence ranged from 0 to 2%. Among patients with PVT, MPNs were diagnosed in 102 of the 361 patients tested (28.3%), in which the prevalence of JAK2V617F and CALR mutation were 22.9% and 3.5%, respectively. Among all of the patients with BCS, MPNs were diagnosed in only 24 of 384 patients tested (6.3%). However, in the subgroup of patients with HV-type of BCS, MPNs were diagnosed in 15 of the 51 patients confirmed by bone marrow biopsy and the prevalence of MPNs in HV-type was significantly higher than combined-type or IVC-type of BCS (29.4% vs 10.7% or 0%, $p < 0.001$).

Table. Prothrombotic Factors in Patients with different types of Budd-Chiari Syndrome.

Risk Factor	HV-type (n=114)	Combined-type (n=191)	IVC-type (n=113)	P-value
Local risk factor[&]	2/114(1.8%)	7/191(3.7%)	3/113(2.7%)	0.619
Inherited thrombophilia				
Protein C deficiency	10/107(9.3%)	10/183(5.5%)	8/107(7.4%)	0.451
Protein S deficiency	13/107(12.1%)	29/183(15.8%)	15/107(14.0%)	0.682
Antithrombin deficiency	0/107	4/183(2.2%)	2/107(1.9%)	0.318
Acquired thrombophilia				
MPN*	15/51(29.4%)	9/84(10.7%)	0/46	**<0.001**
JAK2V617F mutation	9/107(8.4%)	4/172(2.3%)	0/97	**0.002**
CALR mutation	1/60(1.7%)	4/101(4.0%)	0/61	0.242
APS	4/98(4.1%)	17/163(10.4%)	5/96(5.2%)	0.106
Hormonal risk factors#	3/55(5.5%)	5/97(5.2%)	4/41(9.8%)	0.570
Systemic disorder$	1/114(0.9%)	1/191(0.5%)	0/113	0.627
PNH	1/104(0.9%)	1/171(0.6%)	0/97	0.644

HV: Hepatic vein; IVC: Inferior vena cava; MPN: Myeloproliferative neoplasms; APS: Antiphospholipid antibody syndrome; PNH: Paroxysmal nocturnal hemoglobinuria.
[&] abdominal trauma, Intra-abdominal inflammation, infection, or abscess.
* All patients from the groups had a bone marrow biopsy to confirme MPN if JAK2V617F and CALR mutation were both negative.
# Oral contraceptive use or Pregnancy within 3 month before diagnosis.
$ Behcet disease, sarcoidosis, vasculitis, connective tissue disease or lymphoide hemopathy.

Conclusion: Our results confirm that, the same as in western countries, MPNs are the leading cause in HV-type of BCS or PVT but not in combined-type or IVC-type of BCS. However, unlike in western countries, other prothrombotic factors are rare in chinese SVT patients.

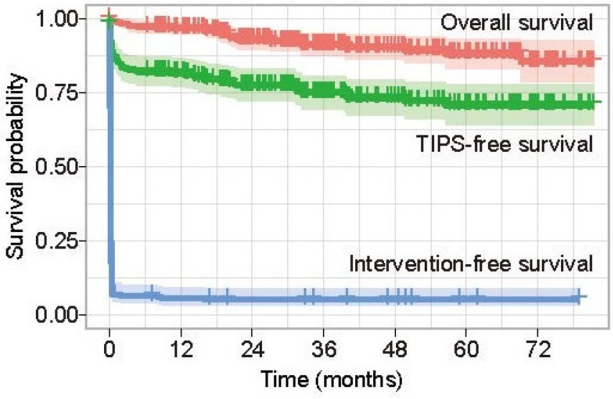
Email: machaelia@163.com

Background and Aims: A step-wise approach has proven to provide a good long-term outcome in European Budd-Chiari syndrome (BCS)

patients. We aimed to investigate whether Chinese BCS patients, with different constitutions of aetiology and obstruction types, would achieve favourable long-term outcome under this management strategy.

Method: From September 2010 to December 2016, 252 treatment-naïve BCS patients admitted to Xijing Hospital of Digestive Disease were included and prospectively followed-up. All patients received anticoagulation as soon as diagnosed, and membranous or short-length stenosis were addressed by angioplasty with or without stent placement. Patients who did not respond to these therapeutic models underwent transjugular intrahepatic portosystemic shunt (TIPS). No patient received orthotopic liver transplantation (OLT), and OLT-free survival was not analysed. Therefore, overall survival, TIPS-free survival and intervention-free survival were calculated with Kaplan-Meier method. Cox regression analysis was used to identify prognostic factors of overall survival in the entire cohort.

Results: During a median follow-up duration of 36.6 months (interquartile range, IQR: 20.5–58.9 months), a total number of 4 patients were lost to follow-up. Since no patients received OLT in the cohort, OLT-free survival was not calculated. The 1-year, 2-year and 5-year overall survival of the cohort were 96.8%, 92.9%, and 88% respectively. Specifically, the 1-year, 2-year and 5-year TIPS-free survival 81.7%, 77.4%, and 70.7% respectively, whereas only 6%, 5% and 5% patients were amenable to mere anticoagulation therapy at these time points. In univariate analysis, platelet count, total protein, albumin, total bilirubin, and creatinine were identified as prognostic factors, whereas in multivariate analysis, only total protein and creatinine were significant prognostic factors ($p < 0.05$).



Conclusion: Compared to previous reports from other regions, the step-wise strategy was not only applicable but could achieve better long-term outcome in Chinese BCS patients even without OLT. Mere anticoagulation provided survival benefits in only a small proportion of these patients. Moreover, unlike in European countries where TIPS played a more significant role, angioplasty with or without stents appear to contribute most in improving survival in current cohort.

SAT-036

Hepatic outcomes from childhood intestinal failure: A meta-analysis of 8223 patients

A. Pierret[1], J. Wilkinson[2], J. Mann[3]. *[1]University of Cambridge, Pharmacology Department, Cambridge, United Kingdom; [2]University of Cambridge, School of Clinical Medicine, Cambridge, United Kingdom; [3]University of Cambridge, Department of Paediatrics, United Kingdom*
Email: acsp4@cam.ac.uk

Background and Aims: Paediatric intestinal failure (IF) is usually congenital or acquired neonatally and may lead to IF-associated liver disease (IFALD). Due to improved neonatal care, the prevalence of IF is increasing. Understanding its natural history is vital for decisions regarding small bowel and liver transplant however, to date, cohort studies have primarily been from single centres and of small size. Therefore, we aimed to describe natural history of hepatic outcomes in childhood-onset IF.

Method: A MEDLINE search was performed using terms including: 'intestinal failure', 'parenteral nutrition (PN)', 'liver disease', and 'IFALD'. The inclusion criteria were: IF before 18 years, reporting of clinical outcomes (e.g. liver failure, death, transplant), and >12 months follow-up. IF was defined as PN dependence for at least two months. Studies were excluded if IF patients could not be separated from non-IF patients. Studies were grouped by patient cohort: IF or IFALD. Risk of bias was assessed using the ROBINS-I tool.

Results: 1,584 abstracts were screened, from which 148 patient cohorts were included with a total of 8,223 patients.

131 cohorts (7371 patients) with intestinal failure were identified, of which 51 cohorts (3156 patients) had defined follow up. Overall mortality was 0.16 (95% CI 0.13–0.20). 46.1% patients developed IFALD and 7.5% developed hepatic failure, of the 3683 and 1644 patients respectively in which data was available. 1.0% had an isolated liver transplant and 4% had combined liver-small bowel transplant. Overall native liver survival was 89%.

17 cohorts (852 patients) with IFALD were meta-analysed. Overall mortality was 0.21 (95% CI 0.12–0.30) at 1–3 years and 0.32 (95% CI 0.15–0.50) at 3–9 years. Leading causes of death were liver-related in 50% and sepsis in 35%. Isolated liver transplant was performed in 12.5%; therefore native liver survival was 77%. Patients with IFALD were born at a younger gestational age (32.4 vs. 33.6 weeks) and with lower birth weight (1725g vs 1948g) than those with IF. Small bowel length and presence of ileocaecal valve were not associated with IFALD.

Conclusion: IFALD is associated with high morbidity and mortality, though liver failure affects a minority of all patients with IF. Non-modifiable risk factors (gestational age and birth weight) influence liver-related outcomes.

SAT-037

Characteristics and outcomes of cystic fibrosis paediatric patients admitted with cirrhosis in the United States

R. Somayaji[1], M.G. Swain[2], M. Parkins[1], K. Ramos[3], C. Goss[3], A.-A. Shaheen[2]. *[1]University of Calgary, Cumming School of Medicine, Division of Infectious Diseases, Canada; [2]University of Calgary, Cumming School of Medicine, Gastroenterology and Hepatology, Canada; [3]University of Washington, Seattle, Department of Medicine, United States*
Email: azshaheen@me.com

Background and Aims: Cystic fibrosis (CF) is the most common fatal genetic disease of Caucasians. Although lung disease is the primary cause of mortality, CF liver disease (CFLD) is increasingly important due to improvements in survival, and is the third leading cause of death in CF patients. In this study, we defined the characteristics of pediatric CF patients admitted with a cirrhosis-related diagnosis and estimated predictors of in-hospital mortality and hospitalization outcomes.

Method: We used the 2012 **K**id's **I**npatient **D**atabase (KID) to identify cirrhosis-related hospitalizations among pediatric CF patients (age 0–20 years) in the USA. An admission was considered "cirrhosis" if a diagnosis of cirrhosis or cirrhosis-related complication was identified (based on ICD-9 codes). We compared demographic, socio-economic and clinical characteristics for CF patients (e.g. demographics, insurance status, and Elixhauser comorbidities) with and without a cirrhosis-related diagnosis. Adjusted multiple linear and logistic regression models were used to identify predictors of in-hospital mortality, LOS and hospitalization charges among CF patients with cirrhosis.

Results: Of the 10,256 pediatric CF hospitalizations identified in 2012, 555 (5.4%) were cirrhosis-related admissions. Compared with CF admissions without cirrhosis, patients with cirrhosis were older

(median age: 16 vs. 14; p < 0.001), more likely male (58.2% vs. 44.2%; p < 0.001), more likely to be admitted on weekend (13.3% vs. 10.6%; p = 0.04), and had ≥2 comorbid conditions (19.3% vs. 7.7%, p < 0.001). Among pediatric CF admissions with cirrhosis, 47.4% had esophageal varices, 15.0% had ascites, and 21.8% had a previous liver transplant. CF patients with cirrhosis had higher in-hospital mortality compared to CF patients without cirrhosis (2.0% vs. 0.6%, p < 0.001). Although LOS was similar between CF patients with and without cirrhosis (median LOS 8 days, p = 0.40), CF patients with cirrhosis had higher hospitalization charges compared to those without cirrhosis (median $66,543 vs. $53,365, p < 0.001). In our age and sex adjusted models, admission with ascites was the only independent predictor of in-hospital mortality (adjusted odds ratio (OR): 5.29, 95%CI: 1.67–16.1). Predictors of increased LOS among CF patients with cirrhosis were male sex, private insurance, having multiple comorbidities and ascites. Only ascites and having multiple comorbidities were independent predictors of increased hospitalization charges in CF patients with cirrhosis.

Conclusion: Pediatric CF patients with cirrhosis had greater in-hospital mortality compared to those without cirrhosis. Having ascites was the major independent predictor of in-hospital mortality, LOS and increased hospitalization costs. Future interventions should be designed to enhance care for pediatric patients with ascites.

SAT-038

Comparison between room-temperature susceptometry and MRI with respect to the cell-specific detection of liver iron

J. Mueller[1], H. Raisi[1], V. Rausch[1], D. Simons[2], C. Ziener[2], H.-P. Schlemmer[2], H. Seitz[1], B. Straub[3,4], N. Waldburger[4], S. Mueller[1].
[1]Salem Medical Center and Center for Alcohol Research and Liver Disease, Heidelberg, Germany; [2]Deutsches Krebsforschungszentrum, Radiology Dept., Heidelberg, Germany; [3]University of Mainz, Institute of Pathology, Mainz, Germany; [4]University of Heidelberg, Institute of Pathology, Heidelberg, Germany
Email: joh-mueller@gmx.de

Background and Aims: Liver iron not only accumulates in hemochromatosis but also in various chronic liver diseases such as HCV and ALD where it has been identified as an important prognostic and cancerogenic factor. Unfortunately, the non-invasive and cost-efficient assessment of liver iron is still insufficiently resolved. We here compare the non-invasive methods Room-temperature Susceptometry (RTS) and Magnetic Resonance Imaging (MRI) with the invasive liver biopsy and lab parameters and their association to the cellular distribution of iron in the liver tissue.

Method: 106 patients with various diseases such as alcoholic and non-alcoholic liver disease or hemochromatosis were prospectively enrolled. All 106 patients underwent liver biopsy with quantitative iron determination via atomic absorption spectroscopy (AAS) and blood serum markers such as serum ferritin were determined. In 78 patients liver iron was determined histologically by semi-quantitative Prussian Blue staining (grade 0–3). In 95 patients, liver iron concentration (LIC) was also determined by RTS and in 34 patients via MRI (1.5T Magnetom Aera, Software: LiverLab, Siemens).

Results: Both MRI and RTS correlated well with AAS with Pearson correlation coefficients of 0.75 ($p < 0.001$) and 0.48 ($p < 0.001$), respectively. AAS, MRI and RTS all correlated better with hepatocellular iron scores from Prussian Blue Staining than with RES-iron. The Spearman correlation coefficients with hepatocellular iron scores for AAS, MRI and RTS are 0.60 ($p < 0.001$), 0.62 ($p < 0.001$) and 0.55 ($p < 0.001$), respectively, and in comparison with RES-iron scores are $r = 0.47$ ($p < 0.001$), 0.26 ($p > 0.05$) and 0.48 ($p < 0.001$). Serum ferritin on the other hand correlated equally well with hepatocellular and RES-iron scores with correlation coefficients of 0.52 and 0.56 ($p < 0.001$), respectively. This is also reflected in the diagnostic accuracies for the detection of the pathologic hepatocellular iron. When using a hepatocellular iron grade 2 as cutoff value, the diagnostic accuracies are as follows: AAS: 92%, cutoff 4 mg/g dry weight; RTS: 88%, cutoff 400 µg/g wet weight; MRI: 80%, cutoff $33 s^{-1}$; Ferritin: 67%, cutoff 890 ng/ml.

Conclusion: RTS, MRI and AAS are primarily detecting hepatocellular iron and not macrophage iron most likely due to the abundance of hepatocytes in the liver tissue. On the opposite side, serum ferritin is more dependent on RES-iron than on hepatocellular iron. Since RTS reaches good diagnostic accuracies in the detection of severe pathological hepatocellular iron we consider it as a promising bedside method for the screening of liver iron overload.

Alpha1-antitrypsin augmentation therapy is associated with an improvement in liver-related parameters in patientes with severe alpha1-antitrypsin-deficiency

C.V. Heimes[1], K. Hamesch[1,2], M. Mandorfer[3], L.S. Moeller[4], M.C. Reichert[5], V. Woditsch[1], J. Voss[1], C. Lindhauer[1], S. Janciauskiene[6], F. Lammert[5], M. Trauner[7], A. Krag[4], C. Trautwein[1,2], P. Strnad[1,2].
[1]University Hospital RWTH Aachen, Medical Clinic III, Gastroenterology, Metabolic diseases and Intensive Care, Aachen, Germany; [2]Coordinating center for alpha1-antitrypsin deficiency-related liver disease of the European Reference Network (ERN) "Rare Liver" and the European Association for the Study of the Liver (EASL) registry group "Alpha1-Liver"; [3]Division of Gastroenterology und Hepatology, Department of Internal Medicine III, Vienna, Austria; [4]Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark; [5]Saarland University Medical Center, Saarland University, Department of Medicine II, Homburg, Germany; [6]Clinic for Pneumology, German Center for Lung Research (DZL), Hannover, Germany; [7]Department of Internal Medicine III, Division of Gastroenterology und Hepatology, Vienna, Austria
Email: cheimes@ukaachen.de

Background and Aims: Severe alpha1-antitrypsin deficiency ('PiZZ' genotype) constitutes one of the most common genetic disorders, and its letality is due to the associated lung and liver disease. While alpha1-antitrypsin (AAT) augmentation therapy inhibits the progression of PiZZ-related lung affection, liver transplantation constitutes the only cure for PiZZ-related chronic liver failure. Since AAT augmentation decreases the production of toxic PiZ *in vitro*, we evaluated its impact on liver-related parameters in PiZZ carriers.

Method: Overall, 364 adult PiZZ carriers without known liver disease underwent a systematic clinical and laboratory work-up to exclude hepatic comorbidities and to assess pulmonary symptoms. Liver fibrosis was non-invasively quantified by liver stiffness measurement (LSM) using transient elastography. Liver-related parameters were compared in PiZZ carriers with (221) and without (143) AAT augmentation therapy. Results were adjusted for age, sex, BMI, and diabetes mellitus.

Results: Quantitative measures are expressed as mean with standard deviation or as relative frequency (%). Abbreviations: BMI, body mass index; AAT, alpha1-antitrypsin; CAT, chronic obstructive pulmonary disease assessment test; ULN, upper limit of normal (sex-specific); APRI, AST to platelet ratio index, FIB-4, Fibrosis-4 score.

PiZZ carriers receiving AAT augmentation therapy were older and presented with more advanced lung disease, as demonstrated by higher CAT (COPD assessment test) values and a more frequent need for long-term oxygen treatment. In contrast, they displayed lower serum AST and GGT activities, lower liver stiffness, APRI and Fib4 values (surrogate markers of liver fibrosis) as well as higher platelet counts (marker of portal hypertension). Multivariate analysis confirmed the association of AAT augmentation with improved liver-related parameters.

Table 1: Features of PiZZ patients who do or do not receive alpha1-antitrypsin augmentation therapy.

	PiZZ, non-augmented $n = 143$	PiZZ, augmented $n = 221$	Multivariate p value
Characteristics			
Age (years)	49.4 ± 15.3	57.3 ± 10.4	
Women (%)	52.4	42.1	
BMI (kg/m^2)	24.3 ± 3.7	25.0 ± 4.7	
Diabetes mellitus (%)	5.6	5.8	
AATD-related features			
AAT serum level (mg/dL)	29.0 ± 17.2	104.9 ± 47.8	<0.0001
CAT score (points)	14 ± 8	18 ± 6	<0.0001
Long-term oxygen therapy (%)	7.7	34.4	<0.0001
Liver status			
LSM(kPa)	6.9 ± 6.9	6.1 ± 3.7	0.015
LSM >10 kPa (%)	15.8	10.6	0.005
AST (% of ULN)	75.9 ± 28.0	70.9 ± 25.8	<0.0001
GGT (% of ULN)	98.2 ± 128.8	89.3 ± 115.5	0.002
Platelets (G/L)	227.1 ± 68.54	233.7 ± 61.8	0.044
APRI (units)	0.43 ± 0.44	0.37 ± 0.19	0.001
Fib4	1.58 ± 1.38	1.48 ± 0.86	<0.0001

Conclusion: These data suggest that AAT augmentation might improve PiZZ-related liver phenotypes. However, further studies are needed to confirm this observation and identify the underlying mechanisms.

SAT-040

Impact of acute hepatic porphyrias on quality of life and work loss: An analysis of EXPLORE natural history study

Email: sagarwal@alnylam.com

Background and Aims: Acute hepatic porphyrias (AHPs) are rare, often misdiagnosed genetic diseases caused by a mutation in aminolevulinic acid synthase 1 enzyme responsible for heme synthesis. AHPs include acute intermittent porphyria (AIP), variegate porphyria (VP), and hereditary coproporphyria (HCP). The enzyme defect results in accumulation of neurotoxic heme intermediates, aminolevulinic acid and porphobilinogen, that can cause life-threatening attacks; chronic, debilitating symptoms; and the need for urgent medical care and/or hospitalization. Thus, patients may experience substantial impact on their daily living activities and decreased quality of life (QoL). This analysis presents data from the largest international natural history study to describe impact on QoL and work loss among patients with AHP with recurrent attacks.
Method: EXPLORE (NCT02240784) is a prospective, international, observational study characterizing the natural history and clinical management of patients with AHP who have recurrent attacks (≥3 attacks/year) or receive prophylactic treatment to prevent attacks. EQ-5D-5L measured QoL, while work loss for patients and caregivers was self-reported by patients at baseline and 6 and 12 months. EQ-5D-5L consists of 5 domains (mobility, self-care, usual activities, pain, anxiety/depression) and a visual analog scale for health. Descriptive statistics are presented.
Results: 112 patients were enrolled (mean age, 39 years; 89% female; and 93% with AIP, 4% VP, and 3% HCP). Based on baseline EQ-5D-5L, 35% of patients had mobility issues, >50% had some difficulty performing usual activities as well as anxiety/depression, and 72% reported some pain. Similar impairment occurred at 12 months. 70% of patients were not employed full time, of whom 67% were not working full time due to porphyria. Among employed patients, 85% reported missed work days and a mean of 53 lost work days (standard deviation [SD] 77) over a year. In addition, 52% of patients reported that caregivers had lost work days (mean: 17; SD 22) per year.
Conclusion: Patients with AHP, with a mean age of 39 years in this study, reported decreased QoL most frequently in the domains of pain, anxiety/depression, and difficulty in performing usual activities and mobility. Having AHPs with recurrent attacks impacts the ability of both patients and their caregivers to work. Thus, burden of disease impacting daily living is high for these patients and their caregivers.

Background and Aims: Acute hepatic porphyrias (AHPs) are rare, often misdiagnosed genetic diseases caused by an enzyme mutation responsible for heme synthesis. This results in accumulation of neurotoxic heme intermediates, aminolevulinic acid and porphobilinogen, that can cause life-threatening attacks and chronic, debilitating symptoms due to injury to the nervous system. AHPs include acute intermittent porphyria (AIP), variegate porphyria (VP), and hereditary coproporphyria (HCP), often requiring urgent medical care and/or hospitalization. EXPLORE (NCT02240784) is the first international, prospective study (currently ongoing) characterizing the natural history and clinical management of AHP in patients with recurrent attacks. High healthcare utilization has been previously reported in the overall EXPLORE population. Given regional differences in healthcare systems, the objective is to report differences in healthcare utilization in the United States (US) and Europe (EU).
Method: EXPLORE enrolled patients with AHP with recurrent attacks (≥3/year) or receiving hemin prophylactically. Patients' medical history and questionnaires on porphyria symptoms, quality of life, and healthcare utilization were collected at prespecified intervals and during attacks. Trends in emergency room visits, hospitalizations, and general practitioner and specialist visits in the US and EU are presented as descriptive statistics.
Results: 112 patients (US: 44%; EU: 56%) were enrolled (mean age, 39 years; 89% female; and 93% with AIP, 4% VP, and 3% HCP). Patients reported slightly higher mean emergency visits in the US vs EU (3.1; standard deviation [SD] 4.1 vs 2.6; 4.7) in the year before enrollment. Mean overnight hospitalizations in the US and EU were 5.3 (SD: 11; mean length of stay [LOS]: 5 days) and 4.0 (SD: 7; mean LOS: 7 days), respectively. 18% of patients in the US and EU visited their general practitioner monthly; 22% (US) and 15% (EU) visited a specialist monthly for porphyria-related care in the prior year. Additional data, including hemin prophylaxis and attacks that required urgent treatment in a healthcare setting (emergency, clinic, or infusion center) or hospital and/or intravenous hemin treatment, will be reported.
Conclusion: Patients with AHPs with recurrent attacks have a high degree of healthcare utilization in the US and EU. Healthcare utilization in this study was higher in the US than the EU, due perhaps to differences in healthcare systems.

Email: luis.tellez@salud.madrid.org

Background and Aims: Fontan surgery (FS) allows the venous return to reach the pulmonary circulation bypassing the ventricle in patients with single ventricle. This results in sustained systemic venous hypertension and liver damage in the long-term. Frequency, characterization and risk of hepatocarcinoma in liver nodules in Fontan-associated liver disease are poorly known. The AIM was to characterize liver nodules and the predictive factors of their presence in patients with FS.
Method: Multicentre, observational, transversal and prospective study. 65 consecutive FS patients were evaluated by blood tests; Fibroscan®; abdominal Doppler-US, MRI or CT (if pacemaker); and echocardiography and other cardiological test. The main variable was the presence of nodules in CT/MRI.
Results: 65 patients were included, 39 male (60%). (mean ± SD) Age was 27 ± 8.1yr, time since FS was 19 ± 7.4yr. Tricuspid (20, 31%) atresia was the most frequent congenital cardiac defect. Nodules were detected in the liver in 58% (95%CI: 42–69%) of patients by CT/MRI and in 39% (95%CI: 27–50%) by US. US did not identify focal lesions in 8 of 27 patients with nodules detected by CT/MRI (sensitivity = 70%; 95%CI: 51–84%). Sixty-four of the 70 nodules (91%, 95%CI: 82–96%) detected by CT/MRI were hypervascular, and 7 of them (10%) in 4 patients showed late venous washout. Hepatocarcinoma (by histology, AFP >200 ng/ml) was diagnosed in 2 of the 4 patients with hypervascular and venous washout nodules. US detected 10 nodules in 6 patients that were not identified by CT/MRI, all of them were hyperechogenic with a diameter <1 cm. In univariate analysis, enteropathy, GGT > 90 IU/ml and bicavopulmonary FS variant were significantly ($p < 0.05$) associated with the presence of nodules in the CT/MRI. In the binomial logistic regression analysis, GGT > 90 (OR: 4.86, $p = 0.04$) and the bicavopulmonary variant (OR: 5.66, $p = 0.02$) remained as predictive factors.

Characteristics of nodules

US (65 patients)	**MRI/CT** (48 patients)
Patients with nodules: 25 (38.5%)	**Patients with nodules:** 27 (57.5%)
Subgroup with nodules:	**Subgroup with nodules:**
• **N° of nodules:** 65	• **N° of nodules:** 70
• **N° of nodules/patient:** 2 (1–10) (median, rank)	• **N° of nodules/patient:** 2(1–9) (median, rank)
• **Diameter:** 0.8 (0.4–4.5) cm	• **Diameter:** 1.1 (0.4–4.3) cm
• **Peripheral:** 46 (76.9%)	• **Peripheral:** 52 (74.3%)
• **Echogenicity:**	• **LiRADS:**
◦ **Hyper:** 57 (87.7%)	◦ 2: 7 (10%)
◦ **Isoe:** 5 (7.7%)	◦ 3: 34 (48.5%)
◦ **Hypo:** 3 (4.6%)	◦ 4: 8 (11.4%)
• **Hepatocarcinoma shown:** 2/2, (100%)	◦ 5: 5 (7%)
	◦ Unclassified: 16 (22.85%)
	• Hypervascular: 64 (91.4%)
	• **Washout venous/late phase:** 7 (10%), 4 nodules in 2 patients hepatocarcinoma.

Conclusion: Hepatic nodules are frequent in patients with FS, especially in those with increased GGT and the bicavopulmonary variant. Hepatic nodules in FS patients are hyperechogenic, hypervascular predominantly peripheral and can progress to hepatocarcinoma.

SAT-043

The effect of re-exposure to somatostatin analogues in patients with polycystic liver disease

R. van Aerts[1], M. Kolkman[1], F. Nevens[2], W. Kievit[3], J.P.H. Drenth[1].
[1]*Radboud university medical center, Gastroenterology & Hepatology, Nijmegen, Netherlands;* [2]*UZ Leuven, Department of Hepatology, University Hospitals Leuven, Leuven, Belgium;* [3]*Radboud university medical center, Department for Health Evidence, Nijmegen, Netherlands*
Email: rene.vanaerts@radboudumc.nl

Background and Aims: Symptomatic patients with hepatomegaly resulting from polycystic liver disease (PLD) are eligible for treatment with somatostatin analogues (SA). SA decrease liver volume and its effect is mainly achieved in the first 3–6 months of treatment while prolonged administration maintains the achieved effect and prevents further growth. In view of the apparent tolerance and extensive costs, we sought to explore alternative administration schemes. It is unknown whether re-exposure of SA results in a similar effect on liver volume. In this study we aimed to determine and compare the treatment effect of SA during two separate treatment periods separated by a drug holiday.
Method: Patients who were treated with somatostatin analogues (lanreotide or octreotide) for at least 3 months for two separate periods (On-I & On-II), spaced by a period without treatment (Off-I) for at least 3 months, were selected from our international PLD registry. Data was retrospectively retrieved from the medical chart in two tertiary centers. Effectiveness of both On-treatment periods was expressed as percentage change in height adjusted liver volume (hTLV), which was compared between the 2 periods using generalized linear mixed models with adjustment for liver volume at start of each treatment.
Results: Out of a total 741 patients, 35 patients were selected. Total length of the observation period was 44.0 months (IQR 10.0) and baseline height adjusted liver volume was 3198 ml/m (IQR 2152). Duration of On-I, Off-I and On-II were respectively 11.0 months (IQR 0), 20 months (IQR 14.0) and 11.0 months (IQR 9.0). There was no significant difference between the effect in On-I (−2.7% per 6 months) and On-II (−1.5% per 6 months) after correction for baseline hTLV, p = 0.176. 69% of patients (n = 24) had a decrease in liver volume during On-I. Out of these 24 patients, re-exposure to SA again led to a decrease in 83% (n = 20) after a period without treatment. Of all non-responders after On-1, 36% (n = 4) did show a decrease in hTLV after On-II.

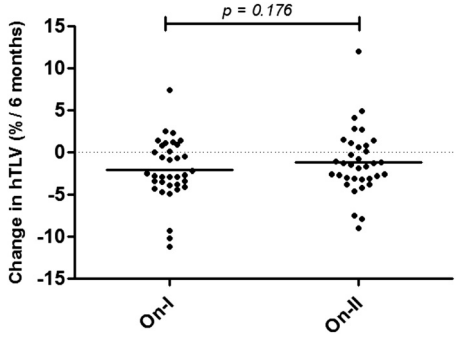

Figure 1: Percentage change in hTLV per 6 months in the first and second treatment period.

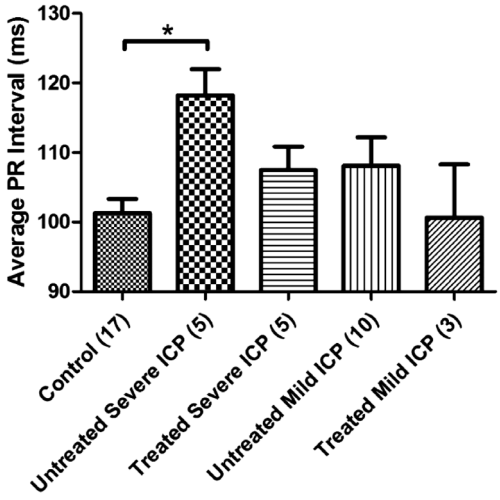
Conclusion: This study suggests that patients who have an initial response on SA are likely to show a similar response during subsequent treatment periods. Future studies should explore the effect of intermittent exposure to SA on hTLV, symptoms and quality of life in and compare this with continuous therapy.

SAT-044

The PR interval in the fetal electrocardiogram is significantly prolonged in severe intrahepatic cholestasis of pregnancy and potentially normalised by UDCA therapy

T. Vasavan[1], C. Martin[1], I.A. Jayawardane[2], S. Deepak[1], V. Geenes[1], M. Lucchini[3], J. Chambers[1], L. Kurlak[2], J. Thornton[2], F. Broughton-Pipkin[2], B. Hayes-Gill[4], W. Fifer[3], C. Williamson[1]. [1]*King's College London, Department of Women and Children's Health, London, United Kingdom;* [2]*Nottingham University, Division of Child Health, Obstetrics & Gynaecology, Nottinham, United Kingdom;* [3]*Columbia University, Sackler Institute of Developmental Psychobiology, New York, United States;* [4]*Nottingham University, Faculty of Engineering, Nottingham*
Email: tharni.vasavan@kcl.ac.uk

Background and Aims: Intrahepatic Cholestasis of Pregnancy (ICP) is typically described as mild or severe based on total serum bile acid (TSBA) concentrations; severe ICP is diagnosed when TSBA concentrations are ≥40 µmol/L and is associated with an increased risk of adverse pregnancy outcomes, including intrauterine death (IUD). ICP is often treated with ursodeoxycholic acid (UDCA). There are case reports of abnormal cardiac rhythm, e.g. supraventricular tachycardia, bradycardia and prolongation of PR intervals in ICP fetuses. Bile acids are arrhythmogenic in *in vitro* cardiomyocyte models of the fetal heart, and arrhythmia is prevented by co-administration of UDCA. We hypothesise that severe ICP causes detrimental changes in the fetal electrocardiogram (fECG) and that UDCA can protect against these changes.
Method: We used the Monica AN24, a non-invasive transabdominal ECG device, to record overnight fECGs in women who were ≥20 weeks in gestation. Controls, defined as women with uncomplicated pregnancies, were recruited in addition to patients who had been diagnosed with severe or mild ICP who were either untreated or undergoing UDCA treatment. fECG files were downloaded and analysed using Monica DK software. A 2-hour period with minimal fetal heartrate dropout and no maternal movement was identified and the PR interval was marked on an averaged fECG waveform of up to 1000 complexes in 5-minute epochs over this period.
Results: We found that the electrocardiographic fetal PR interval was significantly prolonged in patients with untreated severe ICP (118.2 ± 8.5 ms, n = 5) in comparison to controls (101.3 ± 8.4 ms, n=17, p = 0.02). This prolongation was not seen in patients with severe ICP who had been treated with UDCA. Patients with untreated mild ICP had a non-significant prolongation of PR interval (108.1 ± 12.8 ms, n = 10, p = 0.11). Statistical analysis was performed via a one-way ANOVA with post-hoc Bonferroni's test, results are presented ± standard deviation values.



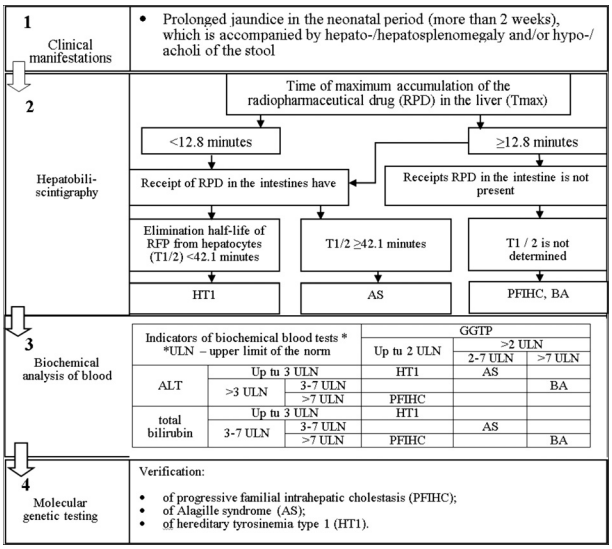
Conclusion: We have demonstrated a significant prolongation of PR interval in the fECG of patients with untreated severe ICP, a defect which is known to be a common indicator of atrioventricular block. A prolongation of PR interval is also seen in untreated mild ICP, indicating a role of increased TSBA in this defect. UDCA treatment appears to normalise the length of PR interval. More data is required to assess the clinical impact of ICP-associated prolonged PR interval on the fetal heart and the usefulness of UDCA in reversing this.

SAT-045

Differential diagnostics of congenital cholestatic diseases in children of early age

G. Volynets[1], A. Khavkin[1], A. Nikitin[2], T. Skvortsova[2], O. Komarova[1], V. Panfilova[3]. *[1]Pirogov Russian National Research Medical University (RNRMU), Separate structural subdivision Scientific Research Clinical Institute of Pediatrics named after Academician Yu.E.Veltischeva, Department of Gastroenterology, Moscow, Russian Federation; [2]Federal State Autonomous Institution "National Medical Research Center of Children's Health" of the Ministry of Health of the Russian Federation, Department of Gastroenterology, Moscow, Russian Federation; [3]Krasnoyarsk State Medical University of the Ministry of Health and Social Development of the Russian Federation, Department of Gastroenterology, Krasnoyarsk, Russian Federation*
Email: volynec_g@mail.ru

Background and Aims: Diagnosis of cholestatic diseases is very important in young children. It is necessary to develop an algorithm for differential diagnosis of congenital cholestatic diseases in children of early age.
Method: There were 81 children (49 boys and 32 girls) aged 1 month to 16 years (mean age 62 months ± 6 months): 20 children with biliary atresia (BA); 17 – with hereditary tyrosynemia type 1 (HT1), 23 – with progressive familial intrahepatic cholestasis (PFIHC) type 1 and 2; 21 – with the syndrome of Alagill (AS). Multivariate statistical analysis has made it possible to identify the criteria necessary for differential diagnosis: Hepatobiliary scintigraphy (HBSG) and biochemical blood test.
Results: Clinical manifestations of cholestatic diseases in infants are similar and characterized by prolonged jaundice in the neonatal period, which is accompanied by hepato-/hepatosplenomegaly and/or fecal hypo-/aholia of fecess. However, despite the similarity of clinical manifestations of cholestatic diseases, differential diagnostic criteria have been identified. HBSG parameters: the time of maximum accumulation (Tmax) of the radiopharmaceutical drug (RPD) in hepatocytes <12.8 minutes and the entry of RPD into the gut was recorded with HT1 and SA, which can be differentiated by elimination half-life of RPD (T1/2) from hepatocytes: at HT1 T1/2 < 42.1min, at SA T1/2 ≥ 42.1min. Tmax ≥12.8min, the RAP does not enter in the intestine (Tint), and the absence of T1/2 is characteristic of PFIHC and BA. Then analyzes the level of alanineaminotransferase (ALT), gammaglutamyltranspeptidase (GGTP) and bilirubin in serum. When BA: the GGTP level [147.0 **329.0** 577.5]U/l (>7 upper limits of the norm – ULN), ALT level [150.2 **203.0** 338.0]U/l (3–7 ULN), the level of total bilirubin [154.6 **187.2** 202.9]μmol/l (>7ULN) with predominance of the direct fraction [87.3 103.3 120.6] μmol/l. When AS: the level of GGTP was [58.0 **127.0** 178.0] U/l (2–7ULN), ALT [43.0 **50.0** 57.0]U/l (up to 3ULN), the level of total bilirubin was [158.2 **195.8** 233.4]μmol/l (3–7ULN) with predominance of the direct fraction [122.2 **124.5** 126.8]μmol/l. When PFIHC уровень ALT [148.0 **319.5** 890.7] U/l (>7ULN), of total bilirubin [75.6 **130.5** 180.6] μmol/l (>7ULN) with predominance of the direct fraction [45.0 **82.9** 113.3]μmol/l, and the level of GGTP does not interrupt 2 ULN. Cholestasis due to HT1 is characterized by GGTP level [24.0 **47.0** 99.5], which does not exceed 2ULN, ALT [14.7 **27.5** 35.0] U/L (≤3ULN), total bilirubin [15.5 **30.1** 53.0]μmol/l (≤3ULN) with predominance direct fraction [2.8 **10.7** 24.5]μmol/l.



Conclusion: The developed examination algorithm allows to differentiate congenital cholestatic diseases in infants (figure), and if suspected of a genetically determined disease, conduct molecular genetic research.
Algorithm of differential diagnosis of congenital cholestatic diseases in children of early age.

SAT-046

Quantitative and qualitative lymphocyte alterations in patients with autoimmune hepatitis: What is the clinical relevance?

A. Renand[1], S. Habes[2], J.-F. Mosnier[3], H. Aublé[4], I. Mabile-Archambeaud[2], S. Brouard[1], J. Gournay[2], S. Conchon[1]. *[1]Centre de Recherche en Transplantation et Immunologie UMR1064, INSERM, Université de Nantes, Nantes, France; [2]CHU nantes, Service Hepato-gastro-entérologie et Assistance Nutritionnelle, Nantes, France; [3]CHU nantes, Service Anatomie et Cytologie Pathologiques, Nantes, France; [4]CHU nantes, Centre d'Investigation Clinique gastro-nutrition, Nantes, France*
Email: amedee.renand@univ-nantes.fr

Background and Aims: Autoimmune hepatitis (AIH) is a rare disease characterized by an immune attack of the liver. Various lymphocyte populations have been involved in hepatocellular damage, but the relationship between immune alterations and clinical outcome during AIH is poorly understood. The aim of this study was to identify new immune markers related to the clinical status of AIH patients, which can be useful for future therapeutic research programs.
Method: A flow cytometry strategy was designed to analyze 38 relevant lymphocyte populations (including CD4 and CD8 T cell subsets, Regulatory CD4 T cell subsets, Innate lymphocyte subsets and B cell subsets) from peripheral blood of treatment-naive AIH patients at diagnosis (AIHn; n = 11), age-matched AIH patients with controlled disease (AIHc; n = 11), and healthy subjects (n = 11). Liver biopsy analyses (including immunohistochemistry and immunofluorescence) and correlations with stage of fibrosis and disease activity were performed to complete the blood phenotypic analysis.

Results: Five blood lymphocyte populations were significantly altered in AIHn patients at diagnosis compared with healthy subjects. Levels of mucosal-associated invariant T cells (MAIT; $p < 0.0001$), TH1/TH17 CD4 T cells ($p = 0.0048$), and invariant natural killer T cells (iNKT; $p = 0.001$) were decreased, while MAIT Granzyme B+ (GrB) cells ($p = 0.001$) and CD8 + CD161 + GrB+ T cells ($p = 0.0025$) increased. These immune alterations were not restored with standard immunosuppressive treatments. Disease activity was correlated with the blood decrease in TH1/TH17 CD4 T cells ($r = -0.68$; $p = 0.02$), whereas stage of hepatic fibrosis was correlated with MAIT GrB+ frequency ($r = 0.64$; $p = 0.034$). At diagnosis, AIHn patients with a hepatic fibrosis stage F3-F4 had a higher frequency of MAIT GrB+ cells ($p = 0.03$) than AIHn with a hepatic fibrosis stage F0-F2. In the livers of AIHn patients, compared with control non-inflammatory livers, CD4 and MAIT cell markers were enriched in the portal tract, and CD8, CD161, and GrB markers were enriched in the hepatic lobule. Expression of PD1 and CD161 by circulating TH1/TH17 CD4 T cells was higher in AIH patients ($p = 0.02$) compared to healthy subjects, and was correlated with disease activity ($r = 0.9$; $p = 0.006$).
Conclusion: Our work identified new immune actors of AIH pathogenesis. TH1/TH17 CD4 T cells and CD8 + CD161+ T cells are involved in disease activity. MAIT cells seem to be related to the progression of fibrosis.

Background and Aims: Wilson disease is a copper storage disease, caused by mutations in the copper transporter ATP7B, resulting in hepatic copper accumulation and liver damage. Steatosis is an early and frequent observed feature in Wilson disease patients, suggesting that impaired copper homeostasis associates with liver steatosis. Hepatic mitochondria are key organelles affected by copper overload in patients with Wilson disease and steatosis. Therefore, we addressed the question whether a high caloric diet promotes Wilson disease progression via amplified mitochondrial damage.
Method: Homozygous *Atp7b*$^{-/-}$ rats, a Wilson disease animal model, and their heterozygous controls were either fed a normal- (ND) or high caloric diet (HCD, approximately 2-fold amounts of calories due to elevated chow fat and fructose-containing water). The degree of liver damage, steatosis and hepatic mitochondrial impairment was assessed. As a therapeutic intervention, the copper chelating agent methanobactin was studied in HCD-fed *Atp7b*$^{-/-}$ rats.
Results: Overt hepatic injury (AST >200 U/l, bilirubin >0.5 mg/dl, hepatic injury score >10) and steatohepatitis (NAS >5) were omnipresent in HCD- but not in ND-fed *Atp7b*$^{-/-}$ rats. In contrast, HCD-fed controls only developed steatosis without signs of severe liver injury. HCD feeding strongly increased mitochondrial copper in *Atp7b*$^{-/-}$ rats that correlated with the grade of liver damage and steatohepatitis. HCD-fed *Atp7b*$^{-/-}$ mitochondria presented with copper overload, massive structural damage, elevated H_2O_2 production and severely impaired ATP production in comparison to ND-fed controls. The reduction of mitochondrial copper in HCD-fed *Atp7b*$^{-/-}$ rats by methanobactin clearly improved mitochondrial structure and function, ameliorated steatosis and cured overt liver damage.
Conclusion: A high caloric diet massively impaired hepatic mitochondria and aggravated liver damage in Wilson disease rats. Effective mitochondrial copper depletion resolved such damage and ameliorated steatosis/steatohepatitis, demonstrating the close relationship of hepatic copper and lipid metabolism.

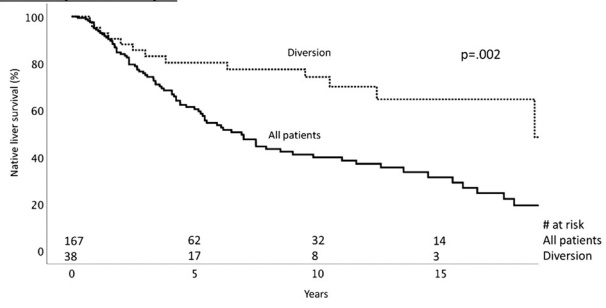
Email: d.b.e.van.wessel@umcg.nl

Background and Aims: Severe deficiency of FIC1 (FIC1-def) and of BSEP (BSEP-def), due to mutations in the *ATP8B1* and *ABCB11* genes, respectively, are responsible for progressive familial intrahepatic cholestasis type 1 and 2. Because of impaired biliary bile salt secretion, patients typically present with pruritus and jaundice in early childhood. Patients may benefit from ursodeoxycholic acid or from surgical diversion (SBD) techniques. However, many patients need liver transplantation. To better understand the nature of these diseases and the efficacy of interventions, we have set up an extensive international consortium, "NAPPED".

Method: We present retrospective follow up data on individual patients from 22 European and Asian centers who were either compound heterozygous or homozygous for disease associated mutations in *ATP8B1* or *ABCB11*. We used time-dependent Cox regression for native liver survival (NLS), adjusted for gender and birthyear, in patients that had undergone SBD (SBD+) or not (SBD-). Continuous variables are expressed as median [range].
Results: We included 42 FIC1-def and 192 BSEP-def patients. Age at first visit was 6 months [0–201] in FIC1-def and 9 months [0–195] in BSEP-def. Use of ursodeoxycholic acid prior to first visit was 33% in FIC1-def and 47% in BSEP-def patients. Age at last follow up was 69 months [3–334] in FIC1-def and 63 months [1–487] in BSEP-def. SBD rates at five/ten years of age were 33/39% in FIC1-def and 27/34% in BSEP-def patients. Five/ten-year NLS was 73/51% in FIC1-def and 61/45% in BSEP-def patients. NLS was significantly higher in SBD+ than in SBD- BSEP-def patients (HR = 0.37; 95%CI (0.18–0.74), p = 0.002; Figure). NLS in FIC1-def patients did not differ significantly between the SBD+ and SBD- groups. Before the age of five/ten years 27/49% in FIC1-def and 37/53% in BSEP-def patients had been transplanted. HCC was not seen in FIC1-def and in 8% in BSEP-def patients. Pre-transplant mortality was 2% for FIC1-def and 4% for BSEP-def. The observed NLS at 18 years of age for FIC1-def and BSEP-def was 51% and 32%, respectively.

Cumulative NLS in BSEP deficiency patients that had undergone SBD or not, based on retrospective analysis



Observed native liver survival in BSEP deficiency using a clock-reset approach. The solid line represents available native liver survival data of all included patients from birth (N=167). The dotted line represents native liver survival following diversion surgery (N=38).

Conclusion: The largest cohort yet of genetically defined FIC1-def and BSEP-def patients can further improve our insights in the natural course of disease and the relationships between genotype and effects of medical and surgical treatments. A significant proportion of these patients reaches adulthood and thus becomes an important, relatively new patient entity for adult hepatology practice.

SAT-049

Mild iron overload in homozygous carriers of the alpha1-antitrypsin PiZ variant is not a major driver of liver fibrogenesis

N. Guldiken[1,2], K. Hamesch[1,3], S. Schuller[1], C.V. Heimes[1,4], S. Janciauskiene[5], C. Trautwein[1,4], P. Strnad[1,4]. *[1]RWTH University Hospital Aachen, Medical Clinic III, Gastroenterology, Metabolic diseases and Intensive Care, Aachen, Germany; [2]University Hospital RWTH Aachen, Interdisciplinary Center for Clinical Research (IZKF), Aachen, Germany; [3]RWTH University Hospital Aachen, Coordinating center for alpha1-antitrypsin deficiency-related liver disease of the European Reference Network (ERN) "Rare Liver" and the European Association for the Study of the Liver (EASL) registry group "Alpha1-Liver", Aachen, Germany; [4]RWTH University Hospital Aachen, Germany, Coordinating center for alpha1-antitrypsin deficiency-related liver disease of the European Reference Network (ERN) "Rare Liver" and the European Association for the Study of the Liver (EASL) registry group "Alpha1-Liver", Aachen, Germany; [5]Medical University Hannover, Clinic for Pneumology, Hannover, Germany*
Email: pstrnad@ukaachen.de

Background and Aims: Carriage of the common alpha1-antitrypsin (AAT) "PiZ" variant predisposes to liver fibrosis progression, but the disease-promoting factors remain largely unknown. Therefore, we studied the extent of iron overload in patients with homozygous carriage of the PiZ variant ('PiZZ') and the impact of mild iron overload on PiZ-overexpressing transgenic mice (PiZ mice).
Method: 297 PiZZ carriers and 196 subjects without an AAT mutation (non-carrier), all without known liver disease, underwent a thorough clinical and laboratory workup including measurement of serum iron, ferritin, and transferrin. FibroScan determined liver fibrosis via liver stiffness measurement (LSM) and liver steatosis via controlled attenuation parameter (CAP), respectively. Data were adjusted for age, sex, BMI, diabetes mellitus and alcohol consumption where appropriate. PiZ mice were crossbred with HFE-knockout mice (HFE-KO) and evaluated at the age of 3 and 18 months by quantitative RT-PCR, immunoblotting and histological/immunological staining.
Results: Serum parameters of iron metabolism were mostly within the normal range in PiZZ carriers. However, compared to non-carriers, PiZZ carriers had lower transferrin levels (261 vs. 280 mg/dl), but displayed higher transferrin saturation (30% vs. 26%) and ferritin levels (212 vs. 145 ng/ml; all $p < 0.001$). PiZZ subjects with LSM ≥ 7.1 kPa, indicating significant fibrosis, had higher ferritin levels than individuals with LSM < 7.1 kPa (325 vs. 177 ng/mp, $p < 0.001$). Likewise, PiZZ carriers with CAP ≥ 280 dB/m, suggesting severe steatosis, had higher ferritin levels than subjects with CAP < 280 dB/m (270 vs. 182 ng/ml, $p = 0.002$). HFE-KO and double transgenic (DTg) mice displayed similar extent of iron overload. Moreover, loss of HFE did not modify the amount of PiZ expression and accumulation in the liver. 18 months old PiZ and DTg mice showed a comparable amount of fibrosis in Sirius red staining and the hydroxyproline assay.
Conclusion: Using a large PiZZ patient cohort, we demonstrated that PiZZ accumulation does not typically lead to a clinically relevant iron overload. Studies in PiZ mice revealed that a minor iron overload is well tolerated and does not promote progression of liver fibrosis.

SAT-050

Compound library screening for the identification of a new treatment for polycystic liver disease

L. van de Laarschot, K. van der Ende, R.H.M. Te Morsche, J.P.H. Drenth. *Institute for Molecular Life Sciences, Radboud University Medical Center, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands*
Email: liyanne.vandelaarschot@radboudumc.nl

Background and Aims: Polycystic liver disease is caused by genetic defects in *PRKCSH* in most patients. Pharmaceutical treatment of polycystic liver disease is aimed at curtailing cyst volume and limited to the use of somatostatin analogues. Disadvantages of somatostatin analogues are the limited efficacy, common frequency of side effects, and high costs. There is an urgent need for a safe treatment that decreases cyst proliferation, and hence cyst volume. The aim of our study is to identify pharmaceutical compounds that target cystic cell proliferation, but do not affect healthy cell proliferation.
Method: The Selleckchem FDA-approved drug screening library contains 1442 compounds with a wide spectrum of therapeutic targets. *PRKCSH* knockout H69 cholangiocytes were used as *in vitro* model for polycystic liver disease. Cells were incubated with compounds at 10 microM concentration for 24 hours in triplicate. Proliferation was measured as absorbance after addition of WST-1 proliferation reagent (Sigma-Aldrich) for 3 hours. Compounds changing proliferation >20% compared to DMSO controls were selected for incubation in wildtype H69 cholangiocytes. Compounds showing >50% of proliferation compared to control and >20% absolute difference between knockout and wildtype H69 cells were identified as most promising.
Results: 1,278 compounds showed proliferation rates of 80–120% relative to control in *PRKCSH* knockout H69 cholangiocytes. 26 compounds increased proliferation >120% of control and 138 compounds decreased proliferation below 80% of control proliferation rate. These 164 compounds were further tested in wildtype H69 cholangiocytes, while octreotide was added as reference. 18

compounds showed proliferation >50% of control proliferation rate and >20% absolute difference between knockout and wildtype H69 cholangiocytes. Of these, 7 compounds showed higher proliferation in wildtype than *PRKCSH* knockout cells. These included 3 anti cancer drugs, 1 haemostatic drug, 1 antipsychotic drug, 1 antimalarial drug, and 1 antimicrobial agent. Octreotide showed no difference in proliferation between incubated cells and controls, nor between knockout and wildtype cells.

Conclusion: We identified 7 FDA approved drugs that reduce proliferation rates in *PRKCSH* knockout cholangiocytes without large effect on proliferation rates in wildtype H69 cells. These drugs target different pathways than somatostatin analogues, and may become future pharmaceutical options for patients unresponsive to current treatment.

SAT-051

Splenic iron deficiency is characteristic for HFE-associated hemochromatosis

A. Viveiros[1], B. Schaefer[1], M. Tobiasch[1], A. Finkenstedt[1], C. Kremser[2], M. Plaikner[2], B. Henninger[2], H. Tilg[1], H. Zoller[1]. [1]*Medical University Innsbruck, Internal Medicine, Innsbruck, Austria;* [2]*Medical University Innsbruck, Radiology, Innsbruck, Austria*
Email: andre.viveiros@i-med.ac.at

Background and Aims: Non-invasive hepatic iron quantification using magnetic resonance imaging (MRI) is a staging method for patients with known iron overload and a diagnostic tool for the work-up of patients with suspected or unexplained iron overload. The aim of the present study was to assess the utility of spleen iron concentrations for the evaluation of hyperferritinemia.

Method: Of all patients who presented with high serum ferritin between July 2001 and August 2015, 443 were *HFE* genotyped and underwent non-invasive liver and spleen iron quantification by T2* weighted MRI, where the degree of iron content is expressed as R2* (=1/T2*). Liver iron overload was defined as a R2* > 60 sec^{-1} and spleen iron overload as a R2* > 50 sec^{-1}.

Results: Clinical, biochemical and radiological data are summarized in Table 1. Fifty-five patients were homozygous for the p.C282Y mutation in the HFE gene. When the latter were compared to patients with all other genotypes, median R2* was significantly higher in the liver (179.3 vs. 68.6, p < 0.001) but also significantly lower in the spleen (38.3 vs. 47.1, p = 0.003). Similar results were found when patients with compound heterozygosity for the p.C282Y and p.H63D mutations and homozygous for the p.H63D mutation were excluded from the analysis. Patient groups did not differ in terms of age, BMI and serum ferritin. Median transferrin saturation (%) was significantly higher in the p.C282Y homozygous group (77 vs. 35, p < 0.001).

Table 1: Median values are represented and the 25th and 75th percentiles are given between parentheses.

	p.C282Y homozygous (n = 55)	all other *HFE* genotypes (n = 388)	p value
Age, years	53 (36–62)	52 (42–63)	0.33
BMI, kg/m^2	25.3 (23.8–27.1)	26.3 (23.2–29.6)	0.14
Serum iron, µmol/L	34.1 (25.8–40.6)	21.5 (17.3–28.2)	<0.001
Serum ferritin, µg/L	624 (282–1344)	618 (388–961)	0.70
Transferrin, mg/dL	204 (180–220)	247 (221–271)	<0.001
Transferrin saturation, %	77 (51–83)	35 (28–46)	<0.001
Alanine aminotransferase, U/l	29 (22–50)	38 (24–66)	0.049
R2* liver, sec^{-1}	179.3 (95.9–342.1)	68.6 (53.0–91.5)	<0.001
R2* spleen, sec^{-1}	38.3 (28.8–52.3)	47.1 (34.7–63.8)	0.003

Conclusion: High ferritin is a common clinical finding that can indicate iron overload, inflammation and cell death. Our study shows that p.C282Y homozygous patients have significantly higher hepatic iron. In accordance with the low hepcidin state of hemochromatosis, reduced splenic iron concentrations in this condition indicate uncontrolled iron release and high transferrin saturation. Splenic iron can therefore be used to guide genetic testing beyond HFE genotyping, where patients with high liver but low spleen iron should preferably be tested for non-HFE mutations. In patients with high spleen iron, dietary and metabolic factors should be considered the main cause of high ferritin.

SAT-052

Transcatheter recanalization with angioplasty and/or stenting: a novel, minimally-invasive treatment option for children with chronic portal vein thrombosis with cavernous transformation

H. Justino[1], K. Kukreja[2], J.A. Hernandez[2], Y. Pham[1], S. Harpavat[1], L. Karam[1], P. Hertel[1], B. Carter[1], B. Shneider[1], T. Miloh[1]. [1]*Texas Children's Hospital, Pediatrics, Houston, United States;* [2]*Texas Children's Hospital, Radiology, Houston, United States*
Email: hjustino@bcm.edu

Background and Aims: Chronic portal vein thrombosis (CPVT) with cavernous transformation of the portal vein (PV) is a leading cause of gastrointestinal (GI) bleeding in children. We sought to evaluate the feasibility of performing transcatheter recanalization of CPVT with balloon angioplasty (BA) and/or stenting for CPVT.

Method: Retrospective study of patients (pts) taken to catheterization (cath) for recanalization of CPVT from April 2014 to November 2017.

Results: 13 pts (7 female) underwent 18 caths; median weight = 13.9 kg (range 7.5–88) and age = 4.1 years (1–15.3). Pre-procedural imaging included MRI and Doppler ultrasound in all, with CPVT and cavernous transformation diagnosed in all. 4 pts had history of prematurity and prior umbilical venous catheterization. CPVT manifestations included GI bleeding (10 pts), hyperammonemia (3), thrombocytopenia (11) and splenomegaly (11). Right heart cath & hepatic vein wedge angiography were performed, followed by percutaneous trans-splenic and/or direct puncture of intrahepatic portal veins. Additional findings at cath: mild pulmonary hypertension (1 patient) and mild hepatopulmonary syndrome (1). Median cath time was 7.2 hours (range 2–11.5). Recanalization of CPVT was successful in 4 pts (single cath in 3 pts, 4 caths in 1 patient), unsuccessful in 7, and not attempted in 2. Successful procedures entailed BA of main and right PV with rheolytic thrombectomy in left PV in one case, BA of main PV and 4 branches of right PV with rheolytic thrombectomy in another case, BA of main, right and left PV in another case, and BA of main PV and 6 intrahepatic PV branches followed by re-occlusion requiring re-angioplasty of 4 intrahepatic PV branches and placement of multiple stents during 3 subsequent caths in fourth case. Diffuse intrahepatic PV occlusion with non-confluent left and right PVs was found in 2 of 4 successful cases. There were no major complications or mortality. Minor complication of bleeding from splenic puncture requiring transfusion in 3 caths (2 among unsuccessful cases). All 4 successful cases were treated with low molecular weight heparin, with additional dual antiplatelet therapy in 1. At follow-up from final cath (range 4–20 months), the 4 pts with successful CPVT recanalization have patent PVs on ultrasound, with no recurrence of GI bleed and improved platelet count and spleen size.

Conclusion: Transcatheter recanalization of CPVT with BA/stenting is feasible in a subset of pts, including those with diffuse intrahepatic PV occlusion that would not otherwise be candidates for meso-Rex shunting. Although transcatheter recanalization is lengthy and technically challenging, it can be attempted with low risk. Further research is needed to determine the most suitable candidates, and whether this approach should be considered as a first-line option for children with CPVT.

Figure 1 (below). (a) Early phase of initial venography revealed a portal cavernoma (*), but late phase of the same angiogram (b) disclosed a hypoplastic and nearly occluded main PV (arrow) with small intrahepatic portal veins (arrowheads).

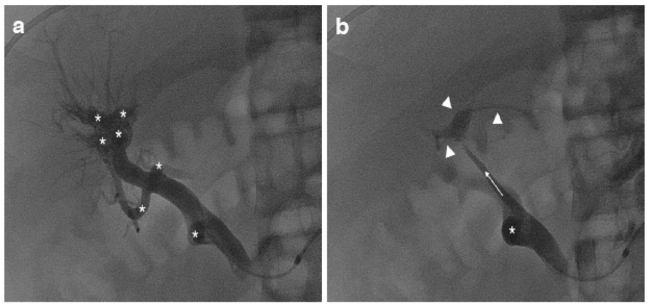


Figure 2 (right). Post-intervention venography shows increased main PV caliber (x1) with filling of the right anterior (x2) and posterior (x3) portal veins and a persistent non-occlusive thrombus in the left portal vein (arrow)

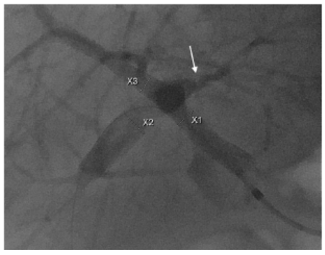

Figure 3 (below left). Initial venography revealed a portal cavernoma with no discernible main PV. Figure 4 (below right) showing early result during angioplasty with 3 guidewires in various PV branches.

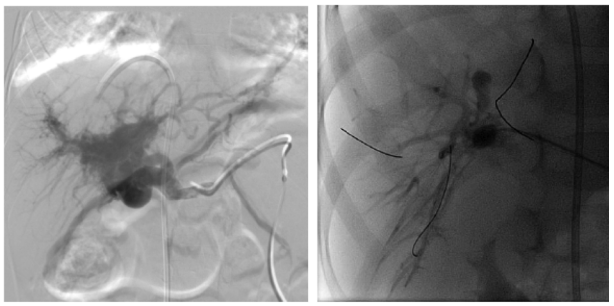

Figure 5 (right). Post-intervention venography shows patent main PV and numerous patent right PV branches.

SAT-053

Clinical response after laparoscopic fenestration of large simple hepatic cysts: a systematic review

L.H.P. Bernts[1], S.G. Echternach[1], C. Rosman[2], J.P.H. Drenth[1]. [1]*Radboud University Medical Center, Gastroenterology and hepatology, Nijmegen, Netherlands;* [2]*Radboud University Medical Center, Surgery, Nijmegen, Netherlands*

Email: lucas_bernts@hotmail.com

Background and Aims: Laparoscopic fenestration (LF) is one of the treatment options for symptomatic simple hepatic cysts, either solitary or in context of polycystic liver disease (PLD), but indications and effect size are under debate. The purpose of this study was to assess the efficacy and safety of LF through a systematic review of the literature.

Method: We performed a systematic search (1950–2017) of PubMed MEDLINE, Embase, Web of Science and the Cochrane Library. We included studies that assessed symptomatic relief or symptomatic recurrence after LF in patients with simple hepatic cysts for full-text evaluation. Case reports, unpublished data and studies with a mean or median follow-up <6 months were excluded. Risk of bias was assessed by use of an adjusted Newcastle-Ottawa scale (NOS) for cohort studies. Pooled estimates and 95% confidence intervals (CI) were calculated using a random effects model for meta-analysis.

Results: We traced 5,277 citations, 248 were selected for full-text assessment and 61 studies (n = 1279) were included. Weighted average of follow-up duration was 36,2 months (range: 9,6–86,4) for reported means. In the risk of bias assessment, studies scored well on "selection" (median 3 out of 4) and "outcome" (median 3 out of 3). In view of a lack of a control arm, studies scored low (median 0 out of 2) on "comparability". The pooled estimate of full or partial symptomatic relief after LF was 90,8% (CI: 84.9–95.4). Symptomatic recurrence after LF was 9,5% (CI: 6.7–12.7) and re-intervention rate was 6,8% (CI: 4.8–9.1). Intra-operative or post-operative complications occurred in 11,9% (CI: 9.0–15.2%) of patients, typically bleeding, ascites or pleural effusion. Procedure-related mortality was 1,0% (CI: 0.5–1.6). Weighted average of hospital stay was 5,1 days (range: 1.2–17.8) for reported means. In a subgroup analysis of PLD patients (n = 135), symptomatic recurrence and re-intervention rates were significantly higher with respective rates of 30.7% (CI: 15.0–48.9) and 26,4% (CI: 12.6–43.0). Complications were more frequent in PLD patients (32.9%; CI: 20.2–46.9).

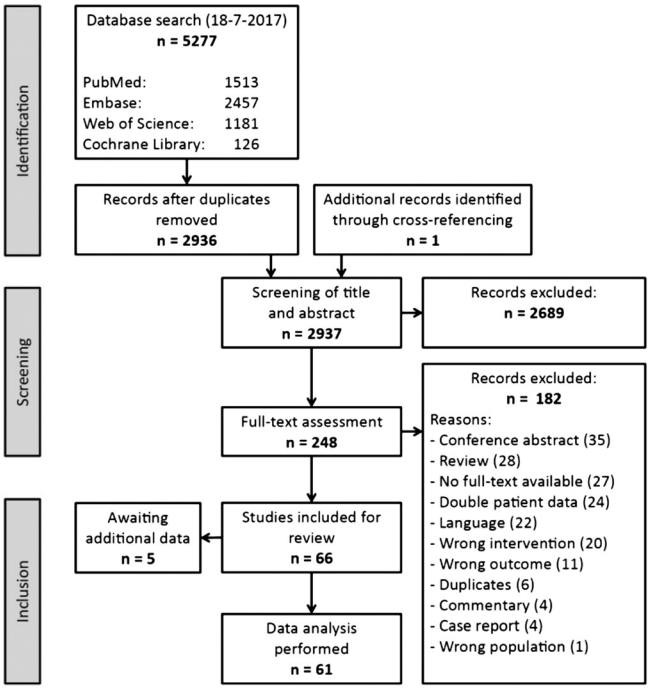

FIGURE 1. Flow chart shows elements of systematic review (identification, screening, inclusion).

Conclusion: Laparoscopic fenestration is an effective procedure for treatment of simple hepatic cysts with a low symptomatic recurrence rate. The symptomatic recurrence rate and risk of complications are significantly elevated in PLD.

SAT-054

Pertinence of liver stiffness measurement inpatients with Wilson's disease for assessment of initial fibrosis and treatment follow-up

R. Sobesky[1], M. Darce[2], H. Agostini[3], I. Fernandez[2], A. Usardi[2], R. Adam[1], D. Cherqui[1], E. Gonzales[4], E. Jacquemin[4], D. Samuel[5], A. Poujois[4], F. Woimant[4], J.-C. Duclos-Vallée[1]. *[1]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Villejuif, France; [2]Plateforme d'expertise maladies rares Paris Sud, France; [3]Unité de Recherche Clinique, Hopitaux Universitaires Paris-Sud, France; [4]Centre de reference Maladie de Wilson, France, France; [5]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Villejuif, F-94800, France, Inserm, Unité 1193, Université Paris-Saclay, Villejuif, F-94800, France, Villejuif, France*
Email: rodolphe.sobesky@aphp.fr

Background and Aims: Wilson's disease (WD) is a rare autosomal recessive disorder of copper metabolism, leading to liver cirrhosis and neurologic disorders. A liver biopsy may be useful to assist in diagnosis and to estimate the extent of fibrosis. However, non-invasive methods of fibrosis assessment seem useful considering the invasive character of the biopsy and the help of molecular biology for diagnosis. The aim is to determine the pertinence of liver stiffness measurement (LSM) in patients with WD, for assessment of initial fibrosis and for treatment follow-up.
Method: We performed a retrospective analysis of all patients with diagnosis of WD, examined in a liver reference center (Paul-Brousse Hospital, Villejuif, France). Patients were evaluated clinically, biologically, morphologically and genetically. Hepatic involvement was assessed with liver biopsy and/or LSM.
Results: We included 107 patients with hepatic symptoms of the WD, 54 (50.5%) females and 53 (49.5%) males, from 1974 to 2016. The mean age at diagnosis of WD was 20.1 (± 10.54) years. Fifty-seven (53.3%) had mixed symptoms (neurologic and hepatic) at admission. The mean follow up was 15 years [extr: 1–44 years]. 65 patients (60.7%) had liver pathological analysis and 72 (67.2%) had LSM. 73 patients (68%) had cirrhosis at diagnosis of the disease. 42 patients (75%) had cirrhosis among patients with neurologic and hepatic symptoms. Thirty-four (31%) patients were transplanted. Fourteen patients have a liver biopsy associated with LSM in a short interval of 1 month. Eleven of these 14 patients had cirrhosis at biopsy (Metavir F4). The 3 other patients were respectively F2, F1 and F0. The mean LSM for patients with cirrhosis was 32.3 (± 15.9)kPa and was 6.2 (± 2.1)kPa for patients with mild or moderate fibrosis (F0 to F2). Forty of non-transplanted patients (54.8%) had multiple measurements of liver stiffness during follow up. The mean LSM was 33.7 (± 22.5)kPa at diagnosis. Mean LSM with chelators therapy was 17.6 (± 18)kPa at 1 year, 16.5 (± 12)kPa at 2 years, 9.38kPa (± 5.4) at 5 years, 10.4 (± 4.7) kPa at 10 years, 7.7 (± 3.6)kPa at 15 years and 7.2 (± 2) after 20 years.
Conclusion: In case of a proven diagnosis of WD, LSM is pertinent for the estimation of liver fibrosis and can be useful to adapt the follow-up. During follow-up, there is a gradual decrease in the LSM under chelator treatment. The LSM can be a useful tool for monitoring the effectiveness of treatment.

SAT-055

Clinical presentation and outcome of Wilson's disease patients in a monocentric cohort of liver reference center

R. Sobesky[1], M. Darce[2], H. Agostini[3], I. Fernandez[2], A. Usardi[2], R. Adam[1], D. Cherqui[1], E. Gonzales[4], E. Jacquemin[4], D. Samuel[5], A. Poujois[4,6], F. Woimant[6], J.-C. Duclos-Vallée[1]. *[1]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Villejuif, France; [2]Plateforme d'expertise maladies rares Paris Sud, France; [3]Unité de Recherche Clinique, Hopitaux Universitaires Paris-Sud, France; [4]Centre de reference Maladie de Wilson, France, France; [5]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire, Villejuif, F-94800, France, Inserm, Unité 1193, Université Paris-Saclay, Villejuif, F-94800, France, Villejuif, France; [6]APHP Hopital Lariboisiere, Service de Neurologie, France*
Email: rodolphe.sobesky@aphp.fr

Background and Aims: Wilson's disease (WD) is a rare autosomal recessive disorder of copper metabolism, leading to liver cirrhosis and neurologic disorders. Clinical data on larger cohorts are limited, owing to low disease frequency.
The aim is to determine clinical presentation and outcome of patients with WD in a cohort of patients from a French liver reference center.
Method: This is a retrospective analysis of patients with diagnosis of WD in a liver reference center (Paul-Brousse Hospital, Villejuif, France). Patients were evaluated clinically, biologically, morphologically and genetically. Hepatic involvement was assessed with liver biopsy and/or liver stiffness measurement.
Results: We included 107 patients with hepatic symptoms of the WD, 54 (50.5%) females and 53 (49.5%) males, from 1974 to 2016. The mean follow up was 15 years [extr: 1–44 years]. Fifty-seven (53.3%) had neurological symptoms (mixed symptoms, neurologic and hepatic) at admission. The mean age at diagnosis was 20.1 (± 10.54) years with a difference between the age concerning the patients with hepatic symptoms (17 ± 8.6 years) and mixed symptoms (23 ± 11.4 years) (p = 0.0081). 65 patients (70%) had liver pathological analysis and 72 (67%) had liver stiffness measurement. Seventy-three patients (68%) had cirrhosis at diagnosis of the disease. Forty-three patients (77%) had cirrhosis among patients with mixed symptoms and 30 (61%) in patients with isolated hepatic symptoms. Thirty-four patients (32%) were transplanted, at a mean age of 27 (± 12.2) years. Among patients who required liver transplantation 18 (52%) had decompensated cirrhosis, 8 (23%) fulminant liver failure, 8 (23.5%) severe neurological disease and 5 (14%) liver cancer. The chelating treatment was very predominantly D Penicillamine, in 104 (97%) patients. A change in treatment was necessary in 37 (35%) patients because of adverse events to Trientine or Zinc salts. Four patients died in this cohort; two after primary liver cancer (1 HCC and 1 cholangiocarcinoma), one after hemorrhagic stroke and one after liver transplantation for severe neurological symptoms.
Conclusion: At presentation of WD, two thirds of patients referred to a reference center of hepatology, had cirrhosis and one-third required liver transplantation. Cirrhosis was diagnosed in 77% patients who have neurological symptoms of the disease. Even if WD can be a severe disease, the prognosis is good for patients in charge in a specialized center.

SAT-056

Abnormalities in left ventricular geometry are associated with mortality and morbidity in children with biliary atresia and end stage liver disease

N. Gorgis, C. Kennedy, K. Thompson, J. Goss, T. Miloh, M. Desai.
Texas Children's Hospital
Email: noelle.gorgis@gmail.com

Background and Aims: Abnormalities in cardiac geometry – an essential component of cirrhotic cardiomyopathy- is associated with adverse outcomes in adults with cirrhosis. We aimed to characterize the structural abnormalities of the left ventricle (LV) in children with biliary atresia (BA) and end stage liver disease (ESLD) listed for liver transplant (LT) and evaluate their associations with perioperative morbidity and mortality. We hypothesized that markers of LV hypertrophy (LVH) correlate with serious perioperative adverse events (AE) including post-LT mortality.
Method: 73 patients with BA and a complete pre-operative 2-dimensional echocardiogram were listed for LT at our institution (2011–2016). 4 patients with congenital heart disease were excluded. In the remaining 69 patients (median age 11mo [IQR: 8–20], 65% female), LVH was defined as a LV mass indexed to BSA (LVMI) ≥ 90 g/m^2 or a relative wall thickness (RWT) ≥ 0.42 cm. Comparison of primary (post-LT death and a composite of serious AE) and secondary (ICU and hospital lengths of stay (LOS)) were made between those with and without LVH. Statistical analysis: Mann-Whitney, Fischer Exact, and Spearmen. Reported as number (%) or median (Interquartile Range).

Results: 29 (42%) of 69 patients listed for LT had LVH, including all 4 wait-list deaths. Of the 65 patients who survived to LT, those with LVH had a higher incidence of peri-LT multi-organ dysfunction, with a significantly increased need for mechanical ventilation (MV), vasopressors (VP), and dialysis (HD), as well as a higher incidence of serious AE and post-LT death (Table). Median LVMI was significantly higher in patients with a serious AE (92 [IQR: 84–112] vs. [75 [IQR:63–84], $p < 0.001$) and in those who died post-LT (96 [IQR: 84–132] vs. 77 [IQR:67–88], $p < 0.01$). ICU and hospital LOS was also longer in this cohort ($p < 0.01$).

Table 1: Comparison of characteristics between those with and without LVH

Variable	LVH (n = 25, 38%)	No LVH (n = 40, 62%)	p
Multi-organ failure	15 (60%)	6 (15%)	<0.001
MV need	20 (80%)	17 (43%)	<0.01
VP need	15 (60%)	6 (15%)	<0.001
HD need	15 (60%)	6 (15%)	<0.001
Any AE	15 (60%)	2 (5%)	<0.0001
Post-LT Death	6 (24%)	1 (3%)	0.01
ICU LOS	40 (5–117)	5 (2–20)	<0.01
Hospital LOS	97 (13–158)	16 (7–39)	<0.01

Conclusion: LVH is significantly associated with morbidity and mortality in patients with BA and ESLD requiring LT. These findings support the need to recognize and monitor for LVH while listing children with BA for LT.

SAT-057

Disease severity, obeticholic acid disposition and dose selection in patients with biliary atresia

J. Edwards[1], C. Lacerte[1], Y. Zhang[1], S. Karpen[2], J. Owens-Grillo[1], L. Macconell[1]. [1]*Intercept Pharmaceuticals, Inc.;* [2]*Emory University School of Medicine, Department of Pediatrics*
Email: jeffrey.edwards@interceptpharma.com

Background and Aims: Biliary atresia (BA) is a rare neonatal disease that presents as a progressive, obstructive cholangiopathy leading to rapid development of portal hypertension, cholestasis, and cirrhosis. A Phase 2 clinical trial evaluating the safety, tolerability, and pharmacokinetics (PK) of obeticholic acid (OCA) in pediatric patients with BA who have undergone successful hepatoportoenterostomy is currently ongoing. OCA, a selective and potent farnesoid X receptor agonist, is a modified bile acid with a metabolic disposition like endogenous bile acids. Since bile acid disposition processes appear to mature by late infancy, OCA exposure is expected to be similar for adults and children when adjusting dose by body weight. However, the PK of OCA and bile acids are expected to vary with disease severity in BA. The goal of this analysis was to explore potential relationships between biomarkers of disease status and OCA exposure in support of defining a dosing regimen for BA.
Method: OCA plasma concentrations observed after a single body weight-adjusted dose of OCA in pediatric patients with BA (N = 6; ages 3–17) were compared to exposure levels in healthy adults. Relationships were assessed between OCA exposure levels and status of portal hypertension, bilirubin levels, and markers of disease severity including aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, gamma-glutamyl transferase, platelets, and AST to platelet ratio index (APRI).
Results: The PK of OCA was altered in patients with more advanced BA. Patients with elevated bilirubin and/or portal hypertension showed higher systemic exposure of OCA with the highest levels observed in patients with both elevated bilirubin and portal hypertension (Figure 1). Relationships between the PK of OCA and liver biomarkers, ALT and APRI, were detected. These results are consistent with those previously reported, showing a relationship between disease severity and APRI in patients with BA.

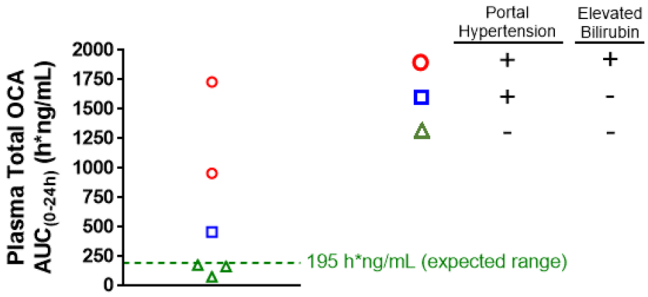

Figure 1:

Conclusion: Positive relationships were found between the systemic exposure of OCA and bilirubin, ALT, APRI, and the presence of portal hypertension or vascular shunting. Although trends were observed between drug exposure and these biomarkers, it is premature to assign OCA dosing based on these biomarkers. Instead, a conservative approach of characterizing the individual PK of OCA after a single dose in each patient with BA is used to determine an appropriate multiple-dosing regimen.

SAT-058

The Galactose Elimination Capacity test may monitor treatment response and disease progression in patients with Wilson Disease

T.D. Sandahl, J.A.E. Björklund, T.L. Laursen, P. Ott, H. Grønbæk. *Aarhus University hospital, Department of Hepatology and Gastroenterology, Aarhus*
Email: thomas.damgaard.sandahl@ki.au.dk

Background and Aims: The prognosis of Wilson disease (WD) has changed radically since the introduction of medical therapy with chelating agents and medications to block copper absorption. However, there is an unmet need for methods to evaluate the long-term treatment response in order to identify treatment failures. The galactose elimination capacity test (GEC) is a physiological measure of the total metabolic capacity of the liver, and a predictor of long- and short-term mortality in patients with liver cirrhosis. Our aim was to investigate whether repeated GEC measurements can be used to evaluate treatment response and identify treatment failures in patients with WD.
Method: We included all cases with WD in Denmark from 1992 through 2016. We retrieved data on GEC and fibroscan along with data on transplantation and survival for all patients. We analysed the development in liver function in each patient by comparing their GEC's over time.
Results: We identified 57 patients with WD. Of these 46 were alive, 10 were dead, 9 transplanted and 1 was lost to follow-up. Eighteen living non-transplanted patients had completed more than one GEC since 1993. Of these, 16 patients showed improvement in their GEC. Two patients had a decreasing GEC over time and these were clinically confirmed as treatment failures. All patients, who underwent liver transplantation or died had a prior decrease in their GEC. There was no significant difference in median values of the index GEC between patients who were later transplanted or dead and patients who were not (GEC 1.87mmol/min (IQR 1.22) vs. 1.66 mmol/min (IQR 0.64). The GEC correlated inversely with fibroscan values, rho=–0.49 p = 0.02.
Conclusion: Repeated GEC measurements may be a useful tool to monitor treatment response and identify treatment failures in patients with WD.

SAT-059

The global prevalence of lysosomal acid lipase deficiency estimated by meta-analysis of pathogenic mutations and functional variants from next-generation sequencing data

A. Carter[1], S. Brackley[2], J. Gao[2], J. Mann[3]. [1]*Manchester University Foundation Trust, Manchester, United Kingdom;* [2]*University of Cambridge, Clinical School, Cambridge, United Kingdom;* [3]*University of Cambridge, Dept of Paediatrics, Cambridge, United Kingdom*
Email: Anna.carter@nhs.net

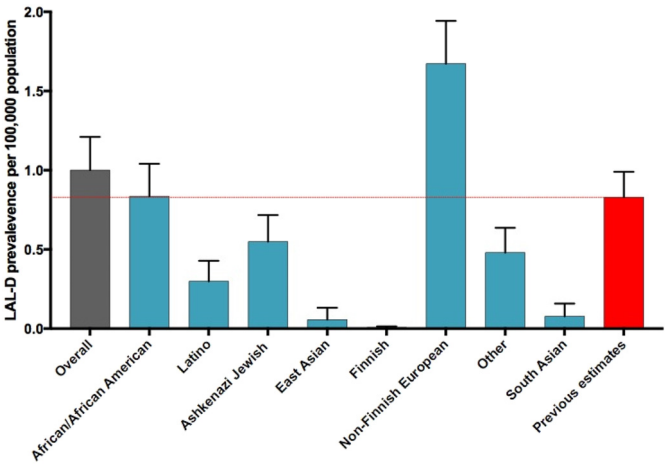
Background and Aims: Lysosomal Acid Lipase Deficiency (LAL-D) is a rare autosomal recessive disorder caused by mutations in *LIPA*. It presents with a spectrum of severity: from infantile liver failure in Wolman disease to Cholesterol Ester Storage Disease (CESD), which mimics features of non-alcoholic fatty liver disease (NAFLD). It has been suggested that CESD is under-diagnosed and may represent significant proportion of patients with NAFLD. We aimed to meta-analyse published prevalence estimates and predict the prevalence of LAL-D using population sequencing data and a validated methodology.

Method: MEDLINE and EMBASE were systematically searched for articles related to LAL-D, CESD, Wolman disease, and *LIPA*. Previous prevalence estimates were meta-analysed. All previously reported pathogenic mutations in *LIPA* were recorded from articles and ClinVar. Using Ensembl and gnomAD, a list of all predicted pathogenic variants in *LIPA* was collated and the Ensembl Variant Effect Predictor (https://ensembl.org/Tools/VEP) was used to annotate variants with allele frequencies from gnomAD and 1000G data sets. A pooled global prevalence estimate was generated using the Hardy-Weinberg equation, in addition we estimated the prevalence for 8 separate ethnicities.

Results: 341 abstracts were screened and 57 studies were included, reporting population prevalences ranging from 0.2 to 23 per 100,000. Meta-analysis of previous data gave an estimate of 0.83 per 100,000 (95%CI 0.66–0.99).

70 previously reported pathogenic variants were elucidated from publications. 28 *LIPA* variants were found from reports of *in vitro* testing. A further 47 predicted functionally significant variants were identified. From the 70 previously reported pathogenic variants, CESD had a total allele frequency of 0.0017 and prevalence 0.29 per 100,000 (95%CI 0.2–0.4).

The predicted total prevalence for LAL-D from all 141 variants was higher at 1.0 per 100,000 (95%CI 0.8–1.2). Non-Finnish Europeans had the highest estimated prevalence (1.7 per 100,000 (95%CI 1.5–1.9)) compared to only 0.007 per 100,000 ((95%CI 0.003–0.01)) in Finnish ethnicity.



Conclusion: These data provide the first global prevalence estimate of LAL-D, in addition to an unbiased description of the multi-ethnic risk. Though LAL-D may be underdiagnosed, it is a rare disorder and will account for only a minority of patients presenting with non-alcoholic fatty liver disease.

SAT-060

Correlation of autotaxin levels, serum bile acids, and pruritus in a multiple-dose, open-label, multinational study of the ileal bile acid transport inhibitor A4250

E. Gonzales[1], E. Sturm[2], U. Baumann[3], F. Lacaille[4], H. Arnell[5], B. Fischler[5], M.H. Jørgensen[6], R. Thompson[7], J. Mattsson[8], M. Ekelund[8], E. Lindstrom[8], P.-G. Gillberg[8], K. Torfgard[8], P. Soni[9]. [1]*University Hospitals of Paris-Sud, Pediatric Hepatology and Liver Transplantation, Bicetre, France;* [2]*University Children's Hospital Tübingen, Pediatric Gastroenterology and Hepatology, Tübingen, Germany;* [3]*Hannover Medical School, Klinik für Pädiatrische Nieren- Leber- und Stoffwechselerkrankungen, Hannover, Germany;* [4]*Necker- Enfants Maladies Hospital, Pediatric Gastroenterology Hepatology-Nutrition, Paris, France;* [5]*Astrid Lindgren Children's Hospital, Karolinska University Hospital, CLINTEC, Karolinska Institutet, Stockholm, Sweden;* [6]*Rigshospitalet, Pediatric and Adolescent Medicine, Copenhagen, Denmark;* [7]*Institute of Liver Studies, King's College London, London, United Kingdom;* [8]*Albireo AB, Gothenburg, Sweden;* [9]*Albireo Pharma, Inc., Boston, United States*
Email: paresh.soni@albireopharma.com

Background and Aims: The endophosphatase/phosphodiesterase autotaxin (ATX) and lysophosphatic acid have been proposed to play a role in cholestatic pruritus. Ileal bile acid transporter (IBAT) inhibition is a novel treatment approach for cholestatic pruritus and progression of cholestatic liver disease. A4250 is a potent, highly selective reversible IBAT inhibitor that decreases enteric bile acid reuptake with minimal systemic exposure. In a Phase 2, open-label study in children with cholestatic liver disease and pruritus, A4250 was well tolerated overall and reduced serum bile acid levels and pruritus in most patients. Statistically significant correlations were observed between reduction in serum bile acids and improvement on several pruritus scales. Here we report findings from this study on ATX levels and the relationship between ATX, serum bile acids, and pruritus.

Method: A4250 was administered orally once daily for 4 weeks at 5 doses (10–200 μg/kg) in 20 children. Endpoints included changes in serum bile acid levels (primary efficacy endpoint), pruritus, sleep disturbance, and ATX protein levels (measured by ELISA). Correlations between bile acids, ATX, and pruritus as measured by visual analog scale (VAS)-Itch score were also examined.

Results: At baseline, the correlation between ATX level and pruritus score was strong (VAS-Itch, Pearson $r = 0.67$; $p = 0.001$), whereas ATX was not strongly correlated with serum bile acids (Pearson $r = 0.33$; $p = 0.12$). ATX decreased in most patients following treatment with A4250, with an overall mean reduction of 21 5% (SEM). Percent decrease in ATX was strongly correlated with percent decrease in serum bile acids (Pearson $r = 0.60$; $p = 0.003$). There was a trend toward correlation of percent change in ATX and absolute change in VAS-Itch (Pearson $r = 0.39$; $p = 0.075$).

Conclusion: While improvements in pruritus have been previously reported in this study to be correlated with reductions in serum bile acids, this is the first report of a correlation between reductions in serum bile acids and reductions in ATX with an IBAT inhibitor in this patient population. Further studies to investigate the role and importance of ATX as a biomarker of cholestatic pruritus in children are warranted.

SAT-061

Liver disease in a cohort of patients with Gaucher disease from Southern Brazil: a cross-sectional study

R. Starosta[1], A.D. Dornelles[2], F.P. Vairo[1,3], M.R. Álvares-Da-Silva[4], I.V.D. Schwartz[1]. [1]*Post-Graduation Program on Genetics and Molecular Biology, Service of Medical Genetics, Porto Alegre, Brazil;* [2]*Post-Graduation Program on Child and Adolescent Health, Service of Medical*

Genetics, Porto Alegre, Brazil; [3]Mayo Clinic, Center for Individualized Medicine, Rochester, MN, United States; [4]Hospital de Clínicas de Porto Alegre, Service of Gastroenterology, Porto Alegre, Brazil
Email: rodrigo.starosta@ufrgs.br

Background and Aims: Gaucher disease (GD) is characterised by glucosylceramide build-up in macrophages, which may cause liver damage. Still little is known about the natural history of liver injury in GD, which ranges from mild steatosis to full-blown cirrhosis. We aim to describe the liver involvement found in patients followed at the Gaucher Reference Centre of Hospital de Clínicas de Porto Alegre (HCPA).
Method: A cross-sectional, retrospective study. Data were obtained from patients' electronic medical records. The most recent value for each exam was considered. When the most recent exam was older than two years, the patient was excluded from the analysis. Values were presented as median + IQR.
Results: Thirty-nine patients were included in the study (GD type I = 36, GD type III = 3; median age = 35 ± 24 yr; male = 18). Thirty-eight patients were on treatment, most with enzyme replacement therapy (ERT, n = 35). Seven patients were splenectomised (17.95%). According to the abdominal ultrasound or abdominal MRI (n = 31), 12 patients (38.7%) have had liver findings, being steatosis and cirrhosis the most frequent (n = 5 and 2, respectively). The following liver biochemical abnormalities were found: AST in 2 patients (median of all patients = 20 ± 8 UI/dl), ALT in 2 patients (median = 21 ± 11 UI/dl), γGT in 15 patients (median = 26 ± 14.5 UI/dl), alkaline phosphatase in 4 patients (median = 65 ± 22.5 UI/dl), total bilirubin in 3 patients (median = 0.6 ± 0.6 mg/dl), and albumin in 1 patient (median = 4.5 ± 0.5 g/dl). Serum ferritin in 27 patients (median = 439.7 ± 555.6 ng/ml). Hepatitis B was present in one case. Five patients had liver biopsies, which showed iron deposition in the cytoplasm of hepatocytes and in Kupffer cells in all patients, ranging from mild to severe; one of the biopsies showed a hepatic gaucheroma.
Conclusion: Liver disease may be more frequent than expected in GD. Despite treatment, many patients present at least one altered liver enzyme, which may indicate chronic liver damage activity. The high prevalence of steatosis may reflect chronic steatohepatitis due to disease activity. Hepatologists should be aware of liver involvement in GD.

SAT-062

Characteristics associated with non-response to ursodeoxycholic acid in primary biliary cholangitis

Email: marta.gomes@exigoconsultores.com

Background and Aims: Non-response to treatment with ursodeoxycholic acid occurs in 20–40% of patients with primary biliary cholangitis, leading to disease progression. The aim of our study is to assess the patients characteristics associated with non-response.
Method: We performed a retrospective cohort study using a nationwide registry of liver diseases, selecting exclusively patients with primary biliary cholangitis as primary diagnosis. Main endpoints included the evaluation of treatment response to ursodeoxycholic acid and the assessment of the patients' characteristics associated with non-response. Response to treatment was evaluated according to Barcelona, Paris I and Paris II criteria. Logistic regression was used to assess the patients' characteristics associated with non-response to treatment, according to Paris-II criteria. The significance level adopted was 5%. All analysis were conducted in R software.
Results: A total of 345 patients were identified with primary diagnosis of primary biliary cholangitis. At diagnosis, mean age was 55.0 years, 89.9% were women, 89.9% had positive anti-mitochondrial antibodies, 21.8% had cirrhosis and almost half (55.7%) of the population were asymptomatic. More than one fifth of patients (21.6%) developed symptoms (pruritus, fatigue and jaundice) between diagnosis and the time of assessment cut-off date, despite treatment initiation. Non-response to ursodeoxycholic acid was 33.9% (63/186), 43.7% (59/135) and 64.3% (101/157) according to the Barcelona, Paris-I and Paris-II criteria, respectively. In the multivariate analysis the presence of symptoms (OR = 7.7 [95%CI = 2.5–24.3], $p < 0.001$) and cirrhosis (OR = 4.2 [95%CI = 1.2–17.9], $p = 0.027$) at diagnosis was significantly associated with non-response to ursodeoxycholic acid according to Paris II criteria, after one year of treatment.
Conclusion: Rate of treatment response with ursodeoxycholic acid varies substantially according to different criteria. Non-response to ursodeoxycholic acid is more likely in patients with symptoms and more advanced liver disease at diagnosis. Assessment of the patient's characteristics at diagnosis can be useful to guide clinical and therapeutic decision making.

SAT-063

Evaluation of the new criteria in the diagnosis of cystic fibrosis liver disease

A. Alexopoulou[1], S. Pouriki[1], L. Vasilieva[1], T. Alexopoulos[1], F. Diamantea[2], M. Gioka[2], A. Nakou[2], D. Zampetas[1], I. Mani[1], S. Ntourakis[1]. *[1]2nd Department of Internal Medicine and Research Laboratory, Medical School, National and Kapodistrian University of Athens, Hippokration Hospital, Athens, Greece; [2]Third Respiratory Medicine Department, Sismanogleio General Hospital, Athens, Greece*
Email: alexopou@ath.forthnet.gr

Background and Aims: In cystic fibrosis (CF), liver disease (CFLD) is the third leading cause of mortality. As liver biopsy has been considered as inconsistent in diagnosis of CFLD, a combination of modalities additional to liver histology, including physical examination, biochemical and imaging were utilized in the conventional Debray criteria (DC). More recently, noninvasive biomarkers have been applied and were included in the New criteria (NC) (Koh C et al, Hepatology 2017;66:591–601). In current study we aimed to evaluate the NC for the diagnosis of CFLD.
Method: Longitudinal data were collected from a cohort of genetically confirmed CF patients. CFLD was diagnosed by both DC and NC. According to NC, CFLD was present if there was radiologic or histologic evidence of cirrhosis or diffuse liver disease or a positive finding in at least two of the four categories including liver function tests, imaging, transient elastography (>6.8 kPa) or other noninvasive liver fibrosis biomarkers [AST/ALT ratio (AAR), ≥1, FIB-4 index ≥3.25, APRI > 0.50].

Results: 62 patents with CF, [56.5% male, median age at diagnosis 6.00 (2.25–33.00) months, age at enrollment 25 (22–31) years], were prospectively followed up for 33 (28–36) months. 16 (25.8%) patients met the classical DC for CFLD. No difference in demographics, INR, AAR and FIB4 were observed in patients with CFLD vs those without according to DC. However, AST (P = 0.012), ALT (p = 0.045), ALP (p = 0.022), g-GT (p = 0.026), liver stiffness (p = 0.03) and APRI (p = 0.032) were higher in CFLD vs no CFLD patients. According to NC, 26 (41.9%) had CFLD. No difference in age at diagnosis and enrollment, sex, genotypes and duration of follow-up were shown between CFLD and no CFLD. However, AST (p = 0.001), ALP (p = 0.002), g-GT (p = 0.002), INR (p = 0.023), liver stiffness (p < 0.001), AAR (p = 0.035), FIB4 (p < 0.001) and APRI (p = 0.001) were higher in CFLD vs no CFLD patients. 13 (50%) of patients who were classified as CFLD according to the NC had evidence of diffuse liver disease/cirrhosis in imaging and all of them had at least one additional parameter. From the 13 (50%) patients with no evidence of diffuse liver disease, 38.4%, 30.8% and 30.8% had 2, 3 and 4 of the four sets of parameters, respectively, classifying them as CFLD.
Conclusion: The New criteria are able to identify 16.1% more CFLD patients compared to historical ones. The multiple non invasive biomarkers incorporating in New criteria may enhance the ability to detect CFLD.

Non-invasive assessment of liver disease except NAFLD

SAT-065

Transient elastography as a screening method for chronic liver disease in apparently healthy population. Results from de ETHON cohort

E. Llop[1,2], P. Iruzubieta[2,3], C. Perelló[1], J. Cabezas[3], D. Escudero-García[4], M. González[3], M.H. Conde[1], L. Puchades[4], M.T.A. Loste[3], M. Serra[4], J. Crespo[3,5], J.L.C. Panero[1,5]. *[1]Servicio de Aparato Digestivo. Hospital Universitario Puerta de Hierro Majadahonda. CIBERHD. Facultad de Medicina. Universidad de Cantabria; [4]Servicio de Medicina Digestiva. Hospital Clínico Universitario Valencia. INCLIVA; [5]Co-Senior Author*
Email: elballop@gmail.com

Background and Aims: Transient elastography (TE) has been very useful for the diagnosis of chronic liver diseases. The aim of this study was to evaluate the use of TE in apparently healthy population and to determine the factors associated with the presence of significant fibrosis (SF) and advanced fibrosis (AF).
Method: Epidemiological, cross-sectional, population based multicenter (Santander, Madrid, Valencia) study from the ETHON cohort. The participants were selected through a random and representative sample by means of sampling by two-stage conglomerates with stratification according to socioeconomic status, rural/urban area and age, being representative of the general population. TE, an epidemiological questionnaire, laboratory test and anthropometric measurements were obtained in the same day.
Results: Between 2015 and 2017, 12519 subjects were included, in 1079 (8.6%) no reliable TE results were obtained. Data of 11440 subjects were analyzed. 53.8% of subjects aged 50–79 years, 58.1% women. 16.3% presented strict criteria for metabolic syndrome (MS) (NCEP ATP-III), 1.3% with anti-HCV+, 0.8% HBsAg+, 7.3% reported harmful alcohol consumption. 7.4% had SF (TE > 7 ≤ 12.6 KPa) and 1.6% had AF (TE > 12.6 KPa). 66.1% of patients with SF and 41.1% of patients with AF had normal liver function tests. In 48.8% of the subjects with SF Controlled Attenuation Parameter (CAP) values were suggestive of severe steatosis (S2 > 280 db/m) OR 2.2 (1.7–2.8) (p < 0.001) and in 60% of the subjects with AF CAP values were suggestive of severe steatosis (S2 > 280 db/m) OR 3.3 (1.9–5.7) (p < 0.001). In the multivariate analysis, factors independently related to the presence of SF were: age OR 1.5 (1.3–1.7) (p = 0 < 0.001), male sex OR 1.7 (1.5–2.0) (p < 0.001), the MS OR 1.8 (1.5–2.1) (p < 0.001), anti-HCV + OR 1.9 (1.1–3, 0) (p = 0.02) and HBsAg+ OR 2.5 (1.4–4.4) (p = 0.002). In AF, age OR 1.5 (1.3–1.7) (p < 0.001), male sex OR 1.7 (1.5–1.9) (p < 0.001) and the MS OR 1.8 (1.5–2.1) (p < 0.001) were independently related to its presence.
Conclusion: A high percentage of the apparently healthy population showed SF. The independent predictors of its presence were age, male sex, MS, antiHCV+ and HBsAg + . On the other hand, a non-negligible percentage of the apparently healthy population had AF. Age, male sex and MS were the independent factors of its presence. TE is a useful tool for screening chronic liver disease in healthy population, even with normal liver function tests.

SAT-066

Prognostic value of 2D-shear wave elastography for staging cirrhosis in chronic liver diseases in two severity classes according to liver-related complications

P. Pollo-Flores[1], M. Munteanu[2], A. Ngo[3], Y. Ngo[3], E. Luckina[4], T. Phim[5], H. Perazzo[6], L. Bonyhay[7], M. Rudler[7], P. Lebray[7], D. Thabut[8], V. Ratziu[8], T. Poynard[8]. *[1]CAPES, UFF Internal Medicine Department, Niteroi, Brazil; [2]Biopredictive, APHP, Paris, France; [3]Biopredictive, APHP, Paris, Brazil; [4]APHP, Inserm; [5]APHP, Biopredictive; [6]FIOCRUZ, Infectious National Institute, Rio de Janeiro, Brazil; [7]APHP, Paris, France; [8]APHP, UPMC, Paris, France*
Email: priscilapollo96@gmail.com

Background and Aims: In chronic liver disease (CLD), FibroTest (FT, BioPredictive), and transient elastography (TE M-probe, Echosens), are associated with increased overall and liver-related mortality and morbidity. Moreover, FT and TE-M were validated as markers of occurrence of cirrhosis without complications (F4.1), oesophageal varices (EV) grade 2 or more (F4.2), and severe complications (SC) (F4.3) – EV rupture, encephalopathy, ascites and hepatocellular carcinoma (HCC) (J Hepatol 2014). The aim of this study was to extend the validation of elastography by 2D-shear wave elastography (2D-SWE), as a prognostic marker of occurrence of cirrhosis without complications (F4.1) versus cirrhosis with EV and SC (F4.2-F4.3).
Method: 3,853 patients (pts) with CLD were pre-included prospectively from Jan-2012 to Dec-2013. 3627pts had 2D-SWE, and 2686pts (74.1%) had all methods. Appli-2D-SWE was defined after excluding minimal stiffness <0.2 kPa. Cirrhosis was defined by FibroTest ≥0.74 and TE-M ≥12.5 kPa respectively. The applicable 2D-SWE, TE-M, -XL and M or XL and FT were, respectively, 90.4%, 80.0%, 90.8%, 94.5% and 99.5%.
Results: 585pts with applicable-2D-SWE and cirrhosis as per FT or TE-M-XL were followed up for a median (range) 30(0–62.3) months and 13(4.2%) died. None had history of complications, after 30 months had occurred 47 varices (F4.2, incidence of 8.0%) and 50 severe complications (F4.3 8.6%), including HCC in 20 (3.4%). The survivals (95%CI) without EV/SC were: 78.8% (69.4–88.2) in the group F4.23 (2D-SWE ≥ 20 kPa); 89.9% (84.3–95.5) in F4.1 (12.5 kPa ≥ 2D-SWE < 20 kPa, p = 0.025 vs F4.23); and 94.5% (91.4–97.6) in the group without cirrhosis (noF4) (p = NS vs F4.1). (Figure 1). Among pts with concomitant appli-TE, FT and 2D-SWE, the prognostic AUROCs (95% CI) for esophageal varices and severe complications were: 0.94 (0.90–0.97), 0.92 (0.87–0.95, p = NS vs TE) and 0.79 (0.69–0.86, p < 0.01 vs TE and vs FT), respectively.

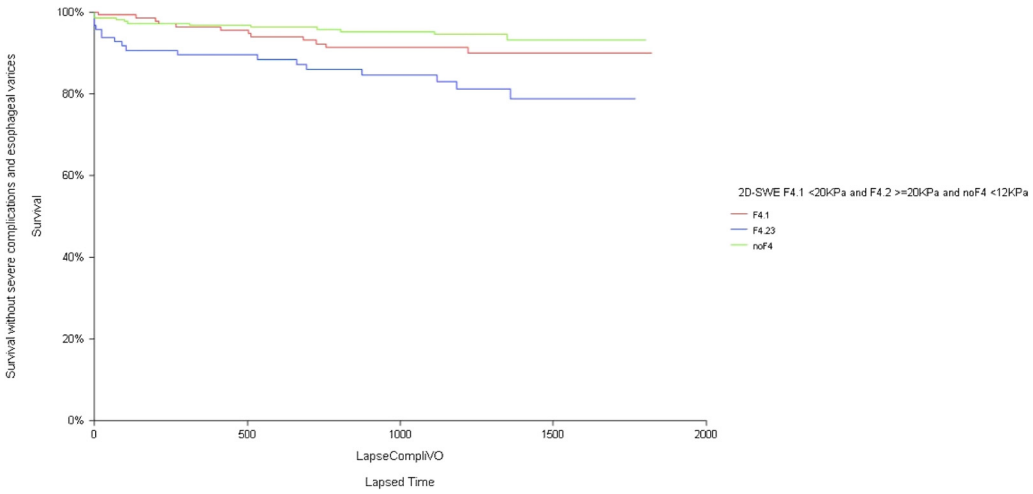

Figure 1: (abstarct: SAT-066): Survival Curves according to 2D-SWE classes of liver disease severity.

Conclusion: Liver biomarkers, such as 2D-SWE, have prognostic values in patients with CLD for predicting varices and severe complications in cirrhotic patients. Previously validated FT and TE predictions of varices and severe complications were comparable and both were superior to 2D-SWE.

Oberti[1,2], I.F. Hubert[1,2], F. Chermak[7], C. Aubé[2,5], V.D. Ledinghen[10]. *[1]Angers University Hospital, Hepato-Gastroenterology, Angers, France; [2]Angers University, HIFIH Laboratory, Angers, France; [3]Bordeaux University Hospital, Radiology, Bordeaux, France; [4]Bordeaux University Hospital, Hepato-Gastroenterology, Pessac, France; [5]Angers University Hospital, Radiology, Angers, France; [6]Bordeaux University Hospital, Radiology, Bordeaux, France; [7]Bordeaux University Hospital, Hepato-Gastroenterology, Bordeaux, France; [8]Angers University Hospital, Pathology Department, Angers, France; [9]Bordeaux University Hospital, Pathology Department, Bordeaux, France; [10]Bordeaux University Hospital, Hepato-Gastroenterology, Bordeaux, France*
Email: jeboursier@chu-angers.fr

Background and Aims: Acoustic Radiation Force impulse (ARFI, also named point-shear wave elastography), is an elastography modulus included in a widely used ultrasonographic device which allows for the non-invasive evaluation of liver fibrosis in chronic liver diseases through liver stiffness measurement (LSM). We aimed to determine the reliability criteria of LSM with ARFI.
Method: 1,094 patients with chronic liver diseases had liver biopsy and LSM with ARFI in two centres. ARFI examination was performed in fasting condition by experienced radiologists. Pathological examinations of liver biopsies were performed in each centre by a senior expert specialized in hepatology. Advanced fibrosis was defined as NASH CRN F ≥ 3 or Metavir F ≥ 2.
Results: LSM with ARFI failed (no measurement) in 10 patients (0.9%). Among the 1084 remaining patients included in the statistical analysis (male: 61.9%; age: 54.3 ± 13.3 years; NAFLD 48.5%, BMI: 28.9 ± 6. kg/m2), 48.5% had advanced fibrosis and 16.8% were cirrhotic. The cause of chronic liver disease was NAFLD in 48.5%, virus: 26.3%, alcohol: 12.2%, and other: 13.0%. AUROC, diagnostic cut-offs, and rate of patients correctly classified for advanced fibrosis and cirrhosis were, respectively: 0.773 ± 0.014 and 0.839 ± 0.014, 1.37 m/s and 1.87 m/s, 72.0% and 78.4%. ARFI reliability relied on the IQR/M ratio, especially for intermediate/high levels of liver stiffness. Three reliability categories were defined for LSM with ARFI: "very reliable" (IQR/M < 0.15), "reliable" (0.15 ≤ IQR/M < 0.35 or IQR/M ≥ 0.35 with ARFI median <1.37 m/s), and "poorly reliable" (IQR/M ≥0.35 with ARFI median ≥1.37 m/s). Using these new criteria, the rate of patients correctly classified for advanced fibrosis was, respectively: 80.9%, 73.7%, and 57.8% (p = 0.029 between very reliable and reliable; p < 0.001 for other paired comparisons); and for cirrhosis: 92.6%, 83.4%, and 50.0% (p < 0.001 for each paired comparison). Results were not significantly different between the two centres. 23.6% of the ARFI examinations were very reliable, 55.0% reliable, and 21.4% poorly reliable. The skin-liver capsula distance was an independent predictor of poorly reliable ARFI examination which occurred in 52.7% of patients having a distance ≥30 mm.
Conclusion: Based on IQR/M ratio and ARFI median, we defined three reliability categories for LSM with ARFI associated with significantly different diagnostic accuracies. These new reliability criteria for ARFI will help physician to accurately evaluate the severity and follow chronic liver diseases.

SAT-068

The ProC3 marker of type III collagen formation accurately reflects hepatic inflammation and fibrosis stage in asymptomatic alcoholic liver disease patients

M. Thiele[1,2,3], M.J. Nielsen[4], B.S. Madsen[1], M. Kjærgaard[1], J. Hansen[5], S. Antonsen[6], L.M. Rasmussen[7], D. Leeming[4], S. Detlefsen[8], M. Karsdal[4], A. Krag[1,2]. *[1]Odense University Hospital, Department of Gastroenterology and Hepatology, Odense C, Denmark; [2]University of Southern Denmark, Department of Clinical Research, Odense C, Denmark; [3]Odense University Hospital, OPEN, Odense Patient data Exploratory Network, Odense C, Denmark; [4]Nordic Bioscience A/S, Biomarkers & Research, Herlev, Denmark; [5]Odense University Hospital, Department of Infectious Diseases, Odense C, Denmark; [6]Odense University Hospital Svendborg, Department of Clinical Biochemistry, Svendborg, Denmark; [7]Odense University Hospital, Department of Clinical Biochemistry and Pharmacology, Odense C, Denmark; [8]Odense University Hospital, Department of Pathology, Odense C, Denmark*
Email: maja.thiele@rsyd.dk

Background and Aims: Alcoholic liver disease (ALD) is characterised by a long, compensated phase of collagen accumulation, driven by hepatic inflammation and profibrotic signalling. Most physicians therefore evaluate ALD patients using liver fibrosis markers. However,

currently available markers are static and fail to reflect the dynamics of fibrosis progression. Neoepitopes are extracellular matrix protein fragments that reflect true collagen formation and degradation. We therefore aimed to assess whether collagen formation, measured by novel neoepitope markers, reflect alcoholic liver fibrosis stage and inflammatory activity grade.

Method: Prospectively conducted study from 2013 to 2016. All investigations performed on the same day. We used liver biopsy as reference for fibrosis (Kleiner fibrosis stage F0-4) and alcoholic steatohepatitis (NAFLD Activity Score; ballooning 0–2, lobular inflammation 0–3 and steatosis 0–3). We recruited two cohorts of asymptomatic, compensated ALD patients; one from primary care (n = 132, 6% prevalence of ≥ F3) and one from secondary healthcare (n = 172, 35% prevalence) and compared them to 50 healthy controls, matched 1:6 for age and gender (no chronic illnesses, medication, alcohol or NAFLD).

Results: We screened 12 neoepitope markers. The N-terminal pro-peptide of type III collagen formation (ProC3) correlated strongest with fibrosis, steatosis and hepatic inflammation (sum of ballooning and lobular inflammation scores). ProC3 also correlated with non-invasive markers of fibrosis: Enhanced Liver Fibrosis test (r = 0.750), FibroScan (r = 0.552) and FibroTest (r = 0.534). Similarly, ProC3 correlated with inflammation markers: ActiTest (r= 0.203), cytokeratin-18 markers of apoptosis (M30, r = 0.516) and necrosis (M65, r = 0.533). ProC3 was lowest in the control population (median 8.4 ± 2.1), increased in ALD patients with fibrosis stage 0–1 and inflammation grade 0–1 (11.1 ± 5.1; p < 0.001; n = 121), and further increased (average 3.4 ± 0.3; p < 0.001) for every one fibrosis stage or activity grade elevation. We measured the highest ProC3 values in patients with both advanced fibrosis and high inflammatory activity (64.8 ± 26.6; n = 27). ProC3 diagnosed advanced fibrosis (F ≥ 3) with good accuracy, both in the primary care (AUROC 0.90) and in the secondary care cohort (AUROC 0.84). ProC3 were also good to detect patients with the highest inflammation grades in both cohorts (AUROCs 0.83 and 0.81).

Conclusion: ProC3, the N-terminal pro-peptide of type III collagen formation accurately reflects biopsy-verified fibrosis stage and hepatic inflammation grade in alcoholic liver disease patients. The marker may therefore be suited as tool to monitor disease progression.

SAT-069

Serum hyaluronic acid is an independent predictor of mortality in patients with chronic liver disease

N. Plevris[1], R. Sinha[1], A. Hay[2], J. Plevris[1], P. Hayes[1]. [1]*Royal Infirmary of Edinburgh, Hepatology, Edinburgh, United Kingdom;* [2]*Royal Infirmary of Edinburgh, Critical Care, Edinburgh, United Kingdom*
Email: n.plevris@hotmail.co.uk

Background and Aims: Hyaluronic acid (HA) is a well established non-invasive marker of liver fibrosis. Despite this its prognostic abilities still remain to be fully established. The aim of this study was to investigate the ability of a single serum HA measurement to independently predict mortality in patients with chronic liver disease (CLD) of varying aetiology.

Method: This was a retrospective single centre cohort study. All serum HA measurements in patients with CLD, irrespective of aetiology, between 1995 and 2010 were identified. Patient characteristics, blood parameters (Cr, Na, Bi, Alb, PT, INR) and MELD score at point of HA were determined from review of medical records. All cases were followed up from the date of index HA measurement until the date of death, date of transplant or censor date (1/7/2015). Patients with a known diagnosis of hepatocellular carcinoma or rheumatoid arthritis were excluded. Primary outcomes were all-cause mortality and liver-related mortality. For survival analysis patients were categorised into three groups according to their HA value (Group 1 HA < 100 µg/l, Group 2 HA 100–300 µg/l, Group 3 HA > 300 µg/l).

Results: 589/615 (95.8%) patients with HA levels fulfilled inclusion criteria. 371 (63.0%) patients were males and the median age was 58.0 (IQR 19.0–88.0). Median follow-up was 5.6 years (IQR 0.1–19.7). 207 (35.1%) patients died during the follow-up period, 29 (4.9%) were transplanted, and 353 (60.0%) were transplant free survivors. 37 (6.3%), 403 (68.4%) and 109 (18.5%) patients had HA levels < 100 µg/L, 100–300µg/l and >300 µg/l respectively. Kaplan-Meier survival analysis showed survival was significantly different between the three HA groups for liver related mortality as well as all cause mortality (p < 0.001, Figure). In multivariate Cox regression analysis, HA level (HR 1.04, 95% CI 1.02–1.06, p < 0.001) together with MELD score (HR 1.12, 95% CI 1.09–1.15, p < 0.001), age (HR 1.03, 95% CI 1.01–1.04, p < 0.001) and aetiology of liver disease (p < 0.01) were independent predictors of survival. The unadjusted area under the ROC curve for predicting all-cause and liver related mortality was: 0.75 and 0.85 for HA vs 0.80 and 0.84 for MELD at 1-year; 0.67 and 0.77 for HA vs 0.78 and 0.82 for MELD at 3-years; 0.65 and 0.77 for HA vs 0.73 and 0.78 for MELD at 5-years.

Conclusion: To our knowledge this is the largest study investigating the prognostic ability of HA in a cohort of CLD patients with varying aetiologies. In patients with CLD we have shown that a single HA measurement can independently predict liver-related and all-cause mortality with accuracy comparable to MELD.

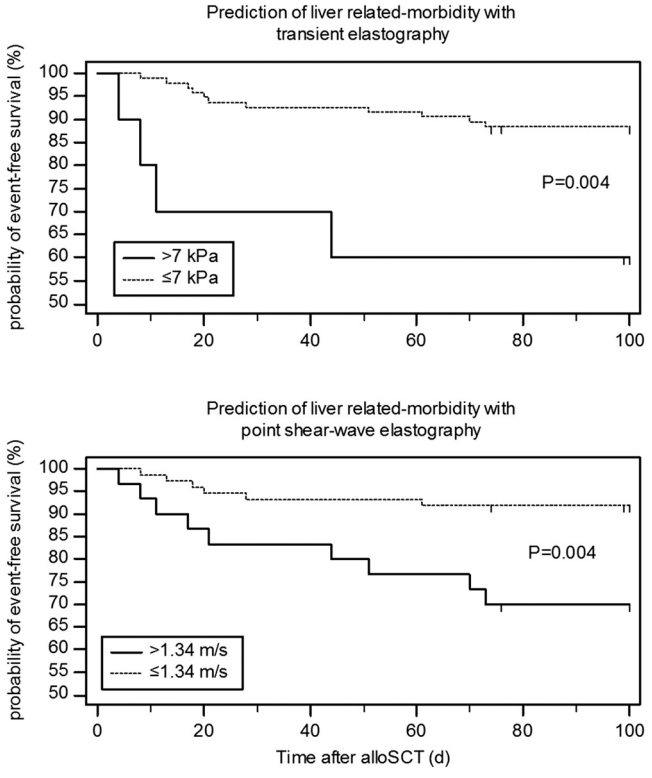
SAT-070

Liver stiffness measurement predicts short-term liver related-morbidity of allogeneic hematopoietic stem cell transplantation

T. Karlas[1], W. Tina[1], B. Sebastian[1], D. Christine[2], L. Franziska[1], D. Niederwieser[2], B. Gerhard[2], J. Mössner[1], J. Wiegand[3], V. Keim[1], G.-N. Franke[2]. *[1]University Hospital Leipzig, Division of Gastroenterology, Leipzig, Germany; [2]University Hospital Leipzig, Division of Hematology and Oncology, Leipzig, Germany; [3]University Hospital Leipzig, Division of Gastroenterology, Section of Hepatology, Leipzig, Germany*
Email: thomas.karlas@medizin.uni-leipzig.de

Background and Aims: Allogeneic hematopoietic stem cell transplantation (alloHCT) is the treatment of choice for various forms of leukemia and lymphoma. Unfortunately, the intended graft-versus-leukemia effect is frequently accompanied by potentially severe side effects of the conditioning regimen and the graft-versus-host disease (GvHD). Especially sinusoidal obstruction syndrome (SOS), drug-induced liver injury (DILI) and liver GvHD contribute to early morbidity and mortality of alloHCT. Liver stiffness measurement (LSM) may potentially help to predict these liver-related complications.

Method: For this monocentric prospective study patients (pts) scheduled for alloHCT underwent LSM with point shear-wave elastography (pSWE) and transient elastography (TE) before start of the conditioning therapy. Pts were followed up for 100 days after alloHCT and classified according to liver-related outcome. Selected symptomatic patients underwent LSM during follow-up.



Results: Of 120 screened patients, 105 fulfilled the inclusion criteria: 40% female, median age 74 (range 18–74) years, body mass index 24.6 ± 4.6 kg/m². Indications for alloHCT comprised acute leukemia/ myelodysplastic syndrome/ lymphoma and other in 50/29/21% of cases. Conditioning regimens were non-myeloablative in 56 pts, reduced intensity in 22 pts and myeloablative in 27 pts. 22 pts had a 10/10 HLA-matched related donor, 62 a matched unrelated donor (UD) and 21 a mismatched UD. 32 (30%) pts developed severe complications and 9 of these died during follow-up. 15 pts (40% female, age 59 (39–68) years) developed liver-related complications: n = 7 SOS, n= 6 liver GvHD, and n = 2 DILI. In this group, baseline TE (>7 kPa) and pSWE (>1.34 m/s) were increased in 27% and 60% of cases compared to 7% and 23% in the group without liver events ($p < 0.05$, respectively). Pts with increased LSM showed a significantly reduced event-free survival (Figure).

15 pts underwent LSM after alloHCT when a liver event was suspected. Pts with definite diagnose of liver-related complications (n = 7) had higher TE and pSWE values compared to pts without confirmed event (median/IQR): 17.3 (8.8–25.8) vs. 5.3 (4.4–7.9)kPa, and 1.77 (1.44–2.47) vs. 1.15 (1.05–1.3)m/s (p = 0.028, respectively).

Conclusion: Elevated baseline liver stiffness assessed with either TE or pSWE is associated with higher risk of liver-related morbidity in the early phase after allogeneic hematopoietic stem cell transplantation. LSM can be useful to diagnose liver complications after alloHCT.

SAT-071

Liver stiffness measurement by 2D SWE from General Electric is similar with Transient Elastography in clinical significant portal hypertension diagnosis

R. Corina[1], B. Procopet[2], M. Platon[3], A. Maniu[1], F. Petra[3], C. Grigoras[3], A. Bugariu[1], M. Tantau[3], R. Badea[3], H. Stefanescu[1]. *[1]Regional Institute of Gastroenterology and Hepatology "O Fodor"; [2]University of Medicine and Pharmacy "Iuliu Hatieganu", 3rd Medical Clinic, Gastroenterology Department; [3]University of Medicine and Pharmacy "Iuliu Hatieganu", Imaging department*
Email: bogdanprocopet@gmail.com

Background and Aims: In compensated advanced chronic liver disease the occurrence of clinical significant portal hypertension (CSPH) has great negative prognostic impact. The standard method for portal hypertension assessment is hepatic venous pressure gradient (HVPG) measurement but is not widely available. Liver stiffness measurement (LSM) by transient elastography (TE) was extensively validated as valid method for diagnosis of CSPH. However, it is not technical feasible in a significant amount of patients. Lately, many other elastographic methods had emerged but still need validation. 2D shear-wave elastography from General Electric (2D-SWE.GE) is a new method developed to assess liver fibrosis.

The aim of the study is to test if 2D-SWE.GE is able to diagnose CSPH in comparison with TE and HVPG.

Method: 81 consecutive patients with advanced liver disease referred to HVPG measurement and concomitant LSM by 2D-SWE. GE and TE were included. The diagnostic performances were assessed by calculating receiver operating characteristic (ROC) curves.

Results: CSPH was found in 57 (70%) of patients [median HVPG = 16 (3–31) mmHg] and 34 (42%) had esofageal varices. There was significant difference between the median of LSM by 2D-SWE.GE in patients with or without CSPH [16.8 (6.3–36.5)kPa vs. 6.4 (3–12.4) kPa]. There was very good correlation between LSM by 2D-SWE.GE and HVPG ($r^2 = 0.750$, $p < 0.001$).

For CSPH diagnosis the AUROC for 2D-SWE.GE was 0.95 (95%CI: 0.90–0.99) ($p < 0.001$) which was identical with TE that had 0.95 (95%CI: 0.91–1.00) ($p < 0.001$). The best cut-off for 2D-SWE.GE for CSPH diagnosis according to the Youden index was 11.4 kPa (Se = 0,83 and Sp = 0.92). However, LSM by 2D-SWE.GE <9 kPa rule-out and >13 kPa rule-in CSPH.

For EV diagnosis LSM by 2D-SWE.GE's performances were lower 0.67 (95%CI: 0.54–0.80) (p = 0.01) but similar with TE 0.68 (95%CI: 0.56–0.80) (p = 0.007).

Conclusion: LSM by 2D-SWE.GE is similar with LSM by TE in CSPH. However, the performances for EV diagnosis seem to be inadequate.

SAT-072

Controlled attenuation parameter reflects intrahepatic fat content in patients with compensated advanced chronic liver disease

R. Piccinni[1], S. Rodrigues[1], M. Montani[2], G. Murgia[1], M.G. Delgado[1], S. Casu[1], J.-F. Dufour[1], A. Berzigotti[1]. *[1]Inselspital, University of Bern, Swiss Liver Center, Hepatology, University Clinic for Visceral Surgery and Medicine, Bern, Switzerland; [2]Univesity of Bern, Institute of Pathology, Bern, Switzerland*
Email: rosangela.piccinni@yahoo.it

Background and Aims: Overweight/obesity and steatosis on histology have been identified as predictors of clinical decompensation in compensated Advanced Chronic Liver Disease (cACLD). Controlled attenuation parameter (CAP) is often elevated in patients with cACLD but it is not known whether in this population it correctly mirrors hepatic fat content. This study aimed at assessing the accuracy of CAP for steatosis in patients with cACLD of any cause. Secondary aim was validation of CAP IQR <40 dB/m as good quality criterion.
Method: This is a single center retrospective study including patients with liver biopsy, CAP measurement and cACLD defined according the Baveno VI criteria (LSM ≥ 10 kPa). 461 patients consecutively undergoing liver biopsy in 06/2015–06/2017 were screened. Exclusion criteria were: LSM < 10 kPa; any hepatic decompensation; no LSM/CAP available within 6 months; LSM IQR/M > 0.30.
On histology, steatosis was graded as S0 (<5%), S1 (5–33%), S2 (33–66%), S3 (>66%). Bridging fibrosis (F3) or cirrhosis (F4) of any cause was considered to confirm ACLD. For VCTE, M or XL probe were used as appropriate. The discriminative ability of CAP for any grade of steatosis and S2-S3 steatosis was studied using the area under receiving operating characteristic curves (AUROC).
Results: 124 patients with Baveno VI-defined cACLD were finally included (63% male, median age 55 y, median BMI 27.4 Kg/m^2, etiology: 30.5% NASH, 30.5% alcohol + metabolic or viral+ metabolic, 15.2% viral, 7.2% autoimmune, 4.2% alcohol, 12.4% others; median ALT 60 U/l, PTL 168). Median LS and CAP were respectively: 16.3 kPa (range: 10–75) and 272 dB/m (range 0–400; IQR < 40 dB/m in 60%). On liver biopsy, steatosis was found in 69.4% (S1 33.9%, S2 19.4%, S3 16.1%), and S2-S3 was almost exclusively seen in patients with NAFLD/NASH or metabolic syndrome + alcohol or viral disease (43 out of 44). CAP was accurate in identifying any steatosis (AUROC 0.827; 95%CI 0.746–0.908, p < 0.0001), and S2-S3 steatosis (0.864; 95%CI 0.796–0.93, p < 0.0001). Restricting the analysis to the 73 patients with bridging fibrosis/cirrhosis on histology, 55 (75%) had steatosis (S2-S3 in 27). In this subgroup CAP performance for any degree of steatosis and S2-S3 steatosis was 0.766 (0.631–0.900), p = 0.001 and 0.828 (0.727–0.930), p < 0.001 respectively. CAP performed worse in patients with CAP IQR ≥ 40dB/m (any steatosis: AUROC 0.675 vs 0.781 in patients with CAP IQR < 40dB/m; steatosis S2-S3: AUROC 0.675 vs. 0.799).
Conclusion: Steatosis is very frequent in patients with histologically confirmed advanced fibrosis and cirrhosis and clinical features of metabolic syndrome. CAP discriminative ability in this specific population is fair for steatosis and good for steatosis S2-S3. CAP IQR ≥ 40dB/m should be considered an indicator of lower diagnostic accuracy in this setting.

SAT-074

Usefulness of liver stiffness measurement by transient elastography for predicting complications in patients with alcoholic liver disease

A. Gomez, B. Redondo, M. Fraile, A. Castano-Garcia, M. Torner, M.L.G. Dieguez, V. Cadahía-Rodrigo, M. Varela, P. Alonso, C. Álvarez-Navascués, M. Rodríguez. *Hospital Universitario Central de Asturias, Liver Unit. Gastroenterology & Hepatology department, Oviedo, Spain*
Email: anagomezoutomuro@gmail.com

Background and Aims: Measurement of liver stiffness by transient elastography (TE) has shown to be useful to predict the risk of developing cirrhosis complications (CC) in patients with viral liver cirrhosis, but there are no data in patients with alcoholic liver cirrhosis (ALC). Aim: To know the ability of TE to predict the development of CC in patients with ALC.
Method: 276 patients with Child class A/B ALC, without hepatocellular carcinoma (HCC) and without decompensation at the time of inclusion were enrolled, all of them with a valid TE measurement (Fibroscan®), and clinical-demographic variables recorded at inclusion, were analyzed. 82% male sex, mean age 56.5 ± 8.4 years, 93% Child A, 80% had esophageal varices and 63.4% had had at least one previous episode of CC. Patients were followed prospectively with clinical, analytical and ultrasound controls, and CC during the follow-up were registered. For statistical analysis, the usual methods were used.
Results: During a mean follow-up of 29.2 ± 17.3 months, 73 patients developed CC (29 ascites, 17 variceal bleeding, 14 encephalopathy and 13 HCC) with a 4-year cumulative probability of 37.2%. The diagnostic accuracy of TE to predict the development of CC showed an AUC of 0.675 (0.607–0.743). TE value of 25 kPa allowed to distinguish two groups with different risk of developing CC: ≤25 and >25 with a mean annual incidence of 4.5% and 15.5% and a 2-year cumulative probability of 11.6% and 27,8% respectively (p < 0.001). Other variables that were associated in the univariate analysis with the risk of developing CC were: male sex (p = 0.04), esophageal varices (p = 0.040), platelet count < 130 × 10^3/mm^3 (p = 0.003), Child B (p < 0.001), AST > ULN (p = 0.040) and GGT > ULN (p = 0.053). On the contrary, age (p = 0.94) previous CC (p = 0.20) or ALT > ULN (p = 0.50) were not associated with the development of CC. In multivariate analysis, variables independently associated with the development of CC were male sex (OR:2.30; 95% CI:1.04 to 5.09; p = 0.039), Child B (OR:2.91; 95% CI:1.42–5.97, p = 0.003) and FS > 25 kPa (OR:2.72, 95% CI:1.41.5.24, p = 0.003).
Conclusion: Measurement of liver stiffness using elastography is useful to predict the risk of developing complications in patients with alcoholic liver cirrhosis. A value of 25 kPa allows to distinguish two groups of patients with different risk. In patients with compensated alcoholic cirrhosis, the history of previous decompensation does not influence the development of future complications.

SAT-075

Evaluation of multiparametric MRI in comparison with MR elastography in patients evaluated for chronic liver disease

S. Bravo[1], M. Kelly[2], P. Xu[2], K. Hollar[3], M. Raymer[3], R. Banerjee[2], S. Neubauer[2]. *[1]Sand Lake Imaging, Orlando, United States; [2]Perspectum Diagnostics Ltd, Oxford, United Kingdom; [3]Perspectum Diagnostics Ltd, Raleigh-Durham, United States*
Email: mattdkelly@gmail.com

Background and Aims: Liver*MultiScan*™ (LMS) uses multiparametric MR to provide surrogate markers of hepatic fat, iron content, and liver inflammation and fibrosis (LIF), which has been shown to distinguish simple steatosis from nonalcoholic steatohepatitis (NASH). We evaluated LMS in the context of a high volume Radiology practice, and compared results with those of MR Elastography (MRE).
Method: 258 patients were scheduled for MRE and LMS scanning at the same setting on Siemens 3T magnets. Clinical histories included abnormal LFTs (78), Hep B/C (41), non-alcoholic fatty liver disease NAFLD (52), liver fibrosis/NASH (27), hepatic fibrosis (50), and other (biliary cirrhosis, autoimmune Hep, hepatic transplant) (10). Examinations were performed without gadolinium contrast. MRE scores were calculated by proprietary Siemens software. The LMS LIF score was calculated with proprietary software using Perspectum Diagnostics' centralized evaluation and reporting portal. Correlations between variables were computed using Spearman's Rho.

Results: MRE was successfully calculated 96% (248/258) of patients, and a LIF score and hepatic fat (PDFF) were successfully calculated in 98% (248/253) of patients attempted. MRE stiffness values were mapped onto a F1-F4 scale to provide a rough approximation of fibrosis stage. LIF score showed a significant correlation with MRE F-score ($r_s = 0.39$; $p = 3.0e-9$), with better concordance at higher stiffness (F3-4) vs. lower stiffness (F1-2). In the subset of patients lacking concordance (LIF ≥ 2 and F1-2), 80% (90/113) had PDFF > 5% (vs. 23% (14/60) in the LIF < 2 and F1-2 group), which may indicate early stage disease.

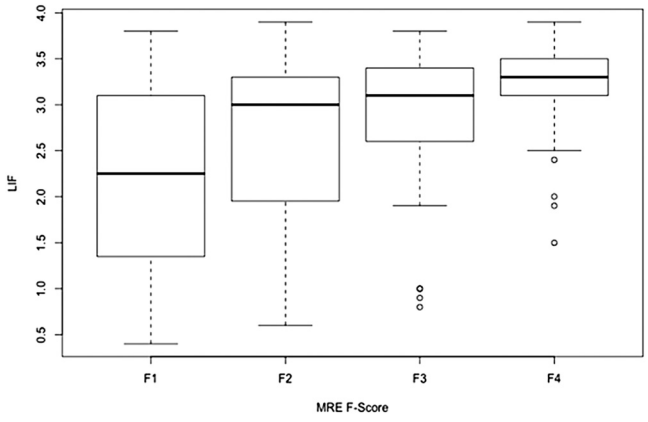

Figure 1: Relationship between LIF score and MRE-derived "F" score.

Conclusion: There is high concordance between LMS and MRE in patients predicted to have moderate to severe fibrosis. The lack of concordance in a sub-fraction of patients predicted by MRE to have mild fibrosis may be indicative of inflammation which has not yet progressed to significant fibrosis. LMS may be a more sensitive determinant of patients with elevated PDFF who are progressing to NASH.

SAT-076

Glomerular filtration rate evaluation in patients with cirrhosis, which equation shall be used in clinical daily practice?

S. Monteiro[1], M. Bibi[2], R. Lucas[3], J. Gandara[4], V. Lopes[4], D. Valadares[4], S. Ferreira[4], C.S. Macedo[4], M.T. Gomes[4], C. Rosário[2], H.P. Miranda[4], F.G.C. Nery[4]. *[1]Unidade Local de Saúde de Matosinhos - Hospital Pedro Hispano, Internal Medicine, Matosinhos, Portugal; [2]Unidade Local de Saúde de Matosinhos, Hospital Pedro Hispano, Internal Medicine, Porto, Portugal; [3]Instituto De Saúde Pública Da Universidade Do Porto, EPIUnit, Epidemiology Research Unit, Portugal; [4]Centro Hospitalar do Porto, Hospital Geral de Santo António, Porto, Portugal*
Email: amonteiro.sofia@gmail.com

Background and Aims: Kidney function evaluation is still a problem in cirrhotic patients, as the clearance of exogenous markers are expensive and may not be feasible in all centers. An incorrect evaluation of the glomerular filtration rate (GFR) has multiple implications such as, drug toxicity, omission of a kidney biopsy or simultaneous liver and kidney transplant when indicated.
This study aimed to assess, in patients with cirrhosis, which equation(s) to predict GFR is(are) the best for use in clinical practice, when compared to MDRD-6, which has been found to best correlate with GFR determined by clearance of exogenous markers.
Method: Demographic data, health status characterization, clinical evaluation and laboratorial data (serum sodium, blood urea nitrogen (BUN), creatinine, albumin and cystatin-c) were prospectively collected. GFR was determined by Cockroft-Gault formula, MDRD-4, MDRD-6, CKD-EPI Creatinine, CKD-EPI Cystatin C, CKD-EPI Creatinine-cystatin C and Larsson's. Agreement was estimated using Cohen's kappa and was stratified by variables. Mean differences between GFR calculated by MDRD-6 and all the other equations and their significance where analyzed with t-test.
Results: 123 patients with cirrhosis (91 Child A, 25 Child B, 7 Child C) were included, with mixed etiology. For all the spectrum of GFR, CKD-EPI Cystatin C correlated the best with MDRD-6 (Kappa = 1), and CKD-EPI Creatinine the worst (Kappa = 0.5505). All the other equations showed a substantial agreement of correlation with MDRD-6, with Kappa ≥ 0.7338. Liver's disease severity did not interfere with GFR measurement, but few patients were in Child-Pugh C class.
The mean differences between the equations with the poorest agreement (CKD-EPI Creatinine, MDRD-4, Cockcroft-Gault) and MDRD-6 where, in general, statistical significant ($p < 0.007$), with a pattern of overestimation of GFR.
Conclusion: Beyond demographic features, physicians shall demand for a panel of analysis gathering creatinine, cystatin c, BUN and albumin in order to calculate GFR using the abovementioned equations. As CKD-EPI Creatinine, MDRD-4 and Cockcroft-Gault may overestimate GFR, necessary interventions may be excluded, reason why caution should be taken when used. As a portion of patients included in the study had normal GFR, the power may not be enough to withdrawn other conclusions. Further studies should compare measured GFR with equations using cystatin-c.

SAT-077

Predictions from a very hard liver: The role of liver stiffness in alcoholic hepatitis

F. Petra[1], A. Horhat[1], A. Suciu[1], R. Corina[1], M. Lupsor-Platon[2], B. Procopet[1], D. Matei[1], R. Badea[2], M. Tantau[1], H. Stefanescu[3]. *[1]University of Medicine and Pharmacy "Iuliu Hatieganu", 3rd Medical Clinic, Gastroenterology Department; [2]University of Medicine and Pharmacy "Iuliu Hatieganu", Imaging department; [3]Regional Institute of Gastroenterology and Hepatology "O Fodor", Gastroenterology Department*
Email: bogdanprocopet@gmail.com

Background and Aims: Liver stiffness measurement (LSM), especially assessed by transient elastography (TE), is not considered a useful tool for the management of alcoholic hepatitis (AH) patients, because it is difficult to perform and is not reliable due to severe inflammation. However, LSM is considered a very good prognostic tool in advanced liver disease. Recently, real-time bi-dimensional shear-wave elastography (2D-SWE) became available, offering significant advantages for examination. On the other hand, in patients with severe AH (SAH) a robust predictor of mortality is still lacking.
The aim of this study was to evaluate whether LSM using TE and 2D2-SWE could predict mortality in AH patients.
Method: Consecutive patients with AH were included and liver function and severity of AH (Maddrey score (MDF)) was assessed at admission. Whenever possible and accepted by the patient, liver biopsy was performed to confirm the diagnosis. Patients with either SAH confirmed at biopsy, or with MDF ≥ 32 were treated with Prednisone, in the absence of contraindications. LSM by TE (Fibroscan, EchoSens, France) and by 2D-SWE (Aixplorer, SuperSonic Imagine, France) was also performed at baseline and after 7 days of therapy. Overall mortality was assessed during follow-up.
Results: 118 patients (80% males, mean age 52.5 years) were included. 76(64.4%) patients underwent LB and 67(56.8%) received Prednisone. 90 (76.2%) patients had MDF ≥ 32. 40 (33.9%) patients died during the mean follow up of 17.4 months.
TE could be performed in 70/90 of patients (77.8% applicability), while 2D-SWE in 59/64 patients (92.2% applicability).
LSM was significantly higher in patients with MDF ≥ 32, irrespective of the technique, but no significant difference was observed in LSM in patients who survived compared with those who died. However, baseline LSM values ≥64.5 kPa (by TE) and ≥17.3 kPa (by 2D-SWE)

predicted mortality with moderate accuracy (AUC of 0.688 [95%CI: 0.545-0.831] for TE and 0.713 [95%CI: 0.548–0869]).
A decrease in LSM after 7 days of therapy by 10% (by TE) or by 8% (by 2D-SWE) appears to be predict survival: AUC for ΔLSM of 0.712 [95% CI: 0.420–0.905] for TE and 0.745 [95%CI: 0.490–0.901].
Conclusion: LSM by 2D-SWE has a better applicability in AH compared with TE. Baseline LSM, irrespective of technique is higher in more severe patients, but there is no or limited value in predicting mortality. However, a decrease of 8–10% in LSM by 2d-SWE/TE could predict overall survival.
This work was supported by the a national grant (PN-II-RU-TE-2014-4-0356).

SAT-078

Soluble serum vascular adhesion protein (sVAP)-1: A new biomarker in primary sclerosing cholangitis?

F. Saffioti[1,2], P. Trivedi[3,4], C. Weston[3], M. Salmi[5,6], D. Roccarina[1], G. Hirschfield[3,4], W. Rosenberg[1], A. Marshall[1], D. Adams[3,4], D. Thorburn[1]. *[1]UCL Institute for Liver and Digestive Health, The Royal Free Sheila Sherlock Centre, Royal Free Hospital, London, United Kingdom; [2]University of Messina, Department of Clinical and Experimental Medicine, Division of Clinical and Molecular Hepatology, Messina, Italy; [3]University of Birmingham, National Institute of Health Research Birmingham Liver Biomedical Research Centre Institute of Immunology and Immunotherapy, Birmingham, United Kingdom; [4]University Hospitals Birmingham Queen Elizabeth, Liver Unit, Birmingham, United Kingdom; [5]MediCity Research Laboratory, University of Turku, Turku, Finland; [6]University of Turku, Department of Medical Microbiology and Immunology, Turku, Finland*
Email: fsaffioti.83@gmail.com

Background and Aims: Vascular adhesion protein (VAP)-1 is an adhesion molecule with potent amine oxidase activity recently proposed as a biomarker for primary sclerosing cholangitis (PSC). Hepatic VAP-1 expression is increased in PSC, and elevated circulating soluble levels (sVAP-1) have been shown to predict clinical outcome for these patients. Our aim was to compare sVAP-1 values in PSC patients vs. primary biliary cholangitis (PBC) and autoimmune hepatitis (AIH), correlate with clinical features and markers of disease severity, and validate predictive utility in a well characterised cohort of patients with PSC.
Method: sVAP-1 was measured by chemiluminescence ELISA in the sera of 62 PSC, 68 PBC and 51 AIH patients attending the Royal Free Hospital, London. We performed correlation between sVAP-1, laboratory values and non-invasive indices of liver fibrosis from the time of serum collection. Mann-Whitney or Kruskall-Wallis test were used due to the non normal distribution of the variables. Kaplan-Meier survival estimates were generated to stratify outcomes according to the previously reported cut-off of 923 ng/mL (Trivedi et al. Gut 2017) for the combined endpoint time to liver transplant, PSC-related death or liver cancer (EP).

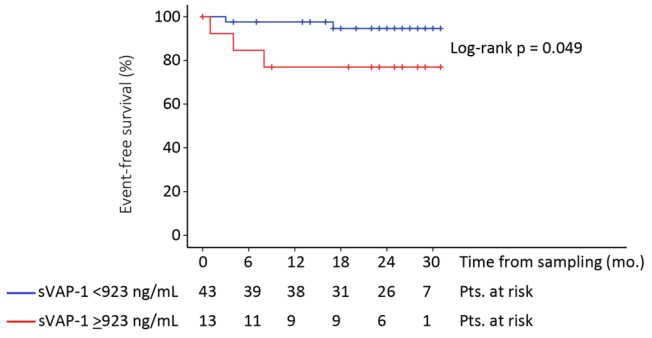

Figure 1: EP-free survival from time of serum sampling, according to sVAP-1 values.

Results: sVAP-1 values were not significantly different between the 3 aetiologies of immune-mediated liver disease. In the PSC group specifically, sVAP-1 significantly correlated with age at time of sampling ($p = 0.004$), age at diagnosis ($p < 0.001$), presence of cirrhosis ($p = 0.025$) and oesophageal varices ($p = 0.015$), absence of inflammatory bowel disease ($p = 0.005$), ELF score ($p = 0.003$), FIB-4 ($p < 0.001$), APRI ($p = 0.006$), Mayo risk score ($p = 0.002$) and Amsterdam-Oxford risk score ($p < 0.001$); but not with liver stiffness (transient elastography) and the MELD score. Spearman's Rho coefficient was ~0.4 for all the significant correlations. Remarkably, elevated sVAP-1 values predicted shorter time EP-free survival ($p = 0.047$) in PSC patients (Figure).
Conclusion: We validate across a small group of patients that heightened sVAP-1 values are predictive of EP in PSC. Moreover, sVAP-1 values are elevated in cirrhotic compared with non-cirrhotic individuals, but show varying degrees of correlation with indices of disease severity. Larger sample sizes with prospective, extended follow-up times are needed to substantiate predictive utility of sVAP as a marker of rapidly progressive vs. already advanced disease.

Comparison of twelve noninvasive liver reserve models in HCC patients undergoing resection

S.Y. Ho[1], T.-I. Huo[2], P.-H. Liu[2], C.Y. Hsu[2], C.-Y. Hsia[2], Y.-H. Huang[3]. *[1]Taipei Veterans General Hospital, Division of Gastroenterologist, Taipei, Taiwan; [2]Taipei Veterans General Hospital, Taipei, Taiwan, No.201, Sec. 2, Shipai Rd., Beitou District, Taipei City, Taiwan 11217, R.O.C, Taipei, Taiwan; [3]Division of Gastroenterology and Hepatology, Taipei Veterans General Hospital, Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan*
Email: tihuo@vhgtpe.gov.tw

Background and Aims: Various noninvasive liver reserve models have been proposed, but their prognostic ability in patients with hepatocellular carcinoma (HCC) is unclear. We aimed to investigate the performance of 12 noninvasive models on HCC patients undergoing surgical resection.
Method: A total of 645 HCC patients undergoing resection were prospectively identified and analyzed. Baseline demographics, tumor status and noninvasive models were investigated. Comparison of noninvasive models by homogeneity and corrected Akaike information criteria (AICc) was performed. Tumor recurrence, overall survival, and independent prognostic factors were evaluated by the Cox proportional hazards model and Kaplan-Meier analysis.
Results: Of the 12 models, significant differences in recurrence-free survival were found in APRI, FIB-4, GUCI, King's score and PALBI ($p < 0.05$). Among these models, the King's score showed the highest homogeneity and lowest AICc value, suggesting a better predictive ability for tumor recurrence. In multivariate Cox analysis, we confirmed that King's score, tumor size and alpha-fetoprotein were independent predictors associated with recurrence. In survival prediction, ALBI, FIB-4, King's score and PALBI showed significant differences across groups ($p < 0.05$). Among these models, ALBI revealed the highest homogeneity and lowest AICc value, indicating a better prognostic performance. In the Cox model, ALBI, tumor burden, alpha-fetoprotein, vascular invasion, diabetes mellitus and performance status were independent predictors linked with overall survival.
Conclusion: The currently used liver function models have differential predictive ability for HCC patients undergoing surgical resection. The King's score is a feasible tool to predict tumor recurrence, whereas ALBI grade is a more robust model for prognostic prediction.

Email: p.trembling@ucl.ac.uk

Background and Aims: Chronic liver disease (CLD) is often clinically silent until life-threatening complications develop. Risk factors include high alcohol consumption and increased BMI. The Enhanced Liver Fibrosis (ELF) test, a liver fibrosis biomarker panel, accurately assesses fibrosis in a range of CLD aetiologies. ELF ≥ 10.51 is consistent with advanced fibrosis. We report performance of ELF in predicting CLD in postmenopausal women with risk factors in a nested case control study using the PRoBE (prospective-specimen-collection, retrospective-blinded-evaluation) design.

Method: Participants in the UK Collaborative Trial of Ovarian Cancer Screening (UKCTOCS) provided serum samples at recruitment & 2 subsequent time points. They were prospectively followed up for first liver-related event (LRE) consistent with CLD (ICD-10: K70, K73, K74, K76, I85, Z944, C220) following recruitment using Hospital Episode Statistics, Cancer Registry and death certificate data. ELF was measured in blinded samples from 58 participants who developed LRE and self-reported alcohol use >16.5 units/week and/or BMI ≥ 25 kg/m^2 (cases), and in 115 controls matched for age, alcohol & BMI who did not develop LRE. Using conventional Cox regression unadjusted hazard ratio (HR) for LRE was calculated, then adjusted for deprivation & self-reported hypertension, heart disease, hypercholesterolaemia or diabetes, for ELF ≥ 10.51 at recruitment. To evaluate ELF as a time dependent variable, the time where ELF ≥ 10.51 was assumed to be time of the first serial sample in which ELF ≥ 10.51. Cox regression was performed with ELF ≥ 10.51 as a time dependent variable.

Results: Median recruitment age was 61 years (range 52–74). High alcohol use was reported by 19% & BMI ≥ 25 in 88%. Median time to LRE/censor was 8.5 years (range 0.5–11.4). HRs are shown in the table & cumulative hazards for the conventional Cox model in the figure. In participants who developed ELF ≥ 10.51 during follow up, risk of LRE was lower than those with ELF ≥ 10.51 at recruitment.

	Conventional Cox model		Cox model with ELF as time dependent variable	
Model	HR (95% CI)	p-value	HR (95% CI)	p-value
Unadjusted	4.88 (2.37–10.03)	<0.0001	1.94 (1.10–3.39)	0.021
Adjusted	4.62 (2.12–10.08)	<0.0001	2.05 (1.16–3.64)	0.014

Conclusion: This is the first study to evaluate performance of ELF to predict CLD in a community-based population. In postmenopausal women with risk factors, ELF ≥ 10.51 predicts LRE. In women who developed ELF ≥ 10.51 in follow up risk of LRE was increased compared to those with ELF < 10.51 but risk was lower than those with baseline ELF ≥ 10.51 highlighting the opportunity to intervene to reduce liver mortality & morbidity. Although larger studies are required, these results demonstrate the possible role for ELF as a prognostic tool in primary care.

SAT-081

Correlation between controlled attenuation parameter assessed with Fibroscan and steatosis percent objectively quantified from the entire liver biopsy specimen using a computer analysis tool: Preliminary results

M. Lupsor-Platon[1,2], G. Bianca[3], A. Maniu[1], V. Cristian[4], R. Ioana[5], H. Stefanescu[6], U. Radu[7], A.H. Email: monica.lupsor@umfcluj.ro

Background and Aims: Usual ultrasonography is a useful method in diffuse liver disease (DLD) patients, but it cannot always differentiate steatosis from fibrosis. Liver biopsy (LB) has traditionally been considered the reference method for the steatosis and fibrosis evaluation, but its accuracy has also been questioned in relation to intra- and inter-observer variability that may lead to over- or under-staging or grading. Therefore, discovering more precise analysis of the LB specimens, rather than the subjective histological diagnosis, was desirable for the future development of noninvasive liver assessment tools, like transient elastography (TE) which measures liver stiffness

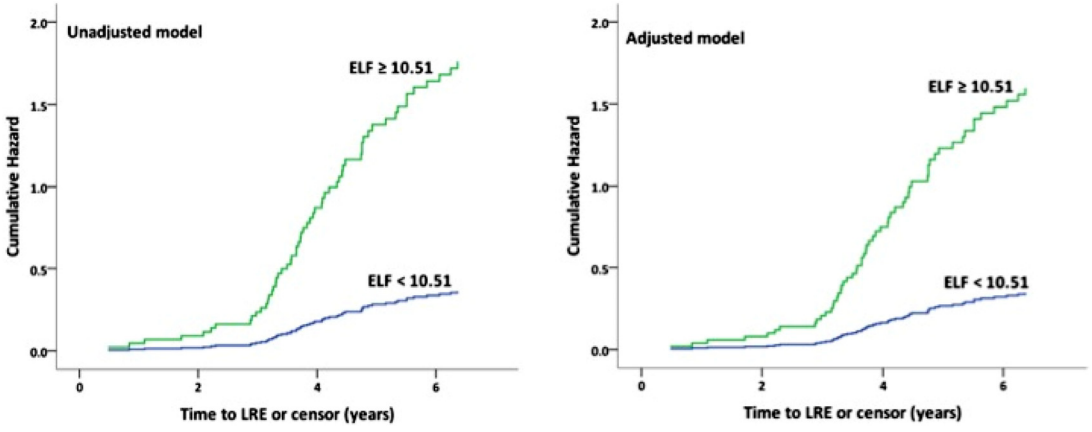

Figure: (abstract: SAT-080).

(LS) for fibrosis prediction, respectively controlled attenuation parameter (CAP) for steatosis prediction.
We aim to determine whether there is a correlation between CAP and steatosis, respectively fibrosis percent, objectively quantified from the biopsy specimen using an exact computer analysis tool.
Method: 163 DLD biopsied patients were prospectively included in the study. They underwent both LB and CAP measurements using Fibroscan with M probe. After preparation with hematoxylin and eosin, LB samples were photographed and analyzed using a special computer software for objectively determining the steatosis (SP), respectively fibrosis percent (FP), defined as the ratio between the total number of pixels labeled as steatosis, respectively as fibrosis, divided by total tissue area.
Results: CAP values varied between 160–373 dB/m. SP and FP values ranged between 0.0082–43.557 (mean 5.440), respectively 0.0642–69.0190 (mean 11.205). CAP correlated significantly with SP ($r = 0.312$, $p < 0.0001$), but not with FP ($r = 0.118$, $p = 0.211$) from the biopsy samples. The mean CAP value differed significantly in patients with SP ≤ 6 (226.29 ± 48.70 dB/m) from those with SP > 6 (254.66 ± 48.63 dB/m), $p = 0.002$. The correlation between CAP and the total area of steatosis (TSA) on the biopsy specimen is suggested in the formula Log(CAP) = 0.3624 + 0.03723 Log(TSA).
Conclusion: CAP is significantly correlated only with the steatosis percent quantified using a computer analysis tool. The mean CAP value differed significantly in patients with SP ≤ 6 from those with SP > 6. Further studies are needed to establish CAP cutoff values in relation to the steatosis area of the entire biopsy specimen.

SAT-082

Performance of shear-wave elastography to detect high-risk esophageal varices in cirrhosis is improved by spleen stiffness estimation

S.H. Kang[1], M.Y. Kim[1], Y.O. Jang[1], M. Lee[2], B.G. Jun[3], T.-S. Kim[2], K.T. Suk[4], S.K. Baik[1]. *[1]Yonsei University Wonju College of Medicine, Internal Medicine, Wonju, Korea, Rep. of South; [2]Kangwon National University Hospital, Internal medicine, Chuncheon-Si, Korea, Rep. of South; [3]University of Ulsan College of Medicine, Internal Medicine, Gangneung-si, Korea, Rep. of South, [4]Hallym University College of Medicine, Internal Medicine, Chuncheon-si, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

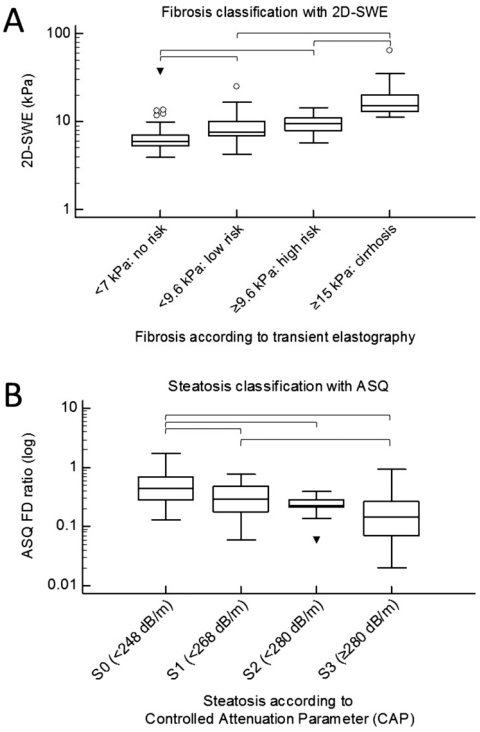
Background and Aims: There is considerable interest in developing non-invasive models to predict the presence of varices. Liver and spleen stiffness measured by 2 dimensional shear-wave elastography (2D-SWE) have become methods of interest with good reliability in detecting portal hypertension. In this regard, measurement of the spleen stiffness reflects more accurately the dynamic changes occurring in advanced stages of cirrhosis compared to liver stiffness. We investigated the feasibility of liver- and spleen-SWE for detection of esophageal varices and high-risk varices.
Method: We included 191 cirrhotic patients who underwent liver and spleen stiffness measurements and were scored for related parameters (liver stiffness spleen-diameter-to-platelet-ratio score [LSPS] and spleen stiffness spleen-diameter-to-platelet-ratio score [SSPS]), using 2D-SWE (APLIO 500, Toshiba), along with endoscopic screening. Large esophageal varices (F2 or F3) were defined as high-risk esophageal varices.
Results: Esophageal varices were present in 130 patients (68.1%). Regarding the presence of esophageal varices, diagnostic accuracy was better for stiffness in liver-SWE than in spleen-SWE (area under the receiver-operating characteristic curve [AUC], 0.830 vs. 0.740; DeLong test, $p = 0.050$). The best cut-off values in detecting esophageal varices were 14.1 kPa for liver-SWE and 16.5 kPa for spleen-SWE. Unlike stiffness in liver-SWE, that in spleen-SWE was positively correlated with the grade of esophageal varices. For the presence of high-risk esophageal varices, the AUC in spleen-SWE was higher than liver-SWE (0.764 vs. 0.742), albeit not significantly. The strongest association was found between high-risk esophageal varix and spleen-SWE ($r = 0.397$, $p < 0.001$), while the second strongest association was found between Child–Turcotte–Pugh score ($r = 0.353$, $p < 0.001$) and liver-SWE ($r = 0.314$, $p < 0.001$). The best cut-off values for predicting high-risk esophageal varices were 14.3 kPa for liver-SWE and 22.1 kPa for spleen-SWE. LSPS and SSPS, with AUC values between 0.837 and 0.799, also had good diagnostic accuracy in identifying esophageal varices.
Conclusion: In patients with cirrhosis, stiffness measurements obtained by using 2D-SWE have effective non-invasive method for detection of esophageal varices. Moreover, for high-risk esophageal varices that require prophylactic therapy, stiffness estimation in spleen-SWE carries a better diagnostic value than that in liver-SWE.

SAT-083

Non-invasive estimation of hepatic fibrosis and steatosis: comparison of 2D shear-wave elastography and acoustic structure quantification with transient elastography and controlled attenuation parameter

V. Blank[1,2], S. Wohland[1], J. Wiegand[3], V. Keim[1], T. Karlas[1]. *[1]University Hospital Leipzig, Division of Gastroenterology, Leipzig, Germany; [2]Integrated Research and Treatment Center Adiposity Diseases, MetaRot program, Leipzig, Germany; [3]University Hospital Leipzig, Division of Gastroenterology, Section of Hepatology, Leipzig, Germany*
Email: blank@medizin.uni-leipzig.de

Background and Aims: Transient elastography (TE) combined with controlled attenuation parameter (CAP) represents the reference standard for non-invasive assessment of hepatic fibrosis and steatosis. Although liver stiffness measurement (LSM) with TE is fast and easy to learn, its application is limited by the intercostal approach, patients' anthropometry, and requirement of a dedicated device. 2D shear-wave elastography (2D-SWE) techniques provide potential alternatives for LSM, but do not give information on steatosis. Recently, acoustic structure quantification (ASQ) has been proposed as an ultrasound based option for steatosis quantification. The aim of this study was the comparison of TE and CAP with 2D-SWE and ASQ.
Method: Patients with chronic liver diseases prospectively underwent LSM with TE (Fibroscan, M or XL probe) and CAP subsequently followed by 2D-SWE (Toshiba Medical Systems) and liver parenchyma speckle analysis by ASQ (focal disturbance ratio/FD ratio). Exclusion criteria comprised invalid or unreliable TE, elevated aminotransferase levels >5x upper limit of normal, ascites and focal liver lesions. Fibrosis and steatosis were classified according to established TE and CAP cut-offs. Diagnostic performance of 2D-SWE and ASQ was analyzed using receiver operating characteristics curves (ROC).
Results: 200 patients were included in the analysis (49% female, median age 54 years, body mass index/IQR 26 [24–29]kg/m², 30/25/9/36% NAFLD/viral/autoimmune/other).
LSM with 2D-SWE and TE showed a good correlation ($r = 0.775$ 95%CI [0.712; 0.825]; Figure A). 2D-SWE showed an excellent accuracy for detection of significant fibrosis (defined by TE ≥ 9.6 kPa: area under the ROC 0.927, sensitivity 88%, specificity 90%, cut-off >8.85 kPa) and cirrhosis (TE ≥ 15 kPa: AUROC 0.976, sens. 100%, spec. 94%, cut-off >11.1 kPa).
ASQ (log_FD ratio) and CAP values correlated well ($r = -0.602$ [−0.684; −0.506], Figure B). ASQ showed a good accuracy for detection of steatosis (defined by CAP ≥248 dB/m: AUROC 0.800, sens. 72%, spec. 74%, cut-off ≤0.29) and advanced steatosis (CAP ≥ 280 dB/m: AUROC 0.795; sens. 55%, spec. 90%, cut-off ≤0.15).



Conclusion: 2D-SWE shows an excellent agreement with TE and can be used for non-invasive fibrosis classification. ASQ correlates well with the reference standard CAP and provides an alternative for classification of steatosis. The combination of 2D-SWE and ASQ incorporated in a conventional ultrasound device could facilitate patient care.

SAT-084

CT-driven mfor end-stage liver disease: Comparison of survival prediction with MELD score

J.E. Lee. *Soonchunhyang University Hospital, Department of Radiology, Bucheon, Korea, Rep. of South*
Email: leeje1211@gmail.com

Background and Aims: Model for End-stage Liver Disease (MELD) score was developed as a disease severity index for patients with end-stage liver disease. Although MELD score is widely used for predicting survival, there are still some limitations. Imaging study contains important information about severity of liver cirrhosis and portal hypertension. The purpose of this study is to investigate the role of a new model with abdominal CT for prediction of survival in patients with liver cirrhosis and compare it with MELD score.
Method: 145 consecutive patients with diagnosis of liver cirrhosis and underwent abdominal CT at our institution were included retrospectively. Two radiologists reviewed the CT images and measured the imaging parameters associated with liver cirrhosis and portal hypertension, such as the maximum diameters of the main portal vein (øMPV), superior mesenteric vein (øSMV), splenic vein (øSV), and calculated the estimated spleen volumes. The grade of esophageal (EV), paraesophageal (PEV), gastric varices and amount of ascites were also evaluated with CT images semi-quantitatively. We explored the statistically significant CT features related to overall survival and established a model to calculate a risk score using multivariate Cox proportional hazard regression and validated this system using CT data (n = 86) of another hospital. To compare the prediction accuracy of two scoring systems, time-dependent ROC curve and Harrell's c-index were used.
Results: øSMV/øSV, splenic volume, grade of EV, PEV, and amount of ascites were significant imaging predictors of survival in patients with liver cirrhosis. The risk score was calculated by following formula: risk score = 0.72 × øSMV/øSV + 0.59×splenic volume + 0.88 × grade 1 EV + 0.50 × grade 2 EV + 1.00×grade 3 EV + 0.49 × grade 1 PEV + 0.61 × grade 2 PEV + 0.82 × grade 3 PEV + 1.44×moderate amount of ascites + 2.24×large amount of ascites – 1.95. All patients were divided into two groups (low- and high-risk groups) according to the cutoff value of 2.22 for risk scores. In both sets, the high risk group had significantly poor overall survival rates compared with the low risk group ($p < 0.05$). Time-dependent AUC revealed that in both sets, the MELD score was superior to the imaging model for the first 20 months. However, the imaging score showed slightly better performance than the MELD score after 50 months in the training set and after 30 months in validation set. Harrell's c-index showed that the imaging score demonstrated good properties in predicting survival in patients with liver cirrhosis, and were not significantly different from MELD score in both training and validation set ($p = 0.206$ and $p = 0.648$, respectively).
Conclusion: This prediction model with abdominal CT may predict the survival in patients with liver cirrhosis, and may even show better performance than MELD score in predicting long-term survival.

SAT-085

Non invasive assessment of liver fibrosis by three different Shear Wave Techniques: Head-to-Head Performance

S. Atzori, T. Hoogenboom, S. Taylor-Robinson, P. Manousou, H. Marcinkowski, J. Clancy, A. Dhar, M. Thursz, A. Lim. *Imperial College, Hepatology*
Email: s.taylor-robinson@imperial.ac.uk

Background and Aims: Ultrasound-based non-invasive methods for evaluation of liver disease severity are becoming increasingly used. This study aimed to compare liver stiffness assessed by 3 shear wave elastography techniques: Philips EPIQ7^{TM}; Siemens Acuson^{TM} Virtual Touch Tissue Quantification (VTQ) and Transient Elastography (TE) measured by Echosens Fibroscan^{TM}. Results were compared to histological results in patients with chronic liver disease.
Method: 109 patients underwent same-day liver biopsy, and measurement of liver fibrosis. Liver biopsy yielded insufficient tissue in 9 patients. Statistical analysis was conducted in 100 patients. Liver fibrosis and necroinflammatory activity were evaluated histologically using METAVIR score. 10 measurements in the left lobe, 10 in the right lobe were taken with EPIQ7^{TM} and VTQ and the median value obtained. The median of ten measurements was obtained with TE. Statistical analyses were performed using SPSS 24. Histological staging was correlated with median values and Spearman correlation calculated ($p < 0.05$).
Results: 100 consecutive patients with chronic liver disease were enrolled [mean age: 48.41 years, 41 female; 59 male]. 46 patients had non-alcoholic fatty liver disease, 22 patients had chronic hepatitis B and the remainder were of various aetiologies. Spearman correlation with METAVIR score was higher with EPIQ7^{TM} and Fibroscan^{TM} (EPIQ7^{TM} 0.568; TE 0.627; VTQ 0.429). Mean value for EPIQ7^{TM} in the left lobe were higher to those obtained from the right lobe of the liver (Right 8.16 kPa; Left 8.87 kPa) but this was not statistically significant ($p = 0.338$). Areas under the Curve (AUC) were: TE 0.835; EPIQ7^{TM} 0.785; VTQ 0.678 for no or mild fibrosis ($F < 2$; n = 52); TE 0.826; EPIQ7^{TM} 0.817; VTQ 0.712 for significant fibrosis (F) ($2 < F < 4$; n = 32); TE 0.865; EPIQ7^{TM} 0.820; VTQ 0.792 for cirrhosis (F4, n = 16). Bland Altman plots showed agreement between values obtained with TE and EPIQ7^{TM} with lower value measured by EPIQ7^{TM}. The mean optimal cut-off for significant fibrosis F2/3 (n = 32) was 8.45 kPa for TE (sensitivity (se) 0.76, specificity (sp) 0.78); 7.52 kPa (se 0.79, sp 0.76) for EPIQ7^{TM} and 9.3 kPa (se 0.76, sp 0.75) for VTQ. The mean optimal cut-off for cirrhosis F = 4 were 11.85 kPa for TE (se 0.79, sp 0.72); 9.01 kPa (se 0.70; sp 0.70) for EPIQ7^{TM} and 13.35 KPa (se 0.73; sp 0.79) for VTQ.
Conclusions: TE and EPIQ7^{TM} correlate well with histological scores of liver fibrosis and perform better than VTQ.

The gamma-glutamyl transpeptidase to platelet ratio: a novel index for predicting significant liver inflammation in chronic hepatitis B

R. Huang[1], J. Wang[1], X. Yan[1], Y. Liu[2], Y. Chen[2], Z. Zhang[1], W. Ding[3], C. Wu[1]. [1]*Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Infectious Diseases, Nanjing, China;* [2]*Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Experimental Medicine, Nanjing, China;* [3]*Huai'an No. 4 People's Hospital, Department of Hepatology, Huan'an, China*
Email: doctor_hr@126.com

Background and Aims: Evaluating the degree of liver inflammation is important for patients with chronic hepatitis B(CHB). However, few indexes can predict significant liver inflammation accurately in CHB patients. We aimed to develop a simple predictive index for significant liver inflammation in CHB using the routinely clinical parameters.

Method: A total of 384 treatment-naïve CHB patients who had undergone liver biopsy were enrolled in this study. The relation between hematological parameters and liver inflammation were analyzed and a novel predictive index for significant liver inflammation (≥G3) based on these parameters was developed. The diagnostic values of this novel index for liver inflammation were compared with other conventional inflammation parameters by the areas under the receiver-operating characteristic curves (AUROCs).

Results: Based on routinely clinical parameters, gamma-glutamyl transpeptidase (GGT) and platelets (PLT) were independent predictors of significant liver inflammation by multivariable analysis in entire patients ($p < 0.001$ and $p < 0.001$, respectively), hepatitis B e antigen (HBeAg) positive ($p = 0.021$ and $p = 0.019$, respectively) and HBeAg negative patients ($p = 0.009$ and $p = 0.006$, respectively). Accordingly, a novel index, the GGT to PLT ratio (GPR) was developed to amplify the opposing effects of liver inflammation on the GGT and PLT. The AUROCs of GPR in predicting significant liver inflammation were 0.793 (95%CI 0.748 to 0.839), 0.799 (95%CI 0.738 to 0.859) and 0.786 (95%CI 0.712 to 0.859) in entire patients, HBeAg positive and HBeAg negative CHB patients, respectively. Further comparisons showed the diagnostic performance of GPR for significant liver inflammation was significantly superior than that of alanine aminotransferase (ALT) (AUROC: 0.691, $p < 0.001$; AUROC: 0.679, $p = 0.002$, respectively), aspartate transaminase (AST) (AUROC: 0.716, $p = 0.006$; AUROC: 0.710, $p = 0.015$, respectively) and GGT (AUROC:0.768,

p = 0.040; AUROC: 0.764, p = 0.020, respectively) in entire patients and HBeAg positive CHB patients, but was comparable with AST (AUROC: 0.717, p = 0.123) and GGT (AUROC: 0.770, p = 0.437) in HBeAg negative CHB patients.
Conclusion: The GPR index has a better diagnostic value than conventionally predictive parameters to assess liver inflammation in CHB patients, especially for HBeAg positive CHB. The application of the novel index may reduce the need for liver biopsy in CHB patients in clinical practice.

SAT-087

Comparison of T2* and signal intensity ratio methods for MRI assessment of hepatic iron overload

C. Kagay[1], T. Frederick[2]. [1]*California Pacific Medical Center, Radiology, San Francisco, CA, United States;* [2]*California Pacific Medical Center, Transplant Hepatology, San Francisco, CA, United States*
Email: ckagay@gmail.com

Background and Aims: Excess hepatic iron (primary or secondary) can be seen in the context of chronic liver disease and may have a synergistic effect in promoting fibrosis. Patients proceeding to liver transplant with iron overload have a worse prognosis than those without. Patients with significant hepatic iron overload are at risk for cardiac iron overload. Biopsy is invasive and subject to sampling error. MRI is sensitive to hepatic iron content, as tissue iron causes paramagnetic effects on local proton spins, accelerating spin dephasing. Several methods have been described to measure hepatic iron content using MRI, including the Signal Intensity Ratio (SIR) method of Gandon et al. as well as measurement of hepatic parenchymal T2* values. To our knowledge, the performance of SIR and T2* methods with respect to histologic iron staining and quantification have not previously been compared head-to-head.
Methods: 126 iron-protocol liver MRI exams were performed between 1/1/14 and 19/4/17 including both SIR analysis (Univ. Rennes web tool) and T2* analysis (GE StarMap). 92 exams lacked pathology data, 1 exam was prospectively unreliable, 1 exam was a repeat on the same patient, and 4 exams had greater than 365 days between MRI and pathologic data. After exclusions, 28 MRI studies had data correlating to Modified Scheuer iron grade and 15 had data from pathologic iron quantification. Cutoff points were identified using the Youden method of Receiver Operator Curve (ROC) analysis. Area Under the Curve (AUC) was calculated comparing Scheuer grade to mean T2* value and estimated Liver Iron Concentration (LIC) by SIR. Pathological iron quantification was correlated to T2* and SIR-LIC by linear equation, with R^2 values calculated.
Results: Optimal cutoff points for the T2* method were ≤23.8 ms (0.987 AUC) for ≥1+ iron staining; ≤14.3 ms for ≥2+ iron staining (0.831); ≤12.5 ms for ≥3+ iron staining (0.792); and ≤6.1 ms for 4+ iron staining (0.740). Optimal cutoff points using SIR estimated LIC were >90 µmol/g for ≥1+ iron staining (0.880 AUC); >95 µmol/g for ≥2+ iron staining (0.800); >95 µmol/g for ≥3+ iron staining (0.756); and >230 µmol/g for 4+ iron staining (0.880). R^2 value correlating T2* to pathologic iron quantification was 0.48. R^2 value correlating LIC estimated by SIR to pathologic iron quantification was 0.14.
Conclusion: Performance of the T2* method with reference to Scheuer grade was superior to the SIR method as measured by AUC analysis at 3 of the 4 cutoff points, and correlation to pathologic iron quantification was also superior, but limited by small sample size. Comparison of Scheuer iron grade to T2* method closely mirrored results from Chandarana et al., suggesting that T2* is a reliable and reproducible method. As the T2* method additionally involves less scanner time and faster image analysis, this may be the preferred method for noninvasive estimation of hepatic iron overload.

SAT-088

Serum biomarker use in decentralized care sites to overcome liver assessment barriers in patientswith chronic hepatitis C and HIV co-infection

A. Loarec[1], C. Fortas[1], M. Iwamoto[1], A. Nguyen[2], A. Mesic[3], S. Balkan[4], D. Donchuk[5], D. Maman[1]. [1]*Médecins Sans Frontières, Epicentre, PARIS, France;* [2]*Médecins Sans Frontières, Medical department, Geneva, Switzerland;* [3]*Médecins Sans Frontières, Medical Department OCA, Amsterdam, Netherlands;* [4]*Médecins Sans Frontières, Medical Department OCP, Paris, France;* [5]*Médecins Sans Frontières, Medical Department OCB, Bruxelles, Belgium*
Email: anne.loarec@epicentre.msf.org

Background and Aims: A call for elimination of viral hepatitis by 2030 was endorsed in 2016. Access to Hepatitis C (VHC) diagnosis and treatment, as well as decentralization of these services to more tertiary care sites, are essential to reach this goal. Guidelines recommend a liver fibrosis assessment to identify chronic Hepatitis C (CHC) patients with advanced disease. In remote settings, only simple blood tests are usually available, without transient elastography and the use of most biomarkers is limited. In these cases, APRI (Aspartate-to-Platelet ratio Index) and FIB4 (Fibrosis-4) are two tests commonly used. Yet, questions remain about their utility in HIV-infected populations as well as their accuracy in diagnosing a patient's cirrhosis stage.
Method: Data from CHC patients in 7 clinics supported by Medecins Sans Frontieres (MSF) were collected between January 2014 and October 2017 in 4 countries (Phnom Penh, Cambodia; Dawei and Yangon, Myanmar; Manipur and Meerut, India, Maputo, Mozambique). Liver fibrosis was assessed for each patient at baseline. We used elastography using Fibroscan© as a reference method to compare the results of APRI and FIB4 biomarkers in identifying patients with an F4 liver stage, defined as ≥11 kPa by Fibroscan©. We also calculated the receiver operating characteristic (ROC) curves for all CHC patients by HIV status.
Results: A total of 3,074 CHC patients were included, among which 20% were HIV co-infected (n = 615). Elastography scores (median 13.8 kPa [IQR 10.0–23.1]) were distributed by stage as: 14.4% F0-F1, 6.57% F2, 13.11% F3, 68.88% F4. APRI tests had a median score of 1.05 (IQR 0.58–2.21), while FIB4 tests had a median score of 2.55 (IQR 1.55–4.92), with 22% of patients having a FIB4 < 1.45 and another 38.7% of patients with FIB4 > 3.25. Among APRI tests, areas under the receiver operating characteristic curve (AUROC) were 0.83 (95% CI 0.80–0.86) for HIV/HCV co-infected patients and 0.81 (0.80–0.83) for mono-infected HCV patients. Among FIB4 tests, AUROC were 0.83 (0.80–0.87) for HIV/HCV co-infected patients, and 0.82 (0.80–0.84) for mono-infected HCV patients. AUROC did not differ by HIV status in either case (p < 0.001).
Conclusion: HIV status did not influence the correlation between the two biomarkers and Fibroscan. Optimal biomarker thresholds should balance specificity and sensibility needs with screening and care strategies. Use of biomarkers will be a key tool to scale up Hepatitis C care.

SAT-089

Normal liver elasticity values in a healthy population, by age and gender, for two novel elastography systems

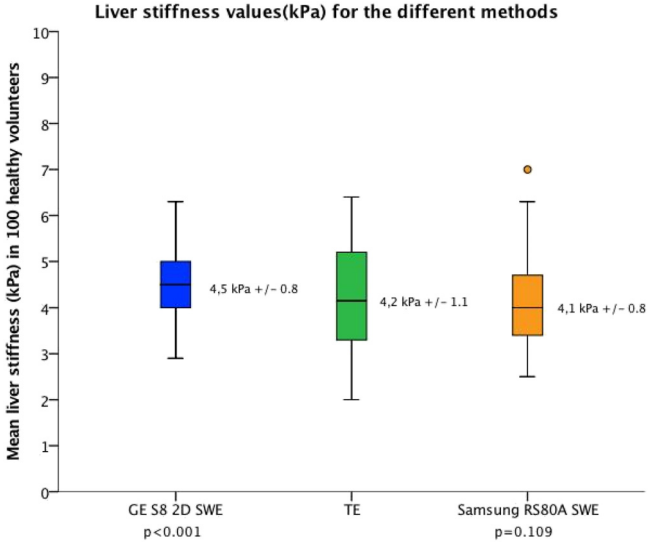
A. Mulabecirovic[1,2], M. Vesterhus[2,3], A. Mjelle[1,2], R.F. Havre[2], O.H. Gilja[2]. [1]*University of Bergen, Department of Clinical Medicine, Bergen, Norway;* [2]*National Centre for Ultrasound in Gastroenterology, Haukeland University Hospital, Bergen, Norway;* [3]*Norwegian PSC Research Center, Department of Transplantation Medicine, Division of Cancer Medicine, Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Oslo, Norway*
Email: anesa.mulabecirovic@gmail.com

Background and Aims: Estimates of liver stiffness may vary between elastography technologies within the same liver. The establishment of normal liver stiffness values in healthy livers for each specific

equipment model is a prerequisite for the definition of pathology and fibrotic stages. We aimed to define normal liver stiffness using two novel elastography methods for different age, weight and gender segments, and to assess inter-and intraobserver variability and reproducibility. To our knowledge, this is the first study to evaluate liver stiffness in healthy liver subjects using 2D shear wave elastography (SWE) from GE S8 and SWE from Samsung RS80A.

Method: We prospectively evaluated two novel elastography methods (Samsung RS80A SWE and GE S8 2D SWE) compared to Fibroscan (TE) by obtaining head-to-head liver stiffness measurements for each method in 100 healthy subjects. All subjects underwent B-mode ultrasound examination, elastography and biochemical laboratory analyses, including viral markers.

Results: All methods showed excellent feasibility. Mean liver stiffness (LS-mean) for GE S8 2D SWE was statistically higher than LS-mean of TE (4.5 ± 0.8 kPa vs. 4.2 ± 1.1, respectively, $p < 0.001$) and Samsung RS80A (4.1 ± 0.8 kPa, $p < 0.001$). The coefficient of variation (CV) was similar for the ultrasound based SWE methods ($p = 0.026$) whereas TE had larger CV compared to both GE S8 and Samsung RS80A ($p < 0.001$ and $p = 0.005$, respectively). The intraclass correlation coefficient (ICC) was good for both Samsung RS80A and GE S8 2D SWE ($r = 0.85$ vs. $r = 0.78$, respectively) and the methods were reproducible. LSM-mean for all SWE methods applied was significantly higher for males than for females (4.5 ± 0.9 kPa vs. 4.0 ± 0.9 kPa, respectively, $p < 0.001$) but similar across age and weight groups. There was no significant difference in LSM-mean based on 5 vs. 10 measurements for either Samsung RS80A SWE or GE S8 2D SWE.



Conclusion: LSM-mean was significantly higher for GE S8 2D SWE compared to Samsung RS80A or TE. There was no significant difference in LS between age or BMI groups, however males had higher LS. Using 5 or 10 liver stiffness measurements did not significantly affect results.

SAT-090

Detection of hereditary haemochromatosis in the clinic and community using standard haematological tests: a comparison with iron studies

N. Whalen[1], N. Adris[1], S. Hazeldine[1], P. Bentley[2], D. Trinder[3,4], A. Chua[3,4], G. Ramm[5], L. Ramm[5], J. Olynyk[1,6,7]. *[1]Fiona Stanley Hospital, Gastroenterology and Hepatology, Murdoch, Australia; [2]Austrlian Red Cross, Melbourne, Australia; [3]University of Western Australia, School of Medicine and Pharmacology, Crawley, Australia; [4]Harry Perkins Institute for Medical Research, Murdoch, Australia; [5]QIMR Berghofer Medical Research Institute, Liver Fibrosis Section, Herston, Australia; [6]Curtin University Health Innovation Research Institute and School of Biomedical Sciences, Faculty of Health Sciences, Bentley, Australia; [7]Edith Cowan University, School of Medical and Health Sciences, Joondalup, Australia*
Email: john.olynyk@health.wa.gov.au

Background and Aims: Hereditary Haemochromatosis (HH) is a common genetic disorder seen in persons of Northern European descent. Serum ferritin is the most commonly used blood test for screening and detection of HH and exhibits sensitivity and specificity values of 75% and 87%, respectively. Previous studies show that subjects with HH have significantly different haematological parameters compared to non HH control subjects. Our study determined the sensitivity and specificity of haematological parameters in the detection of HH in the general population and in subjects with chronic disease.

Method: Subjects with HH aged 20–70 years were detected in primary care and referred for diagnosis and treatment at specialist clinics between 2005 and 2015. The control group included subjects enrolled in the Busselton Population Study, Western Australia. The chronic disease cohort was identified from outpatient clinics and included male and female subjects with chronic hepatitis C (HCV), chronic hepatitis B (HBV), cirrhosis, rheumatoid arthritis (RA) and other rheumatic conditions (non-RA), diabetes mellitus (DM) and chronic pulmonary disease (Pulm). We evaluated mean cell volume (MCV), mean cell haemoglobin (MCH), and ferritin. Statistical analyses including receiver-operator-curve analyses and analysis of variance were performed using GraphPad Prism software.

Results: For HH subjects, the mean pre- and post-phlebotomy values of MCV and MCH were always significantly higher compared with all other groups whilst ferritin was only elevated in pre-treatment HH subjects (Table 1). For detection of HH in male subjects, MCV >90.8fL provided sensitivity and specificity values of 75% and 65%, respectively (AUC 0.8012) whilst MCH >31.2 pg provided sensitivity and specificity values of 81% and 75%, respectively (AUC 0.8175). In female subjects, MCV >91.9fL provided sensitivity and specificity values of 78% and 71%, respectively (AUC 0.8618) whilst MCH >31 pg provided sensitivity and specificity values of 80% and 78%, respectively (AUC 0.8295). For detection of HH in pre-treatment males and females, serum ferritin levels provided sensitivity and specificity values of 79% to 86%, respectively, compared with the general population. Serum ferritin had low sensitivity and specificity for detection of HH in chronic disease and post-treatment individuals.

Conclusion: MCV and MCH are equally as sensitive and specific for detection of HH in the population, with added advantages over ferritin including utility following successful therapy and in screening chronic disease subjects.

resonance imaging (MRI), could be used to distinguish parenchymal and biliary disease.

Method: Patients with autoimmune hepatitis (AIH), primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) were recruited from a single tertiary ambulatory practice and evaluated in a dedicated study visit, including clinical and laboratory disease phenotyping, alongside dedicated quantitative MRI. Quantitative T2* and T1, and an iron corrected T1 (cT1) quantitative map of the liver were derived from the ShMOLLI and DIXON MRI sequences, where elevation of cT1 is known to correlate with histological hallmarks of disease (inflammation, ballooning and fibrosis). Imaging features were derived to capture patterns of inflammatory liver disease, including skewness and kurtosis of the distribution of cT1 in the liver, as well as local variation of the liver parenchyma, which is a measure of texture. A machine learning classifier was used to combine the imaging features, and was trained on 60% of the cases and validated on 40% of the cases.

Results: 180 patients were recruited, 62 with AIH, 118 with either PBC or PSC. Mean age was 50 years (range 18–84), 29% were male and 85% were Caucasian. 24% had evidence of cirrhosis with portal hypertension. Serum transaminases were moderately associated with clinical diagnosis (AUROC 0.75) with improvement in this when MRI derived features with machine learning was applied (AUROC 0.84). Alkaline phosphatase (ALP) alone was a good discriminator between biliary disease and auto-immune hepatitis (AUROC 0.89) with a modest improvement in this with the addition of quantitative MRI analysis (AUROC 0.91). In patients with an ALP < 200 U/l (62 AIH and 71 biliary cases), ALP alone was moderately correlated with diagnosis (AUROC

0.76). However, addition of MRI analysis improved this considerably (AUROC 0.85, see figure).

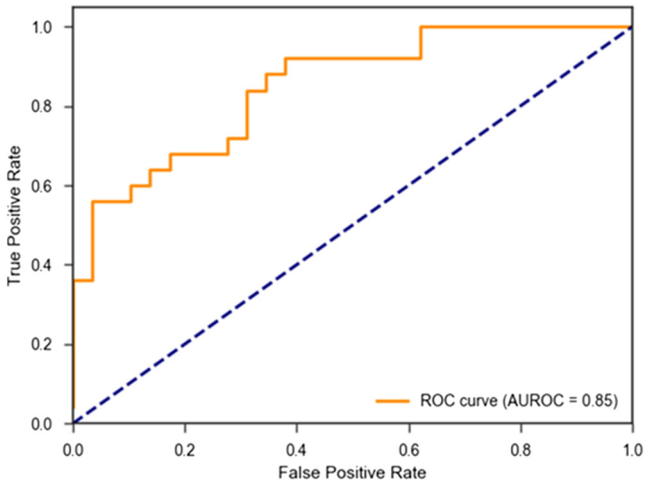

Figure 1: A receiver operating characteristic curve on the validation set showing the classification of AIH vs biliary disease with the addition of image features to cases with ALP < 200U/l.

Conclusion: Quantitative non-biased MRI imaging features have the ability to potentially be used to change how liver disease is evaluated and classified in the future.

SAT-092

Non invasive diagnostic approach for screening and grading of portal hypertension in patients with advanced liver disease

S. Kozlov[1], P. Fomin[1], A. Dolot[1], V. Sidorenko[2]. [1]*Bogomolets National medical university, General surgery #3, Kyiv, Ukraine;* [2]*B, Kyiv, Ukraine*
Email: sergiinikol@gmail.com

Background and Aims: Between 80 and 90% of totally asymptomatic patients already have an elevated PPG (measured clinically as an increase in the hepatic venous pressure gradient (HVPG) and endoscopy discloses that 40% already have esophageal varices. HPVG is an invasive test (as well as endoscopy) that demonstrates high sensitivity but low specificity for prediction first variceal bleeding. Our primary objective was to search a non-invasive screening procedure in order to substitute invasive methods (HVPG, endoscopy) for patients with chronic liver disease (CLD) and suspicion of portal hypertension (PH).
Method: Splenic artery and splenic vein volume blood flow (SAVBF/SVVBF) were evaluated in patients with clinically significant portal hypertension (CSPH) (n = 190) by means of Doppler US in comparison with that in normal controls (control 1 group– healthy volunteers, n = 36), and patients with CLD but absence of signs of PH (n = 34) – control 2 group. Volume flow was calculated as Vf = Tamx*S (vessel cross sectional area). All measurements were done by single operator according to extended sonography protocol.
Results: Means of SABF/SVBF in patients with CSPH were 1.35/1.11l/min, median 1.22/0.88l/min. There was no significant difference in patients with or without bleeding episode or ascities. In C2 and C1 groups means of SAVBF/SVVBF were 0.47/0.43l/min, median 0.46/0.41l/min and 0.30/0.26l/min, median 0.29/0.24l/min respectively. Difference in splenic arterial and venous flow means (1.35 and 1.11) could be explained by opening of retroperitioneal (for example, natural spleno-renal shunts etc) collaterals.
Elevated splenic artery and vein blood flow were significantly increased in patients with clinically significant portal hypertension compared with C1 and C2 groups (p < 0.001) and are the evidence of development a hyperdynamic circulatory state in the splanchnic circulation. According to obtained data the threshold mean of esophageal varix appearance (or any other related to portal hypertension events) could be marked at SAVBF range of 0.8–1.0l/min.
Conclusion: Splenic artery blood flow measurement is a safe non-invasive diagnostic procedure in patients with hepatic portal hypertension. It could be regarded as a predictive factor of development of portal hypertension complications. The measurement of SAVBF/SVVBF might be beneficial to make a decision to activate primary prophylaxy of first variceal hemorrhage in patients with cirrhosis but further trials are needed. Obtained data support the concept of applying partial splenic embolization for effective portal pressure control and primary prophylaxy of index variceal bleeding.

SAT-093

Circulating micro-ARNs as biomarkers of alcohol liver disease and hepatocellular carcinoma

C.-A. Papillon[1], R. Buttolo[1], M. Ingrid[1], H. Houchi[1], N. Mickaël[1], E. Nguyen-Khac[1,2]. [1]*University of Picardie Jules Verne, GRAP INSERM U1247, Amiens, France;* [2]*CHU Amiens-Picardie, Hepato-gastro enterology, Amiens, France*
Email: charles.antoine.papillon@u-picardie.fr

Background and Aims: In Europe, 60–80% of hepatocellular carcinoma (HCC) cases are an alcohol liver disease (ALD) form, which has a worse outcome than any other aetiology (HCV, non-alcoholic fatty liver disease,…).
In this study, we propose to evaluate the interest of using a combination of candidate micro-RNAs (miRNA) as potential diagnostic biomarkers of HCC related to ALD-cirrhosis. Indeed, the current non-invasive markers used for HCC diagnostic have a poor sensitivity, which could be improved by the use of miRNAs.
We have selected 4 circulating miRNAs for their implication in hepatic physiology (miR-122) and liver carcinogenesis (miR-21, miR-34a and miR-126*). The miR-155 was selected for its association to inflammatory and immune response.
Method: We have recruited 165 patients and create 3 groups: HCC due to ALD, ALD without HCC and a control group without liver disease. MicroRNAs were then extracted from blood serum and quantified using TaqMan Technology.
Results: Compared to controls, we observed in ALD patients' bloodstream an increase of the number of copies of miR-122, miR-155, miR-21, miR-34a and miR-126* (of 3-fold, 46-fold, 12-fold, 24-fold and 10-fold, respectively). In HCC patients compared to controls, we also found an increased levels of all miRNAs (of 7-fold, 1133-fold, 12-fold, 28-fold and 12-fold, respectively).
Moreover, the miR-122 and miR-155 levels were significantly higher in HCC patients than in ALD patients without HCC. We propose different thresholds corresponding to the number of copies of these miRNAs that allow us to distinguish the HCC patients from ALD cases.

Thresholds combined	PPV	NPV	p
miR-122 + 155 + 21	69.4	47.9	**0.047**
miR-122 + 155 + 34a	68.0	51.5	**0.044**
miR-155 + 21 + 34a	76.9	56.4	**<0.001**
miR-122 + 155 + 126*	68.9	44.0	0.214
miR-122 + 155 + 21 + 34a	44.8	81.3	**<0.001**

PPV: Positive Predictive Value.
NPV: Negative Predictive Value.

Conclusion: We propose the miR-122 and miR-155 as potential biomarkers for the early diagnostic of HCC. These miRNAs could be used in combination with the miR-21 and miR-34a for the follow-up of ALD patients.

