Results: 306 patients were included. The majority of patients were male (53%), non-Hispanic white (70%), and insured (98%). The mean age was 57 years and nearly one-third of patients were active smokers (29%). Eight-four percent of patients were genotype 1, 49% were cirrhotic, 14% were decompensated, and 5% had hepatocellular carcinoma. The majority of patients were treatment naïve (70%) and received ledipasvir/sofobuvir (83%). At baseline, the mean creatinine level was 0.96, and 90% had normal renal functioning and 10% had renal impairment. Of those with normal renal functioning at baseline, GFR stayed the same in 97% of patients and worsened in 3%. Of those with renal impairment at baseline, GFR improved in 23% of patients, stayed the same in 68%, and worsened in 10%. Altogether, GFR improved or stayed the same in 96% of patients and worsened in 4% of patients. There were no differences of statistical significance between creatinine levels before and after treatment insert here (0.96 vs. 1.00, t (305) = 1.44, p = 0.15).

Table: Proportion of HCV Patients with Renal Improvement, No Change, or Worsening 3–6 Months Post-SVR

Renal Function Before Treatment	GFR Improved at Follow Up (3–6 months)	GFR Stayed the same at Follow Up (3–6 months)	GFR Worsened at Follow Up (3–6 months)
Normal (GFR > 60): 275 (90%)	0 (0%)	266 (97%)	9 (3%)
Impaired (GFR < 60): 31(10%)	7 (23%)	21 (68%)	3 (10%)
Grand Total: 306 (100%)	306 (100%)	287 (94%)	12 (4%)

Conclusion: In this study, DAAs were well tolerated from a renal function standpoint. Nearly one-fourth of patients with baseline renal impairment had improvements in renal function achieving SVR. DAA treatment may improve renal function in some patients. Larger, prospective studies are needed to further investigate our findings.

THU-353

Fast-track HCV check-up enhances possibility of sustained virologicalresponse in HCV infected patients

T. Antonini[1], M.G. Tateo[2], P. Attali[2], E. De Martin[2], A. Coilly[2], B. Roche[2], R. Sobesky[2], D. Samuel[3], A.M. Roque-Afonso[2], J.-C. Duclos-Vallée[4]. Email: teresa.antonini05@aphp.fr

Background and Aims: New direct acting antiviral (DAA) against chronic hepatitis C virus (HCV) have drastically changed and shortened duration of treatments. However, the "HCV care course" (from diagnosis to sustained virological response (SVR)), represents an important challenge.
Aims: To evaluate the impact of a new fast-track HCV check-up in terms of retention in care and SVR. In order to assess the efficacy we provide a comparison between the first 50 pts of the FT-HCV (Fast track HCV check-up) in 2016 to 50 pts followed in our "standard" out clinic practice (control group (CG)) in 2015.
Method: FT-HCV is a new assessment unit of our center. In the same half-day, pts benefit of a complete assessment of liver function: blood test with HCV-Ab and HCV viral load, genotype (G) determination, Fibrotest® and transient elastography. Three hours after admission, we were able to confirm HCV and to discuss the eligibility to an HCV treatment in accord to regulatory framework.
Results: Groups were comparable for age and sex**:** 50 pts of each group were analysed (FT-HCV: Male n = 34 (68%), mean age: 49 ± 14 years; CG: Male n = 35 (66.6%), mean age: 53 ± 13 years). In FT-HCV and CG fibrosis (F) was: mild F0-F1 n = 15 (30%), F2 n = 12 (24%), F3 n = 10 (20%), F4 n = 13 (26%), and F0-F1 n = 18 (36%), F2 n = 12 (24%), F3 n = 9 (18%), F4 n = 10 (20%), unknown n = 1 (2%) respectively. All cirrhotic pts had compensated cirrhosis (Child A/MELD 8–10). Six pts (12%) in the FT-HCV group were excluded because HCV viral load was negative. G distribution in the FT-HCV and in CG was: G1 n = 25(50%), G3 n = 8 (16%), G4 n = 11 (22%), and G1 n = 29 (58%), G2 n = 5 (10%), G3 n = 7 (14%), G4 n = 7 (14%), G6 n = 6 (4%) respectively. Thirty (69%) and 26 (52%) pts received DAA in FT-HCV and CG.
Mean delay and numbers of out-clinic visits in FT-HCV and CG for treatment were 108 days (± 84) *versus* 260 days (± 85) p = 0.009 and 2 (2–5) vs 4 (2–9) p = 0.0003, respectively.
To date in FT-HCV pts: SVR was achieved in 22 pts (74%), waiting for SVR12 in 7 pts (23%) and 1 pt was not responder (3%). Complete results SVR 12 for all pts will be presented. In CG SVR was achieved in 23 pts (88%), 1 pt was non-responder (3%) and 2 pts (6%) were lost of follow-up.
Conclusion: FT-HCV is a performing assessment of HCV infected patients and improves retention in care, management and rates of SVR.

THU-354

Grazoprevir/elbasvir dosing according to viral load and NS5A resistance: real world confirmation of the efficacy of EASL guidance

F. Marra[1,2], A. Boyle[1,2], R. Gunson[3], A. Bradley[3], E. Thomson[4,5], S. Barclay[6]. [1]*NHS Greater Glasgow and Clyde, Pharmacy Department;* [2]*University of Liverpool, Department of Molecular and Clinical Pharmacology;* [3]*NHS Greater Glasgow and Clyde, West of Scotland Specialist Virology Centre;* [4]*NHS Greater Glasgow and Clyde, Brownlee Centre for Infectious Diseases;* [5]*MRC Centre for Virus Research;* [6]*NHS Greater Glasgow and Clyde, Glasgow Royal Infirmary*
Email: fiona.marra@liverpool.ac.uk

Background and Aims: Twelve weeks of grazoprevir/elbasvir (GRZ/ELB) is highly effective against genotype 1a infection. The presence of elbasvir specific NS5a resistance-associated substitutions (RASs) in patients with a high baseline viral load may have a suboptimal response, which may be overcome by extending treatment duration to 16 weeks and adding ribavirin. As per EASL guidelines, our local

protocol is to treat patients with a baseline viral load <800,000 IU/ml for 12 weeks, and to conduct resistance testing for those >800,000. Those with elbasvir RASs are treated for 16 weeks with RBV, those without with 12 weeks GRZ/ELB. We report the initial outcomes of this approach.

Method: Patients with GT1a commencing treatment with GRZ/ELB in Glasgow treatment centres, prior to 01/09/2017 were identified from the Scottish HCV database. Baseline data on age, gender, cirrhosis status, and virological response were collected. RAS testing for mutations at positions M28, Q30, L31, H58 and Y93 was conducted using Sanger sequencing by the West of Scotland Specialist Virus laboratory.

Results: Of 176 patients who met the inclusion criteria, 125 (71.0%) were male with a mean age 45.7 years (± 9.0) and 94 (53.4%) were on opiate substitution therapy. There were 39 (22.2%) patients with a diagnosis of cirrhosis. Ninety-eight patients (55.6%) with a high viral load underwent RAS testing, of whom 5 (5.1%) had elbasvir specific RASs, and were treated with 16 weeks in combination with ribavirin. All other patients were treated with 12 weeks of GRZ/ELB. To date, 126 patients have completed treatment, 5 (3.9%) prematurely. To date, 45 patients have attended for SVR12 bloods (1 treated for 16 weeks plus ribavirin, 12 with cirrhosis). 44/45 (97.8%) have achieved SVR, including all with cirrhosis.

Conclusion: Early results confirm the efficacy of 12 weeks of GRZ/ELB for patients with a low viral load, or a high viral load in the absence of elbasvir specific RASs, with 16 weeks plus RBV reserved for those with a high viral load and RASs. Further SVR12 data will be presented.

THU-355

Impact of HCV viral load on elbasvir/grazoprevir effectiveness in Chronic Hepatitis C: Updated retrospective data analyses from the Trio network

S. Flamm[1], B. Bacon[2], M. Curry[3], S. Milligan[4], C. Nwankwo[5], N. Tsai[6], N. Wick[4], Z. Younossi[7], N. Afdhal[3]. *[1]Northwestern University Feinberg School of Medicine, Chicago, United States; [2]Saint Louis University School of Medicine, St. Louis, United States; [3]Beth Israel Deaconess Medical Center, Boston, United States; [4]Trio Health, La Jolla, United States; [5]Merck & Co., Inc., Kenilworth, United States; [6]Queens Medical Center- University of Hawaii, Honolulu, United States; [7]Inova Fairfax Hospital, Department of Medicine, Falls Church, United States*
Email: s-flamm@northwestern.edu

Background and Aims: Lengthening elbasvir/grazoprevir (EBR/GZR) treatment to 16 weeks and adding ribavirin (RBV) is recommended by the EMA for patients with Genotype (GT) 1A or 4 Chronic Hepatitis C (HCV) and baseline viral load >800 K IU/ml. This study examines the association of viral load and observed SVR12 outcomes in patients treated with EBR/GZR.

Method: Data were collected from providers and specialty pharmacies in the US through Trio Health's disease management program. Patients (n = 1032) who initiated EBR/GZR therapy between Jan 28, 2016 (FDA approval) to Jun 2017 were included. The primary outcome assessed was per protocol sustained virologic response at 12 weeks post treatment (SVR12).

Results: 381/1032 (37%) patients had baseline viral load ≤800 K IU/ml and 651/1032 (63%) >800 K IU/ml. 12-week EBR/GZR without RBV was the predominant therapy regardless of baseline viral load, used in 347/381 (91%) of ≤800 K IU/ml group and 605/651 (93%) of >800 K IU/ml group. At time of data extraction, outcomes were available for 694/1032 patients and were: 10/694 (1%) died, 42/694 (6%) discontinued, 28/694 (4%) completed but were lost to follow up, 11/694 (2%) completed therapy and had virologic failure, and 603/694 (87%) achieved SVR12. The per protocol (PP) SVR12 rate (limited to patients who completed therapy and had an SVR assessment), was 603/614 (98%). Outcomes were similar between groups stratified by baseline viral load: PPSVR12 rates of 230/232 (99%) for ≤800 K IU/ml and 373/382 (98%) for >800 K IU/ml. For patients with GT1A HCV and baseline viral load >800 K IU/ml, 12-week EBR/GZR resulted in PPSVR12 of 228/231 (99%). For patients with GT4 HCV and baseline viral load >800 K IU/ml, 12-week EBR/GZR resulted in PPSVR12 of 6/6 (100%).

Conclusion: In clinical practice in the US, no obvious impact from baseline viral load >800 K IU/ml on PPSVR12 was observed as patients in the ≤800 and >800 K IU/ml groups had similar PPSVR12. Full SVR12 data across sub populations will be presented at the conference.

THU-356

Therapeutic Drug Monitoring of DAAs overcomes contra-indications against anti-epileptics in HCV treatment (HepNed003)

M. van Seyen[1], S.J. Elise[2], V.W. Peter[3], J.P.H. Drenth[4], M. Wouthuyzen-Bakker[5], R. de Knegt[6], H. Pieter[7], O. El Sherif[8], D. Back[9], D. Burger[1]. *[1]Radboud University Medical Center, Dept of Pharmacy, Nijmegen, Netherlands; [2]Isala Hospital, Dept of Pharmacy, Zwolle, Netherlands; [3]Amphia Hospital, Dept of Internal Medicine, Breda, Netherlands; [4]Radboud University Medical Center, Dept of Gastroenterology & Hepatology, Nijmegen, Netherlands; [5]University Medical Center Groningen, Medical Microbiology and Infection Prevention, Groningen, Netherlands; [6]Erasmus MC, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [7]Albert Schweitzer Hospital, Dept of Gastroenterology & Hepatology, Dordrecht, Netherlands; [8]St James's Hospital, Dept of Hepatology, Dublin, Ireland; [9]University of Liverpool, Dept of Molecular and Clinical Pharmacology, Liverpool, United Kingdom*
Email: minou.vanseyen@radboudumc.nl

Background and Aims: Drug-drug interactions between direct-acting antivirals (DAAs) and co-medication occur frequently. They may have clinical consequences necessitating dose modification, intensified monitoring and/or drug substitution. The anti-epileptic drugs carbamazepine, phenytoin and phenobarbital, which are strong inducers of CYP450 enzymes and membrane transporters, are contra-indicated with all available DAA combinations, and therefore should be replaced. In rare cases, patients and/or neurologists are unable to substitute the anti-epileptic drug. As separate sofosbuvir (SOF) and daclatasvir (DAC) formulations are available, dose adjustment of individual agents is possible. We hypothesize that increased dosage of DAC with PK monitoring against a backbone of SOF could be an effective approach in these difficult to treat patients.

Method: We established a cohort of HCV patients on anti-epileptics who were unable stopping treatment. Patients were treated with an increased dose of DAC and underwent intensive PK monitoring followed by further dose-adaptation if needed. Patients were treated with a standard dose of SOF as this is a P-gp substrate and expected to be less vulnerable to the inducing effects of anti-epileptics. Addition of ribavirin and treatment duration was according to treatment guidelines. Here we report on six patients (n = 4 male) with a median age of 55.4 (48.5–66.5) years using the anti-epileptic drugs carbamazepine 400–1200 mg/day (n = 4), phenytoin 225 mg/day (n = 1) or phenobarbital 100 mg/day (n = 1). Most patients were infected with genotype 1 (n = 5) and treatment-naïve (n = 4). METAVIR scores were F0 (n = 3), F3 (n = 1) and F4 (n = 2).

Results: The standard dose of DAC 60 mg QD was adjusted to 60 mg BID (n = 2) and 60 mg TID (n = 4). After PK evaluation, one of the patients receiving 60 mg DAC BID, had the DAC dose increased to

60 mg TID because of suboptimal levels. The median C_{last}, C_{max} and AUC_{0-24h} of DAC were 0.097 (0.086–0.45)mg/l, 0.42 (0.34–0.94) mg/l and 4.75 (4.03–14.93)mg*h/l, respectively. These values were 58.2%, 72.8% and 66.3% lower for C_{min}, C_{max} and AUC_{0-24h} respectively, when compared to reference values for DAC. No serious adverse events were reported. So far, three patients reached SVR12, another patient had SVR4, and for the two other patients SVR data are pending.
Conclusion: This cohort study using an adaptive dosing strategy demonstrates the feasibility of studying DAA combinations with the contra-indicated anti-epileptic drugs. Despite lower exposure to DAC, all patients with sufficient follow-up have achieved SVR.

THU-357

What impact do the new direct acting antiviral drugs have on the patients' quality of life?

M. Gentili[1], C.F. Magni[2], C. Carnovale[1], E. Cesari[1], D. Cattaneo[1], M. Schiavini[2], S. Landonio[2], F. Niero[2], V. Scalzi[3], S. Vimercati[3], S. Radice[1], E. Clementi[1], G. Rizzardini[2]. Email: marta.gentili77@gmail.com

Background and Aims: The non-specific symptomatology of hepatitis C (HCV) as well as the side effects of its therapy can significantly influence patients' quality of life. To date, the number of real life studies investigating this aspect are still limited. For this reason, a retrospective observational study was performed using a questionnaire to understand the impact of new direct acting antiviral drugs (DAAs) on the patients' quality of life.
Method: The survey consists of 19 open and multiple choices questions divided into 5 sections. The questionnaires were administered to all patients from the Infectious Diseases Department of our hospital, who had completed the anti-HCV therapy with DAAs. The collected responses were matched against clinical data.
Results: 201 patients who had completed therapy with DAAs were interviewed: 111 (55.2%) were naive and 90 (44.8%) had been treated with previous HCV therapies. 90% of this latter group said they prefer the new therapy. All patients showed significant improvement in symptomatology. However, calculating the incidence of symptomatology related to the period before and during DAA therapy, there were 322 adverse drug reactions (ADR), which led to the discontinuation of therapy in two cases (one case of hepatocellular carcinoma and one of skin cancer). As shown in Figure 1, only 10.5% of ADRs were reported by the attending physicians' worthy of mention, 50,3% of all ADRs were unknown, as they are not reported previously on the clinical data sheet of suspected drug. The most frequent ADRs were insomnia, altered mood, loss of appetite, anxiety and irritability whereas the most clinically relevant were herpes zoster, optic ischemia, amaurosis and breast hypertrophy.
Conclusion: Despite the good safety profile shown by DAAs during registration trials, the patients' point of view has provided important, new information on their safety profile, helping us to identify novel drug-related adverse reactions. Nevertheless, physicians are still mandatory for a correct and appropriate differential diagnosis of iatrogenic pathology, eventually working in team with pharmacologists, which have the tools, skills and expertise to check and prevent drug-to-drug interaction-related ADRs, identifying them before the introduction of DAAs. Lastly, the identification of ADRs not known and the search for a possible mechanism of action that may have exacerbated them is certainly one of the strengths of our work.

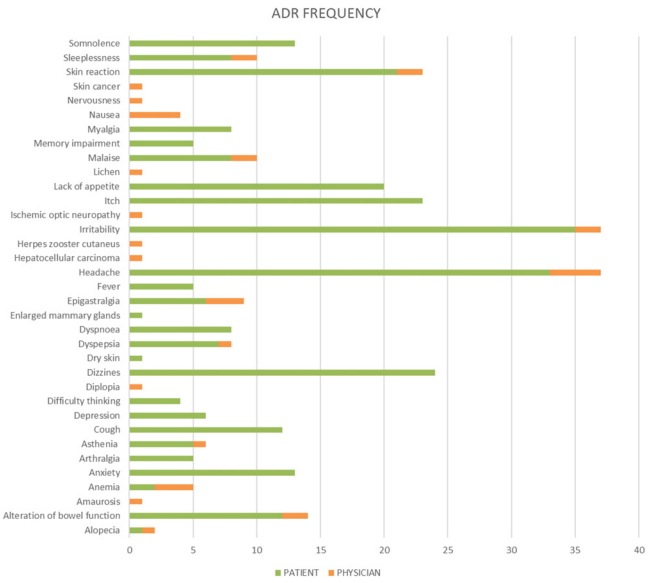

Figure 1: Frequency of Adverse drug reactions recorded in our real life survey.

THU-358

Significant changes of HCV patient characteristics over time in the era of direct antiviral agent therapy – are all HCV subpopulations treated similarly? – Results from the German hepatitis C Cohort

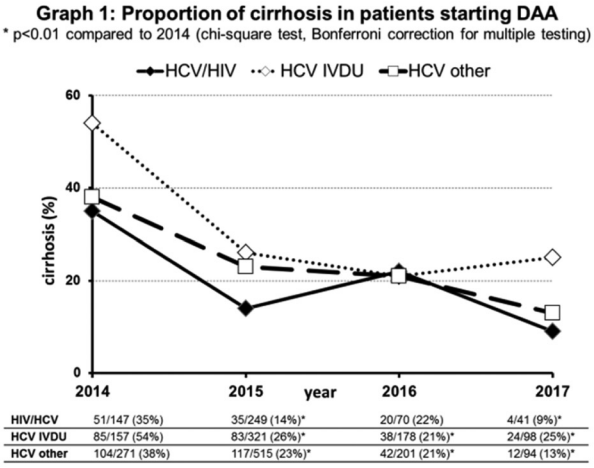
Email: christensen@cim-ms.de

Background and Aims: The German healthcare system provides access to all approved direct antiviral agent (DAA) regimen allowing pangenotypic therapy and retreatment of patients with relapse and reinfection. However, access to care and therapy may differ between patient populations at risk in the real life setting, which could potentially result in differences in the proportion of patients presenting with advanced liver disease.
Method: The German hepatitis C Cohort (GECCO) cohort is a prospective multicenter cohort from 9 sites in Germany. For this analysis all chronically HCV infected patients started on a DAA based therapy between 2/2014 and 9/2017 were included. Baseline demographics and treatment outcome according to the calendar year DAA treatment was initiated are reported.
Results: Until September 2017 n = 2,367 patients, 64% GT1 and 25% GT3 infected, initiated DAA based therapy, mostly with sofosbuvir/



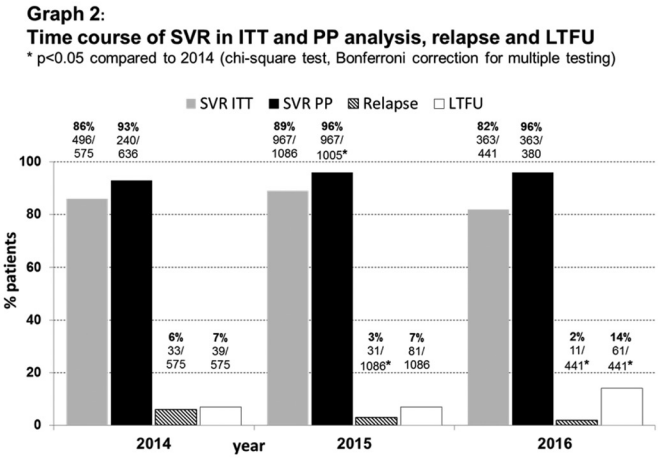


Figure: (abstract: THU-358)

ledipasvir ± ribavirin (45%). There has been a continuous decrease in (a) the proportion of previously treated HCV patients (2014:83%, 2017:24%, p < 0.0001), and (b) patients with liver cirrhosis defined by FibroScan® >12,5 kPa or APRI >2 (2014:42%, 2017:17%, p < 0.0001). More importantly, the decrease in the proportion of patients with liver cirrhosis was comparable in patients with HCV-monoinfection and history of intravenous drug use (IVDU), HIV/HCV coinfection or neither of those (Graph 1). The proportion of HIV/HCV coinfection decreased (2014 26%, 2017 19%, p < 0.01), whereas the number of patients with history of IVDU increased from 33% 2014 to 50% 2017 (p < 0.001). Mean age dropped from 52 years in 2014 to 48 years in 2017 (p < 0.01). Neither in the intention to treat analysis (ITT) (2014: 86%, 2016: 82%, p = 0.096) nor in the per protocol analysis (PP) (2014: 93%, 2016: 96%, p = 0.072) SVR12 significantly changed over time. In fact, relapse rates decreased from 6% 2014 to 2% 2016 (p < 0.05) but lost to follow (LTFU) doubled between 2014 (7%) and 2016 (14%) (Graph 2).

Conclusion: In this real life cohort the decrease in the proportion of patients initiating therapy with liver cirrhosis was comparable in different risk groups including IVDU. A shift to younger, treatment naïve and patients with IVDU as transmission risk occurred. Antiviral effectiveness increased over time as indicated by the very low relapse rates in the last two years of analysis. However, lost to follow up after end of therapy increased substantially indicating lower adherence to structured monitoring in more recently treated patients.

Email: tinarugg@gmail.com

Background and Aims: International guidelines currently recommend HCV genotypic resistance testing (GRT) in selected cases. However, GRT application is limited in many countries by the lack of a commercial assay. Within the Italian VIRONET C activity, we conducted a multicentre HCV Sanger GRT quality control study, with the aim of providing a standardized GRT at National level.

Method: A panel of 10 blinded clinical samples with HCV genotypes (GT)1a-1b-2c-3a-4a-4d, with a median (IQR) HCV-RNA of 5.8 (5.6–5.9) logIU/ml, was provided to 23 laboratories (lab)of VIRONET C. NS3, NS5A and NS5B GRT was performed by using different Sanger sequencing protocols at 22 labs, while Illumina next-generation sequencing (NGS) was performed at 1 lab, and used as comparator with 15% detection cut-off. The Geno2pheno (G2P) tool was used for detection of resistance associated substitutions (RASs).

Results: Fourteen labs generated all the 30 expected sequences, while the remaining 8 generated a mean ± SD of 24.3 ± 3.6 sequences. Fourteen labs used the same Sanger protocol while all the others used a unique system. G2P identified a total of 7 RASs in the 30 sequences generated by NGS. Comparing the NGS sequences to the Sanger consensus sequences derived from all the available results revealed four major RASs discordances, including a NS5A Y93H and a NS3 Q168QK detected by 100% and 35% Sanger reactions, respectively, but not by NGS, and a NS5B S556G detected by NGS (98%) in 2 samples

(GT 3a and 2c) but not by any Sanger reaction. When excluding these method discrepancies, the overall Sanger accuracy with respect to the consensus sequence was 85%, and particularly 81% for NS3, 85% for NS5A and 90% for NS5B. The disagreement was more common for particular GT/subtypes (2c and 3a for NS3, 1b and 4a for NS5A). The rate of sequencing success and RAS disagreement were almost equal among the labs using the same assay *vs* the others (86% *vs* 85% and 14% *vs*15%, respectively). The overall RAS detection disagreement among laboratories was 9% in NS3, 7% in NS5A, 0% in NS5B.
Conclusion: Most of the 22 labs participating to the Italian VIRONET C network provided HCV GRT results for all circulating HCV GTs and all clinically relevant genes. Accuracy and inter-laboratory precision were affected by the use of different methods, highlighting the challenge of HCV variability. Quality control programs for HCV GRT should be promoted to allow its fruitful use in optimizing HCV treatment.

Email: vincent.thibault@chu-rennes.fr

Background and Aims: With 26 described subtypes, genotype 6 (Gt6) exhibits the highest genetic diversity among the 7 HCV genotypes. The aim of this study was to document Gt6 diversity among 14,603 HCV mono-infected patients recruited between 08/06/12 and 10/09/17 in the French ANRS-CO22 Hepather cohort (NCT01953458) and to analyze treatment efficacy within each subtype.
Method: For all Gt6 HCV infections identified in the database, HCV subtype was determined on a plasma sample drawn at inclusion. After HCV RNA extraction, NS3, NS5A and NS5B regions were RT-PCR amplified and sequenced by the Sanger method. Phylogenetic analyses were performed by comparing obtained and reference Gt6 sequences. Resistance polymorphisms were also studied.
Results: Gt6 infections were identified in 38 patients. Two were excluded as NS5B analysis revealed misclassified Gt1 and Gt3 infections. Gt6e was the most prevalent (27.8%), followed by 6a (22.2%), 6q (13.9%) and 6o (11.1%). Each subtype p and xc were found in 2 patients (5.6%) and subtypes f, h, k, r and t were each detected in only one patient. Concordant phylogenetic analyses whatever the studied HCV fragment eliminated any recombination event in this part of the genome. All but 3 patients were born in an Asian country, Cambodia (44%), Vietnam (42%) or Laos (8%). Subtype 6a and 6e were found in 17% of patients born in Vietnam and Cambodia, respectively. Subtype 6q was mostly found in patients from Cambodia (80%). Among the 3 patients born in Europe, 2 were contaminated with subtype 6o, also found in 2 Vietnamese. Phylogenetic analyses indicated a harmonious distribution reflecting genetic heterogeneity from different countries and no specific clustering. Twenty-six patients received sofosbuvir based DAA combinations and 3 received glecaprevir/pibrentasvir. For the 23 patients with a documented follow-up, 14 with advanced fibrosis (≥F3), SVR12 was reached. Several polymorphisms potentially impacting sensitivity to each DAA classes were identified in baseline sequences. Resistance associated substitutions were unevenly distributed according to each subtype but did not seem to impact treatment efficacy.
Conclusion: Genotype 6 infections are not common in France and show a large genetic diversity, likely reflecting contamination within the country of origin rather than locally acquired infections. Despite the presence of genetic polymorphisms potentially affecting DAA efficacy, all treated patients were successfully treated using recommended DAA associations.

THU-361

Hepatitis C direct-acting antiviral failures: clinical characteristics and resistance testing from a real-world setting

R. Mitchell[1], G. Ou[1], A. Leung[2], J. Feizi[2], A. Howe[3], O. Cerocchi[4], H. Kuriry[4], J. Feld[4], H.H. Ko[1], A. Ramji[1]. *[1]University of British Columbia, Vancouver, Canada; [2]St. Paul's Hospital, Gastrointestinal Research Institute, Vancouver, Canada; [3]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada; [4]University of Toronto, Toronto, Canada*
Email: rmitch86@gmail.com

Background and Aims: A small proportion of patients fail Hepatitis C (HCV) treatment with direct-acting antivirals (DAAs) for various reasons. Real-world data on DAA failures and the development of resistance associated substitutions (RAS) are limited. This study aims to characterize clinical parameters and RAS patterns in patients who failed DAA regimens.
Method: Retrospective chart review at two tertiary hepatology clinics between 01/2015 and 11/2017. Patients treated with DAAs who did not achieve SVR12 were included. Baseline clinical characteristics and RAS testing at SVR12 were collected. HCV sequence data were obtained from Next Generation Sequencing. Mutations >5% of viral population were reported. Resistance phenotype was predicted based on EC_{50} fold-shift in mutant vs. wild-type replicons.
Results: Sixty-three patients were included: mean age 59.7 years (range 43–84) and mostly male (82.5%). Genotypes (GT) included GT1a (n = 28; 44.4%), GT1b (n = 8; 12.7%), GT2 (n = 5; 7.9%), GT3 (n = 19; 30.2%), GT4 (2; 3.2%), GT6 (n = 1; 1.6%). DAA regimen durations were 8 weeks (n = 6; 9.7%), 10 weeks (n = 1; 1.6%), 12 weeks (n = 38; 61.3%), 16 weeks (n = 2; 3.2%) or 24 weeks (n = 15; 24.2%). Pre-treatment fibrosis by transient elastography (n = 41) revealed F0–2 (39.0%), F3 (12.2%) and F4 (48.8%).
Post-DAA RAS testing was available for 59 patients. In 21 GT1a patients treated with SOF/LDV, 16 had a NS5A RAS, 8 of which were 93 position variant. All 6 GT1b patients who failed SOF/LDV had a NS5A RAS, with 5 being at position 93. 17 of 21 GT1a patients had an NS3 RAS, 10 were Q80K. Two GT1a EBR/GZR failures had both a NS5A and a non-Q80K NS3 RAS. Of 2 GT1a patients who failed OBV/PTV/r + DSV/RBV, 1 had NS5A.
In 17 of 19 GT3 patients RAS testing was available. DAA regimes included SOF/RBV (n = 11), SOF/VEL (n = 2), SOF/VEL/RBV (n = 2), SOF/RBV/Interferon (n = 2) and SOF/LDV/RBV (n = 2). Three patients had NS5B RAS, conferring possible SOF resistance (159wt/F, 321wt/A, 142S). There were no S282T RAS. All 4 GT3 patients failing SOF/VEL +/-RBV had NS5A RAS, 3 were Y93H. Of 11 GT3 patients with SOF/RBV +/-IFN treatment and RAS testing, 2 had NS5A RAS (S62L, A30K).
Conclusion: Distinct RAS patterns are present depending on genotype and DAA regimen failed. Virologic failure with a NS5A based regimen confers a high risk of developing a NS5A RAS, which may have implications on future treatments in these patients. Additional analysis to explore baseline patient characteristics associated with RAS is pending.

THU-362

Prevalence of baseline NS5A resistance associated substitutions in treatment naive patients with genotype 1a or 3

A. Ramji[1,2], E. Tam[3], J. Feld[4], C. Cooper[5], A. Wong[6]. *[1]University of British Columbia, Gastroenterology, Vancouver, Canada; [2]University of British Columbia, Vancouver, Canada; [3]LAIR Center, Vancouver, Canada; [4]Toronto, Canada; [5]University of Ottawa, Ottawa, Canada; [6]Regina Qu'Appelle Health Region, Regina, Canada*
Email: ramji_a@hotmail.com

Background and Aims: HCV DAA treatment achieves high SVR in almost all populations. However, a small proportion of patients fail. The primary virologic reason for failure is the presence of baseline resistance-associated sequences (RAS). International Guidelines

(EASL & AASLD) recommend assessment of baseline NS5A RAS testing in persons with GT1a and GT3, dependent on the DAA regimen and fibrosis stage. Uptake and impact of these recommendations are unclear.

Aim: To evaluate the prevalence and impact of baseline NS5A RAS in NS5A treatment naïve (TN) persons with GT1a and GT3 in clinical practice.

Method: A retrospective chart review from 5 centres in Canada between January 2016 to November 2017. Patients evaluated included NS5A TN with GT 1a or GT 3, with baseline RAS testing. Patient demographics and fibrosis stage were collected. HCV sequence data by Next Generation Sequencing from the BC Centre for Excellence in HIV. Mutations >5% of viral population were reported. Resistance phenotype was determined on EC_{50} fold-shift in mutant vs. wild-type replicons. Only RAS that confer high level resistance to elbasvir or ledipsavir for GT1a and velpatasvir for GT3, as suggested by EASL/AASLD guidelines and the reference laboratory were evaluated.

Results: A total of 366 patients were included (264 GT1a and 98 GT3). Mean age was 52 years, 59% were male. Fibrosis data were available in 326 patients, with F0-2 in 197 (53.8%), F3 in 25 (7.6%) and F4 in 104 (32%) patients. Baseline NS5A RAS were present in 13 GT1a (4.9%) and 16 with GT3 (16.3%) patients tested. Of the 29 patients with baseline RAS 14 (48%) were F3-F4. In GT1a patients, 7 of 13 had a Y93H RAS, and 6 persons had 2 or more RAS. In GT3 patients 7 of 16 had a Y93H RAS, 12 had an A30 RAS, and 10 had 2 or more baseline RASs. No baseline S282T RAS were detected. In patients with treatment data available, ribavirin was added in 7 of 13 persons with a baseline RAS. SVR data in persons with a baseline RAS is pending. Overall SVR is 93% (70/75). Relapse occurred in 5 persons, none had a high potency baseline RAS. However, 1 GT1a patient had H54Y baseline RAS and a GT3 patient failed SOF/RBV had a S62 baseline RAS.

Conclusion: The prevalence of baseline NS5A RAS in this Canadian cohort is low in GT1a at <5%, and high in GT3 is higher at 16%. Half of the baseline NS5A RAS conferring high level resistance are of the Y93 type. Testing is preferentially conducted in those with advanced fibrosis.

THU-363

Efficacy and safety of glecaprevir/pibrentasvir in renally-impaired patients with chronic hepatitis C virus genotype 1–6 infection

M. Persico[1], R. Flisiak[2], M. Abunimeh[3], M. Sise[4], J.Y. Park[5], M. Kaskas[6], A. Bruchfeld[7], M.-A. Wörns[8], A. Aglitti[1], Z. Xue[3], J. Rullman[3], A. Pocalla[3], E. Lawitz[9]. [1]*University of Salerno, Internal Medicine and Hepatology Unit, Salerno, Italy;* [2]*Medical University of Bialystok, Department of Infectious Diseases and Hepatology, Bialystok, Poland;* [3]*AbbVie, Inc, North Chicago, United States;* [4]*Massachusetts General Hospital, Department of Medicine, Boston, United States;* [5]*Yonsei University College of Medicine, Department of Internal Medicine, Seuol, Korea, Rep. of South;* [6]*Northwest Louisiana Nephrology, Shreveport, United States;* [7]*Karolinska Institutet, Department of Renal Medicine, Karolinska University Hospital, Stockholm, Sweden;* [8]*University Medical Center of the Johannes Gutenberg-University Mainz, Department of Internal Medicine, Mainz, Germany;* [9]*University of Texas Health San Antonio, The Texas Liver Institute, San Antonio, United States*
Email: mpersico@unisa.it

Background and Aims: The direct acting-antivirals (DAA) glecaprevir (NS3/4A protease inhibitor; developed by AbbVie and Enanta) and pibrentasvir (NS5A inhibitor), coformulated as G/P, are a once-daily, all-oral treatment regimen with high rates of sustained virologic response at 12 weeks post-treatment (SVR12) and a favourable safety profile indicated for use in patients at any stage of chronic kidney disease (CKD). Here we report preliminary data from a Phase 3b study assessing the efficacy and safety of 8, 12, and 16 weeks of G/P treatment in patients with chronic hepatitis C virus (HCV) genotype (GT) 1–6 infection and CKD Stage 3b, 4, or 5, including those on dialysis. This study aims to provide further evidence supporting G/P's labeled regimen among patients with moderate or severe CKD, including efficacy of an 8-week G/P treatment duration for patients who are treatment naïve and non-cirrhotic.

Method: EXPEDITION-5 (NCT03069365) is an ongoing, Phase 3b, multicenter study evaluating the efficacy and safety of G/P in patients without cirrhosis or with compensated cirrhosis and with CKD. Patients were either treatment-naïve or -experienced with interferon (IFN), pegIFN ± ribavirin (RBV), or sofosbuvir (SOF) + RBV ± pegIFN. Prior treatment with a DAA other than SOF was not permitted. Patients had an estimated glomerular filtration rate (eGFR) < 45 ml/min/1.73 m^2 without a history of acute renal failure within 3 months prior to screening. Patients were treated with label (U.S. and E.U.) indicated treatment duration. Efficacy was evaluated by the percent of patients achieving SVR12 (HCV RNA < lower limit of quantification). Safety was assessed in all patients.

Results: In total, 101 patients were enrolled with 84, 13, and 4 patients receiving G/P for 8, 12, and 16 weeks, respectively. Demographics for the first 99 patients are as follows: 41 (41%) were female, 72 (73%) were white and 13 (13%) had compensated cirrhosis. At screening, 7 (7%), 17 (17%), and 75 (76%) patients had CKD stage 3b, 4, and 5, respectively; 73 (74%) patients required dialysis. Preliminary safety information identified pruritus, occurring in 14%, as the only adverse events (AEs) reported in ≥5% of patients. Grade ≥3 serious and non-serious treatment-emergent AEs were reported in 5% of patients; none of which were related to G/P or led to treatment discontinuation. To date, 5/5 patients treated with G/P for 8 weeks have achieved SVR12.

Conclusion: Preliminary safety data suggest that G/P was safe and well-tolerated. Complete SVR12 results will be presented at the congress.

THU-364

Multicenter study on outcome of HCV elimination using LDV/SOF combination in Mongolians

L. Nemekhbaatar[1,2], B. Oidov[2], D. Radnaa[2], S. Ulziibayar[2], M. Sarandavaa[2], J. Palam[2], T. Davaadorj[2], E. Damba[2], B. Dorjgotov[3], N. Dulmaa[4], A. Jenskhan[2], C. Nagir[2], S. Batmunkh[2], G. Uugantsetseg[5], M. Batmunkh[1], A. Jazag[2,6]. [1]*Institute of Medical Sciences, Mongolia, Central Scientific Research Laboratory, Ulaanbaatar, Mongolia;* [2]*Mongolian Association for the Study of Liver Diseases (MASLD);* [3]*Third Generel Hospital of Mongolia;* [4]*Darkhan-Uul Province Central Hospital;* [5]*National Center of Communicable Diseases;* [6]*Happy Veritas Diagnostic Center*
Email: lkhaasuren.ims@mnums.edu.mn

Background and Aims: The incident of liver cancer in Mongolia generally caused by HBV and HCV, and it is 7 times higher than that of world average. HCV, the most prevalent cause of HCC in Mongolia, is number one public health issue. Mongolia is one of the first countries that registered Ledipasvir/Sofosbuvir (LDV/SOF) regimen from developing countries. By the support of Access program run by Gilead Sciences, USA, we started HCV treatment program from January 2016.

Method: We followed and evaluated treatment outcome of patients with HCV infection using combination of 90 mg ledispavir/400 mg sofosbuvir (manufactured by Gilead Science) in 937 treatment naïve and 83 treatment experienced patients. All patients were treated with LDV/SOF for 12 weeks and, their treatment was evaluated by quantitative HCV-RNA assays prior and W (week) 4 and W12 of treatment. Sustained virological response (SVR) after 12 weeks treatment was assessed. Virus genotype analysis using cDNA microarray, liver enzymes, CBC and drug related adverse events were assessed in every patient. The laboratory tests were conducted at National Center of Communicable Diseases, Happy Veritas Laboratories and other provinces' health care center.

Results: We conducted largest ever (415/1020) HCV genotype (GT) distribution study in Mongolian chronic HCV patients. 96.6% (n = 401) of assessed patients were GT1b; 0.7% (n = 3) were GT2; 0,2% (n = 1) were GT1a and b; 0.9% (n = 4) were GT1b and 2; 0.5% (n = 2) were

GT1b and 6;0.2% (n = 1) were GT5 and 0.2% (n = 1) were GT1b and 80 k mutants respectively.
992/1020 (97.3%) patients achieved SVR12W, 28 (2.7%) patients who did not achieve SVR12W were all genotype 1b. Median ALT level significantly dropped during treatment from 95.5 ± 84,1 IU/l to 27.2 ± 18.6 IU/l and slightly increased by the end of treatment 42.9 ± 17.4 IU/l. Total of 39 adverse events were observed in 595/1,020 patients (58,3%). Single adverse events were observed in 401/1,020 (39.3%) whereas 2 and more events were observed in 194 (19%) patients respectively. Unreported adverse events such as partial facial palsy, AFP (alpha-fetoprotein) increase, melasma were observed.
Conclusion: We achieved 97.3% SVR12W for 3 months treatment with LDV/SOF this time. But viral relapse has to be determined repeatedly at weeks 24 and 48 post treatment. All viral relapses (n = 14) and non-responders (n = 14) were GT1 in our study. According to HCV genotype assessment, there was no difference in treatment outcomes between patients who had different genotypes. Genotype distribution of Mongolian patients confirmed the results of other smaller studies. HCV RNA clearance during treatment was no different than clinical trials, but the slight increase of ALT by the end of treatment was commonly observed. It might have happened due to rebound of immune reaction after clearance of HCV or a drug induced effect.

THU-365

Salvage treatment of HCV patients by Sofosbuvir, Daclatasvir, Simeprevir and Ribavirin after repeated treatment failures is associated with SVR and reduced risk of hepatocellular carcinoma

A. Hanafy[1], S. Abd-Elsalam[2], S. Soliman[3]. [1]*Zagazig University, Faculty of Medicine, Internal Medicine, Hepatology and Endoscopy Division, Zagazig, Egypt;* [2]*Tanta University, Tropical Medicine, Egypt;* [3]*Menoufyia University, Public Health, Egypt*
Email: dr_amr_hanafy@yahoo.com

Background and Aims: Although the response rates are enhanced after direct acting antiviral agents (DAAs), re-treatment of patients who failed prior DAAs remains challenging. No current FDA-approved regimen for prior DAA treatment failures. The aim was to evaluate the impact of repeated treatment failures to combined antiviral therapy on fibrosis progression, development of HCC and the efficacy of treatment of those patients with Sofosbuvir, Daclatasvir, Simeprevir and Ribavirin on the rate of SVR.
Method: The study included 100 patients with previous repeated treatment failures due to relapse, breakthrough or null response more than once to weight based ribavirin and pegylated interferon, ribavirin and sofosbuvir, or sofosbuvir, daclatasvir and weight based ribavirin. They were assigned as a study group (n = 50) who were given salvage treatment composed of Sofosbuvir 400 mg, Daclatasvir 60 mg, Simeprevir 150 mg and weight based Ribavirin for 3 months or a control group (n = 50) who were matched for age and gender and received placebo. Both groups were followed up for 2 years starting from the last non-respnse. All underwent routine investigations preliminary to combined anti viral therapy. Quantitative

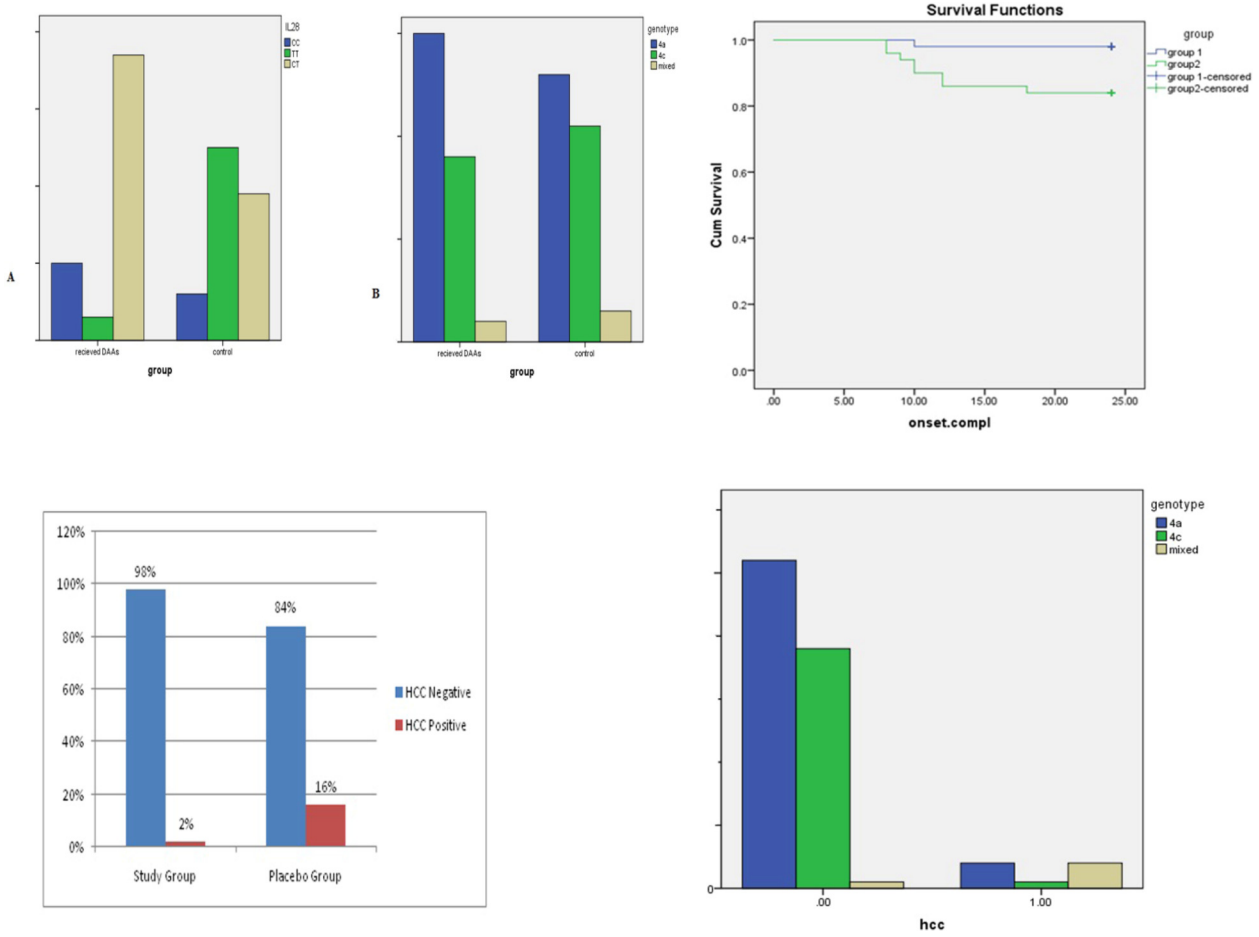

Figure: (abstract: THU-365)

measurement of HCV load by real time Quantitative PCR. Baseline Genotyping for the IL-28B polymorphism by PCR-based restriction fragment length polymorphism. Genotyping for HCV using INNO-LiPA II.

Results: IL-28 polymorphism CT was predominant (74%) followed by CC (20%) in the study group (p = 0.001). TT (50%) and CT (38%) were prominent in the control group (p = 0.000). Patients who received salvage treatment achieved SVR (100%) which was safe and well tolerated. one case (2%) in the study group developed HCC, while 8 cases (16%) in the placebo group developed HCC (p = 0.03) with risk ratio of 4.85 folds more in developing HCC than the study group. 3 cases (6%) in the HCC subgroup experienced hypoalbuminemia and ascites. The study group had significantly longer mean time to develop HCC than placebo group. A logistic regression analysis was performed to ascertain the effects of the drug, on the likelihood of having HCC and showed that Patients who did not have the assumed treatment were 9.33 times more likely to develop HCC. Variables independently associated with the occurrence of HCC if salvage therapy was not given were diabetes, BMI, and HCV genotype with a likelihood ratio (69.4, 15.4 and 29.8 respectively). The whole HCC patients were diabetics (n = 9, 100%), 4 patients were genotype 4a (44.4%), 4 patients were mixed 4,1b (44.4%). Although salvage therapy was protective from HCC, however SVR was not associated with improvement of liver stiffness by fibroscan.

Conclusion: Salvage Treatment of HCV by Sofosbuvir, Daclatasvir, Simeprevir and Ribavirin is highly effective in HCV patients with repeated treatment failures and is associated with 100% SVR and much lower risk of HCC in these patients.

THU-366

Sofosbuvir/Ledipasvir: Efficacy and tolerance in HCV positive patients naïve or pre-treated in Cameroun

S. Tchamgoue[1], H. Leundji[2], M. Tagny-Sartre[3], C. Tzeuton[4], G. Esmat[5].
[1]*Polyclinique Bordeaux Douala, Infectious Disease, Douala, Cameroon;* [2]*SOS Hepatites, Viral Department, Douala, Cameroon;* [3]*Cabinet medical la Cathedrale, Viral Hepatitis, Yaounde, Cameroon;* [4]*Cameroun Hepatogastroenterologic Society, Viral Hepatitis, Douala, Cameroon;* [5]*Cairo University, Faculty of Medicine, Cairo, Egypt*
Email: stchamgoue@yahoo.fr

Background and Aims: In Cameroun, HCV sero prevalence is around 2–7%. HCV is characterized in Cameroun by its high genetic diversity with the circulation of three genotypes HCV-1, HCV-2 and HCV-4 and more than 10 HCV subtypes. Health authorities have decided to import and prescribe Direct Acting Antivirals (DAA) in generic form from 29/07/2016. Decentralization of DAA prescriptions in five of the ten regions followed, under the operational responsibility of the Regional Therapeutic Committees. This was the genesis of this observational study, approved by Cameroon's National Committee of Ethics, whose purpose was to check the efficiency of these new generic antiviral treatment on local VHC viral strains characterized by their phylogenetic diversity, under normal conditions of use in the regions.

Objective: To assess the safety and efficacy of fixed-dose combination SOF/LED (Sofosbuvir 400 mg/Ledipasvir 90 mg) in HCV G1 & 4 patients.

Method: Observational study. **Inclusion criteria:** Age ≥ 18, HCV G 1 or 4, HCV naïve or pre-treated, consent to treatment. **Exclusion criteria:** Pregnant woman, HBV co-infection, Liver decompensation, malignancy, Impaired clinic disorder, Creatinine Clairance MDRD <70 ml/mn**,** drugs: Amiodarone, Digoxin, Amlodipine, Diltiazem, Rosuvastatin, Rifampicine, Carbamazepim, Ongoing Local Traditional Drugs.

Intervention: Drug1: SOF/LDV, ***Mpiviropack Plus****(*Marcyl pharmaceutical-Le Caire, Egypt*): one tablet per day during 12W. Drug 2: Ribavirine 200 mg (<75 kg = 1000 mg and ≥75 kg = 1200 mg). If previous Peg IFN.

Endpoint: % of patients with SVR 12.

Results: Socio-demographic: Female Sex: n = 38/65 (58%), Alcohol Consumption n = 16/59 (27%), Age > 63 ans n = 32/64 (50%), BMI > 27 n = 23/45 (50%), HIV positive n = 2/55 (3.6%), Tobacco n = 2/64 (3.1%), Cannabis n = 0, Diabetes n = 10/63 (16%), HTA n = 25/64 (39%). **Clinic** : Pre treated Peg IFN n = 9/64 (14%), Pre treated (Telap/Bocep/Sofosbuvir) n = 0, Fibrosis : Fibroscan F0 (0–1 kpa) n = 5/61 (8.2%), F1 (2–5 kpa) n = 16/61 (26.2%), F2 (6–9 kpa) n = 18/61 (29.5%), F3 (10–13 kpa) n = 7/61 (11.4%), F4 (≥14 kpa) n = 15/61 (24.5%), Cirrhosis n = 15/61 CHILD A n = 15/15, Ascite n = 0, Digestive Bleeding n = 0, Encephalopathy n = 0. **Virology**: VHC genotype 1 n = 33/65 (50.7%), Genotype 4 n = 32/65. Subtypes G1 (n = 33): a= 6 b = 19 ab = 1 h = 1 l = 1 nc = 2 undetermined n = 3. Subtypes G4 (n = 32): abc = 1 acd = 2 e = 1 f = 18 nc = 1 r = 1 t = 1 undetermined n = 7.

Outcome August 31, 2017: HCV VL < 15 UI at **SVR12 n = 30/33 (90.91%).** HCV VL < 15 UI at W12 n = 45/46 (97.8%). HCV VL < 15 UI at S4 n = 16/22 (72.7%). **Tolerance at W4**: headache n = 2/43 (4.7%), Insomnia n = 1/43 (2.3%), Asthenia n = 3/43 (6.9%).

Conclusion: In this local regional Camerounian context, the efficiency (90% of patients cured) and tolerance of this Sofosbuvir/Lédipasvir generic form was similar to the data previously published in developed country.

Hepatitis B virus reactivation during direct-acting antiviral therapy in hepatitis B/C co-infected patients on hemodialysis

C. Hu[1], J. Wang[2], J. Liu[2], T. Yan[2], Y. Yang[2], T. Chen[2], Y. Zhao[2], Y. He[2].
[1]*School of Medicine, Xi'an Jiaotong University, Department of Infectious Diseases, Xi'an, China;* [2]*First Affiliated Teaching Hospital, School of Medicine, Xi'an Jiaotong University, Department of Infectious Diseases, Xi'an, China*
Email: xjtuhuchunhua@163.com

Background and Aims: There are increased reports of hepatitis B virus (HBV) reactivation during direct-acting antivirals (DAAs) treatment in HBV and hepatitis C virus (HCV) co-infected patients. The potential risk of HBV reactivation in the patients with end-stage renal disease who are undergoing hemodialysis has been also noted. Whereas, there are a lack of data pertaining to the reactivation risk during DAAs treatment in those co-infected patients undergoing hemodialysis.

Method: HBV/HCV co-infected patients were screened from 178 persons in the two blood purification centers of Zhen'An County, Shaanxi province, China and received sofosbuvir (200 mg) combined with daclatasvir (60 mg) daily. The risk of HBV reactivation during DAAs treatment in those co-infected patients undergoing hemodialysis was retrospectively analyzed.

Results: HBV reactivation occurred in 5 of 11 (45.45%) HBV/HCV co-infected patients with hemodialysis during DAAs treatment, which was much higher than the reported rate (approximately 12%) in co-infected patients without hemodialysis. Among the 11 co-infected patients, 7 were HBsAg(+) before DAAs treatment, 5 of the 7 subjects had significant increase of HBV DNA load (5.04 ± 3.41 Log_{10} IU/ml) after the treatment; 4 patients were negative for HBsAg and positive for anti-HBc or HBV DNA at baseline, all of the 4 subjects were persistent HBsAg(−) and had no elevated HBV DNA levels during the whole DAAs treatment. None of the 11 patients had severe hepatitis, hepatic failure or icteric hepatitis due to HBV reactivation, 3 in 5 (60%) patients with HBV reactivation had mild hepatitis (peak ALT levels were 45.92, 54.00 and 63.74 U/l, respectively), whereas none of the 6 patients without HBV reactivation developed hepatitis.

Conclusion: A significant proportion of HBV/HCV co-infected patients undergoing hemodialysis developed HBV reactivation after DAAs therapy. The risk of HBV reactivation was more significant in the HBsAg(+) patients compared to those patients with HBsAg(−) and anti-HBc(+) or HBV DNA(+).

Background and Aims: Hepatitis C Virus Genotype 3 treatment with conventional regimens results in higher rates of virological non-response than in other genotypes. Here we describe the characteristics of genotype 3 infected patients that have failed to first line direct acting antiviral (DAA) treatment, how they have been retreated and what was the efficacy when the new regimen was resistance guided.

Method: Genotype 3 patients from the GEHEP004 cohort were selected. After virological failure, population sequencing of NS5B & NS5A HCV genes was performed, and a comprehensive resistance report was given to the treating physician. After follow up, SVR12 of the retreatment regimen was evaluated.

Results: GEHEP-004 includes 86 patients infected by GT3a that have failed a first line treatment with DAA [93.0% male, median age 53 (IQR 49–56), median log Viral Load 5.90 (IQR 5.32–6.56), 70.6% cirrhotic, 28.2% HIV coinfected, 40.6% treatment experienced-TE]. Patients had failed SOF/DCV ± RBV (59.3%), SOF/LDV ± RBV (28.0%) and SOF/RBV (8.1%). Six patients were GT3a at failure but GT1 (2 GT1a, 4 GT1b) at baseline; 4.7% of the patients failed PrO ± DSV ± RBV. At failure, Y93H was detected in 47 patients (54.7%), and was significantly more prevalent in PrOD ± RBV (100.0%; 4/4) and SOF/DCV ± RBV (70.6%; 36/51) than SOF/LDV ± RBV (25.0%; 6/24) failures [$p < 0.01$]. Almost two thirds of the patients (53) have not been retreated. Cirrhosis (23 vs 25, $p = 0.55$), HIV coinfection (11 vs 9, $p = 0.29$), TE (14 vs 12, $p = 0.75$) and RASs (25 vs 23, $p = 0.13$) were not significantly related to the decision of starting retreatment. Of the 33 patients that have been retreated, 24 have completed treatment evaluation, and 21 have reached SVR12: 12/14 (85.7%) with SOF/DCV ± RBV for retreatment, 1/1 SOF/VEL, 3/3 SOF/LDV ± RBV, 2/2 SOF/GRZ/EBV/RBV, 2/2 PegINF/SOF/RBV and 1/2 with SOF/RBV. Three additional patients have reached EOT response with SOF/VEL/RBV and 1 with SOF/GRZ/EBV/RBV.

Conclusion: More than half of the GT3a infected patients that have failed a first line treatment with DAAS are on hold for retreatment. Waiting for new regimens was not related to cirrhosis, HIV coinfection, TE or RASs detection at failure. Resistance guided retreatment of GT3a resulted in high SVR12 rates, close to 90%.

Z-PROFILE: Real-world utilization and effectiveness of elbasvir/grazoprevir in adult patients with chronic hepatitis C in Canada

B. Conway[1], E. Tam[2], J. Tremblay[3], C. Fraser[4], A. Ramji[5], S. Borgia[6], K. Tsoi[7], E. Yoshida[8], B. Rajendran[9], K. Stewart[10], G. Macphail[11], B. Trottier[12], P. Ghali[13], J. Halsey-Brandt[14], J. Trepanier[14]. *[1]Vancouver Infectious Diseases Centre, Vancouver, Canada; [2]LAIR Centre, Vancouver, Canada; [3]Centre Sida Amitié, Canada; [4]The Cool Aid Community Health Centre, Victoria, Canada; [5]GI Research Institute (GIRI), Gastroenterology Division, Vancouver, Canada; [6]William Osler Health System, Canada; [7]St. Joseph's Healthcare Hamilton, Hamilton, Canada; [8]Vancouver General Hospital, Vancouver, Canada; [9]The Peterborough Clinic, Canada; [10]Saskatchewan Infectious Disease Care Network, Saskatoon, Canada; [11]Calgary Urban Project Society (CUPS), Canada; [12]Clinique Médicale du Quartier Latin, Canada; [13]McGill University Health Center, Canada; [14]Merck Canada Inc., Canada*
Email: brian.conway@vidc.ca

Background and Aims: Elbasvir/grazoprevir (EBR/GZR) is approved in Canada for the treatment of chronic HCV infection: genotypes (GT) 1 and 4, with/without ribavirin, and GT3 with sofosbuvir (SOF). The aim of this study is to describe the effectiveness of EBR/GZR and the profile of patients selected for treatment in a Canadian real-world setting.

Method: A multicenter retrospective chart review of HCV-infected patients treated with EBR/GZR among selected Canadian health care providers was undertaken.

Results: In this interim analysis, a total of 267 patients from 13 sites who initiated treatment between 01/2016 and 10/2017 were included. The mean age was 53.5 years, 61.0% were male, 76.8% Caucasian and 7.9% Aboriginal. Genotype distribution included GT1a (n = 153, 57.3%), GT1b (n = 47, 17.6%), GT3 (n = 34, 12.7%), GT4 (n = 13, 4.9%), and other (n = 20, 7.5%). Pre-treatment fibrosis evaluation (by FibroScan in 84% of cases) included F0-1 (n = 144, 53.9%), F2 (n = 44, 16.5%), F3 (n = 23, 8.6%), F4 (n = 51, 19.1%) and 5 (1.9%) not assessed for fibrosis. In this cohort, 8.6% had CKD stages 3–5 and 18.4% had documented injection of illicit drugs within 12 months of EBR/GZR treatment initiation. There were 36 patients tested for baseline resistance-associated substitutions (RAS). Baseline NS5A RAS of potential clinical relevance (ie. 28, 30, 31 or 93) were detected in 2 patients at position 28 and in 1 patient at position 30. Prescribed regimens included: EBR/GZR × 8 weeks (n = 1, 0.4%); EBR/GZR × 12 weeks (n = 245, 91.7%); EBR/GZR +/− RBV × 16 weeks (n = 21, 7.9%). Patients receiving longer courses of treatment were most often infected by GT1a (n = 14) and/or treatment experienced (n = 17, including 3 who previously failed all-oral DAAs). Sofosbuvir was prescribed with EBR/GZR for all 35 patients with GT3, including the 2 with mixed genotypes. Among patients who had SVR data available at the time of data collection, the per protocol SVR12 rate was 96.6% (140/145).

Conclusions: The combination of EBR/GZR is highly effective in a variety of patient populations in real life, including a broad range of genotypes, disease stages, with or without RAS testing and in special populations (CKD, PWUD). Its use in clinical practice will play an important role in achieving the World Health Organization goals of eliminating HCV infection as a public health concern by 2030. Final results of the full cohort (n = 400) will be presented.

THU-370

Efficacy of Elbasvir-Grazoprevir/Sofosbuvir and Ribavirin in direct acting antiviral therapy failures in pre and post liver transplant patients: A single center experience

H. Elbeshbeshy[1], H. Hasan[2], I. Salih[2], H. Elsiesy[2], W. Alhamoudi[2], F.A. Alkhail[2]. *[1]King Faisal Specialist Hospital & Research Center, Liver Transplant; [2], Saudi Arabia*
Email: hany.elbeshbeshy@yahoo.com

Background and Aims: Hepatitis C Virus (HCV) is the leading cause of liver cirrhosis and hepatocellular carcinoma (HCC). It is also so far still the most common indication of liver transplantation. Treatment of HCV will lead to reduction of progression to advanced liver disease, decrease the incidence of HCC and increase overall survival both patient & graft, patients who achieve Sustained Virologic Response (SVR) have better graft outcome.
Significant advances in treatment of HCV have been achieved with the use of Direct Acting Antivirals (DAA's). Treatment of HCV in DAA failures is a new challenge with limited data available. There has been new data supporting treatment of HCV DAA failures with fixed dose Elbasvir-Grazoprevir/Sofosbuvir with Ribavirin.
To determine the efficacy of fixed dose Elbasvir-Grazoprevir/Sofosbuvir with Ribavirin, in the treatment of HCV DAA failures, pre & post liver transplant.
Method: This is a single arm retrospective observational study of patients with HCV DAA failures pre & post liver transplant. Patients received fixed dose Elbasvir-Grazoprevir/Sofosbuvir with Ribavirin for 16 weeks, with weeks 4 & 16 HCV-PCR & SVR 12 reported.
Data was collected from the liver transplant Clinic over 16 months from June 2016 to October 2017 for adult patients (>18 years) before & after liver transplant with HCV who previously failed prior DAA regimens. Only patients who completed 16 weeks of therapy were enrolled. Follow up every 2–4 weeks during treatment & every 3 months after treatment or as clinically indicated.
Results: 22 patients have been identified & included in this study, 14 males & 8 females, with age range between 39–75 years old. With 2 patients had genotype 1a, 2 patients had genotype 1b, 1 patient had genotype 3, 7 patients had mixed genotypes 1 & 4, & 10 patients had genotype 4. From the study cohort, 8 (36.4%) were treated preLiver transplant, & 14 (63.6%) were treated post liver transplant. 19 patients were relapsers to prior treatment with one DAA regimen & 3 patients relapsed to treatment with two DAA regimens. The baseline HCV-PCR before starting re-treatment ranged from 89,473 to 18,212,025 IU/ml. HCV-PCR was undetectable at week 4 in 9 patients (45.5%), and at week 16 HCV-PCR was undetectable in 20 patients with 2 patients have no results as they missed their week 16 HCV-PCR testing.
At the time of reporting this data, SVR12 was achieved in 100% of 19 patients (86.4%) with 3 patients (13.6%) still awaiting SVR12 results.
Conclusion: Fixed dose Elbasvir-Grazoprevir/Sofosbuvir with Ribavirin is highly effective in patients who are DAA relapsers with intention to treat SVR12 of 100%.

Background and Aims: Large majority of cirrhotic patients were up to now treated with addition of ribavirin, which was associated with enhanced risk of adverse events. We evaluated efficacy of 12 weeks interferon-free regimens without ribavirin in cirrhotic patients in real-world experience.
Method: Data of HCV infected patients with compensated liver cirrhosis from 22 centers were analysed. Patients were assigned to treatment schedule based on physician decision, then treated according to recommendations. Data were collected retrospectively using the online questionnaire.
Results: A total of 1105 cirrhotic patients infected with genotype 1 (97% genotype 1b) HCV treated with any regimen were included into analysis. Among them 240 were treated for 12 weeks without ribavirin, that included: 44% treatment-experienced (mostly PegIFN + RBV), 78% patients with comorbidities (mostly hypertension and diabetes), 70% with concomitant medications. They were assigned to OBV/PTV/r + DSV regimen (90%), LDV/SOF (9%) or SOF + SMV (1%) and were treated for 12 weeks. Overall, SVR rate was 96% in ITT analysis and 98% in modified ITT analysis that excluded patients lost to efficacy follow-up. SVR rate for LDV/SOF and SOF + SMV regimens reached 100%, and for OBV/PTV/r + DSV 98%. Adverse events were documented in 38% with the most common weakness/fatique. Serious adverse events were observed in 5% patients and one death not related to medication was reported.
Conclusion: In this real-world study we confirmed no need of ribavirin addition and treatment lenght exceeding 12 weeks in genotype 1 HCV infected compensated cirrhotics.

Background and Aims: Currently available therapeutic options for patients infected with genotype 3 HCV are based on sofosbuvir. Aim of the study is analysis of treatment available for those patients in Poland at the beginning of interferon-free era and evaluation of efficacy and safety of different therapeutic options administered in real world setting.
Method: We analysed data of HCV genotype 3 infected patients who started antiviral therapy after 1 July 2015 and completed before 31 December 2016. Patients were assigned to treatment regimen based on the physician discretion.
Results: A total of 198 patients were enrolled to the analysis. 57.6% of them had liver cirrhosis and 46% were treatment-experienced. 60.8% of study cohort presented comorbidities and 61.3% were treated with concomitant medications. 50% of patients were assigned to SOF + PegIFNa + RBV, 9% to PegIFNa + RBV, 36% received SOF + RBV and 5% SOF + DCV ± RBV. Cirrhotic patients were assigned more frequently to IFN-free regimens. Overall, the sustained virological response achieved 84% patients in intent-to-treat analysis (ITT) and 87% in modified ITT. For SOF + PegIFNa + RBV or SOF + DCV ± RBV regimens SVR rate reached 94% and 100% respectively, whereas two other therapeutic options demonstrated efficacy below 80%. SVR rate in non-cirrhotics was higher compared to cirrhotics irrespective of regimen. There was no difference of adverse events prevalence in respect to interferon administration (51% vs 54%) with the most common weakness/fatique and anemia related to RBV.
Conclusion: We confirmed effectiveness and safety of the sofosbuvir-based treatment in real-world cohort of patients with chronic HCV genotype 3 infection. Most notably we demonstrate good tolerability and high efficacy of SOF + PegIFNa + RBV regimen which are comparable to DCV + SOF ± RBV.

THU-373

Naturally occurring drug resitance substitutions in the NS5A and NS5B regions in Hepatitis C virus genotype 2 and response to sofosbuvir plus ribavirin therapy

K. Hayashi, M. Ishigami, Y. Ishizu, T. Kazuya, T. Honda, Y. Hirooka, H. Goto. *Nagoya University, Gastroenterology and Hepatology, Nagoya, Japan*
Email: kazuh@med.nagoya-u.ac.jp

Background and Aims: Interferon (IFN) free therapy has improved sustained virological response (SVR) and decreased adverse events compared than IFN based therapy. However, IFN free therapy has resistance associated amino acid substitution (RAS) in the target regions and preexisting these RAS reduces the SVR rate. Majority of these reports about association between RAS and SVR were investigated among patients infected with HCV genotype 1. However, little was known about association between RAS and effect on response to Sofosbuvir (SOF) plus ribavirin (RBV) therapy in patients with genotype 2. Although SOF plus RBV combination therapy has been recently replaced by the new regimen as SOF plus velpatasvir combination in Europe and USA, SOF and RBV combination therapy was still standard care for patients with HCV genotype 2 in Japan. The aim of this study was to investigate the prevalence of RAS in NS5A and NS5B regions and association between RAS and SVR to SOF and RBV combination therapy in patients with genotype 2.
Method: One hundred sixty five patients with chronic hepatitis C genotype 2 were enrolled. Patients received SOF once day plus weight dose RBV for 12 weeks. HCV was genotyped by direct sequencing of the 5'-untranslated region and/or NS5B region. Identification of RAS in the NS5A and NS5B regions was detected by direct sequencing at pretreatment.
Results: NS5A RAS T24A (n = 8), L31M (n = 100), and C92S/Y (n = 2) in genotype 2a and T24A (n = 1), L31M (n = 38), and C92S/Y (n = 24) in genotype 2b were detected at pretreatment. NS5B RAS M298V/I (n = 3) in genotype 2a and M298V/I (n = 10) in genotype 2b and were detected. NS5A Y93H and NS5B S282T which are lead to a high level resistance to NS5A and NS5B inhibitors respectively were not found. One hundred thirty of 136 (95.6%) patients showed a SVR. RAS at baseline was not related to SVR on univariate analysis. There were no significant differences in other factors related to SVR, including age, sex, aspartate aminotransferase, alanine aminotransferase, platelet count, HCV genotype, and HCV viral load. We compared the alignment of the amino acid sequence of NS5A and NS5B region at baseline and at the time of relapse in patient with non-SVR but RAS did not emerged after failure to treatment.
Conclusion: The naturally occurring RAS such as T24A (5%), L31M (83.6%), C92S/Y (3.6%) in NS5A and M298V/I (7.9%) in NS5B were found in patients with HCV genotype 2. The presence of RAS in NS5A and NS5B region at pretreatment was not associated with response to SOF plus RBV combination in patients with HCV genotype 2. No RAS in NS5A and NS5B region emerged in patients who fail to SOF plus RBV combination therapy.

THU-374

Effectiveness and safety of direct-acting antiviral therapies in chronic hepatitis C infections patients with cirrhosis in Turkey

F. Tabak[1], N.O. Cuvalci[2], B. Kurtaran[3], Y. Onlen[4], N.D. Sari[5], S. Kaya[6], N. Ince[7], S. Esen[8], I. Dokmetas[9], M. Namiduru[10], A. Batirel[11], T. Email: fehmitabak@yahoo.com

Background and Aims: Turkish Viral Hepatitis Society (VHSD) and Infectious Diseases and Clinical Microbiology Specialty Society (EKMUD) created an online database and collect data of patients with chronic hepatitis C (CHC) patients using direct-acting antiviral therapies (DAA) in Turkey. This abstract aims to evaluate effectiveness and safety of DAA in chronic hepatitis C infection patients with cirrhosis in Turkey.

Method: Between April 2017 and October 2017, 36 centres from Turkey recorded 1500 patients to the database. Patients >18 years with CHC under direct-acting antiviral therapies were enrolled in this non-interventional observational study. Efficacy and safety results are only given for the patients with SVR12 data. The study was approved by ethics committee and registered to clinicaltrials.gov (NCT03145844)

Results: Of the 1500 patients; 13.7% (205/1500) were cirrhotic. Of those, 51.2% (105/205) were female and mean age was 64.2 (SD:10.9) years. The most common HCV genotype was GT1 (90.7%, 186/205; of those 86.6% GT1b, 7.0% GT1a). 87.3% (179/205) had compensated cirrhosis whereas 11.2% (23/205) had decompensated cirrhosis (Child-Pugh B-C).

Of the patients 51.2% (105/205) were treatment experienced and 86.7% (91/105) had used peginterferon/ribavirin, 6.7% (7/105) peginterferon/ribavirin plus boceprevir and 2.9% (3/105) peginterferon/ribavirin plus telaprevir. Current treatments were ledipasvir/sofosbuvir ± ribavirin (60.5%, 124/205), paritaprevir/ritonavir/ombitasvir ± dasabuvir ± ribavirin (27.8%, 57/205) and sofosbuvir + ribavirin (3.9%,8/205).

Of the 205 cirrhotic patients; 48.8% (100/205) had an SVR12 evaluation. Before DAA and at SVR12; median AST was 52.0 and 22.4 U/l, median ALT was 49.0 and 19.0 U/l, median INR was 1.10 and 1.10, median platelet was 119,000 count/mL and 122,500 count/mL, respectively. Before DAA, median HCV RNA was 1.49×10^6 copies/mL. At month 1, treatment end and 12 weeks after treatment end (SVR12); 92.1% (70/76), 100% (99/99) and 97% (97/100) had HCV viral load <12 IU/ml, respectively (Figure). After DAA had been started; 25% (25/100) patients experienced 44 adverse events, reported adverse events were pruritus (10%, 10/100), asthenia (7%, 7/100), headache (4%, 4/100), nausea (4%, 4/100), insomnia (3%, 3/100), and others (14%, 14/100).

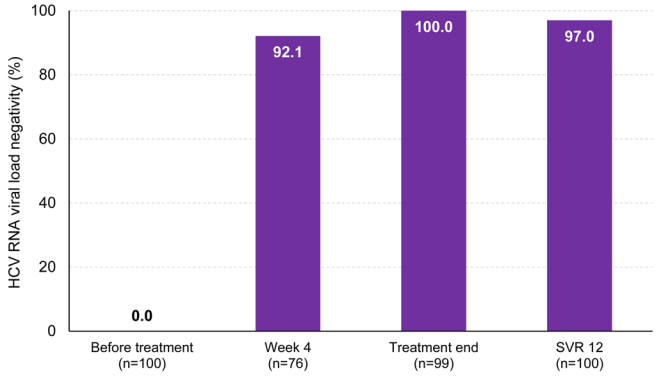

Figure: HCV RNA viral load negativity (cut-off point <12 IU/mL) over time.

Conclusion: DAA are effective and safe treatment for HCV infection among cirrhotic patients. The results from a real-life setting in Turkey are similar to those from real-life settings in other countries and previous clinical trials.

THU-375

Prevalence of baseline NS5A resistance associated substitutions in a real world cohort of veterans with chronic genotype 1 HCV infection

N. Oliver[1], S. Levy[2], E.J. Cartwright[1]. *[1]Atlanta Veterans Affairs Medical Center, Infectious Diseases, Decatur, United States; [2]Atlanta VA Medical Center, Internal Medicine, Decatur, United States*

Email: oliver.nora@gmail.com

Background and Aims: Data examining prevalence of Hepatitis C virus (HCV) NS5A resistance-associated substitutions (RAS) are limited to clinical trial cohorts. The aim of this study is to characterize the prevalence of baseline and pre-treatment NS5A RAS in a real world veterans cohort.

Method: This retrospective chart review examined 793 veterans with chronic HCV from the Atlanta Veterans Affairs Medical Center from March 16, 2016 to present. A convenience sample of 415 patients with HCV genotypes 1a, 1b, or 3 was analyzed. These patients underwent baseline/pre-treatment NS5A RAS testing at the Public Health Reference laboratory (PHRL) in Palo Alto, CA. PHRL uses RT-PCR and population-based sequencing to determine the HCV NS5A gene amino acid sequence. Mixtures are scored at positions where the minority population is 20% or more. Demographic information included sex, age, and race. Other clinical information included HIV status, pre-treatment HCV viral load, any prior HCV treatment, and pre-treatment fibrosis-4 (FIB-4) score. Cirrhosis (including F3, F4 stages) designation was based on clinical information, radiology, FIB-4 score, and/or transient elastography results. NS5A RAS testing detailed the presence of signature NS5A mutations at the Y93, L31, M28, and Q30 codon positions. Descriptive analysis was performed with Microsoft Excel (2010, version 14.6.5).

Results: The cohort included 415 veterans (Table). The average age was 63 years, and the majority was men (99%), African American (79.5%), and HIV negative (92%). Most patients were infected with HCV genotype 1a (87.4%), and cirrhosis was present in 33% of patients. Most patients were HCV treatment naïve (84%), and of those with prior therapy, interferon-based therapy was the main regimen (9%). Baseline NS5A signature RAS were found 21.4% (89) of the total cohort. In patients with genotype 1a infections, NS5A signature RAS were found in 80 (22%) patients. The most common NS5A RAS in the total cohort and in genotype 1a patients was at the M28 codon (7.4% and 8.2%, respectively). In the genotype 1b group, RAS were mostly at the L31 position (10%). In treatment naïve patients, NS5A RAS were found at the Y93 (10, 2.8%), M28 (25, 7%), Q30 (10, 2.8%), and L31 (9, 2.5%) positions. Of the patients with prior treatment, NS5A RAS were at positions Q30 (12, 18.4%), Y93 (10, 15.4%), L31 (7, 10.7%), and M28 (6, 9%). In 137 patients with cirrhosis, NS5A RAS were at positions Y93 (10, 7%), Q30 (12, 9%), L31 (6, 4%), and M28 (8, 6%). 74% of patients with cirrhosis were treatment naïve.

Conclusion: In this real world cohort, veterans with chronic HCV commonly had NS5A RAS on baseline testing. Our study found signature NS5A RAS that often confer significant resistances to standard, first-line DAA therapy in 20% of patients tested at baseline, which could impact treatment success. Limitations include single center location and homogenous study population.

THU-376

Efficacy and safety of sofosbuvir-containing regimen for Korean patients with chronic hepatitis C virus infection: A retrospective, nationwide, real-world study

S.-H. Jeong[1], E.S. Jang[1], K.-A. Kim[2], I.H. Kim[3], W.J. Chung[4]. *[1]Seoul National University Bundang Hospital; [2]Inje University Ilsan Paik Hospital; [3]Chonbuk National University Hopital; [4]Keimyung University Hospital*

Email: jsh@snubh.org

Background and Aims: Sofosbuvir-based therapy (SOF-regimen) had been widely used for chronic hepatitis C virus (HCV) infected patients since Jan 2016 in Korea. This study aimed to describe a real-world efficacy and safety of SOF-regimen in South Korea.

Method: A total of 541 patients with chronic HCV infection who started SOF-regimen were consecutively enrolled from 7 tertiary hospitals during Jan 2016 ~ Dec 2016. Retrospective analysis on the end-of-treatment response (ETR), sustained virological response (SVR), and adverse events was performed.

Results: Mean age of enrolled patients was 61.2 (SD 11.3) y.o., 222 (41.6%) were males. The patients with genotype (GT) 1, 2, and 3 were

72 (13.3%), 435 (80.4%) and 8 (1.5%), respectively. Treatment-experienced patients were 37 (51.4%), 77 (10.1%) and 2 (25%) in genotype 1, 2, and 3, respectively. Follow-up was lost in 63 patients during (n = 19) and after (n = 44) treatment. Per-protocol ETR and SVR rates in treatment-naïve patients were 100% (29/29) and 100% (29/29) in genotype 1, respectively. Those of genotype 2 were 100% (317/317) and 96.2% (305/317) respectively. In genotype 3 patients, all the 3 obtained ETR, but one of them did not show SVR. Among treatment-experienced patients, SVR rates were 90.9% (30/33), 97.2% (69/71), and 100% (2/2) in genotype 1, 2, and 3, respectively. Among139 (25.7%) liver cirrhosis (LC) patients, 10 of 11 decompensated LC had completed scheduled antiviral therapy without serious adverse events and showed SVR (90.9%). Antiviral therapy had been withdrawn in 24 (4.6%) due to high cost (n = 4), viral breakthrough (n = 1), and follow-up loss (n = 19). Any grade of adverse events had been reported in 177 (33.2%) of treated patients, but none discontinued the antiviral therapy due to adverse event.

Table: Per-protocol sustained virologic response rates according to treatment regimens in genotype 1, 2, and 3

	Sofosbuvir + ribavirin	Sofosbuvir/ ledipasvir	Sofosbuvir + daclatasvir
Genotype 1 (n = 62)		49/50 (98%)	10/12 (83.3%)
Naïve (n = 29)		24/24 (100%)	5/5 (100%)
Experienced (n = 33)		25/26 (96.2%)	5/7 (71.4%)
Genotype 2 (n = 388)	369/383 (96.3%)		5/5 (100%)
Naïve (n = 317)	302/314 (96.2%)		3/3 (100%)
Experienced (n = 71)	67/69 (97.1%)		2/2 (100%)
Genotype 3 (n = 5)	1/1 (100%)		3/4 (75%)
Naïve (n = 3)			2/3 (66.7%)
Experienced (n = 2)	1/1 (100%)		1/1 (100%)

Conclusion: Sofosbuvir-containing antiviral therapy showed very high real-life efficacy and safety in Korean patients with chronic HCV infection regardless of previous antiviral treatment experience. Moreover, SOF-regimen could be an effective and safe antiviral therapy to treat decompensated HCV related LC patients.

THU-377

Real-life efficacy and safety of daclatasvir and asunaprevir therapy for genotype 1b chronic hepatitis C patients without NS5A resistance-associated substitution: A nationwide study in South Korea

S.-H. Jeong. *Seoul National University Bundang Hospital*
Email: jsh@snubh.org

Background/Aim: Daclatasvir (DCV) and asunaprevir (ASV) combination therapy have been widely used for Korean patients with chronic hepatitis C virus (HCV) genotype 1b infection since May 2015. This study aimed to investigate the real-life effectiveness and safety of dual all-oral therapy with DCV and ASV in Korean patients.
Methods: A total of 533 patients with genotype 1b HCV infection, who were treated with at least one dose of DCV plus ASV therapy during May 2015 ~ Oct 2016 were consecutively enrolled in the 7 tertiary hospitals located in different major regions in South Korea. Retrospective review of medical record and data analysis was performed.
Results: Mean age of enrolled patients was 58.9 ± 12.4 years old, and 247 (46.3%) were males. The diagnosis of liver disease was chronic hepatitis in 380 (71.3%) patients, liver cirrhosis (LC) in 117 (22.0%), and hepatocellular carcinoma in 36 (6.8%). Of 369 treatment naïve patients, end-of treatment response (ETR) rates were 91.3% (337/369) in intention-to-treat analysis and 95.7% (331/346) in per-protocol analysis. Sustained virological response (SVR) rate was 88.9% (328/369) and 93.6% (324/346), respectively. Of 164 treatment-experienced patients, ETR rates were 92.7% (152/164, ITT) and 94.4% (151/164, PP), and SVR rates were 92.1% (151/164, ITT) and 93.8% (151/161, PP), respectively. DCV plus ASV therapy was withdrawn in 46 (8.6%) due to no early virologic response or breakthrough (11), adverse event (9), high cost (4) and lost to follow-up (18). Any grade of adverse events was reported in 186 (34.9%), but 9 (4.8%) of them discontinued DCV plus ASV therapy due to transaminase elevation (6), ascites (1), seizure (1) and headache (1). Transaminase elevation more than 2 times of upper normal limit during treatment had developed in 42 (7.9%) and resulted in discontinuation of the treatment in 6 (1.1%).
Conclusions: Dual all-oral therapy with DCV and ASV showed high efficacy with tolerable safety in genotype 1b compensated HCV infected patients with pretreatment RAV negativity. Discontinuation of DCV and ASV combined therapy due to adverse event was observed in 4.8%, and adequate monitoring for transaminase elevation is warranted.

THU-378

Genotype 3 Infection in HIV/HCV co-infected subjects in the DAA era: Real life data from the ICONA/HepaICONA Foundation cohorts

R. Rossotti[1], P. Lorenzini[2], M. Merli[1], A. Castagna[3], A. De Luca[4], A. Antinori[2], M. Chiamenti[5], I. Mastrorosa[2], G. Verucchi[6], F. Maggiolo[7], A.D. Monforte[5], M. Puoti[1]. *[1]ASST Grande Ospedale Metropolitano Niguarda, Infectious Diseases, Milan, Italy; [2]National Istitute for Infectious Diseases "Lazzaro Spallanzani" IRCCS, Rome, Italy; [3]San Raffaele Scientific Institute, University Vita-Salute San Raffaele, Department of Infectious Diseases, Milan, Italy; [4]Infectious Diseases Unit, Azienda Ospedaliera Universitaria Senese, University of Siena, Department of Medical Biotechnologies, Siena, Italy; [5]ASST Santi Paolo and Carlo, Department of Health Sciences, University of Milan, Clinic of Infectious and Tropical Diseases, Milan, Italy; [6]Infectious Diseases Unit, Sant'Orsola-Malpighi Hospital, University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [7]ASST Papa Giovanni XXIII, Infectious Diseases Unit, Bergamo, Italy*
Email: roberto.rossotti@ospedaleniguarda.it

Background and Aims: Genotype (GT) 3 has emerged as a difficult-to-treat viral strain, achieving Sustained Virologic Response (SVR) rates lower than other genotypes. Data about GT3-infected HIV patients are scarce either from clinical trials or real life.
Aims: describe the outcome of GT3 co-infected individuals treated with DAA; explore factors associated with virological failure.
Method: Retrospective analysis included all GT3 patients starting DAA and with a 12-week follow up enrolled in the ICONA/HepaICONA cohorts up to October 2017. SVR rates were assessed and univariable/multivariable models evaluating predictors of viral response were developed.
Results: 176 patients were included: 132 males (75%), mainly intravenous drug users (80.7%); 27 individuals had a diagnosis of AIDS (15.3%). 96 subjects were cirrhotic (54.6%), 29 were anti-HCV treatment experienced (16.5%); few individuals were HBV co-infected (1.1%). Median HCV RNA was 5.8 $\log_{10}$ UI/mL (IQR 5.0–6.3). The combination sofosbuvir plus daclatasvir was used in 132 individuals (75.0%), mainly for 24 weeks of treatment (70.5%) and with ribavirin (66.5%). Cumulatively, SVR rate was 90.9%; univariable/multivariable analyses are shown in Table 1.
Conclusion: The rate of SVR was high and similar to what reported in the main trials for GT3 in mono-infected subjects. Traditional predictors of viral response (except BMI) failed to foretell SVR achievement while AIDS status and sub-optimal DAA regimens were strong predictors of virological failure.

Email: roberto.rossotti@ospedaleniguarda.it

Background and Aims: Daclatasvir (DCV) is a pan-genotypic NS5A inhibitor. In HIV co-infected subjects standard 60 mg daily dose should be adjusted to 30/90 mg depending on concomitant anti-retroviral regimen according to SmPC.
Aims: describe the use of different DCV dosages in the ICONA cohort; assess if dose prescription complies with SmPC; evaluate safety and efficacy of 60 *versus* 30/90 mg and adequate (i.e. concordant with SmPC) *versus* incorrect (not concordant with SmPC) prescriptions.
Method: Retrospective analysis included all patients starting DCV with sofosbuvir up to October 2017: demographic, clinical and laboratory data were collected. Sustained Virological Response (SVR) achievement and liver adverse events (LAE) development were assessed. Incidence rates of LAE were calculated and Poisson regression model was used to identify factors associated with the incidence of LAE.
Results: 290 patients were included: 221 males (76.2%), mainly infected by genotype 3 HCV (70.4%). 141 subjects were cirrhotic, 33 had decompensated disease. DCV 60 mg was prescribed in 230 subjects; an inadequate dosage was used in 32 individuals (10.7%): 8.3% had a lower and 2.7% a higher dose than what recommended by SmPC. No difference in terms of SVR was observed (92.9% with 60 and 90.9% with 30/90 mg, p = 0.658; 92.1% with adequate and 95.2% with incorrect dosage, p = 0.610). There were 28 LAE with an incidence rate of 3.06 per 100 patients/months of follow up (95%CI 2.11–4.43) with no differences in the two-paired groups. Relative risk assessment for LAE is shown in Table 1.

Table 1: Relative Risk of developing LAE

Factor	Unadjusted Model			Adjusted* Model		
	RR	95%CI	p	RR	95%CI	p
DCV dose						
60 mg	1					
30/90 mg	0.92	0.35–2.41	0.859			
Appropriate DCV dose	0.83	0.28–2.40	0.737			
HCV Genotype						
3	1					
Non-3	2.14	1.02–4.49	0.045	1.97	0.84–4.62	0.116
Ribavirin Use	0.56	0.27–1.18	0.127			
FIB-4						
<1.45	1					
1.45–3.25	0.79	0.21–2.91	0.722			
>3.25	0.84	0.24–2.88	0.781			
Decompensated Cirrhosis	2.57	1.13–5.83	0.024	2.33	0.89–6.08	0.084
Baseline HIV RNA <50 cps/mL	0.29	0.10–0.83	0.021	0.13	0.03–0.45	0.001
Baseline GGT per 10 increase	0.94	0.88–0.99	0.050	0.93	0.88–0.99	0.029
Baseline total bilirubin per 10 increase	0.45	0.01–27.80	0.705			
Baseline ALT per 10 increase	0.98	0.93–1.04	0.527			

*Adjusted for GTT, HIV RNA, Decompensated Cirrhosis, HCV Genotype.

Conclusion: DCV led to high SVR rate regardless of dosage and adequate prescription. Baseline GGT and HIV RNA < 50 copies/mL resulted to be protective for LAE. A not negligible number of incorrect regimens were prescribed but it did not affect SVR or LAE rate. Potency and safety of DCV have been confirmed, but wrong prescriptions could have led to a cost increase.

THU-380

Cost-effectiveness analysis of baseline testing for resistance-associated polymorphisms to optimise treatment duration in genotype 1 non-cirrhotic treatment-naive patients with chronic hepatitis C virus

C. Fawsitt[1], P. Vickerman[1], G. Cooke[2], N.J Welton[1]. [1]*University of Bristol;* [2]*Imperial College London, United Kingdom*
Email: c.fawsitt@bristol.ac.uk

Background and Aims: Sustained virologic response (SVR – effective cure) to direct-acting antiviral regimens containing non-structural protein 5A (NS5A) inhibitor over UK standard eight weeks treatment duration is 95% in genotype 1 (GT1) non-cirrhotic treatment-naïve

(TN) patients with chronic hepatitis C virus (HCV). However, patients with resistance to the NS5A inhibitor have lower SVR (<85%), and there is evidence that higher SVR (>95%) can be achieved with 12 weeks treatment. We compare the lifetime cost-effectiveness of testing for NS5A resistance at baseline and optimising treatment duration based on the presence of NS5A polymorphisms, using a UK National Health Service perspective.

Method: A decision tree and Markov model is used to simulate treatment outcomes and natural disease progression for HCV GT1 non-cirrhotic TN patients in the UK. We compare baseline testing with "no testing". Under "no testing", patients receive eight weeks treatment with ledipasvir/sofosbuvir (LDV/SOF). Under "testing", patients with (15%) and without (85%) NS5A polymorphisms are given LDV/SOF for 12 and eight weeks, respectively. We model retreatment with the same regimen for 12 weeks in patients that fail initial treatment and consider a range of SVR thresholds. Evidence on model parameters are taken from a review of the literature.

Results: Baseline testing for NS5A polymorphisms generates marginally higher lifetime costs (£32,593.78) and quality-adjusted life years (QALYs) (15.29) per 1,000 patients over "no testing" (£31,207.36; 15.27), assuming 80% SVR to retreatment in each arm, and produces an incremental cost-effectiveness ratio (ICER) of £75,618.55. If the SVR rate for retreatment is 100% in those without NS5A polymorphisms, against 80% in other patients, the ICER is £30,797.79; if the SVR rate is reduced to 70% in NS5A-resistant patients, the ICER is £33,289.90.

Conclusion: Optimising treatment duration with LDV/SOF for HCV GT1 non-cirrhotic TN patients based on NS5A resistance is not cost-effective, unless high levels of SVR to retreatment are observed in patients with and without NS5A polymorphisms. Results are also sensitive to the prevalence of NS5A polymorphisms and baseline test-costs.

THU-381

Recurrence and occurrence of hepatocellular carcinoma following ledipasvir and sofosbuvir treatment for chronic hepatitis C in patients with advanced liver disease: Turkish multicenter early access program

Turkey[14]. *[1]Ankara University School of Medicine, Department of Gastroenterology; [2]Mustafa Kemal University School of Medicine, Department of Gastroenterology; [3]Inonu University School of Medicine, Department of Gastroenterology; [4]Istanbul University School of Medicine, Department of Gastroenterology; [5]Ege University School of Medicine, Department of Gastroenterology; [6]Hacettepe University School of Medicine, Department of Gastroenterology; [7]Sisli Memorial Hospital, Department of Gastroenterology; [8]Mersin State Hospital, Department of Gastroenterology; [9]Karadeniz Technical University Farabi Medical Faculty, Department of Infectious Diseases; [10]Osmangazi University School of Medicine, Department of Gastroenterology; [11]Sakarya University School of Medicine, Department of Gastroenterology; [12]Uludağ University School of Medicine, Department of Gastroenterology; [13]Turkiye Yuksek Ihtisas Hospital, Department of Gastroenterology; [14]Turkey*
Email: ramazan.idilman@medicine.ankara.edu.tr

Background and Aims: The aim of the present study was to investigate the efficacy and safety of ledipasvir (LDV)/sofosbuvir (SOF) ± ribavirin (RBV) in chronic hepatitis C (CHC) patients with advanced liver disease and in patients with liver transplantation (LT) in a Turkish multicentre early access program. The natural course of HCC after LDV/SOF treatment was also assessed.

Method: Patients received LDV 90 mg and SOF 400 mg in a fixed dose combination tablet once daily plus RBV (800–1200 mg/day) according to the physician's discretion. Recommended treatment duration was 24 weeks.

Results: Between Apr2015-Jan2016, a total of 200 patients were enrolled; 8 patients were lost to follow-up, 16 patients died during the study; 11 during the treatment, 5 after discontinuing the treatment. All patients were Caucasian, 53% were female and the median age was 62 years. Median serum HCVRNA level was 5.14 $\log^{10}$ IU/ml and ALT was 55 U/l, 81% of the patients had GT1b HCV infection. 58% of patients had previously received interferon-based treatment. Median CTP and MELD scores were 8 and 16, respectively. 7 patients had HBV co-infection. 37 patients had the previous HCC treated by surgical resection, LT, ablation, trans-arterial chemo/radioembolization or medical treatment. 48 (24%) had liver transplantation. The median interval between transplantation and LDV/SOF treatment start was 29.4 months.

With ITT analysis, SVR12 was 86.0% (172/200), whereas SVR12 was 98.3% (172/175) with per protocol analysis. Three patients with GT1b experienced a virologic failure (relapse). From baseline to SVR12, serum ALT level and MELD score were significantly improved ($p < 0.001$).

Most common adverse events (AE) were headache (5%), nausea (1%), anaemia (1%), constipation (1%), pruritus (1%) and rash (1%) 3 patients had serious AE, one patient had to prematurely discontinue therapy. No HBV reactivation was observed. No clinically relevant drug-drug interactions were noted. None of the deaths was related to LDV/SOF.

37 patients (M/F: 21/15, 85% GT1b) had previous HCC. During the follow-up period; the median time between HCC treatment and the start of LDV/SOF treatment was 4 months. Twelve (12/200, 6.0%) (M/F: 7/5, median age: 68 years) of them had HCC recurrence or progression after treatment. Median time from LDV/SOF treatment start to recurrence was 7 months. Among these 12 patients, 10 had GT1b, 2 had radical HCC treatment (surgical resection, LT). De novo HCC was detected only in one patient without previous HCC. Four patients died due to liver function deterioration and HCC progression.

Conclusion: Based on the results of this study, LDV/SOF ± RBV treatment is an effective treatment for HCV genotype 1,4 infected patients with the advanced liver disease. LDV/SOF treatment was well tolerated. Virologic suppression is associated with an improvement of hepatic function but does not seem to reduce HCC recurrence.

THU-382

Resistance analysis of hepatitis C virus NS5A gene in Brazilian patients infected with genotypes 1 and 3 treated with Daclatasvir

V. Costa[1], C. Brandão-Mello[2], M.M.A. Pires[3], F.C.D.A. Mello[1], P.G.C.S. Silva[1], E.P. Nunes[4], L.L. Lewis-Ximenez[1], E. Lampe[1]. *[1]Oswaldo Cruz Institute, Viral Hepatitis Laboratory, Rio de Janeiro, Brazil; [2]University of Rio de janeiro, Internal Medicine Department, Rio de Janeiro, Brazil; [3]Gaffrée e Guinle University Hospital, Gastroenterology & Hepatology Division, Rio de Janeiro, Brazil; [4]Oswaldo Cruz Institute, Evandro Chagas Institute, Rio de Janeiro, Brazil*
Email: cedubrandao@gmail.com

Background and Aims: In Brazil, hepatitis C virus (HCV) seroprevalence is about 1.3% and approximately 10,000 cases are notified each year. The most prevalent subtypes are 1a and 1b, followed by 3a. Daclatasvir, a NS5A protein inhibitor, is a direct-acting antiviral (DAA) approved for combined IFN-free therapies for both genotypes and is characterized by a low genetic barrier to resistance. Several amino acid changes at positions M28, Q30, L31 and Y93 for HCV-1 and A30, L31, S62 and Y93 for HCV-3 have been associated with daclatasvir resistance. The aim of this study was to investigate the presence of resistance-associated variants (RAVs) in HCV NS5A gene in responders and non-responders patients infected with HCV genotypes 1 and 3 treated with daclatasvir.

Method: A total of 119 serum samples (HCV-1a: n = 54; HCV-1b: n = 46; HCV-3: n = 19) was collected at baseline along with 13 serum samples from non-responders patients (HCV-1a: n = 7; HCV-1b: n = 1; HCV-3: n = 5) after 12-week of treatment with daclastavir. Methodology included viral RNA extraction, RT-PCR reactions with

specific primers for each genotype and purification followed by nucleotide sequencing reaction.
Results: Considering HCV-1a responders, RAVs L31M (1/47; 2.1%) and Q30L (1/47; 2.1%) were identified at baseline. NS5A mutation L31M has been potentially associated with reduced response rates to daclatasvir in HCV-1a patients, however, here, treatment outcome was not influenced by this particular mutation. Substitutions M28T and Q30R, characteristic of RAVs for NS5A DAAs daclatasvir, ledipasvir and ombitasvir, were identified in HCV sequence from one (1/7; 14.2%) non-responder patient infected with HCV-1a after 12-week treatment with daclatasvir. For HCV-3 responders, amino acid residues at position 31 and 93 were conserved in all sequences analyzed. RAVs at position 62, S62T and S62L, were observed in 4/14 (28.5%) and 1/14 (7.1%) baseline sequences, respectively. Among five non-responders patients infected with HCV-3, RAVs A30S (1/5; 20%) and A30K (1/5; 20%) were identified in baseline and after therapy, respectively. A30K is highly associated with resistance to daclatasvir.
Conclusion: Viral factors, such as the infecting genotype, alongside drug resistance mutations, represents negative predictive factors to achieve sustained virologic response for Brazilian patients. This study highlights the importance of identifying baseline RAVs for HCV-3 prior to treatment prescription, as conventional combined therapy using daclatasvir might not be effective when primary resistance mutations are present in the infecting viral variants.

Variables associated with persistence of elevated ALT after SVR in patients with chronic hepatitis C: Data from the German Hepatitis C-Registry (DHC-R)

S. Mauss[1], P. Buggisch[2], K. Boeker[3], H. Klinker[4], T. Müller[5], R. Guenther[6], J. Wiegand[7], M. Cornberg[8], C. Lange[9], T. Berg[7], S. Zeuzem[10], F. Tacke[11] and Deutsches Hepatitis C-Register[12]. *[1]Center for HIV and Hepatogastroenterology, Düsseldorf, Germany; [2]ifi-Institute for Interdisciplinary Medicine, Hamburg, Germany; [3]Center of Hepatology, Hannover, Germany; [4]University Hospital Würzburg, Würzburg, Germany; [5]Charité Campus Virchow-Klinikum (CVK), Berlin, Germany; [6]Universitätsklinikum Schleswig-Holstein (UKSH), Campus Kiel, Kiel, Kiel, Germany; [7]Universiyt Hospital Leipzig, Leipzig, Germany; [8]Hannover Medical School, Hannover, Germany; [9]University Hospital Frankfurt, Frankfurt am Main, Germany; [10]University of Frankfurt, Department of Medicine, Frankfurt, Germany; [11]Universiyt Hospital Aachen, Aachen, Germany; [12]Leberstiftungs-GmbH Deutschland, Hannover, Germany*
Email: stefan.mauss@center-duesseldorf.de

Background and Aims: Patients with hepatitis C achieving SVR that do not normalize ALT levels might have confounding hepatic and extrahepatic comorbidities. We therefore analyzed variables associated with persistent elevations of SVR after successful HCV therapy in a large nationwide real-life cohort.
Method: The German Hepatitis C registry is a national multicentre cohort that includes a high fraction of no to early fibrotic (F0-1, 28.4%) patients treated with direct antiviral agents. Patients were treated at the discretion of the physician. Data were collected by a web-based data system and confirmed by plausibility checks and on site monitoring. Normal ALT activity was defined as <35 U/l (at 37°C) regardless of sex. Variables assessed were HCV genotype, sex, HIV-coinfection, BMI, alcohol consumption, opioid substitution, age, liver cirrhosis, treatment response (EOT, SVR), treatment regimen, cardiovascular disease, psychiatric disorders, diabetes mellitus, thyroid disorders, statin use, hypertension, ethnicity, country of origin. Statistical analyses were performed using univariate and multivariate regression analysis.
Results: 3,440 patients had data available for ALT at baseline, all variables and 12 weeks after therapy. At week 12 after end of therapy 18.1% of the patients remained ≥35 U/l. By multivariate analysis, ALT ≥35 U/l at week 12 after therapy was independently associated with male sex ($p < 0.0001$), higher BMI ($p < 0.0001$), liver cirrhosis ($p < 0.0001$) and no SVR ($p < 0.0001$). On the contrary, ALT <35 U/l was associated with female sex ($p < 0.0001$), lower BMI ($p < 0.0001$), no liver cirrhosis ($p < 0.0001$) and SVR12 ($p < 0.0001$).
Conclusion: ALT levels may remain persistently elevated in a substantial fraction of HCV-infected patients despite completion of DAA therapy. Risk factors associated with increased ALT at week 12 after end of therapy apart from virologic non-response were primarily related to metabolic risk factors and liver cirrhosis.

THU-384

Time to viral suppression does not impact SVR in patients treated with Glecaprevir/Pibrentasvir for 8 weeks

C. Sarrazin[1,2], T. Tran[3], D. Dylla[4], J. Feld[5], S. Arora[6], D. Victor[7], Y. Hu[4], S. Wang[4], F. Mensa[4], D. Wyles[8]. *[1]JW Goethe University Hospital, Frankfurt, Germany; [2]St. Josefs-Hospital, Wiesbaden, Germany; [3]Cedars Sinai Medical Center, Los Angeles, United States; [4]AbbVie, Inc., North Chicago, United States; [5]University of Toronto, Toronto Centre for Liver Disease, Toronto, Canada; [6]University of New Mexico, Albuquerque, United States; [7]Houston Methodist Hospital, Houston, United States; [8]Denver Health Medical Center, Denver, United States*
Email: sarrazin@em.uni-frankfurt.de

Background and Aims: The pangenotypic direct-acting antivirals (DAAs) glecaprevir (developed by AbbVie and Enanta) coformulated with pibrentasvir (G/P) are approved as an 8-week regimen to treat chronic HCV infection for all six major genotypes (GT). Historically, an on-treatment predictor of HCV cure with interferon (IFN)-containing regimens has been viral suppression at treatment week 4. However, the relevance of viral kinetics as predictors of cure in the era of shortened, 8-week DAA regimens is unclear, and concerns remain that failure to suppress HCV RNA quickly may lead to relapse. An integrated analysis of patients treated with G/P for 8 weeks was performed to investigate factors impacting time to viral suppression, and whether lack of viral suppression by treatment week 4 was predictive of relapse.
Method: Data were pooled from five phase 2 or 3 clinical studies, and included patients with HCV GT 1–6 infection without cirrhosis who were either treatment naïve or experienced with IFN or pegIFN with or without ribavirin (RBV) or sofosbuvir and RBV with or without pegIFN. G/P (300 mg/120 mg) was orally dosed once-daily for 8 weeks. Patients lost to follow up or with missing SVR12 data (n = 13) were excluded from the analysis since the impact of viral suppression (HCV RNA below lower limit of quantification [LLOQ]) on response cannot be assessed in these patients. Two patients with on-treatment virologic failure were excluded since we sought to determine whether detectable HCV RNA at treatment week 4 was predictive of relapse.

Table 1. HCV RNA Suppression at Treatment Week 4 and Achievement of SVR12

	Patients with HCV RNA < LLOQ at Treatment Week 4, n/N (%)	Patients with SVR12, n/N (%)
Total	906/942* (96)	943/950 (99)
Subgroup		
HCV RNA <6,000,000 IU/mL†	695/716 (97)	720/724 (99)
HCV RNA ≥6,000,000 IU/mL†	211/226 (93)	223/226 (99)
BMI <30 kg/m^2	737/772 (96)	774/779 (99)
BMI ≥30 kg/m^2	169/170 (99)	169/171 (99)
Black race	63/63 (100)	63/63 (100)
Non-black race	843/879 (96)	880/887 (99)
HCV genotype 3	184/198 (93)	198/203 (98)
Treatment-compliant‡	805/835 (96)	832/839 (99)
Treatment non-compliant‡	101/107 (94)	111/111 (100)

*8 patients missing data at treatment week 4
† For phase 2 studies, HCV RNA levels quantified by COBAS Ampliprep/TaqMan® RT-PCR assay v. 2.0; LLOQ = 15 IU/mL. For phase 3 studies, HCV RNA levels were manually processed using the High Pure System and quantified by COBAS TaqMan® RT-PCR assay v. 2.0; LLOQ = 25 IU/mL.
‡Treatment compliance measured by pill count; values <80% and/or >120% were considered non-compliant.

Results: The analysis included 950 patients; 63 (7%) were black, 171 (18%) had BMI ≥ 30, and 24% had baseline HCV RNA ≥ 6 million. The majority of patients were white, male, and HCV treatment-naïve. Among 942 patients with data, 906 (96%) had HCV RNA < LLOQ at treatment week 4, and of those, 899/906 (99%; 95% CI 98.4–99.6) achieved SVR12; additional results by subgroups are in Table 1. There was no common baseline factor more frequently observed among the 7 seven patients who relapsed other than male sex (5/7; 71%). Of the 36 patients with HCV RNA > LLOQ at treatment week 4 (median baseline HCV RNA 6.7 $\log_{10}$ IU/ml; range 5.2–7.6 $\log_{10}$ IU/ml), 100% (95% CI 90.4–100.0) achieved SVR12.
Conclusion: In patients treated with G/P for 8 weeks, failure to suppress HCV RNA by treatment week 4 was not predictive of treatment outcome, suggesting that treatment extension in patients eligible for 8-week regimens based on this milestone is not warranted.

THU-385

Identification, by Cold-PCR, of treatment-resistant HCV mutations in baseline samples of patients treated with DAAs

A. Madejón[1,2,3], I. Francisco-Recuero[1,2,3], M. Romero[1,2,3], A. García-Sánchez[1], A.O. Martin[1,3], J.C. Erdozaín[1], P. Castillo[1], R. Mena[4,5], F.J.G.-S. Rey[1,3,5]. *[1]Hospital Universitario La Paz, Hepatology Unit, Madrid, Spain; [2]IdiPAZ, m; [3]CIBERehd, Madrid, Spain; [4]Instituto de Genética Médica y Molecular (INGEMM), Madrid, Spain; [5]IdiPAZ, Madrid, Spain*
Email: javiersamaniego@telefonica.net

Background and Aims: Baseline testing of HCV resistant mutants is not routinely indicated –especially using ultradeep sequencing techniques-due to the high response rates observed with DAAs. In this setting, the use of techniques for the selective amplification of minor variants in complex mixtures of nucleic acids, such as Cold-PCR, could be a useful tool. For this reason, the aim of this work was to analyze the usefulness of the Cold-PCR for the rapid identification of minor treatment resistant variants in patients with chronic hepatitis C at risk of therapeutic failure.
Method: We included 8 non-responder patients (without SVR): 5 Gt 1 (4 Gt 1a and 1 Gt 1b) treated with SOF/LDV and 3 Gt 3a with SOF/DCV. A control group of 22 cured patients was also included: 17 treated with SOF/LDV and 5 with SOF/DCV. The baseline samples of all patients and the end of follow-up samples of non-responders were analyzed by both conventional and COLD-PCR, and subsequent analysis by bulk sequencing. In addition, 5 samples of non-responders were analyzed by ultradeep sequencing.
Results: Analysis of baseline samples: Sixteen (53%) of the 30 baseline samples were positive by Cold-PCR (presence of minority variants), including 7/8 (87%) non-responder patients. In 5 of the non-responder patients, treatment resistant variants were detected by bulk sequencing: among the 4 patients treated with SOF/LDV, the L31M mutation was identified in one, Y93H in another one, and both mutations simultaneously in the remaining 2 patients. In a patient treated with SOF/DCV the Y93H mutation was identified. By contrast, the analysis of the baseline samples with conventional PCR did not detect any resistant mutants in none patient. **Analysis of follow-up samples:** The final samples of the 8 non-responder patients gave a positive result using both conventional and Cold-PCR techniques. The bulk sequence analysis showed resistant variants in the 8 patients by conventional PCR and in only 7/8 with Cold-PCR. The high throughput sequencing of 5 of these samples demonstrated a 100% correlation with the results of the other techniques.
Conclusion: These results show that it is possible to identify resistance mutations in baseline samples in up to 62% (5/8) of non-responders, coupling a Cold-PCR reaction and population sequencing. This strategy, which uses technology implanted in most hospitals, is considerably faster and cheaper than the universal analysis by massive sequencing.

THU-386

Persistence and risk of transmission of the hepatitis C virus NS5B S282T substitution in a HIV-positive man who has sex with men

A. Newsum[1], J.T.M. Van Der Meer[2], R. Molenkamp[2], S.P.H. Rebers[2], M. Prins[1], M. van der Valk[2], J. Schinkel[2]. *[1]Public Health Service of Amsterdam, Amsterdam, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands*
Email: anewsum@ggd.amsterdam.nl

Background and Aims: The hepatitis C virus (HCV) nonstructural protein 5B (NS5B) S282T is a resistance-associated substitution (RAS) which confers major resistance to sofosbuvir in vitro. This substitution has never been found in treatment-naïve patients because it is associated with a severe fitness loss and therefore usually not persists after cessation of treatment. Here, we report a case of a HIV/HCV coinfected patient with persistence of S282T upon treatment failure.
Method: Clinical and laboratory data were extracted from patient records. For resistance analysis, PCR and Sanger sequencing of NS5B and NS5A was performed.

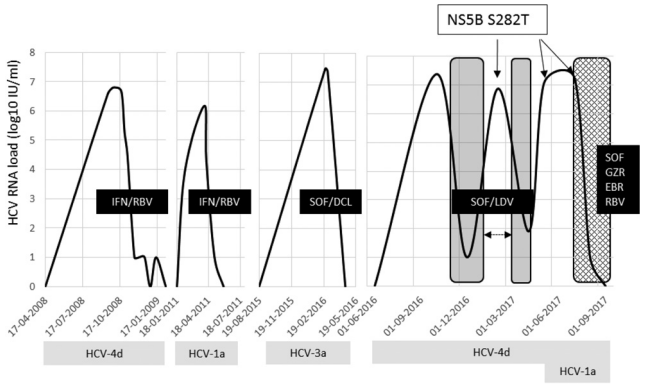

Figure: HCV RNA dynamics during and following several HCV infections in a HIV/HCV coinfected patient: Grey and square-patterned boxes indicate period of treatment. Black boxes contain treatment regimens (IFN = (pegylated)-interferon-alpha; RBV = ribavirin; SOF = sofosbuvir; DCL = daclatasvir; LDV = ledipasvir; GZR = grazoprevir; EBR = elbasvir).

Results: A 66-year-old HIV-infected man who has sex with men (MSM) acquired his fourth HCV infection with genotype 4d in September 2016. He reported an active sex life with multiple male partners at different locations across Europe and the USA. All previous HCV infections were successfully treated with diverse antiviral regimens (Figure). He initiated treatment with SOF/LDV in November 2016, for a planned duration of 12 weeks. At treatment initiation, sequence analysis showed no RAS in NS5B, but P/T58L in NS5A. Twelve weeks after treatment initiation, presumably during treatment discontinuation, HCV RNA load was 7,570,000 IU/mL. Sequence analysis showed the S282T substitution in NS5B (Figure). In NS5A, 58L was still present. Hereafter, HCV RNA load levels fluctuated but increased again over time (Figure). At treatment failure the patient reported that he stopped taking SOF/LDV at week 8 and restarted 2–4 weeks afterwards. The latter might have explained the HCV RNA rise and decrease in February 2017 (Figure). Remarkably, the S282T substitution persisted over time, even when HCV RNA levels were rising (Figure). Surprisingly, after this rise a superinfection with genotype 1a was found. This genotype was not detectable in earlier samples, using a subtype specific PCR. Sequence analysis did not show any RAS in genotype 1a. In July 2017, the patient initiated treatment consisting of sofosbuvir, elbasvir/grazoprevir and ribavirin, after which HCV RNA decreased quickly. Final treatment outcome is pending.
Conclusion: In this HIV-infected MSM the NS5B S282T substitution remained detectable for >5 months after treatment for his 4th HCV infection, indicating that viral fitness was not compromised. Given the very high HCV RNA load at HCV superinfection combined with

high-risk sexual behavior, onward transmission of a S282T strain, associated with sofosbuvir resistance, cannot be excluded.

THU-387

On treatment HCV-RNA evaluation in real-life: Still a role in the era of direct acting antiviral agents?

Silberstein[1]. *[1]University of Rome Tor Vergata, Department of Experimental Medicine and Surgery, Rome, Italy; [2]ASST Fatebenefratelli Sacco, Clinical Microbiology, Virology and Bioemergencies, Milan, Italy; [3]University Hospital of Rome Tor Vergata, Hepatology Unit, Rome, Italy; [4]ASST Fatebenefratelli Sacco, Division of Infectious Disease, Milan, Italy; [5]University Hospital of Rome Tor Vergata, Infectious Diseases, Rome, Italy; [6]Polyclinic Tor Vergata Foundation, Laboratory of Molecular Virology, Rome, Italy; [7]University Hospital of Rome Tor Vergata, Infectious Disease Unit, Rome, Italy; [8]University of Milan, Milan, Italy*
Email: ceccherini@med.uniroma2.it

Background and Aims: Guidelines recommend HCV-RNA measurements at specific time-points during direct acting antivirals (DAA)-therapy. However, it remains unclear, how these results should be interpreted today and how can be helpful for treatment management.
Method: This retrospective study includes 571 HCV patients (pts) treated in 2 Italian hospitals receiving recommended DAA-regimens by 2017 guidelines: sofosbuvir + ledipasvir ± ribavirin (RBV) (n = 203), sofosbuvir + daclatasvir ± RBV (n = 125), paritaprevir/r + ombitasvir ± dasabuvir ± RBV (n = 197/46). All pts had baseline and 4w HCV-RNA values, and at least one early assessment of HCV-RNA at 1w [n = 466] and/or 2w [n = 375]. Serum HCV-RNA was quantified by Abbott Real*Time* HCV (lower limit of detection: 12 IU/ml). RBV use (n = 348) and treatment-duration (12w n = 212, 16w n = 1, 24w n = 358) were at the investigator's discretion.
Results: Pts were infected with HCV-genotype (GT) 1a/1b/1g (n = 135/233/2), GT2 (n = 34), GT3 (n = 77) and GT4 (n = 77). Overall, median [IQR] liver stiffness was 14.0 [10.3–21.3]kPa; 55.7% of pts were cirrhotic. In addition, 16.5% were HIV-coinfected, and 37.1% had a previous treatment-experience (including 5.2% with DAAs). Median (IQR) baseline HCV-RNA was 5.9 (5.2–6.2) log IU/ml, and 47.1% of pts had values ≥800,000 IU/ml. Sustained virological response (SVR) at 12w of follow-up was 98.1%: 2 pts were non-responders (NRs), 1 was re-infected and 8 pts relapsed.
After DAA therapy initiation, an increased number of pts with HCV-RNA ≤ 12 IU/ml was observed over time: 66 at 1w (50.0% cirrhotic), 112 at 2w (43.7% cirrhotic), 354 at 4w (52.2% cirrhotic). Interestingly, few pts showed detectable HCV-RNA at the end of therapy (EOT): 15.3% at 12wEOT and 6.8% at 24wEOT. However, all achieved SVR with the exception of the 2 NRs treated for 12w.
Due to the high rate of SVR, HCV-RNA levels during early treatment were not significantly related to failure, neither with cirrhosis, HIV coinfection, or RBV use. However, early HCV-RNA ≤ 12 IU/ml at 1w was associated with GT2, HCV-RNA < 800,000 IU/ml and no-treatment experience, while at 2w only with HCV-RNA < 800,000 IU/ml.
Conclusion: Given the high efficacy of the current DAA regimens, and a considerable number of pts with early HCV-RNA ≤ 12 IU/ml, beyond baseline HCV-RNA, also on-treatment HCV-RNA could be interesting for guiding shorter treatment durations with the aim of reducing treatment costs and increasing the number of pts to be treated. This hypothesis requires further investigation.

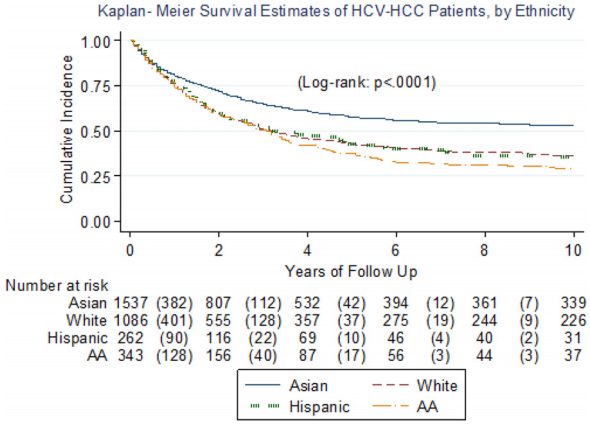
Viral hepatitis C: Clinical aspects except therapy

THU-389

Ethnic differences in HCV-related HCC outcomes: Report from the Real-world Evidence by the Asia Pacific Rim Liver Consortium for HCC (REAL-HCC)

People's Rep. of; [8]E-Da Hospital, Department of Gastroenterology and Hepatology, Kaohsiung, Taiwan; [9]Changhua Christian Hospital, Division of General Surgery, Changhua, Taiwan*
Email: mindiehn@stanford.edu

Background and Aims: HCV is one of the leading causes of HCC globally. The impact of ethnicity on the clinical presentation and subsequent outcome of HCV-related HCC (HCV-HCC) is unknown.
Method: In a retrospective study, HCV-HCC patients enrolled at 4 U.S. centers and 5 Asia Pacific (AP) centers were analyzed to identify ethnic differences in their presentation and outcome.



Results: Of 3339 patients identified with HCV-HCC, 1601 (48%) were Asian (330 US, 1271 AP), 1119 (34%) Caucasian, 272 (8%) Hispanic and 347 (10%) African American (AA). Asian patients were more likely to be female (41.8% vs. 25.9% for non-Asians) and older (mean age 65.9 vs. 60.1) (p < 0.0001 for both). The proportion of patients with decompensated cirrhosis (CTP Class B/C) was highest in Hispanic (64.4% vs. 44.4% non-Hispanics, p < 0.0001). Among cases of HCC where screening history was documented, AA had a much lower proportion of screen-detected HCC (42.5% vs 75% in non-AA, p < 0.0001). Screening was documented for 66.7% of US Asians and highest at 84.9% for AP Asians. HCC was diagnosed at an early or intermediate stage (BCLC stage 0/A/B) in 83.5% Asian (80.1% US, 84.5% AP), 75.3% Caucasians, 74.1% Hispanics, and 76.0% AA (p < 0.0001). Rate of OLT listing was lowest at 16.6% for Asian (20.7% US, 1.3% AP) and 25% for AA compared with White 42.9% and Hispanic 42.9% (p < 0.0001). Actual OLT rates were even lower for Asian at 4.1% overall (9.0% US, 2.7% AP) followed by AA 16.9%, Hispanic 21.5%, and highest in White 24.5% (p < 0.0001). However, curative treatment rate overall

(OLT, resection, RFA) were highest for AA 27.6%, followed by Asian 18.0%, White 17.3% and lowest for Hispanic 14.0%. On Kaplan-Meier survival estimates (see Figure), respective 5 and 10-year overall survival was lowest for African Americans (37.6% and 29.0%), followed by Whites (42.8% and 36.5%) and Hispanics (42.7% and 34.4%) and highest for Asians (57.8% and 53.2%)($p < 0.0001$), with AP Asians having higher 5- (40.7% US and 61.6% AP) and 10-year survival (26.7% US and 58.7% AP) than US Asians ($p < 0.0001$).

Conclusion: In this large international collaborative study, ethnicity was an important determinant of HCV-HCC presentation, treatment, and long-term survival. African Americans with HCC have poor outcomes, likely reflecting both poor screening uptake and poor access to OLT. In contrast, despite lower OLT rates and overall curative treatment rate, Asians had the highest HCC screening rates and better long-term outcomes.

THU-390

Changes in the characteristics of hospital admissions due to complications of cirrhosis in the era of direct-acting antivirals against HCV

M. Fraile, L. Franco, A. Gomez, M. Torner, A. Castano-Garcia, P.F. Díez, V.J. Beltrán, N.R. Ferreiro, M. Varela, M. Luisa, G. Dieguez , V. Cadahía-Rodrigo, C. Álvarez-Navascués, M. Rodríguez. *Hospital Universitario Central de Asturias, Liver Unit. Division of Gastroenterology & Hepatology, Oviedo, Spain*
Email: miguelfrailelopez@gmail.com

Background and Aims: To determine if there have been changes in the characteristics of patients admitted to a general hospital due to liver cirrhosis (LC) complications in the era of direct-acting antivirals (DAAs).

Method: Hospital admissions were prospectively analyzed in a hepatology unit of a general hospital in two periods of time: P-I: Nov/12-Sep/14 and P-II:Jul/16-Oct/17. Clinical and demographic variables were collected and the usual statistical methods were used. LC and its complications were diagnosed according to the universally accepted criteria.

Results: 622 admissions were collected in 382 patients; 348 admissions in 198 patients in the P-I and 275 in 184 patients in the P-II. The number of incomes was 15.1/month in P-I and 17.1/month in P-II. Comparing both periods, no differences were observed in sex, prevalence of hepatocellular carcinoma (HCC) or in the proportion of patients with previously unknown LC (12% vs. 11%; p = 0,69). Patients were younger in P-I (61 ± 11 vs. 64 ± 11 years; p = 0.005). Regarding the etiology of LC, there was no difference between P-I and P-II in the proportion of admissions for LC due to alcohol (71.4% vs. 71.2%, p = 0.69), HBV (2.8% vs. 3.2%, p = 0.77) or autoimmunity (1.7% vs. 2.1%, p = 0.68). Admissions for HCV cirrhosis were more frequent in P-I (21.9% vs. 15.2%, p = 0.036), while admissions for cirrhosis due to NASH (11.2% vs. 4.3%; p = 0.001) and CBP (6.1% vs. 2.0%, p = 0.007) were more frequent in P-II. The number of admissions for HCV cirrhosis was 3.3/month in P-I and 2.6/month in P-II. There were no differences between the two periods in the reasons for admission: encephalopathy (30.2% vs. 29.1%), variceal hemorrhage (21.6% vs. 19.6%), ascites (16.4% vs. 19.6%) or SBP (7.8% vs. 7.6%). Comparing patients with HCV cirrhosis in both periods, no differences were observed in sex, age, proportion of unknown LC, prevalence of HCC or reason for admission. Patients in P-II were less frequently viremic (59.5% vs. 98.6%, p < 0.001) and had more frequently coexistence of another cause of cirrhosis (52.3% vs. 30.2%, p = 0.018).

Conclusion: The proportion of hospital admissions due to complications of cirrhosis attributable to HCV has decreased by 30% in the era of DAAs; in addition, the characteristics of patients with HCV cirrhosis have changed. On the contrary, the proportion of incomes related to cirrhosis due to NASH has increased. Approximately one in 10 patients admitted for a complication was not previously diagnosed of cirrhosis and this rate has not changed during the study period.

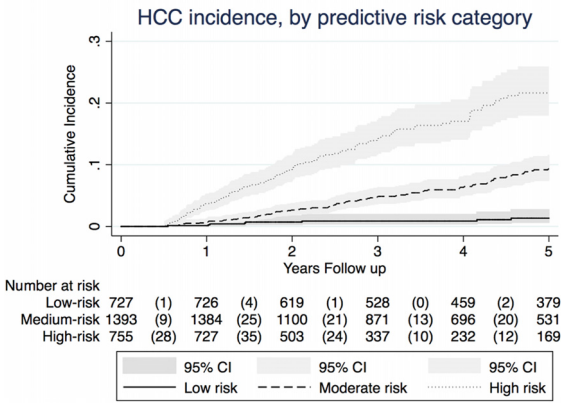
Email: mindiehn@stanford.edu

Background and Aims: Hepatitis C virus (HCV) is one of the leading causes of hepatocellular carcinoma (HCC). However, currently there is no well-established algorithm to predict high-risk HCV patients for HCC development. Our goal was to validate an algorithm inclusive of age, aspartate transaminase (AST), alanine transaminase (ALT), HCV RNA, HCV genotype, and cirrhosis developed by the REVEAL-HCV study.

Method: This is a retrospective study of 2,875 patients aged 30 to 65 with chronic HCV without HBV or HIV co-infection and without HCC at baseline or within 6 months of presentation at 4 U.S. centres and 1 Hong Kong centre from 11/1994–10/2017. We stratified patients as low-, medium-, and high-risk using the REVEAL-HCV risk scores described above and used the area under receiver operating curve (AUROC) to assess model performance.

Figure 1. HCC incidence in total cohort, by predictive risk category (log rank p<0.0001)



Results: Our cohort consisted of 53.2% White, 18.9% Hispanic, 12.4% Asian, and 6.8% African-American patients. The Hispanic cohort had a higher proportion of male (65.1%) and patients with cirrhosis (80.9%), as well as the highest percentage of patients in the high-risk category (31.6%) relative to other racial groups. Asian patients had the lowest percentage of patients in the medium-risk (36.5%) but had the highest percentage of patients in the low-risk category (43.8%).

HCC incidence were 1.34, 9.35, and 21.6 per 1,000 person-years for low, medium and high-risk patients, respectively ($p < 0.0001$) (Figure 1). Compared to treated patients, untreated patients had a much higher HCC incidence (13.4 vs. 2.9 per 1,000 person-years, $p < 0.0001$). As shown in Table 1, AUROC was high for untreated patients overall and for most ethnic groups except Hispanic patients.

Table 1: (abstract: THU-391)

Table 1. The 1-, 3-, and 5- year predicted risk for hepatocellular carcinoma among untreated patients with HCV, by ethnicity

Year	Overall AUROC (95% CI) N= 2,875	Caucasian AUROC (95% CI) N= 1102	Hispanic AUROC (95% CI) N= 407	African American AUROC (95% CI) N= 161	Asian AUROC (95% CI) N= 185
1	0.806 (0.734-0.853)	0.798 (0.701-0.895)	0.728 (0.609-0.844)	0.900 (0.857-0.943)	0.814 (0.694-0.935)
3	0.771 (0.734-0.812)	0.776 (0.732-0.838)	0.700 (0.640-0.816)	0.804 (0.616-0.975)	0.770 (0.662-0.875)
5	0.773 (0.745-0.819)	0.784 (0.729-0.836)	0.676 (0.624-0.797)	0.813 (0.674-0.946)	0.811 (0.724-0.919)

Conclusion: The REVEAL-HCV risk score has good validity and discrimination for most untreated patients except Hispanic patients. Further studies are needed to develop a risk prediction model for untreated Hispanic patients and for patients treated with DAA.

THU-392

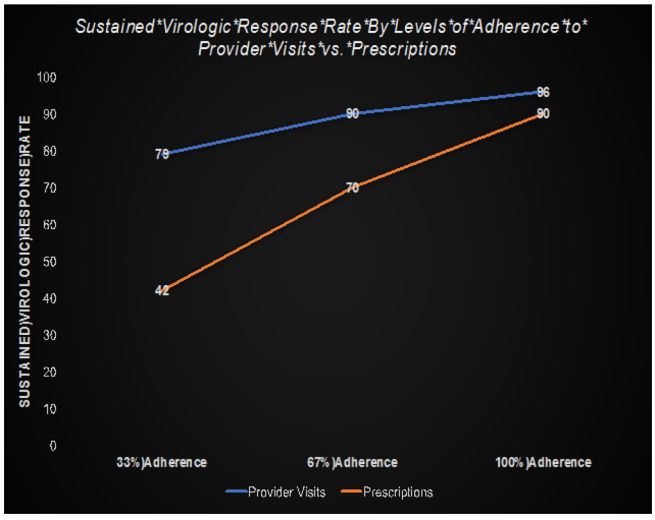
Minimal monitoring of direct-acting antiviral therapy within a real world, urban population

B. Emmanuel[1], S. Kottilil[1], H. Masur[2], S. Kattakuzhy[1]. [1]*Institute of Human Virology at the University of Maryland School of Medicine Baltimore, Baltimore, United States;* [2]*National Institutes of Health, Critical Care Medicine, Bethesda, United States*
Email: skattakuzhy@ihv.umaryland.edu

Background and Aims: The treatment of hepatitis C (HCV) utilizing direct-acting antiviral therapy (DAA) has traditionally been monitored with monthly treatment visits, laboratory evaluation, and prescriptions, followed by assessment of sustained virologic response (SVR) 12 weeks after medication completion. However, limited evidence exists on the minimal monitoring necessary to retain high rates of cure. We investigated different monitoring measures of patients who underwent DAA therapy within a real-world, urban population.

Method: Chronic HCV-infected patients received treatment with ledipasvir/sofosbuvir under the phase IV clinical trial ASCEND, and underwent three measures of monitoring: provider visits, prescription receipt, and SVR testing. Adherence to provider visits was defined as attendance ± 14 days from the scheduled on-treatment visit date. Adherence to prescriptions was defined as picking up of prescribed number of pill bottles. A composite monitoring score used both provider visits and prescription receipt. Adherence to SVR testing was defined as lab testing completed 12-weeks ± 14 days from the end date of DAA therapy.

Results: 551 patients were predominately male (69%), black (96%), genotype 1a (72%), treatment-naïve (82%) with 21% cirrhotic and 20% HIV/HCV-coinfected. 134 patients (24%) had 100% adherence to provider visits, while 417 (76%) did not, which was associated with SVR (96% vs. 83%, p < 0.0001). SVR decreased to 90% in patients with 67% adherence to provider visits (n = 230), to 79% in patients with 33% adherence (n = 108), and to 55% in patients with no provider visits (n = 44). For prescription adherence, 477 (87%) picked up all prescription bottles, while 74 (13%) did not, with a significant difference in SVR (90% vs. 62%, p < 0.0001). SVR decreased to 70% in patients with 67% adherence to prescriptions (n = 46), and further to 42% in patients with 33% adherence (n = 19). With a composite monitoring score, 128 patients had 100% adherence to provider visits and prescriptions, while 68 did neither, with a siginificant difference in SVR (SVR 96% vs. 58%, p < 0.0001). 349 patients had both 100% prescription adherence but <100% provider visit adherence, while 6 patients had 100% provider visits but <100% prescription adherence (SVR 87% vs. 100%, p = 1.0). After DAA therapy, 213 (39%) came within the SVR testing window and 338 (61%) did not, which was not associated with SVR (95% vs. 93%, p = 0.21).



Conclusion: In the era of safe and efficacious DAA therapy, SVR can likely be achieved with a minimalistic approach which includes adherence to most prescriptions and some provider visits. Further studies with validation of provider visit and prescription adherence is needed to design the optimal monitoring approach.

THU-393

Improving detection and management of HCV infection in prisons

N. Ekeke[1], S. Francis-Graham[2], T. King[3], S. Demma[1], W. Rosenberg[1]. [1]*UCL Institute for Liver and Digestive Health, Royal Free London NHS Foundation Trust, London, United Kingdom;* [2]*UCL NIHR Health Protection Research Unit, Royal Free London NHS Foundation Trust, London, United Kingdom;* [3]*HMP Pentonville, London, United Kingdom*
Email: w.rosenberg@ucl.ac.uk

Background and Aims: Prisons have a high prevalence of hepatitis C virus (HCV) infection where diagnosis and treatment can be offered. In the UK HCV has been reported to infect 20% of prisoners compared to 1% of the general population. Highly effective and safe oral treatments have led to the introduction of blood bourn virus (BBV) opt-out testing in UK prisons in 2016. Diagnosis of infection mandates linkage to care including treatment so we developed a linked pathway of care for HCV positive prisoners. We have evaluated the initial introduction of BBV opt-out testing and linkage to care for HCV infected prisoners in a London remand prison with the aim of identifying opportunities to improve effectiveness.

Method: Quantitative data relating to opt-out testing and linkage to care were collected from December 2015 to February 2017. Data were extracted from prison and hospital electronic patient records and analysed using Microsoft Excel 2016.

Results: 6,767 prisoners entered Pentonville prison between December 2015 and February 2017. 6,450 (95%) were offered BBV opt-out testing and health promotion. 1,324 (21%) accepted testing. HCV infection was confirmed in 96 cases (7%). Investigations were complete for 79 (82%) cases.
22 (23%) HCV infected prisoners were referred to the hepatology nurse specialist; 11 patients (50%) were seen and all were discussed at the Operational Delivery Network (ODN) multi-disciplinary team (MDT) meeting. 6 (54%) either started treatment after MDT approval (3) or were referred to another ODN for ongoing care (3).
Overall 1.4% of prisoners were diagnosed with HCV infection and 6% of these cases were managed in accordance with ODN policy. 3% were cured.
Reasons for failure of BBV testing included communication of the offer, access to testing and test acceptance. Reasons for failure of linkage to care included completion of investigations, provision of results and failure to refer to the ODN MDT.
Low prioritisation scores and NHSE treatment quotas resulted in prisoners not accessing treatment during custody.
Conclusion: This initial evaluation revealed that neither BBV opt-out testing nor the planned linkage to care was effective. The reasons behind the failure of this pathway have been identified and are being addressed through better training of staff, the use of mandatory scripts for opt-out testing and strategies to ensure investigation and referral occur within one week. ODN prioritisation and NHSE quotas will continue to limit the number of prisoners who can be cured.

THU-394

Full analysis of comorbidities in chronic hepatitis Cpatients compared with matched comparators: A nationwide population-basedregister study from 2001 to 2013

J. Söderholm[1,2], K. Buesch[2,3], L. Frelin[2], A. Brolund[1], J. Kövamees[1], M. Sällberg[2], M. Lagging[4]. [1]*AbbVie, Medical Affairs, Stockholm, Sweden;* [2]*Karolinska Institutet, Department of Laboratory Medicine, Stockholm, Sweden;* [3]*AbbVie, HEOR, Stockholm, Sweden;* [4]*University of Gothenburg, Institute of Biomedicine, Gothenburg, Sweden*
Email: jonas.soderholm@abbvie.com

Background and Aims: Patients with Chronic hepatitis C (CHC) have shown an increased risk of comorbidities. However, in order to make the analysis of comorbidities more easily manageable and more relevant to capture extra-hepatic manifestations of hepatitis C, most previous studies have grouped morbidity diagnoses into larger groups often using comorbidity indexes like the Charlson Comorbidity Index. In the present study we analyzed the risk of comorbidities in CHC patients for all ICD-10 diagnoses.
Method: CHC patients were identified using B18.2 according to ICD-10 from 2001 through 2013 in the inpatient care, day surgery, and non-primary outpatient care in the nationwide Swedish Patient Register (n = 42,522). For each patient up to 5 non-CHC diagnosed age/sex/place of residency-matched comparators were drawn from the general population at time of diagnosis (n = 202,694). Follow-up started at date of CHC diagnosis and patients accrued person-time until death, emigration or 31st December 2013, whichever came first. Risk of disease was calculated as Standardized Incidence Ratio (SIR) with 95% confidence interval (CI). Diseases were grouped depending on blocks according to WHO (n = 264) or individual ICD-10 codes (n = 2213). Poisson probability distribution with Bonferroni correction for multiple analyses was used to calculate the P-value (significance $p < 0.0002$ for block analysis and $p < 0.00002$ for individual ICD-10 code analysis).
Results: CHC were at higher risk for 194 blocks of ICD-10 diagnoses (73%) with Viral Hepatitis (B15–B19 excluding B18.2 [SIR 86.1, 83.9–88.3 95% CI]), Disease of liver (K70–K77 [SIR 23.6, 23.0–24.3 95% CI]), and HIV (B20–B24 [SIR 21.6, 20.2–23.1 95% CI]) being the three groups the CHC patients had the highest increased risk. The CHC patients had a lower risk for three blocks of diagnoses (1%); Demyelinating diseases of the central nervous system (G35–G37 [SIR 0.43, 0.31–0.57 95% CI]), Glaucoma (H40–H42 [SIR 0.74, 0.67–0.80 95% CI]), and Malignant neoplasms of male genital organs (C60–C63 [SIR 0.81, 0.73–0.90 95% CI]). In addition, the CHC patients were at higher risk for 878 (40%) ICD-10 diagnoses and lower risk for 12 (5%) ICD-10 diagnoses.
Conclusion: CHC patients were at higher risk of being diagnosed with between 40% to 73% of the diseases captured by the ICD-10 classification either alone or in group after comparing with the matched comparator from the general population. Also the CHC patients were at lower risk 1%–5% of the diagnoses.

THU-395

Lower risk of multiple sclerosis in patients with chronic hepatitis C: A nationwide population-based register study 2001–2013

J. Söderholm[1,2], A. Yilmaz[3], K. Buesch[2,4], R. Wejstål[3], A. Brolund[1], J. Kövamees[1], M. Sällberg[2], M. Lagging[3], M. Gisslén[3]. [1]*AbbVie, Medical Affairs, Stockholm, Sweden;* [2]*Karolinska Institutet, Department of Laboratory Medicine, Stockholm, Sweden;* [3]*University of Gothenburg, Institute of Biomedicine, Gothenburg, Sweden;* [4]*AbbVie, HEOR, Stockholm, Sweden*
Email: jonas.soderholm@abbvie.com

Background and Aims: Patients with a previous infection with some neurotropic viruses such as Epstein-Barr, measles, rubella, and varicella zoster have been shown to be at higher risk of developing multiple sclerosis (MS). In contrast, people living with HIV, which is also a neurotropic virus, have been demonstrated to have a lower risk of developing MS. The aim of the present study was to investigate the risk for MS in chronic hepatitis C (CHC) patients by using the Swedish patient registries.
Method: CHC patients were identified using diagnose code B18.2 and MS using G35 according to International Classification of Diseases (ICD)-10 in the inpatient care, day surgery (1997–2013), and non-primary outpatient care (2001–2013) in the nationwide Swedish Patient Register. For each patient up to five non-CHC diagnosed age/sex/place of residency-matched comparators were drawn from the general population at time of diagnosis. Follow-up time was calculated from date of CHC diagnosis until death, emigration, or 31st December 2013, whichever came first. Risk of disease was calculated as Standardized Incidence Ratio (SIR) with 95% confidence interval (CI).
Results: CHC were at lower risk of developing MS (SIR 0.36, 0.26–0.50 95% CI). The prevalence of MS in the CHC cohort was 0.087% (37/42,522) compared with 0.27% (544/202,694) in the matched comparator cohort. The mean age at onset of MS was 46 years in the CHC cohort and 49 in the comparator cohort. The proportion men in the full cohorts were 64%, with the proportion men with MS in the CHC cohort was 57% and 44% in the comparator cohort.
Conclusion: Patients with CHC patients were at a lower risk of developing MS compared with the comparators. Life-style associated factors, or possibly that the altered immune milieu during the chronic infection could have some impact.

THU-396

A universal offer of blood borne virus testing substantially increases diagnosis and treatment of hepatitis C in prisons

S. Morey[1,2], A. Hamoodi[3], M. Valappil[1], D. Jones[4], C. Thompson[4], J. Dhuny[5], M. Hewett[1], E. Buchanan[1], C. Miller[1], T. Young[1], E. Hunter[1], S. Mcpherson[1,6]. [1]*The Newcastle upon Tyne Hospitals NHS Foundation Trust, Viral Hepatitis Service, Newcastle upon Tyne, United Kingdom;* [2]*Northumbria University, United Kingdom;* [3]*Public Health England North East, United Kingdom;* [4]*G4S Health Services, United Kingdom;* [5]*NHS England North East and Cumbria, United Kingdom;* [6]*Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom*
Email: stuart.mcpherson@nuth.nhs.uk

Background and Aims: Chronic hepatitis C virus infection (HCV) is a major cause of end stage liver disease. With recent advances in anti-viral therapy there is an opportunity to "eliminate" HCV from the UK.

It is known that HCV is common in incarcerated individuals, with previous estimates suggesting ~7% of the UK prison population is anti-HCV antibody positive. Increasing diagnosis and treatment of HCV in prison is therefore a priority in order to achieve "elimination". HCV testing rates in UK prisons are, however low (4%) and largely opportunistic. In order to increase diagnosis and treatment of HCV in prisons in the North East of England (NEE) we have implemented: 1. A universal offer of blood borne virus testing (UBBVT) using dry blood spot testing for prisoners at reception to increase diagnosis; 2. Prison Telemedicine clinics within NEE Prisons to increase HCV treatment rates.

Method: We present the results of the 1 year pilot of UBBVT in Durham Prison (DP) and the pilot of Telemedicine HCV treatment clinics in Northumberland Prison (NP).

Results: UBBVT was implemented at DP, the major remand prison in NEE, in Mar 2016. From Mar 2016 to Feb 2017 2,831 of the 4280 (66%) new receptions were offered BBV testing, compared with 164 of the 7,000 new receptions (2.3%) in 2013–14. A total of 1,495 (53% of offered) of new receptions accepted BBV testing, of whom 95 (6.4%) were anti HCV antibody positive. Of these 47 (49.5%) were HCV RNA positive confirming active infection (3.1% of all tested). 7 (0.5%) individuals were HBsAg positive and 2 (0.1%) were HIV positive. Common reasons for non-acceptance of the test were "doesn't want it" (54%) and "already had test" (37%). In parallel, a Consultant-led Telemedicine clinic (TC) with Specialist Nurse in-reach was implemented in NP. This prison houses longer stay prisoners that are frequently transferred from DP. Between August 2015 and October 2017 80 individuals were seen in the TC. Prior to implementation of the TC, in 2015 only 6 patients/year received HCV treatment. Of those seen in the TC, 57 (71%) commenced anti-HCV treatment. Overall, satisfaction with the TC among the prisoners was very high (80% good or excellent). Moreover, this is very cost effective with reduced cost of prisoner movement (Est £500/hospital visit). SVR and adherence data will also be presented.

Conclusion: A universal offer of BBV testing to prisoners at reception to prison can substantially increase testing rates and lead to many new diagnoses of HCV. Non-acceptance rates still remain high so it is important that there are other opportunities for testing within the prison. Telemedicine clinics with Nurse-led Prison in-reach offer a cost effective and efficient method of treating HCV in the prison environment. These services have now been implemented in all but one NEE Prisons.

THU-397

Multifactor risk evaluation in patients who have eradicated HCV infection: an interim analysis in the PITER cohort

L. Kondili[1], M.G. Quaranta[1], S. Rosato[1], M. Monti[2], B. Coco[3], R. Filomia[4], E. Biliotti[5], A. Iannone[6], A. Zanetto[7], S. Bruno[8], A. Giorgini[9], M. Loi[10], F. Baragli[11], C. Email: loreta.kondili@iss.it

Background and Aims: High SVR rates are reported in patients treated with DAAs in the real life. However, other than HCV, several factors are involved in the progression of liver damage. We aimed to evaluate the prevalence of cofactors involved in liver disease progression in HCV-treated patients who achieved the SVR12 following a DAA therapy in the PITER cohort.

Method: Data of HCV-infected patients, consecutively enrolled in PITER, who were treated and achieved the SVR12, were evaluated. In patients for whom at least 6 months follow-up post-SVR12 was available, the liver function tests and Child Pugh score changes according to the presence of these cofactors were evaluated.

Results: Of 3,485 patients who achieved the SVR12, 1,965 (56%) had liver cirrhosis, 1,164 (33%) reported actual alcohol use, 693 (20%) reported non-virus-non-alcohol-related fatty liver, 567 (16%) were diabetics, 1,781 (51%) had BMI > 25 of whom 60% had hypertension and 30% had BMI ≥ 30, 43 (1%) were HBsAg positive and 185 (5%) were HIV-infected. Of the overall treated patients: none of the above concurrent risk factors for liver disease progression was recorded in 523 (15%) patients of whom 46% had cirrhosis; one cofactor was recorded in 1093 (31%) patients of whom 57% had cirrhosis; two or more cofactors were present in the remaining 1869 (54%) patients of whom 59% had cirrhosis. Age, male sex, actual alcohol use, BMI > 25, previous IFN treatment, diabetes and HCV genotype 3 were independent factors associated to cirrhosis by logistic regression analysis (see table below). After a median follow-up of 12 months (range 9–18 months) following the SVR12, no differences regarding liver function tests according to the cofactors analyzed were observed. Improvement (median 1 point: range 1–4 points) in the Child Pugh score was observed in 72% of 324 patients with a Child Pugh score equal or higher than A6, without significant differences (chi-square test: p > 0.5) according to the different cofactors analyzed.

Factors independently associated with liver cirrhosis by Logistic Regression Analysis in patients who achieved the SVR12 in the PITER cohort

Parameters	Adjusted OR	95% Confidence Limits	
Age	1.03	1.02	1.04
Male sex	1.19	1.09	1.29
BMI>25	1.29	1.02	1.63
Actual alcohol use	1.21	1.10	1.33
HCV Genotype3	1.22	1.07	1.39
HIV positivity	1.08	0.91	1.29
HBV positivity	1.02	0.81	1.70
Previous IFN Therapy	1.22	1.13	1.31
Diabetes	1.53	1.37	1.71

Conclusion: Concurrent risk factors for liver disease progression are present in a significant proportion of patients who successfully eradicated HCV infection. Although no further liver disease progression was associated to the presence of such cofactors in a short term evaluation, their role in the overall morbidity and mortality is a health issue that need to be addressed. In the lack of longer prospective studies, a modelling of liver disease progression after HCV eradication, using these real life data, is ongoing.

THU-398

DNA methylation and immune cell markers demonstrate associations of accelerated aging with chronic HCV/HIV co-infection and liver fibrosis

S. Kottilil[1], Y. Gindin[2], B. Emmanuel[1], A. Ghosh[1], B. Poonia[1], J.G. Mchutchison[2], A. Gaggar[2], M. Subramanian[2]. *[1]University of Maryland School of Medicine, Institute of Human Virology; [2]Gilead Sciences Inc.*
Email: anuj.gaggar@gilead.com

Background and Aims: DNA methylation (DNAm) levels in whole blood have been previously shown to indicate age acceleration (AA) in HIV-infected patients (Horvath & Levine, 2015). Here, we evaluated blood DNAm to explore biological AA in patients with chronic HCV infection, with or without HIV infection. We also developed an immune cell marker panel that is associated with DNAm, and explored the impact of treatment on changes in AA.

Method: DNA, extracted from PBMCs, was assayed for DNAm on the Illumina 450k methylation array for HCV (n = 32) and HCV/HIV co-infected patients (n = 31) who underwent DAA therapy as well as publically available healthy control samples, selected to match the age range of HCV/HIV patients (n = 253). A regression model was derived relating chronological and DNAm-based age in controls. AA was calculated as the difference between an individual's DNAm age and one calculated from a linear model derived using the control samples. Blood immune marker data were collected for HCV and HCV/HIV patients who achieved SVR (n = 269) using flow cytometry, including the 63 patients assayed for DNAm. A model to infer AA from immune cell marker data was built using a regularized regression method (elastic net) using baseline data from the 63 patients for whom both immune marker and DNAm data were available. The elastic net model identified a set of 16 derivative immune markers, along with their coefficients as optimal predictors, which was then used to predict AA independently of DNAm.

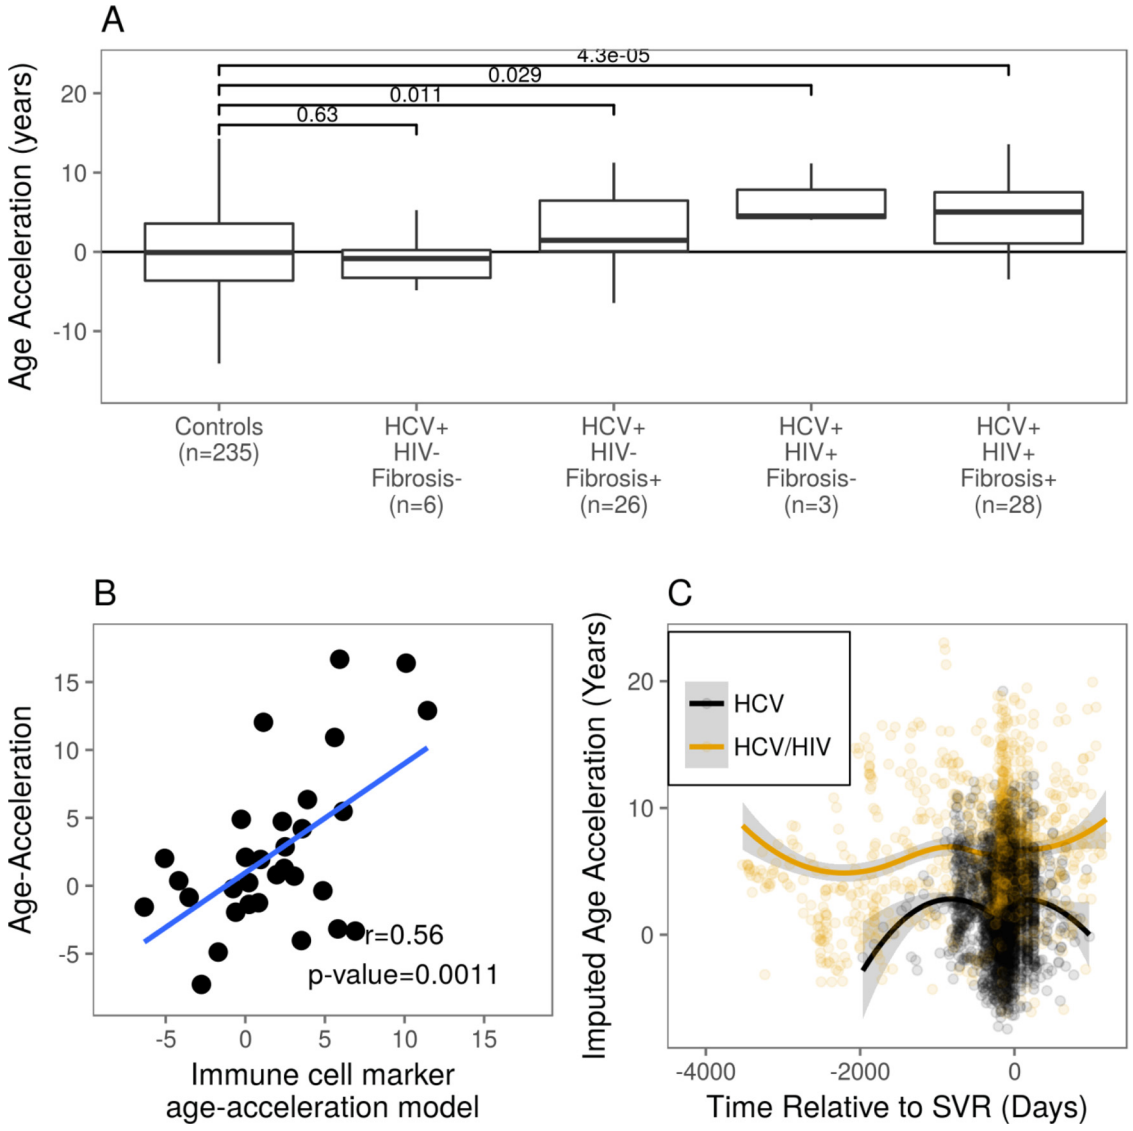

Figure: (abstract: THU-398)

Results: HCV patients co-infected with HIV were observed to have greater AA compared to controls regardless of the presence of liver fibrosis (liver fibrosis: 5.02 years; $p = 4.3 \times 10^{-5}$; no liver fibrosis: 4.51 years; $p = 0.029$). HCV mono-infected patients with liver fibrosis are more age accelerated (1.84 years; $p = 0.011$) whereas HCV mono-infected patients without liver fibrosis are not age accelerated (−0.84 years; $p = 0.63$) compared to controls (Figure 1A). We developed and validated an AA model based on immune cell marker data. AA inferred from post-treatment blood marker data (validation dataset) is concordant with DNAm-based measure ($r = 0.65$; $p = 0.00022$) (Figure 1B). Longitudinal immune marker-inferred AA data shows distinct patterns of AA relative to SVR depending on the patient's infection status: greater AA in HCV/HIV dual-infected patients prior to DAA therapy and a trend of AA reversal in HCV patients post SVR ($p = 0.021$; Figure 1C).

Conclusion: Liver fibrosis and HIV infection are associated with AA in chronic HCV patients. AA can be inferred from a novel set of peripheral cell activation markers. While SVR is associated with reversal of AA in chronic HCV, patients with HIV/HCV co- infection have persistent AA despite SVR, likely suggestive of persistent HIV-induced immune activation.

THU-399
Incidence and prevalence of extrahepatic manifestations of HCV

H. El-Serag[1], I. Christie[1], A. Puenpatom[2], D. Castillo[1], F. Kanwal[1], J. Kramer[1]. [1]*Michael E. DeBakey VA Medical Center, Center for Innovations in Quality, Effectiveness and Safety (IQuESt), Houston, United States;* [2]*Merck Sharp & Dohme Corp, Whitehouse Station, United States*
Email: hasheme@bcm.edu

Background and Aims: Chronic hepatitis C virus (HCV) infection has been associated with several extrahepatic manifestations (EHMs). Direct acting antiviral (DAA) therapy has revolutionized the treatment of HCV, and may have a beneficial role in EHMs. However, contemporary DAA era data on the prevalence and incidence of EHM in patients with active HCV are limited.
Methods: We conducted a retrospective matched cohort study of patients with and without HCV in the national U.S. Veterans Affairs Corporate Data Warehouse. The HCV positive cohort included individuals with positive HCV RNA between 10/1999 and 10/2016, age 20 to 85 years at earliest positive HCV date (index date), and with more than one year of follow-up after index date. The HCV negative cohort was defined using the same criteria but with absence of a positive HCV RNA and their index date was a clinic visit date in the same year. Cases and controls were matched using 1:1 ratio on DOB (±5 years), first visit date in VA system (± 1 year), HCV/visit index date (±1 year), and gender. Prevalence, incidence rates (IR), and incidence rate ratios (IRR) were estimated for EHMs, including mixed cryoglobulinemia, glomerulonephritis, porphyria cutanea tarda, lichen planus, non-Hodgkin's lymphoma, and diabetes. EHMs were identified by the presence of at least one inpatient or outpatient ICD-9/10 diagnoses between 10/1999–10/2017. Prevalence was defined as diagnosis either prior to or up to one year following index date. Incidence rates were calculated by dividing new diagnoses by total person-years from index date through either the patients' diagnosis or last clinic visit in the VA system; all prevalent cases were excluded for the purpose of incidence rate calculation.
Results: We identified 244,655 patients (mean age = 54.6 years, 96.3% men, and 32.5% African American, 55.1% white) with active HCV, and 244,655 matched controls without HCV. The prevalence, IRs and IRRs of EHM in HCV– and HCV+ cohorts are shown in the Table. Baseline prevalence and IRRs were higher in patients with HCV compared with no HCV for mixed cryoglobulemia, glomerulonephritis, porphyria cutanea tarda, and lichen planus but not for non-Hodgkin's lymphoma and diabetes. For example, patients with HCV were 4 times more likely to develop mixed cryoglobulemia than patients without HCV. In the DAA era (post 9/2014), the prevalence of one or more of these 4 EHM conditions was 5.78% (12,183 of 210,564) of HCV+ cases.
Conclusion: Both the prevalence and risk of several EHMs of HCV infection is elevated among HCV positive patients. Extrahepatic benefits of SVR attainment should be examined so it can be included in the cost-benefit analyses of new antiviral drugs for HCV infection.

THU-400
Changes in hepatic steatosis measured by CAP-fibroscan in patients with chronic hepatitis C treated with direct action antivirals

P. Linares[1], R. Quiñones[1], B. Álvarez-Cuenllas[1], F. Jorquera[2], N. Reyes[1], C. Villar[1], G. Molina[1], R.P. Fernandez[1], L. Vaquero[1]. [1]*Complejo Asistencial Universitario de León, Servicio de Digestivo, Unidad de Hepatología, León, Spain;* [2]*Complejo Asistencial Universitario de Léon, Servicio Aparato Digestivo, Spain*
Email: plinares68@gmail.com

Background and Aims: The relationship between the hepatitis C virus (HCV) and the development of hepatic steatosis is well known, due to different mechanisms that include a direct cytopathic effect, interaction in the liver turnover of triglycerides, etc. Likewise, liver steatosis next to HCV can contribute to the progression of hepatic fibrosis. At present, the CAP (Controlled Attenuation Parameter) allows the quantification of hepatic steatosis in a non-invasive way at the same moment of the realization of fibroscan. Our aim is to analyze what happens with steatosis measured by CAP after treatment of hepatitis C with direct action antivirals (DAA) and its relationship with anthropometric variables, lipid profile, viral variables, elastometry and type of treatment used.
Method: retrospective study from January 2015 to March 2017 of the cases treated with DAA in which a baseline and 24 weeks post-treatment determination of a CAP-fibroscan was made.
Results: 364 patients were collected (40% women), mean age 57 years (20 to 88), 53% naive, 26% with hypertension, 12.4% diabetes,

Table 1: (abstract: THU-399)

Table: Prevalence and crude incidence rates of extrahepatic outcomes of hepatitis C virus infection (HCV+ vs HCV-).

	HCV+			HCV-			
Outcome	**Prevalence**	**Events**	**IR/1000 PY**	**Prevalence**	**Events**	**IR/1000 PY**	**IRR (95% CI)**
Mixed cryoglobulinemia	0.27%	1,689	0.76	0.08%	391	0.19	4.03 (3.61-4.49)
Glomerulonephritis	1.50%	6,139	2.82	1.20%	4,224	2.07	1.36 (1.31-1.41)
Porphyria cutanea tarda	0.61%	903	0.41	0.05%	105	0.05	8.04 (6.57-9.84)
Lichen planus	0.33%	1,573	0.71	0.22%	690	0.33	2.12 (1.94-2.32)
Non-Hodgkin lymphomas	0.72%	2,258	1.02	0.65%	2,091	1.02	1.00 (0.95-1.06)
Diabetes mellitus	20.50%	36,322	22.5	24.40%	38,098	26.3	0.86 (0.84-0.87)

Abbreviations: CI, confidence intervals; IR, incidence rate; IRR, incidence rate ratio; PYs, person-years

12.8% with dyslipidemia and 28.2% cirrhosis, which reached the sustained viral response (SVR). The predominant genotype was 1b (48.6%) and genotype 3 was 11.6%. The mean basal fibroscan was 12.4 KPa and post-treatment was 9.19 KPa ($p < 0.05$). The mean baseline CAP was 239.1 ± 50 and after treatment was 246.27 ± 56 dB/m ($p < 0.05$). 38.66% of the patients had basal liver steatosis moderate-severe (CAP ≥ 248 dB/m) and this percentage increased to 44.63% after treatment ($p = 0.004$). A direct relationship was found between the basal quantification of steatosis and the degree of liver fibrosis ($p < 0.05$): F0 (216.5 dB/m), F1 (222.1 dB/m), F2 (239.2 dB/m), F3 (254 dB/m) and F4 (247 dB/m). 20% of patients with fibrosis F < 2 had steatosis grade 2–3 (CAP > 250 dB/m) vs 42.23% of patients with F ≥ 2, ($p = 0.003$). The same occurred in the post-treatment CAP (17.9% in F < 2 vs 52% in F ≥ 2, $p = 0.009$). 66.7% of patients with genotype 3 had basal steatosis grade 2–3 vs 34.5% of the rest of genotypes, ($p = 0.023$) and this difference decreased after treatment (55.9% vs 43.5%). In the multivariable analysis, the increase in basal CAP was significantly related to weight gain, high viral load, genotype 3, high HOMA, atherogenic index (HDL/total cholesterol), coronary risk (HDL/LDL) and degree of hepatic fibrosis. No association was found with age, sex, type of treatment used and other comorbidities.
Conclusion: In our cohort, 40% of the patients with hepatitis C had a moderate-severe steatosis measured by CAP, which was more evident in patients with genotype 3, high viral load and greater degree of fibrosis. The cure of hepatitis C was associated with an increase in liver steatosis, which was directly related to changes in lipid profile, insulin resistance, weight gain and increased atherogenic and coronary risk.

THU-401

Influence of statines in the modifications of lipid and hydrocarboned metabolism in patients with chronic hepatitis C treated with direct-acting antivirals

P. Linares[1], B. Álvarez-Cuenllas[1], F. Jorquera[1,2,3], R. Quiñones[1], N. Reyes[1], G. Molina[1], C. Villar[1], M. Guerra-González[4], E. Fernández-Moran[4], E. Gutiérrez-Gutiérrez[4], D. Fierro-González[5].

Email: plinares68@gmail.com

Background and Aims: The hepatitis C virus (HCV) modifies the lipid and hydrocarbon metabolism of the host. Statins interact with direct-acting antivirals (DAA) and are stopped before the start of ADAs and reintroduced at the end. Objective: To compare the variations of the lipid profile and insulin resistance in HCV patients treated with DAA after obtaining the sustained viral response in week 24 (SVR-24) and to evaluate statins as a possible modifying factor.
Method: Retrospective study of patients with HCV treated from January 2015 to December 2016, collecting different variables: age, sex, genotype, degree fibrosis, type of DAA, comorbidities, use of statins and analytical determinations: total cholesterol (TCh), triglycerides (TGL), HDL, LDL, insulin and HOMA at four different times: Basal (B), Final treatment (F), Week 12 after treatment (12) and Week 24 (24). To evaluate the influence of statins we use TCh.
Results: 332 patients treated (60.5% men), mean age 57 years. 26% had hypertension, 13% diabetes, 12.3% dyslipidemia and 27% liver cirrhosis. Only 5.45% of patients received treatment with statins prior to the start of treatment. The distribution of the genotypes was: 1a (27.5%), 1b (50%), 2 (2.5%), 3 (11%), 4 (9%). Mean viral load: 3,153,432 IU/ml. SVR-24 was reached in 98%. The baseline serum concentrations of TCh, TGL, HDL and LDL were 165.2, 135.7, 52.5 and 118.64 mg/dl respectively. In genotype 3, the mean baseline TCh concentrations were lower ($p < 0.005$) and the baseline HOMA was higher ($p = 0.029$). Overall, the mean serum concentration at the end of the TCh (F) treatment increased 18.65 mg/dl, 21.24 mg/dl at week 12 and 20.19 at week 24 compared to baseline values ($p < 0.0001$). The mean increase in LDL (F) was 26.03 and 22.81 mg/dl (12) ($p < 0.0001$). The atherogenic risk (TCh/HDL) increased from 3.46 (B) to 3.93 (F), 4.2 (12) and 3.8 (24) ($p < 0.005$) and coronary risk (HDL/LDL) increased 0.27 (24). In the non-statin group (mg/dl ± SD): TCh (B) 165.23 ± 35.15, TCh (F) 182.67 ± 40.5; TCh (12) 186.44 ± 36.21, TCh (24) 186.71 ± 36.65. In the statin group: TCh (B) 164.89 ± 35.15, TCh (F) 204.33 ± 40.5, TCh (12) 186.47 ± 36.21, TCh (24) 158.92 ± 36.65. The values of TCh (F) and TCh (24) were significant in the group of statins vs non-statins.
Conclusion: the low use of statins in patients with chronic hepatitis C suggests a metabolic blockade of HCV and variations in the lipid profile after antiviral treatment may reflect the physiological response to viral elimination. However, the increase in TCh, LDL and atherogenic risk may have a potential impact on atherosclerosis. Statins imply an additional block of lipid metabolism that is recovered with greater intensity in patients who suspend them. No effects of the type of DAA used on lipid changes were observed.

THU-402

Changes in serum neurotransmitters are associated with changes in patient reported outcomes and neurocognitive performance in patients with hepatitis C virus-genotype 1 who achieved sustained virologic response

L. Deavila[1], A.A. Weinstein[2], M. Curry[3], P. Golabi[1], J.M. Estep[1], C. Escheik[1], A. Birerdinc[1], M. Stepanova[4], L. Gerber[1,2,5], Z. Younossi[6].
[1]Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; [2]George Mason University, Center for the Study of Chronic Illness and Disability, College of Health and Human Services, Fairfax, United States; [3]Beth Israel Deaconess Medical Center, Boston, United States; [4]Center for Outcomes Research in Liver Disease, Washington DC, United States; [5]Inova Fairfax Hospital, Center for Liver Disease, Department of Medicine, Falls Church, United States; [6]Inova Fairfax Hospital, Department of Medicine, Falls Church, United States
Email: zobair.younossi@inova.org

Background and Aims: Although neurotransmitters (NTs) in Hepatitis C Virus (HCV) infection have been shown to be associated with Patient Reported Outcomes (PROs) and neurocognitive performance (NP), changes in the relationships between NTs and PROs/NP in patients with Sustained Virologic Response (SVR) have not been assessed.
Method: HCV subjects without cirrhosis (N = 40, age: 45.3 ± 11.5, 48% male, 90% white) received 12 weeks of ledipasvir/sofosbuvir (LDV/SOF) or placebo followed by 12 weeks of LDV/SOF with 92% achieving SVR24. Baseline, and post-SVR PROs were assessed using Short-Form (SF-36), Chronic Liver Disease Questionnaire-HCV (CLDQ-HCV), Functional Assessment of Chronic Illness Therapy-Fatigue; and (2) NP: digit span/symbol span (working memory), Trail Making B/Color Word Interference (executive function), Hopkins Verbal Learning/Brief Visuospatial Memory tests (memory). Serum NTs (serotonin, BDNF, and GABA) were measured by ELISA at baseline and SVR24. Correlations among the NTs and PROs and NP were performed at baseline and at SVR24 using non-parametric Spearman correlations. Correlations of the amount of change from baseline (SVR24-baseline) was the correlation of interest.
Results: Relationships between NTs and PROs and NPs differed at baseline and SVR24. At baseline serum GABA and BDNF correlated with PROs of physical functioning ($r = 0.32$; $r = -0.40$, p's < 0.05). In contrast, Serotonin was related to perceptions of vitality, emotional well-being, fatigue, and activity/energy ($r = 0.32$ to 0.41; p's < 0.05). At SVR24, PROs improved and these relationships between NTs and PRO domains were no longer present. On the other hand, changes in magnitude and direction of the following remained significant: GABA was associated with the changes in measures of working memory, memory, executive function, fatigue and physical role ($r = 0.33$ to 0.47; $p = <0.05$). BDNF was associated with pain, physical composite score, physical well-being ($r = 0.4$ to 0.46; $p = <0.015$) and serotonin

correlated with general health and executive function (r = 0.34 to 0.40; p = <0.05).

Conclusion: After achieving SVR24, serum BDNF correlates with physical performance, while serum serotonin correlates with general health and executive function. During viremia, GABA levels associate with physical function. These data suggest that the relationships between NTs with PRO and NP seen during HCV viremia, change with SVR24 and the magnitude of these changes may have clinical relevance.

THU-403

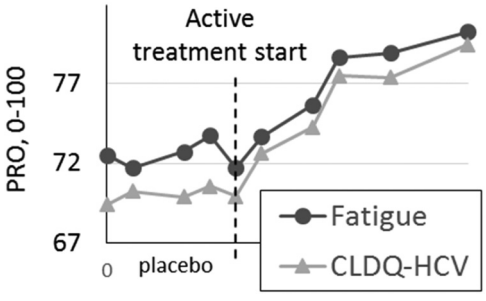
Patient-reported outcomes in chronic hepatitis C: The impact of placebo, active treatment, and sustained viral eradication

Z. Younossi[1], M. Stepanova[2], M.P. Manns[3], R. Reddy[4], S.C. Gordon[5], M. Bourliere[6]. [1]*Inova Fairfax Hospital, Department of Medicine, Falls Church, United States;* [2]*Center for Outcomes Research in Liver Disease;* [3]*Dept. of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany;* [4]*University of Pennsylvania;* [5]*Henry Ford Hospital;* [6]*Hopital Saint Joseph*
Email: zobair.younossi@inova.org

Background and Aims: Clearance of HCV infection is known to improve quality of life and other patient-reported outcomes (PROs). To longitudinally assess changes in PROs in patients with HCV infection who were initially randomized to placebo and then subsequently received SOF/VEL/VOX for 12 weeks in a "deferred treatment" study.

Method: HCV-infected patients who received 12 weeks of placebo in the POLARIS-1 study were subsequently treated with SOF/VEL/VOX (400 mg/100 mg/100 mg) daily for 12 weeks. During placebo treatment and active treatment periods, PROs were prospectively collected using SF-36v2, CLDQ-HCV, FACIT-F, and WPAI:SHP assessing 26 PRO domains.

Results: Of 147 HCV patients included, most were male (79%), white (82%), 33% had cirrhosis, and 99% had HCV genotype 1. The SVR-12 rate was 97%. During treatment with placebo, there were no significant changes in any PRO domains from patients' own baseline levels (all p > 0.05) except for the Worry domain of CLDQ-HCV. However, soon after the initiation of SOF/VEL/VOX, significant PRO improvements were noted in a number of PRO domains. By week 4 of active treatment, scores improved in 6/26 PRO domains (+2.4% to +8.1%, p < 0.05) and continued to improve until the end of treatment week 12 in 14/26 PRO domains (+2.0% to +8.3%, p < 0.05). Achieving SVR was associated with improvement in 24/26 PRO domain scores by post-treatment week 12 and in 23/26 domain scores by post-treatment week 24 (+3.2% to +14.9%). The greatest PRO improvements were observed in the domains of Vitality, Activity, and Presenteeism (>8% of a PRO range size). In multivariate analysis, being viremic was associated with significantly impaired PRO scores: β ranging from −2.4% to −8.5%, p < 0.05 for all but one PRO.



Conclusion: This study shows that PROs do not change during placebo treatment but significantly improve with active DAA treatment and with sustained viral eradication. These data provides strong evidence supporting the positive impact of HCV viral suppression on PROs.

THU-404

Universal access to DAA therapy paves the way for HCV control and elimination among people living with HIV in Australia

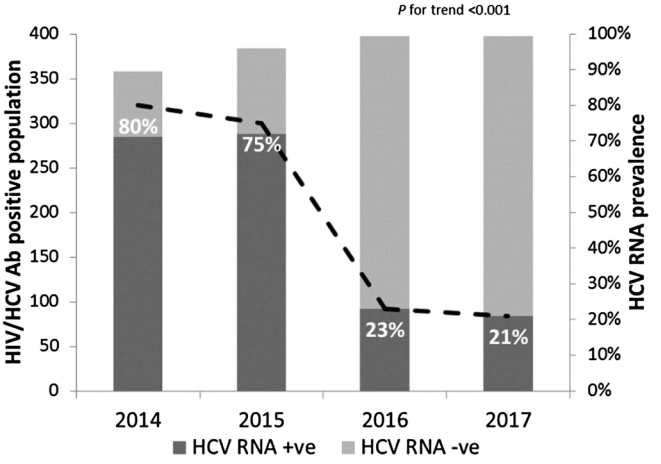
Email: mmartinello@kirby.unsw.edu.au

Background and Aims: HCV elimination among people living with HIV may be possible in Australia, given population size (n = 2,500–3,000), high proportion diagnosed and linked to care (>80%), and unrestricted government-subsidised access to direct-acting antiviral (DAA) therapy (as of March 2016). The aim of this analysis was to assess HCV treatment uptake, outcomes, and HCV RNA prevalence among HIV/HCV co-infected adults enrolled in the Control and Elimination of HCV from HIV-infected individuals within Australia (CEASE-D) cohort study following the availability of DAA therapy.

Method: Cumulative HCV treatment uptake was defined as the proportion of individuals diagnosed with chronic HCV infection who ever initiated HCV treatment (censored 13 October 2017). Annual (2014–2016) HCV treatment uptake was defined as the proportion of individuals with chronic HCV who initiated treatment per year. Sustained virological response was assessed in those who had completed 12 weeks post treatment follow-up (SVR12). Factors associated with DAA uptake in 2016 and 2017 were evaluated by logistic regression analysis. HCV RNA prevalence was calculated per study year, accounting for new diagnoses, treatment outcome, reinfection post SVR and death.

Results: Of 402 HIV/HCV antibody-positive individuals enrolled (mean age 49, SD 10), 95% were male (80% gay and bisexual men [GBM]), 13% had cirrhosis, and 22% had ever received interferon-based therapy. Injecting drug use (IDU) ever and current was reported by 80% and 36%, respectively, predominantly (meth) amphetamine (ever 66%, current 30%). The principal modes of HCV transmission were IDU (54%) and sexual exposure in GBM (28%). Cumulative HCV treatment uptake among individuals ever diagnosed with chronic HCV infection was 85% (95%CI 81%, 88%); 67% had received interferon-free DAA regimens. Annual HCV treatment uptake increased from 7% (95%CI 5%, 11%) and 10% (95%CI 7%, 14%) in 2014 and 2015, respectively, to 78% (95%CI 73%, 83%) in 2016 (p < 0.001). Among those treated, SVR12 was 70%, 86% and 92% in 2014, 2015 and 2016, respectively. No clinical or demographic factors, including current IDU, were associated with DAA uptake. HCV RNA prevalence decreased significantly between 2014 and 2017, from 80% (95%CI 75%, 84%) to 21% (95%CI 17%, 25%) (p < 0.001) (Figure).

Conclusion: High uptake and efficacy of government-subsidised DAA therapy has permitted rapid treatment scale-up with a marked reduction in HCV RNA prevalence among people living with HIV, paving the way for HCV elimination in this population.



THU-405

The Rapid-EC study – A feasibility study of point-of-care testing in community clinics targeted to people who inject drugs in Melbourne, Australia

B. Williams[1], A. Pedrana[1,2], J. Howell[1,2,3,4], J. Doyle[1,5], A. Thompson[3,4], F. Bramwell[6], D. Membrey[6], M. Mcpherson[7], C. Layton[6], B. Draper[1], J. Roney[8], N. Latham[1,9], M. Hellard[1,2,10]. *[1]Burnet Institute, Disease Elimination Program, Melbourne, Australia; [2]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia; [3]St Vincent's Hospital, Department of Gastroenterology, Melbourne, Australia; [4]University of Melbourne, Department of Medicine, Melbourne, Australia; [5]Alfred Health and Monash University, Infectious Diseases, Melbourne, Australia; [6]Cohealth, Melbourne, Australia; [7]North Richmond Community Health, Melbourne, Australia; [8]Alfred Hospital, Infectious Diseases, Melbourne, Australia; [9]Monash University, Department of Infectious Diseases, Melbourne, Australia; [10]The Alfred and Monash University, Department of Infectious Diseases, Melbourne, Australia*
Email: margaret.hellard@burnet.edu.au

Background and Aims: Increasing the number of people who inject drugs (PWID) accessing hepatitis C virus (HCV) diagnosis and treatment is essential to Australia's success in eliminating HCV. Point-of-care (POC) diagnostics may reduce barriers to HCV care by allowing same-day diagnosis and facilitating testing in locations already frequented by PWID, such as needle and syringe exchange programs (NSPs). The Rapid-EC study was conducted to assess the feasibility and acceptability of POC testing for HCV in three community clinics with NSPs.

Method: Clients of the NSP service, who were not engaged in HCV care, were invited to participate. Participants underwent OraQuick HCV antibody mouth swab test (20 minutes to result); those positive were offered venepuncture for the Xpert HCV viral load (105 minutes to result). Participants were offered same-day results delivered on site, via phone or text message, or on return to the service. Participants were invited for follow-up review and those diagnosed with chronic HCV were assessed for treatment by a nurse and linked to community or specialist prescribers. Analysis of treatment uptake is ongoing. Participants also completed demographic, behavioural and acceptability surveys.

Results: A total of 174 participants completed POC testing for HCV antibodies, of whom 150 (86%) had a reactive result. Of these, 140 (93%) underwent a POC HCV RNA test, of which 76 (54%) had detectable RNA. The median age of participants was 41 years, 118 (67%) were male, 154 (88%) had injected drugs within six months and 93 (53%) had shared injecting equipment within six months. Of the 67 participants for whom a four-week period had elapsed since HCV diagnosis, 40 (60%) had been reviewed and linked to care in that time. Only 7 (5%) participants waited on-site to receive their POC RNA result, while 85 (61%) opted to receive their result via phone call or text message. The majority (85%) of participants preferred POC compared to standard HCV testing.

Conclusion: Provision of POC testing at community clinics with NSPs was feasible and acceptable to clients at high risk of HCV infection. Point-of-care tests streamlined HCV testing and enhanced linkage to care opportunities, however the ability to provide same-day diagnosis with current tests is limited. The utility of HCV POC diagnostics may be improved by reducing time to result and number of tests to diagnosis.

THU-407

Evaluation of APRI index to identify cirrhosis prior to direct-acting antiviral HCV treatment

J. Doyle[1,2], B. Harney[1,2], D. Brainard[3], A. Osinusi[3], L. Stamm[3], M. Hellard[4], A. Thompson[5,6]. *[1]Monash University and The Alfred, Department of Infectious Diseases, Melbourne, Australia; [2]Burnet Institute, Australia; [3]Gilead Sciences, Foster City, United States; [4]Burnet Institute, Melbourne, Australia; [5]St Vincent's Hosptial Melbourne, Melbourne, Australia; [6]University of Melbourne, Melbourne, Australia*
Email: joseph.doyle@monash.edu

Background and Aims: Direct acting antivirals have been shown to be effective in treating hepatitis C (HCV) regardless of cirrhosis stage. However identifying cirrhosis prior to treatment is still important for clinical care and follow up. Liver biopsy (LB) and transient elastography (TE) are standard of care but access is limited by cost and training. Aspartate aminotransferase to platelet ratio index (APRI) is requires only routine blood tests and is simple to calculate. We aimed to identify an APRI value where LB or TE may not be required to identify cirrhosis.

Method: An analysis of data pooled from 10 sofosbuvir-based interferon free clinical trials that included participants with and without cirrhosis was conducted. Participants who underwent cirrhosis screening by LB or TE were included in this analysis. Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) were calculated for a range of APRI values and stratified by age (<50 or >50 years). Poisson regression adjusted for sex, body mass index, HCV genotype and IL28B genotype was used to identify associations with cirrhosis.

Results: APRI data and LB or TE results were available for 3,835 participants among whom 23% (n = 898) were identified to have cirrhosis. The mean age of participants was 54 years (range 18–85), 64% were male and 82% were white. Approximately 34% underwent LB and there was no significant difference in cirrhosis identification between LB and TE (χ^2 0.138 p = 0.71). APRI value ≤0.5 had an NPV of 92% to exclude cirrhosis (95% CI: 90–94) among participants aged >50 and a NPV of 98% (95%CI 96–99) among those aged <50. Participants aged >50 with an APRI value ≤0.5 were 77% less likely to have cirrhosis (adjusted prevalence ratio [aPR] 0.23, 95%CI 0.18–0.30) compared to those with an APRI >0.5. Among those aged <50, an APRI ≤0.5 was associated with being 90% less likely to have cirrhosis (aPR 0.10, 95%CI 0.04–0.20).

	APRI 0.5	APRI 1.0	APRI 2.0
Participants under 50 years old	n = 380	n = 663	n = 850
Sensitivity, % (95% CI)	95 (89–98)	77 (69–84)	38 (29–47)
Specificity	46 (41–49)	78 (75–80)	94 (92–96)
PPV	22 (18–25)	35 (30–41)	51 (40–61)
NPV	98 (96–99)	96 (94–97)	91 (88–92)
Participants over 50 years old	n = 847	n = 1835	n = 2535
Sensitivity	92 (89–93)	68 (65–72)	33 (30–37)
Specificity	37 (35–39)	75 (73–77)	95 (94–96)
PPV	34 (32–37)	50 (47–53)	72 (67–77)
NPV	92 (90–94)	87 (85–88)	80 (78–81)

Conclusion: In settings with limited access to liver biopsy or transient elastography, APRI could be used to triage further fibrosis assessment. An APRI of <0.5 among people over 50, and APRI <1.0 among under 50 year olds may an appropriate cut-off to rule out cirrhosis and avoid additional fibrosis testing.

THU-408

Hepatitis C treatment success in primary and tertiary care among people with HCV/HIV coinfection

J. Doyle[1,2], D. Iser[1], J. Sasadeusz[3], J. Roney[1], J. Cutts[2], A. Bowring[2], R. Winter[2], M. O'reilly[4], C. Fairley[5], E. Gane[6], J. Hoy[1], G. Matthews[7], N. Medland[8], R. Moore[9], M. Prins[10], B. Tee[11], M. Stoove[2], M. Hellard[1,2].
[1]Monash University and The Alfred, Department of Infectious Diseases, Melbourne, Australia; [2]Burnet Institute, Melbourne, Australia; [3]Melbourne Health, Melbourne, Australia; [4]Prahran Market Clinic, Melbourne, Australia; [5]Alfred Health, Melbourne Sexual Health Centre, Melbourne, Australia; [6]Auckland Hospital, Auckland, New Zealand; [7]Kirby Institute, Sydney, Australia; [8]Alfred Health, Melbourne Sexual Health Centre, Carlton, Australia; [9]Northside Clinic, Melbourne, Australia; [10]GGD Amsterdam, Amsterdam, Netherlands; [11]Centre Clinic, Melbourne, Australia
Email: joseph.doyle@monash.edu

Background and Aims: In Australia, subsided access to hepatitis C (HCV) direct-acting antivirals (DAAs) without disease stage restriction provides an opportunity to dramatically increase HCV treatment uptake. The co-EC study aims to eliminate HCV through community treatment of HIV coinfected gay and bisexual men in Melbourne, Australia.
Method: The co-EC study is an ongoing (March 2016–) nurse-managed, clinician-directed, non-randomised trial of therapy among HCV/HIV coinfected people. Assessment and work-up are performed by nurses at tertiary (n = 2) and primary care (n = 4) sites to facilitate prescription of DAAs by specialists or general practitioners. Routine clinical data, including haematological, biochemical and fibrosis assessment, is collected at baseline and post-treatment visits (SVR12).
Results: Overall 190 HIV positive individuals with chronic HCV infection (98% male, median age 47 years) were enrolled; 67% in primary care. At baseline, 98% of participants were on ART and 91% had a suppressed HIV viral load. In the cohort, 67% of participants had HCV genotype 1 and 27% genotype 3. The most common modes of HCV infection were sexual contact with a person of same sex (38%) and injecting drug use (31%). Thirty participants (16%) had previously been treated for HCV. Of the 16 (8.5%) who were cirrhotic, 10 (63%) were cared for in tertiary settings.
One hundred and sixty nine participants commenced treatment, with the majority prescribed sofosbuvir with daclatasvir (47%) or ledipasvir (46%). At their SVR12+ visit, HCV RNA by PCR was undetectable in 131/136 participants (96%, 95% CI 91–98%), comprising 86/91 (95%) patients seen in primary care and 45/45 (100%) patients seen in tertiary care (p = 0.109). All cirrhotic participants (11/11) were undetectable at SVR12 + . Three participants discontinued treatment and did not achieve SVR12: one due to non-adherence; one self-discontinuation due to side-effects; and one clinician advised discontinuation due to adverse events.
Conclusions: HCV treatment was safe and highly effective in this real-world cohort. Despite HCV/HIV coinfection traditionally requiring specialist management, our findings suggest that most people can be managed in primary care settings without referral. Nurses undertook the vast majority of patient care – facilitating treatment commencement and undertaking patient monitoring. This network also provides an opportunity for regular testing to detect HCV reinfection in community settings.

Email: p.a.m.kracht@umcutrecht.nl

Background and Aims: The Netherlands may be one of the first countries to achieve elimination of the hepatitis C virus (HCV). Case finding of formerly identified yet untreated HCV patients is essential in this Dutch HCV elimination process. The Retrieval and Cure of Hepatitis C (REACH)-project aims to retrieve and cure all previously diagnosed and lost to follow-up (LFU) HCV patients in the Utrecht province in the Netherlands.
Method: All positive HCV diagnostic tests (anti-HCV Ig or HCV-RNA) from all four hospitals and one diagnostic center in the Utrecht province between 2006–2015 were linked to clinical records. Untreated patients with available contact information were deemed eligible for retrieval. Patients were classified as having a chronic HCV (cHCV, i.e. 2x positive HCV-RNA ≥ 6 months) or possible chronic HCV (i.e. positive HCV immunoblot without HCV-RNA available). Thus, selected patients were invited for reevaluation with (virology) blood tests, fibroscan measurement, qualitative interview to assess LFU reasons and subsequent direct-acting antiviral (DAA) therapy.

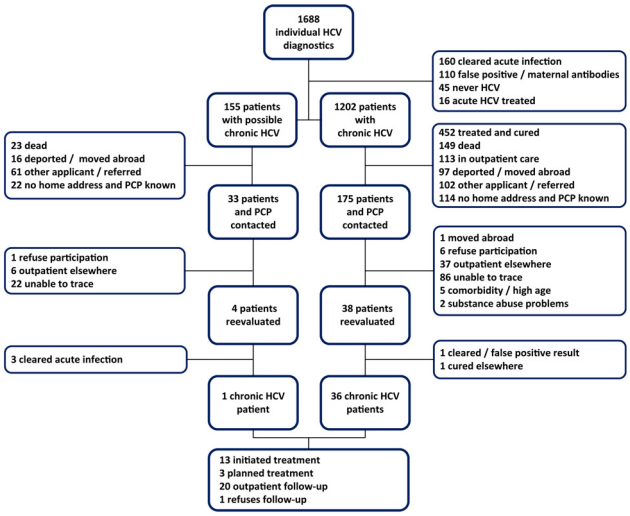

Figure 1: Flowchart: screening of HCV diagnostic tests. PCP, Primary care physician.

Results: Of the 1,688 patients with a positive HCV diagnostic test, 208 (12%) were eligible for retrieval and invited for screening (flowchart in Figure 1). The majority of patients (115/208, 55%) continued to live in the Utrecht province. Eventually, 42/208 (20%) visited the outpatient. After reevaluation, 37/42 patients (88%) had a persistent

cHCV infection characterized by a mean age 54 years (±9.4), 62% male gender, genotype 1a (48%), 1b (27%), 1c (3%), 2 (3%), 3 (8%) and 4 (11%) 14% cirrhosis, 84% treatment naïve, 78% history of intravenous drug use and 31% immigrants. Overall, 13 patients already initiated treatment, 3 are scheduled to start, 20 are in outpatient follow-up and 1 refused further appointments. The LFU from routine clinical practice of the 208 contacted HCV patients was not time dependent (median 13 patients per year, IQR 12–14). Main reasons for previous LFU by qualitative interviewing amongst the 37 traced HCV patients consisted of: deferral of treatment (43%) and substance abuse problems (19%).

Conclusion: In the REACH-project, 42 lost to follow-up chronic HCV patients, i.e. 20% of all individuals elligible for retrieval, were found through re-evaluation of positive HCV diagnostic tests. Therefore, re-evaluation of positive HCV diagnostics in combination with patient recall can be of value for the identification of previously diagnosed however yet untreated cHCV patients.

THU-410

Preliminary analysis of the Prime Study; A randomized controlled trial comparing the hepatitis C care cascade in primary care vs. tertiary care

A. Wade[1,2], J. Doyle[1,3], E. Gane[4], C. Stedman[5], B. Draper[1], D. Iser[3,6], S. Roberts[7,8], W. Kemp[2,3], D. Petrie[9], N. Scott[1], P. Higgs[1,2,10], P. Agius[1,2,11], J. Roney[3], L. Stothers[6], A. Thompson[6,12], M. Hellard[1,2,3].

Email: amanda.wade@burnet.edu.au

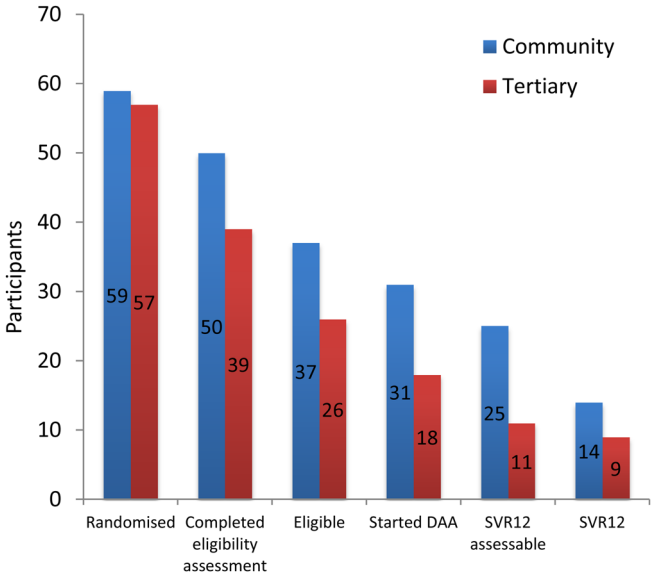
Background and Aims: In order to achieve the World Health Organisation hepatitis C virus (HCV) elimination targets, it is essential to increase access to treatment and retention in the HCV care cascade. The Prime Study is an Australasian study that aims to determine the effect of providing transient elastography (TE) and direct acting antiviral (DAA) treatment in the community on the proportion of people commencing treatment and achieving cure, especially amongst people who inject drugs (PWID).

Method: People with HCV infection were recruited at primary health care centres and randomized to receive eligibility assessment including TE (Australian sites only) and DAAs at their primary health centre (intervention arm), or the local tertiary hospital (standard of care (SOC) arm). Participants assessed as cirrhotic (liver stiffness ≥ 12.5 kPa) were ineligible and were referred to tertiary care. Study endpoints included key milestones in the care cascade; eligibility assessment, commencing DAA and achieving cure. Participants could exit the study at any milestone by failing to attend or declining to schedule further appointments.

Results: We report preliminary findings from the first 120 participants. 97% had ever injected drugs; 48% had injected in the last six months. 116 participants were randomized; 59 to the intervention arm and 57 to the SOC arm.

Of 59 participants in the intervention arm; 50 (85%) completed their eligibility assessment (37 were eligible, 13 were ineligible) and 9 exited the study. Of the 37 eligible participants, 31 commenced DAA and 6 exited the study. The overall treatment uptake rate, excluding ineligible participants, was 31/46 (67%). To date, 25 participants have reached their SVR12 time-point, of which 14 have completed an SVR12 test demonstrating cure and 11 are yet to have an SVR12 test.

Of 57 participants in the SOC arm; 39 (68%) completed their eligibility assessment (26 were eligible, 13 were ineligible) and 18 exited the study. Of the 26 eligible participants 18 commenced DAA and 8 exited the study. The overall treatment uptake rate, excluding ineligible participants, was 18/44 (41%). 11 participants have reached their SVR12 time-point, of which 9 completed an SVR12 test demonstrating cure and 2 are yet to have an SVR12 test.



Conclusion: Preliminary analysis suggests that providing liver assessment and DAA in the community may increase treatment uptake, including in PWID – a key to achieving the elimination targets.

THU-411

Strategic elimination: Efficacy of hepatitis C treatment in people who inject drugs in an urban, underserved clinic in the United States

C. Ramers[1,2], S. Rojas[2], M. Khasira[2], C. Cavanaugh[2], L. Asmus[3]. *[1]School of Medicine, Medicine/Infectious Diseases, La Jolla, United States; [2]Research, Special Populations, San Diego, United States; [3]Public Health, Public Health, San Diego, United States*
Email: christianr@fhcsd.org

Background and Aims: In 2014, only 16% of Americans living with Hepatitis C (HCV) had been treated and half of those cured. Statistical modeling suggests that in order to reach the World Health Organization's goal to treat 80% of those infected with HCV by 2030, scale up of treatment in people who inject drugs (PWID) is needed.

Method: Our urban, underserved clinic system of 23 sites and multiple mobile units started an HCV treatment clinic in 2013. Patients are screened in community drug rehab centers, methadone clinics, at mobile medical units, and needle syringe exchange programs using rapid point-of-care diagnostics followed by immediate phlebotomy for HCV RNA confirmation. Patient Navigators link HCV RNA positive individuals to care and guide them through complex barriers to care, i.e. transportation, health insurance authorization, linkage to drug/alcohol or mental health services. We collected disease and demographic information prospectively; and drug use information on a subset of patients. Non-invasive means were used to assess fibrosis staging, and patients were treated according to published guidelines.

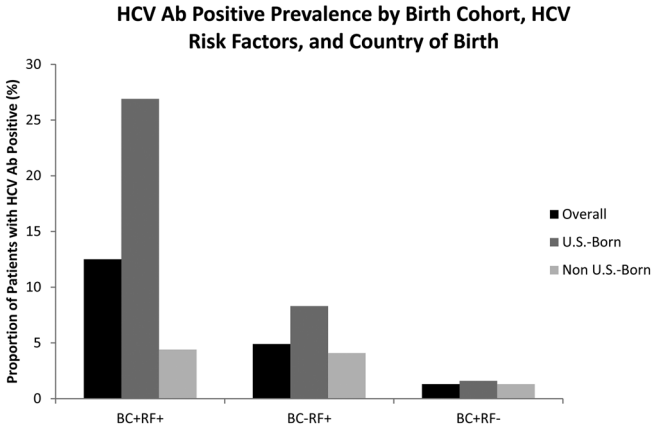
Results: Between 3/1/2013 and 9/30/2017, 413 patients with a detectable HCV RNA test provided information about their injection drug use habits. Most (92%) reported having ever injected drugs, and 50% reported injecting drugs within the previous12 months. Most of the sample was male (73%), Caucasian (39% non-Hispanic, 23% Hispanic) and the average age was 43 years. Of the 380 persons having ever injected drugs, 41% started HCV treatment, compared to 39% of those who had never injected drugs ($p = 0.856$). Of the 153 people injecting drugs in the prior 12 months, 24% started treatment compared to 50% in the group with no injection within 12 months ($p < 0.001$). There was no significant difference in virologic response between patients who had never injected drugs, had ever injected drugs and those who had injected within the past 12 months (99%, 100%, 90%, $p > 0.05$ for all comparisons). Overall, 99% had a sustained virologic response. Only 1 known re-infection has been diagnosed since the start of our program.
Conclusion: Injection drug use within 12 months is associated with decreased likelihood to initiate treatment, but not decreased cure rates. This supports the modeling theory of treatment as prevention. More research is needed to understand what modifiable factors or barriers might be addressed to increase treatment uptake in those who injected drugs in the past 12 months.

THU-412

Among 1945–1965 birth cohort patients with at least one additional hepatitis C virus risk factor, one in eight were positive for HCV antibody: an underserved safety-net population experience

G. Hirode[1], B. Liu[2], T. Bhuket[2], R. Wong[2]. *[1]Alameda Health System-Highland Hosp, Gastroenterology and Hepatology, Oakland, United States; [2]Alameda Health System – Highland Hospital, Gastroenterology and Hepatology, Oakland, United States*
Email: rowong@alamedahealthsystem.org

Background and Aims: Safety-net hospitals are enriched in high risk populations, providing an opportunity for high impact hepatitis C virus (HCV) screening. We aim to evaluate the impact of a pilot program integrating HCV screening into an outpatient endoscopy unit at an urban safety-net hospital.
Method: Consecutive adults undergoing outpatient endoscopy from July 2015-July 2017, who were not previously screened for HCV, were prospectively assessed for HCV screening eligibility using U.S. Preventative Services Task Force guidelines. HCV antibody positive (HCV Ab+) patients were categorized by birth cohort and presence of at least one HCV risk factor: 1945–1965 birth cohort with HCV risk factor (BC + RF+), non-1945–1965 birth cohort with HCV risk factor (BC – RF+) and 1945–1965 birth cohort without HCV risk factor (BC + RF–). Test completion and HCV Ab+ prevalence between groups were compared using chi-squared testing.
Results: Among 1,752 patients evaluated, 67.1% (n = 1,175) were eligible for HCV screening (mean age 57.9 ± 8.2 years, 48.1% male, 90.0% were 1945–1965 birth cohort, 25.7% with at least one HCV risk factor (2.6% HIV positive, 2.6% hepatitis B virus positive, 4.3% history of intravenous drug use, 14.0% previously incarcerated, 5.4% received a blood transfusion pre-1992)). Overall, 15.7% were BC + RF+, 10.0% were BC-RF+, and 78.8% were BC + RF–. Among patients offered testing, HCV Ab test acceptance was significantly higher in BC-RF+ patients compared to BC + RF– (93.9% vs. 82.5%, $p = 0.004$), whereas test completion was significantly higher in BC + RF– compared to BC+ RF+ patients (66.0% vs. 55.8%, $p = 0.03$). Among those who completed testing, overall HCV Ab+ prevalence was 3.4%. When stratified by birth cohort and HCV risk factors, HCV Ab+ prevalence was 12.5% in BC + RF +, 4.9% in BC-RF+, and 1.3% in BC + RF– ($p < 0.001$). When stratified by country of birth, HCV Ab+ prevalence was significantly higher in U.S.-born BC + RF+ vs. non-U.S.-born BC + RF+ patients (26.9% vs. 4.4%, $p = 0.005$), but no significant differences were observed in BC – RF+ patients (8.3% in U.S.-born vs. 4.1% in non-U.S. born, $p = 0.542$) or BC + RF– patients (1.6% in U.S.-born vs. 1.3% in non-U.S.-born, $p = 0.854$).



Conclusion: Among our pilot program integrating HCV screening into outpatient endoscopy, HCV Ab+ was 3.4% among those completing HCV testing. The highest HCV Ab+ prevalence was seen in patients who were born in 1945–1965 birth cohort and had additional HCV risk factors (BC + RF+:12.5%), particularly U.S.-born BR + RF+ patients (26.9%).

THU-413

Among patients being treated in addiction center, alcohol consumption increases the risk of hepatitis C seroconversion and the severity of hepatic fibrosis in those seropositive for hepatitis C virus

M. Doffoël[1,2], F. Habersetzer[2,3,4], T. Baumert[3,4], F.D. Nino[2], L. Jean-Philippe[2], E. Florence[2], H. Carmen[5], C. Frederic[2]. *[1]Pôle Hépato-digestif, Hôpitaux Universitaires de Strasbourg, Strasbourg, France; [2]SELHVA – Service Expert de Lutte contre les Hépatites Virales d'Alsace, Hôpitaux Universitaires de Strasbourg, Strasbourg, France; [3]Hôpitaux Universitaires de Strasbourg, Pôle Hépato-digestif, NHC, Strasbourg, France; [4]Inserm 1110, Strasbourg, France; [5]SOS Hépatites Alsace Lorraine, SOS Hépatites, Strasbourg, France*
Email: francois.habersetzer@chru-strasbourg.fr

Background and Aims: Drug abuse is a recognized risk factor for hepatitis C transmission among users of psychoactive substances, and excessive consumption of alcohol, which is frequently observed, may be associated with an increased risk of advanced hepatic fibrosis. This study in addiction treatment centers aimed to investigate the prevalence of hepatitis C virus infection and the severity of hepatic fibrosis and its correlation with alcohol consumption.
Method: Overall, 934 drug users from eight addiction centers were included between December 2012 and March 2016. They were divided into three groups based on their main addiction: (1) alcohol (n = 511); (2) drug abuse (n = 142); (3) alcohol and drug abuse (n = 281). Seropositivity rates for hepatitis C were compared between the three groups, as were significant ($F \geq 2$) and severe (F3–F4) fibrosis rates evaluated by FibroScan.
Results: The detection rate of hepatitis C was lower in Group 1 (62%) than in Groups 2 (85%) and 3 (81%) ($p < 0.001$). Hepatitis C seropositivity rates were, respectively, 4.4%, 30% and 42.3% in Groups 1, 2, and 3, and differed significantly between Group 1 and Groups 2 and 3 ($p < 0.001$) as well as between Groups 2 and 3 ($p = 0.02$). Significant fibrosis ($F \geq 2$) was observed in, respectively, 34%, 15% and 29% of users in Groups 1, 2 and 3, and differed significantly between Group 2 and Groups 1 and 3 ($p < 0.001$). The rate of severe fibrosis was lower in Group 2 (7%) than in Groups 1 (21%) and 3 (18%) ($p < 0.001$).
Conclusion: Between 7% and 21% of drug users consulting at addiction centers had severe hepatic fibrosis. The risk of severe fibrosis was 2.6 times greater among those addicted to alcohol. The seropositivity rate for hepatitis C increased with excessive alcohol consumption (+41%), suggesting a rise in risk behaviors.

THU-414

Prevalence and clinical characteristics of portal vein thrombosis in HCV related cirrhosis: a cohort of Egyptian patients

O. Alhadad[1], E.A. Sameea[1], M. Elsabaawy[1], O. Elshaarawy[1], M. Houseni[2]. [1]*National Liver Institute, Hepatology Department, Shebine Elkom, Egypt;* [2]*National Liver Institute, Radiology Department, Shebiene Elkom, Egypt*
Email: oelshaarawy@liver.menofia.edu.eg

Background and Aims: Portal vein thrombosis (PVT) is not an uncommon complication occurring during the course of liver cirrhosis, frequently in its advanced stages. We aim to estimate the prevalence of PVT and its clinical characteristics in a cohort of Egyptian HCV related cirrhotic patients.
Method: This prospective cohort study was conducted on 1,000 cirrhotic patients who were consecutively admitted at National Liver Institute (NLI) hospital, Menoufia University in the period from February 2017 to August 2017. All cases were investigated at least by abdominal ultrasound and Doppler study for presence as well as the extent of PVT and any focal lesion(s), and/ or any better modality like triphasic computed tomography (CT) scan or magnetic resonance imaging (MRI). Patients were divided into the PVT and non-PVT groups and accordingly, the clinical characteristics and complications associated with PVT in cirrhotic patients were analyzed.
Results: PVT was found in 216 (21.6%) out of the one thousand cirrhotic patients, consecutively admitted to our hospital and included in the study. Hepatocellular carcinoma associated PVT represented 72.7% (n = 157) of PVT group. Most of these patients (70.4%) and (85.2%) had complete PVT and were in the stage of hepatic decompensation respectively. In PVT group, 56% of patients had at least one episode of portal hypertensive bleeding, 33.8% had abdominal pain and 27.8% presented with jaundice. Portal bilopathy was diagnosed in two cases (%0.9). Extent of portal vein system occlusion to superior mesenteric vein was detected in 5.6% of patients with PVT (n = 12). There were significant differences between PVT and no PVT patients as regards platelet count, AST, ALT, total bilirubin, creatinine and alfa fetoprotein. In respect to complications; abdominal pain, portal hypertensive bleeding, jaundice and hepatic encephalopathy, no statistically significant differences were found between both groups. However, there was a significant association between ascites and PVT ($p < 0.001$). Male gender and presence of focal lesion were independent predictors of PVT development in HCV cirrhotic patients.

Table: Backward stepwise logistic regression analysis of factors associated with development of PVT in cirrhotic HCV patients.

	B 1	S.E.	Wald test	p-value	OR	95% C.I.	
						Lower	Upper
B 0	0.016						
Gender	−0.773	0.299	6.662	0.010	0.462	0.257	0.830
Presence of focal lesion	0.249	0.121	4.266	0.039	1.283	1.013	1.625
Portal Cavernoma	21.583	9323.808	0.000	0.998	2362861875.419	0.000	–

Conclusion: The PVT is as prevalent as 21.6% in a cohort of Egyptian patients with HCV-related cirrhosis and is significantly associated with ascites. The severity of liver disease, Presence of focal lesion and male gender are independent predictors of PVT.

THU-415

Outcomes of an opt-out strategy for Hepatitis C testing in the East Midlands prison estate

K. Jack[1], B. Thomson[2], W. Irving[2]. [1]*Queens Medical Centre, Hepatology, Nottingham, United Kingdom;* [2]*Queens Medical Centre, Microbiology, Nottingham*
Email: kathryn.jack@nottingham.ac.uk

Background and Aims: Prison populations in the UK have a high prevalence of hepatitis C (HCV) infection and are likely to support propagation of viral infection. In 2014, Public Health England (PHE) introduced a new and radical strategy of opt-out testing for blood borne virus infection, linked to the use of Dried Blood Spot (DBS) as the default sampling technique. The HCV elimination campaign is dependent upon a both a proactive testing and an accurate sampling process. We have evaluated the implementation and outcomes of this policy for HCV infection in the prison establishments in the East Midlands region of England.
Method: Seven prisons operationalized the policy of offering DBS testing for a 12 month period beginning in January 2016 and were included in the study. Details of the numbers of individuals entering each prison per three months were obtained via a Freedom of Information request to the UK Ministry of Justice and therefore provided an accurate denominator population. All DBS samples are sent to a single microbiology laboratory that routinely reported outcome data to the research team.
Results: 15,290 people entered the seven prisons during 2016, of whom 1,417 were tested using DBS (9.3%). Of those, 280 (19.8%) were noted to be small DBS samples but still tested, and 47 (3.3%) samples were rejected. Overall 108/1417 (7.6%) were found to be anti-HCV positive. The four prisons who predominantly received intake directly from the courts tested the lowest percentage of people: 2.4%, 2.6%; 5.3% and 10.9%, yet n = 93/523 (17.4%) tested anti-HCV positive. The three prisons who primarily received prisoners transferred from another establishment tested a higher proportion: 22%; 27% and 37.5% but only n = 15/879 (1.7%) tested anti-HCV positive.
Conclusion: Our study demonstrates that, despite the introduction of an opt-out testing strategy and the widespread uptake of DBS testing, rates of testing for HCV in East Midlands Prisons remains both low and variable. There was striking variability in both testing and positivity rates in prisons which received directly from the court system in comparison to those which received transfers solely from other prisons. The effect of the small DBS samples on the accuracy of the test results is not clear. Prison nurses require on-going training and support to undertake this sample collection technique effectively, and adequate resources to operationalize this policy.

Evaluation of a hepatitis C virus core antigen assay in dried-blood spots: a cohort study

F. Lamoury[1], S. Bajis[1], D. Martinez[1], Y. Mowat[1], I. Jayasinghe[1], M. Martinez[1], P. Cunningham[2], B. Catlett[2], B. Jacka[1,3], P. Marks[1], J. Grebely[1], G. Cloherty[4], G. Dore[1], T. Applegate[1]. [1]*The Kirby Institute, UNSW Sydney, Viral Hepatitis and Clinical Research Program, Sydney, Australia;* [2]*St Vincent's Centre for Applied Medical Research, Sydney, Australia;* [3]*Centre de recherche du CHUM, Montreal, Canada;* [4]*Abbott Diagnostics, Chicago, United States*
Email: tapplegate@kirby.unsw.edu.au

Background and Aims: Simple and affordable tests that enable diagnosis of active hepatitis C virus (HCV) infection are required to scale up treatment. This study evaluated the performance of HCV core antigen (HCVcAg) detection in plasma samples and capillary-blood samples collected by dried blood spot (DBS).
Method: Plasma and DBS samples were collected from participants in an observational cohort enrolled at three sites in Australia (two drug treatment clinics and one homelessness service). This study evaluated the sensitivity and specificity of the ARCHITECT HCV Ag (Abbott Diagnostics) test for the detection of HCV core antigen (HCVcAg) in plasma and DBS compared with the Abbott RealTime HCV Viral Load assay on plasma. The sensitivity and specificity for the detection of HCVcAg (>3 fmol/l) for the detection of HCV RNA and diagnosis of HCV RNA >3,000 IU/ml were calculated for both plasma and DBS.
Results: Of 205 participants enrolled with sufficient sample available, 200 had paired HCVcAg results on plasma and capillary DBS samples, in addition to HCV RNA on plasma. Participants receiving HCV

therapy were excluded from analyses (n = 14). HCV RNA was detected in 29% of participants ([95% CI 22.6–36.1], 54 of 186). For detection of HCV RNA and diagnosis of HCV RNA (≥3,000 IU/ml) in plasma, the sensitivity of the ARCHITECT HCV Ag plasma assay was 98.1% (95% CI 90–100) and 100% (95% CI 93–100), respectively. For the detection of HCV RNA and diagnosis of HCV RNA (≥3,000 IU/ml) in plasma, the sensitivity of the ARCHITECT HCV Ag DBS assay was 90.7% (95% CI 80–97) and 92.5% (95% CI 82–98), respectively. The specificity for HCVcAg in plasma and DBS was 100% (95% CI 97–100), for both RNA thresholds. One participant had a viral load less than 3,000 IU/mL (424 IU/ml), and tested HCVcAg negative on plasma and DBS. Five HCV RNA positive samples were false negatives when assessed for HCVcAg in DBS (424, 3437, 28674, 85114, 26595 IU/ml).
Conclusion: These data indicate HCVcAg in plasma and DBS may be a suitable tool for HCV surveillance and diagnosis of chronic HCV infection, particularly in low- and middle-income countries. Further studies are required to evaluate the clinical performance of HCVcAg in individuals with low viral load, including those on HCV therapy.

THU-417
Antiviral treatment of hepatitis C improves glucose metabolism along the entire spectrum from normal glucose tolerance to diabetes

A. Gualerzi[1], M. Bellan[1], S. Bianco[1], M.T. Minh[1], C. Smirne[1], R. Bonometti[1], A. Re[1], S. Favretto[1], R. Minisini[1], G.P. Carnevale-Schianca[2], M. Pirisi[1]. [1]*Università del Piemonte orientale, Translational Medicine, Novara, Italy;* [2]*AOU Maggiore della Carità, SCDU Medicina Interna 1, Novara, Italy*
Email: rosalba.minisini@med.uniupo.it

Background and Aims: Insulin resistance (IR) complicates frequently chronic hepatitis C virus (HCV) infection, leading to an increased incidence of type 2 diabetes mellitus among infected patients. Indeed, it is well known that diabetes control of these patients benefits of successful treatment with either interferon-based regimens or direct antivirals (DAA). Whether the same applies to more subtle alterations of glucose metabolism is unknown. We aimed to fill this gap.
Method: The study population included 82 HCV RNA positive patients (48 males, median age 66 years, 73 with advanced fibrosis, 41 HCV-1b), attending the liver clinic of an academic hospital, not previously known to be diabetics. A standard oral glucose tolerance test (OGTT) was performed in all patients before starting DAA treatment and after its conclusion. OGTT results were interpreted according to the American Diabetes Association guidelines.
Results: Based on the results of the baseline OGTT, the majority of patients had evidence of abnormal glucose metabolism (N = 45, 54%; impaired fasting glucose (IFG) 10%, impaired glucose tolerance (IGT) 16%, IFG + IGT 12%, while 17% were diabetics). Conversely, only a minority of them (N = 37, 45%) were normally glucose tolerant. At the end of treatment, HCV RNA quantification was below the detection threshold (HCV RNA <12 UI/ml), for all the subjects enrolled. A significant decrease in glucose and insulin plasma concentrations was evident both at fasting and after 60 and 120 minutes, leading to a significant reduction in the Homeostasis model assessment (HOMA)-IR (from 3.42 [2.66–5.38] to 2.80 [1.78–3.95]); $p < 0.001$ and a corresponding increase in insulin sensitivity (ISI Belfiore from 0.49 [0.26–0.75] to 0.64 [0.42–0.91]; $p < 0.001$) despite a significant reduction in insulin secretion (EFP Stumvoll from 1363.0 [959.2–1730.0] to 1264.0 [975.8–1588.0]; p = 0,027). Moreover, a significant decrease in glycated hemoglobin was observed ($p = 0.008$), and two patients, formerly categorized as diabetics, did not satisfy criteria OGTT for diabetes anymore. The number of patients with normal glucose tolerance increased from 37 (45.1%) to 53 (64.6%); $p = 0.013$), which was paralleled by a reduced number of those satisfying criteria for prediabetic conditions (31 (37.9%) vs. 17 (20.8%); $p = 0.025$).
Conclusion: After treatment with DAA, glucose metabolism parameters of HCV infected patients improve early and affect the entire pathophysiologic spectrum of glucose metabolism.

THU-418
Lymphomas incidence in HIV/HCV coinfected versus HIV monoinfected patients over twenty-one years of follow up (1993–2014)

Á.M. de Cea, I. Rodríguez-Osorio, H. Meijide, J. Baliñas, J.D. Pedreira, M. de Los Ángeles Castro Iglesias. *Instituto de Investigación Biomédica de A Coruña (INIBIC)-Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC), Grupo de Virología Clínica, Spain*
Email: alvaro.mena.de.cea@sergas.es

Background and Aims: Hepatitis C virus (HCV) in coinfected HIV patients could play a role in the development of lymphomas. The aim of this study was to evaluate the incidence of Hodgkin lymphoma (HL) and non Hodgkin lymphoma (NHL) in HIV-monoinfected and HCV coinfected (HIV/HCV) patients and to compare them with the general population and to analyze the time from HIV infection to lymphoma development.
Method: All lymphomas in HIV infected patients in follow up (FU) in a tertiary hospital were recorded. The period of time of the study was: 1993–2014. A data base was created where epidemiological, demographic, clinical and immunovirogical characteristics were recorded. Lymphomas incidence was evaluated and comparative analysis was done between HIV-monoinfected and HIV/HCV. The FU of the patients was done until last programmed visit, death or lost of FU. GLOBOCAN register was used to calculated the standard incidence rate (SIR) to compare with general population.
Results: A total of 2,318 patients where included (37% of them HIV/HCV), being a total of 27,086 patients-years. Lymphomas were identified in 63 cases: 59 NHL and 15 HL; of them, 37 were diagnosed in monoinfected patients and 27 in HIV/HCV, no differences between them were observed (OR:1.25, IC 95%:0.76–2.97). SIR in NHL in monoinfected was 15.6 (9.4–29.7) and in HIV/HCV 12.1 (6.8–23.4), while in HL for monoinfected patients was 17.2 (5.0–60.3) and 28.4 (8.3–98.8) in HIV/HCV. HIV monoinfected were diagnosed of lymphoma at the HIV diagnosis or first year after diagnostic in 64.9% of the cases, while in HIV/HCV this statement happened in 25.9%. Only 18.9% of monoinfected patients were on antiretroviral treatment at the diagnostic while 66.7% of the HIV/HCV ($p < 0.001$). The median of CD4 count at the lymphoma diagnostic was 36 cél/µl (10–212) in monoinfected vs 198 cél/µl (24–608) in HIV/HCV ($p < 0.001$). Over the FU 62.5% of the patients died (11 months [0–23] after lymphoma diagnostic). Of them, 52.5% mortality cause was lymphoma, with no significance differences observed between monoinfected and HIV/HCV. In HL, 13/15 of the cases achieved complete remission. Survival rate was better for HL than NHL (86.6% after 2 years of diagnosis vs 32.5%).
Conclusion: Lymphomas incidence (HL and NHL) observed in HIV-monoinfected and HIV/HCV is 15 times higher than in general population. Lymphomas in HIV/HCV developed latter and with a good immunovirological control. It is remarkable the high incidence of HL in HIV/HCV population. This data supports the presumption of a role of HCV chronic infection in the development of lymphomas in HIV-infected patients. It is necessary the HCV cure in this special and vulnerable population.

THU-419

Using hepatitis C viral load distribution data from a global database to derive the optimal limit of detection for a point-of-care diagnostic test

J Morgan Freiman[1], J. Wang[1], P. Easterbrook[2], G. Kamkamidze[3], M. Krajden[4], A. Loarec[5], F. Marinucci[6], N.V. Kinh[7], R. Njouom[8], S.S. Solomon[9], T. Tsertsvadze[10], L.F. White[11], C. Denkinger[6], B. Linas[12]. *[1]Boston University Medical Center, Infectious Diseases, Boston, United States; [2]World Health Organization; [3]Georgia Hepatitis C Elimination Program; [4]British Columbia Center for Disease Control; [5]MSF; [6]FIND; [7]TREAT Asia; [8]Center Pasteur of Cameroon; [9]Johns Hopkins University; [10]Infectious Diseases and Clinical Immunology Research Center; [11]Boston University School of Public Health; [12]Boston University Medical Center, Infectious Diseases, Boston,*
Email: j.morgan.freiman@bmc.org

Background and Aims: A low-cost point-of-care test (POCT) for hepatitis C virus (HCV) viraemia is a critical step toward HCV elimination. Our aim is to inform the limit of detection (LOD) for an affordable POCT.