SAT-094

Liver function assessment using magnetic resonance imaging with gadoxetic acid administration

C. Levick[1,2], M. Pavlides[1,2], M. Robson[2], S. Neubauer[2], E. Barnes[1,3].
[1]*University of Oxford, Translational Gastroenterology Unit, Oxford, United Kingdom;* [2]*University of Oxford, Oxford Centre for Clinical MRI Research, Oxford, United Kingdom;* [3]*University of Oxford, Peter Medawar Building, Nuffield Department of Medicine, Oxford, United Kingdom*
Email: christina.levick@gmail.com

Background and Aims: We have previously developed multiparametric magnetic resonance imaging (MRI) to assess liver fibrosis, inflammation and steatosis. However, there is no current gold standard method to assess liver function. In this study we use MRI with the contrast agent gadoxetic acid (Primovist, Gd-EOB-DTPA), which has hepatocyte-specific uptake and lowers the T_1 relaxation time. The percentage reduction in liver T_1 with gadoxetic acid (%rT_1) therefore may be a marker of liver function, with a lower value representing poorer function. Gadoxetic acid is used routinely for liver lesion evaluation. This study aims to assess the ability of MRI with gadoxetic acid to quantify liver function in comparison with standard blood parameters.
Method: In this prospective observational study, liver biochemical dysfunction was defined as either a bilirubin >21 μmol/l and/or an international normalised ratio ≥1.2. Twenty-one healthy controls, 5 patients with acute liver injury and 84 patients with cirrhosis were recruited. The acute liver injury patients had liver biochemical dysfunction with no evidence or risk factors for chronic liver disease or biliary obstruction. Participants were excluded if they had contraindications to MRI or gadoxetic acid, portal vein thrombosis, transjugular intrahepatic porto-systemic shunt or primary/secondary liver cancer. All participants were assessed following a >4 hours fast with liver MRI T_1-mapping pre and 20 minutes post 0.025 mmol/kg gadoxetic acid and blood tests. T_1 maps were analysed by region of interest and the %rT_1 calculated as 100 x (T_1baseline-T_1post contrast)/ T_1baseline.
Results: Of the cirrhotic patients, 44 (52%) had liver biochemical dysfunction. %rT_1 was lower in cirrhotic patients with liver biochemical dysfunction than without (48 vs 58%, $p < 0.001$). Patients with acute liver injury and patients with cirrhosis and liver biochemical dysfunction had lower %rT_1 than healthy controls (39% and 48% vs 64%, respectively, both $p < 0.001$). There were no significant differences between patients with compensated cirrhosis and healthy controls (58 vs 64%, $p = 0.11$) or patients with liver biochemical dysfunction with and without cirrhosis (48 vs 39%, $p = 0.15$).
The %rT_1 correlated ($p < 0.001$ for all) with bilirubin ($r = -0.58$), prothrombin time ($r = -0.33$), albumin ($r = 0.46$), Child Pugh ($r = -0.51$) and MELD ($r = -0.55$). The %rT_1 identified liver biochemical dysfunction with area under the receiver operator curve of 0.85 (0.77–0.92 95%CI). A diagnostic cut off of 55% had 0.82 sensitivity and 0.77 specificity.
Conclusion: The percentage reduction in liver T_1 with gadoxetic acid is a promising marker of liver function that is unaffected by the degree of liver fibrosis and measures liver function in an alternative way to standard blood tests. Follow up studies should assess the use of %rT_1 alone, or in combination with blood parameters as a prognostic tool.

SAT-095

Platelet and spleen volume criteria exclude more oesophageal varices needing treatment than Baveno VI criteria with 100% sensitivity

C. Levick[1,2], M. Pavlides[1,2], M. Robson[2], S. Neubauer[2], E. Barnes[3,4].
[1]*University of Oxford, Translational Gastroenterology Unit, United Kingdom;* [2]*University of Oxford, Oxford Centre for Clinical MRI Research, United Kingdom;* [3]*University of Oxford, Peter Medawar Building, Nuffield Department of Medicine, Oxford, United Kingdom;* [4]*University of Oxford, Translational Gastroenterology Unit, Oxford, United Kingdom*
Email: christina.levick@gmail.com

Background and Aims: Baveno VI consensus recommendations can reduce unnecessary screening endoscopies for varices needing treatment (VNT; grade 2 or 3, or grade 1 with red sign) in patients with compensated advanced chronic liver disease (cACLD) by only 11–33%. This study aims to develop non-invasive strategies to reduce unnecessary endoscopies further through combinations of blood tests, liver stiffness measurement (LSM) and splenic magnetic resonance imaging (MRI). This builds on our previous liver MRI work.
Method: Fourty-nine patients (71% male, mean age 61 ± 10 years) with cACLD of mixed etiologies (35% ALD; 22% NAFLD; 16% viral; 27% other) were assessed with LSM, blood tests and MRI. All had endoscopy screening for VNTs within 1 year of recruitment. MRI scans were analysed for spleen diameter, volume and iron-corrected T_1 (cT_1). Baveno VI (platelets > 150×10^9 cells/l; LSM < 20 kPa), expanded-Baveno VI (platelets > 110×10^9cells/l; LSM < 25 kPa), MELD = 6 and platelets > 150×10^9 cells/l, and platelet count to spleen size ratio criteria were evaluated. Cut off values for unestablished criteria were selected for 100% sensitivity to detect VNTs.
Results: The median time between endoscopy and study assessment was 5 days (IQR -12–43). Ten (20%) participants had VNTs. LSM was technically impossible in 8% of cases and the XL probe was used in 33%. Only the expanded-Baveno VI criteria missed VNTs (5%). The Baveno VI consensus would have saved 14% of endoscopies, saving fewer than most other criteria tested (Table 1). The criteria platelets >112×10^9cells/l and spleen volume <790 ml would have saved the most endoscopies (53%), with an 18.1 likelihood ratio ($p < 0.001$).
Conclusion: The Baveno VI consensus saves few screening endoscopies for VNTs, whilst the expanded-Baveno VI criteria misses an

Table: (abstract: SAT-095): Performance of non-invasive criteria to rule out varices needing treatment (n = 49)

Criteria	Endoscopies saved (%)	Likelihood ratio	Specificity (%)	Positive predictive value (%)	Negative predictive value (%)
Baveno VI: Plts > 150×10^9 cells/l, LSM <20 kPa	7 (14)	3.48	24	24	100
Expanded-Baveno VI : Plts > 110×10^9 cells/l, LSM < 25 kPa	16 (33)	1.63	41	26	89
MELD = 6, plts > 150×10^9 cells/l	4 (8)	1.92	10	22	100
Spleen cT_1 <1244 ms	11 (23)	5.95*	32	27	100
Baveno or spleen cT1 criteria	15 (31)	9.10*	39	30	100
Spleen diameter < 138 mm	19 (39)	11.40*	49	33	100
Platelet to spleen diameter ratio < 1.267	13 (27)	7.05*	33	28	100
Spleen volume < 468 ml	23 (47)	16.92*	59	36	100
Platelet to spleen volume ratio <0.267	25 (51)	18.80*	64	39	100
Plts > 112×10^9 cells/l, spleen volume < 790 ml	26 (53)	18.10*	67	43	100

Abbreviations: Plts, platelets; LSM, liver stiffness measurement; MELD, modified end stage liver disease score.
*$p < 0.05$.

unacceptably high proportion of VNTs. More screening endoscopies could be avoided without missing VNTs if platelet count and spleen volume criteria were used. These results require validation in future studies.

SAT-096

Overestimation and underestimation of liver fibrosis stage classification assessed by transient elastography and two-dimensional shear wave ultrasound

S.G. Kim, J.-J. Yoo, Y.S. Kim. *Soon Chun Hyang University Bucheon Hospital, Gastroenterology and Hepatology, Bucheon, Korea, Rep. of South*
Email: mcnulty@schmc.ac.kr

Background and Aims: The accuracy of detailed fibrosis stage classification assessed with transient elastography (fibroscan) was only 65% and, what is more, significant discrepancy rate (≥ 2 fibrosis stage) reached up to 13%. Several causative factors such as age, elevated liver enzyme, body mass index (BMI), skin to liver distance (SLD) are considered to contribute to this discrepancy, but there are few authentic evidences of what really works. In this study, we compared the discordance of fibrosis stage classification between fibroscan and two-dimensional shear wave ultrasound (2D-SWE) and looked for which variables are related with it.
Method: Patients who had a valid measurement and an adequate liver biopsy specimen were 291. The fibrosis stage classifications derived from the cumulated cut-offs calculated for different fibrosis stage by fibroscan as well as 2D-SWE. The discrepancy score took into account the size of error between fibrosis stage (Metavir) and fibrosis stage classification (fibroscan, 2D-SWE). This score was defined as follows: 0 for correct classification, then 1, 2 or 3 as per the misclassification in fibrosis stages.
Results: Patients were male predominant (54.0%), their mean age was 48.9 ± 13.5 years old. Liver fibrosis stage consisted of F0 (13.4%), F1 (22.0%), F2 (24.1%), F3 (16.8%) and F4 (23.7%). The optimal cut-off for each fibrosis stage observed by fibroscan was 6.9 (≥F2), 7.9 (≥F3), 10.4 (F4) and 6.7 (≥F2), 7.1 (≥F3), 10.0 (F4) by 2D-SWE. Accurate assessment of fibrosis stage classification by discrepancy score showed that the proportion of underestimation and overestimation was 19.6%, 22.0% in fibroscan, and 21.0%, 17.9% in 2D-SWE. The descrepancy score of fibroscan was higher than that of 2D-SWE (p = 0.032). In multivariate analysis, viral liver disease, shorter SLD, lower prothrombin time were associated with underestimation in both fibroscan and 2D-SWE. Longer SLD and higher AST level significantly increased overestimation in fibroscan and, in 2D-SWE along with age. When a skin to liver distance is over 2.5 cm, 80.0% (12/15) of fibroscan and 46.7% (7/15) of 2D-SWE were overestimated.
Conclusion: Fairly large number of patients are misclassified by both fibroscan and 2D-SWE. Skin to liver distance rather than BMI was most important factor to affect the over and underestimation of liver fibrosis classification.

SAT-097

Using Wisteria floribunda agglutinin-positive Mac2-binding protein in combination with the FIB-4 index to predict significant liver fibrosis

T. Jun[1], Y. Tanaka[2], Y.-C. Hsu[3], M. Nguyen[1], M.-L. Yu[4]. *[1]Stanford University Medical Center, Division of Gastroenterology and Hepatology, Stanford, United States; [2]Nagoya City University Graduate School of Medical Sciences, Department of Virology and Liver Unit, Nagoya, Japan; [3]E-Da Hospital, Division of Gastroenterology and Hepatology, Kaohsiung, Taiwan; [4]Kaohsiung Medical University, Hepatobiliary Division, Kaohsiung, Taiwan*
Email: tjun@stanford.edu

Background and Aims: *Wisteria floribunda* agglutinin-positive Mac2-binding protein (M2BPGi) is a novel biomarker which has been shown to correlate with liver fibrosis. The FIB-4 index is a clinical risk score that has been validated for ruling in or out significant liver fibrosis. We conducted this study to determine whether the use of M2BPGi in conjunction with FIB-4 could improve the prediction of significant liver fibrosis.
Method: This clinical-pathological correlative study involved 116 patients with chronic hepatitis B (HBV) seen between 2001 and 2015 at a tertiary referral center in Taiwan. All patients had a serum sample drawn within 180 days of liver biopsy. Patients who had received antiviral treatment prior to serum sample collection were excluded. Significant liver fibrosis was defined as METAVIR stage 3 or 4 fibrosis. M2BPGi was measured as a cutoff index (COI). The FIB-4 index was calculated as previously described, with patients classified as low-risk (<1.45), indeterminate (1.45–3.25) and high-risk (>3.25). M2BPGi levels were also classified into low (<0.27), intermediate (0.27–1.155) and high (≥1.155) based on the 25th and 75th percentile values. We tested several combinations of FIB-4 and M2BPGi using various cutoffs of M2BPGi to reclassify FIB-4-indeterminate patients into high or low risk for significant fibrosis.

Table. Accuracy assessment of fibrosis stage classification.

Variable	By 2D-SWE				By Fibroscan				p-value
	F0-F1 (<6.7)	F2 (6.7-7.0)	F3 (7.1-9.9)	F4 (≥10.0)	F0-F1 (<6.9)	F2 (6.9-7.8)	F3 (7.9-10.3)	F4 (≥10.4)	
By liver biopsy									
F0-1	91 (31.3%)	40 (13.7%)	5 (1.7%)	0 (0%)	91 (31.3%)	47 (16.2%)	10 (3.4%)	2 (0.7%)	
F2	3 (1%)	5 (1.7%)	2 (0.7%)	1 (0.3%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)	
F3	9 (3.1%)	19 (6.5%)	18 (6.2%)	4 (1.4%)	9 (3.1%)	11 (3.8%)	17 (5.8%)	5 (1.7%)	
F4	0 (0%)	6 (2.1%)	24 (8.2%)	64 (22%)	3 (1%)	12 (4.1%)	22 (7.6%)	62 (21.3%)	
Overall accuracy (%)	61.2%				58.4%				0.554
Under-estimated (%)	21.0%				19.6%				0.254
Over-estimated (%)	17.9%				22.0%				0.757
Discrepancy score†	0.46 ± 0.63				0.56 ± 0.75				0.030

Figure: (abstract: SAT-096)

Table: (abstract: SAT-097).

	% indeterminate	% correctly classified (excl. indeterminate)	Positive predictive value	Specificity	Negative predictive value	Sensitivity
FIB-4	25.9	88.4	0.65	0.93	0.95	0.83
M2BPGi-IQR	18.1	84.2	0.54	0.88	0.96	0.83
M2BPGi-1.8	0	87.1	0.56	0.90	0.95	0.72
M2BPGi-0.67	0	81.0	0.44	0.81	0.96	0.83

Results: Area under the receiver operating curve (AUROC) for significant fibrosis for M2BPGi and FIB-4 were 0.85 and 0.86, respectively ($p = 0.78$). Using the FIB-4 index, 25.9% of patients were indeterminate, but 88.4% of the other patients were correctly classified. A binary M2BPGi cutoff eliminated the indeterminate classification, but at the expense of sensitivity or specificity. Reclassifying the FIB-4 indeterminate patients using a three-tiered M2BPGi classification (<0.27, 0.27–1.155, ≥1.155) led to a smaller percentage of indeterminate patients (18.1%), with slightly reduced specificity (0.88 vs. 0.93) and a slightly reduced correct classification (88.4% vs. 84.2%) rate.

Conclusion: M2BPGi had a similar AUROC for predicting significant liver fibrosis as the FIB-4 index. M2BPGi could be used to stratify patients who are indeterminate by the FIB-4 index. Depending on the M2BPGi cutoff chosen, this can reduce the number of FIB-4-indeterminate patients without significantly worsening the diagnostic characteristics of the FIB-4 index.

SAT-098

Assessing liver function: Diagnostic efficacy of parenchymal enhancement and liver volume ratio during hepatobiliary phase of gadolinium-ethoxybenzyl-diethylenetriaminepentaacetic acid (Gd-EOB-DTPA) enhanced-magnetic resonance imaging (MRI) studies

A. Pecorelli[1], E.B. Orsini[2], S. Famularo[3], D. Bernasconi[1], L. Gianotti[2], S. Sironi[4], D. Ippolito[2]. *[1]Ospedale San Gerardo, Statistics, Monza, Italy; [2]Ospedale San Gerardo, Surgery, Monza, Italy; [3]Ospedale San Gerardo, Radiology, Monza, Italy; [4]ASST Papa Giovanni XXIII, Surgery, Bergamo, Italy*

Email: pecorelli.anna@gmail.com

Background and Aims: To assess whether Gd-EOB-DTPA enhanced-MRI study is useful to determine liver function in comparison to Child Pugh (CP) and Model for End-stage Liver Disease (MELD) score and biochemical test.

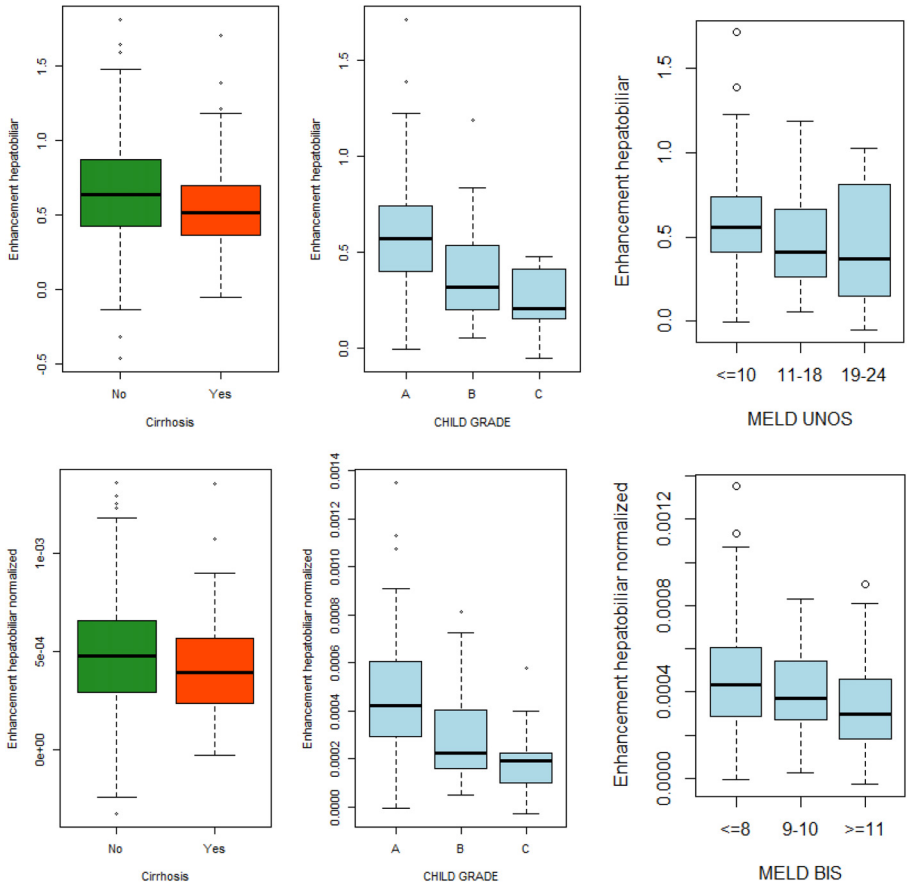

Figure: (abstarct: SAT-098): (1) Association between IrHEP and cirrhosis, Child-Pugh score and MELD score. (2) Association between IrHEP/LV and cirrhosis, Child-Pugh score and MELD score.

Method: We retrospectively reviewed all Gd-EOB-DTPA enhanced-MRI studies performed between May 2010 and September 2016 in patients with focal liver lesions. Patients were divided in study and control group according to the presence or absence of liver cirrhosis. Liver volume was calculated using the software Intellispace Portal (Philps) on hepatobiliary phase. The rate of liver-to-muscle ratio was calculated on T1 sequence in portal (irPOR) and hepatobiliary phase (irHEP) and than normalized for liver volume (irPOR/LV and irHEP/LV). Pearson correlation coefficient was computed to assess the relationship among both these indexes and CP score, MELD score and biochemical test.

Results: A total of 303 Gd-EOB-DTPA enhanced-MRI studies were included in the study. Mean age was 63.8 years (± 12.9) and the majority were male (186; 61.4%). Cirrhosis was present in 175 (57.8%) cases.

IrHEP was significantly lower in cirrhotic than in non-cirrhotic patients (0.54 ± 0.28 vs 0.66 ± 0.39, $p = 0.001$), while no difference was found in irPOR.

When considering only cirrhotic patients, irHEP significantly correlates with both CP and MELD score ($R = -0.316$, $p < 0.0001$ and $R = -0.170$, $p = 0.010$ respectively) while no correlations were found with irPOR.

The irHEP progressively decreased from CP-A to CP-C (0.59 ± 0.29 to 0.25 ± 0.19, $p < 0.0001$) and from MELD ≤ 10 to MELD 19–24 (0.58 ± 0.29 to 0.45 ± 0.41, $p = 0.030$).

Same results were observed when irHEP was normalized for liver volume.

Among biochemical parameters total bilirubin, GOT and albumin had the strongest correlation both with irHEP and irHEP/LV ($R = -0.278$ and-0.285, $R = -0.277$ and -0.291; $R = 0.282$ and 0.262 respectively).

Conclusion: Dynamic Gd-EOB-DTPA enhanced-MRI studies significantly correlates with clinical score routinely utilized to evaluate liver function. In clinical practice this imaging technique could be used both to correctly characterize focal liver lesion and to assess liver function especially in the perspective of surgical treatment.

SAT-099

Distribution and changes of FIB-4 index in normal health checkup examinees

S. Hige[1], I. Ozeki[1], J. Akaike[2], R. Tatsumi[1], M. Yamaguchi[1], M. Kimura[1], T. Arakawa[1], T. Nakajima[1], Y. Kuwata[1], T. Ohmura[1], J. Toyota[1], Y. Karino[1]. *[1]Sapporo Kosei General Hospital, Hepatology, Sapporo, Japan; [2]Sapporo Kosei General Hospital, Health Care Department, Sapporo, Japan*
Email: shuhei.hige@ja-hokkaidoukouseiren.or.jp

Background and Aims: FIB-4 index was developed as a simple noninvasive marker indicating the degree of hepatic fibrosis of various liver diseases. It has been widely used because the value can be easily obtained only by calculating with routine blood tests. The index tends to increase with age since the age is included in the formula. Therefore, the accurate estimation of liver fibrosis by FIB-4 index may be difficult especially for elderly healthy person. However, the distribution of FIB-4 index among healthy population has not been fully estimated. In this study, we investigated the distribution of FIB-4 index of health checkup examinees and determined the normal range and time course changes in healthy participants to provide the range of FIB-4 index of healthy population.

Method: A total of 22,915 people visited the Health Examination Center in our institute in 2015. Those who were undergone ultrasonography (US) and whose FIB-4 index could be calculated were selected as the subjects of this study. The presence of fatty liver was judged by US findings. As a result, 1,886 examinees who fulfilled the following criteria were judged to be "normal": within normal range in hematology and biochemistry (CBC, T. prot., Alb., T. Bil., AST, ALT, LDH, gamma-GTP, ALP, Cr., T.Chol., FBS, HbA1c), HBsAg negative, anti-HCV negative, 18.5≦BMI < 25.0, no US findings in hepatobiliary and pancreatic lesion, complications of diabetes (DM)/hypertension (HT)/dyslipidemia (DL)/malignant diseases. Changes of FIB-4 index were compared for 9,464 people (including 758 normal examinees) who underwent health checkup in both 2010 and 2015.

Results: Median value of FIB-4 index in 30's/40's/50's/60's/≥70's for "normal" examinee was 0.75/0.97/1.30/1.68/2.15. The standard deviation (SD) was 0.04/0.07/0.02/0.18/0.30. SD value was smaller than that of whole examinees (0.07/0.11/0.31/0.90/0.82). According to the regression line analysis, estimated median FIB-4 index and the 75 percentile value for each age was expressed by the following equation: [0.020×age−0.036], [0.025×age−0.006] for the group of 35–44 years old (Gr. A) and [0.038×age−0.819], [0.045×age−0.942] for the group of ≥45 years old (Gr. B). ($r = 0.99$, $p < 0.01$) Percentage of those whose FIB-4 index ≥ 3.25 in 30's/40's/50's/60's/≥70's was 0.08/0.17/0.59/1.68/9.71% for overall subjects and 0/0/0/0/4.8% for "normal" examinees. FIB-4 index was maintained low and the extent of increase by age was also low for normal examinees even in the elderly. During 5 years between 2010 and 2015, mean increase in FIB-4 index per year was 0.03 for "normal" examinees and 0.29/0.34/0.28/0.33 for the subgroup of liver diseases/DM/DL/HT.

Conclusion: FIB-4 index was maintained in a narrow range of lower value for normal examinees. Since the index tended to increase for those who had complications, high value of FIB-4 might indicate any unhealthy state.

SAT-100

Which is the chance for type 2 diabetes patients to develop severe liver disease?

I. Sporea[1], R. Lupusoru[1], R. Mare[1], R. Sirli[1], A. Popescu[1], N. Silviu[1], B. Adina[2], R. Timar[2]. *[1]University of Medicine and Pharmacy "Victor Babes" Timisoara, Department of Gastroenterology and Hepatology; [2]University of Medicine and Pharmacy "Victor Babes" Timisoara, Department of Diabetes*
Email: isporea@umft.ro

Background and Aims: The aim of the study was to assess the severity of liver fibrosis and steatosis in a cohort of type II diabetic patients, using non-invasive methods: Transient Elastography (TE) and Controlled Attenuation Parameter (CAP) and see what happen after the controlled attenuation parameter adjustment algorithm is apply.

Method: The study included 464 type II diabetic patients, who were prospectively randomized (every first 6 patients who were referred to the Metabolic Disease Outpatient Clinic on a consultation day), evaluated in the same session by means of TE and CAP (FibroScan EchoSens) to assess both liver fibrosis and steatosis. Reliable liver stiffness measurements (LSM) were defined as the median value of 10 LSM with an IQR/median <30%. A cut-off value of 10.5 kPa was used to define clinically relevant fibrosis (F ≥ 3). For differentiation between stages of steatosis we used the following cut-off values [2]: S2(moderate)-255 db/m, S3(severe)-290db/m, than we corrected the CAP values according to the presence of diabetes (we deducted 10dB/m) and according to the degree of obesity (we deducted 4.4dB/m for each BMI > 25 kg/m^2 added 4.4 dB/m for each BMI < 25 kg/m^2).

Results: Out of 464 diabetics screened we excluded those with associated viral hepatitis, those with an AUDIT-C score ≥8 and those with unreliable LSM. The final analysis included 424 subjects (55.6% women, 44.4% men, mean age 60.8 ± 9.3; BMI = 31.7 ± 6 kg/m^2) with reliable LSM. Patients with obesity grade I were 61.5%, with obesity grade II 29.1% and 9.4% with obesity grade III (IMC ≥ 40kg/m^2). Mild, moderate and severe steatosis by means of CAP was found in 20.3%, 17.1% and 66.9% cases respectively. After the correction we found moderate steatosis in 12.2% cases and severe steatosis in 59.1% cases. We found no difference in mild and moderate steatosis after the algorithm was apply, $p = 0.23$, but we found significant statistical differences regarding the severe steatosis, (66.9% vs 59.1%, $p = 0.02$). Clinically relevant fibrosis was detected by means of TE (LSM ≥ 10.5 kPa) in 12.4% (54/424) of subjects.

Conclusion: In our group, 79.3% of diabetic patients had moderate and severe steatosis by CAP, 66.9% had severe steatosis, but after applying the controlled attenuation parameter adjustment algorithm we had a signifficantly decrease (59.1%). Regarding the liver fibrosis, we found that 12.4% of them had severe fibrosis (TE ≥ 10.5 kPa), suggesting the need for their systematical assessment.

SAT-101

Intelligent liver function diagnostic pathway – Relevance of alanine transaminase normal values

E. Robinson[1], M. Miller[1], P. Brennan[1], J. Dillon[1], E. Dow[2], P. Donnan[3], B. Bartlett[2], P. Mcintyre[4], R. Neville[5], K. Boyd[6]. *[1]University of Dundee, Ninewells Hospital and Medical School, Department of Molecular and Clinical Medicine, Dundee; [2]Ninewells Hospital and Medical School, Department of Biochemical Medicine and Blood Sciences, Dundee; [3]University of Dundee, Dundee Epidemiology and Biostatistics Unit, Dundee, United Kingdom; [4]NHS Tayside, Department of Medical Microbiology and Virology, Dundee, United Kingdom; [5]NHS Tayside, Westgate Medical Practice, Dundee, United Kingdom; [6]University of Glasgow, Health Economics and Health Technology, Glasgow*
Email: e.robinson7@nhs.net

Background and Aims: Liver Function Tests (LFTs) are frequently checked in primary care although liver disease is not suspected in the majority of cases. Despite this up to 20% of LFTs are abnormal. A significant percentage are never investigated, raising the possibility of missing significant and potentially treatable liver disease at an earlier stage.

The intelligent LFT pathway (iLFT) was designed to risk stratify patients with abnormal LFTs into three categories. 1 Serious or complex liver disease that requires secondary care 2. Less significant disease that could be managed in primary care 3. Diagnostic uncertainty requiring further investigation.

Alanine transaminase in an important component of LFTs. Previous studies have suggested the accepted reference range is too high for certain diseases, leading to the possibility of missed diagnosis. It is thought that ALT < 19 in women and <30 in men is more accurate.

Method: The iLFT algorithm uses the combination of diagnostic criteria for liver disease, an investigation ordering and reporting system (ICE), and the tracked blood sciences system (Siemens). iLFT produces an automated diagnosis or description of the abnormality with staging information and suggestions for further management including referral criterion which is sent to the GP.

A step wedge design trial was conducted in 6 GP practices (covering 30,000 patients). Patients with LFTs measured in the previous 6 months with abnormalities were retrospectively used as controls. During the intervention period (6 months); GPs requested the iLFT option and those patients with abnormal LFTs were assessed.

A sub study analysis was performed within the iLFT intervention arm, an alternative normal range for ALT (male <30, Female <19) was implemented and outcomes compared to the conventional normal range (M and F < 55) including a cost effectiveness analysis.

Results: Using the lower ALT reference range: the number of subjects with abnormal LFTs increased from 64 to 140. Of those 140, 14 more patients were found to have liver disease. The majority of these additional diagnoses were NAFLD and ARLD. Detection of fibrosis is unchanged despite the lower reference range.

iLFT remained cost effective and showed an incremental care-equivalent ratio (ICER) of £137 as well as a lifetime increase in quality adjusted life years.

Conclusion: Using a reduced ALT cut off increases the rate of liver diagnosis using iLFT enabling earlier intervention. It also remains cost effective compared to standard practice.

SAT-102

The impact of inflammation grade of liver histology on the improvement of liver stiffness assessed by transient elastography

J.-J. Yoo, S.G. Kim, Y.S. Kim. *Soonchunhyang University Bucheon Hospital, Internal Medicine, Bucheon, Korea, Rep. of South*
Email: mcnulty@schmc.ac.kr

Background and Aims: Transient elastography (TE; Fibroscan) is now almost indispensable tool to estimate liver fibrosis. Although many clinical factors are known as confounding factors of liver stiffness (LS), there is no knowledge of who will achieve an improvement of liver stiffness if they have a similar liver fibrosis stage. The aim of this study is to see whether baseline hepatic inflammation may affect accurate LS measurement and which factors are associated with improvement of LS in Fibroscan.

Method: This retrospective study included consecutive 678 patients who underwent baseline liver biopsy and sequential LS assessment from 2006 to 2016 at 6 tertiary hospitals in Korea. Liver fibrosis and inflammation were graded on the basis of standard guideline proposed by the Korean Study Group for the Pathology of Digestive Diseases. LS measurement was performed at baseline and 1, 3, 5 years. Improvement of LS was defined as decreased LS value compared with baseline. Logistic regression was used to evaluate factors associated with improvement of LS in Fibroscan.

Results: Mean age of the patients was 47.12 ± 12.25 years and 48.5% were male. Six hundred 2 patients had viral hepatitis (419 HBV; 183 HCV), 76 non-viral hepatitis. Fibrosis stages 0, 1, 2, 3 and 4 were identified in 13 (1.9%), 96 (14.2%), 132 (19.5%), 186 (27.4%) and 251 (37.0%) patients, inflammation grade 0, 1, 2 and 3 were in 28 (4.1%), 278 (14.0%), 279 (41.2%), and 93 (13.7%), respectively. Baseline inflammation grade was correlated with baseline LSM value, and showed linear correlation with ΔLSM. In addition, as the grade of inflammation increased, the higher percentage of patients showed improvement of LSM. A multivariate analysis showed that higher degree of hepatic inflammation was an independent good predictor for LS improvement (adjusted hazard ratio, 3.33; 95% confidence interval, 1.20–9.26; p = 0.021) after adjustment for fibrosis stage, platelet count, total bilirubin and alanine aminotransferase level. The association of LSM and hepatic inflammation was more significant in viral hepatitis compared with non-viral etiology.

Conclusion: Baseline hepatic inflammation has significant impact on LS value and improvement of LSM, and should be considered as one of the confounding factors of measuring liver stiffness using Fibroscan.

SAT-104

Phenotypic characteristics and improvement of liver stiffness measurement during follow-up in patients with Wilson's disease

R. Iacob[1], S. Iacob[1], A. Oana[2], A.D. Cristina[1], A. Constantinescu[1], I.G. Lupescu[1], I. Popescu[1], L. Gheorghe[1]. *[1]Fundeni Clinical Institute, Bucharest, Romania; [2]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*
Email: msiacob@gmail.com

Background and Aims: Wilson's disease (WD) is an autosomal recessive genetic disorder leading to hepatic and neurologic impairement. The aim of our study was to assess phenotypic and therapeutic particularities of WD patients treated in a tertiary hospital between 2012–2016.

Method: A retrospective study has been conducted including 88 patients diagnosed with WD during the defined period.

Results: Age at diagnosis below 7 years was found in 12.9% of cases, between 7–18 years in 44.7%, 18–35years in 37.6% and >35years in 7%. At time of diagnosis, hepatic disease was encountered in 67%,

hepatic and neurologic disease in 27.3%, exclusive neurologic disease in 5.7%. In patients with hepatic WD, 30.3% had compensated and 14.2% decompensated liver cirrhosis (LC), 50% chronic hepatitis, and 5.3% acute liver failure. In patients with hepatic and neurologic impairment, 66.6% had compensated and 11% decompensated LC and 22.2% chronic hepatitis. Exclusive hepatic disease was encountered in 77.7% of children in comparison to only 50% of adults (p = 0.02). At last follow-up visit, treatment consisted in D-penicillamine 32.1%, trientine 8.3%, zinc 5.9%, D-penicillamine and zinc 41.7%, trientine and zinc 3.6%, liver transplantation being performed in 8.4% of cases. In patients with hepatic disease, clinical improvement was established in 65.8% of patients while worsening of disease in only 20.3%. In patients with hepatic and neurologic disease, clinical improvement was found in 59.1%, while worsening in 22.7%. Patients with isolated neurological impairment had a favorable clinical course in 75% of cases and the rest worsened. Liver stiffness measured in all patients with compensated liver diseases at the moment of diagnosis decreased significantly after 12 months of chelating therapy (14.6 ± 10.9 vs 8.4 ± 5.1 kPa, p < 0.0001).

Conclusion: In a romanian tertiary center, WD with hepatic phenotype is the most frequently encountered especially in children and exclusive neurological disease is rare. A favorable disease course could be confirmed in >60% of cases in all phenotypes, with significant decrease of liver stiffness. During the study period, liver transplantation was performed in <9% of cases due to timely diagnosis and effective chelating therapy.

SAT-105

Is food-intake a confusing factor for liver stiffness evaluation by 2D-SWE in normal subjects?

D. Gherhardt[1], A. Popescu[1], C. Foncea[1], T.-V. Moga[1], B. Marius[1], C. Laura[1], V. Corina[2], I. Sporea[1]. [1]*"Victor Babes" University of Medicine and Pharmacy, Gastroenterology Department, Timisoara, Romania;* [2]*Victor Babes University of Medicine and Pharmacy, Timisoara, Medical Informatics and Biostatistics, Romania*
Email: diana1310tm@yahoo.com

Background and Aims: Ultrasound based elastography has become a method frequently used by the gastroenterologist, allowing a noninvasive assessment of liver fibrosis. 2D-Shear wave elastography (2D-SWE) is a technique used for real time visualization of liver's elasticity. Our aim was to observe if the values obtained by 2D-SWE SSI were influenced by food-intake.

Method: We performed a prospective study on 42 healthy volunteers, recruited during 1 month-October 2017 from our Department of Gastroenterology. Subjects were evaluated by 2D-SWE (Aixplorer, Supersonic Imagine) 4 times: in fasting condition, at half an hour after food intake (a sandwich + water), after 1 hour as well as after 2 hours. The subjects were examined in supine position, by intercostal approach in the right liver lobe, by the same operator.
The trapezoid sample box was placed in full liver parenchymal area, avoiding large tubular structures. We placed the ROI in the most homogeneous area of the sample box, at a depth between 2.5 and 6 cm.
One examiner (with an experience of more than 50 examinations) performed 5 liver stiffness measurements (LSM) for each evaluation. Two quality technical parameters were taken into account: standard deviation/median liver stiffness <0.10 and stability index (SI) > 90%.

Results: The mean age of the 42 healthy volunteers was 27.1 ± 3.7 years. The distribution according to gender was 59.5% women (25) and 40.5% (17) men. All of them had normal weight, mean body mass index = 21.8 ± 2.5 kg/m^2.
The mean liver stiffness value at fasting was 4.8 ± 0.8 kPa (median value 4.8 kPa). Women had slightly lower LSM than men (4.7 ± 0.8 kPa vs 5 ± 0. kPa, p = 0.173).

The results of the LSM according to time spent after food-intake are illustrated in the Table 1 bellow:

Table 1: Results of LSM by 2D SWE SSI

	Fasting	30 minutes after food intake	1 hour after food intake	2 hours after food intake
Mean LSM (kPa)	4.8 ± 0.8	5.0 ± 0.8	5.1 ± 0.7	4.9 ± 0.8
P		0.25	0.07	0.56

Conclusion: Food-intake did not significantly increase liver stiffness values obtained by 2D SWE SSI method in healthy subjects.

SAT-106

Spleen stiffness decrease as mirror of portal hypertension changes after successful interferon-free therapy in chronic-HCV patients

F. Ravaioli[1], E. Dajti[1], A. Colecchia[1,2], V. Alemanni[1], G. Marasco[1], M. Tamé[1], F. Azzaroli[1], S. Brillanti[1], G. Mazzella[1], D. Festi[1]. [1]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy;* [2]*Azienda Ospedaliera Universitaria Integrata, UOC. Gastroenterologia, Verona, Italy*
Email: antonio.colecchia@aovr.veneto.it

Background and Aims: Interferon-free direct-acting antivirals (DAAs) have enormously increased the number of patients with advanced chronic liver disease (ACLD) achieving sustained viral response (SVR). Hepatic venous pressure gradient (HVPG) has been shown to decrease after SVR. The clinical impact of SVR in terms of changes in portal hypertension (PH) and the role of non-invasive tests (NITs) in the follow-up of SVR patients is still under discussion. We aimed to investigate the changes in spleen stiffness measurement (SSM) and other NITs at 6 months of follow-up, as well as to identify the predictors of SSM change after SVR.

Method: We retrospectively analysed prospectively collected data of compensated ACLD patients treated with DAA between January 2015 and September 2017 at our tertiary centre and with available paired SSM at baseline (BL) and 6 months after end of therapy. Changes in SSM, liver stiffness measurement (LSM), spleen diameter (SD), platelet count (PLT) and Liver Stiffness-Spleen Diameter-to-Platelet Count Ratio Score (LSPS) were investigated. According to Baveno VI Criteria, LSM ≥ 21 kPa was used as a cut-off to rule-in clinically significant portal hypertension (CSPH).

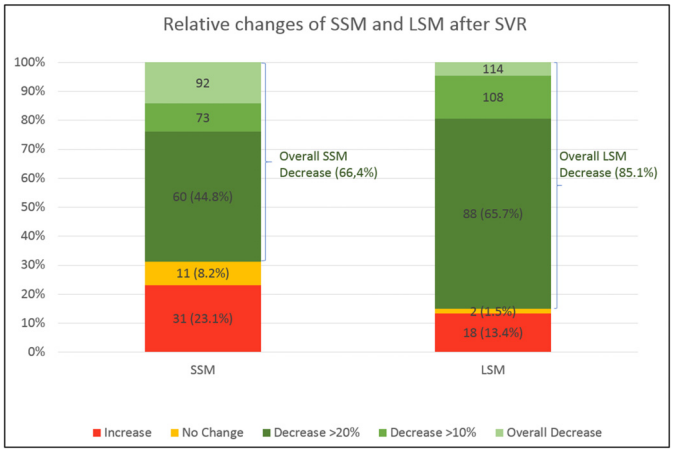

Figure: Relative changes of SSM and LSM after SVR. SSM/LSM decrease is represented as cumulative number of patients in which a decrease >20%, 10% and <10% was observed.

Results: One hundred-thirty (134) patients who achieved SVR were included in the final analysis. SSM significantly decreased from

median 58.8 kPa at BL to 38.2 kPa at SVR24; relative median change was -4.7% in patients with CSPH and -20.4% in patients without CSPH. SD and PLT differed significantly only in patients without CSPH. LSPS significantly improved after SVR. SSM decrease >20% in 60 (44.8%) patients (see Figure); independent predictor of such SSM decrease was the median relative change of LSM (OR: 0.33, 95%CI: 0–0.005, p < 0.0001). CSPH persisted in 32 (54.4%) patients after SVR; delta LSM (OR: 0.011; 95%CI: 0.0007–0154, p = 0.001) and BL SSM (OR: 1.046; 95%CI: 1.014–1.078; p = 0.004) were independent factors associated with CSPH persistence.
Conclusion: SSM faithfully reflects changes in portal hypertension. Even though LSM decrease is evident in almost all patients, a decrease >20% of SSM could more accurately identify patients with a clinically meaningful benefit in portal hypertension after viral eradication.

Liver transplantation and hepatobiliary surgery: Experimental

SAT-109
Rictor/mTORC2 signaling protects ischemic liver injury by targeting both liver parenchymal and non-parenchymal cells

H. Zhou[1,2], Z. Rao[3], J. Rao[1], Y. Xia[1], Y. Zhai[2], X. Wang[1], L. Lu[1]. *[1]The First Affiliated Hospital of Nanjing Medical University, Liver Transplantation Center, Nanjing, China; [2]David Geffen School of Medicine at University of California-Los Angeles, Department of Surgery, Los Angeles, United States; [3]The First Affiliated Hospital of Nanjing Medical University, Dept. of Anesthesiology, Nanjing, China*
Email: doc2012zhm@163.com

Background and Aims: Mammalian target of rapamycin (mTOR) signaling controls many essential cellular functions. However, the role and its underlying mechanism of Rictor/mTOR complex 2 (mTORC2) in regulating liver ischemia and reperfusion (IR) injury remains largely unknown.
Method: In a murine liver partial warm IR model, we selectively knockdown Rictor signaling in liver parenchymal and non-parenchymal cells. Hepatocellular injury and Kupffer cell (KC) pro-inflammatory activation were studied. Rictor signaling in human liver tissues post ischemia was also analyzed.
Results: Liver mTOR2 was constitutively active in mice. Ischemia triggered a transient inactivation followed by a rapid reactivation during reperfusion. Abrogation of mTORC2 signaling in hepatocytes by Rictor-shRNA-AAV8 resulted in significantly increased liver IR injury, as evidenced by higher sALT levels and worse preserved liver architectures. In vitro, knockdown of Rictor in hepatocyte inhibited hepatocellular autophagy, enhanced CHOP and pro-apoptosis signaling pathway activation, leading to increased TNF-a induced primary hepatocyte cell death. Studies have shown that KC medicated innate immune activation plays an important role in liver IR injury. Rictor siRNA with mannose-conjugated polymers was used to specifically block Rictor signaling in KC. KCs post IR were isolated and inflammatory cytokine secretion was evaluated. Specific Rictor knockdown in KC resulted in significant increase in TNF-α and IL-6 secretion but dramatically decreased anti-inflammatory IL-10 secretion. Interestingly, autophagy in KC was inhibited by Rictor knockdown as well. We further analyzed the role of Rictor in KC M1/M2 polarization. Interestingly, we found that Rictor knockdown inhibited IL-10-secreting M2-like macrophage polarization, as revealed by decreased Arg1 and Mrc1 gene induction accompanied by a decrease in STAT6 signaling pathway activation. In vivo Rictor knockdown decreased intrahepatic anti-inflammatory IL-10 gene induction, leading to aggravated liver IR injury. Finally, human liver tissues were collected in patients undergoing liver partial resection with blockade of hepatic portal. Rictor activation was analyzed by Western blot. We found that Rictor activation was inhibited by liver ischemia, which are consistent with our findings in mouse model.
Conclusion: Our findings defined a critical role of mTORC2 signaling in both liver parenchymal and non-parenchymal cells. mTORC2 protected livers against IR injury by inhibiting hepatocellular apoptosis and promoting KC M2 polarization. Targeting Rictor signaling pathway may shine light on ways to protect against liver ischemic injury in patients.

SAT-110
Hyperglycemia-triggered ATF6-CHOP pathway exacerbates liver ischemia/reperfusion injury: immnomodulation by beta-catenin signaling

J. Rao, C. Yang, F. Cheng, S. Yang, L. Lu, X. Wang. *The First Affiliated Hospital of Nanjing Medical University, Liver Surgery/Liver Transplantation Center, Nanjing, China*
Email: raojh@njmu.edu.cn

Background and Aims: Hyperglycemia is a risk factor for hepatic ischemia/reperfusion injury (IRI) during liver transplantation or hepatectomy; however, the underlying mechanism remains unclear. Our previous studies implicated endoplasmic reticulum (ER) stress in the pathophysiology of hepatic IRI. In this study, we addressed the question of whether and how hyperglycemia triggered ER stress and affected liver IRI.
Method: Diabetic patients and streptozotocin (STZ)-induced diabetic mice were involved in vivo. Bone marrow-derived macrophages (BMDMs) were used in vitro.
Results: The ER stress-ATF6-CHOP pathway was specifically activated in liver tissues and Kuppfer cells (KCs) from diabetic patients and STZ-induced diabetic mice. The ER stress inhibitor, 4-phenylbutyrate (PBA), attenuated hyperglycemia-related liver IRI based on biochemistry and histology, and decreased TLR4-related pro-inflammatory responses based on inflammatory cytokines and macrophage/neutrophil trafficking. Furthermore, CHOP-knockout (CHOP-KO) had markedly reduced hyperglycemia-related liver IRI and inflammatory responses. Importantly, expression of β-catenin, as a negative regulator of inflammatory responses, was effectively inhibited, accompanied by activation of ATF6-CHOP pathway in diabetic mice, and was almost restored in liver tissues from PBA-treated or CHOP-KO diabetic mice. In addition, β-catenin small interfering RNA (siRNA) targeting KCs abrogated the CHOP-KO-related protective effects against hyperglycemia-related liver IRI. High glucose (HG) specifically activated ATF6-CHOP signaling, inhibited β-catenin expression, and enhanced TLR4-related inflammatory responses in BMDMs in vitro; these effects were partly reversed in PBA- or CHOP siRNA-treated/CHOP-KO BMDMs. However, the anti-inflammatory functions of CHOP-KO were almost abolished by β-catenin siRNA in BMDMs under HG conditions.
Conclusion: This study revealed that hyperglycemia specifically triggers ER stress-ATF6-CHOP signaling, inhibits β-catenin activity, promotes inflammatory responses, and exacerbates liver IRI, which might provide the rationale for novel therapeutic strategies aimed at managing diabetic-related liver surgery.

SAT-111
An effective defatting cocktail to reduce liver graft steatosis before transplantation

L. Aoudjehane[1,2], W.L. Goff[1,3], E. Savier[1,2,4], P. Bonnefoy[2], P. Lesnik[1,3], Y. Calmus[1,3,5], O. Scatton[1,2,4], C. Housset[1,2], F. Conti[1,2,5]. *[1]Institute of Cardiometabolism and Nutrition (ICAN), Paris, France; [2]Sorbonne Universités, UPMC Univ Paris 06 & INSERM, UMR_S 938, Centre de Recherche Saint-Antoine (CRSA), Paris, France; [3]Sorbonne Universités, UPMC Univ Paris 06 & INSERM, UMR_S 1166, Paris, France; [4]Department of Hepatobiliary and Liver Transplantation Surgery, APHP, Pitié–Salpêtrière Hospital, Paris, France; [5]Department of Medical Liver Transplantation, APHP, Pitié–Salpêtrière Hospital, Paris, France*
Email: lynda.aoudjehane@inserm.fr

Background and Aims: Graft dysfunction after liver transplantation is correlated with the percentage of donor liver steatosis. *Ex vivo* liver perfusion could be efficient to defat steatotic liver, as demonstrated in isolated perfused rat fatty liver. In this study, we designed a new defatting cocktail and tested its effect *in vitro* on primary human steatotic hepatocytes.
Method: Primary human hepatocytes were obtained from normal liver samples. They were incubated with a free fatty acid (FFA) mixture (oleic acid and palmitic acid at a molar ratio of 2:1) for 48 h, to induce steatosis. Steatotic hepatocytes were treated with a combination of pharmacological agents referred to as a defatting cocktail (DC) for 24 h. Cell viability, oxidative stress, intracellular lipid accumulation, ketone bodies and VLDL secretion were evaluated, as well as the expression of genes involved in lipid metabolism or inflammation.
Results: Oil-Red O staining and triglyceride quantification showed abundant steatosis in hepatocytes following exposure to FFA mixture. There was no significant cytotoxicity, oxidative stress or apoptosis in steatotic hepatocytes treated with the DC. The treatment of steatotic hepatocytes with the DC induced a significant reduction of intracellular fat droplet and of intracellular triglycerides when compared to controls, by 30% and 27%, respectively. The analysis of supernatants showed that DC treatment, caused an increase in the secretion of ketone bodies and a trend towards increased ApoB-containing lipoproteins export.
The DC induced a significant upregulation in the expression of enzymes (Carnitine palmitoyltransferase I (CPT-1) and Peroxisomal proliferator activated receptor coactivator (PGC-1α) implicated in FFA oxidation, as assessed by RT-qPCR. The expression of pro-inflammatory cytokines IL1-β and TNF-α was decreased in steatotic hepatocytes treated with DC, whereas an increase in IL6 mRNA expression occurred in steatotic hepatocytes incubated with DC *vs* controls.
Conclusion: We designed an effective defatting cocktail that promotes rapid mitochondrial oxidative metabolism and reduces the amount of intracellular fat droplet and triglycerides in steatotic hepatocytes without toxicity. These results suggest that our defatting cocktail could be efficient to induce the reduction of steatosis in donor livers during normothermic reperfusion before liver transplantation.

SAT-112

A merged protocol of hypothermic oxygenated machine perfusion and normothermic machine perfusion optimizes the reconditioning of marginal donor livers

Y. Boteon[1,2], A. Schlegel[1], R. Laing[1,2], L. Wallace[2], A. Smith[1], J. Attard[1,2], D. Neil[1], T. Perera[1], D.F. Mirza[1], J. Isaac[1], P. Muiesan[1], S. Afford[2], H. Mergental[1]. Email: yurimed43@yahoo.com.br

Background and Aims: The shortage of organ for transplantation requires the acceptance of donors with extended criteria which are more susceptible to ischaemic injury during cold storage. Extra-corporeal machine perfusion of donor livers offers safer preservation and potentially allows organ reconditioning prior to transplantation. Hypothermic oxygenated machine perfusion (HOPE) was shown to improve mitochondrial function lowering oxidative injury after reperfusion. Normothermic machine perfusion (NMP) allows viability assessment and extended organ preservation. In this study we used a combination of both techniques to determine whether we could improve the rescue rate of marginal organs.

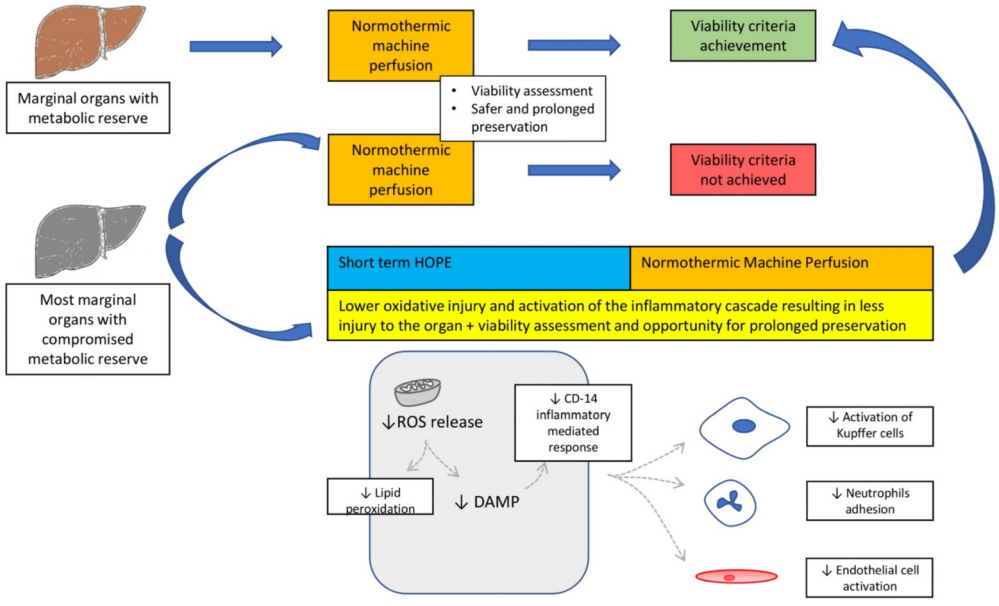

Figure 1: Pre-conditioning with short term hypothermic oxygenated perfusion lowered the oxidative stress and activation of the inflammatory cascade induced by the rewarming on the normothermic machine perfusion. This combination suggests to be fundamental for the most marginal organs to overcome the ischaemic injury and achieve viability. Therefore this technique can successfully improve the rescue rate of marginal organs.

Figure: (abstarct: SAT-112).

Method: Ten discarded human livers were randomly allocated to two experimental groups: (1) the NMP group, in which 5 organs were perfused at 37°C using an acellular oxygen carrier based perfusate for 6 hours; and, (2) the HOPE + NMP group, in which 5 organs had 2 hours of HOPE at 10°C with Belzer UW Machine Perfusion as the perfusion fluid followed by 4 hours of the previous described NMP. Viability was assessed at the end of 6 hours perfusion using the lactate clearance criteria. Perfusate and histological samples were collected for analysis throughout.
Results: Mitochondria respiratory rate decreased during HOPE (oxygen uptake: 0.009 [0.005–0.010] to 0.006 [0.001–0.007] kpa/gr/L, p = 0.043; pCO2 in the perfusate 1.27 [1.17–1.86] to 0.69 [0.57–0.82], p = 0.040) and the median ATP content increased (1.77-fold nmol/g [range: 3.89–1.33]). This resulted in slower oxygen consumption during rewarming and decreased tissue expression of markers of reactive oxygen species production (Uncoupling protein 2, p = 0.016), oxidative injury (4-hydroxynonenal, p = 0.008; TLR-4 activation, p = 0.008) and activation of the inflammatory cascade (Kupffer cells, neutrophil adhesion, p = 0.016; vascular cell adhesion protein 1, p = 0.050) for the livers that had HOPE. Liver deemed non-viable at the end of the NMP had lower ATP levels (1.10 [1.08–1.15] vs. 2.53 [2.4–10.9] nmol/gram, p = 0.050) and higher lactate levels (8.45 [5.2–11.5] vs. 1.4 [0.8–1.5] mmol/L, p = 0.020). All the livers from the HOPE + NMP group were deemed compared with three (60%) in the NMP alone group (p = 0.222).
Conclusion: The merged protocol of HOPE + NMP together combined the benefits of individual techniques increasing the rescue rate of marginal livers into the pool of transplantable organs compared with NMP alone.

SAT-113

The effectiveness of a pharmacological intervention for defatting of primary human hepatocytes and its effect on other cell types of the liver: a precursor in-vitro study to the defatting of steatotic human livers using normothermic machine perfusion

Y. Boteon[1,2], L. Wallace[2], R. Bhogal[1], A. Boteon[1], R. Laing[1,2], G. Reynolds[2], D.F. Mirza[1], H. Mergental[1], S. Afford[2]. [1]*Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Liver Unit, Birmingham, United Kingdom;* [2]*National Institute for Health Research, Birmingham Liver Biomedical Research Centre, Institute of Immunology and Immunotherapy, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom*
Email: yurimed43@yahoo.com.br

Background and Aims: Macrovesicular steatotic donor livers are often discarded because of the risk of graft dysfunction post-transplantation. Therapeutic interventions for defatting using extra-corporeal machine perfusion (MP) could rescue these organs into the pool of transplantable organs. We aimed to test in vitro the efficacy of a combination of drugs for defatting of primary human hepatocytes (PHH) and the effect of these drugs in the other cell types of the liver.
Method: Steatosis was induced in static cultures of isolated PHH by exposure for 48 hours to equal concentrations of 0.25 mM of palmitic, oleic and linoleic acid. This was followed by defatting using a medium supplemented with a cocktail of defatting agents for up to 48 hours. Human intra-hepatic endothelial cells (HIEC) and human biliary epithelial cells (HBEC) were isolated and incubated with the same drugs for 48 hours. The control group received the medium with only the vehicle of the drugs. MTT assay was used to estimate cell

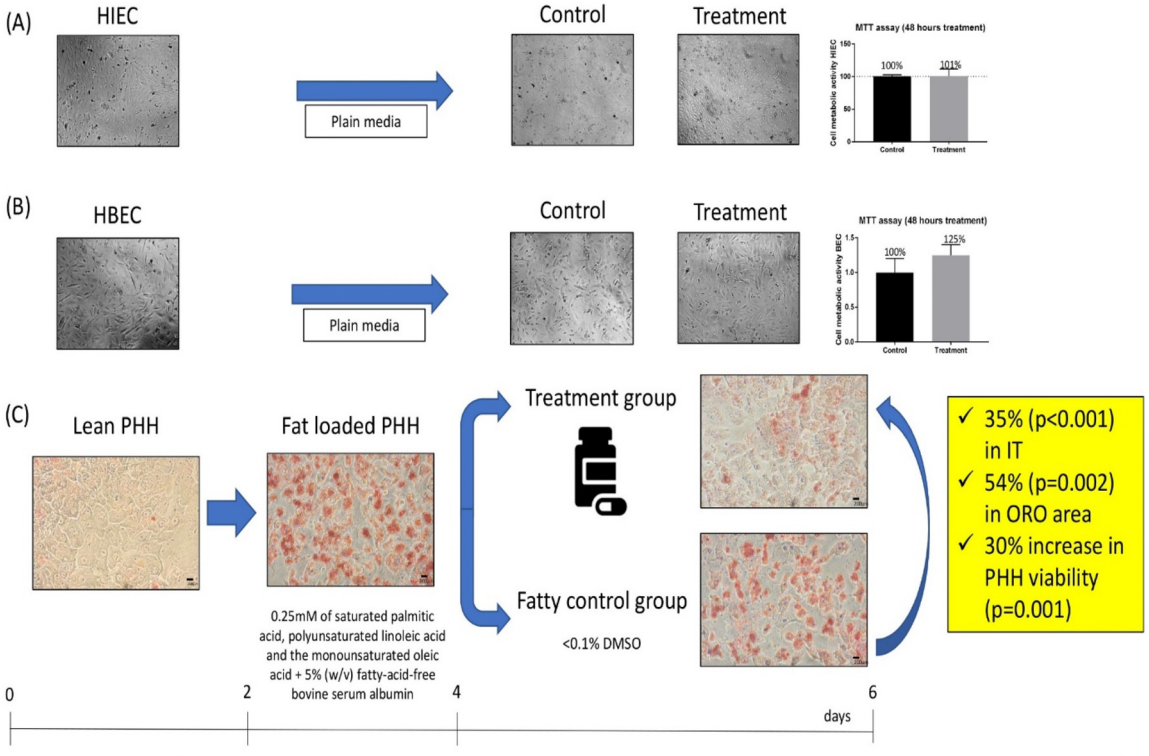

Figure 1: Schematic summary of the findings. (A) Human intrahepatic endothelial cells (HIEC) were freshly isolated from donor human livers discarded for transplantation and consented for research. These cells were left in plain media until 4 days and then randomly allocated to a control group that had the media supplemented with the vehicle of the drugs (<0.1% DMSO) and the treatment group that received the cocktail of defatting agents in the media. MTT assay for cell viability did not show any cytotoxic effect of the drugs to the cells. (B) Human biliary epithelial cells (HBEC) were also left in plain media for 4 days after harvesting and then divided into the control and treatment group as described. The viability of the HBEC increased in 25% with the treatment. (C Isolated primary human hepatocytes (PHH) were left in plain media for two to stabilise the metabolism. After that they were incubated with a media supplemented with a combination of fatty acids. Once loaded with large lipid droplets after 2 days they were allocated to two experimental groups: (1) the treatment group that received a media containing the defatting combination of drugs; and, the (2) control group which had plain media plus the vehicle of the drugs (<0.1% DMSO). After 48 hours cell viability was assessed using the MTT assay and the intracellular lipid load using the oil red O staining (ORO) and a commercial kit for measurement of the intracellular triglycerides.

Figure: (abstract: SAT-113)

viability. Intracellular triglyceride quantification (IT) and oil red O (ORO) staining were used to assess lipids content. Ketone bodies (3-hydroxybutyric acid + acetoacetic acid-mM) were measured in the supernatant up to 48 hours.
Results: Incubation of PHH with the fatty acids induced intracellular accumulation of large lipid droplets (14-fold induction in the ORO area and 8-fold in IT levels, $p < 0.050$). Treatment of fatty loaded PHH with the cocktail resulted in a median reduction of 28% (6–43%) over 24 hours and 46% (33–67%) along 48 hours in the area of lipid droplets assessed by ORO ($p < 0.050$). The IT dropped by 18% (17–19%) and 32% (28–34%) during 24 and 48 hours of treatment respectively ($p < 0.050$). Total ketone bodies measured in the supernatant increased 1.22 and 1.40-fold by 24 and 48 hours in the treated group compared with controls ($p < 0.050$). The treatment induced an increased in cell viability in more than 30% for PHH over 48 hours ($p < 0.050$), it has not affected HIEC metabolism and increased the viability of HBEC in 25% ($p < 0.050$).
Conclusion: These data showed for the first time in an in vitro primary human cell culture model that a pharmacological intervention can decrease the intracellular lipid content of PHH inducing fatty acids beta-oxidation. The treatment also increased the viability of PHH and HBEC without any harm for HIEC. These findings support future attempts to use MP as a delivery tool for extra-corporeal defatting of human livers.

SAT-114

The postoperative serumcourse of the liver regeneration-associated signaling molecules bile salts and FGF19 in cholestatic patients undergoing liver resection

K. Koelfat[1], K. van Mierlo[1], M. Schmeding[2], T. Cramer[3], I. Sauer[2], C. Dejong[1], F. Schaap[1,2], U. Neumann[2], S.O. Damink[1,2]. *[1]Maastricht University Medical Centre & NUTRIM School of nutrition and translational research in metabolism, Maastricht University, Surgery, Netherlands; [2]Uniklinikum RWTH Aachen, Aachen, Germany, Department of general-, visceral- and transplant surgery, Netherlands; [3]Uniklinikum RWTH Aachen, Aachen, Germany, Molecular Tumorbiology, Germany*
Email: k.koelfat@maastrichtuniversity.nl

Background and Aims: Systemic and hepatic bile salt (BS) levels rise shortly after partial hepatectomy (PHx) in rodents, likely providing input signals for the regenerative response. Deficiency of the nuclear bile salt receptor FXR or its target gene Fgf15/FGF19, results in delayed liver regeneration (LR) and mortality after PHx. This is due to dysregulated bile salt homeostasis and attendant bile salt-toxicity in the remnant liver, and is reminiscent of impaired LR in patients with perihilar cholangiocarcinoma (pCCA) and cholestasis. Little is known about the role of bile salt/FGF19 signaling in human LR. Here, we explored the post-resectional course of these signaling molecules in patients with different hepatobiliary malignancies.
Method: Data was collected of adult patients who underwent major hepatectomy (≥3 segments) at the Uniklinikum Aachen between 01.06.2013 and 01.02.2016 for colorectal liver metastases (CRLM, $n = 50$) and pCCA ($n = 23$). Plasma BS, FGF19 and C4 (surrogate marker of BS synthesis) levels were determined preoperatively and on postoperative days (POD) 1, 3 and 7.
Results: Preoperative bilirubin, AST, GGT and AP levels were significantly higher in pCCA-patients compared with CLRM ($P < 0.001$). At baseline, BS levels were 3-fold higher in patients with pCCA compared with CLRM ($P < 0.001$). Similar, FGF19 levels were 2.5-fold higher in patients with pCCA ($P < 0.001$). Subsequently, plasma C4 levels were significantly lower in pCCA-patients versus CLRM-patients ($P < 0.001$). Conversely, BS levels on POD7 were higher in CLRM-patients compared with pCCA ($P < 0.001$), and on the other hand FGF19 levels were significantly lower in pCCA-patients ($P = 0.03$). C4 levels on POD7 were comparable in both group. Longitudinal analysis revealed a significant postoperative rise of BS levels in CLRM patients, whereas BS levels declined on POD1 and remained low on POD3 and POD7 in pCCA-patients.
Conclusion: These data demonstrate that the postoperative rise of BS in non-cholestatic CLRM patients, potentially providing a stimulus for the regenerative machinery, is strongly attenuated in pCCA patients. Furthermore, reduced FGF19 levels in pCCA-patients after resection may negatively impact on the early course of liver regeneration in these patients.

SAT-115

Establishing a porcine model of small for size syndrome following liver resection

M. Golriz[1], A. Majlesara[1], E. Khajeh[1], O.G. Nejad[1], C. Flechtenmacher[2], A. Mehrabi[1]. *[1]Department of General, Visceral, and Transplantation Surgery, Heidelberg, Germany; [2]University of Heidelberg, Department of General Pathology, Heidelberg, Germany*
Email: Omid.Ghamarnejad@med.uni-heidelberg.de

Background and Aims: Small for size syndrome (SFSS) is responsible for a high proportion of mortalities and morbidities following extended liver resection. The aim of this study was to establish a porcine model of SFSS.
Method: Twenty-four Landrace pigs underwent liver resection with a remnant liver volume of 50% (group A, $n = 8$), 25% (group B, $n = 8$), and 15% (group C, $n = 8$). After resection, the animals were followed up for 8 days and clinical, laboratory, and histopathological outcomes were evaluated.
Results: The survival rate was significantly lower in group C compared with the other groups ($p < 0.001$). The international normalized ratio, bilirubin, aspartate transaminase, alanine transaminase, and alkaline phosphatase levels increased shortly after surgery in groups B and C, but no change was observed in group A ($p < 0.05$ for all analyses). The histopathological findings in group A were mainly mild mitoses, in group B severe mitoses and hepatocyte ballooning, moderate congestion, and hemorrhage, along with mild necrosis, and in group C extended tissue damage with severe necrosis, hemorrhage, and congestion.
Conclusion: Combination of clinical, laboratory, and histopathological evaluations is needed to confirm the diagnosis of SFSS. 75% liver resection in porcine model results in SFSS. 85% liver resection causes irreversible liver failure.

SAT-116

Induction of beta-catenin in embryonic stem cell-derived dendritic cells alleviates liver damage in mouse liver inflammatory injury

S. Yue[1], C. Li[2], L. Jiang[2], M. Ke[2], R. Busuttil[2], Q.-L. Ying[3], J. Kupiec-Weglinski[2], B. Ke[2]. *[1]Eli and Edythe Broad Center for Regenerative Medicine and Stem Cell Research at USC, Department of Stem Cell Biology & Regenerative Medicine, Los Angeles, United States; [2]The Dumont-UCLA Transplant Center, Department of Surgery, David Geffen School of Medicine at UCLA, Los Angeles, United States; [3]Eli and Edythe Broad Center for Regenerative Medicine and Stem Cell Research at USC, Department of Stem Cell Biology & Regenerative Medicine, Keck School of Medicine, University of Southern California, Los Angeles, United States*
Email: bke@mednet.ucla.edu

Background and Aims: Liver inflammatory injury induced by ischemia and reperfusion injury (IRI) is the major causes of hepatic dysfunction and failure following liver transplantation. Embryonic stem (ES) cell derivatives offer a potentially important renewable source of cell therapy for tissue injury. However, the host immune response leading to liver damage remains the greatest challenge during hepatic IR. This study was designed to regulate immune response through induction of β-catenin activity in ES cell-derived Dendritic cells (ES-DC) in vitro and in vivo.
Method: Mouse ES cells were cultured and maintained in MEFs/LIF conditions. ES cells were seeded onto OP9 feeder cell layers and

differentiated into DC with granulocyte macrophage colony-stimulating factor (GM-CSF). ES-DC were transfected with a CRISPR/Cas9-mediated β-catenin activation (pCRISPR-β-catenin) or knockout (pCRISPR-β-catenin KO) vector. For the in vivo study, wild type (WT) mice were subjected to 90min partial liver warm ischemia followed by 6h of reperfusion. The pCRISPR-β-catenin-modified ES-DC or control ES-DC were adoptively transferred into mice 24h prior to liver ischemia.

Results: The pCRISPR-β-catenin-modified ES-DC diminished the expression of proinflammatory cytokines (IL-12p40, TNF-α, and IL-1β) and chemokine receptors (CXCR4, CCR2, and CCR7) in response to LPS stimulation. Induction of β-catenin in ES-DC upregulated Notch1, NICD, and Hes1 with reduced IL-2 and IFN-γ, yet increased IL-10 and TGF-β production in antigen-responsive T cells after co-culture of ES-DC and OVA-stimulated CD4+ T cells. However, the pCRISPR-β-catenin KO resulted in augmented PTEN/TLR4 and reduced Akt phosphorylation in ES-DC. Unlike in control ES-DC, adoptive transfer of β-catenin-modified ES-DC improved IR-induced liver injury, as evidenced by reduced sALT levels and ameliorated liver histopathology, which was accompanied by diminished PTEN/TLR4 and increased NICD, Hes1, and Akt phosphorylation, with reduced proinflammatory mediators.

Conclusion: This study demonstrates that liver inflammatory response induced by IR can be modulated by induction of β-catenin activity in ES-DC. Our novel findings underscore the crucial role of β-catenin in stem cell-mediated immune regulation in IR-triggered liver inflammation. Using genetically modified ES-DC system, our study provides a novel approach and establishes a potential clinical feasibility for the amelioration of ischemic tissue injury in organ transplantation.

SAT-117

Sealant pathology

H. Fonouni, O.G. Nejad, E. Khajeh, E. Aydogdu, A. Mehrabi. *University of Heidelberg, Department of General, Visceral, and Transplantation Surgery, Heidelberg, Germany*
Email: hamidreza.fonouni@med.uni-heidelberg.de

Background and Aims: Despite remarkable developments in perioperative patient's care, surgical techniques, and surgical instruments, the risk of complications following liver resection such as bile leakage and hemorrhage is still high. Sealants are used frequently with the intention of reducing these complications. To our knowledge, detailed postoperative histopathological changes of sealants on liver surface after hepatectomy have not been studied so far. Accordingly, we aimed to assess and provide dependable evidence-based data to determine the impact of different sealant materials on histopathological changes after liver resection in an experimental study.

Method: Twenty-seven landrace pigs (weight: 32.6 ± 4.2 kg) underwent left hemihepatectomy and were randomized in control group (n = 9) with no sealant and treatment groups (each n = 9), in which resection surfaces were covered with collagen-based sealant and fibrinogen-based sealant. After postoperative day 5, the tissue samples were examined and graded by and indipendent pathologist using a semi-quantitive scale for degree of hepatocellular regeneration, necrosis, fibrin production, associated inflammation, demarcation, intraparenchymal bleeding, granulation tissue formation, microabscess, bacterial colonization, and parenchymal inflammation.

Results: There were no significant differences regarding preoperative cardiocirculatory parameters between three groups. Relative and absolute bleeding times were significantly lower in collagen-based sealant group (both $p < 0.01$). Hepatocellular necrosis occurred more in fibrinogen-based sealant group and less in collagen-based sealant group ($p = 0.01$). As expected, the rate of bacterial colonization and inflammation was significantly lower in control group (both $p < 0.01$). However, increased hepatocellular regeneration potential was seen in sealant groups, which was significantly higher in collagen-based sealant group.

Conclusion: The usage of sealants after hepatectomy is safe and is not associated with major morbidities. Sealants significantly decreased bleeding after hepatectomy. Furthermore, collagen-based sealant increases the rate of posthepatectomy regeneration. Future randomized clinical studies should be performed to establish indications of using sealants in clinical setting.

SAT-118

Preoperative biliary drainage reverses cholestasis-associated inflammatory and fibrotic gene signatures in patients with perihilar cholangiocarcinoma

R. van Golen[1], M. Reiniers[1], L. de Haan[1], R. Weijer[1], J. Wiggers[1], A. Jongejan[2], P. Moerland[2], L. Alles[1], A. van Kampen[2], T. van Gulik[3], M. Heger[1]. *[1]Academic Medical Center, Experimental Surgery, Netherlands; [2]AMC, Bioinformatics Laboratory, Amsterdam, Netherlands; [3]Academic Medical Center, Amsterdam, Netherlands*
Email: r.f.vangolen@amc.nl

Background and Aims: Perihilar cholangiocarcinoma (PHCC) can only be cured by major liver surgery. Preoperative biliary drainage (PBD) alleviates cholestasis in PHCC patients, but postoperative mortality rates remain high. PBD-related complications contribute substantially to perioperative morbidity. There is currently no agreement on the timing, technique, or extent of PBD for PHCC. The aims of this study were to investigate the mechanisms through which cholestasis impairs the hepatic resilience to partial liver resection and to assess the extent to which PBD reverses these changes.

Method: Eight patients with resectable PHCC underwent unilateral PBD, meaning that only the future remnant liver received biliary decompression. During surgery, paired cholestatic and post-cholestatic (after PBD) liver biopsies were collected. Control ('healty') liver biopsies were collected from 8 patients with a non-PHCC hepatic malignancy or a benign liver lesion. Patients with pre-existent parenchymal pathology, patients who received preoperative chemotherapy, or patients who underwent preoperative portal vein embolization were excluded. Gene expression profiles of the 24 collected liver biopsies were generated by microarray according to standard bioinformatics methods/protocols.

Results: The median(± IQR) duration of cholestasis in the PBD group was 87 (67–91) days. Total bilirubin levels peaked at 270 (193–304) μmol/l and dropped to 20 (12–33) μmol/l prior to surgery. The incidence of cholangitis and pancreatitis prior to surgery was 3 out of 8 and 1 out of 8, respectively. The control group comprised patients with (cyst)adenoma, giant haemangioma, hepatocellular carcinoma, intrahepatic cholangiocarcinoma, or angiosarcoma.

Cholestasis triggered the expression of extracellular matrix-related genes (e.g., collagens), pro-fibrotic (transforming growth factor beta pathway) gene sets, and pro-inflammatory (tumor necrosis factor alpha and inflammasome pathway) gene sets. In addition, gene sets reflecting hepatocyte-specific function were suppressed by cholestasis. Following unilateral PBD, the expression of hepatocyte-specific genes normalized. In addition, the aforementioned pro-fibrotic and inflammatory changes in gene expression were largely alleviated.

Conclusion: Unilateral preoperative biliary drainage reverses cholestasis-associated pro-fibrotic and inflammatory hepatic gene signatures in the future remnant liver of patients with perihilar cholangiocarcinoma.

Distinct functions of phosphorylated and un-phosphorylated STAT1 in hepatocellular carcinoma

B. Ma, W. Cao, M. Li, J. Liu, W. Wang, M. Peppelenbosch, Q. Pan.
Erasmus MC-University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands
Email: 136365449@qq.com

Background and Aims: Interferons (IFNs) with antiviral and immune-stimulatory functions have been widely used in prevention and treatment of hepatocellular carcinoma (HCC), in particular for patients with viral hepatitis. Phosphorylation of STAT1 is a hallmark for the activation of the IFN signaling. This study aims to investigate the functions of phosphorylated and un-phosphorylated STAT1 (p- and u-STAT1) in HCC and their involvement in the anti-HCC effect of IFN-alpha.

Methods: Liver tissues from 141 HCC patients has been used for detection of u-STAT1 and p-STAT1 expression by tissue microarray technique. CRISPR/Cas9 system was applied to construct STAT1 knockout.
HCC cell lines including Huh6 and Huh7. Cell cycle and apoptosis were analyzed by flow cytometry (FACS). Gene expression were measured by quantitative real-time polymerase chain in reaction (qRT-PCR).
Results: STAT1 protein level in the cytoplasma, but not in the nuclear, was significantly increased in patient HCC tumors as compared to adjacent liver tissues ($n = 141$, $p \leq 0.01$). However, p-STAT1 expression was undetectable in both tumor and adjacent tissues ($n = 37$). This is consistent with the finding in HCC cell lines, which express high level of u-STAT1, but almost no p-STAT1 expression. Knockout of u-STAT1 significantly reduced the colony formation and led to cell cycle arrest in G1 phase in HCC cell lines. We further investigated the function of p-STAT1 with IFN-alpha stimulation. As expected, knockout of u-STAT1 remarkably abolished the induction of interferon-stimulated genes (ISGs) upon IFN-α treatment in both HCC cell lines. However, IFN-α treatment with activation of p-STAT1 only exerted moderate inhibition of cell growth and induction of cell apoptosis, and this effect was not influenced by u-STAT1 knockout.

Conclusion: STAT1 is predominantly present as un-phosphorylated form and sustains the growth of HCC. Although p-STAT1 is robustly induced by IFN treatment, it is not involved in the anti-HCC effect of IFN-alpha. These findings separate the function of u-STAT1 and p-STAT1 and provide insight of the biology and therapy of IFN in HCC.

Email: sarah-maria.fendt@kuleuven.vib.be

Background and Aims: Epidemiological studies have shown that there is a clear connection between high fat diet (HFD) and the development and progression of hepatocellular carcinoma (HCC). We hypothesize that HFD induces metabolic alterations in hepatocytes (HEPs), stimulating a pro-tumoral metabolism which, in turn, increases the susceptibility of HEPs to the development of HCC.
Method: We modeled hepatic metabolism using a genome scale model to predict the response of hepatocytes to lipids and investigate whether lipid induced changes overlap with HCC induced changes. Next, we verified our predictions in vivo by determining liver and HCC metabolism using ^{13}C glucose infusions in mice on HFD versus control diet. Finally, we studied the mechanistic relationship between liver metabolism and lipids using an in vitro model.
Results: Using *in silico* modelling we predicted that several metabolic pathways induced by lipids are also present in HCC. These include glycolysis, mitochondrial anaplerosis and serine biosynthesis. Indeed, we observe that all of the predicted pathways are elevated in HFD challenged livers compared to control diet livers even before the development of tumors. Moreover, we verified that these pathways are also present and exacerbated in HCC. Thus, this suggests that lipids induce a tumor–like metabolism in the liver. Next, we asked how lipids alter liver metabolism. Using an *in vitro* model, we found that lipids increase fatty acid oxidation and reactive oxygen species (ROS) production. Inhibiting these pathways resulted in decreased mitochondrial anaplerosis and glycolysis, respectively. Thus, this suggest that lipids change liver metabolism by directly impacting hepatocytes.
Conclusion: Our results show that prior to the development of HCC, HFD challenged hepatocytes exhibit a HCC-like metabolism. Therefore, HFD can be considered a "metabolic primer" for the development of HCC. In conclusion, we discovered that HFD induces a tumour-like metabolism in the liver and induces metabolic prerequisites of HCC development.

SAT-124

Nrf2 pathway plays an important role in the development of hepatocellular carcinoma: the gene expression signature of Nrf2 observed in a rat hepatocarcinogenesis model

C.D. López, J.E. Torres-Mena, P. Castro-Gil, J.I. Pérez-Carreón. *Instituto Nacional de Medicina Genómica, Liver Diseases Laboratory*
Email: davik.loto@gmail.com

Background and Aims: Schiffer's model is one of few hepatocarcinogesis models that additionally induces cirrhosis in rats. Tumors are induced by administration of weekly intraperitoneal doses of diethylnitrosamine (DEN). The liver of animals submitted to this protocol develops cirrhosis at twelve weeks and multinodular hepatocellular carcinoma (HCC) at eighteen weeks. The aim of this work was to evaluate the gene expression changes within the time-course development of HCC in Schiffer's hepatocarcinogenesis model.
Method: Four groups of rats Fisher-344 were administered with a weekly dose of DEN and sacrificed at 6, 12, 18 and 22 weeks once the treatment began. The gene expression profile of each group was compared to livers of non-treated rats using the Affymetrix Genechip Rat Gene 1.0. A set of eight genes was used to validate the differential gene expression through Western blot and real time RT-PCR.
Results: More than a thousand of differentially expressed genes were identified throughout hepatocarcinogenesis. The Nrf2-mediated gene transcription was the main dysregulated pathway with 28 differentially expressed genes. Dysregulation of this pathway was observed from week 6 with 11 overexpressed genes and this number reaches a peak of 27 at week 18. A group of seven genes, including Nqo1, Akr1B10 and Gstp1 were upregulated since week 6 until week 22, suggesting that these genes are important in HCC development. Several genes among those belonging to Nrf2 pathway were upregulated in this animal model and their human orthologs can also be found overexpressed on human liver tumors and other cancers types according with Oncomine's database.
Conclusion: Dysregulation of Nrf2 pathway occurs from early stages in Schiffer's model and seems to be a conductor of hepatocarcinogenesis. These results suggest that this animal model could be used in the investigation of different types of cancer in which Nrf2 has a significative role as well as a model in which targeted genes of this pathway may be studied.

ADAR-mediated A-to-I RNA editing in human hepatocellular carcinoma

G. Song[1,2], Y. Zhao[3,4,5], J. Zhu[1,2], X. Shen[1,2]. *[1]Fudan University, Zhongshan Hospital, Department of Gastroenterology, Shanghai, China; [2]Shanghai Institute of Liver Diseases, Shanghai, China; [3]University of Texas Health Science Center at Houston, Texas Therapeutics Institute, Brown Foundation Institute of Molecular Medicine, Houston, United States; [4]University of Texas Health Science Center at Houston, Graduate School of Biomedical Sciences, Houston, United States; [5]University of Texas Health Science Center at Houston, Division of Oncology, Department of Internal Medicine, and Memorial Herman Cancer Center, Houston, United States*
Email: song_guangqi@fudan.edu.cn

Background and Aims: Adenosine deaminase acting on the RNA (ADAR) proteins mediated adenosine-to-inosine (A-to-I) editing is one of the most frequent modifications during post- and co-transcription in human cells. Due to inosine (I) residues preferentially base pair with cytidine (C), edited sites in the coding and noncoding RNA sequences are recognized as guanosine (G), which may interfere in mRNA translation, alternative splicing and miRNA-3′UTR binding. Recently, several studies report that aberrant expression of ADAR proteins in different human cancers, including hepatocellular carcinoma. However, the affection and regulating mechanism of A-to-I editing in hepatocellular carcinoma are still unclear.
Method: We generated a large-scale prediction platform (***RNA Editing Plus***) for one-step identifying of the A-to-I RNA editing events and their downstream effects from RNA high-seq data. To reveal the affection of A-to-I RNA Editing in hepatocellular carcinoma, we performed the editing sites calling using ***RNA Editing Plus***. We compared the data from 20 human hepatocellular carcinoma tissues, 20 para-carcinoma tissues and 5 hepatocellular carcinoma cell line transduced with siRNA for ADAR prroteins.
Results: 714 A-to-I RNA Editing events were identified only occur in hepatocellular carcinoma tissues, including 99 events in exon region

and 5 events on intron region leading to amino acid sequences mutation, as well as 610 events on 3′UTR region. Several genes edited in exon and intron region were reported inhibiting the replication of hepatitis B virus and the proliferation of hepatocellular carcinoma, while most of 3′UTR edited RNAs involve with the DNA replication and cell proliferation.
Conclusion: These results indicat that modification of genes by A-to-I RNA editing possibly be associated with the evolution and progression of hepatocellular carcinoma. Hence, more research is needed to identify the critical editing events, which may reveal the mechanism of A-to-I RNA editing in hepatocellular carcinoma and provide novel clinical therapeutic targets. The ***RNA Editing Plus*** platform is available for free at **https://www.rnaeditplus.org/**.

Introduction: Enzymatic removal of 6-O-sulfate from heparan sulfate proteoglycans by sulfatase 2 (SULF2) modulates the activity of heparin-binding growth factors including WNT, FGF and TGFbeta known oncogenic pathways promoting hepatocellular carcinoma (HCC). Recent studies have shown that autophagy, an essential cellular process involved HCC cancer initiation and progression, can be modulated by the aforementioned growth factors. However, to our knowledge, the role of SULF2 in the regulation of autophagy has not been reported yet. Here we demonstrate a new of SULF2 in starvation-induced autophagy through the modulation of phosphoinositide 3-kinase/protein kinase B/mammalian target of rapamycin (PI3K/AKT/mTOR) growth signaling pathway.
Methods: Autophagy was induced using serum-free starvation medium. SULF2-negative cells, Hep3B, were transfected with SULF2 expression constructs and SULF2-positive cells; Huh7, were transfected with short hairpin RNA targeting SULF2. The levels of p62, microtubule-associated protein light chain 3B (LC3B) and AKT/mTOR pathway activation were assessed by immunoblotting and immunofluorescence. The cellular effect of SULF2-regulated autophagy under starvation was examined by soft agar colony formation assay.
Results: Autophagy was inhibited by SULF2 overexpression Hep3B cells and enhances in SULF2-knockdown Huh7 cells. SULF2 inhibited the accumulation of LC3B-II, rescues p62 levels and promoted colony formation in cells cultured under starvation conditions. Transfection of SULF2 in Hep3B cells increased the phospho-AKT, phospho-mTOR and downstream factors of mTOR phospho-ULK1 (kinase 1 of type UNC-51), phospho-p70S6 kinase and phospho-4E binding protein 1. Knockdown of SULF2 in Huh7 cells decreased levels of these factors. The PI3K inhibitor LY294002 and the mTOR rapamycin inhibitor block the inhibitory effect of SULF2 on autophagy.
Conclusions: Together, these findings support a role for SULF2 in the regulation HCC cell autophagy through activation of the PI3K/AKT/mTOR pathway and suggest SULF2 as new therapeutic target for this disease.

Email: f.duong@unistra.fr

Background and Aims: Hepatocellular carcinoma (HCC) is a major cause of cancer death worldwide. Treatment options for advanced HCC are still unsatisfactory. RNAi-based gene silencing is emerging as therapeutic clinical approach allowing personalized medicine. One challenge is the development of robust and safe vectors for delivery of active siRNA *in vivo*. We aimed to generate a trackable clinical GMP-grade nanoparticle that features a high siRNA loading capacity, is biodegradable, and efficient and safe for treatment of HCC.
Method: We used a modified Stöber process to generate controllable and uniform size breakable mesoporous silica particles. To enhance the biomaterial loading capacity of the particles, we enlarged the pore size to 10–15 nm by treating them with a swelling agent. The breaking of the particles is induced by glutathione, a natural reducing agent present in rather large amount in cancer cells. siRNA was loaded on the particles by electrostatic interactions and then wrapped with jetPEI® to protect siRNA from degradation. Transmission and scanning electron microscopy, DLS and zeta potential measurements were used to characterize the particles, and UV spectroscopy and TGA to quantify the amount of siRNA loaded. *In vitro* siRNA delivery efficacy and particles-induced cell cytotoxicity were analyzed in Huh7 cells by using luciferase reporter gene siRNA and by measuring cell viability respectively. For *in vivo* evaluation, intrahepatic injections of 1mg/kg of Plk1 siRNA-containing mesoporous silica particles or of Plk1 siRNA-carrying jetPEI® were done 3 times per week in an orthotopic model of Huh7-derived tumors. Tumor growth was monitored by echography.
Results: Mesoporous silica particles show a loading capacity of 66µg siRNA per mg of nanoparticles. Particles efficiently deliver siRNA into liver cancer cells with potent and significant gene silencing. The breaking of the particles can be followed by TEM directly after their internalization in the cells. The breaking occurs after 24 hours and it is complete after 96 hours. No nanoparticle-mediated cell cytotoxicity was observed. Intra-tumoral injection of Plk1 siRNA-loaded particles significantly delayed the onset of tumor growth in an orthotopic model of Huh7-derived tumors without detectable off-target toxicity.
Conclusion: High siRNA loading capacity breakable mesoporous and biodegradable silica particles efficiently and safely deliver Plk1 siRNA *in vivo* resulting in a reduction of tumor growth. The successful *in vivo* proof-of-concept suggests that this nanoparticle is suitable for RNA-targeted therapy of HCC. The amount of siRNA can be further increased and the breaking on demand feature, ensure a perfect timing and full release of the cargo. Furthermore, the possibility to entrap chemotherapeutics and labels allows multiple delivery and spatiotemporal visualization of the nanosystems.

Email: guillermo.fernandez@ciberehd.org

Background and Aims: Sorafenib is the only compound that has shown efficacy increasing survival of patients with advanced hepatocellular carcinoma (HCC) in the first line. However, the emergence of resistance and tumor progression highlight the need to develop new more effective therapies. We recently reported that the administration of antioxidant CeO_2 nanoparticles (CeO_2NPs) in rats with HCC reduce cell proliferation and improve survival. The current study was addressed to investigate the therapeutic efficacy of CeO_2NPs in an experimental model of HCC.
Method: The study included 48 Wistar rats induced to HCC by a weekly intraperitoneal administration of diethyl-nitrosamine (DEN, 50 mg/kg) for 16 weeks. In the first protocol, the tissue distribution of the CeO_2NPs was analyzed by mass spectrophotometry. The animals received two weekly doses of CeO_2NPs (0.1 mg/kg, n = 10) at the 16^{th} and 17^{th} weeks by tail vein and were distributed and sacrificed sequentially after 3 days, 2 weeks and 3 weeks. In the second protocol, liver cell apoptosis and changes in the expression of proteins involved in tumor progression was evaluated. The rats were randomized into two groups receiving two weekly intravenous doses of CeO_2NPs (0.1 mg/kg, n = 10) or vehicle (0.8 mM TMAOH, n = 10) at the 16^{th} and 17^{th} weeks. The animals were sacrificed at the 18^{th} week and liver biopsies were obtained. In the third protocol, 18 rats with HCC randomly received CeO_2NPs or vehicle intravenously or an intragastric administration of sorafenib (10 mg/kg) administered daily for 14 days and the effect on survival was compared.
Results: The tissue analysis showed that the liver and the spleen are the main targets of the CeO_2NPs in DEN-treated rats. CeO_2NPs induced an increase in cellular apoptosis, as demonstrated by the TUNEL assay and the increased expression of activated caspase-3. Decreases in the phosphorylation levels of GSK-3α and ERK1/2 were observed in CeO_2NPs-treated rats compared to the animals that received vehicle. This was associated with a similar increase in overall survival of the animals treated with CeO_2NPs and those receiving sorafenib.
Conclusion: The activity of CeO_2NPs promotes changes in cellular mechanisms involved in tumor progression. CeO_2NPs and sorafenib have similar effectiveness in increasing survival in rats with HCC, thereby suggesting that CeO_2NPs may have therapeutic usefulness in patients with HCC.
Acknowledgments: Supported by grant from MINECO (SAF15-64126-R).

Hepatocyte c-Jun N-terminal kinases determine cell fate and carcinogenesis in NEMO-deficient mice

M.R. Mohamed[1,2], F.J. Cubero[1,3], M. Woitok[1], C. Liedtke[1], C. Trautwein[1]. *[1]University Hospital, RWTH Aachen, Department of Internal Medicine III, Germany; [2]National Research Centre (NRC), Therapeutic Chemistry Department, Cairo, Egypt; [3]Complutense University School of Medicine, Department of Immunology, Madrid, Spain*
Email: ctrautwein@ukaachen.de

Background and Aims: JNK1 and JNK2 are the two major JNK genes ubiquitously expressed in all the mammalian cells, including hepatocytes. While JNK activation mediates hepatocyte death, nuclear factor (NF)-κB promotes cell survival and protects from JNK-induced hepatocyte death. Thus, the cellular interaction between JNK and NF-κB is a major determinant in the fate of hepatocytes. Here, we sought to determine the contribution of JNK1 and JNK2 signaling to spontaneous carcinogenesis in the NEMO model of chronic liver disease.
Method: To generate mice with complete deletion of the JNK genes in NEMO mice, hepatocyte-specific NEMO and JNK1 deleted mice ($NEMO^{\Delta hepa}/JNK1^{\Delta hepa}$) were crossed with constitutive $JNK2^{-/-}$ mice ($Nemo^{\Delta hepa}/JNK^{\Delta hepa}$). We investigated activation of essential pathways in liver sections in response to deletion of JNK1 and JNK2 in hepatocytes of NEMO mice. The phenotype was characterized during disease progression. The regulation of essential genes was performed by RT-PCR and at the protein level by western blot analysis. The investigations included immunostainings for cell death and compensatory proliferation.
Results: Combined JNK1 and JNK2 inactivation in hepatocytes exacerbated liver damage caused by NEMO deletion. Interestingly, liver parenchyma of these mice was characterized by liver cysts accompanied by a significant increase of markers of liver damage (e.g.; ALT, AST, AP and GLDH). Furthermore, macroscopic examination of 1 year $Nemo^{\Delta hepa}/JNK^{\Delta hepa}$ livers showed significant decrease in number and size of HCC nodules formation compared to $NEMO^{\Delta hepa}$ and $NEMO^{\Delta hepa}/JNK1^{\Delta hepa}$ mice. Microscopic analyses of $NEMO^{\Delta hepa}/JNK^{\Delta hepa}$ livers revealed strong ductular proliferation which was further confirmed by overexpression of CK19. These mice also showed increased markers of fibrogenesis indicated by up-regulation of collagen IA1, alpha-SMA, MMP7, MMP9 and TIMP1. Overexpression of cell death markers was a main feature of $NEMO^{\Delta hepa}/JNK^{\Delta hepa}$ as assessed by TUNEL assay and cleaved caspase-3 immunoblot and staining. Additionally, overexpression of Ki67 /and PCNA, as markers for compensatory proliferation was observed in $NEMO^{\Delta hepa}/JNK^{\Delta hepa}$ livers. Next, we sought to investigate the impact of molecular pathways in response to compound JNK deficiency in NEMO mice. We found $Nemo^{\Delta hepa}/JNK^{\Delta hepa}$ livers exhibited overexpression of the EGFR-Raf-MEK-ERK cascade.
Conclusion: JNK1 and JNK2 play an essential role during carcinogenesis of NEMO deleted hepatocytes. Additionally, they are a switch to determine differentiation between hepatocytes and cholangiocytes.

Chemokine receptor CXCR3 modulates polarization of tumor associated macrophages limiting tumor growth and angiogenesis in murine hepatocellular carcinoma

E.F. Brandt, P. Fischer, T. Wirtz, H. Sahin, M.-L. Berres. *University Clinic RWTH Aachen, Department of Gastroenterology, Metabolic disorders and Internal Medicine Intensive Care, Aachen*
Email: elisa.brandt@rwth-aachen.de

Background and Aims: HCC progression is linked to the dynamic process of neovascularization, chronic liver inflammation and the crosstalk between tumor cells, peritumoral parenchymal cells as well as non-parenchymal cells e.g. infiltrating immune cells. The chemokine receptor CXCR3 is implicated in these processes and plays a key role during acute and chronic liver injury in mice and human. Here we aimed to investigate the role of CXCR3 in HCC progression.
Method: In *Cxcr3*$^{-/-}$ and wild-type (WT) mice, we applied a fibrosis-triggered cancer mouse model encompassing a single i.p. injection of N-Diethylnitrosamin (DEN, 14 d after birth) and weekly i.p. injections of low dose carbon tetrachloride (CCl_4, week 4–26). Tumor burden was assessed after 26 weeks. Tumor and surrounding tissue was characterized by histological staining of proliferation, apoptosis and vascularization markers (Ki67, cleaved caspase 3 and CD31). Leukocyte subpopulations were measured by flow cytometry and immunofluorescence staining (e.g. CD68, F4/80) with specific focus on tumor associated macrophage (TAM)-related immune responses. *In vitro*, *Cxcr3*$^{-/-}$ and WT bone marrow culture-derived macrophages (BMM) and TAMs were analyzed utilizing qRT-PCR, flow cytometry and immunofluorescence staining.
Results: The deletion of *Cxcr3* in a murine liver cancer model led to an increased tumor burden ($p < 0.01$) compared to WT mice which was linked to a higher number of Ki67+ tumor cells ($p < 0.05$) and

enhanced CD31+ neovascularization ($p < 0.01$). Moreover, immunofluorescence staining showed an accumulation of CD68+ macrophages ($p < 0.01$) associated with reduced number of apoptotic macrophages (cleaved caspase 3, $p < 0.01$) in tumor and surrounding tissue of *Cxcr3*$^{-/-}$ mice. These cells could be further subcategorized to an anti-inflammatory Ly6Clow/MHCIIlow phenotype by flow cytometry analysis and qRT-PCR. *In vitro* analysis of WT and *Cxcr3*$^{-/-}$ BMM and TAMs showed that *Cxcr3* deficiency fosters survival, expression of anti-inflammatory and pro-angiogenic cytokines as well as hepatic growth factor (qPCR) in macrophages, which was also reflected by expression analysis in the mouse model.

Conclusion: Our results revealed a functional link between CXCR3 and angiogenesis as well as tumor cell proliferation mediated by TAM polarization and survival in a murine liver cancer model. These data implicate CXCR3 and its ligands as new targets for HCC treatment modulating macrophage polarization and neovascularization.

Hepatocyte-derived Osteopontin drives the development of hepatocellular carcinoma

X. Ge[1], R. Desert[1], I. Abraham-Enachescu[2], C. Blajszczak[1], Y. Chen[1], X. Sun[2], A.P. Koh[2], G. Guzman[1], Y. Hoshida[2], N. Nieto[1,2,3]. [1]*University of Illinois at Chicago, Pathology, Chicago, United States;* [2]*Icahn School of Medicine at Mount Sinai, Medicine, New York, United States;* [3]*University of Illinois at Chicago, Medicine, Chicago, United States*
Email: rdesert@uic.edu

Background and Aims: Osteopontin (OPN) expression correlates with tumor progression and metastasis in a wide variety of cancers including hepatocellular carcinoma (HCC); yet, the mechanisms by which hepatocyte-derived OPN contribute to HCC remain unclear.

Method: To investigate the role of OPN in HCC, we analyzed *OPN* mRNA and protein expression in liver tumor and non-tumor tissue from patients with HCC of different etiologies and used a mouse model of HCC with genetic manipulation of the *Opn* gene.

Results: In human normal liver, OPN expression was modest; however, it increased in cirrhosis and dysplasia and was much higher in HCC. There was no remarkable difference in OPN expression in HCC between hepatitis B (HBV) and hepatitis C (HCV) patients. Elevated *OPN* mRNA in HBV-induced HCCs was associated with overall and disease-free survival, increased tumor stage, vascular invasion, tumor size, alpha fetoprotein and metastasis signature and negatively associated with the periportal signature typical of well differentiated HCC. Otherwise, OPN expression in non-tumor liver was associated with late recurrence, generally interpreted as novo carcinogenesis, with increased metastasis signature, tumor stage, AFP and with decreased periportal signature. In HCV patients with early cirrhosis, *OPN* mRNA was significantly associated with the progression to advanced cirrhosis, hepatic decompensation and death. In addition, a subtype of patients expressing a network of genes including *OPN* had a significant increase in HCC incidence. This group of patients also expressed signatures of extracellular matrix (ECM) remodeling, integrin signaling, liver metastasis, tumor field effect and activation of MYC or AKT as well as a decrease in signatures of normal liver, sensitivity to chemotherapy and activation of P53. Next, we injected diethylnitrosamine (DEN) in WT, Opn global knockout (*Opn*$^{-/-}$) and transgenic mice overexpressing *Opn* in hepatocytes in either WT (*Opn*^{Hep} Tg) or global *Opn* null background (*Opn*$^{-/-Hep}$ Tg) and followed them for the development of liver tumors for one year. *Opn*^{Hep} Tg mice showed significant increase in the number of preneoplastic lesions (dysplastic foci or adenoma) along with the number and size of HCCs compared to *Opn*$^{-/-}$ or WT mice. In *Opn*^{Hep} Tg mice, RNASeq analysis of non-tumor tissue revealed association with signatures of integrin activation, cell proliferation and inflammation and with a decrease in liver metabolic processes and DNA repair while in HCC tissues, it was associated with signatures of epithelial-to-mesenchymal transition, ECM remodeling, inflammation and poor outcome.

Conclusion: Hepatocyte-derived OPN drives HCC onset and progression by activating ECM-cell signaling, cell cycle and inflammation. Hence, targeting hepatocyte OPN could be a useful strategy to prevent the onset and/or the progression of HCC.

Email: jessica.zucman-rossi@inserm.fr

Background and Aims: We reported the first study showing the involvement of the adeno-associated virus type 2 (AAV2) in the pathogenesis of human hepatocellular carcinoma (HCC) developed on normal liver (Nault et al, 2015). Recurrent somatic viral clonal insertions were described in 11 HCC (5%) targeting cancer driver genes, *TERT*, *TNFSF10*, *CCNA2*, *CCNE1* and *MLL4*, leading to their overexpression. The inserted sequences displayed a minimal common region that includes the 3′ inverse tandem repeat (ITR) of the virus, which is important for virus integration in host DNA and exhibit a promoter/enhancer activity. These results prompted us to investigate the natural history of AAV2 infection in the liver and the functional consequence in tumor development.

Method: Screening and quantification of AAV2 DNA were performed in a large series of benign and malignant liver tumors and their corresponding counterparts (n = 1346 patients) by quantitative PCR. The distribution of viral copy number per cell was used to test association with clinical and molecular features. The presence of both episomal and viral active forms were explored using a DNAse/TaqMan based assay and quantitative RT-PCR. *In silico* analyses using viral capture and next generation sequencing data explored new clonal insertions.

Results: We observed the presence of AAV2 DNA in 18% of the patients in the non-tumor liver tissues, with significant enrichment in non-cirrhotic ($p = 1e\text{-}6$) and female ($p = 7e\text{-}3$) patients. On the presence of AAV2 DNA, we observed a distinct pattern of viral infection in malignant and benign tumors. HCC tumors exhibited a significant higher viral copy number/cell compared to the non-tumor counterpart ($p = 2e\text{-}3$). New clonal integrations were identified in 5 cases, which displayed the highest AAV2 copy number. The new viral insertions targeted *CCNE1* (n = 2), *CCNA2* (n = 1), *TERT* (n = 1) and a new oncogene, *GLI1* in one case. In contrast, in benign tumors we observed a selection of the virus in the non-tumor tissues with frequent episomal forms (11%) versus 2% only in HCC patients. Interestingly, the presence of episomal form was found associated with the expression of viral RNA suggesting an ongoing active infection in patients with adenoma or focal nodular hyperplasia. Further analysis on viral sequences allowed us to define two distinct genotypes: one relative to the reference AAV2 genome sequence and a new genotype displaying 11% nucleotide mistmatches in the capsid.

Conclusion: We demonstrated a positive selection of clonal AAV2 viral insertion during HCC development in young patients without cirrhosis. The presence of active AAV2 infection in patients with

benign tumors suggests it may promote the development of adenoma and FNH at early stage.

SAT-133

Sorafenib increases the percentage and cytotoxicity of circulating NK cells in hepatocellular carcinoma patients

J. Hu[1], D. Xia[1], M. Zhang[1], E. Wang[1], L. Liu[1], Q. Wang[1], W. Bai[1], J. Tie[1], X. Li[1], J. Yuan[1], J. Niu[1], K. Li[1], C. He[1], W. Guo[1], H. Chen[1], X. Yuan[1], T. Yu[1], Z. Wang[1], B. Luo[1], N. Han[1], Y. Zhu[1], Z. Zhang[2], Z. Yin[1], D. Fan[3], K. Yang[4], G. Han[1]. *[1]National Clinical Research Center for Digestive Disease and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Liver Disease and Digestive Interventional Radiology, Xi'an, China; [2]Northwestern University, Department of Radiology, Chicago, United States; [3]National Clinical Research Center for Digestive Disease and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, State Key laboratory of Cancer Biology, Xi'an, China; [4]Fourth Military Medical University, Department of immunology, Xi'an, China*

Email: hangh@fmmu.edu.cn

Background and Aims: Sorafenib is the first-line treatment agent for patients with advanced hepatocelluler carcinoma (HCC) that inhibits tumor-cell proliferation and angiogenesis. Furthermore, recent studies revealed that sorafenib also played a key role in antitumor response of natural killer(NK) cells. Therefore, characterizing the effects of sorafenib on NK cell immunity in HCC will be important if the clinical response with single sorafenib or combined with other immunotherapies is to be improved. However, the interaction between sorafenib and NK cells remained controversial. The present study evaluated the effect of sorafenib on the activity of peripheral NK cells in HCC patients.

Method: From June 2015 to August 2017, 59 BCLC stage B or C HCC patients were enrolled, and whole blood samples were collected at baseline and at two months with sorafenib treatment (400 mg bid). Meanwhile, blood samples from 42 healthy donors were also collected as normal controls. We evaluated the accumulation of NK cells (defined as $CD56^{+}CD3^{-}$ cells) and their subsets distribution (defined as $CD56^{bright}CD16^{neg}$ and $CD56^{dim}CD16^{pos}$ NK cells) in perpheral blood from HCC patients (n = 40) and healthy donors (n = 25) by flow cytometry analysis. The expression levels of CD107a, granzyme B and perforin in NK cells from 20 HCC patients after stimulated with ionomycin/phorbol myristate acetate were also detected (normal controls, n = 20).

Results: Compare to baseline status, the percentage of peripheral NK cells remarkably increased after sorafenib administration (mean, 13.04% vs 15.29%, p = 0.033). An increase of $CD56^{dim}CD16^{pos}$ NK cells has been also observed (mean, 91.18% vs 93.81%, p = 0.009), while the percentage of $CD56^{bright}CD16^{neg}$ NK cells reduced (mean, 2.94% vs 1.94%, p = 0.004). Sorafenib also led to a dramatically reduced ratio of $CD56^{bright}$ and $CD56^{dim}$ NK cells (p = 0.004). NK cells and their subsets from patients showed impaired expression levels in CD107a, granzyme B and perforin compared with healthy subjects. However, the expression levels of granzyme B and perforin in NK cells were higher than baseline (mean, 93.89 ± 6.48% vs 82.95 ± 19.69%, p = 0.008; 86.73 ± 12.25% vs 72.78 ± 27.67%, p = 0.025, respectively).

Conclusion: Sorafenib stimulated an increase of circulating NK cells which is mainly composed of the increase in $CD56^{dim}CD16^{pos}$ NK cells, and could revert the weakened activity of NK cells in HCC by enhancing expression levels of granzyme B and perforin.

SAT-134

Rapamycin and Zoledronic Acid strongly inhibit growth of advanced murine hepatocellular carcinoma via activation of innate and adaptive immunity

M. Ashfaq-Khan[1], M. Aslam[1,2], A. Qureshi[3], S.Y. Weng[4], D. Schuppan[4,5]. *[1]Institute of Translational Immunology, University Medical Center, Mainz, Germany; [2]Shaheed Benazir Bhutto Women University, PESHAWAR, Germany; [3]Dow university of medical sciences; [4]Institute of Translational Immunology, University Medical Centre, Mainz, Germany; [5]Division of Gastroenterology, Beth Israel Deaconess Medical Centre, Harvard Medical School, Boston, United States*

Email: m.ashfaq_biotech@yahoo.com

Background and Aims: Treatment options for hepatocellular carcinoma (HCC) remain limited. Activation of the cancer immune microenvironment opens novel therapeutic opportunities to control tumor progression and block metastatic spread. We assessed single and combined treatment of experimental HCC with Zoledronic Acid (ZA) and Rapamycin (RA), two drugs that display myeloid cell regulating potential.

Method: Mdr2(Abcb4)−/− mice were injected intraperitoneally with diethyl-nitrosamine DEN (10 μg/g of bw) at the age of 5 days, followed

by 0.05% phenobarbital in drinking water starting at the age of 3 weeks. This syngenic mouse model replicates key features of human HCC, with a genetic defect found in man and an external carcinogen. Mice were treated with vehicle, (ZA thrice a week as IP injection 100 µg/kg), RA (trice a week as oral gavage 5 mg/body weight), or a combination of ZA and RA from age 5–6 months. After 6 months tumor volume and number of nodules were counted. 50% of livers were digested and CD45+ immune cells subjected to multicolour fluorescence assisted cell sorting using antibodies to CD11b, CD11c, Ly6C, Ly6G, CD86, CD4, CD8, CD25, CD3, CD90.2, CD206, F4/80, MHC-II, NK1.1, Foxp3 and CD19. qPCR and IHC were performed for target molecules of interest.

Results: Treatment with RA > ZA significantly reduced tumor growth. The combination of ZA and RA synergistically reduced the volume and number of HCC foci by 90 and 85% respectively ($p < 0.0001$). The combination significantly reduced the population of M0-($CD45^+CD11b^+LY6G^-F4/80^+$) and M2 macrophages ($CD45^+CD11b^+LY6G^-F4/80^+CD206^+$), and of myeloid derived suppresser cells ($CD45^+CD11c^+LY6C^{high}$), representing central tumor promoting myeloid cell populations, while Myeloid derived dendric cells ($CD45^+CD11c^{high}$ $CD11b^+$ $CD86^+$) that promote anti-cancer immunity were significantly upregulated. In parallel, total CD4+ T cells and especially CD4 + CD25 regulatory T cells were significantly suppressed, while CD8 + T cells were significantly increased in the combination treatment vs the untreated group. Changes in immune cell populations were confirmed by transcript patterns and IHC. Ki-67-positive cancer cells were nearly undetectable, and IHC for CD68 and YM-1 confirmed a dramatic shift from tumour associated M2 to M1 macrophages. The combination of ZA and RAPA significantly downregulated TAMs and MDSC markers like CSF-1, VEGF, TGFβ1, Cox2, HIF1α, CCL2, CCL3, CCL5 and CCL17 that attract circulating monocytes into the tumour stroma.

Conclusion: (1) Combination therapy of RAPA and ZA polarize myeloid (and T cells) towards a robust anti-HCC response; (2) Their combination is synergistic in an optimized syngenic model of murine HCC; (3) Both drugs have proven safety for other indications, and clinical studies in patients with HCC are warranted.

Inflammation driven hepatocarcinogenesis is associated with a progenitor-like phenotype and Trp53 dependent differentiation

M. Svinarenko[1], K. Sarah-Fee[1], H. Maier[1], Y. Sunami[2], A. Tannapfel[3], T. Seufferlein[1], A. Lechel[1]. *[1]University Hospital Ulm, Internal Medicine I, Ulm, Germany; [2]University Hospital Halle (Saale), Visceral, vascular and endocrine surgery, Halle (Saale), Germany; [3]Ruhr-Universität Bochum, Institut für Pathologie, Bochum, Germany*
Email: andre.lechel@uni-ulm.de

Background and Aims: Chronic liver damage activates the wound healing program, which in long-term promote the formation of liver cancer. In that process, the inflammatory microenvironment is of central importance for malignancy. In addition, defects in the p53-signaling pathway occur frequently in liver cancer, thereby worsen prognosis of the disease. In this study, we analyzed the influence of Trp53 deletion within an inflammatory environment on hepatocarcinogenesis.

Method: To investigate the interaction of inflammation and Trp53 deletion, we crossed two transgenic mouse models. For the modulation of an inflammatory response, we used an inducible mouse model (Tet-Off system) with a permanent expression of a constitutively active IKK2 isoform ($IKK2^{ca}$). The expression of $IKK2^{ca}$ leads to a continuous activation of the NF-kB pathway promoting a chronic inflammatory response. To modulate disruption of p53 signaling, the inducible Cre-recombinase expressing transgenic mouse line AlfpCre-ERT2 was crossed with a conditional Trp53 knockout mouse. Liver-specific Trp53 deletion was induced by the treatment with tamoxifen at the age of 4 weeks.

Results: $IKK2^{ca}$ expression in mice results in persistent liver fibrosis, increased proliferation and increased levels of inflammatory cells independent of p53 status. Accumulation of ectopic lymphoid structures, which form a microniche for liver progenitor cells, were detected in $IKK2^{ca}$ mice and were increased in absence of Trp53. Both $IKK2^{ca}$ expressing cohorts show formation of hepatocellular carcinoma (HCC), intrahepatic cholangiocarcinoma (ICC) as well as mixed differentiated tumors. However, mice with deleted Trp53 have a higher tumor burden and show a shift in the tumor spectrum towards ICC formation compared to Trp53 wildtype mice. Liver tumors from both $IKK2^{ca}$ expressing cohorts indicate a progenitor-like phenotype with activated YAP signaling.

Conclusion: The study shows that liver-specific Trp53 deletion in combination with an inflammatory background results in elevated tumor burden and leads to a different liver tumor entity due to a shift in the tumor spectrum towards ICC. Moreover, the expression of constitutively active IKK2 promotes tumor formation with a progenitor-like phenotype.

SAT-136

Insulin receptor isoform A is a new player in the progression of hepatocellular carcinoma

E. Benabou[1], Z. Salame[1], D. Wendum[2], M. Lequoy[3], S. Tahraoui[1], F. Merabtene[4], C. Yves[1], O. Scatton[5], O. Rosmorduc[6], L. Fouassier[1], L. Fartoux[6], F. Praz[1], C. Desbois-Mouthon[1]. *[1]INSERM, Saint-Antoine Reearch Center, Paris, France; [2]AP-HP, Saint-Antoine Hospital, department of Pathology, Paris, France; [3]AP-HP, Saint-Antoine Hospital, department of hepatology; [4]UPMC, Histomorphology platform, UMS 30 Lumic, Paris, France; [5]AP-HP, Pitié-Salpétrière Hospital, department of hepatobiliary surgery and liver transplantation, Paris, France; [6]AP-HP, Pitié-Salpétrière Hospital, department of hepatology, Paris, France*
Email: christele.desbois-mouthon@inserm.fr

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most common and deadly neoplasms. Insulin receptor (IR) exists in two isoforms, IR-A and IR-B, resulting from the exclusion and inclusion of exon 11, respectively. IR-B is predominantly expressed in normal adult hepatocytes and binds insulin while IR-A is expressed in the developing liver and binds both insulin and insulin-like growth factor-II (IGF-II). Mounting evidence suggests a role for the ligand IGF-II and its receptor IR-A in cancer cells. Unfortunately, the role of IGF-II/IR-A is not known in HCC. The present study aims to evaluate the biological functions associated to IR-A overexpression in HCC in relation to IGF-II overexpression.

Method: We used a collection of 85 paired HCC /nontumour liver obtained from patients who undergone curative hepatectomy. Two human HCC cell lines expressing IGF-II (Huh7) or not (PLC/PRF5) were used. Subcutaneous xenografts of HCC cell lines were performed in 5 week-old female *nude* mice. The migration and invasion tests were conducted *in vitro* using Boyden's chambers. Hepatospheres were obtained after 14 days in culture under non-adherence conditions.

Results: The IR-A:IR-B ratio was upregulated in 70% of HCC compared to adjacent nontumour tissue and associated with clinicopathological markers of aggressive tumours (*i.e*, high serum alpha-fetoprotein (AFP), low differentiation, microvascular invasion, cytokeratin 19 expression (CK19)) and reduced patient survival after surgery. No association was observed when total IR mRNA content was considered. *IGF2* mRNA upregulation was observed in only 9.4% of HCC and was not associated with higher IR-A:IR-B ratio. The stable overexpression of IR-A in Huh7 and PLC/PRF5 cells increased their tumorigenicity *in vivo* in comparison with control cells while IR-B overexpression had no effect. IR-A-mediated tumorigenicity was associated with the induction of a pro-inflammatory gene program (evidenced by Gene Set Enrichment Analysis) involving the stimulation of *CXCL10* and *VCAM1* mRNA expression. While IR-A overexpression did not promote HCC cell proliferation *in vitro*, it stimulated migration and invasion and increased stemness/

progenitor features (such as CK19, CD133 and CD44 expression in Huh7 cells; AFP and CD133 in PLC/PRF5 cells). IR-B overexpression had no effect on migratory and invasive potential and decreased the expression of some stemness/progenitor markers.
Conclusion: These results demonstrate that the expression of total IR is not as important as the ratio of IR isoforms in HCC cells. IR-A, but not IR-B, is a new player in HCC progression by modulating cell plasticity, regardless of the presence of an autocrine IGF-II secretion loop.

Defective DNAM-1 mediated cytotoxicity in NK cells infiltrating hepatocellular carcinoma

B. Oliviero[1], S. Mantovani[1], D. Mele[1], M. Donadon[2], C. Soldani[3], G. Torzilli[4], R. Santambrogio[5], E. Opocher[5], S. Chiellino[6], C. Porta[6], M.U. Mondelli[7]. *[1]Fondazione IRCCS Policlinico San Matteo, Division of Infectious Diseases and Immunology Department of Medical Sciences and Infectious Diseases, Pavia, Italy; [2]Humanitas University, Department of Hepatobiliary and General Surgery, Milano, Italy; [3]Humanitas Clinical and Research Center, Department of Hepatobiliary and General Surgery, Milano, Italy; [4]Humanitas Clinical and Research Center, Department of Hepatobiliary and General Surgery, Rozzano (MI), Italy; [5]San Paolo Hospital Univiersity of Milan School of Medicine, Chirurgia 2, Epatobilio-pancreatica e Digestiva, Milano, Italy; [6]Fondazione IRCCS Policlinico San Matteo, Medical Oncology, Pavia, Italy; [7]Fondazione IRCCS Policlinico San Matteo, University of Pavia, Division of Infectious Diseases and Immunology, Department of Medical Sciences and Infectious Diseases, and Department of Internal Medicine and Therapeutics, Pavia, Italy*
Email: mario.mondelli@unipv.it

Background and Aims: Natural Killer (NK) cells play a key role in the immune response to tumors, their function being regulated by NK receptors and their ligands. It has been shown that binding of the DNAM-1 receptor, a DNAX accessory molecule, to its ligands (CD155 and CD112) expressed on target cells enhance NK cytotoxic activity and cytokine secretion. Low expression of CD155 has been associated with poor prognosis in patients with hepatocellular carcinoma (HCC). We studied DNAM-1 expression and cytotoxic-mediated activity in circulating and intrahepatic NK cells from HCC patients.
Method: DNAM-1 expression was evaluated by flow cytometry on circulating NK cells of 46 HCC patients (HCC) and 16 healthy controls (HC) as well as on liver infiltrating NK cells (n = 30). Liver-infiltrating lymphocytes were obtained from tumorous (TIL) and surrounding non-tumorous (LIL) tissue by mechanical and enzymatic treatment. DNAM-1-mediated cytotoxic NK function was studied by triggering DNAM-1 receptor in redirecting experiments using P815 as target cells and the percentage of CD107a+ NK cells was evaluated by flow cytometry in unstimulated or IL15-stimulated PBMC, LIL and TIL. Moreover, soluble CD155 (sCD155) levels were measured by ELISA in 23 HC and 57 HCC sera.
Results: There was a significantly decreased proportion of DNAM-1+ circulating NK cells in HCC patients compared with controls ($p < 0.0018$). Surprisingly, the cytotoxic activity of HCC NK was significantly higher than in HC in unstimulated conditions ($p < 0.0102$). No significant differences in DNAM-1 expression were found on NK cells isolated from LIL and TIL samples. However, TIL NK cytotoxic activity was significantly lower than that of LIL NK under both unstimulated and IL15-stimulated conditions ($p < 0.0059$ and $p < 0.0195$, respectively). Interestingly, HCC patients showed increased levels of sCD155 that directly correlated with AST, bilirubin and with the liver fibrosis indices FIB4 and APRI. Of note, soluble CD155 was also significantly higher in patients with high MELD and Child-Pugh scores and inversely correlated with serum albumin and platelet count.
Conclusion: Circulating NK cells from HCC patients showed conserved DNAM-1-mediated cytotoxic ability despite reduced receptor expression. DNAM-1-mediated cytotoxicity was instead defective in TIL compared to LIL NK cells, suggesting a possible mechanism of tumor resistance to innate immune surveillance.

Difference of gene mutational profile among viral- and non-viral HCC with or without prior HBV infection: Results of comprehensive deep sequencing analyses of cancer genes and HBV/AAV integration

F. Kawai-Kitahata[1], Y. Asahina[1], S. Kakinuma[1], M. Murakawa[1], S. Nitta[1], H. Nagata[1], S. Kaneko[1], E. Inoue[1], M. Miyoshi[1], T. Tsunoda[1], A. Sato[1], M. Nakagawa[1], Y. Itsui[1], S. Azuma[1], S. Tanaka[1], M. Tanabe[1], S. Maekawa[2], N. Enomoto[2], M. Watanabe[1]. *[1]Tokyo Medical and Dental University; [2]University of Yamanashi*
Email: fkawai.gast@tmd.ac.jp

Background and Aims: The incidence of hepatocellular carcinoma (HCC) without viral infection has been increasing. However, the underlying mechanism that links these non-B non-C HCC (NBNC-HCC) remains unclear. The aim is to elucidate difference of cancer gene profile among viral- and NBNC-HCC including those with or without prior HBV infection.
Method: 194 HCC patients consisting of 75 NBNC-, 78 HCV Ab positive- and 41 HBsAg positive- HCC were investigated. Of patients with NBNC-HCC, 21 had evidence for prior HBV infection (patients with HBsAg-negative and anti-HBc and/or anti-HBs positive). Genomic DNA obtained from HCC and corresponding background liver were deep-sequenced targeting 54 cancer-related genes. *TERT* promoter mutation at 2 hot spots, HBV- and AAV-human genomic junction breakpoints were also deep-sequenced on a MiSeq instrument.
Results: In 67 NBNC-HCC, recurrent mutations were frequently found in *TP53* (34.6%), *TERT* (73.7%) and *CTNNB1* (34.6%), and these gene mutational profile were similar to those in HCV Ab positive HCC (*TP53* 28%, *TERT* 84%, *CTNNB1* 61%). However, 21 NBNC-HCC with prior HBV infection had substantially different gene mutational profile compared to those in HCV Ab positive- and HBsAg positive HCC (prior HBV infection; *TP53* 71.4%, *TERT* 71.4%, *CTNNB1* 38.0%: HBsAg positive; *TP53* 67.9%, *TERT* 30.0%, *CTNNB1* 10.7%: $p < 0.05$). Although a total of 88 HBV integration breakpoints were detectable in 92.6% (26/28) of HBsAg positive HCC, 2 patients without HBV integration had no recurrence after locally curative therapy for initial HCC. In contrast to persistent HBV infection, HBV integration breakpoints were only detected in 4 (9.3%) NBNC patients with prior HBV infection, and these HCC were developed from normal liver and significantly associated with younger age (67 years old versus 75 years old, $p < 0.01$). AAV integration breakpoints were not detected in patients with prior HBV infection.
Conclusion: Mutational profile of cancer gene in most of NBNC-HCC was similar to those of HCV Ab positive HCC, but not HBsAg positive HCC. However, about 10% of NBNC HCC with prior HBV infection had HBV integration and these were developed from normal liver at a younger age. The underlying mechanism of hepatocarcinogenesis in NBNC-HCC with HBV integration among patients with prior HBV infection may be similar to those of HBsAg positive patients.

SAT-139

Therapeutics of cell-specific MAPK modulation in chronic liver disease using (siJNK2) nanodelivery

M. Woitok[1], D. Doleschel[2], M. Zoubek[1], W. Lederle[2], F. Kießling[2], C. Trautwein[1], F.J. Cubero[3]. *[1]Department of Internal Medicine III, Aachen, Germany; [2]Institute for Experimental and Molecular Imaging, Aachen, Germany; [3]Department of Immunology, Madrid, Spain*
Email: fcubero@ukaachen.de

Background and Aims: The prevalence of non-alcoholic fatty liver disease (NAFLD), including the more aggressive non-alcoholic steatohepatitis (NASH), and its complications cirrhosis and hepatocellular carcinoma (HCC), is continuously increasing in developed countries. The c-Jun N-terminal kinases (JNKs) play a crucial role in

liver physiology and disease pathogenesis. In the present study, we aimed to investigate the outcome of hepatocyte-specific *Jnk* inhibition, in an experimental model of chronic liver disease (CLD).
Method: Inhibition of *Jnk2* specifically in hepatocytes using siRNA (*siJnk2*) was first performed *in vitro* in Hepa 1–6 cells and validated *in vivo* in NEMO mice, a well-known animal model to study CLD. The effects of *siJnk2* administration were investigated at different stages of CLD. Biochemistry and molecular biology techniques, microcomputed tomography (FMT, μCT) and FACS were performed.
Results: *siJnk2* treatment in the acute phase of CLD in Nemo mice caused increased liver damage seen by elevated serum parameters, hepatocellular apoptosis and compensatory proliferation. In addition, elevated hepatic stellate cell activation/matrix deposition markers evoked deteriorated hepatic fibrogenesis progression. In contrast, chronic *siJnk2* administration in aged NEMO mice resulted in improved serum values and a significant reduction of immune cell infiltration in the liver parenchyma. Compensatory hepatocyte proliferation (PCNA) was significantly decreased in livers of NEMO + *siJnk2* alongside with the absence of MAPK signaling. Sirius red collagen staining revealed significantly improved hepatic fibrogenesis also displayed by a reduction of hepatic stellate cell activation/matrix deposition markers. In addition, FMT/μCT analysis revealed reduced hepatocellular apoptosis in these mice. Moreover, chronic si*Jnk2* treatment dramatically reduced end-stage HCC formation typically seen in NEMO mice within 52 weeks by a reduced presence of premalignant and malignant liver tumors corresponding to dysplastic nodules and differentiated adenomas, respectively.
Conclusion: *siJnk2* therapy successfully depleted *Jnk2* levels both *in vivo* and *in vitro*. Interestingly, siJnk2 treatment differentially changed stage dependent liver disease progression. In particular, siRNA formulated delivery to hepatocytes in the chronic phase leads to the amelioration of NASH and HCC progression and hence might be a novel suitable therapeutic option.

SAT-140
Deletion of MyD88 in non-parenchymal cells, but not in parenchymal cells attenuates the progression of hepatocellular carcinoma

A. Mohs[1], N. Hermanns[1], T. Otto[1], S.A.Y. Hassan[2], A. de Bruin[2,3], C. Trautwein[1]. [1]*Department of Internal Medicine III, University Hospital, Aachen, Germany;* [2]*Dutch Molecular Pathology Centre, Faculty of Veterinary Medicine, Utrecht University, Utrecht;* [3]*University Medical Centre Groningen, Department of Paediatrics, University of Groningen, NL- 9713 Groningen, Groningen*
Email: amohs@ukaachen.de

Background and Aims: Increased translocation of intestinal bacteria is a pathological hallmark in patients with chronic liver disease (CLD). Thereby, Toll-like Receptor (TLR) signaling, stimulated by bacterial components, derived from the intestinal microbiota, has been shown to trigger inflammation driven promotion of hepatocellular carcinoma (HCC). In the current study, the role of MyD88 in parenchymal and non-parenchymal cells in the development of fibrosis and tumour initiation and progression was studied in a murine model of inflammation triggered HCC development.
Method: To explore the impact of Myd88 for hepatitis, fibrogenesis and HCC formation, B6-MyD88$^{-/-}$ mice or alternatively hepatocyte-specific B6-MyD88$^{-/-}$(MyD88$^{\Delta hepa}$) were crossed with hepatocyte-specific NEMO knockout mice (NEMO$^{\Delta hepa}$) to generate NEMO$^{\Delta hepa}$/MyD88$^{-/-}$ or NEMO$^{\Delta hepa}$/MyD88$^{\Delta hepa}$ mice respectively.
Results: Surprisingly, the hepatocyte specific genetic deletion of MyD88 in NEMO$^{\Delta hepa}$ mice neither resulted in an altered onset of chronic liver disease nor in changes of tumour initiation and progression. Contrary to this, constitutional deletion of MyD88 aggravated the access of chronic liver disease (CLD) in NEMO$^{\Delta hepa}$ mice, characterized by elevated serum alanine (ALT), aspartate serum transaminases (AST) as well as glutamate dehydrogenase (GLDH) values. Histopathological examination of H&E stained liver tissue confirmed an aggravation of liver injury in NEMO$^{\Delta hepa}$/MyD88$^{-/-}$ compared with NEMO$^{\Delta hepa}$ mice which was associated with a mild increase of apoptosis. In this context, especially monocyte derived macrophages and CD4^{+} T cells were changed in NEMO$^{\Delta hepa}$/MyD88$^{-/-}$ livers. Furthermore a reduction of TNFα and MCP1 could be detected in NEMO$^{\Delta hepa}$/MyD88$^{-/-}$ livers compared to NEMO$^{\Delta hepa}$ livers.
As a consequence late stage NEMO$^{\Delta hepa}$/MyD88$^{-/-}$ mice displayed a lower cumulative tumour burden as well as reduced tumour size in comparison with NEMO$^{\Delta hepa}$ tumours. These findings were accompanied by a decrease in serum level transaminases likewise a reduction in liver body weight ratio. In line with this data, histological examination by two blinded pathologists revealed that the non-neoplastic and neoplastic phenotypes of the NEMO$^{\Delta hepa}$ livers were rescued by the concomitant constitutional deletion of MyD88 as indicated by a lower total lesions burden score and tumor incidence.
Conclusion: Deletion of MyD88 in non-parenchymal, but not in parenchymal cells in NEMO$^{\Delta hepa}$ mice leads to an accelerated onset of chronic liver disease and, but reduces HCC progression. These results indicate that MyD88 in non-parenchymal cells might be an attractive target for the treatment of chronic liver disease.

SAT-141
Interventional gene targeting of cell cycle regulators identifies Cyclin E1 as a suitable target for attenuating hepatocellular carcinoma progression

R. Sonntag, A. Mohs, M. Kohlhepp, U. Haas, D. Lambertz, C. Trautwein, C. Liedtke. *University Hospital RWTH Aachen, Department of Medicine III, Aachen*
Email: rsonntag@ukaachen.de

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most severe tumor diseases with limited treatment options. Early and advanced stages of carcinogenesis are associated with sustained proliferation of hepatocytes and non-parenchymal cells (*e.g.* hepatic stellate cells, immune cells) regulated by Cyclins and Cyclin-dependent kinases (Cdks). E-Type Cyclins (E1, E2) and Cdk2 are involved in cell cycle re-entry of quiescent cells. Our previous unpublished work demonstrated that constitutive ablation of Cyclin E1 or Cdk2 in mice prevented HCC initiation. Therefore, in the present study we tested the hypothesis that Cyclin E1 or Cdk2 could be suitable targets for interventional HCC therapy.
Method: We used conditional Cyclin E1 (CcnE1$^{f/f}$) or Cdk2 floxed (Cdk2$^{f/f}$) mice in a C57B6/J background with inducible Cre expression controlled by the Mx-gene promoter. This approach allows efficient gene deletion in liver cells and in the hematopoietic cell compartment. For HCC induction, 14 days old male mice were intraperitoneally (*i.p.*) injected with a single dose of diethylnitrosamine (DEN). Cre-negative littermates were used as controls. After 22 weeks (reflecting a stage of early HCC development), interventional inactivation of Cyclin E1 or Cdk2 was performed by three *i.p.* injections of poly-I: poly-C. At the age of 40 weeks, mice were analyzed for number and size of HCC nodules. Additionally, liver microenvironment was investigated by flow cytometry at the age of 26 and 40 weeks.
Results: Sequence analysis of 337 human HCC samples provided by the publicly available data of The Cancer Genome Atlas (TCGA) revealed that 30% of the patients had inherited genetic alterations or aberrant expression of E-type Cyclins or Cdk2, supporting the rational for this study. All DEN-treated mice developed liver tumors at the age of 40 weeks. However, interventional inactivation of Cyclin E1 resulted in a significant reduction of tumor numbers, tumor size and liver weight indices compared to DEN-treated control mice. This finding was associated with a reduced overall proliferation and down-regulation of positive cell cycle regulators. Interestingly, Cyclin E1 inactivation also changed the composition of the HCC microenvironment (*e.g.* T-cells), pointing to a potential new role of Cyclin E1 for immune cell regulation during early and late liver cancer development. In sharp contrast, interventional inactivation of Cdk2 did not reveal any significant effect on tumor growth.

Conclusion: Cdk2 is fully dispensable for advanced HCC progression. However, interventional inactivation of Cyclin E1 in an early stage of HCC development has beneficial effects and attenuates the progression of HCC. Thus, Cyclin E1 could be a promising therapeutic target for treatment of HCC patients.

Quantitative comparison of PD-L1 immuno-histochemical assays in hepatocellular carcinoma: The Blueprint-HCC study

D.J. Pinato[1], F. Mauri[1], P. Spina[1], O. Cain[2], A. Siddique[1], R.D. Goldin[1], S. Victor[1], C. Pizio[3], A. Akarca[4], R. Boldorini[3], L. Mazzucchelli[1], J.R.M. Black[1], S. Shetty[2], T. Marafioti[4], R. Sharma[1]. *[1]Imperial College London, Surgery & Cancer, London, United Kingdom; [2]University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom; [3]Universita' del Piemonte Orientale "A. Avogadro", Department of Translational Medicine, Novara, Italy; [4]University College London, Histopathology, London, United Kingdom*
Email: david.pinato09@imperial.ac.uk

Background and Aims: Programmed cell death ligand 1 (PD-L1) expression by immunohistochemistry (IHC) enriches for responses to PD-1/PD-L1 inhibitors across malignancies, however its role as a predictive biomarker in hepatocellular carcinoma (HCC) is elusive and no gold standard assay exists. We evaluated the performance of 4 different PD-L1 detection assays used in landmark clinical studies.
Method: PD-L1 IHC was performed on 4 serial sections from tissue microarray (TMA) blocks containing 100 archival cases of HCC that included tumour and surrounding non-tumorous tissue. Antibody clones E1LN3, 28-8, 22c3, SP263 were compared on the basis of percentage and intensity of staining in malignant cells (M) to generate an H-score (range 0–300). Immune cells infiltrating (ICI) and at the periphery, in non-tumorous tissue (ICP) were scored on a 4-tier system (0–3).
Results: Patients were 76% males, 20% HCV-positive, 64% cirrhotic with a median age of 67 years. Median tumour size was 4 cm, 70% of patients had T1-T2 tumours and 48% were of grade 2. The proportion of PD-L1 positive cases according to M-ICI-ICP pattern was 2-6-2% for E1LN3, 10-18-19% for 28-8, 9-22-18% for 22c3 and 5-14-13% for SP263. Pairwise comparison of M H-scores revealed heterogeneity across antibodies, with highest concordance between E1L3N/SP263 ($R2 = 0.95$), E1L3N/22c3 ($R2 = 0.65$), 22c3/SP263 ($R2 = 0.66$) and increasing discordance for 28-8/22c3 ($R2 = 0.44$), E1L3N/28-8 ($R2 = 0.29$), and 28-8/SP263 ($R2 = 0.26$). Detection of PD-L1-positive immune infiltrates using a semi-quantitative scoring system revealed significantly different scores in pairwise non-parametric comparisons of ICI ($p < 0.05$) but not ICP ($p > 0.05$ for chi-square test).
Conclusion: In Blueprint-HCC we demonstrated that quantification of PD-L1 protein levels in HCC in tumour cells, intra-tumoural and peri-tumoural infiltrate is characterised by significant inter-assay discordance. This has profound implications in the clinical development of predictive correlates of efficacy to immunotherapy in HCC and sources of such discordance should be explored.

SAT-143

Mixed HCC-ICC liver cancer derives from hepatic progenitor cells-A lineage tracing investigation in mouse liver inflammation models

N. Rosenberg[1], N. Barashi[1], H. Giladi[1], D. Goldenberg[1], M. Shoshkes-Carmel[2], K. Kaestner[3], M. Van Haele[4], T. Roskams[4], E. Galun[1]. *[1]Gene Therapy Institute, Hadassah University Hospital, Jerusalem, Israel; [2]Department of Genetics and Center for Molecular Studies in Digestive and Liver Diseases, University of Pennsylvania, Philadelphia, United States; [3]Department of Genetics and Center for Molecular Studies in Digestive and Liver Diseases, Philadelphia, United States; [4]Department of Translational Cell and Tissue Research, University of Leuven, Leuven, Belgium*
Email: nofar.ros@gmail.com

Background and Aims: Primary liver cancer is the second leading cause of cancer-related death worldwide. Primary liver cancer includes: Hepatocellular carcinoma (HCC), intrahepatic cholangiocarcinoma (ICC) and a mixed HCC-ICC tumor. Preceding the development of primary liver cancer, there is usually a prolonged period of chronic inflammation that leads to cirrhosis. It has been proposed that hepatic progenitor cells (HPCs) could contribute to hepatocarcinogenesis. However, this was not proven. These cells proliferate in response to injury and chronic inflammation in the liver. Although stem cells residing in highly proliferative tissues, such as skin, are essential for sustaining normal tissue homeostasis, their contribution in quiescent tissues, such as liver, is still a matter of debate. In this study, we aimed to determine whether HPCs contribute to liver cancer development in the MDR2 KO mouse model of inflammation-induced HCC.
Method: In order to enable tracing of progenitor cells, we generated a transgenic mouse based on the MDR2 KO that harbors a YFP reporter gene driven by the Foxl1 promoter, the promoter of a liver progenitor specific marker. These mice (MDR2 KO$^{Foxl1CRE;\ RosaYFP}$) develop chronic inflammation by the age of 1 months and HCC by the age of 16 months and mixed HCC-ICC by the age of 18 months.
Results: Using immunofluorescence we show that HPCs are present in the chronically inflamed livers and within dysplastic nodules at the age of a year and later. At the age of 3 months, upon severe inflammation, YFP positive progenitor cells proliferate and also differentiate, giving rise to both cholangiocytes and hepatocytes. Analysis of livers of 16-month MDR2 KO$^{Foxl1CRE;RosaYFP}$ revealed that only a minority of dysplastic nodules were positive for YFP expression. Furthermore, HCC tumors were YFP negative, containing only scattered YFP-positive HPCs, which did not exhibit hepatocyte-like morphology that expressed cancer stem-like cells (CSCs) markers. At late stages of the MDR2 KO model (18-month) these mice developed ICC and HCC-ICC mixed tumors. Surprisingly, the cholangiocytes in tumour cells were YFP positive, implying that they were derived from HPCs. The HCC-ICC YFP positive tumors accounted for 30% of the total tumors observed. Additionally, the YFP cells in the tumors expressed stem cell-like markers including: Epcam, Cd24a and Krt19. These findings recapitulate the characteristics of human ICC-HCC tumors which also have stem cell like features.
Conclusion: Taken together, our results suggest that HPCs may not be the origin for HCC but may be the origin for the mixed type HCC-ICC tumors in a chronic inflamed liver model.

SAT-144

Circulating exosomal non-coding RNAs as prognostic biomarkers in human hepatocellular carcinoma

Y.R. Lee[1], S.Y. Park[1], K. Hur[2], G. Kim[2], S.Y. Jang[3], W.Y. Tak[1], Y.O. Kweon[1], B. Jeong[1], G.-E. Kang[1], S. Seo[1], J.G. Park[4], H.W. Lee[5]. *[1]Kyungpook National University Hospital, Department of Internal Medicine, Daegu, Korea, Rep. of South; [2]School of Medicine, Kyungpook National University, Department of Biochemistry and Cell Biology, Daegu, Korea, Rep. of South; [3]Kyungpook National University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of South; [4]Yeungnam University Medical Center, Department of Internal Medicine; [5]Dongsan Medical Center, School of Medicine, Keimyung University, Department of Pathology*
Email: deblue00@naver.com

Background and Aims: Exosomal non-coding RNAs (ncRNAs) have unique expression profiles reflecting the characteristics of a tumor, and their role in tumor progression and metastasis is emerging. However, the significance of circulating exosomal ncRNAs in the prognosis of hepatocellular carcinoma (HCC) remains to be elucidated. We therefore determined the prognostic significance of circulating exosomal ncRNAs (miRNA-21 and lncRNA-ATB) for human HCC.
Method: This prospective study enrolled 79 HCC patients who attended Kyungpook National University Hospital, Republic of Korea between October 2014 and September 2015. Exosomes were extracted from serum samples using the ExoQuick Exosome

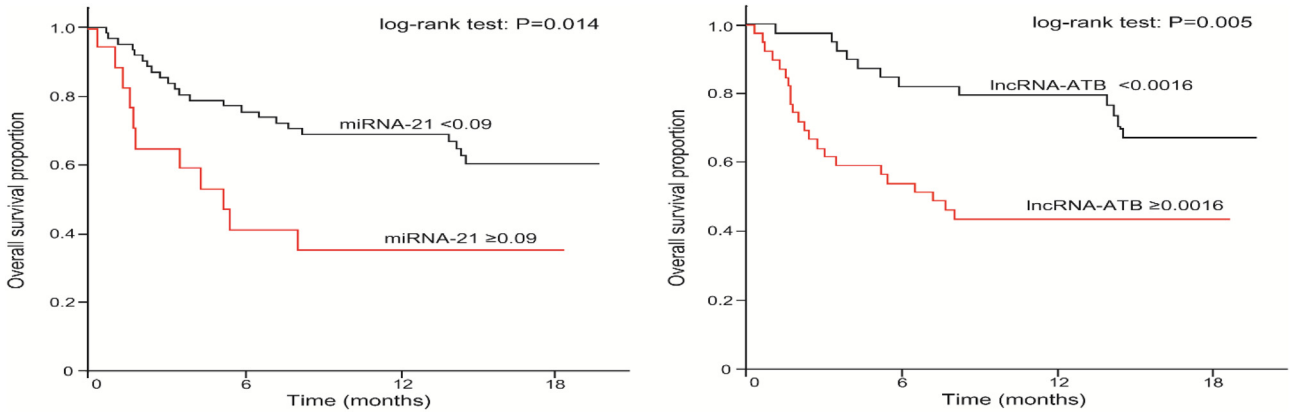

Figure: (abstract SAT-144) Kaplan-Meier plots of overall survival according to the miRNA-21 (*A*) and lncRNA-ATB (*B*) expression levels. (*A, B*) The survival rate was significantly lower in patients with higher circulating levels of exosomal miRNA-21 and lncRNA-ATB (log-rank test: both $p < 0.05$).

Precipitation Solution (System Biosciences). NcRNAs were isolated from exosomes using the miRNeasy serum/plasma micro kit (Qiagen).

Results: During the study period (median 14.0 months), disease progression and mortality were found in 44 and 34 patients, respectively. Exosomal miRNA-21 and lncRNA-ATB were successfully detected in the HCC serum samples. Both circulating exosomal miRNA-21 and lncRNA-ATB were related to TNM stage and other prognostic factors, including the T stage and portal vein thrombosis, but they were not associated with age, sex, presence of cirrhosis, or etiology. Multivariate analysis using the Cox regression test identified that both higher miRNA-21 and higher lncRNA-ATB were independent predictors of mortality and disease progression, along with larger tumor size and higher C-reactive protein (all $p < 0.05$). The overall survival was significantly lower in patients with higher circulating levels of exosomal miRNA-21 and lncRNA-ATB (log-rank test: both $p < 0.05$).

Conclusion: This study has provided strong evidence that circulating exosomal ncRNAs (miRNA-21 and lncRNA-ATB) are novel prognostic markers and therapeutic targets for HCC.

Fgl2 contributes to hepatocellular carcinoma via suppressing the inflammatory phenotypes and functions of dentritic cells and cytotoxic lymphocytes in tumor microenvironment

M. Yang, Z. Zhang, J. Chen, X. Luo, Q. Ning. *Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, China*
Email: qning@vip.sina.com

Background and Aims: Immunosuppressive molecules are crucial for the survival and progress of tumor cells in hepatocellular carcinoma (HCC). Our previous studies have shown that fibrinogen-like protein 2(FGL2) can promote the growth of tumor cells and angiogenesis in liver cancer. However immunological regulatory effect of FGL2 in HCC is largely unknown. The purpose was to elucidate if FGL2 contributes to HCC development via influencing tumor microenviroment.

Method: BNL cells were subcutaneously implanted into Balb/c (WT) and $fgl2^{-/-}$ mice, respectively. Different doses of fgl2 antibody (α-FGL2) were injected intratumorally twice a week when the tumor volume was over 100 mm^3. 11 days after α-FGL2 treatment, the mice were sacrificed and single cell suspension of tumor and draining lymph node (dLN) was prepared. The proportions, numbers and phenotypes of T cells and DCs were analysed by flow cytometry. Isolated by MACS, $CD8^+$T cells from α-fgl2 treated tumor were mixed with BNL cells, and the death rate of BNL cells were examined. DCs from mice injected with α-FGL2 were separated by MACS and mixed with tumor T cells, and theproliferation index of T cells was measured.

Results: The results showed that α-FGL2 inhibited HCC tumor growth in a dose-dependent manner. Similarly, the size of HCC tumor in $fgl2^{-/-}$ mice was significantly smaller than that of WT mice. Tumor and dLN of α-FGL2 treatment group contained more $CD8^+$ T cells ($p < 0.05$ in tumor and $p < 0.01$ in dLN) which expressed high level of perforin ($p < 0.05$ in tumor and $p < 0.05$ in dLN) and granzyme B ($p < 0.01$ in tumor) compared with control. The death rate of BNL cells was higher when mixed with $CD8^+$ T cells from α-FGL2 treatment mice ($p < 0.05$). Besides, DCs from α-FGL2 treatment mice presented mature state, expressing more CD80 ($p < 0.05$ in dLN), CD83 ($p < 0.05$ in dLN) and less CD31 ($p < 0.05$ in tumor and $p < 0.05$ in dLN), B7-H4 ($p < 0.01$ in tumor). These DCs promoted the proliferation of tumor $CD4^+$and $CD8^+$ T cells in *ex vivo* mixture test. Similarly, the proportion of $CD8^+$ T cells were higher in tumor and dLN of $fgl2^{-/-}$ mice compared with WT mice ($p < 0.05$ in tumor). And there was higher level of granzyme B ($p < 0.05$ in dLN) in $CD8^+$ T cells and decreased CD31 expression ($p < 0.05$ in tumor) on DCs in $fgl2^{-/-}$ mice.

Conclusion: Our data suggested that fgl2 inhibited the maturation of DCs which dampened the anti-tumor effect of T cells in HCC microenvironment and FGL2 might be a novel therapeutic target in HCC.

SAT-146

Molecular characterization of autophagic and apoptotic signaling induced by Sorafenib in liver cancer cells: In vitro and in vivo studies

Email: jmuntane-ibis@us.es

Background and Aims: Sorafenib is the unique accepted molecular targeted drug for the treatment of patients in advanced stage of hepatocellular carcinoma (HCC). The present study evaluated cell signaling regulation of endoplasmic reticulum (ER) stress, JNK, Akt, and AMPK leading to autophagy and apoptosis induced by Sorafenib.
Method: We carried out a kinetic study of autophagy and apoptosis induction by Sorafenib in HCC cells. Different parameters related to the induction of ER stress and cell signaling involved in cell survival and death were assessed. The involvement of autophagy and apoptosis in the antitumoral properties of Sorafenib were also evaluated in a xenograft mouse model.
Results: Sorafenib (10–100 μM) induced early (3–12 h) ER stress characterized by an increase of ^{Ser51}P-eIF2α/eIF2α, CHOP, IRE1α and sXBP1, but a decrease of ATF6 expression, overall temporally associated with the increase of ^{Thr183}P-JNK/JNK, ^{Thr172}P-AMPα, ^{Thr308}P-Akt/Akt and ^{Thr32}P-Foxo3a/Foxo3a ratios, and reduction of ^{Ser2481}P-mTOR/mTOR and protein translation. This pattern was related to an increase of autophagy markers (Beclin-1, LC3II/LC3I and p62), and reduction of Mcl-1 and Bcl-2 protein expression. The progressive increase of CHOP expression, and reduction of ^{Thr308}P-Akt/Akt and ^{Ser473}P-Akt/Akt ratios were associated with the reduction of autophagic flux and increase of Bim expression and caspase-3 activity (24 h). The different experimental interventions showed that ER-induced autophagy played a survival role in Sorafenib-treated HepG2 cells. Interestingly, siRNA assays and immunoprecipitation studies of Beclin-1 showed that its sequestration by Bim shifted autophagy to caspase-3-dependent apoptosis in Sorafenib-treated HepG2 cells. The *in vivo* study showed that Sorafenib increased autophagic and apoptotic markers, and reduced the size, proliferative, angiogenic and fibrotic markers in tumors derived from subcutaneous implantation of HCC cells in nude mice.
Conclusion: The induction of ER stress by Sorafenib was the driving mechanism involved in the sequential induction of autophagy and apoptosis in HepG2 cells. The early Sorafenib-induced ER stress and regulation of JNK and AMPK-dependent signaling were related to the induction of survival autophagic process (3–12 h). The sustained activity of the drug induced a progressive increase of ER stress and PERK-CHOP-dependent rise of Bim, which induced the shift from autophagy to apoptosis. However, the kinetic of Bim expression profile and apoptosis might also be related to the tight balance between Akt- and AMPK-related signaling that also modulated the Foxo3a-dependent Bim upregulation.

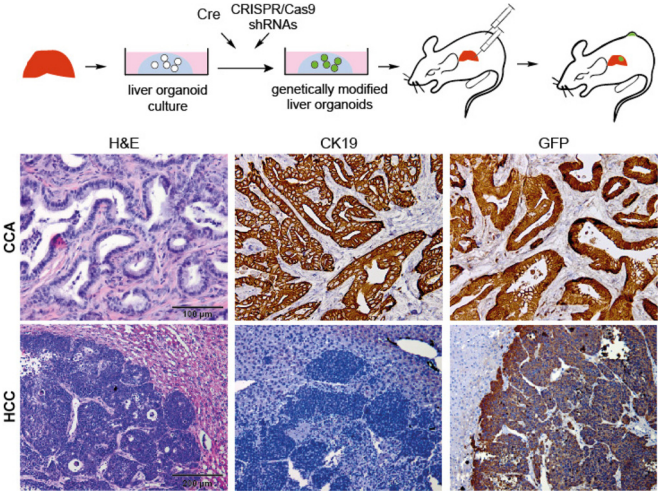
Email: saborowski.anna@mh-hannover.de

Background and Aims: A rising incidence of intrahepatic cholangiocarcinoma (CCA) cases and a 5-year-survival rate that remains below 10% illustrates the urgent need for therapeutic advances. Recently, sequencing studies have shed light on the genetic landscape of this aggressive malignancy. To improve our understanding of the pathophysiology of CCA, as well as to address the immediate clinical relevancy of the genomic data, versatile model systems that facilitate the rapid functional annotation of putative CCA driver- and maintenance genes are needed. Here, we aimed to develop an easily tractable murine CCA model that is based on the genetic manipulation and transplantation of liver organoid cultures.
Method: Murine liver organoid lines harboring latent cancer-defining alleles are derived following established protocols. Latent alleles are activated by introduction of a Cre-recombinase, and further genetic manipulation is achieved using RNAinterference- and CRISPR/Cas9-technology. The cells are then transplanted either subcutaneously or orthotopically into syngeneic, immunocompetent mice.



Results: Liver organoids harboring the endogenous KrasG12D allele in conjunction with loss of p53 give rise to moderately differentiated CCA in recipient mice with 100% penetrance. Histologically, tumors closely resemble the human disease, displaying CK19 positive ductal structures surrounded by a dense desmoplastic stroma. Tumor formation is readily accelerated by tumor suppressor gene loss or oncogene expression, and co-transduction of a fluorescent marker gene conveniently allows for the easy identification of the epithelial tumor cells in the primary tumor, as well as at metastatic sites. Tumors are serially transplantable both as 2- and 3-dimensional cell lines, thus allowing to rapidly generate genetically defined tumor cell lines for downstream studies, such as drug screening. In addition, we show that, depending on the genetic context, liver organoids can also give rise to hepatocellular carcinoma, illustrating the plasticity of the organoid system.
Conclusion: Genetically modified liver organoids give rise to CCA and HCC and can be used for the functional annotation of candidate liver cancer genes. The organoid system combines the advantage of utilizing non-transformed, pre-malignant cells to recapitulate tumorigenesis as a multi-step process, with the convenience of a cell culture system that abrogates the need for recurrent isolation of primary cells.

SAT-148

Activated platelets contribute to the progression of hepatocellular carcinoma by altering the immune cell environment

N. Pavlovic[1], F. Heindryckx[1], L. Edlund[1], P. Gerwins[1,2]. *[1]Uppsala University, Department of Medical Cell Biology, Uppsala, Sweden; [2]Akademiska sjukhuset, Department of Surgical Sciences, Radiology, Uppsala, Sweden*
Email: natasa.pavlovic@mcb.uu.se

Background and Aims: The inflammatory process plays a critical role in the complex molecular pathogenesis of hepatocellular carcinoma (HCC). Macrophages are a key part of the inflammatory environment, and their role in tumour progression is determined by their state of activation, which can be classified as anti-tumoural (M1) and pro-tumoural (M2). Platelets have been reported to interact with different cell types in the tumour microenvironment, including macrophages and Kupffer cells. This study aimed to identify the effect of platelets on the inflammatory cell population and HCC development, as well as to determine whether anti-platelet therapy can decrease the progression of HCC.
Method: Mice were injected weekly with diethylnitrosamine to induce HCC. From week 10, mice were treated with anti-platelet drug

Clopidogrel or control, samples were taken for RNA-analysis and histology after 25 weeks. Tumour burden and collagen deposition was quantified on H&E and Sirius red staining, respectively. Platelets and macrophages were quantified by immunohistochemical stainings with CD41 and F4/80 antibodies, respectively. For *in vitro* experiments, fluorescently labelled HCC-cells (HepG2) and differentiated macrophages (PMA-treated THP1-cells) were co-cultured with platelets isolated from healthy donors.

Results: Blocking platelet activation with Clopidogrel significantly decreased tumor burden *in vivo*, compared to untreated controls. mRNA analysis confirmed a decreased expression of PCNA in Clopidogrel-treated mice with HCC, suggesting a decrease in proliferation. CD41 immunohistochemistry revealed that treatment with Clopidogrel significantly decreased the number of infiltrated platelets in the liver of mice with HCC. Anti-platelet therapy also significantly decreased collagen deposition in mice. Clopidogrel treatment led to a significant decrease in the total number of F4/80-positive macrophages, while it increased mRNA expression of several anti-tumoral M1 macrophage activation markers (TNFa, IL-1, CD40, Fpr2) and decreased M2-marker Arginase-1 expression. *In vitro* experiments showed THP1-differentiated macrophages phagocytose HepG2-cells and that adding platelets to a co-culture of macrophages and tumor cells significantly decreased the macrophage's capacity to phagocytose tumor cells.

Conclusion: These findings suggest that platelets play an important role in creating a pro-tumoural inflammatory environment and thereby facilitate HCC progression. The use of anti-platelet drugs may therefore be therapeutically relevant for patients with HCC.

Email: laia.bassaganyas@gmail.com

Background and Aims: Chromosomal instability (CIN) is a hallmark of cancer and has been related to aggressiveness in several tumors, including hepatocellular carcinoma (HCC). CIN is characterized by the presence of somatic copy-number alterations (SCNAs) and is associated with polyploidy. However, the role of CIN, the incidence of polyploidy, and their molecular/ clinical implications on HCC remain ill-defined.

Method: 150 paired (tumor/adjacent) fresh-frozen surgically resected tissues from HCC patients were analyzed for SCNA detection (Illumina SNParray) and gene expression profiling (Affymetrix). ASCAT and saasCNV were used to define tumor ploidy and SCNA profiles, respectively. Three CIN scores were generated measuring the number of focal (low structural CIN, LS_{CIN}), arm (high structural CIN, HS_{CIN}), and chromosome (numerical CIN, N_{CIN}) SCNAs weighted by its copy number and length. Samples were clustered according to ploidy and CIN-scores. Each cluster was further characterized based on gene expression profiling and correlation with clinic-pathological data. Analysis of clonal cell fraction to define the occurrence of SCNAs is ongoing.

Results: Analysis of SCNA profiles showed that 40% of HCC of tumors displayed a pattern consistent with polyploidization (mean ploidy 3.89). Assessment of the CIN-scores revealed that N_{CIN} and HS_{CIN} were significantly higher in polyploid tumors ($p < 0.001$). In contrast, LS_{CIN} score remained homogeneous throughout the cohort. Compared to diploid tumors, polyploids showed a higher incidence of *TP53* deletions ($p < 0.01$) and were associated with gene sets related to loss of TP53/RB1 signaling, DNA replication, DNA damage response, and G2/M checkpoint evasion and lack of immune –related signatures ($p < 0.01$). Instead, diploid tumors were enriched in immune-related signatures and presented a higher degree of cell differentiation ($p < 0.05$), feature related to the less aggressive *non-proliferation* HCC class. Polyploid/high N_{CIN}/HS_{CIN} tumors showed proliferation-like traits such as enrichment of EpCAM and vascular invasion signatures ($p < 0.05$), which are associated with worse outcome.

Conclusion: Numerical and high-structural CIN both correlate with polyploidy. Polyploid tumors are associated with cell cycle deregulation signatures and proliferation-like traits. Diploid tumors are related to immune signatures and non-proliferation-like features. The study highlights the importance of CIN in exploring molecular and immune-oncology therapies in HCC.

SAT-150

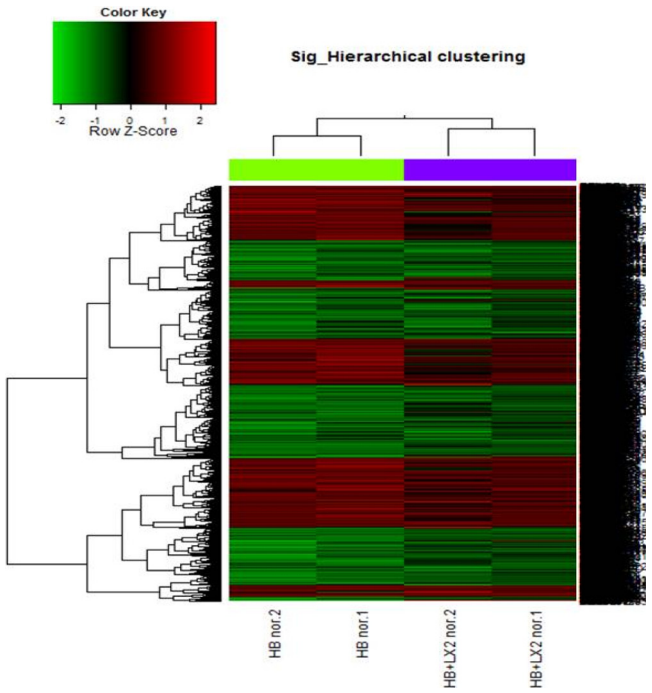
Tumor-stroma crosstalk enhances Reg3A expressions that drives the progression of hepatocellular carcinoma

Y. Cho[1], M.J. Park1[1], J.-Y. Park[2]. [1]*CHA University, Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Seoul National University College of Medicine, Orthopaedic Surgery*
Email: yuricho@chamc.co.kr

Background and Aims: Crosstalk between tumor cells and their microenvironment plays a crucial role in the progression of hepatocellular carcinoma (HCC). In this study, we investigated the key signal that modulates crosstalk between HCC cells and their microenvironment.

Method: Human HCC cell lines (Huh-7, HepG2, and SNU-761) were cocultured with an activated human hepatic stellate cell line (HSCs; LX-2) under normoxic (20% O_2 and 5% CO_2, at 37 °C) conditions. Complementary DNA (cDNA) microarray analysis was performed to find the molecule which is significantly enhanced by crosstalk between HCC cells and stroma. In vivo study using a subcutaneous xenograft model by injecting MH134 cells (C3H mice) was performed to confirm the effect of coculturing HCC cells and HSC cells and the inhibitory effect by small interfering RNA (siRNA) transfection. Immunoblot analyses were used to investigate the signaling pathway.

Results: Using cDNA microarray analysis, we found the molecule, REG3A, which was significantly enhanced by coculturing Huh-7 cells and HSC cells (+ 8.2 log) as compared to mono-culturing Huh-7 cells. Coculturing HCC cells (Huh-7, HepG2, and SNU-761) with HSC cells enhanced the mRNA and protein expressions of REG3A as compared to mono-culturing HCC cells. Downregulation of REG3A by siRNA significantly decreased the proliferation of tumor cells in vitro and in vivo, when HCC cells were cocultured with HSCs (both $p < 0.05$). In immunoblot assay, downregulation of REG3A by siRNA decreased the expressions of phosphorylated p42/44 and β-catenin, especially when HCC cells were cocultured with HSCs. Immunofluorescence study also revealed that deoxycholic acid-induced HCC cell apoptosis was inhibited when REG3A was down-regulated in HSCs-cocultured HCC cells. Interestingly, crosstalk-induced REG3A up-regulation was modulated by PDGF-β in p42/44-dependent manner.



Conclusion: In conclusion, crosstalk between HCC cells and HSCs cells was modulated by up-regulation of REG3A in p42/44-dependent manner. Moreover, the up-regulation of REG3A by crosstalk between HCCs and HSCs was mediated by PDGF-β. Targeting REG3A might be a novel therapeutic target in the management of human HCCs by inhibiting crosstalk between HCCs and HSCs.

SAT-151

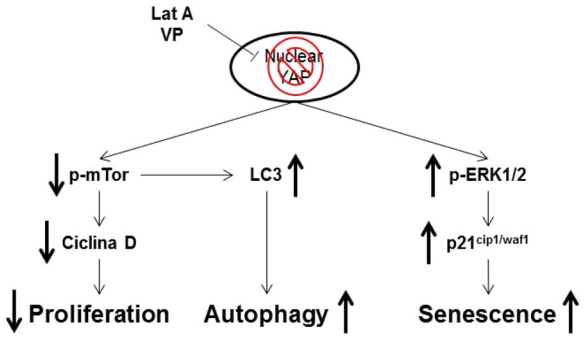
Inhibition of YAP activation induces cell senescence and autophagy while blocking cell proliferation in cholangiocarcinoma (CCA)

M. Cadamuro[1,2,3], G. Casati[1], T. Stecca[4], S. Brivio[1], C. Milani[1], V. Mariotti[3], E. Kaffe[5], C. Spirli[2,5], M. Amenduni[5], R. Fiorotto[2,5], U. Cillo[6], G. Maria[7], L. Fabris[2,3,5], M. Strazzabosco[1,2,5]. *[1]University of Milan-Bicocca, School of Medicine and Surgery, Monza, Italy; [2]University of Milan-Bicocca, International Center for Digestive Health, Monza, Italy; [3]University of Padua, Department of Molecular Medicine, Padova, Italy; [4]University of Padua, Department of Surgery, Oncology and Gastroenterology, Padova, Italy; [5]Yale University, Section of Digestive Diseases, New Haven, United States; [6]Liver Transplant and HBP Surgery Unit, Padua Universit, Padua, Italy; [7]University of Padua, Department of Medicine, Padova, Italy*
Email: massimiliano.cadamuro@unimib.it

Background and Aims: Cholangiocarcinoma (CCA) is an aggressive cancer of the biliary epithelium, with dismal prognosis due to the lack of effective treatments. Yes-associated protein (YAP) is a pleiotropic morphogen that, when expressed in the nucleus, regulates several pro-tumorigenic functions, such as proliferation, motility, survival, and chemotherapy resistance. However, its effects in CCA are not well known. YAP is regulated by several stimuli, including cell density, matrix stiffness, and cytoskeletal dynamics. We then aimed to evaluate the role of YAP in modulating proliferation, senescence and autophagy in CCA cells, and the underlying molecular mechanisms.

Methods: Nuclear expression of YAP (nYAP) was studied in 3 human CCA cell lines (EGI-1, TFK-1, and HuCCT-1) by immunofluorescence at different culture density, and upon exposure to the YAP inhibitors dobutamine (Dob), latrunculin A (Lat), Y27632 (Y), or verteporfin (VP). Expression of CTGF, ANKRD1 and Cyr61 (RT-PCR) were used as readouts of YAP activation. *In vitro,* effects of YAP inhibition on CCA cell proliferation, senescence and autophagy were analysed by BRDU assay (proliferation) and by Western blotting (WB) for ERK1/2 (MAPK pathway), p70S6K, Cyclin D1 (PI3K/AKT/mTOR pathway), p21(senescence), and LC3 (autophagy). Interactions between mTOR and ERK pathways to regulate p21 were analysed using specific inhibitors, rapamycin (rapa, for mTOR), LY294002 (LY, for PI3K). Expression of nYAP together with p-mTOR and p21 was also studied by immunohistochemistry in human archival CCA samples (n = 10).

Results: All CCA cell lines constitutively expressed nuclear YAP (nYAP) that was negatively regulated by high confluence culture conditions. Among the YAP inhibitors, Lat and VP were the most effective in reducing expression of the YAP-induced target genes (CTGF, ANKRD1, Cyr61); following YAP inhibition, mTOR and Cyclin D1 were down-regulated and CCA cells proliferation was significantly reduced. At the same time, after YAP inhibition, cell senescence (p21) and autophagy (LC3) markers increased. In fact YAP inhibition stimulated ERK1/2 phosphorylation, and hyperexpression of p21. ERK1/2 activation is selectively repressed by LY, indicating its dependence on the PI3K pathway. Consistent with the role of ERK1/2, overexpression of p21 induced by inhibition of YAP is reduced by the MEK inhibitor U0126. In human CCA specimens nYAP was expressed by CCA cells at the tumor-host interface, while p21 expression was preponderant in the bulk of tumor.



Conclusion: CCA is characterized by a strong nuclear expression of YAP both *in vitro* and *in vivo*. Targeting YAP activation blocks cell proliferation by decreasing mTOR phosphorylation and Cyclin D1 expression, and in turn, stimulates autophagy and the cell senescence program via ERK/p21. Targeting the YAP signaling could therefore be an innovative therapeutic strategy for CCA.

Dietary cholesterol and StARD1 overexpression aggravate chemically induced hepatocarcinogenesis in vivo

L.C. de la Rosa[1,2], V. Ribas[1,2], M.C. Garcia-Ruiz[1,2,3,4], J. Fernandez-Checa[1,2,3,4]. *[1]Instituto Investigaciones Biomédicas Barcelona (IIBB-CSIC), Cell Death and Proliferation, Barcelona, Spain; [2]Centro Investigaciones Biomédicas en Red (CIBEREHD), Enfermedades Digestivas y Hepáticas, Barcelona, Spain; [3]University of Southern California, Kerk School of Medicine, Los Angeles, United States; [4]IDIBAPS, Liver Unit Hospital Clinic Barcelona, Barcelona, Spain*
Email: lcondedelarosa@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death worldwide and the end-stage of chronic liver disease. Hypercholesterolemia is also a growing health concern emerging as a critical factor in the progression of fatty liver disease. StARD1, responsible for cholesterol trafficking to mitochondria, has a role in the transition from steatosis to steatohepatitis which can progress to HCC. Obesity and hepatic steatosis promotes tumorigenesis, but the role of cholesterol and StARD1 overexpression in HCC progression has not been elucidated yet. **Aim**: To study the role of cholesterol and StARD1 in chemically-induced HCC and the therapeutic effect of ezetimibe *in vivo*.

Method: 14 days-old wild type mice were injected i.p. with a single dose of the carcinogen diethylnitrosamine (DEN). Mice were fed a choline-deficient diet (CD) or a cholesterol-enriched diet (HC) for 5 months. In parallel, mice were fed high fat diet (60%) containing cholesterol (0.5%) (HFHC) supplemented or not with ezetimibe (Ez) for 32 weeks. In some cases, DEN-treated mice fed HFHC were injected with adenovirus to overexpress StARD1. Liver samples were analyzed for inflammation, fibrosis and tumor markers by WB, IHC and qRT-PCR. StARD1 expression was examined in samples from patients with HCC.
Results: (**1**) CD diet increases triglyceride levels in the liver in contrast to the HC diet that specifically increases cholesterol. Liver cholesterol was higher in the HFHC fed group compared to HFHC + Ez group. (**2**) Inflammation (IL-6, Ly6D, Ly6c), proliferation (PCNA, Ki-67) and fibrosis markers (collagen 1A1, αsma, TGFβ) were increased in CD + DEN group and exacerbated in HC + DEN group. Moreover, the expression of these markers was elevated in the HFHC group compared to HFHC + Ez group. (**3**) Tumour markers (AFP, CK-19, GP-73, Birc5) induced by DEN were increased in the presence of CD and further elevated with the HC diet. The expression of these markers was elevated in mice fed the HFHC, and ezetimibe reversed this increase. (**4**) StARD1 overexpression doubled the multiplicity of tumors in DEN-treated mice fed HFHC and increased the expression of tumor, fibrosis and inflammation markers. (**5**) Liver biopsies from patients with HCC exhibit increased StARD1 levels compared to samples from control subjects.
Conclusion: Cholesterol aggravates HCC and ezetimibe reverse this effect. StARD1 overexpression increases HCC, likely by stimulating the trafficking of mitochondrial cholesterol.

Email: diletta.overi@uniroma1.it

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic cholangiopathy characterized by inflammation and bile duct fibrosis. Massive proliferation of biliary tree stem/progenitor cell (BTSC), expansion of peribiliary glands (PBG) and dysplasia were observed in PSC. Cholangiocarcinoma (CCA) frequently complicates the course of PSC. The aims of the present study were to evaluate the involvement of PBGs and BTSCs in CCA emerging in PSC patients.
Method: Specimens from normal liver (n = 5), PSC (n = 20), and CCA arising in PSC patients (n = 20) were included. Samples were processed for histology, immunohistochemistry and immunofluorescence. *In vitro* experiments were performed on human (h) BTSCs isolated from extrahepatic biliary tree from organ donors, on human primary CCA cell cultures obtained from mucin producing CCA specimens and on H69, a normal human cholangiocyte cell line. Cultures were analyzed by immunofluorescence and reverse-transcription polymerase chain reaction.
Results: All CCAs emerging in PSC patients were mucin-producing tumors characterized by the involvement of PBGs and high expression of stem/progenitor cell markers. In surrounding tissue, pre-neoplastic and neoplastic lesions affected several bile ducts and the associated PBGs. Ducts with neoplastic lesions showed higher inflammation, wall thickness and PBG activation compared to PSC-affected ducts. CCA showed higher expression of nuclear factor-kappa B, interleukin-6 and vascular endothelial growth factor 1, and displayed higher microvascular density compared to non-cancerous ducts. In tissue samples, CCA cells were characterized by higher expression of epithelial-to-mesenchymal transition (EMT) traits and by the absence of primary cilia compared to controls and PSC. *In vitro* study demonstrated that CCA cells and hBTSCs, when stimulated with lipopolysaccharide and oxysterols, increased the expression of EMT traits, nuclear factor-kappa B, and interleukin-6, and showed the loss primary cilia compared to control conditions.
Conclusion: CCA arising in PSC patients is characterized by extensive PBG involvement and the activation of BTSC niche. In these patients, the presence of duct lesions at different stages (from inflammation to fibrosis and to neoplastic transformation) suggests a progressive tumorigenesis. Lipopolysaccharide and oxysterols induced, in vitro, in hBTSCs and CCA cell cultures, pathologic features similar to those detected in situ in PSC specimens.

Transforming growth factor-βeta and AXL collaborate to induce CXCL5 and neutrophil infiltration in hepatocellular carcinoma

C. Haider[1], H. Julia[1], W. Roland[1], H. Heidemarie[1], L. Zell[1], G. Timelthaler[1], M. Grubinger[1], C. Coulouarn[2], K. Schlangen[3], W. Sieghart[4], M. Peck-Radosavljevic[4], W. Mikulits[5]. *[1]Medical University of Vienna, Department of Medicine I, Division: Institute of Cancer Research, Vienna, Austria; [2]Inserm, UMR991, Liver Metabolisms and Cancer, Rennes, France; [3]Medical University of Vienna, Section of Biosimulation and Bioinformatics, Center for Medical Statistics, Informatics and Intelligent Systems, Vienna, Austria; [4]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; [5]Medical University of Vienna, Department of Medicine I, Division: Institute of Cancer Research, Vienna*
Email: wolfgang.mikulits@meduniwien.ac.at

Background and Aims: Transforming growth factor (TGF)-beta suppresses hepatocellular carcinoma (HCC) development at early stages but triggers pro-oncogenic abilities at later stages. Recent data suggest that the receptor tyrosine kinase Axl causes a TGF-beta switch towards epithelial to mesenchymal transition (EMT) and cell invasion.
Method: Establishment of human HCC models with opposing migratory phenotypes in response to long-term TGF-beta. Analysis of TGF-beta-dependent regulatory networks and target genes underlying cell invasion by transcriptome profiling and TCGA database mining. Inhibition of Axl and TGF-beta signalling in HCC cells by CRISPR/Cas9 and RNA interference. Analysis of HCC patients (n = 130) using tissue microarrays.
Results: We exploited two human HCC models with a pro- and an anti-migratory phenotype in response to TGF-beta and analysed the TGF-beta-dependent target genes underlying the invasion of HCC cells. Both HCC models displayed dedifferentiation by EMT, autocrine TGF-beta signalling and TGF-beta-dependent cell migration. Interestingly, these HCC cell models showed reduced proliferation and clonogenicity upon TGF-beta stimulation suggesting that cells evade specific traits of TGF-beta-induced tumor suppression. Transcriptome profiling revealed a set of invasion-addicted genes, among them the chemokine CXCL5, which showed a correlation with TGF-beta expression and low survival of HCC patients by analysing TCGA datasets. Notably, the expression and secretion of CXCL5 was

dependent on the expression of Axl, suggesting that CXCL5 is a TGF-beta target gene collaborating with Axl signalling. Loss of either Axl or TGF-beta signalling abrogated CXCL5-dependent migration and attraction of neutrophils. In HCC patient samples, high levels of Axl, TGF-beta and CXCL5 correlated with neutrophil infiltration and reduced survival of patients.
Conclusion: The synergy of TGF-beta and Axl targets CXCL5 which facilitates a pro-metastatic TGF-beta switch by HCC migration and neutrophil recruitment.

SAT-155
Mitochondrial VDAC1 based peptide as a new therapeutic agent for hepatocellular carcinoma
S. Pittala, Y. Krelin, V. Shoshan-Barmatz. *ben Gurion University of the Negev, Life Sciences, Beersheba, Israel*
Email: sirinivas9@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the third-most cancer worldwide. Despite progress in identifying risk factors, the incidence of HCC is increasing. Moreover, therapeutic options are limited and survival is poor. Therefore, alternative and innovative therapeutic strategies are urgently required.
Method: R-Tf-D-LP4, a cell-penetrating peptide derived from the mitochondrial multi-functional protein the voltage-dependent anion channel (VDAC1) is identified here as a highly effective liver cancer treatment. Recently, we demonstrated that R-Tf-D-LP4 induced apoptosis and inhibited tumor growth in mouse models. We now demonstrate that R-Tf-D-LP4 induced apoptosis in cancer liver-derived cell lines and inhibited tumor growth in three different liver cancer mouse models. These included diethylnitrosamine (DEN)-induced HCC, metabolically high-fat diet-induced HCC, and using a sub-cutaneous HepG2 cell xenograft mice model.
Results: Intravenous injection of the peptide into tumor-carrying DEN-treated mice resulted in dose-dependent inhibition of tumor growth up to complete tumor elimination. TUNEL staining of liver sections demonstrated peptide-induced apoptosis. Haematoxylin/eosin and Sirius red staining of liver sections showed decreased stromal formation. Immunohistochemical staining demonstrated reduced numbers of α-SMA-expressing stellate cells in R-Tf-D-LP4-treated mouse livers. Additionally, macrophage infiltration in liver tissue was reduced in R-Tf-D-LP4-treated mice. Liver sections from DEN-treated mice showed non-alcoholic steatohepatitis pathology, reflected as fatty liver, inflammation, ballooning degeneration and fibrosis; all were eliminated upon peptide treatment. Peptide treatment also inhibited tumor development in a non-alcoholic steatohepatitis-hepatocellular carcinoma (NASH-HCC) mouse model induced by high fat diet. In HepG2 sub-cutaneous tumor xenografts, R-Tf-D-LP4 inhibited tumor growth.
Conclusion: The results show that the VDAC1-based peptide R-Tf-D-LP4 has multiple effects on liver cancer cells, leading to impairment of cell energy and metabolism homeostasis, induction of apoptosis, and elimination of liver cancer-associated processes and thus represents a promising therapeutic approach for liver cancer.

The role of Lysyl oxidase in tumor microenvironment of primary liver cancer
M. Lewinska[1], M.J. Perugorria[2], J. Banales[2], J. Andersen[1]. [1]*University of Copenhagen, Biotech Research & Innovation Centre (BRIC), Copenhagen, Denmark;* [2]*Biodonostia Research Institute, Department of Liver Diseases, San Sebastian, Spain*
Email: monika.lewinska@bric.ku.dk

Background and Aims: Lysyl oxidases (LOX) are a family of extracellular proteins involved in collagen and elastin crosslinking causing stiffening and modulation of extracellular matrix (ECM). Although LOX has been reported to play tumor-suppressive roles, members of this family often show elevated tumor expression and play an essential role in hypoxia-induced metastasis. We investigated the role of LOX in modulation of the tumor microenvironment (TME) in primary liver cancer (PLC).
Method: We have analyzed our transcriptome profiles generated from patient cohorts including 219 cholangiocarcinoma (CCA), 143 matched adjacent tissues and 9 normal dissected common bile ducts, as well as 53 hepatocellular carcinoma (HCC) with matched adjacent liver tissues to investigate expression levels of LOX family members and correlate expression with clinical outcomes (survival analysis). Next, we performed gene set enrichment analysis (GSEA) to define deregulated pathways associated with aberrant LOX expression. Importantly, we have investigated LOX expression in a subset of 23 CCAs following laser-microdissection of the intra-tumor stroma and epithelial compartments. We utilized CIBERSORT to investigate the association of LOX expression with modulation of immune cell component in TME. Using hypoxic camber conditions, we modified expression of LOX in primary normal human cholangiocytes (NHC), hepatocytes (THLE5b), and PLC cancer lines. Lastly, conditioned media transfer models were used to alter LOX expression in hepatic stellate cells (HSC).
Results: Members of the LOX family are significantly overexpressed in PLC compared to adjacent normal liver, with LOX itself showing the highest fold change. High expression of LOX is associated with decreased survival in both HCC ($p = 0.035$) and CCA ($p = 0.017$). Expected, GSEA shows hypoxia gene sets associated with increased LOX expression in PLC. We confirmed that LOX expression correlates significantly with HIF1α in PLC tissues and increase in cultured cells at hypoxic conditions (1% O_2). Analysis of dissected intra-tumor stroma and epithelium showed that LOX is expressed both by the epithelial and stromal components, with significant association linked to the desmoplastic compartment. Culture systems utilizing hypoxia and conditioned media transfer generated from PLCs significantly stimulate LOX expression in HSC. Interestingly, LOX^{high} expression in PLC patients is associates with enrichment of macrophages M0 and depletion of CD4+ resting T cells in the tumors, but not correlating with tumor size.
Conclusion: Taken together our results suggest that LOX is expressed by multiple cell types in PLCs, with high expression associated with CCA desmoplasia. Elevated LOX is predictive of poor survival, but not tumor size. LOX is a putative candidate in promoting the progression of PLCs.

SAT-157
The anti-inflammatory receptor TREM2 halts the generation of HCC in mice through the inhibition of liver inflammation and hepatocyte proliferative responses
A. Esparza-Baquer[1], I. Labiano[1], O. Sharif[2,3], F. Oakley[4], E. Hijona[1,5], R. Jimenez-Aguero[1], C.O. Rourke[6], J. Andersen[6], S. Knapp[2,3], D.A. Mann[4], L. Bujanda[1,5], J. Banales[1,5,7], M.J. Perugorria[1,5,7].

Email: matxus.perugorria@biodonostia.org

Background and Aims: Hepatocellular carcinoma (HCC) is the most prevalent primary liver tumor and the third most common cause of cancer related death. Even though a number of interventional treatment methods are currently in use, this tumor remains highly chemo-resistant and shows a poor prognosis. HCC slowly unfolds on a background of chronic liver injury, where inflammation and liver

regeneration processes are involved. Toll-like receptor (TLR) derived signaling in non-parenchymal liver cells accelerates carcinogenesis by modulating inflammatory responses. Therefore, regulation of pro-inflammatory signals arises as a promising therapeutic strategy for HCC. The triggering receptor expressed on myeloid cells 2 (TREM2) acts as an anti-inflammatory receptor, as it inhibits TLR-derived signaling in various tissues, yet its role in the liver and in HCC is still unknown. This study aims to unravel the role of TREM2 in HCC development and progression.

Method: TREM2 mRNA expression was analyzed in liver tissue samples from patients with HCC compared to control individuals and murine models of HCC and liver regeneration. To study the role of TREM2 in HCC development and progression, *wild type* (WT) and *Trem2*$^{-/-}$ mice were treated with the hepatocarcinogen diethylnitrosamine (DEN) and analyzed at different time-points during disease development. The early molecular mechanisms triggered in response to DEN were analyzed in WT and *Trem2*$^{-/-}$ mice in acute phases (6, 24, 72 h). To evaluate the role of TREM-2 in liver regeneration a ~70% partial hepatectomy (PHx) model was performed in WT and *Trem2*$^{-/-}$ mice, and animals were sacrificed at 1, 6, 36, 72 hours and 5 days post-surgery.

Results: *TREM2* mRNA expression is significantly upregulated in human HCC samples compared to control livers. Similarly, *Trem2* mRNA expression is also elevated in murine HCC and in a liver regeneration model compared to control livers. *Trem2*$^{-/-}$ mice show augmented tumor number and bigger tumors after DEN. This was accompanied by an increase in the expression of liver damage and hepatocyte proliferation markers, together with a downregulation of the anti-tumoral gene farnesoid X receptor (*Fxr*). *Trem2*$^{-/-}$ mice exhibited exacerbated liver damage in acute phases in response to DEN. Regarding liver regeneration following PHx, PCNA expression and BrDU incorporation indicated an increased hepatocyte proliferation in the *Trem2*$^{-/-}$ mice. The expression of pro-inflammatory genes was also elevated in these mice. Interestingly, the results observed in the HCC model could be rescued with an anti-inflammatory diet (BHA).

Conclusion: TREM2 is upregulated in human and murine HCC and in murine liver regeneration. This anti-inflammatory receptor inhibits proliferation and HCC tumor generation in mice through the inhibition of liver inflammation. TREM2 arises as a novel therapeutic strategy for HCC.

SAT-158

Functional genomics identified actin cytoskeleton remodeling required for the hypoxia-mediated EMT: A mechanistic link of tumor size to metastasis

S.-Y. Hsieh. *Chang Gung Memorial Hospital, Linkou, Chang Gung University College of Medicine, Taoyuan, Taiwan*
Email: siming.shia@msa.hinet.net

Background and Aims: High invasiveness is a hallmark of human hepatocellular carcinoma (HCC). Large tumors predict invasion and metastasis. Epithelial-mesenchymal transition (EMT) is crucial for cancer invasion and metastasis. However, the mechanisms whereby large tumors tend to undergo EMT remain unclear.

Method: We conducted a subgenome-wide screen for invasion suppressor genes and identified *KLHL2*. We used patient-derived HCC xenograft model to validate our hypothesis.

Results: *KLHL23* was an HCC invasion suppressor via inhibiting EMT. Downregulation of *KLHL23* was associated with invasion, metastasis, and poor prognosis of HCC and pancreatic cancer. KLHL23 binds to actin and suppresses actin polymerization. *KLHL23* silencing induced

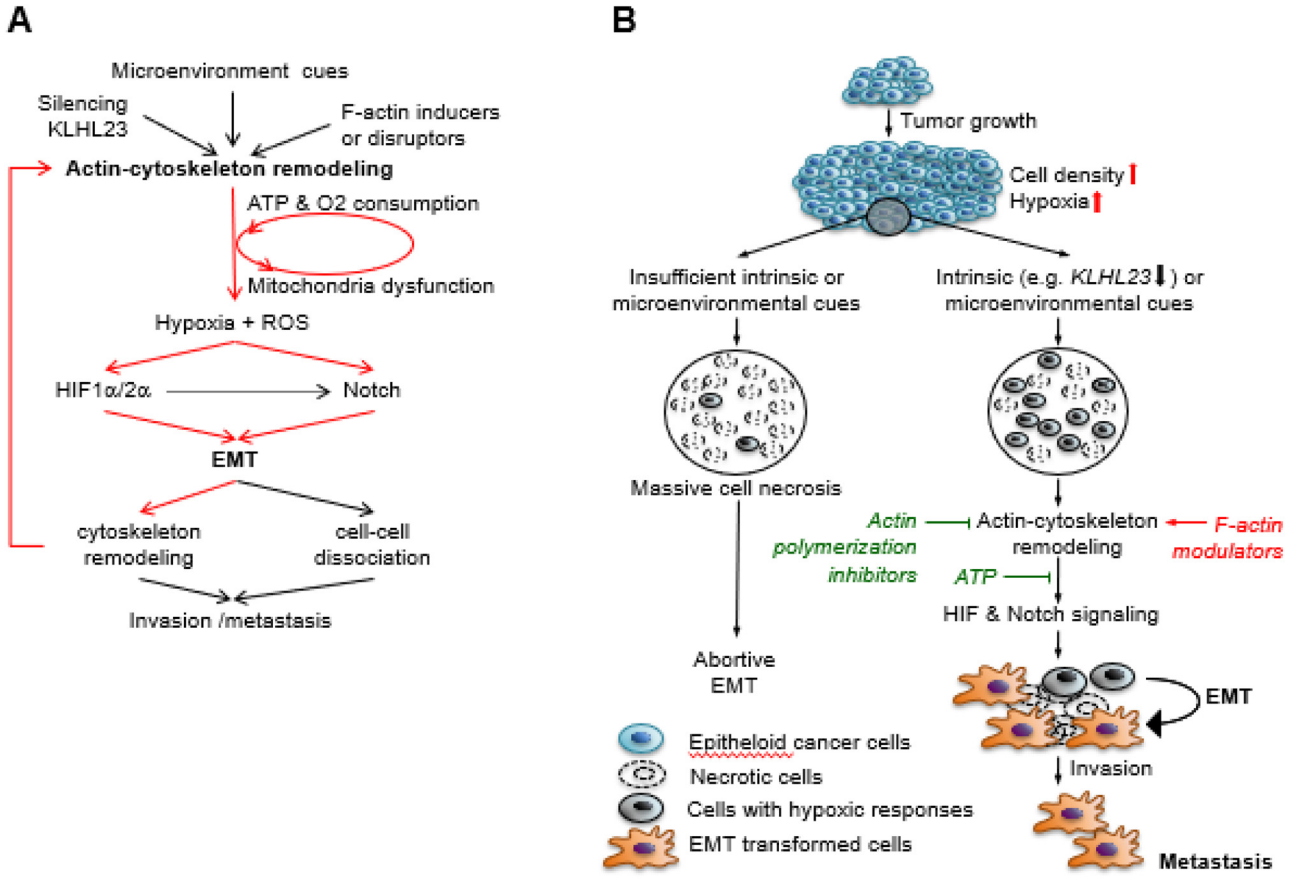

Figure: (abstract: SAT-158): **(A)** Induction of actin cytoskeleton remodeling by microenvironmental or intrinsic (such as *KLHL23* downregulation) cues drive HIF and Notch signal, thereby inducing EMT, invasion, and metastasis. (**B**) The crucial roles of actin cytoskeleton remodeling in orchestrating tumor cells

filopodium and lamellipodium formation. Traditionally, actin cytoskeleton remodeling is downstream of EMT reprogramming. It is, therefore, intriguing to ask why and how KLHL23, an actin modulator, inversely regulates EMT. Activation of actin cytoskeleton remodeling by either *KLHL23* silencing or treatment with actin cytoskeleton modulators augmented cellular hypoxic responses in a cell density-dependent manner resulting in HIF and Notch signals and subsequent EMT. Environmental hypoxia did not induce EMT unless actin cytoskeleton remodeling was simultaneously activated only were cells at high density. The EMT thus induced was reversed by either adenosine 5′-triphosphate supplementation or actin polymerization inhibitors. Correlations of tumor size with EMT and inverse association of the expression of KLHL23 with HIF-/Notch-signals were further validated in patient-derived xenograft HCCs in mice.
Conclusion: Simultaneously activation of actin cytoskeleton remodeling by intrinsic (such as *KLHL23* downregulation) or microenvironment cues is crucial for cell density-dependent, hypoxia-mediated EMT, providing a mechanistic link between large tumor size and invasion/metastasis. Our findings open a new door to development of prevention and treatment strategies for tumor invasion and metastasis.

The HDAC inhibitor belinostat enhances the anti-tumor efficacy of immune checkpoint inhibitors in a murine hepatocellular carcinoma model

D. Llopiz[1], M. Ruiz[1], L. Villanueva[1], T. Iglesias[1], J.J. Lasarte[1], P. Pivette[2], V. Trocon-Joseph[2], B. Vasseur[2], G. Dixon[2], B. Sangro[3], P. Sarobe[1].
[1]Centro de Investigación Médica Aplicada (CIMA), Universidad de Navarra, Pamplona, Spain; [2]Onxeo, Paris, France; [3]Clinica Universidad de Navarra-IDISNA and CIBEREHD, Liver Unit, Pamplona, Spain
Email: psarobe@unav.es

Background and Aims: Immune checkpoint inhibitors are currently being tested in different combinations in patients with advanced hepatocellular carcinoma (HCC). Nivolumab, an anti-PD-1 agent, has been approved in the US in the second line setting after Sorafenib. Epigenetic drugs have immune-mediated antitumor effects that may improve the activity of immunotherapy agents. Our aim was to study the therapeutic efficacy of checkpoint inhibitors (anti-CTLA-4 and anti-PD-1 antibodies) in combination with the histone deacetylase inhibitor Belinostat.
Method: Therapeutic efficacy and studies on antitumor immunity were performed in a subcutaneous Hepa129 murine hepatocellular carcinoma model that similar to human tumors have an infiltrate rich in CTLA-4+ regulatory T lymphocytes and effector PD-1+ T lymphocytes. Animals treated with Belinostat, an anti-PD-1 monoclonal antibody and an anti-CTLA-4 monoclonal antibody as monotherapy or in combinations as well as control animals receiving a non-immunostimulatory antibody were followed to monitor tumor growth and survival, or sacrificed at different days after treatment for obtaining tumor, spleen and blood samples for analysis.
Results: Belinostat improved the anti-tumor activity of anti-CTLA-4 but not the activity of anti-PD-1 therapy. This effect correlated with enhanced IFN-gamma production by antitumor T-cells and a decrease in regulatory T-cells. Moreover, the combination induced early upregulation of PD-L1 on tumor myeloid cells and late expression of PD-1 on tumor-infiltrating effector T-cells, suggesting the convenience of PD-1 blockade. Indeed, Belinostat combined with the simultaneous blockade of CTLA-4 and PD-1 led to complete tumor rejection in treated animals.
Conclusion: These results provide a rationale for testing Belinostat in combination with checkpoint inhibitors in order to enhance their therapeutic activity in patients with HCC.