Method: We established a cross-sectional dataset with HCV testing data from 8 countries. We included participants of all ages with HCV viraemia. We excluded individuals on HCV treatment. We analysed the distribution of HCV viral load for the first detectable HCV RNA available, and derived the LOD required to identify 97% of infections. We then performed multivariate logistic regression to identify characteristics associated with low-level viraemia in the bottom 3% of the distribution to investigate risk for false negative results with a less sensitive POCT.

Results: The dataset included 66,061 individuals with HCV viraemia from Canada (41.6%), Cameroon (4.8%), Georgia (44.8%), India (8.3%), Indonesia (0.2%), Malaysia (0.001%), Thailand (0.2%), and Vietnam (0.1%). The mean age was 48.3 years. The majority were male (75.8%), and genotype 1 infected (40%). There were 5.8% with HIV, and 10.8% with hepatitis B virus (HBV) co-infection. Fibrosis stage was known for 44.8%, among whom 11.5% were Metavir stage 4. HCV RNA showed a normal distribution with a 97% threshold value of 1130 IU/mL (95% CI 1125, 1140). The OR for low-level HCV viraemia among those with HIV was 1.05 (95% CI 1.01, 1.77). HBV co-infection was not significant. Multivariate analyses adjusting for age, country, genotype, sex, and fibrosis found an OR of 2.9 (95% CI 2.32, 3.63) among 18–30 year olds compared to those > 65, and an OR of 1.84 (95% CI 1.49, 2.26) for individuals in Cameroon compared to Canada. Females had an OR of 1.22 (95% CI 1.09, 1.36) compared to males. Lastly, the OR for fibrosis stage F4 was 2.59 (95%CI 2.06, 3.27) compared to stages F0-1. Despite higher ORs for low-level viraemia in these subpopulations, the threshold of 1,130 IU/ml held >95% sensitivity in all sub-groups.

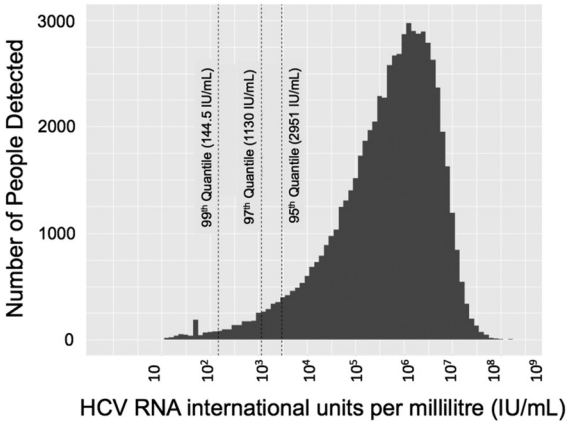

Figure: Frequency distribution of HCV RNA in international units per mililitre (IU/mL) among 66,061 patients with hepatitis C viraemia in a global database assembled from cohorts and laboratory data in the countries of Canada, Cameroon, Georgia, India, Indonesia, Malaysia, Thailand, and Vietnam.

Conclusion: In this global dataset, a POCT with a LOD of 1130 IU/mL would identify 97% of chronic HCV. Recently acquired infection with fluctuating viraemia likely contributed to the increased OR among 18–30 year olds. Additionally, as HCV predominantly replicates in hepatocytes low-level viraemia in advanced cirrhosis is expected. A criterion for an HCV POCT to have LOD = 1,130 IU/ml could facilitate affordable product development and expand the reach of HCV testing in resource-limited settings.

THU-420

Early HCV viral kinetics in the setting of transplantation of kidneys from HCV-infected deceased donors into HCV-negative recipients

D. Goldberg[1], R. Reddy[1], E. Blumberg[1], G. Cloherty[2], V. Holzmayer[2], M. Kuhns[2], R. Bloom[1], P. Abt[1], D. Sawinski[1], A. Sicili[1], M. Levine[1], A. Naji[1], P. Porrett[1], S. Nazarian[1], M. Kaminski[1], V.V. Deerlin[1], J. Smith[1], C. Gentile[1], P. Reese[1]. *[1]University of Pennsylvania, Philadelphia, United States; [2]Abbott Laboratories, East Windsor, United States*
Email: David.goldberg@uphs.upenn.edu

Background and Aims: Hundreds of organs from deceased donors with HCV are discarded each year, leading to proposals to transplant these organs into HCV-negative patients. Yet little is known about the transmissibility and kinetics of viral replication in this setting.

Method: THINKER (Transplanting Hepatitis C Kidneys into Negative Kidney Recipients; CT.gov # NCT02743897) is a single-center trial of transplanting kidneys from HCV-infected donors into HCV-negative recipients. Kidney transplant (KT) recipients were tested for HCV RNA on day 3 post- KT via the hospital assay (Roche Cobas Apliprep/ Taqman) and treated with Elbasvir/Grazoprevir when HCV was detected. Recipient blood was drawn with plasma extracted, frozen, and archived, and tested in batches using the Abbott RealTime HCV 0.5 ml Viral Load assay.

Results: Among 20 subjects, 12 (60%) had post-KT day 1 and/or 2 samples archived (8 did not have samples archived due to timing of KTs). Among 7 subjects with day 1 samples, HCV RNA was detectable in 5 cases on day 1 and was detectable in a sixth on day 3 [Table]. HCV RNA was detectable in all 5 subjects whose first HCV RNA was on post-KT day 2 [Table]. On day 3, 11 (91.7%) of subjects had a quantifiable HCV RNA; the twelfth had an undetectable HCV RNA on the Abbott platform, but a detectable but not quantifiable HCV RNA at the hospital lab and was started on treatment per protocol. Median time from initiation of Elbasvir/Grazoprevir to an undetectable viral load was 8 days (IQR: 6–12 days). KT recipients from donors with an HCV viral load ≥5 log all had detectable HCV within 48 hours.

Table: Table of viral loads (Abbott RealTime HCV assay)

Donor viral load, log IU/mL	Post-transplant							
	Day 1	Day 2	Day 3 (treatment start date)	Day 4	Day 5	Day 7 ± 1 day	Day 14 ± 3 days	Day 21 ± 3 days
5.1	1.7	1.84	2.95	2.74	1.54	–	0	0
5.1	1.41	2.35	3.02	2.97	2.29	–	0	0
3.8	0	0	1.36	–	1.81	–	–	0
N/A	1.0	1.85	2.58	–	–	1.59	0	0
N/A	1.56	3.01	3.29	–	–	1.46	–	0
5.5	–	1.83	2.58	–	1.0	0	0	0
5.5	–	1.76	2.73	1.84	–	1.0	0	0
7.3	3.31	3.71	3.86	–	2.56	1.94	0	0
5.4	–	1.1	1.29	1.81	1.08	0	0	0
5.4	–	1.76	2.24	1.32	1.42	1.0	0	0
6.0	–	1.0	1.28	1.1	–	0	0	0
3.1	0	0	0	0	0	0	0	0

Conclusion: During acute HCV infection via intentional transmission thru KT, HCV showed early viral positivity. Some donors had low viral loads, thus it is unclear if spontaneous HCV clearance might have occurred had we not started therapy after detection of HCV. Despite thymoglobulin induction, the time to HCV clearance on therapy was short, suggesting the potential for trials of shorter therapy duration in the future.

Screening for neurocognitive dysfunction in non-cirrhotic chronic hepatitis C infection in an Irish academic unit

D. Ferguson[1,2], O. Strahan[3], P. O'gorman[4], M. Iqbal[5], J. Gormley[4], S. Mckiernan[6,7], R. Coen[8], C.P. Doherty[1,2], S. Norris[6,7]. [1]*University of Dublin, Trinity College Dublin, Academic Unit of Neurology, Dublin, Irland;* [2]*St. James's Hospital, Neurology, Dublin, Ireland;* [3]*University of Dublin, Trinity College Dublin, Psychology, Dublin, Ireland;* [4]*University of Dublin, Trinity College Dublin, Physiotherapy, Dublin, Ireland;* [5]*St. James's Hospital, Hepatology, Dublin, Ireland;* [6]*University of Dublin, Trinity College Dublin, Clinical Medicine, Dublin 8, Ireland;* [7]*St. James's Hospital, Hepatology, Dublin, Ireland;* [8]*St. James's Hospital, Mercer's Institute for Successful Ageing, Dublin, Ireland*
Email: dr.dwj.ferguson@gmail.com

Background and Aims: The reported prevalence of neurocognitive dysfunction in chronic hepatitis C (HCV) infection is 30%. In Ireland, between 30,000–50,000 people are believed to be infected with HCV, however, there is no Irish data on the prevalence of HCV-related neurocognitive dysfunction. The reversibility of neurocognitive dysfunction with viral eradication using newer HCV treatments is also unknown. We have designed the CANDI study (Hepatitis **C A**ssociated **N**eurocogntive **D**ysfunction in **I**reland) to address these questions. The first part of the study aims to determine the prevalence of neurocognitive dysfunction by screening all chronically infected, non-cirrhotic patients using the Brief NeuroCognitive Screen (BNCS).
Method: Since August 2016 we have been undertaking a prospective, cross-sectional, assessment of patients attending the hepatology service at St James's Hospital, (Dublin, Ireland). Screening involves an interview with the research team and administration of the BNCS and HADS (Hospital Anxiety and Depression Scale). Results are adjusted using age and education matched normative data. Inclusion criteria are as follows: age ≥ 18, hepatitis C virus RNA positive and capable of giving informed consent. Pertinent exclusion criteria include: co-infection with HIV and/or hepatitis B, visual/motor impairment and liver cirrhosis. Those who screen positive for impairment are then recruited to the CANDI study, a longitudinal study employing neuropsychological tests and neuroimaging techniques to investigate the impact of exercise and viral eradication with direct acting antivirals (DAA) on cognitive dysfunction.
Results: Between August 2016 and November 2017 580 subjects were screened and 431 were eligible for analyses. Of those, 48% screened positive for cognitive dysfunction. The majority were male (64.2%), the median age was 41 years and the median education attained was 11 years. Most subjects (65.8%) were born in Ireland. The most common method of HCV acquisition was from previous intravenous drug abuse (59.1%) and 34.2% are currently prescribed methadone. Factors associated with a positive screen for impairment included lower educational attainment, self-reported symptoms of cognitive dysfunction, screening positive for anxiety or depression using HADS and current prescription of methadone, anxiolytics or anti-depressants.
Conclusion: The interim results of this study highlight the importance of screening for cognitive dysfunction in non-cirrhotic HCV+ patients. Co-morbid conditions increase the burden of this problem. Future results from the CANDI study will address the potential reversibility of this neurocognitive dysfunction using an exercise intervention or viral eradication.

THU-422

Decrease in blood borne viral infections, liver fibrosis and drug use in a Danish prison population

J. Soeholm[1], D. Holm[2], B. Mössner[1], J. Hansen[1], P.B. Christensen[1]. [1]*Odense University Hospital, Department of Infectious Diseases, Odense, Denmark;* [2]*Odense University Hospital, Department of Clinical Immunology, Odense, Denmark*
Email: Jacob.Soeholm@rsyd.dk

Background and Aims: Our study aimed to describe the current prevalence of blood borne viral infections and liver fibrosis in Danish prison inmates and to characterize their drug use behaviors and opioid substitution therapy (OST) coverage.
Method: In seven Danish prisons, prisoners ≥18 years were offered participation in the study. Participation included a questionnaire, testing for blood borne viral infections by Dried Blood Spot sampling and Vibration-Controlled Transient Elastography as a marker for liver fibrosis.
Results: Among 1,098 prisoners, 801 (73%) participated. Of these 618 (77%) had snorted cocaine. Heroin use was reported in 146 (18%). Only 68 (8.5%) had ever injected drugs, 29 (3.5%) had injected while incarcerated and only one (0.1%) was currently injecting, compared to the 43%, 22% and 14% measured 20 years earlier in the same population. Median duration of injecting drug-use was 10 (IQR 4–18) years.
Of the people who inject drugs (PWID) 58 (85%) had received OST compared to 13% 20 years earlier.
The prevalence of chronic viral infections was: hepatitis C (HCVRNA) 3.2% (26/801), hepatitis B (HBsAg) 1.1% (9/801), and antiHIV 0.2% (2/801) compared to 29%, 4.3% and 0% 20 years ago. The prevalence of HCV among PWIDs was 28% compared to 56% 20 years ago.
Median age of the HCV infected prisoners was 44 (IQR 39–47) years, significantly older than non-infected prisoners (30 years, IQR 24–38) $p < 0.001$. Of the HCV infected prisoners 92% had previously been tested for HCV and 62% were aware of being infected.
Prisoners with viral hepatitis (n = 35) had significantly higher liver stiffness measurements with 68% < 7 kPa, 26% 7–10 kPa and 6% > 10 kPa compared to 95%<7 kPa, 2% 7–10 kPa and 3% > 10 kPa among non-infected prisoners (n = 763), p = 0.001.
Conclusion: We found a ninefold decline in the prevalence of HCV corresponding to a fourfold decline in PWIDs and a twofold decrease in prevalence of HCV among PWIDs in Danish prison inmates over the last two decades. There was a more than sixfold increase in OST coverage in the same period. The prevalence of fibrosis was low among the HCV infected prisoners probably reflecting a short duration of infection. Almost all prisoners with chronic hepatitis C had been tested previously but only two-thirds were aware of their infection.
The decreasing HCV prevalence in prisons suggests that the WHO target of 90% reduction in prevalence by 2030 may be within reach in Denmark.

THU-423

Strong correlation of hepatitis B virus prevalence among Mongolian adults 40 to 65 years old of age with HCC mortality rate: A result from the national general hepatitis screening program

U. Baatarsuren[1], M. Myanganbayar[1], S. Narankhuu[1,2], E. Enkhbayar[1], A. Imashkhan[1,3], O.-E. Battulga[1,4], B. Surenpurev[1], U. Dagva[1,2,3], O. Oidosambuu[3,4], A. Enkhbat[3,4], D. Email: n.dashdorj@onomfoundation.org

Background and Aims: Mongolia has the highest mortality rate of hepatocellular carcinoma (HCC) in the world that is nearly twelve times higher than the global average. Our recent study revealed that approximately 400 thousand people are chronically infected with hepatitis B (HBV) or C virus (HCV) in Mongolia and they are at higher risk for developing liver cirrhosis and HCC. According to our recent

study, 60% of Mongolians with chronic HBV infection have hepatitis D virus. Within the Screening Campaign of the Hepatitis Prevention, Control, and Elimination (HPCE) Program, the Government of Mongolia, in cooperation with all relevant public and private stakeholders, is conducting a decentralized general population hepatitis B and C screening in Mongolia. Under the first-ever general population hepatitis screening program in the world, Mongolian citizens who are 40–65 years of age are being screened for hepatitis B and C in 2017. In the current study, we intended to determine the prevalence of hepatitis B (HBsAg), hepatitis C (anti-HCV) among people are 40 to 65 years and their correlation with HCC morbidity and mortality rate in Mongolia.

Method: Total of 286,898 and 287,249 people (~33.4% of Mongolian population in the 40–65 years of age cohort) were screened for anti-HCV and HBsAg, respectively, from June to October of 2017. HBsAg and anti-HCV in participants' venous bloods were detected using HBsAg and anti-HCV rapid diagnostic tests. All participants completed a structured demographic questionnaire. The Pearson's correlation test was used to determine a correlation between the prevalence of HBsAg, anti-HCV and mortality rates (2010 to 2016) in Mongolia.

Results: Overall, 26,193 (9.91%) and 49,389 (15.65%) people were positive for HBsAg and anti-HCV, respectively (Figure). The average HCC mortality rate between 2010 and 2016 was 77.73 ± 37.4 per 100,000 people. By correlating the prevalence with the HCC mortality rate, the Pearson's coefficients resulted at r = 0.64 and r = 0.20 for HBsAg and anti-HCV, respectively.

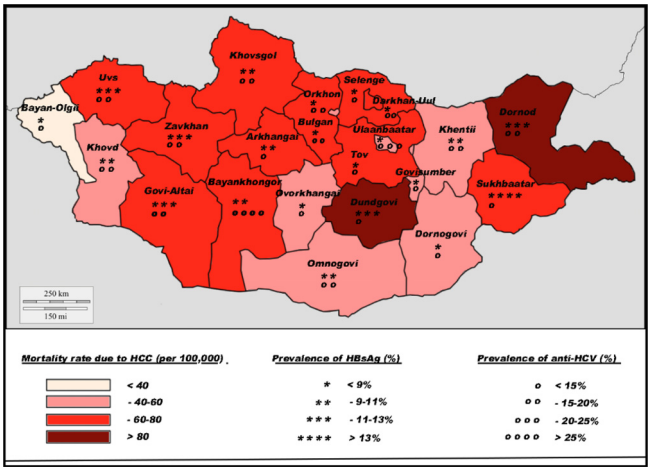

Figure: The mortality rates of HCC by provinces of Mongolia (per 100'000 people). Star and circular shapes denote the prevalence in percentage of HBsAg and anti-HCV positivity in each province. Color coding indicates HCC mortality rates in provinces.

Conclusion: HBV and HCV prevalences are at a similar level compared to recent nationwide prevalence study among Mongolian adults are 40–65 years old (9.91% vs 10.53% for HBV and 15.65% vs 16.17% for HCV). HBV prevalences in Mongolian provinces are strongly correlated with the HCC mortality rates. In contrast, high HCV prevalence showed more strong correlation with HCC mortality rate in Uvs Province in our previous study, indicating the difference between national and provincial differences. More studies need to be carried out and the results of this study need to be furthered refined.

THU-424

Identification of the fast progression and spontaneous regression liver fibrosis phenotypes by a serological collagen turnover profile

S.T. Hjuler[1], D.G.K. Rasmussen[2], M.J. Nielsen[1], D. Leeming[1], S. Gardner[3], Z. Goodman[4], K. Patel[5], D. Schuppan[6], M. Karsdal[7].
[1]Fibrosis Biology, Herlev, Denmark; [2]Fibrosis Biology; [3]Infectious Diseases Therapeutic Area Unit, United States; [4]Hepatic Pathology Consultation and Research, United States; [5]Centre for Liver Disease; [6]Institute of Translational Immunology, Research Center for Immune Therapy (FZI), University Medical Centre Mainz, Mainz, Germany; [7]Biomarkers & Research, Denmark
Email: stp@nordicbio.com

Background and Aims: Collagens are the main constituents of the extra cellular matrix (ECM) and the accumulating fibrotic tissue. There is a need for non-invasive biomarkers that can identify patients with progressive fibrosis and permit monitoring of the response to anti-fibrotic therapy. However, an equally important but often overlooked clinical need is the identification of patients with spontaneous fibrosis regression, as they should neither be included in clinical studies nor treated. Collagen biomarkers may provide a valuable tool for precision medicine.

Methods: Samples of patients with hepatitis C (baseline Ishak scores 2–4) receiving placebo treatment (n = 52) in a phase II trial of a PPAR agonist were included. We excluded the treatment arms of the study to avoid treatment bias. The patients followed with matched liver biopsies at baseline and 52 weeks follow-up, were analysed for serological biomarkers of collagen formation: Type 3 (PRO-C3), Type 4 (P4NP7S), Type 5 (PRO-C5), and markers of collagen degradation Type 3 (C3M), Type 4 (C4M), and Type 6 (C6M) and optimal cut offs were calculated for each biomarkers using the Youden-index. Progressors were defined as patients with an increase in Ishak score from baseline, regressors with a negative Ishak score from baseline.

Results: Logistic regression analysis including PRO-C3 and C6M could identify progressors with liver fibrosis (n = 11) with an AUROC of 0.91 ($p < 0.0001$) and positive and negative predictive values (PPV/NPV) of 54.5%/95.7%. The cut offs associated with progression for PRO-C3 was >22.4 ng/ml and for C6M it was >11.6 ng/ml. High levels of both PRO-C3 and C6M are associated with progression. Logistic regression analysis using PRO-C5, identified those individuals with regression of liver fibrosis (n = 5), with an AUROC of 0.78 $p = 0.0019$ with positive and negative predictive values (PPV/NPV) of 60.0%/95.74%. The cut off associated with regression for PRO-C5 was ≤239.9 ng/ml. Low levels of PRO-C5 are indicative of a regression phenotype.

Conclusions: High levels of markers reflecting Type 3 collagen formation and Type 6 collagen degradation at baseline predicted progressive fibrotic disease. Type 5 collagen formation at baseline could predict regression of disease. These data are the first to demonstrate that progressors and regressors can be identified by a biomarker panel of collagen remodelling. These models might prove efficient as tools to aid in patient identification and drug development.

Email: momoko.iwamoto@epicentre.msf.org

Background and Aims: GeneXpert® (Cepheid) is the only WHO prequalified platform for Hepatitis C Virus (HCV) Nucleic Acid Amplification Testing that is affordable for point-of-care (POC) use in resource-limited contexts. However, its field application in Southeast Asia is constrained by the lack of evidence on its performance among genotype (GT) 6 patients, which is one of the predominant GTs in the region. We therefore aimed to evaluate its field performance among GT6 predominant patient population.
Method: Two 4-module Xpert® machines were set up in an outpatient clinic setting on Jul 27, 2017. Between Aug 1, 2017 and Sep 6, 2017, 775 adult patients seeking HCV diagnosis at Médecins Sans Frontières' clinic inside the HepatoGastro Department of Preah Kossamak Hospital (Phnom Penh, Cambodia) were consecutively recruited. We tested fresh plasma samples for VL using GeneXpert® at POC, and venous samples were also sent to the reference laboratory (Pasteur Institute in Cambodia) for GT and VL testing using Cobas Ampliprep-Cobas TaqMan® HCV test v2.0 (Roche) as the gold standard test. We calculated the sensitivity, specificity, agreement of quantitative VL using the Bland-Altman method, error frequency, and turn-around-time (TAT).
Results: Among 769 consenting patients, 590 seropositive patients were enrolled into the study. The median age was 57; 60% were female; and the fibrosis stages by fibroscan® were 17% F0, 21% F1, 15% F2, 20% F3, and 25% F4. Of the seropositive patients, 77% (n = 454) had detectable VL above the limit of detection (LOD) using the Roche platform and 43% were GT6, 44% GT1, 8% GT2, and 5% indeterminate GT. Considering VL below the lower LOD as undetectable VL, the sensitivity of Xpert® compared to the Roche assay was 100% (95% CI 99.2, 100) and specificity was 98.5% (95% CI 98.4, 99.9). Mean difference between the two quantitative VL results was −0.01 (95%CI −0.05, 0.02) Log_{10} IU/ml for all 454 samples, and −0.07 (95%CI −0.12, 0.02) Log_{10} IU/ml for GT6 (n = 195). The limit of agreement (LOA) was −0.76 to 0.73 for all GTs, and −0.76 to 0.62 for GT6. Among the 454 detectable VL results, 29 (6.4%) Xpert VL results were outside the LOA, among which 7 (3.6%) were GT6. Frequency of error for all samples was 1.2% (7/590), and the median TAT for Xpert® was 0 days compared to 4 days using the gold standard test.
Conclusion: We demonstrated that Xpert® HCV assay has very good sensitivity, specificity, agreement of quantitative results, and TAT compared to the gold standard test in real-world, resource-limited clinical setting even among GT6 predominant HCV patient population.

THU-426

Screening for hepatitis C at the emergency department: Babyboomers should also be screened in Belgium

R. Bielen[1,2], C. Kremer[3], Ö. Koc[1,2,4], D. Hendrickx[3], P. Vanelderen[2,5], N. Hens[6,7], F. Nevens[8], G. Robaeys[1,2,8]. *[1]Ziekenhuis Oost-Limburg, Department of Gastroenterology and hepatology, Genk, Belgium; [2]Hasselt University, Faculty of Medicine and Life Sciences, Hasselt, Belgium; [3]Hasselt University, Faculty of Science, Center for Statistics, Diepenbeek, Belgium; [4]Maastricht University Medical Centre, Department of Medical Microbiology, School of Nutrition and Translational Research in Metabolism, Maastricht, Netherlands; [5]Ziekenhuis Oost-Limburg, Department of Anaesthesiology, Intensive Care, Emergency Medicine and Pain Therapy, Genk, Belgium; [6]Hasselt University, Interuniversity Institute for Biostatistics and statistical Bioinformatics, Diepenbeek, Belgium; [7]University of Antwerp, Centre for Health Economics Research and Modeling Infectious Diseases, Centre for the Evaluation of Vaccination, Vaccine & Infectious Disease Institute (WHO Collaborating Centre) and Unit of Epidemiology and Social Medicine, Antwerpen, Belgium; [8]University hospitals KULeuven, Department of Gastroenterology and Hepatology, Leuven, Belgium*
Email: rob.bielen@uhasselt.be

Background and Aims: The estimated prevalence of Hepatitis C viral infection (HCV) in Belgium is low (0.87%), and to date, there is no screening policy available. Several studies in Europe and in the United States have reported higher rates of HCV infection when screening is performed in emergency departments (ED) (2–3% and 10–18%,

Table 1: (abstract: THU-426): Age (by gender), drug use and high endemic birth country are significant risk factors in the final weighted model.

Parameter	Inclusion (HCVAb+)	Estimate	S.E.	*p*-value	Adjusted OR (95% C.I.)	
(Intercept)		-8.19	1.64	< .0001

respectively) and the Centre for Disease Control recommends screening for patients born in the baby boom period (1945–1965) in the United States. We aimed to study the prevalence of HCV in an ED population in Belgium (including the baby boom cohort) and to study the risk factors associated with HCV infection.

Method: We performed a monocentric, cross-sectional seroprevalence study between January and November 2017 in a large non-university hospital in Belgium (Ziekenhuis Oost-Limburg, Belgium). Patients between 18 and 70 years old who presented at the ED were eligible. After informed consent, patients completed a risk assessment questionnaire and were screened for HCV Ab (Abbott HCV 3.0 ELISA) with reflex HCV RNA testing (qRT-PCR). A multiple logistic regression model with post-stratification analysis for the age and gender distribution of the population of Middle-Limburg was used to study the risk factors for HCV infection. A post-hoc power analysis was performed in order to determine the probability of detecting an effect of a given size with a given level of confidence, given the observed sample sizes.

Results: Of 2,913 patients, 2,330 agreed to participate. Of the HCV Ab positive patients, 10 (32.3%) were previously cured, and 9 (29.0%) spontaneously cleared the virus. None of the 12 patients with chronic HCV infection were in follow-up at a hepatology department. We obtained enough power (≥0.8; 95% CI) for the analysis of the baby boom cohort, drug use, tattoos, and imprisonment. In the final weighted model, age (by gender), drug use, intravenous drug use and being born in a high endemic birth country were withheld as significant risk factors for HCV infection ($p < 0.05$, see table). In the final model, the specificity and sensitivity were 0.97 and 0.74, respectively, indicating good discriminative ability.

Conclusion: The prevalence of HCV Ab was higher than previously estimated for the general population in Belgium. However, HCV RNA prevalence was lower. None of the patients with chronic HCV infection were in follow-up at a hepatology department. Screening in drug users, immigrants from high-endemic countries and people born between 1948–1967 is recommended.

THU-427

Factors related to differential HCV therapy success or failure based on clinic location within a single health system: A possible role for increasing access to co-located support services?

J. Sherbuk[1], K. Mcmanus[2], E. Rogawski[3], T. Knick[4], Z. Henry[4], R. Dillingham[1]. *[1]University of Virginia, Division of Infectious Diseases and International Health, Charlottesville, United States; [2]University of Virginia, Charlottesville; [3]University of Virginia, Department of Public Health Sciences, Charlottesville, United States; [4]University of Virginia, Division of Gastroenterology and Hepatology, Charlottesville, United States*

Email: jes2nk@hscmail.mcc.virginia.edu

Background and Aims: The University of Virginia Health System (UVAHS) catchment area includes Appalachia, a region with the nation's largest increase in hepatitis C virus(HCV) infections, fueled by the opioid epidemic. At UVAHS, two specialty clinics provide treatment, gastroenterology/hepatology(GI) and infectious diseases (ID). Our aim was to determine the current state of care within the UVAHS and to identify demographic and behavioral factors that may influence achievement of sustained virologic response (SVR).

Method: A retrospective open cohort study was performed. The study population included individuals ≥18 years with a positive HCV test since 2010. Patient characteristics, including history of substance abuse based on ICD codes, were obtained from the UVA clinical data repository, an anonymized data warehouse.

Results: 5,186 individuals met inclusion criteria. Viral load (VL) was measured in 4,713(91%), and 3,991(85%) had a positive VL confirming chronic HCV. Among those with chronic HCV, 2,536(64%) were evaluated by a specialist, and 916(23%) achieved SVR. Of the 2,233 individuals evaluated by GI, 764(34%) achieved SVR. Of the 805 individuals evaluated by ID, 260(32%) achieved SVR. For the GI clinic, multivariate analysis revealed that outpatient diagnosis and proximity were associated with increased odds of SVR and substance abuse and indigent status with decreased odds (Table). For the ID clinic, male gender and outpatient diagnosis were associated with increased odds of SVR and age with decreased odds.

Table: Patient characteristics associated with SVR

Characteristic	GI		ID	
	OR(95% CI)	p	OR (95% CI)	p
Age ≥30 years	1.2 (0.8–1.8)	0.42	0.2 (0.2–0.8)	0.01
Male	0.9 (0.7–1.1)	0.28	1.5 (1.1–2.1)	0.02
History of substance abuse	0.4 (0.3–0.7)	<0.001	0.8 (0.5–1.5)	0.53
Outpatient diagnosis	1.5 (1.0–2.1)	0.03	1.9 (1.1–3.3)	0.03
Diagnosis in 2014–2017	1.1 (0.9–1.4)	0.23	1.3 (0.9–1.8)	0.19
Indigent	0.7 (0.6–0.9)	0.001	1.1 (0.8–1.6)	0.66
Proximity	1.7 (1.4–2.1)	<0.001	1.1 (0.8–1.6)	0.44

Conclusion: Patient characteristics associated with achieving SVR differed by clinic, though overall SVR rates were similar. Those with substance abuse and low income had lower odds of SVR in the GI clinic. The ID clinic is co-located with a Ryan White clinic, a federally-funded clinic that provides comprehensive care to people living with HIV. The ID clinicians can access established protocols and referral networks for social services, mental health treatment, and substance abuse counseling. The GI clinic does not have the same resources. Successful completion of HCV treatment for patients with social barriers including substance use and/or poverty may require additional support services not routinely available in GI practices. The Ryan White model of HIV care may be a useful template for building programs across health systems to address the HCV epidemic.

THU-428

Use of medications with clinically important drug-drug interactions with direct-acting antivirals for the treatment of chronic hepatitis C infection: Focus on ethinyl estradiol and HMG CoA reductase inhibitors

S. Corman[1], J. Liu[2], C. Nwankwo[2]. *[1]Pharmerit International; [2]Merck & Co., Inc*

Email: chizoba.nwankwo@merck.com

Background and Aims: The development of new direct-acting antivirals (DAAs) has expanded treatment options and improved outcomes in patients with chronic hepatitis C (CHC). However, clinically important drug-drug interactions (DDIs) with concomitant medications can limit therapeutic options for patients with comorbid conditions. Product labeling for some recently approved DAAs includes recommendations for avoidance and/or modified dosing of ethinyl estradiol-containing medications (including, but not limited to oral contraceptives) and HMG CoA reductase inhibitors ("statins"). The aim of this study was to estimate the proportion of CHC patients who would be impacted by these DDIs among Medicaid and commercially insured populations.

Methods: This is a retrospective cohort study using Truven MarketScan® Commercial Claims and Encounters and Medicaid claims data. The study included patients aged ≥18 years who were continuously enrolled in the respective health plan between January 1, 2015 and December 31, 2015. Patients with CHC were identified based on ICD-9 codes (70.44, 70.54). Study outcomes included the prevalence of ethinyl estradiol-containing medications among women (stratified by age 18–44 and ≥45), and the prevalence of statin use among both men and women, over 12 months.

Results: A total of 38,917 Medicaid and 26,035 commercially insured patients with CHC were included in the analysis. Of these, 48% of Medicaid patients and 39% of commercially insured patients were females. Among females of child-bearing age (18–44 years), 9.4% of Medicaid and 17.5% of commercially insured patients received ethinyl estradiol-containing medications during the study period (Table).

Table: (abstract: THU-428): Prevalence of use of ethinyl estradiol-containing medications and statins in patients with CHC

	Medicaid			Commercial		
	Males n = 20,166	Females 18–44 years n = 6038	Females ≥45 years n = 12,713	Males n = 15,888	Females 18–44 years n = 1586	Females ≥45 years n = 8561
Ethinyl estradiol-containing medication, n (%)	N/A	570 (9.4%)	10 (0.08%)	N/A	277 (17.5%)	55 (0.6%)
Statin, n (%)	3028 (15.0%)	221 (3.7%)	1946 (15.3%)	2286 (14.4%)	40 (2.5%)	932 (10.9%)
Ethinyl estradiol-containing medication or statin (%)	3028 (15.0%)	783 (13.0%)	1955 (15.4%)	2286 (14.4%)	313 (19.7%)	979 (11.4%)

The prevalence of statin use was approximately 15% in both males and females ≥45 years old who are insured by Medicaid, and was 14.4% and 10.9% in male and female commercially insured patients, respectively. Overall, 14.8% of Medicaid and 13.7% of commercially insured patients received at least one medication from either of the classes of interest.

Conclusions: Medications with clinically important DDIs assessed in this study are used in nearly 15% of patients with CHC. Clinicians caring for patients with CHC should consider these interactions when selecting DAA regimens.

THU-429

Strong increase of acute HCV infections in HIV-negative men having sex with men

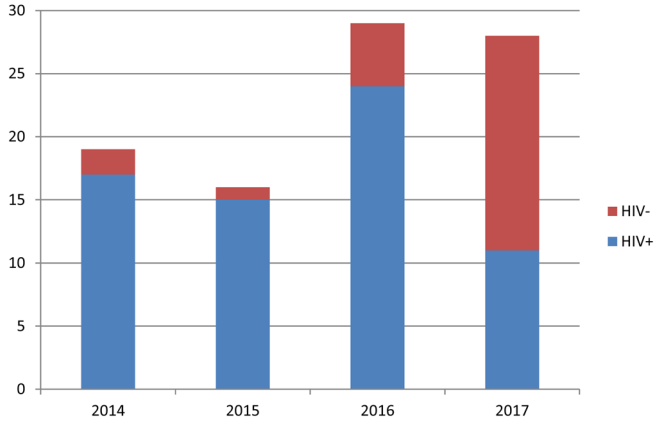
L. Cotte[1], M. Astrie[2], A.-C. Uhres[3], F. Bailly[4], S. Radenne[5], C. Ramière[6], C. Brochier[2], P. Miailhes[1], M.-A. Trabaud[6], J.-C. Tardy[6], M. Godinot[7], P. Chiarello[7], O. Guillaud[8], P. Pradat[2]. *[1]Hôpital de la Croix-Rousse – HCL, Infectious Diseases, Lyon, France; [2]Hôpital de la Croix-Rousse – HCL, Clinical Research Center, Lyon, France; [3]Hôpital de la Croix-Rousse – HCL, Pharmacy, Lyon, France; [4]Hôpital de la Croix-Rousse – HCL, Hepatology, Lyon, France; [5]Hospices Civils de Lyon, Hepatology Department, Lyon, France; [6]Hôpital de la Croix-Rousse – HCL, Virology Laboratory, Lyon, France; [7]Hôpital Édouard Herriot – HCL, Infectious Diseases, Lyon, France; [8]Hôpital Édouard Herriot – HCL, Gastroenterology, Lyon, France*
Email: laurent.cotte@chu-lyon.fr

Background and Aims: The epidemic of sexually transmitted HCV initially started in HIV-infected (HIV+) men having sex with men (MSM) reporting at-risk sexual practices such as Chemsex or other practices leading to mucosal trauma. Only anecdotal cases were reported to date in HIV-negative (HIV−) MSM.

Method: All acute HCV infections in MSM diagnosed in Lyon University Hospital from 2014 were identified from mandatory multidisciplinary discussions before DAA initiation and from database extraction for spontaneously cured infections. HIV status, at-risk practices for HCV (IV/ nasal drug use, participating in sex party, fisting), bacterial STI diagnosis within 3 months, HCV genotype and treatment status were retrieved from medical chart. Each patient gave written consent. The study was approved by the institution' Ethics Committee.

Results: From January 2014 to October 2017, 92 acute HCV infections (71 first infections, 21 reinfections) were observed in 86 MSM (63 HIV +, 23 HIV−). Median age (IQR) was 45 (36–52) years. Risk factors for HCV included IV drug, nasal drug, sex party, fisting and any drug or sexual risk in 34%, 31%, 66%, 22% and 83% respectively. All HIV+ MSM but one were receiving antiretroviral treatment. Median (IQR) CD4 cell count was 647 (510–758) cells/mm^3, and HIV viral load was <50 copies/ml in 95% of cases. Only 68% of HIV− patients were receiving PrEP at the time of diagnosis, while HCV was diagnosed at PrEP screening in 16% of cases. Genotype was 1a, 3a, 4d and unknown (spontaneous cure) in 53%, 5%, 33% and 9% of cases, respectively. The number of cases per year in HIV− MSM increased from 2 cases in 2014 to 17 cases in 2017 (figure). G4d decreased from 11 cases in 2014 to 5 cases in 2017, while G1a increased from 3 cases in 2014 to 19 cases in 2017. Spontaneous cure occurred in 11 cases (12%). Three patients were lost to follow up and 1 patient died from suicide. HCV treatment was initiated in 74 cases and is pending in 3 cases. SVR12 was observed in 43 cases, 2 patients were reinfected before SVR12, 1 patient relapsed and SVR results are pending in 28 cases.

Figure 1: acute HCV infections in MSM



Conclusion: The epidemic of sexually transmitted HCV infections in MSM in Lyon appears on the rise, both in HIV+ and in HIV− patients receiving or attending PrEP. Whether this increase is related to an increase in high-risk practices in PrEP users or to early identification of cases following systematic screening remains unclear. Screening of at-risk patients, harm reduction interventions and early treatment should be combined to contain this epidemic.

THU-430

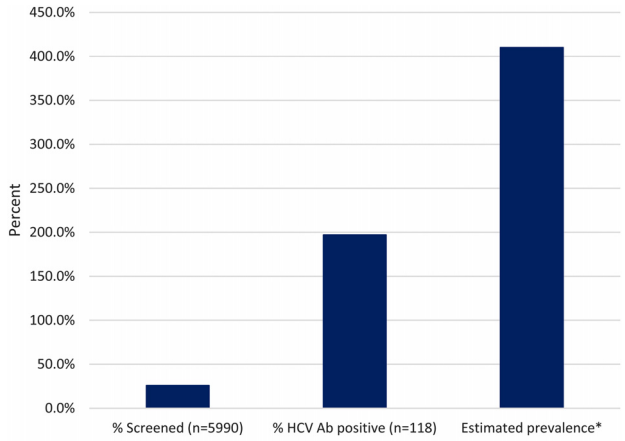
Implementation of a unique hepatitis C care continuum model in a resource limited setting

P. Mathur, E. Comstock, B. Emmanuel, D. Riedel, S. Kottilil. *Institute of Human Virology, University of Maryland School of Medicine*
Email: pmathur@ihv.umaryland.edu

Background and Aims: There has been a rapid evolution of chronic hepatitis C (HCV) treatment with the introduction of direct-acting antivirals. However, a lack of trained providers hinders the escalation of HCV treatment in resource-limited settings. Recently, we conducted the NIH ASCEND study, demonstrating that provider task-shifting is a safe and effective model to expand HCV treatment. We sought to translate the ASCEND model to Rwanda and evaluate the effectiveness of our training program internationally.

Method: An ASCEND-model didactic training program was established in Kigali, Rwanda for providers who had never treated HCV. Our training sessions focused on HCV diagnosis and management, as outlined by the AASLD and Rwanda National Guidelines. We evaluated the effectiveness of our training in three ways. First, each provider completed the same 10-question test (1 point each) before the didactic training and immediately after. Paired and independent *t*-test analyses were used to determine the difference in test score between pre- and post-training overall and by country in SAS 9.4. Second, we evaluated the number of patients screened for HCV after the training. Third, we identified the number of patients who were HCV antibody positive.

Results: We analyzed the pre- and post-test results for 11 new HCV providers in Rwanda and 18 in the U.S. (as part of the ASCEND study). The mean difference in score among Rwandan and U.S. providers was an increase of 17% (p = 0.03) and 21% (p = 0.005), respectively. In the paired analyses from pre-test to post-test, there was an overall increase of score by 20% (p < 0.0001), an increase of 17% (p = 0.008) among matched Rwandan providers, and an increase of 21%(p = 0.0014) among matched U.S. providers. During the follow-up phase of the study, 5,990 of 23,119 (26%) patients seen in Kigali were screened for HCV, and 118 (2%) had a positive antibody (Figure).



*Reference: Gupta et al. (2017). PLOS ONE 12(3): e0174148.

Figure: Number of patients screened for hepatitis C antibody and prevalence of HCV Ab in Rwanda, based on study findings. Our results estimate a lower prevalence than that which has been estimated in the literature.

Conclusion: The ASCEND model is highly effective in training new providers and can be applied to resource-limited settings, such as Rwanda. Our program provides insight into prevalence of HCV in an area where the epidemiology of HCV is relatively unknown. However, despite initiatives to increase HCV screening in Rwanda, our findings suggest there may be barriers to screening that have yet to be elucidated. Given Rwanda's significant accomplishments in the HIV era, the HCV care continuum can be successfully escalated using the ASCEND training model.

THU-431

The IL6-174 C/C genotype is associated with high quality of life scores in patients with chronic hepatitis C

D.A. Vieira[1], G.A. Rocha[2], L.R. Da Cunha[1], A.D. Gomes[2], R. Teixeira[1,3], D.M.M. Queiroz[2], L.D. Silva[1,3]. *[1]Viral Hepatitis Ambulatory, Instituto Alfa de Gastroenterologia, Hospital das Clínicas, Belo Horizonte, Brazil; [2]Laboratory of Research in Bacteriology, Faculdade de Medicina da Universidade Federal de Minas Gerais, Brazil; [3]Faculdade de Medicina da Universidade Federal de Minas Gerais (UFMG), Internal Medicine, Minas Gerais, Brazil*
Email: lucianadinizsilva@gmail.com

Background and Aims: Little is known about the association between cytokine genetic variations and health-related quality of life (HRQOL) in patients with chronic liver diseases. In chronic hepatitis C (CHC), single nucleotide polymorphisms (SNPs) in the promoter region of *IL10* has been associated with clearance of HCV and progression of hepatic disease. Furthermore, the presence of the *IL6*-174 G/G genotype (high-producing IL-6) was associated with a worse outcome of the chronic hepatopathy. Taking into account that the influence of these SNPs on the HRQOL of patients with CHC has not been studied, we investigated the frequency of *IL10*-1082G/A, -819C/T and -592C/A, and *IL6*-174G/C SNPs in CHC patients. We also evaluated their association with domains and summaries of HRQOL.

Method: One hundred and thirty-two consecutive patients (mean age 52.6 ± 11.4 years; 45.5% males; 81.8% non-cirrhotic patients and 18.2% with compensated cirrhosis) attending a referral centre for hepatitis and 98 age- and sex-matched healthy controls were evaluated using the Mini-International Neuropsychiatry Interview and the Medical Outcomes Study 36-Item Short-Form Health Survey. Cytokine genotyping was carried out by a pre-designed Taqman SNP genotyping assay. Multiple linear regression analyses were used to quantify independent associations between HRQOL summaries [physical component summary (PCS) and mental component summary (MCS)] and the variables of interest (clinical, psychiatric, sociodemographic, *IL6* and *IL10* SNPs). The study was approved by Ethics Committee of UFMG.
Results: The distribution of the genotypes followed the Hardy-Weinberg equilibrium. No single polymorphism was distributed differently between CHC patients and healthy individuals. In the multivariate analysis, educational level (>9 years of schooling) (β = 5.42; 95%CI = 1.97 to 8.86; p = 0.002) was positively associated with, but systemic arterial hypertension (HTN) (β = –4.50; 95%CI = –8.13 to –0.86; p = 0.02) was inversely associated with PCS scores. *IL6*-174 C/C (low-producing IL-6) genotype (β = 4.55; 95%CI = 0.45 to 8.65; p = 0.03) was positively associated with, but major depression disorder (β = –16.58; 95%CI = –21.29 to –11.86; p = <0.001) was inversely associated with MCS scores.
Conclusion: This is the first study to show that *IL6*-174C/C genotype (low-producing IL-6) is associated with high scores of MCS in patients with CHC.

THU-432

Has increased rollout of DAA therapy decreased the burden of late presentation and advanced liver disease in patients starting HCV therapy in Germany?

J. Rockstroh[1], C. Boesecke[1], P. Ingiliz[1], B. Florian[2], K.-G. Simon[3], L. Thomas[4], K. Schewe[5], J. Schulze, Z. Wiesch[6], D. Hüppe[7], S. Christensen[8], S. Mauss[2]. *[1]Bonn University Hospital, Department of Medicine I, Bonn, Germany; [2]Center for HIV and Gastroenterology, Düsseldorf, Germany; [3]Practice for Gastroenterology, Leverkusen, Germany; [4]Infektiologikum, Frankfurt, Germany; [5]Infektionsmedizinisches Zentrum Hamburg, Hamburg, Germany; [6]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [7]Practice for Gastroenterology, Herne, Germany; [8]CIM Infectious Diseases, Münster, Germany*
Email: christoph.boesecke@ukbonn.de

Background and Aims: Directly-acting agents (DAA) against HCV have impressively improved treatment outcome of HCV therapy including patients with cirrhosis. To date, it remains unclear if widespread DAA usage has already led to a reduction in HCV-positive patients presenting with advanced liver disease. More recently, a consensus definition of advanced liver disease has been developed which defines advanced liver disease due to chronic viral hepatitis as a patient with chronic hepatitis B, C or D who shows significant fibrosis (≥F3 assessed by APRI score >1.5, FIB-4 > 3.25, Fibrotest >0.59 or alternatively a transient elastography (FibroScan) >9.5 kPa) with no previous antiviral treatment. Therefore, we assessed the proportion of HCV-positive patients presenting with advanced liver disease at DAA treatment initiation over time in the German hepatitis C cohort (GECCO).
Method: The GECCO cohort is a multicenter cohort from 9 German sites. All treatment-naïve HCV mono- (n = 1.168) and coinfected (n = 282) patients (n = 1450) initiating DAA-based treatment since 2014 were analysed. Advanced liver disease was considered a liver stiffness ≥9.5 kPa in transient elastography (n = 1.036) or APRI score ≥1.5 (n = 414). Fisher's exact, chi-square and Mann-Whitney U test were used for statistical analysis.
Results: 938/1.450 (65%) patients were male, median age was 50 years (IQR:41–57). HCV genotype (GT) distribution was: GT1 60%, GT2 5%, GT3 29%, GT4 5%. 157/478 (33%) had IL28B C/C GT polymorphism.

Median baseline HCV RNA was 1.097.704 Mio IU/mL (989.320–1.243.600). Median baseline ALT was 69 U/l (66–73). Liver cirrhosis was present in 323/1.450 (22%). Median baseline CD4 was 596/ul (554–632). 353/1450 (24%) were on opiate substitution therapy (OST). Overall SVR rate was 95.8%.
In 2014 35% (94/272) of all patients presented with advanced liver disease. In the following years that proportion decreased to 24% (149/631) in 2015, to 26% (92/357) in 2016 and to 20% (37/357) in 2017 (p = 0.001).
Conclusion: In line with recommendations from clinical guidelines our real life data confirm that initially DAA therapy was prioritized to HCV patients with advanced liver disease. As a consequence the proportion of patients initiating DAA-based therapy with no or minimal HCV related liver disease has increased in recent years. The use of a consensus definition for advanced liver disease will contribute to both improving the epidemiological understanding of viral hepatitis and other liver diseases as well as testing policies and linkage to care.

Table: Distribution of DAA-treated HCV patients with/without advanced liver disease over time

year	% no/minimal fibrosis (n)	% advanced fibrosis (n)
2014 (n = 272)	65 (178)	35 (94)
2015 (n = 631)	76 (482)	24 (149)
2016 (n = 357)	74 (265)	26 (92)
2017 (n = 190)	80 (153)	20 (37)

THU-433
Cost-effectiveness of one-time screening for hepatitis C virus infection in Korean general population

K.-A. Kim[1], W. Chung[2], H.Y. Choi[3], E.S. Jang[4], M. Ki[3], S.-H. Jeong[4]. *[1]Inje University College of Medicine, Ilsan Paik Hospital, Internal Medicine, Goyang, Korea, Rep. of South; [2]Graduate School of Public Health, Seoul National University, Department of Public Health Science, Seoul, Korea, Rep. of South; [3]Graduate School of Cancer Science and Policy, National Cancer Center, Department of Cancer Control and Population Health, Goyang, Korea, Rep. of South; [4]Seoul National University College of Medicine, Seoul National University Bundang Hospital, Department of Internal Medicine, Seongnam, Korea, Rep. of South*
Email: jsh@snubh.org

Background and Aims: In the new era of direct-acting antivirals (DAA) which are highly efficacious and widely applicable, screening and treating hidden hepatitis C virus (HCV) infection should be considered to control HCV infection. We aimed to evaluate the cost-effectiveness of HCV screening in the targeted Korean general population.
Method: We developed a Markov model simulating the natural history of chronic HCV infection using the data from published literatures, and other secondary sources. We analyzed the cost-utility of one-time screening and treatment with DAA in Korean general population aged 40–65 years from a payer's perspective and the impact of screening on HCV-related health events. Deterministic and probabilistic sensitivity analyses were performed to address the associated parameter uncertainty.
Results: Screening was associated with quality-adjusted life years (QALY) increase of 0.0015 and cost increase of $11.27 per a screened person, resulting in an incremental cost-effectiveness ratio (ICER) of $7,435 per QALY gained, compared with no screening. The introduction of screening was estimated to prevent 32 HCV-related deaths, 19 hepatocellular carcinoma and 15 decompensated cirrhosis per 100,000 screened persons. Sensitivity analyses revealed that ICERs ranged from $4,602 to $12,588 and were sensitive to screening costs, discount rates, and treatment acceptability. At a willing-to-pay of $27,205 per QALY, Korea GDP per capita in 2015, screening was optimal 98.8% of the time.
Conclusion: One-time HCV screening and treatment with DAA in Korean general population aged 40–65 years would be likely to be highly cost-effective, and significantly reduce HCV-related morbidity and mortality compared with no screening.

THU-434
Case finding can successfully re-engage persons lost to follow-up and increase treatment rates in hepatitis C virus services

Y. Gao-Du, S. Brocklesby, L. Corless. *Hull and East Yorkshire Hospitals NHS Trust, Gastroenterology, Herpetology and Endoscopy, Hull, United Kingdom*
Email: lynsey.corless@nhs.net

Background and Aims: The introduction of direct-acting anti-viral agents has transformed the therapeutic landscape of Hepatitis C virus (HCV) in the United Kingdom. Unfortunately however, the myriad challenges of historical treatments led to a sizeable proportion of patients being lost to follow up (LTFU) over the past decade, that are now at risk of progressive liver disease and onward transmission to others. As these patients are likely to derive benefit from currently available treatments we sought to actively re-engage them in care.
Method: Patients were identified through retrospective review of all positive HCV polymerase chain reaction (PCR) tests in our laboratory over 10 years. Letters were sent to primary care practitioners of those who had been LTFU for any reason advising re-referral and highlighting key benefits of new therapies. Available records of attenders and non-attenders were reviewed and analysed for demographic and clinical characteristics.
Results: Of 778 letters sent the majority (77.25%; n = 601) did not trigger a re-referral from primary care, 1 person declined referral and 1 had relocated. 177 (22.75%) were referred, but 104 of these (58.76%) subsequently did not attend. 34.46% (n = 61) of referrals have been seen, with a further 6.78% (n = 12) awaiting an appointment.
Attenders were predominantly male (77.04%; n = 47), with median age 44. Most were previously known to our service, but for 6.56% (n = 4), this was the first referral. The longest period since last contact was 7 years. 2 patients (3.28%) had cirrhosis requiring long-term follow-up. 27 (44.26%) had on-going mental health issues which may have previously precluded therapy. Attenders were significantly less likely to be active injecting drug users (IDU) than non-attenders (27.87% vs 50.96%; p = 0.00374).
37 of 61 attenders (60.66%) have started or are awaiting treatment. A further 15 (24.59%) are completing investigations prior to treatment decision. 4 (6.56%) had spontaneously cleared HCV and have been discharged, and 5 (8.20%) did not attend follow up.
Conclusion: A simple act of letter writing resulted in successful re-engagement of 7.8% of all LTFU to date. Over 85% of attenders have had, or are being worked up for curative therapy, and we also identified a small proportion with cirrhosis. The majority of referral requests resulted in no action from primary care, highlighting an opportunity to boost re-engagement by raising awareness of the individual and public health benefits of therapy. IDU remain hard to reach and are unlikely to re-engage in traditional settings in large numbers, therefore novel approaches should be considered.

THU-435
Direct acting anti-viral therapy rescues neutrophil dysfunction in hepatitis C infection by reduction of heamolysis

B. Leber[1,2], A. Horvath[3], B. Schmerboeck[1,2], A. Posch[4], A. Streit[4], W. Spindelböck[5], P. Stiegler[1], R.E. Stauber[6], V. Stadlbauer[5]. *[1]MEDICAL UNIVERSITY OF GRAZ, Surgery, Transplantation surgery; [2]Center of Biomarker Research in Medicine (CBmed); [3]Department of Gastroenterology and Hepatology, Medical University of Graz, Graz, Austria; [4]Medical University of Graz, Graz, Austria, Austria; [5]Medical University Graz, Internal Medicine; [6]Institute of Pathology, Graz, Austria*
Email: bettina.leber@medunigraz.at

Background and Aims: Hepatitis C (HCV) is a systemic disease that not only impacts on the liver but also shows extrahepatic manifestations from earlier stages of liver dysfunction. HCV induced immune

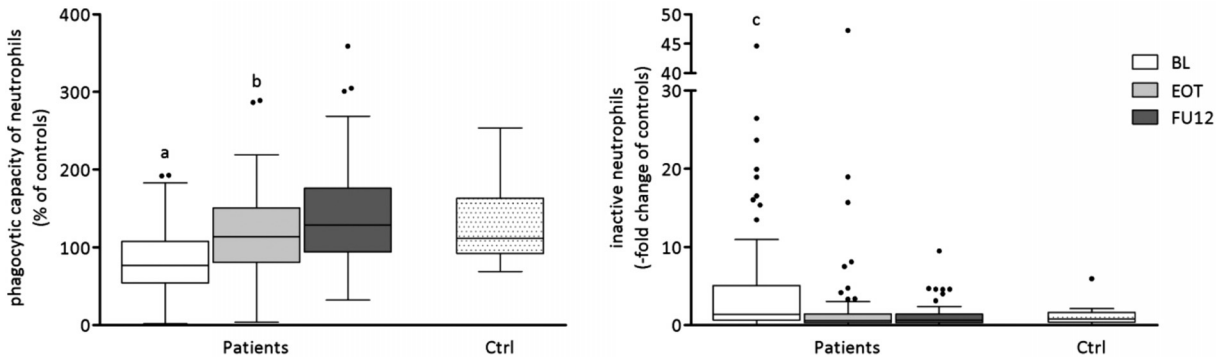


Figure: (abstract: THU-435): Influence of DAA therapy on neutrophil phagocytic capacity and inactive neutrophils of patients compared to control levels. a: $p < 0.001$ vs EOT, FU12 and Ctrl; b: $p = 0.001$ vs FU12; c: $p < 0.001$ vs EOT and FU12; $p = 0.004$ vs Ctrl; BL: baseline; EOT: end of anti-viral therapy; FU12: 12 weeks after EOT.

dysfunction that may lead to an increased risk of infection, is an underestimated extrahepatic manifestation.

Method: A real life cohort of 85 (mean age 57 ± 11 years; 34 female) patients undergoing DAA therapy (sofosbuvir combined with ribavirin or daclatasvir or simeprevir or ledipasvir or a combination of paritaprevir/ritonavir/ombitasvir and dasabuvir) between 4/2014 and 9/2015 was studied. Neutrophil phagocytosis was analysed at baseline, at end of therapy and after 12 weeks follow-up by flow cytometry (Phagotest). Data were compared to 21 healthy controls (mean age 58 ± 7, 12 female). For ex-vivo experiments isolated neutrophils of healthy volunteers and patients were used and incubated with serum of healthy controls and/or patients.

Results: Overall SVR rate was 86%, 66% had cirrhosis and 6 infections occurred during therapy. Baseline phagocytosis was significantly reduced and the number of inactive neutrophils was increased in HCV patients. Both recovered fully after DAA therapy (Fig.). Type of DAA regimen did not impact on neutrophil function. Ex-vivo experiments revealed serum components above 30 kDa to be responsible for neutrophil dysfunction in HCV patients and 3D gel electrophoresis pointed towards haemolysis as a potential mechanism for neutrophil dysfunction. Haptoglobin was investigated as marker of haemolysis during DAA therapy. Changes of haptoglobin levels during therapy mirrored the improvement of neutrophil function over time. Ribavirin delayed the improvement in haemolysis and neutrophil function.

Conclusion: DAAs are able to rescue HCV induced neutrophil dysfunction probably by reducing haemolysis and hence oxidative stress.

THU-436

Treatment of adolescents genotype 4 chronic HCV infected patients with Ledipasvir/Sofosbuvir combination: A real world experience

H.E. Khayat[1], I. Kamal[2], M.H. El-Sayed[3], H. Ayoub[3], M.E. Shabrawy[4], A. Rizk[4], R. Yehia[2], M. Maher[5], Y. Fouad[2], D. Attia[6]. *[1]Theodor Bilharz Research Institute, Hepatology, Gastroenterology and Endemic Medicine, Cairo, Egypt; [2]Faculty of Medicine, Menia University, Hepatology, Gastroenterology and Endemic Medicine, Menia, Egypt; [3]Faculty of Medicine, Ain Shams University, Pediatrics, Cairo, Egypt; [4]Faculty of Medicine, Cairo University, Pediatrics, Cairo, Egypt; [5]Egyptian Military Akademy, Hepatology, Gastroenterology and Endemic Medicine, Cairo, Egypt; [6]Faculty of Medicine, Beni-Suef University, Hepatology, Gastroenterology and Endemic Medicine, Benisuef, Egypt*
Email: dinaattia14@yahoo.com

Background and Aims: The efficacy and safety of Ledipasvir/Sofosbuvir in treatment-naïve adolescent (12–17 years) HCV genotype 1 patients was shown in few clinical trials. The aim of this study was to investigate the effectiveness and safety of Ledipasvir/Sofosbuvir in chronic HCV adolescent patients genotype 4 in the real-world.

Method: This prospective multicenter (6 centers) open label study included 144 adolescent chronic HCV patients with genotype 4 (mean age 14 ± 2, 69% males). All patients received a combination tablet containing 90 mg Ledipasvir and 400 mg Sofosbuvir once daily for 12 weeks. Laboratory and virological markers were evaluated at baseline, week4, week8 and week12 (EOT), and 12 weeks after end of treatment SVR12.

Results: SVR12 was observed in 142/144 patients (99%). The relapsers were previous naïve patients (n = 2/128, 2%) while the experienced patients showed 100% SVR12. ALT normalized at W4 with 88% decrease from baseline ($p < 0.001$), 89% decrease at W8 ($p < 0.001$) and 90% decrease at EOT ($p < 0.001$). AST also normalized at W4 with 86% decrease from baseline ($p < 0.001$), 86% decrease ($p < 0.001$) and 87% decrease ($p < 0.001$) at EOT. No serious side effects were associated. Headache was the most common side effect in all patients (20%). in the experienced patients, Pruritis (31%, $p = 0.007$), diarrhea (44%, $p < 0.001$) and skin rash (19%, $p = 0.002$) were higher than the naïve patients.

Conclusion: Ledipasvir/Sofosbuvir regimen is well tolerated and effective and can be used safely in treating adolescent patients with chronic hepatitis C genotype 4.

THU-437

Impact of a hepatitis C virus electronic medical record screening alert for baby boomers

R. Teply[1], S. Mukherjee[2], M. Goodman[2], T. Guck[2]. *[1]Creighton University; [2]Creighton University*
Email: robynteply@creighton.edu

Background and Aims: It is recommended all patients born between 1945 and 65 have a one-time screen for HCV, but adherence to this guideline is seriously deficient. To improve screening at a health system consisting of 35 primary care clinics, an electronic medical record (EMR) prompt was initiated to identify patients in need of screening. The purpose of this study was to evaluate the impact of the alert and compare the HCV antibody (Ab) positive patients identified prior to the alert to those after.

Method: Data was collected retrospectively for patients seen at a primary care clinic within a regional healthcare system in Midwest United States during June 1, 2016-November 30, 2016 ("Pre-Alert") and December 1, 2016-May 31, 2017 ("Post-Alert"). Data included number screened, demographics, laboratory measurements, referral for treatment and completion of appointment for treatment. Descriptive statistics were determined along with Chi-square and ANOVA tests to examine the differences between the groups.

Results: To date, data has been analyzed for 4 months before and after the alert with the full data set to be presented at the conference.

During the Pre-Alert time period, 29,703 patients were seen in primary care and 482 were screened for HCV (1.62%) with 20 patients found to be Ab positive (4.15%). During the Post-Alert period, 29,913 patients were seen and 5,685 were screened for HCV (19.00%) with 107 patients found to be Ab positive (1.88%). There were no statistical differences between the 2 groups in regards to race, gender, insurance provider, drug use or HCV viral load detection. The Pre-Alert group had 60% of patients with elevated liver tests whereas the Post-Alert group had 27% (p = 0.004). Mean AST to platelet ratio index (APRI) for the Pre-Alert group was 0.84 and Post-Alert was 0.45 (p < 0.001) and mean Fibrosis-4 (FIB-4) score for Pre-Alert group was 2.13 and Post-Alert was 1.55 (p = 0.076).

Conclusion: An alert within the EMR increased the rate of screening for HCV 10-fold for patients being seen in primary care. Five times the amount of HCV Ab positive patients were identified with the screening alert and most of which did not have elevated liver tests or a history of drug use. Such prompts should be implemented to improve screening and linkage to care rates for HCV.

NAFLD: Experimental and pathophysiology

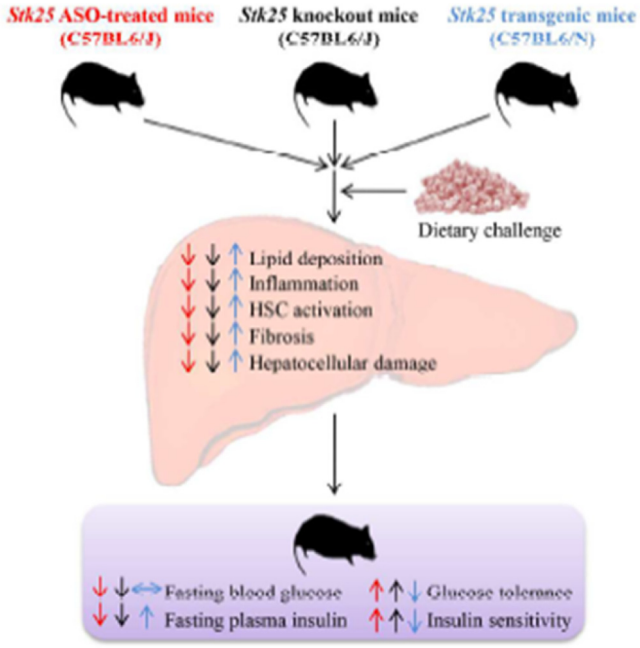
Email: margit.mahlapuu@gu.se

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) contributes to the pathogenesis of type 2 diabetes and cardiovascular disease, and patients with nonalcoholic steatohepatitis (NASH) are also at risk of developing cirrhosis, liver failure, and hepatocellular carcinoma. To date, no specific therapy exists for NAFLD/NASH, which has been recognized as one of the major unmet medical needs of the 21st century. We recently identified serine/threonine protein kinase 25 (STK25) as a critical regulator of energy homeostasis and NAFLD progression. Here, we investigated the effect of antisense oligonucleotides (ASOs) targeting *Stk25* on the metabolic and molecular phenotype of mice after chronic exposure to dietary lipids.

Method: To evaluate the metabolic effect of *Stk25* ASOs *in vivo*, we treated mice on a high-fat diet (for 21 weeks) with *Stk25* ASO#1 or ASO#2 in PBS (50 mg/kg/week), or placebo (PBS), twice weekly for the last 6 weeks of the diet. The NAFLD progression in liver and whole-body glucose and insulin homeostasis were characterized. Furthermore, we genotyped 430 participants of the TÜF study for 11 common tagging SNPs covering major parts of the human *STK25* gene and assessed their associations with liver fat content measured by magnetic resonance spectroscopy.

Results: We found that *Stk25* ASOs efficiently reversed high-fat diet-induced systemic hyperglycemia and hyperinsulinemia, improved whole-body glucose tolerance and insulin sensitivity, and ameliorated liver steatosis, inflammatory infiltration, apoptosis, hepatic stellate cell activation, and nutritional fibrosis in obese mice. Moreover, *Stk25* ASOs suppressed the abundance of liver acetyl-CoA carboxylase (ACC) protein, a key regulator of both lipid oxidation and synthesis, revealing the likely mechanism underlying repression of hepatic fat accumulation by ASO treatment. We also found that STK25 protein levels correlate significantly and positively with NASH development in human liver biopsies, and several common non-linked SNPs in the human *STK25* gene are associated with altered liver fat, supporting a critical role of STK25 in the pathogenesis of NAFLD in humans.



Conclusion: This study provides preclinical validation for the metabolic benefit of pharmacologically inhibiting STK25 in the context of obesity and suggests that therapeutic intervention aimed at reducing STK25 function may provide a new strategy for the treatment of patients with NAFLD, type 2 diabetes, and related complex metabolic diseases.

THU-442

Decreased circulating peripheral blood mucosal associated invariant T cells is correlated with insulin resistance in patients with nonalcoholic fatty liver disease

J. Amer[1], D. Bakry[2], R.A. Sear[2], R. Safadi[3]. [1]*An Najah National University, Faculty of Medicine and Health Sciences, Nablus, Palestine;* [2]*Al-Quds University, Medical Laboratory Sciences, College of Health Professions, Jerusalem, Palestine;* [3]*Hadassah-Hebrew University, Faculty of Medicine, Jerusalem, Israel*
Email: j.amer@najah.edu

Background: Mucosal-associated invariant T (MAIT) cells comprise a subpopulation of T cells that can be activated by bacterial products and cytokines to produce IFN-γ. Little is known about the role of MAIT cells in fibrosis progressions in fatty liver disease.

Aim: To assess frequency and phenotype of MAIT cells with correlation of liver fibrosis severities in NAFLD patients.

Methods: Age, gender, BMI, serum vitamin-D levels, ALT, AST, serum-fasting-insulin levels, HbA1c, HOMA-IR score, TG, HDL, LDL and CRP were correlated with histological outcome (%steatosis, necro-inflammatory activity, fibrosis-scoring) in adult NAFLD cases lacking metabolic-syndrome or other liver etiologies (ANOVA). *In-vitro*, peripheral blood obtained from healthy donors (n = 17) and

NAFLD patients (n = 42, of them 20 with steatohepatitis). Using flow cytometry we identified MAIT cells by the expression of CD3, CD8, CD161 and TCR Vα7.2. For immune phenotyping we used markers like TNFα, CD69, CD38 and IL17.
Results: 42-cases fulfill inclusion/exclusion criteria, all are males, mean age at biopsy 39.4 ± 10.6y, BMI 29 ± 2.8. Ten had cirrhosis as scores were F4. Serum HOMA-IR found the most significant predictor for histological severity. Lower serum insulin levels significantly correlated with decreased hepatic-fat-content but increased liver-injury (CRP, fibrosis-scoring & necro-inflammatory-activity), IR (serum insulin levels, HbA1c & HOMA-IR score) and CRP. Healthy donors had 12.68% ± 1.11 MAIT cells and were significantly decreased in peripheral blood of patients with NAFLD to 10.62% ± 1.37, 3.9% ± 0.71, 1.66% ± 0.08 and 1.2% ± 0.21 with fibrosis grades of F1, F2, F3 and F4, respectively. Moreover, MAIT cells from patients showed higher expression of activation and exhaustion markers such as CD69 and CD38, respectively as compared to heathy donors. MAIT cells had also elevated IL-17 expression, a pro-fibrogenic cytokine as well as TNFα, a pro-inflammatory cytokine. These results were linearly correlated with fibrosis severities. The frequency of MAIT cells was negative correlation with HOMA-IR score ($r = -0.33$, $p = 0.02$).
Conclusion: Decreased expressions of peripheral blood MAIT cells in NAFLD patients were inversely correlated with the fibrosis stage. These results were associated with MAIT cells exhaustions and increased their TNFα and IL17 productions. Our data suggest MAIT cells might contribute to the development of fibrosis in NAFLD and represent a novel therapeutic target.

THU-443

Angiopoietin-2 as therapeutic target for pathological angiogenesis and inflammation in non-alcoholic steatohepatitis

S. Lefere[1], F. Van de Velde[2], S. Raevens[1], S. Van Campenhout[1], A. Vandierendonck[1], S. Neyt[3], C. Vanhove[4], A. Hoorens[5], C. Casteleyn[6], X. Verhelst[1], H. Van Vlierberghe[7], B. Lapauw[2], A. Geerts[7], L. Devisscher[7]. *[1]Ghent University, Gastroenterology and Hepatology, Ghent, Belgium; [2]Ghent University, Endocrinology, Ghent, Belgium; [3]Molecubes, Ghent, Belgium; [4]Ghent University, Institute Biomedical Technology, Medical Imaging and Signal Processing, Ghent, Belgium; [5]Ghent University, Pathology, Ghent, Belgium; [6]Ghent University, Morphology, Merelbeke, Belgium; [7]Ghent University, Gastroenterology and Hepatology, Ghent*
Email: sander.lefere@ugent.be

Background and Aims: Angiogenesis and inflammation are interconnected mechanisms that influence the progression of non-alcoholic fatty liver (NAFL) to non-alcoholic steatohepatitis (NASH). Previous studies have shown that angiopoietin-2 (Ang-2) mediates both these processes. Our aim was to investigate the role of Ang-2 and its potential as therapeutic target in NASH by using human samples, an *in vivo* mouse model and *in vitro* assays.
Method: Serum Ang-2 levels were determined in obese patients undergoing bariatric surgery (n = 105) with concomitant liver biopsy and in healthy controls (n = 30), and in mice fed the methionine choline deficient (MCD) diet. The Ang-2/Tie2 receptor inhibiting peptibody L1-10 (Amgen) was tested *in vivo* (4 mg/kg intraperitoneally three times weekly) in the MCD diet model in a preventive and therapeutic setting (starting at week 0 and after 2 weeks, respectively), and *in vitro* on endothelial MS1 cells. Liver histology and chemokine expression were assessed. The hepatic vascular bed was visualized using corrosion casts. FACS-isolated liver endothelial cells and monocytes were analysed by qRT-PCR.
Results: Serum Ang-2 levels were increased in patients with NASH compared to lean controls, obese patients without steatosis and patients with NAFL (all $p < 0.01$) and correlated with the severity of steatosis ($p < 0.05$), inflammation and ballooning (both $p < 0.001$), but not fibrosis. In line, serum, hepatic, and endothelial Ang-2 levels were increased in MCD diet fed mice ($p < 0.001$), correlating with markers of endothelial dysfunction and inflammation. Efficient *in vivo* dosing was confirmed by increased Ang-2 serum levels in L1-10 treated mice. MCD fed mice treated with L1-10 showed less inflammatory foci and ballooning hepatocytes compared to control treated mice ($p < 0.05$). Chemokine and endothelial dysfunction gene expression were similarly decreased following treatment. Fibrosis, assessed by sirius red area, was reduced. Liver endothelial cells and monocytes from L1-10-treated MCD fed mice expressed lower levels of dysfunction and inflammatory markers compared to cells from control treated mice. LPS-stimulated MS1 cells secreted pro-inflammatory cytokines and showed increased expression of endothelial dysfunction markers which was significantly less pronounced in cells treated with LPS + L1-10.
Conclusion: Angiopoietin-2 mediates the cross-talk between angiogenesis and inflammation in NASH, and is upregulated in humans and MCD fed mice. Our findings provide evidence for Ang-2 inhibition as a therapeutic strategy in NASH.

THU-444

Lipid-induced ASK1 activation in hepatocytes and Kupffer cells mediates the increased vulnerability of fatty liver to Ischemia/Reperfusion injury in mice

C. Imarisio[1], E. Alchera[1], C.B. Revanna[1], G. Valente[2], A. Follenzi[1], E. Trisolini[1], R. Boldorini[1], R. Carini[1]. *[1]University, Health Science, Novara, Italy; [2]University, Translational Medicine, Novara, Italy*
Email: chiara.imarisio@med.uniupo.it

Background and Aims: Steatosis enhances parenchymal injury and inflammation in liver exposed to ischemia/reperfusion (I/R). Several alterations, such as ER stress and increased ROS production are associated to such effects but a final and targetable pathogenic mechanism is still undetermined. This study investigates "in vitro" and "in vivo" a molecular mediator of the interplay among ER stress, ROS and cytotoxic/survival pathways and its role in the susceptibility of steatotic hepatocytes (HP) and Kupffer cells (KC) to hypoxia/reoxygenation (H/R) and of fatty liver to I/R injury and inflammation.
Method: Control or steatotic (treated with palmitic acid, PA) primary mouse HP and KC were exposed to H/R to "in vitro" simulate I/R exposure. C57BL/6 mice fed 9 weeks with control or High Fat diet underwent to a non-lethal partial hepatic I/R.
Results: In HP, PA increases H/R damage, induces ROS production and enhances the stimulation of the ASK1/JNK cytotoxic axis activated by the ER stress mediator TRAF2 during H/R. Prevention of ROS production nullifies the increased susceptibility of HP to H/R and the enhanced ASK1/JNK activation. ASK1 inhibition also completely protects JNK activation and HP damage. In KC, PA alone induces TRAF2 and a consequent ASK1 and p38 MAPK activation. PA also increases KC damage induced by H/R, but oppositely to HP, ASK1 inhibition enhances H/R damage by preventing the stimulation of the survival mediator p38 MAPK. In mice liver, steatosis induces the expression of activated ASK1 in KC, whereas upon I/R exposure, activated ASK1 expression is evident in both in KC and HP. "In vivo", ASK1 inhibition prevents ASK1, JNK and p38 MAPK activation and protects fatty mice liver from I/R-induced transaminases release and from the increase of TNF-alpha and iNOS.
Conclusion: Our results show that: (1) Lipids increase ASK1/JNK activation induced by ER in HP by rising cellular ROS; (2) Lipids activate ASK1/p38 MAPK in KC by promoting ER stress; (3) ASK1 is cytoxic for HP and protective for KC; (4) ASK1 inhibition protects I/R injury and inflammation of fatty liver. These observations indicate that steatosis, by stimulating ASK1, contextually promotes I/R induced liver injury and inflammation by increasing HP damage and protecting the resident hepatic macrophages (KC) and evidence the potentiality of ASK1 inhibitors as novel therapeutic agents to prevent hepatic damage and reduce inflammatory reactions consequent to fatty liver surgery.

Email: serena.pelusi@unimi.it

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is increasingly being recognized as an underlying etiology of hepatocellular carcinoma (HCC), which however remains a relatively rare complication of the disease. Family history and genetic factors (such as the PNPLA3 I148M variant) play an important role in the pathogenesis of progressive NAFLD and HCC.
We examined by whole exome sequencing (WES) approach whether pathogenic and rare mutations predicted to alter protein sequence in candidate genes responsible for inherited liver disease or cancer syndromes are enriched in NAFLD-HCC.
Method: Clinical, biochemical data, personal and family history were collected in 72 HCC, 59 cirrhosis patients from different Italian tertiary centers and 50 local healthy controls without NAFLD. Pathogenic mutations were defined according to ClinVar database, developed to evaluate the genotype-phenotype relationships by integrating data from multiple sources, while enrichment in pathogenic variants was validated using public databases (1000 Genomes, n = 513).
Results: Already known rare pathogenic mutations in candidate genes were enriched in NAFLD-HCC: 40% of patients reported at least one mutation causing liver disease or cancer predisposition ($p < 0.05$ vs. healthy subjects, $p < 0.005$ vs. 1000G). Among the pathogenic mutations, the majority was located in genes involved in predisposition towards genetic liver disease (42%), cancer predisposition (33%) and lipid metabolism (10%).
Furthermore, in NAFLD-HCC patients we identified a significant enrichment of rare mutations (minor allele frequency < 0.001) determining an alteration in protein sequence predicted to alter its function, which resulted in a phenotype predisposing to liver disease (Table).
Supporting the pathogenicity of this second group of mutations, carriage of rare APOB mutations was associated with lower circulating triglycerides ($p = 0.001$) and higher HDL cholesterol ($p = 0.008$).
Conclusion: Rare pathogenic mutations in genes involved in liver disease and cancer predisposition are likely involved in determining predisposition to NAFLD-HCC development.

THU-446

Neurocognitive dysfunction in NAFLD occurs early and is associated with hyperammonemia, neurotransmitter defects, astroglial and microglial activation

N. Arias[1,2], F. De Chiara[1], E. Gómez-Lázaro[3], K.L. Thomsen[1,4], R. Jalan[1]. *[1]UCL Institute for Liver and Digestive Health, Royal Free Campus, London, United Kingdom; [2]Instituto de Neurociencias del Principado de Asturias, INEUROPA, Oviedo, Spain; [3]Basque Country University, Department of Basic Psychological Processes and their Development, San Sebastian, Spain; [4]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus C, Denmark*
Email: karethom@rm.dk

Background and Aims: Memory, concentration and psychomotor dysfunction are frequently described in patients with non-alcoholic fatty liver disease (NAFLD) but the underlying mechanisms are poorly understood. The aim of this study was to characterize the neuropsychological disorders in a rodent model of NAFLD and relate this to the evolution of liver disease.
Method: 45 Sprague Dawley male rats were divided in three groups: chow (NC, n = 15), isocaloric diet (ICD, n = 15) and high-fat high-cholesterol diet (HFHC, n = 15) at different time points (4, 10 and 16 weeks). Severity of liver disease was assessed histologically. Ammonia levels, hepatic ornithine transcarbamylase (OTC) enzyme activity, neuropsychometric tests, brain neurotransmitters and brain astroglial and microglial activation were assessed.
Results: At 16 wks, the HFHC animals developed advanced fibrosis, which was not observed in NC or ICD animals. Progressive hyperammonemia was found from 10 wks in ICD (140 ± 7; $p < 0.01$) and HFHC (138 ± 8; $p < 0.01$), which was associated with progressive reduction in the activity of OTC (ICD: 0.32 ± 0.04, $p < 0.01$; HFHC: 0.25 ± 0.05, $p < 0.001$. Neuropsychometry: Progressive dysfunction was observed in the HFHC animals. Differences in depression and anxiety were found between ICD and HFHC groups at 16 wks compared to NC. Differences in social behavior were found in HFHC group at 4 and 16 wks, paired with differences in spatial working memory in HFHC group at 4 and 16 wks and ICD at 10 weeks, and a delay in the acquisition of spatial reference memory at 16 wks. Neurotransmitters: Dopamine and its metabolites were decreased in the prefrontal cortex in the HFHC group and, serotonin and noradrenaline and their metabolites increased in the hippocampus and striatum of ICD group, respectively. Immunohistochemistry: Microglial cells were activated and increased in the striatum, hippocampus and cerebellum from 10 wks onwards in ICD and HFHC groups. Astroglial changes were increased in the prefrontal cortex, striatum, cerebellum and CA1 subregion of the hippocampus in HFHC group at 10 and 16 wks.
Conclusion: The data show for the first time a temporal evolution of defects of the urea cycle and hyperammonemia that correlate with neurobehavioral disturbances and, microglial and astroglial activation in a clinically relevant rodent model of NAFLD even prior to cirrhosis stages. The data provide an explanation for the poor functioning of NAFLD patients and potential therapeutic targets.

THU-447

Metabolomic patterns associated with known genetic variants for hepatic steatosis and non-alcoholic steatohepatitisidentify biomarkers that may be of utility in predicting adverse liver outcomes

J. Mann[1,2], M. Allison[3], L. Wittemans[1], E.D.L. Rolfe[1], F. Imamura[1], N. Forouhi[1], L.A. Lotta[1], J.L. Griffin[4], A. Koulman[5], C. Langenberg[1], N.J. Wareham[1]. *[1]Institute of Metabolic Science, University of Cambridge, MRC Epidemiology Unit; [2]University of Cambridge, Department of Paediatrics; [3]Addenbrookes Hospital, Cambridge, Department of Hepatology; [4]University of Cambridge, Department of Biochemistry; [5]University of Cambridge, Department of Clinical Biochemistry*
Email: jakemann@doctors.org.uk

Background and Aims: Hepatic steatosis is a common, multifactorial condition strongly associated with obesity and insulin resistance. Not all individuals develop clinical liver disease and biopsy is used in risk stratification of patients with NAFLD. Non-invasive biomarkers for progression are needed. Several loci (rs738409 in PNPLA3, rs58542926 near TM6SF2, and rs641738 near MBOAT7) are associated with non-alcoholic steatohepatitis (NASH), fibrosis, and hepatocellular carcinoma independently of the metabolic syndrome. We aimed to use NASH-associated SNPs to identify biomarkers for NAFLD, in a cohort with detailed metabolic phenotyping.

Method: 9,135 participants from the Fenland Study were assessed for hepatic steatosis using ultrasound and had densely imputed genome-wide genotype data, including NASH-associated SNPs in PNPLA3, TM6SF2, and MBOAT7. All participants underwent DEXA scan for body composition analysis test. 504 metabolites were measured through a combination of targeted metabolomics (176 Biocrates panel, 37 fatty acids, 24 amino acids) and untargeted lipidomics (267

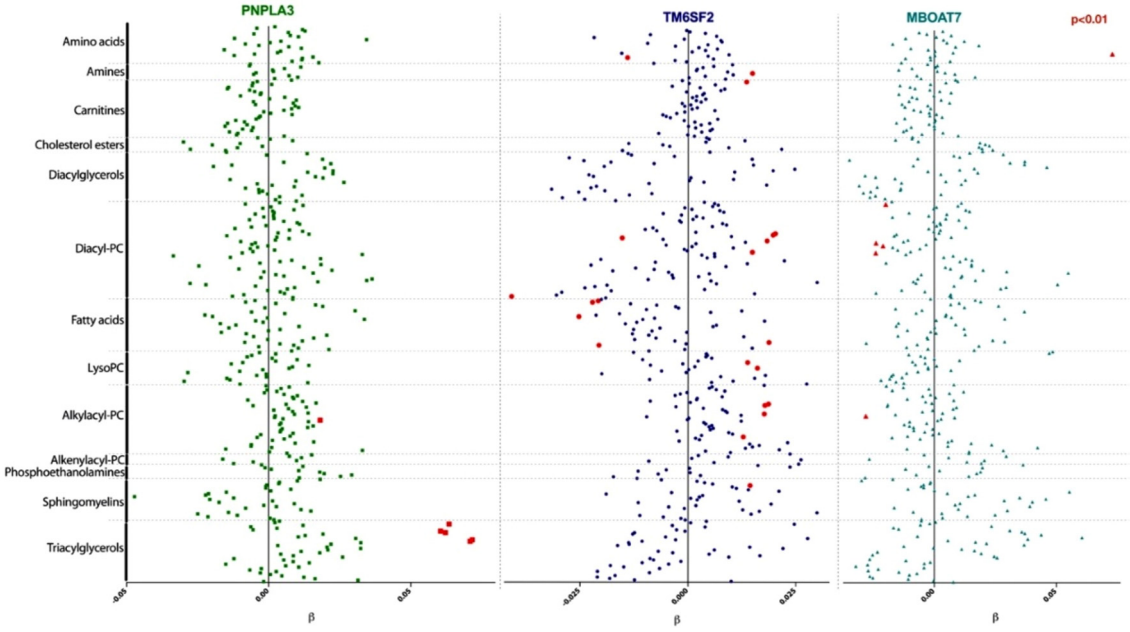

Figure: (abstract: THU-447)

species). Associations of metabolite levels with steatosis variants were assessed using linear regression adjusted for age, sex, ancestry, body fat percentage, hepatic steatosis, fasting glucose, blood lipids, and triglycerides, with $p < 0.01$ considered significant.
Results: Hepatic steatosis was present in 25.1% (2301/9135). Steatosis was independently associated with PNPLA3 (OR 1.4 (CI95% 1.2–1.5)), TM6SF2 (OR 1.3 (CI95% 1.1–1.5)), and MBOAT7 (OR 1.1 (CI95% 1.0–1.2)). Each SNP had a distinct metabolomic profile. The variant inPNPLA3 was associated with higher long-chain, polyunsaturated triacylglycerols, and TM6SF2 variant was associated with higher phosphatidylcholines (PC), whereas MBOAT7 was associated with lower PC, after correction for total lipids. Triacylglycerol C55:5 was the most significantly upregulated metabolite for PNPLA3 (β 0.07 ± 0.02, $p = 1.4 \times 10^{-3}$), whilst diacylphosphatidylcholine C36:2 was most significant for TM6SF2 (β 0.02 ± 0.01, $p = 5.2 \times 10^{-5}$).
Conclusion: Each NASH-associated SNP has a specific lipidomic profile independent of the metabolic markers of glycaemia, lipids and body adiposity is consistent with its reported mechanism of action. We have validated MBOAT7 as a risk factor for steatosis and characterised its metabolomic and lipidomic correlates. These require further assessment in biopsy-cohorts for use as disease-activity biomarkers.

THU-448
Gut barrier dysfunction contributes to the pathological progression of nonalcoholic fatty liver disease induced by high fat diet in mice

J. Peng, F. Huang, J. Leng, H. Tian, Y. Hu. *Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Institute of Liver Diseases, Shanghai, China*
Email: pengjinghua2004@163.com

Background and Aims: To discover the correlation between gut barrier function and the pathological progression of non-alcoholic fatty liver disease (NAFLD).
Methods: (1) Gut barrier dysfunction observation: fourty two C57BL/6J male mice, 12 weeks in age, were randomly divided into control (n

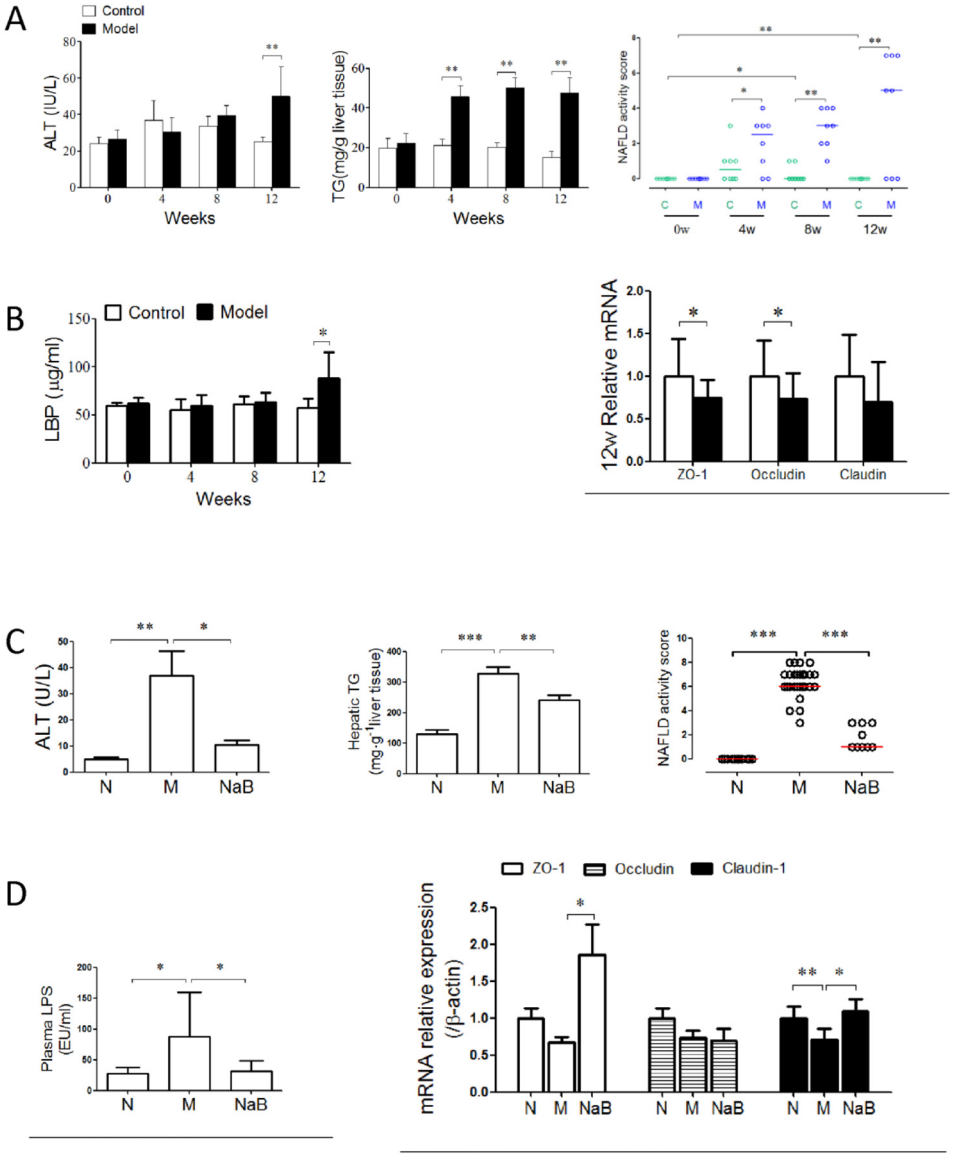

Figure: (abstract: THU-448): (A) Serum ALT, hepatic TG and NAS; (B) Serum LBP content, colonic tight junction mRNA expression; (C) Serum ALT, hepatic TG, NAS; (D) Plama LPS content, mRNA expression of colonic tight junction. ***$p < 0.001$, **$p < 0.01$, *$p < 0.05$.

= 24, control diets, 10% energy originating in fat) and model group (n = 18, high-fat diets, 60% energy originating in fat). At the end of the 0, 4th, 8th and 12th week, mice were harvested. (2) Effects of gut barrier restoration by sodium butyrate (NaB) on NAFLD: thirty C57BL/6J male mice, 12 weeks in age, were randomly divided into control (n = 10, control diets), model group (n = 10, high-fat diets) and NaB group (n = 10, high-fat diets). After 12-week feeding, mice in NaB group were administrated with NaB (200 mg/kg body weight, daily) by gavage, the others with equal volume of sterile water. At the end of the16th week, mice were harvested.

Results: With 12-week high-fat diet feeding, non-alcoholic fatty liver (NAFL) progressed to non-alcoholic steatohepatitis (NASH), as well as increased hepatic triglycerides (TG) and serum alanine aminotransferase (ALT) (Fig. 1A). Simultaneously, sparse and shorten microvilli (data not shown) and decreased tight junction mRNA expression were observed in NASH mice (12-week high fat diet feeding), as well as increased serum LPS binding protein (LBP), the indirect marker of LPS gut-leakage (Fig. 1B). Supply with NaB, the energy source of the intestinal mucosal epithelial cells, the pathological progression in NAFLD was blocked (decreasing NAS, serum ALT and hepatic TG) (Fig. 1C), and LPS gut-leakage was also inhibited (Fig. 1D). Furthermore, NaB supplementation restored the tight junction mRNA expression in colon of the mice (Fig. 1D).

Conclusion: Gut barrier dysfunction contributes to the pathological progression of NAFLD.

THU-449

Inhibitionof IL-1 signaling in hepatocytes retains insulin sensitivity and protects fromhepatocellular injury in non-alcoholic fatty liver disease

N. Gehrke[1], B. Straub[2], N. Hoevelmeyer[3], A. Waisman[3], K.Y. Ook[4], D. Schuppan[5], W. Marcus[1], P.R. Galle[1], J. Schattenberg[1]. *[1]University Medical Center Mainz, Department of Medicine, Mainz, Germany; [2]University Medical Center Mainz, Department of Pathology, Mainz, Germany; [3]Institute for Molecular Medicine Mainz, Mainz, Germany; [4]Institute of Translational Immunology, Johannes Gutenberg-University Mainz, Mainz, Germany; [5]Institute of Translational Immunology, Research Center for Immune Therapy (FZI), University Medical Centre Mainz, Mainz, Germany*
Email: joern.schattenberg@unimedizin-mainz.de

Background and Aims: Despite recent evidence for a causative role of interleukin (IL)-1alpha and IL-1beta in the metabolic syndrome and related liver disease, the impact of IL-1 signaling in hepatocytes in the pathogenesis of non-alcoholic fatty liver disease (NAFLD) remains elusive. Our aim was to study the effect of IL-1 receptor type I (IL-1RI) deficiency in hepatocytes with regards to hepatic steatosis, inflammation and insulin resistance in mice with NAFLD.

Method: Using the Cre/loxP-system we generated transgenic mice lacking all signaling-capable IL-1R isoforms selectively in hepatocytes (Alb-Cre:IL-1RIHep−/−, IL-1RIHep−/−). Male IL-1RIHep−/− mice and wild type (wt) littermates aged 8–12 weeks were fed a high-fat, high-carbohydrate diet (HFD, 35.5% crude fat (58 kJ%)) and drinking water enriched with fructose (55% w/v) and glucose (45% w/v) for 12 weeks (n = 8 mice/group). Gender- and age-matched controls received a corresponding control diet (CD, 5.4% crude fat (13 kJ%)) and plain water (n = 4–7 mice/group).

Results: 12 weeks of HFD-feeding induced obesity and hepatomegaly in all mice, regardless of the genotype. Hepatic tissue analyses from mice fed with HFD revealed an increase in steatosis in comparison to CD-fed animals, but no difference was observed in steatosis induction and the hepatic expression of steatogenic factors including SREBP-1c, ACC, FAS and CPT1 between the genotypes. Despite comparable metabolic alterations on HFD including elevated serum triglycerides, total cholesterol, HDL, LDL and fasting glucose levels, D, insulin resistance was less pronounced in HFD-fed IL-1RIHep−/− mice as proven by intraperitoneal glucose tolerance test, lower insulin and HOMA-IR levels. The expression of the hepatic insulin receptor in IL-1RIHep−/− mice was augmented compared to the wt. In parallel, IL-1RIHep−/− mice were protected from hepatocyte injury as evident by lower ALT levels (20.0 vs. 40.9 U/l). Differences in liver injury were not attributable to the extent of hepatic necro-inflammation as hepatic mRNA levels of IL-1alpha, IL-1beta, IL-6 and CCL2 and macrophage infiltration detected by FACS were comparable between the genotypes.

Conclusion: In a high-fat, high-carbohydrate diet-fed mouse model the disruption of IL-1 signaling in IL-1RIHep−/− hepatocytes retains insulin sensitivity and dampens hepatocellular injury, suggesting that IL-1 suppression could be a promising strategy in the treatment of NAFLD.

THU-450

Mechanism for hypertriglyceridemia and effect of fibrate coadministration during acetyl-CoA carboxylase inhibitor treatment

L. Goedeke[1], J. Bates[2], D. Vatner[1], R. Perry[1], M.W. Ellis[3], T. Wang[2], M. Subramanian[2], R. Myers[2], A. Ray[2], G.I. Shulman[4]. *[1]Yale University School of Medicine, Internal Medicine, New Haven, CT, United States; [2]Gilead Sciences, Inc., Foster City, CA, United States; [3]Yale University School of Medicine, Cellular and Molecular Physiology, New Haven, CT, United States; [4]Yale University School of Medicine, Internal Medicine, Cellular & Molecular Physiology, HHMI, New Haven, CT, United States*
Email: gerald.shulman@yale.edu

Background and Aims: Inhibition of acetyl-CoA carboxylase (ACC) offers an attractive therapeutic strategy for NASH via simultaneous inhibition of fatty acid synthesis and stimulation of fatty acid oxidation. Clinical trials of liver directed ACC inhibitors (ACCi) have found beneficial effects on steatosis. However, elevated plasma triglycerides (TGs) have been observed in some patients. To understand the mechanism for these observations we evaluated the impact of an ACCi on lipid metabolism in diet-induced rodent models of NAFLD.

Methods: Male Sprague-Dawley rats were fed a high fat diet (60% Safflower oil) supplemented with 1% sucrose drinking water (HFSD) for 3 days and then treated with 10 mpk/day ACCi (GS-834356) or vehicle for 21 days. Hepatic TG production was assessed in overnight fasted rats injected with Poloxamer 407, while lipid clearance was measured in rats given an intravenous bolus of 20% Intralipid conjugated with ^{3}H-triolein. Male C57BL/6 mice were fed a fast food diet (FFD) for 5–8 months and then treated with ACCi ± a PPARα agonist, fenofibrate (0.1% in chow), or vehicle for 2–4 weeks.

Results: Oral administration of ACCi to HFSD-fed rats preferentially inhibited ACC enzymatic activity in the liver, reduced hepatic malonyl-CoA levels, and markedly reduced hepatic TG by ~75% ($p \leq 0.05$). Consistent with previous reports, liver-specific inhibition of ACC was associated with an increase in plasma TG levels (~30 to 130% depending on fasting length; $P \leq 0.05$). ACCi-mediated hypertriglyceridemia was attributed to a ~15% increase in hepatic VLDL release and ~20% reduction in lipoprotein lipase activity ($p \leq 0.05$). At the molecular level, these changes were associated with a significant increase in LXR/SREBP1 activation and decrease in PPARα activation. Similar observations, including a dose-dependent increase in plasma TGs, were made in FFD-fed mice. Importantly, combination treatment of FFD-fed mice with fenofibrate reversed alterations in LXR/SREBP1/PPARα, increased fatty acid oxidation and normalized plasma TG levels (all $p \leq 0.05$).

Conclusion: Liver-targeted ACC inhibition reduces hepatic steatosis but increases plasma TGs in rodent models of diet-induced obesity. The change in plasma TGs is mediated by disequilibrium in nuclear hormone receptor regulation that results in increased hepatic VLDL-secretion and reduced systemic TG clearance and was reversed with the PPARα agonist fenofibrate.

THU-451

Effect of exercise on gut microbiota and metabolic status modulation in an in vivo model of early obesity and NAFLD

S. Carbajo-Pescador[1], D. Porras[1], S. Martínez-Flórez[1], M.-V. García-Mediavilla[1], M.J. Cuevas[1], J.L. Mauriz[1,2], E. Nistal[1,3], J. González-Gállego[1,2], S. Sánchez-Campos[1,2]. Complejo Asistencial Universitario de León, León, Spain*
Email: scarp@unileon.es

Background and Aims: Childhood obesity is one of the most serious public health concerns from this century, associated with metabolic syndrome, nonalcoholic fatty liver disease (NAFLD) and gut microbiota alterations. Physical exercise improves obesity and NAFLD progression, modulating the gut microbial balance. We aim to investigate the effect of physical exercise on gut microbiota and the metabolic status of an *in vivo* model of early obesity, metabolic syndrome, and NAFLD.
Method: 21 days old male Wistar rats fed with control (C) or high fat diet (HFD) for 6 weeks followed a 5 weeks-interval aerobic training protocol. Body weight gain and metabolic markers were monitored. Lipid metabolism, pro-inflammatory and oxidative-related gene expression was assessed by RT-qPCR. The total bacteria concentration and the *Firmicutes*/*Bacteroidetes* ratio from faecal samples were assessed by qPCR.
Results: HFD increased body and adipose tissue weight gain (+14% and +44%, vs C, respectively), hepatic steatosis (NAFLD Index NAS:3.4), liver damage (AST:+12%; ALT:+45%, LDH:+36%, vs C), liver triglycerides (TG:+58%, vs C) and insulin resistance (HOMA-IR:+22%, vs C), impairing the gut-liver axis-related inflammation and leading to oxidative stress (TLR4:+286%; TNFα:+154%; NLRP3:+70%; CYP2E1: +380%, vs C). The increased intrahepatic lipid accumulation was associated with altered lipid metabolism-related gene expression (SREBP-1c:+94%; FAT/CD36:+95%; FAS:+57%, vs C). Exercise decreased body weight (−17%), insulin resistance (HOMA-IR:−37%), liver damage (ALT:−20%), NAS (−25%) and the intrahepatic lipid accumulation (−25%) as a result of its lipogenic metabolism modulatory capacity (SREBP-1c:−42%; FAT/CD36:−38%; FAS:−27%), reducing the subsequent lipotoxicity and the exercise ability to improve the inflammatory response induced by the gut-liver axis alteration (TLR4:−26%; TNFα: −5%; NLRP3:−3%; CYP2E1:−43%). HFD-fed rats showed lower intestinal bacteria concentration and higher *Firmicutes*/*Bacteroidetes* ratio, dysbiosis that was partially reverted by exercise.
Conclusion: We provide scientific evidences supporting the use of physical exercise protocols to modulate the intestinal microbiota in the management of childhood obesity and NAFLD development, via its anti-inflammatory, lipid metabolism modulatory and prebiotic capacities. Founded by LE063U16 (Junta de Castilla y León y Fondo Europeo de Desarrollo Regional (FEDER)) y GRS1428/A/16. CIBERehd is funded by Instituto de Salud Carlos III (Spain).

The paracrine effect of visceraladipose tissue obtained at bariatric surgery on primary human hepatic stellatecells grown in human 3D healthy liver scaffolds

Z. Zhang[1], L. Meelberghs[2], L. Frenguelli[1], W. Al-Akkad[1], H. Korf[2], D. Cassiman[2,3], G. Mazza[1], M. Pinzani[1], K. Rombouts[1], S. Van Der Merwe[2,3]. [1]*University College London, Institute for Liver and Digestive Health, United Kingdom;* [2]*University of Leuven, Laboratory of Hepatology, Belgium;* [3]*University of Leuven, Gastroenterology and Hepatology, Belgium*
Email: k.rombouts@ucl.ac.uk

Background and Aims: Emerging data indicate that the progression from simple steatosis (NAFL) to non-alcoholic steatohepatitis (NASH) results from converging pathophysiological events originating in the liver, the adipose tissue, and the gastrointestinal tract. Adipose tissue is recognized as an endocrine organ that secretes adipokines controlling systemic metabolism and energy homeostasis. We previously showed that adipose tissue macrophages are activated in NASH and secrete pro-inflammatory cytokines which play a detrimental role during NAFL/NASH development. In this study the paracrine effect of human visceral adipose tissue (VAT) on primary human hepatic stellate cells (hHSC) cultured on 3D human liver scaffolds was explored.
Method: Freshly obtained VAT biopsies derived from obese patients and control patients undergoing bariatric surgery and cholecystectomy, respectively, were used for short-term culture (LEAN, NAFL and NASH patients). Similar-sized VAT explants were cultured in serum-free medium and conditioned medium was collected after 48 hrs. Human liver 3D scaffolds were obtained by the decellularization of healthy human liver unsuitable for transplantation. Primary hHSC were seeded for 7 days on 3D scaffolds and exposed to adipose tissue conditioned media (AT-CM) for 2 × 24 hrs. H&E staining was performed; RNA was extracted, followed by qPCR for pro-fibrogenic and pro-inflammatory genes.
Results: Primary hHSC homogeneously engrafted in the 3D scaffolds. No significant differences in the expression of pro-fibrogenic and pro-inflammatory genes was found in hHSC exposed to AT-CM derived from LEAN, NAFL and NASH patients and they were similarly upregulated when compared to non-treated cells. Importantly, within the group of samples from NASH patients, the upregulation of ACTA2 and COL1A1 was significantly more evident in samples with evident liver fibrosis. On the other hand, AT-CM derived from diabetic patients induced a significantly higher increase in pro-fibrogenic gene expression in hHSC 3D culture when compared with samples derived from non-diabetic patients, irrespective of the stage of liver fibrosis. HSC-related adipokines expression and characterization of the adipose tissue secretome is ongoing to further explore the mechanism of action on hHSC.
Conclusion: AT-CM-derived from NAFL and NASH patients, marked by different stages of hepatic steatosis, showed a paracrine effect on hHSC. This is the first study exploring the relationship between VAT and hHSCs on human liver 3D scaffold.

Email: luca.valenti@unimi.it

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) represents an emerging cause of cirrhosis and hepatocellular carcinoma (HCC). NAFLD has a strong genetic component and the identification of causal variants underlying disease development and

progression could be important to improve early diagnosis and targeted therapies.
Next Generation Sequencing allows the analysis of entire exomes to underpin disease risk variants. However, an experiment highlights thousands of rare variants per sample leading to high rates of false positives. Variants prioritization methods are hence required.
In this study, we aimed to set up a pipeline to prioritize variants using in silico predictors from a whole-exome sequencing (WES) dataset to highlight novel risk factors for NAFLD progression.
Method:

(i) WES was conducted on a discovery cohort of 105 patients with advanced NAFLD (cirrhosis and/HCC), a preliminary validation cohort of 26 advanced NAFLD patients, and 50 healthy controls.
(ii) Variants were prioritized to select rare damaging variants in genes conserved in humans (Figure A).
(iii) Enrichment in the discovery cohort vs. general population (non-Finnish Europeans of ExAC and 1000G databases and our control group) was evaluated (Figure B).
(iv) Enrichment of variants highlighted in the discovery cohort was evaluated also in the validation cohort (Figure B).
(v) Statistical analysis was performed using R software.

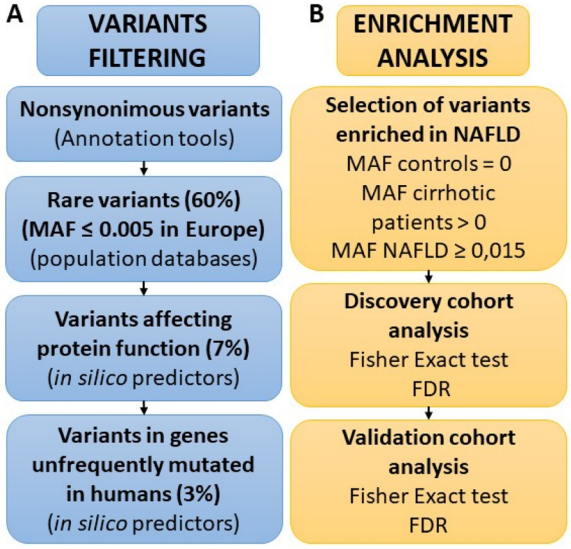

Figure: Filtering (A) and Analysis (B) pipelines.

Results: Enrichment analysis highlighted 8 variants as putative risk factors for liver disease progression. Among these, we found variants in genes of known interest for liver disease progression such as G6PD (FDR = 0.0004, OR = 25.1, CI: 7–69), NOTCH1 (FDR = 0.012, OR = 9.85, CI: 7–69) and ATG7 (FDR = 0.042, OR = 10.7, CI: 3–26).
The enrichment of the variant in ATG7 gene was conformed also in the validation cohort (FDR = 0.02, OR = 29.5, CI: 3–115). This variant resulted enriched in the two cohorts compared with the general population ($p = 4.6*10^{-5}$, OR = 13.8, CI: 4–34).
Conclusion: In conclusion, our analysis highlighted a loss-of-function variant in ATG7 gene and defective lipophagy as a new putative risk factor for progression of NAFLD to cirrhosis and HCC. ATG7 is involved in lipo-autophagy, a biological process of growing interest in the pathophysiology of NAFLD. Moreover, ATG7 deficient mice have been described to develop hepatomegaly and steatohepatitis, supporting an important role for ATG7 in progressive NAFLD.

THU-454
Effect of combined farnesoid X receptor agonist (INT747) and dipeptidyl peptidase-4 inhibitor (sitagliptin) on liver fibrosis
N. Shimozato[1], T. Namisaki[1], T. Akahane[1], K. Moriya[1], M. Kitade[1], H. Kawaratani[1], K. Kaji[1], Y. Okura[1], H. Takaya[1], Y. Sawada[1], N. Nishimura[1], S. Sato[1], S. Saikawa[1], K. Seki[1], M. Furukawa[1], T. Kubo[1], H. Yoshiji[2]. [1]*Japan;* [2]*Nara Medical University, Third Department of Internal Medicine, Kashihara, Japan*
Email: shimozato@naramed-u.ac.jp

Background and Aims: The farnesoid X receptor (FXR) agonist, a bile acid-activated nuclear receptor, has been shown to improve the histologic features of non-alcoholic steatohepatitis (NASH); however, a satisfactory effect on liver fibrosis has not been achieved. We aimed to investigate the combined effect of FXR agonist (INT747) and dipeptidyl peptidase-4 inhibitor [DPP4-I (sitagliptin)] on liver fibrosis in a rat model of NASH.
Method: Fischer 344 rats were fed a choline-deficient L-amino-acid-defined (CDAA) diet for 8 weeks. The therapeutic effect of INT747 (30 mg/kg/day) and Sitagliptin (150 mg/kg/day) was evaluated along with liver fibrosis, lipopolysaccharide (LPS)-toll like receptor 4 (TLR4) regulatory cascade, and intestinal barrier function. The direct inhibitory effect of both INT747 and Sitagliptin on Ac-HSC was assessed in vitro.
Results: The F344 rats fed with CDAA diet developed marked liver fibrosis with deposition of collagen fibers. INT747 and Sitagliptin markedly suppressed CDAA diet induced liver fibrosis as compared with that in CDAA diet group (control group). The combination treatment of INT747 and Sitagliptin exerted a more potent inhibitory effect than either single agent. These inhibitory effects occurred almost concurrently with the suppression of immunohistochemical expression of α-SMA and mRNA expression of TGF-β1 and type-1 collagen-α1 in the liver. The suppressive effects of both agents on hepatic TLR4 mRNA expression were of a comparable magnitude to the observed effect on liver fibrosis, while no significant difference in intestinal TLR4 expression was observed. INT747 and combination treatment significantly attenuated CDAA induced increase in LPS-binding protein (LBP) mRNA expression and intestinal permeability. Semi-quantitative immunofluorescence microscopy revealed that INT747 and combination treatment improved CDAA-diet-induced delocalization and substantially decreased the expression of the tight-junction protein, intestinal zonula occluden-1 (ZO-1) in CDAA-diet-fed rats. In contrast, Sitagliptin had no significant effect on hepatic LPB expression, intestinal permeability or ZO-1 expression. The in *vitro* and in *vivo* inhibitory effects of INT747 and Sitagliptin on TGF-β1 and TLR4 mRNA expression in Ac-HSC were almost in parallel. Sitagliptin was found to directly suppress regulation of Ac-HSC.
Conclusion: INT747 and Sitagliptin have a synergistic repressive effect on liver fibrosis by reversing LPS-induced gut barrier dysfunction and suppressing HSC activation and proliferation, respectively. Combined treatment may represent a promising novel therapeutic approach for NASH.

THU-455
Efficacy of statins for the treatment of non-alcoholic steatohepatitis with mild portal hypertension
M. Bravo[1,2], I. Raurell[1,2], T. García-Lezana[2], M. Torres[2], S. Augustin[1,3], J. Genesca[1,3], M. Martell[1,2]. [1]*CIBERehd, Madrid, Spain;* [2]*VHIR – Vall d'Hebron Institut de Recerca, Liver Unit, Barcelona, Spain;* [3]*Hospital Universitari Vall d'Hebron, Barcelona, Spain*
Email: miren.bravo@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is one of the most common chronic liver diseases in developed countries. Caused by liver fat deposition, it promotes inflammation and cell damage and may progress to cirrhosis. Statins are known for their lipid-lowering ability as well as for exerting pleiotropic effects that could prevent liver steatosis and non-alcoholic steatohepatitis (NASH). Our objective was to prove the efficacy of statins simvastatin

and atorvastatin in an experimental model of NAFLD with mild portal hypertension without fibrosis.
Method: Sprague-Dawley rats were fed with high fat diet combined with a glucose-fructose beverage (HFGFD), or control diet combined with water (CD). After 8 weeks, HFGFD animals were treated during 2 weeks with simvastatin (sim) (10 mg kg^{-1}·day^{-1}), atorvastatin (ato) (10 mg kg^{-1}·day^{-1}) or vehicle, maintaining the original diet. After treatments, hemodynamic parameters were registered and blood and tissue samples collected. Histological analysis of the liver samples and biochemical determinations in serum were performed.
Results: HFGFD animals developed obesity, showing a 20.27% of weight gain difference compared to CD rats. HFGFD also induced steatosis, ballooning and NASH (defined as NAFLD activity score ³3) in a higher proportion of individuals when compared to controls (13.3% NASH in CD *vs* 87.5% in HFGFD), but without fibrosis. Moreover, HFGFD animals showed a significant portal pressure increase compared with CD rats (10.47 ± 0.37 mmHg *vs* 8.30 ± 0.22 mmHg; $p < 0.001$) without changes in systemic hemodynamic. Biochemical analysis revealed a significant rise of alanine aminotransferase (ALT) ($p = 0.043$ *vs* CD) and triglycerides (TG; $p = 0.002$ *vs* CD) in HFGFD animals. Statin treatments had only mild side effects demonstrated by an increase in serum levels of creatine kinase (muscular toxicity) in some treated animals (7.7% of rats treated with sim and 12.5% of rats treated with ato), but absence of increases in serum levels of ALT in treated animals (hepatic toxicity). Moreover, atorvastatin treatment significantly reduced ALT levels ($p = 0.009$) compared to vehicle, despite maintaining the high fat diet, while TG levels were also significantly lower in both treated groups (sim, $p = 0.01$; ato $p = 0.024$). More importantly, HFGFD animals treated with both statins showed a significant portal pressure reduction (sim: 9.29 ± 0.25 mmHg, $p < 0.01$; ato: 8.85 ± 0.30, $p < 0.001$) compared with HFGFD treated with vehicle, as well as NASH reversion, revealed by a decrease of steatosis, ballooning and inflammation in the histological analysis (NAS score ³ 3 in 50% and 57% of treated individuals with sim and ato, respectively).
Conclusion: This study indicates that statins are effective drugs in reducing both portal hypertension and the histological alteration shown by a rat NASH model.

Background and Aims: Common genetic variation in the patatin like phospholipase domain containing 3 (PNPLA3) and transmembrane 6 superfamily member 2 (TM6SF2) genes have been associated with an increased risk of nonalcoholic fatty liver disease (NAFLD) and with the severity of nonalcoholic steatohepatitis (NASH) and fibrosis. However, common variation in these genes can only sufficiently explain a minor fraction of the estimated disease heritability. Thus, additional risk factors, such as rare genetic variants, may influence the risk of NAFLD and disease progression. To identify these rare genetic factors, we performed an exome-wide sequencing study of patients with advanced fibrosis due to NASH.
Method: Whole exome sequencing data was generated for 367 patients with NASH and bridging fibrosis (Ishak stage 3 or 4) or cirrhosis (stage 5 or 6) enrolled in two phase 2b trials of simtuzumab, a monoclonal antibody directed against lysyl oxidase-like-2 (LOXL2). Single variant and gene-based collapsing analyses were used to test for rare variants that were enriched or depleted in NASH cases relative to sequence data from 11,295 population controls. We also tested whether rare variants were associated with quantitative measures of fibrosis (e.g. Ishak fibrosis stage, hepatic collagen content by morphometry, and serum LOXL2 levels) and hepatic venous pressure gradient (HVPG) among cirrhotic subjects. All results were adjusted for multiple testing using a Bonferroni correction.
Results: Exome sequencing identified a total of 3,524,408 rare (<1% minor allele frequency) nonsynonymous variants, including 101,597 rare, loss-of-function mutations among cases and controls. Gene-based collapsing analyses identified a moderate study-wide significant enrichment of rare, loss-of-function mutations in the matrix extracellular phosphoglycoprotein (MEPE) gene among patients with advanced fibrosis due to NASH ($p = 8.19E{-}8$ by Fisher's exact test; Bonferroni threshold for significance after correcting for 18,652 genes, 2.68E–6). No significant associations were found between rare variation and any of the quantitative measures of fibrosis or HVPG in cirrhotic subjects.
Conclusion: We identified a novel, study-wide significant enrichment of loss-of-function mutations in the MEPE gene among patients with advanced fibrosis due to NASH. Replication and further functional study may provide insight into the role of MEPE nonsense mutations in predisposition to NAFLD and/or NASH.

THU-457
Nicotine enhances lipid accumulation and lipotoxicity in hepatocytes via suppression of autophagy

S. Yamashina, T. Aoyama, A. Uchiyama, K. Kon, K. Ikejima, S. Watanabe. *Juntendo University School of Medicine, Gastroenterology, Tokyo, Japan*
Email: syamashi@juntendo.ac.jp

Background and Aims: Previous clinical studies revealed that cigarette smoking enhances the progression of chronic liver diseases and carcinogenesis. It was reported that smokers were likely to have significantly more visceral fat accumulation than nonsmokers with similar body mass index, even though smokers were significantly less obese than nonsmokers. Treatment with nicotine activates mammalian target of rapamycin (mTOR) pathways which negatively regulates autophagy induction. Recently, it was shown that autophagy mediates lipid droplet degradation and lipolysis. The aim of this study was to identify the effect of nicotine on autophagic lipolysis in hepatocytes.
Method: Isolated hepatocytes from C57CL6J mice were cultured in media with 1 mM oleic acid for 6 hours. Subsequently, cells were washed by PBS three times and incubated in media with or without nicotine (10^{-5} M) for 12 hours. Some hepatocytes were incubated in media with both oleic acid and nicotine for 24 hours to evaluate cytotoxicity of nicotine. Cell viability was evaluated by WST-1 assay. Cells were formaldehyde-fixed and lipid accumulation was detected with LipidTOX™ lipid stain. Western blot analysis was performed to evaluate the expression of microtubule-associated protein1 light chain 3 (LC3), phospho-mTOR, perillipin in hepatocytes.
Results: Although accumulation of lipid droplets was observed in hepatocytes cultured in media with oleic acid for 6 hours, subsequent incubation in media without oleic acid for 12 hours decreased lipid accumulation in hepatocytes. On the other hand, addition of nicotine to media suppressed degradation of lipid droplet. Similarly, subsequent incubation in media without oleic acid and nicotine reduced perillipin expression increased by oleic acid; however nicotine treatment sustained an increase in perillipin expression due to oleic

acid. On the other hand, treatment with oleic acid for 6 hours enhanced the expression of phospho-mTOR and suppressed LC3-II expression in isolated hepatocytes. Subsequent incubation in media without oleic acid for 12 hours decreased the activation of mTOR; however, nicotine treatment maintained mTOR activation. Moreover, suppression of lipolysis due to nicotine was ameliorated by the co-incubation with mTOR inhibitor rapamycin. Treatment with only oleic acid did not affect cell viability; however, addition of nicotine to oleic acid decreased cell viability to 62.5 ± 2.42%. Interestingly, mTOR inhibitor rapamycin suppressed cell death by combination of nicotine and oleic acid to 73.8 ± 2.05%.
Conclusion: These results indicated that exposure to nicotine blunts lipolysis via suppression of autophagy. Moreover, it was suggested that suppression of autophagy by nicotine enhances cell death. In conclusion, suppression of autophagy due to nicotine may contribute the progression of liver diseases observed in smokers.

Background and Aims: Obese patients with non-alcoholic fatty liver disease (NAFLD) are at increased risk of developing hepatocellular carcinoma (HCC). However, the mechanisms that promote HCC development in NAFLD patients are not fully understood. Here we investigated the role of E2F2 transcription factor in NAFLD development and progression to HCC.
Method: E2F2$^{-/-}$ and control mice (WT) were used. Liver disease in mice was induced by administration of diethylnitrosamine (DEN) (25 mg/kg) at 14 days-old plus high-fat (HFD) or chow diet until sacrificed at 3 (3m) or 9 months-old (9m). A cohort of 67 obese patients, 15 of which exhibited normal liver (NL) and 52 NAFLD, and 18 samples from non-obese liver donors were used. Protein and lipid content, and metabolic fluxes were analyzed.
Results: In liver, according to oncomine database E2F2 expression is increased in tumoral vs non-tumoral human tissue. We observed that E2F2 expression is also higher in DEN-HFD induced HCC vs NL mice. The number and size of tumors and the content in neutral lipids were higher in 9m DEN-HFD WT mice than in the other WT groups. At 9m, E2F2$^{-/-}$ mice were resistant to HCC development and to lipid accumulation, which was linked to decreased lipogenesis and increased B-oxidation as the metabolic fluxes and the transcriptome showed. This metabolic profile was also evident when E2F2 was kd in HepG2 cells and in 3m mice, in which E2F2$^{-/-}$ mice were totally resistant to hepatoesteatosis. E2F2 protein levels were increased in obese NAFLD patients when compared to non-obese or obese NL subjects, in which E2F2 levels were already higher than in non-obese NL individuals. The anti-steatotic effect in E2F2$^{-/-}$ mice was linked to decreased PPARγ and increased PPGC1 levels, both controlled by CREB. CREB kd demonstrated its involvement in the regulation of lipogenesis and B-oxidation when E2F2 was also kd.
Conclusion: E2F2 is a master regulator of metabolism in obesity related liver disease progression. It regulates the CREB-PPAR axis, involved in the homeostasis of liver lipid metabolism. Deficiency of E2F2 avoids the lipid storage required for NAFLD development and progression to HCC, which points out the value of E2F2 as a therapeutic target.

Email: dpors@unileon.es

Background and Aims: Dysbiosis and gut-liver axis alteration have been pointed as important contributors to obesity and non-alcoholic fatty liver disease (NAFLD) development. Modulation of intestinal microbiota (IM) emerge as a promising therapeutic strategy for obesity-associated NAFLD. This study aims to determine the effect of IM transplantation and quercetin supplementation in a high fat diet (HFD)-based NAFLD model in germ free mice (GFm).
Method: Donor mice were selected from conventional raised mice as follows: control (dC), control supplemented with quercetin (dCQ), responder and non-responder to the HFD (dHFD+ and dHFD−) and highest response to quercetin with HFD (dHFDQ). GFm were colonized with IM from donors and fed with HFD or control diet supplemented or not with quercetin for 16 weeks. Gut bacterial communities were identified by 16S-rRNA pyrosequencing.
Results: A remarkable higher detection of *Verrucomicrobia* phylum and *Akkermansia* genus was observed in HFD-fed dC, dCQ, dHFD− and dHFDQ-receiver groups, which were undetectable in dHFD+ recipients independently of the diet. Relative abundance of *Akkermansia* genus inversely correlated with body weight gain, NAFLD activity score and insulin resistance development (HOMA-IR). Evaluation of these parameters unveiled two protective metabolic phenotypes exhibited by dHFD− and dHFDQ-receiver groups and a predisposal to NAFLD development phenotype showed by dHFD+ transplanted mice. Gut-liver axis alteration was involved in predisposition to NAFLD as showed by enhanced expression of TLR4 and NLRP3 in dHFD+ recipients independently of the diet, associated to IM imbalance evidenced by reduced SCFAs (acetate, propionate and butyrate) production. dHFD−and dHFDQ microbiota transplantation reduced endotoxemia and ethanol production in HFD-fed mice attenuating gut liver axis activation and contributed to partially restore SCFAs profile. These alterations also correlated with *Akkermansia* abundance, positively for butyrate production and negatively for NLRP3 expression.
Conclusion: IM transplantation resulted in a definite microbiota composition establishment which determines susceptibility to NAFLD and metabolic syndrome development, highlighting the significant role of *Akkermansia* genus in the maintenance of a healthy metabolic profile, in a mechanism involving IM functionality and gut barrier integrity. Supported by BFU2013-48141-R, LE063U16 (JCyL and FEDER) and GRS 1428/A/16. CIBERehd is funded by ISCIII.

Email: ebugianesi@yahoo.it

Background and Aims: Bile acids (BAs) are signaling molecules involved in the pathogenesis of non-alcoholic fatty liver disease (NAFLD). BAs can modulate both glucose and lipid metabolism in insulin resistance (IR), a major pathogenic mechanism for the progression to non-alcoholic steatohepatitis (NASH). However, the association between BA composition and insulin sensitivity (IS)/IR has been not fully investigated yet. We aimed to assess the relationship between BA composition and sites and mechanisms of IR in non-diabetic NAFLD patients.
Method: 41 patients with biopsy-proven NAFLD were studied. Plasma BA composition was assessed by GC-MS. Adipose tissue IR (AT-IR), Hepatic IR (Hep-IR) and glucose clearance (GC) were derived from tracer studies. Visceral fat (VF) was assessed by NMR. Liver histology was scored according to Kleiner.
Results: Plasma levels of total primary BAs correlated with waist circumference (WC) ($r = 0.378$, $p = 0.014$), VF ($r = 0.406$, $p = 0.023$) and fasting C-peptide (C-pep) ($r = 0.301$, $p = 0.056$), while secondary BAs showed no correlation with anthropometric/metabolic parameters. Among primary BAs, GCA directly related to visceral adiposity and AT-IR while TCDCA was associated with visceral adiposity (WC and VF), insulin secretion (C-pep), IR in adipose tissue (AT-IR), liver (Hep-IR) as well as with hepatic steatosis and inversely related to muscle IS (GC) (Table 1). UDCA had no correlation with metabolic parameters while TUDCA (hydroxylated) was significantly correlated with visceral adiposity, IR at different sites and liver fat (Table 1).
Conclusion: In NAFLD patients, GCA, TCDCA and TUDCA are increased proportionally to IR at the main sites of insulin action (adipose tissue, liver and muscle) irrespective of diabetes. Since TCDCA is the most potent endogenous agonist of FXR, which upon activation improves insulin sensitivity, and TUDCA treatment in obese individuals has been found to improve insulin sensitivity, these increases may represent compensatory mechanisms to IR.

Pharmacological inhibition of the medium chain fatty acid receptor GPR84 reduces myeloid cell in filtration into injured liver and ameliorates steatohepatitis and fibrosis

T. Puengel[1], S. De Vos[2], O. Krenkel[1], P. Pujuguet[3], M. Auberval[3], F. Marsais[3], K.F. Shoji[3], L. Saniere[3], C. Trautwein[1], R. Brys[2], F. Tacke[1]. Email: tobias.puengel@rwth-aachen.de

Background and Aims: Expression of medium chain free fatty acid receptor GPR84 (G protein-coupled receptor 84) is induced in immune cells under inflammatory conditions. In view of the proposed roles for GPR84 in inflammation and leukocyte chemotaxis, we hypothesize that pharmacological blockade of GPR84 could represent a novel treatment option in NASH. We therefore evaluated the therapeutic inhibition of GPR84 by two novel, structurally distinct small molecule antagonists in mouse models of acute and chronic liver injury. Results were compared to Selonsertib, an apoptosis signal-regulating kinase 1 (ASK1) inhibitor currently evaluated in NASH patients.
Method: C57bl/6 wildtype mice were subjected to carbon tetrachloride (CCl4) injury, methionine-choline-deficient (MCD) diet for 8 weeks or choline-deficient & high-fat diet (CDAHFD) for 10 weeks. Mice were treated with two GPR84 antagonists (30 mg/kg QD PO) or Selonsertib (15 mg/kg BID PO) for the last 4 weeks of MCD or last 6 weeks of CDAHFD, respectively. Chemotaxis experiments were conducted with primary neutrophils and monocytes.
Results: *In vitro*, both GPR84 antagonists blocked neutrophil and macrophage chemotaxis induced by GPR84 activation. Upon acute liver injury (single CCl4 injection) in mice, treatment with both GPR84 antagonists resulted in a reduced necrotic liver area and significantly reduced hepatic recruitment of neutrophils, monocytes and monocyte-derived macrophages (MoMF), as evidenced by FACS analysis of intrahepatic leukocytes and F4/80 immunohistochemistry. Similarly, therapeutic application of the two GPR84 antagonists reduced blood monocytes as well as liver neutrophils and MoMF in the MCD model. Pharmacological GPR84 blockade ameliorated steatohepatitis and fibrosis, as assessed by histological NAFLD activity score and Sirius red staining, to a similar extent as Selonsertib. Similar anti-inflammatory and anti-fibrotic effects, including modulation of related gene expression pathways, were observed following GPR84 inhibition in the CDAHFD model.
Conclusion: Pharmacological blockade of GPR84 inhibits neutrophil and macrophage recruitment to the liver in models of acute and chronic liver injury. Therapeutic application in mouse liver fibrosis models ameliorated steatohepatitis and fibrosis, to a level comparable to the ASK1 inhibitor Selonsertib, corroborating the therapeutic potential of GPR84 antagonists in NASH.

Non-alcoholic steatohepatitis impairs Kupffercell-mediated immune tolerance in the mouse liver

L.A. Orci[1], C. Toso[1], K. Mario[2], F. Slits[1], V. Delaune[1], G. Oldani[1], C. Gonelle-Gispert[1], L. Rubbia-Brandt[2], S. Lacotte[1]. [1]*Centre Médical Universitaire, Surgery, Geneva, Switzerland;* [2]*Centre Médical Universitaire, Pathology and Immunology, Geneva, Switzerland*
Email: stephanie.lacotte@unige.ch

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is increasingly recognized as a threat to human health. Although our understanding of NAFLD and non-alcoholic steatohepatitis (NASH) pathogenesis is improving, there is limited data on the function of resident Kupffer cells in this context, especially when considering their contribution to hepatic immune tolerogenicity.
Method: By using a unique isolation procedure, primary Kupffer cells, and not infiltrating liver monocytes, were studied in a mouse model of prolonged diet-induced liver steatohepatitis. We assessed Kupffer cell phenotype upon exposure to lipopolysaccharide or interleukin 4. We did phagocytosis and antigen presentation assays to investigate Kupffer cell function as scavenger cells and immune response initiators.
Results: Primary Kupffer cells circumscribe endotoxin-mediated inflammatory response by up-regulating anti-inflammatory genes such as arginase 1 and interleukin-10 (IL-10). In the chronically inflamed liver, Kupffer cells acquire immunomodulatory properties by reducing membranous expression of class II major histocompatibility complex (MHC, $p = 0.016$), and by enhancing co-inhibitory signalling (programmed-death ligand 1 [PD-L1], $p = 0.036$). While Kupffer cells isolated from mice with normal livers are capable of achieving endotoxin tolerance, our results indicate an impairment of this protective mechanism in the presence NASH-like parenchymal abnormalities.
Conclusion: Primary Kupffer cells are capable of achieving endotoxin tolerance, but in the chronically-inflamed fatty liver, although they acquire immunomodulatory phenotype, Kupffer cells are not sufficient to dampen immune-mediated damage. Therefore, loss of tolerance induced by ongoing liver insult may be a mechanism contributing to the worsening of NAFLD.

THU-463

BCAA and ER stress activate SREBP-1c cleavage and hepatic lipogenesis through mTOR

F. Phan, M. Flamment, M. Hu, I. Hainault, P. Ferré, F. Foufelle. *INSERM UMRS 1138, Centre de Recherche des Cordeliers, Paris, France*
Email: fabienne.foufelle@crc.jussieu.fr

Background and Aims: Liver plays a central role in energy homeostasis in response to variety of hormones and nutrients. In physiological conditions, upon food intake, insulin inhibits hepatic glucose production and induces *de novo* lipogenesis (DNL). In insulin resistant states, while the insulin action on the hepatic gluconeogenic pathway is impaired, its action on DNL remains intact or even exaggerated, a state referred to as selective insulin resistance. Several mechanisms have been proposed to explain the selective hepatic insulin resistance. We proposed that in obese rodents, the lipogenic transcription factor SREBP-1c is activated by ER stress thus inducing DNL in an insulin-independent way. Others proposed that bifurcation of insulin signaling after PKB, could explain selective insulin resistance with a branch increasing the activation of SREBP-1c by mammalian target of rapamycin complex 1 (mTORC1), and another branch decreasing gluconeogenesis via regulation of FoxO1. One of the nutritional factors that can activate mTORC1 signaling is the amino acids. Interestingly, it was shown that branched-chain amino acid (BCAA), shows strong correlation with insulin resistance (HOMA) in human study, and is especially increased in the plasma of obese individuals and ob/ob mice. In this study, we make the hypothesis that BCAA could stimulate mTOR signaling and the subsequent hepatic lipogenesis in primary hepatocytes.
Method: Primary rat hepatocytes were challenged with a mixture of BCAA or their metabolites BCKA or with ER stress inducers. Nuclear and microsomal extracts were performed to analyse SREBP-1c content. Western Blot were performed with total extracts to assess insulin signaling. RT-qPCR were performed to analyse the expression of gluconeogenic and lipogenic enzymes. Mice were orally forced fed with BCAA or vehicle and liver was collected to assess the same parameters.
Results: In this study, we showed that BCAA and their related metabolites BCKA could independently stimulate mTORC1 signaling, SREBP-1c proteolytic cleavage and the subsequent lipogenesis in primary hepatocytes while displayed no effects on gluconeogenesis. Further studies also demonstrated that BCAA may potentiate the insulin-induced or ER stress-induced SREBP-1c activation in an mTORC1-dependent way. Finally, we showed that force feeding of mice with BCAA leads to mTOR activation, SREBP-1c cleavage and transactivation of target genes.
Conclusion: Our results indicate that BCAA may play an important role in the mTORC1-centered lipogenesis and selective insulin resistance in liver.

THU-464

The vanin 1-cysteamine pathway regulates immune tolerance upon lipid-induced oxidative stress in non-alcoholic fatty liver disease

O. Govaere[1], J. Palmer[1], M. Zhuang[1], M.Y.W. Zaki[1], E. Scott[1], S. Cockell[2], A.K. Daly[1], Q. Anstee[1]. [1]*Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne;* [2]*Newcastle University, Bioinformatics Support Unit, Newcastle upon Tyne, United Kingdom*
Email: olivier.govaere@ncl.ac.uk

Background and Aims: Lipid-induced oxidative stress is considered a critical factor in the progression of non-alcoholic fatty liver disease (NAFLD). In response to lipid-loading hepatocytes release microparticles containing vanin-1, a pantetheinase that hydrolyses Vit B5 to cysteamine in the co-enzyme A pathway. Moreover, vanin-1 has been reported to modulate hepatic triglyceride levels and to be protective against acetaminophen-induced hepatoxicity. This study aims to investigate the role of the vanin-1/cysteamine pathway *in vitro* and *in vivo*, and to determine associations of *VNN1* genetic variations with the progression of NAFLD.
Method: *VNN1* rs4897612 genotype was assessed in a cohort of 465 patients with histologically characterised NAFLD. VNN1 expression was analysed using immunohistochemistry in fresh-frozen liver samples from patients with NAFLD and C57BL/6 mice fed a 20week high fat+/- sugar diet. To mimic hepatocyte-Kuppfer cell interaction, the hepatoma HepG2 and the myeloid Mono-Mac6 cell lines were challenged with oleic, linoleic, palmitic and stearic acid with or without cysteamine and LPS. Read-outs included Oil-Red-O staining, proliferation and ROS assays, ELISA and qPCR.
Results: The *VNN1* variant rs4897612 was associated with an increased risk of advanced hepatic fibrosis ($p = 4.9*10^{-3}$). In mouse vanin-1 showed a plasma membrane expression in hepatocytes which was increased upon high fat diet with or without sugar. Similar results were found in the human samples with strongest intensity in end-stage liver disease where immunopositivity in hepatic progenitor cells was seen. In HepG2 all fatty acids induced lipid accumulation but only linoleic acid significantly induced oxidative stress without inducing cell death. At a concentration of 1 mM linoleic acid a 5-fold increase in ROS levels ($p < 0.01$) was detected in the HepG2 together with an up-regulation in *VNN1*, *GPX1*, *KRT19* and *KRT23* expression ($p < 0.05$). Cysteamine significantly reduced oxidative stress and increased glutathione levels. *In vitro*, linoleic acid exposure primed the monocyte Mono-Mac6 cells for higher LPS-induced release of pro-inflammatory cytokines IL6 and IL8, an effect that was ameliorated by cysteamine treatment.
Conclusion: Our results suggest that under the influence of modifiers including Vanin-1, cysteamine levels can contribute to immune tolerance and thus reduce inflammatory potential in metabolic diseases like NAFLD.

THU-465

BAFF neutralization ameliorates the evolution of experimental NASH

S. Sutti[1], S. Bruzzì[1], G. Giudici[1], R.N. Naik[1], C. Bozzola[1], P. Schneider[2], E. Morello[3], M. Parola[3], E. Albano[1]. [1]*University of East Piedmont (UPO), Dept. of Health Sciences, Novara, Italy;* [2]*University of Lausanne, Dept. of Biochemistry, Epalinges, Switzerland;* [3]*University of Turin, Dept. of Clinical and Biological Sciences, Torino, Italy*
Email: salvatore.sutti@med.uniupo.it

Background and Aims: Recent studies have pointed out the importance of B-lymphocytes in supporting hepatic inflammation in nonalcoholic steatohepatitis (NASH). Moreover, the severity of human NASH correlates with the circulating levels of B-cell Activating Factor (BAFF; TNFSF13b), one of the cytokines that regulate B-cell survival and maturation. We thus investigated whether interfering with BAFF might modulate the evolution of experimental NASH.
Method: NASH was induced in C57BL/6 mice by feeding with a methionine-choline deficient (MCD) diet up to 4 weeks or with a choline deficient amino acid defined (CDAA) diet for 24 weeks. Mice received the BAFF neutralizing monoclonal antibody Sandy-2 (2 μg/g body weight) at the start and after two weeks of MCD diet.
Results: In preliminary tests, we observed that 1 week treatment Sandy-2 reduced by about 40% circulating and liver B-cells, specifically affecting the B2 subset, and prevented liver plasma cell maturation in mice fed with the MCD diet for 1 week. In the animals receiving the MCD diet for 4 weeks, BAFF neutralization ameliorated histological scores for steatosis and lobular inflammation as well as ALT release. Although Sandy-2 treatment did not appreciably affect the prevalence of liver infiltrating $CD4^+$ and $CD8^+$ T-cells, it significantly lowered Th-1 activation of liver $CD4^+$ T-lymphocytes, as evaluated by IFN-γ production. BAFF blockade also decreased the hepatic expression of pro-inflammatory mediators such as TNF, IL-12, CCL2 and CXCL10. Similarly, NASH severity was improved in mice overexpressing a soluble form of the BAFF/APRIL receptor Transmembrane Activator and Cyclophilin Ligand Interactor (TACI-Ig) receiving the CDAA diet. In these animals Sirius Red staining for collagen and the prevalence of α-smooth muscle actin (α-SMA)-positive activated hepatic stellate cells were also significantly reduced as compared to wild-type littermates and this paralleled with a lower hepatic expression of α1-procollagen, α-SMA and Transforming Growth Factor-β1 (TGF-β1).
Conclusion: Altogether, these data indicate that interference with cytokines controlling B-lymphocyte activation effectively prevents NASH progression, suggesting that BAFF inhibition with already available drugs could be a possible treatment for NASH.

THU-466

The multifactorial pathogenesis of nonalcoholic fatty liver disease: connecting inflammation and oxidation

F. Luciano-Mateo[1,2], N. Cabré[1,2], G. Baiges[1,2], A. Hernández-Aguilera[1,2], S. Fernández-Arroyo[1,2], J. Camps[1,2], J. Joven[1,2]. Email: fedranicaury.luciano@urv.cat

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is an immune-linked metabolic disease, which now represents the most frequent cause of chronic liver disease and probably the leading indication for liver transplantation in the years to come. However, the responsible mechanism unclear, we hypothesize that C-C motif chemokine ligand 2 deficiency (CCL2) enhance the metabolic alterations involved NAFLD. The lipid accumulation in the liver increases vulnerability to oxidative stress, lipid peroxidation, liver damage and inflammation. The study of the link between Chemokine (C-C motif) ligand 2 (CCL2), Paraoxonase-1 (PON1), and Low Density Lipoprotein receptor (LDLr) may help to better understand the role of these components in the NAFLD. The aim of this study was to evaluate the multifactorial pathogenesis of diet-induced fatty liver disease.
Method: Using triple deficient mice that combined the three cornerstones of the NAFLD: Inflammation, oxidation and hyperlipemia condition. These mice were deficient in CCL2, PON1 and LDLr (CPL KO) and double deficient mice PON1 and LDLr (PL KO). We used CCL2 KO, PON1 KO, LDLr KO and wild type (WT) as a control group. We performed an integrated analysis of the metabolic phenotypes occurring in two experimental diets treatments during 14 weeks. After this period, a histological and metabolomics analysis of their liver tissue by mass spectrometry (GC-EI- QTOF-MS) were performed.
Results: CPL KO mice were associated with significantly decreasing of steatosis, weight and adipose size and enhance metabolic alterations, mitochondrial dysfunction caused by the diet. All this combined with significative increases of F4/80 stained cell in the liver tissue. In contrast, PL KO mice were associated with opposite effect. It seems that this mechanism is involved in the manipulation of macrophages polarization, mitochondrial dysfunction, energy metabolism regulation and autophagy process. CCL2 deficient condition has a protective effect and preventing the development of these alterations.
Conclusion: We report that C-C motif chemokine ligand 2 (CCL2) is a potent targetable approach to limit NAFLD progression. Blocking CCL2 strongly protects from steatosis development, adipose tissue hyperplasia and manipulation of macrophage plasticity.

Email: halish@netvision.net.il

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease. Inflammation and fibrosis are the key pathological processes involved in the progression of NAFLD to non-alcoholic steatohepatitis (NASH). Chemokines play an important role in inducing inflammation and fibrosis and were found to be central in NASH progression. CCL24, a pro-inflammatory and pro-fibrotic chemokine, was recently found to be involved in the progression of inflammatory and fibrotic diseases and is tested for its involvement in NASH. Our aim was to study the levels of circulating CCL24 and its receptor-CCR3 in NAFLD patients' serum samples and liver biopsies and the association with its clinical features.
Method: Serum samples from NAFLD patients were analyzed for CCL24 levels using commercial ELISA kit (R&D systems). CCR3 levels in peripheral blood mononuclear cells were tested by flow cytometry. Immunohistochemistry staining was performed to evaluate CCL24 and CCR3 in liver biopsies.
Results: Our finding revealed significant elevation of CCL24 serum levels in NAFLD patients compared to healthy volunteers (718 ± 78 and 476 ± 36 pg/ml, respecitively, $p \leq 0.01$). Moreover, we used Fib4 score to divide the NAFLD population to subgroups according to disease progression. We found that CCL24 levels were increased by ~2 fold in high NAFLD Fib4 score patients (n = 23) compare to healthy volunteers (n = 20) ($p \leq 0.01$) and by 1.5 fold compare to low Fib4 score NAFLD patients (n = 28) ($p \leq 0.05$). CCL24 activity is mediated by its binding to its cognate receptor, CCR3. Thus, we assessed the levels of CCR3 expression in peripheral blood mononuclear cells isolated from NAFLD patients (n = 35) and healthy volunteers (n = 16). We found that CCR3 was significantly overexpressed in mononuclear cells isolated from NAFLD patients compared to healthy volunteers (3.81 ± 0.16% and 0.84 ± 0.1%, respectively, $p \leq 0.01$). Significantly higher hepatic expression of CCL24 and CCR3 using immunohistochemistry was revealed in NASH patients' liver biopsies with NAFLD Activity Score equal and higher than 5 compared with normal livers. Importantly ($p \leq 0.01$, $p \leq 0.05$, respectively).
Conclusion: This is the first evidence, that the chemokine CCL24 and its cognate receptor, CCR3, are significantly increased in NAFLD patients both in the circulation and in the liver. These results may indicate a potential involvement of CCL24-CCR3 axis in the pathogenesis of NASH, thus suggesting that CCL24 may serve as a potential prognostic tool and a therapeutic target for the treatment of patients with NASH.

LJN452 (tropifexor) attenuates steatohepatitis, inflammation, and fibrosis in dietary mouse models of nonalcoholic steatohepatitis

B. Laffitte[1], E. Hernandez[1], Y. Kim[1], B. Liu[1], P. Rucker[1], D. Chianelli[1], D. Bao[2], J. Zoll[1], J. Xu[1], V. Molteni[1], P. Mcnamara[1], M. Badman[2]. [1]*Genomics Institute of the Novartis Research Foundation, La Jolla, United States;* [2]*Novartis Institutes for BioMedical Research, Cambridge, United States*
Email: blaffitte@gnf.org

Background and Aims: Farnesoid X receptor (FXR) agonists are investigational agents for the treatment of nonalcoholic steatohepatitis (NASH) and other chronic liver diseases. The bile acid-derived FXR agonist obeticholic acid (OCA) demonstrated efficacy in Phase II NASH trials, but also caused cholesterol elevation and pruritus. LJN452 is a highly potent non-bile acid agonist currently under Phase II development. Here, we compare the efficacy of LJN452 and OCA in two mouse models of NASH.
Method: STAM Model: Streptozotocin-injected 2-day old C57Bl/6J mice were placed on high-fat diet for weeks 4–12. From Week 9, mice received oral doses of LJN452 (0.03–0.3 mg/kg), OCA (25 mg/kg), or vehicle. Hematoxylin & eosin (H&E)-stained liver sections were assessed for nonalcoholic fatty liver disease activity score (NAS). Collagen deposition (fibrosis marker) was estimated by percent of Sirius-red positive area.
AMLN Model: C57Bl/6 mice were placed on high fat (40% kcal), fructose (22% by wt), and cholesterol (2% by wt) diet for 30 weeks. LJN452 (0.03–0.9 mg/kg), OCA (25 mg/kg), or vehicle was orally dosed for the last 4 weeks. Treatment effects were monitored by histopathology (H&E, Trichrome and IBA1 staining) and assessment of liver-damage markers (alanine/aspartate aminotransferases [ALT/AST]) levels and collagen type I, alpha1 (Col1a1) and tissue inhibitor of metalloproteinase 1 (TIMP1) mRNA levels.
Results: Compared with normal mice, STAM mice showed marked increases in NAS and fibrotic area. LJN452 treatment showed significant decrease in NAS at doses ≥0.1 mg/kg ($p < 0.0001$), whereas the effect of OCA tended was less marked. Significant dose-dependent reduction of Sirius Red-positive areas was observed with LJN452 ($p < 0.001$). In the AMLN model, LJN452, but not OCA, showed dose-dependent reduction in ALT/AST levels relative to controls. In addition, LJN452 reduced inflammation, steatosis, and fibrosis in AMLN mice. Steatosis and inflammation were completely resolved at LJN452 doses ≥0.3 mg/kg. LJN452 also dramatically reduced mRNA levels of fibrogenic markers Col1a1 and TIMP1. NASH mice exhibited hepatic inflammation as confirmed by IBA1+ staining of macrophages and Kupffer cells, which was dose-dependently reduced in LJN452-treated, but not OCA-treated, mouse livers.
Conclusion: Marked improvement in NASH endpoints with LJN452 in two distinct models suggests its potential as a treatment for NASH and warrants its further clinical investigation in NASH patients.

THU-469

EDP-305 modulates lipoprotein metabolism via distinct chromatin and microRNA regulatory mechanisms

M. Roqueta-Riverta[1], M. Chau[1], K. Garlick[1], Y. Li[2], Y.S. Or[3], L. Jiang[4]. [1]*Enanta Pharmaceuticals, Inc., Biology, Watertown, United States;* [2]*Enanta Pharmaceuticals, Inc., Pharmacology, Watertown, United States;* [3]*Enanta Pharmaceuticals, Watertown, United States;* [4]*Enanta Pharmaceuticals, Inc, Pharmacology, Watertown, United States*
Email: ljiang@enanta.com

Background and Aims: The Farnesoid X Receptor (FXR) has emerged as an attractive target for the treatment of NASH. EDP-305, a selective and potent small molecule FXR agonist, is currently being developed for the treatment of NASH. We previously demonstrated EDP-305 treatment results in different gene regulatory effects on lipoprotein metabolism *(LDLR, SRB1)* when compared to obeticholic acid (OCA). In this study, we sought to characterize transcriptional and post-transcriptional regulatory mechanisms by which EDP-305 regulates *LDLR* and *SRB1* expression.
Method: To examine the regulatory mechanisms of EDP-305 and OCA independent of drug potency, treatments were conducted near their respective EC_{50} concentrations (EDP-305: 50 nM; OCA: 500 nM) in human hepatocytes (hepatoma, HepaRG). *In vivo*, C57B6/J mice were treated daily by oral gavage for 5 days with EDP-305 (30 mg/kg) or OCA (100 mg/kg). Sonicated hepatocyte chromatin (~500 bp) was used for chromatin immunoprecipitation (ChIP-qPCR) assays to measure histone methylation and transcription factor enrichment at *LDLR* and *SRB1* promoters. miRNAs were isolated using the miRNAeasy kit (Qiagen).
Results: Under basal conditions, both *in vitro* and *in vivo*, EDP-305 exhibited higher *LDLR* and lower *SRB1* expression relative to OCA, despite equivalent expression of the FXR target, *SHP*. Thus, EDP-305 may have distinct transcriptional and post-transcriptional regulatory

mechanisms for *LDLR* and *SRB1* expression. At the transcriptional level, histone methylation and transcription factor binding were evaluated at the promoters of *LDLR* and *SRB1*. Post-transcriptionally, miRNAs targeting *LDLR* (mir-148a-3p) and *SRB1* (miR-96-5p) were measured.

At the LDLR promoter, EDP-305 treatment of hepatoma cells decreased the gene repressive mark of lysine-9 trimethylation at histone-3 (H3K9me3) by 40% ($p < 0.05$) while SREBP2 was enriched 2-fold ($p < 0.05$) relative to vehicle and OCA. In hepatoma cells under basal conditions, EDP-305 decreased mir-148a by 20% ($p < 0.05$) relative to vehicle, which coincided with increased levels of *LDLR* mRNA. In steatotic HepaRG cells, OCA decreased *LDLR* expression, whereas EDP-305 had no effect; this may be attributed to a 50% increase of mir-148a levels by OCA ($p < 0.05$ vs vehicle).

At the SRB1 promoter, OCA decreased H3K9me3 by 25% and mir-96 by 50% ($p < 0.05$ vs vehicle) allowing for increased *SRB1* transcription. In steatotic HepaRG cells, OCA similarly decreased mir-96 by 50% ($p < 0.05$ vs vehicle), while EDP-305 had no effect.

Conclusions: EDP-305 has distinct transcriptional and post-transcriptional regulatory mechanisms for *LDLR* and *SRB1* expression when compared to OCA. The EDP-305 mechanisms driving these lipoprotein-related gene regulatory differences may translate to a more positive lipoprotein profile in patients, making EDP-305 attractive for further investigation in NASH.

THU-470

CXCL16 promotes hepatocyte steatosis and fibrosis in nonalcoholic fatty liver disease via hepatocyte-stellate cell crosstalk

L. Jiang, J. Zhao. *302 Hospital, Department of Pathology*
Email: nnzadl@163.com

Background and Aims: Non-alcoholic liver disease (NAFLD), a common metabolic liver disease, attracts more and more attention in industrialized countries for its rapidly increasing prevalence. CXCL16, a chemokine with both secreting type and membrane type has been implicated in inflammatory and metabolic liver diseases. The effect of CXCL16 on mutual promotion between steatosis and fibrosis might push the progression of NAFLD in patients. In this study, we freshly investigated the contribution of CXCL16 to the steatosis and fibrosis during NAFLD progression.

Method: The study was comprised 104 NAFLD patients with different SAF scores. CXCL16 level in serum of patients was evaluated and its expression in liver biopsy was also detected. CXCL16 induced hepatocytes steatosis was stained by Oil Red O, meanwhile the TG and SOD level were calculated. Lipogenic genes and HSCs activation related factors were quantified by RT-PCR. Hedgehog signaling pathway was detected in CXCL16 influenced co-culture system. Activation of Hh signaling pathway was performed to investigate the function of Hh ligands in CXCL16 induced steatosis.

Results: CXCL16 is markedly increased in groups of steatosis and has siginificant difference among group S0-1, S2 and S3. We found that the difference is due to the data in patients with A or/and F score ≥ 2 in SAF score system. CXCL16 accumulates around hepatocytes with severe steatosis in patient liver biopsy specimens. CXCL16 induced severe steatosis in hepatocyte-stellate cell co-culture system. This induction suppressed respiration rate of hepatocytes and the steatosis related genes were also up regulated. TGF-β, COL1A1 and α-SMA were increased in activated HSCs and Hh ligands SMO, SHH, GLI1/2 and PTCH were down regulated in hepatocytes. Overexpression of SHH inhibited hepatocytes steatosis.

Conclusion: Collectively, our study demonstrates a freshly crosstalk between hepatocytes and HSCs regulated by CXCL16. These findings established CXCL16 as a part of the steatotic and fibrotic pathway in NAFLD progression. CXCL16 is a hopeful non-invasive detection index as well as a future potential therapeutic target to alleviate NAFLD.

THU-471

Inhibition of IL6 trans-signaling leads to NAFLD, mature-onset obesity and metabolic syndrome

T. Lanton[1], O. Levkovitch[1], S. Perles[2], J. Tam[3], S. Udi[3], J. Rachmilewitz[4], R. Abramovitch[1], S. Rose-John[5], E. Galun[1], J. Axelrod[1]. *[1]Hadassah Hebrew University Hospital, The Goldyne Savad Institute of Gene Therapy, Jerusalem, Israel; [2]Raziel Therapeutics, Raziel Therapeutics Ltd, Israel, Jerusalem, Israel; [3]The Institute for Drug Research, Faculty of Medicine, Obesity and Metabolism Laboratory, Jerusalem, Israel; [4]Hadassah Hebrew University Hospital, Hadassah Hebrew University Hospital, Jerusalem, Israel; [5]University of Kiel, Department of Biochemistry, Kiel, Germany*
Email: tali.lanton@mail.huji.ac.il

Background and Aims: Persistent IL6 production has been implicated in altered metabolic states such as exercise and HFD-induced obesity and fatty liver; however the causal role of IL6 and IL6 *trans*-signaling in particular in the spontaneous development of age-related obesity and fatty liver disease remains controversial. IL6 *trans*-signaling relies upon the release of the soluble IL6R (sIL6R), which binds IL6 to form an agonistic IL6/sIL6R complex. Here we have examined the hypothesis that IL6 *trans*-signaling plays a crucial role in the control of weight gain and glucose homeostasis in aging mice.

Method: Transgenic mice expressing high levels of the specific IL6/sIL6R antagonist, sgp130Fc, and wild type (WT) littermates were compared for weight gain, glucose homeostatis, and liver steatosis at 2, 6 and 14 months (mo) of age.

Results: Sgp130Fc mice, in comparison to WT littermate controls, displayed significant hyperphagia from an early age, followed by a dramatic rise in body weight and hyperglycemia by the age of 6 mo. Sgp130Fc mice displayed increased fat storage in the liver while reducing free fatty acid levels in the blood but not by altering hepatic triglyceride synthesis genes" expression. Interestingly, hepatosteatosis was not accompanied by increased inflammatory markers (e.g. TNF). Additionally, inhibition of IL6 *trans*-signaling lead to impaired glucose tolerance due to peripheral insulin resistance in aged mice without altering hepatic gluconeogenesis nor pancreatic secretion defects. Finally, antibiotics treatment rescued the animals from obesity and hyperglycemia indicating that the mechanism by which *trans*-signaling protects against mature onset-metabolic syndrome may involve the gut microbiota.

Conclusion: IL6/sIL6 protects mice against mature-onset obesity, hyperglycemia, and hepatosteatosis in a mechanism that may involve host immune response to the microbiota.

Biomedicina de Sevilla. CiberEHD., Hospital Universitario Virgen del Rocio, Sevilla, Spain
Email: mromerogomez@us.es

Background and Aims: Fibroblast Growth Factor 21 (FGF21) plays a central role in glucose and metabolic homeostasis. The main aim of this study was to evaluate the role of FGF21 in NAFLD/NASH.
Method: This study included: (i) FGF21 evaluation in liver tissue (n = 20, 10 simple steatosis (SS) and 10 NASH) and in peripheral mononuclear blood cells (PBMC) by qRT-PCR (iii) Circulating FGF21 levels assessment in 38 patients (19 NASH, 19 SS) by ELISA (iii) Evaluation of a single nucleotide polymorphism (SNP) located in FGF21 (rs838133) as well as the one discovered in PNPLA3 (rs838109). Kleiner, analysing liver fibrosis and NAS Score assessed liver damage. An additional semi-quantitative scale for significant fibrosis (F2-F4) was further employed (iv) Intrahepatic accumulation of fgf21 in C57BL/6J mice with high-fat diet and choline-methionine diet (HFD-MCD) by immunohistochemistry.
Results: (i) Hepatic FGF21 gene expression was found to be upregulated in NASH vs SS (3.45 + 4.0 vs 0.63 + 0.9). Further, it was found associated with BMI (r = 0.75; p = 0.004) and HOMA-IR values (r = 0.79; p = 0.001). No qRT-PCR products were detected in PBMC
(ii) NASH (2.17 + 0.77 vs 1.55 + 0.79) and ballooning patients (2.30 + 0.71 vs. 1.69 + 076; p = 0.045) showed increased FGF21 levels in serum, and were significantly correlated with NAS Score (r = 0.364, n = 38, p = 0.027). No patients showed FGF21 levels below quantification limit.
(iii) After multivariate analysis, variables independently associated with significant fibrosis were: A-allele of rs838133 [OR 3.91 (CI95% 1.09–14.06); p = 0.006]; age [OR 1.07 (CI95% 1.03–1.11); p = 0.001]; type 2 diabetes mellitus [OR 4.08 (CI95% 1.51–10.97)] and ALT [OR 1.03 (CI95% 1.01–1.04); p = 0.000]. AUROC obtained for significant fibrosis prediction was 0.89 [IC95% CI 0.85–0.95]
(iv) Hepatic fgf21 expression in HFD-MCD mice were found increased vs controls (p < 0.001), accordingly to the hepatic injury.
Conclusion: FGF21 expression, both hepatic and circulating, was found increased in NASH patients. Bearing AA genotype of FGF21 confers susceptibility to significant fibrosis development. In the HFD-MCD model, increased expression of fgf21 was found associated to liver injury. These results highlighted the role of FGF21 as a biomarker and a therapeutic target in NAFLD/NASH.

THU-473

Divergent effects of RIP3 and MLKL inhibition on HF diet induced steatosis

W. Saeed[1], D.W. Jun[1], E. Kim[1], K.S. Jang[2], B.-K. Kang[3], E.C.J. Jang[4], S.B. Ahn[5], M.M. Kim[3], J.Y. Jeong[6], J.H. Sohn[6]. *[1]Hanyang University School of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Hanyang University School of Medicine, Pathology; [3]Hanyang University School of Medicine, Radiology; [4]Soonchunhyang University College of Medicine; [5]Eulji University College of Medicine, Internal Medicine; [6]Hanyang University, College of Medicine, Guri Hospital, Internal Medicine*
Email: noshin@hanyang.ac.kr

Background and Aims: Although, effect of receptor-interacting serine-threonine kinase 3 (RIP3) inhibition has been evaluated in high fat (HF) and MCD diet induced steatosis models. However, whether mixed lineage kinase domain-like (MLKL), RIP3 downstream target, would also depict the similar results is currently unknown. We, therefore, compared the results of RIP3 and MLKL inhibition using HF diet induced steatosis model.
Method: HF diet was fed for 12 weeks to WT, RIP3$^{(-/-)}$KO and MLKL$^{(-/-)}$ KO mice. After 12-weeks, the animals were sacrificed. NAS score was assessed using mice liver tissue. Gluocse tolerance test, indirect caloric metric analysis and PET-Scan was performed in MLKL-HF mice. qRT-PCR analysis for de novo lipid synthesis markers (SREBP1c, FAS, SCD1), VLDL secretion markers (Xpb1, ApoB, MTTP, PDI) and inflammation markers (TNF-α, IL6), and fat browning markers (UCP1, Ppargc1a, Dio2) was performed using mice tissue. Oleic acid (OA) treated primary hepatocytes from WT, RIP3KO mice and HepG2 cells treated with RIP3 and MLKL inhibitors were stained using Nile Red staining. The liver tissue from human NAFLD patients was immunostained for MLKL expression and MLKL immunoreactivity (IR) score correlation with NAS score was assessed.
Results: HF diet fed RIP3$^{(-/-)}$ mice showed significant weight gain. RIP3$^{(-/-)}$ mice had increased serum ALT, liver weight and liver/body

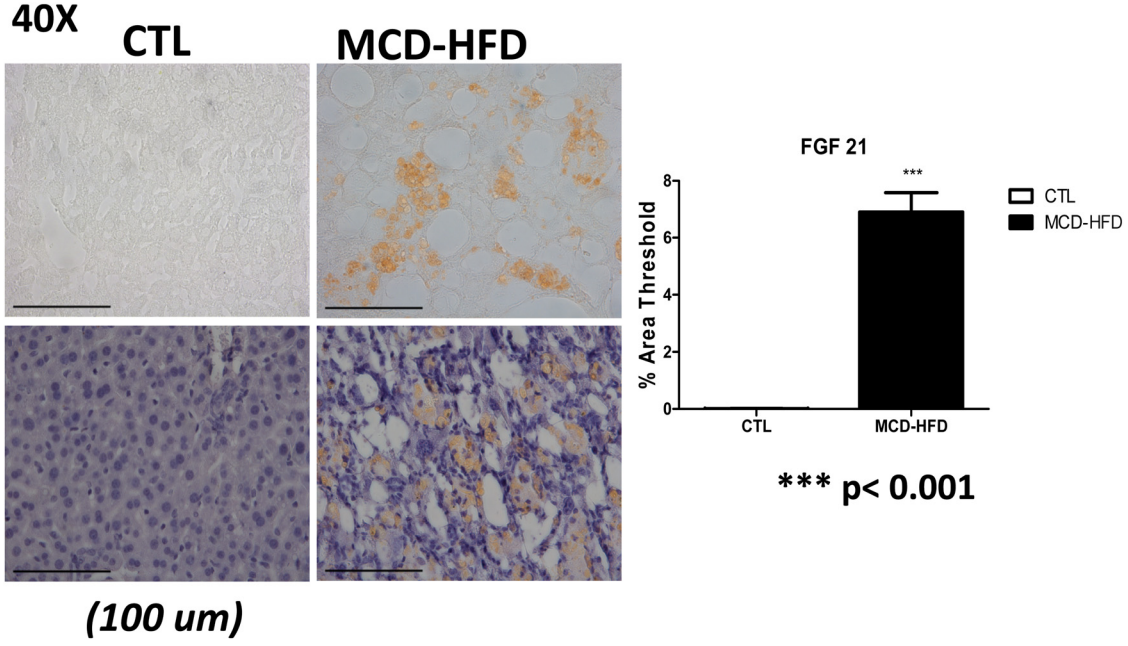

Figure: (abstract: THU-472): Fgf21 immunohistochemistry findings in HFD-MCD mice livers *vs* control group (p < 0.001).

weight ratio compared to wild type mice. RIP3$^{(-/-)}$ mice had decreased hepatic inflammation while increased fatty change, and liver tissue triglyceride; however, total NAS score was same between WT and RIP3$^{(-/-)}$ mice. RIP3$^{(-/-)}$ mice had significantly decreased VLDL secretion markers. MLKL IR score increased in human NAFLD patients and MLKL IR score was correlated with steatosis, lobular inflammation, ballooning degeneration, and NAS score. MLKL$^{(-/-)}$ and WT mice had overall the same body weights; however, interestingly, MLKL$^{(-/-)}$ mice had significantly decreased serum ALT, serum TG, liver weight, fatty change, lobular inflammation, ballooning degeneration and overall NAS score. In contrast to RIP3$^{(-/-)}$KO mice, MLKL$^{(-/-)}$ mice had significantly decreased lipid de novo synthesis markers (SREBP1c, FAS, SCD-1). Adipose tissue F4/80 staining showed decreased crown-like structures in MLKL$^{(-/-)}$ mice. Adipose tissue browning markers, PET-Scan, indirect caloric analysis, and GTT results were the same between WT and MLKL$^{(-/-)}$ mice. OA treated RIP3$^{(-/-)}$ primary hepatocytes had increased Nile Red staining compared to WT hepatocytes. RIP3 inhibitor (Gsk843) treated HepG2 cells showed increased while MLKL inhibitor (Necrosulfonamide) treated HepG2 cells showed decreased Nile red staining.

Conclusion: Both RIP3$^{(-/-)}$ and MLKL$^{(-/-)}$ mouse showed protective effect on hepatic inflammation, but RIP3 and MLKL inhibition depicts divergent effects on hepatic steatosis.

THU-474

Micro RNA 199a-3p attenuates hepatic lipogenesis through regulating specific protein 1

Y. Cheng. *Hospital for Infectious Diseases of Pudong New Area Shanghai China, Department of Liver Disease, Shanghai, China*
Email: drchengyang@126.com

Background and Aims: Emerging studies have demonstrated that microRNAs (miRs) are profoundly involved in non-alcoholic fatty liver disease (NAFLD) and related metabolic diseases. Previously, we revealed a repertoire of miRs dysregulated in NAFLD by high-throughput sequencing. Here, we showed that microRNA-199a-3p was down-regulated in the livers of C57BL/6J mice fed a high-fat-diet (HFD) and oleic acid/palmitic acid-induced Hepa1-6 cells.

Method: Male C57BL/6J mice were fed with HFD and divided into different groups randomly. A group of mice were injected intravenously through the tail vein with the adenovirus expressing a miR-199a-3p mimic or mouse Sp1 and negative control adenovirus vector. Hepa1-6 cell were cultured in routine DMEM supplemented with 10% fetal bovine serum. The NCTC1469 cells were cultured in low-glucose DMEM. Oleate (OA) and palmitate were used to induce the fat overloading cells. The Hepa1-6 cells at 80% confluency were exposed to a long train mixture of OA and PA (HFFA) at a final ratio of 2:1 and final concentration of 1 mM for 24 hr. The miR-199a-3p mimics and inhibitors as well as the negative control (NC) were used for transfection. Quantitative Real-time PCR and Western blot analysis were adopted. Tissues stained with Oil Red O were visualized under a microscope. Hepatic and cellular TG measurement were detected by kits. The luciferase activities were measured consecutively by using the Dual Luciferase Reporter Assay System.

Results: Gain-of-function and loss-of-function studies demonstrated that microRNA-199a-3p exhibited a suppressive role in hepatic lipogenesis. Adenoviral mediated microRNA-199a-3p expression in C57BL/6J mice largely attenuated triglyceride (TG) accumulation and expression of lipogenic genes. Furthermore, we identified Specificity Protein 1 (Sp1) as the functional target of miR-124. Restoration of Sp1 expression largely compromised the effect of microRNA-199a-3p on hepatic TG metabolism.

Conclusion: Taken together, our findings uncover a novel function of microRNA-199a-3p/Sp1 axis in NAFLD and provide a mechanism underlying perturbations of hepatic TG homeostasis.

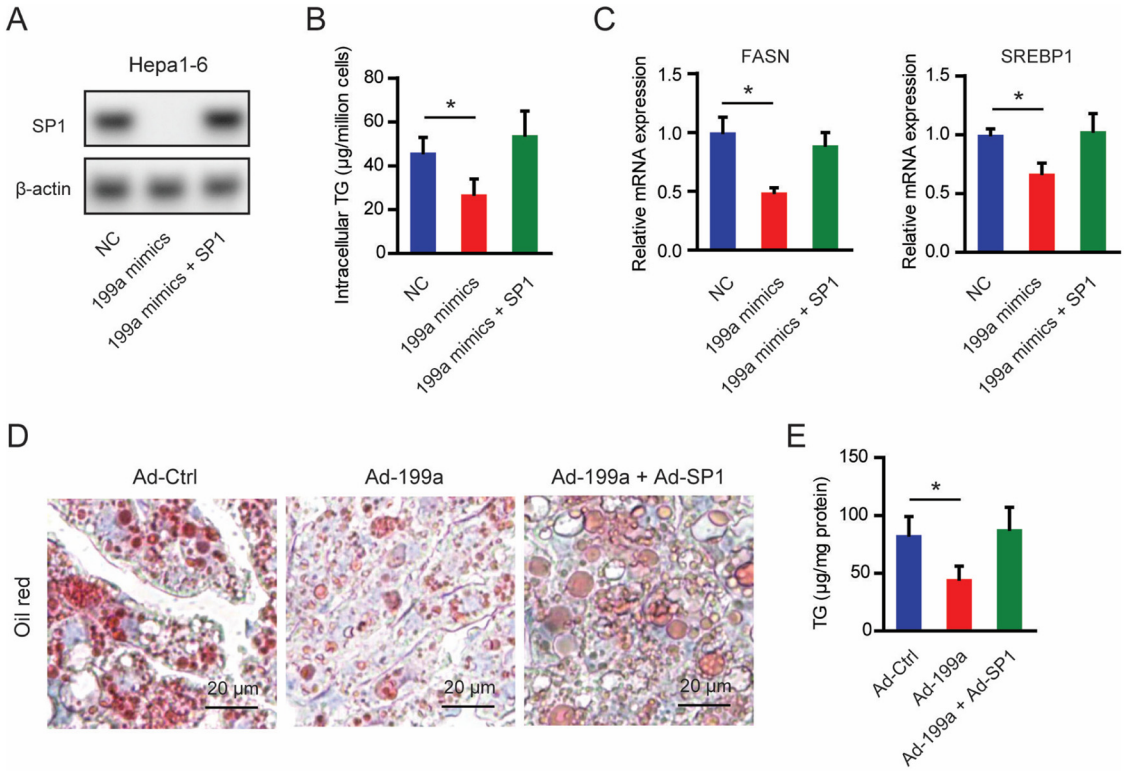

Figure: Restoration of Sp1 abolishes the effect of miR-199a-3p.

THU-475

RIPK1 depletion exacerbates progression of liver fibrosis in high fat diet induced non-alcoholic steatohepatitis (NASH) in mice

M. Farooq, C. Piquet-Pellorce, S. Dion, M.S. Eugenio, K. Santamaria, A. Filliol, M.-T. Dimanche-Boitrel, M. Samson, J. Le Seyec. *IRSET - U.1085 Inserm, Rennes, France*
Email: michel.samson@univ-rennes1.fr

Background and Aims: Non-alcoholic steatohepatitis (NASH) is an emergent chronic liver disease with a high prevalence in occidental countries. NASH can further progress into liver fibrosis, cirrhosis and hepatocellular carcinoma. Hepatocyte death carried through different death ligands plays key role in fibrotic progression. Previously, we showed that RIPK1, a protein kinase known to be involved in pathways related to both cell survival and death, exhibits a protective role in TNFα and FasL-induced hepatocyte death. Our new study aimed to investigate the role of RIPK1 in NASH.
Method: To decipher the role of RIPK1 in NASH, we took advantage of $RIPK1^{LPC-KO}$ mice which are deficient for RIPK1 only in liver parenchymal cells. NASH was induced by feeding both $RIPK1^{LPC-KO}$ animals and their WT ($RIPK1^{fl/fl}$) littermates with High Fat Diet (HFD). Mice were slaughtered at 3, 5 and 12 weeks of HFD feeding and were compared to mice fed with normal chow diet. Cytometry was performed to analyze the recruitment of inflammatory cells during the course of NASH. Plasma cytokine levels were measured by LEGENDplex™. Liver damage was assessed by histological staining and serum transaminase dosages. Liver fibrosis was quantified after Sirius red labelling.
Results: Irrespective of their genotype, mice fed with HFD, showed elevated levels of ALT and liver to body weight ratio during the development of NASH. Important liver infiltrations of immune cells, including NKT cells, were detected at week 3 of HFD. Then, after 5 and 12 weeks of treatment, the number of total immune cells decreased with a total loss of NKT cells. However, some cells such as macrophages and cytotoxic lymphocytes remained over-represented. This inflammation and immune cell infiltration were accompanied by higher plasma doses of cytokines such as TNFα and CCL2. IL-27 and IFNγ were specifically increased at week 3 of HFD. Despite similar inflammatory responses, more fibrosis was significantly evidenced at week 12 in $RIPK1^{LPC-KO}$ as compared to their WT littermates. These findings were further supported by more elevated mRNA expression of TGFBi and TIMP2 (genes indicative of fibrosis) in $RIPK1^{LPC-KO}$ compared to WT mice.
Conclusion: Our results show that RIPK1 in hepatocyte limits the progression of liver fibrosis during NASH.

THU-477

Clinical-grade human liver mesenchymal stem cells reduce NAS score and fibrosis progression in advanced stage NASH pre-clinical model through immunomodulation

M.M. Binda, E. Corritore, L. Menchi, T. Baran, Y. Greiling, S. Michel, J. Tchelingerian, G. Mazza, E. Sokal. *Promethera Biosciences, Mont-Saint Guibert, Belgium*
Email: mercedes.binda@promethera.com

Background and Aims: Nonalcoholic steatohepatitis (NASH), a severe form of nonalcoholic liver diseases (NAFLD), is one of the prominent liver diseases worldwide. There is currently no approved drug for its treatment and liver transplantation is the only therapeutic approach for advanced NASH. Mesenchymal stem cells (MSCs) are promising candidates to modulate the pro-inflammatory and pro-fibrogenic environment of chronic liver because of their immunomodulatory properties. HepaStem, adult human liver-derived MSCs isolated from organs unsuitable for transplantation can be GMP-manufactured, cryopreserved and reconstituted at the bedside as an off-the-shelf product. We previously showed that HepaStem can significantly reduce NAS score and collagen deposition in early stage NASH STAM™ model with necropsy at week 9 (Gellynck K *et al.* 2016). Safety and tolerability have been shown in a phase I/II clinical trial in patients with metabolic disorders. The aim of this study is to evaluate the efficacy of HepaStem in an advanced stage NASH pre-clinical model.
Method: The preclinical NASH mouse model was induced by 2 hits such as streptozotocin at 2 days of age and high-fat diet from 4 weeks of age (first cell infusion at week 10 and necropsy at week 13 STAM™ model). The potency of HepaStem was compared to a vehicle co-administered with immunosuppression (cyclosporine) in order to reduce the potential xenogenic response of the recipient to human cells. As outcome, a NAFLD activity score system, which contains the steatosis, inflammation and ballooning scores, was evaluated.
Results: In an advanced stage NASH model, cell-based treatment (1 and 3 IV injections 12.5×10^6 cells/kg) significantly and dose-dependently decreased NAFLD activity score (22.4% vs 32.6% reduction, $p < 0.05$ and $p < 0.001$, respectively), which was mainly attributed to a significant reduction in inflammation and thus supporting the proposed mechanism of action (Inflammation score: vehicle vs 3 doses of HepaStem: $p < 0.01$). In addition, HepaStem (1 and 3 IV injections 12.5×10^6 cells/kg) cell-based treatment tended to reduce the fibrotic area thus suggesting an inhibition of disease progression in a more advanced NASH model.
Conclusion: In line with our previous results (Gellynck *et al.* 2016), we confirm that clinical grade liver progenitor cells have anti-NASH and may have anti-fibrosis effects in an advanced pre-clinical NASH model. This observation provides significant evidences to open new phase I/II studies including also more severe NASH patients as well as to apply MSCs for the treatment of chronic liver disorders.

THU-478

Ablation of Interleukin-4 Receptor alpha in macrophages ameliorated steatohepatitis and fibrosis in murine model of non alcoholic steatohepatitis (NASH)

M. Ashfaq-Khan[1], M. Aslam[2,3], M. Senkowski[2], M. Nick[1], S.Y. Weng[1], D. Schuppan[1,4]. *[1]Institute of Translational Immunology, University Medical Center, Mainz, Germany; [2]Institute of Translational Immunology, University Medical Center Mainz, Mainz, Germany; [3]Shaheed Benazir Bhutto Women University, Peshawar, Pakistan; [4]Division of Gastroenterology, Beth Israel Deaconess Medical Centre, Harvard Medical School, Boston, United States*
Email: m.ashfaq_biotech@yahoo.com

Background and Aims: The role of immune cell populations in NASH-related inflammation and fibrosis remains controversial. However, targeting of specific receptors that switch immune cell phenotypes is attractive. We aimed to study the role IL-4 receptor alpha (IL-4Rα) which represents a central switch to generate Th2 T cells and M2 macrophages upon stimulation with interleukin (IL)-4 and IL-13 in a representative mouse model of NASH.
Method: 8-week-old male Balb/C wild type mice and Balb/C mice with general or macrophage specific deletion of IL-4Rα (Balb/C IL-$4R^{-}/^{-}$ and $LysM^{cre}$IL-$4R\alpha^{-}/^{lox}$) mice were fed a choline-deficient, L-amino acid-defined (CDAA) diet for an additional 12 weeks. Thereafter mice were sacrificed, and liver tissues sections were snap frozen and fixed in paraformaldehyde for further analysis.
Results: There was significant decrease in the liver weights of both the KO strains (Balb/C IL-$4R^{-}/^{-}$ and $LysM^{cre}$IL-$4R\alpha^{-}/^{lox}$) compare to the wild type mice. H&E and Sirius Red stained sections revealed a significant reduction of the NAS score (adapted for mice) from 7 to 5 and extent of fibrosis in Balb/C IL-$4R^{-}/^{-}$ B and Balb/C $LysM^{cre}$IL-$4R\alpha^{-}/^{lox}$ mice compared to the wild type controls. Hydroxyproline assay revealed significant reduction of fibrosis in CDAA fed IL-4R KO mice (both general and myeloid specific) compare to the CDAA fed

wild type control. In wild type mice, steatosis was >66% and macrovesicular, whereas steatosis in the IL-4Rα knockout mice was reduced and more concentrated in zone 3 with more microvesicular fat. Fibrosis score was 2.X in the wildtype vs <1 in both knockout strains. Specifically, CD68+ macrophages were significantly decreased in both L-4Rα compared to the wildtype mice ($p \leq 0.0096$), paralleled by significantly suppressed hepatic transcript levels for Col1a1, Tgfb and Tnfa.

Conclusion: We showed that 1. Ablation of the IL-4Rα alpha on macrophages as well as in general, comparably suppressed steatosis, inflammation and fibrosis in the CDAA model of NASH; 2. IL-4Rα targeted therapies, including inhibition of IL-4 and IL-13 is a potential therapy of fibrotic NASH.

THU-479

Combined administration of obeticholic acid (OCA) and GFT-505: additive histological improvements in mice with diet-induced and biopsy-confirmed non-alcoholic steatohepatitis (NASH)

J. Roth[1], S. Veidal[2], R. Papazyan[1], K. Rigbolt[2], M. Feigh[2], M. Young[1].
[1]*Intercept Pharmaceuticals, Inc., San Diego, United States;* [2]*Gubra, Horsholm, Denmark*
Email: jonathan.roth@interceptpharma.com

Background and Aims: OCA is a farnesoid X receptor (FXR) agonist and GFT-505 is a dual PPARα/δ agonist. Both have demonstrated efficacy in NASH and their endogenous targets are complementary. Using a prevention paradigm in a CDAA/high cholesterol model, a prior report noted benefits when both were co-administered (Ratziu et al. 2017; J of Hepat 66: S95–S332). The present study used (1) a therapeutic paradigm to examine individual and combined effects upon established diet-induced NASH, and (2) expression analyses to uncover pathways activated by combined FXR/PPAR administration.

Method: *Lep*$^{ob/ob}$ mice were fed the AMLN NASH diet or chow for 12W, biopsied and randomized (n = 12/group) to receive Vehicle (0.5% CMC, PO, QD), OCA (30 mpk), GFT-505 (3 or 10 mpk) or their combination for a further 8W while remaining on the NASH diet. Fractional area (%) calculations were performed for steatosis, galectin-3 (inflammation) and collagen 1a1 (fibrosis). Post-treatment, a portion of liver was collected for RNA Seq.

Results: Monotherapy with OCA or GFT-505 improved all histological parameters and both combinations exerted greater effects than either monotherapy ($p < 0.05$ vs. OCA and GFT-505; table). Monotherapy with FXR or PPARα/δ agonism elicited distinct expression profiles and the combination led to additive decreases in inflammatory and fibrotic genes and pathways.

	Steatosis (%)		Galectin-3 (%)		Collagen-1a1 (%)	
Treatment (mpk)	Baseline	Post-Rx	Baseline	Post-Rx	Baseline	Post-Rx
Vehicle	38.8 ± 2.5	31.8 ± 3.2	10.8 ± 1.0	10.2 ± 1.8	5.5 ± 1.7	13.8 ± 2.4
OCA (30)	38.8 ± 4.1	15.2 ± 3.2*	11.3 ± 1.9	6.8 ± 1.0*	6.0 ± 2.3	10.5 ± 1.5*
GFT-505 (3)	38.8 ± 2.8	22.8 ± 3.8*	10.9 ± 1.6	7.7 ± 2.5	5.7 ± 1.7	9.7 ± 2.7*
GFT-505 (10)	38.6 ± 4.4	19.3 ± 5.6*	11.5 ± 1.5	6.1 ± 1.8*	5.6 ± 2.3	8.9 ± 2.0*
OCA + GFT-505 (3)	36.3 ± 3.3	4.7 ± 3.1*,#	10.2 ± 1.7	3.6 ± 1.2*,#	5.4 ± 2.4	6.3 ± 1.5*,#
OCA + GFT-505 (10)	38.3 ± 1.1	2.4 ± 1.7*,#	10.3 ± 1.8	3.4 ± 0.6*,#	5.1 ± 2.0	6.0 ± 1.2*,#

*p < 0.05 vs. vehicle controls.
#p < 0.05 vs. both monotherapies.

Conclusion: OCA or GFT-505 monotherapy improved multiple histological parameters and combination therapy elicited clear additive (or greater) effects with normalization of steatosis and inflammation to levels below baseline and prevention of fibrosis progression. Histologic additivity was associated with additive improvements for individual genes and core NASH pathways. These preclinical findings provide additional proof-of-concept for combined FXR/PPAR-based therapies using a different NASH model and treatment regimen.

THU-480

Evaluation of the rodent Octodon degus as a pre-clinical model of liver fibrosis

S. Brockbank[1], P. Cogram[2], D. Leeming[3], S.T. Hjuler[3], S. Cruwys[4].
[1]*Grunenthal, Innovative Medicines Unit;* [2]*GeN, Chile;* [3]*Nordic Bioscience, Fibrosis Biology and Biomarkers, Copenhagen, Denmark;* [4]*Grunenthal, Innovative Medicines Unit, Aachen, Germany*
Email: sarah.brockbank@grunenthal.com

Background and Aims: Models of NASH, driven by mechanisms which reflect pathogenesis of human disease and which exhibit advanced steatohepatitis combined with insulin resistance are in short supply. Attempts to recapitulate human disease often involve the use of non-physiological drivers over a long duration. The *Octodon degus* is naturally insulin resistant caviomorph rodent which can readily develop diabetes mellitus on a diet of simple fruit sugars, and in a preliminary study administration of an atherogenic diet (AD) induced fatty liver disease. This study aims to characterise the rodent *O degus* as a natural preclinical model for the study of NASH.

Method: Adult O degus (aged 12m) were included in the study. One group (n = 10) was fed AD (0.25% Cholesterol/6% Palm Oil), titrated from 0.5% to complete AD over 6 weeks (weeks 1 & 2 @ 50%, week 3 & 4 @ 70% and week 5 & 6 @ 100% AD). The control group (n = 10) was fed with standard chow diet. Blood was obtained at basal, 2, 4 and 6 weeks for assessment of clinically relevant serum biomarkers (Pro-C3, C3M). At termination (6 weeks) blood profile of lipids, hepatic enzymes and histological analysis of the liver was undertaken using 3 stains: hematoxylin-eosin, Masson's trichrome and oil red.

Results: Animals retained weight over the duration of the study, while those on the high fat diet showed a 2 fold increase in liver-to-body weight ratio ($p < 0.0001$). The high fat diet induced a notable hepatic steatosis at 6 weeks and increased liver triglyceride concentration 2 fold ($p < 0.0002$), total cholesterol (150% increase, $p < 0.0001$) and LDL increased by 5 fold ($p < 0.0001$) whereas HDL was significantly decreased ($p < 0.0001$). The blood hepatic profile showed significant increases ($p < 0.0001$) in γ-glutamyltransferase, aspartate aminotransferase and alanine aminotransferase. Serum biomarkers (Pro-C3, C3M) were significantly increased on AD and fibrosis induced after 6 weeks, as assessed by histology.

Conclusion: Here we describe the O degus as a natural model of NASH which develops over a short duration and replicates features of the human disease. Features including insulin resistance, advanced steatohepatitis and fibrosis, along with elevation of clinically relevant biomarkers make this a potential preclinical model for drug discovery programs and translation to the clinic.

Email: luca.valenti@unimi.it

Background and Aims: Inherited factors modify the risk of non-alcoholic fatty liver disease (NAFLD), steatohepatitis (NASH) and liver fibrosis by regulating hepatocellular lipid handling. Deregulation of iron and lipoprotein metabolism are typical features of NAFLD. The rs236918 G > C intron variant in the Proprotein Convertase Subtilisin/Kexin Type 7 (PCSK7) gene has been associated with liver fibrosis in hereditary hemochromatosis and its variation influences circulating lipid levels. Aim was to examine the impact of the rs236918 PCSK7 variant on iron metabolism, metabolic traits and liver disease in patients at risk of NASH.
Method: We genotyped rs236918 in 1801 European NAFLD patients from the Liver Biopsy Cross-Sectional Cohort (LBC). Liver damage was assessed according to NAS, PCSK7 hepatic expression by qRT-PCR, protein and circulating levels by Western blot and ELISA respectively, in a subset (n = 78).
Results: The C allele was associated with higher transferrin saturation (Estimate: +4.82; 0.34–9.29; p = 0.035) and circulating triglycerides (Estimate: +0.09; 0.007–0.17; p = 0.03). Concerning liver damage, while it had no effect on steatosis and ballooning, the C allele was independently associated with more severe lobular inflammation at multivariate analysis (Table 1). However, this did not translate in more severe fibrosis. PCSK7 was more expressed in hepatocytes than in hepatic stellate cells (p < 0.05) and gene expression correlated with *de novo lipogenesis* (p < 0.05). The rs236918 variant affected hepatic expression levels of PCSK7 alternative mRNA transcripts. Furthermore, carriers of C allele showed increased PCSK7 protein in the liver and in the circulation compared to non-carriers (p < 0.01, n = 72), and circulating PCSK7 was correlated with serum triglycerides.

Table 1: Impact of PCSK7 rs236918 variant on hepatic lobular inflammation in 1801 NAFLD patients from the LBC

	Estimate	95%CI	*p adjusted
Age, yrs	–0.0008	–0.007 to 0.005	0.80
Sex, M	+0.17	0.07–0.27	0.001
BMI, Kg/m^2	–0.02	–0.03 to –0.01	0.0002
T2DM, yes	+0.33	0.22–0.44	<0.0001
PNPLA3, I148M	+0.42	0.29–0.56	<0.0001
TM6SF2, E167K	+0.28	0.03–0.54	0.03
MBOAT7, T allele	+0.10	–0.02 to 0.23	0.11
PCSK7, C allele	+0.22	0.02–0.42	0.03

Conclusion: The PCSK7 rs236918 G > C variant may bridge hepatic inflammation with deregulation of iron metabolism and dyslipidemia in NAFLD patients. The mechanism may be related to increased PCSK7 protein levels, suggesting PCSK7 as a new therapeutic target for metabolic disorders.

THU-482

Expression profiling of 728 miRNAs in a NASH model identifies excellent correlations of hepatic and circulation miR-34a levels with histological lesions in rats and men

G. Cordonnier[1], F. Texier[1], N. Benoit[1], D. Nathalie[1], F.B. Sudrick[1], J. Brozek[1], R. Hanf[1], A. Sanyal[2]. [1]*GENFIT sa, Loos, France;* [2]*Virginia Commonwealth University, Richmond, United States*
Email: genevieve.cordonnier@genfit.com

Background: Changes in the hepatic expression of miRNAs might be instrumental in the development of non-alcoholic steatohepatitis (NASH) and fibrosis.
Aim: In order to identify miRNAs for non-invasive diagnosis of NASH, the aim of this animal study was to screen for miRNAs showing good correlations of both hepatic and circulating levels with histological lesions. Suitable miRNAs were tested for their clinical utility as new circulating biomarkers of NASH in a cohort of NAFLD patients.
Method: Wistar rats were fed a control diet (CSAA), or a choline deficient amino acid diet (CDAA) with or without 1% cholesterol for 11 weeks. Hepatic expression of 728 mature rno-miRNAs was analyzed using Affymetrix miRNA chip V4.0. The most differentially expressed miRNAs (CDAA + chol vs Control) were quantified by RT-qPCR in liver and plasma samples to assess correlations with NASH histological scores and fibrosis. Diagnostic performances of circulating levels of selected miRNAs were then compared in a cohort of NAFLD patients (GOLDEN study; n = 269).
Results: Expression array analysis of rat liver extracts revealed that 79 miRNAs were upregulated and 17 were downregulated in diseased livers (CDAA + chol vs control, FC ≥ 1.5, p ≤ 0.05). The two most upregulated miRNAs were miR-132-3p (51.7 fold, p < 0.0001), miR-34a-5p (26.2 fold, p < 0.001), while miR-122a-5p expression was not affected. RT-qPCR analyses showed that i) both hepatic and plasma levels of miR-34a strongly increased with NASH histological scores (NAS, steatosis, lobular inflammation, hepatocyte ballooning) and fibrosis stage, ii) for miR-122a, there was a weak negative correlation between hepatic levels and histological scores but, in contrast, there was a strong positive correlation when considering plasma levels. In NAFLD patients, serum level of miR-34a-5p increased with NAS and fibrosis stage whereas serum level of miR-122a-5p increased with NAS, but not with fibrosis stage. Finally, when measuring serum levels, miR-34a-5p was more potent than miR-122a-5p and miR132-3p in detection of patients with active disease and significant fibrosis (NAS ≥ 4 and F ≥ 2): AUROC = 0.74 vs 0.59 vs 0.58.
Conclusion: Hepatic miRNA expression is profoundly modified in NASH, supporting a major role in NASH and liver fibrosis. Compared to other miRNAs and notably miR-122a-5p, both hepatic and circulating levels of miR-34a are significantly correlated with the hepatic lesions, making serum miR-34a a potent biomarker with clinical utility for non-invasive diagnosis of NASH.

THU-483

Discovery of Inhibitors of NLRP3 inflammasome assembly for the treatment of NASH and liver fibrosis

J. Veal[1], C. Mcbride[1], M. Lazic[1], D. Povero[1], G. Ambrus[1], A. Santini[1], R. Stansfield[1], L. Trzoss[1], C.D. Johnson[2], J. Stafford[1], A. Feldstein[2]. [1]*Jecure Therapeutics Inc., San Diego, United States;* [2]*University of California at San Diego, Pediatrics, La Jolla, United States*
Email: jveal@jecuretx.com

Background and Aims: Persistent NLRP3 inflammasome activation has been shown to result in caspase-1 dependent hepatocyte pyroptosis and transdifferentiation/activation of hepatic stellate cells. Here we describe the discovery of novel small-molecule inhibitors of the NLRP3 inflammasome that have the potential to block the progression of NASH and liver fibrosis.
Method: Phenotypic screening was used to identify selective inhibitors of the NLRP3 inflammasome. Compounds were tested on human peripheral blood mononuclear cells (PBMCs), human Kupffer cells (KCs), and mouse bone marrow-derived macrophages (BMDMs). Secreted levels of IL-1β, IL-18 and TNFα were measured in response to distinct inflammasome activators. Effects on pyroptotic cell death and caspase activation were evaluated, and immunofluorescence imaging was used to characterize the mechanism of action of the inhibitor class. Pharmacokinetic profiles of selected compounds were determined in mice. In vivo efficacy studies were performed in *Nlrp3*$^{A350V/+}$*CreT* Muckle Wells Syndrome (MWS) and diet-induced NASH models.
Results: We identified novel molecules that dose dependently inhibited the cellular release of IL-1β and IL-18, following NLRP3 inflammasome stimulation. Lead molecules JT194 and JT349 demonstrated sub-100 nM cellular potency. Production of TNFα was not affected by the compounds. IL-1β secretion was blocked by the inhibitors when cells were stimulated by NLRP3 activators, nigericin or ATP, but not by NLRP1, AIM2 or NLRC4 specific stimuli. Inhibition of cellular caspase-1 activity, but not caspase enzymatic function, was

also observed. Analysis of cell viability in treated PBMCs and BMDMs showed a cytoprotective effect consistent with an anti-pyroptotic phenotype. Immunofluorescence for ASC in stimulated cells detected Nlrp3-ASC specks whose formation were abrogated by JT194 and JT349 treatment, revealing an activity of these compounds on the assembly of the NLPR3 inflammasome complex. Dosed orally in mice, JT194 and JT349 each provided excellent plasma exposure, and in vivo blockade of IL-1β production was demonstrated following a single dose below 5 mg/kg in a mouse acute LPS + ATP challenge model. In both *Nlrp3*$^{A350V/+}$*CreT* mouse and diet induced NASH models, daily oral administration of JT194 was well tolerated and significantly inhibited markers of inflammation and liver fibrosis.
Conclusion: Our studies identified novel compounds JT194 and JT349 that potently and selectively inhibited NLRP3 inflammasome activation in vitro and in vivo. These NLRP3 assembly inhibitors demonstrated favorable pharmacokinetics in mice suitable for oral administration, and efficacy was observed in advanced NASH and liver fibrosis studies. The results support advancement of NLRP3 inflammasome inhibitors into further safety studies and ultimately into clinical trials.

THU-484
Four-and-a-half LIM-domain protein affects diet induced (hepatic) steatosis and lipid droplet formation
J. Sommer, C. Hellerbrand. *Friedrich-Alexander University Erlangen-Nürnberg, Institute of Biochemistry, Erlangen, Germany*
Email: claus.hellerbrand@fau.de

Background: The four-and-a-half LIM-domain protein 2 (FHL2) is expressed in almost all tissues, including the liver, and exerts tissue- and cell context- specific functions. It acts as transcriptional cofactor and has already been shown to interact with >50 proteins, amongst them signaling cascade proteins as well as proteins involved in the regulation of proliferation and apoptosis. Some studies revealed a role of FHL2 in liver disease and hepatocellular carcinoma, but its impact on (hepatic) lipid metabolism or non-alcoholic fatty liver disease (NAFLD) has not yet been studied.
The aim of this study was to investigate the role of FHL2 in NAFLD.
Methods and Results: Starting 8 weeks after birth, male FHL2 wildtype (wt) and knockout (FHL2$^{-/-}$) mice (littermates) were fed with a Western-type diet (WTD) containing 38% fat, 30% sucrose and 0.2% cholesterol for 19 weeks. Controls were fed with standard chow. Basal body weight did not differ between genotypes. However, WTD-induced weight gain was decreased in FHL2$^{-/-}$ compared to wt mice, although food-consumption and fatty-acid (FA) concentration in faeces did not differ, indicative for similar FA-uptake. Glucose tolerance was not impaired in WTD-fed FHL2$^{-/-}$ mice in contrast to their wt counterparts, which exhibited starting insulin resistance. Adipose tissue mass was massively increased in WTD-fed FHL2$^{-/-}$ mice and revealed significantly increased expression of fat-specific protein 27 (FSP27), annexin A6 (Anxa6) and genes of the perilipin family, which are all modulating lipid droplet formation and maturation as well as their lipolysis. Also in the liver, triglycerides (TG) levels were significantly decreased in FHL2$^{-/-}$ mice compared to wt mice, while cholesterol and bile acids (BA) levels did not differ between genotypes. Despite reduced steatosis, WTD-induced pro-inflammatory gene expression was lower in FHL2$^{-/-}$ mice compared to wt mice. Also *in vitro*, primary hepatocytes (mpH) isolated from FHL2$^{-/-}$ mice had lower basal TG levels compared to wt mpH. Similarly, siRNA-mediated FHL2 suppression in the human hepatoma cell line HepG2 caused reduced cellular TG levels. Interestingly, *in vitro* as *in vivo* lipid droplets appeared significantly smaller in FHL2 depleted hepatocytes, and fitting to this, revealed decreased perilipin 2 (Plin2) expression.
Conclusion: FHL2 quantitatively and qualitatively affects (diet) induced (hepatic) steatosis. Analysis of the underlying mechanisms may lead to the identification of new prognostic markers or therapeutic targets for the development and progression of NAFLD.

Background and Aims: NS-0200, a combination of leucine (Leu) with low-doses of metformin (Met) and sildenafil (Sil) that synergize to activate Sirt1-AMPK signaling, is currently in clinical investigation for the treatment of nonalcoholic steatohepatitis (NASH). The objective of the present study was to compare the histopathological effects of NS-0200 with two related leucine combinations (leucine-metformin and leucine-sildenafil) and to compare the effects of the combinations on relevant gene-regulatory pathways in an obese rodent model of diet-induced and biopsy-confirmed NASH (the Gubra DIO-NASH mouse).
Method: NASH was induced by feeding C57BL/6J mice a diet high in trans-fat, fructose and cholesterol (AMLN diet) for 35 weeks. This was followed by liver biopsy to confirm NASH and fibrosis ≥ stage 1. Col1a1 staining was used for stratification of mice into treatment groups for 12 weeks: vehicle; low-fat chow reversal; Leu (1.2 g/kg)+ Sil (1.25–5.0 g/kg); Leu + Met (50 mg/kg)+ Sil (1.25–5.0 mg/kg); or chow vehicle (no NASH induction). Following termination, liver steatosis, inflammation, ballooning and fibrosis stages were assessed, liver Col1a1 and Galectin-3 measured by immunohistochemistry and morphometry and a number of metabolic parameters were measured. The liver was analyzed using RNAseq.
Results: Leu + Met, Leu + Sil and Leu + Met + Sil significantly regressed steatosis, inflammation and ballooning at all doses, and approached the efficacy of the low-fat chow reversal diet. However, only Leu + Met + Sil effectively regressed fibrosis at the lowest Sil dose, with comparable effects only at the highest doses of Leu + Sil in the absence of Met; Leu + Met exerted no independent effect on fibrosis. Col1a1 staining was reduced by Leu + Met + Sil comparable to the effects of chow reversal, while Leu + Met and Leu + Sil exerted no significant effects. Intervention with the Leu + Met + Sil induced robust gene expression profile changes, with notable significant inhibition of stellate cell activation and monocyte recruitment pathways, while Leu + Met and Leu + Sil exerted only minor effects on a small number of genes.
Conclusion: These data indicate that Leu + Met, Leu + Sil and Leu + Met + Sil (NS-0200) all significantly regress steatosis, inflammation and ballooning in this DIO-NASH model, while only NS-0200 exhibited a robust reduction in Col1a1 protein and gene expression, as well as in stellate cell activation pathways, resulting in significant fibrosis regression.

THU-486
Comorbidity-specific augmented hepatic injury in a murine model of obesity-induced NAFLD and peritoneal sepsis
P. Horn[1,2], S. Vlaic[3], R. Steidl[4], M. Bläss[4,5], R.A. Claus[1,4]. *[1]Center for Sepsis Control and Care, Jena University Hospital; [2]Department of Internal Medicine IV, Jena University Hospital; [3]Research Group Systems Biology/Bioinformatics, Leibniz Institute for Natural Product Research and Infection Biology (Hans Knöll Institute), Jena; [4]Department of Anesthesiology and Intensive Care Medicine, Jena University Hospital, Jena; [5]Institute of Precision Medicine, Medical and Life Sciences Faculty, Furtwangen University, Villingen-Schwenningen*
Email: paul.horn@med.uni-jena.de

Background and Aims: Obesity and non-alcoholic fatty liver disease (NAFLD) are increasingly prevalent in the general population and may have a major impact on development and resolution of sepsis-induced hepatic organ dysfunction. Though increased sepsis-induced mortality has been shown in animal models of obesity, underlying mechanisms and specific influence of NAFLD on liver dysfunction in sepsis have not been studied yet. We aimed to implement a murine

comorbidity model of obesity-induced NAFLD and polymicrobial sepsis to study comorbidity specific signaling pathways.
Method: Six weeks old male C57BL/6 mice were fed with control diet (CD) or high fat diet (HFD) for twelve weeks to induce a metabolic-syndrome (MeS)-like phenotype. Mice were repeatedly weighted and intraperitoneal glucose tolerance test was performed. Sepsis was induced by peritoneal contamination and infection (PCI). At baseline, six and 24 hours after sepsis induction, blood and liver samples were collected. We measured laboratory markers of organ function and metabolism, performed H&E liver histology and real-time quantitative PCR (RTqPCR). Using microarray transcriptome data, we performed gene enrichment analyses of differentially expressed genes.
Results: By HFD we induced a MeS-like phenotype, constituting increased body weight, impaired glucose tolerance and hypercholesterolemia. This was accompanied by severe liver steatosis without alterations in ALT or bilirubin levels at baseline. Peritoneal sepsis lead to a significantly increased 72 h mortality in the HFD group (93% vs 47%, $p = 0.022$). We observed increased levels of ALT and bilirubin 24 h after sepsis induction in HFD, indicating increased sepsis-induced hepatic injury. In contrast, renal function was not altered in HFD compared to CD mice 24 h after sepsis induction. Gene enrichment analysis of differentially expressed genes associated with HFD-specific impact on sepsis revealed comorbidity specific regulation predominantly in metabolic pathways besides regulation of inflammatory processes. Compared to CD, we observed a more sustained effect of HFD on sepsis-induced downregulation of hepatic Cyp1a1 and Mrp2 mRNA in confirmatory RTqPCR, pointing towards a more reduced drug metabolism capacity in NAFLD comorbidity.
Conclusion: We evaluated a comorbidity model of obesity-induced NAFLD and peritoneal sepsis reflecting higher mortality rate and increased severity of sepsis-induced hepatic injury. It may serve to discover comorbidity-specific signaling pathways and new therapeutic targets.

THU-487
The anti-inflammatory and anto-fibrogenic effects of namodenoson in NAFLD/NASH animal models

P. Fishman[1], A. Salhab[2], S. Cohen[1], J. Amer[2], I. Itzhak[1], F. Barer[1], R. Safadi[2]. *[1]CanFite Biopharma; [2]Hadassah University Hospital*
Email: pnina@canfite.co.il

Background and Aims: Namodenoson is a novel drug candidate, currently in Phase II clinical study for the treatment of NAFLD/NASH. The drug targets the Gi protein associated A3 adenosine receptor (A3AR), known to mediate differential effects on pathological and normal cells. Namodenoson is an A3AR small molecule agonist that acts as a robust anti-inflammatory agent in the Con. A induced liver inflammation model and at the same time possesses an hepato-protective effect in ischemia-reperfusion and partial hepatectomy models. Based on this dual effect, it has been assumed that namodenoson will positively act as an anti-NAFLD/NASH agent.
Method: NASH model was induced in C57BL/6 mice by injection of streptozotocin two days after birth followed by high fat diet feeding since age of 4 weeks. Namodenoson or vehicle administered orally along 6–9 weeks of age. Hepatic fibrosis model was induced in C57BL/6 mice by intraperitoneal Carbon Tetrachloride (CCl_4) injections, twice weekly, for 6 weeks. Namodenoson 100 μg/kg was injected intra peritoneally. 24 hours after each CCl_4 dosing.
Results: In the NASH model, the namodenoson treated group showed a significant decrease in steatosis, ballooning and lobular inflammation compared to the vehicle treated one. Furthermore, the drug reduced liver-to-body weight ratio ($p = 0.05$) and decreased ALT and Triglyceride levels. Moreover, a significant decrease in CK-18 and increase in adiponectin were also noted. In the CCl_4 model, normal macroscopic liver with no ascites was observed in the namodenoson treated group, and a decrease in ALT serum levels was found as well. Activated pro-fibrogenic NKT ($NK1.1^+$ $CD3^+$ $CD107a^+$) cell numbers were increased from 16.8 ± 3% (naïve) to 76 ± 1.2 ($p < 0.0001$) following CCl_4 induction and alleviated to 14.9 ± 11.4% ($p = 0.001$) after namodenoson therapy. Down-regulation of A3AR protein expression level was followed by a decrease in p-STAT-1, PI3K and αSMA in the liver extracts derived from the namodenoson treated animals.
Conclusion: The robust anti-NAFLD/NASH effect of namodenoson was mediated via a molecular mechanism leading to a decrease in αSMA and CK-18. These data together with the anti-steatotic effect, are positioning namodenoson as a potential drug candidate to combat this liver disease.

Histopathologic assessment of fatty liver progression in a rodent model of chronic intake of high-fat diet, ethanol or both

A.R. Mendoza[1], A. Campos-Espinosa[1], M. Galicia-Moreno[2], B. León-Mancilla[2], T.A. Arévalo-Sánchez[1], K.Z.M. Ávila[3], I.I. Romero-Bello[1], R.O. Dorothy[2], A. Pérez-Torres[4], C. Guzman[1], G. Gutierrez-Reyes[2]. *[1]Hospital General de México, Unidad de Medicina Experimental, Laboratorio de Hígado, Páncreas y Motilidad, Mexico City, Mexico; [2]Universidad Nacional Autónoma de México, Facultad de Medicina, Laboratorio de Hígado, Páncreas y Motilidad, Mexico City, Mexico; [3]Universidad Nacional Autónoma de Méx, Laboratorio de Hígado, Páncreas y Mo, Mexico City, Mexico; [4]Universidad Nacional Autónoma de México, Facultad de Medicina, FSIPyM Depto. Biología Celular y Tisular, Mexico City, Mexico*
Email: carova@prodigy.net.mx

Background and Aims: Obesity is highly prevalent risk factor for non-alcoholic fatty liver disease (NAFLD) worldwide. In developing and developed countries, chronic alcohol intake, another cause of fatty liver and cirrhosis, is common among obese patients. Both etiologies have been independently studied for fatty liver disease and fibrosis development, and share physiopathologic mechanism during disease progression. We aimed to describe the histopathologic liver features of the coincidence of these insults in the mouse with chronic intake of a high-fat diet (HF), ethanol (OH) or both.
Method: C57BL/6 male mice aged 10 weeks and weighing 25 ± 2 g were randomly assigned to received either Chow (control diet, C) or HF (19% lard) and water or OH (20% v/v). Four groups were obtained and maintained for 4 or 6 months. Two additional groups were included with an initial insult (HFD or OH) during 4 months followed by a secondary insult (OH or HFD) during further 4 or 6 months. Both food and beverage were allowed *ad libitum*. Weight gain, food and beverage intake were recorded. Liver samples were collected in tissue-tek or neutral buffered formalin and embedded in paraffin. Paraffin sections were stained by hematoxyline-eosin, Masson's tricrhome and Wilder for reticular fibres. Frozen tissue-tek sections were stained by Oil Red O.
Results: Weight gain was higher in mice receiving HF, food intake was decreased in those drinking OH. Histological changes were observed according to the experimental group. No evident signs of steatosis were observed in COH group; however reticular fibres were present at the sinusoidal space. At 4 months, livers in the HF group showed microvesicular steatosis with 30.6 ± 5.6% of fat and by 6 months 39.5 ± 4.4% of fat accompanied by ballooning and inflammation were observed. Mice receiving both insults simultaneously showed increased macro and microvesicular steatosis in zones 1 and 3 of the acinus. Interestingly, mice receiving a primary insult of OH followed by an insult of HF (COH→HFW) exhibited the highest amount of liver fat compared to insults alone, exhibiting macrovesicular steatosis (4 months: 35.4 ± 2.6; 6 months: 54.7 ± 6.5%) and ballooning by 6 months. In contrast, the group with a primary insult of HF followed by OH (HFW→COH) showed low steatosis and reticular fibres.
Conclusion: Steatosis and other architectural changes in the liver depend on the interaction of the insults received. High fat diet is able to induce NASH after appropriate time. The order of the insults matters, in HFW→COH, reversion of steatosis induced by HF occurred

during OH exposition but not the opposite, in COH→HFW reticular fibre were still present after HF exposition. Our data suggest that, at least in mice, a chronic alcohol intake period followed by an obesogenic diet induces severer steatosis when compared to independent insults.

Nicotinamide, not N1 methylnicotinamide, ameliorates hepatic steatosis via NAD-depended sirtuin activation

S. Morizono[1], K. Ohe[2], S. Kiso[3], K. Tanabe[4], N. Ookubo[5], N. Togawa[6], M. Enjoji[2], M. Nakamuta[7]. *[1]Saiseikai Fukuoka General Hospital, Department of Gastroenterology, Japan; [2]Faculty of Pharmaceutical Sciences, Fukuoka University, Department of Clinical Pharmacology, Fukuoka, Japan; [3]Graduate School of Medicine, Osaka University, Department of Community Medicine, Suita, Japan; [4]LSI Medience Corporation, Medical Solution Promotion Department, Tokyo, Japan; [5]LSI Medience Corporation, Planning and Coordination Department, Tokyo, Japan; [6]Mitsubishi Chemical Corporation, Bio-Device Group,Tsurumi R&D Center, Tokyo, Japan; [7]National Hospital Organization Kyushu Medical Center, Department of Gastroenterology, Fukuoka, Japan*
Email: morizono@saiseikai-hp.chuo.fukuoka.jp

Background and Aims: Nicotinamide (NAM), a metabolite of NAD catalyzed by Sirts, is reutilized for NAD synthesis via nicotinamide mononucleotide (NMN) by nicotinamide phosphoribosyltransferase (Nampt) (Fig. 1). NAM is also converted to N^1 methylnicotinamide (MNAM) by nicotinamide N-methyltransferase (Nnmt) using S-adenosylmethionine (SAM). SAM is a major methyl group donor and is involved in the production of polyamine, phosphatidylcholine, and sarcosine (methylglycine) as well as MNAM. MNAM produced by Nnmt was reported to improve hepatic steatosis (Nat Med. 2015;21:887). On the other hand, the knockdown of Nnmt was reported to protect the liver from hepatic steatosis (Nature. 2014;508:258). We first investigated whether NAM has a protective effect on hepatic steatosis, and then whether NAM works through the NMN~NAD or MNAM pathway.

Method: C57BL/6J mice (n = 20) were divided into four groups and fed with: normal diet (ND); ND + NAM (NAM mixed with ND to 0.1% wt/wt); high fat diet (HFD); HFD + NAM for 8 weeks. The contents of NAM-related materials in the liver, NAM, NAN, NAD, MNAM, SAM, S-adenosylhomocysteine (SAH), spermidine, glycine, sarcosine were measured by LC/MS (Fig. 1). The expression of NAD metabolism-related genes was evaluated by real-time RT-PCR. Finally, microbiota analysis was performed using a deep sequencer.

Results: NAM histologically ameliorated hepatic steatosis as well as body weight gain caused by HFD. With regard to hepatic NAM-related contents, NAD was decreased in HFD + NAM compared to HFD, while MNAM, SAM, SAH, spermidine, glycine, and sarcosine were unchanged. The gene expression of Nnmt was unchanged but that of Nampt was increased in HFD + NAM compared to HFD. These results indicated that NAM converted into NMN rather than MNAM to supply NAD, leading to the activation of Sirts. In line with this, NAM enhanced the expression of Sirt 3, 4, and 5, known for their involvement in lipid metabolism (e.g. beta oxidation in the mitochondria) as well as Sirt 1. Furthermore, NAM enhanced the expression of beta oxidation- and ketone body formation-related genes; oppositely, it suppressed that of fatty acid synthesis-related genes. In microbiota analysis, adding NAM to HFD reduced Proteobacteria and Bacteroidetes, and increased Farmacutes and Actinobacteria at phylum level. Interestingly, Coriobacteria and Erysipelotrichi class was increased in Actionbacteria, and Farmacutes phylum, respectively.

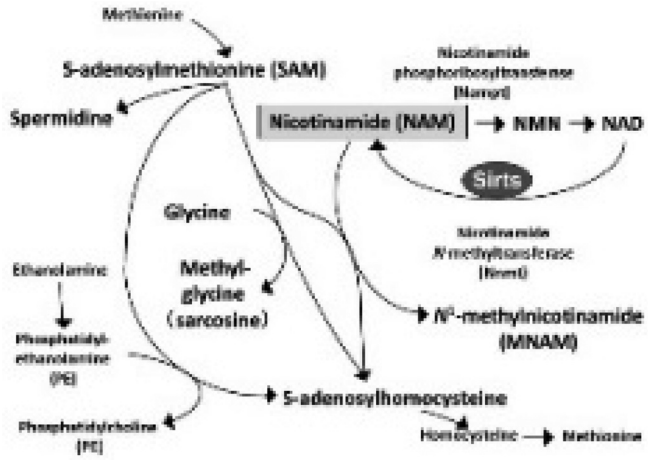

Figure 1:

Conclusion: NAM but not MNAM ameliorated hepatic steatosis through the activation of Sirts, leading to enhanced fatty acid oxidation and suppressed fatty acid oxidation, and also changed microbiota composition. Our results suggest that NAM might have a novel therapeutic application for NAFLD/NASH.

Elafibranor and obeticholic acid differentially alter NASH and lipid metabolism in diet-induced NASH mouse and hamster models

F. Briand, E. Brousseau, N. Faresse, M. Pont, C. Costard, I. Urbain, M. Quinsat, T. Sulpice. *PHYSIOGENEX, France*
Email: f.briand@physiogenex.com

Background and Aims: Non-alcoholic steato-hepatitis (NASH) mouse models present limitations for evaluating drugs, due to a different lipid/bile acids metabolism as compared with human. To overcome this issue, we developed a Diet-induced NASH (DIN) hamster model with features of human-like lipid/bile acids metabolism. Here we evaluated the benchmarks elafibranor (GFT505) and obeticholic acid (OCA), in both DIN mouse and hamster models.

Method: Effects of GFT505 and OCA both at 15 mg/kg/day were evaluated in DIN C57BL6/J mice fed a high fat/cholesterol/fructose rich diet, or DIN hamsters fed a cafeteria diet. Fasting lipids assays, liver histology and NAS scoring were performed at the end of treatment.

Results: In the DIN mouse, OCA and GFT505 significantly reduced total NAS score (both $p < 0.001$ vs. vehicle), including reduced steatosis, hepatocyte ballooning, and fibrosis, while inflammation was only reduced by OCA. Plasma total cholesterol (TC) and LDL-C levels were reduced by 33% and 45% with OCA (both $p < 0.001$ vs. vehicle). GFT505 did not change plasma TC but reduced plasma triglycerides (−32%) and strongly increased plasma ketone bodies (+307%) levels (both $p < 0.001$ vs. vehicle), in line with an inhibition of diet-induced body weight gain.

In the DIN hamster, both OCA and GFT505 reduced total NAS score, including significant reduction in inflammation and trends towards lower ballooning scores, while no significant change was observed for liver steatosis and fibrosis. Hamsters treated with OCA showed significantly higher plasma cholesteryl ester transfer protein activity by 18%, higher LDL-C levels by 27%, and lower HDL-C levels by 20% vs. vehicle. Trends towards lower LDL-receptor and higher SR-BI hepatic protein levels were also observed. GFT505 reduced plasma TC, triglycerides and free fatty acids levels by 13, 10 and 16%, while plasma ketone bodies levels increased by 35% (all $p < 0.05$ vs. vehicle).

Conclusion: OCA and GFT505 differentially alter lipid metabolism and NASH depending on the DIN model. While both drugs markedly improved lipid profile and NASH in DIN mice, moderate improvements were also seen in DIN hamsters. Importantly, the DIN hamster

is the only model showing the same dyslipidemic effect observed in humans treated with OCA. For better translation to human, drug development should not be limited to mouse, but rather extended with models showing a lipid and NASH profile closer to human, such as the DIN hamster.

THU-491

Characterization of ASK1 signaling in human NASH liver and human hepatic stellate cells

G. Budas, F. Wu, S. Turner, A. Zagorska, L. Li, D. Breckenridge. *Gilead Sciences Inc, Foster City, United States*
Email: grant.budas@gilead.com

Background and Aims: Selonsertib is a first-in-class, small molecule inhibitor of ASK1 that is in clinical development for the treatment of NASH. ASK1 is a redox-sensitive kinase that is activated by diverse pathological stimuli including oxidative stress. Activation of ASK1 causes phosphorylation and activation of JNK and p38 MAP kinases, which are known to promote liver fibrosis by inducing hepatocyte apoptosis, hepatic inflammation and myofibroblast activation. In the current study, we evaluated ASK1 pathway activity and cell-specific localization in human NASH liver biopsies and characterized ASK1-dependent signaling and gene expression in human hepatic stellate cells (HSCs).
Method: Liver biopsies were obtained from patients enrolled in a Phase 2 trial evaluating the safety and efficacy of selonsertib in NASH (GS-US-384-1497). Multiplex immunofluorescence was used to evaluate hepatic p-p38 (a marker of ASK1 activation), and its co-localization with markers of activated myofibroblasts including alpha-smooth muscle actin (α-SMA) and fibroblast activated protein (FAP). To characterize ASK1-regulated genes in human HSCs, LX-2 cells were transfected for 24 hours with an adenoviral construct containing human ASK1 in the absence or presence of selonsertib (1μM), then subjected to RNA-seq to delineate differentially expressed genes (fold-change >2 compared to adenoviral vector control, $p < 0.05$). Pathway enrichment analysis was used to identify major gene signatures regulated by ASK1.
Results: p-p38 was localized to hepatocytes, immune cells and fibroblasts in human NASH liver biopsies. Multiplex immunofluorescence demonstrated that p-p38 was co-localized with cells positive for both FAP and α-SMA, indicative of ASK1 pathway activity in activated myofibroblasts. Adenoviral overexpression of ASK1 in human HSCs increased p38 and JNK phosphorylation and resulted in a significant upregulation of stress-response genes including those associated with cytokine-mediated pro-inflammatory signaling (IL-1β, IL-11, and IL-17F, all $p < 0.05$ vs. control). Selonsertib blocked ASK1-induced p38 and JNK phosphorylation and normalized ASK1-dependent gene expression.
Conclusion: ASK1 pathway activity is increased in human NASH and localizes to hepatocytes, immune cells and activated hepatic myofibroblasts. ASK1 overexpression in HSCs causes upregulation of genes associated with stress response and pro-inflammatory signaling. These data provide mechanistic insight into the pathological role of ASK1 in NASH and support the evaluation of selonsertib in patients with NASH and advanced fibrosis.

CD4+ RORgt+ T cells, CD4+ T-bet+ T cells, CD4+ CD25+ Foxp3+ T cells and CD8+ T cells are differentially altered in liver and adipose tissue of mice fed a high-fat high-fructose diet in a time-dependent manner

M. Van Herck[1,2], L. Vonghia[1,2], P. Michielsen[1,2], C. Bridts[3], D. Ebo[3,4], J. De Man[1], B. De Winter[1], S. Francque[1,2]. *[1]University of Antwerp, Laboratory of Experimental Medicine and Pediatrics, Division of Gastroenterology and Hepatology, Antwerp, Belgium; [2]Antwerp University Hospital, Gastroenterology and Hepatology, Edegem, Belgium; [3]University of Antwerp, Translational Pathophysiological Research, Division of Immunology and Allergology, Antwerp, Belgium; [4]Antwerp University Hospital, Immunology and Allergology, Edegem, Belgium*
Email: mikhail.vanherck@uantwerpen.be

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a multisystem condition in which the liver, adipose tissue and the immune system are involved. T cells form a part of the adaptive immune system and can be subdivided in several subsets with differential functions. We investigated the involvement of $CD8^+$ cytotoxic T cells, T helper 1 cells (Th1, $CD4^+$ T–bet$^+$ RORγt$^-$), T helper 17 cells (Th17, $CD4^+$ T–bet$^-$ RORγt$^+$) and regulatory T cells (Treg, $CD4^+$ $CD25^+$ $Foxp3^+$) in the pathogenesis of NAFLD.
Method: Male 8-week old C57BL/6J mice were fed control diet (CD) or high-fat high-fructose diet (HFHFD) for 10, 15, 20 or 25 weeks (n = 6–8 per group). Liver tissue was assessed histologically and the NAFLD Activity Score (NAS) was calculated. T cell subsets were characterized in liver, abdominal and subcutaneous adipose tissue (AAT, SAT) via flow cytometry. $CD8^+$ and $CD4^+$ cells were expressed as percentage of $CD45^+$ $CD3^+$ cells. T–bet$^+$ RORγt$^-$, T–bet$^-$ RORγt$^+$ and $CD25^+$ $Foxp3^+$ cells were expressed as percentage of $CD3^+$ $CD4^+$ cells. For statistical analysis, mice were grouped into two time points (10–15 weeks and 20–25 weeks).
Results: Compared to CD mice, HFHFD mice became obese [Mdn body weight 44.2 g (IQR 9.3) vs. 32.2 g (IQR 4.1)] and developed NAFLD [Mdn NAS 4.0 (IQR 2.5) vs. 0.0 (IQR 1.0)]. Comparing HFHFD mice to CD mice, T-bet$^-$ RORγt$^+$ cells were present in larger numbers in liver tissue as of 10–15 weeks (Table 1). Conversely, T-bet$^+$ RORγt$^-$ cells were less numerous in liver tissue as of 10–15 weeks. This effect dissipated, however, as of 20–25 weeks. In AAT of HFHFD mice, $CD25^+$ $Foxp3^+$ cells were more numerous as of 10–15 weeks. In both AAT and SAT of HFHFD mice, $CD8^+$ cells were more abundant, but only as of 20–25 weeks. Interestingly, in AAT of HFHFD mice, a correlation existed between NAS and $CD8^+$ cells ($r = 0.575$, $p < 0.01$).

Table 1: Median percentages of tissue T cells

Median percentages of tissue T cells (IQR)	CD	HFHFD	p
Liver T-bet$^-$ RORγt$^+$ T cells			
10–15 weeks	0.6 (2.1)	3.0 (1.8)	<0.05
20–25 weeks	0.9 (1.4)	2.7 (4.5)	<0.01
Liver T-bet$^+$ RORγt$^-$ T cells			
10–15 weeks	3.2 (7.1)	0.7 (0.6)	<0.001
20–25 weeks	1.9 (1.2)	1.0 (3.2)	N.S.
AAT $CD25^+$ $Foxp3^+$ T cells			
10–15 weeks	2.0 (2.8)	17.2 (25.7)	<0.01
20–25 weeks	2.5 (3.9)	6.7 (5.7)	<0.01
AAT $CD8^+$ T cells			
10–15 weeks	17.2 (7.8)	19.1 (10.8)	N.S.
20–25 weeks	22.6 (10.7)	36.4 (7.1)	<0.001
SAT CD8+ T cells			
10–15 weeks	27.0 (12.5)	33.8 (5.6)	N.S.
20–25 weeks	29.0 (18.6)	38.0 (9.7)	<0.01

Conclusion: Differential T cell subsets seem to be implicated in various tissues involved in NAFLD in a time-dependent manner. In an early stage, $CD4^+$ T–bet$^-$ RORγt$^+$ Th17 cells were more abundant and $CD4^+$ T–bet$^+$ RORγt$^-$ Th1 cells less abundant in liver tissue of HFHFD mice, whereas $CD4^+$ $CD25^+$ $Foxp3^+$ Treg cells were more numerous in AAT of HFHFD mice. In a later stage, $CD8^+$ T cells became more abundant in both AAT and SAT of HFHFD mice. Additionally, $CD8^+$ T cells in AAT seemed to be associated with progression to a more severe disease state.

Treatment with the Adra2a antagonist, Yohimbine, reduces fibrosis progression and liver inflammation in a NASH fibrosis rat

H. Jones[1], S.E. Andreasen[2], A. Habtesion[1], P.L. Eriksen[2], N. Davies[1], R. Jalan[1], K.L. Thomsen[2], R. Mookerjee[1]. [1]*UCL, Institute for Liver and Digestive Health, London, United Kingdom;* [2]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Denmark*
Email: helen.jones@ucl.ac.uk

Background and Aims: Fatty liver disease (NAFLD) is increasing worldwide and is a disease spectrum from mild steatosis to non-alcoholic steatohepatitis (NASH) to cirrhosis. Fibrogenesis in NAFLD is key and correlates with long term morbidity and mortality. New treatments that slow fibrosis are needed. Noradrenaline, through alpha 2a subtype adrenergic receptors (Adra2a), may trigger development and progression of NAFLD. We previously showed blocking Adra2a signaling reduces hepatic stellate cell (HSC) activation and contractility in bile duct ligated rats. Here we studied whether blocking Adra2a, using the antagonist Yohimbine hydrochloride (YoHCl), can reduce fibrosis progression in a diet-induced NAFLD fibrosis rat model.
Method: Male Sprague Dawley rats were fed either high fat high cholesterol- inducing NASH- (HFHC; 65% kcal fat + 2% g cholesterol), or normal chow (NC; 7.5% kcal fat) diet ad libitum for 16 weeks. Rats in the HFHC group were randomized to receive YoHCl (titrated to 0.4 mg/kg daily) in drinking water for the final 8 weeks. Subsequently, formalin fixed liver sections were stained with picrosirius red. The fat proportion area (FPA) and collagen proportionate area (CPA) were measured on digitized sections using ImageJ.
Results: HFHC diet markedly increased Adra2a mRNA expression in liver tissue. HFHC diet also increased liver/body weight ratio (6.51 (0.89) vs. 2.76(0.25); $p < 0.0001$), and plasma AST (333(34.0) vs. 106 (24.5) U/L; $p < 0.0001$) compared to NC. Furthermore, the HFHC fed animals had higher FPA (23.7(3.37) vs. 1.89(1.28) %; $p < 0.0001$) and CPA (13.6(6.50) vs. 1.12(0.53) %; $p = 0.0005$) than controls. Hepatic proteome array analysis showed the HFHC group had higher levels of cytokines and chemokines involved in induction (IL1a, IL3, GM-CSF) and chemotaxis of immune cells (Ccl3, Cx3Cl1, CxCl1, CxCl5). Treatment with YoHCl in HFHC rats reduced liver/body weight ratio (5.73(0.44); $p = 0.034$), and AST levels (260.2(65.8) U/L; $p = 0.019$). Importantly, CPA (7.02(2.56) %; $p = 0.0397$) was reduced by YoHCl, and was associated with reduced cytokine and chemokine levels.
Conclusion: This study demonstrates that Adra2a antagonism reduces fibrosis progression in NAFLD, associated with reduced immune activation. This suggests Adra2a antagonism may slow progression of NAFLD with potential therapeutic translation in NAFLD and NASH patients that warrants further investigation.

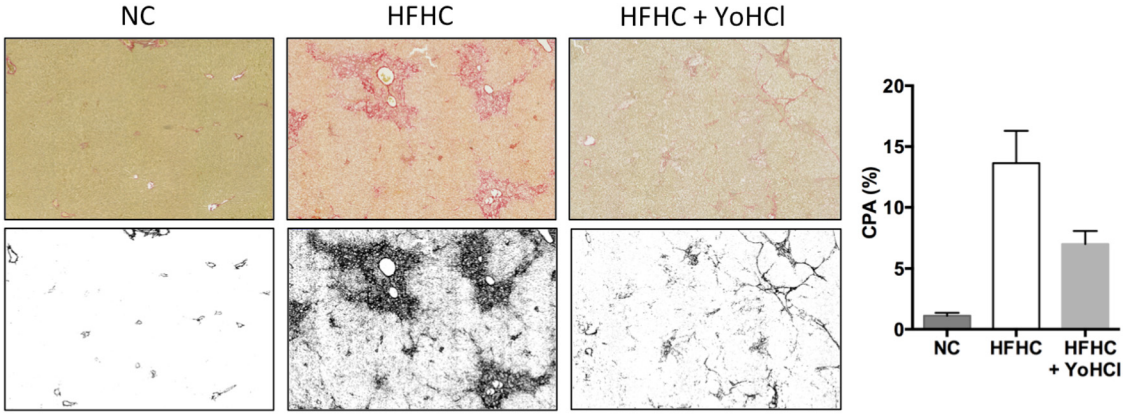
Background and Aims: Drug combinations are increasingly required for the successful treatment of complex liver diseases. In NASH, drug combination has recently emerged as a new treatment paradigm to increase the proportion of patients that reach all treatment goals. Among these goals, NASH resolution and improvement of fibrosis are of tantamount importance. The ideal NASH medication will both reverse NASH histology and stop the progression of fibrosis in patients at high risk of cirrhosis and complications.
Elafibranor (ELA), a PPARα/δ agonist can reverse NASH histology and decrease fibrosis, especially in patients with advanced disease (GOLDEN-505 phase 2b trial), and is currently being evaluated in the RESOLVE-IT phase 3 trial. We have recently identified nitazoxanide (NTZ), a phase-2 ready drug candidate with a good safety profile in man as a potent anti-fibrotic agent, by using an unbiased phenotypic screening approach.
The aim of this proof of concept study is to assess ELA/NTZ combination in a disease model of NASH to establish its potential value for treating human disease.
Method: A NASH phenotype was induced in C57Bl/6J mice by feeding a cholesterol-supplemented CDAA diet (CDAA/c) for 12 weeks. Histological evaluation of NASH and fibrosis was performed in a blinded fashion. Additional biochemical and molecular analyses were also performed on relevant biomarkers. Animals received ELA alone (1 mg/kg/day), NTZ alone (100 mg/kg/day) or ELA/NTZ combination for the entire study period of 12 weeks.
Results: Histological examination revealed a severe NASH phenotype with maximal scores for steatosis and inflammation in mice fed the CDAA/c diet. Hepatocyte ballooning was also present. NASH histology was accompanied by perisinusoidal fibrosis (F2) and the picrosirius positive area occupied between 4% and 6% of the liver parenchyma. Liver fibrosis area was reduced by 41% and by 32% in mice treated with ELA and NTZ, respectively. Similarly, hepatic collagen content was reduced by 31% and 33% in mice administered with ELA and NTZ, respectively. As established by the EOHSA model, ELA/NTZ



Picro sirius red stained liver (top) and corresponding collagen area quantified (bottom)

Figure: (abstract: THU-493)

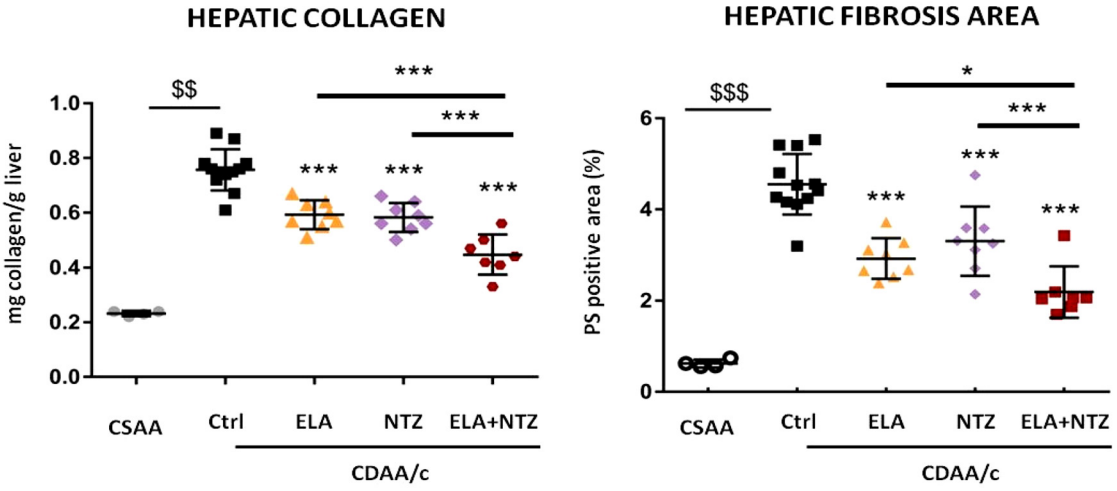


Figure: (abstract: THU-494)

combination showed a synergistic reduction of both fibrosis area (60%) and collagen content (59%), as compared to each single drug. Steatosis, inflammation and ballooning were partially improved by ELA but NTZ as a single drug had no effect on NASH histology. However, steatosis and ballooning were moderately improved in mice that received ELA/NTZ combination as compared to mice that only received ELA.
Conclusion: Elafibranor and nitazoxanide synergize *in vivo* to reduce liver fibrosis in a model of advanced NASH, opening interesting perspectives for further clinical development.

THU-495

LXR inverse agonists inhibit de novo lipogenesis and reduce intestinal lipid and cholesterol absorption in a NAFLD mouse model

C. Kremoser, U. Deuschle, C. Gege, O. Kinzel, H.D. Krol, M. Albers, M. Birkel, E. Hambruch. *Phenex Pharmaceuticals AG, Heidelberg, Germany*
Email: claus.kremoser@phenex-pharma.com

Background/Aims: Nuclear receptors LXR alpha and beta are both involved in the control of *de novo* lipogenesis and of lipid and fatty acid uptake in various tissues including small intestine and liver. We have developed potent synthetic LXR inverse agonists, PX25593 and PX25788, which block transcriptional activity of both LXRs. Both compounds display anti-steatotic effects in a mouse NAFLD model. Through stable and radioactive isotope labeling we could demonstrate that these effects are exerted through a combined inhibition of liver and intestinal *de novo* lipogenesis which also results in a reduced intestinal lipid and cholesterol uptake. This offers a new opportunity to address NAFLD clinically through LXR inverse agonists.
Method/Results: PX25593 and PX25788 were both characterized as potent synthetic LXR inverse agonists (LXRa/b EC50s: '593 = 2 nM/1.2 nM; '788 = 17 nM/19 nM). A key difference between these compounds is their distribution between liver and plasma ([liver]/[plasma] ratio at 4 h after oral administration: '593 = 3; '788 = 34). Hence, PX25788 can be regarded as a liver-selective LXR inverse agonist whereas PX25993 has a longer blood residence time. C57BL/6J mice which were prefed on a 60% kcal Survit-type high fat diet for 14 days and then dosed with PX25593 (3 and 10 mg/kg/d), PX25788 (10 and 30 mg/kg/d) and Tropifexor ((=LJN-452, a clinical stage potent FXR agonist) 3 mg/kg/d) for 28 days. Liver triglycerides were reduced by all compounds ('593 3 mg/kg: −33% ± 7; '593 10 mg/kg −41% ± 7; '788 10 mg/kg −31% ± 10; '788 30 mg/kg −30% ± 8; LJN-452 −73% ± 2). Plasma lipid and lipoprotein analysis yielded a differential reduction in HDLc by the treatments ('593 3 mg/kg: −13% ± 3; '593 10 mg/kg −35% ± 8; '788 10 mg/kg + 24% ± 4; '788 30 mg/kg + 14% ± 5; LJN-452 −52% ± 6). Plasma triglyceride reduction was observed to varying extents ('593 3 mg/kg: −19% ± 11; '593 10 mg/kg −21% ± 6; '788 10 mg/kg −3% ± 10; '788 30 mg/kg + 8% ± 10; LJN-452 −37% ± 7). A short term mechanistic study in C57 mice on HFD for four days demonstrated that LXR inverse agonists as well as Tropifexor reduced intestinal lipid and cholesterol uptake as well as inhibited liver-borne de novo lipogenesis (DNL).
Conclusion: LXR inverse agonists, similar to FXR agonists are capable of reducing liver fat in animal models. Like FXR agonists they reduced DNL in intestine and liver and markedly reduced intestinal lipid and cholesterol uptake. Thus, LXR inverse agonists might offer a new treatment option for NAFLD/NASH which potentially lacks the FXR-associated liabilities like HDLc lowering.

THU-496

Maternal obesity programs offspring's liver immune cells intra-uterine

J. Li[1,2], P. Cordero[3], A. Solanki[4], M. Vinciguerra[5], T. Crompton[4], J.A. Oben[1]. *[1]Institute for Liver and Digestive Health, London, United Kingdom; [2]Institute of Child Health, London, United Kingdom; [3]Institute for Liver and Digestive Health, United Kingdom; [4]Institute of Child Health, United Kingdom; [5]Center for Translational Medicine (CTM) International Clinical Research Center (FNUSA-ICRC) St. Anne's University Hospital, Brno, Czech Republic*
Email: jiawei.li.10@ucl.ac.uk

Background and Aims: Non-alcoholic Fatty Liver Disease (NAFLD) is now one of the leading causes for liver transplant. Based on developmental programming theory, insults and stimuli at critical periods have impact on the adult health status of offspring. Previously, our studies have shown that subjecting an offspring to maternal obesity peri-natally interacts with the post-natal diet, increasing the risk of developing NAFLD, with hepatic immune cells alteration suggested to play a role. The role however, of maternal obesity on pre-natal offspring livers is unclear.
Aims: To study the influence of maternal obesity on pre-natal offspring liver development, and the role of the immune system.
Method: Adult wild-type (WT) female mice were subjected to either control (Con) or high fat/high-sugar (Ob) diet for 8 weeks, and were then time-mated with a male stud. At Embryonic Day 14.5 (E14.5) and 17.5 (E17.5), all foetuses were harvested and the livers were analysed for their immune profile by flow cytometry, and transcriptomic changes by real-time polymerase chain reaction.
Results: At E17.5, the WT foetuses from the Ob mothers had, unexpectedly, a lower body mass compared to foetuses from the Con mothers. At E14.5, there is no weight difference between the foetuses from the two groups. However, the foetal livers subjected to maternal

obesity *in utero* have reduced cell numbers in both E14.5 and E17.5. Flow cytometric analysis showed an increased presence of granulocytes and natural killer (NK) cells foetal livers subjected to maternal obesity (Ob) compared to controls. This was accompanied by a relative increase in the markers of injury and inflammation: tumour necrosis factor-alpha and transforming growth factor beta-1.
Conclusion: Offspring are affected by maternal obesity pre-natally with an unexpected reduction of body mass at E17.5, and reduced liver cell number at both E14.5 and E17.5. Markers indicating liver were also elevated, along with changes of immune cells in the liver. This suggests maternal obesogenic status may predispose offspring for NAFLD by affecting the foetal immune development.

THU-497
Elafibranor restores lipogenic gene expression in a human skin stem cell-derived non-alcoholic fatty liver disease (NAFLD) model
J. Boeckmans[1], A. Natale[1], K. Buyl[1], J. De Kock[1], V. Rogiers[1], T. Vanhaecke[1], R.M. Rodrigues[2]. *[1]Vrije Universiteit Brussel (VUB), In Vitro Toxicology and Dermato-Cosmetology (IVTD), Brussels, Belgium; [2]Vrije Universiteit Brussel (VUB), In Vitro Toxicology and Dermato-Cosmetology (IVTD), Brussels*
Email: joost.boeckmans@vub.be

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a leading cause of chronic liver disease. It ranges from uncomplicated hepatic steatosis to non-alcoholic steatohepatitis (NASH), fibrosis, cirrhosis and cancer. NASH is the first stage in the spectrum of NAFLD which is associated with increased health risk. No anti-NASH drug has been approved so far as discovery and development are largely hampered by the lack of adequate human-based *in vitro* systems that recapitulate the human pathophysiology.
Earlier, we showed that hepatic cells derived from human skin precursors (hSKP-HPC) represent a unique *in vitro* model for the investigation of drug-induced NAFLD. In this study we use hSKP-HPC to construct a human-relevant metabolically-induced NAFLD system that aims to mimic the progression of simple steatosis to NASH. As a proof-of-principle, the applicability of the hSKP-HPC-based disease model is evaluated in the context of anti-NAFLD drug discovery.
Method: In the current study, hSKP-HPC exposed to insulin (100 nM) and glucose (4500 mg/L) represent the *in vitro* steatosis model. NASH conditions were created by additional exposure to sodium oleate (65 µM) and palmitic acid (45 µM) in combination with a pro-inflammatory fibrotic cytokine cocktail (50 ng/mL TNF-alpha + 25 ng/mL IL-1beta + 8 ng/mL TGF-beta). Furthermore, the phase III anti-NASH drug elafibranor (Genfit) was tested in both *in vitro* systems.
Results: Gene expression analysis revealed a typical lipogenic gene expression profile concordant with human data: key lipogenic genes (*ACC*, *FAS* and *SREBP-1c*) were upregulated in the steatosis stage, but downregulated in the NASH model (24 h exposure; one-way ANOVA, $p < 0.05$). Gene expression changes were accompanied by an increased lipid load and caspase-3/7 activity in the NASH condition and a gradual increase in ATP production (72 h exposure).
In the steatotic setup, elafibranor (10 µM) restricted the increased expression of *SREBP-1c*, *ACC* and *FAS* (24 h treatment; student t-test, $p < 0.05$). Under NASH conditions, elafibranor induced the expression of *ACC* and *FAS* and tended to reverse NASH to a steatotic stage.
Conclusion: These first data provide the fundamental basis to further explore hSKP-HPC as a valuable *in vitro* model for anti-NAFLD drug discovery.

THU-498
The interplay between liver and muscle begins much earlier than cirrhosis. A diet-induced animal model
F.M. Trovato, P. Castrogiovanni, M.A. Szychlinska, F. Purrello, G. Musumeci. *University of Catania, Department of Clinical and Experimental Medicine, Internal Medicine Unit, Catania, Italy*
Email: trovatofrancesca@gmail.com

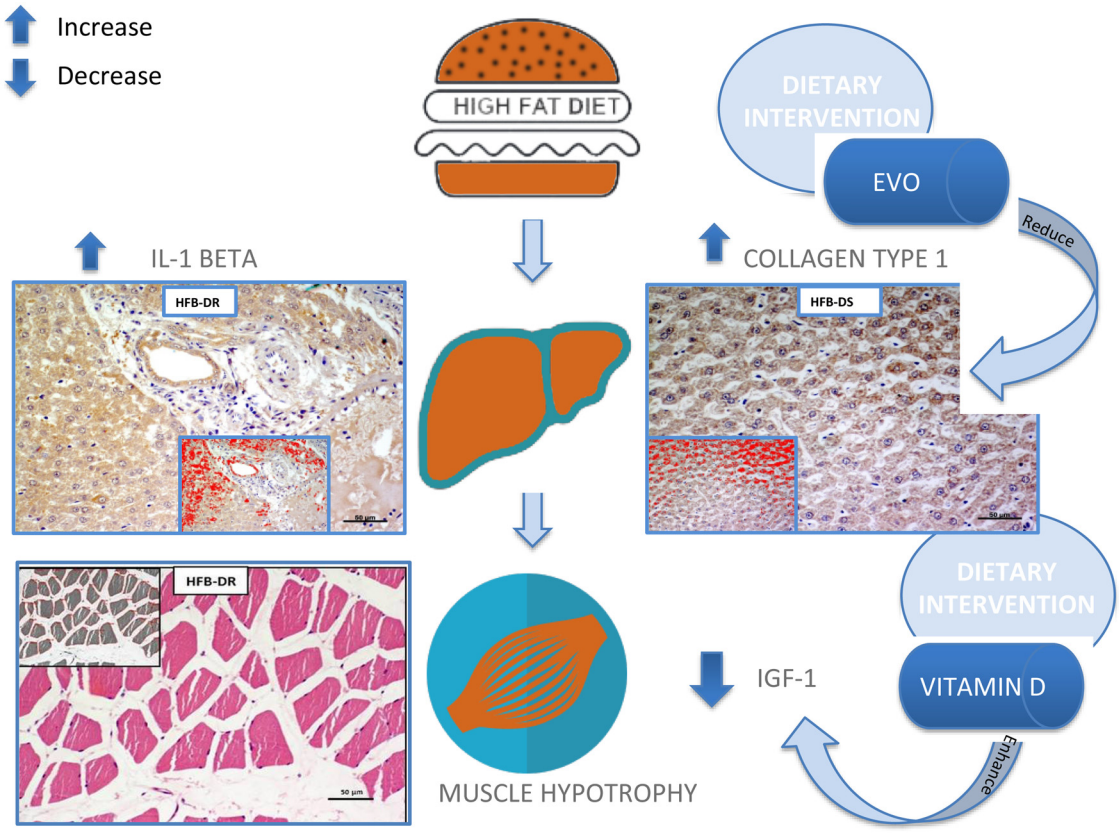

Figure: (Abstract: THU-4498)

Background and Aims: The growth hormone/insulin-like growth factor 1(IGF1) axis is involved in skeletal muscle metabolism. NAFLD and advanced fibrosis are associated with sarcopenia, and decreased levels of Vitamin D (VitD) and IGF1 and mutual relationship were reported. We aimed to evaluate whether different dietary profiles, containing or not VitD, may exert different effects on liver and muscle morphology, which may contribute to explain sarcopenia in NAFLD. In order to detect early defects induced by high fat diet, we decided to use a 10 weeks period of diet exposure.
Method: Twenty-eight male rats were fed by different dietary regimens for 10 weeks: **R**, regular diet; **R-DS** and **R-DR**, regular diet with respectively VitD supplementation (DS) and restriction (DR); **HFB-DS** and **HFB-DR** (41% energy from fat), high fat (butter) diet; **HFEVO-DS** and **HFEVO-DR** (41% energy from fat), high fat (Extra-virgin olive oil-EVO) diet. Collagen I in the liver and IL1 beta, VitD receptor (VDR), IGF1 in both liver and muscle were evaluated by immunohistochemistry. Perimeter of muscle fibers was measured by morphometric analysis; NAFLD severity was assessed by the NAFLD Activity Score (NAS).
Results: No difference was found in weight and NAS, that in all groups was between 0 and 2. Collagen I was more expressed in HFB-DS and HFB-DR, while in R and R-DS groups it was almost absent. HFEVO, DR or DS, seems to be protective against collagen I expression, in comparison with HFB. VitD did not show effect on collagen I. IL1 was higher in the liver and muscle of group HFD and HFEVO vs R, R-DS and R-DR ($p < 0,01$). Inside the R groups, the DR had a greater expression of IL1, so that VitD seems protective ($p < 0,01$). Muscle fibers perimeter analysis showed a highly significant hypertrophy in groups R-DS and HFEVO-DS ($p < 0,01$), and a statistically highly significant hypotrophy in group HFB-DR ($p < 0,01$): accordingly VitD supplementation showed trophic effect. However, VitD restriction did not show any detrimental effect vs. controls. HFEVO has no different effect on muscle trophism from the R diet. As expected, VDR was expressed more in groups DS in comparison with the respective DR. IGF1 was mostly expressed in R groups vs both HFB and HFEVO ($p < 0,01$). Liver and muscle IL1 were inversely, while VitD and IGF1 were directly related to muscle fibers perimeter. Liver collagen was directly related to dietary fat content, IL1 in muscle and liver, while IGF1 was inversely related to fat content and IL1 in muscle.
Conclusion: Even short-term high fat diets increase IL1 both in liver and muscle, thus reducing the expression of IGF1 in muscle. Moreover, EVO seems protective against collagen I expression in the liver. Vitamin D has a trophic effect on muscle fibers, probably through the interaction with IGF1. According to our results, liver and muscle damages begin early in rats fed with high fat diet and are modifiable by dietary intervention.

THU-499

Hyperreactivity to vasoconstrictors in a rat model of non-alcoholic fatty liver disease

D. van der Graaff[1,2], W. Kwanten[1,2,3], J. De Man[1], B. De Winter[1], P. Michielsen[1], S. Francque[1,2]. [1]*Laboratory of Experimental Medicine and Pediatrics (LEMP), Gastroenterology & Hepatology, Wilrijk (Antwerp), Belgium;* [2]*Antwerp University Hospital, Department of Gastroenterology and Hepatology, Edegem, Belgium;* [3]*Massachusetts General Hospital & Harvard Medical School, Department of Radiation Oncology, Boston, United States*
Email: denise.vandergraaff@uantwerpen.be

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) has become the most prevalent chronic liver disease. Prior to development of inflammation or fibrosis, the intrahepatic vascular resistance (IHVR) is increased, impairing hepatic blood flow and potentially causing disease progression. Similar to the mechanisms in cirrhosis, hyperreactivity to vasoconstrictive agents is a potential mechanism. Therefore, our aim was to study the effects of alpha 1-adrenergic mediators and endothelin-1 (ET-1) on the IHVR in severe steatosis.
Method: The IHVR was studied by measuring the transhepatic pressure gradient (THPG) in an *in situ ex vivo* perfusion model. The THPG was studied in Wistar rats ($n \geq 6$/group) fed a methionine-choline-deficient diet, inducing severe steatosis after 4 weeks, and in rats fed a control diet. The effects of the alpha 1-adrenergic agonist methoxamine (Mx, 10^{-6}–3×10^{-4} M), the alpha 1-adrenergic antagonist prazosin (PRZ, 10^{-7}–10^{-4} M) and the vasoconstrictor ET-1 (10^{-12}–3×10^{-10} M) were studied in dose-response experiments. Subsequently, flow-pressure curves were constructed investigating the effects of 10^{-5} M Mx and 10^{-10} M ET-1 at different flows (10–50 ml/min).
Results: The basal THPG in steatotic livers was significantly increased compared to controls.

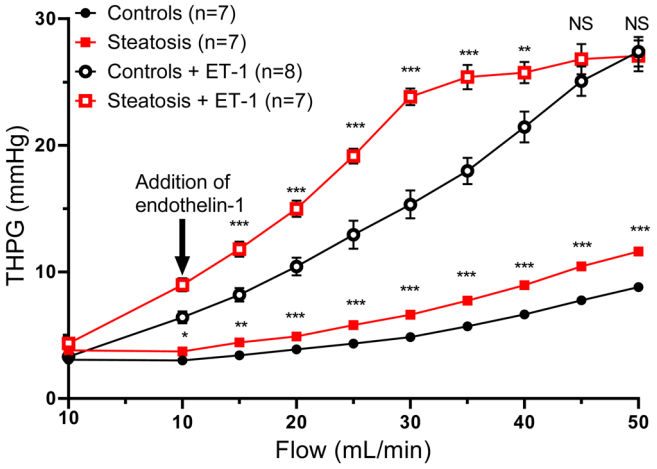

Figure 1: Flow-pressure curves presenting the THPG (mean ± SEM) in control and steatotic rats with and without the addition of ET-1.
The THPG was significantly higher in steatosis compared to controls at all flows (10–50 ml/min). Addition of ET-1 enhanced the THPG in controls and steatosis.
*$p < 0.05$; **$p < 0.01$; ***$p < 0.001$ significantly different from controls; NS: not significantly different from controls

Dose-response curves showed a significantly increased vascular sensitivity and responsiveness of steatotic livers to Mx (EC50 = $10^{-5.0}$ M, T_{max} = 9.8 mmHg) compared to controls (EC50 = $10^{-4.8}$ M, T_{max} = 8.2 mmHg [$p < 0.05$]). In flow-pressure experiments, the THPG of steatotic livers showed a significantly increased reactivity to Mx at all flows. PRZ did not alter THPG in both controls and steatosis.
ET-1 induced a dose-dependent increase of the THPG in both controls and steatosis, with significantly increased sensitivity and responsiveness to ET-1 in steatosis (20.3 ± 1.3 mmHg at 3×10^{-10} M) compared to controls (14.9 ± 1.4 mmHg at 3×10^{-10} M, $p < 0.001$). Flow-pressure experiments confirmed the hyperreactivity to ET-1 in steatotic livers with a more rapid and higher increase in THPG and the maximum THPG was reached at significantly lower flows compared to controls (controls 15.3 ± 1.1 mmHg, steatosis 23.8 ± 0.6 mmHg at 30 mL/min, $p < 0.001$, Figure 1).
Conclusion: The reactivity to both Mx and ET-1 is significantly increased in steatotic rat livers compared to controls, pointing towards an hyperreactivity to vasoconstrictors as a cause of the observed (and repeatedly confirmed) increased THPG associated with NAFLD.

THU-500

Role of mitofusin-2 in NAFLD and targeting by miRNAs

A. Simão[1], M.B. Afonso[1], P. Rodrigues[1], A.J. Amaral[2], M. Gama-Carvalho[2], A. Zorzano[3], C.M.P. Rodrigues[1], R. Castro[1].
[1]*Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal;* [2]*BioFIG - Center for Functional and Integrative Genomics, Faculty of Sciences, Universidade de Lisboa, Lisbon, Portugal;* [3]*Institute for Research in Biomedicine (IRB Barcelona), Barcelona, Spain*
Email: adlsimao@ff.ul.pt

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) associates with intracellular lipid accumulation in the liver. Recent evidence supports a functional role for both miRNA and mitochondrial dysfunction in regulating NAFLD pathogenesis. In particular, deregulation of mitochondrial dynamics proteins, like mitofusin-2 (Mfn2), were recently described in obese and diabetic patients, while liver-specific Mfn2 silencing in mice promotes numerous metabolic abnormalities. Our aims were to profile global liver miRNA expression changes during NAFLD and correlate them with the development of mitochondrial dysfunction in experimental and human NAFLD.
Method: C57BL6/N mice were fed either a standard or a fast food (FF) diet for 25 weeks, or a methionine and choline-deficient (MCD) diet for 2 and 8 weeks. Liver RNA from 8 weeks MCD-fed mice was run in TaqMan miRNA arrays. Liver biopsies were obtained from NAFLD patients with steatosis or nonalcoholic steatohepatitis (NASH). mRNA and protein expression were analysed by qRT-PCR and immunoblotting, respectively. miRNA targeting was evaluated by dual-luciferase reporter assays in HepG2 cells.
Results: FF-fed mice developed steatosis, inflammation and insulin resistance. MCD-fed mice developed progressive steatohepatitis and fibrosis. Liver Mfn2 mRNA and protein levels were significantly decreased in both MCD- and FF-fed animals, comparing with control diet-fed mice. Inversely, expression of dynamin-related protein-1 (Drp1), a mitochondrial fission protein, was found increased. In humans, liver Mfn2 protein levels decreased from steatosis to NASH. Twenty-five miRNAs were found significantly increased in the liver of MCD-fed mice. Inversely, 27 miRNAs were decreased. Among the increased miRNAs, 4 have at least one targeting Mfn2 3'UTR binding site in Mfn2 mRNA (miR-134, miR-125a, miR-222 and miR-34a). Dual-luciferase reporter assays confirmed targeting of Mfn2 by miR-125a, miR-222 and miR-34a in liver cells. Further, overexpression of either of these miRNAs in HepG2 cells inhibited Mfn2 expression.
Conclusion: Altogether, inhibition of Mfn2 constitutes a key mitochondrial dysfunction event during NAFLD triggering and progression. A better understanding of miRNAs modulated during NAFLD that directly target Mfn2 might aid in the elucidation of novel molecular pathways for therapeutic intervention. (SFRH/BD/104160/2014, FCT, PT and Gilead Sciences International Research Scholars Program 2015).

Diseased human 3D microtissues as building blocks for complex metabolic in-vitro systems

O. Frey, B. Yesildag, R. Kostadinova, S. Messner, P. Guye. *InSphero AG, Schlieren, Switzerland*
Email: patrick.guye@insphero.com

Background and Aims: NAFLD, obesity, insulin resistance, metabolic syndrome, and Type 2 Diabetes are closely connected clinical pathologies. Further, insults, as for example inflammatory stimuli, contribute to the progression of NAFLD to NASH, an increasing healthcare burden in developed countries and major indication for liver transplant. Studying the etiologies for this group of diseases, with the goal of developing novel therapeutic approaches, presents multiple challenges, such as having readily available organotypic, human tissues with inducible disease states, as well as simple and robust methods for studying organ-organ interactions.
Method: We developed a new generation of screening-compatible 3D microtissue models that emulate the healthy and various diseased states of human liver and pancreatic islets, adaptable to a unique standard multi-well microtissue plate format and novel microphysiological system (MPS) to accommodate interconnected culture and assay of such microtissues. The MPS design enables culturing of microtissues under physiological flow conditions, with the flexibility to interconnect and culture different types of microtissues for a variety of pre-clinical testing applications. The full polystyrene device is based on SBS-plate standards, includes 8 separate channels, each channel containing up to 10 microtissue compartments. Thus, up to 10 same or different microtissues can be interconnected and cultured in 8 identical or different conditions in parallel per plate. Such a setup enables microfluidic linking of, for example, liver and islet microtissues and investigation of organ-organ interactions.
Results: Organotypic liver and islet tissues are metabolically active, highly accessible to experimentation, and importantly, immune competent. Starting from their healthy state, we demonstrate induction of liver steatosis by exposure to high Glucose/Insulin media supplemented with dietary fatty acids (imaging/lipidomics). Treatment with inflammatory agents stimulate molecular events leading to NASH, as shown by induction of liver fibrosis markers (qRT-PCR, imaging, ELISA). Moreover, we demonstrate modulation of glucose-stimulated insulin secretion by Tolbutamide and Exendin-4 under physiological flow conditions, highlighting the unprecedented insights achievable with advanced physiologically relevant in-vitro systems.
Conclusion: We demonstrated that complex metabolically competent 3D microtissues are able to mimic human liver and islet disease states and are thus a physiological relevant in vitro drug discovery tool.

THU-502

A novel microtissue-based 3D human liver NASH model for drug discovery

J. Rupp, T. Strassfeld, S. Steiert, P. Guye, S. Messner, R. Kostadinova. *InSphero AG, Schlieren, Switzerland*
Email: radina.kostadinova@insphero.com

Background and Aims: Non-alcoholic steatohepatitis (NASH), an advanced form of non-alcoholic fatty liver disease (NAFLD), is defined as the presence of hepatic steatosis with inflammation and hepatocyte injury. NASH can eventually lead to advanced fibrosis, liver cirrhosis and liver failure. At present, there are no approved and safe therapies for NASH. The most frequently used in vitro model to study the effect of anti-NASH drugs are simple mono-layer cultures of hepatic stellate cells (HSCs) and hepatocytes, which are not relevant enough to account for the complex mechanism of the disease. We aimed to develop a physiological relevant 3D Human Liver NASH model, amenable for drug safety screening.
Method: 3D Human Liver Microtissues were engineered to incorporate all the relevant primary human liver cell types responsible for the development of the disease: hepatocytes, HSCs, Kupffer cells (KCs) and liver endothelial cells (LECs). The resulting 3D InSight™ Human Liver NASH model has been induced by treatment of the tissues with Free Fatty Acids (FFA) such as Oleic and Palmitic acids (1:1), LPS and TGF-β1 for 7 days. We characterized the tissues under basal and induced liver disease conditions on morphological and phenotypic levels by Nile-Red staining of incorporated lipids using confocal microscopy, immunostaining techniques, gene-expression analysis, and cytokine release.
Results: Using cell type specific markers and immunohistochemistry we demonstrated the presence of various cell types such as hepatocytes, HSC, KCs and LECs during the cultivation and treatment period. Treatment of the tissues with FFA, LPS and TGF-β1 for 7 days induced lipid accumulation in the hepatocytes as well as increased secretion of pro-inflammatory markers such as MCP-1, IL-6 and TNF-α. The treatment of the 3D microtissues with the described NASH inducers increased the mRNA and protein expression of the α-smooth

muscle actin (α-SMA), a marker of the activated HSCs and of the extracellular matrix proteins such as collagen type I.
Conclusion: We demonstrated that FFA, LPS and TGF-β1 treatment induced liver inflammation, steatosis and fibrosis in vitro, making this model an ideal tool for anti-NASH drug discovery.

THU-503
Modeling NAFLD using 3D bioprinted human liver tissue

D. Carter[1], S. Presnell[1], B. David[2], A. Chen[1]. [1]*Organovo, R&D, San Diego, United States;* [2]*University of California, Department of Medicine, San Diego, United States*
Email: achen@organovo.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is a chronic condition that originates as lipid accumulation within hepatocytes (steatosis) and progresses into nonalcoholic steatohepatitis (NASH), characterized by lipid accumulation, inflammation, oxidative stress, and fibrosis. NAFLD is now recognized as the most common cause of chronic liver disease in the western world, with an estimated prevalence of 25% worldwide, and is projected to become the leading indication for liver transplant by 2025. Despite decades of research, the mechanisms of NAFLD progression, therapeutic approaches and non-invasive diagnostics are still resoundingly absent. The study of steatosis and NASH has traditionally utilized rodent models, which are time consuming to generate and do not fully recapitulate the complex phenotypes associated with the human disease. Furthermore, current 2D cell culture models lack relevant liver cell types, do not accurately display diseased phenotypes, and have limited utility due to rapid loss of cell viability and function. Thus, there is a significant need for a more predictive human multicellular 3D *in vitro* model to study the progression of steatosis into NASH.
Method: ExVive™ Human Liver Tissue, a human *in vitro* 3D bioprinted liver model comprising primary human hepatocytes, hepatic stellate cells, and endothelial cells exhibits a complex multicellular architecture similar to that of native liver and retains metabolic competence and liver-specific functions for at least 4 weeks in culture. To mimic the proposed pathogenesis of NASH via a "Two-Hit Hypothesis", immune competent tissues containing Kupffer cells were exposed to steatogenic cues via a nutrient overload approach of simple sugars and fatty acids, followed by inflammatory stimulation using prototypical inducers.
Results: Preliminary evidence suggests that steatosis can be induced via chronic exposure to lipids in the presence of high glucose. Treated tissues exhibit increased incidence of lipid vesicles positive for Oil Red O and the lipid droplet-associated protein, Perilipin 5, and increased triglyceride content. Incorporation of both hepatic stellate and Kupffer cells into the tissues, concomitant with activation via inflammatory inducers and nutrient overload, leads to activation of stellate cells, inflammatory cytokine release, and an increase in extracellular matrix deposition and fibrosis, characteristic of NASH.
Conclusion: Together, these features suggest that 3D liver tissues hold promise for the study of complex, chronic conditions such as NASH, enabling better understanding of disease processes, discovery of novel therapeutics, biomarkers, and the safety assessment of drugs in a disease-relevant background.

THU-504
The changing profile of extracellular vesicles in non-alcoholic fatty liver disease progression and their role in signalling to hepatocytes

Email: lban4851@uni.sydney.edu.au

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a prevalent comorbidity of obesity, however current diagnostic tools are often unreliable or impractical, and so tissue biopsy remains the gold standard. Extracellular vesicles (EVs) are submicron, membrane-bound structures that are released from activated or stressed cells, and have been shown to be involved in paracrine and endocrine signalling. This study aimed to investigate the potential of EVs as biomarkers in NAFLD, and their role in mediating the disease.
Method: Six-week old male C57Bl/6 mice were randomly assigned to receive high-fat diet (HFD; 45%kcal fat) or standard laboratory chow for 10, 20, 30 or 50 weeks. Physical profile, plasma biochemistry, and liver histology and phenotype were analysed at the conclusion of each time-point. Plasma EVs were isolated by ultracentrifugation and enumerated by nanoparticle tracking analysis. The uptake of EVs into a hepatocyte cell line (AML12) was assessed by flow cytometry, while changes in the gene expression of cells upon exposure to EVs (1000/ul) were assessed by real-time PCR.
Results: Within the HFD cohort, there was a progressive increase in liver weight and worsening histological severity of NAFLD across the time-points. This was reflected in the liver gene expression of inflammation and matrix remodeling markers by real-time PCR. Plasma insulin was consistently increased in HFD (all time-points: $p < 0.001$), while ALT was increased from 20 weeks onwards (20–50 weeks: $p < 0.0001$). Plasma EVs fluctuated across the duration of HFD, with a peak at 20 weeks ($p = 0.0001$ vs 10 weeks) followed by a gradual decline. Interestingly, AML12 hepatocytes were most responsive to EVs from 50 weeks HFD ($p = 0.009$ vs chow), which was associated with an increase in TNF mRNA ($p = 0.004$). In contrast, gene expression of molecules associated with matrix remodeling declined with exposure to HFD-derived EVs from 20 weeks diet onwards (collagen I: $p < 0.002$, TIMP1: $p < 0.001$ vs 10 week HFD). Similar trends were observed upon exposure to chow EVs, suggesting an age-dependent change in hepatocyte mediated tissue remodeling.
Conclusion: Intercellular communication by EVs may be an important event in NAFLD progression. While absolute number of plasma EVs fluctuate with diet duration, this doesn't necessarily reflect the level of responsiveness of cells. EVs mediate an inflammatory phenotype but suppress the tissue remodeling response in hepatocytes, suggesting a role in global feedback mechanisms to control organ-specific pathology.

THU-505
RIP3-dependent signalling contributes to non-alcoholic fatty liver disease-related hepatocarcinogenesis

M.B. Afonso, P.M. Rodrigues, A. Simão, M.M. Gaspar, R.E. Castro, C.M.P. Rodrigues. *Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal*
Email: mbafonso@ff.ulisboa.pt

Background and Aims: Hepatocellular death, inflammation and fibrosis are implicated in the pathogenesis of non-alcoholic steatohepatitis (NASH), including development and progression to hepatocellular carcinoma (HCC). Necroptosis is a highly immunogenic regulated cell death routine that depends on receptor-interacting protein 3 (RIP3) kinase activity. We aimed to evaluate the role of necroptosis in the pathogenesis of non-alcoholic fatty liver disease (NAFLD)-driven carcinogenesis.
Method: C57BL/6 wild-type (WT) or RIP3-deficient ($RIP3^{-/-}$) mice were fed a choline-deficient L-amino acid-defined diet (CDAA; n = 14) or a control choline-sufficient L-amino acid-defined (CSAA; n = 14) diet for 66 weeks, with subsequent histological and biochemical analysis of hepatic damage and carcinogenesis. Insulin resistance and oxidative stress were also investigated.
Results: CDAA-fed WT mice exhibited all the main histological features of liver injury associated with NASH, namely steatosis, hepatocellular ballooning, immune cell infiltration, and fibrosis. RIP3 deficiency ameliorated CDAA-induced inflammation and fibrosis, and decreased the NAFLD activity score. In agreement, hepatic gene

expression of pro-inflammatory mediators was also significantly decreased in CDAA-fed RIP3$^{-/-}$ mice, compared with WT. Intriguingly, RIP3$^{-/-}$ mice displayed increased body weight gain with time, as well as insulin resistance at 66 weeks as assessed by homeostasis model assessment-estimated insulin resistance and decreased insulin receptor substrate phosphorylation, compared with WT mice on CSAA or CDAA diet. RIP3$^{-/-}$ mice tended to show reduced incidence of macroscopic preneoplasic nodules, accompanied by significantly reduced Ki67 positive hepatocytes and increased proapoptotic Bax and cell cycle regulator cyclin-dependent kinase 2-associated protein 1 (CDK2AP1). Absence of RIP3 further hampered signaling pathways controlling tumor microenvironment and protected against oxidative stress and mitochondrial dynamic dysfunction.

Conclusion: Overall, RIP3 ablation halts long-term inflammation, fibrosis, hepatocyte proliferation, and genetic resistance of dysplastic hepatocytes to cell death, oxidative stress and tissue microenvironment changes associated with NASH-driven hepatocarcinogenesis. Targeting RIP3-dependent signalling might be a promising approach to arrest NAFLD progression to HCC, although complementary approaches may be required to control insulin resistance in obese patients. (Funding: PTDC/BIM-MEC/0895/2014; SAICTPAC/0019/2015).

NAFLD in HIV mono-infection is a consequence of insulin resistance but not bacterial translocation

J. Maurice[1], P. Kelleher[2], M. Nelson[3], M. Thursz[1], M. Lemoine[1].
[1]*Imperial College London, Hepatology;* [2]*Imperial College London, Immunology;* [3]*Imperial College London, Infectious Disease*
Email: james.maurice@imperial.ac.uk

Background and Aims: Chronic non-communicable co-morbidities such as non-alcoholic fatty liver disease are an increasing concern in aging patients with HIV. Loss of gut-associated lymphoid tissue from HIV infection may contribute to bacterial translocation and the development of NAFLD. We aimed to investigate the role of bacterial translocation in the development of NAFLD, NASH and fibrosis in HIV mono-infected patients.

Method: Patients were prospectively recruited in a dedicated HIV liver clinic. Inclusion criteria were HIV mono-infection with biopsy-confirmed NAFLD, in the absence of alcohol excess, viral hepatitis or other causes of chronic liver disease. HIV infected patients with normal liver function and BMI <30 were used as controls. Fasted blood samples were collected. Bacterial DNA was extracted from whole blood and quantified using qPCR. Lipopolysaccharide (LPS) was measured using a cell reporter line expressing TLR-4 (HEK-Blue, Invitrogen). sCD14, sCD163, lipopolysaccharide binding protein (LBP) (RND Systems), leptin and adiponectin (Invivogen) were measured by ELISA. A subset of patients also conducted a PEG based gut permeability test. Liver histology was reported using the NASH CRN scoring system.

Results: Thirty cases (NASH n = 21, NAFL n = 9, age 47(38–55), male 97%, BMI 31(27–33)) and 30 controls (age 48(41–53), male 100%, BMI 25(23–28)) were included. NAFLD was not associated with bacterial DNA (3.72 vs 3.74 ng/ml, p = 0.772), LPS (0.024 vs 0.014 EU/ml, p = 0.176), sCD14 (6062 vs 5370 pg/ml, p = 0.074) or LBP (5.91 vs 5.85 ug/ml, p = 0.376), but was significantly associated with sCD163 (868 vs 738 ng/ml), leptin (13339 vs 4109, p < 0.001), reduced adiponectin (552 vs 1593 ng/ml p = 0.0091) and increased leptin:adiponectin ratio (13.9 vs 2.9 p < 0.001). There was no difference in patients with increased gut permeability measured by PEG between NAFLD and controls (18% vs 16%, p = 0.94). In a sub-analysis by disease severity in cases with NAFLD, no markers distinguished NASH from NAFL, but significant fibrosis (≥F2) was associated with sCD14 (6614 vs 5478 pg/ml p = 0.016), and leptin (16651 vs 6870 pg/ml p = 0.004).

Conclusion: NAFLD in HIV mono-infection is a consequence of insulin resistance and not bacterial translocation.

THU-507

Hepatic steatosis potentiates irinotecan-induced hepatocellular injury via dysregulation of irinotecan-metabolizing enzymes

A. Mahli[1], A. Koch[1], W. Thasler[2], C. Hellerbrand[1]. [1]*Friedrich-Alexander University Erlangen-Nürnberg, Institute of Biochemistry, Erlangen, Germany;* [2]*Ludwig-Maximilians-University Munich, Grosshadern Tissue Bank and Center for Liver Cell Research*
Email: claus.hellerbrand@fau.de

Background and Aims: Inclusion of irinotecan (IX) in preoperative chemotherapy regimens is associated with the risk to develop steatohepatitis known as chemotherapy-associated steatohepatitis (CASH) which increases the risk of perioperative morbidity and mortality. Observational clinical studies indicate that obese patients have a higher risk for developing CASH. However, the underlying mechanisms are elusive.

The aim of this study was to analyze the impact of hepatic steatosis on the hepatotoxicity of irinotecan.

Methods and Results: Lipid accumulation in primary human hepatocytes (PHH) was induced by incubation with the fatty acid oleate. Subsequently, steatotic and control hepatocytes were incubated with up to 50 µM irinotecan (IX). In this dose range, IX alone had only minimal hepatotoxic effects but lipid accumulation enhanced synergistically the hepatotoxic effects of IX. Moreover, the effects of IX on cellular triglyceride content, as well as lipid peroxidation, oxidative stress and ERK-mediated pro-inflammatory gene expression were significantly enhanced in fat-loaded hepatocytes compared to control cells. Furthermore, the expression of carboxylesterase 2 (CE2), which metabolizes IX to its active metabolite SN38, was significantly induced in fat-loaded hepatocytes while the expression of UDP-glucuronosyltransferase UGT1A1 (the main hepatic enzyme responsible for IX-inactivation) was significantly reduced in fat-loaded hepatocytes. Next, we applied IX to mice with hepatic steatosis (induced by feeding a high-fat diet for 4 weeks) and control mice. In mice with fatty livers, IX treatment further increased hepatocellular lipid accumulation and induced a significantly higher increase of serum transaminases and hepatic oxidative stress, ERK-activation and inflammation compared to control mice. Furthermore, hepatic expression of CE2 was induced and UGT1A1-expression was reduced in steatotic murine livers. This altered hepatic CE2 and UGT1A1 expression pattern was confirmed in patients with non-alcoholic fatty livers.

Conclusion: Our data indicate that irinotecan and steatosis synergistically induce pathological mechanisms in hepatocytes *via* dysregulation of IX-metabolizing enzymes which lead to higher hepatic levels of its toxic metabolite SN38. These findings may have important implications for prediction, prevention and treatment of irinotecan-induced CASH particularly in obese individuals.

Email: jsimon@cicbiogune.es

Background and Aims: Non-alcoholic fatty liver disease (NAFLD), comprehends a group of conditions and has an estimated worldwide prevalence of 25% of the adult population (Younossi et al., 2016). Its first stage, steatosis, is characterized by an accumulation of lipids in

the liver. If steatosis progresses into inflammation and fibrosis it turns into non-alcoholic steatohepatitis (NASH). Although first stages are rather benign conditions, NAFLD can turn into cirrhosis and hepatocellular carcinoma (HCC) (Ascha et al., 2010). Despite dietary and lifestyle interventions are enough to resolve the disease in the earliest stages, sometimes long-term compliance of the patients is so hard that pharmacological approaches are needed to target NAFLD. In fact, a huge economical effort of a billion US$ was estimated in 2015 with only novel experimental approaches and emerging therapies available.

Our group has focused on Glutaminase 1 (GLS1) whose main substrate, glutamine (Gln), has an altered metabolism in liver disease. GLS, located in the mitochondria, is the main regulator of Gln catabolism into glutamate (Glu) and ammonium. It has 2 isoforms: liver-type glutaminase (GLS2) and kidney-type glutaminase (GLS1). The higher affinity isoform, GLS1, has been shown to be regulated by cMyc and overexpressed in many cancer cell types (Yu et al., 2015). It also has been found to be overexpressed in earlier stages of HCC such as cirrhosis.

Method: GLS1 expression and activity was studied in NASH patients. Mice were fed a lipogenic diet (0.1% MCD diet) and targeted silencing of GLS1 was performed through tail vein injection of 4 nmol siCtrl/siGLS1 RNA using Lipofectamine 3.0®. Primary hepatocytes have been obtained through perfusion and targeted silencing was performed using 50 nM siCtrl/siGLS1 RNA and 0.4%v/v Darmaphect®.

Results: Gln/Glu ratio was decreased in serum from a cohort of 467 NASH patients, suggesting an increased Gln catabolism. Related to this, we have characterized GLS1 overexpression in NASH both in human patients and mice. We also have shown lower lipid accumulation when targeted silencing of GLS1, both in mice and primary hepatocytes. Reduced ROS levels have been found in cells and *in vivo* silencing of GLS1, showing to be a consequence of a decreased TCA cycle activity, a lower β-oxidation and a reduced ETC activity. The mechanism underlying these effect has been investigated.

Conclusion: Targeted silencing of GLS1 reduces ROS through a decrease in ECT and TCA activity and a lower β-oxidation. As a consequence, less glutathione is required and serine availability may be increased restoring phospholipid levels and finally restoring VLDL export implying a lower lipid accumulation in the liver.

Email: francesco.chiara@ucl.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a spectrum of liver disease ranging from steatosis, through non-alcoholic steatohepatitis (NASH) to cirrhosis. We have previously shown reduced function of urea cycle enzymes (UCE) in an experimental diet-induced NASH model. The resulting hyperammonemia contributes to hepatic stellate cell activation and risk of progression of fibrosis. We hypothesised that changes in function and expression of UCE are as a consequence of epigenetic modifications. The aims of this study were to investigate the potential mechanisms underlying these changes by assessing the methylation status of UCE promoter genes both in rats and humans.

Method: Rats were fed a high-fat, high-cholesterol diet (HFHC) for 10 months resulting in advanced experimental NASH and then changed to normal chow for 2 months to recover. In humans, we obtained liver biopsies from 20 patients with steatosis and 15 NASH patients. We measured the urea cycle enzymes' gene and protein expression, the OTC activity and ammonia concentrations. Also, we assessed the promoter methylation status of the UCE, ornithine transcarbamylase (OTC) in rats and OTC and carbamoyl phosphate synthetase (CPS1) in human.

Results: In NASH rats, gene ($p < 0.01$ vs. 10 and 12 m) and protein expressions of OTC and CPS1 as well as the enzyme activity of OTC were reduced ($p < 0.01$ both). Reversal of NASH by changing the diet to normal chow restored these changes ($p < 0.01$ vs. 12 m). Methylation of the OTC promoter gene ($p < 0.01$ both) was partially restored by reversal of the diet ($p = 0.02$ vs 12 m) and this was associated with reduced severity of NASH. In humans, NASH patients had significantly lower OTC enzyme activity and protein expression compared to controls ($p < 0.05$). This was associated with increased ammonia concentrations in both plasma and liver tissue ($p < 0.05$). Several sites upstream of the start codon in the OTC and CPS1 promotors were hypermethylated in NASH patients compared with controls.

Conclusion: Experimental and human NASH was associated with a reversible reduction in gene and protein expression and activity of UCE resulting in hyperammonemia. The promoter region of the genes for OTC, and in humans also CPS1, showed increased methylation indicating that hypermethylation of UCE may be the mechanism underlying the reduction in urea synthesis. Our investigations describe for the first time, a link between NASH, function of UCE and hyperammonemia that provides potential new targets for therapy.

Ammonia: A novel target for the prevention of NAFLD progression in NASH

F. De Chiara[1], K.L. Thomsen[2,3], A. Habtesion[3], N. Davies[4], A. Hall[3,5], K. Rombouts[3], F. Andreola[3], H. Jones[3], R. Mookerjee[3], R. Jalan[3]. *[1]Royal free Hospital, ILDH, London, United Kingdom; [2]Aarhus University Hospital, Hepatology and Gastroenterology, Denmark; [3]University College of London UCL, ILDH, London, United Kingdom; [4]ILDH, UCL, United Kingdom; [5]Royal Free London NHS Foundation Trust, Sheila Sherlock Liver Centre, United Kingdom*

Email: francesco.chiara@ucl.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a spectrum of liver diseases ranging from steatosis, through non-alcoholic steatohepatitis (NASH) to cirrhosis. Fibrosis is the most important factor contributing to NAFLD-associated morbidity and mortality and reduction in fibrosis is the main aim for treatment. Urea synthesis is down regulated in NASH resulting in hyperammonemia, which activates hepatic stellate cells (HSCs); the main cell type responsible for hepatic fibrosis. Therefore, we aimed to investigate whether lowering of ammonia prevents development of fibrosis in an animal model of NASH.

Method: Male Sprague Dawley rats ($n = 10$/group) were subdivided into 5 groups and fed, normal chow (NC), an isocaloric (IC) diet, a high fat, high cholesterol (HFHC) diet or the HFHC or IC diet plus the ammonia lowering drug ornithine-phenylacetate (OCR002) for up to 16 weeks. At the end of the study, biochemical parameters were measured, and histological staining was employed for detection of changes in hepatic architecture and collagen accumulation. Hepatic pro-fibrotic markers such as Col1A1, MyosinIIA, MyosinIIB and alpha-SMA were assessed. In liver tissue, activity of the urea cycle enzyme (UCE), ornithine transcarbamylase (OTC) was quantified. Plasma and liver markers of cell death was assessed with ELISA and TUNEL.

Results: In liver tissue, the HFHC diet induced massive and progressive downregulation of OTC activity compared with NC ($p < 0.05$), which was followed by progressive hyperammonemia. The

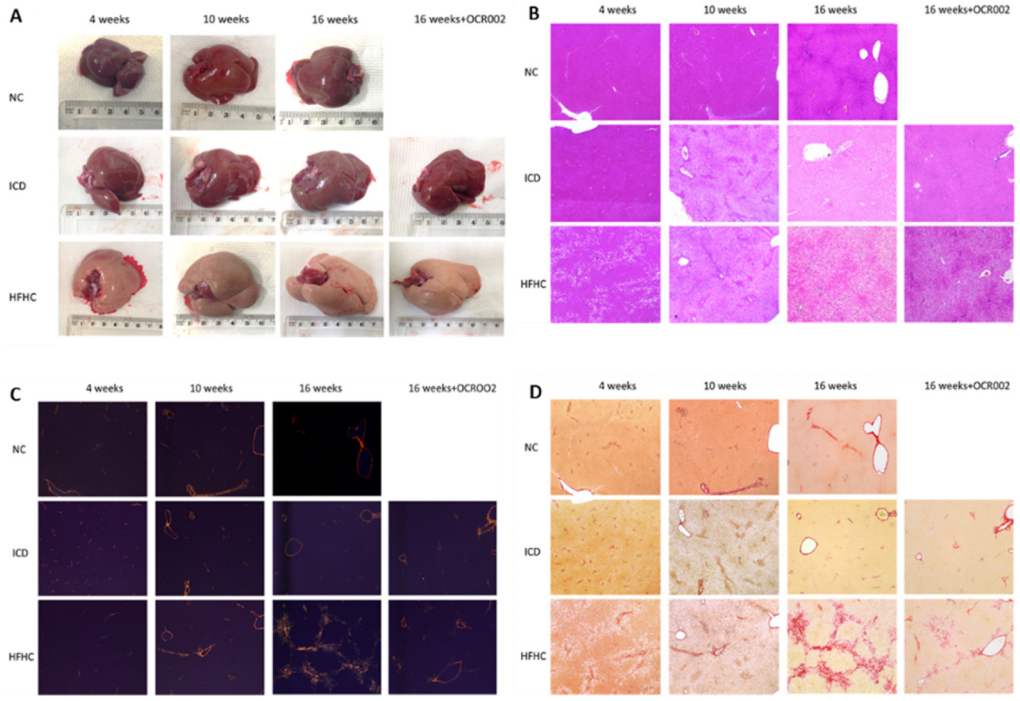

Figure: (abstract: THU-510): (A) Naked-eye assessment; (B) Hematoxylin and eosin; (C) Circularly polarized light; (D) Picro-siriusi red staining.

HFHC fed group showed cell death markers at 4, 10 and 16 weeks vs NC ($p < 0.05$). Hepatocyte lipid accumulation caused by HFHC diet led to dramatic increase of Col1A1, MyosinIIA, MyosinIIB and α-SMA protein expression in liver tissue compared with NC (2 or higher fold increase). High levels of ammonia and cell death markers in HFHC animals were confirmed in the plasma ($p < 0.05$). OCR-002 treated animals had significantly lower hepatic and serum ammonia, lower cell death markers in liver and plasma, and a reduced severity in fibrosis (HFHC vs HFHC + OCR-002, $p < 0.05$).

Conclusion: The above data show that experimental NASH is associated with early and progressive reduction in the activity of urea cycle enzyme OTC resulting in hyperammonemia, increased liver cell death markers, and hepatic stellate cell activation which exacerbates fibrosis. Reduction in ammonia concentrations with OCR-002 prevents hepatocyte cell death and progression of fibrosis supporting a rationale for targeting ammonia as a potential treatment for NASH.

THU-511

During aging osteopontin deficiency increases vulnerability to non-alcoholic fatty liver disease progression and the associated extrahepatic metabolic complications

B.G. Santos[1], F. Gonzalez-Romero[1], M. Nuñez-García[1], D.M. Congregado[1,2], D.S. de Urturi[1], V.G. de Juan[3], M.L. Martínez-Chantar[3], I. Aurrekoetxea[1,2], X. Buque[1,2], P. Aspichueta[1,2]. *[1]Faculty of Medicine and Nursing, Univesity of The Basque Country, Department of Physiology, Leioa, Spain; [2]BioCruces Health Research Institute, Barakaldo, Spain; [3]Center for Cooperative Research in Bioscience (CIC bioGUNE), CIBERehd, Derio, Spain*
Email: patrietal@hotmail.com

Background and Aims: Osteopontin (OPN), a cytokine part of the senescence associated secretory phenotype, overexpresses in liver fibrosis and hepatocellular carcinoma. Non-alcoholic fatty liver disease (NAFLD) is common in the elderly and carries more metabolic complications than in younger individuals. Here we investigated the involvement of OPN in the development and progression of aging related NAFLD and the extrahepatic metabolic complications.

Method: OPN deficient mice (OPN-KO) mice and their control littermates (WT) of 3, 10 and 20 month-old were used. A group of mice was fed a high-fat diet (HFD) for 16 weeks until sacrificed at 20 months-old. Immunohistochemistry analysis, lipid concentration, de novo lipogenesis and beta oxidation fluxes were analyzed.

Results: During aging circulating and liver OPN levels increased at 10 month-old and maintained high in 20 month-old WT mice, in which the increase in serum OPN was even higher when fed a HFD. The number of senescent hepatocytes, liver p21 and E2F1 protein levels, which controls de novo lipogenesis in liver, were higher in 10 month-old OPN-KO mice than in their control mice. p53 levels increased at 20 month-old just in OPN-KO. Liver triglycerides (TG), diglycerides and cholesteryl esters, de novo lipogenesis fluxes and fatty acid synthase levels together with serum TG levels were higher in 10 month-old OPN-KO mice than in WT mice. Liver lipid storage maintained stable in 20 months-old OPN-KO mice liver, in which fibrosis was increased as compared to their age-matched WT mice. Feeding a HFD to 16 month-old mice induced similar weight gain in both genotypes, but led to a higher metabolic dysregulation in OPN-KO mice; the HFD worsened insulin sensitivity, increased serum TG levels and adipose tissue lipolysis. Even though the HFD did not induce the liver lipid storage of the WT mice, Sirius red staining and F4/80 protein levels were higher.

Conclusion: OPN deficiency during aging induces a premature age related phenotype. It plays a protective role in the metabolic dysregulation of aging. E2F1 transcription factor could be involved in liver lipid storage and the associated extrahepatic metabolic complications in OPN-KO mice.

Discovery and validation of new modulators of necroptosis using phenotypic high throughput screening of a large compound library

H.M. de Sousa Brito[1], V. Marques[1], M.B. Afonso[1], D. Brown[2], U. Börjesson[3], N. Selmi[3], M. Fitzek[4], C.M.P. Rodrigues[1]. [1]*Research Institute for Medicines, iMed.ULisboa, Faculty of Pharmacy, University of Lisbon, Cellular Function and Therapeutic Targeting, Lisboa, Portugal;* [2]*Astrazeneca, Hit identification, Waltham, United States;* [3]*Astrazeneca, Hit identification, Mölndal, Sweden;* [4]*Astrazeneca, Hit identification, Cambridge, United Kingdom*
Email: hugobrito1@gmail.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is the most common liver disease in the Western world, representing an important public health concern. Disruption of the equilibrium between cell death and proliferation may be at the origin of NAFLD pathogenesis. We have previously shown that regulated necrosis or necroptosis plays a key role in non-alcoholic steatohepatitis (NASH). Here we aim to discovery novel, selective and potent inhibitors of necroptosis, which might evolve to potential therapeutic strategies. Benefiting from privileged research collaborations on target innovation between academia and pharma industry, we have gained access to a high-quality, large compound pharma collection of over 250,000 compounds.
Method: Compounds were screened at 30 μM for their ability to block TNF-α-induced necroptosis (30 μM; 8 h) in murine fibrosarcoma L929 cell line, using a bioluminescent cytolysis assay.
Results: From the full library screening, valid data was achieved for 251,879 compounds. For hit selection, exclusion criteria included qualitative and quantitative parameters, ZScore and percentage of cell death inhibition. A cut off threshold of >30% inhibition of cell death by tested compounds and a ZScore <−10, led to 3,353 active hits, corresponding to 1.3% hit rate for the full library. For positive hits, dose-response curves were built using a 10-point concentration range of 0.004–100 μM to quantitatively assess inhibitory potency of selected compounds in murine L929 and human Jurkat T FADD(−/−) cell lines. Further selection comprised exclusion criteria of pEC50 < 5 (EC50 < 10 μM) in both cell lines, leading to 1,000 actives at 29.8% hit rate. Next, using Jurkat E6.1 cells stimulated with cycloheximide (0.5 μg/ml; 8 h) for apoptosis induction, selected compounds were tested in caspase-3/-7 enzymatic activity assays using a 4-point concentration range of 0.03–30 μM, active hits protecting from apoptosis were excluded. Moreover, 33 and 21 compounds showed RIPK1 and RIPK3 inhibitory kinase activity, respectively, although the vast majority protected from necroptosis through yet undetermined mechanisms of action. 109 compounds were selected based on chemically clusters and EC potency.
Conclusion: Target identification and hit to lead medicinal chemistry is now expected to deliver optimized molecules that will then be evaluated in experimental murine models of NASH.

Pharmacological inhibition of myeloperoxidase attenuates non-alcoholic steatohepatitis-induced liver fibrosis in mice

A. Koop[1], N. Thiele[1], D. Steins[1], T. Diedrich[1], E. Michaëlsson[2], J.S.Z. Wiesch[1], A.W. Lohse[1], J. Heeren[3], J. Kluwe[1]. [1]*University Medical Center Hamburg-Eppendorf, I. Department of Internal Medicine, Hamburg, Germany;* [2]*AstraZeneca R&D;* [3]*University Medical Center Hamburg-Eppendorf, Institute of Biochemistry and Molecular Cell Biology, Hamburg, Germany*
Email: a.koop@uke.de

Background and Aims: Myeloperoxidase (MPO) activity has been associated with obesity, arterial hypertension and cardiovascular disease all of which are outcome-relevant comorbidities of non-alcoholic steatohepatitis (NASH). Moreover, MPO-positive cells are present in the histology of NASH. Our aim was to explore the therapeutic potential of MPO inhibition in a mouse model of NASH.
Methods: MPO levels were assessed by ELISA in the sera of healthy controls and patients with non-alcoholic fatty liver disease (NAFLD). C57/Bl6J mice were fed a high-fat, high-carbohydrate (HFHC) diet to induce NASH. After several weeks, a subgroup of mice was sacrificed to characterize the baseline NASH phenotype. Another subgroup was switched to a HFHC diet containing the MPO inhibitor AZM198, provided by Astra Zeneca, while the control group was continued on HFHC diet without the inhibitor. The NASH phenotype was characterized by histology, qPCR and ALT levels. We performed 2 independent experiments with different timelines: For a short-term experiment mice received baseline HFHC feeding for 10 weeks, and 16 weeks baseline feeding for a long-term experiment, each followed by 8 weeks on HFHC diet with or without AZM198.
Results: MPO serum levels were elevated in patients with NAFLD compared to healthy controls. Also, mice fed a HFHC diet displayed significantly elevated MPO serum levels and increased numbers of MPO-positive cells on liver histology compared to mice on a chow diet. Reduced MPO-mediated liver damage was demonstrated by decreased 3-Chlorotyrosin-staining in AZM198-treated mice in both experiments. In the long-term experiment, alpha smooth muscle actin (aSMA) and sirius red staining demonstrated a significant decrease in liver fibrosis in AZM198-treated mice compared to control mice. This could be confirmed in the short-term experiment by aSMA staining, while collagen deposition was too mild at this time point for sirius red quantification. However, in AZM198-treated mice, qPCR revealed a decreased expression of fibrosis-related genes (Col1a1, TIMP1) and ALT levels were significantly lower compared to controls at the early time-point. Hepatic steatosis assessed by oil-red o staining was significantly decreased in AZM198-treated mice in both experiments. AZM198 had no effect on HFHC diet-induced weight gain or insulin resistance in either experiment.
Conclusion: Our data indicate that pharmacological MPO inhibition attenuates the progression of NASH including NASH-induced liver fibrosis in mice.

Email: garciamonzon@hotmail.com

Background and Aims: Circulating vitamin D (VD) deficiency (VDD) and increased hepatic VD receptor (VDR) expression have been reported in patients with non-alcoholic fatty liver disease (NAFLD) but whether a relationship between serum VD and its hepatic receptor exists as well as the significance of VD/VDR signalling in NAFLD setup remain to be elucidated.
Method: Serum VD and bile acid (BA) concentrations, and hepatic mRNA levels of VDR and VD/VDR-related genes were evaluated in patients with biopsy-proven non-alcoholic fatty liver (NAFL) and in subjects with histologically normal liver (NL). We also aimed to uncover novel VDR target genes and the potential mechanisms for VDR upregulation in human hepatocytes.
Results: Prevalence of VDD was similar in NAFL patients (60%) and subjects with NL (57.3%) whereas hepatic mRNA levels of VDR, cytochrome P450 (CYP) 2R1, CYP27A1, CYP3A4 and angiopoietin-like protein 8 (ANGPTL8) were significantly higher in NAFL patients than in NL subjects. Noteworthy, hepatic VDR mRNA levels correlated inversely with serum VD concentrations and positively with liver

ANGPTL8 mRNA as well as with both serum triglycerides and total cholesterol levels but only in NAFL patients. Moreover, a significant increase in serum conjugated BA, largely glycine-conjugated litho-cholic acid (LCA), was observed in NAFL patients. In addition, we demonstrated in cultured human hepatocytes that ANGPTL8 mRNA is induced upon VDR activation with VD and/or LCA, and that free fatty acids and insulin are able to upregulate both VDR and ANGPTL8 gene expression.
Conclusion: In a setting of low VD and high BA circulating levels, VDR signalling is increased in the liver of NAFL patients which could contribute to NAFL setup by upregulating lipogenic target genes, such as ANGPTL8, in human hepatocytes.

THU-515
The liver-specific deletion of the respiratory chain inhibitor MCJ attenuates NAFLD progression by enhancing hepatic beta-oxidation

L. Barbier-Torres[1], T.C. Delgado[1], P. Iruzubieta[1,2], D.F. Ramos[1], V.G. de Juan[1], M. Varela-Rey[1], P.F. Tussy[1], I. Zubiete-Franco[1], J. Simón[1], F.L. Otsoa[1], D.M. Congregado[3], B.G. Santos[3], X. Buqué[3], J. Crespo[2], S.C. Lu[4], J. Matos[5], P. Aspichueta[3], J. Anguita[6,7], M. Rincón[8], M.L. Martínez-Chantar[9]. *[1]CIC Biogune, Liver Disease Laboratory, Derio, Spain; [2]Marqués de Valdecilla University Hospital, Digestive Unit, Santander; [3]University of Basque Country & Biocruces Health Research Institute, Physiology, Faculty of Medicine and Nursering, Leioa & Barakaldo, Spain; [4]Cedars-Sinai Medical Center, Division of Gastroenterology, Los Angeles; [5]CIC bioGUNE, Director, Derio; [6]CIC bioGUNE, Macrophage and Tick Vaccine Lab, Derio, Spain; [7]Ikerbasque, Ikerbasque Foundation for Science, Bilbao, Spain; [8]University of Vermont, Robert Larner College of Medicine, Disivion of Immunobiology, Burlington, VT, United States; [9]CIC bioGUNE, Liver Disease Lab, Derio, Spain*
Email: dfernandez.ciberehd@cicbiogune.es

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease worldwide affecting over one-third of the population in the U.S. NAFLD comprises a broad range of clinical disorders from steatosis and non-alcoholic steatohepatitis (NASH) to cirrhosis and liver cancer. The molecular mechanisms underlying NAFLD progression are not completely understood and the tools for its early diagnosis are limited. Mitochondrial alterations have been described in a variety of chronic liver diseases including NAFLD. MCJ, also known as DNAJC15, is localized at the inner mitochondrial membrane where it binds and inhibits the electron transport chain complex I.
Method: MCJ expression and activity was studied in NAFLD patients. There were studied MCJ-KO mice and MCJ-wt mice after a targeted silencing of MCJ through tail vein injection of 4 nmol siCtrl/siMCJRNA using Lipofectamine 3.0®. Primary hepatocytes have been obtained through perfusion and targeted silencing was performed using 50 nM siCtrl/siMCJ RNA and 0.4%v/v Darmaphect®.
Results: In this work, we studied the role of MCJ in the pathogenesis of NAFLD and investigated the effect that the absence of MCJ exerts in the progression of the disease. MCJ expression is increased in human NAFLD. Moreover, MCJ silencing protected against hepatic lipid accumulation, liver injury and inflammation in the methionine-choline deficient diet mouse model of NASH. Loss of MCJ led to increased β-oxidation and enhanced mitochondrial respiration, TCA cycle function and glycolysis rate, which maintained mitochondrial function and ATP production. This metabolic adaptations were able to couteract the cytotoxic effects of fat accumulation on mitochondria and ultimately on hepatocytes.
Conclusion: Overall, MCJ emerges as a key regulator of NAFLD paving the way for new therapeuthical approaches.

THU-516
Targeting the NAFLD metabolome and the shaping of precision medicine for patients with NASH

M. Iruarrizaga-Lejarreta[1], I. Martínez-Arranz[1], M.C. Morrison[2], M. Varela-Rey[3], D.F. Ramos[3], L. Delacruz-Villar[3], M. Noureddin[4], M.L. Martínez-Chantar[3], R. Kleemann[2], C. Alonso[1], S.C. Lu[4], J.M. Mato[3]. *[1]OWL Metabolomics, Derio, Spain; [2]TNO, Metabolic Health Research, Leiden, Netherlands; [3]CIC bioGUNE, CIBERehd, Derio, Spain; [4]Cedars-Sinai Medical Center, Division of Digestive and Liver Diseases, United States*
Email: jmmato@cicbiogune.es

Background and Aims: NASH therapy is being developed under the "one drug treats all patients" paradigm. We show here, that a better characterization of the NAFLD metabolome reveals the existence of distinct NASH subtypes, providing the base for personalized treatment.
Method: We have compared the serum metabolome of three mouse models of NASH [Mat1a−/−, methionine and choline deficient diet (MCD), and high-fat fed Ldlr−/−.Leiden mice] with the metabolome of a cohort of 535 individuals with biopsy proven diagnosis of NAFLD.
Results: Analysis of the data indicates the existence of two major NAFLD phenotypes, each of them characterized by a specific metabolic alteration. One (named M-subtype), comprising 40% of the patients and showing a metabolic profile compatible with low hepatic SAMe, impaired VLDL secretion, increased fatty acid uptake and normal de novo lipogenesis (DNL); and a second phenotype (named L-subtype), including 32% of the patients, showing a metabolic profile compatible with normal SAMe and VLDL secretion, and increased DNL. Treatment with obeticholic acid improved NASH in the Leiden mouse model but had no effect in the MCD model, confirming the need of developing a personalized treatment in NASH.
Conclusion: These results indicate, that serum metabolomic profiling will give the opportunity to identify those patients that respond better to a specific treatment.

THU-517
The pathophysiological significance of nerve growth factor in non-alcoholic fatty liver disease via FXR upregulation

M.-S. Tsai[1], Y.-H. Kao[2], T.-C. Chiu[2], Y.-C. Lin[2], P.-H. Lee[2]. *[1]E-Da Hospital, Department of Surgery, Kaohsiung, Taiwan; [2]E-Da Hospital, Department of Medical Research, Kaohsiung, Taiwan*
Email: drmstsai@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) has become the most common cause of liver disease not only in the western world, but also a major health concern in industrialized countries worldwide. Nerve growth factor (NGF) is a prototypic neurotrophin previously shown to exert hepatoprotective effect in cholestatic disease. Whether NGF is involved in liver metabolic disease remains obscure. This study investigated the regulatory role of NGF in farnesoid X receptor (FXR) expression during NAFLD development.
Method: The expression and histological expression patterns of NGF propeptide (proNGF) and FXR were studied in human liver tissues with NAFLD (n = 100). The mechanism underlying NGF-regulated FXR expression was studied in cultured primary and clone-9 hepatocytes.
Results: Downregulation of proNGF and FXR was simultaneously noted in human NAFLD livers. Immunohistochemistry indicated that NGF and FXR were mainly localized in parenchymal hepatocytes. Correlation analysis indicated strong and positive correlation between the hepatic NGF and FXR expression levels. In vitro mechanistic studies demonstrated that exogenous NGF treatment significantly increased FXR expression in primary hepatocytes. NGF receptor blocker pretreatment demonstrated that both NGF receptors, TrkA and p75 NTR, were involved in the NGF-induced FXR upregulation.

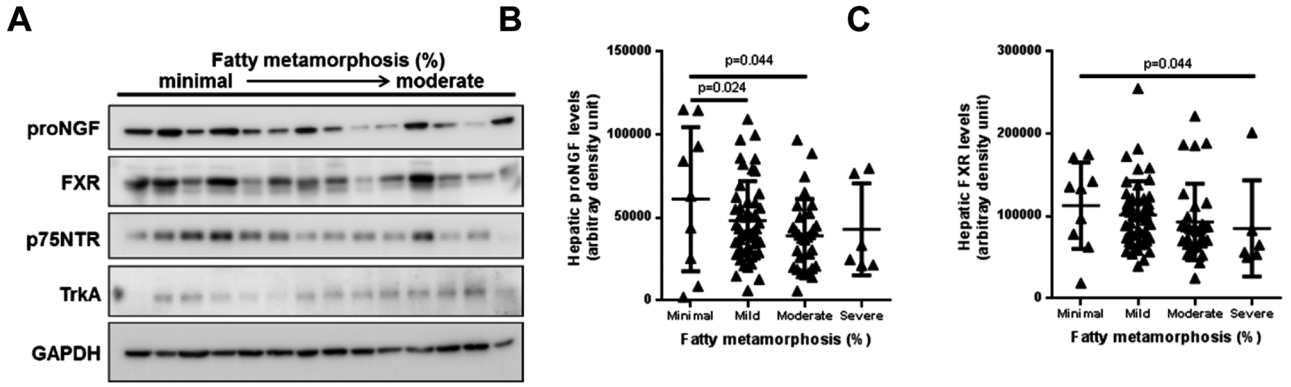

Figure: (abstract: THU-517): The pathophysiological role of NGF in the NAFLD development via FXR upregulation. (A) Expression of NGF precursor (proNGF), FXR, and NGF receptors in human NAFLD livers with minimal or moderate fatty metamorphosis. (Minimal:<5%; Mild: 5–33%; Moderate: 33–66%; Severe:>66% of fatty area) (B) Densitometry measurement of proNGF and FXR protein levels. (C) Pearson's correlation analysis between hepatic proNGF and FXR levels.

Conclusion: NGF and FXR downregulation was concomitantly evidenced in human NAFLD livers. NGF upregulates hepatic FXR expression through NGF-NGFR signaling axis.

THU-518

Modulation of the NLRP3 inflammasome pathway mediates the anti-inflammatory action of indoleamine dioxygenase in experimental NASH

B. Piombanti, E. Vivoli, F. Marra. *University of Florence*
Email: fabio.marra@unifi.it

Background and Aims: The inflammasome pathway is implicated in the pathogenesis of NAFLD, but its regulatory mechanisms are only partially understood. Indoleamine 2,3-dioxygenase (IDO-1), generates kynurenine degrading tryptophan, and is involved in immune regulation and tolerance. In this study, we analyzed the possible cross-talk between the IDO and inflammasome pathways in the setting of experimental NASH.
Method: In mice, steatohepatitis was induced by feeding for 4 weeks a diet deficient in methionine and choline (MCD), with or without administration of 1-methyl-D-triptophan (1MT, 5 mg/ml), an inhibitor of IDO. Cultured RAW264.7 murine macrophages were used for in vitro experiments.
Results: Inhibition of IDO with 1MT was associated with increased expression of proinflammatory genes, including CCL2, IL-1beta, and iNOS. In addition, 1MT treatment was associated with downregulation of components of the NLRP3 inflammasome, including NLRP3, ASC, and IL-1beta. RAW264.7 were treated with low-dose LPS together with 1MT to inhibit IDO. In these conditions, IDO inhibition was associated with up-regulated secretion of IL-1beta, and increased expression of NLRP3 inflammasome components.
Conclusion: We demonstrate the novel interaction between the IDO pathway and NLRP3 inflammasome in murine macrophages and in a mouse model of steatohepatitis. This cross-talk may contribute to explain the complex inflammatory picture observed in NASH.

THU-519

The role of dendritic cells in different stages of non-alcoholic fatty liver disease

O.L. Ramírez-Pérez[1], B. Barranco-Fragoso[2], R. Pichardo-Bahena[3], V.C. Cruz-Ramón[1], P. Chinchilla-López[1], S. Canizales-Quinteros[4], N. Méndez[1]. *[1]Medica Sur Clinic and Foundation, Liver Research Unit, Mexico City; [2]National Medical Center "20 de Noviembre" ISSSTE, Gastroenterology Department, Mexico City, Mexico; [3]National Institute of Rehabilitation, Department of Pathology, Mexico City, Mexico; [4]The National Institute of Genomic Medicine, Genomics Unit, Mexico City, Mexico*
Email: oscartuzos94@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the leading cause of chronic liver disease worldwide. The pathogenesis has not been completely elucidated but it has observed that multiple inflammatory and non-inflammatory factors are implicated. The oxidative stress induces hepatic cell injury, with subsequent inflammatory cell infiltration. Liver Dendritic Cells (DC) are a heterogeneous population of hepatic antigen-presenting cells; their main function is to induce T-cell mediated immunity by antigen processing and presentation to T cells. Nevertheless, the role of DC in NAFLD is incompletely defined. The aim of this study was to investigate the role of DC in fibrosis severity in NAFLD between patients with morbid obesity and obesity grade I.
Method: We enrolled 93 adult patients with NAFLD confirmed by biopsy. They were categorized into two groups; seventy-four morbid obesity patients and nineteen patients with obesity grade I. We collected clinical, biochemical and anthropometric variables. The degree of fibrosis was evaluated in all patients using the liver biopsy and the inflammatory activity was assessed according to the NAS Score System (NAS). In addition, the expression of DC were detected by immunohistochemistry using CD11c.
Results: We have summarized the main results in the Table 1 related to metabolic and anthropometric variables. We found that the expression of DC were similar in the morbid obesity group with and without fibrosis; however, in patients with grade I of obesity the DC expression was higher in group of fibrosis. On the other hand the mean of NAS score in all patients was 4. As we expected those patients with fibrosis and higher expression of DC were male and older.

Table 1: NAFLD patients according to the grade of obesity

	Patients with morbid obesity		Patients with obesity grade I	
	Non-fibrosis (n = 44)	Fibrosis (n = 30)	Non-Fibrosis (n = 9)	Fibrosis (n = 10)
Male, n (%)	13 (29.5)	10 (33)	3 (33)	5 (50)*, **
Age mean, SD	36.8 (9.5)	37.1 (9.9)	49.5 (12.8)	58.4 (4.2) **
Metabolic syndrome n (%)	29 (66)	16 (53)	4 (44)	4 (40) *
BMI (Kg/m^2) mean, SD	45.4 (6.9)	44.1 (6.0)	30 (1.4)	30.2 (2.77)
Glucose (mg/dL) mean, SD	100.7 (27.3)	99.3 (26.6)	103.7 (28.1)	113.4 (39.8) **
Triglycerides (mg/dL) mean, SD	174.5 (96)	136.3 (589	261 (209.6)	166.3 (88.5) **
ALT (U/L) mean, SD	42.5 (32)	38.9 (24)	35.5 (10.93)	57.9 (30.7) **
DC (CD11C) n(%)	29 (66)	20 (67)	8 (88)	10 (100)*

All presented as mean (SD) T Student test, *Proportions Chi-Square Test **p < 0.05.

Conclusion: We found that DC are expressed mostly in patients in the early stage of fibrosis and we believe that this kind of cells are important in the progression of the non-alcoholic steatohepatitis (NASH). We speculated that since the DC are involved in the immune response. Its role in the liver inflammation is important in the progression of NAFLD. However more studies are needed to define the molecular mechanism implicated in this process.

THU-520

Evolving alterations of hepatic macrophage population in the disease progression of non-alcoholic ateatohepatitis in a mouse model

X. Zhou, F. Yang, B. Ye, G. Ying, Y. Yang, H. Zhu, Z. Chen. *Zhejiang University, State Key Laboratory of Infectious Disease Diagnosis and Treatment, Institute of Infectious Diseases, First Affiliated Hospital, School of Medicine, Hangzhou, China*
Email: 11418232@zju.edu.cn

Background and Aims: NAFLD (non-alcoholic fatty liver disease) becomes one of the most common forms of chronic liver disease. The aim of the study was to investigate the role of liver macrophages in the development of liver inflammation and injury caused by non-alcoholic steatohepatitis (NASH).
Method: In the study, an experimental mouse model of NASH was established by MCD diet feeding. During the 4 weeks of MCD diet, content and subtypes of hepatic macrophages and serum cytokines were detected weekly.
Results: The percentage of F4/80+ macrophages in liver MNCs (mononuclear cells) increased on the 1st week and kept on a high level in the following weeks. And the increased macrophages were $CD11b^+$ $F4/80^+$, which were thought to be recruited from the peripheral blood. Further, we found that CD206+ $F4/80^+$ M2 macrophage increased and peaked on the 1st week, and gradually fell to a level lower than normal at the 4th week. In contrast, the level of iNOS, an M1 marker, began to increase on the 3rd week as the progression of NASH. And the level of serum pro-inflammatory cytokines such as TNF-α and IL-6, and anti-inflammatory cytokines such as IL-10, was altered in parallel with macrophage polarization.
Conclusion: These observations suggested that the macrophage recruitment and polarization were associated with NASH progression.

THU-521

Partial hepatectomy and hemodynamics: insights from numerical modeling on vascular response

C. Audebert[1], P. Bucur[2], M. Bekheit[3], N. Boissier[1], D. Drasdo[1], J.-F. Gerbeau[1], E. Vibert[3], I. Vignon-Clementel[1*]. *[1]Inria and Sorbonne Université UPMC, France; [2]CHRU Hop. de Tours, France; [3]Inserm and AP-HP Hop. Paul Brousse, France*
*Presenting and corresponding author

Background and Aims: Partial hepatectomy triggers hemodynamics changes, which causes and consequences are still matter of debate. The precise link between liver architecture, perfusion and function remains to be fully elucidated. The aim of this work is to qualitatively and quantitatively characterize the link between architecture and hemodynamics in the context of partial hepatectomy, based on mathematical models of systemic and hepatic hemodynamics.
Method: Partial hepatectomy was performed in a swine model, during which multimodality data were collected (CT imaging, continuous pressures and flow rates, histological material, …) (Bucur et al. 2017). First, hemodynamics after 75% partial ablation was simulated in a whole-body dynamic model (Audebert et al. JBM 2017). The model parameters were calibrated with pre-operative hemodynamics measurements. The impact of blood infusion or blood volume change on hemodynamics was analyzed. Changes in hepatic artery pressure and flow cardiac pulsatility were also studied with a whole-body hemodynamics model, where arteries from the heart to the liver were modeled with a spatially more precise mathematical model (1D Euler equations) (Audebert et al. CMAME 2017). Finally, the first post-operative day was studied with a multiscale model. The resistance of the model representing the micro-circulation of the liver was estimated from a more precise model of the micro-circulation based on histological analysis (Hoehme et al. PNAS 2010). In addition, different mechanisms impacting hemodynamics were studied (organ vascular dilation, liver micro-circulation changes …). All the simulations were compared to measurements made on the first post-operative day after 75% partial ablation on swine.
Results: The model quantitatively captures the typical increase of portal pressure, increase of liver portal to venous pressure 'gradient', slight decrease of portal flow and major decrease in arterial flow, for a 75% hepatectomy. The 75% decrease in hepatic arterial flow can be explained by the resistance increase induced by the surgery, without hepatic arterial buffer response (HABR) mechanism being needed to account for this change. The different post-operative states, observed in swine experiments, are reproduced with the proposed model. An architectural change of the liver vascular structures appears to be the cause of the hepatic artery hemodynamics pulsatility change, rather than just a mass reduction due to 75% hepatectomy. This hypothesis is compatible with a lesser change observed when going from 75% to 90% hepatectomy. Finally, the multiscale study makes apparent the need to take into account the microcirculation but also systemic vascular responses to understand the early days of liver regeneration.
Conclusion: An explanation for the major hemodynamics changes and inter-subjects post-operative hemodynamics variability is thus proposed for partial hepatectomy. The presented framework enables us to make hypothesis on the probable vascular mechanisms that can take place during the first days of regeneration. Moreover, it can be easily adapted to other species circulations and to different pathologies (e.g. cirrhosis – Audebert et al. IEEE Trans.Biom.Eng. 2018). Clinical translation is on-going.

FRI-001

A six month follow-up study to determine the clinical utility and patient acceptability of fibroelastography in detection and treatment of alcohol-related liver disease

L. Owens[1,2], A. Thompson[2], C. Siju[1,3], P. Richardson[1]. [1]*Royal Liverpool University Hospital, Hepatology, Liverpool, United Kingdom;* [2]*University of Liverpool, Wolfson Centre for Personalised Medicine, Liverpool, United Kingdom;* [3]*University of Liverpool, Medical School, Liverpool, United Kingdom*
Email: lynno@liv.ac.uk

Background and Aims: It is axiomatic that all alcohol-related death is preventable. Furthermore, 1/3 of all deaths from liver disease are attributed to alcohol, and these deaths are increasing. One reason for this is that alcohol-related liver disease (ARLD) remains under-recognised and undertreated. We suggest that early detection by means of fibroelastography (FE) in alcohol treatment clinics (ATC) is an ideal opportunity for early detection of ARLD in a high risk population with no previous diagnosis.
Aim: To determine the clinical utility and patient acceptability of FE to identify the presence of liver fibrosis.
Method: An observational prospective clinical audit. The primary outcome was to detect the presence of fibrosis using FE, and a secondary outcome was to measure FE change over time related to alcohol consumption. Patients were also asked to complete a satisfaction survey including a question "Did knowing your fibroscan result encourage you to reduce or stop drinking". Participants**:** Acute hospital, ATC patients attending for treatment of an alcohol-use disorder with no previous history of ARLD.
Results: Of the 428 patients screened Dec 2015 – Sept 2017; 314 had no evidence for fibrosis with a Kpa score <8, 47 had a score ≥8 and <12, 19 had a score ≥12, <19.4 and 48 had a score ≥19.5. Sixty-three participants had FE at baseline and six month follow-up. At baseline, patients had an average daily consumption of 18.2 (SD = 10.5) UK units and a mean FE result of 11.9Kpa (SD = 11.9); F0-1 = 30, F1-2 = 15, F2-3 = 7, F3-4 = 11. At six months, there was a positive relationship between units consumed and FE result, such that a reduction in units was associated with a decrease FE score (B = 0.36, 95%CI = 0.16 to 0.57; p = 0.01). Of 120 patients surveyed 117 stated that knowing the FE score helped motivate them to reduce their drinking.
Conclusion: Nurse-led ATC setting is a valuable and effective setting for the early detection of ARLD utilising FE. Importantly, we identified 67 patients with an FE score consistent with cirrhosis and no previous history of ARLD. Furthermore, reductions in alcohol consumption were associated with reductions in fibrosis. The FE score is therefore potentially useful as an objective measure for comparisons over time, and perhaps more importantly is a useful clinical tool for patient feedback in motivation to reduce/stop drinking, and provides objective evidence for the positive effects of alcohol reduced drinking.

FRI-002

Pilot study: Evaluation of the role of the coordinating nurse in the management of patients with hepatocellular carcinoma and treated with chemoembolization

J. Devictor[1], W. Aurélie[2], Y. Mouelhi[3], B. Mohamed[4], F. Durand[1].
[1]*hôpital beaujon, hépatologie, Clichy, France;* [2]*Centre hospitalier de Lens, Lens, France;* [3]*Aix-Marseille Université, Faculté de Médecine La Timone, Marseille, France;* [4]*Hôpital Beaujon, Oncologie, Clichy, France*
Email: julie.devictor@aphp.fr

Background and Aims: Hepatocellular carcinoma is a significant public health problem with an annual incidence of 16.4/100,000 adults. In a context of constant healthcare adaptation, the management of these patients has been revamped. The notion of "care pathway" has been introduced and led to the creation of new positions such as complex care pathway coordinating nurses. We wanted to determine whether the presence of the coordinating nurse improves care efficiency for patients with hepatocellular carcinoma treated with chemoembolization.
Method: A comparative and retrospective cohort pilot study was carried out in two french university hospitals. The coordinating nurse position was effective in center A but not in center B. Clinical and coded medical data from 107 patients with hepatocellular carcinoma and treated for the first time with trans-arterial chemoembolization (TACE) between January 1rst, 2015 and January 31rst, 2015 were collected (center A: 62/center B: 45). Center A was using two different approaches for TACE (DC Beads and lipiodol), whilst center B only lipiodol TACE. There was no significant difference observed regarding tumor features: the average tumor size was 4.68 ± 3.08 cm in center A and 3.60 ± 3.56 cm in center B. The average number of nodules was 2.95 ± 2.01 in center A and 2.47 ± 1.46 in center B. All treated patients were Child A or B7. Higher proportion of Child B patients were observed in center B compared to center A (37.8% and 19.4% respectively).
Results: Univariate then multivariate analysis, adjusted for possible confounding factors such as disease stages, showed that the average length of stay in hospital of patients hospitalized for their treatment was significantly shorter in the center with coordinating nurses: 2.98 ± 1.91 days in center A vs. 4.67 ± 4.25 days in center B (p = 0.01). There was no significant difference for re-admissions and early emergencies. No differences were observed regarding tumor features, patients' characteristics or treatment approaches.
Conclusion: The anticipation and regulation missions of the coordinating nurse may contribute to improving care efficiency. However, a center effect cannot be excluded. These results will be confirmed by a planned prospective multicentric study. Interesting results from such studies can promote the nursing role in our health system while the position of advanced practice nurse soon to be implemented in France.

FRI-003

Patient education results in better sustained virological response to anti-viral therapy in a high number of patients with chronic hepatitis C than conventional care

François Habersetzer[1,2,3], M. Doffoël[1,3], C. Frederic[3], F.D. Nino[3], L. Jean-Philippe[3], E. Florence[3], H. Carmen[4], T. Baumert[1,2]. [1]*Pôle Hépato-digestif, Hôpitaux Universitaires de Strasbourg, Strasbourg, France;* [2]*Unité 1110, INSERM, Strasbourg, France;* [3]*SELHVA, Service Expert de Lutte contre les Hépatites Virales d'Alsace, Hôpitaux Universitaires de Strasbourg, Strasbourg, France;* [4]*SOS Hépatites Alsace Lorraine, SOS Hépatites, Strasbourg, France*
Email: francois.habersetzer@chru-strasbourg.fr

Background and Aims: Patient education may add benefit to chronic hepatitis C management and improve response to anti-viral therapy. This study aimed to evaluate the factors associated with participation in a patient education program for the treatment of chronic hepatitis C and the program's impact on treatment effectiveness.
Method: Overall, 453 consecutive patients were treated with direct-acting anti-viral therapy (DAA) between April 2014 and December 2016. Of these, 30 were treated with pegylated interferon, ribavirin, and sofosbuvir, and 423 with DAA alone, with or without ribavirin. All patients were proposed to take part in a patient education program.
Results: Altogether, 312 patients took part in the patient education program (69%). The number of nurse-led consultations varied between one and six per patient. On univariate analysis, the patients who participated in patient education were younger ($p < 0.001$) and more often in a precarious situation, migrants, or drug users ($p < 0.0001$). They also were receiving psychiatric or addiction treatment and lived near the hospital ($p < 0.0001$) more often. Treatment for the first time and treatments with pegylated interferon were also more common ($p < 0.01$). On multivariate analysis, four factors were associated with participation in a patient education: precarious situation (OR = 25.76), pegylated interferon therapies (OR = 5.93), place of residence (OR = 5.52), and first treatment (OR = 2.70).
All treatments taken together, sustained virological response for 12 weeks or more (SVR 12) was higher among patients who participated in patient education (94.2%) than those who did not (89.3%) ($p = 0.06$). This superiority was also observed in patients treated with DAA ± ribavirin (94.7% *vs.* 88.6%; $p = 0.009$). In patients who participated in patient education, SVR was independent of precarious situation, migrant status, and drug use, being around 95%.
Conclusion: Most patients treated for chronic hepatitis C agreed to patient education, thereby improving the rate of sustained virological response among patients treated with DAA.

FRI-004

Reliability and validity study of the Turkish version of the chronic liver disease questionnaire

F. Celik, H. Bektaş. *Akdeniz University, Antalya, Turkey*
Email: feryacelik@gmail.com

Background and Aims: The aim of this study was to adapt of the Chronic Liver Disease Questionnaire to Turkish and determine the validity and realibility of the scale.
Method: This methodological study was conducted between November 24, 2016 and April 5, 2017 at the Gastroenterology Clinic and Gastroenterology Policlinic of the Akdeniz University Hospital with 235 chronic liver patients. "Personal Information Form", "Child-Pugh Scoring System Form", "Chronic Liver Disease Questionnaire (CLDQ)" and "Chronic Liver Disease Quality of Life Scale 2.0" were used as data collection tools. This project received ethical approval from the ethics committee of Akdeniz University Clinical Research Ethics Committee and obtained permission from Center for Outcomes Research in Liver Diseases and individuals.
Results: Half of the participants are men, half of the patients diagnosed with cirrhosis. In evaluating the validity analysis; scope validity, validity according to a reference, structure validity methods were used. As a result of the validity analysis, it was determined that the scale consists of six sub-dimensions. There was no substance removed from the original scale. In evaluating the reliability analysis, internal consistency, invariance, assessment of substance analyzes was used. The overall Cronbach alpha coefficient of the scale was 0.95, and the Cronbach alpha values of the subscales ranged from 0.53 to 0.94. In the internal consistency evaluation, the correlation coefficient between the two applications ($r = 0.79$) was found to be high in the test re-test analysis results. When substance analyzes were examined, it was found that the mean of the substances were close to each other, when the average of the upper and lower groups were examined, the discriminatory properties of the substances were high and the behaviors to be measured in the symptoms of chronic liver diseases were found to be reliable.
Conclusion: The Chronic Liver Disease Scale was a valid and reliable tool to measure the quality of life of chronic liver disease patients by determining the frequency of symptoms in chronic liver diseases. It was suggested that the Turkish version of the Chronic Liver Disease Scale should be be used in symptomatic evaluation of chronic liver disease.

FRI-005

Using healthcare professionals' views to update and improve the Royal College of Nursing Caring for people with liver disease: A competence framework to deliver quality person centred care

L. Greenslade[1], M. Clayton[2]. [1]*Royal Free Hospital, Hepatology Department, London, United Kingdom;* [2]*University of Leeds, School of Healthcare, Leeds, United Kingdom*
Email: lynda.greenslade@nhs.net

Background and Aims: Liver disease is the third most common cause of premature mortality in the United Kingdom (UK). Two National Confidential Enquiry into Patient Outcome and Death (NCEPOD) reports on alcohol related liver disease and upper gastrointestinal bleeding raised concerns about suboptimal care of patients with complications of cirrhosis. Reflecting concerns that many healthcare professionals (HCPs) have poor understanding of how to identify and treat those with liver disease leading to poor quality care. Increased HCPs awareness of alcohol, viruses and obesity related liver disease can support the public health agenda in tackling rising rates of liver disease.
In 2013 the Royal College of Nursing (RCN) *Caring for people with liver disease: a competence framework for nursing* was published to help improve HCPs knowledge and skills identifying those at risk of developing liver disease; and care for those with existing liver disease. A recent review of the framework included how HCPs had used the framework and what other factors might improve future use by HCPs.
Method: A detailed survey sent to members of the RCN Gastrointestinal Nursing Forum to capture views of nurses throughout the UK who had experience of using the framework. This feedback was used to inform the revised edition.
Results: There was a range of responses from those surveyed ($n = 93$) with mostly positive feedback including narrative quotes. Identified barriers to implementation included perceived difficulty in fitting the right competence to the right patient; some nurses found the translation of theory into practice a challenge due to external issues such as time and level of seniority. Many wanted help with signposting and further examples of how to use the framework. An unexpected bonus was the use of the framework to develop and support new clinical roles and redefine original job descriptions to be more person centred. Many nurses said they could add existing liver nurse teaching packages into the implementation of the framework. The section on how to implement the framework in practice was strengthened by mirroring the nursing process of assessment, planning, implementing and evaluation to assist nurses to feel more confident in completing the competence framework.
Conclusion: The revised edition should further support all nurses who work with people with or at risk of liver disease to be able to identify and develop person centred liver care throughout the spectrum of care from early identification and prevention to end of

life care ensuring that quality care is embedded into practice for all liver patients.

FRI-006

Hepatitis C treatment in prisons through a nurse-led program with telemedicine

A. Olsson[1], K. Roos[1], S. Larsen[1], K. Lindahl[2], C. Gahrton[2], A. Oksanen[1], F. Öhrn[3], S. Aleman[2], K. Said[1]. *[1]Karolinska University Hospital, Dep. of upper GI diseases, Stockholm, Sweden; [2]Karolinska University Hospital, Dep. of Infectious Diseases, Stockholm, Sweden; [3]Karolinska University Hospital, Center for Innovation, Stockholm, Sweden*
Email: annika.el.olsson@sll.se

Background and Aims: Hepatitis C virus (HCV) infection is highly prevalent in prison population. Until now, several barriers to the HCV treatment for incarcerated as e.g. substantial side effects of previous interferon-based treatment, and the need of prisoner movement for assessing the care have led to treatment of only a small fraction of the incarcerated. With introduction of new direct acting antivirals (DAAs), there is an opportunity to treat HCV infected persons with mild side effects, high cure rate and short treatment time. The barrier with transport of prisoners needs though to be overcome with local delivery of HCV care to prisons.
The main objective of this project is to facilitate the assessment of liver fibrosis and treatment of HCV for prisoners through a nurse-led program.
Method: This is a nurse-led program with implementation of telemedicine in eight prisons of Stockholm County, Sweden. Planning, implementation and administration is handled by a project team consisting of two registered nurses and one part-time administrator, in collaboration with physicians, at Dep. of upper GI diseases/Dep. of Infectious Diseases at Karolinska University Hospital. The program includes: 1. The team has developed educational lectures for health care personal at prisons through video-link. 2. The initial consultation of the HCV infected patient, including liver elasticity measurement with portable FibroScan, is performed by a nurse at the local prison. 3. Consultation by physician via telemedicine. 4. Nurse-supervised HCV treatment for patients who meet the treatment criteria (at present at least F2 fibrosis).
Results: Through a collaboration between Karolinska University Hospital and The Swedish Prison and Probation Service, 42 incarcerated patients (74% men, 26% women) have been included so far in the program. Liver elasticity measurements have showed following distribution of fibrosis: 62% F0-F1, 26% F2, 7% F3 and 4% F4. Start of DAA treatment has been initiated in 13 persons. The final results of the project are planned to be analyzed at the end of 2018.
Conclusion: This is a project designed to enhance the care of HCV patients in prison settings, with new paths of delivering individualized care in a key population for targeting HCV epidemics. Program with delivery of HCV care to local prisons need to be part of HCV elimination plan.

FRI-007

Comparison of different models of nursing care delivery in the management of hepatitis C treatment among people who inject drugs

G. Rudel[1], V. Finessi[1], A. Nottaris[1], M. Borojevic[2], P. Messina[1], A. Moriggia[1,2]. *[1]Epatocentro Ticino, Lugano, Switzerland; [2]Ingrado Addiction Clinic, Viganello, Switzerland*
Email: giovanna.rudel@epatocentro.ch

Background and Aims: Hepatitis C Virus (HCV) treatment can be successfully administered in People Who Inject Drugs (PWID) if delivered in adequate settings with multidisciplinary models of care.
Method: We described the role of nurses in three different settings of HCV treatment for PWID in Southern Switzerland: (1) tertiary center for liver disease with specifically trained nurses; (2) integrated treatment "all under one roof" in addiction center; (3) directly observed therapy. We analyzed and compared HCV therapy results and characteristics of the patients in the three groups.
Results: Hundred and thirty-four PWID started HCV treatment and were included in the analysis. Among 66 treated patients with available results at the moment of the abstract submission, an interim analysis was completed: mean age was 48 years, 24% (16) were women and 27% (18) failed a previous HCV therapy. Most of the patients (41) were treated in a tertiary clinic for liver disease with the support of nurses with expertise in PWID management (Model 1). One patient was lost of follow up, 3 had a virological failure and 37 (93% of those who completed treatment) met a sustained virological response 12 weeks after end of treatment (SVR12). Twenty-one patients were treated in an addiction center through an integrated care model involving HCV specialist doctor, psychiatrist, nurses and psychosocial support "all under one roof" (Model 2). Of those, 2 died during treatment for reasons unrelated to HCV therapy, 1 stopped treatment for nonadherence, 1 had a virological failure and 17 (94% of those who completed treatment) met SVR12. Only 4 patients were treated as a directly observed therapy during their stay in a stationary rehabilitation center (Model 3). All of them completed the treatment successfully and reached the SVR12 (100%).
Conclusion: Our observation suggests a similar efficacy among the three models of treatment of HCV among PWID. It is important to offer different models of management of HCV, to be able to remove the barriers to access to care in this population.

FRI-008

Is the presence of fat and fibrosis a higher mortality risk factor versus cardiovascular disease?

A.M. Hefner, T. Hassanein. *Southern California Liver Centers, Coronado, United States*
Email: ahefner@livercenters.com

Background and Aims: The epidemic of fatty liver around the world is well recognized. The primary cause of death in this population is cardiovascular disease. Recent data clearly identifies advanced liver fibrosis as the main risk factor of death from NASH. These patients are primarily seen by the primary care physician. To help stratify patients with fatty liver who are at risk of dying from liver diseases we used Fibroscan® as a screening tool. We screened patients and classified them into 3 groups; Group 1 = high fat and liver fibrosis; Group 2 = high fat without liver fibrosis; and Group 3 = high fat and cardiovascular disease and no liver fibrosis.
Method: Between March 6, 2017 and May 29, 2017, 1,650 patients attending a primary care clinic, who have no known history of liver disease, were asked to participate in the screening program. 1,026 individuals agreed to be screened and their demographics, past medical history, and current medications were recorded, as well as their laboratory tests.
Results: 1,026 consecutive patients in a primary care office received a Fibroscan®. There were 376 (36.6%) males and 650 (63.4%) females. The mean age was 44.6 ± 16.8 years. The results are presented in Table 1. A breakdown by age of ≥50 showed that the presence of a risk factor for cardiovascular disease increases by 5 times and is a clinical significant, unlike the presence of significant fat and fibrosis.

Table 1

CAP	<250	≥250
n=	433	593
Fibrosis ≥ 7kPa	5%	10.6%
Presence of Diabetes	2.3%	3.7%
Cardiovascular Risk	12.2%	15.7%

Conclusion: The accumulation of fat alone is unlikely to be the sole stimulus to fibrosis and inflammation. We found co -morbidities of hypertension and hyperlipidemia indicating cardiovascular risk as the main risk factors for mortality and not the presence of significant fat and fibrosis.

FRI-009

Nurse-led clinic for liver cirrhotic patients: Effects on health-related quality of life

M. Hjorth[1], D. Sjöberg[2], E. Kaminsky[3,4], A. Svanberg[3,5], S. Langenskiöld[3], F. Rorsman[6]. *[1]Medical science, Department of medical science, Falun, Sweden; [2]Cerntre for Clinical Research, Dalarna, Falun, Sweden; [3]Uppsala universitet, Department of Public Health and Caring Sciences, Uppsala, Sweden; [4]Mälardalens högskola, School of Health, Care and Social Welfare, Västerås, Sweden; [5]Högskolan Dalarna, School of Health, Care and Social Welfare, Falun, Sweden; [6]Uppsala University, of Gastroenterology and hepatology, Uppsala, Sweden*
Email: maria.hjorth@ltdalarna.se

Background and Aims: Liver cirrhosis affects health-related quality of life (HRQoL) even in early stages. Morbidity is especially high when the disease decompensates, when self-care actions become essential. For the patient, nurse-led clinics in secondary prevention in other chronic diseases has contributed to:

(1) better symptom control
(2) decreased need of inpatient care
(3) improved HRQoL

Firm evidence supporting the role of nurse-led clinic in the management of patients with liver cirrhosis is lacking. In order to improve HRQoL in patients with liver cirrhosis, we decided to compare structured nurse-led clinics, founded in Orem self-deficit theory and motivational strategies, with a group of patients receiving standard care according to clinical routine.

Method: A pragmatic, multicentre randomized controlled study comparing two follow-up models:

Intervention group: Scheduled visits to a nurse-led clinic in addition to visits to physician at gastroenterology departments. Intervals of visits to the nurse-led clinic depends on disease severity (Table 1).

Control group: Standard care at gastroenterology departments.

The areas of the nursing intervention is:

I. Monitoring risk factors due to disease deterioration
II. Information and motivation to perform self-care and medical treatment
III. Nutrition assessment and support
IV. Motivation of life-style changes essential for preventing or delaying disease progress
V. Psychosocial care

Eligible patients are adults with diagnose of liver cirrhosis (n = 500) at six Swedish gastroenterology departments. Primary outcomes are the summary component of the physical and mental domain of HRQoL as measured by RAND-36 at enrolment, and after one and two years.

Results: Recruitment is ongoing and scheduled to continue until 2019.

Liver transplantation and hepatobiliary surgery: Clinical aspects

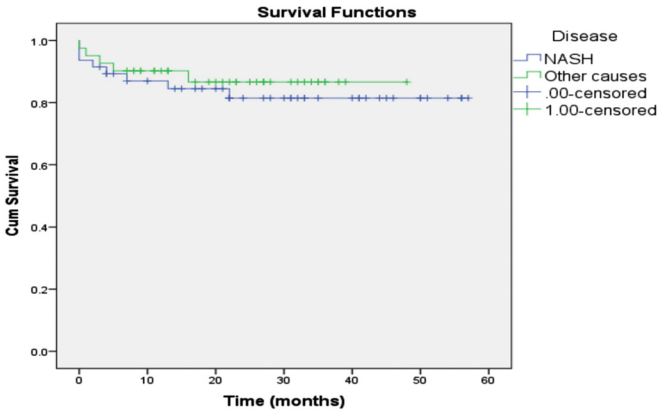
FRI-016

Outcomes of liver transplantation in patients with non-alcoholic steatohepatitis: High recurrence rate in ultrasound and transientelastography

A. Eshraghian[1], M.R. Fattahi[1], S. Nikeghbalian[2], S.A. Malek-Hosseini[2]. *[1]Shiraz University of Medical Science, Gastroenterology and hepatology; [2]Shiraz University of Medical Science, Transplant surgery*
Email: eshraghiana@yahoo.com

Background and Aims: Non-alcoholic steatohepatitis (NASH) is a rapidly increasing indication for liver transplantation surpassing other causes of liver cirrhosis. Recurrence of diseases like auto-immune hepatitis and primary sclerosing cholangitis have been reported after liver transplantation. This study aimed to investigate outcomes including recurrence of disease after liver transplantation in patients with NASH.

Method: In a cross-sectional study, adult (>18 years) patients with liver cirrhosis underwent liver transplantation at Shiraz Transplant Center, Shiraz, Iran between January 2011 and March the 2017 were included. Recurrence of steatosis in patients with NASH was evaluated by ultrasound and transient elastography (TE). Kaplan-Meier curve was used for analysis of post-transplant survival of patients.



Results: Totally 1950 patients were included. 71 patients with NASH underwent liver transplantation during the study period. 14 patients passed away during the study period. Mean post-transplant survival was 42.38 ± 2.35 months in NASH patients and 47.71 ± 2.98 in non-NASH patients (p = 0.558). From 57 patients underwent ultrasound evaluation in a mean follow-up of 15.5 ± 12.6 months after liver transplantation, 33 (57.8%) patients had recurrence of hepatic steatosis. 12 patients had grade II and III and 21 patients had grade I steatosis. In univariate analysis, lower high density lipoprotein (HDL), higher low density lipoprotein (LDL) and warm ischemic time

Table: (abstract: FRI-009)

Study group		Visit intervals: Intervention group		Visit intervals: Control group	
Disease severity		Nurse-led clinic	Physician	Nurse-led clinic	Physician
Compensated disease		1 visit/year	According to clinical routine, minimum 1 visit/year	No visits	According to clinical routine
DeCompensated disease	Within past 12 months	1–2 visit/month			
	Previous decompensation, without symptoms of decompensation	Every 3rd month			

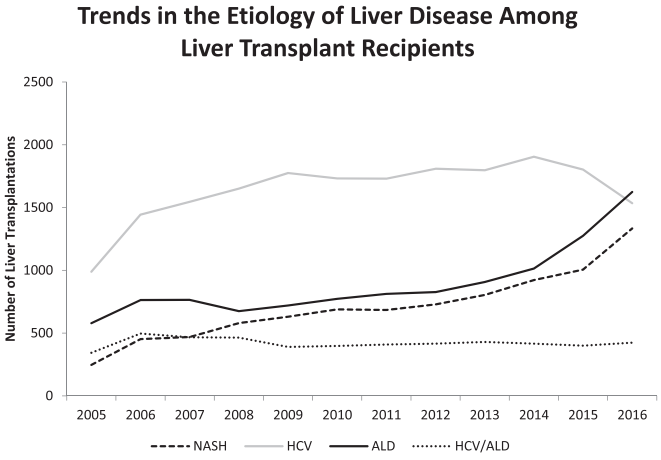
were associated with recurrence of hepatic steatosis ($p < 0.05$). In regression analysis, none of these factors were independent predictor of recurrence in our study population ($p > 0.05$). From 18 patients underwent TE, one patient had no steatosis (S0), 2 patients had S1 steatosis, 3 patients had S2 steatosis and 12 patients had S3 steatosis. 13 patients had different degrees of liver fibrosis. Post-transplant hypertension (OR: 5.3; $p = 0.016$), diabetes mellitus requiring insulin therapy (OR: 4; $p = 0.034$) and higher body mass index (BMI) ($p = 0.015$) were associated with significant fibrosis in TE.
Conclusion: Long-term survival of patients with NASH is comparable with other causes of liver cirrhosis. Recurrence of steatosis both in TE and ultrasound is prevalent and patients with hypertension, DM on insulin therapy and high BMI are susceptible to significant fibrosis.

FRI-017
Can liver transplantation or hepatic resection achieve cure for hepatocellular carcinoma?
A. Cucchetti[1], C. Sposito[2], T. Yang[3], V. Mazzaferro[2], L.D. Carlis[4], J. Zhou[5], S. Roayaie[6], S. Feng[3], M. Cescon[1], S.D. Sandro[4], H. Yifeng[5], P. Johnson[7], A. Pinna[1]. *[1]Alma Mater Studiorum – University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [2]Fondazione IRCCS Istituto Nazionale Tumori di Milano, Gastrointestinal surgery and liver transplantation, Milan, Italy; [3]Second Military Medical University, Eastern Hepatobiliary Surgery Hospital, Shangai, China; [4]University of Milano-Bicocca and Niguarda-Cà Granda Hospital, General Surgery and Abdominal Transplantation Unit, Milan, Italy; [5]Zhongshan Hospital, Fudan University, Liver Surgery Department, Liver Cancer Institute, Shangai, China; [6]White Plains Hospital – Montefiore Health System, Liver cancer program, New York, United States; [7]University of Liverpool, Department of Molecular and Clinical Cancer Medicine, Liverpool, United Kingdom*
Email: aleqko@libero.it

Background and Aims: Hepatic resection (HR) and liver transplantation (LT) are considered potentially curative therapies for hepatocellular carcinoma (HCC). However, their impact on the life-term has never been investigated. *Statistical cure* occurs when the mortality of a specific population returns to values of that of the general population. The present study aims to provide such estimate after HR and LT for HCC in different clinical scenarios.
Method: Data from 3286 HCC patients treated with LT ($n = 1218$) or HR ($n = 2068$) in 7 tertiary referral hospitals were used to estimate statistical cure. Disease-free survival (DFS) was the primary survival measure, defining cure as the chance of being alive without tumor equivalent to that of the general population matched by age, sex, year and race. Overall survival (OS) was a secondary measure, defining the only chance of being alive, regardless of tumor recurrence, equivalent to that of the matched general population. Distinct multivariable non-mixture (DFS) and mixture (OS) cure models were built for LT and for HR and results within different morphologic criteria were compared. Variations of estimated cure fractions after LT were also adjusted for different drop-out risks in waiting-list to provide an intention-to-treat analysis. Differences between cure fractions were measured through effect size.
Results: Five and 10-year DFS rates were 73.3% and 66.0% after LT, and 33.6% and 19.2% after HR. On this ground, the whole cure fraction after LT was 74.1% and after HR was 24.1% (effect size >0.8). Considering DFS, LT outperformed HR in all transplant criteria considered (effect size >0.8), especially for multiple tumors (effect size > 0.9) and even in presence of a drop-out risk up to 20% (effect size >0.5). Considering OS, 5 and 10-year rates were 77.1% and 67.4% after LT, and 57.3% and 33.9% after HR. On this ground, the cure fraction after LT marginally increased to 75.8% and that after HR increased to 40.5%. Using OS, the effect size of LT over HR in terms of cure decreased (effect size ~0.5), became small (effect size <0.2) when the drop-out risk increased toward ~20%, and even negligible for single tumors <5cm.
Conclusion: As other malignancies, statistical cure can occur even for HCC, primarily with LT and secondarily with HR, depending on waiting-list capabilities and efficacy of treatments of tumor recurrence after HR. In presence of high drop-out risks, HR can be considered as the first treatment option for single tumors <5cm

FRI-018
Alcoholic liver disease surpasses hepatitis C virus in 2016 to become the leading indication for liver transplantation among adults without hepatocellular carcinoma in the United States
J. Wang[1], B. Liu[2], T. Bhuket[2], R. Wong[2]. *[1]California Pacific Medical Center, Medicine, United States; [2]Alameda Health System – Highland Hospital, United States*
Email: rowong@alamedahealthsystem.org

Background and Aims: The success of direct acting antivirals for hepatitis C virus (HCV) is expected to decrease the burden of HCV on adults awaiting liver transplantation (LT). To further investigate this, we aim to evaluate recent trends in etiology of liver disease among LT recipients in the U.S.
Method: Using data from the 2005–2016 United Network for Organ Sharing LT registry, overall trends in etiology of liver disease among adult LT recipients were evaluated, with specific focus on HCV, nonalcoholic steatohepatitis (NASH), alcoholic liver disease (ALD), and combined HCV/ALD. Annual liver disease etiology-specific trends in LT recipients were stratified by sex, race/ethnicity, and presence of hepatocellular carcinoma (HCC), and differences in LT trends were evaluated using Student's t-test.
Results: Among 45,966 adult LT recipients (72.6% male, 74.4% non-Hispanic white, 8.6% African American, 14.8% Hispanic, mean age at LT 56.2 ± 7.9, 24.9% with HCC), 45.1% had HCV, 24.2% ALD, 19.0% NASH, and 11.7% HCV/ALD. The number of LT recipients with HCV peaked in 2014 (1905 patients) and has been declining since, and 2016 was the first year in which ALD surpassed HCV to become the leading indication for LT (2016: ALD, 1624; HCV, 1535; NASH, 1334; HCV/ALD, 424). The number of NASH patients receiving LT increased by 440% (from 247 in 2005 to 1334 in 2016). While ALD also became the leading indication for LT in 2016, among females, NASH surpassed HCV to become the leading indication for LT in 2016. ALD also surpassed HCV in 2016 as the leading indication for LT in non-Hispanic whites and Hispanics, whereas HCV remained the leading indication for LT among African Americans, accounting for 63.8% of LT. Among patients without HCC, similar trends were observed and HCV declined to the third leading indication for LT in 2016, accounting for 21.8% of LT, compared to 29.5% for NASH and 40.2% for ALD, $p < 0.01$. However, among patients with HCC, HCV remained the leading indication for LT in 2016, accounting for 58.6% of LT, compared to 20.1% for NASH and 12.2% for ALD, $p < 0.01$.



Conclusion: HCV as an indication for LT in the U.S. peaked in 2014 and has been declining. 2016 was the first year where ALD surpassed

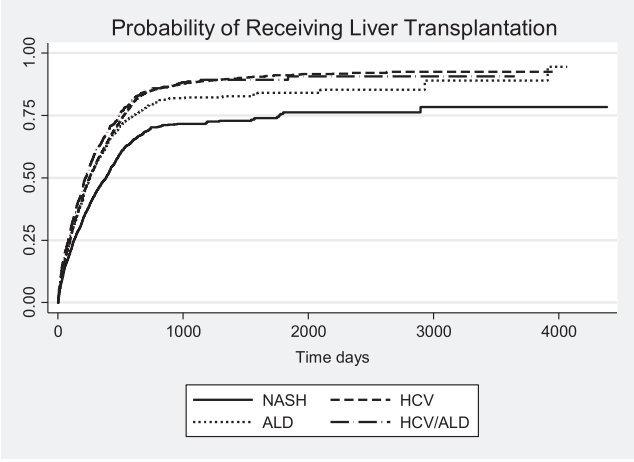
HCV as the leading indication for LT among patients without HCC, with the exception of African Americans where HCV remains the leading indication. NASH became the leading indication for LT among women. HCV remains the leading indication for LT among HCC patients.

FRI-019

Among adults with hepatocellular carcinoma awaiting liver transplantation, Asians, Hispanics, and patients with nonalcoholic steatohepatitis have disproportionately lower likelihood of receiving liver transplantation

J. Wang[1], B. Liu[2], T. Bhuket[2], R. Wong[2]. [1]*California Pacific Medical Center, Medicine, San Francisco, United States;* [2]*Alameda Health System - Highland Hospital, Gastroenterology and Hepatology, Oakland, United States*
Email: rowong@alamedahealthsystem.org

Background and Aims: Liver transplantation (LT) remains one of the primary curative options for patients with unresectable hepatocellular carcinoma (HCC). While HCC is a leading etiology for LT in the U.S., the demand for LT far outweighs the supply of donor organs in many regions, and disparities in receipt of LT persist. We aim to evaluate disparities in receipt of LT among U.S. adults with HCC with a focus on sex-specific, race/ethnicity-specific, and etiology-specific disparities.
Methods: Using data from the 2005–2016 United Network for Organ Sharing LT registry, probability of receiving LT among U.S. adults with HCC on the LT waitlist was stratified by race/ethnicity (non-Hispanic white, African American, Hispanic, Asian), sex, and liver disease etiology (nonalcoholic steatohepatitis (NASH), hepatitis C virus (HCV), alcoholic liver disease (ALD), or HCV/ALD). Comparison of LT rates between groups utilized Kaplan Meier methods and log-rank testing. Multivariate Cox proportional hazards models evaluated for independent predictors of receiving LT.



Results: Among 24,044 HCC patients listed for LT (77.3% male. 63.8% non-Hispanic white, 16.2% Hispanic, 10.3% African American, 9.7% Asian), 59.2% had HCV, 22.1% NASH, 10.4% ALD, and 8.4% HCV/ALD. Compared to females with HCC, males were significantly more likely to receive LT within 1 year (61.9% vs. 59.0%, $p = 0.01$). Compared to non-Hispanic whites (65.0%), significantly lower rates of receiving LT within 1 year were observed in African Americans (60.8%, $p < 0.001$), Hispanics (52.9%, $p < 0.001$) and Asians (51.1%, $p < 0.001$). When evaluating by liver disease etiology, HCC patients with HCV/ALD were most likely to receive LT within 1 year (65.6%) and NASH patients were least likely (48.6%). On multivariate regression, males were significantly more likely to receive LT than females (HR 1.09, 95% CI 1.04–1.14, $p = 0.001$). Compared to non-Hispanic whites, Asians (HR 0.86, 95% CI 0.77–0.95, $p = 0.003$) and Hispanics (HR 0.77, 95% CI 0.73–0.81, $p < 0.001$) were significantly less likely to receive LT. Compared to HCC patients with HCV, NASH-HCC patients (HR 0.65, 95% CI 0.61–0.68, $p < 0.001$) and ALD-HCC patients (HR 0.80, 95% CI 0.75–0.85, $p < 0.001$) were significantly less likely to receive LT.
Conclusion: Among U.S. adults with HCC awaiting LT, significant disparities in receipt of LT were observed, with the lowest rates of receiving LT seen among females, among Asians and Hispanics, and among HCC patients with NASH and ALD.

FRI-020

Risk factors for dropout from the liver transplant waiting list under locoregional treatment

H.A. Lee[1], Y.S. Seo[1], T.H. Kim[1], Y.-S. Lee[1], S.J. Suh[2], Y.K. Jung[1], J.H. Kim[1], H.J. Yim[1], J.E. Yeon[1], K.S. Byun[1], S.H. Um[1]. [1]*Korea University, College of Medicine, Department of Internal Medicine, Korea, Rep. of South;* [2]*Korea University Ansan Hospital, Department of Internal Medicine, Ansan-si, Gyeonggi-do, Korea, Rep. of South*
Email: gandorie@gmail.com

Background and Aims: Liver transplantation (LT) has been recognized as the most effective treatment for hepatocellular carcinoma (HCC) in carefully selected patients. In new liver allocation policy, patients with HCC have 6-month delay in granting Model for End-Stage Liver Disease (MELD) exception points. However, it may not be fair, because of the risk of dropout by progression of HCC within 6 months in some patients.
Method: All patients who were diagnosed as United Network for Organ Sharing (UNOS) stage 1 or 2 of HCC between January 2004 and December 2012 were included. Patients who received surgical resection or LT as a primary treatment and who did not receive any treatment for HCC were excluded. Patients with baseline MELD score ≥22 were also excluded because they have a higher chance of receiving LT with their own MELD score. Patients who developed extrahepatic progression within 1 years were considered as high risk group of early recurrence after LT.
Results: A total of 586 patients with UNOS stage 1 or 2 of HCC were included. Age was 59.9 ± 10.3 years and 409 patients (69.8%) were men. Chronic hepatitis B virus infection was the most common underlying liver disease (380 patients, 64.8%), followed by chronic hepatitis C virus infection (104 patients, 17.7%) and alcoholic liver disease (66 patients, 11.3%). MELD score was 9.9 ± 3.0. Number of tumors was 1.3 ± 0.6 and size of the maximum nodule was 2.0 ± 0.9 cm. Serum alpha-fetoprotein (AFP) level was 1.3 ± 0.8 $\log_{10}$ ng/ml. Cumulative incidence of eDO by downstaging approach was 0.7%, 4.1%, 7.2%, and 12.0% at 3, 6, 9, and 12 months, respectively. Within 6 months, 24 patients reached eDO by downstaging approach. On multivariate logistic regression analysis, size of the maximum nodule (≥4 cm) was the only independent factor for eDO within 6 months. Extrahepatic progression was developed in 16 (2.7%), 45 (7.7%), and 73 (12.5%) patients at 11.3% at 1, 2, and 3 years, respectively. On multivariate analysis, size of the maximum nodule (≥4 cm) and serum AFP level (>100 ng/ml) were independent predictors for extrahpeatic progression within 1 year.
Conclusion: HCC progressed to above the Milan criteria during 6 months in 4.1% of patients with UNOS stage 1 or 2. Granting MELD exception points at the time of enrollment would be needed for patients with high risk of eDO (maximum size ≥4 cm). Nontheless, in patients with maximum size ≥4 cm and high serum AFP level (>100 ng/ml), high caution is needed, because of the risk of early progression after transplantation. Considerations about risk factors of dropout and posttransplant prognosis would reduce disparity between HCC patients and non-HCC patients in LT allocation system.

FRI-021

Outcome of liver grafts procured from hepatitis C-positive donors in the era of direct-acting antiviral drugs: a preliminary single centre experience

S. Martini[1], F. Calvo[1], C. Chialà[1], F. Tandoi[2], S. Mirabella[2], A. Ottobrelli[1], A. Amoroso[3], M. Salizzoni[2], G.M. Saracco[1], R. Romagnoli[2].
[1]Gastrohepatology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [2]Liver Transplant Center and General Surgery 2U, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [3]Regional Transplant Center, Piedmont, AOU Città della Salute e della Scienza di Torino, Turin, Italy
Email: sivima21@hotmail.com

Background and Aims: Organ shortage continues to push the transplant community to expand the donor pool and HCV-positive donors represent a precious resource. We aimed to evaluate clinical and virological outcomes of HCV antibody (Ab)-positive donors compared with negative ones, in the era of direct-acting antivirals (DAA).

Method: Between August 2014 and August 2016, 213 adult cirrhotic patients underwent a first liver transplant (LT) in our Centre, with grafts from brain-dead donors; 83 recipients (39%) were HCV Ab-positive and 11 (13%) received a HCV Ab-positive graft.

At retrieval of HCV Ab-positive donors: 4 tested HCV RNA negative and were allocated to 4 HCV Ab-positive HCV RNA-negative recipients (on DAA until LT); 3 grafts did not show fibrosis; 7 were fibrosis stage 1/6 or 2/6 and 1 was 3/6, according to Ishak score.

Immunosuppression regimen was based on tacrolimus, mycophenolate mofetil and steroids (tapered to suspension in 6 months).

Virological and clinical outcomes were recorded until October 31, 2017.

Results: *Eleven HCV Ab-positive donors vs 72 HCV Ab-negative donors*: median age 52 *vs* 63 years (p = 0.04); BMI 24 *vs* 26 Kg/m^2; HBcAb positive 27% *vs* 13%; moderate macrosteatosis 0% *vs* 10%, donor risk index 1.73 *vs* 1.87, cold ischemia time 432 *vs* 405 minutes (all p: ns).

Eleven HCV Ab-positive recipients of HCV Ab-positive donors (group A) vs 72 HCV Ab-positive recipients of HCV Ab-negative donors (group B): median age 57 *vs* 57 years; median BMI 26 *vs* 26 Kg/m^2; MELD at LT 9 *vs* 12; hepatocellular carcinoma (HCC) rate 91% *vs* 71%; HCV RNA negative 36% *vs* 65% (all p: ns).

All 7 HCV viremic recipients of HCV viremic donors achieved sustained virological response (SVR) at 48 weeks after the end of therapy (6 out of 7 patients underwent preemptive DAA therapy).

One of the 4 HCV non-viremic donor/recipient pairs relapsed the recipient genotype (4d) and achieved SVR48 after re-treatment.

All 66 surviving recipients in group B achieved SVR48 with pre- (79%) or post-LT (21%) DAAs.

Group A vs B post-LT outcome: 1-year and 2-year graft and patient survival: 100% *vs* 92% and 100% *vs* 89%, respectively; median hospitalization time 11 *vs* 13 days; early allograft dysfunction according to Olthoff 9% *vs* 35%; 1-year treated acute rejection: 9% *vs* 4.5%, 1-year biliary complications: 36% *vs* 27%; HCC recurrence 0 *vs* 3% (all p: ns); 1-year and 2-year liver stiffness 7.8 *vs* 6.3 kilopascal (kPa) (p = 0.09); 6.1 *vs* 6.2 kPa, (p = 0.49), respectively.

Conclusions: Preliminary data in our HCV-positive recipients, suggest comparable clinical, virological and 2-year liver stiffness between liver grafts from HCV Ab-positive and Ab-negative donors, even with HCV-viremic bridging fibrosis graft, provided that DAA therapy is started as soon as possible after LT.

FRI-022

Preemptive direct-acting antiviral therapy in naive or NS5A-relapser liver transplant recipients: a single centre experience

S. Martini[1], C. Chialà[1], F. Calvo[1], F. Tandoi[2], D. Patrono[2], D. Cocchis[2], A. Ottobrelli[1], M. Salizzoni[2], G. Maria Saracco[1], R. Romagnoli[2].
[1]Gastrohepatology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy; [2]Liver Transplant Center and General Surgery 2U, AOU Città della Salute e della Scienza di Torino, Turin, Italy
Email: sivima21@hotmail.com

Background and Aims: In HCV-positive patients with active replication at liver transplant (LT), the best timing for direct-acting antiviral (DAA) treatment is still matter of debate. Immediately post-LT, HCV RNA levels fall sharply and this period could represent a unique opportunity to cure HCV infection, before rebound of viremia. We aimed to evaluate efficacy and safety of preemptive DAA therapy in LT recipients (DAA-naïve or relapsers to prior NS5A inhibitor treatment).

Method: Between January 2016 and May 2017, 63 adult HCV-positive cirrhotic patients underwent a first LT in our Centre, with a graft from brain-dead HCV-negative donor.

Immunosuppression regimen was based on tacrolimus, mycophenolate mofetil and steroids (tapered to suspension in 6 months).

Twenty recipients (20/63, 32%) underwent preemptive DAA therapy (15 DAA-naïve patients received sofosbuvir plus ledipasvir or daclatasvir ± ribavirin for 12 weeks; 5 NS5A-inhibitor relapsers received sofosbuvir plus velpatasvir plus ribavirin for 24 weeks), starting from the day of LT, and represent our study population.

Clinical and virological outcomes were recorded until October 31, 2017.

Results: Recipients: median age 56 years, BMI 26 kg/m^2; MELD at LT 12 (interquartile range 9–17), hepatocellular carcinoma (HCC) rate 60%, HCV RNA at LT 5.6 Log IU/ml; HCV genotype (GT) 1a: 5 patients; GT1b: 9 patients (1 NS5A-relapser), GT3: 3 patients (1 NS5A-relapser) and GT4 3 patients (all NS5A-relapsers); *IL28B* C/C: 25%. Median LT waiting-list time: 10 days.

Donors: median age 63 years, BMI 26 Kg/m^2, none with macrovesicular steatosis ≥30%, 15% HBcAb positive, donor risk index 1.48, cold ischemia time 415 minutes.

Post-LT follow-up: median hospitalization time: 13 days, early allograft dysfunction according to Olthoff: 25%, 30-day treated acute cellular rejection: 10%.

All grafts and patients are alive after a median follow-up of 335 days (range 155–643 days), 1 patient with HCC recurrence at 10 months after-LT (exceeding Milan criteria on explant pathology).

Within week 4 post-LT all patients were HCV RNA <15 IU/ml; all 15 DAA-naïve patients achieved a sustained virological response (SVR) at 12 weeks after the end of therapy; the 5 NS5A relapsers are all negative at the end of therapy, with 1 patient reaching SVR4 and 1 SVR12.

No patient had to discontinue DAA therapy post-LT.

Conclusions: In our 20 HCV-positive patients (15 naïve and 5 NS5A inhibitor relapsers) with a median LT waiting time of 10 days, preemptive DAA therapy (since the day of LT) was safe and well tolerated and HCV RNA <15 IU/ml was achieved within week 4 after LT in all of them. All the 16 patients who reached 12 weeks of follow-up after the end of therapy, are SVR12.

Donor-specific anti-HLA antibodies are not associated with non-anastomotic biliary strictures, but both are independent risk factors for graft loss after liver transplantation

A.C. den Dulk[1], X. Shi[2], C. Verhoeven[3], J. Dubbeld[4], F.H.J. Claas[5], R. Wolterbeek[6], S. Brand-Schaaf[5], H.W. Verspaget[1], A.F. Sarasqueta[7], L. van der Laan[3], H. Email: bvhoek@lumc.nl

Background and Aims: Donor-specific alloantibodies (DSA) have been associated with rejection and shorter graft survival after orthotopic liver transplantation (OLT). We examined the role of DSA in non-anastomotic biliary strictures (NAS) after OLT.
Method: Patients receiving first OLT who developed NAS ($n = 68$) and a control group without NAS ($n = 83$), with pre-OLT and 12 months post-OLT serum samples were included. DSA were specified using the Luminex single antigen test. Risk factors for NAS and graft survival were analysed.
Results: The presence of preformed DSA was not significantly different between patients with NAS and controls ($p = 0.89$). After 12 months, 26.5% of NAS patients and 16.9% of controls had generated de novo DSA ($p = 0.15$). Neither de novo class I DSA nor de novo class II DSA were associated with NAS. De novo DSA generally developed after the diagnosis of NAS. Time-dependent regression analysis identified both NAS (aHR 8.05, CI 3.28–19.77, $p < 0.01$) and de novo class II DSA (aHR 2.84, CI 1.38–5.82, $p < 0.01$) as independent risk factors for graft loss.
Conclusion: Preformed or de novo DSA were not associated with the development of NAS. However, NAS as well as de novo class II DSA were independent risk factors for graft loss after OLT.

FRI-024

Short-term suvival after liver transplantation depends on the matching of graft and recipient caracteristics

E. Levesque[1], E. Audureau[2], A. Winter[3], C. Antoine[4], J.P. Daures[5], P. Landais[3], D. Azoulay[6], C. Duvoux[7], C. Feray[7], O. Group[8]. Email: eric.levesque@aphp.fr

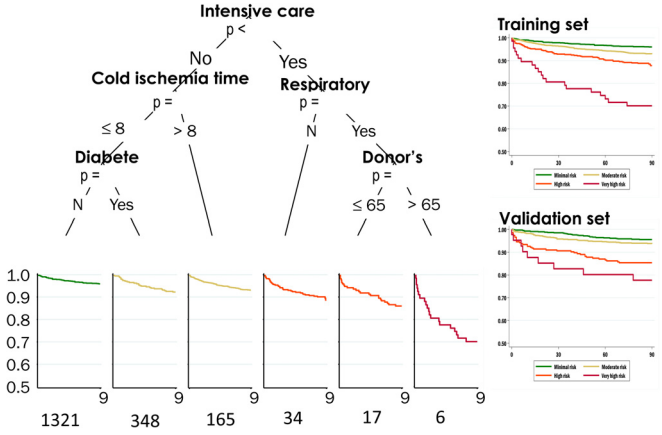
Background and Aims: Liver transplantation offers an immediate benefit for decompensated cirrhosis while it offers a differed advantage for hepatocellular carcinoma. No matching rules other than blood group exists in most allocation systems.
Method: 5509 consecutive cirrhotic adult patients receiving a first liver graft between 2009 and 2015 were analysed through cox model and through unsupervised decision tree analysis. The training and the validation sets comprised 3905 and 2004 patients. Criteria was 90-days mortality post transplant.
Results: Cox analysis showed that presence in ICU, artificial ventilation, kidney failure, cold ischemic time were independent risk factors for short-term mortality. Decision tree analysis confirmed ICU as the main predictor. In patients in ICU, those who were ventilated had 30% of mortality if the donor was older than 65y and of 15% if not. In those not in ICU, the cold ischemic time less that 8 hours gave excellent results. These findings were reproduced in the validation set.



Conclusion: Cox analysis evidenced variables with an average effect in the whole population and point to the importance of organ failures at the time of LT. Decision tree analysis indicated matching between graft and candidate characteristics which may reduce the short-term mortality. Cold ischemic times remains the best predictor for excellent short-term results.

Emil: cyrille.feray@gmail.com

Background and Aims: Liver transplantation is hampered by the shortage of donor leading to the use of graft from donors with extended criteria (ECD) such as age or ischemia times, defining the donor risk index (DRI). In France, each graft is patient-Oriented (PO) according to a national score. In some occasions, a graft may be refused by all transplant teams to which it is offered and then attributed to a transplant team or Center-Oriented (CO), which in turn chooses the most appropriate candidate for this rescue allocation (RA).
Method: Patients receiving PO or CO liver graft were compared for recipient and donor covariates. A propensity score (PS) including covariates explaining the allocation type in order to make comparable groups was determined using logistic regression. Retained recipient's covariates were: age, sex, MELD at transplant and hepatocellular carcinoma (HCC). The PS was validated considering its ability to provide balanced groups. Cases were weighted using the PS, considering the Inverse Probability of Treatment Weighting (IPTW) method in a Cox model and using several covariates for adjustment. Analyses were performed using R statistical software version 3.3.0.
Results: 5516 adults received a liver graft from 2009 to 2014 in France; 5218 recipients were selected and 336 (6.4%) received a graft through a CO offer (G1). These patients received a graft from older donors ($p < 0.01$), had lower MELD ($p < 0.01$), and more frequently with an HCC ($p < 0.01$). The survival were similar between CO and PO patients. Using PS, we showed that the risk of mortality was increased

in CO patients compared to PO patients (HR 1.18 [95% CI: 1.09–1.28]). However, in 25% of centers, for which transplanted patients had a CO offer, in more than 6.5% of cases, this increased risk did not appear (HR: 0.95 [95% CI : 0.84–1.07]). Better result was observed between these centres than in the others (HR: 1.37 [95% CI: 1.21–1.54]) in which DRI of CO donor graft were lower.

Conclusion: Although PO graft came from ECD, survival of PO and CO liver grafts were similar suggesting that centres chose appropriate candidates for PO liver grafts. This confirmed small series published on this issue. However, PS cox model demonstrated that CO graft induces an intrinsic risk of mortality and this was only observed for centres with low usage of such grafts.

FRI-026

Role of interventional radiology in the scenario of liver transplantation

M.B. Pitton[1], T. Zimmermann[2], J. Mittler[3], S. Schotten[1], R. Klöckner[1], P. Galle[2], G. Otto[3], H. Lang[3], C. Düber[1]. [1]*University Medical Centre of Mainz, Diagnostic and Interventional Radiology, Mainz;* [2]*University Medical Centre of Mainz, Internal Medicine, Mainz, Germany;* [3]*University Medical Centre of Mainz, Visceral Surgery, Mainz, Germany*
Email: michael.pitton@unimedizin-mainz.de

Background and Aims: To analyze the role of Interventional Radiology (IR) in the complex scenario of liver transplantation (LTx).

Method: Patients with history of liver transplantation (LTx) were included in our analysis. Patients were analyzed for number and type of interventional procedures in the scope of liver transplantation. The institutional data bases were searched for all interventional procedures during the time on the waiting list, in the immediate perioperative phase as well as during follow-up after LTx. The interventional procedures were categorized in image-guided punctures (e.g. biopsies, drainages), local tumor treatment (eg. tumor ablations, TACE, SIRT), biliary interventions (e.g. percutaneous biliary drainages in ischemic or ischemic-type biliary lesions [IBL / ITBL]), vascular interventions (portal, venous, arterial recanalization or embolization), TIPS, and others. The numbers end time points of interventional procedures during the patient's course were analyzed.

Results: Between 1996 and 2016 a total of 815 patients received liver transplantation in our centre. 24.4% of patients had no interventions at all. 44.7% of patients received interventions during time on the waiting-list (in 20.4% ≤3 procedures per patient, in 24.3% >3 procedures per patient, e.g. TACE etc.). 23 patients (2.8%) received procedures within the immediate perioperative phase (≤3 days after LTx). During 30d-follow-up, a total of 60% of patients received some IR-procedures: in 28.7% only one per patient, however, 3.6% of patients received >3 procedures per patient (range 4–8).

Conclusion: Interventional procedures are an integral part in the scenario of liver transplantation and cover the whole scope of IR, particularly TIPS and local tumor treatment before LTx, peri-/postoperative vascular issues, as well as biliary interventions in IBL/ITBL during follow-up.

FRI-027

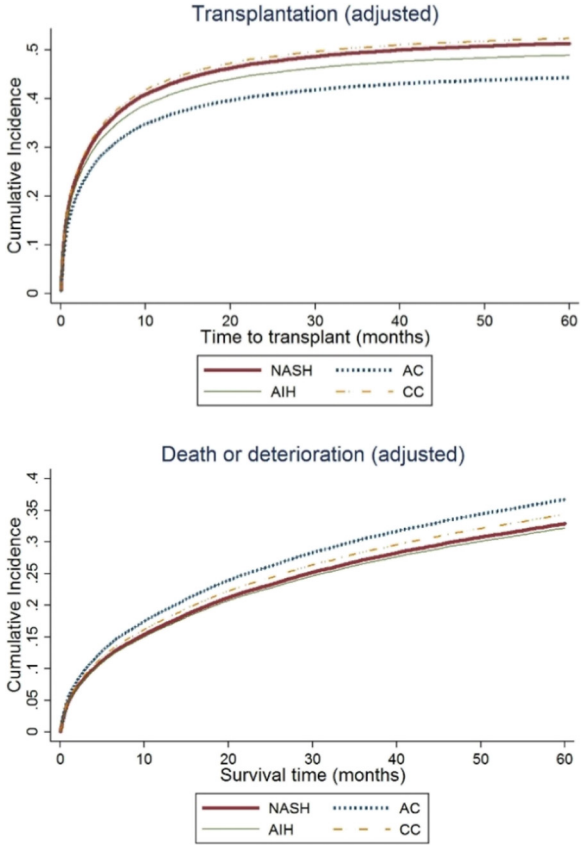
Incidence of waitlist removal and transplantation rates are similar in NASH, cryptogenic and autoimmune hepatitis cirrhosis

P.J. Thuluvath[1], Y. Savva[2]. [1]*Mercy Medical Center & University of Maryland School of Medicine, Medicine, Baltimore, United States;* [2]*Mercy Medical Center, Medicine, Baltimore, United States*
Email: thuluvath@gmail.com

Background and Aims: Cirrhosis secondary to nonalcoholic steatohepatitis (NASH) has become the 3rd most indication for liver transplantation (LT) in the USA. Patients with NASH cirrhosis are relatively older and have multiple comorbidities. Although post-LT survival of patients with NASH is acceptable, we hypothesized that they are more likely to be removed from the waitlist because of clinical deterioration or death, and therefore less likely to be transplanted when compared to those with cryptogenic (CC), alcoholic (AC) or autoimmune hepatitis (AIH) cirrhosis.

Method: To test the above hypothesis, we analysed the United Network for Organ Sharing (UNOS) data from 2002 to 2016. After excluding those with liver cancer (HCC) and multiple-organ transplants, the study included 8,656 NASH, 6,550 CC, 17,857 AC and 2,839 AIH. The absolute risk (unadjusted cumulative incidence) for removal from list due to death/deterioration or transplantation was analysed using a cumulative incidence competing risk method.

Results: In the first three years on the waiting list, the risk for death/deterioration was 32% (CI 31–33) for NASH, 30% (CI 29–31) for AC or CC, and 25% (CI 23–26) for AIH. The factors increasing the risk of waiting list death/deterioration were poor performance status (HR = 1.73), encephalopathy (HR = 1.20), diabetes (HR = 1.12), dialysis (HR = 1.11), high MELD score (HR = 1.11), being Hispanic (HR = 1.10), older age (HR = 1.03) and a low serum albumin (HR = 0.98). After controlling for known demographic and disease confounders, the relative risk of death/deterioration was 13% higher for AC (SHR = 1.13) when compared to NASH, but the other two groups had the same risk as NASH. During the first three years on the waiting list, the incidence of receiving a transplant was 49% (CI 48–50) for NASH, 48% (CI 47–49) for CC, 45% (CI 44–45) for AC, and 47% (45–49) for AIH. The factors associated with a lower incidence of LT were dialysis (HR = 0.48), being a female (HR = 0.82), not White (HR = 0.92 for Blacks, HR = 0.73 for Hispanics, and HR = 0.77 for Asians), having a higher albumin (HR = 0.98) and higher serum creatinine (HR = 0.98). The factors that increased the incidence of LT were a poor performance status (HR = 1.32), encephalopathy (HR = 1.18) and a high MELD score (HR = 1.14). The adjusted cumulative incidence of transplantation was 19% lower for AC (sub-distribution HR [SHR] = 0.81) and similar for CC and AIH when compared to NASH.



Conclusion: In this study, we found that NASH, CC and AIH had similar risk of removal from waitlist and similar incidence of transplantation and but those with AC had a higher risk of wait list death/removal and lower incidence of transplantation.

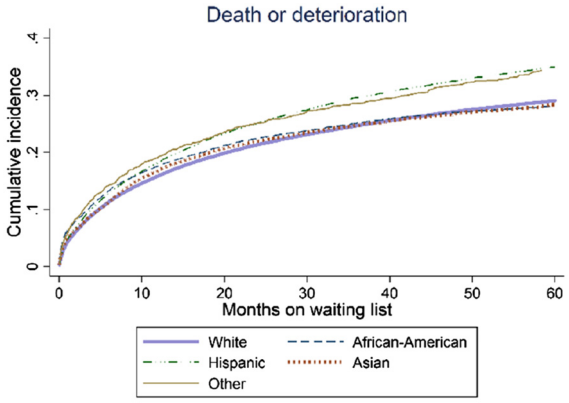
FRI-028

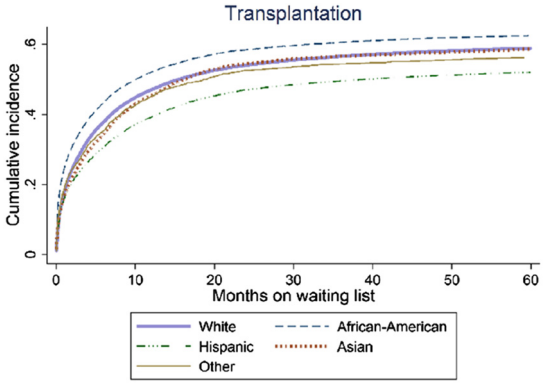
Liver transplant waitlist mortality, transplantation rates and post-liver transplant outcomes in Hispanics

P.J. Thuluvath[1], Y. Savva[2]. [1]*Mercy Medical Center & University of Maryland School of Medicine, Medicine, Baltimore, United States;* [2]*Mercy Medical Center, Medicine, Baltimore, United States*
Email: thuluvath@gmail.com

Background and Aims: It has been previously reported that African American (AA) have a lower post-liver transplant (LT) survival compared to Whites (Lancet 2002; 359; 287–93). In the USA, Hispanics are the fasting growing population, and yet there is a paucity of data on waitlist mortality, transplantation rates and post-LT outcomes of this population.

Method: In this study, we examined UNOS data between 2002 and 2016 to determine the relative outcomes of Hispanics compared to Whites. Kaplan-Meier estimator was used to construct removal due to death/deterioration, transplantation and post-transplant survival curves. Multivariate Cox proportional hazard regressions were used to study the association between the risk factors.





Results: During this period, 19,217 Hispanics, 92,892 Whites, 11,534 AA, 5,914 Asians and 1,638 "Others" were listed for LT. Cumulative incidence of removal from the waitlist either due to death or deterioration was highest for Hispanics, and similar for Whites, AA and Asians (Figure 1). Transplantation rates were lowest for Hispanics, and highest for AA followed by Whites and Asians (Figure 2). After adjusting for clinical characteristics and other confounders, adjusted waitlist removal was 26% higher for Hispanics, and transplantation rates were 22% lower for Hispanics compared to Whites. Donor quality based on Donor Risk Index (DRI) was similar for all groups. 1-year and 5-year post-LT graft and patient survival was similar for Hispanics (90% and 75% respectively) and Whites (89% and 75% respectively). As in previous reports, survival was lowest for African Americans.

	Patient survival (%)					Graft survival (%)				
	White	AA	Hispanic	Asian	Other	White	AA	Hispanic	Asian	Other
30 days	0.97	0.96	0.97	0.97	0.97	0.96	0.94	0.95	0.95	0.96
1 year	0.89	0.87	0.90	0.92	0.90	0.87	0.84	0.88	0.89	0.89
2 years	0.85	0.79	0.85	0.88	0.86	0.82	0.76	0.83	0.85	0.85
3 years	0.81	0.75	0.82	0.84	0.83	0.79	0.72	0.79	0.82	0.81
5 years	0.75	0.67	0.75	0.80	0.77	0.72	0.64	0.73	0.77	0.75
10 years	0.58	0.52	0.62	0.69	0.59	0.56	0.49	0.59	0.67	0.59

Conclusion: This study based on a large dataset shows that Hispanics are more likely to be removed from the waitlist, less likely to be transplanted, and yet have similar post-LT outcomes when compared to Whites.

FRI-029

Pretransplant Karnofsky Performance Status is an independent predictor of post-liver transplant survival

P.J. Thuluvath[1], A. Cherry[2], A. Thuluvath[3], Y. Savva[2]. [1]*Mercy Medical Center & University of Maryland School of Medicine, Medicine & Surgery, Baltimore, United States;* [2]*Mercy Medical Center, Medicine, Baltimore, United States;* [3]*Johns Hopkins University, Medicine, Baltimore, United States*
Email: thuluvath@gmail.com

Background and Aims: Karnofsky Performance Status (KPS) has been used for almost 70 years in clinical practice as a subjective "eyeball" assessment of overall performance status of patients. KPS score, administered by the provider, assign scores to patients on a scale of 0–100%, in increments of 10, where 100% is normal activity and 0% is dead. In this study, our objective was to determine whether KPS score is an independent predictor of post-LT survival after adjusting for other known confounders.

Method: We included all adult patients listed with UNOS from 2006 to 2016 (UNOS started collecting KPS scores in a consistent manner since 2006). We grouped patients into 3 groups based on KPS score: 10–40% severe disability, 50–70% mild to moderate disability and 80–100% minimal or no disability. Kaplan-Meier survival analysis was done to examine graft and patient survival. Multivariate Cox regression was used to analyze the independent effect of KPS on survival after adjusting for other variables including age, sex, race, disease etiology, BMI, organ failures, stage 3–4 hepatic encephalopathy, MELD scores and donor risk index (DRI). We adjusted for stage 3–4 hepatic encephalopathy (HE) as it may influence assessment of KPS.

Results: During the study period, 18,673 patients with severe disability, 22,293 with moderate disability and 13,159 with minimal or no disability were transplanted. The graft and patient survival of these patients are shown in the figures 1 & 2. The graft and patient survival differences were significantly lower (log-rank $p < 0.0001$) in in those with poor KPS scores. This patient survival was lowest for those with KPS score <40 and highest for those with scores 80–100% [1-yr (86, 91, 93%), 2-yr (81, 86, 89%) for the 3 groups]. Cox regression analysis showed that KPS is an independent predictor of graft and patient (see table) survival. Other independent predictors of graft and patient survival were age, race, presence of stage 3 or 4 HE, disease etiology and DRI,

	Level	HR (unadjusted)	p-value	HR (adjusted)	p-value
Age		1.02 (1.017–1.021)	<0.01	1.02 (1.016–1.021)	<0.01
MELD score		1.01 (1.004–1.007)	<0.01	1.01 (1.005–1.009)	<0.01
Encephalopathy (3–4)		1.10 (1.063–1.144)	<0.01	1.05 (1.002–1.091)	0.04
KPS score	80–100	1.00		1.00	
	50–70	1.18 (1.130–1.238)	<0.01	1.17 (1.116–1.232)	<0.01
	≤40	1.44 (1.371–1.505)	<0.01	1.48 (1.395–1.566)	<0.01
Donor Risk Index		1.29 (1.242–1.338)	<0.01	1.34 (1.286–1.389)	<0.01

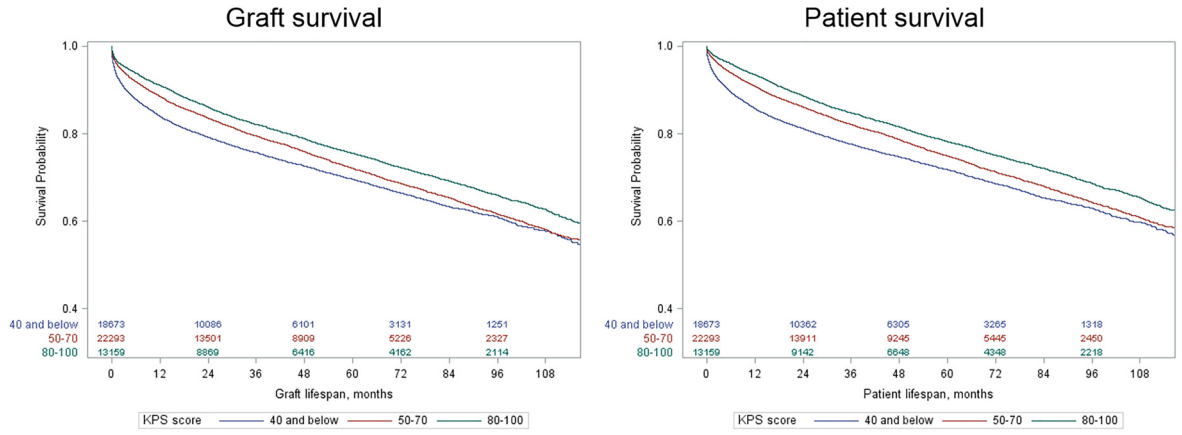


Figure 1 & 2: (abstract: FRI-029)

Race and aetiology of liver disease were also independent predictors of survival (not shown).

Conclusion: Karnofsky Performance Status (KPS) is an independent predictor of graft and patient survival after adjusting for other important predictors of survival including age, race, HE, disease etiology and DRI.

FRI-030

Survival benefit of liver transplantation in Catalonia: A 2007–13 analysis

J. Colmenero[1], J. Lombardo[1], N. Trota[2], G. Crespo[1], I. Bilbao[3], A. Rafecas[4], X. Xiol[5], L. Castells[6], C. Baliellas[5], P. Ruiz[1], S. Biggins[7], C. Fondevila[8], J. Tort[2], M. Navasa[1]. *[1]Hospital Clínic, Barcelona, Liver Transplant Unit, Barcelona, Spain; [2]OCATT, Generalitat de Catalunya; [3]Hospital Vall d'Hebron, Barcelona, Transplant Surgery; [4]Hospital de Bellvitge, Barcelona, Transplant Surgery; [5]Hospital de Bellvitge, Barcelona, Hepatology, Barcelona; [6]Hospital Vall d'Hebron, Barcelona, Hepatology; [7]University of Washington Medical Center, Seattle; [8]Hospital Clínic, Barcelona, Liver Transplant Surgery, Spain*
Email: jcolme@clinic.ub.es

Background and Aims: The survival benefit (SB) of liver transplantation (LT) is the comparative risk of death after LT compared to remaining on the waiting list (WL). Observational studies suggest that the mortality risk after LT is greater for LT candidates with MELD < 14 and lower for those with MELD > 17. We aimed to investigate the SB of LT in Catalonia (7.5M people).

Method: Data was extracted from the Catalan Organization of Transplantation. WL and post-LT mortality at 1-year was studied among 990 adult patients with ESLD listed for LT (07/2007–12/2013). Liver allocation was based on the last MELD score and 3996 MELD score updates were analyzed. Candidates with hepatocellular carcinoma (single ≥ 3cm, 2–3 nodules or treatment failure) received 19 MELD points (+1point/3m). Refractory ascites and hepatic encephalopathy were *not* granted with exception points. Candidates with acute liver failure or MELD exceptions at listing were excluded while those with exception points after listing, or removed from the WL due to improvement or living donor LT were censored. Time-dependent Cox regression models were fitted to compare mortality for LT candidates and recipients at equal duration since listing adjusted for age, sex, race, diagnosis, and MELD.

Results: Overall, covariate-adjusted mortality risk of LT recipients was 79% lower than candidates (HR = 0.25; 95%CI= 0.18–0.34; p < 0.001), supporting a significant SB of LT. Forty percent of candidates had hepatitis C virus infection. The WL drop-out rate (death/*too-sick*) was 8.9% and the probability of survival at 1-year after LT was 90.2%. The SB after LT varied across the range of MELD score: post-LT mortality risk was markedly higher than WL mortality for MELD 6–11 (HR = 6.72; 95%CI= 1.29–35.0; p = 0.024). Conversely, a significant SB of LT was observed at a MELD ≥ 19 (Figure) and the magnitude of SB increased markedly at a MELD ≥ 23 [MELD 19–23: HR = 0.426, p = 0.0076; MELD 24–26: HR = 0.047, p < 0.001; MELD 27–29: HR = 0.074, p < 0.001; MELD ≥ 30: HR = 0.078, p < 0.001]. LT candidates with MELD 12–14 and MELD 15–18 showed a reduction on the mortality risk after LT, but it was not statistically significant (HR = 0.792 (0.15–3.31) and HR = 0.556 (0.23–1.32), p = 0.662 and p = 0.179 respectively). Only 5% of LT candidates with MELD scores <12 at listing progressed to a MELD ≥ 19.

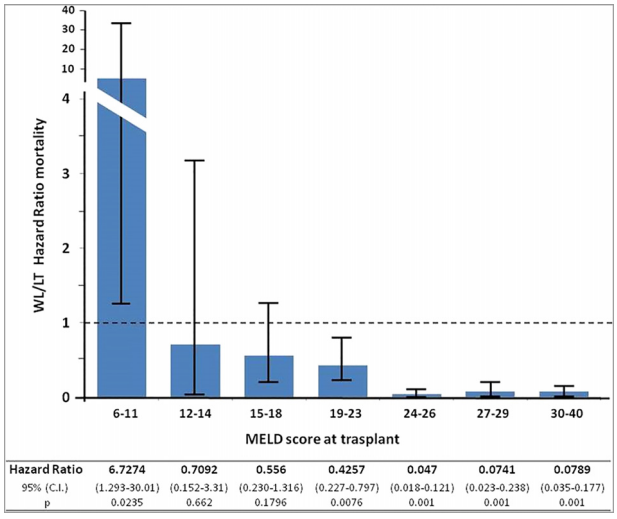

Figure 1: Comparison of mortality risk expressed as hazard ratio by MELD for recipients of liver transplantation (LT) compared to candidates on the waiting list (WL). A hazard ratio of less than 1 favors LT.

Conclusion: LT carried a significant SB for ESLD recipients. Candidates with low MELD scores (<12) did not have SB after LT while those at a MELD score ≥19 had significant SB after LT. In our cohort, the SB of LT for candidates with MELD 12–18 did not reach statistical significance. These results support our MELD-based current criteria for listing (MELD ≥ 12) and our current organ allocation policy.

FRI-031

The survival benefit of hepatic resection in advanced cases for intrahepatic cholangiocarcinoma: a surveillance, epidemiology and end results (SEER) analysis

M. Moustafa, U. Cillo, E. Fasolo. *Padua University Hospital, Liver Transplant and HBP Surgery Unit, Padua, Italy*

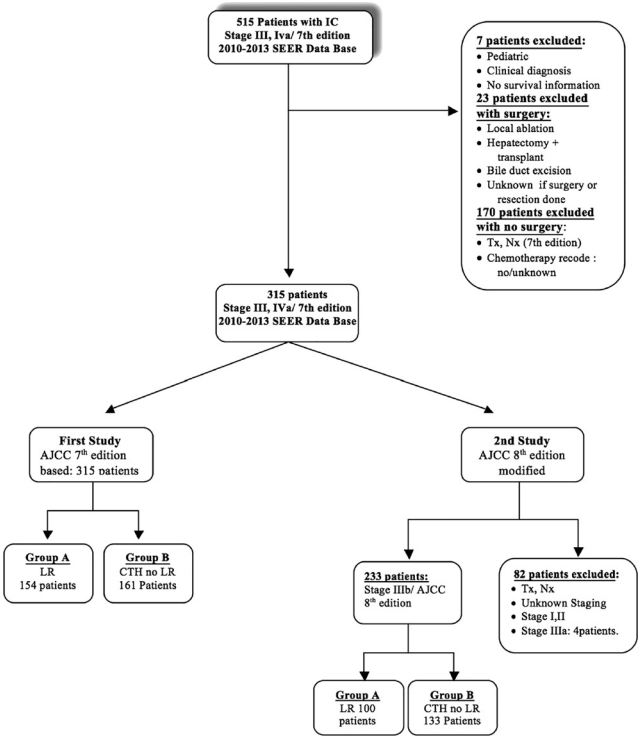
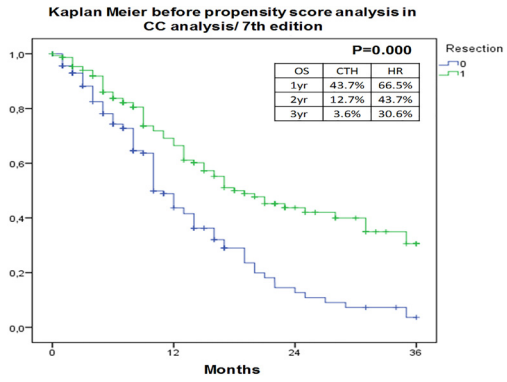
Background and Aims: Liver resection (LR) is the cornerstone in the treatment of Intrahepatic Cholangiocarcinoma (IC). However, it is a

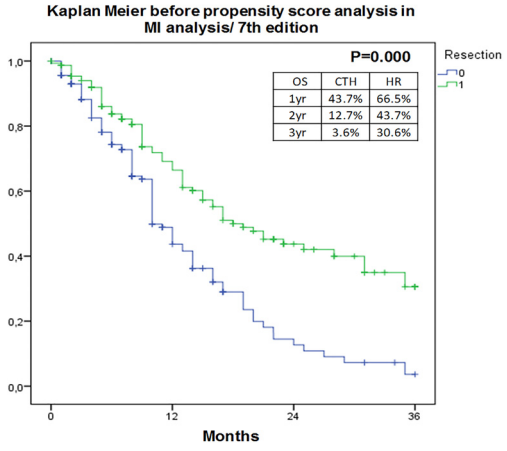
controversial solution for advanced lesions not only due to surgical technical aspects but also its survival benefit remains questionable. The aim of this study is to verify the survival benefits of LR in advanced stages of IC based on the 7th and 8th editions of American Joint Committee on Cancer (AJCC) Staging System, and to identify prognostic factors that directly influence patients' survival after LR.

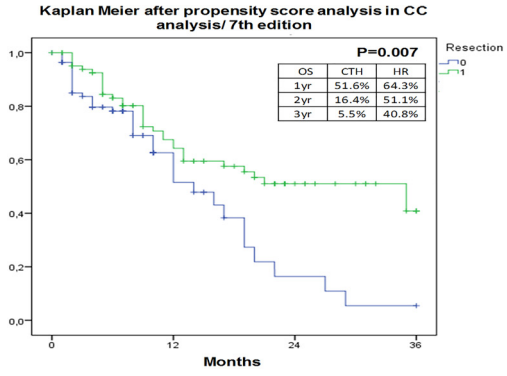
Method: A retrospective cohort study was performed using the Surveillance, Epidemiology, and End Results (SEER) database to identify stage III and IVa of IC patients based on the 7th edition of AJCC staging system. 315 patients were enrolled in this study, during the period 2010–2013 and classified into 2 groups; group A includes 154 patients who underwent LR and group B includes 161 patients who received only chemotherapy. The selected population has been classified according to the AJCC 8th edition. 233 patients out of 315 were enrolled and classified into group A with LR and Group B with CTH. To account for missing data, two sets of analyses were performed; complete cases (CC) data set and multiple imputation (MI). The survival was estimated and compared in the two groups using the Kaplan-Meier method with log-rank test. The patients in group A and B were matched and propensity score (PS) analysis performed for both 7th and 8th edition modules in both CC and MI data set. A Cox proportional hazards model were developed using relevant clinic-pathologic variables to determine the prognostic factors.

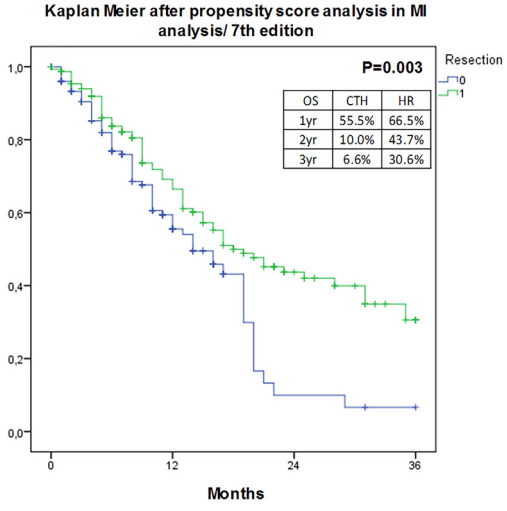
Results: In CC/ AJCC 7th edition data set with PS analysis the median survival was 35 months (12.5–57.4) 95% CI, and 1, 2, and 3years survival rates were 64.3%, 51.1%, and 40.8%. In matched group B, the median survival was 14 months, (9.1–18.8) 95% CI and the 1, 2, and 3years survival rates were 51.6%, 16.4%, and 5.5% for matched group B patients (p = 0.007). In CC/AJCC 8th edition with PS analysis the median survival for group A was 17 months (8.1–25.8) 95% CI and 1, 2, and 3years survival rates were 57.8%, 43.4% and 32.6%. In group B, the median survival was 12 months (8.7–15.2) 95% CI and the 1, 2, and 3years survival rates were 46.6%, 7.4%, and 3.7% for matched group B patients (p = 0.013). In CC/AJCC 7th edition data set; poor prognosis has been shown in patients above 65 years old (HR 1.804, 95% CI 1.139–2.858, P.012), Multi focal lesion (HR 1.588, 95% CI 0.950–2.654, P 0.077) and positive lymph node (HR 1.885, 95% CI 1.012–3.513, P 0.046).

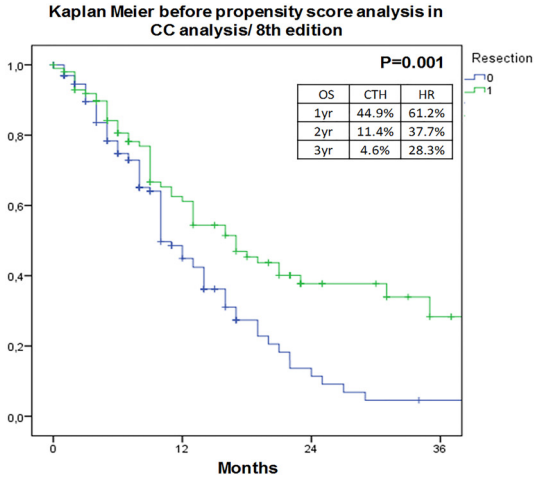


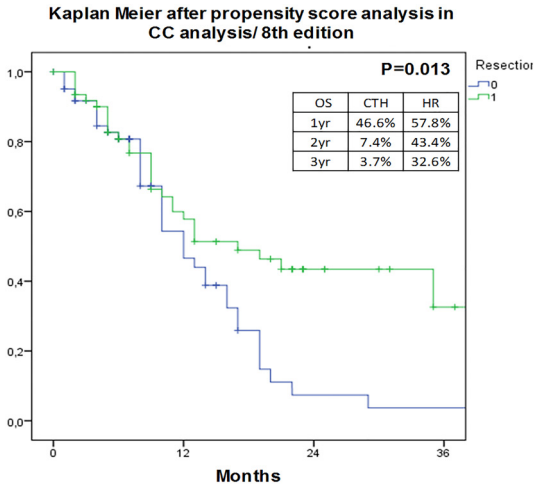












Conclusion: LR has showed a significant survival benefit over chemotherapy for IC stage III and IVa of the 7th edition and some survival benefit in stage IIIb of 8th edition of AJCC staging system. Poor outcome has been observed in patients >65 years and with multifocal lesions and lymph node metastasis.

FRI-032

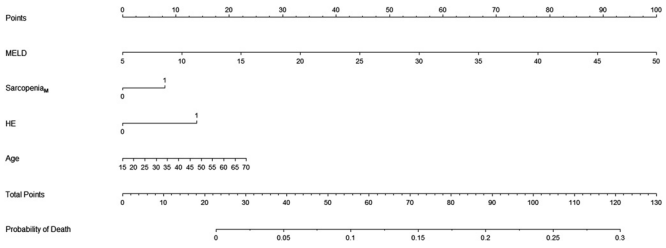
A nomogram with sarcopenia surpasses the MELD score in predicting waiting list mortality in cirrhotic liver transplant patients: a competing risk analysis in a national cohort

J. van Vugt[1], L. Alferink[2], S. Buettner[1], M. Gaspersz[1], D. Bot[3], S.D. Murad[4], S. Feshtali[5], P. van Ooijen[6], W. Polak[7], R. Porte[8], B.V. Hoek[9], A. van den Berg[10], H. Metselaar[11], J. Ijzermans[12]. *[1]Erasmus MC, Surgery, Rotterdam, Netherlands; [2]Erasmus Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands; [3]LUMC, Dietics, Netherlands; [4]Erasmus MC, Hepatology, Rotterdam, Netherlands; [5]LUMC, Radiology, Netherlands; [6]UMCG, Radiology, Netherlands; [7]Erasmus MC, University Medical Center Rotterdam, Department of Surgery, Division of HPB and Transplant Surgery, Rotterdam, Netherlands; [8]UMCG, Surgery, Netherlands; [9]LUMC, Hepatology, Leiden, Netherlands; [10]UMCG, Hepatology, Groningen, Netherlands; [11]Erasmus Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands; [12]Erasmus MC, Department of Surgery, Rotterdam, Netherlands*
Email: j.l.a.vanvugt@erasmusmc.nl

Background and Aims: Frail patients with low MELD scores may be underprioritised. Low skeletal muscle mass (i.e. sarcopenia) has been identified as risk factor for waiting list mortality and a recent study proposed to incorporate sarcopenia in the MELD score (i.e. MELD-Sarcopenia score). We aimed to investigate the association between sarcopenia and waiting list mortality, and to validate the MELD-Sarcopenia score (i.e. MELD + 10.35*Sarcopenia).

Method: We identified consecutive patients with cirrhosis listed for liver transplantation in the Eurotransplant registry between 2007–2014 and measured skeletal muscle mass on computed tomography (CT). A competing risk analysis was used to compare survival of patients with and without sarcopenia, and concordance (c) indices were calculated to assess performance of the MELD and MELD-Sarcopenia score. We created a nomogram of the best predictive model.

Results: We included 585 patients with a median MELD score of 14 (IQR 9–19), of which 254 (43.4%) were identified as having sarcopenia. Median waiting list survival was shorter in patients with sarcopenia than those without ($p < 0.001$). This effect was even more pronounced in patients with MELD ≤15. The discriminative performance of the MELD-Sarcopenia score (c-index 0.820) for 3-month mortality was lower than MELD score alone (c-index 0.839). Apart from sarcopenia and MELD score, other predictive variables were occurrence of hepatic encephalopathy before listing and recipient age. A model including all these variables yielded a c-index of 0.851 (figure).



Conclusion: Sarcopenia was associated with waiting list mortality in liver transplant candidates with cirrhosis, particularly in patients with lower MELD scores. The MELD-Sarcopenia score was successfully validated in this cohort. However, incorporating sarcopenia in the MELD score had limited added value in predicting waiting list mortality.

FRI-033

Tacrolimus cumulative exposure after liver transplantation is associated with a progressive derangement of renal function despite routine dose adjustments

M. Rodríguez-Perálvarez[1], M. Guerrero[1], L.D. Luca[2], B. Gros[1], D. Thorburn[2], D. Patch[2], R. Westbrook[3], R. Fernández[1], P. Aguilar[1], J.L. Montero[1], J. O'beirne[4], J. Briceño[1], M.D.L.M. Garcia[1], E. Tsochatzis[4]. *[1]Reina Sofía University Hospital, IMIBIC, CIBERehd, Hepatology and Liver Transplantation, Spain; [2]Royal Free Hospital and UCL, UCL institute for liver and digestive health and Sheila Sherlock liver unit, London, United Kingdom; [3]Royal Free Hospital, London, United Kingdom; [4]Royal Free Hospital and UCL, UCL institute for liver and digestive health and Sheila Sherlock liver unit, United Kingdom*
Email: ropeml@hotmail.com

Background and Aims: Liver transplant (LT) patients who develop renal impairment receive tacrolimus minimization. We aimed to evaluate cumulative tacrolimus exposure as a determinant of progressive derangement in kidney function.

Method: A consecutive cohort of patients who underwent LT in two European institutions (2008–2013) and received tacrolimus-based immunosuppression were included. Death within the first 90 days post-LT was the main exclusion criterion. All measurements of tacrolimus trough concentrations within the first 6 months after LT were recorded in each patient. Cumulative tacrolimus exposure was expressed as the area under curve of trough concentrations (AUCtc), which was calculated by the Wagner-Nelson equation. Patients were stratified in low AUCtc (<25 percentile), intermediate AUCtc (25–75 percentile) and high AUCtc (>75 percentile). The AUCtc at 3 and 6

months after LT was correlated with the delta creatinine (Cr) within the same intervals.
Results: 456 patients were included (mean age 52.1 ± 10, 28.3% women). Major etiologies of liver disease were hepatitis C (n = 164; 36%) and alcoholic cirrhosis (n = 151; 31.1%). Pre-LT MELD was 17.9 ± 7.2. Prevalence of renal impairment (Cr > 1.5 mg/dl at least twice with at least one month interval) was 24.8% at 3 months and 27.6% at 6 months after LT. Artificial renal support was required in 8.8% of patients. As part of routine dose adjustments, patients with renal impairment received low AUCtc more frequently, both at 3 months (46.9% vs 22.1%; p < 0.001) and at 6 months (41.3% vs 20.2%; p < 0.001). However, the AUCtc was associated with a progressive increase of serum Cr. At 3 months, delta Cr was 0.25 mg/dl in patients with high AUCtc, 0.17 mg/dl in patients with intermediate AUCtc and 0.10 mg/dL in patients with low AUCtc (p < 0.001). At 6 months, delta Cr was 0.29mg/dl in patients with high AUCtc, 0.18 mg/dl in patients with intermediate AUCtc and 0.17 mg/dL in patients with low AUCtc (p = 0.002). A high AUCtc predicted a progressive increase of serum Cr even in the subgroup of patients without renal impairment: Delta Cr 0.21 mg/dl vs 0.15mg/dl at 3 months, and Delta Cr 0.24 mg/dl vs 0.14 mg/dl at 6 months (p = 0.002 and p = 0.006 respectively).
Conclusion: AUCtc estimates cumulative exposure to tacrolimus and is associated with a progressive increase of serum Cr in spite of routine dose adjustments. Tacrolimus minimization should be universally applied, even for patients with an initially preserved renal function.

FRI-034
Evolution and impact of obesity in patients on the liver transplant waiting list
G. Lassailly[1], M. Favre[2], F. Artru[2], O. Goria[3], E. Nguyen-Khac[4], A. Louvet[2], Stéphanie Truant[2], E. Boleslawski[2], G. Lebuffe[2], F.-R. Pruvot[2], P. Mathurin[2], S. Dharancy[1]. *[1]Liver unit, CHRU Lille, Lille, France; [2]CHRU Lille, 59000, Lille; [3]CHU Rouen, 76000, Rouen, France; [4]CHU Amiens, 80000, Amiens, France*
Email: mathilde.favre@chru-lille.fr

Background and Aims: Obesity increases worldwide and impacts global morbi-mortality. As an example, NASH is now the second cause of liver transplantation (LT) in the US and the third cause of HCC. We aimed at deciphering the evolution and the impact of obesity in patients on the waiting list for LT.
Method: Data between 1990 and 2017 were extracted from the prospective CRISTAL database of the Agence de biomedicine (French Transplant Agency). All patients were registered and followed in our transplant center. Three periods of time were analyzed: 90–97; 97–2007 and 2007–2017. To study the impact of obesity on the access to LT, only the MELD era was studied to avoid allocation bias.
Results: 1393 registrations occurred between 97–17. Characteristics of patients were: age 54 [45–61], BMI 25.3 kg/m² ± 4.8, gender (F:33%), MELD 15.7[9.6–24.7], CPT score 9[7–11]. BMI and the prevalence of obesity significantly increased during the 3 period of time: 22 ± 4.3 vs 24.3 ± 3.9 vs 26.5 ± 4.9 kg/m² and 3.7% vs 7% vs 22.9% (p < 0.0001) respectively. Access to transplant was lower for obese patients 72.9% vs 81% (p < 0.03) than lean patients (BMI < 30 kg/m²). Death and drop out from the waiting list increased with obesity grade (G1 = 23.8%; G2 = 37.1%; G3 = 40%, p = 0.04). Obese patients were older (57 vs.53y) more diabetic (38 vs 26%) and frequently registered for HCC (51.5 vs 39%) [p < 0.01 for all]. MELD (20 vs 20) and CPT (9 vs 9.3) did not differ between the 2 groups. Using univariate analysis, age, gender, BMI, bilirubin, CTP score, alcoholic cirrhosis and hepatic encephalopathy were associated with increased death and drop out. Using multivariate analysis, BMI (CR −0.059 ± 0.02, p = 0.007), HCC (−0.74 ± 0.26 p = 0.005) and CPT score (−0.13 ± 0.06; p = 0.047) and trend for age (CR −0.02 ± 0.01; p = 0.05) were associated with increased death and drop out from the list. Surprisingly, in sensitivity analysis, obese patients registered for HCC had same access to transplant than non-obese (72 vs 77%, p = 0.4). Conversely, obese patients without HCC dropped out more frequently than non-obese (26.5% vs 17.1%, p = 0.04) and trended to disclose more severe liver disease MELD (median 24 vs 20.8, p = 0.08).
Conclusion: The worldwide increase of obesity during the past 3 decades has impacted our waiting list. Obesity was associated with a lower access to liver transplantation.

FRI-035
A beneficial weekend effect? Weekend liver transplantation isassociated with reduced graft and transplant failure
N. Halliday[1,2], K. Martin[3], D. Collett[3], E. Allen[3], D. Thorburn[4]. *[1]University College London, Institute of Immunity and Transplantation, London; [2]Royal Free Hospital, Sheila Sherlock Liver Centre, London, United Arab Emirates; [3]NHS Blood and Transplant, Statistics and Clinical Studies, Bristol, United Kingdom; [4]Royal Free Hospital, Sheila Sherlock Liver Centre, London, United Kingdom*
Email: neilhalliday@doctors.org.uk

Background and Aims: Liver transplantation (LT) is a time critical procedure, as graft cold ischaemic time needs to be minimised and the timing of organ retrieval often cannot be scheduled, hence many procedures occur "out-of-hours'. There is concern that adverse clinical outcomes are associated with weekend and night-time clinical activity. We sought to determine whether weekend or night-time LT was associated with poorer outcomes in the UK.
Method: Rates of graft failure and transplant failure (the occurrence of graft failure and/or death) at 30 days, 1 and 3 years following LT were determined for adult, liver only recipients from all seven UK transplant centres between 2000–2014. A risk adjusted Cox regression model was constructed and outcomes correlated with weekend (5pm Friday to 9am Monday) or night-time (7pm to 7am) LT.
Results: 8816 transplants were included and baseline characteristics between weekend and weekday groups were similar.
In the unadjusted analyses the hazard ratio (HR) for graft failure was the same for weekend transplantation at all time points (HR at 30 days 0.85, p = 0.08; 1 year 0.91, p = 0.16; 3 years 0.92, p = 0.16) but lower for transplant failure at 30 days (0.82, p = 0.01; 0.91, p = 0.09; 0.93, p = 0.12) compared to weekdays. In the risk-adjusted model the hazard of graft failure was lower at early time points (HR 0.81, p = 0.02; 0.87, p = 0.06; 0.892, p = 0.06) and for transplant failure at all time points (0.77, p = 0.001; 0.86, p = 0.01; 0.89, p = 0.02) with weekend LT. For patients without transplant failure at 30 days, there was no weekend effect on LT outcomes.
Night-time transplantation was associated with a higher hazard of graft or transplant failures at all time points in the unadjusted analyses. However, in the unadjusted analyses no differences were observed for outcomes with night-time transplantation or graft retrieval.
Conclusion: Weekend and night-time LT are non-inferior to weekday transplantation and there are potentially benefits with weekend LT in the UK, which are dependent upon peri-transplant factors. These data suggest that the current UK model of liver transplant services avoids adverse outcomes at perceived periods of risk.

FRI-036
Long-term post-transplant liver biopsies of children: central perivenulitis is associated with circulating donor-specific antibodies and tissue C4D deposition
L.N. Souza[1], A. Sanchez-Fueyo[2], A. Dhawan[3], A. Quaglia[4]. *[1]Institute of Liver Studies, Department of Transplantation Immunology and Mucosal Biology (DTIBM), London, United Kingdom; [2]Institute of Liver Studies, MRC Transplant Centre, King's College London University, London; [3]Paediatric Liver, GI and Nutrition Centre, London, United Kingdom; [4]Institute of Liver Studies, Pathology, London, United Kingdom*
Email: k1344108@kcl.ac.uk

Background and Aims: Abnormalities in long-term post-transplant liver biopsies are common. The role of donor-specific alloantibodies

(DSA) in chronic allograft pathology is not completely understood. Our aim was to study the association between post-transplant DSA, C4d immunohistochemistry and chronic allograft histological injury in paediatric liver transplant recipients undergoing a protocol liver biopsy at least 8 years after transplantation, clinically stable and with normal liver function tests.

Method: Post-transplant allograft core needle biopsies were assessed by two histopathologists using semi-quantitative score for inflammation and fibrosis. Immunohistochemistry for C4d was performed with Cell Marque mono-polyclonal antibody and the stain assessed through a semi-quantitative score. Patients" serum was retrieved from our biobank and tested for the presence of circulating DSA.

Results: Fifty-nine patients underwent protocol biopsy between 8.7 and 15.4 (average 12.0) years post-transplant. Recipients age at biopsy ranged from 9.6 to 17.1 (average 15.0) years. Thirty-one children were male. Forty patients (67.8%) had histological abnormalities: twenty-four (42.1%) unexplained chronic hepatitis, 24 (42.1)% significant portal fibrosis (defined as at least bridging), 2 (3.4%) established rejection and 1 patient had chronic cholangiopathy. Thirty-six children had serum and donor's HLA data available for DSA testing. Twenty-five (of 36, 69.4%) had circulating DSA: 19 directed at class II HLA antigens, 3 at class I, and 4 at both classes. The presence of class II DSA with mean fluorescent intensity >10,000 was associated with significant portal fibrosis, present in 90% of patients with these antibodies ($p = 0.002$). There was a link between C4d in portal vein branches and DSA ($p = 0.009$), and all 6 patients who showed moderate or strong C4d deposition in portal veins had circulating DSA. C4d was not sensitive, thought, as 76% of DSA+ recipients had negative or weak C4d positivity in portal vein branches. Furthermore, all patients with DSA and concomitant C4d deposition (focal or diffuse) in portal vein had central perivenulitis (CP) on biopsy ($p = 0.018$). However, 25% of patients without DSA and C4d also had central perivenulitis.

Conclusion: 67.8% of children who underwent liver transplantation developed significant histological injury by the time of biopsy, despite being clinically stable with normal liver function tests. DSA were present in 69.4% of patients, in most cases directed at class II HLA antigens. Circulating class II DSA in high titres were associated with fibrosis. Moderate/strong C4d deposition in portal vein branches was a specific but not sensitive indication of circulating DSA. Central perivenulitis may represent a sensitive although not specific histological indication of chronic antibody-mediated allograft damage in stable transplanted children.

FRI-037

DAA therapy improves early post-liver transplant survival and induces significant changes in wait-list composition

G. Crespo[1], N. Trota[2], M.-C. Londoño[1], E. Mauro[1], C. Baliellas[3], L. Castells[4], José Castellote[3], J. Tort[2], X. Forns[1], M. Navasa[1]. *[1]Hospital Clínic, Liver Unit, CIBERehd, IDIBAPS, Barcelona, Spain; [2]Organització Catalana de Transplantaments, Barcelona, Spain; [3]Hospital Bellvitge, Liver Unit, L'Hospitalet de Llobregat, Barcelona, Spain; [4]Hospital Vall d'Hebron, Liver Unit, CIBERehd, Barcelona, Spain*
Email: gcrespo@clinic.ub.es

Background and Aims: The availability of direct-acting antivirals (DAA) has dramatically changed the treatment and prognosis of patients with chronic hepatitis C. We aimed to evaluate the impact of DAA on the liver transplant (LT) waiting list and the early post-transplant survival.

Method: We included all patients admitted in the waiting list for a primary LT between 1/1/2008 and 31/12/2016 in Catalonia, Spain, using data from the Registry of the Organització Catalana de Trasplantaments (OCATT). Time span was divided into two periods according to the availability of different antiviral therapies: 2008–2013 (IFN-based therapies) and 2014–2016 (DAA). Changes in the indications of LT and aetiology of baseline liver disease, as well as post-LT patient survival, were evaluated according to the year of inclusion and transplantation, respectively.

Results: We included 1483 patients admitted in the waiting list during the study period. Inclusions in the waiting list due to HCV-related liver disease significantly decreased: from 52% in 2008–2013 to 40% in the second period (28% in 2016), particularly those indications related to decompensated cirrhosis ($p < 0.0001$). In contrast, NASH-related inclusions increased significantly, from 4% to 8% ($p = 0.002$) (12% in 2016). Three year post-LT patient survival improved significantly in the second period in the whole cohort (82% vs 91%, $p = 0.002$). The latter was explained by a significant survival increase in anti-HCV positive patients (76% vs 91%, $p = 0.001$), but not in HCV-negative patients (88% vs 91%, $p = 0.359$). Using Cox regression multivariate analysis, HCV serology, time period and donor age were independent predictors of patient survival in the whole cohort; while time period and donor age were independently associated with survival in HCV-positive recipients.

Conclusion: DAA therapy is associated with significant changes in the composition of the LT waiting list and more importantly, results in improved early post-transplant survival.

FRI-038

Long-term subclinical inflammatory lessions in liver transplant recipients

M.-C. Londoño[1], L. Neves Souza[2], R. Miquel[2], A. Quaglia[2], L.P. Llovet[3], M. Navasa[3], A. Rimola[1], A. Sanchez-Fueyo[4]. *[1]Hospital Clínic Barcelona, Liver Unit, Spain; [2]Institute of Liver Studies at King's College Hospital, MRC Transplant Centre, King's College London University, United Kingdom; [3]Liver Unit, Hospital Clínic, Spain; [4]Institute of Liver Studies, King's College London, MRC Transplant Centre, King's College London University, London, United Kingdom*
Email: mlondono@clinic.ub.es

Background and Aims: Sub-clinical inflammatory changes are commonly described in long-term transplant recipients undergoing protocol liver biopsies. The pathogenesis of these lesions and their contribution to progressive allograft fibrosis remain unclear. Therefore, the aim of the study was to determine the prevalence of histological abnormalities in long-term surviving liver recipients and to investigate the molecular profiles of sub-clinical inflammatory changes.

Method: Between 1989 and 1999, 654 liver transplantations (LT) were performed on 589 recipients at Hospital Clínic Barcelona. Patients with recurrence of underlying liver disease, severe biliary or vascular complications, chronic rejection, or ALT >2-fold ULN were excluded. 312 patients were dead and 121 were lost to follow-up. 67 patients underwent extensive laboratory testing and a liver biopsy. Transcriptome profiling was performed on RNA extracted from FFPE liver biopsies employing the next generation sequencing Ion AmpliSeq platform.

Results: Median time since LT to liver biopsy was 155 months (118–268). Most of the patients were on monotherapy with cyclosporine, tacrolimus or mycophenolate at low through levels (mean CyA 38 ng/ml [0–143], FK 1.7 ng/ml [0–4.2]). Six patients (9%) had cirrhosis, 5 (8%) had chronic rejection and 8 (12%) patients had moderate/severe hepatic steatosis. Among the remaining patients the most frequently observed histological abnormality was portal inflammation, present in 45 biopsies (67%). Employing *Weighted Gene Correlation Network Analysis*, we identified 2 modules of genes (Cyan and Pink modules) that significantly correlated with portal inflammation, interface hepatitis and portal fibrosis observed in liver biopsy. Biopsies were assigned into 2 groups according to the level of expression of these modules (High and Low). High group was enriched in canonical pathways associated with allograft rejection and immunopathology (similar to patients with T cell mediated rejection, TCMR). Contrary to what was observed in the low group, after a median follow-up period of 6.8 years, patients in the high group have significantly lower platelet counts and high fibrosis score (FIB-4).

Conclusion: The prevalence of significant histological abnormalities in highly selected long-term surviving liver transplant recipients is high. Samples with portal inflammatory infiltrates exhibit transcriptional changes that greatly overlap with those of TCMR.

FRI-039

Utility of FDG-PET/CT in pre-transplantation workup of the potential liver recipient with hepatocellular carcinoma

S.Y. Yi[1], J.H. Shim[1], G.W. Song[2], G.H. Choi[1], K.M. Kim[1], Y.-S. Lim[1], H.C. Lee[1], Y.-H. Chung[1], Y.S. Lee[1], S.-G. Lee[1]. [1]*Asan medical center, Division of Gastroenterology, Department of Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Asan medical center, Division of Hepatobiliary Surgery and Liver Transplantation, Department of Surgery, Seoul, Korea, Rep. of South*
Email: s5854@amc.seoul.kr

Background and Aims: There is no consensus approach to the decision-making regarding suitability for liver transplantation (LT) in patients with hepatocellular carcinoma (HCC). Positron emission tomography-computed tomography using ^{18}F-fluorodeoxyglucose (FDG PET/CT) has been found to provide helpful information for determining post-LT prognosis in HCC patients. We aimed to assess the performance of FDG-PET/CT for detection of metastatic disease or other malignancy in potential liver recipients with HCC.
Methods: This retrospective study included 423 adult liver transplant candidates with HCC who underwent both FDG-PET/CT and conventional imaging studies such as chest-abdomen-pelvis CT examinations and bone scintigraphy, together with upper and lower gastrointestinal endoscopy, as pre-transplant workup. All patients had no history of cancer other than HCC. The diagnostic performance of FDG-PET/CT was quantitatively evaluated by the calculation of sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).
Results: Out of the 423 patients, 338 (79.9%) were male with a median age of 55 years (54.03–55.43). In terms of extrahepatic evaluation, FDG-PET/CT detected a total of 163 lesions in 142 patents, which consisted of 132 benign and 31 malignant-looking lesions. The number of lesions suspicious for metastatic HCC was initially 24. Further diagnostic procedures confirmed 3 pulmonary, 7 skeletal, and 7 lymphatic metastases in 3, 7, and 7 patients, respectively; and 1 gastrointestinal stromal tumor (GIST) and 1 lung cancer in 1 and 1 patient, respectively. Among the 17 metastases, 4 were suspected to be a metastatic focus only by FDG-PET/CT, not by conventional scanning. All 2 cases of colorectal cancers diagnosed by sigmoidoscopic screening were detected on neither FDG-PET/CT nor abdomen/pelvis CT images. False positive FDG-PET/CT results were identified in 12 patients with benign lesions: 1 Warthin's tumor of the parotid gland, 3 inflammatory nodules of the lung, 2 degenerative bone lesions, 4 reactive lymphadenopathies, 1 focal bladder wall thickening, and 1 prostatic hyperplasia. No false negative errors occurred in FDG-PET/CT, while 1.2% in conventional studies (1 GIST and 4 bone metastases). Taken together, the performance of FDG-PET/CT in detecting metastatic or primary cancer in our series was measured with sensitivity of 90.48%/89.47%, specificity of 97.04%/97.04%, PPV of 61.29%/62.96%, and NPV of 99.49%/99.49% on per-lesion/per-patient basis.
Conclusion: Our results indicate that whole-body FDG-PET/CT, when coupled with colonic examination, is effective for identification of extrahepatic disorders before LT in patients with HCC, and may fully replace multiple organ-specific imaging tests. The future cost-effectiveness study is warranted for the rational use of FDG-PET/CT in potential LT candidates with HCC.

FRI-040

Long-term outcome of donor biliary complications following living donor liver transplantation

H.Y. Woo[1], I.S. Lee[2], J.H. Chang[2], S.H. Bae[2], J.Y. Choi[2], S.K. Yoon[2]. [1]*Pusan National University Hospital, Departments of Internal Medicine, BUSAN, Korea, Rep. of South;* [2]*The Catholic University of Korea, Department of Internal Medicine, College of Medicine*
Email: who54@hanmail.net

Background and Aims: Biliary complications are the most common donor complication following living donor liver transplantation (LDLT). The aim of this study is to investigate the long-term outcomes of biliary complications in right lobe adult-to-adult living donor liver transplantation donors, and to evaluate the efficacy of endoscopic treatment of these donors.
Method: The medical charts of right lobe donors who developed biliary complications between June 2000 and January 2008 were retrospectively reviewed.
Results: Of 337 right lobe donors, 49 developed biliary complications, including 36 diagnosed with biliary leakage and 13 with biliary stricture. Multivariate analysis showed that biliary leakage was associated with the number of right lobe bile duct orifices. Sixteen donors, five with leakage and 11 with strictures, underwent endoscopic retrograde cholangiography (ERC). ERC was clinically successful in treating eight of the 11 strictures, one by balloon dilatation and seven by endobiliary stenting. Of the remained three, two were treated by rescue percutaneous biliary drainage and one by conservative care. Of the five patients with leakage, four were successfully treated using endobiliary stents and one with conservative care. In overall, total 35 improved with conservative treatment. All inserted stents were successfully retrieved after a median 264 days (range 142–502 days) and there were no recurrences of stricture or leakages during a median follow-up of 10.6 years (range 8–15.2 years).
Conclusion: All donors with biliary complications were successfully treated non-surgically, with most improving after endoscopic placement of endobiliary stents and none showing recurrence on long term follow-up.

FRI-041

Impact of surgical margin according to AFP ratebefore hepatectomy for hepatocellular carcinoma

Frédéric Marques[1], E. Boleslawski[2], O. Ciacio[1], D. Cherqui[1], M.-A. Allard[1], N. Golse[1], D. Castaing[1], René Adam[1], J.-M. Regimbeau[3], J.-Y. Mabrut[4], F.-R. Pruvot[2], D. Samuel[1], E. Vibert[1]. [1]*AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire;* [2]*Service de Chirurgie et Transplantation hépatique - Hôpital CLAUDE HURIEZ - CHU Lille;* [3]*Service de Chirurgie Digestive - Hopital Amiens Sud - CHU Amiens;* [4]*Lyon Croix Rousse*
Email: eric.vibert.pbr@gmail.com

Background and Aims: When surgical resection is decided for the treatment of hepatocellular carcinoma (HCC), surgical margins are essential to remove potential satellite nodules associated to microvascular invasions. It remains unclear if resection with narrow margins (<1cm) could be sufficient for some patients and which tumors need to be resected with wide margins (≥1cm) to prevent recurrence. The aim of this study was to determine if the width of resection margin necessary to prevent recurrence could be determined by preoperative alpha-fetoprotein (AFP) rate.
Method: From April 2012 to January 2016, all patients who underwent a first hepatectomy for HCC were included in a multicentric prospective database and analyzed retrospectively. Patients with no extrahepatic disease were included. Patients with remnant tumor after resection (R2) were excluded. We first studied if preoperative AFP rate was correlated to recurrence and pejorative pathological features. Univariate and multivariate analysis of prognostic factors for time to recurrence (TTR) were conducted and we studied the impact of the width of resection margins (<1cm or ≥1cm) in low and high AFP rate patients (≤100 or >100ng/ml).

Results: 397 patients from 5 centers met the selection criterias. 98 patients (25%) had a high AFP rate. Patients with AFP > 100 had significantly larger tumors (p < 0.001), more frequently microvascular invasions (p = 0.01), satellite nodules (p = 0.013) and poorly differentiated tumors (p = 0.014). In multivariate analysis, the only independent preoperative predictive factor for TTR was AFP > 100 (p < 0.001). In High AFP group, TTR was impacted by surgical margins (p = 0.040). Median TTR for patients with narrow margins was 8 months. TTR for patients with wide margins did not reach the median. In Low AFP group, TTR was not impacted by surgical margins (p = 0.625). Patients with narrow and wide resection margins had a median TTR of 38 and 32 months respectively.

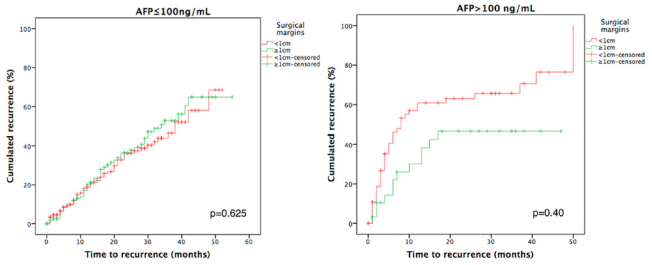


Figure 1: Impact of surgical margins on time to recurrence according to AFP rate

Conclusion: Our study confirmed that AFP > 100 ng/ml is an independent predictive factor of HCC recurrence, associated to invasive pathological features such as microvascular invasion, satellite nodules and poorer tumor differentiation. This study showed that tumors associated with a preoperative AFP > 100 ng/ml should be resected with a wide margin to prevent recurrence. At the opposite, the width of resection margin did not impact survival or recurrence in patients with a preoperative AFP ≤ 100.

FRI-042
Upper limb lean mass by Dual Energy Xray Absorptiometry is associated with increased mortality in men with advanced cirrhosis

M. Sinclair[1,2], R. Hoermann[2], A. Peterson[1], A. Testro[1], P. Angus[1,2], P. Hey[1], B. Chapman[1], P. Gow[1,2]. *[1]Austin health, Liver Transplant Unit, Australia; [2]The University of Melbourne, Medicine, Melbourne, Australia*
Email: mariejsinclair@gmail.com

Background and Aims: Sarcopenia is common in cirrhosis, and accelerates as MELD score rises. Low muscle area at the L3 level on CT scan is an independent predictor of mortality in cirrhosis; this association is strongest in men. Dual Energy X-ray Absorptiometry (DEXA) body composition is not well studied in cirrhosis, but has the advantages of low cost, low radiation dose, and analysis of all body compartments. This study examines the relationship between DEXA lean mass measures including appendicular (APLM = lean mass of arms + legs) and total lean mass (TLM) on clinical outcomes in cirrhotic men awaiting liver transplantation.
Method: We retrospectively reviewed DEXA scans performed during liver transplant assessment of men between September 2001 and November 2016. Baseline clinical data including presence of ascites and MELD score were recorded. DEXA lean mass measures were adjusted for height as previously described. We retrieved clinical outcomes including mortality, sepsis and time-to-outcome. Cox regression was used to identify predictors of outcome.
Results: 421 men with median age 53.4 years [95% CI 49.1; 59.3] and median MELD 16 [12; 20] were studied. Median follow-up was 2533 days [1157; 3823]. 27.6% of patients died, 24.2% suffered major sepsis and 74.3% were transplanted. APLM was inversely associated with overall mortality (HR 0.78 [0.62; 0.98], p = 0.034). Lean mass of arms (HR 0.37 [0.16; 0.83], p = 0.015) rather than legs (HR 0.77 [0.58; 1.03], p = 0.079) was responsible for this association. TLM was not associated with mortality, but increased with MELD score (r=+0.22, p < 0.001) in conjunction with increasing prevalence of ascites (OR for ascites 1.20 [1.15; 1.25], p < 0.001 for each unit increase in MELD). APLM displayed no relationship with MELD score (r = 0.0, p = 0.96) but arms lean mass fell with rising MELD score (r = –0.28, p < 0.001). Neither APLM, leg lean mass nor TLM were associated with sepsis, however a trend was noted for arms lean mass (HR 0.55 [0.30; 1.02], p = 0.056).
Conclusion: Upper limb lean mass by DEXA scan is strongly associated with mortality in men awaiting liver transplant and is inversely associated with liver disease severity. DEXA scans cannot differentiate water (either ascites or peripheral oedema) from muscle, which likely explains the counterintuitive positive association between TLM and MELD score, and the lack of association between either TLM or leg lean mass and outcome. These data suggest that upper limb lean mass is the best DEXA measure of muscle mass in cirrhotic men, and represents a novel, reliable, low cost estimate of sarcopenia in this cohort.

FRI-043
MELD dynamics predicts waitlist outcomes in patients awaiting liver transplantation

B.H. Kim, A. Mannalithara, A. Kwong, W.R. Kim. *Stanford University, Division of Gastroenterology and Hepatology, Stanford, United States*
Email: wrkim@stanford.edu

Background and Aims: Recent advances in the treatment have enabled to alter prognosis of patients with liver disease. Dynamic changes in Model for End-Stage Liver Disease (MELD) among waitlist candidates may provide insight into liver disease trajectories. The aim of this study was to determine whether a change in MELD score over 12 weeks is predictive of transplant-free survival among adult liver transplantation (LT) candidate with end-stage liver disease.
Method: From the United Network for Organ Sharing dataset, adult liver transplant candidates listed from 1/JAN/2010 to 5/DEC/2014, aged 18 years or more, had never undergone LT and not listed for multiorgan transplantation were identified. Patients with hepatitis C-related cirrhosis, non-alcoholic steatohepatitis (NASH), or alcoholic cirrhosis were considered eligible; however, those who listed as status 1A or receiving an exception score were excluded. The change in MELD score over 12 weeks on subsequent transplant-free survival was assessed by the multivariable proportional hazards regression analysis.

Table 1: Incidence rates of death or liver transplantation per 100 people per year (95% CI) in patients who experienced change in MELD score over 12 weeks.

	Initial MELD		
Change in MELD score	10–14	15–20	21–25
Decrease by ≥ 2	15 (13–18)	33 (30–36)	83 (77–90)
No change (± 1)	24 (22–26)	53 (50–57)	102 (95–110)
Increase by 2–5	42 (38–46)	118 (111–126)	251 (228–276)
Increase by 6–10	95 (81–111)	269 (240–302)	704 (605–820)
Increase by 11+	268 (210–341)	718 (608–848)	1730 (1422–2105)

Results: Among 23,075 eligible candidates consisting of 15,591 men and 7,484 women, 11,804 (51.2%) had hepatitis C, 4,258 (18.5%) NASH and 7,013 (30.4%) alcoholic cirrhosis. Of these patients, 6,491 (28.1%) had MELD 10–14, 6,973 (30.2%) had MELD 15–20 and 2,954 (12.8%) had MELD 21–25. The incidence of LT or mortality increased as the initial MELD score increased as shown in Table 1. For each initial MELD strata, those who experienced a decrease by 2 or more points over 12 weeks had lower incidence compared with those who had no change, while those with a rising MELD score showed progressively higher incidence according to the degree of increase. Patients who had initial MELD of 10–14 and experienced a decrease by 2 or more

points had a significantly lower risk of LT or mortality with incidence rate ratio of 0.62 (95% confidence interval [CI] 0.52–0.76). This was consistent for other initial MELD strata; 0.61 (95% CI 0.55–0.68) for MELD 15–20 and 0.82 for MELD 21–25 (95% CI 0.73–0.91).
Conclusion: Reduction of MELD score by 2 or more points over 12 weeks decreases the risk of LT or death – by approximately 40% compared to those whose MELD remained stable. As effective therapeutic agents become increasingly available for patients with viral and non-viral liver disease, the longitudinal trajectory of MELD scores may inform management decisions in patients with hepatic decompensation.

FRI-044
Effects of liver transplantation (LTx) on health-related quality of life (HRQoL) in patients with PBC
M. Krawczyk[1,2,3], Małgorzata Koźma[4], A. Szymańska[5], K. Leszko[4], M. Przedniczek[4], K. Mucha[5,6], B. Foroncewicz[5], L. Paczek[5,6], B. Moszczuk[6], P. Milkiewicz[4,7], R.-W. Joanna[4]. *[1]Department of Medicine II, Saarland University Medical Center, Homburg, Germany; [2]Laboratory of Metabolic Liver Diseases, Center for Preclinical Research, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland; [3]Department of Medicine II, Saarland University Medical Center; Homburg, Germany; [4]Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland; [5]Department of Immunology, Transplantology and Internal Medicine, Transplantation Institute, Medical University of Warsaw, Warsaw, Poland; [6]Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland; [7]Translational Medicine Group, Pomeranian Medical University, Szczecin, Poland*
Email: marcin.krawczyk@uks.eu

Background and Aims: Patients with primary biliary cholangitis (PBC) are known to have a significantly decreased health related quality of life (HRQoL). They suffer from not only pruritus and fatigue, but several other aspects of their well-being are also affected. As clearly shown, treatment with UDCA does not improve HRQoL (Mells et al Hepatology 2013;58:273–83) and in these who develop advanced liver cirrhosis, liver transplantation (LTx) remains the only curative option. Here we investigated HRQoL in two cohorts of patients with PBC who underwent LTx and compare their results to healthy subjects.
Method: Generic SF-36 and disease-specific PBC-40 questionnaires were used in 107 PBC patients (F/M = 99/8, mean age 63 ± 7 years) with mean 91 months after LTx (group 1). They were also implemented in 26 patients (F/M = 23/3, mean age 59 ± 6 years) in whom they were taken before and within a shorter period (mean 12 months) after LTx (group 2). Control group comprised 60 matched healthy controls.
Results: When compared to controls, patients with prolonged period after LTx (group 1) showed a significant impairment of their HRQoL measured with SF-36. It included physical functioning, physical role, emotional role and physical component score domains. In group 2, where HRQoL questionnaires were available before and after LTx, a significant improvement in virtually all domains of SF-36 was seen. Also a significant amelioration of symptoms assessed with PBC-40 was seen in this group including both pruritus (7.8 ± 5.5 vs. 3.7 ± 4.3; p = 0.009) and fatigue (32.7 ± 11.9 vs. 24.2 ± 10.7; p = 0.002). There was no difference in HRQoL between patients in group 1 and 2.
Conclusion: Patient with PBC and prolonged period of time after LTx have worse HRQoL than their matched controls. On the other hand, LTx leads to significant improvement of HRQoL in PBC which is notable within a short period after LTx and does not improve any further later on.

FRI-045
Filamin a expression predicts early recurrence of hepatocellular carcinoma
M. Donadon[1], L.D. Tommaso[2], C. Soldani[1], B. Franceschini[1], L. Vigano[1], M. Cimino[1], M. Roncalli[2], A. Lleo[3], G. Torzilli[1]. *[1]Humanitas University, Department of Hepatobiliary and General Surgery, Rozzano (MI), Italy; [2]Humanitas University, Department of Pathology, Rozzano (MI), Italy; [3]Humanitas University, Department of Internal Medicine and Hepatology, Rozzano (MI)*
Email: ana.lleo@humanitas.it

Background and Aims: The risk of recurrence of hepatocellular carcinoma (HCC) after hepatectomy is very high and predictive markers of early recurrence (ER) are not available. The overexpression of Filamin A (FLNA), a cytoskeleton protein with scaffolding properties, has recently been associated with progression in different tumors. The aim of this study was to test the expression of FLNA in a cohort of patients operated for HCC.
Method: A retrospective cohort of patients who underwent curative hepatic resection at Humanitas Clinical and Research Center between January 2004 and December 2014 was analyzed. FLNA was tested using a tissue-microarray in the extra-tumoral, peri-tumoral, and intra-tumoral tissue compartments. The endpoint was the role of FLNA expression in predicting ER of HCC after hepatectomy. Analyses were performed according to the REMARK guidelines.
Results: A total of 113 patients were included in the study. FLNA was expressed only in the peri-tumoral and intra-tumoral tissue but not in the extra-tumoral normal tissue. Several variables, including T-stage, tumor number, tumor size, type of viral hepatitis, type of hepatectomy, and intra- and peri-tumoral immune-reactivity to FLNA were significantly associated with ER by univariate analysis. With multivariate analysis, only T-stage (HR = 2.108; p = 0.002), tumor number (HR = 1.586; p = 0.023), intra-tumoral (HR = 2.672; p < 0.000) and peri-tumoral immune-reactivity to FLNA (HR = 2.569; p < 0.000), significantly correlated with ER. The logistic regression analysis revealed that advanced T-stage (OR = 2.985; p = 0.001), HCV-infection (OR = 1.219; p = 0.008), and advanced tumor grading (OR = 2.781; p = 0.002) were associated with intra-tumoral FLNA immune-reactivity.
Conclusion: FLNA expression predicts recurrence of HCC after hepatectomy. This finding provides important insights that would help physicians to personalize follow-up strategies and develop a new therapeutic target.