SAT-160

Blocking the CDK1/PDK1/B-Catenin signaling by CDK1 inhibitor RO3306 increased the efficacy of sorafenib treatment with targeting cancer stem cell in preclinical model of hepatocellular carcinoma

C. Wu, X. Wang. *The University of Hong Kong, Center for Cancer Research and Department of Surgery, Hong Kong*
Email: u3003812@hku.hk

Background and Aims: Cyclin-dependent kinase 1 (CDK1) is the key regulator in promoting cell division whose role can't be substituted by any other CDKs. Sorafenib the only approved target therapy for advanced HCC treatment provides limited survival benefits till today. Here we aim to determine the efficacy of CDK1 inhibitor RO3306 alone or combination with sorafenib in the preclinical tumor models of hepatocellular carcinoma.
Method: The clinicopathological parameters CDK1 expression with HCC overall survival and CDK1 related PDK1 with disease-free survival were analyzed. Three HCC patients-derived xenograft tumor models were treated with RO3306 (4 mg/kg), sorafenib (30 mg/kg) alone or combination for one month. The relevant signaling CDK1/PDK1/β-Catenin was measured by western blot. The colony formation, single cell sphere formation and tumorigenicity assay were used for liver cancer stem cells (CSCs). Silencing CDK1 with shRNA and corresponding inhibitors for mechanism and related functional studies.
Results: We reported that CDK1 was frequently augment accounted up to 50% (21/42) of hepatocellular carcinoma (HCC) tissues, which was significantly associated with poor overall survival ($p = 0.008$). Moreover, the CDK1 and PDK1 association shows worse disease-free survival ($p = 0.03$). CDK1 inhibitor RO3306 in combination with sorafenib treatment significantly decreased tumor growth in patients-derived xenograft (PDX) tumor models. Western blot results demonstrated that combined administration resulted in synergistic decreased the pluripotency protein levels of Oct4, Sox2 and Nanog as well as concurrently down-regulating CDK1, PDK1 and β-Catenin. Furthermore, downregulation CDK1/PDK1/ β-Catenin associated with suppressing the process of epithelial mesenchymal transition (EMT) revealed with the downregulation of Snail1 and Snail2 while upregulation of E-Cadherin, which may show synergistic antimetastasis potential in combination treatment. Based on the evidences, we further verified that pharmaceutical combinatorial inhibition dramatically decreased CSCs single cell sphere formation and colony formation. Synergistic down-regulated AKT and pStat3 activation with enhancing suppression on tumorigenicity in vivo. In addition, low dose of RO3306 (2 uM) and sorafenib (2.5 uM) combination could inhibit CSCs growth via decreasing the S phase and promoting cell to enter into a pseudo-G1 phase with 4N DNA. Mechanism with functional study of silencing CDK1 with shRNA and RO3306 combined sorafenib both abolished its oncogenic function via the down-regulation of CDK1, with the downstream PDK1 and β-Catenin inactivation.
Conclusion: Anti-CDK1 treatment can boost sorafenib antitumor responses in PDX tumor models, providing the rational combined treatment to increase sorafenib efficacy in clinical.

Email: sabina.dimatteo@uniroma1.it

Background and Aims: Cholangiocarcinoma is an aggressive cancer, resistant to chemotherapeutics. We demonstrated that CCA is enriched of cancer stem cells associated with aggressiveness and drug resistance. FXR, involved in neoplastic transformation of stem cells and/or cholangiocytes, is down-regulated in human CCA. Our AIM was to evaluate, in primary cultures of human intrahepatic CCA (iCCA) the effects of the FXR agonist, obeticholic acid (OCA), on the cancerogenic potential of human CCA cells.

Method: Primary human cell cultures were prepared from specimens of iCCA obtained from patients submitted to surgical resection and classified into mucin- or mixed-iCCA subtypes by morphologic and immunohistochemical criteria. Increasing concentrations (0–5 μM) of OCA were added to culture media and, after 3–10 days, the effect on

proliferation (MTS assay, cell population doubling time), apoptosis (annexin V-FITC / propidium iodide), cell migration and invasion (wound healing and matrigel invasion assay) and cancerogenic potential (spheroid formation, clonogenic assay, colony formation capacity) were evaluated.
Results: FXR was downregulated (RT-qPCR) in iCCA cells vs normal human biliary tree stem cells ($p < 0.001$) and in mucin-iCCA vs mixed-iCCA ($p < 0.05$). OCA significantly ($p < 0.05$) inhibited proliferation of both mucin-iCCA and mixed-iCCA cells starting at a concentration as low as 0.05 μM (IC_{50} = 0.38 μM in mixed- and 2.1 μM in mucin-iCCA). Also CDCA (but not UDCA) inhibited cell proliferation, although to a much lower extent than OCA, consistent with the different potency in FXR activation (i.e. OCA > CDCA, no agonistic effect for UDCA). OCA significantly induced apoptosis of both iCCA subtypes and decreased the *in vitro* cancerogenic potential of iCCA cells as evaluated by impairment of colony and spheroid formation capacity and delayed wound healing and matrigel invasion. In general, these effects were more evident against mixed- than mucin-iCCA cell. When tested together with gemcitabine and cisplatin, OCA potentiated the anti-proliferative and pro-apoptotic effects of these chemotherapeutics but mainly on mixed-iCCA. OCA abolished the capacity of both mucin- and mixed-iCCA cells to form colonies when administered together with gemcitabine and cisplatin.

SAT-162

Sensitization of cholangiocarcinoma to chemotherapy by SOX17-induced down-regulation of drug export pumps ABCC3 and AGCG2

E. Lozano[1], O. Briz[1], M. Asensio[1], L. Perez-Silva[1], M. Monte[1], M. Perez[2], E. Herraez[1], M. Romero[2], M. Serrano[2], R. Macias[1], L. Bujanda[3], J. Banales[3], J. Marin[1]. *[1]University of Salamanca, IBSAL, CIBERehd, Physiology and Pharmacology, Salamanca, Spain; [2]University of Salamanca, IBSAL, CIBERehd, Biochemistry and Molecular Biology, Salamanca, Spain; [3]Biodonostia Biomedical Research Institute, Department of Hepatology and Gastroenterology, San Sebastian, Spain*
Email: jjgmarin@usal.es

Background and Aims: An important limitation for favorable cholangiocarcinoma (CCA) outcome is its poor response to chemotherapy. Among mechanisms of chemoresistance (MOC) involved, a reduced intracellular concentration of anticancer drugs due to active drug export through ATP-binding cassette (ABC) proteins, such as ABCG2 and ABCC3, plays an important role. SOX17, a transcription factor that inhibits Wnt/β-catenin pathway, has been reported to be downregulated in CCA. Restoration of SOX17 expression in CCA cells results in tumor suppression. Here we have investigated whether viral vector-mediated SOX17 over-expression may be also beneficial by sensitizing CCA to chemotherapy.
Method: Viral vectors containing SOX17 ORF were generated to transduce CCA cells (EGI-1 and TFK-1). Cell viability in response to incubation with commonly used anti-CCA drugs was determined by MTT test. Taqman Low Density Arrays were designed to measure mRNA abundance of ≈100 genes involved in several MOCs. Single RT-qPCR, WB and IF were used to evaluate gene/protein expression. ABC pumps activity of was determined by flow cytometry using specific inhibitors and fluorescent substrates. Firefly luciferase (Luc2) was fused to ABC promoters to carry out promoter-reporter assays. Mouse xenograft model was used for *in vivo* evaluation of chemotherapy efficacy.
Results: SOX17 overexpression selectively enhanced the cytostatic response of CCA cells to SN-38, 5-FU and mitoxantrone, but not to gemcitabine or cisplatin. The magnitude of chemosensitization was dependent on SOX17 expression levels. The analysis of changes in MOC gene expression profile revealed that SOX17 overexpression affected several of these genes, mainly those encoding ABC proteins. Thus, a significant reduction in *ABCC3/ABCG2* expression was found. Interference with ABC gene promoter activity seems to be involved in the mechanism of SOX17-induced *ABCC3/ABCG2* downregulation. Functional studies supported a reduced ability of SOX17-overexpressing CCA cells to export specific substrates of these pumps. Moreover, combined ABCG2/ABCC3 substrate specificity matched the observed selective chemosensitization. SOX17-induced better response to ABCG2/ABCC3 substrates was confirmed by *in vivo* experiments.
Conclusion: In addition to the tumor suppression effect of SOX17, its over-expression induces selective chemosensitization due to down-regulation of some ABC proteins, which reduces the ability of CCA cells to export anticancer drugs.

SAT-163

Defective NKp30-mediated function in hepatocellular carcinoma-infiltrating NK cells

Email: mario.mondelli@unipv.it

Background and Aims: Natural killer (NK) cells play a significant role in innate immune responses to cancer cells, their action being regulated by several activating and inhibitory receptors. The natural cytotoxicity receptor NKp30/NCR is critical for NK cell function. The NCR3 gene is transcribed into three major isoforms that have different biological functions. The expression levels of NKp30 isoforms can negatively impact on the prognosis and evolution of different malignancies and might be associated with advanced liver disease in HCV-infected patients. Current evidence indicates that malignant cells bypass the NK surveillance by releasing the NKp30 ligand B7H6 as soluble proteins that block NKp30 activity, suggesting that this may be an immune escape mechanism of tumor cells from NK cell-mediated killing.
We investigated the NKp30-B7H6 axis in patients with hepatocellular carcinoma (HCC).
Method: *Ex-vivo* isolated PBMC, non-tumor liver-infiltrating lymphocytes (LIL) and tumor-infiltrating lymphocytes (TIL) were examined by flow cytometry. Serum concentration of soluble B7-H6 was measured by ELISA. Expression of the three major NKp30 isoforms was analyzed by quantitative real-time PCR in PBMC, LIL and matched TIL of HCC patients and healthy controls (HC).
Results: The frequency of NKp30-expressing peripheral NK cells and the intensity of its expression were significantly lower in patients with HCC compared to HC. In contrast, NKp30-expressing NK cells were enriched in the neoplastic tissue of HCC patients compared to the non-tumorous surrounding liver. Peripheral and tumor-infiltrating NKp30-expressing NK cells showed defective degranulation capacity and cytokine release after NKp30 triggering, and had altered expression of NKp30 splice variants. Serum levels of the soluble form of B7H6 ligand were increased in HCC patients, particularly those with intermediate and advanced tumors, classified according to Barcelona Clinic for Liver Cancer (BCLC) staging classification, as compared to early stage tumors. Moreover, statistically significant positive correlations were found between sB7H6 levels and HCC nodule size and serum alpha fetoprotein values.

Conclusion: These findings provide evidence in support of a role of NKp30 and its major ligand in HCC development and evolution.

Background and Aims: Commercially available targeted or exome panels miss some genes and regions frequently mutated in hepatocellular carcinoma (HCC). We aim to design and benchmark a targeted sequencing panel specific for mutational profiling for HCC.
Method: We designed a custom Ion AmpliSeq panel targeting all exons of 33 protein-coding and 2 long non-coding RNA genes frequently mutated in HCC, *TERT* promoter. We profiled DNA from fresh frozen tumor (FFT, n = 10, median depth 1495x) and/or formalin-fixed paraffin-embedded (FFPE) tumor with low input DNA (n = 36, median depth 530x), and their non-tumoral counterparts from 39 HCCs using the custom panel. We benchmarked the somatic mutations identified against those from Illumina whole-exome sequencing (WES) of the equivalent FFT samples (median depth 112x).
Results: At least one somatic mutation was identified in 35/39 cases using the custom panel. Median of 2.5 (0–74) and 3 (0–76) mutations were identified in FFT and FFPE samples, respectively. 98% (61/62) of the mutations identified from WES of the 10 FFT samples were successfully recovered using the custom panel, with the identification of an additional 6 and 32 mutations in coding and non-coding regions, respectively. Similarly, all 104 mutations identified from WES were also found based on the analysis of our custom panel of the 36 FFPE biopsies. We identified an additional 18 and 70 somatic mutations in coding and non-coding genes, respectively, using our custom panel, including 2 CTNNB1 activating mutations.
Conclusion: We have established a sequencing assay for the sensitive detection of somatic mutations in HCC-associated driver genes.

SAT-165

Lack of Osteopontin promotes non-alcoholic steatohepatitis (NASH) and fibrosis, but protects against hepatocellular carcinoma (HCC) progression and mortality in a NASH-HCC mouse model

A.D. Nardo[1], N.G. Grün[1], M. Zeyda[1], G. Oberhuber[2], M. Dumanic[3], T. Helbich[3,4], T.M. Stulnig[1]. *[1]Medical University of Vienna, Christian Doppler Laboratory for Cardio-Metabolic Immunotherapy and Clinical Division of Endocrinology and Metabolism, Department of Medicine III, Wien, Austria; [2]General Hospital of Innsbruck, Department of Pathology, Innsbruck, Austria; [3]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Wien, Austria; [4]Medical University of Vienna, Division of Molecular and Gender Imaging, Wien, Austria*
Email: alexander.nardo@meduniwien.ac.at

Background and Aims: Osteopontin (OPN, gene *Spp1*), a multifunctional protein and inflammatory cytokine, has been proposed to play a pivotal role in many pathophysiological events related to metabolic syndrome and carcinogenesis. OPN is overexpressed in adipose tissue and liver during obesity and concurs in the induction of adipose tissue inflammation and non-alcoholic fatty liver (NAFL). Studies performed in both mice and humans demonstrated a putative role for OPN in malignant transformation and tumor growth, including hepatocellular carcinoma (HCC). Metabolic syndrome is nowadays recognized as an important risk factor for HCC. In order to fully understand the role of OPN on the development of HCC in NAFL, we reproduced in our laboratories a recently published NASH-HCC mouse model called STAM on a both wild type (WT) and OPN deficient (*Spp1*–/–) background, and evaluated its properties in non-alcoholic steatohepatitis (NASH), fibrosis and HCC.
Method: Two-days-old WT and *Spp1*–/– mice received a low-dose streptozotocin (STZ) injection in order to induce diabetes and were fed a high-fat diet (HFD) starting from week 4. Different cohorts of

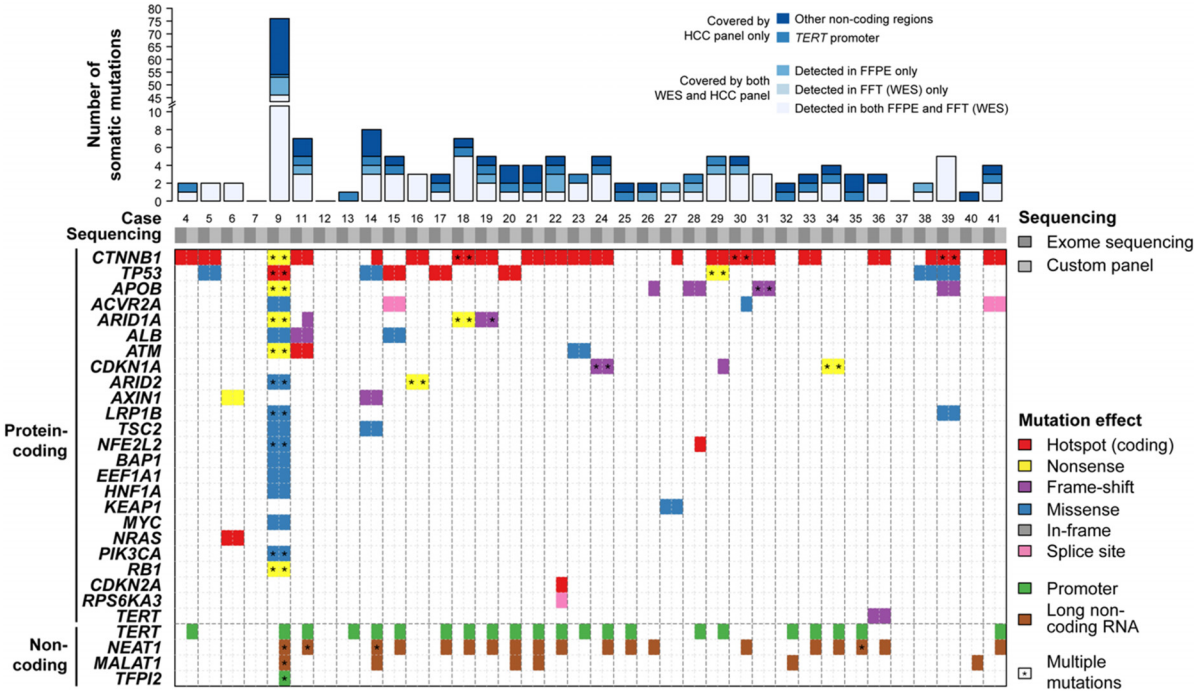

Figure: (abstract SAT-164)

mice of both genotypes were sacrificed at 8, 12 and 19 weeks of age in order to evaluate the NASH, fibrosis and HCC phenotypes, respectively.
Results: Lack of osteopontin prevented HCC progression to less differentiated tumors and improved overall survival rate while enhancing the development of well-differentiated liver tumors. On the other hand, *Spp1*–/– mice developed a stronger fibrosis due to increased hepatocellular apoptosis. OPN-deficient mice also showed an aggravated NASH due to increased *CD36*-mediated lipid uptake. The worse steatotic and fibrotic phenotypes observed in *Spp1*–/– mice were probably a consequence of overall improved metabolic condition.
Conclusion: In a model of metabolic syndrome, the lack of OPN improved overall outcomes but worsened hepatic inflammation and fibrosis. OPN appears necessary for dedifferentiation of HCCs.

SAT-166

Canonical inhibition of Transforming Growth Factor β Receptor 1 triggers proliferation of hepatocellular carcinoma andis associated with Toll like Receptor 7 upregulation

F. Mohamed[1], S. Hammad[2], S. Dooley[3]. [1]*Faculty of medicine, Department of Pathology, El Minia, Egypt;* [2]*Faculty of Veterinary Medicine, Department of Forensic Medicine and Veterinary Toxicology, Qena, Egypt;* [3]*Molecular Hepatology Section, Department of Medicine II, Mannheim, Germany*
Email: fatma.mohamed@medma.uni-heidelberg.de

Background and Aims: Our previous work showed that hepatocellular carcinoma (HCC) proliferation can be modulated by Toll Like Receptor (TLR) 7 and 9. A crosstalk between TLR and TGF-β signaling was reported previously in liver fibrosis, suggesting a possible link between them in HCC.
Our aim is to address (i) expression of TGF-βR1 (ALK5) and TLR7 in human HCC, (ii) investigate the impact of their pathways modulation on HCC proliferation in mouse model and HuH7 cell line, (iii) determine whether inhibition of the TGF-βR1 pathway can modulate TLR activity and in turn HCC proliferation.
Method: Human HCC sections were stained for TLR7 and TGF-βR1 (ALK5) using immunohistochemistry. In addition to TLR7 and TGF-βR1, pSmad2 and Ki-67 immunostaining was performed on tissue obtained from a steatohepatitis-based HCC mouse model. HuH7 cells were treated for 48 hours with imiquimod (5 µg/ml, TLR7 agonist), chloroquine (20 µM/ml, inhibitor for TLR7), siRNA targeting TLR7, 25 pmols, TGF-β1 cytokine (5 ng/ml) and LY2157299 (10 ng/ml, ALK5 inhibitor), in order to detect the effect of TLR7 and TGF-βR1 modulation on cellular proliferation using MTS assays. The expression level of TLR7 upon ALK5 stimulation and inhibition was examined on protein and mRNA levels and correlated to PCNA expression, as measured by immunoblot.
Results: TLR7 is overexpressed in the majority of HCC sections with perinuclear localization in malignant hepatocyte. ALK5 is absent in HCC, but expressed in the cytoplasm of hepatocytes in the cirrhotic surroundings of the corresponding tumor. In mice HCC, TLR7 and ALK5 expression are inversely correlated in the HCC nodules as compared to non-tumoral areas. TLR7 expression is positively correlated with the proliferative index (Ki-67). High levels of ALK5 and pSmad2 are present in fibrotic livers and dysplastic nodules and negative in HCC. Localization of pSmad2 positive signals in HCC is perinuclear instead of nuclear. Proliferation of HuH7 cells is significantly associated with TLR7 stimulation (imiquimod) and ALK5 inhibition (Ly2157299), whereas silencing or inhibiting TLR7 is cytostatic. This result is confirmed at the protein level of PCNA. Importantly, TLR7 expression is increased upon LY2157299 treatment, both at mRNA and protein level.
Conclusion: Targeting ALK5 and TLR7 signaling can be used to modulate HCC proliferation. Although LY2157299 is now in clinical trial for HCC, TLR7 expression must be taken into consideration and careful therapy tailoring is required.

SAT-167

S100a11 is part of a whole network of tumor suppressors and oncogenes deregulatedearly with hepatic steatosis and contributing to hepatocellular carcinoma development

C. Sobolewski[1], A. Daniel[2], F. Berthou[1], N. Calo[1], C. Sempoux[3], A.-S. Ay[1], P. Clavien[4], H. Bostjan[4], J.-F. Dufour[5], A. Alexander[2], M. Foti[1]. Email: daniel.abegg@unige.ch

Background and Aims: Hepatocellular carcinoma (HCC) develops frequently in the context of fatty liver disease (FLD) with distinct etiologies. Genetic mutations of tumor suppressor (TS) and oncogenes (ONC) have been widely characterized in HCC. However, increasing evidence indicate that deregulations of the activity/expression of TS/ONCs may also occur with FLD independently of specific mutations. This study aimed at uncovering and characterizing major TS and ONC deregulated at early stages of FLD and potentially fostering hepatocarcinogenesis.
Method: Hepatic tissues from a mouse model of FLD spontaneously progressing towards the development of HCC (hepatocyte-specific PTEN knockout, LPTENKO mice) were used to identify through unbiased LC-MS/MS spectrometry, deregulations of TS and ONC occurring with steatosis. Expression of TS/ONC identified by mass spectrometry were then investigated in hepatic tissues of various mouse models of FLD, in mouse/human cancer cells and in HCC Human Tissue Microarrays. S100A11 functions in carcinogenesis were examined *in vitro* using human HepG2 cells.
Results: Proteomic analyses of steatotic hepatic tissues from LPTENKO mice identified a network of more than 30 TS/ONC respectively down- or up- regulated in early stages of FLD. Alterations of these TS/ONC expression were further confirmed in various diet-induced and genetic mouse models of hepatic steatosis and were found to be present also in genetically- and carcinogen-induced HCC in mice. Among these TS/ONC, S100A11 was upregulated with hepatic steatosis and further increased in mouse HCC. The relevance of S100A11 overexpression was further confirmed in human hepatic cancer cells, as well as in human HCC tissues, where it correlates in particular with HCC grade III. Finally, *in vitro* analyses showed that inhibition of S100A11 expression in hepatic cancer cells leads to decreased cell proliferation, upregulation of cell cycle inhibitors, induction of cell death, as well as inhibition of cell migration and invasion.
Conclusion: Our findings indicate that deregulation of a whole network of TS/ONCs, which may foster hepatocarcinogenesis, occurs early with steatosis. Among this deregulated network of cancer-related factors, S100a11 has relevant oncogenic functions in HCC and might represent both a target and a risk factor biomarker for high grade HCC development.

SAT-168

Low density neutrophils, as immunosuppressant, increased in HCC patients, highly correlated with advanced stage, predicted stage I HCC recurrence and all patients' survival

C.-H. Huang[1,2], C.-Y. Lin[1,3], T.-H. Wu[1], R.W.-J. Jeng[1,3], S.-K. Shih[1], Y.-C. Hsieh[1], W. Teng[1], Y.-C. Chen[1,4], C.-C. Lin[1], S.-M. Lin[1], I.-S. Sheen[1,4], Y.-C. Lin[5]. [1]*Chang-Gung Memorial Hospital, Linkou Medical Center, Taiwan, Division of Hepatology, Department of Gastroenterology and Hepatology, Taiwan;* [2]*College of Medicine, Chang-Gung University, Graduate Institute of Clinical Medical Sciences, Taiwan;* [3]*Chang-Gung University, College of Medicine, Taiwan, Taiwan;* [4]*Chang-Gung University, College of Medicine, Taiwan, Taiwan;* [5]*Division of Oncology, Chang-Gung Memorial Hospital, Linkou Medical Center, Taiwan*
Email: chunyenlin@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the second most common cause of cancer related deaths in the world. Current curative HCC treatments including surgical resection and liver transplantation are feasible only for less than 30% of patients due to poor liver function or advanced stage at diagnosis. Thus, new HCC therapeutic strategies are warranted. Recently, a subset of low-density neutrophils (LDNs) had been proposed that appear transiently in self-resolving inflammation but accumulate continuously with cancer progression. Their neutrophil extracellular trap (NET) was found to help metastasis in several cancers. Therefore, to investigate the role of LDN in HCC is intriguing.
Method: Peripheral blood was collected from normal controls (NC) and HCC patients (TNM stage I to IV) with Child-pugh class A status. HCC tissues were acquired during liver tumor resection. LDNs were collected from the peripheral blood mononuclear cells (PBMCs) layer after Ficoll–Hypaque density gradient centrifugation then isolated by flow cytometric methods as $CD15^{+}CD45^{+}$ neutrophils.
Results: 14 NC and 170 HCC patients were enrolled in this study. LDN percentage in PBMC increased in HCC patients when compared with normal controls (Figure 1A). The percentage of LDNs in HCC tumor tissue was also higher than that in the corresponding peripheral blood (Figure 1B). HCC patients had increased percentage of Arg-1 + LDN in their PBMC compared to that in NC (Figure 2A). They also showed decreased expressions of pro-inflammatory (anti-apoptotic) receptor TNFR2 ((Figure 2B) and higher PD-1 expressions only after PMA stimulation (Figure 2C) when comparing to NC. The phagocytosis abilities for LDN were decreased as compared to HDN in HCC patients (Figure 3). LDN also showed dose-dependent CD8 + Tcell suppression when adding to PBMC as compared to LDN-depleted PBMC control (Figure 4). They also showed decreased killing to K562 leukemia cells (Figure 5) as compared to HDN counterpart.

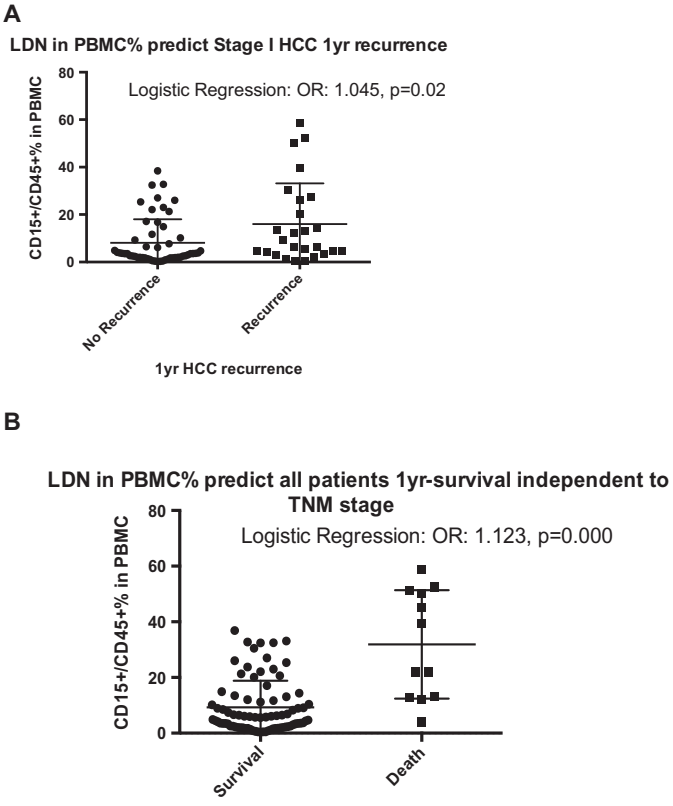

Figure 1: Predictions of 1-year recurrence in stage I HCC patients and survival in all HCC patients

As for clinical significance, LDN% in PBMC correlated with TNM staging (Figure 6). LDN% in PBMC could also predict one-year tumor recurrence in stage I HCC patients (Figure 7A) and 1-year survival in all HCC patients (Figure 7B).
Conclusion: Low-density neutrophils increased in PBMC of HCC patients, accumulated in tumor tissue and were highly correlated with tumor stage. These LDN exhibit the immunosuppressant phenotype with inhibition of CD8 + T cell proliferation, decease phagocytosis and tumor-killing ability. In addition, the percentage of LDNs could predict 1-year recurrence in stage I HCC patients and survival in all HCC patients.

Physiology and Pharmacology "Vittorio Erspamer", Rome, Italy;* [2]*University of Salamanca, IBSAL, CIBERehd Dept. Physiology and Pharmacology, Salamanca, Spain*
Email: silvia.digiacomo@uniroma1.it

Background and Aims: Hepatocellular carcinoma (HCC) is the fifth most frequent malignant tumor, and the third leading cause of cancer-related mortality in the world. Sorafenib is the only drug available for this condition, even if its efficacy is modest due in part to the overexpression of ATP-binding cassette (ABC) proteins. The potential use of ABC-transporter inhibitors (chemosensitizers) in association with cytotoxic drugs represents a new approach to overcome multidrug resistance (MDR). In this context, the present study was aimed at evaluating the ability of the sesquiterpene ß-caryophyllene oxide (CRYO) to act as a chemosensitizer in HCC.
Method: Human HCC PLC/PRF/5 cells, both wild-type (WT) and chemoresistant (R), overexpressing MDR1, MRP1, MRP2, MRP4 and MRP5, mouse hepatoma Hepa 1–6 R cells, overexpressing MRP1 and MRP2, and human lung carcinoma COR-L23 cells, overexpressing MDR1 and MRP1, have been used as *in vitro* models. As a first step, the cytotoxicity of sorafenib and CRYO alone or in combination was evaluated by MTT assay in all cell lines. Then, the inhibition by CRYO of ABC transport function was measured by efflux assay using fluorescent substrates. The actual change in sorafenib cell content, as a result of the combined treatment with CRYO, was measured by HPLC-MS/MS. Finally, the potential chemosensitizing effect of CRYO in combination with sorafenib was investigated using the mouse xenograft model.
Results: Cytotoxicity evaluation *in vitro* revealed a lack of CRYO cytotoxicity up to the concentration of 100 μM together with different sensitivity of PLC/PRF/5 cells to sorafenib. Thus, PLC/PRF/5 WT showed a 3-fold higher sensitivity to sorafenib than R cells. In combination experiments, CRYO (50 μM) significantly increased sorafenib (10 μM) cytotoxicity by + 19% and + 35% in the PLC/PRF/5 WT and R cells, respectively. Hepa 1–6 R and COR-L23 R cells were also affected by chemosensitizing combination: sorafenib cytotoxicity was increased by + 40% and + 29%, respectively. In efflux experiments, CRYO inhibited MDR1 and MRP1/2 function by −75% and −81%, respectively, while no significant effect on MRP3, MRP4, and MRP5 function was found. CRYO was also able to increase sorafenib content by + 62% in PLC/PRF/5 R cells. Regarding *in vivo* experiments, the implant of Hepa 1–6 R cells resulted in the formation of tumors with a final volume (FTV) of 6.6 ± 0.3 cm^3. Interestingly, while the treatment with sorafenib was not able to inhibit tumor growth, its combination with CRYO determined an inhibition of tumor growth by −58% (FTV = 2.8 ± 0.6 cm^3).
Conclusion: Present results support the potential pharmacological interest of CRYO as a new chemosensitizing agent to be used in combination with sorafenib to overcome MDR phenotype in HCC. The combined treatment of CRYO with sorafenib is expected to increase the effectivity of this drug at lower doses and hence reduce the adverse effects of chemotherapy.

Application of patient-derived liver cancer cells for personalized treatment approach: from phenotypic characterization to therapeutic target identification

D. Castven[1], D. Becker[1], C. Czauderna[1], D. Wilhelm[1], J. Andersen[2], S. Strand[1], S. Heilmann-Heimbach[3], W. Roth[4], N. Hartmann[4], B. Straub[4], F. Mahn[1], S. Franck[1], S. Pereira[1], M. Hartmann[1], A. Haupts[4], A. Vogel[5], M.-A. Wörns[1], A. Weinmann[1], S. Heinrich[6], H. Lang[6], S. Thorgeirsson[7], P. Galle[1], J. Marquardt[1]. *[1]Johannes Gutenberg University, Department of Medicine I, Lichtenberg Research Group, Mainz, Germany; [2]University of Copenhagen, Biotech Research and Innovation Centre (BRIC), Department of Health and Medical Science, Kopenhagen, Denmark; [3]University of Bonn, Department of Genomics, Life & Brain Center, Bonn, Germany; [4]Johannes Gutenberg University, Institute of Pathology, Mainz, Germany; [5]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [6]Johannes Gutenberg University, Department of Surgery, Mainz, Germany; [7]National Cancer Institute, NIH, Laboratory of Human Carcinogenesis (LHC), Center for Cancer Research, Bethesda, United States*
Email: castvendarko@gmail.com

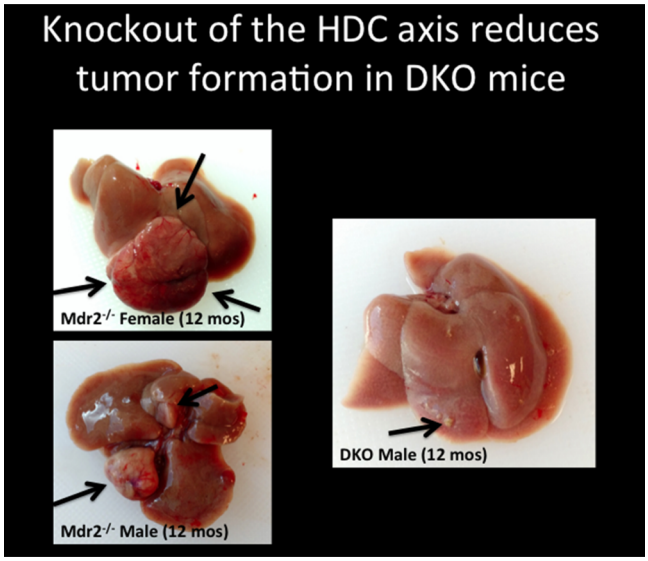
Background and Aims: Primary liver cancers (PLCs) rank among the most lethal solid cancers worldwide due to lack of effective biomarkers for early detection and limited treatment options in advanced stages. While cell lines have been of significant impact for cancer research over the last decades, development of *in vitro* models that closely recapitulate phenotypic and molecular diversity of the primary cancers is urgently needed to improve the outcome of patients.
Method: Long-term culture of 10 liver cancer cell lines of hepatocellular, cholangiocellular and metastatic origin were established using defined culture conditions. Morphological and histological characteristics of obtained cell lines and xenograft tumors were analyzed and compared to original tumors. Further, time course analyses of transcriptomic and genomic changes were performed using next-generation sequencing (NGS). Key oncogenic alterations were further identified by targeted NGS and cell lines carrying potentially actionable mutations were treated with corresponding specific inhibitors. Response to the treatments was further evaluated.
Results: The newly patient-derived cell lines (PDCL) fully resembled morphological features of the primary cancers *in vitro* and *in vivo*. Genomic alterations as well as transcriptome profiles of the PDCL showed high concordance with the primaries and remained stable for at least 30 passages. Next-generation sequencing approaches confirmed that key oncogenic mutations such as TP53, KRAS, CTNNB1 as well as potentially actionable mutations (e.g. MET, cKIT, KDR) were highly conserved in the PDCL. Integrative genomic and transcriptomic approaches demonstrate the utility of PDCL as representative model for distinct prognostic subpopulations of liver cancer patients. Moreover, the PDCL could be effectively used for therapeutic testing. Specific targeting of detected actionable mutations, such as MET and cKIT, confirmed a superior response and sustained sensitivity to specific inhibition in comparison to non-mutated control cells.
Conclusion: Together, our integrative analysis demonstrates that the use of newly established cell lines represents a sophisticated model to discover relevant molecular subgroups and to test drug sensitivity by exploring precision medicine approaches.

SAT-171

Depletion of the HDC/histamine axis ablates tumor formation, angiogenesis, EMT and inflammation in Mdr2 knockout mice

L. Kennedy[1], J. Demieville[2], L. Hargrove[1], V. Meadows[2], G. Alpini[1,2], H. Francis[1,2]. *[1]Texas A&M University HSC COM, Medical Physiology; [2]Central Texas Veteran's Health Care System*
Email: hfrancis@medicine.tamhsc.edu

Background and Aims: Primary sclerosing cholangitis (PSC) is characterized by biliary damage and fibrosis. Multidrug resistance-2 gene knockout ($Mdr2^{-/-}$) mice (i) develop cholestatic liver disease; (ii) mimic some characteristics of human PSC; and (iii) develop hepatocellular cancer (HCC) within one year. We have demonstrated that depletion of the l-histidine decarboxylase/histamine (HDC/HA) axis using 12 week old HDC/Mdr2 double knockout (DKO) mice results in decreased (i) hepatic damage; (ii) MC activation; (iii) biliary mass/proliferation and (iv) hepatic fibrosis/inflammation compared to controls. The **aim** of this study was to determine the effects of loss of the HDC/HA axis on tumor formation and progression in older $Mdr2^{-/-}$ and DKO mice.
Method: 52 week old homozygous DKO mice and aged matched $Mdr2^{-/-}$ mice were utilized. Livers were evaluated for tumor formation and lobular damage by H&E staining. In total liver we evaluated: (i) HDC/histamine receptor (HR) expression by qPCR, (ii) MC activation by qPCR for chymase, tryptase and c-Kit expression and (iii) ductular reaction by CK-19 and Ki67 immunohistochemistry. Changes in liver fibrosis were evaluated by Sirius red staining in liver sections, and qPCR for α-SMA and collagen-type 1a. Hepatic stellate cell (HSC) activation was determined by immunofluorescence and qPCR for SYP-9. Inflammation was evaluated by expression of IL-6 and TNF-α and by immunohistochemistry for F4/80. HA serum levels were measured by EIA. In livers and tumors (when present), we evaluated angiogenesis by VEGF and vWF gene expression and epithelial-mesenchmyal transition (EMT) by immunohistochemistry for vimentin and E-cadherin.
Results: Depletion of the HDC/HA axis in 52 week old DKO mice resulted in little to no tumor formation compared to -matched $Mdr2^{-/-}$ mice, which displayed large HCC tumors. The HDC/HA/HR axis and MC activation were reduced in DKO mice compared to controls. Ductular reaction and hepatic fibrosis were increased in $Mdr2^{-/-}$ mice, but were reduced in DKO mice. Further, angiogenesis, EMT, and inflammation were all reduced in DKO compared to age-matched $Mdr2^{-/-}$ mice.



Conclusion: Our data demonstrates that depletion of the HDC/HA axis blunts tumor growth and progression in $Mdr2^{-/-}$ mice. Therefore, the HDC/HA axis plays a critical role in promoting hepatic damage and tumor formation, and drugs targeting this axis may result in amelioration of disease.

SAT-172

High miR-224 expression in cholangiocarcinoma may predict survival

T. Szekerczés[1], I. Coati[2], M. Fassan[3], K. Schlachter[4], G. Lendvai[1], E. Szabó[1], M. Csengeri[1], Á. Rácz[1], K. Borka[1], Z. Schaff[1], A. Kiss[1].
[1]Semmelweis University, 2nd Department of Pathology, Budapest, Hungary; [2]University of Padua, Department of Medicine, Surgical Pathology Unit, Budapest, Hungary; [3]University of Padua, Department of Medicine, Surgical Pathology Unit, Padua, Italy; [4]National Institute of Oncology, Budapest, Hungary
Email: szekerczes.timea@med.semmelweis-univ.hu

Background and Aims: Primary liver tumours display profound dysregulation in their microRNA (miR) profiles as compared to normal liver. miR-224 is one of the most frequently analyzed miRs implicated in carcinogenesis which has demonstrated elevated expression in malignancies, such as in hepatocellular carcinoma (HCC). Information on miR-224 is limited in cholangiocarcinoma (CC), therefore our objective was to determine the expression of miR-224 in CC and make comparisons with the levels of miR-224 detected in HCC and non-malignant liver lesions.
Method: Altogether 275 samples were analysed, including 43 cases of HCC and the matched surrounding liver tissues, 63 CCs and 51 matching surrounding tissues, 13 hepatocellular adenomas (HCA), 15 focal nodular hyperplasias (FNH) and 47 normal tissues. From these samples a total of 12 tissue multi-arrays were created. The miR-224 expression was determined by *in situ* hybridization using a 5′ digoxigenin-tagged LNA probe (Exiqon) on the established tissue microarrays. The intensity of cytoplasmic miR-224 expression was semi-quantitatively categorized as negative, low, moderate (expression in <50% of the cells) and high (from moderate to strong expression in most of the cells). For statistical analyses, nonparametric Mann-Whitney test and Wilcoxon rank test were applied along with Kaplan-Meier method for generating survival curves.
Results: In comparison to normal liver, increased miR-224 level was found in HCC, HCA and FNH ($p < 0.01$). Elevated miR-224 expression was detected in CC when compared with normal and surrounding tissues ($p < 0.01$). CC showed the highest miR-224 expression when compared with the other investigated liver lesions ($p < 0.01$). Regarding etiology, miR-224 expression was significantly different in hepatitis C virus-associated HCC and HCC of unknown origin as compared to their corresponding surrounding liver. Furthermore, high miR-224 expression level was found to be associated with shorter overall survival in CC patients as compared with patients with low miR-224 levels.
Conclusion: The highest miR-224 expression was detected in CC when compared with HCC, HCA and FNH. The association between high level of miR-224 and shorter survival indicates that it might play an important role as a regulator determining the prognosis of CC.
Financial support: This study was funded by grants from OTKA K108548 from the National Scientific Research Fund.

SAT-174

Do extracellular vesicles secreted from senescent hepatic stellate cells promote or suppress cancer development?

Y. Miyazoe, S. Miuma, Y. Kanda, H. Shibata, H. Miyaaki, N. Taura, K. Nakao. *Nagasaki University Hospital, Department of Gastroenterology and Hepatology, Nagasaki*
Email: yurieast10@hotmail.com

Background and Aims: A recent study indicated that senescent hepatic stellate cells (HSCs) promoted hepatocellular carcinoma (HCC) development by the senescence-associated secretory phenotype (SASP). The effect of senescent HSCs on HCC development has been significant and is currently undergoing intense research. Similar to cytokines induced by SASP, extracellular vesicles (EVs) are important mediators of intracellular communication. However, the role of EVs secreted from senescent HSCs in HCC development is poorly understood. This study aimed to elucidate the characteristics of EVs secreted from senescent HSCs.
Method: Cellular senescence was induced by treating human HSCs (HHSteCs) with etoposide. To confirm cellular senescence, cell cycles were analyzed using 5-ethynyldeoxyuridine (EdU) staining, and 53BP1 and p21 expressions were observed by immunostaining. EVs secreted from HHSteCs were isolated using ultracentrifugation. Qualitative and quantitative changes in EVs secreted from senescent HHSteCs were examined using nanoparticle tracking and microRNA array analyses. Furthermore, we examined the incorporation of EVs secreted from HHSteCs into hepatoma cell lines (Huh7 and HepG2 cells), and these effects on hepatoma cell line proliferation by the co-cultivation of hepatoma cell lines with EVs.
Results: After examining various treatment periods and concentrations of etoposide, we found that the treatment with 25 mM etoposide for 3 days induced senescence in most HHSteCs, showing irreversible cell-cycle arrest and elevated 53BP1 and p21 expressions. The mRNA expression levels of SASP-related cytokines, including IL-8, IL-6, and ICAM-1, were elevated in senescent HHSteCs.
Nanoparticle tracking analysis revealed that EV secretion was higher in senescent HHSteCs than in normal HHSteCs. There was a difference between the microRNA profile of EVs secreted from senescent HHSteCs and those from normal HHSteCs. Co-cultivation of hepatoma cell lines with EVs demonstrated the incorporation of PKH67-labeled EVs into hepatoma cell lines. Furthermore, EVs secreted from senescent HHSteCs decreased hepatoma cells proliferation compared with those from normal HHSteCs.
Conclusion: EVs secreted from senescent HSCs exhibited different characteristics compared with those secreted from normal HSCs and may suppress cancer cell proliferation. Furthermore, we evaluated the impact of EVs secreted from senescent HHSteCs on the mRNA expression in hepatoma cell lines.

Email: ruben.plentz@klinikum-bremen-nord.de

Background and Aims: Cholangiocarcinoma (CC) is the second common hepatic malignancy. Combination of Gemcitabine and Cisplastin is currently the first line treatment for inoperable patients. However, new molecular therapies are needed. Interleukin 6 (IL-6) is an anti-inflammation cytokine that operates survival in various non-solid cancers: lymphoma, myeloma, leukemia… but the anti-cancer effect of IL-6 inhibitor on CC is not totally known yet. The aims of this project are to analyze the role of IL-6 during cholangiocarcinogenesis and the effect of Siltuximab, an IL-6 antibody *in vitro, in vivo.*
Method: Extra- (TFK1) and intra-hepatic CC (SZ1) cell lines were treated with different concentrations of Siltuximab, followed by observation on invasion (2D and 3D culture models), senescence and signalling transformation. Western Blot targeting p.STAT3, EMT markers, p.Akt, Wnt/β-Catenin was performed. RT-qPCR was applied to compare IL-6 mRNA expression in CC tumours and normal livers of CC engineered mice (Alb-Cre/LSL- $KRAS^{G12D}$/$p53^{L/L}$,

n = 7). Xenograft mice were used to investigate anti-cancer effect of Siltuximab *in vivo*.
Results: Siltuximab treatment resulted in deceleration of 2D and 3D cell invasion, IL-6 mRNA and acceleration senescence. Siltuximab led to down-regulation of p.STAT3, Wnt/β-Catenin, EMT markers and up-regulation of p.Akt. On engineered mice, the expression of IL-6 mRNA in tumour tissues was significantly higher than that in adjacent normal livers. The level of mRNA IL-6 in tumours was correlated with tumour volume. On the xenograft model, Siltuximab-treated mice showed smaller tumours than control animals.
Conclusion: IL-6 plays important role in cholangiocarcinogenesis and Siltuximab might become a promising therapy for CC.

Exosome derived from miR-199*-modified adipose tissue-derived MSCs increase chemosensitivity of hepatocellular carcinoma

G. Lou, Y. Liu, T. Zhang, S. Li, Z. Chen, M. Zheng. *State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital of School of Medicine, Zhejiang University, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Zhejiang University, Hangzhou, China*
Email: minzheng@zju.edu.cn

Background and Aims: Hepatocellular carcinoma (HCC) displays high resistance to conventional chemotherapy. Considering the chemotherapeutic sensitization effect of miR-199*, an effective vehicle-mediated miR-199a* delivery system may supply a new strategy for improving HCC chemotherapy. Recently, exosomes as biological vehicles have been developed to deliver oligonucleotides including miRNA. Mesenchymal stem cells (MSCs) can produce large amounts of exosomes and are easy to be genetically modified, Therefore, it is an excellent genetic modify carrier production tools. This study was aimed to determine whether adipose tissue-derived MSC (AMSC) exosomes can be used for miR-199* delivery and improving the HCC chemotherapy.

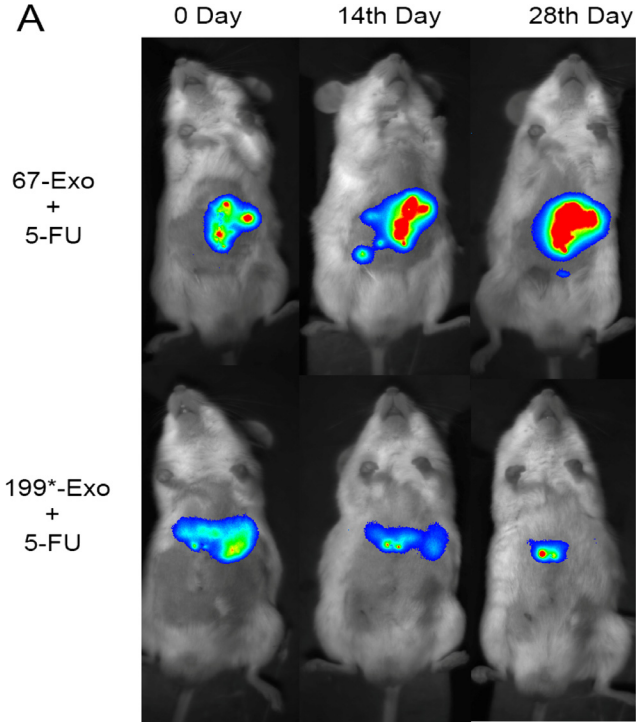

Figure 1: Tail vein injection of 199*-Exo significantly increased the antitumor efficacy of 5-FU on HCC in situ implant model in vivo. A: Imaging of mice at the 0 day, 14th day and 28th day.

Method: miR-199* plasmid was transfected into AMSCs, after 48h incubating, exosomes (199*-Exo) were harvested and added to recipient HCC cells. Expression levels of miR-199* in AMSCs, exosomes, and HCC cells were quantified by real-time PCR. The protein levels of miR-199*-target genes in recipient HCC cells were quantified by Western blot. The effects of 199*-Exo on cell viability, apoptosis of HCC cells were evaluated by MTT and flow cytometry analysis. Xenograft models were used to determine whether 199*-Exo can sensitize HCC cells to 5-FU in vivo.
Results: Data showed that the AMSC transfected with miR-199* can effectively package miR-199* into secreted exosomes, which can mediate miR-199* communication between AMSCs and HCC cells, and it render HCC cells sensitive to chemotherapeutic agents through alteration of miR-199*-target gene expression. Moreover, Tail vein injection of 199*-Exo significantly increased the anti-tumor efficacy of 5-FU on HCC in situ implant model in vivo.
Conclusion: The findings suggest that the export of miR-199* via AMSC exosomes represents a novel strategy to sensitive HCC chemotherapy.

SAT-177

A new insight on the stem cell growth factor beta as astrong predictor of therapy response in hepatocellular carcinoma

C. Sukowati[1], R. Patti[2,3], D. Pascut[1], R.B. Ladju[1,4], P. Tarchi[5], N. Zanotta[6], M. Comar[6], C. Tiribelli[1], L. Crocè[1,2,7]. *[1]Fondazione Italiana Fegato, Trieste, Italy; [2]University of Trieste, Medical Science Department, Trieste, Italy; [3]ASUITS Cattinara Hospital, Liver Disease Unit, Trieste, Italy; [4]University of Hasanuddin, Faculty of Medicine, Makassar, Indonesia; [5]ASUITS Cattinara Hospital, Department of General Surgery, Trieste, Italy; [6]IRCCS "Burlo Garofolo", Institute for Maternal and Child Health, Trieste, Italy; [7]ASUITS Cattinara Hospital, Liver DIsease Unit, Trieste, Italy*
Email: rpatti@units.it

Background and Aims: Inflammatory molecules such as cytokines and growth factors are important factors in the development of hepatocellular carcinoma (HCC). The stem cell growth factor beta (SCGFβ), a newly found protein, is a secreted glycoprotein functions as a growth factor for primitive hematopoietic progenitor cells. The level SCGFβ was elevated in several cancer types, but there is no information on this protein in the clinical study of HCC. The aim of this study is to investigate inflammatory biomarkers in predicting the responsiveness of therapy in HCC patients receiving radiofrequency ablation (RF) or trans-arterial chemoembolization (TACE) with focus on the SCGFβ.
Method: A multiplex immunoassay panel of 48 cytokines and growth factors were used to screen 64 sera from 29 patients (age mean 72 ± 7 y.o, M22/F7, 9 HCV and 20 alcohol/metabolic) at pre-treatment (T0) and 1 month (T1) after RF (n = 15) or TACE (n = 14) treatment. A quantitative real time PCR was performed to analyze gene expression of CLEC11A (SCGF) from 37 PBMC isolates. Diagnosis of HCC was established based on radiologic findings according to EASL criteria and treatment response was evaluated according to mRECIST criteria. Statistical analysis was performed by using SPSS program for non-parametric test (Whitney-Mann) and T-test.
Results: At T0, different factors including cytokines IL-8 ($p < 0.01$), IL-15, IL-12p40, IL-17 ($p < 0.05$), and growth factor SCGFβ ($p < 0.01$) could distinguish responders to non-responders. At T0 and T1, SCGFβ could predict good response (complete response, partial response *vs* stable disease, and progression of disease). Its concentration was highest in non-responders, followed by early recurrence, and the lowest in complete responders, independently from HCV, BCLC stage, and type of treatment. Low SCGF level seemed to be correlated with longer disease-free survival. Analysis of PBMC isolates showed the up-regulation of CLEC11A (SCGF) mRNA expression at the T1 only in non-responders. This pattern was confirmed by using 8 paired samples. CLEC11A T1/T0 ratio was low (0.4 ± 0.2 fold) in responders, while it was almost three times higher (1.4 ± 0.8 fold) in non-responders patients ($p < 0.05$).

Conclusion: In this study, for the first time, we demonstrate that the high level of serum SCGFβ and mRNA expression of PBMC SCGF at pre- and post-treatment is associated with HCC non-responsiveness. SCGFβ can be a potential molecule as HCC prognostic factor and a target of future therapy.

Disrupted cholesterol synthesis leads to female prevalent hepatocellular carcinoma in transgenic mice

K.B. Cokan[1], M. Perše[2], J. Jeruc[2], G. Lorbek[1], Ž. Urlep[1], P. Juvan[3], N. Nadižar[1], U.P. Zmrzljak[1], D. Rozman[1]. [1]*Centre for Functional Genomics and Bio-Chips, Institute of Biochemistry, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, Ljubljana, Slovenia;* [2]*Medical Experimental Centre, Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, Ljubljana, Slovenia;* [3]*Centre for Functional Genomics and Bio-Chips, Institute of Biochemistry, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, Slovenia*
Email: kaja.blagotinsek@mf.uni-lj.si

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most common cancers worldwide. Although the principal causes of its development are infection with hepatitis virus B or C and alcoholism, the non-alcoholic fatty liver disease (NAFLD) is becoming increasingly important for tumor development. About 20% of HCC evolves from NAFLD due to chronic inflammation and by oxidative stress induced fibrosis that could be activated with metabolic dysfunction. We have shown previously that disrupted cholesterol synthesis leads to severe liver injury with oval cell response and fibrosis that becomes visible in young adults and is progressing in adulthood [Urlep Ž., et al, 2017; Lorbek G., et al, 2015]. The aim of this study is to investigate the consequences of this metabolic insult during the aging.
Method: We applied the knockout (KO) mouse model of lanosterol 14α-demethylase (Cyp51) from the late part of cholesterol synthesis. Histopathology was performed on liver sections. Hepatic gene expression was assessed by expression profiling and qPCR. We measured biochemical parameters in plasma. Data were analysed by R, Bioconductor and linear regression modelling.
Results: First HCC cases were observed in livers of 1 year KO mice that also showed advanced fibrosis and oval cell response which was not significantly different from the 19-week mice. At 2 years the prevalence for tumors was 3-times higher for females. Histologically, hepatocyte *Cyp51* ablation was characterized by the sustained strong inflammation, ductular proliferation and fibrosis. The hepatocellular damage could be confirmed with elevated ALT/AST ratio.
The transcriptome data in KO mice clearly indicate up-regulated pathways in cancer and extracellular matrix interaction while multiple metabolic pathways were severely dampened, including the RORC signalling due to the lack of sterol ligands. Diminished was also the activity of transcription factors involved in the cell cycle control, circadian gene regulation and liver regeneration. Some of enriched genes and transcription factors in females suggest higher susceptibility to carcinogenesis.
Conclusion: Disturbed cholesterol synthesis leads to hepatocellular carcinoma during the aging of mice. The injury caused by blocked cholesterol synthesis activates Sox-9, which plays an important role in regulation of cell growth and differentiation. Its possible association with Wnt signalling could lead to higher susceptibility for tumor development in older females.

SAT-179

Impact of Trp53 on tumor heterogeneity in the background of liver fibrosis

U.T. Mathada, M. Svinarenko, N. Bushart, K. Steding, L. in der Stroth, T. Seufferlein, R. Schirmbeck, A. Lechel. *University Hospital Ulm, Department of Internal Medicine I, Ulm, Germany*
Email: andre.lechel@uni-ulm.de

Background and Aims: Cellular complexity along with molecular heterogeneity makes liver cancer as one of the most aggressive malignancies globally. With the global incidence rate of 782,451 new cases and 745,533 related deaths brings liver cancer to 6th most common cancer and 2nd most cancer-related deaths. Association of various risk factors from viral infections to metabolic diseases have an impact on the liver cancer initiation. In combination with *Tp53* mutation, they drive tumor progression and affects tumor differentiation. Liver fibrosis formation is an indication of ongoing liver damage and repair mechanism. Chronic liver fibrosis leads to cirrhosis and possesses itself a risk for liver cancer. Combination of disrupted p53 pathway and persistent fibrosis on liver cancer incidence and tumor differentiation is not yet well understood.
Method: We analysed tumor heterogeneity in the background of liver fibrosis and p53 deletion. For this purpose, we chose a conditional *Trp53* KO mouse, crossed with a liver-specific Cre-driver strain (*AlfpCre*). To modulate liver fibrosis formation we injected mice from 6 weeks of age for a time period of 4 months with CCl_4. We monitored the mice at 6, 9, 12 and14 months for liver fibrosis and liver tumor formation. In addition, we also analysed the inflammatory microenvironment.
Results: Liver-specific deletion of *Trp53* alone resulted in the formation of liver cancer at 12–14 month. Majority of the tumors showed tumor differentiation towards combined hepatocellular-intrahepatic cholangiocarcinoma (HCC/iCC, 80%). Interestingly, liver tumors arise in the background of *Trp53* deletion were without formation of liver fibrosis. *Trp53*−/− mice with CCl_4 treatment resulted in a dramatic increase in tumor formation and impaired survival due to an early tumor onset with 6 month of age compared to *Trp53*+/+ mice and *Trp53*−/− mice without treatment. Tumor differentiation is shifted to HCC formation upon induction of fibrosis.
Conclusion: Liver fibrosis is an important risk factor for early tumor development. Tumor heterogeneity is influenced by liver fibrosis formation in the background of *Trp53* deletion.

SAT-180

Sorafenib/Regorafenib resistance and BH3-mimetics efficacy in hepatocellular carcinoma treatment is determined by mitochondrial changes in the BCL-2 profile

A. Tutusaus[1,2], M. Stefanovic[2,3], B. Cucarull[1,2], M. Mari[1,2], L. Boix[2,4], M. Reig[2,4], J. Bruix[2,4], A. Morales[1,2,4]. [1]*Institut d'Investigacions Biomèdiques de Barcelona, Barcelona, Spain;* [2]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain;* [3]*Institut Català d'Oncologia (ICO), L'Hospitalet de Llobregat, Spain;* [4]*Barcelona clínic liver cancer, Barcelona, Spain*
Email: amorales@clinic.ub.es

Background and Aims: The multi-kinase inhibitor sorafenib has limited efficacy in the treatment of advanced hepatocellular carcinoma (HCC) and sorafenib resistance favours its clinical failure. The mitochondrial damage induced by sorafenib is known. Changes in BCL-2 proteins alter the effectiveness of BH3-mimetics, inhibitors of specific Bcl-2 proteins, in killing cancer cells. Regorafenib usage as second-line treatment after sorafenib failure has been recently approved. The influence of sorafenib and regorafenib on BCL-2 family expression may suggest potential treatment options that have not been thoroughly explored.
Method: Hepatoma cell lines sensitive or resistant to sorafenib (HepG2 and Hep3B) were treated with sorafenib and BH3-mimetics (ABT-263: BCL-2 and BCL-XL, ABT-199: BCL-2, A-1331852: BCL-xL). Western blots and qPCR were performed. Mitochondrial functionality, caspase activation and induction of apoptosis were analyzed in hepatoma cells treated with sorafenib/regorafenib. Tumor growth was determined in mouse xenografts after subcutaneous injection of HepG2 and BCLC9 cells, treated with sorafenib and/or ABT-263. In mRNA samples from control individuals (n = 10) and HCC patients (HCV/EtOH, n = 14) BCL-2 and MCL-1 expression was analyzed in tumoral and non-tumoral tissue.

Results: Sorafenib-resistant Hep3B and HepG2cells showed upregulated BCL-2/MCL-1 ratio facilitating mitochondria-dependent cell death by BH3-mimetics. ABT-263 recovered sorafenib toxicity in vitro and in sorafenib-resistant xenografts, while ABT-199, a specific BCL-2 inhibitor, or A-1331852, a specific BCL-xL inhibitor was less effective, underlining the importance of simultaneous inhibition of BCL-2/BCL-xL. Moreover, in mice xenografts from patient-derived BCLC9 cells, ABT-263 improved sorafenib effectiveness without enhanced inflammatory reaction, being tumor response dependent on the BCL-2/MCL-1 ratio. Of note, HCC patients displayed increased BCL-2/MCL-1 mRNA levels respect to adjacent non-tumoral biopsies. Finally, similar modification of BCL-2/MCL-1 ratio was detected after regorafenib administration to hepatoma cells. Consistently, navitoclax also sensitized hepatoma cells to regorafenib by a mitochondrial caspase-dependent mechanism.
Conclusion: Sorafenib, and regorafenib treatment, by increasing the BCL-2/MCL-1 ratio in HCC, sensitizes drug resistant-tumors against ABT-263 co-administration. Moreover, the anti-apoptotic BCL-2 profile, which is altered in HCC patients, modifies sorafenib/regorafenib efficacy. Tumor anomalies in the BCL-2 profile of particular patients suggest the use of specific BH3-mimetics for combined therapy in HCC treatment.

Maldi imaging of hepatocholangiocarcinomas: A clue to tackle tumor heterogeneity preliminary results

E. Gigante[1], R. Casadonte[2], J. Le Faouder[1], N. Poté[3], M. Albuquerque[1], O. Soubrane[4], V. Paradis[1,3]. *[1]Centre de Recherche sur l'inflammation, UMR 1149, INSERM-Paris Diderot University, Paris, France; [2]Proteopath GmbH, Trier, Germany; [3]Department of Pathology, Beaujon Hospital, Assistance Publique-Hôpitaux de Paris, Clichy, France; [4]Department of Liver Transplantation and Hepatobiliary Surgery, Beaujon Hospital, Assistance Publique-Hôpitaux de Paris, Clichy, France*
Email: elia.gigante@hotmail.it

Background and Aims: Hepatocholangiocarcinomas (H-ChCs), are mixed primary tumors of the liver, defined by the presence of hepatocellular carcinoma (HCC) and cholangiocarcinoma (CC) components that may display stem cell features. Accordingly, H-ChC represents the most illustrative heterogeneous liver malignancies. Its tumoral heterogeneity hampers molecular analysis that may provide various signatures according to the area analyzed. The aim of this study was to assess the peptidic profiles of the different morphological patterns constitutive of H-ChC by MALDI imaging, an in situ approach able to connect molecular profiles with specific histological features, without preliminary step of molecular extraction or labeling.
Method: MALDI imaging (RapifleX and Autoflex III MALDI, Bruker Daltonik GmbH) was applied on paraffin tumor sections of tissues microarrays (TMAs) built from 60 surgical cases of H-ChC. Entire tissue sections of selected cases were also analyzed (10 cases). Peptidic spectra were obtained from the different tumor patterns constitutive of H-ChC as well as from CC (n = 29) and HCC (n = 23) and the most discriminant peaks were identified.
Results: Rich peptides spectra were obtained from all tumor cases tested, with more than 90 peptides peaks identified. The comparison of the relative intensities of each m/z value (peptidic peak) between the three tumor types (H-ChC, HCC, CC) revealed 19 discriminant peaks exhibiting a statistical significance. They showed a receiver operating curve (ROC) curve superior to 0.7 in the identification of H-ChCs when applied on cases and controls (Example, peak 1466 in Figure 1). Comparative analysis of H-ChC cases showed great heterogeneity (1) from case to case (Figure 1 lanes 1 and 2 compared to lanes 3 to 5), (2) within case from different areas of the tumor (Figure 1 lanes 2 and 3), and (3) within case from a single tumor area (Figure 1 lane 1).

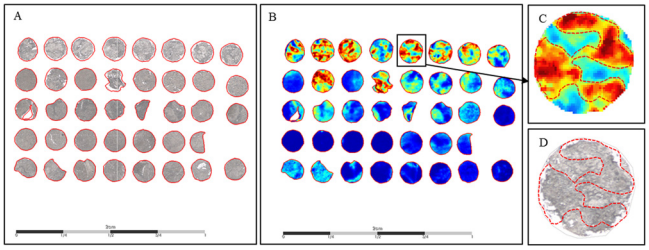

Figure 1: Expression of m/z 1466 peak on a TMA. Each lane corresponds to a H-ChC case. (A) Optical image, (B) ion density map of peak 1466, (C) magnification of core 5, showing an enhanced intensity of m/z 1466 in specific tumoral zones (D) optical image, core 5, tumoral zones are highlighted in red discontinuous line.

Conclusion: This preliminary study demonstrates that MALDI imaging is a powerful tool for providing peptidic signatures from formalin fixed paraffin-embedded tumor samples. In addition, it confirms that H-ChCs are highly heterogeneous at the molecular level both at the inter and intratumoral scale. The identification of the proteins specifically associated with the different tumor components is currently ongoing.

SAT-182
HBx/DLEU2/EZH2 co-regulation of host genes expression in HCC

F. Guerrieri[1], D. Salerno[1], L. Chiodo[2], G. Cottone[3,4], M. Pallocca[5], O. Floriot[6], M. Levrero[6,7]. *[1]Istituto Italiano di Tecnologia, Center for Life NanoScience@Sapienza, Rome, Italy; [2]Università Campus Bio-Medico, Department of Engineering, Unit of Nonlinear Physics and Mathematical Modeling, Rome, Italy; [3]University College Dublin School of Physics, School of Physics, Dublin, Ireland; [4]University of Palermo, Department of Physics and Chemistry, Palermo, Italy; [5]Regina Elena National Cancer Institute, UOSD SAFU, Roma, Italy; [6]INSERM, Cancer Research Center of Lyon (CRCL), INSERM U1052, Lyon, France; [7]Service d'Hepatologie et Gastroenterologie, Hospices Civils de Lyon, Lyon, France*
Email: massimo.levrero@gmail.com

Background and Aims: HBx regulatory protein is required for HBV cccDNA transcription/viral replication and contributes to HBV oncogenicity. HBx affects the epigenetic control of HBV viral chromatin as well as of cellular chromatin. We previously showed by RNA Immune Precipitation (RIP) that HBx binds the DLEU2 lncRNA and that DLEU2 affects viral chromatin transcription. The association of Ezh2 with lncRNAs has been shown to guide Ezh2 interaction with target genes to modulate transcription in cis and in trans. Aim of this study is to verify the formation of HBx-DLEU2-EZH2 complexes and to clarify their role in the regulation of cellular target genes in human primary hepatocytes (PHH) and HepG2-NTCP infected by HBV-infection.
Method: Chromatin Immune Precipitaion (ChIP), Chromatin Isolation by RNA Precipitation (ChIRP) and RIP were analyzed by TaqMan real-time PCR. The nCounter Nanostring technology and real-time RT-PCR were used to evaluate gene and lncRNAs expression. Specific LNA™ longRNA GapmeRs (Exiqon) were used for highly efficient inhibition of DLEU2 lncRNA functions.
Results: In silico analysis of a new model of HBx protein tertiary structure, EZH2 protein and DLEU2 tertiary structure suggested a direct interaction of all three players. RIP experiments confirmed HBx-DLEU2 and EZH2-DLEU2 interactions *in vivo*. HBx activates the promoter of the DLEU2 host gene TRIM13 and, in the absence of HBx, both EZH2 binding and H3me3K27 increase at the TRIM13 promoter. ChIP and a ChIRP experiments showed that HBx and DLEU2 RNA bind to the TRIM13 promoter. Selective degradation of DLEU2 RNA indeed resulted in reduced H4 acetylation on the TRIM13 promoter and a ~50% reduction of TRIM13 expression in HBV replicating PHH. EZH2

inhibitors increase TRIM13 expression. Thus, HBx/DLEU2/EZH2 complexes co-regulate TRIM13 expression. In addition to TRIM13, 260 additional genes were co-regulated with DLEU2 RNA in HBV-related HCC patients and 70 out of them were previously identified as direct HBx targets in ChIP-Seq experiments. We validated CCNB2 as a second direct target of the HBx-DLEU2-EZH2 complex by anti-HBx ChIP and anti-DLEU2 ChIRP.
Conclusion: Ezh2/PRC2 interaction with DLEU2 inhibits Ezh2 activity without altering Ezh2 promoter occupancy. The concomitant increase in DLEU2 and HBx recruitment in HBV replicating cells and in HBV-related HCCs, further increase transcription and freeze the promoters of a subset of Ezh2/PRC2 target genes in an active state.

SAT-183

Aspecific ECM composition regulates Smad dependent – TGFbeta1–induced EMT response in HepG2 cells engineered in cirrhotic and healthyliver 3D scaffolds

M. Marrali[1,2], A. Telese[2], K. Bottcher[2], L. Frenguelli[2], W. Al-Akkad[2], G. Mazza[2], M. Pinzani[2], K. Rombouts[2]. *[1]Engitix Ltd, London, United Kingdom; [2]University College London, Institute for Liver and Digestive Health, London, United Kingdom*
Email: k.rombouts@ucl.ac.uk

Background and Aims: Hepatocellular carcinoma (HCC) is the second cause of cancer deaths motivating the investigation of new therapeutic targets to provide alternative treatments. Recent studies highlight the role of the ECM microenvironment in modulating cancer development. A new 3D model was developed by using decellularized human liver which maintains the original tissue-specific 3D architecture and properties. TGFbeta1 prompts the progression of HCC through activation of the SMAD2/3 signalling pathway. This study investigates the effect of cirrhotic and healthy ECM on TGFbeta1-SMAD2/3 signalling in EMT-related HCC cell behaviour and on the assessment of drug sensitivity.
Method: Human liver 3D scaffolds were obtained decellularizing healthy and cirrhotic human livers. Scaffolds were repopulated with HepG2 cells (2 × 10*6) for 7 days followed by TGFbeta1 (5–10 ng/ml) treatment. Protein expression was assessed for P-SMAD2/3, SMAD2/3 and albumin. Changes in TGFbeta1 response were investigated by pre-treatment/treatment with TGFbetaR1 kinase inhibitor Galunisertib (10 μM) for 48hrs. To investigate the non-canonical TGFbeta1 pathway in HCC, Erk/P-Erk and Akt/P-Akt expression was assessed in HepG2 cells cultured on cirrhotic and healthy scaffolds.
Results: P-SMAD3 had a low expression in HepG2 cells cultured on healthy scaffolds while being highly expressed on cirrhotic scaffolds. In contrast, P-SMAD2 had a low expression in HepG2 cells cultured on cirrhotic scaffolds, while being upregulated in healthy scaffolds. SMAD2/3 proteins were expressed in HepG2 cells cultured on both cirrhotic and healthy scaffolds. Each protein was differently affected by exogenous TGFbeta1 treatment. Pre/simultaneous treatment of TGFbeta1 with Galunisertib affected protein expression depending on the ECM-scaffold used. TGFbeta1-Galunisertib treatment reduced albumin protein expression in HepG2 cultured on cirrhotic scaffolds. Erk protein expression was similar on both types of scaffolds, while Akt showed a higher expression on healthy scaffolds. Uptake/release of TGFbeta1 showed marked differences between healthy and cirrhotic scaffolds.
Conclusion: This study suggests that the ECM composition of the 3D liver scaffold itself can affect protein expression which can be further modified by TGFbeta1 treatment. Although inhibiting the TGFbeta1 signaling pathway alone may not be sufficient, as the tumor ECM microenvironment seems to play a major role, this study suggests that TGFbeta1 and its canonical signaling pathway represent potential targets for the treatment of HCC.

SAT-184

Analysis of HBV DNA integration in tumor and non-tumor liver tissues by a high-throughput viral integration detection method

D. D'aliberti[1], D. Giosa[1], G. Raffa[1], C. Musolino[1], G. Tripodi[1], D. Lombardo[1], F.C.D. Tocco[1], C. Saitta[1], O. Romeo[2], G. Navarra[3], G. Raimondo[1], T. Pollicino[3]. *[1]University Hospital of Messina, Clinical and Experimental Medicine, Messina, Italy; [2]University of Messina, ChiBioFarAm, Messina, Italy; [3]University Hospital of Messina, Human Pathology, Messina, Italy*
Email: tpollicino@unime.it

Background and Aims: HBV DNA integration is found in about 85% of HCC. Most of the data on HBV integration have been generated by specific restriction enzymes and cloning methods that may favor preferential amplification and bias identification of unique integration sites. The more recent next-generation sequencing (NGSs) approaches show a low coverage of HBV reads. Aims of this study were to conduct a high-throughput viral integration detection analysis on tumor (T) and non-tumor (NT) liver tissues, and on PLC/PRF/5 cells, using NGS of enriched HBV integrants, and to identify HBV junctures at the whole-transcriptome level.
Method: A total of 108 integration libraries were constructed from liver genomes of 4 HCC patients and PLC/PRF/5 cells. Each experiment was performed on fragmented genomic DNA by sonication. DNA was blunted and adenosine-tailed. A-tailed DNA fragments were ligated to Linkers. Virus integration sites were recovered by semi-nested PCR using 24 different HBV primers specific to the Core, X, Pol, and Pre-S/S regions. PCR products were paired-end sequenced on Illumina MiSeq. RNA-Seq was performed on an Illumina HiSeq 2500 platform. High-quality reads were mapped with BWA software against hybrid reference including the human genome reference GRCh38.p10 and HBV genome (NC_003977).
Results: A total of 7,536 HBV integration breakpoints were detected (5,186 in T, 2,071 in NT, and 279 in cells). Among them, 3,912 could be mapped to unique sites on human chromosomal DNA (3,157 in T, 484 in NT, and 271 in cells). In particular, 632 integrations occurred at level of exons (601 in T, 31 in NT, and 1 in cells). The remaining 3,624 of 7,536 integrations were located in repeated DNA sequences. The majority in LINE (21.4%), SINE (16.4), and LTR (24%). An enrichment of microhomology sequences between host DNA and integrated HBV DNA was found at the site of integration in a high percentage of chimeras (27%–97%) from each sample. PreS-S genomic sequences and the ENHI/X promoter region were the most frequent HBV integrants detected. RNA-Seq specifically confirmed the production of viral/human fusion transcripts (HBs-CCDC57 fusion in PLC/PRF/5 cells, HBx-LINE/L1 and HBs-PTPRD fusions in 2 different T samples.)
Conclusion: We developed a high-throughput viral integration detection method that allow characterizing the landscape of HBV integration events in host genome, and to identify viral-human chimeric fusion genes that my be involved in HCC development.

SAT-185

New targets for hepatocellular carcinoma therapy: the Myc/PRMT5/RNAP II circuit

C. Porcu[1], B. Illi[2], S. Nasi[2], S. Tavolaro[1], C. Balsano[1]. *[1]University of L'Aquila, Italy, Department of Life, Health & Environmental Sciences MESVA, L'Aquila, Italy; [2]CNR, IBPM, Rome, Italy*
Email: clara.balsano@cc.univaq.it

Background and Aims: HCC is highly heterogeneous from both a genomic and etiologic point of view. Myc deregulation and overexpression represent major mechanisms of tumorigenesis in a variety of cancers, including HCC. Protein arginine methyltransferase 5 (PRMT5) plays a role in chromatin remodelling and control of gene expression by methylating multiple substrates including histones, p53 and RNA Polymerase II (RNAP II). Intriguingly, Myc and PRMT5 rule distinct RNAP II activities like pause release (Myc), transcript termination (PRMT5) and mRNA splicing (both Myc and PRMT5).

Method: Hepatoma cell lines, HepG2 and HuH7, and HEK293T were used to perform in vitro experiments. We evaluated gene expression by RT-PCR, protein levels by western blot. We looked at the binding of myc and PRMT5 by immunoprecipitation (IP) and immunofluorescence analyses.
Results: We demonstrated that HEK293T cells transfected with Myc, showed a prominent increase in histone H4R3me2s. Then, we performed co-immunoprecipitation experiments, both in FlagMyc overexpressing HEK293T and in hepatocarcinoma cells, to assess the formation of a PRMT5/Myc complex. We observed that Myc and PRMT5 are physically and functionally associated.
We asked whether PRMT5 inhibition might affect Myc activation of two specific target genes: carbamoyl-phosphate synthase aspartate-carbamoyltransferase-dihydroorotase 1 (cad1) and cyclin D1 (cycD1). HEK293T cells were cotransfected with a shRNA against COPR5, the nuclear cooperator of PRMT5, to selectively target PRMT5 nuclear activity. Co-transfection of shCOPR5 impaired full transactivation of cad1 and cycD1.
Given the Myc/PRMT5 interaction and the role of Myc in ruling other RNAP II properties, we hypothesized that Myc might play a role in PRMT5-dependent RNAP II methylation. FlagMyc overexpressing HEK293T cells, FlagMyc overexpressing HEK293T cells co-transfected with a shRNA against Myc, and scrambled control cells, were analyzed for RNAP II symmetric dimethylation by immunoprecipitation with an anti-RNAP II antibody and after with a specifically recognizing RNAP II R18010me2s. Myc induces RNAP II symmetric dimethylation, allowing proper termination of transcripts. Moreover, as expected, PRMT5 is associated to RNAP II, but in the presence of low Myc levels, PRMT5 was no longer present in the immunocomplex.
Conclusion: We defined a novel Myc and PRMT5-dependent molecular circuitry, ruling transcription as a whole chromatin domain, elongation, termination, splicing possibly dysregulated in HCC cells.
Our results indicate the Myc/PRMT5/RNAP II axis as a novel druggable target for HCC therapy.

Novel microRNA-based drug CD5–2 reduces liver cancer development in multi-drug-resistance gene-2 knockout mice

K. Liu[1,2,3], Y. Zhao[4], J. Chen[2], J. Gamble[3,4], G. Mccaughan[1,2,3]. *[1]Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Center, Sydney, Australia; [2]Centenary Institute, Liver Injury and Cancer Program, Sydney, Australia; [3]University of Sydney, Sydney Medical School, Sydney, Australia; [4]Centenary Institute, Centre for the Endothelium, Sydney, Australia*
Email: kenliu51@hotmail.com

Background and Aims: Liver cancer is the second commonest cause of cancer death worldwide. Tumours are characterised by abnormal (leaky) vasculature, hypoxia and an immunosuppressive microenvironment. Current treatments for advanced disease are ineffective. Blockmir CD5-2 is an oligonucleotide-based inhibitor of the microRNA27 interaction with VE-Cadherin, the endothelial specific cadherin. Previously we have shown that CD5-2 normalises tumour vasculature by increasing VE-Cadherin expression. We aimed to study the effect of CD5-2 on liver cancer growth, vasculature and immune infiltrate in MDR2-knockout (MDR2KO) mice. MDR2 is essential for biliary phosphatidylcholine excretion and MDR2KO mice spontaneously develop sclerosing cholangitis, liver fibrosis, and liver cancer.
Method: CD5-2 or its control (scrambled Blockmir) was given (30 mg/kg body weight i.v. fortnightly) to MDR2KO mice from age 5-months until sacrifice at age 7-months. Livers from treated (CD5-2 or control), untreated and MDR2 wildtype mice were analysed using immunohistochemistry. Student t-test was used to determine statistical significance.
Results: MicroRNA27 was significantly increased in MDR2 tumours compared to adjacent normal tissue. CD5-2-treated mice had significantly fewer (38% reduction) and smaller liver tumours (26% reduction) compared to control-treated tumours. CD5-2 treatment altered the immune infiltrate. CD5-2-treated tumours had significantly higher CD3+, CD8+ and PD1+ cell numbers compared to control-treated tumours. CD5-2-treated tumours tended to have less CD34 and higher alpha-SMA expression suggesting a trend towards the normal mature vasculature phenotype.
Conclusion: CD5-2 reduces liver tumour number and size in MDR2KO mice possibly by enhancing effector CD8+ T-cell infiltration. This result suggests normalising tumour vasculature using CD5-2 is a promising novel approach to treat liver cancer.

KRAS-dependent AKT signaling drives hepatocyte proliferation to promote tumor development in a genetic model of liver cancer

T. Rösner[1], C. Lechler[1], K.-E. Birgit[1], K. Steiger[2], C. Mogler[2], D. Saur[3], J. Sage[4], R.M. Schmid[1], U. Ehmer[1]. *[1]Klinikum rechts der Isar, Technische Universität München, 81675 Munich, Germany, Department of Medicine II, Munich, Germany; [2]Klinikum rechts der Isar, Technische Universität München, Institute of Pathology and Unit of Comparative Experimental Pathology, Munich, Germany; [3]Klinikum rechts der Isar, Technische Universität München, Department of Medicine II, Munich, Germany; [4]Stanford University, Department of Pediatrics, Stanford, United States*
Email: roesnerthomas@gmx.de

Background and Aims: The identification of key pathways in liver carcinogenesis is a requirement for the development of novel therapies. In a genetic mouse model of liver cancer, we combine liver-specific expression of oncogenic Kras with genetic inactivation of the tumor suppressors *Rb* and p53 to mimic major molecular events in human liver cancer. Gene mutation in adult mice results in the formation of liver tumors resembling human hepatocellular carcinomas (HCC), intrahepatic cholangiocarcinomas (ICC), as well as tumors of mixed differentiation and highly undifferentiated tumor lesions. In this model, RAS-dependent MEK/ERK and AKT signaling are highly activated and likely play a key role in tumor development. Here, we aim to dissect the functional role of these pathways in liver tumor development to identify promising targets for cancer therapy in the context of activated RAS signaling.
Method: To examine the relevance of AKT signaling *in vivo* we activated Cre in hepatocytes of adult $Rb^{lox/lox}$;$p53^{lox/lox}$;$Kras^{LSL-G12D/+}$ (*RPK*) and *RPK*;$Pdk1^{lox/lox}$ mice via CreER-transposon constructs or an albumin-driven CreER. Liver samples, microdissected tumor lesions, and metastases were analyzed for mRNA and protein expression.
Results: Immunohistochemistry of *RPK* tumors shows an overall activation of both $pAKT^{Thr308}$ and pERK at early timepoints and in advanced tumors, indicating increased activity of PDK1 and MEK during Ras-driven tumor development. Genetic knock-out of *Pdk1* in *RPK*;$Pdk1^{lox/lox}$ mice results in decreased hepatocyte proliferation at early timepoints *in vivo*. Investigation of survival proportions shows longer survival as well as reduced tumor formation and metastasis development of *RPK*;$Pdk1^{lox/lox}$ mice in comparison to *RPK*-mice.
Conclusion: Altered RAS signaling is found in the majority of human HCC and ICC with poor prognosis. In our model, Kras-dependent AKT-signaling appears to act as one of the key drivers in hepatic carcinogenesis with impact on early proliferation of transformed cells, tumor and metastasis development. Inhibition of activated PDK1/PI3K/AKT signaling might therefore be a promising approach in the treatment of primary liver cancer with activated Kras signaling. The role of other Ras-dependent pathways for the development of liver tumors and their metastatic potential is under further investigation.

SAT-188

The impact of the epigenetic writer LSD1in the cell cycle control in liver fibrosis and hepatocellular carcinoma

L. Wang, X. Yu, M. Schmiel, L. Steinheuer, H. Eischeid, B. Ulmer, R. Büttner, M. Odenthal. *University Hospital of Cologne, Pathology, Koeln, Germany*
Email: lwang7@smail.uni-koeln.de

Background and Aims: Chronic liver disease is one the leading health problems, worldwide. Chronic liver disease is characterized by fibrosis with a high risk to end up in hepatocellular carcinoma (HCC). The lysine specific histone 3 demethylase LSD1 is epigenetic writer, known to be upregulated in many cancer types and to trigger tumour growth. Its function in liver disease has not yet been addressed. Therefore, in the present study we investigated its function by global transcriptomic and proteomic analysis in liver disease representative cell types such as liver cancer cells and hepatic stellate cells (HSC).
Method: LSD1 function was inhibited in different hepatocellular carcinoma cell lines (Huh7, Hep3B, and HepG2) and in myofibroblastically activated human hepatic stellate cells (HSC, LX-2) by means of RNA interference or application of a specific LSD1 inhibitor. Cells were functionally characterized by cell growth, cell differentiation, and cell cycle assays using immunostaining and FACS analysis. The microRNA (miRNA) pattern in response to LSD1 inhibition was measured by qPCR arrays followed by signalling pathway analysis for target genes of significant miRNAs. Global transcriptomics was carried out by RNA ultra-deep sequencing and protein expression profiles were analysed by protein mass spectrometry.
Results: LSD1 inhibition initiates cell growth arrest in both, hepatocellular carcinoma cells and myofibroblastically activated HSC. Notably, comprehensive bioinformatic analyses of global changes in transcriptomic and proteomic expression profiles demonstrated pronounced alterations of central mediators involved in cell cycle progression and DNA synthesis. Thus PLK1, TP53, various cycline kinases as well as a set of DNA polymerases expression levels are significantly changed in response to LSD1 inhibition. These results were even more pronounced on protein than on transcript level suggesting that posttranscriptional alterations are involved. miRNA are non-coding RNAs, controlling gene expression posttranscriptionally. Indeed, miRNA profiling reveals a change in miRNA pattern. Interestingly, in HSC LSD1 inhibition did not only alter miRNAs involved in cell cycle control such as miR-34 but additionally lead to an increase of antifibrotically acting miRNAs e.g. miR-29.
Conclusion: Our research demonstrates that LSD1 functions as a central mediator of cell cycle control in both HSC and HCC cells, by induction of global changes in expression profiles.

SAT-189

Sofosbuvir directly promotes the clonogenic capability of human hepatocellular cancer cells

J. Liu, W. Cao, B. Ma, M. Li, M. Peppelenbosch, Q. Pan. *Erasmus MC-University Medical Center, Department of Gastroenterology and Hepatology*
Email: j.liu.2@erasmusmc.nl

Background and Aims: Concern has arisen about development of hepatocellular carcinoma (HCC) in patients with hepatitis C virus (HCV) infection treated with direct-acting antivirals (DAAs). However, the mechanism remains largely unknown. This study aims to investigate whether sofosbuvir has direct effect on HCC cells.
Method: Four HCC cell lines including Huh7, Huh6, HepG2 and SNU449, and a Huh7-base HCV replicon were treated with series concentrations of sofosbuvir (0, 0.01, 0.1, 1 umol). Cell viability was investigated by Alamar blue assay and metabolic activity was determined by MTT assay. In addition, colony formation assay was performed to determine clonogenic capability of single cell. The numbers and sizes of colonies were measured and analyzed.
Results: As expected, sofosbuvir potently inhibited HCV replication in the Huh7-based HCV replicon. No major effect was observed on the growth of bulk of HCC cells by sofosbuvir treatment with clinically relevant concentrations in MTT and Alamar blue assays for 48 or 72 hours. Importantly, sofosbuvir significantly increased the colony formation capability of single HCC cells of the four cell lines. Similar effects were also observed in Huh7-based HCV replicon. Sofosbuvir treatment increased the number of formed colonies. For example, in Huh7 cells, treatment with 0.01, 0.1 and 1 umol sofosbuvir resulted in 1.65 ± 0.26, 1.71 ± 0.26 and 1.54 ± 0.20 fold (Mean ± SD, $n = 9$, $p < 0.01$) increase of the numbers of formed colonies, compared with control.
Conclusion: The present study has demonstrated that clinical relevant concentrations of sofosbuvir promote the clonogenic effect of HCC cells. Thus, these results may explain the mechanism how sofosbuvir facilitate HCC development in treating HCV patients.

Gene signature of HDV-associated hepatocellular carcinoma (HCC): differences with HCC associated with other hepatitis viruses

G. Diaz[1], R.E. Engle[2], A. Nice[2], M. Melis[2], S. Montenegro[2], J. Rodriguez-Canale[3], J. Hanson[3], M.R. Emmert-Buck[3], F. Zamboni[4], S. Govindarajan[5], D.E. Kleiner[3], P. Farci[2]. *[1]University of Cagliari, Department of Medical Sciences, Cagliari, Italy; [2]NIAID, National Institutes of Health, Laboratory of Infectious Diseases, Bethesda, United States; [3]NCI, National Institutes of Health, Laboratory of Pathology, Bethesda United States; [4]Hospital Brotzu, Liver Transplantation Center, Cagliari, Italy; [5]University of Southern California, Department of Pathology, Downey, United States*
Email: pfarci@niaid.nih.gov

Background and Aims: Although hepatocellular carcinoma (HCC) develops in patients with chronic hepatitis D, there are no data on the molecular mechanisms whereby HDV promotes liver cancer. Owing to the vital dependence of HDV on HBV, the specific role of HDV in promoting HCC remains to be fully elucidated. The aims were to study the gene expression profiles of patients with HDV-HCC, and to compare them with HCC-HBV alone and HCC-HCV to identify genes that are shared by the three tumors or uniquely associated with one tumor.
Method: Serum and liver specimens obtained at the time of liver transplantation from 5 well-characterized patients with HDV-HCC were analyzed. Gene expression profiling was performed on laser capture-microdissected hepatocytes (LCM, malignant and non-malignant hepatocytes) and whole liver tissue (WLT, tumor and non-tumor tissue) from patients with HDV-HCC, and compared with paired WLT and LCM microarray data from 11 patients with HBV-and 11 with HCV-HCC.
Results: Malignant hepatocytes from HDV HCC were characterized by an enrichment of up-regulated genes associated with pathways involved in cell cycle/DNA replication, damage and repair (sonic hedgehog, GADD45, DNA-damage-induced 14-3-3σ, cyclins and cell-cycle regulation, cell cycle: G2/M DNA-damage checkpoint regulation, and hereditary breast cancer). Moreover, we identified a large network of genes functionally related to DNA repair, cell cycle, mitotic apparatus and cell division, including four cancer testis antigen genes, attesting to the critical role of genetic instability in this tumor. Most genes differentially expressed in malignant hepatocytes from HDV-HCC were co-regulated and over-expressed when compared to non-malignant hepatocytes, as well as to malignant hepatocytes from HCC associated with HBV alone or HCV-HCC. Activation and co-regulation of genes critically associated with DNA replication, damage and repair point to genetic instability as an important mechanism of HDV hepatocarcinogenesis. Interestingly, we found only one pathway shared by HDV- and HBV-HCC and two pathways with HCV-HCC, whereas five pathways were found between HBV- and HCV-HCC.
Conclusion: Gene expression profiling of liver specimens both within and outside the tumor has led to the identification of distinct molecular signatures for each hepatitis virus-associated HCC. Despite

the dependence of HDV on HBV, these two hepatitis viruses appear to promote carcinogenesis by distinct molecular mechanisms.

Cirrhosis: Portal hypertension, and complication

SAT-191

Protective effect of statins in cirrhosis might be dependent on common genetic risk variants

M. Reichert[1], M. Casper[1], R. Liebe[1], R. Greinert[2], E. Vandieken[1], C. Schneider[1], F. Grünhage[1], B. Appenrodt[1], A. Zipprich[2], C. Ripoll[2], F. Lammert[1]. [1]*Saarland University Medical Center, Department of Medicine II, Homburg, Germany;* [2]*Martin-Luther University Halle-Wittenberg, Department of Medicine I, Halle (Saale), Germany*
Email: matthias.reichert@uks.eu

Background and Aims: Complications of liver cirrhosis and hepatic encephalopathy (HE) might be reduced by statins. Common variants in the *PNPLA3* and *MBOAT7* genes contribute to progressive chronic liver disease and cirrhosis, which can cause overt HE (OHE) in risk groups. The aim of this study was to assess the impact of statin therapy in a large cohort of patients with cirrhosis and to investigate its association with complications of cirrhosis including minimal HE (MHE) and OHE in patients stratified for the common genetic risk variants.
Method: During screening for the randomized controlled INCA trial, 750 patients with liver cirrhosis in two German academic medical centers in Homburg and Halle were identified between 02/2014 and 2/2017. Complications of liver cirrhosis were retrospectively assessed applying current EASL criteria. MHE was assessed with critical flicker frequency (CFF), and OHE was defined as West-Haven grade ≥ 2. The patients were genotyped for the common variants *PNPLA3* rs738409 (p.I148M) and *MBOAT7* (rs641738).
Results: In total, 112 statin-users were included in our cohort. CFF measurements were available in 175 patients, and OHE was diagnosed in 144 patients. Concerning cirrhosis complications, OHE (OR 0.46, 95%CI 0.25–0.86; p = 0.013), jaundice (OR 0.54, 95% CI 0.33–0.88; p = 0.011) and variceal bleeding (OR 0.36, 95%CI 0.16–0.80; p = 0.008) were markedly reduced in statin-users, whereas bacterial infections (OR 0.94, 95%CI 0.61–1.42; p = 0.83) or the development of ascites (OR 0.71, 95%CI 0.48–1.07; p = 0.11) where not. In logistic regressions models adjusting for confounders (albumin, bilirubin and age), OHE remained reduced in statin-users (OR 0.46, 95%CI 0.24–0.88; p = 0.018). CFF values show a trend to lower values (40.0 ± 5.9 Hz in statin-users vs. in non-users 42.2 ± 6.4 Hz; p = 0.12). Applying a cutoff of 39.0 Hz, MHE was not associated with statin-use. In total, 435 *PNPLA3* (minor allele frequency [MAF] 29.3%) and 530 *MBOAT7* (MAF 35.6%) risk alleles were detected. In carriers of the risk alleles, no significant effect of statin use on the development of OHE could be detected for the variants in *PNPLA3* (OR 0.55, 95%CI 0.27–1.12; p = 0.12) and *MBOAT7* (OR 0.64, 95%CI 0.32–1.26, p = 0.21), respectively.
Conclusion: In this large cohort, OHE and other complications were markedly reduced in patients with liver cirrhosis who were treated with statins. This effect on OHE was present only in carriers of wild-type alleles of cirrhosis risk genes. Further prospective studies in larger cohorts are warranted to confirm our results.

Email: pangeli@unipd.it

Background and Aims: The early administration of an effective empirical antibiotic treatment is considered the most important measure in treating patients with cirrhosis and bacterial infections. However, the clinical response may involve several other factors that have never been investigated so far. Thus, in this study we looked for predictors of clinical efficacy to empirical antibiotic treatment in patients with cirrhosis and bacterial infections included in the International Club of Ascites (ICA) "Global Study"
Method: Hospitalized patients with cirrhosis and bacterial/fungal infection were prospectively included at 46 centers. Demographic, clinical, microbiological and treatment data were collected at the diagnosis of infection and during the hospitalization. The patients were followed until death, liver transplantation or discharge. Clinical efficacy of empirical antibiotic treatment was defined by the attending physician according to changes in markers of infection/inflammation, vital signs, improvement of organ failure and results of cultures.
Results: From October 2015 to September 2016, 1,302 patients were included. The most common infections were SBP (27%), UTI (22%) and pneumonia (19%). 26% were nosocomial infections. The most common used empirical antibiotics were third generation cephalosporins (40%), beta-lactams/beta-lactamases inhibitors (32%) and carbapenems (16%); 34% of patients received 2 or more antibiotics. The first line treatment was effective in 61% of cases. Independent predictors of lack of response to empirical treatment were C-reactive

protein (OR = 1.16; P = 0.019), leukocyte count (OR = 1.39, p = 0.008), serum albumin (OR = 0.70; p = 0.003), nosocomial infections (OR = 1.96; p = 0.003), pneumonia (OR = 1.75; p = 0.003), inadequate treatment according to antibiotic susceptibility test (OR = 5.32; p < 0.001) and the severity of ACLF grade (grade 2: OR = 1.58, p = 0.033; grade 3: OR = 4.08; p < 0.001). Patients with lack of response to first line antibiotic treatment had a lower rate of resolution of infection (55 *vs.* 96%; p < 0.001), a higher incidence of second infections (29 *vs.* 15%; p < 0.001), shock (35 *vs.* 7%; p < 0.001) and new organ failures (52 *vs.* 19%; p < 0.001) and a higher in-hospital mortality rate (44 *vs.* 9%; p < 0.001) than responders.
Conclusion: The administration of an adequate empirical antibiotic treatment is just one among factors involved in determining the outcome of infections in cirrhosis. The degree of inflammation, low serum albumin levels and ACLF grade affect clinical response to antibiotics.

SAT-193
The mechanism of irreversibility of late stage cirrhosis
I. Wanless, A. Stueck. *Dalhousie University, Halifax, Canada*
Email: iwanless@eastlink.ca

Background and Aims: Some cirrhotic livers regress with clinical improvement; others do not. Regression is largely the result of a successful bud maturation sequence, allowing repopulation with new hepatocytes by the progenitor reaction located in terminal ductules. This study describes a novel anatomic sequence that explains why some late stage cirrhotic livers fail to regress.
Method: 25 explants with non-biliary cirrhosis (Laennec 4A, 12 and 4B/4C, 13) were examined for clusters of ductules in septal regions along with associated features including progenitor activity (budding, as canals of Hering), ductal degeneration, and fibrosis, using sections stained with trichrome, PASD, and CK19.
Results: Most livers with advanced cirrhosis, but not early cirrhosis, had clusters of ductules lacking evidence of budding, located within septa (69% *vs.* 8%). Most of these clusters had degenerative features (cholangiocyte loss, thickened ductal basement membranes, or annular periductal collagen deposits). Similarly, in 4B/4C livers, the periphery of cirrhotic nodules had focal loss of ductules in 38% and ductule-associated fibrosis in 61%. Loss of ductules was often associated with loss of medium-sized ducts in adjacent septa in 4B/4C livers.
Conclusion: In normal bud maturation, distal ductules are present in small numbers as they are consumed in the maturation process. Thus, clusters of ductules lacking a budding reaction appear to represent proliferated ductules that are redundant because of arrest of the normal bud maturation sequence. These redundant ductules involute in a process that is accompanied by thickening of basement membranes, necrosis of cholangiocytes, and collagen deposition that encases ductules and basement membranes. The mechanism of this "involution sequence" is likely related to the high tissue pressure and congestion seen in late cirrhosis. Similar involution is seen in ischemic settings in liver and other organs, probably through leak of plasma components across vessel walls and basement membranes followed by local fibrosis. Involution of the ductular reaction impedes the regenerative capacity of late stage cirrhosis by the destruction of the progenitor cell niche, as well as the deposition of new fibrosis. Finding this involution signature in tissue indicates failure of the bud maturation sequence and may be a useful prognostic feature.

SAT-194
Acellular growth retardation ability (AGRA), a novel biomarker for humoral immune function, predicts the occurrence of severe bacterial infections in cirrhosis
A. Horvath[1], F. Rainer[2], B. Leber[3,4], B. Schmerboeck[3,4], P. Stiegler[3], V. Stadlbauer[5]. *[1]Department of Gastroenterology and Hepatology, Medical University of Graz, Graz, Austria; [2]Medical University of Graz, Graz, Austria; [3]Medical Universtiy of Graz, Division of Transplantation Surgery, Graz, Austria; [4]Center for Biomarker Research in Medicine, Graz, Austria; [5]Medical Universtiy of Graz, Department for Gastroenterology and Hepatology, Graz, Austria*
Email: angela.horvath@medunigraz.at

Background and Aims: Patients with liver cirrhosis often suffer from severe infections which are commonly accompanied by life-threatening complications. A method to predict the occurrence of severe infection in these patients and therefore improve the chance to prevent them is currently missing. Serum, as many other body fluids and tissues, is rich in antimicrobial peptides and proteins that can kill or inhibit the growth of pathogens, including a wide range of bacteria. Here we introduce a novel biomarker, acellular growth retardation ability (AGRA), that is based on these humoral immune responses to determine the infection risk of patients with liver cirrhosis, and describe its possible applications in liver disease.
Method: AGRA was used to quantify the growth of bacteria challenged by serum of patients with liver cirrhosis (n = 146) or pre-cirrhotic chronic hepatitis C patients (n = 81) or healthy controls (n = 42). Patients with cirrhosis of various aetiologies (n = 101) were followed-up for a median time of 36 months to determine the time to occurrence of the first severe infection after inclusion; 88 patients finished the minimum follow up of 1 year. Patients with chronic hepatitis C infection with and without cirrhosis underwent antiviral therapy and AGRA was monitored throughout its course.
Results: AGRA successfully predicted the occurrence of severe infections in patients with liver cirrhosis (AUROC [95%CI]: 0.8[0.7; 0.9]; p < 0.001) and highlighted a severe impairment of humoral immune responses in chronic hepatitis C patients with cirrhosis. Patients with hepatitis C related cirrhosis showed significantly impaired (=higher) AGRA (0.014 ± 0.012ΔOD/h) compared to patients with alcoholic (0.0016 ± 0.009ΔOD/h; p < 0.001) or other types of aetiologies (−0.0022 ± 0.0068ΔOD/h; p < 0.001) which was in accordance with higher incidence of severe infections in this group. Chronic hepatitis C patients also showed impaired AGRA in absence of cirrhosis compared to healthy controls (0.010 ± 0.013 and −0.0015 ± 0.0069ΔOD/h, respectively; p < 0.001). After antiviral therapy AGRA significantly improved in patients with (p < 0.001) and without cirrhosis (p = 0.001).
Conclusion: AGRA can be used to predict severe infection in cirrhosis and therefore identify patients at risk with increased need for preventive measures. It can also be used to show that impaired humoral immune responses are an extrahepatic manifestation of hepatitis C which can be improved by antiviral therapy.

SAT-195
Assessing Baveno VI criteria with a new point-shear wave elastography technique: The BAVElastPQ study
M. Garcovich, G. Gibiino, B.E. Annicchiarico, M.E. Ainora, L. Riccardi, M. Siciliano, M. Pompili, M.A. Zocco, A. Gasbarrini. *Policlinico A. Gemelli, Internal Medicine, Gastroenterology and Liver Unit, Italy*
Email: giulia.gibiino@gmail.com

Background and Aims: To date no study has explored the potential role of ElastPQ, a novel point-SWE technique, in the assessment of clinically significant portal hypertension. The aim of our study was to determine a liver stiffness (LS) cut-off value measured by ElastPQ and/or laboratory parameters that could help identify those patients who can safely avoid screening endoscopy, similarly to the recently proposed Baveno VI criteria which recommends a LS value <20 kPa measured by transient elastography in combination to a platelet count >150,000/μl.
Method: Data was collected on 1432 patients who underwent ElastPQ measurement from January 2013 to January 2016 in our Department. Inclusion criteria were a LS value of ≥7 kPa (to reasonably rule-in all patients with advanced fibrosis and cirrhosis) and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of compensated chronic liver disease. Exclusion criteria

were history of decompensated liver disease, evidence of porto-spleno-mesenteric vein thrombosis and non-cirrhotic portal hypertension. Varices were graded as low risk (grade <2) or high risk (grade ≥2).

Results: The study included 195 patients (120[61%] HCV, and 171 [88%] Child-Pugh A). Varices were present in 35% cases, with 10% prevalence of high risk varices. According to ROC curve analysis LS measurement and platelet count were evaluated as predictors of high risk varices. Overall 75/195 (38%) met the "BAVElastPQ" criteria (that is, LS <12 kPa and platelet count >150,000/μl). Within this group 11/64 (17%) had any grade of varices and only 1/74 (1%) had high risk varices. The BAVElastPQ criteria gave sensitivity of 0.95, specificity of 0.42, positive predictive value of 0.15 and negative predictive value of 0.99. The AUROC for LS and platelet count was 0.80 and 0.76, respectively.

Conclusion: The BAVElastPQ criteria correctly identified 99% of patients without high risk varices. By applying such criteria we could have potentially avoided 38% surveillance endoscopies in our cohort.

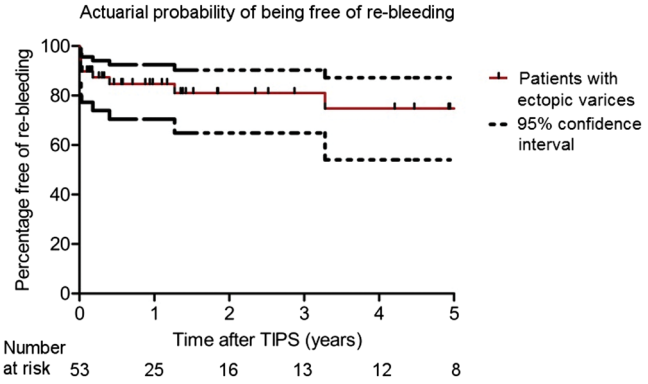
Background and Aims: Ectopic varices – portosystemic venous collaterals located outside the gastro-esophageal region – cause up to 5% of all variceal bleeding. Current evidence suggests that transjugular intrahepatic portosystemic shunts (TIPS) is usually effective for bleeding ectopic varices, but research has been largely restricted to small series. We aimed to study the efficacy and clinical outcome of TIPS for ectopic variceal bleeding and to assess the benefit of concomitant vascular embolization.

Method: Retrospective analysis of chronic liver disease patients with ectopic variceal bleeding, who received TIPS in 3 tertiary centers between 1995–2015.

Results: The study included 53 patients with TIPS placement for ectopic variceal bleeding (70% male, mean age 58 years (±18), median MELD 11 (IQR 9–17)). The ectopic varices were most often located around the insertion of stomas (40%), followed by the duodenum (23%), rectum (17%), and other sites (20%). Before TIPS was created, 76% of the patients had been unsuccessfully treated with endoscopy, medication, surgery, and/or vascular embolization. TIPS decreased the portosystemic gradient from 14 mmHg (IQR 10–20) to 6 mmHg (IQR 4–7). The median follow-up time was 14.0 months (IQR 3.8–45.9). After TIPS placement, the estimated cumulative re-bleeding rate was 23% at 1 year, 26% at 3 years and 32% at 5 years. The hazard ratio for re-bleeding was higher in patients with TIPS dysfunction (HR 9.46; 95%CI 2.46–36.33), and a high MELD score (HR 1.11 per point; 95%CI 1.02–1.20). Post-TIPS hepatic encephalopathy (HE) manifested or worsened in 16 patients (30%). HE could be managed with medication in 12 patients; however, in 4 patients a stent diameter reduction was necessary. In this cohort, 41 patients died, 5 underwent liver transplantation, 6 were alive at the end of follow-up and 1 was lost to follow up. The estimated 30-day, 1-year, and 5-year mortality rates were 11% (SE 0.04), 41% (SE 0.07) and 75% (SE 0.07), respectively. Multivariate analysis identified the presence of gastro-esophageal varices (HR 3.89; 95%CI 1.23–12.29) and MELD score (HR 1.08 per point; 95%CI 1.01–1.15) as independent risk factors for poor survival. Concomitant embolization during the TIPS procedure was performed in 13 patients. The hazard ratios of concomitant embolization compared to TIPS alone, were 0.83 (95% CI 0.30–4.43) for re-bleeding and 1.13 (95%CI 0.52–2.43) for mortality.



Conclusion: TIPS is an effective treatment in patients with ectopic variceal bleeding, preventing re-bleeding in approximately 70% of cases after 5 years. However, overall survival was poor and mainly associated with the severity of the underlying liver disease. Concomitant embolization seemed not associated with a lower risk for re-bleeding or improved survival, but considering the study design and the limited number of patients treated, we were unable to reliably assess the value of embolization as an adjunctive measure.

Email: hannes.hagstrom@ki.se

Background and Aims: Pregnancy in women with cirrhosis is considered a rare event, with little published data on possible complications. We examined pregnancy-related and liver-related outcomes in women with cirrhosis.

Method: We used Swedish population-based registers to define exposure and outcomes. All Swedish women admitted for antenatal care with singleton births were included. Exposure status was defined as an ICD 10-code for cirrhosis obtained prior to or during pregnancy. Pregnancy- and liver-related outcomes during pregnancy were investigated. Poisson regression with cluster robust standard

errors was used to estimate relative risks (RR), adjusted for age, smoking and body mass index.
Results: Between 1997–2011, we identified 68 pregnant women with cirrhosis. These were compared to 1 361 427 women without ICD-coding for cirrhosis. The most common causes of cirrhosis were viral hepatitis and autoimmune hepatitis (14 cases each). During the study period, pregnancy in cirrhotic women increased from 5 cases in 1997–2001 to 16 cases in 2002–2006 and 47 cases in 2007–2011.
Compared to women without cirrhosis, women with cirrhosis were at increased risk of Caesarean section (23 cases, RR 1.88, 95%CI 1.29–2.75), low birth weight (10 cases, RR 3.51, 95%CI 1.60–7.70), preterm delivery (14 cases, RR 3.85, 95%CI 2.20–6.73), neonatal death (1 case, RR 12.42, 95%CI 1.75–88.39), but not from maternal mortality during pregnancy (0 cases), gestational diabetes (0 cases), pre-eclampsia (2 cases, RR 0.74, 95%CI 0.11–5.02), small for gestational age (5 cases, RR 0.69, 95%CI 0.10–4.86), stillbirth (1 case, RR 5.34, 95%CI 0.78–36.33) or malformations (1 case, RR 0.53, 95%CI 0.08–3.58).
During pregnancy, twelve cases were hospitalized due to liver-related events (RR 2369, 95%CI 1052–5336) including five cases with therapy of esophageal varices (RR 2369, 95%CI 1052–5336). There were no cases of liver-related deaths.
Conclusion: In this population-based cohort, cirrhosis was a rare but increasingly common diagnosis in pregnant Swedish women. Women with cirrhosis were at increased risk for hospitalization for liver-related events, and an increased risk for some pregnancy-related outcomes was found. However, severe maternal and fetal adverse events were rare, and a successful pregnancy in cirrhotic women is likely a realistic outcome.

SAT-198

Prevalence and resistance rates of infections with enterococci in patients with cirrhosis

T. Bucsics[1,2], M. Emich[1,2], M.-C. Nackenhorst[1,2], E. Berger[1,2], P. Schwabl[1,2], M. Mandorfer[1,2], B. Scheiner[1,2], A. Ferlitsch[1,2], T. Reiberger[1,2], M. Trauner[1]. *[1]Medizinische Universität Wien, Internal Medicine III, Wien, Austria; [2]Medical University of Vienna, Hepatic Hemodynamic Laboratory, Vienna, Austria*
Email: theresa.bucsics@meduniwien.ac.at

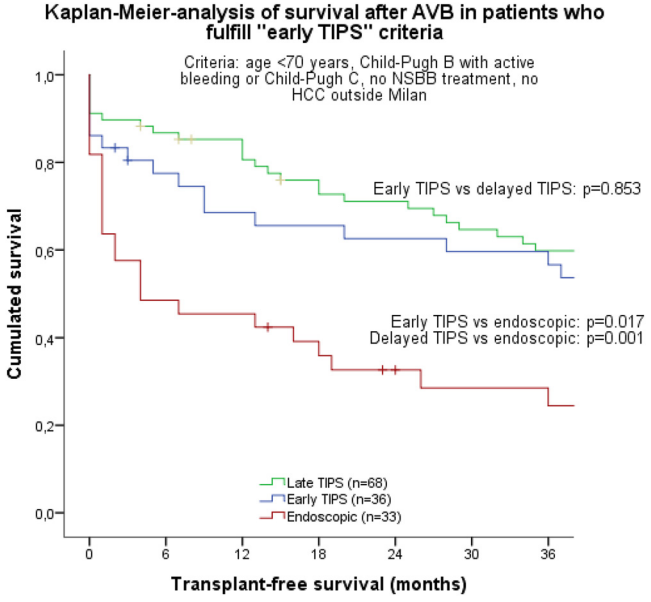
Background and Aims: We and others have recently observed an increase in infections with enterococci in patients with liver cirrhosis. Enterococcal infections comprise a considerable threat to cirrhotic patients, since cephalosphorins (lacking activity against enterococci) are often recommended by guidelines as empirical antibiotic therapy in cirrhosis, and multi-drug resistant enterococci strands might emerge. Thus, we assessed microbial epidemiology and antibiotic resistance (AR) of enterococcal infections in patients with cirrhosis.
Methods: Microbiologic reports of samples collected from consecutive patients treated at a tertiary liver center were systematically screened for bacterial infections. Only patients with a confirmed diagnosis of cirrhosis were considered. Blood stream infections (BSI), urinary tract infections (UTI), respiratory tract infections (RTI), and ascites cultures/spontaneous bacterial peritonitis (SBP) including the respective antibiograms were retrospectively evaluated.
Results: We evaluated 1963 positive cultures (UTI: n = 422, BSI: n = 673, SBP: n = 467; RTI: n = 401) from 7,077 samples of patients with cirrhosis. Enterococci were found in 17.2% of positive cultures (UTI: 25.4%, BSI: 13.4%, SBP: 21.2%, RTI: 6.2%) and AR was tested in 85.3%. Resistances to ≥1 antibiotic classes (AC) were found in 37.9%; 10.9% of cultivated enterococci were resistant to at least 2 AC. While no resistance to aminopenicillins was found in outpatient enterococcal infections, aminopenicillin-resistant strands from nosocomial infections were tested in 36.7% (n = 91/248; UTI: n = 29/76, 38.2%; BSI: n = 19/53, 26.8%; SBP: n = 29/81, 35.8%; RTI: n = 14/20, 70.0%). Vancomycin-resistant enterococci (VRE) were found in 12.1% (UTI: 7.9%; BSI: 15.5%; SBP: 16.0%; RTI: 0.0%). We did not observe any resistance of isolated enterococci species to linezolid.
Conclusions: Enterococci are common pathogens in SBP, respiratory and urinary tract infections in patients with cirrhosis. Thus, we cannot recommend the use of cephalosporins or quinolones for empiric treatment of suspected infections in patients with cirrhosis. Multiclass-resistance and VRE were found in about 10% of cases, respectively. For cirrhotic outpatients or uncomplicated infections, we recommend aminopenicillins as empiric antibiotic treatment, while for nosocomial infections a combination of penems and Gram-positive agents should be used. Our data underline the importance of assessing the local microbial epidemiology and resistance profiles in patients with cirrhosis.

SAT-199

Effectiveness of "early" TIPS implantation versus "late" TIPS versus standard endoscopic treatment for acute variceal bleeding in patients with liver cirrhosis

T. Bucsics[1], M. Schoder[2], M. Mandorfer[1], P. Schwabl[1], F. Riedl[1], D. Bauer[1], M. Trauner[1], M. Peck-Radosavljevic[1,3], J. Karner[4], F. Karnel[5], T. Reiberger[6]. *[1]Medical University of Vienna, Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Biomedical Imaging and Image-guided Therapy, Vienna, Austria; [3]Klinikum Klagenfurt am Woerthersee, Internal Medicine, Klagenfurt am Woerthersee, Austria; [4]Sozialmedizinisches Zentrum Sued, Kaiser-Franz-Josef-Spital, Surgery, Vienna; [5]Sozialmedizinisches Zentrum Sued, Kaiser-Franz-Josef-Spital, Radiology, Vienna; [6]Medical University of Vienna, Internal Medicine III, Vienna*
Email: theresa.bucsics@meduniwien.ac.at

Introduction: Early implantation of a transjugular intrahepatic portosystemic shunt (TIPS) within 72 h is recommended for the treatment of acute variceal bleeding (AVB) in selected patients. However, early TIPS may not always be readily available.
Methods: In this retrospective analysis, we evaluated outcomes of patients who were treated for AVB and fulfilled criteria for early TIPS implantation. We compared patients who received "*early TIPS*" (<72 hours, n = 36), to eligible patients who underwent TIPS implantation at a delayed time point (72h-28 days after AVB, "*delayed TIPS*", n = 68) and to eligible patients who underwent rebleeding prophylaxis by combined endoscopic/nonselective betablocker treatment ("*EBL/NSBB*", n = 33).



Results: With a mean age of 60.5 ± 10.9 years, patients in the "EBL/NSBB" control group were older than TIPS patients (early TIPS: 54.3 ± 9.3 years, p = 0.013; delayed TIPS: 52.2 ± 10.0 years; p = 0.001).

Baseline MELD scores were comparable between groups ("early TIPS" patients: 12.8, 11.7–15.7 *vs.* "delayed TIPS" patients: median 12.4, IQR: 10.4–15.0; p = 0.242 *vs.* "EBL/NSBB" controls: 13.6, 10.5–16.7, p = 0.687). TIPS implantation was generally associated with low early re-bleeding (early TIPS: 8.3% *vs.* delayed TIPS 2.9%, p = 0.338) and low overall re-bleeding rates (early TIPS: 30.6% *vs.* delayed TIPS: 33.8%, p = 0.735) when compared to "EBL/NSBB" controls (36.4% and 51.5%, respectively, p = 0.005 and p = 0.077 *vs.* "early TIPS").
Similarly, bleeding-related mortality within 6 weeks (early TIPS: 16.7%; delayed TIPS: 8.8%) and mortality at one-year (early TIPS: 30.6%, delayed TIPS: 13.2%) appeared lower with TIPS as compared to "EBL/NSBB" controls, who showed a bleeding-related mortality of 35.7% (p = 0.081 *vs.* early TIPS; p = 0.003 vs. delayed TIPS) and 1-year mortality of 53.6%. (p = 0.063 *vs.* early TIPS, p < 0.001 *vs.* delayed TIPS). After adjusting for age and MELD as established risk factors for mortality in Cox regression analysis, both "early TIPS" (OR: 0.524, p = 0.041) and "delayed" TIPS (OR 0.548, p = 0.021) were effective in reducing mortality after AVB.
Conclusions: TIPS implantation effectively prevents variceal re-bleeding and reduces mortality in selected patients after AVB as compared to EBL/NSBB combination therapy – even if not placed not within <72 h but within <28 days. Thus, we recommend TIPS implantation for AVB in all patients who fulfill "early TIPS" criteria, even when "early TIPS" implantation within 72 h is not possible.

SAT-200

Cholemic nephropathy is frequently observed in jaundiced patients and associated with increased mortality

M. Young-Seon[1], J. Schmitz[2], R. Schmitt[3], M.P. Manns[1], J.H. Bräsen[2], I. Mederacke[1]. *[1]Hannover Medical School, Gastroenterology, Hepatololgy, and Endocrinology, Hannover, Germany; [2]Hannover Medical School, Pathology, Hannover, Germany; [3]Hannover Medical School, Nephrology and Hypertension, Hannover*
Email: mederacke.ingmar@mh-hannover.de

Background and Aims: Impairment of renal function often occurs in patients with liver disease and is associated with an increased mortality. Hepatorenal syndrome is a significant cause of acute kidney injury (AKI) in cirrhotic patients (HRS-AKI, type 1), however, a kidney biopsy to exclude structural causes of kidney disease is rarely performed owing to increased risk of bleeding in this cohort. Causes of non-HRS AKI include cholemic nephropathy (CN), a disease that has regained attention recently and that is characterized by intratubular cast and tubular injury. As data on patients with CN is mostly obtained from case reports or autopsy studies, we aimed to investigate the prevalence and clinical course of CN in a tertiary care hospital over a 16-year period.
Method: We identified 149 patients who underwent kidney biopsy from 2000 to 2016 at the Department of Gastroenterology, Hepatology and Endocrinology. Of these 79 had a history of liver disease and deterioration of renal function and were included into this study. Laboratory values and clinical course of the patients were obtained by retrospective chart analysis. Biopsies were reevaluated to confirm the diagnosis of CN.
Results: The mean age of the patients was 52.2 ± 10.8 years and 71% were male patients (56/79). One quarter of the patients had a history of organ transplantation (liver or kidney), cirrhosis detected by liver biopsy or ultrasound was observed in 43 of 79 patients (54.4%). The average creatinine at the time of biopsy was 256 ± 181 µmol/l. Consistent with the increased risk of bleeding in patients with advanced liver disease 25 patients had an INR >2 or platelet count <100.000/µl. Biopsy related complications occurred in six of 79 patients, one of them required surgical therapy. Renal biopsy revealed the diagnosis of CN in 10.1% of the patients (8/79). Patients with CN presented with significantly higher bilirubin (779 ± 306 *vs.* 66 ± 110 µmol/l, p < 0.001), whereas creatinine, ALT, AST, INR, liver function and blood count were similar in both groups. Of note, patients with CN secreted bilirubin (100%) and urobilirubinogen (50%) in the urine, compared to 15% and 13 of the non-CN patients, respectively (p < 0.05). Most importantly, diagnosis of CN was linked with increased mortality (p < 0.05).
Conclusion: Cholemic nephropathy is associated with increased mortality and should be considered as a cause of impaired renal function in patients with liver disease and elevated bilirubin levels.

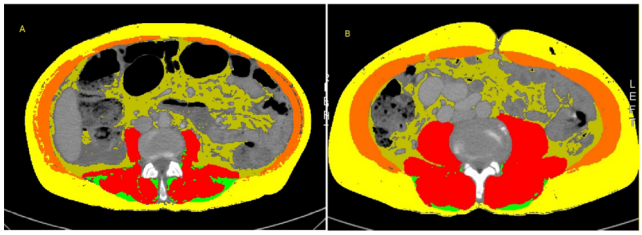
SAT-201

The area of the paarspinal muscle mass in patients with cirrhosis although not different from controls predicts cirrhosis-associated complications and death in a large mono-centric study

C. Engelmann[1,2], I. Nonnenmacher[3], L. Werlich[4], M. Moche[4], S. Ulrich[4], T. Kaiser[5], K. Sandra[3], K. Zeller[3], M. Bartels[6], T. Kahn[4], A. Surov[4], D. Seehofer[6], S. Schob[7], T. Berg[3]. *[1]University College London, ILDH, London, United Kingdom; [2]University Hospital Leipzig, Section Hepatology, Department of Gastroenterology and Rheumatology, Leipzig, Germany; [3]University Hospital Leipzig, Section Hepatologie, Department of Gastroenterology and Rheumatology, Leipzig, Germany; [4]University Hospital Leipzig, Clinic and Policlinic of Diagnostic and Interventional Radiology, Leipzig, Germany; [5]University Hospital Leipzig, Institute of Laboratory Medicine, Clinical Chemistry and Molecular Diagnostics, Leipzig, Germany; [6]University Hospital Leipzig, Department of Visceral, Vascular, Thoracic and Transplant Surgery, Leipzig, Germany; [7]University Hospital Leipzig, Department for Neuroradiology, Leipzig, Germany*
Email: cornelius.engelmann@medizin.uni-leipzig.de

Background and Aims: Loss of skeletal muscle mass (sarcopenia) has been increasingly recognized as a complication of cirrhosis potentially predicting patients' outcome. At present, it is not clear whether sarcopenia contributes to the occurrence of cirrhosis complications or survival after transplantation. We therefore conducted a large retrospective trial exploring the impact of the skeletal muscle mass on complications and survival in cirrhosis.
Method: Of the 1328 patients with liver cirrhosis listed for liver transplantation between March 2001 and September 2014 at the University Hospital Leipzig, 795 met the in- and exclusion criteria including an abdominal CT-scan (± 200 days). 109 patients without liver diseases who received a CT scan as part of the initial work-up for polytrauma served as controls. The area of the paraspinal muscle, the abdominal wall muscles and the combination of both were assessed at L3 and normalized to the height (displayed in cm^2/m^2) (Figure 1). Data were retrospectively analysed and correlation with clinical data obtained from medical records. As the normalized paraspinal muscle mass (nSM1) was the most reliable parameter, data is primarily described for nSM1.

Figure 1: CT-scan at L3 level in a patients with reduced muscle mass (A) and control patients (B)



SM1 (red) – paravertebral muscles; SM2 (orange) – abdominal wall muscles; SMtotal – SM1 + SM2

Results: Of 795 patients with liver cirrhosis 493(62%) had an alcoholic liver disease and 561(70.6%) were male. The majority had a MELD score between 12–24(57.3%) and were allocated to Child-Pugh (CP) class B (45.7%). Median nSM1 of 24.9(12.1–46.2) in cirrhosis was not significantly different to 25.7(12.6–40) in controls. In subgroups of patients with history of cirrhosis-related complications median nSM1 was significantly smaller then in controls (hepatorenal syndrome (HRS) 21(12.1–33.9); hepatic encephalopathy

(HE) 23,6(12.1–40); SBP 22.5(14,5–36.5); ascites 23((12.1–40); p < 0.0001). Patients with high CP class and high MELD score had also a reduced median nSM1. In a multivariate regression model adjusting for gender, age, BMI, MELD a reduced skeletal muscle mass in cirrhosis was associated with an increasing risk for the occurrence of new complications such as SBP (HR 0.93, p = 0.006), HE (HR 0.934, p = 0.046), HRS (HR 0.946, p = 0.013) and variceal bleeding (HR 0.935, p = 0.039). The discrimination of nSM1 (1-year survival on the waiting list) was 0.625 (0.573–0.678). Combining the nSM1 with MELD in a score increased the AUC to 0.697 (0.647–0.746), which was superior to MELD (0.678 (0.628–0.727). The post transplant survival was not associated with any of the muscle parameter.
Conclusion: This is until now the largest study evaluating the impact of skeletal muscle mass on patients' outcome in cirrhosis. The paraspinal muscle mass is a reliable predictor for the occurrence of cirrhosis related complications. This shows, that a reduced skeletal muscle mass is a sign for end-stage liver cirrhosis, necessitating preventive surveillance strategies and curative treatment approaches.

SAT-202

TLR9-mediated immune sensing of bacterial DNA in decompensated cirrhosis is stage-dependent

E. Al-Herwi, S. Stengel, C. Golembiewski, A. Steube, A. Stallmach, T. Bruns. *Jena University Hospital, Dpt. of Internal Medicine IV, Jena, Germany*
Email: eihab.alherwi@med.uni-jena.de

Background and Aims: Altered local and systemic levels of type-I interferons (IFN) have been linked to impaired antibacterial capacity in animal models of cirrhosis and to a higher risk of death in patients with alcoholic cirrhosis. DNA sensing by immune competent cells is known to elicit strong type-I IFN responses, which may play a role in the context of bacterial translocation in cirrhosis. Aim of this study was to characterize immune responses towards CpG-rich single stranded DNA oligonucleotides from E. coli (ssE.coli CpG) in monocytes from patients with decompensated cirrhosis and from healthy controls.
Method: CD14+ monocytes were isolated by density gradient separation and immunomagnetic sorting. Cells were transfected with ssE.coli CpG and bioactive type-I IFN in supernatants or serum was measured using an IFN reporter cell assay. IL-6, TNF, and IL-10 were quantified using ELISA and qRT-PCR.
Results: Serum type-I IFN bioactivity was elevated above 30 pg/ml IFN-β equivalent in 32% of patients with decompensated cirrhosis and ascites. As compared to healthy individuals, purified monocytes from patients with decompensated cirrhosis secreted higher levels of IL-6 (p= 0.007) and type-I IFN (p = 0.001) after isolation indicating recent pro-inflammatory activation. In contrast to LPS, ssE.coli CpG was a potent inducer of type-I IFN release and IFNA, IFNB, and IFN-response gene expression. Overall, the treatment of monocytes from patients with cirrhosis with ssE.coli CpG in vitro resulted in a significantly increased release of IL-6 (p = 0.0001) and bioactive IFN (p = 0.0002) compared to healthy individuals, although some patients had diminished type-I IFN secretion. In patients with decompensated cirrhosis (n = 43), advanced disease states were associated with reduced ssE.coli CpG-induced type-I IFN release from monocytes, which correlated with serum bilirubin (r = –0.41; p = 0.008), international normalized ratio (r = –0.33; p = 0.04), and serum albumin (r = 0.41; p = 0.01). Prevention of endosomal acidification with chloroquine abrogated type-I IFN release, indicating a primary role of endosomal but not cytoplasmatic DNA sensing in this process.
Conclusion: Monocytes from patients with decompensated cirrhosis are potent producers of type-I IFN in response to bacterial DNA. Consistent with a concept of cirrhosis-associated immune dysfunction in cirrhosis, both, TLR9-mediated hyperinflammatory as well as blunted immune responses are observed in different disease states.

SAT-203

Longitudinal outcomes of the application of non-selective beta-blockers in portal hypertension: Are low-dose non-selective beta-blockers effective?

S.H. Kang[1], M.Y. Kim[1], Y.O. Jang[1], M. Lee[2], B.G. Jun[3], T.-S. Kim[2], K.T. Suk[4], S.K. Baik[5]. *[1]Yonsei University Wonju College of Medicine, Internal Medicine, Wonju-si, Korea, Rep. of South; [2]Kangwon National University Hospital, Internal medicine, Chuncheon-si, Korea, Rep. of South; [3]University of Ulsan College of Medicine, Internal Medicine, Gangneung-si, Korea, Rep. of South; [4]Hallym University College of Medicine, Internal Medicine, Chuncheon-si, Korea, Rep. of South; [5]Yonsei University Wonju College of Medicine, Department of Internal Medicine, Wonju, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

Background and Aims: The effect of non-selective β-blockers (NSBBs) on survival in decompensated liver cirrhosis is still disputed. Moreover, the majority of physicians use a low-dose NSBB for cirrhotic patients due to occurrence of side effects, including orthostatic hypotension, dizziness and poor intolerance instead of using the maximally-tolerated dose of NSBB, as recommended by the guidelines. We investigated whether a low-dose NSBB has beneficial effects compared to maximally tolerated doses in real life data.
Method: We conducted a retrospective study involving 260 consecutive patients with controlled esophageal variceal bleeding who had hepatic venous pressure gradient (HVPG) measurements; 195 patients were given a NSBB (NSBB group) and 65 patients were not given a NSBB (non-NSBB group). The NSBB group was divided into 2 sub-groups, as follows: low-dose group, (≤ 80 mg; n = 67); and high-dose group (>80 mg; n = 128). The primary outcome was all-cause mortality in patients receiving or not receiving NSBB as prophylaxis against variceal bleeding.
Results: The baseline characteristics between the NSBB and non-NSBB groups were similar, including the Child-Turcotte-Pugh (CTP) score. The median duration and dose of NSBB therapy were 37.5 months (Interquartile range [IQR], 15.0–58.8) and 120 mg/day (IQR, 80–160). During the median follow-up of 38.5 months, survival was better in the NSBB group than the non-NSBB group (56.4% *vs.* 27.7%; p < 0.001). Based on multivariate analysis, NSBB significantly prolonged survival after adjusting for CTP and MELD score (adjusted hazard ratio [aHR], 0.472; p < 0.001). An analysis according to the dose of NSBB showed that survival was not different between the low- and high-dose groups (59.7% *vs.* 54.7%; p = 0.503). When stratified by the baseline HVPG level, the aHR for NSBB therapy was 0.514 (p = 0.002) in patients with a low HVPG (≤20 mmHg). Among patients with a high HVPG (>20 mmHg), NSBB use was associated with increased survival (aHR, 0.350; p = 0.005). Survival did not differ significantly between the low- and high-dose groups by stratifying the HVPG level (low HVPG [66.0% *vs.* 56.4%; p = 0.113] and high HVPG [35.7% *vs.* 48.4%; p = 0.695]).
Conclusion: In patients with cirrhosis, NSBB therapy was associated with a reduced risk of mortality that was independent of the severity of portal hypertension. Moreover, our study showed that there was a similar effect on survival when a low-dose NSBB was used. This result implies that there is an additional non-hemodynamic benefit to low-dose NSBB use.

SAT-204

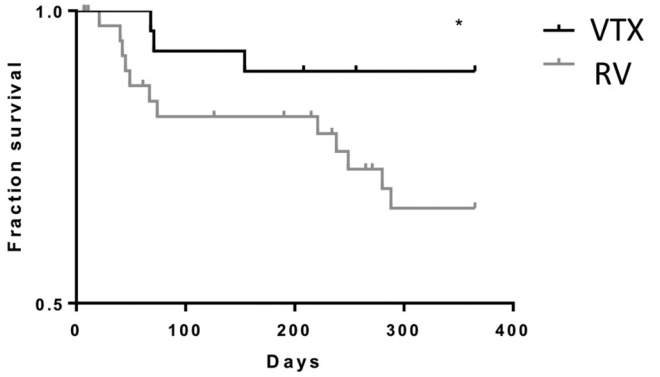
Sub maximally dilated Viatorr CX improves one-year survival compared to conventional covered TIPS: a case-control study

M. Praktiknjo[1], S. Fischer[2], C. Pieper[2], C. Jansen[1], A. Pohlmann[1], J. Lehmann[1], C.P Strassburg[1], D. Thomas[2], C. Meyer[2], J. Trebicka[1,3]. *[1]University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany; [2]University Hospital Bonn, Radiology, Bonn, Germany; [3]EFCLIF, Barcelona, Spain*
Email: jonel.trebicka@ukbonn.de

Background and Aims: Transjugular intrahepatic portosystemic shunt (TIPS) is an effective treatment for complications of portal

hypertension but might also cause complications. Development of hepatic encephalopathy and/or cardiac dysfunction after TIPS might be among others due to the effective shunt diameter. Recently, we showed that all underdilated TIPS passively expand to nominal diameter, and that the use of the novel 10 mm Viatorr® Controlled Expansion (VTX) leads to less readmissions in patients after months compared to regular Viatorr® (RV) and bare-metall-stents in the case of submaximal dilated to 8 mm (EASL 2017). This abstract reports the one-year outcome of Viatorr® Controlled Expansion compared to regular Viatorr®, when both groups received 10 mm stents and are submaximal dilated to 8 mm.

Method: 35 patients receiving VTX were matched with 34 patients receiving RV. All patients reveived 10 mm stents (either VTX or RV), which were submaximal dilated to 8 mm. Indication was ascites in 25 VTX and 27 RV patients. In a subset of 10 patients receiving VTX, portal-systemic pressure gradient (PSPG) was assessed 3 to 10 days after TIPS and compared to the values at TIPS. 3D-ultrasound evaluated the passive expansion of these underdilated stents. Clinical, neuropsychiatric, lab work and duplex sonography data were assessed during follow up visits 3 months and one year after TIPS implantation.



Results: The baseline characteristics were similar in both groups (RV *vs.* VTX: MELD 12 *vs.* 13, MELD-Na 14 *vs.* 15, Child 8 *vs.* 8). After TIPS the PSPG increased significantly in the patients receiving VTX from 9.8 mmHg to 10.5 mmHg ($p < 0.01$). While RV passively dilated to nearly full diameter, VTX did not dilated significantly. 3 months after TIPS MELD did not change significantly, but MELD-Na score improved in significantly only in VTX group (15 to 13). Patients receiving the novel expansion control VTX showed significantly less readmissions for hepatic encephalopathy (16% VTX *vs.* 46% RV; $p < 0.001$) and all-cause readmission (0.46 episodes per patient in VTX group and 1.09 per patient in RV group). While in the short-term follow-up of 3 months, overall survival was not significantly different between the groups, one year follow up revealed a significant improvement in survival in VTX group (see Figure).

Conclusion: The novel Viatorr® Controlled Expansion stents reduces episodes of readmission for hepatic encephalopathy and for any cause. Importantly, this beneficial effect was only observed after 3 months of implantation and improves one-year survival. These data suggest that full passive expansion in patients with submaximal dilation of the TIPS, might be at least partly responsible for post-TIPS complications and mortality.

SAT-205

Prognosis after abdominal surgery in patients with idiopathic non-cirrhotic portal hypertension: A multicenter retrospective study

L. Elkrief[1], J. Ferrusquia[2], P. Audrey[3], L. Moga[4], T. Luis[5], M. Praktiknjo[6], B. Procopet[7], R. Yuldashev[8], H. Geovanni[2], V. Hernandez-Gea[2], A. Albillos[5], J. Trebicka[6], L. Spahr[1], A. Plessier[3], D. Valla[3], L. Rubbia-Brandt[1], C. Toso[1], C. Bureau[4], G.P.J. Carlos[2], P.-E. Rautou[3].

Email: laure_elkrief@yahoo.fr

Background and Aims: Idiopathic noncirrhotic portal hypertension (INCPH) is a heterogeneous group of diseases characterized by portal hypertension in the absence of cirrhosis or other specific causes of portal hypertension. Data on morbi-mortality of abdominal surgery in patients with INCPH is very limited. Our aims were (i) to assess the outcome of patients with INCPH undergoing abdominal surgery; and (ii) to identify predictors of poor outcome.

Method: We retrospectively analyzed the charts of patients with known INCPH undergoing abdominal surgery in 8 centers of the VALDIG consortium between 2002 and 2017. We analyzed features associated with: (i) liver-related complications within 3 months after surgery; (ii) liver transplantation or death, within 6 months after surgery. Data are median (IQR).

Results: Thirty-nine patients (24 men, median age 51 years) with biopsy-proven INCPH were included. One or more extrahepatic condition known to be associated with INCPH (*i.e.* immunological or genetic disorders, infections, drugs or toxins, or prothrombotic conditions) were found in 23 (59%) patients. Surgical procedures included hernia repair (n = 10), cholecystectomy (n = 6), splenectomy (n = 5), colorectal (n = 6), urologic (n = 4), gastric/pancreatic surgery (n = 2) and other procedures (n = 6). Twelve patients had a TIPSS (n = 9) or a portocaval surgical shunt (n = 3) 0.8 (0.1–33.7) months prior to surgery to treat refractory complications of portal hypertension (n = 9) or to prepare surgery (n = 3). Liver-related complications occurred in 15 (39%) patients within 3 months after surgery. Five patients required a TIPSS for refractory complications of portal hypertension after surgery. At multivariate analysis, associated extrahepatic conditions ($p = 0.01$) and open surgery ($p = 0.02$) independently predicted liver-related complications. At 6 months after surgery, 3 patients died. No patient underwent liver transplantation. Serum creatinine >133 µmol/L before surgery predicted death at 6 months (100% *vs.* 12%, $p = 0.006$). Portal hypertension features were not associated with liver-related complications. The outcome did not differ between patients who had TIPSS or surgical shunt prior to surgery (n = 12) and those who did not.

Conclusion: Liver-related complications were observed in 39% of the patients and were more common in those with at least one extrahepatic condition associated with INCPH. Survival of patients with INCPH undergoing abdominal surgery was good when serum creatinine was normal.

SAT-206

Addition of simvastatin to standard treatment is safe, effective and improves quality of life in patients with decompensated cirrhosis

A. Muñoz[1], F. Pollarsky[1], M. Marino[1], M. Cartier[1], C. Miguez[1], D. Alvarez[2], P. Salgado[3], G. Romero[1]. *[1]Hospital Dr. Carlos B. Udaondo, Hepatology Section, Buenos Aires, Argentina; [2]Fundación Favaloro, Ultrasound Service, Buenos Aires, Argentina; [3]Universidad de Buenos Aires, Preventive and Community Dentistry, Buenos Aires, Argentina*
Email: aemunoz@intramed.net

Background and Aims: Simvastatin (SVT) has shown to increase survival in cirrhotic patients with variceal bleeding. However, decompensated cirrhosis actually is a contraindication for statin therapy because risks are largely unknown. We aimed to assess the safety of SVT added to standard therapy in patients with decompensated cirrhosis.

Method: In this open, uncontrolled, ambispective trial we analyzed patients with decompensated cirrhosis associated with different complications, a year before and during 12 months of standard treatment plus SVT 20 mg once a day for 2 weeks, and later 40 mg. The primary endpoint was SVT safety. The secondary endpoints were SVT efficacy and quality of life as measured by the Short-Form 36 (SF-36) questionnaire.

Results: Baseline parameters: 30 patients were included, aged 57 ± 10 years, male 67%. Etiology: alcohol 60%. MELD 12.3 ± 3.3. D'Amico's stages 3: 3%, 4: 47% and 5: 50%. Decompensated cirrhosis due to ascites 90%, variceal bleeding 27%, jaundice 27% and hepatic encephalopathy 17%. SVT safety: Related adverse events were myalgia 23%; myalgia plus creatine kinase increase 13%; new onset diabetes 3%; digestive symptoms 63% and headache 13%; liver injury none. SVT dose reduction by muscle symptoms 27%. No patient developed serious adverse events related to SVT or discontinued it for any reason. SVT efficacy: Survival rate: 90%. Patients with cirrhosis complications in the previous year 97% and during the trial 33%, $p < 0.001$. Hospitalizations for decompensated cirrhosis in the previous year 77% and during the trial 27%, $p < 0.001$. Child-Pugh score improved from baseline 7.3 ± 1.3 to the end of the trial 6.7 ± 1.7, $p = 0.04$. Child-Pugh class also improved from baseline/to the end of the trial: A 20%/53%, B 73%/40%, $p = 0.01$, and C 7%/7%. Liver fibrosis evaluated by transient elastography did not change from baseline (31 ± 16 kPa) to the end of the trial (30 ± 13 kPa). Quality of life: All dimensions and component summaries improved at month 12 compared to baseline. The differences in physical function, role-physical, body pain and general health dimensions, and in the physical component summary were statistically significant, $p < 0.05$.
Conclusion: Addition of SVT to standard treatment of patients with decompensated cirrhosis was safe. It was proved effective through clinical assessments although it did not improve liver fibrosis. A better quality of life was observed.

SAT-207

Characterization of systemic inflammatory response in hepatorenal syndrome in cirrhosis. A major role for il-6, TNF-alpha, and VCAM

C. Sole[1,2,3], E. Solà[1,2,3], M. Morales-Ruiz[2,3,4], P. Huelin[1,2,3], M. Carol[1,5], R. Moreira[6], I. Graupera[1,3,6], E. Pose[1,2,3], L. Napoleone[1,3,6], G. De Prada[1,2], X. Ariza[1,2,3], A. Juanola[1], N. Fabrellas[5], W. Jiménez[3,5,6], P. Ginès[1,3,6]. *[1]Liver Unit, Hepatology, Hospital Clinic of Barcelona, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Barcelona, Spain; [4]Hospital Clinic Barcelona, Biochemistry and Molecular Genetics Department, Barcelona, Spain; [5]Faculty of Medicine and Health Sciences, University of Barcelona, Barcelona, Spain; [6]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*
Email: csolem@clinic.ub.es

Background: Several lines of evidence indicate that progression of cirrhosis from compensated to decompensated state is characterized by marked inflammatory response probably related to systemic spread of bacterial products. HRS represents the end of the spectrum of pathophysiological abnormalities of cirrhosis. However, confirmation of the existence of such inflammatory response in HRS and its possible role on disease outcome is lacking.
Aim: To characterize the systemic inflammatory response in patients with cirrhosis and acute kidney injury-HRS (AKI-HRS) and its relationship with outcome. Patients with cirrhosis without AKI and with prerenal-AKI due to volume depletion were also studied for comparison.
Method: One-hundred and seventy-eight patients admitted for acute decompensation of cirrhosis were studied: 57 without AKI, 63 with prerenal-AKI, and 58 with AKI-HRS. Systemic inflammatory response was estimated by measuring plasma levels of 18 cytokines using a multiplex kit.
Results: Overall, levels of fraktalkine, IL-8, IL-6, MIP-1α, TNF-α, and VCAM were significantly different among the 3 groups of patients. Patients with AKI-HRS had high levels of IL-8, IL-6, and TNF-α and low levels of fraktalkine and MIP-1α; levels of G-CSF were also higher in AKI-HRS compared to prerenal-AKI. Levels of IL-6 and TNF-α were particularly increased in AKI-HRS compared to prerenal-AKI (IL-6: 45 (19–104) *vs.* 14(3–46) pg/mL; TNF-α: 47(35–61) *vs.* 30(18–73) pg/mL ($p < 0.003$ for both). Cytokine levels were unrelated to the severity of AKI-HRS because patients meeting the diagnostic criteria of type-1 HRS had levels similar to those not meeting these criteria. In AKI-HRS, cytokine levels were unrelated to bacterial infections except for IL-6 and IL-1RA, which were higher in infected patients. Of the 58 patients with AKI-HRS, 31 (53%) had resolution of AKI-HRS and 21 survived 3 months without liver transplantation. VCAM was the only cytokine independently associated with lack of resolution of AKI-HRS and transplant-free mortality.
Conclusion: AKI-HRS is characterized by marked systemic inflammatory response with increased serum levels of proinflammatory cytokines, particularly IL-6 and TNF-α. The inflammatory status appears to be particularly intense in AKI-HRS compared to pre-renal AKI. The association between increased VCAM levels and lack of resolution of AKI-HRS and mortality suggests that endothelial dysfunction has a major role in the outcome of AKI-HRS.

SAT-208

Skeletal muscle index indicates mortality risk more accurately than psoas muscle index in patients with cirrhosis. From the FLEXIT consortium.

A.J. Montano-Loza[1], E. Carey[2], M. Ebadi[1], C. Wang[3], S. Dasarathy[4], M.R. Kappus[5], M.A. Dunn[6], J. Lai[7]. *[1]University of Alberta, Gastroenterology, Edmonton, Canada; [2]Mayo Clinic College of Medicine, Division of Gastroenterology and Hepatology, Phoenix, United States; [3]University of California, Gastroenterology, San Francisco, United States; [4]Cleveland Clinic, Division of Gastroenterology and Hepatology, Cleveland, United States; [5]Duke University Hospital, Durham, United States; [6]University of Pittsburgh School of Medicine, Medicine and Biomedical Informatics, Pittsburgh, United States; [7]University of California, San Francisco, United States*
Email: montanol@ualberta.ca

Background and Aims: Sarcopenia is independently associated with mortality in cirrhosis. Total skeletal muscle cross-sectional area in a single CT image at the level of the third lumbar vertebrate (L3) is a valid representative of whole body muscle mass. Skeletal muscle index (SMI) and individual psoas muscle assessments have been used as indicators of sarcopenia-related mortality. Controversy remains regarding applicability of psoas muscle to identify patients at greater risk. We aimed to determine psoas muscle index (PMI) association with SMI, and evaluated the capacity of PMI to predict liver transplant (LT) waiting-list mortality.
Method: We evaluated listed adult patients with cirrhosis from 2012 to 2013 at four North American LT centers. From L3-CT images within 3 months of listing, we determined SMI and PMI (cm^2/m^2). Low SMI was defined as SMI <39 cm^2/m^2 in women and <50 cm^2/m^2 in men as published by us earlier. Cut-offs for PMI to predict mortality were established using a receiver-operating characteristic analysis. Mortality predictors were determined using competing-risk analysis, with LT as a competitive event and results were reported as sub-distribution hazard ratios (sHRs).
Results: Of 353 waitlist candidates, 68% were male, mean age 56 ± 9 years, and MELD of 16 ± 8 points. Low SMI was present in 51% of men and 36% of women ($P = 0.02$). Moderate correlation between SMI and PMI was observed ($r = 0.73$, $P < 0.001$). Low PMI (men: <5.1 cm^2/m^2; women: <4.3 cm^2/m^2) yielded poor and moderate concordance with low SMI in men and women, respectively (Kappa coefficient 0.31 and 0.63). In women, both SMI (sHR 0.94, $p = 0.05$) and PMI (sHR 0.58, $p = 0.002$) were predictors of mortality while in men, SMI was significantly (sHR 0.95, $P = 0.001$) and PMI showed a trend to be (sHR 0.85, $P = 0.09$) associated with mortality. Both Low SMI and low PMI were independently associated with higher mortality in multivariable models (Table 1). Using PMI cutoffs, 66% and 28% of low SMI men and women, who have a higher risk of mortality, were classified as high PMI group.
Conclusion: Low PMI predicts mortality in patients with cirrhosis but identify only small proportions of those at risk for low SMI-associated

Table 1: (abstract: SAT-208).

	Univariate Analysis		Multivariate Analysis			
Men	sHR (95% CI)	P-value	sHR (95% CI)	P-value	sHR (95% CI)	P-value
MELD score	1.01 (0.98–1.04)	0.45	1.02 (0.99–1.06)	0.22	1.02 (0.99–1.05)	0.26
HCC	1.76 (1.07–2.90)	0.03	2.18 (1.22–3.89)	0.008	1.98 (1.12–3.49)	0.02
Low SMI	2.17 (1.29–3.66)	0.003	2.46 (1.38–4.39)	0.002		
Low PMI	1.85 (1.05–3.24)	0.03			2.04 (1.13–3.68)	0.02
Women						
MELD score	1.02 (0.99–1.05)	0.25	1.00 (0.97–1.04)	0.82	1.01 (0.98–1.05)	0.47
Albumin (g/L)	1.02 (1.00–1.05)	0.07	0.79 (0.44–1.41)	0.42	0.77 (0.43–1.36)	0.36
Low SMI	2.12 (1.14–3.93)	0.02	2.05 (1.00–4.21)	0.05		
Low PMI	2.45 (1.32–4.58)	0.005			2.47 (1.24–4.95)	0.01

mortality. SMI should not be replaced by PMI especially in men with cirrhosis.

SAT-209

Loss of subcutaneous adipose tissue associates with higher mortality risk in patients with cirrhosis

A.J. Montano-Loza[1], M. Ebadi[1], P. Tandon[1], V.C. Mazurak[2]. *[1]University of Alberta, Gastroenterology, Edmonton, Canada; [2]University of Alberta, Agricultural, Food and Nutritional Science, Edmonton, Canada*
Email: montanol@ualberta.ca

Background and Aims: Cross-sectional anthropometric assessments of muscle and adipose tissue in patients with cirrhosis at the time of liver transplant (LT) evaluation correlate with adverse prognosis. We have a limited understanding of the prognostic value of longitudinal changes in these body composition parameters. In a retrospective cohort of 136 patients with cirrhosis, our aim was to explore the rate of change in muscle and adipose tissue depots [visceral adipose and subcutaneous adipose tissue (SAT)] in the year after LT evaluation.
Method: CT images taken at the 3rd. lumbar vertebra were used to determine cross sectional areas of muscle, visceral and subcutaneous adipose tissue expressed by cm^2/m^2. The baseline CT was part of the LT evaluation and the second one was conducted at approximately one year. Differences between two consecutive CT images were reported as percentage (%) change per 100 days to enable comparison between patients. A change between –2% and 2% was considered as tissue maintenance, given the precision error of 1.5% for muscle and adipose tissue longitudinal change estimation. Cox proportional hazards models were conducted to assess associations between body composition changes and mortality.
Results: The majority of patients were male (70%) with a mean age of 57 ± 7 years, MELD score of 12 ± 6 point and mean BMI of 27 ± 6 kg/m^2. Skeletal muscle loss occurred in 50% of patients with a mean change of –3 ± 16% per 100 days (150 ± 35 *vs.* 143 ± 33 cm^2/m^2, $p < 0.001$), whereas the rate of change for SAT was 32 ± 91% per 100 days (168 ± 126 *vs.* 195 ± 129 cm^2/m^2, $p < 0.001$) with 33% of patients experiencing SAT loss. There was no difference in visceral adipose tissue areas between the baseline and second CT (114 ± 77 *vs.* 109 ± 71 cm^2/m^2, $p = 0.30$). No significant difference in median survival was observed between patients who lost and those who maintained/gained muscle (24 ± 2 *vs.* 55 ± 14 months, $p = 0.11$). However, median survival was significantly shorter in patients who lost SAT compared to patients who maintained or gained SAT (17 ± 2 *vs.* 41 ± 12 months, $p = 0.002$). SAT loss increased mortality risk by 2-fold compared to patients who gained/maintained SAT (HR 2.21; 95% CI 1.27–3.82; $p = 0.005$) after adjusting for MELD score and serum albumin.
Conclusion: SAT loss increases mortality risk in patients with cirrhosis. Given the important role of SAT in storing energy, higher mortality in patients who experienced SAT loss might be related to the depletion of body energy reservoirs.

SAT-210

Assessment of biventricular function in patients with decompensated cirrhosis and hepatopulmonary syndrome

S. Soulaidopoulos[1], M. Vlachou[2], T. Oikonomou[1], T. Tzoumari[1], P. Doumtsis[1], A. Karasmani[1], G. Giannakoulas[2], H. Karvounis[2], E. Cholongitas[1,3], I. Goulis[1]. *[1]Medical School of Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Hippokratio General Hospital, Thessaloniki, Greece; [2]Medical School of Aristotle University of Thessaloniki, First Cardiology Department, AHEPA University Hospital, Thessaloniki, Greece; [3]Medical School of National & Kapodistrian University of Athens, First Department of Internal Medicine, Laiko General Hospital, Athens, Greece*
Email: soulaidopoulos@hotmail.com

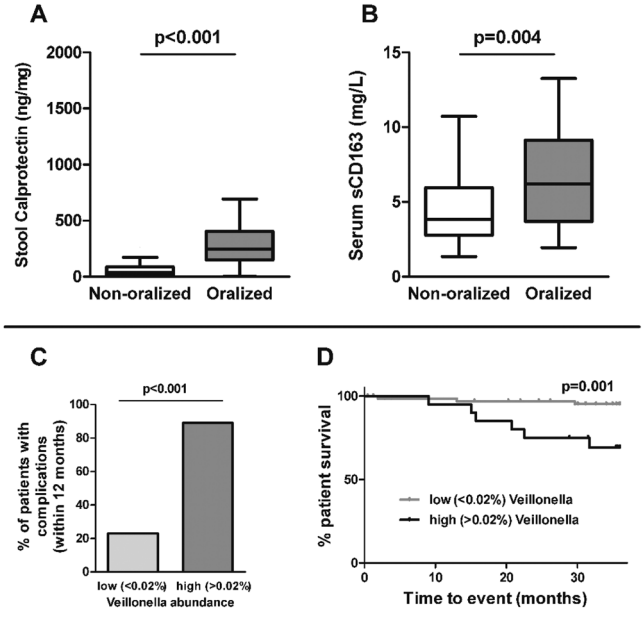
Background and Aims: The impairment of cardiac function in the setting of hepatopulmonary syndrome (HPS) in patients with end stage liver disease constitutes an issue of debate. The aim of this study was to evaluate possible correlations between the presence of HPS and biventricular cardiac systolic function in patients with decompensated cirrhosis
Method: We prospectively evaluated consecutive liver transplantation candidates with stable decompensated cirrhosis. HPS was defined as the presence of an elevated alveolar-arterial oxygen gradient and intrapulmonary vasodilatation, detected by contrast enhanced echocardiography (left atrial bubble opacification between third and sixth cardiac cycle after right atrial opacification). HPS severity was determined as mild ($PaO2 \geq 80$ mmHg), moderate ($60 \leq PaO2 < 80$ mmHg), severe ($50 \leq PaO2 < 60$ mmHg) and very severe ($PaO2 < 50$ mmHg). A semi-quantitative assessment of shunt size was performed according to the number of bubbles calculated in one still frame in left heart chambers (grade 1:<29, grade 2:30–100 and grade 3:>100). M–mode echocardiography and tissue Doppler imaging (TDI) measurements were performed. Global longitudinal strain (GLS) was calculated for left ventricular (LV) and right ventricular (RV) myocardium.
Results: 140 patients (pts) (age 52 ± 12 years, M/F: 96/44, MELD score 14.7 ± 5) were enrolled. HPS was diagnosed in 45 (32.1%) pts (mild: 57.4%, moderate: 36.2%, severe 2.1% and very severe 4.3%). Intrapulmonary vascular dilatations were present in 59 (42.1%) pts (grade 1: 84.7%, grade 2: 8.5%, grade 3: 6.8%). There was no significant difference in LVGLS (–22.2 ± 2.6 *vs.* –21.9 ± 2.4%, $p = 0.71$) or in RVGLS (–23.2 ± 4.5 *vs.* –23.3 ± 4%, $p = 0.89$) between HPS and non-HPS group. However, lower LV ejection fraction values were recorded in the HPS group (59 *vs.* 61%, $p = 0.007$). No other echocardiographic parameter was correlated to HPS. Intrapulmonary shunt grading was significant correlated to HPS classification ($\chi^2 = 18.9$, $p = 0.029$), with lower arterial oxygen values being recorded in higher stages of intrapulmonary shunt. Interestingly, patients receiving diuretics had higher LVGLS values (–22.6 ± 2.5 *vs.* –21.1 ± 2.3%, $p = 0.01$).
Conclusion: Although lower LV ejection fraction values were recorded in HPS patients, TDI and biventricular GLS was unable to predict the presence of HPS. HPS severity was significantly correlated to the echocardiographical staging of intrapulmonary shunt.

SAT-211

Loss of colonization resistance in cirrhosis facilitates proton pump inhibitor-associated oralization of the colonic microbiome

F. Rainer[1], A. Horvath[1], M. Bashir[1], B. Leber[1], B. Schmerboeck[1], A. Blesl[1], T. Madl[1], I. Klymiuk[1], A. Groselj-Strele[1], M. Durdevic[1], H. Grønbæk[2], H.J. Møller[2], D.E. Freedber[3], J.A. Abrams[3], R.E. Stauber[4], P. Fickert[1], P. Stiegler[1], V. Stadlbauer[1]. [1]*Medical University of Graz, Graz, Austria;* [2]*Aarhus University Hospital, Aarhus, Denmark;* [3]*Columbia University Medical Center, New York, United States;* [4]*Institute of Pathology, Graz, Austria*
Email: florian.rainer@medunigraz.at

Background and Aims: In patients with liver cirrhosis, gut microbial diversity, an indicator of colonization resistance, is significantly reduced. In this setting, proton pump inhibitor (PPI) use is suspected to promote stool colonization with bacteria that are highly abundant in the oral cavity. Our aim was to assess whether cirrhosis-typical alterations of the microbiome predispose for PPI-associated oralization and whether this is associated with intestinal and systemic inflammation, complications, and mortality.
Methods: We compared stool microbiome composition (16S sequencing of stool samples) and markers of intestinal and systemic inflammation (i.e. fecal calprotectin and serum sCD163) of cirrhotic patients (56 ± 9 years, 29% female) with (n = 48) and without (n = 41) PPI use. Stool microbiome composition and overgrowth of individual OTUs (i.e. the disproportional increase of an OTU compared to other members of their families) were compared to a control cohort of 12 healthy volunteers prior and after a 4-week regime of PPI intake. Patients were observed for a median time of 37 months and cirrhosis complications and mortality rates were assessed.



Results: Microbiome composition of cirrhotic patients showed alterations typical for cirrhosis, including a significant reduction in microbial diversity. Furthermore, cirrhotic patients with PPI use showed significant overgrowth of Veillonella parvula (p = 0.001) and Streptococcus salivarius (p < 0.001) compared to non-users. PPI use in healthy volunteers did not result in substantial overgrowth of these OTUs (p = 0.18 and 0.08). In cirrhotic patients with PPI use, microbial diversity was inversely correlated with abundance of V. parvula, indicating that a loss in colonization resistance facilitates the overgrowth these OTUs. Oralization (combined overgrowth of Veillonella parvula and Streptococcus salivarius) was strongly associated with an increase in intestinal and systemic inflammation (see Figure 1A, B). Especially Veillonella parvula was associated with the occurrence of complications and predictive for mortality (see Figure 1C, D).
Conclusion: Loss of colonization resistance is prominent in cirrhosis. PPI therapy in these patients is associated with an increase of oral bacteria in the stool microbiome. PPI-associated oralization is linked to increased intestinal and systemic inflammation, occurrence of complications and mortality.

SAT-212

The amelioration of muscle wasting leads to the improvement of cognitive impairment after transjugular intrahepatic portosystemic shunt: A proof of concept that sarcopenia and hepatic encephalopathy are causally related

S. Gioia, S. Nardelli, F. Pitocchi, R. Pileggi, B. Lattanzi, M. Merli, O. Riggio. *La Sapienza, University of Rome, Department of clinical medicine, Rome, Italy*
Email: stensgioia@hotmail.com

Background and Aims: in cirrhotic patients a statistical correlation between sarcopenia and hepatic encephalopathy (HE) has been shown. The transjugular intrahepatic portosystemic shunt (TIPS) induces an amelioration of the nutritional status and muscle wasting, without inducing a parallel amelioration of liver function. The aim of the study is to evaluate the evolution of the skeletal muscle index (SMI), as a measure of sarcopenia, and HE in patients submitted to TIPS.
Method: 22 cirrhotic patients submitted to TIPS were included in the study. The modification of SMI by means of CT scan and of HE (both overt and minimal, by means of the Psychometric Hepatic Encephalopathy Score, PHES) as well as of venous ammonia were evaluated before and after a mean follow up of 15 ± 10 months after TIPS.
Results: In the whole group, SMI significantly increased after TIPS, from 38.8 ± 10.7 to 44.9 ± 12.2 cm/m^2 (p = 0.0008), with a mean increase of 15%. PHES and ammonia were also significantly improved at the end of follow up compared to the values observed one week after the procedure. Comparing the patients without (n = 10) or with (n = 12) an improvement in SMI >10%, PHES (−4.4 ± 1.7 *vs.* −1.3 ± 2.2 respectively; p = 0.002) and ammonia (91 ± 31 *vs.* 48 ± 32 µmol/L, respectively; p = 0.004) significantly improved in the second group. Moreover, the prevalence of minimal HE (70% *vs.* 16.7% respectively, p = 0.001) as well as the number of episodes of overt HE were significantly reduced in the group of patients who improved SMI. MELD remained stable or worsened after TIPS and was not significantly different between the groups with or without SMI improvement.

Table 1: Prevalence of cognitive impairment (minimal and overt) in the patients with or without improvement of SMI >10% at the end of follow up compared to the basal values

	SMI improvement < 10% (n= 10)	SMI improvement >10% (n= 12)	P value
Minimal HE (PHES≤−4) (yes/no)	7/3 (70%)	2/10 (17%)	0.01
PHES score	−4.4 ± 1.7	−1.3 ± 2.2	0.002
Overt HE (yes/no)	8/2	7/5	NS
OHE in the first 3 months (N of episodes/pt)	0.8 ± 1.03	0.58 ± 0.51	NS
OHE in the following months (N of episodes/pt)	1.2 ± 1.3	0.08 ± 0.3	0.009
Venous plasma Ammonia (µg/dl)	91.3 ± 30.56	48.16 ± 32.05	0.004
Follow up (months)	17 ± 10	14 ± 10.4	NS

Conclusion: TIPS represents a model to study the relationship between sarcopenia and HE independently of liver function. The data support the causal relationship between sarcopenia and HE being the prevalence of minimal HE, the number of episodes of overt HE as well as the plasma venous ammonia levels significantly reduced in the

group of patients in whom sarcopenia ameliorated compared to the patients in whom the nutritional status remained stable.

SAT-213

Non cirrhotic portal hypertension secondary to oxaliplatin therapy: Incidence and presentation

S. Gioia[1], S. Nardelli[1], R. Pileggi[1], F. Pitocchi[1], C. Pasquale[1], M.D. Martino[2], O. Riggio[1]. *[1]La Sapienza, University of Rome, Department of clinical medicine, Rome, Italy; [2]La Sapienza, University of Rome, Department of Radiological, Oncological and Pathological Sciences, Rome, Italy*
Email: stensgioia@hotmail.com

Background and Aims: Recently, several studies have identified a possible relationship between the therapy with oxaliplatin and the development of non-cirrhotic portal hypertension. However, the incidence and the way of presentation of the disease in series of patients treated with oxaliplatin have not been yet described.
The aim of the study is to search for the development of radiological signs of portal hypertension (PH) in a series of patients submitted to therapy with oxaliplatin.
Method: From a total of 570 neoplastic patients consecutively observed, based on stringent selection criteria aimed at the elimination of all patients with active or potential portal hypertension, 94 patients undergoing oxaliplatin therapy and with a computed tomography (CT) performed prior to treatment were finally included in the study.
Changes in portal vein and spleen diameters, the appearance of esophagogastric varices and of other collaterals at the CT performed after at least 4 months from the therapy have been evaluated by an experienced radiologist. Portal hypertension was defined by the contemporaneous presence of portal vein diameter > 15 mm and longitudinal spleen diameter > 12 cm or by the presence of esophagogastric varices and/or portosistemical shunts.
Results: 85 patients were affected by colorectal cancer, 9 were affected by other gastrointestinal neoplasia for which they underwent to neoadiuvant (9) or adiuvant (85) chemotherapy. The most used therapeutic regimens were XELOX and FOLFOX. Before the chemotherapy no one of the 94 patients had portal hypertension.
After 5 ± 1.6 months from the therapy, 9 patients (9.6%) developed radiological signs of portal hypertension. In particular, 7 patients showed portal vein diameter >15 mm and splenomegaly (Table 1), one patient developed esophageal varices (1.1%) and one gastric varices (1.1%).

Table 1: Comparison between the CT scans before and after therapy with oxaliplatin

	Before Oxaliplatin	After Oxaliplatin	P value
Portal vein diameter (mm)	12.3 ± 1.8	12.9 ± 1.7	0.0009
Longitudinal diameter of the spleen (cm)	10.1 ± 2.5	11.1 ± 2.1	<0.0001
Spleen volume (cm^3)	298 ± 156	373 ± 201	<0.0001
n of pts with portal vein dilatation*	6 (6.4%)	10 (10.6%)	NS
n of pts with splenomegaly**	18 (19.3%)	26 (28%)	NS
n of pts with oesophageal varices	0	1 (1.1%)	
n of pts with gastric varices	0	1 (1.1%)	
n of pts with paraumbelical vein recanalization	0	0	
n of pts with portal dilatation* and splenomegaly**	0	7 (7.5%)	0.006

Data are expressed as mean ± SD
*portal vein diameter >15 mm
**longitudinal diameter of the spleen > 12 cm

Conclusion: Liver vascular damage causing the development of PH is common in the patients undergoing oxaliplatin-based chemotherapy regimens. Thus, this side effect should be always considered by submitting this kind of patients to specific controls to early recognize its onset.

SAT-214

The Cost-effectiveness of albumin in the treatment of decompensated cirrhosis in Italy, Spain and Germany

M.C. Runken[1], P. Caraceni[2], J. Fernandez[3], A. Zipprich[4], R. Carlton[5], M. Bunke[1]. *[1]Grifols SSNA, Research Triangle Park, United States; [2]University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [3]University of Barcelona, Liver ICU, Liver Unit, Barcelona, Spain; [4]Martin-Luther-University-Halle-Wittenberg, Department of Internal Medicine, Halle (Saale), Germany; [5]Xcenda, Global Health Economics and Outcomes Research, Palm Harbor, United States*
Email: rashad.carlton@xcenda.com

Background and Aims: Ascites is the most common and frequently the first complication of cirrhosis to appear signaling the presence of decompensated cirrhosis. The European Association for the Study of the Liver (EASL) guidelines support the use of albumin to treat cirrhotic patients with ascites undergoing large volume paracentesis (LVP), spontaneous bacterial peritonitis (SBP) and hepatorenal syndrome (HRS). This study's objective was to evaluate the cost-effectiveness of albumin in the treatment of complications of decompensated cirrhosis across Italy, Spain and Germany.
Method: A decision tree cost-effectiveness model from a hospital perspective, was developed to evaluate the cost-effectiveness of albumin in the treatment of patients requiring LVP, having SBP or HRS. In the LVP model, albumin was compared to saline, gelatins or no fluid. Albumin plus antibiotics were compared to antibiotics alone in SBP, and albumin plus terlipressin was compared to terlipressin alone in HRS. The models included pharmacy costs and medical complication costs in decompensated cirrhosis. The medical complications included in the LVP model were hyponatremia, renal dysfunction, and hepatic encephalopathy; renal impairment and hospital length of stay for SBP; and renal impairment for HRS. Effectiveness inputs were literature-based and included mortality and the rates of medical complications. Quality-adjusted life years (QALYs) were calculated based on existing health state utilities for decompensated cirrhosis, encephalopathy, and SBP. The primary model results were the incremental cost-effectiveness ratios (ICERs) for cost per life saved and cost per QALY.
Results: In the ICER calculation for LVP, albumin was less costly and more effective (i.e. a dominant treatment) than saline, gelatins or no fluid in both survival and QALYs in Italy, Spain and Germany. In the ICER calculation for SBP, antibiotics plus albumin were a dominant treatment in Spain in both survival and QALYs. Antibiotics plus albumin were cost-effective in Italy and Germany with ICERs less than €8,000 per life saved and below €18,000 per QALY. In the ICER calculation for HRS, albumin plus terlipressin was a dominant treatment in both survival and QALYs across all 3 countries.
Conclusion: This analysis suggests that the use of albumin in the treatment of decompensated cirrhosis associated with large volume paracentesis, spontaneous bacterial peritonitis, or hepatorenal syndrome is cost-effective in both survival and QALYs across Italy, Spain, and Germany.

SAT-215

The role of HbA1c as a risk factor for the development of spontaneous bacterial peritonitis in patients with decompensated liver cirrhosis

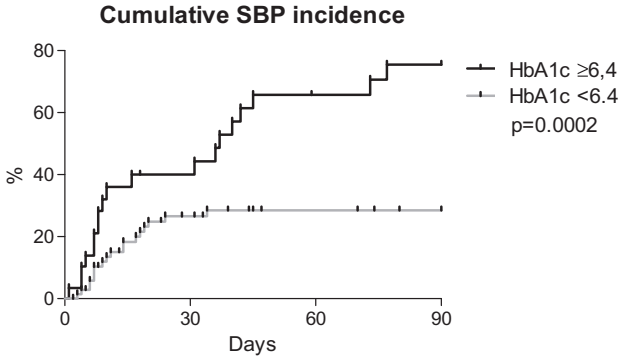
T. Tergast[1], H. Laser[2], S. Gerbel[2], M.P. Manns[1,3,4], M. Cornberg[1,3,4], B. Maasoumy[1,3]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology; [2]Hannover Medical School, Centre for Information Management (ZIMt); [3]German Centre for Infection Research (Deutsches Zentrum für Infektionsforschung DZIF); [4]Centre for Individualised Infection Medicine (CIIM)*
Email: tergast.tammo@mh-hannover.de

Background and Aims: Type 2 diabetes mellitus (DM) is a well-known risk factor for infections. DM is frequent in patients with

cirrhosis. However, data regarding the impact of DM on the development of spontaneous bacterial peritonitis (SBP) are quite rare. Glycated hemoglobin A1c (HbA1c) is the most important marker for the 90-day surveillance of mean blood glucose levels. In patients with cirrhosis HbA1c levels are usually lower due to the increased hemolysis. In this study we investigated the role of HbA1c as a risk factor for SBP incidence and mortality in patients with liver cirrhosis and ascites.

Method: A number of 626 consecutive patients with liver cirrhosis and ascites who underwent paracentesis at Hannover Medical School between January 2012 and June 2016 were included and further followed up (mean 200days). DM diagnosis was based on patients' medical records. HbA1c was assessed at the time of the first paracentesis. To identify optimal HbA1c cut-offs ROC analyses were performed. Log-rank test was used for survival analysis and uni- and multivariate Cox-regression analysis for the identification of risk factors for mortality and SBP.

Results: DM was present in 152 patients (24%). Patients with DM were more likely to develop a SBP during follow-up (DM: 42% vs. no-DM: 33%; HR = 1.5, p = 0.03). Risk for SBP development was particularly high in patients with higher HbA1c levels. We identified 6.4% as the optimal HbA1c cut-off to predict SBP. Individuals with HbA1c values ≥6.4% were at a significantly higher risks for SBP than patients with HbA1c values <6.4% and those without DM within 90 days (HbA1c ≥6.4%: 66% vs. HbA1c <6.4%: 25%; HR = 4.16; p = 0.0002 and HbA1c ≥6.4%: 66% *vs.* no-DM: 26%; HR = 6.3; p < 0.0001, respectively) (Figure 1). Interestingly, the risk for SBP development in DM patients with HbA1c values <6.4% was not different from patients without DM (HbA1c <6.4%: 25% and no-DM: 26%; p = 0.78). High HbA1c values remained a statistical significant risk factor for SBP development in the multivariate analysis (HR: 3.5; p = 0.005). Of note, presence of DM as well as the HbA1c level had no impact on 90-day mortality in patients with SBP (DM: 32% *vs.* no-DM: 25%; p = 0.56 and HbA1c ≥6.4%: 32% *vs.* HbA1c <6.4%: 29%; p = 0.79, respectively).



Conclusion: HbA1c values may identify patients with a higher risk for SBP and be useful to select patients for antibiotic prophylaxis. Due to the increased hemolysis in individuals with liver cirrhosis modified HbA1c target values might be necessary.

SAT-216

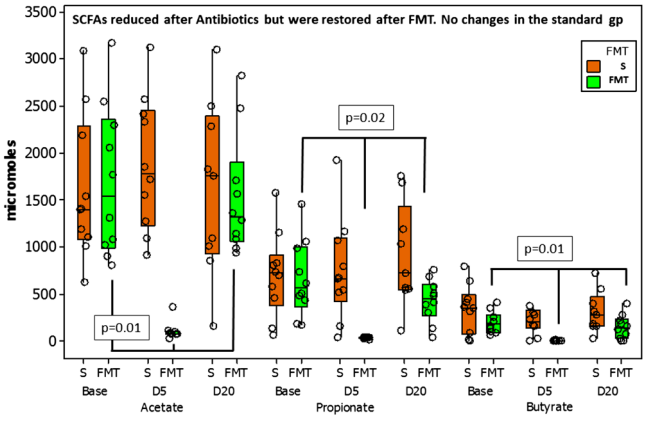
Antibiotic-associated disruption of microbial composition and functionality is restored after fecal transplant in cirrhosis

J.S. Bajaj[1], A. Fagan[1], G. Kakiyama[1], T. Savidge[2], E. Gavis[1], M. Sikaroodi[3], D. Heuman[1], H. Nittono[4], H. Takei[4], Z. Kassam[5], M. Fuchs[6], P. Boonma[2], A. Haag[2], P. Gillevet[3]. *[1]Virginia Commonwealth University and McGuire VA Medical Center, Richmond, United States; [2]Baylor College of Medicine, Houston, United States; [3]George Mason University, Manassas, United States; [4]Junshin Clinic Bile Acid Institute, Tokyo, Japan; [5]Openbiome and Finch Therapeutics, Boston, United States; [6]Virginia Commonwealth University and McGuire VAMC, Richmond, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: Cirrhotic pts are often prescribed antibiotics (Abx) which impact microbial diversity and functionality. These can result in antibiotic resistance and fungal infections but there are few options to restore these disruptions. Short-chain fatty acids (SCFA) and secondary bile acids (BAs) are bacterially produced molecules that help intestinal barrier function and may prevent superinfections. We aimed to determine the impact of fecal microbial transplant (FMT) on restoring microbiota functionality after antibiotics in cirrhotic patients.

Method: Decompensated cirrhotic patients on rifaximin were randomized 1:1 to receive standard of care(SOC) or FMT after 5 days of broad-spectrum Abx (ciprofloxacin, amoxicillin and metronidazole) as part of a trial to treat hepatic encephalopathy (HE). FMT was administered by enema (90ml) from a single well-characterized donor after pre-treatment Abx. MELD score, microbial diversity, fecal BA and SCFA profiles were studied at baseline, day 5 and day 20 in both groups. Bacterial metabolism of BAs (deconjugated/secondary BA) was evaluated.

Results: Among 20 HE participants, 10 patients were randomized to SOC and 10 to Abx followed by FMT, in addition to SOC. Sample analysis was performed at days 0, 5 and 20 in both groups. Groups were matched on MELD score (13 *vs.* 12) at baseline. Overall, there was a decrease in microbial diversity after Abx that recovered post-FMT (Table 1). MELD score increased significantly after Abx, which reduced post-FMT. Deconjugation and secondary BA conversion capacity and SCFA levels (Figure) reduced post-Abx but were restored after FMT to baseline levels. No changes were seen in the SOC group.



Conclusion: Antibiotic-associated disruptions in microbial diversity and production of SCFAs and secondary BAs were restored to baseline with one FMT enema. FMT could be promising to restore microbiota composition and functionality disruptions in decompensated cirrhotic patients on rifaximin.

SAT-217

Beta-blocker use in cirrhosis is independently associated with minimal hepatic encephalopathy

C. Acharya, A. Fagan, L. Thacker, M. White, J.S. Bajaj. *Virginia Commonwealth University and McGuire VA Medical Center, Richmond, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: Minimal hepatic encephalopathy (MHE) is epidemic in cirrhosis. MHE can predict overt HE (OHE) and mortality. Beta-blockers (BB) are used in cirrhosis for variceal bleeding prevention & have underlying CNS effects that could worsen cognition. We aimed to determine the effect of BB use on MHE diagnosis in cirrhotic outpts.

Method: We enrolled cirrhotic pts at 2 tertiary-care centers. All pts underwent testing per guidelines using two strategies (Psychometric

Table 1: (abstract: SAT-216).

Median values for BAs; mean ± SD for rest	Fecal Microbial Transplant			Standard of Care (no intervention)		
	Baseline	Day 5 (post-Abx)	Day 20 (post-FMT)	Baseline	Day 5	Day 20
MELD score	12.0 ± 2.9	13.5 ± 3.2‡	11.6 ± 3.0†	13.2 ± 3.7	12.5 ± 3.4	13.4 ± 3.8
Shannon diversity	6.46 ± 1.07	4.59 ± 1.67‡,*	6.42 ± 1.42†	7.23 ± 0.77	7.21 ± 0.95	7.34 ± 0.86

Total Primary BAs	1.1	3.76‡,*	1.32†,*	0.20	0.31	0.69
Total Secondary BAs	0.88	0.13‡,*	0.75†	0.93	0.96	1.11
Total Conjugated BAs	0.12	1.75‡,*	0.21†	0.07	0.02	0.08

*p < 0.05 between groups,
†p < 0.05 within gp compared to day 5,
‡p < 0.05 within group compared to baseline, BAs in μg/gm stool

hepatic encephalopathy score PHES and EncephalApp Stroop). Impaired performance on both was considered MHE. Demographics, cirrhosis and prior OHE details, and BB use and reasons were recorded. Two sets of analyses were performed (1) Logistic regression: 2 models with MHE as dependent variable using age, gender, education, MELD, alcoholic etiology, prior OHE were created. Model 1 had BB use (yes/no) in the entire population while model 2 used an ordinal variable for BB use (0 = no BB, 1 = BB for primary prophylaxis/ selective BB, 2 = BB for secondary prophylaxis) (2) Propensity matching using OHE and MELD score and then comparing the impact of BB on MHE diagnosis.

Results: 218 cirrhotic outpts (45% MHE, 93 OHE, MELD 11 ± 8, 60 ± 9 yrs age, Education 13 ± 4 yrs, 19% women) were included. 84 patients were on BB (37% Selective, 50% primary & 18% secondary prophylaxis). Logistic regression (Table 1): model 1 with BB (yes/no) showed independent association of BB use on MHE. Model 2 showed that selective/primary BB use was associated with MHE but not secondary prophylaxis. (2) Propensity matching: Matching by OHE & MELD resulted in 152 pts (76/gp) of BB+/BB-. Despite matching by these variables, MHE prevalence was significantly higher in BB users (n = 45, 59%) compared to those without (n = 29, 38%, p = 0.01). This trend was seen when MHE by PHES alone (BB + 59% *vs.* BB- 41%, p = 0.02) or Stroop alone (BB + 86% *vs.* BB- 71%, p = 0.04) were used.

Conclusion: BB use, regardless of selective or non-selective, is associated with a higher diagnosis of MHE using both PHES and Stroop using propensity matching and logistic regression approaches. Controlling for BB use may be needed for MHE data interpretation. Alternative s to BB may be needed if patients continue to have impaired cognition despite HE therapy.

SAT-218

Validation of the baveno criteria for endoscopic surveillance of varices in cholestasic diseases

S. Tasayco[1], M.P. Delgado[1], V.M.V. Blasco[1,2], S. Augustin[1,2], J. Genesca[1,2]. [1]*Servicio de Medicina Interna-Hepatología, Hospital Universitari Vall d'Hebron, Institut de Recerca (VHIR), Universitat Autònoma de Barcelona, Barcelona, BARCELONA, Spain;* [2]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain*
Email: stephanietasayco0105@gmail.com

Background and Aims: The Baveno VI and AASLD 2016 guidelines recommend the use of non-invasive diagnostic tools (mainly transient elastography-TE) in the identification of patients with compensated advanced chronic liver disease (cACLD) in whom upper endoscopy (UE) screening for varices can be safely avoided, especially in those who require treatment (VNT: large varices or small varices with high-risk stigmata). These recommendations are a liver stiffness mesurement (LSM) by TE <20 kPa and a platelet count >150,000/mm^3. Later, the expanded Baveno VI criteria (a LSM <25 kPa and a platelet count >110000/mm^3) have suggested a significant increase in UE saved, without increasing the risk of undetected VNT. This tool has not been investigated in patients with cholestasic liver diseases. The aim of this study was to evaluate the performance of Baveno VI criteria in a group of patients with primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) with cACLD.

Method: This was a retrospective-prospective cross-sectional study including patients with PBC or PSC assessed with UE between 2009 and 2017 and with paired LSM within one year of the UE. During the study period, criteria to perform an UE were the presence of cACLD as assessed by a LSM ≥10 kPa. Patients with previous complication (ascites, variceal bleeding, hepatic encephalopathy), being on primary prophylaxis for variceal bleeding, HCC diagnosis and liver transplant were excluded from the analysis.

Results: Of 194 patients diagnosed with PBC, 29 were excluded. In 17 of the 165 patients included TE was not performed and 39 of the remaining 148 had a TE ≥10 kPa. UE was performed in 34 of the 39 patients with cACLD; 11 (32%) had varices and 2 (6%) were VNT. 20 of these 34 patients were within the Baveno VI criteria and 5 varices were detected, none with VNT. In addition, 24 of the 34 patients were within the expanded Baveno VI and again no VNT were missed. Regarding PSC, 23 patients were included and in 4 of them it was not possible to perform TE. 13 of the remaining 19 patients had a TE

Table 1: (abstract: SAT-217): Logistic regression models with MHE on Stroop and PHES as the dependent variable

Model 1: using BB yes/no			Model 2: using BB divided according to indications		
Variables	p-value	OR (95% CI)	Variables	p-value	OR (95% CI)

High-dose but not low-dose enoxaparin substantially improves survival in cirrhotic patients with portal vein thrombosis

L. Turco[1], N. Gualandi[1], R. Vukotic[2], M. Bianchini[1], F. Schepis[1], P. Andreone[2], E. Villa[1]. [1]*Azienda Ospedaliero-Universitaria Policlinico di Modena, University of Modena and Reggio Emilia, Division of Gastroenterology, Modena, Italy;* [2]*Centro di Ricerca per lo Studio delle Epatiti, Università degli Studi di Bologna, Dipartimento di Scienze Mediche e Chirurgiche, Bologna, Italy*
Email: erica.villa@unimore.it

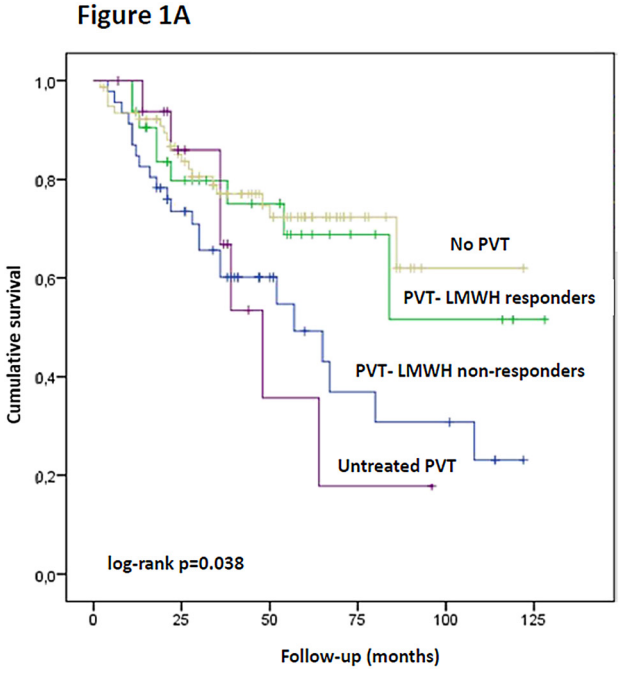
Background and Aims: Discordant data are present in the literature on the influence of portal vein thrombosis (PVT) on mortality of cirrhotic patients. Similarly no sound data are available on the effect of low molecular weight heparin (LMWH) on survival. We evaluated the impact of PVT and LMWH dose on survival of cirrhotic patients in a retrospective case-control study.
Method: 78 consecutive cirrhotic patients with LMWH-treated non-neoplastic PVT (cases) were matched 1:1 by age, sex, Child-Pugh score and presence of gastro-esophageal varices with untreated cirrhotic patients with PVT and with cirrhotic patients without PVT (controls). PVT characteristics, clinical features, dose of LMWH, bleeding events and survival were collected and analyzed by Kaplan-Meier (K-M) and Cox regression analysis. Patients with neoplastic PVT (diagnosed by imaging and/or biopsy) were excluded.
Results: Cases had lower platelets count ($p = 0.0001$), higher C-reactive protein levels ($p = 0.018$) and higher HCC prevalence ($p = 0.005$) than controls. Cases had lower, although non-significantly different, survival than controls (LMWH-PVT 74.5 ± 52.8 *vs.* untreated PVT 51.7 ± 36.0 *vs.* controls 91.2 ± 55.4 months respectively, log rank $p = 0.095$) (K-M). However, stratifying the cases by achievement of complete portal vein recanalization, cases achieving complete recanalization (PVT-LMWH-responders) had similar survival to controls while PVT-LMWH-non-responders clustered with untreated PVT (log rank $p = 0.038$, K-M, Figure 1A). Additionally, only cases treated with high-dose LMWH (≥12.000 IU daily) had a substantial survival advantage (log rank $p = 0.043$, K-M, Figure 1B). At Cox regression analysis, high-dose LMWH (OR 0.330, 95%CI 0.132–0.883, $p = 0.017$), HCC at baseline (OR 2.984, 95%CI 1.142–7.798, $p = 0.026$), and bilirubin levels at baseline (OR 1.408, 95%CI 1.126–1.760, $p = 0.003$), were independently related with survival. No differences in term of bleeding events were found between cases and controls ($p = 0.490$).
Conclusion: In cirrhotic patients, untreated PVT or PVT unresponsive to LMWH–mediated recanalization has significantly lower survival than PVT-LMWH-responders or no-PVT controls. High-dose LMWH (≥12.000 IU daily) is required to improve survival while low-dose LMWH is unsuccessful. The final outcome of the patients in term of survival independently depends on the clinical condition (e.g. stage of disease and HCC at enrollment) and on high-dose LMWH.

SAT-220

Higher in-hospital and post-discharge mortality and hospital charges in cirrhotic patients with acute respiratory illness in the United States

B. Zou[1], Y.H. Yeo[1], D. Jeong[1], E. Sheen[1], H. Park[2], P. Nguyen[1], Y.-C. Hsu[3], G. Garcia[1], M. Nguyen[1]. [1]*Stanford University Medical Centre, Division of Gastroenterology and Hepatology, Palo Alto, United States;* [2]*University of Florida College of Pharmacy, Pharmaceutical Outcomes & Policy, United States;* [3]*Fu-Jen Catholic University Hospital, Division of Gastroenterology, New Taipei, Taiwan*
Email: mindiehn@stanford.edu

Background and Aims: Both cirrhosis and acute respiratory illness (ARI) carry substantial disease and financial burden. Cirrhotic patients are more vulnerable to develop an ARI requiring hospitalization. This study aimed to explore the ARI burden among hospitalized cirrhotic patients.
Method: A retrospective cohort study was performed using the California Office of Statewide Health Planning and Development database for three recent influenza seasons (2010–2013). The prevalence of ARI, and hospital charges, and mortality risk among



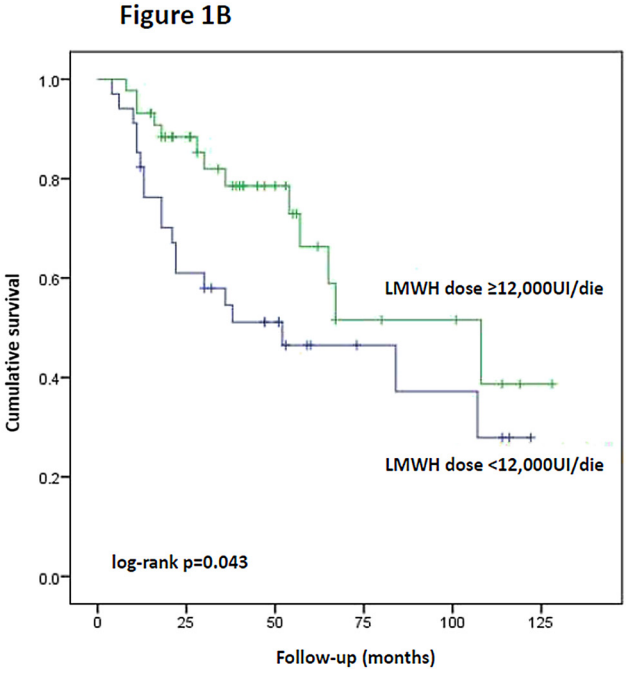


Figure: (abstract: SAT-219)

hospitalized cirrhotic patients was compared to cirrhotic patients without ARI. Propensity score matching (PSM) was used to control for imbalances in the groups. Survival analysis was used to determine variables associated with higher mortality.

Results: A total of 46,192 cirrhotic patients were identified during the three influenza seasons (14,049, 15,699, and 16,444 patients, respectively) which yielded 4244, 4551, 4791 patients in 2010–11, 2011–12 and 2012–13 after PSM. In the 2011–12 influenza season, the prevalence of ARI was 8.4% in all cirrhotic patients consistent across the three seasons. Older, Asian, non-Hispanic, Medicare, and Medicaid subgroups experienced significantly higher prevalence rates ($p \leq 0.002$). Compared to the matching controls, cirrhotic patients with ARI had 53.8% higher adjusted hospital charge ($122,555 vs.$79,685 per patient per admission, $p < 0.0001$), longer stay in hospital (16.92 *vs.* 14.23 days, $p < 0.0001$) but fewer hospital admissions (1.82 *vs.*1.96, $p = 0.001$) (Figure). Cirrhotic patients with ARI suffered 35.0% higher adjusted in-hospital mortality ($p < 0.0001$),13.0% higher adjusted 30-day post discharge mortality ($p = 0.023$), 19% higher adjusted 1-year post discharge mortality ($p = 0.001$) and twice the rate of respiratory deaths (5.0% *vs.* 2.3%, $p < 0.0001$) than cirrhotics without ARI. Older patients, patients with alcoholic liver disease or hepatocellular carcinoma were at particularly higher risk (adjusted hazard ratio = 2.94, 1.22, and 2.17 respectively, $p = 0.028$ to <0.001).

Conclusion: Hospital charges and mortality risk in hospitalized cirrhotic patients with ARI are higher than in cirrhotic patients without ARI. Research is needed to determine what preventive measures to include. Influenza and pneumococcal vaccinations could be recommended to decrease the significant burden of ARI in cirrhotic patients especially in the older patients and those with hepatocellular carcinoma, or alcoholic liver disease.