FRI-046
Patients with 18F-FDG PET-positive hepatocellular carcinoma and elevated values of alpha-fetoprotein and C-reactive protein have an extraordinary high risk of tumor recurrence following liver transplantation
A. Kornberg[1], U. Witt[1], J. Kornberg[2], K. Müller[3], H. Friess[1], K. Thrum[4]. *[1]Technical University Munich, Klinikum rechts der Isar, Department of Surgery;, [2]Ludwig-Maximilians-University, Department of Anesthesiology; [3]Friedrich-Schiller-University Jena; [4]Helios Klinikum Berlin, Institute of Pathology*
Email: arnokornberg@aol.com

Background and Aims: Biological tumor aggressiveness rather than macromorphology of hepatocellular carcinoma (HCC) determines outcome following liver transplantations (LT). Recently, standard procedures such as ^{18}F-FDG positron emission tomography (PET), alpha-fetoprotein (AFP) and C-reactive protein (CRP) were suggested to describe tumor biology of HCC. The aim of this study was to assess the prognostic significance of combining ^{18}F-FDG PET data with serum values of AFP and CRP for selecting appropriate liver transplant patients.
Method: We performed a retrospective observational trial including 123 patients that were identified from a prospectively maintained LT database. All of them underwent pre-LT ^{18}F-FDG PET to distinguish between PET-negative and PET-positive tumors. The most optimal cut-off values of AFP (100 ng/ml; Area under the curve [AUC] = 0.826;

r = 0.042; 95%Confidence Interval [CI] 0.743–0.909) and CRP (0.8 mg/dl; AUC = 0.824; r = 0.039; 95%CI 0.747–0.901) for predicting HCC recurrence were determined by receiver operating characteristic analysis. Recurrence-free survival (RFS) rates were determined using the Kaplan-Meier method. Uni- and multivariate analyses using Cox's proportional hazards model were performed to identify pre-LT available clinical predictors of RFS.

Results: Median post-LT follow-up was 73 months (range: 5–184). Tumor recurrence rate was 23.6%. In multivariate analysis, only CRP < 0.8 mg/dl (Hazard ratio [HR] = 9.3; 95%CI 2.199–41.035; p = 0.003), AFP < 100 ng/ml (HR = 4.3; 95%CI 1.754–10.563; p = 0.001) and PET-negativity (HR = 4.2; 95%CI 1.491–11.867; p = 0.007) were identified as independent predictors of RFS, whereas macromorphologic tumor features were not independently significant. Five year RFS rates were 93.5% in ^{18}F-FDG-non-avid patients (n = 77) and 100% in PET-positive patients with low AFP/CRP levels (n = 8), defining a low biological risk group (n = 85). In contrast, it was only 32.7% in PET-positive patients with high CRP and/or AFP levels (log ran < 0.001; n = 38; high risk group), respectively. The special subset of patients with a triplet of unfavorable biological features (PET-positive + AFP > 100 ng/dl + CRP > 0.8 mg/dl; n = 16) demonstrated a 5 year RFS rate of 0%. Hazard ratios for predicting RFS were 16.9 for patients with low biological risk (95%CI 6.384–44.521), and 3.2 for meeting MC tumors (95%CI 1.471–7.109). Application of tumor biological variables instead of macromorphology increased transplant eligibity by 23.2%.

Conclusion: Combining ^{18}F-FDG PET with serological parameters of tumor viability, such as AFP and CRP improves prognostic accuracy and increases the number of eligible liver transplant patients. Thus, strict macromorphologic tumor burden limits may be crossed.

FRI-047

Multi-frequency bioelectrical impedance output correlates to liver disease severity, nutritional status and functional capacity

R. Sinha[1], J. Foo[2], P. Hayes[1]. [1]*Royal Infirmary and The University of Edinburgh, Scottish Liver Transplant Unit, Edinburgh, United Kingdom;* [2]*College of Medicine & Veterinary Medicine, The University of Edinburgh, Medical School, The Chancellor's Building, 2nd Floor, Edinburgh, United Kingdom*
Email: rohit.sinha@nhs.net

Background and Aims: Malnutrition and poor physical endurance is highly prevalent in patients with advanced liver disease requiring liver transplant and bear significant impact on morbidity and mortality. Traditional assessment of nutritional status is subjective and has limitations. Additionally, measurement of physical fitness with cardiopulmonary exercise (CPEX) cannot be extended globally to all patients. Bioelectrical impedance analysis (BIA) is increasingly used to measure body composition, malnutrition and clinical progression of various diseases. The aim this study is to assess the clinical usefulness of BIA as a bedside tool for assessing nutritional status, functional exercise capacity and relationship to severity of liver disease.

Method: This is a retrospective, observational cross-sectional study of 68 consecutive patients who underwent liver transplant assessment at our centre between the period of January 2017 and July 2017. Acute liver failure cases were excluded. Various clinical, biochemical, nutritional assessment [Dry BMI, albumin and mean arm muscle circumference (MAMC)] and functional assessment [Hand-grip strength (HGS) and CPEX data – maximal oxygen consumption (VO2 max) and anaerobic threshold (AT)] data were collected. All patients underwent body composition assessment on a multi-frequency BIA – Seca analyser 515 device, and outputs [Total Body Water, Extracellular Water, Fat Mass Index, Fat-free Mass Index, Skeletal Muscle Mass and Phase Angle] were considered. Correlation analysis was carried out using Spearman's rho correlation. Multivariate stepwise linear regression analyses were used to determine the independent predictors of the severity of liver disease (MELD) and functional exercise capacity (AT) respectively.

Results: 63.2% were males and median age was 59.5 (IQR 11.5) years. The results showed strong correlations between BIA parameters, in particular PA and CPEX data. PA correlated positively with VO2 max (r = 0.521, p < 0.01) and AT (r = 0.440, p < 0.01). PA was positively correlated with HGS (r = 0.548, p < 0.01). PA strongly correlates to serum albumin (r = 0.503, p < 0.01), dry BMI (r = 0.296, p < 0.05) and MAMC (r = 0.380, p < 0.01). PA showed a negative correlation with UKELD (r =-0.408, p < 0.01) and MELD (r=-0.431, p < 0.01). In the linear regression model, AT was primarily predicted by PA (beta = 0.281, p < 0.001) and MELD was by PA (beta=-0.420, p < .001)

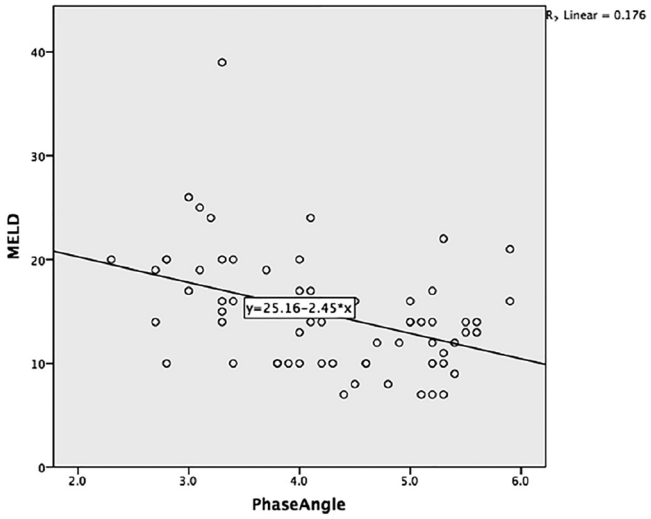

Figure 1: A positive correlation between Phase angle (PA)

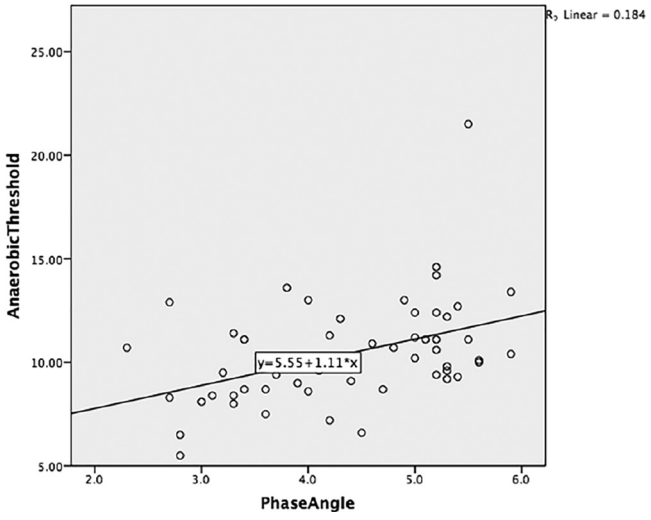

Figure 2: A negative correlation between Phase angle (PA) and severity of Functional capacity liver disease

Conclusion: BIA offers non-invasive, relatively inexpensive, portable bed-side assessment. PA correlates strongly to nutritional status, functional capacity and severity of liver disease. Further prospective studies are required to validate our finding.

FRI-048

Pregnancy outcomes and reproductive health after liver transplantation

C. Lindenmeyer[1], G. Flocco[1], L. Bell[2], R. Baird[2], V. Sanghi[3], R. Lopez[4], A. Mccullough[1]. [1]*Cleveland Clinic, Gastroenterology and Hepatology, Digestive Disease and Surgery Institute, Cleveland, United States;* [2]*Cleveland Clinic, Lerner College of Medicine, Cleveland, United States;* [3]*Cleveland Clinic, Internal Medicine, Cleveland, United States;* [4]*Cleveland Clinic, Quantitative Health Sciences, Digestive Disease and Surgery Institute, Cleveland, United States*
Email: christina.lindenmeyer@gmail.com

Background and Aims: Contemporary advances in liver transplantation (LT) have steadily increased post-LT survival. As patients are now expecting to live longer, fertility has become a major component of the patient's quality of life. However, our current understanding of the implications of LT and immunosuppressant medications on mother, fetus, and graft remains limited. In addition, previous data suggest that pre-LT, post-LT and prenatal counseling regimens are non-standardized and poorly implemented. This study attempts to expand our understanding of reproductive health in female LT recipients.
Method: This is a single center retrospective cohort study of female LT recipients who were less than the age of 50 at the time of LT. An online survey was utilized to collect self-reported immunosuppressive therapy, fertility counseling, and fertility and pregnancy outcomes. Women with hysterectomy, oopherectomy, tubal ligation and primary amenorrhea were excluded. Demographic and medical data were collected from the electronic medical record. Generalized linear mixed models were used to compare pre- and post- LT pregnancy characteristics. Binary variables were modeled using a logit link and ordinal variables were modeled using a cumulative logit link; a random effect was included in the models to account for multiple pregnancies in the same subject.
Results: 175 living women under the age of 50 were identified for enrollment. To date, 62 women have completed the survey. The average age at time of LT was 34 ± 12 years and 8 subjects underwent LT under the age of 18. Twenty-five women reported between 1–10 pre-LT pregnancies and 10 women reported between 1–6 post-LT pregnancies. Only 2 women reported pregnancies both before and after LT. Thirteen percent (n = 6 of 48 respondents) of women reported active attempts at pregnancy post-LT and only 4% (n = 2) of these women were successful (3 and 6 pregnancies each). Of the 42 women who were not actively attempting to achieve pregnancy post-LT, 8 (19%) did. There was no significant difference between rates of pre- or post-LT gestational diabetes, pre-eclampsia, eclampsia, spontaneous abortion, graft rejection or graft failure. Pre-term birth was significantly more common in pregnancies post-LT than pre-LT (75% vs. 41%; p = 0.007). Twenty-three percent of women (n = 12 of 53 respondents) reported receiving pre-LT fertility and pregnancy counseling, and 21% of women (n = 11) received any counseling after LT. Forty percent of women (n = 21) used any form of contraception after LT, and of the patients who received counseling, only 15% of women (n = 8) were counseled on contraceptive methods post-LT.
Conclusion: Ongoing study is needed to further characterize changes in fertility post-LT, to identify risk factors associated with post-LT fertility and pregnancy complications, and to standardize fertility counseling strategies for women undergoing LT.

FRI-049

Is a telehealth-to-home group lifestyle intervention a feasible and safe option for specialist liver clinics?

I. Hickman[1,2], S. Keating[3], A. Hannigan[2], L. Elvin-Walsh[2], A. Barnett[2], C. Salisbury[3], M. Jarrett[4], J. Fawcett[4], I. Croci[3], K. Campbell[2,5], J. Coombes[3], G. Macdonald[6]. [1]*Mater Research Institute – University of Queensland, Brisbane, Australia;* [2]*Princess Alexandra Hospital, Nutrition and Dietetics, Brisbane, Australia;* [3]*University of Queensland, School of Human Movement and Nutrition Science, Brisbane, Australia;* [4]*Princess Alexandra Hospital, Queensland Liver Transplant Service, Brisbane, Australia;* [5]*Bond University, Faculty of Health Sciences and Medicine, Gold Coast, Australia;* [6]*Princess Alexandra Hospital, Gastroenterology and Hepatology, Brisbane, Australia*
Email: i.hickman@uq.edu.au

Background and Aims: Addressing obesity and cardio-metabolic complications presents a challenge for clinical care in liver disease. We piloted the feasibility of a 12-week group-based telehealth-to-home cardioprotective lifestyle (Mediterranean diet and individualised aerobic and resistance exercise) intervention for liver transplant recipients. The study aimed to identify the feasibility of delivering the telehealth lifestyle intervention and accuracy of home-based clinical outcome measures.
Method: Feasibility was assessed by recruitment rate, sessions completed, adequacy of technology, attrition and adverse events/safety. Accuracy of home-based assessment including waist circumference, repeated chair stand, 6 minute walk test (6MWT) was assessed by comparing clinician (face-to-face) and repeated by the participant unsupervised at home (within approximately 1 week of clinician assessment) using Bland-Altman analysis. All patients were >6 months post transplant.
Results: Recruitment rate was 24% (n = 28 of 119 eligible), age 21–68 years and 64% males. Reasons for not participating included being too busy or unwell or already eating/exercising well. Attrition was 11% (3/28). Of the 87 sessions completed to date, 91% of patients rated confidence with home technology ≥8/10. Staff reported technology was adequate for delivering the intervention >90% of the time. Completion of scheduled sessions was 91% for nutrition and 56% for exercise. Only 46% (13/28) participants agreed to repeat clinical measures at home. Of these, the mean difference and limits of agreement between researcher and participants were: Waist, 1.0 ± 2.6cm (−4.0 to 6.0cm); Chair Stand, 0.4 ± 1.7s (−3.1 to 3.8s); 6MWT, 64 ± 7.2m (−134 to 147m). There were no study-related adverse events.
Conclusion: Group telehealth-to-home is a feasible option to provide lifestyle intervention from a specialised liver clinic and patients can accurately self-assess outcomes at home. Considerations when establishing a telehealth service for lifestyle include the need for technical support related to patient orientation to internet connection, clinical support for risk assessment of complex patients and exploring enablers to support more patients to perform functional outcome measures at home.

FRI-050

Pre-liver transplant visceral adipose tissue predicts the early development of metabolic syndrome post-transplant

A. Woodward[1], M. Wallen[2], J. Ryan[1], L. Ward[2], J. Coombes[2], G. Macdonald[1]. [1]*Princess Alexandra Hospital, Woolloongabba, Australia;* [2]*The University of Queensland, Saint Lucia, Australia*
Email: aidanjwoodward@gmail.com

Background and Aims: Post liver transplantation metabolic syndrome (PTMS) is a significant independent risk factor for cardiovascular disease. Risk factors for developing PTMS include pre-transplant diabetes, obesity and increasing age. Low muscle mass, excess adipose tissue, and poor cardiorespiratory fitness are risk factors for metabolic syndrome in the general population which have had limited evaluation post liver transplantation. Our aim was to assess the role of these variables in predicting the early development of PTMS.
Method: A retrospective cohort study was performed by assessing consecutive adult patients for inclusion who received a liver transplant by the Queensland Liver Transplant Service between August 2012 and June 2016. We included seventy-seven patients for analysis. Demographic, anthropometric and metabolic data were collected pre-transplant and at 3 months post-transplant. Metabolic Syndrome was defined in accordance with international guidelines. Pre-transplant Computed Tomography (CT) skeletal muscle (SMA), visceral adipose (VAT) and subcutaneous adipose (SAT) areas were

measured at the level of the 3rd Lumbar vertebrae using ImageJ software (NIH, Bethesda, MD, USA). Skeletal Muscle Index (SMI) was calculated by correcting the SMA for height, squared. Cardiorespiratory fitness [using the ventilatory threshold (VT)] was determined from a cardiopulmonary exercise test.
Results: The median age was 56.0 years [interquartile range 51.0–59.0] with 58 (77%) males. Primary liver disease aetiology was hepatitis C (57%) followed by primary sclerosing cholangitis (13%) and alcohol (12%). Thirty patients (40%) had a diagnosis of hepatocellular carcinoma. Ten patients (13%) developed early onset PTMS by 3 months post-transplant. Patients who developed PTMS had higher pre-transplant body mass index (BMI) ($p = 0.012$), VAT ($p = 0.001$) and SAT ($p = 0.008$). There was no difference in VT ($p = 0.772$) or SMI ($p = 0.313$) between those who did or didn't develop PTMS. Univariate logistic regression found that BMI ($p = 0.019$), VAT ($p = 0.004$) and SAT ($p = 0.01$) were significant predictors for the development of PTMS. After multivariate analysis, only VAT remained a significant predictor (Odds ratio 1.02, 95%CI 1.00–1.04; $p = 0.042$). A sensitivity and specificity analysis determined that the optimal cut-off value for VAT predicting PTMS was >153.4cm^2 (Sensitivity 80%; Specificity 80%).
Conclusion: Pre-transplant VAT is independently associated with the early development of PTMS. Body composition analysis using cross-sectional imaging prior to liver transplant can assist with risk stratification for PTMS. These patients could be targeted for interventions to prevent this, either pre- or early post-liver transplantation.

FRI-051

Follow-up of non-HLA and anti-HLA antibodies: Importance in graft failure after liver transplantation

S. Iacob[1], V. Cicinnati[2], M. Maschmeier[2], H. Schmidt[2], S. Beckebaum[2]. *[1]Fundeni Clinical Institute, Bucharest, Romania; [2]University Hospital Munster, Munster, Germany*
Email: msiacob@gmail.com

Background and Aims: Patient and graft survival after liver transplantation (LT) has strongly improved in the last decades. However, new data are emerging regarding causes of graft failure. Studies indicate that humoral response to both HLA and non-HLA antigens have a detrimental effect on allograft survival. The aim of our study was to investigate clinical and immunological risk factors for graft failure at 5 years following LT.
Method: A total of 174 LT recipients were enrolled in the study. Patients underwent biopsy for histologic and C4d examinations. Assessment of sMICA, sMICB and sULBP2 was realized by enzyme linked immunosorbent assay. Screening for anti-HLA class I, class II or MICA antibodies was performed using Luminex technology. Graft failure was defined as histologically proven liver cirrhosis or allograft dysfunction requiring relisting for LT or leading to death. Cox proportional hazards regression model was used to identify predictors of graft failure after LT.
Results: In the univariate analysis, the following factors were identified as risk factors for graft failure at 5 years: increasing donor age ($p = 0.0002$), as well as the increasing recipient age ($p = 0.04$), presence of disease recurrence after LT ($p = 0.03$), presence of donor specific anti-HLA II antibodies >5000MFI ($p = 0.001$), high serum levels of sMICA ($p = 0.01$) and ULPB2 ($p < 0.0001$), positive complement-dependent cytotoxic crossmatches at LT ($p = 0.0003$), presence of positive C4d staining liver biopsies ($p < 0.0001$). In multivariate analysis, C4d deposition ($p < 0.0001$) and increased donor age ($p = 0.001$) were independent predictors for graft failure at 5 years after LT.
Conclusion: C4d deposition and advanced age of the donor (>66 years) correlated with allograft injury among LT patients.

FRI-052

CXCL9 and CXCL10 gene polymorphisms are associated with earlier onset of acute cellular rejection after liver transplantation

A. Ostojic[1], A. Markotic[2,3], T. Kelava[3,4], A. Mrzljak[1,4]. *[1]University Hospital Merkur, Liver Transplant Centre, Zagreb, Croatia; [2]University Clinical Hospital Mostar, Mostar; [3]Croatian Institute for Brain Research, Laboratory for Molecular Immunology, Zagreb, Bosnia and Herzegovina; [4]School of Medicine, University of Zagreb, Zagreb, Croatia*
Email: anna.mrzljak@gmail.com

Background and Aims: Despite the improvement and optimization of immunosuppressive protocols, acute cellular rejection (ACR) is still a frequent complication after liver transplantation. Recent studies showed that increased concentrations of chemokines CXCL9 and CXCL10 are associated with the ACR occurrence. The aim of this study was to examine the association of CXCL9 and CXCL10 single nucleotide polymorphisms with ACR after liver transplantation.
Method: DNA was isolated from the whole blood of 215 patients transplanted due to alcoholic liver disease from 1/2009 to 3/2017 in University Hospital "Merkur", Zagreb, Croatia. Polymorphisms of CXCL9 (rs10336) and CXCL10 (rs3921) were determined by polymerase chain reaction using commercially available TaqMan SNP assays. ACR was defined as biopsy proven (Banff score ≥3) within 6 months after liver transplantation. All patients received the same immunosuppressive protocol comprising of calcineurin inhibitors, steroids (discontinued after 3 months) and mycophenolate mofetil.
Results: 59 patients with ACR and 156 patients without ACR were included into the study. There were no statistically significant differences in age, sex or MELD score at the time of transplant between rejection and non-rejection groups. Genotypes were in Hardy-Weinberg equilibrium ($p > 0.05$), with strong linkage disequilibrium ($D' = 0.99$, $r = 0986$) between CXCL9 and CXCL10. In the rejection group 22 (37.3%) patients had GG, 25 (42.4%) had AG and 12 (20.3%) had AA genotype of the CXCL9 polymorphism, with similar genotype distribution observed in the non-rejection group, in which 54 (34.6%) patients had GG, 75 (48.1%) had AG and 27 (17.3%) had AA genotype. Lack of association between CXCL9 genotypes and incidence of ACR was found in codominant, dominant, recessive, overdominant or log-additive model ($p > 0.05$). Similar results were obtained for CXCL10 genotypes. On the other hand, we observed significant association between both CXCL9 and CXCL10 genotypes and the time of ACR occurrence. Patients with CXCL9 genotype AA developed ACR earlier (median 5 days (IQR 4.0–7.5)) than patients with the GG genotype (median 8 days (IQR 6.0–18.3)) ($p = 0.003$), with similar results for CXCL10 gene (CC vs GG; $p = 0.005$).
Conclusion: Single nucleotide polymorphisms of CXCL9 (rs10336) and CXCL10 (rs3921) are not associated with the incidence of acute cellular rejection after liver transplantation, but are associated with the time of ACR onset.

FRI-053

Post-transplantation outcomes in cirrhosis secondary to granulomatous liver diseases

A. Thuluvath[1], Y. Savva[2], P.-H. Chen[1]. *[1]The Johns Hopkins School of Medicine, Medicine, Baltimore, United States; [2]The Mercy Medical Center, Medicine, Baltimore, United States*
Email: athuluv1@jhmi.edu

Background and Aims: Cirrhosis is a rare complication of sarcoidosis, and cirrhosis from other granulomatous diseases is even rarer. The published center specific data available are limited to case series. Therefore, we examined the UNOS data from 2002–2016 to determine post liver transplant outcomes of those who were transplanted for sarcoidosis and other granulomatous diseases.
Method: The patients with sarcoidosis were defined as individuals with a primary diagnosis code of 4210 (cirrhosis: other specify, e.g., histiocytosis, sarcoidosis, "granulomatous"), which were further specified as sarcoidosis at the time of listing. We compared this

group with a mixed group that may include many with sarcoidosis too; this is a group with a diagnosis code of 4210 but without explicitly stating sarcoidosis as the primary diagnosis. We excluded 100 (10%) individuals with HCC, 91 (9.1%) with Hepatitis C or B and 88 (8.8%) listed for multi-organ transplants. Only the data for the first transplant were used. The final sample size included 117 recipients with a firm diagnosis of sarcoidosis and 255 individuals with "granulomatous liver diseases" (not specified as sarcoidosis). Kaplan-Meier survival estimates were done for graft and patient survival and log rank test was used to estimate the differences.

Results: The sarcoidosis group had more black patients, as well as more patients with diabetes. Otherwise there were no noteworthy differences between the two groups. The graft and patient survival rates at 1, 3, 5 and 10 years were similar between the two groups, with more than 69% of patients surviving at 5 years and 58% surviving at 10 years.

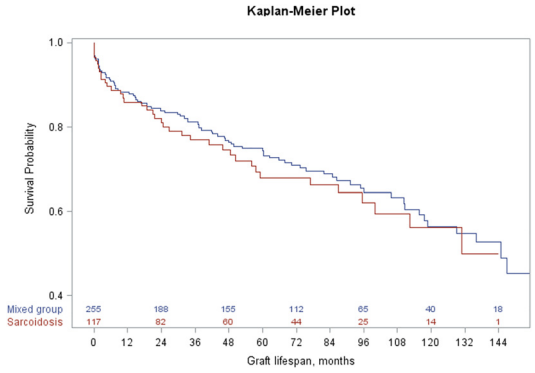

Figure 1: Graft survival in sarcoidosis and mixed group

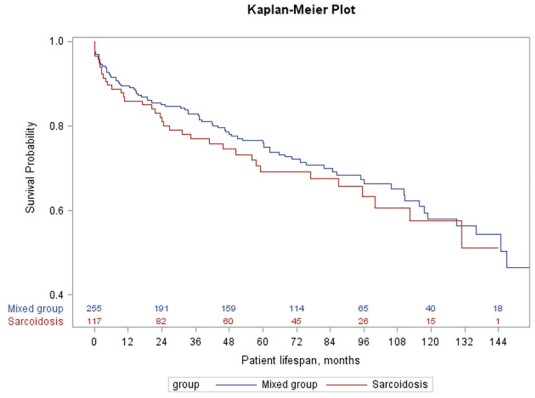

Figure 2: Patient survival in sarcoidosis and mixed group

Conclusion: The above data show that patients who are transplanted for sarcoidosis or other granulomatous liver diseases (most of whom may have sarcoidosis) have similar survival outcomes. Moreover, survival outcomes of both groups are similar to the published outcomes for those who are transplanted for other indications.

FRI-054
The effect of immunosuppression on coagulation in patients after liver transplantation

S. Bedreli[1], K. Piras-Straub[1], A. Achterfeld[1], A. Katsounas[1], F. Saner[2], G. Gerken[1], K. Herzer[1]. *[1]University Hospital Essen, Department of Gastroenterology and Hepatology, Essen, Germany; [2]University Hospital Essen, Department of General, Visceral and Transplantation Surgery, Essen, Germany*
Email: kerstin.herzer@uk-essen.de

Background and Aims: Everolimus (EVR) is an immunosuppressive (IS) agent commonly used in patients after liver transplantation (LT). However, there are concerns whether mTor inhibitors may impair coagulation and cause thromboembolic events after solid organ transplant. The present investigation aimed to identify coagulation disorders after use of EVR.

Method: We evaluated 51 patients who underwent a conversion of their IS regimen after LT either to EVR in combination with low dose tacrolimus (TAC; n = 26) or to extended-release TAC (n = 25). Common coagulation parameters, rotational thromboelastometry (ROTEM), as well as anti-coagulation and fibrinolysis factors were measured at baseline, 1 and 6 months after conversion. Statistical analysis was performed with paired t-test, one-way ANOVA and Tukey's multiple comparison test. Statistical significance was assumed for $p < 0.05$.

Results: Compared to baseline, there was a significant increase of von Willebrand factor (vWF), fibrinogen and factor VIII ($p < 0.0001$ respectively) 1 month after conversion to EVR. Furthermore, there was an increase in ROTEM-parameters, such as maximal clot firmness (MCF, $p = 0.0001$ for EXTEM, $p = 0.0006$ for INTEM, $p < .0001$ for FIBTEM). Maximum lysis (ML) was lower one month after conversion to EVR ($p < 0.0001$ for EXTEM, $p = 0.0004$ for INTEM and $p = 0.0002$ for APTEM). In those patients who were converted to extended-release TAC we could not observe any changes in coagulation parameters. Evaluation of so far 17 patients with EVR and 10 with TAC after 6 months shows a persistently significant increase of vWF ($p = 0.0005$), fibrinogen ($p < 0.0001$) and factor VIII ($p = 0.0017$) after conversion to EVR. ROTEM-parameters, such as MCF, also increased ($p < 0.0001$ for EXTEM, $p = 0.0003$ for INTEM, $p = 0.0003$ for FIBTEM). ML was lower after conversion to EVR ($p = 0.0001$ for EXTEM, $p = 0.0008$ for INTEM and $p = 0.002$ for APTEM). In general, coagulation parameters did not change between 1 and 6 months after start of EVR. In patients who were converted to extended-release TAC, there were no significant changes on coagulation parameters at all.

Conclusion: Application of EVR seems to activate coagulation to a procoagulant state in patients after LT. However, it remains uncertain whether these changes are transient or may persist and could in deed result in thromboembolic events. Ongoing clinical observation will clarify whether these changes of coagulation have a clinical impact in patients after LT.

FRI-055
99mTechnetium-MebrofeninHepatobiliary Scintigraphy predicts portal hypertension in Child-Pugh Acirrhosis

T. Chapelle[1], G. Roeyen[1], V. Hartman[1], B. Bracke[1], H. Ivan[2], T. Vanwolleghem[3], D. Ysebaert[1], S. Francque[3]. *[1]UZA, Dept. of Hepatobiliary, Transplantation and Endocrine surgery, Edegem, Belgium; [2]UZA, Nuclear Medicine, Edegem, Belgium; [3]UZA, Gastroenterology and Hepatology, Edegem, Belgium*
Email: thiery.chapelle@uza.be

Background and Aims: The Child-Pugh (CP) score and the Model for End Stage Liver Disease (MELD) are commonly used to estimate the risk of liver resection in cirrhosis. Liver resection is usually considered safe in CP grade A, whereas MELD scores ≥ 9, 10 or 11 predict post-hepatectomy liver failure (PHLF). Portal hypertension, measured by Hepatic Venous Pressure Gradient (HVPG) ≥ 10 mmHg, predicts a higher risk for PHLF. Differentiation between 5 and 6 CP points (Grade A) does not distinguish between low and high risk patients within this group. ^{99m}Technetium-Mebrofenin Hepatobiliary Scintigraphy (HBS) corrected for body surface area (HBS^{BSA}) assesses the functional reserve of the liver and may be of added value in differentiating the additional surgical risk of portal hypertension (PHT) in cirrhosis CP grade A.

Method: 99 patients with cirrhosis were divided into 3 groups according to the CP classification, grade A, B or C. The predictive value of MELD, HBS and HBS^{BSA} for CP grade and HVPG <10mmHg was evaluated.

Results: MELD, HBS and HBS^{BSA} predicted the different CP-grades. In CP grade A, only HBS and HBS^{BSA} were predictive of HVPG. Our research further revealed a cut-off value for HBS^{BSA} >3.6%/min/m² to be predictive of HVPG <10mmHg.

Table 1: Median HBS, HBS^{BSA} and MELD score for HVPG < 10mmHg and ≥ 10mmHg in Child-Pugh A *and* in Child-Pugh B/C

		HVPG < 10mmHg	≥ 10mmHg	p
Child-Pugh A	(n)	31	17	
HBS	%/min	9.18 (4.61–13.88)	7.19 (2.43–10.30)	0.001
HBS^{BSA}	%/min/m²	5.23 (2.56–7.95)	3.28 (1.13–5.20)	<0.001
MELD		8 (3–14)	8 (6–14)	0.974
Child-Pugh B or C	(n)	14	37	
HBS	%/min	3.84 (1.81–10.60)	2.48 (0.41–10.00)	0.005
HBS^{BSA}	%/min/m²	2.12 (0.97–6.76)	1.23 (0.17–5.34)	0.003
MELD		11.50 (6–18)	16 (2–28)	0.005

Abbreviations: HBS: Hepatobiliary Scintigraphy; HBS^{BSA}: HBS corrected by body surface area; MELD: Model for End Stage Liver Disease; HVPG: hepatic venous pressure gradient

Conclusion: HBS^{BSA} may identify patients with a HVPG <10mmHg in Child A cirrhosis. As HBS^{BSA} is predictive for PHT, it helps to determine if liver resection can be performed with low risk for PHLF. Hence, it might help to avoid invasive HVPG measurement prior to liver resection in Child A.

FRI-056

Chronic rejection in children: Risk factors, diagnosis and outcome

A. Cheng[1], K. Mysore[1,2], K. Hosek[2], R. Himes[1,2], D. Schady[3], J. Goss[1,2], T. Miloh[1,2]. *[1]Baylor College of Medicine, [2]Texas Children's Hospital, Transplant; [3]Texas Children's Hospital, Pathology*
Email: tamir.miloh@bcm.edu

Background and Aims: Chronic rejection (CR) is the leading indication for long term graft loss. We discuss our centre's experience with diagnosis and management of CR.
Method: Electronic medical records were searched for histologically confirmed CR (ductopenia, aberrant cytokeratin-7 of periportal hepatocytes with absent ductular proliferation and minimal portal inflammation) between years 2000–2016. Clinical data was extracted and compared to patients without CR. Standard immunosuppression induction included tacrolimus and steroids.
Results: Of 435 patients, 17 (3.9%) had CR over an average follow up of 7.4y: 5 had biliary atresia, 2 each: Alagille, other cholestasis, autoimmune hepatitis, indeterminate acute liver failure and 1 each: OTC deficiency, CF, A1AT deficiency, and hepatoblastoma. Median age at LT was 1.8y (4m–17y), similar to control. Median age of CR was 5y (2–21 y) with range of 3m–14y post LT. Demographics in CR vs control included male (59% vs 51% NS), Hispanic (41% vs 46%), African Americans (35% vs 12%), Caucasians (12% vs 36%) $p < 0.0001$ and public insurance (71% vs 64% NS). Whole graft (76% vs 85%) and ABO incompatible (6% vs 5%) (NS). On average, patients had 2.8 episodes of acute cellular rejection (ACR) prior to CR and 13 had acute on chronic rejection. In 5 cases tacrolimus (TAC) was reduced; 4 PTLD and 1 PRESS. Presenting symptoms were: 41% asymptomatic; 42% icterus, 42% splenomegaly, 24% ascites and 12% had pruritus. At CR average ALT 242 IU/l, AST 190 IU/l, GGT 603 IU/l, total bilirubin 4.6 mg/dl, conjugated bilirubin 3.7 mg/dl, albumin 3.4, platelet count 192K, INR 1.3 and 9 (53%) had positive ANA. Prior to CR the TAC medication level variability index (MLVI) was 4.2. Therapy included monotherapy; Rapamune (Rapa) 3, combination Rapa + Mycophenolate (MMF) 4 or prednisone 2, TAC + MMF 1 or Pred 1 and 6 on triple therapy. Rapa trough averaged 4.9. Outcomes included mortality in 4 patients (3 multi-organ failure 1 unknown) at average 9.3y, 1 re-transplanted after 1.5y, 2 sustained normalization of liver enzymes and the remainder 10 had fluctuating lab values.
Conclusion: CR was infrequent in our population. Risk factors included non adherence (high MLVI), ACR, ANA, ethnicity and intentional TAC dose reduction. Most patients were treated with additional immunosuppressants and only minority normalized graft function. Further research is required to identify risk factors, effective therapy and prevention of chronic rejection.

FRI-057

Hyperglycemia-triggered S1P-S1PR3 signaling worsens liver ischemia/reperfusion injury by regulating M1/M2 polarization

J. Rao[1], C. Yang[2], F. Cheng[3], S. Yang[4], L. Lu[5], X. Wang[3]. *[1]the First Affiliated Hospital of Nanjing Medical University, Liver Surgery/Liver Transplantation Center, Nanjing, China; [2]the First Affiliated Hospital of Nanjing Medical University the First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [3]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [4]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [5]the First Affiliated Hospital of Nanjing Medical University, nanjing*
Email: raojh@njmu.edu.cn

Background and Aims: Hyperglycemia/Diabetes is an adverse risk factor for hepatic ischemia/reperfusion injury (IRI) during liver transplantation or hepatectomy; however, the underlying mechanism remains unclear. Sphingosine 1-phosphate (S1P)/S1P receptor (S1PR1–3) system has been implicated in the pathological of variety organs damage. The aim of this study was to clarify whether and how (S1P)/S1P receptor (S1PR1–3) system is involved in hyperglycemia-exacerbated liver IRI.
Method: Diabetic patients and streptozotocin (STZ)-induced diabetic mice were involved in vivo. Bone marrow-derived macrophages (BMDMs) were used in vitro.
Results: S1P-S1PR3, not S1P-S1PR1 and S1P-S1PR2 signaling pathway, was specifically activated in liver tissues and Kuppfer cells (KCs) from diabetic patients and STZ-induced diabetic mice. CAY-10444, as an antagonist of S1PR3, effectively attenuated hyperglycemia-exacerbated liver IRI based on hepatic biochemistry, histological liver damage, and inflammatory responses. Interestingly, diabetic mice administrated with CAY-10444 expressed higher levels of M2 markers and lower levels of M1 markers compared with untreated diabetic mice. What's more, diabetic mice administrated with CAY-10444 also enhanced Stat3- and Stat6-signaling pathway activation. In vitro, hyperglycemia triggered S1P-S1PR3 signaling, promoted TLRs activation, and enhanced synthesis and release of pro-inflammatory cytokines in BMDMs. S1PR3 knockdown (KD) expressed lower levels of M1 markers and produced lower TNF-a, IL-6 but higher IL-10 in response to TLR ligands compared with the controls. In addition, S1PR3 KD had also enhanced Stat3- and Stat6-signaling pathway activation, but diminished Stat1-signaling pathway activation, in response to TLR4 stimulation.
Conclusion: This study demonstrates hyperglycemia specifically triggers S1P-S1PR3 signaling, promotes inflammatory responses, and exacerbates liver IRI by facilitating M1 polarization and inhibiting M2 polarization.

FRI-058

Stabilization of acute-on-chronic liver failure patients before liver transplantation predicts post-transplant survival

P. Huebener[1], M. Sterneck[1], K. Bangert[2], A. Drolz[2], A.W. Lohse[1], S. Kluge[2], L. Fischer[3], V. Fuhrmann[2]. *[1]University Medical Center Hamburg-Eppendorf, I. Department of Internal Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Department of Intensive Care, Hamburg; [3]University Medical Center Hamburg-Eppendorf, Department of Hepatobiliary Surgery and Transplantation, Hamburg*
Email: p.huebener@uke.de

Background and Aims: Acute-on-chronic liver failure (ACLF) is a severe complication of liver cirrhosis and associated with excess

short-term mortality rates. Orthotopic liver transplantation (OLT) is a potentially life-saving therapeutic modality for ACLF patients, but selection of transplant candidates with acceptable post-OLT outcomes is challenging. The aim of this study was to assess the risk of OLT in patients with ACLF, and to determine parameters that predict post-OLT survival in this patient cohort.
Method: We retrospectively analyzed all 250 patients with liver cirrhosis who underwent their first OLT between 2009 and 2014 at our institution, and assessed post-transplant outcomes.
Results: Of 250 cirrhotic liver transplant recipients, 98 patients fulfilled the diagnostic ACLF-criteria in the 3-month pre-transplant period. Compared to non-ACLF patients, ACLF was associated with significantly higher short-term morbidity and mortality after OLT (90-day patient survival 96.1% non-ACLF versus 72.4% ACLF patients, $p < 0.0001$). Clinical improvement in the pre-transplant period, as defined by recovery of at least one previously failed organ system, was observed in 37 of 98 ACLF patients, mostly within several days after diagnosis. Most notably, clinical improvement prior to OLT was associated with excellent post-transplant survival rates that approximated non-ACLF OLT recipients. Following the 90-day post-transplant period, patient survival and long-term graft functions were comparable between ACLF and non-ACLF OLT recipients for up to five years.
Conclusion: Given the dismal prognosis of ACLF, our results indicate that ACLF patients can be transplanted with comparably good outcomes, in particular patients who improve under conservative therapeutic measures.

FRI-059
High mortality after liver transplantation for cirrhotic patients with previous spontaneous peritonitis occurring within one year prior to transplantation
M. Elnegouly[1], E. Matevossian[2], K. Lange[2], S. Thorban[2], M. Abdelhafez[1], R.M. Schmid[1], M. Guba[3], A. Umgelter[1]. *[1]Klinikum rechts der Isar der Technischen Universität München, 2nd Medical Department, Munich, Germany; [2]Klinikum rechts der Isar der Technischen Universität München, Department of Surgery, Munich, Germany; [3]Großhadern Clinic, University of Munich, Department of General, Visceral and Transplant Surgery, Munich, Germany*
Email: mayada.elnegouly@tum.de

Background and Aims: Infection is a leading cause of acute-on-chronic liver failure (AoCLF) and death in patients with end-stage liver disease. Spontaneous Bacterial Peritonitis (SBP) is the commonest infection in those group of patients. In urgency based liver allocation systems high MELD scores resulting from AoCLF may prioritize patients after infection for transplantation (OLT). Post-OLT mortality of these sicker patients may be higher. The aim of the study is to evaluate the impact of SBP occurring within one year before transplantation on mortality within one year after transplantation.
Method: A retrospective analysis of all liver transplants for cirrhotic patients at a German University Center since introduction of MELD-based allocation was performed. The association between SBP during one year before transplantation and mortality within one year after transplantation was analyzed.
Results: A total of 147 patients (107 (72.8%) male, mean age 57 ± 9 years) were included. Child-Pugh-class was A in 15 (17.0%), B in 57 (38.8%) and C in 65 (44.2%). Laboratory MELD at allocation was 18 (13–24). Ten patients had laboratory MELD scores >35, 49 (33.3%) patients had exceptional MELD scores, mostly (n = 40 (27.3%)) for HCC within Milan criteria. 26 patients had at least one episode of SBP one year prior to transplantation. The most recent episode of SBP was culture-positive in 10 (38.5%) patients yielding gram-positive cocci in 5 and gram-negative rods in another 5.
Mortality during one year after transplantation was 25.2%. Mortality of patients with (n = 26) or without (n = 121) SBP during one year before transplantation was 61.5% and 17.4%, respectively ($p < 0.001$). In univariable analysis, mortality after OLT was associated with Age (OR 1.067; 95% confidence interval (CI) 1.014–1.122; p = 0.012), MELD (OR 1.046; 95% CI 1.009–1.084; p = 0.014) and SBP (OR 7.619; 95% CI 3.038–19.110; $p < 0.001$).
In multivariable analysis including MELD, SBP and age, only age (OR 1.104; 95% CI 1.040–1.172; p = 0.001) and SBP (OR 9.354; 95% CI 3.049–28.718; $p < 0.001$) were independently associated with mortality
Conclusion: SBP defines a subset of patients with a higher mortality after OLT.

FRI-060
Sofosbuvir-based antiviral therapy in patients with HCV recurrent infection after liver transplant had a high rate of SVR but can be a trigger to a graft rejection
A. Araujo, M.T. Michalczuk, A.B. Lopes, M.R. Álvares-Da-Silva. *Hospital de Clinicas de Porto Alegre, Department of Gastroenterology, Brazil*
Email: alexandredearaujo12@gmail.com

Background and Aims: Recurrent HCV infection after liver transplant (LT) has a negative impact on graft and patient survival. The aim of this study is to describe the efficacy and safety of Sofosbuvir (SOF-based) regimens in the treatment of recurrent HCV after LT. liver transplant.
Method: This study included 68 adults with recurrent HCV after LT, treated with different SOF-based regimens between March 2015 and December 2016. The choice of regimens, their duration and use of ribavirin (RBV) was performed by their treating physician. The efficacy of antiviral treatment was assessed by sustained viral response 12 weeks after the end of treatment (SVR12), according to intention-to-treat analysis.

Table 1: Baseline characteristics of the study population

Patients characteristics	n = 68
Genotype	
1	36 (52.9%)
1a	16
1b	15
2	
3	2 (3%)
	30 (44.1%)
Male	48 (70.6%)
PEG experienced	46 (67.6%)
Cirrhosis	7 (10.2%)
Decompensated cirrhosis	2 (3%)
F3	4 (5.8%)
SOF + DCV	63 (92.6%)
SOF + SMV	3 (4.4%)
SOF + RBV	2 (3%)
RBV use	56 (82.3%)
12 weeks treatment	66 (97%)

SOF: sofosbuvir; DCV: daclatasvir; SMV: simeprevir; RBV: ribavirin

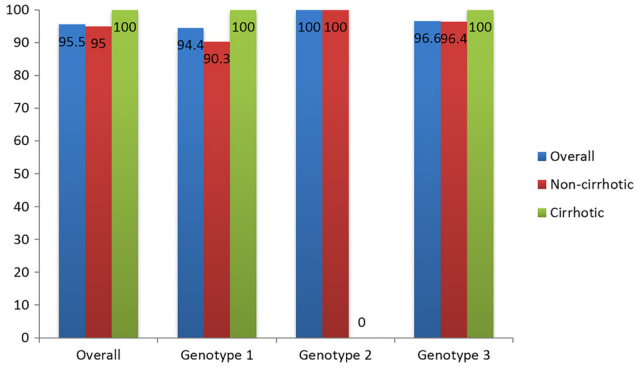

Figure 1: SVR12 according HCV genotype and cirrhosis status

Results: The most frequent HCV genotypes were 1 and 3 (n = 35, 51.4% and n = 31, 45.6%, respectively). 22 patients were treatment naïve

Table 2: (abstract: FRI-060): Characteristics of four patients with severe graft rejection after HCV clearance

Patient	Age (years)	Gender	Time to DAA therapy after LT (months)	Immunos supressive regimen	Antiviral therapy	Liver biopsy	Treatment	Outcome
1	68	F	10	Tac + MMF+ Ev	SOF + DCV+ RBV	PCR	IS4	Remission
2	59	M	52	Tac	SOF + DCV+ RBV	TCR (RAI 6)	IS4	CR
3	47	M	42	Tac	SOF + DCV+ RBV	TCR (RAI 5)	MPT + IS4	Remission

DAA: Direct-activing Antiviral Therapy; Tac: Tacrolimus; MMF: Mycophenolate Mofetil; Ev: Everolimus; IS4:Tac + MMF+ Ev + Prednisone; PCR: Plasma-Cell Rejection; TCR: T-Cell Mediated Rejection; RAI: Rejection Activity Index; CR: Chronic Rejection; MPT: Methylprednisolone Pulse Therapy; IS3:Tac + MMF + Prednisone

(32.3%) and 7 had cirrhosis (10.2%). SOF + daclatasvir (DCV) was the most commonly used regimen (n = 63, 92.6%). Most patients used RBV (n = 56, 82.3%) and were treated for 12 weeks (n = 66, 97%). Overall SVR12 was 95.5% (65/68 patients). Three patients had virological failure. Three patients had serious adverse events, however, no one discontinued treatment prematurely. Anemia was the most frequent adverse event (n = 34, 50%). Four patients had severe graft cellular rejection after HCV elimination, while maintaining stable immunosuppression.

Conclusion: SOF-based therapy is highly effective and safe to treat HCV recurrence after LT. The lymphocytic exhaustion induced by the persistent HCV antigenic exposure could be restored after HCV clearance with DAA. This form of immune reconstitution could be the trigger to T-Cell mediated graft rejection and needs further studies.

FRI-061

Donor liver small droplet macrovesicular steatosis is associated with reduced graft survival after liver transplantation

F. Ferri[1], A. Molinaro[2], E. Poli[1], L. Parlati[3], B. Lattanzi[1], G. Mennini[1], F. Melandro[1], F. Nudo[1], F. Pugliese[1], F. Maldarelli[1], A. Corsi[1], M. Riminucci[1], M. Merli[1], M. Rossi[1], S.G. Corradini[1]. [1]*Sapienza Università di Roma, Roma, Italy;* [2]*Università di Göteborg, Sweden;* [3]*Hospital Cochin, Paris, France*
Email: flaminia.ferri@gmail.com

Background and Aims: Modern hepatic steatosis classification includes large droplet macrovesicular (L-MaS), small droplet macrovesicular (S-MaS) and true microvesicular (MiS). Based on previous classification simply describing macrovesicular and microvesicular steatosis, donor livers with ≤30% of hepatocytes with macrosteatosis, which should represent L-MaS, are considered safe to be transplanted, while microsteatosis is usually not considered a risk factor for graft loss. Microsteatosis is differently associated with the type and severity of hepatocellular damage, according to the presence or absence of hepatitis c virus (HCV) infection. Thus, we analyzed the impact of steatosis on post-transplant liver graft survival, separately in HCV-RNA negative (HCV-) and positive (HCV+) recipients.

Method: We retrospectively analyzed 206 routinely performed pre-ischemia graft biopsies in consecutive adult patients submitted to deceased-donor liver transplantation in our Center between 2001 and 2011. Steatosis was defined as follows: L-MaS as one or few large vacuoles in the cytoplasm with nuclear displacement; S-MaS as few or discrete vacuoles in the cytoplasm without nuclear displacement; MiS as intracytoplasmic accumulation of numerous, tiny and undiscernable vesicles with a foamy appearance. Graft ATP content was measured by bioluminescence assay.

Results: Only 2 grafts had MiS and were excluded from the statistical analysis. The maximum L-MaS was 40% (6 grafts). A S-MaS ≥40% was present in 9 grafts. The median follow-up was 2432 and 2264 days respectively for the HCV – (n = 122) and HCV+ (n = 82) patients. At Cox regression analysis, in the HCV – group S-Mas >15% was independently associated with overall graft loss (HR 2.386, 95% CI 1.176–4.841, p = 0.005), after normalization for several recipient, donor and intraoperative variables. No association of graft survival was found with L-MaS in the HCV – group and with both S-MaS and L-MaS in the HCV+ group. In HCV – but not in HCV+ recipients, the first three post-operative days serum AST peak positively correlated with S-MaS. Graft S-MaS >15% was associated with reduced graft ATP content.

Conclusion: A donor liver graft S-MaS >15% is associated with low graft ATP content. S-MaS is associated with clinical signs of severe ischemia reperfusion damage and with reduced graft survival only in HCV – recipients. These data are relevant for organ allocation and because the percentage of HCV – recipients is rapidly increasing.

Liver transplantation in HIV patients: a descriptive cohort study

S.C. Branco[1], J. Martins[2], J. Gandara[3], V. Lopes[3], J. Daniel[3], H.P. Miranda[3], S. Ferreira[3]. [1]*Medicina Interna;* [2]*Medicina Interna, Portugal;* [3]*Unidade de transplantação hepática e pancreática*
Email: sara.castellobranco@gmail.com

Background and Aims: With the widespread use of highly antiretroviral therapy, survival of the HIV-infected patients has improved over the last years. Conversely, end stage liver disease has become an important cause of death among these patients and liver transplantation (LT) is becoming the best treatment option for selected cases. The aim of this study was to describe the clinical characteristics of the HIV-infected patients at time of evaluation for LT and the outcomes of LT.

Methods: All HIV patients referred for their first LT evaluation at Centro Hospitalar do Porto between 2009 and 2017 were included in this retrospective, descriptive cohort study.

Results: Forty-four HIV patients were evaluated for LT, with 11 (25%) listed for LT and 33 (75%) not listed. Two patients (4,5%) died during the evaluation process and 13 (29,5%) were too early for listing. The median age was 46 (±7) years. The major HIV risk factor was the use of intravenous drugs (84%). The underlying cause of liver disease was hepatitis C (89%) and the majority of patients had detectable HCV RNA (74%). Eighteen patients (41%) were declined for listing and the major reasons were psychosocial (44%) and HIV related (38%). The median MELD score at first evaluation and at LT were 10 (±5) and 15,3 (±7), respectively. All patients listed were transplanted (except for one who is still waiting) and the average time between the first evaluation and LT was 16,5 months. Within the transplanted patients, 50% died and the median MELD score at first evaluation and at LT in this subgroup was 11,6 (±5) and 17,8 (±8), respectively.

Conclusion: After the first major decompensation of their liver disease, HIV-infected patients have a rapid progression to death. Thus, it is extremely important to recognize the clinical characteristics of these population and the ideal referring time for LT. As previously reported, attention should be paid to the MELD score as it is a predictor for death and a crucial tool to indicate LT.

Email: sophie.lotersztajn@inserm.fr

Background and Aims: Persistent chronic inflammation along with immune dysfunction is a major driving force of chronic liver disease progression to fibrosis. Mucosal-Associated Invariant T (MAIT) cells are unconventional T cells characterized by the invariant TCR-chain, Vα7.2 in humans (Va19 in mice) and restricted by the non-classical MHC-1b molecule, MR1. Owing to their involvement in the pathogenesis of various infectious, autoimmune and chronic inflammatory diseases, we hypothesize that MAIT cells may be involved in immune-dysfunction associated with liver fibrosis.
Method: MAIT ($CD161^{hi}$ $Va7.2^{+}$) cells were analyzed in the PBMC of cirrhotic patients (decompensated (n = 59), compensated (n = 15)) of alcoholic and non-alcoholic origin, in comparison with healthy donors (n = 47) by FACS. Liver MAIT cells were analyzed by FACS and immunofluorescence labeling. Functional relevance of MAIT cells was studied in mice deficient ($MR1^{-/-}$) or enriched (Vα19TCRTg) in MAIT cells, following chronic challenge with CCl_4 or bile duct ligation. Interactions between human MAIT cells and human hepatic myofibroblasts (HMF) were studied in *in-vitro* co-culture experiments.
Results: MAIT cell frequency was reduced in PBMC from cirrhotic patients and was independent of cirrhosis etiology and severity. Peripheral MAIT cells from cirrhotic patients displayed an activated phenotype with increased CD25 and CD69, and produced increased levels of intracellular IL-17 and granzyme B. Despite their reduced frequency, MAIT cells in cirrhotic livers preferentially accumulated along the fibrotic septa. However cirrhotic liver MAIT cells showed an activated phenotype as evidenced by increased intracellular IL-17 production. Moreover, cirrhotic MAIT cells displayed exhaustion features, as revealed by increased expression of TIM-3 and PD-1 compared to MAIT cells from control livers. *In vivo*, following chronic administration of CCl_4 or bile duct ligation, Vα19TCRTg mice showed exacerbated fibrosis and accumulation of fibrogenic cells, while $MR1^{-/-}$ mice were resistant. Profibrogenic properties of MAIT cells were related to mitogenic effects on HMF, as demonstrated in co-culture experiments. HMF expressed MR1, and MAIT cell-induced proliferation of HMF was reduced by an anti MR1 antibody.
Conclusion: Our results reveal a novel pro-fibrogenic role for MAIT cells in liver injury and identify MAIT cells as a novel target for anti-fibrogenic therapy.

FRI-064

Effects of a PEGylated fibroblast growth factor 21 variant on steatosis, inflammation, and fibrosis in a mouse model of non-alcoholic steatohepatitis

B. Zinker[1], S. Boehm[1], S. Gao[1], A. He[1], B. Strassle[2], P. Morin[3], R. Christian[3], J. Krupinski[3]. *[1]Bristol-Myers Squibb, Pennington, United States; [2]Bristol-Myers Squibb, Lawrenceville, United States; [3]Bristol-Myers Squibb, Lawrenceville*
Email: bradley.zinker@bms.com

Background and Aims: Analogues of fibroblast growth factor 21 (FGF21), a key regulator of lipid and glucose metabolism, improve insulin sensitivity, lipid profiles, steatosis, and fibrosis in preclinical and clinical studies of non-alcoholic steatohepatitis (NASH). Here, the effects of a PEGylated-FGF21 variant (PEG-FGF21v) were examined in the choline-deficient amino acid-defined, high-fat diet (CDAHFD) mouse model of NASH and liver fibrosis.
Method: C57BL/6J mice were fed either normal chow or a CDAHFD (60% kcal from fat, 0.1% methionine), which induces NASH. Mice (10/group) received twice weekly (BIW) subcutaneous (SC) injections of 0.6 mg/kg PEG-FGF21v for either 4 or 8 wks after 4 wks on CDAHFD, or for 4 wks after 8 wks on CDAHFD. Control mice were fed normal chow or CDAHFD, and were given vehicle BIW SC corresponding to the diet and treatment (tx) durations above. Mice were maintained on their respective diets until sacrificed; their plasma and livers were harvested for biochemical, histological, and gene expression analyses.
Results: Mice fed a CDAHFD (4 wks) compared with normal chow showed increased hepatic triglycerides (TG) and reduced adiponectin levels (−30% to −40%). In CDAHFD-fed mice (4 wks), PEG-FGF21v tx for 4 or 8 wks reduced TG similar to mice on normal chow, reduced body weight (12%–22% vs vehicle tx), and improved adiponectin levels compared with vehicle tx (48%–139%; $p < .05$). PEG-FGF21v tx vs vehicle tx significantly reduced hepatic steatosis (−60% to −80% change by morphometry [CBM] on H&E-stained liver sections [SLS]), microgranulomatous inflammation (−40% CBM on MAC-2 IHC-SLS), and fibrosis (−15% to −50% CBM of trichrome-SLS; and −62% to −75% change in hydroxyproline content) in CDAHFD-fed mice (all $p < .05$). Additionally, gene expression markers of fibrosis (eg, *Col1a1*, *Col1a2*, *Col3a1*, *Itga2*, *Lox*) and inflammation (eg, *Spp1*, *Tnf*, *Ccl2*, *Ccl3*) were reduced with PEG-FGF21v tx vs vehicle tx ($p < .05$). After 8 wks of a CDAHFD, 4 wks of PEG-FGF21v tx compared with vehicle tx reduced hepatic steatosis, fibrotic and inflammatory gene markers (all $p < .05$), but had no effect on liver fibrosis.
Conclusion: In a CDAHFD mouse model of NASH, tx with PEG-FGF21v increased plasma adiponectin, and reduced body weight, hepatic steatosis, inflammation, and fibrosis (by histology and hydroxyproline content) and gene expression of markers of fibrosis and inflammation. These data further support the benefits of PEG-FGF21v analogues for the tx of NASH.

FRI-065

Cholesterol-mediated expression of ganglioside GD3 acetylation contributes to liver fibrogenesis

C. Vallejo[1,2], V. Ribas[1,2,3], D. Robles[1,2], S. Torres[1,2], J. Ramos[1], J. Caballeria[2,3,4], M. Elena[2,4], José Fernandez-Checa[4], M.C. Garcia-Ruiz[4]. *[1]Instituto de Investigaciones Biomédicas de Barcelona-CSIC; [2]IDIBAPS; [3]Centro de Investigación Biomédica en Red (CIBERehd); [4]Liver Unit-Hospital Clinic i Provincial de Barcelona-UB*
Email: carmen.garcia@iibb.csic.es

Background and Aims: Liver fibrosis is an indication of advanced chronic liver disease caused by different etiologies, including NASH that can lead to progressive liver dysfunction and failure. Cholesterol (chol), and particularly mitochondrial-chol accumulation, has emerged as a key factor in NASH. Moreover, cholesterol has been shown to promote liver fibrogenesis through activation of hepatic stellate cells (HSC). Ganglioside GD3 is a glycosphingolipid that induces apoptosis by a dual mechanism involving MMPT and inactivation of NF-κB-dependent survival program. Recent findings

have shown that GD3 acetylation by O-acetyl disialoganglioside synthase (OAcGD3S) antagonizes the proapoptotic actions of ganglioside GD3. As the relationship between cholesterol and the status of ganglioside GD3 in liver fibrosis has not been explored, our aim was to investigate the effects of nutritional cholesterol feeding in GD3 synthesis and acetylation and in HSC and impact in liver fibrogenesis.

Method: Free cholesterol levels in HSC were induced by incubation of HSC with cholesterol and an inhibitor of ACAT. Eight weeks old male C57BL/6J mice were fed a 60% high fat diet enriched in 0.5% with cholesterol (HFHC) for up to six months. Expression of a-SMA, Col1A1, TGFb, PDGF, GD3 levels and OAcGD3S were analyzed by WB and IHC. The impact of OAcGD3S silencing was examined in the activation of HSC in vivo and in mice fed HFHC. Moreover, OAcGD3S expression was monitored in human biopsies from subjects with chronic liver disease.

Results: Cultured HSC challenged with cholesterol increased HSC activation and stimulated the levels of ganglioside GD3 and its acetylated form. Mice fed a HFHC diet showed increased liver damage, hepatomegaly, and inflammation. HFHC feeding increased StARD1 expression and cholesterol levels in HSC and translated in enhanced levels of a-SMA, Col1A1, TGFb, and PDGFRb (protein and mRNA). Liver tissue hydroxyproline levels, carbonylated proteins, Sirius red and DHE staining revealed increased levels in samples from HFHC-fed mice. The gene expression and IHC time-course of aSMA, PCNA, GD3 and 9-O-acetyl GD3, showed a progressive and extensive expression from 1 to 6 months. In vivo OAcGD3S silencing through intravenous adenovirus administration prevented HSC activation and GD3 acetylation, resulting in reduced liver fibrogenesis markers. In vitro studies indicated that TUDCA ameliorated cholesterol-mediated HSC activation, pointing to cholesterol-induced ER stress as a key mechanism linking cholesterol to GD3 acetylation in HSC biology and liver fibrosis. Importantly, samples from patients with chronic liver disease exhibit increased GD3 and GD3 acetylated expression.

Conclusion: Dietary cholesterol induced liver damage and fibrogenesis is mediated, in part, through GD3 acetylation, suggesting that OAcGD3S emerges as a potential target to regulate liver fibrosis.

FRI-066

Inducible ablation of TGFß receptor type 2 limited to hepatic stellate cells potently inhibits liver fibrosis and attenuates inflamation

O. Molokanova[1], K. Schönig[2], S.-Y. Weng[1], X. Wang[1], S. Ohngemach[3], A. Nikolaev[4], D. Strand[5], L. Eshkind[3], D. Schuppan[6], S. Lorenz[5].
[1]University Medical Center, Johannes Gutenberg University, Mainz, Germany, Institute of Translational Immunology, Mainz, Germany; [2]Central Institute of Mental Health, Medical Faculty Mannheim / Heidelberg University, Mannheim, Germany, Department of Molecular Biology, 68159 Mannheim, Germany; [3]University Medical Center, Johannes Gutenberg University, Mainz, Germany, Translational Animal Research Center (TARC), Mainz, Germany; [4]University Medical Center, Johannes Gutenberg University, Mainz, Germany, Institute of Molecular Medicine, Mainz, Germany; [5]University Medical Center, Johannes Gutenberg University, Mainz, Germany, Dept. of Medicine I, Mainz; [6]Institute of Translational Immunology, Research Center for Immune Therapy (FZI), University Medical Centre Mainz, Mainz, Germany
Email: lemol1970@gmx.de

Background and Aims: Transforming growth factor β (TGFβ) is a central fibrogenic activator of hepatic stellate cells and myofibroblasts (HSC). However, TGFβ also profoundly modulates almost all other cell types, including immune cells, and its general genetic ablation causes early lethality in mice due to severe intestinal inflammation. We therefore generated and tested a conditional knock-out mouse of TGFßRII in activated HSC, to assess the effect on liver fibrosis and inflammation.

Method: An activated myofibroblast/fibroblast (HSC) specific promoter driven Col3a1-CreERT2 mouse was generated by microinjection of a purified, linearized Col3a1-CreERT2 BAC DNA fragment into the pronucleus of C57BL/6N oozytes. The Col3a1-CreERT2 mice were bred with TGFbR2 flox/flox mice to generate Col3a1CreERTΔTGFbR2fl/fl mice. The bi-transgenic mice were treated with escalating doses of oral CCl4 for three weeks to induce advanced parenchymal liver fibrosis. A group of Col3a1CreERTΔTGFbR2fl/fl mice was treated with tamoxifen, to activate Cre recombinase and induce TGFßRII gene excision (5 injections during the three week fibrosis induction). Matched wildtype mice treated with tamoxifen served as additional controls. Livers were analyzed using histology, immunohistochemistry, biochemical and morphometrical determination of collagen, and qPCR.

Results: In the induced Col3a1-CreERTΔTGFbR2fl/fl mice Sirius red stained collagen area was reduced by 47% (both $p < 0.001$), total liver collagen (hydroxyproline content) by 40% ($p < 0.01$), and α-SMA positive HSC were suppressed by 57% ($p < 0.001$). This was accompanied by a significant dowregulation of key fibrogenic transcripts. Notably, histological inflammatory infiltrates, necro-apoptotic hepatocytes and serum ALT and AST significantly reduced in the conditional HSC-TGFßRII ablated vs the control mice.

Conclusion: 1. We generated the first (activated) HSC-specific inducible knockout mice. 2. HSC-specific disruption of TGFß signaling using Col3a1CreERTΔTGbR2fl/fl mice potently inhibits fibrosis progression. 3. Notably, the HSC-specific TGFbR2 ablation also attenuated hepatic inflammation, a detrimental side-effect of general TGFß blockade, possibly via beneficially affecting the structure and function of the extracellular matrix as coactivator of inflammation. 4. Inhibition of TGFßRII, when targeted to HSC, is a highly promising antifibrotic therapy.

FRI-067

Caspase-8 is a gender-specific modulator of chronic cholestatic liver disease in female Mdr2 knockout mice.

J. Jung, D. Lambertz, U. Haas, R. Sonntag, C. Trautwein, C. Liedtke.
University Hospital RWTH Aachen, Department of medicine III, Aachen, Germany
Email: julia.hennings@rwth-aachen.de

Background and Aims: Females are more susceptible to hepatic cholestasis, but the underlying mechanisms are incompletely understood. Mdr2 knockout ($Mdr2^{-/-}$) mice are a well-established animal model of human primary sclerosing cholangitis (PSC) also comprising enhanced fibrosis susceptibility in female mice. We aimed to investigate the impact of extrinsic apoptosis in PSC by deleting Caspase-8 in hepatocytes of $Mdr2^{-/-}$ mice.

Method: $Mdr2^{-/-}Casp8^{\Delta hepa}$ double knockout mice were generated in a C57Bl/6 background by crossing $Mdr2^{-/-}$ mice with animals lacking Caspase-8 in hepatocytes ($Casp8^{\Delta hepa}$). Cre-negative littermates ($Mdr2^{-/-}Casp8^{f/f}$) and C57Bl/6 WT mice were used as reference. Male and female animals were analyzed for liver fibrosis by quantification of hepatic collagen deposition at the age of 12, 26 and 52 weeks. Expression of genes related to inflammation, cell death, proliferation and cancer was determined by qPCR.

Results: In good agreement with earlier studies we detected increased liver fibrosis in female compared to male $Mdr2^{-/-}$ mice at the age of 26–52 weeks. Unexpectedly, deletion of Caspase-8 in male $Mdr2^{-/-}$ mice did not affect the degree of liver fibrosis at any age investigated. However, in female $Mdr2^{-/-}$ at the age of 26 weeks, concomitant inactivation of Caspase-8 triggered approximately 2fold increased gene expression of Tumor Necrosis Factor alpha (TNF) and Receptor-interacting serine/threonine-protein kinase 3 (RIPK3). Of note, both genes are involved in regulating inflammation and programmed cell death including apoptosis and necroptosis. In contrast, basal TNF and RIPK3 gene expression was not different between male and female WT or $Mdr2^{-/-}$ mice suggesting that the observed gender disparity observed in $Mdr2^{-/-}Casp8^{\Delta hepa}$ mice was

provoked specifically by Caspase-8 deletion. In addition, we found a significant correlation between the fibrosis level in 26 week old Mdr2$^{-/-}$Casp8$^{\Delta hepa}$ mice and gene expression levels of RIPK3, Cyclin E2 (involved in cell cycle regulation) and c-myc (related to fibrosis and cancer). In agreement with these findings, loss of Caspase-8 significantly enhanced liver fibrosis exclusively in female Mdr2$^{-/-}$ mice at the age of 52 weeks reflecting a stage of advanced disease progression.
Conclusion: Caspase-8 is dispensable for initiation and progression of liver injury in male Mdr2$^{-/-}$ mice. However, ablation of Caspase-8 triggers significantly elevated liver fibrosis in female Mdr2$^{-/-}$ mice which precedes enhanced gene expression of TNF and RIPK3. Thus Caspase-8 can be considered as a gender-specific modulator of death pathways in the cholestatic liver.

FRI-068
Novel pro-fibrotic properties of macrophage migration inhibitory factor in non-alcoholic steatohepatitis is associated with a shift in natural killer T cell populations
D. Heinrichs[1], E.F. Brandt[1], P. Fischer[1], J. Koehncke[1], T. Wirtz[1], S. Djudjaj[2], P. Boor[2], R. Bucala[3], D. Kroy[1], F. Schumacher[1], H. Wasmuth[1], C. Trautwein[1], Jürgen Bernhagen[4], M.-L. Berres[1].

Email: dheinrichs@ukaachen.de

Background and Aims: The cytokine macrophage migration inhibitory factor (MIF) shows inflammatory properties and has chemokine-like functions. In previous models of chronic liver injury, MIF shows anti-fibrotic and anti-steatotic properties via the receptor CD74 and the stress kinase AMPK. Because the pathophysiology of chronic non-alcoholic steatohepatitis is associated with liver fibrosis, we here investigated the role of MIF on liver fibrosis in the methionine-choline deficient (MCD)-diet-model. This model combined fibrosis formation and steatohepatitis within the liver of the mice.
Method: *Mif* gene-deficient (*Mif*$^{-/-}$), hepatocyte-specific *Mif* gene-deficient (*Mif*$^{\Delta hep}$) and wild-type mice were fed an MCD diet. Fibrosis was analyzed histologically by Sirius Red stainings, by hydroxyproline content and intrahepatic mRNA expression of fibrosis-related genes. Immune cell infiltration was determined by flow cytometry analysis. *In vitro* stimulation experiments with recombinant MIF were performed in isolated murine NKT cells. Furthermore, mRNA expression patterns of fibrosis marker and NKT marker from NASH patients were correlated.
Results: In contrast to prior findings in hepatotoxic fibrosis models, *Mif*$^{-/-}$ and *Mif*$^{\Delta hep}$ mice showed decreased fibrosis after MCD diet as assessed by histology and hepatic collagen levels. Reduced liver fibrosis was associated with a strong down-regulation of fibrosis-relevant genes in *Mif*$^{-/-}$ and *Mif*$^{\Delta hep}$ mice and a substantial reduction of stellate cell activation. FACS analysis revealed no difference in monocyte or lymphocyte infiltration between *Mif*$^{-/-}$ and wild-type mice; however, the NKT cells were skewed to type II subpopulation in *Mif*$^{\Delta hep}$ mice. *In vitro* studies show a direct effect of recombinant MIF on NKT cell polarization. MIF favored the pro-fibrotic type I NKT subtype. Gene expression analysis between fibrosis marker and NKT subtype marker show strong correlations in human NASH patients.
Conclusion: In the metabolism-driven MCD liver fibrosis model, MIF exacerbates liver fibrosis. Our new results show a yet undiscovered relation of MIF and NKT cell subsets within the liver. NKT cell subsets are skewed towards the pro-fibrotic type I NKT subtype by MIF. These findings offer a novel mechanism through which MIF affects liver disease dependent on the pathogenic context.

FRI-069
High density lipoproteins production induced by selective intestinal LXR activation protects against the progression of liver injury by shifting M1 to M2 Kupffer cell phenotype
I. Pierantonelli[1], C. Pinto[1], C. Rychlicki[1], D.M. Giordano[1], L. Trozzi[1], M. Marzioni[1], A. Benedetti[1], G. Svegliati-Baroni[1,2]. *[1]Università Politecnica delle Marche, Department of Gastroenterology and Hepatology, Ancona, Italy; [2]Università Politecnica delle Marche, Obesity Center, Ancona, Italy*
Email: pierantonelli_irene@libero.it

Background and Aims: Liver fibrosis is the result of wound healing response during chronic liver injury. Liver X receptor (LXR) exerts anti-inflammatory and anti-oxidant effects, but its activation is associated with hypertriglyceridemia and liver steatosis, due to hepatic fatty acid synthesis. However, its selective induction in the gut might regulate hepatic inflammation and fibrogenesis via specific gut-liver signaling.
Method: Mice with an intestinal constitutive LXRα activation (iVP16LXRα) and their controls (iVP16) were exposed to i.p. injection of carbon tetrachloride twice a week for 8 weeks.
Results: iVP16LXRα mice showed a lower expression of the hepatic pro-inflammatory genes NF-kB, TNF-α, IL-6 and MCP-1 ($p < 0.005$; $p < 0.05$; $p < 0.05$ and $p < 0.005$ respectively vs iVP16) that was associated with reduced macrophage infiltration by immunohistochemistry for the macrophage marker F4–80 ($p < 0.05$). The suppression of liver inflammation was coupled with decreased fibrogenesis, measured by immunohistochemistry for α-SMA and by TGF-β expression (both $p < 0.005$ vs iVP16). Reduced hepatic stellate cells activation in iVP16LXRα decreased collagen deposition, quantified by morphometry for Sirius Red staining ($p < 0.0005$) and hydroxyproline content ($p < 0.05$). Gut selective activation of LXRα induced the synthesis of high density lipoproteins (HDL), as shown by increased gene expression of intestinal ABCA1 and by the quantification of plasmatic lipoproteins (both $p < 0.005$), without affecting mucosal inflammation (evaluated by H&E and immunohistochemistry for CD3). These beneficial effects did not induce metabolic side effects, as shown by hepatic expression of SREBP1c and its downstream target FAS and by the quantification of hepatic triglyceride content. The anti-inflammatory effect of HDL was demonstrated by the shift from pro-inflammatory (M1) to anti-inflammatory (M2) hepatic macrophage phenotype, as shown by STAT6-dependent increase of Arginase-1 (both $p < 0.0005$ vs iVP16). The anti-inflammatory properties of HDL were confirmed *in vitro* when Kupffer cells activation, measured by gene expression of TNF-α, IL-6, IL1β and MCP-1 ($p < 0.05$) was restored by HDL pre-incubation.
Conclusion: Specific intestinal LXRα activation might represent a new target for the treatment of liver fibrosis by modulating macrophage response to injury, thus reducing hepatic inflammation without the occurrence of the side effects related to hepatic LXR induction.

FRI-070
Increased expression of pregnancy-associated plasma protein-A in activated hepatic stellate cells is a potential therapeutic target and serum marker of hepatic fibrosis
F. Kim, C. Hellerbrand. *Friedrich-Alexander University Erlangen-Nürnberg, Institute of Biochemistry, Erlangen, Germany*
Email: claus.hellerbrand@fau.de

Background: Pregnancy-associated plasma protein-A (PAPP-A) was firstly discovered as a placental protein present in the circulation of pregnant women. Recently, we have discovered PAPP-A as a tumor promotor in hepatocellular carcinoma applying causal modeling (PLoS Comput Biol. 2015;11(5):e1004293). PAPP-A is a metalloproteinase that specifically cleaves insulin-like growth factor (IGF) binding proteins (IGFBPs). The IGF-system is known to play a role in hepatic fibrosis, however, the expression and function of PAPP-A in chronic liver disease is unknown.

The aim of this study was to analyze the expression and function of PAPPA in liver fibrosis.
Methods and Results: Quantitative RT-PCR analysis revealed significantly increased PAPP-A expression in different murine models of hepatic fibrosis (TAA-induced liver injury A, bile duct ligation, dietary NASH-models). Furthermore, PAPPA expression revealed a significant correlation with collagen I and alpha-smooth-muscle expression in human hepatic tissue specimens from patients with chronic liver disease, and PAPPA serum levels were significantly increased in patients with cirrhosis as compared to individuals without liver disease. Fitting to this, PAPPA expression significantly increased in hepatic stellate cells (HSC) during *in vitro* activation, and siRNA-mediated PAPPA suppression in activated HSC resulted in reduced PAPPA secretion into the supernatant. Furthermore, PAPPA suppressed HSC showed significantly reduced proliferation. Next, we isolated primary HSC from PAPPA-deficient (PAPPA-/-) and wildtype (wt) control mice. Histomorphological analysis and monitoring of markers of HSC activation revealed a significantly retarded *in vitro* activation process in PAPPA-/- HSC. Furthermore, fully activated PAPPA-/- HSC revealed significantly reduced proliferation. In addition to PAPP-A, we newly discovered strong expression of IGFBP-4 in activated HSC, and analysis of human activated HSC isolated from 14 different donors revealed a significant correlation between PAPP-A and IGFBP-4 expression. In the model of bile duct ligation, PAPPA-/- revealed significantly reduced HSC activation and fibrosis.
Summary and Conclusions: PAPP-A expression and secretion increase during HSC activation, and our data suggest that this leads to an autocrine induction of HSC proliferation, potentially via cleavage of IGFBP-4 and consecutive release of (bioactive) IGF. Future studies need to examine the potential of PAPP-A as a therapeutic target, and the impact of inter-individual differences in PAPP-A/ IGFBP-4 for the development and progression of hepatic fibrosis. Furthermore, circulating PAPP-A levels could have potential as potential novel biomarker for hepatic fibrosis.

FRI-071

Oncostatin M regulates the role of macrophage during progression and resolution of hepatic fibrosis

M. Matsuda, M. Tanaka. *National Center for Global Health and Medicine, Regenerative Medicine, Tokyo,*
Email: michimtd@gmail.com

Background and Aims: Hepatic macrophages (HM) contribute both fibrosis progression and resolution. However, underlying mechanism regulating these opposing roles of HM is to be elucidated. We have recently reported Oncostatin M, a member of IL-6 family cytokines, causes fibrosis progression by regulating cooperation between hepatic stellate cell (HSC) and macrophages during chronic liver injury (CLI) (Hepatology 2017). Base on these findings, this study aims to elucidate the role of OSM in fibrosis resolution by focusing on origin and phenotype of HM.
Method: Hepatic fibrosis was developed by the administration of 0.03% thioacetamide in drinking water for 12 weeks. After cessation of TAA, spontaneous resolution of fibrosis was evaluated. Continuous expression of OSM in the normal liver was enabled by hydrodynamic tail vein injection (HTVi). HSC and HM was isolated and cultured to examine the effect of OSM. HM was further divided into F4/80^{hi} CD11b^{lo} resident macrophage (KC) and F4/80^{lo} CD11b^{hi} infiltrating macrophage (infM) based on FACS and IHC analyses. In adoptive transfer experiments, bone-marrow-monocytes/macrophages (BM) were isolated by using anti-Ly6C, Ly6G and CD115 antibodies.
Results: During TAA-induced fibrosis progression, OSM was continuously produced by immune cells in the chronically injured liver. Compared to wild type mouse (WT), OSM deficient mouse showed less severe fibrosis. Conversely, continuous expression of OSM in normal liver by HTVi (OSM-HTVi) induced fibrosis with HSC activation. *In vitro* analyses showed OSM up-regulates fibrogenic genes including TGF-beta1 in HM, leading collagen production from HSC. FACS and IHC analyses on subpopulation of HM suggested that infM is more responsible than KC for OSM-induced fibrosis. Consistently, blocking infiltration of macrophage by CCR2 inhibitor administration prevented fibrosis progression and HSC activation in OSM-HTVi. These findings suggested BM earned fibrogenic phenotype by OSM stimulation in the liver. Then we examined the role of OSM in fibrosis resolution phase. WT mouse developed severe fibrosis with 12 weeks administration of TAA and even after cessation of TAA, residual fibrosis and prolonged OSM expression was observed for at least one week. During this phase, adoptive transfer of WT BM had no effect or even exacerbated the fibrosis compared to spontaneous resolution. In contrast, adoptive transfer of OSM receptor knockout BM promoted resolution of fibrosis, suggesting BM can exert fibrolytic potential if there were no OSM signal.
Conclusion: Continuous expression of OSM is a risk factor for fibrosis during CLI and even after cessation of causative agents of CLI. OSM not only induces fibrogenic potential but also suppresses fibrolytic potential of monocyte/macrophage. OSM could be a therapeutic target for CLI patients with prolonged fibrosis even after elimination of causative agents.

FRI-072

Selective NDRP1 E3 ubiquitin ligase overexpression in inflammatory macrophages using functionalized carbon nanoparticles promotes fibrosis regression in cirrhotic mice

P. Melgar-Lesmes[1,2,3], A. Luquero[1], E. Edelman[2], W. Jiménez[1,4].
[1]*University of Barcelona, Barcelona, Spain, Department of Biomedicine, Spain;* [2]*Massachusetts Institute of Technology, Cambridge, MA, Edelman lab, Spain;* [3]*Hospital Clinic de Barcelona, Fundació Clínic per a la Recerca Biomèdica, Spain;* [4]*Hospital Clínic Universitari, IDIBAPS, CIBERehd, Barcelona, Spain, Biochemistry and Molecular Genetics Service, Spain*
Email: pmelgar@clinic.cat

Background and Aims: Hepatic macrophages are important in all stages of chronic liver disease; their activation is prognostic for survival in patients with cirrhosis. Macrophages also mediate wound repair and fibrosis by regulating extracellular matrix turnover. We investigated whether NRDP1 E3 Ubiquitin ligase might switch inflammatory M1 into pro-regenerative M2 macrophages to promote fibrosis regression in cirrhotic mice.
Method: Carbon nanoparticles, typically used to selectively stain macrophages, were covalently attached to PAMAM G5-dendrimer, and characterized by dynamic light scattering and electron microscopy. Carbon-dendrimer nanoparticles transported plasmid DNA (pDNA) expressing NRDP1 under CD11b promoter, and high constitutive levels of the fluorescent reporter GFP. Murine macrophages RAW 264.7 were used to test the uptake, functionality and activity of carbon-dendrimer-pDNA nanoparticles (CDDN) at transforming M1 to M2 macrophages. Cirrhosis was induced in ten Balb/c mice by i.p. injection of CCl_4 for 9 weeks twice a week. Cirrhotic mice received an i.v. injection of NRDP1 or scrambled-control CDDN (50 µg/Kg) every 3 days for 9 days. Tissue samples were analyzed for fibrosis by Sirius Red staining, M1 gene expression profiles and metalloproteinases by Real-Time PCR.
Results: *In vitro*: Stimulation of RAW 264.7 macrophages with TNF-α increased carbon nanoparticle uptake 7-fold (92.3 ± 1.1 vs. 13.6 ± 2.1%, $p < 0.01$). CDDN efficiently and selectively delivered NRDP1 plasmid into inflamed macrophages promoting switch to M2 subset, highlighted by the high presence of mannose receptor and increased gelatinase activity. *In vivo*: Cirrhotic mice treated with NRDP1 CDDN drastically reduced liver fibrosis (1.5 ± 0.3 vs. 11.1 ± 1.0 fibrosis area%, $p < 0.001$) and hepatic expression of markers of M1 macrophage phenotype (IL1-β: 0.5 ± 0.1 vs. 1.0 ± 0.1, $p < 0.01$; NOS2: 0.2 ± 0.0 vs. 1.1 ± 0.1, $p < 0.01$; COX-2: 0.4 ± 0.1 vs. 1.1 ± 0.1 fold change, $p < 0.05$), while increasing collagenase MMP-9 expression (2.6 ± 0.5 vs. 1.1 ± 0.1 fold change, $p < 0.05$) and recovery of parenchymal structure.

Conclusion: These outcomes show new mechanistic insights into NRDP1 regulating the behavior of macrophages in fibrosis regression, and offer an innovative strategy to combat cirrhosis.

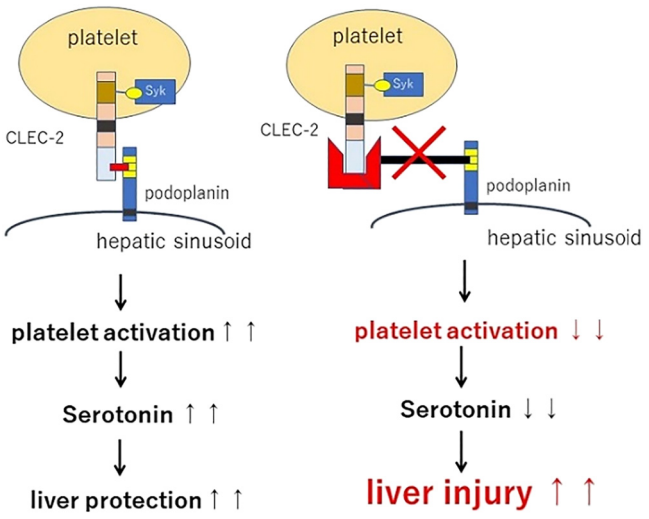
Platelet c-type lectin-like receptor reduces cholestatic liver injury in mice
S. Maruyama[1], H. Kono[1], S. Furuya[2], D. Ichikawa[1]. [1]*universitiy of yamanashi hospital, first department of surgery, chuo-yamanashi;* [2]*University of Yamanashi, First Department of Surgery, Chuo, Japan*
Email: hkouno@yamanashi.ac.jp

Background and Aims: Bile duct obstruction is caused by various factors, and lead to liver dysfunction and death due to serious complications. It was recently reported that platelets reduced cholestatic liver damage, but its mechanism has not been unclear. In addition, it was recently found that c-type lectin-like receptor (CLEC-2), new platelet receptor different from known receptors, activated platelets by binding with ligand podoplanin. CLEC-2-podoplanin interactions induced powerful platelet activation through the tyrosine kinase-dependent pathway, and facilitated tissue regeneration. Therefore, the aim of this study was to evaluate the role of CLEC-2 on cholestatic liver injury in mice.
Method: Mice (C57BL/6J, male, 9 weeks age) were intraperitoneally administered anti-CLEC-2 antibody (2A2B10) every week for deleting CLEC-2 on platelets. Then, mice were subjected to left and middle bile duct ligation(LMBDL) procedure. Mice were sacrificed 1 week later (2A2 B10-BDL group). In addition, control antibody + laparotomy alone (sham group), anti-CLEC-2 antibody + laparotomy only (2A2B10-sham group), and control-antibody + LMBDL (BDL group) were also prepared. we compared to these groups.
Results: Serum T-Bil and transaminase significantly increased in 2A2B10-BDL group, and hepatocellular necrosis also increased histologically compared to BDL group. The mRNA expression of inflammatory markers (TNF-alpha, IL-6) and fibrosis markers (Timp1, Epcam1, TGF-beta, and Col1a1) significantly increased in 2A2B10-BDL group compared to BDL group. In addition, histologically expression of MPO, Sirius red, and alpha-SMA increased in 2A2B10-BDL group. In BDL group, podoplanin was strongly expressed in hepatic sinusoid compared to sham group. Serum serotonin level, protecting from cholestatic liver injury, significantly increased in BDL group compared to sham group. In contrast, serum serotonin level did not increase in 2A2B10-group. These results suggested that anti-CLEC-2 antibody suppressed the platelet activity and the release of serotonin, as a result, the bile acid regulation failed and then caused hepatic injury.



Conclusion: Platelet activation via new platelet receptor CLEC-2 reduced cholestatic liver injury. Podoplanin expressed in hepatic sinusoid and serotonin released from platelets play an important role for reducing cholestatic liver injury in mice.

FRI-074
AXL increase in NASH patients and anti-fibrotic efficacy of AXL inhibition in experimental NASH
A. Tutusaus[1], E.D. Gregorio[1], B. Cucarull[1], H. Cristobal[1], I. Graupera[2], G. Gausdal[3], A. Holmes[3], J. Lores[4], P.G. de Frutos[1], M. Mari[1], A. Morales[1,5]. Email: amorales@clinic.ub.es

Background and Aims: GAS6 and the TAM receptor tyrosine kinases AXL and MERTK regulate the activation of hepatic stellate cells (HSC) during hepatic fibrogenesis as observed in animal studies and in vitro. Serum levels of GAS6 and AXL are elevated in a number of hepatic etiologies, however GAS6/AXL/MERTK levels in nonalcoholic steatohepatitis (NASH) are unclear. The distinctive subcellular signaling of the GAS6/TAM receptors during NASH development and the efficacy of AXL intervention to prevent diet-induced liver fibrosis remains to be explained. Several inhibitors against TAM receptors are in clinical development. The selective small molecule AXL kinase inhibitor BGB324 is currently being evaluated in Phase 2 clinical trials.
Method: Human activated HSC cells (LX2) and RAW264.7 cells were exposed to LPS, TGF-beta, AXL activation, and selective AXL kinase inhibitor (BGB324, BerGenBio AS). Mice were fed a high-fat diet choline-deficient with methionine restriction (HFCD) or methionine-choline-deficient diet (MCD) for 8 weeks. Serum levels of Gas6, AXL and MERTK were measured by ELISA. The collagen content was measured by Sirius Red staining and image-analysis software. HSC activation, liver inflammation and cytokine/chemokine production were measured by qPCR, mRNA array analysis, Western Blot and ELISA.
Results: Among individuals with different degrees of nonalcoholic liver disease (steatosis / fibrosis / cirrhosis), only cirrhotic patients displayed increased Gas6 and MERTK serum levels. However, AXL values were significantly elevated in all NASH groups in parallel to disease progression. Consistent with AXL influence in HSC transdifferentiation, human LX2 cells expression of profibrogenic genes after AXL activation was blocked by BGB324 treatment. AXL and MERTK control of inflammatory response was analyzed in activated human THP-1 macrophages. While Gas6 reduced LPS-induced gene expression, AXL inhibition did not affect it. Finally, HFCD-fed mice developed significant hepatic steatosis and fibrosis, and exhibited increased AXL serum levels, recapitulating human NASH observations. Besides inhibiting AXL, BGB324 administration increased circulating GAS6, favoring GAS6 liver protection via MERTK signaling. Oral administration of BGB324 to HFCD-fed mice reduced liver fibrosis and hepatic inflammation. Analogous protection was provided by BGB324 in animals receiving MCD diet.
Conclusion: AXL serum levels are an early marker of NASH that correlates with disease development. Stimulation of AXL signaling in HSCs is sufficient to induce HSC activation and expression of profibrotic genes in vitro. In experimental NASH models, therapeutic administration of the AXL inhibitor BGB324 diminishes liver fibrosis by blocking HSC activation and reduces hepatic inflammation possibly due to GAS6 hepatoprotective action.

Platelet-derived growth factor receptor alpha deprived hepatocytes attenuate thioacetamide induced liver fibrosis in mice

J.II. Lee[1], K.S. Lee[1], H.W. Lee[1], W.-K. Lee[2], H.Y. Chang[3]. [1]*Yonsei University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Inha Univeristy College of Medicine, Biomedical Sciences, Incheon, Korea, Rep. of South;* [3]*Gangnam Severance Hospital, Medical Research Center, Seoul, Korea, Rep. of South*
Email: mdflorence@yuhs.ac

Background and Aims: Platelet-derived growth factor receptor (PDGFR)-alpha expression is very low in normal liver. It dramatically increases in cirrhotic liver where activated hepatic stellate cells (HSCs) are suggested to be responsible for this increment. Although normal hepatocytes scarcely express PDGFR-alpha, cancerous hepatocytes may have up-regulated PDGFR-alpha expression. Since hepatocellular carcinoma is very often preceded by liver fibrosis, we hypothesized that upon repetitive liver insult, PDGFR-alpha on abnormal hepatocytes might play an important role in liver fibrosis by means of cell-to-cell crosstalk between hepatocytes and HSCs.
Method: Hepatocytes were isolated from normal and thioacetamide (TAA) induced cirrhotic liver respectively for assessment of PDGFR-alpha expression on hepatocytes. Then, we generated conditional knock-out mice from C57BL/6 mice where PDGFR-alpha was deleted on hepatocytes. Liver fibrosis was induced by injecting TAA for 8 weeks. Hep3B cells were transfected with siRNA (PDGFR-alpha or control) and co-cultured with LX2 cells.
Results: PDGFR-alpha expression was increased on hepatocytes from cirrhotic liver compared with that from normal liver. After PDGFR-alpha on hepatocytes was deleted, TAA induced liver fibrosis was significantly attenuated in mice. Although expressions of *transforming growth factor beta* and *Smad2/3* were enhanced after deletion of hepatocyte PDGFR-alpha, this was compensated by increased inhibitory *Smad7* expression, resulting in decreased liver fibrosis. From the co-culture system, LX2 cells, cultured with PDGFR-alpha siRNA infected Hep3B cells, showed decreased *PDGFR-alpha* expression as well as attenuated *alpha-smooth muscle actin (SMA)* and *collagen 1 (Col1) alpha* expression.
Conclusion: Deleting PDGFR-alpha on hepatocytes resulted in attenuated TAA induced liver fibrosis. This suggests that although PDGFR-alpha is scarcely expressed on normal hepatocytes, in the event of chronic liver injury, PDGFR-alpha on hepatocytes plays an important role, facilitating liver fibrosis.

Platelet deactivation attenuates CCL4 induced liver fibrosis progression in mice

A. Bhat[1], S. Mg[1], A. Parasar[1], A. Rastogi[2], S.K. Sarin[1,3]. [1]*ILBS, Molecular and cellular medicine, New Delhi, India;* [2]*ILBS, Department of Histopathology, New Delhi, India;* [3]*ILBS, Department of Hepatology, New Delhi, India*
Email: shivsarin@gmail.com

Background and Aims: Platelet activation induces liver fibrosis by PDGF-B dependent fibrogenic activation of hepatic stellate cells, and use of aspirin significantly attenuates the liver fibrosis progression by deactivating platelets in the animal model. The aim of this study is to further investigate the molecular mechanism of platelet deactivation by aspirin in liver fibrogenesis.
Method: Forty-two male C57/B6 mice were randomly divided into the control group (n = 7), ASA group (n = 7), CCL4 group (n = 14), and CCL4 + ASA group (n = 14). CCL4-induced fibrotic mice received 0.5μl/g bw of 50% carbon tetrachloride (CCL4) by intraperitoneal injection i.p. twice a week for 10 weeks while two different doses of Aspirin were given in drinking water. We compared the liver injury in both low (5mg/kg) and the moderate dose (50mg/kg) post euthanization after 10 weeks. Both hematoxylin-eosin and Masson's trichrome staining were performed to observe pathological changes in liver tissue. Liver fibrosis was evaluated by histology, biochemical determination of liver enzymes, collagen content and QRT-PCR.
Results: The aspirin-treated group displayed a decrease in platelet counts as compared to the control groups. Further, Alanine aminotransferase, aspartate aminotransferase, and total bilirubin were found to be higher in CCL4 group as compared to the aspirin-treated group. Assessment of Hepatic fibrosis by METAVIR score showed a significant decline in fibrotic areas and hydroxyproline contents in the aspirin-treated group as compared to CCL4 group ($p < 0.01$). Moreover, usage of aspirin at moderate-doses significantly improved the long-term fibrosis outcomes in the CCL4 model of liver fibrosis. Platelet deactivation by aspirin revealed a significant correlation with the expression levels of collagen type I as well as alpha-smooth muscle actin, a marker of HSC activation. Quantitative RT-PCR results revealed a downregulation of PDGFR expressions in the aspirin-treated group as compared to the CCL4 model group.

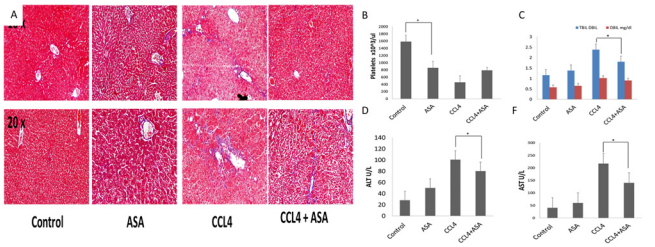

Figure 1 **Hepatoprotective effect of platelet inhibition in CCl4 induced hepatic injury. (A)** Representative photomicrographs of liver histology from normal healthy mice, ASA alone, CCl4 + vehicle alone and CCl4 + ASA. Mice were given repeated injections of CCl4 for 10 weeks in CCL4 model group. (**B-E**)Platelet number, Serum aminotransferases, direct and total bilirubin levels are plotted. Grading of hepatic fibrosis was evaluated on a scale of 1–4 as follows: 1, scattered; 2, mild; 3, moderate and 4, marked. The histological changes were assessed in 200× magnification fields of slides stained with H&E and Masson's trichrome.

Conclusion: Platelets may promote fibrosis during liver injury and pharmacological targeting of platelet activation could be beneficial and strongly attenuate fibrosis progression.

Combination of an FXR agonist and an ACC inhibitor increases anti-fibrotic efficacy in rodent models of NASH

J. Bates, D. Hollenback, A. Zagorska, G. Budas, J. Liles, H. Liu, K. Liu, S. Kusam, R. Brockett, D. Newstrom, I. Mikaelian, T. Wang, A. Ray, D. Breckenridge. *Gilead Sciences, Inc., Research, Foster City, United States*
Email: jamie.bates@gilead.com

Background and Aims: GS-9674 a selective, non-steroidal Farnesoid X Receptor (FXR) agonist (FXRag), and GS-0976, a liver-directed Acetyl-CoA Carboxylase (ACC) inhibitor (ACCi), are currently being investigated in clinical trials for NASH. FXR activation inhibits bile acid synthesis, and increases bile salt export. ACC 1 and 2 catalyze the rate limiting step of *de novo* lipogenesis (DNL) and inhibit mitochondrial fatty acid oxidation (FAO), respectively, which is hypothesized to promote lipotoxicity in NASH. We evaluated the potential efficacy of combination therapy agonizing FXR and inhibiting ACC in rodent models of NASH.
Method: Male C57BL/6 mice were administered a fast food diet (FFD) enriched in fat, cholesterol, and sugar for 6 months and treated with vehicle, FXRag, ACCi, or FXRag + ACCi from months 5 to 6 (n = 14–16/group). Endpoints included quantification of hepatic triglycerides (TG), plasma ALT, and hepatic gene expression by NanoString (*Col1a1* and *Timp1*). Male Wistar Han rats were fed a choline deficient high fat diet (CDHFD) for 12 weeks and administered vehicle, FXRag, ACCi, or FXRag + ACCi from week 6 to 12 (n = 15–16/group). Fibrosis and fibroplasia were assessed by picrosirius red (PSR) staining and α-SMA

IHC, respectively, with quantitative image analysis. Plasma TIMP-1, HA and PIIINP were quantified by ELISA.
Results: Hepatic triglycerides, serum ALT, and expression of fibrosis related genes *Col1a1* and *Timp1* were increased in vehicle treated FFD mice compared to mice on standard diet. FXRag + ACCi caused significant reductions in hepatic triglycerides and ALT (47% and 74%, respectively; $p < 0.001$), and liver gene expression of *Col1a1* and *Timp1* (80% and 74% reduction, respectively; $p < 0.0001$). *Col1a1* and *Timp1* expression were significantly reduced relative to either monotherapy ($p < 0.05$). Compared to normal diet, CDHFD significantly increased hepatic fibrosis at 6weeks (3% PSR area) and at 12 weeks (8% PSR area). FXRag + ACCi inhibited progression of fibrosis by 73% ($p < 0.001$) and α-SMA area by 85% ($p < 0.01$). Plasma levels of TIMP1, PIIINP, and HA were increased by CDHFD and were reduced by >98% by FXRag + ACCi ($p < 0.05$). The combination significantly inhibited α-SMA area and plasma PIIINP more than either monotherapy ($p < 0.05$).
Conclusion: Combining therapies targeting complementary mechanisms resulted in increased anti-fibrotic efficacy in rodent models of NASH. These data support investigation of a combination of GS-9674 and GS-0976 in patients with NASH.

FRI-078

Non-invasive phenotyping of hepatic fibrosis using unsupervised machine learning

J. Brag[1], Y. Nakano[1], R. Cabrera-Lozoya[1], E. Oubel[1], M. Wagner[2], O. Lucidarme[2]. [1]*Median Technologies, R&D, France;* [2]*Pitié Salpêtrière Hospital, Radiology, Paris, France*
Email: johan.brag@mediantechnologies.com

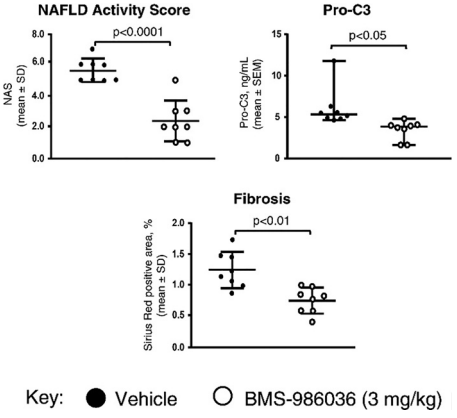
Background and Aims: Diagnosis and severity assessment of chronic liver diseases typically relies on histopathological analysis from biopsy samples. With novel anti-viral and NASH therapies there is a need for reliable non-invasive assessment of hepatic fibrosis. Earlier studies have shown that radiological signatures reflect biological phenotypes from tomographic images such as computed tomography. The aim of this study is to demonstrate the feasibility of applying routine CT imaging protocols, combined with unsupervised machine learning, to the non-invasive phenotyping of hepatic fibrosis.
Method: Two hundred patients with focal liver lesions referred for ex-vivo liver resection or transplantation at the academic hospital Pitié-Salpêtrière in Paris underwent a non-contrast CT exam as well as a standard triphasic contrast CT scan. The patients also had tissue samples surgically excised and graded for fibrosis by histopathology per the METAVIR score (F0-F4).
The liver was automatically segmented from the CT scans. Radiological signatures were automatically extracted from more than 10,000 individual 1 cm^2 size patches using a moving window scanning the entire liver. A similarity metric, (EMD) was used to compute the distance between radiological signatures. An unsupervised machine learning algorithm was used to group the patch signatures into clusters based on similarity with reference signatures corresponding to various tissue types and fibrosis score.
Robustness of the radiological signatures was tested against variations in reconstruction algorithms, equipment models and slice thickness as well as variations in intensity and contrast injection. Temporal stability was also assessed using test-retest procedures at different time points. The ability of the radiological signatures to discriminate between malignant and non-malignant tissue types and fibrosis classes was also evaluated.
Results: The signatures were generally insensitive to variations in equipment configuration, reconstruction or slice thickness as well as to variations in intensity or contrast with a distance variability of less than 5%. Local or temporal distance variations from matched tissue samples were also small compared to variations across tissue types. Tissue classification tests using unsupervised clustering showed classification ranging from 50 to 90% of patches correctly classified based on pathology data. Substantial heterogeneity of fibrosis distribution throughout the liver was also apparent.
Conclusion: Unsupervised machine learning can be applied to the non-invasive phenotyping of hepatic fibrosis and hepatocellular carcinoma. Radiological signatures extracted from contrast CT images reflect underlying tissue cellular biology. Unsupervised machine learning can be used for the classification and staging of hepatic fibrosis and hepatocellular carcinoma.

FRI-079

BMS-986036, a PEGylated fibroblast growth factor 21 analogue, reduces fibrosis and Pro-C3 in a mouse model of non-alcoholic steatohepatitis

Y. Luo[1], J. Krupinski[2], S. Gao[2], E. Charles[3], R. Christian[3]. [1]*Bristol-Myers Squibb, Pennington;* [2]*Bristol-Myers Squibb, Pennington, United States;* [3]*Bristol-Myers Squibb, Lawrenceville, United States*
Email: yi.luo@bms.com

Background and Aims: Non-alcoholic steatohepatitis (NASH) is characterised by steatosis, inflammation, and liver cell injury with or without fibrosis. BMS-986036 is a PEGylated recombinant analogue of human fibroblast growth factor 21 (FGF21) with a prolonged half-life and has been shown to improve insulin sensitivity, lipid profiles, steatosis, and biomarkers of liver injury and fibrosis in clinical studies. This study examines the effect of BMS-986036 treatment (tx) in a mouse model of NASH.
Method: In the STAM (Stelic) mouse model, male C57BL/6 mice were injected with streptozotocin 2 days after birth and placed on high-fat diet (57% kcal fat) at 4 wks of age. STAM mice develop evident steatohepatitis at 7 wks of age that later progresses to fibrosis and hepatocellular carcinoma, a disease profile that resembles NASH in humans. Mice were dosed at 7 wks of age with vehicle or 3 mg/kg BMS-986036 ($n = 8$/arm) for 2 wks by twice-weekly subcutaneous injection. Plasma and livers were collected for biochemical and histological analysis at the end of tx. Liver fibrosis was measured by Sirius Red staining and the non-alcoholic fatty liver disease activity score (NAS) was evaluated according to NASH Clinical Research Network histological criteria. Statistical analyses were performed using Student's t-test.
Results: Compared with vehicle, BMS-986036 tx significantly improved whole blood glucose (–30%; $p < .001$), body weight (–7.9%; $p < .05$), and liver/body weight ratio (–20%; $p < .01$), as well as liver and plasma triglycerides (–68% and –58%, respectively; both $p < .001$). BMS-986036 tx also decreased mean grades for steatosis, lobular inflammation, and hepatocellular ballooning (all $p < .005$ vs vehicle), resulting in a lower mean NAS (5.63 for vehicle vs 2.38 for BMS-986036; $p < .0001$; figure). BMS-986036 tx significantly decreased the mean serum fibrosis biomarker Pro-C3 by 44% (3.4 vs 6.1 ng/mL for vehicle; $p < .05$). Finally, BMS-986036 tx significantly decreased mean liver fibrosis, determined by Sirius Red-positive area, by 40% (0.75% vs 1.25% for vehicle; $p < .01$).



Conclusion: BMS-986036 tx for 2 wks in the STAM mouse model of NASH resulted in significant improvements in lipid and metabolic profiles, histological indicators of NASH, fibrosis-associated biomarkers, and liver fibrosis. These results suggest that BMS-986036 impacts several key drivers of NASH pathogenesis and fibrosis and support further clinical studies of BMS-986036 in patients with NASH and advanced fibrosis.

Email: majid.g.alhomrani@monash.edu

Background and aim: Chronic liver disease is characterised by progressive hepatocyte injury, inflammation and accumulation of extracellular matrix. Treatment for end stage liver disease is limited to liver transplantation. Liver progenitor cells (LPC) are bipotent cells induced during liver injury that can regenerate both hepatocytes and cholangiocytes. In addition, macrophages play a pivotal role in fibrogenesis and fibrosis resolution. Classically, macrophages are classified into M1 (pro-inflammatory macrophages) and M2 (pro-resolution macrophages). Recently, Ly6C expression has been used to identify distinct macrophage populations; Ly6C^{hi} (inflammatory) and Ly6C^{low} (resolution). We are developing a therapy for chronic liver fibrosis using human amnion epithelial cells (hAECs). The choline-deficient ethionine- supplemented (CDE) diet is a non-invasive and quick method to induce liver injury and LPC proliferation. Here, we aimed to investigate the effect of hAECs on macrophages and LPC during liver injury induced by CDE diet.
Methods: Male C57Bl/6J mice (6–8-weeks) were fed a CDE diet for up to 42 days; 2 or 4 million hAECs were infused intra-peritoneally 24h following initiation of the CDE diet. Outcomes were assessed at days 1, 3, 5, 14, 21 and 42 of the CDE diet following hAEC administration. The extent of liver fibrosis was determined by Sirius red staining and computer assisted morphometry was used to quantify the percentage of positively stained liver (expressed as % fibrosis area). LPC activation was determined by staining with wide spectrum screening cytokeratin (Pan-CK). Macrophages were further identified and characterised using flow cytometery sorting and PCR. Monocyte-derived macrophages (MDM) were distinguished from resident hepatic macrophages (Kupffer cells) based on expression CD45^{+} CD11b^{Hi} F4\80^{intermediate} Ly6G^{-} CD3^{-} B220^{-} NK1.1^{-}. Further, MDM were divided into two subpopulations based on high and low Ly6C expression.
Results: In CDE treated mice, hAEC significantly reduced liver fibrosis compared to untreated mice. hAEC decreased the number of proinflammatory (Ly6C^{hi}) MDM cells and increased the number of anti-inflammatory and tissue remodelling (Ly6C^{low}) MDM cells at days 1 and 42. hAEC also enhanced the expression of MMP12 and MMP13 in Ly6C^{Low} sorted cells. LPC numbers were reduced significantly in hAEC treated mice.
Conclusion: This is the first study to assess the efficacy of cell-based therapy on LPC and macrophage LyC6 phenotype. hAEC therapy significantly reduced liver fibrosis, induced a resolution Ly6C^{Low} macrophage phenotype and significantly decreased the number of LPC. Our data confirm the potential efficacy of hAECs as an effective therapy in liver fibrosis.

FRI-081

Stimulation of soluble guanylate cyclase inhibited fibrosis and inflammation in human liver microtissues and in an animal model of liver disease

K. Hall[1], S. Bernier[1], S. Jacobson[1], G. Liu[1], R. Sarno[2], V. Catanzano[2], J. Sheppeck[3], J. Hadcock[4], M. Currie[5], J. Masferrer[5]. [1]*Ironwood Pharmaceuticals, Pharmacology, Cambridge, United States;* [2]*Ironwood Pharmaceuticals, DMPK, Cambridge, United States;* [3]*Ironwood Pharmaceuticals, Medicinal Chemistry, Cambridge, United States;* [4]*Ironwood Pharmaceuticals, Cambridge;* [5]*Ironwood Pharmaceuticals, Pharmacology, Cambridge*
Email: khall@Ironwoodpharma.com

Background and Aims: Liver fibrosis in nonalcoholic steatohepatitis (NASH) is a risk factor for liver failure. Liver disease is associated with endothelial dysfunction and reduced nitric oxide (NO), the endogenous ligand of soluble guanylate cyclase (sGC). Drugs known as sGC stimulators activate the NO-sGC-cGMP signaling pathway, which modulates vascular function, metabolism, inflammation and fibrosis. Human liver microtissues (HLMs) and the carbon tetrachloride (CCl_4) liver fibrosis model were used to assess the antifibrotic/anti-inflammatory activity of sGC stimulators and explore their mechanism of action
Method: The sGC stimulators IWP-597 and IW-1973 were used in 2 studies: (1) HLMs (InSphero) composed of human hepatocytes, Kupffer and stellate cells, were treated with TGF-beta and IWP-597 for 48 h. (2) CCl_4 was administered to rats by PO dosing for 2 wk, then CCl_4+IW-1973 for 6 wk. mRNA levels were determined by bDNA, PCNA protein levels by Western blot, Ki67 by immunohistochemistry (IHC), and MCP-1 levels by ELISA.
Results: TGF-beta-treatment of HLMs increased expression of alpha-SMA mRNA, a key fibrosis marker, by 1.6x after 48 hours. IWP-597 treatment inhibited this increase in a dose-dependent fashion. All doses significantly inhibited TGF-beta-induced MCP-1 secretion relative to control. The antifibrotic and anti-inflammatory responses to IWP-597 observed in the HLMs were consistent with the effects of IW-1973 in the CCl_4 rats, suggesting similar responses to sGC stimulation between these two models. sGC expression was restricted to stellate-derived myofibroblasts in fibrotic livers from the CCl_4-model; we hypothesized that myofibroblast proliferation explained sGC's increase in fibrotic livers which was decreased in IW-1973 treated animals. PCNA, a proliferation marker, was 6.4x higher in fibrotic livers than in normal livers; IW-1973 treatment yielded lower PCNA expression, similar to levels in normal livers. Ki67 IHC revealed that proliferation of hepatocytes and myofibroblasts was increased in fibrotic livers. Proliferation was significantly reduced in the IW-1973 group.
Conclusion: In human liver microtissues, sGC stimulation reduced markers of fibrosis and inflammation compared to control. In the rat CCl_4 fibrosis model, in addition to decreasing fibrosis and inflammation, IW-1973 treatment reduced sGC expression and proliferation of hepatic cells. Several sGC-regulated proliferation factors are being explored as mechanistic candidates

Zoledronic Acid suppresses tumour associated macrophages andmyeloid derived suppressor cells in murine HCC

M. Aslam[1,2,3], M. Ashfaq-Khan[1], A. Qureshi[4], M. Nick[1], M. Senkowski[1], S.Y. Weng[1], K.Y. Ook[1], D. Schuppan[1]. [1]*Institute of Translational Immunology, University Medical Centre, Mainz, Germany;* [2]*;* [3]*Shaheed Benazir Bhutto Women University;* [4]*Dow university of medical sciences*
Email: m.ashfaq_biotech@yahoo.com

Background and Aims: HCC is associated with chronic inflammation leading to recruitment of bone marrow derived cells, mainly tumour associated macrophages (TAM, M2) and myeloid-cell derived suppressor cells (MDSC). Both cell types markedly suppress anti-HCC immune responses and are present in all stages of HCC. Zoledronic acid (ZA) is used in patients with osteoporosis to inhibit osteoclasts,

i.e., bone macrophages with TAM-like properties. We hypothesized that ZA can polarize tumour promoting TAM and MDSC towards M1 macrophages with anti-tumour activity.
Method: Mouse bone marrow derived in vitro M1 or M2 polarized macrophages () were exposed to increasing concentrations of ZA. Transcript levels of M1 markers (TNFα, IL-1β, iNOS, TIMP1) and M2 markers (Fizz1, ARG1, VEGF, YM1, MRC1, MMP-9) were determined by qPCR. IL-12 and SOCS3 (M1), IL-10 and VEGF (M2) secretion were measured by ELISA. Mice bearing a syngenic HCC (DEN/Mdr2KO model) received 3 doses of 100µg ZA/kg BW or vehicle control intraperitoneally weekly for a period of one month from age month 5–6. After four weeks of treatment mice were sacrificed to measure hepatic tumor number and volume and livers were assessed by H&E histology, IHC and qPCR.
Results: ZA dose-dependently decreased M2 (Fizz1, ARG1, STAT6, YM1, MRC1, MMP-9) and increased M1 macrophage (iNOS, TNF-alpha, IL-1beta, SOCS3) specific transcript levels without affecting cell viability in vitro. This was paralleled by a significant upregulation of IL-12 and dowregulation of IL-10 protein secretion into the cell supernatant. Compared to vehicle controls, treatment of DEN/Mdr2KO mice with ZA reduced tumour number and volume by 33.3% and 68%, respectively ($p < 0.004$). Tumour cell proliferation as evaluated via Ki-67-positive cells was significantly blunted by ZA. Staining of YM-1 and glypican positive M2 and CD68 positive total macrophages of ZA treated HCC liver sections showed a significant upregulation of M1 > M2 macrophages and reduced numbers of TAM. ZA significantly downregulated hepatic transcript levels the TAM/MDSC markers CSF-1, VEGF, TGFβ1, Cox2, Hif1α, CCL2, CCL3, CCL5 and CCL17.
Conclusion: 1. ZA exhibits potent macrophage (and MDSC) repolarizing activity (M2 towards M1) in- vitro and in-vivo, thereby increasing anti-HCC immune responses and limiting angiogenesis. 2. Since ZA has a well-known clinical safety profile, it should be assessed alone or in combination with other anti-cancer agents in patients with HCC.

FRI-083
Rapamycin and Zoledronic acid exert a potent antifibrotic effect in murine biliary fibrosis
M. Aslam[1,2], M. Ashfaq-Khan[1], A. Qureshi[3], M. Senkowski[1], M. Nick[1], S.Y. Weng[1], K.Y. Ook[1], D. Schuppan[1]. *[1]Institute of Translational Immunology, University Medical Centre, Mainz, Germany; [2]Shaheed Benazir Bhutto Women University, Pakistan; [3]Dow university of medical sciences, Pakistan*
Email: m.ashfaq_biotech@yahoo.com

Background and aims: There is an urgent need for effective antifibrotic therapies for biliary fibrosis. The *in vivo* microenvironment, especially macrophages, can modulate hepatic stellate cell (HSC) activation. We therefore assessed the antifibrotic efficacy of a combination of two clinically used drugs, Zoledronic acid (ZA) and Rapamycin (RA), that affect macrophage polarization and putative fibrogenic activation.
Methods: Mdr2-knockout (Mdr2KO) mice that had received one dose of diethylnitrosamine (DEN) at day 5 after birth were treated from month 5–6 (stage of advanced fibrosis with emerging HCC) with 1) ZA alone (100µg/kg body weight i.p., thrice weekly), 2) RA alone (5mg/kg body weight in the chow), 3) the combination of both drugs. A fourth group of Mdr2KO mice (without DEN and no signs of HCC) was treated with the combination. The degree of fibrosis and extent of inflammation was quantified histologically using staining with H&E, Sirius Red, for αSMA and CD68. Collagen deposition was confirmed by hydroxyproline determination. Real time PCR was performed to analyze the hepatic expression of fibrosis-related and macrophage-specific target genes produced by KCs (TNF-α, CCL2, TGFβ1, HIF1α and several MMPs), liver SECs(VEGF) involved in the activation of HSCs thereby progression of liver fibrosis.
Results: Compared to the untreated controls and to animals treated with the single drugs alone, Mdr2KO KO mice that received the ZA/RA combination for only one month demonstrated a twofold reduced collagen deposition, with elimination of bridging fibrosis ($p < 0.0001$). This was accompnied by a similar reduction of αSMA expression and a significant suppression of profibrogenic transcripts like Col1a1, Col3a1, Asma, Tnfa, and of markers of M2 macrophage polarization, including Hif1a and Mmp9. Moreover, the number of YM-1 relative to CD68 positive macrophages was significanatly
Conclusion: The combination of RA and ZA, two agents with macrophage modulating activity, induces a remarkable regression of even advanced biliary fibrosis. This antifibrotic effect goes along with a marked antitumorous activity. Since both drugs are used in the clinic for other indications, with a reasonable safety profile, their clinical testing should be considered in patients with fibrotic and (pre) cancerous PSC and other unaddressed indications.

FRI-084
EDP-305, a highly selective and potent farnesoid X receptor agonist, favorably regulates the expression of key fibrogenic genes in vitro and in vivo
Y. Li[1], J. Shang[2], M. Chau[2], M. Roqueta-Riverta[2], K. Garlick[2], P. An[3], K. Vaid[3], Y. Popov[3], Y.S. Or[4], L. Jiang[5]. *[1]Enanta Pharmaceuticals, Inc., Pharmacology, Watertown, United States; [2]Enanta Pharmaceuticals, Inc., Biology, Watertown, United States; [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States; [4]Enanta Pharmaceuticals, Watertown, United States; [5]Enanta Pharmaceuticals, Inc, Pharmacology, Watertown, United States*
Email: ljiang@enanta.com

Background and Aims: Fibrosis drives disease progression in people with advanced nonalcoholic steatohepatitis (NASH). EDP-305, a potent Farnesoid X Receptor (FXR) agonist, is currently being developed for the treatment of NASH. Herein, we report the anti-fibrotic activity of EDP-305 *in vitro* and *in vivo*. The effect of EDP-305 on post-transcriptional regulatory mechanism via microRNA29a (miR29a) was also characterized.
Method: To investigate the effects of EDP-305 on liver fibrosis *in vitro*, primary human hepatic stellate cells (HSC) were induced with 5 ng/ml of transforming growth factor beta (TGFβ) and co-treated with DMSO or EDP-305 for 18 hours. The *in vivo* anti-fibrotic effect of EDP-305 was investigated using mice with methionine/choline-deficient diet (MCD)-induced steatohepatitis and peri-sinusoidal fibrosis. EDP305 (10 mg/kg) was orally administered to mice 4 weeks after MCD-induced early fibrosis was established and treatment duration was 4 weeks. The expression of essential genes involved in modulating the pathogenic fibrogenic response associated with NASH was analyzed by RT-PCR.
Results: EDP-305 significantly ($p < 0.05$) decreased expression of α-smooth muscle actin (α-SMA), collagen type 1 α2 (COL1A2), collagen type 3 α1 (COL3A1), metallopeptidase inhibitor 1 (TIMP1) and metallopeptidase inhibitor 2 (TIMP2) by 68%, 42%, 57%, 80%, and 65%, respectively, *in vitro* in HSC cell cultures. Consistent with *in vitro* observations, these key fibrogenic genes were also significantly down-regulated by EDP-305 in mice. Moreover, EDP-305 favorably upregulated miR29a, a crucial player in fibrosis. EDP-305 increased miR29a expression by 89% when compared to the vehicle control, which led to 70% reduction of hepatic collagen content, in mice with MCD-induced fibrosis.
Conclusions: EDP-305 exhibits potent anti-fibrotic activity *in vitro* and *in vivo*. Moreover, EDP-305 can favorably upregulate miR29a, a key post-transcriptional regulator of profibrotic genes. These results warrant further clinical study of EDP-305 for the treatment of NASH.

FRI-085

Fibrosis involves increased fibroblast and hepatocyte collagen species, reflecting the interstitial and basement membrane matrix: Restoration of the local tissue milieu with FXR agonism

J. Roth[1], S. Veidal[2], R. Papazyan[1], K. Rigbolt[2], M. Feigh[2], M. Karsdal[3], D. Leeming[3], M. Young[1]. *[1]Intercept Pharmaceuticals, Inc.; [2]Gubra, Horsholm, Denmark; [3]Nordic Bioscience, Herlev, Denmark*
Email: jonathan.roth@interceptpharma.com

Background and Aims: Fibrosis involves an induction of both basement membrane (BM) and interstitial matrix components. Most NASH pharmacology studies focus exclusively on the myofibroblast-derived fibrillar collagens, type I collagen (Col1) and type III collagen (Col3). By contrast, the role of hepatocyte and endothelial-derived BM proteins like the network forming type IV collagen (Col4) in disease progression/regression are not well understood. Previously, INT-767 reduced Sirius Red staining (Col1 and Col3) and Col1 immunoreactivity. We assessed INT-767's impact on major components of the BM and its remodeling and regeneration, including Col4 and laminin (LAM), using histological, molecular and biomarker assessments.
Method: *Lep$^{ob/ob}$* mice were fed the AMLN NASH diet for 12W, biopsied and randomized to receive vehicle or INT-767 10 mg/kg for 8W. Hepatic collagen and BM-related gene expression were measured by RNA-Seq. Fractional area (FA%) calculations were performed for Col1a1, LAM and Col4 (BM). Serum P4NP7S (a marker of Col4 formation) was sampled during diet induction, at baseline prior to treatment, and after 4W and 8W of INT-767.
Results: INT-767 reduced mRNA levels of BM proteins including Col4, BM-40, nidogens, laminins, and fibrillins vs vehicle controls. Consistent with transcriptional changes, INT-767 reduced FA% hepatic Col1a1 (-38%), LAM (-39%) and Col4 (-19%) vs. controls (all $p < 0.05$). P4NP7S (ng/ml) increased during diet-induction (from 86 to 104 at baseline) and continued to rise in vehicle-treated mice (to 141 and 152, at 4W and 8W; all $p < 0.05$). INT-767 reduced levels of P4NP7S at 4W (115) and 8W (113; both $p < 0.05$). Circulating P4NP7S correlated with endpoint hepatic levels of Col1a1 ($p = 0.015$, R^2=0.2125).
Conclusion: We demonstrated that fibrosis is not only associated with increased Col1 and Col3 of the fibroblasts, but also a significant thickening of the BM involving a completely different functional type of collagen, Col4. INT-767 treatment reduced Col4 and LAM, the major components of the BM which are likely contributors to improvements in endpoint fibrosis. For Col4, these changes were evident at the mRNA level and linked to circulating P4NP7S. Notably, P4NP7S was also associated with improved fibrosis as assessed by Col1a1. These preclinical findings raise the possibility that FXR agonism restores both fibroblast and hepatocyte/epithelial cell phenotypes to ultimately improve liver function.

FRI-086

Possible liver regeneration and anti-fibrogenic effect of NOTCH1 selective inhibitor in the diseased liver model

M. Kitade, K. Kaji, H. Yoshiji. *Nara Medical University, Third Department of Internal Medicine, Kashihara, Japan*
Email: kitademitsu@yahoo.co.jp

Background and Aims: Recently several arguments have arisen in the true potential of hepatic progenitor cells (HPC) on regeneration of diseased liver. We hypothesized that HPC shifts their differentiation fate towards "too biliary" direction by NOTCH signal, and this may prevent HPC to provide new hepatocytes (HC) in the diseased liver. We speculated that NOTCH1 selective inhibition may contribute efficient HPC-derived hepatocyte repopulation which results in a more efficient liver regeneration in the diseased liver.
Method: We employed a small molecule NOTCH1 inhibitor (N1inh) developed by Interprotein Inc. We treated both 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)- and carbon tetrachloride (CCL4)-induced mice liver injury model with N1inh and observed several serological and histological parameters related with liver regeneration.
Results: N1inh successfully gained both body and liver weight with recovery of liver function in both DDC and CCL4 models. Treatment with N1inh increased the number of A6-positive CK19-negative newly differentiated HC from HPC. Also, Ki-67 positive hepatocytes in the liver were significantly increased in N1inh-treated group which may reflect the increase of newly differentiated HC from HPC. We also found that N1inh-treated diseased livers exerted significantly less liver fibrosis development than compared with the livers without N1inh in both models. Our in vitro experiments revealed that N1inh did not affect proliferation of activated HSC-LX2, however, N1inh altered tubular formation of human umbilical vascular endothelial cells, suggesting that anti-angiogenic effect of N1inh may ameliorated liver fibrosis development.
Conclusion: Our experiments suggested that NOTCH1 selective inhibition in the liver could successfully augment not only differentiation of HPC towards HC but also amelioration of liver fibrosis development. Since both compensation of the loss of HC and hepatic fibrolysis are prerequisite for the effective liver regeneration, these dual functions of NOTCH1 inhibition could be a new possible therapeutic option for liver regeneration.

FRI-087

ACC inhibitor demonstrates potent anti-fibrotic activity in vitro and in vivo

J. Bates[1], S. Ghoshal[2], L. Wei[2], D. Hollenback[1], K. Liu[1], S. Kusam[1], M. Sulfab[1], H. Liu[1], R. Brockett[1], D. Newstrom[1], I. Mikaelian[1], T. Wang[1], G. Harriman[3], W.F. Westlin[3], J. Rocnik[3], H.J. Harwood[3], R. Kapeller[3], A. Ray[4], D. Breckenridge[4], B.C. Fuchs[2]. *[1]Gilead Sciences, Inc., Research, Foster City, CA, United States; [2]Massachusetts General Hospital, Division of Surgical Oncology, Boston, MA, United States; [3]Nimbus Therapeutics, Cambridge, MA, United States; [4]Gilead Sciences, Inc., Foster City, CA, United States*
Email: jamie.bates@gilead.com

Background and Aims: GS-0976, a liver-directed acetyl-CoA carboxylase (ACC) inhibitor is currently being investigated in clinical trials for NASH. ACC1 and 2 catalyze the rate-limiting step of *de novo* lipogenesis (DNL) and inhibit mitochondrial fatty acid oxidation (FAO), respectively, promoting lipotoxicity in NASH. We evaluated the direct antifibrotic efficacy of ACC inhibition in rat models of liver fibrosis and in isolated hepatic stellate cells (HSCs).
Method: Rats were fed a choline deficient high fat diet (CDHFD) for 12 weeks and administered vehicle, or 10 mg/kg ACCi (GS-834356, an analog of GS-0976) from weeks 6–12. Rats were injected weekly with DEN 50 mg/kg IP for 18 weeks and from weeks 13–18 were administered vehicle or 10 mg/kg ACCi, or in a separate study vehicle or 30 mg/kg ACCi. Hepatic fibrosis was assessed by quantitative morphometry of liver sections stained with picrosirius red (PSR) or α-SMA immunohistochemistry or by determination of hepatic hydroxyproline content. Primary human HSCs were treated for 48 hours with TGFβ (2ngmL) +/– GS-0976, after which HSC activation was assessed by collagen and α-SMA expression. DNL in HSCs was quantified by measuring the incorporation of ^{14}C-acetate into fatty acids.
Results: CDHFD significantly increased hepatic PSR and α-SMA at 6 weeks (3% and 1% area, respectively) and at 12 weeks (8% and 6% area, respectively) compared to normal diet ($p < 0.05$). ACCi treatment inhibited fibrosis progression as measured by PSR and α-SMA area by 62% and 44%, respectively ($p < 0.01$). DEN significantly increased hepatic PSR from 13 weeks (4% area) to 18 weeks (7% - 11%). 10 mg/kg and 30 mg/kg ACCi reduced the progression of fibrosis as assessed by PSR area (61% and 86% inhibition, respectively, $p < 0.05$) and liver hydroxyproline content (70% and 100% reduction, respectively, $p < 0.05$). In isolated stellate cells, TGFβ stimulated DNL and HSC activation. GS-0976 dose-dependently inhibited DNL, induction of HSC activation markers, and increased PPARγ expression.

Conclusion: ACC inhibition suppressed the activation of HSCs in vitro and reduced liver fibrosis in two rodent models, one of which was driven by a non-metabolic insult. These data demonstrate that, in addition to decreasing lipotoxicity in hepatocytes, ACC inhibition directly inhibits fibrogenesis in HSCs. The data support clinical evaluation of GS-0976 in patients with NASH and advanced fibrosis.

FRI-088

During the progression of liver fibrosis, myofibroblasts develop endoplasmic reticulum stress that both decreases their proliferation and increases their pro-angiogenic activity

E. Loeuillard[1], H.E. Mourabit[1], L. Lei[1], S. Lemoinne[1,2], C. Housset[1,2], A. Cadoret[1]. *[1]Inserm UMR_S 938, Centre de Recherche Saint-Antoine, UPMC Univ Paris 06, Paris, France; [2]Assistance Publique-Hopitaux de Paris, Hopital Saint-Antoine, Centre de Référence Maladies Rares des Maladies Inflammatoires des Voies Biliaires, Service d'Hépatologie, Paris, France*
Email: axelle.cadoret@inserm.fr

Background and Aims: Portal myofibroblasts (PMFs) are a sub-population of liver myofibroblasts. Compared with hepatic stellate cell-derived myofibroblasts, they derive from a smaller cell niche and proliferate much more. PMFs sub-population is predominant at early stages of biliary-type liver fibrosis and trigger angiogenesis during the progression of all types of fibrosis. Mechanisms regulating PMFs expansion and functions are poorly known. Endoplasmic reticulum (ER) stress was previously shown to regulate liver fibrosis. The aims of this study were to determine if ER stress occurs in PMFs and affects their functions.
Method: PMF were expanded in culture after isolation from control or 14-day bile duct-ligated (BDL) rats. PMFs from BDL rats were used as a model of *in vivo*-activated PMFs. *In vitro*, ER stress was induced or inhibited using tunicamycin and the PERK inhibitor GSK2656157, respectively. The degree of ER stress was determined using the markers CHOP, TRB3, GADD34.
Results: *In vivo*-activated PMFs obtained from BDL rats, displayed reduced proliferative and migratory capacities, together with increased pro-angiogenic properties, compared to control PMFs obtained from sham-operated rats. In BDL rats, CHOP expression was detected in peri-portal fibrotic areas of the liver. *In vivo*-activated PMFs showed ER dilatation and increased expression of ER stress markers of the PERK pathway. *In vitro*, tunicamycin-induced ER stress had no effect on the expression of myofibroblastic markers (alpha-SMA and collagen-1) in PMFs, but caused a significant reduction of proliferation and migration in these cells, as well as an increase in VEGF production by these cells and in their angiogenic properties, as assessed in matrigel plugs *in vivo*. GSK2656157 treatment of *in vivo*-activated PMFs reduced ER stress, which caused a decrease in VEGF expression and in their angiogenic properties. GSK2656157 treatment also partially restored the proliferative and migratory capacities of these cells.
Conclusion: ER stress occurs in PMFs during the progression of liver fibrosis and may contribute to this progression by stimulating their proangiogenic properties. However, ER stress also inhibits proliferation and migration of PMFs, and thereby may provide an incoherent feedback loop that restricts their expansion.

FRI-089

The antiretroviral rilpivirine induces hepatic regeneration in liver fibrosis and cirrhosis by modulating the STAT3/STAT1 balance

A. Martí-Rodrigo[1], Ángela B. Moragrega[1], P. Martí-Rodrigo[1], D. Castelli[1], N. Apostolova[1,2], Juan V. Esplugues[1,2,3], A. Blas-García[1,2]. *[1]Universitat de València, Pharmacology Department, Valencia, Spain; [2]CIBERehd, Valencia, Spain; [3]FISABIO-Hospital Universitario Dr. Peset, Valencia*
Email: alberto.marti-rodrigo@uv.es

Background and Aims: Liver fibrosis constitutes a serious health problem with no current cure and whose prevalence is rising worldwide. We have previously reported that chronic treatment with the antiretroviral rilpivirine (RPV), widely used in anti-HIV therapy, induces anti-steatotic, anti-inflammatory and anti-fibrotic effects in a nutritional mouse model of non-alcoholic fatty liver disease, though the underlying mechanisms are unknown.
Activation of STAT3 and STAT1 transcription factors in the liver induces different cellular responses depending on the cell population affected. Generally, parenchymal activation of STAT3 induces anti-fibrotic, anti-inflammatory and regenerative pathways, while its activation in hepatic stellate cells (HSCs) induces inflammation and fibrogenesis. Conversely, STAT1 in HSCs induces their inactivation and is pro-fibrogenic in hepatocytes.
We aimed to characterize the effect of RPV on the progression/regression of liver fibrosis, focusing on the regulation of STAT3- and STAT1-mediated signalling pathways
Method: Two different models of CCl_4-induced liver fibrosis were established in C57BL/6-WT mice to determine the effects of chronic RPV administration on the progression (4 weeks of CCl_4 and RPV) and regression (6 weeks of CCl_4 and the last two weeks of RPV) of liver fibrosis. Serum and enzyme activity determinations, histological studies and molecular biology techniques were carried out to assess liver inflammation, fibrosis and alterations of the STAT3/STAT1 ratio
Results: Liver fibrosis was clearly induced in both models. All the parameters of liver injury (AST, ALT and bilirubin), inflammation (macrophage infiltration, NFkB activation and MPO activity) and fibrosis progression (collagen deposition and vimentin expression) we evaluated were attenuated in RPV-treated mice with respect to controls. In addition, RPV modulated the STAT3/STAT1 balance in the liver and induced a clear inactivation of HSCs.
Conclusion: Beyond its well-known antiviral effect, RPV exerts a strong protective role in all our chronic liver injury models (NAFLD, fibrosis and cirrhosis). Although further studies are needed to clarify the mechanism involved in this off-target effect of RPV, our results are clinically relevant in that they highlight the therapeutic potential of RPV in the management of chronic liver diseases, particularly since this drug is known not to have a toxic profile.

FRI-090

Performance of quantitative collagen parameters for assessing longitudinal non-advanced liver fibrosis

Y. Wang[1], X. Liang[1], J. Sun[1], J. Yang[2], Y. Zheng[1], Y. Chen[1], J. Hou[1]. *[1]Southern Medical University Nanfang Hospital, Department of Infectious Diseases and Hepatology Unit, GZ, China; [2]Southern Medical University, School of Pharmaceutical Science, GZ, China*
Email: yanwang@i.smu.edu.cn

Background and Aims: Non-advanced fibrosis is a common scenario in therapeutic trials of chronic liver disease. However, current tools generally lack sufficient performance in detecting the longitudinal change. We aimed to evaluate whether using quantitative fibrous collagen parameters (q-FP) can be as accurate as but more sensitive than the standard histology for addressing this issue.
Method: A well-established CHB cohort (NCT00962533) with mostly the non-advanced fibrosis were used for this study. 301 subjects with paired liver biopsies were consecutively included. Of them, 139 subjects were used to establish the test and the rests for internal validation. Fibrosis change between baseline and 104 weeks of treatment was blindly assessed with Ishak fibrosis staging and q-FP.
Results: 70% subjects were Ishak F0-2 at baseline. Imaging data were collected yielding a dataset of 69 q-FPs per biopsy specimen, which then composed a single score, q-FS representing the overall fibrosis status. Using q-FP profile, variations of fibrosis response in different clinical settings could be extensively visualized (Figure). For diagnosing overall fibrosis endpoint, 67% (93/139) patients got decrease in their Ishak stages ($p < 0.0001$), and the decrease extent showed a significant association with baseline Ishak stage (OR 6.7, 95%CI 4.4–10.5, $p < 0.0001$); on q-FP analysis, 68% (94/139) patients achieved decrease in their q-FS ($p < 0.0001$), of which the extent also

demonstrated a significant association with baseline q-FS (Spearman ρ -0.7, 95%CI -0.7–-0.6, p < 0.0001). However, while q-FP identified the independent association between fibrosis regression and anti-viral efficacy (OR 3.0, 95%CI 1.4–6.5, p = 0.005), Ishak failed the detection (OR 0.6, 95%CI 0.3–1.3, p = 0.24). Moreover, on analysis of statistical consistency, there showed no difference between their diagnoses of fibrosis endpoint (difference 0.7%, 95%CI -9.2–10.6, p = 1.00). The indices of positive (p_{pos}) and negative (p_{neg}) agreement were 0.8 (95%CI 0.7–0.8) and 0.5 (95%CI 0.4–0.7), respectively, for which, the disagreement was identified more likely occurring to the baseline Ishak staging (p = 0.003), mainly involving some pairs with baseline moderate fibrosis, but had not relation to Ishak staging at week 104 (p = 0.55). In contrast, the disagreement had no significant relation to q-FP assessment, either at baseline (p = 0.18) or at week 104 (p = 0.78). Moreover, neither did the disagreement correlate to the biopsy size at baseline (p = 0.22) or at week 104 (p = 0.37). Eventually, these findings were verified by reviewing through the paired Ishak staging and q-FP score for every subject. The above results were confirmed in the validation subjects.

Conclusion: Compared with standard histology, q-FP could have an equivalent accuracy as well as a higher sensitivity in monitoring the longitudinal non-advanced fibrosis.

Email: d.ramnath@imb.uq.edu.au

Background and Aims: Liver fibrosis, resulting from injury- and inflammation-driven production and accumulation of extracellular matrix proteins, is characteristic of most type of chronic liver diseases (CLD). Although our understanding of the cellular and molecular mechanisms of liver fibrosis has greatly advanced, current methods

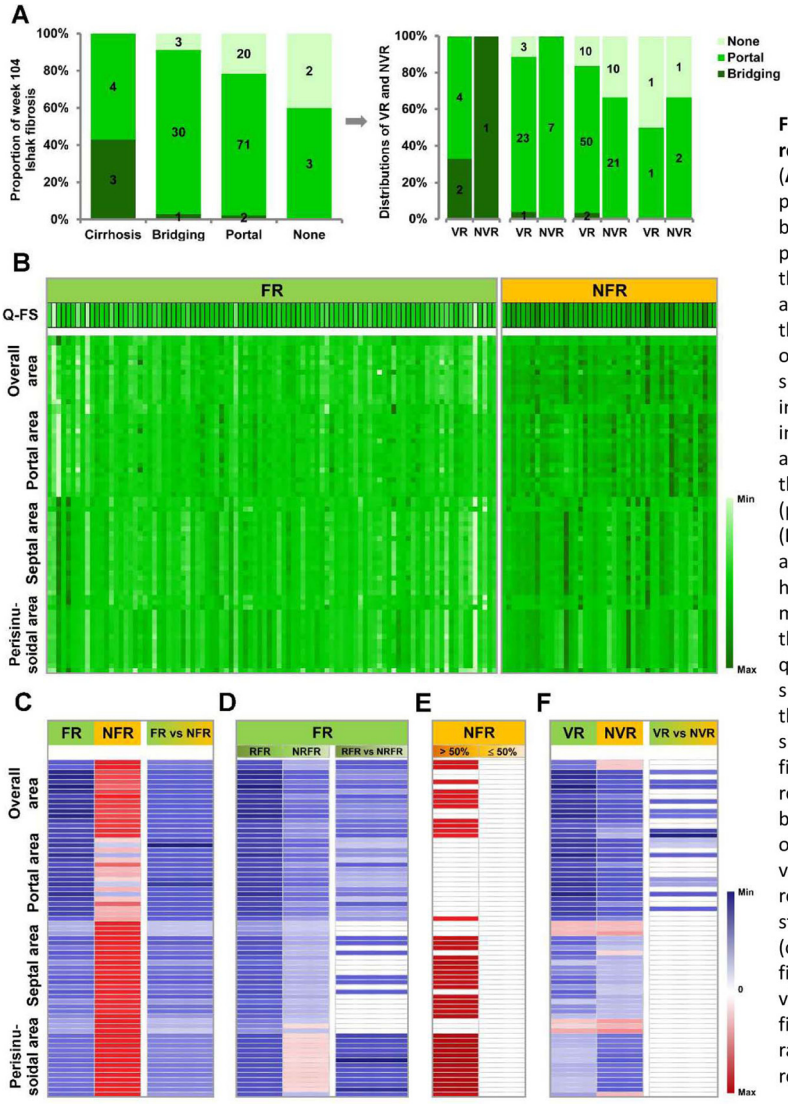

Figure. Ishak staging versus q-FP profiling of the fibrosis response in test subjects.
(**A**) Ishak staging data show the proportions of different patterns in the week 104 liver biopsies grouped by their baseline patterns. Numerals on each bar represent patients' number. Q-FP heat-map shows the data: (**B**) For the 139 individuals, the exact extent of fibrosis change across sublobule regions can be visualized precisely; of these, the FR subjects appeared more reduction in overall fibrosis than NFR subjects. (**C**) For the FR vs NFR subjects, all q-FPs of FR subjects had significant decrease in their values (p<0.05), and the most decrease localized in the portal area. (**D**) For the RFR vs NRFR subsets among FR subjects, the subset of RFR had their q-FPs in the portal and sinusoidal regions decreased more (p<0.05), and sinusoidal region had the most decrease. (**E**) For the subsets of >50% vs ≤50% increase in q-FS among the NFR subjects, 57% q-FPs of the '>50%' subset had a significant 3.1 ± 0.5-fold increase (p<0.05), which mostly localized in the septal and sinusoidal regions. For the '≤50%' subset, no region had significantly increased q-FPs. And (**F**) for the subjects achieving VR or NVR, VR subjects showed more reduction in overall fibrosis, and the significance was in the portal region (p<0.05); NVR subjects appeared more reduction in the sinusoidal fibrosis, but it was not significant. In the matrix, each cell represents the level of a Δq-FS or Δq-FP in an individual biopsy (panel B), or represents the mean level of a Δq-FP of the subgroups (panels C-F). Dark vs light green, or red vs blue in cells reflects high to low expression levels, respectively. Blank cell in panels C-F represents no statistical significance. Δq-FP (or Δ q-FS) = week 104 q-FP (or q-FS) – baseline q-FP (or q-FS). Q-FP, quantitative fibrosis parameter; Q-FS, quantitative fibrosis score; VR, virological remission; NVR, non-virological remission; FR, fibrosis regression; NFR, non-fibrosis regression; RFR, rapid fibrosis regression; NRFR, non-rapid fibrosis regression.

Figure 1: (abstract: FRI-090)

for diagnosing and treating liver fibrosis are limited. Existing non-invasive methods of liver fibrosis diagnosis involve transient elastography and certain serologic tests such as the enhanced liver fibrosis (ELF) score; however, these methods are not able to reliably detect fibrosis stage. Liver biopsy still remains the only effective way to accurately determine the stage of fibrosis, but it is an invasive procedure, which can be accompanied by complications such as internal bleeding. In this study, we aimed to identify the core gene signature associated with liver fibrosis to identify novel biomarkers and/or therapeutic targets for liver disease.

Method: In this study, we performed RNA-sequencing using liver tissue RNA from 69 chronic liver disease patients at different stages of fibrosis and with different aetiologies to identify gene signatures associated with advanced liver disease.

Results: RNA-sequencing analysis identified 171 genes that were differentially expressed between early versus advanced stages of fibrosis, 60 of which encoded extracellular proteins. By gene correlation analysis with matched patient ELF score data, we identified 52 genes that strongly correlate with advanced fibrosis. One such gene represents a candidate master transcriptional regulator of the pro-fibrogenic gene signature associated with liver fibrosis. By comparing gene profiles of HCV or HCV with steatohepatitis patient biopsies, we also identified a steatohepatitis-enriched set of genes associated with progressive fibrosis.

Conclusion: In summary, our approach of using samples from patients with different CLD aetiologies has enabled us to deconvolute the inherit heterogeneity that exists within clinical samples, and has led to the identification of a core set of liver fibrosis-associated genes. Several of these encode immune-related proteins that may represent tractable targets and/or biomarkers for chronic liver disease.

FRI-092

Interference of PTTG1 mRNA dramatically reduces portal hypertension and liver fibrosis in fibrotic rats

S.C. Restoy[1], V. Reichenbach[1], D. Oró[1], S. Marfa[1], G. Fernández Varo[1,2], S. Lamas[3], W. Jiménez[1,2]. *[1]Biochemistry and Molecular Genetic Service, Hospital Clínic de Barcelona, Institut d'Investigacions Biomèdiques August Pí i Sunyer (IDIBAPS), Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; [2]Department of Biomedicine, University of Barcelona, Barcelona, Spain; [3]Laboratorio Mixto Consejo Superior de Investigaciones Científicas (CSIC)-Fundación Renal Iñigo Álvarez de Toledo, Centro de Biología Molecular Severo Ochoa, Madrid, Spain.*
Email: scarvajal@clinic.ub.es

Background and Aims: Pituitary tumor transforming gene (PTTG1) encodes a protein with roles in gene regulation and migration. It is highly expressed in hepatocellular carcinoma promoting tumor progression and metastasis, however little is known about its role in pre-neoplastic stages. Recent studies suggest that PTTG1 could be implicated in liver fibrosis development. The aim of this study was to assess whether PTTG1 inhibition reduces the fibroproliferative process and ameliorates hemodynamics in a rat model of liver fibrosis by CCl_4 inhalation.

Method: 12 Wistar rats were induced to liver fibrosis by CCl_4 inhalation for 14 weeks and randomly treated with siRNA against PTTG1 or scramble siRNA (0.25 mg/kg) intravenously from the 9th to the 13th week. 6 healthy rats were used as control. Mean arterial pressure (MAP) and portal pressure (PP) were measured at the end of the study and serum and liver samples were collected. Liver fibrosis content was quantified by Sirius Red and biochemical parameters of liver damage were assessed in serum. Hepatic expression of PTTG1 and other fibrosis-related genes were analyzed by Real Time PCR.

Results: PTTG1 expression was markedly increased in the liver of fibrotic rats treated with scramble siRNA, while its expression in rats treated with siRNA against PTTG1 was similar to that observed in healthy rats, demonstrating the effectiveness of the treatment. PTTG1 inhibition dramatically reduced the liver fibrosis formation compared to fibrotic rats treated with siRNA (4.3 vs 10.0%). This was associated with a significant improvement in the hemodynamic function, reflected by a marked reduction in the PP in the rats subjected to PTTG1 inhibition (7.3 vs 10.4 mmHg). PTTG1 inhibition also reduced the hepatic expression of key genes related to liver fibrosis, such as MMP2 and PDGFRβ1. Interestingly, a close relationship was found between the hepatic expression of PTTG1 and DLK1 (r = 0.96), a key protein in the fibrogenic process through promoting HSC activation,

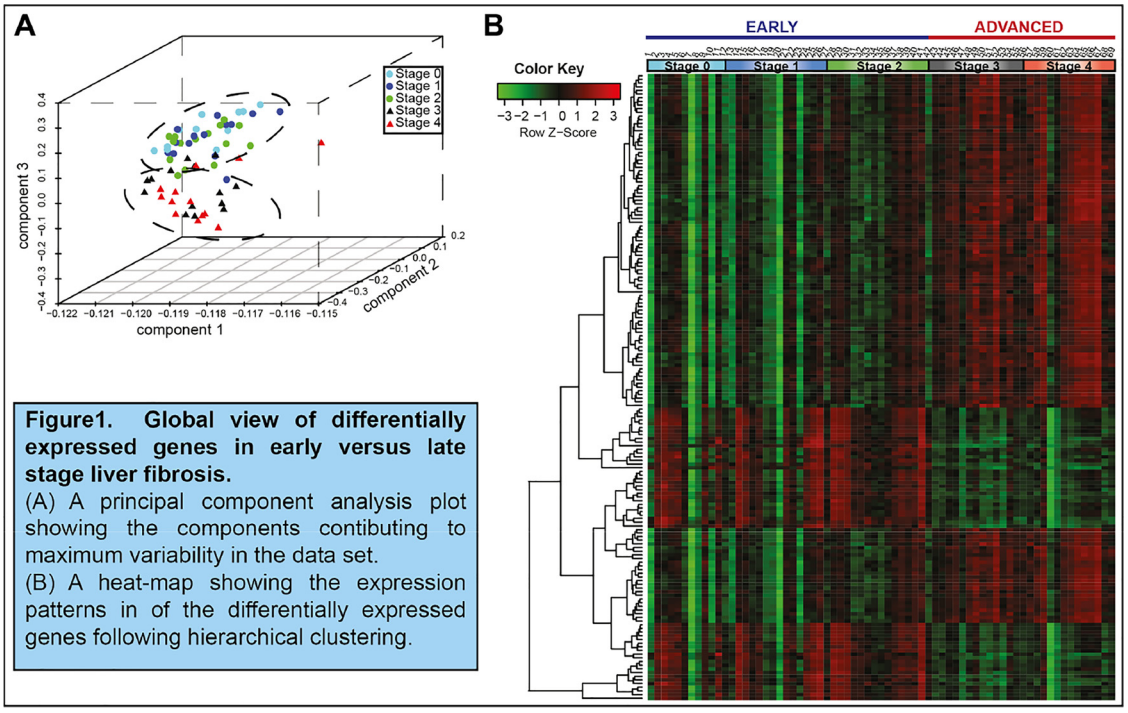

Figure1. Global view of differentially expressed genes in early versus late stage liver fibrosis.
(A) A principal component analysis plot showing the components contibuting to maximum variability in the data set.
(B) A heat-map showing the expression patterns in of the differentially expressed genes following hierarchical clustering.

Figure 1: (abstract: FRI-091)

and whose expression is tightly related to PTTG1. Hepatic expression of PTTG1 was also related with αSMA, Col1α2, Col3α1, TIMP1, TIMP2, and with GGT, AST and T-Bil serum levels.
Conclusion: These results demonstrate that PTTG1 play a critical role in the hepatic fibroproliferative process in an animal model of chronic liver injury, revealing this protein as a new target for the prevention and treatment of liver fibrosis.

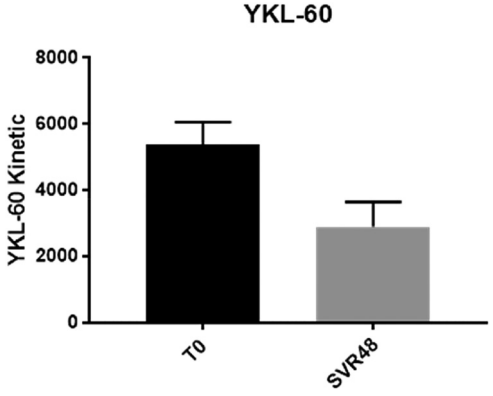
FRI-093
Direct fibrosis markers kinetic in patients undergoing antiviral treatment with DAA for chronic hepatitis C
C. Mazzarelli[1,2], M. Bruce[1], S. Imbert[1], M.D. Cannon[1], G. Dusheiko[1], K. Agarwal[1], I. Carey[1]. *[1]King's college Hospital, Institute of liver studies, London, United Kingdom; [2]ASST Ospedale Niguarda, Hepatology and Gastroenterology, Milan, Italy*
Email: chiaramazzarelli@hotmail.com

Background and Aims: Registration trials and real-life cohorts have demonstrated that a significant percentage of patients with decompensated liver disease may potentially experience clinical improvements following HCV eradication. Liver fibrosis is characterized by excess collagen deposition, decreased extracellular matrix degradation and activation of hepatic stellate cells. Different markers seem to be involved in liver fibrosis. Transforming growth factor beta (TGF-β), Hyaluronic acid (HA) and Osteopontin (OPN) are well-recognized as promoter of hepatic fibrogenesis. IL-6 is an inducer of the acute phase response as well it has been demonstrated to be involved in liver regeneration. YKL-40 is involved in matrix remodeling. We aimed to evaluate the kinetics of direct fibrosis biomarkers in HCV patients in relation to DAA antiviral treatment.
Method: 75 cirrhotic patients, treated with SOF + NS5A inhibitors (daclatasvir or ledipasvir) at King's College Hospital from 2015–17, were identified and divided into 3 different cohorts: 40 patients with a Child A cirrhosis, 18 patients with Child A cirrhosis but with a previous decompensating event and 17 patients with decompensated liver disease. Plasma levels of TGF-β, IL-6, HA and OPN were measured by ELISA at three different time-points: treatment baseline (T0), End of treatment (EOT) and 48 weeks after the EOT (SVR48). YKL-60 was evaluated at T0 and SVR48.



Results: Patients demographics and clinical characteristics of our cohorts were illustrated in table 1. Decompensated patients were younger (p = 0.01), had lower pre-treatment HCV-RNA (p = 0.08), more adverse events post-therapy (p < 0.01), higher incidence of HCC during or after treatment (p = 0.03), and a lower PLTs count (p < 0.01 compared to other groups). IL6, YKL-60 and TGF beta levels were similar between 3 groups at all time-points. Levels of HA differ between 3 groups and all time-point (p = 0.01, p=<0.01, p = 0.01), while OPN levels were similar at T0 and SVR48, but varied among 3 groups at SVR48. When compared for all patients between time-points IL-6 levels were similar at all time-points, for TGF-β and OPN levels were comparable between TO and EOT, however we observed a significant increase in TGF-β (p < 0.01) and OPN between T0 and SVR48 (p < 0.01) as well as EOT and SVR48 (p < 0.01 & p < 0.01). HA levels declined significantly between T0, EOT and SVR48 (p = 0.02, p = 0.09, p = 0.05), in contrast to a significant increase in YKL-60 levels between T0 and SVR 48 (p < 0.01).
Conclusion: HA is confirmed in our cohort as a strong marker of liver fibrosis stages. DAA treatment impacts fibrosis markers kinetics. Significant changes in HA can be observed quickly after the start of DAA treatment, while modification in TGF-β and OPN are slower and can be observed later after ending of treatment. Finally, YKL-60 decreased significantly along our cohort as expression of matrix remodeling.

FRI-094
SWAVE: Steady State Shear Wave Elastography for Fibrosis Evaluation in Liver Disease
C. Schneider[1], J. Lobo[1], M. Honarvar[1], E. Tam[2], R. Rohling[1], T. Salcudean[1]. *[1]University of British Columbia, Electrical and Computer Engineering, Vancouver, Canada; [2]LAIR Centre, Vancouver, Canada*
Email: caitlin.m.schneider@gmail.com

Background and Aims: Non-invasive liver elasticity measurements have previously been shown to be correlated with histologic liver fibrosis stage on biopsy. Measurement of the propagation speed of shear waves within the liver is directly related to the accumulation of fibrosis within the liver. Herein we present initial results of a new technology developed to non-invasively measure deep volumetric liver elasticity using steady state shear waves, known as shear wave absolute viboelastography, or SWAVE. This technology enables measurements of liver elasticity to a depth equal to the B-mode image, or in excess of 15 cm.
Method: The system consists of an ultrasound machine, a vibration device to excite shear waves in the patient and a 3D ultrasound transducer (m4DC7-3). The vibration device induces shear waves in the liver at four different frequencies between 40Hz and 70Hz simultaneously. The ultrasound volume is acquired through the ribs at the same location as a typical transient elastography (TE) measurement. Volumes are collected in a fan of approximately 15 degrees and taken at a depth of 15cm.
SWAVE (Sonic Incytes), TE (FibroScan®), and magnetic resonance elastography (MRE) were performed on a cohort of healthy volunteers. A second cohort of patients with chronic liver disease (Hepatitis C (HCV), Hepatitis B (HBV), or Non-alcoholic steatohepatitis (NASH)) were evaluated with SWAVE and TE.
Results: 12 healthy volunteers (mean age 37 years [range 25 to 49], 25% female) and 8 patients (mean age 56 years [range 34 to 65], 37% female, diagnosis of HCV (n = 3), HBV (n = 2) and NASH (n = 3)) were included in the study. Of the volunteers the mean elasticity and standard deviation measured with SWAVE was 3.9 ± 0.4 kPa, with TE was 4.5 ± 0.7 kPa and with MRE was 4.9 ± 0.3 kPa. Figure 1a compares the SWAVE, TE and MRE results. For the cohort of patients, the mean elasticity was 5.4 ± 0.7 kPa with SWAVE and 8.4 ± 1.5 kPa with TE, with staging ranging from F0-F3. Since each elastography measurement algorithm is unique, the correlation between the SWAVE and TE for all subjects is shown in Figure 1b. This correlation yields an R^2 value of 0.64.
Conclusion: These initial results demonstrate promise for SWAVE as a new technique for non-invasive fibrosis assessment in chronic liver disease. SWAVE is volumetric, works at depth, uses the same principle as MRE, and is suitable for point-of-care diagnosis and regular patient monitoring during and after treatment.

A PEGylated fibroblast growth factor 21 variant improves hepatic steatosis in a mouse model of non-alcoholic steatohepatitis, as determined by magnetic resonance imaging-derived hepatic fat-fraction

H. Tang, M. Fronheiser, S. Boehm, A. Pena, A. Shorts, B. Zinker, J. Krupinski, H. Malone, P. Chow, E. Charles, S. Du, W. Hayes. *Bristol-Myers Squibb, Lawrenceville, United States*
Email: haiying.tang@bms.com

Background and Aims: Non-alcoholic steatohepatitis (NASH), characterised by steatosis with inflammation and liver cell injury, can progress to fibrosis. Fibroblast growth factor 21 (FGF21) regulates energy and lipid metabolism; analogues have been shown to improve steatosis, biomarkers of liver injury and fibrosis, lipid profiles, and insulin sensitivity in clinical studies. This study evaluated the effects of a PEGylated-FGF21 variant (PEG-FGF21v) in a mouse model of NASH using magnetic resonance imaging-derived hepatic fat-fraction (MRI-HFF), a non-invasive imaging technique to assess hepatic steatosis.

Method: C57BL/6J mice were fed a control (10% kcal fat; n = 12) or a choline-deficient amino acid-defined, high-fat diet (CDAHFD; 60% kcal fat, 0.1% methionine; n = 48) for up to 8 wks, with baseline (BL) MRI performed at 4 wks on diet. Mice (12/arm) received twice-weekly subcutaneous PEG-FGF21v (0.06, 0.18, or 0.6 mg/kg) or vehicle after BL MRI, and were imaged again after 4 wks on treatment (tx), followed by sacrifice and liver collection for biochemical assessment of triglycerides (TG) and histological assessment of steatosis. MRI was performed on a Bruker Biospec 7T 20 cm system with an 86 mm volume coil and a phase array receive coil. MRI-HFF derived from the DIXON water-fat MRI technique was used to quantitate steatosis. Repeated measures ANOVA was used to test tx effects.

Results: Mice on CDAHFD developed liver steatosis with a mean MRI-HFF of 35.7%, 36.8%, 35.0%, and 36.4% in vehicle and PEG-FGF21v 0.06, 0.18, or 0.6 mg/kg tx groups, respectively, vs 10% ($p < .001$) in control mice at BL. Tx of CDAHFD mice with vehicle or PEG-FGF21v 0.06, 0.18, or 0.6 mg/kg for 4 wks resulted in absolute MRI-HFF reductions of 4.4%, 4.5%, 6.6% and 10.8% from BL, respectively, with significant improvements in hepatic steatosis with PEG-FGF21v 0.18 and 0.6 mg/kg vs vehicle tx (figure). MRI-HFF correlated with histology-determined steatosis (r = 0.93) and biochemical TG content (r = 0.93).

Conclusion: MRI-HFF accurately quantified hepatic steatosis in a mouse model of NASH, with strong correlation with histological and biochemical assessments of steatosis and hepatic TG, respectively. PEG-FGF21v significantly reduced MRI-HFF–assessed hepatic steatosis in a dose-dependent manner. These results support the use of MRI-HFF as an endpoint to evaluate efficacy in preclinical and clinical NASH studies, as well as further preclinical and clinical studies of FGF21 analogues for NASH.

Email: amaia.navarrocorcuera2015@my.ntu.ac.uk

Background and Aims: Transforming growth factor β (TGFβ) is the main pro-fibrogenic cytokine involved in hepatic stellate cells (HSC) regulation, promoting its proliferation and migration, and increasing the production of extracellular matrix proteins. TGFβ-receptor (TGFβR) I and II can be internalised into the cells via clathrin-coated vesicles triggering Smad activation. AGAP2 (ArfGAP with GTPase domain, ankyrin repeat and PH domain 2) is a new proto-oncogene involved in tumorigenesis, promoting cellular proliferation and invasion through Akt activation. AGAP2 seems to be part of the actin remodelling system, and promotes the endosomal recycling of β_2-adrenergic receptors. Our aim was to investigate the role of AGAP2 in hepatic fibrosis in response to TGFβ. We analysed the gene expression profile of TGFβ-mediated fibrotic genes in the presence/absence of AGAP2. We also studied the implication of AGAP2 in HSC viability, proliferation, migration and TGFβR trafficking in response to TGFβ.

Method: LX-2 cells were transfected with scramble siRNA or with AGAP2 siRNA and stimulated with TGFβ to determine the genes induced by TGFβ through AGAP2: a RT^2 Profiler PCR Array of human fibrosis was performed. The role of AGAP2 in HSC viability was evaluated by RTCA iCELLigence™ instrument. The effects of AGAP2 in LX-2 proliferation and migration were analysed using IncuCyte® S3 Live-Cell Analysis System. Protein expression of AGAP2, Collagen-I, and phosphorylated Focal adhesion kinase (p-FAK) was analysed by Western-Blot. U-2 OS cell line was employed to perform live tracking of TGFβR trafficking with CLIP- and SNAP-tag technology.
Results: Within the array, 45% of genes showed ≥2-fold differential expression in scrambled LX-2 treated with TGFβ *versus* LX-2 without TGFβ. AGAP2 silencing prevented some gene expression changes induced by TGFβ. The genes MMP1, MMP9, IL1A, ILB and SERPINA1 were up-regulated in AGAP2 knocked-down cells treated with TGFβ, whereas ACTA2, COL1A2, COL3A1, EDN1 and LOX were down-regulated (Fig.1). The viability and proliferation were lower in AGAP2 knocked-down LX-2 treated with TGFβ. The wound-healing assay showed a significant difference in the reduction in wound size in scrambled cells treated with TGFβ. TGFβ treatment increased AGAP2, p-FAK and collagen-I protein levels in a time-dependent manner. TGFβ-mediated increase in p-FAK protein levels required the presence of AGAP2. p-FAK protein was also required to increase collagen-I protein expression and the absence of AGAP2 interfered with this process.

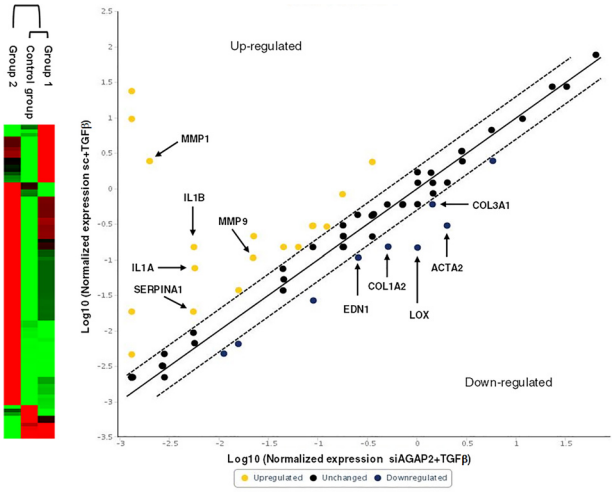

Figure 1 Potential targets of AGAP2 in response to TGFβ.

Conclusion: We show here for the first time that AGAP2 is a pro-fibrogenic gene involved in TGFβ-signalling. TGFβ increases collagen-I protein expression through p-FAK in an AGAP2-dependent manner. After TGFβ treatment, AGAP2 increases HSC viability, and promotes their proliferation and migration.

FRI-097

Role of the interleukin 15/macrophage axis in the immune response of liver fibrosis

M. Myllys[1], U. Albrecht[2], S. Dooley[3], S. Hammad[3], T. Weiß[4], H. Jan G.[1], P. Godoy[1]. *[1]IfADo - Leibniz Research Centre for Working Environment and Human Factors at the Technical University Dortmund, Systems toxicology, Dormund, Germany; [2]Universitätsklinikum Düsseldorf, Klinik für Gastroenterologie, Hepatologie und Infektiologie, Düsseldorf, Germany; [3]Medical Faculty Mannheim, Heidelberg University, Molecular Alcohol Research in Gastroenterology, Mannheim, Germany; [4]University Hospital Regensburg, Department of Pediatrics and Juvenile Medicine, Regensburg, Germany*
Email: myllys@ifado.de

Background and Aims: Interleukin-15 (IL-15) plays important roles in both innate and acquired immune responses by promoting the development and function of leukocytes. IL-15 and its cognate receptor IL-15Ralpha are expressed in multiple cell types including leukocytes, fibroblasts and epithelial cells. Previous studies using IL-15Ralpha-KO mice reported hepatoprotective effects of IL-15 in liver fibrosis and hepatitis. However, since this constitutive KO mouse line suffers from basal alterations in leukocyte physiology, more precise studies are required to understand the role of IL-15 in immune modulation on acute and chronic liver pathology.
Method:
Results: We observed increased IL-15 mRNA expression in diseased human liver tissue, and its expression levels correlated positively with disease severity. Also, serum levels of IL-15 were increased in patients with liver cirrhosis compared to healthy controls (p = 0.011). In line with this, we observed upregulation of IL-15 mRNA in mouse liver tissue after both acute and chronic liver damage by intraperitoneal CCl_4 administration. Furthermore, IL-15 induction was detected in hepatocytes but not in non-parenchymal liver cells after acute injury by CCl_4. A screening with multiple cytokines in vitro showed that TGF-beta can strongly induce IL-15 mRNA in primary mouse hepatocytes. The strong upregulation induced by this pro-fibrogenic cytokine suggested a potential pro-fibrotic role of IL-15. This hypothesis was supported by two experimental approaches. Firstly, stimulation of bone marrow-derived macrophages with IL-15 caused a strong induction of multiple pro-inflammatory cytokines including IL-28b, IL-13 and Gdf2. Secondly, liver fibrosis markers (sirius red and alpha-SMA expression) were reduced in IL-15 knockout in mice in comparison to wild type mice after chronic CCl_4 administration.
Conclusion: These results suggest that IL-15 may promote liver fibrosis by inducing pro-fibrotic cytokines in macrophages.

Establishment of an ex vivo model of human fibrotic liver slices culture: characterization of intrahepatic immune cells and TH17 cytokines

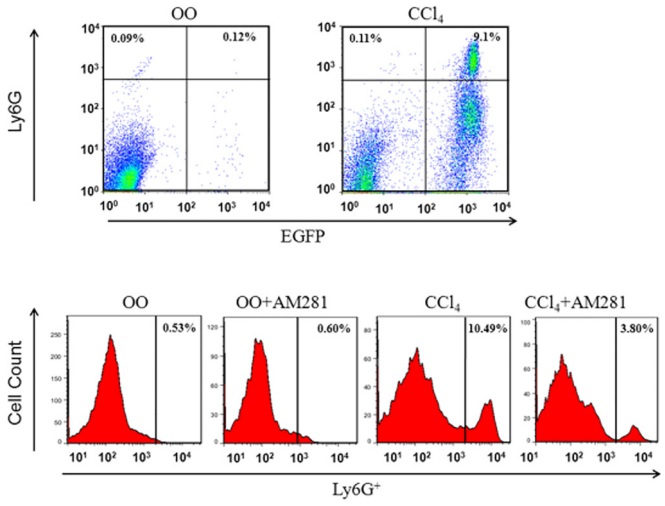
D. Kartasheva[1], J. Gaston[1,2], O. Scatton[3], J.-C. Vaillant[3], V.A. Morozov[4], P. Stanislas[1,2,5,6], S. Lagaye[1]. *[1]Institut Pasteur INSERM U1223, paris; [2]Université Paris-Descartes, Paris, France; [3]Hôpital Pitie-Salpétrière, Chirurgie Digestive, Hépatico Pancréatique et Transplantation Hépatique, Paris; [4]Robert Koch Institute, Berlin, Germany; [5]Hopital Cochin, service d'Hépatologie, Paris, France; [6]Institut Pasteur, Centre de Recherche Translationelle, Paris, France*
Email: sylvie.lagaye@inserm.fr

Background and Aims: To establish an ex vivo model of human fibrotic liver
Methods: Human fibrotic liver samples were collected after partial hepatectomy. Samples had from F2 to F4 fibrosis stage according to the METAVIR score. Liver slices (LS) obtained from human liver resection and cut in 350 µm-thick slices (2.7×10^6cells per slice), were cultivated for up to 21 days. Fibrotic liver slices (FLS) were infected or not with HCVcc supernatant infection [Con1/C3 (genotype1b)] (MOI = 0.1) (INF FLS). Human healthy liver slices (HLS) were used as controls. Ursodeoxycholic acid (UA) treatment (SOC) was tested on HLS and FLS cultures. The intrahepatic immune cells were extracted at day 0, 1. We evaluated the following fibrosis markers in HLS, in FLS and in INF FLS: expression of tumor growth factor β (TGFβ), Heat shock protein 47 (*Hsp47*), Alpha smooth muscle actin *(αSma), Procollagen1 A1 (Procl1A1), Matrix metalloproteinases 2, 9 (MMP-2, 9), Vascular Endothelial Growth Factor (VEGF),* which were checked by RT-qPCR and triglyceride production by ELISA assays. The immune cells were characterized by flow cytometry. IL-17A expression was determined by westernblot or ELISA assays.
Results: We succeeded to establish fibrotic livers slices culture up to day 21 with a viability rate of 55%. The TGFβ, Hsp47, αSma, Procl1A1, MMP-2, MMP-9, VEGF expression and a triglyceride production in HLS and FLS increased both but to a higher extent in FLS as compared

to HLS: a significant 6, 8, 5, 4, 5.2, 5, 5.2 fold increase, respectively as compared to controls with a triglyceride production higher in FLS [~ x 3.2]. HCV infection increased significantly, TGFβ, Hsp47, αSma, Procl1A1, MMP-2, MMP-9, VEGF expression and triglyceride production in NIFL and INF FLS to a higher extent in INF FLS as compared to controls. [at day 21, in INF FLS a significant 3, 3, 4, 2, 3, 2, 4, 2 fold increase as compared to NI FLS, respectively]. At day 0, 1, we could highlight the liver infiltration by the immune populations (LT CD4 +, CD8 +, NKT, MDSC). A higher IL-17A expression [~x4] was found in FLS compared to controls. FLS UA treatment gave a significant 2.5 fold decrease of TGF β expression.
Conclusion: The ex vivo model of human fibrotic liver slices culture supporting hepatocyte-specific gene expression for 21 days should be an easy tool for studying human liver fibrosis and evaluating the potency of new antifibrotic therapies, as immunotherapy, alone or in combination in the human liver tissue.

FRI-099
Endocannabinoid system contributes to activation of neutrophils in mouse chronic liver injury
X. Fan[1], L. Tian[1], X. Zhou[1], L. Yang[2], L. Yang[2], L. Li[2]. [1]*Capital Medical University, Department of Cell Biology, b, China;* [2]*Capital Medical University, Department of Cell Biology, Beijing, China*
Email: liliying@ccmu.edu.cn

Background and Aims: Neutrophil might be an initial factor that it triggers the inflammatory cascade. In recent research, more attention was focused on the role of neutrophil in sterile inflammatory disease process. Neutrophils are recruited to the site of liver injury shortly, thus mediating the early responses to tissue injury. The infiltration and accumulation of neutrophil in injured liver further contribute to the inflammation-associated damage by releasing reactive oxygen species (ROS), myeloperoxidase (MPO) and forming neutrophil extracellular traps (NETs). Our previous results showed that endocannabinoid system participated in liver injury. However, the concrete mechanism of endocannabinoids changing and function of neutrophil-expressed cannabinoid receptors (CBs) are unclear.
Method: Carbon tetrachloride (CCl_4) injection was used to induce chronic liver injury. The amount and activation of neutrophil in injured liver was measured by Fluorescence-activated cell sorting and RT-qPCR. *In vitro*, we isolated neutrophil from bone marrow. The expression of CB1 and CB2 were measured by gel electrophoresis and Western blot. Migration assays were performed by transwell chambers. The ROS, MPO release and NETs formation were detected by immunofluorescence and high content analysis.



Results: Here, we found Ly6G (neutrophil marker) and MPO expression and the amount of neutrophil were significantly elevated in CCl_4-induced mouse injured livers. Moreover their expression showed positive correlation with fibrosis parameter (procollagen α1(III)) and CB1/2 expression. *In vitro*, we found that both CB1 and CB2 were expressed in neutrophils at mRNA and protein levels. CB1 activation promoted the migration of neutrophils, but CB2 activation had no such effect. Pharmacological ablation of CB1 reduced ACEA-induced migration, whereas CB2 did not. Meanwhile, CB1-mediated migration was associated with cytoskeletal remodeling. Furthermore, activation of CB1 enhanced the releasing of ROS and MPO. Formation of NETs has been recently found in response to various stimuli. We noted CB1 activation contributed to NETs formation. *In vivo*, administration of CB1 antagonist AM281 markedly inhibited the recruitment and activation of Neutrophil to the injured liver and significantly attenuated liver injury.
Conclusion: Blockage of CB1 limited neutrophil infiltrations and over-activation, which might attenuates the inflammation enlargement and reduce fibrosis of injured liver.

Exosomes secreted by the hepatocytes can inhibit and reverse hepatic stellate cells stimulation
M. Safran[1], R. Masod[1], I. Tachlytski[1], M. Sultan[1], Z.B. Ari[2]. [1]*Chaim Sheba Medical Center, Liver Disease Center, Tel Hashomer, Israel;* [2]*Sheba Medical Center at Tel Hashomer, Center of Liver Diseases, Tel Aviv, Israel*
Email: michal.safran@sheba.health.gov.il

Background and Aims: In the normal liver, hepatic stellate cells (HSCs) constitute quiescent, vitamin A–storing cell. Upon activation by a specific stimuli released by an injured liver, HSCs undergo activation and differentiation into a myofibroblast-like cell, thereby inducing hepatic fibrosis. Recent findings demonstrated that activated HSCs have the ability to revert into their quiescent state. Our aims were to investigate the mechanisms adopted by the normal liver that maintained the HSCs in quiescent state and to try to elucidate the role of the hepatocytes in the process.
Method: Primary HSCs were purified from normal mice liver using enzymatic digestion. Mediums were collected from primary hepatocytes, primary kidney cells, hepatocytes cell-line or kidney cell-line. The purified HSCs were cultured with the different cells media for 24h or 96 hours. HSCs activation level was analyzed by the expression of αSMA and Col1a (qRT-PCR and Western blot analysis). HSCs were stained with Oil-Red-O as a marker of lipid accumulation and activation. Exosomes were purified from the hepatocytes using ultracentrifuge. The level of CD63, a marker of exosomes, was measured using western blot analysis. Exosomes size was measured either by Nanostream analysis or TEM. Exosomes secretion inhibitor GW4869 (20μM) was also used to inhibit exosomes production and to prevent the hepatocytes activity.
Results: We have shown that medium collected from normal hepatocytes have the ability to inhibit and even reverse the HSCs stimulation and prevent their differentiation toward myofibroblast like cells. Furthermore, using a cellulose membrane with a cutoff of 100kDa, we have demonstrated that the size of the particles responsible for the HSCs inhibition is larger than 100kDa. Using ultra-centrifuge we have purified the particles from the medium and by western blot, nanostrean and TEM analysis we have proven that the fraction contains exosomes. Using exosomes secretion inhibitor we have demonstrated that the exosomes are the active component in the medium and we have shown that purified hepatocytes secreted exosomes can inhibit the stimulation of primary HSCs.
Conclusion: We have demonstrated for the first time that in the normal liver hepatocytes can regulate HSCs stimulation and inhibit their differentiation toward fibroblast like cells. This inhibition is mediated by the exosomes, extracellular nanovesicles vesicles that

play a role in intercellular communication. Further exploration of our proposed mechanism for the exact role and reliability of exosomes as screening, diagnostic and treatment targets will facilitate the development of new therapeutic options that can be used to inhibit the development and progression of hepatic fibrosis

The anti-fibrotic effect of Aramchol on rat liver fibrosis induced by TAA and in vitro on primary hepatic stellate cells

R. Golan-Gerstl[1,2], M. Valitsky[1], R. Oren[1], E. Brazowski[3], L. Hayardeni[1], S. Reif[1,4]. *[1]Hadassah Medical Center, The Liver Unit, Jerusalem Israel; [2]Hadassah Medical Center, Pediatrics, Jerusalem, Israel; [3]Tel Aviv Medical Center, The Pathology Department, Tel Aviv, Israel; [4]Hadassah Medical Center, Pediatrics, Jerusalem, Israel*
Email: reginag@hadassah.org.il

Background and Aims: Cirrhosis is the end result consequence of wide variety chronic liver diseases; including nonalcoholic fatty liver disease/nonalcoholic steatohepatitis (NAFLD/NASH). Liver fibrosis results from an accumulation of extracellular matrix (ECM) following the activation and proliferation of hepatic stellate cells (HSCs). HSCs secrete pro-collagen, and also tissue inhibitor metalloproteinase (TIMP). Aramchol (arachidyl amido cholanoic acid) is a fatty acid-bile acid conjugate which has been shown to reduce liver fat content in nonalcoholic fatty liver disease (NAFLD) and is presently in a Phase 2b study for nonalcoholic steatohepatitis (NASH). In MCD diet model, Aramchol down regulated steatosis, inflammation and fibrosis. The total amount of collagen accumulated in the Aramchol treated mice was significantly lower than in the shame treated mice. The aim of this study was to investigate the direct anti fibrotic effect of Aramchol using Thioacetamide (TAA) rat model of fibrosis and in vitro model of activated primary HSCs.
Method: *In vitro:* HSCs were isoalted from rats by sequential digestion of the liver with Pronase and collagenase, followed by arabinogalactan gradient centrifugation. Proliferation, TGF-**β,** TIMP-1, collagen and αSMA levels were analysed in activated HSC. *In vivo:* Liver fibrosis was induced by intraperitoneal injections of TAA at a dose of 20mg/100g body weight twice-weekly intra peritoneal for up to 10 weeks. Rats were treated orally by gavage with Aramchol (1 mg/kg/day) or vehicle. Control TAA induced fibrosis rats were treated with vehicle for the same duration. At the end of the experiment, liver samples were obtained. A histological assessment of the livers was performed after staining with hematoxylin-eosin (H&E) and Mason trichrome staining. Evaluation of fibrosis was based on the Ludwig and Batts staining system
Results: TAA-treated animals developed cirrhosis. However, rats that received TAA and Aramchol 1mg/Kg showed marked macroscopic morphologic improvement. Microscopically, the TAA treatment group displayed a periportal fibrosis characterized by portal-portal septa surrounding the hepatic lobules and received a fibrotic score of 3.25 ± 0.21, whereas rats treated with the TAA and Aramchol demonstrated significantly lower fibrosis and scored 1.6 ± 0.2. No fibrosis was observed in the control rats or the group that received Aramchol alone. Consistently, Aramchol treatment improved liver histology as determined by a reduction of 40.2% in fibrosis score. PDGF treatment up regulated the HSCs number; this elevation was reduced following incubation with Aramchol (10 μM) compared to untreated cells. Moreover, following TGF-β stimulation, the expression of TIMP-1 collagen and αSMA were down regulated by Aramchol treatment.
Conclusion: The *in vivo* and *in vitro* results support the ameliorative effect of Aramchol on liver fibrosis.

FRI-102

25(OH) D3 alleviate liver NK cytotoxicity in early but not in late fibrosis model of Balb/c mice due to modulations in vitamin D receptor

J. Amer, A. Salhab, R. Safadi. *Hadassah Hebrew University Hospital, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background & Aims: Low 25-Hydroxy-vitamin-D; "25(OH) D3" serum and vitamin D receptor (VDR) levels were recently correlated to advanced fibrosis in Chronic Hepatitis C (CHC). However, vitamin D receptor mechanism in liver fibrosis modulations is not well understood. We aimed to evaluate associations of VDR with NK cell modulations during fibrogenesis.
Methods: Carbon-tetrachloride (CCl_4) hepatic-fibrosis was induced in Balb/c mice for 4 weeks. Along 1th to 4th weeks; 25 (OH) D3 were i. p injected/2x week. Liver NK cells were isolated and were identified as resident ($CD49a^+/CD49b^-$) NK1.1. NK cells were further stained for CD107a (LAMP-1; Lysosomal-associated membrane protein 1) as activation marker. Liver proteins were quantified for VDR and αSMA expressions by western blot and RT PCR, respectively. Livers were also assessed histologically and serum ALT levels were estimated. *In vitro*, 25 (OH) D3 was incubated with pHSCs obtained from Balb/c WT-mice and assessed for αSMA intensities.
Results: Hepatic fibrosis increased along 4 weeks injections of CCl_4 as indicated by serum ALT levels and αSMA expressions ($P < 0.02$) as well as H&E staining of liver necro-inflammatory lesions. These results were associated with increased activations of NK1.1 CD107a. While 25 (OH) D3 administrations did not modulate fibrosis of early stages (weeks 2 & 3); 25(OH) D3 significantly worsen hepatic-fibrosis of late stage (week 4) as hepatic αSMA expressions and serum ALT levels increased. In week 4, no further activations of NK cells were seen following 25(OH)D3 injections and were associated with down-expressions of VDR (1.7 Fold, $P < 0.01$) indicating the inability of 25 (OH)D3 to ameliorate hepatic fibrosis were lost due to modulations in VDR. These results were correlated with changes in serum calcium levels; in early fibrosis model calcium levels were unchanged and while hypercalcemia were noticed in serum of the animals with advanced fibrosis. *In vitro*, pHSCs showed to have 3 sub-populations that differ in the size and granularity. Two of these populations were excluded as they do not express VDR and a low amount of αSMA. pHSCs subpopulation with high VDR (50% ± 12%) were further elevated with increased concentrations of 25 (OH) D3 ($p < 0.02$).
Conclusions: 25(OH) D3 alleviate liver NK cytotoxicity in early but not in late fibrosis model of Balb/c mice due to modulations in vitamin D receptor and calcium. Hypercalcemia associated with late fibrosis may inhibited levels of VDR, however, may not explain the profibrogenic effects of 25(OH) D3. While in the vitro data showed anti-fibrotic effects, more studies are needed to clarify the role of VDR in attenuation of liver fibrosis.

FRI-103

Role of the protein tyrosine kinase Mer (MerTK) in the cross-talk between macrophages and hepatic stellate cells

M. Pastore[1], G.D. Maira[1], A. Caligiuri[1], S. Petta[2], F. Marra[1]. *[1]DMSC, University of Florence; [2]University of Palermo, Department of Gastroenterology and Hepatology Di.Bi.M.I.S*
Email: fabio.marra@unifi.it

Background and Aims: One of the first events that defines the liver fibrogenic process is the activation of resident macrophages and the recruitment of further inflammatory cells such as monocytes/macrophages, resulting in the activation of quiescent hepatic stellate cells (HSCs) via paracrine pathways. MerTK, a receptor tyrosine kinase mainly expressed in macrophages, plays a key role in the initiation of efferocytosis, a process by which dying cells are removed by phagocytes. MerTK is overexpressed in murine models of

fibrogenesis and by human HSCs, where mediates profibrogenic actions. In addition, MerTK mutants are associated with higher protein expression are present with higher frequency in patients with NAFLD and significant fibrosis, and macrophages contribute to its expression. This study was undertaken to evaluate the potential effects of MerTK activation in macrophages on HSC phenotype modulation

Method: Primary human HSCs, isolated from human liver tissue and activated on plastic, and the immortalized monocytic line THP1 were employed. THP1 monocytes were differentiated into THP1 macrophages after treatment with phorbol 12-myristate 13-acetate (PMA). Inhibition of MerTK expression or activity was performed by knockdown with siRNA or with the specific inhibitor UNC569. Migration of HSCs was assessed by modified Boyden chamber. HSC viability was measured by MTT assay and gene expression were evaluated by

Results: Exposure of THP1 cells to PMA resulted in a dramatic upregulation of MerTK expression, at the gene and protein levels. Incubation with Gas-6, a MerTK ligand, caused time-dependent phosphorylation of MerTK on tyrosine residues. Exposure of HSCs to conditioned medium (CM) of differentiated, PMA-treated THP1 cells exposed to Gas-6 induced a significant increase in cell migration and in cell viability compared to control CM. Furthermore, the CM from Gas-6-stimulated THP1cells induced in HSCs an increase in the gene expression of profibrogenic factors compared to control CM. These effects were specifically related to MerTK activity/expression, as indicated by knockdown experiments and by pharmacologic inhibition

Conclusion: These data highlight a novel important role of MerTK in the fibrogenic responses, through a cross-talk between HSCs and inflammatory cells.

FRI-104

PBI-4547 decreases hepatic stellate cell activation via AMPK signaling pathway, and reduces fibrosis in carbon tetrachloride (CCL4)-induced hepatic fibrosis model

François Sarra-Bournet, B. Grouix, K. Hince, A. Felton, Mikaël Tremblay, S. Abbott, J.-S. Duceppe, B. Zacharie, P. Laurin, L. Gagnon. *Prometic Biosciences Inc., Laval, Canada*
Email: f.sarra-bournet@prometic.com

Background and Aims: Hepatic stellate cells (HSC) are considered a key player in the fibrogenic process of the liver. In response to liver injury, HSC become activated and transdifferentiate into myofibroblast-like cells, which display increased proliferation and collagen synthesis. Recent studies have shown that AMPK modulates HSC activation and inhibits transforming growth factor (TGF)-β1-induced fibrosis. In the present study, we investigated whether treatment with PBI-4547, a novel first-in-class orally active compound, could decrease *in vitro* HSC activation via AMPK, and ameliorate CCL4-induced fibrosis in mice.

Method: *In vitro*, primary human HSC were stimulated with TGF-β1 (10 ng/ml) in the presence or absence of PBI-4547 (20 and 10 μM) for 24 hours. AMPKα and α-SMA proteins were detected by Western blot. Expression of fibrotic and activation markers in stellate cell was investigated by qPCR. Liver fibrosis was induced in C57BL/6 mice by administration of 10% CCL4 in olive oil at 2 ml/kg, twice a week for eight weeks, and mice were treated with PBI-4547 (10 and 50 mg/kg) or vehicle. The degree of fibrosis in the liver was evaluated by histopathology and gene expression analysis.

Results: *In vitro*, TGF-β1-induced activation of HSC was decreased by PBI-4547, as shown by the significant inhibition of stellate cell activation marker α-SMA mRNA and protein expression. Profibrotic factor CTGF mRNA expression was also downregulated by PBI-4547. As evidenced by protein analysis, PBI-4547 significantly activated AMPK signalling in TGF-β1 activated HSC. After induction of hepatic fibrosis with CCL4, mice treated with PBI-4547 showed reduced liver fibrosis compared to CCL4 controls, as evaluated by histological analysis. The hepatocyte growth factor (HGF) tissue regeneration factor, upregulated in CCL4-treated mice, was also reduced by treatment with 50 mg/kg of PBI-4547. Moreover, PBI-4547 restored expression of peroxisome proliferator-activated receptor-γ (PPARγ), which was reduced in the liver of CCL4-animals and in TGF-β1-activated HSC.

Conclusion: This study demonstrated that PBI-4547 significantly reduced HSC activation through AMPK signalling pathway. PBI-4547 reduced collagen deposition in CCL4-induced liver. Ours results suggest that PBI-4547 may be developed as a novel therapeutic agent to treat hepatic fibrosis.

FRI-105

The wrong or "right" effects of HCV on cardiac function in patients with low-mild liver fibrosis: A case-control study

A. Dalbeni[1], S. Romano[1], E. Imbalzano[2], A. Tagetti[1], G. Torin[1], A. Mantovani[1], G. Cavallon[3], V. Paon[1], C. Fava[1], L.I. Prat[1,4], F. Capra[5]. *[1]Division of General Medicine and Hypertension, Medicine, Verona; [2]Division of Internal Medicine, Clinical and Experimental Medicine, Messina, Italy; [3]Azienda Ospedaliera Universitaria Integrata, Division of Liver Unit, Verona, Italy; [4]UCL Institute for Liver and Digestive Health, Royal Free Hospital and UCL, London, United Kingdom; [5]University and Azienda Ospedaliera Universitaria Integrata of Verona, University of Verona, Italy*
Email: andrea.dalbeni@aovr.veneto.it

Background and Aims: Hepatitis secondary to hepatitis C virus (HCV) infection is one of the most common causes of viral hepatitis. Association between HCV infection and increased incidence of cardiovascular disease has already been described in literature: vascular and cardiac alterations related to HCV seem to be Cardiovascular disease incidence and HCV infection is described and a possible mechanism due to this vascular and cardiac alterations seems to be explained by HCV proinflammatory effects on endothelium and myocardium. Few studies describe echocardiographic modifications in subjects with HCV vs a control population. In particular, a modified systolic and diastolic left function seems to be present in HCV subjects. Only one study reported a right ventricular systolic dysfunction and pulmonary hypertension in HCV patients. In this study we examined right and left ventricular systolic function in patients affected by HCV infection in low-mild liver fibrosis stage.

Method: In this study we included 65 consecutive naïve HCV patients with low-mild liver fibrosis stage at Fibroscan referring to our clinic (Liver Unit) because of eligibility for HCV eradication with DAA (Directly Acting Antivirals) (mean age 58.0 ± 12.8; M 46%). We also included 60 age-sex-BMI and cardiovascular risk factors matched controls Transthoracic echocardiography was performed in all participants. Therefore, we aimed to analyse left and right ventricular systolic functions in HCV patients and in the control group and parameters were compared between these 2 groups.

Results: In the two groups the left ventricular function was similar. Left ventricular mass (LVM), dystolic function E/A, mitral annular plane excursion (MAPSE) and ejection fraction (EF%) showed no difference between the two groups. Also left atrial measures showed no difference in the two groups. Conversely, when we analysed the right sections, tricuspid annular plane excursion (TAPSE) and right atrium volume (RA), we found significant differences: TAPSE HCV (mean ± SD) was 14.8 ± 6.1 mm vs TAPSE controls 18.9 ± 1.9 mm ($p < 0.001$); RA HCV 36.9 ± 20.4 mm3 vs RA controls 25.2 ± 2.9 mm3 ($p < 0.001$). PAPs showed no differences. When we subdivided the HCV patients according to fibrosis stage (1, 2 or 3) or viral load (>800.000 copies) no differences were detectable in echocardiographic measures.

Conclusion: our study is the first case-control study that shows right-sided heart alterations due to the presence of HCV which do not seem to be linked to the severity of liver fibrosis and to viral load. Other studies are necessary to understand the right cameras modifications due to HCV infection.

FRI-106

BMS-986036, a PEGylated fibroblast growth factor 21 analogue for the treatment of non-alcoholic steatohepatitis: A population pharmacokinetics and exposure-response analysis

G. Tirucherai[1], M. Magnusson[2], C. Acharya[2], E. Charles[1], D. Shevell[1], R. Christian[1], Y. Luo[1]. [1]*Bristol-Myers Squibb, Lawrenceville;* [2]*Pharmetheus, Sweden*
Email: giridhar.tirucherai@bms.com

Background and Aims: Fibroblast growth factor 21 (FGF21) is a key regulator of energy and lipid metabolism. BMS-986036, a PEGylated analogue of human FGF21, decreased steatosis (hepatic fat fraction [HFF]) and improved biomarker (BM) responses of fibrosis (Pro-C3), adiponectin, and injury (ALT) in a phase 2 study of patients (pts) with non-alcoholic steatohepatitis (NASH); a population pharmacokinetic (PopPK) model was developed to assess the exposure response of BMS-986036 on key BMs.
Method: The PopPK model was developed from randomized, placebo (PBO)-controlled trials: MB130-001 (phase 1; single [0.3–60 mg] and multiple ascending doses [0.3–30 mg/d or 21 mg/wk] of BMS-986036 in healthy obese adults), MB130-002 (NCT02097277; phase 2; 1, 5, or 20 mg once-daily [QD], 20 mg once-weekly [QW] BMS-986036, or PBO QD in obese pts with type 2 diabetes), and MB130-045 (NCT02413372; phase 2; 10 mg QD or 20 mg QW BMS-986036, or PBO QD, in pts with NASH [stage 1-3 fibrosis]). Non-linear mixed effects modelling was performed (NONMEM VII). The PopPK model was used to describe the PK-pharmacodynamic (PD) relationship between BMS-986036 and HFF, ALT, Pro-C3, adiponectin, triglycerides, LDL, and HDL. PK-PD relationships were used to simulate BM response at various QD and QW dosing for 16 wks.
Results: The PK of SC BMS-986036 was adequately described by a two-compartment model with sequential zero- and first-order absorption, and first-order elimination from the central compartment. Duration of zero-order absorption, bioavailability, and central- and peripheral-volume of distribution supported interindividual variability terms. Direct- or indirect-response PK-PD models described the time course of BM responses. Simulations showed that BM responses were similar for QD and QW dosing at a similar total dose/wk (table).

Model-predicted % change in response at trough concentrations (baseline to wk 16), for QD and QW dosing of BMS-986036

BM	~10 mg/wk		~20 mg/wk		~40 mg/wk	
	1.5 mg QD	10 mg QW	3 mg QD	20 mg QW	6 mg QD	40 mg QW
	%					
HFF	−33.7	−24.8	−34.1	−29.7	−34.3	−31.9
ALT	−22.5	−16.7	−27.9	−22.6	−31.6	−26.7
ProC3	−8.3	−7.0	−13.7	−12.4	−20.3	−17.4
Adiponectin	14.1	11.4	21.3	18.3	28.9	24.0

Conclusion: PopPK-PD models described the PK and PD responses following QD and QW dosing of BMS-986036 in 3 trials. Simulations identified QW doses of BMS-986036 projected to have significant PD responses comparable with QD dosing (at a similar total dose/wk), supporting the use of a less frequent dosing regimen for future trials.

FRI-107

Primary human HSC cell phenotype is differently regulated by pro-fibrogenic and pro-inflammatory stimuli in cirrhotic and healthy human liver 3D ECM scaffolds

E. Caon[1], Z. Zhang[2], L. Frenguelli[1], W. Al-Akkad[1], G. Mazza[3], M. Pinzani[1], K. Rombouts[1]. [1]*University College London, Institute for Liver and Digestive Health, London, United Kingdom;* [2]*University College London, Institute for Liver and Digestive Health, London, United Kingdom;* [3]*Institute for Liver and digestive he, London, United Kingdom*
Email: k.rombouts@ucl.ac.uk

Background and Aims: Hepatic stellate cells (HSCs) are key mediators in liver fibrosis. A common platform to investigate HSCs activation is the usage of classical 2D cultures. However, the ECM microenvironment plays a crucial role in reason of the liver-specific 3D microarchitecture, which favours essential cell-ECM interactions. The aim of this study is to evaluate a novel in vitro 3D model based on human liver scaffolds in order to combine the advantage of the liver's specific 3D architecture as well as the preserved bioactive cues to achieve a more accurate in vitro phenotype of primary human HSCs.
Method: Human liver 3D scaffolds were obtained by the decellularization of healthy and cirrhotic livers. Scaffolds were repopulated with the hHSC cell line LX2 or with primary hHSCs ($0.25*10^6$) in serum-rich medium for 10 days. Cells were exposed to profibrogenic agents: PDGF-BB (1–10ng/mL), TGFbeta1 (2–5ng/mL) for 24hrs or LPS (1ng/mL) for 1–3hrs. In parallel, LX2 cells or primary hHSCs were grown in 2D cultures and treated as above. Histology was performed to compare hHSCs cell phenotype/engraftment in the 3D scaffolds. QRT-PCR was performed.
Results: Significant differences were observed in gene expression of hHSCs cultured on 2D vs 3D healthy scaffolds, especially when exposed to LPS, PDGF-BB and TGFbeta1. Human HSCs in 3D cultures treated with LPS showed a strong increase in Acta2, CYGB, COL1A1, IL-6 whereas LOX gene expression remained unchanged. TGFbeta1 induced a significant increase in Acta2, Col1A1 and LOX gene expression, but not CYGB and IL-6. In contrast, PDGF-BB significantly decreased Acta2 in comparison to non-treated hHSCs in 3D cultures. Furthermore, the HSC activation markers Acta2 and COL1A1 were significant upregulated in cirrhotic scaffolds compared to healthy scaffolds, whereas CYGB, LOX and IL-6 were not affected. In contrast, LX2 cells on cirrhotic scaffolds showed a downregulation of Acta2, Col1A1, and Col3A1 gene expression compared to LX2 cells on healthy scaffolds, indicating that, when cultured in a natural 3D ECM microenvironment, LX2 cells do not show the same gene expression pattern of primary hHSCs.
Conclusion: This study shows that primary hHSCs have different gene expression patterns when cultured in 3D scaffolds derived from healthy and cirrhotic human livers and in comparison to 2D cell culture. By using human tissue-specific 3D scaffolds, as models of human physiology and pathophysiology, specific and novel drug targets and biomarkers will be identified.

FRI-108

Integrin αvβ6-targeted near-infrared/positron emission tomography contrast agent for liver fibrosis imaging

Y.O. Kim[1], K.-S. Park[1], N. Engelbogen[2], M. Diken[3], Y. Popov[4], T. Ross[5], D. Schuppan[1,4]. [1]*University Medical Center of the Johannes Gutenberg University Mainz, Institute of Translational Immunology, Research Center for Immune Therapy (FZI), Mainz, Germany;* [2]*Johannes Gutenberg University Mainz, Germany, Institute of Nuclear Chemistry, Mainz, Germany;* [3]*University Medical Center of the Johannes Gutenberg University Mainz, Institute for Translational Oncology (TrOn), Mainz, Germany;* [4]*Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Gastroenterology, Boston, United States;* [5]*Hannover Medical School, Department of Nuclear Medicine, Radiopharmaceutical Chemistry, Hannover, Germany*
Email: kimy@uni-mainz.de

Background and Aims: There is an urgent need for quantitative imaging of liver fibrosis. The integrin αvβ6 is highly upregulated on cholangiocytes that drive liver fibrogenesis. We therefore developed and validated a bimodal αvβ6-targeted contrast agent to quantitatively image liver fibrogenesis.
Method: We designed a dual-labeled cyclic peptide recognizing integrin αvβ6 based on a 9-mer cyclic RGD peptide, attaching a

functional group with sulfo-Cy5.5 and a Ga-68-chelator for near infrared (NIR) and PET imaging, resp. Binding specificity was tested in vitro on αvβ6-positive and -negative cell lines. In vivo uptake, biodistribution and clearance were studied in mouse models of biliary (Mdr2 KO) and parenchymal (CCl_4-induced) fibrosis compared to nonfibrotic controls. For NIR imaging, 20 µg (5.84 nM/mouse) of contrast agent were injected intravenously and whole body and organ imaging were performed at 20 min, and 2, 4, 6 and 12 h post injection. For micro-PET imaging the Ga-68-labeled construct (5 MBq/mouse) was injected and followed by micro-PET. Organ specific signals were also quantified using a gamma-counter. Fibrosis and target expression were assessed by determination of collagen content and αvβ6 protein expression by qRT-PCR.

Results: The dual-labeled cyclic peptide dose-dependently bound to αvβ6 expressing, but not to αvβ6 deficient cells (highest at 1 µM in 5.2-fold vs control; $p < 0.01$). The activity was blocked with excess unlabeled peptide. Mdr2 KO fibrotic mice displayed a 3-fold elevated hepatic collagen content ($p < 0.0001$) and a 43-fold increased αvβ6 mRNA expression compared to wildtype mice ($p < 0.05$). CCl_4-treatment induced a 3-fold elevated hepatic collagen content ($p < 0.0001$), and a 4.6-fold αvβ6 expression ($p < 0.05$). NIR imaging with the bimodal cyclic peptide revealed a liver-specific 3.4-fold ($p > 0.001$) and a 3.2-fold ($p > 0.01$) enhanced uptake in the fibrotic livers, respectively, 6 h post injection, compared to the non-fibrotic controls. Comparable results were obtained with micro-PET imaging using the Ga-68-radiolabeled bimodal cyclopeptide.

Conclusion: We designed a bimodal integrin αvβ6-specific fibrogenesis imaging agent based on a cyclic RGD peptide that can be used for NIR and PET-imaging in mice and for PET-imaging in patients. This opens the possibility of molecular imaging to quantify liver fibrogenesis in vivo and therefore to assess early treatment responses in patients treated with potential antifibrotic agents.

Glycosyltransferase GLT25D2 acts as a negative regulator of autophagy to promote acetaminophen-induced hepatotoxicity

J. Zhang[1], X. Zhang[1], H. Shi[1], Z. Duan[1], H. Wei[2], F. Ren[1]. [1]*Capital Medical University, Beijing Youan Hospital, Beijing, China;* [2]*Capital Medical University, Beijing Ditan Hospital, Beijing, China*
Email: renfeng7512@hotmail.com

Background and Aims: The glycosylation of proteins in acetaminophen-induced hepatotoxicity remains enigmatic. The aims of this study is to explore the role of the collagen galactosyltransferase GLT25D2 in pathogenesis of acetaminophen-induced hepatotoxicity.

Method: The mice were given a single intraperitoneal (i.p.) injection of acetaminophen. Livers tissues analyzed by histology, reverse-transcription polymerase chain reaction, western bolting, immunohistochemistry, and electron microscopy, respectively. Primary hepatocytes were isolated and analyzed. Liver biopsy samples from patients with acetaminophen overdose were analyzed by immunofluorescence staining.

Results: GLT25D2 expression was significantly elevated in the livers of mice exposed to acetaminophen. Knockout of GLT25D2 ameliorated the hepatocellular damage, evidenced by reduced serum alanine aminotransferase levels and well-preserved liver architecture compared with controls. Mechanistic investigations elucidate that GLT25D2 acts as a negative regulator of autophagy, whereby enhancing the susceptibility of hepatocytes to acetaminophen-induced cytotoxicity. Indeed, (1) knockout of GLT25D2 promoted autophagy and enhances autophagy flux in vitro and in vivo; (2) inhibition of autophagy reversed liver protection and hepatocyte protection of GLT25D2 knockout; (3) autophagy induced by GLT25D2

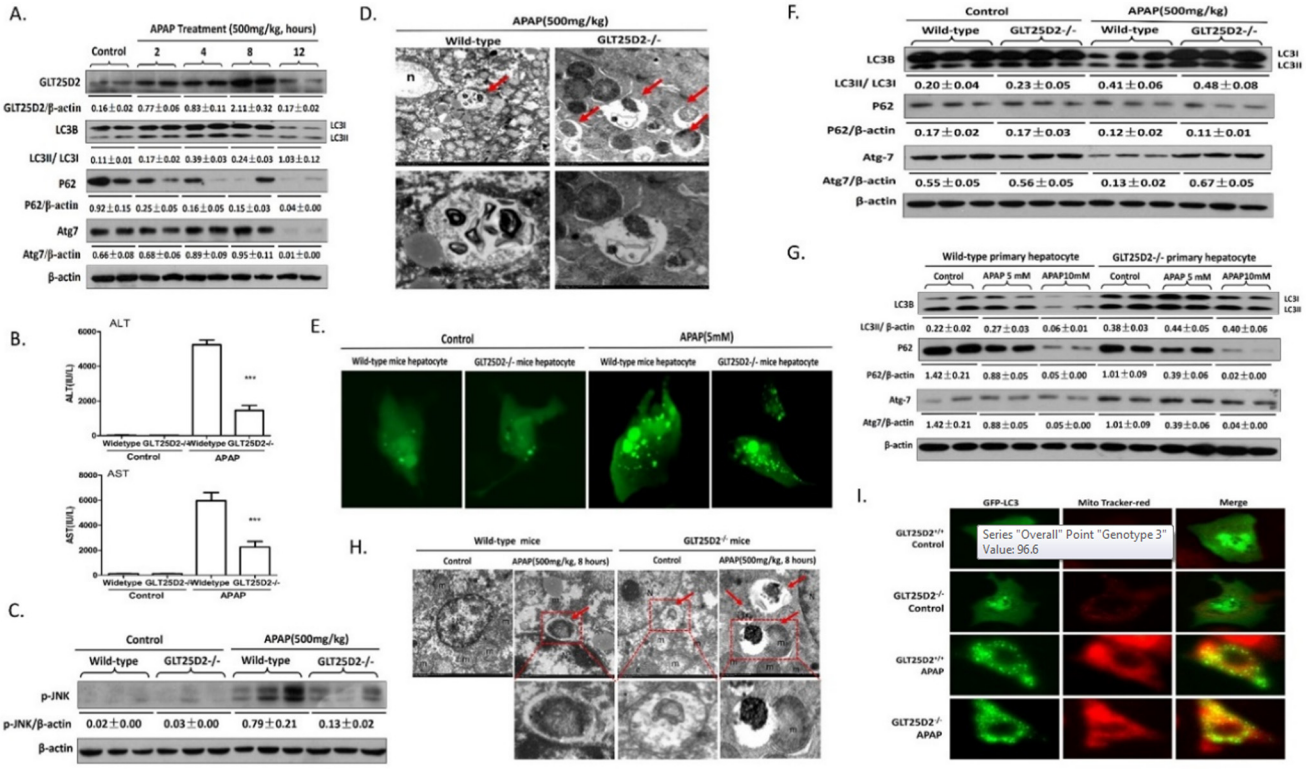

Figure 1: (abstract: FRI-111)

knockout seemed to be selective for damaged mitochondria. More importantly, the expression of GLT25D2 is significantly down-regulated in drug-induced liver injury patients.
Conclusion: The increased GLT25D2 suppresses autophagy to promote the occurrence and development of acute liver injury and suggest that GLT25D2 can be a potential therapeutic choice for acetaminophen-induced hepatotoxicity.

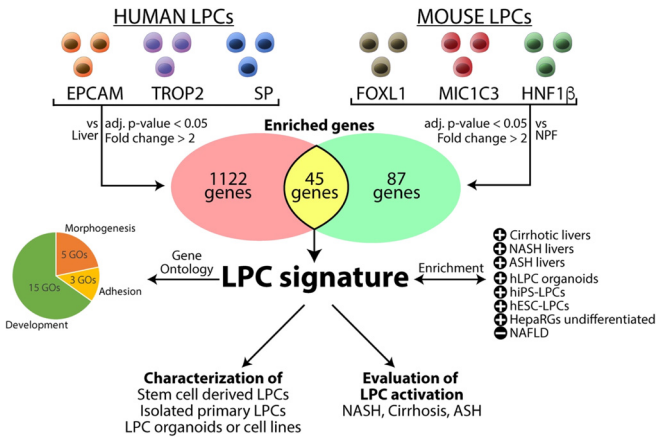
Generation of a unique liver progenitor cell gene signature to identify LPCs and LPC activation in chronic liver diseases
S. Verhulst[1], A. Ceulemans[2], P. Sancho-Bru[3], T. Roskams[2], L. van Grunsven[1]. [1]*Vrije Universiteit Brussel, Biomedical Sciences, Brussels, Belgium;* [2]*KU Leuven, Imaging and Pathology, Leuven, Belgium;* [3]*Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain*
Email: stefaan.verhulst@vub.be

Background and Aims: Chronic liver diseases are frequently associated with a ductular reaction. This includes the activation of liver progenitor cells (LPCs), especially in conditions in which hepatocytes are senescent. The extent to which LPCs contribute to liver regeneration is still a subject of debate. The different isolation methods and the use of diverse LPC markers to isolate, characterize and lineage-trace LPCs in healthy, damaged and regenerating livers is certainly one of the culprits. In this study we compared the gene expression profiles of different LPC populations, i.e different species and isolation methods as well as LPC cell lines, and established a gene signature that identifies LPCs and their activation.
Method: In this study, we analyzed online available gene expression profiles of human (enriched in EPCAM, TROP2 or side population) and mouse (enriched in HNF1b, FOXL1 or MIC1C3) LPCs. We compared their transcriptomes and analysed co-expressed genes by using supraHex and AmiGO. A unique LPC signature was created by pooling enriched genes from each LPC population using venn diagrams. Gene set enrichment analysis using this LPC signature was performed on different iPS- and ESC-derived LPCs, differentiated HepaRGs and on data sets from livers of patients with cirrhosis, ASH, NAFLD or NASH.
Results: Comparison between human and mouse LPC populations showed high similarities in genes involved in proliferation and development. Overlap of genes enriched in all LPC population resulted in 45 genes and contains well-known LPC markers but also genes never described in LPCs. LPCs derived from human iPS- or ESC-derived LPCs and undifferentiated HepaRGs showed a higher enrichment of our signature compared to previously established LPC signatures. Gene set enrichment analysis with the LPC signature of liver expression profiles of ASH, NASH and cirrhosis suggests that only these diseases are accompanied by a strong LPC activation.



Conclusion: We compared and characterized for the first time human and mouse LPC gene profiles and created a unique LPC signature through an unbiased approach. This signature can be used to identify primary LPCs, LPC cell lines or LPCs derived from iPS or hESCs and as a tool to evaluate LPC expansion in liver diseases. In the future, we would like to correlate the LPC signature with the outcome of the liver disease.

FRI-113
Osteopontin might be a central regulator of inflammation during postoperative liver regeneration in humans
D. Pereyra[1], S. Holzer[1], M. Herac[2], J. Stift[2], M. Finsterbusch[3], C. Brostjan[1], T. Grünberger[4], P. Starlinger[1]. [1]*Medical University and General Hospital of Vienna, Department of Surgery, Vienna, Austria;* [2]*Medical University of Vienna, Clinical Institute of Pathology, Vienna, Austria;* [3]*Medical University of Vienna, Institute of Pharmacology and Pathology, Vienna, Austria;* [4]*Rudolfstiftung Hospital, Department of Surgery, Vienna, Austria*
Email: N1342352@students.meduniwien.ac.at

Background and Aims: Osteopontin (OPN) was described as an important factor for liver regeneration (LR) in mice. However, a rat model investigating postresectional LR, showed development of necrosis and inflammation in OPN overexpressing livers. Of note, there is no human data on OPN after liver resection available. The present study was conducted to elucidate the role of OPN in patients undergoing liver resection. As YAP1 dependent sonic hedgehog (SHH) signaling was described as a possible determinant of OPN expression in fatty liver disease, we also aimed to assess whether this pathophysiologic model might be applicable to the setting of human postoperative LR.
Method: 48 patients were included in this investigation. Plasma OPN levels were investigated preoperatively and on the first (POD1) and fifth day after surgery (POD5). Further, 2 hours after induction of LR blood was collected from the liver vein and concentration of OPN was assessed. Additionally, liver biopsies were gathered at baseline and at 2 hours of LR. Gene expression was assessed using RT-PCR. Patients were followed up for morbidity and liver dysfunction (LD) after hepatic resection.
Results: Circulating levels of OPN significantly increased within 2 hours of LR in the liver vein ($p = 0.017$). Interestingly, there was a significant correlation of both SHH and YAP1 with OPN expression during regeneration ($r = 0.628$, $p = 0.005$; $r = 0.558$, $p = 0.016$; respectively). Further, patients with high induction of SHH showed significantly higher fold changes in mRNA of both YAP1 ($p = 0.035$) and OPN ($p = 0.044$). Postoperatively, OPN showed an increase on POD1 ($p = 0.001$), with a subsequent decrease up to POD5 ($p = 0.050$). Patients that developed LD showed significantly higher levels of OPN on POD1 ($p = 0.039$, AUC = 0.704). Ultimately, a cut-off at 250 ng/µl postoperative OPN was identified and patients above this cut-off were found to have a significantly higher incidence of postoperative LD (10.5% in OPN $\leq$ 250 ng/µl vs 52.4% in OPN > 250 ng/µl, $p = 0.005$).
Conclusion: Within this study, we were able to elucidate a central role of OPN, possibly expressed in a YAP1 and SHH dependent manor, during postoperative LR. While circulating OPN shows an initial increase already 2 hours after induction of LR in all patients, an excessive increase of OPN might lead to adverse effects in patients after liver resection. This made it possible to identify patients at risk for postoperative LD via OPN already on POD1.

FRI-114
Obeticholic acid improves fetal hypercholanaemia during cholestatic gestation
V. Pataia[1], G. Papacleovoulou[1], E. Jansen[2], L. Adorini[3], H.-U. Marschall[4], C. Williamson[1]. Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden
Email: vanessa.formigo_pataia@kcl.ac.uk

Background and Aims: Intrahepatic cholestasis of pregnancy is characterized by a supraphysiological elevation of maternal circulating bile acid levels, concomitant with a deranged lipid profile. Intrahepatic cholestasis of pregnancy leads to accumulation of bile acids in the fetal compartment and increasing bile acid levels are associated with increased risk of adverse fetal outcomes, including preterm birth, perinatal death and stillbirth. The most common treatment is ursodeoxycholic acid administration but not all patients respond. The semi-synthetic farnesoid x receptor agonist obeticholic acid (OCA) has shown efficacy in the treatment of cholestatic conditions such as primary biliary cholangitis, and is approved for this indication. In this study, we hypothesized that OCA administration during cholestatic pregnancy results in improved maternal and fetal bile acid and lipid profiles.
Method: Female C57BL/6 mice were fed either: a normal chow diet, a 0.5% cholic acid (CA)-supplemented diet (equivalent to 700 mg/kg/day), a 0.03% OCA-supplemented diet (Intercept Pharmaceuticals) (equivalent to 42 mg/kg/day), or a 0.5% CA + 0.03% OCA-supplemented diet for 1 week prior to mating and throughout pregnancy. Pregnant females were euthanized on day 18 of pregnancy and maternal and fetal body and organ morphometry were studied. The effects of CA and OCA feeding during pregnancy on maternal and fetal serum bile acid levels were investigated. Maternal and fetal serum and hepatic lipid levels were also assessed.
Results: OCA administration during gestation did not alter the maternal or fetal body weight or organ morphometry (n = 6–8). OCA administration during cholestatic pregnancy resulted in decreased bile acid levels in the fetal compartment (172.4 ± 15.5 μmol/l vs 246.1 ± 31.5 μmol/l, n = 4–6, $p < 0.05$). However, fetal BA levels remained higher in this group than in controls (6.8 ± 0.3 μmol/l, n = 4–6) and fetal dyslipidemia was not reversed (n = 4–6). OCA administration during cholestatic pregnancy did not reduce maternal bile acid levels or improve dyslipidemia (n = 4–6).
Conclusion: OCA administration during gestation did not have negative effects on maternal or fetal morphometry and improved fetal hypercholanemia during cholestatic gestation. As raising bile avid levels in intrahepatic cholestasis of pregnancy are correlated with increased rates of adverse fetal outcomes, further investigations into the potential use of OCA during cholestatic gestation are warranted.

In vivo functional genetics for liver regeneration and disease

V. Iakovleva[1], T. Wuestefeld[1,2], A. Potapova[1], S.H.J. Dass[1]. *[1]Genome Institute of Singapore, Stem Cell & Regenerative biology, Singapore, Singapore; [2]National Cancer Centre Singapore, SingHealth, Singapore, Singapore*
Email: Iakovlevav@gis.a-star.edu.sg

Background and Aims: We conducted functional genetic *in vivo* shRNA screens for modulators of liver regeneration taking advantage of the Fumarylacetoacetate hydrolase (FAH) knockout mouse model before. We further developed our approach conducting these functional genetic screens in wild-type (wt) mice opening functional *in vivo* genetic shRNA screens to any genetic background and genetically modified mice. We have already identified potential new therapeutic targets.
Method: We used hydrodynamic tail vine injection to deliver transposon-based constructs for the expression of GFP and shRNA together with a sleeping beauty transposase (SB13) expressing plasmid to C57Bl6 mice. We reached stable integration of our construct into the genome of around 10% of hepatocytes. As a proof of principle, we first tested this system using a library we researched before in FAH knockout mice. We applied chronic thioacetamide (TAA) treatment to induce chronic liver damage. After this time we harvested the liver, isolated genomic DNA, amplified the expression cassette and did Illumina based deep sequencing. We determined the relative abundance of each shRNA. Then, we calculated the fold change in abundance after chronic liver damage *in vivo* to the starting pool for each shRNA. We determined the limitations of the system regarding the potential pool size for screening purposes and conducted a novel screen using a shRNA library consisting of 2300 shRNAs targeting 1000 cDNAs.
Results: Using the previously published ROMA-HCCdel shRNA library in our wt mouse set-up recapitulates the results obtained in the FAH knockout mouse model. The top-enriched shRNAs perfectly overlap, indicating the feasibility of functional genetic screens for modulators of liver regeneration and disease in our novel set-up. Conducting the first *in vivo* functional shRNA screen in wild-type mice using a library of 2300 shRNAs, we identified new potential regulators of liver regeneration. Confidence in the screening results is reflected by enrichment of shRNAs for targets known to enhance regeneration as well as depletion of shRNAs for targets essential for regeneration. We also examined the maximal pool size for in vivo screening in this system. We could reliably retrieve more than 5000 shRNAs. This shows the potential for genome-wide screens using our system.
Conclusion: We established a novel and highly versatile *in vivo* functional screening set-up for identification of modulators of liver regeneration and disease. This system is scalable for genome-wide screens and therefore will allow identifying new therapeutic targets for liver disease.