SAT-221

Sepsis in HBV associated decompensated cirrhosis: A comparison between SIRS (Sepsis-1) and qSOFA (Sepsis-3) based criteria

Z. Cao[1], Y. Liu[2], X. Lu[2], L. Chen[3], S. Yin[3], Z. Li[1], R. Mo[2], P. Ren[2], L. Chen[2], J. Lu[1], X. Wang[2], G. Zhao[2], W. Tang[2], X. Xiang[2], H. Wang[2], W. Cai[2], H. Li[4], Q. Xie[1]. Email: xieqingrjh@163.com

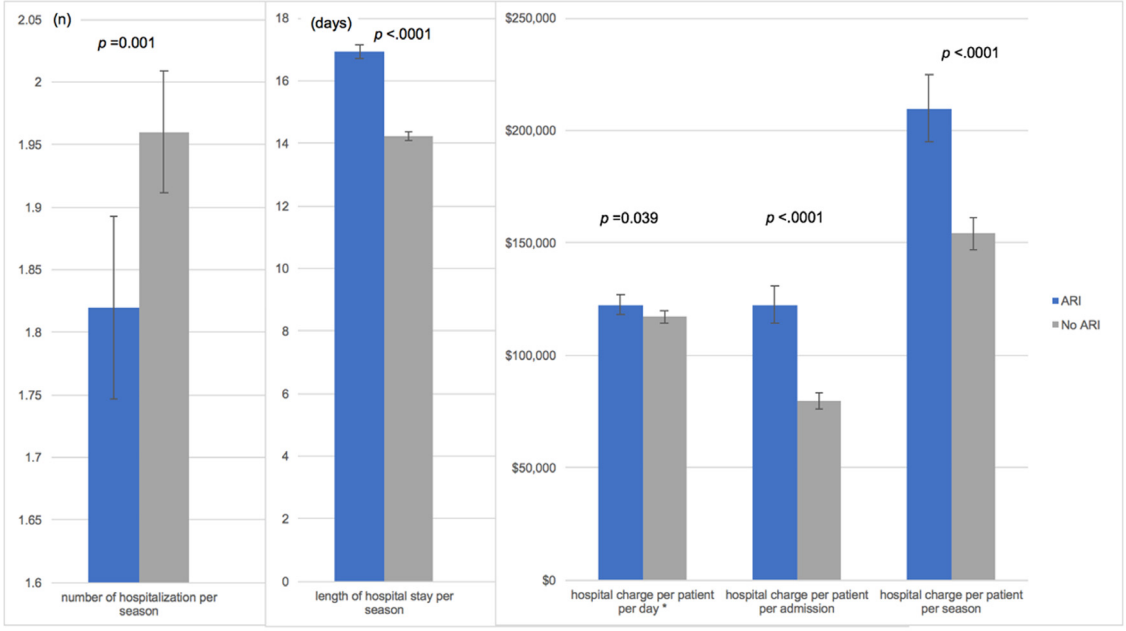
Background and Aims: The proposed Sepsis-3 criteria based on sequential assessment of quick SOFA (qSOFA) and delta SOFA score has been shown to predict poor outcomes in general population with suspected bacterial infection and was validated in cirrhosis recently (Piano.S, et al. Gut 2017). The current study aimed to compare the Sepsis-1 criteria (based on the combination of SIRS and infection) and Sepsis-3 for the ability of risk stratification and prognostic value.

Method: This is a retrospective observational cohort study. Patients with HBV associated cirrhosis were identified from medical records data between 2005 and 2010 at two tertiary teaching hospitals in China. The qSOFA, delta SOFA and SIRS was calculated for each patient at admission and during hospitalization. Pre-admission SOFA was set to 4 based on previous publications (Piano.S, et al. Gut 2017). The primary outcome was 90-day survival. Outcomes were measured using a time-to-event format and were analyzed using competing risk approach with the Fine and Gray method. Liver transplantation was considered as a competing event for death.

Adjusted number of hospitalizations, length of hospital stay, hospital charge per patient per day, hospital charge per patient per admission, and hospital charge per patient per season for cirrhotic patients with and without acute respiratory illness (ARI) in the 2011-2012 season



Adjusted for age, sex, race, ethnicity, insurance, severity of cirrhosis, cause of cirrhosis, cause of cirrhosis, comorbidities and history of severe comorbidities *: The value of charge on the y axis equals to the *hospital charge per patient per day* times 10

Figure: (abstract: SAT-220)

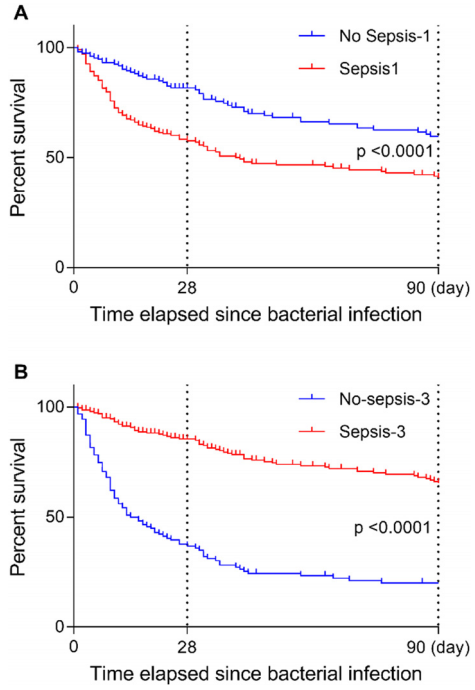


Figure 1. 90-day survival according to Sepsis-1 or Sepsis-3 in HBV-DC patients with bacterial infection.

Result: A total of 359 decompensated cirrhotic patients with bacterial infection met all study criteria were included from 5102 unique patients with HBV associated cirrhosis. Two hundred and ten (59%) were confirmed within 48h of admission and 149 (41%) were diagnosed afterwards, *i.e.*, nosocomial infection. The prevalence of positive SIRS (≥2 points in four parameters), qSOFA (≥2 points in three parameters) and positive delta SOFA (increase of 2 SOFA score) at admission was 29%, 15% and 55%, respectively. Accordingly, Sepsis-1 was diagnosed in 80 (22.3%) patients with 53% of resolution from BI and 65% transplant-free mortality; Sepsis-3 was diagnosed in 41 (11.4%) patients with 29% of resolution from BI and 79% transplant-free mortality. However, patients with Sepsis-1 had a similar 90-day survival with those without Sepsis-1 (40% *vs.* 59%, p < 0.001), though the difference reach significance. In contrast, patients with Sepsis-3 had strikingly lower 90-day survival in comparisons with those without Sepsis-3 (35% *vs.* 80%, p < 0.001) (Figure 1). In the multivariate analysis, Sepsis-3 (sHR, 2.90 [95%CI, 1.74–4.83]) rather than Sepsis-1 was an independent predictor for 90-day mortality. In addition, appropriate empirical antibiotics reduce the risk of 90-day mortality by 56% (sHR, 0.44 [95%CI, 0.28–0.69]) independent of the presence of Sepsis-1 or -3.

Conclusion: In patients with bacterial infection, Sepsis-3 is better than Sepsis-1 in prognosticating cirrhotic patients with bacterial infection. The results may be extended to patients with fungal infection but remains to be confirmed.

SAT-222

Assessment of portal hypertension evolution in hepatitis C virus cirrhosis patients with baseline large oesophageal varices after sustained virological response

M. Abadia, M. Montes, D. Ponce, Rubén Fernandez, J. Poza, E. Marín, M. Romero, T. Hernández, C. Froilán, A. García-Sánchez, J. Novo, P. Castillo, F.J. Garcia-Samaniego Rey, A.O. Martin. *Madrid, Spain*
Email: mabadiab@gmail.com

Background and Aims: There's scarce information on evolution of portal hypertension after sustained virological response (SVR). Furthermore, current guidelines do not address how to manage large oesophageal varices in HCV-cirrhosis after SVR. Therefore, data are needed on their evolution as well as their non-hemodynamic evaluation.

Method: Single-centre, prospective study. Patients were included if: 1) HCV cirrhosis with baseline large oesophageal varices; 2) SVR after direct-acting antivirals (DAA). Hepatic venous pressure gradient (HVPG) was performed. On the same day, upper gastrointestinal endoscopy (UGE), and liver stiffness measuring with transient elastography (TE; Fibroscan, Echosens, France) and bidimensional shear-wave elastography (2D-SWE; Aplio 500, Toshiba, Japan) were also performed. Betablockers were stopped 5 days before.

Results: 30 patients were included (male 56%, median age 66 years, Child-Pugh A/B 73%/27%, median MELD 10 [7–14], overweight 76%, median TE before DAA 27.3 kPa, median time from end of DAA treatment to GPVH 67 weeks [30–171]). GPVH was <12 mmHg (bleeding threshold; BT) in 12/30 (40%) and <10 mmHg (clinical significant portal hypertension; CSPH) in 6/30 (20%). UGE showed regression of varices in 21/26 (81%; 4 patients refused). Feasibility rates for TE and 2D-SWE were 93% (28/30) and 100% (30/30), respectively. Correlation of UGE, TE, and 2D-SWE with HVPG is shown in Table 1 (per protocol).

Table 1: (abstract: SAT-222).

	HVPG ≥12 mmHg (n = 14)	HVPG 10–12 mmHg (n = 6)	HVPG <10 mmHg (n = 6)
Varices (%)			
Large	3 (21)	1 (16)	1 (16)
Small	10 (72)	4 (68)	5 (84)
Absent	1 (7)	1 (16)	0

	HVPG <12 mmHg	HVPG <10 mmHg
Transient elastography		
AUROC (CI95%; *p*)	0.72 (0.67–0.76; 0.04)	0.84 (0.82–0.86; 0.0001)
Best cut-off (kPa)	20.3	20.6
Se/Sp/NPV/PPV/Acc (%)	82/55/67/73/71	69/84/42/84/72
Rule in/out ≥90% (kPa)	26.4/15.8	23.1/14.1
Bidimensional shear-wave		
AUROC (CI95%; *p*)	0.68 (0.63–0.73; 0.13)	0.88 (0.86–0.89; 0.0001)
Best cut-off (kPa)	21.2	20.3
Se/Sp/NPV/PPV/Acc (%)	78/50/60/70/67	80/67/45/91/77
Rule in/out ≥90% (kPa)	27.1/18.6	21.9–14.1

Conclusion: After >1 year of SVR in patients with baseline large oesophageal varices, portal hypertension evolved below the BT in 40% and below the CSPH in 20%. In this situation, there's a weak correlation between endoscopic variceal size and HVPG. TE and 2D-SWE perform well and similarly to detect CSPH; results are poorer for BT.

SAT-223

The impact of hepatic steatosis on portal hypertension

B. Scheiner, G. Semmler, P. Schwabl, T. Bucsics, M. Mandorfer, M. Trauner, A. Ferlitsch, T. Reiberger. *Medical University of Vienna, Dep. of Internal Med. III, Div. of Gastroenterology & Hepatology, Vienna, Austria*
Email: bernhard.scheiner@meduniwien.ac.at

Background and Aims: Studies in animal models suggested an effect of hepatic steatosis on portal pressure, since diet-induced hepatic steatosis has been shown to promote liver sinusoidal endothelial dysfunction and increase intrahepatic resistance. Thus, we aimed to evaluate the effect of hepatic steatosis on portal pressure in patients with chronic liver disease.
Method: Patients who underwent paired hepatic venous pressure gradient (HVPG) and controlled attenuation parameter (CAP®, FibroScan®, Echosense, France) measurements between 01/2014 and 12/2016 were included in this retrospective study.
Results: In total, 243 patients with valid HVPG and transient elastography (TE)-based CAP®-measurements were identified. The majority of patients (n = 194, 79.8%) had cirrhosis, as according to published disease-specific cut-offs, and 72.8% had clinically significant portal hypertension (CSPH; HVPG ≥10 mmHg). The most common etiologies of liver disease were virus hepatitis (n = 116, 47.7%) and alcohol abuse (n = 72, 29.6%). Any hepatic steatosis (S1/2/3; CAP®-value ≥248 dB/m) was present in n = 101 (41.6%). Overall, HVPG was comparable between patients with and without hepatic steatosis (14 (2–34) vs. 17 (3–41) mmHg; p = 0.612). Apart from BMI (Pearson's ρ: 0.136; p = 0.034), no baseline characteristics showed a correlation with CAP®.
To control for severity of liver disease, the correlation between CAP® and HVPG was analyzed within HVPG-strata. Neither in patients with subclinical portal hypertension or normal portal pressure (HVPG < 10mmHg; p = 0.383) nor in patients with CSPH (HVPG ≥ 10; p = 0.495) any correlation between CAP® and HVPG could be found. The subgroup analysis in different etiologies of liver disease also showed no positive correlation between CAP® and HVPG. Interestingly, in patients with F2/3 liver fibrosis as assessed by TE, there was a significant negative correlation between CAP® and HVPG (Pearson's ρ: –0.470; p = 0.004). This may be explained by the fact that TE could overestimate liver fibrosis stage in patients with pronounced hepatic steatosis. This negative correlation vanished in patients with cirrhosis (F4; Pearson's ρ: –0.096; p = 0.183).
Conclusion: Hepatic steatosis does not increase portal pressure. Liver stiffness assessment by TE tends to overestimate liver fibrosis stage in patients with hepatic steatosis.

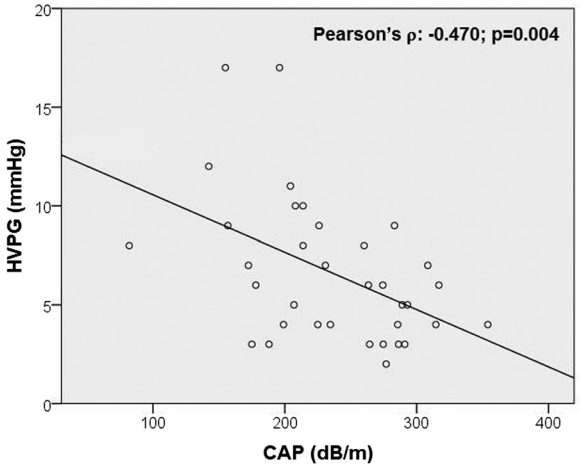

Figure: Correlation of CAP® and HVPG in patients with F2/F3 fibrosis

SAT-224

Controlled attenuation parameter does not predict hepatic decompensation in patients with advanced chronic liver disease

B. Scheiner, L. Steininger, G. Semmler, P. Schwabl, T. Bucsics, R. Paternostro, A. Ferlitsch, M. Trauner, T. Reiberger, M. Mandorfer. *Medical University of Vienna, Dep. of Internal Med. III, Div. of Gastroenterology and Hepatology, Austria*
Email: bernhard.scheiner@meduniwien.ac.at

Background and Aims: Transient elastography (TE)-based controlled attenuation parameter (CAP®) is a non-invasive marker of hepatic steatosis. Recently, CAP® has been proposed as a predictor of decompensation in patients with compensated advanced chronic liver disease (cACLD), although there was no association with liver-related events in another study. Therefore, our aim was to evaluate the prognostic value of CAP® in patients with cACLD and decompensated cirrhosis (DC).
Method: 189 patients who underwent simultaneous TE (stiffness ≥10 kPa) and hepatic-venous pressure gradient (HVPG) measurements between 01/2014 and 12/2016 were included in this retrospective analysis based on prospectively collected data. In cACLD-patients, hepatic decompensation was defined by new onset of ascites, hepatic encephalopathy, or variceal bleeding. In patients with DC, the following events were considered as (further) hepatic decompensation: requirement of paracentesis, admission for grade III/IV hepatic encephalopathy, variceal (re-)bleeding or liver-related death.
Results: For analysis, the study population was stratified into patients with cACLD (without prior hepatic decompensation, n = 86) and patients with DC (n = 103).
Hepatic decompensation occurred in 13 (15.1%) cACLD patients and in 33 (32.0%) patients with DC during a mean follow-up of 23.2 and 16.1 months, respectively. CAP® was not predictive of (further) hepatic decompensation in cACLD patients (per 10 dB/m; OR: 0.991, 95%CI: 0.906–1.084, p = 0.884) or in patients with DC (OR: 0.983, 95%CI: 0.925–1.045, p = 0.587). Adjusting for baseline characteristics including the presence of clinically significant portal hypertension/HVPG did not affect these results. Using the well-established CAP®-cutoff of ≥248 dB/m for any steatosis, the incidence of (further) hepatic decompensation was comparable between CAP® groups (cACLD: p = 0.657; DC: p = 0.743). Serum albumin level (per mg/dL; OR: 0.773, 95%CI: 0.684–0.874, p < 0.001) and HVPG (per mmHg; OR: 1.087, 95% CI: 1.005–1.175, p = 0.036) were the only parameters independently associated with (further) hepatic decompensation in patients with cACLD and DC, respectively.
Conclusion: CAP® does not predict the development of (further) hepatic decompensation in patients with cACLD or decompensated cirrhosis, while serum albumin levels and HVPG are of prognostic value.

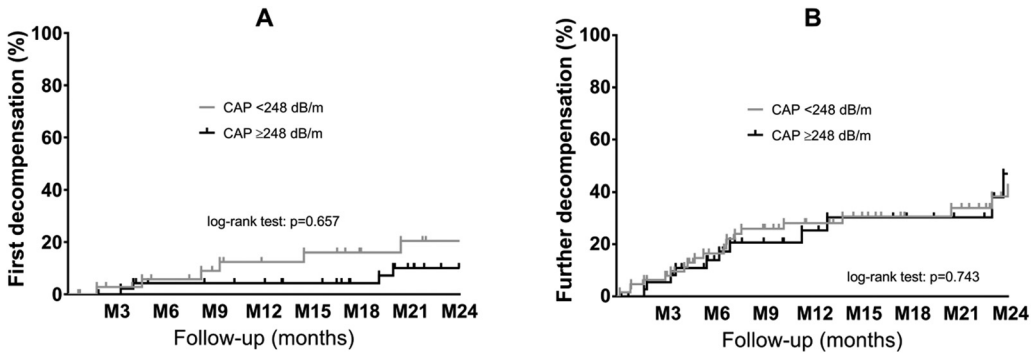

Figure: (abstract: SAT-224) Incidence of (further) hepatic decompensation in **A.** patients with cACLD and **B.** patients with decompensated cirrhosis.

SAT-225

Thromboelastography guided blood product transfusion in cirrhosis patients with acute variceal bleeding: A randomized controlled trial

G. Rout, D. Gunjan, S. Kedia, B. Nayak, S.J. Mahapatra, A. Iqbal, Shalimar. *All India Institute of Medical Sciences, New Delhi, India, Department of Gastroenterology, New Delhi, India*
Email: drshalimar@yahoo.com

Background and Aims: Coagulopathy (low platelet count and prolonged prothrombin time) is common in cirrhosis with acute variceal bleeding. Consensus guidelines recommend correction of prolonged international normalized ratio >1.8 and platelet count <50,000/mm^3 prior to invasive procedures. We aimed to assess use of thromboelastography (TEG) directed blood product transfusion in patients with acute variceal bleeding.
Method: In this randomized control trial, patients were randomly allocated to TEG-guided transfusion or standard of care (SOC) from Jan 2017 till September 2017. Patients with acute on chronic failure and hepatocellular carcinoma were excluded.
Results: Of the 43 recruited patients, 21 were randomized to the TEG group and 22 to the SOC. There were no statistical differences in patient characteristics between the two groups. Among the SOC group- 11 (50.0%) received fresh frozen plasma (FFP), 14 (63.6%) received platelet transfusion and 3 (13.6%) received both FFP and platelets. Among the TEG group- 2 (9.5%) received FFP (p = 0.004) and 2 (9.5%) received platelets (p < 0.001). The median (IQR) red blood cell transfusions in the TEG and SOC groups were 1 (0–3) and 1 (0–3), respectively (p = 0.729). The control of bleeding was achieved in 21 (95.5%) and 21 (100%) of patients in SOC and TEG groups (p = 0.323), respectively. Re-bleeding rates in SOC and TEG groups at 5 days and 6 weeks were (13.6% *vs.* 0%, p = 0.079) and (27.3% *vs.* 9.5%, p = 0.135), respectively. Survival rates in SOC and TEG groups at 5 days and 6 weeks were (95.5% and 100.0%, p = 0.323) and (77.3% and 90.5%, p = 0.241), respectively.
Conclusion: TEG-guided blood product transfusion strategy, when compared to standard of care, is associated with similar control of bleeding and survival in patients with acute variceal bleeding. The use of TEG can prevent unnecessary prophylactic transfusions of FFP and platelets.

SAT-226

Chronic kidney disease in patients with cirrhosis surviving an episode of acute kidney injury. Frequency and impact on patient's outcome

O. Bassegoda[1,2,3,4], P. Huelin[1,2,4,5], E. Pose[1,2,4,5], L. Napoleone[1,2,4,5], A. Juanola[1,2,4,5], R. Moreira[6], M. Carol[2,3,4,6], G. De Prada[1,3,4,6], N. Fabrellas[1,2,3,4], C. Solé[1,4,7], I. Graupera[1,4,5,7], E. Solà[1,4,5,6], P. Ginès[1,2,4,5]. *[1]Hospital Clinic de Barcelona, Liver Unit, Barcelona, Spain; [2]University of Barcelona, Faculty of Medicine and Health Sciences, Barcelona, Spain; [3]IDIBAPS, Barcelona, Spain; [4]CIBEReHD, Barcelona, Spain; [5]IDIBAPS, Barcelona, Spain; [6]Hospital Clinic de Barcelona, Barcelona; [7]University of Barcelona, Barcelona, Spain*
Email: pgines@clinic.ub.es

Background and Aims: AKI is common in cirrhosis and is associated with poor prognosis. However, there is little information on outcome of patients who survive an episode of AKI. Specifically, it is not known how often the acute injury leads to chronic impairment of kidney function, known as chronic kidney disease (CKD), and whether this has a negative influence on patient's outcome. The primary endpoint was to investigate the frequency of CKD in patients surviving an episode of AKI. Secondary endpoints were to evaluate whether CKD had a negative impact on natural history, as assessed by new episodes of AKI, liver transplantation rate and survival.
Method: We analyzed a prospective database including all patients admitted for management of complications of cirrhosis during a 6-year period. All patients were evaluated using the same protocol which included assessment of kidney function at regular intervals during and after hospitalization. CKD was defined as an estimated GFR(eGFR) < 60 mL/min at 3 months of AKI. Patients with previous CKD (n = 231), those who where dead, lost to follow-up or transplanted at 3 months of AKI (n = 127) and those in whom baseline creatinine value before AKI was not available (n = 36) were excluded. Of the remaining 375 patients, 122 developed AKI (32,5%) and constitute the study population.
Results: Twenty-nine of the 122 (23.8%) patients had developed CKD at 3 months (mean eGFR 45 ± 15 mL/min). This rate of CKD was much higher than that observed in the contemporary group of patients admitted for complications of cirrhosis who did not develop AKI (6/253; 2.4%, p < 0.001). Factors independently associated with development of CKD were diabetes and baseline serum creatinine before AKI. During follow-up, the frequency of new episodes of AKI was higher among patients with CKD compared to patients without (62% vs 39%; p = 0.027). Need for renal replacement therapy was also significantly higher (7% *vs.* 0%, p = 0.001). Patients with CKD were more frequently transplanted during follow-up (28% *vs.* 12%, p = 0.04). However, transplant-free survival was not significantly different among groups.
Conclusion: Approximately one fourth of patients with cirrhosis surviving an episode of AKI have developed CKD after 3 months of follow-up. This is associated with higher frequency of new episodes of AKI and higher need for renal replacement therapy and liver transplantation.

SAT-227

Non-selective beta-blockers increase liver mortality when MELD is ≥12 in a prospective 5-year follow-up cohort of alcoholic cirrhosis

P. Cales, S. Bertrais, J. Boursier, I.F. Hubert, L. Adrien, F. Oberti. *University of Angers, Hepato-Gastroenterology, Angers, France*
Email: paul.cales@univ-angers.fr

Background and Aims: The effects of non-selective beta-blockers (BBNS) on mortality of patients with cirrhosis are controversial. We evaluated the BBNS impact on mortality according to liver severity and cause of mortality. The present final results extend interim analysis performed in 2013 limited to overall mortality. Thus, the mean follow-up has been doubled to 5 years whereas all published studies have a short follow-up (<2 yr in most studies) and did not analyze the mortality cause.
Method: 259 patients with alcoholic cirrhosis were included in a retro-prospective cohort: 130 BBNS-treated and 129 as controls
Results: BBNS group had the following significant baseline differences: higher Child-Pugh and MELD score, more frequent previous gastro-intestinal bleeding and large esophageal varices, and lower heart rate. During an average follow-up of 5.3 ± 2.6 yr, MELD progression was: 2.7 ± 6.4 in the BBNS group vs 1.5 ± 7.4 in controls ($p = 0.017$). Kaplan-Meier estimates of overall survival did not significantly differ between BBNS and control groups ($p = 0.296$). However, in Cox analysis for overall mortality, baseline MELD score interacted with BBNS ($p = 0.065$). Liver related survival was decreased in the BBNS group ($p = 0.032$). In competing risk multivariate analysis for liver-related mortality, the MELD-BBNS interaction was significant ($p = 0.003$). Liver mortality was not related to BBNS in patients with Meld <12 (HR [95%CI]: 0.97 [0.26–3.68]) whereas BBNS was associated with an increase in liver-related mortality in patients with MELD ≥12 (HR [95%CI]: 3.32 [1.20–9.19]). Competing risk multivariate survival analysis in propensity risk score matched patients confirmed an interaction between baseline MELD and BBNS group ($p = 0.005$), HR for BBNS: 0.81 [0.22–2.96] in MELD <12 vs 3.41 [1.10–10.58] in MELD ≥12. In contrast, BBNS was associated with a decrease in non-liver-related mortality, especially in patients with baseline MELD ≥12 ($p = 0.142$ in whole study population).
Conclusion: In alcoholic cirrhosis, liver survival is improved by BBNS in MELD <12 but aggravated in MELD ≥12. This result extent other results observed in selected populations (refractory ascites, spontaneous bacterial peritonitis).

SAT-228

Men have higher mortality in cirrhosis: outcomes by gender and etiology in a large, diverse cohort

A. Yeluru[1], M.H. Le[1], C. Zhao[1,2], P. Nguyen[1], S. Trinh[1], H. Le[1], H. Dang[1], A. Pura[1], N. Dang[1], B. Alviar[1], S. Tran[1], T. Johnson[1], A. Le[1], J. Hoang[1], M. Nguyen[1]. *[1]Stanford University, Division of Gastroenterology and Hepatology, Palo Alto, United States; [2]Shanghai University, Department of Cirrhosis, Institute of Liver Disease, Shanghai, China*
Email: mindiehn@stanford.edu

Background and Aims: Cirrhosis results from a diverse group of etiologies, ranging from infectious to autoimmune to metabolic, which behave differently between the two genders. The purpose of this study is to explore differences in complications and mortality between men and women with cirrhosis of various etiologies.
Method: This is a retrospective analysis of 7254 patients (2905 female, 4349 male) with cirrhosis treated at a large academic tertiary care center in California, USA between 1998 and 2015. Data was collected via electronic and manual chart extraction. We report incidence of hepatic decompensation, HCC, and overall mortality over a follow-up period of up to 10 years in male vs. female patients with various etiologies of cirrhosis.
Results: Men and women had similar age at first presentation (54.9 *vs.* 55.5 years, $p = 0.084$), but women had higher rates of other

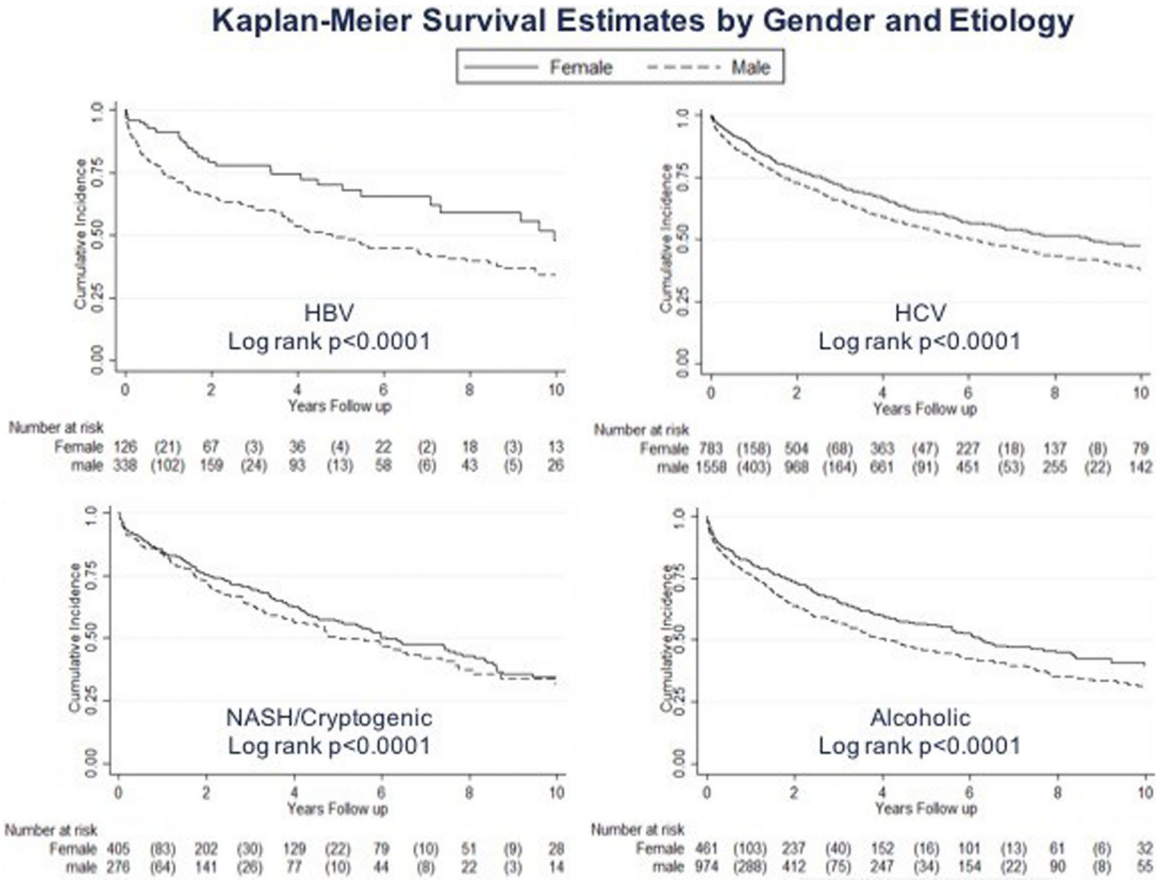

Figure: (abstract SAT-228)

medical comorbidities ($p < 0.01$). Women had lower median serum creatinine ($p < 0.0001$) and bilirubin levels ($p < 0.0001$) at baseline, correlating with lower median MELD scores (12 *vs.* 14, $p < 0.0001$). Men had higher rates of HCC (3.4% *vs.* 1.4%, $p < 0.0001$) and hepatic decompensation (48.9% *vs.* 46.5%, $p = 0.039$) at baseline. Male patients were more likely to have viral and alcoholic cirrhosis, whereas a much higher proportion of women had NASH, cryptogenic, biliary and autoimmune disease ($p < 0.001$). The rate of hepatic decompensation was significantly higher in male vs. female patients over 10- year follow-up (441 patients; $p = 0.03$), and similarly trended towards significance even at five years (1153 patients; $p = 0.09$). The cumulative incidence of HCC was significantly higher in men both at 5- and 10-year follow-up ($p < 0.0001$). Subgroup analysis showed that this was driven primarily by HCV patients: men with HCV had significantly higher annual incidence of HCC than women with HCV (5.5% *vs.* 3%, $p < 0.0001$). Looking at survival, in both male and female patients, those with viral etiologies (HBV, HCV) had significantly higher survival rates than those with NASH and cryptogenic cirrhosis ($p < 0.0001$). Men had worse mortality than women in all etiologies of cirrhosis ($p < 0.001$) except surprisingly in cryptogenic cirrhosis ($p = 0.28$).

Conclusion: To our knowledge, this is the largest cohort of cirrhotic patients studying gender differences in outcomes among etiologies. Men have significantly worse rates of decompensation, HCC, and mortality across diverse viral and nonviral etiologies. Incidence of HCC was highest in males with HCV.

SAT-229

Prior or on-treatment infection does not affect response to treatment or survival in patients with hepatorenal syndrome type 1

S. Pappas[1], F. Wong[2], K. Jamil[3]. [1]*Baylor College of Medicine, Houston, United States;* [2]*University of Toronto, Toronto, Canada;* [3]*Mallinckrodt Pharmaceuticals, Bridgewater, United States*
Email: spappas1@comcast.net

Background and Aims: The effect of prior infection or infection during treatment on response to terlipressin therapy and survival in patients with hepatorenal syndrome type 1 (HRS-1) remains unclear. Infection, particularly pneumonia and urinary tract infection (UTI), may impair response and decrease survival in these patients. To more clearly define the effects of infection on response and survival in patients with HRS-1, we examined outcomes in patients from a large randomized controlled trial of terlipressin in HRS-1.

Method: Subjects with prior infection (within 14 days of randomization) and infection reported as an adverse event, during the study period, from the REVERSE trial of terlipressin versus placebo in subjects with HRS-1 were identified. The incidence of HRS reversal and survival (defined as alive at day 90 and by Kaplan Meier estimates) were determined in these subjects. The full results of the REVERSE trial have been reported (Gastroenterology 2016;150:1579).

Results:

Conclusion: Overall, prior infection and infection reported as an AE did not appear to significantly affect response to therapy or survival in patients with HRS-1. In subjects with prior pneumonia, response was similar to the overall study group but survival was lower. In contrast, subjects with pneumonia reported as an AE and those with prior UTI showed a lower response rate but similar survival; subjects with prior UTI had a significantly lower response rate compared to those without prior UTI. In aggregate, these results suggest that prior or on-treatment infection should not discourage aggressive therapy for HRS-1.

SAT-230

Anticoagulant treatment for atrial fibrillation and decompensation rate in patients with liver cirrhosis

I. Girleanu[1], A. Trifan[1], O. Stoica[1], L. Huiban[1], C. Stanciu[2]. [1]*"Gr. T. Popa" University of Medicine and Pharmacy, Gastroenterology, Iasi, Romania;* [2]*Institute of Gastroenterology and Hepatology, Gastroenterology, Iasi, Romania*
Email: gilda_iri25@yahoo.com

Background and Aims: Anticoagulant treatment in patients with liver cirrhosis (LC) is still controversial. Recent studies demonstrated that anticoagulant treatment could reduce decompensation and mortality rates in cirrhotic patients. Our aim was to evaluate decompensation rate in patients with LC and atrial fibrillation treated with acenocoumarol for thrombotic events prophylaxis.

Method: The study group included patients diagnosed with compensated liver cirrhosis and atrial fibrillation treated with an oral anticoagulant (acenocoumarol), admitted in a tertiary center between January 2012 and December 2013. The control group included consecutive patients diagnosed with LC, matched by age, etiology and liver stage disease with the study group. All patients were regular follow-up since December 2016 or until first hepatic decompensation (ascites, hepatic encephalopathy, variceal bleeding) occurred.

Results: During the study period there were admitted 1151 cirrhotic patients of whom 118 patients (10.2%) were diagnosed with LC and atrial fibrillation of whom 76 and received an oral anticoagulant treatment with acenocoumarol, mean age 60.5 ± 11.2 years at diagnosis, 48 (61.53%) males, all of them with compensated liver cirrhosis. The majority of the patients were diagnosed with alcoholic LC- 46 patients (60.5%). There were no differences regarding baseline characteristics and LC severity between the patients with or without atrial fibrillation. Mean follow-up period was 32 ± 13.2 months. During the follow-up period 353 patients (30.6%) developed hepatic decompensation in both study groups of whom 102 died. The cumulative decompensation rate was 17.9% in the study group and 38.6% in the control group, respectively ($p < 0.0001$). The rate of decompensation was higher in the first year in both groups. There were 27 cases of epistaxis in the study group, and 34 cases of variceal bleeding in both groups, with no other major bleeding side effect to anticoagulant treatment.

Conclusion: Anticoagulant treatment in patients with LC is relatively safe, and may improve patient outcome and decrease decompensation rate, despite association of atrial fibrillation.

Table 1: (abstract: SAT-229).

	N	HRS reversal N	(%)	Alive at Day 90 N	(%)
Prior infection	86	12	**14%**	32	**37.2%**
No prior infection	109	20	**18%**	48	**44%**
Infection reported as an AE	49	6	**12.2%**	19	**38.8%**
No infection reported as an AE	147	26	**17.7%**	62	**42.2%**
Prior pneumonia	9	2	**22.2%**	2	**22.2%**
Pneumonia reported as an AE	12	1	**8.3% (p = N.S.prior vs. AE)**	5	**41.7%**

SAT-231

Decreased model for end-stage liver disease score after antiviral treatment predicts reduced risk of mortality and hepatic events in chronic hepatitis B related cirrhosis – a study of 1729 subjects

L.-H. Grace Wong[1], T.C. Yip[2], H. Chan[3], Y.-K. Tse[4], W. Sun, V. Wong[1].

Email: wonglaihung@cuhk.edu.hk

Background and Aims: The Model for End-Stage Liver Disease (MELD) is a scoring system for assessing the severity of chronic liver disease and to prioritize patients with liver cirrhosis for liver transplantation. Yet there has been scanty data on whether improvement in MELD score after antiviral treatment leads to improvement in clinical outcome and reduced hepatic events. We aimed to study the impact of baseline and on-treatment MELD score in patients with chronic hepatitis B (CHB) related cirrhosis.
Method: CHB patients with cirrhosis were identified from a territory-wide cohort of patients who were treated with entecavir (ETV) and/or tenofovir disoproxil fumarate (TDF) from January 2005 to December 2016 in Hong Kong. Patients with MELD scores available at baseline and one year after ETV/TDF were included in the final analysis. The primary and secondary outcome were all-cause mortality and hepatic event based on ICD-9-CM diagnosis codes. Patients with pre-existing hepatocellular carcinoma or at first year of antiviral treatment, and survival <1 year were excluded.
Results: 1,729 CHB patients (71.0% male, mean age 59.8 ± 11.5 years) with cirrhosis were identified and followed-up for a median (interquartile range) of 4.6 (2.6–6.0) years. The mean MELD score was 11.2 ± 4.5 at baseline and 9.9 ± 3.4 at one year; 238 (13.8%) patients died. Among 1,191 cirrhotic CHB patients without prior hepatic events, 99 (8.3%) patients developed hepatic events. The baseline and Year 1 MELD score had a time-dependent area under the receiver operating characteristic curve (td-AUROC; and 95% confidence interval[CI]) of 0.70 (0.67–0.74; $P < 0.001$) and 0.69 (0.65–0.73; $P < 0.001$) respectively to all-cause mortality. The td-AUROC of baseline and Year 1 MELD score was 0.73 (0.67–0.77; $P < 0.001$) and 0.71 (0.64–0.76; $P < 0.001$) respectively to predict hepatic event. Adjusted hazard ratio (aHR) with 95% CI for baseline MELD and decrease of MELD from baseline to Year 1 (DMELD) for all-cause mortality was 1.19 (1.16–1.22; $P < 0.001$) and 0.87 (0.85–0.89; $P < 0.001$) respectively; aHR of baseline and DMELD for hepatic event was 1.20 (1.15–1.25; $P < 0.001$) and 0.89 (0.85–0.93; $P < 0.001$) respectively.
Conclusion: MELD score at baseline and one year after antiviral treatment predicted all-cause mortality and hepatic events in CHB patients with cirrhosis. For each unit of improvement in MELD score at Year 1, there would be 13% reduction in all-cause mortality and 11% reduction in hepatic events in the next 5 years. Our findings support the current practice of delisting patients for liver transplantation after substantial improvement in MELD score after antiviral treatment.

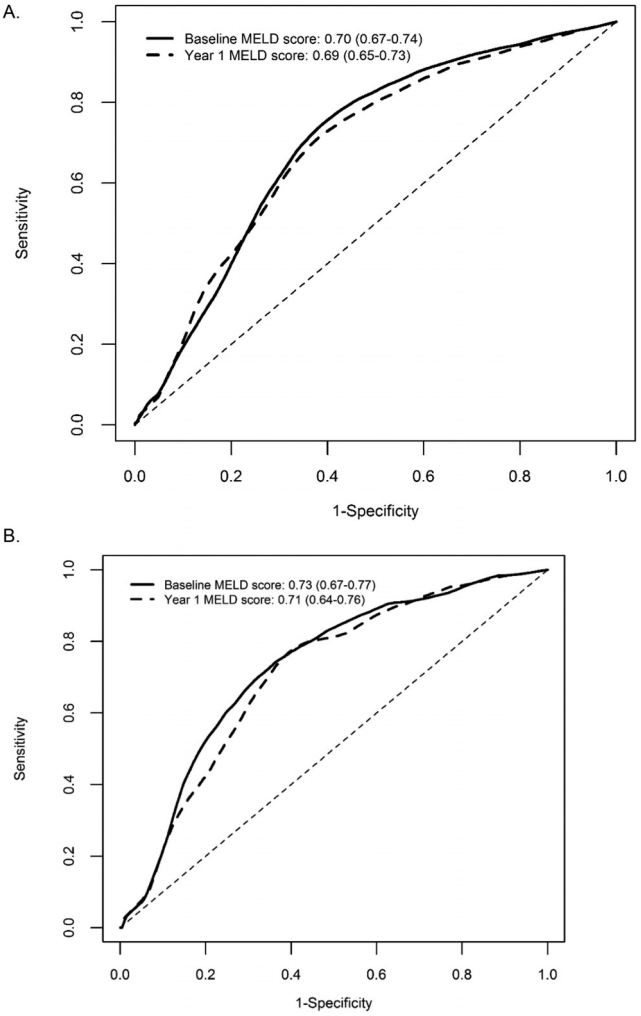

Figure: The receiver operating characteristic curves of baseline and Year 1 MELD score to predict A. all-cause mortality and B. hepatic events.

SAT-232

Propranolol treatment associated with better survival and reduced sepsis in cirrhotic patients with hepatic encephalopathy

P.-C. Lee[1], Y.-J. Chen[2], C.-W. Su[3], Y.-C. Cho[2], P.-H. Chen[1], W.-Y. Kao[4], Y.-H. Huang[1], H.-C. Lin[1], M.-C. Hou[1], J.-C. Wu[1]. *[1]Taipei Veterans General Hospital, Gastroenterology and Hepatology, Taipei; [2]Taipei Veterans General Hospital, Pharmacy, Taipei, Taiwan; [3]Division of Gastroenterology and Hepatology, Taipei Veterans General Hospital, Taipei, Taiwan; [4]Taipei Medical University Hospital, Gastroenterology and Hepatology, Taipei, Taiwan*
Email: tympanum3688@gmail.com

Background and Aims: Use of non-selective beta blockers (NSBBs) in cirrhotic patients with complications such as refractory ascites and spontaneous bacterial peritonitis is still controversial. Hepatic encephalopathy (HE) would impair survival of cirrhotic patients and is related to systemic inflammation and gut-liver disequilibrium. Considering the propranolol effects on gut permeability and inflammation, this study aims to investigate the association between propranolol treatment and the outcomes of cirrhotic patients with HE.
Method: By analyzing data from the Taiwan National Health Insurance Research Database, we identified 4,754 cirrhotic patients with newly diagnosed HE between January 2001 and December 2011. After excluding patients who had experience of liver transplantation,

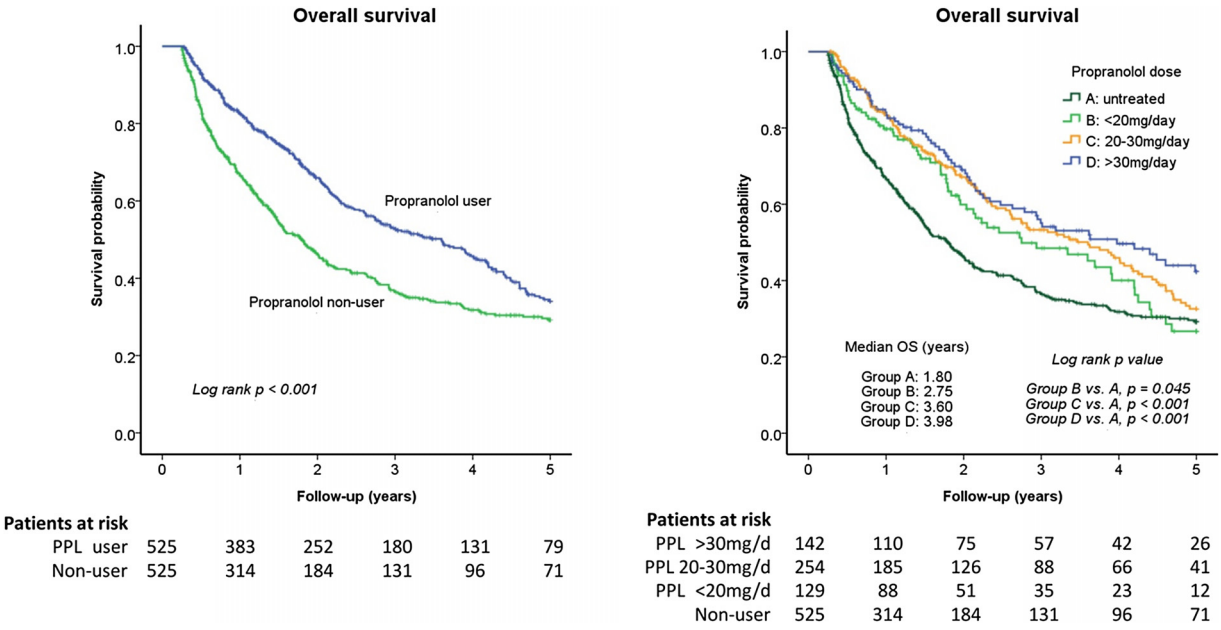

Figure: (abstract: SAT-232)

short follow-up duration, combined exposure to other NSBBs and short propranolol treatment, one-to-one matching by sex, age and propensity score was performed. Finally, 525 patients with and without propranolol treatment, respectively were enrolled for analyses. The Kaplan-Meier method and modified Cox proportional hazards models were employed for survival and multivariable, stratified analyses.

Results: The overall survival (OS) of cirrhotic patients with HE was significantly better in propranolol treated cohort than the untreated cohort (median OS: 3.60 versus 1.80 years, $p < 0.001$). Besides, dose dependent survival benefit was declared remarkably (median OS: 3.98, 3.60, and 2.75 years in patients treated with propranolol >30 mg/day, 20–30 mg/day, and <20 mg/day, respectively. [$p < 0.001$, $p < 0.001$, $p = 0.045$ versus untreated group, respectively]) Not only reduced the risk of overall mortality (adjusted hazard ratio, 0.60; $p < 0.001$), propranolol treatment also diminished the risk of sepsis related death (adjusted hazard ratio, 0.31; $p = 0.006$) in the multivariable analysis. However, risks of circulatory or hepatic failure were non-significantly altered.

Conclusion: Propranolol treatment was associated with a better overall survival in cirrhotic patients with hepatic encephalopathy in a dose-dependent manner. The risk of sepsis related death was reduced by propranolol treatment, but circulatory or hepatic failure was not significantly affected.

SAT-233

Six-minute walk test and sarcopenia in predicting mortality in patients with cirrhosis

T. Dang, M. Ebadi, A.J. Montano-Loza, P. Tandon. *University of Alberta, Gastroenterology, Edmonton, Canada*
Email: thucnhi@ualberta.ca

Background and Aims: Low muscle mass (sarcopenia) is associated with increased mortality in patients with cirrhosis. The association of functional performance with sarcopenia and its impact on mortality has not been well established in cirrhosis.

Objectives:

(1) Determine the association of functional performance assessed by the six-minute walk test (6MWT) and sarcopenia.
(2) Assess the prognostic value of the 6MWT in patients with cirrhosis.

Method: Patients who were assessed for liver transplant (LT) at the University of Alberta hospital were retrospectively enrolled in the study. Cross-sectional imaging within 1 year of assessment was used to determine sarcopenia. The third lumbar vertebra was used to quantify skeletal muscle cross sectional areas, which was then normalized to height to calculate the skeletal muscle index (SMI; cm2/m2). Sarcopenia was defined using pre-established cut-offs in patients with cirrhosis. Cut-offs for 6MWT to predict mortality (death or delisting for being too sick for LT) were determined using receiver-operating characteristic (ROC) curves. Cox proportional hazard models were conducted to assess associations between sarcopenia, functional performance assessed by the 6MWT, and mortality.

Results: There were a total of 180 cirrhotic patients who were evaluated for liver transplant who had a 6MWT test at the time of assessment and corresponding CT imaging (Table 1). There was a weak association between SMI and 6MWT observed as dimensional variables (r = 0.022; P = 0.003). A 6MWT < 489 m was independently associated with mortality, with AUC of 0.61 (95% CI, 0.51–0.71, P = 0.03) and subsequently defined as "poor physical performance." By univariate Cox analysis, both sarcopenia (HR 3.27; 95% CI 1.82–5.89; P < 0.001) and low 6MWT (HR 2.72; 95% CI 1.45–5.13; P < 0.001) were predictors of mortality. In a multivariate model, adjusted for MELD, sarcopenia (HR 2.96; 95% CI 1.59–5.51; P = 0.001) and low 6MWT (HR 2.33; 95% CI 1.21–4.51; P = 0.01) were independently associated with mortality. Poor physical performance was observed in 31 (60%) out of 52 sarcopenic patients. Sarcopenic patients with poor physical performance experienced a 6 times higher risk (HR 6.24; 95% CI 2.65–14.68; P < 0.001) of death. Sarcopenic patients with low 6MWT survived for 25 months (95%CI, 12–38) compared to 69 months (95% CI, 27–112) in sarcopenic patients with normal 6MWT (Log Rank = 0.04).

Conclusion: Sarcopenia and poor physical performance independently associate with mortality in patients with cirrhosis. Although poor physical performance was observed in more than half of the sarcopenic patients, its ability to discriminate mortality requires further investigation.

Baseline Characteristics (means or %)	
	Total Cohort (n = 180)

SAT-234

The effect of primary prophylaxis therapy for large esophageal varices in patients with hepatocellular carcinoma

H.-S. Lu[1], C.-W. Su[1,2], M.-C. Hou[1,3], P.-H. Chen[4,5], P.-C. Lee[1,6], W.-Y. Kao[3,7], T.-I. Huo[1,6], Y.-H. Huang[1,2,8], H.-C. Lin[1,3], J.-C. Wu[8,9]. *[1]Taipei Veterans General Hospital, Divison of Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan; [2]National Yang-Ming University, Faculty of Medicine, School of Medcine, Taipei, Taiwan; [3]National Yang-Ming University, Faculty of Medicine, School of Medicine, Taipei, Taiwan; [4]Taipei Veterans General Hospital, Endoscopy Center for Diagnosis and Treatment, Taipei, Taiwan; [5]National Yang-Ming University, Institute of Biophotonics, Taipei, Taiwan; [6]National Yang-Ming University, Institute of Pharmacology, Taipei, Taiwan; [7] Taipei Medical University Hospital, Divison of Gastroenterology and Hepatology, Department of Internal Medicine, Taipei, Taiwan; [8]National Yang-Ming University, Institute of Clinical Medicine, Taipei, Taiwan; [9]Taipei Veterans General Hospital, Department of Medical Research, Taipei, Taiwan*
Email: cwsu2@vghtpe.gov.tw

Background and Aims: Whether or not primary prophylaxis therapy could improve the prognosis of patients with hepatocellular carcinoma (HCC) and with high risk esophageal varices (EVs) is not fully elucidated. We aimed to investigate the effect of primary prophylaxis therapy in determining the outcomes of patients with HCC and with large EV.

Method: We retrospectively enrolled 1157 HCC patients who received an esophagogastroduodenoscopy at the time of HCC diagnosis in Taipei Veterans General Hospital from October 2007 to May 2014. Among them, 352 patients had large EV (F2 and/or F3) indicated for primary prevention. A total of 127 patients received primary prevention therapy (37 patients received non-selective beta-blocker and 90 patients received endoscopic variceal ligation, respectively) and the remaining 225 patients did not receive primary prevention. Prognostic factors were analyzed in terms of overall survival and variceal bleeding-free survival.

Results: The median age and the model for end-stage liver disease (MELD) score of enrolled patients were 67 years (interquartile range IQR, 60–77.0 months) and 10.67 (IQR 8.7–14.06), respectively. Hepatitis B virus infection (54.9%) and hepatitis C virus infection (32.2%) were the major etiologies of HCC. Moreover, 186 (52.8%) patients had ascites. After a median follow-up of 8.7 months (interquartile range, 2.8–30.9 months), 299 patient dead and the remaining 53 patients were alive at their last visit. The cumulative 1- and 3-year overall survival rates were 52.8% vs. 36.2% and 31.5% vs. 20.4%, respectively ($p = 0.019$). The cumulative 1- and 3-year bleeding-free survival rates were 86.6% vs. 64.6% and 82.7% vs. 59.6%, respectively ($p < 0.001$). Multivariate analysis disclosed that serum bilirubin levels > 1.6 mg/dL (Hazard ratio HR 1.681, 95% confidence interval CI 1.317–2.145, $p = < 0.001$), aspartate aminotransferase > 40 U/L (HR 1.451, 95% CI 1.048–2.008, $p = 0.023$), presence of ascites (HR 1.964, 95% CI 1.488–2.591, $p = < 0.001$), serum alpha-fetoprotein level >20 ng/ml (HR 1.682, 95% CI 1.228–2.304, $p = 0.001$), tumor size > 3 cm (HR 2.000, 95% CI 1.462–2.734, $p < 0.001$), portal vein invasion (HR 2.491, 95% CI 1.852–3.351, $p < 0.001$), and without primary prevention (HR 1.368, 95% CI 1.037–1.804, $p = 0.027$) were the independent risk factors associated with 3-year overall mortality.

Conclusion: For HCC patients with large EVs, primary prevention therapy could decrease the risk of variceal bleeding and improve overall survival.

SAT-235

Characteristics of bone marrow drived mesenchymal stem cells in patients with liver cirrhosis

K.T. Suk[1], D.J. Kim[1], Y.L. Ham[2], D.B. Choi[1], S.J. Yoon[1]. *[1]Hallym University College of Medicine, Internal Medicine, Chuncheon, Korea, Rep. of South; [2]Daewon University, Emergency, Jaecheon, Rep. of South Korea*
Email: ktsuk@hallym.ac.kr

Background and Aims: Cirrhosis is the end stage of chronic liver disease, which may lead to severe hepatic dysfunction and even life-threatening conditions. The beneficial impact of mesenchymal stem cells (MSCs) transplantation on liver diseases has been confirmed on several studies include our previous clinical trial for autologous bone marrow-derived mesenchymal stem cells (BM MSCs) transplantation to patients with liver cirrhosis, which have shown the ability of MSCs to reduce liver cirrhosis and improve liver function. We aimed to identify secreted factors by undifferentiated BM-MSCs in order to describe related pathways potentially targeted gene by MSC in liver cirrhosis.

Method: Human BM-MSCs from normal and patients who had liver cirrhosis after autologous BM-MSCs transplanted and cultured specific medium condition for mesenchymal stem cells. We evaluated the potential of differentiation to osteoblast and adipocytes, morphological changes and cell proliferation depending on culture period, and immunophenotyping assay with flow cytometer with CD14, CD34, CD45, CD73 and CD105. At passage 4–5 of BM-MSCs were used for cDNA microarrays to identify secreted genes and related pathway that differentially expressed in specific stem cell population in liver cirrhosis and identified by biomathmatical analysis.

Results: On immunophenotyping analysis to determine mesenchymal function, CD14, CD34 and CD45 were 0.88%, 0.68% and 0.78%, respectively, however CD73 and CD105 for specific antigen of MSCs were 99.81% and 99.92%. BM MSCs secreted different factors in normal and patients with liver cirrhosis. We found 2968 genomes of 15 maps in KEGG pathway include Metabolic pathways, TGF-beta signaling pathway, Wnt signaling pathway, Cytokine-cytokine receptor interaction, HIF-1 signaling pathway, Ras signaling pathway and Natural killer cell mediated cytotoxicity. Within these pathways, functionally up-regulated genes were 7 genes and down-regulated genes were 9. In particular, we were able to identify potential specific genes might have typical function for regulation of liver cirrhosis and regeneration (FBN2, P4HA1 and STC1), and KIR3DL2, which is gene for regulation of immune system process.

Conclusion: Based on our previous clinical trial for autologous BM MSCs transplantation to patients with liver cirrhosis, the results have shown the ability of MSCs to reduce liver cirrhosis and improve liver function. Application of MSCs might target a widespread pattern of biological, cellular compositional and molecular functional event in the liver. MSC secreted genes and proteins can be differ depending on pathways and molecular mechanisms. Genes involved liver cirrhosis are able to release hepatotropic factors from transplanted MSCs, also potentially supporting liver regenerations.

SAT-236

Efficacy of L-ornithine L-aspartate for minimal hepatic encephalopathy in cirrhosis: A systematic review and meta-analysis of randomized controlled trials

R.F. Butterworth[1], N. Hilger[2], G. Kircheis[3], M.J.W. McPhail. [1]*University of Montreal, CHUM St-Luc Hospital, Montreal;* [2]*University of Bonn, Institute of Psychology, Methodology, Diagnostics and Evaluation, Bonn;* [3]*Medical University of Brandenburg Theodor Fontane, Clinic of Brandenburg, Brandenburg;* [4]*Kings College London, Liver Intensive Therapy Unit, Institute of Liver Studies, Division of Transplantation and Mucosal Biology, London, United Kingdom*
Email: rb@enceph.com

Background and Aims: Minimal hepatic encephalopathy (MHE) may seriously impact on reaction times, the ability to drive an automobile and on a patient's health-related quality of life. L-ornithine L-aspartate (LOLA) is an effective ammonia-lowering agent that is effective for the improvement of mental state in clinical hepatic encephalopathy (HE). However, its efficacy for the treatment of MHE remains the subject of debate. Published randomised controlled trials (RCTs) assessing the efficacy of LOLA in MHE are rare involving small numbers of patients and the results of these trials remain equivocal. Consequently, the aims of the present study were to meta-analyse the efficacy of LOLA in patients with cirrhosis and MHE. Efficacy was defined as the extent of improvement of mental state assessed by psychometric testing together with the lowering of blood ammonia.
Method: Appropriate keywords were used for searches of databases including The Cochrane Register, Medline, Google Search and Clinicaltrials.gov in order to identify RCTs for inclusion. Study quality and risk of bias were assessed using a novel combination of the established Jadad Composite Scale together with The Cochrane Scoring Tool. Group differences were assessed using the Random effects model and were expressed as pooled risk ratio (RR) or mean difference (MD) with associated 95% confidence intervals (CI).
Results: Seven RCTs with 332 patients satisfied inclusion criteria. Regression analysis revealed no evidence of publication bias or other small study effects. Five out of seven included RCTs had low risk of bias by Jadad/Cochrane criteria. Comparison with data from placebo/no intervention controls revealed that LOLA was significantly more effective for improvement of mental state (RR: 2.14, 95% CI: 1.62 to 2.83, $p < 0.01$) and for lowering of blood ammonia ($p < 0.01$) in MHE. The extent of improvement of mental state was greater in trials with low risk of bias and in trials using the oral formulation of LOLA ($p < 0.003$). Complete normalization of psychometric test scores occurred in 32/111 (28.8%) of MHE patients treated with LOLA compared to 14/120 (11.7%) in controls ($p < 0.02$).
Conclusion: Treatment with the oral formulation of LOLA resulted in significant improvement of mental state assessed by psychometric testing and lowering of blood ammonia in patients with cirrhosis and MHE.

SAT-237

Deleterious effect of proton pump inhibitors on the disease course of cirrhosis

Z. Vitális[1], T. Janka[1], T. Tornai[1], I. Tornai[1], D. Tornai[2], M. Papp[2]. [1]*University of Debrecen, Faculty of Medicine, Institute of Internal Medicine, Department of Gastroenterology, Debrecen, Hungary;* [2]*University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Debrecen*
Email: drvitaliszs@gmail.com

Background and Aims: Proton pump inhibitors (PPIs) are widely used without rigorous indications in patients with cirrhosis. Association of PPI use with the occurrence of spontaneous bacterial peritonitis (SBP) has been the most extensively evaluated adverse outcome but a controversial issue so far. Long-standing PPI use might enhance pathologic bacterial translocation (BT) due to various reasons. Thus, we hypothesized that beyond SBP longstanding PPI use is associated with accelerated disease progression in cirrhosis (development of diseases-specific complications and/ or liver-related death).
Method: A 5-year follow-up observational cohort study was conducted to assess the impact of long-standing PPI use on the clinical course of cirrhosis in a large referral patient cohort. Three hundred and fifty patients with cirrhosis (male: 188, age: 56 ± 6 years, alcohol: 242 [69.1%], Child-Pugh stage A/B/C: 206/108/36) were included and assigned into two groups: regular PPI users (n = 154) and non-users (n = 196). Occurrence of SBP, decompensation events (development of ascites, hepatic encephalopathy and variceal bleeding) and liver-related death were assessed.
Results: Regular PPI use was associated with an increased cumulative probability of SBP [55.0% vs. 30.0%, pLogrank = 0.012] compared to non-users in patients with ascites (n = 113). Similar association was found with progressive disease course. First, the risk of the development of first decompensation event was higher in regular PPI users compared to non-users in patients with compensated clinical stage at enrollment (HR: 3.04, 95%CI: 1.56–5.92, p = 0.001, n = 163). Secondly, the risk of liver-related death was also significantly increased in case of regular PPI use ($p < 0.001$). In multi-variate Cox-regression analysis, regular PPI use (HR: 2.01, 95%CI: 1.38–2.93, $p < 0.001$), clinical stage (HR: 1.66, 95%CI: 1.12–2.45, p = 0.011) and MELD score (HR: 1.12, 95%CI: 1.08–1.55, $p < 0.001$) remained independent predictor of mortality.
Conclusion: In the present follow-up cohort, long-term PPI use was associated with the development of SBP and the progressive diseases course in patient with cirrhosis that might be caused by enhanced pathologic BT.

SAT-238

The impact of pulmonary arterial hypertension therapy in patients with portopulmonary hypertension: a single tertiary center cohort analysis

F. Nevens[1], H. Peeters[1], W. Laleman[1], C. Verslype[1], S. van der Merwe[2], D. Monbaliu[3], J. Pirenne[3], M. Delcroix[4]. [1]*UZ Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium;* [2]*UZ Leuven, Department of Gastroenterology and Hepatology, Belgium;* [3]*UZ Leuven, Department of Abdominal Transplant Surgery, Leuven, Belgium;* [4]*UZ Leuven, Department of Pneumology, Leuven, Belgium*
Email: frederik.nevens@uzleuven.be

Background and Aims: Portopulmonary hypertension (PoPH) has an ominous prognosis. Pulmonary arterial hypertension (PAH) specific medical therapy aims to improve hemodynamics to a threshold at which liver transplantation could safely be performed. However, currently there is limited long-term outcome data available. The aim of the present study was to evaluate efficacy of PAH therapy on cardiopulmonary hemodynamics, functional status, liver related complications and transplant outcome in patients with cirrhosis and PoPH in a single tertiary liver center with transplant facilities.
Method: In patients treated for PoPH the evolution of New York Heart Association (NYHA) classification, the six-minute walk distance (6MWD), MELD score, complications of portal hypertension and final outcome were prospectively monitored. Hemodynamic parameters were re-evaluated by serial right heart catheterization.
Results: Between 1997 and 2016, 31 patients were diagnosed with PoPH of which 29 received medical treatment and had long-term follow-up. All patients with PoPH subjected to PAH therapy responded to therapy with a significant improvement of mPAP (−15%, p = 008), PVR (−42%, p = 0.012), CO (+36%, p = 0.01), CI (+40%, p = 0.011) and functional capacity (NYHA functional class (-0.9 points, $p < 0.001$) and 6MWD (+65 m, $p < 0.001$)) at 6 months. In addition, PAH treatment was associated with an improvement of MELD score (10 ± 3.7 to 8.8 ± 4.6, p = 0.025) and a significant decrease in portal hypertensive complications. Of the 10 patients with advanced liver disease (mean MELD >12) that evolved to mild PoPH, and thus became eligible for LTx, 7 showed hepatic recompensation. Overall, the 5 years mortality due to liver

impairment in the absence of LTx was 8% and there was no difference in the 5-year survival in patients at baseline with or without advanced liver disease: 49% *vs.* 42%. Mortality was primarily driven by cardiopulmonary complications.
Conclusion: These data confirm the benefit and safety of PAH therapy also in patients with PoPH. Moreover, a favorable response to PAH therapy not only affected prognosis but also seems to hold the potential to improve liver dysfunction and reduce portal hypertensive complications. This combined impact therefore questions the need for LTx in patients with compensated liver disease and PoPH.

Non-selective beta-blockers reduce cardiac systolic function and impair renal function in patients with refractory ascites

L. Téllez[1], L. Ibañez[2], C. P. del Villar[3], E. Rodríguez-Santiago[1], R. Yotti[3], J. Martinez[1], M.Á. Rodríguez-Gandía[1], L. Carrión[2], M. Rivera[4], J. Bermejo[5], F. Gea[1], R. Bañares[2], A. Albillos[1]. *[1]Hospital Universitario Ramón y Cajal. IRYCIS. Universidad de Alcalá. CIBEREHD, Gastroenterology and Hepatology, Madrid, Spain; [2]IiSGM. CIBERehd. Universidad Complutense, Cardiology. Hospital General Universitario Gregorio Marañón*
Email: luis.tellez@salud.madrid.org

Background and Aims: Systolic dysfunction, a component of cirrhotic cardiomyopathy, is defined by an impaired cardiac contractile response to stress, and results in the inability of the heart to meet tissue perfusion demands. It has been related to renal dysfunction and prognosis in cirrhosis and could be at the root of the potential risk of beta-blockers in refractory ascites. In contrast to conventional echocardiography methods that depend on loading conditions, Doppler-derived intracardiac pressure differences, such as ejection intraventricular pressure difference (EIVPD), are highly sensitive and reliable to address systolic function independently of load conditions. Aims: To evaluate and compare systolic function by EIVPD in cirrhotic patients with diuretic-sensitive (DSA) and refractory ascites (RA), at baseline and after treatment with non-selective beta-blockers (NSBB).
Method: Muticentre, prospective, observational and controlled study in 25 patients with cirrhosis and ascites, 17 with RA and 8 with DSA. Patients underwent heart function assessment (pulmonary pressures and cardiac index by Swan-Ganz catheter, conventional echocardiographic measurements and EIVPD and EKG), renal function (renal Doppler US, blood and urine test) and hepatic hemodynamics were assessed at baseline and after 4 weeks on non-selective beta-blockers.
Results: (RA *vs.* DSA, mean ± SD) Child score (8.8 ± 1.7 *vs.* 9.2 ± 1.0), MELD (13.9 ± 3.3 *vs.* 14.1 ± 3.1) and HVPG (22.6 ± 3.9 *vs.* 23.6 ± 5.2 mmHg) were similar in both groups. Systolic function as measured by EIVPD was greater in DSA than in RA (5.56 ± 1.52 *vs.* 4.08 ± 1.39 mmHg, $p < 0.05$). In contrast, left-ventricular ejection fraction and cardiac index were similar in both groups (66.9 ± 4.93 *vs.* 67.9 ± 3.86%, and 4.3 ± 0.9 *vs.* 3.6 ± 0.9 l/min/m^2). Beta-blockade led to similar reductions in heart rate, cardiac index, mean arterial pressure and HVPG in both groups. Beta-blockade significantly reduced EIPVD in RA (4.08 ± 1.39 *vs.* 3.35 ± 0.91 mmHg, $p < 0.05$) but not in DSA (5.56 ± 1,53 *vs.* 5.24 ± 2.18 mmHg, NS). Absolute change in EIPVD (ΔEIPVD) directly correlated ($p < 0.01$) with worsening of renal function measured by cystatin C ($r = –0.69$) and creatinine ($r = –0.63$) in RA group. Changes in EIVPD after beta-blockade were similar in HVPG non- and responders (↓HVPG > 10%). ΔEIPVD was inversely correlated with baseline mean pressure in the whole group of patients ($r = 0.43$, $p < 0.05$).
Conclusion: Systolic function by robust Doppler derived indexes is reduced in cirrhosis with RA compared to DSA. Beta-blockade compromises systolic and renal function at short-term, especially in patients with lower arterial pressure

SAT-240

High risk of esophageal varices in patients with Fontan surgery: The VALDIG FONLIVER study

L. Téllez[1], E. Rodríguez-Santiago[1], E. Garrido[1], A. Baiges[2], V.L. Mura[3], E. Garrido-Lestache[4], R. Romera[5], J. Martinez[6], A. Clemente[7], L. Aguilera[1], E. Llop[8], D. Email: luis.tellez@salud.madrid.org

Background and Aims: Fontan surgery (FS) allows the venous return to reach the pulmonary circulation bypassing the ventricle in patients with single ventricle. This results in sustained systemic venous hypertension and liver damage in long-term. Nevertheless, natural history of liver disease in these patients has been poorly studied; prevalence and features of esophageal varices (EV) are unknown. The AIM of this study is to estimate the prevalence and characterize EV in this population.
Method: Multicentre, observational, trans versal, prospective and analytical study. 32 patients with >5yr since FS underwent Doppler US, Fibroscan®, cardiac and hepatic catheterization, blood test and upper endoscopy. Haemorrhagic risk EV was defined according to Baveno VI criteria.
Results: 32 patients were included. Age: median 27.9 yr, IQR: 11; 34% were females. Time from FS was: median 21, IQR 8.3 yr. Prevalence of EV was 53% (17/32; CI95%:36–69%). 18% (6/32; CI95%:9–35%) had high-risk stigmata and 1 patient presented with variceal haemorrhage. The most frequent location was the mid-lower esophagus. There were not gastric varices. In the univariant analysis, inferior vena cava pressure > 16 mmHg ($p = 0.09$), platelets <125000/mm3 ($p = 0.06$) and Fibroscan® >30 kPa ($p = 0.04$) were associated with the presence of EV. The most relevant incidental finding was diffuse gastritis (16/32, 50%), followed by peptic ulcer in 4 patients (13%). Sedation conducted by experienced endoscopist had more sedation-related complications than expected (2/6, severe hypoxemia and sustained hypotension). Sedation guided by anaesthesiologists (22/32,69%) was safe.
Conclusion: Prevalence of EV is very high in patients after FS. Some of them have high-risk EV and haemorrhage may occur. Screening with upper endoscopy in patients with liver stiffness >30 kPa and platelets < 125000/ml is highly advisable.

SAT-241

Distinct MELD trajectories in liver transplant candidates with hepatitis C and non-alcoholic steatohepatitis

A. Kwong, A. Mannalithara, W.R. Kim. *Stanford University, Gastroenterology and Hepatology, Stanford, United States*
Email: wrkim@stanford.edu

Background and Aims: Since its inception as a scale to determine priority for liver transplant (LT) candidates, the Model for End-stage Liver Disease (MELD) has been agnostic regarding the etiology of the underlying liver disease. The aim of this study was to identify and

Figure. Distinct MELD trajectories with 95% confidence intervals for LT candidates in 2016
1-year survival with LT censored, TFS = transplant-free survival.

	COHORT 1 (NASH)			COHORT 2 (HCV)		
Trajectory groups	N (%)	1-YR SURVIVAL	1-YR TFS	N (%)	1-YR SURVIVAL	1-YR TFS
1 (no change/linear trend)	883 (84.2)	83.0%	57.6%	1539 (90.1)	87.3%	62.7%
2 (late deterioration)	117 (11.2)	48.0%	12.8%	120 (7.1)	43.7%	8.6%
3 (early deterioration)	49 (4.7)	24.8%	0.0%	35 (2.1)	24.9%	0.0%

Figure: (abstract: SAT-241)

compare clusters of disease trajectory for LT candidates with HCV and non-alcoholic steatohepatitis (NASH).
Method: All adult primary LT candidates with end-stage liver disease who were on the waitlist as of February 1, 2016, were identified in the OPTN waitlist registry data. All patients, including those who met MELD exception criteria, with at least 1 recorded MELD within 1 year were included. Patients were censored at the time of LT. Latent subpopulations with heterogeneous disease trajectories were identified, using latent class growth mixture modeling to group individuals based on longitudinal changes in MELD over the 1 year of follow-up. Statistical fit was determined by Bayesian information criteria, and trajectories with similar patterns were categorized into separate groups for analysis.
Results: Three distinct trajectory groups were identified among 1049 patients with NASH and 1694 with HCV: (1) high MELD/early deterioration, (2) late deterioration, and (3) no change/linear trend (Figure). There was a greater proportion of patients with HCV exhibiting no change/linear trend (90.1%) compared to those with NASH (84.2%). In this trajectory group, HCV patients, in comparison to NASH patients, had better 1-year waitlist survival (87.3% v. 83.0%, respectively) and transplant-free survival (62.7% v. 57.6%, respectively). Of waitlist candidates belonging to the late deterioration trajectory group, HCV patients had a higher baseline MELD and a higher prevalence of ascites and hepatic encephalopathy compared to those with NASH ($p < 0.01$). Patients in the early deterioration trajectory group made up 4.7% of the NASH cohort and 2.1% of the HCV cohort, with 0% transplant-free survival at 1 year in both cohorts.
Conclusion: Using latent class trajectory modeling methods, distinct trajectory groups are identifiable for LT candidates with HCV and NASH. The reduced rate of disease progression among LT candidates with HCV compared to NASH may be related to the availability of antiviral therapy. Trajectory analysis may enable early identification of LT candidates at risk for deterioration on the waitlist and recognition of etiology-specific risk factors for clinical deterioration.

SAT-242

Natural history of patients with compensated cirrhosis and a hepatic venous pressure gradient >20 mmHg: A prospective longitudinal cohort study

A. Bhardwaj[1], A. Jindal[2], V. Arora[2], V. Rajan[2], A.S. Bhadoria[1], G. Kumar[1], L. Anand[2], A. Choudhury[3], S.M. Shasthry[2], R. Maiwall[2], M. Kumar[4], S.K. Sarin[5]. *[1]ILBS, Clinical Research, New Delhi, India; [2]ILBS, Hepatology, New Delhi, India; [3]Institute of Liver & Biliary Sciences, Hepatology, New Delhi, India; [4]Institute of Liver and Biliary Sciences, D1, NEW DELHI, India; [5]Institute of Liver and Biliary Sciences, Department of Hepatology, Vasant kunj, India*
Email: shivsarin@gmail.com

Background and Aims: HVPG >10 mm Hg predicts clinical decompensation (CD) in compensated cirrhotics. A proportion of cirrhotics have high HVPG (>20 mm Hg) despite no CD. The natural history, pattern of CD (ascites, hepatic encephalopathy, variceal bleed) and complications (HCC, mortality) in this group are largely unknown.
Method: Consecutive compensated cirrhosis patients with HVPG ≥6 mm Hg (n = 747) were followed-up every 3–6 months for any decompensation. Patients were classified based on HVPG (<12 mmHg (low HVPG group), 12–20 mmHg (Intermediate HVPG group) and >20 mmHg (High HVPG group). We analyzed only the low and high HVPG groups to identify predictors of new CD.
Results: 295(39.4%) patients developed CD at mean follow-up of 1.9 ± 0.3 years. In comparison to low HVPG group, first CD in high HVPG group developed early (1.4 ± 0.3 years *vs.* 2 ± 0.3 years, p = 0.02), more often (ascites- 27.1% *vs.* 13.2%, variceal bleed- 31.9% *vs.* 7.9%, AKI- 31% vs 12.8%, HCC- 12.4% *vs.* 3.9%; all $p < 0.05$) with higher mortality (15.9% *vs.* 1.9%; $p < 0.05$). There was no significant correlation between baseline HVPG level and grade of esophageal varices (p = 0.457). All patients in high HVPG group received carvedilol (maximum dose-25 mg/d, divided) and a repeat HVPG measured after a mean duration of 1.8 ± 0.4 years showed suboptimal HVPG

response (≥20% reduction in HVPG or <12 mmHg) in 26.6% patients (mean HVPG reduction, 3.3 ± 1.3 mm Hg). Etiology of cirrhosis and grade of varices were not significantly associated with CD or HVPG response. On multivariate analysis, baseline HVPG >20 mm Hg (hazard ratio [HR], 5.09; 95% confidence interval [CI], 2.909–8.926, p = 0.001) and high MELD score (HR, 1.125; 95% CI, 1.066–1.187, p = 0.001) were independent predictors of CD.
Conclusion: An HVPG of >20mm Hg independently predicts early and more frequent CD in compensated cirrhotics. Only a quarter of these patients respond to carvedilol and hence mandates us for careful HVPG monitoring and low threshold for additional drugs or interventions.

SAT-243

Effect of vardenafil on portal hemodynamics in patients with mild and moderate liver dysfunction: a randomized, placebo-controlled trial

R. Paternostro, B. Heinisch, R. Schwarzer, T. Reiberger, M. Wewalka, P. Schwabl, M. Ferlitsch, M. Mandorfer, M. Peck-Radosavljevic, M. Trauner, A. Ferlitsch. *Medical University of Vienna, Internal Medicine III, Gastroenterology and Hepatology*
Email: rafael.paternostro@meduniwien.ac.at

Background and Aims: Erectile Dysfunction (ED) is a frequent complication in patients with cirrhosis. Phosphodiesterase type 5 inhibitors (PDE5i) are effective to treat ED. Experimental studies have suggested beneficial effects of PDE5i on portal hypertension (PHT). We assessed the effects of 7 days treatment with vardenafil (10 mg o.d.; Bayer, Germany) or placebo on hepatic venous pressure gradient (HVPG) and safety in patients with cirrhosis and PHT.
Method: 20 male patients with stable cirrhosis and Child Pugh Score A and B were included. HVPG was assessed while under fasted conditions at baseline. After 7 days of treatment HVPG response (2 h after last dose) was recorded.
Results: 20 patients (age: 54 ± 13; etiology: 8 alcohol, 9 viral, 1 alcohol + viral and 2 others) were included. Three patients on vardenafil did not finish the HVPG study (n = 1 discontinuation due to headache, n = 2 failure to obtain second HVPG). Thus, n = 9 patients on vardenafil (Child A:4, B:5) and n = 8 on Placebo (Child A:4, B:4) were analyzed per protocol. Baseline HVPG (vardenafil: 18.1 ± 5.5; placebo: 18.3 ± 4.5; p = 0.952) was similar between groups. After 7 days of treatment HVPG was 17.8 ± 5 mmHg in the vardenafil group and 17.4 ± 3.9 mmHg in the placebo group; showing no significant decrease in HVPG in the vardenafil group (p = 0.724) and no statistical difference in on-treatment HVPG between groups (p = 0.858). Safety: One patient reported tinnitus and one patient reported fatigue and diffuse pain (foot, eyes) both on vardenafil. Considering the patient that discontinued the study medication due to headache, 30% of patients on vardenafil vs. 0% of patients in the placebo group reported side effects. Hence the study medication was not very well tolerated in our patient cohort.
Conclusion: Within this randomized control pilot study 30% of patients on Vardenafil reported side effects. Seven days of Vardenafil treatment did not decrease HVPG in patients with stable Child-Pugh A/B cirrhosis. These results do not support previous reports on portal pressure reduction with other PDE5i.

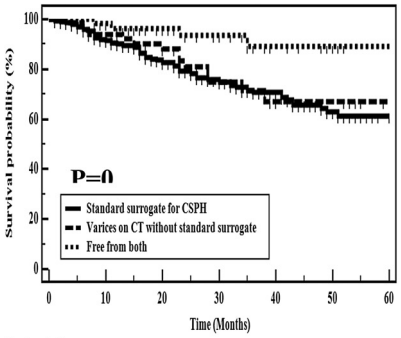
SAT-244

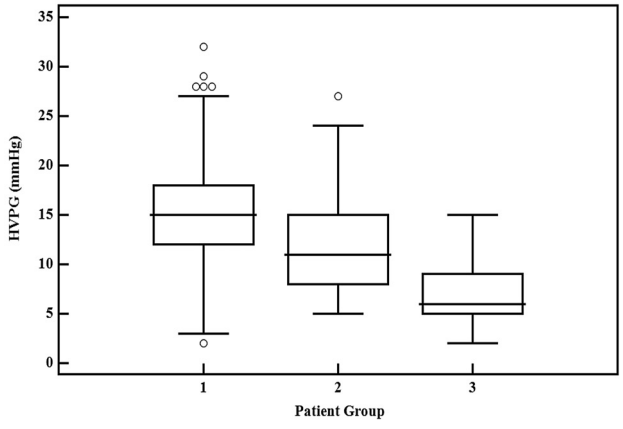
Varices on CT is the surrogate of clinically significant portal hypertension and can predict survival in patients with cirrhosis

D.H. Lee. *Seoul National University Hospital, Radiology, Seoul, Rep. of South Korea*
Email: dhlee.rad@gmail.com

Background and Aims: To investigate the prognostic value of varices on CT and redefine surrogate criteria for clinically significant portal hypertension (CSPH).

Method: We retrospectively enrolled 525 patients with cirrhosis who underwent hepatic venous pressure gradient (HVPG) measurement from 2008 to 2013. Using CT and upper endoscopy findings obtained within 3 months from HVPG measurement, patients were classified into three groups: presence of standard surrogate for CSPH, defined as presence of varices on upper endoscopy and/or splenomegaly associated with thrombocytopenia (Group 1, n = 375); varices on CT without standard surrogate for CSPH (Group 2, n = 76); and free from both (Group 3, n = 74). HVPG value and overall survival (OS) rates were compared among three patient groups. Revised surrogate for CSPH was defined as the presence of standard surrogate and/or presence of varices on CT (i.e., both group 1 and group 2).
Results: Mean HVPG value in Group 2 was significantly higher than that in Group 3 (11.5 mmHg vs. 6.8 mmHg, P < 0.001), but significantly lower than that in Group 1 (15.0 mmHg vs. 11.5 mmHg, P < 0.001). 5-year OS rates in Group 2 was similar to those in Group 1 (67.1% *vs.* 61.2%, P = 0.648), but significantly poorer than those in Group 3 (67.1% vs. 89.1%, P = 0.012). The presence of standard surrogate for CSPH was not a significant factor for OS (61.2% *vs.* 77.3%, P = 0.068). However, presence of revised surrogate for CSPH was a significant predictive factor for OS (61.9% *vs.* 89.1%, P = 0.017).





Conclusion: The presence of varices on CT was a significant sign for CSPH, predicting poor overall survival outcome in patients with cirrhosis.

SAT-245

Predictors of endoscopic high risk esophageal varices in compensated cirrhosis: Can we avoid Fibroscan?

G. Huard[1], J. Hercun[1], M. Bilodeau[2], J. Bissonnette[3], J.-M. Giard[1].
[1]*Centre Hospitalier de l'Université de Montréal, Montreal, Canada;* [2]*Centre Hospitalier de l'Université de Montréal, Montreal, Montreal, Canada;* [3]*Hôpital Beaujon, Centre Hospitalier de l'Université de Montréal, Paris, France*
Email: julianhercun@gmail.com

Background and Aims: Patients with cirrhosis are at risk of developing esophageal varices (EV). Recently, criteria based on elastography and platelet count (Baveno VI criteria) have been adopted and included in practice guidelines to circumvent screening endoscopy (EGD). However, elastography measurement is not widely available. The aim of the study was to determine predictive factors excluding liver stiffness in order to predict high-risk EV in patients with compensated cirrhosis.

Method: Retrospective chart review of all compensated cirrhotic adult patients who underwent screening EGD at Saint-Luc Hospital between 01/2014 and 12/2016. Patients with decompensated cirrhosis (ascites, hepatic encephalopathy, jaundice), past history of EV/TIPS or liver transplantation, acute upper gastrointestinal bleeding, acute alcoholic hepatitis were excluded. High-risk EV were defined as medium or large EV and/or presence of red wale signs. Splenomegaly was defined as a spleen ≥13 cm on imaging. Thrombopenia was defined as a platelet count $<150 \times 10^9$/L. Baseline characteristics, laboratory values and EGD findings were analyzed.

Results: A total of 463 patients were included. The median (IQR) age was 60.2 (13.4) years and the majority were males (n = 289; 62.4%). The most frequent causes of liver disease were chronic hepatitis C infection (n = 117; 25.3%) and non-alcoholic steatohepatitis (n = 112; 24.2%). At screening EGD, the median (IQR) MELD score was 7.5 (2.7), the median (IQR) platelet count was $154\ (87) \times 10^9$/L, and 203 (43.8%) patients had splenomegaly. A total of 45 (9.7%) patients had high-risk EV at screening EGD. In multivariate analysis adjusting for age and gender, the following variables were predictive of high-risk EV: thrombopenia (OR 4.7; p= 0.001) and splenomegaly (OR 3.8; p = 0.001). MELD >6 score was not predictive of high-risk EV (OR 1.7; p = 0.337). Among the 172 patients having normal spleen size and platelet count $\geq 150 \times 10^9$, only 2 (1.2%) patients had high-risk EV at screening EGD. The presence of splenomegaly and/or thrombopenia had a sensitivity of 95.6% and a negative predictive value of 98.8% for the presence of high-risk EV at screening endoscopy.

Conclusion: In compensated cirrhosis, the combination of normal spleen size and normal platelet count translates into a 98.8% chance of absence of high-risk EV at screening EGD. Using these criteria, 172 (37.1%) screening EGD could have been avoided in our population. Therefore, the use of elastography is not mandatory in the decision of recommending screening EGD in patients with compensated cirrhosis.

SAT-248

Uncontrolled diabetes increases all causes of mortality and particularly cardiovascular death in patients with cirrhosis

F.H.-d.L. Tijera[1], A. Servin-Caamaño[2], A.E. Navarro-Estrada[2], R. Rabago[3], A. Cruz-Estrada[4]. [1]*Hospital General de Mexico, Head of Gastroenterology Department, Mexico;* [2]*Hospital General de Mexico, Internal Medicine;* [3]*Hospital General de Mexico, Gastroenterology, Liver Clinic;* [4]*Hospital General de Mexico, Head of Internal Medicine Department*
Email: fatimahiguera@yahoo.com.mx

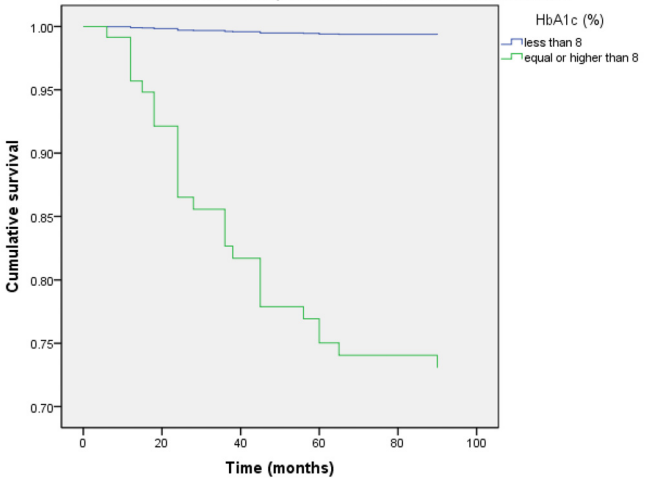
Background and Aims: Diabetes is a comorbidity that is increasing in patients with cirrhosis; nevertheless, there are not specific guidelines to treat diabetes in this population. The aim of this study was to investigate risk factors increasing all causes of mortality, with special attention on cardiovascular death in patients with cirrhosis with type 2 diabetes.

Method: A cohort study which included patients with cirrhosis and diabetes, seen at the Liver Clinic in the last 10 years. We excluded patients with other conditions potentially related to immunosuppression. Demographic, clinic, metabolic and biochemical data were collected; the date of diabetes and cirrhosis diagnosis was verified, during follow-up we specially search for all causes of mortality and cardiovascular death. Univariate analysis was performed using t Student's test or Mann-Whitney U test, or with X2 or Fisher's exact test. Cox regression model was used for the multivariate analysis. Kaplan-Meier curves was constructed to compare between those death or alive. A $p < 0.001$ value was considered significant.

Results: 380 patients with cirrhosis and diabetes were included, 193 (50.8%) were men. The mean of age was 62.6 + 9.0 year-old. Causes of cirrhosis were: alcohol 156 patients (41.1%), hepatitis C 76(20.0%), non-alcoholic steatohepatitis 111(29.2%), cryptogenic 37(9.7%). According to Child-Pugh: 141 patients (37.1%) were assessed as A, 170(44.7%) B, 69(18.2%) C. Thirty three (8.7%) died for liver-related causes, 29(7.6%) died for cardiovascular death.

Patients who died had higher fast serum glucose compared with those alive: 220 ± 85 mg/dL vs. 143 ± 62 mg/dL, $p < 0.0001$; and higher Hb_{A1c} serum levels: 8.4 ± 1.5% *vs.* 6.8 ± 1.1%, $p < 0.0001$. In the univariate analysis, hepatic encephalopathy (HE), ascites, spontaneous bacterial peritonitis (SBP), level of Hb_{A1c} >8.0%, and decompensated cirrhosis (Child B/C) were factors associated with all causes of mortality, ($p < 0.0001$). In the multivariate analysis, only Hb_{A1c} >8.0% was associated with all causes of mortality (HR = 6.3; 95%CI = 3.2–12.6; $p < 0.0001$). When we analysed specifically for cardiovascular death, those who died had higher serum glucose levels: 230 ± 92 mg/dL vs. 143 ± 62 mg/dL, $p < 0.0001$; and Hb_{A1c} serum levels: 8.8 ± 1.6% *vs.* 6.8 ± 1.1%, $p < 0.0001$. In the univariate analysis, ascites ($p = 0.001$), HE, SBP, level of Hb_{A1c} >8.0% were associated with cardiovascular death ($p < 0.0001$). Decompensated liver disease, variceal bleeding, sex were not significant. In the multivariate analysis Hb_{A1c} >8.0% was strongly associated with cardiovascular death (HR = 48.6; 95%CI = 10.6–222.4; $p < 0.0001$).

Kaplan Meier curves showing survival rate for cardiovascular death according to HbA1c serum levels in patients with cirrhosis and diabetes



Conclusion: When diabetes coexists with cirrhosis, uncontrolled glycaemia seems to be the most important risk factor predicting all causes of mortality, but specially is strongly associated with cardiovascular death.

SAT-249

TIPS placement improves sarcopenia and modifies fat distribution: A monocentric retrospective study

F. Artru[1], M. Xavier[1], A. Mustapha[1], N. Amelie[1], T. Pierre[1], E. Olivier[1], G. Lassailly[2], S. Dharancy[3], S. Geraldine[1], P. Mathurin[1], A. Louvet[1].
[1]CHRU Lille, Liver unit, Lille, France; [2]Liver unit, CHRU Lille, Lille, France; [3]Liver unit, CHRU Lille, Lille, France
Email: florent.artru@chru-lille.fr

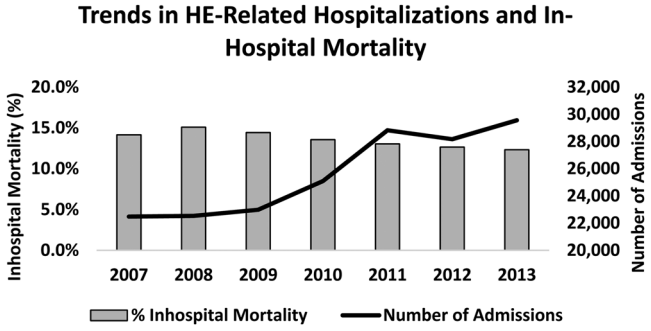
Background and Aims: Sarcopenia is associated with mortality in decompensated cirrhosis and has been suggested being reversible after TIPS placement based on the results of only one study. Computed tomography (CT) scan enables to assess body composition after TIPS placement. The aims of our study were to evaluate the impact of TIPS placement on body composition and to assess its changes by radiological sequential analysis.
Method: All patients who underwent TIPS insertion for elective indication (refractory ascites and secondary prophylaxis of portal hypertension related GI bleeding) between July 2011 and March 2017 have been retrospectively included. Clinical, biological and CT data have been recorded sequentially 1, 3 and 6 months after TIPS placement.
Results: 132 patients were included. 84.1% (n = 111) had alcohol-related cirrhosis. Median age was 58.5 (IQR 52.8–63.3) years, MELD score 10.7 (8.5–13.2) and Child-Pugh score 8 (7–8). TIPS indication was refractory ascites in 71.2% (n = 98) and secondary prophylaxis of GI bleeding in 28.8% (n = 38). 6-month survival was 84.8 and 97.3% respectively (p = NS). We observed a progressive improvement in sarcopenia at 3 and 6 months after TIPS as shown by an increase in umbilical level psoas axial diameter (AD) from 42.5 to 45.4 mm ($p < 0.0001$), psoas transverse diameter (TD) from 33.8 to 37.2 mm ($p < 0.0001$), and L3-L4 intervertebral level sum of psoas area from 2017.7 à 2249 mm² ($p < 0.0001$). Such improvement was not observed in patients who developed TIPS obstruction when compared to those who did not developed obstruction: TD 33.6 to 34.2 mm ($p = 0.63$) vs. 34.3 to 38.1 mm ($p < 0.0001$), AD 40.7 to 41 mm ($p = 0.86$) *vs.* 43.7 to 46.6 mm ($p < 0.0001$), sum of area 1868.9 to 1869.2 mm² ($p = 0.99$) vs. 2083.3 to 2333.8 ($p < 0.0001$). From baseline to 3 and 6 months, subcutaneous fat (SCF) increased from 163.8 cm² to 225.1 cm² ($p < 0.0001$) and visceral fat (VF) decreased from 158.6 cm² to 143.7 cm² ($p = 0.02$). At 6 months, we observed an increase of SCF from 174.8 to 225.2 cm² ($p < 0.0001$) and a decrease of VF from 152.5 to 130.8 cm² ($p = 0.002$) in patients without TIPS thrombosis. In the others, VF decreased from 207.3 to 180.3 cm² ($p = 0.03$) without significant increase of SCF from 207.4 to 231.5 cm² ($p = 0.13$). In univariate analysis, at time of TIPS placement, VF (RR 1.005 95% CI 1.005–1.1, $p = 0.05$), AD (RR 0.9, 0.83–0.96, $p = 0.005$), TD (RR 0.91, 0.85–0.98, $p = 0.01$) and MELD score (1.09, 1.02–1.2, $p < 0.04$) were associated with 6-month mortality. No multivariate analysis was performed because of a too small sample size.
Conclusion: Elective insertion of TIPS is followed by a rapid improvement of sarcopenia, an increase of SCF and a decrease of VF, which depends on the permeability of the stent. This confirms the role of portal hypertension on body composition of cirrhotic patients.

SAT-250

Increasing burden of hepatic encephalopathy among hospitalized adults, with significantly higher risk of in-hospital mortality in African Americans: An analysis of the 2007–2013 nationwide inpatient sample

G. Hirode, B. Liu, T. Bhuket, R. Wong. *Alameda Health System, Highland Hospital, United States*
Email: rowong@alamedahealthsystem.org

Background and Aims: Hepatic encephalopathy (HE) is a common complication associated with decompensated liver disease among patients with acute liver failure or advanced cirrhosis. Development of HE is associated with significant morbidity and mortality, contributing to significant burden on healthcare systems. We aim to evaluate trends in the burden of HE among hospitalized adults in the U.S.
Method: Using the 2007–2013 Nationwide Inpatient Sample, we identified HE-related hospitalizations using International Classification of Diseases, Ninth Revision codes. Annual trends in HE-related hospitalizations and in-hospital mortality were evaluated. Multivariable logistic regression was performed on weighted data to identify factors associated with in-hospital mortality adjusting for patient- and hospital-level characteristics. Variables that demonstrated statistically significant associations ($p < 0.05$) in univariable analysis, and with biological plausibility, were included.
Results: Among 179,604 HE-related hospitalizations (58.3% male, 67.4% non-Hispanic white, median age 58 IQR 51–67, 67.1% with cirrhosis diagnosis), overall hospital length of stay was 5 days (IQR 3–10) and in-hospital mortality was 13.5%. From 2007 to 2013, HE-related hospitalizations increased by 31.5% (22,471 to 29,559, $p < 0.001$). During this same period, in-hospital mortality rates among HE hospitalizations decreased from 14.1% in 2007 to 12.3% in 2013, $p < 0.001$. On multivariable regression, African Americans had significantly higher in-hospital mortality compared to non-Hispanic whites (OR, 1.21; 95% CI, 1.13–1.30; $p < 0.001$). Significantly higher risk of in-hospital mortality was also observed in patients with acute liver failure (OR, 3.73; 95% CI, 3.48–4.00; $p < 0.001$), hepatorenal syndrome (OR, 4.04; 95% CI, 3.79–4.30; $p < 0.001$), ascites (OR, 1.36; 95% CI, 1.30–1.42; $p < 0.001$), and hepatocellular carcinoma (OR, 1.58; 95% CI, 1.43–1.74; $p < 0.001$). Additionally, being admitted to an urban teaching hospital (relative to rural) was also associated with higher odds ($p < 0.05$).



Conclusion: The burden of HE-related hospitalizations in the U.S. continues to rise. While overall in-hospital mortality has declined, significant race/ethnicity-specific disparities are observed, with the significantly higher risk of mortality seen in African Americans with HE compared to non-Hispanic whites.

SAT-251

Health care costs are double for non-alcoholic fatty liver disease non-alcoholic steatohepatitis patients with compensated cirrhosis who progress to end-stage liver disease

R. Loomba[1], S. Li[2], Y. Peng[2], X. Wang[2], S. Harrison[3]. *[1]University of California at San Diego, Division of Gastroenterology, Department of Medicine, San Diego, United States; [2]Chronic Disease Research Group, Minneapolis, United States; [3]Pinnacle Clinical Research, San Antonio, United States*
Email: roloomba@ucsd.edu

Background and Aims: NAFLD/NASH is one of the most common causes of CC in the United States. CC patients often develop complications and advance to ESLD which includes decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC) and liver transplant (LT) which may lead to death. The study objective was to characterize long-term economic burden in compensated cirrhosis (CC) patients who progressed to end-stage liver disease (ESLD) compared to those who did not.

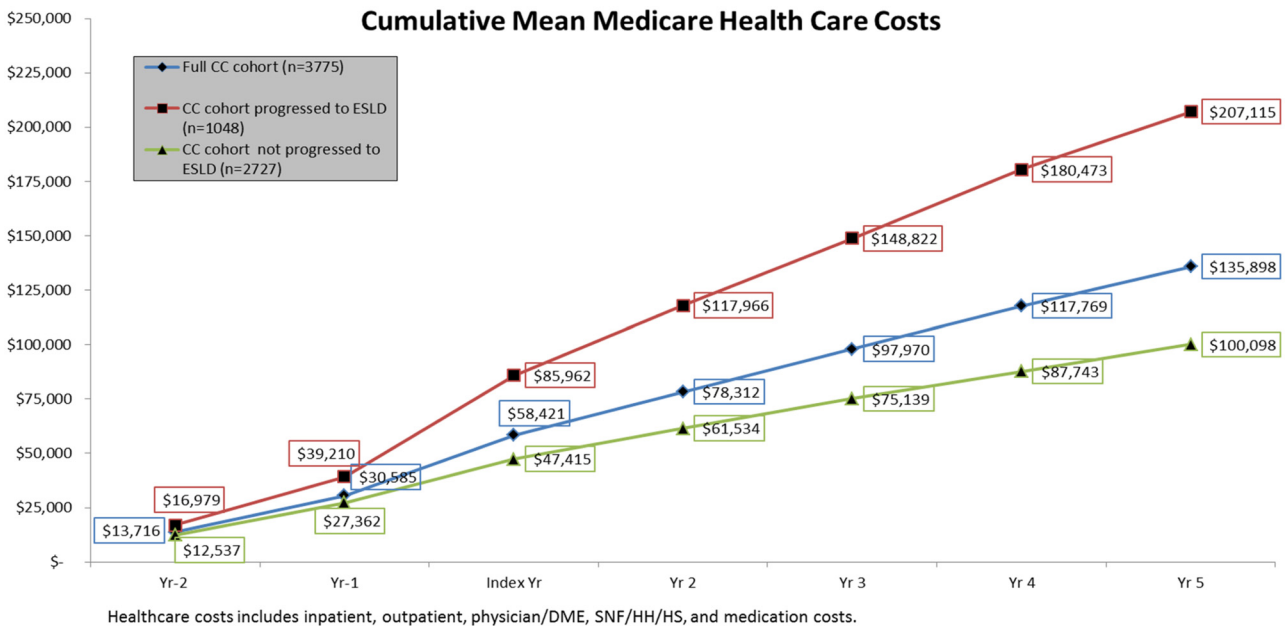


Figure: (abstract: SAT-251)

Method: The study population was extracted from the 2007–2015 US Medicare 20% sample data and included NAFLD/NASH patients with CC aged ≥18 years. The first CC diagnosis date was defined as the index date. Any patients with hepatitis B, hepatitis C, other viral hepatitis, HIV, alcoholism, toxic liver disease, Wilson's disease, autoimmune hepatitis, gaucher + LAL-D, biliary cirrhosis, primary sclerosing cholangitis, and hemochromatosis were excluded. Medicare costs were estimated during 2 year pre-index and 1 year pre-index along with 1 year, 2 years, 3 years, 4 years, and 5 years of follow-up post-index. Total 7-year cumulative costs were calculated per patient (PP) annually and adjusted for 2015 USD.
Results: The study identified 3,775 NAFLD/NASH patients with CC having 67 (10.9) years mean age, 63.3% females and a high comorbidity burden 74.8% with DM; 91.6% with hyperlipidemia; 93.9% with hypertension. Cumulative Medicare costs increased 890.8% over 7 years, from $13,716 (2 year pre-index) to $135,898 (5 year post-index). Of the total cohort, 27.8% (1,048) patients progressed to ESLD (progressors) and 72.2% (2727) remained in CC (non-progressors) during the study period. The comorbidity burden was high for both progressors and non-progressors – DM 79.1% (progressors) and 73.2% (non- progressors); hyperlipidemia 92.7% (progressors) and 91.3% (non-progressors); hypertension 96.4% (progressors) and 93.1% (non-progressors). The 7 year cumulative increase in Medicare costs was found to be 1120% for progressors [$16,979 (2 year pre-index) to $207,115 (5 year post-index)] and 698% for non-progressors [$12,537 (2 year pre-index) to $100,098 (5 year post-index)].
Conclusion: NASH/NAFLD patients upon progression to CC keep accumulating substantial costs over a long duration. Progressors experienced 1120% increase and the non-progressors experienced 698% increase in health care costs. This study underscores the need for effective treatments for patients with NAFLD/NASH with CC due to the significant morbidity and mortality, and the high economic burden.

SAT-252

High real-world healthcare costs in non-alcoholic fatty liver disease/non-alcoholic steatohepatitis compensated cirrhosis patients with and without type-2 diabetes mellitus: A large German database study

A. Canbay[1], J. Altevers[2], S. Braun[2]. [1]*Department of Gastroenterology, Hepatology and Infectiology, University of Magdeburg Medical School, Magdeburg, Germany;* [2]*Xcenda GmbH, Hannover, Germany*
Email: ali.canbay@med.ovgu.de

Background and Aims: Comorbid type-2 diabetes mellitus (DM) in NAFLD/NASH patients is associated with an increased risk of progression and mortality leading to increased healthcare costs. This study examined the comorbidities and healthcare costs among German NALFD/NASH DM and non-DM patients once they were diagnosed with compensated cirrhosis (CC).
Method: Patients aged ≥18 years with a NAFLD/NASH diagnosis between 2011 and 2016 were identified retrospectively from the InGef research claims database with about 4 million insurees. CC diagnosis followed the NASH/NAFLD diagnosis, with the first CC diagnosis as the index date. Patients were stratified by DM or non-DM status. Patients were excluded if they had <1 year of continuous enrolment (CE) pre- and post-index, and other causes of liver disease. Progression to end-stage liver disease (ESLD; decompensated cirrhosis, hepatocellular carcinoma, liver transplant) in the post-index period was not allowed. All-cause mortality was evaluated within 1-year post index. Mean annual all-cause healthcare costs were examined for patients with 1–5 years of CE pre- and post-index.
Results: The study population included 555 NAFLD/NASH CC patients with 1 year of CE pre- and post-index — 307 with DM (mean age 68.1 ± 10.9; 56% male) and 248 non-DM (mean age 63.7 ± 13.9; 59% male). NAFLD/NASH CC DM and non-DM patients had a high prevalence of comorbidities: hypertension was 90% and 67%, obesity was 53% and 25%, and dyslipidemia was 61% and 42%, respectively. In the post-index period, 7.8% and 7.3% of DM and non-DM patients deceased. The 307 DM patients cumulated €2,985,320 and the 248 non-DM patients cumulated €1,717,607 all-cause annual healthcare costs in the 1-year post-index period. Prior to cirrhosis index, DM patients had mean annual all-cause healthcare costs of €6,934 and non-DM of €4,305 ($P < 0.001$). Following index, these costs increased for DM

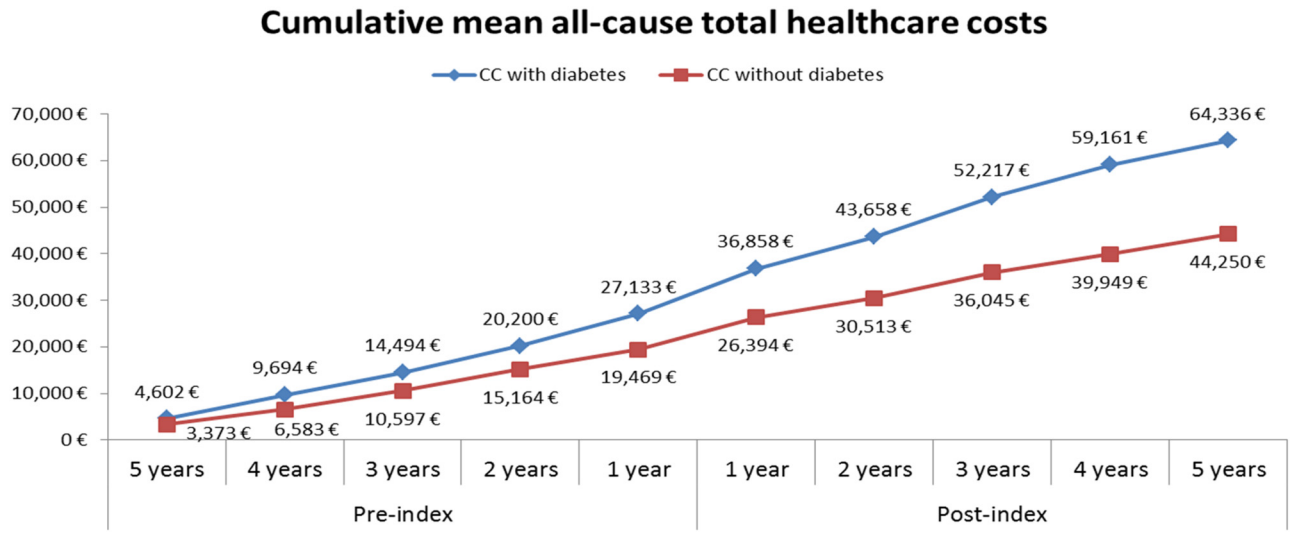

Figure: (abstract: SAT-252)

patients to €9,724 and non-DM to €6,926 (P < 0.001 for DM vs. non-DM and pre- and post-index). DM patients' cumulative mean annual all-cause total costs increased 137% over a five-year period, from €27,133 (pre-year 1) to €64,336 (year 5), while non-DM patients increased 127% from €19,469 (pre-year 1) to €44,250 (year 5) (Figure).

Conclusion: In the 5 years following cirrhosis diagnosis German NAFLD/NASH DM patients experienced an increase of over €37,000 in cumulative costs and non-DM patients a nearly €25,000 increase. Improved patient management and treatment options are needed to improve patient outcomes and reduce healthcare costs.

SAT-253

Functional polymorphisms of innate immunity receptors are not risk factors for non-SBP type bacterial infections in cirrhosis

T. Tornai[1], T. Dinya[2], Z. Vitális[1], I. Tornai[1], B. Balogh[1], D. Tornai[3], P. Antal-Szalmás[3], A. Sümegi[4], H. Andrikovics[5], A. Bors[5], A. Tordai[6], M. Papp[1]. [1]*University of Debrecen, Faculty of Medicine, Institute of Internal Medicine, Department of Gastroenterology, Debrecen, Hungary;* [2]*University of Debrecen, Faculty of Medicine, Department of Surgery;* [3]*University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine;* [4]*Hungarian Academy of Sciences, Vascular Biology, Thrombosis and Haemostasis Research Group;* [5]*Hungarian National Blood Transfusion Service;* [6]*Semmelweiss University, Department of Pathophysiology, Budapest, Hungary*
Email: tornaitamas@gmail.com

Background and Aims: Innate immunity pattern recognition receptors (PRRs) recognize distinct pathogen-associated molecular patterns (PAMPs) on the cell surface or in the cytoplasm. Functional polymorphisms of various PRRs have been established to contribute to susceptibility to spontaneous bacterial peritonitis (SBP). However, their role in the development of cirrhosis-associated bacterial infections (BI) beyond SBP remains unknown. We aimed to investigate the link between PRR gene variants, pathological bacterial translocation (BT) and thus the development of cirrhosis-associated complications

Method: 349 patients with cirrhosis (stable outpatients: 243 and acute decompensation: 106) were genotyped for the common *NOD2* (p.R702W, p.G908R and c.3020 insC), *TLR2* (g.6686T/A), *TLR4* (D299G) and *CD14* (c. 159C/T) gene variants. In the stable outpatients (male: 116, age: 56 ± 11 yrs, alcohol: 62.6%, ascites: 36.2%, MELD score: 11) incidence of BI, decompensating events (ascites, variceal bleeding and hepatic encephalopathy) and liver-related death were prospectively assessed in a 5-year followup observational study. BT was assessed based on the presence of anti-microbial antibodies (anti-OMP Plus IgA and/or Endotoxin core IgA antibody [EndoCab]) or increased serum level of lipopolysaccharide-binding protein (LBP).

Results: Ninety-four (38.7%) patients encountered at least one episode of BI. Distribution of bacterial infections were as follows: urinary tract infection (39.4%), SBP (27.7%), pneumonia (13.8%) and miscellaneous (24.5%). 5.3% of the cases were multifocal. PRR genetic profile was not associated with prior BI episode and also not with the risk of overall BI or infection-related death during the follow-up. Decompensated clinical stage (HR,[95%CI]: 2.11 [1.38–3.25]) and prior history of a BI episode (HR: 2.42 [1.58–3.72]) were the major clinical risk factors of a subsequent BI. *NOD2* variants however, were associated with an increased cumulative probability of SBP in patients with ascites(n = 88) as compared to wild type (76.9 ± 19.9% *vs.* 30.9 ± 6.9%, $P_{LogRank} = 0.047$). Frequency of anti-microbial antibodies and LBP levels did not differ between various PRR genotypes. Correspondingly, PRR genetic profile was not able to predict the long-term disease course in cirrhosis.

Conclusion: In a Hungarian patient cohort with cirrhosis, common *NOD2* gene variants but not the other PRR polymorphisms enabled to improve identification of patients with high risk for SBP. None of the examined PRR gene variants influenced the risk of other types of BI or the long-term disease course. They were also not associated with serological markers of BT.

SAT-254

The prognosis following bacterascites is as poor as spontaneous bacterial peritonitis

J.J. King[1], N. Halliday[1], E. Wey[2], E. Tsochatzis[1], A. Gerussi[1,3], D. Patch[1], J. Ryan[4], J. Graff[1], R. Westbrook[5]. [1]*Royal Free London NHS Trust, UCL Institute for Liver and Digestive Health, The Royal Free Sheila Sherlock Centre, London, United Kingdom;* [2]*Royal Free London NHS Trust, Centre for Clinical Microbiology, Division of Infection & Immunity, London, United Kingdom;* [3]*University of Udine, Liver unit, Internal Medicine, Department of experimental and clinical medical sciences, Martignacco, Italy;* [4]*Royal Free London NHS Trust, UCL Institute of Liver and Digestive Health, The Royal Free Sheila Sherlock Centre, United Kingdom;* [5]*Royal Free Hospital, london, United Kingdom*
Email: jijadeking@gmail.com

Background and Aims: Spontaneous bacterial peritonitis (SBP) is defined as an ascitic PMN count >250 cells/mm³ and is associated with a significant morbidity and mortality. Bacterascites (BA) (the presence of organism on culture but ascitic WCC <250 cells/mm³)

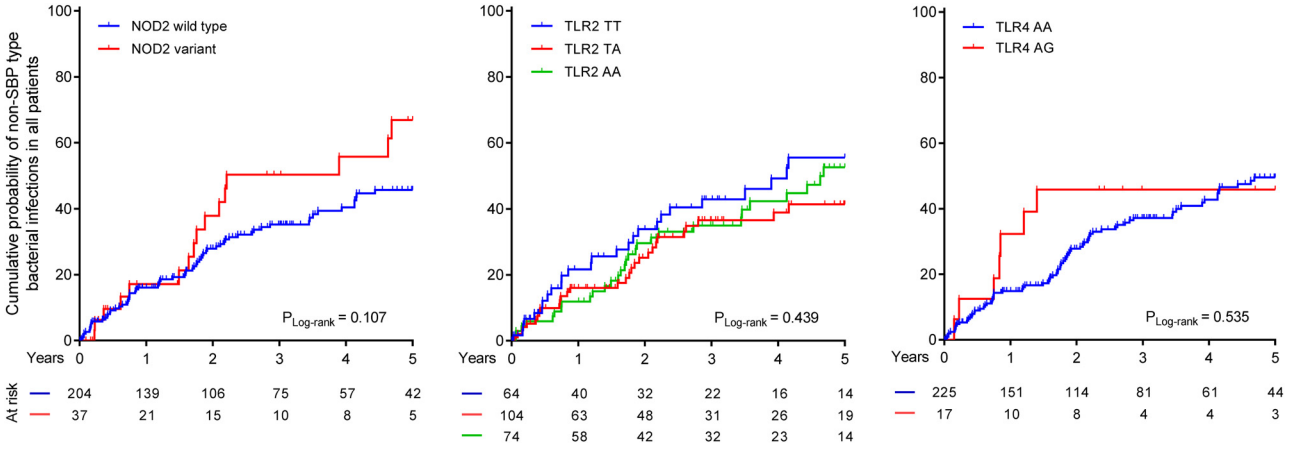

Figure: (abstract: SAT-253)

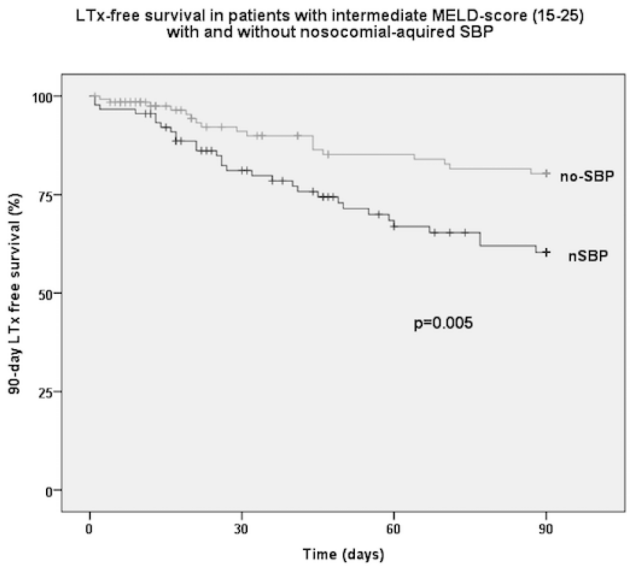
may progress to SBP or spontaneously resolve. The prognostic significance of a treated episode of BA on 2-year survival is undefined.
Method: Ascitic fluid cultures from consecutive cirrhotic patients from 2014 to 2016 were reviewed and patients assigned to SBP, BA or sterile culture groups. Baseline data on disease aetiology, laboratory parameters, MELD scores, pathogens and antimicrobial sensitivities were obtained. Clinical outcomes evaluated over a 2-year period and censored at the time of death or liver transplantation (LT). Patients with previous SBP/BA were excluded, and over the study period only the index case was recorded.
Results: 178 patients (71 female) were included. Median age was 56-years (IQR 48–64 years) and median MELD score 18 (IQR 12–21). 30 had BA, 18 SBP and 130 had sterile ascites. Alcohol related liver disease was the underlying aetiology in 53% of cases.
No differences were found in MELD scores between those with BA (19 *vs.* 17, p = 0.26) or SBP (20 vs. 17, p = 0.08), or the individual components, WCC or serum albumin when compared to sterile controls. Comparing those with BA to SBP, no significant differences in age (p = 0.4), MELD (p = 0.4), albumin (p = 0.3) or WCC (p = 0.5) existed.
Survival (without LT) at 2-years in the 3 groups were SBP 6/18 (33%), BA 9/30 (30%) and 69/130 (53%) in the sterile controls. Survival at 2 years (without LT) was significantly higher in the sterile controls when compared to those with BA/SBP (p = 0.01) and BA alone (p = 0.02), but equivalent in patients with SBP and BA (33 vs 30% NS).
The BA group had lower rates of pathogenic isolates (50%) when compared to the SBP group (100%) and Enterobacteriacae comprised a smaller proportion of isolates cultured (46 *vs.* 60%, NS). Resistance rates of Enterobacteriaceae were equivalent in both the BA and SBP groups (29% *vs.* 33%, NS).
Conclusion: Data from this study highlights bacterascites is a poor prognostic factor, independent of MELD score and synthetic parameters. The long-term impact on prognosis appears equivalent in SBP and BA (despite SBP cultured organisms being more likely pathogenic) and this needs to be acknowledged in patients with BA when management decisions regarding LT and antibiotic prophylaxis is being considered.

SAT-255

MELD-score underestimates mortality in patients with nosocomial spontaneous bacterial peritonitis

M. Kimmann[1], T. Tergast[1], H. Laser[2], M.P. Manns[1,3,4], M. Cornberg[1,3,4], B. Maasoumy[1,3,4]. [1]*Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*Centre for Information Management, Hannover, Germany;* [3]*German Centre for Infection Research, Braunschweig, Germany;* [4]*Centre for Individualised Infection Medicine (CIIM), Hannover, Germany*
Email: Kimmann.Markus@mh-hannover.de

Background and Aims: Spontaneous bacterial peritonitis (SBP) is a severe complication in patients with liver cirrhosis. Model of End-stage Liver Disease (MELD)-score is widely used to predict mortality and the main criteria for liver transplant allocation in several countries. However, only limited data exist regarding the prognostic value of the MELD-score in patients with SBP. The aim of this study was to investigate whether SBP affects the accuracy of the MELD-Score in patients with decompensated liver cirrhosis in predicting mortalilty.
Method: A number of 608 consecutive patients with liver cirrhosis and ascites who underwent a paracentesis at Hannover Medical School between January 2012 and June 2016 were included. Patients were divided into three groups: Patients without SBP within 90 days after baseline paracentesis (no-SBP) (n = 334), those with a community-acquired SBP (caSBP) (n = 59) and patients with a nosocomial-acquired SBP (nSBP) (n = 215). LTx-free survival (within 90 days) was analyzed using the log-rank test. Uni- and multivariate Cox-Regression was performed to identify risk factors for mortality.
Results: Survival was significantly lower in patients with nSBP compared to no-SBP patients (nSBP 60.5% *vs.* no-SBP 79.6%; p < 0.001). In the multivariate analysis MELD-score (p < 0.001; HR = 1.130) and nSBP (p = 0.006; HR = 1.567) were the only significant predictors of mortality. In contrast, survival was not different between caSBP and no-SBP patients (caSBP 86.4% *vs.* no-SBP 79.6% p = 0.16). To further investigate the impact of nSBP on mortality the no-SBP and nSBP cohorts were divided into a low (<15), an intermediate (15–25) and a high (>25) MELD group. In the low MELD group, there was no difference in survival between nSBP (n = 56) and no-SBP patients (n = 129) (nSBP 91.1% *vs.* no-SBP 93.8%; p = 0.55). Among the high MELD group survival was numerically lower in patients with nSBP (n = 69) compared to the no-SBP group (n = 75) (nSBP 27.5% vs. no-SBP 44.0%; p = 0.065). However, the most prominent difference was documented among patients in the intermediate MELD group. Survival was significantly impaired in the nSBP cohort (n = 90) in comparison to the no-SBP cohort (n = 130) (nSBP 66.7% *vs.* no-SBP 86.2%; p = 0.005; Figure). Importantly, mean MELD-score was not different between these two groups (nSBP 19.8 *vs.* no-SBP 19.9; p = 0.8). Furthermore, MELD-score was not a statistical significant risk factor for mortality in the group of patients with intermediate MELD-scores and nSBP (p = 0.102; HR = 1.104).



Conclusion: MELD-score seems to underestimate mortality in patients with nSBP, in particular in those with intermediate MELD-scores.

SAT-256

The role of transjugular intrahepatic portosystemic shunt in the management of portal vein thrombosis: A systematic review and meta-analysis

N. Valentin, P. Korrapati, J. Constantino, A. Young, I. Weisberg.
Mount Sinai Beth Israel, Division of Digestive Diseases, New York, United States
Email: ilan.weisberg@mountsinai.org

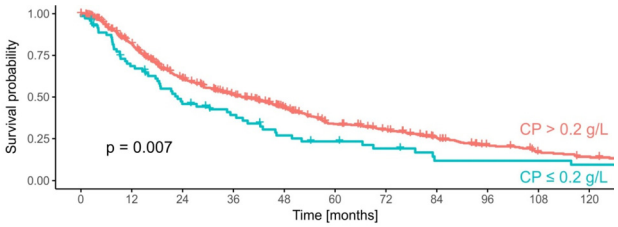
Background and Aims: The role of Transjugular Intrahepatic Portosystemic Shunt (TIPS) in the management of Portal Vein Thrombosis (PVT) remains controversial. The aim of this study was to conduct a systematic review and meta-analysis to evaluate the role of TIPS for the management of PVT in adult patients with underlying liver disease.
Method: Multiple databases were searched through April 2017. Data were gathered to estimate the rates of technical success, portal vein recanalization, portal patency after shunt placement, hepatic encephalopathy (HE), and the mean change in portal pressure gradient (PPG) in patients with PVT who underwent TIPS. Estimates were pooled across studies using the random effects model.
Results: A comprehensive search of the literature identified 495 potential studies. Eighteen studies with 439 patients who underwent TIPS for the management of PVT were included in the analysis. The technical success rate of TIPS ranged between 60% and 99% with a pooled rate of 86.7% (95%CI = 78.6%–92.1%). The rate of portal vein recanalization ranged between 68% and 98% with a pooled rate of 84.4% (95%CI = 78.4%-89.0%). Complete recanalization ranged between 57% and 96% with a pooled rate of 73.7% (95%CI = 64.3%–81.3%). The rate of portal patency ranged between 72% and 96% with a pooled rate of 86.9% (95%CI = 79.7%-91.8%). The mean change in portal pressure gradient ranged between 12 mmHg and 19 mmHg with a pooled change of 14.5 mmHg (95%CI = 11.3 mmHg–17.7 mmHg). The rate of HE ranged between 5% and 41% with a pooled rate of 25.3% (95%CI = 19.2%–32.6%). In patients who successfully underwent TIPS placement, the number of major adverse events reported across studies was low. The majority of the analyses were not associated with substantial heterogeneity. Intervention analysis in comparison to a gold standard was unable to be estimated due to lack of comparative studies.
Conclusion: The use of TIPS in the management of PVT is feasible and effective in achieving a significant and sustainable reduction in clot burden with a low risk of major complications. TIPS should be considered as a viable treatment option in patients with PVT. Given the limited amount of randomized comparative studies reported, additional trials are warranted to assess the safety and efficacy of TIPS as treatment in PVT in comparison to other treatment options, such as anticoagulation.

SAT-257

Reduced serum ceruloplasmin concentration is common in patients with cirrhosis and a NaMELD independent predictor of transplantation or death

B. Schaefer, A. Viveiros, R. Al-Zoairy, M. Tobiasch, M. Effenberger, H. Tilg, H. Zoller. *Medical University of Innsbruck, Internal Medicine I, Innsbruck, Austria*
Email: benedikt.schaefer@i-med.ac.at

Background and Aims: Reduced concentrations of the copper-binding plasma ferroxidase ceruloplasmin (CP) are both indicative of Wilson disease, but also commonly found in patients with NASH cirrhosis. Not all patients with multiple metabolic risk factors for NASH cirrhosis and low CP receive full diagnostic workup for the confirmation or exclusion of Wilson disease. The aim of the present study was to determine the prevalence and prognostic relevance of CP concentration in an unselected cohort of patients with cirrhosis referred for PNPLA3 genotyping.
Method: Patients referred for PNPLA3 to the Hepatology Laboratory at the Medical University of Innsbruck were retrospectively assessed and included if the diagnosis cirrhosis was made. Demographic, clinical and biochemical parameters were extracted from patient records. PNPLA3 genotype was determined by an allelic discrimination PCR.
Results: Reduced CP concentration ≤ 0.2 g/L was present in 11.7% (72/613) of patients. The diagnosis Wilson disease had been made in 4 of 613 patients, only 3 of which had CP ≤ 0.2 g/L. The prevalence of low CP was 75% in Wilson disease patients and 23% (3/13) in hemochromatosis patients followed by 16% in alcoholic cirrhosis (24/142) and 13% (15/150) in patients with NAFLD/NASH. Median NaMELD score was significantly higher in the patient group with CP < 0.2 g/L (23 vs 17, p < 0.001) and a significant negative correlation between CP and INR but not with albumin was found. Correlation analysis further showed a significant association between CP and markers of iron metabolism/inflammation (transferrin, transferrin saturation, C-reactive protein). Median time to transplantation or death as combined endpoint was also significantly reduced in the group of patients with low CP concentration (log rank test p = 0.07, Figure 1). CP but not PNPLA3 genotype was an independent predictor of the time to transplantation or death in a Cox proportional hazards model including age, NaMELD and CP.



Number at risk

CP > 0.2 g/L:	541	414	283	223	168	118	98	73	52	38	31
CP ≤ 0.2 g/L:	72	47	30	23	15	12	9	5	5	5	4

Conclusion: Hypoceruloplasminemia is common in an unselected cohort of patients with liver cirrhosis with highest frequencies in Wilson disease followed by hemochromatosis and alcoholic or non-alcoholic liver cirrhosis. The negative association of CP with C-reactive protein and INR confirm its role as a marker of hepatic function and inflammation. CP is a NaMELD-independent predictor of survival indicating that ferroxidase activity is implicated in the progression of cirrhosis.

SAT-258

Development and predictive validity of the cirrhosis-associated ascites symptom scale: A cohort study of 103 patients

A. Riedel[1], N. Kimer[1], A.-S.H. Jensen[2], M. Israelsen[3], E. Dahl[4], L. Aamann[5], L.L. Gluud[4]. *[1]Copenhagen University Hospital Hvidovre, Gastro Unit, Medical Division, Hvidovre, Denmark; [2]University Hospital Zealand, Slagelse, Denmark; [3]Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark; [4]Copenhagen University Hospital Hvidovre, Hvidovre, Denmark; [5]Aarhus University Hospital, Department of Hepatology, Aarhus, Denmark*
Email: agnete.nordheim.riedel.03@regionh.dk

Background and Aims: Cirrhosis is associated with a detrimental effect on health-related quality of life (HRQL). The Chronic Liver Disease Questionnaire (CLDQ) is used to evaluate HRQL in patients with all stages of liver disease. CLDQ correlates with the severity of liver disease and is associated with active medical and psychiatric comorbidity. No studies have specifically evaluated the association between the severity of ascites related symptoms and HRQL. We therefore aimed to develop and evaluate the predictive ability of a scale specifically designed to assess symptoms associated with cirrhosis-related ascites. We subsequently undertook a multicenter cohort study to evaluate the association between our scale and a disease specific scale (CLDQ) as well as a generic HRQOL questionnaire.
Method: We initially undertook literature searches and a qualitative study, which included assessment by patients and health-care professionals in order to design a Cirrhosis- Associated Symptom (CAS) scale. The final scale included 14 items describing symptoms with a potential detrimental impact on HRQL (the higher the score, the worse the symptoms). Discriminatory validity was assessed in a validation cohort including patients with I) tense/severe, II) moderate/mild or III) no ascites (controls). Patients also completed CLDQ and the EQ-5D-5L questionnaire evaluating HRQL. The relation between scale scores was analysed using Spearman correlations.
Results: The final CAS scale included 14 items. Equivalent reliability was high (Chronbach's alpha 0.88). The validation cohort included 103 patients (72% men, mean age 62.4 years). The mean scores for each question in the CAS scale were higher for patients with severe/tense ascites than for mild/moderate ascites and controls. Compared with controls (mean = 9.9), the total CAS scale score was higher for severe/tense ascites (mean = 23.8) as well as moderate/mild ascites (mean = 18.6) ($p < 0.001$ both groups). We found a strong correlation between the total CAS and CLDQ score (rho = 0.82, p= < 0.001) and a moderate correlation between the CAS and the EQ-5D-5L score (0.67, p= < 0.001).
Conclusion: The CAS addresses relevant questions of symptom burden of ascites and correlates strongly with CLDQ score in patients with cirrhosis and ascites.

SAT-259

Clinical, paraclinical and MR-spectroscopy profile in cirrhotic and non-cirrhotic portal hypertension patients with minimal hepatic encephalopathy

B. Hermann[1], N. Weiss[1], M. Rudler[2], D. Galanaud[3], M. Mallet[2], C. Duvoux[4], A. Coilly[5], C. Francoz[6], A. Plessier[7], D. Thabut[2]. *[1]Groupe Hospitalier Pitié-Salpêtrière Charles Foix, Assistance Publique – Hôpitaux de Paris, Unité de réanimation neurologique, département de neurologie, Pôle des Maladies du Système Nerveux, Paris, France; [2]Groupe Hospitalier Pitié-Salpêtrière Charles Foix, Assistance Publique – Hôpitaux de Paris, Unité de soins intensifs d'hépatologie, service d'hépatogastroentérologie, Paris, France; [3]Groupe Hospitalier Pitié-Salpêtrière Charles Foix, Assistance Publique – Hôpitaux de Paris, Service de Neuroradiologie, Paris, France; [4]European Liver Transplant Registry, Paul Brousse Hospital, France; [5]Hôpital Paul Brousse, Centre Hépato-Biliaire, Villejuif, France; [6]Hopital Beaujon, Hépatologie, AP-HP, France; [7]Hôpital Beaujon, Service d'Hépatologie, Réanimation Hépatique et Transplantation, Clichy, France*
Email: bertrand.hermann@gmail.com

Background and Aims: Minimal hepatic encephalopathy (MHE) can be the result of either cirrhotic liver disease (CLD) or non-cirrhotic portal hypertension (NCPH). Whether the clinical and paraclinical profile of MHE is the same in these two conditions is unclear. We sought to compared the clinical, psychometric and paraclinical profile of MHE between CLD and NCPH.
Method: We conducted a retrospective study in a specific hepato-neurology out-patients consultation of a single tertiary university hospital in Paris, France. We included all the patients diagnosed as having MHE by the consensus of two experts and compared their clinical (complaints, neurological physical neurological examination), psychometric (Critical Flicker Frequency-CFF, Psychometric Hepatic Encephalopathy Score-PHES) and paraclinical (ammonemia, EEG and cerebral MRI with spectroscopy (MRS)) profile according to the underlying hepatopathy.
Results: Between February 2013 and April 2016, among the 56 patients referred to the consultation, 32 were diagnosed by the experts as having MHE. The underlying hepatopathy was a CLD in 22 patients (etiology: alcoholic 44%, NASH 9%, viral 19%, alcoholic and non-alcoholic steatohepatitis 24%, others 5%; median MELD of 11 [9–12]) and a NCPH in 10 patients (Budd-Chiari 40%, extra-hepatic portal hypertension 30%, idiopathic portal hypertension 10%, portal agenesia 10% and nodular regenerative hyperplasia 10%). Patients with CLD were older than patients with NCPH (median age 61 years [54–64] vs. 44 years [33–58], p = 0,018) and had less frequently a portosystemic shunt (either surgical or TIPS). No statistical differences were found in any of following variables between the two groups: patients' or family's complaints, neurological examination, CFF, PHES, ammonemia, EEG and MRI (T1 hyperintensity of the basal ganglia and MRS). Notably, no differences were found in the ammonemia levels (69 µmol/L [54–115] vs. 67 µmol/L [93–51], p = 0,56), the number of patients with ammonemia ≥ 50 µmol/L (with 14 patients (88%) vs. 7 (88%), p = 1,0), the MRS choline/creatine ratio (0,82 [0,78–0,85] vs. 0,86 [0,81–0,87], p = 0,18) nor the myoinositol/creatine ratio (0,58 [0,53–0,66], vs. 0,59 [0,58–0,64] p = 0,43) between CLD and NCPH respectively. During follow-up, six CLD patients developed at least one overt HE episode, but none in the NCPH group.

	CLD *n = 22*	NCPH *n = 10*	p
		MRI findings	
Basal ganglia T1 hypersignal	16 (80)	9 (100)	0,28
Typical HE profile on MRS	19 (95)	8 (100)	1,00

Glx/Cr	0,87 [0,82–1,01]	0,9 [0,86–1,05]	0,42
Cho/Cr	0,82 [0,78–0,85]	0,86 [0,81–0,87]	0,18
mIns/Cr	0,58 [0,53–0,66]	0,59 [0,58–0,64]	0,43

Conclusion: There seem to be no differences in the clinical, neuropsychological, and imaging profile of CLD and NCPH MHE.

SAT-260

Multimodal approach including MR-spectroscopy for the diagnosis of minimal hepatic encephalopathy

B. Hermann[1], N. Weiss[1], M. Rudler[2], D. Galanaud[3], M. Mallet[2], C. Duvoux[4], A. Coilly[5], C. Francoz[6], A. Plessier[6], D. Thabut[2]. *[1]Groupe Hospitalier Pitié-Salpêtrière Charles Foix, Assistance Publique – Hôpitaux de Paris, Unité de réanimation neurologique, département de neurologie, Pôle des Maladies du Système Nerveux, Paris, France; [2]Groupe Hospitalier Pitié-Salpêtrière Charles Foix, Assistance Publique – Hôpitaux de Paris, Unité de soins intensifs d'hépatologie, service*

Email: bertrand.hermann@gmail.com

Background and Aims: There is no gold-standard for the diagnosis of hepatic encephalopathy (HE) and especially in case of minimal HE (MHE) where the value of paraclinical examinations is debated. MR-spectroscopy has been proposed as a valuable diagnostic tool for the diagnosis of HE by showing increased glutamate/glutamine peak and decreased myoinositol and choline peaks. However, access to MRI is difficult and no real life experience has been reported. We studied the interest of a multimodal approach combining clinical, neuropsychological, biological and MR-spectroscopy in the diagnosis of MHE.
Method: We conducted a retrospective study in a single tertiary university hospital in Paris, France, where all out-patients referred to a specific hepato-neurology consultation dedicated to the diagnostic of MHE underwent a clinical examination, psychometric tests (Critical Flicker Frequency-CFF, Psychometric Hepatic Encephalopathy Score-PHES), ammonemia and cerebral MRI with spectroscopy (MRS). Patients were classified as having MHE or not by consensus between two experts.
Results: We included 56 patients between February 2013 and April 2016. Median age was 57 years [49–63]. Forty-four (79%) had a cirrhosis (alcoholic 35%, NASH 9%, viral 23%, alcoholic and non-alcoholic steatohepatitis 26%, other 7%) with a median MELD of 10 [7–12]. Twelve (21%) had non-cirrhotic portal hypertension (Budd-Chiari 33%, extra-hepatic portal hypertension 33%, idiopathic portal hypertension 16%, portal agenesia 9% and nodular regenerative hyperplasia 9%). According to the experts, 57% had an MHE, whereas 43% hadn't. Among the clinical informations, only the presence of a portosystemic shunt (TIPS or surgical) was associated with MHE. A venous ammonemia >50 μmol/l, MRI T1 hyperintensity of the basal ganglia and an MRS HE profile suggestive of HE were all statistically associated with the diagnosis of MHE ($p < 0{,}0001$). The best diagnostic performance was achieved by combining MRS with either MRI T1 hyperintensity (AUC = 0,93) or ammonemia (AUC = 0,91). Neither the CFF nor the PHES had good diagnostic performances in our setting.
Conclusion: A multimodal approach combining clinical data, ammonemia and cerebral MRI with MRS seems to have good accuracy for the diagnosis of MHE. Further prospective studies are mandatory.

SAT-261
Kinetics of polymorphonuclear count in ascitic fluid. Persistent spontaneous bacterial peritonitis

A. Amador[1,2,3], A. Cachero[1,3,4], E. Dueñas[1,2,3], F. Bas[1,2,3], L.C. De la Peña[1,2,3], S. Salord[1,2,3], C. Baliellas[1,2,3], J. Castellote[1,2,3]. *[1]IDIBELL; [2]Hospital Universitario de Bellvitge, Hepatology Unit; [3]Universidad de Barcelona; [4]Hospital Universitario de Bellvitge, Hepatology Unit, Hospitalet de Llobregat. Barcelona, Spain*
Email: aamadornavarrete@gmail.com

Background and Aims: the slow decrease of the polymorphonuclear count (PMN) in ascitic fluid is considered a sign of worse short-term prognosis in spontaneous bacterial peritonitis (SBP). The concept of persistent SBP is not well defined. The aims of our study are: 1. Study the relationship between the kinetics of PMN in ascitic fluid at 48h and the resolution of SBP at the 2nd and 5th day with the prognosis of the infection. 2. Systematically define the concept of persistent SBP.
Method: retrospective observational study of 293 episodes of spontaneous bacterial peritonitis diagnosed at universitary hospital between 2010 and 2017. Clinical, analytical, microbiological variables and the PMN delta have been collected at 48 h (PMN48) and resolution of SBP at 48 h and 5th day defined as ≤ 250 PMN/μL with negative culture. A univariate and multivariate analysis was performed to determine the predictive factors of mortality and resolution on the 5th day.
Results: 12.7% of the episodes showed an increase in PMN at 48 h over the baseline, and 20.4% of the episodes were not resolved at 5th day. In-hospital mortality was 17.4%. The AUC-ROC of the delta PMN48h was 0.598 for mortality (p 0.074) and 0.731 (p 0.000) for the resolution at the 5th day. In the multivariate analysis, the PMN increase at 48 h over the baseline (HR 10.91 [1.2–98.7]) and the absence of resolution at the 5th day (HR 4.84 [1.8–13.8]) were independent predictors of in-hospital mortality, as well as other classical parameters: SIRS at admission (HR 3.58 [1.22–10.5]), urea (HR 1.11 [1.03–1.17]), peripheral blood leukocytes (HR 1.07 [1.01–1.14]) and Child Pugh score (HR 2.02 [1.44–2.83]). Besides, SIRS (21.9 vs 34.2%, p 0.03), peritonism (19.2 vs 34.2%, p 0.024), MELD (20.5 ± 7.2 vs 23.2 ± 8.4, p 0.032) and hyponatremia (134.3 ± 5.8 vs 131.9 ± 6.6, p 0.01), proteins (11.5 ± 7.5 vs 15.6 ± 9.9, p 0.001) and LDH (1.3 ± 0.7 vs 2.7 ± 2.9, p 0.004) in ascitic fluid were associated with the absence of resolution at the 5th day, without differences in the culture of ascitic fluid, the gram negative origin, the resistance to cephalosporins or in the inadequate empirical treatment.
Conclusion: (1) The increase in PMN at 48h and the absence of resolution at the 5th day are independently associated with in-hospital mortality. (2) The paracentesis at 48h is justified given its prognostic value. (3) The absence of resolution the 5th day could be the best definition for persistent SBP.

SAT-262
Impact of an antimicrobial stewardship policy on the reduction of empirical antibiotic treatment failure and the spread of multidrug-resistant organisms in hospitalized cirrhotic patients

S. Incicco[1], V.D. Gregorio[1], C. Lucidi[1], B. Lattanzi[1], D. D'ambrosio[1], D. Tavano[1], S.D. Cola[1], G. Ceccarelli[2], M. Venditti[2], M. Merli[1]. *[1]Sapienza University of Rome, Department of Clinical Medicine, Rome, Italy; [2]Sapienza University of Rome, Department of Infectious Disease, Rome, Italy*
Email: simone.incicco@gmail.com

Background and Aims: Bacterial infections are among the most relevant complications of cirrhosis and are associated with poor outcomes. The application of antimicrobial stewardship (AMS) policies is the best strategy in the management of cirrhotic patients with infections, since they help to avoid inappropriate antibiotic use and development of multidrug-resistant organisms (MDRO). The aim of the study is to evaluate the effect of AMS on the empirical antibiotic treatment failure, the onset of infection-related complications and in-hospital mortality, and the spread of MDRO.
Method: This is an observational study performed in patients consecutively admitted to our department from 2009. The population was divided into two groups: the first (Group A) includes patients in which non-specific policies were adopted (until August 2014); the second (Group B) includes patients in which AMS policy was used. AMS policy consisted in addressing a dedicated infectious disease consultant.
Results: We enrolled 313 infected patients, 207 in Group A and 106 in Group B. The two groups were similar for demographic and severity of liver disease (Child Pugh score 8.6 ± 1.8 vs 8.9 ± 1.8). In both groups main sites of infection were urinary tract and pneumonia. The application of AMS resulted in a reduced use of fluoroquinolones (25% in Group A vs 10.4% in Group B, $p = 0.002$) and third-generation cephalosporins (25% in Group A vs 6.6% in Group B, $p < 0.001$) as empirical antibiotic treatment, and an increased use of Piperacillin-Tazobactam (17.4% in Group A vs 40.6% in Group B, $p < 0.001$). In group B: incidence of MDRO was reduced (59 vs 30.2%, $p < 0.001$), the rate of failure of empirical antibiotic treatment was decreased (44 vs 19%, $p < 0.001$), the prevalence of sepsis was lower (54 vs 24.5% $P < 0.001$), the infection-related mortality showed a trend of reduction (17.4 vs 8.5%). The multivariate analysis showed that the introduction of the

AMS policy was responsible for the reduced rate of empirical treatment failure (p = 0.005; OR 0.42; 95% CI 0.25–0.59).
Conclusion: Our results show that AMS policies, by optimizing the use of antimicrobial drugs, are able to reduce the rate of empirical antibiotic treatment failure. In our experience this strategy has been effective in reducing incidence of MDRO and sepsis in cirrhotic patients.

SAT-263
Outpatient terlipressin infusion increases dietary intake and functional muscle strength in patients awaiting liver transplant
B. Chapman[1], P. Gow[2], P. Angus[2], M. Sinclair[2], A. Testro[2]. [1]*Austin Health, Nutrition and Dietetics, Heidelberg, Australia;* [2]*Austin Health, Liver Transplant Unit, Heidelberg, Australia*
Email: Brooke.chapman@austin.org.au

Background and Aims: Portal hypertension has multiple negative effects on gastrointestinal function, including the development of ascites, reduced gastric reserve, slowed intestinal transit and malabsorption; thereby contributing to malnutrition and sarcopenia. Our centre offers outpatient continuous terlipressin infusion as a bridge to transplantation to patients with hepatorenal syndrome or refractory ascites. We describe for the first time the effect of terlipressin on nutritional and functional muscle parameters in this novel cohort.
Method: Nutritional (subjective global assessment) and functional muscle assessment (handgrip strength), dietary intake (energy and protein), volume and frequency of paracentesis, severity of liver disease (MELD, MELD-Na) and complications of therapy were prospectively recorded at commencement of terlipressin and again at follow up (transplantation, cessation of therapy or census date). Terlipressin non-responders and infusion duration <2 weeks were excluded.
Results: Thirteen of 19 patients treated with terlipressin (100% male, mean age 58 years, hepatorenal syndrome n = 9, ascites n = 4) met inclusion criteria. All patients were malnourished at commencement of therapy, 70% (n = 9) had poor muscle strength (grip strength <30 kg), and 70% required weekly large-volume paracentesis (>5 L). Median duration of treatment was 74 days (range 24–376). Terlipressin therapy resulted in a significant improvement in multiple biochemical, functional and nutritional parameters. Improvement in MELD was primarily driven by reduction in creatinine (Table 1). Paracentesis volume and frequency reduced by >50% in all patients. Seven patients (53%) were transplanted, 2 were delisted and 4 continue on terlipressin. There have been no clinical complications attributed directly to terlipressin therapy.

Table 1: Change in outcome measures following terlipressin

Parameter Median (range)	Pre-Terlipressin	Post-Terlipressin	p value
MELD	23 (14–34)	16 (12–26)	0.001
MELD-Na	26 (18–36)	19 (15–24)	<0.001
Creatinine, umol/L	176.5 (99–300)	123 (50–127)	<0.001
INR	1.5 (1.2–2.8)	1.6 (1.1–2.8)	0.611
Bilirubin, umol/L	28 (18–293)	26 (13–146)	0.109
Handgrip strength, kg	24.5 (12–39)	29.5 (16–40)	0.001
% energy requirements met	56 (25–75)	86 (60–100)	<0.001
% protein requirements met	60 (35–90)	89 (50–100)	<0.001

Conclusion: Continuous terlipressin infusion significantly improves both nutritional and functional muscle parameters in cirrhotic patients on the liver transplant waitlist, in whom such parameters usually demonstrate a progressive decline. Through sustained reduction in portal hypertension, we postulate that continuous terlipressin infusion reduces ascites and its associated protein losses; increases calorie and protein intake by improving gastric reserve; and may improve enteral absorption, with subsequent net gain of muscle strength.

SAT-264
Dynamic Visual Processing in Patients with Decompensated Cirrhosis
K. Wong[1], D. Liston[2], S. Papademetriou[2], A. Yeoh[3], A. Goel[1], P. Kwo[1], P. Okafor[1]. [1]*Stanford University School of Medicine, Medicine, Division of Gastroenterology and Hepatology, Stanford, CA, United States;* [2]*NeuroFit, Inc, Mountain View, CA, United States;* [3]*Stanford University School of Medicine, Medicine, Stanford, CA, United States*
Email: katherinew1@gmail.com

Background and Aims: Patients with decompensated cirrhosis are at increased risk of overt and covert hepatic encephalopathy (HE), falls, and motor vehicular accidents (MVA). Visual processing can reveal changes in cognitive function and remains understudied in cirrhosis. We hypothesize that decompensated cirrhotics have impairment in visual processing that negatively impacts aforementioned outcomes.
Methods: We utilized a validated, non-invasive, oculometric assessment tool to prospectively study adult patients with cirrhosis in the Stanford University liver clinic after informed consent. We excluded patients who had undergone liver transplantation. Baseline demographic and oculometric data were obtained. Oculomotor metrics included latency, acceleration, gain, proportion smooth pursuit, saccadic amplitude, direction noise, speed tuning responsiveness and noise. A composite visual processing score (nFit) was also generated. Results were compared to a historical control group of noncirrhotics.
Results: Results of the first 18 decompensated cirrhotic patients enrolled are presented. Median age was 59 (range 39–71) years and median BMI was 29.4 (range 25–42). Seventy-two percent of the cohort were male. Most common aetiologies for cirrhosis were hepatitis C (28%), NASH (28%), and alcohol (22%). The most common forms of decompensation were ascites (78%) and hepatic encephalopathy (78%). Seventy-eight percent of patients were on lactulose, 67% on rifaximin, 78% on diuretics, 33% on nonselective beta blockers, 22% on statins, and 22% were on antidepressants. No patient had been in a MVA while driving in the past year, but 6 (33%) patients had experienced falls. Median MELD-Na was 14, while median Child-Pugh score was 7. Median nFit z-score (compared to historical controls) was −2.9. Median z-scores for other domains were: latency (−1.8), acceleration (−1.4), saccadic amplitude (−0.99), gain (−2.3), proportion smooth pursuit (−2.4), direction noise (−5.5), speed tuning responsiveness (−3.3), and speed tuning noise (−1.3).
Conclusion: Compared to non-cirrhotics, patients with decompensated cirrhosis score lower for all domains of visual processing, most pronounced in the proportion of smooth tracking, speed tuning responsiveness, and direction noise. Further studies are needed to assess the utility of oculometric testing as a screening tool for HE, falls, and MVA in patients with advanced liver disease.

SAT-265
The physical component of the SF-36 Quality of Life tool is an independent predictor of mortality in patients with severe ascites
S. Macdonald[1], P. Jepsen[2,3], H. Watson[4], H. Vilstrup[2], R. Jalan[1]. [1]*University College London, Liver Failure Group, Institute for Liver and Digestive Health, London, United Kingdom;* [2]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark;* [3]*Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark;* [4]*Sanofi-Aventis R&D, Infectious Diseases Unit, Marcy l'Etoile, France*
Email: stewart.macdonald@ucl.ac.uk

Background and Aims: Severe ascites in cirrhosis is associated with increased mortality rates, which is not captured by conventional prognostic markers. These patients have a poor Health-related Quality of Life (HRQL), which has also been shown to be an independent predictor of mortality in a number of medical conditions. The aim of this study was to determine the prognostic value of HRQL in defining the outcome of patients with severe ascites.

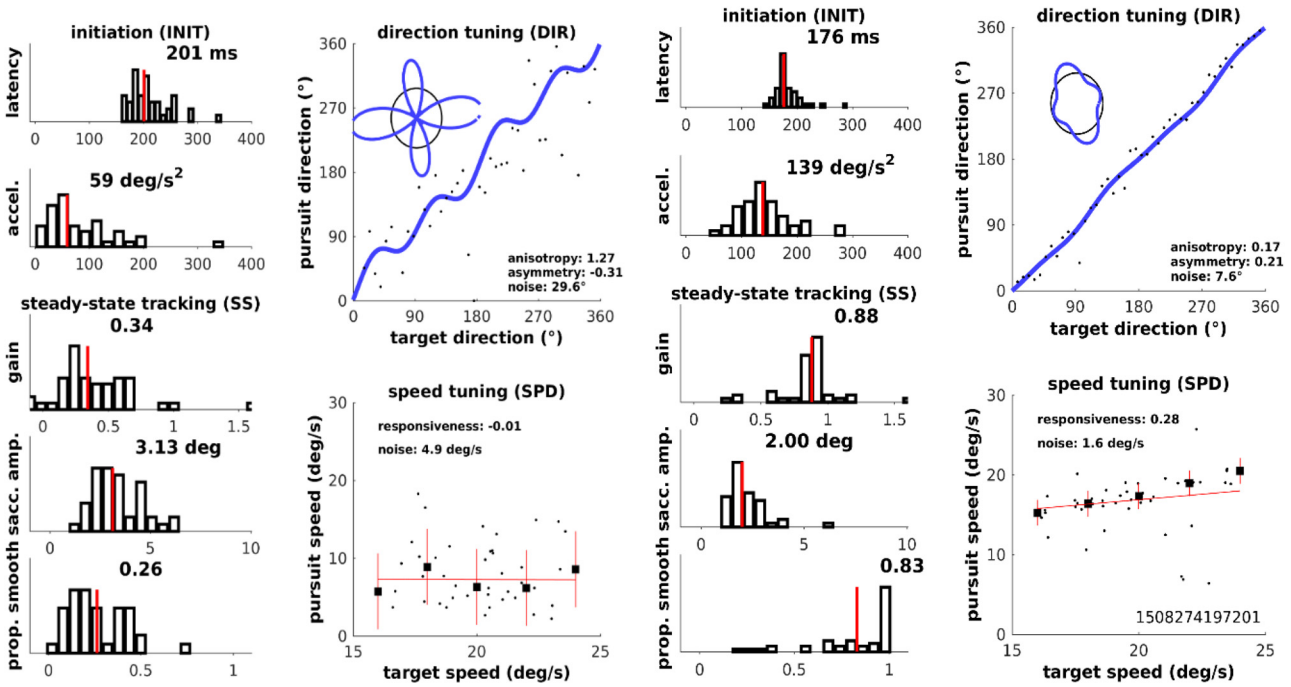

Figure: (abstract: SAT-264): Visual Processing Impairments in Decompensated Cirrhosis. A representative decompensated cirrhotic patient (left) shows sluggish and disorderly visual tracking as compared to a representative control subject (right).

Methods: 405 patients, as part of a randomised controlled trial testing the efficacy of satavaptan in ascites, were included. All patients had either difficult-to-treat ascites (2 paracentesis in 3 months prior to enrolment, n = 164) or refractory ascites (n = 241). Patients completed the SF-36 HRQL tool [a combination of physical component score (PCS) and mental component score (MCS) sub-scores] in addition to standard biochemical tests and were followed up for 52-weeks. Data were analysed to determine the role of factors associated with mortality.

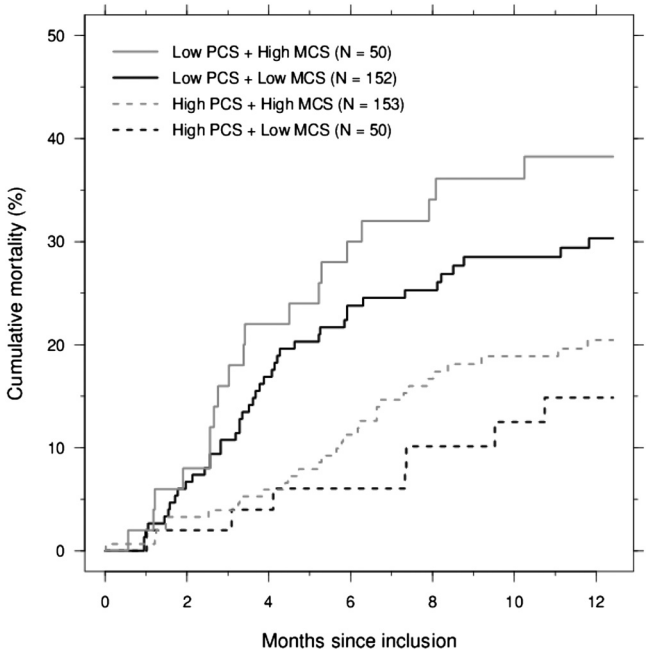

Figure 1: Cumulative all-cause mortality for all patients defined by below- or above-median physical component score (PCS) and mental component score (MCS). A high PCS or MCS indicates better quality of life, as measured by the SF-36 tool.

Results: The two ascites groups were combined for analysis as no significant difference in rate of liver-related complications or mortality was observed. Satavaptan therapy had no effect on clinical outcomes, PCS or MCS. MCS and PCS correlated with each other (0.68) but not with any other variables. 99 deaths occurred during follow up. Death was associated with markers of impaired hepatic function but also a poorer (lower) overall PCS [median (IQR) died: 34 (24–49), survived: 41 (29–53) p = 0.01]. This was not seen with MCS, and in several domains of the MCS higher scores were associated with increased mortality. A 10-point increase in PCS score was associated with a reduction in the Hazard ratio (0.87 95% CI 0.78 to 0.97), which remained statistically significant after adjustment for confounders (0.83 95% CI 0.72–0.97) and when mortality was restricted to only cirrhosis-related deaths (0.84 95% CI 0.71 to 0.99). PCS was highly significant when modeling cumulative risk of death over the study period (Figure 1).

Conclusion: The data demonstrated that patients with difficult to treat ascites had the same risk of death as those with refractory ascites and therefore this should be recognised in the management of their condition. The data also showed for the first time that in cirrhotic patients with severe ascites the PCS component of the SF-36 tool is predictive of mortality and this risk is independent of the traditional prognostic markers and scores.

SAT-266

Clinical frailty scale as a novel tool predicts unplanned hospitalisation and/or death in outpatients with cirrhosis

A.P. Singh, K. Devadas, K. Sandesh, G. Kapur. *Government Medical college, Medical gastroenterology, Thiruvananthapuram, India*
Email: doc.aniruddha85@gmail.com

Background and Aims: Hospitalizations in patients are the major cause of morbidity and healthcare expenditure in patients with cirrhosis. Predictive factors determining which outpatients with cirrhosis are at highest risk for unplanned admissions are lacking. We aimed to study factors predicting unplanned hospitalization or death at 3 months and study utility of Clinical Frailty scale in outpatients with cirrhosis.

Method: Prospective study with all the assessment carried out on the same day with study population comprising consecutive outpatients with cirrhosis in a single Tertiary care centre. Patients with active malignancy, ESRD and any condition requiring immediate admission were excluded. Frailty was defined as Clinical frailty scale (CFS) >4. Unplanned hospitalization was defined as any admission to acute care hospital that was not planned. Data on socioeconomic status, MELD, CHILD score, Burden of total comorbidity using Charlson comorbidity index were recorded. The outcome was defined as unplanned hospitalization or/and death at 1 and 3 months from study entry. Variables found to be significant with P < 0.05 on univariate analysis were used for Binary backward logistic regression.
Results: Overall 124 patients included, 52(41.9%) were frail, Etiology was predominantly alcohol 63/124 (51%) followed by HBV 30/124 (24%) then NASH 12/124(16.7%) related cirrhosis. Mean MELD was 20 and CTP score was 10.6 in frail patients.CFS mean value was 5.2 with CRP mean of 3.2 mg/dl in frail outpatients. 26/52 (50%) of frail patients as compared to 2/72 (2.8%) non-frail patients had unplanned hospitalization at 1 month whereas 44/52(84.6%) as compared to 11/72(15.3%) had unplanned hospitalization at 3 months. 9/52 (17.3%) frail patients died in comparison to only 1/72(1.46%) in the non-Frail group at 3 months. On Univariate regression analysis variables found to have p values <0.05 were considered for Multivariate cox regression analysis. Multivariate Binary logistic regression (Backward LR) patients taking B- blocker more than 20 mg with P < 0.07, OR 7.16(CI 1.73–29.6), Frail patients with CFS > 4 P < 0.01, OR:5.38(CI: 1.3–21.6), Presence of AKI with P < 0.006, OR:17.24 (CI:2.2–133.7), CRP >2 mg/dl with P < 0.001, OR:11.23 (CI:2.6–47) were found to independently predict unplanned admission at 1 month and unplanned admission/death at 3 months. We also observed that CRP with a cut-off of 2 mg/dl with sensitivity of 77.5% and specificity of 92.42% with AUC of 0.88 predicted unplanned hospitalization/death at 3 months.

Variable		Frail				Total		P
		Yes (N=52)		No (N=72)				
		N	%	N	%	N	%	
Admission at 1 month	Yes	26	50.0	2	2.8	28	22.6	<0.001
	No	26	50.0	70	97.2	96	77.4	
Admission at 3 month	Yes	44	84.6	11	15.3	55	44.4	<0.001
	No	8	15.4	61	84.7	69	55.6	
Death	Yes	9	17.3	1	1.4	10	8.1	.001
	No	43	82.7	71	98.6	114	91.9	

Multivariate Logistic Regression (Backward LR) for prediction of hospitalization/death at 3 months.

Variables	p-value	OR	CI
B-Blockers (>20 mg)	0.07	7.16	1.73-29.67
CFS > 4	0.01	5.38	1.3-21.6
AKI	0.006	17.24	2.2-133.7
CRP	0.001	11.23	2.6-47
Hosmer Lemeshow goodness-of-Fit test, X^2 (P-value)			9.32(0.15)

Conclusion: Clinical frailty scale as rapid 1-minute screen and Serum CRP with a cut-off 2 mg/dl predicts unplanned hospitalization and/or death at 3 months and can be utilized in outpatients with cirrhosis for stratifying patients at risk of adverse outcomes.

SAT-267

Relationship between visceral fat and portal vein thrombosis in patients with liver cirrhosis

M.H. Conde[1,2], E. Llop[1,3], M. López-Gómez[1], C. Perelló[1], C. Fernández-Carrillo[1], J.A. Guerra[1], J.L.M. Porras[1], N.F. Puga[1], M. Magaz[1], J.L.C. Panero[1]. *[1]Hospital Universitario Puerta de Hierro Majadahonda, Spain; [2]Co-autors; [3]co-autors*
Email: marta.hernandez.conde@gmail.com

Background and Aims: It has been shown that an increased waist circumference (WC) is important in the association between obesity and venous thrombosis. Therefore, central obesity, due to the accumulation of visceral fat (VF), is one of the main risk factors for the development of venous thrombosis. In addition, it has been shown that it could be the first risk factor for the development of non-cirrhotic portal vein thrombosis (PVT). The aim of this study was to determine if WC and VF could be risk factors in the development of PVT in patients with liver cirrhosis (LC).

Method: Between 2016 and 2017, outpatients with LC were prospectively included. Patients with active alcohol consumption, active viral hepatitis and those with hepatocellular carcinoma outside the Milan Criteria were excluded. All patients underwent a complete anthropometric evaluation, blood tests and bioimpedence (BIA) (TANITA DC430PMA).
Results: One hundred seventy-five patients were included (men 70.3%, mean age 63 years (SD 9.9)). The most frequent etiology was HCV (49.7%), followed by alcohol (32%). Child-Pugh classification A/B/C 75.3%/18.4%/6.3% and median MELD score 10.3 (SD 3.5). Eighty patients (45.7%) had prior liver decompensation and 62 patients (35.4%) had large esophageal varices. The mean spleen diameter measured by abdominal ultrasound was 135.2 mm (SD 30.9). The mean body mass index (BMI) was 28.7 Kg/m^2 (SD 4.5). 21.3% of the patients were normal weight, 37.9% were overweight and 40.8% were obese. The mean WC was 103.6 mm (SD 13.4), with an increase in WC (≥102 mm in men and ≥88 mm in women) in 119 patients (68%).
Fourteen patients (8%) had PVT at the time of inclusion. PVT was more frequent in patients with prior liver decompensation (78.6 vs. 21.4%, p = 0.01) and with large esophageal varices (64.3 vs. 35.7%, p = 0.02). WC and VF were higher in patients with PVT (113.6 vs. 102.9 mm, p = 0.01 and 17.4 vs. 14.3, p = 0.01). PVT was more frequent in patients with an increased WC (92.9% vs. 7.1%, p = 0.04). Patients with PVT also presented a larger diameter of the spleen (153.2 vs. 133.9 mm, p = 0.005).
In the multivariate analysis, the parameters associated with PVT in patients with LC were: the presence of prior liver decompensation (OR 6, 95%CI 1.22–29.1, p = 0.03), VF (OR 1.2, 95%CI 1.02–1.35, p = 0.02) and the presence of large esophageal varices (OR 3.8, 95%CI 1.03–13.77, p = 0.04).
Conclusion: VF has been independently associated with the presence of PVT in patients with LC. In our study, other previously proven factors such as previous liver decompensation and the presence of esophageal varices were confirmed.

SAT-268

Terlipressin for variceal bleeding induces severe plasma sodium disturbances in non-cirrhotic portal hypertension

P.L. Eriksen, A.L. Hartkopf-Mikkelsen, P. Ott, H. Vilstrup, N.K. Aagaard. *Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark*
Email: ple@clin.au.dk

Background and Aims: Variceal bleeding is a severe complication of portal hypertension in patients with cirrhosis of the liver. While treatment with terlipressin is highly efficient, one side effect is a reduction of plasma sodium, which is usually not severe. In patients with variceal bleeding due to non-cirrhotic portal hypertension, terlipressin may also be used. Casuistic observations and theoretical considerations suggested that the latter patient group could be at special risk of terlipressin induced sodium disturbances. That question was studied in a retrospective cohort study.
Method: During a 39-month period, 134 patients with liver cirrhosis and 11 patients with non-cirrhotic prehepatic portal hypertension were treated for variceal bleeding and received a minimum cumulative terlipressin dose of 4 mg during at least 24 hours. Plasma sodium changes were compared between the groups.
Results: As compared to patients with cirrhosis, those with prehepatic portal hypertension displayed a greater reduction in plasma sodium [mean 8.3 mmol/l (95% confidence interval: 1.9–14.6) vs. 1.8 mmol/l (1.0–2.7); p = 0.048], a lower nadir plasma sodium during terlipressin treatment [129 mmol/l (123–135) vs. 133 mmol/l (132–134), p = 0.06], and a greater increase in plasma sodium within 48 hours after discontinuation of terlipressin [12.6 mmol/l (3.4–21.7) vs. 2.3 mmol/l (1.5–3.0); p = 0.03].

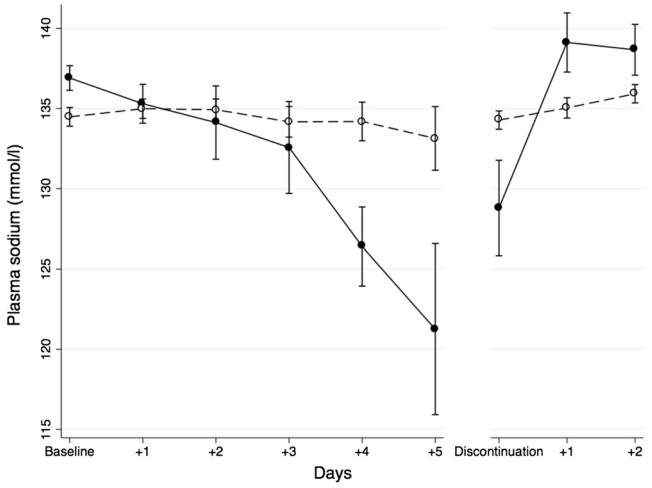

Figure: Plasma sodium profile during and after terlipressin treatment (mean ± SEM). •: Pre-hepatic portal hypertension ○: Cirrhotic portal hypertension

Conclusion: Patients with non-cirrhotic prehepatic portal hypertension constitute a group at particular risk of severe hyponatremia during terlipressin treatment for variceal bleeding, and of rapid normalisation of plasma sodium upon discontinuation. Special caution is warranted if terlipressin is used in these patients.

SAT-269

Outcome after the use of SX-ELLA Danis bleeding stents for refractory variceal bleeding- a Vienna Multicenter Experience

N. Pfisterer[1,2], W. Dolak[2], T. Pachofszky[1], M. Schoniger-Hekele[2], B. Schuster[1], B. Tribl[2], M. Mandorfer[2], L. Unger[2], F. Riedl[2], P. Schwabl[2], T. Bucsics[2], K. König[3], L. Kramer[3], M. Gschwantler[4], C. Madl[1], M. Trauner[2], T. Reiberger[2]. [1]*Krankenanstalt Rudolfstiftung, IV Medical Department of Gastroenterology and Hepatology;* [2]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III;* [3]*Krankenhaus Hietzing, I. Department of Gastroenterology;* [4]*Wilhelminenspital, IV Medical Department of Gastroenterology and Hepatology*
Email: nikolauspfisterer@hotmail.com

Background and Aims: Current guidelines favor the use of bleeding stents over balloon tamponade for refractory esophageal variceal bleeding (EVB). However, data on the efficacy of and outcomes after the placement of an SX-ELLA "Danis-stent" are limited.
Method: Retrospective multicenter study including cirrhotic patients receiving Danis-stents for massive/refractory EVB at 4 specialized bleeding/endoscopy units in Vienna. Rates of bleeding control (5 days), bleeding-related mortality (6 weeks) and overall mortality were assessed.
Results: Among 34 patients, 12 patients had an unsuccessful endoscopic band ligation (EBL) prior to Danis-stent placement. Danis-stent controlled EVB in 79.4% (27/34) of patients. In the remaining uncontrolled bleeders (n = 7), 3 patients had subsequent EBL, while in 3 patients the stent had to be replaced and 1 patient received a Linton-tube. Among these patients with initial Danis-stent failure, 3 died of uncontrollable EVB, 3 experienced early bleeding-related mortality, and only 1 patient achieved a successful long-term bleeding control.

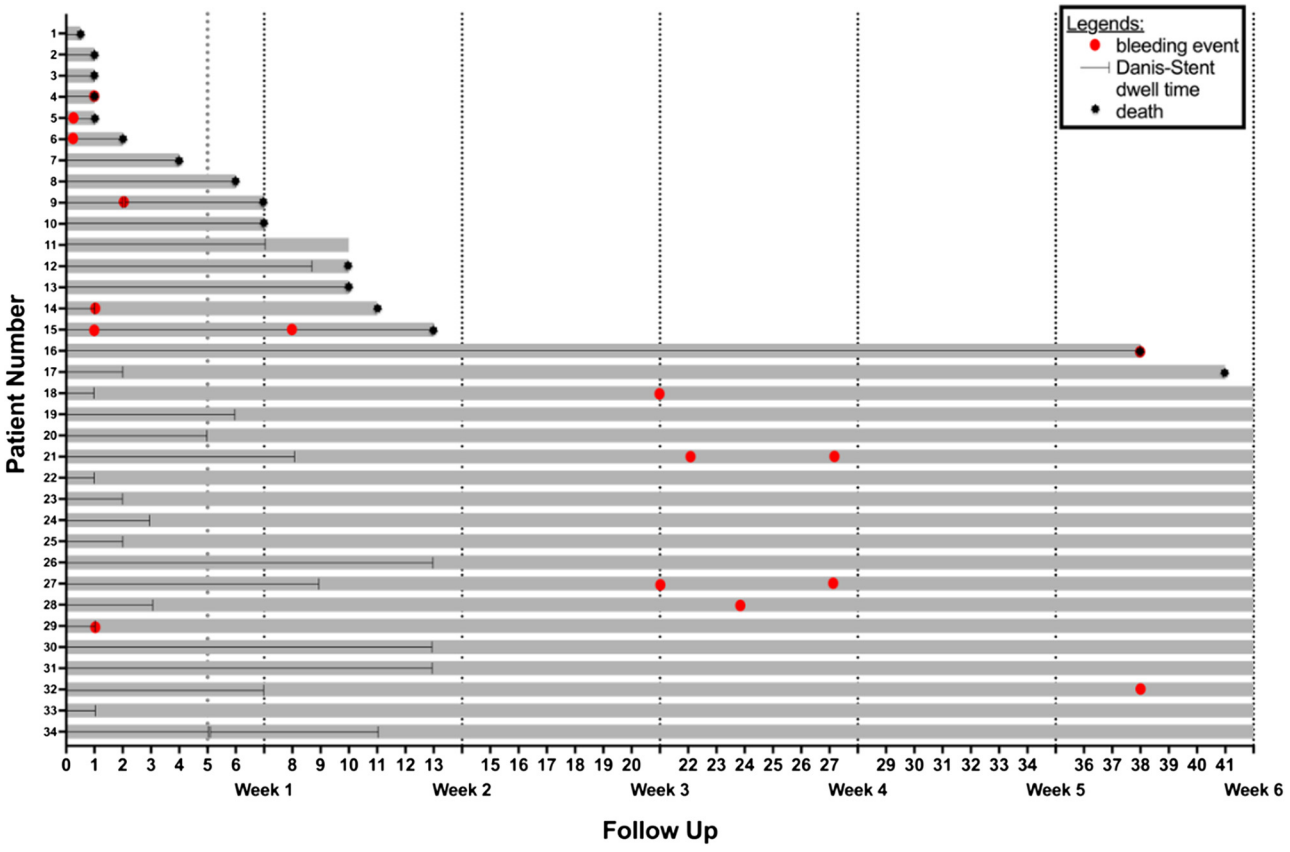

Figure: (abstract: SAT-269)

In total, early-rebleeding within 6 weeks occurred in n = 5 (14.7%): 3 underwent EBL, 1 received a subsequent Danis-stent, and 1 patient was treated with a Sengstaken tube.
Moreover, among n = 22 patients without early rebleeding within 6 weeks, only n = 3 (8.8%) showed rebleeding later during follow-up: n = 2 patients were treated with a Sengstaken-tube (both experienced bleeding-related death) and n = 1 had another Danis-stent placed (successful bleeding control).
Only n = 11 (32.4%) patients did not experience any rebleeding after Danis-stent removal, while n = 13 patients died with the Danis-stent in situ. Notably, no "early-TIPS" was performed in this study, but 4 (11.8%) received an elective TIPS during follow-up. Ultimately, n = 7 patients (20.6%) died due to uncontrolled bleeding (≤5days) and n = 9 died within 6 weeks (bleeding-related mortality: 26.5%). Overall, n = 22/35 (64.7%) patients died. The median survival was 62 (IQR538.5) days after Danis-stent placement.
Median Danis-stents dwell time was 5 (range: 0.5–38) days. The most common adverse events were stent dislocations (n = 13; 38.2%), while ulcers/necrosis of the esophageal mucosa were seen in only 4 (11.8%) patients.
Conclusion: Danis-stent controlled refractory/massive EVB in 79.4% of patients but bleeding-related mortality was still as high as 47.1%. While stent dislocations were frequent, esophageal ulcers/necrosis were rare with a median stent dwell time of 5 days. The implementation of an early-TIPS strategy might improve the overall outcome after Danis-stent placement.

SAT-270

The beneficial effects of non-selective betabockers in secondary prophylaxis are most pronounced in patients without refractory ascites

N. Pfisterer[1,2], C. Dexheimer[2], E.-M. Fuchs[1], T. Bucsics[2], M. Mandorfer[2], P. Schwabl[2], I. Gessl[2], L. Sandrieser[2], L. Baumann[2], F. Riedl[2], B. Scheiner[2], T. Pachofszky[1], W. Dolak[2], C. Schrutka-Kölbl[1], A. Ferlitsch[2], M. Schoniger-Hekele[2], M. Peck-Radosavljevic[3], M. Trauner[2], C. Madl[1], T. Reiberger[2]. *[1]Krankenanstalt Rudolfstiftung, IV Department of Gastroenterology and Hepatology; [2]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III; [3]Klinikum Klagenfurt am Wörthersee, Dept. of Gastroenterology/Hepatology, Endocrinology and Nephrology*
Email: nikolauspfisterer@hotmail.com

Background and Aims: Endoscopic band ligation (EBL) is used for primary (PP) and secondary prophylaxis (SP) of variceal bleeding. For SP, current guidelines recommend combined use of non-selective beta-blockers (NSBBs) and EBL for SP, while either NSBB or EBL should be used in PP.
Method: (Re-)bleeding rates and mortality were retrospectively assessed with and without concomitant NSBB therapy after first EBL in PP and SP.
Results: 766 patients with esophageal varices underwent EBL from 01/2005–06/2015. In PP, among 284 patients undergoing EBL, n = 101 (35.6%) received EBL only, while n = 180 (63.4%) received EBL + NSBBs. In 482 patients on SP, n = 163 (33.8%) received EBL only, while n = 299 (62%) received EBL + NSBBs.
In PP, concomitant NSBB therapy neither had an impact on bleeding rates (log-rank p = 0.353) nor on mortality (log-rank p = 0.497) as compared to EBL alone.
Patients in SP with EBL + NSBB showed similar rebleeding rates as compared EBL alone (log-rank p = 0.247). However, in SP, a

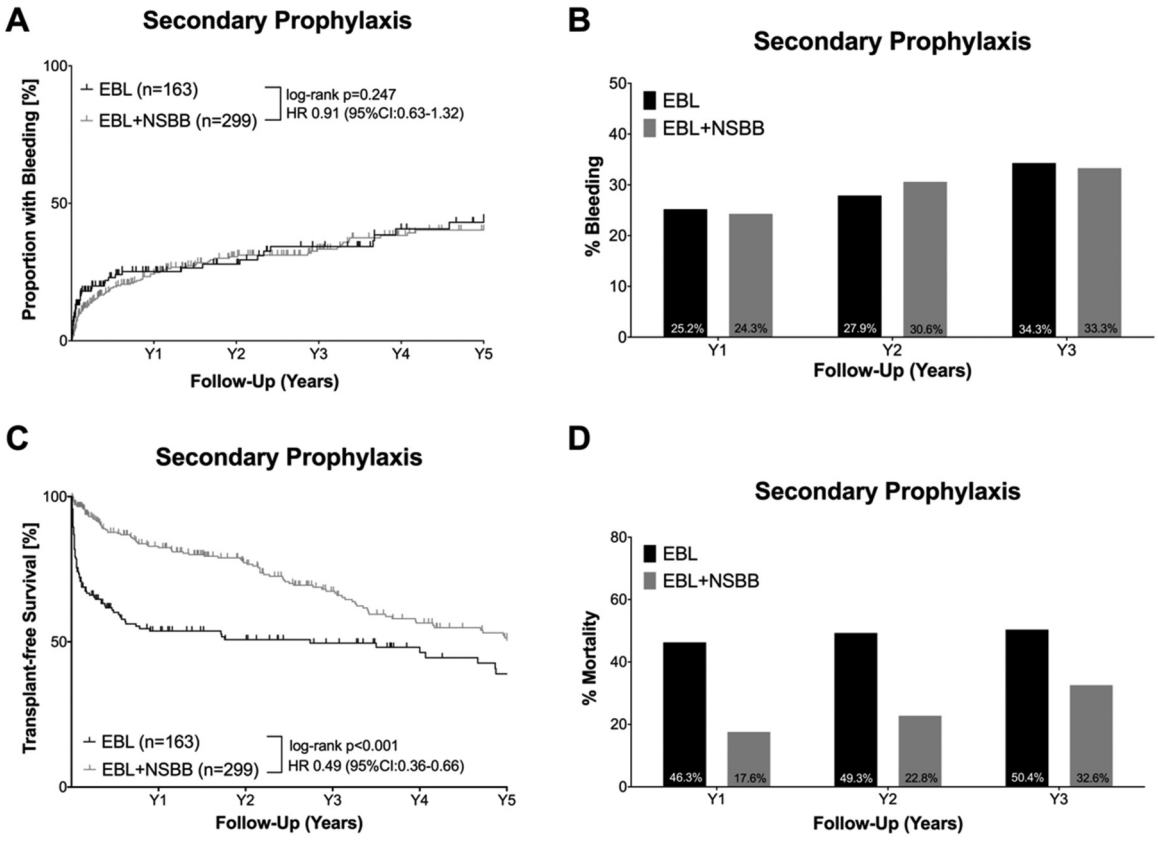

Figure: (abstract: SAT-270)

concomitant NSBB therapy resulted in a significantly lower mortality rate (log-rank $p < 0.001$) with fewer deaths related to liver failure, bleeding, and infections with EBL + NSBB combination therapy. A decreased risk of death with EBL + NSBB in SP (hazard ratio, HR:0.50; $p < 0.001$) but not of rebleeding, transplantation or further decompensation was confirmed by competing risk analysis. Interestingly, in SP, NSBB intake reduced 6-months mortality (HR:0.53, $p = 0.008$) in patients without severe/refractory ascites (HR:0.37; $p = 0.001$) only but this effect was not seen in patients with severe/refractory ascites (HR:0.80; $p = 0.567$).
Conclusion: EBL alone seemed to be sufficient for PP of variceal bleeding. In SP, concomitant NSBB to EBL improves survival within the first 6 months after EBL, as compared to EBL alone. In patients with severe/refractory ascites these beneficial effects of NSBB therapy have to be weighted against their potential side-effects.

SAT-271

The post-living donor liver transplantation survival-defining factor high tricuspid regurgitation pressure gradient in liver cirrhosis correlates with the diastolic heart failure and a high oxidative stress status

A. Takaki[1], T. Yasunaka[1], H. Okada[1]. [1]*Okayama University, Gastroenterology and Hepatology, Okayama, Japan*
Email: akitaka@md.okayama-u.ac.jp

Background and Aims: We previously reported that mild liver congestion as defined by a high tricuspid regurgitation pressure gradient (TRPG) measured by transthoracic echocardiography (TTE) is the survival-defining factor after living donor liver transplantation (LDLT), although such a condition is widely accepted as not critical after deceased donor OLT (DDLT). Given that left or right lobe LDLT grafts are smaller than DDLT grafts, even mild hepatic vein pressure might result in a strong congestive impact on the LDLT grafted liver. Although the mean pulmonary artery pressure (mPAP) is the standard method for diagnosing pulmonary hypertension and congestive pressure to the liver, TRPG but not mPAP was the survival-defining factor in our previous analysis. To determine the difference between a high mPAP and high TRPG status, we compared the clinical characteristics of these two conditions.
Method: The clinical characteristics and course post-LDLT of patients were investigated according to high mPAP and high-TRPG status. We recruited 84 LDLT candidates with liver cirrhosis. Patients exhibiting a TRPG $\geq$ 25 mmHg (median) on TTE were categorized as potentially having high TRPG (subclinical high-TRPG; n = 34). Patients exhibiting a high mPAP (>25 mmHg) measured after general anesthesia with $FIO_2$0.6 (mPAP-$FIO_2$0.6) were categorized as potentially having pulmonary hypertension (PH) (subclinical PH; n = 19). As oxidative stress is known to be correlated with the vascular function, the oxidative stress marker and anti-oxidative marker were also investigated.
Results: A subclinical high TRPG ($p = 0.012$) and older donor age ($p = 0.008$) were correlated with a poor 40-month survival. Subclinical high-TRPG but not subclinical PH was associated with a high E/e', indicating diastolic heart failure that could lead to heart failure with preserved ejection fraction. Levels of the oxidative stress-related marker dROM were not markedly different between the two conditions, but those of the anti-oxidative marker OXY were lower in the subclinical high-TRPG group. The staining pattern of the oxidative stress-related marker 4-HNE in the excised liver showed a larger stained area in the subclinical high-TRPG group but not in the subclinical PH group.
Conclusion: The post-LDLT survival-defining factor high TRPG was associated with a diastolic heart failure tendency and high oxidative stress status that should be controlled.

SAT-272

Hemodynamic disturbances across different stages of decompensated cirrhosis and influencie on outcomes

M.G. Guix[1], E. Alvarado[1], A. Ardevol[1], R. Montañés[1], B. Cuyas[1], M. Poca[1], X. Torras[1], C. Guarner[1], C. Aracil[2], C. Villanueva[1]. [1]*Hospital Santa Creu i Sant Pau, Spain;* [2]*Hospital Arnau de Vilanova, Spain*
Email: martagguix89@gmail.com

Background and Aims: Different stages can be identified in decompensated cirrhosis, such as bleeding without any other decompensation, ascites without bleeding or bleeding with other concomitant decompensation. Whether hemodynamic derangements change across these stages has not been clarified despite the potential clinical implications. This study aimed to assess systemic and hepatic hemodynamic changes across the different stages of decompensated cirrhosis
Methods: From January 2007 patients consecutively admitted due to variceal bleeding were included. All received secondary prophylaxis with non-selective β-blockers (NSBB) plus EVL. A baseline hemodynamic study was performed before starting therapy. Hemodynamic data were compared in patients with bleeding alone (BlAl) vs those with other decompensation in addition to bleeding (BlPlus). Mean arterial pressure (MAP), hearth rate (HR), cardiac output (CO), systemic vascular resistance (SvR) and HVPG were measured. Patients with ascites and varices without previous bleeding (AsAl) referred during the study period for primary prophylaxis, were also investigated to assess differences with the previous bleeding groups.
Results: 231 patients with variceal bleeding were included, 70 without any other decompensation. Patients with BlAl had better baseline liver function than those with BlPlus. Patients with BlAl had, as compared with those with BlPlus, lower risk of developing further decompensation of cirrhosis during follow-up and better survival (90% *vs.* 55% at 3 years, $p < 0.001$ by log-rank). Patients with BlAl were less hyperdynamic than those with BlPlus as indicated by a lower CO (7.2 ± 2.3 *vs.* 8.0 ± 2.6 L/min, $p = 0.05$) and higher SvR (990 ± 368 *vs.* 872 ± 309, $P = 0.01$), had lower HR (84 ± 16 vs 89 ± 15, $p = 0.04$) and lower HVPG (17.6 ± 4 vs 21.0 ± 4 mmHg, $P < 0.001$). MAP, CO and SvR were similar between patients BlAl and the cohort with AsAl, while HVPG was lower in those with BlAl (17.6 ± 4 *vs.* 19.4 ± 5, $p = 0.03$). Survival probability was better in patients with BlAl vs those with AsAl (90% *vs.* 73% at 3 y, $p = 0.3$). Patients with BlPlus had lower MAP ($p = 0.03$) and SvR ($p = 0.09$) than those with AsAl and had slightly higher CO ($p = 0.154$) and higher HVPG (21.1 ± 5 *vs.* 19.4 ± 5, $p = 0.01$). Survival was better in patients with AsAl than in those with BlPlus (73% *vs.* 55% at 3 y, $p < 0.001$).
Conclusion: Hyperdynamic circulation, portal pressure and survival are worse in patients with other decompensation in addition to bleeding than in those with bleeding alone. Patients with ascites alone have an intermediate situation

SAT-273

Prevalence and clinic impact of rectal colonization by multidrug-resistant bacteria in descompensated cirrhosis

M. Hernandez-Tejero, F.M. Reverte, F. Aziz, C. Pitart, I. Campo, A. Carpio, E. Reverter, A. Escorsell, P. Ginès, A. Soriano, J. Vila, J. Fernandez. *Clinic Hospital, Liver ICU, Liver Unit, Barcelona, Spain*
Email: mhdeztejero@hotmail.com

Background and Aims: Infections caused by multidrug-resistant (MDR) bacteria are increasingly reported in cirrhosis. Rate and clinical impact of rectal colonization by MDR strains in this population is poorly known.
Method: Prospective study in 119 patients admitted to our unit (86 in the regular ward and 33 in the ICU). Rectal swabs were obtained at admission and weekly thereafter until discharge and cultured for ESBL-producing *Enterobacteriaceae* and carbapenem-resistant bacteria. Patients were followed up for bacterial infections within the

next 3-months. MDR microbiological isolations were considered to guide antibiotic therapy and isolation strategies.
Results: Twenty-seven percent of patients (n = 32) were colonized by MDR strains at inclusion. Prevalence was slightly higher in patients admitted to the regular ward (30% *vs.* 18% in the ICU, p = ns). Twenty-one percent of the non-colonized patients became colonized during hospitalization, with similar rates between ICU and regular ward. Among the 40 MDROs isolated in rectal swabs, the most common strains were ESBL-producing *Klebsiella pneumoniae* (n = 16), ESBL-producing Escherichia Coli (n = 14), and carbapenem-resistant-*Enterobacteriaceae* (n = 5). Multivariate analysis identified MDR isolation in the previous 6 months (HR: 20.4; p = 0.009) and hospital and ICU admission within the last 3 months (HR 3.2 and HR 3.1; p = 0.02 and p = 0.047, respectively) as independent risk factors for MDR colonization at admission. Twenty-one percent of colonized patients developed an infection caused by MDR bacteria during follow-up compared to 1% in patients without colonization (p < 0.0001). Infections occurring in patients colonized by MDR bacteria were frequently caused by the same MDR strain.
Conclusion: Rectal colonization by MDR bacteria is frequent in patients with decompensated cirrhosis whether admitted or not to the ICU. MDROs carriage is associated to a higher risk of infection caused by the same MDRO. Studies assessing cost-effectiveness of epidemiological surveillance in cirrhosis are needed.

Email: fshan1@student.monash.edu

Background and Aims: Overt hepatic encephalopathy (OHE) is a simple diagnosis based on clinical signs; however, minimal hepatic encephalopathy (MHE) can only be diagnosed with special tests that are impractical in the clinic setting. MHE diagnosis is important as it is associated with impairment to quality of life and driving performance, yet the prevalence of MHE amongst cirrhotic patients in Australia remains unknown. A new app, *EncephalApp: Stroop Test*®, may be a practical alternative to diagnose MHE in an outpatient setting.
This study aimed to determine the prevalence of MHE in a cirrhotic outpatient population, assess the feasibility of *EncephalApp*® use in real-world clinic settings, and to identify factors independently associated with MHE.
Method: Patients with cirrhosis were recruited prior to their outpatients' appointment for a cross-sectional study at two Victorian public health services between March-July 2017. Participants performed EncephalApp® on an iPad® under supervision, and the time taken was documented to determine its feasibility as a diagnostic tool. EncephalApp® scores were blinded to clinicians until after initial clinical assessment had been undertaken. After the patient's appointment, the clinician's assessment of HE was documented, and patient demographics and cirrhosis features were collected from the patient's case file. Patients with factors affecting cognition, such as acquired brain injury and stroke were excluded, as were patients with hepatocellular carcinoma.
Results: A total of 1685 patients were screened, 433 had the diagnosis of cirrhosis. 125 patients (median age 56y (interquartile range 50–63), 65.6% male) were recruited of which 46 (36.8%) had MHE according to EncephalApp®. Of these participants, only 13 (28.3%) were also diagnosed with HE by the clinician. 5 patients were diagnosed with HE by the clinician but not EncephalApp®. The median times taken to explain and complete EncephalApp® were 1 and 7 minutes respectively. On multivariate logistic regression, increasing age (odds ratio (OR) 1.08, p = 0.002), and lactulose therapy (OR 22.5, p = 0.01) were strongly associated with MHE according to EncephalApp®, suggesting pre-existing suspicion of HE from the clinician commencing lactulose therapy. No other clinical factors were useful in identifying risk of MHE.
Conclusion: E*ncephalApp®* is a quick and easy to administer tool that could be employed in the real-world clinic setting to assess MHE. It may identify a significant number of cases that would otherwise remain undiagnosed yet may benefit from intervention.

SAT-275
Proton pump inhibitors increase the risk of minimal and overt hepatic encephalopathy and they are associated with high mortality in cirrhotic patients
S. Nardelli[1], S. Gioia[1], C. Pasquale[1], L. Ridola[2], O. Riggio[1]. [1]*Sapienza University of Rome, Gastroenterology, Rome, Italy;* [2]*Ospedale Santa Maria Goretti, Latina, Italy*
Email: nardelli.silvia@gmail.com

Background and Aims: Proton pump inhibitors (PPIs) can contribute to small-bowel bacterial overgrowth and are a risk factor for overt hepatic encephalopathy (HE). Minimal hepatic encephalopathy (MHE) is a subclinical cognitive dysfunction, frequently observed in cirrhotic patients, that can be detected only with psychometric tests; no study investigated the link between PPIs and MHE. The aim of this study was to investigate the incidence of minimal and overt HE in a cohort of cirrhotic patients treated with PPIs. Another aim was to evaluate if long term therapy with PPIs influenced survival in cirrhotic patients.
Method: 310 consecutive cirrhotic patients without overt HE were included in the study. All patients underwent a psychometric evaluation and MHE was diagnosed when the Psychometric Hepatic Encephalopathy Score (PHES) was ≤ –4. Demographic data, PPIs dosage as well as a number of clinical and laboratory variables collected in each patient were analysed. Logistic and Cox regression multivariable models were used to assess if PPIs therapy was independently associated with MHE, overt HE and survival. Survival curve was estimated with the Kaplan-Meier method.
Results: at inclusion, 125 patients (40%) used PPI; the comparison among patients with and without PPI is shown in the Table 1. Three outcomes were considered. The variables independently associated to the presence of MHE were: PPIs (p < 0.001), Child-Pugh score (p = 0.03), MELD score (p = 0.02), serum albumin level (p = 0.03) and history of overt HE (p = 0.002). The variables independently associated to the presence of overt HE were: PPIs (p = 0.008), MHE (p = 0.001), age (p = 0.03), serum albumin level (p < 0.001) and history of overt HE (p < 0.001). The variables independently associated to mortality were: PPIs (p = 0.05), MHE (p = 0.04), age (p = 0.002), serum albumin level (p = 0.01) and MELD score (p < 0.001). During a mean follow-up of 14.1 ± 12.3 months, overall survival was evaluated and among PPIs users' mortality was higher than in cirrhotic patients not treated with PPI (p < 0.001).
Conclusion: the chronic administration of PPIs is frequent in cirrhotic patients and seems to be associated with the presence of MHE and with the development of overt HE. Furthermore, the use of PPIs is associated to an increased mortality in cirrhosis.