FRI-116

Differentiation of human pluripotent stem cells into hepatocytes is more efficient in spheroids than in 2D culture

M. Antonietta[1,2], U. Pereira[2,3], Cécile Legallais[2,3], A. Dubart-Kupperschmitt[1,2]. *[1]UMR_S1193 INSERM/Université Paris-Sud, Villejuif, France; [2]Département Hospitalo-Universitaire Hépatinov, Villejuif; [3]Laboratoire de Biomécanique et Bioingénierie (BMBI), UMR CNRS 7338/ Université de Technologie de Compiègne, Compiègne, France*
Email: anne.dubart@inserm.fr

Background and Aims: The self-renewing abilities and differentiation potential of the human induced pluripotent stem cells (hiPSCs) appoint them as one of the most promising reliable source of hepatocytes for cell therapy, regenerative medicine and bio-engineering. Beside safety issues, the challenges regarding these applications are the number and the functionality of hepatocyte-like cells (HLCs). Moreover, 2D cultures appear restricted while 3D cultures offer easier upscaling and expected improved differentiation into HLCs, due to better cellular interactions. Here, we used hepatoblasts differentiated from hiPSCs to generate spheroids investigating cell survival, hepatocytic differentiation and functionality in 2D versus 3D cultures.
Method: hiPSCs were differentiated towards hepatocytic lineage and seeded at different stages of differentiation and different cell densities into inert micro-wells to induce their self-assembly. 2D cultures were performed as control. We studied cell aggregation rates comparing cell viability and expression of hepatic specific markers and functions along time.
Results: Hepatoblast stage (day 10) appeared to be the more suitable for the spheroid generation. Cells re-arranged themselves into aggregates of 100–120 μm in diameter 24h after seeding. Secretion of AFP and expression of ALB mRNA after 1 and 3 days of aggregation, respectively, attested the hepatic differentiation in 3D condition. In contrast ALB mRNAs was detectable only after 20 days of culture in the 2D controls where AFP expression and secretion persist along time. Immunostaining and ELISA confirmed the precocious expression of ALB and the rapid loss of AFP expression into the 3D systems in comparison with the 2D controls. Albumin secretion from spheroids regularly increased then reached a plateau after 7 days of culture with values threefold higher and statistically significant versus the 2D controls. Moreover, metabolic activity (Cytochrome

P450 and the phase II enzyme expression) and functionality (Periodic acid–Schiff and Oil Red O staining) of the spheroids were successfully assessed.
Conclusion: The 3D approach results in a quicker and more complete maturation of HLCs with respect to classical 2D cultures. Therefore, these spheroids can be used across multiple clinical and research applications especially as the cellular component for the development of bioartificial liver devices where they can replace single cells.

Email: brunetti@tigem.it

Background and Aims: Ammonia is a potent neurotoxin that is converted into urea by the healthy liver. Hyperammonemia is a common complication of a wide variety of both inherited and acquired liver diseases, such as urea cycle disorders, organic acidemias, or acute and chronic liver diseases. If not treated early and thoroughly, it results in encephalopathy and death. Available therapeutic options to treat hyperammonemia are often unsatisfactory. Autophagy is a lysosomal recycling pathway that plays a major role in metabolism. In this study, we investigated the role of hepatic autophagy in ammonia detoxification.
Method: Liver autophagy was investigated in well established mouse models of acute and chronic hyperammonemia in which C57BL/6 wild-type mice received intraperitoneal injections of ammonium chloride or were fed ad libitum with a diet supplemented with ammonium acetate (20% w/w), respectively. Ammonia detoxification was evaluated in mice with either induced or deficient autophagy. Pharmacological enhancement of autophagy was investigated in models of acute and chronic hyperammonemia, including thioacetamide-induced acute liver failure and ornithine transcarbamylase deficiency, the most frequent urea cycle disorder.
Results: Hepatic autophagy is triggered *in vivo* by hyperammonemia through an α-ketoglutarate-dependent inhibition of the mammalian target of rapamycin complex 1 (mTORC1). Ammonia detoxification capacity was impaired in mice with hepatic-specific suppression of autophagy. In contrast, autophagy enhancement by means of hepatic gene transfer of the master regulator of autophagy transcription factor EB (TFEB) or treatments with the autophagy activators rapamycin and Tat-Beclin-1 increased ureagenesis and protected against acute and chronic hyperammonemia. Moreover, stable isotope studies and liver metabolomic analyses suggested that during hyperammonemia autophagy potentiates ureagenesis by furnishing the urea cycle with key intermediates metabolites and preventing ammonia-induced depletion of ATP.
Conclusion: Our study suggests the novel concept that hepatic autophagy potentiates ureagenesis under both acute and chronic hyperammonemia. The enhancement of autophagy has potential for therapy of both primary and secondary causes of hyperammonemia. These findings may lead to development of new drugs promoting ammonia clearance in patients with hyperammonemia.

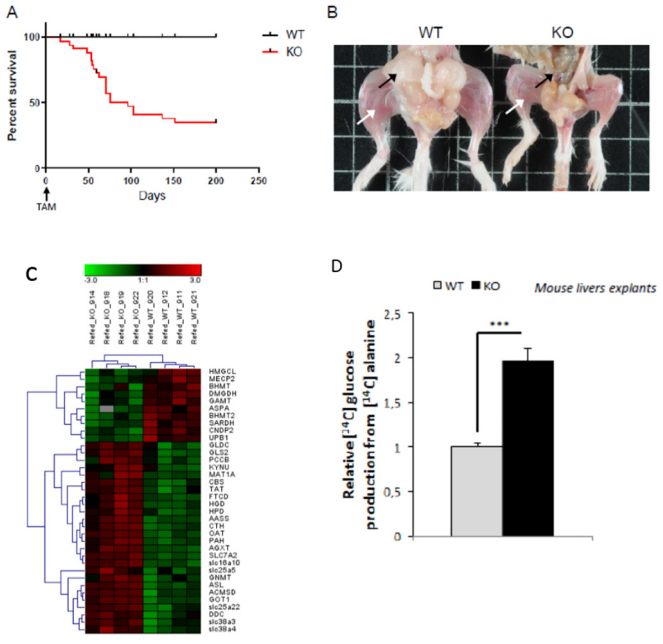
lkb1 inhibits the hepatic gluconeogenis by impeding the availability of amino acids

C. Perret[1], S. Charawi[2], J. Pierre-Alexandre[2], Raphaël Denis[3], T. Massire[4], B. Sultan[4], S. Nadia[4], S. Pierre[4], S. Mathilde[4], W. Maud[4], L. Marjorie[4], G. François[4], S. Luquet[3], P. Bossard[4]. [1]*Institut Cochin, Development Reproduction Cancer, Paris, France;* [2]*institut Cochin, Paris;* [3]*bfa University Paris 7;,* [4]*institut Cochin*
Email: Christine.Perret@Inserm.Fr

Background and Aims: Liver kinase B1 (LKB1) is a known inhibitor of hepatic gluconeogenesis. AMPK was proposed to be the kinase involved in this control, but recent reports demonstrated that the salt-inducible kinases (Sik) were the true gatekeeper effectors of *Lkb1*. However the mechanisms by which *Lkb1* controlled hepatic gluconeogenesis are still undefined.
Method: We developed a mouse model with a tamoxifen inducible hepatocyte-specific deletion of *Lkb1*. Mutant and control mice were analyzed by metabolic and proteomic approaches as well as IRM and indirect calorimetry.
Results: We confirmed that mice injected with tamoxifen to induce a hepatocyte-specific deletion of *Lkb1* revealed a fasted hyperglycemia two weeks after tamoxifen injection. In addition, we observed a striking phenotype at longer term. More than 60% of the mutant mice died in a cachexic context with a dramatic sarcopenia (Figure A-B). Analysis by IRM of the whole body composition in short-term mice (15 days after tamoxifen injection) showed a significant modification of the body composition of the mutant mice with a decrease of lean mass and an increase in fat mass although the body weight was unchanged. Proteomic analysis of liver of mutant and control mice identified the gluconeogenesis and amino acid metabolism as the TOP canonical pathways enriched in the liver of the *Lkb1* mutant mice. More specifically, there was a strong up-regulation of enzymes of the amino-acid catabolism and urea cycle in the liver of mutant mice, indicating that *Lkb1* played a critical role on the hepatic breakdown of the amino-acids (Figure C). The loss of lean mass that culminated in sarcopenia, combined with the hepatic breakdown of amino-acids observed in the *Lkb1* mutant mice suggested that *Lkb1* may control the availability of the amino-acids as gluconeogenic substrates. Using hepatocyte primary culture and liver explants, we showed that *Lkb1*-deficient hepatocytes have an increased capacity to synthetize glucose from the amino-acid, glutamine and alanine compared to controls (Figure D).



Conclusion: Altogether, our results showed that *Lkb1* inhibits gluconeogenesis by decreasing the availability of the amino acids as gluconeogenic precursors.

Email: diego.calabrese@unibas.ch

Background and Aims: Hepatocyte-like cells (HLCs) differentiated from induced pluripotent stem cells (iPSCs) have emerged as a promising cell culture model to study metabolism, biotransformation, viral infections and inherited liver diseases. However the derivation of iPSCs is restricted by ethical and procedural constraints. Furthermore, incomplete HLC differentiation remains a major challenge. iPSC may carry-on a tissue of origin dependent expression memory influencing iPSC differentiation into different cell types. Whether liver derived iPSCs (Li-iPSCs) maintain a liver specific gene expression profile is not known. It is also not known whether Li-iPSCs would allow the generation of more fully differentiated HLCs.
Method: Primary liver cells (PLCs) were expanded from liver needle biopsies and reprogrammed into Li-iPSCs using a non-integrative Sendai virus-based system. Li-iPSCs were differentiated into HLCs using established differentiation protocols. The HLC phenotype was characterized at the protein, functional and transcriptional level. RNA sequencing data were generated from the originating liver biopsies, the Li-iPSCs, fibroblast derived iPSCs, and differentiated HLCs, and used to characterize and compare their transcriptome profiles.
Results: PLCs were obtained from small pieces of liver biopsies and could be reprogrammed into Li-iPSCs. Li-iPSCs indeed retain a liver specific transcriptional footprint. Li-iPSCs can be propagated to provide an unlimited supply of cells for differentiation into Li-HLCs. Similar to HLCs derived from fibroblasts, Li-HLCs could not be fully differentiated into hepatocytes. Relative to the originating liver, Li-HLCs showed lower expression of liver specific transcription factors and increased expression of genes involved in the differentiation of other tissues.
Conclusion: PLCs and Li-iPSCs obtained from small pieces of human needle liver biopsies constitute a novel unlimited source for the production of HLCs. Despite the preservation of a liver specific gene expression footprint in Li-iPSCs, the generation of fully differentiated hepatocytes cannot be achieved with the current differentiation protocols.

FRI-120

Mechanisms of action of cortisol in steatotic and non-steatotic livers subjected to partial hepatectomy with vascular occlusion

E. Bujaldon[1], María E. Cornide-Petronio[1], E. Negrete-Sánchez[1], C.G. Ávalos De León[1], A.I. Álvarez-Mercado[1], J. Gulfo[2], Mónica Jiménez-Castro[3], F. Rotondo[1], J. Gracia-Sancho[4], C. Peralta[1,2]. [1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Experimental Liver Surgery and Liver Transplantation, Barcelona, Spain;* [2]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Barcelona, Spain;* [3]*Transplant Biomedicals S.L., Barcelona, Spain;* [4]*Barcelona Hepatic Hemodynamic Laboratory, IDIBAPS, CIBEREHD, Barcelona, Spain*
Email: ebujaldonormaechea@gmail.com

Background and Aims: In clinical practice, partial hepatectomy (PH) under vascular occlusion, is a common technique used in hepatic surgery to avoid bleeding. Hepatic steatosis is a major risk factor in hepatic surgery, associated with high rates of complications and postoperative mortality. Cortisol is the main active hormone of the HPA axis, released as a response to stress, and it stimulates hepatocellular proliferation in PH without vascular occlusion. It is suggested that these effects rely upon the acetylcholine (ACh) signalling pathway. The aim of this study was to examine if the beneficial effects of cortisol, previously reported in PH, are applicable when vascular occlusion is necessary.
Method: Male Zucker rats, lean and obese, were used in the well-known model of 70% PH with vascular occlusion. We modulated the ACTH-cortisol pathway pharmacologically and studied levels of hepatic cortisol and enzymes involved in its metabolism, its relevance in hepatic injury and regeneration, as well as the underlying cortisol-ACh mechanisms in these animals.
Results: In this context, lean animals undergoing liver resection displayed no changes in cortisol, whereas cortisol levels in plasma and liver were elevated in obese animals due to an overexpression of cortisol-producing enzymes (11b-HSD1) and downregulation of cortisol clearing enzymes (5bR). Lean animals given exogenous cortisol showed high circulating cortisol but maintain low hepatic cortisol levels because of an upregulation of cortisol clearing enzymes (5aR1 and 5bR), thus avoiding its harmful effects on liver injury and regeneration. In obese animals, high plasmatic cortisol triggers a negative feedback loop through the HPA axis that maintains low circulating ACTH. However, it is not enough to counteract the rise in hepatic cortisol and consequently exacerbates tissue damage and regeneration failure. We also found that cortisol administration caused hepatic ACh accumulation in steatotic livers. ACh administration caused an increase in transaminases and lowered hepatic levels of PI3k/Akt and regenerative markers, exerting harmful consequences on hepatic injury and regeneration. These deleterious effects could be reverted with the administration of M3 muscarinic acetylcholine receptor antagonist, but not a7 nicotinic acetylcholine receptor antagonist.
Conclusion: In instances of PH under vascular occlusion, HPA fundamentals, hepatic cortisol levels and enzymatic shifts are all dependent on baseline liver status. Cortisol administration has virtually no impact on non-steatotic livers, whereas steatotic livers are actually harmed by exogenous cortisol. Strategies aimed to block cortisol activity in order to block ACh accumulation and/or blockade of M3 mAChR are probably worthwhile to protect steatotic livers and reduce the incidence of postoperative complications following PH under vascular occlusion.

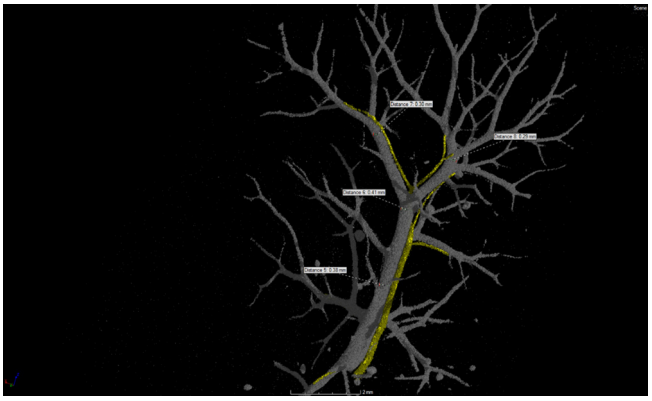
Double resin casting micro computed tomography (DUCT) of biliary and vascular system

S. Hankeova[1,2], T. Zikmund[3], M. Kavkova[3], A. Brinek[3], U. Lendahl[1], J. Kaiser[3], V. Bryja[2], E. Andersson[1]. [1]*Karolinska Institutet;* [2]*Masaryk University;* [3]*CEITEC - Central European Institute of Technology*
Email: simona.hankeova@ki.se

Background and Aims: DoUble resin Casting micro computed Tomography (DUCT) is a novel technique that aims to visualize two tubular lumenized structures at the same time. We applied DUCT to investigate the morphology of blood vessels and intra hepatic bile ducts (IHBDs) in a mouse model for Alagille syndrome (ALGS). ALGS is a multisystem pediatric disorder caused by a mutation in *JAGGED 1 (JAG1)* that is characterized by liver cholestasis due to a lack of IHBDs. Jag1 is a ligand in the Notch signaling pathway and is necessary for proper development of both blood vessels and IHBDs. To study ALGS liver disease we have developed a mouse model carrying a point mutation in *Jag1*, nicknamed Nodder (Jag1 H268Q, Ndr). Nodder mice are jaundiced at early postnatal stages and histological evaluation of liver shows IHBD abnormalities and missing hepatic arteries (Andersson *et al*, in press). Since blood vessels and IHBDs are 3D structures, histological sections do not provide sufficient information

to understand perfusion of whole liver by these structures, or their 3D interaction.
Method: DUCT employs injection of synthetic resin followed by micro computed tomography (μCT) to simultaneously assess multiple three dimensional (3D) networks. Hus it allows measurement and quantification of the architecture and perfusion of different systems and reveals the relationship between the two systems *in vivo*.
Results: The injection of two synthetic resins (MICROFIL®) with different radiopacities enabled us to reconstruct portal vein vascular branching in parallel with the IHBD network. DUCT revealed that homozygous Nodder portal vein branching is reduced with sprouting abnormalities, while bile ducts are tortuous and misplaced.



Conclusion: DUCT represents a unique tool to visualize the tubular systems and dissect out the relationships between any two lumenized structures in 3D.

Email: jdekock@vub.ac.be

Background and Aims: Often the only effective treatment for patients suffering from severe liver failure is orthotopic liver transplantation (OLT). Yet, the scarcity of donor organs and the complexity of the intervention significantly limits its general application. Therefore, new treatment options need to be urgently developed. Primary hepatocyte transplantations offer an alternative, but their limited availability, inability to significantly expand *ex vivo*, short life span and difficulties with cryopreservation necessitate the search for other sources of hepatic cells. A plausible solution could be offered by stem cell technology as these cells exhibit the ability of self-renewal and multi-lineage differentiation. Stem cell transplantation could be particularly interesting for patients suffering from severe liver dysfunction with no immediate chance of OLT. In this study, we investigated the potential of a multipotent human stem cell population, so-called human skin-derived precursor cells (SKPs), for the treatment of severe parenchymal liver damage.
Method: 0.5 million luciferase-positive SKPs were injected into the spleen of a transgenic murine model of liver deficiency (uPA$^{+/+}$/SCID). Ten weeks post transplantation, the SKP-derived hepatic grafts were characterized by dianabol metabolisation studies, bioluminescence imaging and immunohistochemistry. In many degenerative diseases, a pronounced inflammatory micro-environment is present that might increase the immunogenicity of SKP, facilitate their rejection and thus hamper their future therapeutic application. Therefore, *in vitro* and *in vivo* studies were performed to evaluate the immunogenicity of SKPs in the presence and absence of a pro-inflammatory environment.
Results: We found that SKPs successfully engraft, survive and repopulate the hepatic tissue in the uPA$^{+/+}$/SCID mouse model. Immunohistochemistry shows that SKPs acquire hepatic morphology, express hepatic markers and store glycogen. Most importantly, after oral administration of dianabol, *in vivo* generated SKP-derived hepatic grafts produce human-specific metabolites that can be detected in the urine of the chimeric mice demonstrating their *in vivo* human biotransformation capacity. In addition, we found that pro-inflammatory stimulation of SKPs does not increase their immunogenicity *in vitro* nor *in vivo*, but it evokes significant changes in their cytokine and growth factor secretion. In this context, we found that SKPs drastically increase their secretion of hepatocyte growth factor (HGF), a hepatotrophic factor, in the presence of inflammation. In-depth pathway analyses show that this increase in HGF is linked to the combined activation of CCL2, CSF2, IL6 and LIF.
Conclusion: Our data shows for the first time that SKPs can represent a potential source for cellular therapy of the liver.

FRI-123

PRMT5 deficiency results in liver abnormalities and impairs liver regenerationfollowing partial hepatectomy

Y.X. Tan[1], M. Caldez[1], N.K.M.V. Hul[1], C.L. Lee[1], P. Kaldis[1], E. Guccione[1,2]. *[1]Institute of Molecular and Cell Biology, Singapore; [2]Icahn School of Medicine at Mount Sinai*
Email: yxtan@imcb.a-star.edu.sg

Background and Aims: Arginine methylation is a major post-translational modification that regulates a myriad of biological processes including transcription, pre-mRNA splicing, mRNA translation and cell signalling. PRMT5 is the major mammalian type II arginine methyltransferase and plays an essential role in regulating gene expression and pre-mRNA splicing. Constitutive genetic ablation of PRMT5 caused early embryonic lethality (E3.5) and maintenance of its activity in proliferating cells is required for growth and survival. Therefore, it remains unclear if and how PRMT5 plays a role during hepatogenesis and in the adult liver during liver regeneration.
Method: PRMT5 was deleted specifically in the liver in PRMT5flox/flox ALB-Cre (PRMT5 LKO) mice or in hepatocytes only by injecting AAV8-TBG-Cre into adult PRMT5flox/flox mice (PRMT5 HKO). 70% partial hepatectomy was performed on these mice.
Results: PRMT5 LKO mice are born at Mendelian ratio and are viable and fertile through adulthood. However, they have slightly reduced body weight compared to control mice. Macroscopically, the livers of PRMT5flox/flox ALB-Cre mice have uneven surfaces, although liver-to-body weight ratio did not differ from control mice. Histological examination revealed marked multifocal hepatocellular (periportal, coalescing and random) hypertrophy accompanied by anisokaryosis, karyomegaly, binucleation and increased hepatocellular mitoses. Oval cell proliferation and bile duct hyperplasia were also observed. We detected small but significant increases in the ALT and ALP levels in PRMT5 LKO mice, suggesting mild liver dysfunction. On the other hand, deleting PRMT5 in adult hepatocytes in PRMT5 HKO mice did not result in liver abnormalities or dysfunction one month post deletion. During liver regeneration in wildtype mice, PRMT5 protein is upregulated, suggesting it may play a role in the regenerative process. Accordingly, following 70% partial hepatectomy, PRMT5 HKO mice have reduced liver to body weight ratio compared to control

mice one week post surgery. This correlated with reduced hepatocyte mitoses and increased steatosis at 36h and strong oval cell activation at 96h post liver resection.
Conclusion: Our data suggests that in the absence of PRMT5, hepatocytes are unable to proliferate and compensatory mechanisms such as cellular hypertrophy and oval cell activation are triggered. We are currently investigating the molecular mechanism(s) by which PRMT5 regulates hepatocyte proliferation.

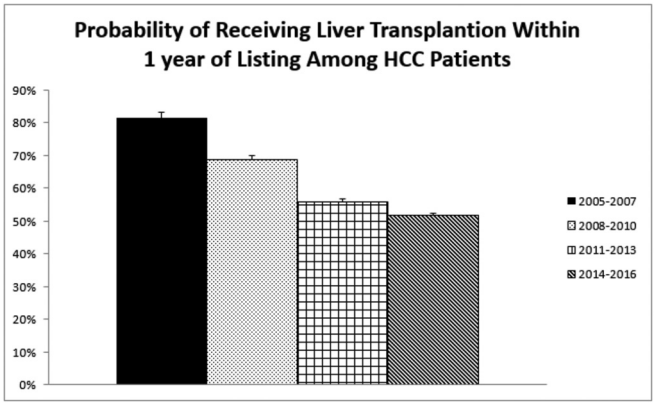
FRI-124
Bile duct organogenesis using ECM micropatterning
B. Latifa[1], M.-A. Elsa[2], F. Alexandra[2], F. Dominique[3], J.-C. Duclos-Vallée[4], P. Dupuis-Williams[1,5]. *[1]INSERM U1174, Université Paris Sud, ORSAY, France; [2]CEA/DRF/PCV/BIG, INSERM U1160, Paris, France; [3]Institut Pasteur, Paris, France; [4]Hôpital universitaire Paul Brousse, Inserm, Unité 1193, Université Paris-Saclay, Villejuif, F-94800, France, Villejuif, France; [5]ESPCI, Paris, France*
Email: pascale.dupuis-williams@u-psud.fr

Background and Aims: Bile duct disease accounts for a significant part of liver transplants. Most biomimetic liver projects though, have precluded the construction of a functional bile duct system, mostly because of the difficulty of procuring cholangiocytes, the biliary epithelial cells. As a result, experimental models and mechanisms of tubulogenesis, which have been recently developed for kidney tubules and vascular networks are still lacking for bile ducts.
Tubulogenesis is a complex process that requires the orchestration of multiple molecular pathways including cell surface receptors, cell matrix, adhesion molecules, the cytoskeleton and vesicular transport. Interestingly, the recent input of bio-engineered microfabrication techniques like protein and cell micropatterning, stereolithography or microfluidics brought opportunities to rationalize bioengineered tissue construction.
The aim of our work is to identify in vitro conditions (extracellular matrices: ECM, topological constraints and needs for co-culture with ectopic cell types) that will allow the construction of functional single or interconnected biliary ducts from self-organization of cholangiocytes or liver precursor cells.
Methods and Results: Based on our previous work showing that biliary cells can self-organize into luminal structures when grown in appropriate 3D ECM, we further aimed to construct biliary structures of given topologies. This work explores how biliary cells may develop simple or complex 3D luminal structures whose topologies are defined in 2D by micropatterning or in 3D by stereolithography.
In a first step, biliary cells were grown in 2,5D on ECM surfaces of simple defined geometries obtained by micropatterning. This step allowed us to probe the ECM and topological conditions that favor the 3D self-organization of biliary cells into luminal organoids.
ECM conditions and critical dimensions inducing efficient self-organization of differentiated biliary cells into luminal spheres or single tubes have been identified. Further work aims in inducing organogenesis from hepatic progenitors and in co-culture conditions with hepatic or endothelial cells.
In a second step, biliary cells were grown in complex 3D hydrogel architectures built by stereolithography to induce the development of interconnected functional tubes, where cell proliferation, migration and coalescence conditions can be recorded. This work in progress contributes to the identification of topological cues for self-organogenesis of bile ducts cells from differentiated hepatic cells.
Conclusion: This work explores 3D self-organogenesis of biliary cells cultured in simple or complex micropatterned 2D or 3D topologies. We have already shown that biliary cells self-organize into luminal structures whose geometry can be controlled by restricting cell adhesion.

Liver tumours: Clinical aspects except therapy

FRI-127
While hepatocellular carcinoma (HCC) has become the leading indication for liver transplantation in the United States, the probability of receiving liver transplantation among adults with HCC has rapidly declined
J. Wang[1], R.G. Gish[2], B. Liu[3], T. Bhuket[3], R. Wong[3]. *[1]California Pacific Medical Center, Medicine, San Francisco, United States; [2]Stanford Health Care, Gastroenterology and Hepatology, Palo Alto, United States; [3]Alameda Health System - Highland Hospital, Gastroenterology and Hepatology, Oakland, United States*
Email: rowong@alamedahealthsystem.org

Background and Aims: The number of patients with hepatocellular carcinoma (HCC) listed for liver transplantation (LT) has been steadily increasing. However, demand for LT far outweighs the supply of donor organs, and results in disparities in receipt of LT that persist and may be increasing. We aim to evaluate overall trends in probability of receiving LT among U.S. adults with HCC with a focus on age-specific and insurance-specific disparities.
Method: Using data from the 2005–2016 United Network for Organ Sharing LT registry, probability of receiving LT among U.S. adults with HCC was stratified by age (age < 50, 50–59, 60–69, ≥70), year of listing (2005–2007, 2008–2010, 2011–2013, 2014–2016) and insurance type (private/commercial [PC], Medicare [MC], Medicaid [MA] and Veterans Affairs [VA]). Comparison of LT rates between groups utilized Kaplan Meier methods and log-rank testing. Multivariate Cox proportional hazards models evaluated for independent predictors of receiving LT.
Results: Among 24,044 HCC patients listed for LT (8.5% age <50 years, 43.0% 50–59 years, 43.6% 60–69 years, and 4.8% ≥70 years), the majority had PC insurance (56.2%), followed by MC (26.6%), MA (14.5%), and VA (2.7%). When stratified by age, probability of receiving LT within 1 year of listing was highest among HCC patients age 50–59 years (64.6%) and lowest among those age 60–69 years (58.1%), p < 0.01. When stratified by insurance, 1-year probability of receiving LT was highest among HCC patients with PC (63.6%) and lowest among those with MC (52.8%), p < 0.001. With later time periods, the probability of receiving LT for HCC patients declined dramatically (1-year probability, 81.5% in 2005–2007 vs. 51.7% in 2014–2016, p < 0.001). On multivariate regression, increasing age was not associated with likelihood of receiving LT. HCC patients in the most recent era (2014–2016) had significantly lower likelihood of receiving LT compared to 2005–2007 (HR 0.43, 95% CI 0.40–0.46, p < 0.001). Compared to HCC patients with PC, those with MA were significantly less likely to receive LT (HR 0.79, CI 0.75–0.84, p < 0.001).



Conclusion: Despite the increasing number of adults with HCC awaiting LT in the U.S., the probability of receiving LT has declined significantly, and HCC patients in 2014–2016 were 57% less likely to receive LT compared to 2005–2007. Furthermore, HCC patients with Medicaid insurance were significantly less likely to receive LT compared to patents with private/commercial insurance.

FRI-128

Two new blood tests for identifying patients with chronic liver diseases, at high risk of primary liver cancer

T. Poynard[1,2], V. Peta[3], M. Munteanu[3], J. Moussalli[1], M. Rudler[1], P. Lebray[1], J. Massard[1], R. Pais[1], L. Bonyhay[1], F. Charlotte[1], V. Thibault[1], O. Lucidarme[1], D. Eyraud[1], E. Savier[4], O. Scatton[1], M.A. Valantin[1], Y. Ngo[5], A. Ngo[5], F. Drane[5], F. Bismut[4], L. Fartoux[4], O. Deckmyn[5], P. Cacoub[4], O. Rosmorduc[4], C. Housset[6], D. Thabut[4], V. Ratziu[4]. *[1]APHP, Hepatology, Paris, France; [2]UPMC, UMR938; [3]BioPredictive, Research, Paris, France; [4]APHP; [5]BioPredictive; [6]UPMC*
Email: tpoynard@teaser.fr

Background and Aims: The identification of patients (pts) with chronic liver disease and a high-risk profile of primary liver cancer (PLC) is needed. We hypothesized that certain FibroTest (FT) components mediating hepatoprotection could be predictive of the development of PLC. The main aim was to assess the predictive value of two new blood tests in pts with chronic liver disease who underwent FT in the prospective FibroFrance cohort NCT01927133 since 1997.
Method: 2 panels of components were constructed (Patents pending) in a baseline population (P0) using AUROCs and logistic regression, one (HR-Test) to identify pts with a high-risk profile and one combining HR and alpha-fetoprotein (HR-AFP). Their prognostic values were longitudinally assessed using KaplanMeier, Cox model and AUROCs in pts who did not develop PLC at least 1 year (yr) after baseline (P1), and in a subpopulation who received at least 2 tests to assess intra-patient variability (P2).

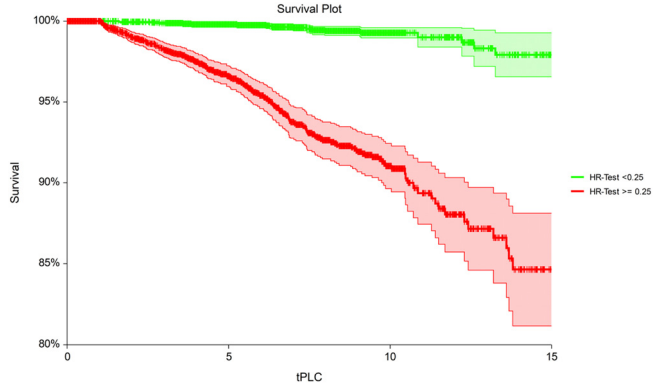


Figure 1: 15-year survival without occurrence of primary liver cancer (95% CI) in patients with HR-Test <0.25 versus those > = 0.25

Results: 9,925 pts were included in P0, 34%, 20%, 12%, 5% and 29% with CHC, CHB, NAFLD, ALD and other or mixed causes, respectively. The HR-Test for the diagnosis of 134 contemporaneous PLC had an AUROC (95%CI) = 0.903 (0.874–0.926) that was higher than FT .877 (0.845–0.903 p = 0.01) and AFP 0.810(0.725–0.862 p = 0.03). In P1, 226 incident PLC (98% HCC) occurred/9791 pts, with a 15-yr-survival without PLC (SwC)) 95%CI = 90% (88–92). Pts with an HR-Test <0.25 (HR- n = 6020) had SwC = 99.3% (99.0–99.6) at 10yr and 97.7% (96.2–99.1) at 15yr (28 PLC), compared to pts >=0.25 (HR+ n = 3771) 91.1% (89.6–92.5) at 10yr and 84.5% (80.9–88.1) at 15yr (198 PLC). The risk (hazard-ratio) of PLC was 12.7(9.6–16.6 p < 0.0001) times greater in the HR+ than HR- pts (Figure). PLC occurred less often in HR- than in HR+ pts, whatever the cause of liver disease: 14/1727 vs 114/1637, 6/1532 vs 27/475, 4/682 vs 20/416, and 2/159 vs 27/317, in CHC, CHB, NAFLD, and ALD respectively (all p < 0.001). HR-AFP had an AUROC = 0.860 (0.833–0.883) which was higher than that of single tests: AFP (0.740; 0.698–0.778; p = 0.01), HR1 (0.802; 0.772–0.828 p = 0.0001) and FT (0.813; 0.784–0.838 p = 0.0001). In P2, among 1818 pts with at least 2 repeated HR-tests, 16 incident PLC occurred at 10yr, (SwC = 70%; 49–91). When repeated 5.2yr (5.0–5.4) later, the HR-Test had a higher AUROC than the first test 0.851 (0.796–0.892) vs 0.772 (0.699–0.829) at baseline (p = 0.001). The results of Cox sensitivity analyses, which take into account the repeated tests, the impact of antiviral treatment, and HIV infection were similar. These results were confirmed by internal validation but external validation must be performed.
Conclusion: The HR-Test identified a group of pts at high risk of PLC among those with CHC, CHB, NAFLD and ALD. Combining the HR-Test and a specific cancer marker such as AFP significantly increased the value of a single test.

FRI-129

Contrast-enhanced ultrasound for non-invasive diagnosis of hepatocellular carcinoma: A comparison between CEUS LI-RADS and ESCULAP criteria in a large high-risk cohort of patients

A. Saviano[1], L. Riccardi[2], M.A. Zocco[2], T. Baumert[1,3], G.L. Rapaccini[2], M. Pompili[2], A. Gasbarrini[2]. *[1]Inserm Unit 1110; Institut de Recherche Sur Les Maladies Virales et Hépatiques, Strasbourg, France; Université de Strasbourg, Strasbourg, France; [2]Internal Medicine, Gastroenterology and Liver Disease Unit, Policlinico "A. Gemelli", Catholic University, Rome, Italy; [3]Institut Hospitalo-Universitaire, Pôle Hépato-Digestif, Nouvel Hôpital Civil, Strasbourg, France*
Email: saviano.ant@gmail.com

Background and Aims: Contrast-enhanced ultrasound (CEUS) for the non-invasive diagnosis of hepatocellular carcinoma (HCC) in patients with liver cirrhosis raised concerns for the risk of misdiagnosis with intrahepatic cholangiocarcinoma (ICC) and was removed as diagnostic technique from international guidelines. To address this issue, the American College of Radiology recently released the CEUS LI-RADS criteria for HCC diagnosis in liver cirrhosis. Other criteria, named ESCULAP (Erlanger Synopsis of Contrast-enhanced Ultrasound for Liver lesion Assessment in Patients at Risk) were also recently published and reported to have a better accuracy compared to CEUS LI-RADS. Aim of this study was to assess and compare, for the first time, the diagnostic accuracy of these criteria in a large independent cohort.
Method: Between 2005 and 2015, 181 nodules in 156 patients with chronic liver disease at high HCC risk were retrospectively collected in the Center of Liver Diseases at the Catholic University of Rome and were enrolled in this study. The diagnostic accuracy of the CEUS LI-RADS LR-5 and ESCULAP-4 categories for the diagnosis of HCC was assessed and compared. The 2005 AASLD criteria applied to HCC > 1cm were also evaluated. A comparison of the diagnostic performance of the categories CEUS LI-RADS LR-M (non-HCC malignancies) and ESCULAP-C (ICC diagnosis) was made. The diagnostic reference was histology or CT/MRI.
Results: The 58.6% of patients had HCV cirrhosis and the median nodule size was 1.8 cm (range 0.7–9.0 cm). HCC represented the 78.5% of diagnosis while ICC the 2.2%. LR-5 category (52% of nodules) had a positive predictive value (PPV) for HCC of 100% and a sensitivity of 58% with no risk of misdiagnosis with ICC. ESCULAP-4 (76% of nodules) had a PPV of 92% and a sensitivity of 77% for HCC. In this cohort, the 2005 AASLD criteria showed a PPV and a sensitivity for HCC diagnosis of 93% and 64%, respectively. No nodules could be classified as ICC using the ESCULAP-C category whereas all the non-HCC malignancies (included all the ICCs) were classified as LR-M according to CEUS LI-RADS.
Conclusion: CEUS LI-RADS LR-5 category has a high specificity and PPV for HCC diagnosis eliminating the risk of failure to diagnose ICC. ESCULAP criteria have higher sensitivity but lower specificity for HCC

diagnosis and do not avoid the risk of ICC misdiagnosis. A marked and/or early wash-out in CEUS (LR-M feature) is the most important feature for CEUS diagnosis of ICC arising in liver cirrhosis.

FRI-130

Tumour progression and recurrence after direct acting antiviral therapy for hepatitis C in patients with previously treated or active hepatocellular carcinoma

M. Wong, G. Mccaughan, S. Mason, B. Moore, D. Bowen, D. Koorey, S. Strasser. *Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Camperdown*
Email: may.wong1@health.nsw.gov.au

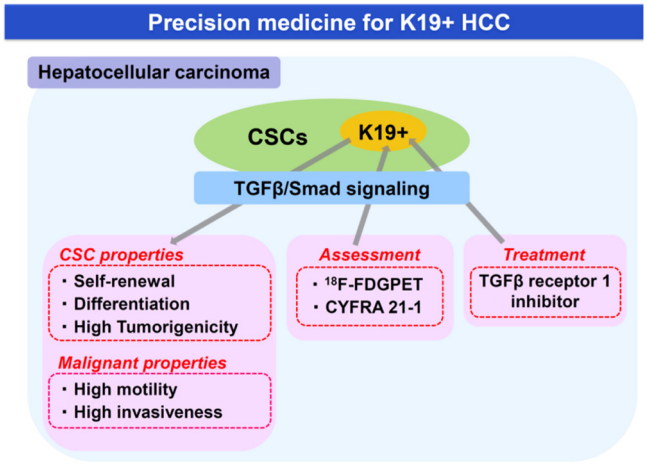
Background and Aims: Data on tumour recurrence rate in patients with previously successfully treated hepatocellular carcinoma (HCC) after direct acting antiviral (DAA) therapies are conflicting. Data on tumour progression in patients with active HCC at the time of DAA therapy are sparse. Furthermore, the significance of indeterminate nodules and its role in HCC development is unclear. We explore the incidence and pattern of HCC events, sustained virological response (SVR) rates and patient outcomes of individuals with a history of HCC who have had DAAs.
Method: All HCV patients with a prior history of HCC who started DAAs in a transplant-referral center were included. Clinical, laboratory and radiologic characteristics at DAA baseline and during followup (FU) were registered. Patients were grouped by HCC status at time of DAA therapy; complete response (CR), ongoing active disease (AD) and indeterminate nodules (IN). DAAs were administered for 12 or 24 weeks according to label.
Results: 80 patients with a prior history of HCC received DAAs between March 2014–2017. 40 had no evidence of active HCC (CR) before starting DAA. 30 had active HCC at time of DAA therapy (AD), and of those, 13 had residual disease from previously treated HCC. 9 had indeterminate nodules (IN). For those with CR, baseline BCLC stage at HCC treatment was BCLC-0/A in 94% and 32/40 received locoregional therapy (chemoembolization/ablation). Median time to DAA initiation post CR was 9.3 months. HCC recurrence was 22/40 (55%) at median 7.4 months (14/22 (64%) within 6 months after start of DAAs). In those with AD at time of DAAs, progression occurred in 25/30 (83.3%) at a median 7.6 months from start of DAAs. At the time of progression for patients with AD their tumor biology seemed to be more aggressive with instances of rapid progression to BCLC and D. 9 patients had IN at the time of DAA initiation; 4 developed HCC beyond six months from start of DAAs. With regard to rates of SVR, 97.4% of patients with CR achieved SVR, in comparison to 55.6% in those who still had active HCC, where a high relapse rate was observed. Overall, tumour-related mortality was seen in 4 patients; where 3 had recurrent HCC within 6 months of DAA initiation.
Conclusion: As previously reported, DAA treatment may be associated with high rates of rapid tumour recurrence in patients with prior HCC CR. Furthermore, patients with active HCC at the time of DAA therapy are at risk of rapid progression. Deferral of antiviral treatment in patients with HCC should be considered.

FRI-131

Identification of keratin 19-positive cancer stem cells associating human hepatocellular carcinoma using 18F-FDGPET and CYFRA 21-1

T. Kawai, T. Ishii, K. Yasuchika, S. Seo, S. Ogiso, Y. Miyauchi, R. Yamaoka, H. Kojima, T. Minami, K. Fukumitsu, S. Uemoto. *Graduate School of Medicine, Kyoto University, Department of Surgery, Kyoto city, Japan*
Email: u12323@kuhp.kyoto-u.ac.jp

Background and Aims: The current lack of tools for easy assessment of cancer stem cells (CSC) prevents the development of therapeutic strategies for hepatocellular carcinoma (HCC). We previously reported that keratin 19 (K19) is a novel HCC-CSC marker associated with transforming growth factor beta (TGFb)/Smad signaling, and that K19+ HCC-CSC could be a new therapeutic target of TGFb receptor 1 inhibitor. To develop precision medicine for K19+ HCC, we examined whether K19+ HCC-CSC can be tracked using PET with 18F-fluorodeoxyglucose (18F-FDGPET) and cytokeratin 19 fragment (CYFRA 21-1).
Method: K19 and glucose transporter-1 (GLUT1) expression were evaluated by immunohistochemistry in consecutive 255 HCC patients who underwent liver resection or liver transplantation. Preoperative SUV, tumor-nontumor SUV ratio (TNR), and preoperative serum CYFRA 21-1 level were compared in K19+/K19- patients. Using HCC cell lines encoding with a K19 promoter-driven enhanced GFP, 18F-FDG uptake, GLUT1 expression, and supernatant CYFRA 21-1 level were examined in FACS-isolated K19+/K19- cells.
Results: In HCC patients, K19 expression was significantly correlated with GLUT1 expression, FDG accumulation, and serum CYFRA 21-1 levels. ROC analyses revealed that among preoperative clinical factors, TNR (AUC = 0.87, $p < 0.001$) and serum CYFRA 21-1 (AUC = 0.81, $p < 0.001$) were most and second-most sensitive indicator of K19 expression in HCC tumors. In HCC cells, FACS-isolated K19+ cells displayed significantly higher FDG uptake and supernatant CYFRA 21-1. Moreover, gain/loss of function experiments confirmed that K19 regulates FDG uptake and CYFRA 21-1 level through TGFb/Smad signaling including Sp1 and its downstream target GLUT1.



Conclusion: 18F-FDGPET and CYFRA 21-1 can be used to predict K19 expression in HCC, and should thereby aid in the development of individual therapeutic strategies targeting K19+ HCC-CSC.

Email: carlorodriguez@humv.es

Background and Aims: Direct-acting antivirals (DAA) represent a revolution for the treatment of hepatitis C virus (HCV), with rates of sustained virological response (SVR) > 90%. Recent publications suggest that incidence of HCC after DAA could be increased and more aggressive due to an imbalance of the immune surveillance. Aim: analyze if HCV patients diagnosed with HCC have differences in tumor stage depending on the antiviral treatment received.
Method: We used data from the Spanish HCC-Registry supported by the AEEH and CIBERehd (prospective database of patients with primary liver tumors in Spain).
Results: Between March 1, 2016 and October 31, 2017, 35 centers registered 843 primary liver tumors: 809 (96%) HCC, HCV + 377; available information of previous antiviral treatment in 263: 125 had never received antiviral treatment and 138 had received at least one (27 IFN-based; 111 DAA). Last antiviral treatment started at a median of 338 days (range 12–3640) before HCC diagnosis. Patients that had received antiviral treatment had 1) higher SVR rate (80.4% vs 3.2%, $p < 0.001$); 2) earlier stages (BCLC 0-A 68.6% vs 48.8%; $p < 0.001$); 3) more radical treatments [resection, ablation, transplant] (61.4% vs 32.2%; $p < 0.001$); 4) higher albumin (4 vs 3.6 g/dl; $p < 0.001$); 5) lower INR (1.11 vs 1.18; $p = 0.028$); and 6) more frequently diagnosed under surveillance programs (80% vs 37.2%; $p < 0.001$). Considering only patients under surveillance, those with previous antiviral treatment were younger (60.1 vs 74.7 years, $p = 0.003$); earlier stages (BCLC 0-A 79.2% vs 52.4%, $p < 0.001$); more radical treatments (71.6% vs 33.3%, $p < 0.001$). Comparing patients according to the last antiviral treatment (IFN vs DAA), patients treated with IFN had larger main nodule (34 mm vs 25 mm, $p = 0.04$); more extrahepatic dissemination (23.1% vs 8.1%, $p = 0.028$); and higher AFP (16.4 vs 7.6 ng/ml, $p = 0.022$). These differences disappeared when considering patients under surveillance only.
Conclusion: Patients that have received antiviral treatment were diagnosed in earlier stages, partially because of better adherence to surveillance programs. Patients whose last treatment was DAA were diagnosed with smaller tumors, less extrahepatic spread and lower AFP compared to patients that had received IFN-based treatment. However considering only patients under surveillance, these differences disappeared. Surveillance is key for HCC detection in patients with cirrhosis even after successful antiviral treatment.

FRI-133

Regression of fibrosis stage after treatment in patients with HFE haemochromatosis and severe fibrosis at diagnosis: relevance to hepatocellular carcinoma

E. Bardou-Jacquet[1,2,3], M. Emilie[1], A. Gregory[3], G. Ramm[4], L. Ramm[4], M. Jeff[5], D. Jeannette[3], C. Andrew[6,7], L. Fabrice[1,8], T. Bruno[9], L. Powell[3], Y. Deugnier[1]. *[1]CHU Rennes, Liver disease department, Rennes, France; [2]CHU Rennes, National Reference Centre for Haemochromatosis and Iron Metabolism disorder, Rennes, France; [3]QIMR Berghofer Medical Research Institute, Iron Metabolism Laboratory, Brisbane, Australia; [4]QIMR Berghofer Medical Research Institute, Hepatic Fibrosis Group, Brisbane, Australia; [5]CHU Rennes, INSERM CIC1414, Rennes, France; [6]Faculty of Health Sciences, University of Queensland, Brisbane, Australia; [7]Envoi Specialist Pathologists, Brisbane, Australia; [8]CHU Rennes, INSERM CIC1414, France; [9]CHU Rennes, Pathology Department, France*
Email: edouard.bardou-jacquet@chu-rennes.fr

Background and Aims: HFE hemochromatosis treatment by removing iron through bloodletting is effective and is standard therapy. Regression of fibrosis stage following treatment has been reported, although reversal of cirrhosis itself remains controversial. Our aim was to assess fibrosis stage regression and the ensuing risk of hepatocellular carcinoma (HCC) in patients with HFE haemochromatosis after treatment.
Method: The Rennes and Brisbane databases of HFE C282Y homozygous patients were searched for patients with F3 or F4 fibrosis stage at diagnosis and at least one second liver biopsy (LB) during follow-up. Initial clinical and biological data were recorded. Follow-up information collected included HCC occurrence and fibrosis stage.
Results: Overall, 112 patients (89% males) were included (71 with F4; 41 with F3 fibrosis). At diagnosis, the median age was 46[40–53] years, serum ferritin was 2940[2000–4060] μg/l and transferrin saturation was 87[80–95] %. The median time between first and last LB was 9.25[3.5–15.3] years. Median follow-up time was 16.9[9.5–23.75] years. HCC developed in 35 patients during the study period (3 had F2, 1 had F3 and 30 had F4 fibrosis at last LB).
Of the F3/F4 patients at diagnosis, 44 (39%) had fibrosis ≤ F2 at last LB. HCC occurred in 31(45.5%) patients with F3/F4 fibrosis at last LB, versus 4(9%) patients with fibrosis ≤ F2 at last LB ($p < 0.001$). The incidences were, respectively, 29.4 and 4.6 per 1000 person-years.
Of the F4 patients at diagnosis, 14 (19.7%) had fibrosis ≤ F2 at last LB. HCC occurred in 31 (54.4%) patients with F3/F4 fibrosis at last LB, versus 3 (21.4%) patients with fibrosis ≤ F2 at last LB ($p = 0.03$). The incidences were, respectively, 35.3 and 12.0 per 1000 person-years.
In F3/F4 patients, multivariate analysis showed that younger age at diagnosis, and lower GGT were significantly associated with fibrosis regression to ≤ F2 at last LB. In F4 patients, multivariate analysis showed that fibrosis stage regression was associated with a reduced, HCC risk.
Conclusion: Our results show that in HFE hemochromatosis, fibrosis stage improves after treatment even in patients with severe fibrosis (F3 and F4). Further, while our study does not allow us to assess the question of cirrhosis reversibility, the reduction in fibrosis stage is associated with a significant reduction of HCC risk. Respective roles of duration of iron overload and fibrosis regression requires further investigation. Our findings are clearly relevant to surveillance for HCC and show the importance of aggressive therapy in such patients to reduce their iron burden.

FRI-134

Nonalcoholic fatty liver disease is the most common cause of hepatocellular carcinoma (HCC) in individuals without cirrhosis: A United States multicenter study

A. Delemos[1], L. Dakhoul[2], P. Roche[1], E. Miller[3], H.A. Sbeih[3], E. Mao[3], A. Scanga[4], E.V. Gomez[2], S. Gawrieh[2], N. Chalasani[2], J. Wattacheril[5]. *[1]Carolinas Healthcare System; [2]Indiana University School of Medicine; [3]MD Anderson Cancer Center; [4]Vanderbilt University Medical Center; [5]Columbia University College of Physicians and Surgeons*
Email: andrew.delemos@carolinas.org

Background and Aims: The etiologies and characteristics of HCC arising in patients with chronic liver disease but without cirrhosis are not well understood. The aims of this study were to (i) determine the frequency of non-cirrhotic HCC relative to cirrhotic HCC seen at 5 U.S. academic liver centers over time, and (ii) to compare patient and tumor characteristics among the two groups.

Method: Patients diagnosed with HCC between January 2000 through June 2014 were identified using center specific cancer registries. After confirming the diagnosis of HCC in the medical record, clinical information, tumor characteristics, and survival data were extracted. Patients were categorized as non-cirrhotic (when ascertained with either very high or high probability) or as confirmed cirrhosis as per Mittal S, et al. criteria (CGH 2016; 14: 124–131). The number of non-cirrhotic and cirrhotic HCC cases was compared over 5-year intervals (2000–2004, 2005–2009, and 2010–2014).
Results: A total of 2,454 patients with HCC were available for analysis. 2,095 HCC cases (85%) occurred in patients with cirrhosis, whereas 359 patients (15%) had HCC without underlying cirrhosis. The frequency of non-cirrhotic HCC decreased over time (2000–04, 23%; 2005–09, 18%; 2010–2014, 11%), while there was an increase in cirrhotic HCC (81.5%, 82.2%, and 89% for respective periods, $p < 0.001$). Non-alcoholic fatty liver disease (NAFLD) was the most common liver disease etiology (45%) in non-cirrhotic HCCs compared to viral hepatitis and alcohol (79%) in cirrhotic HCCs ($p < 0.001$). Patients with cirrhosis had higher mortality rate with a HR of 1.28 (1.12–1.47; $p < 0.01$). Selected characteristics of the two groups are shown below.

Table 1: Characteristics of HCC Patients with and without Cirrhosis

Variable	HCC with cirrhosis (n = 2095)	HCC without cirrhosis (n = 359)	P-value
Age, mean (SD)	62 (10)	64 (14)	<0.001
BMI, mean (SD)	28.6 (6.0)	27.3 (5.8)	<0.001
Female (%)	22	39	<0.001
Largest Tumor size (cm), mean (SD)	4.9 (3.7)	8.9 (4.9)	<0.001
Within Milan Criteria (%)	42	15	<0.001
Resection (%)	8.5	53	<0.001
Liver Transplantation (%)	21	3	<0.001
1-year survival rate (%)	56	66	0.001
5-year survival rate (%)	14.4	18.6	0.04

Conclusion: NAFLD accounts for nearly half of all non-cirrhotic HCCs in the US. A majority of non-cirrhotic HCCs fall outside the Milan criteria and seldom receive liver transplantation.

FRI-135

Clinical effectiveness of enhanced surveillance in "super-high risk" cirrhotics as evaluated in the ITA.LI.CA. Study Group

F. Pelizzaro[1], M. D'elia[2], G. Peserico[1], A. Meneghetti[2], A. Imondi[2], E.G. Giannini[3], F. Trevisani[4], F. Farinati[1]. *[1]Università Degli Studi di Padova, dip. Scienze Chirurgiche, Oncologiche e Gastroenterologiche, Università di Padova; [2]Università Degli Studi di Padova; [3]Università Degli Studi di Genova; [4]Università Degli Studi Di Bologna*
Email: giulia88.fish@gmail.com

Background and Aims: Surveillance of cirrhotics in the secondary prevention of HCC is mandatory but the ideal surveillance interval is still under discussion. The Japanese guidelines consider HCV/HBV-related cirrhotics as "super-high risk" patients, with shorter doubling time, and indicate an enhanced surveillance (3–4 months). Aim of the study were to evaluate the impact of a three-month enhanced surveillance (3MS) in patients with viral cirrhosis in terms of tumour stage, survival and direct costs.
Method: The multicenter ITA.LI.CA database (5849 HCC patients) was used. Inclusion criteria were: cirrhosis, viral etiology and diagnosis under surveillance (3MS versus 6MS). Overall 1576 cirrhotics met the definition of "super-high risk": 194 underwent 3MS, 1382 6MS. The survival analysis took into account the lead time bias (LTB) (by Schwartz's algorithm, Cancer 1961).
Results: The 3MS did not increase the proportion of lesions diagnosed as "very early" ($p = 0.622$) or within Milan Criteria ($p = 0.067$). In the 3MS patients a greater portion of HCC were multifocal ($p = 0.025$), probably due to an increased likelihood of the 3MS to diagnose more aggressive tumors. The survival of the 3MS patients was not significantly different, also when corrected for LTB ($p = 0.987$), with actually a shorter survival in the 3MS group (35 months, 95% CI 32–38, vs 42 months, 95% CI 37–43). These results were confirmed in the multivariate analysis. Micro-economic analysis estimated an increase of 1447 euros in the costs for each HCC while the cost for year of life saved was not computable.
Conclusion: In patients at "super-high risk" an enhanced 3MS does not improve tumor stage, feasibility of curative treatments and patients' survival, with an increase in direct costs. It can be concluded that "super-high risk" patients should be managed as all the population at risk at 6MS, as indicated by the European guidelines.

FRI-136

Patterns of glutamine synthetase expression as marker of beta catenin activation in hepatocellular adenomas

C. Balabaud[1], C. Sempoux[2,3], A.S. Gouw[4,5,6,7], D. Cappellen[8], B. Bisig[3], B.L. Bail[9], P. Bioulac-Sage[8]. *[1]Inserm U1053, Bordeaux; [2]CHUV, Institut Universitaire de pathologie, Lausanne, Switzerland; [3]CHUV, Pathology, Lausanne, Switzerland; [4]Groningen, Netherlands; [5]Pathology; [6]UMCG, Pathology, Groningen, Netherlands; [7]University Medical Center Groningen, Pathology, Groningen, Netherlands; [8]Inserm U1053, Bordeaux, France; [9]CHU Bordeaux, Pathology, Bordeaux, France*
Email: charles.balabaud@u-bordeaux.fr

Background and Aims: In hepatocellular adenomas (HCA) different types of b-catenin (b-cat) mutations have been identified by molecular analysis, occurring in exons 3 or 7/8 with different levels of b-cat pathway activation and risk of malignant transformation. The aim of the study was to describe the immunohistological patterns of Glutamine Synthetase (GS) as a surrogate marker of the different levels of b-catenin activation and to establish a genotype-phenotype correlation.
Method: HCA cases already classified by molecular analysis were collected from 3 centers. GS and CD34 were analysed in 19 b-cat activated HCA (b-HCA) and 23 b-cat activated inflammatory HCA (b-IHCA) identified by CRP expression. Cases had been previously classified according to their specific genotype (ex3 non S45; ex3 S45; ex7/8). GS staining was divided in 4 groups based on the immunohistological patterns: diffuse, "starry sky", "empty sky" but with GS patches around hepatic veins or elsewhere, and none of the above. Additional features were also taken into account: presence of a GS border, CD34 staining diffuse or not. The control group consists of IHCA and HNF1a inactivated HCA (H-HCA) without any b-cat mutation. The study was performed on sections from resection specimens containing tumoral and non-tumoral tissue in areas devoid of necrosis/hemorrhage.
Results: Cases with ex3 (non S45) mutations were characterized by diffuse GS (3b-HCA, 11 b-IHCA) and non-diffuse CD34 expression. Ex3 S45 b-HCA (9) showed a diffuse "starry sky" pattern with an obvious border and diffuse CD34 expression except in the border. The GS expression of b-IHCA ex3 S45 mutations (3) often shows GS patches combined with a "starry sky" pattern; CD34 was rarely diffuse. The GS pattern in ex7/8 b-HCA (7) is characterized by an obvious border but none or only a few solitary positive cells in the lesion. Ex7/8 b-IHCA (10) showed often a quite similar pattern with the b-IHCA S45 although with less "starry sky" component. In IHCA cases without any b-cat mutations, GS was frequently expressed around veins restricted to a few rows of hepatocytes, rarely wider which may resemble b-IHCA ex7/8 (5/46). Focal GS staining, usually faint, can sometimes be seen in atypical H-HCA (no steatosis), that is rare in all H-HCA (5/59).
Conclusion: GS staining is a good surrogate marker to identify all HCA with ex3 non S45 and typical "starry sky" S45 mutated HCA, both harboring higher risk of malignant transformation. In b-HCA/b-IHCA, the differentiation between ex3 S45 and ex 7/8 pattern depends on the extent of the "starry sky" component, more difficult in b-IHCA than in b-HCA. CD34 helps in interpreting GS patterns to suspect

possible b-cat mutation. In aberrant and inconclusive patterns, molecular analysis should be performed, particularly to differentiate S45 and 7/8, which is important for the patient management.

Email: hirage@gmail.com

Background/Aim: For evaluation of hepatic function, Child-Pugh classification (CP) is used worldwide, while indocyanine green test (ICG-R15) is also examined in Japan. We examine the usefulness of albumin-bilirubin (ALBI) grade, a newly proposed method for assessment of hepatic function and graded by ALBI score calculated only with albumin and total-bilirubin, in hepatocellular carcinoma (HCC) patients.

Method: Of 64,928 naïve HCC patients included in a Japan nationwide survey (2001–2007), the records of 31,011 were subjected to analysis after exclusion for lack of data (CP-A/B/C = 24,599/5883/529) [tumor node metastasis stage (TNM) 1/2/3/4 = 4566/14,982/8793/2670] [resection/ablation/transcatheter arterial chemoembolization (TACE)/others = 13487/7669/7761/2094]. Their median age was 68 years old (IQR: 61–73 years) and 22,639 (73.0%) were male. Patients with hepatitis C virus were 19,873 (64.1%) and those without viral hepatitis were 8389 (27.1%). To compare ALBI, LD, and CP, values for predicting prognosis based on Japan Integrated Staging (JIS) score using CP/TNM, modified JIS (mJIS) with LD/TNM, and ALBI-TNM (ALBI-T) with ALBI-grade/TNM were evaluated. As a sub-analysis, we modified the 3 ALBI grades to 4 grades (mALBI) using ICG-R15 (30%) for more detailed evaluation of hepatic function and also evaluated the predictive value of mALBI/mALBI-T for prognosis.

Results: ALBI-score had a good correlation with ICG-R15 (r = 0.563, 95%CI: 0.550–0.570, p < 0.0001). The cut-off value for ICG-R15 (<30%) was an ALBI score of -2.270 (AUC: 0.828, 95% CI 0.823–0.833) and ALBI grade 2 could be divided into sub-grades (2a, 2b). For each grade of mALBI, prognosis was clearly stratified by TNM (p < 0.01). Akaike's information criterion (AIC) values for ALBI-T, mALBI-T, mJIS, and JIS were 157,696.4, 157,668.7, 157,630.9, and 157,591.4, respectively, for all patients. On the other hand, those were 41,054.6, 40,887.7, 41,094.1, and 41,107.9, respectively, for patients within the Milan criteria and treated curatively (resection or ablation) (n = 13,404). Kaplan-Meyer curves for patients with low ALBI-T and mALBI-T scores were always superior to those with the same mJIS and JIS scores.

Conclusions: Although ALBI and mALBI are calculated only with albumin and total-bilirubin, they showed a good ability to highlight patients with better hepatic function as compared to LD and CP. In addition, ALBI-T/mALBI-T had better predictive value regarding prognosis, especially for patients with early HCC who were treated in a curative manner.

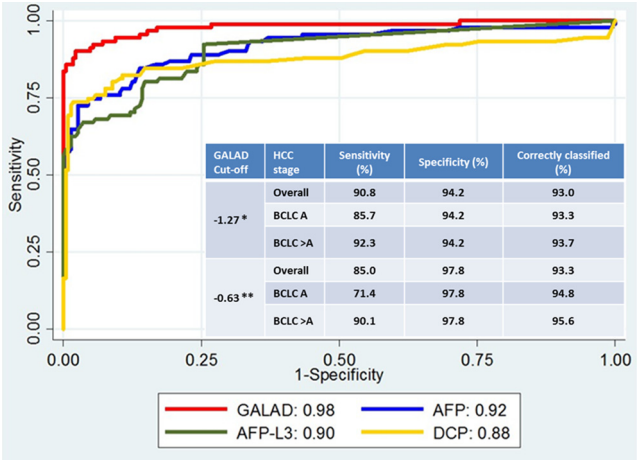
Background and Aims: Hepatocellular carcinoma (HCC) is one of the leading causes of death in cirrhotic patients worldwide. There is increasing incidence of HCC in non-alcoholic steatohepatitis (NASH), even in the absence of cirrhosis. NASH is frequently associated with obesity resulting in poor performance of ultrasound surveillance in these patients. This creates an urgent need for serological approaches to ameliorate the current situation with HCC detection predominantly at advanced stages. Therefore, this study aims to explore whether the biomarkers AFP, AFP-L3 and DCP have the potential to be used in the screening setting in NASH patients in a German multicenter cohort.
Method: From 8 German centers, 121 NASH patients with newly diagnosed HCC and 224 NASH control patients were enrolled. AFP, AFP-L3 and DCP were measured using the µTASWako i30® automated immunoanalyzer. The diagnostic performance of biomarkers was measured as single parameters, in a logistic regression model and by ROC analysis. A diagnostic algorithm (GALAD) that combined gender, age and the three biomarkers mentioned above was tested in this NASH cohort.
Results: AFP, AFP-L3 and DCP showed comparable sensitivities and specificities for HCC detection. The GALAD score achieved an AUROC of 0.98 compared to individual application of AFP (0.88), AFP-L3 (0.92) and DCP (0.88) ($p < 0.0005$) (Figure 1). In early stage HCC (BCLC A) the GALAD algorithm again provided the highest overall AUROC (0.93) which was significantly superior to any of the individual markers.



GALAD Cut-off	HCC stage	Sensitivity (%)	Specificity (%)	Correctly classified (%)
-1.27*	Overall	90.8	94.2	93.0
	BCLC A	85.7	94.2	93.3
	BCLC >A	92.3	94.2	93.7
-0.63**	Overall	85.0	97.8	93.3
	BCLC A	71.4	97.8	94.8
	BCLC >A	90.1	97.8	95.6

Figure 1: This figure exhibits the ROC curves, sensitivities and specificities of the individual biomarkers and their combined utilization in the GALAD Score for HCC detection.
*This is the optimal GALAD cut-off for specificity and sensitivity for this dataset.
**This is the published optimal GALAD cut-off for specificity and sensitivity according to the original GALAD publication (Johnson PJ et al.; Cancer Epidemiol Biomarkers Prev; 2014; 23; 144–53).

Conclusion: This German multicenter NASH-HCC cohort demonstrates a high sensitivity and specificity of the GALAD score for HCC early cases and warrants future prospective study in the surveillance setting.

Trauner[1]. *[1]Medical University of Vienna, Internal Medicine III, Vienna; [2]Musashino Red Cross Hospital, Gastroenterology and Hepatology, Tokyo, Japan; [3]Medical University of Vienna, Clinical Institute of Pathology, Vienna, Austria; [4]Institute of Pathophysiology and Allergy Research, Medical University of Vienna, Center of Pathophysiology, Infectiology and Immunology, Vienna, Austria; [5]The Interuniversity Messerli Research Institute of the University of Veterinary Medicine of Vienna, Medical University of Vienna and University of Vienna, Comparative Medicine, Vienna, Austria; [6]Medical University of Vienna, Internal Medicine I, Institute for Cancer Research, Vienna, Austria; [7]Clinikum Klagenfurth, Division of Gastroenterology and Hepatology, Klagenfurth am Wörthersee, Austria*
Email: nataliya.rohr-udilova@meduniwien.ac.at

Background and Aims: Tumor-infiltrating immune cells are highly relevant for prognosis and identification of immunotherapy targets in hepatocellular carcinoma (HCC). The recently developed CIBERSORT method allows immune cell profiling by deconvolution of gene expression microarray data.
Method: We assessed the abundance of immune cells in 42 healthy human livers, 305 HCC samples and 82 HCC adjacent tissues by CIBERSORT analysis (Newman et al. 2015 Nat Meth 12: 453–457). The obtained immune cell profiles were calculated for each human patient and provided enumeration and activation status of 22 immune cell subtypes. Key CIBERSORT findings were validated by immunohistochemistry combined with tissue morphometric analysis in a tissue array constructed from a patient subgroup of an Austrian HCC cohort (tumor tissues and corresponding surrounding tissues, n = 53) and from healthy livers (n = 24).
Results: Activated mast cells, monocytes and plasma cells were decreased in HCC, while resting mast cells, total and naïve B cells, CD4 + memory resting and CD8+ T cells were increased when compared to healthy livers (Figure 1). Strong total immune cell infiltration into tumor tissue - but not into tumor-adjacent tissue - correlated with improved patient survival ($p = 0.04$). In particular, high intratumoral numbers of T cells and monocytes correlated with improved survival (HR = 2.71, 95%CI 1.23–5.99 and HR = 2.26, 95% CI 1.06–4.80 respectively, both $p < 0.05$). In contrast, intratumoral resting and total mast cells correlated with poor survival. Immunohistochemical staining of mast cell tryptase in the validation cohort confirmed the results from CIBERSORT: density of activated mast cells was in average 7.67 times (95% CI 3.15–12.2) lower in tumors as compared to corresponding adjacent tissues (n = 52, $p < 0.0001$). Healthy liver tissues showed the highest density of activated mast cells.

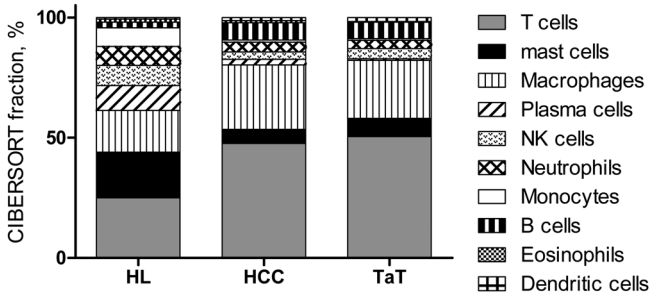

Figure 1: Immune cell composition of human healthy livers (HL), hepatocarcinoma tumor tissue (HCC) and tumor adjacent tissue (TaT) as determined by CIBERSORT methodology.

Conclusion: Deconvolution of gene expression data by CIBERSORT provides valuable information about immune cell composition and

immune cell-based prognosis of HCC patients. The abundance of activated mast cells is diminished in HCC as compared to corresponding surrounding tissue or healthy liver tissue. The potential benefit of mast cell reactivation for HCC therapy should be further evaluated.

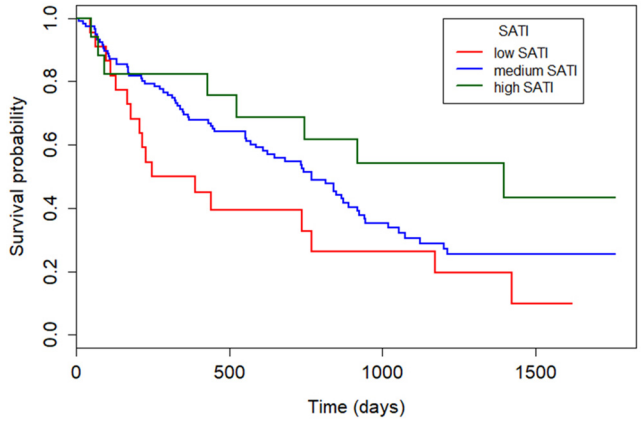
Email: leona.vk@gmx.de

Background and Aims: Prognostic stratification in patients with hepatocellular carcinoma (HCC) is based on clinical parameters as tumor burden, liver function and performance status. Imaging features of body composition have been suggested to refine prognosis stratification in patients with cancers including HCC. However, data in European patients with HCC are scarce. This study aimed at evaluating whether skeletal muscle mass and regional fat distribution on computed tomography (CT) adds to the standard prognostic indicators, predicting overall survival (OS) of patients with HCC.
Method: This is a retrospective analysis of patients with HCC consecutively included in a prospective cohort at a tertiary European university hospital between 08/2010–10/2016. Patients with CT scan available at time of diagnosis were selected. Cross-sectional areas of skeletal muscle mass (SM), intramuscular adipose tissue (IMAT), subcutaneous (SAT) and visceral adipose tissue (VAT) were measured by CT (SliceOmatic software) at the level of the third lumbar vertebra and normalized to height (cm^2/m^2), to obtain indexes (I). Univariate and multivariate Cox regression analysis was used to assess the prognostic significance of standard predictors and imaging features for OS. Maximally selected rank statistics were used to define cut-off values to split the population into different groups according to their OS.
Results: 157 patients fulfilled inclusion criteria (male 81%, cirrhotic 80%, hepatitis C infected 30%, BCLC 0 + A/B/C/D 34/34/21/11%) and showed OS of 68% and 33% at 1 and 3 years, respectively. In the univariate analysis, VATI and SATI were associated with survival (HR 0.995, p = 0.044 and HR 0.992, p = 0.020, respectively), while SMI and IMATI were not. In the multivariate analysis only SATI remained significant when adding the BCLC stage (p = 0.046). Cut-off values for SATI of < 28, 28–110 and > 110 allowed splitting the population into 3 groups with mean OS of 596 days (95% CI 356–837), 1067 (853–1282) and 1290 (855–1724), respectively (p = 0.042) (Figure).



Conclusion: In this European HCC population low SATI, but not low SMI, is associated with poor survival. These results suggest that in the body composition subcutaneous fat is a better predictor of survival than muscle mass.

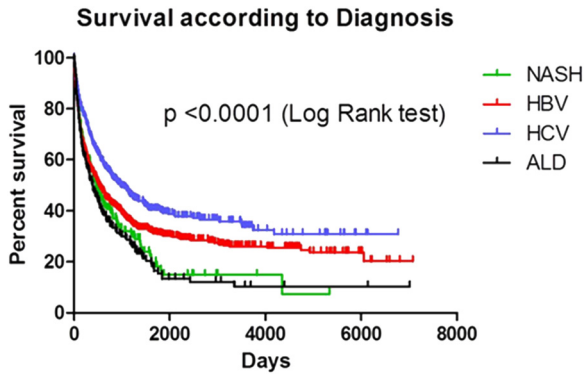
Background and Aims: We recently identified a novel histological subtype of hepatocellular carcinoma, designated as "macrotrabecular-massive" (MTM-HCC) and associated with specific molecular features. In order to assess the clinical relevance of this novel variant, we aimed to investigate its prognostic value in two large series of patients treated either by surgical resection or radiofrequency ablation (RFA).
Method: We retrospectively included 389 HCC surgical samples and 284 HCC liver biopsies from patients treated by surgical resection and RFA, respectively. Histological slides were reviewed by pathologists specialized in liver disease, and the MTM-HCC subtype was defined by the presence of a predominant (>50%) macrotrabecular architecture (more than 6 cells thick). The main clinical and biological features were recorded at baseline. Clinical endpoints were early and overall recurrence.
Results: The MTM-HCC subtype was identified in 14% of the whole cohort (19% of surgically resected samples, 8.5% of liver biopsy samples). Interobserver agreement for the diagnosis of MTM-HCC was good (k = 0.72) and excellent (k = 0.82) in the surgical and RFA series, respectively. This subtype was associated at baseline with known poor prognostic factors (tumor size, AFP level, satellite nodules and vascular invasion). Multivariate analysis showed that MTM-HCC subtype was an independent predictor of early and overall recurrence (surgical series: OR 2.90 (1.29–6.53), p = 0.01 and 2.83 (1.66–4.82), p < 0.001); RFA series: 2.37 (1.36–4.13), p = 0.002 and 2.19 (1.35–3.54), p = 0.001, respectively). Its prognostic value was retained even after patients' stratification according to common clinical, biological and pathological features of aggressiveness. The relative risk of relapse associated with MTM-HCC was also higher than those associated with classical HCC outcome predictors, such as AFP serum levels, vascular invasion or satellite nodules. No other baseline parameter was independently associated to recurrence in the RFA series.
Conclusion: The MTM-HCC histological subtype, reliably observed in 14% of patients eligible for a curative treatment, represents an aggressive form of HCC that may require more specific therapeutic strategies.

FRI-142

Improving survival in patients with hepatocellular carcinoma related to chronic hepatitis C and B but not in those related to non-alcoholic steatohepatitis or alcoholic liver disease: A 20 year experience from a national programme

I. Hassan, E. Gane, D. Prasad, A. Bartlett, O. Lithgow. *Auckland city hospital, New Zealand liver transplant unit, Auckland, New Zealand*
Email: ibrahim20.hassan20@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the most rapidly increasing cause of cancer mortality in New Zealand due to endemic hepatitis B (HBV) infection and recent hepatitis C (HCV) and obesity epidemics. The objectives of this audit are to describe the changing landscape of HCC referred to a national HCC service since1998, in particular changes in the underlying liver disease, rate of screening uptake and curative treatments and survival.
Method: All newly diagnosed cases of HCC referred to New Zealand liver transplant unit between 1998 and 2016 were included, with follow-up available until June 2017. Data on patient demographics, liver disease aetiology, screening status and HCC stage at diagnosis were collected from chart review. Data were also collected on transplantation, resection and ablation. Kaplan Meier survival estimates were derived from the national mortality database. Recruitment in and adherence with HCC surveillance were recorded.
Results: HCC diagnosis rates have increased from 25 cases in 1998 to 260 in 2016, an increase of 20% per annum. The total of 1683 HCC cases were divided into 3 cohorts (Era 1: Jan 1998 to Dec 2008; Era 2: Jan 2009 to July 2013; Era 3: August 2013 to June 2016), each comprising 561 patients.
During the study period, overall survival improved ($p = 0.005$). The proportion with screen-detected HCC was similar across the 3 cohorts (43% in Era 1, 42% in Era 2 and 47% in Era 3) as was the proportion who received curative therapy (35% in Era 1, 37% in Era 2 and 41% in Era 3). 5 and 10-year survival were higher in screen-detected cases (49% and 43%) than in non-screen detected cases (14% and 10%), $p < 0.0001$. Over the 3 eras, survival improved in the nonscreen-detected cases ($p = 0.002$) but not in the screen-detected cases ($p = 0.23$).
The most common underlying liver diseases were HBV (43%), HCV (26%), alcoholic live disease (ALD)(11%), and non-alcoholic steatohepatitis (NASH) (9%).Over the study period, the proportion with HBV has decreased from 56% to 32%, whilst the proportion with HCV has increased from 17% to 32% and NASH from 4% to 15%. Survival was higher in patients with HCV and HBV than is those with NASH or ALD – 5 and 10-year survival was 40% and 34% in HCV-HCC, 30% and 26% in HBV-HCC, 15% and 14% in NASH-HCC, 13% and 10% in ALD-HCC, $p < 0.0001$.



Conclusion: The improvement in survival in patients with HCC over the past 20 years likely reflects improved screening uptake and better management of the nonscreen-detected cases. Lower survival in NASH and ALD patients may reflect poor screening uptake and lack of awareness of risk factors in these patients.

FRI-143

Prospective evaluation of gadoxetic-acid MR for the non-invasive diagnosis of hepatocellular carcinoma in newly detected nodules <=2 cm in cirrhotic patients

A. Forner[1], A. Darnell[1], C. Ayuso[2], J. Rimola[1], M.Á. García-Criado[1], R. Vilana[1], L. Bianchi[1], María Reig[1], J. Bruix[2]. *[1]Hospital Clínic Barcelona. IDIBAPS. University of Barcelona. Spain, Barcelona Clínic Liver Cancer group (BCLC). Liver Unit; [2]Hospital Clínic Barcelona. IDIBAPS. CIBERehd University of Barcelona. Spain, Barcelona Clínic Liver Cancer group (BCLC). Radiology Department*
Email: aforner@clinic.ub.es

Background and Aims: To prospectively evaluate the diagnostic accuracy of gadoxetic-acid enhanced MR (Gd-EOB-DTP MR) for the non-invasive diagnosis of hepatocellular carcinoma (HCC) in nodules <2 cm detected by screening ultrasound (US).
Method: Between July 2012 and October 2015, we prospectively included asymptomatic Child-Pugh A-B cirrhotic patients with newly US-detected solitary nodule between 1–2 cm. Hepatic extracellular-contrast-enhanced MR (ECCE-MR) followed by Gd-EOB-DTP MR were obtained in less than 1-month interval. Two independent radiologists blindly reviewed the Gd-EOB-DTP MR studies and the diagnosis of HCC was assigned when the lesion showed arterial enhancement followed by portal venous phase wash-out and/or hypointensity on the hepatobiliary phase (HBP). The final HCC diagnosis was made by ECCE-MR according the accepted non-invasive criteria, or by biopsy in lesions with atypical vascular profile. We calculated the sensitivity, specificity and positive and negative predictive value (PPV, NPV) and their 95% confident interval. The protocol was approved by the Ethics Committee for Clinical Research.
Results: A total of 62 patients were included in the study. Final diagnoses were: HCC (n = 41), intrahepatic cholangiocarcinoma (ICC) (n = 2), colorectal metastases (n = 1) and benign conditions (n = 18). The sensitivity, specificity, PPV and NPV of Gd-EOB-DTP MR for HCC diagnosis were 56.1% [95%CI: 39.7–71.5], 90.5% [95%CI: 69.6–98.8], 92.0 [95%CI: 74.0–99.0], and 51.4 [95%CI: 34.4–68.1] respectively, while sensitivity of ECCE-MR was 63.4% [CI95%: 46.9–77.9]. The most specific contrast pattern for HCC diagnosis was homogeneous contrast uptake in arterial phase followed by washout in portal phase (95.2% [CI95%: 77.3–99.1], but it was penalized by a low sensitivity (41,5% [CI95%: 27.8–56.6]). Low rate of hypointense HCCs in the HBP (26 out of 41 HCC, 63.4%), suboptimal image acquisition in a relevant proportion of patients (37%) because of motion artifacts or incorrect arterial timing, and suboptimal liver uptake of contrast agent could justify the low sensitivity of Gd-EOB-DTP MR for HCC diagnosis.
Conclusion: Gd-EOB-DTP MR is not superior than ECCE-MR for non-invasive diagnosis of HCC in nodules <2 cm in cirrhotic patients.

FRI-144

Risk of early de-novo hepatocellular carcinoma (HCC) in patients with genotype-1b HCV compensated cirrhosis treated with 3 direct-acting antivirals (DAAs) - a real life, multicenter study

C.-M. Muzica[1,2], C. Stanciu[1], O. Stoica[3], I. Girleanu[1,3], L. Huiban[1,3], C. Alexandru[1,3], T. Cucureanu[1,3], A.-M. Singeap[1,3], S. Chiriac[3], A. Trifan[1,3]. *[1]Institute of Gastroenterology and Hepatology, Iasi, Romania, Gastroenterology, Iasi, Romania; [2]"Grigore T Popa ' University of Medicine and Pharmacy, Iasi, Romania, Gastroenterology, IASI, Romania; [3]"Grigore T Popa ' University of Medicine and Pharmacy, Iasi, Romania, Gastroenterology, Iasi, Romania*
Email: lungu.christina@yahoo.com

Background and Aims: Recent studies have reported an increased risk of HCC after treatment with 3-DAAs. The aim of our study was to evaluate the incidence and factors associated with *de- novo* HCC in patients with genotype-1b HCV compensated cirrhosis treated with 3-DAAs: real-life study.
Method: We prospectively analysed a cohort of patients with HCV-related liver cirrhosis treated with paritaprevir/ritonavir, ombitasvir

and dasabuvir (PrOD) ± ribavirin for 12 weeks between 01 December 2015 and 31 March 2017, in two tertiary referral centers from North-Eastern Romania. All patients with genotype-1b HCV-infected, treatment-experienced or naive patients with Child-Pugh class A cirrhosis assessed by Fibromax (cut off 0.71 for F4) or liver biopsy (F4 METAVIR) were evaluated pretreatment according to our National Protocol. Demographics, imaging, laboratory tests, end of treatment (EOT), and 12 weeks after therapy (sustained virological response - SVR) were assessed. All underwent surveillence by US, ALT, AST, alpha-fetoprotein (AFP) within six months after EOT.

Results: The study included 480 consecutive HCV-infected cirrhotic patients, predominantly female (54.8%), mean age 59.1 ± 8.3 years, with no prior history of hepatocellular carcinoma, who completed 12 weeks of treatment with PrOD and were followed by a median of 8 months after EOT. EOT virological response was 100% and SVR rate was 99.2%. Of these, 12 patients (2.5%) developed early *de-novo* HCC, predominantly males (61.5%) mean age 59.6 ± 7.8 years. The mean period between EOT and HCC diagnosis was 26.7 ± 4 weeks. The imaging findings revealed the predominance of unicentric lesions in 8 (61.5%) patients and the predominant localization of the lesions was in the VII liver segment (23%). At multivariate analysis, the only independent predictor of HCC was AFP ≥ 10 ng/ml at EOT.

Conclusion: The risk of *de-novo* HCC in patients with genotype-1b HCV compensated cirrhosis treated with PrOD ± ribavirin for 12 weeks, remains in range of the expected rate risk of that reported in untreated HCV patients with cirrhosis. An elevated AFP level at EOT (≥10 ng/ml) is the only significant predictor of HCC development.

FRI-145

Incidence of HCC in TIPS bearing cirrhotic patients

J.M. Garcia-Ortiz[1], A. Giraldez-Gallego[1], V. Nacarino-Mejías[2], J.M. Sousa-Martin[1], M. Teresa Ferrer[1], J. Ampuero[1], J.M. Pascasio[1].
[1]*Virgen del Rocio University Hospital, Digestive Diseases, Sevilla, Spain;* [2]*Virgen del Rocio University Hospital, Interventional Radiology, Sevilla, Spain*
Email: jm.garortiz@gmail.com

Background and Aims: For varied reasons, tranjugular intrahepatic portosystemic shunt (TIPS) has been proposed to have a possible role on the onset of hepatocellular carcinoma (HCC), although this statement has never been proved. Our aim was to know the cumulative incidence of HCC during long-term follow up of cirrhotic patients on whom TIPS has been placed.

Method: Retrospective observational study of a cohort of 88 TIPS bearing cirrhotic patients without previous HCC or liver transplant (LT), during a 7 years period. Follow-up consisted of conventional screening by Doppler-ultrasound with a periodicity of at least 6 months until death, LT, HCC diagnosis or loss to follow-up happened.

Results: Our sample was formed by 88 patients (71.6% male) with a mean age of 55.0 ± 10.7 years. Cirrhosis ethiology was alcohol (37.5%), HCV (37.5%), NASH (8%), HBV (5.7%) or others (11.3%). Median MELD was 12 (RIC 10–16.8). Indications for placing TIPS had been: acute variceal bleeding (33%), secondary profilaxis of variceal bleeding (36.4%), refractory ascites (13.6%) recurrent hydrotorax (6.8%). 34 patients (38.6%) had portal thrombosis –present or recanalized- and 4.5% (4/88) were HIV-infected.

After a medium follow-up of 24.1 ± 20.1 months, 23 patients had died (26.1%) and 16 had been transplanted (18.2%). 44/48 patients (47.7%) remained alive and without HCC, and only two patients (2.3%) were lost on follow-up. In 9/88 patients (10.2%) there was a *de novo* diagnosis of HCC.

None of the studied variables showed a statistically significant association with the onset of HCC, on univariant analysis. Nevertheless, patients who developed HCC were older (59.6 ± 8.0 vs 54.5 ± 10.9 years; p = 0,084) and had a longer follow-up (33.3 ± 21.6 vs.23.1 ± 19.8 months; p = 0.148) compared to those who did not.

The possibility of remaining HCC-free after TIPS (Kaplan-Meier) in months 6 and 12 was 98.7% and 97.1% respectively. After 2, 3 and 4 years of follow-up, the proportion of HCC-free patients consecutively reduced to 95.2%, 92.6% and 88.6%.

Conclusion: After rigorous screening of HCC in our sample of cirrhotic patients bearing TIPS because of previous severe portal hypertension complications, we established a cumulative incidence rate of 2.9% on year-1, 4.8% on year-2, 7.4% on year-3 and 11.4% on year-4. *De novo* HCC becomes a more relevant problem as liver transplant-free survival improves in our patients bearing TIPS.

FRI-146

Lymphoid infiltrate predicts prognosis of mass-forming intrahepatic cholangiocarcinoma undergoing complete liver resection

L. Vigano'[1], C. Soldani[1], A. Lleo[2], L. Di Tommaso[3], B. Franceschini[1], M. Cimino[1], M. Donadon[1], G. Torzilli[1]. [1]*Humanitas University, Department of Surgery - Division of Hepatobiliary & General Surgery;* [2]*Humanitas University, Department of Internal Medicine and Hepatology;* [3]*Humanitas University, Pathology*
Email: ana.lleo@humanitas.it

Background and aims: In colorectal cancer, the lymphoid infiltrate has shown a prognostic impact. Similar data have been reported for hepatocellular carcinoma. No study focused on intrahepatic mass-forming cholangiocarcinoma (MFCCC). To assess the presence of lymphoid infiltrate and its prognostic impact in patients undergoing liver resection for MFCCC.

Methods: All consecutive patients undergoing surgery for MFCCC between 2005 and 2015 were considered. The inclusion criteria were complete resection (R0/R1) and follow-up ≥12 months. Patients with operative mortality were excluded. Formalin-fixed, paraffin-embedded tissue sections from MFCCC were immunostained for CD3+, CD4+, CD8+, Foxp3+ and CD68+. The number of positive cells was quantified using a computer-aided image analysis system. The percentage of positive cells in the analyzed area was computed. Different cut-off values were tested as predictors of overall and recurrence-free survival (OS and RFS). For each marker, the value with the most significant p-value was included in the multivariable analysis of OS and RFS.

Results: Overall, 53 patients were analyzed. MFCCC were multiple in 10 (19%) patients, >50 mm in 26 (49%), and N+ in 12 (23%). 28 patients (53%) had T1 tumor.

After a median follow-up of 41 months, 5-year OS was 56.1% and 3-year RFS was 40.1%. At univariate analysis, the following lymphoid infiltrate values had a prognostic impact: CD3+ >0.10% (OS p < 0.001, RFS p < 0.001); CD8+ >0.10% (OS p = 0.044, RFS p = 0.001), CD4+ >0.30% (OS = 0.094, RFS p = 0.009), and Foxp3+ present (OS p = 0.097). CD68+ cells were not associated with prognosis. At the multivariable analysis, CD3+ value was a prognostic factor of both OS and RFS [> 0.10%, 5-year OS 66.9% vs. 18.2% if ≤0.10%, HR = 0.287, p = 0.049; 3-year RFS 48.1% vs. 9.1%, HR = 0.232, p = 0.001] and Foxp3+ was a negative prognostic factor of OS [present, 5-year OS 21.4% vs. 61.9% if absent, HR = 2.924, p = 0.044] (Figure).

CD3+ values stratified prognosis in T1 patients (5-year OS 73.9%/14.3%, p < 0.001; 3-year RFS 60.8%/14.3%, p < 0.001), in N+ patients (OS 71.4%/0%, p = 0.028; RFS 42.9%/0%, p = 0.011) and in patients without lymph node metastases (RFS 49.7%/20.0%, p = 0.062).

Conclusions: The lymphoid infiltrate impacts prognosis of MFCCC after complete surgery. CD3+ infiltrate is associated with higher survival and lower recurrence risk, while Foxp3+ is associated with worse prognosis. CD3+ infiltrate allows to refine prognosis in early tumors and across different N stages.

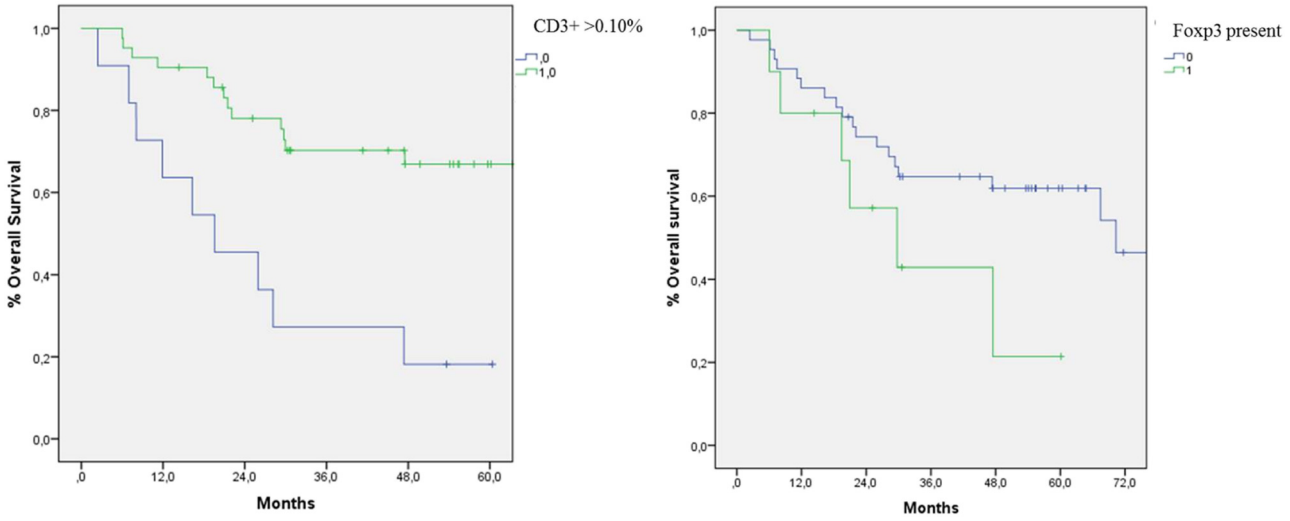


Figure 1: (abstract: FRI-146): Overall survival curves of MFCCC patients according to $CD3^+$ and to $Foxp3^+$ infiltrate.

FRI-147

Clinical correlates of the genetic variability of the CD274 gene (Programmed Cell Death-Ligand 1) among patients with hepatocellular carcinoma

F. Daffara, L. Salmi, M.N. Barbaglia, V. Mulas, D. Camatta, M.T. Minh, M.E. Burlone, R. Minisini, M. Pirisi. *Università del Piemonte orientale, Translational Medicine, NOVARA, Italy*
Email: rosalba.minisini@med.uniupo.it

Background and Aims: A deranged Programmed Death-Ligand 1 (PD-L1, a protein encoded by the *CD274* gene) pathway is an important mechanism of immunological escape exploited by different cancers. Specifically, PD-L1 germline mutations modulate outcome and response to therapy in non-small cell lung cancer. Our aim was to verify the clinical correlates of three single nucleotide polymorphisms (SNPs) on the CD274 gene among patients with hepatocellular carcinoma (HCC).
Method: The study population included n = 387 patients: n = 214 with HCC (Group A: 162 males, median age 71 years, cirrhosis in 97% and hepatitis C in 56%) and n = 164 with cirrhosis, similar for age and sex distribution (Group B: 118 males, median age 72 years, and hepatitis C in 63%) to Group A. All were genotyped for the following SNPs: rs2279136, rs4143815 and 8923A/C. The status of all these patients was known and documented up to (and including) the censor date of 31 Jul 2017.
Results: The study population did not depart from what expected based on the Hardy-Weinberg equilibrium for any of the three SNPs. For rs2279136, the allelic frequencies in Group A vs. Group B were 0.39 and 0.61 vs. 0.41 and 0.59, respectively for the ancestral and variant gene (p = 0.941); for rs41438156, they were 0.70 and 0.30 vs. 0.71 and 0.29 (p = 0.935); for 8923A/C, they were 0.57 and 0.73 vs. 0.52 and 0.48 (p = 0.137). Patients in group A did not show differences based on the rs2279136 and 8923A/C genotypes with regard to age at diagnosis, gender distribution, hepatitis C etiology, major tumor node size, number of tumor nodes, Milan-in criteria, serum alpha-fetoprotein concentration and neutrophil-to-lymphocyte ratio. However, carriage of the variant gene for the rs4143815 was associated with younger age at diagnosis, obtained at a median of 73 years (interquartile range, 65–79) for G/G homozygotes, 70 years (62–76) for G/C heterozygotes, and 68 years (59–73) for C/C homozygotes (p = 0.032). Moreover, there was a trend for higher number of nodules at diagnosis in the same direction (p = 0.070). Finally, median survival in Group A was 24 months; at logrank test, survival probabilities in Group A were not statistically different based on carriage of any of the germline mutations, either analyzed genotypically or using a dominant or a recessive model.
Conclusion: Carriage of the rs4143815 germline mutation may affect the natural history of HCC superimposed on cirrhosis by predisposing to its earlier and multinodular occurrence.

FRI-148

Gp38+ hepatic progenitor cell-derived large extracellular vesicles in biliary cancers - a novel liquid biopsy marker?

S. Urban[1], M. Krawczyk[1], A. Willms[2], J. Ligocka[3], H. Sänger[1], K. Jankowski[4], M. Krawczyk[3], K. Zieniewicz[3], W. Patkowski[4], R. Schwab[2], A. Wöhler[2], S. Gehlert[5], J.M. Banales[6], P. Milkiewicz[7], F. Lammert[1], V. Lukacs-Kornek[1], M. Kornek[1]. *[1]Saarland University Medical Center, Saarland University, Department of Medicine II, Homburg, Germany; [2]German Armed Forces Central Hospital, Department of General, Visceral and Thoracic Surgery, Koblenz, Germany; [3]Medical University of Warsaw, Department of General, Transplant and Liver Surgery, Warsaw, Poland; [4]Medical University of Warsaw, Department Internal Medicine and Cardiology, Warsaw, Poland; [5]Institute of Cardiovascular Research and Sport Medicine, German Sport University Cologne, Department of Molecular and Cellular Sport Medicine, Cologne, Germany; [6]Biodonostia Health Research Institute – Donostia University Hospital, University of the Basque Country (UPV/EHU), CIBERehd, Ikerbasque, Department of Liver and Gastrointestinal Diseases, San Sebastian, Spain; [7]Medical University of Warsaw, Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery, Warsaw, Poland*
Email: miroslaw.kornek@uks.eu

Background and Aims: Large extracellular vesicles (EVs), so-called microparticles (MPs), are cell-derived membrane vesicles that harbor the same surface antigens as their parental cells. Recently, we showed that tumor-associated MPs (taMPs) could be used to discriminate hepatic cancers from cirrhosis. To further distinguish biliary cancer (CCA and GbC) from HCC and other cancer entities, we utilized this minimal-invasive MP approach with surface marker compositions based on gp38/podoplanin, a recently described novel marker for liver progenitor cell subpopulations (Eckert. C. et al. 2016, Lukacs-Kornek et al. 2017 JHEP).
Method: The presence of $gp38^+$ progenitor cells was confirmed in various organs in wild type C57Bl/6J mice by FACS. TaMPs from patients' sera were isolated by sequential ultracentrifugation at 2,000

and 20,000xg. To identify taMP populations FACS was applied. In total, 43 HCC, 26 NSCLC and 91 biliary cancer patients were enrolled in the study. 47 cirrhosis patients and 46 healthy individuals served as controls.
Results: i) Recently described liver progenitor marker gp38 was evaluated in additional organs in order to assess their potential as biomarkers for biliary cancer. Indeed, $gp38^+EpCAM^+$ and $gp38^+EpCAM^+CD133^+$ cells were found in murine liver, lung and gallbladder. ii) $AnnexinV^+EpCAM^+ASGPR1^+$ taMPs pinpointed liver cancers (HCC and CCA) and distinguished these from NSCLC and cirrhosis. Of note, gp38 in the combinations $AnnexinV^+gp38^+EpCAM^+$ and $AnnexinV^+gp38^+EpCAM^+CD133^+$ identified taMPs that allowed the distinction of biliary cancer from non-biliary cancers (here, HCC and NSCLC). In detail, $AnnexinV^+gp38^+EpCAM^+$ taMPs were increased in biliary cancer patients by 4.7-fold as compared to non-biliary cancer patients. AUROC value (0.778), sensitivity (71%), specificity (71%) as well as positive predictive value (77%) indicated their diagnostic value as a novel biomarker for biliary cancer. $AnnexinV^+gp38^+EpCAM^+CD133^+$ taMPs confirmed our differentiation between biliary and non-biliary patients, albeit with slightly better sensitivity (74%) but with lower positive predictive value (71%).
Conclusion: Our results provide evidence that the novel progenitor marker gp38/podoplanin in the combination $AnnexinV^+gp38^+EpCAM^+$ identifies taMPs that serve as a novel biomarker for biliary cancer. Thus, this method represents a minimal-invasive, accurate liquid biopsy screening tool for early and specific detection of biliary cancer.

FRI-149

Recommendations for the management of women with suspected hepatocellular adenoma and childbearing potential

M. Gaspersz[1], J. Klompenhouwer[1], M. Broker[1], F. Willemssen[2], M. Thomeer[2], Türkan Terkivatan[1], R.D. Man[3], J. Ijzermans[1]. [1]*Erasmus MC, Surgery, Rotterdam, Netherlands;* [2]*Erasmus MC, Radiology, Rotterdam, Netherlands;* [3]*Erasmus MC, Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: a.klompenhouwer@erasmusmc.nl

Background and Aims: Hepatocellular adenoma (HCA) is a rare benign liver tumor occurring mostly in females in their reproductive phase. Pregnancy in these women requires special consideration, as hormone induced growth and bleeding can occur. Therefore, pregnancy is often discouraged or surgical resection is performed before pregnancy. However, a definitive diagnosis is not always made due to suboptimal imaging. If conception does take place in these patients with suspected or diagnosed HCA, intensive follow-up with ultrasound to detect lesion growth is recommended. The aim of this study was to assess the accuracy of diagnostics of the liver lesion in women included in a study to monitor change of liver adenoma during pregnancy.
Method: This study was performed in patients included in the Pregnancy And Liver adenoma Management (PALM) study cohort, an ongoing multicenter prospective cohort study investigating the incidence of growth during pregnancy in HCA <5cm. In this study, pregnant patients with suspected HCA on imaging underwent extensive follow-up to assess growth of the liver lesion. Definitive diagnosis was established with state of the art contrast enhanced MRI (CE-MRI) with gadolinium based contrast agents, preferably before pregnancy. Patients who did not have a definitive diagnosis underwent CE-MRI after giving birth. Patients who were still pregnant in October 2017 were excluded.
Results: Between October 2011 and October 2017, a total of 57 patients were included in this study. Median age was 34 years (IQR 32–37) and median HCA size 25 mm (IQR 20.8–41.5). Twenty-nine patients did not undergo CE-MRI before pregnancy. Out of these patients, HCA was suspected based on conventional MRI in 19 (66%), ultrasound in 7 (24%), CT in 2 (7%) and contrast-enhance ultrasound in 1 (4%). CE-MRI confirmed HCA diagnosis in 48 patients (84%), 9 patients (16%) turned out to have Focal Nodular Hyperplasia (FNH). Out of the 9 patients who were diagnosed with FNH, 8 were treated in a non-referral hospital and 1 in a tertiary referral centre ($p = 0.018$). None of the patients who eventually were diagnosed with FNH underwent CE-MRI before pregnancy.
Conclusion: This study indicates that a large proportion of childbearing women suspected of having a HCA are misdiagnosed and have FNH. Misdiagnosis may have major impact on patients as FNH does not require intensive follow-up. Therefore, diagnostic work-up with state of the art imaging of a benign liver lesion in younger fertile women should be performed at the moment of first presentation. This approach may prevent unnecessary anxiety and inconvenience if they present with pregnancy in follow up.

FRI-150

Preoperative van Willebrand factor is a predictor for early recurrence and overall survival in patients undergoing liver resection for oncological entities

D. Pereyra[1], R. Baumgartner[1], A. Padickakudy[1], C. Schuetz[1], S. Haegele[1], P. Jonas[2], C. Brostjan[1], T. Grünberger[2], P. Starlinger[1]. [1]*Medical University of Vienna, Department of Surgery, Vienna, Austria;* [2]*Rudolfstiftung Hospital, Department of Surgery, Vienna, Austria*
Email: N1342352@students.meduniwien.ac.at

Background and Aims: We previously reported on the predictive role of van Willebrand factor–antigen (vWF-Ag) for poor post-operative outcome. Briefly, a preoperative cut-off at 182% vWF-Ag was found to be predictive for prolonged hospitalization and intensive care stay, postoperative liver dysfunction and morbidity. However, vWF-Ag was also implicated as an important factor for tumor metastasis. In addition, levels of vWF-Ag were shown to be higher in patients with metastasized colorectal carcinoma in comparison to patients with only localized disease. Interestingly, levels of vWF-Ag were found to be predictive for overall survival (OS) in this cohort. Thus, within the present study we evaluated oncological outcome in patients undergoing liver resection and aimed to assess a possible association to levels of vWF-Ag.
Method: VWF-Ag was evaluated prior to surgery in 96 patients undergoing liver resection for any malignant entity of the liver. Postoperatively, disease free survival (DFS) and OS were assessed.
Results: Applying the cut-off at 182% vWF-Ag, we were able to identify a group of patients with higher incidences of disease recurrence after 6 months (vWF < 182%=8.6% vs vWF ≥ 182%=19%) and 12 months (vWF < 182%=16.4% vs vWF ≥ 182%=41.2%, $p = 0.031$). Using logistic regression, we observed a significantly increased risk for the development of disease recurrence within 12 postoperative months (Odds ratio = 3.578, $p = 0.038$). Of note, multivariable analysis showed independency of our proposed cut-off from other confounding and baseline characteristics including tumor properties. Interestingly, also OS was found to be reduced in patients with preoperative vWF-Ag levels above 182% (1 year: vWF < 182% = 92.7% vs vWF ≥ 182% = 58.3%, $p < 0.001$; 2 years: vWF < 182% = 68.9% vs vWF ≥ 182% = 38.1%, $p = 0.018$; 3 years: vWF < 182%=58.3% vs vWF ≥ 182%=16.7%, $p = 0.004$), which was also shown in Kaplan-Meier analysis, where median OS of patients in vWF < 182% was 1.2 years, while median OS was not reached after 4.4 years in vWF ≥ 182% ($p < 0.001$).
Conclusion: To our knowledge, this investigation represents the first evidence on the predictive potential of vWF-Ag for oncological short-term outcome after liver resection in patients suffering from malignant liver tumors. Interestingly, the higher incidence of early tumor recurrence in patients with preoperative levels of vWF-Ag above 182%, potentially in synergy with a higher incidence of postoperative complications, seem to ultimately translate into decreased OS.

FRI-151

Treatment and prognosis of hepatic epithelioid hemangioendothelioma based on SEER data analysis from 1973 to 2007

S.S. Kim[1], J.Y. Cheong[1], H.J. Cho[1], S.W. Cho[1], O.K. Noh[2]. *[1]Ajou university school of medicine, Gastroenterology, Suwon; [2]Ajou university school of medicine, Radiation oncology, Suwon*
Email: cocorico99@gmail.com

Background and Aims: Malignant hepatic epithelioid hemangioendothelioma (HEH) is a rare malignant tumor of vascular origin with unknown etiology and a variable natural course. This study evaluated the current management and prognosis of HEH status based on SEER data analysis from 1973 to 2007.
Method: Using SEER database, a total 79 patients with HEH were analyzed from 1973 to 2014. Patient survival was calculated using Kaplan-Meier survival curves with log rank test.
Results: The mean age of patients with HEH was 53.0 years, and the male to female ratio was 1:2.6. About one third (40.8%) of patients were diagnosed at regional metastatic stage followed by local (30.3%) and distant metastatic stage (28.9%). Median tumor size was 3.85cm (IQR, 2.50–7.93cm). Thirty four (43.0%) of patients received no treatment or the treatment information was missing. Of the 45 treated patients, the most common treatment was chemotherapy (48.9%) followed by resection (22.2%). About 22.2% of patients were treated with more than one method. The 1-year and 5-year survival rates were 88% and 88%, respectively in resection or liver transplantation group; 72% and 49%, respectively in other treatment or observation group. Resection or liver transplantation based treatment was only independent predictive factor for survival (hazard ratio 0.17, 95% confidence interval 0.04–0.75, P = 0.020).
Conclusion: Resection or liver transplantation is worth considering for treatment of patients with HEH.

FRI-152

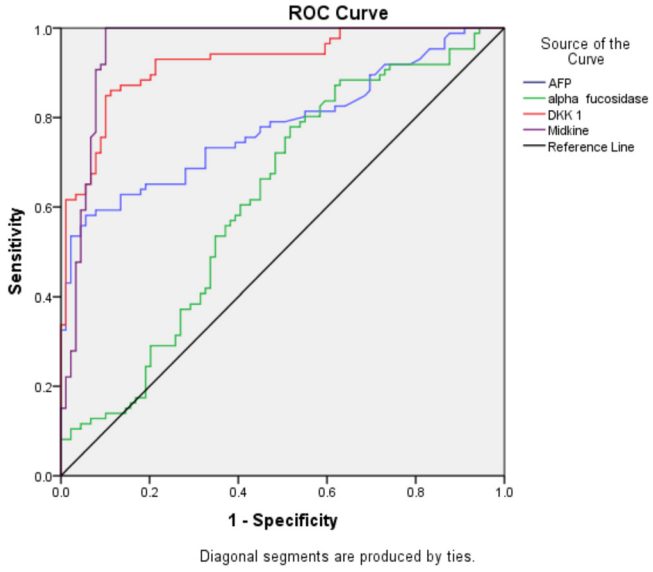
The validity of serum midkine, dickkopf-1 and alpha-L-fucosidase as surrogate biomarkers for the diagnosis of hepatocellular carcinoma

N.A. Habachi[1,2], A. El-Shayeb[2,3], A. Mansour[2,4], M. Zaghloul[2,5]. *[1]Alexandria University, Faculty of Medicine, Physiology department, Alexandria, Egypt; [2]Alexandria University, Faculty of Medicine, Alexandria clinical research center, Alexandria, Egypt; [3]Alexandria University, Faculty of Medicine, Tropical medicine department, Alexandria, Egypt; [4]Alexandria University, Faculty of Medicine, Clinical pathology, Alexandria, Egypt; [5]Kafrelsheikh University, Faculty of Medicine, Hepatology, Gastroenterology and Infectious diseases, Kafr ElSheikh, Egypt*
Email: mariam_zaghloul@med.kfs.edu.eg

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most common cancers worldwide, particularly in Egypt where hepatitis C (HCV) is highly prevelant. Currently, alpha fetoprotein (AFP) level is the gold standard diagnostic tool for detection and monitoring HCC but with low sensitivity. Thus, the identification of alternative or combined serum markers of HCC is highly needed. Therefore, the aim of this work was to verify the value of serum midkine, dickkopf-1(DKK-1) and alpha-L-fucosidase (AFU) in detection of HCC development in cirrhotic HCV patients.
Method: Serum midkine, DKK1and AFU were investigated in 175 patients (89 cirrhotic HCV patients as group I and 86 cirrhotic HCV patients with HCC as group II). Besides, 69 apparently healthy volunteers as controls were enrolled. Serum AFP, midkine, DKK-1and AFU were measured by ELISA.
Results: Serum AFU was significantly higher in group II than in groups I and III (z = 2.75 and 8.99 respectively) (p = 0.006 and 0.00respectively). Also, serum DKK-1 was significantly higher in group II than in groups I and III (z = 9.66 and 10.55 respectively) (p = 0.00 and 0.00respectively). Moreover, serum midkine was significantly higher in group II than in groups I and III (z = 10.38 and 10.58 respectively) (p = 0.00 and 0.002 respectively). Both serum DKK-1 and midkine were significantly higher in advanced HCC patients than in those with early HCC (z = 2.64 and 3.05 respectively) (p = 0.008 and 0.002 respectively).
ROC curve analysis showed that the diagnostic potential of serum midkine and DKK-1to detect HCC occurrence was superior to that of AFP.

	Cut-off value	Specificity	Sensitivity	Positive predictive value	Negative predictive value	Efficacy	AUC
AFP(ng/ml)	40	64%	82%	77%	70.19%	73.14%	0.78
alpha -L-fucosidase (U/l)	0.37	50%	74%	58.33%	65.67%	61.14%	0.62
DKK-1(ng/ml)	2.32	80%	89%	80.2%	88.6%	84%	0.92
Midkine(ng/ml)	5.1	90%	100%	89%	100%	94%	0.95

Using 40ng/ml as a diagnostic cut-off value for AFP, It was diagnostic in 55/86 HCC patients and missed 31patients (36%). While, serum AFU was positive in 24/31 (77.4%), seum DKK-1 was positive in 28/31 (90%) and serum midkine was positive in 30/31 (96.77%). A logistic regression analysis was performed to ascertain the effects of serum midkine, DKK1and AFU on the likehood that cirrhotic HCV patients would have HCC. The logistic regression model was statistically significant x^2=137.45 and p = 0.000. Among the three variables tested, only serum midkine and DKK-1 significantly predicted HCC development in cirrhotic HCV patients (p = 0.00 and 0.017 respectively).



Conclusion: Serum midkine and DKK-1 are reliable and promising diagnostic as well as prognostic biomarkers for HCC in cirrhotic HCV patients.

FRI-153

The impact of platelets on patients with hepatocellular carcinoma

B. Scheiner[1], S. Popp[1], F. Hucke[1], S. Bota[2], M. Peck[2], N. Rohr-Udilova[1], T. Reiberger[1], C. Müller[1], M. Trauner[3], W. Sieghart[1], M. Pinter[1].
[1]Medical University of Vienna, Department of Internal Medicine III, Div. of Gastroenterology and Hepatology, Vienna, Austria, [2]Klinikum Klagenfurth am Wörthersee, Department of Gastroenterology & Hepatology, Endocrinology and Nephrology, Klagenfurth, Austria; [3]Medical University of Vienna, Div. of Gastroenterology and Hepatology, Wien, Austria
Email: bernhard.scheiner@meduniwien.ac.at

Background and Aims: Platelets have been reported to influence tumor biology and may promote metastasis. Traditionally, thrombocytopenia (TCP) – a hallmark of cirrhosis – was associated with hepatocellular carcinoma (HCC) development. However, the impact of platelet count (PLT) on the outcome in patients with established HCC is not well studied. Therefore the aim of this study was to evaluate the effect of platelet count and function on survival in patients with advanced HCC.
Methods: Outcomes of cirrhotic patients with a diagnosis of HCC between 1995–2013 who were not eligible for surgical treatment and did not receive any anti-platelet therapy were retrospectively studied. TCP was defined as a PLT < 150G/L. Mean platelet volume (MPV) is a surrogate marker of platelet production in the bone marrow.
Results: Among 626 patients with unresectable HCC, TCP was present in 378 (60.4%) and was associated with favourable tumor characteristics: lower diameter of the largest nodule (5.6 ± 3.2 vs. 7.6 ± 4.2 cm), less extrahepatic spread (9.5% vs 20.2%, both $p < 0.001$), less macrovascular invasion (21.2% vs 31.0%, $p = 0.005$), lower BCLC stages (63.0% vs 73.4% BCLC C/D; $p = 0.007$) as compared to patients with normal PLT. On univariate analysis, TCP and a larger MPV ≥ 11fL were associated with longer overall survival (OS) (median OS (95%CI), 11.5 (9.3–13.8) vs. 5.5 (3.8–7.1) months; $p = 0.001$; MPV ≥11fL: 11.7 (9.1–14.2) vs. 6.0 (4.4–7.6) months; $p < 0.001$). In multivariate analysis, the combined variable of TCP and larger MPV was independently associated with longer OS (HR (95%CI), 0.79 (0.64–0.97); $p = 0.026$). This effect was most pronounced in advanced tumor stages (BCLC C/D).

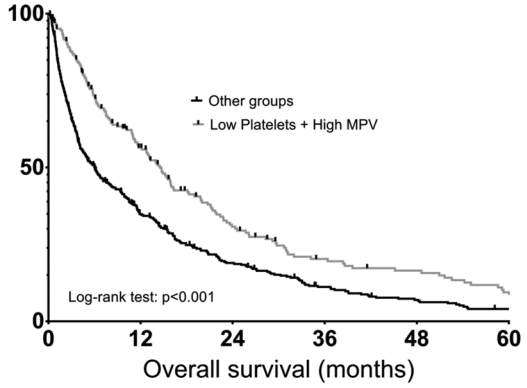


Figure 1: Comparison of overall survival between patients with a platelet count <150 G/L and a MPV ≥11 fL versus patients with other platelet characteristics

Conclusions: Thrombocytopenia and higher MPV are associated with better outcome in patients with advanced HCC. These findings may prompt further clinical research on additive anti-platelet therapy in the management of HCC.

FRI-154

Proton pump inhibitors and risk of hepatocellular carcinoma: a population-based study

W.-Y. Kao[1], C.-W. Su[2], E.C.-H. Tan[3], P.-C. Lee[2], Y.-H. Huang[2], C.-C. Chang[4], M.-C. Hou[2], H.-C. Lin[2], J.-C. Wu[5]. *[1]Taipei Medical University Hospital, Division of Gastroenterology, Department of Medicine, Taipei, Taiwan; [2]Taipei Veterans General Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan; [3]Ministry of Health and Welfare, National Research Institute of Chinese Medicine, Taipei, Taiwan; [4]Taipei Medical University Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan; [5]Taipei Veterans General Hospital, Department of Medical Research, Taiepi, Taiwan*
Email: cwsu2@vghtpe.gov.tw

Background and Aims: The long term use of proton pump inhibitors (PPIs) has been associated with hypergastrinemia. The pro-growth effects of gastrin have been hypothesized to create the potential for increased cancer risk in different organs for all PPIs. The association between PPIs use and hepatocellular carcinoma (HCC) risk are scarce. This study aims to investigate the association between PPIs use and HCC risk in a national population-based cohort.
Method: By analyzing data from the Taiwan National Health Insurance Research Database between year 2003–2013, we identified 35,356 patients with hepatitis B virus (HBV) or hepatitis C virus (HCV) after excluding patients who both diagnosed HBV and HCV, HCC or other cancers within one year before the cohort entry date, follow-up duration less than one year and survival time less than 180 days. PPI use was defined as more than 28 cumulative defined daily doses. After one-to-one propensity score matching by gender, age, follow-up time, comorbidity and medication, 7,517 patients with and without PPIs use, including 11,192 patients with HBV and 3842 patients with HCV, were enrolled for analyses, respectively. The Kaplan-Meier method and Cox proportional hazards models were performed for multivariable and stratified analyses to estimate the association between PPIs use and HCC risk.
Results: Among the HBV cohort, 284 developed HCC during a median follow-up of 51 months. PPIs use was not associated with an increased HCC risk (adjusted hazard ratio, 0.88; 95% confidence interval, 0.70–1.12; $p = 0.306$). Among the HCV cohort, 220 developed HCC during a median follow-up of 50 months. PPIs use was not associated with an increased HCC risk (adjusted hazard ratio, 1.01; 95% confidence interval, 0.77–1.32; $p = 0.942$). We observed no relationship between dose of PPI taken and HCC risk in the HBV and HCV cohorts, respectively. Subgroup analysis also confirmed PPIs use was not associated with an increased HCC risk.
Conclusion: PPIs use in clinical practice was not associated with HCC risk in the present population-based study.

FRI-155

Virologic control increased overall survival after radiofrequency ablation of hepatocellular carcinoma developed on hepatitis related cirrhosis

M. Allaire[1], S. Rekik[2], L. Richard[3], A. Mamana[2], E. Guyot[4], N. Gisèle[2], B. Valerie[2], Véronique Grando[2], M. Ziol[5], P. Nahon[2,6], N. Ganne-Carrié[2,6], O. Sutter[7], E. Audureau[3], O. Seror[7], J. Charles Nault[2,6]. *[1]CHU CAEN, Service d'Hépato-gastroentérologie et nutrition, CAEN, France; [2]CHU Jean Verdier, Service d'Hépatologie, BONDY, France; [3]Université Paris-Est, Unit EA4393, Créteil, France; [4]CHU Jean Verdier, Service de biochimie, Bondy, France; [5]CHU Jean Verdier, Service d'anatomopathologie, BONDY, France; [6]Inserm UMR 1162, PARIS, France; [7]CHU Jean Verdier, Service de radiologie, BONDY, France*
Email: allama5@hotmail.fr

Background and Aims: The effect of virologic suppression on long-term outcomes after radiofrequency ablation (RFA) of hepatocellular carcinoma (HCC) on hepatitis B and C cirrhosis remains to be determined.

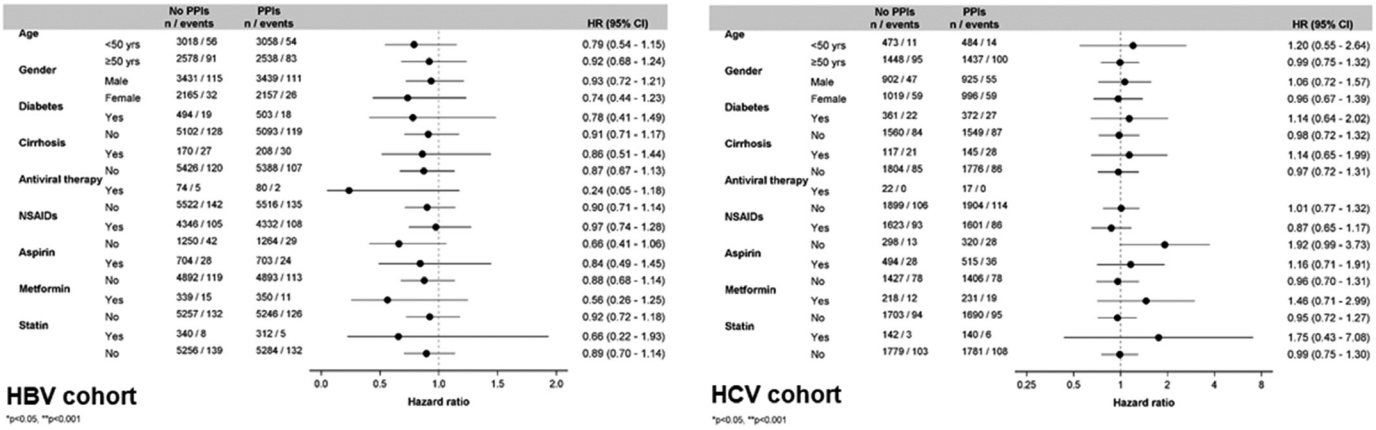

Figure 1: (abstract: FRI-154)

Method: Cirrhotic patients treated by RFA for HCC within Milan criteria and naïve of previous treatment were included. Time-to-events data were estimated by Kaplan-Meier with the log rank test, using Cox uni- and multivariate models and after adjustment using an ITWP propensity score.
Results: 389 patients (Child-Pugh A 86.6%, 473 tumors, median size 25 mm) were included with cirrhosis due to HCV in 166 patients, due to HBV in 43 patients and due to alcohol and/or metabolic syndrome alone in 182 patients. Overall survival (OS) was 79.8%, 42.4% and 16%; overall tumor recurrence 45%, 78% and 88% at 2, 5 and 10 years, respectively. HBV patients have an increased median overall survival (119 vs 51 mths, p = 0.0059) and decreased distant tumor recurrence (52% vs 79% at 5 yrs and 68% vs 88% at 10 yrs, p = 0.02) compared to patients with HCV, alcohol or NASH, even in multivariate analysis (HR = 0.55, p = 0.01 for recurrence and HR = 0.45, p = 0.03 for survival). 39 HBV patients among 43 achieved negative PCR before or after RFA either spontaneously or due to antiviral treatment. Patients with negative PCR obtained before RFA had longer median time to tumor recurrence than patients with a persistent positive at the time of RFA (13 mths vs 90 mths, p = 0.01) with a trend to an increased OS (70 mths for PCR- vs 120 mths for PCR+, p = 0.11).
HCV patients have the same OS or tumor recurrence compared to patients with alcohol or NASH. 54 of 166 HCV patients (33%) obtained sustained virologic response (SVR) before RFA or during follow-up (interferon regimens n = 33, direct antiviral agents (DAA) n = 20, other n = 1). Using time-dependent analysis, no significant difference was noted in tumor recurrence between SVR and non-SVR patients. In contrast, SVR patients had increased median OS (median survival not reached at 120 mths) compared to non-SVR patients (49 mths, p < 0.001), independently of other prognostic factors in multivariate analysis (HR = 0.44, p = 0.026). No increase in tumor recurrence after SVR using DAA was observed before or after adjustment using an ITWP propensity score.
Conclusion: Virologic suppression reduces overall mortality after RFA for HCC developed on HBV and HCV related cirrhosis suggesting that treatment of etiology is crucial for improving survival after efficient percutaneous treatment.

FRI-156

Clinical and biological features according to fibrosis of HBV related HCC in a Western country

M. Allaire[1], E.H. Weam[2], S. Brichler[3], L. Blaise[2], N. Gisèle[2], B. Valerie[2], V. Grando[2], F. Arbadi[2], P. Nahon[2,4], M. Ziol[5], J. Charles Nault[2,4], N. Ganne-Carrié[2,4]. *[1]CHU CAEN, Service d'Hépato-gastroentérologie et nutrition, CAEN, France; [2]CHU Jean Verdier, Service d'Hépatologie, Bondy, France; [3]CH Avicenne, Service de bactériologie et virologie, AVICENNE, France; [4]Inserm UMR 1162, PARIS, France; [5]CHU Jean Verdier, Service d'anatomopathologie, Bondy, France*
Email: allama5@hotmail.fr

Background and Aims: Hepatitis B virus (HBV) is a major cause of hepatocellular carcinoma (HCC). HCC characteristics in HBV patients without cirrhosis have been poorly studied, especially in Western countries. The aim of our study was to compare the characteristics of HCC complicating HBV infection within the presence or absence of underlying liver cirrhosis (LC).
Method: All patients with HBV infection and HCC discussed between 2007 and 2017 in an expert French center multidisciplinary meeting were included retrospectively. The diagnosis of cirrhosis was defined by histological criteria and/or the combination of clinico-biological, ultrasonography and elastometry data. Data were collected at the diagnosis of HCC.
Results: Among the 2,039 HCC discussed, 152 HBV patients were included. Patients (men 93%, mean age 54.8 ± 16 years, BMI > 25 kg/m^2 36%, chronic alcohol intake 40%), from Africa (63%), Europe (18%) and Asia (16%), had HBV viral load >2000IU/l, positive AgHBe and HBsAg titre > 1000IU/l in 39%, 12% and 54% of cases respectively. 53% of them received HBV antiviral treatment at HCC diagnosis.
The majority of HCC (76%) had <3 lesions (median size of the largest lesion 90.1 ± 58.9mm) and 28% were infiltrative. Portal thrombosis and/or metastasis were observed in 18% and 10% of cases respectively; 60% were BCLC B-D. The median AFP level was 13.81 ± 16.37 ng/ml; 55% of patients had AFP level > 100ng/ml and 54% an AFP score > 2.
130 out of 152 patients (86%) had LC (Child-Pugh A/B/C: 77%/18%/5%), among whom 57% had endoscopic signs of portal hypertension. Among the 22 patients without LC (14%), 80% were classified as F0-F1 according to the METAVIR classification.
Compared to patients with LC, non-LC patients had fewer risk factors for HCC (HCV, HDV and NASH) (5 vs 42%, p < 0.001). No difference was observed for alcohol consumption (36 vs 38%, p = 0.91) nor virological parameters. Regarding HCC characteristics, non-LC patients had larger lesions (lesion > 6 cm: 64 vs 30%, p = 0.002) and AFP level > 100ng/ml (68 vs 41%, p = 0.02).

Conclusion: In a French expert center, 14% of HCC complicating HBV infection are diagnosed in a non-cirrhotic liver, are mainly developed in non-fibrotic liver F0–1 (80%), with larger and/or more aggressive tumors (high AFP level) compared with HCC developed in HBV cirrhosis. In addition, non-cirrhotic patients have fewer risk factors for HCC (HCV, HDV and NASH) than patients with cirrhosis suggesting a direct viral mechanism in the process of carcinogenesis.

Email: david.pinato09@imperial.ac.uk

Background and Aims: HCC is a leading cause of mortality in people living with HIV. However, studies evaluating whether HIV can affect the natural history of HCC have been inconsistent due to heterogeneity in geographical origin, stage, and treatment status. In this large, multicenter study we aimed to assess the prognostic impact of HIV status in two large cohorts of patients who did not receive active anticancer treatment.

Method: HIV-infected patients with untreated HCC were retrospectively identified from 47 centers in North and South America, Europe, and Australia and compared to 776 HIV-negative subjects with treatment-naïve HCC recruited from the ITALICA consortium. The primary endpoints were overall survival, with HIV status being tested as prognostic factor in uni- and multivariable survival analyses. Secondary endpoints were presentation and staging of HCC at diagnosis.

Results: Among the 132 HIV-positive patients, 56% had undetectable plasma HIV RNA, and the median CD4+ cell count was 256/mm^3. Compared to the 776 HIV-negative patients, they were younger (53 vs. 67 years, $p < 0.001$), more commonly male (95% vs. 80%, $p < 0.001$), hepatitis C virus positive (74% vs. 54%, $p < 0.001$), but had similar Child-Turcotte-Pugh (CTP) scores at diagnosis (7 vs. 7, $p = 0.37$). They presented more commonly with larger tumours (median diameter, 6.0 vs. 4.0 cm, $p < 0.001$), with uni-nodular lesions (62% vs 51%, $p = 0.012$), had higher AFP level (median 714 vs. 77 ng/dl, <0.001) and a higher proportion of portal venous invasion (36% vs 26%, $p = 0.034$) and distant metastases (28% vs. 8%, $p < 0.001$). HIV-positive patients had lower median survival (3.0 vs. 8.0 months HIV [-], Log rank $p < 0.001$) with estimated 1-year survival rates of 13% vs. 24%. Multivariable Cox regression analysis identified HIV infection as an independent predictor of worse survival (H.R., 1.62; 95% C.I., 1.19–2.19, $p = 0.002$) together with age, male sex, living in the Americas vs. Europe, CTP score, AFP level, portal vein invasion and BCLC stage. Among HIV-positive patients, independent predictors of mortality were CTP score, AFP level, and presence of metastases, but not HIV viral load, CD4+ cells or BCLC stage.

	Median Survival	1-yr	2-yr	5-yr	Estimated Survival
HIV-positive	3.0 months		13%	5%	3%
HIV-negative	8.0 months	34%	17%	4%	

Conclusion: HIV infection is independently associated with adverse survival in patients who did not receive treatment for HCC. Mechanistic studies to investigate the biologic foundations of such survival difference are urgently required.

FRI-158

Factors implicated in the risk of developing hepatocellular carcinoma (HCC) in patients with cirrhosis due to HCV. Implications of Sustained Virological Response (SVR)

A. Castaño, A. Gomez, M. Torner, M. Fraile, C. Álvarez-Navascués, V. Cadahía-Rodrigo, M.L.G. Dieguez, M. Varela, M. Rodríguez. *Hospital Universitario Central de Asturias, Liver Unit. Division of Gastroenterology&Hepatology, Oviedo, Spain*
Email: castaogarciacongresos@gmail.com

Background and Aims: One of the goals of the treatment of HCV is the reduction in the risk of developing HCC. With the new DAAs, high rates of SVR are obtained in patients with cirrhosis. Aim: To analyze the factors involved in the development of HCC in a series of patients with HCV cirrhosis and to determine if SVR reduces the risk.

Method: 699 patients with HCV cirrhosis, Child A/B, included in a surveillance program for the early diagnosis of HCC based on semi-annual AFP and US controls. The patients who reached SVR during the follow-up were considered viremic until that moment, censored at that point and included again as patients with SVR, updating the clinical and demographic variables.

Results: 72% male sex, mean age 53 ± 9 years, 89% Child A, 22% with previous decompensation, 60% with varices and 34.6% with SVR (53 with IFN and 189 with DAAs). During a mean follow-up of 44 ± 50 months, 98 patients developed HCC, with a mean annual incidence of 3.7% and a cumulative probability at 5 and 10 years of 17% and 33% respectively. The probability of developing HCC was significantly lower in patients with SVR than in those without SVR (annual incidence: 1.7% vs. 4.3%, $p = 0.013$). The follow-up of patients with SVR was lower than that of those without SVR (26 ± 32 vs. 54 ± 55 months, $p < 0.001$). In the univariate analysis the following other variables were associated with the risk of developing HCC: male gender ($p = 0.051$), age > 55 years ($p < 0.001$), previous

decompensation (p = 0.001), absence of HIV (p = 0.015), alcohol intake (p = 0.050), Child B (p < 0.001), varices (p < 0.001), platelet count < $115\times10^3/mm^3$ (p < 0.001), AFP > 5ng/ml (p = 0.003) and AST > UNL (p = 0.006). There was no association with GT-3 (p = 0.45), diabetes (p = 0.97), ALT > UNL (p = 0.42) or GGT > UNL (p = 0.55). In the multivariate analysis, the variables that were associated independently were: male sex (OR:2.58, 95%CI:1.55–4.30; p < 0,001), age > 55 (OR:3.04, 95%CI:1.93–4.77; p < 0,001), previous decompensation (OR:1.68, 95%CI:1.00–2.79; p = 0.046), Child B (OR:2.26, 95% CI:1.25–4.09, p = 0.007), varices (OR:2.01, 95%CI:1.19–3.38, p = 0.009), platelet <$115\times10^3/mm^3$ (OR:1.60, 95% CI:1.01–2.55, p = 0.044) and AFP > 5 ng/ml (OR:1.75, 95%CI:1, 11–2,75; p = 0.016).

Conclusion: Classical factors, sex, age, advanced disease and AFP levels continue to be the main conditioning factors in the development of HCC in patients with HCV cirrhosis. In this series of patients, SVR, achieved mainly with DAAs, has not been associated independently with a decrease in HCC risk in the short-term.

FRI-159

Increased intestinal permeability and inflammation are associated with hepatocellular carcinoma in patients with NAFLD-related liver cirrhosis

F. Ponziani[1], S. Bhoori[2], V. Petito[1], F.P. Sterbini[3], D. Morelli[4], T.D. Michele[3], M. Sanguinetti[5], A. Gasbarrini[1], V. Mazzaferro[4], M. Pompili[6]. *[1]Policlinico Agostino Gemelli, Internal Medicine, Gastroenterology, Hepatology, Roma, Italy; [2]Istituto Nazionale Tumori, Hepatobiliary and Liver Transplant Surgery, Milano, Italy; [3]Policlinico Agostino Gemelli, Microbiology, Roma; [4]Istituto Nazionale Tumori, Hepatobiliary and Liver Transplant Surgery, Milano; [5]Policlinico Agostino Gemelli, Microbiology, Roma, Italy; [6]Policlinico Agostino Gemelli, Biochemistry, Roma*

Email: francesca.ponziani@yahoo.it

Background and Aims: Increased intestinal permeability (IP) is common in patients with cirrhosis. Leaky gut is associated with the translocation of microbial products and fragments and this process is involved in the pathogenesis of NAFLD.

The aim of this study is to investigate if intestinal permeability and inflammation are associated with HCC in NAFLD patients.

Method: 21 Cirrhotic patients with NAFLD and HCC, 33 liver cirrhotic patients (20 with NAFLD and 13 with chronic hepatitis C) comparable for age, liver function and portal hypertension and 20 age-matched healthy controls were included in the study. Quantification of zonulin-1 (ZO1) and lipopolysaccharide (LPS), as indices of IP, and fecal calprotectin as marker of intestinal inflammation were performed using ELISA and the Liaison® analyzer.

Subjects affected by gastrointestinal or systemic diseases potentially affecting IP and those with documented alcohol intake during the last year or who had taken antibiotics during the last 6 months were excluded from the study.

Results: IP was increased in patients with liver cirrhosis who had higher serum levels of ZO1 and LPS compared to controls (ZO1: 11.33 (1.93) vs. 7.05 IQR 2.41 ng/ml p <0.0001; LPS 13.17 IQR 13.01 vs 2.52 IQR 2.14 EU/ml p = 0.012; Figure 1). There was no significant difference between cirrhotic patients with HCC and those without HCC (ZO1: 11.35 IQR 1.16 vs 11.23 IQR 53.93 ng/ml p = 0.993; LPS 12.82 IQR 12.82 IQR 12.2 p = 0.974 EU/ml Figure 1).

Fecal calprotectin levels were increased in cirrhotic patients with and without HCC compared to controls (75.65 IQR 335.25 vs 10.35 IQR 9.2 mcg/g p < 0.0001 Figure 1). Within the cirrhosis group, patients with HCC showed higher calprotectin levels than patients without HCC (457 IQR 603 vs 59.85 IQR 185 mcg/g, p < 0.005 Figure 1).

Conclusion: IP is increased in cirrhotic patients with and without HCC, but the latter also show higher fecal calprotectin. This could be related to a higher intestinal inflammatory status, which may contribute to exacerbate the inflammatory liver injury contributing to the development of neoplastic lesions in cirrhotic NAFLD patients.

Background and Aims: Hepatocellular carcinoma (HCC) is a major contributor to disease burden globally with the majority of cases occurring in resource-limited settings. The current lack of an accurate method for early diagnosis is a major factor limiting treatment outcome in countries like Nigeria, where tumours present late. This work draws upon British populations presenting earlier and Nigerian populations with more advanced disease (with HCC arising from different aetiologies). We aimed to identify discriminatory signals that could be potential universal diagnostic biomarkers using metabolic profiling of both serum and urine.

Methods: Urine and serum samples from European and African populations were collected (United Kingdom: n = 252, 128 HCC, 44 cirrhosis, 80 healthy control; Nigeria: n = 496, 140 HCC, 97 cirrhosis, 133 non-cirrhotic hepatitis B, 126 healthy controls). Un-targeted metabolic profiling using proton nuclear magnetic resonance (NMR) and liquid chromatography-mass spectrometry (LC-MS) were performed. Data were analysed by multivariate statistical analyses.

Results: Unsupervised principal component analysis of both urine and serum data of all datasets show observable differential clustering of HCC and cirrhosis samples from hepatitis B and healthy controls (NMR data - Figure 1). Predictive models of the supervised partial least squares analysis could be built, comparing HCC against non-cirrhotic hepatitis B and healthy controls ($R2 > 0.5$, $Q2 > 0.4$, $p < 0.001$), and also in comparisons to cirrhosis ($R2 > 0.5$, $Q2 > 0.1$, $p < 0.01$), respectively for each dataset. Identified discriminatory signals include metabolites related to gut microbial metabolites (hippurate and p-cresol sulphate) in urine, choline metabolism (choline and betaine) and intermediates of central energy metabolism (succinate and lactate) in serum.

Conclusion: Results of urine data validates previously published results and this is the first comprehensive profiling of serum samples of studies of similar kind. Together, these comprehensively characterised cohorts provide in-depth insights into the metabolic phenotypes of HCC patients, which will inform a shortlist of discriminatory compounds for further investigations for their utility as potential diagnostic biomarkers that are universally applicable irrespective of underlying aetiology, ethnicity and environmental exposure.

Presence of steatosis does not increase the risk of Hepatocellular Carcinoma in patients with Chronic Hepatitis B over long follow-up

C.T. Lim[1], B.B.G. Goh[1], K.H.T. Lim[2], W.Q. Leow[2], R. Azhar[2], W.K. Wan[2], R. Kumar[1]. [1]*Singapore General Hospital, Gastroenterology and Hepatology;* [2]*Singapore General Hospital, Pathology, Singapore*
Email: thomson.lim@mohh.com.sg

Background and Aims: Chronic Hepatitis B (CHB) remains an important disease in many parts of the world and with the rising prevalence of metabolic syndrome worldwide; patients with concomitant CHB and hepatic steatosis are increasingly encountered. However the characteristics, interactions and long term follow-up among these patients remain to be elucidated.
The aim of this study is to assess the liver histology, clinical characteristics and progression to hepatocellular carcinoma (HCC) in CHB patients with or without concomitant hepatic steatosis who had liver biopsy performed.
Method: 292 CHB patients with liver biopsy performed between the years 2000–2014 were identified from hospital records. Liver biopsy histology was reviewed again by trained pathologists for presence of >5% steatosis and non-alcoholic steatohepatitis (NASH). The clinical characteristics were analysed and stratified by presence (Group 1) or absence (Group 2) of hepatic steatosis. Patients were prospectively followed-up for progression of development of HCC till 01/06/2017. HCC was confirmed based on contrast enhanced imaging.
Results: Hepatic steatosis was seen in 64% (100/182) of patients with hepatitis B on biopsy. At the time of biopsy, the mean age was 45.3 ± 11.9 years with 72.6% males and predominantly of Chinese ethnicity (94.9%).
On mean follow-up of 10.6 ± 3.8 years, HCC was seen in 26 patients with follow-up of up to 17 years-patient years follow-up. Hepatic steatosis was not a significant risk factor for HCC on cox-regression analysis (p = 0.555), while advanced age and presence of cirrhosis were significant for HCC development (p value = 0.016 and 0.04 respectively). There is also no significant association between types of CHB treatment and HCC development.
In a subgroup analysis of even low HBV DNA defined as HBVDNA < 7 log copies/ml, presence of hepatic steatosis was not associated with increased risk of HCC as well. (p value = 0.471)
Conclusion: In patients with Hepatitis B presence of concomitant steatosis does not increase the risk of hepatocellular cancer development.

FRI-162

Sarcopenia is not a predictor of survival or sorafenib toxicity in advanced hepatocellular carcinoma: A Dutch multicenter study

T. Labeur[1,2], J. van Vugt[3], D.T. Cate[3], B. Takkenberg[1], B.G. Koerkamp[3], R.D. Man[4], O. van Delden[5], J. Ijzermans[3], F. Eskens[6], H.-J. Klümpen[2]. [1]*Academic Medical Center, Gastroenterology & Hepatology, Amsterdam, Netherlands;* [2]*Academic Medical Center, Medical Oncology, Amsterdam, Netherlands;* [3]*Erasmus University Medical Center, Surgery, Rotterdam, Netherlands;* [4]*Erasmus University Medical Center, Gastroenterology & Hepatology, Rotterdam;* [5]*Academic Medical Center, Radiology, Amsterdam, Netherlands;* [6]*Erasmus University Medical Center, Medical Oncology, Rotterdam, Netherlands*
Email: t.a.labeur@amc.uva.nl

Background and Aims: Sorafenib is standard of care for patients with advanced stage hepatocellular carcinoma (HCC), but there is no baseline biomarker to predict treatment outcomes. In several other cancer types, sarcopenia is associated with impaired survival and increased treatment toxicity, but such studies in European patients with advanced stage HCC are lacking.
This study aims to assess the association between sarcopenia and sorafenib outcomes and toxicity in a large European cohort of patients with advanced stage HCC.
Method: A retrospective analysis was performed in a Dutch cohort of 323 patients with HCC treated with sorafenib at two tertiary referral centers between 2007 and 2016. Skeletal muscle mass and density were measured at the third lumbar vertebra level (L3) using computed tomography (≤3 months prior to start) and correlated with overall survival (OS), time-to-progression (TTP), response rate and toxicity.
Results: A total of 273 patients (85%) were included, of which 142 (52%) had sarcopenia and 111 (41%) had a low muscle density. Sarcopenic patients were older (67 vs 62 years, p < 0.01) and slightly more often Child Pugh B (15% vs 8%), although this was not statistically significant (p = 0.06). Skeletal muscle mass showed an independent association with TTP, but not with OS, response rate or toxicity. Sarcopenic patients had more grade 3/4 liver toxicity (31% vs 23%) during treatment, but this was not statistically significant (p = 0.13). In Child-Pugh A patients, there were no significant associations with OS, TTP or sorafenib toxicity.

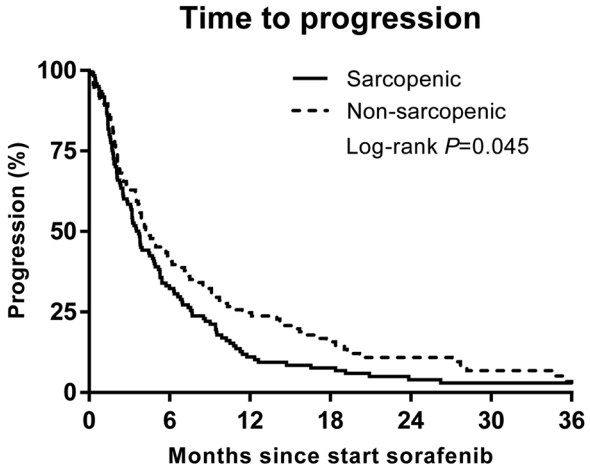

Figure 1: TTP in patients with and without sarcopenia (3.7 vs 4.4 months, p = 0.045).

Conclusion: In Dutch patients receiving sorafenib for advanced stage HCC, sarcopenia is associated with TTP, but is not an independent predictor of survival, response rate or toxicity.

FRI-163

The direct comparison between 7th AJCC staging system and 8th AJCC staging system for prediction of survival with Korean multicenter HCC patients

Y.-S. Lee[1], J.H. Kim[1], C.U. Lee[2], S.J. Suh[3], Y.K. Jung[2], Y.S. Seo[4], H.J. Yim[4], J.E. Yeon[4], K.S. Byun[4]. [1]*Korea University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Korea University College of Medicine, Department of Internal Medicine, Ansan;* [3]*Korea University Ansan Hospital, Department of Internal Medicine, Ansan-si, Gyeonggi-do, Korea, Rep. of South;* [4]*Korea University College of Medicine, Department of Internal Medicine, Seoul*
Email: kjhhepar@naver.com

Background and Aims: AJCC staging is the most commonly used staging system in most solid tumors, and recent AASLD hepatocellular carcinoma (HCC) guideline also endorsed this AJCC staging system based on status of tumor, node, and metastasis. Recently, 8th edition of AJCC staging system was released in December 2016. This study aimed to compare prediction of survival in HCC patients between 7th AJCC staging system and 8th AJCC staging system.

Method: From 2004 to 2013, 2211 newly diagnosed HCC patients were consecutively enrolled in three Korea University medical centers and the medical records of patients were retrospectively reviewed. Each patients were classified following both of 7th AJCC staging system and 8th AJCC staging system.
Results: Chronic hepatitis B (1523, 68.9%) was main attributable factor in development of HCC, followed by chronic hepatitis C (256, 11.6%) and alcohol consumption (241, 10.9%). 1514 patients (68.5%) died during study period and median overall survival (OS) was 24.7 months. According to 7th AJCC staging system, 894 (40.4%) patients were included into stage I; 459 patients (20.8%) into stage II; 180 patients (8.1%) into stage IIIa; 354 patients (16.0%) into stage IIIb; 3 patients (0.1%) into stage IIIc; 119 patients (5.4%) into stage IVa; and 202 patients (9.1%) into stage IVb. According to 8th AJCC staging system, 400 (18.1%) patients were categorized into stage IA; 498 patients (22.5%) into stage IB; 442 patients (20.2%) into stage II; 193 patients (8.7%) into stage IIIa; 357 patients (16.1%) into stage IIIb; 119 patients (5.4%) into stage IVa; and 202 patients (9.1%) into stage IVb. Both 7th staging system and 8th staging system show distinct survival outcomes according to each stage. Although 7th AJCC staging system significantly well predicted 1 year of survival than 8th AJCC staging system (AUROC; 0.796 vs 0.784, p = 0.013), AUROCs of 3 year and 5 year were similar in 7th and 8th AJCC staging system (0.754 vs 0.752 in 3 year, p = 0.601; 0.744 vs 0.742 in 5 year, p = 0.643).
Conclusion: Both 7th and 8th AJCC staging system show distinct survival outcome according to each stage. Moreover, both 7th and 8th AJCC staging system are similar in prediction of survival outcomes compared to BCLC staging system.

FRI-164

Serum and urine extracellular vesicles contain mRNA biomarkers for primary sclerosing cholangitis (PSC) and cholangiocarcinoma (CCA)

Email: jesus.banales@biodonostia.org

Background and Aims: Cholangiocarcinoma (CCA) represents a heterogeneous group of biliary cancers with poor prognosis. The etiology of the majority of CCAs is unknown, but conditions such as primary sclerosing cholangitis (PSC) are risk factors. Simultaneously, PSC patients frequently (80%) present inflammatory bowel disease, mainly ulcerative colitis (UC). To date, there are not available sensitive and specific non-invasive biomarkers for the early diagnosis and monitoring of CCA, PSC and UC. The aim of this study was to investigate the potential value of serum and urine extracellular vesicles (EVs) as carriers of mRNA biomarkers for CCA, PSC and UC.
Method: EVs were isolated from serum and urine of CCA (n = 13 and 28), PSC (n = 8 and 7), UC (n = 8 and 12) and healthy (n = 9 and 5) individuals, using ultracentrifugation/filtration methods. The content of EVs was determined by mRNA microarray-based transcriptomics.
Results: Both serum and urine EVs showed round morphology (by transmission electron microscopy), similar size (~180 nm diameter by nanoparticle tracking analysis) and markers (CD9, CD63 and CD81 by immunoblotting) consistent with exosomes and small-size microvesicles. The mRNA profiles of serum EVs revealed 1,091 mRNA transcripts differentially expressed ($p < 0.01$) in CCA *vs.* controls, 100 in PSC *vs.* controls, 87 in UC *vs.* controls, 1,522 in CCA *vs.* PSC, and 107 in PSC *vs.* UC. Moreover, the mRNA profiles of urine EVs revealed 963 mRNA transcripts differentially expressed ($p < 0.01$) in CCA *vs.* controls, 334 in PSC *vs.* controls, 386 in UC *vs.* controls, 263 in CCA *vs.* PSC, and 98 in PSC *vs.* UC. In serum EVs, *RCN1* and *PON1* transcripts had area under the ROC curve (AUC) values of 0.974 and 0.959 in CCA *vs.* controls, respectively, *MTRF1L* (AUC = 0.947) and *XKR6* (AUC = 0.936) in PSC *vs.* controls, *LOC441376* (AUC = 0.937) and *P4HA1* (AUC = 0.927) in UC *vs.* controls, *CMIP* (AUC = 1.000) and *CCNB1IP1* (AUC = 1.000) in CCA *vs.* PSC, and *SNORA11B* (AUC = 0.941) and *GRM3* (AUC = 0.929) in PSC *vs.* UC. In urine EVs, *ERRFI1* and *SF4* transcripts had AUC values of 0.986 and 0.964 in CCA *vs.* controls, respectively, *FASN* (AUC = 1.000) and *KHNYN* (AUC = 1.000) in PSC *vs.* controls, *SFRS17A* (AUC = 1.000) and *PTPRT* (AUC = 0.983) in UC *vs* control, *LDHA* (AUC = 0.911) and *MT1F* (AUC = 0.893) in CCA *vs.* PSC, and *ROGDI* (AUC = 0.976) and *AOF2* (AUC = 0.964) in PSC *vs.* UC.
Conclusion: Our results underscore the value of serum and urinary EV transcriptomic (mRNA) signatures as diagnostic tools for CCA, PSC and UC.

FRI-165

Age and not comorbidity determines access to liver transplantation of patient with hepatocellular carcinoma

A. Lué[1], S. Lorente[1], F.J. Aranguren[1], L. Cortes Garcia[1], A. García-Gil[2], T. Serrano[1]. *[1]Hospital Clínico Universitario Lozano Blesa, Gastroenterology and Liver Unit; [2]Hospital Clínico Universitario Lozano Blesa, Hepatobiliopancreatic Surgery Unit*
Email: alberto.lue@hotmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the second most frequent cause of cancer mortality worldwide and the leading cause of mortality in patients with liver cirrhosis (LC). Liver transplantation (LT) is the treatment that increases survival the most in the early stages of this cancer. However, due to the shortage of donors, not all patients can access to LT. Our objective is to evaluate the applicability of this treatment and the factors related to the access to LT with main focus on comorbidity.
Method: Analysis was performed from a prospective registry of patients with HCC attended in our center. Cirrhotic patients with HCC who met Milan criteria were selected. The patients were divided into 3 groups: not evaluated for LT (A); evaluated for LT but not transplanted (B) and transplanted (C). Clinical and analytical variables, related to the tumor and comorbidity were evaluated, Charlson Comorbidity Index (CCI) was performed.
Results: Between February 2008 and February 2017, 338 patients were included in the registry and 150 (44%) of them met the Milan criteria. The 80% were males, with a median age of 62 (IQR: 57–69) years. In almost half of the patients liver transplantation was not considered (group A, n = 72) and therefore only 52% of these patients were evaluated for LT although almost a third of them could not be transplanted (group B, n = 24). Finally, only 36% of the patients who fulfilled the Milan criteria underwent to LT (group C, n = 54). When the different variables were analyzed in the three groups of patients, there were significant differences between the three

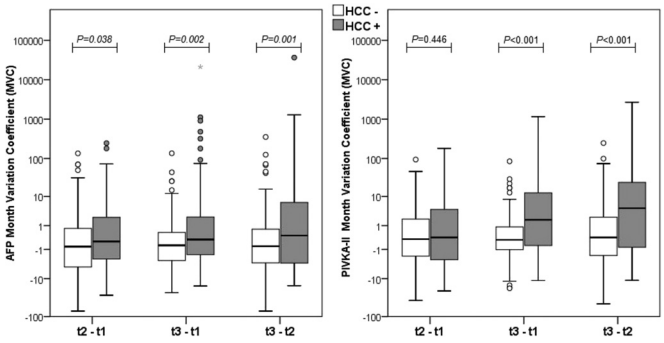
groups in age (p < 0.001), CCI (p = 0.006), creatinine levels (p = 0.037) and bilirubin levels (p = 0.002). No significant differences were observed between the groups in the etiology of LC, diagnosis on screening program, tumor size, number of nodules, Child's stage or alpha-fetoprotein levels. In the multivariate analysis, only age was associated with a lower probability of receiving LT (OR 0.942, 95% CI: 0.908–0.978 per year of age) and no other comorbidity factors.
Conclusion: Only one third of patients with hepatocellular carcinoma who meet Milan criteria can benefit from liver transplantation. Age and not comorbidity is the only factor that significantly determines access to LT.

FRI-166

Clinical significance of time related fluctuations of AFP and PIVKA-II serum levels in single patients with cirrhosis undergoing surveillance for hepatocellular carcinoma

G. Ricco[1], C. Cosma[2], G. Bedogni[3], A. Biasiolo[4], M. Guarino[5], P. Pontisso[4], F. Morisco[5], F. Oliveri[1], D. Cavallone[1], F. Bonino[3,6,7], M. Plebani[2], M.R. Brunetto[1,8]. *[1]University Hospital of Pisa, Hepatology Unit and Laboratory of Molecular Genetics and Pathology of Hepatitis Viruses, Reference Center of the Tuscany Region for Chronic Liver Disease and Cancer, Pisa, Italy; [2]University Hospital of Padua, Department of Laboratory Medicine, Padua, Italy; [3]Italian Liver Foundation (FIF), Trieste, Italy; [4]University of Padua, Department of Internal Medicine, Padua, Italy; [5]University of Naples "Federico II", Department of Clinical Medicine and Surgery, Gastroenterology Unit, Napoli, Italy; [6]National Research Council, Institute of Biostructure and Bioimaging, Napoli, Italy; [7]University of Pittsburgh Medical Center, Institute for Health, Chianciano Terme, Italy; [8]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy*
Email: maurizia.brunetto@unipi.it

Background and Aims: The clinically meaningful variations of circulating HCC biomarkers in the single patient are uncertain. We studied the dynamics of AFP and PIVKA-II in 2–3 consecutive sera obtained at random time points in cirrhotic patients with and without HCC.
Method: AFP and PIVKA-II were measured in 1163 sera of 418 cirrhotics (31.1% HBV, 58.6% HCV, 10.3% Non-viral) undergoing ultrasound HCC surveillance at 3 centres: 124 developed HCC (29 with 1 and 95 with 2 sera before the serum at diagnosis), 294 remained HCC free for at least 12 months after the last specimen (2 sera in 62 and 3 sera in 232). HCC diagnosis was made according to EASL guidelines. Tests were performed in a single laboratory using automated chemiluminescent-enzyme-immunoassays (Fujirebio, Tokyo, Japan): AFP and PIVKA-II dynamic ranges 0.8–22,451 ng/ml and 1.37–75,000 mAU/ml and normality upper limits 7.4 ng/ml and 48 mAU/ml, respectively. Time between time-points (t1, t2, t3) was expressed in months. AFP/PIVKA-II time-related changes were analysed by calculating the month-related variation coefficients ($MVC=\{[(xt_{last}-xt_{first})/xt_{first}]\times 100\}/(xt_{last}-xt_{first})$) and using a random-effect generalized least squares (RE-GLS) regression model.
Results: In figure 1 we report the MVC between groups. Multiple time-related ROC curve analysis of MVC shows 6 months (± 1.5) as best time frame for both biomarkers. Using 10% MVC as cut-off the Sensitivity/Specificity for HCC diagnosis were 17.8/96.3% and 27.7/93.8% for AFP and PIVKA-II, respectively. Log_{10}AFP time-related (1–6 months) changes estimated by RE-GLS ranged between 1.06–1.19 (95%CI 0.72–1.63) and 0.87–1.16 (95% CI 0.92–1.45) for HCC+ and HCC-, whereas the values of log_{10}PIVKA-II were 1.07–1.18 (95%CI 0.75–1.39) and 1.01–1.05 (95%CI 0.93–1.16), respectively. In HCC- patients AFP was influenced by disease activity and showed more variability than PIVKA-II. The gap of median MVC between HCC+ and HCC- was up to six-fold higher for PIVKA-II than AFP.



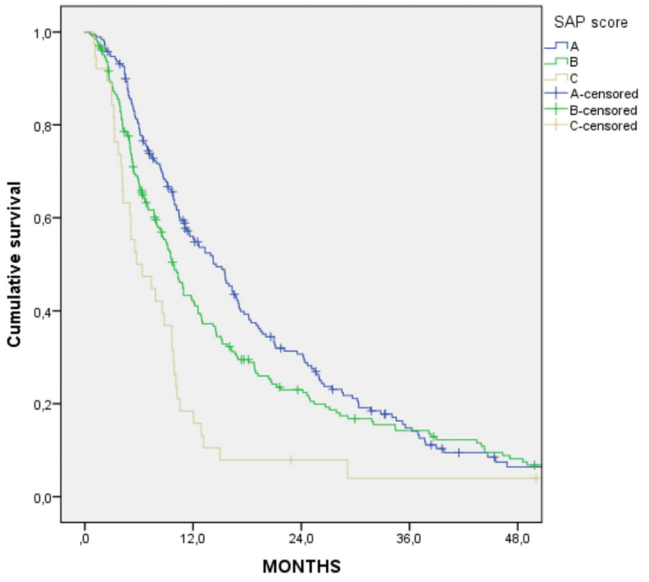
Conclusion: The month-related variation coefficient (MVC) of AFP and PIVKA-II appears a reliable measure for individualized HCC surveillance with an optimal time frame [6 (± 1.5) months] coincident with the suggested timing of ultrasound surveillance. A 10% MVC cut-off for both biomarkers qualifies as a candidate diagnostic tool worth to be tested in prospective studies.

FRI-167

Prognostic scores for sorafenib-treated hepatocellular carcinoma patients: a validation study of the HAP and SAP scores

F. Tovoli[1], G.G.D. Costanzo[2], G. Magini[3], F. Trevisani[1], T. Pressiani[4], R. Sacco[5], S. Marinelli[1], R. Tortora[2], L. Bucci[1], M.G. Lucà[6], L. Bolondi[1], A. Granito[1]. *[1]University of Bologna, Department of Medical and Surgical Sciences, Italy; [2]Cardarelli Hospital, Department of Transplantation – Liver Unit, Italy; [3]Papa Giovanni XXIII Hospital, Gastroenterology and Transplant Hepatology, Italy; [4]Humanitas Clinical and Research Center, Medical Oncology and Hematology Unit, Italy; [5]Pisa University Hospital, Department of Gastroenterology; [6]Papa Giovanni XXIII Hospital, Gastroenterology and Transplant Hepatology*
Email: francesco.tovoli2@unibo.it

Background and Aims: Prognostic classifications for patients treated with sorafenib for hepatocellular carcinoma (HCC) are lacking. Very recently, Edeline and collaborators reported that both the hepatoma arterial embolisation prognostic score (HAP, previously used as a prognositic indicator for patients undergoing trans-arterial che-moembolizatio) and the authors' proposed Sorafenib Advanced HCC Prognosis (SAP) score were able to provide discriminant prognostic information. Aim of our study was to validate these findings in a large cohort of sorafenib-treated patients in Italy.
Method: We analyzed a large retrospective-prospective database gathering the clinical data of 432 patients from 6 Italian centres, who were prescribed with sorafenib between 2008 (date of licence in Italy) and 2016. The HAP score was calculated according to the following criteria: largest tumor nodule > 7 cm (1 point); bilirubin >1 mg/dl (1 point); albumin <36 g/l (1 point); alfa-fetoprotein > 400 mg/dl (1 point). It was subsequently categorized as follows: HAP A (0 points); HAP B (1 point); HAP C (2 points); HAP D (>2 points). The SAP score calculation was very similar, but included a further criterion (PS > 0 = 1 point). This score was categorized as proposed by Edeline et al: SAP A (0–1 points); SAP B (2–3 points); SAP C (>3 points).
Results: The SAP score was significantly associated with the overall survival (OS), with a median OS of 14.6 months for SAP A, 9.8 months for SAP B and 5.7 months for SAP C (p < 0.001, log-rank test). Also the HAP score provided prognostic information, however HAP B and HAP C patients showed similar OS (median OS: HAP A 16.7 months, HAP B 10.9 months, HAP C 10.5 months, HAP D 5.9 months).
Conclusion: Our results validate both the SAP and the HAP score as prognostic indicators for HCC patients undergoing treatement with sorafenib. Differently from the previously published paper on this topic, however, our results suggest that the SAP may be a better prognosticator compared with the HAP score. The use of these simple scores may facilitate stratification in trials and inform clinical decision making.



FRI-168

CD44 rs187115 gene polymorphism in cirrhotic hepatitis C patients with hepatocellular carcinoma

A. El-Shayeb[1], N. Abdeen[1], N. Lewis[2], A. A. Khalifa[1]. *[1]Faculty of Medicine, Alexandria University, Tropical Medicine, Alexandria, Egypt; [2]Faculty of Medicine, Alexandria University, Clinical Pathology, Alexandria, Egypt*
Email: nermodean@gmail.com

Background and Aims: The burden of hepatocellular carcinoma (HCC) has been increasing in Egypt over the past 10 years owing to the high prevalence of HCV. It has been strongly suggested that stepwise, irreversible accumulation of genetic alterations is the responsible driving force to the development and progression of malignancies. CD44 is an extracellular matrix-cell adhesion molecule that regulates tumor cell differentiation, epithelial-mesenchymal transition, p53 stress response, invasion, metastatic deposits, and chemoresistance. The correlation between CD44 rs187115 SNP expression and HCC is not thoroughly established.And hence, we aimed to study the possible contribution of CD44 rs187115 SNP polymorphism regarding HCC development, tumour behaviour and aggressiveness.
Methods: This study was carried out on 120 Egyptian individuals classified into **four groups:**

- **Group I** Twenty patients having metastatic HCC
- **Group II** Twenty patients having non metastatic HCC
- **Group III** Forty patients with HCV related liver cirrhosis
- **Group IV** Forty healthy subjects as control

CD44 rs187115 SNP(C/T) was detected by allelic discrimination using Real-Time PCR after DNA Extraction.
Results: CC/CT genotypes were the most frequent genotypes present in the metastatic HCC group in comparison to the non metastatic HCC, cirrhotic and control groups ($p < 0.001$, 0.006 and 0.033 respectively), HCC patients possessing CT + CC genotypes were more likely to have an aggressive malignancy and thus poor prognosis compared to Wild type (TT) carriers. Significant positive correlation was noted between the presence of CT/CC genotypes and tumor size, multicentricity, Infiltrative behaviour, portal vein thrombosis, portahepatis lymph node metastases and distant metastases. ($p = 0.038$, 0.025, 0.028, 0.010 and 0.001 respectively), Presence of C allele was found to be associated with an increase of 6 folds of the risk of developing portal vein thrombosis and 8 folds of the risk of developing metastases with $p = 0.028$ and 0.010 respectively.
Conclusion: CD44 SNPrs187115 may serve as a novel prognostic biomarker for HCC that identifies patients who are at a risk of faster tumor progression and metastasis.

FRI-169

Hepatocellular carcinoma as second primary malignancy: exposing an overlooked presentation of liver cancer

D. Dandachi[1,2], M. Hassan[3], A. Kaseb[4], G. Angelidakis[1], H. Torres[1,4]. *[1]The University of Texas MD Anderson Cancer Center, Department of Infectious Diseases, Houston, United States; [2]Baylor College of Medicine, Department of Infectious Diseases, Houston, United States; [3]The University of Texas MD Anderson Cancer Center, Department of Epidemiology, Houston, United States; [4]The University of Texas MD Anderson Cancer Center, Department of Gastroenterology, Hepatology, and Nutrition, Houston, United States*
Email: dima.dandachi@bcm.edu

Background and Aims: Hepatitis C (HCV) infection is the leading cause of hepatocellular carcinoma (HCC) in the United States. Antiviral therapy in patients with HCV infection reduces the risk of HCC development by 71 to 75%. HCV-infected patients with different primary cancers are also at risk for HCC development as a second primary malignancy (HCC-SPM). Limited information is available on the characteristics of HCC-SPM. Herein, we determine the prevalence and clinical features of HCV-associated HCC-SPM when compared to primary HCC (HCC-P).
Method: Patients with HCV-associated HCC seen at MD Anderson Cancer Center (2011–2017) were enrolled in a prospective observational study. At enrollment, patients completed a questionnaire on medical history and HCC risk factors. Information on demographics, co-morbidities, HCV treatment, tumor characteristics, virologic and oncologic outcomes were extracted from the medical records. Patients with multiple cancers diagnosed simultaneously or with Hepatitis B, or HIV coinfections were excluded.
Results: Of the 213 enrolled, 193 were included in the final analysis: most patients were ≥ 50 years old (97%); white (64%); and men (78%). Twenty-eight (14%) patients developed HCC-SPMs. The majority of underlying primary cancers were solids tumors (86%), predominantly skin and breast cancers. In 20 (71%) patients, the diagnosis of HCC-SPM was made incidentally. When HCC-SPM and HCC-P were compared, there were no differences between the 2 groups in smoking, alcohol intake, body mass index, diabetes mellitus, and pathology. However, HCC-SPM had better liver function tests and tumor characteristics. The majority of patients with HCC-SPM (76%) and HCC-P (71%) had chronic viremia due to lack of diagnosis, lack of treatment, or prior unsuccessful treatment. Among all patients, those treated with direct-acting antivirals had significantly higher sustained virologic response compared to interferon-based therapy (80% vs.45% $p < 0.01$). Among the 28 patients with HCC-SPM, 22 (79%) had their primary cancer in remission at time of HCC diagnosis; 19 of those had outcome data, 6 (32%) of whom died.
Conclusion: Cancer patients with any type of malignancies must be screened for HCV as HCC-SPM can develop in 14% of infected patients. Regular cancer surveillance on these patients could favor a better outcome, but early HCV treatment to prevent the development of HCC-SPM should decrease the mortality rate observed in one-third of such patients.

FRI-170

Adherence to enhanced post-treatment surveillance is associated with increased detection of early stage recurrence after radiofrequency ablation but not surgical management of hepatocellular carcinoma

Y. Chan[1], S. Maclennan[1], L. Douglas[1], S. Congly[1], C. Coffin[1], E. Dixon[2], J. Wong[3], K. Burak[1]. [1]*University of Calgary Liver Unit, Division of Gastroenterology and Hepatology;* [2]*University of Calgary, Department of Surgery;* [3]*Foothill Medical Center, Department of Diagnostic Imaging*
Email: yingenics@gmail.com

Background and Aims: Little is known about the optimal surveillance schedule after curative intent treatment of hepatocellular carcinoma (HCC). Current guidelines advocate cross-sectional imaging at 3–6 months intervals for the first 2 years, but are not backed by strong evidence of benefit. In Calgary, we perform MRI one month after radiofrequency ablation (RFA) and 3–6 months after surgery. Thereafter we alternate contrast enhanced ultrasound and MRI every 3 months for two years and then every six months for another 3 years. We conducted a retrospective study to investigate the impact of surveillance intensity on clinical outcomes following curative HCC treatment.
Method: From a combined surgery and interventional radiology database in Calgary (2012–2015), 124 unique HCC patients receiving post-treatment surveillance after successful resection (n = 46) or RFA (n = 78) were identified after excluding patients who received transarterial chemoembolization (TACE) (n = 43), failed to achieve radiological remission (n = 38) or died within three months (n = 10). Baseline characteristics, imaging frequency, and clinical outcomes were collected. A surveillance rate defined as sum of actual number of images performed divided by the sum of the expected number of images in the defined surveillance period for each subject was calculated.
Results: Baseline characteristics including age, gender and liver disease were similar in both groups. The surgery group had a higher percent of Barcelona Clinic Liver Cancer (BCLC) staging 0 (p = 0.00052), non-cirrhotic (p = 0.0045), and first HCC (p = 0.00027) then the RFA group. The two-year disease-free survival and five-year mortality rate on Kaplan-Meier analysis, as well as mean surveillance rate (89 ± 15% vs 84 ± 21%) were comparable. Interestingly, BCLC B/C recurrence (n = 8) was significantly associated with a lower surveillance rate as compared to BCLC 0/A (n = 32) recurrence in RFA patients (76 ± 22% vs 92 ± 14%, p = 0.015), but this was not observed in the surgical cohort. Comparison of mean imaging interval (120 ± 47 days vs 82 ± 29 days, p = 0.038) and time to recurrence (591 ± 245 days vs 399 ± 222 days, p = 0.048) between BCLC B/C and 0/A recurrence also differed in the RFA cohort but not in the surgery cohort. Univariant analysis did not identify other predictors of more significant recurrence.
Conclusion: In conclusion, high intensity post-treatment surveillance of HCC patients after locoregional therapy, but not surgical resection, appears to be associated with detection of recurrence at an earlier stage. Ongoing follow-up will determine if this is associated with a survival benefit.

FRI-171

Hepatocellular carcinoma: pretreatment computed tomography texture analysis as an independent predictor of survival after surgical resection

L.B. Defour[1], S. Mulé[2], T. Piardi[3], D. Sommacale[3], C. Hoeffel[2], G. Thiéfin[1]. [1]*Centre Hospitalo-Universitaire de Reims, Service d'Hépatogastroentérologie, Reims, France;* [2]*Centre Hospitalo-Universitaire de Reims, Département de Radiologie, REIMS, France;* [3]*Centre Hospitalo-Universitaire de Reims, Service de Chirurgie Générale, Digestive et Endocrine, REIMS, France*
Email: gthiefin@chu-reims.fr

Background and Aims: Image texture analysis is an emerging method of quantifying tumor heterogeneity that may provide valuable non invasive information about tumor prognosis. The purpose of this study was to determine whether texture parameters analyzed on pre-operative contrast-enhanced CT can predict overall survival and recurrence-free survival in patients with hepatocellular carcinoma treated by resection.
Method: We retrospectively included all patients operated for hepatocellular carcinoma who underwent liver contrast-enhanced CT scan within three months prior to treatment in our center between 2009 and 2015. Tumor texture analysis was performed using TexRad software in a two-step process including image filtration and statistical quantification of tumor CT texture. The following texture parameters were evaluated on both contrast-enhanced arterial and portal phases: mean gray-level kurtosis, standard deviation, kurtosis, skewness and entropy values. Measurements were made before and after spatial filtration at different anatomic scales (SSF) ranging from 2 (fine texture) to 6 (coarse texture). Univariate and multivariate Cox analyses were performed to identify independent predictors of overall survival and recurrence-free survival.
Results: Forty-seven patients were included (37M/10F; median age: 66 years). Median follow-up time was 345 days. Nineteen patients had a recurrence. At arterial CT phase, kurtosis at SSF = 3 hazard ratio (HR = 4.24, p = 0.041), SSF = 4 (HR = 4.07, p = 0.003), SSF = 5 (HR = 1.83, p = 0.027) and skewness at SSF = 6 (HR = 6.66, p = 0.04) were independent predictors of overall survival. At portal-venous phase, skewness without filtration (HR = 76.98, p = 0.025), SSF2 (HR = 178.26, p = 0.009) and SSF3 (HR = 26.26, p = 0.006) were independently associated with overall survival. No textural feature was identified as an independent predictor of recurrence free survival.
Conclusion: In patients with resectable hepatocellular carcinoma, pretreatment CT texture features such as skewness and kurtosis are significantly associated with overall survival and may have the potential to become a useful tool to select the best candidates for resection.

FRI-172

Particularities of hepatocellular carcinoma on chronic hepatitis C in the era of all- oral antiviral treatment

E.L. Iliescu[1], S. Ioanitescu[1], R. Dumitru[2], L. Toma[1], M.B. Ureche[1], A. Mercan-Stanciu[1], C. Iancu[1], M. Dodot[1]. [1]*Fundeni Clinical Institute, Internal Medicine, Bucharest, Romania;* [2]*Fundeni Clinical Institute, Interventional Radiology, Bucharest, Romania*
Email: laura_ate@yahoo.com

Background and Aims: Despite the high efficacy of direct antiviral agents in curing chronic hepatitic C virus (HCV) infection, the risk of complications, including hepatocellular carcinoma (HCC) persists. This study aims to analyze the particularities of HCC in patients who are undergoing or have finished treatment with ombistavir/ paritaprevir/ ritonavir (OMB/PTV/r), dasabuvir (DSV) with or without ribavirin (RBV) in the setting of chronic HCV hepatitis or compensated cirrhosis.
Method: This is a prospective study which included 368 patients admitted who underwent or are undergoing treatment with OMB/PTV/r + DSV +/- RBV, for a duration of 12 weeks, from December 2015 to October 2017. Screening for HCC was based on abdominal ultrasonography and levels of alpha fetoprotein (AFP) at the beginning of the therapy, monthly during therapy and 3 months after the end of treatment (at evaluation of SVR). If abnormalities were detected, contrast-enhanced ultrasongraphy or computer tomography were performed. The patients were categorized as follows, depending of the degree of liver fibrosis determined by Fibromax® or liver biopsy: F4 (compensated cirrhosis), F3 with or without HCV related comorbidities, F2 with HCV related comorbidities.
Results: The mean age in the study group was of 57+/-21.5 years, with a predominance of female sex (57%). Distribution of the degree of fibrosis was F4–53.8%, F3- 29.9%, F2- 16.3%. Initial AFP levels were

above normal in 50.2% of the patients, but CEUS and CT scan showed no signs of HCC. On treatment, HCC was diagnosed in 4 patients. At the end of treatment, other 4 patients were diagnosed, while at SVR 6 patients presented with HCC (total HCC incidence 0.03%). All patients had F4 fibrosis. A particularity was the small increase of AFP levels-up to 50ng/ml, requiring abdominal imaging for further evaluation. Antiviral treatment was continued in all patients, with the achievement of SVR. 2 patients underwent transarterial chemoembolization (TACE) during antiviral treatment, without significant complications. Furthermore, out of the 10 patients diagnosed after treatment, 6 underwent TACE. Abdominal CT in these patients was unable to detect the extent of the tumor (with an infiltrative aspect) and 7 patients required abdominal MRI for a complete evaluation. For the time being, 4 patients required 2 TACE procedures; at the moment only one patient has developed a new HCC nodule.
Conclusion: Patients with chronic HCV hepatitis, especially cirrhosis, are still at risk of developing HCC even after obtaining SVR. Slight changes in AFP levels and dedicated imaging with special consideration to infiltrative tumors are the screening and diagnostic keys in these patients.

FRI-173
Short-term evaluation of hepatocellular carcinoma after locoregional treatment: Usefulness of contrast-enhanced ultrasonography
G. Gibiino, M.E. Ainora, M. Pompili, M. Garcovich, L. Riccardi, E.D. Stasio, F. Ponziani, A.M.D. Gaetano, G. Ludovico Rapaccini, A. Gasbarrini, M. Assunta Zocco. *Policlinico Agostino Gemelli, Internal Medicine, Gastroenterology and Liver Unit*
Email: ainoramariaelena@yahoo.it

Background and Aims: In patients with hepatocellular carcinoma (HCC), an accurate assessment of the therapeutic response is of crucial importance in order to schedule further treatments. Contrast-enhanced ultrasound (CEUS) with second generation contrast agents performed 1 month after treatment is almost as sensitive as CT in depicting the residual tumor. However, the efficacy of CEUS performed early after the procedure is still debated. The aim of our study was to evaluate the diagnostic accuracy of CEUS for the assessment of tumour response shortly after locoregional therapy in patients with unresectable HCC.
Method: Ninety-four patients with 104 HCC lesions who were scheduled to receive percutaneous ethanol injection (PEI), radiofrequency ablation (RFA), transarterial chemoembolization (TACE) or combined treatment (RFA + TACE) were enrolled in this study. With contrast-enhanced computed tomography (CECT) at 1 month as the reference standard, the ability of CEUS performed 48 hours after the procedure in detecting residual disease was evaluated. Sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV) and accuracy of the avascular pattern at CEUS were calculated. Patients were followed periodically to look for tumor or disease progression. Survival probability was estimated with the Kaplan-Meier method and relate to CEUS responses.
Results: Based on CECT findings 43/104 lesions (41.3%) were diagnosed as having residual viability after 1 month. CEUS performed 48 hours after treatment detected residual tumor in 34 of the 43 nodules with treatment failure at CECT with a sensitivity, specificity, PPV, NPV and accuracy of 79.1%, 96.7%, 94.4%, 86.8% and 89% respectively. There was a high degree of concordance between CEUS and CECT (kappa coefficient = 0.78). A hyperemic halo was visible in 35 lesions without a statistically significant difference between concordant and discordant cases ($p = 0.2$). Responders according to 48 hours CEUS had a significantly longer mean overall survival and time to progression compared to non-responders (1169 *vs* 887 days, and 453 *vs* 271 days, respectively).
Conclusion: CEUS performed 48 hours after treatment can be considered a reliable modality for the evaluation of the real extent of necrosis and has a prognostic value in the assessment of hepatocellular carcinoma.

FRI-174
Performance of Wisteria floribunda agglutinin-positive Mac2-binding protein as an HCC biomarker in an ethnically diverse cohort of patients with chronic HBV and HCV
T. Jun[1], M.-L. Yu[2], Y.-C. Hsu[3], Y. Tanaka[4], M. Nguyen[1]. [1]*Stanford University Medical Center, Division of Gastroenterology and Hepatology, Stanford, United States;* [2]*Kaohsiung Medical University, Hepatobiliary Division, Kaohsiung, Taiwan;* [3]*E-Da Hospital, Division of Gastroenterology and Hepatology, Kaohsiung, Taiwan;* [4]*Nagoya City University Graduate School of Medical Sciences, Department of Virology and Liver Unit, Nagoya, Japan*
Email: tjun@stanford.edu

Background and Aims: *Wisteria floribunda* agglutinin-positive Mac2-binding protein (M2BPGi) is a novel biomarker which has been shown to correlate with liver fibrosis. M2BPGi has also been investigated as a biomarker for hepatocellular carcinoma (HCC). Single-center studies in East Asian populations with chronic hepatitis B (HBV) or chronic hepatitis C (HCV) infections have shown promising results. We conducted this study to assess M2BPGi as a biomarker for HCC in an ethnically diverse cohort of patients with both HBV and HCV.
Method: This was a prospective cohort study of 947 adult patients with liver disease and serum samples drawn between 2001 and 2016 at three centers in the US and Taiwan. Patients with chronic hepatitis B (HBV, n = 714) or chronic hepatitis C (HCV, n = 233) and at least 1 year of follow-up were included. Patients were excluded if they developed HCC within 6 months of entering the study, had antiviral treatment prior to enrollment, had HBV-HCV coinfection or had non-viral HCC. Cirrhosis was diagnosed based on imaging, clinical and histopathological findings. The primary outcome was development of HCC within 10 years. M2BPGi was measured as a cutoff index (COI).
Results: Median M2BPGi was significantly higher among patients with cirrhosis compared to patients without cirrhosis (2.7, IQR 1.14–6.07 vs. 0.83, IQR 0.51–1.54, $p < 0.001$). Median M2BPGi was also significantly higher among the 85 patients who developed HCC compared to those who did not (3.22, IQR 1.38–7.2 vs. 1.16, IQR 0.62–3.00, $p < 0.001$). M2BPGi had a higher area under the receiver operating curve (AUROC) for predicting HCC for all patients than for cirrhotic patients (0.72 vs 0.58). M2BPGi also had a higher AUROC for HCC among HBV patients than HCV patients (0.84 vs. 0.48). Among cirrhotic patients, the AUROC for HCC was higher for HBV patients than HCV patients (0.68 vs 0.47). M2BPGi was a predictor of HCC in univariate analyses, but it was not an independent predictor of HCC in a multivariate analysis of cirrhotic patients controlling for age, gender, ethnicity, treatment status, etiology and MELD score.
Conclusion: M2BPGi is strongly correlated with cirrhosis, which is a powerful predictor of HCC. In our ethnically diverse cohort, M2BPGi had more discriminatory value among HBV patients than HCV patients. When considering only cirrhotic patients, M2BPGi performed better among HBV patients than HCV patients.

A functional ATG16L1 (T300A) gene variant is associated with increased risk for hepatocellular carcinoma in cirrhosis
P. Reuken[1], P. Lutz[2], M. Casper[3], E. Al-Herwi[1], A. Stallmach[1], F. Lammert[3], H.D. Nischalke[2], T. Bruns[1]. [1]*Jena University Hospital, Dpt. of Internal Medicine IV, Jena;* [2]*Bonn University Hospital, Department of Internal Medicine I, Bonn, Germany;* [3]*Saarland University Medical Center, Department of Medicine II, Homburg*
Email: philipp.reuken@med.uni-jena.de

Background and Aims: Protein and organelle turnover by autophagy is a key component to maintain cellular homeostasis in liver diseases. Loss of the autophagy protein ATG16L1 is associated with reduced intracellular bacterial killing, Paneth cell abnormalities, and aberrant

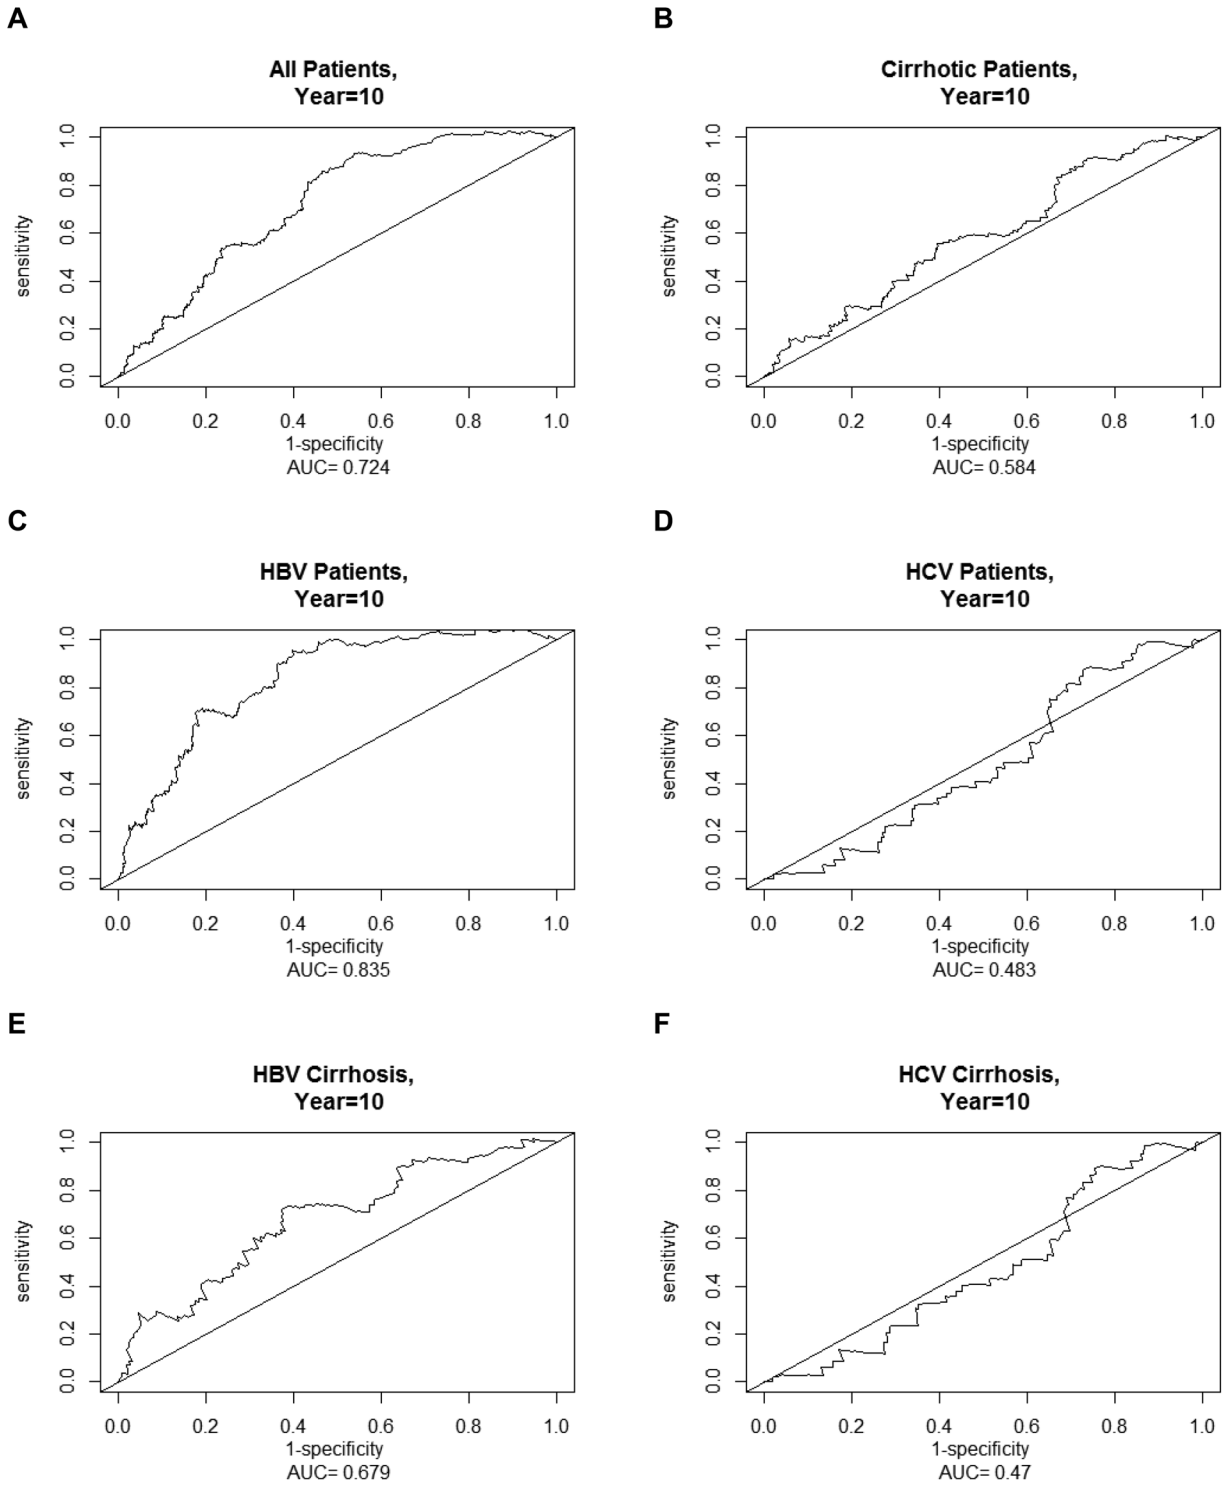

Figure 1: (abstract: FRI-174): Time-dependent receiver operating characteristic (ROC) curves for M2BPGi as a predictor of HCC for (A) All patients (B) Cirrhotic patients (C) HBV patients (D) HCV patients (E) Cirrhotic HBV patients (F) Cirrhotic HCV patients

interleukin-1β production, perpetuating chronic inflammation and carcinogenesis. Here we hypothesized that the functional p.T300A gene variant in *ATG16L1* is associated with an increased risk for hepatocellular carcinoma (HCC) in cirrhosis.

Method: A case control study was performed using a prospective derivation cohort (107 patients with HCC in cirrhosis and 101 controls with cirrhosis) and an independent validation cohort (124 patients with HCC in cirrhosis and 108 controls with cirrhosis) in patients with cirrhosis of any aetiology. The p.T300A variant (rs2241880) was determined by Taqman PCR.

Results: The majority of patients had alcoholic cirrhosis (70%). Patients with HCC were older, more often male and showed higher serum transaminase activities than patients without HCC. The G allele of the variant was found more frequently in patients with HCC in cirrhosis as compared to cirrhotic patients without HCC both in the derivation cohort (62% vs. 51%; odds ratio [OR] 1.58; 95% confidence

interval [CI] 1.07–2.33) and in the validation cohort (59% vs. 50%; OR 1.46; 95% CI 1.01–2.10). Overall, the association of the homozygous p.T300A variant with HCC (univariate OR 1.81; 95% CI 1.19–2.76; p = 0.006) remained significant after adjustment for male sex, older age, and aetiology in multivariate analysis (adjusted OR 2.09; 95% CI 1.28–3.26; p = 0.003). Patients, who had developed HCC, did not show worse survival in presence of the p.T300A variant.
Conclusion: The functional *ATG16L1* gene variant p.T300A is associated with an increased risk of HCC in this cohort study. In addition to clinical features, *ATG16L1* variants may be taken into account when performing risk-based HCC surveillance in cirrhosis.

FRI-176

Serial changes in alpha-fetoprotein, lectin-bound alpha-fetoprotein and Des-r-Carboxy prothrombin in prospectively collected serum samples before the diagnosis of hepatocellular carcinoma

J. Choi[1], S. Young Yi[2], Y.-S. Lim[1], W. Lee[3], S. Chun[3]. [1]*Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South;* [2]*Asan Medical Center, University of Ulsan College of Medicine, Hepatology, Seoul, Korea, Rep. of South;* [3]*Asan Medical Center, University of Ulsan College of Medicine, Department of Laboratory Medicine, Seoul, Korea, Rep of South*
Email: limys@amc.seoul.kr

Background and Aims: Few biomarker studies using prospectively collected specimens in patients at risk of hepatocellular carcinoma (HCC) has been reported. The aims of our study were to evaluate the performance of alpha-fetoprotein (AFP), Lectin-Bound alpha-fetoprotein (AFP-L3) and Des-r-Carboxy Prothrombin (DCP) and their ability to detect preclinical disease before the clinical diagnosis of HCC.
Method: Samples from a total of 689 patients were collected by previously conducted four randomized trials in patients with compensated cirrhosis or chronic hepatitis B. Forty-two HCC cases and controls (n = 168) were matched for age, gender, etiology of liver disease, cirrhosis, and duration of follow-up in a 1:4 ratio for the analyses. Samples at the time of HCC diagnosis, 6- and 12- months prior to the diagnosis of HCC were tested for AFP, AFP-L3 and DCP for performance in discriminating HCC cases from controls.
Results: Of 42 cases with HCC, 38 (90.5%) had early stage HCC (BCLC stage 0 and A) and median tumor size was 1.6 cm (range: 0.9–11.0). AFP and AFP-L3 started to increase from 6 months before the diagnosis of HCC ($p < 0.05$), while they remained unchanged in the controls. The AUROCs for AFP, AFP-L3, and DCP at month 0 were 0.77, 0.73, and 0.71, respectively. Combination of AFP and AFP-L3 showed the highest AUROC of 0.83. No additional benefit in performance was observed by adding DCP. The sensitivity and specificity for detecting HCC by the combination of AFP and AFP-L3 were 79% and 87%, under optimal cut-off values for AFP and AFP-L3 (4.7 ng/ml and 0.5%, respectively).
Conclusion: Combination of AFP and AFP-L3 showed better performance than any single biomarkers in detecting HCC among patients at risk. AFP and AFP-L3 began to increase from 6 months before the clinical diagnosis of HCC. AFP-L3 may improve the performance of HCC surveillance when used as a supplementary test to AFP.

FRI-177

Sphingolipids: a further step into the detection of early and intermediate hepatocellular carcinoma

I. Nenu[1], C. Hebristean[2], P. Fisher[1], A. Suciu[1], H. Stefanescu[1], B. Procopet[3], D. Liliana[1,4], A. Cavasi[1,4], A. Seicean[1,4], Z. Sparchez[1,4], M. Tantau[5], C. Socaciu[6], M. Grigorescu[1,4]. Email: iuliana.nenu@gmail.com

Background and Aims: Throughout the last years metabolomics has played an important role in providing new insights into the detection and progression of hepatocellular carcinoma (HCC). Sphingolipids, a family of membrane lipids, are involved in numerous cell functions, including cell death pathways and have an altered expression in many types of cancer. The aim of the study was to identify a metabolomic biomarker for HCC diagnosis and to compare its diagnostic accuracy with alpha fetoprotein (AFP).
Method: 104 patients (54 HCC BCLC stages 0, A and B developed on compensated cirrhosis and 50 compensated cirrhotic controls) were included. Common workup for the assessment of liver disease and AFP was carried out in each patient. High pressure liquid chromatography (HPLC) coupled with quadruple time of flight electrospray in a positive ionization mode mass spectrometry (QTOF-ESI+-MS) was performed from serum samples of each patient. MetaboAnalysis, performing univariate and multivariate statistical analysis was used to identify candidate biomarkers. Their performance for detection of early/intermediate HCC was evaluated using semi-quantitative assessment and through a leave-one-out cross-validation based on area under the receiver operating characteristics (ROC) curve.
Results: 15 metabolites were identified. Sphingolipids are the most upregulated in HCC patients, particularly C16 sphinganine (C16-SPH) ($p < 0.001$ vs. compensated cirrhosis). The expression of C16-SPH was 4.869 times higher in HCC than in cirrhotic controls ($p < 0.005$). The area under the curve (AUC) of C16-SPH for the diagnosis of HCC was significantly higher compared to AFP [0.969 (95%CI, 0.923–1) vs. 0.544 (95%CI, 0.415–0.673), p (deLong test) <0.001]. For a cutoff value of 0.737, C16-SPH correctly classified 97/104 (93.26%) of patients.

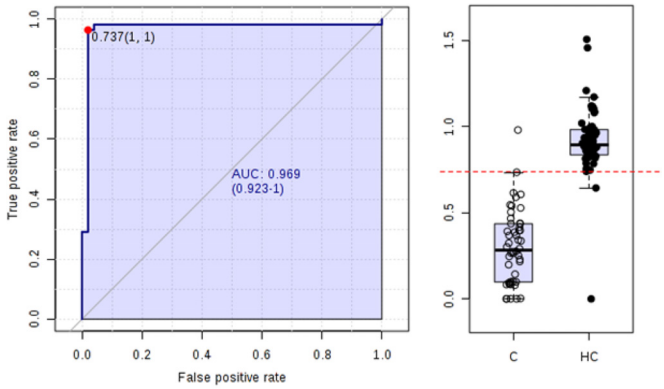

Figure 1- ROC curve for C16-sphinganine

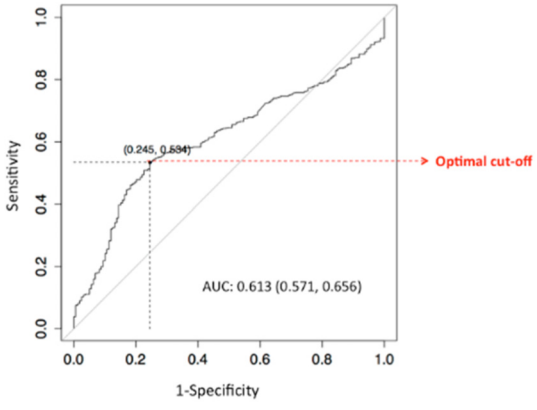
Conclusion: Sphingolipids show a significant upregulation in patients with HCC compared to patients with cirrhosis. Of them, C16-SPH might stand as a novel diagnostic marker for the identification of early and intermediate HCC in patients with chronic liver diseases.

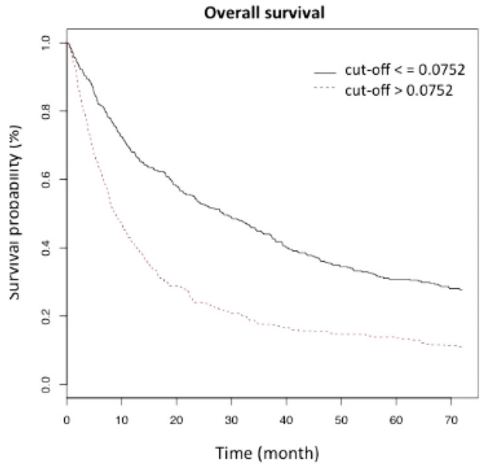
FRI-178

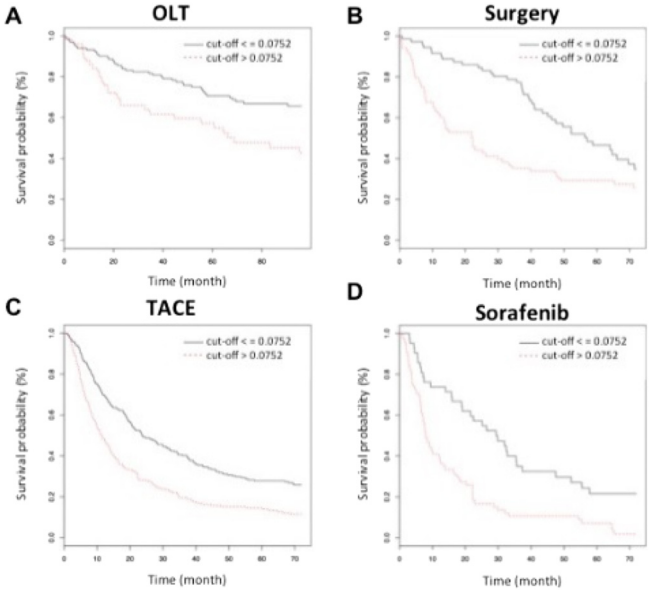
A high alpha-fetoprotein slope prior to therapy correlates with poor prognosis of patients with hepatocellular carcinomas

C. Czauderna[1], S. Koch[1], L. Pilz[1], S. Franck[1], H. Lang[2], R. Klöckner[2], M.-A. Wörns[1], P. Galle[1], J. Marquardt[1], A. Weinmann[3]. [1]*Johannes Gutenberg University, Mainz, Department of Medicine I, Mainz, Germany;* [2]*Johannes Gutenberg University, Mainz, Department of Diagnostic and Interventional Radiology, Mainz;* [3]*Johannes Gutenberg University, Mainz, Department of General, Visceral and Transplant Surgery, Mainz*
Email: carolin.czauderna@unimedizin-mainz.de

Background and Aims: Hepatocellular Carcinoma (HCC) is the second leading cause of cancers death worldwide. Biomarkers for accurate prediction of prognosis are limited and urgently needed to improve patient management. Alpha-fetoprotein (AFP) is a well-established biomarker for HCC and widely used in prognostic score systems. However, diagnostic accuracy of "static" AFP-values is limited and clinical potential as a prognostic and/or predictive marker needs to be more precisely defined. Here we evaluated the prognostic value of pre-treatment serum AFP changes on the overall survival (OS) of HCC-patients in a German cohort.
Method: We retrospectively analyzed patients with confirmed HCC (n = 859) treated at the University Medical Center of the Johannes Gutenberg-University Mainz between 1998 and 2014. Baseline parameters concerning patient status, tumor size and liver function, as well as pre-treatment static and dynamic AFP were investigated. AFP-slope was defined as the delta of two pre-treatment measurements normalized to daily increment/decline. Prognostic impact was assessed using Kaplan-Meier analyses as well as by univariate and multivariate cox regression models. Optimal-cut-off values were defined using receiver operating characteristic curves.







Results: In univariate cox regression analyses, single AFP-value failed to show a prognostic impact (p = 0.81), while pre-treatment AFP-slope showed a strong association to OS (p < 0.001). Besides several known clinical parameters such as Child Pugh B (p < 0.001) and C (p < 0.001), portal vein thrombosis (PVT) (p < 0.001), extra-hepatic spread (p = 0.0001) and tumor size (p < 0.001), pre-treatment AFP-slope (p < 0.001) could be confirmed as an independent factor on OS of HCC-patients in multivariate analyses. Receiver operating characteristic analysis showed that the best discriminant cut-off value was a pre-treatment AFP-slope greater than 0,0752ng/ml/day with an area under the curve of 0.613. At this cut-off sensitivity was 53,4% and specificity reached 75.4%. Patients with an AFP-slope greater than 0,0752ng/ml/day prior to liver transplantation, surgery, local ablation or Sorafenib therapy had a worse overall survival than those with an AFP-slope under the threshold.
Conclusion: AFP changes prior to therapy are predictive for the overall survival of HCC-patients. The addition of an AFP-slope to established prognostic parameters might improve prognostic classification of HCC.

FRI-180

In Moldova, social situation is a primary modulator of survival in a hepatocellular carcinoma

A. Turcanu[1], P. Pineau[2], E. Tcaciuc[1], V.-T. Dumbrava [1]. [1]*State University of Medicine, Gastroenterology and Hepatology, Chisinau, Moldova;* [2]*Institut Pasteur, Unité « Organisation nucléaire et Oncogenèse », INSERM U993, Paris, France*
Email: adela_turcanu@yahoo.com

Background and Aims: Moldova is the country with the highest primary liver cancer incidence in Europe in both sexes. Many factors modulate the risk of developing hepatocellular carcinoma (HCC) in the settings of a chronic viral hepatitis. Especially, individual patients risks that include geographical origin; host-related factors (both genetic and lifestyle); and specific viral determinants are known to be players of unequal importance.
Method: We conducted a retrospective study on 148 HC cases diagnosed in the main University Hospital of Chisinau, to delineate tolls attributable to the different risk factors prevalent in Moldova. HCC diagnosis was based on the presence of a liver mass at imaging, on the clinical context, notably the presence of a chronic liver disease or cirrhosis, on serological markers of viral infections, and on alpha fetoprotein levels. Data about socio-demographic status, clinical

symptoms, clinical biochemistry, blood cell count, tumor number and diameter, lymph nodes involvement, metastases, treatment and survival length were recovered from medical files and stored in a database.

Results: The overall survival of patients was known for 108 of them. The median survival was 12 months (inter-quartile range 7–24). No tumor risk factor was significantly associated with poor survival. Tobacco use and Type 2 Diabetes were risk factors only marginally associated with difference of survival (Log rank test, p = 0.059 and p = 0.073). By contrast, lower education level (primary school) was significantly associated with a poorer survival (p = 0.0169). Self-recognized alcohol intake was a frequent hallmark of lower level of education (p = 0.0017), and low family income (67.1 vs 48.3%, OR = 2.16, 95%CI: 1.00–4.47, p = 0.0330). Habitants from Southern Moldova were more often represented among alcohol drinkers than in non-drinkers (24.6 vs 9.6%, OR = 3.0, 95%CI: 1.05–10.04, p = 0.0255). Other features conditioning survival length were tumor diameter, clinical symptoms (portal thrombosis, hemorrhage, hepatic encephalopathy), biochemical markers (AST, urea) and of course surgical treatment.

Conclusion: In Moldova, social status of the patients greatly influences survival in HCC. Level of education, closely conditioning alcohol consumption, is linked to late stage addressing for medical consultation in HCC when therapy is only palliative. Efforts should now be made to raise the degree of awareness about liver disease in the deprived sections of Moldovan population.

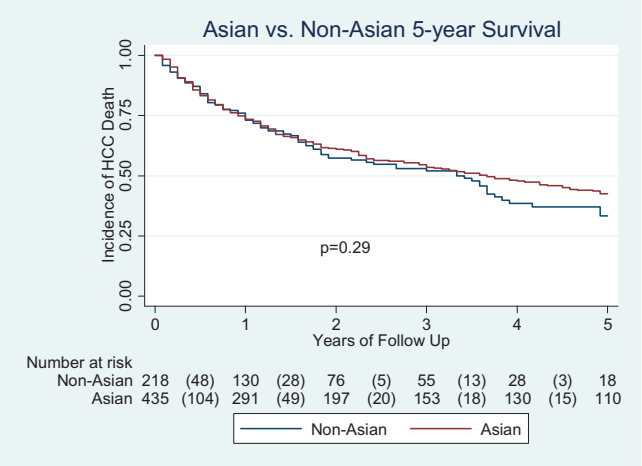
Background and Aims: Studies comparing clinical presentation of Asians and Non-Asians with HBV-related HCC are limited. Our goal was to evaluate clinical presentation and long term outcomes for HBV-HCC between Asians and Non-Asians in the United States (US).

Method: We performed a retrospective cohort study of 767 (508 Asian, 259 Non-Asian) consecutive adult patients ≥18 years-old diagnosed with HBV- HCC at three U.S. medical centers from 1993–2016. Patients were identified by ICD-9 diagnosis codes and confirmed to have HBV-HCC by chart review. Structured data extraction was performed for each medical record using the same data frame at each center. Kaplan-Meier analysis was conducted to determine differences in 5-year survival between the two groups.

Results: The cohort was predominantly male (79.7% of Asians vs. 80.7% of Non-Asians). Asians were younger (mean age 60.1 vs. 63.7, p = 0.0002), had lower BMI (mean 24.1 vs. 27.2, p < 0.0001), longer follow-up years (mean 3.0 vs. 2.4, p = 0.04), and were less likely to be decompensated (21.9% vs. 33.4%, p < 0.0001). There were no Asians with HCV infection (0% vs. 10.0%, p < 0.0001) or with HBV-HIV co-infection (0% vs. 6.2%, p < 0.0001). Asians had similar HCC treatment rates (74.0% vs. 76.5%, p = 0.46) and cirrhosis prevalence (60.6% vs. 64.8%, p = 0.25) compared to Non-Asians. Asians presented with lower Child-Pugh Class (B: 27.3% vs. 48.8%, C: 7.9% vs.12.5%, p < 0.0001), MELD score (mean 10.8 vs. 11.6, p = 0.13), and BCLC stage (Stage B: 40.7% vs. 47.2%, Stage C: 14.0% vs. 34.8%, p < 0.0001). Asians were less likely to receive curative HCC treatments (77.4% vs. 81.8%, p < 0.0001) and were less likely to be listed for transplantation (23% vs. 33.5%, p < 0.003) or have transplantation (7.8% vs. 20.7%, p < 0.0001) despite higher rates of meeting the Milan criteria (32.1% vs. 26.6, p < 0.12). HCC death incidence per 1000 person-years was lower in Asians than Non-Asians (101.68 vs. 145.33) with a cumulative five-year incidence of 43.9% vs. 56.1%, respectively, though the overall long-term five-year survival was not significantly different (p = 0.29) (Figure).



Conclusion: There were distinct differences in clinical presentation of Asian and Non-Asian patients with HBV-HCC. Asians are less likely to undergo liver transplantation and have lower HCC treatment rates despite meeting the Milan criteria. Research is needed to determine the cause of the disparity.

FRI-182

Dynamic [18F] FLT-PET is sensitive in detecting hepatocellular carcinoma

R. Sharma, E. Aboagye, T. Barwick. *Imperial College, Medical Oncology, London, United Kingdom*
Email: r.sharma@imperial.ac.uk

Background and Aims: Contrast enhanced multiphase CT and MRI are standards by which the effectiveness of palliative treatments in the management of hepatocellular carcinoma (HCC) is monitored. However, conventional imaging techniques have limited sensitivity in visualising HCC, and in particular, CT/MRI cannot effectively differentiate necrotic or dysplastic nodules from residual tumour. Furthermore, as most tyrosine kinase inhibitors result in a cytostatic rather than cytotoxic response, conventional imaging modalities are not adequate in assessing efficacy.

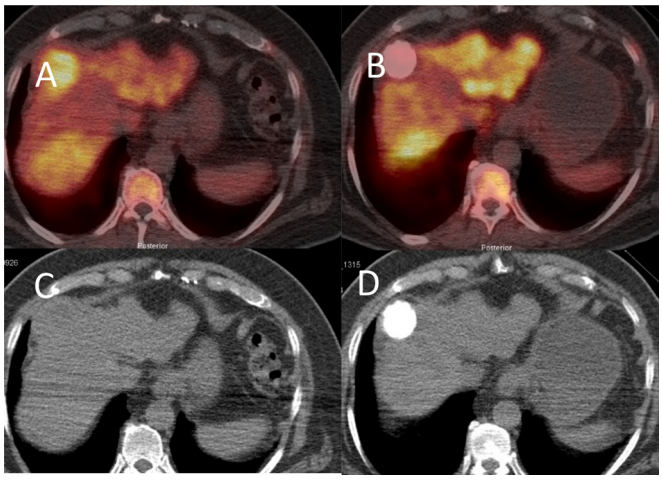
PET imaging not only assesses tumour size but also functional changes at a cellular level. Fluorothymidine (FLT) is a marker of proliferation that is a substrate for the cell cycle regulated enzyme, thymidine kinase-1 (TK-1). FLT is not susceptible to inflammation and has a high specificity for malignancy. Previous studies investigating PET imaging in HCC have been hampered by poor signal to background noise within the liver.

The OVERALL OBJECTIVES of this project are to assess sensitivity of FLT PET/CT in detecting HCC at baseline compared to multiphase contrast-enhanced CT (CECT), and to evaluate response to transterial chemoembolisation (TACE) in patients with advanced stage HCC with [18F]FLT-PET/CT compared to CECT using modified RECIST (mRECIST) and progression free survival.

Method: A tissue microarray (TMA) consisting of HCC and surrounding cirrhotic tissue was constructed (n = 38) and expression of TK-1 assessed. 18 patients with BCLC-C disease suitable for TACE underwent dynamic [18F]FLT-PET/CT imaging 1 week prior to TACE and 6 weeks following, at the time of follow-up imaging. Response was assessed by mRECIST.

Results: A significant increase in TK-1 was observed in HCC compared with surrounding cirrhotic tissue (p < 0.05). [18F]FLT-PET/CT was sensitive in detecting HCC at baseline (A) and following TACE (B)

compared to CECT (C-D). The correlation between [18F]FLT uptake and mRECIST will be assessed and ability to predict hepatic PFS.



Conclusion: Despite a previous study suggesting that [18F]FLT-PET/CT has low sensitivity and specifity in detection HCC due to high liver to background ratio, we found that using dynamic scanning protocol, [18F]FLT-PET/CT is a sensitive imaging modality which should be pursued in larger studies.

FRI-183

Monofocal HCC: Milan Criteria or BCLC staging system? An analysis of the ITA.LI.CA. Database

G. Peserico[1], B. Penzo[2], F. Pelizzaro[1], A. Imondi[1], A. Meneghetti[2], A. Sartori[1], M. D'elia[2], A. Vitale[1], F. Trevisani[3], F. Farinati[1]. *[1]Università degli Studi di Padova, Dip. Scienze Chirurgiche, Oncologiche e Gastroenterologiche, Università di Padova; [2]Università degli Studi di Padova; [3]Università degli studi di Bologna*
Email: giulia88.fish@gmail.com

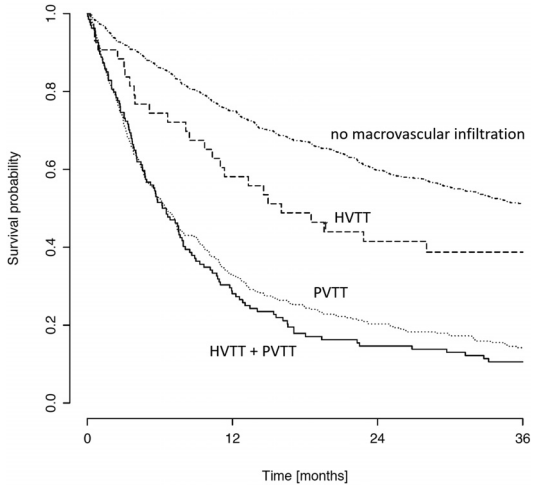
Background and Aims: The Barcelona Clinic Liver Cancer (BCLC) algorithm, adopted by the EASL (European Association for the Study of the Liver) guidelines, predicts prognosis and recommends treatment choices in hepatocellular carcinoma (HCC). This study aimed at evaluating the need of the 5 cm cut-off adopted in the Milan Criteria to correctly stage and treat monofocal HCC.
Method: 1623 monofocal, not "very early", HCCs, recruited in the 2001–2014 Italian Liver Cancer (ITA.LI.CA) database and stratified by diameter (1345 SMALL HCC, >2/≤5cm, and 278 LARGE HCC, >5cm), were analysed. Among them, 1087 were "early" monofocal HCC. The monofocal HCCs were compared to 1048 BCLC B stage HCC and sub-grouped according to the adherence to the guidelines for resection. Statistics included chi-square, Kaplan-Meier (Log-rank) and Cox multivariate analysis.
Results: Overall median survival was 38 months (Confidence Interval – C.I. – 36–41), with 41 months (C.I.: 38–45) in SMALL HCC and 21 in LARGE HCC (C.I.: 17–26) ($p < 0.0001$). At multivariate analysis, the two subgroups presented different predictors of survival and statistically different therapeutic choices; surgery provided the best survival in both groups. BCLC B HCC median survival was similar to that of LARGE HCC (Hazard Ratio – H.R. – 1.103, C.I.: 0.932–1.304). Considering only resection, the survival of BCLC B HCC was significantly shorter than that of the SMALL tumors ($p = 0.0002$). According to the adherence to guidelines, patients resected out of the BCLC criteria were the largest group (57%), especially in LARGE HCC (64%); a multivariate analysis showed that diameter was the only independent predictor of survival ($p < 0.0001$) ("adherence to guidelines", $p = 0.99$). Similar results were obtained analysing the 1087 BCLC A monofocal HCC, sub-grouped according to the 5 cm cut-off (49 months, C.I.: 45–53, in the 924 SMALL HCC and 31 months, C.I.: 25–44, in the 163 LARGE HCC).
Conclusion: The 5 cm cut-off – according to the Milan criteria – stratifies monofocal (early or not) HCC in two categories different in survival, predictors and therapeutic choices. Single HCC >5 cm have a median survival comparable to BCLC B HCC. In monofocal HCC, surgery correlates with the longest survival; although the best survival is reached in SMALL HCC, resection should be recommended even in the large tumours, due to the better survival achievable. In fact, tumour burden has a heavier impact on survival than "adherence to guidelines".

FRI-184

Hepatic vein tumor thrombosis in patients with hepatocellular carcinoma

S. Schotten[1], A. Weinmann[2], V. Steinle[1], S. Koch[3], D. Graafen[1], F. Meyer[1], C. Düber[1], A. Maehringer-Kunz[1], R. Kloeckner[1]. *[1]Medical Center of the Johannes Gutenberg University, Diagnostic and Interventional Radiology, Mainz, Germany; [2]Medical Center of the Johannes Gutenberg University, Internal Medicine I, Mainz, Germany; [3]Medical Center of the Johannes Gutenberg University, Clinical Registry Unit (CRU), Mainz, Germany*
Email: sebastian.schotten@gmail.com

Background and Aims: Portal vein tumor thrombosis (PVTT) significantly impairs the prognosis of patients with hepatocellular carcinoma (HCC) and classifies them as advanced stage (BCLC-C). However, the relevance of hepatic vein tumor thrombosis (HVTT) remains unclear. Aim of this study is to compare the prognosis of patients with different forms of macrovascular infiltration as this might influence the choice of treatment.
Method: 1478 HCC-patients were extracted from the clinical registry of our tertiary referral center treated between 01/2005–01/2017. Macrovascular infiltration was diagnosed by re-evaluation of all available CT- or MRI-studies by two experienced radiologists in consensus reading. Overall survival (OS) was calculated for all subgroups (no infiltration, PVTT, HVTT, HVTT + PVTT).
Results: 1341 patients could finally be included. 807 patients (60.2%) had no infiltration, 358 showed PVTT (26.7%), 43 (3.2%) an isolated HVTT and 133 (9.9%) had HVTT + PVTT. The corresponding overall survival was: 37.3, 6.5, 16.0, and 6.5 months, respectively ($p < 0.001$).



Conclusion: Overall, HVTT was more common than expected (13.1%). Often it occurs in combination with PVTT which leads to dismal prognosis. However, in the subgroup with isolated HVTT, prognosis was significantly better compared to patients with PVTT (16.0 versus 6.5 month). This renders the question if patients with isolated HVTT should be classified as BCLC-C, like patients with PVTT, or whether BCLC-B might be more appropriate.

FRI-185

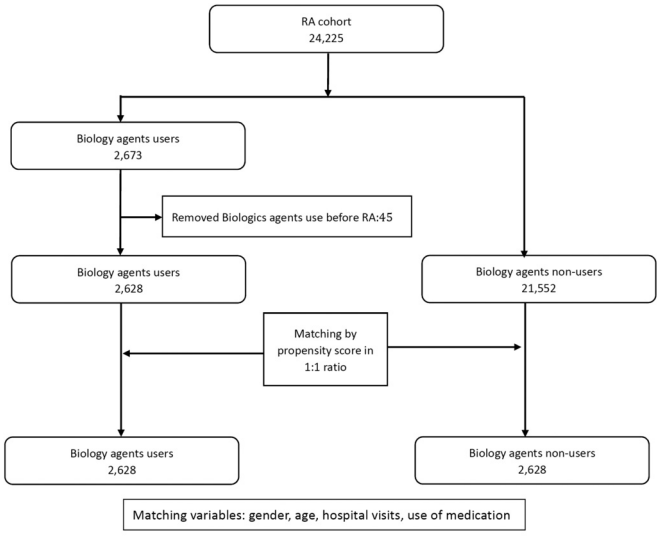
Risks of hepatocellular carcinoma and cirrhosis-associated complications in patients with rheumatoid arthritis receiving biologics: A 10-year population-based propensity-score matched cohort study

C.-S. Hsu[1], H.-C. Lang[2], H.H. Lin[3], Y.-C. Chao[4], C.-L. Chen[5]. *[1]LIver Diseases Research Center, Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, New Taipei, Taiwan; [2]Institute of Hospital and Health Care Administration, National Yang-Ming University, Taipei, Taiwan; [3]Division of Gastroenterology, Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Taiwan; [4]Division of Gastroenterology, Department of Internal Medicine, Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Taiwan; [5]Division of Gastroenterology, Department of Internal Medicine, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Taiwan*
Email: hsu.chingsheng@gmail.com

Background and Aims: Using immunomodulatory agents for the management of rheumatoid arthritis (RA) may not only modify the involved immunologic pathways but also alter normal immunosurveillance and the risk of malignancy. Several studies have shown an increased risk of HBV or HCV infection in RA patients, which likely increases the risk of developing hepatocellular carcinoma (HCC) for RA patients. However, few studies have addressed the relationship between the HCC risk and RA. We aimed to examine the risk of HCC and cirrhosis-associated complications in patients with RA who took biologics.

Method: All patients with RA aged ≧ 18 years in the Taiwan National Health Insurance program between January 1, 2000, and December 31, 2009, were enrolled. We matched biologics RA users and non-users by propensity scores in a 1:1 ratio. Our primary outcome was a diagnosis of HCC and cirrhosis-associated complications during a 10-year follow-up period. The risk of outcomes was represented as a hazard ratio (HR) calculated in Cox proportional hazard regression models.

Results: 2,628 biologics users and 2,628 non-users were included in the primary outcome analysis (Figure). 6 biologics users and 15 non-users developed HCC, and 39 biologics users and 54 non-users developed cirrhosis-associated complications (HCC excluded) at the end of 10-year observation. The biologics users had a comparable risk of HCC (HR = 1.01, 95% CI = 0.37–2.77, p = 0.9811) and cirrhosis-associated complications (HR = 1.35, 95% CI = 0.76–2.38, p = 0.30) to the biologics non-users after adjusting for all baseline covariates, including age, sex, the frequency of medical visits, and CCI.



Note:
The index date of biologics users was defined as the date of using biologics; and the index date of biologics non-users was defined as the date of first RA diagnosis.

Conclusion: Although immunomodulatory agents may alter the risk of malignancy, use of biologics does not increase the risk of HCC and cirrhosis-associated complications in RA patients.