Table 1:

	PPI – (n = 185)	PPI + (n = 125)	P value

SAT-276

The time trend of hospital admissions, inpatient mortality rate, and hospital cost of hospitalizations associated with cirrhosis in the United States: an analysis on the National Inpatient Sample

B. Zou[1], Y.H. Yeo[1], D. Jeong[1], E. Sheen[1], H. Park[2], D.H. Lee[1], G. Garcia[1], M. Nguyen[1]. *[1]Stanford University Medical Centre, Division of Gastroenterology and Hepatology, Palo Alto, United States; [2]University of Florida College of Pharmacy, Pharmaceutical Outcomes & Policy, United States*

Email: mindiehn@stanford.edu

Background and Aims: Liver cirrhosis carries high morbidity, mortality and economic burden and affects 6% of the U.S. population. The study aimed to investigate the time trend of the disease burden in terms of number of inpatient admissions, inpatient mortality rate and hospital cost of hospital admissions for cirrhotic patients.

Method: We used the National Inpatient Sample database which samples 20% of all discharges from U.S. community hospitals (excluding rehabilitation and long-term acute care hospitals) to determine the trend of cirrhosis associated hospitalizations and inpatient mortality rates from 2005 to 2011. Generalized linear model was used to compare the hospital cost per admission within different racial/ethnic groups and patients with different causes of cirrhosis, adjusting for age, sex, insurance type, region, income, severity of cirrhosis, and comorbidities. All cost was inflation (3%) adjusted to 2013 US dollars.

Results: A total of 880,005 hospitalizations associated with cirrhosis were identified during 2005 and 2011. The total number of cirrhotic admissions increased from 102,158 in 2005 to 160,246 in 2011. The total cost of cirrhotic admissions per year also showed an increasing trend from 1.55 billion dollars in 2005 to 2.56 billion dollars in 2011. In 2011, the inpatient mortality rate was significantly higher in Asians vs. Hispanics (7.87% *vs.* 5.82%, $p < 0.0001$). Moreover, the adjusted cost per admission for Hispanics was $1107 lower than that of the Whites ($16,219 *vs.* $17,326, $p < 0.0001$). The number of hospitalizations related to hepatitis C virus infection (HCV), alcoholic liver disease (ALD), non-alcoholic fatty liver disease (NAFLD) and other liver diseases all increased over time except for admissions for cirrhosis associated with hepatitis B virus (HBV) which remained stable (Figure 1a). In regards to the hospital cost per admission for cirrhotic patients, the cost was significantly lower in HCV, ALD and NAFLD-related cirrhosis compared to the cost on the HBV-associated cirrhotic admissions (Figure 1b).

Conclusion: The number of hospital admissions for cirrhosis and their total hospital cost witnessed an increasing trend from 2005 to 2011 for most liver diseases including HCV and NAFLD. Hepatitis B patients, in contrast, showed a stable number of admissions for cirrhosis but a higher cost per admission compared to HCV, ALD and NAFLD related cirrhosis admissions.

SAT-277

Validation and modification of Baveno criteria to rule out high-risk varices in patients with compensated cirrhosis

V. Tadkalkar, R. Gunjal, K. Devadas. *Govt Medical College, Department of Medical Gastroenterology, Thiruvananthapuram, India*

Email: kdas40@gmail.com

Background and Aims: Baveno VI criteria defines patients with compensated cirrhosis in whom endoscopy can be avoided as those with a liver stiffness (LSM) by TE <20 kPa and platelet count and >150,000/mm^3. The aim was to validate Baveno criteria in our cohort from India and to determine whether alternate parameters not including TE would be equal/more accurate in ruling out high risk varices (HRV).

Method: Cross-sectional study evaluating patients with liver stiffness >10 kPa who had endoscopy within 6 months of TE evaluation. Factors like Hemoglobin, Platelet, LFT, RFT, INR, etiology, LSM and

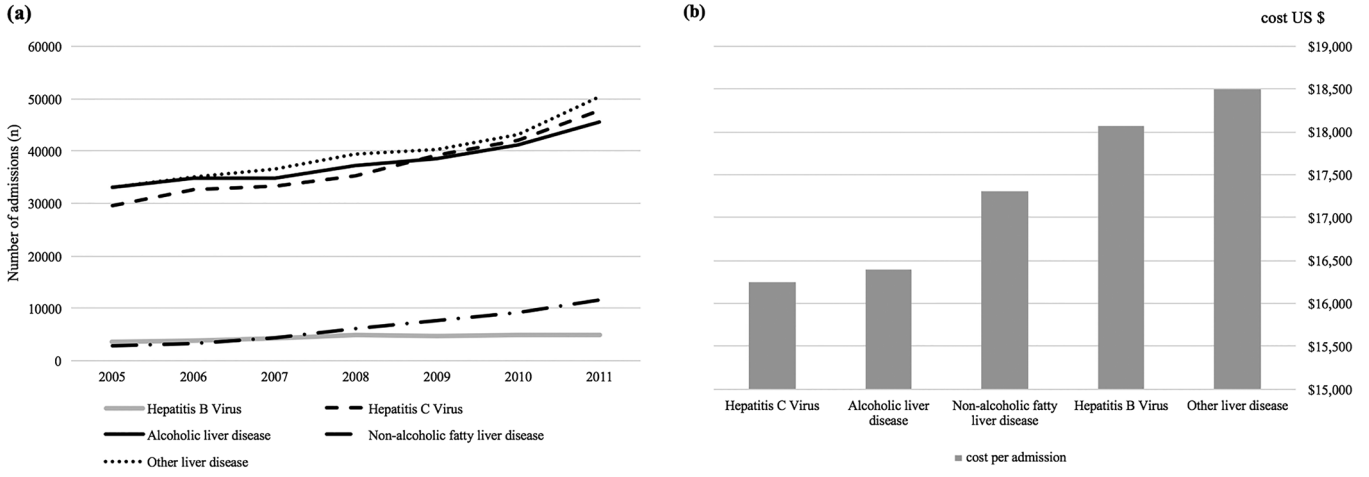

Figure: (abstract: SAT-276): (a) The time trend of number of hospital admissions associated with cirrhosis by aetiology from 2005 to 2011; (b) The cost per admission for hospital admissions associated with cirrhosis by aetiology in 2011. Other liver disease: Autoimmune hepatitis, alpha-1-antitrypsin deficiency, hereditary hemochromatosis, hemochromatosis due to repeated red blood cell transfusions, other hemochromatosis, disorders of copper metabolism, cholangitis.

MELD score were compared between the groups who had HRV and who did not have HRV.
Results: This study included 272 patients who underwent Transient elastography (TE) and upper GI endoscopy from September 2015 to August 2017 at our centre. 168 (61%) patients were male while 104 (38%) patients were female. Most common etiology was HCV (43%) followed by HBV, NASH and ethanol. Out of 192 patients satisfying Baveno criteria (LSM <20 kPa and platelet >150000/mm^3), 190 patients did not have HRV. Sensitivity, specificity, Positive predictive value (PPV) and Negative predictive value (NPV) was 98%, 78%, 91% and 97% respectively. (AUC = 0.89). In all patients, among the factors studied, Platelet count, S. Bilirubin, MELD and LSM significantly differed between patients who had HRV and those who did not have HRV by Mann Whitney U test. An alternative strategy excluding TE and including platelet count and MELD score was also used. No patients with MELD score 6 showed HRV irrespective of platelet count (Sensitivity and NPV = 100%), No patient with MELD score 7 and platelet >150000/mm^3 had varices (Sensitivity and NPV = 100%). One out of 147 patients with platelet >150000/mm^3 had HRV whose MELD was 8. By using MELD 6 or MELD <8 and platelet >150000/mm^3 criteria, 180 (66%) endoscopies could have been circumvented, while using Baveno criteria, 190 (70%) endoscopies could have been circumvented.
Conclusion: This study validates Baveno VI criteria defining patients in which screening endoscopy can be safely avoided. It also describes a new strategy with MELD 6 or MELD <8 and platelet >150000/mm^3 which can be used when TE is not available to screen patient who can safely avoid endoscopy in resource constrained settings.

SAT-278

Outcomes of intrahepatic porto-systemic shunt in the treatment of portal vein thrombosis: A systematic review and meta-analysis

S. Rodrigues[1], S. Sixt[2], A. De Gottardi[3], I. Baumgartner[2], A. Berzigotti[1]. *[1]Hepatology, UVCM, Inselspital, University of Bern, Switzerland; [2]Clinic for Angiology, Swiss Cardiovascular Center, Inselspital, University of Bern, Switzerland; [3]University hospital of Berne, Hepatology, Bern, Switzerland*
Email: susanagrodrigues@gmail.com

Background and Aims: In recent years, minimally-invasive endovascular therapy, and in particular intrahepatic porto-systemic shunts (IPS), (transjugular, transhepatic or transplenic), has been increasingly used to recanalize portal vein thrombosis (PVT). Data regarding the efficacy and safety of endovascular therapy in PVT are scarce, making evidenced-based decisions challenging. The aims of this systematic review and meta-analysis were to determine the feasibility and safety of IPS, and the 1-year shunt patency and PV recanalization rates in patients with PVT undergoing IPS.
Method: Relevant publications up to October 15, 2017 in English were searched in four electronic databases: PubMed, Web of Sciences, Scopus and Embase. Studies were screened and reviewed by two independent investigators for eligibility, according to the PRISMA-guided protocol. Disagreements were resolved by the senior authors. Studies including sufficient information on the characteristics of patients, of PVT, and on the outcomes of IPS were analysed. Data was extracted, and meta-analysis of the results was performed using a random effects model.
Results: The initial search yielded 709 candidate studies; among them 14 studies were included (397 patients). Most patients (93%) had cirrhosis. PVT was complete in 68%, chronic in 96%, cavernoma was present in 18% and superior mesenteric vein involvement in 40%. IPS was technically feasible in 92% (95% CI: 9–96%) with significant heterogeneity among studies (I^2 = 77%). Major complications occurred in 3.7% (95% CI: 1.3–6.1%), with no significant heterogeneity (I^2 = 13%). The mean follow-up after IPS was 19.8 + 8 months. Shunt patency was maintained at 1 year in 80% (95% CI: 72–87%) with significant heterogeneity (I^2 = 79%), largely explained by the use of uncovered stents in 24%. The one-year portal vein recanalization rate was 84% (95% CI: 78–91%), with significant heterogeneity (I^2 = 72%). Among the 3 studies that included non-cirrhotic patients, the 1-year recanalization rate was 64% (95% CI: 37–91%), with significant heterogeneity (I^2 = 64%). Recanalization rate correlated with a higher number of patients per study (r = 0.89). The overall one-year survival rate was 87%.
Conclusion: Endovascular therapy is highly feasible, effective and safe in recanalizing PVT. Experienced-centers achieve a higher PV recanalization rate.

SAT-279

Clinically significant portal hypertension in chronic liver disease: Always cirrhosis?

S. Rodrigues[1], A. Berzigotti[1], M. Montani[2], A. De Gottardi[1], J. Bosch[1]. *[1]Hepatology, UVCM, Inselspital, University of Bern, Switzerland; [2]Institute of Pathology, University of Bern, Inselspital, Bern, Switzerland*
Email: susanagrodrigues@gmail.com

Background and Aims: Clinically significant portal hypertension (CSPH) is defined by a hepatic venous pressure gradient (HVPG) ≥ 10 mmHg. In the setting of chronic liver disease, CSPH is highly correlated with the presence of cirrhosis, is used in the prognostic stratification of patients with cirrhosis and has been even proposed as a diagnostic surrogate of the presence of cirrhosis on histology. The aim of this study was to characterize patients showing HVPG ≥ 10mm Hg in whom histology did not confirm the presence of cirrhosis.
Method: A prospective database of 185 consecutive patients with liver diseases submitted to simultaneous HVPG measurements and transjugular liver biopsy (TJLB) between January 2015 and June 2017 was retrospectively analyzed. Patients with CSPH (HVPG ≥ 10 mmHg) and chronic liver disease were selected, and liver biopsies were reviewed to detect cases that were not showing a histological stage of cirrhosis.
Results: Among the 185 patients, 92 (50%) had CSPH defined by an HVPG ≥ 10 mmHg. After excluding 3 patients with haematological infiltration of the liver (lymphoma and amyloidosis), a HVPG ≥ 10 and a METAVIR score below F4 was found in 16% of the patients (14/89). All of the patients had representative biopsies with ≥ 10 portal tracts. The median HVPG in this group was 12 mmHg (10–16.5). METAVIR stages were F3 (n = 7), F2 (n = 1) and F1 (n = 6). The aetiologies included chronic hepatitis C (n = 2), non-alcoholic steatohepatitis (n = 4), portal sinusoidal disease (n = 5), cholestatic (n = 2) and autoimmune diseases (n = 1). The median spleen size was 13 cm (10.5–13.9) and median platelet count was 138 × 10^9/L (102–159). Perisinusoidal fibrosis (6/14, 43%) and hepatocyte ballooning (7/14, 50%) were common histological features of these patients.
Conclusion: CSPH in patients with chronic liver disease is not always synonymous of cirrhosis. Sixteen percent of patients with chronic liver disease had CSPH, although they did not have cirrhosis on histology. In these patients, perisinusoidal fibrosis and hepatocyte ballooning likely contribute to the increase in sinusoidal pressure beyond that expected from their histological stage of fibrosis.

Screening of esophagogastric varices: Performance of the "Expanded Baveno VI criteria" and the "platelet 150/MELD 6" strategy in all etiology compensated advanced chronic liver disease

G. Tosetti[1], V.L. Mura[1], R. D'ambrosio[1], E. Degasperi[1], N. Mezzina[2], M. Viganò[2], M.G. Rumi[2], A.L. Fracanzani[3], R. Lombardi[3], M. Fraquelli[4], A. Aghemo[5], P. Lampertico[1], M. Primignani[1]. *[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, CRC A.M. and A. Migliavacca for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Ospedale San Giuseppe, Università degli Studi di Milano, Division of Hepatology, Milan, Italy; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, University of Milan, Internal Medicine, Department of pathophysiology and Transplantation, Italy; [4]Fondazione IRCCS Cà Granda Ospedale Maggiore*

Policlinico, Division of Gastroenterology and Endoscopy, Milan, Italy; [5]Humanitas University, Department of Biomedical Sciences, Rozzano, Italy
Email: pietro.lampertico@unimi.it

Background and Aims: Baveno VI criteria (liver stiffness measurement-LSM <20 kPa and/or platelet count >150,000/mm^3) in viral compensated advanced chronic liver disease (cACLD) patients allow to spare 20–25% variceal screening endoscopies. More recently, less conservative strategies to further reduce the number of unneeded endoscopies ("Expanded Baveno VI criteria": LSM <25 kPa and/or platelet count >110,000/mm^3) were proposed. Due to the limits/unavailibilty worldwide of LSM a "Plt >150,000/MELD 6 criteria" was also proposed. Both criteria proved accurate and effective but need external validation.
The aim is to assess the accuracy of the new "Baveno VI expanded criteria" and "Plt >150,000/MELD 6 criteria" in a large cohort of cACLD patients of any etiology, as compared to the original "Baveno VI" criteria.
Method: cACLD patients undergoing endoscopic screening for varices were evaluated. Laboratory data within 6 months and LSM within one year were retrospectively collected. Exclusion criteria were: LSM unavailable or unsuccessful, liver decompensation, previous variceal treatment, portal vein thrombosis, current hepatocellular carcinoma or other neoplasm and splenectomy.
Results: 471 of 1182 patients fulfilled inclusion criteria: 79% viral cACLD (316 HCV, 56 HBV), 21% metabolic/ETOH cACLD (ETOH 32, metabolic 50, mixed ETOH/metabolic 17), platelet count (PLT) was 124 (36–347) × 10^9/L, LSM 19,1 kPa (7,7–75,0). 144 (31%) had varices; of these, 31 (21%) had varices requiring prophylaxis. Baveno VI criteria had 100% sensitivity (Se) and 100% negative predictive value (NPV): according to these criteria 100 (21%) patients could have safely avoided endoscopy. The "expanded Baveno VI" criteria maintain the highest accuracy (Se 100% and NPV 100%) sparing 211 (45%) endoscopies (original "Baveno VI criteria" vs "expanded Baveno VI" criteria p <0.001, McNemar test). Conversely, the "platelet count >150,000/MELD 6 criteria" proved less accurate (Se 0,9; NPV 0,985), since, similarly to the expanded Baveno VI criteria, led to save up to 41% endoscopies, but would have lost 3 out of 31 patients (10%) of those with varices requiring prophylaxis.
Conclusion: The new "Expanded Baveno VI" criteria are valid and reproducible in all etiology cACLD patients and allow sparing screening endoscopies up to 45% without losing accuracy. The "Plt >150,000/MELD 6" strategy is less accurate.

SAT-281

Combined elastin and collagen proportionate area sub-classifies cirrhosis and predicts clinical outcomes

A. Majumdar[1,2], A. Hall[1], T.V. Luong[3], M. Pinzani[1], E. Tsochatzis[1]. *[1]UCL Institute for Liver and Digestive Health and Sheila Sherlock Liver Centre, Royal Free Hospital, London, United Kingdom; [2]AW Morrow Gastroenterology and Liver Centre, Australian National Liver Transplant Unit, Royal Prince Alfred Hospital, Sydney, Australia; [3]Department of Histopathology, UCL Medical School, Royal Free Campus, London, United Kingdom*
Email: avikmajumdar@me.com

Background and Aims: Hepatic fibrosis comprises both collagen and elastic fibres. Morphometric quantification of fibrosis with collagen proportionate area (CPA) can sub-classify cirrhosis and is a validated histological predictor of clinical outcomes. We aimed to explore the role of elastin quantification in this context.
Method: A historical CPA validation cohort of 69 patients with cirrhosis was investigated. Slides were re-cut and stained from paraffin blocks using modified Elastic Van-Gieson (EVG). After digital image acquisition at x4 objective magnification, semi-automated quantification of elastin was performed using a purpose built MATLAB script. Elastin proportionate area (EPA), CPA and ECPA were compared to existing semi-quantitative histological criteria (Laennec, Kumar, Nagula, Sethasine) and clinical scores. The outcomes of interest were decompensation at baseline and future decompensation. Standard statistical methods were employed using STATA v14.0.
Results: 59 patients (59% male) with a mean age of 51 ± 11 had complete EPA and CPA measurements. Cirrhosis was mostly due to alcohol (37%), hepatitis C (25%) and hepatitis B (10%). At biopsy, 21 (36%) were decompensated, while 9/38 (24%) of the compensated patients decompensated during a median follow-up of 57 months (IQR 16–92). Mean MELD score was 12 (± 6). Mean biopsy length was 22.1 mm(± 11). Mean EPA, CPA and ECPA were 3 (± 3.40), 22.6 (± 12.2) and 25.7 (± 14.8) respectively. At baseline, CPA (cut-off 26.1) correctly classified 88% as decompensated (sensitivity 88%, specificity 89%) compared to ECPA (cut-off 25.8), which correctly classified 92% (sensitivity 96%, specificity 90%). The AUC for prior decompensation for CPA and ECPA were similar (both 0.91, p = 0.07). On multivariate analysis, only the models containing ECPA (OR 1.16 [1.03–1.30]) or CPA (OR 1.20 [1.05–1.36]) in combination with MELD were significant. The AUC for predicting future decompensation was 0.75 for ECPA and 0.76 for CPA (p = NS). On Cox regression, only ECPA (HR 1.04 [1.01–1.08], p = 0.02) and CPA (HR 1.05 [1.00–1.10], p = 0.03) predicted future decompensation when compared to other scores.
Conclusion: We provide a proof of concept study for the measurement of elastin using digital image analysis and its relation to clinically relevant outcomes. The combination of EPA and CPA should be further explored in larger cohorts.

SAT-282

Transjugular intrahepatic portosystemic shunt is highly effective in patients with a MELD score <20 and does not require routine Doppler ultrasound follow-up

K. de Wit[1], O. van Delden[2], U. Beuers[1], B. Takkenberg[1]. *[1]Academic Medical Centre, Gastroenterology and Hepatology, Amsterdam, Netherlands; [2]Academic Medical Centre, Radiology, Amsterdam, Netherlands*
Email: k.dewit@amc.uva.nl

Background and Aims: A transjugular intrahepatic portosystemic shunt (TIPS) is a highly effective intervention to treat complications of portal hypertension. Since the introduction of polytetrafluoroethylene (PTFE)-covered stents patency rates have improved. Nevertheless, TIPS is still a second line treatment. The aims of this study were to assess the indications, overall response, clinical outcome and yield of ultrasound follow-up in patients receiving PTFE-covered TIPS in an academic centre.
Method: A retrospective cohort study of all consecutive patients (aged 18 years or older) who underwent PTFE-covered TIPS placement between 2001 and 2016. Imaging, laboratory and clinical parameters were reviewed and analysed.
Results: A total of 120 patients were included, of whom 47% had alcoholic liver cirrhosis. Main indications for TIPS were variceal bleeding (42%) and refractory ascites (38%). At 1-year follow-up control of bleeding was successful in 94%, and control of refractory ascites was successful in 82%. Within 30 days post TIPS-placement, 33% developed hepatic encephalopathy (HE). Overall one-year transplant free (TF)-survival was 58%. Irrespective of TIPS indication patients with MELD score <20 had a significantly better TF-survival compared to patients with a MELD >20 (p < 0.001; Figure). In patients with Child Pugh-B cirrhosis, one-year TF-survival significantly differed between patients with variceal bleeding (94%) and refractory ascites (36%) (p = 0.001). Predictors of mortality in patients with variceal bleeding were INR > 1.4 and a serum bilirubin level >43 µmol/L. In patients with refractory ascites, a serum albumin level <34 g/L was a predictor of mortality. Doppler ultrasound investigations during regular follow-up at the outpatient clinic revealed abnormalities in 3%, which were all associated with clinical deterioration, while abnormalities were detected in 13% of patients who presented at the emergency ward with clinical symptoms of TIPS-dysfunction.

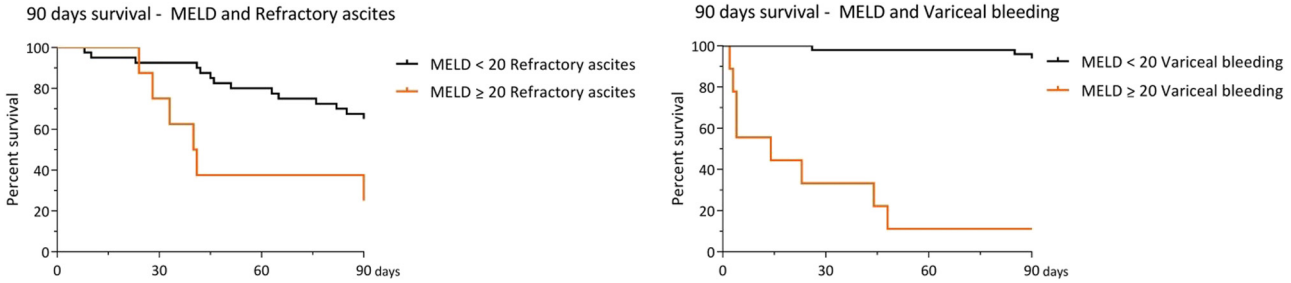

Figure: (abstract: SAT-282): Kaplan-Meier survival curves of 90 days survival, divided by MELD score lower than 20 and greater or equal to 20, for refractory ascites ($p < 0.001$) and variceal bleeding ($p < 0.001$).

Conclusion: In selected patients TIPS is a highly effective treatment for variceal bleeding and refractory ascites, but patients with a MELD score greater or equal to 20 have a poor survival asking for most critical judgement before decision for TIPS placement. The use of routine Doppler ultrasound follow-up after PTFE-covered TIPS placement seems unnecessary as abnormal Doppler findings are almost always associated with clinical symptoms of TIPS-dysfunction.

SAT-283

Efficacy of liver stiffness measurement and platelet count in screening for high grade varies in patients with cirrhosis

A. Agarwal, G. Rout, S.K. Vuyyuru, D. Gunjan, S. Kedia, B. Nayak, Shalimar. *All India Institute of Medical Sciences, Gastroenterology and Human Nutrition Unit, New Delhi, India*
Email: drshalimar@yahoo.com

Background and Aims: Endoscopy is the gold standard for detection and staging of varices; guidelines recommend screening endoscopy in newly diagnosed cirrhosis. The aim of this study was to validate the recently published Baveno VI guidelines which recommend avoiding endoscopy in patients with compensated cirrhosis with liver stiffness measurement (LSM) ≤20 kPa and platelet count ≥150,000/mm^3.
Method: Consecutive cirrhosis patients of viral etiologies- hepatitis B virus (HBV) and hepatitis C virus (HCV) evaluated from Jan 2015 to May 2017 were included. High grade varices (HGVs) were defined as grade III and grade IV varices or lower grade varices with red color signs on endoscopy. Receiver operator characteristic (ROC) curves were computed for LSM and platelet count and presence of HGVs. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy (DA) were reported.
Results: In this analysis from an ongoing prospective study- 295 patients (HBV 154 and HCV 141); mean age 43.1 ± 13.2 years; 127 (43.1%) males were included. The median LSM (IQR) and platelet counts (IQR) were 19.7 (14.8–28.8) kPa and 119000/mm^3 (80000–160000/mm^3), respectively. The area under ROC (AUROC) curve for LSM, platelet count and both combined as predictors for presence of HGVs were 0.58 (95% CI, 0.48–0.67), 0.68 (0.60–0.76) and 0.63 (0.54–0.71), respectively. LSM (at a cut-off of 21.4 kPa) had sensitivity, specificity, NPV, PPV and DA of 58.3%, 58.7%, 87.9%, 27.5% and 0.58, respectively. Platelet count (at a cut-off of 106500/mm^3) had a sensitivity, specificity, NPV, PPV and DA of 62.5%, 61.1%, 86.6%, 19.4%, and 0.61, respectively. The use of LSM and CAP in conjunction did not significantly improve the overall diagnostic accuracy over individual values. Using the Baveno VI cut-offs (LSM 20 kPa and platelet count 150000/mm^3), the sensitivity, specificity, NPV, PPV and DA for prediction of HGVs for LSM and platelet count were 60.4%, 53.4%, 20.1%, 87.4%, 0.54 and 85.4%, 32.4%, 19.7%, 91.9%, 0.41 respectively. There were no differences in predictive values of LSM and platelet in patients with hepatitis B and C etiologies.
Conclusion: The diagnostic performance of liver stiffness measurement and platelet count for prediction of high grade varices is modest and more data is required before it can replace screening endoscopy.

SAT-284

Correlation and prognostic accuracy between noninvasive liver reserve markers and portal pressure in cirrhosis: Role of ALBI score

Y.-C. Hsieh, H.-C. Lin, K.-C. Lee, Y.-Y. Yang, M.-C. Hou, T.-I. Huo. *Taipei Veterans General Hospital, Department of Gastroenterology and Hepatology, Taipei, Taiwan*
Email: hclin@vghtpe.gov.tw

Background and Aims: The role of non-invasive liver reserve markers which developed to evaluate the severity of chronic liver disease remained unclear in cirrhosis. We aimed to evaluate the correlation between noninvasive liver reserve markers and hemodynamic parameters and their prognostic performance in cirrhotic patients.
Method: A total of 242 cirrhotic patients undergoing hemodynamic study were analyzed. The correlations between noninvasive models, including the FIB-4, aspartate aminotransferase to platelet ratio index, cirrhosis discriminant score, Lok index, Goteborg University Cirrhosis Index, and albumin-bilirubin (ALBI) score and hemodynamic parameters were investigated, along with their predictive accuracy in short-term and long-term survival.
Results: There was a significant correlation between all noninvasive markers and hepatic venous pressure gradient (HVPG), and ALBI score had the best correlation ($r = 0.307$, $p < 0.001$). For the prediction of 3-month and 6-month mortality, serum sodium (sNa) levels had the highest area under curve (AUC; 0.799 and 0.818, respectively) among all parameters, and ALBI score showed the best performance (AUC = 0.691 and 0.740, respectively) compared with other 5 noninvasive models. Of 159 patients with low MELD scores (<14), high ALBI score (>−1.4) and low sNa (<135 mmol/L) predicted early mortality. In the Cox multivariate model, ALBI, MELD, HVPG and sNa were independent predictors of long-term survival.
Conclusion: Among noninvasive markers, ALBI score is best correlated with HVPG and associated with short-term outcome in cirrhotic patients. A high ALBI score and low sNa identify high-risk patients with low MELD scores. High MELD, HVPG, ALBI and low sNa levels are independent predictors of decreased long-term survival.

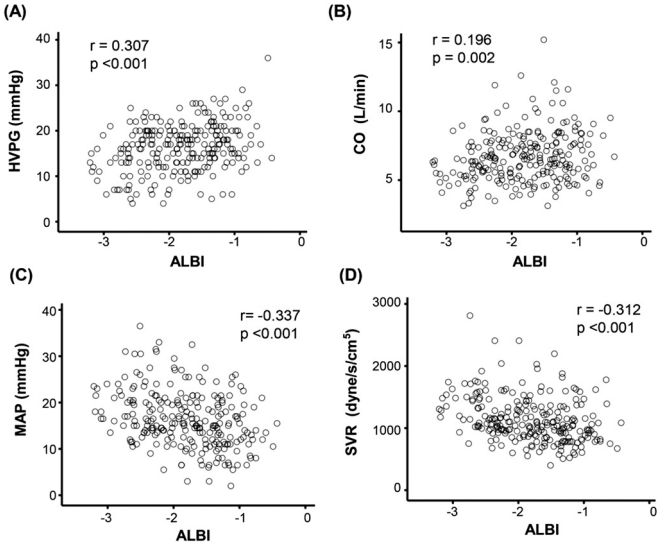

Figure 1. Correlation between the albumin-bilirubin (ALBI) scores and hemodynamic parameters in cirrhotic patients. The correlation between the ALBI scores and hepatic venous pressure gradient (HVPG, panel A), cardiac output (CO, panel B), mean arterial pressure (MAP, panel C), and systemic vascular resistance (panel D).

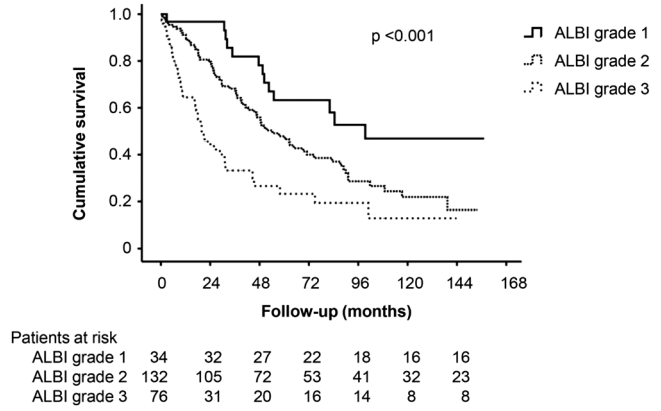

Figure 2. Comparison of long-term survival according to different ALBI grades.

SAT-285

Tolerability and kinetics of SYNB1020 in a Phase 1, first-in-Human, healthy adult volunteer study

M. Puurunen[1], W.S. Denney[2], L. Blankstein[1], R. Goldwater[3], T. Parsons[1], Y. Millet[1], C. Kurtz[1], A. Brennan[1]. *[1]Synlogic Inc.; [2]Human Predictions; [3]Parexel*
Email: marja@synlogictx.com

Background and Aims: Patients with impaired liver function accumulate toxins in the blood stream, which presents as hepatic encephalopathy (HE) in approximately 55% of patients with chronic liver disease. The pathogenesis of HE is believed to be largely attributable to hyperammonia. Current standard of care for HE aims at reducing blood ammonia levels using lactulose or rifaximin. SYNB1020 is an orally administered live biotherapeutic product that is a genetically modified strain of *Escherichia coli* Nissle 1917 (EcN) designed to consume ammonia and produce arginine in the intestinal tract. To prevent gut colonization, additional modifications were performed to make SYNB1020 a thymidine auxotroph (Figure 1). The rationale for development of SYNB1020 was to create a commensal strain of EcN that would produce excess arginine and continuously consume excess ammonia where it is naturally produced, in the colon, before it can be absorbed into the blood.
Method: A Phase 1, first-in-human, oral single and multiple dose-escalation, randomized, double-blinded, placebo (PBO)-controlled Study of SYNB1020 in healthy adult volunteers (HV) was conducted to evaluate safety and tolerability of SYNB1020 following single (SAD) and multiple (MAD) ascending doses (NCT03179878). Secondary objectives were assessment of gastrointestinal (GI) tolerability using the Gastrointestinal Symptom Rating Scale (GSRS), and SYNB1020 microbial kinetics in feces.
Results: 52 HV received SYNB1020 or PBO (ratio 3:1). SYNB1020 was well tolerated at total daily doses up to 1.5×10^{12} CFU for 14 days. Higher doses were associated with mild to moderate nausea and vomiting during the first 1–2 days of dosing. There were no SAEs or deaths. No clinically significant change in total GSRS was observed in the MAD cohorts. qPCR revealed rapid clearance of the strain following discontinuation of dosing. There was no evidence of colonization in any subject. Strain activity was demonstrated in feces from subjects who received SYNB1020 but not PBO.
Conclusion: This first in human trial demonstrated safety and tolerability of SYNB1020 in healthy volunteers. Tolerability and microbial kinetic data will guide future clinical studies in patients with liver disease and hyperammonemia.

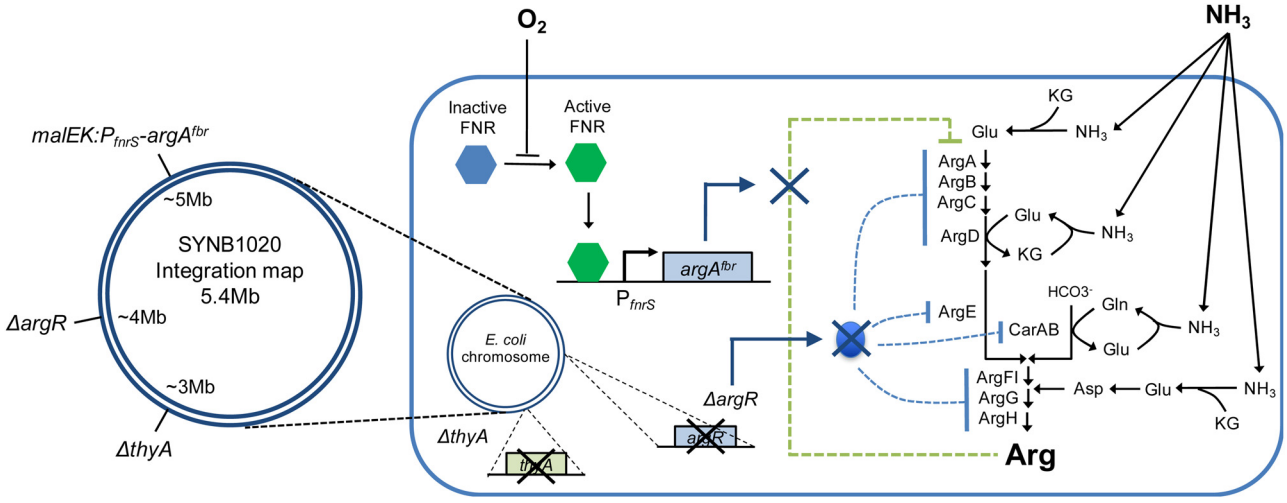

Figure 1: (abstract: SAT-285): SYNB1020 genetic modifications. (1) argR repressor gene deleted, (2) argA gene replaced with a feedback-resistant version, (3) Control of argA gene by anaerobic promoter (fnr), (4) thyA gene deleted to confer auxotrophy.

SAT-286

Cardiac fibrosis and coronary atherosclerosis in cirrhosis. Indications of cirrhotic cardiomyopathy?

S. Wiese[1,2,3], J. Hove[2,4], S. Mo[5], F. Bendtsen[2,5], S. Møller[2,3]. [1]*Hvidovre Hospital, Gastro Unit, medicial division, Denmark;* [2]*University of Copenhagen, Faculty of health and medical sciences, Denmark;* [3]*Hvidovre Hospital, Dept. Clinical Physiology, Denmark;* [4]*Hvidovre Hospital, Dept. Cardiology, Denmark;* [5]*Hvidovre Hospital, Gastro Unit, medical division, Denmark*
Email: signeswiese@gmail.com

Background and Aims: The underlying etiology of cirrhotic cardiomyopathy remains partly unknown. Quantification of the extracellular volume fraction (ECV) by cardiac MRI (CMR) is a new method to assess structural myocardial changes, including diffuse myocardial fibrosis. Patients with cardiac failure have increased myocardial ECV and we have recently shown in cirrhosis, that ECV is related to disease severity and poor outcome. In patients with cirrhosis the relation between coronary artery sclerosis, cardiac fibrosis, and cirrhotic cardiomyopathy has not been explored. Our aim was therefore to investigate if the degree of myocardial fibrosis as assessed by CMR-derived myocardial ECV was related to well-established cardiovascular risk factors and coronary artery atherosclerosis.
Method: 52 patients with cirrhosis and 10 healthy controls were included. All patients underwent CMR with ECV quantification, coronary-CT angiography including coronary artery calcium (CAC)-score, tissue Doppler echocardiography, clinical and biochemical assessments. In the controls, contrast-enhanced CMR alone was performed.
Results: Myocardial ECV was higher in patients compared with healthy controls (31.2 ± 6 *vs.* 27.4 ± 3%, $p = 0.04$). Moreover, ECV increased across Child Pugh A/B/C classes (26.9 ± 4/ 31.5 ± 5/ 34.4 ± 6%, $p = 0.02$). There were no differences between patients with a high ECV (>31.2%) versus a low ECV (≤31.2%) with respect to prevalence of smoking (46% vs. 55%), hypercholesterolemia (22% *vs.* 78%), arterial hypertension (48 *vs.* 52%) or type II diabetes (40 vs. 60%) (P = NS). Even though the median CAC-score (289 HU (26; 645)) was increased in the patients we found no association between myocardial ECV and CAC-score ($r = -0.18$; $P = 0.22$). Myocardial ECV correlated with cardiac index ($r = 0.35$, $p = 0.015$), CRP ($r = 0.47$, $p = 0.001$), and proANP ($r = 0.4$, $p < 0.001$). No associations to age, etiology or portal hypertension (P = NS).
Conclusion: Myocardial fibrosis in cirrhosis is related to disease severity, but not to well-established cardiovascular risk factors or presence of coronary artery atherosclerosis. Since ischemic heart disease does not seem to be involved in the development of structural myocardial changes in cirrhosis, increased myocardial fibrosis may represent an early manifestation of cirrhotic cardiomyopathy.

SAT-287

The role of bile acids in the development of structural myocardial changes and cardiac dysfunction in patients with cirrhosis

S. Wiese[1,2,3], J. Hove[3,4], S. Mo[2], F. Bendtsen[2,5], S. Møller[5,6]. [1]*Hvidovre Hospital, Dept. Clinical Physiology, Denmark;* [2]*Hvidovre Hospital, Gastro Unit, Medical Division, Denmark;* [3]*University of Copenhagen, Faculty of Health and Medical sciences, Denmark;* [4]*Hvidovre Hospital, Dept. Cardiology;* [5]*University of Copenhagen, Denmark; Faculty of Health and Medical sciences;* [6]*Hvidovre Hospital, Dept. Clinical Physiology, Copenhagen, Denmark*
Email: signeswiese@gmail.com

Background and Aims: Bile acids (BA) suppress cardiac function in experimental models of cirrhosis. However, the potential deleterious cardiac effects of BA in patients with cirrhosis have only been sparsely investigated. Cardiac MRI (CMR) with quantification of the extracellular volume fraction (ECV) is a new method that allows for noninvasive assessment of structural myocardial changes, in particular diffuse myocardial fibrosis. Our aim was to investigate if abnormal levels of circulating BA contribute to the development of structural myocardial changes and cardiac dysfunction in patients with cirrhosis.
Method: 52 patients with cirrhosis and 10 healthy controls were included. All patients underwent CMR with ECV quantification, coronary-CT angiography including coronary artery calcium (CAC)-score, tissue Doppler echocardiography, clinical and biochemical assessments including total bile acid (tBA) concentrations. In the controls, contrast-enhanced CMR alone was performed.
Results: Patients with cirrhosis had increased circulating levels of tBA, median 42 µmol/L (19;86) with the highest levels in patients with advanced disease (86 µmol/L (37;116) *vs.* 24 µmol/L (17;46), $p < 0.001$). When patients were divided into two groups based on a tBA cut-off of 42 µmol/L those with high levels of tBA had an increased myocardial ECV in comparison with those with lower levels of tBA (33.2 *vs.* 29.6%, $p = 0.011$). Patients with high tBA levels also had increases in cardiac index ($p = 0.02$), left atrial volume ($p = 0.047$), left ventricle end diastolic volume ($p = 0.01$) and right ventricle end diastolic volume ($p = 0.013$). Additionally, tBA correlated with MELD ($r = 0.67$, $p = 0.000$), lateral e' ($r = 0.30$, $p = 0.02$) and hepatic venous pressure gradient ($r = 0.39$, $p = 0.006$). No correlations were seen to natriuretic peptides (p = NS).
Conclusion: Circulating levels of tBA are increased and related to disease severity, portal pressure and cardiac dimensions in patients with cirrhosis. Moreover, increases in tBA levels are associated with an increased myocardial ECV reflecting myocardial fibrosis. This may indicate that BAs are involved in the development of structural myocardial changes in cirrhosis and that BAs most likely play a contributing role in cardiac changes relating to cirrhotic cardiomyopathy.

SAT-288

Hepatopulmonary syndrome: a spontaneously reversible condition? Variability in prevalence in a prospective follow-up study of cirrhotic patients

A. Chiricuta[1], T. Voiosu[1,2], B. Mateescu[1,2], A. Voiosu[1]. [1]*Colentina Clinical Hospital, Gastroenterology, Bucharest, Romania;* [2]*UMF Carol Davila*
Email: radoiaurelia@yahoo.com

Background and Aims: Hepatopulmonary syndrome (HPS) is a pulmonary vascular complication of liver disease associated with increased mortality in patients awaiting liver transplantation. Repeating arterial blood gas analysis may lead to reclassification in some cases. We aimed to assess the variability in prevalence of HPS at different timepoints in a cohort of cirrhotic patients.
Method: This is a prospective observational study of 87 consecutive patients with cirrhosis. Patients with significant pulmonary or cardiovascular disease were excluded. Routine blood tests, pulse oxymetry and blood gas measurements were performed at baseline and at 1 and 2 years of follow-up. Contrast enhanced echocardiography examination for detecting intrapulmonary vascular dilations was performed at baseline. The main outcomes were prevalence of HPS and cirrhosis-related complications and death during follow-up.
Results: Patients were followed up for a mean of 19 months. Of the 87 patients enrolled, 19 had HPS at baseline, but during follow-up visits only 6 (after 1 year) respectively 3 (after 2 years) fulfilled the oxygenation criteria for HPS. After one year there were 2 new and 6 persistent cases of HPS and after 2 years there were 5 HPS cases (2 new). One patient had a variable oxygenation gradient compatible with the HPS criterion at baseline and at 2 years, but not at the 1 year visit. HPS at baseline was associated with decreased survival: 18.7 vs. 21 months ($p = 0.021$ log rank). Of the initial 19 HPS patients 10 died during follow-up and there were 8 cases of new onset ascites, 4 of gastrointestinal bleeding, 8 of hepatic encephalopathy, 2 severe infections and 1 hepatorenal syndrome recorded in this group.
Conclusion: Oxygenation abnormalities diagnostic for HPS fluctuate in time and may lead to reclassification of patients with HPS but an initial diagnosis is associated with adverse outcome at 2 years.

Periodic reassessment of arterial oxygen concentrations may be advisable when monitoring cirrhotic patients.

SAT-289

Is obesity an additional negative factor in sarcopenic cirrhotic patients?

D. D'ambrosio, B. Lattanzi, V. Di Gregorio, V. Fedele, S. Incicco, M. Merli. *Clinical Medicine, Rome, Italy*
Email: daria.damb@gmail.com

Background and Aims: Sarcopenia is an important burden in cirrhotic patients and is recognized as a negative prognostic factor in these patients. Nowadays, non-alcoholic steatohepatitis (NASH) is among the most common causes of cirrhosis also leading to liver transplantation. These patients may present obesity and sarcopenia at the same time, a condition known as sarcopenic obesity. Obesity is associated with a proinflammatory state caused by the increase in inflammatory cytokines and has been shown to increase the rate of decompensation in patients with liver cirrhosis. The aim of the study was to analyze the role of sarcopenic obesity in hospitalized cirrhotic patients.
Method: All consecutive cirrhotic patients hospitalized from 2012 to 2015 at our tertiary care center were enrolled in the study. In each patient, we performed anthropometric evaluation. Sarcopenia was diagnosed according to mid-arm muscle circumference (MAMC), body mass index (BMI) was corrected for ascites. Sarcopenic obesity was diagnosed in presence of sarcopenia and BMI ≥ 30.
Results: We analyzed 466 cirrhotic patients. Sarcopenia was present in 306 patients (66%). Concomitant obesity was present in 139 patients with sarcopenia (45%). Cirrhotic patients with sarcopenic obesity presented a higher rate of complications linked to portal hypertension (85% *vs.* 62% $p < 0.001$), an increased prevalence of variceal bleeding (34% *vs.* 18%; $p = 0.008$) and hepatic encephalopathy (38% *vs.* 25% $p = 0.03$) vs cirrhotic patients with sarcopenia and not obese. No difference was found for in-hospital mortality ($p = 0.17$).
Conclusion: Sarcopenic obesity is a condition often underestimated that may increase morbidity in patients with cirrhosis leading to a higher frequency of complication in comparison with sarcopenic cirrhotic patients with normal/low weight.

SAT-290

Liver cirrhosis and wound healing: Activation of von Willebrand factor and platelets

L. Langholm[1], M. Karsdal[1], F. Bendtsen[2], D. Leeming[3], T. Manon-Jensen[1], S. Møller[4]. *[1]Nordic Bioscience A/S, Biomarkers & Research, Herlev, Denmark; [2]Hvidovre Hospital, Gastro Unit, medical division, Hvidovre, Denmark; [3]Nordic Bioscience, Biomarkers & Research, Herlev, Denmark; [4]Hvidovre Hospital, Department of Clinical Physiology, Hvidovre, Denmark*
Email: lla@nordicbio.com

Background and Aims: Portal hypertension (PHT) is closely related to development of complications to liver cirrhosis. PHT is often accompanied by endothelial dysfunction leading to an impaired wound healing response and decreased platelet count and activity. Increased Von Willebrand Factor (VWF) formation in cirrhosis has been suggested as a compensatory mechanism for low platelet count. The ADAMTS13-processing yields a VWF form that efficiently binds and activates platelets, and consequently is considered a platelet activation factor. VWF antigen and ADAMTS13 levels and activity have previously been assessed in cirrhosis, thus only indirectly assessing the role of VWF processing. The aim of this study was to measure the true ADAMTS13 cleaved VWF form (VWF-A) in addition to VWF formation (VWF-N) to investigate the association of platelet activation and would healing in relation to PHT in liver cirrhosis.
Method: Plasma samples from 105 participants undergoing liver vein catheterization and with liver cirrhosis of varying severity were included in the study together with 20 controls without liver disease. A competitive ELISA format was used to estimate biomarkers of VWF formation (VWF-N) and ADAMTS13-processing (VWF-A) using neo-epitope specific monoclonal antibodies.
Results: VWF-N levels and VWF-A levels were significantly elevated in cirrhotic patients compared to controls ($p < 0.001$) and both markers could discriminate mild from severe cirrhosis (Child-Pugh score A vs C) (VWF-N, $p < 0.0001$; VWF-A, $p = 0.0061$). Discriminating patients with cirrhosis from controls using AUROC analysis showed equally good diagnostic accuracy for both markers (AUC 0.87, $p < 0.0001$). When stratifying the patients based on PHT, the biomarkers were capable of separating cirrhotic patients with from patients without clinically significant/severe PHT as defined by a HVPG cutoff of ≥10 (VWF-N, $p = 0.0003$; VWF-A, $p = 0.028$).
Conclusion: The data clearly indicate that not only is VWF formation increased in cirrhosis, but more importantly VWF activation which is a surrogate of active wound healing. Total VWF-N and activated VWF-A identified subjects with cirrhosis and discriminated between those with and without PHT and may therefore contain additional information to assess the presence and severity of PHT as an early indicator of cirrhosis. Whether the increased would healing has impact on long-term outcome needs to be addressed in future studies.

SAT-291

The incidence of ulcer bleeding post endoscopic band ligation of esophageal varices

S. Machlab[1], J. Da Costa[1], D. Horta[2], P. Ruiz[2], J. Profitós[3], M.V. Gómez[1,4], M. Miquel[1,4], M. Casas[1], B. Dalmau[1], R. Campo[1], E. Brullet[1], F. Junquera[1], V. Puig-Diví[1], E. Martínez-Bauer[1], P. García-Iglesias[1], A. Villoria[1], M. Gallach[1], L. Melcarne[1], X. Calvet[1,4], J. Sánchez-Delgado[1,4]. *[1]Parc Taulí Hospital Universitari. Institut d' Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Digestive Diseases Department, Sabadell; [2]Hospital Universitario Mútua de Terrassa, Digestive Diseases Department, Terrassa, Spain; [3]Consorci Sanitari de Terrassa (CST), Digestive Diseases Department, Terrassa, Spain; [4]Instituto Carlos III, CIBERehd, Madrid, Spain*
Email: machlab@gmail.com

Background and Aims: Endoscopic esophageal varices band ligation can be complicated by bleeding from post-ligation ulcers. Most published studies on prophylaxis with this procedure do not report the incidence of this event. Our aim is to assess the incidence and risk factors of post-ligation early hemorrhage.
Method: Retrospective multicenter study. Patients treated with elective band ligation between January 2013 and December 2015 in three centers were included. Clinical, endoscopic and analytical variables were collected
Results: 297 banding sessions in 133 patients were included. The average number of sessions were 3 per patient with an average of 5 bands. Twelve patients developed eschar bleeding, which represents an incidence of 4% and that 9% of the patients bled. Three patients required endoscopic treatment with adrenaline and/or sclerosis injection and another patient also required combined treatment with hemoclips and Endoclot. The 90% required transfusion of 1.3 ± 0.8 red blood cell concentrates. We found no statistically significant differences. The patients who bled had a mean age of 59 years, 10 patients (83.3%) were males, with cirrhosis due to alcohol (33.3%), HCV (25%), cryptogenic (16.7%), OH + HCV (16.7%) and NASH (8.3%). 5 of the 12 patients (41.7%) presented bleeding after the second banding session. 66.7% had signs of hypertensive gastropathy and 41.7% red spots on varicose veins. Regarding the Child-Pugh stage, 41.7% were Child A and B and 16.7% C. 25% had portal thrombosis and 41.7% had ascites at the time of endoscopy. 58.3% were in treatment with PPI and 50% with beta-blockers. An average 4 ± 2 band were placed. The mean platelet count was $81 \pm 40 \times 10^9$ / L, albumin 38 ± 5 g/L and INR of 1.2 ± 0.2 ratio.
Conclusion: Endoscopic esophageal varices band ligation has a 4% incidence of bleeding from eschar. A 33% of the bleeding patients

required endoscopic treatment, a 90% transfusion of packed red blood cells and there was no death. No clinical, analytical or endoscopic factors have been associated with an increased risk of bleeding from eschar.

SAT-292

Association between hospital type and transplant-free survival in patients with cirrhosis receiving transjugular intrahepatic portosystemic shunts: A population-based study

J. Mah[1], Y. Dewit[2], C. Booth[1,2], A. Menard[3], J. Flemming[1,2]. [1]*Queen's University, Medicine, Canada;* [2]*Institute for Clinical Evaluative Sciences, Canada;* [3]*Queen's University, Radiology, Canada*
Email: flemmij@hdh.kari.net

Background and Aims: The transjugular intrahepatic portosystemic shunt (TIPS) procedure is designed to reduce portal pressure in patients with cirrhosis, thereby treating complications of portal hypertension. It has been recently suggested that TIPS performed at high volume centres are associated with improved in-hospital survival. Whether this association persists over the long-term following discharge from hospital has yet to be studied. The aim of this study was to determine the association between the type of hospital (academic vs. community) where the TIPS was performed and long-term survival in the general population of patients with cirrhosis.

Method: We conducted a population-based retrospective cohort study utilizing administrative health care data from Ontario, Canada accessed through the Institute of Comparative Evaluative Sciences. All adult patients with cirrhosis who received a TIPS between January 1, 1998 and December 31, 2015 were included, with follow-up until December 31, 2016. Our primary exposure was hospital type based on whether the TIPS was performed at an academic or community hospital. Liver transplant-free (LTF) survival was described using Kaplan-Meier curves and the log-rank test. The association between hospital type and LTF survival was evaluated using multivariate Cox proportional hazards regression.

Results: Our study cohort consisted of 837 unique patients and was 62% (n = 579) male with a mean age of 57.2 years (SD 10.4). TIPS was performed at an academic hospital for 84.6% (n = 708) and at a community hospital for the remaining 15.4% (n = 129). LTF survival post-TIPS was lower in community hospitals compared to academic hospitals (1 year 48.4% *vs.* 58.9%; 5 years 23.9% *vs.* 32.6%; P < 0.001). Using multivariate Cox regression adjusting for age, sex, comorbidity, and indication for TIPS, patients had a higher hazard of death if their procedure was performed at a community hospital compared to at an academic centre (HR 1.36, 95% CI 1.09–1.69, p = 0.006). Other factors independently associated with mortality included older age (HR 1.03 per year increase, 95% CI 1.02–1.04, p < 0.001), Charlson-Deyo Comorbidity Index ≥4 (HR 1.32, 95% CI 1.08–1.63, p = 0.008), and indication for TIPS related to variceal haemorrhage (HR 1.33, 95% CI 1.11–1.61, p = 0.002).

Conclusion: TIPS performed in a non-academic centres are associated with a higher risk of death following the procedure. These results suggest that patients who require a TIPS may be best served by transferring to an academic centre, if possible. Future research focusing on centralization of TIPS to high-volume academic centres is warranted.

SAT-293

A simple patient-reported instrument can predict development of overt hepatic encephalopathy

M.M. Lauridsen[1], C. Wernberg[1], H. Vilstrup[2], O.B.S. de Muckadell[3], D.M. Heuman[4], J.S. Bajaj[4]. [1]*Hospital of South West Jutland, Department of Gastroenterology and Hepatology, Esbjerg, Denmark;* [2]*Aarhus University Hopsital, Department of Gastroenterology and Hepatology, Aarhus, Denmark;* [3]*Odense Universitetshospital, Department of Gastroenterology and Hepatology, Odense;* [4]*Virginia Commonwealth University Medical Center, Division of Gastroenterology, Hepatology and Nutrition, Richmond, United States*
Email: mettelauridsen@gmail.com

Background and Aims: Minimal hepatic encephalopathy (MHE) impinges on health-related quality of life (HRQoL) and prognosticates overt HE (OHE). However, MHE is rarely diagnosed in practice due to the need for specialized tests. Simple, patient-administered HRQoL questionnaires e.g. sickness impact profile (SIP), could aid in identifying patients with MHE without requiring specialized testing. This approach was tested in a US-based study introducing the SIPCHE score (formula of 4 SIP statements, gender and age; score >0 = abnormal) and was validated in a separate Danish population with a sensitivity of >80% cross-sectionally. However, the utility of a positive SIPCHE score in predicting OHE is unclear. Our aim was to determine the value of a positive SIPCHE score in the prediction of OHE development.

Method: Cirrhotic outpatients without OHE completed specialized cognitive testing with Continuous Reaction Time (CRT) and Portosystemic Hepatic Encephalopathy Score (PHES) and SIP at baseline. Abnormal CRT and/or PHES diagnosed MHE. SIP consists of 136 yes/no questions inquiring about HRQoL. The SIPCHE score was calculated from gender, age and the answer to 4 specific SIP statements related to balance problems, loss of appetite and irritable, impatient or passive behaviour. The patients were followed subsequently for OHE defined as grade 2 or higher on West Haven Criteria requiring hospitalizations.

Results: We included 110 patients (age 60 years on average, mean MELD 11.4, 80% blue-collar workers, 95% alcohol aetiology) and 64% were diagnosed with MHE on specialized tests. These patients had a worse HRQoL in SIP categories and statements addressing balance problems, vegetative symptoms and the need for assistance in daily activities. Mean follow up time was 2.7 years (SD 40 days). 33/110 (30%) of patients developed OHE during follow up – 8 experienced more than 1 episode. Patients with abnormal SIPCHE experienced HE episodes more frequently during follow up (35% vs. 14%, p = 0.05). On multivariate analysis including Child Pugh score (OR 1.6, 95% CI 1.2–2.1), CRT index (0.98, 95% CI 0.4–2.2), PHES (OR 1.02, 95% CI 0.9–1.1), and years of education (OR 1.1, 95% CI 0.9–1.3), SIPCHE (OR 3.5 95% CI 1.0–12), remained a significant predictive factor for OHE development along with Child Pugh Score.

Conclusion: The SIPCHE, a tool based on patient-reported instruments and demographics, can predict the development of future OHE in cirrhotic outpatients while avoiding the need for specialized tests. Patient-reported instruments such as SIPCHE could increase the diagnosis of MHE and improve prediction for OHE in cirrhotic patients.

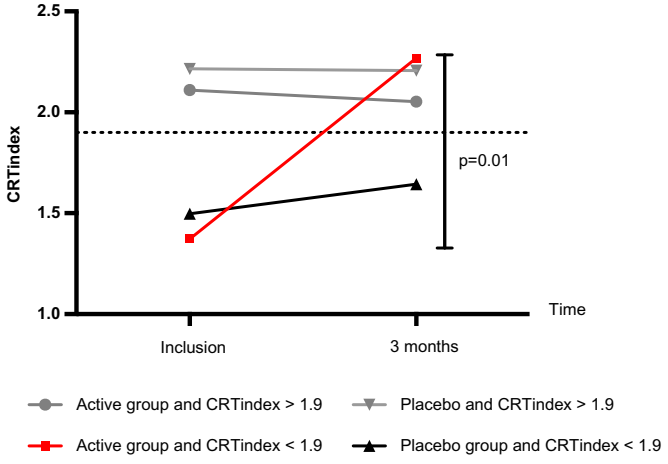
SAT-294

The continuous reaction time test for minimal hepatic encephalopathy validated by a randomized controlled multimodal intervention

M.M. Lauridsen[1], J. Gram[2], O.B.S. de Muckadell[3], H. Vilstrup[4]. [1]*Hospital of South West Jutland, Department of Gastroenterology and Hepatology, Denmark;* [2]*Hospital of South West Jutland, Department of Endocrinology, Denmark;* [3]*Odense Universitetshospital, Department of Gastroenterology and Hepatology, Denmark;* [4]*Aarhus University Hopsital, Department of Gastroenterology and Hepatology, Denmark*
Email: mettelauridsen@gmail.com

Background and Aims: Minimal hepatic encephalopathy (MHE) is clinically undetectable and the diagnosis requires psychometric tests. However, a lack of clarity exists as to whether the tests are in fact able to detect changes in cognition. Our aim was to examine if the continuous reaction time test (CRT) can detect changes in cognition with anti-HE intervention in patients with cirrhosis and without clinically manifest hepatic encephalopathy (HE).

Method: Firstly, we conducted a reproducibility analysis and secondly measured change in CRT induced by anti-HE treatment in a randomized controlled pilot study: We stratified 44 patients with liver cirrhosis and without clinically manifest HE according to a normal (n = 22) or abnormal (n = 22) CRT. Each stratum was then block randomized to receive multimodal anti-HE intervention (lactulose + branched-chain amino acids + rifaximin) or triple placebos for 3 months in a double-blinded fashion. The CRT is a simple PC-based test and the test result, the CRT index (normal threshold >1.9), describes the patient's stability of alertness during the 10–minute test. Our study outcome was the change in CRT index in each group at study exit. The portosystemic encephalopathy (PSE) test, a paper-and-pencil test battery (normal threshold above -5), was used as a comparator test according to international guidelines.
Results: The patients with an abnormal CRT index who were randomized to receive the active intervention normalized or improved their CRT index (mean change 0.92 ± 0.29, p = 0.01). Additionally, their PSE improved (change 3.85 ± 1.83, p = 0.03). There was no such effect in any of the other study groups



Conclusion: In this cohort of patients with liver cirrhosis and no manifest HE, the CRT identified a group in whom cognition improved with intensive anti-HE intervention. This finding infers that the CRT can detect a response to treatment and might help in selecting patients for treatment.

SAT-295

Transjugular intrahepatic portosystemic shunt versus beta-blocker and/or endotherapy for prevention of variceal rebleeding in adults with EHPVO

H. Chen, J. Fan, S. Tang, C. He, Y. Lv, Q. Wang, H. Liu, J. Yuan, B. Luo, T. Yu, X. Yuan, Z. Yin, G. Han. *National clinical research center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of liver Diseases and Digestive interventional radiology, Xi'an, China*
Email: qychenhui@163.com

Background and Aims: Optimal strategy for the prevention of variceal rebleeding in adults with extrahepatic portal vein obstruction (EHPVO) has never been established due to extremely insufficient comparative studies between different modalities. The present study aimed to compare transjugular intrahepatic portosystemic shunt (TIPS) versus non-selective β-blocker and/or endoscopic therapy for the prevention of variceal rebleeding among patients with EHPVO.
Method: Between March 2002 and June 2016, 127 consecutive adult patients with EHPVO and a recent variceal bleeding were included. We compared the clinically significant variceal rebleeding, recanalization of the portal venous system, hepatic encephalopathy (HE) and survival between successful TIPS (group A, n = 27), failed TIPS (group B, n = 27) and NSBB and/or endoscopic (group C, n = 73).
Results: During a median follow-up of 35.3 months, cumulative incidence of clinically significant variceal rebleeding was similar between the groups (34.6%, 39.5% and 29.3% at 5-years for group A, B and C, respectively). Group A has a signifcantly higher portal vein recanalization rate (65.2% *vs* 0% and 0%) and a relatively lower recurrence rate (8.7% *vs* 34.8% and 14.3%) compared with group B and C (p < 0.001). There were no statistically signifcant differences in spontaneous overt HE (3.7% *vs.* 0% and 1.4%; p = 0.54) and survival (83.0%, 88% and 94.3% at 5-years, respectively, p = 0.50).

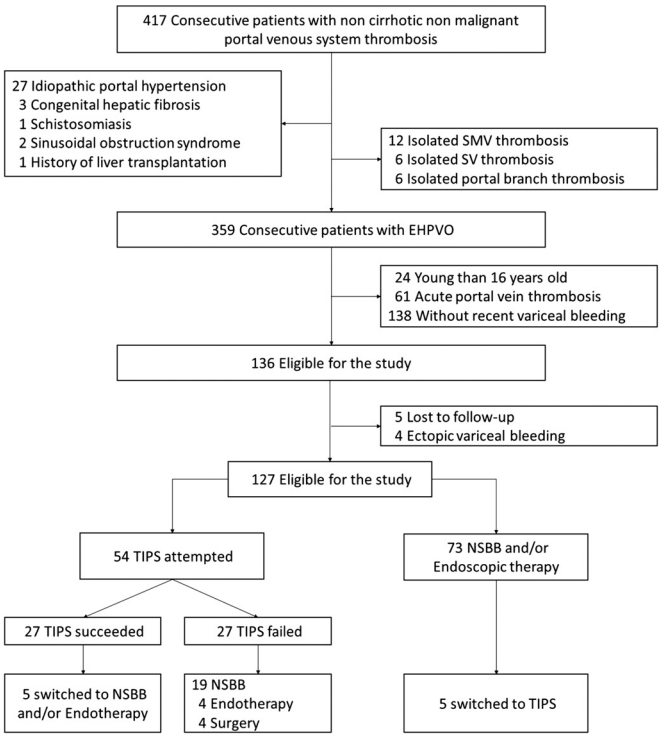


Figure 1: Flow chart showing patients' enrollment and its distribution between groups. EHPVO, extrahepatic portal vein obstruction; NSBB, non-selective beta-blockers; SMV, superior mesenteric vein; SV, splenic vein; TIPS, transjugular intrahepatic portosystemic shunt.

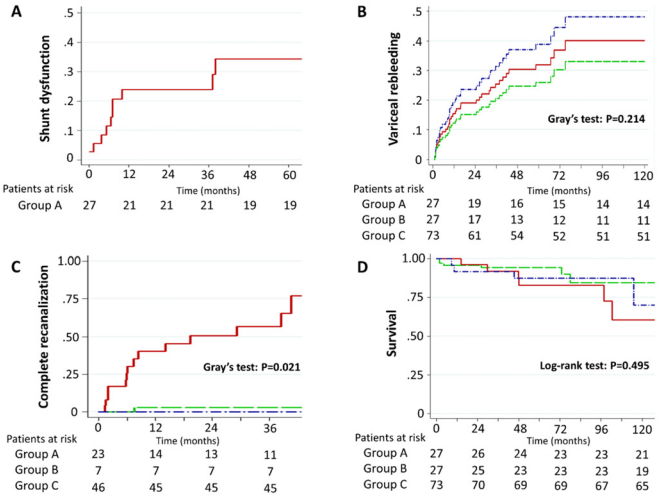

Figure 2: Cumulative incidence of (*A*) shunt dysfunction, (*B*) clinically significant variceal rebleeding, (*C*) complete Recanalization of portal venous system and (*D*) survival in Group A (continuous red line), Group B (dash dot blue line) and Group C (long dash green line). Note: Group A, successful TIPS; Group B, failed TIPS; Group C, NSBB and/or endotherapy.

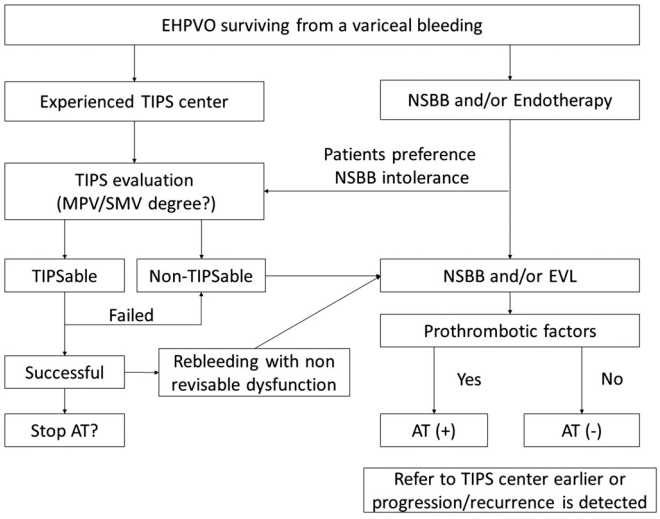

Figure 3: Proposed algorithm for the prophylaxis of variceal rebleeding in adults with EHPVO. AT, anticoagulation; EHPVO, extrahepatic portal vein obstruction; NSBB, non-selective beta-blockers; MPV, main portal vein; SMV, superior mesenteric vein; TIPS, transjugular intrahepatic portosystemic shunt.

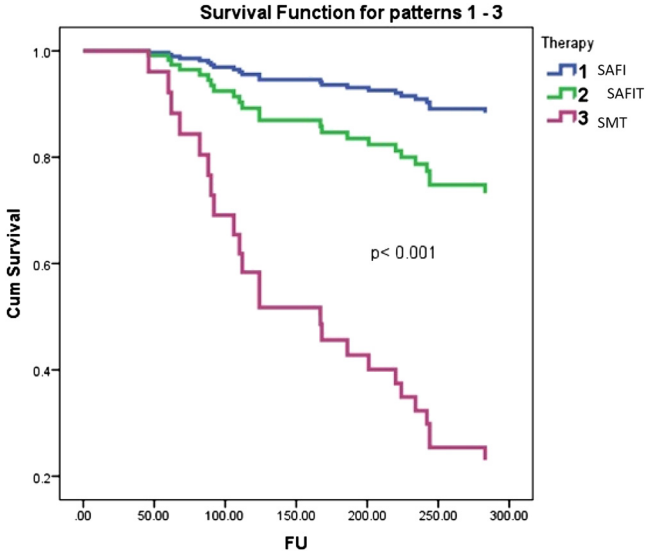
Conclusion: TIPS is as effective as NSBB and/or endoscopic therapy for the prevention of variceal rebleeding without increasing the risk of spontaneous overt HE and mortality in adults with EHPVO. Furthermore, TIPS has unique role in recanalizing obstructed portal vein and prevent progression and additional portal hypertensive complications.

SAT-296

Slow continuous albumin Infusion with furosemide with or without terlipressin in cirrhotic patients with refractory ascites

G. Pandey[1], M. Durgappa[2], A. Kumar[2], A. Singh[2], A. Nehra[2], K. Vp[2], P. Mishra[3], S. Mohindra[2], V. Saraswat[2]. *[1]Sanjay Gandhi Institute of Medical S, Hepatology and Gastroenterology, Lucknow, India; [2]Sanjay Gandhi Institute of Medical S, Gastroenterology, Lucknow, India; [3]Sanjay Gandhi Institute of Medical S, Biostatics, Lucknow, India*
Email: drgauravpandey@yahoo.com

Background and Aims: Mobilization of refractory ascites (RA)is challenging in decompensated cirrhosis. To study efficacy and safety of low-dose furosemide with albumin ± Terlipressin (SAFI ± T) to a response-guided protocol to achieve urinary sodium (UNa+) >80 mmol/L and continued till clinically complete mobilisation in RA
Method: Patients with RA (diuretic intractable or resistant) undergoing multiple sessions of large volume paracentesis (LVP) in the previous 3 months were enrolled in a 5:1 ratio. Arm 1 received SAFI ± T. Central line was placed in oliguric patients and infusions of Furosemide at 2 mg/hour and albumin at 2 g/hour (20 g/d) were started. Urine samples were collected 12 hourly for electrolytes. Furosemide infusion rate was increased by 1 mg/h, (maximum 5 mg/h), if UNa+ excretion was < 80 mmol at 24 hours. All patients received aggressive potassium supplementation. If, after 48 hours UNa+ < 80 mmol/L, terlipressin infusion at 2 mg/24 hours was started after correcting anemia and ECG monitoring. Terlipressin was increased by 1 mg/12th hourly in a response guided manner to a maximum of 6 mg/24 hours. Arm 2 received LVP and oral diuretics. After clinically complete mobilization, patients were stepped down to oral diuretics for discharge with dose adjusted to maintain UNa+ > 80 mmol/24 hours.
Results: 87 patients (intractable 58, resistant 29; arm 1: arm 2 = 73:14; M:F-60:30) were enrolled between 2013 and 2016. Mean age (46.7 ± 11.7 years *vs.* 49 ± 9.4 years), baseline mean CTP score (11.4 ± 1.4 *vs.* 12 ± 0.9), MELD (23 ± 5.7 *vs.* 24.3 ± 5.6) were similar in the two arms, as was the etiology. Arm 1 included 8 patients with hepatic hydrothorax (HH), 18 with spontaneous bacterial peritonitis (SBP) and 13 with hepatic encephalopathy grades 1–2 (HE). All patients in arm 1, but none in arm 2, were clinically dry in a median period of 10.8 ± 2.5 days. Only in Arm Imean urinary sodium excretion in increased from 17.2 ± 5.9 mmol/d to 171.2 ± 61.3 (p = 0.001), urine output from baseline of 563 ± 275 ml to maximal volume of 2972.08 ± 803 ml/day (p = 0.001). Weight decreased by mean of 14.8 ± 3.7 kgs. At end of treatment (EOT), serum sodium (130 ± 7 to 131.8 ± 4.7 meq/l; p = 0.00) and serum creatinine improved (1.6 ± 1.2 to 0.94 ± 0.43 mg/dl), as did e-GFR from 63.4 ± 50 ml/min to 93.9 ± 43.7 ml/min (p = 0.023). At mean follow up of 287 ± 83 days survival in Arm 1 was 88% for SAFI, 72% for SAFIT and 33% in Arm 2. In Arm 1 survival with and without HH was 82.8% *vs.* 62.5% and with and without SBP was 81.3% *vs.* 75%.



Conclusion: SAFI ± T is a safe and effective treatment was LVP-dependent RA, even in difficult –to-treat subsets such as those with HH, SBP and HE.

SAT-297

A prospective evaluation of symptom burden, opioid risk in cirrhosis patients

M. Niazi[1], S. Chavda[2], E. Hjartarson[2], R. Bailey[3], A. Brisebois[2], P. Tandon[1]. *[1]University of Alberta Hospital, Gastroenterology and Hepatology; [2]University of Alberta Hospital, Medicine; [3]Royal Alexandra Hospital, Gastroenterology and hepatology*
Email: ptandon@ualberta.ca

Background and Aims: Cirrhosis is associated with magnitude of symptoms leading to disability and poor quality of life. In literature it has been shown that significant number of cirrhotic patients experience chronic pain and pain-related disability. Although opioids are effective in many cases, opioid use has been associated with increased frequency of hepatic encephalopathy, cost related to hospital admission and longer hospital stay. In other chronic disease population including cancer, non-pharmacological therapies such as mindfulness-based stress reduction therapy (MBSR) have been efficacious for reducing pain, emotional distress, and fatigue. Patient interest, current use as well as perceived benefit and barriers for utilization of non-pharmacological therapies are unclear in cirrhosis patients. Within a population of patients with cirrhosis, we aimed to: (1) assess symptom burden; (2) risk of opioid dependency; (3) willingness to consider non-pharmacological therapy for symptom management.
Method: In a prospective study, we recruited 135 patients with chronic liver disease attending Cirrhosis Care Clinic at the University

of Alberta Hospital and Royal Alexandra Hospital. Our inclusion criterion for the study was documented cirrhosis on imaging in individuals 18 years of age and older. We collected data on patient demographics, symptom burden using the Edmonton Symptoms Assessment Scale (ESAS-r), perceived overall wellbeing using Euroquol Visual Analogue Scale (EQ-VAS), and risk of opioid dependency using Opioid Risk Tool Calculator. In addition, we assessed patients' familiarity with non-pharmacological therapy, willingness to try these therapies and any barriers preventing them from utilizing non-pharmacological treatment modalities.

Results: 135 patients were prospectively recruited, mean age of 60 years with 62% male patients, Child Pugh Class: A (58%), B (36%), and C (6%). Overall health status using EQ-VAS (EQ-VAS 0–100 Scale) was rated at 63.9 ± 22. Most commonly reported symptoms included: tiredness (52%), mood disorder (40%), drowsiness (36%), and pain (22%). In our study, 33% of the patients had moderate and 24% had severe opioid risk score, with higher scores being correlated with increased risk for opioid dependency and future opioid abuse. Eighty-five percent (85%) of patients were willing to learn about non-pharmacological approaches for their symptoms.

Conclusion: Despite the relatively well-compensated status of our cirrhosis cohort, symptom burden was significant, and quality of life was low. In our study, we observed significant risk of opioid dependency. Patients have a high willingness to proceed with non-pharmacological therapy, with only few noted barriers. Therefore, more research is needed surrounding non-pharmacological therapeutic options in cirrhosis patients.

SAT-298

Critical flicker frequency improves its diagnostic and predictive accuracy of hepatic encephalopathy by decreasing the dispersion between measures

C. Sendra[1], V. Aguilera[2], M.C. Rico[1,3], R. Millan[1,3], A. Gil-Gomez[1,3], J. Ampuero[1,3,4], M.R. Gomez[1,3,4]. *[1]Digestive Diseases Unit. Virgen del Rocío University Hospital; [2]Huelva Hospital Complex. Digestive Diseases Unit, Spain; [3]Institute of Biomedicine of Seville (IBIS); [4]CIBERehd, Spain*
Email: csendra.fernandez@gmail.com

Background and Aims: To determine the utility of using quality criteria to improve the ability of critical flicker frequency (CFF) to detect minimal hepatic encephalopathy (MHE) and predict overt hepatic encephalopathy (OHE).

Method: Prospective study including 115 patients with liver cirrhosis. CFF resulted from averaging ten consecutive measurements (pathological <=39 Hz). MHE was detected by the psychometrical hepatic encephalopathy score (PHES) (pathological <–4 points). We analyzed some quality criteria of CFF related to dispersion values: (a) median; (b) interquartile range (IQR); and (c) standard deviation (SD). Sensitivity (Se), specificity (Sp), positive (PPV) and negative predicted values (NPV) of CFF were calculated to detect MHE according to the presence of quality criteria. OHE was predicted by CFF (according to the best quality criteria) during a follow-up of 1.6 ± 1.1 years.

Results: MHE was detected in 40.9% of patients and 16.8% developed an episode of OHE. A lack of concordance between CFF and PHES was observed in 36.5% (42/115) of patients. The SD was the dispersion value associated with the greater discordance. MHE was correctly classified by CFF in 62.6% (72/115) of patients in the absence of any quality criteria (Se 51%; Sp 70.6%; PPV 54.5%; NPV 67.6%). If CFF was adjusted by SD < 2, the percentage of patients properly classified increased to 69.6% (55/79) (Se 71.9%; Sp 68.1%; PPV 60.5%; VPN 78%). However, the number of well-classified patients was 47.2% (11/36) (Se 6.7%; Sp 76.2%; VPP 16.7%; VPN 53.5%) when SD was >=2. CFF <= 39 Hz was associated to the development of OHE during the follow-up in patients with SD < 2 (28.2% (11/39) *vs.* FCP > 39 Hz 8,7% (4/46); logRank 8.301, p = 0.004), but did not in those with SD >= 2 (14.3% (1/7) *vs.* FCP > 39 Hz 10% (3/30); logRank 0.007, p = 0.935) (Figure).

Conclusion: CFF accuracy to detect MHE and predict OHE was superior when the dispersion between measures was low, obtaining a greater diagnostic accuracy and higher quality results when the standard deviation was lower than 2. CFF assessment, adjusted by standard deviation, will allow solving some of the limitations of this technique.

SAT-299

Four years outcomes of Baveno VI low risk cirrhotic patients

P. Pollo-Flores[1], M. Rudler[2], M. Munteanu[3], A. Ngo[4], Y. Ngo[4], D. Thabut[5], T. Poynard[6]. *[1]CAPES, UFF Internal Medicine, Niteroi, Brazil; [2]Hôpital Pitié Salpétrière, UPMC, Paris, France; [3]Hôpital Pitié Salpétrière, Biopredictive, Paris, France; [4]Biopredictive, Paris, France; [5]UPMC, Université Pierre et Marie Curie, Hôpital Pitié-Salpétrière, Paris, France; [6]UPMC Université Pierre et Marie Curie, Hôpital Pitié-Salpétrière, Paris, France*
Email: priscilapollo96@gmail.com

Background and Aims: Baveno VI statement established that screening endoscopy can be avoided in patients with compensated chronic liver disease, platelet count >150.000/mm^3 and liver stiffness measurement <20 kPa. However, there is few data regarding further development of complications of cirrhosis and survival in patients at low risk. The aim of this study was to evaluate 4 years survival and complications in patients at low risk according to Baveno VI criteria.

Method: Retrospective study was conducted in cirrhotic patients consecutively evaluated in a tertiary center between 2012 and 2017. Patients with compensated cirrhosis (defined by an applicable liver

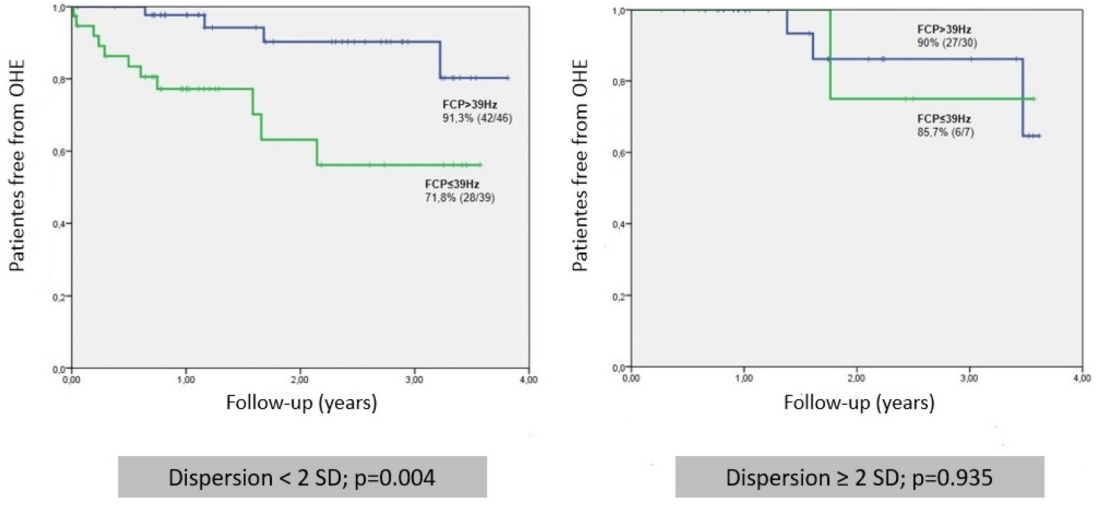


Figure: (abstract: SAT-298)

stiffness measure (LS) >12.5 kPa) were included. They were divided into two groups according to BAVENO VI criteria: Baveno VI positive (Bav+) with platelet count <150.000/mm^3 and FS >20 kpa, Baveno VI negative (Bav-) with platelet count >150.000 mm^3 or FS <20 kPa. Complications of cirrhosis including ascites, hepatic encephalopathy, jaundice, variceal bleeding and hepatocellular carcinoma were recorded. Survival was compared between groups.

Results: 241 patients with mean age of 57 yrs, male gender 70,5% and Child-Pugh(CP) score 5. Etiologies were 52% HCV, 18% NASH, 11% alcohol, 10% HBV and 9% other causes. One hundred and fifty-six patients (65%) were classified in group Bav+ and 85 (35%) in Bav- with mean age of 57 years in Bav+ and in Bav-; Preponderance of male gender was observed in both groups, 70,5%, Bav+ and Bav-; Etiologies HCV and alcohol were significantly more frequently in Bav+ than Bav-. High risk varices were observed in 14% of patients:1 patient in Bav- (1,2%) and 33 patients in Bav+ (21%), p = 0,004. In Bav+ CP median was 5.2 *vs.* 5.1 in Bav– (p = 0,12). Bav+ vs Bav– showed Platelet count (137.000 U/mm^3 *vs.* 214. 000 U/mm^3, p = 0.004) and LS measure (23.7 *vs.* 14.5 kPa, respectively, p = 0,0004) different; sixty-one (25%) patients were submitted to HCV treatment and 50 (21%) acquired sustained virological response (82%SVR). During follow-up, in Bav + group 5 patients developed encephalopathy, 4 variceal bleeding, 12 ascites and 14 CHC; in Bav- nobody developed encephalopathy (p = 0.09) or variceal bleeding (p = 0.13), 3 patients developed ascites (p = 0,27) and 5 CHC (p = 0,39) All portal hypertension complications considered, excluding hepatocellular carcinoma, tended to be more common in Bav+ patients (p = 0.06); In HCV patients PH complications were also more common in Bav+ (p = 0,05); In Bav+, 2 deaths (1%) were observed and no deaths were observed in Bav- group (p = 0.29).

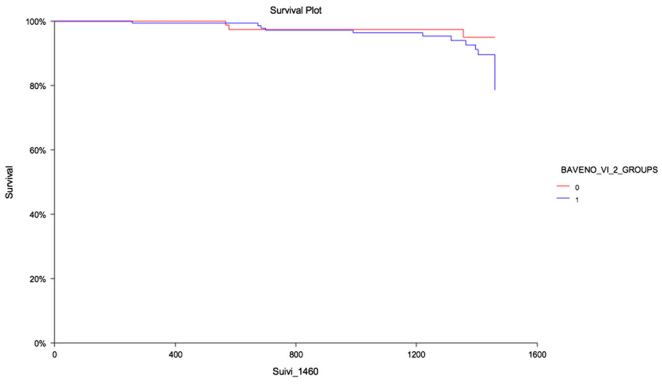

Figure: Portal Hypertension complications (follow-up of 4 years)

Conclusion: In this study, followed for 4 years, Bav- patients did not presented variceal bleeding, liver encephalopathy or death. All portal hypertension complications tended to be less often observed in Bav- group. Therefore, Baveno's criteria seems to be a reliable tool for predicting cirrhosis complications.

SAT-300

A novel sonographic parameter for the quantification of muscle mass in cirrhosis

K. Kobayashi, H. Maruyama, S. Kiyono, S. Ogasawara, E. Suzuki, Y. Ooka, T. Chiba, N. Kato. *Chiba University Graduate School of Medicine, Department of Gastroenterology, Japan*
Email: maru-cib@umin.ac.jp

Background and Aims: Sarcopenia is the common complication in patients with cirrhosis. As it is a significant prognostic factor, muscle mass quantification is an important issue in their practical care. Computed tomography (CT) is frequently used as a standard tool to evaluate the muscle volume. However, repeatedly available less-invasive procedure without radiation exposure may be preferred for the long-term clinical course. The aim of this study was to propose ultrasound-based parameter for the diagnosis of muscle mass loss (MML) in Japanese cirrhosis patients.

Method: This is an IRB-approved cross-sectional study (October 2013 to March 2017) after obtaining written informed consent. Consecutive cirrhosis patients who underwent both ultrasound (US) and CT were participated in our University Hospital. The study used the skeletal muscle index at the L3 level (L3-SMI) on CT as a standard to diagnose MML with the cut-off values of 42 cm^2/m^2 for males and 38 cm^2/m^2 for females according to the recent previous report from Japan [Nishikawa et al. Hepatol Res 2016]. Transcutaneous US was used to demonstrate a cross-section of the right iliopsoas muscle, and the iliopsoas muscle index (IP index) was defined by the iliopsoas muscle area/height^2 (mm^2/m^2).

Results: There were 248 patients with cirrhosis (150 males and 98 females), and 83 patients (33.5%; 41 males and 42 females) were diagnosed as having MML. The iliopsoas muscle was successfully detected in all subjects by US. The iliopsoas muscle area showed correlations between US and CT in males (r = 0.905, $P < 0.0001$) and in females (r = 0.905, $P < 0.0001$). Also, the L3-SMI and the IP index showed correlations in males (r = 0.707, $P < 0.0001$) and in females (r = 0.714, $P < 0.0001$). The IP index was lower in patients with MML than in those without: males (154.0 ± 42.8 *vs.* 234.7 ± 70.7, $P < 0.0001$) and females (150.3 ± 35.7 *vs.* 239.7 ± 70.6, $P < 0.0001$). Multivariate analysis detected body mass index and IP index as independent factors for MML, in both males and females. Sensitivity, specificity, and area under the receiver operating characteristic curve by IP index to detect MML were 78.1%, 76.2%, and 0.851, respectively, with the best cut-off value of 189.2 for males, and 83.3%, 80.4%, and 0.882, respectively, with the best cut-off value of 180.6 for females.

Conclusion: The study clearly reported the clinical value of the IP index by transcutaneous US as a novel diagnostic parameter for MML in cirrhosis.

SAT-301

Repeated episodes of acute kidney injury on the transplant waiting list: Impact on post-liver transplantation renal and patient outcomes

S. Neong[1], R. Rajakumar[1], N. Selzner[1], F. Wong[2]. [1]*Toronto General Hospital, Multi-Organ Transplant, Toronto, Canada;* [2]*Toronto General Hospital, Division of Gastroenterology, Dept of Medicine, Toronto, Canada*
Email: sagigal314@hotmail.com

Background and Aims: It is unclear whether repeated episodes of AKI pre-transplant, defined as an increase in serum creatinine (sCr) of >26.5 µmol/L in ≤48 hours or >50% increase from known baseline, will cumulatively & negatively impact patient and renal outcomes post-transplant. We aim to evaluate impact of repeated AKI episodes in the 18 months prior to liver transplantation on renal and patient outcomes post-transplant.

Method: Single-centre retrospective study of prospectively collected data on consecutive adults receiving single organ liver transplant between 01/01/2007 to 31/12/2014 was conducted. Data retrieved included demographics, every laboratory tests ever performed, co-morbidities, hospital admissions and pre-and post-transplant course.

Results: 194/402 cirrhotics with ascites wait-listed for liver transplantation with AKI were included. They were mostly middle-aged men [aged 54 (49–60)] (70%) with alcoholic cirrhosis (61%) with similar baseline demographics divided into groups of 1, 2, 3, ≥4 AKI episodes. Patients with ≥4 episodes of AKI have significantly higher MELD score at listing [23 (17–34)] (p = 0.039) and at transplant [31 (25–37)] (p < 0.001) with shorter time to transplant [42 days (7–162)] (p = 0.089). Infection was not statistically more common amongst the higher number of AKI groups. Patients with higher number of AKI episodes had significantly higher AKI stages, with higher peak and delta sCr within 48 hours (all p < 0.001), and more likely to have AKI progression and less likely to reverse their AKI with

Table 1: (abstract: SAT-301).

	AKI episodes				
Median (IQR)	1 (n = 85)	2 (n = 41)	3 (n = 20)	>= 4 (n = 48)	p-value
AKI stage					
1	71 (83.5%)	32 (78.0%)	17 (85.0%)	42 (87.5%)	0.69
2	10 (11.8%)	14 (34.1%)	14 (70.0%)	30 (62.5%)	<0.001
3	4 (4.7%)	8 (19.5%)	8 (40.0%)	29 (60.4%)	<0.001
Peak sCr	133 (115–167)	196 (148–262)	286 (183–379)	360 (250–479)	<0.001
Delta sCr in 48h	49 (38–63)	73 (49–142)	103 (74–174)	138 (98–273)	<0.001
AKI stage progression	0 (0.0%)	7 (17.1%)	13 (65.0%)	26 (54.2%)	<0.001
Response					
Full	65 (76.5%)	29 (70.7%)	15 (75.0%)	38 (79.2%)	0.83
Partial	10 (11.8%)	18 (43.9%)	7 (35.0%)	29 (60.4%)	<0.001
No	10 (11.8%)	17 (41.5%)	17 (85.0%)	42 (87.5%)	<0.001
Need for RRT					
Pre-transplant	1 (1.2%)	6 (14.6%)	4 (20.0%)	16 (33.3%)	<0.001
Post-transplant	2 (2.4%)	6 (14.6%)	5 (25.0%)	15 (31.3%)	<0.001
Survival					
12-month	94%	88%	80%	77%	0.030

treatment (all p < 0.001), associated with reduced post-transplant survival at 12 months.

Conclusion: Repeated episodes of AKI are detrimental to patients wait-listed for liver transplant. Greater efforts should be made to prevent recurrent episodes of AKI on the transplant waiting list.

SAT-302

Eradication of hepatitis C virus in patients with decompensated cirrhosis does not improve the management of ascites after one year of follow-up

A. Juanola[1,2,3,4], I. Graupera[1,2,3,4], A. Risso[1,2,3], G. Mezzano[1,2], S. Lens[1,2,3,4], Z. Mariño[1,2,4], X. Ariza[1,2,3,4], E. Solà[1,2,3], V. Hernandez-Gea[1,2,3,4], X. Forns[1,2,3,4], P. Ginès[1,2,3,4]. *[1]Hospital Clinic de Barcelona, Liver Unit, BARCELONA, Spain; [2]University of Barcelona, Faculty of Medicine and Health Sciences, BARCELONA, Spain; [3]IDIBAPS, BARCELONA, Spain; [4]CIBEReHD, BARCELONA, Spain*
Email: pgines@clinic.ub.es

Background and Aim: Treatment of HCV infection is effective in compensated cirrhosis and prevents decompensation in most patients. However, the effects of HCV eradication in decompensated cirrhosis, particularly the impact on the management of ascites, is less defined. We investigated whether treatment with oral antiviral drugs improves the management of ascites in decompensated cirrhotic patients.

Methods: A cohort of 42 consecutive patients with HCV cirrhosis and ascites treated with interferon-free regimes was analyzed. Patients with Child A or B cirrhosis were included. Primary endpoints were average dose of diuretics required, proportion of patients in whom diuretics could be withdrawn, and need for large-volume paracentesis (LVP). Secondary endpoints were hepatic venous pressure gradient (HVPG), which was measured in 18 patients before and after 6 months, and liver function. Endpoints were analyzed within 6 months before therapy and for two consecutive periods of 6 months (0–6 and 7–12) after SVR12.

Results: SVR12 was achieved in all patients. Two patients died (months 0–6) and 2 were lost to follow-up (months 7–12). HCV eradication was neither associated with reduction in the mean dose of diuretics required (furosemide: 20 ± 29, 30 ± 30 and 31 ± 35 mg/day; spironolactone: 53 ± 43, 70 ± 58 and 73 ± 57 mg/day at 6 months before therapy and 0–6 and 7–12 months after SVR12, respectively; p = NS for both) nor in the need for LVP. Diuretics could be withdrawn only in 3 of the 42 (7%) patients. HVPG did not change significantly (18.6 ± 4.8 vs 19.4 ± 5.3 mmHg; p = 0.84) and decreased below the threshold value of 10 mmHg in only one patient. Child-Pugh score decreased slightly but significantly during follow-up (7.3 ± 1.1, 6.6 ± 1.3 and 6.6 ± 1.3, respectively; p = 0.02), due to a significant reduction in serum bilirubin and a significant increase in serum albumin. By contrast, MELD score did not change significantly (12.9 ± 3, 12.2 ± 2.9, 12.3 ± 3, respectively, p = 0.12).

Conclusions: Eradication of HCV in patients with decompensated cirrhosis improves liver function but this is not associated with better management of ascites within 1-yr period after SVR12. The latter may be related to pathophysiology of ascites, which is related to portal hypertension (and thus severe architectural changes in the liver). Nonetheless, further studies are needed to investigate whether ascites management improves after a longer follow-up.

SAT-303

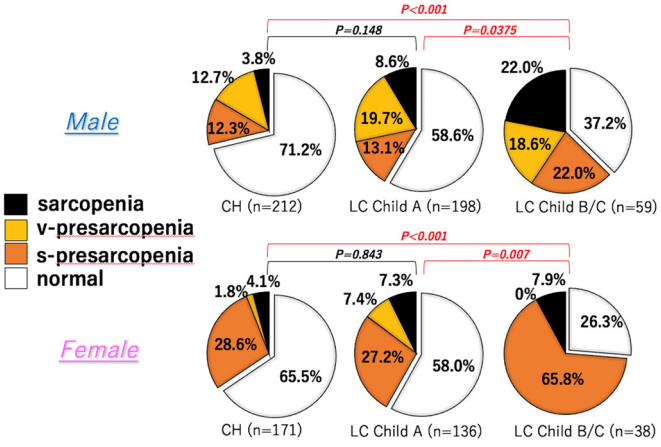
Gender differences regarding sarcopenia development in chronic liver disease

A. Hiraoka[1], K. Michitaka[2], T. Ninomiya[3], H. Masashi[4], B. Matsuura[5], M. Abe[5], Y. Hiasa[6]. *[1]Ehime Prefectural Central Hospital, Gastroenterology Center, Matsuyama, Japan; [2]Ehime Prefectural Central Hospital, Gastroenterology enter, Japan; [3]Ehime Prefectural Central Hospital, Gastroenterology Center, Japan; [4]Ehime University Graduate School of Medicine, Touon, Japan; [5]Ehime University Graduate School of Medicine, Departments of Gastroenterology and Metabology, Japan; [6]Ehime University, Gastroenterology and Metabology, Toon, Ehime, Japan*
Email: hirage@gmail.com

Background and Aims: In chronic liver disease (CLD) patients, sarcopenia is defined by decreased muscle strength and muscle volume loss according to the European and Asian diagnostic criteria for sarcopenia (EWGSOP/AWGS) and Japanese Society of Hepatology (JSH) for patients with CLD. However, few studies have investigated gender differences in regard to sarcopenia. We aimed to elucidate clinical features in male and female CLD patients with muscle volume loss and decreased muscle strength.

Method: From April to September 2015, 807 Japanese patients with CLD were enrolled (males 466, females 341). Muscle volume loss (v-presarcopenia) was evaluated by a previously reported method using psoas muscle area and height [psoas index (PSI): psoas muscle area (cm^2)/height $(m)^2$] based on computed tomography findings (cut-off value: males 4.24, females 2.50 cm^2/m^2). Decreased muscle strength (s-presarcopenia) was determined using the criteria for handgrip strength of the JSH for CLD (males 26, females 18 kg). When patients had findings indicating both v- and s-presarcopenia, they were diagnosed with sarcopenia in the present study. Clinical features for each gender were then investigated.

Results: The median age for males was 67 years [interquartile range (IQR): 59–73] and for females was 69 years (IQR: 64–76). The proportions of male patients with chronic hepatitis (CH), and liver cirrhosis (LC) Child-Pugh class A and B/C were 45.5%, 41.8%, and 12.7%, respectively, while those of female patients were 49.9%, 39.3%, and 10.9%, respectively. The frequency of sarcopenia, and s- and v-presarcopenia regardless of CLD grade was 7.9%, 13.5%, and 16.5%, respectively, for males, and 5.6%, 32.3%, and 3.8%, respectively, for females. The frequency of s-presarcopenia was higher in females ($P < 0.001$), whereas that of v-presarcopenia was higher in males ($P < 0.001$). The relationship between PSI and handgrip strength was more significant in males ($r = 0.284$, $P < 0.001$) as compared to females ($r = 0.127$, $P = 0.019$), while that between CT value and handgrip strength was similar between males ($r = 0.236$, $P < 0.001$) and females ($r = 0.274$, $P < 0.001$).



Conclusion: In CLD patients, the 2 types of pre-sarcopenia were not rare regardless of gender, though differences between males and females may exist in regard to ratios of pre-sarcopenia type.

SAT-304

Assessment of subclinical hepatic encephalopathy by using EncephalApp Stroop test and brain MRI

I.-C. Lupescu[1], S. Iacob[2,3], L. Gheorghe[2,3]. [1]*Fundeni Clinical Institute, Neurology, Bucharest, Sector 2, Romania;* [2]*Fundeni Clinical Institute, Gastroenterology and Hepatology, Bucharest, Sector 2, Romania;* [3]*Carol Davila University of Medicine and Pharmacy, Gastroenterology and Hepatology, București, Romania*
Email: ioan.cristian.lupescu@gmail.com

Background and Aims: Subclinical hepatic encephalopathy remains difficult to assess, despite numerous psychometric and paraclinical tests available. New possibilities can emerge with advancement in portable devices, through the development of applications that allow rapid testing of cognitive functions.
Method: We evaluated 65 cirrhotic patients and 15 controls using the new EncephalApp Stroop test on an Apple iPad Mini 4. All participants had a MMSE ≥24 and presented neither overt hepatic encephalopathy nor other neurologic/psychiatric conditions at the time of testing. Brain MRI (including MR-spectroscopy) was also performed in 25 of the patients.
Results: Mean age for cirrhotic group was 51.8 ± 10.4 years and 69.2% were males; mean age for controls was 47.3 ± 13.9 years. Mean Stroop result (On + Off) was 170.54 ± 30.6 seconds. Mean MELD score was 14 ± 6. Stroop results correlated positively with age ($p < 0.0001$) and MELD score ($p = 0.01$); there was a negative association with haemoglobin ($p = 0.029$) and cholesterol levels ($p = 0.026$). Mean Stroop results varied significantly ($p = 0.0003$) between age groups: patients ≤45 years scored 155.97 ± 23.42 seconds, those between 46 and 55 years scored 159.01 ± 21.22 and patients with 56–65 years scored 189.35 ± 34.89. Stroop results varied significantly ($p = 0.01$) between Child A (156.81 sec) and Child B/C patients (173.86 sec). There was a statistically significant difference ($p = 0.00006$) between mean Stroop result of controls (138.85 ± 17.84 seconds) and that of cirrhotic patients. Brain MRI revealed Globus pallidus abnormalities in the form of T1 hyperintensities ± SWI hypointensities, with raised glutamate and lowered myo-inositol peaks in 84% (n = 21). Mean Stroop result for these 21 patients was 170 ± 24.1 seconds and mean MELD 16 ± 4. Child B cirrhosis was present in 67% (n = 14), Child C in 19% (n = 4) and Child A in 14% (n = 3). Discrete-to-moderate cerebellar and cortical atrophy was present in 10 of 25, but no differences were found between patients with and without atrophy.
Conclusion: Stroop results correlated with increasing age and severity of cirrhosis measured by both MELD and Child-Pugh scores. Brain MRI can be a helpful examination in revealing changes compatible with hepatic encephalopathy, thus confirming the value of EncephalApp Stroop test.

SAT-305

Impact of antibiotic prophylaxis of spontaneous bacterial peritonitis on colonization and infections with multidrug-resistant bacteria

M. Mücke[1], A. Mayer[1], J. Kessel[2], V.T. Mücke[1], K. Schwarzkopf[1], A. Vermehren[1], N. Weiler[1], M.W. Welker[1], J. Vermehren[1], V.A.J. Kempf[3], S. Zeuzem[4], C. Lange[2]. [1]*J.W. Goethe University Hospital, Department of Internal Medicine 1, Frankfurt am Main, Germany;* [2]*J.W. Goethe University Hospital, Department of Internal Medicine 2, Frankfurt am Main, Germany;* [3]*J.W. Goethe University Hospital, Institute of Medical Microbiology and Infection Control, Frankfurt am Main, Germany;* [4]*University of Frankfurt, Department of Medicine, Frankfurt, Germany*
Email: marcus.m.muecke@gmail.com

Background and Aims: Spontaneous bacterial peritonitis (SBP) is the most frequent infection in patients with liver cirrhosis. Current guidelines recommend primary antibiotic prophylaxis of SBP for patients with liver cirrhosis and ascites who are at risk for the development of SBP and secondary prophylaxis for all patients with resolved SBP. However, little is known about the efficacy and safety of SBP prophylaxis in patient populations with high prevalence of multidrug-resistant bacteria.
Method: This is an ongoing prospective observational study in patients with liver cirrhosis and indication for primary or secondary prophylaxis of SBP in a large German tertiary liver transplant center. All patients underwent scheduled microbial and clinical monitoring at baseline and after 4, 8, 12 and 24 weeks of SBP prophylaxis with norfloxacin or ciprofloxacin. Uni- and multivariate analyses were performed to identify predictors of infection or de-novo colonization with multidrug-resistant organisms (MDROs) during antibiotic prophylaxis.
Results: To date, 53 patients were included and followed for an average of 12.4 weeks. Most patients had Child-Pugh C cirrhosis and the mean MELD score was 16. Overall, 21 (39.6%) and 32 patients (60.4%) received primary and secondary SBP prophylaxis, respectively, with ciprofloxacin (n = 26) or norfloxacin (n = 27). At baseline, 24 patients (45%) were colonized with MDROs, and 14 patients (26%) obtained de-novo colonization with MDROs during antibiotic prophylaxis. Secondary infections during SBP prophylaxis were frequent (41.5%), including infections with MDRO in 9 patients (17%). Overall, 17 patients (32%) died. In multivariate analysis, MELD score ($p = 0.01$, OR 1.12) and any known MDRO colonization prior to SBP prophylaxis ($p = 0.02$, OR 6.55) were the only independent predictors of mortality. SBP during antibiotic prophylaxis occurred significantly more frequent in patients who acquired new MDROs ($p = 0.02$, OR 18.00).
Conclusion: Our study reveals a substantial risk of de-novo colonization and infection with MDRO during antibiotic prophylaxis

of SBP with fluoroquinolones, which – however – did not adversely affect short-term survival.

SAT-306

The Indication, dosage and duration of proton pump inhibitors in liver cirrhosis

M. De Roza, J.H. Chen. *Singhealth, Department of Gastroenterology and Hepatology, Singapore, Singapore*
Email: marianneanastasia.deroza@mohh.com.sg

Background and Aims: There are increasing concerns about Proton Pump Inhibitor (PPI) use in liver cirrhosis. Yet, it is still widely prescribed in this population and sometimes with no indication. However, PPI users are not well defined and there is little data on the cumulative dosage of PPI in the cirrhotic population. This study aims to review the indication, cumulative dosage and duration of PPI use in liver cirrhosis

Method: Patients admitted to a tertiary hospital with a confirmed diagnosis of liver cirrhosis by histology or transient elastography from January 2016 to June 2017 were identified. Only the following were included: those on follow up with a hepatologist and with complete inpatient records including: Baseline blood tests, previous medical records, medication lists and recent liver imaging. For patients prescribed with PPIs, the indication, dosage and duration were reviewed. We used the cumulative defined daily dose (cDDD) as recommended by the WHO to describe both inpatient and discharge PPI prescriptions and stratified them into 4 groups: cDDD <28 (<1-month use), cDDD 28–56 (1 to 2 months use), cDDD 57–84 (2–3 months use) and cDDD >84 (>3 months use).

Results: A total of 100 patients were included into the study. 32% were female and 68% were male. 46% were Chinese, 35% Malay, 17% Indian and 2% Eurasian. Mean age was 62.6 ± 10.9 years. Hepatitis C was the most common etiology of cirrhosis (25%). 42% of patients were child-pugh B and 41% were child-pugh A. A total of 64 patients were prescribed with PPI of which 37 (57.8%) had unclear or no indication. Of these 64 patients, 42(65.6%) were overprescribed in terms of dose and duration. On discharge, up to 31 (48.4%) were prescribed a cDDD > 3 months of which 16 (51.6%) had unclear or no indication. Interestingly, using logistic regression analysis, those >75 years old (OR-8.22, (1.24–54.78); p = 0.029) and with history of hepatic encephalopathy (OR-7.03, (1.11–44.49); p = 0.038) were more likely to be PPI users after adjustment.

Conclusion: A majority of inpatients with liver cirrhosis are on PPIs of which 57.8% had unclear or no indications and 65.6% were over-prescribed in terms of dose and duration. This continued even on discharge where 48.4% were prescribed 3 months of PPI and 51.6% had no clear indication. PPI users were also more likely to be older and have hepatic encephalopathy at baseline.

SAT-307

The effect of new infection control measures for the prevention of hospital acquired infections in cirrhotic patients

V. Di Gregorio[1], S. Incicco[1], C. Lucidi[1], B. Lattanzi[1], D. D'ambrosio[1], D. Tavano[1], G. Ceccarelli[2], M. Venditti[2], M. Merli[1]. *[1]Sapienza University of Rome, Department of Clinical Medicine, Rome, Italy; [2]Sapienza University of Rome, Department of Infectious Disease, Rome, Italy*
Email: vincenzadg@yahoo.it

Background and Aims: Healthcare-related infections are a matter of great relevance in cirrhosis. The prevalence of multidrug-resistant organisms (MDRO) has dramatically increased worldwide, especially in hospital setting. Although a number of measures used to control the spread of Hospital Acquired Infections (HAIs), especially in intensive care setting (ICS), the relevance of more stringent precautions in cirrhotic patients hospitalized in a non-ICS have not been studied so far. The aim of the study was to evaluate the effects of the introduction of stringent control measures for the prevention of HAIs in cirrhotic patients in a non-ICS.

Method: This is an observational study performed in patients consecutively admitted to our department from 2009. The population was divided into two groups: the first (Group A) includes patients in which "basic practices" were adopted (from 2009 to August 2014); the second (Group B) includes patients in which "additional special approaches" were used. These approaches consist in the reduction of the number of beds per room, the single-site placement of patients with MDRO and the use of dedicated medical instruments, the careful disinfection of the room after discharge of patients with MDRO, the implementation of hand hygiene and positioning within each room of antiseptic gel dispensers.

Results: We enrolled 799 patients, 442 in Group A and 357 in Group B. The two groups were similar for age, (61.4 ± 12.7 vs. 60.6 ± 10.9 yrs, NS), gender (71.5 *vs.* 79.8% males) and severity of liver disease (MELD 13.8 ± 5.5 *vs.* 13.5 ± 5, NS). Group B showed a significantly lower incidence of HAIs (39.1 vs. 28.3%, p = 0.03). Main site of HAIs were similar being urinary tract infections (40.7 *vs.* 26.7%) and pneumonia (21 *vs.* 26.7%) the more frequent. In Group B a trend in reducing MDRO (57.1 *vs.* 36.8%) was observed. At multivariate analysis, the introduction of the "additional special approaches" was selected as a protective factor in the development of HAIs (OR 0.56; 95% CI 0.32–0.8; p = 0.04). As a result, the infection-related mortality was significantly lower in Group B (8.1 *vs.* 2.5; p = 0.05).

Conclusion: Our results underline the need of "additional special approaches" measures for the control of infectious risk to reduce morbidity and mortality in cirrhotic patients hospitalized in non-ICS. The control of HAIs infections may also limit the spread of MDRO infections.

SAT-308

Presepsin, C reactive protein and procalcitonin have similar accuracy for bacterial infection and sepsis in decompensated cirrhosis

P. Fischer[1], C. Grigoras[1], A. Bugariu[2], O. Farcau[1], A. Benea[2], H. Stefanescu[2], I.M. Gabriela[1], S. Pascalau[1], D. Matei[1], D. Ionescu[2], M. Tantau[1], B. Procopet[1]. *[1]University of Medicine and Pharmacy "Iuliu Hatieganu", 3rd Medical Clinic, Gastroenterology Department; [2]Regional Institute of Gastroenterology and Hepatology "O Fodor", Regional Institute of Gastroenterology and Hepatology "O Fodor"*
Email: bogdanprocopet@gmail.com

Background and Aims: Bacterial infections may precipitate decompensation in cirrhosis. Rapid diagnosis for appropriate empiric treatment is essential but frequently patients do not exhibit specific signs of infection. Therefore, surrogate infection markers are needed but validation in cirrhosis is still warranting. Recently, presepsin, the soluble fraction of CD14, has been described as biologic marker for early diagnosis of severe bacterial infections. The aim of the study is to compare presepsin, C relative protein (CRP) and procalcitonin (PCT) as early infection markers in patients with decompensated cirrhosis and their association with 28-days mortality.

Method: 110 consecutive patients (75% males) with decompensated cirrhosis due to alcohol (69%), B or C viral infection (27%) and other (4%) were enrolled. A complete infection workup was performed at admission. CRP, procalcitonin and presepsin levels were measured within the first 6 hours from admission. Patients were followed-up for 28 days. To assess the performance of presepsin, CRP and PCT in diagnosis of bacterial infection and sepsis, receiver operating characteristic (ROC) curves and accuracy were calculated.

Results: Fifty-six (50.4%) patients were infected at admission and among them 24 (43%) had sepsis. The most frequent types of infections were: spontaneous bacterial peritonitis (34%), urinary tract infections and spontaneous bacteremia (18%) and respiratory tract infections (12.5%). Eleven (20%) patients had multiple infections. For diagnosis of infection the AUROCs for presepsin, CRP and PCT were 0.71 (95%CI: 0.62–0.81) (p < 0.001), 0.71 (95%CI: 0.60–0.82) (p = 0.002) and 0.70 (95%CI: 0.60–0.80) (p < 0.001) respectively. For sepsis the AUROCs were superior for all the tests, 0.85 (95%CI: 0.77–0.94) (p

< 0.001) for presepsin, 0.82 (95%CI: 0.71–0.93) (p < 0.001) for CRP and AUROC 0.84 (95%CI: 0.74–0.94) (p < 0.001) for PCT. The recommended cut-offs for presepsin (1000 pg/ml) had 62% accuracy and for PCT (0.5 ng/ml) had 66% accuracy. For CRP the best cut-off in our population was 3.4 mg/dl, with 66.2% accuracy. Combining a high sensitivity cut-off for CRP (2 mg/dl) and high specificity cut-off for presepsin (1000 pg/ml) the accuracy was increased to 72%. During follow-up 26 patients died. Only presepsin and CRP were significantly associated with 28-day mortality.
Conclusion: Presepsin, CRP and PCT have similar diagnostic performances for bacterial infection and sepsis in cirrhosis. Combining presepsin and CRP the accuracy may increase.

SAT-309
Predictive factors of esophageal varices recurrence after prophylactic endoscopic band ligation
J. Rodrigues[1], S. Fernandes[1], L. Proença[1], M. Sousa[1], J.C. Silva[1], S.A. Leite[1], A.P. Silva[1], T. Freitas[1], J. Carvalho[1]. [1]*Centro Hospitalar Vila Nova de Gaia/Espinho, Gastroenterology, Vila Nova de Gaia, Portugal*
Email: jaimepereirarodrigues@gmail.com

Background and Aims: Eradication of esophageal varices (EV) by endoscopic band ligation (EBL) is an effective variceal bleeding prophylactic therapy. However variceal recurrence following EBL is common and frequently associated with severe outcomes. We aimed to determine the outcome of prophylactic EBL and understand factors related to EV recurrence following successful eradication.
Method: We included all patients with cirrhosis who entered a protocol of EBL between 2010 and 2015, for primary or secondary variceal bleeding prophylaxis, with ≥24-month follow-up. EBL was regularly performed until EV were eradicated, then at 3 and 9 months and thereafter annually. Eradication was defined as absence of EV or identification of small EV with no EBL indication. Recurrence corresponded to large EV with additional EBL need or variceal bleeding, in patients with previous successful variceal eradication. Demographic, clinical, analytical and technical data were collected.
Results: 101 patients were selected, 75.2% (n = 76) male, mean age = 57.2 ± 10.9 years. Child-Pugh class distribution was A (52.5%, n = 53), B (41.6%, n = 42) and C (6.0%, n = 6). MELD ranged between 6 and 27 (mean 12.3 ± 4.2). Mean follow-up was 45.8 ± 21.5 months. Mortality rate was 50.5% (n = 51), 38.6% (n = 39) directly related to cirrhosis complications. Successful eradication of EV was achieved in 89.1% (n = 90) of patients, with 2.8 ± 1.6 endoscopic sessions and 13.7 ± 8.6 total bands applied over 17.0 ± 14.5 weeks. Recurrence rate was 61.1% (n = 55), including 5.6% (n = 5) variceal rebleeding episodes. Recurrence occurred 16.9 ± 16.4 months after eradication. Concomitant non-selective beta-blocker therapy (≥40 mg propranolol or carvedilol) reduced recurrence rate (p = 0.017). Variceal bleeding *stigmata* (p = 0.023), portal hypertensive gastropathy (p = 0.031), interbanding interval ≥6 weeks (p = 0.023) and higher total number of bands used (p = 0.017) were associated with recurrence. On multivariate analysis adjusted for age, gender, MELD, primary/secondary prophylaxis and cirrhosis etiology, beta-blocker therapy was independently associated with less recurrence (OR = 3.72; 95%CI: 1.09–15.54). Variceal bleeding *stigmata* (OR = 9.94; 95%CI: 1.74–56.93) and a higher number of bands necessary for eradication (OR = 1.13; 95%CI: 1.02–1.25) were independently associated with recurrence (r^2 = 0.45).
Conclusion: EBL was an effective therapy for EV eradication however recurrence was high (61.1%). Concomitant beta-blocker therapy diminished recurrence rate. Variceal bleeding *stigmata* at index endoscopy and a higher need of bands for eradication predicted higher recurrence.

SAT-310
A study evaluating outcomes of cirrhotic patients managed in a dedicated liver cirrhosis clinic and factors influencing survival
D. Kockerling[1], R. Nathwani[1], S. Balarajah[1], P. Manousou[1], H. Antoniades[1], A. Dhar[1]. [1]*St. Mary's Hospital, Hepatology, London, United Kingdom*
Email: rooshi_n@hotmail.com

Background and Aims: Liver cirrhosis results in increased morbidity and mortality and treating patients in a dedicated cirrhosis clinic may improve outcomes. The aim of this study was to demonstrate whether survival was improved by managing cirrhotics in a specialist clinic and factors that influenced survival, admission and infection rates in this patient cohort.
Method: A retrospective analysis was performed on patients attending specialist cirrhosis clinics, in a UK based university teaching hospital between November 2015 and March 2017. Data was collected for demographic details, aetiology of disease, biochemical and clinical parameters and pharmacological agents at baseline, 6-months and 12-months from clinic attendance to evaluate factors influencing survival. One-year mortality was stratified by Childs-Pugh (CP) grade and compared to historical published values.
Results: 174 patients were eligible for analysis (M:F;114:60). Alcohol-related cirrhosis was the commonest aetiology (80/174;46%). 149/174 (86%) patients survived at one-year post attendance to clinic. 25/174 (14%) died. One-year mortality was significantly lower than predicted values in CPC patients (n = 30; 33.3% vs 55.0%, 95% CI 17.3–52.8%). No significant difference was observed for CPA (n = 73;2.7% vs 5.0%) and CPB (n = 71;18.3% *vs.* 20.0%) patients. In CPB and CPC patients (n = 101) univariate analysis demonstrated increased survival with rifaximin (survivors *vs.* non-survivors: 42/78 *vs.* 6/23; p = 0.03) and Non-Selective Beta-Blockers (NSBB) use (survivors *vs.* non-survivors: 55/78 *vs.* 10/23; p = 0.02). Of these, on restricted multivariate analysis only NSBB demonstrated significant survival benefit (p = 0.018; OR 3.5). On univariate analysis NSBB use resulted in a significant reduction in incidence of infection (p = 0.03) and a reduction in admission rates in (p = 0.04) in CPB patients alone. Rifaximin use was associated with a borderline reduction in incidence of infection (p = 0.05).
Conclusion: Managing patients in a dedicated cirrhosis clinic improves survival in CPC patients when compared to historical published values. Admission and infection rates and survival were positively influenced by the use of NSBB. Rifaximin use was associated with a borderline reduction in incidence of infection. Further studies are required to delineate the mechanisms of these effects.

Email: eroman@santpau.cat

Background and Aims: Frailty associated with chronic diseases could have important consequences on the prognosis of patients with

cirrhosis. The aim was to analyze the prevalence and characteristics of frailty, and its prognostic value to predict hospital admissions, falls and mortality in patients with cirrhosis.
Method: Outpatients with cirrhosis and primary care non-cirrhotic controls matched by age and gender were included. Patients with MELD >25, hepatocellular carcinoma, overt or covert hepatic encephalopathy (Psychometric Hepatic Encephalopathy Score [PHES] <−4), or active alcohol intake (<3 months) were excluded. Frailty was defined according to the five Fried's criteria (unintentional weight loss, reduced handgrip strength, slow walking speed, self-reported exhaustion, and low physical activity): frail ≥3 criteria, pre-frail 1–2 criteria, and robust 0 criteria. In addition to the Fried index, other parameters of frailty were evaluated in patients with cirrhosis (risk of falls, cognitive function, biomarkers), and their ability to predict hospital admissions, falls and mortality.
Results: One hundred and thirty-five patients with cirrhosis (age 62.7 ± 8.8, 72% men and MELD 9.4 ± 2.9) and 135 controls were included. The prevalence of frailty was higher among patients with cirrhosis: 37 (27.4%) frail, 72 (53.3%) pre-frail and 26 (19.2%) robust *vs* 14 (10.4%) frail, 67 (49.6%) pre-frail and 54 (40%) robust in the control group ($p < 0.001$), mainly due to decreased muscle strength in cirrhotic patients. During 2-year follow-up, frail patients with cirrhosis showed a higher incidence of hospital admissions and falls compared to pre-frail and robust cirrhotic patients (35%, 13.9% and 3.8%, p = 0.001, and 18.9%, 8.3% and 3.8%, p = 0.04, respectively), with similar mortality. MELD score (HR 1.232, 95%CI 1.095–1.387, p = 0.001) and frailty (HR 2.453, 95%CI 1.050–5.732, p = 0.03) were independent predictive factors of hospital admissions, and frailty for falls (HR 3.199, 95%CI 1.075–9.513, p = 0.03). Among biomarkers, vitamin D deficiency (p = 0.02) and the increase in cystatin (p = 0.007) were associated with frailty.
Conclusion: Frailty is more frequent in patients with cirrhosis than in controls, mainly due to decrease in muscle strength, and is an independent predictive factor of hospitalization and falls in these patients. Detection of frailty and pre-frailty in cirrhotic patients will allow the implementation of preventive measures to reduce hospital admissions and falls.

SAT-312
Cardiac assessment in children with chronic liver disease: cholestatic and non-cholestatic

T.Y.A. Ghaffar[1,2], W.A.I. Ahmed[2], W.M.E. Guindy[2], M. Moafy[2], S.M.M. Hassan[1]. [1]*Yassin Abdel Ghaffar charity center for liver disease and research, Cairo;* [2]*Ain Shams University, pediatric department, Cairo, Egypt*
Email: tyghaffar@gmail.com

Background and Aims: Chronic liver disease (CLD) may affect cardiac performance. We aimed to study the effects of CLD on cardiac electrical activity, structure and function in children.
Method: 32 patients (20 males & 16 females; mean age = 7.39 years) with various causes of CLD (free from any primary cardiac disease) and 15 age and sex matched controls were studied. For all, blood pressure (BP) was measured and: ECG, 2D, M-mode and Doppler echocardiography were done. Patients were divided into 2 groups: cholestatic (C) (n = 16) and non-cholestatic (NC) (n = 16).
Results: The median Z score of systolic BP (−0.01), diastolic BP (−0.11) and mean BP (0.122) was not significantly different from controls. There was no significant difference between C verses NC patients as well.
40.6% of CLD children had a prolonged QTc (mean = 0.44 sec). C had a prolonged QTc than NC (62.5% v 18.8%, mean = 0.46 sec ± 0.06 v 0.42 sec ± 0.04, p = 0.034). Cardiac geometry was normal in 37.5% of CLD children. Concentric hypertrophy was more common in C (18.8% v 6.3%).
CLD patients compared to controls showed cardiac functional and structural derangement on 2D echo with statistically higher pulmonary arterial pressure (28.3 mmHg + 8; p = 0.000) and left ventricle mass index (79 g/m2 + 35; p = 0.00), with no statistical difference between C and NC. Yet compared to controls, C children showed impaired diastolic filling properties (mean E/A ratio 2.4 v 1.5; p = 0.001), as well as LV structural changes (p < 0.05 for (mean values): LV mass (70.3 v 46.4 g), LVMI (86 v 37 g/m2), relative wall thickness (0.49 v 0.31 cm), interventricular septal thickness dimension (0.68 v 0.6 cm) and LV posterior wall in diastole (0.7 cm v 0.6 cm)). Compared to controls, a hyperdynamic status evidenced by higher mean values of FS% (40 v 33%; p = 0.001), stroke volume (50 v 39 ml; p = 0.025) & cardiac output (5 v 3.6 L/min; p = 0.023) was found in C but not NC children.
Child score correlated positively with QTc interval (r = 0.403, p = 0.022) and cardiac index (r = 0.49, p = 0.004), while the duration of the cholestatic disease correlated positively with structural abnormalities: end diastolic volume (r = 0.299, p = 0.028), left ventricle internal diastolic diameter (r = 0.274, p = 0.037), LVM (r = 0.23, p = 0.035) and LVMI (r = 0.094, p = 0.001).
Conclusion: CLD affects cardiac performance in children. C children are specifically liable to QTc prolongation, structural changes, hyperdynamic status, and diastolic dysfunction.

SAT-313
Non-invasive predictors of varices in non-cirrhotic portal hypertension

M. Cunningham, G.P. Chehr, O. Cerocchi, D. Wong, K. Patel. *University Health Network, Centre for Liver Disease, Toronto, Canada*
Email: morven_c@hotmail.com

Background and Aims: Non-cirrhotic portal hypertension (NCPH) comprises a heterogenous group of liver disorders causing portal hypertension in the absence of cirrhosis, and carries a high risk of variceal bleeding. Recent guidelines, based largely on patients with viral cirrhosis, suggest that a combination of liver stiffness measurement and platelet count can predict low risk of clinically significant varices and select patients in whom screening gastroscopy can be deferred. In NCPH, LSM is often higher than healthy controls but lower than matched cirrhotic patients. LSM correlates with early portal hypertension in cirrhosis, but data in NCPH are lacking. The aim of this study was to assess whether LSM or other non-invasive assessments of portal hypertension could be used to predict varices in patients with NCPH.
Method: Records of patients with NCPH seen at a single centre between 2007 and 2017 were reviewed retrospectively. Outcome measures were presence or absence of varices at screening gastroscopy and history of variceal bleed. As well as LSM, platelet count/spleen length ratio (PSL) and liver stiffness-spleen length/platelet count ratio (LSP) were calculated for each patient. The association of these variables with presence of varices or on history of variceal bleed was analysed by univariate and multivariate analyses.
Results: 51 patients with NCPH were identified. 73% (37/51) had varices on most recent screening gastroscopy and 27% (14/51) had a history of variceal bleeding. There were no significant differences in age, BMI, liver biopsy fibrosis stage (all F0-3, n = 36), MELD, Childs-Pugh, FIB4 or APRI between those with and without varices. On univariate analysis, spleen size (17.8 ± 3.7 vs 13.8 ± 3.7 cm, p = 0.002), platelet count (95 ± 55 vs 124 ± 47 x10^9/L, p = 0.046), PSL (5.24 ± 3.34 vs 10.38 ± 6.26, p = 0.003) and LSP (3.08 ± 3.89 vs 1.18 ± 0.98, p = 0.018) correlated with presence of varices but LSM alone did not. No variable correlated with variceal bleeding. In a multivariate model, LSP was an independent variable associated with the presence of varices in this cohort (β = 2.22, p = 0.02; OR 9.23, 95% CI 1.4–60.7).
Conclusion: In patients with NCPH, LSM alone does not help to differentiate between patients with and without varices but combining LSM with spleen size and platelet count does predict the presence of varices. LSP warrants further evaluation as a non-invasive tool to identify patients with NCPH at low risk of varices who could defer gastroscopy.

Email: graziella.privi@gmail.com

Background and Aims: Sarcopenia is a feature of cirrhosis and contributes to mortality, but its pathogenesis is still poorly understood. Adrenal insufficiency (AI) is also common in cirrhosis. Nausea and weight loss are common symptoms of AI and could contribute to muscle waste. Therefore, the aim of our study was to evaluate the role of adrenal dysfunction on psoas muscle thickness assessed by CT scan in a cohort of cirrhotic patients.
Method: A study population of 74 cirrhotic patients was examined. Laboratory parameters of malnutrition (albumin, pre-albumin, transferrin and lymphocytes count) were assessed in all patients. Axial (APMT) and Transversal psoas muscle thickness (TPMT) were measured on a computed tomography (CT) image at the level of the umbilicus. Psoas muscle thickness was normalized to stature by division by height (APMT/h and TPMT/h). Adrenal function was assessed using the Standard-Dose short synacthen test. Normal adrenal response was defined as a peak cortisol >18 µg/dl.
Results: A significant reduction of TPMT values was observed in female compared to male (23.5 ± 6 vs 31 ± 8; p = 0.002), while no significant correlation was found between the radiologic parameters of sarcopenia and the severity and etiology of liver disease. Indeed, when we stratified our population according to the presence of ascites, we observed a significant reduction of APMT and APMT/h values in patients with ascites (37 ± 5 vs 43 ± 7; p = 0.02 and 23 ± 3 vs 26 ± 4; p = 0.02 respectively). In contrast TPMT and TPMT/h were not influenced by the presence of ascites. Adrenal insufficiency was present in 23 patients. The severity of cirrhosis graded by Child and MELD score was significantly increased in patients with AI compared to normal adrenal function (NAF) patients (p = 0.001). AI patients exhibited lower values of pre-albumin (6 ± 3 vs 10 ± 8 mg/dl; p = 0.03) and transferrin (150 ± 84 vs 220 ± 76 mg/dl; p = 0.003) compared to NAF independently to Child class. In contrast, cirrhotic patients with AI showed increased levels of both APMT (44 ± 6 vs 20 ± 5; p = 0.02) and TPMT (32 ± 8 vs 27 ± 7; p = 0.03) compared to NAF. A significant correlation was found between TPMT/h and peak cortisol (r = 0.38; p = 0.01).
Conclusion: Our data suggest that AI is associated with biochemical parameters of malnutrition but does not contribute to sarcopenia. Cortisol is one of the most important catabolic hormone, and its deficiency seems to play a protective role on muscle waste in cirrhotic patients.

SAT-315

Drug-induced encephalopathy in cirrhotic patients with neurological symptoms: A metabolomic study

N. Weiss[1], P.B.S. Hilaire[2], A. Schaefer[1], M. Rudler[1], S. Mouri[1], F. Sedel[3], F. Fenaille[2], B. Colsch[2], C. Junot[2], D. Thabut[1]. [1]*La Pitie Salpetriere University Hospital, Brain Liver Pitie Salpetriere Study Group, France;* [2]*CEA, CEA, iBiTec-S, Service de Pharmacologie et d'Immunoanalyse, Laboratoire d'Etude du Métabolisme des Médicaments, MetaboHUB-Paris, France;* [3]*Medday Pharmaceuticals, PARIS, France*
Email: nicolas.weiss@aphp.fr

Background and Aims: Encephalopathy is a classical complication of liver disease and/or portosystemic shunts. Its pathophysiology is not completely elucidated; mechanisms include the role of elevated ammonia levels in association with systemic inflammation. An impairment of blood-brain barrier (BBB) permeability is also hypothetised. Metabolomics enables to detect a wide range of metabolites without any a priori. In a recent metabolomic study including patients who underwent cerebrospinal fluid (CSF) collection, our group outlined that xenobiotics/drugs that usually don't cross BBB were retrieved in the CSF, suggesting a potential neurological toxicity of drugs. CSF collection is invasive. Hence, we aimed to describe the xenobiotics present in the plasma of cirrhotic patients, using the same metabolomic approach.
Method: We conducted a retrospective study of plasma samples in the Hepatological ICU. Plasma samples from cirrhotic patients displaying encephalopathy were compared to plasma from cirrhotic patients without neurological symptoms, and to plasma from healthy controls. Liquid chromatography coupled to high-resolution mass spectrometry was performed and thenafter the metabolic fingerprints were compared to database and between the different groups.
Results: Plasma samples were obtained from 12 cirrhotic patients with encephalopathy (age 59 [40–68], MELD 20 [16–31], alcohol 58%), 13 cirrhotic patients without encephalopathy (age 56 [55–64], MELD 17 [14–29], alcohol 38%) and 9 healthy controls. Among 495 identified metabolites, 25 corresponded to xenobiotics or its derivatives. Fluoxetine was detected with a more than 200-fold increase, aminosalicylic acid with a more than 10-fold increase and benzyl alcohol (present in cough pills and antiseptics) with a 3 fold increase in cirrhotic patients with encephalopathy as compared to cirrhotic patients. In cirrhotic patients with or without encephalopathy, propranolol was detected with a more than 8500-fold increase, acetaminophen with a 40-fold increase, penicillamine and ampicillin both with a 2 fold increase as compared to healthy controls. Interestingly, several substances which were not expected to have systemic diffusion were detected in cirrhotic patients and in healthy controls: eugenol, isoeugenol (used in mouth bathing solution), triethanolamine (trolamin, used in cutaneous creams) and resorcinol monoacetate (used in mouth bathing solution and in cutaneous creams).
Conclusion: Cirrhotic patients, especially those with neurological symptoms, display dramatically increased levels of several xenobiotics in plasma. These results confirm that PK/PD parameters of commonly used drugs are highly modified in those patients. This suggests a potential role of xenobiotics in the pathophysiology of encephalopathy in patients with liver diseases.

SAT-316

Endoscopic radiofrequency ablation for the treatment of gastric antral vascular ectasia in cirrhotic patients: A bi-centric clinical and economical cost-effective analysis

M. Senzolo[1], S. Realdon[2], B. Simoncin[1], A. Zanetto[1], S. Caronna[3], G.M. Saracco[4], C. De Angelis[3], W. Debernardi-Venon[5]. Email: marcosenzolo@hotmail.com

Background and Aims: Gastric Antral Vascular Ectasia (GAVE) represents a rare, but clinically significant cause of GI bleeding and transfusion dependent chronic anaemia in cirrhotic patients. In approximately one third of cases it is refractory to argon plasma (APC) treatment and radiofrequency ablation (RFA) have been described to be potentially useful in heterogeneous cohorts of patients. To prospectively evaluate the safety and efficacy of RFA for the treatment of GAVE in cirrhotic patients with severe transfusion dependent anaemia (including patients without APC response) as well as to compare the cost and the advantage of the RFA treatment.
Method: cirrhotic patients with GAVE, recurrent GI bleeding and/or severe chronic anemia were enrolled at Padua and Turin University Hospital Gastroenterology Units. RFA treatment was performed by HALO90ULTRA – Ablation System. All the clinical data (levels of

haemoglobin, number of transfusions, need of re-treatment), the GAVE endoscopic grade and the GI bleeding related hospitalizations were collected over a 6 months follow-up. An economic cost-effective analysis was also performed in the same interval time.
Results: 25 patients (mean age 70 years; 50% Child B) were enrolled. Eighty-four per cent (21/25) of them didn't respond to conventional APC. RFA obtained eradication of GAVE in 100% and 13/25 patients received 2 sessions. During the 6 months of follow up, median Hb increased from 8 ± 0.7 g/dL to 11 ± 1 g/dL ($p < 0.001$) and most of patients (15/25) were free from transfusion. After RF therapy, there was a significant reduction in the median number of red blood cells transfusion (25 ± 14 to 1 ± 1.7; $p < 0.001$) as well as a significant reduction in GI bleeding related hospitalizations (1.6 ± 0.4 to 0.3 ± 0.1; $p < 0.001$). The economic analysis showed a significant reduction of total cost (€ 13.933 to € 6.233), packed red blood related cost (€ 10.048 vs € 2448) and hospitalizations for GI bleeding related cost (€ 3407 vs € 648), after RFA procedure.
Conclusion: RFA is safe and effective procedure for cirrhotic patients with GAVE, in particular if refractory to APC. Although the cost of RF is high, cost analysis shows a significant overall economic savings. RF could be considered as a first line treatment in severe form of GAVE in cirrhotics.

SAT-317
Avatrombopag decreases need for platelet transfusion in patients chronic liver disease and thrombocytopenia undergoing medical procedures with low to high associated bleeding risks

N.S. Reau[1], S. Sammy[2], L.F. Allen[3], K. Aggarwal[4], M. Vredenburg[3], W.R. Kim[5]. [1]*Rush University;* [2]*UCLA;* [3]*Dova Pharmaceuticals;* [4]*Dova Pharmaceuticals, Durham, United Kingdom;* [5]*Stanford, United States*
Email: kaggarwal@dova.com

Background and Aims: Thrombocytopenia (TCP) is common in patients with chronic liver disease (CLD). Because of the associated bleeding risks, patients may require prophylactic platelet transfusions before invasive procedures. Avatrombopag (AVA) is an oral thrombopoietin receptor agonist being developed as an alternative to platelet transfusions. Two randomized, double-blind, placebo (PBO)-controlled Phase 3 trials evaluated the efficacy of AVA to increase platelet counts (PC) and reduce platelet transfusions in patients with TCP and CLD undergoing scheduled procedures.
Method: Two randomized, double-blind, placebo (PBO)-controlled Phase 3 trials (ADAPT-1 and ADAPT-2) enrolled adults with CLD and PC < 50×10^9/L, scheduled to undergo a procedure. Patients were divided into 2 cohorts by baseline PC (**Cohort 1**- <40×10^9/L; **Cohort 2**- 40 to <50×10^9/L) and were randomized 2:1 to once-daily oral AVA (**Cohort 1**- 60 mg; **Cohort 2**- 40 mg) or PBO for 5 days, with the procedure scheduled 5 to 8 days after the last dose. Patients were stratified by procedure bleeding risk (low, moderate, high). The primary efficacy endpoint was the proportion of patients not requiring platelet transfusion or any bleeding rescue procedure up to 7 days post-procedure.
Results: Overall, 435 patients were randomized. The primary endpoint was met by 66.9% of AVA-treated vs 28.6% of PBO-treated in **Cohort 1** ($p < 0.0001$), and 88.0% of AVA-treated vs 35.8% of PBO-treated patients in **Cohort 2** ($p < 0.0001$). The proportion of patients across all the pooled treatment groups in each bleeding risk category was: 60.8% in the low, 17.2% in the moderate, and 22.1% in the high bleeding risk categories, and was balanced across treatment groups. The primary efficacy endpoints in the low, moderate, and high risk of bleeding categories all favored AVA and were consistent with the overall study results. A positive AVA treatment effect was noted across the various bleeding risk subgroups in both **Cohort 1** (AVA vs PBO: low risk- 78.1% vs 45.8%, moderate risk- 61.9% vs 17.6%, and high risk- 55.9% vs 6.7%, respectively), and **Cohort 2** (AVA vs PBO: low risk- 92.4% vs 34.2%, moderate risk- 90.0% vs 50.0%, and high risk- 88.9% vs 35.7%, respectively).
Conclusion: Subgroup analyses indicated that neither the type of procedure nor associated bleeding risk impacted the superiority of AVA to PBO in increasing PC and reducing platelet transfusions in patients with TCP and CLD undergoing a medical procedure.

SAT-318
Efficacy of avatrombopag compared with placebo across various mean baseline platelet count subgroups- pooled data from 2 Phase 3 studies

S. Sammy[1], N. Alkhouri[2], L.F. Allen[3], K. Aggarwal[3], M. Vredenburg[3], W. Tian[3], N. Terrault[4]. [1]*UCLA;* [2]*Texas Liver Institute;* [3]*Dova Pharmaceuticals;* [4]*UCSF*
Email: kaggarwal@dova.com

Background and Aims: Thrombocytopenia (TCP) is common in patients with chronic liver disease (CLD), increasing in severity with worsening liver disease. TCP presents a significant challenge in these patients who require multiple invasive procedures. Prophylactic platelet transfusions to reduce bleeding risk expose patients to the safety risks associated with transfusions. Avatrombopag (AVA) is an oral thrombopoietin receptor agonist that has completed Phase 3 development as an alternative to platelet transfusions. This analysis evaluated the efficacy of AVA in increasing platelet count (PC) in various subgroups based on their pre-treatment PC at Baseline.
Method: Two randomized, double-blind, placebo (PBO)-controlled Phase 3 trials (ADAPT-1 and ADAPT-2) enrolled adults with CLD and PC <50×10^9/L scheduled to undergo a procedure. Patients were randomized 2:1 to AVA or PBO and dosed orally for 5 days based on Baseline PC. Those with PC <40×10^9/L received 60 mg AVA and those with PC 40 to <50×10^9/L received 40 mg AVA; Procedure Day was scheduled 5 to 8 days after the last dose (Day 10 to 13). For analysis, patients were pooled by treatment group and then divided into subgroups by Baseline PC. The mean change in PC from Baseline to Procedure Day was a pre-defined secondary efficacy endpoint.
Results: In a preliminary analysis (Table 1), AVA was shown to increase Baseline PC 1.6 to 2.3-fold across all Baseline PC subgroups with the mean change in PC ranging from ~10 to 41 × 10^9/L, and larger AVA-induced increase in the 20 to <30, 30 to <40; and 40 to <50×10^9/L Baseline PC subgroups. There were few patients enrolled in the 10 to <20×10^9 Baseline PC subgroup, limiting the interpretation, and the smaller change in PC may have resulted from bone marrow toxicity or suppression, increased platelet destruction and/or splenic sequestration.

Table 1: Mean Change in Platelet Count from Baseline to Procedure Day

	Avatrombopag		Placebo	
Baseline Platelet Count Group ($x10^9$/L)	Number of Subjects n	Mean Change from Baseline n (+/–SD) $x10^9$/L	Number of Subjects n	Mean Change from Baseline n (+/–SD) $x10^9$/L
10 to <20*	9	9.6 (10.0)	6	–0.2 (2.2)
20 to <30*	41	33.2 (25.8)	23	–0.6 (5.4)
30 to <40*	106	33.1 (24.7)	61	3.1 (9.3)
40 to <50**	113	41.1 (30.7)	64	3.7 (12.6)

*60 mg AVA;
**40 mg AVA

Conclusion: Administration of AVA to patients with TCP and CLD resulted in measured increases in PC across the various Baseline PC subgroups.

SAT-319

Consistent efficacy of avatrombopag compared to placebo in patients with thrombocytopenia and chronic liver disease undergoing procedures across various disease severities and etiologies

S. Sammy[1], L.F. Allen[2], K. Aggarwal[3], M. Vredenburg[2], N. Terrault[4].
[1]*UCLA;* [2]*Dova Pharmaceuticals;* [3]*Dova Pharmaceuticals, Dova Pharmaceuticals, Durham, United States;* [4]*UCSF*
Email: kaggarwal@dova.com

Background and Aims: Thrombocytopenia (TCP) is common in patients with chronic liver disease (CLD) and known to increase in severity with worsening liver disease. It presents a significant challenge in the management of these patients who require multiple invasive procedures. Avatrombopag (AVA) is an oral thrombopoietin receptor agonist being developed as an alternative to platelet transfusions. This analysis evaluated the efficacy of AVA compared to placebo (PBO) in increasing platelet counts (PC) and reducing the need for platelet transfusion in patients with TCP and CLD undergoing scheduled procedures based on Baseline MELD score, CTP score, and liver disease etiologies.
Method: Two randomized, double-blind, placebo (PBO)-controlled Phase 3 trials (ADAPT-1 and ADAPT-2) enrolled adults with CLD and PC $<50 \times 10^9$/L who were scheduled to undergo a procedure. Patients were divided into 2 cohorts by Baseline PC (Cohort 1- PC $<40 \times 10^9$/L; Cohort 2- PC 40 to $<50 \times 10^9$/L) and randomized 2:1 to receive once-daily oral AVA (Cohort 1- 60 mg; Cohort 2- 40 mg) or PBO for 5 days, with Procedure Day scheduled 5 to 8 days after the last dose. The primary efficacy endpoint was the proportion of patients not requiring platelet transfusion or any bleeding rescue procedure up to 7 days post-procedure; subgroup analyses were done based on MELD, CTP, and liver disease etiology.
Results: Overall, 435 patients were randomized. AVA was superior to placebo with 66.9% of AVA-treated patients vs 28.6% of PBO-treated patients in Cohort 1 meeting the primary efficacy endpoint ($p < 0.0001$), and in Cohort 2, 88.0% of AVA-treated patients vs 35.8% PBO-treated patients ($p < 0.0001$). In a combined cohort analysis (Figure 1), consistently more AVA-treated patients met the primary efficacy endpoint compared with PBO-treated patients across the various Baseline MELD, CTP and disease etiology subgroups. As expected, subgroups with the smallest number of subjects had wide confidence intervals, e.g., CTP Grade C and Nonalcoholic Steatohepatitis and Other disease etiologies, although the point estimates of the treatment difference remained positive in favor of AVA-treated patients.

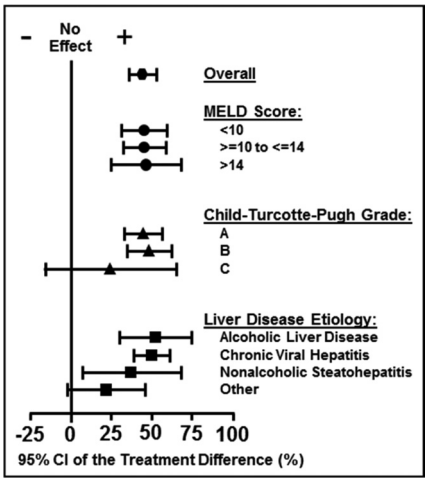

Figure 1: Proportion of Subjects Not Requiring a Platelet Transfusion or Rescue Procedure for Bleeding Results: Across Subgroups in the Combined Baseline Platelet Count Cohorts - Pooled Phase 3 ADAPT-1 & ADAPT-2 Studies

Conclusion: Baseline liver disease severity or etiology did not impact the efficacy of AVA in increasing PC or reducing platelet transfusions in patients with TCP and CLD scheduled for a procedure compared with PBO.

SAT-320

Rifaximin ameliorates hepatic encephalopathy and endotoxemia without affecting the gut microbiome diversity

H. Takaya, K. Kaji, S. Saikawa, M. Furukawa, S. Sato, Y. Sawada, H. Kawaratani, M. Kitade, K. Moriya, T. Namisaki, T. Akahane, A. Mitoro, H. Yoshiji. *Nara Medical University, Third Department of Internal Medicine, Kashihara, Japan*
Email: htky@naramed-u.ac.jp

Background and Aims: Hepatic encephalopathy (HE) is characterized by deficits in cognitive, psychiatric, and motor function and ranges in severity from minimal to overt HE and coma. Rifaximin is used for standard treatment of HE, targeting reduction of ammonia and gut bacterial translocation. We examined the efficacy of rifaximin for HE with the linkage of endotoxin activity and gut microbiome in patients with decompensated cirrhosis.
Method: Twenty patients (12 men and 8 women; median age, 66.8 years; range, 46–81 years) with decompensated cirrhosis (Child-pugh score >7) underwent cognitive neuropsychological testing, endotoxin analysis, and fecal microbiome assessment at baseline and after 4 weeks of treatment with rifaximin 400 mg thrice a day. Changes in cognition, endotoxin, and microbiome were analyzed by the number connection test (NCT)-A, endotoxin activity assay, and 16S ribosome RNA gene sequencing, respectively. HE was determined by serum ammonia level and NCT-A.
Results: Treatment with rifaximin for 4 weeks improved hyperammonemia (from 90.6 ± 23.9 [mean ± SD] to 73.1 ± 33.1 μg/dL; $p < 0.05$) and time required for NCT-A (from 68.2 ± 17.4 to 54.9 ± 20.3 sec; $p < 0.05$) in patients who had higher levels at baseline. Endotoxin activity was reduced (from 0.43 ± 0.03 to 0.32 ± 0.09; $p < 0.05$) in direct correlation with decrease in serum ammonia levels ($r = 0.5886$, $p < 0.05$). No statistically significant differences were observed in the diversity estimator and major components of the gut microbiome between the baseline and after treatment groups (Shannon diversity index:3.948 ± 0.548 at baseline vs. 3.980 ± 0.968 after treatment; $p = 0.544$), but the relative abundances of genus Veillonella and Streptococcus were lowered.
Conclusion: Rifaximin significantly improved cognition and reduced endotoxin activity without significantly affecting the composition of the gut microbiome in patients with decompensated cirrhosis.

Sustained long-term improvement in clinical and cognitive outcomes after fecal microbiota transplantation in cirrhosis

J.S. Bajaj[1], A. Fagan[1], D. Heuman[1], E. Gavis[1], M. Fuchs[1], B. John[1], Z. Kassam[2], M. Sikaroodi[3], P. Gillevet[3]. [1]*Virginia Commonwealth University and McGuire VAMC, Richmond, United States;* [2]*OpenBiome, Boston, United States;* [3]*George Mason University, Manassas, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: In a randomized clinical trial (RCT), fecal microbial transplantation (FMT) prevented short-term hospitalizations and improved brain function in cirrhotic patients with hepatic encephalopathy (HE). However, the long-term consequences of FMT in this population are unclear. We aimed to determine the long-term (>1 year) impact of FMT on cognition, hospitalizations and HE episodes.
Method: In a previously described RCT, HE patients on rifaximin were randomized to pre-treatment broad-spectrum antibiotics and FMT or standard of care (SOC) with follow-up at month 6. Cognitive function was tested at baseline, day 5 and 20 with Psychometric hepatic encephalopathy score (PHES; higher score indicates good cognition) and EncephalApp (low score indicates good cognition). Subsequently, we followed participants who were alive and without liver transplant

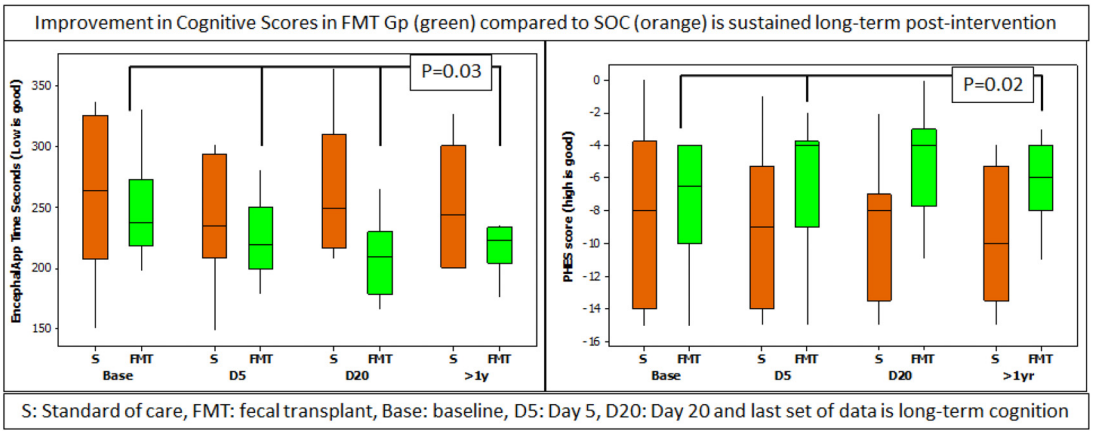

Figure: (abstract: SAT-321)

for 6 additional months (total 1 year after randomization) and assessed cognitive function and hepatic outcomes.
Results: 20 HE subjects (mean age: 58 years, 20 males, mean MELD 12.5) were randomized 1:1 into the FMT or SOC arm, and the RCT demonstrated that FMT reduced hospitalizations and HE episodes over 6 months and improved PHES and EncephalApp scores at day 20. *Long-term clinical outcomes*: One year after randomization, 1 participant in FMT arm (end-stage organ failures unrelated to FMT) and 3 in SOC arm died or underwent liver transplant. There was no related SAE in the FMT arm. Overall, there were persistently higher HE episodes/hospitalizations in SOC arm compared to FMT arm ($p = 0.02$) (Table), while MELD score was similar statistically. *Long-term cognitive outcomes*: The FMT arm showed sustained, statistically significant improvement post-FMT compared to baseline and SOC (Figure).

Long-term outcomes (>1 year)	FMT arm	SOC arm	P-value
MELD score delta	2.8 ± 4.5	2.78 ± 4.7	0.9
Hospitalizations	0 (0–1.50)	3 (0.75–5.75)	0.02
HE episodes	0 (0–1.00)	1.5 (0.75–2.75)	0.05
Death/liver transplant	3	1	0.4

Conclusion: FMT is associated with long-term improvements in hospitalizations, HE episodes and cognitive performance in patients with HE compared to standard of care.

Viral hepatitis A/E: Clinical aspects

High mortality rate in HBV-related cirrhosis patients with HEV superinfection

T.-C. Tseng[1], C.-J. Liu[1], T.-H. Su[1], W. Yang[2], C.-L. Chen[3], H.-C. Yang[1], C.-H. Liu[1], P.-J. Chen[1], D.-S. Chen[4], J.-H. Kao[1]. *[1]National Taiwan University Hospital, Division of Gastroenterology, Department of Internal Medicine, Taipei, Taiwan; [2]National Taiwan University Hospital, Hepatitis Research Center, Taipei, Taiwan; [3]National Taiwan University College of Medicine, Graduate Institute of Clinical Medicine, Taipei, Taiwan; [4]Academia Sinica, Taiwan, Genomics Research Center, Taipei, Taiwan*
Email: cjliu@ntu.edu.tw

Background and Aims: Hepatitis E virus (HEV) infection causes acute hepatitis, which is usually a self-limiting disease. However, it is unclear whether superinfection with HEV is associated with worse prognosis in patients with chronic hepatitis B virus (HBV) infection.
Method: A total of 2123 Taiwanese HBV patients who were negative for IgG-HEV at baseline were enrolled. IgG-HEV seroconversion was used to define HEV infection. We explored whether IgG-HEV seroconversion was associated with liver-related mortality in HBV patients after a long-term follow-up.
Results: With a mean follow-up of 12.08 years, there were 46 patients experienced IgG-HEV seroconversion and the annual incidence was 0.18%. Patients with HEV exposure had a higher liver-related mortality than those without, and the adjusted hazard ratio was 4.39 (95% confidence interval: 1.33–14.46). To be noted, 2 of 4 compensated liver cirrhosis patients (50%) had liver-related mortality within 3 months after IgG-HEV seroconversion. In contrast, only 1 of 42 non-cirrhotic IgG-HEV seroconverters (2.3%) had liver-related mortality after HEV exposure. Thus pre-existing liver cirrhosis was significantly associated with liver-related mortality in HBV patients with HEV superinfection ($p < 0.001$).
Conclusion: Superinfection with HEV is not rare in Taiwanese HBV patients, and may cause liver-related mortality in those with liver cirrhosis.

SAT-326
Clinical features and outcomes of hepatitis E in patients with underlying chronic liver disease: a respective case-control study

Y. Wang[1], H. Tang[1], C. Yang[1], Q. Pan[2], J. Zhao[1]. *[1]302 hospital, Department of Pathology and Hepatology, Beijing, China; [2]Erasmus MC-University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: yijinwang927015@163.com

Background and Aims: Although hepatitis E virus (HEV) infection generally causes acute and self-limiting disease, fulminant hepatitis are frequently reported in HEV patients with underlying chronic liver disease (CLD). However, the differences of clinical features upon HEV infection in individuals with or without existing chronic liver disease haven't been comprehensively understood. This study aims to investigate the clinical symptoms, manifestations and outcomes of HEV infection in presence or absence of CLD.
Method: From January 2015 to October 2017, 124 patients diagnosed with solely HEV infection and 103 patients diagnosed with HEV infection combining pre-existing CLD, including chronic hepatitis B, C, alcoholic liver disease, moderate/severe fatty liver and cirrhosis by presence of anti-HEV immunoglobulin (Ig) M, were enrolled. Epidemiological and clinical features were collected. Chi-squared or Fisher's exact tests were performed to compare proportions. The results based on two-sided tests and $p < 0.05$ was defined as statistically significant.

Results: Analysis of total 227 patients with positive anti-HEV IgM showed an overall high median age (54 years) and overwhelming proportion of males (189/227, 83%). Compared with patients of solely HEV infection, HEV infected patients with pre-existing CLD were more commonly to present abdominal pain/distension (35.92% vs. 20.97%, p = 0.017), but less likely to present nausea/vomiting (63.11% vs. 78.23%, p = 0.013). Higher level of procalcitonin (0.91 ± 0.92 μg/l vs 0.61 ± 0.52 μg/l; p = 0.047) and alkaline phosphatase (ALP) (205.54 ± 97.78U/l vs 176.20 ± 63.41U/l; p = 0.005) were demonstrated to associate with solely HEV infection than CLD combined HEV infection. While the presence of anti-HEV IgM in CLD patients had higher proportion of seroperitoneum (37.86% vs. 20.97%, p = 0.005), pleural effusion (17.48% vs. 4.84%, p = 0.002) and peritonitis (14.56% vs. 4.84%, p = 0.02). In addition, HEV patients with pre-existing CLD were more likely to develop liver failure (22.33% vs. 12.1%, p = 0.049) and shock (3.88% vs. 0.81%, p = 0.263).

Table 1: Characteristics in HEV patients with or without CLD

Characteristic	HEV infection with CLD (n = 103) No. (%)	HEV infection alone (n = 124) No. (%)	p value
Abdominal pain/distension	37 (35.92%)	26 (20.97%)	0.017
Nausea/vomiting	65 (63.11%)	97 (78.23%)	0.013
Electrolyte disturbance	44 (42.72%)	40 (32.26%)	0.129
Seroperitoneum	39 (37.86%)	26 (20.97%)	0.005
Pleural effusion	18 (17.48%)	6 (4.84%)	0.002
Peritonitis	15 (14.56%)	6 (4.84%)	0.02
Anemia	28 (27.18%)	26 (20.97%)	0.348
Shock	4 (3.88%)	1 (0.81%)	0.263
Liver failure	23 (22.33%)	15 (12.1%)	0.049

Conclusion: HEV infection in absence of pre-existing CLD presented typical clinical symptoms of acute hepatitis. However, HEV infection with underlying CLD showed more clinical manifestations and severe outcomes than HEV infection alone.

SAT-327

Risk factors of hepatitis E related liver failure: a restrospective case-control study

Y. Wang[1], H. Liu[1], Q. Pan[2], J. Zhao[1]. *[1]302 hospital, Department of Pathology and Hepatology, Beijing, China; [2]Erasmus MC-University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: yijinwang927015@163.com

Background and Aims: Hepatitis E virus (HEV) is one of the most common causes of non-chronic liver failure (NCLF) in developing countries. However, the risk factors for HEV patients developing liver failure have not been comprehensively investigated. The aim of this study was to understand the risk factors of HEV complicating with ALF.
Methods: 62 patients diagnosed with HEV who developed to NCLF (acute/subacute/acute-on-chronic liver failure) and 210 non-NCLF HEV infected patients as control were enrolled from November 2011 through September 2017. Clinical index and epidemiological records were analyzed. Differences were tested using Student's t test for continuous measures, and Chi-square or Fisher's exact test for categorical measures. The results based on two-sided tests and $P < 0.05$ was defined as statistically significant.
Results: Median age of HEV infected patients with or without NCLF were 54.55 ± 9.33 years vs 52.87 ± 13.58 years (p = 0.360), respectively. Development of NCLF upon HEV infection were more common in male (98.39% vs 79.52%; p < 0.001). Compared with solely HEV infected patients, HEV complicating NCLF presented a lower level of γ-glutamyltransferase (GGT) (123.36 ± 105.97U/l vs 236.91 ± 299.93U/l; p < 0.001), and prealbumin (PA) (50.93 ± 34.41 mg/l vs 99.04 ± 64.38 mg/l; p < 0.001), choline esterase (3450.25 ± 1471.04U/l vs 4925.83 ± 1958.22U/l; p < 0.001), leucine aminopeptidase (87.17 ± 25.95 U/L vs 104.15 ± 47.50U/l; p < 0.001), triglyceride (1.79 ± 0.72 mmol/l vs 2.36 ± 1.16 mmol/l; p < 0.001), low density lipoprotein cholesterol (1.92 ± 0.59 mmol/l vs 2.80 ± 1.13 mmol/l; p < 0.001) and γ1-globulin (3.56 ± 0.94 vs 4.88 ± 1.01, p < 0.001). While a higher value of aspartate aminotransferase (AST) (679.70 ± 1018.39U/l vs 394.07 ± 475.03U/l; p = 0.038), lactate dehydrogenase (317.23 ± 220.59U/l vs 252.89 ± 115.27U/l; p = 0.040) and alpha-fetoprotein (114.96 ± 201.01 ng/ml vs 54.43 ± 111.32ng/ml; p = 0.029) were significantly associated with NCLF development in HEV infected patients. Furthermore, a multivariate logistic regression model was constructed to identify independent risk factors of NCLF due to HEV. HEV infected patients with underlying chronic liver disease (CLD) (odds ratio, 2.640; 95%CI, 1.254, 5.559), including alcoholic liver disease, cirrhosis, hepatitis B virus (HBV) and autoimmune liver disease, high level of AST (odds ratio, 1.002; 95%CI, 1.001,1.003), lower level of GGT (odds ratio, 0.994; 95%CI, 0.990,0.998), low level of PA (odds ratio, 0.985; 95%CI, 0.973,0.997) were more likely to associate with NCLF. Furthermore, of the 62 HEV related NCLF patients, there is no difference between the improvement rate of NCLF in patients with or without underlying CLD (63.63% vs 66.67%, p = 1.000).
Conclusions: HEV infected patients with male gender, underlying CLD, higher level of AST, lower level of GGT and lower level of PA are more likely to develop non-chronic liver failure.

SAT-328

The role of hepatitis E in acute non-traumatic neuropathy in China: a prospective case-control study

Y. Wang[1], S. Wang[1], Y. Jiang[1], J. Wu[2], H. Liu[1], Q. Pan[3], J. Zhao[1]. *[1]302 Hospital, Department of Pathology and Hepatology, Beijing, China; [2]First People's Hospital, Yancheng, Department of Laboratory, Yancheng, China; [3]Erasmus MC-University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: yijinwang927015@163.com

Background and Aims: Neurological complications have been increasingly reported in hepatitis E virus (HEV) infected patients in western countries and mainly due to genotype 3 HEV. Whether other genotypes of HEV are also related to neurological injury is largely unknown. The aim of this study is to determine the frequency of hepatitis E in patients with acute non-traumatic neurological disorder in China, where genotype 4 HEV is prevalent.
Method: From September through November 2017, 765 patients consecutively diagnosed with acute non-traumatic neurological injury, including posterior circulation ischemia (n = 210), cerebral infarction (n = 171), stroke (n = 133), neurodegenerative diseases (n = 108), central nervous system infections (n = 31), and others (n = 112) were enrolled, matched with 1,171 healthy controls. Serum samples were collected for testing anti-HEV immunoglobulin (Ig) M and IgG by ELISA. Subjects with detectable anti-HEV IgM were also tested for HEV RNA. All patients' demographic and clinical data are documented. Differences were tested using Student's t test for continuous measures, and Chi-square or Fisher's exact test for categorical measures. The results based on two-sided tests and $P < 0.05$ was defined as statistically significant.
Results: Anti-HEV IgM were positive in only 1 encephalitis (0.13%) of the neurological injured patients, and 8 (0.68%) in healthy controls. The 1 patient and 4 of the 8 controls with positive anti-HEV IgM were also positive for anti-HEV IgG. Overall, 290 of the 764 patients (37.96%) and 409 of the 1163 controls (35.2%) without anti-HEV IgM were detectable for anti-HEV IgG. Further study in our patients' cohort revealed that anti-HEV IgG positivity was more common in male (181/290, 62.41% vs 109/290, 37.59%, p = 0.006) and older patients (67.17 ± 12.65 vs 64.03 ± 13.69, p = 0.002). Of note, stratification analysis showed that central nervous system infections were less likely to be in patients with detectable anti-HEV IgG, compared with of ant-HEV IgG negative patients, although not statistically significant (2.41%, 7/290 vs 4.85%, 23/474, p = 0.124).

Table 1: Features of non-traumatic neurological injury patients with detectable versus undetectable anti-HEV IgG at enrollment

	HEV IgG+ (n = 290)	HEV IgG– (n = 474)	t	χ^2	p Value
Age, years	67.17 ± 2.65	64.03 ± 13.69	3.163		0.002
Sex					
Male	62.41%	52.11%		7.754	0.006
Female	37.59%	47.89%			
Posterior circulation ischemia	29.66%	26.16%		1.103	0.317
Cerebral infarction	23.10%	21.94%		0.140	0.721
Stroke	17.59%	17.30%		0.010	0.922
Neurodegenerative diseases	13.45%	14.56%		0.182	0.748
Central nervous system infections	2.41%	4.85%		2.807	0.124
Other diseases	13.79%	15.19%		0.281	0.601

Conclusion: Non-traumatic neurological injury is rarely associated with current/recent HEV infection in China. Past exposure to HEV seems a protective factor for central nervous system infections.

SAT-329

Clinical impact, morbidity and mortality of Hepatitis E at tertiary referral centres in central Europe

J. Hartl[1], P. Behrendt[2], M. Cornberg[2], K. Deterding[2], D. Westhölter[3], M. Luetgehetmann[4,5], A. Lohse[3], M.P. Manns[2], S. Pischke[3], H. Wedemeyer[2]. *[1]University Hospital Hamburg-Eppendorf (UKE), First Medial Centre, Hamburg, Germany; [2]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [3]University Hospital Hamburg-Eppendorf (UKE), First Medical Centre, Hamburg, Germany; [4]University Hospital Hamburg-Eppendorf (UKE), Microbiology and Virology, Hamburg, Germany; [5]university Hospital Hamburg-Eppendorf (UKE), Microbiology and Virology, Hamburg*
Email: j.hartl@uke.de

Background and Aims: It has become increasingly evident that infection with the hepatitis E virus (HEV) is a frequent cause of viral hepatitis in Europe. Nevertheless, HEV-infections are mainly considered as a self-limiting and benign, however, this might not hold true for patient-groups treated at tertiary centres with comorbidities and immunosuppressive medications.
Methods: This retrospective study was conducted at two major tertiary referral hospitals and transplant-centres in Northern Germany. Medical charts of all consecutive patients were reviewed testing positive for HEV-RNA in serum between May 2011 and June 2017 were reviewed.
Results: In total, 150 HEV-RNA positive patients were identified. The vast majority (92%) had a locally-acquired HEV-infection and more than half of the patients were immunocompromised (54%).
53% of the immune-competent individuals with autochthonous HEV-infection were treated as inpatients (53%), which resulted in a total of 74 hospital days. 77% of patients had ALT values of >10x the upper limit of normal (ULN) and 20% presented with jaundice. Nine patients had a pre-existing liver disease, including 4 patients presenting with severe hepatitis (ALT > 1200U/l, INR > 1.2) and two with a fulminant course of hepatitis (INR > 2.5; ALT > 6635U/l). Both patients developed acute-on-chronic liver failure with jaundice, ascites and hepatic encephalopathy. Liver transplantation was not feasible due to infectious complications and both patients died.
In immunocompromised individuals, HEV-infection took a chronic course in 32/81 patients (40%), even though anti-viral treatment with ribavirin had been initiated in 17 patients within 2 months after diagnosis. Overall, 50/81 patients (61%) received treatment with ribavirin, which led to viral clearance in 42/50 (82%) after a median treatment time of 133 days (range 35–295). Eight (10%) immunosuppressed individuals died within 5 years after diagnosis of HEV-infection including three fatal outcomes being related to HEV infection.
Conclusions: HEV-infection is associated with significant morbidity and even mortality in patients treated at tertiary centres in central Europe. Severe courses of HEV infection are not limited to immunocompromised individuals. Hepatitis E should be considered as differential diagnosis in patients with acute-on-chronic liver failure.

SAT-330

Dynamics of HBsAg clearance in a UK cohort of chronic HBV infection

L. Downs[1], M. Patel[2], M.A. Ansari[3], A. Mcnaughton[3], M. Andersson[1], E. Barnes[2,3], K. Jeffery[1], P. Matthews[1,3]. *[1]Oxford University Hospitals NHS Foundation Trust, Department of Infectious Diseases and Microbiology, Oxford, United Kingdom; [2]Oxford University Hospitals NHS Foundation Trust, Department of Hepatology, Oxford, United Kingdom; [3]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom*
Email: p.matthews@doctors.org.uk

Background and Aims: Hepatitis B surface antigen (HBsAg) has recently gained traction as a biomarker that may provide prognostic information and inform treatment decisions in chronic hepatitis B virus (HBV) infection. It may be particularly useful when HBV DNA levels are low and therefore difficult to quantify accurately, either as a result of treatment or natural immune control of the virus. There are few published descriptions of the kinetics of HBV clearance, and most existing data come from Asia. We therefore set out to identify adults who cleared HBsAg in a UK cohort, to characterise those who clear, and to describe the dynamics of HBsAg clearance.
Methods: Our cohort was collected from the records of a large UK teaching hospital that provides >1 million patient contacts per year. We measured serum HBsAg levels using the semi-quantitative Abbott Architect i2000SR, and HBV DNA levels using the Cobas taqman assay (Roche). We identified individuals with HBV infection confirmed between 2011 and 2016 (n = 442), but in whom HBsAg levels fell consistently (serial decline and two or more consecutive readings <1000 IU/ml) or became completely undetectable.
Results: HBsAg clearance occurred in 21 of 442 individuals (4.8%), and a further 43 (9.7%) progressed towards HBsAg clearance but did not clear completely during the time period under review (total n = 64). In this group of 64, the median age was 46 years (IQR 37–56), and males predominated (39/64, 61%). The majority were HBeAg negative (61/64, 95%) and had HBV DNA <20 IU/ml (42/64, 66%). The majority of patients were treatment naïve (45/64, 70%). In individuals with an elastography score recorded, most were <10 kPa (45/50, 90%). In this clearance phase, there was no correlation between HBsAg and HBV DNA viral load (p = 0.4). For individuals starting with HBsAg ≥1000 IU/ml, the median time to clearance was 46 months (IQR 29–58 months) (Figure). There was no difference in time to clearance between patients on and off treatment (p = 0.6).
Conclusions: The majority of clearance events occurred in untreated patients, suggesting an underlying immunological mechanism. In the longer term, developing a robust understanding of the interplay between host and virus that leads to HBsAg clearance could provide insights into natural immunological control, and therefore underpin new approaches to immunotherapy. Developing insights into the use of HBsAg as a biomarker could be influential in informing prognosis and treatment of HBV, particularly in resource-limited settings in which HBV DNA measurements are not accessible.

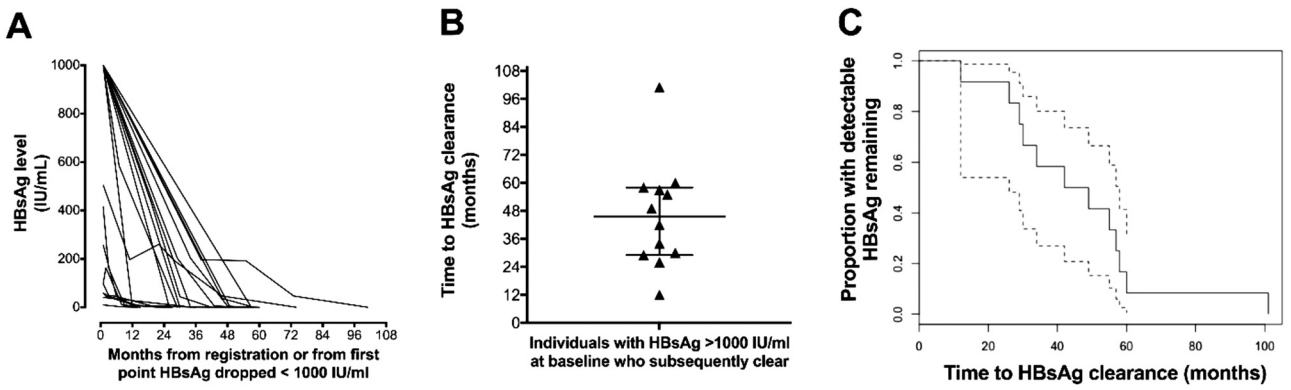

Figure: (abstract: SAT-330): Trends in HBsAg clearance. A: Longitudinal decline in HBsAg levels in 21 adults who cleared infection. B: Time taken to clear HBsAg in 12 individuals who started with HBsAg > 1000IU/ml (median and 95%CI in solid lines). C: Kaplan-Meier curve showing loss of HBsAg over time (95% CI in dashed lines).

SAT-331

Blood products as source of HEV transmission? 1-year experience with routine HEV screening at a tertiary center

T. Horvatits[1], D. Westhölter[1], J. Hiller[2], U. Denzer[2], P. Sven[2], S. Polywka[3], A. Lohse[1], S. Pischke[1], M. Luetgehmann[3]. *[1]University Medical Center Hamburg-Eppendorf, Internal Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Transfusion Medicine, Hamburg, Germany; [3]University Medical Center Hamburg-Eppendorf, Microbiology, Hamburg, Germany*
Email: t.horvatits@uke.de

Background and Aims: Hepatitis E virus (HEV) infection has become a relevant topic with increasing attention. Routine HEV testing of blood products has recently been implemented in Great-Britain and the Netherlands. The relevance of bloodborne HEV-transmission is still controversially discussed in numerous countries. Hereby we report an update of our experience at a tertiary center in Germany covering one year routine HEV testing of blood products.
Methods: From 10/2016 onwards all blood donors at the University Hospital Hamburg-Eppendorf were routinely screened for HEV RNA by PCR using the Roche cobas 6800® (LLOD single: 19 IU/ml, 24 pool: 456 IU/ml). Pools of 24 donations were tested, whereas reactive pools were tested individually to identify HEV RNA positive donors. HEV RNA positive blood products were not transfused. HEV-PCR positive donors and a control cohort (n = 256) were asked to answer a questionnaire.
Results: We identified 0.1% (30/28981) HEV-RNA-positive donors with a median viral load of 960 IU/ml. Only three of them (10%) presented with increased serum transaminases at time of donation (ALT: 83U/l, 192U/l and 101U/l). Retrospective analysis of all HEV-positive donors revealed that four donors (asymptomatic infection) had been HEV-viraemic for up to three months and the longest duration of HEV-viraemia exceeded four months. Despite the HEV testing efforts, 2 cases of clinical relevant blood borne hepatitis E occurred. Out of those one recipient developed fatal acute-on-chronic liver failure complicated by pseudomonas septicemia. The questionnaire revealed that HEV-viraemic donors significantly more often consumed raw pork meat (12/19; 63%) than controls (89/256, 35%, p < 0.01). In two donors undercooked pork liver dishes were identified as the source of infection.
Conclusions: Incidence of HEV RNA in asymptomatic blood donors in our cohort is higher than previously reported although most donors have low viral load. Since prolonged viraemia (more than 3 months) can be observed, a single HEV-positive blood donor can cause HEV infections in several patients with possible fatal clinical outcome. Uncooked or undercooked pork meat is a relevant risk factor for HEV infection.

SAT-332

Poor outcome of acute hepatitis E in liver cirrhosis and transplant recipients

M.R. Barciela[1,2], A. Barreira[1], M. Bermúdez[3], J. Llaneras[4], E. Mena[4], S. Romero[4], M.V. Cots[4], F. Sanpedro[4], M.B. Ferret[1,2], R. Esteban[1,2]. *[1]Hospital Universitari Vall de Hebrón, Liver Unit, Department of Internal Medicine; [2]CIBERehd; [3]Hospital Universitari Vall de Hebrón, Gastroenterology Department; [4]Hospital Universitari Vall de Hebrón, Emergency department*
Email: mar.riveiro@gmail.com

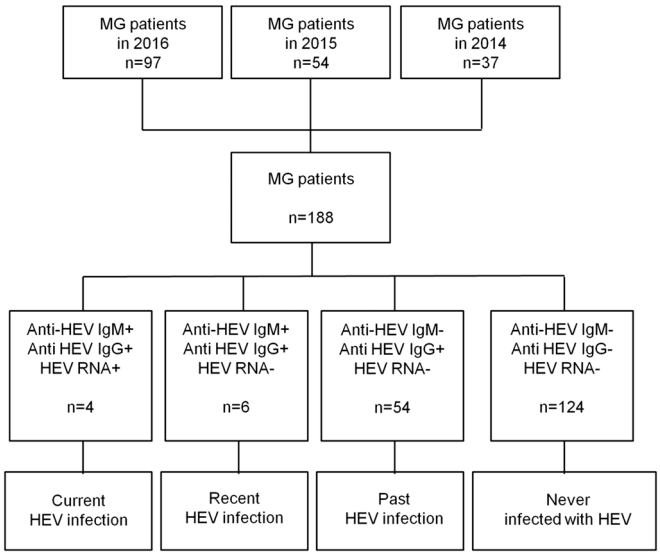
Background and Aims: Acute hepatitis E (AHE) is the most common cause of acute viral hepatitis in some Western countries, though there is scarce data concerning the outcome and associated complications.
Method: Prospective study including all consecutive AHE in subjects aged over 16 years attended at our hospital from October 2014 to October 2017. Diagnosis of AHE was based on the presence of positive HEV Ig M and abnormal liver function tests (ALT > 5xULN).
Results: 239 cases of acute hepatitis were recorded during the 3 years period. 60 (25%) were AHE: 53% female, median age 52 years (IQR 38–71). 15 (25%) were undergoing immunosuppressant therapy, 7 (12%) were transplant recipients and 6 (10%) with liver cirrhosis (1 HBV, 2 HCV, 3 alcohol). Epidemiology of AHE: 13% subjects lived in rural areas, 13% usually eat raw or undercooked meat or game meat, 7% had received blood products during the previous 3 months, 5% had travelled to an endemic HEV area within the previous year. At diagnosis of AHE 40 (67%) patients presented mild symptoms and 19 (32%) jaundice. Baseline median ALT value was 443 IU/ml (IQR 238–840), platelets 217 × 10E9/ml (IQR150–268) and albumin 3.9mg/dl (3.4–4.3). HEV RNA was carried out in 29 (48%) cases of AHE and it was positive in 9 (31%). HEV RNA remained positive more than 1 month in 5 (17%) cases and infection became chronic (positive HEV RNA for more than 6 months) in 3/7 (43%) transplant recipients with AHE. Previous solid organ transplant was the only factor associated with chronic hepatitis E (OR 1.9, p < 0.001). 6 (10%) presented extrahepatic manifestations associated with AHE: 1 neuralgic amyotrophy, 1 red cell aplasia, 4 thrombocytopenia.
3 (5%) subjects died. Mortality rate was higher in patients with liver cirrhosis (33% vs 2%, p = 0.025) due to the development of acute-on-chronic liver failure. The only dependent factor associated with higher mortality rate was platelet count <150 × 10E9/ml (OR 1.7, p = 0.001), regardless of the presence of liver cirrhosis.
Conclusion: Acute hepatitis E presented a high risk of chronic infection development in transplant patients and high mortality rate in patients with cirrhosis or low platelets account.

SAT-333

Preceding hepatitis E virus infection in patients with myasthenia gravis

L. Wang, L. Wang. *Peking University Health Science Center, Microbiology and Infectious Disease Center, Beijing, China*
Email: lingwang@bjmu.edu.cn

Background and Aims: Hepatitis E virus (HEV) is the commonest cause of acute viral hepatitis worldwide. HEV infection is associated with a broad spectrum of neurological injuries. Recently, one study described an immunocompetent woman suffered with muscle-specific kinase (MuSK) antibody–positive myasthenia gravis (MG) as a complication of acute HEV infection. However, this potential relationship between HEV and MG patients has not been systematically investigated in a larger MG patient cohort.
Methods: MG patients seen within the Department of Neurology of Peking University First Hospital between Jan. 2014 and Dec. 2016 were enrolled. A total number of 188 patients fulfilled the study criteria of a definitive MG diagnosis and serum samples being available at the time of diagnosis. All samples were tested for the presence of anti-HEV IgM and IgG using commercial EIA assays (Wantai, Beijing), according to the manufacturer's instructions. Nested reverse transcriptase polymerase chain reaction (RT-nPCR) was performed to detect HEV genome in all samples.
Results: Demographic analysis showed that 51.1% (96/188) of the patients were male and 48.9% (92/188) were female. The median onset age of the study cohort was 51 years, but ranged from 1 to 85. When assessing possible acute HEV infection preceding MG, positive anti-HEV IgM was found in 10 patients (~5%, 10/188). Anti-HEV IgG was detected in 64 patients (34%, 64/188). The 10 anti-HEV IgM-positive patients were all anti-HEV IgG-positive (Figure). Four of the anti-HEV IgM-positive samples (2.1%, 4/188) were also positive for HEV RNA (Figure). Phylogenetic analysis showed that the four HEV isolates were genotype 4. Of the 10 patients who had a current/recent HEV infection (HEV+), six were male and four female. They had a median age of 51, and ranged from 22 to 79. Their maximum Myasthenia Gravis Foundation of America Grade was obtained and compared to HEV- MG patients but this revealed no statistically significant difference. There was also no statistical difference between HEV+ and HEV- patients regarding age at onset, sex, MG antibodies and preceding thymic hyperplasia. However, HEV+ MG patients did have a significantly higher rate of preceding thymoma than HEV- MG patients (40.0% versus 9.6%, p = 0.02).



Conclusions: The current study, conducted on a large well-defined cohort of Chinese patients with MG, indicates that approximately 5% of the patients have acute HEV infection at the start of their neurological illness. HEV viraemia was detected in 4/188 MG patients (2.1%, 1:47), a prevalence that is at least 20 times greater than that reported for Chinese blood donors (0.09%, 1:1094). In addition, the four HEV strains detected were all HEV-4 and closely related to strains isolated from swine in China. Additional studies conducted in other geographical areas are warranted and patients with MG should be screened for HEV infection.

SAT-334

Hepatitis A affecting men having sex with men: ongoing outbreak in Israel, December 2016–September 2017

Y. Gozlan[1], I. Bar-Or[1], A. Rakovsky[1], M. Savion[2], N. Cider[3], E. Mendelson[1], Z.B. Ari[4], O. Mor[1]. *[1]Chaim Sheba Medical Center, Central Virology Laboratory, Ramat Gan, Israel; [2]Ministry of Health, Tel Aviv, Israel; [3]Ministry of Health, Jerusalem, Israel; [4]Sheba Medical Center at Tel Hashomer, Center of Liver Diseases, Tel Aviv, Israel*
Email: orna.mor@sheba.health.gov.il

Background and Aims: Since June 2016, a hepatitis A virus (HAV) outbreak mainly affecting men having sex with men (MSM) in multiple European countries has been reported. The first cases in Israel were identified at the end of December 2016, despite infant HAV vaccination program implemented since 1999, which have brought to a 90% decline in disease incidence. Here, we report the clinical and environmental surveillance of the current ongoing HAV outbreak, spanning January 2017–September 2017.
Methods: Blood samples from acute viral hepatitis cases (HAV immunoglobulin M positive) and 113 sewage samples, collected monthly from 14 facilities around the country, were analyzed. Total nucleic acids were extracted with NucliSENS EasyMag (bioMérieu, France). Real-time PCR (RT-PCR) and sequencing of the VP1-2a region were performed according to national protocols. Phylogenetic analysis included the current three 1a European outbreak strains (RIVM_HAV16-90 (EUROPRIDE), VRD_521_2016 (UK/SPAIN) and V16-25801_VP1). Demographic and clinical information from all affected cases was also collected.
Results: Reports of 56 HAV infections were filed in the study period, affecting patients with median age of 34 (range 15–62). Among these, 94.6% (53/56) were male, 29 of whom were self-identified as MSM, of whom 86.5% (25/29) were from the Tel Aviv area. Only 22.7% (5/22) of those identified as non-MSM were from the Tel Aviv area. Information on HAV vaccination was available for 43 of the patients; most (93%, 40/43) were unvaccinated. In parallel, HAV positivity was measured in 20.4% (23/113) of all sewage samples, with a high prevalence (70%, 16/23) in facilities in the Tel-Aviv area. The rate of HAV-positive samples increased between Q1 2017 (8.1%, 3/37) and Q3 2017 (28.9%, 11/38) (Figure 1a). Most (94.2%) HAV-positive clinical samples and all sewage-derived HAV sequences clustered with RIVM_HAV16-90 (EUROPRIDE) or VRD_521_2016 (UK/SPAIN) 1a subtypes (Figure 1b).
Conclusions: These observations confirm an ongoing HAV 1a outbreak in Israel. In addition, the parallel seen between sewage and clinical results, demonstrates the value of enviormomental sampling in disease surveillance. As all clinical cases occurred in individuals older than 24 years of age, and many of the infections were in the MSM population, this study further demonstrates that despite efficient vaccination program, HAV can still be transmitted to the unvaccinated, high-risk population.

SAT-335

Incidence of hepatitis E infection in renal transplant patients in The Netherlands

R. Erken, S. Willemse, M. Sinnige, H. Reesink, F. Bemelman, H. Zaaijer. *Academic Medical Center, Hepatology, Amsterdam, Netherlands*
Email: h.w.reesink@amc.uva.nl

Background and Aims: Hepatitis E virus (HEV) infection is a major cause of hepatitis worldwide. HEV genotype (gt) 1 and 2 are endemic

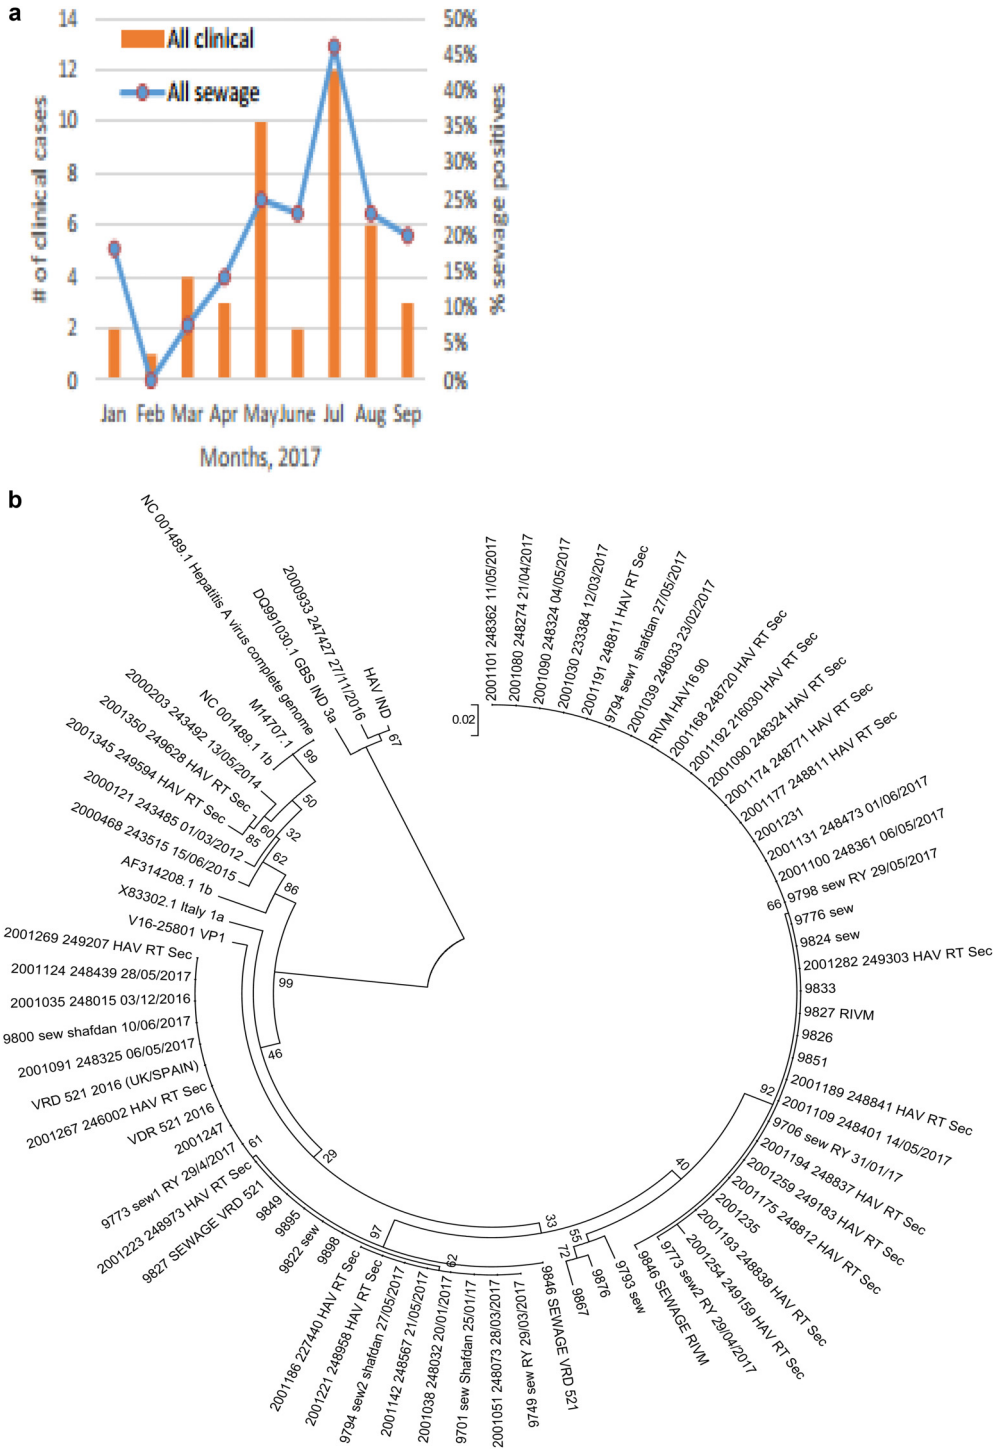


Figure: (abstract: SAT-334)

in developing countries where they cause self-limiting acute hepatitis. The zoonotic genotypes 3 and 4 mainly cause asymptomatic infections and are endemic in developed countries such as in Western Europe. HEV gt3 infection in immunocompromised patients can persist and patients may develop chronic hepatitis. Subsequently, chronic hepatitis E can result in rapid development of liver cirrhosis and liver failure. In this retrospective study, we aimed to identify HEV infections in immunocompromised kidney transplant recipients in a transplantation center in The Netherlands.

Methods: Between 2001 and 2012, serum samples of 677 kidney transplant recipients were prospectively collected and cryopreserved for research purposes. Patients who had elevated alanine transferase (ALT) levels at some time point after kidney transplantation were selected for HEV testing. Samples for HEV measurement were selected in time, in the period of an ALT elevation. Samples were pooled per 10 and HEV RNA was determined using an in-house made polymerase chain reaction (PCR) (lower limit of detection (LLD)10 IU/ml). Consequently, the LLD in these pools corresponded with 100 IU/ml.

Results: Of the total of 677 patients, 359 had at least one episode of elevated ALT levels. Of these patients, there were 300 patients with available samples for testing. Furthermore, 73 of these 300 patients had two or more episodes with ALT elevations after transplantation. Of all of these 73 patients, samples were available for testing. In total, two out of 300 patients (0.7%) with ALT elevations tested positive for HEV RNA while in these patients, no HEV RNA could be detected around the time of transplantation. Both patients developed chronic HEV infection, one of which was successfully treated with ribavirin. The other patient cleared the infection spontaneously after 3 years without treatment. After clearance of the HEV-infection, both patients developed anti-HEV IgG antibodies.
Conclusions: In this cohort of 677 immunocompromised kidney transplant recipients, 300 (44.3%) patients had one or more ALT elevations post -transplantation. With 0.7%, the incidence of chronic HEV infection in renal transplant recipients with elevated transaminases in our center is low.

SAT-336
Hepatitis E Virus adapts to cell culture, but shows limited mutagenesis in immune compromised hosts
M. Van de Garde[1], A. van Schoonhoven[1], G.S. Kaplan[1], R.D. Man[1], A. Boonstra[1], S. Pas[2,#], T. Vanwolleghem[1,2,#]. *[1]Department of Gastroenterology and Hepatology, Erasmus University Medical Center, Rotterdam, The Netherlands; [2]Laboratory of Experimental Medicine and Pediatrics, Faculty of Medicine and Health Sciences, University of Antwerp and Department of Gastroenterology and Hepatology, Antwerp University Hospital, Antwerp, Belgium; [3]Department of Viroscience, Erasmus University Medical Center, Rotterdam, The Netherlands*
Email: t.vanwolleghem@erasmusmc.nl

Background and Aims: Hepatitis E viruses (HEV) in patient blood, feces or liver have different in vivo and in vitro infectivities, which has been ascribed to biophysical differences of the virions. Less is known about the selection of viral quasispecies in these different body compartments. Since single nucleotide variants have been suggested to alter HEV virulence, we examined the genomic stability of HEV virions in different clinical samples and experimental conditions
Methods: Near full HEV genome Sanger sequences of untreated chronic phase serum- and feces samples from two immunocompromised chronic HEV gt3 patients were obtained. In vitro derived HEV was obtained from A549 cell culture supernatant after seven passages of patient feces-derived HEV, showing increased replication capacity over other passages. In vivo derived HEV was obtained from a human-chimeric mouse infected with patient feces derived HEV.
Results: After prolonged in vitro culture, a clinical HEV gt3 strain acquired 19 nucleotide mutations, leading to 7 non-synonymous amino acids changes in the papain-like cystein protease, variable, viroporin and capsid regions. The same clinical HEV gt3 strain showed only 4 nucleotide mutations without alterations in the amino acid sequence after prolonged infection in a human liver-chimeric mouse model with impaired adaptive and innate immune responses. Similarly, intra-patient comparison of feces- and serum-derived HEV gt3 showed 7 and 2 nucleotide mutations with 2 and 0 amino acid changes, in two patients respectively.
Conclusion: Overall, our data suggest that in vivo selection pressure in immunodeficient hosts is minimal, but adaptation to in vitro culture occurs.

Longitudinal analysis of HCV full genomes in patients failing NS5A inhibitors reveals the selection of novel amino acid substitutions outside NS5A
S. Fourati[1,2], C. Rodriguez[1,2], A. Soulier[1,2], L. Poiteau[1,2], D. Vanessa[1,2], I. Ruiz[2], C. Hezode[2,3], S. Chevaliez[1,2], J.-M. Pawlotsky[1,2]. *[1]National Reference Center for Viral Hepatitis B, C and delta, Department of Virology; [2]INSERM, INSERM U955 equipe 18; [3]Henri Mondor Hospital, Hepatology*
Email: slim.fourati@aphp.fr

Background and Aims: When treatment fails, HCV NS5A inhibitors select Resistance Associated substitutions (RASs) located in domain I of the NS5A protein. NS5A RASs persist for many years, probably forever, after DAA-containing treatment failure. By analogy to HIV or HBV resistance, it is thought that compensatory or fitness-associated substitutions are also selected during treatment and could at least partly explain the long-term persistence of NS5A RASs. However, very limited information on compensatory mutations selected under antiviral therapy has been generated thus far, principally due to the sequencing methods available that characterize short genome fragments only. Here, we used an original shotgun metagenomics method based on deep sequencing of full-length HCV genomes to characterize amino acid substitutions selected by DAA therapy in regions targeted or not targeted by the NS5A inhibitors in patients who fail to achieve SVR.
Method: Using shotgun metagenomics, we generated the full-length HCV genome sequences at treatment initiation and at virological relapse in 12 patients who failed to achieve SVR on an NS5A-containing regimen (sofosbuvir + daclatasvir or sofosbuvir + ledipasvir). Briefly, universal DNA/RNA extraction was performed followed by library preparation using Total RNA and Nextera XT kit (Illumina). Deep sequencing was performed by means of NextSeq500 (Illumina). Full-length HCV sequences at baseline and at virological relapse were analyzed using our original in-house MetaMIC® software (quality, filtering, identification, genome reconstruction and comparison) and the sequences were analyzed using a 15% cutoff, according to EASL guidelines.
Results: A significant relationship was found between the HCV RNA levels and the number of equivalent HCV genome sequences generated ($p < 0.01$; $r^2 = 0.91$). Sequential analysis of full-length genome sequences identified selection of known RASs in NS5A domain I targeted by the inhibitors, but also of a number of substitutions in other genomic regions (core, E1, E2, NS3, NS4B, NS5A domain III). The majority of failures occurred in patients infected with genotype 3 ($n = 5$) and genotype 4 ($n = 4$). In genotype-3 infected patients, the following amino acid substitutions were selected together with NS5A RASs: in NS3 T98S or T98A, NS4B T48A and G114S, NS5A N448S and NS5B K114R.
Conclusion: Using an original shotgun metagenomics method based on deep sequencing that generates full-length HCV sequences, we could detect amino acid substitutions independently selected in the NS3, NS4B, NS5A (domain III) or NS5B regions in patients failing sofosbuvir plus an NS5A inhibitors. Some mutated residues were known to influence viral replication. These changes could increase RAS-related reduced drug susceptibility and/or compensate for losses of viral replication capacity they confer (e.g. Y93H). Phenotypic characterization is underway.

SAT-340

Efficient, reproducible, and long-term hepatitis B virus infection in cryopreserved primary human hepatocytes

M. Yu, L. Gamelin, S. Xu, X. Xie, J.J. Chia, T. Cheung, J. Song, D. Burdette, C. Niu, S. Daffis, R. Choy, H. Yang, B. Delaney, G. Cheng. *Gilead Sciences, Inc, Biology, Foster City, United States*
Email: mei.yu@gilead.com

Background and Aims: HepG2 cells expressing NTCP support HBV infection; however, the infection remains inefficient and HepG2 is a transformed cell line. Freshly isolated primary human hepatocytes (PHHs) support efficient HBV infection, but have limited availability. The use of cryopreserved PHHs can avoid these limitations but historically has not yielded efficient and reproducible HBV infection. Here, we report establishment of an efficient and reproducible HBV infection model using cryopreserved PHHs.
Method: Cryopreserved PHHs and culture media were purchased from Thermo Fisher Scientific or other commercial suppliers. In vitro HBV inocula were produced by HepAD38 cells. HBV patient viruses were purchased from various clinical contract research organizations. HBV DNA and RNA were quantified by qPCR. HBe and HBs antigens were measured by ELISA. HBV cccDNA was quantified by Southern Blot and qPCR. NTCP knockdown was achieved using siRNA (Thermo Fisher).
Results: Under culture conditions recommended by suppliers, cryopreserved PHH from two donors did not produce significant HBsAg (<1 ng/ml) following infection with Hep-AD38-derived HBV (500 genome equivalents/cell). However, optimization of culture medium to include 4% PEG8000 and 1.5% DMSO resulted in >100-fold higher HBsAg levels within 13 days of infection. Using these modifications, cultured PHHs also supported robust infection by plasma-derived patient viruses of multiple genotypes. To achieve similar infection in HepG2-NTCP cells, at least 10 times more viruses were needed. In infected PHH, HBV cccDNA was detected by Southern Blot as early as day 1 post infection and reached a steady level at day 3–4 post infection. Addition of the HBV entry inhibitor Myrcludex B or knockdown of NTCP by siRNA inhibited >90% HBV infection. Importantly, these culture conditions have been successfully applied to 20 cryopreserved PHHs donors, although not all donors tested support efficient infection. These infection and culture conditions have also permitted effective passage of infection to naïve PHH cultures and supported persistent HBV infection for >40 days. Treatment with nucleoside inhibitors or capsid assembly modulators inhibited viral DNA replication but had minimal effect on antigen production. Finally, IFN-α inhibited both viral DNA and antigens with >10-fold higher potency than in HepG2-NTCP, but had no effect on cccDNA level.
Conclusion: An efficient HBV infection model has been established using cryopreserved PHHs. Its high efficiency, reproducibility, and ability to support long-term infection will facilitate a better understanding of HBV life cycle and discovery of novel therapeutics.

SAT-341

NLRX1 and the p.Arg707Cys variant in NLRX1 affect host susceptibility of hepatitis B virus infection in Huh7-NTCP cells

L. Peng, J. Qian. *3rd Affiliated Hospital of Sun Yat-sen University, Department of Infectious Diseases, Guangzhou, China*
Email: pliang@mail.sysu.edu.cn

Background and Aims: NLRX1 is a negative regulator of mitochondrial antiviral immunity. Expression of NLRX1 results in the potent inhibition of RLH- and MAVS-mediated interferon-β promoter activity and in the disruption of virus-induced RLH- MAVS interactions. How NLRX1 affects the individual susceptibility to HBV is not clear. Our previous study found that a rare genetic mutation NLRX1 p.Arg707Cys affects the structure of NLRX1 and contributes to influence host susceptibility of CHB.
The purpose of this research was to investigate the effects and mechanisms of NLRX1 and the p.Arg707Cys Variant in NLRX1 on the individual susceptibility to HBV.
Method: The Huh7- NTCP model was established. In the same way, lentiviral vectors were used to establish both stable wild type NLRX1 (WT)- overexpressing and p.Arg707Cys NLRX1 (MT)- overexpressing Huh7- NTCP cell lines. Western blot and real time quantitative PCR were used to confirm the overexpressing of WT NLRX1 and MT NLRX1 in Huh7- NTCP cells. The susceptibility to HBV of MT and WT were tested on Huh7- NTCP infected cells with HBV, HBsAg, HBcAg, HBV DNA and HBV cccDNA were detected.
Results: WT NLRX1 and MT NLRX1 in Huh7- NTCP cells were demonstrated significantly increased. Cell model experiments confirmed that NLRX1 reduced HBV infection and p.Arg707Cys impairs the individual susceptibility to HBV of NLRX1. HBsAg, HBcAg, HBV cccDNA and HBV DNA levels were significantly increased in both WT and MT NLRX1-overexpressing Huh7- NTCP cells compared with naive Huh7- NTCP cells. While the levels in MT NLRX1-overexpressing Huh7- NTCP cells was significantly lower than the WT ones.
Conclusion: NLRX1 is a negative regulator of host response to HBV, and its coding gene mutation NLRX1p.Arg707Cys will weaken the negative regulation function, enhances the ability of host resistance to HBV infection. Therefore, this means that the p.Arg707Cys Variant in NLRX1 is a new target for HBV antiviral therapy.

SAT-342

The stapled peptides derived from hepatitis B virus core protein hijack viral replication

J. Han, X. Cong. *Peking university people's hospital, Peking university hepatology*
Email: hjcaizhh@126.com

Background and Aims: Protein-protein interactions (PPI) are involved in all aspects of the viral lifecycle, including genome packaging, reverse transcription, intracellular trafficking and cccDNA epigenetic regulation. Those processes depend on the correct function and conformation of HBV core protein. To develop PPI inhibitors targeting core protein is attractive for HBV therapy. Here we designed a series of stapled peptides based on α-helix domains of core protein, and completed antiviral activity assay.
Method: Helical peptides with hydrocarbon staples were synthesized, uptake of peptide by cell and stabilization were assayed. Antiviral activity was measured by qPCR from HepG2 cells transiently transfected with four genotype expressing vectors (A~D). HBsAg and HBeAg were measured by ELISA in HepDes19 cells. HBV replicative DNA intermediates and viral RNA were detected by southern and northern blot analysis. The interaction of stapled peptides with core protein was determined by co-immunoprecipitation.
Results: Those stapled had more highly levels of cell penetration, proteolytic resistance, and target affinity than natural α-helix peptides. Several stapled peptides derived from core protein intra-dimmer interface exhibited potent viral load reduction in vitro. Surprised, Stapled peptides inhibited HBsAg and HBeAg expression (EC50 50~100 mM). HBV cccDNA was reduced in HepDeS19 cells treated with stapled peptides.
Conclusion: Hydrocarbon stapled α-helix peptides derived from core protein interfere HBV replication, which could be attractive tools for HBV therapy.

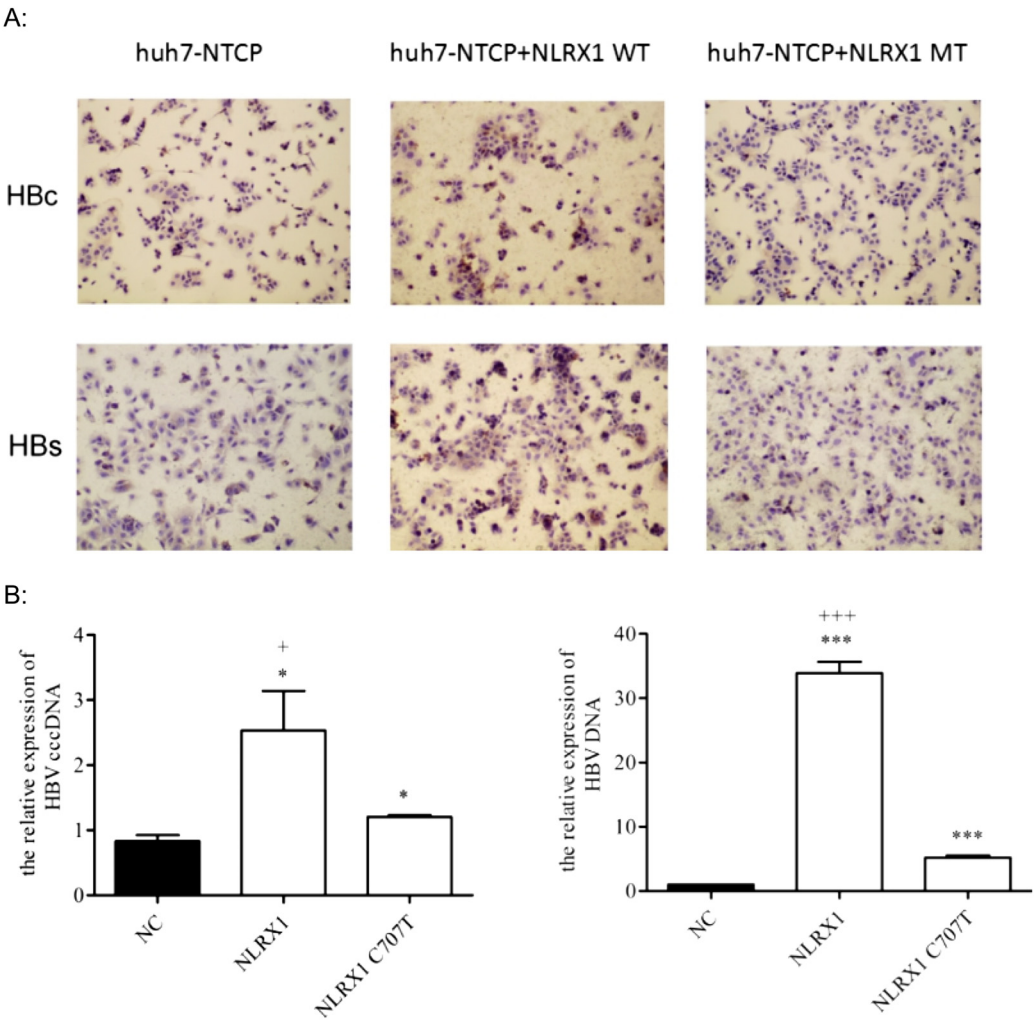

Figure: (abstract: SAT-341): Figure legend: Levels of HBcAg, HBsAg, HBV cccDNA, and HBV DNA in HBV-infected Huh7- NTCP cells with NLRX1 WT and MT overexpression. (A) IHC results showed higher levels of HBcAg and HBsAg in NLRX1 WT and MT overexpression Huh7- NTCP cells than in naive Huh7- NTCP cells. While the levels of HBcAg and HBsAg were lower in NLRX1 MT than WT overexpression Huh7- NTCP cells. (B) Quantitative analysis of HBV cccDNA and HBV DNA levels in HBV-infected Huh7- NTCP cells with NLRX1 WT and MT overexpression. After HBV infection, the level of HBV cccDNA ($^{*}p < 0.05$) and HBV DNA ($^{***}p < 0.001$) in Huh7- NTCP cells with NLRX1 WT and MT overexpression were higher than in naive Huh7- NTCP cells. While the levels of HBV cccDNA ($^{+}p < 0.05$) and HBV DNA ($^{+++}p < 0.001$) were lower in NLRX1 MT than WT overexpression Huh7- NTCP cells.

SAT-343

DEAD-box helicases DDX5 and DDX17 areinvolved in the fine tuning of hepatitis B virus minichromosome transcriptional regulation

F. Chapus[1,2], M. Locatelli[1,2], J. Fresquet[1], B. Testoni[1,2], F. Zoulim[1,2,3].
[1]*CRCL, Inserm U1052, LYON, France;* [2]*Université de Lyon 1, LYON, France;* [3]*Hospices Civiles de Lyon, LYON, France*
Email: fabien.zoulim@inserm.fr

Background and Aims: Hepatitis B virus (HBV) minichromosome, the covalently-closed-circular (ccc)DNA, is responsible for HBV chronicity and reactivation. Current antiviral treatments inhibit viral replication, but do not significantly affect cccDNA reservoir in the hepatocyte nuclei. cccDNA is a stable episome with a dynamic chromatin structure regulated by epigenetic mechanisms. It is the template for all viral subgenomic transcripts and for the pre-genomic RNA (pgRNA), which is retrotranscribed and encapsidated to ensure both newly synthesized viral progeny and cccDNA pool replenishment via intracellular nucleocapsid recycling. Overlapping open reading frames and regulatory elements on HBV genome have to be precisely and timely controlled to ensure correct cccDNA transcription and viral mRNA processing. To better understand the mechanisms orchestrating cccDNA transcriptional regulation, we investigated the role of DDX5 and its highly related paralog DDX17, two DEAD-box helicases known to play a driving role in connecting cellular chromatin topology to correct transcriptional initiation and termination in concert with the architectural proteins CCCTC-binding Factor (CTCF) and Matrin-3.
Method: Chromatin Immunoprecipitation (ChIP), RNA-IP, protein co-immunoprecipitation (co-IP) and knockdown by RNAi were performed in HepG2-NTCP cells and Primary Human Hepatocytes one week after HBV infection, when cccDNA pool is stable.
Results: ChIP analysis demonstrated that DDX5/17, CTCF and Matrin-3 bind to cccDNA in both HepG2-NTCP cells and PHH, together with the HBV core protein (HBc). Protein co-IP in a HepaRG cell line overexpressing HBc in an inducible manner, demonstrated that HBc, DDX5/17, CTCF and Matrin-3 belong to the same complex. In particular, sequential ChIP with an anti-HBc and then an anti-CTCF antibody confirmed the simultaneous presence of both proteins on the same cccDNA molecule. RNA-IP also showed the binding of DDX5/17, CTCF and Matrin-3 to viral RNAs and to preC/pgRNA in particular. DDX5/17 knockdown by small interfering RNA (siRNA) induced a strong decrease of preC/pgRNA levels and viral HBe antigen secretion, without affecting global cccDNA levels.
Conclusion: These data highlight the presence of a complex formed by HBc, DDX5/17, CTCF and Matrin-3 at the interface between cccDNA and viral RNAs and suggest a functional role for the helicases DDX5/17 on cccDNA transcriptional regulation and/or mRNA processing.

SAT-344

Rolling circle amplification and nanopore-based deep sequencing of full-length HBV genomes

A. Mcnaughton[1], D. Bonsall[2], M.D. Cesare[2], A. Brown[1], D. Parkes[3], R. Bowden[3], E. Barnes[1,4], P. Matthews[1,5]. [1]*University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom;* [2]*Wellcome Centre for Human Genetics, Nuffield Department of Medicine, Oxford, United Kingdom;* [3]*University of Oxford, Wellcome Centre for Human Genetics, Oxford, United Kingdom;* [4]*Oxford University Hospitals NHS Foundation Trust, Department of Hepatology, Oxford, United Kingdom;* [5]*Oxford University Hospitals NHS Foundation Trust, Department of Infectious Diseases and Microbiology, Oxford, United Kingdom*
Email: p.matthews@doctors.org.uk

Background and Aims: The optimisation of unbiased deep-sequencing methods for full-length HBV genomes will inform detailed insights into the evolution and diversity of this pathogen. Nanopore-based sequencing technologies offer the potential for real-time detection and sequencing of blood-borne viruses, useful for clinical diagnosis, drug-resistance calling and high-resolution molecular epidemiology. To date, sequencing accuracy has limited the full potential of Oxford Nanopore's long-read capabilities. We here describe use of an isothermal rolling-circle amplification (RCA) method, (i) to amplify HBV DNA and (ii) to derive concatemers of whole HBV genomes thus providing a mechanism to correct sequencing errors.
Method: DNA was extracted from plasma samples from patients with chronic HBV infection using the NucliSENS magnetic extraction system. Partially double-stranded HBV DNA genomes were converted into fully double-stranded, covalently closed circular DNA using T4 polymerase followed by T4 ligase. RCA was undertaken by incubation with a panel of 8 HBV-specific primers (complementary to both strands) and phi29 DNA polymerase at 30°C for 22 hours. Products were "debranched" using T7 endonuclease and sequenced on the Nanopore MinION device using the 1d ligation sequencing kit and R9.4 flowcell (SQK-LSK108; Oxford Nanopore technologies). On-target HBV sequences were filtered from base-called fastq files using Kraken and BLAST; consensus sequences were derived from multiple concatenations to correct error.
Results: We successfully sequenced individual whole HBV genomes as single reads. The highest-yield sample produced 1,296,131 reads, of which 87% contained human sequence. BLAST identified 16,297 HBV reads, of which 2,738 contained at least one contiguous, complete HBV genome. Consensus averaging of concatenated genomes facilitated error correction of complete viral haplotypes. Based on BLAST analysis with a database of reference sequences for subtypes A-H, this sample genotyped as E.
Conclusion: We have demonstrated that an isothermal RCA method can provide enrichment of HBV DNA and concatenation of the HBV genome. This is the first example of a deep-sequencing method for characterising HBV variants that takes full advantage of Nanopore's ability to sequence whole genomes within single reads, and also facilitating correction of sequencing error. There is exciting potential for these tools to be refined for full-length, high-resolution sequencing analysis of HBV (and other viruses), impacting both clinical and research settings.

SAT-345

LTPprodrug technology offers new generation nucleotide antiviral agents

L. Zhi[1], E. Vajda[2]. [1]*Nucorion Pharmaceuticals, Suite 110, San Diego, United States;* [2]*Ligand Pharmaceuticals, Ligand Pharmaceuticals, San Diego, United States*
Email: lzhi@ligand.com

Background and Aims: Nucleotide analog reverse-transcriptase inhibitors (NtRTI) have been one of the major antiviral arsenals in combating HBV and HIV. Improving prodrug efficiency over clinically validated nucleotide molecules has demonstrated to be a cost-effective new drug development strategy to offer more effective and safer medicines, e.g. tenofovir alafenamide fumarate (TAF) offers significant advantages over tenofovir disoproxil fumarate (TDF). We report that LTP technology improves prodrug delivery efficiency to a new level over the HepDirect(HD) technology and ProTide technology.
Method: Three types of tenoforvir prodrugs were orally administered to Sprague-Dawley rats at the same doses. Blood and tissues were harvested and snap-frozen in liquid nitrogen. Tenofovir and tenofovir-diphosphate (TDP) concentrations were measured by LC-MS/MS to compare oral delivery and liver-targeting efficiency.
Results: At 5 mg/kg doses, NCO-8548 (LTP-tenofovir) achieved TDP levels in the liver at 1 and 5 hours after dosing over 92- and 21-fold higher than that of NCO-8429 (HD-tenofovir) and over 15- and 7-fold higher than TAF-base (ProTide-tenofovir) (see Table 1 below). Since NCO-8429 and NCO-8548 are mainly metabolized by CYP3A4 and phosphoramide bond of TAF-base was cleaved by histidine triad nucleotide-binding protein 1 (HINT1), one can expect that exposure levels of the nucleotides in other target tissues will be largely dependent on the tissue expression levels of these enzymes. CYP3A4

is expressed at particularly high levels in the liver, making it ideal for enhanced liver targeting of NCO- compounds.

Table: Liver TDP and blood tenofovir levels after oral dosing of TAF-base, NCO-8429, and NCO-8548 in male Sprague Dawley rats

Compound	TAF-base (ProTide prodrug)	NCO-8429* (HD prodrug)	NCO-8548* (LTP prodrug)
TDP_{liver} at 1, 5 h(nmol/g)	0.86 ± 0.91	0.14 ± 0.06	13.0 ± 9.5
	2.16 ± 1.06	0.75 ± 0.30	16.1 ± 8.2
$Tenofovir_{blood}$ at 1, 5 h (nmol/mL)	0.22 ± 0.13	<0.007	0.11 ± 0.03
	0.030 ± 0.007	<0.007	0.051 ± 0.007
TDP_{liver}/ $Tenofovir_{blood}$ at 1, 5 h	3.9, 72	>20, >107	118, 316
$Drug_{liver}$ at 1, 5 h(nmol/g)	<0.02	0.074 ± 0.014	0.32 ± 0.10
	<0.02	0.026 ± ND	<0.01
$Drug_{blood}$ at 1, 5 h(nmol/g)	<0.003	0.015 ± 0.002	0.016 ± 0.006
	<0.003	0.005 ± 0.002	<0.003

*Results are adjusted to the doses that are nucleotide equivalent.

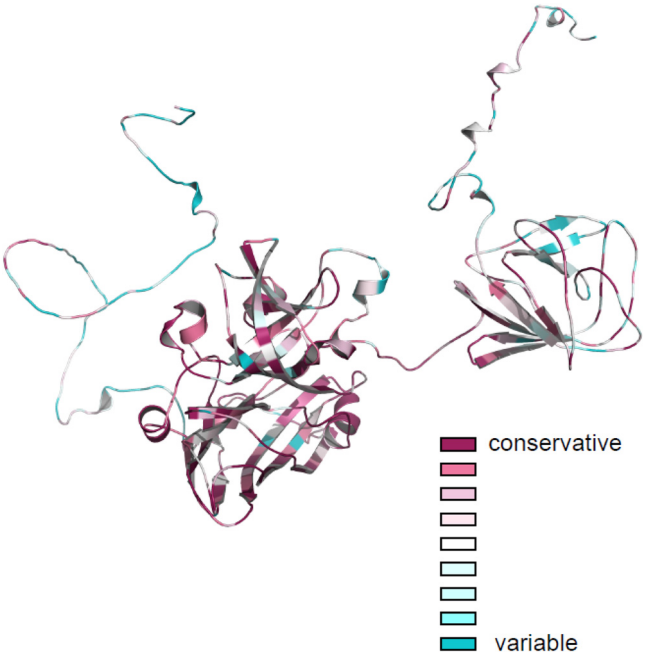
Conclusion: LTP-tenofovir compound demonstrated higher level of TDP in the liver and enhanced liver-targeting relative to the HD-tenofovir and ProTide prodrugs. LTP technology can be an effective method to increase the antiviral therapeutic index of nucleotides.

SAT-346

Conservation and variation of the hepatitis E virus open reading frame 2 proteome

S. Zhang[1], C. Qu[2], M. Peppelenbosch[2], Q. Pan[2]. [1]*Gastraenterology and hepatology, Erasmus University Medical Center, Rotterdam, Netherlands;* [2]*Erasmus University Medical Center, Gastroenterology and Hepatology*
Email: s.zhang@erasmusmc.nl

Background and Aims: Hepatitis E virus (HEV) infection is emerging as a global health issue. HEV particles are made up of capsid proteins and viral genomic RNA. As the major protein component of mature viral particle, capsid carries almost all the information of viral assembly and interactions with hosts. With tremendous advances in computing technology and algorithm, bioinformatics has allowed us to map the evolutionary features and model high-accuracy structures of the open reading frame 2 (ORF2) proteome across different strains. Importantly, we were able to model the binding affinity of ORF2 from different strains towards neutralizing antibody.
Method: We systematically retrieved 307 high quality ORF2 sequence from more than 30 countries with collection date cover three decades and performed conservation analysis. We have also modelled up to 41 ORF2 structures across the defined reference sequences and subtypes. Structure alignment and docking with neutralizing antibodies were accomplished.
Results: HEV ORF2 has a conservative length, 660 is typical and 674 is the longest. With conservation analysis, we confirmed up 138 evolutionary conservative sites of ORF2, some of which are consistent with protein modification in experimentation. Systematically modelling of reference sequences revealed five functional regions of ORF2 and we found P domain more variable than S and M domains. Despite known S, M and P domains, we also find chain structures of N and C termination which possibly are cleaved during viral assembly. Docking with neutralizing mouse monoclonal antibodies shows that there is no clear association with viral evolution and binding affinity with antibody.
Conclusion: ORF2 is evolutionary conservative and can be important clue to biology of HEV. As building blocks in viral assembly, S and M domain are conservative while P domain is more variable. Therefore, the effectiveness of neutralizing with antibody is significantly different across subtypes.



SAT-347

Mutations in HCV NS3 but no Sec14L2 variants alter HCV RNA replication of natural occuring viruses in cell culture

R. Costa[1], D. Todt[2], F. Belinchon[1], A. Walker[3], C. Schenk[4], J. Timm[3], V. Lohmann[4], V.H. Thomas[1], S. Ciesek[5]. [1]*Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*Experimental Virology, Twincore, Hannover, Germany;* [3]*Institute of Virology, Düsseldorf, Germany;* [4]*Molecular Virology, Heidelberg, Germany;* [5]*Institute of Virology, Essen, Germany*
Email: Sandra.ciesek@uk-essen.de

Background and Aims: With 71 million chronically infected patients worldwide, HCV remains an important element in the aetiology of chronic liver disease. Since the discovery of the virus several breakthroughs allowed the development of effective therapies to combat the infection, nonetheless, important elements of the viral life cycle remained elusive. Chief among them, the inability to consistently replicate pan-genotype virus samples in cell culture. This changed in 2015 with the discovery of SEC14L2 as a necessary factor for viral replication. In this study we aim to broaden the understanding of the role of SEC14L2 and its variants.
Method: We employed the model reported by Saeed et al to enable HCV viral replication in cell culture. Following model validation we introduced single nucleotide polymorphisms of SEC14L2 in cell culture populations and characterized relevant phenotypes such as cytosolic vitamin E abundance, cellular cholesterol abundance and variant expression levels. Following characterization we infected the cells with patient isolates to compare replication enhancement effects among variants. Finally we selected two variants and screened a cohort of 35 HCV infected patient sera, containing genotypes 1a, 1b, 2a, 2b, 3a, 3c, 4a, 4d and 5 to validate our observations in an extensive virus panel and identify genotype specific dependencies.
Results: We were able to reproduce SEC14L2 dependent HCV replication in our cell model yet, not all isolates exhibited the same levels of replication in cell culture. When testing SEC14L2 variants, we observed no statistically significant differences in the analyzed phenotypic traits; nonetheless only 7 out of 13 Sec14L2 variants enabled HCV replication in cell culture. Isolates from genotypes 1 and 3 exhibited a marked enhancement from the expression of SEC14L2 whereas genotypes 2, 4 and 5 remained largely unaffected. Furthermore, after isolate sequencing, we were able to identify

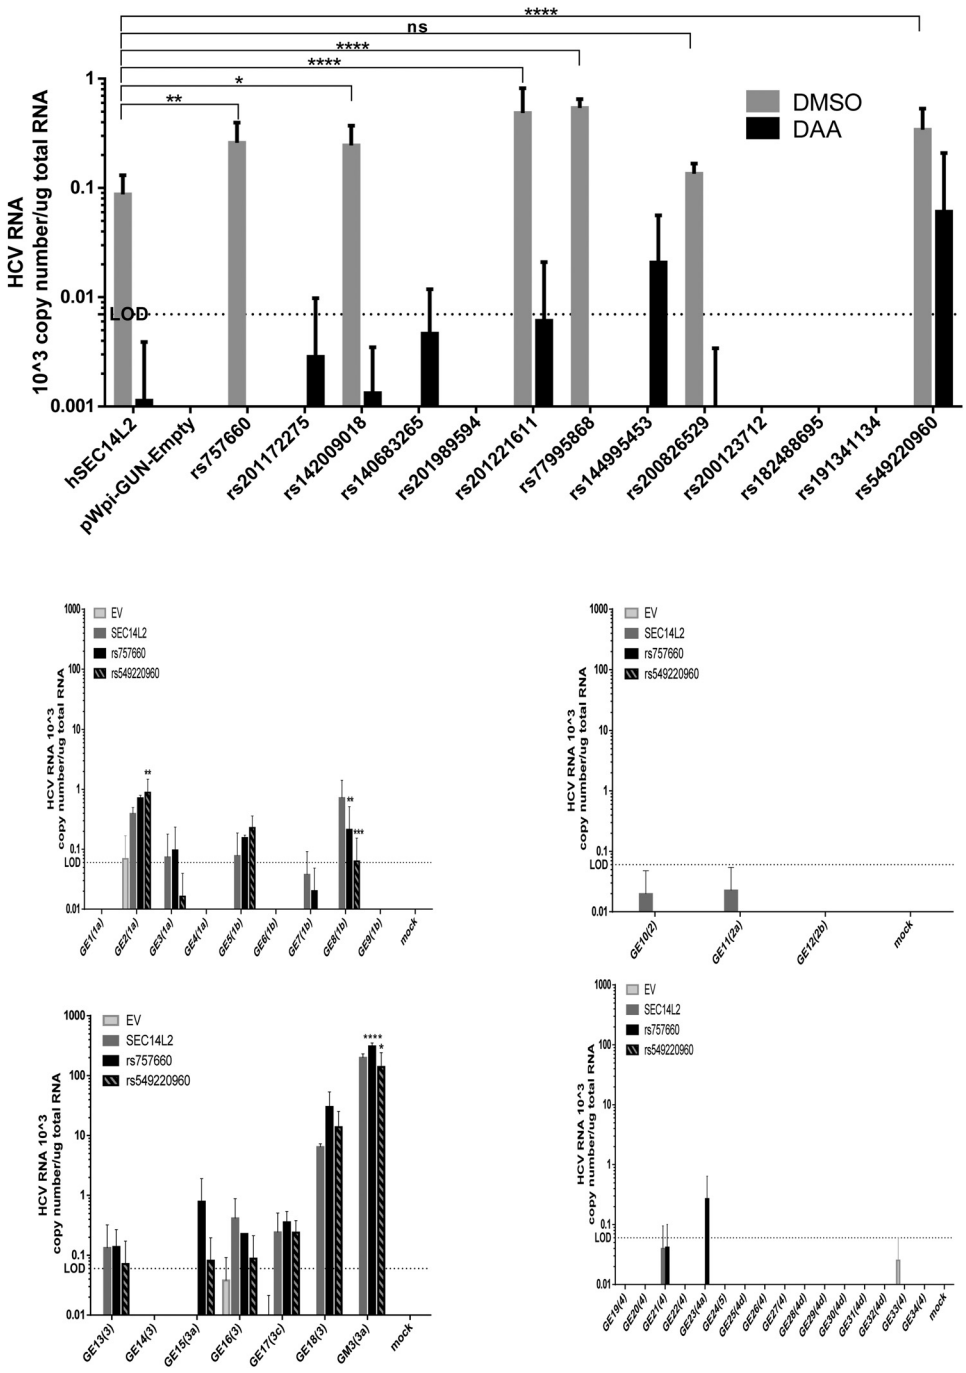


Figure: (abstract: SAT-347)

several candidate mutations mapped to NS3 and NS5A that were present in the replicating isolates and not the non-replicating, these may impact the replication phenotype.

Conclusion: SEC14L2 is an important factor for HCV viral replication. In this work we set out to report the effect of SEC14L2 variants in viral replication in cell culture and possible viral determinants that mediate dependency of SCE14L2. Interestingly, in our observations, only 7 of the 13 SEC14L2 enabled replication although the vitamin E phenotype did not vary in a statistically significant way among them which argues in favor of a further mechanism that is yet to be described. Furthermore the pattern of replication among isolates suggests the level of SEC14L2 dependency may be genotype specific. Here, we identified several mutations that may provide new insights in the mechanism behind the HCV SEC14L2 dichotomy.

SAT-348

Expanding the donor pool-decontamination of HCV RNA positive kidneys with methylene blue

F. Helfritz[1], D. Bojkova[2], S. Westhaus[2], E. Steinmann[3], T. Minor[1], P. Meuleman[4], A. Paul[1], S. Ciesek[2]. *[1]General, Visceral and Transplantation Surgery; [2]Institute of Virology, Essen, Germany; [3]Twincore, Hannover, Germany; [4]Dept. Clinical Chemistry, Microbiology and Immunology, Ghent University, Ghent, Belgium*
Email: Sandra.ciesek@uk-essen.de

Background and Aims: Although organ shortage is a rising problem, organs from HCV RNA positive donors are not routinely transplanted in HCV negative individuals. Since HCV can only infect hepatocytes, other organs such as kidneys are merely contaminated with HCV.

Consequently, we established an HCV decontamination protocol for kidneys making them available for transfer into HCV negative recipients.
Method: Standard virological assays were used to investigate the effect of preservation solutions on the HCV replication cycle and to examine several antivirals, including methylene blue (MB), in preservation solutions. Kidneys from mini pigs were contaminated with Jc1 or HCV RNA positive human serum. Afterwards, organs were flushed with MB. Hypothermic machine perfusion was used to optimize inactivation of HCV.
Results: All preservation solutions enhanced HCV infectivity: while IGL-1 increased HCV attachment, UW and Perfadex boosted HCV entry. In HTK HCV was significantly more stable. Investigation of different antivirals for their ability to inactivate HCV revealed that MB completely inactivates HCV in the presence of all perfusion solutions. HCV contaminated kidneys from mini pigs were successfully decontaminated from HCV by hypothermic machine perfusion treatment with MB without any negative effect on the graft. In addition, human liver-uPA-SCID mice did not establish HCV infection after inoculation with flow through from these kidneys.
Conclusion: While several perfusion solutions enhance HCV infectivity, MB treatment reduces HCV infectivity efficiently. Flushing of an HCV contaminated kidney with MB inactivates all HCV genotypes. Finally, kidneys from HCV RNA positive donors might serve as a useful extension of the donor pool after treatment with MB.

SAT-349

Seeking genetic determinants of resistance to hepatitis C virus infection in a highly resistant cohort

D. Felmlee, P. Redondo, M. Ow, M. Cramp. *Peninsula Schools of Medicine and Dentistry*
Email: Daniel.Felmlee@plymouth.ac.uk

Background and Aims: We have studied a very rare cohort of individuals with evidence of high-level resistance to HCV infection to better understand how HCV interacts with hepatocytes. We seek to use this knowledge to translate into new approaches to deal with HCV and other related viral illnesses. Historically the major mode of transmission of HCV infection was from infected blood and blood products prior to routine screens for HCV in 1991. The blood transfusion service in England instigated a Lookback Programme in 1995 to identify individuals who had received HCV contaminated blood or blood products from donors before 1991, who tested positive.
Method: We have painstakingly gone over the records of 1340 recipients of blood/blood products from HCV infected donors and from these identified 13 individuals with confirmed HCV exposure but without any evidence of HCV infection testing negative for HCV antibody and HCV RNA. These 13 remained uninfected despite high level exposure to HCV and appear to be highly resistant to HCV infection. 8 of the 13 patients were traced, still alive, and consented to contribute to this study. We sought to determine genetic contributions to resistance to HCV infection by whole-exome sequencing of the genomes of these individuals, with 96% coverage of all exomes. We studied the genes of 11 known host entry factors for HCV, including CD81, scavenger receptor B-1 (SRB1), occludin (OCLN) claudin-1 (CLDN1), epidermal growth factor receptor (EGFR), Cideb, Ldlr, Epha2, for allelic changes.
Results: The primary screen revealed no significantly over-represented SNPs present in the gene transcripts of any HCV entry host factors within the EU cohort. One EU individual showed a single synonymous allele change in the OCLN gene (MAF = 0.023) and two had a heterozygous serine to phenylalanine change in epidermal growth factor receptor (EGFR), however no trends in the known host entry factors could be attributed to resistance to infection.
Conclusion: The findings to date suggest that variation in canonical HCV host entry factors is not the cause of the high level of resistance to HCV. We are undertaking further analysis of the sequencing data and speculate that there could be novel genes involved in the HCV lifecycle, that with a specific mutation could confer high-level resistance to HCV infection. Much remains to be learnt from this interesting cohort and our future work will include a secondary screen of the SNP output to identify novel gene targets.

SAT-350

A hyper-glycosylation of HBV surface antigen characterizes immunosuppression-driven HBV reactivation and hinders HBsAg recognition in vitro

Email: piermatteolorenzo@gmail.com

Background and Aims: The aim of the study was to investigate N-linked glycosylation (N-glyc) patterns of HBsAg in immunosuppression-driven HBV-reactivation *in vivo* and to evaluate their impact on HBsAg antigenicity and HBV replication *in vitro.*
Method: Mutations associated with acquisition of N-glyc site are investigated in HBsAg genotype-D sequences from 55 patients with immunosuppression-driven HBV-reactivation (defined as Hwang, 2014). The impact of N-glyc sites on pgRNA, core particle-associated HBV-DNA, and extracellular HBsAg is assessed by transfecting Huh7 cells with a plasmid containing wt or mutated HBV genotype D full-length genome. The impact of N-glyc sites on HBsAg antigenicity is analyzed by transfecting Huh7 cells with a plasmid encoding WT and mutated HBsAg-linked to a streptavidin-tag (strep-tag). The strep-tagged HBsAg amount in supernatants is quantified by a specifically-designed ELISA recognizing the Strep region (thus, not affected by HBsAg mutations) and also by an ELISA directly targeting the HBsAg. Tunicamycin, an inhibitor of N-glyc, is used on cells transfected with the strep-tagged HBsAg to confirm the role of N-glyc in altering HBsAg recognition by antibodies.
Results: At HBV reactivation, median [IQR] serum HBV-DNA and ALT are 6.7[5.3–8.0]logIU/ml and 149[42–630]U/l, respectively. Notably, 12.7% (7/55) of pts remains HBsAg-negative despite HBV reactivation (serum HBV-DNA range:2.9–7.6 logIU/ml). >1 additional N-glyc site in HBsAg is detected in 5/7 HBsAg-negative pts. I*n-vitro*, compared to wt, N-glyc sites strongly reduce extracellular HBsAg titer without affecting viral replication parameters. In particular, S113N + T131N + M133T determines 80% decrease in HBsAg titer, while ins114 + T115N, T115N and T123N cause a 68%, 62% and 32% reduction, respectively. Similarly, N-glyc sites decrease strep-tagged HBsAg titer by using the ELISA targeting the HBsAg (% reduction: 20% to 94%). Conversely, no decrease of strep-tagged HBsAg is revealed by ELISA targeting the Strep-tag, suggesting that N-glyc sites hamper HBsAg-recognition by antibodies without affecting HBsAg-release. Notably, in presence of

N-glyc sites, tunicamycin restores HBsAg titers observed in wt, confirming the direct role of N-glyc in hampering HBsAg recognition.
Conclusion: Additional N-glyc sites correlate with HBsAg-negativity despite HBV-reactivation, and profoundly alter HBsAg-antigenicity *in-vitro*. This supports the role of N-glyc in immune-escape and the importance of HBV-DNA (more than HBsAg) for a proper diagnosis of HBV-reactivation.

SAT-351

Palmitoylation determines the subcellular localization of the hepatitis E virus ORF3 protein

J. Gouttenoire[1], P. Angela[1], A. Laurence[2], M. Maxime[1], D.T.V. Loan[1], S. Dagmara[1], O. Joël[1], M. Johann[1], G. van der Goot[2], D. Moradpour[1]. *[1]Lausanne University Hospital, University of Lausanne, Service of Gastroenterology and Hepatology, Lausanne, Switzerland; [2]Ecole Polytechnique Fédérale de Lausanne, Global Health Institute, School of Life Sciences, Lausanne, Switzerland*
Email: darius.moradpour@chuv.ch

Background and Aims: Hepatitis E virus (HEV) is a positive-strand RNA virus encoding 3 open reading frames (ORF), namely ORF1, ORF2 and ORF3. HEV ORF3 protein is a small, hitherto poorly characterized protein involved in viral particle secretion and possibly other functions. Here, we investigate the structure and function of this essential viral protein.
Method: A panel of ORF3 constructs and the full-length protein expressed by infectious HEV were investigated by confocal laser scanning microscopy and immunoblot using GFP fusion proteins and newly established recombinant antibodies. Oligomerization was studied by coimmunoprecipitation and fluorescence resonance energy transfer. A wheat germ-based system was used for the cell-free expression of ORF3 protein. Posttranslational modifications were probed by site-directed mutagenesis and different biochemical assays.
Results: HEV ORF3 protein forms membrane-associated oligomers. HEV ORF3 proteins produced in cell-free and mammalian cell expression systems displayed different apparent molecular weight. Sequence analyses revealed the presence of 8 conserved cysteine residues within the first 21 amino acids which were found to be palmitoylated, as corroborated by ^{3}H-palmitate labeling, the investigation of cysteine-to-alanine substitution mutants and treatment with the palmitoylation inhibitor 2-bromopalmitate (2-BP). Abrogation of palmitoylation by site-directed mutagenesis or 2-BP treatment relocalized ORF3 protein from the plasma membrane to the cytoplasm and decreased stability of the protein. Moreover, we found, using selective permeabilization conditions coupled to immunofluorescence, that HEV ORF3 protein is entirely exposed to the cytosolic side of the membrane. The functional consequences of palmitoylation are currently being investigated using cell-culture derived infectious HEV.
Conclusion: HEV ORF3 protein forms membrane-associated oligomers and is palmitoylated at conserved N-terminal cysteine residues. This posttranslational modification determines the subcellular localization, stability and likely also the function of HEV ORF3 protein. These findings provide new insights into the life cycle of HEV and may yield new angles for therapeutic intervention.

SAT-352

Identification of hepatitis B virus core protein nuclear interacting factors points to RNA binding proteins as major regulators of HBV replication

Background and Aims: Converging evidences suggest that the Hepatitis B virus core protein (HBc), beside its well-known structural role to form nucleocapsids around pregenomic RNA in the cytoplasm, could have important regulatory functions in the hepatocyte nucleus, in particular by binding to the HBV genome (cccDNA) and to cellular DNA and possibly regulate their expression. However, HBc nuclear functions and mode of action still remain undefined. The aim of this project was to decipher HBc regulatory functions, by identifying its cellular partners in the nucleus of human hepatocytes.
Method: Nuclear HBc-protein complexes, treated or not with Benzonase, were purified on Strep-Tactin® columns from differentiated HepaRG cells expressing an inducible Strep-tagged HBc protein (ST-HBc), analyzed by Mass Spectrometry (LC-MS/MS), and data processed using the MaxQuant and ProStaR softwares. Functional validation were performed in HBV-infected primary human hepatocytes (PHH) and HepaRG in which selected factors were invalidated by RNA interference, or using biochemical inhibition of their functions.
Results: This analysis identified more than 200 proteins, 1/5 of which were significantly enriched in ST-HBc versus control samples. Functional annotation revealed that approximately 50% of these factors were RNA binding proteins (RBPs), and in particular SR proteins, with the most relevant functional category corresponding to factors involved in RNA splicing which were highly interconnected. Functional analyses identified SRSF10 and RBMX as able to strongly and differentially modulate HBV replication. In addition, small compounds targeting the activity of selected SR proteins induced a strong decrease of viral replication suggesting that they could be used as host-targeting agents (HTA).
Conclusion: These data reveal that HBc interacts with a highly interconnected network of RBPs, in particular SRSF10 and RBMX which are involved in several post-transcriptional processes, in particular pre-mRNA splicing and associated trafficking, strongly suggesting that HBc might interfere with these processes to control the fate of viral and/or cellular mRNAs. Current studies are being performed to precisely evaluate the impact of these interactions on viral replication, as well as on viral or/and cellular RNA splicing. The former is important for the potential development of HTA, whereas the latter may lead us to better understand the role of HBc in HBV-induced pathogenesis.

SAT-353

Potential contribution of more sensitive hepatitis B surface antigen assays to detect and monitor hepatitis B infection

C. Pronier[1,2], L. Boizeau[3], D. Candotti[3], B. Jeremy[2], S. Laperche[3], V. Thibault[1,2]. *[1]CHU Pontchaillou, Virology, RENNES, France; [2]IRSET – INSERM UMR 1085 – University Rennes 1, Infection, immunité, facteurs environnementaux et foie (2IFEF), RENNES, France; [3]Institut National de la Transfusion Sanguine, Département d'étude des agents transmissibles par le sang/Centre National de Référence Risques Infectieux Transfusionnels, PARIS, France*
Email: charlotte.pronier@chu-rennes.fr

Background and Aims: Hepatitis B surface antigen (HBsAg) remains the main viral marker for screening and monitoring hepatitis B virus (HBV) infection. The limit of quantification (LoQ) of most current HBsAg quantification assays is around 0.05 IU/mL. The new Lumipulse G HBsAg-Quant assay (Fujirebio) claims a 10-time improved sensitivity. This study aims to assess the performance of this assay in detecting low HBsAg levels in clinical samples.
Method: Plasma or serum samples were selected among individuals with HBV DNA+ and undetectable HBsAg levels (n = 46): 10 samples collected during the early infection ramping phase (panel 1) and 36 from occult HBV carriers (panel 2). An additional panel 3 was composed of 22 samples with low or previously tested discrepant

HBsAg levels. Samples were retrospectively tested with Lumipulse and HBsAg Liaison-XL (DiaSorin; LoQ: 0.05 IU/ml) assays according to manufacturer's instructions. Samples (n = 38), with an initially HBsAg value ≥0.005 IU/ml with the Lumipulse assay, with values just below the threshold, or with an inconclusive result were tested twice to ascertain sensitivity and specificity of the assay.

Results: Overall, 8 of 46 samples (17%), initially screened HBsAg-negative, were tested Lumipulse reactive with mean HBsAg values ranging between 0.010 and 0.054 IU/ml, mostly below the Liaison-XL assay LoQ. Upon initial testing with Lumipulse, 5 (13%) positive results, ranging from 0.006 to 0.051 IU/ml (panel 1–2), were challenged on a second aliquot and were finally concluded as negative. The remaining 33 were confirmed as negative (n = 8) or positive (n = 25). From panel 1, only 1 sample was found positive with a concentration of 0.017 IU/ml. On panel 2, 7 (19%) samples were positive. On panel 3, 21 (95%) samples could be quantified by Lumipulse with a median value of 0.24 IU/ml and 17 (77%) with the Liaison-XL (med. 0.20 IU/ml). Quantification values obtained with the two assays were correlated (r = 0.944, Spearman) with a mean bias of 0.19I U/ml. Most HBsAg quantified samples had detectable viral loads.

Table: Comparison of HBsAg testing in 68 samples using Lumipulse and Liaison-XL assays

Samples	N	Lumipulse		Liaison-XL	
		Reactive	Non-reactive	Reactive	Non-reactive
Panel 1: early infection ramping phase HBV DNA+/HBsAg–/anti-HBcAb–	10	1	9	0	10
Panel 2: occult HBV carriers HBV DNA+/HBsAg–/anti-HBcAb+	36	7	29	0	32*
Panel 3: low or previously tested discrepant HBsAg levels HBV DNA ± /HBsAg+	22	21	1	17	5

*4 not tested because of insufficient volume but non-reactive with the Roche HBsAg qualitative assay.

Conclusion: This study confirms the high sensitivity of the Lumipulse assay allowing the detection of HBsAg in 17% of samples previously classified as negative by current assays. Assays with improved sensitivity will likely modify the clinical interpretation of HBV serological profiles as defined with lower sensitivity assays.

SAT-354

Compare HBsAg retention in the endoplasmic reticulum and the ER stress between the cells transfected or infected by the wild type and pre-S HBV mutants using in vitro transfection and in vivo infection of FRG mice

J.Y.-J. Liang[1], J.-C. Wu[1,2], Y. Chi[1], C.-P. Sun[3], C.-W. Su[4,5], M.-H. Tao[3].
[1]Taipei Veterans General Hospital, Department of Medical Research, Taipei, Taiwan; [2]National Yang-Ming University, Institute of Clinical Medicine, Taipei, Taiwan; [3]Academia Sinica, Institute of Biomedical Science, Taipei, Taiwan; [4]Taipei Veterans General Hospital, Divison of Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan; [5]National Yang-Ming University, Faculty of Medicine, School of Medicine, Taipei, Taiwan
Email: jcwu@vghtpe.gov.tw

Background and Aims: In the natural history of chronic hepatitis B virus (HBV) infection, pre-S deletion HBV mutants are more frequently found in cirrhosis and HCC patients. It is hypothesized that the HBV mutants escape the host`s immune attack due to the deletion of the pre-S segment containing immune epitopes. And the persistent replication of mutants account for hepatocarcinogenesis. In this study, we compare the HBV surface antigen (HBsAg) retention in endoplasmic reticulum (ER) and the subsequent ER stress between the Huh-7 cells transfected or hepatocytes in FRG mice infected by the wild type and various pre-S HBV mutants.

Method: Huh-7 cells were transfected by the wild type and the paired pre-S2 deletion HBV mutants. In addition, several pre-S2 deletion mutants were further generated by the substitution of Proline 142 by histidine or alanine, or deletion of Proline 142. Also, pCDNA3.1 was also transfected as a negative control. HBV DNA and HBsAg in transfected cells and culture media were measured. ER stress markers were analysed by Western blot analysis. HBV virions from culture media of transfected cells were purified and used as inoculum to infect the FRG mice that contain implanted human hepatocytes.

Results: The HBsAg in cells/HBsAg in media (retention ratio) was the lowest in the wild type, followed by the pre-S2 deletion HBV mutant with proline 142, and were the highest in the pre-S deletion HBV mutants without proline. The secretion of pre-S deletion mutants was rescued by the co-transfection with the wild type HBV, but the secretion gradually decreased as the wild type HBV decreased. ER stress markers (pIRE1α, XBP1, CHOP) were significantly higher in pre-S mutants without proline. The serum HBV DNA levels of FRG mice infected by the pre-S deletion HBV mutant were 2 logs lower than those infected by the wild type, consistent with the in vitro findings.

Conclusion: Pre-S deletion HBV mutants were impaired in secretion which resulted in the retention of HBsAg and generation of ER stress were verified both in vitro and in vivo systems. The secretion of pre-S deletion HBV mutants was rescued by the coexistence of the wild type HBsAg, but the secretion was further impaired and the retention gradually increased as the wild type HBV was reduced. Although circulating HBV DNA and HBsAg may decrease in late stage of infection, antiviral therapy may better be extended to assure the reduction of HBV DNA replication and HBsAg retention in ER and further decrease of HCC development.

SAT-355

HBV peptide array demonstrates candidate mechanisms of CRV431 anti-HBV activity

R. Foster[1], A. Levin[2], C. Le[2], D. Ure[1], D. Trepanier[1], L. Tyrrell[2]. *[1]ContraVir Pharmaceuticals, Inc., Drug Development, Edison, United States; [2]Li Ka Shing Institute of Virology, Department of Medical Microbiology and Immunology, Edmonton, Canada*
Email: ltyrrell@ualberta.ca

Background and Aims: CRV431 is a cyclosporine A analog that reduces HBsAg, HBV DNA, and other HBV markers. Most of the CRV431 activities are thought to occur by blocking participation of cellular cyclophilins, the primary molecular target of CRV431, in the HBV life cycle. However, the specific cyclophilin interactions that influence HBV have not yet been identified. The aims of the current study were to determine whether cyclophilin A can bind directly to HBV proteins, whether CRV431 blocks the interactions, and to identify the specific HBV protein sequences to which cyclophilin binds.

Method: Soluble, recombinant cyclophilin A was applied to immobilized, 15-amino acid, overlapping peptides representing the entire HBV proteome, and cyclophilin A binding to the peptides was detected with cyclophilin A antibody. CRV431 was additionally applied in some experiments to block the binding. The sequences of the peptides that bound to cyclophilin A were analyzed in detail, and soluble peptides were used in competition experiments to validate cyclophilin A binding to the HBV proteins.

Results: Cyclophilin A bound to 10 HBV-derived peptides, and all 10 binding events were inhibited by CRV431. The peptides that bound cyclophilin A were derived from preS1 HBsAg, HBV polymerase, precore, and core antigen. Furthermore, the peptides overlapped with sequences implicated in regulation of polymerase nuclear import, HBsAg transport and secretion, and capsid formation. One additional interaction between cyclophilin A and a polymerase-derived peptide was found but only in the presence of CRV431. Current studies are

investigating the physiological relevance of the cyclophilin A binding events observed in the peptide arrays.
Conclusion: These studies identified multiple cyclophilin-HBV interactions that may be the target(s) of CRV431 action.

Assessing the in vitro anti-HBV activity of combinations including CRV431, TXL, and prototype capsid assembly modulators

R. Foster[1], J. Greytok[1], D. Ure[1], D. Trepanier[1], J. Kulp[2], P. Gallay[3].
[1]ContraVir Pharmaceuticals, Inc., Research and Development, Edmonton, Canada; [2]Barach S. Blumberg Institute, Research, Doylestown, United States; [3]The Scripps Research Institute, Department of Immunology & Microbial Science, San Diego, United States
Email: jgreytok@contravir.com

Background and Aims: It is expected that a functional cure for chronic HBV infection will require drug combinations targeting the viral life cycle at multiple, complementary stages. CRV431, a cyclophilin inhibitor, blocks HBV interactions with host cyclophilins (cyp) essential for viral replication and chronicity. CRV431 reduces HBV DNA, suppresses HBsAg, inhibits viral uptake via NTCP and blocks HBx-cypA and HBsAg-cypA binding, as shown *in vitro* and in mouse models. TXL, a novel tenofovir (TFV) prodrug in Phase 2 clinical development, inhibits HBV polymerase and is designed to deliver high intra-hepatic tenofovir (TFV) concentrations, while minimizing off-target effects of high circulating TFV blood levels. Capsid assembly modulators (CAMs) block several HBV replication steps, including pre-genomic RNA packaging and cccDNA formation. The aim of our current studies was to investigate the antiviral activity of combinations of TXL, CRV431, and prototype CAMs (BAY41-4109, DVR-56).
Method: Combinations of TXL and CRV431, TXL and CAMs, as well as CRV and CAMs were tested in cell lines supporting HBV replication: AD38, DE19, and DES19. Drug concentrations tested bracketed the EC_{50} of the individual drugs. The endpoints measured for antiviral effect varied according to the cell lines and included intracellular HBV DNA, extracellular HBV DNA, extracellular HBsAg and HBeAg. Endpoints were quantitated according to published methods. Drug concentrations versus antiviral effect were evaluated using Prichard-Shipman MacSynergy and Chalice.
Results: As measured by the suppression of HBV DNA, synergy scores for combinations of CRV431 and TXL, CRV431 and CAMs, TXL and CAMs, ranged from additive to synergistic. None of the combinations tested showed any evidence of antagonism. Cells were viable within the ranges of drug concentrations tested.
Conclusion: These studies extend previous observations of synergy between CRV431 and TXL. Our data demonstrate that novel combinations of antivirals interrupting the HBV life cycle at multiple, previously untested, targets, were additive to synergistic. Importantly, none of the combinations showed antagonism. Two drug classes are currently approved for chronic HBV treatment, nucleoside analogs and alpha interferons. Innovative drugs and treatment strategies will be essential for achieving the HBV functional cure. These results lay the foundation for therapeutic strategies including TXL and/or CRV431 as the basis of drug combinations for the functional cure.

Establishment of a method to compare antiviral effect of drug products by human hepatitis B virus infected humanized chimeric mice

H. Enomoto[1], H. Tachiki[1], M. Moriyama[2]. *[1]Towa Pharmaceutical Co., Ltd., Scientific Research and Business Development Department, Kyoto; [2]Nihon University School of Medicine, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Tokyo, Japan*
Email: h-tachiki@towayakuhin.co.jp

Background and Aims: There are few reports on evaluation models that can compare the antiviral effects of drug products against hepatitis B virus without clinical trials, and the establishment of the evaluation model is considered to be useful for determining treatment strategies. In this study, for the purpose of establishing a comparative model of antiviral effect in drug products, we evaluated the antiviral effect when using two entecavir (ETV) formulations and pegylated interferon- alfa (PegIFN-α) plus ETV formulation.
Method: The human liver-chimeric mice (PXB-mice) were inoculated with HBV genotype C. After for 8 weeks, animals were treated with saline (p.o.), brand name ETV (bETV: 30 μg/kg p.o./daily), generic drug ETV (gETV: 30 μg/kg p.o./daily), gETV + PegIFN-α (30 μg/kg p.o./daily, 30 μg/kg i.p./two times week) for 2 weeks. Serum HBsAg, HBeAg and HBcrAg were evaluated chemiluminescence immunoassay (CLIA) or chemiluminescence enzyme immunoassay (CLEIA) method. The levels of HBV DNA and intrahepatic HBV covalently closed circular DNA (cccDNA) were quantified by RT-PCR. Intrahepatic HBsAg, HBcAg and HBV DNA localization were evaluated using an immunohistochemical procedure or fluorescence in situ hybridization (FISH). Statistical tests were two-sided; $p < 0.05$ was considered statistically significant.
Results: Among the two treated groups, significant decrease in the serum HBV DNA level were observed in bETV and gETV, and no significant different between bETV and gETV ($p = 0.997$). There were no significant differences in the HBsAg, HBeAg, HBcrAg and HBV cccDNA levels between bETV and gETV. Thus, antiviral effects of bETV and gETV was shown equivalent by this method. In addition, compared to the gETV group, several parameters reduced in the gETV + PegIFN-α group (serum HBV DNA: >1 logIU/ml, serum HBeAg: >0.5 log S/CO, intrahepatic HBsAg and HBcAg: $p < 0.05$). These results were considered to enhance the antiviral effect of gETV + PegIFN-α treatment.
Conclusion: This method was shown equivalence or enhancement of the antiviral effect depending on the type and combination of drugs, it was considered that antiviral effects of drug products can be compared. The present model system using humanized PXB-mice is promising to evaluate the antiviral effects of various drug formulations.

SAT-358

Identification of HBV genotypes and mutations associated to antiviral resistance and vaccine escape in serum and oral fluid samples from chronic hepatitis B patients

M.M. Portilho[1], A.C.D.F. Mendonça[1], B. Lago[1], C. Villela-Nogueira[2], L. Nabuco[2], C.A.P. Ivantes[3], L.L. Lewis-Ximenez[1], E. Lampe[1], L. Villar[1].
[1]Oswaldo Cruz Institute, Laboratory of Viral Hepatitis, Rio de Janeiro, Brazil; [2]Federal University of Rio de Janeiro, Clementino Fraga Filho University Hospital, Rio de Janeiro, Brazil; [3]Center of Orientation and Guidance (COA), Curitiba, Brazil
Email: moyramp@gmail.com

Background and Aims: HBV genotyping and identification of antiviral resistance and vaccine escape mutants are performed using serum samples. However oral fluid samples could be a non-invasive sample to increase the access of diagnosis, particularly, in low resource areas. This study aims to investigate the usefulness of oral fluid samples for identification of HBV genotypes and mutations associated to antiviral resistance and vaccine escape.
Method: Paired samples of serum and oral fluid from 10 chronic hepatitis B patients were submitted to PCR for amplification of HBV polymerase(RT)/surface gene. Biochemical and serological data were also obtained in serum samples. PCR products were purified with a QIAquick PCR Purification Kit (Qiagen, Netherlands) and sequenced with forward and reverse primers using a BigDye Terminator 3.1 Cycle Sequencing kit (Thermo Fisher Scientific). The reactions were performed in an automatic ABI PRISM 3100 Genetic Analyzer Sequencer (Thermo Fisher Scientific). Sequences were analyzed using Mega Software v7.0 and submitted to web-based software (Geno2pheno) for subtyping and prediction of phenotypic resistance

to genotype-specific mutations in the polymerase gene (RT mutation) and escape mutation (HBs mutation).

Results: Among 10 patients, all presented detectable HBV DNA in both types of samples. All individuals presented the same genotypes and subgenotypes in each serum and oral fluid (4 pairs of A1, 2 pairs of A2, 2 pairs of D3, 1 pair of F2 and 1 pair of E) and five pairs presented 100% of homology between HBV sequences in serum and oral fluid. A total of 51 and 57 described RT mutations were found in serum and oral fluid, respectively, but none of them confers resistance to antiviral treatment with lamivudine, Tenofovir, Entecavir or Adefovir, with exception of V173L that is a compensatory mutation for Lamivudine found in an oral fluid sample. The HBs mutation 144A was identified in a pair of samples and three secondary HBs mutations were found in some oral fluid samples (Table 1).

Conclusion: Oral fluid samples demonstrated to be efficient in genotyping HBV since all samples presented the same genotype and subgenotype classification and homology to paired serum sequence. A high number of mutations of RT domain could be identified in paired samples and mutation 144A, which is related to vaccine escape, was detected in a pair.

SAT-359

Identification of a stable HBV inter-genotype (A/G) recombinant strain in a guinean patient in "grey zone" of treatment

A.I. Gil[1,2,3], A. Madejón[1,2,3], I. Francisco-Recuero[1,2,3], E. Villafranca[1], M. Romero[1,2,3], A. García-Sánchez[1], A.O. Martin[1,3], J.C. Erdozaín[1], P. Castillo[1], R. Mena[2,4], F.J.G.-S. Rey[1,2,3]. *[1]Hospital Universitario La Paz, Hepatology Unit, Madrid, Spain; [2]IdiPAZ, Madrid, Spain; [3]CIBERehd, Madrid, Spain; [4]Instituto de Genética Médica y Molecular (INGEMM), Madrid, Spain*

Email: javiersamaniego@telefonica.net

Background and Aims: There are scarce data about the prevalence of hepatitis B virus (HBV) inter-genotype recombination and its effect on the progression of HBV liver disease. The aim of this project was to analyze the presence of recombinant HBV strains in patients with HBV active replication and no treatment (grey zone).

Method: We included plasma samples from 28 HBeAg-negative patients in the grey zone of treatment (HBV DNA titers between 2,000–20,000 IU/ml and mild or moderate necroinflammatory activity). In all cases the HBV genotype was determined by sequencing of the PreS1/PreS2/S and Precore/core coding regions, and subsequent phylogenetic analysis using the MEGA5 program.

Table: (abstract: SAT-358): Clinical, biochemical, molecular aspects and mutations profile of serum and oral fluid samples

Patient	Age (years)	Gender	AST/ALT (IU)	HBeAg status	Previous treatment	Genotype/ Subgenotype	Nucleotide divergence between serum and OF sequences	rt(HBV) mutations (pair)	rt(HBV) mutations (only in serum)	rt(HBV) mutations (only in OF)	s(HBV) mutation (pair)	s(HBV) mutations (only in OF)

9	64	F	14/12	No reagent	No	A1	0.023%	N122H, M129L, V163I, I253V	-	I53V, W153R, S159T, S219A	-	100C
10	46	M	13/12	Reagent	Yes (TNF)	D3	0.000%	N53K, F122L, Q130P, Y135S, D263E, I266V, V278I	-	-	-	-

Abbreviations: M (Male); F (female); rtHBV (reverse transcriptas of HBV); sHBV (escape mutants of HBV); OF (oral fluid); TNF (Tenofovir); LAM (lamivudine).

Results: Only 2 (7%) patients showed discrepancies among the genotyping results. One of them, Caucasian, did not present evidence of recombination. By contrary, a Guinean patient, previously typed as a mixed infection A + E by LIPA, was typed as HBV-A in the HBsAg region and as a recombinant A/G in the PreC/C region. Structurally, this region had a fragment of 91 bases (nucleotides 1814-1905) with homology with genotypes no-A (D or E), an insertion of 36 nucleotides characteristic of the genotype G and the rest of the coding region of genotype A. In addition, this strain presented the mutation in position 1896, characteristic of genotype G, which induces a stop codon that prevents the synthesis of HBeAg. Of the 14 recombinant A/G sequences described in the literature, only 3 of them showed recombination points in the coding region of the core, and the maximum homology (94%) was found with a Nigerian patient (access number: AM110794) diagnosed as triple recombinant E/G/A. In addition to the high rate of homology, the structure of the recombination zone was identical between the sequence described here and the Nigerian isolate. The patient showed detectable HBV-DNA levels for 11 years [HBV-DNA levels (mean ± SD): 2,594 ± 2,920 IU/ml; range: 52-9,554 IU/ml]. The presence of the recombinant sequence as the major viral species was confirmed in the three samples analyzed, separate for a maximum period of 4 years. The ALT and AST figures were normal throughout the follow-up and the hepatic fibrosis stage (fibroscan) was F2.
Conclusion: The first identification of HBV A/G recombinants sequences with an identical structure in the recombination zone and a 95% homology rate in two patients from West Africa (Nigeria and Guinea) suggests the possibility of transmission of a recombinant A/G strain in this population. Supporting this hypothesis the stability in time of the recombinant in the Guinean patient, the extremely low prevalence of the G genotype in West Africa and the absence of previous reports of A/G strains with conserved recombination structure, even in patients from the same region geographical.

SAT-360

In vitro and in vivo antiviral characterization of RO7049389, a novel small molecule capsid assembly modulator for the treatment of chronic hepatitis B

X. Zhou[1], Y. Zhou[1], X. Tian[1], F. Shen[1], G. Yang[1], W. Zhu[1], G. Ottaviani[2], J. Xie[1], H. Shen[1], J. Young[2], L. Gao[1]. *[1]Roche Innovation Center Shanghai, China; [2]Roche Innovation Center Basel*
Email: lu.gao@roche.com

Background and Aims: The hepatitis B virus (HBV) core protein plays critical roles in multiple steps of the HBV life cycle. The proper assembly of HBV core proteins into capsids around viral pregenomic RNA is essential for HBV replication and maintenance of the nuclear cccDNA pool, thus representing an attractive direct antiviral target. RO7049389 is a small molecule HBV capsid assembly modulator in Phase I clinical development for the treatment of chronic hepatitis B. It is a new generation heteroaryldihydropyrimidine analogue that differentiates from earlier generation by demonstrating no induction potential for major CYP isoforms or UGTs, thus causing less concern on drug–drug interaction liabilities. Here we report *in vitro* and *in vivo* antiviral activities of RO7049389.
Method: In vitro assessments of the antiviral potency, cytotoxicity, HBV genotype coverage, and potential cross-resistance with approved HBV drugs were performed using appropriate cell culture models including HBV-producing stable cell line HepG2.2.15, HepG2 cells transiently transfected with HBV variants construct, and HBV-infected primary human hepatocytes (PHH). In vivo efficacy of RO7049389 was studied in a mouse model with a recombinant adeno–associated virus carrying hepatitis B virus genome (AAV–HBV). HBV DNA was quantified by quantitative real-time PCR. HBsAg and HBeAg were quantified using commercial chemiluminescence immunoassay kits.
Results: RO7049389 exhibited potent inhibition of HBV DNA in HepG2.2.15 cells with an average EC_{50}(± SD) of 6 ± 1 nM and CC_{50} > 100 µM. The molecule demonstrated activity against prevalent HBV genotypes (A, B, C, D) and against a panel of nucleos(t)ide analogues-resistant HBV variants. When RO7049389 was added together with the HBV inoculum in PHH, it prevented cccDNA establishment, leading to a reduction of HBsAg and HBeAg levels. RO7049389 demonstrated *in vivo* efficacy in the AAV-HBV mouse model when orally administered, by not only reducing serum HBV DNA as expected but also HBsAg and HBeAg levels. Once daily dosing of RO7049389 at 20 mg/kg for 8 weeks reduced HBV DNA by 3.0-log, HBsAg by 2.4-log, and HBeAg by 1.5-log. Remarkably, reductions in all of these viral markers, including HBsAg were maintained with no rebound observed within the 3-weeks off-treatment follow-up period.
Conclusion: RO7049389 is a promising anti-HBV agent that exhibited potent antiviral activity in cell culture systems and sustained suppression of HBV DNA, as well as HBsAg and HBeAg in the AAV-HBV mouse model. These effects have clearly differentiated RO7049389 from approved HBV drugs and may translate into higher functional cure rates in a clinical setting.

Background and Aims: Reactivation of hepatitis B virus (HBV) during direct acting antivirals (DAAs) treatment against hepatitis C virus (HCV) have been reported in patients coinfected with HBV and HCV. However, mechanism responsible for HBV reactivation in such cases remains unknown. As an *in vitro* model, we have recently demonstrated that human induced pluripotent stem (iPS) cell-derived hepatocyte-like cells (iPS-Heps) are susceptible to HBV infection, and exhibit innate immune responses in host cells against HBV. The aim of this study is to investigate the mechanisms associated with HBV reactivation during DAAs treatment for HCV in coinfection with HBV and HCV.
Method: Several human iPS cell lines were differentiated into hepatic lineage using modified 4-step protocol as previously described (Kamiya, 2013). HBV and HCV were obtained from the culture supernatant of HepG2.2.15.7 and Huh7.5.1 transfected with HCV-RNA (JFH1 clone), respectively. HBV-related products and responses of interferon-stimulated genes (ISGs) were analysed using the culture system of iPS-Heps coinfected with HBV and HCV under the culture condition with or without sofosbuvir (SOF).
Results: Quantitative RT-PCR analyses demonstrated that the expression levels of host factors related to HCV life cycle in iPS-Heps were significantly higher than those in Huh7.5.1. The concentrations of HBe-antigen (Ag) and HCV-core Ag in culture supernatant of coinfected iPS-Heps were increased in a time-dependent manner after HBV and HCV coinfection. HCV infection induced the expression of ISGs in host cells, whereas the expression levels of ISGs were relatively lower in HBV-infected host cells. Expression levels of intracellular ISGs were significantly lower in the coinfected host cells than those in cells infected with HCV alone. HCV-core Ag in the culture supernatant was significantly decreased in the coinfected iPS-Heps after SOF treatment. On the other hand, HBeAg in the supernatant, intracellular HBV pregenomic RNA and total HBV transcripts were significantly increased in such cells compared to vehicle-treated cells. Furthermore, the expression levels of

intracellular ISGs were significantly decreased in SOF-treated cells compared to vehicle-treated cells.
Conclusion: Our data demonstrated that our *in vitro* system of iPS-Heps could be a novel research model for coinfection of HBV and HCV, and suggested that HBV reactivation during DAAs treatment for HCV is induced by suppression of ISGs.

Email: patrick.soussan@inserm.fr

Background and Aims: Hepatitis B virus transcription leads to expression of several transcripts, namely pregenomic, subgenomic and spliced RNAs. Epigenetic studies showed that its regulation depends on the amount and status of viral DNA. However, post-transcriptional regulation and impact on viral lifecycle remains elusive. Our aim was to investigate the different forms of HBV transcripts in liver tissue and correlate them to the circulating viral particles.
Method: A prospective cohort of 50 HBV chronically monoinfected, treatment naïve patients was constituted. Concomitant serum DNA and liver RNA samples were analyzed. HBs and HBe antigens, ALT levels and Metavir score were measured. Viral DNA and RNA were quantified by Abbott and in-house PCR, expressed in IU/ml and copies/µg RNA respectively. Selected serum samples were used for infection of differentiated HepG2-NTCP cells.
Results: Patients were split in high (n = 24) or low (n = 26) viral load using a cut-off value of 10^4 IU/ml. Despite highest serum ALT levels in highly replicative patients, liver histology was similar in both groups with mainly moderate liver damage. Quantitative HBsAg was not related to the level of replication. In liver samples, HBV pregenomic RNA (pgRNA) was reduced in low viral load group while the level of subgenomic RNAs was similar. We defined a "viral production marker" as the ratio of serum viral load/liver pgRNA. Surprisingly, this marker showed a viral synthesis 100 fold less efficient in low compared to high replicative patients, suggesting that post-transcriptional regulation of pgRNA differed in both groups. Thus, the level of spliced forms of HBV RNA (spRNAs) and subsequent HBV defective particles (dHBV), in serum and liver samples was compared in both groups. The ratio spRNA/pgRNA did not show an increase of the splicing efficiency in low replicative group, suggesting a preferential orientation of pgRNA towards the translation machinery. In accordance with this result, dHBV particles in sera were only detected in the high replicative group. However, our data revealed an alteration of the post-transcriptional machinery in liver tissues. Indeed, despite an overall correlation between pgRNA and spRNAs, spRNAs were unexpectedly detected in 1/3 of low and only in 2/3 of high replicative patients. Viral production and HBV splicing regulation were assessed *in vitro* with serum samples from 4 selected highly replicative patients (3 spRNAs positive and 1 spRNAs negative). Ten days post-infection, efficiencies of viral particles synthesis related to the intracellular pgRNA expression were weak and included in the range of those observed in low replicative patients. In contrast, spRNAs were detected in all infected cells.
Conclusion: Our data showed a dynamic process of the pgRNA outcome toward viral production, translation or splicing and highlighted a role of the liver microenvironment in the viral lifecycle.

Statin inhibits HDV assembly, secretion, and large hepatitis delta antigen-Smad3-Twist mediated epithelial-mesenchymal transition

J.-C. Wu[1,2], Y.-C. Hsu[2], J.Y.-J. Liang[2], C.-W. Su[3,4]. *[1]National Yang-Ming University, Institute of Clinical Medicine, Taipei, Taiwan; [2]Taipei Veterans General Hospital, Department of Medical Research, Taipei, Taiwan; [3]Taipei Veterans General Hospital, Divison of Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan; [4]National Yang-Ming University, Faculty of Medicine, School of Medicine, Taipei, Taiwan*
Email: jcwu@vghtpe.gov.tw

Background and Aims: Hepatitis D virus (HDV) infection is one of the important causes of fulminant hepatitis. In addition, HDV superinfection in chronic hepatitis B (CHB) patients may accelerate CHB to cirrhosis or hepatocellular carcinoma (HCC). Currently, there is no effective treatment. HDV encodes small delta antigens (S-HDAg) and large form HDAg (L-HDAg). S-HDAg is essential for HDV RNA replication, while L-HDAg needs to be isoprenylated to perform HDV virions assembly. In our previous reports, L-HDAg transactivated TGF-β and induced epithelial-mesenchymal transition (EMT) which may contribute to liver fibrosis. However, the mechanism is unclear. In this study, we hypothesized that L-HDAg can activate *twist*, the major regulator of EMT, expression which induces TGF-β, EMT, and may further lead to liver fibrosis. On the contrary, statin treatment may indirectly decrease isoprenylation of L-HDAg. As a result, expression of *twist* and TGF-β may be down-regulated, which may lead to the decrease of EMT.
Method: In this study, human HCC cell line HuH7 was transfected in vitro with three genotypes of S-HDAg, L-HDAg and vector. HBsAg or HBV expression plasmids were also co-transfected to evaluate if stain treatment could reduce secretion of L-HDAg.
Results: Using luciferase reporter, chromatin immunoprecipitation and co-immunoprecipitation assays, we confirmed that L-HDAg specifically activated *twist* promoter through interaction with Smad3. Furthermore, mutation of Smad-binding element in *twist* promoter significantly repressed *twist* promoter expression. Six types of statin were used in the treatment of HuH7 cells which transfected with L-HDAg or S-HDAg at a concentration of 5µM and 25µM. The results showed that all six statins indirectly decrease isoprenylation of L-HDAg and further reduced *twist* expression. In addition, we also observed that a dose-dependent negative correlation between Atrovastatin/Simvastatin treatment and *twist* promoter activity. Furthermore, statin treatment lead to the reduction of EMT and EMT markers expression. Interestingly, statin treatment reduced secretion of L-HDAg and TGF-β in culture medium.
Conclusion: L-HDAg interacted with Smad3 and activated twist promoter. Activated twist promoter increased the expression of TGF-β, which lead to the induction of EMT and EMT markers expression. On the contrary, L-HDAg secretion, TGF-β expression and the properties of EMT are decreased after statin treatment. This study demonstrated that in addition to decrease cholesterol biosynthesis, statin also showed great potential as a novel therapy for the treatment of chronic hepatitis D

SAT-364

Murine hepatocytes with humanized sodium taurocholat polypeptide (NTCP) limit HDV infection in vivo independent of adaptive immune responses

Background and Aims: NTCP is the functional entry receptor for HBV and HDV and infection. Aim was to establish HDV mono-infection in immunocompetent mice expressing humanized NTCP and to compare efficiency and fate of infection with immunodeficient human liver chimeric mice.
Method: Murine NTCP in C57BL/6J mice was humanized by altering the residues 84–87 using the CRISPR/Cas technology (hNTCP mice). HDV virions of genotype (GT) 1 or 3 were injected i.p. or i.v. into adult hNTCP mice. 5 to 21 days post inoculation (p.i.) viral loads in livers were analysed by qRT-PCR, immunofluorescence staining and RNA in situ hybridisation. Human liver chimeric mice were generated by transplanting human hepatocytes into uPA/SCID/beige mice (USB mice) and were infected similarly. Murine hepatocytes of hNTCP mice were also isolated and transplanted into USB mice.
Results: In hNTCP mice, i.v. administration and HDV GT3 resulted in higher intrahepatic infection levels than i.p. administration and HDV GT1 inoculation, respectively (median copies HDV RNA/ng liver RNA in GT1 i.p.: undetectable, GT1 i.v.: 0.4, GT3 i.p.: 7.5; GT3 i.v.: 3.8). Although less than 0.1% of cells were HDAg-positive in livers of HDV GT3-infected hNTCP mice, the presence of antigenomic HDV RNA, demonstrated intracellular viral replication. Compared to hNTCP mice, HDV GT3-infected USB mice showed substantially higher amounts of intrahepatic HDV RNA (36-fold) and of HDAg-positive cells (0.4%). Infection kinetic studies in hNCTP mice showed detectable intrahepatic HDV RNA levels till day 14 p.i.. At day 21, HDV RNA levels were below detection limit, suggesting virus clearance or death of HDV-infected hepatocytes. Strikingly, intrahepatic HDV infection was also cleared by day 21 p.i. in murine hepatocytes of hNTCP mice which were transplanted into immunodeficient USB mice, while no reduction of intrahepatic infection was observed for at least 42 days in human hepatocytes in humanized USB mice.
Conclusion: HDV mono-infection can successfully be established in hNTCP mice, although intrahepatic HDV loads are higher in human liver chimeric mice. Moreover, HDV infection was cleared within 21 days both in immune competent (hNTCP mice) and in immune deficient systems (after transplantation of hNTCP murine hepatocytes in USB mice), suggesting that additional restriction factors exist in murine hepatocytes that limit HDV persistence. Better understanding of these factors might be important to develop novel antiviral strategies.

Email: julie.lucifora@inserm.fr

Background and Aims: Current therapies for hepatitis B virus (HBV) chronic infections are effective at decreasing viremia in long-life treatment regimen, but do not lead to viral eradication. Recent studies highlighted the therapeutic potential of immune-stimulators to restore immune responses to HBV in various animal models as well as in early clinical trials. Our overall aim was to explore the anti-HBV effect of free or particulated TLR1/2 agonists *in vitro* and *in vivo* in monotherapy approaches.
Method: HBV-infected primary human hepatocytes (PHH), HBV-infected differentiated HepaRG cells (dHepaRG), as well as HBV-infected liver-humanized (HuHep) mice or AAV-HBV transduced mice were treated with TLR1/2 agonist. HBV replication and immune markers/correlates were followed by ELISA, qPCR, qRT-PCR, Southern Blot, and IHS.
Results: Pam3CSK4 (TLR1/2-ligand) was amongst the best TLR agonists tested that reduced viremia and antigenemia in HBV-infected models. Importantly, its antiviral effect was long-lasting *in vitro*, as a result of a strong transcriptional/post-transcriptional inhibition of cccDNA and a slight, but significant, decrease in its level. This effect was associated with an activation of the NFkB pathways in hepatocytes and immune cells, as demonstrated by analyses of mRNA and cytokines production as well as knock down experiments. To prevent systemic immune activation and improve its efficacy, Pam3CSK4 was encapsulated in either "naked or functionalized" nanoparticles that mostly accumulate in the liver of injected mice. Interestingly, nano-Pam3CSK4 led to a stronger antiviral activity as compared to free Pam3CK4 in HBV-infected models, without any toxicological issues.
Conclusion: Our data highlight the potential of innate immunity stimulators, such as TLR1/2 agonists, as direct antiviral effectors in hepatocytes and overall modulators of immune responses. This work further supports the clinical evaluation of TLR agonists as immune adjuvants in more complex immune-therapeutic strategies, based on either prime-boost vaccination or T-cell adoption to cure HBV infections.

Inhibition of hepatitis B virus X protein in HBV-infected primary human hepatocytes leads to the reappearance of the Smc5/6 complex

R. Beran, C. Voitenleitner, D. Kornyeyev, C. Livingston, W. Xing, H. Kwon, S. Fletcher. *Gilead Sciences, Biology, Foster City, United States*
Email: simon.fletcher@gilead.com

Background and Aims: The host structural maintenance of chromosome 5/6 complex (Smc5/6) suppresses cccDNA transcription. HBV counters this restriction by expressing hepatitis virus X protein (HBx), which redirects the cellular DDB1-containing E3 ubiquitin ligase to target Smc5/6 for degradation. HBx is an attractive therapeutic target because inhibition of this key viral protein has the potential to transcriptionally silence cccDNA. However, it is challenging to evaluate the impact of different therapeutic approaches on this important viral protein due to the lack of a highly specific HBx antibody. Here we describe spatiotemporal analysis of HBx in HBV-infected primary human hepatocytes (PHH) using a novel monoclonal antibody.
Methods: Recombinant proteins and HepG2 cells transduced with a lentivirus expressing HBx were analyzed by Western blot. PHH were infected with wild-type HBV, HBx-negative HBV (HBVΔX), or were mock-infected. In certain experiments, PHH were transfected with siRNA targeting DDB1 (siDDB1), the HBx region of HBV RNA (siHBV) or a non-targeting control at day 3 post-infection. HBx, HBV core, HBsAg and Smc6 were measured by confocal microscopy at various times post-infection.
Results: An antibody that selectively detects recombinant HBx as well as HBx over-expressed in HepG2 cells was selected for confocal imaging studies. HBx exhibited a diffuse nuclear staining pattern in HBV-infected PHH and was not detected in the cytoplasm. Nuclear HBx positively correlated with HBV core and HBsAg and inversely correlated with the presence of Smc6. HBx was not detected in PHH infected with HBVΔX. Consistent with a previous study that characterized the kinetics of Smc6 degradation in HBV-infected PHH, HBx was expressed 1-2 days after infection. Treatment with siDDB1 (which blocks HBx function) and siHBV (which reduces all HBV RNAs, including HBx mRNA) decreased HBx levels and was associated with the reappearance of Smc6 in the nuclei of most HBV-infected PHH by day 18 post-infection.

Conclusions: Using a novel monoclonal antibody, we demonstrated that HBx is localized to the nucleus and is expressed early after HBV infection of PHH. We also determined that inhibition of HBx function or reduction of HBx mRNA levels in HBV-infected PHH leads to the reappearance of Smc6. These data suggest that cccDNA transcriptional silencing by the Smc5/6 complex may be restored by therapeutic targeting of HBx.

SAT-367

FXR is a proviral factor whose binding to HBV genome is modulated by FXR agonist and correlates with presence of the activated chromatin mark H3K4me3 in an HBx dependant manner

B. Lacombe, K. Mouzzanar, C. Ménard, V. Lotteau, C. Ramière, P. Andre.
INSERM U 1111 – CNRS UMR5308 Université Lyon 1, ENS de Lyon, Centre de Recherche International en Infectiologie, Lyon, France
Email: patrice.andre@inserm.fr

Background and Aims: HBV infection, bile acids (BA), and BA nuclear receptor FXR activity are intertwined. HBV compete for binding to the BA receptor NTCP and entry into hepatocytes. FXR response elements have been identified in the Enh2/Cp regulatory region. HBV infection modulates FXR activity in vivo and in HepaRG and PHH cellular models. Reciprocally, FXR agonists repress HBV replication in these models. HBx is known to be a major proviral factor and to bind to and affect FXR dependent expression of cellular genes. We aimed at further deciphering the role of FXR in HBV replication and that of HBx in this regulation.
Methods: An FXR KO HepaRG cell line was generated with shFXR lentiviral vector without affecting its differentiation or NTCP expression. ChIP were performed in Huh7 cells transfected with 1.3xHBV wild type plasmid or 1.3xHBV carrying a premature stop codon in HBx (1.3HBV-ΔHBx). HBV was produced by HepAD38 cells. FXR agonist GW4064 (GW) was used at 10μM.
Results: Permissiveness to HBV infection was dramatically reduced in shFXR-HepaRG cells and was further repressed by GW4064 treatment (GW-txt). In HepaRG, short 4-hour GW-txt quickly and transiently repressed FXR expression. During a single HBV replication cycle in HepaRG, 4-h GW-txt at day 2 p.i. decreased the cccDNA pool and all subsequent viral markers assessed at day 11 p.i. while same txt at day 6 reduced only the expression of the viral mRNA and proteins controlled by the Enh2/Cp. ChIP analysis in presence of 1.3xHBV showed moderate presence of FXR on BSEP and SHP promoters (BSEPp, SHPp), 2 genes up-regulated by FXR activation, and at a higher level on Enh2/Cp, preS1p, and ApoA1p, a gene down-regulated by FXR activation. GW-txt increased FXR binding to BSEPp and SHPp while it decreased FXR binding to Enh2/Cp and preS1p, and ApoA1p. Presence of HEK4me3 followed variations of FXR binding in similar proportions. Absence of HBx, in cells transfected with 1.3HBV-ΔHBx, did not significantly modify the variations of FXR binding and H3K4ME3 presence on BSEPp and SHPp in response to GW-txt. On the opposite, in HBx absence, FXR binding to Enh2/Cp and preS1 promoter, and ApoA1p was decreased and surprisingly, FXR binding to these regions was increased in response to GW-txt.
Conclusion: FXR is a proviral factor that plays an important role in cccDNA formation and maintenance as well as, later, on viral mRNA transcription. Presence of FXR on HBV DNA seems to be critical for both effects. FXR agonist, in addition to the feed-back repression of FXR expression, dramatically releases FXR from viral DNA, an effect that correlates with reduction of cccDNA formation and expression. Activity of Enh2/Cp region seems negatively regulated by FXR agonist as it is for ApoA1. Interestingly, HBx tends to increase FXR and H3K4me3 presence on HBV and ApoA1 promoters in absence of FXR agonist and to favor the release of these factors from the DNA after agonist treatment.

SAT-368

Developing a new world monkey model of chronic HBV infection in the post-chimpanzee era

C. Chen[1], D. Chavez[1], E. Salas[2], D. Tam[2], S. Eng[2], B. Delaney[2], R. Lanford[1], C. Voitenleitner[2]. [1]*Texas Biomedical Research Insitute;* [2]*Gilead Sciences, Biology, Foster City*
Email: christian.voitenleitner@gilead.com

Background and Aims: Hepatitis B virus (HBV), remains a global epidemic in urgent need of curative therapeutics. Scientific progress has been hampered by the lack of an immune-competent non-human primate model for chronic HBV infection. While woolly monkeys can be infected with woolly monkey HBV (WMHBV) they are an endangered species. However, WMHBV has been shown to infect spider monkeys, resulting in low titer viremia. Macaques are readily available research animals but significant differences in the sequence of their viral receptor, sodium taurocholate co-transporting polypeptide (NTCP), render these animals non-susceptible to HBV infection. Comparing NTCP amino acid sequences in the HBV binding region of alternative new world monkeys identified the Bolivian Squirrel Monkey (Saimiri boliviensis) as a potential candidate for infection.
Method: HepG2 cells were transfected with a plasmid expressing the Saimiri NTCP sequence and treated with fluorescently labeled Myrcludex B, a peptide spanning the preS1 region of HBV. Adult animals were inoculated with either HBV or WMHBV and viral DNA in the serum was determined by qPCR. A second cohort of animals was infected with an intravenous injection of either AAV-HBV or AAV8-WMHBV, a recombinant AAV8 carrying an infectious construct of HBV and WMHBV, respectively. Weekly bleeds and liver biopsies were

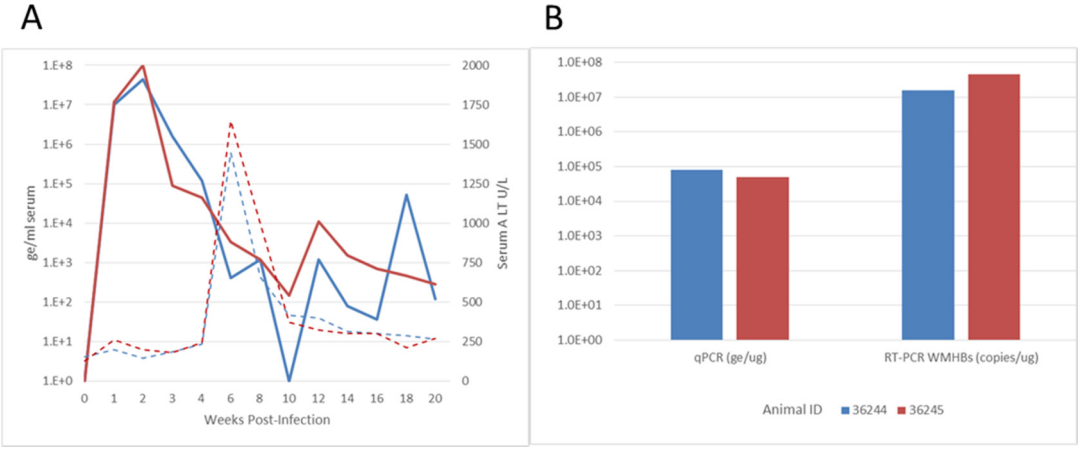

Figure: (abstract: SAT-368)

performed and DNA and WMHBV surface antigen (WMHBs) were analysed by ELISA and qPCR.
Results: HepG2 cells expressing the Saimiri NTCP bind fluorescently labeled Myrcludex B, suggesting that HBV should bind to Saimiri hepatocytes. Preliminary studies with viral inoculation of adult Saimiri with HBV and WMHBV low viremia with titers up to 6.6×10^4GE/μg but provided encouraging results, so we designed a study involving an AAV vector. Squirrel monkeys were injected with AAV8-HBV or AAV8-WMHBV virions. Viral genomes were monitored in serum after injection. A maximum viral titer of 9.9×10^7GE/ml serum for AAV8-WMHBV was observed two weeks after injection followed by an ALT spike (Figure 1A). ALT is a biomarker indicating immune-mediated inflammation and potential removal of infected hepatocytes. We observed a maximum viral titer of 8.2×10^4GE/μg tissue in the liver at week 4. In addition, WMHBs RNA expression was determined to be over 10^7 copies/μg by qPCR (Figure 1B).
Conclusion: Our data suggest that Squirrel monkeys may be a viable alternative to chimpanzees for modelling chronic HBV infection.

SAT-369
Reduction of serum infectivity of hepatitis Delta virus-infected patients treated with Myrcludex B: An in vitro assay to determine infectious units

K. Schöneweis[1], F. Lempp[1], M. Bock[1], F. Schlund[1], B. Bremer[2,3], A. Alexandrov[4], H. Wedemeyer[3], S. Urban[1,5]. *[1]Molecular Virology, Department of Infectious Diseases, Heidelberg, Germany; [2]Gastroenterologie, Hepatologie und Endokrinologie, Medizinische Hochschule Hannover, Hannover, Germany; [3]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [4]MYR GmbH, Bad Homburg, Germany; [5]German Center for Infectious Diseases, TTU hepatitis, Heidelberg, Germany*
Email: stephan.urban@med.uni-heidelberg.de

Background and Aims: The entry inhibitor Myrcludex B (MyrB) blocks the HBV/HDV receptor NTCP. In a phase II clinical trial (MYR202), MyrB profoundly reduces HDV serum RNA levels as determined by RT-PCR diagnostics. It is presently unknown HDV serum levels reflect fully infectious virions. Moreover, it is unclear if MyrB treatment induces resistance. We therefore, developed an in vitro cell culture assay to analyze HDV infectivity and MyrB resistance in patient serum.
Method: HuH7-hNTCP cells were inoculated with sera from patients obtained at baseline (BL) or week 12 (w12) on treatment with MyrB/TDF or TDF alone. At day 3 post infection medium was exchanged and Hepatitis Delta antigen-specific immunofluorescence and automated cell quantification was performed (day 5).
Results: Infection rates obtained with sera from w12 during MyrB/TDF treatment were reduced by 43-fold in 100% of the 32 analyzed patients. In comparison serum infectivity at w12 from patients on TDF alone remained unchanged (n = 11). To quantitatively correlate serum infectivity with serum HDV RNA levels, we developed a TCID50 assay to define infectious units. In most of the cases, we found a remarkable correlation of the TCID50 values with HDV RNA quantified by RT-PCR. Interestingly, we identified patient sera from BL and week 12 with lower (>1 log10) TCID50 values compared to the respective serum HDV RNA level. This indicates the presence of defective HDV RNA containing particles. Vice versa, we identified sera (n = 3) with a higher infectivity (>1 log10) than predicted by the RT PCR values, indicting a reduced sensitivity of the PCR towards this HDV sub genotype. We finally applied our assay to test for MyrB resistance. All of the 120 patients were still sensitive to MyrB indicating no development of resistance within 12 weeks of treatment.
Conclusion: Our assay highlights HDV serum infectivity tests as a novel parameter to monitor HDV patients. The identification of poorly infectious HDV particles requires subsequent studies to characterize whether these defective particles have defects in the HBV envelope and/or carry HDV replication-deficient genomes. As expected for a drug that targets a cellular receptor no short term resistance against MyrB was observed.

SAT-370
The protein complex structural maintenance of chromosomes reappears after interferon alpha treatment in hepatitis B virus infected humanized mice but its presence does not hinder viral rebound

K. Giersch[1], T. Volz[1], L. Allweiss[1], A. Lohse[1], S. Urban[2], J. Petersen[3], M. Lütgehetmann[1], M. Dandri[1]. *[1]University Medical Center Hamburg Eppendorf, Department of Medicine, Germany; [2]University of Heidelberg, Department of Infectious Diseases, Germany; [3]IFI Institute Hamburg, Liver Center, Germany*
Email: m.dandri@uke.de

Background and Aims: The hepatitis B virus (HBV) X protein (HBx) is essential to initiate cccDNA transcription and HBx was shown to mediate the degradation of the structural maintenance of chromosomes (Smc) 5/6 complex, suggesting that Smc5/6 acts as a host restriction factor by inhibiting cccDNA transcription. **Aim** of this study was to investigate (1) whether interferon-mediated suppression of cccDNA transcription, which should lower also HBx expression, leads to smc5/6 reappearance in infected cells and (2) whether viral rebound is hindered by the presence of this host factor in cells already harboring an established cccDNA.
Method: We treated HBV infected human liver chimeric mice with pegylated interferon alpha (peg-IFNα) for 6 weeks. After that mice were either sacrificed, or left untreated to assess viral rebound or received the entry inhibitor Myrcludex-B (MyrB) to prevent occurrence of new infection events. HBV loads in serum and liver were analyzed by qRT-PCR. HBcAg and Smc6 protein were visualized by immunofluorescence. RNA in situ hybridization was combined to immunofluorescence to detect Smc6 and pgRNA at single cell level.
Results: Peg-IFNα treatment reduced viremia by 1.7 log and compared to untreated controls lowered intrahepatic pgRNA, total HBV DNA and cccDNA 7.3-, 16- and 5.3-fold, respectively. Smc6 protein appeared degraded in almost all human hepatocytes in HBV-infected mice, while Smc6 was clearly detected in uninfected mice and in HBcAg- and pgRNA-negative human hepatocytes (around 50%) in livers of peg-IFNα treated mice. After stopping IFN-treatment, viremia rebounded to BL within 3 weeks and intrahepatic HBV markers were comparable to those obtained in HBV-infected untreated controls. Viremia rebound was associated with renewed degradation of Smc6 and reappearance of HBcAg and pgRNA in nearly all human hepatocytes. Interestingly, HBV rebound was delayed in MyrB-treated mice, which also displayed higher amounts of Smc6 positive cells.
Conclusion: Peg-IFNα treatment is accompanied by the reappearance of Smc5/6 complex in human hepatocytes in vivo, indicating that drugs lowering HBV RNA levels promote Smc5/6 rebound. While Smc6 appears to be a reliable marker of infection and cccDNA activity, these results suggest that the presence of Smc6 does not hinder viral rebound in the setting of established HBV infection. Notably, MyrB delayed viral rebound by blocking reinfection of cells that may have cleared the cccDNA during IFN treatment.

SAT-371
Hepatitis B virus escapes non-canonical CTL effector function

K. Sandra[1], K. Steiger[2], U. Protzer[3], P.A. Knolle[1], D. Wohlleber[1]. *[1]Technische Universität München, Institute of Molecular Immunology, Munich, Germany; [2]Technische Universität München, Institute of Pathology, Munich, Germany; [3]Technische Universität München, Institute of Virology, Munich, Germany*
Email: dirk.wohlleber@gmail.com

Background and Aims: The effector molecule of the non-canonical CTL effector function, Tumor necrosis factor (TNF), induces apoptosis selectively in adenovirus- or lymphocytic choriomeningitis virus-infected hepatocytes but not in non-infected hepatocytes. Therefore,

viral infection sensitizes virus-infected hepatocytes towards TNF-mediated death-inducing signaling processes. Mitochondria serve as central integrators of death signaling in hepatocytes and alterations in mitochondrial functionality influence TNF-induced signaling that can either promote death or cell survival. Here we aimed to elucidate whether a Hepatitis B virus (HBV) infection also induces changes in mitochondria functionality and thereby sensitizes infected hepatocytes towards TNF-induced apoptosis.

Method: To investigate the non-canonical CTL effector function in clearing HBV infection we used an adenovirus as a model for liver infection in mice. We transferred 1.3 overlengh HBV genomes via an adenoviral virus (AdHBV) into mice and compared this to an adenoviruses encoding for GFP (AdGFP), known to sensitize hepatocytes towards TNF induced apoptosis. To investigate only the non-canonical CTL effector function we applied recombinant TNF systemically in the mice and checked for apoptosis induction in virus infected hepatocytes. In addition, we isolated mitochondria from AdHBV and AdGFP infected murine livers and analyzed mitochondrial functionality.

Results: We found that Hepatitis B virus escapes the TNF-induced apoptosis signaling in hepatocytes. Systemically applied TNF in mice infected with AdHBV did not cause liver damage detected by a lack of elevated serum ALT levels. In contrast, high levels of serum ALT could be detected in TNF treated mice that were infected with AdGFP. The responsible factor for the inhibition of the TNF induced apoptosis in AdHBV infected hepatocytes could so far not be identified, but the HBV core proteins, the X-protein and S-antigens could be excluded as inhibitors of apoptosis, shown by using AdHBV with selective mutations in these proteins. Moreover, the altered mitochondrial functionality, namely lack of stable energy production, decreased mitochondrial membrane potential, increased calcium sensitivity and enhanced cytochrome C release detected after AdGFP infection, which is most likely the cause for sensitization of virus-infected hepatocytes is absent in AdHBV infection.

Conclusion: Our observations for the first time identify an immune escape of HBV in infected hepatocytes that circumvents the non-canonical CTL effector function at the level of mitochondrial functionality. These results may be helpful for the development of therapies against chronic HBV infection, by restoring the mitochondrial sensitivity in HBV-infected hepatocytes.

SAT-372

HBsAg transcomplementation of defective HBV genomes in HBeAg negative chronic HBV infected patients

K.-H. Peiffer[1,2], L. Kuhnhenn[1,2], B. Jiang[2], J. Vermehren[1], V. Knop[1], S. Zeuzem[1], C. Sarrazin[1,3], E. Hildt[4]. *[1]J.W. Goethe University Hospital, Medical Clinic 1, Frankfurt am Main, Germany; [2]Paul-Ehrlich-Institut, Department of Virology, Langen (Hessen), Germany; [3]St. Josefs-Hospital Wiesbaden, Gastroenterology, Wiesbaden, Germany; [4]Paul-Ehrlich-Institut, Virology, Langen (Hessen), Germany*
Email: kai-henrik.peiffer@kgu.de

Background and Aims: The HBV surface proteins (HBsAg) coat the viral particle and form in addition subviral particles (SVPs). Loss of HBsAg represents a functional cure and is an important treatment goal in HBV infected patients. We aimed to analyze the impact of the HBV genotypes A-E (GTA-GTE) and mutations in the preS-domain on HBsAg expression, composition, and morphology of SVPs in a large European cohort of HBeAg negative chronic HBV infected patients.

Method: Sera of HBeAg negative chronic HBV infected patients from the German multicenter Albatros study were used. Mutations in preS were determined by direct and deep sequencing. SVPs were characterized via HBsAg-specific western blotting, sucrose density gradient centrifugation and electron microscopy. For a more detailed analysis of the impact of pre S mutations on HBsAg expression a GTA 1.5-fold HBV genome with a 15 aminoacid deletion in the preS1 domain was analyzed in cell culture in comparison to a GTA 1.5-fold genome from a patient without mutations in the preS domain.

Results: We observed a genotype-specific ratio of the three surface proteins (SHBs/MHBs/LHBs), which reflects differences in the morphology and composition of released SVPs with a higher particle density in HBV GTB and GTD in comparison to GTA, GTC and GTE. A higher filaments/spheres ratio was observed in HBV GTB and GTD. While deletions/mutations in the preS1/preS2 domain detected in the released viral genomes do not affect the molecular weight of MHBs and LHBs in our patients, LHBs molecular weight is altered in our *in vitro* analysis using a HBV genome harboring a preS1-deletion. As secreted HBsAg and the released viral genomes cannot be derived from the same genetic source in these patients, HBsAg must be derived from the integrated DNA.

Conclusion: Differences in composition and morphology of SVPs may result in a genotype-specific immunogenicity and pathogenesis. As HBsAg can be sufficiently expressed from integrated DNA, this HBsAg source has to be considered for novel antiviral strategies in HBeAg negative chronic HBV infected patients.

SAT-373

Recapitulation of the complete HDV replication cycle in a novel hepatoma cell line allows for efficient antiviral compound evaluation

F. Lempp[1,2], F. Schlund[1], L. Rieble[1], L. Nussbaum[1], C. Eck[1], Y. Ni[1,2], S. Urban[1,2]. *[1]University Hospital Heidelberg, Molecular Virology, Heidelberg, Germany; [2]German Center for Infection Research (DZIF), Partner site Heidelberg, Heidelberg, Germany*
Email: florian.lempp@med.uni-heidelberg.de

Background and Aims: Chronic Hepatitis Delta Virus (HDV) infections represent the most severe form of viral hepatitis. As a satellite virus, HDV depends on the helper function of Hepatitis B Virus providing the envelope proteins for progeny virus secretion. After the identification of the cellular receptor NTCP, novel cell culture models for HDV have been established allowing entry and replication of the virus. However, virus assembly and progeny release is blocked due to the lack of the HBV surface proteins. Our aim was to generate a novel cell line that recapitulates the full HDV replication cycle including progeny secretion and to use this cell line for evaluation of antiviral compounds currently in clinical development and to test the infectivity of patient-derived serum HDV compared to cell-culture derived virus (HDVcc).

Method: HepG2 cells were stably transduced to overexpress NTCP and the three HBV surface proteins. An in-cell ELISA assay was established for fast and reliable quantification of HDV infection. Drug treatment during initial infection with the two investigational drugs Myrcludex B and Lonafarnib and the approved drug Interferon-alpha (IFNa) were performed and progeny virus was quantified by reinfection experiments.

Results: After infection with HDV, our novel cell line secreted infectious progeny virions for more than 20 days. Evaluation and activity testing of antiviral drugs showed that Myrcludex B (IC50: 1 nM) and IFNa (IC50: 20 IU/ml) dose-dependently inhibited initial infection, but in the case of IFNa, inhibition was only to about 20-30% of uncompeted infection. Lonafarnib inhibited progeny virus secretion (IC50: 35 nM) but lead to a substantial intracellular accumulation of Hepatitis Delta Antigen. Inoculation of the cell line with patient-derived virus versus HDVcc lead to similar infection extents, however, kinetics of progeny secretion was delayed and induction of innate immune responses was drastically reduced in patient-derived virus versus HDVcc.

Conclusion: We have established the first susceptible cell line that recapitulates the full replication cycle of HDV. Using these cells, we have validated the mechanism of action of investigational drugs and, for the first time, determined IC50 concentrations based on progeny virus secretion. The cell line presents an ideal tool for drug evaluation and small compound or siRNA/CRISPR-Cas screening.

Email: barbara.testoni@inserm.fr

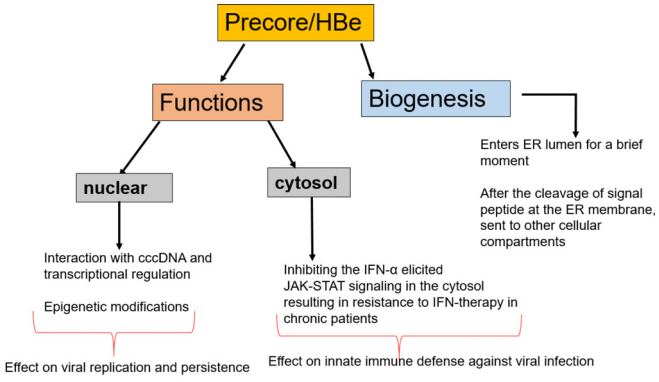
Background and Aims: Covalently-closed-circular (ccc)DNA is responsible for the persistence of hepatitis B virus (HBV) infection. The cccDNA pool stably resides in the nucleus of infected cells, unaffected by current available antiviral therapies, and serves as template for all viral transcripts. Histones, HBV core (HBc) protein and cccDNA are closely linked together to build a dynamic chromatin structure that is subject to the regulation by transcription factors and cofactors translating into different levels of biological activity. A comprehensive knowledge of the network of cccDNA-interacting partners controlling its activity during chronic infection is still lacking. To this aim, we developed a new approach to identify and characterize the global cccDNA-associated proteome combining cccDNA-specific ChIP to high-throughput Mass Spectrometry (MS) analysis, named chromatin proteomics (ChroP).
Method: The ChroP protocol was performed using 4 batches of HepG2-NTCP cells and 5 batches of primary human hepatocytes (PHHs) comparing mock *versus* HBV-infected cells at 9 days post-inoculation, when the cccDNA pool is stable and transcriptionally active. The HBV minichromosome and its associated proteins were specifically enriched by performing an Hirt DNA extraction followed by a sequential histone H3 + HBc ChIP to exclude all HBV replicative intermediates not associated to chromatin structure.
Results: Gene Set Enrichment Analysis highlighted fundamental differences in the cccDNA-associated protein network between PHH and HepG2-NTCP cells: while transcription and RNA dynamics were among the most enriched pathways in PHH, innate immune response, lipid metabolism and angiogenesis were the most over-represented pathways in HepG2-NTCP cells. By applying the majority voting system, the overall data reflect a core network of cccDNA partners involved in nuclear matrix localization, transcriptional regulation and RNA processing/export. Functional silencing of selected network members by RNA interference severely affected viral replication and indicated the FUS protein as one of the key players in coupling the regulation of viral RNA transcription and processing by connecting cccDNA with the spliceosome machinery and the Transcription Export (TREX) complex involved in RNA nuclear export.
Conclusion: We developed a new methodology able to identify host factors essential for cccDNA biological activity in HBV infectious models and to reveal new potential therapeutic targets.

SAT-375

Biogenesis and function of intracellular hepatitis B e antigen

B. Mitra[1], E.S. Kim[1], R. Mao[1,2], J. Wang[2], Y. Liu[1], J. Zhang[2], H. Guo[1]. [1]*Indiana University School of Medicine, Microbiology and Immunology, Indianapolis, United States;* [2]*Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China*
Email: haitguo@umail.iu.edu

Background and Aims: Antagonism of host innate immune defenses against HBV infection by the viral proteins and existence of nuclear, covalently closed circular (ccc) HBV DNA are speculated to cause HBV persistence and development of chronic hepatitis. The circulating HBeAg (p17) is known to manipulate host immune responses to assist in the establishment of persistent viral infection. However, the function(s) of the intracellular form of HBeAg, previously reported as the precore protein intermediate (p22) without the N-terminal signal peptide, remains elusive. Here, we report that p22 is playing a role in maintaining HBV chronic infection by inhibiting IFN-α mediated antiviral response and interacts with ccc DNA. Further, we also confirm the presence of a novel ER sorting mechanism for distribution of p22 and secretory HBeAg.
Method: Liver biopsies from HBeAg(-) and HBeAg(+) patients treated for six months with interferon-alpha (IFNα) were used for the RNA-seq. To investigate the effect of p22 in regulating host IFN-α elicited JAK-STAT signalling, interferon-sensitive response element (ISRE) activity was measured by a luciferase reporter assay and quantitative RT-PCR was done to detect the expression level of interferon stimulated genes (ISGs) upon IFN-α stimulation in absence or presence of p22. Transient overexpression of HA-tagged p22 in HepG2 and 293T cells preceding subcellular and microsomal fractionations was used for the mechanistic study of p22-mediated JAK-STAT inhibition and for understanding the biogenesis of p22, respectively. Co-immunoprecipitation was employed to study p22's interaction with karyopherin-α1 (Kα1). Chromatin immunoprecipitation using stable cell lines with cccDNA-dependent HA-tagged p22 expression in a tet-off system were used to study the p22-cccDNA interaction.
Results: The p22 but not the secreted HBeAg(p17) significantly reduced ISRE activity and expression of ISGs upon IFNα stimulation. RNA-seq analysis of ISG induction profile from IFN-α treated patients showed that HBeAg(+) patients exhibited reduced and weak antiviral ISG upregulations compared to HBeAg (-) patients. Mechanistic study indicated that p22 blocks the nuclear translocation of pSTAT1/2 by competing with the latter to interact with Kα1. Secondly, we found a nuclear form of p22 that can bind to cccDNA. Thirdly, we have identified that a portion of p22, after the cleavage of its signal peptide and formation in endoplasmic reticulum, gets released back into the cytosol through an ERAD-independent mechanism.
Conclusion: Thus, our results indicate that there is a novel ER sorting mechanism for the distribution of the p22 and secretory p17, and p22 may contribute to HBV persistence and affect prevailing IFN-therapy by interfering with IFNα elicited JAK-STAT signalling and regulating cccDNA metabolism.



SAT-376

EFTUD2 restricts hepatitis B virus infection by regulating RIG-I expression

C. Zhu[1], F. Xiao[2], Q. Wang[3], T. Zhu[3], L. Kong[3], J. Li[3]. [1]*The First Affiliated Hospital of Nanjing Medical University, Department of Infectious Disease, Nanjing, China;* [2]*Stanford University School of Medicine, Department of Microbiology and Immunology;* [3]*The First Affiliated Hospital of Nanjing Medical University, Department of Infectious Disease*
Email: chuanlong@yahoo.com

Background and Aims: Recently, RIG-I has been identified dually functions as an innate sensor and direct antiviral factor for hepatitis B virus (Sato S, et al. Immunity, 2015). We have reported that EFTUD2 exercised antiviral ability via RIG-I pathway in HCV JFH1 culture

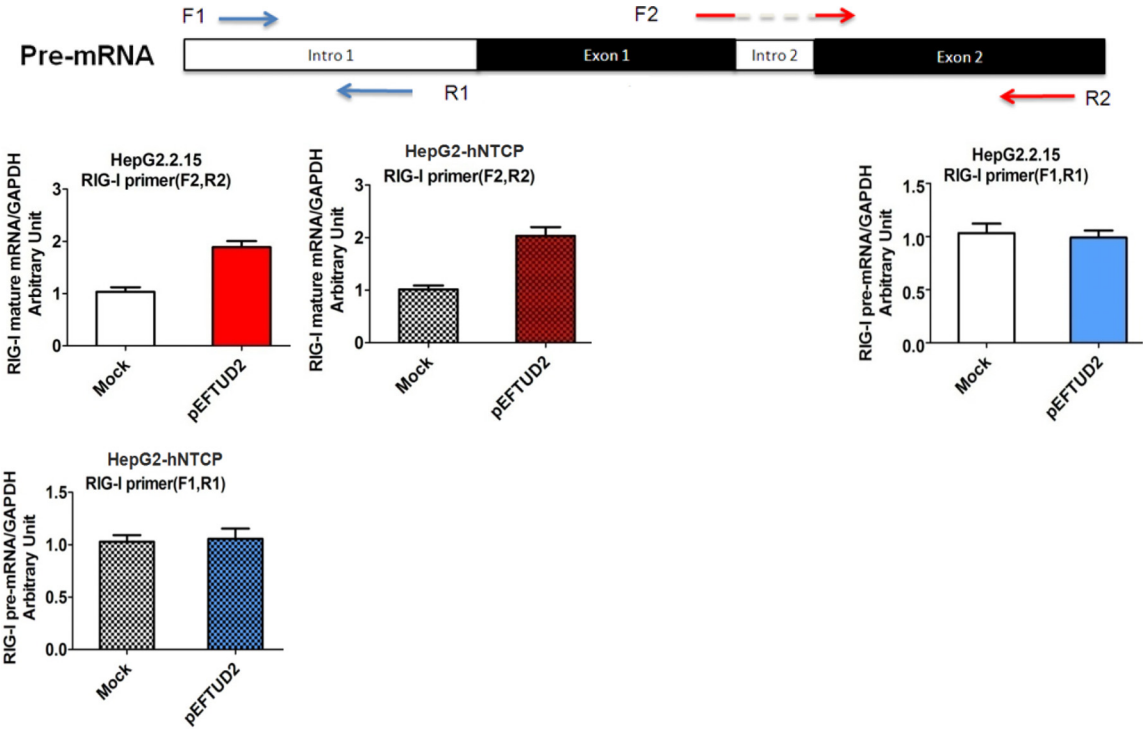


Figure 1: (abstract: SAT-376): EFTUD2 upregulates RIG-I mature mRNA expression.

system (Zhu C, et al. J Virol, 2015), but its role in HBV infection remains unknown. In this study, we evaluate whether EFTUD2 can restrict HBV infection through regulating RIG-I expression.

Method: We overexpressed EFTUD2 by plasmid transfection, then performed siRNA knockdown of RIG-I in HepG2.2.15 or HBV-infected HepG2-NTCP cells. Selected gene expression were monitored by quantitative PCR and Western-blot. Levels of viral antigen expression and HBV DNA were measured by enzyme-linked immunosorbent assay and quantitative PCR, respectively.

Results: EFTUD2 overexpression inhibited HBV replication from 6,511,626 ± 1,108,827 to 3,030,405 ± 403,128 IU/ml ($p = 0.0069$) in HepG2.2.15 cells, and meanwhile reduced HBsAg and HBeAg production by 58.9 ± 9.1% (13.49 ± 1.27 vs 5.54 ± 1.25; $p = 0.0015$) and 39.7 ± 2.0% (22.86 ± 1.83 vs 13.79 ± 1.34; $p = 0.0022$) in culture supernatants, respectively. We further confirmed EFTUD's anti-HBV ability in a novel HBV culture system, namely HepG2-NTCP infected with HBV. Moreover, EFTUD2 overexpression resulted in a increase in RIG-I mature mRNA level in both HepG2.2.15 and HBV-infected HepG2-NTCP, indicating RIG-I mediate EFTUD2's antiviral effect, which could be reversed by specific siRNA against RIG-I.

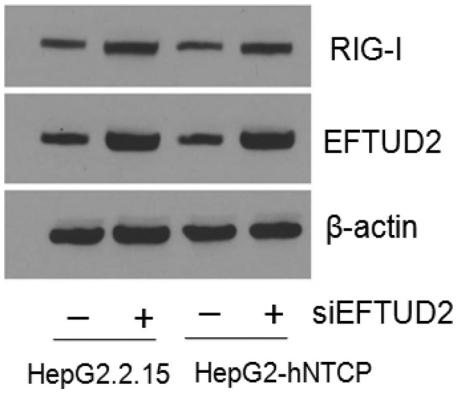

Figure 2: EFTUD2 upregulates RIG-I protein expression.

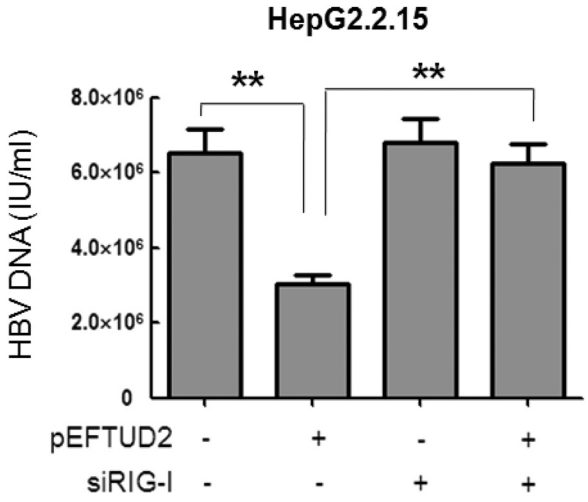

Figure 3: EFTUD2-induced antiviral effect is dependent of RIG-I pathway.

Conclusion: Our data demonstrate that EFTUD2 inhibits HBV infeciton through upregulating RIG-I expression, and may provide a potential antiviral target for anti-HBV therapy in the future.

Hepatitis E virus activates signal transducer and activator of transcription 3 to facilitate virus replication

W. Wang[1], Y. Wang[2], C. Qu[1], S. Wang[2], J. Zhao[2], M. Peppelenbosch[1], Q. Pan[1]. [1]*Erasmus University Medical Center, Rotterdam, Netherlands;* [2]*Beijing 302 hospital, Beijing, China*
Email: w.wang.2@erasmusmc.nl

Background and Aims: Hepatitis E virus (HEV) is the most common causes of acute viral hepatitis globally, but the mechanisms by which it corrupts hepatocyte cellular machinery to facilitate its replication remain only partially understood. STAT3 is a vital transcription factor centrally involved in cell signaling pathways to exert diverse cellular

responses. This study aims to reveal the interactive dynamics of STAT3 with hepatitis E virus (HEV) and the consequences for viral replication.
Method: The HEV infectious model (Huh7 cells containing the full-length HEV genome, Kernow-C1 p6) was used. Paraffin-embedded liver tissues from 21 HEV patients were also used.
Results: Here, we demonstrate that HEV potently activates STAT3 phosphorylation in the liver of hepatitis E patients and in cell cultures. This corresponded to a concomitant increase in STAT3-related transcriptional activity. Mechanistically, HEV-mediated STAT3 activation is independent of classical humoral IL-6 and interferon signaling but involves hijacking of Janus kinases (JAKs) and Src kinases via the active viral infection. Importantly, genetic or pharmacological inhibition of STAT3 activation constrained HEV replication. Conversely, over-expression of the activated form of STAT3 increased HEV replication.
Conclusion: Our results revealed a previously undescribed function of STAT3 as a pro-HEV host factor. HEV-induced STAT3 phosphorylation in turn create a favorable environment to facilitate HEV replication. Therefore, STAT3 serves as a promising target for the development of antivirals against HEV.

SAT-378

Pro-fibrogenic mediator osteopontin is intimately involved in chronic hepatitis B and promotes cccDNA production

S. Phillips[1,2], J. Coombes[1,2], S. Mistry[1,2], M. Simonova[3], T. Hadzhiolova[3], S. Pavlova[3], K. Katzarov[3], P. Kennedy[4], U. Gill[4], T. Pereira[5], F.E. Pereira[6], R. Williams[1,2], W. Syn[1,2], S. Chokshi[1,2].

Email: s.phillips@researchinliver.org.uk

Background and Aims: We have previously shown that host proteins actively participate in HBV replication (Phillips et al, Gastroenterology 2015). This study aimed to dissect the role of host-protein and pro-fibrogenic mediator Osteopontin (OPN) in chronic HBV infection (CHB) during the clinical phases of CHB, HBV-driven liver injury and to also evaluate its role in driving covalently closed circular DNA (cccDNA) formation.
Method: OPN levels were measured by ELISA in sera/plasma (S/P) of healthy controls (HC) and 102 CHB patients during disease phases; HBeAg(+)CHB (CI;Immunotolerant), HBeAg(+)chronic hepatitis (CH; Immune active), HBeAg(-)CI (Inactive carrier) and HBeAg(-)CH. OPN was also quantitated in CHB patients with different fibrosis stages (n = 81) intrahepatically, in S/P and in paired CHB patients undergoing NUC treatment (n = 9). Finally, HepaRG cell-line infected with HBV was cultured over 72h in presence/absence of recombinant OPN (recOPN) and neutralizing OPN-specific aptamers. Cells and supernatants were harvested at 24, 48 and 72 hours. HBV replication and antigenemia were assessed by qPCR and cccDNA was quantified using digital droplet PCR.
Results: S/P OPN levels were elevated by 4-fold in CHB ($p = 0.002$) and increased with fibrosis stages ($p = 0.006$). In HBeAg(-)CI and CH, OPN levels were elevated in comparison to HC (4.3-fold; $p = 0.054$; 4.7-fold; $p = 0.005$). However, HBeAg(+)CI exhibited decreased OPN levels compared to all other groups; HC (5.2-fold; $p = 0.001$), HBeAg(+)CH (13.8-fold; $p = 0.06$), HBeAg(−)CI (22.6-fold; $p < 0.001$) and HBeAg(−)CH (24.7-fold; $p < 0.001$). Interestingly, CHB patients with no fibrosis but with elevated vireamia displayed increased level of S/P OPN compared to HC (4.5-fold; $p = 0.0003$). Furthermore, patients whose viral load became undetectable during antiviral treatment had a significant reduction in S/P OPN (1.5-fold; $p = 0.039$). In vitro, HepaRG treatment with recOPN significantly enhanced viral replication, antigen production and cccDNA levels (34-fold; $p = 0.02$) whereas neutralising OPN aptamers decreased all viral parameters and cccDNA levels ($p = 0.04$).
Conclusion: OPN levels directly correlate with viral replication rates, severity of HBV-driven fibrosis and exhibit differential expression during the different phases of CHB disease, thus identifying a marker for CHB driven liver disease. We also demonstrate that OPN is directly involved in HBV replication and can augment cccDNA levels. Finally, we show that neutralisation of OPN can reduce cccDNA and reveal a novel therapeutic strategy for CHB.

SAT-379

Whole genome viral sequencing reveals subgenotype specific dynamics of antiviral treatment response in HBeAg positive and treatment naive chronic hepatitis B patients

O. Podlaha[1], K. Agarwal[2], A. Thompson[3], G. Foster[4], D. Samuel[5], H. Yatsuhashi[6], A. Gaggar[1], K. Kitrinos[1], Z. Jiang[1], M. Tong[7], E. Gane[8], M. Brunetto[9]. *[1]Gilead Sciences, Inc., Foster City, California, USA; [2]Kings College Hospital NHS Trust, London, United Kingdom; [3]St. Vincent's Hospital Sydney, Sydney, Australia; [4]Barts Health NHS Trust, London, United Kingdom; [5]Hopital Paul Brousse, Villejuif, France; [6]National Hospital Organization Nagasaki Medical Center, Nagasaki, Japan; [7]Huntington Medical Research Institutes, Pasadena, California, USA; [8]Auckland Clinical Studies, Auckland, New Zealand; [9]UO Epatologia, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy*
Email: ondrej.podlaha@gilead.com

Background and Aims: Full genome viral deep sequencing may provide valuable insights into which clinical outcomes are genetically driven. Our goal was to identify associations between the baseline population genetic structure of the hepatitis B virus (HBV) and antiviral treatment response.
Method: Whole genome HBV amplicons from 1098 HBeAg positive and negative chronic hepatitis B patients enrolled in two global phase 3 studies of tenofovir alafenamide versus tenofovir disoproxil fumarate (GS-US-320-0108 and GS-US-320-0110) were sequenced on Illumina MiSeq instrument. Single nucleotide variation was assessed across the entire ~3.2Kb HBV genome and multidimensional scaling approach was applied to patient-level HBV genome consensus to identify genetic clusters within each HBV genotype. Sub-genotype groups defined by genetic clusters were investigated for treatment response differences measured by HBV DNA and HBsAg decline from baseline while controlling for relevant confounding factors.
Results: Among all patients, we identified multiple genetic clusters of HBV within each viral genotype (GT A = 2, B = 3, C = 2, D = 2). Only genotype C clusters (Figure 1A), broadly corresponding to subgenotype C1 and C2, displayed significant differences in treatment response dynamics among HBeAg positive treatment naïve patients (C1 N = 197, C2 N = 83, Figure 1B). HBV C1 patients experienced ~0.5 $\log_{10}$IU/ml greater reduction in HBV DNA at week (wk) 4, 8, and 12 compared to HBV C2 patients ($p = 7.9e-05$, 1.1e-04, and $p = 2.7e-03$ respectively). Although HBV C1 patients had significantly higher median levels of baseline HBV DNA (7.9 $\log_{10}$IU/ml) than HBV C2 patients (7.3 $\log_{10}$IU/ml, $p = 2.8e-04$), the viral genetic structure remained a significant factor in treatment response dynamics (wk 4 $p = 1.0e-04$, wk 8 $p = 1.5e-05$, and wk 12 $p = 3.0e-03$). Geographically, two locations displayed clear HBV C1 and C2 distribution separation (HBV C1: Korea + Japan, HBV C2: Hong Kong) suggesting lower HBV migration rates between these regions. Analogous but non-significant trend differences were also observed in HBsAg decline between HBV C1 and C2 cohorts. Importantly, despite different treatment response dynamics, viral suppression at wk 24 and 48 was similar between HBV C1 and C2 patients.

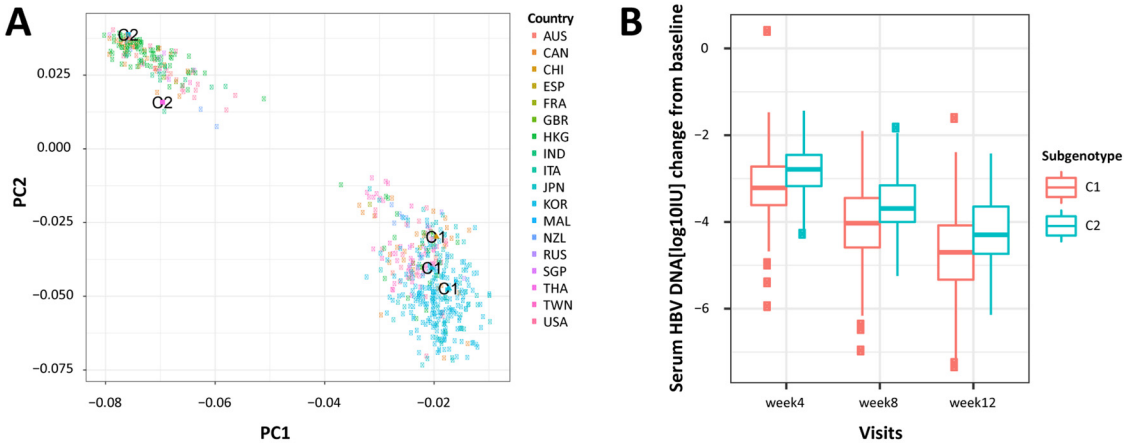

Figure 1

A. HBV genotype C population substructure. Multidimensional scaling approach was applied to patient-level HBV genome consensus to identify genetic clusters within HBV genotype C. HBV subgenotypes C1 and C2 were included for reference. **B.** Significant differences in decline of HBV DNA in serum between patients infected with C1 and C2 HBV at week 4, 8, and 12 during antiviral therapy (p=1.1e-05, p=2.6e-05, and p=7.7e-05 respectively).

Figure: (abstract: SAT-379)

Conclusion: Our data indicate that the population genetic structure within genotype C of HBV contributes to variation in treatment response dynamics. The geographic association with baseline HBV DNA warrants further investigation.

SAT-380

Control of glycokinase activity by the HCV protein NS5A increases lipogenesis

C. Jacquemin[1], B. Panthu[1], C. Ramière[1], X. Hanoulle[2], L. Perrin-Cocon[1], P. Andre[1], V. Lotteau[1], O. Diaz[1]. *[1]INSERM U1111 – CNRS UMR5308 Université Lyon 1, ENS de Lyon, Centre International de Recherche en Infectiologie (CIRI), LYON cedex 07, France; [2]CNRS UMR8576 Université de Lille1, Unité de Glycobiologie Structurale et Fonctionnelle, France*
Email: olivier.diaz@inserm.fr

Background and Aims: We have previously shown that HCV increases glycolytic rate, through a direct interaction between NS5A and hexokinase 2 in Huh7 cells. There are four hexokinase isoenzymes, HK1-3 and glucokinase (GCK), with different tissue, subcellular distributions, molecular and enzymatic properties. All HK catalyze the synthesis of glucose-6P from glucose, GCK has a lower affinity for its substrate and is not inhibited by Glc-6P, which makes its activity tightly regulated by Glc concentration but not by the demand for end pathway products. Huh7 expresses HK2 but in vivo hepatocytes express GCK isoenzyme. This differential expression of HK isoenzymes raises the question of the ability of NS5A to interact with GCK and increase glycolysis in normal hepatocytes. We therefore investigated whether NS5A could increase GCK activity and the glycolysis flux of hepatocarcinoma cells expressing this isoenzyme.
Method: Modulation of GCK catalytic parameters by NS5A and its domains in acellular assays was investigated with purified proteins. To determine whether the modulation catalytic activity of GCK was functional in cells, we invalidated Huh7 for HK2 by CRISPR/Cas9 and expressed GCK by lentiviral transduction. The generated cell line was used to analyze the impact of GCK modulation by NS5A on glycolysis and viral replication.
Results: NS5A interacts with GCK and acts as an allosteric activator through its domain 2. In GCK-Huh7 cells, expression of NS5A increased Glc consumption and intracellular lipid droplets. Interestingly, we observed that the expression of GCK in Huh7 cells was sufficient to increase intracellular neutral lipids and secretion of apoB-lipoproteins indicating that *de novo* lipogenesis was restored in this cell line. In addition, HCV-RNA association to lipoprotein fractions was enhanced in supernatant of HCV-infected GCK-Huh7.
Conclusion: NS5A increases glycolysis by its direct interaction with GCK thus supporting the supply of energy and metabolites necessary for viral replication. The resulting lipogenesis observed in cells expressing GCK could promote viral assembly and production of the low-density form of HCV in the form of lipo-viral-particles (LVP) which are the most infectious particles in vivo. Our model will allow to functionally analyze how HCV modulates glycolysis and lipogenesis leading to the production of LVP.

SAT-381

Evolution and persistence of resistance-associated substitutions of hepatitis c virus after daclatasvir plus asunaprevir treatment failures

Y. Jeong[1,2], B. Jin[1,2], H.W. Lee[3], H.J. Park[1], D.Y. Kim[1], K.-H. Han[1], S. Kim[1], S.H. Ahn[1]. *[1]Institute of Gastroenterology, Department of Internal Medicine, Yonsei University College of Medicine; [2]Brain Korea 21 Plus Project for Medical Science, Yonsei University; [3]Yonsei University College of Medicine, Department of Internal Medicine, Institute of Gastroenterology, Seoul, Korea, Rep. of South*
Email: ycjeong0919@yuhs.ac

Background and Aims: Daclatasvir plus asunaprevir (DCV + ASV) treatment is an all-oral direct-acting antiviral (DAA) therapy for the genotype 1b HCV-infected patients. Despite its high sustained virologic response (SVR) rate, the treatment failures are observed even in patients without baseline NS5A polymorphisms. In this study, we investigated how resistance-associated substitutions (RASs) of NS5A and NS3 evolved after treatment failures and assessed the effect of those substitutions on viral fitness.
Method: Sera from the patients who failed in DCV + ASV treatment were collected and viral RNA was isolated. The viral genome sequences of NS3 and NS5A were determined by direct sequencing after RT-PCR amplification. In order to assess the effect of RASs on viral fitness, they were introduced in the genotype1a or 1b HCV RNA either as single substitutions or as multiple substitutions and investigated by Luciferase reporter assay and focus-forming assay after transfection into the Huh7.5 cells. To make quasi-species *in vitro*,

wild-type (WT) and mutant RNAs were co-transfected into Huh7.5 cells in different ratios and investigated by reporter assay.
Results: We followed up the RASs identified in patients who failed in DCV + ASV treatment. Typical RASs of NS3 at D168 and those of NS5A at L31 and Y93 were commonly observed after DCV + ASV treatment failures. Interestingly, the RASs of NS3 reverted to the wild-type amino acid within one year after treatment failures. However, the RASs of NS5A were stable over one year after cessation of treatment. The effect of NS3 and NS5A RASs on viral RNA replication was assessed after mutagenic substitution in the genotype 1b HCV RNA. Among the single substitutions, the effect of D168V was more substantial than the others and the effect of the triple mutant combination (D168V + L31V + Y93H) was the most severe. When the Y93 mutagenic substitution was tested with infectious genotype 1a HCV RNA, the Y93 affected both viral RNA replication and virus production. To make quasi-species environment *in vitro*, WT and Y93N RNAs were co-transfected into the Huh7.5 cells and the RNA replication capacity measured report assay was plotted as percentage compared to that of the 100% transfection of luciferase HCV RNAs. The RNA replication capacity of Y93N increased from 50% to 69% and WT decreased from 50% to 28%.
Finally, the effect of *trans*-complementation of NS5A protein was assessed for Y93N substitution and the result suggests that such *trans*-complementation effect of NS5A protein may help maintain the RASs of NS5A for a long time even after cessation of the DAA treatment.
Conclusion: The RASs of NS5A and NS3 after DCV + ASV treatment failures were identified and analyzed regarding viral evolution and fitness change. The results from this study would help understand the emergence and persistence of RASs and provide retreatment guidelines for the patients who failed in DCV + ASV therapy

SAT-382

FXR agonist GW4064 represses HBV replication in adult but not in young C3H/HeN mice after HBV transduction with rAAV2/8-HBV

F. Fusil, C. Ménard, C. Ramière, A. Ollivier, K. Mouzzanar, V. Lotteau, F.L. Cosset, P. Andre. *INSERM U 1111 – CNRS UMR5308 Université Lyon 1, ENS de Lyon, Centre de Recherche International en Infectiologie, Lyon, France*
Email: patrice.andre@inserm.fr

Background and Aims: HBV life cycle is linked to the bile salts (BS) nuclear receptor FXR activity. HBV competes with BS for entry through NTCP and FXR response elements in HBV genome have been identified. HBV infection modulates BS pathway in vivo and in HepaRG and PHH cellular models. Reciprocally, treatments with FXR agonists repress HBV replication in these models. HBV transfection by hydrodynamic injection in C3H/HeN leads to rapid viral clearance in adult mice but to chronic HBV infection in young or gut microbiota free adult mice. We wondered if transduction with rAAV2/8-HBV vector lead also to chronic and acute infections in young and adult C3H/HeN mice and if treatment with the FXR agonist GW4064 influences the infection outcome.
Results: Transduction with 5×10^{10} GE rAAV2/8-HBV lead to chronic HBV replication with stable viral load (around 1×10^{8} copies/ml) and HBsAg titers from d7 to d91 p.i. in 6-week old C3H/HeN mice. In 12-week old mice, viral load was lower at d7 and d35 (−0.5 and −1.5 log10 copies/ml respectively) than in younger mice and went back to d7 level at d91. HBsAg titers evolved similarly. In 6-week old mice infected with 2×10^{10} GE rAAV2/8-HBV and treated for 4 week with GW4064 at 50 mg/kg by daily gavage or diluent, viral load remained stable and did not vary between the two groups. In 12-week old mice, GW4064 treatment inhibited the viral load and HBsAg rebounds observed in control mice (−1.1 Log10 copies/ml and −0.8 log10rfu/ml respectively). Surprisingly HBeAg titers did not vary during the 4-week treatment.
Conclusion: HBV infection outcome in C3H/HeN varied with age at time of infection. HBV replication was stable at a high level in young mice when in adult mice HBV replication was first repressed before rebounding after several weeks. This model of infection has limitations with numerous rAAV2/8-HBV extra-chromosomic concatemers and integrated genomes. The presence of these rAAV-HBV forms may explain the late rebound of HBV replication in adult mice that does not occur after hydrodynamic injection of HBV genome. Interestingly, treatment with FXR agonist represses HBV expression in adult only, suggesting that the difference of infection evolution with age is partially dependent on FXR activity. BS metabolism matures with gut microbiota maturation. These data further stress out the role of FXR in HBV life cycle and suggest that the frequent chronic infections in childhood are also in part due to the immaturity of BS metabolism.

SAT-383

Cellular retinoic acid-binding proteins regulation of hepatitis C virus infection

B.R. Bang, T. Saito. *University of Southern California, Medicine, Los Angeles, United States*
Email: saitotak@usc.edu

Background and Aims: Retinoic Acid (RA) is known to potentiate both innate and adaptive immunity, and therefore has been termed "the anti-infective agent". Epidemiological and immunological studies reported its potent anti-microbial properties to a variety kind of viral pathogens such as, but not limited to, measles, HIV, and influenza virus.
The majority of dietary *retinoid (vitamin A)* is *stored* in hepatic stellate cells and hepatocytes. The biogenesis of RA, the final metabolite of vitamin A, takes place in the cytoplasm. Cellular retinoic acid-binding protein (CRABP) 1 and 2 are localized in the cytoplasm and binds to RA. Then, CRABPs translocate to the nucleus, resulting in the regulation of more than 500 genes through the activation of the nuclear receptors, retinoic acid receptor (RAR) and retinoid X receptor (RXR). CRABP1 and 2 shares high homology, and thus are predicted to have redundant functionality. To date, however, the role of CRABPs in the cell biology of hepatocytes as well as the potential influence on HCV lifecycle has never been investigated.
Consequently, this study is designed to define the biological functions of CRABPs with an ultimate goal to understand the mechanism by which HCV establishes an efficient viral lifecycle in the cells comprising a substantially high concentration of the antiviral organic compound, RA.
Method: Huh7 cells expressing CRABP1 or CRABP2 at the comparable degree to primary human hepatocytes were established as in vitro study tools. Then, Huh7-CRABP1 and 2 cells were used for molecular virological studies with biochemical and genetic approaches to assess the significance of CRABPs on HCV lifecycle.
Results: Our results found HCV replication was suppressed in the cells expressing CRABP2 while viral lifecycle was substantially upregulated in the cells expressing CRABP1. Our transcriptome analysis of Huh7-CRABP1 and 2 cells suggested that these CRABPs differentially regulate the cellular metabolism of lipids. Follow up microscopic analysis revealed that CRABP1 offers a platform for the formation of HCV replication complex via accumulation of lipid droplet (LD). In contrast, we found that antiviral effect of CRABP2 resulted from the inhibition of LD formation.
Conclusion: This study results revealed the unrecognized role of vitamin A in the regulation of lipid metabolism in hepatocytes. We discovered that CRABP1 and 2 differentially regulate HCV infection via modulation of LD abundance. These findings indicate that CRABPs can be an attractive therapeutic target for both HCV infection and fatty liver diseases.

GalXC technology enables potent and durable RNAi-mediated inhibition of hepatitis B virus in preclinical models

M. Koser, K. Craig, G. Chopda, W. Cyr, C. Lai, H. Dudek, W. Wang, B. Brown, M. Abrams. *Dicerna Pharmaceuticals, Cambridge, United States*
Email: mabrams@dicerna.com

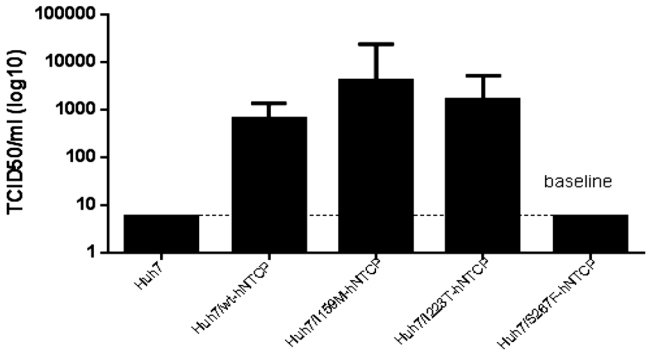
Background and Aims: Chronic Hepatitis B Virus (HBV) infection is a significant cause of worldwide morbidity and mortality. RNA interference (RNAi) technology offers the potential to pharmacologically intervene at every stage of the viral life cycle. GalXC technology represents a novel structural class of subcutaneously- or intravenously-administered, hepatocyte-targeting RNAi therapeutics which can silence any expressed RNA with high specificity and long duration. In this poster, we will review the identification, optimization, and characterization of two GalXC compounds targeting the HBsAg and HBx protein open reading frames (ORFs).
Method: GalXC drug candidates were evaluated in wild type mice, nonhuman primates and in three preclinical HBV models: HDI-HBV (hydrodynamic injection), AAV-HBV (adeno-associated virus model) and PXB-HBV (PhoenixBio humanized liver mouse). Potency, duration, translational potential, tolerability, and pharmacokinetic properties were investigated.
Results: GalXC-HBV lead compounds, which cover >95% of HBV genomes across all genotypes, resulted in >90% reduction of HBV pregenomic RNA (pgRNA) and viral mRNAs in the liver. Maximum inhibition of HBsAg was of >3.5 logs, with suppression lasting >7 weeks after a single 3 mg/kg dose. Differences in magnitude of response from model to model were noted and will be discussed. We will also report pharmacodynamic differences observed between the two lead compounds, which target different open reading frames in the viral genome.
Conclusion: These data strongly support clinical development of GalXC RNAi therapeutics for chronic HBV infection, and highlight the need to evaluate preclinical-stage HBV therapeutics in multiple models.

SAT-385

Sodium taurocholate cotransporting popypeptide variants modulate HDV entry according to their function as a bile acid transporter but do not influence the antiviral effect of Myrcludex-B

O. Anastasiou[1,2], S. Westhaus[2], M. Anspach[2], L. Timmer[2], S. Susser[3], C. Sarrazin[3], G. Gerken[1], V. Keitel[4], H. Wedemeyer[5], M. Lu[2], J. Stindt[4], S. Ciesek[2]. [1]*University Hospital Essen, Department of Gastroenterology and Hepatology, Essen, Germany;* [2]*University Hospital Essen, Institute of Virology;* [3]*University Hospital Frankfurt, Department of Gastroenterology and Hepatology;* [4]*University Hospital Düsseldorf, Department of Gastroenterology and Hepatology;* [5]*Department of Gastroenterology and Hepatology, University Clinic Essen, Essen, Germany*
Email: olympia.anastasiou@uni-due.de

Background and Aims: Several polymorphisms have been described in the sodium taurocholate cotransporting polypeptide (NTCP). Some of them have been associated with the course of hepatitis B virus (HBV) infection. Aim of the present study was to characterize to what extend HDV entry and bile acid transport capability differ in three coding NTCP variants (I159M, I223T, S267F) and to evaluate if these NTCP variants may alter sensitivity to antiviral treatment with Myrcludex-B.
Method: Huh7 cells stably expressing wildtype (wt) or mutant NTCP were infected with *in vitro* generated HDV particles in the presence or absence of Myrcludex-B. Infectivity was assessed with immunofluoresence staining for HDV antigen and standard 50% tissue infectious dose (TCID50) assay. Bile acid transport was assessed via a 3[H]-taurocholate transport assay.
Results: While Huh7 cells expressing NTCP S267F were resistant to HDV infection, cells expressing I159M or I223T were more susceptible to HDV. In line, NTCP I159M showed enhanced bile acid transport activity while bile acid transport activity was strongly reduced for NTCP S267F. All NTCP variants had no impact on the antiviral effect of Myrcludex-B. Other HDV virus cycle steps such as particle assembly, release or replication were not affected.



Conclusion: NTCP mutations can influence its function as a bile transporter and entry receptor for HDV. The S267F mutation leads to loss of function in both cases, while the I159M and I223T lead to greater infectivity by HDV viral particles, but have no effect on Myrcludex-B efficacy in blocking the entry of the virus.

SAT-386

Hepatitis E virus lifecycle and identification of 3 forms of the ORF2 capsid protein

Email: laurence.cocquerel@ibl.cnrs.fr

Background and Aims: Hepatitis E virus (HEV) infection is a major cause of acute hepatitis worldwide. Approximately 2 billion people live in areas endemic for HEV and are at risk of infection. The HEV genome encodes 3 proteins, including the ORF2 capsid protein. Detailed analyses of the HEV lifecycle has been hampered by the lack of an efficient viral culture system.
Methods: We performed studies with gt3 HEV cell culture-produced particles (HEVcc) and patient blood and stool samples. Samples were fractionated on iodixanol gradients and cushions. Infectivity assays were performed in vitro and in human liver chimeric mice. Proteins were analyzed by biochemical and proteomic approaches. Infectious particles were analyzed by transmission electron microscopy. HEV antigen levels were measured with the Wantaï ELISA.
Results: We developed an efficient cell culture system and isolated HEV particles that were infectious in vitro and in vivo. Using transmission electron microscopy, we defined the ultrastructure of HEVcc and particles from patient sera and stool samples. We also identified the precise sequence of the infectious particle-associated ORF2 capsid protein. In cultured cells and in samples from patients, HEV produced 3 forms of the ORF2 capsid protein: infectious/

intracellular ORF2 (ORF2i), glycosylated ORF2 (ORF2g), and cleaved ORF2 (ORF2c). The ORF2i protein associated with infectious particles, whereas the ORF2g and ORF2c proteins were massively secreted glycoproteins not associated with infectious particles. ORF2g and ORF2c were the most abundant antigens detected in sera from patients.
Conclusions: We developed a cell culture system and characterized HEV particles; we identified 3 ORF2 capsid proteins (ORF2i, ORF2g, and ORFc). These findings will advance our understanding of the HEV lifecycle and improve diagnosis.

SAT-387

Serum HBcrAg levels as a predictor of slow HBV DNA suppression following initiation of nucleoside therapy in HBV/HIV co-infected individuals

R. Byrne[1], S. Montague[1], M. Bruce[1], K. Childs[1], I. Carey[1], K. Agarwal[1], G. Dusheiko[2]. *[1]Kings College Hospital, Instittute of Liver Studies, London, United Kingdom; [2]Kings College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: ruthbyrne@nhs.net

Background and Aims: Hepatitis B core-related antigen (HBcrAg) has emerged as a surrogate marker for intrahepatic cccDNA and has a potential use in the monitoring of chronic hepatitis (HBV) infection. There are little data on its utility in HBV/HIV coinfected patients. A proportion of HBV/HIV co-infected patients adhering to dual active antiviral therapy with suppressed HIV have persistent HBV replication and may warrant more intensive surveillance, monitoring and management of liver disease co-factors. The aim of this small pilot study is to evaluate HBcrAg levels in HBV/HIV infected patients to determine if it is has a role in risk stratification of this cohort.
Method: 30 patients with chronic HBV/HIV coinfection, on tenofovir (TDF)-based antiretroviral therapy (ART), were identified retrospectively. Patients were classified into two groups: those with fully suppressed HIV(<50 copies/ml) and HBV(<20 IU/ml) at week 48 of TDF-based ART (group A, n = 15) and those with persistent HBV replication despite an undetectable HIV viral load, reflecting adherence to therapy, at week 48 of TDF based ART (group B, n = 15). Serum HBcrAg was tested at baseline (initiation of TDF-based ART) and at week 48 of therapy. HBcrAg was measured by an automated CLEIA-method (Lumipulse G 1200 HBcrAg, Fujirebio).
Results: There was no significant difference between group A and B in sex, age, distribution of HBV genotypes, baseline CD4 count and HBV DNA level. In group A, 6/15(40%) patients were e-Antigen positive at baseline; 4(67%) of whom seroconverted e-Antigen by week 48. Higher levels of e-Antigen positivity were observed in group B (n = 10, 67%) and rates of e-Antigen seroconversion were lower than group A (n = 1, 10%). At baseline there was a significant difference in HBcrAg levels between the two groups (group A 4.88 ± 1.75 $\log_{10}$ kU/ml, and group B 6.84 ± 0.59$\log_{10}$ kU/ml, p < 0.001). At week 48 there was a significant difference in HBcrAg levels between the two groups (group A 3.71 ± 1.67 $\log_{10}$ kU/ml, and group B 6.21 ± 1.08 $\log_{10}$ kU/ml, p <0.001).
Conclusion: In this small, HBV/HIV cohort baseline HBcrAg levels were higher in those that failed to suppress HBV DNA despite good adherence to HBV active ART. There may be a role for HBcrAg as a predictor of slow HBV response and therefore a potential tool to risk stratify this group and identify those that need closer surveillance. Further work in larger cohorts is required to fully establish the clinical utility of HBcrAg in this group.

SAT-388

Statins suppress hepatitis B virus replication and reduce hepatoma cell viability by interfering with Rho-GTPases

M. van de Klundert[1], M. Ringelhan[1,2], U. Protzer[1]. *[1]Institute of Virology, Technical University of Munich/Helmholtz Zentrum München, Munich, Germany, Germany; [2]Technical University of Munich, Munich, Germany, Second Medical Department, University Hospital rechts der Isar*
Email: maarten.van-de-klundert@tum.de

Background and Aims: It has been observed that statins reduce the chance of developing hepatocellular carcinoma (HCC) in hepatitis B virus (HBV) infected individuals, and reduce HCC related mortality when applied during palliative care. Statins inhibit the HMG-CoA-reductase dependent cholesterol synthesis pathway, but also have immune modulatory functions and interfere with the activity of Rho-GTPases by preventing their prenylation. In this study, we aim to assess the effect of statins and Rho-GTPases on HBV replication and on HCC formation and viability.
Results: We previously identified terbinafine, an FDA-approved, orally available antifungal drug, to functionally affect the HBV accessory protein HBx. Beside its antifungal activity, terbinafine suppresses the activity of Rho-GTPases and was thus chosen for comparison to fluvastatin, a clinically approved statin. In primary human hepatocytes (PHH), HBx expression is critical for the initiation and maintenance of HBV RNA transcription. Terbinafine efficiently suppressed HBV replication in PHH, with an IC50 of 2–3 ug/ml (PHH). In hepatoma cell lines, terbinafine and fluvastatin efficiently suppressed the replication of wildtype HBV. The suppression of HBV replication by fluvastatin was relieved by pretreatment with geranylgeraniol, indicating that the antiviral effect of this statin relies on interfering with Rho-GTPase activity. Interestingly, we observed that fluvastatin and terbinafine were already toxic to hepatoma cells at concentrations that were not affecting PHH viability in cell culture. In HBV transgenic mice, terbinafine and fluvastatin concentrations that critically interfered with hepatoma cell line viability were well tolerated, and did not lead to an increase in ALT. We are currently investigating the effect of fluvastatin and terbinafine on early markers of HCC development in HBV transgenic mice.
Conclusion: Inhibition of Rho-GTPases reduces HBV antigen expression by suppressing HBV RNA transcription, and selectively reduces the viability of transformed hepatocytes. Our results suggest that statins prevent HCC development by suppressing Rho-GTPases.

SAT-389

Understanding the multiphasic viral kinetics of cute HBV infection observed in humanized uPA/SCID mice using an agent-based modeling approach

A. Hailegiorgis[1], Y. Ishida[2,3], M. Imamura[3], N. Hiraga[3], C. Tateno[2,3], S. Uprichard[4], K. Chayama[3], H. Dahari[1]. *[1]Loyola University Medical Center, Division of Hepatology, Medicine; [2]PhoenixBio Co., Ltd, Japan; [3]Hiroshima University, Japan; [4]Loyola University Medical Center, United States*
Email: harel.dahari@gmail.com

Background and Aims: The uPA/SCID humanized chimeric mouse model is a useful tool for studying the dynamics of HBV infection and treatment response. Interestingly, despite the absence of an adaptive immune response or cell death due to HBV, we found that HBV infection from initiation to steady state in these mice (n = 42) is highly dynamic with 7 distinct kinetic phases. Current models of HBV infection based on differential equations are not able to reproduce this highly dynamic picture. Thus to explain this multiphasic kinetics and gain insight into dynamics that produce this complex viral expansion pattern, we have developed a stochastic agent-based model (ABM).
Methods: In the model, each human hepatocytes is represented as an individual agent. With the inoculation of free virus into the blood, the model attempts to recapitulate the initial infection of human hepatocytes and subsequent production and spread of progeny virus in humanized chimeric mouse liver. When uninfected cells are exposed to HBV, they become infected and enter an eclipse phase in which they do not yet secret virus. They then proceed to a productive phase in which they are able to release virions which can go on to infect additional human hepatocytes. Initial model conditions (e.g., HBV inoculums and number of human hepatocytes) and several model parameters (e.g., viral clearance from blood) were calculated/defined based on experimental design and detailed kinetic analysis.

Results: The model reproduces well the complex serum HBV kinetic pattern of 7 distinct phases observed in chimeric mice inoculated with 10^8 HBV genome equivalents when the following parameters are assumed: (1) The eclipse phase lasts between 10–48 hours, (2) Once the infected cell passes the eclipse phase, its production rate is not constant, but rather increases over time initially starting with long production cycle of 1 virion per 20h but gradually reaching 1 virion per hour after 3 days. Thereafter (about ~3.25 days), the virion production increases dramatically to reach to a steady state production rate of 3 virions per hour. The model was validated by showing it could accurately simulate the viral kinetics observed with lower HBV inoculation doses (10^4–10^7 genome equivalents), in which similar (but delayed) patterns were observed.
Conclusions: Modeling suggests that the initial slow but increasing rate of virus production from each cell plays major role in generating the observed multiphasic HBV kinetic patterns in humanized mice. However, further experiments are necessary to confirm nature and causes of the emerging patterns.

SAT-390

Understanding HDV and HBV dynamics during acute co-infection in humanized uPA/SCID chimeric mice using an agent-based modeling appraoch

U. Kumar[1], T. Uchida[2], A. Hailegiorgis[1], N. Hiraga[2], K. Walsh[1], M. Imamura[2], C. Koh[3], T. Heller[3], J. Glenn[4], S. Uprichard[1], K. Chayama[2], H. Dahari[1]. *[1]Loyola University Medical Center, United States; [2]Hiroshima University, Japan; [3]Liver Diseases Branch, NIDDK, NIH, United States; [4]Stanford University School of Medicine, United States*
Email: harel.dahari@gmail.com

Background and Aims: Studying hepatitis D virus (HDV) and hepatitis B virus (HBV) dynamics during acute co-infection in humans is lacking due to the uncertainty of the exact time of infection and limited frequent kinetic data. The humanized uPA/SCID chimeric mouse model is a useful tool for studying the dynamics of HDV/HBV co-infection. We previously showed that while HBV infection from initiation to steady state in mice (n = 4) was highly dynamic (with 5 distinct kinetic phases eventually reaching a viral plateau at ~8.7 log cp/ml), HDV was below detection until week 2 post inoculation (pi), but once detected increased until week 5 pi followed by a plateau of ~9.8 log cp/ml. To explain these kinetic patterns we have developed a stochastic agent-based model.
Methods: In the model, each human hepatocytes is represented as an individual agent. With the inoculation of HDV and HBV into the blood, the model attempts to recapitulate the initial infections of human hepatocytes and subsequent production and spread of progeny viruses in humanized chimeric liver. When uninfected cells are exposed to HBV and/or HDV, they become infected and enter an eclipse phase in which they do not yet secret virus. HBV-infected cells then proceed to a productive phase in which they are able to release HBV virions which can go on to infect additional human hepatocytes. HDV-infected cells can proceed to a productive phase in which they are able to release HDV virions only if the cells are also infected with HBV. Initial model conditions (e.g., 10^6 HBV and 10^6 HDV genome equivalents and ~10^8 human hepatocytes) and several model parameters (e.g., viral clearance from blood) were calculated/defined based on experimental design and detailed kinetic analysis.
Results: The model reproduces well the 5 distinct HBV kinetics phases observed when the following parameters are assumed: (1) The eclipse phase lasts between 10–48 h, (2) Once the infected cell passes the eclipse phase, its production rate is not constant, but rather increases over time initially starting with a long production cycle of 1 virion/20 h but gradually reaching 1 virion/h after 3 days, followed by a dramatically increase to reach to a steady state production rate of 3 virions/h. To reproduce the observed HDV kinetic patterns the following parameters were assumed to be different relative to HBV: (i) ~20-fold higher HDV infection rate, (ii) shorter production cycle with HDV reaching its max production within ~2 days pi, and (iii) ~7-fold higher steady state production rate (~26 virions/h).
Conclusions: Modeling results provide insights into HDV and HBV dynamics during acute infection in humanized chimeric mice. Further experiments are necessary to confirm nature and causes of the emerging patterns.

Molecular diversity of HDV strains that spread in France: a study of 2224 clinical strains prospectively collected during fifteen years

A. Gerber[1], F.L. Gal[1], S. Dziri[1], C. Alloui[1], D. Roulot[2], Z.B. Abdesselam[2], S. Brichler[1], E. Gordien[1]. *[1]Hôpitaux universitaires de Paris Seine Saint Denis, laboratoire de microbiologie clinique, BOBIGNY, France; [2]hôpitaux Universitaires de Paris Seine Saint Denis, Unité d'Hépatologie, BOBIGNY, France*
Email: athenais.gerber-ext@aphp.fr

Background and Aims: We recently described that HDV genus is composed of 8 different genotypes characterised by a nucleotide sequence similarity of 85% and 80% according to the partial so called *R0* region or to the full-length genome respectively. Furthermore, genotypes can be segregated into 2 to 4 subgenotypes, characterised by an inter-subgenotype similarity >90% and >84% for HDV-1. We aimed in this study to provide the main results of a molecular characterization of strains that infected all new HDV-positive patients diagnosed in France between 2001 and 2016 and to highlight the main possible consequences of such a genetic diversity.
Method: A total of 2,224 serum/plasma samples were collected. Demographical data (age, gender, country of origin, date of infection, risk factors) were recorded. HDV genotyping was performed as previously described, using sequencing and phylogenetic analyses of *R0* amplicons.
Results: About 150–250 new HDV-infected-patients per year were diagnosed. They were originated from Africa (mainly Cameroon, Mali, Côte d'Ivoire, Central African Republic), 49.3%; Western (France) 16.7% and Eastern Europe (Romania, Georgia), 16.4%; Asia, (Mongolia), 8%; Turkey and The Middle East (3%). They were more often infected at birth in their country of origin. Since 2004, the rate of infected-Eastern European patients reached from less to 5% to near 20%, while the number of French patients regularly decreased since this date from 45% to less than 10%. We characterised 1771 HDV-1 (79.6%); 321 HDV-5 (15%); 62 HDV-7 (2.8%); 33 HDV-6 (1.5%); 33 HDV-8 (1.5%) and 2 HDV-2 and HDV-3 (each 0.08%). Subgenotypes 1a and 1b from Africa and 1d from Europe were found equivalently.
Conclusion: HDV genotypes -1 and -5 to -8 circulate in all regions of France. Infected-patients came mainly from countries of high endemic, mainly Sub-Saharan Africa and Eastern Europe. African strains account for 60%. This is a main point for the management of these patients as we previously showed that most "in-house" or commercial assays underestimated or failed to quantify HDV viral load of these strains. In addition, HDV-5, was found to be significantly associated to hepatocellular carcinoma compared to HDV-1 and to other African genotypes. In conclusion further studies are still needed to assess for a role of the HDV genetic diversity in the natural history of the infection and under treatment at the era of news developing drugs.

SAT-392

Molecular diversity of HBV and HDV amino-acid sequences involved in HDV virion morphogenesis according to HBV and HDV genotypes: study of 1590 clinical strains

A. Gerber[1], S. Dziri[1], S. Brichler[1], C. Alloui[1], D. Roulot[2], Z. Ben Abdesselam[3], F. Le Gal[4], E. Gordien[4]. *[1]Hôpitaux Universitaires de Paris Seine Saint Denis, Laboratoire de microbiologie clinique, Bobigny, France; [2]Hôpitaux Universitaires de Paris Seine Saint Denis, Unité d'Hépatologie, BOBIGNY, France; [3]Hôpitaux Universitaires de Paris Seine*

Saint Denis, Unité d'Hépatologie, BOBIGNY, France; [4]Hôpitaux Universitaires de Paris Seine Saint Denis, Laboratoire de microbiologie clinique, BOBIGNY, France
Email: athenais.gerber-ext@aphp.fr

Background and Aims: Hepatitis delta virus (HDV) is a satellite of the hepatitis B virus (HBV) that requires HBV envelope to form its own virions. HBV and HDV are characterized by a high genetic diversity in respectively 10 and 8 different genotypes and in several subgenotypes within genotypes. Molecular determinants involved in HDV virion morphogenesis, have been previously described within the third antigen loop (AGL-3) of the HBV surface envelope and at the C-terminus of the large delta protein (L-HDAg), involving respectively conserved Tryptophan residues (W) and a Proline-rich region. In this study, we aimed to analyze the molecular diversity of these sequences according to genotypes from a large cohort of clinical samples.
Method: A total of 1,590 plasma samples of HDV-infected patients were studied. HBV-HDV genotyping was performed using sequencing (Sanger method) and phylogenetic analyses of amplicons encompassing the regions of interest (AGL-3 and L-HDAg). Amino-acid sequences were determined, aligned, and compared according to the different HBV/HDV genotypes couples, to several human and animal (for HBV) reference sequences.
Results: Overall, 526 HBV/HDV couples were characterized, showing various genotype combinations with significant association between strains of a same geographic origin, while 21 (4%) unexpected associations could be found. We identified: 62 HBV/A, 9 HBV/B, 3 HBV/C, 221 HBV/D, 222 HBV/E, 9 HBV/G; and 416 HDV-1, 1 HDV-2, 71 HDV-5, 7 HDV-6, 21 HDV-7 and 8 HDV-8. Considering the sequence of the AGL-3, 3 of the four key positions involved in HDV particles morphogenesis previously described were conserved i.e., W196, Methionine (M) 197 and W201 in 99% of the sequences. Interestingly, these same positions were also strictly conserved in Bat, Ground Squirrel, Woodchuck and Wooly Monkey sequences, suggesting as for the Woodchuck, that these animals would support experimental HDV infection. On the HDV side, despite a high apparent polymorphism of the L-HDAg C terminus, several hydrophobic amino-acids, remarkably Proline residues known to be involved protein-protein interactions, are found all along this region.
Conclusion: HDV virion morphogenesis seems to be the result of an adaptation of the L-HDAg via a Proline-rich motif to allow Delta ribonucleoprotein binding to a conserved hydrophobic motif of the helper HBV-AGL-3 (WMXXXW), where X is a W or M. To date this has occurred, only in humans in different parts of the world.

SAT-393
Deep sequencing analysis highlights variations associated with HBeAg seroconversion in adolescents with chronic hepatitis B

C. Combet[1], N. Bhardwaj[2], O. Podlaha[2], A. Gaggar[3], B. Feierbach[2], K. Kitrinos[2], K. Murray[4], F. Zoulim[1]. *[1]Inserm 1052, Lyon, France; [2]Gilead Sciences, Foster City, United States; [3]Gilead Sciences, Inc, Foster City, California, United States; [4]University of Washington School of Medicine, and Seattle Children's Hospital, Seattle, United States*
Email: neeru.bhardwaj@gilead.com

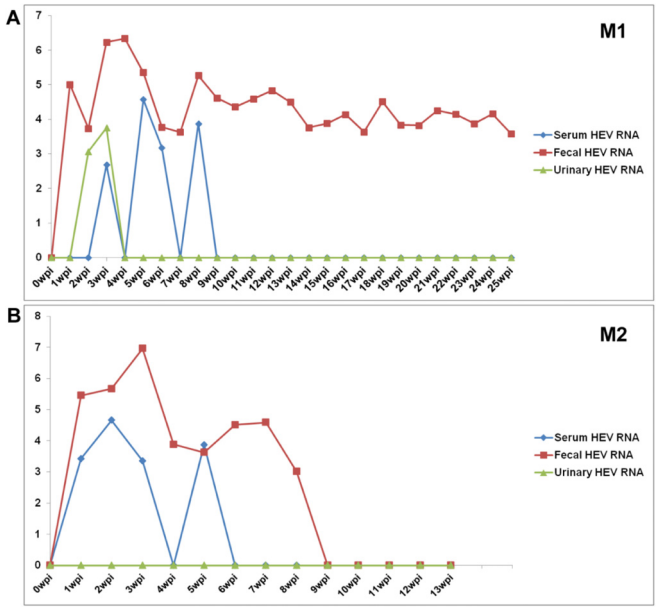
Background and Aims: HBeAg seroconversion (SC) is an important outcome for chronic hepatitis B (CHB) infected patients. The influence of viral dynamics on HBeAg SC is unclear. To address this gap, a longitudinal study of HBV full genome (FG) viral diversity was conducted in patients who experienced spontaneous HBeAg SC.
Method: GS-US-174-0115 was a double-blind, placebo (PBO)-controlled, phase 3, 192-week clinical trial that evaluated tenofovir disoproxil fumarate (TDF) in adolescents (12 to <18 years) with CHB. In PBO patients (n = 42), deep sequencing of HBV FG amplicons was performed using the Illumina MiSeq (150bp paired-end reads) at baseline (BL), Week 8 and Week 72. Additionally, for PBO patients with HBeAg SC prior to Week 72 (genotype (GT) A = 3; GTB = 1; GTD = 3), the time of HBeAg SC was also sequenced. The average nucleotide diversity of the HBV FG was calculated using Shannon entropy and variants were detected with a cutoff of 2%.
Results: In PBO patients who either were HBeAg+ without SC (n = 31) or HBeAg- at baseline (n = 4), there was not a significant change in diversity in the HBV FG over 72 weeks. Conversely, HBeAg+ PBO patients that achieved HBeAg SC (n = 7) experienced a drop in viral diversity at Week 72 (p = 0.04; Avg time post-SC = 26 weeks; Avg change from BL = −17%). The drop in viral diversity coincides with the reduction of serum HBV DNA (Avg change from BL = −4.10 $\log_{10}$ copies/mL). We analyzed the dynamics of 15 basal core promoter (BCP), pre-Core (pC), and Core (C) variants previously identified to be associated with HBeAg status [EASL 2017: ILC2017-RS-2810]. One to 4 of these variants enriched or reached a frequency of >98% in the viral population at Week 72 in all HBeAg SC patients. Two pC and C variants, A1846T and T2441C, were commonly present at high frequency from BL and did not appear related to SC in GTA or D. The most frequently sampled variants that enriched at or after SC were the BCP variants A1762T and G1764A (lower HBeAg production), and the pC variant G1896A (stop mutation), which was not seen in GTA patients. Interestingly, the single nucleotide deletion variants A1762del and G1764del also emerged in patients prior to SC, but were eliminated or reduced post-SC.
Conclusion: At the time of spontaneous HBeAg seroconversion in CHB adolescents, multiple BCP, pC and C mutations are present, indicating complex viral dynamics. Unique combinations of variants enrich in a patient's viral population post-SC, indicating selection for HBeAg defective viruses during natural history.

SAT-394
Prevalence, pathogenesis and cross-species transmission of a novel hepatitis E virus from bactrian camels

L. Wang, H. Zhuang, L. Wang. *Peking University Health Science Center, Microbiology and Infectious Disease Center, Beijing, China*
Email: lingwang@bjmu.edu.cn

Background and Aims: Hepatitis E virus (HEV) is a major cause of acute viral hepatitis worldwide. There are currently 7 major genotypes of HEV (HEV1-7). HEV mainly transmits via fecal-oral route and is considered a porcine zoonosis. However, novel HEV strains have been detected in various species of animals. The ever-expanding host range has posed a threat to humans. In 2016, a study reported the identification of a novel genotype of HEV (temporarily classified as HEV8) in Bactrian camels (*Camelus bactrianus*) in Xinjiang, China. Bactrian camels mainly live in northwestern China and southwestern Mongolia, and are important domestic livestock for transportation, tourism, meat and milk product. Therefore, people with close contact to Bactrian camels may be at risk of zoonotic infection. In this study, we investigated the prevalence, pathogenesis and the capacity of cross-species transmission of HEV8.
Method: During January 2017 and April 2017, we collected fresh fecal samples from Bactrian camels from four different provinces/regions in China, including Inner Mongolia (25 samples), Gansu (40 samples), Hebei (200 samples), Anhui (30 samples). Real-Time and nested reverse transcriptase PCR was performed. Two healthy female cynomolgus macaques were intravenously inoculated with 10^5 copies of HEV8-positive fecal suspension. Viraemia, fecal and urinary shedding of virus, liver functions and seroconversion to anti-HEV were monitored weekly. Liver biopsy was performed at one week pre-inoculation, 3 week-post-inoculation (wpi), 13 wpi and 25wpi. Immunofluorescence analysis was carried out for detection of HEV ORF2/3 proteins (Bioss, Woburn) in liver.
Results: HEV8 was detected in four fecal samples (1.4%, 4/295) collected from Bactrian camels in Anhui province (1/30, 3.3%), Gansu province (2/40, 5%) and Inner Mongolia (1/25, 4%). Two inoculated macaques (M1 and M2) subsequently developed robust infection with viraemia, uremia, fecal shedding and seroconversion (Figure). Liver functions of M1 and M2 remained normal during the study. M2 stopped virus shedding at 9 wpi (Figure A). Surprisingly, M1

developed chronic infection and HEV could be detected in both feces and liver at 25 wpi (Figure B). Liver histopathology showed inflammatory cells infiltration, focal necrosis and hydropic degeneration at 13 and 25 wpi.



Conclusion: We performed a comprehensive study unraveling previous unknown knowledge of epidemiology, pathogenesis and cross-species transmission of the novel HEV8 strain from Bactrian camels. Our results showed that HEV8 circulated in different regions of China. The successful infection of two macaques suggests a high risk of zoonotic infection to humans. Both acute and chronic-type infections were observed in the infected macaques indicating diverse patterns of pathogenesis which warrants further investigating.

SAT-395

Mitochondrial electron transport chain complex III: a promising antiviral target for hepatitis E virus

C. Qu, S. Zhang, W. Wang, M. Li, M. Peppelenbosch, Q. Pan. *Erasmus MC, Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: c.qu@erasmusmc.nl

Background and Aims: Hepatitis E virus (HEV) infection has emerged as a global health issue; whereas no approved medication is available. Although ribavirin is effective as off-label treatment for chronic hepatitis E, a substantial proportion of patients do not tolerate or develop resistance and eventually fail to clear the virus. Electron transport chain (ETC), a key component of the mitochondria, is the main site that produce Adenosine triphosphate (ATP) and Reactive oxygen species (ROS). This study aims to investigate the role of ETC in HEV infection.
Method: An HEV infectious model and an HEV sub-genomic model were used. Western-blot assay, luciferase activity and qRT-PCR were used to evaluate the effects on HEV. Flow cytometry was used to analyze ROS level.
Results: To investigate the potential role of ETC in HEV infection, we have profiled the effect of targeting different complexes of ETC by pharmacological inhibitors. We found that Antimycin A (AMA), a FDA-approved drug that inhibits complex III of ETC, effectively inhibited HEV viral RNA. This effect is equivalent to the anti-HEV potency of ribavirin. The anti-HEV effect of AMA was further confirmed by western-blot assay of the viral protein ORF2. We further demonstrated that the anti-HEV of AMA is independent of ATP production, ROS level and pyridine depletion. By using pharmacological inhibitors and genetic approaches, we shed light on an effective basal defense role of mitochondria permeability transition pore (MPTP) against HEV replication and showed that MPTP inhibitors attenuate the anti-HEV effect of AMA.
Conclusion: The complex III of ETC is essential in sustaining HEV infection representing a viable target by existing FDA-approved inhibitors.

Email: sophie.clement@unige.ch

Background and Aims: Hepatitis C virus (HCV) infection is a major cause of chronic liver metabolic disorders that may lead to hepatocellular carcinoma. We previously reported the critical role of the phosphatase PTEN in both HCV-induced steatosis and HCV life cycle. PTEN was downregulated by the core protein of HCV genotype 3a (HCV-3a core) through a mechanism involving a 3′ untranslated region-dependent repression of mRNA translation. We further demonstrated that miR-21, a potent oncomiR targeting PTEN, is involved in hepatic steatosis associated with diet-induced obesity in mice. Here, we investigated the role of miR-21 in HCV-induced PTEN downregulation and its potential impact on both HCV-3a-induced steatosis and viral life cycle.
Method: miR-21 expression and activity were measured in Huh-7 cells overexpressing HCV-3a core or infected with culture-derived Jc1 HCV. PTEN expression, lipid droplet (LD) morphology and cholesterol ester (CE) levels were assessed in HCV-3a core transduced Huh-7 cells exposed to miR-21 inhibitors, and in mouse primary hepatocytes isolated from either Flox/flox control or miR21 knockout (KO) mice and expressing HCV-3a core protein. HCV replication, entry and viral particle production were investigated, using a subgenomic replicon, pseudoparticles and cell cultured-derived Jc1 HCV, respectively. A meta-analysis was performed to evaluate the expression of miR-21 in livers from chronic hepatitis C patients.
Results: While miR-21 expression level was not affected by HCV-3a core, its activity was significantly and transiently increased at days 2 and 3 post transduction. The anti-miR-21 partially prevented the HCV-3a core-induced PTEN downregulation and CE accumulation in LD in Huh-7 cells. Furthermore, the lack of miR-21 expression in primary mouse hepatocytes from miR-21 KO mice prevented the increase of LD size induced by the HCV-3a core. The anti-miR-21 also decreased both HCV replication and the production of infectious particles in Huh-7 cells, while no effect on HCV entry was noted as assessed using pseudoparticles. Finally, in the meta-analysis, HCV infection was significantly associated with increased liver miR21-5p (standardized mean difference 0.65 [95%CI 0.19–1.10, p = 0.005]) with limited heterogeneity (I^2 = 39%, p = 0.18).
Conclusion: Altogether, our data indicate that miR-21 activation by HCV is a key molecular step promoting both HCV 3a-induced steatosis and HCV life cycle.

SAT-397

Hepatitis E virus replication and interferonresponse in human placental-derived cells

Email: behrendt.patrick@mh-hannover.de

Background and Aims: The Hepatitis E virus (HEV) is one major cause of viral hepatitis and shows high epidemic potential in developing countries. Notably, HEV infection has a high incidence among pregnant women and might take a serious course. High maternal mortality rates of about 25% in association with fulminant hepatic failure have been observed in HEV-infected pregnant women. However, the underlying pathogenic mechanisms remain largely unexplained and the cases have only been reported for infections with genotype (gt) 1 HEV, while gt 3 infections remain often subclinical without severe impairment. In this study, we investigated whether HEV is capable of performing the full viral life cycle in placental-derived cells (JEG-3).
Method: In this study, subgenomic replicons (SGR) for both genotypes and a full-length HEV clone for gt 3 were utilized to investigate, whether HEV is capable of performing the whole viral life cycle in the human placental-derived cell line JEG-3. Viral replication and release was compared to the human hepatoma cell line HepG2. Additionally, viral response upon IFN-alpha-a1 as well as Ribavirin treatment was investigated.
Results: JEG-3 cells supported HEV RNA replication of both SGRs and the full-length gt 3 clone and showed high replication capacity. We could confirm virus assembly and release by the detection of intra- and extracellular viral capsid through an HEV antigen ELISA and of viral entry by infection with cell culture-acquired genotype 3 virions. Furthermore, we could show that both genotypes in placental cells have a similar sensitivity to Ribavirin compared to HEV in hepatoma cells. In contrast, we experienced HEV gt 1 SGR to respond significantly lower to the antiviral activity of Interferon IFN-alpha-a1 in JEG-3 cells compared to HEV gt 3 SGR. However, this effect cannot be seen in HepG2 cells. Simultaneous determination of interferon-stimulated gene expression levels demonstrated an efficient downregulation by both HEV genotypes, although the gt 1 SGR replicates less efficient in tissue culture in comparison to the gt 3 SGR.
Conclusion: In conclusion, we found that HEV is capable of performing the full viral life cycle in a placental cell line *in vitro* and identified a potential pathogenic mechanism in host interferon response contributing to severe outcomes of HEV infection during pregnancy. Further studies should address the identification of genotype-dependent differences and a follow up on the host interferon response in HEV infection. JEG-3 cells could serve as an *in vitro* model for future research in this field.

SAT-398

Are there different profiles in microRNA expression in HBV/HDV co-infected patients reflecting plasma HBsAg and HBcrAg concentrations?

I. Carey[1], B. Li[2], M. Bruce[1], S. Montague[1], A. Gaggar[2], K. Agarwal[1]. [1]*King's College Hospital, Institute of Liver Studies, London, United Kingdom;* [2]*Gilead Sciences, Inc. Research and Development Department, Foster City, United States*
Email: ivana.kraslova@kcl.ac.uk

Background: MicroRNA expression in plasma of HBV/HDV co-infected patients demonstrated 2 distinct patterns: one driven specifically by HDV replication (miR-98-5p and miR-663b down-regulation) and second linked with HBV replication (f.e. upregulation of miRNA122-5p). HBsAg is critical for HDV replication and the patients with "active" HBV/HDV co-infection (HDV RNA positive) have higher HBsAg concentrations than HDV "exposed" patients (anti-HDV antibodies positive, HDV RNA negative). Plasma HBsAg originates from cccDNA and integrated DNA. Hepatitis B core related antigen (HBcrAg) reflects more accurately cccDNA transcription activity than HBsAg. "Active" HBV/HDV co-infected patients have higher HBcrAg levels in plasma than HDV "exposed" patients. There are no data assessing the differences in microRNA expression patterns linked with HBsAg and HBcrAg.
Aims: To compare miRNA profiles between patients with high HBsAg (>10,000 IU/ml) vs. low HBsAg (<10,000 IU/ml) and between patients with detected HBcrAg (>2 $\log_{10}$U/ml) vs. not detected HBcrAg (<2) and assess their relationship with plasma HBsAg and HBcrAg levels.
Materials and Methods: MiRNA was extracted from serum of 50 HBV/HDV co-infected patients, all HBeAg negative: 25 HDV RNA positive and 25 HDV RNA negative. Plasma levels of HBsAg, HBV DNA and HBcrAg were measured by Abbott ARCHITECT®, TaqMan real-time PCR and on LuminexG assay. MiRCURY LNA™ Universal RT microRNA PCR was performed for 742 miRNAs and 165 miRNAs were detected in all patients. Based on HBsAg levels: 15 patients had HBsAg > 10,000 IU/ml and 35 patients had HBsAg < 10,000 IU/ml. For HBcrAg concentrations: 24 patients had HBcrAg > 2 $\log_{10}$ U/ml (detected) vs. 26 patients with not detected HBcrAg. The comparison of miRNA profiles according to HBsAg levels and HBcrAg detectability was performed using limma algorithm with P values adjusted for multiple testing correction and Spearman correlations.
Results: 41 microRNAs were expressed differently between patients with high vs. low HBsAg and 40 of them showed strong bivariate correlations with HBsAg levels. miRNA122-5p was upregulated in patients with high HBsAg and correlated with HBsAg levels ($r = 0.91$, $p < 0.001$). The expression of 31 microRNAs differ between patients with detected vs. not detected HBcrAg. While 27 mircoRNAs were expressed similarly in patients with high HBsAg and detected HBcrAg, there were some microRNA expressing exclusively only patients with high HBsAg (miRNA125a-5p linked with disease progression) or patients with detected HBcrAg (miRNA142-3p linked with inflammation).
Conclusions: Patients with high HBsAg levels have a distinctive microRNA profile, which are broadly similar to microRNA expression in patients with detected HBcrAg, but with differences for few microRNAs which reflect dissociations between individual HBV replication steps (HBsAg production or cccDNA transcriptional activity).

SAT-399

Dimerization: A structural feature for the protection of Hepatitis E virus capsid protein against trypsinization

W. Wei[1], J. Meng[2], N. Behloul[3], S. Baha[3]. [1]*School of Medicine, Southeast University, Department of Microbiology and Immunology, Nanjing, China;* [2] *School of Medicine, Southeast University, Nanjing, Department of Microbiology and Immunology;* [3] *School of Medicine, Southeast University, Department of Microbiology and Immunology*
Email: jihongmeng@hotmail.com

Background and Aims: Orally-transmitted viruses have evolved the ability to resist the extreme conditions of the host's gastrointestinal environment, especially the proteolysis of their structural proteins. However, the mechanisms allowing these viruses to survive these harsh conditions remain unclear. Here we use truncated HEV capsid proteins to gain insights into the proteolysis resistance of HEV capsid protein.
Method: We adopted computational and biochemical methods to investigate the resistance of different ORF2 proteins to trypsin proteolysis. Further, we expressed the mutated p179 proteins, naturally occurring as monomers and investigated the influence of

dimerization state on the proteolytic resistance of HEV capsid proteins. Then we applied computational methods to elucidate how the dimerization could protect the P2 domain from trypsinization. At last, we use western blot assay to investigate if trypsin action could affect the exposure of the neutralizing epitopes or not.

Results: In our research, we found the trypsin digestion sites to be highly conserved among the HEV strains. Furthermore, the constructs of the HEV capsid protein that contain an extended P2 domain were digested within the extensions leaving the P2 domain intact. The trypsinization seems to occur in three possible double cleavages at R451-R619, R460-R631 or R460-R631. The dimerization disrupts the trypsin action at three main sites in the P2 domain R542, K544 and K554. These sites are very exposed in the monomeric P2 domain constructs which makes the monomeric forms very susceptible to trypsin action. Western blot analysis showed that all the truncated proteins and the proteolysis products were strongly reactive against the HEV-neutralizing monoclonal antibody.

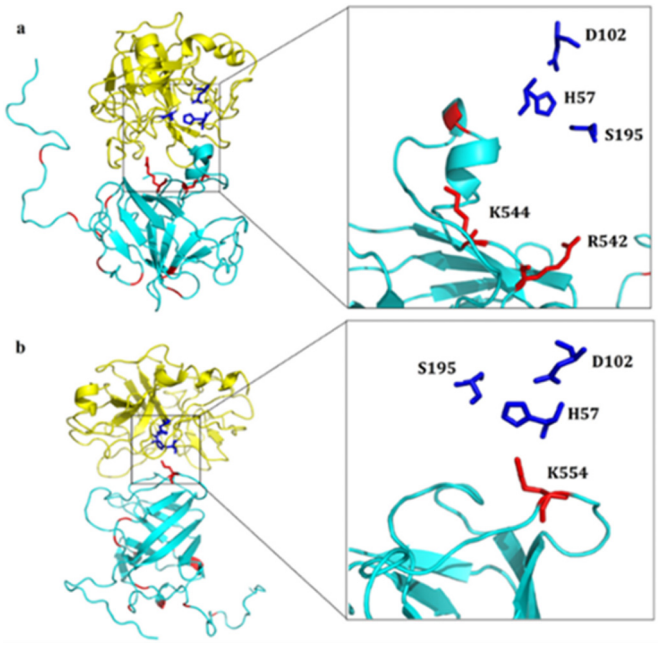

Figure: Illustration of the docking results of p179 monomer and trypsin (PDB ID: 418G). The trypsin and the monomeric p179 are shown in yellow and cyan cartoon representation, respectively. The trypsin catalytic triad is shown in blue sticks and the proteolytic sites in p179 (K554, K544 and R542) in red sticks.

Conclusion: Given the transmission route of HEV, the evolutionary forces may have selected sequence and structural features (P2 domain dimerization) that make the HEV capsid protein highly resistant to trypsin but more likely, for all the other gastrointestinal proteases. Another interesting application of our findings could be that the trypsinization did not affect the antigenicity of HEV ORF2 proteins and therefore they could be regarded as potential oral vaccine candidates.

SAT-400

The correlations between HBV markers in sera and HBVcccDNA for genotypes

M. Takeshi, K. Jong-Hon, Y. Yasushi, T. Kunihiko, M. Hiroyuki. *Teine-Keijinkai Hospital, Center for Gastroenterology, Sapporo, Japan*
Email: mtake0402@gmail.com

Background and Aims: Covalently closed circular (ccc) DNA in hepatitis B plays important roles in viral natural history. It is well known that HBV markers in sera are linked to quantified HBV ccc DNA in liver tissue. However, it remains unknown as to whether similar correlation exists between genotype(Gt) B and C. We investigated the association between HBV Gt B and Gt C, HBV markers in sera, and HBV ccc DNA in liver tissue.

Method: Intrahepatic HBV ccc DNA was quantified using specimen obtained by liver biopsy or from excised liver tissue, and serum HBV markers such as Hepatitis B core related antigen(HBcrAg), HBV DNA and Hepatitis B antigen(HBsAg) were also quantified in Hepatitis B e antigen (HBeAg)-negative patients. Correlation between the HBV ccc DNA and serum HBV marker was investigated for respective HBV genotypes.

Results: A total of 50 HBeAg-negative patients were enrolled in this study. Among them, 12 patients had Gt B and 38 had HBV Gt C. The median age was 61/50.5 (Gt B/C) year old. Seven cirrhotic cases were included in Gt C group. The median HBV ccc DNA levels was 4.1/3.3 log copies/μg (<1.7–5.3). The median levels of HBV markers in sera, namely HBV DNA, HBcrAg and HBsAg were 4.70/3.35 log copies/ml, 3.15/3.60 logU/ml and 3.15/3.25 logIU/ml, respectively. HBV ccc DNA was significantly lower in Gt C (p 0.0429), but no difference was observed in other HBV markers for genotypes. HBV ccc DNA was correlated with HBV DNA (r = 0.697; p = 0.0118) and HBcrAg (r = 0.5810; p = 0.0476), but not related with HBsAg (r = 0.3558, p = 0.2564) in Gt B. In Gt C, HBV ccc DNA was correlated with HBV DNA (r = 0.614; p = 0.0001, HBcrAg (r = 0.542; p = 0.0006 and HBsAgr = 0.476; p = 0.0033). The median ratio of HBV DNA to HBV ccc DNA was 0.7033/0.9121 (GtB/GtC), the median ratio of HBcrAg was 0.875/1.3250, and the median ratio of HBsAg was 1.250/1.250. The median ratio of HBcrAg to HBV ccc DNA was significantly lower in GtB (p = 0.0058) than in GtC and the median ratio of HBsAg tended to be lower (p = 0.0812) in GtB.

Conclusion: The HBV markers were correlated with HBV ccc DNA in Gt C. However, the correlation was not observed for all of the markers for Gt B, with HBsAg showing no correlation with HBV ccc DNA level. In addition, it was suggested that the secretion ability of HBsAg and HBcrAg may be different depending on the Gt.