FRI-186

Risk assessment of hepatocellular carcinoma in chronic liver disease patients with a combination of liver stiffness measurement and controlled attenuation parameter by FibroScan

K. Morikawa[1], T. Izumi[1], T. Sho[1], K. Suzuki[1], A. Nakamura[1], M. Ohara[1], N. Kawagishi[1], M. Umemura[1], M. Nakai[1], G. Suda[1], K. Ogawa[1], Y. Kudo[2], M. Nishida[2], M. Baba[3], K. Furuya[3], N. Sakamoto[4]. *[1]Hokkaido University, Department of Gastroenterology and Hepatology, Sapporo-shi, Hokkaido, Japan; [2]Hokkaido University Hospital, Division of Laboratory and Transfusion Medicine, Japan; [3]JCHO Hokkaido Hospital, Department of Gastroenterology; [4]Hokkaido University, Department of Gastroenterology and Hepatology, Sapporo-shi, Hokkaido*
Email: kenichi.morikawa@med.hokudai.ac.jp

Background and Aims: Patients with chronic liver disease (CLD) have hepatocellular carcinoma (HCC) causing risk. Recent advantage based on ultrasound technology provide us to evaluate liver stiffness measurement (LSM) and amount of hepatic fat quantitatively. This study aimed to investigate the applicable cutoff values of LSM and controlled attenuation parameter (CAP) for primary HCC development, and evaluate its clinical usefulness for risk assessment of HCC in hepatitis C virus (HCV), hepatitis B virus (HBV), and non-alcoholic fatty liver disease (NAFLD) patients.

Method: 1054 patients (88 with primary HCC and 966 without HCC) with a clinically evident CLD (HCV, 419; HBV, 377; NAFLD, 258) were enrolled in this retrospective and cross-sectional study.

Results: In HCV, LSM of more than 8.0 kPa (OR: 4.06, 95%CI: 1.46–13.19, p = 0.0066) and CAP of less than 221 dB/m (OR: 2.80, 95%CI: 1.07–8.81, p = 0.0355) were independent risk factors for primary HCC development. In HBV, LSM of more than 6.2 kPa was an independent risk factor for primary HCC development (OR: 11.22, 95%CI: 4.10–34.49, $p < 0.0001$). In NAFLD, LSM of more than 5.4 (OR: 7.53, 95%CI: 1.97–49.81, p = 0.0018) and CAP less than 265 dB/m (OR: 4.56, 95%CI: 1.80–12.46, p = 0.0012) were independent risk factors for primary HCC development. Other risk factors for primary HCC development were low albumin and elevated α-fetoprotein for HCV, old age and low platelets for HBV, low albumin and complication with high-blood pressure for NAFLD.

Conclusion: The cutoff values of LSM and CAP for the risk of HCC development were different depending on the etiology. The determining the cutoff values of fibrotic stage and hepatic steatosis for HCC occurrence and its combination use would be useful in daily clinic in assessing HCC risks among CLD patients.

Email: ddavola@unav.es

Background and Aims: Hepatocellular carcinomas (HCC) release circulating tumor cells (CTCs) to the bloodstream. Despite that numerous reports found a direct correlation between the number of CTCs and poor clinical outcomes, only few studies have provided a molecular characterization of CTCs. The aim of our study was to develop a method to extensively analyze the transcriptome of CTCs from HCC patients using single-cell mRNA sequencing (scRNAseq).
Method: For this pilot study we included 6 patients with HCC and 1 control (no cancer). Our approach included 3 sequential steps: 1) 8 ml of blood were withdrawn using heparin tubes and CD45 cells were depleted using an immunodensity assay (Rosette depletion kit). The enriched cellular suspension was separated in 2 aliquots. 2) The presence of CTCs was assessed in the first aliquot by flow cytometry imaging (Imagestream, Amnis®). CTCs were defined as: having a compatible shape by bright field morphologic analysis, being CD45 negative, and expressing at least one of the following markers: ASGPR1, pan-CK, EPCAM and GPC3. 3) If candidate CTCs were detected, the second aliquot was subjected to scRNAseq using 10X Chromium Genomics. The analytical pipeline was adjusted to be specifically sensitive to detect outliers and included principal component analysis (PCA), non-linear clustering methods (t-SNE) and differential gene expression.
Results: Most patients had advanced HCC (BCLC-C, 3/6), and in 4/6 we detected candidate CTCs upon Imagestream analysis, while the control patient was negative. From the 2 patients analyzed by scRNAseq, we sequenced a total of 7,381 and 3,560 cells in patient 1 and 2, respectively. Both PCA and differential expression confirmed the presence of 2 cells with hepatic lineage (i.e., overexpression of ADH, HFE, TTR, FABP11, GSTA1, APOH, FGB, APOA2, ALB, ORM1) in the blood of patient 1, and one in patient 2. Also, the 3 CTCs identified in the 2 patients overexpressed genes typically deregulated in HCC tissue samples (e.g., HULC, SPP1, SPINK1). Gene expression profiling of the 2 CTCs found in patient 1 revealed significant differences between them, including the overexpression of the known HCC driver IGF2 in one of these CTCs.
Conclusion: Application of scRNAseq enables the identification of CTCs in HCC patients. Genome-wide transcriptome profiling allows for a dense molecular characterization of CTCs, which underscores its potential role to monitor HCC heterogeneity using a minimally invasive approach.

FRI-188
Validation of the MESH, HKLC and BCLC classification in a large German cohort of hepatocellular carcinoma patients

S. Franck, I. Schmidtmann, E. Heil, S. Koch, C. Czauderna, M.-A. Wörns, M. Sprinzl, R. Klöckner, P. Galle, J. Marquardt, A. Weinmann. *University Medical Center Mainz*
Email: sophia.franck@icloud.com

Background and Aims: The BCLC staging system is most frequently used to classify HCC patients in the US and Europe and is endorsed by guidelines of EASL and AASLD. However, staging systems vary among different countries and a variety of other classification schemes have been proposed, but clinical utility across different cohorts is a matter of ongoing scientific discussion. Here, we evaluate the prognostic accuracy of Hong Kong Liver Staging System (HKLC) and MESH (Model to Estimate Survival for HCC) Score in comparison to BCLC staging in a Western cohort of HCC patients.
Method: We retrospectively analyzed 1102 patients of the HCC cohort treated at the University Medical Center of Mainz between 1998 and 2014 and compared the predictive ability of survival time of three classification systems (BCLC, HKLC, MESH). 903 patients were treated in accordance with all three scoring systems. Predictive ability was tested using integrated Brier score (IBS), a measure for prediction error, and variants of the c-index such as Harrell's C.
Results: From the 903 investigated patients 98% were Caucasian, 82.2% male and 17.8% female. HCC etiology was mainly alcohol abuses (38.3%), chronic hepatis C (22.5%) and hepatitis B infection (10.4%). The majority of patients were CHILD A (52.3%). Patients were classified as HKLC I: 12.8%, II: 31.4%, III: 28.5%, IV: 9.2% and V: 18.1%. MESH 0: 4.5%, 1:15.5%, 2: 24.3%, 3: 21.1%, 4: 11.7%, 5: 5.2%, 6: 0.9%. BCLC A: 22%, B: 16.1%, C: 44.37, D: 17.4%.
Kaplan-Meier analyses showed significant differences in survival between stages defined by BCLC (median survival BCLC A: 51.1, BCLC B: 20.5, BCLC C: 10.1, BCLC D: 3.5 months respectively; $p < 0.0001$), HKLC (HKLC I: 54.6, HKLC II: 31.3, HKLC III: 10.8, HKLC IV: 5.1, HKLC V: 3.1 months respectively; $p < 0.0001$) and MESH (MESH 0:NA, MESH 1: 37.1, MESH 2: 22, MESH 3: 10.6, MESH 4: 5, MESH 5: 3.6, MESH 6: 1.3 months respectively; $p < 0.0001$). However, MESH and HKLC showed more robust classification concordance ($c = 0.701$ and 0.692 respectively) and lower prediction error (IBS 0.166 and 0.161) than BCLC ($c = 0.659$; IBS: 0.177).
Conclusion: Our analyses of different scoring system for HCC confirmed prognostic ability of all three scores. Our comparative analyses and subsequent evaluation by IBS and c-index suggest that MESH and HKLC possesses a high predictive accuracy in Western HCC patients with lower prediction error than BCLC. Prospective head-to-head evaluation of different scoring systems is warranted.

Autoimmune and chronic cholestatic liver disease: Experimental and pathophysiology

FRI-191
Obeticholic acid response in primary biliary cholangitis associated with differential expression of antigen presentation, Wnt signalling and mRNA splicing

M. Seifi[1], J. Jovel[1], K. Siminovitch[2], R. Pencek[3], D. Shapiro[3], A.L. Mason[1]. *[1]University of Alberta, Medicine, Edmonton, Canada; [2]University of Toronto, Toronto, Canada; [3]Intercept Pharmaceuticals, San Diego, United States*
Email: andrew.mason@ualberta.ca

Background and Aims: In the POISE phase III trial, PBC patients unresponsive to UDCA were treated with 5–10mg obeticholic acid (OCA) with a response rate of 47% using the primary endpoint of alkaline phosphatase level <1.67 times the upper limit of normal and 15% reduction. To better understand biomarkers for response, differences in transcriptional activity of whole blood were evaluated in responders versus non-responders using RNA-seq.
Method: 174 samples of whole blood RNA from 86 PBC patients were cloned into TruSeq libraries and processed by Illumina HiSeq to generate 5 GB data per library. After removal of low quality reads, sequences were aligned to the human genome GRCh38.81 using TopHat2 aligner and counted with HTSeq. Differential expression analysis was conducted using the DESeq2 R package and genes deregulated with a false discovery rate < 0.05 were considered differentially expressed. Pathway analyses were conducted using Gene Ontology Consortium and compared to prior databases of PBC "omics" studies.

Results: After OCA therapy, increased expression was observed in 161 genes and decreased expressed in 158 genes with a FDR < 0.05 in responders versus non-responders. The major upregulated genes in the OCA-responsive patients were the genes associated with negative regulation of mRNA splicing via the spliceosome (38 fold enrichment, p < 0.0002) and regulation of alternative mRNA splicing via the spliceosome (30 fold, p < 0.0000003). Non-responders experienced increased expression of genes associated with antigen processing and presentation of exogenous peptide antigen via the major histocompatibility (MHC) class I (14 fold, p < 0.0014), Wnt signaling developmental pathway (11 fold, p < 0.009), negative regulation of mitotic cell cycle (11 fold, p < 0.05), tumor necrosis factor-mediated signaling pathway (11 fold, p < 0.005), Fc receptor signaling pathway (7 fold, p < 0.003) and regulation of endocytosis (6 fold, p < 0.05). Notably RNASE transcripts associated with interferon innate responses were some of the most upregulated genes in the non-responders.
Conclusion: Non-responders displayed a peripheral blood transcriptome of increased antigen presentation, cytokine signaling, with elevated developmental gene and cell cycle gene expression. Whereas the responders experienced increased expression of genes associated with regulation of mRNA splicing that include the ribonucleoprotein targets for autoantibodies in patients with SLE. Wnt signaling and cell cycle genes have been previously linked to PBC in prior microarray studies and pathway-based analysis of PBC genome-wide association studies, whereas differential production of spliceosome proteins have been found in proteomics studies of PBC patients. These studies suggest that OCA non-responders have increased monocyte proliferation, antigen presentation and immune activation.

FRI-192

TGR5 modulates gallbladder function and bile acid pool composition : potential hepatoprotective impact in mice

B.J. Valeska[1], G. Mathilde[1], M. Gregory[1], D. Isabelle[1], B. Raphael[2], C. Ullmer[3], L. Humbert[4], D. Rainteau[4], T. Tordjmann[1]. *[1]INSERM, U1174, Orsay, France; [2]CEA, SHFJ, Orsay, France; [3]Roche Innovation Center, Basel, Switzerland; [4]INSERM, U1057, Paris, France*
Email: thierry.tordjmann@u-psud.fr

Background and Aims: The BA receptor TGR5 protects the liver against BA overload in obstructive context and after partial hepatectomy in mice, although mechanisms are undefined. We explored TGR5 impact on GB function and BA pool composition.
Methods: WT and TGR5-KO mice were submitted to: extended 89% hepatectomies (EH) upon normal (ND) or cholestyramin (CT2%)-enriched diet; bile duct ligation (BDL, 7 and 15 days); cholic acid (CA 1%, 5 days)-enriched diet; cholecystectomies (CCT); TGR5 agonist (RO5527239 10 mg/kg/d, Roche) treatment. Survival, liver injury (H&E, plasma ALT and Bilirubin) and regeneration (liver weight, PH3, Ki67, PCNA), BA pool composition (plasma, liver; LC-MS) were analyzed. GB weight, volume and filing (99Tc Mebrofenin scintigraphy) were measured in WT and TGR5-KO mice, upon vehicle or RO5527239 treatment. GB and hepatic bile pH were analyzed upon vehicle and RO5527239 treatment.
Results: In TGR5-KO as compared with WT mice, post-EH survival was reduced (25 vs 64% at day 9), hepatic necrosis (bile infarcts) and BA overload were exacerbated, while regeneration parameters were similar at both early and late stages. CT treatment (which restrains BA overload), and UDCA (which makes a more hydrophilic BA pool) strikingly improved survival, suggesting that BA overload and composition contributed to post-EH liver failure and mortality in TGR5-KO mice.
In TGR5-KO as compared with WT mice, GB weight and volume were smaller, and GB filling was deeply impaired (mebrofenin scintigraphy). RO5527239 treatment induced rapid GB dilatation in WT but not in TGR5-KO mice, while the BA pool was shifted towards a more hydrophilic (less toxic) composition (less secondary BA) in WT mice. This treatment had no significant effect on BA synthesis enzymes (hepatic CYPs mRNAs). Upon RO5527239 treatment, GB but not hepatic bile pH was strongly acidified in WT but not TGR5-KO mice, greatly facilitating BA passage from GB bile towards the blood, shunting BA route to the intestine (thus reducing secondary BA).
In the BDL and CA-enriched diet models, GB had a protective effect in WT but not TGR5-KO mice, as shown by more body weight loss, liver injury and inflammatory infiltration observed in CCT versus sham operated mice.
Conclusion: TGR5 significantly impacts GB function (filing and pH regulation) and thereby BA pool composition/toxicity, potentially supporting TGR5 hepatoprotective properties in the context of massive liver resection or other BA overload settings.

FRI-193

NLRP3 deletion leads to decreased inflammation and prevents fibrosis formation in mice after chronic bile duct ligation

M. Frissen[1], L. Lijun[1], V. Bieghs[1], K.M. Schneider[1], A. Mohs[1], E. Latz[2], A. Wree[1], C. Trautwein[1]. *[1]Uniklinik RWTH Aachen, Department of Internal Medicine III, Aachen, Germany; [2]Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn, Germany*
Email: mfrissen@ukaachen.de

Background and Aims: Hepatic toxicity caused by cholestasis triggers different cell death pathways. Caspases activity, one of the main players in apoptotic and pyroptotic cell death initiation, is modulated by the NLRP3 inflammasome. The NLRP3 inflammasome complex hereby modulates liver inflammation, fibrosis and hepatocyte pyroptosis in mice. Thus we studied the role of NLRP3 inflammasome complex formation after cholestatic liver injury.
Method: Bile duct ligation (BDL) was performed on WT, NLRP3 knockout (NLRP3-/-) and ASC-/- mice. Mice were sacrificed after acute (48 hours) or chronic (28 days) BDL injury. Inflammation, fibrosis and cell death were evaluated with histologic quantification, immunostaining, qPCR, western blot and flow cytometry analysis.
Results: Acute cholestatic liver injury in NLRP3-/- mice resulted in a significant increase in serum transaminases compared to WT mice. In addition, severe hepatic inflammation, as evidenced by higher mRNA levels for TNF, IL-1b, MCP-1 and the influx of Ly6G + Cd11b+ cells, was observed in NLRP3-/- mice. The exacerbated liver injury can be explained by an excessive necroptotic response in NLRP3-/- mice, as shown by increased mitochondrial ROS production and RIPK1 and 3 expression. In contrast, during chronic cholestasis, the lack of NLRP3 expression leads to reduced serum transaminases, less inflammation and liver fibrosis. TUNEL, caspase-3 and -8 staining showed decreased cell death in NLRP3-/-mice. Furthermore, clusters of caspase-3 positive cells were observed only in WT mice 28d after BDL, associated with pyroptosis. Since NLRP3-/- mice are unable to activate caspase-1 and cleave IL-1b, pyroptotic cell death was absent in these mice, subsequently leading to ameliorated fibrosis. Moreover, expansion of CK19+ (progenitor/oval) cells was triggered in NLRP3-/- mice which may explain the protective phenotype in knockout mice. ASC-/- mice showed a similar but less severe phenotype than NLRP3-/- mice; after 2d BDL the serum transaminases and hepatic inflammation was slightly elevated compared to WT mice. In the chronic phase ASC-/- mice were comparable to NLRP3-/- mice, since they also lack inflammasome activation and accompanied pyroptotic cell death.
Conclusion: The inability to form NLRP3 inflammasome complex after bile duct ligation leads to an early increase in liver injury, mediated by mitochondrial ROS and RIPK activation. However, in the chronic phase in NLRP3-/- and ASC-/- mice, lack of pyroptosis leads to less inflammation and subsequent fibrosis.

Activation of pyruvate kinase isoform M2 (PKM2) in myeloid cells protects from Concanavalin A-mediated liver injury

J.P. Weltzsch[1], T. Krech[2], M.G Vander Heiden[3], G. Tiegs[1], A. Horst[1].
[1]*University Medical Center Hamburg-Eppendorf, Inst. Exp.Immunology and Hepatology, Hamburg, Germany;* [2]*University Medicl Center Hamburg-Eppendorf, Department of Pathology, Hamburg, Germany;* [3]*Massachusetts Institute of Technology, Koch Institute for Integrative Cancer Research, Cambridge, MA, United States*
Email: ahorst@uke.de

Background and Aims: Immune-mediated liver injury is a common complication in autoimmune liver disease. Immune cells switch from their steady state to inflammation by a metabolic switch from oxidative phosphorylation to aerobic glycolysis. Pyruvate kinase M2 (PKM2) is a key regulator of the metabolic switch; its poorly active dimeric isoform limits the glycolytic flux. In macrophages, the PKM2 dimer enhances HIF-1α-dependent transcription of glycolytic enzymes and pro-inflammatory cytokines, such as IL-1β, fostering myeloid M1-like polarization. Contrary, the highly active PKM2 tetramer promotes myeloid M2-type polarization and production of anti-inflammatory cytokines, such as IL-10. Tetramerization and activation of PKM2 by the small molecule activator TEPP-46 could bias myeloid cell polarization towards an anti-inflammatory phenotype and elicit liver protection. It is our goal to identify a protective role for PKM2 activation in immune-mediated liver injury.
Method: In Concanavalin A (ConA)-induced liver injury in mice with a myeloid-specific knockdown of PKM2 ($PKM2^{\Delta myel}$), plasma ALT and cytokine levels were measured by enzyme assays/ELISA. Myeloid cells from liver, spleen, bone marrow and peripheral blood were characterized by flow cytometry. Glycolysis enzyme and cytokine profiles in macrophages and liver tissue were analyzed with RT-PCR. Hepatic immune cell influx and necrosis was studied in immune histology. TEPP-46 was applied i.p. prior to i.v. ConA injection.
Results: ConA-induced liver injury was exacerbated in $PKM2^{\Delta myel}$ mice, evident by significant elevation of plasma ALT, IL-1β and IL-6 levels, and increases in hepatic myeloid cell infiltration and necroses. Bone marrow-derived macrophages and hepatic tissue exhibited a pro-inflammatory cytokine profile and increases of glycolytic regulators. We found that the myeloid-specific knockdown of PKM2 produced predominant dimerization of the residual PKM2 protein. Contrary, administration of TEPP-46 and PKM2 tetramerization attenuated liver injury and pro-inflammatory cytokine release.
Conclusion: Lack of PKM2 activity exacerbated ConA-induced hepatitis in $PKM2^{\Delta myel}$ mice. Contrary, activating PKM2 by TEPP-46 prior to ConA challenge conveyed liver protection. PKM2 activation offers a novel therapeutic strategy to ameliorate immune-mediated liver injury.

Email: ahorst@uke.de

Background and Aims: Disturbance in regulatory T cell (Treg) homeostasis, dysbalance between effector T cells (Tconv) and Treg and impaired Treg function can cause autoimmune liver disease. Ceacam1 is an immune co-receptor with dichotomous roles in T cell regulation: its short isoform (Ceacam1S) can activate T cells and induce Tregs, whereas its long isoform (Ceacam1L) with two intracellular immune receptor tyrosine-based inhibitory motifs (ITIMs), inhibits activated T cells, natural killer (NK) a, NKT and myeloid cells. In the liver, Ceacam1 has anti-fibrotic effects in models of non-alcoholic steatohepatitis. However, its role in immune-mediated hepatitis is unknown. Here, we define a Ceacam1 isoform-specific role for Ceacam1 in the regulation of Treg homeostasis.
Method: Immune-mediated liver injury was induced by Concanavalin A (ConA) in wildtype and *Ceacam1*$^{-/-}$ mice. Liver injury was assessed by measurement of plasma ALT activities. Cytokine concentrations/expression was measured by ELISA and qRT-PCR. Treg conversion and Treg markers were analyzed in T cell-hepatocyte cocultures and *in vivo* by flow cytometry. Treg function was analyzed *in vitro* and *in vivo* after adoptive cell transfer. In liver biopsies from patients with AIH and alcoholic hepatitis, Ceacam1 expression by intrahepatic T cells was analyzed by qRT-PCR.
Results: ConA-inudced liver damage was aggravated and persisted in *Ceacam1*$^{-/-}$ mice. Congruently, we observed hyperexpansion of Tconv, but reduction of IL-2 production and hepatic $Foxp3^+$ $CD4^+$ Treg frequencies. Also, IL-2-mediated signal transducer and activator of transcription (STAT)5 phosphorylation was impaired in Ceacam1$^{-/-}$$CD4^+$ T cells, and expression levels of Foxp3, CD25 and Bcl-2 were reduced in Ceacam1$^{-/-}$ Tregs. Lack of IL-2 hampered Treg conversion from naïve Ceacam1$^{-/-}$$CD4^+$ T cells *in vitro*. Adoptive cell transfer experiments revealed that hepatic Treg expansion and suppressive activity required Ceacam1 expression by $CD4^+$ T cells and Tregs. Importantly, we found predominant Ceacam1S expression on $CD4^+CD25^+$ T cells from mice with acute liver injury and expression of both isoforms in liver-derived $CD4^+$ T cell clones from patients with liver injury.
Conclusion: Ceacam1S confers protection from T cell-mediated liver injury by augmenting IL-2 production and phosphorylation of STAT5 in $CD4^+$ T cells, thereby promoting Treg induction and stability.

FRI-196

The suppressive effect of Interleukin-17-expression in antigen specific CD8+ T cells in acute experimental cholangitis in mice

S. Stein[1], D. Schwinge[1], T. Krech[2], A. Lohse[1], J. Herkel[1], C. Schramm[1].
[1]*University Medical Center Hamburg-, Eppendorf, I. Medical Clinic and Polyclinic, Hamburg, Germany;* [2]*University Medical Center Hamburg-, Eppendorf, Department of Pathology, Hamburg, Germany*
Email: st.stein@uke.de

Background and Aims: Interleukin (IL)-17 has been associated with the pathogenesis of several autoimmune disorders. Increased numbers of Th 17 lymphocytes and IL-17 could be observed in serum and livers of patients with inflammatory liver diseases, including autoimmune hepatitis (AIH), primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC). We here investigate the role of IL-17 in disease induction using an inducible mouse model of acute cholangitis.
Method: K14-OVAp recipient mice express an ovalbumin peptide, the SIINFEKL sequence, on biliary epithelial cells. Acute cholangitis was induced by adoptive transfer of transgenic OVA-specific OT-1 $CD8^+$ T cells and OT-1 $CD8^+$ T cells lacking IL-17A/F to investigate the role of IL-17 in the initiation and progression of cholangitis. Liver enzymes, histology, cytokine expression and flow cytometry were used to assess liver inflammation.
Results: Adoptive transfer of antigen specific OT-1 $CD8^+$ T cells led to portal inflammation in K14-OVAp recipient mice with the transferred cells mainly localized around bile ducts. The lack of IL-17A/F in transferred OT-1 CD8+ T cells resulted in enhanced liver inflammation compared to the transfer of IL-17-competent OT-1 cells. Liver infiltrating antigen-specific CD8+ T cells lacking IL-17 were highly activated, secreted large amounts of IFN-gamma and displayed increased proliferative capacity. Since biliary epithelial cells were activated after contact with $CD8^+$ T cells the increased accumulation

of IL-17-deficient transferred OT-1 cells led to the enhanced expression of T cell directed chemokines with subsequent recruitment of endogenous T cells into the liver.
Conclusion: We could here show that the lack of IL-17 in antigen specific $CD8^+$ T cells induces a severe phenotype of experimental cholangitis. Our results indicate an important suppressive function of IL-17 during the onset of antigen dependent cholangitis. Caution should be taken when targeting IL-17 for the treatment of cholangitis.

FRI-197
Batf3-dependent CD103 + CD11b-dendritic cells are crucial for the development of primary biliary cholangitis
D. Reuveni[1], S. Assi[1], P. Leung[2], O. Shibolet[1], E. Gershwin[2], E. Zigmond[1]. *[1]Tel-Aviv Sourasky Medical Center and Sackler School of Medicine, Tel-Aviv University, The Research Center for Digestive Tract and Liver Diseases, Tel Aviv, Israel; [2]University of California at Davis, Division of Rheumatology, Allergy and Clinical Immunology, Davis, United States*
Email: zigmondu@gmail.com

Background and Aims: Primary biliary cholangitis (PBC) is a progressive autoimmune cholestatic liver disease characterized by non-suppurative cholangitis. Dendritic cells (DCs) are professional antigen presenting cells composed of distinct subsets with unique functions and phenotypic characteristics. DCs were identified in liver sections of PBC patients embedded in the damaged bile ducts, however, solid data evaluating their importance and function in the *in-vivo* context is still missing. Conventional type 1 - $CD11b^-CD103^+$ (cDC1s) are unique subset of DCs efficiently perform cross presentation of antigens to $CD8^+$ T cells. Our aim was to assess the role of cDC1s in the pathogenesis of PBC.
Method: We utilized an inducible murine model of PBC by immunization of mice with the xenobiotic 2-octynoic acid conjugated to bovine serum albumin. We took advantage of the reporter mouse $Zbtb46^{gfp/+}$ to identify hepatic DCs by flow cytometry and Immunofluorescence and the Batf3 KO mice that specifically lack the cDC1s subset, to evaluate their role in PBC pathogenesis.
Results: Immunofluorescence of $Zbtb46^{gfp/+}$ reporter mice revealed that $CD103^+$ cDC1s are predominantly located within the portal tracts. Histopathology assessment demonstrated peri-portal infiltration of lymphocytes and mononuclear cells in WT mice, whereas, in Batf3 KO mice only minor abnormalities were observed (histological disease severity score of 6.5 vs. 2.75, $p < 0.05$). Alkaline phosphatase and total bile acid, the biochemical hallmarks of PBC, were decreased in Batf3 KO mice (103 vs. 81 IU/l and 30 vs. 8 μmol/l, respectively, $p < 0.005$). Hepatic expression level of TNFα and IFNγ were both about 2 fold decreased in Batf3 KO mice, $p < 0.05$, further supporting reduced hepatic inflammation in cDC1s-deficient mice. Flow cytometry analysis revealed about 2 fold reduction in hepatic CD4/CD8 T cells ratio in Batf3 KO mice, $p < 0.05$, indicating reduced hepatic $CD8^+$ T cells infiltration. Importantly, Sirius red staining of liver sections exhibit peri-portal collagen deposition only in the control group, a finding that was supported by a statistical significant pro-fibrotic hepatic gene-expression signature in this group.
Conclusion: Overall, these results indicate a role for DCs and specifically the $CD11b^-CD103^+$ DC subset in the pathogenesis of autoimmune cholangitis and improve our understanding concerning break of tolerance mechanisms in PBC. Our findings may pave the road to new immune based cell specific targeted therapeutic endeavours.

FXR agonist obeticholic acid increases gallbladder FGF19 in gallstone patients
S. Al-Dury[1], A. Wahlström[1], P. Katrin[2], T. Anders[3], M. Ståhlman[1], L. Olsson[1], M. Trauner[4], P. Fickert[2], D. Moore[5], F. Backhed[1], L. Fändriks[6], M. Wagner[2], H.-U. Marschall[1]. *[1]Sahlgrenska Academy, University of Gothenburg, Department of Molecular and Clinical Medicine/ Wallenberg Laboratory, Gothenburg, Sweden; [2]Medical University of Graz, Department of Medicine, Graz, Austria; [3]Ersta Hospital, Department of Surgery, Stockholm, Sweden; [4]Medical University of Vienna, Division of Gastroenterology and Hepatology, vienna, Austria; [5]Baylor College of Medicine, Molecular and Cell Biology, Houston, TX, United States; [6]Sahlgrenska Academy, University of Gothenburg, Department of Gastrosurgical Research and Education, Gothenburg, Sweden*
Email: hanns-ulrich.marschall@gu.se

Background and Aims: Obeticholic acid (OCA) is the first in class steroidal agonist of the nuclear farnesoid X receptor (FXR) and was recently approved for the treatment of primary biliary cholangitis (PBC). We aimed to explore the molecular actions of OCA in human liver and gallbladder in patients awaiting laparoscopic gallstone surgery.
Method: As part of the investigator-initiated randomized placebo-controlled OCABSGS trial (NCT01625026) twenty otherwise healthy gallstones patients were randomized to OCA (25mg/day) or matching placebo during three weeks until the day before surgery (study medication kind gift of Intercept). Sampling for serum liver enzymes, lipids, bile acids (BAs), BA synthesis marker C4 (7α-hydroxy-cholest-4-ene-3-one), FGF19 and markers of insulin resistance (HOMA-IR) were obtained before treatment and at the day of surgery. During surgery, biopsies were taken from the liver and the gallbladder, for FXR ChIPSeq, RNASeq, and proteomics. Gallbladder bile acid was investigated for BAs and FGF19.
Results: All patients finished the study per protocol. OCA vs. placebo groups were well matched by gender (female, 80 vs. 80%), age (48.8 ± 8.9 vs. 50.8 ± 13.3 years, all data mean ± SD), BMI (27.9 ± 4.9 vs. 28.7 ± 4.5 kg/m^2), HOMA-IR (2.4 ± 1.5 vs. 2.7 ± 1.8). OCA significantly ($p < 0.05$) increased serum FGF19 (from 95.0 ± 25.2 to 234.4 ± 106.8 ng/L) and decreased serum C4 (from 25.4 ± 22.6 to 1.3 ± 1.7 nmol/L) and endogenous BAs (from 1341 ± 900 to 422 ± 435 nmol/L). FGF19 in gallbladder bile of OCA-treated patients was significantly ($p < 0.005$) higher than in controls (403 ± 165 vs. 135 ± 131 ng/L), whereas biliary BAs were significantly ($p < 0.05$) lower (98.6 ± 76.9 vs. 186.6 ± 100.9 mmol/L). No changes occurred in controls. OCA and its conjugates contributed to total serum and biliary BAs by 45.7 ± 17.3% and 16.9 ± 6.4%, respectively, at the day of surgery. There were no significant correlations between individual serum and gallbladder bile levels of total BAs, OCA and FGF19.
Conclusion: This is the first report describing enriched levels of FGF19 in human bile during treatment of OCA, suggesting that hepatobiliary tree can produce FGF19 in humans. In contrast, the murine homologue FGF15 is not expressed in the hepatobiliary tree.

FRI-199
Loss of BSEP protects MDR2/ABCB4 KO mice from cholestatic liver injury by altering bile acid profile and signaling
C. Fuchs[1], G. Paumgartner[1], V. Mlitz[1], S. Wolfrum[2], A. Wahlström[3], M. Ståhlman[3], T. Stojakovic[4], C. Wolfrum[5], H.-U. Marschall[6], M. Trauner[1]. *[1]Medical University of Vienna, Internal Medicine III, Gastroneterology&Hepatology, Vienna, Austria; [2]ETH Zürich, Laboratorium für Organische Chemie; [3]University of Gothenburg, Department of Molecular and Clinical Medicine; [4]Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics; [5]ETH Zürich, Institute of Food, Nutrition and Health; [6]Department of Molecular and Clinical Medicine, University of Gothenburg, Gothenburg, Sweden*
Email: michael.trauner@meduniwien.ac.at

Background and Aims: Cholestasis is characterized as intrahepatic accumulation of potentially cytotoxic bile acids (BAs) subsequently leading to liver injury reflected by disruption of hepatocellular integrity, inflammation, fibrosis, cirrhosis and increased risk for cancer. Bile salt export pump (Bsep/Abcb11) is the main canalicular BA transporter and rate limiting step for hepatobiliary BA secretion. Here we aim to investigate the role of Bsep in development of liver

injury in a mouse model of sclerosing cholangitis - the Mdr2KO mouse.
Method: To explore the consequences of Bsep loss in a mouse model of sclerosing cholangitis, Mdr2/Bsep double knockout (DKO) mice were generated. WT mice subjected to bile duct ligation (BDL) as well as Mdr2KO mice were fed with a tetrahydroxylated bile acid (THBA). Gene expression profile of inflammatory and fibrotic markers, serum biochemistry, liver histology, immunohistochemistry (IHC) and serum BA composition were assessed.
Results: In contrast to Mdr2KO mice, DKO mice were protected against liver and bile duct injury, reflected by serum biochemistry and H&E staining. Gene expression of inflammatory markers F4/80, Tnfα and Mcp1 remained unchanged (compared to WT Ctrls) in DKO mice, while in Mdr2KO mice these markers were increased (4fold, 6fold and 8fold, respectively; $p < 0,05$). Fibrosis markers were increased in Mdr2KO mice (Desmin 9fold, Col1a1 24fold; $p < 0,05$) but remained unchanged in DKO mice. mRNA expression of Cyp3a11 and Cyp2b10, two enzymes involved in BA hydroxylation/detoxification were increased 5fold and 100fold in DKO mice, respectively, while Mdr2 KO mice showed unchanged levels. In line, 67% of serum BAs in DKO mice were polyhydroxylated, with tetrahydroxylated BAs being most prominent. In Mdr2KO mice, polyhydroxylated BAs were completely absent. Notably THBA feeding profoundly reduced expression levels inflammatory markers (IL1b and Cxcl1 by 50%) and fibrotic marker (Col1a2 by 80%) in Mdr2 KO. In line, THBA feeding improved inflammation in WT BDL mice, reflected by reduced number of F4/80 positive cells and improved gene-expression profile (F4/80 by 50%, Cxcl1 by 55% and Cxcl2 by 75%; $p < 0,05$) compared to WT BDL mice.
Conclusion: Loss of Bsep results in increased expression/activity of enzymes involved in BA hydroxylation/detoxification, thus protecting Mdr2 KO mice from development of cholestatic liver disease. Therefore, THBA may be a new potential treatment strategy for cholestatic liver diseases.

FRI-200
The faecal microbiome of patients with primary sclerosing cholangitis has a characteristic signature across different geographic regions
T. Liwinski[1], F.-A. Heinsen[2], M.-C. Rühlemann[2], C. Bang[2], R. Zenouzi[1], J.R. Hov[3], M. Kummen[3], T.H. Karlsen[3], W. Lieb[4], A. Lohse[1], A. Franke[2], C. Schramm[1]. *[1]University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany; [2]Christian-Albrechts-University of Kiel, Institute of Clinical Molecular Biology, Kiel, Germany; [3]Oslo University Hospital and University of Oslo, Norwegian PSC Research Center, Oslo, Norway; [4]Christian-Albrechts-University of Kiel, Institute of Epidemiology and Biobank Popgen, Kiel, Germany*
Email: t.liwinski@uke.de

Background and Aims: Characteristic changes in the faecal microbiome of patients with primary sclerosing cholangitis (PSC) have been reported in single centre studies. However, it is unknown whether PSC is associated with a common microbial signature across geographical regions.
Method: Stool samples were collected from two independent cohorts in Norway and Germany. A total of 388 patients at a median age of 47 years (range, 15–78) were included in the analysis: 137 patients with PSC including 75 patients with concurrent inflammatory bowel disease (IBD), 118 patients with ulcerative colitis (UC) and 133 healthy controls (HC). The microbiomes were profiled by sequencing of the 16S ribosomal RNA gene targeting the V1-V2 region, biodiversity analysis, machine learning classification, receiver operating characteristic (ROC) analysis and gene set enrichment analysis of the predicted metagenome.
Results: In both cohorts as well as in a pooled analysis, the global microbiota composition (beta diversity) was significantly different between PSC and HC ($p < 0.001$) and between PSC and UC ($p < 0.001$) measured by the Bray-Curtis-dissimilarity. In contrast, no differences were observed between PSC with and without IBD. We found a common microbial signature of 7 genera distinguishing patients with PSC from HC in both the Norwegian and German cohort. Intra-individual (alpha) diversity was not different between PSC and HC in the German cohort, but a decreased alpha diversity was present in the Norwegian PSC patients. We further assessed whether the faecal microbiota can be used to distinguish between healthy and diseased individuals across geographical regions. A random forest classifier trained on the common microbial signature of 7 genera in the German cohort yielded an area under the curve (AUC) of 0.81 classifying the Norwegian subjects in PSC or HC (accuracy 0.72, sensitivity 0.65, specificity 0.84), suggesting a cross-regional common microbiome profile associated with PSC. Gene set enrichment analyses of the predicted metagenomes of patients with PSC were performed independently in the Norwegian and German patients. In both cohorts, we found overexpression of proinflammatory bacterial pathways and pathways of bacterial invasion of epithelial cells.
Conclusion: The faecal microbiome of patients with PSC has a distinct signature common across different geographic areas, underlining the potential pathogenetic relevance of the identified bacterial genera. The metagenomic profile might be skewed towards bacteria-driven intestinal inflammation and gut barrier disruption. Potential causal relationships between PSC and gut microbiota dysbiosis should be further explored by longitudinal analyses.

FRI-201
The faecal microbiome of patients with autoimmune hepatitis is characterised by reduced diversity and is different from healthy subjects and patients with ulcerative colitis
T. Liwinski[1], C. Casar[1], M.-C. Rühlemann[2], C. Bang[2], F.-A. Heinsen[2], R. Zenouzi[1], D. Gerald[3], W. Lieb[4], A. Lohse[1], A. Franke[2], C. Schramm[1]. *[1]University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany; [2]Christian-Albrechts-University of Kiel, Institute of Clinical Molecular Biology, Kiel, Germany; [3]LMU Munich University Hospital, Department of Medicine II, Munich; [4]Christian-Albrechts-University of Kiel, Institute of Epidemiology and Biobank Popgen, Kiel, Germany*
Email: t.liwinski@uke.de

Background and Aims: The intestinal microbiome might affect liver inflammation and hepatic immune regulation via the gut-liver axis. In autoimmune hepatitis (AIH), a disease of unknown aetiology, the intestinal microbiota has not been characterised in detail.
Method: Stool samples were collected from 75 adult patients (58 women and 17 men, median age 62 years) with biopsy-proven diagnosis of AIH, 88 patients with ulcerative colitis (UC) and 95 healthy control (HC) subjects. Seven patients with AIH were excluded because of recent antibiotic use. The microbiomes were analysed by sequencing of the 16S ribosomal RNA gene targeting the V1-V2 region, taxonomic and phylogenetically informed ecological statistics, predictive modelling with random forests, receiver operating characteristic (ROC) analysis and predicted metagenome profiling. All analyses were adjusted for relevant demographic and clinical data and controlled for the false discovery-rate.
Results: The mean intra-individual (alpha) diversity of the stool microbiota in patients with AIH was significantly decreased compared to HC (Faith's phylogenetic diversity (PD), $p = 0.006$), but significantly higher than in patients with UC (PD, $p = 0.001$). The overall microbiota composition (beta diversity) was different in patients with AIH compared to both HC ($p < 0.001$) and UC ($p < 0.001$) as measured by the weighted unique fraction (UniFrac) metric. Biochemical remission was associated with a different microbiome structure in AIH ($p = 0.002$). Several differentially abundant genera were identified comparing AIH to HC (e.g. *Erysipelotrichaceae*, *Lachnospiraceae* and *Streprococcus*) and comparing AIH to UC (e.g. *Lachnospiraceae*, *Clostridia Family XIII* and *Blautia*). The identified

microbial signature was used for predictive modelling of the diagnosis class on patient samples that were randomly split from the whole cohort. In the respective validation cohorts, the classifiers were able to distinguish between AIH or HC (area under the curve (AUC) 0.82, accuracy 0.83, sensitivity 0.75, specificity 0.89) and AIH or UC (AUC 0.89, accuracy 0.8, sensitivity 0.8, specificity 0.81). The predicted metagenome profile showed different expression patterns in several microbial pathways including enrichment of lipopolysaccharide (LPS) synthesis in AIH patients.
Conclusion: The stool microbiome of patients with AIH is characterised by reduced diversity and is different from both healthy subjects and patients with UC. Biochemical remission was associated with changes in faecal microbiota abundance. The predicted metagenome profile hints at an increased exposure of patients with AIH to gut-microbiome derived LPS, which should be confirmed by metagenomic sequencing.

FRI-202
Different bile acids display distinct ability to trigger Nlrp3 inflammasome activation in a cell-dependent manner contributing to cholestatic liver injury and fibrosis
M. Inzaugarat[1], T.M. Holtmann[1], M. Frissen[1], L.J Geisler[1], J. Reissing[1], K. Markus Schneider[1], Z.H. Wolfgang[1], V. Bieghs[1], C. Trautwein[1], A. Wree[1,2]. *[1]RWTH University Hospital Aachen, Department of Internal Medicine III, Aachen, Germany; [2]University of California San Diego, Department of Pediatrics, La Jolla, United States*
Email: minzaugarat@ukaachen.de

Background and Aims: Bile acids are a major component of bile and crucial for the development of liver injury, although the exact mechanisms remained unknown. Thus, our aim was to test the hypothesis that toxic bile acids trigger inflammasome activation, contributing to cholestatic liver fibrosis progression.
Method: Primary hepatocytes, Kupffer Cells (KC) and hepatic stellate cells (HSC) isolated from C57BL/6 WT and Nlrp3 knockout (Nlrp3-/-) mice were stimulated with cholic acid (CA), deoxycholic acid (DA) or lithocholic acid (LCA) for 3 h followed by nigericin or ATP. Additionally, WT and Nlrp3-/- mice were fed with diet supplemented with 0,5% CA, DA or LCA for 7 days. Activation of the NLRP3 inflammasome and inflammatory or fibrotic changes were assessed via histologic quantification, inmunofluorescence, ELISA, gene expression and flow cytometry analysis.
Results: WT HSC displayed increased Nlrp3 and IL1β mRNA levels mature IL1α and Caspase1 activity after treatment with DA or DA + ATP. This Nlrp3 activation was accompanied by an upregulation of connective tissue growth factor (CTGF) and TGF-β mRNA levels, collagen1 and vimentin protein expression after DA or DA + ATP stimulation. On the other hand, LCA or LCA + nigericin treatment increased Nlrp3 and IL1α mRNA levels and mature IL1α by inducing ROS production but not cathepsin B activity in WT KC. Moreover, pyroptosis but not necrosis, mRNA levels of TNF, iNOS, CCR8, Activin A and CCL22, as well as galectin 3 protein expression were found increased in WT KC after LCA or LCA + nigericin treatment. Interestingly, Nlrp3-/- HSC or KC failed to upregulate IL1α expression as well as fibrotic or inflammatory markers after DA or LCA treatment. In contrast, bile acids did not show an effect on Nlrp3 expression or ALT and AST levels in WT hepatocytes. LCA-fed WT mice showed increased ALT, AST, and GLDH serum levels and presence of inflammation; while DA-fed mice displayed augmented ALT, AST, and GLDH serum levels, and signs of fibrosis. Nlrp3-/- mice fed with LCA or DA diet showed an improvement in AST serum levels as well as ameliorated inflammation and fibrosis. WT or Nlrp3-/- mice fed with CA supplemented diet did not show any change in the liver.
Conclusion: Toxic bile acids are able to trigger Nlrp3 inflammasome expression and activation in a cell-specific manner, inducing upregulation of inflammatory and fibrotic markers.

FRI-203
Decreased ratio of Tregs to Th17 cells exacerbates disease progression of autoimmune hepatitis
Y. Liu, W. Yan, W. Yuan, P. Wang, D. Huang, Q. Ning. *Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology*
Email: qning@vip.sina.com

Background and Aims: $CD4^+$ $CD25^+$ $Foxp3^+$ regulatory T cells (Tregs) functions to restrain excessive effector T cell responses, IL-17-producing Th cells (Th17) is a key player in the pathogenesis of autoimmune disorder. In this study, we aimed to explore the role of Treg/Th17 balance in a murine model of autoimmune hepatitis (AIH) induced by human cytochrome P4502D6 (CYP2D6) and patients with AIH.
Method: The AIH murine model was established by delivering adenovirus vector containing CYP2D6 (Ad-2D6) into the liver of C57BL/6 mice intravenously and intraperitoneally. Treg/Th17 balance in the liver of Ad-2D6 mice including their frequencies and production of functional cytokines were evaluated by multi-colour flow cytometric assay and Enzyme-linked immunosorbent assay (ELISA) respectively. An immunotherapy strategy was performed on Ad-2D6 mice by adoptively transferring with $CD4^+CD25^+$ T cells isolated from healthy mice using MACS microbeads at week 3 and week 4 post infection. The peripheral Treg/Th17 balance was also detected in 18 AIH patients.
Results: Compared with control group, Ad-2D6 mice exhibited progressive liver damage including inflammatory cell infiltration and piecemeal necrosis in the portal area and central vein from 2–4 weeks post infection. A significantly higher serum titers of IgG (week 2 and week 4, $P < 0.05$) and detectable autoantibody against CYP2D6 were observed. Interestingly, Ad-2D6 mice showed a significant and sustained decrease in proportion of hepatic Tregs and ratio of Treg/Th17 (week 4 and week 6, $P < 0.05$), and an obvious increase in hepatic IL-17 and IL-22 expression (week 4, $P < 0.05$). Adoptive transfer with $CD4^+CD25^+$ T cells resulted in improved hepatic pathological feature, decreased IgG and autoantibody titers, which might be attributed to the significantly increased Treg/Th17 ratio ($P < 0.05$) and decreased levels of hepatic IL-17 ($P < 0.05$) and IL-22. AIH patients with Child-Pugh class B or C showed significant lower treg proportions ($P < 0.05$) and relative lower ratio of Treg/Th17 than those of patients with Child-Pugh class A.
Conclusion: The decreased ratio of Treg/Th17 was involved in the immunopathogenesis of AIH. Adoptive immunotherapy with $CD4^+CD25^+$T cells could be in favor of correcting Treg/Th17 imbalance and preventing poor prognosis of AIH.

FRI-204
A novel CCL24 blocking monoclonal antibody ameliorates liver injury in experimental models of cholestasis
M. Segal[1], A. Katav[2], S. Hashmueli[3], A. Aharon[1], M. Pinzani[4], J. George[5], A. Hall[4], A. Mor[1]. *[1]Chemomab, Chemomab, Tel Aviv, Israel; [2]Chemomab, Chemomab, Israel; [3]Chemomab, Chemomab, TelAviv, Israel; [4]University College London, University College London, London, United Kingdom; [5]Kaplan medical center, Kaplan medical center, Israel*
Email: adimor@chemomab.com

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease characterized by progressive destruction of bile ducts caused by diffuse inflammation and fibrosis. Chemokines are proteins that share the ability to induce migration and activation of specific subsets of cells and play a critical role in inducing liver inflammation and fibrosis. CCL24, a pro inflammatory and profibrotic chemokine, was recently found to be involved in the progression of inflammatory and fibrotic pathways and tested for its involvement in PSC.
In this study we tested the expression levels of CCL24 and its cognate receptor-CCR3 in liver tissues from PSC patients and explored the effect of CM101, a novel CCL24 blocking monoclonal antibody, on

biliary inflammation and fibrosis progression in two experimental animal models of cholestasis recapitulating features of PSC.
Method: Immunofluorescence was performed to detect CCL24 and CCR3 expression in liver biopsies from PSC patients. The antifibrotic and anti-inflammatory effects of CM101 were evaluated in two animal models: bile duct ligation (BDL) in rats and acute α-naphthylisothiocyanate (ANIT) induced cholestasis in mice. For the BDL model, Sprague Dawley rats underwent bile duct ligation and treated with CM101 at 10mg/kg IV twice weekly for two weeks. ANIT induced cholestasis model was evaluated in mice treated with 60 mg/kg ANIT with or without a single IV dose of 10mg/kg CM101 and scarified on day 3.
Results: Liver samples from PSC patients exhibited a significant overexpression of CCL24 in immune cells and hepatocytes; CCL24's receptor, CCR3, was significantly overexpressed in hepatocytes.
Blockade of CCL24, using CM101, showed significant reduction of liver damage employing the two experimental cholestasis models. In the BDL model 10mg/kg CM101 resulted in 50% reduction in the fibrosis area compared with the control treated group, $p < 0.05$. Additionally, ALT levels were reduced significantly in the CM101 treated group compared to vehicle (154.9 ± 13.8, compare to 119.7 ± 9.5), $P \leq 0.05$. In the ANIT induced cholestasis model, we found that liver enzymes including ALK phosphatase, Bilirubin, AST and ALT were significantly reduced in the CM101 treated mice group as compared to control mice. $P \leq 0.05$, $P \leq 0.01$. Biliary necrosis, biliary neutrophilic infiltration, fibroblast proliferation and Hepatic necrosis were scored using a 1–3 score according to histological findings. CM101 treated animals exhibited significantly reduced scores (4.5 ± 1, n = 8) as compared with vehicle treated group (5.8 ± 0.8, n = 8) in ANIT induced cholestasis model $P \leq 0.05$.
Conclusion: The CCL24-CCR3 is significantly over expressed in patients with PSC. Ablation of CCL24 with the novel monoclonal antibody CM101 resulted in attenuation of experimental cholestasis. Thus, CCL24 appears as an attractive new target for treatment in patients with PSC.

FRI-205
Generation of a novel mouse model for the study of autoimmune liver disease overlap syndrome
S. Fuchs[1], M. Bayer[1], M.P. Manns[2], E. Hintermann[1], U. Christen[1].
[1]Goethe University Hospital Frankfurt, Pharmazentrum Frankfurt, Frankfurt am Main, Germany; [2]Dept. of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany
Email: christen@med.uni-frankfurt.de

Background and Aims: Autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC) have in common that an aggressive autoimmune reaction results in liver tissue destruction and development of severe hepatic fibrosis. Patients are classified as having an overlap syndrome (OS) if they display overlapping features within the spectrum of these autoimmune liver diseases (ALD). AIH-PSC OS is characterized by an interface hepatitis with or without plasmacytosis, portal edema or fibrosis, ductopenia, ductal distortion and proliferation, cholate stasis or obliterative fibrous cholangitis. Further the criteria include elevated levels of AST/ALT, γ-globulin, IgG, AP, GGT as well as the absence of AMA. The aim of our study was to generate a mouse model that reflects human AIH-PSC OS and allows for an investigation of the pathogenesis.
Method: We combined two well-established mouse models: First, the CYP2D6 mouse model for AIH, in which wildtype mice are infected with an Adenovirus encoding the human autoantigen cytochrome P450 2D6 (Ad-2D6). Second, the mdr2 KO mouse which develop PSC-like disease spontaneously. Thus, mdr2 KO mice were infected with Ad-2D6 and the obtained data compared to those from mice with solitary AIH or PSC.
Results: Ad-2D6-infection of mdr2 KO mice at week 7 of age resulted in several clinical AIH-PSC OS features.
Serology: ALT and AP levels were strongest in the AIH-PSC OS model group. The kinetic pattern of ALT seems to follow the one found for solitary AIH. Similarly, the kinetic pattern for AP followed the one from the solitary PSC group, indicating that one ALD is exacerbating the serological markers of the other disease.
Histology: Cholangitis, fibrosis, and cellular infiltration was significantly exacerbated in the AIH-PSC OS group as detected and quantified for selected markers, such as CK19 (cholangiocytes), desmin (HSC), collagen III (fibrosis), CD4 T cells, B cells, CD11b+ and CD11c+ cells. Enhanced expansion of cholangiocytes was accompanied by a high number of HSC in the fibrotic periductal region.
Specific immune response: No significant increase in anti-CYP2D6 antibody titer has been observed in the AIH-PSC OS group. In contrast, we found a higher activity of pANCA-like antibodies in the AIH-PSC OS group compared to mice with solitary PSC. However, the frequency of CYP2D6-specific T cells was enhanced in the AIH-PSC OS group.
Conclusion: Our data suggest that infection of mdr2 KO mice with Ad-2D6 indeed results in a model system that reflects many aspects of an AIH-PSC OS as found in patients including elevated serologic liver damage makers, enhanced cholangitis and fibrosis, exacerbated interface hepatitis-like cellular infiltration of the liver, higher levels of pANCA-like antibody reactivity and enhanced CYP2D6-specific T cell immune response.

FRI-206
Anticholestatic mechanisms of ursodeoxycholic acid in inflammatory cholestasis induced by lipopolysacharide
M.V. Razori[1], P.M. Maidagan[1], E.S.S. Silva[2], N. Ciriaci[1], I. Barosso[1], M.L. Ruiz[1], M.G. Roma[1]. *[1]Institute of Experimental Physiology (CONICET-UNR), Faculty of Biochemical & Pharmaceutical Sciences, Rosario; [2]Health Science Department, DCBS, Universidad Autónoma Metropolitana (UAM), D.F., Mexico*
Email: roma@ifise-conicet.gov.ar

Background and Aims: Sepsis-induced cholestatic is causally associated with the release of lipoplysacaride (LPS) from Gram (-) bacteria; LPS stimulates the production of inflammatory cytokines, and the further impairment in expression/localization of transporters involved in bile formation, such as Bsep (bile salt transporter) and Mrp2 (bilirubin/GSH transporter). There is no established therapy for sepsis-induced cholestasis. Ursodeoxycholic acid (UDCA) is the most widely used therapeutic agent for human cholestatic diseases, but its action mechanisms in inflammatory cholestasis are largely unknown. Therefore, we addressed this issue in the rat model of LPS-induced cholestasis.
Method: Male Wistar rats were randomized in 4 experimental groups: Control, UDCA (25 mg/Kg/day, i.p., 5 days), LPS (10 mg/Kg, i.p., over the last 2 days), and UDCA + LPS. On the 6th day, we assessed serum alkaline phosphatase (ALP, a membrane enzyme induced/removed by bile salts accumulated in cholestasis), bile salt output (BSO), total glutathione output (GSHtO), Bsep expression by real-time RT-PCR and Western blotting, and Bsep localization by immunofluorescence staining followed by confocal microscopy, image analysis, and statistical comparison of the densitometric profiles along a line perpendicular to the canaliculus by Mann-Whitney test. Circulating levels of the inflammatory cytokines TNF-α and IL-6 were measured by ELISA.
Results: (expressed as % of control; $^{*}p < 0.05$ *vs.* control; $^{\#}p < 0.05$ *vs.* LPS). Administration of UDCA to LPS-treated rats reduced serum ALP (199 ± 16$^{*\#}$ *vs.* 280 ± 16%*), and increased BSO (85 ± 20%$^{*\#}$ *vs.* 58 ± 10%*), but not GSHtO. This was associated with an improvement in the proportion of Bsep in the apical membrane, assessed by western blot (85 ± 20% *vs.* 66 ± 9*). Improved membrane localization was confirmed by comparing Bsep densitometric profiles in confocal images (see figure); LPS decreased the fluorescence intensity in the canalicular area, associated with an increase in the pericanalicular region ($p < 0.001$ *vs.* control), and this was counteracted by UDCA.

UDCA also normalized Bsep mRNA levels ($119 \pm 40^{\#}$ *vs.* $15 \pm 3^{*}$), without attenuating LPS-induced serum TNF-α and IL-6 elevations.

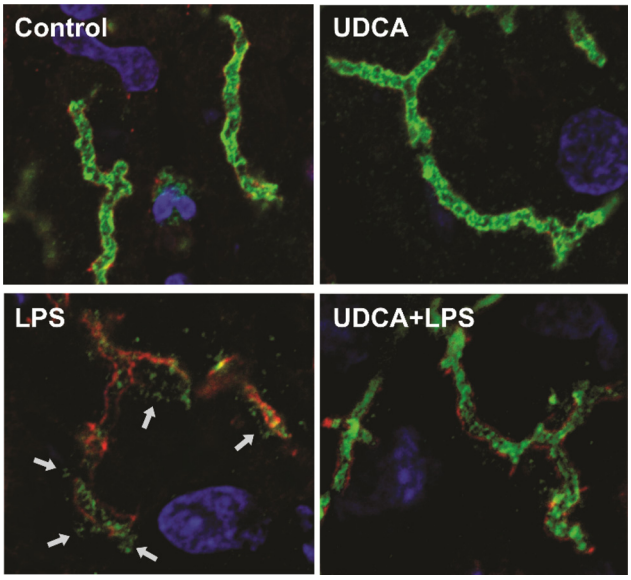

Figure 1: Co-immunostaining of Bsep (green), occludin (red, a canalicular limit marker). LPS relocalized Bsep from the canalicular to the pericanalicular area (arrows), and this effect was prevented by UDCA.

Conclusion: UDCA improves bile salt biliary excretion by mechanisms unrelated to immunosuppressive effects. Its beneficial effects rather involve improvement in gene expression and canalicular membrane localization of Bsep. These effects are likely due to the well-recognized properties of UDCA as a nuclear-receptor ligand and as a stimulator of Bsep canalicular trafficking from its synthesis place, respectively, thus affording proper localization to the newly synthesized transporters.

Email: naiara.beraza@quadram.ac.uk

Background and Aims: Human cholestasis comprises etiologically heterogeneous conditions characterized by the accumulation of bile acids in the liver that actively contribute to liver injury. We previously described that Sirtuin 1 (SIRT1), a histone deacetylase, controls bile acid (BA) metabolism via the regulation of farnesoid X receptor (FXR). We found that the overexpression of SIRT1 impaired liver regeneration that was associated with the inhibition of FXR and increased BA synthesis. Notably, we found that Nor-Ursodeoxycholic acid (NorUDCA) reduces SIRT1 expression in the liver, overall alleviating the damaging phenotype found in SIRT1 overexpressing mice ($SIRT^{oe}$) after PH. We aim to investigate the implication of SIRT1 during cholestatic liver disease.
Method: SIRT1 expression was determined in livers from patients with cholestatic disease (PSC and PBC), in mice following bile duct ligation (BDL) and in primary hepatocytes in response to bile acid (BA) load. The BDL experimental model was applied to SIRT1 overexpressing mice ($SIRT^{oe}$) to determine the biological relevance of SIRT1 during cholestasis. Additionally, a group of $SIRT^{oe}$ mice were treated with NorUDCA and subjected to BDL.
Results: SIRT1 gene and protein expression were up-regulated in livers from PBC and PSC patients, suggesting the regulation of SIRT1 as a general mechanism occurring during cholestasis regardless of the aetiology. Further studies in mice after BDL and in mouse primary hepatocytes confirmed the up-regulation of SIRT1 in response to BA. To gain understanding on the biological relevance of SIRT1 up-regulation during cholestasis, $SIRT^{oe}$ mice were subjected to BDL and showed aggravated parenchymal injury and increased fibrogenesis when compared to WT/BDL animals. SIRT1 overexpression correlated with lower FXR expression and increased BA synthesis. Increased accumulation of toxic BA in the liver was further associated with higher apoptotic cell death and lower NF-κB activation in hepatocytes from $SIRT^{oe}$ mice compared to WTs, both *in vivo* and *in vitro*. Finally, reduced liver parenchymal damage found in $SIRT^{oe}$/NorUDCA/BDL mice was associated with attenuated SIRT1 expression and restored FXR and NF-κB signalling.
Conclusion: SIRT1 expression is increased during human and murine cholestasis and has a detrimental role in mediating cholestasis-induced liver injury. Attenuation of SIRT1 represents a potential mechanism of action for NorUDCA in attenuating liver injury during cholestasis.

FRI-208

Leukemia inhibitory factor induces cholangiocyte proliferation and corrects the impaired bile duct proliferation in sortilin-deficient mice following cholestatic injury

I. Zvibel[1], E. Hubel[1], R. Avraham[1], E. Lavoie[2], S. Fishman[1], J. Dranoff[2], O. Shibolet[1]. [1]*Ichilov Hospital, Tel Aviv-Yafo, Israel;* [2]*University of Arkansas at Little Rock, Little Rock, United States*
Email: isab@tlvmc.gov.il

Background/Aims: Sortilin, a member of the Vps10 domain receptor family, acts both as a trafficking molecule and as a co-receptor. In its role as co-receptor, sortilin enhances the leukemia inhibitory factor (LIF) receptor/gp130 signal, which may regulate cholangiocyte proliferation, induction of reactive cholangiocytes and bile duct morphogenesis. We have investigated the role of played by sortilin in the induction of reactive cholangiocytes and in bile duct morphogenesis in cholestatic liver injury, and whether it is mediated via LIF signaling.
Methods: Cholestatic liver injury was induced by bile duct ligation (BDL) in WT and *Sortilin1*$^{-/-}$ (*Sort1*$^{-/-}$) mice. LIF (1μg/mouse) was administered daily to WT and *Sort1*$^{-/-}$ mice for 3 and 14 days following BDL. Cholangiocyte proliferation was assessed by Ki67 immunohistochemistry (IHC) and bile duct morphogenesis by IHC for cytokeratin 19 (CK19). Reactive cholangiocytes were characterized by immunofluorescence and immunobloting for integrin β6, connective tissue growth factor and osteopontin.
Results: *Sort1*$^{-/-}$ mice displayed strikingly diminished ductular reaction, demonstrated by reduced cholangiocyte proliferation and attenuated formation of reactive cholangiocytes 3 days after BDL. Notably, 14d after BDL, while WT and *Sort1*$^{-/-}$ had similar numbers of CK19-positive cholangiocytes, *Sort1*$^{-/-}$ mice had significantly less CK19-positive cholangiocytes forming ducts, indicating impaired bile duct morphogenesis. The impaired bile duct morphogenesis was accompanied by attenuated expression of morphogenesis transcription factor Hes1, a target of Notch2-Jagged1 signaling. LIF administration for 3 days to bile duct-ligated WT or *Sort1*$^{-/-}$ mice increased cholangiocyte proliferation, but did not induce expression of reactive cholangiocyte markers. LIF administration for 14 days to bile duct ligated *Sort1*$^{-/-}$ corrected the impaired bile duct morphogenesis, accompanied by increased expression of Hes1.

Conclusion: Sortilin mediates the ductular reaction and ductular morphogenesis in the setting of cholestatic injury at least in part by regulation of LIF signaling.

FRI-209

Relapse of autoimmune hepatitis is associated with a low intrahepatic ratio of regulatory T cells to cytotoxic T cells prior to immunosuppression withdrawal

F. Derben[1], J. Hartl[2], J. Schlue[3], A. Lohse[2], M.P. Manns[4], C. Schramm[2], E. Jaeckel[1], R. Taubert[1]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]University Medical Centre Hamburg-Eppendorf (UKE), 1st Department of Medicine, Hamburg, Germany; [3]Hannover Medical School, Institute for Pathology, Hannover, Germany; [4]Dept. of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany*
Email: Finn.C.Derben@stud.mh-hannover.de

Background and Aims: The majority of autoimmune hepatitis (AIH) patients reach biochemical remission (BR) under steroid and azathioprine based therapies. After at least 2 years of BR an immunosuppression withdrawal can be attempted, although a relapse is common. Intrahepatic regulatory T cells (Tregs) decline overproportionally under immunosuppressive therapy and more intrahepatic Tregs are associated with the achievement of BR. In the current study the intrahepatic T cells compartment in pre-weaning biopsies should be assessed with regard to the success of the subsequent immunosuppression withdrawal.
Method: Intrahepatic $CD4^+$ and $CD8^+$ T cells as well as $CD4^+FOXP3^+$Tregs were quantified with immunofluorescence co-staining of CD4, CD8 and FOXP3 in liver biopsies taken from 24 AIH patients at two centers before immunosuppression withdrawal.
Results: All patients had stable BR before pre-weaning liver biopsies were taken. All biopsies exhibited a histological remission (hepatitis activity index (HAI) ≤ 3). AIH relapsed in 12/24 (50%) patients after in median 7 (range: 1–66) months after initiation of weaning. Patients with sustained remission (SR) were followed in median 20 (3–54) months after initiation of weaning.
From all histological parameters of intrahepatic T cell infiltration (portal infiltration densities and portal cell ratios of $CD4^+$, $CD8^+$, and $CD4^+FOXP3^+$ cells; size of portal infiltrates) only the ratio of $CD4^+FOXP3^+$ Tregs to $CD8^+$ cells was significantly higher (SR: 0.15 ± 0.07; relapse (R): 0.10 ± 0.04; p = 0.045) in pre-weaning liver biopsies with subsequent SR. Furthermore, SR was associated with a lower HAI in pre-weaning biopsies (SR: 0.7 ± 0.5; R: 1.6 ± 1.1; p = 0.039). However, T cell infiltration parameters were not significantly associated with the HAI in the pre-weaning biopsy. Time until AIH relapsed was not reliably associated with any T cell infiltration parameters also.
Liver biopsies from the time of AIH diagnosis were only available from 2 patients with relapse and 8 patients with SR. Thus, no reasonable analysis of the initial T cell infiltration was possible, yet.
Conclusion: The local balance of Tregs and cytotoxic T cells in the liver itself seems to be related to the degree of sustained AIH remission. An increased Treg/CD8 ratio in the liver is also associated with liver graft protection in T cell-mediated rejection and with a worse prognosis in hepatocellular carcinoma.

FRI-210

Experimental autoimmune hepatitis in mice is associated with formation of ectopic lymphoid tissue in the liver

M. Preti, A.-L. Mueller, D. Krzikalla, D. Schwinge, A. Lohse, C. Schramm, A. Carambia, J. Herkel. *Uniersitätsklinikum Hamburg Eppendorf, I. Department of Medicine, Hamburg, Germany*
Email: max_preti@yahoo.it

Background and Aims: We have previously described a new autoimmune hepatitis model in mice, which express an MHC class II-restricted immunodominant T cell epitope of the Lymphocytic Choriomeningitis Virus glycoprotein (GP_{61-80}) specifically in hepatocytes, and which are also transgenic for a T cell receptor recognizing the GP_{61-80} peptide (EASL Abstract in: Journal of Hepatology 2017; Vol.66, Issue 1, S74). Using this model, we here investigated the formation of ectopic lymphoid tissue (ELT) in the pathogenesis of autoimmune hepatitis. ELT are inducible centres for generating antigen-specific immune responses, formed in non-lymphoid organs mainly by T and B cell aggregates together with follicular dendritic cells.
Method: ELT formation was characterized by histological analysis of HE-stained paraffin-embedded liver sections taken at various disease stages. ELT encapsulation was confirmed by Sirius red staining. Immune cell aggregates within ELT were characterized by staining of CD4+ T cells, B220+ B cells or follicular dendritic cells.
Results: Already at an age of 4 weeks, almost all mice showed ELT formation exclusively in the liver. At that age, these mice displayed only mild periportal infiltrates and no overt hepatitis. ELTs were encapsulated and showed a high degree of organisation, with T and B cell zones, interspersed with Foxp3+ regulatory T cells and dendritic cells. At an advanced disease stage, at 20–30 weeks of age, these mice spontaneously developed autoimmune liver disease resembling human autoimmune hepatitis, marked by periportal lymphocytic infiltrates, interface hepatitis, elevated serum ALT, and antinuclear autoantibodies, resulting in over 50% mortality by the age of 30 weeks. At that disease stage with overt hepatitis, hepatic ELTs had vanished and the characteristic cell aggregates of T cells, B cells and dendritic cells were dispersed and had merged into the large hepatic infiltrates.
Conclusion: Hepatic ELT formation occurs early in the pathogenesis of autoimmune liver disease. However, the pathogenic drive exerted by hepatic ELTs may be concealed in advanced disease stages, as ELTs merge into the inflammatory liver infiltrates, suggesting that the pathogenic relevance of ELTs for autoimmune liver diseases might have been underestimated.

FRI-211

Cell therapy for acute liver injury- *in vivo* efficacy of mesenchymal stromal cells in toxic and immune-mediated murine hepatitis

M. Alfaifi[1], V. Vigneswara[1], N.-T. Luu[1], C. Baan[3], M. Hoogduijn[3], M. Gargesha[2], D. Roy[2], S. Elliman[4], L. O'flynn[4], G.M. Hirschfield[1], P.N. Newsome[1]. *[1]National Institute for Health Research (NIHR) Birmingham Liver Biomedical Research Unit and Centre for Liver Research, University of Birmingham, United Kingdom, [2]BioInVision, Cleveland, United States, [3] Erasmus Medical Centre, University of Rotterdam, Rotterdam, Netherlands, [4]Orbsen Therapeutics, Galway, Ireland.*
Email: p.n.newsome@bham.ac.uk

Background and Aims: The ability of umbilical cord-derived mesenchymal stromal cells (MSC) to immunomodulate offers therapeutic potential in liver injury but the inherent heterogeneity of unsorted MSC populations may explain varied/reduced function as well as posing regulatory challenges. Thus, we aimed to evaluate the therapeutic potential and the mechanism of action of purified CD362+ MSC infusion in murine models of acute liver injury.
Method: Umbilical cord (UC) derived MSC were injected intravenously into 8–10 week old male C57Bl/6 injured by single dose of Carbon tetrachloride (CCl4) & Ova-Bil mice (allo-immune liver injury induced by infusion of OT1 and OT2 cells). MSC used were either unsorted or sorted CD362+. The extent of liver damage was determined by liver histology, serum analysis, gene expression and FACS analysis 3 or 5 days after cell infusion. Homing and biodistribution of stem cells was determined by whole mouse cryo-imaging of Q-dot labelled MSC following infusion of UC-MSC into injured mice.
Results: $CD362^+$ MSC were as effective as unsorted MSC in ameliorating liver injury, with reductions in serum ALT seen in both models: CCl_4 - ALT 138 IU vs 50 IU in control (Con) group. Ova-Bil

mice - ALT 345 IU vs 102 IU in Con group. In contrast heat-inactivated MSC had no effect on liver injury. MSC also led to a reduction in CD45+ staining on liver sections in both models of liver injury corroborated by an accompanying reduction in hepatic CD45+ cells in (FACS analysis of liver digest). In addition there was a significant reduction in hepatic CD19+ B cells (75005 cells/g tissue vs 143801/g tissue) in digested liver in CCl_4 injury. Cryo-imaging of three or five days' time-course in both animal models indicated that MSC had migrated to the lung within 1 hour and were then cleared rapidly, although there was a liver-specific increase in MSC 2–3 day in Ova-Bil mice.

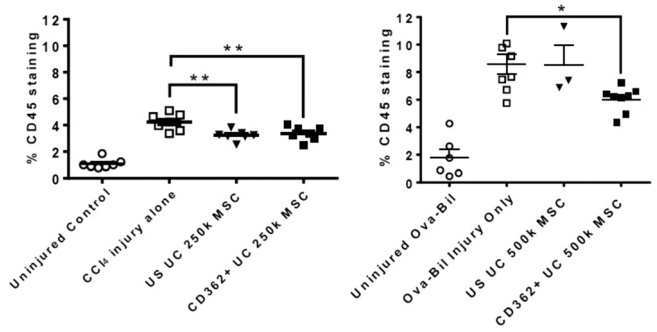

Figure 1: Hepatic CD45 staining following MSC administration

Conclusion: CD362^{+} human MSC exert potent anti-inflammatory activity in toxic and immune-mediated murine liver injury with demonstrable reductions in infiltrating inflammatory leucocytes and B cells.

FRI-212

Cu isotope ratio shifts in common bile duct ligated mice and correlates with the degree of cholestatic-induced liver disease

S.V. Campenhout[1], M. Costas-Rodríguez[2], A.A.M.B. Hastuti[2], S. Raevens[1], A. Geerts[1], X. Verhelst[1], F. Vanhaecke[2], H.V. Vlierberghe[2], L. Devisscher[1]. *[1]Ghent University, Gastroenterology and Hepatology, Ghent, Belgium; [2]Ghent University, Chemistry, Ghent, Belgium*
Email: Sanne.VanCampenhout@UGent.be

Background and Aims: Chronic liver disease covers a range of hepatic disorders which have resulted in liver cirrhosis. Identifying mechanisms which drive disease progression and non-invasive markers that can identify patients at risk are important challenges. We have previously shown that the serum Cu isotope ratio shifts in female cirrhotic patients in favour of the lighter isotope ^{63}Cu compared to ^{65}Cu, and that the magnitude of this shift correlates with disease severity. To date, it is unclear which mechanisms are at the basis of this shift. Here, we used the common bile duct ligation (CBDL) model to investigate the different stages of cholestatic-induced liver disease and its correlation to Cu isotope ratios.
Method: Eight-week-old SV129 mice underwent a CBDL or sham surgery and were analysed 2, 4, 6 and 8 weeks post surgery. Liver disease was determined by serum bilirubin levels, Metavir fibrosis score and hepatic pro-inflammatory cytokine and chemokine levels. Multi-collector inductively coupled plasma-mass spectrometry was applied to determine Cu isotope ratios in serum and tissues. Duodenal explants from CBDL and sham operated mice were used to evaluate the contribution of two metal receptors CTR1 and DMT1 to Cu isotope uptake specificity.
Results: CBDL operated mice gradually developed cholestasis as demonstrated by higher total and direct bilirubin levels 2, 4, 6 and 8 weeks post surgery ($p < 0.05$). This was associated with increased absolute and relative liver and spleen weights ($p < 0.0001$) and a decrease in body weight ($p < 0.001$). Hepatic inflammatory chemokines CXCl1 and CCl2 were increased in CBDL mice compared to sham operated mice, independent of gender or time post surgery ($p < 0.0001$). Mice developed F2 and F3 fibrosis after 6 and 8 weeks of CBDL, respectively. Determination of Cu isotope ratios in different organs and serum revealed an overall shift in favour of the lighter isotope ^{63}Cu (ranged from -0.2 to -1.4 per mille) which correlated with the levels of bilirubin, inflammatory chemokines and fibrosis ($p<0.003$). Duodenal explants from CBDL mice incubated with Fe, Zn and Cu showed a lower ^{65}Cu/^{63}Cu isotope ratio compared to tissue from sham mice whereas this was not observed when DMT1 inhibitor was co-administered.
Conclusion: Cholestasis is associated with a Cu isotope ratio shift in favour of the lighter isotopes in mouse serum and tissue and this might be mediated by a changed preference of DMT1 for Cu isotope uptake in the duodenum.

FRI-213

Sarcopenia induction in a mouse model of chronic cholestatic liver disease: Role of the ubiquitin-proteasome system and oxidative stress

C. Cabello-Verrugio[1], F. Campos[1], J. Abrigo[1], F. Aguirre[1], B. Garces[1], M. Arrese[2], D. Cabrera[3], F. Simon[1]. *[1]Facultad de Ciencias Biológicas & Facultad de Medicina, Universidad Andres Bello, Departamento de Ciencias Biológicas, Santiago, Chile; [2]Facultad de Medicina, Pontificia Universidad Católica de Chile., Departamento de Gastroenterologia, Santiago, Chile; [3]Facultad de Salud, Universidad Bernardo O Higgins., Departamento de Ciencias Químicas y Biológicas, Santiago, Chile*
Email: claudio.cabello.verrugio@gmail.com

Background and Aims: Sarcopenia is defined as decreased muscle mass and strength and has been associated with the progression of chronic liver diseases (CLD). However, the physio pathological mechanisms behind this association remain ill-defined. The most common mechanisms of muscle weakness induction are decreased fiber diameter and myosin heavy chain (MHC) levels and increased activity of ubiquitin-proteasome system (UPS) and reactive oxygen species (ROS). In this study, we aim to characterize the development of sarcopenia secondary to CLD induced by the hepatotoxin 5-diethoxycarbonyl-1,4-dihydrocollidine (DDC), a model of Sclerosing Cholangitis and Biliary Fibrosis.
Method: Six four-months-old male mice (C57BL6) were fed a normal diet or DDC supplemented diet for 6 weeks. Functional tests to evaluate muscle strength, mobility, and motor skills were performed while the mice were alive. The muscle strength in isolated gastrocnemius was also assayed via electrophysiological measurements. Morphometric measures of fibers' diameter and types were determined through immunofluorescence. Total and ubiquitinated protein levels of myosin heavy chain (MHC) and E3 ubiquitin ligases were evaluated by Western Blot and Immunoprecipitation assays. Reactive oxygen species (ROS), and oxidation-dependent modified protein in gastrocnemius tissue were also determined.
Results: Our results showed that DDC fed mice developed sarcopenia as evidenced by a loss of muscle mass and strength (Fig.1A). Likewise, muscle fiber cross sectional area also was decreased in DDC fed mice which also present a different pattern of muscle fibers types and a reduced MHC protein levels (Fig 1B and C, respectively). While muscle UPS activity (Fig. 1D), ROS levels, and oxidation-modified protein levels were increased. Interestingly, these results were correlated with serum bile acids levels and additionally the results observed were not due to changes in food and water intake or mice mobility (Fig. 1E) since we did not find any differences in these parameters. Fig. 1F shows the histological injury and inflammation observed in DDC fed mice evaluated through Hematoxylin/Eosin staining.
Conclusion: Together, our results shows that DDC fed mice develops sarcopenia involving decreased levels of myofibrillar proteins, increased UPS activity, and oxidative stress. These results were correlated with serum bile acids levels but not with food intake or mobility.

The atypical antidepressant mirtazapine is hepatoprotective in a mouse model of immune-mediated hepatitis

W. Almishri[1], A.A. Shaheen[2], G. Kaplan[3,4], M.G Swain[5,6]. *[1]University of Calgary, Department of Medicine, Snyder Institute for Chronic Diseases; [2]Cumming School of Medicine, Department of Medicine, Division of Gastroenterology and Hepatology; [3]Department of Medicine, Division of Gastroenterology and Hepatology; [4]Cumming School of Medicine; [5]Snyder Institute for Chronic Diseases, Department of Medicine; [6]Division of Gastroenterology and Hepatology*
Email: swain@ucalgary.ca

Background and Aims: Depression is a prevalent comorbidity in many immune-mediated diseases, often requiring antidepressant therapy. Some antidepressants exhibit immunomodulatory activity, including the atypical antidepressant mirtazapine (mitz). Therefore, we performed a series of experiments to determine the impact of mitz treatment on liver injury in a well characterized model of immune-mediated liver damage due to administration of concanavalin A (con A) in mice.

Method: C57BL/6 mice were treated with vehicle (veh), con A (13.5 mg/kg IV) or con A+ mitz (20 mg/kg ip) and liver/ blood samples collected 3 and 16 hrs later. Liver injury was assessed by measuring plasma ALT levels and microscopic hepatic necrosis scores. Hepatic cytokine/ chemokine levels were measured by Luminex® and immune cell infiltration by flow cytometry and immunohistochemistry (IHC). Expression of hepatic adhesion molecules was determined by IHC.

Results: Mitz administration markedly attenuated Con A-induced liver damage, as reflected by decreased ALT levels (ALT IU/L: veh = 39.8 ± 26.0 vs. con A+ veh = 3769 ± 1703 vs. Con A+ mirtz = 416 ± 237; ***p ≤0.001 conA+ veh vs. other groups) and hepatic necrosis scores. Moreover, mitz treatment significantly reduced con A-induced increases in hepatic TNFα and IFNγ levels. IFN-γ pg/mg protein: veh = 0.1 ± 0.02 vs. con A+ veh = 1.4 ± 0.068 vs. con A+ mitz = 0.9 ± 0.13; ***p ≤ 0.001 veh vs. other groups; **p ≤ 0.01 con A+ veh vs. con A+ mitz group; TNFα pg/mg protein: veh = 0.5 ± 0.05 vs. con A+ veh = 1.3 ± 0.07 vs. con A+ mitz = 0.8 ± 0.1; ***p ≤ 0.001 con A+ veh vs. other groups; **p ≤ 0.01 veh vs. con A+ mitz group. Mitz also prevented con A-induced increases in hepatic ICAM-1 expression. Hepatic lymphocyte recruitment was similar in con A vs. con A+ mitz treated groups, however mitz treatment reduced Con A-induced hepatic neutrophil recruitment by ~50% (*p ≤ 0.017) and hepatic expression of the key neutrophil chemoattractants CXCL1 and CXCL2.

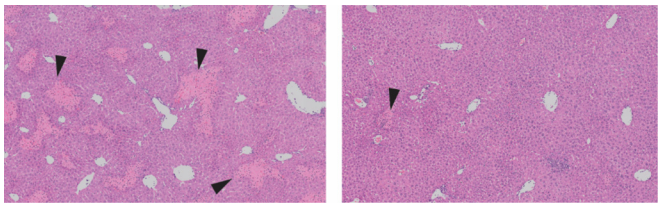

Figure 1: Mirtazapine pretreatment profoundly attenuates ConA-induced immune-mediated hepatitis Administration of mirtazapine leads to a striking reduction in liver damage 16 hrs post-con A treatment, as reflected by degree of histological damage in H&E stained liver sections. This figure shows two representative liver sections from con A treated mice (16 hrs post-con A) that received either PBS vehicle (left panel) or mirtazapine (right panel).

Conclusion: Mitz treatment exhibits robust hepatoprotective effects in the con A hepatitis through a striking attenuation of hepatic proinflammatory cytokine and neutrophil chemokine expression, and a marked reduction in hepatic ICAM-1 expression. Given the growing recognition of neutrophils in the regulation of hepatic immunity, mirtazapine may represent a novel therapy for treating immune-mediated liver diseases.

Fine-mapping and colocalisation analysis of GWAS risk loci in Primary Sclerosing Cholangitis suggests role for proto-oncogene ETS2 in disease pathogenesis

E. Goode[1,2], L. Moutsianas[2], N. Soranzo[2], S. Rushbrook[3], T. Raine[2,4], C. Anderson[2]. [1]*University of Cambridge, Institute of Metabolic Science, Cambridge, United Kingdom;* [2]*Wellcome Trust Sanger Institute, Human Genetics, Cambridge, United Kingdom;* [3]*Norfolk and Norwich University Hospital, Department of Gastroenterology, Norwich, United Kingdom;* [4]*University of Cambridge, Department of Medicine, Cambridge, United Kingdom*
Email: ecg44@cam.ac.uk

Background and Aims: Primary Sclerosing Cholangitis (PSC) is a biliary disease leading to cholestatic cirrhosis and high risk of cholangiocarcinoma. Genome-wide association studies (GWAS) have identified 22 PSC-associated non-HLA risk loci. Attempts to extract disease-relevant biological insights have been hindered by challenges identifying the causal variants driving the signals within each locus, due to linkage disequilibrium. Furthermore, identifying the genes impacted by these variants has proven difficult as the majority lie in non-coding genomic regions. This study aimed to identify the most likely causal variant within each risk locus and assess its impact on gene regulation by assessing the probability that the PSC association signal and functional quantitative trait loci (QTL) are driven by the same causal variant.
Method: Using the software package *Finemap,* we performed Bayesian fine-mapping analysis of PSC risk loci, focusing on 1Mb regions centred on the most associated SNP, to determine the most likely causal variant or credible set that explained >95% of the observed signal within each locus. We then performed colocalisation analyses with QTL for expression (eQTL), methylation and histone modifications in common peripheral blood cell types.
Results: Fine-mapping of the Chr21:rs2836883 region identified rs4817988 as the most likely causal variant (Posterior probability of causality = 0.58), with a credible set of 10 SNPs. Due to its proximity to the most associated SNP, the gene commonly assigned to this region is *PSMG1.* However, the PSC association signal was found to colocalise with an eQTL in peripheral blood monocytes for *ETS Proto-Oncogene 2* (*ETS2*), where the PSC risk allele increased expression of *ETS2* (*Fig 1a*). Furthermore, this signal also colocalised with an H3K27ac histone acetylation marker, associated with higher activation of transcription (Fig 1b). *ETS2* is highly expressed in PSC-relevant tissues, liver and colon, and encodes a transcription factor that regulates human telomerase activity, silencing of which has been implicated in the death of human breast cancer tissue cells. rs4817988 overlaps a promotor flanking region involved in distal transcriptional regulation of *ETS2* in monocytes.
Conclusion: Increased risk of PSC is associated with increased expression of *ETS2* and thus a pro-cancer phenotype. This study suggests that further investigation of the ETS2 pathway as a potential mechanism for PSC-related dysplasia, is warranted.

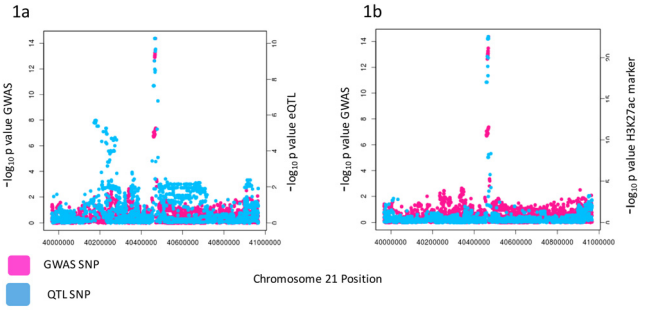

Figure: 1a) Colocalisation plot for PSC-associated regions and eQTL in monocytes with $-\log_{10}$ p-values plotted against chromosomal position; 1b) Colocalisation plot for PSC-associated regions and H3K27ac histone acetylation marker in monocytes with $-\log_{10}$ p-values plotted against chromosomal position

Hypersensitivity and constitutive activation of the IL-12/STAT4 pathway in NK cells in Primary Biliary Cholangitis: A novel mechanism

T. Hydes[1], S. Khakoo[2], J. Naftel[2]. [1]*University Hospital Southampton, Department of Gastroenterology and Hepatology, Southampton, United Kingdom;* [2]*University of Southampton, Faculty of Medicine, Southampton, United Kingdom*
Email: therasa@doctors.org.uk

Background and Aims: Natural Killer (NK) cells are cytotoxic against biliary epithelial cells in Primary Biliary Cholangitis (PBC). GWAS studies have identified IL-12/STAT4 axis polymorphisms as being associated with developing PBC. NK cells express the IL-12 receptor & respond to stimulation via the STAT4 pathway. We recently showed the human liver to be enriched in NK cells expressing the "homing" & "hyperfunctional" markers, CXCR6 & CD49a, & identified IL-12 to be important in the upregulation of these markers on peripheral NK cells. We therefore assessed the IL-12-STAT4 axis in NK cells in PBC.
Method: PBMCs were isolated from patients with PBC (n = 35), the non-inflammatory liver disease haemochromatosis (HFe) (n = 31) & healthy controls (HC) (n = 9). NK cells were analysed for surface markers (CXCR6, CD49a), intracellular pSTAT4 & IFNγ at rest & post purification & stimulation with IL-12/IL-15.
Results: Circulating NK cells, expressed greater levels of CD49a & CXCR6 compared to HFe & HC groups (CD49a: 2.2% vs 1.3% vs 0.9%, p = 0.0013, p = 0.0039 respectively; CXCR6: 3.4% vs 2.4 vs 2.0%: p = 0.0052, p = 0.0014 respectively). Stimulation with a low concentration of IL-12, 0.005ng/ml for 12 hours, led to significant upregulation of CXCR6 on NK cells from patients with PBC (3.1% to 4.8%, p = 0.0005), but not those with HFe (2.7% vs 2.6%, p = ns) (PBC 4.8% vs HFe 2.7%, p = 0.0056). Furthermore NK cells from individuals with PBC produced IFNγ in response to this low dose of IL-12 (1.1% rest, 2.9% IL-12 0.005ng/ml, p = 0.0004) & in greater quantities compared to HFe patients (2.9% vs 1.2%, p = 0.001) & HCs (2.9% vs 0.4, p < 0.0001). CD49a+ NK cells from PBC patients contained the highest frequencies of IFNγ+ NK cells (median 8.6%, range 0–43%) in response to low-dose IL-12 & were more sensitive than CD49a+ NK cells from HFe patients (median 2.6%). To investigate if NK cells from PBC patients are primed *in vivo* by IL-12 we tested STAT4 phosphorylation. A higher percentage of NK cells from PBC patients (4.3%) expressed pSTAT4 at rest compared to HFe patients (2.3%) & HCs (0.5%) (p = 0.0012 & p < 0.0001). No differences were found in T-cells.
Conclusion: Our data provide a functional correlate to the PBC GWAS studies. Circulating NK cells from individuals with PBC are hypersensitive to IL-12, leading to activation & expression of liver homing markers. NK cells in PBC exist in an IL-12 primed state, therefore blocking NK cells downstream of STAT4 may provide a novel therapeutic target.

FRI-217

Deletion of tumor necrosis factor alpha receptor 1 leads to an increased Th17 cell response in the chronically inflamed liver

L. Berkhout[1], B. Schiller[1], G. Ravichandran[1], T. Krech[2], G. Sass[1], G. Tiegs[1], R. Barikbin[1]. [1]*Institute of experimental immunology and hepatology, University medical center Hamburg-Eppendorf, Hamburg;* [2]*Department of Pathology, University medical center Hamburg-Eppendorf, Hamburg, Germany*
Email: l.berkhout@uke.de

Background and Aims: Chronic hepatic inflammation has several major consequences including cirrhosis, liver failure and cancer. Tumour necrosis factor alpha receptor-1 (TNFR1) activation is known to induce cell death, inflammation, and fibrosis but also hepatocyte survival and regeneration. In this study we analysed the role of TNFR1 during chronic liver inflammation.
Method: We ablated TNFR1 in a mouse model of chronic hepatitis and inflammation induced hepatocellular carcinoma (multidrug resistance protein 2 knockout mice; *mdr2*$^{-/-}$) creating *tnfr1*/*mdr2*$^{-/-}$ mice. Liver injury was assessed by plasma levels of alanine aminotransferase (ALT) and alkaline phosphatase (ALP). Cytokine concentrations were determined by Legendplex assay. Immune cell composition was analysed by flow cytometry. Hepatic immune cells were stimulated *ex vivo* with PMA & Ionomycin. Fibrosis was analysed via quantification of the hepatic hydroxyproline content and Sirius Red staining. Hepatic expression levels of targets involved in inflammation, fibrosis, and tissue regeneration were analysed via real time RT-PCR.
Results: We observed significantly increased ALT and ALP plasma levels, as well as significantly increased neutrophil and Th17 cell infiltration into the liver of *tnfr1*/*mdr2*$^{-/-}$compared to *mdr2*$^{-/-}$ mice. *Ex vivo* stimulated hepatic immune cells of *tnfr1*/*mdr2*$^{-/-}$ mice produced significantly more IL-17, which directly correlated with tissue injury. *Tnfr1*/*mdr2*$^{-/-}$ mice showed significantly increased hepatic expression of pro-inflammatory cytokines (*il-1beta, il-23, tgf-beta, ccl2, cx3cl1*), mediators of cell death (pycard, rip3), and fibrosis (*alpha-sma, collagens I and III, mmps*) compared to *mdr2*$^{-/-}$ mice. The *tnfr1*/*mdr2*$^{-/-}$ mice further showed increased hepatic hydroxyproline levels and Sirius Red positive areas in stained tissue sections. The expression of proliferation markers (*pcna*, *ccnA2*) was up-regulated in the *tnfr1*/*mdr2*$^{-/-}$.
Conclusion: Constitutive knockout of TNFR1 did not improve the pathological phenotype of *mdr2*$^{-/-}$ mice. It instead caused enhanced Th17 cell and neutrophil infiltration, accompanied by higher IL-17 production and exacerbated tissue damage, which resulted in increased fibrosis. Increased inflammation and fibrosis in combination with active regeneration implies an ideal microenvironment for tumour development in the livers of *tnfr1*/*mdr2*$^{-/-}$ mice. Long term studies will show whether the *tnfr1* knockout alters tumour development and progression in the *mdr2*$^{-/-}$ model.

Lysophosphatidic acid activates peripheral glia cells via LPA receptor 1

K. Wolf[1], L. Gebhardt[2], J. Robering[2], M. Fischer[3], A. Kremer[1]. [1]*Friedrich-Alexander University Erlangen-Nürnberg, Department of Medicine 1, Erlangen;* [2]*Friedrich-Alexander University Erlangen-Nürnberg, Institute of Physiology and Pathophysiology, Erlangen, Germany;* [3]*University of Vienna, Center for Physiology and Pharmacology, Vienna, Austria*
Email: andreas.kremer@uk-erlangen.de

Background and Aims: Pruritus is a frequently observed symptom in hepatobiliary disorders which can dramatically reduce the quality of life of affected patients. Lysophosphatidic acid could be identified as potential pruritogen, however, the molecular mechanisms resulting in neuronal activation remain elusive.
Methods: C57BL/6, TRPV1$^{-/-}$, TRPA1$^{-/-}$ mice as well as Wistar rats served as source for dorsal root ganglia (DRG) cultures. A Schwann cell culture was established from sciatic nerve preparations. Transient receptor potential (TRP) A1 and V1 were cloned from murine and human mRNA. Expression analyses were performed by qPCR. Fura-2 microfluometry was performed to quantify changes in cytosolic free calcium concentrations.
Results: LPA 18:1 elevated cytosolic free calcium concentrations in mouse and rat DRG cultures. Only a minor fraction (1.6%) of sensory neurons were activated by LPA, whereas the majority of activated cells were satellite glial cells (SGC). The magnitude of LPA-responses was inversely correlated with calcium responses to potassium and capsaicin. Besides satellite glial cells also Schwann cells responded to the application of LPA 18:1. Intriguingly, satellite glia cells responding to LPA were also activated by the TGR5 agonist INT-777. A striking cross-desensitization of LPA and established pruritogens could be observed. Heterologously expressed human and murine TRP channels in HEK293T cells showed at best a marginal involvement of TRP channels in cellular responses to LPA. The respective gial cells of TRPV1$^{-/-}$ and TRPA1$^{-/-}$ mice showed not relevant reduction in LPA-induced calcium responses. Various pre-treatments of wildtype DRG cultures using thapsigargin, the phospholipase C inhibitor (PLC) U73122, and the LPA receptor 1 and 3 blocker Ki16425 indicated a G protein-coupled LPA receptor signaling via a PLC-IP3 pathway releasing calcium from intracellular stores. Real-time PCR experiments indicated a high expression of LPAR1 in mouse and rat DRGs and Schwann cells as well as a weak expression of LPAR4, LPAR5, and LPAR6.
Conclusion: LPA 18:1 largely activated satellite glia cells and peripheral Schwann cells via LPAR1. Intriguingly, LPA response SGCs were also activated by a TGR5 agonist, indicating that a cooperative effect of two or more pruritogens may be required for the onset of cholestatic itch.

FRI-219

Intrahepatic type II natural killer T cells switch to a pro-inflammatory cytokine profile in patients with autoimmune hepatitis

M. Sebode[1], C. Schramm[1], L. Fischer[2], A. Lohse[1], P. Arrenberg[1]. [1]*University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany;* [2]*University Medical Center Hamburg-Eppendorf, Department of Hepatobiliary Surgery and Transplantation, Hamburg, Germany*
Email: marcialsebode@web.de

Background and Aims: Natural killer T (NKT) cells are unconventional T cells that recognize lipid antigens presented by the non-classical MHC molecule CD1d. NKT cells have been investigated in murine models of autoimmune hepatitis (AIH), in which type I NKT cells are pathogenic, whereas type II NKT cells protect from liver disease. However, the role of human NKT cells, especially human type II NKT cells, in autoimmune liver diseases is unclear. Here, we have analyzed peripheral and intrahepatic human NKT cells and the intrahepatic expression of CD1d in AIH compared to control groups.
Method: The frequency and cytokine profile of peripheral and intrahepatic type I NKT and type II NKT cells from patients with AIH, primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) were analyzed by flow cytometry. Healthy liver tissue of the resection margin of liver adenomas and liver biopsies from patients with drug-induced liver injury (DILI) served as control groups. Type I and type II NKT cells were specifically stained by a-Galactosylceramide- and Sulfatide-loaded human CD1d-tetramers, respectively. CD1d was stained immunohistochemically in liver biopsies.
Results: The frequency of peripheral and intrahepatic type I NKT cells was very low in patients with AIH (0.005% and 0.03% of peripheral and intrahepatic leukocytes) and did not differ significantly in comparison to control groups. In contrast, AIH patients revealed an increased frequency of peripheral type II NKT cells compared to

healthy controls (0.11% of peripheral leukocytes vs. 0.05%, p = 0.02). Furthermore, an increased number of intrahepatic type II NKT cells in patients with AIH (3.78% of intrahepatic leukocytes) compared to healthy controls (1.82%) and patients with DILI (2.07%, p = 0.02) was detected. Intrahepatic, but not peripheral type II NKT cells of AIH patients had a different cytokine profile than healthy controls with an increase of TNFa (77.8% vs. 59.1%, p = 0.03), a decrease of IFNg (32.7% vs. 63.0%, p = 0.02) and suppression of IL-4 (0% vs 2.1%, p = 0.05). Infiltrating immune cells in portal areas of patients with AIH expressed significantly more CD1d compared to control groups.
Conclusion: Intrahepatic Sulfatide-reactive type II NKT cells of AIH patients reveal an increased production of TNFa and show a complete suppression of IL-4. Contrasting with a protective role in their murine counterpart, human type II NKT cells could contribute to the pro-inflammatory mechanisms of AIH. Neither cholangiocytes nor hepatocytes, but infiltrating cells in portal areas of AIH patients show an increased expression of CD1d and could thereby activate type II NKT cells in AIH patients.

FRI-220

Human chorionic-plate-derived mesenchymal stem cells restore hepatic lipid metabolism in a rat model of bile duct ligation

Y.B. Lee[1], J.H. Choi[2,3], E.N. Kim[4], J. Seok[2], H.-J. Lee[2], G.J. Kim[2]. *[1]CHA Bundang Medical Center, CHA University, Department of Internal Medicine, Seongnam, Korea, Rep. of South; [2]CHA University, Department of Biomedical Science, Seongnam, Korea, Rep. of South; [3]The Feinberg School of Medicine, Northwestern University, Department of Dermatology, Chicago, United States; [4]CHA Bundang Medical Center, CHA University, Clinical Research Center, Seongnam, Korea, Rep. of South*
Email: yunbin@hanmail.net

Background and Aims: In cholestatic liver diseases, impaired bile excretion disrupts lipid homoeostasis. We investigated changes of lipid metabolism, including mitochondrial β-oxidation, in a rat model of bile duct ligation (BDL) in which chorionic-plate-derived mesenchymal stem cells (CP-MSCs) were transplanted.
Method: Male 7-week-old Sprague-Dawley rats were used. One week after BDL, rats in the transplanted group were injected with CP-MSCs (2×10^6 cells, 8–10 passages) intravenously via tail vein, whereas rats in the nontransplanted group were injected with culture medium. Liver tissues and blood samples for further analysis were collected 1, 2, 3, and 5 weeks post-transplantation in the transplanted group and 1, 2, 3, and 5 weeks post-BDL in the nontransplanted group.
Results: The concentration of serum cholesterol, which was elevated after BDL, was significantly decreased following transplantation of CP-MSCs. The expression levels of genes involved in intracellular lipid uptake, including long-chain fatty acyl-CoA synthetases and fatty acid transport proteins, were decreased in rats after BDL, however, were not significantly changed by subsequent CP-MSC transplantation. Carnitine palmitoyltransferase 1A (CPT1A), a rate-limiting enzyme in mitochondrial β-oxidation, was upregulated after BDL and then was downregulated after CP-MSC transplantation. CPT1A expression was changed via microRNA-33–a posttranscriptional regulator of CPT1A–in a peroxisome proliferator-activated receptor α-independent manner. Cellular adenosine triphosphate production–an indicator of mitochondrial function–was reduced after BDL and was restored by CP-MSC transplantation. Expression levels of heme oxygenases also were significantly affected following BDL and CP-MSC transplantation.
Conclusion: Lipid metabolism is altered in response to chronic cholestatic liver injury and can be restored by CP-MSC transplantation. Our study findings support the therapeutic potential of CP-MSCs in cholestatic liver diseases and help understanding fundamental mechanism by which CP-MSCs affect energy metabolism.

In vitro rescue of ABCB11 nonsense mutations: Induction of a readthrough of premature stop codons

R. Amzal[1], A. Thebaut[1,2], M. Almes[1,2], M. Lapalus[1], B. Grosse[1], L. Bidou[3,4], O. Namy[3], E. Jacquemin[1,2], E. Gonzales[1,2]. *[1]Inserm, UMR-S1174, Hepatinov, University of Paris-Sud 11, ORSAY; [2]Pediatric Hepatology and Pediatric Liver Transplantation Unit, National Reference Centre for Rare Pediatric Liver Diseases, Bicêtre Universitary Hospital, Assistance Publique-Hôpitaux de Paris, Le Kremlin-Bicêtre, France; [3]Institute for Integrative Biology of the Cell (I2BC), CEA, CNRS, University Paris Sud, University Paris-Saclay, Gif sur Yvette, France; [4]University Pierre et Marie Curie, Paris, France*
Email: emmanuel.gonzales@aphp.fr

Background and Aims: Progressive familial intrahepatic cholestasis type 2 (PFIC2) is due to mutations of *ABCB11*, encoding the canalicular bile salt export pump (BSEP). Nonsense mutations (premature termination codon, PTC) are responsible for severe forms of the disease. The aim of this study was to assess the ability of drugs to induce a readthrough of PTC of *ABCB11*.
Methods: Six PTC identified in PFIC2 patients were studied (p.Y354X, p.R415X, p.R470X, p.R1057X, p.R1090X and p.E1302X). The readthrough levels of the human and rat PTC in their nucleotide environment were first quantified before and after treatment with aminoglycosides (G418 (200µg/mL), gentamicin (800, 1200µg/mL)) and Ataluren® (15µM) using a dual reporter assay (luciferase/galactosidase) in NIH3T3 line. Mutagenesis was used to reproduce non-sense patient mutations in Bsep cDNA. After transfection of these Bsep-GFP plasmids in HEK293, MDCK and Can 10 lines, cells were treated with gentamicin. Expression and cellular localization of the full-length Bsep protein resulting from the readthrough were studied by epifluorescence and confocal microscopies after immunostaining using anti-GFP, anti-Ntcp and anti-ZO-1 antibodies. Stable MDCK clones co-expressing $Bsep^{WT}$ or $Bsep^{R1090X}$ and Ntcp were used to study the vectorial transport of [^{3}H]taurocholate.
Results: In NIH3T3 cells, aminoglycosides significantly increased the readthrough levels of all human and rat mutations while Ataluren® only slightly increased the readthrough level of the human p.E1302X. In HEK293 cells, gentamicin induced a readthrough of 4 PTC (p.R415X, p.R470X, p.R1057X, p.R1090X). The resulting full-length proteins localized within the cytoplasm, except $Bsep^{R1090X}$ that was also detected at the plasma membrane. In Can 10 cells, gentamicin treatment significantly increased readthrough of the R1090X PTC and the resulting full-length protein was detected mainly in the cytoplasm but also at the canalicular membrane. At 27°C, a condition known to mimic the effect of chaperone therapy, the proportion of $Bsep^{R1090X}$ full-length protein localized at the canaliculus significantly increased. In MDCK cells, functional study of $Bsep^{R1090X}$ full-length protein performed after gentamicin-induced readthrough showed a significant increase in the transport of [^{3}H]taurocholate.
Conclusion: This study constitutes a proof of concept for readthrough therapy in selected patients with PFIC2 due to PTC of *ABCB11*, such as p.R1090X and suggests that combination with chaperone therapy might further improve the rescue.

Email: aitor.esparza@biodonostia.org

Background and Aims: Cholestasis is a common feature of different cholangiopathies such as PSC and PBC. Cholestasis causes liver inflammation and injury in epithelial cells, thereby inducing ductular reaction and activation of non-parenchymal liver cells [i.e. kupffer cells (KC) and hepatic stellate cells (HSC)] that ultimately results in biliary fibrosis. Liver injury leads to alterations in the intestine epithelial barrier, enabling the translocation of bacterial components to the liver via the portal vein. In the liver, these bacterial components bind to toll-like receptors (TLRs) expressed in KC and HSC promoting inflammation and progression of the wound-healing response. The triggering receptor expressed on myeloid cells 2 (TREM2) is an anti-inflammatory receptor that inhibits TLR-mediated signaling. This study aims to evaluate the role of TREM2 in cholestasis.
Method: TREM2 expression was analyzed in the liver of PBC and PSC patients and normal controls. Wild type (WT) and *Trem-2* knock out (*Trem2*$^{-/-}$) mice were subjected to bile duct ligation (BDL), or sham, for 7 days. Thereafter, sera were collected for the analysis of biochemical markers and livers were obtained for further histological and gene expression analysis. *In vitro*, KCs were isolated from WT and *Trem2*$^{-/-}$ mice, treated with lipopolysaccharide (LPS) and cytokine and chemokine expression was assessed.
Results: TREM2 expression is upregulated in the liver of PBC and PSC patients as compared to healthy controls; this receptor was also upregulated in a BDL based model of murine cholestasis. After BDL, *Trem2*$^{-/-}$ mice showed exacerbated liver injury with increased hepatocyte necrosis and immune-cell infiltration compared to WT, as assessed by H&E staining. This was accompanied by augmented mRNA levels of cholangiocyte (*Ck-7* and *Ck-19*) and proliferation markers (*Ki67* and *PCNA*), indicating that *Trem-2*$^{-/-}$ animals suffered exacerbated ductular reaction. Likewise, *Col1a1* and α *Sma* mRNA levels revealed enhanced fibrogenesis in *Trem2*$^{-/-}$ livers compared to WT after BDL. In addition, the expression of pro-inflammatory cytokines (*Il-6* and *Tnf-*α) and chemokines (*Mcp-1* and *Cxcl1*) were upregulated in these mice. LPS-treated *Trem2*$^{-/-}$ KC displayed increased expression of pro-inflammatory (*Il-6, Il-1*β and *Tnf-*α) and chemokine (*Cxcl1*) markers, both at mRNA and protein level, as compared to WT-derived KC.
Conclusion: TREM2 is overexpressed in the livers of PBC and PSC patients and during experimental cholestasis in mice. This receptor negatively regulates TLR4-mediated pro-inflammatory cytokine expression in KC, thereby protecting the liver from cholestatic injury in mice.

FRI-223
Elevated plasma levels of FGF19 isassociated with repression of bile salt synthesis in patients with obstructivecholestasis

K. Koelfat[1], E. Neis[1], S. Rensen[1], P. Jansen[1], C. Dejong[1,2], F. Schaap[1,2], S.O. Damink[1,2]. *[1]Maastricht University Medical Center and NUTRIM School of Nutrition and Translational Research in Metabolism, Maastricht University, Surgery, Netherlands; [2]RWTH University Hospital Aachen, Aachen, Germany, Department of General, Visceral and Transplantation Surgery, Germany*
Email: k.koelfat@maastrichtuniversity.nl

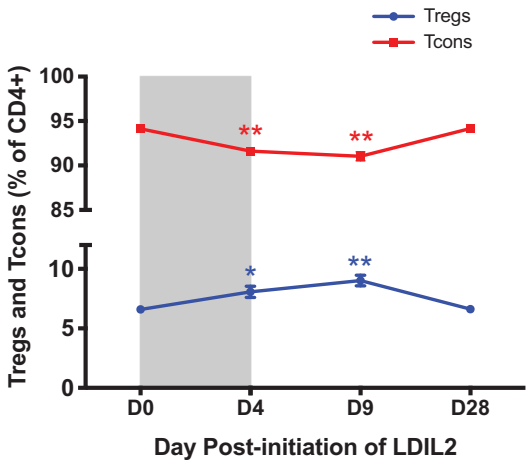
Background and Aims: The enterokine fibroblast growth factor 19 (FGF19) represses bile salt (BS) synthesis in the liver. It is hypothesized that production of FGF19 is shifted to the liver in patients with obstructive cholestasis (viz. lack of luminal BS). To study the orgin of FGF19 under conditions of cholestasis, we studied venous-arterial (VA) differences across major abdominal organs and investigated the relation with BS synthesis under cholestatic conditions.
Method: Plasma levels of BS/FGF19 and C4 (plasma marker of BS synthesis) were determined in arterial blood (RA), and portal (PV), hepatic (HV), superior (SMV) and inferior mesenteric (IMV) veins of cholestatic patients (n = 6) and controls (n = 14), who underwent pancreatic surgery.
Results: Cholestatic patients had higher levels of bilirubin ($P < 0.001$), ALP ($P = 0.009$), γGT ($P = 0.02$), ALT (P 0.02) and AST ($P = 0.02$), reflecting cholestatic injury. FGF19 levels were higher in all blood vessels of cholestatic patients (range 0.37 to 34.0 ng/mL) compared with controls (range 0.03 to 0.37 ng/mL) ($P < 0.001$). Likewise, BS levels were increased in all vessels in the cholestatic group, except for in SMV, (range 11.6 to 536.3 vs 0.4 to 122.7 µmol/L, ($P < 0.05$). Indeed, BS and FGF19 were closely related ($\rho = 0.72$, $P < 0.001$). FGF19 was not significanlty released by the small/large intestine or liver in cholestatic patients and controls. Nonetheless, we observed higher splanchnic release of FGF19 ($P = 0.03$) in cholestatic patients, suggesting increased production across the splanchnic area under conditions of obstructive cholestasis. In controls, BS were released by the small intestine ($P < 0.001$), not by the large intestine ($P = 0.24$), and taken up by the liver ($P < 0.001$). BS and FGF19 levels were positvely correlated with bilirubin levels ($\rho = 0.57$, $P = 0.02$, $\rho = 0.63$, $P = 0.008$, respectively). C4 levels were significantly lower in OC-patients compared with controls ($P < 0.05$). Moreover, BS and FGF19 levels were negatively related to C4 levels ($\rho = 0.74$, $P < 0.001$, $\rho = -0.75$, $P < 0.001$, respectively).
Conclusion: This study reveals that circulating levels of FGF19 are elevated during obstructive cholestasis and this is associated with cholestasis and decreased BS synthesis. Hepatic production is unlikely to contribute to the elevated FGF19 levels in obstructive cholestasis.

FRI-224
Low-dose interleukin-2 expands the number of circulating regulatory T cells in patients with treatment-refractory autoimmune hepatitis

T.Y. Lim[1,2], E. Codela[2], E. Gray[2], M. Heneghan[1], M. Martinez-Llordella[2], A. Sanchez-Fueyo[1]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]King's College London, MRC Transplant Centre, London, United Kingdom*
Email: llty24@gmail.com

Background and Aims: Low-dose interleukin-2 (LDIL-2) selectively expands regulatory T cells (Tregs) and improves their functional capacity. It has been administered to patients with a variety of autoimmune disorders including type 1 diabetes, systemic lupus erythematosus and graft-versus-host disease. However it has not been used in the setting of autoimmune hepatitis (AIH).
Method: We conducted immunomonitoring experiments on sequential blood samples collected from 2 patients not responding to second line immunosuppression and receiving 6 monthly courses of LDIL-2 (daily subcutaneous of 1 million IU IL-2 for 5 days).
Patient 1 is a 21 years old woman, diagnosed age 13. Although initially stable on azathioprine and prednisolone, she relapsed and was switched to mycophenolate mofetil (MMF) and tacrolimus treatment. However she relapsed again despite high dose steroids. Patient 2 is a 57 years old woman, diagnosed age 53, and was intolerant to azathioprine. She was maintained on MMF and prednisolone but relapsed. Patient 1 was cirrhotic on biopsy and Patient 2 had F3 fibrosis.
Results: There was no significant biochemical response in Patient 1, but Patient 2 achieved biochemical remission after 6 cycles of LDIL-2 therapy (AST from 259 to 44 IU/ml, and IgG from 20.9 to 16.2g/L). Neither patient developed any serious adverse events. Both patients experienced only transient injection-site erythema.

In both patients, LDIL-2 increased circulating Tregs ($CD25^+FOXP3^+$) significantly after each cycle at day 4 and peaked at day 9. However this returned to baseline at day 28. The median relative increase in Tregs was 26% (IQR 18–50%). A more detailed immunophenotypic analysis revealed that the changes in Treg numbers were due to increases in the proportion of resting and effector Tregs ($CD45RA^+FOXP3^{lo}$ and $CD45RA^-FOXP3^{hi}$, respectively), with no significant changes being observed in the non-suppressive $CD45RA^-FOXP3^{lo}$ $CD4^+$ Treg subset. In contrast, the proportion of conventional T cells (Tcons, $CD25^-FOXP3^-$) was reduced significantly following LDIL-2 therapy (Fig.1). In addition, LDIL-2 therapy led to an increase in expression of the proliferation marker Ki-67, as well as the activation markers CD25 and FOXP3, in Tregs, but not in Tcons. LDIL-2 also increased the responsiveness of Tregs to IL-2, as measured by expression intracellular phosphorylated signal transducer and activator of transcription-5 (pSTAT5). LDIL-2 also transiently increased the levels of the immunosuppressive cytokine, IL10, and CXCL-10, which promotes the trafficking into the liver of CXCR3 expressing Tregs.



Conclusion: We report for the first time that LDIL-2 can be safely used in AIH patients. It results in selective expansion of endogenous circulating Tregs and increases their sensitivity to IL-2. Our observations demonstrate the feasibility of improving inflammatory liver damage using this novel immunostrategy.

FRI-225

Intrahepatic recuriment of cytotoxic NK cells contributes to autoimmune hepatitis progression

F. Xiao[1], G. Ai[1], W. Yan[1], X. Luo[2], X. Wan[1], Q. Ning[1]. *[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, China; [2]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology*
Email: qning@vip.sina.com

Background and Aims: It is widely accepted that multiple subsets of immune cells are involved in the pathogenesis of autoimmune hepatitis AIH during which the autoimmune response is initiated by self-antigen recognition by the uncommitted CD4 helper T-cells (Th0) leading to Th1/Th2/Th17 differentiation in response to different cytokine stimulation. This is followed by the differentiation and activation of monocyte/Macrophage, natural killer (NK) cells, cytotoxic CD8 T cells, B cells leading to the destruction of liver parenchyma. However, exact contribution of NK cells to AIH remains poorly understood. In this study, we aim to dissect the role of peripheral and liver resident NK cells in AIH progression.
Methods: Peripheral blood mononuclear cells were isolated from AIH at patients at active phase and remission phase and subjected to flow cytometry for NK cells detection. Liver NK cells was isolated from mice of experimental autoimmune hepatitis and analyzed by flow cytometry. $CD56^{dim}$/ $CXCR3^-$ and $CD56^{bright}$/ $CXCR3^+$ NK cells in AIH patients/mice were drafted as cytotoxic and regulatory NK cells, respectively.
Results: Frequency of peripheral NK cells, more accurately CD56dimNK subset, was reduced in AIH patients. The reduction of $CD56^{dim}$NK was negatively correlated with disease progression. In experimental autoimmune hepatitis (EAH), hepatic accumulation of NK cells was observed along with a decrease of NK cells in the periphery. In addition, infiltrated NK cells are almost conventional $CXCR3^-$ NK cells, the counterpart of $CD56^{dim}$NK cells in the human. Both conventional $CXCR3^-$ NK cells of infiltration and liver resident NK cells are activated progressively at active phase as demonstrated by expression of granzyme B, Perforin, and IFN-γ.
Conclusion: Recruitment of peripheral cytotoxic NK cells into the liver, but not liver resident NK cells expansion, accounts for AIH progression.

FRI-226

Deep immunophenotyping of liver infiltrating lymphocytes reveals distinct differences in the T cell compartment of patients with primary sclerosing cholangitis

T. Poch[1], L. Glau[2], A. Langeneckert[3], L. Hess[3], W. Salzberger[3], G. Martrus[3], S. Lunemann[3], D. Schwinge[1], M. Koch[4], L. Fischer[4], K. Oldhafer[5], M. Altfeld[3], A. Lohse[1], E. Tolosa[2], C. Schramm[1].

Email: t.poch@uke.de

Background and Aims: Although genetic associations point towards immune dysregulation as part of the pathogenesis of Primary Sclerosing Cholangitis (PSC), the contribution of immune cells to the development and progression of PSC remains elusive. Few studies have so far analysed specific cell subsets within PSC livers. We here report on an unbiased investigation of the immunophenotype within liver and peripheral blood of patients with PSC.
Method: In an ongoing study, liver tissue and corresponding peripheral blood of five PSC patients has been obtained at time of liver transplantation. Liver tissue from resection margins of liver tumours and corresponding blood was used as controls. Lymphocytes were stained for surface markers or restimulated for cytokine measurements. More than 70 different antibodies to cell surface markers were used and analysed in a BD LSR Fortessa™. Conventional data analysis was performed using the BD FACSDIVA™ software for guided hierarchical gating. In addition, unsupervised analysis of differentially abundant clusters was conducted using SPADEVizR, and for visualization of high dimensionality data we used t-SNE algorithms.
Results: We provide extensive flow cytometric data on immune cell subsets in blood and livers of patients with PSC. Previously described changes in cellular subsets could be reproduced, such as diminished frequencies of mucosal associated invariant T cells (MAIT) in patients with PSC compared to controls, and a marked increase in MAIT frequencies in liver compared to peripheral blood, which supports the validity of this approach. Our data suggests that, in end stage PSC livers, major T cell populations do not differ in frequency but in expression of specific surface markers. Focusing on the $CD4^+$ T cell compartment, we were able to detect significant differences in the abundance of specific subsets between diseased livers and controls. Potentially exhausted $CD4^+$ T cells ($PD\text{-}1^+BTLA^+CD57^+$) were enriched in PSC livers, whereas presumably regulatory cells ($CD25^+LAG3^+CD44^+$) were significantly less frequent.

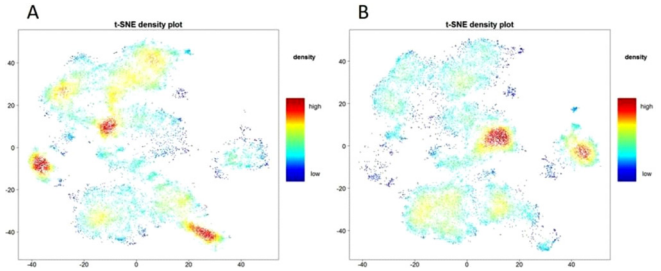

Figure 1: The T cell compartment differs clearly between PSC and control samples. Flow cytometric data of five PSC-LTx and five controls was used for analysis by t-distributed stochastic neighbour embedding (t-SNE). Density maps of the T cell compartments illustrate the different distribution of the respective cells across the clusters. (A) Events of controls are shown. (B) Events of PSC-LTx are displayed.

Conclusion: We show for the first time in-depth data of the hepatic immunophenotype in comparison to peripheral blood in patients with PSC. Significant differences were observed in the intrahepatic $CD4^+$ T cell compartment between PSC and controls, and also between liver and blood. We believe that our data will contribute to unravel the role of immune cells in the pathogenesis of PSC.

FRI-227

Cross-species molecular imaging of bile salts and lipids: Identification of hydroxyl-sulfatides as marker of bile ducts

B. Flinders[1], L. Huizing[1], M. van Heerden[2], F. Cuyckens[2], S. Olde Damink[3], R.M.A. Heeren[1], F. Schaap[4], R. Vreeken[2]. *[1]Maastricht Multimodal Molecular Imaging Institute (M4I), Maastricht University, Maastricht, Netherlands; [2]Janssen Research & Development, Beerse, Belgium; [3]Maastricht University Medical Centre, Maastricht University Medical Center, Maastricht, Netherlands; [4]Maastricht University, Dept of Surgery, Maastricht, Netherlands*
Email: frank.schaap@maastrichtuniversity.nl

Background and Aims: The liver is the primary organ involved in handling of bile salts, a class of amphipathic molecules with beneficial signaling activities as well as detrimental detergent action. To allow in-depth investigation of functions of bile salts in healthy and diseased liver, the spatial distribution of bile salt species within the liver needs to be studied. We furthermore aimed to identify specific lipid markers that define the structural elements of the liver.
Method: Matrix-assisted laser desorption/ionization-mass spectrometry imaging (MALDI-MSI) was used to monitor the spatial distribution of bile salts and lipids in liver sections of rat, dog, and patients with unaffected and cholestatic parenchyma.
Results: MALDI-MSI in negative ion mode showed the local presence and identity of a variety of bile salts, predominantly taurine-conjugates, as localized patches of varying sizes (representing the bile ducts) throughout the liver tissue. Specific molecular markers were identified for the connective tissue (a phosphatidic acid [PA (18:0_18:1)–H]$^-$), the liver parenchyma (a phosphatidylinositide [PI (18:0_20:4)-H]$^-$), and the bile ducts (a hydroxyl-sulfatide [ST-OH (18:1_24:0)-H]$^-$). The sulfatide (m/z 906.6339) was found to be localized in a thin lining on the inside of the bile duct, co-localizing with cytokeratins, and encasing luminal bile salts. In a liver specimen of a patient with primary sclerosing cholangitis (PSC), a similar distribution of aforementioned sulfatide was observed, albeit in constricted ductular structures. PSC-specific lipid markers species were not apparent in connective tissue or the bile ducts.
Conclusion: MALDI-MSI indicates that hepatic bile salts are primarily contained within the biliary network. Lipid markers were identified that define the distinct structural elements of the liver. Of these novel markers, sulfatides are uniquely expressed in the bile duct epithelium.

Cirrhosis and its complications: Experimental and pathophysiology

Necroptosis signalling pathway in hepatic fibrosis; role of receptor-interacting serine-threonine kinase 3 and mixed lineage kinase domain-like in cirrhosis

W. Saeed[1], D.W. Jun[1], E. Kim[1], B.-K. Kang[2], J.Y. Jeong[3], S.B. Ahn[4], M.M. Kim[5], H. Oh[1], K.S. Jang[6], E.C.J. Jang[7], J.H. Sohn[8]. *[1]Hanyang University School of Medicine, Department Internal Medicine, Seoul, Korea, Rep. of South; [2] Hanyang University School of Medicine, Department of Radiology, Seoul, Korea, Rep. of South; [3]Hanyang University, College of Medicine, Guri Hospital, Department of Internal Medicine, Guri-si, Gyeonggi-do; [4]Eulji university college of medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [5]Hanyang University School of Medicine, Department of Radiology, Seoul; [6]Hanyang University School of Medicine, Department of Pathology, Seoul, Korea, Rep. of South; [7]Soonchunhyang University College of Medicine, Department of Occupational and Enviroment Medicine, Cheonan-si, Chungcheongnam-do, Korea, Rep. of South; [8]Hanyang University, College of Medicine, Guri Hospital, Department of Internal Medicine, Guri-si, Gyeonggi-do, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and Aims: The key necroptosis molecules, receptor-interacting serine-threonine kinase 1 (RIP1) and RIP3, have been recently studied extensively in hepatic pathologies. We evaluated anti-fibrotic properties of RIP3 and mixed lineage kinase domain-like (MLKL) inhibition in hepatic fibrosis models.
Method: Common bile duct (CBD) ligation and thioacetamide (TAA) induced fibrosis models were established in $RIP3^{(-/-)}$ mouse and $MLK^{(-/-)}$ KO *in vivo* model. Serum AST, ALT, bilirubin and tissue analysis for H&E, Sirius Red staining and immunohistochemistry was performed. RIP3 and MLKL inhibitor (GSK-872, and Necrosulfonamide) treated LX-2 cells were analysed for wound healing, and α-SMA, colla1α, p-MLKL, and RIP3 immunostaining. qRT-PCR analysis for RIP3, α-SMA, colla1α, TIMP1, vimentin, Bax, Bcl2, JNK1, JNK2 and MLKL was performed.
Results: Human liver tissue MLKL immunoreactivity (IRS) score increased in NASH patients and IRS score was correlated with fibrosis. In CBD ligation induced fibrosis model extensive fibrosis was observed compared to TAA-induced fibrosis model. Both $RIP3^{(-/-)}$ and $MLKL^{(-/-)}$ KO mice had significantly decreased fibrosis compared to wild type animals, while the serum AST, ALT, and bilirubin were not significantly decreased. Both $RIP3^{(-/-)}$ and $MLKL^{(-/-)}$ KO mice had significantly decreased α-SMA, coll1α, and TIMP-1 expressions. MLKL expressed in activated stellate cell as well as necroptic condition (TNF-α, and pancaspase inhibitor). MLKL inhibitor delayed wound healing, and decreased α-SMA, coll1α, and vimentin expressions in LX-2 cell. MLKL inhibitor increase intracellular lipid accumulation. RIP3 inhibitor increased M2 phenotype marker in RAW cell.
Conclusion: RIP3 and MLKL inhibition protects from CBD ligation and TAA induced hepatic fibrosis via inhibited stellate cell reversion.

FRI-229

Role of Toll-like receptor 4 (TLR4) in regulating severity of hyperammonemia and gene expression of urea cycle enzymes

A. Kerbert[1,2], Y. Sharifi[1], R. Jalan[1], F. Andreola[1]. *[1]UCL Medical School, Royal Free Hospital London, Liver Failure Group, UCL Institute for Liver and Digestive Health, London, United Kingdom; [2]Leiden University Medical Center, Gastroenterology & Hepatology, Leiden, Netherlands*
Email: j.c.kerbert@lumc.nl

Background and Aims: In liver failure, hyperammonemia (HA) is thought to result from reduced urea cycle enzyme (UCE) activity due

to diminished hepatocyte cell mass. However, episodic HA is observed in cirrhotic patients with superimposed sepsis, suggesting that alternative mechanisms may be involved. Deletion of toll like receptor-4 (TLR4) was shown to protect against neuroinflammation in hyperammonemic mice. The present study aimed to determine whether 1) stimulation of TLR4 with lipopolysaccharide (LPS) in cirrhotic animals resulted in HA and 2) to investigate whether TLR4 regulates gene expression of UCEs in HA mice.

Method: Two animal models were performed. 1) in bile duct ligated (BDL) rats (n = 4), 0.03 mg/kg LPS was administered intravenously 4 weeks after surgery. Plasma ammonia levels were assessed. 2) 4 groups of mice were studied: wild type control (WTC, n = 5), WT with hyperammonemia (WTH, n = 5), TLR4 knockout control ($TLR4^{-/-}C$, n = 5) and $TLR4^{-/-}$ with HA ($TLR4^{-/-}H$, n = 5). HA was induced by addition of 0.28 M ammonium chloride to drinking water for 3 days after which mice were sacrificed. qPCR was used to assess gene expression of UCEs in liver tissue. Relative gene expression is presented using the comparative C_T method ($2^{-\Delta CT}$ and $2^{-\Delta\Delta CT}$) using WTC as a calibrator.

Results: Administration of LPS to BDL animals was associated with a significant increase in plasma ammonia concentrations (p = 0.048). In the $TLR4^{-/-}$ mice, the increase in plasma ammonia levels was significantly lower compared to WT animals (p < 0.001). HA resulted in an increase in relative expression levels ($2^{-\Delta CT}$) of Carbamoyl Phosphate Synthetase 1 (CPS1) and Argininosuccinate Syntethase 1 (ASS1) in both WT (not significant) and $TLR4^{-/-}$ animals (CPS1: p = 0.002, ASS1: p = 0.071). Using $TLR4^{-/-}C$ as a calibrator, relative gene expression of CPS1 (figure) and ASS1 was shown to be approximately twice as high in the $TLR4^{-/-}H$ animals [fold changes ($2^{-\Delta\Delta CT}$): 2.6 and 1.9, respectively]. Gene expression of the other UCEs was similar between groups.

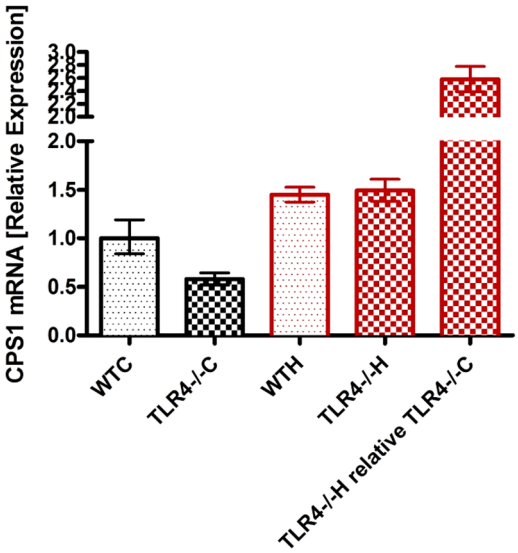

Figure 1: Relative gene expression ($2^{-\Delta\Delta CT}$) of CPS1 in WT and TLR4KO mice with and without hyperammonemia using WTC and $TLR4^{-/-}C$ as calibrators.

Conclusion: The results of this study show for the first time the role of TLR4 in modulating gene expression of UCE and therefore the severity of HA. As CPS1 is a key, rate-limiting UCE, these data point towards a novel pathway of ammonia removal and underline that TLR4 may be a therapeutic target for treating HA.

FRI-230

Regulatory T cells modulate the concentration of short chain fatty acids and the Th function in response to induced bacterial traslocation episodes, and improve the integrity of the gut barrier in an experimental cirrhosis model

O. Juanola[1,2,3], I. Gómez-Hurtado[1,2], P. Piñero[1,2], R. García-Villalba[4], A. Marín[4], E. Caparrós[1,2,3], F.T. Rodrigo[1,5], P. Zapater[2,6,7], J.M. González-Navajas[1,2,8], F.T.-B. Barberán[4], R. Francés[1,2,3,9]. *[1]Instituto ISABIAL, FISABIO, Alicante, Spain; [2]Instituto de Salud Carlos III, CIBERehd, Madrid, Spain; [3]Universidad Miguel Hernández, Medicina Clínica, San Juan de Alicante, Spain; [4]CEBAS-CSIC, Campus de Espinardo, Murcia, Spain; [5]Hospital General Universitario de Alicante, Hematology, Alicante, Spain; [6]Hospital General Universitario de Alicante, Pharmacology; [7]Universidad Miguel Hernández, Pharmacology, Pediatrics and Organic chemestry; [8]Hospital General Universitario de Alicante, Alicante, Spain; [9]Hospital General Universitario de Alicante, Alicante, Spain*
Email: ojuanola@gmail.com

Background and Aims: Regulatory T cells (Tregs) are a key population in keeping a balanced inflammatory response to the intestinal dysbiosis developed during cirrhosis. The short chain fatty acids (SCFAs) produced by the microbiota contribute to achieve a mature host's immune system. Our hypothesis is that Tregs participate in maintaining stable SCFAs levels against induced bacterial traslocation (BT) and improve the integrity of the gut barrier in experimental liver damage.

Method: Rag 1 knockout (KO) mice with oral CCl4 induced cirrhosis during 12 weeks were included (n = 65). A subgroup of animals received *E. coli* 24 hours before laparotomies (n = 38). Naïve T cells and Treg cells were purified from C57Bl/6 WT mice spleens by negative selection and sorted by flow citometry. Recipient Rag KO mice were injected i.p, either with splecnic 2×105 naïve T cells or with 1×105 naïve T cells plus 1×105 Treg cells, from donor WT mice. Laparotomies were performed 48 hours after the adoptive transfer inductions. Intestinal content, ileum, colon, spleen, mesenteric lymph nodes and liver were collected. SCFAs concentration was determined by mass spectroscopy. Th response to *E. coli* was determined by flow cytometry. Gut barrier integrity markers were analized at gene and protein expression levels.

Results: The SCFAs concentrations in the study groups are represented in Figure 1. All SCFAs, but acetic acid, decreased their concentration in response to *E. coli* significantly. However, Treg transferred group showed similar levels in animals treated or untreated with *E. coli*. Th17 and Th1 response in Tnaïve + Treg cotransferred mice was significantly reduced compared with those Rag KO animals transferred just with Tnaïve cells. The gene and protein expression of ZO1, Occludin, Claudin 1, Claudin 2 was significantly increased in Rag KO mice cotransferred with Tnaïve + Tregs.

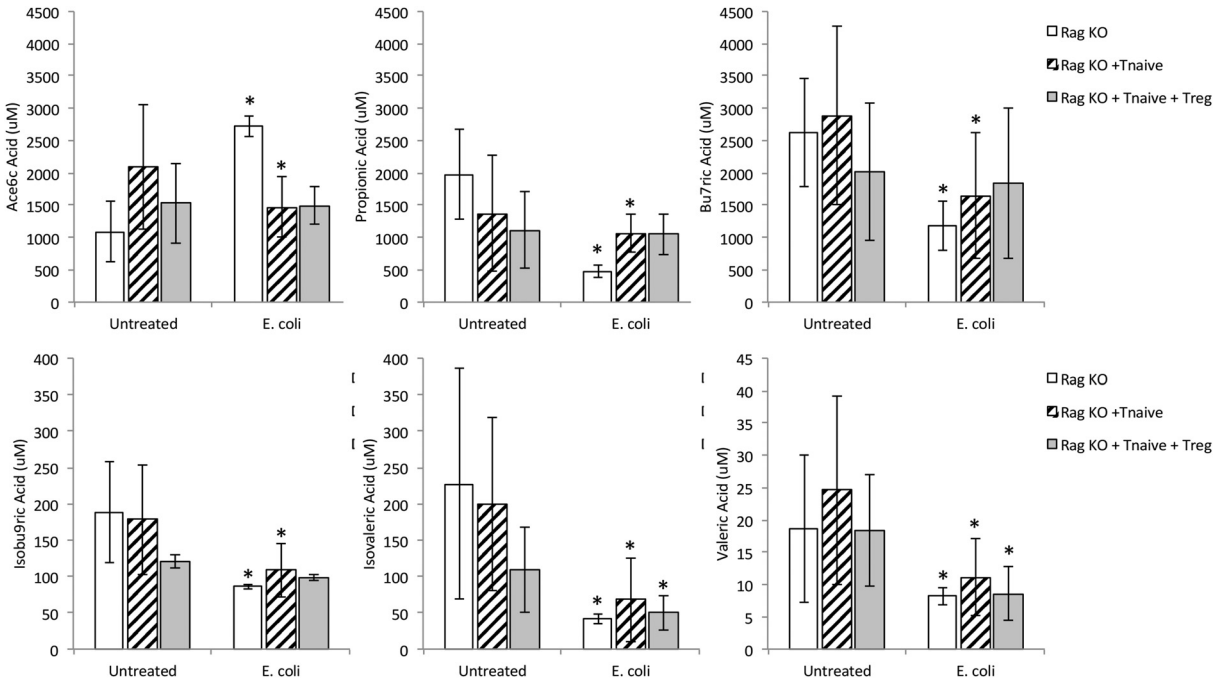
Conclusion: Tregs buffer the intestinal concentration of SCFAs and limit the intensity of Th response to *E. coli*. This association could be mediated by the protective effect of Tregs on gut barrier integrity.

FRI-231

Characterization of the protective effects of yaq-001on organ injury in cirrhosis

F.D. Chiara[1], J. Li[2], H. Lu[1], N. Davies[1], R. Mookerjee[1], R. Jalan[1], J. Macnaughtan[1]. *[1]University College London, ILDH, United Kingdom; [2]Imperial College, Human Development and Microbial Signalling, United Kingdom*
Email: francesco.chiara@ucl.ac.uk

Background and Aims: Bacterial translocation is central to the pathogenesis of complications of cirrhosis. Selective intestinal decontamination with antibiotic therapy is associated with the attendant risk of resistance and superinfection leaving an unmet clinical need. Yaq-001 is a safe, non-absorbable enterosorbant with a high affinity for bacterial toxins which does not exert an antibiotic effect. Previous studies have demonstrated that Yaq-001 reduces ALT,



** p=0.01 comparado con el grupo no tratado*

Figure 1: (abstract: FRI-230)

portal pressure and improves immune function in a rodent model of cirrhosis but the mechanisms by which this occurs are incompletely characterized. The purpose of this study was to evaluate the interorgan effect of Yaq-001.

Method: 4 weeks- BDL Male Sprague-Dawley rats were randomized to receive chow +/- Yaq 001 from week 2. Liver, ileal and colonic tissue RNA was extracted and RNA-Seq libraries were prepared by using Illumina's TruSeq Sample Preparation Kit. Reads were mapped to the rat genome. To identify the pathways that were significantly enriched in samples was performed using Kyoto Encyclopedia of Genes and Genomes (KEGG) and Ingenuity pathway analysis (IPA). The gene sets showing FDR, 0.25, a well-established cutoff for the identification of biologically relevant genes, were considered enriched between the

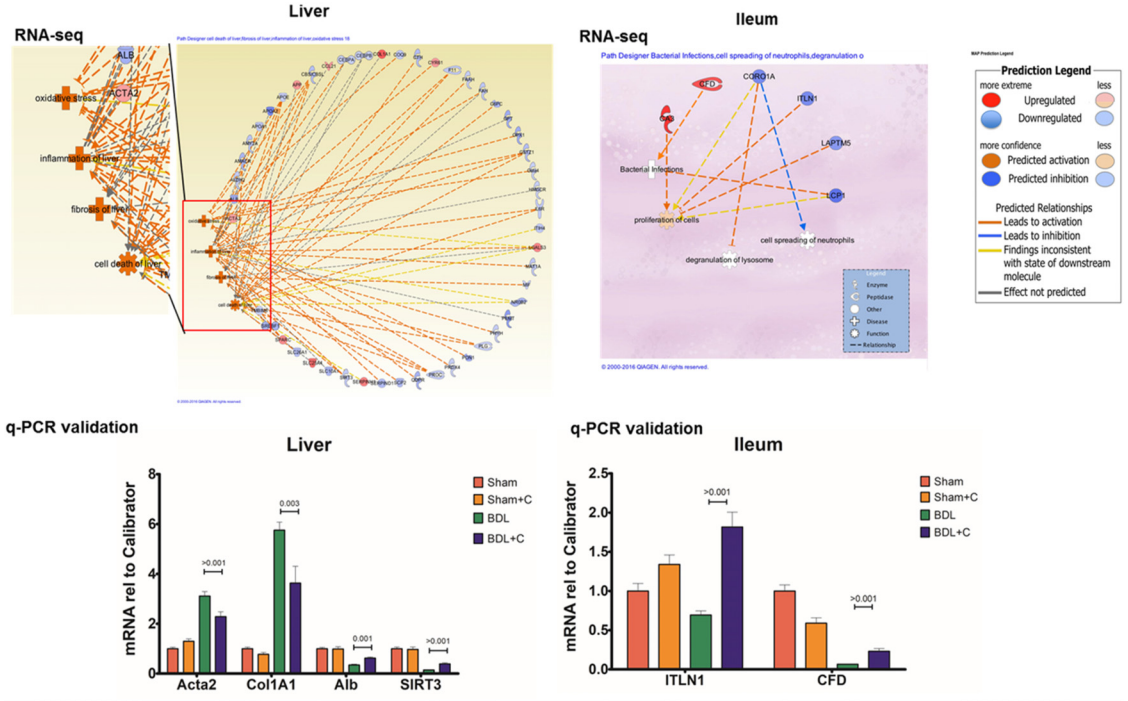


Figure 1: (abstract: FRI-231)

classes under comparison. 1H-NMR spectroscopy was performed on liver ileal and colonic tissue.
Results: In the ileum of BDL rats, RNA-seq analysis showed that bacterial infections (z-score 1.47; P 2×10^{-4}), proliferation of cells (z-score 2.17; 1×10^{-6}) and inhibition of degranulation of lysosomes (z-score –1.49; P 3×10^{-4}) mechanisms are activated. These pathways were inhibited by Carbon treatment. Genes such as ITLN1 and CFD, which play a role in the defense system, were validated by q-PCR. In the liver, Yaq-001 treatment led to regulation of genes involved in the inhibition of oxidative stress (z-score –2.59; P 2×10^{-5}), inflammation (z-score –1.35; P 4×10^{-3}), fibrosis (z-score –1.29; P 1×10^{-4}), and cell death (z-score –1.19; P 1×10^{-3}). Q-PCR analysis confirmed that α-SMA (ACTA2) and Col1a1 were significantly down regulated upon the treatment. Significant shifts in metabolomic profile were observed in lipid and water-soluble fractions on principal component analysis of liver tissue but not ileum or colon. Yaq-001 treatment did not significantly alter metabolomic profile of BDL or sham liver, ileal or colonic tissue.
Conclusion: Yaq-001 attenuates organ injury in cirrhosis by effects on inflammation, fibrosis and cell death pathways. No deleterious effects on the small or large intestine were observed at a gene expression or metabolomic level. Yaq-001 is therefore a safe, efficacious intervention to reduce organ injury in cirrhosis.

FRI-232
Systemic inflammation and portal vein thrombosis in gastroesophageal varices
X. Huang, S. Chen. *Zhongshan Hospital, Fudan University, Department of Gastroenterology, Shanghai, China*
Email: huangxiaoquan1010@aliyun.com

Background and Aims: Patients combined with portal vein thrombosis (PVT) have the higher risk of re-bleeding and the poor prognosis. Growing evidence showed that cirrhosis is associated with the ongoing pro-thrombotic state and systemic inflammation, that possible originating from gut microbiome. However, the correlation between systemic inflammation and PVT is unknown.
Method: We prospectively enrolled cirrhotic patients with gastroesophageal varices between Dec 1st, 2016 and Aug 31st 2017. Patients were divided into PVT group (n = 107) and non-PVT group (n = 139) according to computer tomography angiography. Peripheral blood levels of IL-2R, IL-6, IL-8, IL-10, TNF-α, IFN-γ, ICAM-1, VCAM-1 were quantified by ELISA and cytometric bead array. Furthermore, stool microbiota was quantified to investigate the role of the gut microbiota in the formation of PVT.
Results: Among groups, characteristics were similar including age (55.1 ± 11.9 v.s. 55.1 ± 11.9, p = 0.957) and hepatic venous pressure gradient (HVPG, 16.5 ± 6.7 v.s. 17.0 v.s. 4.8, p = 0.673). Comparing to the control, cirrhotic patients with PVT displayed significant higher serum levels of IL-6 [4.85 (3.15–6.99) v.s. 3.09 (2.06–5.20) pg/ml, p < 0.001], TNF-α [10.75 (7.77–17.75) v.s. 9.16 (7.01–12.40 pg/ml, p = 0.029), IFN-γ (2.27 ± 1.48 v.s. 1.29 ± 1.01, p = 0.018), ICAM-1 (53615.70 ± 25264.07 v.s. 41890.56 ± 21283.02 pg/ml, p = 0.124), VCAM-1 (20210.62 ± 1556.62 v.s. 19245.87 ± 1778.75 pg/ml, p = 0.092). In addition, IL-2R correlated with HVPG (r = 0.3072, p = 0.0114). Fecal microbiota analysis showed that Bacteroides, Prevotella, Enterobacter, Faecalibacterium and Alistipes are the most abundance genera in these patients. The diversity of gut microbiome in PVT group were significant reduced, and Eggerthella was notably increased in PVT group (p = 0.032), while Barnesiella (p = 0.053), Phascolarctobacterium (p = 0.070) and Clostridium XI (p = 0.086) were increased in PVT group.
Conclusion: The study provides the first evidence that systemic inflammation plays the important role in portal vein thrombosis. The changes in gut microbiota might be underlying mechanism in the formation of thrombus.

FRI-233
Pharmacokinetics study of 2 investigational rifaximin soluble solid dispersion formulations (immediate release and sustained extended release) in healthy volunteers
J. Vittitow, Z. Heimanson, R. Israel, E. Lowe. *Salix Pharmaceuticals, Bridgewater, United States*
Email: Jason.Vittitow@bausch.com

Background and Aims: Rifaximin, a nonsystemic antibiotic with low aqueous solubility, is administered as a 550-mg tablet twice daily for prevention of overt hepatic encephalopathy recurrence in adults. To improve gastrointestinal (GI) luminal solubility while minimizing systemic exposure, a new investigational formulation, rifaximin soluble solid dispersion (SSD), was developed. The oral rifaximin SSD tablet was designed to target the small (immediate release [IR]) or large (sustained extended release [SER]) intestine. This phase 1 trial evaluated single-dose pharmacokinetics (PK).
Method: A 2-stage, open-label, randomized, crossover study evaluated the PK of single doses of 80-mg rifaximin SSD IR or 80-mg rifaximin SSD SER tablets in volunteers (fasted [stage 1] or fed state [stage 2]). In stage 2, volunteers were randomly assigned to receive IR or SER after a high-fat meal. Blood samples were collected at baseline and through 48 hours postdose.
Results: 48 adults (mean age, 31.9 y) entered stage 1; 39 entered and completed stage 2. As expected, based on drug release criteria, exposure parameters were different between IR and SER tablets (Table). In the fasted state, rifaximin systemic exposure was greater after a dose of rifaximin SSD IR vs SER (Table). Based on bioequivalence acceptance criteria, exposure in the fasted state, measured by AUC and C_{max}, was statistically different between IR and SER tablets. In stage 2 (fed state), rifaximin systemic exposure (C_{max} and AUC) with IR and SER tablets was not clinically significantly impacted when administered with food, with only small changes in mean values vs fasted state. Median T_{max} was delayed in fed state for IR (3.0 h) and SER (4.0 h) tablets but differences vs fasted state were not significant. A single dose of rifaximin SSD IR and SER tablets was well tolerated.

Table 1: Single-dose PK (fasted state)

	Rifaximin SSD IR tablet (n = 48)*	Rifaximin SSD SER tablet (n = 46)*
C_{max}, mean, ng/ml (SD)	5.2 (4.4)	1.4 (0.8)
T_{max}, median, h (range)	1.5 (0.5–6.0)	2.0 (0.5–6.0)
AUC_{0-last}, h·ng/ml	22.7 (16.3)	8.5 (5.4)
AUC_{0-inf}, h·ng/ml	24.9 (16.6)	10.2 (5.7)
$t_{1/2}$, mean, h (SD)	8.7 (4.1)	6.6 (3.4)

*Patients with sufficient samples. AUC_{0-inf} = area under the plasma concentration–time curve from time zero to infinity; AUC_{0-last} = area under the plasma concentration–time curve from time zero to the last measurable concentration; C_{max} = maximum observed plasma concentration; SD = standard deviation; $t_{½}$ = terminal half-life; T_{max} = time to maximum observed plasma concentration.

Conclusion: Data suggest progressive decreases in systemic exposure as a function of increasing delay in GI release (eg, IR vs SER) and show minimal effects of food. Also, 80-mg rifaximin SSD IR and SER tablets exhibit half-lives that may indicate increased GI residence times and the feasibility of a once-daily dosing regimen.

FRI-234

Simvastatin-loaded polymeric micelles are a new, safe and effective drug delivery system targeting liver sinusoidal endothelial cells

D. Hide[1,2], I. Raurell[1,2], D.F. de So Rafael[3], F.D.S. Andrade[3], S. Schwartz[3], S. Augustin[2,4], J. Genesca[4], M. Martell[1,2]. *[1]VHIR - Vall d'Hebron Institut de Recerca, Liver Unit, Barcelona; [2]CIBERehd, Madrid, Spain; [3]VHIR - Vall d'Hebron Institut de Recerca, CIBBIM - Nanomedicina, Barcelona; [4]Hospital Universitario Vall d'Hebron, Liver Unit, Barcelona, Spain*
Email: diana.hide@vhir.org

Background and Aims: Self-assembled polymeric micelles (PM) are versatile nanocarriers that can load hydrophobic or hydrophilic drugs and can be functionalized in its surface potentially reaching any cell type. Simvastatin has been tested in many models of acute and chronic liver injury showing promising results, but also some adverse effects such as muscular and hepatic toxicity. Thus, the main aim of this study is to characterize the effect of two types of PM loaded with simvastatin targeting liver sinusoidal endothelial cells (LSEC) as a new drug delivery system to improve the treatment of liver diseases
Method: PM with two different polymers (F108 and F127) were produced and analyzed in parallel. Physicochemical characterization included drug encapsulation, size, and polydispersion index. Functional characterization performed in HUVEC and LSEC comprise internalization, cytotoxicity, gene expression assays and phenotype examination by scanning electronic microscopy (SEM). *In vivo* administration of simvastatin-loaded PM was performed for biodistribution and maximum tolerated dose (MTD) assays.
Results: Entrapment efficiency of 20mg/ml simvastatin with a 50:1 polymer: drug ratio was >96%. Size of the produced PM was 22.4 ± 0.23nm and polydispersity index 0.192 ± 0.009nm. Internalization of PM both in HUVEC and LSEC endothelial cells was over 90% in the first hour of incubation regardless the detection method employed. Toxicity assay of PM + SIMVA revealed a 100% cell viability up to 1mM simvastatin concentration in HUVEC and 50 μM in LSEC. In HUVEC, PM + SIMVA were less toxic that the non-encapsulated drug. In LSEC, toxicity values were similar for PM + SIMVA and free simvastatin, indicating no increased toxicity by PM formulation. Functionally, the effects of PM + SIMVA were similar to free simvastatin in HUVEC and LSEC cultures. In summary, a significant increase in KLF2 and eNOS compared to vehicle treated cells was observed, and in both cases simvastatin (free or encapsulated) caused a significant increase in fenestrae frequency and endothelial porosity. Intravenously administered PM were mainly found in the liver. After PM + SIMVA in vivo administration 3 days a week during two weeks, survival was 100% in all concentrations (0.5, 1 or 2 mg/kg) tested and no adverse effects were observed.
Conclusion: PM loaded with simvastatin are less toxic for endothelial cells than the free drug and are effective improving endothelial phenotype. In vivo administration of PM + SIMVA at high concentrations is possible and mainly targets the liver.

Transcriptome analysis of human and murine cirrhotic livers identifies shared molecular pathways as potential targets to enhance cirrhosis regression

E. Lafoz, M.V. Barceló, Héctor García-Calderó, M. Vila-Casadesús, D. Tripathi, M. Ruart, J. Lozano, J. Gracia-Sancho, V. Hernandez-Gea, J.-C. Garcia-Pagan. *Barcelona Hepatic Hemodynamic Laboratory. Hospital Clínic. IDIBAPS, University of Barcelona. CIBEREHD, Barcelona, Spain*
Email: jcgarcia@clinic.ub.es

Background and Aims: In patients with advanced liver disease, etiological treatment partially improves liver fibrosis and portal hypertension. This pattern is replicated in preclinical models of advanced cirrhosis after 8 weeks of etiological agent discontinuation. The aim of our study was to unravel core molecular pathways involved in cirrhosis regression to identify potential new targets to enhance it.
Method: Microarray analysis was done in livers from 1) cirrhotic patients 2) healthy control patients 3) TAA or CCl_4 cirrhotic rats 4) cirrhotic rats after 8-week of CCl_4 or TAA discontinuation 5) control rats. RNA was hybridized to GeneChips (Affimetrix). Differentially expressed genes were analysed in human and rat cirrhosis in relation to their control counterparts (gene list enrichment analysis: Kyoto Encyclopedia of Genes and Genomes and reactome). Enriched pathways shared in human and both models or rat cirrhosis were identified. From those, pathways that did not normalize during cirrhosis regression in rat models were selected.
Results: 6885 genes were upregulated in cirrhotic patients and 1052 genes in rat models. Gene list enrichment analysis revealed 10 shared pathways enriched in rats and human including: ECM (ECM organization, elastic fibre formation), immune system (cytokine signaling, signaling by interleukins, hematopoietic cell lineage), developmental biology, muscle contraction (striated muscle contraction, dilated cardiomiopathy), cancer (pathways in cancer) or hypertrophic cardiomyopathy. Of these, only 2 (hematopoetic cell lineage and striated muscle contraction) normalized during regression while the other 8 remained upregulated.
On the other hand, 7734 genes were downregulated in patients with cirrhosis and 628 in cirrhotic rat livers. Gene list enrichment analysis revealed 5 shared pathways including: metabolism (metabolic pathways, metabolism of lipids and lipoproteins, biological oxidations, peroxisomal lipid metabolism) and transport and catabolism (peroxisome). Three of these pathways (lipid and lipoproteins metabolism, peroxisomal lipid metabolism and peroxisome) did not normalize during regression.
Conclusion: The current study identifies molecular pathways commonly altered both in human and rat cirrhotic livers that do not normalize during cirrhosis regression. Characterization and identification of druggable pathways may reveal innovative and translational therapeutic strategies able to promote cirrhosis regression.

FRI-236

In cirrhotic rats, mitochondria-targeted antioxidant mitoquinone attenuates liver inflammation and fibrosis by modulating oxidative stress and mitophagy

S. Turkseven[1,2], M. Bolognesi[1], A. Brocca[1], P. Angeli[3], M.D. Pascoli[1]. *[1]University and General Hospital of Padova, Unit of Internal Medicine and Hepatology, Department of Medicine (DIMED), Padova, Italy; [2]Ege University, Department of Pharmacology, Izmir, Turkey; [3]Unit of Internal Medicine and Hepatology, University and General Hospital of Padova, Padova, Italy*
Email: m.dipascoli@tin.it

Background and Aims: Mitochondrial dysregulation is responsible for excessive reactive oxygen species production. Selective removal of dysfunctional mitochondria from the mitochondrial network by mitophagy is a crucial step for maintaining mitochondrial quality control. Since in liver cirrhosis oxidative stress plays a major role in triggering liver inflammation and fibrosis, in an experimental model of cirrhosis, we investigated the effect of mitochondria-targeted antioxidant mitoquinone on these processes.
Method: Liver cirrhosis was induced in Spraque-Dawley rats by common bile duct ligation. Mitoquinone (10 mg/kg/day, oral gavage) or vehicle were administered from 3rd to 28th day after common bile duct ligation. The day of the last administration animals were sacrificed. Liver oxidative stress, inflammation, fibrosis and parkin dependent mitophagy was evaluated.
Results: In cirrhotic rats, histological examination showed that mitoquinone prevented liver inflammation, hepatocyte necrosis and fibrosis. Mitoquinone administration was associated with a decreased gene expression of transforming growth factor beta, collagen1A1 and tumor necrosis factor alpha. Moreover, mitoquinone

reduced hepatic oxidative stress, as shown by reduced oxidative carbonylation of the proteins, by modulating antioxidants such as catalase, Mn superoxide dismutase and Cu/Zn superoxide dismutase. Parkin-dependent mitochondrial quality control was improved by mitoquinone, as shown by the increase in Parkin translocation to mitochondria, suggesting an increased selective removal of dysfunctional mitochondria. Furthermore, mitoquinone attenuated apoptosis by reducing hepatic protein expression of cleaved caspase-3.
Conclusion: Mitochondria-targeted antioxidant mitoquinone improves liver inflammation and fibrosis in cirrhotic rats by reducing hepatic oxidative stress, preventing apoptosis and promoting removal of dysfunctional mitochondria. Therefore, it may represent a promising strategy for prevention and treatment of liver cirrhosis.

FRI-237

Ascites NK cells are phenotypically distinct from blood and liver NK cells in patients with liver cirrhosis and become activated by bacterial stimulation in-vitro and during spontaneous bacterial peritonitis

P. Lutz[1,2,3], H.C. Jeffery[3], N. Jones[4], B. Krämer[1,2], J. Birtwistle[5], J. Nattermann[1,2], U. Spengler[1,2], C.P. Strassburg[1,2], D. Adams[3,6], Y.H. Oo[3,6]. *[1]Department of Internal Medicine I, University of Bonn; [2]DZIF, University of Bonn; [3]Centre for Liver Research and National Institute of Health Research Liver Biomedical Research Unit Birmingham, University of Birmingham; [4]Institute of Life Science, Swansea University; [5]Human Biomaterial Resource Centre, University of Birmingham; [6]University Hospital of Birmingham NHS Foundation Trust*
Email: philuweltweit@web.de

Background and Aims: Ascites is frequent in liver cirrhosis and further complicated by bacterial translocation and spontaneous bacterial peritonitis (SBP). Despite the clinical impact of SBP, little is known about ascites as an immune cell compartment. Therefore, we analysed lymphocytes in different human tissues to compare their phenotype and function.
Method: Mononuclear cells from blood, ascites and liver explants of patients with advanced liver disease were extracted by density centrifugation. Phenotyping and analysis of functional responses were carried out using flow cytometry. Migration and cell metabolism were assessed by transwell assays and using Seahorse technology, respectively.
Results: At first, ascites, blood and liver explants from 43 patients without SBP were studied (74% male; median age 53 years; alcoholic cirrhosis in 51%). In contrast to B-, CD4-, CD8-, regulatory T-, MAIT- and γδ T-cells, NK cell frequency was increased in ascites compared to blood (median 27% vs 7%; $p < 0.001$), but not to liver. Most ascites NK cells were $CD16^{positive}$ (73% vs 83% in blood and 41% in liver; $p < 0.01$). Expression of the activating receptor NKG2D was decreased on ascites and liver $CD16^{positive}$ NK cells ($p = 0.009$), while expression of the inhibitory receptor NKG2A was comparable on blood (64%) and ascites (57%) $CD16^{positive}$ NK cells, but decreased in liver (45%; $p = 0.02$). As demonstrated by HLA-DR expression, ascites and liver $CD56^{dim}$ NK cells were more activated compared to blood ($p = 0.03$). Consistently, a significantly increased maximal respiration of ascites versus blood NK cells indicated a greater capacity to respond to activation. Ascites $CD16^{positive}$ NK cells expressed higher levels of CXCR3 than blood or liver NK cells, corresponding to increased ascites levels of CXCL10 secreted by $CD14^{positive}$ monocytes/macrophages. Stimulation of mononuclear cells with Escherichia coli (E. coli) led to downregulation of NKG2D-, upregulation of HLA-DR-expression and secretin of Interferon-gamma (IFNg) mediated by IL-12 and IL-18 in NK cells from ascites, but not from blood. Blocking IFNg modulated the inflammatory response of E. Coli stimulated ascites $CD14^{positive}$ monocytes/macrophages. Similarly, ascites NK cells were more activated and expressed less NKG2D in SBP compared to uninfected ascites in a second cohort of patients.
Conclusion: Ascites NK cells may be implicated in local immune defense against translocating bacteria by interacting with monocytes/macrophages.

FRI-238

Protective role of VEGF-A165b in liver cirrhosis with portal hypertension

R. Schierwagen[1], C.-E. Ruiner[1], J. Lehmann[1], A. Pohlmann[1], S. Klein[2], F. Uschner[1], F. Magdaleno[1], C. Jansen[1], R. Pe[3], J. Trebicka[1,4,5,6]. *[1]University of Bonn, Department of Internal Medicine I, Bonn, Germany; [2]Newcastle University, Fibrosis Research Group, Newcastle; [3]Paris Cardiovascular Research Center, INSERM U970, Paris, France; [4]European Foundation for the Study of Chronic Liver Failure - EF Clif, Barcelona, Spain; [5]Institute for Bioengineering of Catalonia, Barcelona, Spain; [6]Odense University Hospital, Department of Medical Gastroenterology and Hepatology, Odense, Denmark*
Email: robert.schierwagen@ukbonn.de

Background and Aims: Chronic liver damage and vascular diseases may lead to the development of portal hypertension. The vascular endothelial growth factor A (VEGF-A) plays a central role in this context by regulating vascular angiogenesis. However, it is still uncertain in which way VEGF-A contributes to the development of portal hypertension. Several alternative splice variants of VEGF-A may explain the opposing results gathered so far. This study investigates the role of the splice variant $VEGF\text{-}A^{b}_{165}$ for the development of portal hypertension.
Method: Blood from cirrhotic patients was gathered at transjugular portosystemic shunt insertion. Levels of total VEGF-A and $VEGF\text{-}A^{b}_{165}$ were measured using ELISA-kits. miRNAs were assessed by RT-PCR. Hepatic and vascular contractile, as well as endothelial cells were *in vitro* incubated with $VEGF\text{-}A^{b}_{165}$ and effects on contraction, fibrogenesis and angiogenesis were measured by gene expression and protein synthesis.
Results: Total levels of VEGF-A showed an increased gradient over the liver in cirrhotic patients and are packed in microparticles of endothelial origin to a large extent. Furthermore, high levels of total VEGF-A in the portal vein are associated with an unexpected improvement of survival, which seems to be affiliated to the splice variant $VEGF\text{-}A^{b}_{165}$. Along with increasing $VEGF\text{-}A^{b}_{165}$ levels over the liver, higher levels of miRNAs 125b and 126 were measured post-hepatic, which may act as regulators of the VEGF-A production. Only levels of $VEGF\text{-}A^{b}_{165}$, but not total VEGF-A levels, reflect disease progression with highest values in patients without ascites and decreasing levels with developing ascites. Incubation with $VEGF\text{-}A^{b}_{165}$ decreased vascular angiogenesis and contractility. However, intrahepatic $VEGF\text{-}A^{b}_{165}$ increases contraction of hepatic stellate cells and tends to increase proliferation.
Conclusion: Circulating $VEGF\text{-}A^{b}_{165}$ turns out to be a marker of complication severity in cirrhotic patients with portal hypertension. Higher levels of $VEGF\text{-}A^{b}_{165}$, representing no/less severe complications, explain the benefit in survival. If the decreased vascular angiogenesis and contractility in patients accounts for this benefit has to be investigated extensively in regard to treatment approaches for portal hypertension and its complications in cirrhotic patients. Care needs to be taken to the possible unfavorable effects on hepatic cells, especially hepatic stellate cells.

FRI-239

Real world experience of lusutrombopag for thrombocytopenia in patients with liver cirrhosis

H. Takada, N. Izumi, M. Kurosaki, J. Itakura, K. Tsuchiya, H. Nakanishi, Y. Yasui, T. Nobuharu. *Musashino Red Cross Hospital*
Email: takadahi@musashino.jrc.or.jp

Background and Aims: Lusutrombopag is an oral thrombopoietin receptor agonist which have been approved for use to improve thrombocytopenia in cirrhotic patients before invasive procedures. We herein report the efficacy and safety of administration of lusutrombopag for thrombocytopenia in real-world setting.
Method: A total of 1606 consecutive cirrhotic patients who were scheduled to undergo invasive procedures from January 2014 to September 2017 in our hospital was studied. Platelet counts and the

frequency of platelet transfusion were monitored. From November 2013 to September 2017, lusutrombopag was administered in 16 patients with liver cirrhosis whose platelet count <50.000/microl. Lusutrombopag administration was stopped at day 5 if the patients achieved platelet counts ≥50.000/microl or increase of ≥20.000/microl within day 5, and was continued for a total of 7 days in other patients.

Results: The median platelet counts with radio-frequency ablation (RFA, n = 686), transarterial chemoembolization (TACE, n = 770) and endoscopic injection sclerotherapy/endoscopic variceal ligation (EIS/EVL, n = 150) was 123.000, 116.000, and 116.000/ microl, respectively. The proportion of patients with platelet count <50.000/microl were 6.0%, 6.4%, and 6.0%, respectively. For these patients with low platelet counts, platelet transfusion was given in 67%, 42%, and 60%, respectively. Lusutrombopag was administered in 16 patients, the platelet counts before administration of lusutrombopag was 39.000 ± 11.000/microl which increased to 78.000 ± 29.000/microl before the invasive procedure ($p < 0.05$). Platelet transfusion was necessary in only one patient (6%). There was no adverse events such as bleeding and thrombosis.

We developed a scoring system where each of the following was scored as 1 (platelet counts 30.000–50.000/microl, Child-Pugh grade A, Spleen index 20–35, and alcohol drinkers), and each of the following was scored as 2 (platelet count less than 30.000/microl, Child - Pugh grade B, and Spleen index over 35). Among lusutrombopag administered patients, 10 patients had total scores of 4, and 6 patients had scores of 5. In patients of score 4, a significant increase in platelet count was observed compared with the patients of score 5 (52.000 ± 22.000 vs. 26.000 ± 16.000/microl, $p = 0.023$). The platelet counts reached to plateau at day 10 in patients with baseline platelet counts 30000–50000/microl (n = 13) and at day 12 in patients with <30000 /micro (n = 3).

Conclusion: The administration of lusutrombopag for thrombocytopenia in cirrhotic patients was effective and safe in the real-world setting, and reduced the need for platelet transfusion in 94% of patients.

FRI-240

Chronic liver damage causes a reduction in the number and a dysfunction of the activity of liver resident macrophages

E. Pose[1,2,3,4], M. Coll[2,3,4], B. Surewaard[5], Z. Zeng[5], D. Blaya[3,4], L. Perea[3,4], B. Aguilar-Bravo[3,4], J. Vallverdú[3,4], I. Graupera[1,2,4], P. Sancho-Bru[3,4], P. Kubes[5], P. Ginès[1,2,4]. *[1]Hospital Clinic de Barcelona, Liver Unit, Barcelona, Spain; [2]University of Barcelona, Faculty of Medicine and Health Sciences, Barcelona, Spain; [3]IDIBAPS, Barcelona, Spain; [4]CIBEReHD, Barcelona, Spain; [5]The Calvin, Phoebe & Joan Snyder Institute for Chronic Diseases, University of Calgary, Calgary, Canada*
Email: pgines@clinic.ub.es

Background and Aim: Patients with decompensated cirrhosis have high risk of infections, which are the main cause of death in this population. Liver resident macrophages or Kupffer cells (KCs) play an essential role in the immune system given their high capacity of eliminating bacteria from the circulation. Although immune function of the liver is thought to be impaired in cirrhosis and contribute to the risk of infections, there is lack of information about KCs population and function. Our aim was to evaluate the number, function and role in the predisposition to infections of KCs in patients with cirrhosis.

Methods: KCs were quantified by CD68+ area in liver biopsies from patients with compensated (n = 22) and decompensated cirrhosis (n = 19), acute liver failure (n = 9) or controls (n = 9). KCs isolated from explants of patients with cirrhosis and from a control group were stimulated with LPS; response was evaluated by inflammatory cytokines expression. In vivo KCs phagocytic capacity in patients with cirrhosis was evaluated by hepatic SPECT with 99mTc-phytate. In vivo KC function was studied in a mouse model of chronic liver injury (DDC diet) infected with bacteria over-expressing GFP (*MRSA*, $5{\cdot}10^7$ cfus, *iv*). Bacterial catching capacity was determined by spinning-disc intravital microscopy. Bacterial dissemination to extra-hepatic organs and survival were evaluated.

Results: The area occupied by KCs in liver biopsies from patients with cirrhosis was significantly lower compared to the other groups ($p < 0.01$). KCs from patients with cirrhosis showed a decreased response to inflammatory stimulus compared to controls. Patients with decompensated cirrhosis showed a lower uptake of 99mTc-phytate by the liver. In DDC mice, bacterial catching capacity by KCs was reduced compared to that in controls ($p < 0.05$). Bacterial dissemination and bacteremia were markedly increased in chronic liver injured mice. Moreover, survival after infection was reduced in DDC mice compared to controls ($p < 0.05$).

Conclusion: Patients with cirrhosis have a reduction in liver resident macrophages. This cell population exhibits an impaired phagocytic capacity and response to inflammation. KCs from mice with chronic liver injury show a reduced capacity of capturing bacteria from the circulation, leading to a major susceptibility to infections. Therefore, increasing the number and promoting phagocytic capacity of KCs might be a good strategy to reduce the risk of infections in patients with cirrhosis.

FRI-241

An immuno-metabolic phenotype of acute-on-chronic liver failure predicts early mortality

R. Zia[1], U.-K. Umlai[1], K.L Leary[1], V. Patel[2], I.D Wilson[1], J. Wendon[2], M. Coen[1], M.J.W. Mcphail[2]. *[1]Imperial College London, Computational and Systems Medicine, London, United Kingdom; [2]Kings College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: rabiya.zia08@imperial.ac.uk

Background and Aims: Mortality rates for acute-on-chronic liver failure (ACLF) remain high and immune dysfunction is a key accelerator of disease progression in ACLF patients. More accurate prognostic biomarkers are needed and changes in phospholipid (PC) metabolism accurately predict survival in acutely decompensated (AD) cirrhosis. We expand on this by profiling ACLF patients and quantifying downstream inflammatory mediators: eicosanoids (ECs). We aim to characterize immune-metabolic changes that explain progression to ACLF and aid prognostic scoring.

Method: Metabotyping of lipids in human serum was performed by untargeted ultra-performance liquid chromatography-mass spectrometry (UPLC-MS) in positive (LPOS) and negative (LNEG) ionisation modes, and targeted UPLC-MS to quantify EC in the following patients: ACLF (n = 49), AD (n = 50), stable cirrhosis (n = 13) and HC (n = 38). Univariate analysis using the Kruskal-Wallis (KW) with a post-hoc Dunns test and multivariate analysis using principal component analysis (PCA) and orthogonal projections to latent structures discriminant analysis (OPLS-DA), were used for analyses. External validation was performed on LNEG and LPOS datasets by calculating area under the receiver operating curve (AUROC). Tentative metabolite identification (metID) from LPOS and LNEG data was performed using online metabolite databases.

Results: Multivariate analysis of the LNEG and LPOS data generated models which show separation between all groups in PCA in PC1 – (LPOS: $R2 = 0.56$ $Q2 = 0.52$ and LNEG: $R2 = 0.60$ $Q2 = 0.56$). Tentative metID of LPOS and LNEG data revealed that most discriminant endogenous metabolites for AD vs ACLF were PCs. OPLSDA models of survival (30 days) were computed from LNEG ($R2Y = 0.50$, $Q2Y = 0.29$, CV-ANOVA p-value = $1{\times}10^{-6}$) with AUROC of 0.92, sensitivity = 90%, specificity = 79%, $p < 0.001$, LPOS ($R2Y = 0.56$, $Q2Y = 0.35$, CV-ANOVA p-value = $5{\times}10^{-8}$) with AUROC of 0.96, sensitivity = 90%, specificity = 88%, $p < 0.001$ and EC ($R2Y = 0.43$, $Q2Y = 0.32$, CV-ANOVA p-value = $4{\times}10^{-6}$) data. Univariate analysis of ECs showed that anti-inflammatory ECs were raised in survivors: Lipoxin-A4($p = 0.005$), 5,6-DHET($p = 0.0001$), Lipoxin-B4($p = 0.007$), 5(S)-HETE($p = 0.007$), PGE2($p = 0.001$) and PGD2($p = 0.002$).

Conclusion: We demonstrate that changes in lipid and EC metabolism are discriminant between AD and ACLF. Furthermore, greater

circulating levels of anti-inflammatory ECs may be involved in resolution of the inflammatory response and are characteristic of survival in AD and ACLF.

FRI-242

Etiology-specific hemostatic profiles in cirrhosis

S. Bos, J. Adelmeijer, H. Blokzijl, P.W. Kamphuisen, S. Tim, T. Lisman.
University medical center Groningen, Groningen,
Email: s.bos01@umcg.nl

Background and Aims: Patients with cirrhosis may acquire profound changes in their hemostatic system. Although hemostatic changes have been extensively studied, most studies were performed in groups of patients with mixed etiology. We hypothesized that hemostatic changes might be different across etiologies.
Methods: 41 healthy controls and 79 patients with cirrhosis (21 alcoholic liver disease (ALD), 16 non-alcoholic steatohepatitis (NASH), 28 cholestatic liver disease (17 primary sclerosing cholangitis, 11 primary biliary cholangitis), 14 viral hepatitis (7 hepatitis C, 7 hepatitis B)) were studied. Patients with malignancy were excluded. Routine diagnostic tests of hemostasis, thrombin generation assays, and a plasma-based fibrinolytic assay were performed. In addition, plasma levels of individual hemostatic factors were determined.
Results: All cirrhotic patients had comparable severity of disease according to their MELD-score (9 [7–11]). Prothrombin time was significantly prolonged for all etiologies and highest in ALD. The platelet adhesive protein VWF was elevated in all groups, but substantially lower in viral hepatitis than in other etiologies. The VWF-cleaving protease ADAMTS13 was decreased in cholestatic disease and viral hepatitis but not in ALD and NASH. The endogenous thrombin potential was significantly increased compared to controls in all patient samples with the highest values in NASH. Plasma levels of factor VIII were elevated in all groups except viral hepatitis, FVII was similarly decreased in all groups and prothrombin levels were decreased in all groups except in viral hepatitis. Protein C and antithrombin were similarly decreased in all groups. Fibrinogen levels were elevated in all groups and highest in the cholestatic group. Fibrinolytic potential was similar in all groups, with a small decrease in fibrinolytic potential in the cholestatic group.
Conclusion: There are notable differences in the hemostatic profile in cirrhotic patients of different etiologies. For example, the hemostatic status of patients with cholestatic liver disease has notable hypercoagulable features, but also decreased thrombin generation compared to the other groups. In line with our previously published data, patients with NASH do not appear particularly hypercoagulable, although TGA was highest in this group. These distinct differences necessitate further research focussing on individualized management of bleeding and thrombosis in patients with cirrhosis.

FRI-243

Prediction of blood ammonia levels in modeled human liver dysfunction and application to gut-restricted ammonia lowering therapeutics

C. Brew[1], S. Smith[1], L. Noiret[2], E. Labonté[1], C. Rose[3], S. Harrison[1].

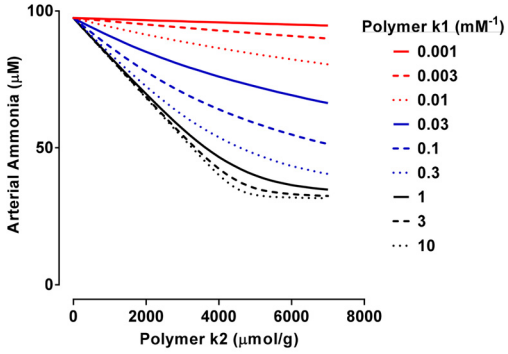
Background and Aims: Hepatic encephalopathy (HE) is a debilitating complication of cirrhosis which is defined as an array of neuropsychiatric abnormalities. Patients with HE suffer from a poor quality of life including impaired driving skills, inability to work, and susceptibility to frequent falls. A primary cause of HE is the accumulation of ammonia in the systemic circulation which leads to toxic levels of ammonia in the brain. Because a majority of ammonia is generated in the gut, one therapeutic strategy is to bind ammonia in the lumen using a gut-restricted polymer, preventing ammonia absorption into the systemic circulation. To understand the optimal binding properties required to efficiently lower blood ammonia, it is imperative to understand inter-organ ammonia metabolism in cirrhosis.
Method: We have developed a dynamic *in silico* model of ammonia distribution using Berkeley Madonna PK/PD modeling software. Physiological parameters were defined to describe the flux of ammonia in healthy and cirrhotic states, and were obtained from reported inter-organ fluxes of ammonia in fasted individuals with and without cirrhosis. Key physiological changes in cirrhosis include an increase of splanchnic blood flow, porto-systemic shunting and a loss of hepatic functions. The model was validated by assessing how it predicts blood ammonia levels at baseline and following an oral ammonia challenge, as well as its prediction of ammonia concentrations in the portal vein and feces under various degrees of portal-systemic shunting and liver impairment.
Results: Arterial ammonia levels were very sensitive to factors such as ammonia production in the gut, hepatic and muscle ammonia extraction, degree of porto-systemic shunting, and portal blood flow. Other parameters, such as the GI absorption rate constant for ammonia and gut volume had less impact on arterial ammonia levels. We assessed the impact of various theoretical, gut-restricted ammonia binding therapeutics, and found it is feasible to significantly reduce blood ammonia levels by removing ammonia from the gut. The model has been used to evaluate how a change in affinity and/or capacity of the binding agent impacts systemic ammonia levels (Figure).



Theoretical impact of polymer on arterial ammonia levels in a model of human cirrhosis; evaluation of the sensitivity to polymer capacity (k2) and affinity (k1)

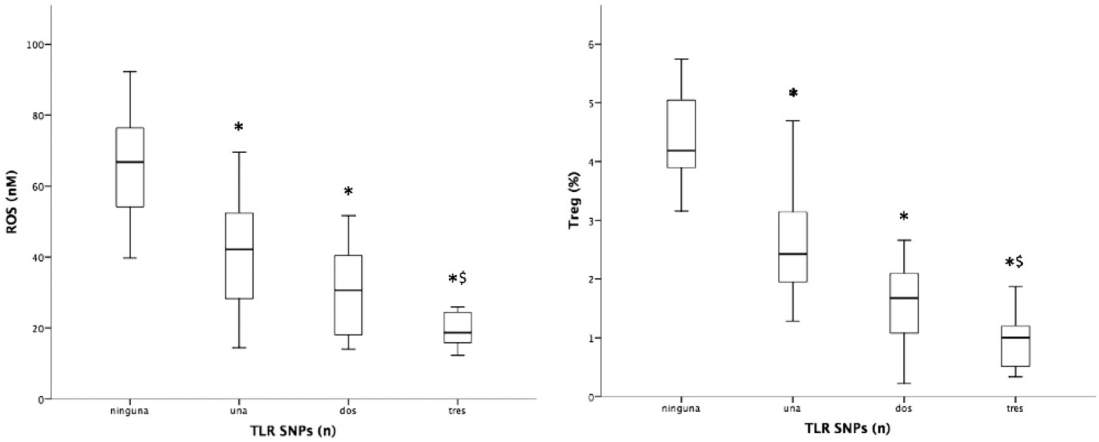
Conclusion: In summary, we developed the first dynamic model of interorgan ammonia metabolism in cirrhosis. The model demonstrates that binding ammonia in the gut should meaningfully lower arterial blood ammonia levels in cirrhosis.

FRI-244

Polymorphisms in toll-like receptors identify a defective oxidative response and a reduction in the regulatory T cell population in patients with cirrhosis and non-infected ascites

P. Piñero[1], O. Juanola[2], I. Gómez-Hurtado[3], P. Zapater[3], E. Caparrós[2], José Such[2,4], J.M. González-Navajas[5], Rubén Francés[2,3,5]. *[1]Fundación Isabial-Fisabio, Hospital General Universitario de Alicante, CIBERehd, Alicante, Spain; [2]Universidad Miguel Hernández, Dpto. Medicina Clínica, Alicante, Spain; [3]CIBERehd, Instituto de Salud Carlos III, Madrid, Spain; [4]Cleveland Clinic Abu Dhabi, Digestive Disease Institute, Abu Dhabi, United Arab Emirates; [5]Fundación Isabial-Fisabio, Hospital General Universitario de Alicante, Alicante, Spain*
Email: paupinrom@gmail.com

Background and Aims: Patients with cirrhosis are frecuently exposed to the translocation of bacterial antigens that complicate the course of the disease. Toll-like receptors (TLRs) are a fundamental part of the innate immune response in the resolution of these episodes, which requires the production of reactive oxygen species (ROS) for clearance. This response is controlled by regulatory T



** p=0.01 comparado con la ausencia de SNPs; $ p=0,01 comparado con la presencia de 1 ó 2 SNPs*

Figure (abstract FRI-244)

lymphocytes (T reg), which balance the response and favor immunological tolerance.
We aim to evaluate if the accumulation of polymorphisms in the TLR genes decreases the oxidative response and the proportion of Treg cells in patients with cirrhosis.
Method: Prospective observational study in patients with cirrhosis and non-infected ascites. Serum ROS concentration was determined by ELISA and the blood Treg cell population was quantified by flow cytometry using a CD3+ CD4+ CD25+ CD127-FoxP3+ panel.
Results: We included 71 patients with a mean age of 60 ± 10 years. The main etiology was alcohol and the mean Child-Pugh was 9.2 ± 1.8. Twenty-two patients (30.9%) were taking β-blockers and 25 (35.2%) PPIs. Seven patients did not show SNPs (9.9%), 33 showed 1 SNP (46.5%), 26 patients the combination of 2 SNPs (36.5) and 5 carried the 3 SNPs studied (7.1%). The concentration of ROS and the percentage of Treg cells in blood are shown in Figure 1. Patients without SNPs showed significantly higher ROS and Treg levels than those observed in patients with one or more SNPs. In addition, patients with 3 SNPs showed significantly lower levels in both variables compared with patients with 1 or 2. A positive correlation was observed between ROS concentrations and the percentage of Tregs in the sample studied (r = 0.615, p = 0.001).
Conclusion: Polymorphisms in TLR genes limit the immune response and its modulation. Therefore, they could hinder the clearance of translocated bacterial antigens in patients with cirrhosis and non-infected ascites.

FRI-245
Bacterial translocation during experimental cirrhosis coincidences with the infiltration of inflammatory monocytes in the gut
L. Meelberghs[1], S. van der Merwe[1,2], F. Nevens[1,2], L. Verbeke[1,2], H. Korf[1], P. Windmolders[1], I.V. Elst[1]. *[1]KU Leuven, Laboratory of Hepatology, Leuven, Belgium; [2]UZ Leuven, Gastroenterology and Hepatology, Leuven, Belgium*
Email: lore.meelberghs@kuleuven.be

Background and Aims: Patients with advanced cirrhosis are susceptible to bacterial infections. The majority of infections originate from the gut due to a failure of the intestinal barrier function and the local innate immune system to dampen the response towards translocated bacteria. Indeed, we have previously demonstrated that intestinal myeloid cells from decompensated cirrhosis patients feature elevated levels of inflammatory parameters that may aggravate intestinal barrier dysfunction. However, the mechanisms governing the intricate cross talk between host and microbe, remain incompletely understood. Here we aim to elucidate the role and dynamics of inflammatory monocytes and macrophages during cirrhosis pathogenesis.
Method: C57BL/6J mice received subcutaneous carbon tetrachloride (CCl_4) injections (2ml/kg of CCl_4 50% (v/v)) (n = 5–8) or vehicle only (n = 3–4) twice a week. Mice were sacrificed after 4-, 9-, 14-, or 19 weeks and the extent of liver fibrosis/cirrhosis was assessed histologically following Picrosirius Red staining. Additionally, intestinal samples (proximal- distal small intestine, and colon) were collected for flow cytometry and mesenteric lymph nodes (MLNs) and plasma were collected for bacterial culture and liver function tests respectively.
Results: Histological analysis confirmed advanced fibrosis and cirrhosis development at week 14 and 19 respectively. Bacterial translocation as evaluated by culture positive MLN's, occurred at week 19, although elevated levels of bacterial products such as LPS, were detected both at week 14 and week 19 of CCl_4 exposure. Flow cytometric analyses of lamina propria cells isolated from the small bowel and colon revealed a gradual decrease in the frequencies of $MHC^{high}CD11b^{high}CX3CR1^{pos}CD64^{pos}$ resident macrophages. Conversely, intestinal samples from cirrhotic mice were enriched with $MHCII^{int}CD11b^{int}CX3CR1^{pos}Ly6C^{pos}$ inflammatory monocytes and the latter observation coincided with the presence of bacterial products in the circulation. Moreover, infiltrating inflammatory monocytes expressed high levels of CCR2 implicating their responsiveness towards the chemokine microenvironment.
Conclusion: These studies reinforce the pathogenic role of monocytes in dysregulated responses to intestinal bacteria during cirrhosis. Further understanding of their importance during intestinal barrier dysfunction are ongoing and may lead to strategies aimed at interrupting cirrhosis-driven pathology.

FRI-246
Effectiveness of a practical nutritional intervention in advanced liver disease: A prospective study
D. Costa[1], H. Silva[2], A.Célia Caetano[1], Luís Meira-Machado[3], C. Rolanda[1], R. Gonçalves[1], D. Fernandes[1]. *[1]Braga Hospital, Gastroenterology; [2]School of Medicine; University of Minho; [3]University of Minho, Centre of Mathematics and Department of Mathematics and Applications*
Email: dc.dalilacosta@gmail.com

Background and Aims: Malnutrition is one of the most prevalent complications of advanced liver disease and is associated with poor clinical outcome. In mixed populations of malnourished patients, the benefits of nutrition therapy are evidenced by reduction in mortality, infections and hospital length of stay. However, cirrhosis-specific studies are limited. The aim of the present study was to evaluate the

impact of an adequate oral diet on nutritional status of patients with advanced liver disease (ALD) during a period of 3 months.
Methods: A prospective, interventional and single-center study was performed. Nutritional assessment was achieved in 75 consecutive patients with ALD (Child-Pugh B and C) evaluated between January and May 2017. 24 patients diagnosed with protein-caloric malnutrition according with Bioelectrical impedance analysis (BIA) measures were introduced to an appropriate nutritional plan (energy intake of 35–40 kcal/kgBW/d and a protein intake of 1.5 g/kgBW/d) developed and implemented (verbal and written) by the Department of Nutrition. Patients were divided into two equal groups according with diet compliance (DC v non-DC). Clinical, anthropometrical and biochemical data were assessed at a 3-month follow-up.
Results: Patients in both groups did not differ significantly. Most were male (21; 87.5%), Child-Pugh B (21; 87.5%) with a mean age of 57.6 years. According to BIA, the controlled diet significantly improved nutritional status in DC group (p = 0.003), since 8 patients were no longer malnourished at 3-month follow-up. At paired analysis, all nutritional parameters improved in DC group, though only dry-weight body mass index (BMI) (p = 0.010), triceps skinfold (TSF) (p = 0.019) and arm circumference (AC) (p= 0.006) were significant. When compared to non-DC, mid-arm muscle circumference (MAMC) also improved (p = 0.01). At biochemical analyses, leucocyte count significantly decreased (p = 0.029) in DC and no significant differences were identified between the groups.
Conclusion: We showed that a rational and practical nutritional approach is effective in improving nutrition status in ALD during a short-term follow-up.

FRI-247
Udenafil decreases portal pressure and improves erectile dysfunction in liver cirrhosis

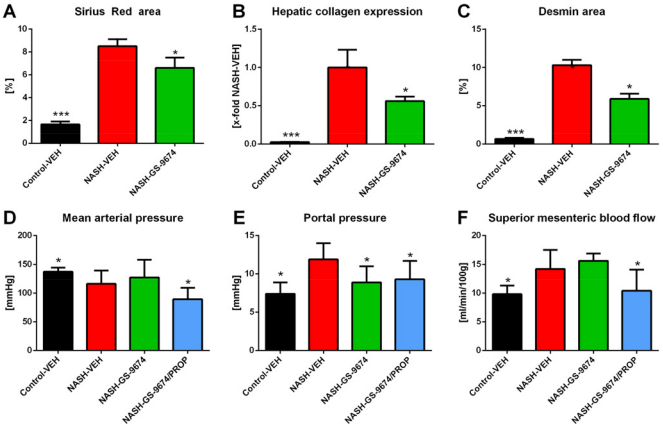
F.E. Uschner[1], K. Glückert[1], S. Klein[2], F. Magdaleno[1], R. Schierwagen[1], J. Trebicka[1,3,4,5]. *[1]University Hospital Bonn, Internal Medicine I, Bonn, Germany; [2]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne; [3]European Foundation for the Study of Chronic Liver Failure - EF Clif, Barcelona, Spain; [4]Odense University Hospital, Department of Medical Gastroenterology and Hepatology, Odense, Denmark; [5]Institute for Bioengineering of Catalonia, Barcelona, Spain*
Email: frank.uschner@ukb.uni-bonn.de

Background and Aims: In liver cirrhosis contraction of myofibroblasts leads to increased hepatic resistance and portal hypertension. As a consequence, patients develop varices and gastrointestinal bleeding. Even though the prophylaxis with non-selective ß-blockers (NSBB) reduces bleeding risk, it may induce or augment erectile dysfunction, which impairs quality of life in these patients. Udenafil has been shown to reduce portal pressure (PP) and as a phosphodiesterase-5 (PDE-5) inhibitor it might improve erectile dysfunction. Therefore, the present study investigated the effects of udenafil and NSBB on portal hypertension and erectile function in cirrhotic rats.
Method: Erectile function in male cirrhotic patients was investigated by standard questionnaire (International Index of Erectile Function). Liver cirrhosis was induced by bile duct ligation (BDL) or CCl_4 intoxication. The portal pressure (PP) was measured invasively *in vivo* before and after i.v. bolus-injection of udenafil and was compared to placebo. The portal and systemic hemodynamics were investigated using the coloured microsphere technique. Isolated *in situ* liver perfusion in BDL and CCl4 intoxicated rats investigated the relaxation of the hepatic vascular bed by udenafil. Erectile function was assessed *in vivo* by cavernous nerve stimulation and simultaneous corpus cavernosum pressure (CCP) measurement before and after treatment with propranolol and udenafil in sham operated and BDL rats.
Results: 8 out of 13 male cirrhotic patients (61%) report erectile dysfunction and 5 out of them (62%) are under NSBB. Udenafil decreased the PP *in vivo* and consequently the hepatic vascular resistance in experimental liver cirrhosis. Furthermore, udenafil reduced the perfusion pressure dose-dependently during *in situ* liver perfusion. Interestingly, erection related increase in CCP was significantly lower in BDL compared to sham operated rats at baseline and propranolol treatment even worsened the erection in these animals. Remarkably, udenafil treatment significantly increased CCP in untreated, as well as in propranolol pre-treated cirrhotic rats.
Conclusion: Udenafil treatment ameliorated portal hypertension and improved erectile dysfunction in experimental liver cirrhosis. Therefore, udenafil could be a treatment option for portal hypertension with particularly improving quality of life in male cirrhotic patients.

FRI-248
The FXR agonist GS-9674 reduces fibrosis and portal hypertension in a rat model of NASH

P. Schwabl[1,2], G. Budas[3], E. Hambruch[4], P. Supper[1,2], M. Burnet[5], J. Liles[3], T. Sullivan[3], E. Huntzicker[3], M. Birkel[4], D. French[3], D. Tumas[3], M. Peck-Radosavljevic[1,6], W. Watkins[3], M. Trauner[1], D. Breckenridge[3], C. Kremoser[4], T. Reiberger[1,2]. *[1]Medical University of Vienna, Div. of Gastroenterology and Hepatology, Dept. of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Vienna, Austria; [3]Gilead Sciences, Inc., Foster City, United States; [4]Phenex Pharmaceuticals AG, Heidelberg, Germany; [5]Synovo GmbH, Tübingen, Germany; [6]Klinikum Klagenfurt, Abteilung für Innere Medizin, Klagenfurt, Austria*
Email: philipp.schwabl@meduniwien.ac.at

Background and Aims: FXR agonists reduce fibrosis and portal pressure (PP) in rat models of toxic and cholestatic cirrhosis. Moreover, FXR agonists improve histological features of NASH in patients. We studied the effects of FXR agonism on hepatic fibrosis and hemodynamics in a rat model of advanced NASH with or without non-selective betablockade as medical standard treatment of portal hypertension.
Methods: Male Wistar rats received a choline-deficient high fat diet (CDHFD) for 14 weeks with repeated $NaNO_2$ injections (25mg/kg i.p., 3x/week) from weeks 4–14 to induce NASH. Vehicle (VEH) or FXR agonist GS-9674 (30mg/kg) were gavaged daily from weeks 4–14. In each group a subset also received the beta-blocker propranolol (PROP, 25mg/kg). Mean arterial pressure (MAP), heart rate (HR), portal pressure (PP) and superior mesenteric artery blood flow (SMABF) were measured. Fibrosis was assessed by Sirius Red area (SR) and collagen expression. As indicator of hepatic stellate cell (HSC) activation desmin area (DA) was quantified by immunofluorescence. Target engagement was assessed by qRT-PCR profiling of FXR downstream signaling in hepatic and ileal tissue.



Results: NASH rats had significant steatosis, fibrosis and portal hypertension compared to healthy controls. GS-9674 significantly increased *Fgf15* expression in the ileum (+282%; p = 0.045) and decreased *Cyp7a1* in the liver (–63%; p = 0.005). In GS-9674 treated NASH rats, liver fibrosis (SR: 6.6 ± 0.9 vs. 8.5 ± 0.6%; p = 0.047) and hepatic collagen expression (–43.7%; p = 0.032) were significantly

reduced, compared to VEH treated controls. In line, GS-9674 also significantly reduced HSC activation (DA: 5.9 ± 0.7 vs. 10.3 ± 0.8%; p = 0.004). Treatment with GS-9674 significantly decreased PP (8.9 ± 2.2 vs. 11.9 ± 2.1 mmHg; p = 0.020), without affecting systemic hemodynamics (MAP, HR). GS-9674 seemed to non-significantly increase SMABF by 10%. Interestingly, the combination of FXR agonism with beta-blockade (GS-9674 + PROP) significantly reduced SMABF (10.5 ± 3.7 vs. 14.2 ± 3.3 mL/min/100g; p = 0.032) without further decrease in PP. However, in PROP treated groups significant lower MAP (−23%) and HR (−37%) were noted.

Conclusion: The non-steroidal FXR agonist GS-9674 reduces liver fibrosis and HSC activation in NASH rats, and decreases portal pressure without deteriorating systemic hemodynamics. The combination of GS-9674 with propranolol additionally decreases mesenteric hyperperfusion, yet also affects mean arterial pressure and heart rate.

FRI-249

Genetic factors of hepatic encephalopathy on patients with cirrhosis: candidate gene study

A. Gil-Gomez[1], J. Ampuero[1], Ángela Rojas[1], Rocío Gallego-Durán[1], R.M. Hernandez[1], J.-R. Garcia-Lozano[2], M.R. Gomez[1]. *[1]Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla. CIBERehd., SeLiver Group, Sevilla, Spain; [2]Departamento de Inmunología, Hospital Universitario Virgen del Rocío, Sevilla, Spain*
Email: agil-ibis@us.es

Background and Aims: To determine the impact of genetic factors on the development of hepatic encephalopathy (HE) in patients with cirrhosis.

Method: Two-hundred and ninety-four cirrhotic patients followed-up for 4.7 ± 3.6 years were included. Up to 62 SNPs in candidate genes involved in the pathophysiology of HE: inflammation, hyperammonemia, intestinal barrier integrity or oxidative stress were selected. Samples were genotyped by using OpenArray custom plates. Likewise, a haplotype formed by four SNPs within *GLS* plus the length of a microsatellite in the promoter region of *GLS* were determined and all together considered as a single factor (GLS mutations).

Results: GLS mutations, together with in *FUT2*-rs601338, *TLR9*-rs5743836, *SLC1A3*-rs2562582 and *SLC1A5*-rs313853 SNPs, encoding for proteins involved in maintenance of intestinal barrier integrity by host-microbial interactions, pro-inflammatory response triggered by pathogens and glutamine transport, respectively, were associated to HE development. Multivariate analysis by Cox Regression showed that MELD, sodium, albumin, previous episodes of HE, *GLS mutations* and SNPs risk-genotypes were independently associated to HE risk (Fig. 1). Further, 4 groups were segregated according to presence of risk mutations within these five genes: 0–1, 2, 3 and 4–5. Finally, the cumulative survival free of HE after 10 years was 74.5%, 60.6%, 57.2% and 19.5% respectively (Log Rank 39.55; p = 0.000).

Conclusion: The presence of unfavorable genotypes in risk variants could explain the differences in the appearance of HE. This genetic fingerprint could be implemented in clinical practice for decision making in the management of cirrhotic patients.

FRI-250

LSECtin and CD206 participate in the regulation of the hepatic inflammatory response to E coli in a model of cirrhosis

E. Caparrós[1,2], P. Piñero[2], O. Juanola[2,3], I. Gómez-Hurtado[2], P. Zapater[4], J.M. González-Navajas[2], Rubén Francés[2,4,5]. *[1]universidad Miguel Hernandez, Medicina Clínica, San Juan de Alicante, Spain; [2]Fundación ISABIAL-FISABIO, Hospital General Universitario de Alicante, Spain; [3]universidad Miguel Hernandez, Farmacología; [4]Universidad Miguel Hernandez, Medicina Clínica, Spain; [5]CIBERehd, Hospital General Universitario de Alicante, Spain*
Email: ecaparros@umh.es

Background and Aims: The function of the hepatic immune system in the clearance of bacterial products is essential to maintain tissue homeostasis. Antigen presenting cells (APCs) play an important role in this regulation through different pathogen receptors.

Method: Sprague-Dawley rats were treated with oral CCl_4 for 12 weeks (Group 1). In addition, one subgroup received intraperitoneal *E. coli* 24h before laparotomy (Group 2) and another subgroup received oral norfloxacin during the week prior to laparotomy (Group 3). The perfused livers were harvested and Kupffer cells (KCs), dendritic cells (DCs) and endothelial sinusoidal cells (LSECs) were purified using labelled microbeads. The gene expression and phenotypic profile of different receptors of innate immunity were analyzed.

Results: Gene expression of different markers in hepatic APCs is shown in figure 1. After administration of *E. coli* in cirrhotic rats, the response of the innate immune system is polarized towards the induction of local inflammation, represented by a significant reduction of the complement inhibitors (CR1 and CR4) in KCs and an increase in costimulatory molecules in DCs. Transcription of CD206, indicator of anti-inflammatory response, decreases significantly in all populations. On the other hand, the LSECtin receptor, involved in the inhibition of sustained T cell response, increases

Table (abstract: FRI-249).

Variable	No-HE (n = 198)	HE (n = 96)	Univariate	Multivariate (HR, CI95%)

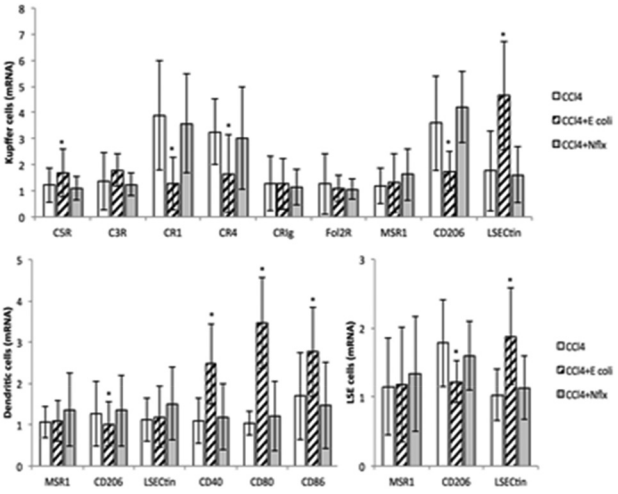
Liver Transplantation	10.6% (21/198)	21.9% (21/96)	.000	

significantly in KCs and LSECs. The profile analysis of these molecules by flow cytometry correlates with the genetic findings.



Conclusion: The expression of LSECtin in KCs and LSECs could compensate the hepatic proinflammatory response induced by E. coli, thus collaborating in the prevention of hepatic damage mediated by the immune system.

FRI-251

Changes of bile acids profile in different etiologies of liver cirrhosis and its association with neutrophil response

I. Komarova[1], A. Horvath[1], E. Krones[1], B. Leber[1], B. Schmerboeck[1], F. Durchschein[1], G. Zollner[1], R.E. Stauber[1], W. Spindelböck[1], P. Douschan[2], P. Stiegler[3], D. Kniepeiss[3], T. Stojakovic[4], Günter Fauler[4], V. Stadlbauer[5]. [1]*Medical University of Graz, Department of Gastroenterology and Hepatology, Graz, Austria;* [2]*Medical University of Graz, Department of Pulmonology, Austria;* [3]*Medical University of Graz, Department of Surgery, Division of Transplant Surgery, Austria;* [4]*Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Austria;* [5]*Medical University of Graz, Department of Gastroenterology and Hepatology, Austria*
Email: irina.komarova@medunigraz.at

Background and Aims: Liver cirrhosis is associated with high risk of bacterial infections. Impaired neutrophil function can contribute to the development of this complication. Bile acids are important signaling molecules and immune modulators, but their influence on the immune response in liver cirrhosis is not yet fully understood. Our aim was to analyze the changes in bile acids profile in liver cirrhosis depending on its etiology and severity and their role in neutrophil functional response.

Method: Unconjugated, glycine and taurine conjugated cholic (CA), chenodeoxycholic (CDCA), deoxycholic (DCA), lithocholic (LCA), ursodeoxycholic (UDCA) bile acids concentration in serum of 109 liver cirrhotic patients (mean age = 56.9 ± 8.9) and 21 healthy volunteers (mean age = 58.0 ± 6.9) was measured by high-resolution mass spectrometry. Respiratory burst and phagocytic ability of neutrophils were assessed by flow cytometry (Phagoburst and Phagotest, Glycotope, Germany). Patients were grouped by cirrhosis etiology (alcoholic etiology – n = 54, viral etiology – n = 32, other etiology – n = 23) and liver function (Child-Pugh A – n = 79, Child-Pugh B + C – n = 30).

Results: All bile acids were increased in liver cirrhosis and their composition significantly changed. This was reflected in decreased proportions of secondary, unconjugated, glycine conjugated, 12-alpha-hydroxylated bile acids, as well as decreased CDCA, DCA and UDCA relative abundances compared to healthy volunteers. These changes increased with deterioration of the liver function. Within the cohort of patients with Child A cirrhosis, there were significantly higher levels of glycocholic acid (p = 0.005), total UDCA (p = 0.055), total unconjugated (p = 0.006), 12-alpha-hydroxylated (p = 0.007) bile acids in alcoholic cirrhosis compared to viral cirrhosis. Elevated total UDCA levels were associated with increased neutrophil priming, indicating an increased readiness of neutrophils to respond to a stimulus and glycocholic acid levels were associated with decreased oxidative burst in response to E.coli bacteria (Figure 1).

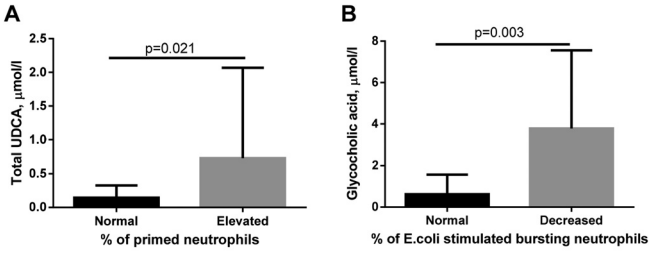


Figure 1. UDCA and glycocholic acid serum levels in 79 patients with Child A cirrhosis according to neutrophil priming and E.coli stimulated burst function.

Conclusion: Bile acids profile in liver cirrhosis depends on etiology and disease severity. The changes in bile acids composition are associated with changes in neutrophil functionality. In order to investigate the direct influence of bile acids on neutrophils and to understand the underlying mechanisms further studies are required.

FRI-252

Assessment of conjugated, primary and secondary bile acids in the portal venous system across the spectrum of chronic HCV associated liver disease; link to inflammation and microbial products

R. Ali, G. Zhang, E. Townsend, C. Koh, E. Levy, D.E. Kleiner, O. Etzion, T. Heller. *National Institutes of Health, Translational Hepatology Section, NIDDK, Bethesda, United States*
Email: rabab.ali@nih.gov

Background and Aims: There is growing evidence of the critical role bile acids (BA) play in chronic liver disease, particularly in the cross-talk between the diseased liver and gut microbiome. Altered BA conjugation and hydroxylation are potential mechanisms modulating the gut-liver axis and may contribute to disease progression. The relative proportions of BA metabolites in the portal vein have not been well explored. The aim of this study was to characterize BA in association with liver injury and immune markers in the portal vein of HCV patients across the spectrum of liver disease severity.

Method: HCV-infected patients underwent liver biopsy with portal vein cannulation (LBPVC) and portal serum was obtained. Ultrahigh Performance Liquid Chromatography-Tandem Mass Spectroscopy and ELISAs were used to assess 28 BA and microbial products and cytokines, respectively.

Results: 29 patients had LBPVC; 16 were non-cirrhotic {Ishak Fibrosis (IF) 0–4} and 13 compensated cirrhotic (IF 5–6). Conjugated/unconjugated ratio (CR), and primary/secondary ratio (P/S) was calculated for each BA. For all reported correlations Spearman r > 0.35, and p < 0.05. CR of chenodeoxycholate (CDCA), cholate (CA), and deoxycholate (DCA) was associated with higher ALP, and CR of Ursodeoxycholate (UDCA) with higher ALT and AST. Conjugated CDCA, not CA, positively correlated with portal zonulin; a gut epithelial integrity marker. CR for CDCA, not CA, positively correlated with sCD14 and sCD163. CR for DCA and UDCA was associated with elevated sCD14, and sCD163 and zonulin, respectively. In primary BA, conjugated CDCA/CA ratio was higher in cirrhotics (Mann-Whitney p < 0.05) and positively correlated with hepatic activity index, portal CXCL9, IL12p40, IL16, E-selectin, Thrombomodulin, and HMGB-1. Increased P/S correlated with higher ALT, increased portal LPS (gram negative marker), decreased lipoteichoic acid (gram positive marker), and higher tauro-beta-muricholate (TBMCA).

TBMCA was higher in cirrhotics (Mann-Whitney $p < 0.05$) and associated with higher ALT, ALP, Bilirubin, AFP, and PT.
Conclusion: Higher conjugation of portal BA is linked to liver injury, macrophage activation and loss of gut epithelial integrity. In cirrhotics, a greater CDCA/CA ratio not only suggests a shift from classic to alternative BA pathway, but an association with inflammatory markers in the portal vein. Increased P/S is related to hepatic injury, microbial products, and emergence of a hydrophilic BA; TBMCA, which in turn, is strongly associated with cirrhosis. These changes in BA have biological and therapeutic implications that are worthy of further study.

Occult hepatitis B infection in hepatocellular carcinoma patients with negative HBsAg

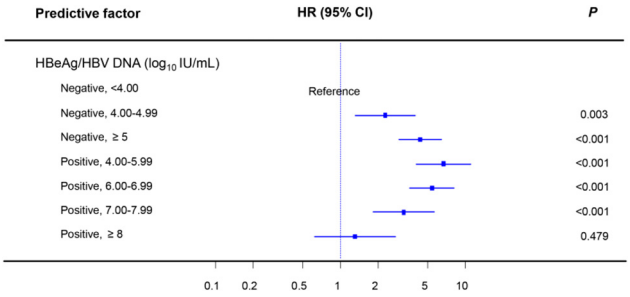
D. Wong[1,2], L.-Y. Mak[1], W.P. To[1], T.-t. Cheung[2,3], W.-K. Seto[1,2], Y.Y.J. Fung[1,2], K. Man[2,3], C.L. Lai[2,4], M.-F. Yuen[2,4]. *[1]The University of Hong Kong, Medicine, Hong Kong, Hong Kong; [2]The University of Hong Kong, State Key Laboratory for Liver Research, Hong Kong, Hong Kong; [3]The University of Hong Kong, Surgery, Hong Kong; [4]The University of Hong Kong, Medicine, Hong Kong*
Email: dannykhwong@gmail.com

Background and Aims: Chronic hepatitis B and C infections are the two major causes of hepatocellular carcinoma (HCC) worldwide. However, HCC can also be caused by non-viral etiologies such as alcoholic liver disease (ALD), non-alcoholic fatty liver disease (NAFLD), autoimmune hepatitis (AIH), and primary biliary cholangitis (PBC). It is not known whether patients with non-viral causes of HCC may have superimposed occult hepatitis B infection (OBI) as an additional risk factor causing HCC. We aimed to investigate the incidence of OBI in HCC patients with undetectable hepatitis B surface antigen (HBsAg).
Method: Tumor and adjacent non-tumor liver tissues were obtained from 90 patients with non-viral causes of HCC. Eighty-four patients had paired tumor and non-tumor tissues available, while three patients had only non-tumor tissues and three had only tumor tissues available. Total liver DNA was extracted from the non-tumor tissues and from the tumor tissues if non-tumor tissues were not available. OBI was detected by 4 sets of independent nested PCR, using primers targeting the S, precore, polymerase, and X regions of the hepatitis B virus (HBV) genome. OBI was diagnosed when positive PCR detection was identified in two or more HBV genomic regions.
Results: All 90 patients had undetectable serum HBsAg and anti-HCV. Of these, 18 (21%) had ALD, 14 (16%) had either NASH or NAFLD (denoted by mild histological fatty changes), two had PBC, two had recurrent pyogenic cholangitis (RPC), one patient had AIH, and the remaining 53 patients (60%) had no cause identified i.e. cryptogenic HCC. Histological analysis of the non-tumor tissues identified that 19 (21%) patients had liver cirrhosis. Overall, OBI was detected in 45/90 (50%) of HCC patients. Specifically, OBI was detected in 7/18 (39%) HCC patients with ALD, 7/14 (50%) patients with NAFLD/NASH, and 1/2 (50%) patient with PBC, and 30/53 (57%) patients with cryptogenic HCC.
Conclusion: Half of the HCC patients with no serum marker for HBV had underlying OBI. Nearly 60% of patients with cryptogenic HCC had viral hepatitis B disease in the form of OBI. This suggests that the significance of HBV infection causing HCC is likely to be underestimated. In patients with ALD or NAFLD/NASH, around 40–50% HCC patients had OBI, suggesting that OBI may be a common synergistic factor (with ALD or NAFLD/NASH) for hepatocarcinogenesis in these patients.

FRI-255
Non-linear association between serum hepatitis B virus DNA levels and hepatocellular carcinoma risk in treatment-naive, non-cirrhotic chronic hepatitis B patients

G.-A. Kim[1], S. Han[2], G.H. Choi[3], J. Choi[3], Y.-S. Lim[3]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Health Screening and Promotion Center, Seoul, [2]Gachon University, Department of Applied Statistics, Gyeonggi-do, Korea, Rep. of South; [3]Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South*
Email: limys@amc.seoul.kr

Background and Aims: The REVEAL-HBV studies on the natural history of chronic hepatitis B showed a linear correlation between serum hepatitis B virus (HBV) levels and the risk of hepatocellular carcinoma (HCC). However, virus titers above 10^6 copies/ml were not quantified, and most of the patients were HBeAg-negative (85%). The progression of these HBeAg-negative patients would not be identical to that of young HBeAg-positive immune-tolerant phase patients with very high HBV DNA levels.
Method: The study subjects were recruited from a historical cohort of 4367 treatment-naïve, non-cirrhotic CHB patients (1240 HBeAg-positive and 3127 HBeAg-negative) with serum ALT levels lower than 2 × upper limit of normal (females, <19IU/ml; males, <30IU/ml) at a tertiary referral hospital in Korea. Cox proportional hazards regression model predicted HCC risk considering sex, age, HBeAg status, serum HBV DNA levels, ALT levels, and platelet counts.
Results: During the total follow-up of 23,690 person-years, 221 patients (5.1%) developed HCC. Old age, male gender, and lower platelet counts were found to be associated with an increased risk of HCC. Among HBeAg-negative patients, HBV DNA levels were linearly associated with increasing risk of HCC. In contrast, among HBeAg-positive patients, HBV DNA levels were inversely associated with the risk of HCC. The risk of HCC was the lowest in HBeAg negative patients with HBV DNA level below 4 $\log_{10}$IU/ml (reference group), and was the highest in HBeAg positive patients with HBV DNA levels between 4 $\log_{10}$IU/ml and 6 $\log_{10}$IU/ml (hazard ratio [HR] 6.89; 95% confidence interval [CI] 4.20–11.29). HBeAg-positive patients with HBV DNA levels above 8 $\log_{10}$IU/ml showed similar risk of HCC compared with the reference group (HR 1.36; 95% CI 0.65–2.84).



Conclusion: In our large cohort of treatment-naïve, non-cirrhotic chronic hepatitis B patients, the association between HBV DNA levels and HCC risk was not linear, but was parabolic. HCC risk was the highest in patients with HBV DNA levels between 4 $\log_{10}$IU/mL and 6 $\log_{10}$IU/ml. These data may help assess the HCC risk among the patients who are not subject to antiviral treatment which consequently call attention to the necessity of developing a new treatment indication.

FRI-256
Hepatitis B splice variants are strongly associated with and are indeed predictive of hepatocellular carcinoma

M.-H. Pan[1], H.-H. Hu[1], H. Mason[2], J. Bayliss[2], M. Littlejohn[2], Y.-L. Lin[3], C.-Y. Su[1], C.-T. Chiang[1], C.-J. Chen[1], S. Locarnini[2], H.-I Yang[1], P. Revill[2]. *[1]Genomics Research Center, Academia Sinica, Taipei 115, Taiwan;*

[2]*Peter Doherty Institute of Infection and Immunity, VIDRL Royal Melbourne Hospital, Melbourne, Australia;* [3]*Genomics Research Center, Academia Sinica, Melbourne, Australia*
Email: peter.revill@mh.org.au

Background and Aims: Over 257 million people live with chronic hepatitis B, resulting in up to 880,000 deaths annually due to cirrhosis and liver cancer (hepatocellular carcinoma, HCC). Chronic HBV (CHB) is incurable, and infected persons have a life-long risk of developing liver cancer, the 5th most common cancer and 3rd leading cause of cancer-related mortality. Identifying mechanisms by which HBV causes liver cancer is of paramount importance. We have previously shown that HBV splice variants were strongly associated with liver cancer[1]. The purpose of the current study was to validate these findings using a large international cohort of patients with HBV-mediated liver cancer, from the REVEAL[2] study in Taiwan.
Method: HBV DNA in serum was purified from over 150 patients with liver cancer and 370 control patients who had chronic HBV but had not developed liver cancer. The ratio of splice variant to wild-type HBV was quantified by real time PCR and associations between the relative abundance of splice variants and liver cancer was determined by univariate and multivariate analysis.
Results: Quantitative real time PCR was performed for splice (spHBV) and wild-type HBV DNA on over 600 samples. After adjustment for known HCC-related risk factors (serum HBV DNA, α-fetoprotein, HBV genotype), subjects with spliced HBV DNA level >10% were at least 3 times more likely to develop HCC than patients with lower levels of splice variants. For patients with secreted spHBV of >20%, the adjusted OR (95% CI) of HCC development was 23.3, $p < 0.0001$). In most HCC patients with elevated spHBV levels, this occurred up to 5 years prior to HCC diagnosis.
Conclusion: Our previous pilot study of Australian patients suggested that the secretion of splice HBV variants into the blood compartment was strongly associated with liver cancer. We have now validated this finding utilising the highly characterised REVEAL Taiwanese cohort. The striking finding that HBV infected subjects were more likely to develop liver cancer if splice variants formed at least 20% of the secreted viral pool suggests we have identified a novel biomarker of HCC in this setting.

FRI-257

Lower baseline quantitative HBcAb may help predict response to sequential combination therapy with IFN, rhIL-2 and HBV therapeutic vaccine in entecavir-suppressed CHB patients

W. Yan[1], Q. Yuan[2], D. Wu[1], M. Han[1], G. Chen[1], K. Ma[1], N. Xia[3], Q. Ning[1]. [1]*Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Institute and Department of Infectious Disease, Wuhan, China;* [2]*School of Public Health, Xiamen University, Diagnostics and Vaccine Development in Infectious Diseases, Xiamen, China;* [3]*National Institute of Diagnostics and Vaccine Development in Infectious Diseases, School of Public Health, Xiamen University, State Key Laboratory of Molecular Vaccinology and Molecular Diagnostics, Xiamen, China*
Email: qning@vip.sina.com

Background and Aims: HBcAb has been revealed to be closely correlated with hepatic inflammatory activities and treatment response in HBeAg positive chronic hepatitis B (CHB) patients recently. The aim of this study was to investigate the relationship of quantitative serum HBcAb levels and antiviral efficacy in 94CHB patients undergoing a multi-center, randomized trial (Endeavor Study, ClinicalTrials.gov: NCT02360592).
Method: HBeAg positive CHB patients who had received entecavir (ETV) for 1–5 years, with HBeAg loss and HBVDNA ≤ 1000 copies/ml, were randomized to continue with ETV therapy for 48 weeks (Group I) or switch to conventional interferon (IFN)-α-2bfor 48 weeks (Group II) or IFN-α-2b for 48 weeks in combination with recombinant human interleukin-2 (rhIL-2) for 12 weeks plus HBV therapeutic vaccine for 48 weeks (Group III). Treatment response was defined as HBsAg loss and/or HBeAg seroconversion at week 48. Serum HBcAb was quantified in a blinded fashion by using a newly developed double-antigen sandwich immune-assay calibrated by WHO standards.
Results: Compared with the patients continuing with monotherapy (Group I), patients switching to combined therapy (Group II and III) exhibited a significant higher rate of response (7.41% vs. 23.88%, $p = 0.048$). A positive correlation between baseline HBcAb levels and HBsAg levels was observed in all patients included ($r = 0.364$, $p = 0.001$), while positive correlation between the two variables during treatment only existed among patients undergoing combined therapy ($r = 0.446$, 0.315, 0.315, $p = 0.000$, 0.014, 0.026 at week 0, week 12, week 48, respectively). In contrast to monotherapy which had no obvious influence on serum HBcAb levels, combined therapy resulted in a significant decline in HBcAb levels (week 12 VS. week 0, $p = 0.038$, week 36 VS. week 0, $p = 0.034$). Compared with non-responders within combined therapy group, responders showed significantly lower HBcAb levels during early phase of treatment ($p = 0.017$, 0.016, 0.012 at week 0, week 4, and week 12, respectively). Furthermore, baseline HBcAb level appeared to be an ideal predictor for response to combined therapy, including having a larger AUROC curve (0.714, 95% CI 0.588–0.840, $p = 0.003$). We defined 2.695 $\log_{10}$IU/ml as the optimal cut-off value of baseline HBcAb level to predict response (sensitivity 80.8%, specificity 60.1%, PPV 56.76%, NPV 83.33%). Patients with baseline HBcAb ≤ 2.695 $\log_{10}$IU/ml had significantly more chances to achieve response than those with baseline HBcAb > 2.695 $\log_{10}$IU/ml (56.76% [21/37] VS. 16.67% [5/30]).
Conclusion: For CHB patients with HBeAg loss post ETV treatment, baseline quantitative HBcAb titer might be a novel non-invasive biomarker for predicting treatment response to sequential combination therapy with IFN, rhIL-2 and HBV therapeutic vaccine.

FRI-258

Antiviral therapy can be avoided in most HBeAg-negative Caucasian patients in the Gray Zone

M. Bonacci, S. Lens, Z. Mariño, M.C. Londoño, S. Rodriguez-Tajes, A. Mas, M. García-López, Sofía Pérez del Pulgar, J.M. Sanchez-Tapias, X. Forns. *IDIBAPS, CIBERehd, Liver Unit, Barcelona, Spain*
Email: bonacci@clinic.cat

Background and Aims: Gray zone (GZ) is an ill-defined situation including patients not accomplishing criteria of Inactive Carrier [(IC) HBV-DNA < 2,000IU/ml/ALT < 40U/l] or HBeAg-negative chronic hepatitis B [(CHB) ALT > 80U/l, HBV-DNA > 2,000IU/ml and fibrosis (≥2) or ALT > 80U/l and HBV-DNA > 20,000IU/ml]. We aim to investigate long-term outcomes of untreated GZ patients compared to IC.
Method: Non-cirrhotic, HBeAg-negative patients with HBV-DNA ≤ 20,000IU/ml and ALT ≤ 80U/l were retrospectively studied. At baseline patients were grouped into: 1) ICs; 2) GZ-1 (HBV-DNA < 2,000IU/ml and ALT 40–80U/l); 3) GZ-2 (HBV-DNA 2,000–20,000IU/ml and ALT < 40U/l), and GZ-3 (HBV-DNA 2,000–20,000IU/ml ALT 40–80U/l). Data were also analyzed using the AASLD threshold for ALT normality.
Results: In total 287 subjects were studied, including 137 ICs and 150 GZ patients (60 GZ-1, 54 GZ-2 and 36 GZ-3). Baseline features were similar across groups and 84% were Caucasian. APRI, FIB-4 and GPR excluded advanced fibrosis in all patients. Genotype (GT) was available in 185 (64%) patients and similarly distributed across Groups. Prevalence of GT A, D, F, B/C and E/H was 48%, 36%, 6.5%, 6.5% and 3%, respectively. After a median FU of 8.2 (5–19) years ALT elevations >40U/l occurred in 30% of IC, and >80U/l in 6.6% of IC and 28% of GZ patients. HBV-DNA elevations >2,000 IU/ml occurred in 23% of IC and >20,000IU/ml in 3% of IC and in 40% of GZ. Overall, HBsAg loss rate was 18% in IC and 13% in GZ (p = ns) and occurred only in GT A/D patients. Excluding patients who lost HBsAg, transition into IC occurred in 60/131 (45%) GZ patients. Indeed, GT A was associated with higher HBsAg loss [HR = 2.6 (1.1–6); 0.01]. whereas HBV-DNA fluctuation >2,000IU/ml negatively predicted this outcome [HR = 0.54 (0.4–0.8); 0.01] and transition into IC [HR = 0.31 (0.16–0.62); 0.01].

Progression to CHB occurred in only 18 (6,3%) GZ patients and was more frequent in GT B/C (33%) than in GT A/D (8%). At last FU, markers of hepatic fibrosis and liver stiffness excluded advanced fibrosis in all patients. One non-cirrhotic GT C patient developed HCC. Using AASLD diagnostic criteria, 77 (227/287) more subjects fell into the GZ at baseline, but its long-term outcome was equally favorable.
Conclusion: The prognosis of untreated Caucasian GZ patients is excellent, with high rate of HBsAg loss and low rate of CHB. Based on these observations antivirals may safely be avoided in most GZ patients, particularly in GT A/D. Genotyping may help to predict outcomes in GZ.

FRI-259

Basal values and on treatment decline of hepatitis B core-related antigen are predictive of response to interferon therapy in chronic hepatitis D

A. Olivero[1], G.P. Caviglia[1], A. Ciancio[1], C. Bosco[1], R. Fontana[2], G. Niro[2], M. Rizzetto[1], G. Maria Saracco[1], A. Smedile[1]. *[1]University of Turin, Department of Medical Sciences; [2]IRCCS Casa Sollievo della Sofferenza, Gastroenterology Unit*
Email: caviglia.giampi@libero.it

Background and Aims: Therapy with pegylated interferon-alpha-2a (Peg-IFN) is considered the standard of care for patients with chronic active HDV infection (CHD). Since reliable predictors of treatment response are still debating, we investigated the role of hepatitis B core-related antigen (HBcrAg) for the prediction of response in CHD patients treated with Peg-IFN.
Method: A total of 65 sequential serum samples from 13 CHD patients (8M/5F; median age 54 years) who underwent Peg-IFN treatment between 2010 and 2015 were analyzed. All patients were HBV genotype D and HDV genotype 1; 11 were anti-HBe+. Serum HBcrAg and HBsAg levels were determined by CLEIA (Lumipulse®, Fujirebio, Japan). HBV DNA and HDV RNA were detected by real-time quantitative PCR. All markers were measured at baseline, 6, 12, 18 and 12 months after end of therapy (12MFU). HBcrAg kinetics were analyzed by repeated measures ANOVA.
Results: Overall, 8 out of 13 patients cleared HDV RNA and were still negative at 12MFU (responders, R). Among them, 2 patients cleared HBsAg and 1 became anti-HBs+. Five patients were nonresponders (NR). Mean baseline HBcrAg, HBsAg, HBV DNA and HDV RNA levels were 3.6 ± 1.4logU/ml, 3.17 ± 1.33LogIU/ml, 2.02 ± 1.67logIU/ml and 4.79 ± 1.21logIU/ml, respectively. We observed a significant correlation between HBcrAg and HBsAg ($r = 0.763$, $p < 0.001$), HBV DNA ($r = 0.844$, $p < 0.001$) and HDV RNA ($r = 0.761$, $p < 0.001$). Baseline HBcrAg levels were slightly higher in NR compared to R patients (4.6 ± 1.3 vs. 3.1 ± 1.1logU/ml, $p = 0.052$). Optimal baseline HBcrAg threshold to discriminate Rs from NRs was 3logU/ml; this cut-off was associated to an area under the curve (AUC) of 0.787, with a sensitivity (Se) of 63% and specificity (Sp) of 80%. On-treatment HBcrAg kinetics showed a significant ($p = 0.026$) linear decline in R patients from baseline to 12MFU; conversely, no decline was observed in NRs ($p = 0.256$). A 6M on treatment HBcrAg redsuction >0.1 LogU/mL showed a AUC = 0.737 (Se = 88% and Sp = 60%). By combining baseline HBcrAg levels and reduction values at 6 months this accuracy improved (AUC = 0.925, Se = 100% and Sp = 80%).
Conclusion: Serum levels of HBcrAg, at baseline and at month 6 on therapy, are predictors of treatment response to Peg-IFN in patients with CHD.

FRI-260

Soluble cytotoxic T-lymphocyte-associated antigen-4 and soluble programmed cell death protein-1 are predictive immune checkpoint seromarkers for spontaneous functional cure of chronic hepatitis B with opposite effects

H.-I. Yang[1], H.-H. Hu[1], M.-H. Pan[1], W.-S. Luo[1], R.W.-J. Jeng[2], C.-Y. Su[1], C.-T. Chiang[1], C.-L. Jen[1], S.-N. Lu[3], L.-Y. Wang[4], M.-H. Lee[5], J. Liu[6], M. Nguyen[7], C.-J. Chen[8]. *[1]Academia Sinica, Genomics Research Center, Taipei, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan; [3]Chang-Gung Memorial Hospital, Department of Gastroenterology, Kaohsiung, Taiwan; [4]MacKay College of Medicine, Taipei, Taiwan; [5]National Yang-Ming University, Institute of Clinical Medicine, Taipei, Taiwan; [6]Stanford University School of Medicine and Lucile Packard Children's Hospital, Perinatal Epidemiology and Health Outcomes Research Unit, Division of Neonatology, Department of Pediatrics, Palo Alto, CA, United States; [7]Stanford University Medical Center, Division of Gastroenterology and Hepatology, Palo Alto, CA, Taiwan; [8]Academia Sinica, Taipei, Taiwan*
Email: hwaii.yang@gmail.com

Background and Aims: The seroclearance of hepatitis B surface antigen (HBsAg) is regarded as a functional cure for patients with chronic hepatitis B, who often show an immune inhibitory checkpoint-associated T cell exhaustion. We aim to assess soluble cytotoxic T-lymphocyte-associated antigen-4 (sCTLA-4) and programmed cell death protein-1 (sPD-1) as novel seromarkers for spontaneous HBsAg seroclearance.
Method: Serum levels of sPD-1 and sCTLA-4 were evaluated in all 1,046 patients from the REVEAL-HBV study who were hepatitis B e antigen-seronegative with serum HBV DNA undetectability. Multivariate Cox regression analyses were used to assess associations of baseline sPD-1 and sCTLA-4 level with subsequent spontaneous HBsAg seroclearance, and to estimate rate ratio (RR) with 95% confidence interval (95% CI).
Results: A total of 390 patients achieved spontaneous HBsAg seroclearance during a mean 5.4 years of follow-up. Baseline sPD-1 levels were positively correlated with baseline sCTLA-4 levels ($p < 0.0001$). Incidence rates of spontaneous HBsAg seroclearance increased with decreasing levels of baseline sPD-1 ($p_{trend}<0.0001$), but with increasing sCTLA-4 levels ($p_{trend}<0.0001$). After adjustment for gender, age, serum levels of alanine aminotransferase, sPD-1 and sCTLA-4, the RR (95%CI) of HBsAg seroclearance was 3.6 (2.2–6.0), 4.5 (2.8–7.4), and 11.6 (6.9–19.6), respectively, for baseline sPD-1 levels of 536–3999, 125–535, and <125pg/ml compared to sPD-1 levels of ≥4000pg/ml; and were 1.2 (0.8–1.9), 1.7 (1.1–2.7), and 2.1 (1.3–3.4), respectively, for baseline sCTLA-4 levels of 0.5–1.2, 1.3–2.5, and 2.6–16ng/ml compared to sCTLA-4 levels of <0.5ng/ml as the referent. Using patients who had sPD-1 levels ≥536pg/ml and sCTLA-4 < 0.5ng/ml as the referent, the RR (95% CI) of HBsAg seroclearance was 0.9 (0.4–1.8), 1.0 (0.5–2.0), and 2.5 (1.4–4.5), respectively, for patients had the same levels of sPD-1 and sCTLA-4 levels of 0.5–1.2, 1.3–2.5, and 2.6–16ng/ml; the RR (95%CI) was 3.9 (1.7–9.2), 3.9 (1.7–8.9), 5.3 (2.3–12.0), and 4.6 (1.9–10.7) respectively, for those who had sPD-1 levels <536pg/ml and sCTLA-4 levels of <0.5, 0.5–1.2, 1.3–2.5, and 2.6–16ng/ml.
Conclusion: Reduced sPD-1 levels while increased sCTLA-4 levels predict greater chance of spontaneous HBsAg seroclearance in HBeAg-seronegative CHB patients with HBV DNA undetectability. Serum sCTLA-4 levels offer addition predictability on HBsAg seroclearance in patients with high sPD-1 levels.

FRI-261

The levels of middle surface HBV antigen increase in patients with HBV-driven liver cancer despite prolonged virological suppression: implications for a novel marker of HBV-driven hepatocarcinogenesis

G. Brancaccio[1], R. Salpini[2], L. Colagrossi[2], V. Fini[2], M. Cantone[1], A. Battisti[2], L. Piermatteo[2], Y. Oda[2], C.F. Perno[2], G.B. Gaeta[1], V. Svicher[1]. *[1]Infectious Diseases Naples Italy; [2]Department of Experimental Medicine and Surgery, Rome Italy*
Email: p.brancaccio@alice.it

Background and Aims: HBV ORF S is composed by 3 regions: preS1, preS2 and S, encoding the Large-HBs (L-HBs), Middle-HBs (M-HBs), and Small-HBs (S-HBs). Here, we investigate the still unknown kinetics of HBs forms in virologically suppressed patients (pts) developing HCC.
Method: This study enrolled 30 cirrhotic HBV chronically infected pts on HBV-DNA suppression by potent antiviral therapy. Among them,

13 developed HCC after a median [IQR] time of15 [8–18] months and 17did not develop HCC despite a median [IQR] observation time of 41 [30–48] months. For each patient, 2 plasma samples under virological suppression were collected at enrolment (T0) and at HCC diagnosis or at last control for not-HCC pts (T1). Ad hoc ELISAs were designed to quantify L-HBs, M-HBs and total-HBs at T0 and T1 (Beacle Inc). Each sample was processed at least in duplicate. Spearman and Bland-Altman tests were used to verify the concordance in total-HBs quantification between Beacle and COBAS HbsAg II assays (Roche Diagnostics).

Results: Total-HBs quantification by Beacle and Cobas assays showed high concordance (Rho = 0.82, p < 0.001). At T0, median (IQR) levels of total-HBs, M-HBs and L-HBs were 3.5 (2.6–4.0)log ng/ml, 2.3 (1.4–2.6)log ng/ml and 0.7(0.1–1.9)ng/ml(with no significant differences between HCC- and not-HCC pts). By analysing the kinetics of HBs forms, total-HBs showed >10% reduction in most pts (53.8% [7/13] of HCC- vs 47.1% [8/17] of not-HCC pts). Similarly, in HCC- and not-HCC pts, total-HBs remained stable (30.8% [4/13]vs 29.4% [5/17]) or showed >10% increase (15.4% [2/13] vs 23.5% [4/17], p = 0.67). Regarding M-HBs,>10% reduction of this form was observed in a similar proportion of HCC- and not-HCC pts (30.8% [4/13] vs 29.4% [5/17]). Conversely and notably, the proportion of patients undergoing > 10% increase in M-HBs was significantly higher in HCC- than in not-HCC group (46.2% [6/13] vs 11.8% [2/17], p = 0.049) suggesting an enhanced M-HBs production in the setting of HBV-driven hepatocarcinogenesis. Finally, no difference in L-HBs kinetics is was observed in HCC- and not-HCC pts.

Conclusion: An increase in M-HBs levels characterizes a conspicuous proportion of HCC-pts despite prolonged suppression and stable/reduced total-HBs. This suggests the contribution of M-HBs in mechanisms underlying HBV-driven hepatocarcinogenesis, presumably driven by an enhanced transcriptional activity of pre-S2 promoter from cccDNA and/or HBV-DNA integrated into the host genome. The role of M-HBs as marker predictive of HCC deserves further investigation.

Identifying epigenetic markers for characterization of host response to hepatitis B virus infection during the development of hepatocellular carcinoma

W.-J. Wu[1], S.-H. Yang[1], W.-J. Liu[1], W.-Y. Kao[1], Y.-C. Kuo[1], C.-L. Lin[2], C.-J. Liu[3], Y.-W. Huang[4], C.-F. Wu[1], M.-W. Yu[1]. *[1]National Taiwan University, College of Public Health; [2]Ren-Ai Branch, Taipei City Hospital, Department of Gastroenterology; [3]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [4]Cathay General Hospital Medical Center, Liver Center*
Email: yumw@ntu.edu.tw

Background and Aims: High viremia is a strong risk factor of hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC). There is increasing evidence that HBV has mechanisms to alter immunity via epigenetic control. We used microarray and pyrosequencing to assess methylation sites related to viral load, and determine the effect of such epigenetic changes on the risk of HBV-related HCC.

Method: We first conducted epigenome mapping of leukocyte DNA with the Infinium HumanMethylation450 array in a case-control study (n = 96) nested in a cohort of men with chronic HBV infection. For identified signals, we then conducted an extended analysis with pyrosequencing in a case-cohort sample with longitudinal viremia data from the cohort (n = 561). CpG sites that remained significant in the extended analysis were tested in a case-sibling study (n = 444).

Results: After adjustment for age and blood cell composition, epigenome-wide analysis indicated 3.38-fold (p = 2.61·e-49) enrichment of viremia-related CpGs in HCC-related CpGs compared to HCC-unrelated CpGs. The strongest association signal of viremia among HCC-related CpGs was in the promoter of the *IFI44L* gene (p = 5.69·e-6), involved in type I/II interferon pathways. Co-methylation analysis identified functional link of 191 genes located on different chromosomes (absolute correlation > 0.5; p < 1·e-6) with *IFI44L*, which were significantly enriched for specific immune pathways relevant to HBV infection. The association between *IFI44L* methylation intensity and HCC was independent from alanine aminotransferase and was confirmed in both the case-cohort study (p = 0.0030) and case-sibling study (p < 0.0001), showing a multivariate odds ratio of 1.69 (95% CI = 1.19–2.38) and 4.97 (95% CI = 3.18–7.78), respectively, for every 0.1 decrease in methylation beta value. In addition, we found negative effects of *IFI44L* methylation on viremia levels (p = 0.0039) and HBeAg positivity (p = 0.0018) in cross-sectional analyses, and a negative effect of *IFI44L* methylation on viremia levels in longitudinal analysis (p = 0.0220). Mediation analysis showed that viral load and HBeAg explained part of the effect of *IFI44L* methylation on HCC.

Conclusion: Our data provide new insights into the virus-host interaction, and decreased *IFI44L* methylation is predictive of viremia levels, linking hepatitis B progression to HCC.

External validation of clinical scoring system for the prediction of hepatocellular carcinoma in chronic hepatitis B treated by nucleotide/nucleoside analogue

M. Kurosaki, J. Itakura, T. Nobuharu, Y. Yasui, K. Tsuchiya, H. Nakanishi, K. Takaura, N. Izumi. *Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology*
Email: kurosaki@musashino.jrc.or.jp

Background and Aims: The PAGE-B score using age, platelet counts, and gender, is a simple risk scoring system that predict risk of hepatocellular carcinoma (HCC) in Caucasian hepatitis B patients treated with nucleotide/nucleoside analogue (NUC). This study validated the reliability of PAGE-B score in Asian patients treated with NUCs. The role of NUC therapy for HCC risk reduction was also evaluated by using by this score to adjust for the baseline HCC risk.

Method: The PAGE-B score was calculated in 300 chronic hepatitis B patients treated by NUCs for an average of 8.2 years, and in 431 patients not treated with NUCs and observed for average of 6.3 years. The accuracy of this score to predict HCC development was evaluated. The cumulative incidence of HCC was compared between NUC treated and not treated patients after stratification by PAGE-B score to evaluate the role of NUC therapy for HCC risk reduction.

Results: The 3-, 5-, and 7-year cumulative HCC incidence in NUC treated vs. not treated patients was 2.5% vs. 6.2%, 3.7% vs. 8.3%, and 5.1% vs. 10.4%, respectively (p = 0.009). The proportion of NUC treated patients with PAGE-B ≤9, 10–17, ≥18 was 27%, 48%, and 25%, respectively, and their 5-year cumulative HCC incidence rates was 0%, 3.2%, and 9.5%, respectively (p < 0.0001). The area under the receiver operating characteristic curve of PAGE-B score for the prediction of HCC at 5-year in NUC treated patients was 0.829. The hazard ratio (HR) of PAGE-B ≥ 18 for HCC development during NUC treatment was 6.9 (95% confidence interval (CI) 4.3–11.0, p < 0.0001). Similarly, in patients not treated by NUC, area under the receiver operating characteristic curve of PAGE-B score for the prediction of HCC at 5-year was 0.834, and the HR of PAGE-B ≥18 for HCC development during NUC treatment was 7.7 (95% CI 4.4–13.7, p < 0.0001). NUC treated and not treated patients were stratified by PAGE-B score to adjust for the baseline HCC risk and the role of NUC therapy for HCC risk reduction was evaluated. The 5-year cumulative HCC incidence was significantly lower in NUC treated patients

compared to not treated patients if PAGE-B ≥18 (9.5% vs. 33.7%, p = 0.002), lower with borderline significance if PAGE-B 10–17 (3.2% vs. 5.8%, p = 0.059), and did not differ if PAGE-B ≤9 (0% vs. 1.3%, p = 0.13). In multivariable analysis including all patients, PAGE-B ≥18 (HR 7.4, 95%CI 4.6–11.8, p < 0.0001) and no NUC treatment (HR 1.5, 95%CI 1.2–1.9, p = 0.002) was an independent risk of HCC development.
Conclusion: The PAGE-B score which was originally developed based on data of Caucasian hepatitis B patients treated with NUC was also a reliable predictor for HCC development in Asian patients treated by NUCs. Adjustment of the baseline HCC risk by this score revealed that long term NUC therapy significantly reduced the incidence of HCC in patients with high PAGE score but not in those with low score.

FRI-264
Monitoring patients with a resolved hepatitis B virus infection for HBV reactivation
A. Tamori, R. Kozuka, H. Motoyama, H. Fujii, A. Hagihara, S. Uchida-Kobayashi, H. Morikawa, M. Enomoto, Y. Murakami, N. Kawada. *Osaka City University, Hepatology, Osaka, Japan*
Email: atamori@med.osaka-cu.ac.jp

Background and Aims: Hepatitis B virus reactivation (HBV-R) can occur in various conditions, such as in patients taking immunosuppressive or immuno-modified agents. It is speculated that the incidence rate of HBV-R depends on the drug used and the treatment duration. However, few reports are available about HBV-R in patients undergoing short-duration immunosuppressive therapy, particularly in HBV resolved patients. In the present study, we prospectively examined the incidence rate of HBV-R in patients with resolved HBV infection receiving various treatments.
Patients and Method: HBV DNA was prospectively examined by polymerase chain reaction analysis in 437 HBsAg-negative and anti-HBc positive patients who received cytotoxic or immunosuppressive therapy. The present cohorts consisted of 155 patients receiving long-duration immunosuppressive therapy; 113 with rheumatoid arthritis (RA), 15 with psoriasis, 14 who underwent renal transplantation, and 13 with inflammatory bowel disease, as well as 60 patients receiving short-duration immunosuppressive therapy. There were also 49 with sudden deafness and 11 with Bell's palsy. In addition, HBV-R was examined in 763 patients with chronic hepatitis C virus treated with direct acting anti-viral (DAA).
Results: The observation period for long-duration immunosuppressive therapy was a median of 41 months (range, 2–110 months). HBV-R occurred in five (4.4%) of 113 patients with RA and three (21%) of 14 patients who underwent renal transplantation. Rituximab was administered to two of three HBV-R patients who underwent renal transplantation. HBV reactivated at 2–27 months from the start of immunosuppressive therapy. Pre-emptive therapy with entecavir prevented hepatitis related to HBV-R. HBV-R did not occur in patients who received short-duration immunosuppressive therapy with prednisolone; the observation period was a median of 5 months (range, 1–14 months). HBV reactivated without hepatitis flare in one patient treated with sofsbuvir + ledipasvir.
Conclusion: HBV-R rarely occurred in HBV resolved patients treated with short-duration prednisolone or DAA. In contrast, continuous HBV monitoring was necessary in patients with RA and those who underwent renal transplantation.

FRI-265
Relationship between hepatitis B core-related antigen and chronic hepatitis B outcome in HBeAg negative patients: a 10-year longitudinal study
W. Pan To[1], D. Wong[1,2], L.-Y. Mak[1], W.-K. Seto[1,2], K.-S. Cheung[1], Y. Yue, J. Fung[1,2], C. Lung Lai[1,2], M.-F. Yuen[1,2]. *[1]Queen Mary Hospital, Medicine, Hong Kong, Hong Kong; [2]The University of Hong Kong, State Key Laboratory of Liver Research, Hong Kong, Hong Kong*
Email: mfyuen@hku.hk

Background and Aims: Hepatitis B core-related antigen (HBcrAg) is a novel serological marker of HBV. It correlates well with serum HBsAg, HBV DNA and intrahepatic cccDNA levels. However, long-term data regarding the predictive value of HBcrAg is limited. We aim to determine the relationship between HBcrAg levels after spontaneous HBeAg seroconversion and hepatocellular carcinoma (HCC).
Method: We recruited chronic HBV patients with a documented time of spontaneously HBeAg seroconversion. Blood tests including liver function test and alpha-fetoprotein were performed. Cirrhosis was defined as the presence of cirrhotic features in the ultrasonography. HBcrAg and HBsAg were checked at three time points: within 3 years (the baseline), at 5 years and 10 years after HBeAg seroconversion. HBcrAg were measured by the Lumipulse G HBcrAg assays in a Lumipulse G1200 analyzer (Fujirebio Inc, Tokyo, Japan). HBV DNA was measured at the baseline. Multivariate logistic regression was used to investigate the predictors for the development of HCC.
Results: We recruited 209 patients. There were 120 (57.4%) male and the median age was 40 year-old (interquartile range [IQR]: 34–45 years). The median duration for follow-up was 13.1 years (IQR: 11.8–15.5 years). Cirrhosis was present at baseline in 9 patients (4.3%). HCC developed in 16 patients (7.7%) during the follow-up period. The median level of HBcrAg at baseline was 68.0kU/ml (IQR: 14.2–363.0kU/ml) while the median level of HBV DNA at baseline was 4.02 log IU/ml (IQR: 3.05–5.38logIU/ml). Patients who developed HCC had a significantly older age of HBeAg seroconversion compared with those without HCC (median age 50.1 vs 39.3 respectively, p = 0.002). More patients in the HCC group than in patients without HCC had baseline cirrhosis (31.3% vs 2.1%, p < 0.001). The median level of HBcrAg at baseline was significantly higher in HCC patients when compared with patients without HCC (518.6 vs 59.6kU/ml respectively, p = 0.003), while there were no differences in the levels of HBsAg and HBV DNA (3.24 vs 3.47logIU/ml and 4.61 vs 4.01logIU/ml, respectively; all p > 0.05). Independent risk factors for development of HCC included age of HBeAg seroconversion older than 50 years (odds ratio [OR]: 10.84, 95% confidence interval [95%CI]: 3.04–38.66), presence of baseline cirrhosis (OR: 6.29, 95%CI: 1.06–37.50) and a higher baseline HBcrAg (OR: 1.77, 95%CI 1.01–3.12). HBcrAg levels at 5 years and 10 years after HBeAg seroconversion were found to have no association with HCC, probably due to the limited number of patients with HCC after 5 years of HBeAg seroconversion (n = 9).
Conclusion: High HBcrAg level within 3 years after HBeAg seroconversion was independently associated with the development of HCC in chronic hepatitis B patients, while other independent risk factors included older age (>50 years) at HBeAg seroconversion and presence of baseline cirrhosis.

FRI-266
Real-world rates of hepatitis B surface antigen seroclearance in patients with chronic hepatitis B: a systematic review, conventional aggregated data meta-analysis and individual patient data meta-analysis

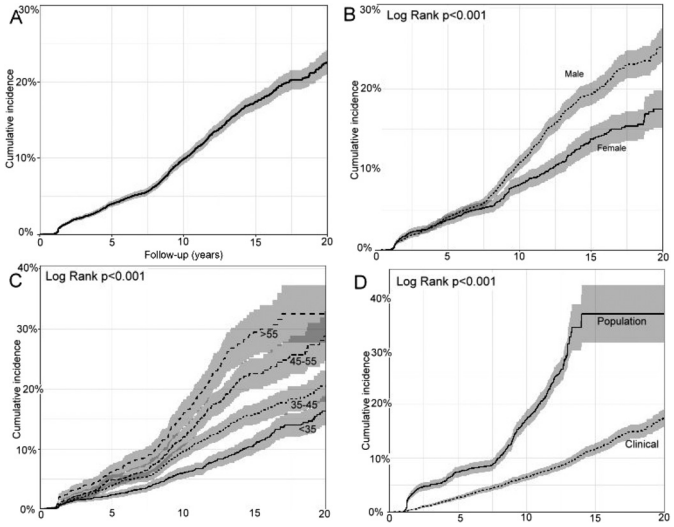
Email: mindiehn@stanford.edu

Background and Aims: Hepatitis B surface antigen (HBsAg) loss is a rare but important marker of chronic hepatitis B (CHB) functional control. However, there is considerable heterogeneity across published datasets with variable HBsAg clearance rates. Our goal was to perform aggregated data meta-analysis (ADMA) and individual patient data meta-analysis (IPDMA) to estimate pooled annual and cumulative HBsAg seroclearance rates and to identify their predictors.
Method: Two researchers independently searched PubMed and Embase from inception to July 5, 2017 for relevant studies and extracted data. Authors of all included studies were contacted for original individual participant level data. We estimated pooled rates of HBsAg loss using random effects model in ADMA and Cox proportional-hazard models with a cluster statement in IPDMA. This study with pre-planned subgroup analyses has been registered in PROSPERO.
Results: Out of the 4,469 abstracts and articles reviewed, 26 full-article studies (n = 39,661) were included. ADMA showed a pooled annual HBsAg seroclearance rate of 1.11% (95%CI 0.84–1.37%). In IPDMA of original data from 9 cohorts from the US, Europe and Asia (n = 12,317), 1,196 patients had HBsAg loss over 100,393.9 person-years of follow-up, yielding an annual incidence rate of 1.13% (95%CI: 1.08–1.20%) (Fig 1A). The 5-, 10-, 15-, and 20-year pooled cumulative rates were 4.03%, 9.90%, 17.40%, 22.51%, respectively. In subgroup analysis, older patients, males, and population-based community participants (vs. clinical cohorts) had significantly higher rates of HBsAg seroclearance (Figs. 1B-D). Multivariate Cox regression showed that males (adjusted hazard ratio [aHR]:1.17, 95% CI:1.02–1.34) and age >55 years (aHR:1.77, 95%CI:1.45–2.15) were significant independent predictors for higher rates of HBsAg loss, while positive HBeAg (aHR:0.33, 95%CI:0.26–0.42), antiviral therapy (aHR:0.52, 95% CI:0.31–0.86), cirrhosis at entry (aHR:0.58, 95%CI:0.34–0.97), HBV DNA > 20,000IU/ml (aHR:0.31, 95%CI:0.25–0.39) and quantitative HBsAg (qHBsAg) > 1200IU/ml (aHR:0.2, 95%CI:0.17–0.24) were independently associated with lack of HBsAg seroclearance. However, Asian (vs. non-Asian) ethnicity and population-based community (vs. clinical center) study setting were not.
Conclusion: The pooled annual HBsAg seroclearance rate was approximately 1.1% from both ADMA and IPDMA. Male sex, older age, antiviral treatment, HBeAg negativity, non-cirrhosis, lower HBV DNA and qHBsAg were independent predictors of HBsAg loss, but not ethnicity or study setting (population-based community vs. clinical cohorts).



FRI-267
Association of common polymorphism in the Interleukin 1 beta gene with Hepatitis B virus-related hepatocellular carcinoma in Caucasians

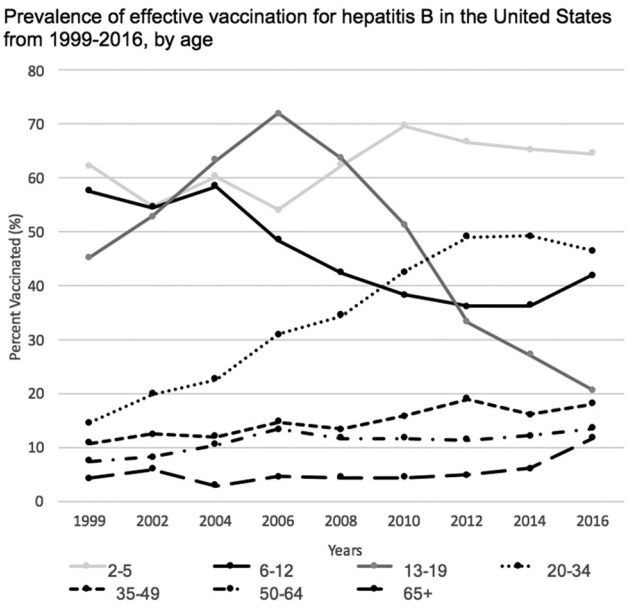
J. Fischer[1], L. Shuang[2], K. Eleni[3], E. Schott[4], F. Balazs[5], H. Renate[6], T. Berg[7], F. van Boemmel[3]. *[1]University Hospital Leipzig, Section of Hepatology, Division of Gastroenterology and Rheumatology, Leipzig, Germany; [2]University Hospital Leipzig, Section of Hepatology, Division of Gastroenterogy and Rheumatology, Leipzig, Germany; [3]University Hospital Leipzig, Section of Hepatology, Division of Gastroenterogy and Rheumatology, Leipzig, Germany; [4]HELIOS Klinikum Emil von Behring, Klink für Innere Medizin ll, Berlin, Germany; [5]HELIOS Klinikum Berlin-Buch, Department of Internal Medicine and Gastroenterology, Berlin, Germany; [6]Liver and Study Center Checkpoint, Berlin, Germany; [7]University Hospital Leipzig, Section of Hepatology, Division of Gastroenterogy and Rheumatology, Leipzig, Germany*
Email: janett.fischer@medizin.uni-leipzig.de

Background and Aims: Chronic hepatitis B (CHB) is a major risk for the development of liver cirrhosis and hepatocellular carcinoma (HCC). Pro-inflammatory cytokines such as interleukin 1 beta (IL1beta) mediate several immune responses and promote liver disease progression. Genetic variations within the promotor of IL1beta might alter cytokine expression and affect the progression to cirrhosis and HCC. We aimed to investigate the association of polymorphisms within the promotor of the IL1beta gene with CHB progression in Caucasian patients.
Method: 609 Caucasian patients with CHB and 235 individuals with spontaneous HBs-antigen sero-clearance (SC) were retrospectively enrolled. In the CHB group, 83% were HBe-antigen negative and 49% of patients were inactive carriers. 89 patients had developed liver cirrhosis and 41 were diagnosed with HCC and cirrhosis. Host genomic DNA was extracted from peripheral blood samples. Genotyping of the IL1beta rs1143623, rs1143627 and rs16944 was performed by polymerase chain reaction and melting curve analysis.
Results: Between the CHB and SC groups gender distribution (61% vs. 54% males; p = 0.042) and mean age (53.7 ± 13.8 vs. 65.1 ± 14.4 years; p < 0.0001) were significantly different. There were no differences in genotype distribution of all three IL1beta SNPs between the CHB and SC groups and stages during CHB. The C allele of rs1143623 was more frequent in patients with liver cirrhosis (62% vs. 49%, p = 0.030) and multivariate analysis revealed an association with an increased likelihood for cirrhosis development (OR = 1.63 [95%CI: 1.01–2.61] p = 0.044). The C alleles of rs11463623 and of rs1143627 were more frequent in patients with HCC (73% vs. 49%, p = 0.003; 80% vs. 64%, p = 0.028). In contrast, carriers of the C allele of rs16944 had fewer HCC

(71% vs. 86%, p = 0.013). In multivariate analyses the C allele of rs1143623 remained independently associated with HCC (OR = 2.81 [95% CI: 1.24–6.39] p = 0.014).
Conclusion: We identified for the first time an association of a common polymorphism within the interleukin 1 beta gene with the development of HBV-related liver cirrhosis and HCC in Caucasian patients. The risk conferred by this polymorphism is independent from the CHB disease stages which are currently regarded as important HCC risk factor. Further studies in larger cohorts and functional analysis are needed to confirm these results and elucidate the impact of these genetic variants in liver fibrogenesis and carcinogenesis.

FRI-268
Effective hepatitis B vaccination by serologic results in the United States: a population-based study from 1999–2016
M. Huan Le[1], D.H. Lee[1], M.-H. Lee[2], E. Gane[3], S. So[4], M. Nguyen[1].
[1]Stanford University Medical Center, Department of Gastroenterology and Hepatology, Palo Alto; [2]National Yang Ming University, Taipei, Taiwan; [3]The University of Auckland, Auckland, New Zealand; [4]Stanford University School of Medicine, Asian Liver Center, Palo Alto, United States
Email: mindiehn@stanford.edu

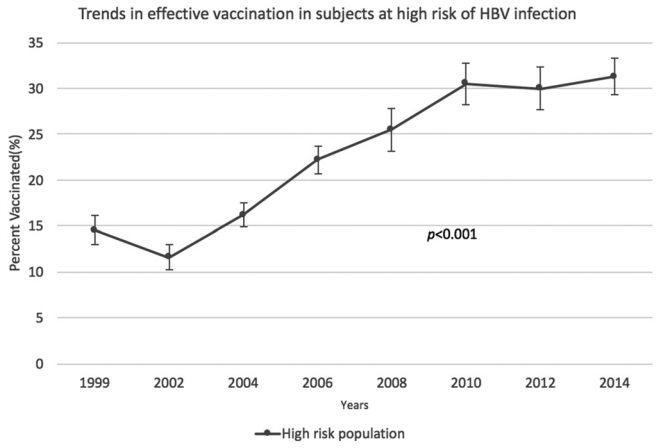
Background and Aims: In the United States (USA), the Centers for Disease Control and Prevention have estimated vaccine coverage to be greater than 90% in all children and teens and 24.6% in adults aged 19 and older in 2015. However, these results were obtained through survey questionnaire and have not yet been confirmed through serologic results. The aim of this study was to determine the trends in vaccination in the general USA population from 1999–2016 based on serologic results.
Method: Of the 92,062 participating in the National Health and Nutrition Examination Survey from 1999–2016, 71,777 subjects age 2 years and older who completed HBV serology tests were included in this analysis. Subjects age 2–5 years were defined as having effective vaccination if they were HBV surface antibody positive, as this group did not undergo HBV core antibody testing. Subjects age 6 years and older were defined as having effective vaccination if they were HBV core antibody negative and HBV surface antibody positive. Analyses were weighted to represent the USA population.
Results: From 1999 to 2016, overall effective vaccination increased significantly from 19.3% to 25.9% (p < 0.001). Across various demographic and socioeconomic groups, significant increases in vaccination were seen in male (18.8–23.3%, p = 0.001), female (19.8–28.4%, p < 0.001), USA born (20.5–26.4%, p < 0.001), foreign born (12.7–23.4%, p < 0.001), non-Hispanic White (18.2–25.0%, p = 0.001), non-Hispanic Black (21.8–26.8%, p = 0.002), Other-multiracial (20.2–31.0%, p = 0.004), uninsured (13.5–19.9%, p < 0.001), insured (20.7–26.8%, p < 0.001) and in higher income individuals (19.4–26.2%, p < 0.001). No significant changes in effective vaccination were seen in Mexican American/Hispanic and low income individuals. There was a significant increase in effective vaccination in subjects age 2–5 years old (p for trend = 0.003) and in age 20 years and older (p for trend < 0.001). Surprisingly, there was a significant decrease in effective in subjects age 6–12 years and 13–19 years (p for trend < 0.001) from 1999–2016 (Figure). Based on population estimates from 2011–2014, 79.6 million Americans (25.9%) have effective vaccination while 221.7 million Americans remain at risk of infection.
Conclusion: Despite significant improvements in vaccination from 1999 to 2016, hundreds of millions of Americans remain at risk of HBV infection. Further efforts must be made to educate and immunize all subjects that may be at risk of infection and to understand factors associated with the decreasing rate of effective vaccination for the school-age group in the more recent period (6–19 years old).



FRI-269
Suboptimal rates of effective hepatitis B vaccination in adults at high risk of infection in the United States from 1999–2014
M. Huan Le[1], D.H. Lee[1], M.-H. Lee[2], E. Gane[3], S. So[4], M. Nguyen[1].
[1]Stanford University Medical Center, Department of Gastroenterology and Hepatology, Palo Alto, United States; [2]National Yang Ming University, Taipei, Taiwan; [3]The University of Auckland, Auckland, New Zealand; [4]Stanford University School of Medicine, Asian Liver Center, Palo Alto, United States
Email: mindiehn@stanford.edu

Background and Aims: In the United States, hepatitis B vaccination in adults at high risk of infection has been recommended by the Centers for Disease Control and Prevention (CDC) since 1982. In 2006, the CDC updated their immunization guidelines to call for increased vaccination of high risk populations. However, the effectiveness of these guidelines are unclear since the high risk group remains understudied. Therefore, using objective serologic results, the aims of this study were to determine the trends and predictors of vaccination in those at high risk of infection.
Method: A total of 42,364 adults age 18 and over who completed HBV serologic tests from 1999–2014 were included in this study. Subjects were defined as having effective vaccination if they were HBV surface antibody positive and HBV core antibody negative. High risk populations were defined by CDC and US Preventive Services Task Force recommendations (intravenous (IV) drug use, high risk sexual behavior, risk of exposure to blood borne diseases). Analyses were weighted to represent the USA population.
Results: 6,465 adults (34.8%, 95%CI: 33.5–36.1) were identified as persons that engaged in behaviors that put them at high risk for HBV infection. In this high risk group, effective vaccination increased significantly from 14.5% in 1999 to 31.3% in 2014 (Figure). In those at high risk of infection, significant increases in vaccination from 1999–2004 to 2011–2014 were observed in those who were evaluated for a sexually transmitted disease (16.3–29.6%, p < 0.001) and those with multiple sex partners (14.2–36.9%, p < 0.001). No statistically significant changes in vaccination were observed in IV drug users (7.36–14.5%, p = 0.109), HCV positive individuals (6.41–8.34%, p = 0.556), homosexual men (11.8–24.0%, p = 0.051), and hemodialysis patients (50.1–37.2%, p = 0.450). Independent predictors of vaccination include younger age (OR: 4.13 95%CI: 2.35–7.23, p < 0.001), female (OR:1.7 95%CI: 1.45–2.05, p < 0.001), other-multiracial ethnicity (OR: 1.58 95%CI: 1.09–2.28, p = 0.016), college educated (OR = 2.54 95%CI:

2.81–3.56, p < 0.001), being single (OR: 1.46 95%CI: 1.20–1.78, p < 0.001), and having health insurance (OR: 1.56 95%CI: 1.29–1.89, p < 0.001).



Conclusion: Significant increases in vaccination have been observed in subjects at high risk of infection from 1999–2014. However, approximately 70% of this group remains unvaccinated, especially in HCV positive individuals and IV drug users. Further efforts must be made to educate and immunize subjects that are at high risk of HBV infection.

Email: fabien.zoulim@inserm.fr

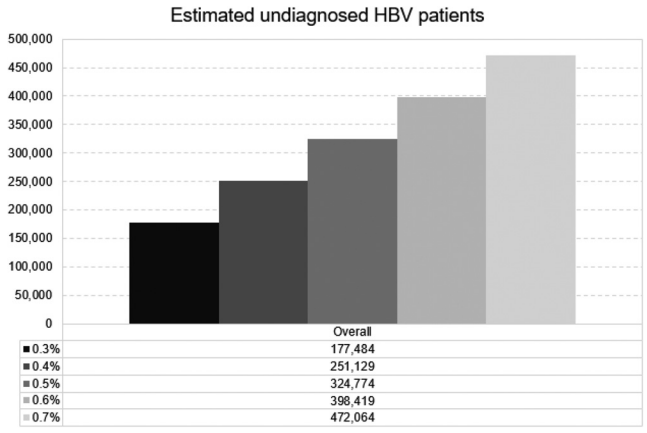
Background and Aims: Nucleos(t)ide anssalogue (NA) therapy for chronic hepatitis B leads to viral suppression in the majority of patients. However, no significant effect on the established pool of covalently closed circular (ccc)DNA has yet been described. cccDNA stably resides in the nucleus of infected hepatocytes and serves as a unique template for pre-genomic RNA (pgRNA), the essential intermediate for full viral replication. Robust data on the effect of long-term (>2 years) NA therapy on intrahepatic cccDNA pool levels are lacking because of technical limitations associated with the sensitivity of cccDNA quantitation in small liver biopsy samples.
Method: To address this issue, a droplet digital PCR (ddPCR) assay to absolutely quantify both cccDNA and transcriptional activity (calculated as pgRNA/cccDNA ratio) was set up and applied to 64 liver biopsy samples. Fifty-six samples were obtained from patients treated with telbivudine for 3–5 years, and 8 samples from 4 patients who received mixed NA therapy in the PEGAN study with paired biopsy samples before and after the administration (or not) of add-on 48-week peg-IFN.
Results: ddPCR was ten times more sensitive than classic qPCR for cccDNA detection in HepG2-NTCP infected cells. A duplex ddPCR protocol was designed for absolute quantification of pgRNA content and internal normalization using the *gusb* housekeeping transcript. Among the samples from the 56 telbivudine-treated patients, 70% were negative for cccDNA quantification by classic qPCR. However, ddPCR analysis detected cccDNA in 89% of these qPCR-negative samples. In total, only 11% of NA-treated patient samples had undetectable intrahepatic cccDNA by ddPCR, a percentage comparable to a matched control group of non-treated patients (12%). Notably, absolute quantitation by ddPCR showed that both cccDNA amount and pgRNA/cccDNA ratio were significantly decreased in samples from NA-treated patients as compared to non-treated patient samples. All of the 8 biopsies derived from the PEGAN patients had undetectable cccDNA levels by qPCR, but ddPCR detected cccDNA in 7 of them. Analysis of cccDNA and pgRNA in matched samples revealed no significant effect of the peg-IFN add-on on both cccDNA amount and activity.
Conclusion: This ddPCR protocol extended the limits and precision of cccDNA and pgRNA detection in vivo and demonstrated that liver samples from most long-term NA-treated patients still harbour transcriptionally active cccDNA.

FRI-271

Estimated the number of undiagnosed patients and antiviral treatment rate of chronic hepatitis B in the U.S. based on the Truven Health MarketScan Database

E. Ogawa[1,2], D. Jeong[1], Y.H. Yeo[1], M. Nguyen[1]. *[1]Stanford University Medical Center, Department of Gastroenterology and Hepatology, Palo Alto, United States; [2]Kyushu University Hospital, Department of General Internal Medicine, Fukuoka, Japan*
Email: mindiehn@stanford.edu

Background and Aims: Prior studies suggest that only one-third of chronic hepatitis B (CHB) in the U.S. are aware of their diagnosis and only 10–20% or less of diagnosed patients are treated with antiviral therapy. Our goal is to estimate total number of undiagnosed CHB and treatment rate of CHB patients in a large nationwide sample of U.S. population.
Method: We used the commercial U.S. Truven Health MarketScan Database (n = 73,644,921; 1/1/2007-12/31/2014) to identify the number of patients with CHB diagnosis (≥1 inpatient or ≥2 outpatient ICD-9-CM codes for CHB). Other study inclusion criteria include continuous insurance and prescription coverage for 6 months prior to the first CHB diagnosis and 6 months after. Then, using the National Health and Nutrition Examination Survey (NHANES) prevalence estimates of HBV infection of 0.3%–0.7%, we estimated the number of undiagnosed CHB patients by subtracting the number of estimated CHB patients by NHANES prevalence in this population of approximately 73 million people with the number of patients who were identified as having CHB in this population sample. We also estimated the proportion of diagnosed CHB patients who received a prescription of any of the FDA-approved anti-HBV medications.
Results: In total, we identified 43,765 CHB in this cohort of 73,644,921 during the study period, yielding a prevalence of known or diagnosed CHB of 0.059% (95%CI: 0.059–0.060). The prevalence of diagnosed CHB increased with age and were 0.036% (95%CI: 0.036–0.037) for the 18–34 age group, 0.069% (95%CI: 0.068–0.070) for the 35–44 group, 0.072% (95%CI: 0.071–0.073) for the 45–54 group, and 0.077% (95%CI: 0.076–0.079) for the 55–64 group. Notably, diagnosed CHB prevalence was higher among HMO insured patients vs. other insurance types: 0.088% (95%CI: 0.086–0.090) vs. 0.056% (95%CI: 0.055–0.057). Based on the NHANES prevalence rate with 0.3–0.7% in HBV infection, the estimated number of undiagnosed patients by sensitivity analysis was shown in Figure. The overall treatment rate with anti-HBV drugs was 11.5% (95%CI: 11.2–11.8) (5,033/43,765). HBV treatment rate among aged 55–64 (10.7%, 95%CI: 10.1–11.3) group was lower than the aged 35–44 (12.9%, 95%CI: 12.2–13.5) and 45–54 (13.2%, 95%CI: 12.6–13.9) groups. HBV treatment for insured patients with HMO (14.3%, 95%CI: 13.6–15.0) was also higher than those with other insurance type (11.0%, 95%CI: 10.6–11.3).



Conclusion: In this large U.S. nationwide sample of over 73 million people with insurance coverage, the prevalence of diagnosed CHB was only 0.059%, 5–12 times lower than the NHANES estimates. In this sample alone, there were an estimated total of 177,484–472,064 people with CHB but have not been diagnosed. Treatment rate was also dismally low. Further efforts are needed to improve the current poor linkage to care for CHB patients.

FRI-272

Combination of HBV serological markers to predict the burden and productivity of intrahepatic HBV reservoir and disease progression in HBeAg negative Chronic Hepatitis B

V. Svicher[1], R. Salpini[1], L. Colagrossi[1], D.D. Carlo[1], A. Battisti[1], L. Piermatteo[1], N. Hansi[2], F.C. Silberstein[1], C.F. Perno[3], U.S. Gill[2], P. Kennedy[2]. *[1]Tor Vergata University, Experimental Medicine and Surgery, Italy; [2]Blizard Institute, Barts and The London SMD, QMUL, Hepatology, Centre for Immunobiology, London, United Kingdom; [3]University of Milan*
Email: valentina.svicher@uniroma2.it

Background and Aims: The persistence of HBsAg and ongoing viral replication is associated with an increased risk for the development of hepatocellular carcinoma in chronic hepatitis B (CHB). At present serological markers measured in the peripheral compartment alone are used to risk stratify patients for disease progression and treatment candidacy. Limited data exist on the intrahepatic (it) compartment and how serum markers reflect the intrahepatic HBV reservoir and its transcriptional activity. We investigated if improved virological characterisation could better inform treatment decisions particularly in those patients with HBV DNA <20,000 IU/ml.
Method: The peripheral and intrahepatic compartments of HBeAg negative CHB patients (n = 84) were compared between disease cohorts with different virological characteristics. Patients were classified as follows: Group 1 (HBV DNA <2,000 IU/ml; n = 12), Group 2 (HBV DNA 2,000–20,000 IU.ml; n = 25), Group 3 (HBV DNA >20,000 IU/ml; n = 47). cccDNA, itHBV DNA and pgRNA were assayed by qPCR and serum HBcrAg measured by Lumipulse (Fujirebio). Correlations between peripheral and intrahepatic compartments were assessed with Spearman rank. AUROC was used to define the threshold ability of peripheral parameters to predict the intrahepatic reservoir.
Results: Overall serum HBV DNA and HBcrAg positively correlated with cccDNA (Rho = 0.56 & 0.48; p = <0.001), itHBV DNA (Rho = 0.49 & 0.59; p = <0.001) and pgRNA (Rho = 0.74 & 0.45; p = <0.001 & 0.004). Conversely weaker correlations were noted for quantitative HBsAg (qHBsAg) with cccDNA (Rho = 0.31, p = 0.007), itHBV DNA (Rho = 0.39 p = 0.001) and pgRNA (Rho = 0.13, p = 0.43). On sub-group analysis groups 1 and 2 demonstrated a comparable intrahepatic reservoir. In contrast, compared to group 2, patients in group 3 were characterised by higher levels of cccDNA (p = 0.004), itHBV DNA (p = 0.004) and pgRNA (0.002). By AUROC, the combination of: serum HBV DNA <20,000 IU/ml, HBcrAg <2.0 log IU/ml and qHBsAg <3.2 log IU/ml identified a limited HBV reservoir with a 75% positive predicted value and 95% specificity.
Conclusion: Serum HBcrAg correlates with the burden and productivity of the intrahepatic HBV reservoir in HBeAg negative CHB patients. This parameter combined with serum HBV DNA and qHBsAg can enhance disease stratification and identify those patients at low risk of disease progression. The combination of these serological parameters could be utilised to inform treatment decisions particularly in those patients with HBV DNA <20,000 IU/ml.

FRI-273

Comparison of the risks of hepatocellular carcinoma in patients with chronic hepatitis B virus infection: estimation of direct carcinogenic effect of hepatitis B virus

Y. Chang, J.-H. Lee, J.Y. Nam, H.Y. Lee, H. Cho, Y.Y. Cho, E.J. Cho, S. Yu, Y.J. Kim, J.-H. Yoon. *Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine*
Email: pindra@empas.com

Background and Aims: Chronic hepatitis B virus (HBV) infection is one of the major risk factors for hepatocellular carcinoma (HCC) development. The major mechanism of HBV-induced hepatocarcinogenesis is an indirect pathway through the process of inflammation and fibrosis, but a direct oncogenic effect of HBV also contributes. It remains still unknown the impact of direct carcinogenic effect of HBV.
Method: This study included consecutive patients diagnosed as chronic HBV infection with normal alanine aminotransferase (ALT) levels and without evidence of cirrhosis at a tertiary referral hospital in Korea. Study participants were classified according to the presence of HBeAg, serum HBV DNA levels, and antiviral treatment: HBeAg-positive chronic infection (HBeAg-positive and HBV DNA >20,000 IU/ml), untreated HBeAg-negative chronic infection (HBeAg-negative and HBV DNA <2,000 IU/ml without antiviral treatment), or treated HBeAg-negative chronic infection (HBeAg-negative and HBV DNA <2,000 IU/ml with antiviral treatment). Primary endpoint was an HCC development. Cox proportional hazard model and inverse-probability weighting (IPW) were utilized to adjust baseline characteristics.
Results: A total of 1,197 patients were included: 373 HBeAg-positive, 308 untreated HBeAg-negative, and 516 treated HBeAg-negative chronic infection. Age and baseline liver function were significantly more favorable for HBeAg-positive group than HBeAg-negative groups. In multivariate analyses to adjust confounding factors, HBeAg-positive group showed significantly higher risks of HCC than both untreated HBeAg-negative group (adjusted hazard ratio [aHR] = 7.93, 95% confidential interval [CI] = 2.87–21.91, p < 0.001) and treated HBeAg-negative group (aHR = 8.51, 95%CI = 3.32–21.5, p < 0.001). After balancing baseline characteristics with IPW, HBeAg-positive group consistently showed significantly higher risks of HCC than both untreated (HR = 4.44, 95%CI = 2.22–8.88, log-rank p < 0.001) and treated HBeAg-negative group (HR = 3.03, 95%CI = 2.14–4.29, log-rank p < 0.001).
Conclusion: Even with normal ALT level, HBeAg-positive chronic infection phase had 4.4–7.9-fold and 3.0–8.5-fold higher risk of HCC than untreated and treated HBeAg-negative chronic infection, respectively. These results might suggest the considerable impact of direct oncogenic effect of HBV in HCC development.

Modified PAGE-B score predicts the risk of hepatocellular carcinoma in Asians with chronic hepatitis B on antiviral therapy

M. Lee[1], J.H. Kim[1], B.G. Jun[2], T.S. Kim[1], E.-H. Cho[1], D.H. Choi[1], K.T. Suk[3], S. Kang[4], M.Y. Kim[4], Y.D. Kim[2], G.J. Cheon[2], D.J. Kim[3], S.K. Baik[4]. *[1]Kangwon National University Hospital, Department of Internal Medicine, Korea, Rep. of South; [2]Gangneung Asan Hospital, Department of Internal Medicine, Korea, Rep. of South; [3]Chuncheon Sacred Heart Hospital, Department of Internal Medicine, Korea, Rep. of South;*

[4]*Wonju Severance Christian Hospital, Department of Internal Medicine, Korea, Rep. of South*
Email: minjonglee2@naver.com

Background and Aims: Recently, PAGE-B score has been developed to predict the risk of hepatocellular carcinoma (HCC) in Caucasian patients with chronic hepatitis B (CHB). We aimed to validate PAGE-B scores in Asian patients with CHB and suggested modified PAGE-B scores to potentiate the predictive performance.
Method: From 2007 to 2017, we examined 2,844 Asian patients with CHB receiving entecavir/tenofovir therapy. We assessed the performances of PAGE-B and three conventional risk prediction models (CU-HCC, GAG-HCC, and REACH-B) for HCC development. A modified PAGE-B score (mPAGE-B) was developed (derivation set from three centers, n = 1,896) based on multivariable Cox models. Bootstrap for internal validation and external validation (validation set from one center, n = 948) were performed.
Results: The 5-year cumulative HCC incidence rates were 5.6% and 5.0% in the derivation and validation datasets, respectively. In the derivation dataset, age, gender, serum albumin levels, and platelet counts were independently associated with HCC. The mPAGE-B score was developed based on age, gender, platelet counts, and albumin levels (time-dependent area under receiver operating characteristic curves [AUROC] = 0.81, 0.80 after bootstrap validation). In the validation set, the original PAGE- B showed similar AUROCs to CU-HCC, GAG-HCC, and REACH-B at 5 years (0.73 vs 0.67, 0.69, and 0.68 respectively; all p > 0.05), whereas the AUROCs of mPAGE-B at 5 years were significantly higher than those of the PAGE-B and the three other models (0.82, all p < 0.001). HCC incidence rates within 5 years of antiviral therapy initiation in CHB patients were significantly lower compared with rates beyond year 5.

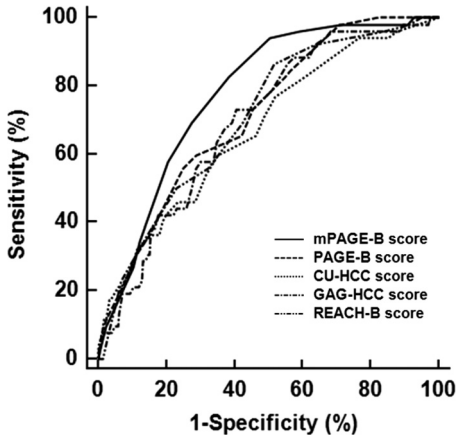

Figure 1: Time-dependent AUROCs of mPAGE-B scores and other prediction models for the prediction of HCC development within 5 years.

Conclusion: Although PAGE-B is applicable in Asian CHB patients receiving entecavir/tenofovir therapy, mPAGE-B scores including additional albumin levels showed better predictive performance than the original PAGE-B score.

FRI-275

Role of hepatitis B core-related antigen and antibodies to hepatitis B core antigen level in the natural history of chronic HBV infection

G.P. Caviglia[1], A. Olivero[1], A. Ciancio[1], F. Tandoi[2], G. Troshina[1], C. Bosco[1], L. Boglione[1], M. Rizzetto[1], R. Romagnoli[2], G.M. Saracco[1], A. Smedile[1]. [1]*University of Turin, Department of Medical Sciences, Turin, Italy;* [2]*University of Turin, Department of Surgical Sciences*
Email: caviglia.giampi@libero.it

Background and Aims: The natural history of chronic hepatitis B (CHB) is characterized by different dynamic phases which are not necessary sequential. Antiviral therapy is recommended only in patients with chronic hepatitis (CH) or cirrhosis, whereas patients with chronic infection (CI) should be periodically monitored. However, a reliable identification of CHB patients requiring treatment could be challenging when hepatitis is in a biochemical remission simulating a CI profile. We assessed the added value of hepatitis B core-related antigen (HBcrAg) and anti-hepatitis B core antibody class IgG (anti-HBc IgG) levels for the discrimination between the different CHB phases.
Method: Serum samples of 132 CHB patients (13 CH-HBeAg+, 64 CH-HBeAg- 21 low viremic CI-HBeAg- [fluctuating HBV DNA between 2000 and 20,000 IU/mL] and 34 true CI-HBeAg- [HBV DNA persistently <2,000 IU/ml]) and 97 HBsAg-/anti-HBc+ subjects (51 occult HBV infection [OBI]+ and 46 OBI-) were analyzed. HBsAg, HBcrAg and anti-HBc IgG level were assessed by CLEIA (Lumipulse®, Fujirebio, Japan). Biomarkers levels were reported in logIU/ml, logU/ml and Log cut-off index (COI), respectively. OBI+ was defined according to consensus statements.
Results: Mean HBsAg, HBcrAg and anti-HBc IgG levels were different among CHB phases (one-way ANOVA, p < 0.001), with higher values in CH-HBeAg+ (4.47 ± 0.79 log IU/ml, 6.9 ± 0.3 log U/ml and 4.07 ± 0.69 logCOI, respectively) and lower in true CI-HBeAg- (2.25 ± 1.26 log IU/ml, 2.2 ± 0.4 log U/ml and 3.29 ± 0.52 logCOI, respectively). We observed a correlation between HBV DNA and HBsAg (r = 0.642, p < 0.001), HBcrAg (r = 0.875, p < 0.001) and anti-HBc IgG (r = 0.515, p < 0.001). Area under the curve (AUC) for the discrimination between low viremic and true CI-HBeAg- was 0.736 for HBsAg, 0.749 for HBcrAg and 0.648 for anti-HBc IgG; a higher accuracy (AUC = 0.812) was obtained combining HBcrAg and anti-HBc IgG. Among HBsAg-/anti-HBc+ subjects, anti-HBc IgG levels were different between OBI+ and OBI- (1.16 ± 0.60 vs. 0.78 ± 0.64 logCOI, p = 0.004) with AUC = 0.671.
Conclusion: The combination of HBcrAg and anti-HBc IgG levels may improve the correct identification of true CI-HBeAg- patients (HBV DNA persistently <2,000 IU/ml) that do not require antiviral therapy. Anti-HBc IgG is the only circulating HBV marker detectable and quantifiable in HBsAg- subjects with previous HBV exposure and may help clinicians to predict HBV reactivation in OBI+ subjects undergoing pharmacological immunosuppression.

FRI-276

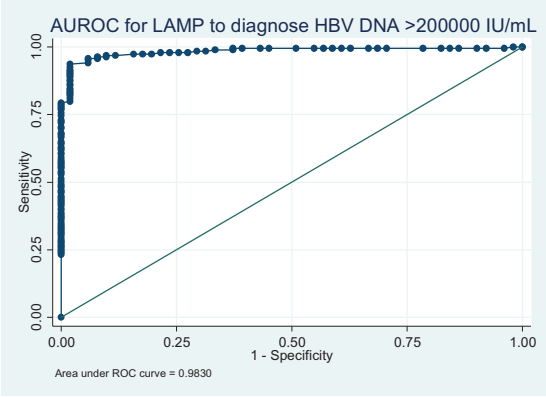
Pan-genotypic loop-mediated isothermal amplification assay for HBV: a simple, rapid and affordable point-of-care test to semi-quantify HBV DNA

J. Vanhomwegen[1], A. Kwasiborski[1], V. Sauvage[2], L. Boizeau[2], D. Hoinard[1], D. Candotti[2], S. Laperche[2], Y. Shimakawa[3]. [1]*Institut Pasteur, Unité de recherche et d'expertise Environnement et risques infectieux;* [2]*Laboratoire associé aux centre Nationaux de Référence des Hépatites B et C, et du VIH, Institut National de la Transfusion Sanguine (CNR-INTS), Département des agents transmissibles par le sang;* [3]*Institut Pasteur, Unité d'Epidémiologie des Maladies Emergentes*
Email: yusuke.shimakawa@pasteur.fr

Background and Aims: To achieve the global elimination of HBV, it is essential to scale up antiviral therapy through decentralized services in low- and middle-income countries (LMIC). However, the access to nucleic acid amplification test to quantify HBV DNA, a key marker to determine treatment eligibility, is limited and non-affordable in LMIC. Loop-mediated isothermal amplification assay (LAMP) is a simple, rapid and inexpensive technique to efficiently amplify DNA at a constant temperature. We designed a pan-genotypic LAMP assay to semi-quantify HBV viral load (VL) and evaluated its performance.
Method: Pan-genotypic primers sets were designed on conserved HBV gene regions using the LAMP Explorer software. The ability of LAMP to discriminate two clinically important HBV DNA levels (2,000 and 200,000 IU/mL), determined by the reference PCR assay (Roche COBAS®), was evaluated using well-characterized plasma samples from 240 French blood donors with positive HBV DNA (genotype A (n = 67), B (31), C (37), D (45), E (51) and F (9)) and 50 HBV-negative controls. HBV DNA was extracted from plasma using a simple

bead-based extraction method (Dynabeads™ SILANE), and amplified at 65°C for 60 minutes using real-time fluorescence reader (Genie III, OptiGene, UK) and real-time turbidmeter (Loopamp EXIA, Eiken Chemicals, Japan).

Results: The broadness of the LAMP was confirmed through a successful detection of synthetic DNAs from 8 major HBV sub-genotypes (A1/2/3, B, C, D, E, and F) with detection limits ranging from 10 to 100 genome copies/µL. Results obtained from donor samples showed a linear correlation between time-to-result (minutes) using LAMP and HBV DNA level. The AUROC was 0.91 (95%CI: 0.87–0.94) with 75.7% sensitivity and 92.0% specificity to diagnose high VL (2,000 IU/ml) and 0.98 (0.97–1.00) with 98.0% sensitivity and 92.6% specificity to diagnose very high VL (200,000 IU/ml) (Figure). The performance did not vary according to genotypes. No cross-reactivity was observed with HCV, HIV, or CMV in 37 tested samples. The cost per assay was <10€, and the completion time (extraction and amplification) was 90 minutes.



Conclusion: We developed a pan-genotypic LAMP assay to semi-quantify HBV VL. High accuracy to diagnose VL >200,000 IU/ml support its use as a rapid point-of-care test to identify women at elevated risk of mother-to-child transmission at peripheral antenatal clinics in LMICs. Real-life field evaluation of HBV-LAMP is ongoing in Africa.

FRI-277

Basal core promoter mutations as potential predictors of an enlarged intrahepatic HBV reservoir and enhanced cccDNA transcriptional activity in HBeAg negative chronic hepatitis B infection

L. Colagrossi[1], R. Salpini[1], U.S. Gill[2], A. Battisti[1], L. Piermatteo[3], D.D. Carlo[1], N. Hansi[2], F.C. Silberstein[3], C.F. Perno[4], P. Kennedy[5], V. Svicher[3]. *[1]Tor Vergata University, Department of Experimental Medicine and Surgery, Rome, Italy; [2]Blizard Institute, Queen Mary University of London, Centre for Immunobiology, London, United Kingdom; [3]Tor Vergata University, Department of Experimental Medicine and Surgery, Roma, Italy; [4]University of Milan, Milan, Italy; [5]Blizard Institute & Barts and the London School of Medicine & Dentistry QMUL, Hepatology Unit, Centre for Immunobiology, London, United Kingdom*
Email: luna_colagrossi@yahoo.it

Background and Aims: The basal core promoter (BCP) mutations 1766T, 1764A + 1762T are known to cause HBeAg-negativity. However, their impact on modulating the burden and productivity of intrahepatic HBV reservoir in vivo is still controversial.

Method: This study includes 72 drug-naïve patients (pts) with HBeAg negative chronic HBV infection (D:45.8%, C:19.4%, E:18.1%, A:9.7%, B:7%), with a BCP sequence (nucleotide:1742–1814) obtained from liver biopsy. Intrahepatic cccDNA and pregenomic RNA (pgRNA) are assessed by qPCR. Serum HBcrAg is measured by Lumipulse (Fujirebio). BCP mutations are defined according to the reference sequence of each specific genotype. Mann-Whitney test is used to compared levels of intrahepatic and serum parameters in presence of each BCP mutation and in its absence (referred as wt). AIggen algorithm is used to estimate BCP binding affinity for transcription factors (TF) (a decreased dissimilarity score [DS] indicates an increased binding affinity in presence of a mutation).

Results: 1766T and 1764A + 1762T (occurring in 9.7% and 29.2% of pts) are the only BCP mutations tightly correlated with increased cccDNA (median [IQR]:2.6[2.2–3.2] and 2.0[1.0–2.5] vs 1.8[0.9–2.2]logcps/1000cells for wt, p = 0.001 and 0.01) and serum HBV-DNA (median [IQR]:4.9[3.8–5.4] and 5.0[4.7–5.4] vs 3.4[2.2–4.5] IU/ml for wt, p = 0.003 and 0.001). Multivariable analysis confirms that the presence of ≥1 of these mutations independently correlates with higher cccDNA and serum HBV-DNA after correcting for patients' demographics, HBV genotypes, virological parameters (OR[95%CI]:2.9[1–8.2] p = 0.05 and 3.3[1.1–9.7] p = 0.03). 1766T and 1764A + 1762T also determine a higher burden of pgRNA (median [IQR]:20[13–32] and 460[5–1077] vs 2[1–10]cps/1000cells for wt, p = 0.02 and 0.006) and HBcrAg (median [IQR]:4.3[3–5.1] and 4.0[3–4.9] vs 2.6[2–3.3]logU/ml for wt, p = 0.03 and 0.002), supporting their contribution to an enlarged and more productive HBV reservoir. Moreover, 1762T + 1764A increases binding affinity for HNF-1alfa TF (DS:1.8 vs 4.6 for wt) and introduces TF binding site HNF-1beta (absent in wt). Finally, all patients with 1766T present a Ishak score ≥2 (p = 0.001), suggesting its role in liver damage.

Conclusion: 1766T and 1764A + 1762T tightly correlate with an enriched intrahepatic HBV reservoir endowed by enhanced productivity. These mutations should be considered in therapeutic strategies aimed at silencing cccDNA and could act as markers to identify patients at higher risk of disease progression.

FRI-278

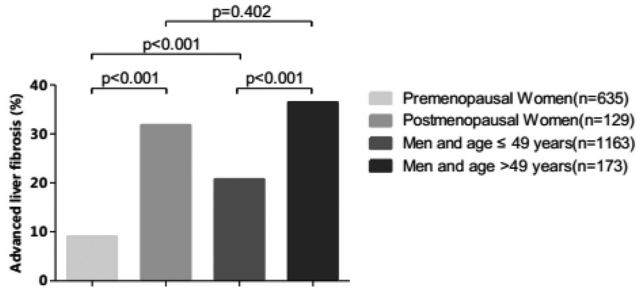
Impact of gender, menopause status and age at menarche on severity of liver fibrosis among patients with chronic hepatitis B

M. Xiong[1], Y. Shuling, F. Zeng[2], J. Li[2], J. Liu[2], Q. Wu[2], J. Chen[2], J. Hou[2]. *[1]Guangzhou; [2]Guangzhou, China*
Email: chjj@smu.edu.cn

Background and Aims: The role of menopause status and age at menarche in the development of chronic hepatitis B(CHB) remain poorly understood. We performed a cross-sectional study to assess the role of menopause status and age at menarche in relationship to advanced liver fibrosis in CHB cases prior to antiviral therapy.

Method: Seven hundred and sixty-four consecutive female and one thousand three hundred and thirty-six age-matched male patients during the same period of time were prospectively evaluated, which all had positive serum HBsAg over 6 months and without antiviral therapy. Liver fibrosis was assessed by Liver stiffness measurement (LSM) using transient elastography (Fibroscan®502). Menopause status and age at menarche were collected and documented from all female patients using a standardized questionnaire.

Results: 129 (16.9%) patients were postmenopausal, 98 (12.8%) had advanced fibrosis in females. The median age of overall, menopause and menarche was 35, 49 and 14 years among women, respectively. Prevalence of advanced liver fibrosis increased from premenopausal to postmenopausal women (9.0 vs. 31.8%, p < 0.001, figure 1). Moreover, the menarche age was positively associated with liver fibrosis, the frequency of advanced fibrosis in groups of menarche age < 13, 13 or 14, and >14 years were 5.9%, 10.7% and 18.8% (p < 0.001, figure 2), respectively. Menopause status (postmenopausal vs. premenopausal, OR = 2.12–4.02, p < 0.05) and age at menarche (>14 vs. <13 years, OR = 2.38–3.83, p < 0.05) were consistently independent risk factors of advanced liver fibrosis across all four multivariate logistic regression models in female patients (table 1). Compared to premenopausal women, men and age < 50 (OR = 1.84–2.86, p < 0.05) had higher odds of advanced liver fibrosis. However, compared to postmenopausal women, men and age > 49 (p = 0.402) had a similar prevalence of advanced liver fibrosis (figure 1).



1B. Relationship of advanced liver Fibrosis to menarche age.

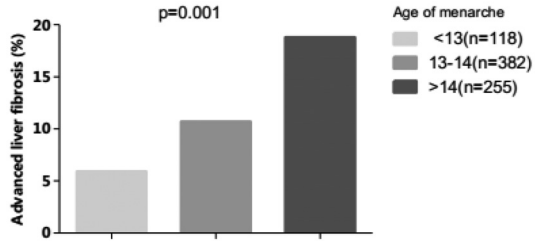


Table 1: Associations between the advanced liver fibrosis and menopause or age at menarche

	N	OR	95% CI	P value
Menopause				
Model 1	764	2.22	1.10–4.49	0.027
Model 2	763	2.12	1.04–4.33	0.040
Model 3	694	2.91	1.31–6.46	0.009

>14		3.83	1.25–11.78	0.019

model 1 was adjusted for age; model 2: model 1 plus adjustment for BMI, Diabetes and Hypertension. model 3:model 2 plus adjustment for ALT. model 4: model 3 plus adjustment for HBeAg status and HBV DNA level.

Conclusion: Menopause status and age at menarche were associated with advanced liver fibrosis in antiviral treatment naive female patients with CHB. The protective effect of female gender against severity of liver fibrosis was lost for postmenopausal women.

FRI-279

Early on-treatment alanine aminotransferase normalization reduces risk of hepatic events in patients with chronic hepatitis B

L.-H. Grace Wong[1,2,3], Y.-K. Tse[2], H. Chan[4], T.C. Yip[2], W. Sun, V. Wong[2,3]. *[1]The Chinese University of Hong Kong, Institute of Digestive Disease, Hong Kong; [2]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong; [3]The Chinese University of Hong Kong, State Key Laboratory of Digestive Disease, Hong Kong; [4]The Chinese University of Hong Kong, Hong Kong, Hong Kong, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and Aims: Alanine aminotransferase (ALT) normalization is regarded as biochemical response to antiviral treatment. Recent studies showed that patients receiving tenofovir alafenamide (TAF) were more likely to achieve ALT normalization than those receiving tenofovir disoproxil fumarate (TDF), despite a similar rate of viral suppression. We aimed to evaluate the impact of ALT normalization during antiviral treatment with entecavir or TDF in patients with chronic hepatitis B (CHB).

Method: A territory-wide cohort of CHB patients who received entecavir and/or TDF from January 1, 2005 to December 31, 2016 in Hong Kong was identified. Serial on-treatment ALT levels were collected and analyzed. ALT normalization (ALT-N) was defined as ALT <30 U/l in males and <19 U/l in females. The primary and secondary outcome were composite hepatic events (including hepatocellular carcinoma [HCC]) based on ICD-9-CM diagnosis codes. Patients with pre-existing hepatics or during the first year of antiviral treatment, follow-up and survival <1 year were excluded.

Results: 21,182 CHB patients (10,437 with and 10,745 without ALT-N at 12 months after antiviral treatment) were identified and followed for 4.0 ± 1.7 years. Patients with and without ALT-N differed in gender distribution (76.9% *vs.* 58.4% male), baseline ALT (58 *vs* 61 U/l), rate of positive hepatitis B e antigen (31.5% *vs.* 37.1%), baseline serum HBV DNA (4.9 *vs.* 5.1 $\log_{10}$ IU/ml), less cirrhosis (8.8% *vs.* 10.5%) and prevalence of diabetes mellitus (8.1% *vs.* 9.1%). 627 (3.0%) patients developed hepatic events (509 HCC and 172 other cirrhotic complications). Compared to no ALT-N, ALT-N at 3, 6, 9 and 12 months reduced the risk of hepatic events, after adjustment for baseline ALT and other important co-variates, with adjusted hazard ratios (95%CI) 0.61 (0.48–0.76), 0.54 (0.44–0.66), 0.53 (0.44–0.64) and 0.50 (0.42–0.61) respectively (all $p < 0.001$). The cumulative incidence (95%CI) of hepatic events at 6 years was 3.51% (3.06%–4.02%) in ALT-N and 5.70% (5.15%-6.32%) in no ALT-N group ($p < 0.001$).

Cumulative incidence of composite endpoint at 6 years (%) (95% CI)	3 months	6 months	9 months	12 months
Without ALT normalization	4.76 (4.34–5.21)	5.24 (4.76–5.77)	5.57 (5.04–6.16)	5.70 (5.15–6.32)
With ALT normalization	4.27 (3.54–5.15)	3.60 (3.07–4.21)	3.44 (2.98–3.97)	3.51 (3.06–4.02)

Conclusion: Early on-treatment ALT normalization can be translated into improved clinical outcomes in CHB patients receiving NA treatment.

FRI-280

Occult Hepatitis B infection is frequent and a risk factor of advanced liver disease in The Gambia, West Africa

G. Ndow[1,2], D. Cohen[3], Y. Shimakawa[4], M.L Gore[5], R. Njie[2,6], P. Suso[2], B. Sanneh[7], I. Baldeh[7], M. Mendy[6], U. D'alessandro[8], M. Thursz[1], I. Chemin[9], M. Lemoine[1]. *[1]Imperial College London, Division of Integrative Systems Medicine & Digestive Diseases, Department of Surgery & Cancer, London; [2]MRC Unit The Gambia, Hepatitis Department, Disease Control & Elimination, Fajara, Gambia; [3]INSERM, Cancer Research Center of Lyon (CRCL), Lyon, France; [4]Institut Pasteur, Paris, Unité d'épidémiologie des maladies émergentes, Paris, France; [5]Imperial College London, Faculty of Medicine, London, United Kingdom; [6]International Agency for Research on Cancer (IARC), Lyon, France; [7]National Public Health Laboratories, Ministry of Health, The Gambia, Kotu, Gambia; [8]MRC Unit The Gambia, Fajara, Gambia; [9]INSERM, Lyon, France*
Email: g.ndow@imperial.ac.uk

Background and Aims: Occult hepatitis B infection (OBI) has been poorly documented in Africa. Yet, its prevalence and clinical implication may impact the objectives and strategies currently recommended by the World Health Organization to achieve hepatitis B virus (HBV) control and elimination. We aimed to estimate the prevalence and its clinical outcomes on liver disease in The Gambia, West Africa.

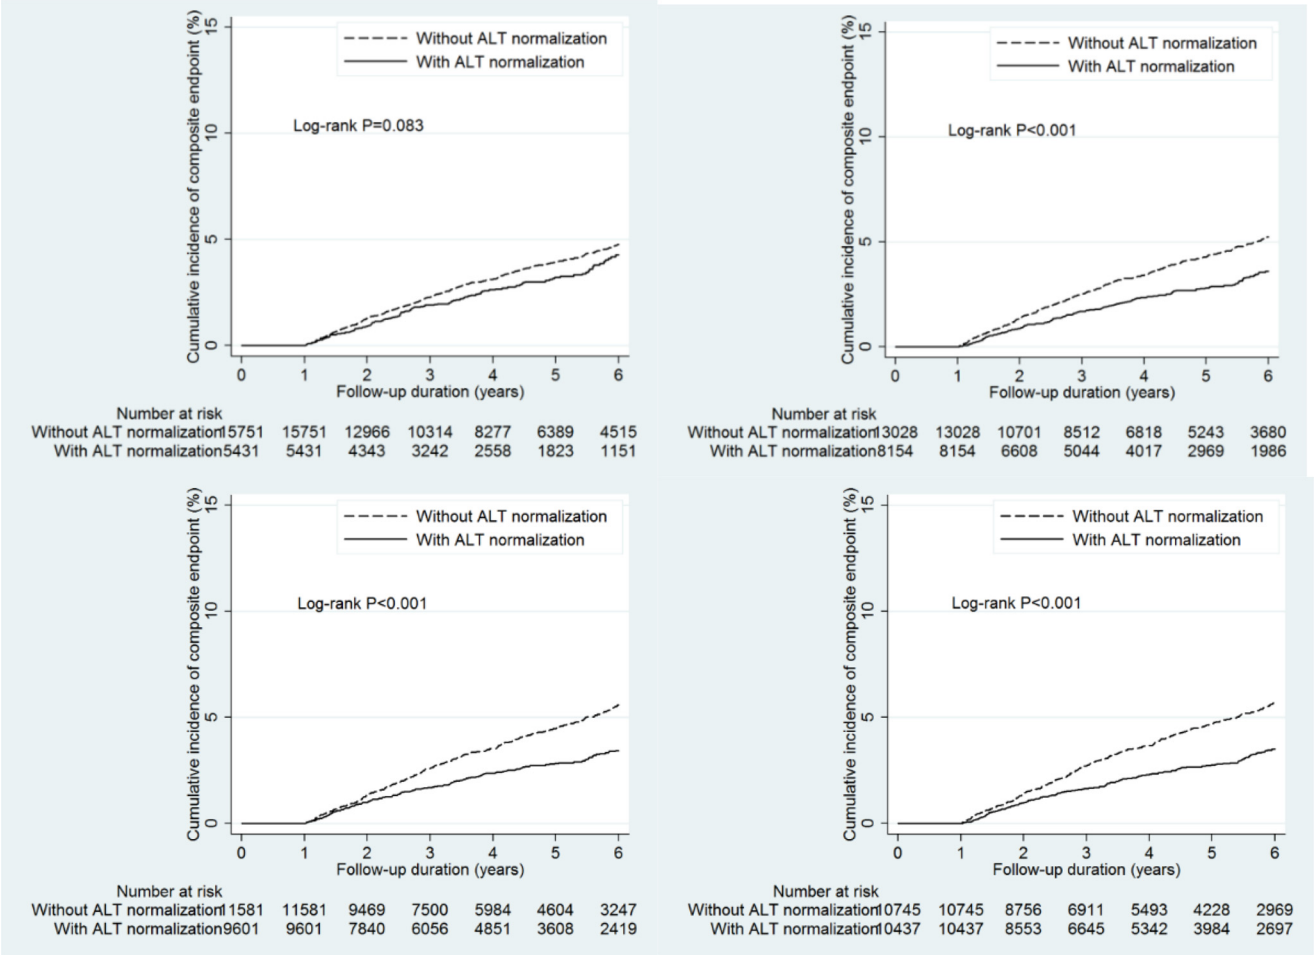

Figure 1: (abstract: FRI-279): Kaplan-Meier analysis of the cumulative incidence of hepatic events according to normalization of alanine aminotransferase (ALT) [AASLD criteria] after antiviral treatment: (A) 3 months, (B) 6 months, (C) 9 months and (D) 12 months

Method: A case-control analysis to assess the association between OBI and advanced liver disease [cirrhosis and/or hepatocellular carcinoma (HCC)] was nested in the PROLIFICA programme. This consisted of a large community and hospital-based screening for hepatitis B surface antigen (HBsAg) using a rapid point-of-care test. Those negative for HBsAg were invited for further virological and liver assessment. Negative HBsAg was serologically confirmed using the chemiluminescent microparticle immunoassay (Architect, Abbott) and HBV DNA was measured using nested PCR and DNA quantified using an in-house PCR with limit of detection of 10 IU/l (Ghosh et al., 2016). OBI was defined as negative HBsAg serology with a detectable HBV DNA in the serum.

Results: Of 4,838 people screened negative for HBsAg in the community between December 2011 and January 2014, we randomly selected 330 subjects as control group. The hospital screening enrolled 107 consecutive HBsAg negative patients with suspected advanced liver disease. The prevalence of OBI was significantly higher ($p < 0.001$) among patients with advanced liver disease (18.3%, 95%CI 9.7–26.8) than in community-screened controls (9.4%, 95%CI 6.2–12.6). Patients with cirrhosis (n = 29) had the highest prevalence of OBI (37.9%, 95%CI 19.1–56.7). OBI patients were mainly males (68%) with median age 46yrs (37–62) and median HBV DNA 138IU/ml. PreS2 mutations were observed in 14% (5/57) of patients with OBI. Hepatitis C virus infection, present in 18.3% of patients with advanced liver disease and 2.7% of community-screened controls, was associated with both OBI and advanced liver disease [OR: 10.8 (4.0–29.2), $p < 0.001$]. After adjusting for confounding factors (age, sex, HCV), OBI was significantly associated with advanced liver disease [OR: 2.8 (1.3–6.0), $p = 0.006$].

Conclusion: OBI is common in West Africa where HBV is still endemic. It is an independent risk factor for advanced liver disease in Gambian adults, particularly for liver cirrhosis. In light of HBV elimination, screening strategies based on HBsAg testing alone may not be adequate for sub-Saharan Africa.

FRI-282

Long-term outcomes and significance of HBeAg Seroclearance in Chronic Hepatitis B: Novel Predictive Scores for HCC and HBsAg seroclearance

Y.Y.J. Fung, K.-S. Cheung, D. Wong, L.-Y. Mak, W.P. To, W.-K. Seto, C.L. Lai, M.-F. Yuen. *The University of Hong Kong, Medicine, Hong Kong, Hong Kong*
Email: jfung@gastro.hk

Background and Aims: We aimed to determine the clinical outcomes, the factors and predictive scores for hepatocellular carcinoma (HCC) and hepatitis B surface antigen (HBsAg) seroclearance of a large cohort of patients undergoing HBeAg seroclearance (ESC).

Method: Patients with documented ESC were followed up 3–6 monthly. Baseline characteristics and longitudinal laboratory results were recorded. Predictive scores for HCC (HCC-ESC) and HBsAg seroclearance (HBsAg-ESC) were derived from multivariate Cox regression models.

Results: A total of 723 patients underwent ESC with a median ESC age and follow-up of 36.0 and 18.3 years respectively. Only 3.5% and 3.0% had persistently normal ALT and HBV DNA <2logsIU/ml respectively after ESC. For patients with 100%, 100–90%, 90–50%, 50–10%, 10–0%, and 0% normal ALT after HBeAg seroclearance, the rate of HCC was 4.3%, 2.2%, 3.6%, 3.9%, 17.3%, and 37.2% at 20 years after ESC respectively ($p < 0.001$). At 20 years after ESC, the cumulative incidence of HCC and HBsAg seroclearance was 7.9% and 13.5% respectively, with an overall survival of 91.5%. ESC age, male sex, cirrhosis, hypoalbuminemia, viral load, and ALT were significant factors for HCC, whereas ESC age, male sex, viral load, and antiviral therapy were significant factors for HBsAg seroclearance. The HCC-ESC score to predict the HCC risk for up to 20 years after ESC was calculated using age (years) + 20*sex (male = 1; female = 0) + 29*cirrhosis (presence = 1; absence = 0) + 5*DNA (logIU/ml) + 31*ALT group (flares or persistently abnormal ALT = 1; otherwise = 0) + 23*hypoalbuminemia (<39 g/l, presence = 1; absence = 0). With an optimal cut-off of 129, 121, and 114, the AUROC for predicting development of HCC at 5, 10 and 20 years after HBeAg seroclearance was 0.95, 0.91, and 0.92 respectively. The HBsAg-ESC score to predict HBsAg seroclearance up to 20 years was calculated using age (years) + 15*sex (male = 1; female = 0)–6*DNA (logIU/ml)–40*history of treatment (presence = 1; absence = 0). Using optimal cut-offs of 19, 17, and 12 to predict HBsAg seroclearance at 5, 10, and 20 years after HBeAg seroclearance were associated with an AUROC of 0.88, 0.84, and 0.74 respectively.

Conclusion: Male gender, older age at ESC, ALT, and higher level of HBV DNA were associated with higher rates of HCC after ESC. HCC-ESC and HBsAg-ESC predictive scores can determine the likelihood of developing HCC and achieving HBsAg seroclearance.

FRI-283

Serum WFA+–M2BP level as a diagnostic marker of HBV-related HCC: A case-control study

N. Chuaypen[1], Y. Tanaka[2], P. Tangkijvanich[1]. [1]*Faculty of Medicine, Chulalongkorn University, Department of Biochemistry, Bangkok, Thailand;* [2]*Nagoya City University Graduate School of Medical Sciences, Department of Virology and Liver Unit, Nagoya, Japan*
Email: pisittkvn@yahoo.com

Background and Aims: Serum glycosylated Wisteria floribunda agglutinin-positive Mac-2 binding protein (WFA +– M2BP) is a novel marker for staging liver fibrosis and predicting hepatocellular carcinoma (HCC) occurrence. This study aimed at evaluating the performance of WFA +– M2BP in the diagnosis of HCC in patients with chronic hepatitis B virus (HBV) infection.

Method: WFA+–M2BP levels were measured in stored samples collected at initial diagnosis of 150 patients with HBV-related HCC and 150 age- and gender-matched patients with non-malignant chronic HBV infection.

Results: Patients with HCC had higher levels of WFA+–M2BP than those without HCC [(5.3 ± 3.9 vs 1.8 ± 0.9 cutoff index (COI), $p < 0.001$]. In the HCC group, WFA +– M2BP levels correlated with Child-Pugh classification but did not correlate with HBV markers, alpha-fetoprotein (AFP) and BCLC stage. The areas under the curve (AUROC) for differentiating HCC from non-HCC were 0.92 (95%CI; 0.89–0.95, $p < 0.001$) for WFA +– M2BP, 0.90 (95%CI; 0.87–0.94, $p < 0.001$) for AFP and 0.97 (95%CI; 0.95–0.98, $p < 0.001$) for the combined tests. At the optimal cut-off (2.4 COI), WFA +– M2BP had sensitivity, specificity and accuracy of 79.3%, 91.3% and 85.3%, respectively. WFA+–M2BP was superior to AFP in differentiating early-stage HCC (BCLC stages 0 and A) from cirrhosis with AUROC of 0.80 (95%CI; 0.68–0.91, $p < 0.001$) and 0.73 (95%CI; 0.60–0.86, $p = 0.002$), respectively. By

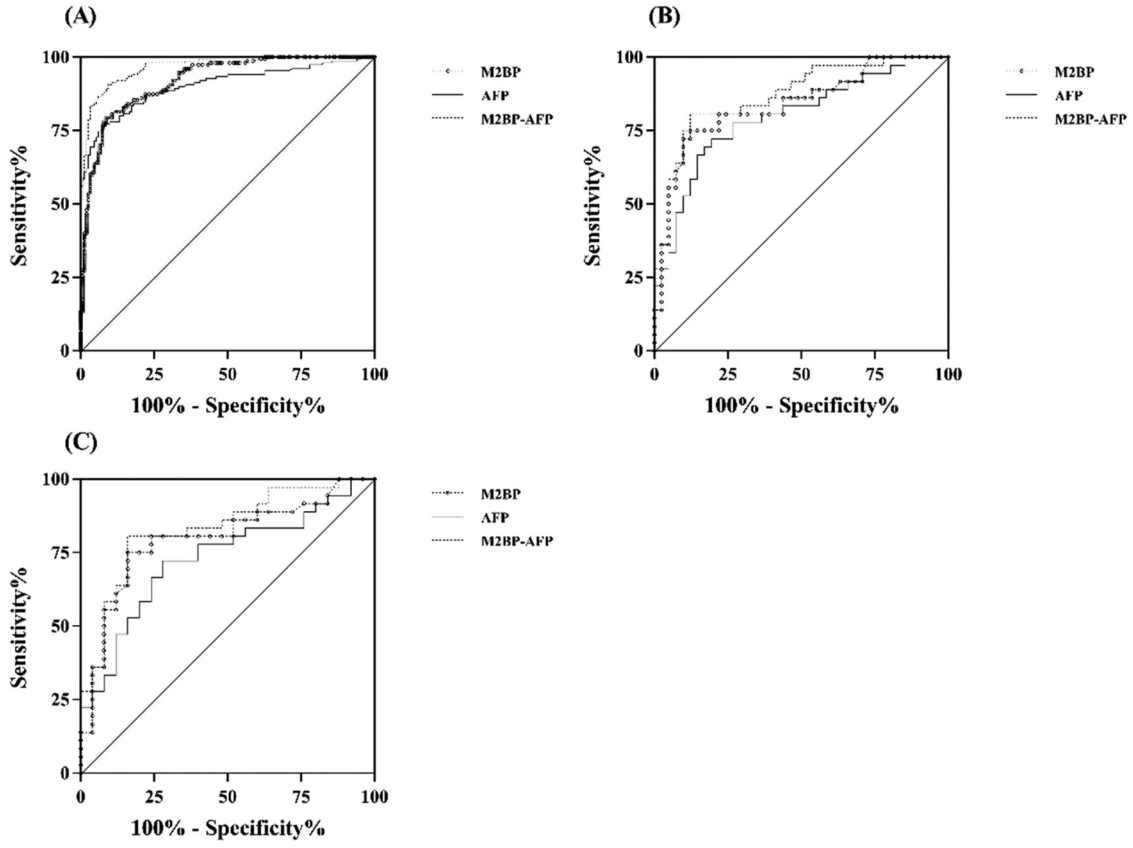

Figure 1: (abstract: FRI-283): ROC curves of serum WFA +– M2BP, AFP and combined markers in differentiating HCC and non-HCC (A) All patients (B) Early HCC vs non-HCC (only F3-F4) (C) Early HCC vs non-HCC (only F4)

univariate analysis, elevated WFA+–M2BP (≥4.0 COI) was correlated with poor overall survival in patients with HCC.
Conclusion: WFA +– M2BP exhibited a better diagnostic performance than AFP in detecting early-stage HCC. Thus, WFA +– M2BP level could represent a promising marker for early diagnosis of HCC in patients with chronic HBV infection.

FRI-284
The incidence of hepatocellular carcinoma in hepatitis B virus infected persons of different origins, living in Sweden
A.-S. Duberg[1], C. Lybeck[1], A. Fält[2], H. Wedemeyer[3], S. Montgomery[2,4,5], S. Aleman[6]. *[1]Örebro University, Infectious Diseases, Faculty of Medicine and Health, Örebro, Sweden; [2]Örebro University, Department of Clinical Epidemiology and Biostatistics, Örebro, [3]Hannover Medical School, Dept. of Gastroenterology and Hepatology, Hannover, Germany; [4]Karolinska Institutet, Clinical Epidemiology Unit, Stockholm, Sweden; [5]University College London, Department of Epidemiology and Public Health, London, United Kingdom; [6]Karolinska Institutet, Department of Infectious Diseases, Stockholm, Sweden*
Email: ann-sofi.duberg@orebroll.se

Background and Aims: Chronic hepatitis B (CHB) is associated with an increased risk of hepatocellular carcinoma (HCC) in both cirrhotic and non-cirrhotic persons. CHB patients with high risk for HCC are therefore recommended to undergo surveillance for HCC, with an estimated cut-off for surveillance in non-cirrhotic patients at incidence rate (IR) of 0.2% per year. People originating from Asia and men from Africa are estimated to have particularly high risks, but the IR for HCC when living in the Western world has not been fully estimated. Therefore, our aim was to study the incidence of HCC by age and origin in persons with CHB who are living in Sweden.
Method: In this national population-based study all persons diagnosed with CHB in Sweden during 1990–2015, their country of birth, co-infections, antiviral therapy, liver cancer or death/emigration were identified retrospectively, using the national HBV-surveillance register and other national registers. Those co-infected with hepatitis C were excluded. Observation time started at date of reported CHB diagnosis. The IR was calculated for different age groups and by region of birth.
Results: In total 16,410 persons (47% women) with CHB were studied. The number of persons and observation time (person-years) by origin were: Western Europe 2,316 (25,415); Eastern Europe 2,349 (26,237); Middle East/North Africa 4,402 (47,320); Sub-Saharan Africa 3,677 (30,565), Asia 3,537 (35,358) and other 129 (1,277). Those from Sub-Saharan Africa were youngest and had the shortest mean time in Sweden, 11.6 years. There were in total 232 diagnosed HCCs (82% in men); 23, 54 and 58 in people from Sub-Saharan Africa, Asia and Middle East/North Africa, respectively. The corresponding mean ages at HCC diagnoses were 45, 51 and 59 years, respectively. The IR exceeded 0.2% for men from Asia from age-group ≥40–49 years (IR 0.63, 95%CI 0.39–1.00), and for men of all other origins from age-group ≥50–59 years. Among African men aged <40 years there were 7 HCC, with incidence rate 0.05 and 0.11 in age groups 20–29 and 30–39 years, respectively. In women, HCC was rare but exceeded 0.2% among those aged ≥60 years with origins from East Europe, Asia and Middle East/North Africa.
Conclusion: In this study only men of Asian origin exceeded the cut-off for HCC surveillance by ages 40–49 years. African men had a few HCCs at younger ages, but did not exceed the cut-off before age 50–59 years. This study confirms the high risk for HCC in especially Asian men living in the Western world, but questions the benefit of surveillance at younger ages for men with African origin who live in a Northern European country.

FRI-285
The efficacy of a computer alert programme for increasing hepatitis B screening rates before starting immunosuppressive therapy
A. Koksal[1], B. Toka[2], A.T. Eminler[2], İlhan Hacibekiroglu[3], C. Sunu[4], M.I. Uslan[2], O. Karabay[5], E. Parlak[2]. *[1]Sakarya University, Department of Gastroenterology, Sakarya, Turkey; [2]Sakarya University Faculty of Medicine, Department of Gastroenterology, Sakarya, Turkey; [3]Sakarya University Faculty of Medicine, Department of Medical Oncology, Sakarya, Turkey; [4]Sakarya University Faculty of Medicine, Department of Hematology, Sakarya, Turkey; [5]Sakarya University Faculty of Medicine, Department of Infectious Diseases, Sakarya, Turkey*
Email: koksalas@yahoo.com

Background and Aims: Hepatitis B Virus (HBV) screening before starting immunosuppressive treatment is of vital importance in order to prevent HBV reactivation and its associated clinical consequences. Despite all recommendations by international organizations, screening rates are far below desired. The aim of this study was to assess the efficacy of a computer alert programme "HBVision" for increasing HBV screening rates.
Method: "HBVision" identifies patients at risk of HBV reactivation by specific ICD-10 codes and immunosuppressive medication reports and sends sequential alert messages to screen for HBsag, anti-HBc IgG and consult a specialist if one of them is positive. The demographic variables, treatment protocols, HBV screening and consultation rates of oncology and hematology patients who received immunosuppressive treatments one year before (control group) and after "HBVision" (study group) were retrospectively compared. Patients <18 years of age and with a prior diagnosis of chronic HBV infection or hepatitis were excluded.
Results: HBsag and anti-HBc IgG screening rates (68.6% and 13.1%, respectively) were significantly higher in the study group (n = 602) compared to control group (n = 815) (55% and 4.3%, respectively) ($p < 0.001$, for both). Subgroup analysis revealed significant improvements in the screening rates of HBsag (65.8%) and anti-HBc IgG (5.1%) in oncology patients ($p < 0.001$), anti-HBc IgG (89.1%) in hematology patients ($p < 0.001$), HBsag (67.2%) and anti-HBc IgG (9.6%) in patients receiving moderately immunosuppressive agents ($p < 0.001$, for both) and anti-HBc IgG (82.8%) in those receiving highly immunosuppressive agents ($p < 0.001$) (Table).The consultation rates in patients with a positive HBV serology increased from 52% to 75% after the alert system ($p = 0.6$).
Conclusion: The computer alert programme significantly increased HBV screening rates before starting immunosuppressive treatments, however the results were still below ideal. Additional efforts, such as modifying the computer programme according to feedback, and seeking other methods to increase awareness and remove concerns of clinicans are probably needed.

FRI-286
First clinical evaluation in chronic hepatitis B patients of the synthetic farnesoid X receptor agonist EYP001
R. Erken[1], F. Stelma[1], E. Roy[2], S. Diane[2], P. Andre[3], J. Vonderscher[2], M. Eric[2], S. Tim[4], P. Philippe[5], L. Christian[5], P. Scalfaro[6], H. Reesink[1], C.M. Sousa[7], E. Jacob[7]. *[1]Academic Medical Center, Hepatology; [2]ENYOPHARMA SA, Lyon; [3]CIRI, Inserm U1111, Lyon, France; [4]UMCG, Department of Gastroenterology & Hepatology, Groningen, Netherlands; [5]CALVAGONE, Pharmacometrics, Liergues, France; [6]ENYOPHARMA SA, Lyon, [7]Nova discovery*
Email: ps@enyopharma.com

Background and Aims: The nuclear farnesoid X receptor (FXR) is an investigational target for non-alcoholic steatohepatitis therapy, while its clinical relevance for inhibition of hepatitis B virus (HBV) replication remains to be established. In a recent study on hepatocytes from fransgenic mice receptive to primary human liver cells infected with HBV for 35 days, the at sacrifice isolated cells were cultured. Treatment with Entecavir of these cells produced a dose

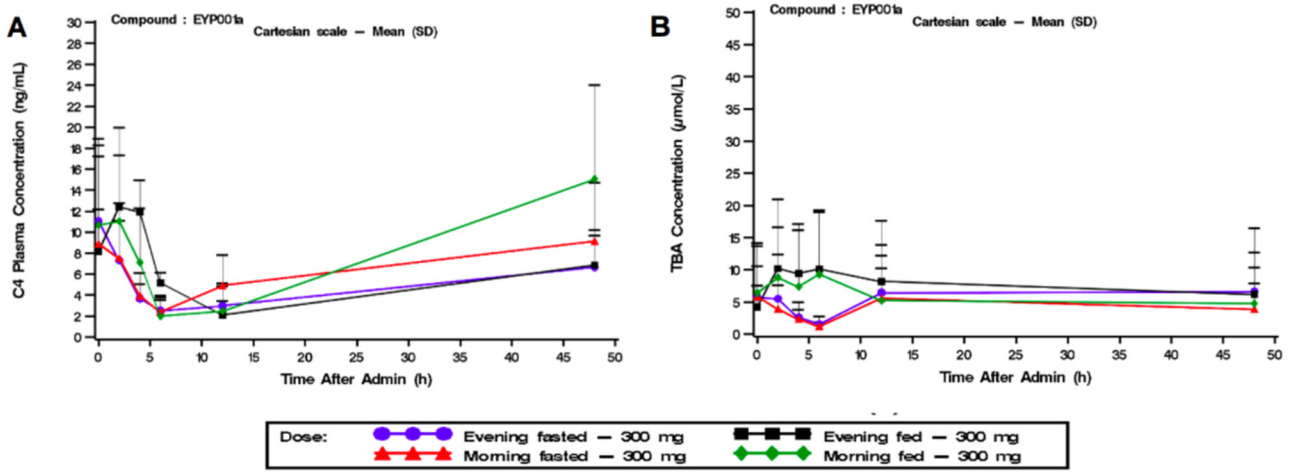

Figure 1: (abstract: FRI-286)

dependant inhibition of HBV DNA secretion (Emax: 80%) with no effect on HBeAg or HBsAg, whereas FXR agonist inhibited in a dose dependant manner both HBV DNA (Emax: 60%) and viral protein secretion (HBeAg, HBsAg: Emax 80% and 60% respectively). We aimed to explore in chronic hepatitis B (CHB) patients the safety and bile acid related pharmacology of FXR agonist EYP001.

Method: CHB patients were randomized to 4 crossover single dose oral treatment periods receiving 300 mg EYP001 administered fasted or fed, either in the morning or evening. Relative EYP001 bioavailability, safety, tolerability, FXR related pharmacodynamic and HBV markers were assessed.

Results: 11 CHB patients (3 females, 8 males, mean age 39.8 years) with a low HBV DNA viral load (mean+/-SD 1266+/-1862IU/ml) were included. All completed the 4 periods and 6 patients had mild, short lasting gastrointestinal adverse effects possibly related to EYP001, one reported mild pruritus resolving spontaneously after few hours. No clinically significant changes in liver enzymes nor lipids occurred. EYP001 reached similar Cmax with all 4 dosing conditions, whereas Tmax tended to increase with food. Exposure was not impacted by food with similar area under the curve (0-last (ng*h/mL), mean (90% CI), $p > 0.05$): morning fasted (8073 (5044–14413)) versus fed 9456 (7203–15272) and evening fasted 8157 (4386–12976) versus fed 8459 (5916–12218). Also in all periods despite similar rapid EYP001 elimination kinetics, FGF19 and C4 showed a prolonged FXR target engagement over at least 12 hours (Figure A). Total bile acids (TBA) decreased in fasted condition and increased with food (Figure B). HBV markers did not change significantly.

Conclusion: Our preliminary results show that oral doses of EYP001 are well tolerated by CHB patients and induce prolonged FXR engagement. Further clinical testing to assess the HBV effect with repeated dosing is in progress. An in silico and an in vivo model further explore the relationship between FXR and HBV (Monteiro Sousa C. and Fusil F. submitted).

FRI-287
Quantification of hepatitis B virus covalently closed circular DNA by a peptide nucleic acid-clamping PCR method

C.-T. Yeh, C.-W. Hsu, M.-W. Lai. *Liver Research Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan*
Email: chautingy@gmail.com

Background and Aims: Recently, new antivirals against hepatitis B virus (HBV) have been vigorously developed. As current antiviral treatments can already persistently suppress HBV replication to an undetectable level, the next reasonable goal of treatment should be to eliminate cccDNA. Assessment of cccDNA requires liver biopsy, where qPCR is unavoidable. However, the traditional cccDNA specific qPCR method has a very limited range of concentrations for accurate quantification. Here, we developed a peptide nucleic acid (PNA)-clamping PCR method to provide a wider range of specific cccDNA quantification.

Method: Two PNA fragments complementary to the minus-strand of HBV DNA were designed. Two sets of PCR primers were synthesized. Set-one: the traditional cccDNA specific primers, flanking the rcDNA gap. Set-two: the UPNA and DPNA primers were up- and down-stream of the two PNA fragments. Serum-derived rcDNA and plasmid-derived cccDNA mimics were serially diluted to examine the specific detection/quantification ranges. HBV-DNA was clamped with PNA fragments before subjected to qPCR using the two sets of primers. Paraneoplastic liver tissues (n = 222) from HBV-related HCCs were included for actual cccDNA quantification.

Results: Following PNA clamping, the Set-one primers can detect and quantify cccDNA specifically within the range of 10(1) to 10(4) copies in the PCR reaction, whereas the Set-two primers can quantify cccDNA specifically within the range of 10(3) to 10(5) copies. Together, cccDNA can be quantified in the range of 10(1) to 10(5) copies. If PNA clamping was not performed, Set-one primers can only detect cccDNA specifically within the range of 10(1) to 10(3) copies. With the PNA clamping method, of 222 paraneoplastic liver tissues subjected for cccDNA quantification, 6 required further dilution to make the sample fall into the effective quantification range. The amount of cccDNA was not associated with postoperative recurrence, metastasis, or survival. Multivariate linear regression analysis showed that cccDNA levels were associated with liver cirrhosis and prothrombin time.

Conclusion: A PNA-clamping PCR method was devised for cccDNA quantification. A wider range of specific cccDNA detection, 10(1) to 10(5) copies, could be achieved. 6/222 liver tissue sample required pre-dilution to avoid out-of-range measurement.

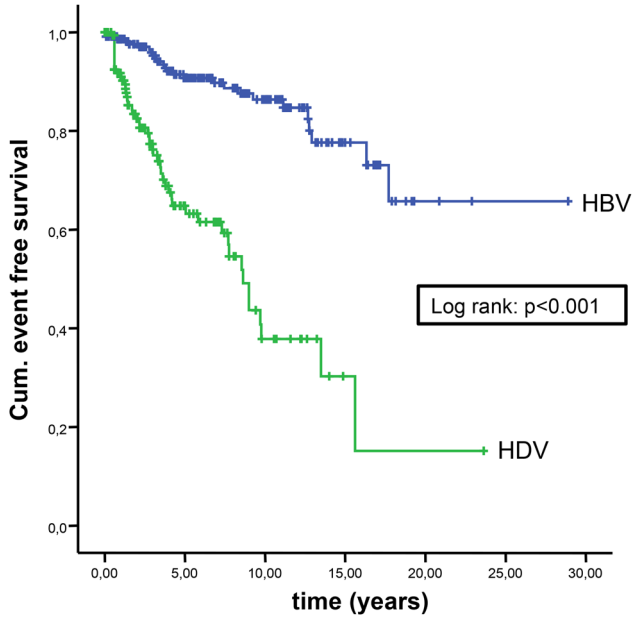
Email: wranke.anika@mh-hannover.de

Background and Aims: Hepatitis D-virus (HDV) infection causes the most severe form of chronic viral hepatitis. Studies suggested that the underlying hepatitis B-virus (HBV) infection may contribute to disease progression. However, the importance of HBV and HDV replication for the development of hepatic complications in patients with hepatitis delta is a matter of debate. Moreover, the introduction of potent nucleos(t)ide analogous (NA) may have altered the course of liver disease. The aim of this study was to compare the clinical long-term outcome of hepatitis delta versus HBV monoinfection in a single center cohort of patients with access to HBV NA according to HBV guidelines.
Method: We retrospectively studied 177 patients with chronic hepatitis D who were followed for at least 6 months. In addition, we selected 225 patients with HBV monoinfection from a large cohort of hepatitis B patients who were matched for gender, age, region of origin, HBeAg status and MELD score. Endpoints were defined as hepatic decompensation (ascites, encephalopathy, variceal bleeding), liver transplantation, HCC, or liver-related death. NA therapy was administered to 64 HDV and 112 HBV patients. 67 HDV and 23 HBV patients had received IFNa-based therapies.
Results: Patients infected with HDV or HBV alone had similar baseline characteristics (male:68% vs. 69%; mean age 39 vs. 37 years; country of birth: eastern Mediterranean 34% vs. 36%; median HBV DNA 4.4 vs. 2.4 logIU/ml and were followed for a median of 6.2 (0.6–23.6) and 7.6 years (0.6–22.9) years, respectively. The incidence of cirrhosis at the first visit was higher in patients with HDV infection (44.6%) than in HBV monoinfection (13.8%) ($p < 0.001$). Clinical complications developed earlier (first episode after a median of 3.6. vs. 6.0 years; $p = 0.04$) and more frequently (29% vs. 12%, $p < 0.001$) in HDV patients. In addition, HDV was significantly associated with the development of endpoints in Kaplan Meier analysis ($p < 0.001$). Even after excluding cirrhotic patients, HDV infected patients showed a worse outcome (Kaplan Meier $p < 0.001$). In a multivariate Cox-regression HDV infection was an independent factor associated with the development of endpoints ($p = 0.04$; HR:2.0;95%CI:1.0–4.1). In addition, albumin levels, platelet counts, age, gamma GT, alkaline phosphatase and INR values were associated with the clinical long-term outcome while HBV DNA levels and NA therapy could not be linked to progression to clinical complications.



Conclusion: HDV infected patients had a higher risk to develop liver-related clinical endpoints compared to HBV monoinfected patients even after the introduction of potent NA against HBV.

FRI-289
The WHO guidelines for chronic hepatitis B fails to detect half of the patients in need of treatment
H. Aberra[1], H. Desalegn[1], N. Berhe[2], G. Medhin[2], S.G. Gundersen[3], A. Johannessen[4]. [1]*St Paul Hospital Millennium Medical College, Addis Ababa, Ethiopia;* [2]*Addis Ababa University, Addis Ababa, Ethiopia;* [3]*University of Agder, Kristiansand, Norway;* [4]*Oslo University Hospital Ullevål, Oslo, Norway*
Email: johannessen.asgeir@gmail.com

Background and Aims: Patients with chronic hepatitis B (CHB) who have liver fibrosis and/or ongoing necroinflammation of the liver are at increased risk of disease progression. Antiviral treatment can stop the progression to cirrhosis and reduce the risk of hepatocellular carcinoma. In 2015, the World Health Organization (WHO) issued guidelines for the management of CHB in low- and middle-income countries Antiviral treatment was recommended based on 3 criteria: (i) clinically diagnosed cirrhosis, (ii) aspartate aminotransferase to platelet ratio index (APRI) >2.0, or (iii) age ≥30 years with abnormal ALT and viral load >20,000 IU/ml. The aim of this study was to evaluate the performance of the WHO guidelines in a large cohort of CHB patients in Ethiopia.
Method: Out of 1303 HIV-negative CHB patients enrolled at St. Paul's Hospital Millennium Medical College in Addis Ababa, 1213 treatment-naïve patients aged 18 years and older were included in this study. All patients underwent a standardized evaluation at baseline, including blood tests and transient elastography (Fibroscan 402, Echosense, France). A Fibroscan threshold of 7.9 kPa was used to define significant fibrosis and 9.9 kPa to define cirrhosis. Treatment eligibility was assessed using the most recent guidelines from the European Association for the Study of the Liver (EASL) as the "gold standard".
Results: Out of 1213 patients with CHB, 317 (26.1%) were eligible for treatment according to the EASL 2017 guidelines. For comparison, only 159 (13.1%) were eligible according to the WHO 2015 guidelines. Most patients (112 of 159, 70.4%) who fulfilled the WHO criteria were patients with decompensated cirrhosis, who might have a dismal prognosis even with therapy. Only 23 of 105 patients (21.9%) with compensated cirrhosis, who are likely to benefit the most from therapy, were eligible for treatment according to the WHO criteria. APRI lacked sensitivity in this setting: only 23 of 317 (7.3%) in need of treatment had an APRI value >2.0.
Conclusion: The WHO guidelines for CHB fails to detect a considerable proportion of patients in need of treatment. A revision of the WHO treatment criteria should be based on local data.

FRI-290
A new utility of HBcrAg – a pan-genotypic predictor of mother to child HBV transmission
I. Carey[1], M. Bruce[1], M.-A. Mcleod[1], T. Bowyer[2], M. Horner[1], R. Byrne[1], B. Wang[1], G. Dusheiko[1], K. Agarwal[1]. [1]*King's College Hospital, Institute of Liver Studies, London, United Kingdom;* [2]*King's College Hospital, Denmark Hill Campus, London, United Kingdom*
Email: ivana.kraslova@kcl.ac.uk

Background: The EASL 2017 guidelines advise commencing antiviral therapy to prevent mother to child (MCTC) transmission of hepatitis B virus (HBV) in all patients with HBsAg >10,000 IU/ml. HBsAg levels vary between HBeAg positive and negative patients and between genotypes as well as stage of disease. In our centre all pregnant mothers with HBV DNA >200,000 IU/ml at 2nd trimester, irrespective

of HBsAg levels are offered antiviral therapy to prevent MTCT, together with infant vaccination and HBIg at birth. Hepatitis B core-related antigen (HBcrAg) is a new serological marker and its clinical importance is emerging. However, its utility for assessing the risk of HBV MTCT has not been evaluated.

Aims: To assess whether HBcrAg plasma concentrations can predict the risk of HBV MTCT (HBV DNA >200,000 IU/ml) more efficiently than HBsAg levels at the 2nd trimester.

Methods: Plasma samples were collected at 2nd trimester (median gestation 25 weeks) from 514 HBsAg+ pregnant women with chronic hepatitis B. All had post-delivery follow-up >1 year and their infants' HBV infection status was assessed. HBV DNA was measured by TaqMan PCR [IU/ml], HBV genotyping was tested by direct sequencing, HBsAg plasma levels were measured on Abbot Architect® [IU/ml] and HBcrAg concentrations were quantified [$\log_{10}$ U/ml] by Luminex G® (Fujirebio) assay. The results were stratified for comparison according to the risk of HBV MTCT (HBV DNA >200,000 IU/ml = high risk vs. HBV DNA <200,000 IU/ml = low risk).

Results: In single centre cross-sectional study 514 patients (median age 31 yrs) were enrolled; 62/514 (12%) patients were HBeAg positive. HBV DNA >200,000 IU/ml was found in 72/514 (14%) patients (50 of these 72 were HBeAg positive). 163/514 (32%) patients had high HBsAg (>10,000 IU/ml): 48 of these 163 patients had both high HBsAg and HBV DNA >200,000 IU/ml and were predominantly infected with genotypes B & C. In contrast 115/163 patients had HBsAg concentrations >10,000 IU/ml, but a HBV DNA < 200,000 IU/ml (mainly genotypes A, D & E). Only mothers with HBV DNA > 200,000 IU/ml were treated with prophylactic nucleoside analogues. There were no cases of MTCT in our cohort. We observed that median HBcrAg concentrations were higher in high risk group patients (7.0 vs. 2.4, $p < 0.01$). All patients with high MTCT risk, defined as HBV DNA >200,000 IU/ml had HBcrAg levels greater than 6 $\log_{10}$U/ml and this did not differ between genotypes or HBeAg status. ROC analysis confirmed that HBcrAg is a more accurate predictor of high risk MCTC than HBsAg (HBcrAg AUROC = 1.0 vs. HBsAg AUROC = 0.78, both $p < 0.01$).

Conclusions: Pregnancy plasma HBcrAg concentrations represent a more accurate tool than HBsAg levels to assess the risk of HBV MTCT, is applicable in both HBeAg positive and negative mothers and is not influenced by HBV genotypes. HBcrAg levels greater than 6 $\log_{10}$U/ml predict a high risk of MTCT and offer a non nucleic acid based alternative for maternal testing.

Email: maibinhtieuhoa108@gmail.com

Background and Aims: Hepatitis delta virus (HDV) is an underestimated pathogen in Vietnam, where HBV is endemic with an estimated prevalence of >10%. HBsAg-positive patients (n = 1062) recruited for three cross sectional studies (2009, Northern Vietnam; 2015, Central Vietnam; and 2015, Northern Vietnam) were utilized. Hepatitis delta virus infections were investigated and the circulating HDV genotypes were subjected to molecular characterization.

Methods: The study cohort comprises of clinically characterized HBV patients, including acute hepatitis (AHB; n = 30), chronic hepatitis

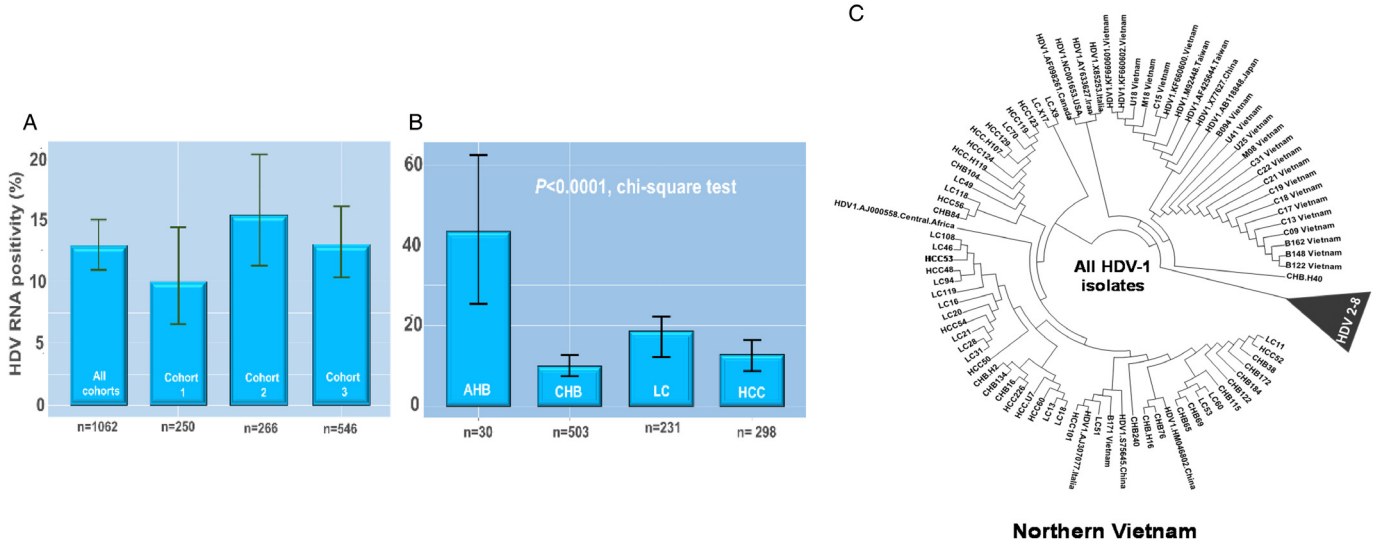

Figure 1: (abstract: FRI-291): Phylogenetic tree was constructed based on the alignment of 235bp of 103 nucleotide sequences isolated from HDV/HBV co-infected patients. Full-length HDV genomes through HDV1-8 retrieved from NCBI database along with GenBank accession numbers were included for the analysis. A neighbor-joining tree was constructed with a bootstrap of 1000 replicates. The bar at the base of the tree indicates the scale for nucleotide substitutions per position. (**A**) Phylogenetic tree of 25 HDV strains isolated from the Central cohort. (**B**) Phylogenetic analysis of 78 HDV strains isolated from 2 cohorts in Northern Vietnam. (**C**) Phylogenetic clade reconstructed with all available HDV genotypes but visualize only HDV1 isolates from 2 cohorts in Northern Vietnam.

(CHB; n = 503), liver cirrhosis (LC; n = 231), and hepatocellular carcinoma (HCC; n = 298). RNA were isolated from serum of HBV patients and were subsequently reverse transcribed to cDNA. HDV specific nested PCR assays were employed. HDV isolates, positive by nested PCR were subsequently sequenced for L-HDAg region and HDV genotypes were determined.

Results: Among all HBV patients investigated, 13% (137/1062) were HDV RNA positive. The distribution of HDV positivity varied between 14% (Northern region) and 10% (Central region). The HDV positivity were significantly distributed among the clinical sub groups (p < 0.0001). Patients with acute hepatitis revealed a high HDV positivity (AHB: 43%), followed by liver cirrhosis (LC: 17%), hepatocellular carcinoma (HCC: 12%) and in chronic hepatitis B patients (CHB: 10%). Both HDV-1 and –2 genotypes were identified with HDV-1 being the predominant genotype in Northern Vietnam (91%) and HDV-2 being detectable mainly in Central Vietnam (80%). Liver enzymes were significantly elevated among patients with HBV and HDV coinfection and were associated with worse clinical outcomes and liver diseases progression compared to HBV mono infection.

Conclusions: HDV is equally endemic to HBV mono infections, with a prevalence of up to 13% in Vietnamese populations. HDV genotypes are differentially distributed among Northern and Central regions. Patients with HBV infections are recommended to undergo screening for HDV.

Papatheodoridis[1]. *[1]Medical School of National and Kapodistrian University of Athens, Laiko General Hospital, Academic Department of Gastroenterology, Athens, Greece; [2]Medical School of Aristotle University of Thessaloniki, 4th Department of Internal Medicine, Thessaloniki, Greece; [3]Medical School of National and Kapodistrian University of Athens, Hippokratio General Hospital, 2nd Department of Internal Medicine, Athens, Greece; [4]University Hospital of Patras, Department of Gastroenterology, Patras, Greece; [5]Thessaly University Medical School, Department of Medicine and Research Laboratory of Internal Medicine, Larissa, Greece; [6]Gilead Sciences Hellas, Medical Department, Greece*
Email: s.siakavellas@gmail.com

Background and Aims: Long-term monotherapy with a high genetic barrier NA represents the treatment option for the majority of chronic hepatitis B (CHB) patients, who are becoming older having increased likelihood for comorbidities and comedications and raising potential safety risks. We assessed the presence of concurrent non-hepatic diseases and drug use in a large cohort of CHB patients receiving nucleos(t)ide analogues (NAs) and their potential impact on the disease course and outcomes of these patients.

Method: We included 500 consecutive CHB patients, who were receiving long-term therapy with a NA in 2016 at the outpatients liver clinics of 5 major tertiary Greek centers (100 patients from each center). HDV, HCV and HIV coinfected patients were excluded. Epidemiological/clinical characteristics and data for concomitant disease, drug use and investigations ordered were collected from the patients' records.

Results: Their mean age was 58 ± 18 years (>60 years: 46%) and 66% were males. The majority of patients (81%) were from Greece and a considerable minority from Albania (12%). Most patients were receiving tenofovir disoproxil fumarate (TDF, 60%) or entecavir (ETV, 37%) monotherapy. Decompensated cirrhosis at baseline was present in 10%, while HCC under therapy developed in 21 (4.2%) patients. Mean duration of total NA(s) therapy was 72 ± 58 (range 1–212) and of the latest therapy 45 ± 31 (range 1–186) months. LFTs and renal tests were determined every 6 ± 3, HBV DNA every 16 ± 9 and liver stiffness every 17 ± 7 months. The most common (prevalence > 2%) comorbidities were hypertension (28%), non-HCC cancer(s) (12%), diabetes (11%), rheumatologic diseases (10%), thyroid diseases (9%), obesity (9%), metabolic bone disease (8%), hyperlipidaemia (6%), organ transplantation (3%) and renal failure (3%). Patients with a longer duration of latest therapy (≥4 vs <4 years) were older (mean age: 58 vs 56 years, p = 0.004) and had more frequent history of prior use of NA(s) (53% vs 35%, p < 0.001) and of pre-treatment liver biopsy (39% vs 14%, p < 0.001) and less frequently liver decompensation (5% vs 13%, p = 0.008) and non-HCC cancers (8% vs 15%, p = 0.020). Liver decompensation was relatively more frequent in obese than non-obese patients (17% vs 9%, p = 0.068) and HCC developed more frequently in patients with than without diabetes (11% vs 3%, p = 0.022).

Conclusion: CHB patients currently treated with NAs, almost exclusively ETV or TDF, are often older than 60 years having several comorbidities and thus requiring careful management.

Email: battisti.arianna@gmail.com

Background and Aims: HBV genotype D is characterized by lower HBsAg levels than other genotypes. The goal of this study is to investigate the role of specific mutations in HBsAg C-terminus (known to be critical for proper HBsAg release) on HBsAg levels in HBeAg-negative patients with chronic HBV genotype D infection.

Method: This study includes 310 consecutive drug-naïve patients (pts) stratified according to HBsAg levels (≤ or >1,000 IU/ml). Correlation of mutations with HBsAg ≤ 1,000 IU/ml is determined by Fisher exact test. Association among mutations in C-terminus is assessed by binomial correlation coefficient (phi). I-Tasser is used to predict three-dimensional HBsAg structures (aa:1–226) and their stability (ΔΔG[wt-mutated] < 0 indicating reduced stability in presence of mutation based on Quan, 2016).

Results: Median (IQR) serum HBV-DNA and HBsAg is 3.6(2.9–4.5) log IU/ml and 2,144(729–6,524)IU/ml, respectively. Specific mutations in HBsAg C-terminus tightly correlate with HBsAg ≤ 1,000IU/ml

(p from <0.001 to 0.04). ≥1 of these mutations occurs in 58.4% of pts with HBsAg ≤ 1,000 IU/ml (range prevalence:6.5–33.4%), while they are present in ≤3.3% (V190A, Y206F, S210N), 7.3% (Y206C) and 12.3% (S204N) of pts with HBsAg > 1,000 IU/ml. These mutations lie on divergent pathways involving other mutations in HBsAg C-terminus: V190A with F220L (Phi = 0.41, p = 0.003), S204N with L205P (Phi = 0.36, p = 0.005), Y206F with S210R (Phi = 0.47, p < 0.001) and S210N with F220L (Phi = 0.40, p = 0.006). Notably, each of these pairs of mutations drastically decreases HBsAg levels compared to wt (250 [15–339]IU/ml for V190A + F220L, 226[123–394]IU/ml for S204N + L205P, 451[81–571]IU/ml for Y206F + S210R and 335[209–417]IU/ml for S210N + F220L vs 2,791[1,009–8,212]IU/ml for wt, P = 0.003–0.02). Some of them also decrease serum HBV-DNA levels (2.2[1.6–2.7]logIU/ml for V190A + F220L and 2.3[1.9–2.9]logIU/ml for S204N + L205P vs 3.4[2.7–4.1]logIU/ml for wt, p = 0.01–0.04), suggesting a detrimental impact also on the release of viral particles. By structural analysis, all the pairs of mutations associated with low HBsAg determine a reduced stability of HBsAg C-terminus (ΔΔG[mut-wt] from −0.52 to −1.92), supporting their role in impairing HBsAg release.

Conclusion: Specific clusters of mutations in HBsAg C-terminus correlate with lower HBsAg levels and determine an impaired stability of HBsAg, supporting their detrimental role on HBsAg release. The knowledge of these mutations can help in optimizing the clinical interpretation of HBsAg levels in HBV genotype D.

FRI-294

Patients with genotype 5 hepatitis delta infection have a favourable outcome of disease and better treatment response to pegylated interferon therapy compared to genotype 1 patients

M. Spaan, M. Bruce, D. Shang, M. Horner, G. Dusheiko, I. Carey, K. Agarwal. *King's College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: m.spaan@erasmusmc.nl

Background and Aims: Co-infection with hepatitis delta virus (HDV) causes rapid progression to liver cirrhosis and hepatic decompensation. HDV has 8 different genotypes and while genotype 1 is the most prevalent in Europe and frequently studied, genotype 5 is found in patients of predominantly African origin. In this study we aim to compare differences in disease progression and treatment response between genotype 1 and 5 patients.

Methods: 46 patients with HBV/HDV co-infection (HBsAg+, anti-HDV antibodies positive, HDV RNA positive) who attended our center between January 2005 and December 2016 were enrolled; none of the patients had an acute HBV or HDV infection or were co-infected with HIV and/or HCV. 39 patients had samples available for HDV genotyping by direct sequencing: 20 patients were found to have genotype 1, and 19 patients were infected with genotype 5.

Results: For 46 patients median age was 34.1 years, median follow-up time was 4.6 yrs and patients were predominantly males (58.7%). 56.6% were of African vs 21.7% of European origin. 50% of patients were cirrhotic upon first presentation. For genotyped patients, most patients with HDV genotype 5 were of African origin (95%) and had HBV genotype E (60%) in contrast to HDV genotype 1 patients who were primarily of European origin (47%) and were infected with HBV genotype D (53%). Age, gender and median follow-up time did not differ between both groups. HBV DNA viral loads were low and similar in both groups. No differences were observed in HDV RNA viral load and HBsAg concentrations. Genotype 1 patients were more often cirrhotic at diagnosis (63% GT1 vs 30% GT5, p = 0.05) and cirrhotic HDV genotype 1 patients were more likely to develop an episode of hepatic decompensation compared to cirrhotic patients with HDV genotype 5 (37% GT1 vs 0% GT5, p = 0.003). 24 patients were treated with pegylated interferon and median follow-up time after treatment was 48 weeks (28–80 weeks). Post-treatment response (>24 weeks) was more favorable in patients infected with genotype 5 (18% GT1 vs 62% GT5, p = 0.047)

Conclusions: Patients infected with hepatitis delta genotype 5 seem to have a better prognosis with fewer episodes of hepatic decompensation and more favorable response to pegylated interferon therapy.

Prevalence and clinical outcome of hepatitis Delta infection in patients with HIV/HBV coinfection

G.B. Gaeta[1,2], S. Milensu[3], G. Brancaccio[4], M. Puoti[5], A. D'arminio Monforte[6], A.D. Luca[7], A. Vergori[8], S. Rusconi[5], A. Mazzarelli[9], A. Castagna[5], A. Antinori[10], A. Cozzi-Lepri[3]. *[1]Infectious Diseases, Specialistic and Internal Medicine, Naples, Italy; [2]Infectious Diseases, Naples, Italy; [3]University College, London, United Kingdom; [4]Infectious Diseases, Internal and Specialistic Medicine, Naples, Italy; [5]Infectious Diseases, Milan, Italy; [6]Clinic of Infectious Diseases, Milan, Italy; [7]Infectious Diseases, Siena, Italy; [8]Clinical Division, Rome, Italy; [9]Banca Biologica, Rome, Italy; [10]Clinical Department, Rome, Italy*
Email: giovannibattista.gaeta@unicampania.it

Background and Aims: Hepatitis Delta virus (HDV) co-infects about 20 million HBsAg+ individuals worldwide. HIV infected persons with HBV coinfection are at risk for HDV. We explored the prevalence of HDV infection and its clinical impactin the ICONA cohort.

Method: Anti-HDV status was assessed among HBsAg + patients enrolled in1997–2015. We performed a cross-sectional analysis to comparebaseline (the date of first HBV test) characteristics of HBV+/HDV+ vs. HBV+/HDV-patients. The proportion of patients HDV+ amongst patients who were HBV+ per year of enrolment was alsocalculated. Composite clinical outcome (CCO) was defined as the occurrence of any of the following events: Fib4 score > 3.25; clinical diagnosis of cirrhosis; decompensation; hepato-carcinoma (HCC) or death. Kaplan Meier method was used to plot the time to develop the CCO, stratified by anti-HDV status. Univariable and multivariable Cox regression models adjusted forage, gender, nationality, region, education, CD4 count, HIV-RNA viral load, smoking status, alcohol consumption, mode of HIV transmission and HCV infection status, were fitted and relative hazards (RH) shown.

Results: Among 13,558 HIV positive patients enrolled as of September 2015, 10,988 were HBsAg-negative, 1,953 were nottested for HBsAg and 617 patients were HBsAg-positive; of these, 115 (18.6%) wereanti-HDVpositive, 403 (65.3%) anti-HDV negative and 99 (16.0%) not tested for HDV. Proportions of anti-HDV positive cases tended to decrease from the year 1997 to 2011 (from 28% to 4%) then appear to increase to 8% in the period 2012–2015. Overall, 171 patients (28%) developed the CCO over time of whom 55/115 (48%) HDV positive, 98/403 (24%) HDV negative and 18/99 (18%) HDV unknown (p < 0.001). In unadjusted Cox regression analysis, RH was 2.34 95%CI:1.68–3.26; the association was attenuated after controlling for HCV coinfection (RH = 1.46; 95%CI:0.98, 2.17). Other factors independently associated with higher risk of CCO were: male gender, older age, lower CD4 count, alcohol use and smoking. In the subset of people who received anti-HBV therapy, 43/79 (54%) HDV+ patients and 84/320 (26%) HDV-neg patients developed CCO (OR = 3.36; 95% CI:1.95–5.78).

Conclusion: Presence of anti-HDV antibodies in HIV-coinfected individuals is a marker of faster progression to severe liver disease and death even in participants who received anti-HBV therapy.

FRI-296

Clinical features of HDV infection in Mongolian patients

A. Enkhbat[1], O. Lkhagva-Ochir[2], D. Boldbaatar[2], B. Dashtseren[2], A. Bungert[3], Z. Genden[2], D. Yagaanbuyant[2], N. Dashdorj[3], N. Dashdorj[2,3]. [1]*Liver Center, Laboratory, Ulaanbaatar, Mongolia;* [2]*Liver Center, Hospital, Ulaanbaatar, Mongolia;* [3]*Onom Foundation, Ulaanbaatar, Mongolia*
Email: anir@livercenter.mn

Background and Aims: It is estimated that 7.14% of Mongolian population having double infection with hepatitis B (HBV) and D (HDV) viruses. By current study our goal was to take an inquiry into the clinical features of delta viral infection in Mongolia.
Method: A total of 445 chronic HDV patients at the Liver Center, Mongolia were randomly chosen, and their clinical parameters were determined.
Results: Majority of patients were female 56% with mean age of 44.87 ± 10.7, ranging from 18–82 years. 409 patients (92%) were HDV-RNA positive, 85 (19.1%) HBV-DNA negative and 68 (15.2%) had positive hepatitis C (HCV) RNA. Mean values of clinical biochemical markers were 82.59 ± 84.2 for ALT and 58.46 ± 53.0 for AST while mean platelet count was 185.4 ± 64.7. Liver fibrosis were staged by elastography (Fibroscan). There were F0-F1–143 (32.13%), F2–44 (9.89%), F2-F3–87 (19.55%), F3 – 17 (3.82%), F3-4 – 96 (21.57%), F4 – 58 (13%) patients, respectively. Clinical immunological markers were determined in 363 patients for HBsAg and 206 for HBeAg out which 23 (11.2%) were positive for HBeAg. Antiviral therapy was administered to 161 patients out of which 154 received with anti HBV nucleos/tide analogues, 6 patients received anti-HCV nucleos/tide analogues and one patient receiving both antivirals.
Conclusion: HDV represent more severe outcomes in male patients compared to females with elevated levels of clinical biochemical markers, viral loads, liver fibrosis as well and may reduce life expectancy as well.
Biochemical markers are not significantly altered and cannot be sufficiently predict HDV clinical course. There is moderate positive correlation (0.42) between AST/Platelet index ratio and liver elastography (Fibroscan) scoring. Notable differences in platelet counts were observed in three cohorts grouped by liver elastography scores: <10 kpa, 10–15 kpa and >15 kpa. HBsAg level had weak correlation (0.14) with HDV viral load. Overall the current clinical tests done for chronic HBV management are largely ineffective for monitoring, diagnosing and predicting future outcome of chronic HDV patients, except maybe for platelet count and liver fibrosis.

FRI-297

Monitoring of subjects with previous hepatitis B exposure on Rituximab for hepatitis B reactivation and on demand treatment for hepatitis B reactivation is safe and reduces cost

V. Ekstrom[1], T. Tang[2], A. Chan[3], F. Mohamad[2], M. Tao[2], W.C. Chow[4], R. Kumar[1]. Background and Aims: Hepatitis B reactivation (HBVr) is known to occur in patients with Hepatitis B virus (HBV) exposure on treatment with Rituximab. On demand treatment remains controversial due to concerns of HBV-related acute liver failure while anti-viral prophylaxis increases cost and potentially induces drug resistance. This study aims to determine prospectively the rate of HBVr in patients with HBV exposure who receive Rituximab and to determine the safety of on demand treatment if they require treatment with nucleoside analogs (NA).

Method: Ongoing single centre, prospective observational study at National Cancer Centre Singapore and Singapore General Hospital. All patients with B-cell lymphoma requiring rituximab were screened for Hepatitis B serology markers. Those who had positive Hepatitis B core total antibody (HBcAb) and negative Hepatitis B surface antigen (HBsAg) and HBV DNA levels were recruited. HBsAg, HBV DNA and Alanine aminotransferase (ALT) were monitored at 4–6 weekly intervals during therapy, 6 weekly intervals after the last dose of rituximab for 52 weeks and 12 weekly intervals for another 52 weeks. Whilst on rituximab, NA would be started if they had 2 readings more than 4 weeks apart of either HBV DNA >100 IU/ml irrespective of ALT, or ALT more than upper limit of normal (ULN) and HBV DNA >20 IU/ml. Following completion of the planned rituximab treatment, NA would be started if they had 2 readings of ALT > ULN and HBV >200 IU/ml at least 4 weeks apart, or ALT > ULN and HBV DNA increasing by >1 log in past 8 weeks or relapse of underlying lymphoma and HBV DNA was detectable.
Results: To date, 27 patients (77.8% Chinese/14.8% Malay/7.4% others) were recruited in the study. Mean age was 70.6 ± 9.9 years and 55.6% were males. 8 developed detectable HBV DNA. Only 3 required treatment with NA while on rituximab due to rising HBV DNA which occurred at a mean duration of 59.7 days after starting Rituximab. All the patients who had increased HBV DNA did not have elevated ALT. None of the patients with Hepatitis B surface antibody (anti-Hbs) >100 IU/ml had HBVr while anti-Hbs >10 IU/ml was not protective for HBVr. The 5 who did not require treatment had a detectable HBV DNA < 20 IU/ml which returned to undetectable levels spontaneously. None developed HBV-related acute hepatitis flare or jaundice. 2 patients passed away (1 from fungaemia, 1 from metastatic cervical cancer).
Conclusion: Close observation without primary antiviral prophylaxis was safe for HBV-exposed patients who were on Rituximab based-chemotherapy. This helped reduce cost of medication that can be avoided. Patients with anti-Hbs >100 IU/ml have very low chance of reactivation.

Email: mfried@med.unc.edu

Background and Aims: Patients with chronic HBV may experience spontaneous biochemical flares of liver disease activity. This study aimed to determine (i) the prevalence of prior HEV infection and possible acute HEV infection among persons with chronic HBV and (ii) whether HEV infection is associated with liver disease flares among persons with chronic HBV.
Method: To obtain prevalence estimates, serum from a random sample of 600 of the 1,991 participants in the Hepatitis B Research Network (HBRN) adult cohort were tested for anti-HEV IgM and IgG (Wantai assay). HEV RNA was measured by qRT-PCR. At or after enrollment, 72 participants (none treated with peg-IFN) experienced biochemical flares [ALT ≥10 × ULN (female = 200, male = 300 U/l)] of select etiologies, adjudicated by hepatologists. Serum samples of flare cases [49 pre-flare (>6 weeks prior to flare), 72 at-flare (–6–12 weeks), and 51 post-flare (>12–48 weeks)] were analyzed for anti-HEV (IgM or IgG) seroprevalence. Sera from flare cases at-flare were matched (1:4) to sera from non-flare controls by propensity scores accounting for sex, age, place of birth, and HBeAg status. Post-flare

samples were matched (1:4) by propensity score and time between samples.
Results: In the prevalence study, mean age was 43 years, 51% were female and 72% were Asian. Anti-HEV IgG and IgM seroprevalence was 28.5% and 1.7%, respectively. None of the 10 anti-HEV IgM + participants had detectable HEV RNA. Their median ALT was 27.5 (range: 9-76)U/l. Characteristics independently associated with anti-HEV (IgG+ or IgM+) included older age, males, not US/Canada-born, less education, and higher HBV DNA. The flare etiology was unknown for 7/72 (10%). Of the others, the most common of the selected causes were spontaneous viral reactivation (49%) and unsuccessful or spontaneous immune clearance (32%). Using at flare matched samples, the odds of flaring was not significantly different between anti-HEV positive (IgG+ or IgM+) and anti-HEV negative (IgG- and IgM-) participants (OR: 1.3, 95%CI: 0.7 to 2.5). Similar results were found using post-flare matched samples (OR: 1.2, 95%CI: 0.6 to 2.6). For the flare cases, seroprevalence of HEV was similar pre- (29%), at- (36%), and post-flare (31%). HEV RNA was not detected in any samples.
Conclusion: Seroprevalence of anti-HEV IgG is high among individuals with chronic HBV in the US and Canada, but acute HEV infection does not appear to account for ALT flares of disease in patients followed in the HBRN cohort.

Email: dr.wu@nju.edu.cn

Background and Aims: It is essential to identify the severity of HBV-related liver diseases and predict long-term prognosis. We aimed to evaluate a novel index, the red blood cell distributionwidth(RDW)-to-albumin ratio(RAR), for the prediction of liver-related mortality in HBV-related liver cirrhosis.
Method: 223 patients with HBV-related liver cirrhosis, 318 chronic hepatitis B(CHB) patients and 197 healthy controls(HC) were recruited as a training cohort. 265 patients with cirrhosis, 194 CHB patients and 167 HC from another center were recruited as an external validation cohort. The diagnostic values of RAR for the severity of HBV-related liver cirrhosis were calculated by ROC curves and compared with other noninvasive methods. The prognostic value of baseline RAR were assessed using Kaplan–Meier analysis.
Results: In the training set, median RAR values were significantly higher in patients with HBV-related liver cirrhosis as compared with CHB patients ($p < 0.001$) and HC ($p < 0.001$). RAR was positively correlated with Child–Pugh scores ($r = 0.569$, $p < 0.001$) and MELD scores ($r = 0.139$, $p = 0.038$). The AUCs of RAR were significantly higher than that of AST-to-platelet(PLT) ratio index (APRI), fibrosis-4 index (FIB-4), gamma-glutamyl transpeptidase (GGT) to PLT ratio (GPR), RDW-to-PLT ratio (RPR), AST-to-ALT ratio (AAR) and neutrophil-to-lymphocyte ratio (NLR) in predicting HBV-related liver cirrhosis and decompensated cirrhosis. The performance of RAR in identifying the severity of HBV-related liver cirrhosis was similar in the validation cohort. The mean follow-up duration was 34.9 (IQR, 25.0–49.5) months in cirrhosis patients in the training cohort, during which 21 patients died. The cirrhosis patients were followed for 33.2 (IQR,16.6–45.9) month in the validation cohort. RAR was an independent predictor of mortality by Cox Regression models (HR 30.6; 95%CI 2.3–409.6; $p = 0.01$). The patients with HBV-related liver cirrhosis were divided into two group by the median (0.48) of RAR value with an incidence rate for liver-related death of 5.9%, 19.0% in the training cohort, and 5.6%, 26.4% in the validation cohort, respectively. Kaplan-Meier analysis showed high RAR values was significantly associated with higher cumulative incidence of death throughout follow-up both in the training cohort ($p = 0.005$) and validation cohort ($p < 0.001$).
Conclusion: RAR can be used as a novel index for the prediction of severity in HBV-related liver diseases. More importantly, RAR is a useful prognostic index for HBV-related liver cirrhosis.

Email: viola.knop@kgu.de

Background and Aims: During the natural course of chronic HBV infection little is known about the effect of alanine aminotransferase (ALT) dynamics for the outcome of long-time follow-up.
The aim of the present study was to investigate the clinical significance of ALT changes between baseline (BL) and 4 years follow-up (FU4) for hepatitis B e antigen (HBsAg) seroconversion as well as for disease progression in a cohort of European untreated HBeAg-negative infected patients.
Method: Patients with HBeAg-negative low-replicative chronic HBV were enrolled for long-term follow-up over 10 years. Definition of low-replicative HBV without indication for antiviral therapy at study inclusion was based on EASL guidelines. Biochemical and virological parameters as well as transient elastography (TE) were performed at BL and 1x/year.
Results: Data of FU4 were available in 227 patients, mainly infected with HBV genotype A and D. Patients were classified according to ALT levels into the following groups: patients with constantly normal ALT ≤ 0.5 × ULN [group A; 18/227 (7.9%)], constantly normal ALT > 0.5 × ULN [group B; 151/227 (66.5%)], transient ALT elevation [group C; 51/227 (22.5%)] and persistent ALT increase [group D; 7/227 (3.1%)]. Overall, HBsAg seroconversion and reactivation with start of antiviral therapy was observed in 12/227 (5.3%) and 14/227 (6.2%) patients, respectively. HBsAg seroconversion was not significantly affected by ALT dynamics during 4 years FU [2/18 (11.1%), group A; 9/151 (6%), group B; 1/51 (2%), group C; 0/7, group D]. Patients with transient or persistent ALT elevation (group C and D) had a significant higher risk of disease progression with parallel increase of HBV DNA (>2000 IU/ml) and started with antiviral treatment compared to group A and B patients [6/51 (11.8%) and 4/7 (57.1%) in groups C and D versus 0/18 and 4/151 (2.6%) in groups A and B, respectively; $p < 0.0001$]. Single-point measurement of ALT showed significant correlations with liver stiffness by TE ($r = 0.34$; $p < 0.0001$), BMI ($r = 0.269$; $p < 0.0001$), triglycerides ($r = 0.229$; $p = 0.001$), quantitative HBsAg ($r = 0.207$; $p = 0.004$) and LDL cholesterol ($r = 0.145$; $p = 0.045$).
Conclusion: In our study cohort with 4-year period of follow-up patients with transient or persistent ALT elevation were shown to have a higher risk of disease progression. ALT levels ≤ 0.5xULN appeared to be no further advantage for the long-term outcome. Beside viral factors transaminase levels were also correlated to metabolic parameters, such as LDL cholesterol and BMI.

FRI-301

Serum Mac-2-binding protein glycosylation isomer in assessing liver fibrosis in chronic hepatitis B infection

L.-Y. Mak[1], W.-K. Seto[1,2], K.-S. Cheung[1], Y.Y.J. Fung[1,2], D. Wong[1,2], C.L. Lai[1,2], M.-F. Yuen[1,2]. *[1]The University of Hong Kong, Li Ka Shing Faculty of Medicine, Hong Kong; [2]State Key Laboratory for Liver Research, Hong Kong, China*
Email: mfyuen@hku.hk

Background and Aims: Mac-2-binding protein glycosylation isomer (M2BPGi) is a novel serum marker for diagnosis of liver fibrosis in various liver diseases, while data in chronic hepatitis B (CHB), especially longitudinal data, is limited. We aimed to evaluate the role of M2BPGi in diagnosing advanced fibrosis (F3) and cirrhosis (F4) in HBeAg-ve CHB using liver stiffness measurement (LSM) as the reference.
Method: We performed transient elastography for HBeAg-ve CHB patients who were managed in Queen Mary Hospital, Hong Kong. LSM was performed by Fibroscan® (Echosens, Paris, France) and presence of no/minimal fibrosis (F0/F1), grey area and F3/F4 was defined using the alanine-aminotransferase-based EASL-ALEH criteria. Serum M2BPGi were measured using the HISCL-800 immunoanalyzer (Sysmex Corporation, Hyogo, Japan).
Results: 240 HBeAg-ve CHB patients (M:F = 116:124) of median age 47.5 years were recruited. The majority were treatment-experienced (85.8%). The median ALT was 26 U/l (range: 10–180 U/l). The median liver stiffness was 6.9 kPa (IQR 4.9–11.7 kPa) and 78 of them (32.5%) had F3/F4 by transient elastography at baseline. The corresponding median M2BPGi values for F0/1/2, F3 and F4 progressively increased in parallel with more advanced stages of liver fibrosis: 0.39, 0.46 and 0.82 COI, respectively ($p < 0.01$) (Figure 1A). The AUROC for diagnosing ≥ F3 by serum M2BPGi was 0.754. Using a cut-off value of 0.605, the sensitivity, specificity, PPV and NPV for ≥ F3 was 62.5%, 79.4%, 60.3% and 80.9%, respectively. In a subgroup of 86 patients who had repeated LSM 10 years after the initial LSM, the proportion of patients with F3/4 was reduced from 36.7% to 16.3% ($p < 0.001$). The median serum M2BPGi levels were significantly different between patients with F3/4 compared to those with F0/1/2 at baseline (0.67 COI vs. 0.41 COI, $p < 0.05$) and also at 10-year (0.62 COI vs. 0.48 COI, $p = 0.039$). 21 (24.4%) showed significant fibrosis regression (i.e. F3 or F4 → F0 or F1). The median change in serum M2BPGi level was -0.11 compared to + 0.03 COI in the other patients who did not showed significant fibrosis regression ($p = 0.011$). (Figures 1C-1D)
Conclusion: Serum M2BPGi was an accurate serum marker for liver fibrosis in HBeAg-ve CHB patients. Using a cut-off level of 0.605 COI, 80.9% patients without ≥ F3 can be excluded. Serum M2BPGi levels remained significantly higher for patients with ≥ F3 compared to those with F0/1/2 even after 10 years. Serum M2BPGi levels also decreased significantly in patients who had fibrosis regression after 10 years.

FRI-302

Changes in serum levels of the novel mac-2 binding protein glycosylation isomer and risk of hepatocellular carcinoma among chronic hepatitis B patients treated with nucleos(t)ide analogues

Y.-C. Hsu[1], T. Jun[2], M.-L. Yeh[3], Y.-T. Huang[4], M.-L. Yu[3], M. Nguyen[2], Y. Tanaka[5]. *[1]Fu-Jen Catholic University Hospital, Department of Medical Research; [2]Stanford University Medical Center, Department of Medicine, Palo Alto, United States; [3]Kaohsiung Medical University Hospital, Division of Hepatology Department of Internal Medicine; [4]Academia Sinica, Institute of Statistical Science; [5]Nagoya City University Graduate School of Medical Sciences, Department of Virology & Liver unit*
Email: holdenhsu@gmail.com

Background and Aims: Current data is limited in how mac-2 binding protein glycosylation isomer (M2BPGi) would change and whether it can predict hepatocellular carcinoma (HCC) development in nucleos (t)ide analogues (NA)-treated chronic hepatitis B (CHB) patients. We

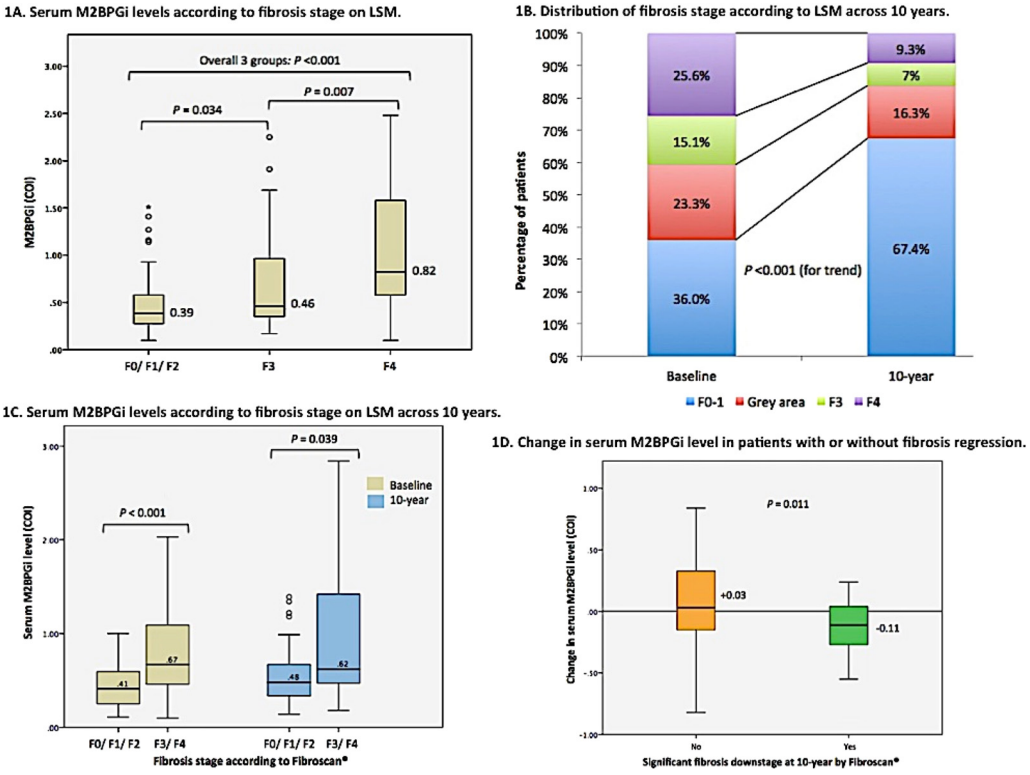

Figure 1: (abstract: FRI-301)

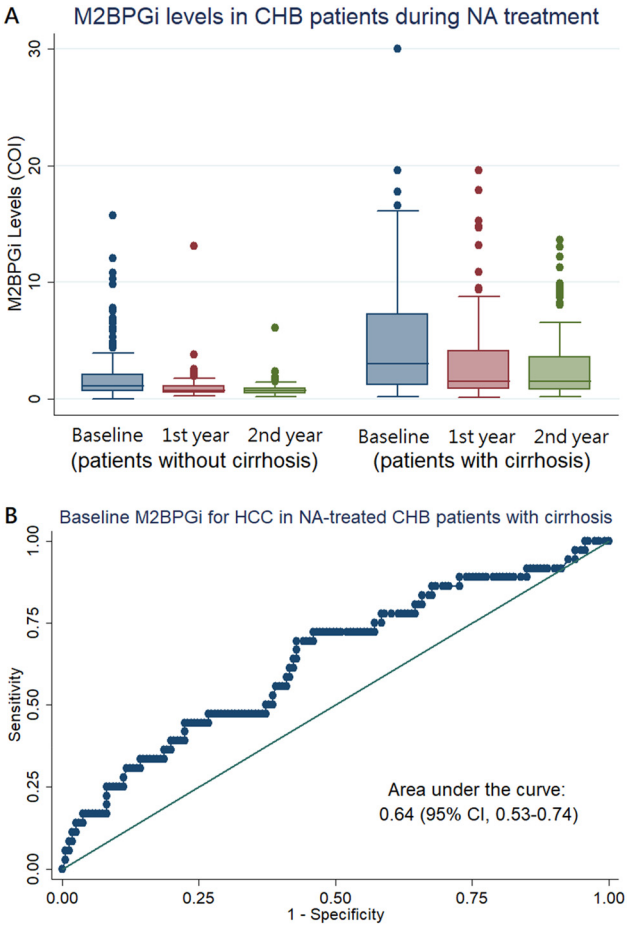
aimed to clarify the dynamic change of M2BPGi and its association with HCC in CHB patients during NA treatment.

Method: Previously untreated CHB (without co-infection) patients were prospectively enrolled at 3 centers in the US and Asia. Sera were serially collected at the time (but prior to) of NA initiation, then at 1 year and at 2 years after therapy. Those with baseline HCC or who developed HCC within one year of therapy were excluded. We used multivariable Cox proportional hazard model to evaluate the association between serial serum M2BPGi levels (cut off index; C.O.I) measured at different time points and subsequent occurrence of HCC.

Results: The analysis included 387 eligible patients: 73.6% male, 50.9% with cirrhosis, and median age of 48 years. Median M2BPGi levels significantly decreased from baseline (1.7; interquartile range [IQR], 0.78–4.4), to 1.0 (IQR, 0.61–1.83) at 1 year, and to 0.88 (IQR, 0.58–1.75) at 2 years after treatment initiation. This trend was consistent with or without cirrhosis (Figure, panel A). In paired analysis of the 275 patients who had M2BPGi measurements at all 3 time points confirmed that the decline during the first year (median, 0.56; IQR, 0.07–2.07) was significantly more pronounced than those during the second year following therapy initiation (median, 0.08; IQR, −0.18–0.40) ($p < 0.0001$, Wilcoxon signed-rank test). During a median follow-up of 72.7 (IQR, 44.2–103.4) months, HCC occurred in 37 patients, almost all of whom (n = 36) had cirrhosis at baseline. On multivariate Cox regression analysis of the 197 patients with cirrhosis, HCC risk was independently and significantly associated with pretreatment M2BPGi (adjusted hazard ratio [aHR], 1.10 per COI; 95%CI, 1.04–1.16) in addition to age (aHR, 1.07 per year; 95%CI, 1.02–1.13) and diabetes mellitus (aHR, 2.21; 95%CI, 1.04–4.70), but serum M2BPGi measured at one year or two years after treatment was not. The concordance rate of baseline M2BPGi for HCC occurrence in NA-treated CHB patients with cirrhosis was 0.64 (95%CI, 0.53–0.74) (Figure, panel B).



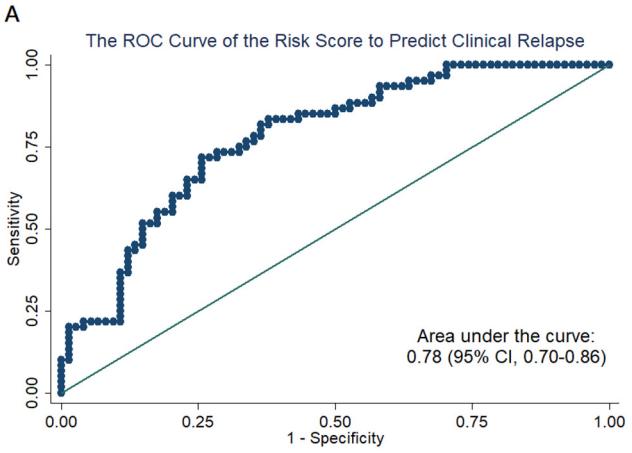
Conclusion: Serum M2BPGi levels decreased in CHB patients during oral antiviral therapy, with the most pronounced decline occurring in the first year of therapy. Baseline M2BPGi levels were independently associated with the risk of HCC among patients with cirrhosis. Further studies with large sample size of treated non-cirrhotic patients are needed to investigate the role of M2BPGi as a predictor of HCC in this population.

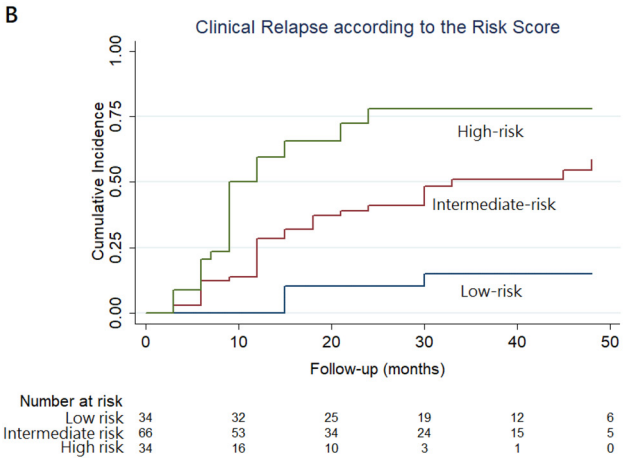
FRI-303

A risk score combining quantitative hepatitis B surface antigen and core-related antigen levels to predict off-therapy relapse after cessation of nucleos(t)ide analogues in patients with chronic hepatitis B

Y.-C. Hsu[1], Y. Tanaka[2], M. Nguyen[3], C.-Y. Chang[1], C.-M. Tai[4], C.-H. Tseng[4], C.-C. Chen[5], M.-S. Wu[5], J.-T. Lin[1]. *[1]Fu-Jen Catholic University, School of Medicine College of Medicine, New Taipei; [2]Nagoya City University Graduate School of Medical Sciences, Department of Virology & Liver unit, Nagoya, Japan; [3]Stanford University Medical Center, Department of Medicine, Palo Alto, United States; [4]E-Da Hospital, Department of Medicine, Kaohsiung; [5]National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan*
Email: holdenhsu@gmail.com

Background and Aims: Clinical relapse frequently follows cessation of nucleos(t)ide analogues (NAs) in patients with CHB; however, there are currently no accurate prediction tools to identify patients who would relapse. We aimed to develop a risk score to predict clinical relapse in CHB patients who discontinue NA therapy.
Method: This prospective study enrolled 134 CHB patients (79.1% male; median age, 49.3 years) without cirrhosis who discontinued NAs after a minimum of 3 years on therapy. Serum HBeAg was negative and hepatitis B virus (HBV) DNA undetectable at the end of treatment (EOT) in all patients, whereas HBeAg was positive in 35 patients prior to treatment). Clinical relapse was defined as serum HBV DNA > 2,000 IU/ml plus alanine aminotransferase (ALT) > 80 U/l. Predictors of clinical relapse were determined by the multivariable Cox proportional hazard model. The regression coefficients in the model were weighted to build a risk score.
Results: During a median follow-up of 21 (range, 3~60) months, 60 patients experienced a clinical relapse with the cumulative incidence of 54.1% (95%CI, 44.9–63.9%) at 4 years. The Cox model identified ALT (adjusted hazard ratio [aHR], 1.02 per U/l; 95%CI, 1.01–1.03), age (aHR, 1.04 per year; 95% CI, 1.02–1.07), HBsAg (adjusted HR, 1.94 per logIU/ml; 95% CI, 1.21–3.11), and HBcrAg (aHR, 1.39; 95% CI, 1.06–1.82) as the independent EOT factors associated with subsequent clinical relapse, and lead to a risk score with the formula of ALT (U/l) + 2*Age (years) + 32*HBsAg (logIU/ml) + 16*HBcrAg (logIU/ml). The score achieved a Harrel's c statistic of 0.78 (95%CI, 0.70–0.86). A score <235 (n = 31) and >285 (n = 35) points distinguished low- and high-risk groups with the 4-year cumulative incidences of 15.6% (95%CI, 6.0–37.1%) and 79.9% (95%CI, 62.7–92.7%), respectively. Moreover, all of the 7 patients who cleared HBsAg during the follow-up had a score <235 points.
Conclusion: The current score based on age, ALT, qHBsAg, and HBcrAg may predict the risk of clinical relapse after cessation of NA therapy in CHB patients and calls for external validation to help identify those who can safely discontinue NAs.





FRI-304

Acute hepatitis B in adulthood: not such a benign disease

J. Llaneras[1], M. Riveiro-Barciela[2,3], P. Suanzes[1], E. Mena[1], S. Romero[1], M. Ventura-Cots[1], F. Sanpedro[1], R. Esteban[2,3], M.B. Ferret[2,3]. *[1]Hospital Universitari Vall d'Hebron, Emergency Department, Barcelona, Spain; [2]Hospital Universitari Vall d'Hebron, Liver Unit, Barcelona, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain*
Email: jllanera@vhebron.net

Background and Aims: Acute hepatitis B (AHB) remains a common cause of acute viral hepatitis though series concerning its outcome date back to the 80s [Tassopoulos NC, Gastroenterology 1987; McMahon BJ, J Infect Dis 1985]. The aim of this study was to analyze the characteristics and prognosis of AHB in adulthood within the last 3 years.
Method: Prospective study including all consecutive AHB in subjects aged over 16 years attended at our hospital from October 2014 to October 2017. Diagnosis of AHB was based on the presence of positive antiHBc IgM.
Results: 239 cases of acute hepatitis were recorded during the 3 years period. 33 (14%) were AHB: 85% male, median age 49 years (IQR: 38–56). Baseline ALT value was 1431 IU/mL (IQR: 412–2211) and bilirubin 5.8 mg/dL (IQR: 1.8–9.9). 64% of patients presented jaundice at diagnosis. Four (12%) subjects had undergone immunosuppressant drugs within the previous year, 2 for oncological malignancies and 2 for transplantation, and all of them were antiHBc positive/HBsAg negative prior to immunosuppression and HBeAg positive with HBV DNA >10E8 at diagnosis of AHB. Prognosis: Twelve (36%) developed chronic hepatitis B and 3 acute liver failure (ALF), the latter treated

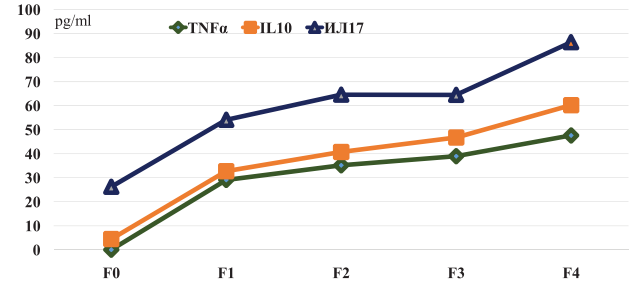
with nucleos(t)ids analogs. Three (9%) out of the 12 AHB that developed chronic infection, presented histological evidence of cirrhosis one year after AHB. Overall, 11 (33%) required hospital admission and 2 (6%) out of 3 ALF died and the other survived after liver transplant. Multivariate analysis showed that jaundice was the only independent factor associated with AHB cure (OD 1.7, p = 0.02).
Conclusion: A high rate of chronification was observed in adults with acute hepatitis B. Jaundice was the only protetive factor against the development of chronic infection.

FRI-305
The first results of genotyping of virus hepatitis D and virus hepatitis B in Kazakhstan
B. Ilyassova[1], B. Baymakhanov[1], Y. Bakhytkali[2], A. Kyzdarbekov[3], V. Ayupova[4]. *[1]National Scient Center of Surgery Named A.Syzganova, of Hepatopancreatobiliary Surgery and Liver Transplantation, Almaty, Kazakhstan; [2]Hospital of Infection Deseases of Shymkent, Shymkent, Kazakhstan; [3]Hospital of Infection Deseases of Taraz, Taraz, Kazakhstan; [4]Hepatological Center of Almaty, Almaty, Kazakhstan*
Email: bs-immunolog@mail.ru

Background and Aims: The 5-year experience of the transplant center in Almaty has shown that out of 100 recipients, 30 patients had cirrhosis and/or HCC in the outcome of chronic hepatitis D (CHD), 19 patient had PBC, 15 had billiary athresia, 15 – chronic hepatitis B (CHB), 10 had chronic hepatitis C, 4- AIH. Cirrhosis in the outcome of CHD is the most common cause of liver transplantation in Kazakhstan.
CHD is associated with the most severe form of hepatotropic-induced viral hepatitis [Rizzetto M et al., 1983]. The severity of the course of CHD may be dependent on host and viral factors. Multivariate analysis identified age, HBV genotype C, and HDV genotype I as independent factors for poor outcomes [Su CW, Huang YH, Huo TI et al., 2006].
The National Scientific Center of Surgery named A. Syzganov in 2017 has started the scientific project to study the factors of progression of liver cirrhosis in the Kazakh population. One of the factors of progression of liver cirrhosis in Kazakhstan are genotypes of HBV and HDV.
Method: Blood samples of patients were examined for the determination of genotypes of HBV and genotypes of HBV by the PCR method. Isolation of HDV RNA and HBV DNA was performed using the GeneJETViral DNA and RNA Purification Kit, ThermoScientific, according to the manufacturer's instructions. PCR was performed using specific primers. Purified PCR products were sequenced in two directions, using a forward and reverse primer (BigDye™ Terminator v3.1 CycleSequencingKit).
Results: 144 patients in chronic hepatitis B and D were examined, including 56 men, 89 women. The average age was 40.9 ± 8,6 years. In 102 patients diagnosed with chronic viral hepatitis D, 42 patients with CHB. Among patients with CHD, 79,4% (82 patients) had a positive PCR result of HDV RNA in the absence of HBV DNA in the blood. 20,6% (21) patients with CHD were HBV DNA-positive and HDV RNA-positive at the same time. In patients with CHD the stage of liver fibrosis F0 (Metavir) had 24 (23,5%) patients, F1–4 (3,9%), F2–5 (4,9%), F3-32 patients (31,3%), F4 had 37 (36,2%) patients.
In patients with CHB, 41 patients were HBeAg-negative, i.e. mutant strain of the virus and only 1 patient (2,3%) was HbeAg-positive. In patients with CHD 6 patients had a viral load of less than 2000 IU. The stage of liver fibrosis F0 (Metavir) had 8 (33,3%) patients with CHB, F1-4 (16%), F2–5 (11,9%), F3-7 patients (17,1%), F4 had 14 (33,3%) patients.
The PCR analysis has showed that in all patients (100%) with CHD have 1 genotype of HDV. In 92.9% (39 patients) of CHB, genotype D was found, in 4.7% (2)-genotype A of HBV and in 2,4% (1)-genotype B. Genotype B has HbeAg-positive patient. The 21 patients with positive PCR of HBV DNA and HDV RNA has genotype D of HBV.
Conclusion: The severe course of chronic viral hepatitis D is due to the prevalence of the 1 genotype of HDV. For chronic hepatitis B, the most common genotype is D.

FRI-306
The levels of cytokines in progression of chronic hepatitis D
B. Ilyassova[1], B. Abzhaparova[2], N. Ibrayeva[3], A. Abdraimova[4]. *[1]National Scient Center of Surgery Named A.Syzganova, of Hepatopancreatobiliary Surgery and Liver Transplantation, Almaty, Kazakhstan; [2]National Scient Center of Surgery Named A.Syzganova, of Multidisciplinary Department 1, Almaty, Kazakhstan; [3]National Scient Center of Surgery Named A. Syzganova, Laboratory, Almaty, Kazakhstan; [4]National Scient Center of Surgery Named A.Syzganova, Laboratory, Almaty, Kazakhstan*
Email: bs-immunolog@mail.ru

Background and Aims: The viral hepatitis D is very important problem in Kazakhstan. Cirrhosis in the outcome of chronic hepatitis D (CHD) is the most common cause of liver transplantation in Kazakhstan. The severity of the course of CHD may be dependent on host and viral factors, as CHD is an immune-mediated disease [Grabowski J, Wedemeyer H., 2010].
The aim of the study was to determine the role of cytokines in the progression of liver fibrosis in chronic hepatitis D.
Method: A total of 105 patients with chronic viral hepatitis D and liver cirrhosis in the outcome of viral hepatitis D were examined, 29 men, 76 women in the age 39,1 ± 7,4 years. Patients were examined by blood test, TNF-α, IL-12, IL-17, IL -10, TGFβ1 concentrations in the serum by ELISA (IBL (Germany). The fibrosis stage was determined by Fibroscan-502.
Results: The results showed significant increase of bilirubin depending on the stage of fibrosis ($p = 0.004$), as well as a significant decrease of platelets ($p = 0.0001$), a significant increase of ALT ($p = 0.40$), AST ($p = 0.004$). The results of the level of signaling fibrogenesis molecules showed increase of TNF-α ($p = 0.009$), IL-10 ($p = 0.002$), depending on the stage of fibrosis. Levels of IL17, IL12/23, and TGFβ1 also appeared to be elevated in F3-F4 compared to patients with F0-F2, however, there is no significant. The TNFα has a positive correlation with the level of ALT ($r = 0.358$, $p < 0.0001$), AST ($r = 0.452$, $p < 0.0001$) and negative with creatinine ($r = –0.396$, $p = 0.002$), urea ($r = –0.280$, $p = 0.019$), platelets ($r = –0.290$, $p = 0.005$); and leukocytes ($r = –0.342$, $p = 0.001$). IL-10 has a positive correlation with ALT level ($r = 0.256$, $p = 0.004$), AST ($r = 0.380$, $p < 0.0001$), bilirubin ($r = 0.194$, $p = 0.037$), and negative with albumin ($r = –0.586$, $p = 0.005$), creatinine ($r = –0.389$, $p = 0.003$), urea ($r = –0.267$, $p = 0.026$), platelets ($r = –0.379$, $p < 0.0001$); and leukocytes ($r = –0.382$, $p < 0.0001$). IL-17 has negative significant relationship with ALT and AST ($r = –0.209$, $p = 0.021$ and $r = –0.249$, $p = 0.006$). The level of TGFβ1 in the blood of patients has a positive statistically significant relationship with ALT indices ($r = 0,263$, $p = 0,014$), AST ($r = 0,263$, $p = 0,004$), albumin ($r = 0,600$, $p = 0,004$), total plasma protein ($r = 0,296$, $p = 0,027$), TNF levels α ($r = 0,897$, $p < 0.0001$), IL-10 ($r = 0.665$, $p < 0.0001$), and negative with IL-17 level ($r = –0.677$, $p < 0.0001$) and creatinine ($r = –0.354$, $p = 0.014$).
Conclusion: Progression of fibrosis in chronic HDV infection is associated with the activity of the level of TNF-α and of IL-10, which have a negative relationship with IL-17 and positive association with TGFβ1. An increase in IL12/23 and the presence of a negative correlation of IL-17 with TGFβ1 indicates that the initiation of autoimmune inflammation occurs in the initial stages of fibrosis and during the progression of fibrosis in cirrhosis occurs decrese of severity autoimmune inflammation



Picture 1. The cytokines levels in patients with CHD on the different stages of fibrosis

Assessment of hospitalizations and comorbidities in 2138 hepatitis B patients followed in diverse specialist care clinics based on administrative data analysis: The Canadian hepatitis B network

C. Coffin[1], A.-A. Shaheen[2], R. Bailey[2], K. Doucette[3], M. Ma[4]. [1]*University of Calgary, Cumming School of Medicine, Calgary, Canada;* [2]*Bailey Health Clinic, Edmonton, Canada;* [3]*University of Alberta, Division of Infectious Diseases;* [4]*University of Alberta, Division of Gastroenterology*
Email: cscoffin@ucalgary.ca

Background: Epidemiological data on chronic hepatitis B (CHB) patients in North American suggest that due to increasing age and adoption of "Western" lifestyle and dietary habits, CHB patients may have significant comorbidities affecting CHB natural history.
Aim: To evaluate the effect of demographics and specific comorbidities on hepatitis B patient ambulatory visits and hospitalization outcomes and to associate these outcomes to type of specialist care.
Methods: We used ambulatory care, hospitalization discharges, and laboratory databases in Alberta, Canada from 2012–2016, to identify CHB patients (HBsAg + ve) who were followed by a specialist. Specialist practice cohorts included community gastroenterology, academic hepatology, liver transplant and infectious diseases. We compared demographics (age, sex), HBV status (HBV DNA, HBeAg serology, ALT), diabetes control (HBA1C ≥6.5%), lipid profile, and CKD (i.e., eGFR <60) between different practices. We evaluated percentage of liver related vs. non-liver related ambulatory care presentations and hospitalizations. We used appropriate statistical methods with two tailed tests in our analyses.
Results: In 2,138 hepatitis B patients (median age 41 y [IQR 33–53], 53% male), the median ALT was 27 (in 93% tested), median HBV DNA 2.4 log IU/ml (in 83% tested), and the majority of those with available HBeAg status (737/2,138) tested HBeAg negative (83%). Overall 5.5% had elevated HBA1C, 2.6% had eGFR <60, and most showed normal lipid profile (median TC, LDL, HDL, TGL was 4.5, 2.6, 1.3, 1.0mmol/l respectively). During the 4-year period, 27% (584/2138) were hospitalized (median length of stay 3 days) but only 10% of hospitalizations were liver related (51/584). Only 13% of ambulatory care visits were liver related (4,710/31,659). Compared to non-liver related admission, CHB patients admitted with liver related causes were older (53 vs 36, $p < 0.01$), male (77% vs. 27%) and had lower eGFR (74 vs. 99, $p < 0.01$) but similar HBA1C and Lipid profile. The rates of liver related admission and ambulatory visits varied per type of specialist care ($p = 0.03$).
Conclusions: In our large cohort of CHB patients, only a small proportion had liver related ambulatory visits or hospitalizations. Older age, male gender and lower kidney function was more common in those with liver related admissions. Additional long-term prospective cohort data is important to determine disease trends for hepatitis B patients in Canada.

FRI-308

Can pre-core region mutations distinguish between HBeAg negative genotype A1 and A2 patients with similar HBV DNA viral load levels?

N. Bolton, M. Bruce, M. Horner, E. Gonsalkorala, G. Dusheiko, K. Agarwal, I. Carey. *Institute of Liver Studies, King's College Hospital, London, United Kingdom*
Email: ivana.kraslova@kcl.ac.uk

Background: A pilot study assessing HBcrAg and HBsAg plasma concentrations in HBeAg negative genotype A patients demonstrated that genotype A2 patients have higher HBcrAg and HBsAg levels than A1 patients despite similar HBV DNA levels. While HBsAg originates from cccDNA and integrated DNA and is encoded by pre-S/S gene, HBcrAg is a new serological marker and combines antigenic reactivity against HBeAg, HBV core antigen and core-related protein (p22cr), and is encoded by pre-core/core gene and can be detected by commercially available assay (Luminex G®, Fujirebio). It is not clear whether mutations within pre-core region (basal core promoter = BCP and pre-core stop codon = PC) can explain this difference in HBcrAg and HBsAg levels between genotypes A1 and A2.
Aims: We aimed to compare the frequency of BCP (A1762T/G1764A) and PC (G1896A) mutations between genotype A1 and A2 HBeAg negative patients matched by HBV DNA.
Method: Plasma samples from 40 HBeAg negative genotype A HBV infected patients (20 patients with genotype A1 vs. 20 patients with genotype A2) (median age 38 years) matched according to HBV DNA (20 patients with HBV DNA <2,000 IU/ml vs. 20 patients with HBV DNA > 20,000 IU/ml) were quantified for HBsAg levels by Abbott Architect® [IU/ml], and HBcrAg by Luminex G® assay [$\log_{10}$U/ml]. The detection of BCP and PC variants was carried out using the INNO-LiPA® line probe assay and confirmed by the direct population sequencing.
Results: Median HBV DNA levels were similar between A1 and A2 (5,400 IU/ml vs. 2,590 IU/ml, $p > 0.05$), in contrast median HBsAg levels were lower in genotype A1 than genotype A2 patients (4,614IU/ml vs. 11,422.5 IU/m, $p = 0.02$) and median HBcrAg concentrations tended to be lower in A1 patients (2.05 $\log_{10}$U/ml vs. 2.8 $\log_{10}$ U/ml, $p = 0.08$). Eight genotype A1 patients (40%) and 4 patients with genotype A2 (20%) possessed the BCP dual variant A1762T/G1764A, while more A2 patients (6 = 30%) than A1 patients (2 = 10%) had the G1896A PC variant. There was no significant association with presence of PC and/or BCP variants with high HBsAg, HBcrAg or HBV DNA levels.
Conclusion: BCP variants (A1762T/G1764A) were more prevalent in A1 patients, whereas PC variants (G1896A) were more frequent in A2 genotype HBeAg negative patients. HBsAg level was significantly higher in A2 patients, although this did not associate considerably with presence of PC and/or BCP variants. Further studies focussing on the pre-S/S region might add more clarity to the dissociation in HBsAg levels between genotype A1 and A2.

FRI-309

Switching immunoglobulin base therapy to nucleoside/nucleotide analogues monotherapy is safe and effective as preventive therapy of reccurent HBV in liver transplanted patients- single centre experience

O. Sneh[1,2], M. Cohen-Naftaly[2,3], Y. Harif[3], A. Issachar[2,3], E. Mor[2,4], R. Tur-Kaspa[1,5], M. Brown[1,6]. *[1]Liver Institute, Rabin medical center, Beilinson hospital, petach tikva, Israel; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, Israel; [3]Liver Institute, Rabin medical center Beilinson hospital, Petach-Tikva, Israel; [4]Rabin medical center beilinson hospital, organ transplantation department; [5]Bar Ilan unviersity, Israel; [6]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel*
Email: orlysneh@gmail.com

Background and Aims: Hepatitis B is common indication for liver transplantation. The recurrence rate of HBV after transplantation decreased dramatically during the 80s due to prophylactic therapy including hepatitis B immunoglobulin(HBIg), and in the introduction of nucleoside/nucleotide (Nuc) analogues reduced the recurrence rates even further. Several studies from Asia demonstrated the effectiveness of 3rd generation Nuc analogues at preventing HBV reactivation after liver transplantation when used as monotherapy. Published data on cessation of HBIg from western world are rather scarce. We aimed to determine the long-term efficacy of nucleot(s)ide monotherapy after cessation of HBIg prophylaxis in patients transplanted due to complications of HBV infection with regard to recurrence of hepatitis, viral replication, and survival.
Method: This is a retrospective study on a prospectively maintained data base. In 2013 we established criteria for interruption of HBIg in liver transplant patients as following- good compliance, at least 2 y post liver transplantation, normal liver function tests, HBeAg negative, viral load less than 2,000 IU/ml at transplantation, undetectable HBV DNA in serum during follow up. The anti-viral therapy had been switched in patients who have been on lamivudine to entecavir or tenofovir.
Results: More than 600 patients were transplanted in our centre, 84 due to HBV. 19 patients were eligible for monotherapy according to the predefined criteria. Six patients were Anti HDV positive and five were transplanted due to HCC. The patients were treated with dual therapy for an average of 8.3+/−4.5y. Twelve patients were treated with lamivudine with negative serum HBV DNA before switching to the newer Nucs. At the time of HBIg cessation, 15 patients treated with entecavir and 4 with tenofovir. During a mean follow up of 3.3+/−1.4 years after HBIG discontinuation there were no hepatitis flares, none of the patients had HBV DNA in serum during follow up, but one of the patients has detectable HBsAg. Two patients had detectable HBsAb, two years after the HBIG was discontinued.
Conclusion: Switching to monotherapy with Nuc analogous in a selected Caucasian population is feasible and is associated with excellent clinical results in liver transplant population including HCC patients and HBV/HDV co-infected patients.

FRI-310

Use of noninvasive biomarkers to assess fibrosis regression in cirrhotic patients during nucleos(t)ide therapy

C. Pan[1], N. Izumi[2], P. Angus[3], A. Duseja[4], E. Nurmukhametova[5], R. Balabanska[6], T. Nguyen[7], J. Yang[8], L. Lin[8], A. Gaggar[8], J.F. Flaherty[8], M. Subramanian[8], S. Ryder[9], W.-L. Chuang[10], P. Marcellin[11]. *[1]NYU Langone Medical Center, NYU School of Medicine, New York, NY, USA; [2]Japanese Red Cross Musashino Hospital, Tokyo, Japan; [3]Austin Health, Heidelberg, Victoria, Australia; [4]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [5]Infectious Clinical Hospital #1 of Moscow Healthcare Department, Moscow, Russia; [6]Tokuda Hospital, Sofia, Sofiya, Bulgaria; [7]Research and Education, Inc., San Diego, CA, USA; [8]Gilead Sciences, Inc., Foster City, CA, USA; [9]Nottingham University Hospital, Nottingham, England, UK; [10]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [11]Université Paris Diderot, Hôpital Beaujon, Clichy, France*
Email: cpan100@gmail.com

Background and Aims: Noninvasive serum biomarkers for the assessment of liver fibrosis are used in monitoring fibrosis progression in CHB patients. However, limited data is available on the usefulness of these biomarkers in evaluating regression of fibrosis in CHB patients with advanced fibrosis or cirrhosis. The aim of this study is to evaluate commonly used and novel serum biomarkers as a tool in monitoring regression of fibrosis in CHB patients with advanced fibrosis on NUC therapy.
Method: Data from patients with baseline FibroTest score ≥0.75 were pooled across 2 Phase 3 studies evaluating TAF and TDF (GS-US-320–0108 and GS-US-320-0110). Differences in noninvasive biomarkers were evaluated using descriptive statistics of absolute and change from baseline at Weeks 48 and 96 in all patients. Effect of liver inflammation on the noninvasive biomarkers was evaluated in a subgroup analysis between patients with normal and abnormal ALT per AASLD criteria at Week 48. Noninvasive biomarkers evaluated include: FibroTest®, AST-to-platelet ratio index (APRI), fibrosis index based on four factors (FIB-4). Additional analysis using enhanced liver fibrosis panel (ELF), and plasma collagen type III (Pro-C3) will be presented.
Results: 118 patients had FibroTest score ≥0.75 at baseline. The mean (SD) absolute values for FibroTest, APRI, and FIB-4 at Weeks 48 and 96 are shown in the Table. All biomarkers showed an improvement (decline) from baseline at Weeks 48 and 96, with the greatest decline occurring during the first 48 weeks. At week 48, 49 patients had normal ALT and 59 patients had abnormal ALT. Patients with normal ALT had numerically lower FibroTest, FIB-4, and APRI at Week 48 compared to those with abnormal ALT. Patients with abnormal ALT at Week 48 had a greater improvement in fibrosis biomarkers from Week 48 to Week 96 compared to those with normal ALT with mean (SD) FIB-4 of -0.22 (0.81) and APRI of −0.08 (0.60).
Conclusion: Improvement observed with FibroTest, FIB-4, and APRI during the first 48 weeks of initial therapy may over estimate improvement of fibrosis and instead show the impact of liver inflammation. Assessment of these biomarkers compared to ELF and Pro-C3 will be presented.

Table: Serum Marker for Fibrosis in Overall Population and Subset of Patients Stratified by ALT Levels at Weeks 48 and 96

Mean (SD) Absolute Value	FibroTest	FIB-4	APRI
Overall	n = 118	n = 111	n = 111
Baseline	0.84 (0.06)	3.71 (2.31)	2.40 (1.95)
Week 48	0.70 (0.17)	2.23 (1.32)	0.71 (0.55)
Week 96	0.70 (0.17)	2.02 (1.28)	0.63 (0.73)
Normal ALT at Week 48	n = 49	n = 48	n = 48
Week 48	0.63 (0.18)	1.86 (0.95)	0.44 (0.27)
Week 96	0.63 (0.19)	1.79 (1.16)	0.41 (0.28)
Abnormal ALT at Week 48	n = 58	n = 56	n = 58
Week 48	0.76 (0.13)	2.55 (1.50)	0.94 (0.61)
Week 96	0.75 (0.12)	2.15 (1.24)	0.80 (0.91)

Email: sandrocferreira@terra.com.br

Background and Aims: HLA-G is a non-classical class I histocompatibility molecule with well-recognized immunomodulatory properties, frequently expressed in the livers of hepatitis B virus (HBV)-infected patients. We evaluated the genetic diversity of *HLA-G* 3′ untranslated region (3′UTR) and associated polymorphic sites and its association with the expression of HLA-G in liver biopsies and the severity of liver injury in patients with chronic hepatitis B.
Method: Polymorphic sites at 3′UTR (14bp DEL/INS, +3001C/T, +3003C/T, +3010C/G, +3027A/C, +3032G/C, +3035C/T, +3142C/G, +3187A/G, +3196C/G and +3227G/A) were characterized by sequencing analyses in blood samples of 106 chronic HBV-infected patients and 157 healthy individuals. The immunohistochemistry expression of HLA-G was performed on 106 liver biopsies in patients with chronic hepatitis and classified as mild, moderate or intense according to the pattern of HLA-G tissue expression.
Results: The frequencies of the +303 T allele (p = 0.022) and the +303 TT genotype (p = 0.042) were overrepresented and the +3187 A allele (p < 0.001) and +3187 AA genotype (p < 0.001) were underrepresented in HBV-infected patients when compared to healthy controls. The frequencies of UTR-1 (p = 0.001) and UTR-4 (p = 0.034) haplotypes were respectively over and underrepresented in in HBV-infected patients. The frequencies of the 14 bp DEL/DEL (p = 0.046) and the +3010 GG genotypes (p = 0.026) were significantly increased in the group of patients with mild fibrosis when compared to patients with severe fibrosis/cirrhosis. The +3003 T allele (p = 0.034) and +3003 TT genotype (p = 0.028) were overrepresented in patients with severe liver fibrosis. The frequencies of the 14bp DEL allele (p = 0.047) and the 14bp DEL/DEL genotype (p = 0.034) were significantly increased in liver samples with mild HLA-G expression when compared to those with intense HLA-G expression. On the other hand, the allele +3142 G (p = 0.007), genotype +3142 GG (p = 0.034), allele +3010C (p = 0.004) and genotype +3010 CC (p = 0.015) were significantly associated with intense HLA-G expression. The UTR-4 haplotype (p = 0.034) was significantly associated with mild HLA-G expression.
Conclusion: *HLA-G* 3′UTR polymorphisms were associated with the magnitude of HLA-G expression in the liver and with severity of liver injury in HBV-infected patients.

Prophylactic antiviral therapy for the prevention of mother-to-child transmission of hepatitis B virus can be stopped at delivery
Q.-L. Zeng[1], G.-H. Xu[2], B. Wang[3], Z.-Q. Li[1], Z.-J. Yu[1]. *[1]Department of Infectious Diseases and Hepatology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou 450052, Henan Province, China; [2]Department of Infectious Diseases, The Affiliated Hospital of Yan'an University, Yan'an 716000, Shaanxi Province, China; [3]Department of Gynaecology and Obstetrics, Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing 102218, China*
Email: 15838120512@163.com

Background and Aims: Many studies have demonstrated that antiviral therapy has an important role in the prevention of mother-to-child transmission of hepatitis B virus (HBV). However, three Regional HBV Guidelines recommend various stopping time points of therapy.
Method: In our observational retrospective study, 35 immune-tolerant pregnant women received telbivudine at week 28 of gestation, and discontinued at delivery, month 1, and month 3 postpartum, respectively (Table 1). All the newborns received 200 IU of hepatitis B immune globulin and 10 μg of the HBV vaccine

Table 1 (abstract: FRI-312): Characteristics of the mothers and infants

Characteristic	Group 1 (n = 12)	Group 2 (n = 12)	Group 3 (n = 11)
Age (years)	25.3 ± 4.7	24.8 ± 5.3	26.2 ± 4.0
Maternal HBV DNA levels (log_{10}IU/ml)			
Gestational week 28	7.8 ± 0.7	8.0 ± 0.7	7.9 ± 0.7
At delivery	5.6 ± 0.7	5.7 ± 0.6	5.5 ± 0.7
Postpartum month 1	n.d.	4.7 ± 0.3	4.9 ± 0.6
Postpartum month 3	n.d.	n.d.	3.8 ± 0.5
Postpartum month 7	8.0 ± 0.7	8.0 ± 0.6	7.9 ± 0.4
HBV DNA reduction at delivery	2.3 ± 0.5	2.4 ± 0.6	2.4 ± 0.7
<200,000IU/ml at delivery, n (%)	4 (33.3)	4 (33.3)	3 (27.3)
Maternal ALT levels (U/l)			
Gestational week 28	22.9 ± 7.4	24.9 ± 9.8	27.1 ± 7.7
At delivery	20.7 ± 8.5	17.6 ± 7.3	22.1 ± 9.4
Postpartum month 1	n.d.	23.2 ± 10.7	26.5 ± 10.1
Postpartum month 3	n.d.	n.d.	17.0 (12.0–37.0)
Postpartum month 7	20.0 (14.8–38.3)	24.1 ± 11.1	26.6 ± 13.5
Infant characteristics at birth			
Number of infants	12	12	11
Gestational age (weeks)	38.2 ± 1.4	38.8 ± 1.2	38.9 ± 1.3
Delivery by means of C-section, n (%)	7 (58.3)	6 (50.0)	6 (54.5)
Breast feeding for the first six months, n (%)			
Exclusive breast feeding	8 (66.7)	9 (75.0)	8 (72.7)
Mixed feeding	3 (25.0)	1 (8.3)	2 (18.2)
Artificial feeding	1 (8.3)	2 (16.7)	1 (9.1)
Infant characteristics at month 7			
Detectable HBV DNA, n (%)	0 (0)	0 (0)	0 (0)
Positive HBsAg, n (%)	0 (0)	0 (0)	0 (0)
ALT (U/l)	18.0 (12.3–29.5)	20.1 ± 7.4	19.9 ± 5.3

ALT, alanine aminotransferase; C-section, cesarean section; HBsAg, Hepatitis B surface antigen; HBV, hepatitis B virus; n.d., no data. When the data had normal distributions, they were presented as mean ± standard deviation; and for abnormal distributions, median (inter-quartile range) was used.

intramuscularly within 12 hours after birth, and 10 μg of HBV vaccine at months 1 and 6, respectively. The primary outcome was the rate of mother-to-child transmission at 7 months old.
Results: The durations of telbivudine treatment before delivery were 10.2 ± 1.4, 10.8 ± 1.2, and 10.9 ± 1.3 weeks in groups 1, 2, and 3, respectively (Table). The overall percentage of mothers who had an HBV DNA level of <200,000 IU/ml at delivery was 31.4% (11/35). At month 7, no infants had HBV viremia or were hepatitis B surface antigen-positive.
Conclusion: Conclusively, antiviral prophylaxis in immune-tolerant pregnant women can be stopped at delivery based not only on current study but also at least in part on the pharmacoeconomic concerns; and future validation studies are needed.

FRI-313
Validation of AASLD treatment guideline eligibility based on disease outcomes of large community and clinical cohorts of chronic hepatitis B patients

D.H. Lee[1,2], A. Le[2], M. Chung[2,3], V.H. Nguyen[2,4], T. Johnson[2,4], F. Ji[2,5], E. Ogawa[2,6], H.N. Trinh[7], J. Zhang[8], C. Wong[9], C. Wong[9], J. Li[10], H.-I Yang[11], M. Nguyen[12]. *[1]Good Gang-An Hospital, Internal Medicine, Korea, Rep. of South; [2]Stanford University, Division of Gastroenterology and Hepatology, United States; [3]Princeton University, United States; [4]University of California, Berkeley, United States; [5]The Second Affiliated Hospital of Xi' an Jiaotong University, Infectious Disease, China; [6]General Internal Medicine, Japan; [7]San Jose Gastroenterology, United States; [8]Chinese Hosiptal, United States; [9]Wong Clinic, United States; [10]Palo Alto Medical Foundation, United States; [11]Academia Sinica, Genomics Research Center, Taiwan; [12]Stanford University, Division of Gastroenterology and Hepatology, United States*
Email: mindiehn@stanford.edu

Background and Aims: The ultimate goal of treatment in chronic hepatitis B patients (CHB) patients is to improve quality of life and survival by preventing progression of the disease. However, treatment decision by current guidelines is based on surrogate tests, such as ALT and HBV DNA. Therefore, it remains unclear whether current guidelines can adequately identify patients who will benefit from treatment to avoid adverse outcomes in the long term.
Method: A total of 5,030 CHB patients from a US cohort of 6 academic and community clinical centers and 3,653 patients from the community-based Taiwanese REVEAL-HBV cohort were included. Exclusion criteria were age <18years, HCV/HIV/HDV co-infection, <1year of follow-up and prior treatment. We initially captured patients who developed adverse outcomes. In the US cohort, these were defined as HCC, cirrhosis and/or liver-related death and in the Taiwan cohort, HCC and/or liver cirrhosis were captured. Utilizing AASLD 2015 CHB treatment guideline, we evaluated patient eligibility for antiviral treatment at baseline and during follow-up.
Results: In the US cohort, a total of 202 patients developed adverse outcomes. Among these patients, 39.6% (80/202) were treatment ineligible at baseline (Figure). Of these, 63.8% (51/80) remained ineligible on median follow-up time of 5.7 years. In total, 25.2% (51/202) never met treatment criteria prior to development of adverse events. In the Taiwan cohort, with a longer median follow-up of 16.8 years, 476 patients or 13.1% developed adverse outcomes. In these patients, 86.3% (411/476) were treatment ineligible at baseline and 24.1% (99/411) of these patients remained ineligible on follow-up. A total of 20.8% (99/476) never met treatment criteria.
Conclusion: We found that close to half of patients who developed adverse outcomes did not meet guideline treatment criteria at presentation and one quarter never met guideline criteria prior to development of adverse events among patients at US clinical centers. In the population based community cohort from Asia, we found even higher rates of baseline treatment eligibility and one-fifth never met guideline criteria on follow-up. Current treatment guidelines should thus address patients who progress to serious liver related complications.

Association between hepatic steatosis and the development of hepatocellular carcinoma in patients with chronic hepatitis B

Y.B. Lee, Y. Ha, Y.E. Chon, M.N. Kim, J.H. Lee, H. Park, K.S. Rim, S.G. Hwang. *CHA Bundang Medical Center, CHA University, Department of Internal Medicine, Seongnam, Korea, Rep. of South*
Email: yunbin@hanmail.net

Background and Aims: As nonalcoholic fatty liver disease becomes a worldwide epidemic, hepatic steatosis has been frequently demonstrated in chronic hepatitis B patients without excessive alcohol intake. Whether presence of hepatic steatosis in these patients is associated with higher risk of developing hepatocellular carcinoma (HCC) has not been well established. We investigated the impact of histologically proven hepatic steatosis on the risk of HCC development.
Method: Chronically hepatitis B virus-infected patients without significant alcohol consumption, who underwent liver biopsy from January 2007 to December 2015 in a single centre, were consecutively included. Patients were categorised into two groups according to the presence or absence of hepatic steatosis ≥ 5%, and the association of steatosis with subsequent HCC risk was analysed. To adjust for differences in patient characteristics including metabolic features, inverse probability weighting (IPW) using propensity scores was used.
Results: Hepatic steatosis was histologically proven in 70 patients (21.8%) among a total of 321 patients. During the median (interquartile range) follow-up of 5.3 (2.9–8.3) years, 17 of 321 patients (5.3%) developed HCC: 9 of 251 patients (3.6%) without steatosis and 8 of 70 patients (11.4%) with steatosis. The 5-year cumulative incidences of HCC were 1.9% and 8.2% among patients without steatosis and with steatosis, respectively (p = 0.004) (Figure A). Steatosis was associated with higher risk of HCC development (adjusted hazards ratio [HR], 3.005; 95% confidence interval [CI], 1.122–8.051; p = 0.029). After balancing with IPW, the incidences of HCC were not significantly different between the groups (p = 0.187) (Figure B), and the association between steatosis and HCC development was not significant (adjusted HR, 2.292; 95%CI, 0.693–7.587; p = 0.17).
Conclusion: Hepatic steatosis was associated with higher risk of developing HCC in patients with chronic hepatitis B. However, the association of steatosis per se with HCC development was not evident after adjustment for metabolic characteristics.

FRI-315
Quantitative Hepatitis B surface antigen in different phases of Vietnamese chronic HBV infected patients

H. Nguyen, H. Pham. *University of Medicine and pharmacy at Ho chi Minh city, Infectious diseases, Ho Chi Minh, Viet Nam*
Email: camhuong37@yahoo.com

Background and Aims: Quantitative serum HBsAg has been considered as a marker that reflects the effect of immune clearance on HBV in chronic hepatitis B patients (CHB). Serum HBsAg level

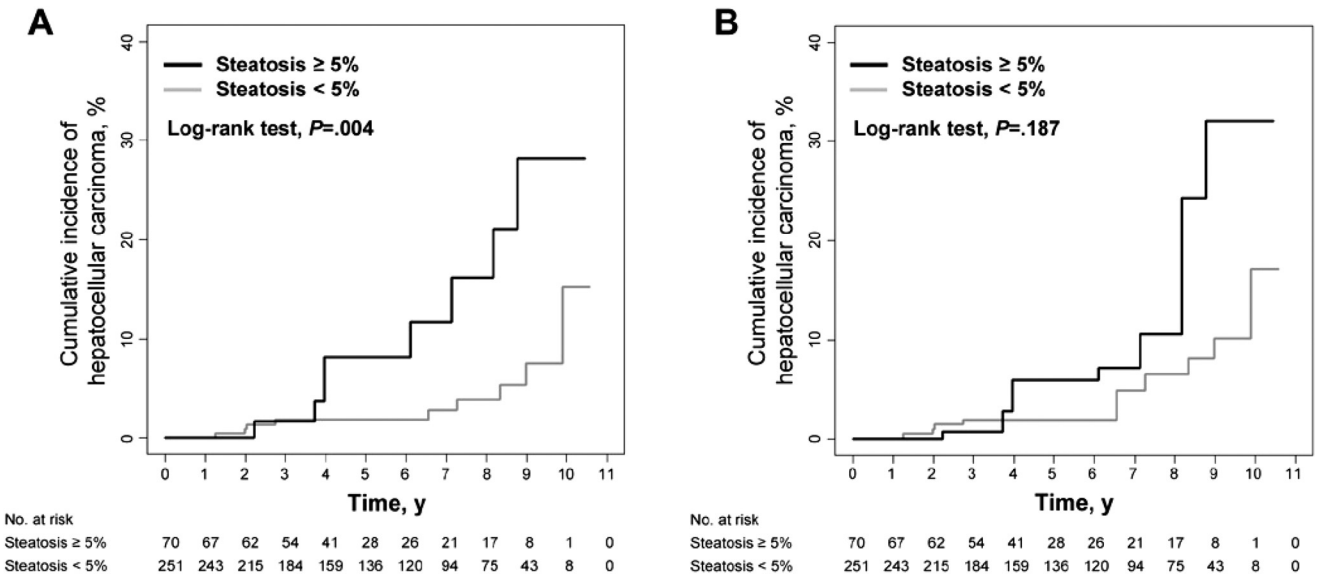

Figure 1: FRI-314

varies in different phases of infection and by genotypes. We aimed to investigate serum HBsAg levels and its correlations with HBVDNA in different phases of Vietnamese CHB.

Method: 450 CHB treatment naïve patients (187 genotype B and 113 genotype C) were recruited in this cross-sectional study. Patients were categorized into 6 groups: Chronic HBV infection HBeAg positive (HBIe+, n = 48), Chronic hepatitis B HBeAg positive (CHBe+, n = 66), Chronic HBV infection HBeAg negative (HBIe- n = 98), Chronic hepatitis B HBeAg negative (CHBe- n = 103), Cirrhosis (n = 63) and HCC (n = 72). The serum HBsAg was measured by ECLIA, using Elecsys HBsAgII kit (Roche). Correlations between HBsAg and HBVDNA were analyzed by Spearman's Rho correlation.

Results: There was no difference of HBsAg levels between genotype B and C. The median HBsAg titers were different between phases of CHB ($p < 0.001$) and significantly higher in HBeAg (+) than that in HBeAg (-) patients. The highest HBsAg level and the narrowest distribution was found in HBIe+ (4.6 log 10 IU/ml), lower in CHBe+ (3.83 log 10 IU/ml), HBIe- (2.8 log 10 IU/ml) and in CHBe- (3.11 log 10 IU/ml), cirrhosis (2.96log10IU/ml) and HCC (3.01log10IU/ml). There were significant correlations between HBsAg and HBVDNA levels in the overall population ($r = 0.572$, $p < 0.001$); The moderate correlations were found in CHBe+ ($r = 0.434$, $p < 0.001$), CHBe- ($r = 0.417$, $p < 0.001$) and HBIe- ($r = 0.393$, $p = 0.002$); The weak correlation was found in HBIe+ ($r = 0.299$, $p = 0.039$) and in the HCC groups ($r = 0.277$, $p = 0.049$). There was not significant correlation between HBsAg and HBVDNA in the cirrhosis group. The ratios of HBsAg/HBVDNA were all distributed around 0.5. Interestingly, the HBIe- group had a widest distribution of HBsAg values and had more cases with high HBsAg values that contributed for the highest ratio of HBsAg/HBVDNA (0.86).

Conclusion: Our study demonstrated that serum HBsAg levels were significantly different in natural phases of chronic HBV infection and was a helpful marker for immune activation; HBsAg were significantly correlated with HBVDNA in all CHB phases but not well correlated in the CHB patients with HCC and cirrhosis. The wide distribution of HBsAg in the HBIe- group suggested the existence of non cccDNA source of HBsAg (the integration source) in this phase.

FRI-316

HBeAg negative chronic hepatitis B patients with HBV-DNA levels between 2,000–20,000IU/ml and normal aminotransferases are really inactive?

B. Ergül[1], Özlem Gül Utku[1], Barış Yılmaz[2], Hüseyin Köseoğlu[2], D. Oğuz[1]. *[1]Kırıkkale University Faculty of Medicine, Gastroenterology, Kırıkkale, Turkey; [2]Hitit University Faculty of Medicine, Gastroenterology, Çorum, Turkey*
Email: bilalergul@gmail.com

Background and Aims: Hepatitis B virus is one of the most important causes of chronic hepatitis, cirrhosis and liver cancer. It is estimated that more than 350 million people are infected worldwide. International guidelines recommend performing biopsy and beginning antiviral therapy to HBeAg negative chronic hepatitis B with HBV-DNA ≥ 2,000 IU/ml and elevated ALT levels. But, datas are limited about HBeAg negative chronic hepatitis B patients with HBV DNA between 2,000 and 20,000 IU/ml and persistently normal ALT levels.

Method: In this study, files of patients who were biopsied due to chronic hepatitis B in Kırıkkale University Faculty of Medicine, Hitit University Faculty of Medicine, Ahi Evran University Training and Research Hospital and Çankırı State Hospital Gastroenterology Clinics between January 2014 and May 2017 were retrospectively evaluated. *Patients were included* in the *study* according to the following criteria: HBeAg negative chronic hepatitis B patients with HBV DNA between 2,000–20,000 IU/ml and persistently normal ALT levels. Persistently normal ALT was defined as 4 consecutive ALT values within a period of 12 months. Exclusion criterias are as follows: history of antiviral therapy, HCV or HDV coinfection, history of cirrhosis or hepatocellular carcinoma and pregnancy. Liver biopsy specimens were evaluated according to Ishak scoring system. Antiviral therapy was started if fibrosis stage ≥2 and/or HAI ≥6.

Results: A total 130 patients were enrolled. The mean age of the study population (72 female, 58 male) was 45.98 (21–73). These patients had a mean ALT: 24.7 (7–40) IU/l, AST: 22.5 (10–38)IU/l, HBsAg: 6342 (1789–10600), HBV-DNA: 8061 (2186–20000)IU/ml. Ninety-seven patients (74.6%) had fibrosis stage ≥ 2 and/or HA ≥6. Of the 33 patients whose treatment could not be started, 21 were over 40 years old (21/91) and 12 were under 40 years old (12/39). There was no significant difference between the rates of treatment initiation of patients older than 40 or under 40 years ($p = 0.35$). HBV-DNA was

found to be 8458 (± 579) IU/ml in the treatment group and 6892 (± 793)IU/ml in the untreated group, and no significant difference was detected between the groups in terms of HBV-DNA (p = 0.11).
Conclusion: Pathological examination of liver biopsies revealed that 74.6% of the patients had significant liver damage and treatment was started. Liver biopsy which is the gold standard method in evaluating chronic hepatitis and fibrosis should be performed for HBeAg negative chronic hepatitis B patients with HBV-DNA levels between 2,000–20,000 IU/ml even though transaminase levels were within normal limits.

FRI-317

Which pregnancy biomarkers predict post-delivery ALT flares in mothers with chronic hepatitis B?

S. Imbert[1], M. Bruce[2], S. Montague[2], M.-A. Mcleod[2], T. Bowyer[2], M. Horner[2], G. Dusheiko[2], K. Agarwal[2], I. Carey[2]. *[1]King's College London, Institute of Liver Studies, London, United Kingdom; [2]King's College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: salome.imbert@kcl.ac.uk

Background: Chronic Hepatitis B (CHB) is an immune mediated disease and the interaction of the virus with the immune system determines its outcome. While pregnancy induces immune tolerance, post-delivery phase is characterised by the immune system reconstitution and ALT flares in 30% of CHB patients. There are no clear in-pregnancy non-invasive markers to predict post-delivery ALT flares. CXCL10 (IP-10) is a chemokine produced by innate immune system within the liver and high plasma levels reflect liver necroinflammation and predict HBeAg seroconversion or HBsAg decline/loss. Hepatitis B core-related antigen (HBcrAg) is a novel serological marker combining antigenic reactivity against HBeAg, HBV core Ag and core-related protein (p22cr) and reflects cccDNA transcriptional activity.
Aims: In this single centre cross-sectional study we explored whether non-invasive markers at 2nd pregnancy trimester including IP-10 and HBcrAg can predict post-delivery ALT flares.
Methods: 201 pregnant CHB patients with plasma samples at 2nd pregnancy trimester (median gestation 26 weeks) and known ALT levels after delivery (median 75 days) were enrolled: 74 patients required therapy with tenofovir (34 due to liver disease & 40 to prevent transmission); 127 patients were therapy naïve. Plasma levels of IP-10 by ELISA [pg/ml], HBV DNA by TaqMan PCR [IU/ml], HBeAg status and HBsAg by Abbott Architect® [IU/ml] and HBcrAg on Luminex G [$\log_{10}$U/ml] were quantified and HBV genotypes were determined by direct sequencing.
Results: 54/201 (27%) patients had post-delivery ALT flares (ALT > 38I U/l and 2-fold increase from pregnancy level) and these were predominant in genotype B & C patients (genotype B&C: 60% = 31/52 vs. genotype A, D & E: 15% = 23/149, p < 0.01). 54 patients were HBeAg positive and had more flares than HBeAg negative (44% = 24/54 vs. 20% = 30/147, p < 0.05, OR 6.12). Pregnancy ALT, HBV DNA and HBsAg did not differ between flare and no flare patients, but flare patients had higher IP-10 and HBcrAg concentrations (medians IP-10: 66.6 vs. 16.7 pg/ml, p < 0.01; HBcrAg: 4.2 vs. 2.65 $\log_{10}$U/ml p < 0.01). When untreated and treated patients were assessed separately; HBV genotypes, HBeAg status, IP-10 and HBcrAg levels differed between no flare and flare patients. For those treated: 36 patients had HBV DNA >200,000 IU/ml; this was associated with more flares (44% = 16/36) than patients with low HBV DNA (23% = 38/165), p < 0.01, OR 2.63. ROC analysis confirmed that plasma IP-10 pregnancy levels were a good predictor (AUROC = 0.82, p < 0.01) and HBcrAg levels were a fair predictor (AUROC = 0.69, p < 0.01).
Conclusions: Pregnancy HBcrAg levels > 5$\log_{10}$ U/ml (OR 3.43, p < 0.01) and IP-10 levels >80 pg/ml predicted post-delivery flares (OR 100.69, p < 0.01) and can act as good non-invasive biomarkers allowing tailored management of CHB in the context of pregnancy. Larger validation studies to confirm the utility of these markers are required.

FRI-318

Adherence to AASLD treatment guidelines on treatment initiation among treatment-eligible patients with chronic hepatitis B: Experiences from primary care and referral practices

V.H. Nguyen[1,2], A. Le[1], M. Chung[1], T. Johnson[1,2], B. Levitt[3], H. Nguyen[3], K. Nguyen[3], H. Trinh[3], C. Wong[4], C. Wong[4], J. Zhang[5], J. Li[6], G. Garcia[1], M. Nguyen[1]. *[1]Stanford University Medical Center, Division of Hepatology and Gastroenterology, Palo Alto, United States; [2]University of California, Berkeley; [3]San Jose Gastroenterology, San Jose, United States; [4]Wong Clinics, San Francisco, United States; [5]Chinese Hospital, San Francisco, United States; [6]Palo Alto Medical Foundation, Gastroenterology, Mountain View, United States*
Email: mindiehn@stanford.edu

Background and Aims: The American Association for the Study of Liver Diseases (AASLD) treatment guidelines for chronic hepatitis B (CHB) patients have changed over time. We aimed to assess the rate of optimal evaluation, treatment eligibility, and treatment initiation for CHB patients in various practice settings in the United States (US).
Method: This was a retrospective cohort study of 4,130 consecutive, treatment-naïve patients with CHB by community primary care physicians (PCP) (n = 616), community gastroenterologists (GI) (n = 2,251), and university hepatologists (n = 1,263) from January 2002 to December 2016. Eligibility was defined by the AASLD criteria and adjusted based on changes over time of the criteria for three lab tests: alanine aminotransferase (ALT), hepatitis B e antigen (HBeAg), and hepatitis B virus (HBV) DNA. Eligibility was assessed in the first 6 months of follow-up. Eligible patients was treated if they were on treatment by 12-month follow-up. The follow-up period was up to 5 years.
Results: By 6-month follow-up, 36.69% of patients had all three lab tests in PCP group, 59.80% in GI, and 79.97% in hepatology (p < 0.0001). All three groups had low eligibility rates:12.76% in PCP group, 24.96% in GI, and 29.43% in hepatology (p < 0.0001). Treatment rates were 38.71% in PCP group, 55.65% in GI, and 57.90% in hepatology (p < 0.0001). Being male (OR: 1.40, 95% CI: 1.09–1.79, p = 0.008); referral to hepatologists (OR: 2.58, 95%CI: 1.45–4.59, p = 0.001); and having positive HBeAg (OR: 1.87, 95%CI: 1.14–3.05, p = 0.013) were the strongest predictors for treatment initiation. Of 3,018 CHB patients who were initially treatment-ineligible, 8.98% became eligible in PCP group, 22.95% in GI, and 14.14% in hepatology (p < 0.0001). Of these patients, hepatology had the highest treatment rate of 81.97%, followed by GI with 61.54%, and lowest in PCP group with 23.91% (p < 0.0001). The strongest predictors for treatment initiation were male gender (HR:1.42, 95%CI 1.06–1.90, p = 0.017); referral to community GI (HR: 3.03, 95%CI: 1.11–8.24, p = 0.03); and having an elevated HBV DNA level (HR: 1.17, 95%CI: 1.04–1.20, p = 0.004). Cumulative incidence of treatment initiation via Kaplan-Meier methods showed higher treatment initiation in GI and hepatology group compared to PCP group in follow-up period (p = 0.006).
Conclusion: The overall treatment rates by 12-month follow-up after diagnosis and in long-term follow-up were significantly low especially for treatment-eligible patients seen by primary care physicians.

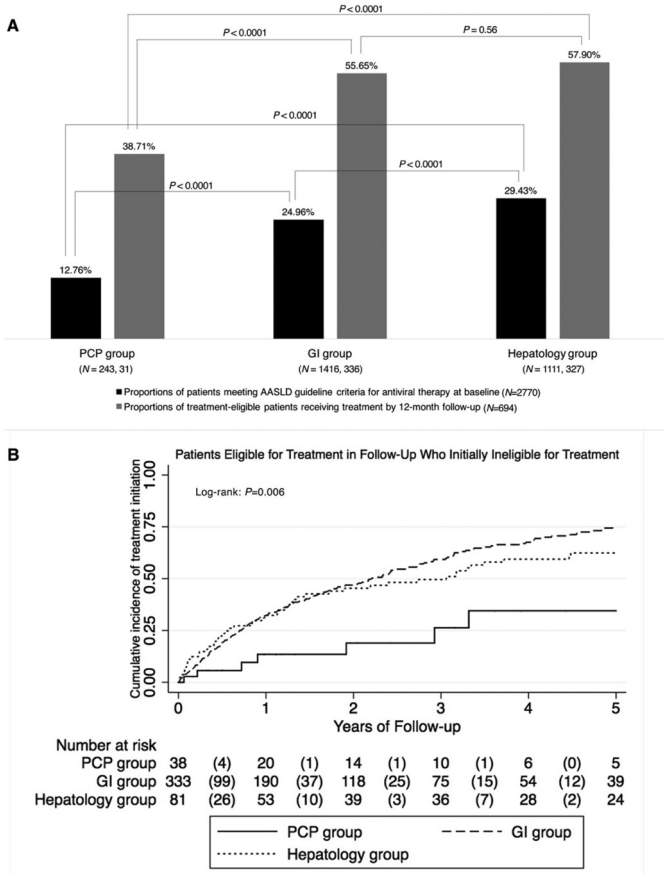

Figure (A) Proportions of eligible patients by 6-month follow-up (n = 2770) and proportions of eligible patients receiving treatment by 12-month follow-up (n = 694); (B) Cumulative incidence of treatment initiation during follow-up by practice settings(n = 452)

Viral hepatitis B/D: Therapy

Durability of HBsAg loss during or after antiviral treatment in a predominantly middle European collective

G. Teuber[1], M. Sprinzl[2], D. Hüppe[3], R. Heyne[4], W.P. Hofmann[5], M. Cornberg[6], S. Arne[7], J. Petersen[8]. *[1]Praxis PD Dr. med. G: Teuber, Frankfurt/M, Germany; [2]UNI-Klinikum, I. Medizinische Klinik, Mainz, Germany; [3]Center of Gastroenterology, Center of Gastroenterology, Herne, Germany; [4]Leberzentrum am Checkpoint, Leberzentrum am Checkpoint, Berlin, Germany; [5]Praxis Wolf Peter Hofmann, Berlin, Germany; [6]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany; [7]Diabetes Zentrum Mergentheim, Diabetes Zentrum Mergentheim, Bad Mergentheim, Germany; [8]IFI-institute for interdisciplinary medicine, Hamburg, Germany*
Email: gerlinde.teuber@t-online.de

Background and Aims: Concerning the durability of HBsAg loss during or after antiviral treatment only a few data are available indicating a high rate of reactivation with reccurance of HBsAg and/or HBV-DNA of up to 16% in Asian patients. This may be due to the high percentage of patients with perinatal infection in these countries. There are no data from european patients available concerning the durability of HBsAg loss during or after antiviral treatment and the impact on further clinical outcome.