SAT-401

Estrogen receptor R1 and CAD are host factors for HDV replication and antiviral targets

E. Verrier[1], A. Weiss[2], C. Bach[1], L. Heydmann[1], L. Mailly[1], T. Garcia[3], P. Pale[3], C. Schuster[1], C. Sureau[4], M. Zeisel[1], L. Brino[2], T. Baumert[1,5]. *[1]Inserm, Institut de recherche sur les maladies virales et hépatiques UMRS 1110, Université de Strasbourg, Strasbourg, France; [2]IGBMC, Plateforme de Criblage Haut-débit, Illkirch, France; [3]Institut de Chimie, Université de Strasbourg, CNRS UMR 7177 Laboratoire de Synthèse, Réactivité Organiques et Catalyse, Strasbourg, France; [4]INTS, Laboratoire de Virologie Moléculaire, Paris, France; [5]Nouvel Hôpital Civil, Institut Hospitalo-universitaire, Pôle Hépato-digestif, Strasbourg, France*
Email: e.verrier@unistra.fr

Background and Aims: Hepatitis D virus (HDV) is a small, circular DNA virus co-infecting hepatocytes with HBV and requiring HBV envelope proteins to produce infectious particles. Chronic hepatitis B/D results in more severe liver disease and an increased risk of liver cancer compared to HBV mono-infection and is considered as the most severe form of viral hepatitis. To date, licensed HDV-specific therapies are absent and novel antiviral strategies are expected to improve patients' outcome and cancer risk.

Method: Taking advantage of the HDV-susceptible NTCP-overexpressing Huh-106 cell line, we combined a dual high-throughput screening approach to identify new host factors as antiviral targets for HDV infection. First, we applied a high-throughput loss-of-function screen using a siRNA library targeting more than 7000 druggable genes to identify hepatocyte factors required for HDV infection. Next, we performed a small molecule screen to identify anti-HDV compounds using the Prestwick library comprising 1200 FDA-approved drugs.

Results: The loss-of-function screen identified 202 host factor candidates for HDV infection. Validation studies identified *ESR1*

(estrogen receptor E1) and *CAD* (trifunctional protein carbamoyl-phosphate synthetase 2, aspartate transcarbamylase, and dihydroorotase) as a host factor pathway playing a key role in host cell pyrimidine biosynthesis. Interestingly, Fulvestrant, an antagonist of the estrogen receptor 1 (ESR1) was identified in the small molecule screen as an efficient inhibitor of HDV infection. On the other hand, the treatment of Huh-106 cells with ESR1 agonists or modulators, such as Norgestimate or Toremifene induced an increase in HDV infection, confirming the relevance of ESR1 for HDV replication. Kinetic assays revealed that ESR1 mediates the early steps of HDV replication. Moreover, the antiviral effect of the Fulvestrant was associated with a decrease in *CAD* expression, which is known to be induced by the SP1/ESR1 complex. Robust antiviral activity of the CAD inhibitor PALA in both Huh-106 and primary human hepatocytes confirmed the role of CAD as antiviral target.

Conclusion: Using a combined small molecule and loss-of-function screening approach we identified ESR1 and CAD as host factors for HDV replication and novel targets for antiviral therapy. Our approach the door to new therapeutic strategies targeting host-dependency factors for HDV cure.

Defining hos DNA repair factors in the formation of the hepatitis B virus covalentrly close circular DNA persistence reservoir

K. Doernbrack[1], E. Verrier[2], L. Heydmann[2], F. Wrensch[2], A. Maglott-Roth[3], L. Brino[3], M. Nassal[1], T. Baumert[2,4]. [1]*University Hospital Freiburg, Dept of Internal Medicine II/Molecular Biology, Freiburg, Germany;* [2]*Inserm, Institut de recherche sur les maladies virales et hépatiques UMRS 1110, Université de Strasbourg, Strasbourg, France;* [3]*IGBMC, Plateforme de Criblage Haut-débit, Illkirch, France;* [4]*Nouvel Hôpital Civil, Institut Hospitalo-universitaire, Pôle Hépato-digestif, Strasbourg, France*
Email: e.verrier@unistra.fr

Background and Aims: Current treatments can control but rarely cure chronic hepatitis B virus (HBV) infection. During HBV replication, the viral relaxed circular (rc) DNA is converted into an episomal covalently closed circular (ccc) DNA, serving as a template for the transcription of viral RNAs and playing a key role in virus persistence. The structure of HBV rcDNA, including a gap, a flap and protein plus RNA adducts implies a crucial role for cellular DNA repair machinery in cccDNA formation. To identify the respective repair factors involved in that process, we set up a novel high-throughput (HS) screening assay for the quantification of cccDNA activity.

Method: Exploiting the highly efficient cccDNA formation by duck HBV (DHBV) even in human cells, we generated TetOFF HepG2 lines harboring a DHBV genome and producing an HA-tagged HBe antigen (HA-HBeAg) exclusively from a functional cccDNA but not from the integrated virus DNA. As the HA-tag is present on the precore region, the HA signals are specific for HBeAg – and not HBcAg (Figure 1). Therefore, the quantification of HA-HBeAg using an HA-specific ELISA allows to quantify cccDNA formation and activity. Using a loss-of-function screening strategy and a targeted shRNA library, we plan to identify the DNA repair factors required for cccDNA formation.

Results: A control DHBV TetOFF line, named HA2/3 cell line, showed increasing, Southern blot-detectable cccDNA after 7 days of induction. Concomitant HA-HBeAg secretion was demonstrated by Western blot and HA-specific ELISA in the supernatant of HA2/3 cells. Assay sensitivity was substantially increased by using chemiluminescent substrate. Secreted HBeAg levels are increasing from day 7 to day 20 before reaching a plateau. Interestingly, the siRNA-mediated silencing of the expression of *POLK*, coding for the DNA Polymerase Kappa which is known to be involved in cccDNA formation triggered a decrease in HBeAg secretion. HA2/3 Cells have been adapted to robust growth in 96-well format, and efficient delivery of shRNA in these cells was demonstrated by a strong decrease in *POLK*-, *TDP2*-, and *SIRT1*- (putative positive controls for the screen) expressions after lentiviral transduction of respective shRNA sequences.

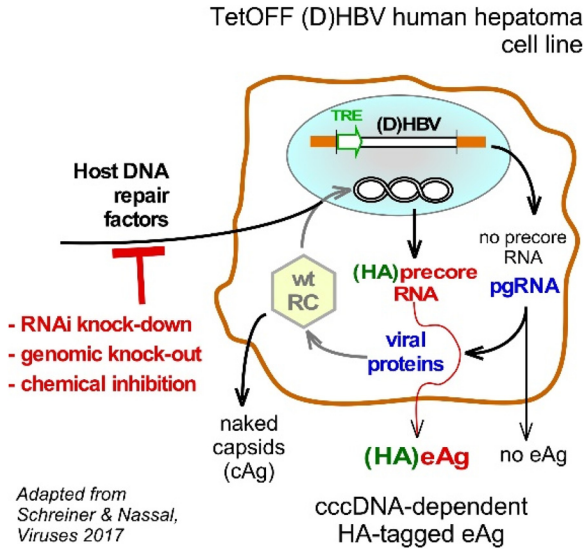

Figure 1: TetOFF inducible cell line allowing the production of DHBV cccDNA-dependent HA-tagged HBeAg.

Conclusion: The new HA2/3 cell line allows sensitive and time-resolved monitoring of cccDNA formation – and its inhibition – by a non-invasive quantifiable and principally HS-suited assay. The shRNA screen using a DNA repair library will allow to identify new host factors required for cccDNA formation. Moreover, this assay is also suitable for small molecule screens. Taken together, our model will allow to identify new host targets and small molecules specifically targeting cccDNA formation and will pave the way to novel antiviral strategies targeting cccDNA for viral cure.

MicroRNA-155 regulates pro- and anti-inflammatory cytokine expression in human monocytes/macrophages during chronic hepatitis C virus infeciton

Y. Zhang, P. Zhang, C. Fan, X. Zheng, Z. Yao, Z. Jia. *Tangdu Hospital, Department of Infectious Diseases, Xi'an, China*
Email: zyfmmu@hotmail.com

Background and Aims: Hepatitis C virus (HCV) dysregulates innate and adaptive immune responses, leading to chronic viral infection in most humans. Monocytes/macrophages (M/M_{Φ}) play a crucial role in linking innate and adaptive immunity to control viral infection. We have previously shown that a transcription factor – T-box expressed in T cells (T-bet) is up-regulated in M/M_{Φ} to dampen M/M_{Φ} functions via enhancing T-cell immunoglobulin and mucin domainprotein-3 (Tim-3) expression in chronic HCV infection; however, the molecular mechanisms that control its expression in M/M_{Φ} remain largely unknown. MicroRNAs (miR) have been implicated as key regulators controlling diverse biological processes through posttranscriptional repression. In this study, we investigated the effect of miRNA-155onM/M_{Φ} function through regulating T-bet signaling in the setting of chronic HCV infection.

Method: Forty chronic HCV infected patients and 40 healthy subjects (HS) were recruited. $CD14^{+}$ monocytes were purified, followed by RT-PCR analysis of miR155 levels. MiR155 levels were also detected in monocytic THP-1 cells stimulated with LPS, HCV core or HCV NS5,

and THP-1 cells co-cultured with HCV$^+$ or HCV$^-$ Huh7.5 cells. Furthermore, CD14$^+$ monocytes isolated from chronically HCV-infected individuals and HS were transfected with miR155 mimics, miR155 inhibitors or negative control. TNF-α and JNK1, 2, 3 were detected by ELISA and RT-PCR. T-bet, IL-12 and Il-10 were tested by flow cytometry. SOCS1 were detected by WB and RT-PCR.

Results: We demonstrated that miR-155 was up-regulated in CD14$^+$ M/M$_\Phi$ in HCV-infected patients compared to healthy subjects. Upon LPS, HCV core or NS5 stimulation, miR-155 was up-regulated in monocytic THP-1 cells. Up-regulation of miR-155 was also observed in THP-1 cells incubated with HCV$^+$ Huh7.5 cells. Moreover, up-regulation of miR-155 in CD14$^+$M/M$_\Phi$ from HCV-infected patients induced TNF-α production and JNK signaling activation, leading to T-bet up-regulation, thereby, promoting inflammatory responses. Also, miR-155 up-regulation in CD14$^+$ M/M$_\Phi$ of HCV-infected patients resulted in increased IL-12 and decreased IL-10 productions via inhibiting the suppressor of cytokine signaling 1 (SOCS1) signaling.

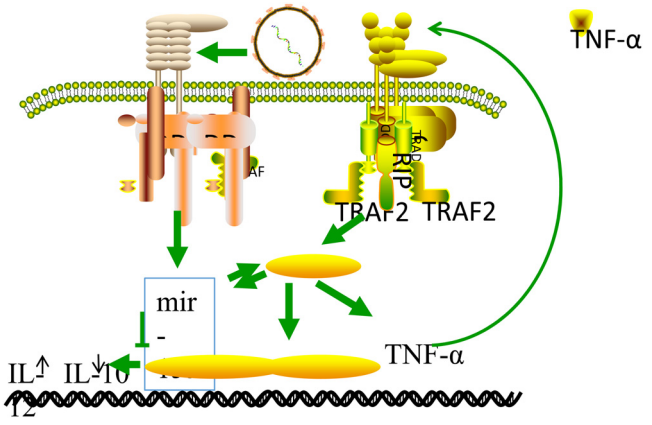

Figure: A model for miR155 regulation of monocyte functions in the setting of chronic HCV infection.

Conclusion: These results indicate that miR-155 up-regulation in M/M$_\Phi$ during HCV infection enhances the activation of TNF-α and JNK pathways to promote the expression of transcription factor T-bet and triggers pro-as well as anti-inflammatory mediators, such as IL-12, TNF-α, and IL-10, via the SOCS1 signaling. Our data reveal new information for elucidating the mechanisms of chronic HCV infection.

Depletion of RIPK1 in hepatocytes exacerbates PolyI:C and Murine Hepatitis Virus induced liver damage

M. Farooq, C. Piquet-Pellorce, S. Dion, M.S. Eugenio, A. Filliol, C. Raguenes-Nicol, M.-T. Dimanche-Boitrel, J.L. Seyec, M. Samson.
IRSET – U.1085 Inserm, Rennes, France
Email: michel.samson@univ-rennes1.fr

Background and Aims: The protein kinase RIPK1 plays a crucial role on the crossroad of stress-induced signaling pathways that affects cell's decision to live or die. Thus, RIPK1 is involved in the signal transduction pathway activated during the recognition of viral pathogen-associated molecular patterns (PAMPs) by the Toll-like receptor 3 (TLR3). The present study aimed to define the role of RIPK1 in hepatocytes when this pathway is stimulated with Poly I:C, a synthetic analog of double-stranded RNA or when a fulminant hepatitis is induced by Murine Hepatitis Virus type 3 (MHV3) infection.

Method: Mice deficient for RIPK1 specifically in liver parenchymal cells (RIPK1$^{LPC\text{-}KO}$) and their wild-type littermates (RIPK1$^{fl/fl}$) have been challenged by Poly I:C. Etanercept, a TNF alpha receptor decoy, or clodronate encapsulated liposomes were injected prior administration of Poly I:C to explore the respective role of TNF alpha and macrophages in induced hepatitis. Primary cultures of mouse hepatocytes isolated from RIPK1$^{LPC\text{-}KO}$ or RIPK1$^{fl/fl}$ mice were also established to investigate the direct impact of Poly I:C on normal or deficient liver parenchymal cells. Besides, fulminant hepatitis induced by MHV3 were compared in RIPK1$^{LPC\text{-}KO}$ and RIPK1$^{fl/fl}$ mice. Different clinico-pathological investigations (ALT, liver histology, qPCR…) were conducted to analyze challenged animals.

Results: Administration of Poly I:C led to increased serum ALT in RIPK1$^{LPC\text{-}KO}$ mice, reflecting liver damage through elevated apoptosis as illustrated by cleaved-caspase 3 labeling. Prior neutralization of TNF alpha protected hepatocytes from apoptosis in Poly I:C challenged RIPK1$^{LPC\text{-}KO}$ mice. Besides, depletion of macrophages also resulted in complete protection. In *in vitro* primary mouse hepatocytes, Poly I:C never induced direct cell death whatever the murine genotype, while it always stimulated an anti-viral response as characterized by the induction of PKR, Mx1 and OAS gene expression even in absence of RIPK1. Additionally, it has been discovered that RIPK1$^{LPC\text{-}KO}$ mice were more sensitive to MHV3 induced fulminant hepatitis.

Conclusion: Our data sustain the protective role played by RIPK1 in hepatocytes during viral induced fulminant hepatitis which is carried out through TNF alpha secreted from macrophages.

A novel chimpanzee adenoviral vectored HBV vaccine, encoding multiple HBV antigens with a shark invariant chain adjuvant, for use in HBV immunotherapy

S.K. Chinnakannan[1], T. Cargill[1], T. Donnison[1], A. Ansari[1], M. Maini[2], T. Evans[3], E. Barnes[1]. [1]*Peter Medawar Building, Nuffield Department of Medicine, Oxford, United Kingdom;* [2]*University College of London, Division of Infection and Immunity UCL, London, United Kingdom;* [3]*Vaccitech, Oxford, United Kingdom*
Email: senthil.chinnakannan@ndm.ox.ac.uk

Background and Aims: Chronic hepatitis B virus (HBV) infects 257 million people globally. Current therapies suppress HBV but rebound occurs on cessation of therapy; novel therapeutic strategies are urgently required. To develop a potent therapeutic HBV vaccine that will induce T-cells to all major HBV antigens and generate anti-HBs antibodies, using Chimpanzee adenoviral vectors and shark class-II invariant (sIi) chain as a genetic adjuvant.

Method: We designed two HBV immunogens SIi-HBV-CP$_{mut}$S and HBV-CP$_{mut}$S; encoding precore (PreC), core, non-functional polymerase (P$_{mut}$), PreS1, PreS2 and surface antigens (Figure 1a). The large envelope protein of HBV (composed of PreS1, PreS2 and surface proteins) was generated separately using furin 2A (F2A) peptide cleavage protein. A 26 amino-acid sequence, derived from shark invariant chain (sIi), was inserted at the 5′ end of the SIi-HBV-CPmutS immunogen. The immunogens were encoded in chimpanzee-adenoviral vector (ChAdOx2) and tested in naïve mice given i.m. HBV-specific T-cell responses were assessed using IFN-ϒ ELISpot and intracellular cytokine (ICCS) assays.

Results: Vaccination generated very high magnitude HBV specific T-cell responses to all HBV antigens (Figure 1b). The mean magnitude of total HBV-specific T-cell responses in inbred BALB/c and outbred CD1 mice were 3858 and 3821 spot forming units [SFU]/10^6 splenocytes (shown on the left side of Figure 1) and 4514 and 2979 SFU/10^6 intrahepatic lymphocytes (shown on the right side of Figure 1b) respectively. ICCS showed that HBV specific CD8+ T cells were polyfunctional producing both IFN-ϒ and TNF-α.

The inclusion of shark invariant chain (data shown in blue coloured bars in Figure 1b) significantly enhances the T-cell magnitude for both splenocytes (3821 mean total SFU/10^6 with sIi vs. 386 mean total SFU/10^6 without sIi, $p < 0.0001$) and intrahepatic lymphocytes (2979 mean total SFU/10^6 with sIi vs. 461 mean total SFU/10^6 without SIi, $p = 0.0002$). Importantly, T cells to the non-HBV SIi peptides were not generated.

Conclusion: We have generated a highly potent HBV vaccine that induces T-cells against all major HBV proteins, using chimpanzee

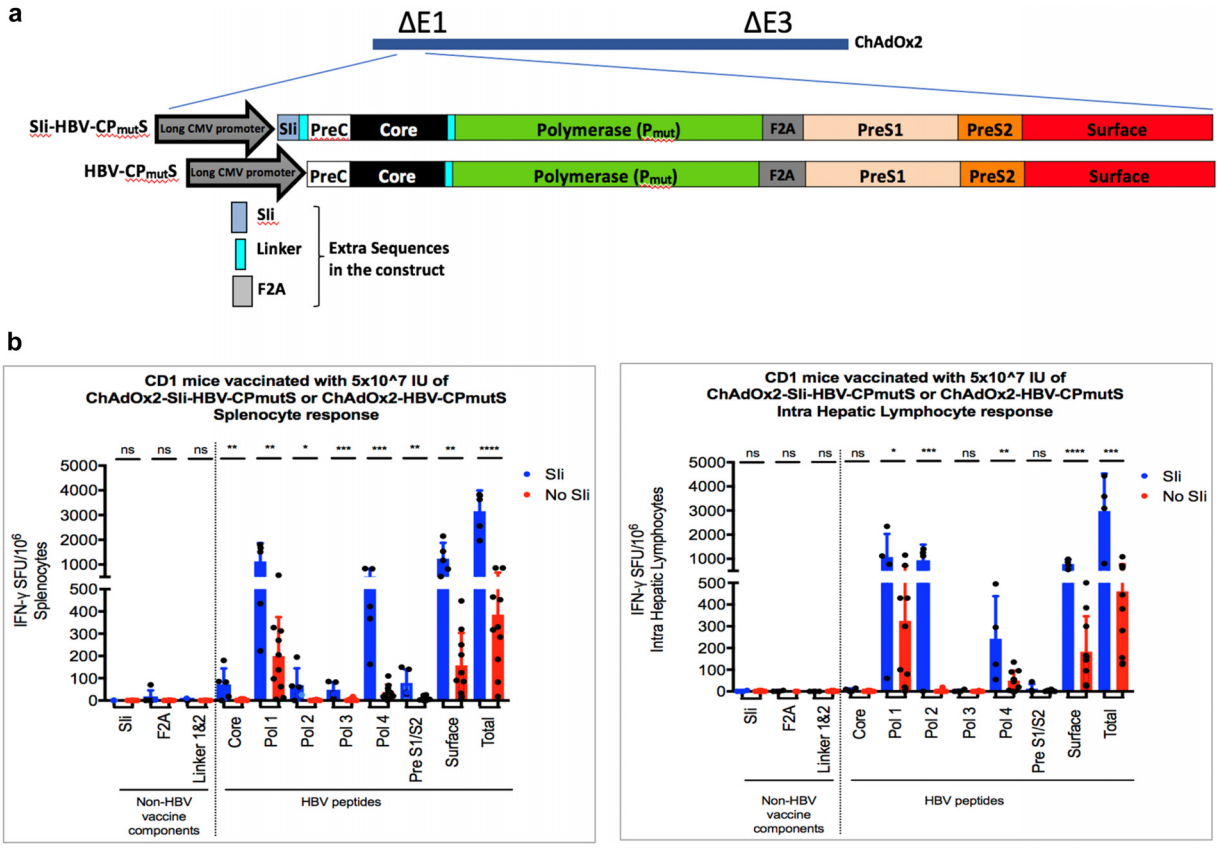

Figure 1: (abstract: SAT-407): ChAdOx2-HBV vaccines. (b) Comparison of the immunogenicity of ChAdOx2-HBV vaccines with and without Shark Invariant Chain (SIi)

adenoviral vector and class-II invariant chain technologies. These pre-clinical studies pave the way for new studies of HBV immunotherapy in humans with chronic HBV infection.

Modeling HBV infections and immune responses in humanized mouse models

M. Dusseaux[1], G. Masse-Ranson[1], S. Darche[1], J. Ahodantin[2], Y. Li[1], E. Beaumont[3], P. Moreau[4], C. Neuveut[4], P. Soussan[5], P. Roingeard[3], D. Kremsdorf[5], J.D. Santo[1], H. Strick-Marchand[1]. *[1]Institut Pasteur, Immunology, Paris, France; [2]CIMI-Paris, Paris, France; [3]Université François-Rabelais Tours, Inserm U966, Tours, France; [4]Institut Pasteur, Virology, Paris, France; [5]CIMI Paris, Inserm U1135, Paris, France*
Email: hstrick@pasteur.fr

Background and Aims: While Hepatitis B virus (HBV) infects and replicates in hepatocytes, its evasion and modulation of the immune response is key to the physiopathology observed in patients. The cross-talk between the immune system and infected hepatocytes results in either viral control with functional cure or viral persistence with chronic infections.
Method: HBV's limited species tropism has restricted the development of relevant in vivo systems, thus we have established a mouse model harboring both a humanized immune system (HIS) and human hepatocytes (HUHEP) in BALB/c Rag2$^{-/-}$IL2Rc$^{-/-}$SIRP^{NOD} Alb-uPA^{tg} hosts. HIS-HUHEP mice are robustly and stably engrafted with human myeloid and lymphoid cells homing to lymphoid organs as well as high levels of human liver chimerism. To model the diversity of pathological outcomes in patients with different viral loads, HIS-HUHEP mice were infected with a low or high dose of HBV, and the human immune response was evaluated.
Results: HBV-infected HIS-HUHEP mice developed chronic HBV with a full viral life cycle (HBV DNA, HBsAg and HBeAg in the plasma, cccDNA in the liver) and maintained partially controlled viremia for several months. Immune responses in HBV-infected HIS-HUHEP mice were characterized by increased NK and T cell recruitment and activation in the liver and spleen, as well as antigen specific antibodies (anti-HBsAg and anti-HBcAg) in the plasma. Elevated levels of pro-inflammatory, as well as immunosuppressive, cytokines and chemokines were observed in the plasma and liver, which was enriched in PD-L1+ cells. Mice inoculated with lower viral loads had more moderate immune responses, whereas higher viral loads resulted in PD-1+ exhausted memory T cells. Antiviral treatment of HBV-infected HIS-HUHEP mice resulted in restoration of naïve immune phenotypes.
Conclusion: Humanized mouse models offer a platform to assess the complex interactions between the virus, host cell, and immune response in viral hepatitis. Immunopathologies induced by co-infections (HIV/HBV, HDV/HBV, HCV/HBV) have yet to be explored in immunocompetent models and could give insights into the accelerated disease phenotypes and allow testing of novel therapeutic strategies.

Email: ilaria.esposito@ndm.ox.ac.uk

Background and Aims: Induction of functional CD4+ T cell helper responses are the hallmark of a protective response against HCV associated with spontaneous clearance of virus. Recent vaccination studies have shown priming and boosting of high levels of T cell

responses against HCV in healthy volunteers, although much less data is available about the specificity, memory phenotype and functional quality of help induced. For this reason, we want to analyse the characteristics of CD4+ T cell helper populations undergoing HCV vaccination with novel recombinant adenoviral prime/poxvirus boost regimens (clinical trials EudraCT number 2007-004259-12 and 2009-018260-10). In addition, we want to compare these responses to a population of 10 HLA-matched individuals with spontaneous resolution of HCV, as well as 21 undergoing DAA-mediated cure following HCV genotype 1 chronic infection (recruited in a separate study).

Method: We analysed CD4+ T cell helper populations using MHC Class II tetramers encoding for NS region of HCV virus in healthy vaccinated individuals, spontaneous resolvers and patients following DAA therapy. Peptide-specific T cell responses were tracked over time using flow cytometry and frequency, proliferative capacity, surface phenotype, functional responses as well as the expression of exhaustion markers measured.

Results: The vaccination regimen induced tetramer positive CD4+ T cells at all measured time points, especially 1–4 weeks after boosting (mean 0.06%). Similar frequencies were obtained for those tracked following spontaneous resolution of disease (mean 0.04%). In addition, the phenotype, including CD127and CD28 expression and functional capacity of peptide specific CD4+ T cell responses characterized after vaccination (mean ± SD = 79.6% ± 11.4% at boosting) are comparable to spontaneous resolver individuals (mean ± SD = 69.3% ± 17.4%). The vaccination is able to induce a high percentage of specific CD4 + effector and central T cells memory at each time points analogous to spontaneous resolvers as well as low expression of exhaustion markers.

In contrast, helper responses in chronic infection were infrequently detected and poorly functional, and did not recover following HCV cure.

Conclusion: The nature of CD4+ T cell help examined in detail using MHC Class II tetramers resembled "protective memory" that is seen following spontaneous clearance of HCV.DAA cure does not allow for resurrection of exhausted CD4+ T cell memory in chronic infection. Further studies to assess the response to vaccination in those cured by DAA therapy will address whether effective help can be induced longer term.

SAT-410

Induction of liver sinusoidal endothelial cells immune activation by HBeAg during HBV infection

Q. Yu, J. Luo, S. Yang, Q. Wang, Y. Liu, L. Wang, D. Yang, J. Liu. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Infectious Diseases, Wuhan, China*
Email: jialiu77@hotmail.com

Background and Aims: Liver sinusoidal endothelial cells (LSECs) play a crucial role in maintaining the homeostasis of the hepatic microenvironment through induction of Ag-specific T cell tolerance. It has been shown that some viruses infection or TLRs stimulation can induce the maturation of LSECs, which reverts their suppressive properties to induce T cell immunity. However, little is known about whether and how the function of LSECs in regulating T cell immunity is regulated during HBV infection. Here, we investigated the function and mechanism of LSECs regulating CD8+ T cell immunity during HBV infection.

Method: Mice were hydrodynamic injected (HI) with plasmid pAAV/HBV1.2 or pSM2, and their LSECs were freshly isolated at different time points post injection and co-cultured with polyclonal TCR-activated T cells. LSECs freshly isolated from naïve mice were stimulated by recombinant HBV antigen protein and co-cultured with polyclonal TCR-activated T cells. Human LSECs were isolated and stimulated by recombinant HBeAg, and were co-cultured with Dynabeads activated T cells. The phenotype and function of LSECs were characterized by flow cytometry, quantitative PCR, and functional assays.

Results: Compared to LSECs of naive mice or HI control mice, LSECs separated from HBV HI mice at 14 days post injection (dpi) reverted their suppressive properties to enhance T cell immunity. Further analysis demonstrated that both in vitro and in vivo HBeAg stimulation could induce the maturation of naive LSECs and enable them to promote the IFN-γ production of TCR-activated CD8+ T cells. LSECs separated from HBeAg-deficiency HBV HI mice were less capable of promoting T cell immunity compared to those separated from wild type HBV HI mice. In contrast, replenishing HBeAg expression in HBeAg-deficiency HBV HI mice resulted in better LSEC activation and led to accelerated HBV clearance. Both LSECs separated from HBV HI mice and HBeAg stimulated LSECs showed increased TNF-α production. TNF-α blockade partially abolished the ability of HBeAg-stimulated LSECs to promote effector T cell response. In contrast, adding TNF-α to the cocultures of unstimulated LSECs and activated T cells abrogated the suppression of T cell IFN-γ production by LSECs. Importantly, in vitro HBeAg stimulation could also induce the maturation of human LSECs and enable them to promote the IFN-γ production of TCR-activated CD8+ T cells.

Conclusion: Our data suggest that HBV replication can revert LSECs suppressive properties to promote T cell immunity, which is partially mediated by HBeAg induced TNF-α production of LSECs.

SAT-411

Regulation of antiviral CD8 T cell response by MMP mediated soluble CD100 releasing in HBV infection

S. Yang, L. Wang, Q. Yu, Q. Wang, Y. Liu, J. Luo, D. Yang, J. Liu. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Infectious Disease, Wuhan, China*
Email: jialiu77@hotmail.com

Background and Aims: CD100 is the first semaphorin described to have immune functions and serves important roles in T cell responses. Proteolytic cleavage of CD100 from the cell surface by matrix metalloproteinases (MMPs) gives rise to a soluble fragment of CD100 (sCD100), which is also thought to have immunoregulatory properties. Here, we characterized the expression and possible role of CD100/sCD100 in regulating antiviral response during HBV infection in patients and HBV-replicating mouse model. However, there is a paucity of information about how CD100 modulates the T cell response during HBV infection.

Results: We found that surface CD100 expression on T cells of chronic Hepatitis B (CHB) patients was significantly increased compared to that of healthy controls (HC). Meanwhile, CHB patients showed significantly lower concentrations of serum sCD100 than HC. Correspondingly, decreased surface CD100 expression on T cells in PBMCs and elevated serum sCD100 levels were observed in the mice which eliminated HBV from their livers but not in the HBV-tolerant mice. In vivo sCD100 treatment led to enhanced CTL response and accelerated viral clearance in the HBV-tolerant mice. Interestingly, activation of liver sinusoidal endothelial cells by sCD100 treatment was observed. In vitro sCD100 treatment also resulted in enhanced HBV-specific CD8 T cell response in PBMCs of some CHB patients. In contrast, blockade of the interaction of CD100 and its ligand CD72 by CD72 blocking antibody treatment resulted in decreased HBV-specific CD8 T cell response and HBV persistence in mice. We also investigated the possible mechanism involved in membrane CD100 shedding during HBV infection. Our results demonstrated that MMP2 and MMP9 are responsible for the cleavage of CD100 from the surface of T cells. In CHB patients, significantly lower serum MMP2 concentration was observed than that of HC. Compared to HBV-tolerant mice, mice which eliminated the virus showed elevated MMP2 expression in the liver during the acute phase of infection. In vivo inhibition of MMP2 and MMP9 activity resulted in decreased HBV specific CTL response and delay HBV clearance in mice.

Conclusion: In conclusion, our results indicated CD100/sCD100-CD72 interaction is important for the induction of antiviral T cell response and viral clearance during HBV infection. We hypothesize that insufficient liver MMP2 production during HBV infection results in impaired membrane CD100 cleavage, which leads to lack of activation stimulation for intrahepatic antiviral T response and thus the persistence of HBV infection. This study provides a new mechanism to elucidate HBV persistence in patients and a new target for developing strategies to overcome T cell tolerance in chronic HBV infection.

Transcriptomic profiling of intrahepatic B cells suggests a B-cell impairment in the immune active phase of chronic hepatitis B

S.V. Hees[1,2,3], J. Hou[3], A. Grooshuismink[3], K. Kreefft[3], S. Bourgeois[1,4], A. Boonstra[3], T. Vanwolleghem[1,2,3]. *[1]Antwerp University Hospital, Department of Gastroenterology and Hepatology, Antwerp, Belgium; [2]Antwerp University, Laboratory of Experimental Medicine and Paediatrics, Antwerp, Belgium; [3]Erasmus Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [4]ZNA Stuivenberg, Department of Gastroenterology and Hepatology, Antwerp*
Email: stijn.vanhees@uantwerpen.be

Background and Aims: Using a systems biology approach, we recently demonstrated a significant activity of B-cell related genes in whole blood and liver biopsies during sequential clinical phases of a chronic Hepatitis B Virus (HBV) infection. We here investigated for the first time the transcriptome of paired sorted B cells from liver and blood across the different HBV clinical phases.

Method: CD19+ B cells were purified by cell sorting (FACS Aria) from PBMC of healthy controls (HC; n = 13) and untreated HBV patients in the 4 different HBV clinical phases: Immune Tolerant (IT; n = 3), Immune Active (IA; n = 14), Inactive Carrier (IC; n = 9) and HBeAg negative phase (ENEG; n = 16). In addition, paired CD19+ B cells were sorted from core needle liver biopsies of 6 IA, 5 IC and 3 ENEG patients. RNA-sequencing and data analysis was performed using Unique Molecular Identifiers. Two different bio-informatical analysis approaches were applied: 1. Analysis of Differentially Expressed Genes (DEG) with q < 0.2 and fold-change > 1.5; 2. Gene pattern analysis on a literature based selected set of B-cell related genes (n = 92). FACS analysis was performed to assess CD10, CD21, CD27, CD38 and IgD expression on peripheral CD19+ B cells.

Results: FACS analysis of peripheral B-cell subsets did not show significant differences between different HBV phases. Analysis of DEG in peripheral B cells revealed only 5 common DEG across all HBV clinical phases vs. healthy controls. However, each individual HBV clinical phase showed a significant number of DEG (IA: n = 912; ENEG: n = 874; IC: n = 785 and IT: n = 562) when compared to the HC B cell transcriptome, with most overlapping DEG (n = 348) in the IA and ENEG phase. This is highly suggestive for different roles of B cells during the distinct HBV clinical phases. Gene pattern analysis demonstrated lower expression of 4 genes, including PDL1 and IL2RA in peripheral B cells across all HBV clinical phases vs. healthy controls. Applying the gene set pattern analysis on intrahepatic B cells showed an upregulation of genes encoding B cell inhibitory proteins in the IA phase relative to the IC and ENEG phase. In addition, intrahepatic CXCR3 transcription was higher in both IA and ENEG phases. These patterns were absent in blood (Figure 1), suggesting a liver-specific HBV-associated B-cell impairment, but active recruitment during the IA phase. Detailed assessment and functional analysis of specific genes is ongoing in both liver and peripheral B cells.

Conclusion: This is the first assessment of gene expression profiles of B cells by RNASeq in blood and liver of chronic HBV patients. Bio-informatical analysis demonstrated a high number of DEG not only when comparing paired liver and blood B cells, but also -more importantly- when comparing the distinct phases of disease differing in levels of viral replication and liver damage.

Dysfunctional surface antigen-specific memory B cells accumulate in chronic hepatitis B infection

A. Burton[1], L.J. Pallett[2], L. Mccoy[1], K. Suveizdyte[1], O.E. Amin[1], F. Froghi[3], B.R. Davidson[3], U.S. Gill[4], P.A. Blair[5], C. Mauri[5], N. Pelletier[6], M. Maini[1]. *[1]UCL, Division of Infection and Immunity, London, United Kingdom; [2]Division of Infection & Immunity, London, United Kingdom; [3]UCL, Institute of Liver and Digestive Health, London, United Kingdom; [4]Barts and the London, Centre for Immunobiology, London, United Kingdom; [5]UCL, Division of Medicine, London, United Kingdom; [6]Roche Innovation Center, Roche Pharma and Early Research Development, Basel, Switzerland*
Email: alice.burton.14@ucl.ac.uk

Background and Aims: One important and under-researched component of the natural control of hepatitis B (HBV) infection is the development of antibodies against HBV surface antigen (HBsAg; anti-HBs), which are a hallmark of functional cure. The production of insufficient antibodies to neutralise the large quantities of circulating HBsAg suggests there may be defects in the global and/or HBsAg-specific memory B cell compartments.

Method: Using a novel bait reagent and 16-color flow cytometry, we have comprehensively analysed the phenotype and function of global

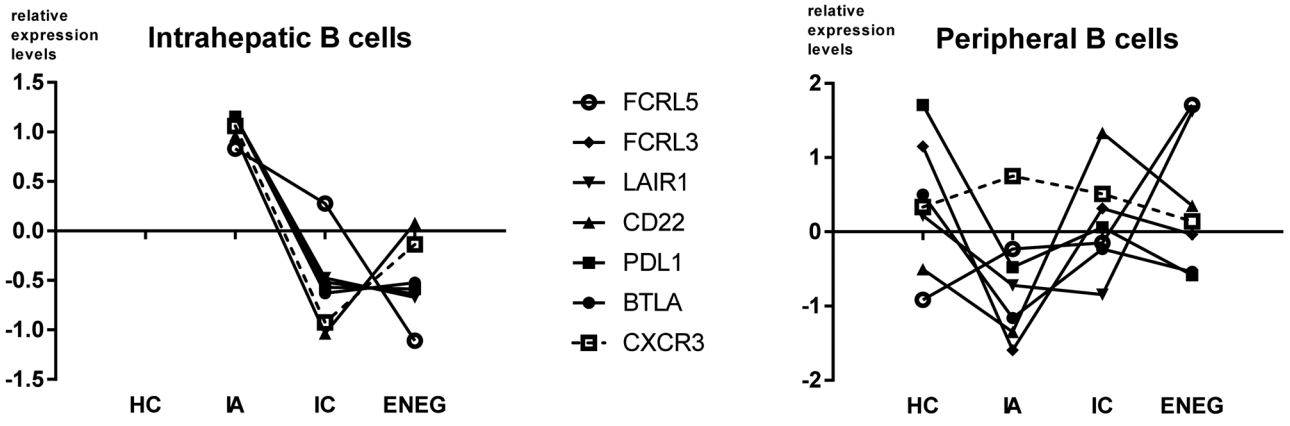

Figure 1: Relative expression levels of genes encoding B cell inhibitory proteins (continuous lines) and CXCR3 (dotted line) in intrahepatic vs peripheral B cells across the different HBV clinical phases.

Figure: (abstract: SAT-412)

and HBsAg-specific B cell subsets in a heterogeneous cohort of patients with chronic HBV infection (CHB) and HBV-vaccinated healthy controls.
Results: We show that HBsAg-specific B cells are detectable in CHB, despite the lack of circulating anti-HBs antibodies in these patients. However, in patients with CHB, HBsAg-specific memory B cells with an atypical, dysfunctional phenotype (defined as $CD27^{-}CD21^{lo/-}$) are expanded compared to vaccinated healthy controls. This population expresses high levels of inhibitory receptors, and accordingly exhibits impaired cytokine production, B cell receptor signaling and differentiation into plasma cells compared to classical memory B cells. Preliminary data suggest that immune complexes, known to circulate in patients with chronic HBV infection, may further suppress B cell receptor signaling through binding to inhibitory Fc-receptors preferentially expressed on atypical memory B cells. Atypical memory B cells with a dysfunctional phenotype are further enriched within the HBV-infected liver, where they constitute a higher proportion of the mature B cell pool than in healthy controls.
Conclusion: Overall, these data suggest that chronic antigen exposure in CHB can drive dysfunction of HBsAg-specific B cells, that may contribute to the failure of immune control.

Email: ruth.broering@uni-due.de

Background and Aims: It has become clear that not only the adaptive but also the innate immune system is involved in the pathogenesis of Hepatitis B virus (HBV) infection. Here, we analyzed the immune activation pattern in primary human hepatocytes (PHH) infected with HBV in vitro.
Method: PHH were isolated after perfusion and digestion of liver tissue obtained after tumor resections or transplantations. PHH were treated with cell culture-derived HBV particles (HepG2.117) or negative control particles and cultured for 1–10 days. Infection was monitored by the release of HBsAg and HBeAg, transcription of viral genes and immunocytochemistry staining. Changes in gene expression were analyzed by microarray, quantitative RT-PCR and western blot analysis. TLR ligands, entry inhibitor and neutralizing antibodies were used to characterize the initial immune response in PHH exposed to HBV.
Results: PHH could be efficiently infected with cell culture-derived HBV particles, indicated by the secretion of viral antigens and expression of viral mRNAs. The exposure of PHH to HBV particles induced a gene expression profile, more comparable to that induced by TLR2 ligand Pam3Cys, than those induced by viral sensors TLR3 or TLR7-9, leading to the induction of inflammatory and chemoattractant cytokines. Treatment with HBV as well as Pam3Cys activated ERK1, JNK and p38 mitogen-activated protein kinases as well as NFκB. Furthermore, HBV-induced gene expression could be neutralized by TLR2-specific antibodies. Blockade of HBV-mediated TLR2 activation enhances viral replication but did not affect HBsAg or HBeAg secretion. Furthermore, pretreatment with HBV entry inhibitor (Mycludex-related peptide) suppressed infectivity as well as the TLR2-mediated immune response to HBV. Interestingly, PHH isolated from HBV-infected patients revealed a higher responsiveness to TLR2 stimulation compared to uninfected resection or transplantation controls, indicated by elevated induction of cytokine gene expression.
Conclusion: The present data suggest that TLR2 is involved in recognition of HBV during the infection process and activate innate immune responses in the early phase of infection. Consistently, recent data suggest that TLR2 might be involved in antiviral responses during hepadnaviral infection and play an important role in the pathogenesis of chronic HBV infection.

SAT-415
Probing new HBV therapies using fine needle aspirates to sample compartmentalised liver-resident immunity and hepatocytes

U.S. Gill[1], L.J. Pallett[2], A. Burton[2], K. Stegmann[2], P. Kennedy[1], M. Maini[2]. *[1]Blizard Institute, Barts and The London SMD, QMUL, Centre for Immunobiology, London, United Kingdom; [2]UCL, Division of Infection & Immunity, London, United Kingdom*
Email: upkargill@hotmail.com

Background and Aims: In order to optimally refine the multiple new therapeutic strategies in the pipeline for Hepatitis B virus (HBV) cure, evaluation of virological and immunological changes at the site of infection is required. This has been underscored by our recent demonstration that specialised subsets of tissue-resident CD8 T *(Pallett et al., JEM 2017)* and NK cells (*Stegmann et al., Sci Rep 2016*), adapted to provide frontline defence, are compartmentalised within the liver and consequently cannot be sampled in the blood. We therefore investigated if fine needle aspirates (FNA), well-suited for repeated sampling, could be used to study the local immune landscape in parallel with HBV-infected hepatocytes.
Method: Patients with HBV (n = 19) and those without viral infection (n = 8) undergoing percutaneous liver biopsy for diagnostic purposes were included. Matched samples for blood, liver biopsy and FNA from the same patients were analysed in parallel. 16-colour multiparameter flow cytometry was used to characterise a range of immune cells including circulating, liver-infiltrating (T, B, NK & MAIT cells) and liver-resident populations (T and NK cells) as well as hepatocytes.
Results: Comparable populations of CD4 T, CD8 T, B, NK and MAIT cells were identified by FNA to those seen in material from liver biopsy. Populations of tissue-resident memory CD8 T cells ($CD69^{+}CD103^{+}$) with a comparable PD-$1^{hi}CD39^{hi}$ phenotype, were identified by both FNA and liver biopsy, and not seen in the blood. Importantly, HBV-specific T cells (analysed by HLA-A2/HBV-dextramer or intracellular cytokine staining following overnight overlapping peptide stimulation) could be identified by FNA at similar frequencies to those from biopsies and significantly enriched compared to blood. The large subset of liver-resident NK cells ($CXCR6^{+}$ T-$bet^{lo}EOMES^{hi}$), seen on biopsy were also identified by FNA and not seen in the blood. Moreover, by FNA we could simultaneously identify populations of live hepatocytes, which expressed SRB-1, PDL1 and HBsAg, whereas these were not viable after the processing required for liver biopsies.
Conclusion: We demonstrate for the first time that FNA identifies a range of immune cells including local specialised sentinel HBV-specific T cells and NK cells, together with HBV-infected hepatocytes. The broad sampling achieved by this rapid, painless and safe technique makes it an attractive method for longitudinal sampling of the liver, important in optimising new therapies for HBV.

SAT-416
HBV-specific T cell responses in low replicating inactive carrier patients are independent of Hepatitis B surface antigen load

U.S. Gill[1], N. Hansi[1], N.L. Bert[2], K. Kunasegaran[2], G.E. Dolman[1], D. Tan[3], W. Tong[4], M. Maini[5], A. Bertoletti[2], P. NHS Trust, Department of Virology, London, United Kingdom; [5]UCL, Division of Infection & Immunity, London, United Kingdom
Email: upkargill@hotmail.com

Background and Aims: HBeAg negative chronic infection *(EASL CPG 2017);* formerly referred to as the inactive carrier (IC) phase of disease; is considered to represent an end to immune mediated liver damage. These patients, however remain at risk of disease progression, thus specialist follow-up is mandated. Characterised by normal ALT & low HBV DNA, recent data highlight the utility of quantitative HBsAg (qHBsAg), where patients with qHBsAg <1,000 IU/ml are potentially at lower risk of disease progression and HCC *(Tseng et al, Hepatology, 2013).* Moreover, the impact of HBsAg level on the immune profile in IC patients remains poorly understood. We investigated whether qHBsAg modulated global and HBV-specific T cell responses in IC patients.
Method: 150 (male = 72, median age 34 years, range 12–70) consecutive treatment naïve HBeAg negative IC patients (ALT < 40, HBV DNA < 2,000 IUml) were longitudinally followed and analysed. In a subset, at the extreme levels of qHBsAg (<1,500 & >15,000) immune responses were measured. Sorted fractions of CD4 & CD8 T cells were evaluated using NanoString, for mRNA transcription of 600 immune genes. HBV-specific T cells were analysed using IFNγ ELISpot and correlated with qHBsAg levels.
Results: A significant negative correlation between qHBsAg and age was observed ($r^2 = 0.09$, $p = 0.0002$). Patients with qHBsAg < 1,500 IU/ml (median = 42 years) were significantly older than those with qHBsAg > 15,000 IU/ml (median = 31 years; $p = <0.0001$). There was no difference in the frequency of HBV-specific T cells in patients with qHBsAg <1,500 IU/ml vs. those with >15,000 IU/ml ($p = 0.7$). Patients with low qHBsAg levels upregulated 16 genes on CD4 and 15 genes on CD8 T cells in comparison to those with high qHBsAg. Significantly upregulated genes on CD4 T cells (KLRG1, HLA-DQ1, PYCARD) and CD8 T cells (KLRG1, MYD88, BST2) associated with senescence, IFNγ and NFκB signaling were seen in IC patients with low qHBsAg.
Conclusion: The addition of qHBsAg may enhance risk stratification and optimise management of IC patients. All patients demonstrated a low frequency of HBV-specific T cells; importantly those with lower qHBsAg did not demonstrate improved antigen-specific immunity, thus challenging the perceived immunosuppressive effect of HBsAg. Patients with lower levels of HBsAg expressed genes associated with inhibitory signaling and transcriptional regulation of DNA potentially due to increased hepatocyte turnover leading to reduced cccDNA and HBsAg production.

Outcome of anti-viral immunity in the liver is shaped by the level of antigen expressed in infected hepatocytes

K. Manske[1], N. Kallin[1], B. Bingsch[2], K. Steiger[3], R. Thimme[2], P.A. Knolle[1], D. Wohlleber[1]. *[1]Rechts der Isar Hospital, Technical University of Munich, Institute of Molecular Immunology and Experimental Oncology, Munich, Germany; [2]University Medical Center Freiburg, Klinik für Innere Medizin II, Freiburg, Germany; [3]Rechts der Isar Hospital, Technical University of Munich, Institute of Pathology, Munich, Germany*
Email: katrin.manske@tum.de

Background and Aims: 5–10% people infected with Hepatitis B virus (HBV) develop chronic hepatitis accounting for 240 million chronic hepatitis B patients worldwide. Still, the decisive factors ruling between elimination or persistence of viral infection of the liver are not entirely understood. We aimed to establish a novel model system to study immune escape and surveillance of acute self-limited and chronic liver infection in mice. Here, we dissect the factors determining the outcome of viral infection with the help of novel recombinant adenoviruses reflecting the hepatropism and hepatocyte-restricted antigen expression of hepatitis viruses.
Method: We generated identical replication-deficient recombinant adenoviruses expressing eGFP and CBG99-luciferase as marker proteins and the antigen ovalbumin driven either by the strong ubiquitous CMV-promoter (Ad-CMV-GOL) or by the weaker hepatocyte-specific Transthyretin (TTR)-promoter (Ad-TTR-GOL). After infection of mice, dynamics of anti-viral immunity was characterized by *in-vivo*-bioluminescence imaging, serum ALT levels, immunohistochemistry and realtime PCR. Antigen-specific CD8 T cells were analyzed by flow-cytometry.
Results: We generated a liver infection model for acute self-limited and chronic hepatitis in mice, where ovalbumin serves as soluble antigen. Ad-TTR-GOL infection developed into persistent infection, whereas Ad-CMV-GOL infection was cleared. We identified that CD8 T cell immunity against virus-infected hepatocytes is controlled at various levels determining self-limited or persistent disease outcome. First, hepatocyte-restricted antigen-expression led to delayed dynamics of the induction of antigen-specific CD8 T cells and curtailed CD8 T cell expansion – 10.000-fold after Ad-CMV-GOL compared to 150-fold after Ad-TTR-GOL infection. Second, antigen-specific CD8 T cells primed against antigens selectively expressed by hepatocytes co-expressed high levels of inhibitory molecules like PD-1, Tim-3, LAG-3, CTLA-4 and CD160. Third, virus-infected hepatocytes expressing sub-critical levels of antigen escaped from MHC I-restricted killing by effector CD8 T cells.
Conclusion: Our study identifies deficits in CD8 T cell immunity and escape of infected hepatocytes from CD8 T cell killing promoting viral persistence and highlights the importance to address both, restoration of CD8 T cell dysfunction and overcoming local hurdles of effector T cell function in the liver to eliminate virus-infected hepatocytes.

SAT-418

The RNA genome of hepatitis E virus robustly triggers antiviral interferon response

W. Wang[1], Y. Wang[2], C. Qu[1], S. Wang[2], M. Peppelenbosch[1], J. Zhao[2], Q. Pan[1]. *[1]Erasmus University Medical Center, Rotterdam; [2]Beijing 302 hospital, Beijing*
Email: w.wang.2@erasmusmc.nl

Background and Aims: The outcomes of hepatitis E virus (HEV) infection are diverse, ranging from asymptomatic carrier, self-limiting acute infection, fulminant hepatitis to persistent infection. This is closely associated with the immunological status of the host. This study aims to understand the innate cellular immunity as the first-line defense mechanisms in response to HEV infection.
Method: Two dimensional hepatic and extra-hepatic cell lines (Huh7.5, HepaRG, HEK293 and U87 cells) as well as three dimensional primary mouse and human liver organoids were used.
Results: Phosphorylation of STAT1, a hallmark of the activation of antiviral interferon (IFN) response, was observed in the liver tissues of majority of HEV infected patients, but not in the liver of uninfected individuals. In cultured cell lines and primary liver organoids, we found that HEV RNA genome potently induced IFN production and antiviral response. This mechanism is conserved among different HEV strains, including genotype 1, 3 and 7 as tested. Interestingly, the single-stranded HEV RNA (ssRNA) is sufficient to trigger the antiviral response, without requirement of viral RNA synthesis and the generation of RNA replicative form or replicative intermediate. Surprisingly, the m^7G cap and poly A tail are not required, although both are the key features of HEV genome. Mechanistically, this antiviral response occurs in a RIG-I-, MDA5-, MAVS- and β-catenin-independent, but IRF3 and IRF7-dependent manner. Furthermore, the integrity of the JAK-STAT pathway is essentially required.
Conclusion: HEV infection elicits an active IFN-related antiviral response in vitro and in patients. It is triggered by the viral RNA and mediated by IRF3/7 and the JAK-STAT cascade. These findings have revealed new insights on HEV-host interactions and provided the basis for understanding the pathogenesis and outcome of HEV infection.

The impact of HBsAg on general and HBV-specific immunity

N.L. Bert[1], M. Hong[2], D. Tan[3], K. Kunasegaran[2], Y. Cheng[4], E. Brecht[3], U.S. Gill[5], C. Frey[6], E. Newell[4], P. Kennedy[5], A. Bertoletti[2,3,4]. *[1]Duke-NUS Medical School, Emerging Infectious Diseases, Sinagpore, Singapore; [2]Duke-NUS Medical School, Emerging Infectious Diseases, Singapore; [3]Singapore Institute for Clinical Sciences, A*STAR, Singapore; [4]Singapore Immunology Network (SIgN), A*STAR, Singapore; [5]Barts and The London School of Medicine and Dentistry, QMUL, London, United Kingdom; [6]Gilead Sciences, Department of Immunology/Inflammation, Foster City, United States*
Email: nina@duke-nus.edu.sg

Background and Aims: The large amounts of subviral particles containing HBsAg that are secreted by hepatocytes infected with Hepatitis B virus (HBV) or with HBV-DNA integration have been suggested to play immunomodulatory roles. This hypothesis has never been convincingly demonstrated. Our aim was to test whether HBsAg can impact on the function of total or antigen specific immune cells.

Method: To address this question we respectively used CyTOF, a novel mass cytometry technology able to simultaneously analyze the expression of 42 markers involved in activation, differentiation, exhaustion and anti-viral effector function of T and NK cells, and classical in vitro ELISPOT assay utilizing libraries of HBV peptides (312) covering the whole proteome of HBV genotypes A, B and C. We studied 145 patients with chronic HBV (CHB) infection characterized by a wide range of serum HBsAg concentrations (0.5–35,600 IU/ml).

Results: We found that patients with different quantities of circulating HBsAg showed similar frequencies of CD4 and CD8 T cells of memory, naïve and effector phenotype. Besides, the frequency of NK cell subsets appeared similar in patients with high and low levels of HBsAg. Production of different cytokines and cytotoxicity-associated molecules was not altered in relation to HBsAg levels, and there was no correlation with expression of several immunoregulatory receptors, including PD-1, CTLA-4 and TIM-3. On the other hand, the determination of the HBV antigen specificity of T cell responses detected in CHB patients (39 HBeAg+, 45 anti-HBe+) showed a progressive reduction of HBsAg-specific T cells that correlated with duration of infection. The majority of detectable HBV-specific T cells target HBsAg (56% of total HBV-T cells) in young HBeAg+ CHB patients (<15 years). HBsAg-specific T cells were still detectable at high frequency in HBeAg+ CHB patients younger than 25 years (46% of HBV-T cells), but progressively declined in patients between 25 and 35 years (22% of HBV-T cells), and were hardly found in adult CHB anti-HBe+ patients (5% of HBV-T cells).

Conclusion: Taken together, our systematic profiling of the impact of HBsAg on the immunity of CHB patients did not detect general immunological parameters of tolerance or suppression that correlate with HBsAg values. However, HBsAg has clearly a progressive and profound effect on the persistence of HBsAg-specific T cells that are progressively eroded in relation to the length of infection.

SAT-420

Normalization of NK cell phenotype is delayed after successful interferon-free therapy in cirrhotic patients with chronic HCV infection

E. Perpiñan[1,2], S.P. del Pulgar[1,2], M.C. Londoño[1,2], Z. Mariño[1,2], S. Lens[1,2], C. Bartres[1,2], A. Pla[1,2], P. González[1,2], M. García-López[1,2], E. Pose[1], X. Forns[1,2], M. Maini[3], G. Koutsoudakis[1,2]. *[1]Liver Unit, Hospital Clinic, University of Barcelona, IDIBAPS, Barcelona, Spain; [2]CIBEREHD, Barcelona, Spain; [3]Division of Infection and Immunity, University College London, London, United Kingdom*
Email: perpinan@clinic.cat

Background and Aims: Natural killer (NK) cells play an important role in control of viral infections, especially in the liver where they are enriched among lymphocytes. Chronic hepatitis C virus (HCV) infection alters NK cell phenotype, which can be normalized rapidly during interferon-free therapy (Serti, E. *et al*, Gastroenterology. 2015). Here, we focused on potential changes of NK cell phenotype induced by viral eradication in patients with liver cirrhosis.

Method: NK cells of 22 HCV-infected cirrhotic patients were analyzed by flow cytometry at baseline (BL), at week 4 during therapy (W4) and at weeks 12 and 48 after the end of therapy (FU12 and FU48). Samples obtained from 12 non-HCV cirrhotic patients and 12 healthy individuals, matched by age and sex, served as two distinct control sets.

Results: At BL, frequencies of $CD56^{dim}$ and $CD56^{bright}$ cells were decreased or increased, respectively, compared to healthy controls ($p < 0.05$). Moreover, frequencies and expression levels of activating NKp30, NKp46, HLA-DR and inhibitory KIR2DL2/L3, NKG2A, CD85j receptors on total NK cells were also significantly increased ($p < 0.05$). At W4 and FU12, despite viral eradication, frequencies of $CD56^{dim}$ and $CD56^{bright}$ cells and their receptor profile remained similar to BL.

However, at FU48, $CD56^{dim}$ and $CD56^{bright}$ cell frequencies were normalized. Moreover, there was a clear decline in the frequency of NKp30+ $CD56^{bright}$ cells and in the frequencies of NKp46+, HLA-DR+, KIR2DL2/L3+, NKG2A+ total NK cells, reaching similar levels to those in healthy controls. A similar restoration pattern was observed for the expression levels of NKp46, KIR2DL2/L3 and NKG2A, but not CD85j, on total NK cells.

Concerning NK cell function, the frequency of the degranulation marker CD107a within the $CD56^{dim}$ cells was higher than that in both control sets, either at BL or during follow-up ($p < 0.005$). Still, the incremental degranulation of the $CD56^{dim}$ population upon *in vitro* stimulation was significantly lower ($p < 0.01$).

Conclusion: NK cell phenotype normalization does not occur immediately after viral eradication in cirrhotic HCV-infected patients. At FU48, NK cell receptor expression was restored while NK cell degranulation remained significantly altered. These data suggest that HCV infection has a more sustained imprint on NK cells in patients with cirrhosis, with implications for immune restoration.

SAT-421

Transcriptome profiling of hepatitis B virus-infected human hepatocyte derived from chimeric mice with humanized liver

S. Nakamoto, T. Kanda, S. Wu, K. Takahashi, M. Nakamura, S. Yasui, S. Ogasawara, E. Suzuki, Y. Ooka, T. Saito, A. Tawada, T. Chiba, M. Arai, K. Kobayashi, S. Kiyono, H. Maruyama, N. Kato, H. Shirasawa. *Nihon University School of Medicine, Japan*
Email: nakamotoer@yahoo.co.jp

Background and Aims: The role of innate immune system on the course of hepatitis B virus (HBV) infection is less well understood. Clinically, relatively long incubation period is observed during acute HBV infection. Furthermore, immune response is minimal during immune tolerant phase of chronic infection. To understand the contribution of immune response in HBV-infected hepatocyte, transcriptome analysis was performed using in vitro model of HBV infection.

Method: Human hepatocytes derived from chimeric mice with humanized liver (PXB cell) were cultured on the cell culture plate and infected with 5 or 25 genome equivalents of HBV per cell (HBV-L or HBV-H, respectively). RNA was collected 6 hours, 1 day, 5 days and 23 days after infection (6H, D1, D5, D23, respectively). RNA sequence was carried out on an Illumina Hiseq 1500 sequencer. Reads are mapped to human and HBV reference, and expression was calculated as RPKM (Reads Per Kilobase of exon model per Million mapped reads).

Results: HBV RNA level of 6H and D1 was around the lower detection limit and only small parts of its entire genome was covered by reads. On day 5, HBV transcription was significantly increased and higher in

HBV-H cells compared to HBV-L cells (670 RPKM vs. 150 RPKM). At this point, nearly the whole HBV genome was covered by mapped reads. On day 23, continuous HBV replication was confirmed by HBV DNA and HBsAg level in the culture medium as well as HBV RNA in the cells (75 RPKM in the HBV-L cells). Gene expression of non-infected cells was compared between different time points. The correlation coefficient was 0.87 between 6H and D1 and 0.78 between 6H and D5. The correlation was much stronger between the same time points: 0.998 (D5 control vs. D5 HBV-L), and 0.989 (D5 control vs. D5 HBV-H). The expression of interferons including interferon alpha, beta and lambda was neither detected nor induced by HBV infection at these time points. The analysis of differentially expressed genes suggested that antiviral genes including RIG-I and ISG15 is less affected by HBV infection (0.9-fold and 1.2-fold). Among the cytosolic DNA sensor pathways, STING was not detected at any time points. The expression of IFI16 and cGAS was low (<1 RPKM) and was not induced significantly by HBV infection (<2 fold). Furthermore, antiviral genes were not significantly enriched in HBV-infected cells by gene set enrichment analysis.
Conclusion: These data indicate that without other cells such as immune cells, hepatocyte is little affected by HBV infection at least in the conditions studied, consistent with the previous findings showing the stealth nature of HBV and the defect of DNA sensor pathway in hepatocyte.

SAT-422

PTEN-mediated beta-catenin/PD-L1 signaling in hepatocytes modulates hepatitis B virus immune evasion from T cell responses

Y. Sun[1], M. Qu[1], M. Yu[1], L. Tang[1], G. Li[1], W. Zheng[1], C. Li[2]. *[1]School of Basic Medical Sciences, Wuhan University, Wuhan, China; [2]School of Basic Medical Sciences, Wuhan University, Department of Physiology, Wuhan, China*
Email: lichangyong@whu.edu.cn

Background and Aims: Hepatitis B virus (HBV) has developed active tactics to evade host immune surveillance or interfere with immune signaling pathways and induce immunosuppression, which favor their replication. However, the underlying molecular mechanisms are still poorly defined. Programmed cell death 1 (PD-1)/programmed cell death ligand 1 (PD-L1) signaling plays a critical role in regulating T cell homeostasis. This study was designed to investigate the functional roles and molecular mechanisms by which phosphatase and tensin homolog deleted on chromosome 10 (PTEN)-mediated β-catenin/PD-L1 signaling in parenchymal liver cells (hepatocytes) influenced T cell immune responses *in vitro* and *in vivo*.
Method: A mouse model of acute HBV infection was produced by hydrodynamic injection with a pUC18 vector containing 1.3-fold over length HBV genome (pHBV1.3) via the tail vein in a volume of saline equivalent to 8% of the body weight. The total volume was delivered within 6–8 seconds. Coculture experiments with hepatocytes and Jurkat T cells were established.
Results: β-catenin and PD-L1 expression in the liver positively correlated with HBV load in mice. Moreover, HBV infection inhibited PTEN, but upregulated β-catenin and PD-L1 expression in hepatocytes, which in turn augmented PD-1 expression, decreased interleukin-2 (IL-2) secretion, and induced apoptosis in Jurkat T cells. However, disruption of β-catenin inhibited PD-L1 expression in hepatocytes, which was accompanied by decreased PD-1 expression, and increased IL-2 production in T cells. Furthermore, PTEN overexpression inhibited β-catenin/PD-L1 expression in hepatocytes in response to HBV infection, which in turn promoted T cell immune response, and enhanced their ability to clear HBV.
Conclusion: By identifying the molecular pathways by which PTEN-mediated β-catenin/PD-L1 signaling in hepatocytes regulates T cell response, our findings provide the rationale for novel therapeutic target to treat chronic HBV infection.

SAT-423

Nuclear DNA sensor protein IFI16 recognizes hepatitis B virus covalently closed circular DNA and regluates the antiviral innate immunity

Y.-Q. Lu, H. Ma, X.-B. Pan, L. Wei. *Peking University People's Hospital, Hepatology Institute, beijing, China*
Email: pxbdxq@hotmail.com

Background and Aims: The nuclear DNA-sensor protein IFI16 has been demonstrated as an essential role in triggering antiviral immunity during several virus infections. Whether IFI16 recognizes hepatitis B virus (HBV) covalently closed circular DNA (cccDNA) in the nucleus of hepatocytes and whether an antagonist strategy is developed, remain unknown.
Method: Expression and distribution of IFI16 in liver-derived cell lines were analyzed by using of western blotting and immunocellulerchemistry. The interaction between IFI16 and HBV DNA was analyzed using of chromatin immunoprecipitation. The effect of IFI16 and its fragments on HBV replication was tested in the cells cultures. IFI16 levels in peripheral blood mononuclear cell (PBMCs) of CHB patients were analyzed by using qPCR and western blotting.
Results: An interferon inducible and exclusively nuclear location of IFI16 was detected in HepG2 cells. Binding of IFI16 with nuclear cccDNA was detected in the stable HBV-replicating HepAD38 cells. IFI16 mostly translocated to cytoplasm and was degraded in the HepAD38 cell, and a blunted interferon inducible response was observed. The translocation and degradation of IFI16 in HepAD38 cells were inhibited by interferon treatment, cellular differentiation induction and inhibition of cccDNA formation. Cytoplasm fragment IFI16 significantly impaired the function of DNA sensors including IFI16, cGAS and DAI. IFI16 mRNA increased in PBMCs in the CHB patients with IFN therapy. The changes of IFI16 positively correlated with the HBeAg seroconversion and decline of serum HBV DNA levels. However, the long degraded fragment of IFI16 in PBMC correlated with high load of serum HBV DNA.
Conclusion: The innate immune DNA sensor IFI16 is differentiation inducible in hepatocytes. IFI16 recognizes nuclear HBV cccDNA but is degraded in cytoplasm. The degraded fragments negatively regulates the DNA sensors-related interferon signal pathway. Our results reveal a key mechanism of chronicity of HBV infection.

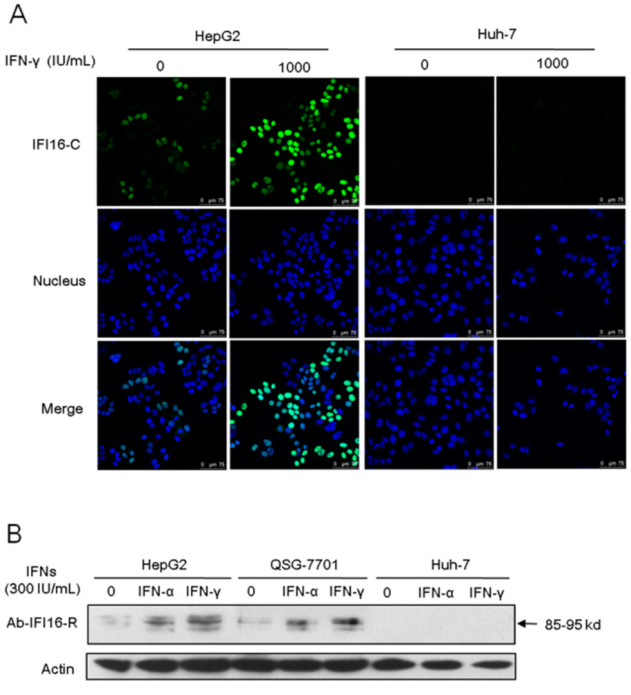

Figure 1: Interferon inducible expression of IFI16 in HepG2 cells.

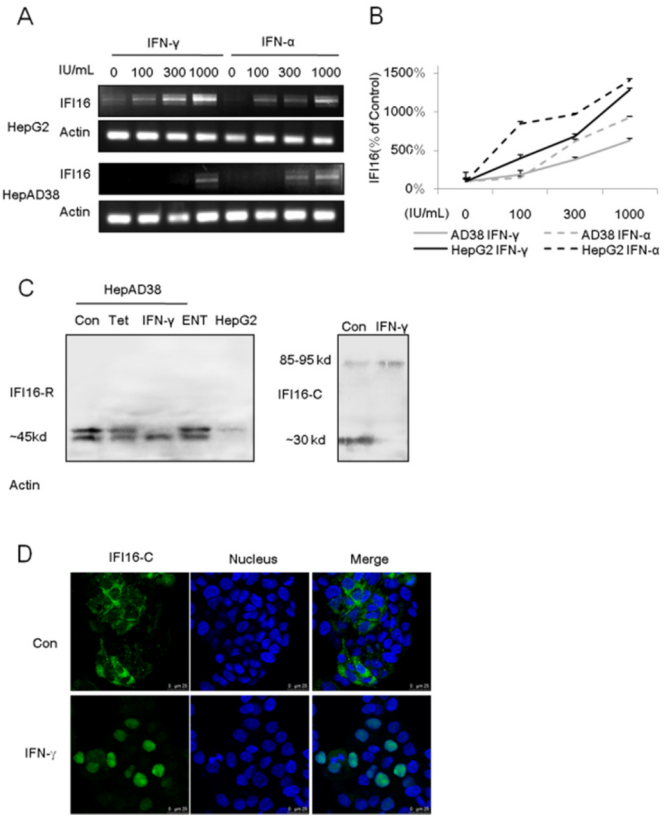

Figure 2: A blunted interferon inducible response of IFI16 in HepAD38 cells (A and B); Degradation and cytoplasmic translocation of IFI16 in HepAD38 cells were inhibited by interferon treatment (C and D).

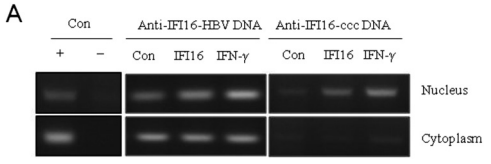

Figure 3: The binding of IFI16 and HBV DNA was detected by CHIP assay.

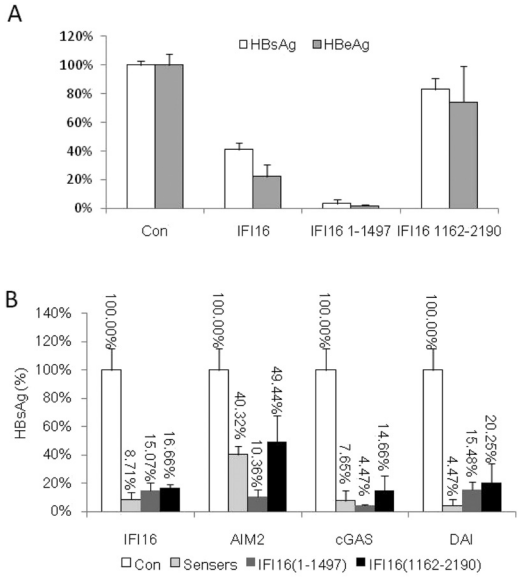

Figure 4: Cytoplasmic fragment of IFI16 inhibited functions of IFI16, cGAS and DAI to inhibit HBV replication.

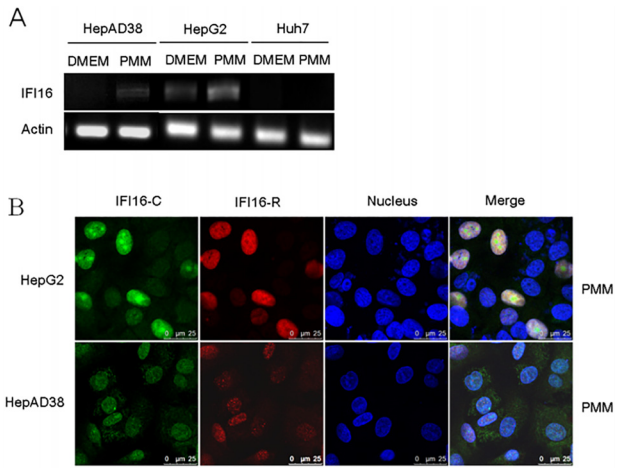

Figure 5: Cellular differentiation induced by PMM culture enhanced the IFI16 expression in HepG2 and HepAD38 cells, and leaded the relocation of cytoplasmic IFI16 into nucleus of HepAD38 cells.

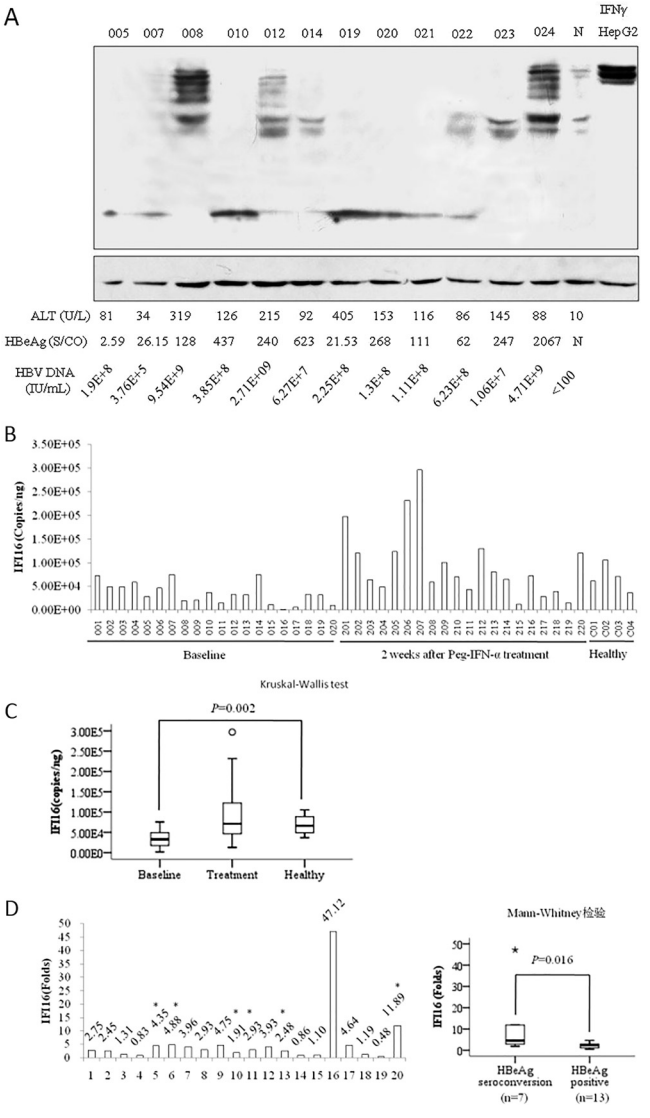

Figure 6: The degradation of IFI16 in PBMC of CHB patients. (A) The changes of IFI16 in PBMC of CHB patients treated with interferon-alpha. (B and C). Change folds of IFI16 in PBMC correlated with the HBeAg seroconversion of in CHB patients treated with IFN-a.

SAT-424

Upregulated innate immune responses in a hepatitis C virus exposed uninfected cohort

I. Shawa, K. Bennett, D. Sheridan, D. Felmlee, D. Hegazy, A. Ahmed, C. Wood, S. Jackson, G. Fejer, M. Cramp. *Plymouth University, Peninsula Schools of Medicine and Dentistry, Plymouth, United Kingdom*
Email: kbennett6@nhs.net

Background and Aims: We have previously defined a proportion of people who inject drugs (PWIDs) who despite a long history of sharing needles and other paraphernalia remain HCV uninfected. This exposed but uninfected (EU) cohort test negative for both HCV antibodies and RNA and exhibit a phenotype of resistance to HCV infection. We have previously reported low level T cell and humoral responses to HCV, but it remains unclear if these can prevent infection and recent evidence points to an important role for innate immune responses in control of HCV infection. The aim was to characterise antiviral innate cytokine responses in EU compared to healthy controls.
Method: 38 EUs and 11 controls were studied. Interferon alpha (IFN-a) production following overnight stimulation of peripheral blood mononuclear cells (PBMCs) with low infective doses of Influenza A virus H3N2 strain was assessed using enzyme-linked immunosorbent assay (ELISA). Influenza A virus was used at an approximate multiplicity of infection (MOI) of 0.14 (29.04×10^6 PFU), and 0.005 (9.68×10^6 PFU), categorized as low dose and very low dose respectively. MOI is the average number of virus particles infecting each cell. Unstimulated PBMCs and medium only were used as negative controls.
Results: EU cases produced significantly greater amounts of IFN-a in response to influenza following both low and very low dose exposure than healthy volunteers with the greatest difference following very low dose exposure.

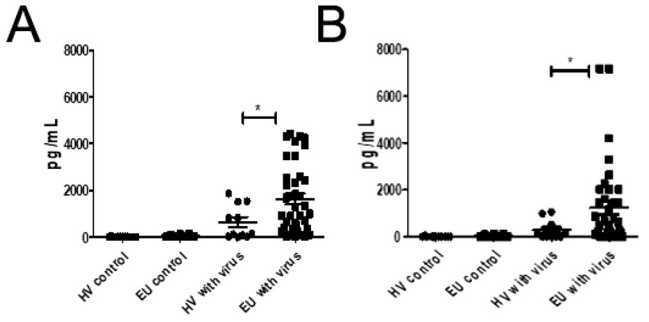

Figure: IFN-a secretion in response to (A) low dose influenza A virus (29.04×10^3 PFU) and (B) very low dose influenza A virus (9.68×10^3 PFU): EU cases show significantly greater IFN-α production in response to both low and very low dose Influenza A virus than healthy volunteers. The Wilcoxon signed rank test was used to determine the differences between the two cohorts ($p < 0.002$ and $p < 0.001$ respectively). HV = healthy volunteer. EU = exposed uninfected.

Conclusion: The increased IFN-a production in response to low dose influenza virus indicates an enhanced induction of early anti-viral innate cytokine responses in EU subjects. We suggest that following exposure to low doses of HCV an enhanced innate immune response may contribute to the resistance to clinical HCV disease seen in our EU cohort.

SAT-425

MicroRNA-181C potentially relieved fulminant viral heaptitis by targeting TNF-a in mice

D. Xi, M. Wang, Z. Zhang, J. Chen, F. Wang, Q. Ning. *Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Department and Institute of Infectious Disease*
Email: qning@vip.sina.com

Background and Aims: Hepatocyte apoptosis induced by tumor necrosis factor (TNF)-α/TNFR1 is an important pathway for the incidence of fulminant viral hepatitis. Accumulating evidence suggests that some microRNAs (miRNAs) are involved in severe exacerbation of hepatitis B. The relationship between circulating miRNAs and HBV associated acute-on-chronic liver failure (HBV-ACLF) needs to be further investigated. The purpose of our study was to identify the aberrant expression of miRNAs in HBV-ACLF and to investigate its potential role during the progression of HBV-ACLF.
Method: miRNA expression profile by miRNA microarray analysis was performed on pooled Peripheral Blood Mononuclear Cell (PBMC) obtained from patients with chronic hepatitis B (CHB) or HBV-ACLF, respectively. Selected unnormal expressed miRNAs were verified in more clinical samples by quantitative real-time PCR (qRT-PCR). A luciferase reporter assay was conducted to confirm whether TNF-α is a direct target of miR-181c. mmu-miR-181c agomir was delivered by tail vein injection into murine hepatitis virus (MHV)-3-infected BALB/cJ mice to evaluate its interference effect in fulminant viral hepatitis mouse model.
Results: The results from microarray analysis showed that 7 kinds of miRNAs were down-regulated and 9 kinds of miRNAs up-regulated in the PBMC of HBV-ACLF patients compared with that of patients with CHB. Among the deregulated miRNAs, the expression of hsa-miRNA-181c significantly decreased in HBV-ACLF, while serum TNF-α significantly increased. Furthermore, TNF-α was verified as a target of miR-181c by luciferase reporter assay. miR-181c significantly improved fulminant viral hepatitis mice survival rate from 0 to 30%, ameliorated inflammatory infiltration, hepatocyte necrosis and apoptosis, and prolonged survival time.

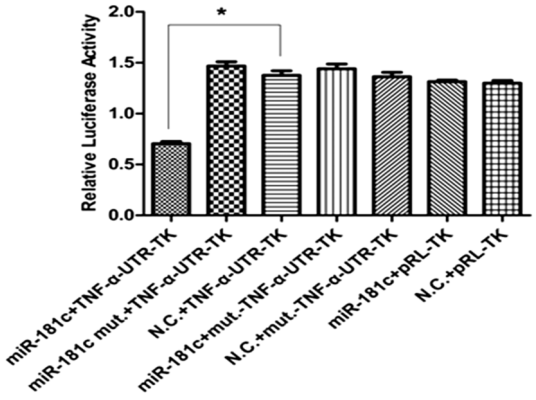

Figure: Luc-3′UTR reporter expression assay showed TNF-α was one target of miR-181c. Mut.-TNF-α-UTR: mutated TNF-α 3′-UTR, TK: pRL-TK vector.

Conclusion: Our data suggested that miR-181c might have therapeutic potential for the treatment of fulminant hepatitis.

SAT-426

HLA-A2 restricted CD8+ T cell immune hierarchy towards full length hepatitis E virus for T cell-based therapy in chronic HEV

C. Soon[1], M.S. Chen[2], M.P. Manns[3], H. Wedemeyer[4], M. Cornberg[1]. *[1]Hannover Medical School; [2]Karolinska Institutet; [3]Dept. of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany; [4]Department of Gastroenterology and Hepatology, University Clinic Essen, Essen, Germany*
Email: Soon.Chai@mh-hannover.de

Background and Aims: Hepatitis E virus (HEV) infection is often asymptomatic and resolves spontaneously in immunocompetent people. But in vulnerable individuals, especially immunosuppressed patients of solid organ transplantation, HEV infection could lead to chronic hepatitis. Currently, there is only one treatment option available for chronic HEV (ribavirin), which is not ideal as cases of resistance have been reported. We aim to identify immune hierarchy

of CD8+ T cells epitopes towards full length HEV, and characterize the immune functionality, as the basis to develop T cell-based therapy for chronic HEV patients.
Method: CD8+ T cells from acute HEV patients (n = 13) and HEV seronegative healthy persons (n = 8), all HLA-A2 positive, were expanded *in vitro* for 3 weeks using 15-mer HEV genotype 3 overlapping peptides, spanning all open reading frame-encoded proteins. T cell response was examined by intracellular cytokine staining and the frequency of HEV-specific CD8+ T cells was determined by staining of dextramers (bearing epitopes that are predicted *in silico*). 15-mer peptides that trigger robust cytokine production are narrowed down to 9-mer. HEV-specific CD8+ T cells were sorted using dextramer for T cell receptor (TCR) repertoire sequencing, the results were used in mRNA synthesis for TCR redirection assay. Donor lymphocytes redirected with TCR are co-cultured with T2 cells loaded with target peptide or with HEV-transfected HLA-A2 HepG2 cells.
Results: HEV-specific CD8+ T cell responses are found across ORF1 and ORF2, the non-structural and capsid part of the HEV genome, respectively. Notable responses are detected more in patients than in HEV-naïve healthy individuals. Of all the identified possible epitopes, only one was seen in both patient and healthy cohorts. This high hierarchy epitope, located in the RNA-dependent RNA polymerase (RdRP) region in ORF1, is then selected for further investigation. T cells with TCR of this epitope were sequenced; the results were used to generate gene constructs for TCR redirection assay. Post TCR redirection, not only the donor lymphocytes could bind to the same dextramer, the lymphocytes also recognize the cognate peptide presented by T2 cells, with significant MIP-1β, IFNγ and TNFα production within 7 hours of co-culturing. Cytokines production was also observed when TCR redirected lymphocytes were co-cultured with HEV-transfected HepG2 cells.
Conclusion: Our study identified potential HEV-specific CD8+ T cell epitope, which is vital to TCR design that possesses strong multi-functionality and specificity for T cell therapy.

SAT-427
Development and characterization of unique hepatitis C virus neutralizing antibodies associated with infection outcome

S.E. Baran[1], S. Eliyahu[1], A. Davidovich[1], M. Brown[2], M. Gal-Tanamy[1], A. Nimer[3]. *[1]Bar Ilan, Faculty of Medicine, Zafed, Israel; [2]Liver Institute, Rabin Medical Center, Sackler School of Medicine, Tel-Aviv University, Tel Aviv, Israel; [3]Western Galilee Hospital, Internal Medicine Department, Naharia, Israel*
Email: mgtanamy@gmail.com

Background and Aims: In most cases, HCV causes chronic infections, however 20–40% of infected individuals experience spontaneous recovery, suggested to be mediated by HCV-specific natural immunity. Therefore, using HCV as a model for comparing immune responses between spontaneous clearers (SC) and chronically infected individuals (CI), may empower identification of unique mechanisms dictating viral infection outcomes and designing vaccines and immunotherapeutics. We hypothesized that SC patients develop a unique set of HCV-specific antibodies with distinct properties, as compared to CI patients. We aimed to study the nature of successful immune response against HCV and develop effective HCV-neutralizing antibodies correlating with infection outcome.
Method: Sera and B cells from a panel of CI and SC patients and healthy controls were isolated. Sera were screened for HCV neutralization and binding and B cells for constructing two antibodies libraries, one from CI samples and second from SC samples, using phage display technology. Specific HCV-binding and neutralizing antibodies were isolated from these libraries and characterized.
Results: We have observed high level of HCV-specific antibodies in the sera of CI patients compared to low levels of antibodies in the sera of SC's. Nonetheless, high levels of HCV neutralization were observed with SC's sera, pointing for the presence of highly neutralizing antibodies in SC. Following five rounds of panning, we have isolated a panel of 10 unique antibodies; 3 from CI library and 7 from SC library. Antibodies isolated from SC library demonstrate moderate binding to genotype 1a HCV envelope protein E2 by ELISA, but higher HCV-neutralization efficiency, compared to those isolated from CI library. However, the Abs from CI demonstrated broader range of neutralization when tested with all HCV 7 genotypes compared to Abs from SC. Interestingly, three Ab isolated from SC showed high sequence similarity to Ab sequences present in HCV-specific B cells and were also enriched in total B-cell repertoires sequenced from cohorts of CI and SC by next generation sequencing.
Conclusion: This study suggests that SC patients exhibit unique, specific and efficient B cells response comparing to CI. The isolation of unique antibodies may open new avenues to effective immunoglobulin-based therapies that could prove helpful in preventing or treating HCV-related liver disease and would benefit vaccine development effort.

SAT-428
EP2 associated with the inflammatory storm in HBV related acute-on-chronic liver failure

Y. Wang, C. Chen, M. Zheng, J. Wo, F. Chen, Z. Chen, H. Zhu. *State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou 310003, China, Hangzhou, China*
Email: zhuhh72@zju.edu.cn

Background and Aims: Systemic inflammation is the major pathogenesis of HBV related acute-on-chronic liver failure (HBV-ACLF). EP2 (Prostaglandin E Receptor 2) and EP4 (Prostaglandin E Receptor 4) receptor are inhibitory receptors that regulate the balance of immunity. However, their sustained hypoexpression promotes excessive immune response. We investigated their role in the immune dysregulation in patients with ACLF.
Method: Blood samples were collected from 50 patients with HBV-ACLF, 50 patients with chronic hepatitis B (CHB), 20 patients with decompensated cirrhosis, and 48 healthy controls (HC). We measured the plasma cytokine levels with luminex and assessed whole blood or peripheral blood mononuclear cells (PBMC) for expression of EP2, EP4, Toll-like re-ceptors and HLA-DR on subsets of innate and adaptive immune effector cells. Immune responses to lipo-polysaccharide (LPS) or Escherichia coli (Ecoli) were measured by flow cytometry, to quantify cytokine production, bacterial phagocytosis and reactive oxygen species (ROS) production in the presence or absence of small molecular chemicals blocking against EP2.
Results: Antibacterial innate and adaptive immune responses were greatly enhanced in patients with HBV-ACLF, compared with controls. Patients with HBV-ACLF have higher levels of plasma cytokines than healthy controls. More PBMC from patients with HBV-ACLF produced IFN-γ in response to LPS, compared with controls. In addition, patients with HBV-ACLF had enhanced levels of neutrophil and monocytic ROS production in response to Ecoli stimulation, compared with controls (MFI of ROS produced in monocyte HC:ACLF = 4905:13336, $p = 0.003$; MFI of ROS produced in neutrophil HC:ACLF = 7366:29162, $p = 0.014$). EP2 expression on CD8+ T cells from patients with ACLF and decompensated cirrhosis, but not with CHB was lower than those from healthy controls (HC: ACLF = 44.5%:6.5%, $p < 0.01$). EP2 expression on CD8+ T cells was associated with the occurrence of multiple organ failure and level of plasma inflammatory cytokines. Small molecular chemicals against EP2 increased both cytokine producing PBMC and neutrophil and monocyte ROS production.
Conclusion: Down regulation of EP2 expression is associated with the occurrence of multiple organ failure and the high expression of inflammatory factors in patients with ACLF, which is related to the dysregulation of immune cell functions.

SAT-429

Cytokine-dependent activation of MAIT cells by the TLR8 agonist GS-9688 but not the TLR7 agonist GS-9620

S. Daffis, M. Morar, D. Pattabiraman, C. Voitenleitner, S. Fletcher, H. Javanbakht. *Gilead Sciences, Biology, Foster City, United States*
Email: Hassan.javanbakht@gilead.com

Background and Aims: GS-9688 is a selective small molecule agonist of toll-like receptor 8 (TLR8) in clinical development for the treatment of chronic hepatitis B (CHB). GS-9620 is an oral small molecule TLR7 agonist which has recently completed phase 2 studies in CHB patients. Oral GS-9688 and GS-9620 induce an immune response by pre-systemic activation of gut-associated and intrahepatic immune cells. Mucosal associated invariant T (MAIT) cells are innate-like T cells enriched in the gut and liver that likely play a role in host antiviral defense. Here we characterized in vitro activation of MAIT cells in human peripheral blood mononuclear cells (PBMCs) from healthy donors (HD) and CHB patients by GS-9688 and GS-9620.
Method: PBMCs obtained from HDs and age-matched CHB patients (n = 8) were treated for 18 hours with GS-9688 (156nM) or GS-9620 (10nM) and cytokines were analyzed by Luminex® assay. Intracellular levels of IFN-γ and TNF-α (antiviral cytokines), and granzyme B (a marker of cytotoxic function) in MAIT cells ($CD3^+TCR\gamma\delta^-CD161^+ V\alpha7.2^+$) were evaluated by flow cytometry.
Results: Consistent with previous studies, GS-9688 strongly induced IL-12p70 and IL-18, but had minimal effect on IFN-α (a TLR7-induced cytokine) in HD PBMCs. GS-9688 also strongly induced intracellular IFN-γ (38-fold increase), granzyme B (17-fold increase) and TNF-α (4-fold increase) levels in MAIT cells. Cytokine neutralization studies demonstrated that GS-9688 indirectly activates MAIT cells, predominantly via production of IL-12p70 and IL-18. The frequency of MAIT cells and activation by GS-9688 were comparable in PBMCs from HDs and CHB patients. GS-9620 induced dose-dependent IFN-α, but little to no IL-12p70 and IL-18 in PBMCs. Consistent with this cytokine profile, GS-9620 only weakly induced intracellular IFN-γ, granzyme B and TNF-α levels in MAIT cells.
Conclusion: In line with previous studies with prototypic TLR agonists, GS-9688 –but not GS-9620– strongly induced cytolytic and non-cytolytic functions of human MAIT cells in vitro. These data confirm that these innate-like T cells are indirectly activated by TLR8 but not TLR7 agonists, suggesting there are important immunological differences in the intrahepatic response induced by GS-9688 and GS-9620.

SAT-430

Characterization of theHEV-specific CD8+ T-cell response in acute and chronic hepatitis E virus infection

J. Kemming[1,2], M. Panning[3], M. Luetgehetmann[4], S. Pischke[4], J.S.Z. Wiesch[4], R. Thimme[2], C. Neumann-Haefelin[2]. *[1]Albert-Ludwigs University Freiburg, Faculty of Biology, Freiburg, Germany; [2]University Hospital Freiburg, Department for Internal Medicine II, Freiburg, Germany; [3]University Hospital Freiburg, Institute of Virology, Freiburg, Germany; [4]UKE Hamburg, 1. Medical Clinic, Hamburg, Germany*
Email: janine.kemming@uniklinik-freiburg.de

Background and Aims: Hepatitis E Virus (HEV) infection is one of the leading causes of viral hepatitis worldwide. Immune competent individuals clear infection spontaneously, whereas in immune suppressed patients chronic infection can occur, ultimately leading to liver cirrhosis and Hepatocellular Carcinoma (HCC).
In order to clear infection an effective virus-specific CD8+ T-cell response is compulsory for other viral hepatitis viruses. For HEV infection this CD8+ T-cell response to date has not been studied in detail. In this study we focused on the HEV-specific CD8+ T-cell response in acute and chronically HEV infected patients.
Method: We comprehensively studied the HEV-specific CD8+ T-cell responses of 22 HEV-infected patients with antigen-specific expansion, functional testing and pMHCI-tetramer stainings. Of the 22 patients, 13 patients were acutely infected, 4 had a chronic HEV infection and 5 patients resolved HEV infection.
Results: We identified the first 13 HEV-specific CD8+ T-cell epitopes to date which are restricted by the HLA alleles A*01:01, A*02:01, A*03:01, B*27:05 and B*3501. We were able to detect HEV-specific CD8+ T-cell responses in all resolvers and in the acutely infected patients, that contracted with time. The magnitude of the CD8+ T-cell response varied according to the HLA allele by which it was restricted. The 4 HLA-B27 restricted epitopes mounted the highest CD8+ T-cell responses. In HLA*B27+ patients up to 40% of bulk CD8+ T-cells stained *ex vivo* were specific for single HEV-specific epitopes. None of the chronic HEV Patients was HLA-B*27:05 positive. The HEV-specific CD8+ T-cell response in the chronic patients was diminished in comparison to the acute disease course, but was partially restored after ribavirin therapy.
Conclusion: Here we show a putative role for host factors like HLA alleles in HEV infection and that a strong and specific CD8+ T-cell response is associated with viral clearance whereas a weak CD8+ T-cell response is associated with viral persistence.

SAT-431

A pan-genotype HCV T cell vaccine, in a simian adenovirus vector, to target T cell epitopes conserved across multiple HCV genotypes

T. Donnison[1], A. von Delft[1], S.K. Chinnakannan[1], J. Lourenco[2], C. Hutchings[1], A. Brown[1], P. Klenerman[1], E. Barnes[1]. *[1]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom; [2]University of Oxford, Department of Zoology, Oxford, United Kingdom*
Email: ellie.barnes@ndm.ox.ac.uk

Background and Aims: The development of a prophylactic hepatitis C virus (HCV) vaccine has been hindered by viral genomic variability. A phase-I human clinical trial demonstrated that a viral vector T-cell vaccine encoding a subtype-1b HCV immunogen (non-structural proteins 3 to 5) induces HCV-specific T-cell responses targeting dominant epitopes that are highly variable and have reduced cross-recognition of variants at the population level. Therefore, we generated simian adenovirus vaccines encoding an immunogen with genetic sequence that is conserved between HCV genotypes with genetic adjuvant, truncated class-II shark invariant chain, sIi(tr) aa47-72.
Method: Combined conserved segments formed novel immunogens for HCV genotypes 1 and 3, and 1–6. Putative artificial epitopes in junction regions were abrogated. *In silico* analysis enabled exclusion of potential cross-reactive human self-peptides and identified HCV T-cell epitopes. Simian adenoviral vaccine vectors encoding the HCV immunogen (ChAdOx1-gt1-6) were constructed with and without sIi (tr). Immunogenicity was evaluated in inbred and outbred mice at 10^{7-8} IU single intramuscular dose, using both genotype-specific and conserved sequence peptide pools in *ex vivo* IFN-γ ELISpot assays and intracellular staining. A genotype-1b HCV immunogen, encoding non-structural proteins 3–5 in the ChAdOx1 vector, was used as a control.
Results: ChAdOx1 conserved segment HCV vaccines primed high-magnitude, broad, cross-reactive T-cell responses in inbred and outbred mice. The mean magnitude of Gt1-6L-induced total T-cell responses was 795 and 859 IFN-γ spot forming units (SFU)/10^6 splenocytes for genotype-1a and -3a peptide pool stimuli, respectively, in outbred mice. Immunogens containing shark invariant chain (sIi; aa47-72) induced T cells with enhanced immunogenicity to genotype-specific peptide pool stimuli. $CD8^+$ and $CD4^+$ cytokine-producing T cells were specific for HCV sequences that have high percentage sequence identity across all HCV genotypes. *In silico* analysis showed that conserved immunogens contain multiple epitopes described in natural HCV infection.
Conclusion: Novel pan-genotypic HCV simian adenoviral vectored vaccines, with genetic adjuvant sIi(tr), encoding conserved segments from all major HCV genotypes, contain multiple T-cell epitopes described in human infection, and are immunogenic in mice. These

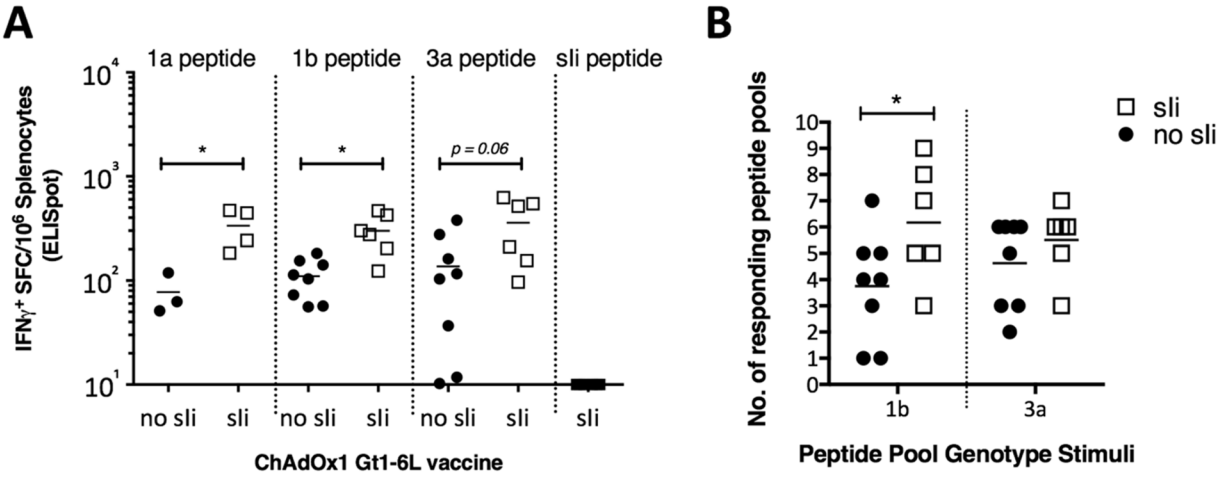

Figure: (abstract: SAT-431): *Ex vivo* IFN-γ ELISpot data displaying the total magnitude (A) and breadth (B) of the HCV genotype-specific T cell response in CD-1 outbred mice three weeks after a single 10^7 infectious unit (IU) intramuscular prime vaccination.

studies pave the way for the assessment of pan-genotypic HCV T-cell vaccines in humans.

SAT-432

Performance of recomWell HEV and Wantai HEV in acute Hepatitis E and German blood donors

S. Schulz, F. Struck. *Mikrogen GmbH, Neuried, Germany*
Email: schulz@mikrogen.de

Background and Aims: Hepatitis E virus (HEV) is now known to be endemic in Europe and often described as the most frequent viral cause for acute hepatitis. HEV ELISA test systems are used routinely as screening assays in serological diagnostics and for epidemiological studies. In this evaluation the performance of the improved versions of *recom*Well HEV IgG, IgM was compared to Wantai HEV IgG, IgM. Both brands represent the two most commonly used commercial HEV ELISA assays in Europe.

Method: Diagnostic sensitivity of *recom*Well HEV IgM (new) and Wantai IgM was evaluated using 89 well-defined samples from patients with confirmed acute HEV infection. PCR-positive patient samples of various HEV genotypes and subsequent follow-up samples from one PCR-positive blood donor have been analyzed. Diagnostic specificity of *recom*Well HEV IgM (new) and Wantai IgM was determined with a panel consisting of 359 samples (200 blood donors, 159 patient samples, clinical suspicion of non-E-hepatitis confirmed as HIV, HCV, HAV, Parvo B19, EBV, or CMV pos.). 200 sera from healthy German blood donors have been analyzed with *recom*Well HEV IgG (new & previous version) and Wantai IgG in order to determine seroprevalences.

Results: *Recom*Well HEV IgM shows excellent diagnostic sensitivity, achieving 98.9%. Only one serum from a total of 89 was not found positive, whereas Wantai HEV IgM missed 6 sera, reaching a sensitivity of 93.3%. Furthermore, *recom*Well HEV IgM is reactive in all PCR-positive patient samples with various genotypes (1a, 3a and 4b, d, f), whereas Wantai IgM is missing one sample. Analysis of paired samples demonstrates that *recom*Well HEV IgM detects IgM specific antibodies for several months starting at the end of the viremic phase. Interestingly, Wantai HEV IgM is not able to detect specific antibodies in any sample of this PCR-positive individual. Both test systems, *recom*Well HEV IgM and Wantai HEV IgM, show a convincing diagnostic specificity of 98.6%. Analysis of 200 German blood donors results in similar HEV seroprevalences for *recom*Well IgG (33%) and Wantai IgG (32%). The clear improvement in sensitivity is demonstrated by the comparison of the new (33%) and previous version (18.5%) of *recom*Well HEV IgG.

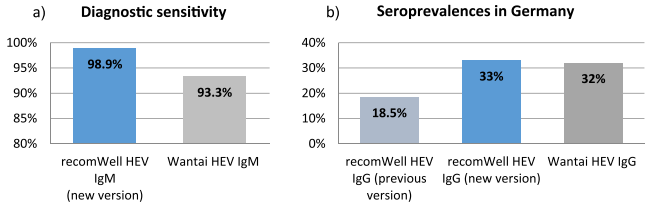

Figure: (a) Diagnostic sensitivity, 89 well-defined patient samples with confirmed acute HEV infection (b) Seroprevalences in Germany (200 healthy blood donors).

Conclusion: Yielding a diagnostic sensitivity of 98.9% *recom*Well HEV IgM performs better compared to Wantai HEV IgM with 93.3%. Furthermore, *recom*Well HEV IgM picks up all PCR-positive samples, including various genotypes, whereas Wantai IgM misses 2 samples. Diagnostic sensitivity for IgG antibodies is similar to Wantai HEV IgG, as reflected by the determination of comparable seroprevalences for German blood donors. In summary, *recom*Well HEV assays are highly suitable for the detection of acute Hepatitis E as well as seroprevalence studies.

SAT-433

Ex vivo characterization of co-inhibitory molecules on MHC class II tetramer positive HCV-specific CD4+ T cells in HCV infection

C. Ackermann[1], S. Kummer[1], M. Smits[2], V. Matzat[1], F. Piecha[1], J. Eberhard[1], T. Böttler[2], J.S.Z. Wiesch[1]. [1]*University Medical Center Hamburg-Eppendorf, I. Department of Internal Medicine, Hamburg, Germany;* [2]*University Hospital Freiburg, Department of Medicine II, Freiburg im Breisgau, Germany*
Email: c.ackermann@uke.de

Background and Aims: In acute HCV infection $CD4^+$ T cells lose their functionality and the infection becomes chronic in a majority of patients. Up-regulation of inhibitory receptors may be a critical step in the development of T cell dysfunction in chronic infection. The comprehensive analysis of this loss of function, including the exact expression profiles and (co-)blockade of these coinhibitory and coactivatory molecules will help to understand the development of chronification versus protection in HCV infection and other viral infections.

Method: MHC class II tetramer-associated magnetic bead enrichment technique and multicolor cytometry were perfomed with PBMCs from patients with acute (n = 10), chronic (n = 8) and resolved (n = 6) HCV infection to assess the expression of different inhibitory and stimulatory markers on total and specific $CD4^+$ T cells. The cells

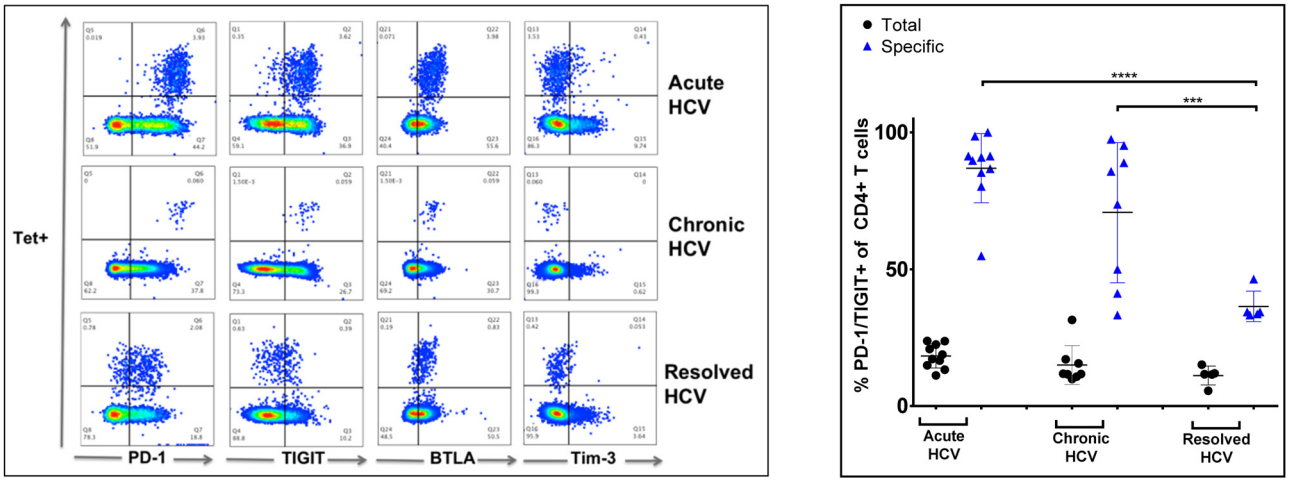

Figure: (abstract: SAT-433)

were stained with fluorescently conjugated monoclonal antibodies against CD3, CD4, CD45RO, CCR7, PD-1, TIGIT, BTLA, Tim-3, Ceacam1, LIGHT, OX40, CD226 and LIVE/DEAD™ Fixable Near-IR. Stained and fixed cells were analyzed by flow cytometry using BD LSRFortessa™.
Results: We were able to detect HCV-specific $CD4^+$ T cells from patients with acute (n = 10), chronic (n = 8) and resolved (n = 6) HCV infection using HLA-DRB1*01:01, DRB1*04:01 and DRB1*15:01-restricted tetramers. In agreement with previous studies, we observed significantly higher ($p = 0.0054$) frequencies of HCV-specific $CD4^+$ T cells during acute compared with chronic infection. Almost all HCV-specific $CD4^+$ T cells show an effector memory (EM) phenotype (CD45RO + CCR7-) independ of the infection state. Nevertheless, we found in slight decrease ($p = 0.0287$) in the EM phenotype of specific $CD4^+$ T cells from patients with chronic compared to acute HCV infected patients. We analyzed the expression pattern of different inhibitory and stimulatory receptors from patients with acute, chronic and resolved HCV infection and found an increased inhibitory receptor expression level on specific $CD4^+$ T cells from patients with acute and chronic HCV infection compared to patients which spontaneously eliminate the virus. Especially, the PD-1 and TIGIT co-expression was significantly higher ($p < 0.0001$) on specific $CD4^+$ T cells from acute and chronic infected patients.
Conclusion: Increased inhibitory receptor expression play a crucial role in the development of T cell dysfunction. We found an increased expression of the inhibitory markers TIGIT and PD-1 on HCV-specific $CD4^+$ T cells. To block molecules such as TIGIT and PD-1 separately or in combination will depend on deeper knowledge of expression patterns and underlying molecular mechanisms. However, these findings reveal TIGIT together with PD-1 as a novel marker of dysfunctional HCV-specific $CD4^+$ T cells and suggest TIGIT along with other checkpoint receptors may be novel curative targets to reverse T cell exhaustion.

SAT-434
Association of PD1 and TIM3 polymorphisms with HBV susceptibility

C. Huang[1], C. Xia[1,2], H. Zhu[1], J. Wo[1], F. Chen[1], M. Zheng[1], Z. Chen[1]. [1]*The State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital of School of Medicine, Zhejiang University, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China, Hang Zhou, China;* [2]*Department of Infectious Diseases, Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou, China.*
Email: chenzhi@zju.edu.cn

Background and Aims: Programmed cell death 1 (PD1) and T-cell immunoglobulin and mucin domain-containing molecule 3 (TIM3) play important roles in regulating immune reaction of hepatitis B virus (HBV) infection. Whether the genetic variants of PD1 and TIM3 can influence the susceptibility and progression of HBV infection or not has not been confirmed. In this article, we tried to investigate the relation of PD1 and TIM3 polymorphisms with HBV infection.
Method: Four PD1 single-nucleotide polymorphisms (SNPs) (rs10204525, rs2227982, rs41386349, rs36084323) and three TIM3 SNPs (rs1036199, rs10515746, rs11742259) were genotyped by TaqMan probe in 898 HBV-infected patients and 364 healthy controls of South China. The 898 patients include 222 asymptomatic carriers (AsC), 276 chronic hepatitis B (CHB), 105 acute on chronic liver failure (ACLF) and 295 liver cirrhosis (LC). The association of the SNP sites with HBV infection was then analyzed using statistical methods.
Results: SNP rs10204525 and rs2227982 of PD1 are significantly associated with HBV infection. Per rs10204525, its odds ratio (OR) is 0.823, 95% confidence interval (CI) is 0.679–0.997 and p = 0.046; per rs2227982, its OR is 1.231, 95%CI is 1.036–1.463 and p = 0.018. On the contrary, SNP rs1036199 and rs10515746 of TIM3 have lower frequency in HBV patients. Per rs1036199, its OR is 0.430, 95%CI is 0.206–0.894 and p = 0.020; per rs10515746, its OR is 0.430, 95%CI is 0.206–0.894 and p = 0.020. Further haplotype-based association analysis indicates that haplotype block AT, formed by SNPs rs10204525 and rs2227982 is significantly associated with HBV infection (OR = 1.230, 95%CI = 1.035–1.463, p = 0.019).
Conclusion: Rs10204525 and rs2227982 of PD1, and rs1036199 and rs10515746 of TIM3 associate with HBV infection.

SAT-435
Preclinical mechanistic and efficacy evaluation of a novel small molecule TLR7 agonist RO7020531 for the treatment of chronic hepatitis B

L. Dai[1], X. Yu[1], Y. Yu[1], L. Gu[1], J. Zhao[1], L. Zhu[1], G. Ottaviani[2], H. Yun[1], M. Ait-Goughoulte[2], M. Ilnicka[2], J. Xie[1], L. Wang[2], A. Feng[1], J. Young[2], L. Gao[1]. [1]*Roche Innovation Center Shanghai;* [2]*Roche Innovation Center Basel*
Email: lu.gao@roche.com

Background and Aims: Chronic hepatitis B (CHB) is a major global healthcare problem. Functional impairment of immune responses is a key feature of chronic HBV infection. An immune enhancer is needed to restore HBV-specific B- and T cell responses. An orally available small molecule RO7020531 is currently being tested in Phase I with the potential to modulate immune responses against HBV infection. Here we report the key features of this compound and its anti-HBV effect in preclinical studies.

Method: In vitro assessments of the potency, specificity, and cytotoxicity were performed using appropriate cell lines overexpressing TLR3, 7, 8, and 9 and human PBMC. In vivo efficacy was studied in a mouse model with a recombinant adeno associated virus carrying hepatitis B virus genome (AAV HBV) in either C57BL/6 mice or SCID mice. The levels of HBV DNA, HBsAg, and HBeAg in mouse serum were measured by quantitative polymerase chain reaction (qPCR), HBsAg chemiluminescent immunoassay (CLIA), HBeAg CLIA kits, and mouse IgG ELISA development kit, respectively.
Results: RO7020531 is a double prodrug of RO7011785, a TLR7-selective agonist. Ex vivo stimulation of human PBMCs by RO7011785 led to the induction of IFNα and various cytokines and chemokines, such as TNFα, IL-6 and IP-10. Depletion of plasmacytoid dendritic cells (pDC) and monocytes in PBMC greatly reduced the production of IFNα and IL-6, respectively, induced by RO7011785. In a mouse model, RO7020531 stimulated type I interferon response mainly in the spleen and lymph nodes, but not in the gastrointestinal (GI) tract. Moreover, anti-HBV effects of RO7020531 were observed in a dose-dependent manner in the AAV-HBV mouse model, where the TLR7 agonist significantly reduced the levels of HBV DNA and HBsAg. The innate immune response triggered by RO7020531, such as the upregulation of cytokines and interferon-stimulated genes (ISG), were recapitulated in the AAV-HBV model. Notably, the ability of RO7020531 to suppress viremia and to reduce HBsAg was dependent upon adaptive immune responses, since these antiviral effects were largely abrogated in the AAV-HBV model using SCID mice where T and B cells were absent. Indeed, we confirmed that RO7020531 promoted the emergence of anti-HBs antibody in the serum and increased HBsAg-specific T and B cells in the spleen.
Conclusion: The small molecule RO7020531 represents a promising anti-HBV agent with the potential to trigger innate and HBV-specific adaptive immune responses to reduce HBV DNA and HBsAg. These unique features warrant further evaluation of the anti-HBV efficacy of this molecule in a clinical setting.

SAT-436

A systematic comparison reveals dynamic differences in early adaptive immune responses of acute-resolving versus chronic HBV replication

Q. Wang, Y. Liu, D. Yang, J. Liu. *Department of infectious diseases, Wuhan, China*
Email: jialiu77@hotmail.com

Background and Aims: Chronic hepatitis B virus (HBV) infection has been characterized by lack of effective adaptive immune responses which are vital for the viral clearance. However, very little is known about the dynamics of adaptive immune responses during the early phase of chronic HBV infection especially in the spleen and the liver.
Method: We kinetically characterized the feature differences of adaptive immunity, including the frequencies, phenotypes and function of antigen presenting cells and T cells in the spleen, the PBMCs and the liver, of chronic versus acute-resolving HBV replication by using hydrodynamic injection (HI) mouse model.
Results: We found that, both mice with acute-resolving HBV replication (AR mice) and mice with chronic HBV replication (CH mice) showed early splenomegaly accompanied by T cell expansion in spleen but not in liver after HI. Interestingly, CH mice showed early and continuous increase of HBV specific CD8+ T cells in spleen in a comparable extent to that in the AR mice. However, the splenic T cells of CH mice showed no activation phenotype compared with those in AR mice. Besides, increases of activated effector CD8+ T cells in PBMCs and liver at later time points were only observed in AR mice but not CH mice. CH mice also showed insufficient dendritic cells (DCs) expansion in spleen and increased DCs PD-L1 expression in liver compared to AR mice. Adoptive transferring total splenocytes or splenic CD8+ T cells of AR mice to CH mice revealed that their ability in breaking HBV tolerance varies at different stages of HBV clearance. Moreover, inducing functional activation of endogenous HBV specific CD8+ T cells of CH mice was achieved through adoptive transfer of splenocytes from AR mice.
Conclusion: Our results suggest that early T cell priming and expansion firstly happen in periphery after HBV antigen exposure in both acute-resolving and chronic replication. The paucity of T cell activation, and following migration and liver infiltration is a key feature of the adaptive immune responses during the early phase of chronic HBV replication, which is probably caused by the dysfunction of DCs. Fully viral clearance and activation of endogenous CD8+ T cells are achievable during this phase through adoptive transfer of splenocytes from AR mice.

Alcoholic liver disease

SAT-441

Alcoholic liver disease replaces HCV infection as the leading indication for liver transplantation in the United States

G. Cholankeril[1], A. Goel[1], P. Puri[2], A. Ahmed[1]. *[1]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, Stanford, United States; [2]Virginia Commonwealth University, Division of Gastroenterology, Hepatology and Nutrition, Richmond, United States*
Email: georgetc@stanford.edu

Background and Aims: The arrival of second-generation direct-acting antiviral agents has reduced the burden of chronic hepatitis C virus (HCV) on the liver transplant (LT) allocation system in the United States (US). However, recent trends have also demonstrated a rise in alcohol use and alcohol-related mortality in the US. Therefore, our aim was to evaluate current trends among the leading indications for liver transplantation in the US.
Method: Using the United Network for Organ Sharing (UNOS) registry, we evaluated annual waitlist additions and LT trends in patients for the three leading indications of chronic liver disease (CLD), (1) HCV, (2) alcoholic liver disease (ALD), and (3) non-alcoholic steatohepatitis (NASH) for LT in the US from January 1, 2012 to October 31, 2017. Etiology of CLD was determined through diagnoses codes and HCV serology and categorized in mutually exclusive cohorts. Patients listed as Status 1A, received prior LT or had concomitant hepatocellular carcinoma were excluded. Clinical demographics and characteristics among waitlist additions were compared using Chi-square test for categorical variables and Kruskal-Wallis for quantitative variables.
Results: During the study period, the annual number of waitlist additions and liver transplant surgeries due to CLD was 2.1% and 7.6%, respectively. From 2012 to 2015, HCV remained the leading etiology among CLD waitlist additions (28%) and LT recipients (24%). Since 2016, ALD was the leading indication for waitlist additions in the US (ALD 28%, HCV 25%, NASH 19%, $p < 0.001$). ALD (31%) and NASH (21%) has accounted for over half of CLD waitlist additions in 2017.
From 2016 onwards, both ALD and NASH have surpassed HCV as the first and second leading indications for LT for CLD, respectively (Figure). There was a notable reduction in the annual percentage of LT recipients with HCV, declining to 17% in 2017. Compared to HCV and NASH waitlist additions from 2015 to 2016, ALD waitlist additions were significantly younger in age (ALD 54, IQR [47–51]; HCV 59, [IQR 55–63]; NASH 60 IQR [54–65]; $p < 0.001$) but had a higher severity of hepatic decompensation including median Model for End-Stage Liver Disease score at listing (ALD 21, IQR [15–30]; HCV 14, IQR [10–21]; NASH 17 IQR [13–24]; $p < 0.001$).

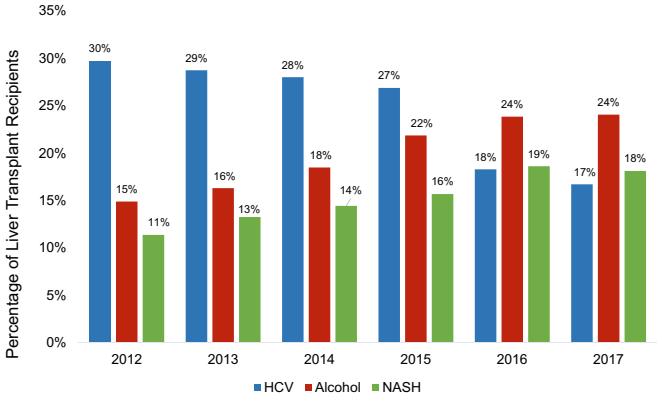

Figure: Annual Trends in the three Leading Indications for Liver Transplantation in the United States.

Conclusion: ALD has now become the leading indication for liver transplantation in the US. However, patients with ALD are presenting for LT with a higher severity of illness than other patients with CLD. Drastic measures are needed to aggressively address these ominous trends in the rising rates of ALD-related liver transplantation.

SAT-442

Individualized prediction of the risk of liver-related death in patients with alcoholic cirrhosis

M. Astrid[1], J. Henrion[2], K. Jean-François[3], S. Florent[4], T. Eric[5], C. Moreno[5], D. Pierre[5,6]. *[1]CHU UCL Namur, Department of Gastroenterology and Hepatology, Yvoir, Belgium; [2]Jolimont Hôpital, Department of Gastroenterology and Hepatology, La Louvière, Belgium; [3]Université de Lausanne, Laboratory for Investigative Neurophysiology (The LINE), Department of Radiology and Department of Clinical Neurosciences, Lausanne, Switzerland; [4]École polytechnique fédérale de Lausanne, Lausanne, Switzerland; [5]Hôpital Erasme, Université Libre de Bruxelles, Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Brussels; [6]Clinique Saint-Luc Bouge, Department of Gastroenterology and Hepatology, Namur, Belgium*
Email: pierre.deltenre01@gmail.com

Background and Aim: In patients with cirrhosis, prognostic models providing a precise estimate of the risk of death are essential for patient care. The aim of this work was to develop a model allowing an individualized prediction of the risk of liver-related death among patients with alcoholic cirrhosis, that takes into account the impact of abstinence.

Method: Data related to death and causes of death were collected among patients with alcoholic cirrhosis consecutively seen in a single center during a 21-year period. Abstinence was defined as discontinuation of any alcohol intake within the first 12 months following inclusion. Multivariate Fine and Gray proportional hazards models were used to identify factors associated with liver-related death. We calculated Akaike information criterion values by adding variables using a forward step by step approach to build the best competing risk regression (CRR) model that predicts liver-related death. To validate the prediction of the model, a cross validation procedure was applied using a training set of 80% and a testing set of 20% of the data randomly chosen. The Brier score was used to estimate the quality of the prediction of the different models tested, the model with the lowest Brier score providing the best prediction.

Results: 489 patients (68% of male, median age 55 years [95% CI: 54–56], 45% Child-Pugh stages B or C, median MELD score 9.0 [95% CI: 8.5–9.7]) were included. During follow-up (median, 57 months), 247 patients died, 12 from hepatocellular carcinoma, 156 from liver failure and 76 from non-liver related causes. Three variables were independently associated with liver-related mortality: age (HR: 1.02, 95% CI: 1.01–1.04, $p = 0.01$), Child-Pugh score (HR: 1.20, 95% CI: 1.11–1.29, $p < 0.001$) and abstinence (HR: 0.42, 95% CI: 0.28–0.63, $p < 0.001$). A CRR model using these 3 variables as covariates was built, providing a continuum risk of death at 5 years in abstainers (Figure 1) and consumers (Figure 2). For any combination of age and Child-Pugh score, patients who did not abstain from alcohol had a greater risk of dying at 5 years than patients who abstained from alcohol. According to the Brier score, the prediction of liver-related death at 5 years was better using the CRR model than with the random model in 100% of the cases, with the Kaplan Meier model in 93%, and with the Cox model in 92%. The prediction of liver-related death was not better when the MELD score was used in the CRR model instead of the Child-Pugh score.

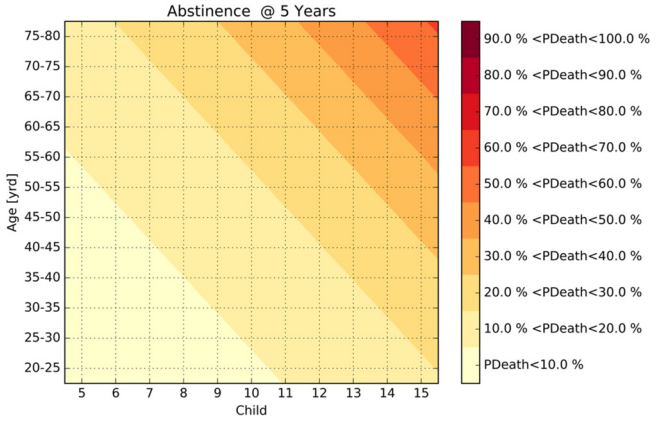

Figure 1

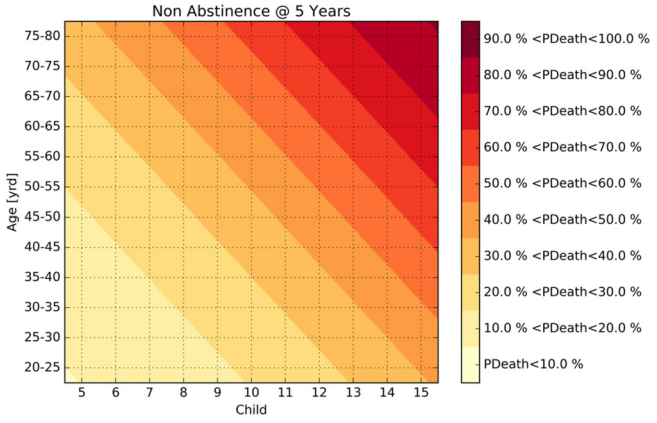

Figure 2

Conclusion: The CRR model combining age, Child-Pugh score and abstinence accurately predicts the risk of liver-related death on an individual basis among patients with alcoholic cirrhosis. Huge differences in 5-years prediction of death were observed in patients who abstained and who did not abstain from alcohol. This model may serve as a tool for prognosis assessment in a daily practice and may help to motivate patients to stop drinking.

SAT-443

Liver transplantation for alcoholic hepatitis: a systematic review with meta-analysis

M. Astrid[1], D. Margaux[2], T. Eric[3], C. Moreno[3], D. Pierre[3,4]. *[1]CHU UCL Namur, Department of Gastroenterology and Hepatology, Yvoir, Belgium; [2]CHUV Centre hospitalier universitaire vaudois, Division of Gastroenterology and Hepatology; [3]Hôpital Erasme, Université Libre de Bruxelles, Department of Gastroenterology, Hepatopancreatology, and Digestive Oncology; [4]Clinique Saint-Luc Bouge, Department of Gastroenterology and Hepatology, Namur, Belgium*
Email: pierre.deltenre01@gmail.com

Background and Aims: The rate of alcohol relapse among patients who underwent liver transplantation for alcoholic hepatitis (AH) is not precisely known. The aim was to synthesize the available evidence on liver transplantation for AH to assess alcohol relapse and 6-month survival.
Method: Meta-analysis of trials evaluating liver transplantation for AH, either clinically severe or diagnosed on the explant.
Results: Eleven studies were included. The pooled estimate rate for alcohol relapse was 0.22 (95% CI = 0.12–0.36) in overall analysis with high heterogeneity between studies (I^2 = 76%), 0.20 (95% CI = 0.07–0.43) in the subgroup analysis including patients with clinically severe AH (I^2 = 84%), 0.14 (95% CI = 0.08–0.23) among patients with clinically severe AH in sensitivity analysis excluding the discrepant studies that did not use stringent selection criteria for liver transplantation (I^2 = 0%), and 0.15 (95% CI = 0.07–0.27) for recurrent harmful alcohol consumption among patients with clinically severe AH (I^2 = 3%). The risk of alcohol relapse was not different between AH transplanted patients and patients with alcoholic cirrhosis who underwent elective liver transplantation in sensitivity analysis excluding the discrepant studies (OR = 1.68, 95%CI = 0.79–3.58, p = 0.2, I^2 = 16%). The pooled estimate rate for 6-month survival was 0.85 (95% CI = 0.77–0.91, I^2 = 49%), and 0.80 among patients transplanted for clinically severe AH (95% CI = 0.69–0.88, I^2 = 30%). AH transplanted patients had as good 6-month survival as patients who underwent elective liver transplantation (OR = 2.00, 95% CI = 0.95–4.23, p = 0.07, I^2 = 0%).
Conclusion: Using stringent selection criteria, 14% of patients with clinically severe AH have alcohol relapse after liver transplantation. The percentage of alcohol relapse of AH transplanted patients is similar than that of patients who underwent elective liver transplantation.

SAT-444

Heparin like effect increases risk of mortality and bleeding tendency in patients with severe alcoholic hepatitis during systemic Inflammatory Response (SIRS) and sepsis

M. Premkumar[1], P. Saxena[2], R. Mirza[2], P. Jain[3], P. Bhatia[4], G. Kumar[3], S. Sukriti[5], C. Bihari[2], A. Choudhury[6], S.K. Sarin[7]. Email: drmadhumitap@gmail.com

Background and Aims: Rebalanced coagulation in liver disease is set to a lower level, and despite an increased prothrombin time (PT),

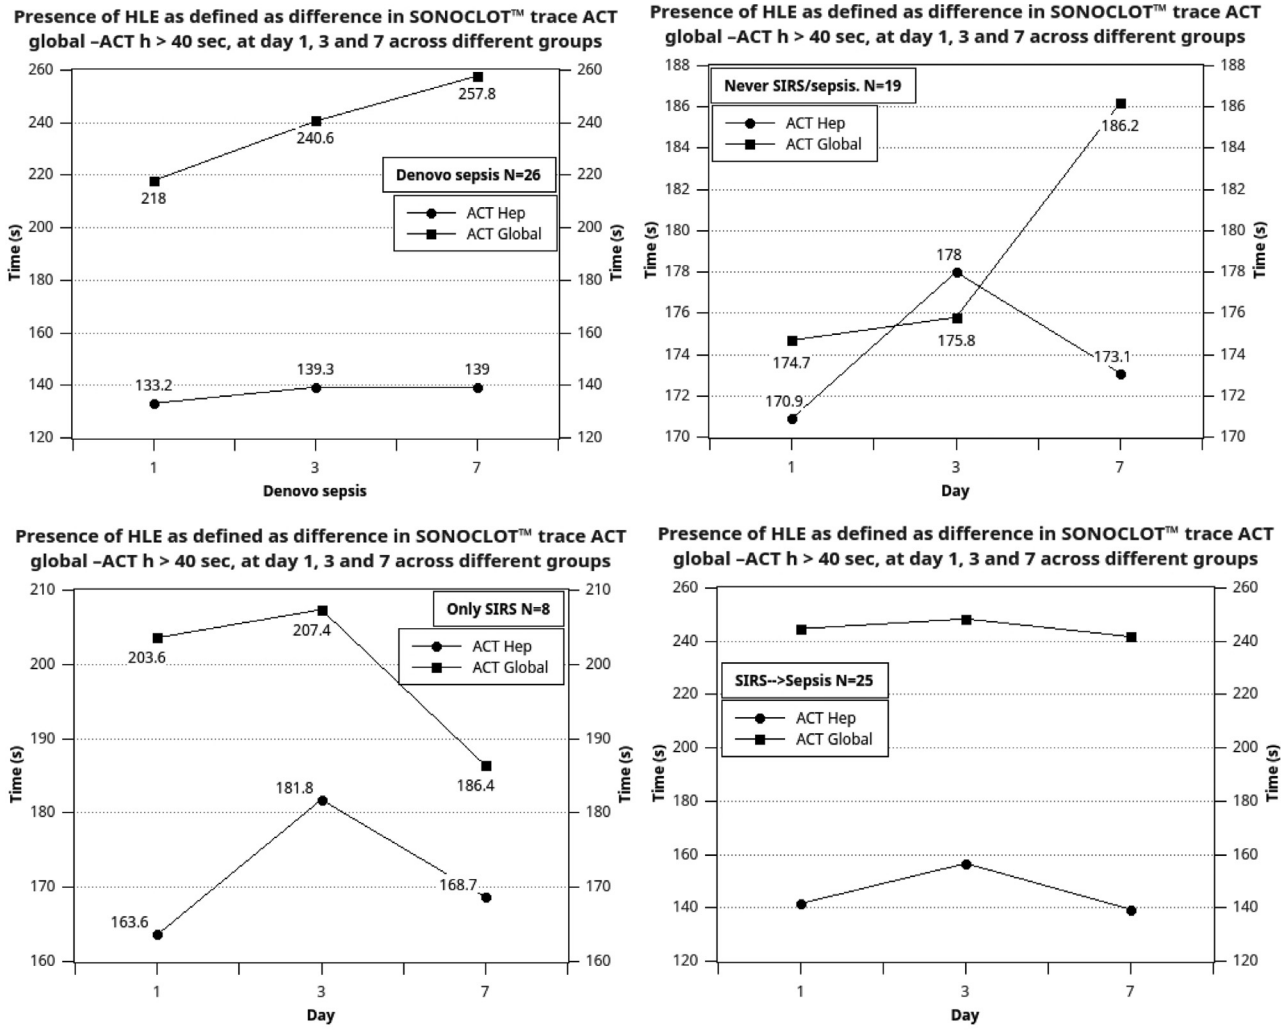

Figure 1: (abstract: SAT-444)

bleeding may only be caused when superadded factors like infection supervenes. The later could be due to generation of endogenous heparinoids or a heparin like effect (HLE) due to sepsis. The coagulation dysfunction in alcoholic hepatitis is not well studied.
Methods: Consecutive patients with severe alcoholic hepatitis (SAH), defined as Discriminant function (DF) >32;[DF = 4.6 × (patient's PT (seconds) – control's PT) + serum bilirubin level (in mg/dl)], who had no sepsis at presentation, were assessed at day 0, 3, and 7 for development of SIRS/sepsis, changes in coagulation parameters, disease progression and bleeding events. A global coagulation assay called SONOCLOT™ (global and heparinized) to measure the HLE, and specific assays i.e. factor VIII, vonWillebrand factor (vWF), protein C (PrC) and antithrombin III (AT), tissue plasminogen activator, tissue factor and plasminogen activator inhibitor were measured at the mentioned time points. These were compared with conventional parameters like platelet count, activated partial thromboplastin time and international normalized ratio (INR).
Results: Out of 145 screened patients with SAH, 78 (44.3 ± 11.7 years; 97% male) with no evidence of sepsis were recruited. At day 0, HLE was present in 20 (71.4%) and severe HLE was noted in 7 (25%) patients with SIRS. Presence of HLE at day 0 was noted in 20 (83.3%) subjects with sepsis at day 3 ($p = 0.003$), and in 32 (82.1%) subjects with sepsis at day 7 ($p = 0.001$). Predictors of mortality at day 0 were Factor 8[OR 4; 95%CI 1.0–1.45; ($p = 0.03$)], and at day 3, low PrC [OR 0.9; 95%CI 0.89–0.98 ($p = 0.007$)], low AT [OR 0.8; 95%CI 0.8–0.94 ($p = 0.008$)] and high INR [OR6.3; 95%CI 1.4–27.9 ($p = 0.015$)]. Bleeding events were seen in 55% [skin-39%, gastrointestinal-18.4%, and multiple sites-39%]. (Figure 1) The effects of sepsis on day28 mortality (OR 7.8;95%CI6.73 to 8.36; P = 0.002) and bleed events [OR 9.01; 95% CI6.74 to 9.39; ($p = 0.004$)] were significant. A deranged SONOCLOT™ was a predictor of bleeding (OR 3.5; $p = 0.05$) and mortality (OR = 2.9; 95% CI2.1–6.9, $p = 0.056$). The presence of HLE, at day 0 showed high mortality risk [OR 4.5; 95%CI 2.8 to 5.6; $p = 0.02$)].
Conclusion: Endogenous heparinoids contribute to coagulation abnormalities in patients with SAH. Presence of HLE in SAH is associated with an increased risk of sepsis, tendency to bleed and mortality.

SAT-445

Prevalence of alcoholic steatosis in the general adult Portuguese population

J.A.M.C.P. Leitao[1], S. Carvalhana[2], J. Cochicho[1], A.P. Silva[3], F. Velasco[4], I.S. Medeiros[5], A.C. Alves[6], M. Bourbon[6], B. Oliveiros[7], V. Rodrigues[8], A. Carvalho[1,9], H. Cortez-Pinto[2,10]. *[1]Centro Hospitalar e Universitário de Coimbra EPE, HUC, CHUC, Internal Medicine A, Coimbra, Portugal; [2]Hospital de Santa Maria, Department of Gastroenterology, Lisboa, Portugal; [3]Centro Hospitalar de Vila Nova de Gaia e Espinho, EPE, Department of Gastroenterology, Vila Nova de Gaia, Portugal; [4]Hospital de Faro, Centro Hospitalar do Algarve, EPE, Department of Gastroenterology, Faro; [5]Hospital Espírito Santo E.P.E, Évora, Department of Gastroenterology, Évora; [6]Instituto Nacional de Saúde Dr. Ricardo Jorge, Biosystems and Integrative Science Institute (BioISI), Lisboa, Portugal; [7]Faculdade de Medicina, Universidade de Coimbra, Laboratório de Bioestatística e Informática Médica, Coimbra, Portugal; [8]Faculdade de Medicina, Universidade de Coimbra, Instituto de Higiene e Medicina Social, Coimbra, Portugal; [9]Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal; [10]Faculdade de Medicina, Universidade de Lisboa, Laboratório de Nutrição, Lisboa*
Email: jorge.a.leitao@gmail.com

Background and Aims: Fatty liver is very frequent in the general population. Although many studies evaluated the prevalence of non-alcoholic fatty liver disease there is scarce information regarding alcoholic fatty liver. We aimed to estimate the prevalence of alcoholic hepatic steatosis, and to what extent it depended on obesity and its interaction.
Method: A cross-sectional study, with a random sample of the adult Portuguese population (18–79 years). All participants were evaluated with anthropometric measures, blood tests, ultrasound (US) to evaluate hepatic steatosis (Hamaguchi's US for steatosis defined by a presence of a score ≥2), and a semi-quantitative food frequency questionnaire (FFQ), representative of the usual intake over the previous year, including alcohol consumption. Three groups were defined regarding alcohol consumption: 1) harmful alcohol consumption (HAC) (males > 30 g/day; females > 20 g/day), n = 308; 2) moderate (MAC) (any alcohol consumption below these limits, n = 267); 3)null alcohol consumption (NC), n = 259. Alcoholic steatosis (AS) was considered if patients had steatosis and harmful alcoholic consumption.
Results: 834 participants were enrolled, 440 male, age 49.8 ± 17.2 years. Prevalence of AS was 18.1% (95% CI: 15.1–21.1%), 29% in male, 5.8% in women. General prevalence of steatosis was 37.9% (CI 95%: 32.9–39.5%), 45.7% in males, 25.6% in females, increasing with age: 16.8% in 18–34 years, 40.8% in 35–64 and 47.0% in > 65 years. Prevalence of hepatic steatosis, in the HAC was 49% (95% CI: 43.6–54.8%), MAC: 32.5% (95% CI: 26.9–38.2%), and NC: 24.7% (95%CI: 19.3–29.9%). Probability of having steatosis, according to different patterns of alcohol consumption and BMI are described in Table, demonstrating the strong increased risk due to interaction of obesity with alcohol consumption. However the risk associated with obesity is stronger than with harmful alcohol consumption.

Table: Odds Ratio (95% Confidence Interval) for the individual effect and interaction with alcohol consumption and BMI

BMI	Drinking status		
	Null	Moderate	Harmfull
		1.49 (CI: 1.02–2.18)	2.89 (CI: 2.02–4.15)
Normal weight	1	1.93 (CI: 0.79–4.68)	1.55 (CI: 0.60–4.00)
Overweight	2.90 (CI: 1.24–8.79)	2.48 (CI: 1.69–3.84)	4.04 (CI: 2.71–6.02)
4.74 (CI: 3.13–7.19)			
Obese	16.50 (CI: 7.01–38.83)	4.25 (CI: 2.35–7.78)	17.97 (CI: 9.63–33.54)
14.77 (CI: 9.25–23.56)			

All p values were <0.05 except Normal * Moderate p = 0.357.

Conclusion: Prevalence of alcoholic steatosis in the general population is lower than that of NAFLD, and obesity seems a strong risk factor than harmful alcohol consumption. However the concomitance of the two factors, obesity and alcohol consumption showed a supra-additive interaction between the two. Nonetheless in obese individuals, moderate alcohol consumption associated with reduced prevalence of steatosis.

SAT-446

Making sense of liver function tests: Is the Intelligent Liver Function Test (iLFT) cost-effective?

K. Boyd[1], J. Dillon[2], S. Inglis[2], M. Rezaeihemami[1]. *[1]University of Glasgow, Health Economics and Health Technology Assessment, IHW, Glasgow, United Kingdom; [2]University of Dundee, School of Medicine, Dundee, United Kingdom*
Email: kathleen.boyd@glasgow.ac.uk

Background and Aims: Liver function tests are widely used by GPs in primary care to identify liver disease. Abnormal results are common though, and are followed by (i) a lengthy process of retesting and referral which is costly to both patients and health services, or (ii) are left uninvestigated – potentially overlooking curable liver disease which would otherwise be fatal. iLFT is a semi-automated liver test cascading system with a structured diagnostic algorithm to maximise the efficiency of requesting LFTs and improve diagnosis. This study undertook a cost-effectiveness analysis of the iLFT decision tool compared to routine practice in Scotland, UK.
Method: An economic evaluation alongside the trial, and lifetime model undertaken from the perspective of NHS of Scotland. A step wedge design trial was carried out which compared effectiveness of diagnosis before and after the introduction of the iLFT system. Within

trial outcomes are reported as incremental cost per correct diagnosis at six months follow up, while a Markov model was used to extrapolate out to a lifetime analysis with discounted costs and quality adjusted life years gained in each arm, to account for early detection of Alcoholic Liver Disease (ALD) and Non-alcoholic Liver Fatty liver Disease (NAFLD). Probabilistic sensitivity analysis was undertaken with a 1000 iteration monte carlo simulation.

Results: The within trial analysis found costs to be £185 (CI 95% £166, £202) and £328 (CI 95% £231, £425) in routine practice and iLFT arms respectively. Probability of correct diagnosis (true positive and true negative) was 0.41 (CI 95% 0.37, 0.45) in routine and 0.92 (95% CI 0.85, 0.99) in iLFT, resulting in an ICER of £284 (CI 95% £128, £440). The lifetime model found iLFT to dominate routine practice with an incremental cost saving of £3216 (CI 95% -£7643, -£897) and an incremental QALY gain of 0.021 (CI 95% 0.009, 0.04).

Conclusion: iLFT increases Liver diagnosis, while improves quality of care and is cost effective with a low ICER of £284 per correct diagnosis and over a patient lifetime is a dominant strategy saving the NHS an average £3,216 per patient. Given these results iLFT should be recommended and widely implemented across the NHS.

SAT-447

Combination of the Lille model with baseline scores is useful to predict mortality in severe alcoholic hepatitis: a confirmation study in a large database of patients

A. Louvet[1], J. Labreuche[2], M. Thursz[3], D.J. Kim[4], S. Atkinson[3], S. Sidhu[5], J. O'grady[6], E. Akriviadis[7], E. Sinakos[7], R. Carithers[8], M.-J. Ramond[9], W.C. Maddrey[10], T. Email: alexandre.louvet@chru-lille.fr

Background and Aims: Prediction of outcome in severe alcoholic hepatitis is important to adapt patient management. For such purpose, we previously showed that the combination of baseline score (i.e. MELD and Maddrey scores) to a dynamic model, the Lille model, is useful. Our aim was to validate in a huge independent database from a meta-analysis of individual data from 11 RCTs testing corticosteroids or pentoxifylline vs. placebo.

Method: We defined 4 risk groups of mortality at 2 and 6 months using the 16th, 50th and 84th centiles of the prognostic index (MELD + Lille or Maddrey + Lille) and report observed and predicted probabilities of overall mortality and in the different treatment groups.

Results: On overall patients, median age was 48 years (IQR 41–55.6), 67% were males, bilirubin was 16.6 mg/dl (10–24.8), prothrombin time was 19.9 s (17–23.5), INR was 1.8 (1.6–2.1). Among the available data, the Maddrey + Lille score was calculated in 1559 patients treated with corticosteroids (n = 865), pentoxifylline (n = 298) and placebo (n = 396). MELD + Lille was available in a total of 1249 patients treated with corticosteroids (n = 746), pentoxifylline (n = 252) and placebo (n = 251). Calibration and discrimination were good for all groups, regarding of the allocated treatment. To illustrate the predictive capacity of the combined scores, we show in the table the observed and predicted survivals at 2 and 6 months for the Lille + MELD score, according to the risk group. Observed and predicted survivals were close in overall and in the three treatment groups (corticosteroids, pentoxifylline, placebo). C-statistics was at 0.72 in the total cohort and ranged between 0.7 and 0.73 in the three treatment groups, close to the previously published study (0.75). We observed that 44.9% (335/746), 60.7% (153/252) and 57% (143/251) of patients were classified at high or very high risk of mortality in the groups corticosteroids, pentoxifylline and placebo respectively. Similar results were observed using the Maddrey + Lille combined score with a good calibration and a good discrimination. C-statistics was at 0.72 in overall and ranged from 0.69 to 0.73 in the three treatment groups.

Conclusion: The combined models (MELD + Lille or Maddrey + Lille) should be used to predict outcome and adapt therapeutic strategy in severe alcoholic hepatitis. Patients with a MELD + Lille greater than 2.53 have a high risk of mortality at 2 and 6 months. Among them, those with a score greater than 3.88 have a predicted risk of mortality of around 80% that make them potential candidates for early liver transplantation.

Table 1: (abstract: SAT-447):

Email: brian.lee6@ucsf.edu

Background and Aims: Increasingly, liver transplantation (LT) is being offered to patients with alcoholic hepatitis (AH) despite a paucity of data regarding post-LT outcomes compared to alcoholic cirrhosis (ALC). The American Consortium of Early Liver Transplantation for Alcoholic Hepatitis (ACCELERATE-AH) is a multi-center cohort from 8 UNOS regions studying early LT for severe AH and here, we compare early and late post-LT mortality in AH vs. ALC in ACCELERATE-AH sites.

Method: All persons transplanted for alcohol-related liver disease since the first LT for AH at each of 12 ACCELERATE-AH centers were included. AH was defined as clinically-diagnosed severe AH, no prior diagnosis of liver disease or episodes of AH, and LT before 6 months of abstinence. ALC was defined as a UNOS listing diagnosis of alcoholic cirrhosis and not already within the AH group. Patients with HCV, hepatocellular carcinoma, HIV, other liver diseases, prior LT, and live-donor recipients were excluded. Site-specific and UN OS registry data were utilized. Graft failure and death were the primary outcomes. To evaluate the likelihood of death and associated factors, Cox proportional hazard ratios were calculated, adjusting for age and center level clustering.

Results: A total of 822 LT recipients from 2006 to 2016 were included: 123 with AH and 699 with ALC. Median follow-up was 2.0 years in both groups. Only 28% of AH patients had the correct listing diagnosis of AH in UNOS. AH patients vs. ALC were younger (42 vs. 54, $p < 0.001$), with college education (50% vs. 41%, $p = 0.005$), and higher MELD (38 vs. 30, $p < 0.001$). Donor characteristics were similar between groups. Cumulative unadjusted 1- and 3- year graft (94% and 83% vs. 90% and 83%, $p = 0.85$) and patient survival (94% and 85% vs. 94% and 86%, $p = 0.47$) were similar for AH vs. ALC. In multivariable analysis, AH as indication for LT (HR 1.42, $p = 0.02$), mechanical ventilation at LT (HR 2.00, $p = 0.02$) and DRI (HR 1.96, $p = 0.002$) were associated with increased risk of death after adjusting for age and center clustering. When stratified by age <50 versus ≥50, AH vs. ALC in those aged ≥50 was associated with increased risk of death ≤90 days post-LT (HR 4.07, $p = 0.003$).

Conclusion: Misclassification of AH in UNOS is frequent, highlighting the challenge in using UNOS alone to study LT outcomes in AH. After adjustment for covariates influencing survival, AH as indication for LT was associated with a 40% higher risk of post-LT death compared to ALC as indication, with the risk most pronounced in patients aged ≥50 and within 90 days post-LT. As mortality within the first 90 days is unlikely related to alcohol use post-LT, additional studies are essential to elucidate the factors contributing to early post-LT mortality in patients with AH.

SAT-449

Bayesian sparse regression modelling more accurately predicts mortality risk than commonly used prognostic scoring systems in patients with severe alcoholic hepatitis

S. Atkinson[1], M. Allison[2], E. Forrest[3], J. Wason[4], M. Thursz[5], P. Newcombe[4]. [1]*Liver Unit, United Kingdom, London, United Kingdom;* [2]*Cambridge University Hospitals NHS Foundation Trust, Department of Medicine, Cambridge, United Kingdom;* [3]*NHS GGC, Hepatology, Glasgow, United Kingdom;* [4]*MRC Biostatistics Unit, Biomedical Campus, Cambridge, United Kingdom;* [5]*Imperial College, Department of Hepatology, London, United Kingdom*
Email: stephen.r.atkinson@gmail.com

Background and Aims: Severe alcoholic hepatitis (sAH) is associated with significant mortality and heterogeneity in outcomes. Understanding mortality risk is important in guiding clinical decision-making. Several scoring systems, derived by logistic regression, have been applied to the condition; even those using biochemical changes over 7 days have modest discrimination and calibration for mortality. The aim of this study was to use Bayesian Variable Selection (BVS) to derive a superior predictive model of mortality in sAH.

Method: Patients with sAH (clinical diagnosis, DF > 32) were recruited to the Steroids or Pentoxifylline for severe Alcoholic Hepatitis (STOPAH) trial. The endpoint was 90-day mortality. Model fitting was performed in patients not treated with prednisolone (n = 534); initially under 10-fold cross-validation. The prednisolone treated population (n = 534) was used for validation. A BVS algorithm "R2BGLiMS" was used to derive prognostic models from 29 candidate biomarkers. Area under the curve (AUC) analysis and net reclassification index (NRI) were used to compare discrimination and calibration with MELD, GAHS and Lille. Low and high mortality risk were defined as <10% and >80% predicted mortality. Modelling was performed first using baseline clinical data and then incorporating data available at day 7.

Results: At 90 days 141 and 143 patients had died in the non-prednisolone and prednisolone treated arms, respectively. The BVS model using baseline data had an AUC of 0.79 when cross-validated in the untreated patients. This was little changed when limited to 6 biomarkers (BVS-6, AUC 0.76) and compared favourably to the MELD and GAHS scores (AUCs 0.71 and 0.70, respectively). BVS-6 offered superior stratification by mortality risk compared to GAHS and MELD (NRI 0.29 [95% CI 0.20–0.38] and NRI 0.26 [95% CI 0.17–0.34], respectively, both $p < 0.0001$). A BVS model using only six day 7 variables offered improved predictive performance (AUC 0.78), and was superior to the Lille score in terms of discrimination (AUC 0.70) and mortality risk stratification (NRI 0.44, 95% 0.32–0.56, $p < 0.0001$, Table 1). The baseline BVS-6 model remained superior to MELD and GAHS in the prednisolone treated cohort (AUCs: 0.74 vs. 0.69 and 0.71, respectively). The day 7 model was also superior to Lille (AUC 0.79 vs. 0.72) and offered much improved mortality risk stratification (NRI: 0.38, 95% CI 0.24–0.51, $p < 0.0001$).

Conclusion: Bayesian Variable Selection to model clinical outcomes in patients with severe alcoholic hepatitis allowed derivation of prognostic models with improved prognostic capacity compared to currently used. Findings were validated in an independent, prednisolone-treated cohort of patients. Such models could significantly enhance clinical decision-making by more accurately informing risk.

Table 1: Reclassification table for Lille score *vs.* BVS model using day 7 data

		Bayesian variable selection Day 7 model		
	Mortality risk	0-10%	10-80%	80-100%
Lille	*Patients who survived (n=264)*			
	0-10%	21	7	0
	10-80%	65	168	3
	80-100%	0	0	0
	Patients who died (n=99)			
	0-10%	0	5	0
	10-80%	5	79	10
	80-100%	0	0	1

SAT-450

Insufficient diagnostic accuracy of general practitioners and routine liver function tests lead to high risk of under-referrals of patients with alcohol induced advanced liver fibrosis

T.L. Hansen[1,2,3], K. Lindvig[1,2,3], S. Detlefsen[2,4], B.S. Madsen[1], J. Hansen[2,5], M. Kjærgaard[1,2,3], M. Thiele[6], A. Krag[1,2]. *[1]Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark; [2]University of Southern Denmark, Institute of Clinical Research, Odense M, Denmark; [3]Odense University Hospital, Odense Patient data Explorative Network (OPEN), Odense, Denmark; [4]Odense University Hospital, Department of Pathology, Odense, Denmark; [5]Odense University Hospital, Department of Infectious Diseases, Odense, Denmark; [6]Odense University Hospital, University of Southern Denmark, Department of Gastroenterology and Hepatology, Odense C, Denmark*
Email: thor.lars.hansen@rsyd.dk

Background and Aims: Alcohol is the leading cause of liver-related death worldwide. The majority of alcoholic cirrhosis patients are diagnosed when they firstly decompensate, but have been in contact with primary healthcare years before decompensation. General practitioners (GPs) rely on standard liver blood tests to assess which patients to refer to secondary care. We therefore aimed to evaluate the diagnostic accuracy and inter-observer variance of experienced GPs and routine liver blood tests for diagnosing advanced alcoholic liver fibrosis, defined as histologic Kleiner fibrosis stage ≥F3.

Method: We presented two GPs with a questionnaire that contained clinical and laboratory data on 235 alcoholic patients, all whom had concomitant reference liver biopsy and biochemistry. GPs were blinded to the histology and to each other's answers. We asked the GPs to guess if the patient had ≥F3. We also assessed the diagnostic accuracy of ALT, AST, GGT, ALP, INR, platelet count and bilirubin using upper limit of normal(ULN) as cut-off. Finally, we calculated GPs inter-observer variance and compared the diagnostic accuracy of GPs and individual routine liver blood tests with fibrosis indices APRI, FIB4 and Forns.

Results: The prevalence of advanced fibrosis was 25%. The two GPs disagreed substantially in their prediction of advanced fibrosis, with a Kappa of 0.46. GP#1 guessed that 34% of patients had ≥F3, while GP#2 guessed that 15% of patients had ≥F3. The GPs (#1 and #2) incorrectly classified 36/58 (62%) and 27/58 (47%) of patients with ≥F3 fibrosis, while 22 (38%) and 31 (53%) guesses were false-negative (Table). Their false-positive rates were 45/177 (25%) and 8/177(5%). Routine liver blood tests were of insufficient help in the diagnosis of ≥F3, since values above ULN had poor sensitivity. The best single test was INR with an AUROC of .80. Indirect fibrosis tests combining routine markers performed better than the INR, but not in a statistically significant manner (P = 0.544 for comparison between Forns index and INR).

Table:

Variable	ULN	Overall AUROC	Sensitivity (%)	Specificity (%)
GP#1	–	–	62	75
GP#2	–	–	47	96
ALP	105 U/L	0.77	69	75
ALT	70/45 U/L	0.54	9	85
AST	45/35 U/L	0.72	60	73
Bilirubin	25 µmol/L	0.75	29	96
GGT	115/75 U/L	0.71	64	64
INR	1.3	0.80	43	96
Platelet count	350/400 10^9-/L	0.76	5	94
FIB-4	3.25	0.83	56	90
APRI score	1.0	0.78	37	89
Forns Index	6.8	0.83	68	87

Conclusion: General practitioners fail to diagnose up to half of alcohol overusing patients with biopsy-verified severe fibrosis or cirrhosis, resulting in a high risk of under-referrals of diseased patients to secondary care. This may be because GPs rely on the upper limit of normal for routine blood tests, which has poor sensitivity. There is consequently a need for better screening tools improving the diagnosis of advanced fibrosis in primary care.

SAT-451

Delineating complement activation molecular patterns in patients with alcoholic hepatitis

R. Mccullough[1], M. Sheehan[1], K. Poulsen[1], R. Chen[2], S. Roychowdhury[1], T. Mcintrye[2], L. Nagy[1]. *[1]Cleveland Clinic, Pathobiology, Cleveland, United States; [2]Cleveland Clinic, Department of Cellular and Molecular Medicine, Cleveland, United States*
Email: len2@po.cwru.edu

Background and Aims: Chronic alcohol abuse underlies the pathogenesis of alcoholic liver disease (ALD). Alcoholic hepatitis (AH), a severe form of ALD, can occur at any point along the ALD spectrum and is characterized by inflammation and hepatocellular injury. Impairment of renal function occurs in ALD; acute kidney injury is associated with higher mortality in AH. Complement, a critical component of the innate immune system, is an important patho-physiological contributor to ethanol-induced liver injury. In addition to mediating microbial defense, complement contributes to the resolution of inflammation by promoting clearance of damaged tissue via recognition molecules, opsonins and receptors. Complement is activated via three independent pathways, the classical, lectin, and alternative; the balance of these pathways generates complement activation molecular patterns (CAMPs). Our recent work in murine models of ALD indicates that classically- versus alternatively-activated complement may have differential impact on progression of ALD, whereby the classical pathway contributes to non-resolving inflammation and the alternative pathway promotes resolution/wound healing via the clearance of damaged tissue/cells. Evidence for complement activation has been reported in AH; however, CAMPs in AH patients are unknown. Delineating CAMPs will further our understanding of the patho-physiological mechanisms of AH and potentially identify individuals particularly susceptible for specific complications associated with increased mortality in AH.

Method: Complement activation was measured in serum and urine from patients enrolled in the Defeat Alcoholic Hepatitis (DASH) consortium and healthy controls (HC). AH explants and HC livers were obtained from the Clinical Resources for AH Investigations at Johns Hopkins University. Sectioned liver biopsies from AH patients were obtained from the Cleveland Clinic coPATH repository.

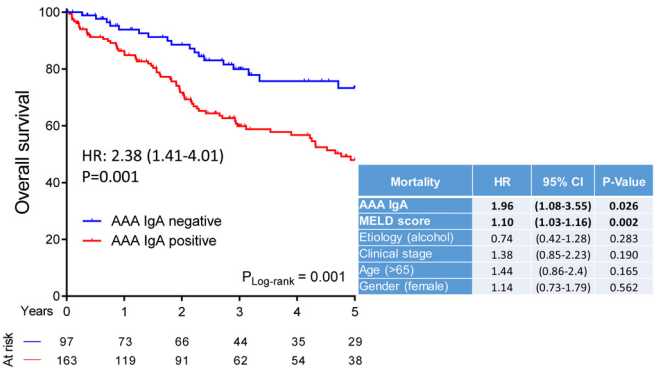
Results: Complement activation was higher in AH patients compared to HC; C3 and C5 activation products accumulated in liver and serum, respectively. Evidence for alternative activation was observed via the accumulation of Factor B fragments (*f*Ba) in liver and serum. C4d accumulation in liver, indicating activation via the classical pathway, was increased in AH patients and positively associated with the degree of fibrosis. Complement activation products C5a and *f*Ba, and KIM-1, a marker of kidney injury, were increased in AH urine. Consistent with a protective function of the alternative pathway, urinary *f*Ba negatively correlated with KIM-1.
Conclusion: Taken together, these data indicate that both classical and alternative pathway activation occurs in AH. These data suggest that CAMPs may be useful to develop as biomarkers to predict clinical outcomes and that targeting specific CAMPs are a potential therapeutic intervention in AH.

SAT-452

Presence of IgA isotype F-actin is frequent in patients with cirrhosis and consitutes the risk of progressive disease course

B. Balogh[1], T. Tornai[1], N. Sipeki[1], Z. Vitális[1], I. Tornai[1], P. Antal-Szalmás[2], T. Dinya[3], G.L. Norman[4], T. Bruns[5], M. Papp[6]. *[1]University of Debrecen, Faculty of Medicine, Institute of Internal Medicine, Department of Gastroenterology, Debrecen, Hungary; [2]University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine; [3]University of Debrecen, Faculty of Medicine, Department of Surgery; [4]Inova Diagnostics Inc.; [5]University Hospital Jena, Department of Internal Medicine IV; [6]University of Debrecen, Faculty of Medicine, Insitute of Internal Medicine, Department of Gastroenterology*
Email: baloghboglarka23@gmail.com

Background and Aims: Gut barrier failure and the consequential pathological bacterial translocation (BT) are characteristic features of cirrhosis and play an important role in the progression of liver disease. Our aim was to investigate, whether hallmarks of gut barrier failure are associated with accelerated progression of liver disease in cirrhosis and the development of specific complications and liver-related death.
Method: Sera from 260 outpatients with cirrhosis (male: 129, age: 56 ± 11 yrs, alcohol: 167 [64.2%]) and from 155 healthy subjects were assayed for the presence of antibodies against filamentous actin [AAA IgA and IgG] and gliadin [AGA IgA and IgG]) and for intestinal fatty acid-binding protein (I-FABP) by ELISA. Association of gut failure markers with disease specific characteristics was assessed at baseline and the course of liver disease was evaluated in a 5-year follow-up observational study for decompensating events (ascites, variceal bleeding, hepatic encephalopathy and/or bacterial infection) and liver-related death. BT was assessed based on the presence of anti-microbial antibodies (anti-OMP Plus IgA and/or endotoxin core antibody IgA [EndoCab]).
Results: Elevated concentrations of IgA-AAA (62.7 vs. 4.4%) and IgA-AGA (27.7 vs. 2.6%) were more often observed in cirrhosis as compared to healthy controls ($p < 0.001$ for both). In addition, I-FABP was increased in cirrhosis as compared to controls (741 vs. 244 pg/mL, $p < 0.001$) and correlated with serum levels of IgA-AAA and IgA-AGA. IgA-AAA positivity was associated with alcoholic etiology, liver oriented scores and decompensated clinical stage (all $p < 0.001$). Serological markers of BT were more often found in patients with elevated IgA AAA compared to those without (72.3 vs. 13.5% for IgA-EndoCab and 85.2 vs. 20.5% for IgA anti-OMP, $p < 0.001$ for both). In patients with compensated disease stage ($n = 131$) the risk of decompensation was higher in patients with elevated IgA-AAA (HR [95%CI]: 1.85 [1.06–3.24]), as was the risk of liver-related mortality (HR: 2.66 [1.27–5.56]). Such associations were not observed for IgG-AAA and IgA/IgG-AGAs. In the overall cohort, IgA-AAA remained an independent predictor of liver-related death (HRadj: 1.96 [1.08–3.55]) when adjusting for important clinical variables (MELD score, etiology, clinical stage).



Mortality	HR	95% CI	P-Value
AAA IgA	1.96	(1.08-3.55)	0.026
MELD score	1.10	(1.03-1.16)	0.002
Etiology (alcohol)	0.74	(0.42-1.28)	0.283
Clinical stage	1.38	(0.85-2.23)	0.190
Age (>65)	1.44	(0.86-2.4)	0.165
Gender (female)	1.14	(0.73-1.79)	0.562

Conclusion: Presence of IgA antibodies against filamentous-actin indicate patients with an unfavourable outcome in cirrhosis, which may be related to intestinal damage beyond being related to bacterial translocation. IgA-AAA might be consider as a novel serologic marker of the disease progression.

SAT-453

The TIM3-Gal9 immune checkpoint axis is inter-linked with severity of Alcoholic Liver Disease

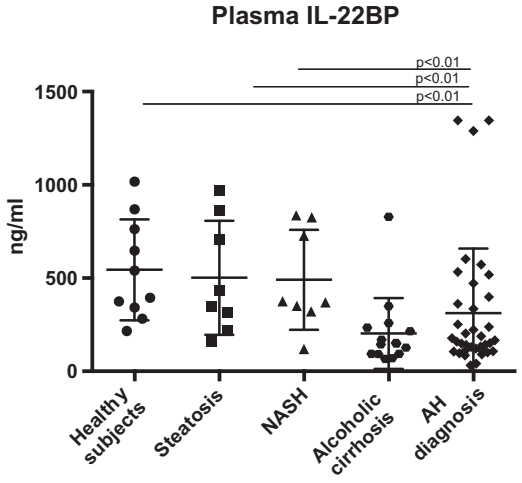
A. Riva[1,2], H. Adams[1,2], V. Patel[1,2], S. Azarian[1,2], G. Wright[3], S. Tarff[3], K. Katzarov[4], M. Simonova[4], T. Hadzhiolova[4], S. Pavlova[4], R. Williams[1,2], A. Evans[5], S. Chokshi[1,2]. *[1]Institute of Hepatology London, Foundation for Liver Research, London, United Kingdom; [2]Division of Transplantation, Immunology and Mucosal Biology, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom; [3]Department of Gastroenterology, Basildon University Hospital, Basildon, United Kingdom; [4]Department of Gastroenterology, Military Medical Academy, Sofia, Bulgaria; [5]Department of Gastroenterology, Royal Berkshire Hospital, United Kingdom*
Email: a.riva@researchinliver.org.uk

Background and Aims: Susceptibility to overwhelming bacterial infection represents a significant cause of mortality in alcoholic liver disease (ALD). T-cell immunoglobulin and mucin domain (TIM)3 is a well characterised immune checkpoint receptor that modulates the equilibrium between protective anti-pathogen immunity and host-induced immunopathology. We have previously shown (Markwick et al, Gastroenterology, 2015) that hyper-expression of TIM3 on adaptive T-cells suppresses antibacterial immunity in ALD and *in vitro* blockade can rescue impaired innate and adaptive immunity. However, the role of soluble (s)TIM3, its ligand Galectin(sGal)9 and other checkpoint receptors in antibacterial immunity and in ALD is unknown and is the aim of this study.
Method: We measured levels of soluble checkpoint receptors in plasma samples from patients with alcohol-related cirrhosis (ARC, Child-Pugh A/B/C, $n = 6/8/8$), severe alcoholic hepatitis (SAH, Maddrey's DF > 32, $n = 13$), alcohol-related acute-on-chronic liver failure (ACLF, $n = 6$, longitudinal) and healthy controls ($n = 13$) and correlated these findings with demographic and clinical characteristics. Receiver operating characteristic area under the curve analysis (AUROC) was used to investigate the discriminatory power of sTIM3 as a disease biomarker.
Results: Plasma sTIM3 was significantly different in patients and controls ($p < 0.0001$), with greater amounts in ARC ($p = 0.0004$), SAH ($p < 0.0001$) and ACLF ($p = 0.0065$) patients. sGal9 was also significantly higher in SAH vs. controls ($p = 0.0116$). Stratification of ARC patients according to Child-Pugh score (CP) indicated greater levels of sTIM3 in CP-C compared to CP-A or CP-B patients. Levels of sTIM3 in CP-C, SAH and ACLF patients were higher than controls ($p = 0.0004$, $p = 0.0003$, $p = 0.0156$ respectively). AUROC analysis for sTIM3 produced a value of 0.936 (95%CI 0.868–1.000, $p < 0.001$) and at a cut-off of 2427.053 pg/mL the discriminatory sensitivity and

specificity between ALD patients and controls were 90.2% and 88.5% respectively.
Conclusion: Our results show that the TIM3-Gal9 axis plays an important role in the pathogenesis of ALD and that sTIM3 represents a novel biomarker of disease severity.

SAT-454
Interleukin-22 binding protein in alcoholic hepatitis
S. Støy, T.L. Laursen, E. Glavind, B. Deleuran, H. Vilstrup, T.D. Sandahl. *Aarhus University Hospital, Hepatology and Gastroenterology, Aarhus, Denmark*
Email: sidsel.stoy@clin.au.dk

Background and Aims: In alcoholic hepatitis, interleukin (IL)-22 production in circulating immune cells is high and associated with improvement in the disease probably through aiding the anti-microbial defence and liver regeneration. Soluble IL-22 binding protein (BP) controls IL-22 bioactivity. A pathological IL-22BP up-regulation may thus block IL-22 anti-microbial and regenerative functions as seen in inflammatory bowl disease. However, IL-22BP knockout mice are more susceptible to acute liver injury and have delayed regeneration. This may point to more complex effects of IL-22BP on IL-22 functions. We investigated the plasma levels of IL-22BP in patients with alcoholic hepatitis, its association with disease outcome and how IL-22BP affects IL-22.
Method: We followed 39 patients hospitalized alcoholic hepatitis for 90 days after diagnosis. Controls were 15 patients with stable alcoholic cirrhosis, 15 healthy subjects, 8 patients with simple steatosis and 8 patients with non-alcoholic steatohepatitis. By ELISA, we measured plasma levels of IL-22BP, IL-22 and the IL-22 induced anti-microbial peptide lipocalin-2. Effects of IL-22BP on IL-22 gene induction in HepG2 cells were measured by qPCR.
Results: Plasma IL-22BP was reduced by 50% in patients with alcoholic hepatitis compared with the levels in all control groups but alcoholic cirrhosis patients (figure 1). Consistently, plasma IL-22 and lipocalin-2 were elevated in alcoholic hepatitis patients ($p < 0.05$). At diagnosis, plasma IL-22BP was negatively associated with Model of Endstage Liver disease ($r=-0.40$, $p = 0.02$). The patients who died before day 90 had lower IL-22BP plasma levels at diagnosis ($p = 0.16$) and this was significant at day 7 (mean(SD) dead: 115(42) ng/ml alive: 292 (221) ng/ml, $p < 0.05$). *In vitro,* IL-22BP dose-dependently inhibited the induction of lipocalin-2 in HepG2 cells by IL-22. Interestingly, IL-22BP also reverted the reduction of IL-22R expression in HepG2 cells induced by IL-22.



Conclusion: In alcoholic hepatitis low plasma IL-22BP is associated with increased mortality. This may be explained by diminished IL-22 signalling at low IL-22BP levels, as IL-22BP seems important for sustaining adequate IL-22R expression.

SAT-455
The bile acid biome and its relationship to the development and severity of alcoholic hepatitis
P. Puri[1], F. Mirshahi[2], S. Liangpunsakul[3], D. Crabb[3], V. Shah[4], G. Gores[4], P. Kamath[4], H. Malhi[4], M. Sikaroodi[5], S. Raedeva[6], P. Gillevet[5], N. Chalasani[3], A. Sanyal[2]. [1]*Virginia Commonwealth University, Division of Gastroenterology, Hepatology and Nutrition, Richmond, United States;* [2]*Virginia Commonwealth University, Gastroenterology and Hepatology;* [3]*Indiana University, Internal Medicine, Gastroenterology, Hepatology and Nutrition;* [4]*Mayo Clinic, Gastroenterology and Hepatology;* [5]*George Mason University, Microbiome Analysis Center;* [6]*The National Institute on Alcohol Abuse and Alcoholism, Bethesda*
Email: drppuri@yahoo.com

Background and Aims: The impact of alcohol consumption and development of alcoholic hepatitis (AH) on the intestinal microbiome, its associated changes in bile acid profile, and the relationship of such changes to the severity of AH are not known. Aims: (1) To characterize fecal BAs in AH subjects with moderate (MAH) and severe (SAH) disease compared to heavy drinking controls (HDC), and (2) To relate changes in fecal BAs with microbial ecology and disease severity.
Method: Three groups of subjects were studied: (1) controls without obvious liver disease who drank heavily (HDC), (2) MAH, and (3) SAH. AH was defined by NIAAA consensus criteria. Bile acids were measured by LC-MS and microbiota were assessed by 16S rRNA pyrosequencing. Pairwise, multiple group comparisons with correction of false discovery (q-value), and regression analyses were performed.
Results: 50 subjects (58% males, mean age 46 ± 12 years) were studied (HDC = 20, MAH = 8, SAH = 22). *Firmicutes Clostridia* was diminished and *Firmicutes Bacilli* was markedly increased in SAH vs. HDC (both $p = 0.0001$). *Firmicutes Clostridia* inversely correlated with total bilirubin ($r2 = 0.22$, $p = 0.0004$), alkaline phosphatase ($r2 = 0.13$, $p = 0.009$), MELD score ($r2 = 0.33$, $p < 0.0001$) and DF ($r2 = 0.22$, $p = 0.02$). While glycine conjugates of chenodeoxycholate and cholate as well as taurochenodeoxycholate were significantly increased in SAH vs. HDC (p-and q-values <0.05 for all), secondary BAs [deoxycholate (DCA), glyco/tauro-DCA, lithocholate (LCA), glyco-LCA, and urso-DCA) were noticeably decreased in SAH vs. HDC (p- and q-values <0.05 to <0.0001 for all). Notably, DCA and LCA directly correlated with *Firmicutes Clostridia* abundance ($r2 = 0.33$, $p < 0.0001$ for both). In univariate analysis, DCA and LCA were inversely correlated with increasing total bilirubin ($r2 = 0.21$ and 0.28, $p = 0.008$ and <0.0001, respectively) and alkaline phosphatase ($r2 = 0.12$ and 0.17, $p = 0.01$ and 0.002, respectively). Least square fit regression modeling showed that interaction of total bilirubin and alkaline phosphatase correlated with DCA ($r2 = 0.36$, $p = 0.003$) and LCA ($r2 = 0.45$, $p = 0.0007$).
Conclusion: (1) Cholestasis perturbs microbial ecology in SAH with depletion in protective commensal Clostridia. (2) Diminished Clostridia in cholestasis likely impairs deconjugation and dehydroxylation given increased fecal primary conjugated BAs and decreased deoxy- and lithocholate. These data support a role for the bile acid biome in the development and severity of alcoholic hepatitis.

SAT-456
Collagen proportionate área is an independent predictor of long term outcome in patients with alcoholic liver disease

University College of London, London, United Kingdom; [5]Department of Pathology, Odense University Hospital, Odense, Denmark
Email: martaguemi@gmail.com

Background and Aims: Quantitative fibrosis assessment with collagen proportionate area (CPA) measurement predicts clinical outcomes in patients with hepatitis C virus (HCV) infection and non-alcoholic fatty liver disease (NAFLD). We tested the ability of CPA to quantify fibrosis and predict clinical outcome in patients with alcoholic liver disease (ALD)
Method: We retrospectively included a cohort of patients, from two centers, with biopsy-proven ALD and long-term follow-up, irrespective of fibrosis stage and a contemporary cohort of patients with similar clinical features and available non-invasive fibrosis assessment with Fibroscan (FS) and shear wave Elastography (SWE). All patients with concomitant primary cause of liver disease were excluded. Clinical details and laboratory parameters were collected at biopsy time. Follow-up data were collected at the time of the last clinical follow-up or death. Hepatic decompensation and liver-related mortality were considered as the combined primary outcome. For CPA analysis, we captured images of liver biopsy sections stained with picro-Sirius red and used digital image analysis to measure collagen deposition areas at whole biopsy macro and x4 power magnification. CPA was calculated as a proportion of the collagen area of the whole parenchyma and expressed as a percentage
Results: We included 352 patients, 242 with long-term follow up and 110 in the contemporary cohort. 86 patients (34.8%) had at least one episode of hepatic decompensation and/or died during a median follow-up of 70.9 (IQR 244) months. CPA significantly correlated with fibrosis stage across the whole spectrum of fibrosis. High magnification CPA (CPA-high) was significantly higher than low magnification CPA (CPA-low) in stage F0-F2 but was similar in patients with significant fibrosis (≥F3). A CPA-low higher than 7.1 and a CPA-high above 9.3 had a sensitivity and specificity of 93.8%, 90.4% and 90.6%, 88%, respectively, to predict significant fibrosis (AUROC of 0.96 CPA-low and 0.95 CPA-high). Both CPA-low and CPA-high significantly correlated with liver stiffness as measured by FS and SWE ($r = 0.84$ and 0.85 for CPA-low, $r = 0.81$ and 0.80 for CPA-high). Presence of advanced fibrosis (OR 2.28, $p = 0.04$), abstinence (OR 0.4, $p = 0.001$) and CPA (CPA-low or CPA-high, OR 1.032, $p = 0.05$; OR = 1.033, $p = 0.03$ respectively) were independent predictors of hepatic decompensation and/or liver-related mortality in multivariable Cox-regression analysis
Conclusion: CPA is an independent predictor of clinical outcomes in patients with ALD and should be routinely measured in biopsy specimens

SAT-457

Hepatoprotective biomarkers, amphiregulin and soluble Fas, increase during ELAD treatment in alcoholic hepatitis subjects

Email: pbedard@vitaltherapies.com

Background and Aims: Hallmarks of alcoholic hepatitis (AH) are increased hepatocellular death, decreased liver function, and additional pro-inflammatory responses if necrotic cells are not removed. We previously reported that TL C3A cells release hepatocyte mitogens (amphiregulin [AR], TGF-α, and PDGF-BB) and can inhibit Fas-induced apoptosis in primary human hepatocyte cultures. This study links the hepatoprotective effects of AR and sFas assessed by in vitro studies with biomarker analysis of severe AH subjects' plasma from the VTI-208 Phase 3 trial conducted by Vital Therapies, Inc.
Method: VTI-208 subjects' plasma (11 Control, 14 ELAD) meeting VTL-308 Phase 3 trial criteria (<50 years, <2.5 INR, <1.3 mg/dL creatinine, <16 mg/dL bilirubin, <30 MELD score) were immunoassayed for AR and sFas at screen and study days 3, 5, 7, 14, and 28 and longitudinally analyzed by ANOVA ($p < 0.05$ significance). Additional comparisons were made of bilirubin (Bili) levels during the 5-day treatment period.
Results: Control and ELAD subjects in this pre-defined subset were not significantly different for demographics, number of organ failures, or concentrations of AR and sFas at screen. MELD scores were not clinically different at screen. AR and sFas levels in ELAD subjects were significantly increased vs screen levels during study D3, D5, and D7 ($p = 0.0003$, D3; $p = 0.043$, D5; $p = 0.027$, D7), and D3 ($p = 0.0012$), respectively (i.e. during ELAD treatment), suggestive of receiving a dose of these factors from the VTL C3A cells. Bili levels were significantly decreased in ELAD treated subjects at D3, D5, and D7 compared to both screen and control subjects.
Conclusion: Subjects on ELAD experienced increases in AR and sFas during treatment, with corresponding early changes in Bili levels, which others have previously shown to be prognostic of survival. These data suggest hepatoprotection occurs during ELAD treatment, perhaps by inhibiting apoptosis through epidermal growth factor receptor activation, competition for Fas ligand, or reducing oxidative stress, as was previously demonstrated using in vitro primary human hepatocyte models. These clinical biomarker data suggest that the observed improvement in 91-d survival in these pre-defined ELAD subjects is likely due to a multi-therapeutic approach via cell-based treatment.

SAT-458

The use of proton pump inhibitors among patients with alcoholic cirrhosis is not related with increased risk of death

U. Bang, F. Bendtsen. *University Hospital of Hvidovre, Gastrounit*
Email: ucb@dadlnet.dk

Background and Aims: There are speculations that the use of proton pump inhibitors (PPI) may be related with increased risk of death in patients with cirrhosis. The aim was to study the association between use of PPI and mortality in patients with alcoholic cirrhosis in a retrospective nationwide cohort.
Method: Patients with alcoholic cirrhosis (ICD-10 code K70.3) from 1994 to 2014 were identified. We used data from the Danish Prescription Database and patients with at least two claims of PPI were categorized as users of PPI. We used covariates and propensity score to match users of PPI with non-users on a 1:1 ratio. We used claims of opioids to determine a healthy adherer profile and address for healthy adherer bias. The cohort entry of the non-users was adjusted to account for immortal time bias. We report the mortality rate in deaths per 1,000 person-years and assessed differences in mortality using Cox regression.
Results: We identified a total of 24,752 patients with alcoholic cirrhosis of whom we excluded 1,763 due to cancer, 584 due to chronic viral hepatitis, 277 due to non-alcoholic fatty liver disease and 3,025 due to a follow-up time shorter than 30 days. Of the remaining 19,687, a total of 6,114 had a history of opioid claims and were eligible for propensity score matching. The final propensity score matched cohort consisted of 2,592 patients. The mean age was 56 (SD 10) years at cohortentry, and we found 35% being females, 14% still working, 66% retired, 82% used diuretics during follow-up, and

16% used non-specific beta-blockers. We found a slightly lower prevalence of admission due to alcohol for the non-users compared with the users of PPI (49% vs. 57%, p = 0.0002). We found that 69% of the PPI users and 70% of the non-users died during follow-up with mortality rates of 132 (95%CI 123–141) and 130 (95%CI 122–139), respectively. No difference in mortality rate between PPI users and non-users was found (HR 1.0; 95%CI 0.9–1.1, p = 0.9) (Figure).

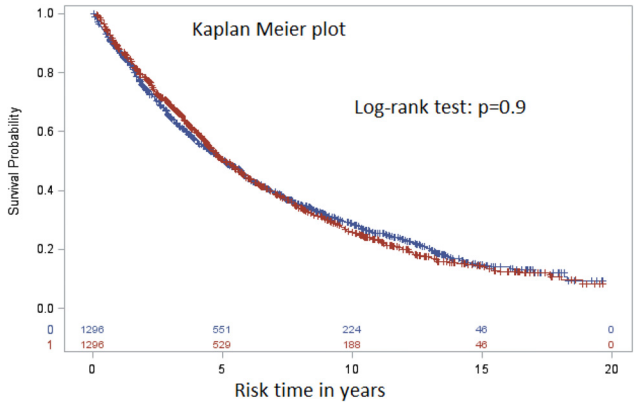

Figure: Kaplan-Meier plot of mortality of patients with alcoholic cirrhosis stratified into user and non-users of proton-pump inhibitor.

Conclusion: This is the first nationwide study of the use of PPI and mortality and we did not find any association between the use of PPI and changes in mortality. We conclude that the use of PPI is safe however we cannot exclude harmful effects in subgroups, which need to be explored further.

SAT-459

miRNA regulation of macrophage M1/M2 polarization of Kupffer cells and PBMCs in alcoholic liver disease

A. Kim, P. Saikia, M. Mcmullen, R. Mccullough, L. Nagy. *Cleveland Clinic, Pathobiology*
Email: kima7@ccf.org

Background and Aims: Alcoholic hepatitis (AH) is an inflammatory condition that leads to increased short-term morbidity among people with alcoholic liver disease (ALD). In response to chronic ethanol, Kupffer cells, the resident macrophage of livers, become sensitized to bacterial lipopolysaccharides (LPS) and express more pro-inflammatory cytokines. Additionally, chronic LPS stimulation leads to increased pro-inflammatory/M1 polarization of macrophages. We recently discovered that 35kD hyaluronic acid (HA35) decreased sensitivity to LPS in Kupffer cells from chronic ethanol-fed rats. Here we use miRNA sequencing to understand the regulation of M1 polarization in AH and a potential role for HA35 in promoting anti-inflammatory M2 polarization. Additionally, we tested PBMCs from AH patients to explore HA35 as a potential therapeutic for inflammation caused by ALD.
Method: Kupffer cells were isolated from male rats fed a chronic Lieber-Decarli diet or pair-fed control diet. Cells were plated then exposed to +/–HA35 for 5 hours or 24 hours and then +/–LPS for 1 hour. We then isolated small RNAs, generated libraries, and sequenced using an Illumina HiSeq. We used Bowtie to align reads and EdgeR to calculate differential expression. PBMCs were also isolated from AH patients with a MELD score >20 and healthy controls then treated similarly with HA35 and LPS.
Results: Differential expression analyses revealed 105 misregulated miRNAs in Kupffer cells from the chronic ethanol-fed rats compared to pair-fed (FDR < 0.2). 39/105 miRNAs clustered in 9 distinct regions of the genome. Each cluster contained at least 3 differentially expressed miRNAs, where 8/9 clusters had decreased expression in chronic ethanol. Three downregulated clusters contained miRNAs with known roles in M2 polarization, including miR125a, let-7c, miR221, and miR222. Treatment with HA35 for 5 hours lead to increased Arg-1 and decreased iNOS expression, indicating a potential anti-inflammatory effect. This result was supported by decreased expression of CD86 (M1 marker) and increased expression of CD206 (M2 marker) after 24 hours of HA35 treatment. PBMCs from AH patients, compared to healthy controls, were protected from LPS stimulation after pre-treatment with HA35. Preliminary results indicated increased expression of M2 polarization markers after long term HA35 treatment, including CD206 and CD23.
Conclusion: We hypothesize that increased M1 polarization of Kupffer cells after chronic ethanol is caused by global repression of miRNAs associated with M2 polarization. Kupffer cells isolated from chronic ethanol-fed rats displayed lower expression of a number of M2 associated miRNAs, but HA35 decreased the pro-inflammatory effect of LPS and increased M2 polarization. HA35 also reduced the effect of LPS in PBMCs from AH patients. Together, these data support HA35 as a potent anti-inflammatory therapy in ALD.

SAT-460

The correlation of obesity with morbidity and mortality in alcoholic hepatitis

Y. Yasiralazzawi, Y. Al-Abboodi, D. Devuni, G. Szabo. *Umass medical center, Gastroenterology, Worcester*
Email: yasiralazzawi@gmail.com

Background and Aims: The incidence of alcoholic hepatitis (AH) in the USA has increased and it is associated with significant morbidities and mortality, that increase paralleled with an increase in the obesity numbers. The correlation of the obesity and the outcomes in patients with AH have not been well studied. Our aim is to study the morbidities (acute kidney injury (AKI), hepatic encephalopathy (HE), spontaneous bacterial peritonitis (SBP) and pneumonia) and the mortality in the obese and non-obese patients with AH.
Method: We used in the National Inpatient Sample (NIS) dataset with the primary diagnosis of AH and we divided the cohort into two groups obese vs non-obese. ICD-9 codes for SBP, AKI, HE, pneumonia and death were used. Obesity defined in the data as body mass index of ≥30.
Multivariate logistic regression statistical test (SPSS softwere) is used to compare the odd ratio of mortality and inpatient morbidity between the two groups.
Results: The NIS 2009 included 18834 patients with AH and we divided the patients into two groups based on their BMI, 952(5%) were obese (BMI ≥ 30) vs 17882 (95%) were non-obese (BMI < 30). Male represented 70% of the cohort while Caucasian race represented 71% of the cohort.
The obese group was found to have more infections when compared to the non-obese group. Pneumonia was found in 6.7% of the obese group and in 5.3% of the non-obese group while SBP was found in 1.5% of the obese group and in 1.3% of the non-obese group. AKI and HE were also reported more frequent in the obese group as AKI was found in 19.5% of the obese group and in 13.5% of the non-obese group while HE found in 14.2% of the obese group and in 10.7% of the non-obese group.
Upon comparison between the two groups, the risk of the infections was not different between the two groups but the risk of AKI was higher in the obese group with an OR of 1.5 (P < 0.0001). The risk of HE in obese group was 1.3 times higher than the non-obese group (P = 0.001) and the mortality rate was significantly higher in the obese group when compared with the non-obese group with OR of 1.5 (P = 0.006).
Conclusion: Obesity is associated with increased morbidity and mortality rate in AH patients when compared to non-obese patients. Obesity is a risk factor for AKI and hepatic encephalopathy in patients with AH.

Table 1:

Age	48+/−18
Race:	Percentage
White	71.8%
African-American	12.3%
Hispanic	11.2%

Serum metabolic profiling for the identification of patients with severe alcoholic hepatitis

A. Horhat[1], P. Fischer[2], H. Corina[3], R. Ioana[4], C. Camelia[5], M. Tantau[6], C. Socaciu[7], B. Procopet[6], S. Horia[8]. *[1]Regional Institute of Gastroenterology and Hepatology "Octavian Fodor", Cluj-Napoca, Romania, Hepatology Department, Cluj-Napoca, Romania; [2]University of Medicine and Pharmacy "Iuliu Hatieganu", University of Medicine and Pharmacy "Iuliu Hatieganu", Cluj-Napoca, Romania; [3]Center for Applied Biotechnology BIODIATECH, Cluj-Napoca, Romania; [4]University of Medicine and Pharmacy "Iuliu Hatieganu", Pathology Department, Cluj-Napoca, Romania; [5]University of Medicine and Pharmacy "Iuliu Hatieganu", Research Center for Functional Genomics and Translational Medicine; [6]University of Medicine and Pharmacy "Iuliu Hatieganu", Gastroenterology and Hepatology, Cluj-Napoca, Romania; [7]Center for Applied Biotechnology BIODIATECH, Applied Biotechnology in Diagnostic and Molecular Therapy; [8]Regional Institute of Gastroenterology and Hepatology "Octavian Fodor", Hepatology Department, Cluj-Napoca, Romania*
Email: adelinahorhat@yahoo.com

Background and Aims: Severe alcoholic hepatitis (SAH) bares high mortality and morbidity rates, as well as high healthcare costs. Although serum biomarkers are available, its diagnostic relies on liver biopsy. Furthermore, the differential diagnosis between SAH and decompensated cirrhosis (DC) is impossible taking into account clinical and biological changes. In both conditions development of infections is common, leading to further impairment of hepatic function, complications, and increased mortality.
The aim of the study was to assess the metabolic phenotype of patients with severe alcoholic hepatitis and to identify potential biomarkers to differentiate SAH from DC.
Method: Seventy patients with biopsy proven SAH (Maddrey Discriminant Function ≥32) and 112 DC patients. Untargeted semiquantitative LC-MS based metabolomic analysis was performed using Thermo Scientific UHPLC UltiMate 3000 system and a Bruker Daltonics MaXis Impact MS detection equipment. After the chromatograms' analysis 3000–4000 molecular masses were identified. The matrix was further analyzed through univariate and multivariate statistical analysis using MetaboAnalyst3.0.
Results: Twelve potential biomarkers were identified. Of the five metabolites with increased levels in SAH, 2-Hydroxyglutarate (HG) (1.6063 fold change, $p = 1.6*10^{-23}$) and 12-Oxo-20-trihydroxy-leukotriene B4 (3OH-LTB4) (2.0671 fold change, $p = 5.23*10^{-12}$) were the most upregulated. Of the seven metabolites with decreased thresholds in SAH, 1,3,7-Trimethyluric acid (TMUA) (1.2289 fold change, $p = 2.9*10^{-7}$) was the most significant one. All three metabolites showed a very good accuracy for differentiation between SAH and DC (AUCs of 0.96 [95%CI: 0.926–0.991], 0.86 [95%CI: 0.796–0.913] and 0.84 [95% CI: 0.765–0.916], respectively).
In the subgroup of patients without infection (42 with SAH and 74 DC), decanoylcarnitine (10-OC) was significantly higher in SAH patients (0.96 fold change, $p = 2.57*10^{-4,}$ AUC= 0.73 [95%CI: 0.616–0.828]) compared with DC.
Conclusion: Alcoholic hepatitis appears to have a different metabolic profile compared with decompensated cirrhosis, in general and in the absence of infection. The identified metabolites (HG, 3OH-LTB4, TMUA and 10-OC) are involved in beta and omega oxidation of lipids, showing the importance of these pathways in the pathogenesis of SAH.

SAT-462

Persistence of decompensation despite long-term abstinence in alcoholic cirrhosis is associated with poor outcomes and lower survival

A. Clemente[1], D. Rincón[1,2,3], C. Martínez[1], C. Villaseca[1], E. Cervilla[1], M. Romero[1], A.M Matilla[1,2], R. García[1,2], G. Clemente[1,2], R. Bañares[1,2,3]. *[1]Hospital General Universitario Gregorio Marañón, Liver Unit, Madrid, Spain; [2]CIBERehd, Madrid, Spain; [3]Universidad Complutense, Madrid, Spain*
Email: ana.clemente@salud.madrid.org

Background and Aims: Alcohol withdrawal is a main prognostic factor in alcoholic cirrhosis. However, it has not been explored whether the effect of abstinence (>6 months) is homogeneous along the whole spectrum of the disease. Aim: to analyse if abstinent patients who remain decompensated have a worse evolution compared to viral or non-abstinent alcoholic ones.
Method: 190 decompensated patients consecutively admitted to our Liver Unit were included (viral n = 106; abstinent n = 54; non-abstinent n = 30). Patients with suspected or confirmed alcoholic hepatitis were excluded. Baseline and epidemiologic features were compared by ANOVA. Kaplan Meier curves were used to compare survival among the groups.
Results: Median age, 59 years (36–87). Male: 74%. MELD score was significantly higher in abstinent alcoholics (16 Vs 12 in active alcoholic and 11 in viral, p = 0.002). Abstinent patients had higher leukocyte count at admission than non-abstinent and viral (8.9×10^3 Vs 8.2×10^3 Vs 6.5×10^3, p = 0.004). CRP was also higher in abstinent patients (3.2 Vs. 2.2 in both non-abstinent and viral patients, p = 0.1). Previous ascites or encephalopathy was more frequent in abstinent patients (76% Vs 60% Vs 60%;p = n.s, and 45% Vs 23% Vs 26%;p = n.s). Bacterial infection and reason for admission were similar among all groups. ACLF at admission was more frequent in abstinent patients (35% Vs 11% in non-abstinent and 8% in viral, p = 0.004). 1-year survival was higher in active alcoholic than in abstinent ones with a trend towards statistical significance (Figure 1, Log-Rank 0.19, Breslow 0.091). No statistically significant differences were found in the proportion of patients who received liver transplantation during follow-up (5.3% non-abstinent Vs 24% abstinent Vs 19% viral, p = n.s). We made a case-control sub-study including 30 patients per group, matched by MELD and age. 1-year survival was similar among all groups (Log-Rank 0.770). MELD (HR 1.04, p = 0.036), age (HR 1.03, p = 0.001) and CRP (HR 1.07, p = 0.04) were found as independently predictive variables of survival.

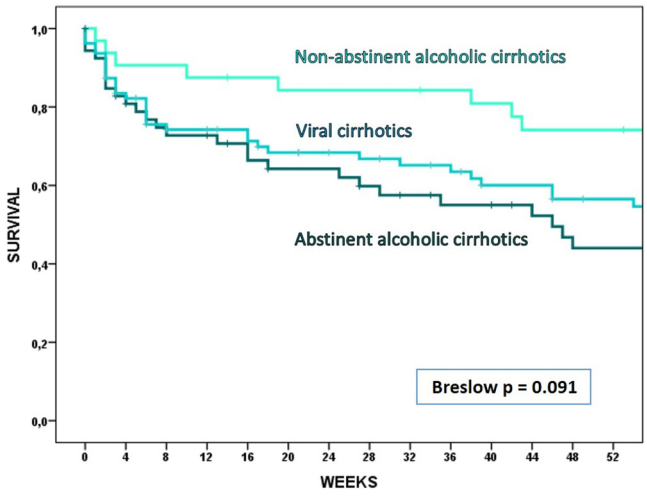

Figure 1:

Conclusion: Alcoholic cirrhotic patients who remain decompensated despite long-term alcohol withdrawal seem to have a worse prognosis as compared to non-abstinent alcoholic or viral cirrhotics due to a more advance disease in spite of etiological treatment. Therefore, this subgroup of patients could benefit from more intensive management as well as prioritization strategies on liver transplant list.

SAT-463

Corticosteroid treatment is associated with a resolution of altered CD4+ T cell phenotype in patients with severe alcoholic hepatitis

A. Dhanda[1,2], E. Yates[1], M. Cramp[1,2]. [1]*Plymouth University, Hepatology Research Group, Plymouth, United Kingdom;* [2]*Plymouth Hospitals NHS Trust, South West Liver Unit, Plymouth, United Kingdom*
Email: ashwin.dhanda@nhs.net

Background and Aims: Severe alcoholic hepatitis (SAH) is an acute inflammatory condition leading to liver failure and death in 30% of patients within 90 days. Corticosteroids have a proven short-term survival benefit but non-responders have the highest mortality. *In vitro* lymphocyte steroid sensitivity predicts 90-day outcome and $CD4^+$ T cell subsets are most resistant. We therefore hypothesised that $CD4^+$ T cells would have altered phenotype and response to corticosteroid treatment in non-responders. We examined $CD4^+$ T cell cytokine expression in patients with SAH before and after corticosteroid treatment.

Method: Consecutive patients with SAH, defined as recent onset jaundice with bilirubin >80 µmol/l in heavy alcohol drinkers (>60 g or 80 g ethanol/day in females and males respectively) with DF >32, were recruited. All patients were treated with prednisolone for 28 days after exclusion or adequate treatment of infection. 90-day outcome was recorded. Blood was taken at baseline and on day 7 of corticosteroid treatment and $CD4^+$ T cells were isolated by negative selection. T cells were cultured for 4 days with anti-CD3/CD28 T cell receptor stimulation before intracellular cytokine expression was quantified by flow cytometry.

Results: 30 patients were recruited (13 male; mean age 52, baseline DF 69). 90-day mortality was 20%. Baseline IL-10 was higher in non-survivors than survivors (2.4% v 1.5% of $CD4^+$ T cells; $p = 0.02$) but IL-17 and interferon gamma (IFNg) expression was similar. There was reversal of IL-10/IL-17 ratio in non-survivors compared to survivors (1.2 v 0.6; $p = 0.04$). On day 7 of corticosteroid treatment, all but 1 patient had an enhanced response to T cell receptor activation with greater IL-17 expression compared to baseline (1.6% v 12.6%; $p = 0.01$). However, cytokine expression (IL-17, IFNg or IL-10) at day 7 was not associated with 90-day survival. IL-10/IL-17 ratio was significantly lower than at baseline (0.9 v 0.1; $p = 0.01$) but was not associated with outcome.

Conclusion: These data suggest that $CD4^+$ T cells from patients who die from SAH have an altered phenotype favouring suppression of inflammation. Corticosteroid treatment enhances $CD4^+$ T cell cytokine expression and reverses the IL-10/IL-17 ratio but does not reveal any association with outcome. Therefore, initial immune dysfunction may predict outcome in SAH but steroid non-response in these patients is not completely explained by changes in T cell phenotype.

SAT-464

Morphometrical quantification of fibrosis correlates with clinical cirrhosis stage and predicts long-term survival in patients with alcoholic liver disease

K. Lackner[1], L. Binder[2], F. Rainer[2], R.E. Stauber[2]. [1]*Medical University of Graz, Institute of Pathology, Graz, Austria;* [2]*Medical University of Graz, Department of Internal Medicine, Graz, Austria*
Email: rudolf.stauber@medunigraz.at

Background and Aims: Histological subclassification of cirrhosis may allow definition of fibrosis stages with different clinical severity and prognosis. However, the value of histological staging is limited by intra- and interobserver variability. We therefore aimed to determine the relationship between morphometrically quantified fibrosis measured as collagen proportionate area (CPA) and clinical cirrhosis stages and long-term survival in patients with alcoholic cirrhosis.

Method: Liver biopsies of 149 consecutive patients with alcoholic liver disease (ALD), without other cause of liver disease were studied. CPA was quantified using TissueStudio® software (Definiens™). In addition, fibrosis was staged semiquantitively using the clinical research network (CRN) and Laennec systems. Clinical cirrhosis stages at the the time of liver biopsy were determined according to D`Amico. Complete follow up and outcome data were available from all patients.

Results: Mean CPA values progressively increased with Laennec fibrosis stage and correlated with clinical D`Amico stage ($p < 0.001$). Based on ROC analysis a CPA cut-off of 35% was found optimal for discrimination of prognosis. Patients with CRN stage ≥3 and CPA >35% had significantly worse 5-year survival than patients with CPA <35% ($p = 0.035$) whereas Laennec stage was not associated with survival ($p = 0.294$).

Conclusion: These findings suggest that morphometrical subclassification yields two cirrhosis stages with distinct clinical outcomes. CPA measurements may favorably substitute for semiquantitative histological fibrosis staging in ALD avoiding intra- and interobserver biases which limit the utility of conventional histological fibrosis staging.

SAT-465

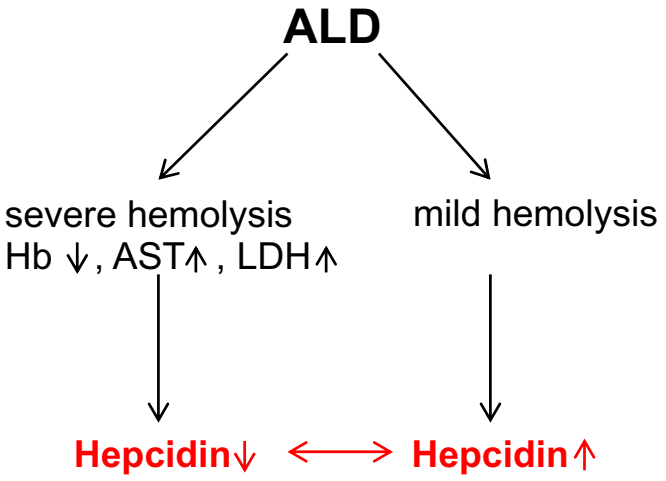
Masked hemolysis as novel factor contributing to hepatic iron overload in ALD

V. Rausch[1], I. Silva[1], T. Peccerella[2], S. Mueller[1]. [1]*Center for Alcohol Research and Salem Medical Center, University of Heidelberg, Heidelberg, Germany;* [2]*Salem Medical Center and Center for Alcohol Research and Liver Disease, University of Heidelberg, Heidelberg, Germany*
Email: vanessa.rausch@uni-heidelberg.de

Background and Aims: Patients with alcoholic liver disease (ALD) develop in ca. 50% prognostically unfavourable hepatic iron overload (HIO) and anemia, however, the underlying molecular mechanisms and the role of the systemic iron masterswitch hepcidin are poorly understood. Herein, we identify hemolysis as novel factor in disrupting hepcidin regulation and eventually causing HIO.

Method: Iron-related parameters, hepcidin (mRNA and serum levels), molecular and laboratory markers were studied in a large cohort of Caucasian heavy drinkers (n = 831, age range 22–87 years, mean alcohol consumption 192 g/day). Severe and mild hemolysis was further studied *in vivo* in age-matched C57BL/6 mice using two different phenylhydrazine (PHZ) treatment regimens. Histology, iron stain, mRNA and protein expression were studied both in liver and

spleen. An erythophagocytosis model (oxidized red blood cells co-cultivated with differentiated human THP-1 macrophages) was finally used to recapitulate *in vivo* findings and to analyse the underlying mechanisms *in vitro*.
Results: Indirect evidence for hemolysis (anemia, high ferritin, high LDH, high MCV) as cause for HIO was found in 16.4% of a large population of heavy drinkers. Notably, further indicators of hemolysis (haptoglobin, vitamin B12, folic acid) were not significantly changed most likely due to impaired liver synthesis in Alcoholics. Despite higher ferritin levels as compared to controls, hepcidin was not adequately upregulated in the hemolysis group suggesting a suppressive effect of hemolysis. We next recapitulated suppression of hepcidin in a murine model of severe PHZ-induced hemolysis. PHZ induced severe anemia, elevated transaminases, transferrin saturation and LDH within 24 hours. In the same time period, hemoxygenase 1 was highly induced while hepcidin was significantly lowered by 50%. Histology confirmed an increased number of phagocytosed erythrocytes in the spleen and iron-loaded Kupffer cells in the liver. In contrast, the mild hemolysis model strongly upregulated hepcidin mRNA. We finally study *in vitro* the process of erythrophagocytosis in human primary macrophages exposed to oxidized red blood cells. In confirmation of the *in vivo* findings, hepcidin showed also a concentration-dependent biphasic response. At physiological low levels of oxidized erythrocytes as found as normal age-mediated turnover, hepcidin was induced while it was strongly suppressed at higher pathological levels of oxidized erythrocytes.



Conclusion: Our data suggest that suppression of hepcidin by masked hemolysis seems to be an important mechanism leading to hepatic iron overload in patients with ALD.

Use of rifaximin in alcoholic hepatitis: Pilot study
C. Jimenez[1], M. Ventura[2], M. Sala[3], N. Cañete[4], M. Poca[5], M. Simón-Talero[1], J. Altamirano[1], R. Bataller[2], V.M.V. Blasco[1]. *[1]Hospital Vall d'Hebron, Liver Unit, Barcelona, Spain; [2]University of Pittsburgh Medical Center., Division of Gastroenterology, Hepatology, and Nutrition; [3]Hospital Germans Trias i Pujol, Gastroenterology Unit, Barcelona; [4]Hospital del Mar, Hepatology, Barcelona; [5]Hospital de la Santa Creu i Sant Pau, Gastroenterology Deparment, Barcelona*
Email: cesarjim14@hotmail.com

Background: Rifaximin (RFX), a non-absorbable oral antibiotic can reduce bacterial overgrowth and bacterial translocation in patients with liver disease.
Aims: To know if addition of RFX to the treatment of patients with alcoholic hepatitis (AH) is safety, can reduce bacterial infections, other complications and mortality at 90 days.
Method: In this multicenter pilot study, 24 consecutive severe AH patients (discriminant function of Maddrey >32) were recruited. They received 1200 mg/day of RFX in addition to standard steroid treatment. Finally, 19 patients were included (5 patients were withdrawn because of infection at admission). Results were compared with a prospective collected historical cohort (HC) of patients with AH paired by MELD (INTEAM cohort). The main variable to evaluate was the presence of bacterial infections at 90 days. Secondary variables to evaluate were safety of RFX, complications (renal failure, hepatic encephalopathy, gastrointestinal bleeding, liver failure) and death at 90 days. Clinical and biochemical variables, decrease of bilirubin (-Δ bili) and decrease of MELD (-Δ MELD) were evaluated at 7 and 90 days, respectively.
Results: In the rifaximin group (RG), 15 patients were male. The basal MELD was 22 ± 4 and basal bilirubin 13.7 ± 8.8 mg/dL; 15 patients had F3-F4 in liver biopsy. In the HC, basal MELD was 23 ± 6 and basal bilirubin 14.6 ± 8.7 (p = ns). Eight infections were observed in 4 patients of the RG while 7 infections were observed in 6 patients of the HC (p = ns). During the 90 days of follow up, there were 3 non-infectious complications in 3 patients of RG compared to 10 complications presented by 8 patients in the HC (p = ns). The overall 90-day mortality was 16% (3 patients) in RG and 47% (9 patients) in HC (p = 0.081). One patient died due to infection in the RG *vs* 5 patients in the HC. At day 7, a decrease in bilirubin was observed in 17 out of 19 patients in RG vs 8 out of 19 in HC (p = 0,006); the (−Δ Bili) was 8.71 mg/dl vs −4.32 mg/dl in the HC (p = 0.043). At day 90, the (−Δ MELD) was 6.7 in RG *vs* 4.7 in the HC (p = ns). No one adverse effect was attributable to RFX.
Conclusion: In this pilot study, we didn't observe a significant decrease of infections with the addition of rifaximin. RFX was a safe and well tolerated in patients with AH. A trend towards lower overall mortality and a significant decrease in bilirubin levels was observed in RG patients. These findings could support a certain beneficial effect of RFX.

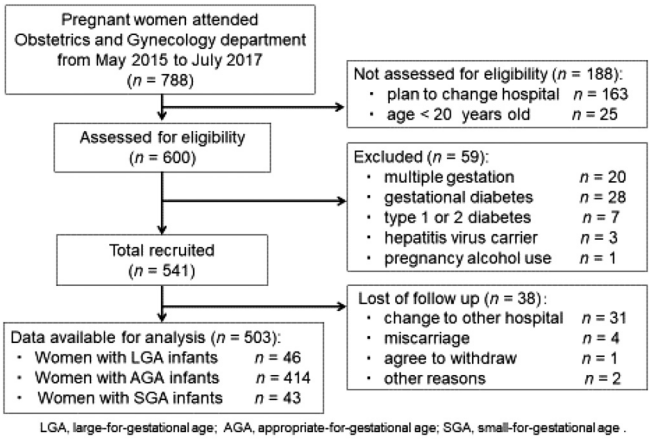
NAFLD: Clinical aspects except therapy

SAT-471
Maternal dietary patterns and the risk of large-for-gestational age births
S. Minato[1,2], N. Sakane[2], I. Hayashi[1,2], M. Suzuki[2], Y. Nose[1,2], S. Nirengi[2], N. Nagai[1]. *[1]University of Hyogo, Graduate School of Human and Environmental Science; [2]National Hospital Organization, Kyoto Medical Center, Division of Preventive Medicine, Clinical Research Institute*
Email: ne16i004@stshse.u-hyogo.ac.jp

Background and Aims: Large-for-gestational age (LGA) births is associated with an increased risk of pediatric obesity and non-alcoholic fatty liver disease (NAFLD). NAFLD is frequently first identified by elevated serum alanine aminotransferase (ALT). Elevated ALT levels in pregnant women are associated with an increased risk of LGA births. However, there is limited evidence on the association between the maternal dietary patterns and LGA. We aimed to identify the maternal dietary patterns among Japanese pregnant women that associated with an increased risk of LGA births.
Method: This case-control study enrolled pregnant women with LGA or appropriate-for-gestational age (AGA) infants attending our hospital from 26-5-2015 to 25-10-2017. LGA was defined as birthweight >90th percentile for gestational age. Exclusion criteria were as follows: multiple gestations, diabetes mellitus (DM), gestational DM, hepatitis virus, and alcohol use in pregnancy. We collected information on maternal diet using a food frequency questionnaire at three time points: first, second, and third trimester.

Maternal ALT levels were measured in the third trimester. In addition, to investigate whether genetic background acts as a related factor of LGA births, PNPLA3 polymorphism (rs738409) and microsomal triglyceride transfer protein (MTP) polymorphism (rs1800591) were determined using ABI PRISM 377 DNA sequencer. Maternal baseline characteristics were compared between the LGA and AGA groups with statistical analysis of Student's t-test and chi-square test or Fisher exact test. A two-tailed $P < 0.05$ was considered statistically significant.

Results: Of 541 recruited pregnant women, we identified 46 women with LGA infants and 414 women with AGA infants. The dropout rate was 7.0%. The maternal body weight gain during pregnancy, log-transformed ALT levels and total energy intake at third trimester were significantly higher in the LGA group than in the AGA group. The intake of low-fat dairy products per 1,000 kcal of energy intake in the LGA group was significantly lower than that in the AGA group. In addition, rates of keeping in mind eating vegetable and fish in the LGA group were significantly lower than in the AGA group. There were no differences in glucose levels, maternal age, pre-pregnancy body mass index, genotype and allele frequency of PNPLA3 and MTP, and intake of normal- and high-fat dairy products between the two groups.



LGA, large-for-gestational age; AGA, appropriate-for-gestational age; SGA, small-for-gestational age .

Figure . Pregnant women recruitment and follow-up flow diagram.

Conclusion: These findings suggest that some maternal dietary patterns are associated with an increased risk of LGA births. Further studies will be required to clarify these issues in the future.

SAT-472

Impact of short term weight loss (very low calorie diet vs bariatric surgery) on hepatic insulin resistance and plasma lipidomic profile

C. Barbieri[1], F. Carli[1], M. Gaggini[1], A. Iaconelli[2], A. Veneziani[2], F. Rubino[3], G. Mingrone[2], A. Gastaldelli[1]. *[1]Institute of Clinical Physiology, CNR, Pisa, Italy, Cardiometabolic Risk Unit; [2]Catholic Univeristy, Department of Internal Medicine, Rome, Italy; [3]King's College, Division of Diabetes and nutritional Sciences, Bariatric and Metabolic Surgery, London,*
Email: amalia@ifc.cnr.it

Background and Aims: Bariatric surgery (BS) is associated with a fast weight loss not only in adipose tissue but also in the liver and it is considered as a possible treatment for obese patients with NAFLD. RYGB in particular is associated with a fast metabolic improvement. We have shown that insulin resistance (IR) especially in the liver (Liver-IR) is reduced already 1-week after surgery. A recent report in diabetic rats reported that 3 days of very low caloric intake (VLCI) are sufficient to change liver lipidomic profile. Thus, we tested if improvement in Liver-IR after 1-week of either VLCI or BS was associated with a better lipid metabolism in the liver reflected by the improvement in plasma lipidomic profile.

Method: The cohort comprised 20 morbid obese non-diabetic patients (BMI = 44.2 ± 0.7 kg/m^2). Subjects were admitted twice to the hospital to measure hepatic, adipose tissue and muscle IR by stable isotope tracer infusion during fasting and during a hyper-insulinemic euglycemic clamp (HE-Cl). The first time patients were studied at baseline and 1-week after VLCI (600 kcal/day). Approximately 3-months later patients were admitted again for bariatric surgery, gastric banding LAGB (n = 10) or bypass RYGB (n = 10), and IR was evaluated one week after surgery. In all subjects we measured endogenous glucose production (EGP), lipolysis (RaGlycerol), peripheral (M/I), hepatic (Liver-IR = (EGP•Ins)) and adipose (Adipo-IR = (RaGlycerol•Ins)) insulin resistance and lipidomic profile (triacylglicerol (TAG), diacylglycerol DAG, lysophosphatidylcholine (LysoPC), phosphocholine (PC) end ceramide (Cer) by LC-MS QTOF).

Results: After 1-week of VLCI, patients lost 2.1 kg without significant changes in Hep-IR, Adipo-IR, M/I or DI. RYGB and LAGB led to greater weight loss, (5.5 and 5.2 kg) and significant improvement in Liver-IR, EGP and lipolysis. Only RYGB improved also Adipo-IR and M/I.
After 1-week of either VLCI or BS circulating triglyceride concentrations were unchanged (from 150 mmg/dl to 149 to 129 mg/dl, p = ns). Despite an improvement in Liver- and Adipo-IR after VLCI or BS, the plasma lipidomic profile was unaltered (in average DAG 1.35%, Cer 0.54%, LysoPC 33.85%, PC 44.22% and TAG 20.03%; after VLCI = DAG 1.39%, Cer 0.54%, LysoPC 32.27%, PC 44.97%, and TAG 20.84%; after BS = DAG 1.95%, Cer 0.51%, LysoPC 34.30%, PC 43.07% and TAG 20.18%). The changes in inflammatory markers were mild and similar in RYGB and LAGB.

Conclusion: The hepatic effects of BS on the liver IR of non diabetic morbid obese subjects are visible already 1-week after surgery and independent of caloric intake; in general the effects were more pronounced after RYGB than LAGB, but 1-week was not sufficient to observe a significant change in plasma lipidomic profile.

SAT-473

Substantial healthcare utilization (HCU) and costs among non-alcoholic steatohepatitis (NASH) patients with comorbid diabetes mellitus (DM): Real-world analysis of 2007–2015 US Medicare data

S.C. Gordon[1], S. Li[2], Y. Peng[2], X. Wang[2], R. Wong[3]. *[1]Henry Ford Hospital, Detroit, United States; [2]Chronic Disease Research Group, Minneapolis; [3]Highland Hospital, Oakland, United States*
Email: sgordon3@hfhs.org

Background and Aims: DM is a known risk factor for NASH. Data on HCU and costs in NASH patients with compensated cirrhosis (CC) by DM status is lacking. This study aimed to evaluate the impact of concurrent DM on HCU and costs among NASH patients with CC.

Method: The study population was extracted from 2007–2015 US Medicare 20% sample data and included NASH/Non-Alcoholic Fatty Liver Disease (NAFLD) patients (identified via ICD codes) with CC aged ≥18 years. First CC diagnosis date marked the index date. Patients with viral hepatitis, HIV, alcoholism or alcoholic liver disease, toxic liver disease, Wilson's disease, autoimmune hepatitis, biliary cirrhosis, gaucher + LAL-D, sclerosing cholangitis, hemochromatosis were excluded. Comorbidities were defined during the 6 months pre-index period (pre). HCU and costs were analyzed during the 6 months pre- and post-index period (post), and adjusted to per patient (PP) annual values in 2015 USD.

Results: The cohort included 3,775 NASH/NAFLD CC patients with mean age 67.0 (± 10.9) years and 63.3% females. More than 98% had at least one comorbidities including DM (74.8%), hyperlipidemia (91.6%), and hypertension (93.9%). Annual mean visits (inpatient, outpatient or physician) for CC cohort were 33.9 (pre) vs. 40.7 (post) ($p < 0.001$). Total costs for CC cohort was $19,385 (pre) vs. $33,504 (post) ($p < 0.001$). Comorbidity burden was high in both CC DM patients and CC non-DM patients – hypertension 97.1% (DM) and

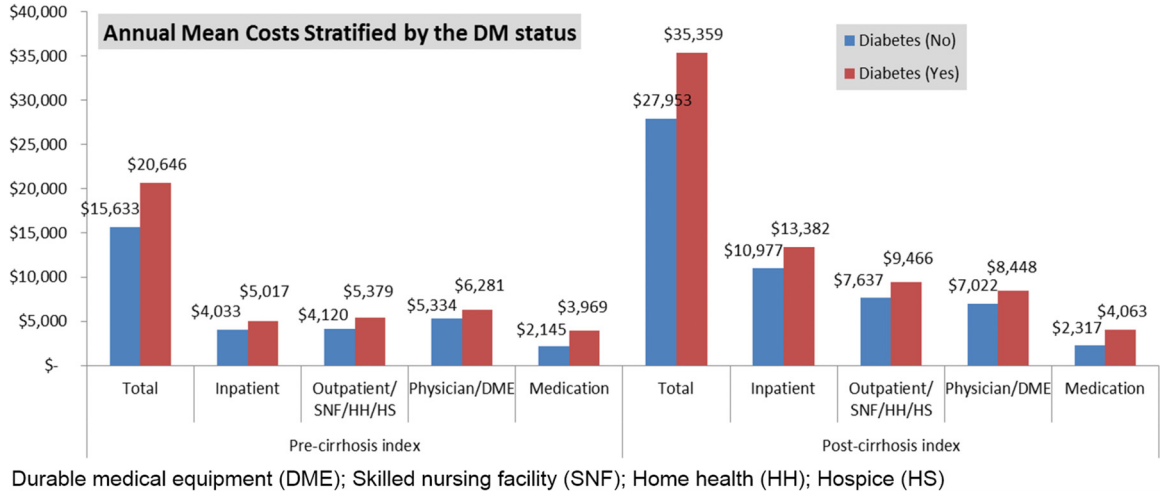


Figure: (abstract: SAT-473)

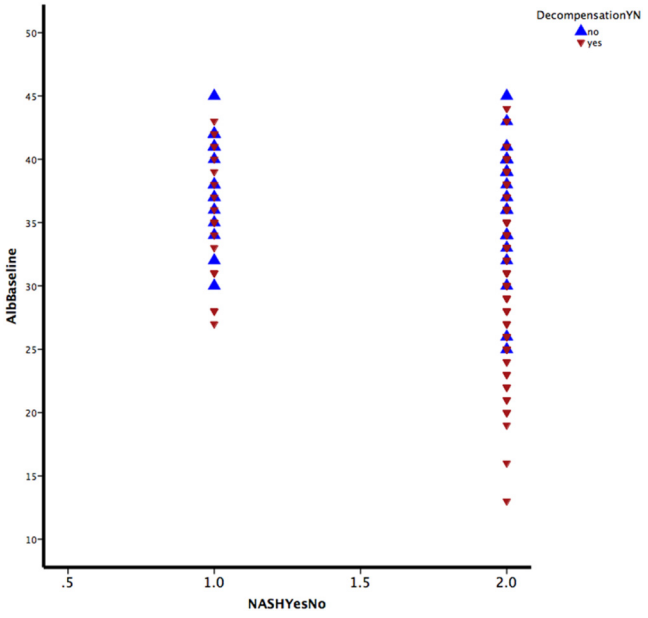
84.7% (non-DM); hyperlipidemia 95.3% (DM) and 80.7% (non-DM). For CC DM patients, mean inpatient visits were 0.52 (pre) vs. 0.99 (post) ($p < 0.001$), and for CC non-DM patients, mean inpatient visits were 0.37 (pre) vs. 0.76 (post) ($p < 0.001$). The total costs for CC DM patients were $20,646 (pre) vs. $35,359 (post) ($p < 0.001$), and for CC non-DM patients were $15,633 (pre) vs. $27,953 (post) ($p < 0.001$).
Conclusion: Medicare patients with NASH/NAFLD and CC reported a high comorbidity burden – 75% of them were diagnosed with DM. Diagnosis of CC increased HCU and costs by 20% and 72.8%, respectively. When stratified by DM status, impact of CC diagnosis on HCU and costs among NASH/NAFLD patients was even more substantial – inpatient visits increased by 89.7% (CC DM) and 102.5% (CC non-DM); costs increased by 71.3% (CC DM) and 78.8% (CC non-DM). Early identification and effective treatment of NASH/NAFLD CC patients is needed to reduce the risk of disease progression and higher associated HCU and costs.

SAT-475

Prediction of decompensation events in NASH cirrhosis patients

R. Forlano[1], D. Kockerling[1], R. Nathwani[1], J. Clancy[1], H. Marcinkowski[1], M. Yee[1], M. Thursz[1], H. Antoniades[1], A. Dhar[1], P. Manousou[1].
[1]*Department of Hepatology, Imperial College London*
Email: robertaforl@gmail.com

Background and Aims: Non-Alcoholic Steatohepatitis (NASH) induced cirrhosis is predicted to be the leading indication for liver transplantation worldwide. Estimating the prognosis of these patients remains challenging, considering the wide heterogeneity of this group. Few studies have compared the predictive value of conventional scoring systems according to different causes.
We aim to examine the performance of biochemical parameters and prognostic scoring systems in predicting the first episode of decompensation in NASH cirrhosis compared to other etiologies.
Method: 204 consecutive patients with cirrhosis referred to a tertiary care centre were prospectively enrolled in the study. Cirrhosis was diagnosed either clinically or histologically. Patients were followed-up for decompensation events and examination and biochemical data collected at baseline and at 6, 12, 18 months. Statistical analysis was performed using chi-square test and Cox regression analysis (SPSS).
Results: 204 patients were enrolled: 63% patients were male, median age 57.4 years. Etiologies were: 20% NASH, 52% alcohol, 20% viral hepatitis and 8% PBC/PSC.
In the whole group, 110 (54%) patients experienced at least one event of decompensation during the follow-up: 17/41 pts (41%) in NASH group, 93/163 (57%) in non-NASH group. Overall, the NASH group showed higher level of baseline albumin (36 ± 5 vs 32 ± 6, $p = 0.002$) (Figure 1) and body weight (94 vs 79, $p = 0.02$) compared to the non-NASH. There was no difference in terms of baseline Child-Pugh score (7 vs 7, $p = 0.1$), MELD (11.2 vs 11.9, $p = 0.4$) and UKELD (50.1 vs 51, $p = 0.23$).



Within the NASH group, baseline creatinine (78 vs 63, $p = 0.001$), PLT count (130 vs 143, $p = 0.001$), albumin (35 vs 39, $p = 0.002$) and UKELD (50.6 vs 46.8, $p = 0.001$) were significantly higher in the subgroup with decompensation compared to the subgroup without. There was no statistically significant difference in Child-Pugh score, MELD, cholesterol and HbA1c levels.
Within the non-NASH group, baseline Child-Pugh score (8 vs 5, $p = 0.002$), MELD (11.3 vs 8.6, $p = 0001$) and UKELD (51.7 vs 48,2, $p = 0.002$) were significantly higher in the subgroup with decompensation compared to the subgroup without. There was no difference in baseline albumin, HbA1c, cholesterol, PLT and creatinine.
Finally, Cox regression analysis for the prediction of cirrhosis decompensation revealed that UKELD was the strongest predictor in the NASH group (HR 1.172, $p = 0.017$, 95%CI 1.029–1.334), while Child Pugh Score in non-NASH group (HR 1.165, $p = 0.004$ 95%CI 1.049–1.293).

Conclusion: UKELD is the strongest predictor of decompensation in NASH related cirrhosis compared to Child Pugh score in the non-NASH aetiologies. Higher albumin and hypothetically body composition may explain a poorer predictive value of Child-Pugh score in the NASH population.

SAT-476

A mobile application for the management and follow-up of patients with Non-Alcoholic Fatty Liver Disease

R. Forlano[1], B.H. Mullish[1], N. Katertsidis[2], N. Giannakeas[3], A. Tzallas[3], M. Tsipouras[4], M. Yee[1], S. Taylor-Robinson[1], M. Thursz[1], P. Manousou[1]. *[1]Department of Hepatology, Imperial College London; [2]Department of Computer Engineering, University of Ioannina, Greece; [3]Department of Computer Engineering, Technological Educational Institute, Epirus; [4], Department of Informatics and Telecommunication Engineering, Greece*
Email: robertaforl@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) represents an increasing cause of chronic liver disease worldwide, with an estimated global prevalence of ~25%. Its prevalence has grown proportionally with obesity, sedentary lifestyle, unhealthy diet and metabolic syndrome. First line treatment is a combination of dietary modifications and increased physical activity. To address the challenge of empowering patients and clinicians to better manage lifestyle, we have designed a novel mobile application entitled F for Fitness.

Method: We have developed an intelligent and integrated solution for patients with Non-Alcoholic Fatty Liver Disease, consisting of: A smart mobile application for coaching and monitoring patients during their daily activities and a cloud-based web application for the management of patients and the storage/analysis of data. The central web application features intelligent issue tracking and a Powerful web analytics providing real-time track of users and their behavior. It is based on Apache Cordova, HTML5, JavaScript and supporting Android, iOS, Windows Phone.

Results: We specified, prototyped and developed a system consisting of an Android app accessible to the patients and a central platform accessible to the clinicians. The app consists of five main screens: Exercise, Food and Water Intake, Alcohol Consumption and Weight/BMI. Exercise is expressed in steps, meters and calories per day. Each meals recorded choosing between different visual options, ranging from raw ingredients to processed food. Similarly, the patients are asked to enter the quantity and the type of alcohol consumed daily. In order to give an educational feedback, nutritional facts are displayed after each choice and a pie chart shows the amount of calories consumed vs burned at the end of the day. Water intake is also required for the correct interpretation of variations in weight and BMI. Finally, each section tracks the history from the beginning of the use of the app. Built-in sensors and third party devices could fit in easily to manage health and environmental records such as heart rate, blood pressure, glucose levels.

Through the central platform, clinicians can access to the records and analyze patients' diet, food intake/exercise balance and alcohol habits. Moreover, each record is pre-filled with clinical data, such as latest Liver Function tests, Liver Stiffness Measurement and Histology report. Push notifications could be send to the patient by the operator, when necessary.

Conclusion: F for Fitness is a novel application prototype in Non-Alcoholic Fatty Liver Disease. This application acts as an educational tool for the patients and as a real-time follow up of lifestyle for the clinicians, allowing for a personalized management in this group. F for Fitness might be used in clinical practice and in future studies to monitor the effectiveness of behavioural programs.

SAT-477

Lipofuscin is detected in early stages of the disease in liver biopsies of patients with Non-Alcoholic Fatty Liver Disease

R. Morrison[1], R. Forlano[2], N. Giannakeas[3], A. Tzallas[3], M. Tsipouras[4], J. Lloyd[1], M. Yee[2], M. Thursz[2], P. Manousou[2], R.D. Goldin[1]. *[1]Department of Cellular Pathology, Imperial College, London; [2]Department of Hepatology, Imperial College London; [3]Department of Computer Engineering, Technological Educational Institute, Epirus; [4]Department of Informatics and Telecommunication Engineering, Greece*
Email: rebecca.morrison@imperial.nhs.uk

Background and Aims: Lipofuscin is a cytoplasmic pigment formed as part of the process of autophagy. Even though lipofuscin modifications have been reported in hepatocytes in a number of conditions, such as aging and carcinogenesis, its role in chronic liver disease is unclear. It is well known that autophagy plays a crucial role in the pathogenesis of Non-Alcoholic Fatty Liver Disease (NAFLD). It has been shown in experimental models that suppression of autophagy aggravates hepatic steatosis and NASH, while an increase improves fibrosis.

We aimed to detect lipofuscin accumulation using autofluorescence in liver biopsies of patients with NAFLD. We further correlated lipofuscin with clinical data.

Method: 78 consecutive patients with biopsy-confirmed NAFLD were retrospectively evaluated. Lipofuscin was reported as either absent or present in zone 3 after examination of Haematoxylin & Eosin stained slides under light microscopy. Biopsies were independently scored by two histopathologists and digitalised. Each image was then analysed by automated softwares to obtain Fat Percentage (Fat%) and Collagen Proportionate Area (CPA). Clinical and biochemical data were collected for all the patients included. Statistical analysis was performed using Chi-square test and logistic regression analysis.

Results: Under light microscopy, 25 liver biopsies were positive and 53 negative for lipofuscin. The group with lipofuscin showed higher HDL levels (2.1 vs 1.2 mmol/l, $p = 0.034$), lower LDL (2.1 vs 3.4 mmol/, $p = 0.04$) and lower ferritin levels (133 vs 277 ng/l, $p = 0.002$). Moreover, in this group, median fibrosis stage and median CPA were respectively 1.1 (±1.3) and 4.8% (± 5.5)compared to 2.5 (± 1.17, $p = 0.003$) and 8.7% (±2.7, $p = 0.002$) in the group without lipofuscin. Similarly, the number of "possible" and "definite" cases of NASH (7vs 22, $p = 0.001$) and the number of acute cardiovascular events (1 vs 4, $p = 0.02$) were significantly lower in the group with lipofuscin compared to the group without. There was no difference regarding steatosis grade and Fat%, lobular inflammation or ballooning score.

Logistic regression analysis showed that the presence of advanced fibrosis stage (F3-F4) was an independent factor for lipofuscin negativity (OR = 1.64, $p = 0.015$).

Conclusion: This is the first study involving the detection of lipofuscin accumulation in liver biopsies of patients with NAFLD. Lipofuscin is detected in early disease stage. Hypothetically, it may reflect the presence of an underlying autophagy mechanism which is still preserved in the early stages of the disease.

SAT-478

Stage-specific benefits of treatment associated fibrosis regression in patients with NASH: a Markov modeling approach

J. Chhatwal[1], S. Samur[1], E. Bethea[1], C. Hur[2], A. Samir[2], K. Corey[2], R. Loomba[3]. *[1]Harvard Medical School, Massachusetts General Hospital, Institute for Technology Assessment, Boston, United States; [2]Harvard Medical School, Massachusetts General Hospital, Boston, United States; [3]University of California at San Diego, Division of Gastroenterology, San Diego, United States*
Email: jagchhatwal@mgh.harvard.edu

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease in Western industrialized countries, and 10–20% of NAFLD patients have

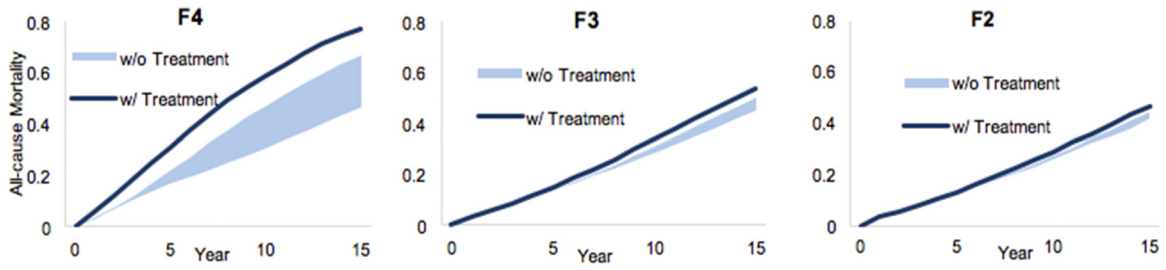


Figure: (abstract: SAT-478)

nonalcoholic steatohepatitis (NASH). Several pharmacological treatments for NASH are in early stages of development and have used fibrosis regression as a primary outcome. Our aim was to project the long-term clinical benefit of fibrosis regression that could result from new potential treatments.

Method: We developed a Markov-based mathematical model that simulated the lifetime course of NASH patients as they progressed through the stages of the natural history: including NASH fibrosis states (F0–F4), decompensated cirrhosis (DC), and hepatocellular carcinoma (HCC). The baseline patient characteristics in the model were derived from NASH Clinical Research Network data. The model accounted for both liver-related and non-liver-related mortality. Disease progression rates and mortalities were derived from published studies. Model-predicted overall survival was independently validated with 15-year data from three published observational studies. Patients with NASH fibrosis stages F2–F4 were assumed to be eligible for treatment. We simulated long-term outcomes of regression of fibrosis by one stage in 40% of patients, as observed in early-stage clinical trials.

Results: Our model predicted that fibrosis regression as the result of pharmacological treatment in 40% of F4 patients could reduce all-cause mortality from 77.0% to 46.3–66.6% (Figure), cumulative incidence of DC from 37.8% to 5.6–25.9%, and cumulative incidence of HCC from 19.7% to 0.5–13.4%. Fibrosis regression in 40% of F3 patients would reduce all-cause mortality from 53.3% to 44.7–50.2%, cumulative incidence of DC from 11.9% to 2.6–8.7% and cumulative incidence of HCC from 6.1% to 1.3–4.4%. Fibrosis regression in 40% of F2 patients would reduce all-cause mortality from 46.8% to 41.5–44.6%, cumulative incidence of DC from 6.1% to 0.29–4.1% and cumulative incidence of HCC from 3.1% to 0.1–2.0%.

Conclusion: Based on available data from investigational NASH therapies, regression of fibrosis could substantially improve overall survival and long-term outcomes in NASH patients—the magnitude of the benefits will be higher in patients having stage F4 followed by stage F3 and F2. Potential new therapies could reduce the rising burden and mortality resulting from NASH, especially if patients are diagnosed and treated in earlier stages.

SAT-479

NAFLD/NASH patients with compensated cirrhosis (CC) had a high prevalence of comorbidities, substantial liver disease progression, and increased annual number of hospitalizations and associated costs in France: a PMSI database analysis

J. Boursier[1], C. Fabron[2], A. Lafuma[2], I. Bureau[2]. [1]*Angers Hospital University, France;* [2]*CEMKA, Bourg La Reine, France*
Email: jeboursier@chu-angers.fr

Background and Aims: Non-Alcoholic Fatty Liver Disease (NAFLD)/Nonalcoholic Steatohepatitis (NASH) can progress to fibrosis, a leading cause of CC and end stage liver disease (ESLD) (decompensated cirrhosis, hepatocellular carcinoma or liver transplant). Limited real-world data exists on disease progression and costs for NAFLD/NASH patients. This study evaluated liver disease progression and hospitalization costs in French NASH/NAFLD CC patients.

Method: Patients ≥18 years of age with NAFLD/NASH (ICD-10: K76.0, K75.8) were identified from the French National Database on hospital care (PMSI) between 2009 and 2015. Patients with other causes of liver disease were excluded. All hospitalizations, whatever the cause, with CC diagnosis were extracted. The index dates were first dates of CC diagnosis in the study period.

Results: This study identified 131,898 NAFLD/NASH patients with a hospitalization. During the study period, 11.2% (n = 14,822) experienced CC, ESLD, and/or death. For the 1.2% (n = 1,546) patients diagnosed with CC in the study period, mean age was 62.4 ± 12.9 years and 54.3% were female. For patients who progressed to CC during the study period, the mean time to progression from NAFLD/NASH to CC was 22.4 months. During the study period, 16.2% (n = 251) of CC patients progressed to ESLD (mean time 20.0 months) and 8.3% of CC patients (n = 128) died (mean time 22.8 months). Comorbidities were: hypertension (67%), hyperlipidemia (40%), obesity (57%), T2DM (68%). The prevalence of comorbidities was significantly higher in T2DM than no T2DM patients. The number of annual hospitalizations per patient and length of stay significantly increased following CC diagnosis (0.5 ± 1.0 to 2.2 ± 2.6 and 1.5 ± 4.2 to 4.4 ± 6.8 days, respectively, both $p < 0.0001$). Mean cost per hospitalization stay and annual hospitalization costs significantly increased following CC diagnosis and these costs were higher for T2DM patients than no T2DM. Specifically, cost per stay increased from €879 ± 1,921 to €2905 ± 3,268 and annual hospitalization costs increased from €2025 ± 6,792 to €7171 ± 21,718 (both $p < 0.0001$).

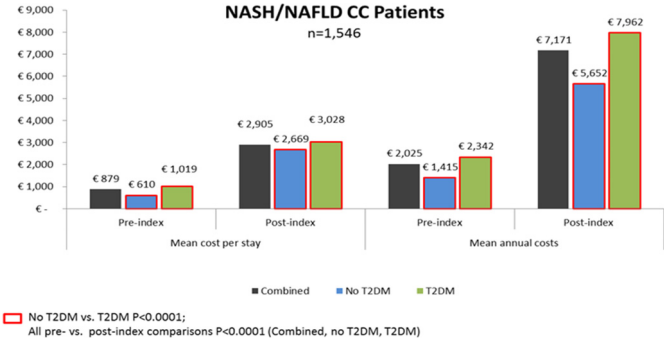

Figure: Mean cost per hospital stay and mean annual hospitalization costs for NASH/NAFLD CC patients pre- and post-index and stratified by T2DM and no T2DM patients

Conclusion: NAFLD/NASH CC patients experienced over 15% progression to ESLD and over 8% died over the 7 year study period. These patients had an over 300% increase in annual number of hospitalizations and over 250% increase in annual hospitalization costs following CC diagnosis. Improved treatment options are needed to decrease disease progression in NAFLD/NASH patients.

SAT-480

Histological severity is related to cardiovascular events in lean but not in overweight and obese subjects with NAFLD

A. Feldman[1], S. Eder[1], S. Ruhaltinger[1], M. Strasser[1], G. Strebinger[2], U. Huber-Schönauer[2], D. Niederseer[2], L. Stechemesser[3], B. Paulweber[3], C. Datz[2], E. Aigner[3]. [1]*Paracelsus Medical University, First Department of Medicine, Salzburg, Austria;* [2]*Hospital Oberndorf, Department of Internal Medicine, Oberndorf, Austria;* [3]*Paracelsus Medical University, First Department of Medicine*
Email: alexandra.feldman@outlook.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) typically affects overweight and obese subjects. Fatty liver is a known risk factor for cardiovascular diseases. We aimed to investigate the baseline characteristics of lean NAFLD subjects who subsequently developed cardiovascular events.
Method: In total, 464 patients had received the clinical and histological diagnosis of NAFLD at our two centres between 1997 and 2014 of whom 353 (76.1%) were available for follow-up after 8.8 (1–19) years. They were allocated to one of 3 groups according to BMI at the time of the liver biopsy: lean (BMI ≤ 25 kg/m, n = 48), overweight (BMI 25–30 kg/m², n = 195) and obese (BMI ≥ 30 kg/m², n = 110). A specific analysis with regard to cardiovascular events was performed.
Results: In 135 (38.2%) subjects a cardiovascular event had occurred, in 19 (39.6%) lean, 67 (34.3%) overweight and 49 (44.5%) obese subjects. In lean subjects with cardiovascular events, a higher degree of perisinusoidal fibrosis ($p < 0.001$; $p = 0.011$) and steatosis ($p = 0.016$; $p = 0.001$) were reported compared to obese and overweight subjects with cardiovascular events. Further, lean subjects with cardiovascular events had a higher degree of ballooning ($p = 0.001$) and periportal fibrosis ($p = 0.01$) in comparison to overweight subjects with events. Moreover, lean subjects with cardiovascular events had a higher rate of perisinusoidal fibrosis ($p = 0.042$) compared to those lean subjects without cardiovascular events. Framingham Risk Score at baseline was higher in each BMI group comparing subjects with to those without an event ($p < 0.01$ for all groups) and was similar comparing all subjects with events among all BMI categories.
Conclusion: Cardiovascular events in lean subjects were related to more pronounced histological changes such as ballooning and fibrosis, while no such link was observed in overweight and obese subjects. Likewise, fibrosis was also linked to cardiovascular disease among lean subjects. These findings suggest that histological severity may be particularly linked to cardiovascular events in lean NAFLD subjects in addition to risk estimates derived from traditional risk scores.

SAT-481

Characterization of patients with Both Alcoholic and Nonalcoholic Fatty Liver Disease (BAFLD) in a large United States cohort

N. Alkhouri[1], A. Singh[2], A. Vigni[3], M. Noureddin[4], R. Lopez[2], K. Watt[5], E. Lawitz[1,6], F. Poordad[1,6], K.V. Kowdley[7]. [1]*Texas Liver Institute, San Antonio, United States;* [2]*Cleveland Clinic;* [3]*Texas Liver Institute;* [4]*Cedars Sinai Medical Center;* [5]*Mayo Clinic;* [6]*University of Texas (UT) Health San Antonio;* [7]*Swedish Medical Center*
Email: alkhouri@txliver.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is the hepatic manifestation of the metabolic syndrome (MetS) and is characterized by the presence of liver steatosis in the absence of significant alcohol consumption. However, MetS and significant alcohol intake coexist in certain individuals which may lead to the development of both alcoholic and nonalcoholic fatty liver disease, an entity we propose to call BAFLD. The aim of the current study was to assess the clinical characteristics of patients with BAFLD in comparison to those with NAFLD in a large cohort of subjects in the United States.
Method: Adult subjects who participated in the National Health and Nutrition Examination Survey (NHANES) between 2003–2014 were included. Diagnosis of NAFLD was made based on elevated alanine aminotransferase (ALT) (>30 U/l in males and >19 in females) and being overweight (body mass index [BMI] ≥25 kg/m²) in the absence of other causes of chronic liver disease. Patients with BAFLD met the criteria for NAFLD but also had either MetS or type 2 diabetes and consumed excessive amounts of alcohol defined as ≥ 3 drinks/day for men and ≥ 2 drinks/day for women. Univariable analysis was performed to assess differences between NAFLD and BAFLD and multivariable analysis was performed to compare disease severity based on a validated fibrosis score (FIB4 index) after adjusting for MetS components.
Results: The prevalence of NAFLD was at 25.9% (95% CI; 25.1, 26.8) and that of BAFLD was 0.84% (0.67, 1.02) which corresponds to an estimated 1.24 million Americans affected by BAFLD. Compared to NAFLD, patients with BAFLD were more likely to be male (75.8% ± 3.9 vs. 46.9% ± 0.87), smokers (45.3% vs 17.6%), have higher ALT (53.1 vs 38.2 U/l), AST (43.3 vs 31.2), triglycerides (268 vs 186 mg/dl) and lower platelets (243 vs 261 k/ul); $p < 0.01$ for all. More importantly, after adjusting for MetS components, BAFLD patients were significantly more likely to have advanced fibrosis [adjusted OR (95% CI) based on FIB4 index > 2.67 was 3.2 (1.4, 7.0), $p = 0.004$].
Conclusion: A significant percentage of the American general population is afflicted by BAFLD. Patients with BAFLD tend to have more advanced disease based on biomarkers of liver injury and fibrosis scores. Therefore, special attention should be paid to this population to identify the burden of liver disease and intervene in a timely fashion.

SAT-482

Increased gut permeability is associated with oxidative stress in patients with NAFLD

F. Baratta[1,2], M.D. Ben[1], D. Pastori[1,2], G. Labbadia[1], M. Novo[1], R. Carnevale[1], F. Violi[1], F. Angelico[2]. [1]*Sapienza University of Rome, Internal Medicine and Medical Specialties, Rome, Italy;* [2]*Sapienza University of Rome, Anatomical, Histological, Forensic Medicine and Orthopedic Science, Rome*
Email: francesco.baratta@uniroma1.it

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) represents the most common liver disease worldwide. Based on multiple hits hypothesis, oxidative stress plays a pivotal role in NAFLD onset and progression from simple steatosis to steatohepatitis (NASH). However, factors inducing oxidative stress in NAFLD are still unknown. Clinical e experimental data demonstrated that intestinal bacterial overgrowth and augmented gut permeability were associated with NAFLD. Aim of the study was to investigate the relationship between oxidative stress and LPS in patients with NAFLD.
Method: We enrolled 44 were patients affected by non-alcoholic steatohepatitis (NASH); 50 subjects with simple steatosis (NAFL) and 50 subjects without hepatic steatosis balanced for age, gender and BMI were used as controls. Serum bacterial lipopolysaccharide (LPS) and serum zonulin, a marker of gut permeability, were measured with ELISA technique. Serum NOX2-derived peptide (sNOX2dp), a marker of NADPH oxidase activation, was detected in serum by enzyme-linked immuno- sorbent assay method.
Results: Patients had no difference in diabetes and arterial hypertension prevalence and in statin and aspirin use. NASH patients, as compared to NAFL and controls, had increased median sNOX2dp ($p < 0.001$) and increased median LPS ($p < 0.001$). At bivariate analysis sNOX2dp was correlated with LPS ($rs = 0.608$, $p < 0.001$), γGT ($rs = 0.576$, $p = 0.000$), AST ($rs = 0.560$, $p = 0.000$) and ALT ($rs = 0.620$, $p = 0.000$). LPS was correlated with zonulin ($rs = 0.375$; $p < 0.001$). At linear regression analysis, after correction for age, sex, BMI and diabetes and aspirin use, LPS above median (Beta = 0.059; $p < 0.05$) and liver diagnosis (Beta = 0.913; $p < 0.001$) were independently associated with sNOXdp.

	NASH (n = 44)	NAFL (n = 50)	Controls (n = 50)	P
Age (ys)	49.6 ± 11,8	51.3 ± 10.0	52.7 ± 14.1	0.449
Women (%)	48.0	56.0	46.7	0.609
Diabetes (%)z	33.3	20.0	14.0	0.069
Arterial Hypertension (%)	37.8	50.0	56.0	0.198
Statins (%)	26.7	32.0	42.0	0.273
Anti-platelet drugs (%)	8,9	10.2	14.0	0.700
Smokers (%)	33.3	30.0	34.0	0.901
Body Mass Index (kg/m^2)	28.9 ± 4.1	29.5 ± 3.6	28.5 ± 4.0	0.327
Obesity (BMI ≥ 30 kg/m^2)	36.0	48.0	33.3	0.289
γGT (UI/l)	45.0 (33.5/100.0)	19.0 (14.2/28.5)	16.0 (11.0/21.0)	0.000
AST (UI/l)	38.0 (29.5/51.5)	18.0 (15.0/21.2)	17.0 (15.0/21.0)	0.000
ALT (UI/l)	61.0 (44.0/96.5)	20.0 (16.0/24.2)	15.0 (13.7/19.0)	0.000
Glycaemia (mg/dl)	103.2 ± 33.7	97.6 ± 20.1	95.3 ± 23.3	0.329
sNOXdp	36.0 (33.0–38.0)	25.0 (23.0–27.0)	9.0 (8.7–11.0)	0.000
LPS	109.2 (45.4–138.6)	77.0 (39.8–107.7)	49.5 (36.2–60.0)	0.000
Zonulin	3.8 (2.0–5.50.000)	2.9 (2.1–4.6)	2.7 (1.9–3.9)	0.092

Conclusion: In conclusion, patients with NAFLD have higher sNOXdp indicating more oxidative stress in this setting. LPS increase may result from impaired gut permeability and induce oxidative stress.

SAT-483

Increasing trend for Hepatocellular Carcinoma (HCC) linked to Nonalcoholic Fatty Liver Disease (NAFLD) in the United States

E. Miller[1], L. Dakhoul[2], H.A. Sbeih[1], E. Mao[1], A. Delemos[3], P. Roche[3], A. Scanga[4], E.V. Gomez[2], S. Gawrieh[2], N. Chalasani[2], J. Wattacheril[5].

Email: emiller1@mdanderson.org

Background and Aims: NAFLD is a leading cause of cirrhosis in the United States (US). In addition to the risk of HCC in cirrhotic patients with NAFLD, there are recent reports of HCC in NAFLD patients without cirrhosis. We aim to identify the proportion of HCC in NAFLD patients with and without cirrhosis and describe their tumour characteristics over a 15-year period at 5 US academic liver centres.
Method: Centre-specific cancer registries were used to identify patients with well-characterized HCC from January 2000 to June 2014. Patient and tumour-related characteristics, liver disease aetiologies, cirrhosis presence/absence, treatment of HCC and survival data were extracted. We defined NAFLD as chronic liver disease with ≥ 3 risk factors (elevated body mass index (BMI), diabetes, hypertension, hyperlipidaemia, coronary artery disease or peripheral vascular disease) in the absence of another aetiology. NAFLD and non-NAFLD patients were compared according to the presence or absence of cirrhosis.
Results: We identified 2,454 HCC patients over the study period. 472 patients (19.2%) had NAFLD; 161 of these (34.1%) had no evidence of cirrhosis. Compared to all others, NAFLD patients were older, more frequently white (83.7% vs. 70.9%), had higher BMI, and had more comorbidities. Among cirrhotic patients, NAFLD-linked HCCs were larger (5.3 cm vs. 4.8 cm; p = 0.019) and more likely to be resected than transplanted, compared to HCC without NAFLD. For non-cirrhotic patients, comparison of NAFLD and non-NAFLD patients revealed no significant differences in tumor size or stage, although non-NAFLD HCC patients were more likely to be transplanted. NAFLD was not associated with higher mortality rates (HR 0.93; p = 0.24). See Table for NAFLD trends in HCC over time.
Conclusions: We observed an increasing trend in the proportion of NAFLD-HCC in the United States. A third of HCCs linked to NAFLD appear to occur in individuals without cirrhosis, but interestingly these patients also exhibited a downward trend among all causes of HCC over time. HCCs linked to NAFLD are larger in size and are less likely to be transplanted.

Table: Trends in HCC linked to NAFLD with or without cirrhosis

	HCC seen			
	2000–2004 (N = 464)	2005–2009 (N = 752)	2010–2014 (N = 1238)	P for trend*
Proportion linked to NAFLD (%)	16	20	20	0.045
with cirrhosis (%)	58	62	71	0.024
without cirrhosis (%)	42	38	28	<0.01

*All P values calculated by Cochran-Armitage trend test for ordered groups.

SAT-484

Non-alcoholic fatty liver disease in non-obese young adults

Y. Maor[1], S. Daher[2], E. Israeli[3], S.D. Malnick[4], E. Melzer[1], L. Katz[5].
[1]Kaplan Medical Center, Institute of Gastroenterology and Hepatology; [2]Hadassah Medical Center, Department og Gastroenterology and Hepatology; [3]Hadassah Medical Center, Department of Gastroenterology and Hepatology; [4]Kaplan Medical Center, Department of Medicine C; [5]Sheba Medical Center, Tel-Hashomer, Department of Gastroenterology
Email: halish@netvision.net.il

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is usually associated with obesity, the metabolic syndrome and insulin resistance. However, relatively little attention has been given to NAFLD in non-obese individuals. Data regarding the outcome of non-obese NAFLD is limited and contradictory. In a cohort of almost 2,000 young adults with NAFLD we previously showed a higher prevalence of metabolic co-morbidity including, diabetes mellitus than in age-matched controls. Our aim was to characterize a sub-group of non-obese young adults with NAFLD from this cohort.
Method: For the study, we included soldiers born after 1975 and who have been recruited after 2000. Cases of NAFLD were diagnosed in those soldiers with a compatible ICD-9 code and from ultrasound reports. Patients with known chronic liver diseases or hepatitis B and C infection were excluded. Individuals with BMI < 27 kg/m^2 at diagnosis of NAFLD were considered non-obese. Epidemiologic, anthropometric, clinical and laboratory data was collected from these groups.
Results: The study group included 1,421 subjects (86.9% male, mean age 22.6 years; range 18–41 years), of whom 204 (14.4%) were non-obese (BMI < 27 kg/m^2). Among young adults with NAFLD there were more women from a higher socioeconomic background. There were more subjects born in Ethiopia among non-obese NAFLD and more subjects born in Western countries among obese. At recruitment, non-obese young adults with NAFLD had a significantly lower BMI (22.6 ± 3.8 *vs.* 29.8 ± 5.4; p < 0.0001), and better military medical profile (less co-morbidity) than obese (0.61, 95% CI = 0.43–0.86; p = 0.003). Non-obese NAFLD had significantly higher HDL, lower LDL serum levels and a lower rate of elevates serum aminotransferases (ALT ≥ 45 IU/l) than obese NAFLD patients (p ≤ 0.02). Compared with obese, non-obese NAFLD in the young was associated with a significantly lower prevalence of: hypertension, dyslipidemia, and impaired fasting glucose (p ≤ 0.025), and borderline lower prevalence of diabetes mellitus (1.5% *vs.* 4.4%; p = 0.051).
Conclusion: Non-obese young adults with NAFLD are affected to a lesser extent with metabolic abnormalities, and probably with diabetes mellitus as well. This factor may put this sub-group at a lower risk of future cardio-metabolic morbidity. Therefore, these individuals may be considered to have a relatively benign disorder.

SAT-485

Risk factors for development of severe liver disease in more than 400 000 patients with type 2 diabetes: A population-based cohort study

K. Björkström[1], S. Franzén[2], B. Eliasson[3], M. Miftaraj[2], S. Gudbjornsdottir[4], Y. Trolle-Lagerros[5], A.-M. Svensson[6], H. Hagström[7]. *[1]Karolinska Institutet, Department of Medicine, Huddinge, Stockholm, Sweden; [2]Swedish National Diabetes Register, Gothenburg, Sweden; [3]University of Gothenburg, Gothenburg, Sweden; [4]National Diabetes Register, Gothenburg, Gothenburg, Sweden; [5]Karolinska Institutet, Department of Medicine, Huddinge, Sweden; [6]Gothenburg University, Gothenburg, Gothenburg, Sweden; [7]Karolinska Institutet, Stockholm, Sweden*
Email: karl.bjorkstrom@ki.se

Background and Aims: Patients with type 2 diabetes mellitus (T2DM) are at an increased risk of liver-related morbidity and mortality. Few studies have examined the association between T2DM and liver disease using population-based cohorts with available data on risk factors and confounders. The aim of this study was to compare the incidence of severe liver disease in patients with T2DM to that of non-diabetic matched controls, and to identify risk factors for development of clinically relevant liver disease.
Method: We used the Swedish National Diabetes Register, covering around 90% of all Swedish patients with T2DM. Each patient with T2DM was matched for age, sex, county and educational level to five controls free of T2DM. We used Swedish population-based registers to identify cases with incident severe liver disease during follow-up, defined as ICD-codes for cirrhosis, decompensated liver disease or liver failure, hepatocellular carcinoma and/or liver-related mortality. A multivariate Cox regression model was applied to estimate hazard ratios and to identify risk factors for development of severe liver disease.
Results: A total of 428 220 patients with T2DM and 2 141 100 non-diabetic controls were included, with a median follow-up of 7.7 years. Having T2DM was associated with an increased risk of developing severe liver disease compared to controls (adjusted HR 2.32, 95% CI 2.25–2.39, $p < 0.001$). Within the group of patients with T2DM, risk factors associated with development of severe liver disease were age, HbA1c, body mass index, glomerular filtration rate, microalbuminuria, blood pressure medication and smoking. Treatment with lipid-lowering drugs and male sex were associated with a reduced risk of development of severe liver disease (Table 1).

Table 1: Risk factors for development of severe liver disease

Variable	Adjusted hazard ratios (95% CI)	
Age (years)	1.04 (1.03–1.04)	<0.001
HbA1c (mmol/mol)	1.01 (1.00–1.01)	0.04
Body mass index (kg/m^2)	1.03 (1.02–1.04)	<0.001
GFR (ml/min/1.73 m^2)	1.01 (1.00–1.01)	<0.001
Microalbuminuria (yes/no)	1.22 (1.06–1.41)	0.01
Blood pressure medication (yes/no)	1.31 (1.14–1.50)	<0.001
Smoking (yes/no)	1.78 (1.55–2.05)	<0.001
Lipid-lowering drugs (yes/no)	0.59 (0.53–0.67)	<0.001
Male sex (yes/no)	0.72 (0.64–0.81)	<0.0001

Conclusion: Patients with T2DM are at a high risk for development of severe liver disease. Knowledge of risk factors can be used to identify patients at an increased risk for manifest cirrhosis or future severe liver disease.

SAT-486

Multidisciplinary intervention on lifestyle improves the management of patients with nonalcoholic fatty liver disease

S. Policarpo[1], M. Machado[2], D. Barreira[2], H. Cortez-Pinto[2]. *[1]Hospital Santa Maria, Serviço de Dietética e Nutrição, Lisbon, Portugal; [2]Hospital Santa Maria, Serviço de Gastrenterologia, Lisbon, Portugal*
Email: saraopolicarpo@gmail.com

Background and Aims: Lifestyle changes are difficult to implement. We aimed to assess the efficacy of a multidisciplinary team (MdT – gastroenterologist, dietitian and psychologist) in a combined intervention in patients with nonalcoholic fatty liver disease (NAFLD).
Method: Patients with NAFLD were invited to be managed in a MdT. Lifestyle modification (physical activity and Mediterranean diet) was applied. Anthropometric and clinical data [including liver biochemistry, transient hepatic elastography, NAFLD Fibrosis Score (NFS) and Fibrosis 4 score (FIB4)] were collected. Patients maintaining follow-up for at least 3 month were compared with those who declined MdT. Pregnant women, patients submitted to bariatric surgery and loss of follow up were excluded.
Results: 67 patients were included, 67.2% males, age 56 ± 12 years, mean time of diagnosis 8.3 ± 7.2 years. At baseline, BMI was 31.3 ± 5.6 kg/m^2, with 89.7% of patients being overweight and 56.7% obese; 50% of patients were F2-F3 and 22.2% F3-F4 as assessed by elastography; FIB4 was >2.67 in 12.5% of patients and NFS >0.675 in 30.5%, suggesting advanced fibrosis. After 3 months, 90.9% of patients lost weight and liver enzymes decreased in the majority of patients (AST in 73.6% and ALT in 71.7%), NFS decreased in 67.5% and FIB4 in 61.2%. From the 67 patients, 23.9% declined MdT (no-MdT group). After 3 months, weight decreased in 96% on MdT vs. 75% on the no-MdT ($p = 0.027$) and patients on MdT presented higher weight loss (3.8 kg vs. 2 kg no-MdT group). AST decreased in 78% of patients on MdT *vs.* 58.3% on no-MdT ($p = 0.018$), ALT decreased in 78% of patients on MdT *vs.* 50% on no-MdT ($p = 0.035$); FIB4 decreased in 50% of patients on no-MdT vs. 64.9% on MdT ($p > 0.005$) and NFS improved in 80% of patients on no-MdT vs. 67.5% on MdT ($p > 0.005$). Analyzing the 25 patients who were previously followed in Hepatology Unit, only 20% had lost weight before MdT, with a global positive variation in weight (0.8 ± 1.01%) as compared to negative variation after 3 months (4.9 ± 0.5%, $p < 0.001$). Similarly, previous to MdT, AST only decreased in 45% (globally increased 72 ± 35% *vs.* 19 ± 10 decrease after 3 months, $p = 0.048$) and ALT decreased in 38% (globally increased 86 ± 38% *vs.* 27 ± 11 decrease after 3 months, $p = 0.023$).
Conclusion: The aggregate data strongly suggests that a multidisciplinary team can improve the management of patients with NAFLD, increasing the efficacy of lifestyle interventions.

SAT-487

Long-term associations between non-high density Lipoprotein Cholesterol and Apolipoprotein B in young adulthood and subclinical atherosclerosis in persons with nonalcoholic fatty liver disease in middle age: the CARDIA study

L. Vanwagner[1,2], J. Wilkins[2,3], H. Ning[2], N. Allen[2], J. Siddique[2], C. Lewis[4], N. Terrault[5], J.J. Carr[6], M. Rinella[7], D. Lloyd-Jones[2,8]. *[1]Northwestern University Feinberg School of Medicine, Medicine-GI & Hepatology; [2]Northwestern University Feinberg School of Medicine, Preventive Medicine; [3]Northwestern University Feinberg School of Medicine, Division of Cardiology; [4]University of Alabama Birmingham, Preventive Medicine; [5]University of California San Francisco, Division of GI & Hepatology; [6]Vanderbilt University, Radiology; [7]Northwestern University Feinberg School of Medicine, GI & Hepatology; [8]Northwestern University Feinberg School of Medicine, Cardiology*
Email: lvw@northwestern.edu

Background and Aims: Coronary heart disease (CHD) is a leading cause of death in nonalcoholic fatty liver disease (NAFLD). Non-high density lipoprotein-C (NHDL-C) represents cholesterol *concentration* within atherogenic lipoproteins, while apolipoprotein B (apoB) represents particle *number* because each particle contains 1 molecule of apoB. High apoB may be the strongest clinical predictor of CHD risk in the general population; whether this is true in NAFLD is unknown. We sought to quantify associations between apoB, NHDL-C and the discordance between apoB and NHDL-C levels in young adulthood, with prevalent NAFLD, and coronary artery calcium (CAC) in adults with NAFLD in midlife.

Method: CARDIA recruited young adults ages 18 to 30 years in 1985–86. Participants with complete baseline data and year 25 (Y25) computed tomography (CT)-measured NAFLD and CAC score were included. NAFLD was defined as liver attenuation ≤ 40 Hounsfield Units after exclusions for other liver fat causes. CAC was defined as Agatston score >0. Baseline NHDL-C or apoB values were divided into tertiles and 4 mutually exclusive concordant/discordant groups, stratified based on being above or below median NHDL-C or apoB levels.

Results: Analysis included 2,508 participants (baseline age 27 years; 58% women; 53% white). Y25 NAFLD prevalence was 10%. Compared with the lowest tertile, higher odds of NAFLD were seen in the middle and high tertiles of apoB and NHDL-C in separate adjusted models. High NHDL-C and low apoB, but not high apoB and low NHDL-C, was associated with NAFLD. Among NAFLD participants (n = 261), NHDL-C/apoB discordance was not associated with CAC. Highest odds of CAC were observed in NAFLD participants with high NHDL-C (**TABLE**).

Table: NHDL-C, ApoB and Concordance/Discordance between NHDL-C and ApoB Categories in Relation to NAFLD or CAC > 0 Among Persons with NAFLD

		NAFLD Prevalence n = 2,508		CAC > 0 among NAFLD n = 261
	N	AOR (95% CI)*	N	AOR (95% CI)*
NHDL-C tertiles[¶]				
Low	835	REF	52	REF
Middle	837	**1.5 (1.0, 2.3)**	79	1.9 (0.68, 5.5)
High	836	**2.5 (1.7, 3.6)**	129	**3.6 (1.4, 9.5)**
ApoB tertiles[†]				
Low	834	REF	56	REF
Middle	832	**1.7 (1.1, 2.5)**	90	1.1 (0.40, 2.8)
High	842	**2.0 (1.4, 2.9)**	115	**3.0 (1.2, 7.2)**
Concordance/Discordance in NHDL-C/ApoB				
Low/low	1036	REF	68	REF
Low/high	217	1.5 (0.79, 2.7)	31	1.1 (0.25, 4.6)
High/low	194	**3.5 (2.1, 5.8)**	144	1.2 (0.38, 3.8)
High/High	1060	**2.1 (1.5, 2.9)**	18	**3.5 (1.5, 8.3)**

*Adjusted for center, sex, race, baseline (age, education, smoking, alcohol, BMI, physical activity, systolic blood pressure/medication).
[¶]Median NHDL-C 121.7; Tertiles: low 27–107; middle 107–135; high 135–326 mg/dl.
[†]Median ApoB 89.0; Tertiles: low 26–79; middle 80–100; high 101–192 g/dl.

Conclusion: High NHDL-C is a strong early risk marker for both NAFLD and atherosclerosis among adults with NAFLD in midlife. Based on our findings, the additional benefit of measuring apoB levels for CHD risk stratification in adults with NAFLD is not apparent.

SAT-488

Association of nonalcoholic fatty liver disease with changes in left ventricular structure and function: The coronary artery risk development in young adults (CARDIA) study

L. Vanwagner[1,2], H. Ning[2], J. Wilcox[3], C. Lewis[4], J. Lima[5], J.J. Carr[6], M. Rinella[7], S. Shah[8], D. Lloyd-Jones[8,9]. *[1]Northwestern University Feinberg School of Medicine, Division of Gastroenterology and Hepatology, Chicago, United States; [2]Northwestern University Feinberg School of Medicine, Preventive Medicine, Chicago, United States; [3]Northwestern University Feinberg School of Medicine, Division of Cardiology, Chicago, United States; [4]University of Alabama Birmingham, Preventive Medicine, United States; [5]Johns Hopkins University, Cardiology; [6]Vanderbilt University, Radiology; [7]Northwestern University Feinberg School of Medicine, Division of Gastroenterology & Hepatology; [8]Northwestern University Feinberg School of Medicine, Cardiology; [9]Northwestern University Feinberg School of Medicine, Preventive Medicine*
Email: lvw@northwestern.edu

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is associated with high cardiovascular morbidity/mortality, including heart failure (HF). Abnormalities in left ventricular (LV) structure/function are associated with HF risk. Thus, understanding the relationship between NAFLD and change in LV structure/function over time may provide insight into the link between NAFLD and HF. In a large prospective population-based sample of U.S. adults, we examined the relationship between NAFLD and markers of LV structure/function.

Method: Participants from the CARDIA study year 25 (Y25) exam (age 43–55, 58% women, 48% black) with CT measured liver fat and comprehensive echocardiography were included (n = 1,876). Echocardiography was repeated at Y30 follow up (age 47–62). NAFLD was defined as liver attenuation ≤ 40 Hounsfield units after exclusions. LV geometry was classified into normal and abnormal by integrating relative wall thickness (RWT) and LV mass index. LV diastolic function was defined using Doppler and tissue Doppler imaging markers.

Results: NAFLD prevalence was 10%. At Y30 NAFLD participants had higher LV mass, RWT, prevalent LV hypertrophy and abnormal LV geometry versus non-NAFLD ($p < 0.01$). Those with NAFLD had impaired LV relaxation (E/A ratio), higher LV filling pressures (E/e" ratio) and lower ejection fraction (58.9% vs. 60.0%, $p < 0.01$). In multivariable analyses NAFLD was independently associated with markers of abnormal LV structure/function (Table). Adjustment for BMI attenuated associations.

Table: Association of NAFLD with Prevalent and Incident Markers of Left Ventricular Structure and Function

Parameters	Base[a]		Multivariable[b]		Multivariable + **BMI**	
	Estimate	P-value	Estimate	P-value	Estimate	P-value

Y25 to Y30 change in LV geometry						
LVH	3.1 (1.9–5.2)	<0.0001	2.1 (1.2–3.8)	0.01	1.6 (0.9–2.9)	0.15
Abnormal LV geometry	2.9 (1.7–4.8)	<0.0001	2.0 (1.2–3.5)	0.01	1.6 (0.9–2.8)	0.09

*Odds ratio (95% confidence interval) or β (standard error) from logistic or linear regression.
[a]Base: Y25 age, race, sex, center, education, income, alcohol use, smoking status, physical activity.
[b]Multivariable: Base + Y25 systolic blood pressure, total and HDL cholesterol, diabetes, GFR, medication for hypertension or lipids, and Y25 LV hypertrophy (LVH models) or LV mass/RWT (geometry models).

Conclusion: NAFLD is associated with subclinical changes in LV structure/function, which are precursors to HF. Obesity mediates this association and thus, may be a potential therapeutic target for prevention of HF in NAFLD.

SAT-489

Investigating the relationship between rare genetic variants and advanced fibrosis in pediatric nonalcoholic fatty liver disease

J. Wattacheril[1], S. Kleinstein[1,2], P.R. Shea[1,2], J. Lavine[1], M. Subramanian[3], R. Myers[3], J. Lefkowitch[1], C. Behling[4], S. Xanthakos[5], D. Goldstein[2,3]. *[1]Columbia University College of Physicians and Surgeons, Medicine; [2]Institute of Genomic Medicine; [3]Gilead Sciences, Inc; [4]Pacific Rim Pathology; [5]Cincinnati Children's Hospital*
Email: jjw2151@cumc.columbia.edu

Background and Aims: Nonalcoholic Fatty Liver Disease (NAFLD) is a common human disease that is estimated to affect 20–40% of the Western population. Common genetic variation in the patatin like

phospholipase domain containing 3 (*PNPLA3*) and transmembrane 6 superfamily member 2 (*TM6SF2*) genes have been associated with an increased risk of developing NAFLD, the severity of nonalcoholic steatohepatitis (NASH), and fibrosis in adults. We aimed to explore the role of rare genetic variants in an extreme phenotype of NAFLD: pediatric patients with advanced fibrosis.

Method: Whole exome sequencing data was generated for 230 pediatric patients diagnosed with NAFLD by histology recruited from the Nonalcoholic Steatohepatitis Clinical Research Network (NASH-CRN). Case-control single variant and gene-based collapsing analyses were used to test for rare variants that were enriched or depleted within the pediatric NAFLD cohort across seven clinically relevant phenotypes: fibrosis (116 bridging/cirrhotic stage 3/4 vs. 114 stage 0), steatosis (160 high vs. 70 low), NASH (132 aggregate vs. 96 no NASH), lobular inflammation (101 high vs. 129 low), hepatocyte ballooning (86 present vs. 144 absent), portal inflammation (203 present vs. 26 absent), and NAFLD activity score (NAS; 96 scored >4 vs. 134 scored ≤4). All results were adjusted for multiple testing using a Bonferroni correction.

Results: No genome-wide significant associations were found between rare variation and advanced fibrosis, steatosis, NASH, lobular inflammation, hepatocyte ballooning, portal inflammation or NAS. A biologically interesting, but non-genome-wide significant enrichment was observed in *MACF1* (microtubule-actin crosslinking factor 1) in NASH vs non-NASH subjects (gene-based p = 0.08) as well as subjects with advanced fibrosis vs those with no fibrosis (gene-based p = 0.06). Other non-significant genes of interest included *HERC1*, *ASCC3*, *CUX1*, and *CACNA2D4*, enriched in subjects without fibrosis. No enrichment of rare variants in *PNPLA3* or *TM6SF2* was observed across phenotypes.

Conclusion: In a cohort of children with histologically proven NAFLD, no genome-wide significant associations were found between rare variation and seven unique histologic features. Of particular interest is the lack of enrichment in established genes of interest in adults: *PNPLA3* and *TM6SF2*. Larger cohorts of children with NAFLD and advanced fibrosis are needed to conclusively determine whether rare genetic variation is an important factor in pediatric NAFLD and if pediatric and adult NAFLD represent different disease phenotypes.

SAT-490

Hepatic steatosis in an adult population: stronger correlation with the presence of obesity and insulin resistence than with the dietary pattern. Results from a cross-sectional study

Email: jorge.a.leitao@gmail.com

Background and Aims: Hepatic steatosis is very frequent in the general population, mostly associated with obesity and insulin resistance. Typical dietary patterns have been difficult to identify with controversial information. We aimed to estimate in a representative sample of the Portuguese adult population, what was the contribution of the dietary pattern in what concerns macronutrients and food groups for the presence of steatosis as well as the other traditional risk factors for steatosis.

Method: Population based study with a random sample of adult people (18–79 years), from National Health System registers not stratified by sex or regions. Participants, underwent past medical history, anthropometric measures, semi-quantitative food frequency questionnaire (FFQ) representative of the usual intake over the previous year, physical activity index (IPAQ), blood tests and ultrasound to diagnose hepatic steatosis (HS) according to Hamaguchi's ultrasonographic score (defined by a score ≥ 2). Statistical analysis was performed using SPSS 23.0.

Results: 834 participants were enrolled: 440 male (52.8%) mean age 49.8 + 17.2 years. Steatosis (S) was present in 37.9% when adjusted to national adult population. Dietary pattern showed that S had a more elevated caloric intake, (2731.97 vs 2589.09 Kcal; p = 0.032), although with no differences regarding the percentage calories from carbohydrates 44.1 ± 8.0 vs 46.7% ± 8.0, ns, lipids: 33.9 ± 3.1% vs 34.7 ± 6.9%;ns) or proteins (17.4 ± 3% vs 17.6 ± 3.1, ns). There was a significantly higher consumption of red meat in S, with no differences in amount of soft drinks, fruits, vegetables or legumes. In univariate analysis, main associations with S were: male sex, age, increased waist circumference, BMI >30 kg/m^2, alcohol abuse (males >30 g/day; females >20 g/day), insulin resistance (IR) (HOMA test >2.5), elevated triglycerides (HTG), and low HDL cholesterol. In multivariate analysis, age 35–64 years (p = 0.0015), BMI 25–30 and >30 kg/m^2 (p = 0.001), alcohol abuse (p = 0.002), serum glucose >100 mg/dl (p = 0.006), IR (<0.001), HTG (p = 0.001), and low HDL (p = 0.024), significantly associated with steatosis.

Conclusion: In the general population, the presence of steatosis strongly correlates with excessive alcohol consumption, obesity, aspects of the metabolic syndrome and insulin resistance, with no particular dietary pattern identified except increased caloric intake as well as red meat consumption.

SAT-491

Mixed hepatic iron deposition but not serum ferritin is associated with the presence of nonalcoholic steatohepatitis (NASH)

E. Buzzetti[1,2], S. Petta[3], R. Manuguerra[4], D. Cabibi[5], T.V. Luong[6], E. Corradini[2], M. Pinzani[1], A. Craxi[3], A. Pietrangelo[2], E. Tsochatzis[1]. Bi.M.I.S., Palermo, Italy;* [4]*Royal Free Hospital, Department of Cellular Pathology, London, United Kingdom;* [5]*University of Palermo, Department of Sciences for the Promotion of Health and Mother and Child Care, Anatomic Pathology, Palermo, Italy;* [6]*Royal Free Hospital, Department of Cellular Pathology, London, United Kingdom*
Email: buzzetti.elena@gmail.com

Background and Aims: High serum ferritin (SF) is a common finding in NAFLD but whether this reflects hepatic inflammation or true iron-overload has not been clarified.

In this study we assessed the presence and pattern of hepatic iron deposition, its correlation with SF and liver disease severity in patients with NAFLD.

Method: Patients with biopsy-proven NAFLD were retrospectively selected at two European centers. Clinical and biochemical details at the time of liver biopsy were collected. Liver biopsy samples were reviewed by a single pathologist in each center; presence of iron was assessed in hepatocytes (HC) and reticuloendothelial cells (RES) and graded. NASH was defined as the combination of any degree of steatosis, hepatocyte ballooning and lobular inflammation.

Results: Of the 472 patients with NAFLD, NASH was found in 248 (52%) patients, 88 of which had advanced fibrosis (≥F3).

Stainable hepatic iron was found in 120 (25%) patients and the pattern of deposition was HC in 38%, RES in 20%, mixed in 42% of cases. Subjects with stainable hepatic iron were more likely to be male and have high SF.

A mixed pattern of iron deposition was significantly associated with the presence of NASH when compared to absence or other patterns of

iron deposition. SF was not significantly different in patients with NASH or ≥ F3 fibrosis compared to those with no NASH or fibrosis <3. BMI, diabetes, ALT and a mixed hepatic iron deposition) were independently associated to NASH (Table).

	HR (95% CI)	p	HR (95% CI)	p
Age	1.01 (1.01–1.02)	0.01		NS
BMI	1.04 (1.01–1.08)	0.02	1.04 (1.01–1.08)	0.02
Hypertension	1.40 (0.95–2.07)	0.09		
Diabetes	3.02 (2.02–4.52)	<0.0001	2.66 (1.67–4.24)	< 0.0001
ALT	1.007 (1.003–1.01)	<0.0001	1.01 (1.01–1.02)	< 0.0001
Ferritin	1.001 (1–1.001)	0.09		
Hepatic iron				
No	–		–	
HC	0.79 (0.43–1.47)	0.46	0.65 (0.32–1.32)	0.24
RES	0.79 (0.35–1.83)	0.56	0.64 (0.24–1.72)	0.38
Mixed	2.29 (1.21–4.32)	0.01	2.41 (1.15–5.05)	0.02

Age (HR 1.04, 95%CI 1.01–1.06, p = 0.008), diabetes (HR 2.57, 95%CI 1.34–4.91, p = 0.004), platelets (HR 0.98, 95%CI 0.98–0.99, p < 0.0001) and BMI (HR 1.06, 95%CI 1.001–1.11, p = 0.044) were the only independent predictors of advanced fibrosis.

Conclusion: In NAFLD patients, presence of iron in both hepatocytes and RES is associated with NASH. The underlying mechanisms need to be investigated in future studies; such finding could provide the basics for the selection of patients at higher risk of disease progression by using modern MRI-based iron detection techniques.

SAT-492

NAFLD has a negligible role for survival in old subjects

L. Terenzi, F. Bergolari, V. Tallarico, D. Magalotti, M. Zoli, G. Bianchi.
University of Bologna, Medical and Surgical Sciences, Bologna, Italy
Email: marco.zoli@unibo.it

Background and Aims: NAFLD is the liver manifestation of metabolic syndrome, a risk factor for mortality and cardiovascular morbidity, but we ignore the role of steatosis "per se" in survival.
Method: Within the Pianoro Project (people > 65 years), anamnestic, clinical and laboratory data related to diabetes, hypertension, obesity, BMI, waist circumference, dyslipidemia were collected in 1144 subjects (551 M, 593 F, median age 72 years). We tried to evaluate the outcome of these subjects.
Results: We had information, with a follow-up of 12 years, for 672 subjects, 352M/320F; 294 were still alive. Among them, 286 have steatosis (176 degree 1, 96 degree 2, 14 grade 3), 355 a pathological waist circumference, 307 overweight, 103 mild obese, 7 moderate/severe obese, 208 with hypertriglyceridemia, 243 with low HDL cholesterol, 90 diabetic, 465 hypertese.
The dead subjects were older (75vs.70 years), there was no statistically significant difference in the BMI class, even though the BMI class, related with the steatosis class, decreased in relation to the age group (for each of the comparisons p < 0.001).
Patients still alive had higher BMI classes, albeit not significant (p = 0.068), and more relevant steatosis (p = 0.037). The variables associated with higher mortality were hypertension (p = 0.026), hypertriglyceridemia (p = 0.027) and low HDL cholesterol (=0.028). A logistic regression found that these variables, except BMI class and steatosis, and age were associated to an increased mortality.
In 516 subjects we know the exact survival and compute the time-dependent role of our variables. Kaplan-Meier analysis found that diabetes (p = 0.015), hypertension (p = 0.001), low HDL-cholesterol (p = 0.026), hypertriglyceridemia (p = 0.034) and advanced age class (>74 years, p < 0.001) were associated with increased mortality, while grade of steatosis (p = 0.017) and BMI class (p = 0.027) are protective. Cox's analysis revealed that aging (p < 0.001, Odds Ratio 1,11), hypertriglyceridemia (p = 0.002; OR 1.64) and diabetes (p = 0.078, OR 1,38) produced a worse outcome. Anamnestic/clinical records of hypertension and low HDL appear to be associated to a low mortality but the exact role of current pharmacological therapy should be considered (p = 0.014, OR 0.71; p = 0.03, OR 0.70, respectively). Steatosis and BMI class had no role.
Conclusion: The data obtained in our study, about elderly subjects, suggest a negligible role of hepatic steatosis and BMI class "per se" in prediction of survival, which need further considerations.

SAT-493

Do patients with abnormal liver tests and nonalcoholic fatty liver disease get statins even when indicated?

R. Rosenblatt[1], A. Buckholz[2], Z. Sherman[2], G. Ghosh[2], C. Lucero[1], A. Jesudian[1], B. Fortune[1], R. Schwartz[1], S. Kumar[1]. [1]*New York Presbyterian Hospital, Weill Cornell Medicine, Gastroenterology and hepatology, New York, United States;* [2]*New York Presbyterian Hospital, Weill Cornell Medicine, Medicine*
Email: RussellRosenblatt@gmail.com

Background and Aims: Hyperlipidemia and other components of metabolic syndrome are often concomitant diseases in patients with nonalcoholic fatty liver disease (NAFLD). Additionally, the most common cause of morbidity and mortality in patients with NAFLD is cardiovascular disease (not liver disease) and statin use is often warranted. However, NAFLD patients commonly have abnormal liver tests and providers can be hesitant to start statins, despite evidence that patients with a baseline elevation in liver enzymes are not at increased risk of hepatotoxicity. The aim of this study is to evaluate statin use in patients with hyperlipidemia using a nationally representative database.
Method: The National Health and Nutrition Examination Survey (NHANES), a nationally-representative survey, from 2005 to 2014 was used. Using a validated algorithm, adult patients with diabetes were included. Patients were excluded if they had viral hepatitis, excessive alcohol consumption, were pregnant, or had transaminase elevation >500 IU/l. Statin use was assessed by NHANES interviewers and hyperlipidemia was defined as an LDL >130 or patient history. Abnormal liver tests were defined as ALT >40 IU/l. Multivariate logistic regression was performed controlling for age and gender to assess for the effect of abnormal ALT on patients with hyperlipidemia, metabolic syndrome, and diabetes.
Results: 136,833,627 weighted participants were included in the sample; 74.6% had hyperlipidemia, 93.5% of which were taking a statin. Patients diagnosed with hyperlipidemia who had abnormal ALT were less likely to take a statin (86.3% vs. 89.1%, p = 0.001). Multivariate analysis noted that, when controlling for age and gender, abnormal ALT significantly decreased the odds of patients taking statins if they had diabetes (OR 0.75, 95% CI 0.57–0.99, p = 0.04), but not metabolic syndrome or hyperlipidemia.

Table 1: Odds of statin use

Variable	OR (95% CI)	P-value
Diabetes	0.75 (0.57–0.99)	0.04
Metabolic syndrome	0.94 (0.75–1.17)	0.60
Hyperlipidemia	1.01 (0.82–1.25)	0.92

*Controlling for age and gender

Conclusion: This study demonstrates that statins are underutilized in patients, who despite having appropriate indications for their use, have abnormal liver tests. When controlling for age and gender, statins are underused in patients with diabetes especially. Further education is needed to encourage providers to use statins to improve cardiovascular outcomes in patients with NAFLD.

SAT-494

The effect of microvascular complications of diabetes on advanced fibrosis in nonalcoholic fatty liver disease

R. Rosenblatt[1], A. Buckholz[2], G. Ghosh[2], A. Jesudian[1], C. Lucero[1], B. Fortune[1], R. Schwartz[1], S. Kumar[1]. [1]*New York Presbyterian Hospital, Weill Cornell Medicine, Gastroenterology and Hepatology;* [2]*New York Presbyterian Hospital, Medicine*
Email: RussellRosenblatt@gmail.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is a rapidly rising cause of liver disease and transplantation. Diabetes (DM) increases risk of advanced fibrosis, which affects overall and liver-related outcomes. While DM is a risk factor, the effect of glucose control has a less clear impact on advanced fibrosis. As hemoglobin A1c only captures glucose control for 3 months, microvascular changes from DM can be a more accurate long-term marker of glucose control. The aim of this study is to identify the impact of microvascular changes from DM on advanced fibrosis.

Method: The National Health and Nutrition Examination Survey (NHANES), a nationally-representative survey, from 2005 to 2014 was used. Using a validated algorithm, adult patients with DM were included. Patients were excluded if they had viral hepatitis, excessive alcohol consumption, pregnancy, or transaminase elevation >500I U/L. Advanced fibrosis was defined by ALT >40 and an elevated NAFLD fibrosis score, FIB-4 score, or AST to platelet ratio index. Microvascular changes included microalbuminuria, defined as a spot urine albumin:urine creatinine ratio >30 mg/g, and self-reported retinopathy. Multivariate logistic regression evaluated advanced fibrosis and included factors that independently increase the risk of advanced fibrosis.

Results: 13,942,859 weighted participants were included; 24.1% of patients had microvascular changes, of which 16.8% had microalbuminuria. These patients were older, had a higher mean hemoglobin A1c and longer DM duration. On multivariate logistic regression controlling for age, gender, race, and other DM characteristics, microvascular changes were not significantly associated with advanced fibrosis. However, with the same model, microalbuminuria significantly increased the risk of advanced fibrosis (OR 1.95, p = 0.03).

Table 1: Risk of advanced fibrosis

Variable	OR (95% CI)	P-value
Microvascular changes	1.33 (0.74–2.38)	0.34
Microalbuminuria	1.95 (1.06–3.57)	0.03
Retinoapthy	0.48 (0.20–1.16)	0.10

*Controlling for age, gender, race, obesity, DM duration, insulin dependence, and hemoglobin A1c

Conclusion: Using a nationally-representative survey, microvascular changes in sum were not associated with advanced fibrosis. However, microalbuminuria, objectively measured, in comparison to retinopathy, nearly doubled the risk of advanced fibrosis even when controlling for hemoglobin A1c. Further studies are required to better assess the effect of glucose control on advanced fibrosis.

SAT-495

Associations between sarcopenia and nonalcoholic fatty liver disease and advanced fibrosis in the United States

K. Wijarnpreecha[1], M. Scribani[2], D. Kim[3]. [1]*Bassett Medical Center, Internal Medicine, Cooperstown, United States;* [2]*Bassett Research Institute, Bassett Medical Center, Cooperstown, United States;* [3]*Division of Gastroenterology and Hepatology, Stanford University, Palo Alto, United States*
Email: dr.karn.wi@gmail.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) may be associated with sarcopenia, which share risk factors including chronic inflammation, insulin resistance, vitamin D deficiency. This study aimed to determine whether sarcopenia is independently associated with NAFLD and advanced fibrosis in a nationally representative sample of US adults.

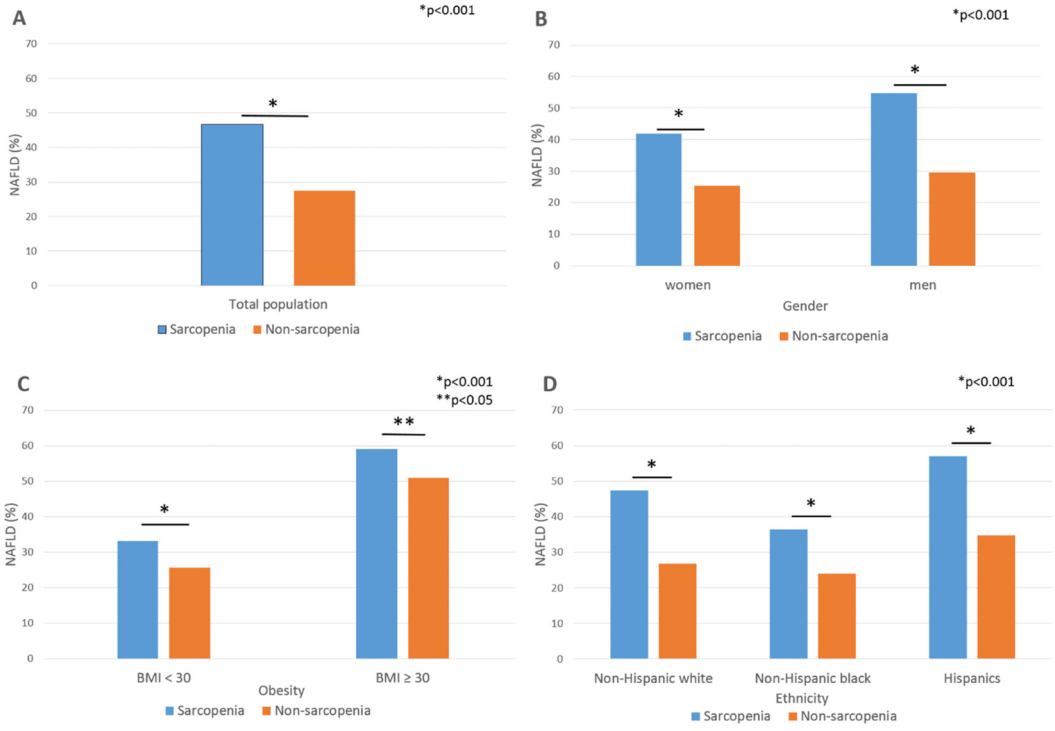

Figure 1: (abstract: SAT-495) Prevalence of NAFLD according to sarcopenia status. (A) Total population, We stratified by (B) gender, (C) obesity status, and (D) ethnicity.

Method: Cross-sectional data from 11,325 participants in the third National Health and Nutrition Examination Survey were analyzed. NAFLD was diagnosed by ultrasonographic hepatic steatosis without evidence of other liver diseases. The presence of advanced fibrosis was determined by the NAFLD fibrosis score. Sarcopenia was defined as skeletal muscle index that was measured by bioelectrical impedance analysis.
Results: NAFLD was more common in subjects with sarcopenia than in those without (46.7% vs. 27.5%), which was consistent in analyses stratified by gender, obesity status, and ethnicity. A univariate analysis showed that sarcopenia was associated with NAFLD (odds ratio [OR], 2.31; 95% confidence interval [CI], 2.01–2.64), which remained significant after adjustment for age, gender, ethnicity, metabolic risk factors, and vitamin D deficiency (OR 1.24; 95% CI 1.03–1.48). This finding persisted even after adjustment for C-reactive protein as a marker of chronic inflammation. Furthermore, NAFLD-associated advanced fibrosis was more common in subjects with sarcopenia than in those without (7.8% vs. 1.6%), which was also consistent in analyses stratified by gender, obesity status, and ethnicity. Sarcopenia was associated with NAFLD-associated advanced fibrosis independent of metabolic risk factors, vitamin D deficiency, and chronic inflammation (OR, 1.79; 95% CI, 1.18–2.72). An additional sensitivity analysis was conducted including insulin resistance in the model with similar results.
Conclusion: In this nationally representative sample of American adults, sarcopenia was independently associated with increased risk of NAFLD and NAFLD-associated advanced fibrosis independent of well-defined risk factors. Interventions to strengthen muscle mass may present an opportunity to reduce the burden of NAFLD and advanced fibrosis.

SAT-496

The platelet count is declining in American adults in parallel with an increase in risk factors for nonalcoholic fatty liver disease

A. Singh[1], A. Vigni[2], A. Tabbaa[3], E. Lawitz[2], F. Poordad[2], A. Scott[2], T. Okubote[2], M. Scott[2], M. Mansouri[2], R. Lopez[4], M. Noureddin[5], N. Alkhouri[2]. *[1]Cleveland Clinic - Main Campus, Gastroenterology and Hepatology, Cleveland, United States; [2]Texas Liver Institute, San Antonio, United States; [3]UC San Francisco, San Francisco, United States; [4]Cleveland Clinic - Main Campus, Cleveland, United States; [5]Cedars Sinai Hospital, Digestive Disease Center, Los Angeles*
Email: singha4@ccf.org

Background and Aims: Platelet count has been shown to be the single most useful laboratory investigation for identifying subclinical cirrhosis of varying etiologies. Evidence suggest that the prevalence of chronic liver disease is on the rise in the US. We aimed to investigate trends in platelet count in the American population and assess its correlation with risk factors for chronic liver disease.
Method: Adult (18 years or older) who participated in the National Health and Nutrition Examination Survey (NHANES) from 1999 to 2014 were identified and divided into 4 time periods (1999–2002, 2003–2006, 2007–2010, 2011–2014). To assess trends in platelet count across the cycles, a linear regression analysis was also performed. Since we combined different NHANES cycles, combined weights were calculated following the instructions provided in the NHANES analytic guidelines.
Results: A total of 19,734 patients were included in the final analysis. There was no difference in gender and age distribution. The platelet count decreased progressively over the years (267 k/uL ± 1.4, 271.9 ± 1.5, 252.3 ± 1.4 and 236.7 ± 1.3, in the 4 time periods respectively; $p < 0.001$). No differences were noted between the time periods in terms of the average number of alcoholic drinks per day or prevalence of chronic viral hepatitis. On the other hand, significant increases were noted in the prevalence of all the major risk factors for nonalcoholic fatty liver disease (NAFLD) including central obesity (45.7% in 1999–2002 to 52.2% in 2011–2014), diabetes (7.5% to 9.6%), glycohemoglobin % (5.3 to 5.5), hypertriglyceridemia (31.6% to 36.2%), and metabolic syndrome (22.9% to 25.3%), $p < 0.001$ for all. Interestingly, Mexican-Americans, an ethnic group with known increased risk for NAFLD, had a steeper decline in platelet count compared to Caucasians.
Conclusion: Over the past 2 decades, the average platelet count in the US general population has decreased by more than 40 k/ul. There was no increase in alcohol consumption or viral hepatitis during the same time period but significant increases of risk factors for NAFLD were present.

SAT-497

Real world evidence showing high rates of cardiovascular events in NAFLD patients regardless of liver disease

A. Sanyal[1], K. Cusi[2], R.J. Firpi[3], N. Gitlin[4], C. Levy[5], L. Malahias[6], R. Reddy[7], C. Schoen[6], L.M. Weiss[8], A. Lok[9]. *[1]Virginia Commonwealth University, Division of Gastroenterology and Hepatology, and Nutrition, Richmond, United States; [2]University of Florida, Division of Endocrinology, Diabetes, and Metabolism, Gainesville, United States; [3]University of Florida, 1600 SW Archer Road, Gainesville, United States; [4]Atlanta Gastroenterology Associates; 550 Peachtree Street NE, Suite 1720, Atlanta, United States; [5]University of Miami Miller School of Medicine; [6]TARGET PharmaSolutions, Inc., Chapel Hill, United States; [7]University of Pennsylvania, Hospital of the University of Pennsylvania, Division of Gastroenterology and Hepatology, Philadelphia, United States; [8]Gastro Florida, Clearwater, United States; [9]University of Michigan, Division of Gastroenterology and Hepatology, Ann Arbor, United States*
Email: lmalahias@targetpharmasolutions.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) affects approximately 30% of the adult population in North America. NAFLD is associated with increased cardiovascular (CV) events and mortality. Most of the existing data are derived from tertiary care centers. There is a need for "real-world" data to confirm the prevalence of CV disease in those with NAFLD. We sought to define the profile of CV risk factors in those with nonalcoholic fatty liver (NAFL), nonalcoholic steatohepatitis (NASH), and NAFLD cirrhosis in a real-world cohort of participants with NAFLD.
Methods: TARGET-NASH is a prospective study of the entire spectrum of NAFLD in the community and enrolls participants from a variety of clinical settings using commonly used, pragmatic case definitions. Across group comparisons were made by ANOVA. CV events were defined as myocardial infarction, stroke, angina, or cardiac interventions. CV disease history was defined as any cardiac disorder. A multivariable regression analysis was performed to identify factors associated with CV events.
Results: A total of 1494 participants (NAFL = 359, NASH = 574, NAFLD cirrhosis = 561) were studied. The median age was similar across groups (55–62 years) but the proportion of participants >50 years of age was highest in those with cirrhosis. Participants with NAFLD cirrhosis had a higher prevalence of type 2 diabetes (66.8 vs 37.3 vs 21.7%), hypertension (64.5 vs 50.0 vs 47.6%), dyslipidemia (39.6 vs 37.9 vs 22.6%), sleep apnea (28.3 vs 19.3 vs 6.7%), and ever smoked status, yes (54.7 vs 40.8 vs 46.8%), than those with NASH or NAFL, respectively ($p < 0.0001$ for all comparisons except ever smoked $p = 0.0003$). A significantly higher proportion of participants with NAFLD cirrhosis had ≥1 CV event (15.7 vs 7.1 vs 6.4%, $p < 0.0001$) and CV disease history (26.4 vs 17.2 vs 13.9%, $p < 0.0001$). Multivariate regression identified age, race, gender, dyslipidemia, smoking, and sleep apnea as independent predictors of experiencing ≥1 CV events. NAFLD cirrhosis was also identified as an independent predictor relative to NASH and NAFL.
Conclusion: A high proportion of participants with NAFLD have risk factors for CV disease and a high proportion regardless of disease severity experienced ≥1 CV event. Attention to CV diseases along with liver diseases is important in all patients with NAFLD.

SAT-498

The relationship between NAFLD and breast cancer: High prevalence and poor prognosis

Y.-S. Lee[1], C.U. Lee[1], S.J. Suh[2], Y.K. Jung[1], J.H. Kim[1], Y.S. Seo[3], H.J. Yim[4], J.E. Yeon[1], K.S. Byun[4]. *[1]Korea University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Korea University Ansan Hospital, Department of Internal Medicine, Ansan-si, Gyeonggi-do, Korea, Rep. of South; [3]KUMC Anam hospital, Internal Medicine, Korea, Rep. of South; [4]Korea University College of Medicine, Department of Internal Medicine, Gyeonggi-do, Korea*
Email: jeyyeon@hotmail.com

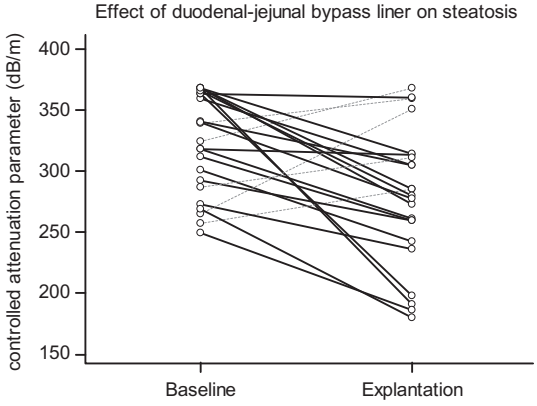
Background and Aims: Breast cancer is most common cancer in women worldwide, and it is a main cause of death in women. The incidence of breast cancer is correlated with metabolic component including diabetes, hypertension, and obesity. Likewise breast cancer, metabolic components are important risk factors for development of nonalcoholic fatty liver disease (NAFLD). In this study, we analyzed the prevalence of NAFLD in patients with breast cancer and the effect of NAFLD on the prognosis of breast cancer.
Method: Total 492 patients with breast cancer who received operation were enrolled from January 2010 to June 2014. Patients who had other chronic liver disease including chronic viral hepatitis B/C, autoimmune hepatitis, and primary biliary cholangitis and significant alcohol abuse (more than 140 g/week in women and 210 g/week in men) were excluded. Hepatic steatosis was evaluated by non-enhanced computed tomography (CT) scan. We measured values of regions of interest (ROI) for 5 times in liver and spleen, respectively. We diagnosed NAFLD when the average ROI of liver is higher than it of spleen 15 or more. 135 healthy controls who took non-enhanced CT scan were also analyzed.
Results: Mean age and BMI were 51.6 ± 11.0 years and 24.7 ± 9.9 kg/m^2, respectively. The prevalence of DM and hypertension were 9.5% and 24.6%, respectively. The prevalence of NAFLD in patients with breast cancer was 43.5% (214/492) and it was significantly higher comparing with healthy control (29.6%, 40/135) ($p = 0.004$). Overall survival did not showed significant difference between NAFLD group and non-NAFLD group ($p = 0.958$ by log-rank test). However, recurrence rate was significantly higher in patients with NAFLD (10.7%, 23/214) comparing with those without NAFLD (5.4%, 15/278) ($p = 0.027$). The disease free survival was significantly higher in in patients with NAFLD comparing with those without NAFLD ($p = 0.033$ by log-rank test). 15.9% of patients (34/214) experienced ALT elevation above 3 times of upper normal range, whereas only 10.4% of patients (29/278) showed elevation of ALT above 3 times of upper normal range ($p = 0.049$).
Conclusion: The prevalence of NAFLD in patients with breast cancer is significantly high compared to healthy control group. Moreover, breast cancer patients with NALFD showed poor prognosis in aspect of recurrence. Therefore, diagnostic evaluation of NAFLD would be important in patients with breast cancer.

SAT-499

Impact of duodenal-jejunal bypass liner on non-alcoholic fatty liver disease

T. Karlas[1], J. Feisthammel[1], T. Schütz[2], M. Blüher[3], R. Lichtinghagen[1], V. Keim[1], A. Hoffmeister[1], J. Wiegand[1]. *[1]Universitätsklinikum Leipzig, Klinik für Gastroenterologie und Rheumatologie; [2]Universitätsklinikum Leipzig, IFB Adipositas Erkrankungen; [3]Universitätsklinikum Leipzig, Klinik für Endokrinologie und Nephrologie*
Email: johannes.wiegand@medizin.uni-leipzig.de

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is strongly linked to obesity and type 2 diabetes mellitus (T2DM). Bariatric surgery induces weight loss, improves T2DM and NAFLD in morbidly obese patients. The endoscopically implanted duodenal-jejunal bypass liner (DJBL) is a less-invasive alternative to bariatric surgery, however data on the influence of NAFLD are limited so far. Thus, we characterized NAFLD after DJBL insertion.
Method: In patients undergoing DJBL treatment for T2DM and/or obesity NAFLD was prospectively characterized by liver stiffness measurement (transient elastography (TE) using M- and XL-probe as appropriate) including controlled attenuation parameter (CAP), and by the enhanced liver function (ELF) score. Alanine-aminotransferase (ALT), gamma-glutamyltransferase (GGT) and ferritin were used as parameters of hepatic inflammatory activity.
Results: DJBL was inserted in 31 patients and explanted in two cases after <2 weeks due to abdominal discomfort. Thus, 29 patients (59% female, median age 57 years) underwent DJBL treatment for a median period of 12 months (range 6.2–16.7). All of these achieved a significant weight loss (median loss 10%; BMI baseline 39.5 ± 8.6 vs. 35.2 ± 8.2 kg/m² at end of treatment, $p < 0.001$) and 52% an improvement of T2DM (HbA1c 7.3 ± 1.3 vs. 7.0 ± 12%, $p = 0.154$).
Serial TE/CAP and ELF values between baseline and end of DJBL treatment were available in 23 and 26 patients, respectively.
CAP improved from 332 (249–368) to 283 (180–368) dB/m ($p = 0.003$, Figure), ALT, GGT, and ferritin from 0.63 (0.31–4.41) to 0.43 (0.18–3.46) µkat/l ($p < 0.001$), 0.66 (0.22–7.74) to 0.37 (0.11–5.46) µkat/l ($p < 0.001$), and 147 (18–487) to 61 (9–402) ng/ml ($p < 0.001$), respectively. The number of patients with ALT, GGT and ferritin values upper the normal limit decreased from 11 to 3, 10 to 3, and 8 to 1.



Hepatic fibrosis assessed by TE (6.3 (3.6–23.4) vs. 4.9 (3–11.6) kPa) and ELF (9.00 (7.96–11.29) vs. 9.02 (7.93–10.77)) did not improve significantly. The number of patients with TE >7.9 kPa or ELF >9.8 was 4 vs. 4 and 4 vs.2.
Conclusion: DJBL is an effective option for endoscopic treatment of obesity and improves hepatic steatosis and inflammatory activity within a short period of time.

SAT-500

Nonalcoholic fatty liver disease in the first trimester and subsequent development of gestational diabetes: A prospective cohort study

W. Kim. *Boramae Medical Center, Internal Medicine, Seoul, Korea, Rep. of South*
Email: wonshiri@yahoo.com

Background and Aims: Recent evidences suggest that nonalcoholic fatty liver disease (NAFLD) is associated with impaired glucose tolerance and may be a manifestation of metabolic syndrome. We explored whether NAFLD can also be an independent risk factor for gestational diabetes in pregnant women.
Method: In this prospective cohort study, singleton pregnant women were assessed for NAFLD at 10–14 weeks by two different approaches: (1) the appearance of the liver on ultrasound and (2) the Fatty Liver-Index (FLI). Stored maternal blood samples at the time of liver ultrasound were assayed for adiponectin and selenoprotein. Patients were screened for gestational diabetes using the two-step approach (50 g oral glucose screening test followed by 100 g glucose tolerance test) at 24–28 weeks.

Results: (1) Among 608 women enrolled in the study, the prevalence of NAFLD was 18.4% based on liver ultrasound, and 5.9% (36/608) of women developed gestational diabetes; (2) Patients with gestational diabetes had higher rate of fatty liver in ultrasound, and had also higher fatty liver index; (3) The risk of subsequent gestational diabetes was significantly increased in cases with NFALD, and appeared to be related to the severity of the disease. This relationship between NAFLD and gestational diabetes remained significant after adjustment for clinical variables and HOMA-IR; (4) The prediction model constructed with clinical factors and fatty liver index predicted better the risk of gestational diabetes than that with clinical factors alone; (5) The maternal serum adiponectin and selenoprotein were closely correlated with both NAFLD and the risk for gestational diabetes.
Conclusion: The sonographic and/or biochemical evidence of NAFLD in early pregnancy is an independent risk factor for gestational diabetes. Both adiponectin and selenoprotein may be the biomarker linking NAFLD and gestational diabetes.

SAT-501

Plasma cells in non-alcoholic steatohepatitis correlates with disease activity

M. Lamba[1], C. Stedman[1,2], J. Ngu[1]. [1]*Christchurch Hospital, Department of Gastroenterology, Christchurch, New Zealand;* [2]*University of Otago, Christchurch, New Zealand*
Email: Mehullamba@gmail.com

Background and Aims: Plasma cells are often seen in liver specimens of patients with non-alcoholic steatohepatitis (NASH), however their significance is not known. We aimed to compare the clinical phenotypes of NASH based on the presence or absence of plasma cell: plasma-cell positive NASH (Ppos-NASH) and plasma-cell negative NASH (Pneg-NASH).
Method: All patients diagnosed with NASH between 01/01/2006 and 31/12/2016 were included. The diagnosis of NASH was confirmed if steatosis was present in over 5% of hepatocytes and non-alcoholic fatty liver disease activity score (NAS) was 3 or more. Patients with significant alcohol consumption (>14 units/week for females, >21 units/week for males), autoimmune liver disease, viral hepatitis, metabolic and hereditary liver diseases were excluded. Diagnosis of Ppos-NASH was based on detection of any number of plasma cells on liver biopsy. Liver decompensation was defined as development of any of the following: ascites, hepatic encephalopathy, hepato-renal syndrome or hospital admission with variceal bleeding.
Results: Sixty consecutive patients with diagnosis of NASH were included. The mean age at presentation was 49 years and 53.3% patients were male. Plasma cells were present in liver histology of 26.7% patients. Majority of patients with Ppos-NASH were female (68.7%) compared to Pneg-NASH (42.5%) ($p < 0.05$). Ppos-NASH patients had higher degree of steatohepatitis at the time of first biopsy compared to Pneg-NASH patients (mean NAS score 5.06 compared to 4.05, $p < 0.05$). Presence of plasma cells was not correlated to age at presentation or presence of advanced fibrosis. Levels of anti-neutrophil antibody, albumin, alanine aminotransferase and aspartate aminotransferase were not significantly different in Ppos-NASH compared to Pneg-NASH. During a median follow-up of 6 years, the risk of liver-decompensation in Ppos-NASH was 19.64% (95%CI 4.77–62.44), which was not significantly different from Pneg-NASH – 7.3% (95%CI 2.51–22.45). Similarly, overall survival at 6 years was not significantly different between Ppos-NASH and Pneg-NASH patients at 84.61% (95%CI 51.22–95.91) and 74.9% (95%CI 56.55–86.36) respectively.
Conclusion: We demonstrate that presence of plasma cells in NASH is associated with higher grade of inflammation, but not with presence of advanced fibrosis. It is not known whether plasma cells actively contribute to liver inflammation or are an epiphenomenon.

SAT-502

Cardiovascular risk factors and fibrosisseverity in NAFLD: is there a link?

D. Roccarina[1], M. Guerrero[1], L.I. Prat[1], E. Buzzetti[1], A. Goyale[1], F. Arico[2], F. Arico'[1], M. Rosselli[1], M. Pinzani[1], E. Tsochatzis[1]. [1]*UCL Institute for Liver and Digestive Health, Sheila Sherlock Liver Unit, Royal Free Hospital, London, United Kingdom,* [2]*University Hospital and School of Medicine, Department of Internal Medicine, Messina, Italy*
Email: davideroccarina@gmail.com

Background and Aims: It is well documented that patients with NAFLD have an increased cardiovascular risk due to the presence of metabolic comorbidities. However, it is not clear whether cardiovascular risk is associated with an increased risk of liver disease in patients with NAFLD. Carotid artery intima media thickness (CCA IMT) can be used as a predictor of increased cardiovascular risk. Therefore, we evaluated if IMT correlates with fibrosis severity in such patients.
Method: Consecutive patients with NAFLD were included. Transient elastography (TE) with FibroScan (Echosens) was performed in all patients and significant fibrosis was defined as a liver stiffness (LS) value ≥ 7.2 kPa. Abdominal fat thicknesses (subcutaneous minimum and maximum (SCmin, SCmax), pre-peritoneal (PP), peri-renal (PR), visceral (VF) and abdominal fat index (AFI, PP/SCmin), epicardial fat thickness (EF), spleen size (SS) and CCAs IMT were measured using Affiniti 70G ultrasound (Philips). A right CCA IMT >75 percentile was considered as significant predictor of cardiovascular disease according to published data.
Results: We enrolled 319 consecutive patients with NAFLD, 56.3% male, mean age 54 ± 13y, BMI 31.7 ± 5.8 kg/m2, waist circumference (WC) 107 ± 15 cm, 44% with diabetes, 55.7% hypertension, 81% hyperlipidaemia.
In the univariate analysis, a LS value ≥ 7.2 kPa was associated with diabetes, hypertension, right CCA IMT >75 percentile, age, BMI, WC, VF, SS, cholesterol, platelets, AFI, EF, GGT and ALT. In the multivariate analysis predictors of significant liver fibrosis were diabetes (OR 3.652, 95%CI 1.814–7.354, p = <0.0001), AFI (OR 0.549, 95% CI 0.342–0.881, p = 0.013), SS (OR 1.305, 95% CI 1.080–1.577, p = 0.006) and ALT (OR 1.012, 95% CI 1.004–1.020, p = 0.003). Conversely, predictors of a right CCA IMT > 75 percentile were increasing age (OR 1.096, 95%CI 1.060–1.134, p < 0.0001) and waist circumference (OR 1.034, 95%CI 1.010–1.057, p = 0.005). In the subset of 112 patients with available liver biopsy, the presence of NASH or significant fibrosis was not associated with an increased CCA IMT or epicardial fat.
Conclusion: Significant liver fibrosis is independent of increased cardiovascular risk in patients with NAFLD and is mainly associated with presence of diabetes, increasing ALT and decreasing AFI. Therefore, the progression of liver fibrosis is at least in part due to factors which are independent of the general features conditioning cardiovascular risk in patients with metabolic syndrome. Targeted interventions for components of the metabolic syndrome should be offered to all NAFLD patients irrespective of the severity of the underlying liver disease.

SAT-503

Prevalence, severity and patterns of clinicalpractice in outpatient visits for suspected NAFLD – the German CONSTANS STUDY

J. Schattenberg[1], U. Schönnenbeck[2], W. Marcus[1], P.R. Galle[1], D. Schuppan[3], Q. Anstee[4], R. Pais[5], V. Ratziu[5]. [1]*University Medical Center Mainz, Department of Medicine, Mainz, Germany;* [2]*University Medcial Center Mainz, Department of Medicine, Mainz;* [3]*Institute of Translational Immunology, Research Center for Immune Therapy (FZI), University Medical Centre Mainz, Mainz, Germany;* [4]*Institute of Cellular Medicine, Newcastle-upon-Tyne, United Kingdom;* [5]*Hôpital La Pitié Salpêtrière, Hepatology, Paris, France*
Email: joern.schattenberg@unimedizin-mainz.de

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) has become one of the most prevalent chronic liver diseases in

Western countries but no real-world data on the burden of NAFLD on health-care resources are available from European countries. The proportion of patients with NAFLD seen in outpatient visits and the utilization of medical resources for the management of these patients are unknown. This study aimed to assess the prevalence of NAFLD among outpatients in a specialized liver clinic at a tertiary care center.

Method: All outpatient visits at the liver clinic of the University Medical Center Mainz over a total of 20 weeks in 2 independent intervals in 2016 and 2017 were included. Data of patients with suspected NAFLD from the 2016 cohort was available for a 6 month follow-up study and the utilized resources, final diagnosis and disease severity was analyzed in this group. The cohort is part of the pan-European EPoS CONSTANS study.

Results: A total of 1973 patients (mean age 51.9 ± 15.3 y, 51% females) were seen in the outpatient clinic. Among the 2016 cohort 15.6% were newly addressed for suspected NAFLD, 40.5% for chronic viral hepatitis, 8.7% for alcoholic liver disease, 2.2% for suspected gastrointestinal cancer, and 28.7% for miscellaneous reasons. In the work-up of these patients, a follow-up visit was scheduled in 78%, 89% of patients underwent additional blood tests, 72% imaging by ultrasound and 20% Fibroscan. A liver biopsy was ordered in 7% and 2.4% of patients were hospitalized. Patients with suspected NAFLD presented with steatosis on imaging studies (2.3%), altered liver function tests (5.9%), known NAFLD (7.8%), increased ferritin level (0.1%) or cirrhosis of unknown origin (3.9%). In the 6 months following the initial 2016 consultation, NAFLD was confirmed in 50% of cases. In this group 23% were diagnosed with NASH on liver biopsy, 10% NAFL on liver biopsy and 9% had NAFLD cirrhosis. 14% of patients did not undergo biopsy but remained with suspected NAFLD. In 24% of patients a final diagnosis was not established in the 6 month follow-up period. The resources utilized to reach these diagnosis was ultrasound in 86%, 31% Fibroscan, 5% MRI, 8% CT, and 37% liver biopsy. In the group of patients that underwent liver biopsy during follow-up, NASH was found in 37% and advanced fibrosis/cirrhosis in 41%. Cost analyses for medical resource utilization will be presented.

Conclusion: In this prospective study, based on real-world data, 15.6% of patients at a Hepatology outpatient clinic were referred with a presumptive diagnosis of NAFLD, which was the second most common cause of consultation. Of these, half had confirmed NAFLD including 46% (3.1% of the entire cohort in 2016) with advanced fibrosis/cirrhosis. Both the prevalence of this condition and medical resource utilization and related costs are indicative of the substantial burden of disease NAFLD places on hepatological practice.

SAT-504

Analyze of ballooning biomarker in patients with non-alcoholic steatohepatitis: A multicenter study

Y. Honda[1], T. Kessoku[1], W. Tomeno[1], K. Imajo[1], M. Yoneda[1], S. Saito[1], T. Nakahara[2], S. Ooeda[3], H. Takahashi[3], H. Hyogo[4], Y. Eguchi[5], A. Nakajima[1]. *[1]Yokohama City University School of Medicine; [2]Hiroshima University; [3]Saga Medical School; [4]JA Hiroshima General Hospital; [5]Saga Medical School*
Email: rainbowman0803@gmail.com

Background and Aims: The progression of non-alcoholic fatty liver disease (NAFLD) has been considered to be complex involving multiple genetic factors interacting with the environment and lifestyle, however, the fundamental pathophysiology of NASH is still unknown. Recently, paired liver biopsy studies revealed that the annual fibrosis progression rate was found to be 0.07 stages for nonalcoholic fatty liver (NAFL) and 0.14 stages for patients with NASH. This means that it is important to noninvasively diagnose the presence or absence of ballooning, which is characteristic pathological findings diagnosis for NAFL or NASH. This study aimed to understand pathophysiology of NAFLD and to identify novel blood markers sensitive to ballooning.

Method: A total of 135 patients with NAFLD (NAFL = 88, NASH = 47) between 2014 and 2016 were enrolled from four Hepatology centers in Japan. NASH was diagnosed by steatosis, lobular inflammation, and hepatocyte ballooning. For the histological feature scoring system, we used the NAFLD activity score. Fibrosis were scored independently using the NASH Clinical Research Network scoring system. RNA-seq data analysis from liver biopsy samples was obtained from Ion Proton system, and pathway enrichment analysis was performed based on the known pathways from Ingenuity Pathways analysis. Metabolomics profiling analysis were carried out in plasma samples. Ethical approval for this study was given by the respective Institutional Review Board and subject written informed consent was obtained for all subjects.

Results: Potential pathways highly correlated with fibrosis stage and ballooning score, e.g. Coagulation System and Axonal Guidance Signaling were identified in NGS profiling in the NAFLD-related subjects. Plasma type IV collagen 7S was highly correlated with ballooning score (correlation coefficient = 0.47), and potential secreted collagens may be a diagnostic marker for ballooning. The metabolomics study indicated plasma metabolites including ether-linked lyso-phospholipids were possible biomarkers of NASH and established a new non-invasive score model, which included lisophosphatidylcholine (LPC) (e-16:0), phosphatidylcholine (PC) (aa-32:0) and xanthine to estimate ballooning score of NASH.

Conclusion: The potential pathways and the potential blood biomarkers need to be evaluated further and may result in target identification in drug discovery and non-invasive diagnosis in NASH.

SAT-505

Health-related quality of life correlates with histological severity in non-alcoholic fatty liver disease

Y. Huber[1], C. Labenz[1], T. Siebler[1], B. Straub[2], M.-A. Wörns[1], P. Galle[1], K. Hallsworth[3], M. Boyle[3], Q. Anstee[3], J. Schattenberg[1]. *[1]I. Department of Medicine, University Medical Center of the Johannes Gutenberg University, Mainz, Germany; [2]University Medical Center of the Johannes Gutenberg University Mainz, Institute of Pathology; [3]Institute of Cellular Medicine, Faculty of Medical Sciences, Newcastle University, Newcastle Upon Tyne, United Kingdom; Liver Unit, Newcastle Upon Tyne Hospitals NHS Trust, Freeman Hospital, Newcastle upon Tyne, United Kingdom*
Email: yvonne.huber@unimedizin-mainz.de

Background and Aims: Chronic liver disease potentially exerts a negative effect on a patient's health-related quality of life (HRQL). Aim of the current study was to explore the impact of disease severity defined by liver histology in patients with non-alcoholic fatty liver disease (NAFLD) on patient reported outcomes (PROs).

Method: As part of recruitment into the prospective EPoS NAFLD Registry, the Chronic Liver Disease Questionnaire (CLDQ), a liver disease specific instrument to assess HRQL, was measured in NAFLD patients within 6 months of routine diagnostic liver biopsy at centers in UK (Newcastle) and Germany (Mainz). A low score represents a lower quality of life.

Results: A total of 247 patients (54.3% male) were included in this study. The mean age was 52.1 (± 12.7) years. Mean CLDQ-overall score was 4.9 (± 1.3) and ranged from the lowest 4.2 (category: worry) to highest 5.4 (category: activity). Women exhibited a significantly lower CLDQ overall score than men (mean (SD) 4.6 (± 1.3) vs. 5.2 (± 1.2), $p < 0.01$). Reflecting lower HRQL, there was a negative correlation between overall CLDQ score and both BMI and presence of type 2 diabetes mellitus ($p < 0.05$). Laboratory parameters, especially liver function tests had no influence on HRQL. In contrast, histological features of NAFLD on liver biopsy had a significant impact on HRQL. Patients with a lower Steatosis-Activity-Fibrosis-score (SAF) showed higher HRQL (SAF0 vs. SAF3: 5.2 (± 1.5) vs. 4.4 (± 1.4), $p < 0.05$). Advanced fibrosis and cirrhosis (F3/F4) was observed in 103 patients

(41.7%) and these patients reported a significantly lower HRQL compared to patients with early or intermediate fibrosis (F0-2) (F3-4 vs. F0-2.: 4.8 (± 1.2) vs 5.1 (± 1.3), p < 0.05).
Conclusion: There is a substantial symptom burden in patients with NAFLD. Histological disease severity negatively impacts the reported HRQL, with an effect evident even in the absence of cirrhosis. Hepatic inflammation and fibrosis had the most profound effect on patient-related outcomes (PROs).

SAT-506

Influence of non-alcoholic fatty liver disease on cardiovascular risk in patients with stable coronary heart disease

I. Vakalyuk. *Ivano-Frankivsk national Medical University, Internal Medicine Department, Ivano-Frankivsk, Ukraine*
Email: ivakal5@gmail.com

Background and Aim: To evaluate the contribution of non-alcoholic fatty liver disease (NAFLD) in predicting risk of major cardiovascular events by cumulative proportion surviving depending on the SYNTAX score (SS) I in patients with stable coronary heart disease (CHD).
Method: 147 patients (aged: 54.2 ± 5.7 years) with stable CHD who have had an acute coronary syndrome with an indication of percutaneous coronary interventions more than 3 months ago were examined. Patients were categorized into 3 groups according to the SS I value, calculated during acute coronary event: Group I – SS I value was less than 22 (n = 61); Group II – SS I value was from 23 to 32 (n = 57); Group III – SS I value was more than 32 (n = 28). In each group, patients without NAFLD (subgroup A), with nonalcoholic steatosis (subgroup B) and with nonalcoholic steatohepatitis (NASH) (subgroup C) were identified. General clinical examination, ECG, EchoCG, liver elastography, liver ultrasound, evaluation of the liver functional state were performed to all patients. Each coronary lesion based on angiogram at the time of acute coronary event was scored to SS I, which was calculated with the SS I online calculator. Survival analysis based on Kaplan–Meier curves was evaluated by a two-year cumulative proportion surviving (%), the difference between groups was determined by Cox's F and Gehan's Wilcoxon tests.
Results. It was established that stable CHD course by SS I values depends on the presence and severity of NAFLD. In particular, in Group I NAFLD was observed in 14 (23.0%) patients: nonalcoholic steatosis was in 12 (19.7%) patients; NASH – in 2 (3.3%) patients. Moreover, 47 (77.0%) patients of Group I had no signs of NAFLD (p < 0.05). In Group II 20 (35.1%) patients were with nonalcoholic steatosis; 12 (21.1%) patients – with NASH; 25 (43.9%) patients – without NAFLD (p < 0.05). The most severe course of stable CHD was observed in patients of Group III: 7 (25.0%) patients were without NAFLD; 9 (32.1%) patients – with nonalcoholic steatosis; 12 (42.9%) patients – with NASH (p < 0.05). A two-year cumulative proportion surviving was the highest in patients without NAFLD: it was 89.6% at Group IA; 72.8% – at Group IIA; 63.7% – at Group IIIA (p < 0.05) respectively. In patients with nonalcoholic steatosis a two-year cumulative proportion surviving was significantly lower: 74.1% – at Group IB; 62.2% – at Group IIB; 55.6% – at Group IIIB (p<0.05) respectively. The lowest a two-year cumulative proportion surviving in patients with NASH was observed: 62.3% – at Group IC; 53.7% – at Group IIC; 43.9% – at group IIIC (p < 0.05) respectively.
Conclusion: The course of stable CHD depends on the NAFLD presence and severity and is the most prognostically unfavorable in patients with NASH. The severe course of NAFLD forms a high risk of major cardiovascular events by SS I values and causes a significant decrease of a two-year cumulative proportion surviving in patients with stable CHD combined with NAFLD.

SAT-507

Metabolically unhealthy status impacts on the risk of significant liver injury in biopsy-proven NAFLD patients beyond obesity

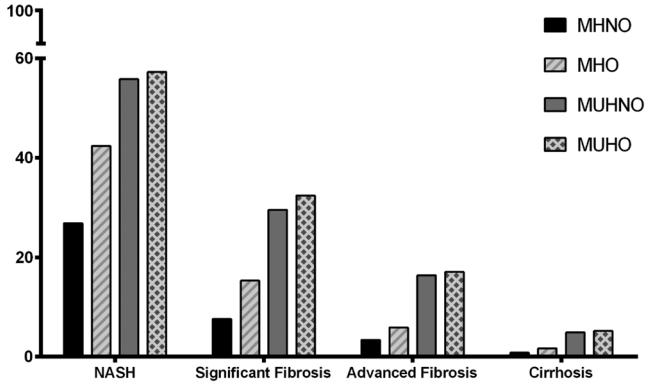
Email: javi.ampuero@gmail.com

Background and Aims: Metabolically healthy obesity (MHO) coud explain the reduced risk compared with metabolically unhealthy obesity (MUHO), while some non-obese people are at risk of NAFLD-related outcomes (metabolically unhealthy non-obesity, MUHNO) in opposite to non-obese subjects with a few metabolic risk (metabolically healthy non-obesity, MHNO). We aimed to define the impact of the metabolically healthy status on the outcomes of obese and non-obese patients showing biopsy-proven NAFLD.
Method: We designed a multi-center cross-sectional study, including 1,058 biopsy-proven NAFLD patients from the HEPAmet Spanish registry. Metabolically healthy status was strictly defined by the lack of metabolic risk factors (T2DM, low HDL, hypertriglyceridemia, arterial hypertension). NASH and significant fibrosis (F2-4) were identified by SAF and Kleiner scores. CKD-EPI equation was used to assess the kidney function. The atherogenic index of plasma was calculated by triglycerides/HDL-c.
Results: NASH and significant fibrosis were present in 52.2% (552/1058) and 12.9% (137/1058). MHO (OR 1.88 (95%CI 1.00–3.66);p =

0.050), MUHNO (OR 3.70 (95%CI 2.11–6.46);p < 0.0001) and MUHO (OR 3.47 (95%CI 2.05–5.87);p < 0.0001) were independently related to NASH together with HOMA, ALT levels, and platelets. Significant fibrosis was more frequently observed in MUHNO (OR 3.89 (95%CI 1.57–9.61);p = 0.003) and MUHO (OR 3.92 (95%CI 1.63–9.44);p = 0.002)), together with platelets, albumin, ALT, HOMA, and age, in comparison with obese and non-obese patients with healthy status. MUHNO showed higher liver damage than obese people with healthy condition (NASH 55.8% (126/226) vs. 42.4% (50/118); p < 0.05; significant fibrosis 31.7% (260/821) vs. 11.4% (27/237); p < 0.0001), despite they showed significant differences in weight (BMI 42 ± 9 vs. 27 ± 2)(Fig). Glomerular filtration rate was lower in the presence of unhealthy (91.7 ± 18) than healthy metabolism (95.6 ± 17) (p = 0.007). Pathological atherogenic index was higher in patients with adverse metabolism conditions (p = 0.0001).



Conclusion: Metabolic unhealthy status showed a greater prevalence of NASH, significant fibrosis, kidney dysfunction and atherogenic profile. Interestingly, there were no differences between obese and non-obese patients with unhealthy status. In addition, we observed that metabolically healthy obesity was not a full healthy condition (risk for NASH). Thus, we should focus our messages especially on obese and unhealthy non-obese NAFLD patients.

Email: javi.ampuero@gmail.com

Background and Aims: To examine clinical outcomes in biopsy-proven NAFLD patients by histological features (fibrosis score).
Method: This prospective multicentre study included 568 Spanish patients with biopsy-proven NAFLD from the Spanish Registry HepaMET from 2015–2017. NASH and fibrosis were defined according to Steatosis, Activity, and Fibrosis (SAF) score. Patients' mortality, fibrosis progression, and comorbidities were examined. Mean follow-up time was 2.6 +* 2.7 years.
Results: Half of the study patients were males. Mean age was 50 +* 11 years old and average BMI was 35.7 +* 9 kg/m^2, 46.7% (265/568) had NASH. Fibrosis stage distribution was: F0 36.6%, F1 26.8%, F2 18.3%, F3 11.1% and F4 7.2%. Prevalence of NAFLD-related risk factors was: obesity 56.7% (322/496), hypertension 46.3% (260/562), hypertriglyceridemia 38.8% (215/554), dyslipemia 32.4% (159/490), and T2DM 31.7% (178/562). During the follow-up period, clinical outcomes were: (a) death 1.2% (7/568), (b) fibrosis progression 12% (39/325), (c) decompensated cirrhosis 12.2% (5/41), (d) cardiovascular events 3.9% (16/417), (e) chronic kidney disease 3.8% (14/368), (f) development of T2DM 5% (19/384), low HDL 22.2% (50/225), hypertriglyceridemia 8.3% (28/339), hypertension 7.3% (22/302), and (g) neoplastic processes 3.2% (18/568). Impact of baseline histology on clinical outcomes was shown in the Table.
Conclusion: Histological features of advanced fibrosis were related to raised mortality. Moreover, baseline fibrosis was strongly related to fibrosis progression, neoplasms, renal insufficiency, and development of new onset of T2DM. NASH was associated with increased risk of developing dyslipidemia during follow-up.

Background and Aims: Recent clinical studies suggested an association between HCV infection and the wide spectrum of cardiovascular damage. Some studies in high selected patients eligible to IFN-based therapies suggested a positive effect of IFN treatment and/or HCV eradication on cardiovascular outcomes. All in all, we aimed to assess whether HCV eradication by direct antiviral agents (DAA)-based therapies improves carotid atherosclerosis in HCV-infected patients with advanced fibrosis/compensated cirrhosis.
Method: 182 consecutive HCV-infected patients with advanced fibrosis/compensated cirrhosis were evaluated by virological, anthropometric and metabolic measurements. Advanced fibrosis was diagnosed by histology (Scheuer score) and/or by liver stiffness measurement (LSM) by FibroScan (≥10 to ≤12 KPa); compensated cirrhosis was diagnosed by histology and/or by LSM (>12 KPa), and/or by evidence of oesophageal varices. All patients underwent DAA-based antiviral therapy according to AISF/EASL guidelines. Intima-media thickness (IMT) and carotid plaques, defined as focal thickening of ≥1.5 mm at the level of common carotid, were evaluated using ultrasonography at baseline and 9–12 months after the end of antiviral therapy.
Results: Fifthy-six percent of the population were males, mean age was 63.1 ± 10.4 years and 65.9% had compensated cirrhosis. One patient in five had diabetes, 14.3% were obese, 41.8% arterial hypertension and 35.2% were smokers. Mean IMT was 0.94 ± 0.29 mm, 42.9% had IMT ≥ 10 mm, and 42.9% had carotid plaques. All patients achieved a sustained virological response (SVR). Baseline factors independently associated with IMT as linear variable, with IMT ≥ 10 mm and with carotid plaques was older age ($p < 0.05$ for all variables in all models). IMT significantly reduced from baseline to 9–12 months after SVR (0.94 ± 0.29 mm vs. 0.81 ± 0.27, $p < 0.001$). Consistently, a significant reduction in the prevalence of patients with IMT ≥ 10 mm from baseline to follow-up was observed (42.8% vs. 17%, $p < 0.001$), while no changes were reported for carotid plaques (42.8% vs. 47.8%, $p = 0.34$). At linear regression analyses no factors were associated with IMT changes from baseline to follow-up ($p > 0.10$ for all). Consistently, a significant reduction in the IMT and in the prevalence of patients with IMT ≥ 10 mm from baseline to follow-up was observed in patients older/younger than 65 years, obese/nonobese, smokers/no smokers, with/without diabetes and with/without arterial hypertension ($p < 0.05$ for all).
Conclusion: HCV eradication by DAA improves carotid atherosclerosis in patients with advanced fibrosis/compensated cirrhosis with/without metabolic risk factors. Data about the impact of HCV eradication in patients with mild liver disease must be explored.

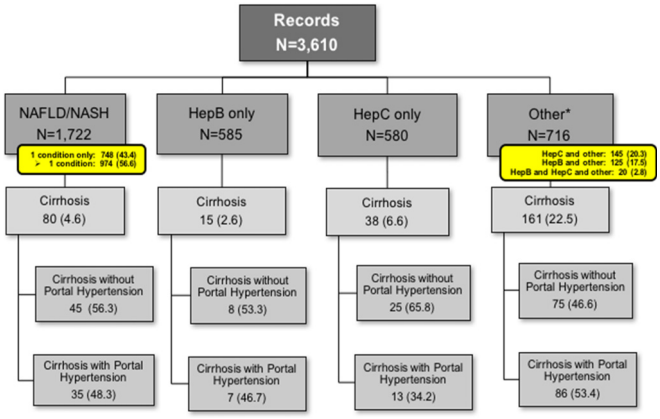
SAT-510

A Comprehensive Assessment of Serial Transient elastography in various Liver disease Etiologies at the Toronto Liver Centre (CASTLE-TLC)

M. Elkashab[1], H. Dallali[1], S. Kausar[1], M. Farshadi[1], M. Khurram[1], O. Muraru[1], M. Khan[2], J. Palmart[3], S. Loo[3], M. Magnes[1], K. Boctor[1].
[1]Toronto Liver Centre, Hepatology; [2]Gilead Sciences Canada; [3]Advisory Physicians Research Services Inc.
Email: boctork@gmail.com

Background and Aims: Liver disease is a major cause of morbidity and mortality globally, with non-alcoholic fatty liver disease (NAFLD) becoming a major cause for concern, followed by viral hepatitis (HBV & HCV) and alcoholic liver disease (ALD). To understand the burden of liver disease in Ontario, a comprehensive retrospective analysis is currently underway to characterize all liver disease patients at the Toronto Liver Centre (TLC).
Method: 3610 medical charts at the Toronto Liver Centre from Feb. 1995 to Sep. 2017 were reviewed and assessed for: patient demographics, liver disease etiology, liver fibrosis staged by Transient Elastography (TE), liver biopsy, imaging, & blood work, were collected & entered into a standardized form. Patient grouping was organized by primary liver etiology: NAFLD/NASH, HBV, HCV & Other (autoimmune hepatitis, alcoholic liver disease, primary biliary cirrhosis, primary sclerosing cholangitis, etc.). Data on cirrhotic patients (based on TE vs. biopsy vs. ultrasound) was also assessed to determine: sensitivity, specificity, positive predictive value (PPV) & negative predictive value (NPV) for the presence or absence of cirrhosis.
Results: Of the 3610 records analyzed, 2378 had TE results with 85.7% having a Metavir score of F2 & below; only 9% of patients had a Metavir score > F3. Similar results were obtained with biopsy samples: 40/403 (9.9%) patients with biopsy results had a Metavir score > F3. For the entire cohort, only 8.14% of patients had cirrhosis, & only 3.91% of patients had cirrhosis with portal hypertension, 1722 patients had NAFLD/NASH, 585 HBV only, & 580 HCV only; the remainder had viral hepatitis plus another liver condition except NAFLD: 145 had HBV plus other liver disease (20.3%), 125 had HCV plus other liver disease (17.5%), & 20 had HBV/HCV coinfection & other liver disease (2.8%). Cirrhosis was present in 6.6% of patients

with HCV, 4.6% in NAFLD/NASH, 2.6% in HBV, and 22.5% in other diseases. Amongst the cirrhotic group as diagnosed by ultrasound distribution was: HCV (2.4%), HBV (1.0%), & NAFLD/NASH (1.1%). The rate of cirrhosis in patients that were reported to be F4 or greater by TE was: (72.7%) NAFLD/NASH, (62.5%) HBV, & (56.0%) HCV. The sensitivity, specificity PPV and NPV of F4 in TE to predict cirrhosis in patients with NAFLD/NASH is 72.73%, 98.08%, 62.50% & 98.79% respectively. For HBV patients the values were 62.50%, 98.26%, 41.67% & 99.25% respectively. For HCV patients the values were 56.00%, 93.54%, 45.16% & 95.72%.



*Made possible with financial support from Gilead Sciences Canada.

Conclusion: In this initial analysis of data from an ongoing retrospective analysis, the vast majority of patients had levels of liver fibrosis of F2 and below, and fewer than 10% had histology or TE results consistent with cirrhosis. There was a high degree of agreement between the various methods used to assess fibrosis and cirrhosis (TE, biopsy and ultrasound).

SAT-511

Predisposition to diabetes is related to insulin resistance in NAFLD patients and to decreased insulin secretion in HCV patients

G. Svegliati-Baroni[1,2], I. Pierantonelli[1], R. Younes[3], C. Rosso[4], C. Rychlicki[1], E. Bugianesi[4], A. Gastaldelli[5]. *[1]Polytechnic University of Marche, Department of Gastroenterology and Hepatology, Ancona, Italy; [2]Polytechnic University of Marche, Obesity Center, Ancona, Italy; [3]University of Torino, Division of Gastroenterology, Dept of Medical Sciences, Italy; [4]University of Torino, Division of Gastroenterology, Department of Medical Sciences, Italy; [5]Cardiometabolic Risk Unit, Institute of Clinical Physiology, CNR, Italy*
Email: pierantonelli_irene@libero.it

Background and Aims: Epidemiological studies have shown that both non-alcoholic fatty liver disease (NAFLD) and HCV are risk factors for the development of type 2 diabetes (T2DM). As the subjects become insulin resistant (IR), their glucose tolerance is maintained until amounts of plasma insulin are sufficient to overcome increased IR in the liver and in the muscle. When the pancreas fails its compensatory action, clinically over diabetes ensues. We undertook this study in order to evaluate the relative role of increased IR versus decreased pancreatic ß-cell function in chronic liver disease due to NAFLD or HCV.
Method: We analyzed the glucose and insulin profiles (at 0,30,60,90,120 min) during a 75 grams OGTT in 190 non diabetic patients (NAFLD n = 109, BMI = 27.4 kg/m^2; HCV n = 14 for genotype 3 and n = 67 for non-3, BMI= 25.3 and 23.8 kg/m^2 respectively) with liver biopsy and 12 controls (CT, BMI = 24.5 kg/m^2). We assessed peripheral insulin sensitivity (OGIS index) and insulin secretion during OGTT (ratio of incremental area under the curve of insulin to glucose, ΔAUC-I/ΔAUC-G), and ß-cell function as the insulin secretion/insulin resistance or disposition index (DI = OGIS·ΔAUC-I/ΔAUC-G). A low DI was used to indicate a predisposition to develop T2DM. Fibrosis was scored according to Metavir for HCV and Kleiner score for NAFLD.
Results: In this cohort of non-diabetic subjects with either NAFLD or HCV we found that NAFLD were more IR (lower OGIS, 8.9 vs 11.4 and 11.2 ml/min kg, NAFLD vs HCV and CT, $p < 0.0001$), while insulin secretion (ΔAUC-I/ΔAUC-G) was decreased in HCV but not in NAFLD compared to CT (0.9 vs 1.9 and 1.7, HCV vs NAFLD and CT, $p < 0.005$). Accordingly, the DI (a measure of ß-cell function) was significantly decreased in HCV but not in NAFLD (9.5 vs 15.8 vs 19.1 in HCV vs NAFLD vs CT, $p < 0.0001$). DI decreased proportionally to the impairment in glucose tolerance in both NAFLD and HCV ($r = -0.48$, $p < 0.0001$) but was unaffected by the degree of fibrosis.
Conclusion: In subjects with NAFLD the predisposition to T2DM is related more to increased muscle IR than reduced pancreatic insulin secretion while in HCV it is mainly due to an impairment in post-load insulin secretion.

SAT-512

The triglycerides and glucose (TyG) index: a new marker associated with Non Alcoholic Steatohepatitis (NASH) and fibrosis in obese patients?

S. Faure[1], R. Benjamin[2], J. Ramos[3], S. Medhi[4], N. David[4], L. Anne[5], F. Galtier[6], G.-P. Pageaux[7]. *[1]CHU Saint Eloi, Liver Unit, France; [2]CHU Saint Eloi, Anatomopathology, Montpellier, France; [3]CHU Saint Eloi, Anatomopathology; [4]CHU Saint Eloi, Bariatric Surgery, France; [5]CHU Montpellier, Montpellier, France; [6]Hospital Saint Eloi, CIC, Montpellier, France; [7]Hospital Saint Eloi, Liver Unit, Montpellier, France*
Email: stephharrys@yahoo.fr

Background and Aims: Non Alcoholic SteatoHepatitis (NASH) concerns 51% of obese patients and 22.5% of diabetics in the world. Patients with NASH in one third of cases develop fibrosis, which leads to cirrhosis and hepatocellular carcinoma. The main objective of this study is to determine a marker for screening patients requiring further liver investigations.
Method: This study concerns patients with morbid obesity, aged from 18 to 65 years, undergoing a bariatric surgery program. A blood test and a liver biopsy were performed at the beginning of bariatric surgery. Liver biopsies were standardly interpreted with evaluation of steatohepatitis and fibrosis by the NAS score. TyG index was calculated as follows: [Ln(fasting triglycerides)(mg/dl)*fasting glucose (mg/dl)/2]. Data were registred in a base ENNOV-CLINICAL and analysed by SAS. Risk factors for NASH were identified by Student or Wilcoxon for quantitative values, and by chi-deux ou test exact de Fisherfor qualitative values.
Results: 147 patients were included in the study (102 women and 45 men, mean age 42 +/- 12 years, mean BMI (body mass index) 42 +/−5 kg/m^2. Thirty patients were diabetic, but among the 117 non diabetics, 47 were insulinoresistants (HOMA >=3). Liver biopsies identified steatosis in 66% of the patients, 17 NASH (11%), 35 fibrosis (24%) with significant fibrosis in 11 patients (4 stage 2,4 stage 3 and 3 4). The risk factors predictive of NASH and/or fibrosis were: TyG index ($p < 0.0001$ and $p < 0.01$ respectively), GGT ($p < 0.001$ and $p < 0.01$), diabetes ($p < 0.001$), ALAT ($p < 0.01$), HOMA-IR ($p < 0.01$ and $p < 0.05$), sexe ($p < 0.01$), age ($p = 0.06$ and $p < 0.01$). Regarding advanced fibrosis F3 or F4, the same risk factors were significantly associated age ($p < 0.01$), ALAT ($p < 0.01$), GGT ($p < 0.01$, diabetes ($p < 0.05$) and TyG index ($p < 0.05$) excepted sexe and HOMA-IR.
Conclusion: TyG index seems to be an interesting marker to predict NASH or fibrosis in obese patients. Its advantage resides in routine blood tests as simple as glucose and triglycerides. Further studies are necessary to confirm these findings.

SAT-513

Saturated fat is more metabolically harmful for the human liver than polyunsaturated fat or simple sugars

P. Luukkonen[1], S. Sadevirta[1], Y. Zhou[2], A. Ali[3], L. Ahonen[3], S. Lallukka[4], M. Gaggini[5], C. Jian[6], A. Hakkarainen[1], N. Lundbom[1], H. Gylling[1], A. Salonen[6], M. Orešič[3], T. Hyötyläinen[3], A. Gastaldelli[5], M. Orho-Melander[7], A. Rissanen[1], L. Hodson[8], H. Yki-Järvinen[1].

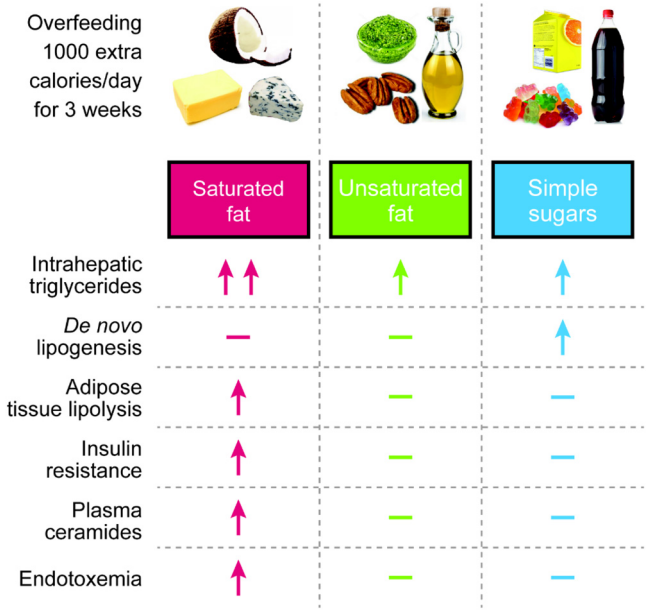
Email: panu.luukkonen@fimnet.fi

Background and Aims: Weight gain predisposes to increased intrahepatic triglycerides (IHTG) and insulin resistance (IR), but these do not occur in all obese subjects. Adipose tissue lipolysis and hepatic *de novo* lipogenesis (DNL) are the main pathways contributing to IHTG, while ceramides are key mediators of IR. Ceramide synthesis is induced by saturated fatty acids and endotoxin, a component of gut microbiota. We hypothesized that dietary macronutrient composition influences the pathways and magnitude of weight gain-induced changes in IHTG and IR.

Method: We overfed 38 overweight subjects (age 48 ± 2 years, BMI 31 ± 1 kg/m^2, liver fat 4.7 ± 0.9%) 1000 extra calories/day of either saturated or polyunsaturated fat or simple sugars for 3 weeks. We measured IHTG (^{1}H magnetic resonance spectroscopy), pathways contributing to IHTG (lipolysis and hepatic DNL using [$^2H_5$]glycerol and ^2H_2O in the basal state and during euglycemic hyperinsulinemia), IR, plasma ceramides (UPLC-MS) and endotoxemia (fecal microbiota and circulating markers) at 0 and 3 weeks.

Results: Overfeeding of saturated fat increased IHTG more (55%, $p < 0.001$) than that of polyunsaturated fat (16%, $p < 0.02$) or simple sugars (32%, $p < 0.01$) despite similar increases in body weight (1.4 ± 0.3, 0.9 ± 0.3 and 1.4 ± 0.5 kg, respectively). Simple sugars increased hepatic DNL ($p < 0.05$) whilst saturated fat increased lipolysis ($p < 0.05$). Saturated fat but not other diets induced IR ($p < 0.05$), increased multiple circulating ceramide species ($p < 0.01$) and induced endotoxemia ($p < 0.05$).



Conclusion: These data demonstrate that macronutrient composition of calories overconsumed matters. Saturated fat exerts greater metabolic harm on the liver than polyunsaturated fat or simple sugars, which may be mediated by saturated fatty acid- and endotoxin-induced synthesis of ceramides.

SAT-514

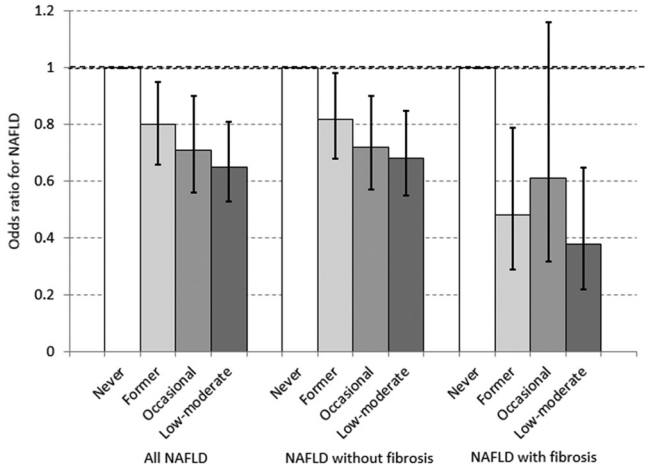
Low-moderate alcohol use is associated with a lower prevalence of non-alcoholic fatty liver disease in Hispanics/Latinos living in the US: Results from the Hispanic Community Health Study/Study of Latinos (HCHS/SOL)

A. Unalp-Arida[1], C. Ruhl[2], E. Kallwitz[3], M. Daviglus[4], D. Sotres-Alvarez[5], D. Vidot[6], D. Lee[6], G. Talavera[7], L. Aviles-Santa[8].
[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, United States; [2]Social & Scientific Systems, Inc., Silver Spring, MD, United States; [3]Loyola University Chicago, Chicago, IL, United States; [4]University of Illinois at Chicago, Chicago, United States; [5]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States; [6]University of Miami, Miami, FL, United States; [7]San Diego State University, San Diego, CA, United States; [8]National Heart, Lung, and Blood Institute, Bethesda, MD, United States
Email: cruhl@s-3.com

Background and Aims: Alcohol use is a known risk factor for liver injury; however, the dose-response effect on the liver has not been well studied among persons of Hispanic/Latino background. We examined the relationship between alcohol intake and non-alcoholic fatty liver disease (NAFLD) in a population-based cohort of Hispanics/Latinos living in the US.

Method: We included 14,786 viral hepatitis seronegative HCHS/SOL participants aged 18–74 years in 2008–2011 with transferrin saturation ≤ 50% and alcohol use in drinks/week ≤14 for women or ≤21 for men at baseline examination. NAFLD and liver fibrosis were defined as a high NAFLD liver fat score (≥1.257) (Kotronen, Gastroenterology, 2009;137:865) and high NAFLD fibrosis score (>0.676) (Angulo, Hepatology, 2007;45:846), respectively, using published cut-offs. Self-reported alcohol use (drinks/week) was categorized as never, former, occasional (<1), or low-moderate (1–14 for women or 1–21 for men). Complex survey logistic regression was used to estimate odds ratios (OR) for NAFLD by alcohol use adjusting for age, sex, Hispanic/Latino heritage group, attained education, BMI, and physical activity.

Results: The prevalence of never, former, occasional, and low-moderate alcohol use was 20%, 31%, 16%, and 33%, respectively. The prevalence of NAFLD and NAFLD with fibrosis was 17.2% and 1.6%, respectively. The prevalence of NAFLD was lower among occasional (15.7%) and low-moderate (14.7%) compared with never (19.9%) and former (18.8%) drinkers ($p < 0.001$). Compared to never drinkers, the age-adjusted odds of NAFLD was lower among occasional (OR, 0.81; 95% confidence interval (CI), 0.66–0.99) and low-moderate (OR, 0.79; 95% CI, 0.66–0.94) alcohol users. After multivariate adjustment, the odds were further decreased for occasional and low-moderate alcohol users, as well as former drinkers (Figure). NAFLD with fibrosis was more strongly associated with low-moderate and former drinking than was NAFLD without fibrosis (Figure). When consumption of wine, beer, and liquor was examined individually, ORs for all NAFLD among low-moderate compared with never drinkers ranged from 0.53 to 0.61 ($p \leq 0.001$ for each). The lower odds of NAFLD among former, occasional, and low-moderate alcohol users was no longer observed when further adjusting by homeostasis model assessment of insulin resistance deciles ($p \geq 0.34$ for each).



Conclusion: Among Hispanic/Latino adults in the HCHS/SOL, former and low-moderate alcohol use was associated with a lower prevalence of NAFLD and liver fibrosis; occasional drinking was associated with a lower prevalence of NAFLD. These cross-sectional associations may be mediated through effects of varying degrees of insulin resistance. Examination of the longitudinal relationship between alcohol use and liver health among HCHS/SOL participants is underway from 2014–2017.

SAT-515

Even modest alcohol use is associated with greater steatosis on magnetic resonance imaging in patients with NAFLD – a pilot study

V. Ajmera[1], M. Le[1], C. Caussy[1], P. Nguyen[1], C. Hernandez[1], R. Bettencourt[1], C. Behling[2], M. Valasek[1], C. Faulkner[1], E. Rizo[1], L. Richards[1], C. Sirlin[1], R. Loomba[3]. *[1]University of California, San Diego; [2]Sharp Medical Center; [3]University of California at San Diego, Division of Gastroenterology, Department of Medicine, San Diego, United States*
Email: v1ajmera@ucsd.edu

Background and Aims: The effect of modest alcohol use on NAFLD is unclear, however, a paired biopsy study suggested modest alcohol use was associated with less improvement in histologic steatosis. Therefore, we aimed to evaluate the cross-sectional and longitudinal associations between modest alcohol use and hepatic steatosis using a prospective cohort of adults with biopsy proven NAFLD and magnetic resonance imaging (MRI) proton density fat fraction (PDFF) as a quantitative measure of liver fat content.
Method: Participants with NAFLD, age ≥ 21 years, with paired MRI and alcohol history were included. Men and women who reported >2 and >1 drinks/day as well as participants in treatment arms of trials were excluded. The associations between alcohol use (baseline drinking status and change in drinking status) and steatosis (baseline PDFF and change in PDFF) were evaluated before and after adjustment for potential covariates.
Results: Of 57 participants (43% Hispanic, 65% female, mean age 50 years) meeting entry criteria, 65% drank monthly or less and 35% drank more than monthly. At baseline, more-than-monthly drinkers had higher mean PDFF (18.3% vs 14.6%, p = 0.08), were more often white (p = 0.05) and male (p = 0.08), but had no significant difference in prevalence of diabetes, hypertension, or aminotransferase levels. In a linear regression model adjusted for race and sex, participants who drank more than monthly had 4.4% higher mean PDFF (95% CI: −0.12 to 8.82%, p = 0.056) at baseline compared to those who drank monthly or less. At follow up MRI (mean ± SD of 380 ± 370 days later), there was no significant difference in PDFF change between participants who at baseline drank more than monthly vs. monthly or less, −2.77% vs −1.64% respectively, p = 0.52. Seven participants reported decreased drinking, 35 no change, and 9 increased drinking, with mean PDFF changes of −3.42%, −2.45% and −1.40% respectively, p = 0.51. In a logistic regression model adjusted for race and sex, no change or an increase in drinking at follow up had lower odds of PDFF reduction (OR: 0.41, 95% CI: 0.14–1.23, p = 0.114) than decreased drinking.
Conclusion: In this pilot study using an accurate, quantitative measure of hepatic steatosis, more than monthly alcohol use at baseline was associated with greater hepatic steatosis on adjusted analysis. Participants who lowered their drinking frequency had greater odds of steatosis reduction.

SAT-516

Role of nutritional intake on clinical presentation of lean and overweight NAFLD

R. Lombardi[1], G. Pisano[1], S. Spreafico[1], F. Iuculano[1], E. Fatta[1], S. Pelusi[1], L. Valenti[1], S. Fargion[1], A.L. Fracanzani[2]. *[1]Ca'Granda IRCCS Foundation, Policlinico Hospital, University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy; [2]Department of Pathophysiology and Transplantation, Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan, Italy, Department of Pathophysiology and Transplantation, Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan, Italy, Italy*
Email: anna.fracanzani@unimi.it

Background and Aims: Dietary macronutrient composition is associated with the presence of NAFLD, and epidemiologic studies show an inverse correlation between Mediterranean diet and cardiovascular events. To evaluate the role of dietary components on clinical presentation of NAFLD.
Method: We enrolled 159 consecutive newly diagnosed, untreated NAFLD, (M/F 89/36 mean age 50 ± 12). A semi-quantitative food-frequency questionnaire (dietary record including 118 food items and covering seven days) administered at enrollment used to calculate intake of energy and nutrients. A complete evaluation of anthropometric clinical and biochemical data was collected at presentation. Assessment and quantification of steatosis and subclinical atherosclerosis (mean carotid IMT and presence of carotid plaques) was obtained by B-mode ultrasound (US), cardiac definition of diastolic dysfunction (E/A), left ventricular mass, and visceral adiposity (epicardial adipose thickness (EAT)), by echocardiography.
Results: The mean BMI and waist circumference were 28.8 ± 5.2 and 103 ± 11 cm, prevalence of hypertension 52%, dyslipidemia 56%, obesity 35%, diabetes 11%, metabolic syndrome 44%. Eighteen % had "lean" NAFLD (BMI < 25). Mean IMT was 0.74 ± 0.2, with carotid atherosclerosis (IMT >1.0 mm) in 14%, and carotid plaques in 29%, E/A < 1 in 40%, mean EAT 5.8 ± 4 mm. Eight patients (5%) had cardiovascular events. Macro-nutrient intake adjusted for percentage of calories was: proteins 23, ± 4, fat 33,1 ± 5, carbohydrates 38.5 ± 8, fiber 2.7 ± 1. No difference of nutrient dietary composition and total amount of calories between lean and overweight/obese patients was observed. Among nutrients, fructose was significantly higher in patients with plaques (p = 0.03), vitamin E lower in patients with diastolic dysfunction (p = 0.03). At multivariate analysis adjusted for age, gender and BMI, fat resulted significantly associated with dyslipidemia (OR 1.2, 95%CI 1–1.4, p = 0.04), protein with hypertension (OR 1.23, 95%CI 1.02–1.5, p = 0.03), fat and carbohydrate with severe US steatosis (OR 1.3, 95%CI 1.1–1.5, p = 0.002 and OR 1.2, 95% CI 1.03–1.4, p = 0.01, respectively). No independent association was found between nutrients and carotid atherosclerosis, plaques and E/A.
Conclusion: Nutritional intake does not differ between lean and overweight NAFLD suggesting a genetic predisposition to NAFLD in lean subjects. It remains to be defined the role of individual micro- and macro-nutrients on cardiovascular damage in NAFLD.

SAT-517

Non-alcoholic fatty liver disease is omega-6 fatty acids diet dipendent in a group of obese children

A. Dalbeni[1], A. Mantovani[1], A. Tagetti[1], S. Bonafini[1], V. Paon[1], R. Gaudino[2], M. Montagnana[3], E. Danese[3], A. Donato[1], P. Minuz[1], C. Maffeis[2], F. Antoniazzi[2], F. Capra[4], C. Fava[1]. *[1]Division of General Medicine and Hypertension, Department of Medicine, Verona, Italy; [2]Pediatric Diabetes and Metabolic Disorders Unit, Regional Center for Pediatric Diabetes, Verona, Italy; [3]Department of Life and Reproduction Sciences, Verona, Italy; [4]University and Azienda Ospedaliera Universitaria Integrata of Verona, University of Verona, Italy*
Email: andrea.dalbeni@aovr.veneto.it

Background and Aims: Obesity leads to the clustering of metabolic syndrome (MetS) and cardiovascular (CV) risk factors, also in children. Non-alcoholic fatty liver disease often accompanies the MetS and it's described like a new independent CV risk factor. Quality of dietary fat, beyond the quantity, could influence the MetS, CV risk profile and also the development of NAFLD. The aim of this cross-sectional observational study was to investigate the associations of individual CV risk factors and NAFLD, characterizing the MetS, with erythrocyte fatty acid (marker of average intake), in a group of 70 obese children.
Method: Enrollment of obese children aged 5–18 years old (BMI > 90th percentile). Calculation of Fatty Liver Index (FLI) and Ultrasound (US) abdomen echography for the detection of NAFLD. Anthropometric measurement by calibrated instruments, ambulatory blood pressure (BP) measurement by validated instruments. Laboratory measurement of lipid, glucose and hepatic function indices. Erythrocyte membrane FA measurement by gas chromatography.
Results: Mean content of Omega-3 FA was low (omega-3 Index = 4.7 ± 0,8%). Non Omega-3 but Omega-6 FA, in particular arachidonic acid, were inversely associated with several futures of the MetS, in particular with the presence of steatosis: total amount of omega-6 FA was inversely correlated with waist circumference (rS = –0.393), waist/hip ratio (rS = –0.260); triglycerides (rS = –0.294), fasting insulin (rS = – 0.341), FLI (rS = –0.435), ALT (rS = –0.297) and GGT (rS = –0.256). They were directly correlated with HDL (rS = 0.327). Arachidonic acid showed inverse correlations with WC (rS = –0.352), waist/hip ratio (rS = –0.311), triglycerides (rS = –0.366), fasting insulin (rS = –0.337), FLI (rS = –0.472) and ALT (rS = – 0.331). Conversely, GLA showed a direct correlation with fasting insulin (rS = 0.347) and HOMA-IR (rS = 0.365). Total content of saturated FA was directly correlated to waist circumference (rS = 0.237), triglycerides (rS = 0.298), nighttime-DBP (rS = 0.251), FLI (rS = 0.479), ALT (rS = 0.291) and GGT (rS = 0.400). Palmitic acid directly correlated with waist circumference (rS = 0.354), waist/hip ratio (rS = 0.247), triglycerides (rS = 0.373), insulin (rS = 0.287) and HOMA-IR (rS = 0.335), FLI (rS = 0.515), ALT (rS = 0.239), GGT (rS = 0.339).
Conclusion: Our data suggest that omega-6 FA, especially AA, could be protective toward CV risk factors including NAFLD featuring the MetS and also to indexes of hepatic steatosis in obese children, whereas SFA seems to exert opposite effects. The level of omega-3 FA in our sample of obese children, is extremely low so that its putative beneficial effect could have not been detectable. Our findings agree with the current dietary recommendation to reduce the intake of SFA and support a possible beneficial effect of polyunsaturated FA intake, especially omega-6 FA.

SAT-518

Sarcopenia is associated with advanced liver fibrosis in patients with non-alcoholic fatty liver disease

J.G. Park[1], M.K. Kang[1], J.H. Baek[1], S.Y. Park[2], H.J. Lee[1], K. Hur[3], W.Y. Tak[3], Y.O. Kweon[4], S.Y. Jang[5], Y.R. Lee[4], H.W. Lee[6]. *[1]College of Medicine, Yeungnam University, Internal Medicine, Daegu, Korea, Rep. of South; [2]Kyungpook National University Hospital, Department of Internal Medicine, Daegu, Korea, Rep. of South; [3]School of Medicine, Kyungpook National University, Biochemistry and Cell Biology, Daegu, Korea, Rep. of South; [4]School of Medicine, Kyungpook National University, Internal Medicine, Daegu, Korea, Rep. of South; [5]Kyungpook National University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of South; [6]Dongsan Medical Center, School of Medicine, Keimyung University, Internal Medicine, Daegu, Korea, Rep. of South*
Email: gsnrs@naver.com

Background and Aims: Sarcopenia has been known to increase risk of non-alcoholic fatty liver diseases (NAFLD) in previous study. However, there are limited studies in relationship between sarcopenia and fibrosis in large papulation. This study is to investigate association between sarcopenia and liver fibrosis in patients with NAFLD.
Method: A total of 53704 subjects were enrolled the study to be analyzed in single healthcare center. Fatty liver, and sarcopenia was diagnosed by ultrasound, and bioimpedance analysis, respectively. The cut-off values for sarcopenia were 7.0 kg/m2 for men and 5.7 kg/m2 for women. The stage of liver fibrosis is assessed by non-invasive scoring model including NAFLD fibrosis score (NFS), Fibrosis-4 (FIB-4) index, BARD score, and Forns index, which was determined as the upper value of each low cut-off.
Results: Of 10711 patients with NAFLD, 1389 (13.0%) were diagnosed with sarcopenia. The scarcopenic patients were older (47.7 vs. 49.1 years, p = 0.001), had lower levels of body mass index (24.4 vs. 20.4 kg/m2, p = 0.000) and waist circumference (82.1 vs. 72.6 cm, p = 0.000) compared to non-sarcopenic patients. In multivariate analysis, sarcopenia is associated with older age (odd ratio [OR]: 1.02, p = 0.001), women (OR: 2.25; p = 0.001), non-obese group (OR: 19.01, p = 0.001), and non-metabolic syndrome group (OR: 1.91, p = 0.001) in patients with NAFLD. The presence of sarcopenia was independent risk factor for liver fibrosis assessed by FIB-4 index, BARD score, and Forns index in multivariate analysis. (OR: 1.39, p = 0.000; OR: 1.64, p = 0.000; and OR: 1.23, p = 0.001, respectively) except NFS.
Conclusion: Sarcopenia is independent risk factor for liver fibrosis in patients with NAFLD.

SAT-519

Change of microbiota in patients with improved fatty liver and obesity

S.B. Ahn[1], D.W. Jun[2], E. Kim[2], H. Oh[2], J.Y. Jeong[3], J.H. Sohn[3], E.C.J. Jang[4]. *[1]Eulji university college of medicine, Internal Medicine; [2] Hanyang University School of Medicine, Internal Medicine; [3]Hanyang University, College of Medicine, Guri Hospital, Internal Medicine; [4]Soonchunhyang University College of Medicine, Department of Occupational and Enviroment Medicine*
Email: noshin@hanyang.ac.kr

Background and Aims: Changes in intestinal microbiota are known to play an important role in the development and progress of NAFLD. The purpose of this study was to investigate the changes in the composition of microbiota in patients with improved fatty liver after administration of probiotics.
Method: This study randomly divided 68 obese NAFLD patients into the probiotics and the placebo group for twelve weeks. The probiotics mixture consists of six kinds of probiotics (*Lactobacillus acidophilus, Lactobacillus rhamnosus, Lactobacillus paracasei, Pediococcus pentosaceus, Bifidobacterium lactis,* and *Bifidobacterium breve*). Intrahepatic fat measured by MRI based technique. Feces samples were collected at the baseline and on a final visit to go through intestinal flora examination to analyze the types and number of microorganism in feces. DNA of bacteria were separately extracted to go through a real-time quantitative PCR.
Results: Significant increase of five strains except *Lactobacillus paracasei* was found in the probiotics group by qPCR in the stool sample. On the other hand, there was no difference of six strains in the control group. Bacteroidetes/Firmicutes ratio significantly increased in the probiotics group (0.46–27.2, p = 0.045). Deep sequencing of the fecal microbiome using next generation

sequencing of 16sRNA revealed that the amount of *Ruminococcaceae-2, Lachnospiraceae-2, Coprococcus, Lachnospiraceae-1, Ruminococcus*, and *Dorea* were increased in patients who were improved fatty liver. *Ruminococcaceae-2, Ruminococcaceae-1, Clostridiales-2, Lachnospiraceae-2* and *Coprococcus* were increased in patients with successful weight loss group.
Conclusion: Specific microbiota are associated with improvement of fatty liver and weight loss. These probiotics may be novel metabolic targets of fatty liver and obesity.

SAT-520
Role of L-carnitine in pathogenesis of the atherogenic dyslipidemia in ischemic heart disease with concominent nonalcoholic steatohepatitis
I. Skrypnyk[1], G. Maslova[1], O. Shcherbak[1]. [1]*Ukrainian Medical Stomatological Academy, Internal Medicine, Poltava, Ukraine*
Email: inskrypnyk@gmail.com

Background and Aims: Cardiovascular diseases are the most frequent reasons of deathless among the population of different worldwide countries, the important place between which is ischemic heart disease (IHD). One of the most perspective alternatives of secondary prevention and treatment of cardiovascular diseases is L-carnitine (LC), which is needed to be observed with a presence of nonalcoholic steatohepatitis (NASH).
Aim: to observe the concentration of L-carnitine in serum of pts with IHD considering of the presence of NASH.
Method: Study involved 68 IHD pts with the presence of Frederickson's atherogenic dyslipidemia types IIa and IIb. IHD's duration was 2–20 years. In the structure of IHD we have noticed: stable angina grade II – in 68 (100%) pts, diffusive cardiosclerosis in 68 (100%) pts among them postinfarction cardiosclerosis – in 27(39.7%) pts. Patients' age was 37–69 years. Ratio women/men was 17(25%)/51 (75%). Control group consists of 20 almost healthy (AH). Depending on NASH presence patients were divided into 2 groups: I(n = 32) – IHD and concomitant NASH; II(n = 36) – IHD without NASH. The parameters of the blood lipid spectrum were studied: cholesterol, triglycerides (TG), high-density lipoproteins (HDL) and low-density lipoproteins (LDL).
The L-carnitine level in the blood serum was determined by immunoenzyme method using special Human L-carnitine ELISA Kit (USA), referent range is 1, 2–50 pg/ml.
Results: In pts of group I the cholesterol level was higher in 1.4, LDL – in 2, TG – in 1.8 times, but the level of HDL was lower in 1.4 times versus AH people. In pts of group II the cholesterol level was increased in 1.3, LDL– in 1.9, TG– in 1.6 times ($p < 0.05$), but the level of HDL was decreased in 1.3 times ($p < 0.05$) versus AH. Also, in pts of group I with the presence of NASH increasing of LC in blood serum in 1.6 times compared with AH was noticed (3.71 ± 1.99 versus 2.35 ± 0.72 pg/ml; $p > 0.05$).
In pts of the group II without NASH was veraciously noticed increasing of blood's serum LC in 2.4 time compared with AH (5.62 ± 1.16 vs 2.35 ± 0.72 pg/ml; $p < 0.05$). In the same time was noticed the weak correlative connection between concentration of LC and TG in the blood serum ($r = +0.6$).
Conclusion: In IHD pts with lipid metabolism disorders an increase of LC concentration in the blood serum was observed in response to a high serum lipid level, namely TG. Mostly the higher concentration in the blood serum LC in pts with IHD without the presence of NASH can be explained by the violation of expressing of carnitine's receptor transporters in muscular tissue, which was observed in results of apart researches. Presence of forward correlative connection between concentration of LC and TG's concentration in the blood serum is arguing practicability of prescribing drugs with LC in complex therapy of diseases which are associated with violation of lipid metabolism.

SAT-521
Assessment of baseline Hepatitis B Virus (HBV) immunity and HBV vaccine responses in prospectively vaccinated adults with Non Alcoholic Fatty Liver Disease (NAFLD)
C. Coffin[1], C. Jenne[1], M.G. Swain[1], S. Jayakumar[1], C. Cooper[2], E. Kelly[3], S. Fung[4], A. Ramji[5], E. Tam[6], M. Ma[7]. [1]*University of Calgary, Cumming School of Medicine, Calgary, Canada;* [2]*University of Ottawa, The Ottawa Hospital and Regional Hepatitis Program, Canada;* [3]*University of Ottawa Health Services, Ottawa, Canada;* [4]*University Health Network, Toronto, Canada;* [5]*The University of British Columbia, Vancouver, Canada;* [6]*Lair Centre, Vancouver, Canada;* [7]*University of Alberta Hospital, Edmonton, Canada*
Email: cscoffin@ucalgary.ca

Background and Aims: The recombinant hepatitis B virus (HBV) vaccine consisting of major viral antigenic (surface) epitopes induces long-lived protective immunity in healthy adults. It is recommended that all persons with end-stage liver disease (including those due to Non-Alcoholic Fatty Liver, NAFLD) be vaccinated against the HBV. We aim to determine HBV vaccine responses in patients with NAFLD.
Method: In this ongoing multisite study, adults with NAFLD referred to hepatology were tested for serological markers of HBV infection (i.e., HBV surface antigen [HBsAg]) or immunity (i.e., antibody to HBsAg [anti-HBs]; antibody to core [anti-HBc]), and offered the HBV vaccine if non-immune (i.e., EngerixB®) or combined HAV/HBV vaccine (i.e., Twinrix®). Anti-HBs titres indicating protective immunity (i.e., >10 IU/l) were assessed at ~1–2 months after completion of 3-dose vaccine series. All prospectively recruited study subjects underwent standard clinical assessment, including anthropomorphic (Body mass index, BMI), liver stiffness measurement (LSM) by FibroScan®, and metabolic risk factors. We used appropriate statistical methods with two tailed tests in our analyses.
Results: In 431 NAFLD patients referred, 47% (202/431) were HBV immune or prior exposure. In 91/202 previously vaccinated, available retrospective BMI data correlated to mean anti-HBs titres (i.e., 92 U/l [BMI 18–25, lean NAFLD], 165 [BMI 25–30], 140 [BMI 30–35] and 102 [BMI >35]). Additionally, 20 naïve subjects were prospectively vaccinated (12 F, median age 52.5 y, median LSM 4.9 kPa, 5 type 2 diabetes mellitus [T2 DM]), and were classified at baseline in obesity class medium-high risk (n = 5, median BMI 39) vs. low-risk (n = 15, median BMI 31). In the 17 subjects that completed the study to date, the median anti-HBs titres was 18.2 mIU/l in the medium-high risk obesity group (n = 4, median LSM 6.1 kPa, 1 T2 DM) versus 1000 mIU/l in the low-risk obesity class (n = 13, median LSM 4.7 kPa, 1 T2 DM) ($p = 0.0078$).
Conclusion: The currently approved HBV vaccine induces protective immunity in low-medium risk obesity class non-cirrhotic NAFLD patients. However, lower anti-HBs titres was observed in those with either normal BMI (lean NAFLD) as well as higher obesity class patients. Given the global obesity epidemic, the impact of NAFLD and co-morbid metabolic syndrome on vaccine efficacy has important public health implications.

disease severity that is recognized. Kaiser Permanente Southern California (KPSC) is a large community-based integrated healthcare system. We sought to identify and characterize KPSC members with NAFLD/NASH.

Method: Patients were included if ≥18 yrs with ICD-10 code for NAFLD, NASH, or cryptogenic cirrhosis from 10/1/2015–12/31/2016, absent other liver disease or alcohol abuse, and met membership criteria. Medical exclusions, comorbidities, and cirrhosis were identified 1/1/2006–12/31/2016 using ICD 9/10 codes and/or other pertinent variables. Biopsy reports between 1/1/2006–12/31/2016 were accessed via procedure codes and reviewed in blinded fashion.

Results: Of 3011580 eligible KPSC members, an ICD10 code for NAFLD/NASH was identified in 49504 (1.6%), 5148 (10.4%) of whom had cirrhosis (Table). Cirrhosis cases were characterized as compensated (CC) (17.5%), compensated with portal hypertension (14.6%), and decompensated cirrhosis (DC) (67.9%). Non-invasive scoring systems were positive among cirrhosis cases as follows: APRI 20.7%, BARD 84.9%, FIB-4 41.4%, NAFLD Fibrosis Score 79.5%. Biopsy reports (n = 194) demonstrated simple steatosis in 10.8%, possible NASH in 49.5%, definite NASH in 8.2%, NASH Cirrhosis in 26.3%, and other diagnosis in 5.2%. 38.6% of biopsies had stage 3–4 fibrosis.

Conclusion: Rates of ICD-10 codes for NAFLD/NASH in a large, community-based healthcare system were 1.6% from 10/1/2015–12/31/2016, 10.4% of whom had cirrhosis at the time of identification. Comorbidity burden was high in this population. The majority of those identified as cirrhotic had advanced disease with 70% having experienced a decompensation event. Liver biopsy reports predominantly contained features of NASH and 36% had advanced fibrosis.

SAT-523

Sex hormone binding globulin levels are increased in HIV-infected men and are independently associated with lower odds of nonalcoholic fatty liver disease regardless of HIV serostatus

J. Price[1], R. Wang[2], E. Seaberg[2], T. Brown[3], M. Budoff[4], L. Kingsley[5], F.P. Jr[6], M. Witt[4], W. Post[3], J. Lake[7], C. Thio[3]. [1]*University of California, San Francisco, Medicine;* [2]*Johns Hopkins Bloomberg School of Public Health, Epidemiology;* [3]*Johns Hopkins University School of Medicine, Medicine;* [4]*Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Medicine;* [5]*University of Pittsburgh Graduate School of Public Health, Departments of Infectious Diseases and Microbiology and Epidemiology;* [6]*Northwestern University Feinberg School of Medicine, Medicine;* [7]*University of Texas Health Science Center at Houston, Medicine*
Email: Jennifer.Price@ucsf.edu

Background and Aims: Sex hormone binding globulin (SHBG) is a liver-derived protein that may have an important role in energy metabolism. In pre-clinical models, overexpression of SHBG is protective against nonalcoholic fatty liver disease (NAFLD) via decreased lipogenesis. SHBG levels are increased in HIV+ individuals. We hypothesized that higher SHBG may be protective against NAFLD in persons with HIV. Thus, we aimed to determine: (1) the association of SHBG with NAFLD among men in the Multicenter AIDS Cohort Study (MACS), and (2) whether adjustment for SHBG alters the association of HIV with lower NAFLD odds in the MACS.

Method: Non-contrast CT was used to assess NAFLD (liver/spleen Hounsfield unit ratio < 1) in 615 MACS participants who drank <3 alcoholic drinks/day and were hepatitis C or B virus-uninfected. Among 334 men with morning serum samples (228 HIV+, 106 HIV-), SHBG levels were measured using radioimmunoassay. Multivariable logistic regression models assessed associations between SHBG concentrations and NAFLD prevalence and evaluated the association between HIV and NAFLD with/without adjustment for SHBG.

Results: HIV+ men had higher SHBG levels than HIV- men. Median SHBG levels were highest in the HIV+ men without NAFLD (59.9 nmol/l), followed by the HIV- men without NAFLD (46.2 nmol/l) and were similar in the HIV+ and HIV- men with NAFLD (38.0 and 38.8 nmol/l, respectively). After adjusting for age, race, MACS site, HIV serostatus, visceral adipose tissue (VAT) area, logHOMA-IR, and *PNPLA3* genotype, higher SHBG was associated with lower NAFLD odds [odds ratio(OR) 0.47 per doubling, 95% confidence interval(CI) 0.28–0.79]. This finding was similar regardless of HIV serostatus. HIV infection was associated with lower NAFLD odds after adjusting for age, race, MACS site, VAT, HOMA-IR, and *PNPLA3,* but this was not statistically significant (OR 0.55, 95%CI 0.26–1.14). Additional adjustment for SHBG attenuated the association of HIV with lower NAFLD (OR 0.72, 95%CI 0.34–1.54).

Conclusion: SHBG levels were higher among HIV+ than HIV- men and were independently associated with lower odds of NAFLD regardless of HIV serostatus. After adjusting for SHBG, HIV serostatus was not significantly associated with NAFLD prevalence, suggesting that SHBG could partially explain previously reported associations between HIV infection and lower NAFLD prevalence in this cohort. Prospective studies of SHBG and NAFLD in HIV+ persons are warranted.

SAT-524

The conundrum of cryptogenic liver disease with advanced fibrosis: Poor clinical outcomes without treatment options

Z. Younossi[1], M. Stepanova[2], S. Harrison[3], A. Sanyal[4], V. Ratziu[5], B. Mccolgan[6], R. Myers[6], N. Afdhal[7], M. Abdelmalek[8], Z. Goodman[9]. [1]*Inova Fairfax Hospital, Department of Medicine, Falls Church, United States;* [2]*Center for Outcomes Research in Liver Disease;* [3]*Pinnacle Clinical Research;* [4]*Virginia Commonwealth University School of Medicine;* [5]*Hopital Pitie-Salpetriere, Medicine;* [6]*Gilead Sciences, Associate Director of Clinical Research;* [7]*Beth Israel Deaconess Medical Center and Harvard Medical School;* [8]*Duke Clinical Research Institute;* [9]*Betty and Guy Beatty Center for Integrated Research, Inova Health System*
Email: zobair.younossi@inova.org

Background and Aims: Currently, enrollment in clinical trials for non-alcoholic steatohepatitis (NASH) requires meeting strict pathologic criteria. Given that, although there are numerous treatment protocols for patients with histologic NASH, there are few protocol options for subjects with cryptogenic liver disease (CD) or

cryptogenic cirrhosis (CC). **Aim:** To compare disease progression outcomes in patients with advanced fibrosis with NASH and CD.
Method: Subjects with advanced fibrosis (NASH CRN stage 3–4) were screened for two phase 2b clinical trials of simtuzumab. All other causes of chronic liver disease were excluded. Based on histologic assessment by the central pathologist, 423 subjects with advanced fibrosis were classified as having advanced fibrosis and NASH (n = 302, stage 3 or 4 fibrosis with steatosis, hepatocyte ballooning, and lobular inflammation) or CD (n = 121, stage 3 or 4 fibrosis with no steatosis regardless of other histologic features). Clinico-laboratory data were available. Clinical disease progression was defined as histologic progression of fibrosis, decompensation, qualification for liver transplant (MELD ≥ 15), or death.
Results: Subjects (age 54 ± 8 years, 35% male, 56% baseline cirrhosis) were followed-up for 25 ± 9 months (max 42 months) during which time 22.0% had disease progression. Compared to subjects with NASH with advanced fibrosis, those with CD with advanced fibrosis had higher baseline ELF, FIB-4, APRI, NAFLD Fibrosis Score, and Fibrotest, as well as higher levels of hyaluronic acid and hepatic expression of alpha-smooth muscle actin (p < 0.05). In these patients, mean time to disease progression was shorter in CD than in NASH (11.6 ± 7.6 vs. 15.6 ± 6.1 months, p = 0.03) while the overall rate of events was similar between groups. Survival analysis showed that CD and NASH with advanced fibrosis have similarly poor outcomes (p = 0.19) (Figure). By limiting the analysis to subjects with baseline cirrhosis (F4 only), there was trend in lower event free survival in cryptogenic cirrhosis than NASH cirrhosis (p = 0.07) (Figure).

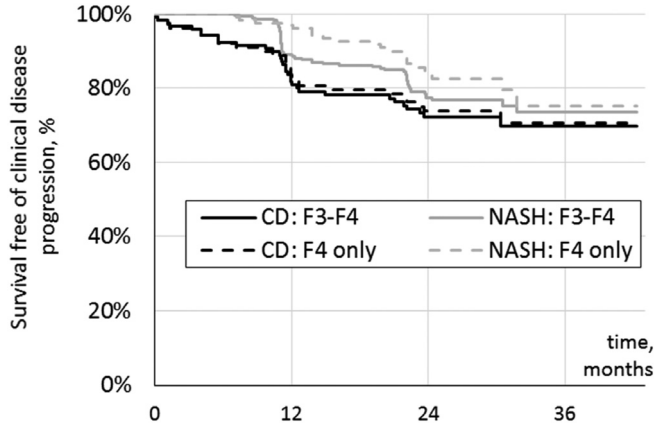

Figure: Clinical disease progression in CD and NASH.

Conclusion: NASH and CD with advanced fibrosis are both associated with similar rates of clinical disease progression. Given that subjects with advanced fibrosis and CD do not qualify for clinical trials of NASH, there is a need to develop new protocols for these patients with poor prognosis and without treatment options.

SAT-525

The worldwide prevalence of Non-alcoholic Steatohepatitis (NASH) in patients with Type 2 Diabetes Mellitus (DM)

P. Golabi[1], J. Paik[1], L. Deavila[1], N. Fukui[2], M. Srishord[1], Z. Younossi[3].
[1]Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; [2]Inova Fairfax Hospital, Center for Liver Disease, Department of Medicine, Falls Church, United States; [3]Inova Fairfax Hospital, Department of Medicine, Falls Church, United States
Email: zobair.younossi@inova.org

Background and Aims: NASH is regarded as the more progressive form of non-alcoholic fatty liver disease (NAFLD). DM is not only a known risk factor higher prevalence of NASH, but also seem to accelerate its progression. Our aim was to assess the global prevalence of NASH in patients with DM.

Method: PubMed, Ovid-Medline, EMBASE and Web of Science were searched from January 1989 to May 2017, for the terms involving NASH and type 2 DM. Morbidly obese and pediatric groups were excluded. Regions were classified according to the World Health Organization (WHO). All studies were reviewed by three independent investigators. Pooled NASH prevalence was calculated using random-effects models. Heterogeneity was investigated by subgroup analysis and meta-regression. The NASH prevalence estimates were stratified by region, diagnostic method, and mean BMI.
Results: After applying the inclusion and exclusion criteria to 1,589 studies (2003–2014), the final sample size was 27,020 patients with DM. The overall prevalence of NASH among patients with DM was 65.26% (95% CI, 51.73–76.71, n = 8) based histologic criteria for NASH. The highest NASH prevalence was reported from Western Pacific region (78%), followed by Southeast Asia (76%) and America (59%). Presence of advanced fibrosis (stage 3 and 4 by histology) was reported in 15 articles and the pooled overall percentage of advanced fibrosis was 15.05% (95% CI: 8.17–26.08, n = 15). A meta-regression model showed significant heterogeneity (I^2 = 96.62%) with WHO region (p = <0.01), diagnostic method (p = 0.403) and follow up time (p = 0.033) jointly accounted for 68% of the heterogeneity.
Conclusion: This meta-analysis reveals that the prevalence of NASH is very high among patients with DM. As the prevalence of DM and NASH are on the rise, an increase in the prevalence of advanced liver disease is inevitable.

SAT-526

Moderate alcohol consumption protects against fatty liver in males

T. Akahane[1], T. Namisaki[1], M. Kitade[1], K. Kaji[1], H. Takaya[1], N. Shimozato[1], S. Sato[1], H. Yoshiji[2]. *[1]Nara Medical University, Third Department of Internal Medicine, Kashihara, Nara, Japan; [2]Nara Medical University, Third Department of Internal Medicine, Kashihara, Japan*
Email: stakemi@naramed-u.ac.jp

Background and Aims: It has been recently reported that light-to-moderate alcohol consumption is associated with reduced prevalence of fatty liver in males, and moderate alcohol use is associated with improved insulin sensitivity and decreased cardiovascular mortality in the general population. We therefore aimed to elucidate the relationship between drinking patterns and fatty liver.
Method: This study assessed 2,429 Japanese males (mean age: 54.2 ± 9 years) who underwent medical examination at the Nara Health Promotion Center in 2012. Each subject's history of alcohol consumption was determined via a questionnaire. Subjects were classified according to alcohol consumption: non-drinker (ND), 0 g/day; light drinker (LD), <30 g/day; moderate drinker (MD), 30–60 g/day; and heavy drinkers (HD), >60 g/day. Fatty liver was diagnosed based on abdominal ultrasonography (hepatorenal echo contrast and liver brightness). Percentages of participants with fatty liver, obesity, elevated alanine aminotransferase (ALT) levels, and insulin resistance were compared among the four groups. Independent predictors of insulin resistance were determined by logistic regression analysis.
Results: The prevalence of fatty liver was the lowest in the MD group and highest in the ND group (p < 0.001). The prevalence of obesity (body mass index ≥ 25 kg/m^2) was not significantly different among the four groups (p = 0.133). The prevalence of elevated ALT levels (≥30 IU/l) was the lowest in the MD group (p < 0.05). The prevalence of insulin resistance (the homeostasis model assessment-insulin resistance ≥2.5) was the lowest in the MD group and highest in the ND group (p = 0.001). Chronic alcohol consumption was independently and inversely associated with insulin resistance after adjusting for obesity, hypertension, fasting hyperglycemia, and age. The odds ratios (95% confidence interval) were as follows: ND, 1; LD, 0.67 (0.50–0.90); MD, 0.48 (0.33–0.69): HD, 0.48 (0.30–0.76).
Conclusion: Moderate alcohol consumption is protective against fatty liver to improve insulin resistance.