Method: In this retrospective german multicentre study, 143 patients with chronic hepatitis B (mean age: 43 ± 13.8 years, 93 males, 50 females) who lost HBsAg during or after antiviral treatment with peginterferon-α and/or nucleos(t)ides between april 2008 and july 2014 were included. Before antiviral treatment, 15 patients had established liver cirrhosis and 2/15 hepatocellular carcinoma, receiving partial liver resection. Primary end points were reactivation with reccurrence of HBsAg Further endpoints were clinical progressive liver disease, liver transplantation and death.

Results: During the follow-up period (mean: 3.0 ± 2.1 years) a recurrence of HBsAg was observed in only 3/143 patients (2.1%), none with previous seroconversion to Anti-HBs. The HBV reactivation in these patients was not associated with detectable HBV-DNA levels or a rise in ALT-levels. 2/3 patients had baseline cirrhosis and 1/2 subsequently died due to recurrent multifocal hepatocellular carcinoma. Among the 140 patients with persisting HBsAg loss, two initially cirrhotic patients died and one received liver transplantation all due to hepatocellular carcinoma.

Conclusion: In a predominantly caucasian patient population HBsAg loss during and/or after antiviral treatment seems to be durable with low rates of reactivation. Cirrhotic patients, however, have a high risk for developing hepatocellular carcinoma even after HBsAg loss and regular surveillance in these patients seems to be mandatory.

FRI-320

The effect of PEG-IFN add on or switch to on HBsAg clearance in HBeAg- CHB patients recieving entecavir treatment

L. Yan, Y. Xu, L. Chen, Y. Ding, Q. Xie, H. Wang. *Shanghai Jiaotong University School, Department of Infectious Diseases and Hepatology, Shanghai, China*
Email: wanghuirj@163.com

Background and Aims: Chronic hepatitis B (CHB) patients rarely achieve HBsAg loss with nucleoside/nucleotide analogue (NA) therapy. It was evaluated HBsAg loss in HBeAg$^-$ patients with entecavir switched to or added on pegylated interferon (PEG-IFN) in a retrospective study.

Method: Totally 87 HBeAg$^-$ CHB patients treated with entecavir for 24 weeks were studied, 21 switched to PEG-IFN, 13 added on PEG-IFN and 53 continued entecavir therapy (ETV group).

Results: HBsAg clearance at week 48 was reported in 2/21 (10%) patients in switch-to group, 2/13 (15%) patients in add-on group; whereas none was in ETV group. HBsAg reduction at week 48 was 1.055logIU/ml, 0.6452 logIU/ml or 0.014 logIU/ml respectively in switch-to, add-on, or ETV group. The response rate of switch-to, add-on and ETV monotherapy was, 44%, 38% or 2%, respectively. It was analysed that age, BMI, ALT, AST, PLT, liver stiffness, HBsAg titer at baseline, or HBsAg reduction at 24-week, showing that HBsAg titers at baseline and HBsAg reduction at week 24 were associated with HBsAg reduction and clearance. HBsAg reduction was associated with the response rate at week 24, showing that ROC Curve analyse the response versus HBsAg at week 48, the AUROC was 0.865. The PPV for response was 70% and NPV was 100% with the cut-off value 0.2logIU/ml.

Conclusion: In summary, we demonstrated that PEG-IFN enhanced HBsAg loss in HBeAg$^-$CHB population. Patients with HBsAg titers at baseline less than 1000 IU/ml and HBsAg reduction more than 0.2logIU/ml achieved HBsAg loss with a higher chance.

Email: hardtke.svenja@mh-hannover.de

Background and Aims: Hepatitis delta virus (HDV) infection causes the most severe form of chronic viral hepatitis associated with accelerated fibrosis progression and an increased risk for developing liver-related clinical complications. PEG-interferon alpha results in HDV RNA suppression in 25–30% of patients but late HDV RNA relapses occur and the impact on the development of clinical endpoints is unclear. The aim of this study was to investigate the long-term outcome after a 48 weeks course of PEG-IFNa therapy.
Method: We performed a retrospective follow-up study of patients included in the HIDIT1 trial (Wedemeyer H. et al., NEJM 2011). Patients received 48 weeks of treatment with either peginterferon alfa-2a plus adefovir dipivoxil (Group I), peginterferon alfa-2a alone (Group II), or adefovir dipivoxil alone (Group III). Liver related complications were defined as liver-related death, liver transplantation, HCC and hepatic decompensation (Child Pugh B,C or an increase in MELD of five or more points in relation to baseline values). Patients were censored for further analysis when patients were (re-) treated with PEG-IFNa.
Results: Follow-up data (at least 1 visit beyond post-treatment week 24) were available for 61 patients of the HIDIT 1 trial (Group I (n = 20), Group II (n = 20), Group III (n = 21)). The median time of follow-up was 6.0 (1.1–13.3) years. During follow up 25 patients were (re-) treated with IFN-based therapy (57.1% in PEG-IFNa arms and 64.7% in the adefovir only arm). At the last available visit, 13 (21.3%) patients were HDV RNA negative. Late-HDV RNA relapses of patients being negative at post-treatment week 24 were observed in 6/14 individuals. HBsAg was negative in 2 patients at post-treatment week 24 and in 6 patients (9.8%) at the last available visit (all after PEG-IFNa therapy). 11 patients (18.0%) developed clinical endpoints after a median time of 3.6 (1.4–9.9) years. Most of the patients developed a hepatic decompensation (n = 7) and four patients underwent liver transplantation (including three subjects with an HCC). No significant differences in clinical outcome could be observed between the three treatment arms in Kaplan Meier analyses. Interestingly, only one of the patients who were HDV RNA negative at post-treatment week 24 developed a clinical endpoint and all patients who had undetectable HDV RNA results throughout follow-up (n = 8) remained free of hepatic events. None of the patients who were HBsAg negative at posttreatment week 24 developed a clinical endpoint and but one patient who lost HBsAg later during follow-up still experienced an episode of hepatic decompensation.
Conclusion: This long-term follow-up study of a large randomized clinical trial suggests that an off-treatment HDV RNA response to PEG-IFNa treatment is associated with an improved clinical long-term outcome of hepatitis delta.

FRI-322

Novel markers predict HBs-antigen seroclearance in chronic hepatitis B patients from the SWAP clinical trial

Lim[1]. *[1]National University Health System Singapore; [2]Abbott diagnostics; [3]Tan Tock Seng Hospital Singapore; [4]Singapore General Hospital; [5]Changi General Hospital Singapore; [6]Khoo Teck Puat Hospital Singapore; [7]Singapore Clinical Research Institute*
Email: mdclimsg@nus.edu.sg

Background and Aims: The utility of novel markers to predict HBsAg loss in Chronic Hepatitis B (CHB) patients have not been compared. In this study, quantitative(q) measurements of HBsAg, HBeAg, HBV core-related antigen (crAg) and HBV RNA were evaluated in a clinical trial of CHB patients.
Method: 111 patients from a randomised control trial of continuing nucleos(t)ide analogues (NA) were compared to add-on or switch-to peginterferon alpha 2b for 48 weeks (wk) 1:2:2 (clinicaltrial.gov NCT01928511), with primary endpoint evaluation after 24 wk follow-up (wk 72). Serum samples were tested with a research HBV RNA assay (log U/ml); qHBeAg, qHBsAg(logIU/ml), and an ultrasensitive HBsAg research assay (sensitivity 0.005IU/ml) (m2000 and ARCHITECT, Abbott Laboratories); and crag (log U/ml; Lumipulse, Fujirebio; HBeAg(-) samples only). Analysis of results was performed with SPSS v20.
Results: 42 patients were in add-on, 46 in switch and 23 in control arms respectively at study completion (wk 72). Baseline (bsl) demographics: mean age 50 years, males 85%, HBV DNA(-) 100%, and HBeAg(+) 31.5%. At end of study, 13(11.7%) patients achieved HBsAg loss (only interferon-treated); 12/13 were HBeAg(-) at bsl. HBsAg loss patients had lower levels of qHBsAg at bsl [1.3 ± 1.1 vs 3.0 ± 0.7 (p < 0.001)], wk 12 [0.3 ± 0.9 vs 2.9 ± 0.8 (p < 0.001)] and wk 24 [0.1 ± 0.6 vs 2.8 ± 0.9 (p < 0.001)]. Patients with HBsAg loss who were bsl HBeAg(-) had lower crAg levels at bsl [3.2 ± 0.3 vs 3.9 ± 0.9 (p = 0.005)], wk 12 [3.2 ± 0.4 vs 3.9 ± 0.9 (p = 0.007)], and wk 24 [3.1 ± 0.2

vs 3.9 ± 0.9 (p = 0.003)]. HBV RNA(-) at wk 24 was also associated with HBsAg loss (61.5% vs 14.3%, p < 0.001). In multivariate analysis adjusted for age, gender, duration of prior NUC treatment and bsl qHBsAg, qHBsAg < 2.0logIU/ml at wk 12 was an independent predictor of HBsAg loss(OR 39.1, 95% CI 1.7–901.5, p = 0.022), with AUROC of 0.96 (96% CI 0.9–1.0, p < 0.001). Other independent predictors were HBV RNA(-) at wk 24[OR 10.6,95% CI 2.8–40.9, p = 0.001] and crAg(-) (<3logU/ml) at wk 12 [OR 6.8 95% CI 1.3–35.5, p = 0.022, AUROC 0.75 (95%CI 0.6–0.9)]. Overall, 24/48 HBsAg(-) samples tested with the ultrasensitive HBsAg research assay were HBsAg(+). None of the specific treatment arms were associated with significant changes in qHBsAg, crAg or HBV RNA that were related to HBsAg loss.
Conclusion: QHBsAg and undetectable crAg at wk 12 and undetectable HBV RNA at wk 24 are important predictors of HBsAg seroclearance.

FRI-323

Pharmacokinetics and pharmacodynamics modeling of ritonavir boosted lonafarnib therapy in HDV patients: A phase 2 LOWR HDV-3 study

P. Dubey[1], C. Koh[2], P. Surana[2], S. Uprichard[1], M.A.T. Han[2], N. Fryzek[2], G. Subramanya[1], D. Kapuria[2], O. Etzion[3], V. Takyar[2], Y. Rotman[2], C. Yurdaydin[4], J. Glenn[5], S. Cotler[5], T. Heller[2], H. Dahari[1]. *[1]Loyola University Medical Center, United States; [2]Liver Diseases Branch, NIDDK, NIH, United States; [3]Soroka University Medical Center, Israel; [4]University of Ankara Medical School, Turkey; [5]Stanford University School of Medicine, United States*
Email: harel.dahari@gmail.com

Background & Aim: The prenylation inhibitor lonafarnib (LNF) has proven anti-hepatitis D virus (HDV) activity in recent phase 2 clinical trials. The phase 2 LOWR HDV-3 study conducted with an all-oral combination of once-daily ritonavir (RTV) boosted LNF was reported safe and tolerable in patients for up to 6 months of therapy. In the current study, we sought to model RTV-boosted LNF pharmacokinetics (PK) and pharmacodynamics (PD) parameters using data from the LOWR HDV-3 study.
Methods: HDV-infected patients were randomized in LOWR HDV-3 into one of six groups: LNF 50/75/100 mg + RTV 100 mg once daily for 24 weeks (n = 12) or 12 weeks of placebo followed by LNF 50/75/100 mg + RTV 100 mg once daily for 12 weeks (n = 9). Since frequent hepatitis B surface antigen (HBsAg), RTV, LNF and HDV RNA kinetics (0, 6, 12, 18, 24, 36 hrs, 2, 3, 7, 14, 21, 28, 56, 84, 112, 140, 168 days) were available in the 24 week arm of LNF 50/75/100 mg + RTV 100 mg, 12 patients in this arm were included in the modeling analysis. All patients were treated with hepatitis B nucleotide analogues. A modeling framework that includes proliferation of uninfected and infected cells and accounts for LNF concentration, HDV RNA, alanine aminotransferase (ALT) and HBsAg kinetics was used to estimate the LNF PK and PD parameters. The standard Emax model was used to account for the time-dependent LNF effectiveness in blocking HDV production.
Results: While HBsAg levels did not change on therapy, four patterns of HDV RNA response were seen in each dosing group: responders (triphasic (n = 3), flat-partial responders (n = 3), rebound (n = 3)) and non-responders (n = 3). ALT normalization was observed in all triphasic and 2 (out of 3) flat-partial responders. In all 12 patients, a transient increase in RTV concentration was observed with median (interquartile range, IQR) peak C_{max_RTV} = 880 (993)ng/ml during the first week after initiation of therapy followed by a set point of 257 (297)ng/ml from week 2 onwards. Interestingly, C_{max_RTV} >1200 ng/ml was associated with the triphasic response (1 in each LNF dosing group) in which there was a continuous HDV decline on treatment. Based on all 12 patients, the LNF-PK model predicted a median LNF elimination rate k_e = 0.7 (0.3)/day, absorption rate k_a = 9.2 (23.7) /day, and bioavailable fraction F = 1012.7 (682.7) ng/ml. There was no association between PK parameters and response to therapy (p ≥ 0.145). LNF-PD modeling in the 9 responders suggests a median LNF EC_{50} of 289 (422) ng/ml, at which LNF's effectiveness in blocking viral production reaches to half of its maximum, with Hill coefficient n = 1.48.
Conclusions: Modeling daily ritonavir boosted lonafarnib indicates a lower average LNF elimination rate (0.76/day) compared to twice a day unboosted LNF (1.08/day – Hepatology Communications 2017; 1:288–292), which confirms the role of ritonavir to maintain high LNF efficacy under low and daily LNF dosing with minimal side effects.

Modeling serum HBsAg, HBV DNA and transaminase kinetics during REP 2139 monotherapy in chronic HBeAg+ HBV infection

L. Shekhtman[1,2], N. Borochov[1], S. Cotler[1], L. Hershkovich[1], S. Uprichard[1], M. Al-Mahtab[3], M. Bazinet[4], A. Vaillant[4], H. Dahari[1]. *[1]Loyola University Medical Center, United States; [2]Bar-Ilan University, Israel; [3]Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh; [4]Replicor Inc., Canada*
Email: harel.dahari@gmail.com

Background and Aims: Nucleic acid polymers (NAPs) block the secretion of HBV subviral particles (SVPs) without affecting secretion of Dane particles or intracellular levels of HBsAg (Blanchet et al. J Hepatol.2017;66:S257). In HBeAg+ chronic HBV infection, NAP monotherapy is associated with almost complete removal of circulating HBsAg and substantial reductions in serum HBV DNA (Al-Mahtab et al., PLOS One 2016;11:e0156667). Here we provide a mathematical model that predicts HBV DNA, HBsAg and transaminase kinetic parameters against HBV during REP 2139 monotherapy in the REP 102 protocol (NCT02646189).
Methods: Twelve HBeAg+ chronically infected HBV patients received weekly 500 mg IV infusions of REP 2139 for 20–40 weeks (Al-Mahtab et al., *idem*). HBV DNA (viral load, VL), HBsAg and alanine aminotransferase (ALT(levels were measured every 1–2 weeks during treatment. A model that includes proliferation of uninfected and infected cells and accounts for HBV DNA, HBsAg and ALT dynamics was developed.
Results: Mean baseline VL, ALT and HBsAg were 7.9 ± 1.3Log copies/ml, 79 ± 36IU/l and 4.5 ± 0.7 logIU/ml, respectively. Three non-responders with no decline in VL or HBsAg were excluded. VL and HBsAg significantly declined from baseline levels during therapy. At the end of NAP monotherapy, mean ALT was lower than baseline (61 ± 29 IU/l) however ALT flares (>3-fold increase) were observed in 4 patients between 4 and 9 weeks after initiation of therapy. Model fits indicate that HBsAg and VL declines started 36 ± 32 days after introduction of REP 2139 and estimate a mean REP 2139 efficacy of 96.7% ± 4.4% in blocking HBsAg secretion. Assuming that REP 2139-mediated reductions in HBsAg allow for restoration of immune function, modeling projects a mean increase in the rate of viral clearance of 541-fold per day (range increase of 0.2–4544 fold per day) with mean maximum fold enhancement of 3.2. ± 1.2 logs within 110 ± 35 days post therapy initiation. The model reproduces the observed ALT kinetics in the 5 patients without an ALT flare.
Conclusions: Modeling fits indicated a potent efficacy/enhancement in blocking HBsAg secretion and associated viral clearance. The delay observed before HBsAg and VL decline after introduction of REP 2139 was variable among patients and in some cases was decoupled, suggesting a variable state of immune function participating in the clearance of HBsAg versus HBV DNA. Further modeling efforts to refine the understanding of the modes of action of NAPs against HBV and the nature of ALT flares are ongoing.

Efficacy and safety of combination therapy with interferon and immunomodulators in entecavir-suppressed chronic hepatitis B patients (the endeavor study)

D. Wu[1], P. Wang[1], M. Han[1], Y. Chen[2], X.-Y. Chen[3], Q. Xia[4], C. Zhu[5], Q. Xie[6], J. Jiang[7], L. Wei[8], D. Tan[9], X. Dou[10], Y.-Y. Yu[11], J. Hou[11], Q. Ning[1]. *[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department and Institute of Infectious Disease; [2]The First Affiliated Hospital of Wenzhou Medical University, China; [3]Beijing You'an Hospital, Capital Medical University, China; [4]The First Affiliated Hospital, School of Medicine, Zhejiang University; [5]Jiangsu Province Hospital; [6]Shanghai Ruijin Hospital, Jiaotong University School of Medicine; [7]First Affiliated Hospital of Fujian Medical University; [8]Peking University People's Hospital, China; [9]Xiangya Hospital, Central South University; [10]Shengjing Hospital of China Medical University, China; [11]Nanfang Hospital, Southern Medical University, China*
Email: qning@vip.sina.com

Background and Aims: The ideal endpoint for anti-HBV therapy is the loss of hepatitis B surface antigen (HBsAg). The purpose of the study was to determine the efficacy and safety of sequential combination therapy with interferon (IFN), recombinant human IL-2 (rhIL-2) and therapeutic vaccine in patients treated with long-term entecavir (ETV).

Method: In this pilot and proof of concept, multicentre and randomized trial, 94 HBeAg positive chronic hepatitis B patients who had received ETV for at least 1 years, with HBV DNA ≤ 1000 copies/ml and hepatitis B e antigen (HBeAg) loss, were randomly assigned (1:1:1) to receive ETV (0.5 mg/day, oral) for 48 weeks (Group I) or IFN-α-2b (600 wIU every other day, subcutaneous) for 48 weeks (Group II) or IFN-α-2b for 48 weeks in combination with rhIL-2 (25 wIU every other day, subcutaneous) for 12 weeks plus vaccine (60ug/month, intramuscular) for 48 weeks (Group III). The primary endpoint was HBsAg loss at week 48 (ClinicalTrials.gov: NCT02360592). Peripheral immune cells were evaluated dynamically.

Results: 94 patients were randomized; 93 received ≧1 study drug dose. One patient who were HBeAg-positive at baseline was excluded from the modified intention-to-treat population (group I, n = 27; group II, n = 33; group III, n = 32). At week 48, 3.70% of subjects in group I, 3.03% of subjects in group II and 9.38% of subjects in group III achieved HBsAg loss. Mean HBsAg decline from baseline to week 48 was significantly greater in group III (0.85 log10IU/ml) and group II (0.74log10 IU/ml) than in groups I (0.13log10IU/ml, respectively, $p < 0.05$ for all comparisons vs group I). Among the patients with 100IU/ml < HBsAg < 1500 IU/ml at randomisation, 25% achieved HBsAg loss and mean HBsAg declined 1.65log10 IU/ml from baseline to week 48 in group III, displaying a significant benefit comparing with group I (0% and 0.04log10IU/ml, respectively), while no significant difference was found between group III and group II (6.67% and 0.61 log10IU/ml, respectively). Besides, patients receiving combination treatment showed a significantly higher increase in the $CD56^{bright}$ $CD16^{-}$NK cells proportions at week 4, patients with good response to combination treatment exhibited a significant decline in Treg proportions from week 12 to week 24.

Conclusion: For ETV suppressed patients, particularly those with low serum HBsAg level, sequential combination therapy with IFN and immunomodulators may enhance HBsAg loss and led to partial immune restoration.

FRI-326

Establishment of persistent functional remission of HBV and HDV infection following REP 2139 and pegylated interferon alpha 2a therapy in patients with chronic HBV/HDV co-infection: 18 month follow-up results from the REP 301-LTF study

M. Bazinet[1], V. Pantea[2], V. Cebotarescu[2], L. Cojuhari[2], P. Jimbei[3], A. Vaillant[1]. *[1]Replicor Inc., Montreal, Canada; [2]Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova; [3]Toma Ciorba Infectious Clinical Hospital, Chisinau, Moldova*
Email: availlant@replicor.com

Background and Aims: HBV/HDV co-infection represents a significant unmet medical need, causes rapid progression of liver disease and has no approved therapy. The previous REP 301 study (NCT02233075) demonstrated the safety and tolerability of REP 2139 in combination with pegylated interferon alpha 2a (pegIFN) and the establishment of functional control of HBV (in 5/12 patients) and HDV (in 9/12 patients) which persisted after the removal of all antiviral therapy (functional remission) in 7 patients (HDV RNA target not detected), 5 of whom also maintained functional remission of HBV (HBsAg < LLOQ, HBV DNA < LLOQ). A three-year supplemental follow-up study (REP 301-LTF, NCT02876419) is currently examining the long-term stability of the functional remissions of HBV and HDV infection achieved in the REP 301 protocol.

Method: All patients completing the proscribed therapy in the REP 301 study were eligible to participate in this study. Supplemental follow up safety and efficacy evaluations are scheduled every 6 months (for a period of three years) following the original 24-week follow-up in the REP 301 study. Virologic status was verified using Architect (HBV) and Robogene MKII (HDV) test platforms. Hepatic stiffness was monitored by Fibroscan.

Results: Of the seven patients which achieved functional remission of their HDV infection at the end of the 24-week follow-up in REP 301 study, all are still maintaining HDV RNA target not detected at 1.5 years of follow-up. Five of these patients also had functional remission of their HBV infection, which is still persisting in 4 patients. In the fifth of these patients, HBV infection is still well controlled (HBV DNA < LLOQ). In all seven patients with functional remission of HDV at 1.5 years of follow-up, liver function is normal and is accompanied by continual reductions in median hepatic stiffness, now below pre-treatment levels in 6 of 7 patients.

Of the remaining five patients who did not achieve functional remission of HBV or HDV infection, new HDV RNA setpoints >1log below baseline are persistent in 2 patients and are accompanied by normal liver function or reduced/stable median hepatitis stiffness.

Conclusion: Functional remission of HDV and HBV infection achieved with REP 2139 and pegIFN is stable at 1.5 years follow-up and is associated with persistently normal liver function and progressive reduction in median hepatic stiffness.

FRI-327

Dose response and safety of the daily, oral RIG-I agonist Inarigivir (SB 9200) in treatment naïve patients with chronic hepatitis B: results from the 25mg and 50mg cohorts in the ACHIEVE trial

M.-F. Yuen[1], M. Elkashab[2], C.-Y. Chen[3], C. Coffin[4], S. Fung[5], S. Greenbloom[6], J.W. Jang[7], R.W.-J. Jeng[8], D.J. Kim[9], Y.J. Kim[10], W. Kim[11], K.S. Lee[12], Y.-S. Lim[13], A. Ramji[14], R. Iyer[15], C. Macfarlane[15], K. Jackson[16], S. Locarnini[16], N. Afdhal[15], H. Chan[17]. *[1]University of Hong Kong; [2]Toronto Liver Centre; [3]Chia-Yi Christian Hospital; [4]University of Calgary; [5]University of Toronto; [6]Toronto Disgestive Disease Associates Inc; [7]The Catholic University of Korea; [8]Chang-Gung University; [9]Hallym University College of Medicine; [10]Seoul National University Hospital; [11]Borame Medical Center; [12]Yonsei University; [13]Asan Medical Center; [14]University of BC; [15]Spring Bank Pharmaceuticals; [16]VIDRL; [17]Chinese University of Hong Kong*
Email: cmacfarlane@springbankpharm.com

Background and Aims: Inarigivir (previously SB 9200) is an oral HBV antiviral with both direct acting activity and immune-modulation

through activation of the pattern recognition receptor retinoic acid-inducible gene 1 (RIG-I). The ACHIEVE trial is a placebo controlled trial of ascending doses of inarigivir daily or placebo for 12 weeks, followed by a switch to 300mg tenofovir for 12 weeks. We report here the dose response at 25 mg (cohort 1) and 50 mg (cohort 2) daily of Inarigivir on HBV DNA, HBsAg and HBV RNA.

Method: All patients were treatment naïve, non-cirrhotic with elevated ALT. 20 patients per cohort were randomized 4:1 to inarigivir or placebo. Two patients in cohort 2 dropped out secondary to patient preference at day 1 and week 2 and are not in the analysis. 38 of 40 patients were Asian and genotypes B/C predominated.

Results: No clinical or biochemical > grade 3 AE's, no SAE's and no interferon like side effects reported. Overall 5 ALT flares > 200 IU/ml were seen, 2 on placebo and three on Inarigivir. One inarigivir 50 mg patient had an ALT of 487 IU/ml at week 4 and was switched to tenofovir. Week 12 anti-viral response is shown in the Table. Compared to placebo both HBV DNA (t-test, $p < 0.001$) and HBV RNA (t-test, $p = 0.008$) declined in combined inarigivir 25 and 50 mg cohorts. Overall HBeAg -ve patients had a greater anti-viral response than HBeAg + ve patients. HBV DNA response was superior in those with baseline HBV DNA < $6\log_{10}$ and HBsAg < $4\log_{10}$ irrespective of HBeAg status indicating effect of viral burden on response. HBV RNA was undetectable at week 12 in 2 of 7 patients with HBeAg –ve disease in cohort 1 and all 4 patients in cohort 2. Overall 4 of 30 inarigivir treated patients had a > 0.5 log reduction in HBsAg.

	Placebo	Inarigivir 25mgHBeAg + ve	Inarigivir 25 mgHBeAg –ve	Inarigivir 50 mgHBeAg + ve	Inarigivir 50 mgHBeAg –ve
Number	8	9	7	11	5
Age	38	37	43	36	47
Gender M:F	6 : 2	5 : 4	3 : 4	9 : 2	5
Baseline ALT	74	82	75	75	65
Baseline HBV DNA $\log_{10}$	6.36	7.86	5.69	7.79	4.55
Change in DNA (BL to week 12) $\log_{10}$	+0.33	–0.37	–0.86	–0.61	–1.05
Baseline HBsAg $\log_{10}$	3.75	4.31	3.17	4.12	2.96
Change in HBsAg (BL to week 12) $\log_{10}$	–0.18	–0.08	–0.34	–0.07	0
Baseline HBV RNA $\log_{10}$	4.23	6.36	4.20	6.58	3.15
Change in HBV RNA (BL to week 12) $\log_{10}$	+0.99	–0.32	–1.84	–0.46	–3.15

Conclusion: Low dose Inarigivir is well tolerated and associated with reduction in HBV DNA and HBV RNA. This effect is seen without a fully activated immune response and consistent with a direct anti-viral effect which may reflect targeting HBV RNA encapsidation.

Email: peijerchen@ntu.edu.tw

Background and Aims: Ropeginterferon alfa-2b (P1101) is a novel mono-pegylated interferon alfa-2b with longer duration of action, allowing every-two-week (q2w) injection with high tolerability shown from previous studies. This study aims to find the optimal dose of P1101 by comparing antiviral activity, and safety across treatment groups in interferon naïve patients with chronic hepatitis B virus (HBV) infection.

Method: Thirty-one hepatitis B e antigen (HBeAg)-positive subjects with baseline HBV DNA > 20,000IU/ml and 31 HBeAg-negative subjects with baseline HBV DNA > 2,000IU/ml were randomized at 1:1:1 ratio to subcutaneous treatment of q2w P1101 350 μg (Group 1), q2w P1101 450 μg (Group 2), or weekly (q1w) peginterferon alfa-2a 180 μg (Group 3, control) respectively. Every patient received 48-week treatment (TW48) and 24-week post-treatment follow-up (FW24).

Results: In HBeAg (+) subjects, cumulative HBeAg seroconversion rate was 27% (3/11), 36% (4/11), 11% (1/9) ($p = 0.21$) with median time to HBeAg seroconversion of 24, 24, and 48 weeks ($p = 0.28$), in Group 1, 2, 3 respectively. At FW24, HBV DNA < 2,000 IU/ml was 27% (3/11), 0% (0/11), and 22% (2/9) ($p = 0.22$), hepatitis B surface antigen (HBsAg) < 1,500 IU/ml was 46% (5/11), 18% (2/11), 11% (1/9) ($p = 0.27$), anti-HBe positive rate was 46% (5/11), 46% (5/11), 18% (2/9) ($p = 0.59$) in Group 1, 2, 3 respectively. In HBeAg (-) subjects at FW24, HBV DNA < 2,000 IU/ml was 10% (1/10), 36% (4/11), 50% (5/10) ($p = 0.17$) and HBsAg < 1,500 IU/ml was 80% (8/10), 91% (10/11), 90% (9/10) ($p = 0.83$), in Group 1, 2, 3 respectively. HBeAg (+) and (–) patients pooled together, 10% (2/21), 5% (1/22), 11% (2/19) discontinued treatment due to adverse events (AEs) in Group 1, 2, 3 respectively. The AEs for discontinuation were Grade 3 myocardial infarction (MI) and Grade 4 alanine aminotransferase (ALT) increased in Group 1, multiple Grade 1 AEs in 1 subject of Group 2, and Grade 3 ALT increased in 2 subjects of Group 3. The subject with MI has risk factors of smoking, and hyperlipidemia. About 14% (3/21), 14% (3/22), 11% (2/19) reduced dose in Group 1, 2, 3 respectively. All were due to Grade 3 neutropenia or ALT increased.

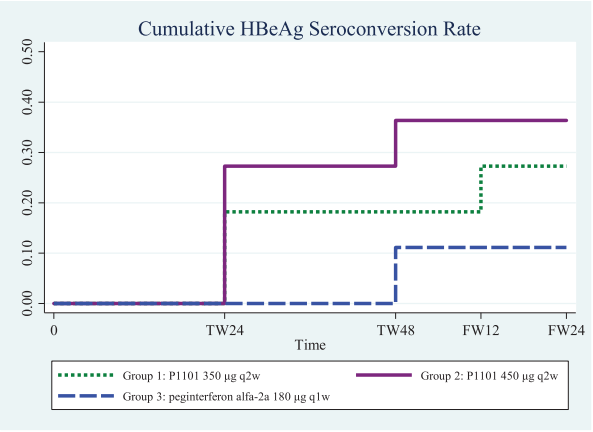

Figure 1: Cumulative HBeAg Seroconversion Rate Over Time in HBeAg-positive Patients

Conclusion: P1101 is safe for chronic HBV infection. P1101 450 µg q2w yielded the highest HBeAg seroconversion rate. Shorter time to HBeAg seronconversion was observed in both P1101 groups. P1101 450µg q2w is selected for a Phase 3 study to confirm efficacy and safety on HBeAg-positive patients.

FRI-329

HBV RNA in serum is an early predictor for sustained immune control following treatment with pegylated interferon alfa in patients with HBeAg negative chronic hepatitis B

Background and Aims: Hepatitis B RNA (HBV RNA) is a novel serum biomarker that is a transcriptional product of HBV covalently closed circular DNA. In recent studies in HBeAg negative patients, kinetics of serum HBV RNA were shown to be associated with serologic response following treatment with nucleos(t)ide analogues or PEG-IFN.
We aimed to study the kinetics of HBV RNA during PEG-IFN treatment in HBeAg negative patients and its potential role as response predictor.
Method: HBV RNA levels were retrospectively measured in stored serum samples of 133 HBeAg-negative chronic HBV patients who were treated in an international randomized controlled multicenter trial (PARC study). Patients received PEG-IFN α-2a 180 mcg/week +/- ribavirin 1000–1200 mg daily for 48 weeks. All patients were followed until week 72. HBV RNA was measured at week 0 (baseline), 12, 24 and 48 and week 72 using a RACE-PCR technique (lower limit of quantification (LLQ) 800c/ml). Response was defined as a combined endpoint HBV DNA level below 2,000 IU/ml and normalization of ALT at week 72.
Results: The mean age was 42.2 (SD 11) years, 98 (74%) were male, and distribution of HBV genotypes was 17/1/3/80% for A/B/C/D. The mean (SD; range) HBV RNA at baseline was 4.0 (1.4; 1.7–7.7) $\log_{10}$ c/ml and HBV RNA was < LLQ in 28 (23%) patients. No difference in response was found between patients with or without ribavirin and patients were thus pooled for further analyses.
At 12 and 24 weeks mean HBV RNA declined by 1.7 and 1.8 log c/ml and HBV RNA was < LLQ in 95 (83%) and 99 (84%) patients at these time points, respectively. At week 72, 24 patients (23%) had achieved response. HBV RNA in the responders showed a marked decline (2.1 and 2.2 log c/ml) compared to the non-responders (1.6 and 1.6) at weeks 12 and 2 4, respectively. None of the patients at week 12 (n = 18) and week 24 (n = 17) who exhibited an HBV RNA level above 1500c/ml (3.2 $\log_{10}$ c/ml) had a response at week 72 with a negative predicative value of 100% (p = 0.01 and 0.02 respectively). However, the positive predictive value of patients who had HBV RNA levels below 1500c/ml (3.2 $\log_{10}$ c/ml) at week 12 and 24 was 28% and 27% respectively.
Conclusion: In HBeAg-negative patients with chronic hepatitis B, serum HBV RNA declined during PEG-IFN treatment. An HBV RNA value above 1,500 c/ml (3.2 $\log_{10}$ c/mL) at week 12 was strongly associated with nonresponse to PegIFN treatment.

FRI-330

Determination of the optimum timing of the start of nucleoside analogue by FIB-4 index for hepatitis B patients from the viewpoint of suppressing hepatocarcinogenesis

S. Hige, I. Ozeki, R. Tatsumi, M. Yamaguchi, M. Kimura, T. Arakawa, T. Nakajima, Y. Kuwata, T. Ohmura, J. Toyota, Y. Karino. *Sapporo Kosei General Hospital, Hepatology, Sapporo, Japan*
Email: shuhei.hige@ja-hokkaidoukouseiren.or.jp

Background and Aims: Nucleotide or nucleoside analogue (NA) treatment to hepatitis B patients has been reported to be useful for suppressing the occurrence of hepatocellular carcinoma (HCC). However, not a few patients progress to HCC after the start of NA treatment. On the other hand, early treatment initiation for young patients should be carefully considered since the treatment may last for a long time. Therefore, it is important to find an optimum timing to suppress HCC occurrence effectively. In this study, we evaluated the meaningfulness of annual average of integral FIB-4 index for determining an adequate timing for the start of NA treatment.
Method: A total of 543 HBs antigen-positive patients who did not have a history of HCC were followed from the start of NA administration [entecavir (ETV) 334, lamivudine (Lam) to ETV 80, Lam 30, Lam or ETV plus adefovir (ADV) 99 cases]. FIB-4 was calculated by the following formula: (age [years]×AST [IU/l] / platelet count [10^9/l]×ALT [IU/l]$^{1/2}$). An annual average value of FIB-4 index (FIB-4aa) which was calculated from the integral value of each FIB-4 index during the same year was used for the investigation of this study.
Results: During an average follow-up of 5.3 years, HCC was confirmed in 70 patients. Overall cumulative 3/5/10 year HCC occurrence rate was 8.4/11.2/20.7%. The cumulative 5/10 year rates of patients whose FIB-4aa before the start of NA administration was <1.0, 1.0–2.0, 2.0–3.0, 3.0–4.0, 4.0 ≤ were 0/0, 3.6/5.2, 1.9/1.9, 16.3/32.3, 30.7/40.5%, respectively. The expected HCC risk of those whose FIB-4aa ≥ 3.0 (high FIB-4aa group) was 10 times greater than those whose FIB-4aa < 3.0 (low FIB-4aa group), (cumulative 5/10 year rates: 25.0/36.9 vs 2.2/3.4, p < 0.001). The cumulative 5-year risk in their 30's/40's/50's/60's/70's was 0/3.6/6.1/0/0% for lowFIB-4aa group and 12.5/12.0/28.2/26.3/37.8% for high FIB-4aa group. Among FIB-4aa high group cases, those whose FIB-4aa declined below 3.0 during NA treatment tended to lower the risk of HCC occurrence. 5-year HCC risk of those cases was 19.2%. The risk of those who did not show FIB-4aa decrease was 29.9% (p = 0.08).
Conclusion: FIB-4 index at the start of NA administration was highly correlated with HCC occurrence afterwards. This tendency was the same in any age group over 30's. NA administration should be started before an annual average value of integral FIB-4 index reaches 3.0.

FRI-331

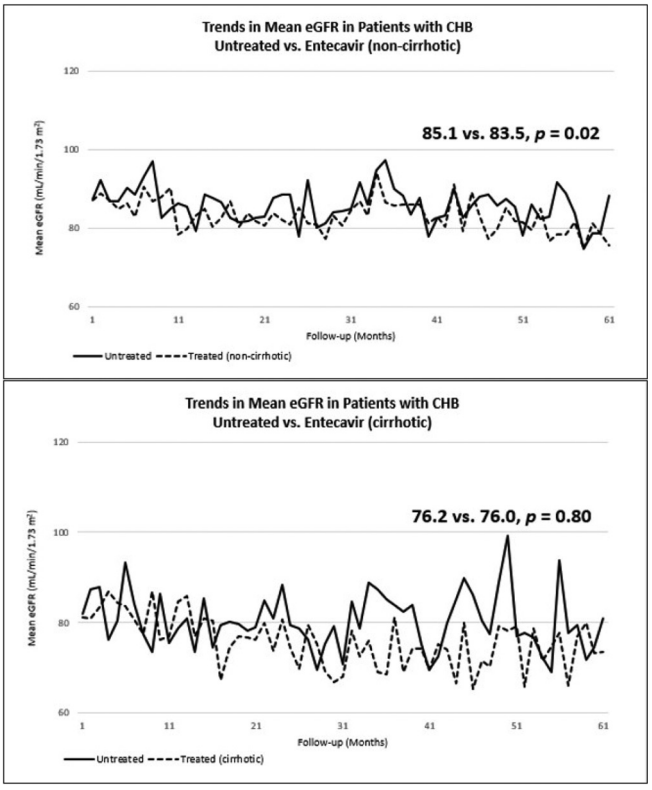
Treatment of chronic hepatitis B and renal impairment in patients with and without cirrhosis

V. Vu, S. Trinh, A. Le, T. Johnson, J. Hoang, D. Jeong, L. Henry, M. Nguyen. *Stanford University Medical Center, Division of Gastroenterology and Hepatology*
Email: mindiehn@stanford.edu

Background and Aims: Recent studies have shown that renal impairment in chronic hepatitis B (CHB) patients may result from treatment with oral nucleos(t)ide analogue medications. However, treatment with entecavir (ETV) has been associated with less renal toxicity, though data on this is limited. It is also unclear whether ETV therapy is more associated with development of poorer renal function compared to untreated CHB patients. The study aim was to determine renal outcomes among CHB patients who are untreated and treated with ETV with and without cirrhosis over time.
Method: Patients infected with CHB who were untreated or treated with ETV were recruited from a retrospective cohort of consecutive adult patients at a U.S. tertiary center between 1996 and 2017. Patients were not recruited if coinfected with hepatitis D, hepatitis C,

or human immunodeficiency virus, or had prior history of treatment with adefovir or tenofovir. Patients were included if they had =>12 months of serial creatinine labs and baseline estimated glomerular filtration rate (eGFR, calculated using the Modification of Diet in Renal Disease Study equation) =>60ml/min/1.73 m^2 (n = 522). Propensity score matching (PSM) for age, sex, race, diabetes (DM), hypertension (HTN), and baseline eGFR was performed to compare untreated patients versus ETV-treated patients without cirrhosis (non-cirrhotic cohort) and with cirrhosis (cirrhotic cohort). Generalized linear regression modeling (GLM) controlling for sex, race, DM, and HTN was performed to generate mean eGFR over time.

Results: The non-cirrhotic cohort (n = 314) had a mean age of 48 ± 12 years. Most were male (58%) and Asian (91%). Twenty patients had DM (6%) and 74 had HTN (24%). Patients had a median eGFR of 85.1 (IQR = 61.5–139.6) and median follow-up of 70 months (IQR = 12–199). The cirrhotic cohort (n = 150) had a mean age of 55 ± 12 years. The majority were male (73%) and Asian (89%), with 27% having DM and 51% having HTN. Median eGFR was 79.1 (IQR = 61.0–118.4) and median follow-up was 69 months (IQR = 13–166). On GLM for the non-cirrhotic cohort, there was a significant difference in the eGFR between untreated patients and ETV-treated patients (85.1 vs. 83.5, p = 0.02). For the cirrhotic cohort, GLM showed no significant difference in the eGFR of untreated patients and ETV-treated patients (76.2 vs. 76.0, p = 0.80) (Figure).



Conclusion: In this PSM study comparing untreated patients and ETV-treated patients with and without cirrhosis, no significant differences in renal function was noted for the cirrhotic group. Mean eGFR was slightly lower in ETV-treated patients than untreated non-cirrhotic patients, but remained at or close to normal range in both groups at 5-year follow-up. These findings suggest that ETV treatment does not have major influence on renal function of CHB patients; but since CHB therapy is often long-term, further studies with longer follow-up is needed.

FRI-332

Is renal impairment associated with chronic hepatitis B - a propensity score matched study of healthy non-hepatitis B patients compared to patients with untreated chronic hepatitis B

V. Vu, S. Trinh, A. Le, T. Johnson, J. Hoang, D. Jeong, L. Henry, M. Nguyen.
Stanford University Medical Center, Division of Gastroenterology and Hepatology
Email: mindiehn@stanford.edu

Background and Aims: Renal impairment has been suggested to occur at higher rate in patients with chronic hepatitis B (CHB). However, questions have been raised as to whether the prevalence of renal impairment is a result of the virus itself, a result of HBV treatment, or other factors. The study aim was to explore and compare renal function over time between healthy non-CHB patients and untreated CHB patients.

Method: Healthy non-CHB patients and patients infected with HBV were recruited from a retrospective cohort of consecutive adult patients at one U.S. tertiary center and 3 community gastroenterology and primary care clinic between 1996 and 2017. Healthy non-CHB patients were recruited if they had no history of liver disease, congestive heart failure, human immunodeficiency virus (HIV), or cancer. CHB patients were recruited if they had no hepatitis D virus, hepatitis C virus, or HIV coinfections. Patients were included in the study if they had never received HBV treatment, had =>12months of serial creatinine labs, and had a baseline estimated glomerular filtration rate (eGFR, calculated using the Modification of Diet in Renal Disease Study equation) =>60 ml/min/1.73 m^2 (healthy n = 26, 519; CHB n = 290). Propensity score matching (PSM) for age, sex, race (Asian vs. non-Asian), diabetes (DM), hypertension (HTN), and baseline eGFR was performed to balance the two groups. Generalized linear regression modeling (GLM) adjusting for sex, race, DM and HTN was performed to generate mean eGFR over time.

Results: The PSM groups included 290 healthy non-CHB patients and 290 untreated CHB patients (n = 580). Mean age was 42 ± 12 years. More than half were male (51%) and a majority were Asian (88%). Forty-nine patients had DM (9%) and 143 patients had HTN (25%). Patients had a median baseline eGFR of 88.3 (IQR = 61.0–143.9) and a median follow-up of 82 months (IQR = 12–217). On GLM, the mean eGFR was significantly higher for healthy non-CHB patients compared to untreated CHB patients (87.4 vs. 85.6, p = 0.004) (Figure).

	0	10	20	30	40	50	60
Healthy non-CHB	290	290	248	212	195	182	169
Untreated CHB	290	290	270	250	228	207	189

Conclusion: In this PSM study, untreated CHB patients' eGFR over time decreased significantly more than the healthy non-CHB patients; however, the change in eGFR may not be clinically significant, at least in short-to-medium term follow-up. Therefore,

further research is needed to determine which factors may have contributed to renal impairment in patients with CHB.

FRI-333

Comparison of fibrosis-adjusted long-term clinical outcomes in patients with minimally active chronic hepatitis B who did not undergo antiviral therapy vs. those with complete virological response by antiviral therapy

H.W. Lee, B.K. Kim, S.U. Kim, J.Y. Park, D.Y. Kim, S.H. Ahn, K.-H. Han. *Institute of Gastroenterology, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: beomkkim@yuhs.ac

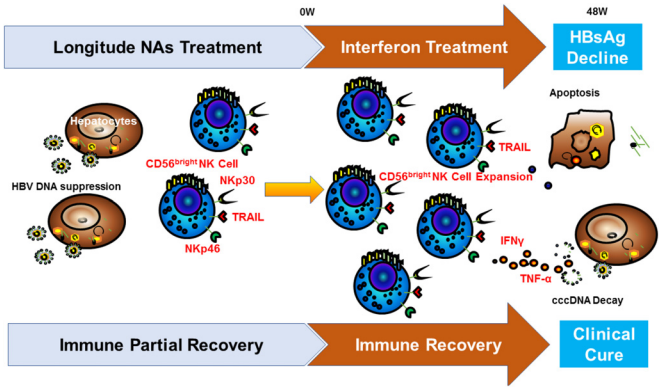
Backgrounds and Aims: The optimal criteria for commencement of antiviral therapy in patients with chronic hepatitis B (CHB) remain to be determined yet. Here, we aimed to compare the risk of hepatocellular carcinoma (HCC) and liver-related event (LRE) between patients with minimally active CHB who did not undergo nucleos(t)ide analog (NUC) therapy according to the current treatment guidelines (MA group) and those with complete virological response by NUCs (VR group).
Methods: We enrolled consecutive patients with CHB who underwent liver stiffness (LS) values by transient elastography between 2006 and 2015. Patients with a history of cirrhosis or hepatocellular carcinoma at the enrollment were excluded. To adjust for imbalances between the MA and VR groups, propensity-score matching (PSM) models with 1:1 ratio were performed based on age, gender, HBeAg, presence of diabetes, and LS value. Cumulative risks of HCC or LRE development were assessed using Kaplan-Meier method.
Results: A total of 915 patients were enrolled. The mean age was 54.2 years old, and 61.2% were male. MA group (n = 209) had higher serum HBV DNA level, alanine aminotransferase (ALT), total bilirubin, LS value and the lower proportion of positive HBeAg compared to VR group (n = 706). Regarding HCC development, MA group had the trend toward the higher risk compared to VR group (p = 0.087). Regarding LRE development, MA group was at the significantly higher risk than VR group (p = 0.003). On the contrary, after PSM, 206 pairs were generated, showing the similar risks between two groups in terms of the cumulative risk of both HCC (p = 0.782) and LRE (p = 0.796) development.
Conclusion: After adjusting the fibrosis degree, the potential prognostic factor for HCC and LE development, MA group also showed similar, cumulative risks compared to VR group, supporting the appropriateness of the current treatment guidelines in patients with CHB.

FRI-334

CD56 bright natural killer cell induces HBsAg clearance via cytolysis and non-cytolysis: Analysis of the OSST patient dataset

A. Shi, X. Zhang, F. Xiao, L. Zhu, W. Yan, M. Han, T. Chen, Q. Ning. *Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department and Institute of Infectious Disease*
Email: qning@vip.sina.com

Background and Aims: HBV surface antigen (HBsAg) reduction is well observed in chronic hepatitis B (CHB) patients treated with pegylate interferon-alpha-2a (Peg-IFNα). However, the mechanism of HBsAg suppression has not been fully elucidated.
Method: Twenty-seven of 55 Entecavir-treated CHB e antigen positive patients were switched to Peg-IFNα treatment (Group A) whereas 28 patients continued entecavir treatment (Group B). The percentage or absolute number of $CD56^{bright}$/$CD56^{dim}$ NK cells, expression of receptors and cytokines were evaluated by flow cytometry for 48 weeks and correlated with treatment efficacy. In Vitro, purified NK cells were co-cultured with HepAD38 cells for measurement of HBsAg, apoptosis and covalently closed circular DNA (cccDNA).
Results: In association with a reduction of HBsAg, the percentage and absolute number of $CD56^{bright}$ NK cell was significantly elevated in patients in group A, especially in Virologic Responders (VRs, HBsAg decreased). Furthermore, percentage of $NKp30^{+}$, $NKp46^{+}$, $TRAIL^{+}$, $TNF\text{-}\alpha^{+}$ and $IFN\gamma^{+}CD56^{bright}$ NK cells were significantly expanded in Group A, which were positively correlated with the decline of HBsAg at week 48. In Vitro, peripheral NK cells from Group A induced decline of HBsAg in comparison with NK cells from Group B which was significantly inhibited by anti-TRAIL, anti-TNF-α and anti-IFNγ antibodies. Furthermore, apoptosis of HepAD38 cells and levels of cccDNA, were significantly reduced by $TRAIL^{+}$ and $TNF\text{-}\alpha^{+}$/$IFN\gamma^{+}$NK cells from Group A respectively.



Conclusion: A functional restoration of $CD56^{bright}$ NK cells in Entecavir-treated patients who were switched to Peg-IFNα contributes to HBsAg and cccDNA clearance through TRAIL-induced cytolysis and TNF-α/IFNγ-mediated noncytolytic pathways.

FRI-335

Loss of HbsAg is enough to discontinue long-term therapy with Nucleos(T)ide analogues in HbeAg negative CHB patients in real clinical practice?

A. Kapatais, P. Labropoulos, E. Ouranou, M. Pavlou, T. Karaoulani. *West Attica-Nikaias Hospital, 1st Pathological clinic, Agia Varvara-Egaleo, Greece*
Email: andreaskapatais@yahoo.gr

Background and Aims: The oral Nucleos(T)ide analogues (Nucs) are the most common therapeutic strategy for treatment of CHB patients. The loss of HbsAg is the endpoint of therapy, but it is still not clear whether the clearance of HbsAg alone is enough to stop long –term therapy with Nucs. The evaluation in clinical practice of the outcome in HbeAg-negative CHB patients who discontinued Nucs therapy after loss of HbsAg.
Method: CHB patients -HbeAg-negative with HbsAg clearance during long –term therapy with Nucs followed for at least 24 weeks, after Nucs discontinuation were examined. HbsAg, anti-Hbs, HBV-DNA levels and ALT/AST were monitored every 3 months after Nucs discontinuation in the first year and every six months thereafter.
Results: Among 420 HbeAg-negative CHB patients who received Nucs therapy between 1999–2014, 24 (5,71%) lost HbsAg after a median duration of therapy about 96 months (range 22–180) were included in our study, median age was 56 years, 15 were males, 16% cirrhotics. 22 patients received monotherapy Nucs (11 lamivudine, 5 entecavir, 4 tenofovir) and 2 patients received lamivudine and adenofovir combination therapy. Only 11 from the 24 patients (46%) developed anti-Hbs (level anti-Hbs <100 IU/ml in 5 and 100–500 IU/ml in 6) whereas 13 patients remained persistantly anti-Hbs negative during follow-up. All the patients stopped Nucs therapy after a median duration of consolidation therapy of 12 months (range 0–70). No case of biochemical and virological breakthrough were reported during 24 months (range 06–180) of post treatment follow.

Conclusion: Loss of HbsAg is a rare event in HbeAg-negative CHB patients who were treated with Nucs. However regardless of anti-Hbs seroconversion and duration of consolidation long –term therapy with Nucs, therapy can be safely discontinued in clinical practice in patients with HbsAg loss, in those with advanced liver disease.

FRI-336

Evaluation of renal and bone safety in post liver transplant patients with chronic kidney disease receiving Tenofovir Alafenamide for HBV prophylaxis

E. Gane[1], B. George[1], S. Munn[1], H. Wang[2], V. Suri[2], J.F. Flaherty[2], A. Gaggar[2]. *[1]NZLTU, Auckland City Hospital, Auckland, NZ; [2]Gilead Sciences, Inc, Foster City, California, USA*
Email: vithika.suri@gilead.com

Background and Aims: Chronic Hepatitis B (CHB) remains a leading indication for orthotopic liver transplantation (OLT) worldwide. Common complications following OLT include renal dysfunction secondary to perioperative renal injury and post-operative nephrotoxicity from calcineurin inhibitors; osteoporosis is also observed secondary to preoperative malnutrition and post-operative corticosteroids. In this setting, antiviral prophylaxis to prevent recurrent HBV infection with tenofovir alafenamide (TAF) may have advantages over tenofovir disoproxil fumurate (TDF) due to its improved renal and bone safety profile.

Method: In this Phase 2 study (NCT02862548), liver transplant recipients with stage 2 or greater chronic kidney disease and receiving antiviral prophylaxis with TDF were randomized 1:1 to either receive TAF 25 mg QD or continue their TDF containing regimen. The primary efficacy analysis was the percent of patients who maintained viral suppression at Week 24. Key pre-specified secondary safety endpoints were changes in hip and spine bone mineral density (BMD), changes in serum creatinine (sCr), estimated GFR by CKD-EPI formula and direct GFR assessment (Chromium-EDTA Renal Scan; Cr-EDTA) over 48 weeks.

Results: 51 patients were randomized and treated at a single site in New Zealand. Baseline characteristics included: mean age 60 years, 75% males, 53% Pacific Islander and mean baseline $eGFR_{CKD-EPI}$ 52 ml/min/1.73 m^2 with 53% of patients with <50 ml/min/1.73m^2. The median baseline surface area corrected $GFR_{Cr-EDTA}$ was 58 ml/min/1.73 m^2. The median interval since transplantation was approximately 9 years. Seventy-six percent of patients were maintained on tacrolimus and 29% remained on long-term prednisone. Of the 47 patients that have reached Week 12 to date, all patients (25 in TAF; 22 in TDF arm) maintained viral suppression. There were no treatment discontinuations and serious adverse events were numerically lower in TAF arm compared to the TDF arm. Switching to TAF treatment resulted in a trend toward improved sCr levels (median change in mg/dl: –0.07 for TAF vs. –0.02 for TDF; p = 0.09) and improved $eGFR_{CKD-EPI}$ (median change in ml/min/1.73 m^2: 2.7 for TAF vs. 0.8 for TDF; p = 0.14) as early as week 12 (Figure). Complete data including changes in bone parameters at week 24 will be available at the time of the presentation.

Conclusion: Early after switching from TDF to TAF in a liver transplant recipient population with high rate of renal dysfunction, viral suppression is maintained while smaller changes in renal function were observed.

FRI-337

RO7020531, a novel prodrug of a toll-like receptor 7 agonist, is safe, well tolerated and activates TLR signaling in healthy volunteers

E. Gane[1], I. Folitar[2], C. Schwabe[1], I. Rodriguez[3], L. Gao[4], E. Calleja[5], R. Upmanyu[6], T. Racek[2], E. Coakley[4], J. Grippo[3]. *[1]Auckland Clinical Studies, Auckland, New Zealand; [2]Roche Innovation Center Basel, Basel, Switzerland; [3]Roche Innovation Center New York, New York, United States; [4]Roche Innovation Center Shanghai, Shanghai, China; [5]Roche Innovation Center New York (former employee); [6]Roche Products Ltd, Welwyn Garden City, United Kingdom*
Email: ilia.folitar@roche.com

Background and Aims: RO7020531 is a double prodrug of RO7011785, a selective toll-like receptor (TLR) 7 agonist with lower potency to activate TLR8. It is being developed as a component of a regimen to cure chronic hepatitis B virus (HBV) infection. TLR7 agonism can drive anti-HBV effects through augmented host immune activity via T- and B- cell activation and cytokine production. The aim of this first-in-human clinical study was to evaluate safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of this immune enhancer in healthy volunteers.

Method: Single oral doses of RO7020531, ranging 3–170 mg, were administered to 80 healthy volunteers in 8 dosing cohorts. Each cohort enrolled 10 subjects randomized 8:2 to RO7020531 or placebo, respectively. Safety and tolerability evaluations included adverse

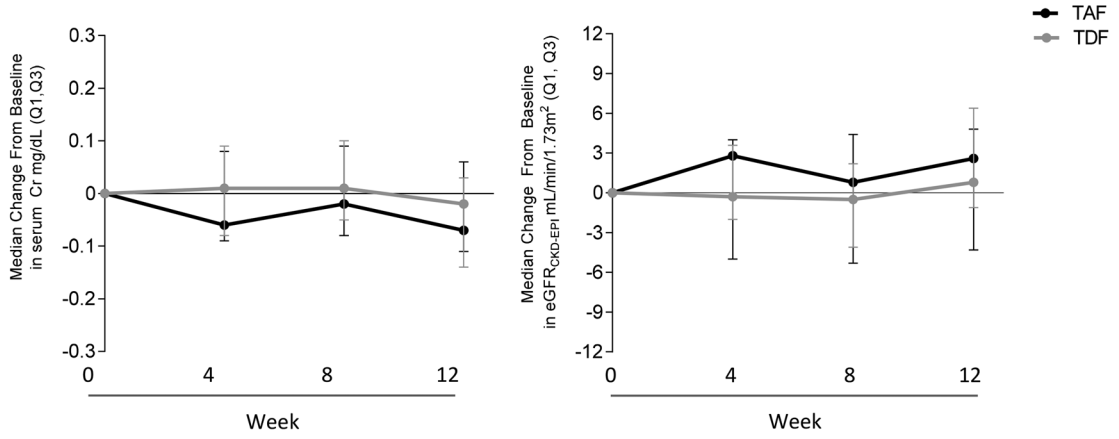


Figure 1: (abstract: FRI-336)

events (AEs), vital signs, ECGs, and laboratory assessments. Plasma PK of RO7020531 and RO7011785, and PD markers of TLR7 response were measured at regular time intervals to 96 hrs post dose.

Results: A blinded safety evaluation demonstrated that all single doses including the highest dose evaluated (170mg) were considered safe and well tolerated. There were few AEs per cohort, the most frequent (>2 subjects) being headache and nausea. All AEs were mild in intensity, and only 3 subjects (10 mg (n = 2) and 170 mg (n = 1)) reported AEs that were considered related to study drug. No serious AEs or discontinuations due to AE were reported.

Across all cohorts, the active TLR7 agonist, RO7011785 appeared rapidly in plasma with a median Tmax of ~0.5 hrs and was eliminated with mean terminal half-life of 3 hrs. Mean plasma RO7011785 AUC increased proportionally from 3 mg to 170 mg doses with relatively low intersubject variability.

Single 100 mg and 140 mg doses activated a cascade of TLR7 responses with initial increases of interferon-alpha within the first 6hrs followed by increased transcription of TLR7, ISG15, MX1 and OAS1 and appearance of plasma IP10 at 12hrs and neopterin 48hrs post dose. The proportion of subjects responding increased from 3/8 (100 mg) to 5/8 (140 mg) with increasing dose. PD data for the 170 mg cohort are pending.

Conclusion: RO7020531, a double prodrug TLR7 agonist, was considered safe and well tolerated with a favorable PK profile in single doses up to 170 mg. The demonstration of TLR7 signaling supports exploring the further development of RO7020531 as a key component of an HBV cure regimen.

Ledipasvir/Sofosbuvir for 12 weeks is safe and effective in adolescents with chronic hepatitis C virus infection and hematological malignancies undergoing chemotherapy

M.H. El-Sayed[1], F.S.E.S. Ebeid[1], A.R. Zekri[2], B. Massetto[3], K. Kersey[3], A. Osinusi[3], F. Zhang[3], D. Brainard[3], W. Elsayed[4], A. El-Haddad[4].
[1]Children's Hospital, Ain Shams University, Pediatric Department, Hematology/Oncology Division, Cairo, Egypt; [2]National Cancer Institute, Virology Department, Cairo, Egypt; [3]Gilead Sciences, Foster City, United States; [4]National Cancer Institute, Pediatric Oncology Department, Cairo, Egypt
Email: manalhelsayed@yahoo.co.uk

Background and Aims: The prevalence of chronic active HCV infection among children in Egypt ranges from 0.2% to 0.8% and among children with haematological malignancies, rates of up to 24% have been reported. While the natural history of HCV infection in children is benign compared to that of adults, ALT flares during chemotherapy in HCV-infected children with hematological malignancies have been associated with more rapid liver disease progression and higher risk of malignancy relapse due to chemotherapy interruption.

Method: Patients 12 to <18 years old with chronic HCV genotype (GT) 1 or 4 infection and undergoing maintenance chemotherapy for hematological malignancies were enrolled into this ongoing open-label, Phase 2 study at 1 site in Egypt, to receive Ledipasvir/Sofosbuvir (LDV/SOF) (90 mg/400 mg) fixed dose combination tablet once daily for 12 weeks. The key efficacy endpoint is sustained virologic response 12 weeks after treatment (SVR12). Safety was assessed by adverse events (AEs) and clinical/laboratory data, including HCV flares defined as an increase in ALT ≥ 3 x baseline and HCV RNA elevation $\geq 1 \times \log_{10}$ from baseline. An interim analysis on the first 13 patients enrolled is presented.

Results: 13 adolescents with a diagnosis of leukemia receiving maintenance chemotherapy were treated with LDV/SOF. 85% were males, 54% had IL28B non CC genotype, and all were infected with HCV GT4 and were HCV treatment naïve. The mean age was 15 years (range 12–17), mean weight was 56 kg (range 46–91) and mean BMI was 21 kg/m^2 (19–32). All patients completed HCV treatment and all 12 patients who have reached 12 weeks post treatment achieved SVR12. The most common AEs reported were diarrhea (3, 23%), vomiting (3, 23%), headache (3, 23%) and pyrexia (4, 31%). 4 patients experienced mild to moderate AEs considered by the investigator related to study drug: headache (3 patients) or generalized pruritus (1 patient); none required chemotherapy interruption. 2 patients had 1 serious AE each (both pneumonia), assessed by the investigator as not related to study drug in both cases. There were no deaths, and no patient experienced HCV flares.

Conclusion: In adolescents with HCV GT4 and leukemia undergoing maintenance chemotherapy, LDV/SOF daily for 12 weeks was well tolerated and resulted in a 100% SVR12 rate in the 12 patients who have reached that timepoint. These data support the use of this all-oral, interferon-and ribavirin-free regimen in adolescents with hematological malignancies.

FRI-339

Clinical and virological predictors of response after antiviral therapy interruption in HBeAg-negative chronic hepatitits B

S. Lens[1], M. García-López[1], Z. Mariño[1], M. Bonacci[1], S. Rodríguez-Tajes[1], E. Perpiñan[1], F. Rodríguez-Frías[2], B. Testoni[3], G. Koutsoudakis[1], M.B. Ferret[2], F. Zoulim[3], Sofía Pérez del Pulgar[1], X. Forns[1]. *[1]Hospital Clinic, IDIBAPS, CIBERehd. Email: slens@clinic.ub.es

Background and Aims: The possibility of stopping nucleos(t)ide analog (NA) therapy in virologically suppressed HBeAg-negative (HBeAg-) patients has been considered in the recent European clinical guidelines. However, the variables predicting a successful discontinuation of NA in this population have not been defined yet. Aim: To investigate the epidemiological, virological and clinical factors associated to a successful NA therapy discontinuation in HBeAg- patients.

Method: Prospective study including non-cirrhotic patients with HBeAg- chronic hepatitis B with viral suppression for more than 3 years under NA therapy. Patients underwent a liver biopsy at inclusion to exclude the presence of advanced fibrosis and to analyze total intrahepatic HBV-DNA(iHBV-DNA) and cccDNA. Standard liver tests with viral serum markers (HBV-DNA, qHBsAg, HBcrAg) were performed at 1-month intervals after NA discontinuation.

Results: Twenty patients have been included so far. Most (85%) were male; median age was 52 years-old. The median duration of NA therapy was 9 years, 16 (80%) received tenofovir. Median (IQR) qHBsAg levels at baseline were 1439 IU/mL (558–3379) and correlated significantly with iHBV-DNA levels (rho = 0.7, $p < 0.01$) and HBcrAg (rho = 0.5, $p < 0.05$) but not with cccDNA levels. After a median follow-up of 43 weeks, 16 patients (80%) remained off-therapy and 5 (25%) presented HBsAg loss. ALT (>3UNL) and DNA peaks (>20,000 IU/ml) were frequently observed during follow-up in 40% and 50% of patients, respectively. Patients with HBsAg loss had significantly lower baseline qHBsAg (63 vs 2122 IU/ml, $p < 0.01$) and iHBV-DNA levels (0.04 vs 0.98 copies/cell, $p < 0.01$). There were no adverse events related to therapy discontinuation.

Conclusion: Antiviral therapy discontinuation is feasible in a high proportion of HBeAg- Caucasian patiens under NA therapy. Interestingly, low qHBsAg levels are associated with a high chance of HBsAg loss, particularly if associated with low iHBV-DNA (but not cccDNA) levels.

FRI-340

Five years follow-up of chronic hepatitis B patients immunized by nasal route with the therapeutic vaccine HeberNasvac

A. Julio, J. Aguiar, G. Guillen, E. Penton, G. Fernandez. *Center for Genetic Engineering and Biotechnology, Vaccines, Havana, Cuba*
Email: julio.aguilar@cigb.edu.cu

Background and Aims: A novel therapeutic vaccine for chronic hepatitis B (CHB) treatment comprising the recombinant hepatitis B surface (HBsAg) and nucleocapsid (HBcAg) antigens has been developed in the last two decades. Preclinical and clinical trials (CT) evidenced safety and immunogenicity in animal models as well as in phase I and I-II CT. Recently, a phase III CT evidenced the superiority of therapeutic vaccination in terms of safety and efficacy compared to PegIFN. These studies were conducted in healthy volunteers and treatment-naïve CHB patients vaccinated by both IN and SC routes. However, pharmacological studies have shown that the nasal route *per se* deserve further attention. The aim of the present study is to evaluate the long term efficacy results in the first 6 patients treated with the therapeutic vaccine HeberNasvac and immunized by the IN route in order to preliminarily understand the effect of the route after five years follow-up.
Method: The phase I clinical trial was conducted in 6 CHB patients previously treated with α-IFN, 3 of them HBeAg positive. Patients were immunized with 100 μg HBsAg and 100 μg HBcAg (HeberNasvac), via nasal spray in ten administrations, every two weeks. Samples from these patients were preserved for a period of five years after the end of treatment to retrospectively analyze the serological and virological variables. Clinical efficacy was monitored by assessing the levels of HBV DNA, ALT, HBeAg to anti-HBeAg seroconversion as well as by qualitative/ quantitative HBsAg serology during this period of time.
Results: After five year follow-up HBeAg loss was verified in the three HBeAg (+) patients, in two cases with seroconversion to anti-HBeAg. A reduction to undetectable viral load was observed in 5 out of 6 patients and in two cases there were HBsAg seroconversion. ALT increases above 2X ULN were only detected in HBeAg (+) patients and associated to HBe antigen loss. All patients were negative for cirrhosis or moderate fibrosis (<7.8 KPa by Fibroscan assessment) at the end of this period. It was not required any alternative medication due to sustainedly normal LFTs and absence of treatment criteria.
Conclusion: In conclusion, HeberNasvac administration was not associated to any safety concern 5 years after the end of treatment. Virological, biochemical, serological variables evidenced the efficacy of this product in this difficult to treat group of patients as well as the absence of disease progression. The use of the intranasal route deserves further evaluation as most of the patients with CHB lives in countries where unsafe injections are frequent and, in addition, the nasal route may further potentiate the immune response in the liver.

FRI-341

Association of metabolic adipokines with persistence of fibrosis in chronic hepatitis B during long-term nucleoside analogue therapy

K.-S. Cheung[1], L.-Y. Mak[1], W.-K. Seto[2,3], D. Wong[2,3], F. Liu[2], Y.Y. James Fung[2,3], C.L. Lai[2,3], M.-F. Yuen[2,3]. *[1]The University of Hong Kong, Queen Mary Hospital, Medicine, Hong Kong; [2]The University of Hong Kong, Medicine, Hong Kong; [3]State Key Laboratory for Liver Research, The University of Hong Kong, Hong Kong*
Email: wkseto@hku.hk

Background and Aims: Liver fibrosis regression during nucleoside analogue (NA) treatment in chronic hepatitis B (CHB) is not guaranteed. There is emerging evidence on metabolic factors being associated with persistence of fibrosis in on-treatment CHB. There are emerging interests in metabolic biomarkers that reflect adipokine dysregulation, e.g. adiponectin, fatty acid-binding protein 4 (FABP4), fibroblast growth factor (FGF-21) and homeostatic model assessment-insulin resistance (HOMA-IR). Their role in CHB-related liver injury has not been well investigated.
Method: We recruited 414 on-treatment CHB patients and performed transient elastography for liver stiffness and controlled attenuation parameter (CAP). Significant fibrosis was defined based on the alanine aminotransferase (ALT)-based EASL-ALEH criteria, while severe steatosis was defined as the presence of CAP ≥ 280 dB/m. Logistic regression was used to investigate the risk factors associated with the development of severe steatosis and significant fibrosis. Apart from the above four variables of interest, we also considered clinical, metabolic, biochemical and virologic parameters.
Results: There were 296 (71.5%) male patients, and the median age of the cohort was 60.2 years (interquartile range [IQR]: 54.2–65.3 years). The median duration of NA treatment was 73.6 months (IQR: 43.0–93.4 months); 378 (91.3%) patients had undetectable HBV DNA (<20IU/ml) at assessment. Severe steatosis and significant fibrosis were found in 89 (21.5%) and 167 (56.4%) patients, respectively. The median adiponectin level was significantly lower among patient severe steatosis than those without severe steatosis (7.6 vs 11.4 ug/ml, $p < 0.001$), while there were no statistically significant differences for

Table: (abstract: FRI-341)

Table 1. Comparison of the median levels of various adipokines between (a) patients with and without severe steatosis; (b) patients with and without significant fibrosis

a	Severe steatosis	Absence of severe steatosis	p-value
FGF-21 (pg/mL)	182.0	231.0	> 0.05
FABP4 (pg/mL)	138.8	93.6	> 0.05
Adiponectin (ug/mL)	7.6	11.4	**< 0.001**
HOMA-IR (mU/L)	6.4	5.7	> 0.05
b	**Significant fibrosis**	**Absence of significant fibrosis**	**p-value**
FGF-21 (pg/mL)	220.0	218.0	> 0.05
FABP4 (pg/mL)	126.8	73.7	**< 0.001**
Adiponectin (ug/mL)	10.2	10.5	> 0.05
HOMA-IR (mU/L)	6.6	5.1	**0.006**

other adipokines (Table 1a). The median FABP4 level was significantly higher among patients with significant fibrosis than those without significant fibrosis (126.8 vs 73.7 pg/ml, p < 0.001), and the median HOMA-IR level was significantly higher (6.6 vs 5.1 mU/l, p = 0.006), while there were no statistically significant differences for other adipokines (Table 1b). Independent risk factors for significant fibrosis included severe steatosis (OR: 2.22, 95% CI: 1.45–4.34), DM (OR: 1.90, 95% CI: 1.03–3.53), thrombocytopenia (OR: 3.78, 95% CI: 2.19–6.65), a lower albumin level (OR 0.90, 95% CI: 0.82–0.98), a higher AST level (OR: 1.05, 95% CI: 1.01–1.10), a higher GGT level (OR: 1.02, 95% CI: 1.01–1.03) and a higher FABP4 level (OR: 1.0016, 95% CI: 1.0003–1.0032).

Conclusion: Both a higher FABP4 level and severe steatosis were independently associated with the presence of severe fibrosis in NA-treated CHB. FABP4 is a marker of fatty acid uptake, transport and metabolism; its role in the fibrogenesis process of CHB requires further investigation.

FRI-342

Tenofovir Disoproxil Fumarate use during pregnancy and infant bone health and growth: the Tenofovir in pregnancy study

A. Kourtis[1], J. Wiener[2], L. Wang[3], B. Fan[4], J. Shepherd[4], L. Chen[5], W. Liu[6], C. Shepard[7], L. Wang[8], A. Wang[8], M. Bulterys[9]. [1]*CDC, dRH;* [2]*CDC, DRH;* [3]*GAP, CDC;* [4]*UCSF, Radiology;* [5]*Guangxi REgion Health and Family Planning Commission, Health and Family Planning Commission;* [6]*Guangxi Center for Disease Control and Prevention, Guangxi Cdc;* [7]*CDC, CGH Gap;* [8]*China Cdc;* [9]*WHO, Dept of HIV and Hepatitis*
Email: apk3@cdc.gov

Background and Aims: There is limited information on bone mineral density and content (BMD, BMC) of infants exposed *in utero* to tenofovir.

Method: The Tenofovir in Pregnancy (TiP) study was a phase II randomized controlled trial of the safety of a regimen containing vs. one not containing tenofovir disoproxil fumarate (TDF), starting as early as 14 weeks gestation, in HIV/HBV co-infected pregnant women and their infants in Guangxi, China (ClinicalTrials.gov, number NCT01125696). Our objective was to assess the effects of TDF exposure *in utero* on infant BMD and BMC, assessed by DXA scans at birth and at 6 months of life, and to assess effects on infant growth, by comparing TDF-exposed and unexposed infants, unadjusted and adjusted for covariates.

Results: Fourteen TDF-exposed and 13 tenofovir-unexposed infants had evaluable BMD and BMC measurements at birth. Tenofovir exposed infants were similar to unexposed infants on mean gestational age (38.1 vs 38.4 weeks) and birth weight (2695 vs 2861 g). The mean difference in BMC between TDF-exposed infants and unexposed infants was −6.4 g (95% confidence interval =−19.9, 7.1) at birth and −5.7 g (95% confidence interval =−26.0, 14.7) at 6 months. The mean difference in BMD at both birth and 6 months between TDF-exposed infants and unexposed infants was −0.01 g/cm^2 (95% confidence interval =−0.02, 0.01). Similar results were obtained when the mean difference in BMC was estimated using a linear mixed model to account for repeated measurements and adjust for relevant covariates (−6.6 g, 95% confidence interval =−16.6, 3.5). Infant weight and height were also similar in the two groups at 6 and 12 months of age.

Conclusion: Maternal TDF use during the second and third trimester of gestation led to non-significant mild decreases in infant BMC and BMD ranging from 10% to 4% and 6% to 3%, respectively, from birth to 6 months of age, that are of uncertain clinical significance. No effects on infant growth were observed through the first year of life.

FRI-343

Updated follow-up analysis in the REP 401 protocol: Treatment HBeAg negative chronic hepatitis B infection with REP 2139 or REP 2165, tenofovir disoproxil fumarate and pegylated interferon alfa-2a

A. Vaillant[1], M. Bazinet[1], V. Pantea[2], G. Placinta[2], I. Moscalu[3], V. Cebotarescu[2], L. Cojuhari[2], P. Jimbei[4], L. Iarovoi[2], V. Smesnoi[4], T. Musteata[4], A. Jucov[3], A. Krawczyk[5]. [1]*Replicor Inc, Montreal, Canada;* [2]*Nicolae Testemitanu State University of Medicine and Pharmacy, Department of Infectious Diseases, Faculty of Postgraduate Education, Chisinau, Moldova;* [3]*ARENSIA Exploratory Medicine, Phase I Unit, Republican Clinical Hospital, Chisinau, Moldova;* [4]*Toma Ciorba Infectious Clinical Hospital, Chisinau, Moldova;* [5]*Universitätsklinikum Essen, Institute for Virology, Essen, Germany*

Background and Aims: The REP 401 study (NCT02565719) is assessing the safety and efficacy of REP 2139 (clinical lead) or REP 2165 combined with tenofovir disoproxil fumarate (TDF) and pegylated interferon α-2a (peg-IFN) in Caucasian patients with chronic HBeAg negative HBV infection.

Method: Lead-in TDF therapy in 40 patients was followed by randomization into an experimental group (48 weeks of TDF, peg-IFN and REP 2139 or REP 2165) or a control group (24 weeks of TDF + peg-IFN) who crossed over to 48 weeks of experimental therapy. Viremia is monitored on the Abbott Architect and Realtime platforms.

Results: Therapy was well tolerated except for one withdrawal due to pegIFN-related depression. Follow-up has been extended to 24 weeks in 18/20 experimental patients and 4–12 weeks in 17/20 crossover patients.

HBV DNA was controlled in all patients during TF lead-in and throughout therapy. Following randomization, experimental patients had HBsAg reductions as follows: 17/20 > 1 log from baseline, 14/20 < 1IU/ml and 13/20 < 0.01 IU/ml. Following crossover in control patients HBsAg reductions were as follows: 19/20 > 1 log from baseline, 14/20 < 1IU/ml and 10/20 < 0.01 IU/ml.

HBsAg < 1 IU/ml in experimental patients was accompanied by increases in anti-HBs (range 25–223,055 mIU/ml) in 13/14 patients and therapeutic liver flares (ALT/AST > 5x ULN with normal synthetic liver function) in 12/14 patients. In control patients, transaminase flares in patients with HBsAg < 1 IU/ml were attenuated but anti-HBsAg elevations were comparable to the experimental group.

Functional control of HBV infection (HBsAg < LLOQ, HBV DNA < LLOQ) is persisting 24 weeks after removal of therapy in 12/14 experimental patients achieving HBsAg <1 IU/ml (REP 2139: 7/10, REP 2165: 5/10) and is stable in the remaining 2 patients. In control patients, functional control of HBV infection is persisting 4-12 weeks in 11/12 patients achieving HBsAg < 1 IU/ml (REP 2139: 4/10, REP 2165 7/10) with available follow-up data and is stable in the remaining patient. Functional control of HBV infection in both groups is accompanied by normalization of ALT/AST in all but 5 patients.

Conclusion: NAPs are effective and well tolerated in combination with peg-IFN and TDF in HBeAg negative chronic HBV infection and elicit the establishment of functional control of HBV infection persisting after removal of therapy and normalization of liver function in a majority of patients.

Email: yyy@bjmu.edu.cn

Background and Aims: The efficacy and safety of long-term entecavir (ETV) treatment in chronic hepatitis B (CHB) has been reported previously. But the limitations in those reports undermined the credibility of the results, including the dosage change of entecavir, exposure to drugs other than entecavir during study, lower percentage of patients completing follow-up, insufficient sample size and lower percentage of patients infected by genotype B and C hepatitis B virus (HBV). The present, randomized, double-blind, double-dummy, controlled, multicenter study was designed to evaluate the efficacy and safety of ETV maleate versus ETV in Chinese patients with CHB predominantly genotype B or C. The results at week 144 have been reported before (2016 AASLD liver meeting). Here we present the results at week 240.
Method: Patients were randomly assigned to receive 48 weeks of treatment with either 0.5 mg/day ETV or 0.5 mg/day ETV maleate, then all patients received the treatment with 0.5 mg/day ETV maleate through week 240. HBV DNA levels were measured by the Roche Cobas Ampliprep/Cobas Taqman PCR assay. Adverse events (AE) were recorded.
Results: Two hundred and eighteen (110 in group A) patients with HBeAg-positive CHB and 57 (26 in group A) patients with HBeAg-negative CHB were enrolled. Baseline characteristics were well balanced between the two groups, predominantly (98.5%) genotype B or C. One hundred and thirty-seven (71 in group A) patients with HBeAg- positive CHB and 46 (21 in group A) patients with HBeAg-negative CHB completed the 240-week treatment and follow-up. For the patients with HBeAg-positive CHB, the mean HBV DNA level had similarly decreased from baseline in both groups (A: by 6.67$\log_{10}$IU/ml vs. B: by 6.74$\log_{10}$IU/ml; $p > 0.05$) at week 240. Patients who achieved undetectable levels of serum HBV DNA (<20 IU/ml) at week 240 were similar in the two groups (A: 91.55% vs. B: 87.88%; $p > 0.05$). Both groups achieved similar HBeAg seroconversion rates at week 240 (A: 26.98% vs. B: 20.97%; $p > 0.05$). Both groups achieved similar normalization of ALT at week 240 ($p > 0.05$). For the patients with HBeAg- negative CHB, the mean HBV DNA level had similarly decreased from baseline in both groups (A: by 6.05$\log_{10}$ IU/ml vs. B: by 6.10 $\log_{10}$IU/ml; $p > 0.05$) at week 240. Patients who achieved undetectable levels of serum HBV DNA (<20 IU/ml) at week 240 were similar in the two groups (A: 100% vs. B: 100%). Both groups achieved similar normalization rates of ALT at week 240 ($p > 0.05$). The overall incidence of AE was similar in the two groups.
Conclusion: ETV maleate and ETV showed similar efficacy and safety in Chinese patients with CHB predominantly genotype B or C.

FRI-345
Sustained virological suppression and improved renal function with reduced dose tenofovir disoproxil fumarate in renally compromised patients with chronic hepatitis B

S. Liem[1,2], D. Wong[1], S. Fung[1], A. Zahirieh[3], C. Yim[1], H.A Shah[1], J. Feld[1,4], B. Hansen[1,2,5], H. Janssen[1]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]Erasmus University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [3]Sunnybrook Health Sciences Centre, Toronto, Canada; [4]University of Toronto, McLaughlin-Rotman Centre for Global Health, Toronto, Canada; [5]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada*
Email: k.s.liem@erasmusmc.nl

Background and Aims: Tenofovir disoproxil fumarate (TDF) therapy effectively suppresses viral replication in patients with chronic hepatitis B (CHB), but occasionally leads to renal impairment. We studied prevalence of viral breakthrough (VBT) and renal function in renally impaired CHB patients on reduced dose TDF, and in patients on full dose TDF.
Method: CHB patients with full and reduced dose TDF (due to eGFR (Cockcroft-Gault) <50 ml/min/1.73 m^2 ± serum phosphate <0.8 mmol/l) were identified at Toronto Centre for Liver Disease. VBT (confirmed HBV DNA > 1logIU/ml above nadir on-therapy (AASLD)), and biochemical breakthrough (confirmed ALT > 1.5xULN) were assessed from 1 month after start of (reduced) TDF dose (baseline) until end of follow-up (EOF). Renal function was assessed by Modification of Diet in Renal Disease (MDRD) and categorized into chronic kidney disease stages 1–5. Outcome was compared between full and reduced dose TDF, and between before and after dose reduction within patients who started on full dose TDF.
Results: Out of 750 patients on TDF, 78 (10%) had reduced dose vs. 672 (90%) full dose. At baseline the mean (SD) age was 69 (10) vs. 45 (13) years, 69% vs.70% was male, mean duration on TDF was 3.4 (2.4) vs. 4.7 (3.1) years for reduced vs. full dose of TDF. Of patients on reduced TDF dose 71% had undetectable HBV DNA (mean 1.4logIU/ml), 82% received TDF 300mg Q48hr (range 75 mg – 300 mg Q48hr), mean MDRD was 52 (19) ml, 42% had chronic kidney disease stage G3b or higher and 12% had decompensated cirrhosis. Mean follow-up was 2.6 (2.3) years. VBT occurred in 1 cirrhotic patient on dialysis using TDF 300 mg weekly (HBV DNA peak 3.6 log) that resolved 4 months after dose increase to biweekly without signs of decompensation, and in 1 patient on full dose TDF (resolved spontaneously). Viral blips (HBVDNA between 1 and 2 logs on 1 occasion) occurred in 2.6% before vs. 5.4% after dose reduction ($p = 0.53$), and in 2.8% of patients on continuous full dose TDF. One biochemical breakthrough occurred in a reduced dose patient (ALT peak 2xULN) and resolved spontaneously without VBT. During dose reduction the MDRD increased from baseline to EOF (+6.0 (21) ml; $p = 0.04$) and 50 (64%) patients reached eGFR > 50ml.
Conclusion: In CHB renal dose adjustment of TDF did not lead to significant VBT while renal function improved. This implies that renal dosing of TDF in CHB is effective and safe, and should be considered a viable option in renally compromised patients.

FRI-346
Low serum HBsAg and HBV DNA predict response of peg-interferon addition to entecavir in HBeAg positive chronic hepatitis B

S. Liem[1,2], B. Hansen[1,3,4], Q. Xie[5], C. Liang[6], W.P. Brouwer[3], H. Chi[3], S. Guo[6], X. Qi[6], N.-P. Zhang[7], T. Fehmi[8], M.V. Campenhout[3], H. Janssen[1]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]Erasmus University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Toronto, Canada; [3]Erasmus University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [4]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; [5]Jiaotong University, Department of Infectious Diseases, Ruijin Hospital, Shanghai, China; [6]Fudan University, Department of Hepatitis Disease, Shanghai Public Health Clinical Center, Shanghai, China; [7]Zhongshan Hospital, Department of Gastroenterology and Hepatology, Shanghai, China; [8]Cerrahpasa Medical Faculty, Istanbul, Turkey*
Email: k.s.liem@erasmusmc.nl

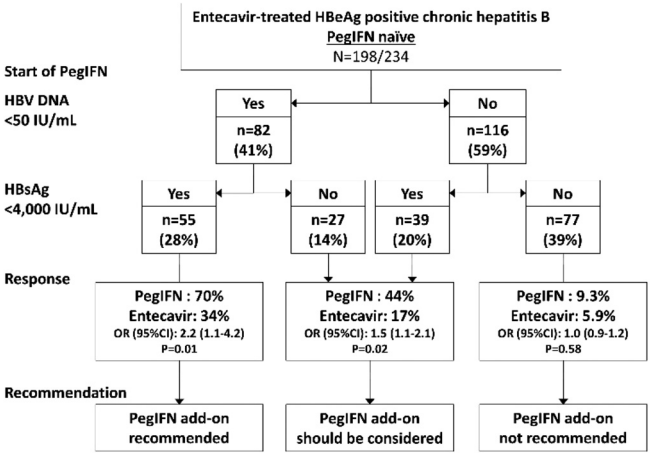
Background and Aims: Addition of peg-interferon (PegIFN add-on) to nucleos(t)ide analogues is effective in a select group of patients with chronic hepatitis B (CHB), but the optimal candidates for PegIFN add-on remain are yet to be identified. To establish clinical starting

rules for PegIFN add-on, we studied the relationship between cut-off values of serum Hepatitis B surface Antigen (HBsAg) and hepatitis B virus (HBV) DNA at start of PegIFN and response at off-treatment follow-up in 234 HBeAg positive CHB patients treated with PegIFN add-on to entecavir (ETV) or continued ETV monotherapy.

Method: HBeAg positive patients from two investigator-initiated, randomized controlled trials were included. Patients received ETV pretreatment for at least 24 weeks and were then (baseline) allocated to 24–48 weeks of ETV + PegIFN alpha add-on, or 24–48 weeks of continued ETV monotherapy. Response was defined as a combination of HBeAg loss with HBV DNA < 200 IU/ml 48 weeks after PegIFN cessation. Cut-off values for HBV DNA and HBsAg at baseline were based on a minimum response difference of 15% between PEG-IFN add-on and ETV monotherapy, and a significant difference between add-on vs. monotherapy below the HBV DNA cut-off, but not above. Receiver Operating Characteristic curves were constructed for each threshold and the Area Under the Curve (AUC) of the thresholds was calculated.

Results: Of 234 patients, 118 started on PegIFN add-on and 116 continued ETV monotherapy. Baseline characteristics of both groups were comparable. Mean baseline HBV DNA was 2.2 (SD 2.4) log IU/mL, median ALT 0.5 (IQR 0.4–0.8) × ULN, and mean HBsAg 3.6 (0.8) logIU/ml. Response was achieved by 38/118 (32%) patients with add-on therapy and 23/116 (23%) on ETV monotherapy ($p = 0.03$). The highest probability of response to PEG-IFN add-on compared to ETV monotherapy (70% vs. 34%, $p = 0.01$) was found in PEG-IFN naïve patients with an HBsAg level below 4,000 IU/ml and HBV DNA level below 50 IU/ml at baseline. The AUC of the combined cut-off values was 0.79 (95%CI: 0.72–0.86). Above these cut-off levels, response rates were very low and not significantly different between treatment groups (9.3% vs. 5.9%, $p = 0.58$).

Algorithm. Probability of response at end-of-follow-up based on HBsAg and HBV DNA



Conclusion: PegIFN add-on to ETV therapy was associated with higher response rates compared to ETV monotherapy in patients with CHB. Based on our study, PegIFN add-on may be recommended in PegIFN naïve patients with serum HBsAg <4,000 IU/ml and HBV DNA <50 IU/ml as off-treatment response was 70%.

FRI-347

Renal outcomes in chronic hepatitis b patients treated with tenofovir disoproxil fumarate or entecavir: a propensity score matched study

S. Trinh[1], A. Le[1], J. Hoang[1], D. Jeong[1], M. Chung[1,2], M.-H. Lee[3], U. Wang[1], M. Nguyen[1]. *[1]Stanford University Medical Center, Division of Gastroenterology and Hepatology, Palo Alto; [2]Princeton University, Princeton, [3]National Yang-Ming University, Institute of Clinical Medicine, Taipei, Taiwan*
Email: mindiehn@stanford.edu

Background and Aims: Studies on the use of tenofovir disoproxil fumarate (TDF) causing nephrotoxicity or impaired renal function remain undetermined. Entecavir (ETV) has been shown to not cause any renal dysfunction. Thus, we aim to further compare renal outcomes of patients with chronic hepatitis b (CHB) who were treated with either TDF or unexposed to TDF, ETV.

Method: This is a matched cohort study with adult CHB patients consecutively identified via ICD-9 query at a tertiary medical center in the United States from 2000 to 2016. Data were collected via individual chart review by standardized procedure. Overall, we identified 240 ETV and 172 TDF patients with serial creatinine labs who were treated for at least 12 months. Patients with prior adefovir treatment, hepatitis C, hepatitis D, or human immunodeficiency virus co-infection, were excluded. Patients with baseline estimated glomerular filtration rate (eGFR) <60 was excluded for one of the analyses (eGFR calculated via the modification of diet in renal disease study formula). Propensity score matching (PSM) (for age, sex, baseline eGFR, hypertension, diabetes mellitus, and follow-up duration) was performed to adjust for background risks and differences in length of follow-up. Generalized linear regression modelling (GLM) was used to determine renal outcomes as measured by mean eGFR.

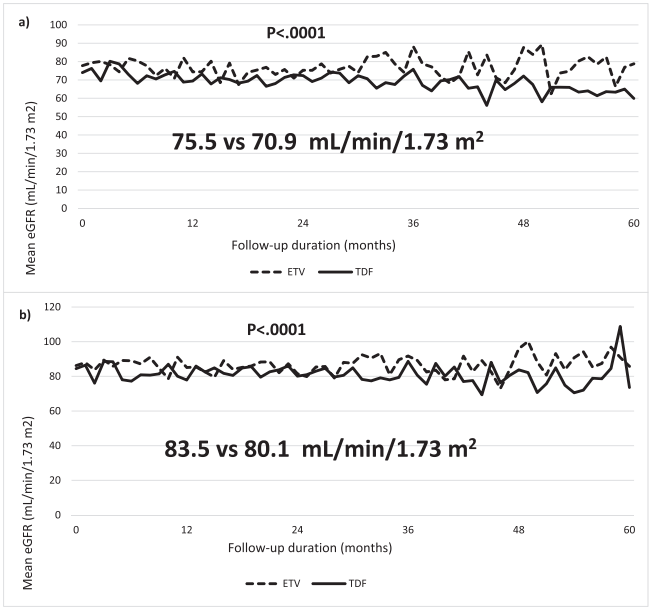


Figure 1: Generalized linear model for trends in mean eGFR in propensity score matched (a) overall, (b) exclusion of eGFR < 60, entecavir and tenofovir treated patients over a long-term follow-up.

Results: After PSM, the overall cohort for both treatment groups (n = 145, 145) were well matched on age, male sex, baseline eGFR, follow-up duration, diabetes mellitus, and hypertension without significant differences between the 2 groups ($p > 0.05$ for all comparisons). On GLM, adjusting for hypertension, diabetes mellitus and cirrhosis, TDF patients had a significantly lower mean eGFR (70.9 vs. 75.5ml/min/1.73 m^2) during follow-up when compared to ETV patients (Figure a). After excluding already renally impaired patients (eGFR < 60ml/min/1.73 m^2) at baseline, we performed another PSM with the same variables above, and found that both groups (n = 124, 124) were also well matched, with no significant differences except for baseline cirrhosis (10.6% in ETV and 22.0% in TDF group, ($p = 0.02$). On GLM, adjusting for the same covariates as above, we again found that TDF patients had a significantly lower mean eGFR (80.1 vs. 83.5 ml/min/1.73 m^2) during follow-up when compared to ETV patients (Figure b).

Conclusion: TDF-treated patients consistently had lower mean eGFR values when compared to ETV overall including patients without renal impairment at baseline and after appropriate matching for

background risks. Thus, renal function should be monitored in CHB patients treated with TDF.

FRI-348

Peginterferon is superior to nucleos(t)ide analogues for reduction ofchronic hepatitis B-related hepatocellular carcinoma in patients with high-riskscore

P. Ren, Z. Cao, R. Mo, Y. Liu, C. Lichang, Z. Tianhui, Z. LI, J. Lu, Y. Liu, Q. Guo, R. Chen, H. Zhou, W. Cai, H. Wang, H. Gui, Q. Xie. *Ruijin Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Department of Infective Diseases, Shanghai, China*
Email: renpeipei1014@163.com

Background and Aims: Although a few studies indicated that pegylated interferon (PEG-IFN) was preferable to nucleos(t)ide analogues (NAs) in reducing hepatocellular carcinoma (HCC) incidence, clinical evidence needs to be strengthened. This study was designed to compare the long-term outcomes of PEG-IFN vs NAs therapy in chronic HBV infection (CHB) patients and further evaluated the treatment type effect on the HCC incidence in patients stratified by previously validated HCC risk scores.

Method: Cumulative HCC incidence rates were calculated using the Kaplan-Meier curve and compared with the log-rank test. To reduce the selection bias, propensity score matching (PSM) was utilized. Area under receiver operating characteristic curves (AUROCs) was used for the predictive performance of different HCC risk scores.

Results: 1,112 CHB patients (755 naïve case) were enrolled to form the main cohort. During the follow-up (median 5.41 years), we finally observed 31, 21 HCC cases respectively in the entire and naïve cohort. The PEG-IFN group had a lower HCC incidence when compared to the NAs group whether in the entire or naïve cohort (8.0% vs 2.3%, p < 0.0001; 8.9% vs 0.0%, p = 0.0002; respectively) (Figure 1 A-B). The result was further confirmed in the baseline PSM subgroup analyses of the entire and naïve cohort (6.8% vs 0.0%, p = 0.0197; 9.9% vs 0.00%, p = 0.0415; respectively) (Figure 1 C-D). Univariate/multivariate cox analysis in the entire cohort manifested older age (hazard ratio [HR] = 2.873, 95% CI 1.093–7.554, p = 0.0323), male (HR = 5.670, 95% CI 1.720–18.696, p = 0.0044), cirrhosis (HR = 5.426, 95% CI 2.487–11.970, p < 0.0001) and treatment type (HR = 0.154, 95% CI 0.036–0.660, p = 0.0117) were associated with HCC occurrence.

In the entire cohort, PAGE-B showed similar AUROCs to GAG-HCC at 3 years (0.884 vs 0.887, respectively; p = 0.9487), 5 years (0.859 vs 0.841, respectively; p = 0.6304) and 10 years (0.822 vs 0.833, respectively; p = 0.7784), whereas AUROCs of PAGE-B or GAG-HCC were significantly higher than REACH-B (0.809, 0.769, 0.758 at 3, 5, 10 years, respectively; all p < 0.05) or CU-HCC (0.787, 0.767, 0.757 at 3, 5, 10 years, respectively; all p < 0.05). The mentioned above HCC scores accuracy analyses in the naïve cohort concurred with the entire cohort. Subgroup analyses in the entire population stratified by PAGE-B or GAG-HCC indicated there was no difference between the PEG-IFN and NAs group in the low-risk patients (PAGE-B <10; GAG-HCC <82) (1.08% vs 0.00%, p = 0.3199; 0.42% vs 3.28%, p = 0.0848; respectively). However, the PEG-IFN group had a lower HCC incidence than the NAs

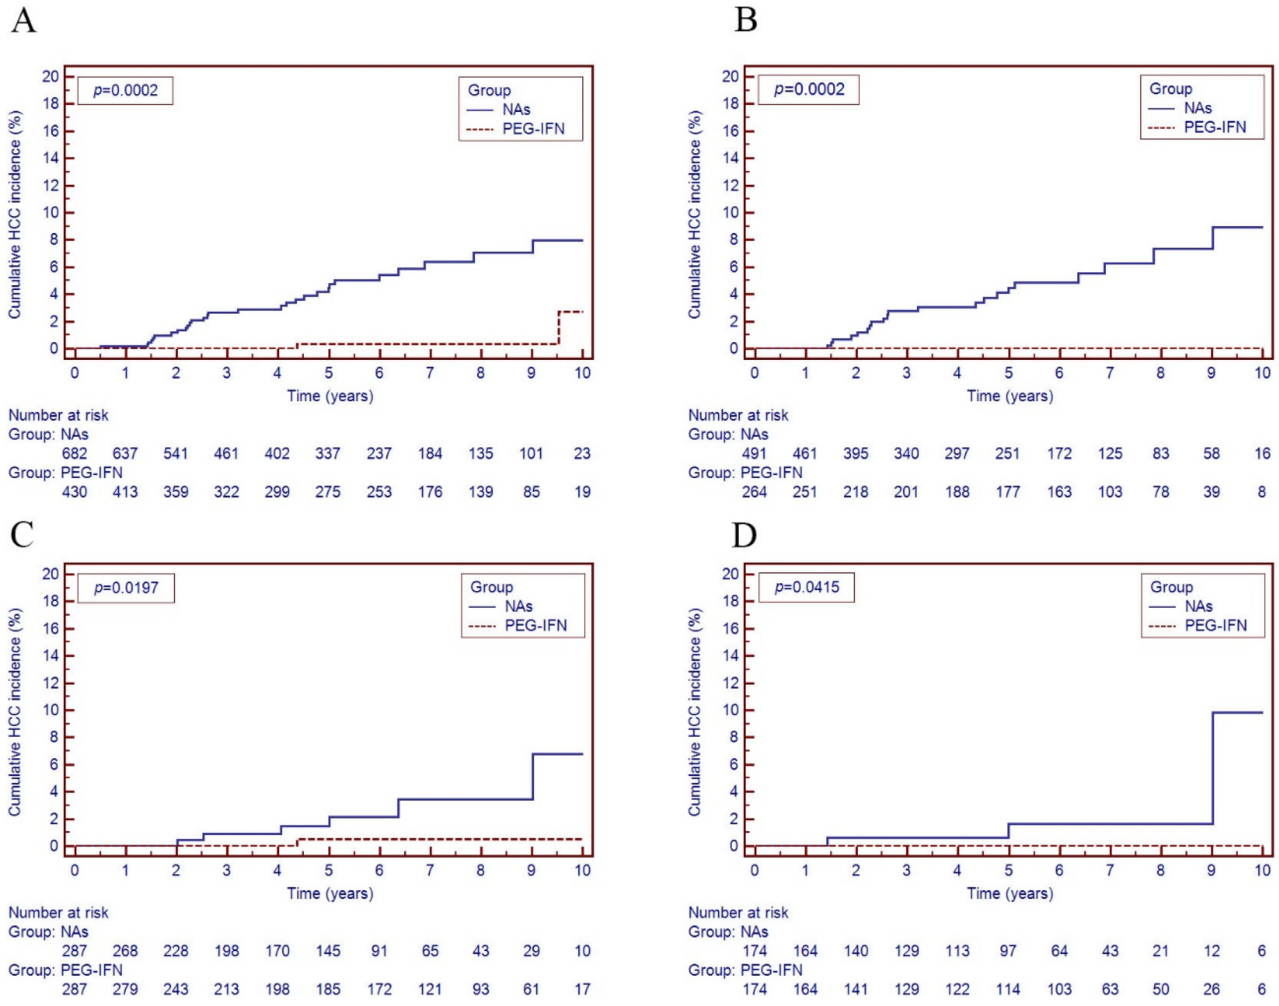

Figure: (abstract: FRI-348)

group in the high-risk score (PAGE-B ≥ 10; GAG-HCC ≥ 82) patients (3.13% vs 10.39%, p < 0.0001; 11.11% vs 13.29%, p = 0.0311; respectively).
Conclusion: Peginterferon is superior to nucleos(t)ide analogues for reduction of chronic hepatitis B-related HCC in patients with high-risk score.

FRI-349
Validation of the EASL 2017 HBV clinical practice guidelines criteria for switching patients long-term treated with Tenofovir difumarate to Entecavir or Tenofovir alafenamide in a real life setting
A. Loglio[1], G. Grossi[1], R. Soffredini[1], M. Borghi[1], F. Facchetti[1], E. Galmozzi[1], G. Lunghi[2], P. Lampertico[1]. *[1]Fondazione Irccs Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, CRC A.M. and A. Migliavacca for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Fondazione Irccs Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, Microbiology and Virology Unit, Italy*
Email: pietro.lampertico@unimi.it

Background and Aims: The 2017 EASL HBV CPG recommend to switch TDF treated patients to TAF (if NUC naïve or NUC experienced) or ETV (only if NUC naïve) if they have one of the following risk factors: (1) age >60 years, (2) bone disease [history of fragility fracture, osteoporosis, chronic use of steroids or of any other drugs that worsen Bone Mass Density], (3) renal alterations [eGFR <60 ml/min, albuminuria >30 mg/24h or moderate dipstick proteinuria, low serum phosphate (<2.5 mg/dl), or hemodialysis]. This study was aimed to assess these risk factors in a large cohort of TDF-treated patients to estimate the number of patients who could benefit from this switch.
Method: All consecutive CHB subjects already on TDF before 31 Dec 2016 were enrolled in a cross-sectional real-life study at the control blood sample, between Jan and 31 Jun 2017. GFR was assessed by CG formula; renal safety by UBCR and TmPO4/GFR ratio were also recorded, as last spine DEXA scans, Vit D, PTH levels, steroid use.
Results: 414 patients were enrolled: 63 (22–88) yr, 95% Caucasian, 79% HBeAg negative, 76% males, 44% cirrhotics, treated by TDF for 93 (9–133) months, 34% on a reduced dose, 95% undetectable HBV DNA, 94% normal ALT, 53% NUCs previously treated, 39% arterial hypertension, 10% diabetes, BMI 25 (16–42)kg/m^2. In terms of bone safety, 6% Vit D <15 ng/ml, 20% elevated PTH, 54% osteopenia and 12% osteoporosis at spine (86% of patients had an available DEXA). In terms of renal alterations, 23% had GFR <60 ml/min (70% already on a reduced TDF dose), 21% low serum phosphate, 17% increased albuminuria, 5% moderate dipstick proteinuria, 58% had increased UBCR (>300 ug/g), 66% hyperphosphaturia (<0.80 TmPO4/GFR ratio). By applying EASL criteria, 57% were >60 years (1), 13% had osteoporosis or were steroid-treated (2), and 41% had reduced GFR, hypophosphatemia or albuminuria/proteinuria (3). Overall, 69% had at least one criterion, 6% all criteria (1 + 2+3), 8% age and bone criteria (1 + 2) and 8% bone and renal criteria (2 + 3). 33% met both the age and renal criteria (1 + 3): in this population UBCR was elevated in 86%, reduced TmPO4/GFR ratio in 81%, both tubular markers altered in 66%, 59% already on reduced TDF dose, 79% LMV/ADV previously exposed.
Conclusion: Based on EASL 2017 HBV CPG recommendations, approximately 2/3 of CHB patients long-term treated with TDF in a real life setting are candidates to a ETV or TAF switch.

FRI-350
The long-term risk and outcome of non-neoplastic portal vein thrombosis developing in compesated caucasian HBV cirrhotics treated with Tenofovir or Entecavir
A. Loglio[1], G. Tosetti[1], G. Grossi[1], M. Iavarone[1], M. Viganò[2], F. Facchetti[1], M.G. Rumi[2], A. Sangiovanni[1], M. Primignani[1], P. Lampertico[1]. *[1]Fondazione Irccs Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, CRC A.M. and A. Migliavacca for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Ospedale San Giuseppe, Università degli Studi di Milano, Division of Hepatology, Milan, Italy*
Email: pietro.lampertico@unimi.it

Background and Aims: The risk of portal vein thrombosis (PVT) in long-term NUCs-treated HBV compensated cirrhotics is not established. We therefore assessed its incidence and predictors in a real-life cohort.
Method: 260 Caucasian HBV-monoinfected compensated HCC-free cirrhotics starting TDF or ETV were consecutively enrolled in a longitudinal cohort study: median age 61 (21–83) years, 81% males, 88% HBeAg negative, 68% with normal ALT, 59% NUCs-experienced, PLT 153 (32–304) x10^9/l, spleen diameter 11 (7–20) cm, liver stiffness 8.8 (3–75) kPa, 13% with esophageal varices (EV) and 4 previously decompensated (1.5%). Patients were followed with blood tests and 6-month abdominal imaging until PVT onset or Nov 2017. PVT was graded with Yerdel classification.
Results: During 103 (16–138) months of study period, 12 (5%) patients developed PVT. Three cases developed a tumoral PVT and were thereby excluded from the analysis. The remaining 9 patients developed non-neoplastic PVT after 58 (23–92) months, with an 8-year cumulative probability of 4.1%. Eight PVT were Yerdel grade 1 (partial thrombosis, without extension into the Superior Mesenteric Vein) while one was grade 2 (partial, with extension into SMV). At multivariable analysis, only previous decompensation (HR 16, 95%CI 2–113, p = 0.005) and EV at baseline (HR 27, 95%CI 5–136, p < 0.001) predicted PVT. The 8-year cumulative incidence of PVT was 28% and 1% among patients with and without baseline EV (p < 0.001) and 50% and 3.4% among those with or without previous decompensation (p < 0.001). PVT was associated with "de novo" ascites in only one patient and with HCC development in 5 patients (56%), but it did not never display any radiological features of neoplastic thrombosis throughout the entire follow-up. Patients underwent anticoagulant therapy (AT) for 8 (2–20) months till PVT resolution (5 patients) or side effects (anemia, variceal bleeding) or events (OLT, end-of-follow-up). Out of 5 resolved PVT, two Yerdel grade 1 recurred 6 and 14 months after AT discontinuation. Out of 9 patients with PVT, 3 died (hepatorenal syndrome, myocardial infarction, gastric ulcer bleeding), 2 were liver transplanted for HCC, 4 are still alive (2 with HCC).
Conclusion: In HBV NUC-suppressed compensated cirrhotics, non-neoplastic PVT is a rare complication, partial in most cases and asymptomatic, but strongly associated with severity of liver disease at baseline and the development of HCC.

FRI-351
Clinical and genetic predictors of HCC occuring in caucasian compensated HBV cirrhotics treated by Entecavir or Tenofovir for 8 years
A. Loglio[1], E. Galmozzi[1], M. Iavarone[1], G. Grossi[1], M. Viganò[2], F. Facchetti[1], M.G. Rumi[2], A. Sangiovanni[1], P. Lampertico[1]. *[1]Fondazione Irccs Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, CRC A.M. and A. Migliavacca for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Ospedale San Giuseppe, Università degli Studi di Milano, Division of Hepatology, Milan, Italy*
Email: pietro.lampertico@unimi.it

Background and Aims: HCC development remains the leading complication in HBV-related compensated cirrhotics long-term treated by TDF or ETV but the clinical and genetic predictors are poorly known. We therefore looked for baseline predictors of HCC,

including the tolloid like 1 gene (*TLL1*) rs17047200 polymorphism which has been recently shown to predict HCC in HCV patients cured by IFN therapy.

Method: 258 Caucasian HBV-monoinfected HCC-free CPT-A cirrhotics were consecutively enrolled in a longitudinal cohort study when starting TDF or ETV. Age was 61 (21–83) yr, 82% males, 88% HBeAg negative, 69% with normal ALT, BMI 25 (17–40) kg/m^2, 12% diabetics, 60% NUCs-experienced, 5% with previously treated HCCs, PLT 153 (48–304)x10^9/l, spleen diameter 11 (7–20) cm, liver stiffness 9 (3–60) kPa, 14% with esophageal varices (EV). Liver stiffness based model (LSPS) 0.62 (0.12–7.57), 14% PAGE-B score ≥ 18. Patients were regularly followed with blood tests and 6-month abdominal imaging until HCC development or Nov 2017.

Results: Over 102 (18–126) months of study period, 36 (14%) patients developed an HCC after 52 (18–100) months. The 8-year cumulative HCC incidence was 15% (yearly rate 1.9%). HCC developed in 10 (15%) out of 66 AT/TT (26%) patients compared to 26 (13.5%) among 192 AA (74%) subjects, with a 5-year cumulative HCC incidence of 13.5% vs 8.8%, respectively (p = 0.642). At univariate analysis, among several baseline genetic, clinical, demographic and virological features, the presence of EV, HCC history, spleen diameter, baseline Fibroscan, PLT count, age, LSPS and PAGE-B score predicted HCC. At multivariate analysis, previous HCC (HR 7.5, 95%CI 3.4–16, p < 0.001), EV (HR 3.3, 95%CI 1.5–7, p = 0.002), diabetes (HR 2.4, 95%CI 1.1–5.5, p = 0.03), age (HR 1.1, 95%CI 1.0–1.1, p < 0.001) and PLT (HR 0.99, 95%CI 0.98–0,99, p = 0.01) independently predicted de-novo HCC. Among the 244 patients without previous HCC, baseline EV (HR 3.6, 95%CI 1.4–9.1, p = 0.008), spleen diameter (HR 1.6, 95%CI 1.1–1.5, p = 0.005) and age (HR 1.3, 95%CI 1.0–1.1, p = 0.001) were independent predictors of HCC. The 8-year incidence of HCC was 43% and 7% among patients with and without baseline EV (p < 0.001), 20% and 9% among those with spleen diameter >12 or ≤12 cm (p = 0.02), and 17% and 6% among those >60 or ≤60 years (p = 0.007).

Conclusion: In HBV compensated cirrhotics NUC-treated for 8 years, older age and severity of portal hypertension at baseline strongly predict HCC, independently from *TLL1* variants.

FRI-352

Pharmacokinetic-pharmacodynamic modeling of Tenofovir Exalidex in HBV subjects

R. Foster[1], M. Conover[1], C. Canizres[1], D. Trepanier[1], D. Ure[1], T. Matkovits[1], P. Mayo[2]. [1]*ContraVir Pharmaceuticals, Inc., Drug Development, Edison, United States;* [2]*University of Alberta, Pharmacy and Pharmaceutical Sciences, Edmonton, Canada*
Email: ccanizares@contravir.com

Background and Aims: Tenofovir Exalidex (TXL), a lipid conjugate of tenofovir (TFV), is designed to mimic lysophosphatidylcholine to take advantage of natural lipid uptake pathways and achieve high intrahepatic concentrations of TFV diphosphate (TFV-PP) while reducing the peripheral TFV concentrations associated with kidney and bone toxicities. As it is not routinely feasible to measure intrahepatic TFV-PP concentrations in patients, a pharmacokinetic-pharmacodynamic (PK-PD) model was developed to aid and optimize further clinical development of TXL.

Method: TXL was administered to 50 HBV subjects (fasted) at doses ranging from 10–100 mg/day orally. The 50 mg cohort (n = 10) was used to derive PK-PD modeling, as this dose resulted in viral load (VL) reductions (log_{10}) that were not statistically different from Standard-of-Care (SOC, 300 mg, tenofovir disoproxil fumarate). Steady-state PK modeling was generated using linear trapezoidal, linear interpolation, Non-Compartmental Analysis for a 24 hour dosing interval (NCA, Phoenix WinNonLin Ver. 7.0). A linked PK-PD non-linear mixed effects (NLME, Monolix 3.2) model was employed, using an inhibitory Emax model. PK data were also examined using model-dependent analyses. Data after 28 days dosing was used for the current model.

Results: Maximum VL reductions of up to 3.9 log_{10} were observed with 50 mg/day TXL dosing for 28 days. The prodrug, TXL, rapidly disappeared from plasma, with mean (SD) Cmax, Tmax, AUC_{last}, and $t_{1/2}$ values of 51.28 (39.9) ng/ml, 1.60 (0.7) h, 109.44 (84.9) ng.h/ml, and 2.10 (2.0) h, respectively, at day 28. TFV mean (SD) values for Cmax, Tmax, AUClast, and $t_{1/2}$ were 8.51 (2.0) ng/ml, 4.95 (2.2) h, 136.35 (33.5) ng.h/ml, and 23.3 (3.4) hours, respectively. The VL IC_{50} on Day 29 was 2.92 ng/ml. Additionally, TXL could be described using a one-compartment model, whereas for TFV the model of best-fit was multi-exponential.

Conclusion: TXL 50 mg VL reductions were not statistically different (p = 0.19) from SOC, TDF. The PK-PD relationship after dosing on Day 28 was described using a NCA and inhibitory Emax model for TFV. TXL was rapidly cleared compared with TFV, and the clinical antiviral reduction IC_{50} approximated 3 ng/ml. Modeling promises to be a useful tool for the further clinical development and optimization of TXL.

Email: mathias.haag@ikp-stuttgart.de

Background and Aims: Metabolomic monitoring of endogenous biomarkers is of increasing importance for the assessment of drug safety and efficacy. Myrcludex B (MyrB), a novel entry inhibitor for the treatment of HBV/HDV infection, exerts its function through inhibition of the hepatic bile acid (BA) transporter Na^+-taurocholate cotransporting polypeptide (NTCP). We report preliminary results of BA monitoring in a subset of plasma samples from HBV/HDV co-infected individuals participating in a Phase 2b clinical trial (Myr-202 study) receiving 2, 5, and 10 mg MyrB daily in combination with TDF or TDF alone.

Method: Quantification of BA species was carried out in plasma samples before (BL) and during treatment (week 4 and week 12) by a validated LC/MS assay. A subset of samples from the treatment arms TDF alone (n = 12), 2 mg (n = 11), 5mg (n = 14) and 10 mg (n = 11) MyrB/TDF were analyzed to assess dose-dependent alterations. Statistical analysis (Dunn's multiple comparison) was done for cholic acid (CA), taurocholic acid (TCA) and glycocholic acid (GCA) in order to assess effects within the group of unconjugated (CA) and conjugated BAs (TCA, GCA).

Results: Median level at BL ranged between 62–255 nM (CA), 199–511 nM (TCA) and 394–897 nM (GCA) and did not show any significant differences between the treatment groups. At week 4, a dose-dependent elevation of CA was evident compared to TDF alone reaching median fold-changes (FC) of 1.8 (2 mg) and 3.8 (5 mg), respectively. CA amounts in the 10mg group leveled off at a FC of 2.8. Notably, at week 12 the highest rise (FC: 10.3) was evident in the 10mg group while in the 5mg group CA exhibited only a moderate increase (FC: 1.2). In contrast to unconjugated CA, which showed modest increase, circulating levels of the conjugated BAs exhibited more pronounced changes. Here, plasma exposure of TCA and GCA

was highest in the 5mg group (FCs > 20, w4 and w12), followed by lower amounts in the 10 mg group (FCs > 8) and the 2 mg treatment resulted in the least pronounced elevation without reaching significance.
Conclusion: In accordance with the high binding specificity of MyrB for NTCP, a significant and sustained elevation of systemic glycine- and taurine-conjugated BAs after 4 and 12 weeks of treatment was observed. In accordance with a lower transporter specificity of unconjugated BAs, CA was affected to a lesser extent. To substantiate these preliminary results, further analysis on the basis of the complete study cohort is required.

FRI-354
HeberNasvac: Novel therapeutic vaccine against chronic hepatitis B
G. Guillen[1], A. Julio[2], E. Penton[3], Y. Lobaina[3], V. Muzio[4], M. Al-Mahtab, S.M. Akbar[6]. [1]*Center for Genetic Engineering and Biotechnology, Vaccine Department, La Habana, Cuba;* [2]*Center for Genetic Engineering and Biotechnology, Vaccine, La Habana, Cuba;* [3]*Center for Genetic Engineering and Biotechnology, Vaccine, Cuba;* [4]*Center for Genetic Engineering and Biotechnology, Clinical Trial, Cuba;* [6]*Toshiba General Hospital, Japan*
Email: gerardo.guillen@cigb.edu.cu

Background and Aims: Despite the existence of effective prophylactic vaccines, hepatitis B virus (HBV) infections remain a major public health problem. About 370 million people are chronically infected worldwide.
As HBV persistence has been associated with a defect in the development of HBV-specific cellular immunity, therapeutic vaccination has been extensively studied in CHB.
HBsAg-based vaccines, including formulations with novel adjuvants have been used with unclear or negative results. New strategies should be taken into account in the improvement of cell-based immune responses in order to prevent and control the infections and eventually clear the virus.
The aim of this work is to develop a therapeutic vaccine against CHB with the capacity to subvert the tolerance.
Method: HeberNasvac include the use of a novel immunization route (intranasal-IN) and a HBcAg expressed in *E. coli*, used in a combination with HBsAg expressed in *Pichia pastoris*, both antigens expressed as virus like particles. The formulation is a simple mixture of proteins in phosphate buffer. The immunogenicity in Balb/C and transgenic mice was measured using ELISA, LPA and IFNg ELISPOT assays.
The clinical trials with human volunteers where approved by the Research Ethics Board of the Hospitals. The clinical regimen with HeberNasvac (100 µg of each antigen per dose) were five to ten IN inoculations only, every 14 days or 5 SC inoculations in addition to the last five IN inoculations in the same days. In the case of the efficacy trial pegIFNα was administered to the control group for a total of 48 weeks vs 24 weeks for HeberNasvac.
Results: The evaluation in mouse support the rationality of the vaccine targeting the stimulation of CD4(+) and CD8(+) T-cell responses and the induction of pro-inflammatory cytokines capable of controlling viral replication. HeberNasvac proved to be immunogenic and able to stimulate mucosal as well as systemic immunity biased in a Th1 sense.
Phase I, II and Phase III, randomized, double blinded and placebo controlled clinical trials were developed in healthy volunteers and CHB patients. In Phase III trial at week 72 (24 weeks after the end of pegIFNα treatment and 48 weeks after the end of HeberNasvac treatment), the HBV DNA levels were significantly lower in the vaccine group than in the pegIFNα group ($p = 0.03$), with almost 80% of vaccine treated patients remaining under 10,000 c/ml. A delayed rebound was observed in the vaccine group suggesting a sustained antiviral effect.
Conclusion: Preclinical and clinical results with HeberNasvac evidenced the induction of functional immune response and antiviral effect. HeberNasvac was safe and well tolerated inducing reactions similar to those caused by pegIFNα but less frequently and less severe, and more sustained antiviral effect. These results support further development to evaluate HeberNasvac in different schedules and therapeutic combinations.

FRI-355
At least 90% long-term adherence is required to lower mortality in patients with chronic hepatitis B taking entecavir
Y.-S. Lim[1], M. Jung Ko[2]. [1]*Asan Medical Center, University of Ulsan College of Medicine, Gastroenterology, Seoul, Korea, Rep. of South;* [2]*National Evidence-based Healthcare Collaborating Agency, Division for Healthcare Technology Assessment Research, Seoul, Korea, Rep. of South*
Email: limys@amc.seoul.kr

Background and Aims: Eradication of hepatitis B virus (HBV) is very rarely achieved, necessitating long-term oral antiviral therapy in patients with chronic hepatitis B (CHB). Medication non-adherence can result in poor virologic suppression and virologic breakthrough in the patients. However, the contribution of non-adherence to the clinical outcomes, such as mortality and hepatocellular carcinoma (HCC), is uncertain. Moreover, there is no consensual standard for the optimal level of drug adherence in the patients.
Method: This was a population-based, observational, longitudinal study of adult CHB patients who initiated treatment with entecavir (0.5 mg/day). The data were obtained from national health insurance service claims database, which covers >99% of the entire population, between 2007 and 2015 in a HBV-endemic country. Patient adherence was subdivided into 3 categories – high (proportion of days covered [PDC], ≥90%), intermediate (PDC, 80%–89%), and low (PDC, <80%) – and compared with incidence of mortality/transplantation and HCC during median 4.4 years of follow-up using multivariable survival models and inverse probability treatment weighting analysis adjusted for sociodemographic factors, cirrhosis, and comorbidities.
Results: Among 51,975 CHB patients treated with entecavir, compared with their high-adherence counterparts, the risk of mortality/transplantation was significantly greater for low-adherers (adjusted hazard ratio [HR], 1.38; 95% confidence interval [CI], 1.27–1.50; $p < 0.001$) and intermediate-adherers (adjusted HR, 1.44; 95% CI, 1.33–1.56; $p < 0.001$). The risk of HCC was not associated with adherence. The higher risk of mortality and similar risk of HCC for low- and intermediate-adherers, compared with high-adherers, were consistently observed in cirrhosis- and non-cirrhosis subcohorts.
Conclusion: Being fully adherent to entecavir (≥90%) was associated with a lower rate of mortality compared with partial adherence. There seemed to be a threshold effect for this benefit in the CHB population; ≥90% adherence may need to be maintained in the long-term to continue to accrue benefit.

FRI-356
Predictors of HBeAg loss and seroconversion by baseline clinical features and viral deep sequencing after 144 weeks of treatment with Tenofovir Alafenamide or Tenofovir Disoproxil Fumarate

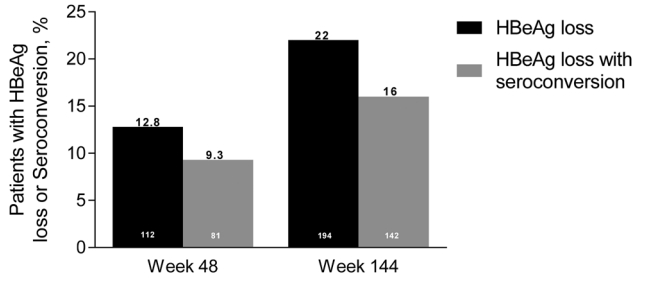
Background and Aims: HBeAg seroconversion remains an important serological endpoint for antiviral therapy. We previously reported on HBeAg loss following 48 weeks of oral antiviral therapy in the ongoing phase 3 study described below. Here we present an updated evaluation of factors associated with HBeAg loss with and without anti-HBe seroconversion following 3 years of antiviral therapy.
Method: The study included adults with HBeAg-positive CHB enrolled in a Phase 3 trial (Study GS-US-320–0110) comparing TAF 25 mg QD vs. TDF 300 mg QD. At Week 144, 340 (39%; TAF 226; TDF 114) patients had received 1 year of open label TAF 25 mg QD after switching from double blind (DB) treatment. The associations between HBeAg loss at Week 144 with host, viral, and treatment-related factors, including on-treatment virologic suppression (Roche COBAS Taqman; lower limit of detection 29 IU/ml), were determined using logistic regression analyses.
Results: Among 873 included patients, the median age was 36 yrs, 82% were Asian, and median baseline (BL) ALT and HBV DNA were 85U/l (IQR 60–138) and 7.9 $\log_{10}$IU/ml (IQR 6.9–8.6), respectively. At Week 144, a total of 194 patients (22%) experienced HBeAg loss and 142 patients (16%) underwent HBeAg seroconversion (Figure). Compared with subjects with persistent HBeAg-positivity, those with HBeAg loss were older (median age, 35 vs. 40 yrs), were infected with non-genotype D HBV (75% vs 86%), had lower median HBsAg levels (4.3 vs 3.8 $\log_{10}$IU/ml), a higher median BL ALT (83 vs. 101U/l), a higher prevalence of presumed cirrhosis (FibroTest ≥0.75: 6.4% vs. 13.2%), and lower median BL serum HBV DNA (8.1 vs. 7.7 $\log_{10}$IU/ml) (all $p \leq 0.005$). In multivariate analysis, baseline HBV DNA <8 $\log_{10}$ was an independent viral predictor of both HBeAg loss (OR: 1.816 [1.174–2.808]; $p = 0.007$) and seroconversion (OR: 2.512 [1.684–3.746]; $p < 0.001$); treatment with TAF in the DB period was a predictor of seroconversion (OR: 1.596 [1.044–2.439]; $p = 0.031$) but not loss. Evaluation of baseline viral diversity as assessed by deep sequencing across the genome did not show strong associations of variants with subsequent HBeAg loss.



Conclusion: Following 144 weeks of treatment, HBeAg loss/seroconversion rates remains low in subjects treated with TAF or TDF with lower baseline HBV DNA levels associated with higher rates of response.

FRI-357
Serum hepatitis B virus DNA and pregenomic RNA levels and kinetics in nucleos(t)ide analogue treated and untreated subjects

E. Butler, J. Gersch, A. Mcnamara, M. Kuhns, G. Cloherty. *Abbott Diagnostics, Infectious Disease Research, Abbott Park, United States*
Email: emily.butler@abbott.com

Background and Aims: HBV pregenomic RNA (pgRNA) is detectable in serum from chronic HBV (CHB) patients on nucleos(t)ide analogue (NA) therapy. In untreated CHB patients, serum pgRNA has been observed at lower levels relative to HBV DNA. We compared the serum nucleic acid levels and kinetics in HBV positive populations, including acute infections, HBsAg-positive blood donors, and CHB patients receiving NA therapy.
Method: Samples included the following: on-therapy CHB patient samples (n = 16, Boca Biolistics or DLS), HBsAg-positive donor samples (n = 102, American Red Cross) and 3 seroconversion series (n = 79 samples). HBV DNA was quantified using the Abbott RealTi*m*e HBV viral load assay. HBV pgRNA was quantified with a dual-target research assay developed on the Abbott *m*2000 instrument.
Results: In CHB patients on NA therapy, HBV pgRNA was observed at concentrations greater than HBV DNA in 13/14 quantifiable samples. Differences between pgRNA and DNA were highly variable, ranging from 0.53–5 log, and the correlation of DNA level to pgRNA levels was low ($R^2 = 0.5$). In 102 HBsAg-positive blood donor samples, HBV DNA was elevated relative to pgRNA. The mean difference between DNA and pgRNA was 1.70 ± 0.71 log and correlation of DNA to pgRNA was higher relative to NA treated samples ($R^2 = 0.8$). Among the blood donor samples, both DNA and pgRNA levels were lower in HBeAg-nonreactive samples compared to HBeAg-reactive samples. In seroconversion series from 2 acutely infected plasmapheresis donors that spontaneously resolved HBV infection, the peak DNA levels were 5.53 and 9.23 logIU/ml. HBV DNA correlated with pgRNA levels over time; the mean differences between DNA and pgRNA for the respective series were 2.33 ± 0.53 and 2.58 ± 0.30 log, with DNA being higher. This trend was also observed in an acute case who progressed to chronicity where the maximum DNA level was 9.38 logIU/ml and the mean difference between DNA and pgRNA was 1.85 ± 0.31 log.
Conclusion: In untreated HBV infections, we observed a trend wherein serum pgRNA levels are approximately 2 log lower than HBV DNA throughout acute infection whether the virus is cleared or persists and in individual HBsAg-positive blood donor samples. Consistent relative detection in the serum is suggestive of a linked mechanism for egress for both HBV DNA and pgRNA containing virions.

FRI-358
On-treatmant serum wisteria fioribunda agglutinin-positive Mac-2 binding protein level and risk of hepatocellular carcinoma development in patients with chronic hepatitis B during nucleot(s)ide analog therapy

A. Murata[1,2], T. Genda[1], S. Sato[1]. [1]*Shizuoka, Izunokuni, Japan;* [2]*Hepatology and gastroenteology, 1129, Izunokuni, Japan*
Email: perseverance3@hotmail.co.jp

Background and Aims: Histological analysis of hepatic fibrosis is an important predictive factor for hepatocellular carcinoma (HCC) development in patients with chronic hepatitis B (CHB). Of late, Wisteria floribunda agglutinin (WFA)-positive Mac-2-binding protein (WFA+–M2BP) was has been developed as a noninvasive glycobiomarker of liver fibrosis, and its predictive value for HCC development was is reported in several chronic liver diseases. However, change of in the serum WFA+–M2BP levels during antiviral treatment and its association with HCC development have not been fully assessed in patients with CHB. The present study aimed to analyze the pre- and on-treatment serum WFA+–M2BP levels and its their association with HCC development in CHB patients with CHB who received receiving nucleot(s)ide analog therapy.
Method: This study included 160 CHB patients with CHB who received nucleot(s)ide analog therapy between 2003 and 2015. WFA+–M2BP level was estimated immediately before treatment and at 48 weeks after treatment initiation. Multivariate Cox proportional hazards analysis was used to estimate the hazard ratios (HRs) of variables for HCC development. Cumulative incidences of HCC development were evaluated using the Kaplan–Meier plot analysis and the log-rank test.
Results: During the median follow-up time of 6.9 years (range: 1.1–13.0 years), 14 of the 160 patients developed HCC. On-treatment

serum WFA+–M2BP levels were significantly decreased significantly comparing compared with pre-treatment levels (median, 0.77 COI vs. 1.05 COI, p < 0.001). Multivariate Cox proportional hazards analysis revealed that on-treatment WFA+–M2BP level was an independent risk factor for HCC development (HR: 2.22, 95% confidence interval: 1.47–3.35, p < 0.001). The areas under the receiver operating characteristic curves indicated that the on-treatment WFA+–M2BP level predicted HCC development with high diagnostic accuracy (0.830). The cut-off value of on-treatment serum WFA+–M2BP level was identified as 1.17 COI. The 5-year cumulative incidences of HCC development were 25.5% and 4.5% in patients with high and low on-treatment serum WFA+–M2BP levels, respectively (p < 0.001).
Conclusion: On-treatment serum WFA+–M2BP level was is a useful predictive biomarker for HCC development in patients with CHB receiving nucleot(s)ide analog therapy.

FRI-359

Hepatitis B surface antigen reduction by switching from long-term preceding nucleoside/nucleotide analog administration to pegylated interferon or tenofovir

T. Nobuharu, M. Kurosaki, Y. Yasui, K. Tsuchiya, H. Nakanishi, J. Itakura, N. Izumi. *Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Japan*
Email: tamaki@musashino.jrc.or.jp

Background and Aims: Hepatitis B surface antigen (HBsAg) reduction during nucleoside/nucleotide analog (NA) therapy is slow and an alternative strategy for patients receiving ongoing NA to facilitate HBsAg reduction is required. We investigated whether switching to pegylated interferon (PEG-IFN) or tenofovir (TDF) after long-term NA administration enhances HBsAg reduction.
Method: Forty-nine patients who switched from long-term NA (entecavir or lamivudine + adefovir) to 48 weeks of PEG-IFN alfa-2a (PEG-IFN group) and 53 patients who switched to TDF (TDF group) were studied. A total of 147 patients who continued NA and matched for baseline characteristics of PEG-IFN group were analyzed for comparison (NA continuation group). HBsAg reduction at week 48 was investigated.
Results: In comparing the PEG-IFN group and the NA group, HBsAg reduction at week 48 was 0.81 ± 1.1 logIU/ml in the PEG-IFN group, which was significantly higher than that in the NA continuation group (0.11 ± 0.3 logIU/ml, p < 0.001). In patients positive for hepatitis B e-Antigen (HBeAg), HBeAg seroconversion was higher in the PEG-IFN group (44% vs. 8%, p < 0.001). In HBeAg negative patients, only patients in the PEG-IFN group achieved HBsAg loss. HBsAg reduction was 0.18 ± 0.3 logIU/ml in the TDF group, which did not differ from the NA continuation group. However, in subgroup of patients with no reduction of HBsAg during preceding NA (0.05 logIU/ml/year increase), significant reduction of HBsAg was obtained after switching to TDF (0.24 logIU/ml, p = 0.02).
Conclusion: Switching to PEG-IFN after long-term NA enhances the reduction of HBsAg, and switching to TDF was effective in the subgroup of case where HBs reduction was not obtained during preceding NA. These switch strategy would be a treatment option to promote HBsAg loss.

FRI-360

Clinical predictors for relapse after cessation of nucleoside analogues by stopping rule in chronic hepatitis B patients

D.S. Song, UI. Chang, J.M. Yang, S.H. Yoo, J.H. Kwon, J.W. Jang, S.H. Bae, S.K. Yoon. *The Catholic University of Korea, Internal Medicine, Seoul, Korea, Rep. of South*
Email: garden@catholic.ac.kr

Background and Aims: The stopping rule of international guidelines in chronic hepatitis B (CHB) patients treated with nucleoside analogues (NA) has not been verified. We assessed the usefulness of stopping rule of Asia-Pacific Association for the Study of Liver (APASL), and investigated predictors of post-treatment relapse, including HBsAg/HBeAg, clinico-biochemical, and fibrosis parameters.
Method: Patients who stopped NA were included regardless of meeting stopping rule of APASL guideline. Virologic relapse was defined as HBV DNA > 2,000 IU/ml, while clinical relapse was defined as HBV DNA > 2,000 IU/ml and ALT > 2xULN.
Results: A total of 359 CHB patients (172 HBeAg-positive and 187 HBeAg-negative) were recruited for the study: 246 entecavir (ETV)-treated and 113 lamivudine (LAM)-treated patients. Patients who met the stopping rule showed lower one-year virologic and clinical relapse rates than those not. There was no difference in virologic and clinical relapse rates between cessation of ETV and LAM. For the entire patients, higher baseline HBV DNA levels and shorter consolidation were significantly associated with clinical relapse. When stopped NA according to APASL guideline, older age (over 30), lower serum albumin and shorter consolidation were significant risk factors for virologic and clinical relapse. Relapse rate was similar between HBeAg-positive and –negative patients (one-year clinical relapse rates of 29.8% and 21.1%, respectively). In HBeAg-positive patients, higher baseline HBV DNA and shorter consolidation were significant predictors for virologic relapse, and Older age (over 30) and lower serum albumin were significant predictors for clinical relapse. However, in HBeAg-negative patients, there were no significant predictors for virologic and clinical relapse. Low HBsAg titers and non-invasive fibrosis markers, such as fibrosis-4 (FIB-4) score and AST to platelet ratio index (APRI) at cessation of NA were not significant predictors for virologic and clinical relapse.
Conclusion: Stopping rule of APASL guideline is generally acceptable and useful as a guide in decision-making when cost and long-term safety of NA is doubted. Younger patients and good synthetic function who met the stopping rule is best considered for NA discontinuation.

FRI-361

Virological response and safety in a cohort of immigrant patients affected by chronic hepatitis delta treated with PEG-IFN

L. Boglione, G. Cariti, T. Lupia, S.M. Pinna, V. Ghisetti, G. DI Perri. *Amedeo di Savoia Hospital, Medical Sciences, Turin, Italy*
Email: lucio.boglione@unito.it

Background and Aims: Chronic hepatitis due to hepatitis delta virus (HDV) represents the most difficult-to-treat viral hepatitis, because the only available treatment is the pegylated (PEG) interferon alfa (IFN), with limited virological response. Recent migration of young people from Africa and East-Europe brought the attention of the clinicians on this issue. In this retrospective study we reported our experience of treatment with PEG-IFN in a cohort of young immigrant patients affected by chronic HDV infection.
Method: Retrospective analysis of all immigrants affected by HDV and treated with PEG-IFN at our centre of Infectious Disease. Virological response was defined as: “complete virological response” (CR) with HBsAg and HDV-RNA negative at 1 year of follow-up; “partial virological response” (PR) with HBsAg positive and HDV-RNA negative; “null virological response” (NR) with HBsAg and HDV-RNA positive.
Results: The enrolment period was 2007–2014; 46 patients were included in this analysis. Geographical origin was: Central Africa 20 (43.5%), East-Europe 24 (52.1%), Pakistan 2 (3.6%). Median age was 34.5 years; males were 40 (86.9%) HBV genotypes: A, 20 (43.5%); D, 6 (13%); E, 20 (43.5%). Median qHBsAg at baseline was 3.7 logIU/ml HBV-DNA 3.5 logIU/ml, HDV-RNA 5.7 logcp/ml, alanine amino transferase (ALT) 75IU. Liver stiffness was 9.2 kPa. Median time of treatment was 11.5 months, with 4.5 years of follow-up. CR was observed in 11 patients (23.9%), PR in 13 (28.2%), NR in 16 (34.8%). Six subjects (13%) interrupted the treatment for side-effects or drop-out. Dose-reduction from 180 μg/weekly to 135 μg/weekly was reported in 23 patients (50%). Predictive factors of CR were: HBV A genotype (OR = 4.605; 95%IC: 1.090–6.709; p < 0.001), absence of cirrhosis (OR = 1.802; 95%IC: 1.003–3.209; p = 0.018), treatment

duration >1 year (OR = 3.906; 95%IC: 1.440–19.667; p < 0.001). Among NR patients, 4 died (3 due to hepatocellular carcinoma and 1 for hepatic decompesation) and 1 received a liver transplantation.
Conclusion: The only available treatment for hepatitis delta is the PEG-IFN; in this cohort of immigrant patients the CR was 23.9% and the NR 34.8%. The patients with NR and cirrhosis presented a high risk of adverse events after treatment interruption such as hepatocellular carcinoma or hepatic decompesation. Favorable outcome was prevalent in patients with HBV A genotype, without cirrhosis and treated with a PEG-IFN course >1 year.

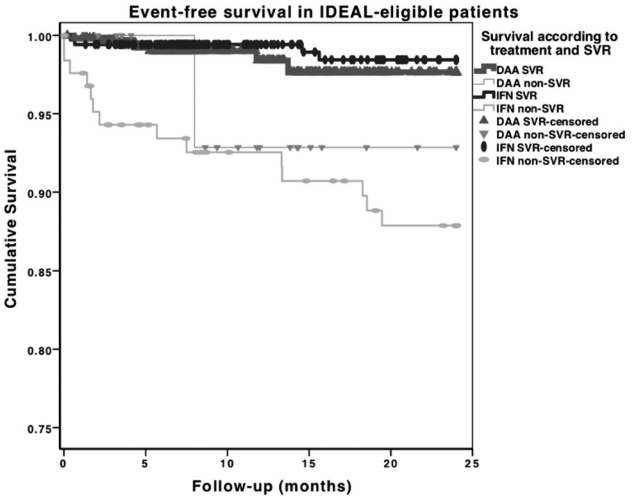
FRI-362
RNA interference therapy with ARC-520 Injection results in long term off-therapy antigen reductions in treatment naïve, HBeAg positive and negative patients with chronic HBV
M.-F. Yuen[1], K. Liu[1], B. Given[2], T. Schluep[2], J. Hamilton[2], C.L. Lai[1], S. Locarnini[3], K. Jackson[3], J.Y. Lau[4,5], C. Ferrari[6], R.G. Gish[7,8].
[1]The University of Hong Kong, Queen Mary Hospital, Hong Kong, Hong Kong; [2]Arrowhead Pharmaceuticals, Pasadena, United States; [3]Victorian Infectious Diseases Reference Laboratory, Victoria, Australia; [4]The University of Hong Kong, Hong Kong, Hong Kong; [5]Hong Kong Polytechnic University, Hong Kong, Hong Kong; [6]University of Parma, Parma, Italy; [7]Stanford University, Palo Alto, United States; [8]Hepatitis B Foundation, Doylestown, United States
Email: tschluep@charter.net

Background and Aims: ARC-520 Injection (ARC), a RNA interference drug, targets cccDNA-derived mRNA in chronic hepatitis B patients (CHB). We previously reported HBsAg reduction and safety in a multi-dose extension study. Here we report additional antigen reductions observed off-therapy during a 6-month follow-up period.
Method: 8 CHB (5 HBeAg-neg, 3 HBeAg-pos) received up to 9 doses of 4 mg/kg ARC once every 4 weeks with daily entecavir (ETV). Treatment naïve CHB who previously received a single IV dose of 4 mg/kg ARC and started daily ETV on the same day were eligible. Viral DNA and antigen knockdown (KD) were measured at regular intervals [qHBsAg, HB core-related antigen (qHBcrAg) in all, qHBeAg in HBeAg-pos]. Patients continued their daily ETV post ARC and were followed for an additional 6 months.
Results: Patients received ETV for 34 to 44 weeks after a single dose of ARC before receiving the first ARC dose of the multi-dose extension. After a single dose of ARC, qHBsAg in 3 of 3 HBeAg-pos and 1 of 5 HBeAg-neg remained below baseline. Multi-dose re-challenge resulted in additional qHBsAg KD in all CHB. Two of three HBeAg-pos and one of five HBeAg-neg had mild ALT elevations post ARC which coincided with additional antigen reductions. In the HBeAg-pos, mean HBsAg reduction was 3.0 log and max reduction 4.6log with one patient achieving an HBsAg level of 1 IU/ml. This patient seroconverted for HBeAg post ARC with mean HBeAg reduction of 2.8 log and max reduction of 4.2 log to LLOQ. Mean HBcrAg reduction was 3.4 log with max reduction of 6.1log in HBeAg-pos. In HBeAg-neg, mean HBsAg KD was 1.0 log and maximum was 2.1 log, HBcrAg reduction was 0.7 log in the only patient positive for this marker.
Conclusion: (1) Consistent with our previous reports, ARC was more active in HBeAg-pos, presumably due to more cccDNA-driven antigen production in treatment naïve HBeAg-pos and a higher fraction of qHBsAg from integrated DNA in HBeAg-neg. (2) Mild ALT elevations off ARC therapy coincided with additional antigen reductions in 2/3 HBeAg-pos and 1/5 HBeAg-neg. (3) Antigen reduction through RNAi in combination with oral ETV may lead to sustained control of CHB off-therapy.

Viral Hepatitis C: Post SVR and long term follow up

FRI-363
Comparison of event-free survival between DAA and IFN-based antiviral therapy for HCV, adjusted for disease severity
L. Krassenburg[1,2], W.R. Zanjir[1], F. Georgie[1], K. Munawar[1], O. Cerocchi[1], E. Stotland[1], J. Lau[1], H. Janssen[1], B. Hansen[1,2,3], J. Feld[1]. *[1]Toronto General Hospital, University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]Erasmus University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [3]Management and Evaluation, University of Toronto, Institute of Health Policy, Toronto, Canada*
Email: lisettekrassenburg@gmail.com

Background and Aims: Long-term follow-up studies have shown that sustained virological response (SVR) is associated with improved clinical outcomes with interferon (IFN)-based therapy. However, the causal link of SVR with outcome has been challenged with the argument that SVR may simply be a component of a "good prognosis" in the natural history of HCV. With markedly improved SVR rates with direct-acting antivirals (DAAs), the benefit of SVR would be expected to diminish if the association of SVR with outcome is not causal. To evaluate this question, we compared liver-related outcomes in IFN-eligible patients treated with DAAs vs. IFN.
Methods: Retrospective data were collected for patients treated with IFN-based therapy or DAAs at the Toronto Centre for Liver Disease from Jun/06 to Dec/16. To control for disease severity, patients were categorized as IFN-eligible (IDEAL) based on meeting criteria for the IDEAL trial comparing PegIFNa2a vs PegIFNa2b. Clinical events, defined as decompensation, hepatocellular carcinoma, liver transplantation and all-cause death, were collected from end of treatment to two years.
Results: Of 1110 IDEAL-eligible patients, 58% received DAAs and 42% IFN, median (IQR) age 55 (48–61) years and genotype (G) distribution 71%/12%/18% for G1/2/3. Cirrhosis was present in 34% DAAs vs 14% IFN (p < 0.001). SVR was 97% with DAAs vs 74% with IFN (p < 0.0001). The 2-year cumulative event-free survival with SVR was 98% for both DAAs and IFN (p = 0.47) and 93% and 88% for non-SVR (p = 0.68). Achieving SVR was associated with improved event-free survival with an adjusted Hazard Ratio (aHR) of 7.69 (95% CI 3–20, p < 0.0001) after controlling for age, sex, genotype, cirrhosis and treatment.



After matching IFN non-responders with DAA patients using inverse probability treatment weighting, the overall event rate was 1.1% in DAA patients compared to 17.9% in IFN non-responders at 2 years underlining the clinical benefit of higher SVR rates.

Conclusion: In IFN-eligible patients, SVR is more commonly achieved with DAAs and confers a similar clinical benefit as in those treated with IFN. The markedly higher SVR rate but reduced overall event rate with DAAs compared to IFN, despite similar disease severity, unequivocally shows that SVR cannot be due to a "good prognosis", but rather SVR is a relevant endpoint leading to improved clinical outcomes.

FRI-364

The number needed to treat to prevent one clinical event at 2 years after antiviral treatment for HCV with DAAs compared to IFN-based therapy

L. Krassenburg[1,2], B. Hansen[1,2,3], W.R. Zanjir[1], F. Georgie[1], O. Cerocchi[1], J. Lau[1], A. Van der Meer[2], H. Janssen[1], J. Feld[1]. [1]*Toronto General Hospital, University Health Network, Toronto Centre for Liver Disease, Toronto, Canada;* [2]*Erasmus University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands;* [3]*Management and Evaluation, University of Toronto, Institute of Health Policy, Toronto, Canada*
Email: lisettekrassenburg@gmail.com

Background and Aims: Sustained virological response (SVR) has been shown to be associated with improved clinical outcomes with interferon (IFN)-based antiviral therapy. The development of direct acting antivirals (DAAs) has markedly increased SVR rates, however there are limited data on the clinical benefits of the improved response rates. We evaluated the number needed to treat (NNT) to prevent one clinical event by using DAAs compared to IFN at 2 years after treatment completion.
Method: Retrospective data were collected on all patients with hepatitis C (HCV) who visited the Toronto Centre for Liver Disease between June 2006 and January 2017. Baseline characteristics and disease severity were evaluated at start of treatment and patients were followed from end-of-treatment until a clinical event (hepatocellular carcinoma, decompensation, liver transplantation or death). The NNT to prevent 1 clinical event at 2 years, was calculated using the estimated survival (Surv) in those with SVR and non-SVR for each treatment group. $NNT = 1/(((Surv_{DAA\text{-}SVR}{}^{*}SVR_{DAA}) + (Surv_{DAA\text{-}nonSVR}{}^{*}(1\text{-}SVR_{DAA}))) - ((Surv_{IFN\text{-}SVR}{}^{*}SVR_{IFN}) + (Surv_{IFN\text{-}nonSVR}{}^{*}(1\text{-}SVR_{IFN}))))$.
Results: Of 1492 patients, 841 (56%) received DAAs and 651 (44%) IFN. SVR was attained by 96% of DAA-treated patients, compared to 69% of IFN-treated patients. Achieving SVR was associated with improved event-free survival compared to non-SVR with an adjusted Hazard Ratio (aHR) of 8.4 (95% CI 5–14, $p < 0.001$), after controlling for age, sex, genotype, cirrhosis and treatment-type. The NNT to prevent 1 clinical event in 2 years with DAA compared to IFN treatment was 21. For patients with compensated cirrhosis at baseline the NNT was 4 and for those with decompensated cirrhosis, the NNT was 6. By HCV genotype (G), the NNT was 21 for G1 and 14 for G3.
Conclusion: The high SVR rates of DAA therapy compared to IFN therapy translate to tangible clinical benefits at two years across patient groups. Although the benefit of DAAs over IFN is greatest in those with cirrhosis at baseline, the NNT is low across patient groups, confirming the broad clinical benefits of DAA therapy.

FRI-365

TLL1 variants do not predict the development of de-novo hepatocellular carcinoma in HCV cirrhotics treated with IFN-free DAA-based regimens

E. Galmozzi[1], F. Facchetti[1], R. D'ambrosio[1], E. Degasperi[1], A. Aghemo[2], R. Soffredini[1], M. Borghi[1], R. Perbellini[1], M. Iavarone[1], A. Sangiovanni[1], P. Lampertico[1]. [1]*Fondazione Irccs Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, CRC A.M. and A. Migliavacca for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy;* [2]*Humanitas University, Department of Biomedical Sciences, Rozzano, Italy*
Email: pietro.lampertico@unimi.it

Background and Aims: A genome wide association study (GWAS) has recently demonstrated an association between the Tolloid Like 1 (TLL1) *rs*17047200 polymorphism and the development of hepatocellular carcinoma (HCC) among hepatitis C virus (HCV) patients with a sustained virological response (SVR) to Interferon, but whether this holds true for direct-acting antivirals (DAA)-treated patients remains unknown. Aim of our study was to assess the association of TLL1 *rs*17047200 with HCC development in a cohort of HCC-free HCV cirrhotics who were treated with a DAA-based regimen.
Method: 278 consecutive HCC-free HCV cirrhotics [aged 66, 57% males, 49% HCV-1b, 86% CPT-A, LSM 17.6 (12.1–75) kPa, αFP 9.5 (0.8–537) ng/mL, 19% with diabetes] treated with DAA between January 2015 and December 2016 were enrolled in a single Center real-life study. Cirrhosis was defined clinically, histologically (METAVIR F4) or by liver stiffness measurement (LSM >11.9 kPa). HCC was diagnosed according to International recommendations. TLL1 *rs*17047200 A/T variant was analyzed using Taq-Man SNP genotyping assay.
Results: The genotype distribution of TLL1 variant was AA in 202 (73%), AT in 71 (25.5%) and TT in 5 (1.5%) patients. Patients carrying the AA or the AT/TT genotypes were similar according to the most important demographic features such as male gender (56% *vs.* 62%), age (63 *vs.* 62) and BMI (25 *vs.* 25). They were also similar in terms of HCV genotype distribution, baseline LSM (18 *vs.* 16 kPa), diabetes prevalence (19% *vs.* 21%) and platelets count (108 *vs.* 121 x 10^3/mm^3). Similar SVR rates were reported in patients carrying the AA or the AT/TT genotypes (96% *vs.* 96%). De-novo HCC occurred in 25 (9%) patients after 3–28 (median 10) months from DAA start, with a 3-year cumulative probability of 6%. The 3-year cumulative incidence of HCC was 9.1% in patients with TLL1 AA and 9.5% in those carrying the AT/TT variants ($p = 0.67$). No differences were found between AA and AT/TT patients according to HCC characteristics; in fact, they were similar in terms of time to HCC development (10 *vs.*12 months), nodules number (single node in 80% *vs.* 50%), αFP values (6 *vs.* 21, $p = 0.50$), BCLC O/A stage (89% *vs.* 66%), Milan-in criteria (89% *vs.* 67%) and severity of liver disease (CPT-A in 90% *vs.*100%).
Conclusion: In a large cohort of HCC-free HCV cirrhotics treated with DAA, TLL1 variants failed to predict the de-novo development of HCC.

FRI-366

Long-term follow up of patients with chronic HCV and F2 or F3 fibrosis after achieving SVR with DAA-based therapy: results from the Gilead SVR registry

Background: HCV infected patients with F0-F1 fibrosis experienced minimal liver-related morbidity and mortality following sustained virologic response (SVR) with direct-acting antiviral (DAA) therapy. Less is known about the clinical progression of liver disease among HCV-infected patients with F2 or F3 fibrosis who have achieved SVR with DAA regimens.
Methods: Patients enrolled in the Gilead SVR Registry were included in this analysis if they were deemed to have F2 or F3 fibrosis pre-DAA treatment as measured by FibroTest (0.32–0.58 or 0.59–0.72, respectively). Patients could be enrolled up to 60 weeks after initiating DAA-treatment that lead to SVR, and study visits occurred every 24

weeks for up to 144 weeks. Assessments for signs of jaundice, ascites, hepatic encephalopathy (HE), varices, and hepatocellular carcinoma (HCC) and measurement of alanine aminotransferase (ALT), aspartate aminotransferase (AST), total bilirubin (Bili), albumin (ALB), prothrombin time (PT), and platelets (PLT), occurred at each visit.

Results: A total of 1,489 and 857 patients with F2 and F3 fibrosis were enrolled, with median (range) registry follow up times of 1.9 (0–3.3) and 1.8 (0–3.2) years, respectively. Of these, 57% and 72% were male and the mean (range) ages were 55 (19–80) and 57 (19–82) years for F2 and F3 patients, respectively. There were 2 and 4 cases of HCC reported in 2509 and 1371 person-years of follow-up time for patients with F2 and F3 fibrosis, respectively. Overall, the prevalence of liver-related events was low at all visits, remaining stable for F2 and numerically decreasing over time for F3 patients (Table). At Week 144, 1 (0.1%) patient with F2 fibrosis had evidence of varices reported and 1 (0.3%) patient with F3 fibrosis had evidence of jaundice reported. Mean week 144 ALT, AST, Bili, ALB, PT, and PLT were within normal limits and comparable to baseline values. Three patients with F2 and 3 patients with F3 fibrosis died, with no causes of death due to liver disease. No liver transplants were reported. There were 4 patients with F2 and 3 patients with F3 fibrosis who experienced virologic failure during follow up; all but one of these patients had clear virologic evidence for reinfection by sequencing.

	Registry Baseline		Week 48		Week 96		Week 144	
Liver-Related Event, n (%)	F2 n = 1,489	F3 n = 857	F2 n = 1159	F3 n = 640	F2 n = 916	F3 n = 484	F2 n = 677	F3 n = 367
Jaundice	0	1 (0.1)	0	0	0	0	0	1 (0.3)
Ascites	1 (<0.1)	4 (0.5)	0	1 (0.2)	1 (0.1)	0	0	0
Hepatic Encephalopathy	0	1 (0.1)	0	1 (0.2)	0	0	0	0
Varices	0	3 (0.4)	0	2 (0.3)	3 (0.3)	1 (0.2)	1 (0.1)	0

Conclusion: In HCV-infected patients with F2 or F3 fibrosis who achieve SVR with DAA therapy, events including liver-related complications, HCC, death and HCV relapse are rare in the first 144 weeks of follow-up. These data support early treatment of HCV infection and may be useful in guiding monitoring strategies for HCC and other liver-related events following SVR.

FRI-367
Serum immune signatures predict HCC development in DAA-treated HCV patients

J. Debes[1], M. van Tilborg[2], A. Grooshuismink[2], B. Hansen[2], J.S.Z. Wiesch[3], J. von Felden[3], R. de Knegt[4], A. Boonstra[2]. *[1]University of Minnesota; [2]Erasmus Mc; [3]UMC hamburg-Eppendorf; [4]Erasmus Mc, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: debes003@umn.edu

Background and Aims: Concern has arisen about development of hepatocellular carcinoma (HCC) in patients with hepatitis C virus (HCV) infection treated with direct-acting antivirals (DAAs). As treatment with DAAs will continue it is imperative to understand which patients might be at risk for HCC following treatment. In this study we aimed to evaluate an immune-signature and its association with development of HCC following DAA treatment.

Method: We evaluated serum levels of 67 immune mediators before, during, and after DAA treatment of HCV infection. Our cohort included 13 patients who developed HCC within 18 months of treatment (3 with HCC recurrence and 10 with *de novo* HCC) and 10 patients who did not develop HCC (controls), within a follow up period of 24 months post treatment, matched for age, HCV genotype and liver fibrosis. All patients had liver ultrasound performed within 3 months of starting DAA treatment and all responded to HCV treatment. Data was analyzed using SAS 9.3 and SPSS version 24. All markers were log transformed to achieve near to normal distributed values. One-way analysis of variance with Bonferroni correction was used to compare the groups.

Results: We identified a set of 12 immune mediators (cytokines, growth factors, and apoptosis markers) whose levels were significantly higher in serum before DAA treatment of patients who eventually developed de novo HCC compared to controls. A panel of 9 of these markers (MIG, IL22, sTRAIL, sAPRIL, VEGF, IL-3, sTWEAK, SCF, IL-21) identified patients who developed *de novo* HCC with an area under the receiver operating characteristic curve (AUROC) value higher than 0.8 and 4 of them showed an AUROC above 0.9. Further analyses in a subset of 7 patients beyond baseline showed modifications of TNF-alpha, sTRAIL and IL-6 levels at 4 and 12 weeks of treatment in those that developed HCC. Moreover, there was a differential modulation of IL-6 in those that developed *de novo* HCC compared to recurrence of HCC.

Conclusion: Our study identified a group of immune mediators that showed significantly higher serum levels before DAA treatment in patients that later developed HCC and could potentially serve as markers for screening. We also provide important input in the potential mechanisms underlying HCC development in patients treated with DAAs.

FRI-368
Long-term immunological and clinical impact of HCV eradication with direct acting antivirals in patients with HCV-associated cryoglobulinemia vasculitis

M. Bonacci, S. Lens, Z. Mariño, S. Rodriguez-Tajes, Concepció Bartres, M. Ramos-Casals, José Hernández-Rodríguez, X. Forns. *IDIBAPS, CIBERehd, Liver Unit, Barcelona, Spain*
Email: bonacci@clinic.cat

Background and Aims: Several reports on patients with HCV-associated vasculitis showed high rates of clinical remission 12–24 weeks after treatment with direct acting antivirals (DAAs). However, cryoglobulins(CRYO) persisted in up to 50% of patients. We aim to assess the long-term clinical/immunological impact of DAA therapy in patients with HCV-related symptomatic or asymptomatic cryoglobulinemia

Method: Patients with circulating CRYO treated with DAA were prospectively followed. Patients were grouped into HCV-vasculitis (CV) or CRYO-asymptomatic (ACC). Complete immunological response (CIR) was defined as CRYO negativization with complement normalization. Among CV, clinical response was complete if BVAS.v3 score = 0 or all affected organs improved; clinical response was partial if BVAS.v3 < 50% of entry score.

Results: 94 patients were included, 50 CV and 44 ACC. Baseline characteristics were similar between groups except for female gender (74% in CV vs. 28% in ACC). CV patients had higher cryocrit (3.2 vs 2.3%; $p < 0.01$), rheumatoid factor (80 vs 10 IU/mL; $p < 0.01$), and lower C4 fraction (0.04 vs 0.09 g/L; $p < 0.01$) than ACC. Main clinical manifestations in CV patients were purpura (56%), polyneuropathy (40%) and nephropathy (16%). SVR rate was 95% (CV:95% vs ACC:93%). Post-treatment follow-up (FU) was 24 (18–27) months and similar between groups. CRYO persisted in 42% and 56% at SVR12, and in only 22% and 18% at last FU in CV and ACC patients, respectively. Overall CIR increased from 38% at SVR12 to 62% [CV (56%) vs ACC (67%), p = ns] at last FU. Complete clinical response increased from 66% at SVR12 to 74% at last FU. Overall, BVAS.v3 decreased from 7 (2–31) at baseline to 3 (0–11) at SVR12 ($p < 0.05$) and to 0 (0–8) at last FU ($p < 0.05$). A BVAS.v3 > 9 and a cryocrit >3% at entry were associated with null clinical response [HR = 0.4 (0.2–0.8), p = 0.01] and non-CIR HR = 0.3 (0.1–0.5), p = 0.01], respectively. Of note, despite viral cure, three cirrhotic CV-patients experienced vasculitis relapse (2 purpura/1 intestinal) associated with reappearance of CRYO during FU. Moreover, one patient experienced non-Hodgkin Lymphoma relapse. No patient with ACC developed an overt CV during FU.

Conclusion: Clinical and particularly immunological response improves significantly overtime after HCV cure in CV and ACC

patients. However, 2 years after HCV elimination CRYO may persist in more than 20% of patients and clinical relapse may occur in a small proportion of CV-patients (even with CRYO reappearance), suggesting that a longer monitoring of these patients is still warranted.

FRI-369

Incidence and predictors of de novo hepatocellular carcinoma in HCV cirrhotic patients treated with direct-acting antivirals: a single-center prospective 3 year study

R. D'ambrosio[1], E. Degasperi[1], M. Iavarone[1], A. Sangiovanni[1], A. Aghemo[2], R. Soffredini[1], M. Borghi[1], R. Perbellini[1], G. Lunghi[3], P. Lampertico[1]. Migliavacca for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy;* [2]*Humanitas University, Department of Biomedical Sciences, Rozzano, Italy;* [3]*Fondazione Irccs Cà Granda Ospedale Maggiore Policlinico, Microbiology and Virology Unit, Milano, Italy*
Email: pietro.lampertico@unimi.it

Background and Aims: Incidence of hepatocellular carcinoma (HCC) in cirrhotic patients treated with direct-acting antivirals (DAAs) for hepatitis C (HCV) virus infection is still controversial. Aim of the study was to evaluate incidence and predictors of de novo HCC in HCV cirrhotics treated with DAAs.
Methods: Consecutive HCV cirrhotics starting DAAs between November 2014 and December 2016 at a single Center were enrolled. Exclusion criteria were HIV infection, previous HCC history, active HCC or undefined liver nodules at baseline and Child-Pugh-Turcotte (CPT) score C. Cirrhosis was defined clinically, histologically or by liver stiffness measurement (LSM > 11.9 kPa). HCC was diagnosed and staged according to EASL recommendations. Baseline clinical features, biochemistry and non-invasive markers of liver fibrosis (LSM, APRI, Fib-4, LSPS) were assessed.
Results: 510 HCV cirrhotics were enrolled: age was 63 (28–87) years, 60% males, 47% HCV-1b, 82% CPT A, 31% with baseline esophageal varices (EV). Median LSM was 17.3 (12.1–75.0) kPa, APRI 2.0 (0.2–30.5), Fib-4 4.6 (0.3–46.3), LSPS 1.7 (0.3–29.0). A sustained virological response was achieved by 491 (96%). After 22 (1–36) months, de novo HCC occurred in 24 (4.9%) patients, with a 3-year cumulative probability of 6% (95% CI 4%-9%). At diagnosis, median HCC size was 18 (10–100) mm, monofocal in 71%, BCLC 0-A in 83%; CPT was A in 79% patients and median alpha-fetoprotein (AFP) was 6 (1–57) ng/ml. At univariate analysis, de novo HCC was associated with male gender (p = 0.013), diabetes (p = 0.001), baseline LSM (<0.0001) and LSPS (<0.0001). At multivariate analysis, in patients without available LSM (n = 489), male gender [HR 4.42 (95% CI 1.26–15.5), p = 0.02], diabetes [HR 3.59 (95% CI 1.57–8.23), p = 0.002] and baseline Fib-4 [HR 1.08 (95% CI 1.01–1.15), p = 0.018] were independently associated with HCC development. In those with available LSM (n = 404), male gender [HR 10.0 (95% CI 1.33–75.7), p = 0.025], diabetes [HR 2.7 (95% CI 1.06–6.91), p = 0.037] and LSM [HR 1.03 (95% CI 1.01–1.06), p = 0.004] predicted the occurrence of HCC. The 3-year cumulative probability of HCC was 8.7% in males *vs.* 1.6% in females (p = 0.005), 18.0% in diabetics *vs.* 3.2% non-diabetics (p = 0.0003), and 3.4% *vs.* 23% in patients with LSM < or ≥30 kPa (p < 0.0001).
Conclusion: In a large, single-center prospective study of DAA-treated HCV cirrhotics, male gender, diabetes and noninvasive markers of fibrosis independently predicted the development of HCC.

FRI-370

The impact of HCV eradication by IFN-free regimens on the transition of precancerous hepatic nodules to HCC: a prospective observational study

H. Toyoda[1], T. Kumada[1], T. Tada[1], T. Yama[1], K. Mizuno[1], T. Akita[2], J. Tanaka[2]. [1]*Ogaki Municipal Hospital, Gastroenterology, Ogaki, Japan;* [2]*Hiroshima University Institute of Biomedical and Health Sciences, Epidemiology, Infectious Disease Control, and Prevention, Hiroshima, Japan*
Email: hmtoyoda@spice.ocn.ne.jp

Background and Aims: It is controversial whether the eradication of hepatitis C virus (HCV) by interferon (IFN)-free anti-HCV therapy using direct-acting antivirals (DAAs) suppresses or promotes hepatocarcinogenesis in patients with chronic hepatitis C. We investigated the influence of HCV eradication by DAA therapy on hepatocarcinogenesis, observing non-hypervascular hypointense nodules (NHHNs) by gadolinium-ethoxybenzyl-diethylenetriamine pentaacetic acid (Gd-EOB-DTPA)-enhanced magnetic resonance imaging (MRI).
Methods: A total of 401 patients treated with DAA therapy who did not have a history of hepatocellular carcinoma (HCC) were enrolled in this prospective cohort study. All study patients underwent Gd-EOB-DTPA-enhanced MRI just before the start of DAA therapy and were followed up by repeated Gd-EOB-DTPA-enhanced MRI periodically after therapy. The incidence of the hypervascularization of NHHNs detected at baseline to typical HCC and the incidence of new emergence of NHHNs were analyzed.
Results: Low platelet counts, low serum albumin levels, high alpha-fetoprotein levels, and cirrhosis were associated with the presence of NHHNs at baseline by multivariate analysis. In comparison of patients who achieved sustained virologic response (SVR) with propensity score-matched patients with persistent HCV infection, there was no difference in the incidence of hypervascularization of NHHNs to typical HCC among patients who had NHHNs at baseline (2-year incidence: patients with SVR vs. patients with persistent HCV infection, 24.4% vs. 24.9%, p = 0.6170). Among patients who did not have NHHNs at baseline, the incidence of the new emergence of NHHNs did not differ between study patients and propensity score-matched patients with persistent HCV infection (1-year incidence: patients with SVR vs. patients with persistent HCV infection, 3.4% vs. 5.2%, p = 0.7282).
Conclusions: During a 2-year observation period after SVR, the eradication of HCV by IFN-free DAA therapy did not influence hepatocarcinogenesis. HCV eradication did not suppress or enhance the development of typical hypervascular HCC from precancerous NHHNs. (umin.ac.jp/ctr/index.htm, number UMIN000017020)

FRI-371

Impact of curative HCC history on the development of HCC after the eradication of HCV by DAA therapy in patients with HCV infection

H. Toyoda[1], T. Kumada[2], T. Tada[2,3], K. Mizuno[2]. [1]*Ogaki Municipal Hospital, Gastroenterology, Japan;* [2]*Ogaki Municipal Hospital, Gastroenterology, Ogaki, Japan;* [3]*Ogaki Municipal Hospital, Gastroenterology, Ogaki, Japan*
Email: hmtoyoda@spice.ocn.ne.jp

Background and Aims: The incidence of hepatocellular carcinoma (HCC) development in patients with a history of curatively treated HCC is higher than in patients without a history of HCC even after the eradication of hepatitis C virus (HCV) by anti-HCV therapy, i.e., sustained virologic response (SVR). We investigated the differences in the patterns of HCC development after the eradication of HCV between patients with a history of curative HCC and those without it, based on the findings by gadolinium-ethoxybenzyl-diethylenetriamine pentaacetic acid (Gd-EOB-DTPA)-enhanced magnetic resonance imaging (MRI).
Method: Gd-EOB-DTPA-enhanced MRI was examined in 454 patients who achieved sustained virologic response (SVR) by interferon-free

direct-acting antiviral regimens just before the start of the therapy and the changes in Gd-EOB-DTPA-enhanced MRI findings after SVR were compared between patients with a history of HCC (n = 71) and without it (n = 383).
Results: The prevalence of patients with non-hypervascular hypointense nodules (NHHNs) during hepatobiliary phase of Gd-EOB-DTPA-enhanced MRI was significantly higher in patients with a history of HCC at baseline than those without HCC (patients with a history of HCC vs. without HCC, 29.6% vs. 8.6%, p < 0.0001). The incidence of typical hypervsacular HCC after SVR was higher in patients with a history of HCC (40.8%) than patients without (1.3%, p < 0.0001). Among patients with NHHNs at baseline, the hypervascularization of NHHNs to typical hypervascular HCC was more frequently observed in patients with a history of HCC (61.9%) than those without (15.2%, p < 0.0001). In addition, direct emergence of hypervascular HCC was observed in 32.0% of patients with a history of HCC despite the absence of NHHNs at baseline, whereas no hypervascular HCC developed in non-HCC-history patients without NHHNs at baseline (p < 0.0001).
Conclusion: In patients with a history of HCC, non-hypervascular hypointense nodules are more likely to show hypervascularization. In addition, direct emergence of hypervascular HCC not through NHHNs enhances the incidence of HCC development after SVR.

FRI-372
Impact of direct-acting antiviral agents on liver function in patients with chronic hepatitis C virus infection

H. Toyoda[1], S. Berhane[2], E. de Groot[3], T. Tada[1], T. Kumada[1], W. Irving[4], P. Johnson[2]. *[1]Ogaki Municipal Hospital, Gastroenterology, Japan; [2]University of Liverpool, Molecular and Clinical Cancer Medicine, Liverpool, United Kingdom; [3]University of St Andrews, St Andrews, United Kingdom; [4]University of Nottingham, NIHR Biomedical Research Unit in Gastroenterology and the Liver, Nottingham, United Kingdom*
Email: philip.johnson@liverpool.ac.uk

Background and Aims: Whilst the benefit of direct-acting antiviral agents (DAAs) in achieving SVR is now well-accepted, the impact of DAAs on survival is difficult to demonstrate because of the long term follow-up that is required. An alternative, shorter term approach is to assess the efficacy of DAAs on liver function.
Methods: We studied 2,653 patients with chronic hepatitis C virus (HCV) infection, 1,535 receiving DAAs and 1,118 interferon-based therapy. Those receiving DAAs came from the UK [n = 752, median follow-up = 23.9 months (95%CI 23.6, 24.0), mainly patients with decompensated cirrhosis] and Japan [n = 783, median follow-up = 20.2 months (95%CI 18.4, 20.7), mainly with compensated disease]. Median follow-up was 11.1 years (95%C.I. 10.3, 11.8) in the Interferon cohort. Liver function was assessed by the ALBI score.
Results: Among the patients receiving DAAs, 87% achieved SVR (Japan = 95%, UK = 79%). A higher rate of SVR achievement was independently associated with Genotype 1 (vs. other, p < 0.0001), better liver function (lower ALBI score p < 0.0001) and Japanese ethnicity (p < 0.0001). The Japanese patients (receiving DAAs) had virtually normal liver function at the time of treatment and there was therefore no scope to demonstrate improvement. However, among the UK patients receiving DAAs who had predominantly decompensated disease, improvement of liver function was clearly evident over the two years after start of treatment, especially in those achieving SVR [Figure]. These early changes in liver function were very similar to those observed in the first 2–3 years after interferon-based therapy [Figure] suggesting that, over the longer term, patients achieving SVR have improvement and subsequent stabilisation of liver function whilst among those not achieving SVR there is progressive deterioration.
Conclusion: DAAs improve liver function especially in those with decompensated disease who achieve SVR. Experience with interferon-based therapy suggests that failure to achieve SVR is associated with long-term decline in liver function, and in contrast, patients who do achieve SVR can expect long-term disease improvement and subsequent stabilisation of liver function. Our initial analysis suggests that those receiving DAAs are likely, in the long term, to follow a similar course. Liver function is an important factor influencing achievement of SVR in patients receiving DAAs.

FRI-373
Sustainable improvement of patient-reported outcomes in cirrhotic patients with hepatitis C who achieved sustained virologic response

Z. Younossi[1], M. Stepanova[2], A. Racila[2], I. Younossi[2], F. Nader[2], A. Muir[3], M. Bourliere[4], A. Mangia[5]. *[1]Inova Fairfax Hospital, Department of Medicine, Falls Church, United States; [2]Center for Outcomes Research in Liver Disease; [3]Duke University Medical Center; [4]Hôpital Saint Joseph; [5]IRCCS "CSS"*
Email: zobair.younossi@inova.org

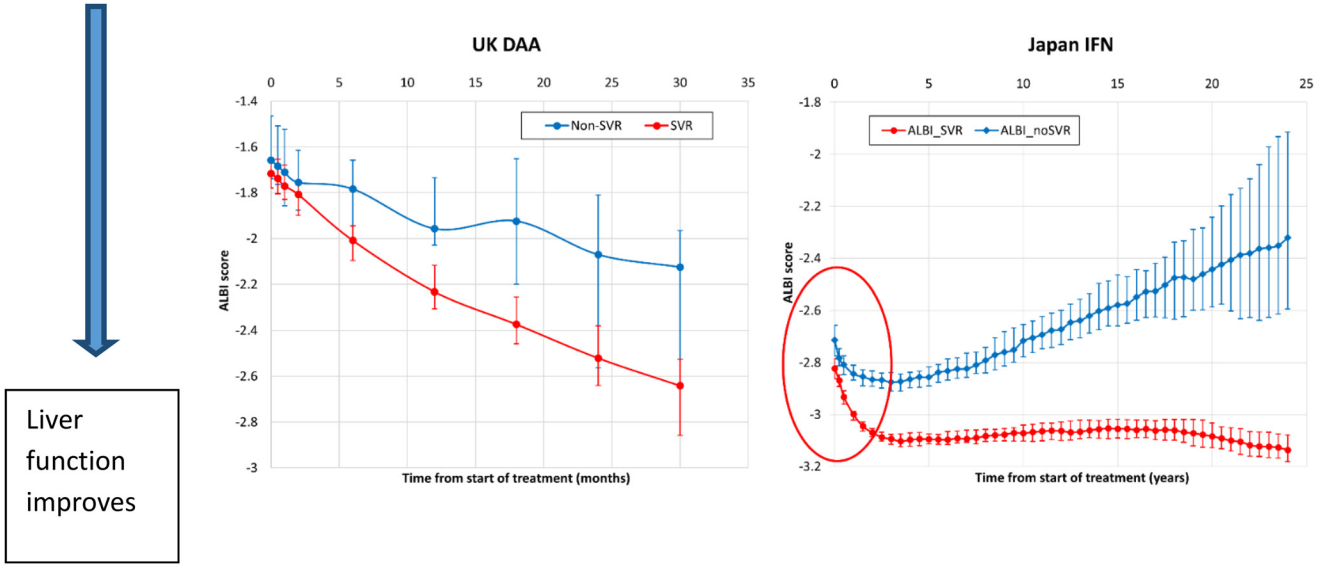

Figure: (abstract: FRI-372): Changes in liver function (ALBI score) over 2.5 years after DAA therapy (left) according to SVR status. Note the similarity of changes in the interferon based-therapy cohort (at the same time of follow-up, red oval). The absolute ALBI score at initiation of therapy is, as expected, much worse in this UK-based cohort of decompensated patients. Note also the difference in scale – months on the left, years on the right.

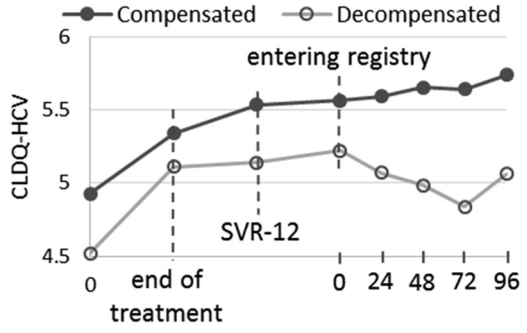
Background and Aims: HCV infection impairs patient-reported outcomes (PROs). Development of cirrhosis further worsens this PRO impairment. Although achieving sustained virologic response (SVR) can lead to PRO improvement, the long-term sustainability of this improvement in hepatitis C (HCV) cirrhotics has not been established. To assess long-term trends in PROs of patients with cirrhosis who have achieved SVR.
Method: Patients with HCV and cirrhosis who were treated in 12 clinical trials and had achieved SVR-12 were prospectively enrolled in a long-term registry. PROs were collected every 24 weeks using Short Form-36v2 (SF-36), CLDQ-HCV, and WPAI-HCV (20 PRO domains).
Results: Baseline data was available for 786 HCV cirrhotics with SVR-12. Of these, 650 had compensated and 136 decompensated cirrhosis before treatment [age 59.0 ± 7.4 years, 69% male, 22% with pre-treatment type 2 diabetes, 50% employed at enrollment]. Prior to their initial treatment, decompensated patients experienced severe impairment in their PROs in comparison to compensated cirrhotics (by 5.0% to 13.6% of a PRO range size; $p < 0.05$ for 15/20 PROs). After achieving SVR and enrollment into the registry, significant PRO improvements from the pre-treatment levels ($p < 0.05$) were noted in 11/20 PRO domains in decompensated (+4.1%–+19.6%) and in 19/20 PRO domains in compensated patients (+2.1%–17.0%). These PRO gains persisted or improved over time up to 96 weeks of follow-up in the registry (Figure). In multivariate regression analysis, younger age, the absence of baseline decompensation and type 2 diabetes, as well as baseline history of depression and fatigue were independent predictors of greater PRO improvements in the long term ($p < 0.05$).



Conclusion: HCV-infected patients with cirrhosis experience severe PRO impairment which improves after SVR in a sustainable and durable manner. There is some residual PRO impairment post-SVR in decompensated patients which is most likely related to the severity of their liver disease.

FRI-374
The impact of sustained virologic response on severe fatigue in patients with chronic hepatitis C: The role of HCV viremia and co-morbidities

Z. Younossi[1], M. Stepanova[2], L. Deavila[3], L. Gerber[3], E. Lawitz[4], S. Flamm[5], B. Willems[6]. *[1]Inova Fairfax Hospital, Department of Medicine, Falls Church, United States; [2]Center for Outcomes Research in Liver Disease, Washington Dc; [3]Inova Fairfax Hospital, Department of Medicine, Falls Curch, United States; [4]Texas Liver Institute, United States; [5]Northwestern University Medical Center; [6]Centre Hospitalier de l' Université de Montreal, Canada*
Email: zobair.younossi@inova.org

Background and Aims: Fatigue is a major extrahepatic manifestation of chronic hepatitis C infection. Studies suggest that fatigue may improve after HCV clearance. The aim is to assess the impact of SVR on fatigue in HCV patients who suffered from severe fatigue before treatment.
Methods: Participants of phase 2 and 3 clinical trials of sofosbuvir-based regimens completed FACIT-F instrument on the first day of treatment and at post-treatment week 12 visit; the Fatigue Scale score (FS, range 0–52) was used to assess baseline and post-treatment fatigue in patients with SVR.
Results: There were 6,113 patients with HCV who achieved SVR after treatment and had FS calculated prior to treatment and at post-treatment week 12 visit. Patients with FS scores in the lowest quartile (FS < 30; n = 1,467) were considered to have severe fatigue [age: 53.4 ± 9.5 years, 56% male, 40.0% employed, 34.6% cirrhotic, 27.5% reported history of anxiety, 43.4% history of depression, 14.5% had type 2 diabetes, and 6.7% coinfection with HIV]. By SVR-12, 42.4% of patients with pre-treatment severe fatigue (FS < 30) continued to experience severe fatigue (FS < 30) while 45.0% of patients with pretreatment severe fatigue improved to moderate fatigue (FS = 30–47), and 12.6% improved to minimal-or-no fatigue (FS ≥ 48). Patients with improved fatigue scores were younger and less likely to have cirrhosis (24.9% in those who improved to FS ≥ 48 vs. 33.9% in patients improved to moderate fatigue vs. 38.3% in patients without fatigue improvement). Similarly, these patients had lower rates of comorbidities (depression, anxiety, sleep disorders, diabetes, HIV co-infection) (all $p < 0.005$). No association of fatigue improvement with baseline demographic data (sex, race), HCV treatment history, baseline HCV viral load, and baseline BMI was found (all $p > 0.05$). In multivariate analysis, independent predictors of remaining severely fatigued after achieving SVR included the presence of cirrhosis (odds ratio (OR) (95%CI) = 1.38 (1.10–1.73)), having history of depression (OR = 2.07 (1.66–2.58)), sleep disorders (OR = 1.52 (1.20–1.92)), and coinfection with HIV (OR = 1.63 (1.06–2.51)) (all $p < 0.03$).
Conclusions: After SVR-12, more than half (57%) of HCV patients with pre-treatment severe fatigue improved their fatigue scores. Patients who continued to experience severe fatigue post-SVR were more likely to have cirrhosis and other co-morbidities. This suggests that post-SVR fatigue management should focus on managing these comorbidities which also contribute to fatigue.

FRI-375
De novo hepatocellular carcinoma in patients with cirrhosis due hepatitis C virus infection after treatment with direct antiviral agents

P. Ruiz[1], L. Deiss[1], L. Buendía[1], I. Erdozain[1], C. Álvarez[1], P. Gutiérrez[1], J.José Pascual[2], A. Baranda[1], S. Blanco[1], F. Menéndez[1], ÁngelJosé Calderón[3], A. Esain[3]. *[1]Basurto Universitary Hospital, Digestive and Liver Diseases, Bilbao, Spain; [2]Basurto Universitary Hospital, Computer Science, Bilbao; [3]Basurto Universitary Hospital, Digestive and Liver Diseases, Bilbao*
Email: andrea.esainurricelqui@sakidetza.eus

Background and Aims: The risk of developing *de novo* hepatocellular carcinoma (HCC) persists after achieving sustained virological response (SVR) in patients infected with hepatitis C virus (HCV). It has been suggested that risk increases in patients treated with the new direct antiviral agents (DAA). In this prospective study we present our results of incidence and prevalence of *de novo* HCC in cirrhotic patients treated with DAA who achieved SVR, and also, the risk factors involved.
Method: We included all cirrhotic patients due HCV infection without previous HCC who reached SVR after DAA treatment in our hospital from February 2014 until July 2017 (n = 226, median follow up 17 months). We evaluated with the chi-square test the following qualitative variables: Child-Pugh class, pre-treatment alcohol and tobacco consumption, pre-treatment diabetes mellitus (DM), HCV genotype, pre-treatment radiologic and endoscopic portal hypertension features. The quantitative variables were evaluated with the Student's test: age, pre-treatment n° of platelets, pre-treatment fibroscan value.
Results: During follow up, 12 patients were diagnosed of HCC (5.3% prevalence, 3.7% annual incidence). Among all qualitative variables evaluated, Child-Pugh class B vs class A ($p = 0.001$), pre-treatment DM ($p = 0.009$), and pre-treatment presence of radiologic features of portal hypertension ($p = 0.001$) were associated with developing *de*

novo HCC. Among quantitative variables, we evidenced statistically significant differences in the mean value of platelets (p = 0.015). The diagnosis of HCC was made in an average of 8.6 months after the start of treatment with DAA. 75% (9/12) was diagnosed in a stage 0 or A of the BCLC classification. At the end of the follow-up, 92% were alive (11/12).

Conclusion: In our group of patients, a worse hepatic function evaluated with the Child-Pugh classification, indirect markers of portal hypertension (platelets and radiological features) and DM are associated statistically significant with the development of *de novo* HCC.

No aggressive evolution has been observed in patients diagnosed with HCC, although the sample and the time of follow-up are scarce. The incidence (>1.5%) of de novo HCC justifies the screening of HCC in this group of patients.

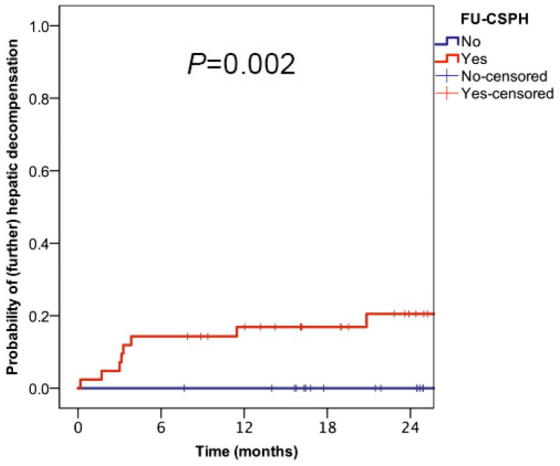
Resolution of clinically significant portal hypertension after sustained virologic response to interferon-free regimens prevents hepatic decompensation

M. Mandorfer[1], K. Kozbial[1], P. Schwabl[1], D. Chromy[1], B. Scheiner[1], R. Paternostro[1], A. Stättermayer[1], P. Munda[1], A. Ferlitsch[1], M. Trauner[1], M. Peck-Radosavljevic[2], P. Ferenci[1], T. Reiberger[1]. [1]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria;* [2]*Klinikum Klagenfurt am Woerthersee, Department of Gastroenterology and Hepatology, Endocrinology, and Nephrology, Klagenfurt, Austria*
Email: mattias.mandorfer@meduniwien.ac.at

Background and Aims: Sustained virologic response (SVR) to interferon (IFN)-free therapies ameliorates portal hypertension. However, the impact of the hemodynamic response on hepatic decompensation has yet to be investigated in this setting.

Methods: Seventy-seven patients with portal hypertension (HVPG ≥6 mmHg) who underwent hepatic venous pressure gradient (HVPG) and liver stiffness (LS) measurement before (baseline [BL]) and after (follow-up [FU]) IFN-free therapy were retrospectively studied.

(Further) hepatic decompensation was defined by variceal (re-) bleeding, incident ascites/worsening of ascites (requirement of paracentesis), incident hepatic encephalopathy (HE)/worsening of HE (admission for grade 3/4 HE).



Results: Patient characteristics at BL: Child-Pugh A: 81%, B: 19%; MELD: 8 (interquartile range [IQR]: 2) points; HVPG: 13 (IQR: 8) mmHg. In the subgroup of patients with a BL-HVPG of 6–9 mmHg (n = 22), no patient progressed to clinically significant portal hypertension (CSPH; HVPG ≥10 mmHg). Among patients with BL-CSPH, a HVPG-decrease ≥10% was observed in 65% (36/55), while 24% (13/55) had a FU-HVPG <10 mmHg (i.e., resolved CSPH). During a median FU of 24.9 (IQR: 15.1) months after the end of HCV treatment, 10 patients developed (further) hepatic decompensation, with variceal bleeding (n = 1), ascites (n = 4), or HE (n = 5) being the first events. Two patients underwent liver transplantation (both had further decompensation) and one patient died (non-liver-related). In patients with BL-CSPH, a HVPG-decrease ≥10% tended to decrease the risk of (further) hepatic decompensation at 2 years (10% vs.27%, p = 0.072). Overall, the absence of FU-CSPH was fully protective of the development of (further) hepatic decompensation (0% vs. 21%, overall p = 0.002; Figure). This was confirmed in the subgroup of patients with BL-CSPH (p = 0.004). The area under the receiver operating characteristic curve (AUROC) of FU-LS for diagnosing FU-CSPH/predicting (further) hepatic decompensation was 0.923/0.887. None of the patients with FU-LS values <12 kPa or <18.9 kPa had FU-CSPH or (further) hepatic decompensation, respectively.

Conclusions: The resolution of CSPH after SVR to IFN-free regimens is associated with a negligible risk of (further) hepatic decompensation, while a HVPG-decrease ≥10% is not fully protective. Moreover, FU-LS seems to provide prognostic information.

Email: veronika-pietsch@gmx.de

Background and Aims: Interferon-free antiviral therapy is associated with high rates of sustained virologic response (SVR). SVR has been associated with a significantly decreased liver stiffness; however, follow-up was mostly limited to 24 weeks after end of treatment (FU24). The aim of this work is to investigate long term liver stiffness changes in SVR patients using both, transient elastography (TE) and ARFI.

Methods: 171 patients (mean age 59 years, 54% male, 81% HCV genotype 1) with chronic HCV infection who achieved a SVR with IFN-free therapies were examined prospectively. 96 patients (56%) had liver cirrhosis (F4) at start of treatment. The duration of therapy was 8 to 24 weeks. All patients underwent liver elastography using TE at baseline and FU96. ARFI was performed at baseline in 169 patients, at FU24 in 126 patients and at FU96 in 92 patients.

Results: TE correlated with ARFI elastography at baseline, FU24 and FU96 (r = 0.779; r = 0.768; r = 0.629, respectively). TE and ARFI values decreased significantly from baseline to FU24 (20.7 ± 16.5 kPa to 14.2 ± 11.4 kPa, p < 0.001; 1.95 ± 0.64 m/s to 1.75 ± 0.64 m/s, p = 0.001). Importantly, neither mean TE nor mean ARFI values showed significant changes from FU24 to FU96 (14.2 ± 11.4 kPa to 13.3 ± 11.5 kPa, p = 0.08; 1.80 ± 0.73 m/s to 1.88 ± 0.88 m/s, p = 0.40). However, between FU24 and FU96 TE decreased in 43% and increased in 23%. ALT levels at baseline were significantly different in patients with and without liver stiffness regression from baseline to FU96 (93 ± 63U/l vs. 57 ± 33U/l, respectively, p = 0.036). Albumin, bilirubin and INR revealed no significant differences between FU24 and FU96. In cirrhotic patients TE changed only significantly from baseline to FU24 and not from FU24 to FU96 (31.3 ± 15.7 kPa to 20.2 ± 12.4 kPa, p > 0.001; 20.2 ± 12.4 kPa to 18.8 ± 12.6 kPa, p = 0.11). At treatment start 16% of patients suffered from Child B/C cirrhosis. 81% of these patients improved to Child A cirrhosis at FU96. Cirrhotic patients at baseline improved to TE values <14.5 kPa in 34% at FU24 and in 48% at FU96.

Conclusions: Using TE and ARFI, we identified a bi-phasic decline in liver stiffness with a more rapid decline observed in almost all patients until FU24 probably driven by decreased inflammation

followed by rather flat phased during further follow-up. TE values may even increase during follow-up in up to 25% of patients.

Wisteria floribunda agglutinin-positive Mac-2 binding protein predicts early occurrence of hepatocellular carcinoma in SVR achieved hepatitis C patients with interferon-free treatment

Y. Yasui, M. Kurosaki, T. Nobuharu, Y. Komiyama, H. Takada, K. Watakabe, M. Okada, W. Wan, T. Shimizu, Y. Kubota, M. Higuchi, K. Takaura, K. Tsuchiya, H. Nakanishi, J. Itakura, N. Izumi. *Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Tokyo, Japan*
Email: izumi012@musashino.jrc.or.jp

Background and Aims: The aim of this study is to clarify the predictability of post-treatment WFA+–M2BP for the development and recurrence of hepatocellular carcinoma (HCC) in chronic hepatitis C patients who underwent interferon-free, DAAs antiviral therapy.
Method: This is a retrospective cohort study which included 571 patients who underwent antiviral therapy with interferon free DAAs regimen. Serum WFA+–M2BP was measured after antiviral therapy. HCC occurrence and recurrence were analyzed in patients stratified by previous treatment history of HCC.
Results: In 519 patients who had no history of HCC, 14 patients developed HCC. Patients whose post-DAA treatment WFA+–M2BP ≥ 1.75 cut off index (C.O.I.) showed significantly higher incidences of HCC development ($p < 0.001$). Post-DAA treatment alpha-fetoprotein (AFP) level ≥6 ng/ml was also a predictive factor for the development of HCC ($p = 0.02$). Multivariate analysis showed that post-treatment WFA+–M2BP ≥ 1.75 C.O.I. was an independent factor which significantly associated with the development of HCC. In 52 patients who had previous history of HCC, 25 patients had recurrence after SVR. Patients with post-DAA treatment AFP ≥ 6 ng/ml showed significantly lower recurrence free survival than those with AFP < 6 ng/ml ($p = 0.01$), and AFP ≥ 6 ng/ml at SVR was an only factor associated with recurrence free survival.
Conclusions: Post-treatment WFA+–M2BP is a predictive factor for the development of HCC in DAAs-treated patients with no previous HCC history. In contrast, AFP was predictive for the HCC recurrence after DAAs.

FRI-379

Lack of reduction of serum alphafetoprotein during treatment with direct antiviral agents predicts hepatocellular carcinoma development in a large cohort of patients with HCV-related cirrhosis

Email: chiara.masetti12@gmail.com

Background and Aims: Residual risk of hepatocellular carcinoma (HCC) in HCV-infected cirrhotic patients treated with oral direct antiviral agents (DAA) is still a matter of debate. We investigated this issue in a large prospective cohort of cirrhotic patients treated in 7 third-level hospitals in Rome.
Methods: The cohort comprised 1045 cirrhotic consecutive patients who completed a full treatment course with DAA, with a median follow up of 17.3 months after the end of treatment (EOT), including 943 patients without a previous history of HCC and 102 successfully treated for HCC before starting DAA. The majority of patients were males (59.9%), genotype 1b (44.6%), with Child-Pugh A cirrhosis (88.8%); mean age was 63 years.
Univariate and multivariate analysis were performed to detect significant predictors of HCC development after DAA treatment. Kaplan Meier curves were used to predict incidence of HCC in patients with and without reduction in alphafetoprotein (AFP) levels during treatment.
Results: SVR was achieved in 95.3% of patients. HCC developed in 95 (9.9%), including 54/943 (5.7%) *de-novo a*nd 41/102 (39%) recurrent tumors. *De-novo* tumors were more often unifocal ($p = 0.01$) and susceptible to curative treatments ($p = 0.029$). Mean AFP levels decreased from 16.9 ± 36.2 mg/dl at baseline to 11.4 ± 55 mg/dl at EOT. At univariate analysis, predictors of HCC were a previously treated HCC, older age, higher bilirubin levels, higher MELD score, prolonged INR, baseline and EOT AFP levels, virological failure and lack of reduction of AFP levels during treatment. Gender, HCV genotype and treatment schedule were unrelated to HCC development. Kaplan Meier curves showed a lower incidence of HCC in patients showing any reduction of AFP levels during treatment ($p = 0.006$). Those in whom AFP dropped to <6ng/ml had the lowest risk of HCC ($p = 0.0001$). At Cox regression analysis, MELD score (HR 1.14, c.l. 1.04–1.25, $p = 0.0002$), history of previously treated HCC (HR 6.57, c.l. 3.30–13.06, $p < 0.00001$,) and lack of reduction of AFP (HR 3.02, c.l. 1.51–6.01, $p = 0.001$,) were confirmed as independent predictors of HCC.
Conclusions: The residual risk of HCC after DAA treatment remains substantial. The risk is remarkably higher among patients with a previously treated HCC, high MELD score and without reduction of AFP levels during treatment. These findings support the need of a strict surveillance for HCC in these patients, especially if AFP remains >6 ng/ml at EOT.

FRI-380

The course of oesophagogastric varices in patients with cirrhosis after DAA-induced HCV clearance

V. Calvaruso[1], I. Cacciola[2], S. Petta[1], G. Caccamo[2], E. Conte[3], M. Licata[1], F. Simone[1], G. Squadrito[2], G. Raimondo[2], A. Craxi[1], V. DI Marco[1]. *[1]University of Palermo, Gastroenterology & Hepatology, Di.Bi.M.I.S., Palermo; [2]University of Messina, Internal Medicin and Hepatology Unit, Messina; [3]University of Palermo, Gastroenterology and Hepatology Unit, DIBIMIS, Palermo*
Email: vincenza.calvaruso@unipa.it

Background and Aims: Use of direct acting antivirals (DAAs) has allowed to clear HCV in almost all patients even in the presence of advanced cirrhosis. Although it has been suggested that cirrhotic portal hypertension may regress after SVR, the ultimate effect of HCV clearance on the development and progression of oesophagogastric varices (OV) is still unexplored. We assessed in a prospective cohort of patients with cirrhosis the evolution of endoscopic features of portal hypertension induced by SVR obtained with DAAs.
Method: 263 consecutive patients (mean age 65.0 ± 10.6, males 56%) with HCV Child-Pugh A cirrhosis treated with DAAs were enrolled between January 2015 and May 2016. All patients underwent esophagogastroscopy (EGS), liver ultrasound (US), liver stiffness measurement (LSM) by Transient Elastography and laboratory tests before the starting DAAs and after achieving SVR. LS * spleen diameter/platelet ratio (LSPS) was calculated as previously described (1).

Results: Twenty-nine patients were excluded from the analysis, 20 (7.6%) since they had F2/F3 OV at baseline and were treated with beta-blockers (BB), and 9 (3.7%) since they did not achieve SVR. Overall, 234 SVR patients were analysed. At baseline, 83 patients (35.5%) did not have OV and 151 (64.5%) had small OV. None received beta-blockers. After a median time of 24.5 months EGS showed *de novo* development of OV in 17/83 (20.5%) patients and progression from F1 to F2/F3 OV in 27/151 patients (17.9%), p = 0.58 by Kaplan Meier. By Cox regression analysis, LSPS as continuum variable (HR:1.05, CI95%:1.01–1.10, p = 0.046) or at a cut off ≥3 (HR:2.87, CI95%:1.44–5.72, p = 0.003) was associated with OV progression. Age (p = 0.15), gender (p = 0.93), BMI (p = 0.84) and SVR did not correlate with progression of OV.
Conclusion: Progression of clinically significant portal hypertension, as assessed by the evolution of oesophagogastric varices, is not uncommon among patients with HCV cirrhosis after HCV clearance. Non-invasive evaluation using combined data of LS, spleen diameter, and platelet count can assist in identifying patients in whom portal hypertension is likely to progress notwithstanding SVR.

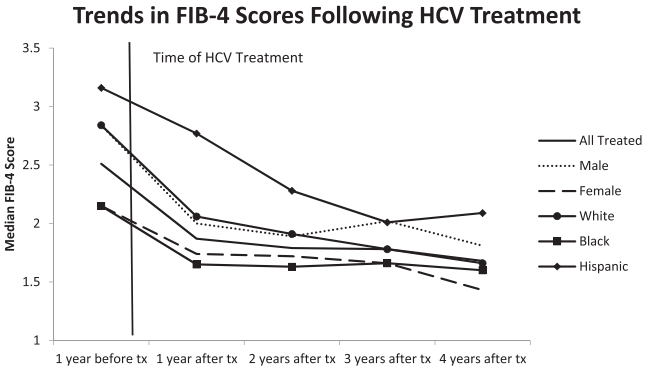
Sustained and continued improvement in hepatic fibrosis beyond the first year following hepatitis C virus treatment
R. Wong[1], M. Jain[2], G. Therapondos[3,3], M. Shiffman[4], O. Kshirsagar[5], C. Clark[6], M. Thamer[5]. [1]*Alameda Health System – Highland Hospital, Gastroenterology and Hepatology, Oakland, United States;* [2]*University of Texas Southwestern, Dallas, United States;* [3]*Ochsner Health System, New Orleans;* [4]*Liver Institute of Virginia, Bon Secours Health System, Richmond;* [5]*Medical Technology and Practice Patterns Institute, Bethesda;* [6]*Parkland Health and Hospital System, Dallas*
Email: rowong@alamedahealthsystem.org

Background and Aims: Achieving sustained virologic response following hepatitis C (HCV) treatment reduces risks of disease progression and hepatocellular carcinoma. It is not clear to what degree and how quickly hepatic fibrosis improves following HCV treatment and whether this improvement is sustained beyond the first year after therapy.
Methods: Adults treated for chronic HCV at four large U.S. healthcare systems from 1/1/2011 to 2/28/2017 were retrospectively evaluated to determine changes in fibrosis-4 (FIB-4) scores following HCV therapy. Baseline pre-treatment FIB-4 (calculated at 1 year prior to therapy) was compared to 1 year post-treatment FIB-4 using Student's t-test. To evaluate whether improvements in FIB-4 were sustained beyond the first year following treatment, we additionally evaluated changes in FIB-4 from 1 year post-treatment to 4 years post-treatment.
Results: Among 2,697 patients treated for HCV, overall baseline pre-treatment median FIB-4 was 2.51 (IQR 1.51–4.39). Baseline median FIB-4 was significantly higher in men compared to women (2.84 vs. 2.15, p < 0.001), significantly higher in whites compared to African Americans (2.84 vs. 2.15, p < 0.001), and significantly higher in the oldest age group (2.73 in age >65 vs. 1.32 in age <45, p < 0.001). In the first year following treatment, median FIB-4 score improved by 25.5% (2.51–1.87); in the subsequent 3 years, FIB-4 continued to improve 3.4%/year. While males had greater improvement in FIB-4 during the first year following treatment (29.6% vs. 19.1% in females, p < 0.001), in the subsequent 3 years, the rate of continued FIB-4 improvement trended higher in females compared to males (10.3%/year improvement vs. 3.2%/year, p = 0.062). When stratified by race/ethnicity, whites had the greatest improvement in FIB-4 during the first year following treatment (27.5% improvement), followed by African Americans (23.2% improvement) and Hispanics (12.3% improvement). However, in the subsequent 3 years, the rate of continued FIB-4 improvement was greatest among Hispanics (8.2%/year improvement), followed by whites (6.5%/year), and African Americans (1.7%/year).



Conclusion: While the greatest improvements in FIB-4 scores were observed in the first year following HCV therapy, these improvements were sustained and fibrosis continued to improve beyond the first year. Sex-specific and race/ethnicity-specific differences in rates of fibrosis improvement following HCV therapy were observed.

FRI-382
The role of hepatitis C virus eradication with DAA on insulin resistence regulation
I. Bortoluzzi[1], M. Gambato[2], E. Franceschet[2], A. Zanetto[2], A. Floreani[2], F. Farinati[2], P. Burra[2], A. Mega[3], F.P. Russo[2]. [1]*Mirano Hospital, Gastroenterology Unit;* [2]*Padua University Hospital, Department of Surgery, Oncology and Gastroenterology, Italy;* [3]*Bozen Hospital, Gastroenterology Unit*
Email: francescopaolo.russo@unipd.it

Background and Aims: Insulin resistance (IR) is a common extrahepatic manifestation of Hepatitis C virus (HCV) infection. The aim of this research was to evaluate if viral eradication obtained with DAA plays a role in the development and/or improvement of IR; we also evaluate if IR improvement reduces hepatic complications incidence.
Method: All HCV patients treated with DAA from May 2015 to December 2016 were prospectively included in the study. For each patient, we analyzed blood test and HOMA score before therapy and at 3, 6 and 12 months after its completion. Liver fibrosis was quantified by stiffness with Transient Elastography before treatment, 6 and 12 months after antiviral therapy. IR has been defined as HOMA score ≥2.5. All patients were treated with DAA drugs.
Results: 161 patients were included in the study, between these 117/161 (72.7%) had IR and 44/161 (27.3%) not. Before receiving antiviral therapy patients with IR had higher BMI (p0.0094) and liver stiffness (p < 0.0001) levels compared to those without IR. 158/161 (98.1%) patients obtained viral eradication. We observed a significant IR improvement both at 6 months (p = 0.0412) and 12 months (p = 0.0045) after therapy completion. 4 diabetic patients before therapy obtained resolution of diabetes. High BMI before antiviral therapy was the only predictive factor related to failure of IR improvement. All patients obtained significant liver stiffness reduction after DAA therapy (p < 0.0001), significant improvement in serum albumin levels and platelets count and transaminases normalization. 8/161 (3.9%) patients had hepatocellular carcinoma (HCC) after the end of therapy (4/8 de novo HCC, 4/8 HCC recurrence); 7/8 of these patients had IR.
Conclusion: Viral eradication with DAA leads to IR improvement. High BMI is a risk factor for IR and a negative predictive factor for IR improvement. Persistence of IR after DAA therapy is a risk factor for liver disease complications, such as HCC.

FRI-383

Therapy with oral directly acting agents in hepatitis C infection is associated with reduction in fibrosis and increase in hepatic steatosis

Shalimar, G. Rout, S. Gupta, D. Gunjan, S. Kedia, B. Nayak. *All India Institute of Medical Sciences, New Delhi, India, Department of Gastroenterology, New Delhi, India*
Email: drshalimar@yahoo.com

Background and Aims: Novel directly-acting antivirals (DAAs) are now the standard of care for hepatitis C (HCV) infection and are associated with high sustained viral response at 12 weeks (SVR12). The aim of this study was to evaluate the change in liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) by transient elastography (FibroScan®) post DAA therapy.
Method: LSM and CAP were measured serially (baseline, 12 weeks post completion of therapy and at one year after completion of therapy) in a prospective cohort of 372 chronic hepatitis C (CHC) treated with DAAs. Patients with at least two FibroScan measurements were included. Linear regression was used to assess for factors predictive of dynamic change in LSM and CAP values.
Results: A total of 372 patients were included; mean ± SD age 38.3 ± 12.6 years; 58.3% were males. Cirrhosis- defined by biopsy or fibroscan measurement (≥12.5) kPa- was present in 25.5%. Overall, on paired analysis (n = 317), the LSM (IQR) decreased from baseline value 7.1 (5.3–13.8) kPa to 12 weeks post therapy 6.2 (4.8–11.2) kPa; median decline 0.7 (−0.6–2.6) kPa, p < 0.001. On paired analysis (n = 105), the LSM value decreased from 12 weeks post therapy 6.8 (4.9–11.8) kPa to 1 year LSM 6.6 (4.9–8.7) kPa; median decline 0.6 (−0.5–2.6) kPa, p = 0.002. Similarly, on paired analysis (n = 160), LSM decreased from baseline value 6.9 (5.1–12.7) kPa to 1 year, 6.1 (4.8–9.4) kPa; median decline 0.9 (−0.6–3.2) kPa, p < 0.001. In contrast, on paired analysis (n = 317), CAP value increased from baseline 213.0 (180.0–254.5) dB/m to 12 weeks post therapy 225.0 (190.0–269.0) dB/m; median increase 7.0 (−23.5–45.5) dB/m, p = 0.001. On paired analysis (n = 105), CAP value increased from 12 weeks post therapy 234.0 (182.5–268.5) dB/m to 1 year 244.0 (206.0–286.0) dB/m; median increase 15.0 (−17.0–43.5) dB/m, p = 0.003. Similarly, on paired analysis (n = 160), CAP value increased from baseline value 210.0 (180.3–260.8) dB/m to 1 year 234.0 (204.0–282.0) dB/m; median increase 25.0 (−12.5–61.5) dB/m, p < 0.001. On multivariate linear regression analysis, higher baseline LSM value, low platelet count and BMI were independently associated with reduction of LSM. On multivariate linear regression analysis, low baseline CAP value and low albumin were significantly associated with increase in CAP values.
Conclusion: Treatment with DAAs reduces liver stiffness, but is associated with increase in hepatic steatosis. Future studies are needed to evaluate the factors associated with increase in hepatic steatosis.

FRI-384

Recurrence of hepatocellular carcinoma in patients with a history of HCC after SVR to DAA for chronic hepatitis C

I. Ozeki, H. Suii, R. Tatsumi, M. Yamaguchi, M. Kimura, T. Arakawa, Y. Kuwata, T. Ohmura, S. Hige, Y. Karino, J. Toyota. *Sapporo-kousei general hospital, Hepatology, Sapporo, Japan*
Email: 3767759101@jcom.home.ne.jp

Background and Aims: In patients with previous treatment for hepatocellular carcinoma (HCC) even after SVR achieved by direct-acting antivirals (DAAs), the subsequent recurrence rate of HCC is high. A high AFP level after the end of DAAs is a potential contributing factor for HCC recurrence. Here, we investigated contributing factors for early HCC recurrence with a focus on the AFP-L3 before and after treatment.
Method: Of 542 patients who had started DAAs for chronic hepatitis C at our hospital and achieved SVR24, 84 patients with previous curative treatment for HCC were included in this study. Median age at the start of DAA therapy was 74 (52–88) years; men, 44 (52%); cirrhosis, 55 cases (66%); age at initial HCC treatment, 70 (48–87) years. HCC recurrence rate and contributing factors for recurrence were investigated. ROC analysis was also performed to determine AFP and AFP-L3 before and after DAAs, allowing the prediction of early recurrence (≤1 year after treatment completion). Before the start of DAAs, the final HCC Stage was I /II/III in 51/29/4 patients. The maximal tumor diameter was 14 (6–15)mm. The number of HCC treatment sessions was 1/2/3/4/5/8 in 43/2/3/4/5/2 patients. The last HCC treatment was RFA/ surgery in 57/27 patients. The time between the last HCC treatment and the start of DAAs was <6/6–11/12-23/24-35/≥36months in 27/12/23/5/17 patients. To investigate contributing factors for HCC recurrence, Cox proportional hazards model was used with the following variables: HCC stage, the number of HCC treatment sessions, the time between the last HCC treatment and the start of DAAs, age at the start of DAAs, sex, AST, ALT, γ-GT, FIB-4, M2BPGi, AFP, and AFP-L3. Moreover, FIB-4, M2BPGi, AFP, and AFP-L3 levels at the time of treatment completion were also assessed as posttreatment variables.
Results: (1) HCC recurred in 28 of the 84 patients (33%; mean follow-up period, 17 months). The cumulative recurrence rates were 18/26/32/39% at 6/12/18/24 months. (2) Among the variables before the start of DAAs, an AFP-L3 of ≥ 0.5% was identified as a contributing factor for recurrence (HR 3.8; 95%CI, 1.6–10.2; p = 0.009). AFP-L3 was also identified as a posttreatment contributing factor (HR, 5.7; 95%CI, 2.4–13.3; p < 0.001). (3) The cut-off values of AFP and AFP-L3 for predicting early recurrence within one year after completion of DAAs were, respectively, ≥11.6 ng/ml (AUC 0.62) and 6.1% (AUC 0.80) before treatment and 4.9 ng/mL (AUC 0.65) and 0.5% (AUC 0.78) after treatment. The rate of early recurrence within one year was 86% in patients with an AFP-L3 of ≥ 6.1% at the time of treatment initiation and ≥ 0.5% at the time of treatment completion, which was significantly higher than the corresponding percentage of 17% in patients with the respective AFP-L3 of <6.1% and <0.5%.
Conclusion: AFP-L3 before and after treatment appear to be useful for predicting early recurrence.

FRI-385

In hepatitis C patients with cirrhosis who achieve SVR with treatment, reduction in transient elastography measures does not translate to reduced risk of hepatocellular carcinoma: A prospective cohort study

J. Howell[1,2,3], T. Papaluca[1,3], S. Glasgow[1], K. New[1], T. Hong[1], J. Snell[1], D. Iser[1], M. Ryan[1], S. Bell[1,3], P. Desmond[1,3], S.L.C.Y. Mei[1], C. Croagh[1], T. Nguyen[1], Z. Valaydon[1], G. Shaw[1], B. Demediuk[1], L. Mcdonald[1], A. Craigie[1], L. Stothers[1], M. Lust[1], C. Jeremiah[1], K. Visvanathan[1,3], A. Thompson[1,3]. *[1]St Vincent's Hospital Melbourne, Gastroenterology, Fitzroy, Australia; [2]Burnet Institute, Disease Elimination, Melbourne, Australia; [3]University of Melbourne, Medicine, Parkville, Australia*
Email: jessica.howell@svha.org.au

Background and Aims: Achieving sustained virological response (SVR) with interferon-based therapy in hepatitis C (HCV) reduces risk of hepatocellular carcinoma (HCC). However, in the era of direct-acting antivirals, real-world risk of HCC post SVR is unknown, particularly in patients with reductions in transient elastography (TE) readings post SVR.
Method: In this prospective cohort study conducted between January 1st 2001 and November 8th 2017, HCV patients with cirrhosis (confirmed by TE, ultrasound and/ or liver biopsy) who achieved SVR post treatment underwent HCC surveillance with 6 monthly ultrasounds and clinic review. Patients with previous HCC (including <6 months post SVR) were excluded. A subset of participants had TE performed 6–12 months post SVR. HCC diagnosis per international guidelines was recorded.
Results: 281 patients with cirrhosis who achieved SVR were prospectively followed with a total follow-up time of 8892 person-months at risk (median 15, IQR 12–26 months). Mean age was 58

years (+/–9.4 years), 216 (70%) were male and 266 (87%) were Caucasian. The majority were genotypes 1 (154, 51%) and 3 (120, 39.5%). 146 (48%) had significant alcohol intake and 25 (8.1%) were decompensated. 227 (74.2%) had received direct-acting antiviral therapy, the remainder having received pegylated interferon-based regimens. 15 (5%) developed new HCC post SVR (incidence rate 2.0 cases per 1,000 months person-time at risk (95% CI 1.22–3.35), median time to diagnosis 22 months (IQR 15–86 months). 5/ 15 (33%) had received DAAs (30%). 77 patients had TE performed post SVR (follow-up time of 1,970 person-months at risk). 55 (71.4%) had post-SVR readings <12.5 kPa and 13 (17%) had readings <7.1 kPa. 36/55 (66%) had cirrhosis on imaging despite fall in TE to <12.5 kPa. 5/ 77 patients (6.5%) developed HCC, incidence rate 2.5 per 1,000 person-months at risk (95%CI 1.1–6.1). 3/5 cases had TE readings <12.5 kPa: liver biopsy revealed two cases (TE 10.1 kPa and 12.4 kPa) had cirrhosis and one case (TE 6.5 kPa) had NASH without cirrhosis. None had clinical evidence of portal hypertension, or significant alcohol intake.

Conclusion: In a real-world population with universal access to DAA therapy, HCC risk diminishes, but persists in patients with HCV cirrhosis after SVR. Importantly, HCC can occur in patients whose post-SVR TE readings fall below <12.5 kPa post SVR. Therefore, HCC surveillance should continue irrespective of improvements in post-SVR TE readings.

FRI-386

Risk of de novo hepatocellular carcinoma after DAA treatment within two years following treatment with Ombitasvir/ Paritaprevir/ritonavir ± Dasabuvir ± Ribavirin in the AMBER – real world experience study

R. Flisiak[1], M. Łucejko[1], D. Zarębska-Michaluk[2], K. Tomasiewicz[3], K. Rostkowska[4], M. Tudrujek[3], M. Grzegorz[5], S. Krzysztof[4], J. Białkowska[6], M. Jablkowski[6]. *[1]Medical University of Białystok, Poland; Department of Infectious Diseases and Hepatology, Białystok, Poland; [2]Voivodship Hospital and Jan Kochanowski University, Department of Infectious Diseases, Kielce, Poland; [3]Medical University of Lublin, Poland; Department of Infectious Diseases and Hepatology, Lublin, Poland; [4]Wrocław Medical University, Division of Infectious Diseases and Hepatology, Wrocław, Poland; [5]Voivodship Specialistic Hospital, 2nd Department of Infectious Diseases, Wrocław, Poland; [6]Medical University of Łódź, Department of Infectious and Liver Diseases, Łódź, Poland*
Email: robert.flisiak@umb.edu.pl

Background and Aims: AMBER was an investigators initiated, real world experience study carried-out in 2014–2015, that included one of the first in the world group of patients treated with Ombitasvir/ Paritaprevir/ritonavir ± Dasabuvir ± Ribavirin (OPrDR) in real world setting. Aim of the current analysis is two years follow-up focusing on risk of hepatocellur carcinoma (HCC) development.

Method: 209 patients included in the AMBER study were scheduled for a 2 years follow-up (2yFU) visit. Medical history, physical and ultrasonography examination focused on HCC de-novo development were analysed. Additionaly changes in hepatic stiffness with elastography and laboratory measures of hepatic function were compared between patients with and without de novo HCC within 2yFU, to find out possible predictors of post treatment HCC.

Results: At the moment of abstract submission 2yFU data were available from 202 patients (97%). They were mostly cirrhotics (60%), infected with genotype 1b (86%). HCC history before OPrDR was noticed in 10 patients (5%) and HCC recurrence happen in 2. De novo HCC was diagnosed after OPrDR treatment in 5 patients, between 10 and 24 month of 2yFU. Four of them were cirrhotics, so the risk of HCC within 2yFU after OPrDR treatment was 3.3% in cirrhotics (4/121) and 1.2% in non-cirrhotics (1/81). All 5 de novo HCC has no hepatic lesions at the end of treatment and cirrhotics were screened every 6 months during 2yFU. Among 4 deaths noticed within 2yFU one was due to recurrent HCC and none due to de novo HCC. In contrast to non-HCC patients those who developed HCC did not demonstrate statistically significant improvement of bilirubin, albumin, INR and MELD values during 2yFU. Significan reduction of stiffness in elastography was noticed in both HCC and non-HCC groups. All 198 patients with available HCV RNA measurements at 2yFU were undetectable.

Conclusion: Risk of de novo HCC after OPrDR is 3 times higher in patients with liver cirrhosis compared to non-cirrhotics, but annual HCC risk rate in cirrhotics did not exceed level observed in the natural history of the disease. Since majority of de novo HCC developed within the second year of the follow-up its association with DAA is unlikely. Cirrhotics with no improvement of laboratory measures of liver function after cure of HCV infection should be closely monitored for possible HCC development. Changes in hepatic stiffness have no predictive value for HCC development after DAA treatment.

FRI-387

Antiviral therapy can prevent in HCV infected patients relapse of diffuse large B cell lymphoma

A. Pellicelli[1], V. Giannelli[1], G.M. Ettorre[2], R. Villani[1], V. Zoli[3], V. Pellicelli[1], A. Zignego[4]. *[1]Azienda Ospedaliera San Camillo Forlanini, Liver Unit Department of Liver Transplant, Rome, Italy; [2]Azienda Ospedaliera San Camillo Forlanini, Surgery Department of Liver Transplant, Rome, Italy; [3]Azienda Ospedaliera San Camillo Forlanini, hematology, Rome, Italy; [4]Univ. degli Studi di Firenze, Medicina Interna, Firenze, Italy*
Email: adriano.pellicelli@uniroma1.it

Background and Aims: Diffuse large B cell lymphoma (DLBCL) patients carring hepatitis C virus (HCV) have a higher risk of complications and liver toxicity but the role of antiviral therapy (AT) to reduce relapse of DLBCL after chemotherapy containing Rituximab (CT-R) is not analyzed in previous studies. In this context we aimed at assessing the role of AT in preventing the recurrence of DLBCL in HCV infected patients treated with CT-R.

Pts patient; gen genotype; CT chemiotherapy; Hematol.response Hematological response; AT antiviral Therapy; Time AT antiviral therapy during o post chemotherapy; SVR sustained virological response; FU follow up; m months; SOF sofosbuvir; SMV simeprevir; DCV daclatasvir; LDV ledipasvir.

Method: We treated 18 consecutive HCV infected patients affected by DLBCL with pegylated interferon (PegIFN) plus Ribavirin (RBV) or II generation DAAs during or after CT-R. Eleven patients had HCV genotype 1 (62%), 8 were treated with DAAs and the remaining with the combination of PegIFN plus RBV. Three patients had compensated cirrhosis (Child Pugh A), 3 had a METAVIR score F3, 12 F0-F2 METAVIR. We have evaluated relapse of DLBCL after CT-R in patients with or without sustained virological response (SVR) to AT.

Results: Sustained virological response was achieved in 14 of 18 patients. In our series, lymphoma relapse was more frequent in patients without virological response (3 out of 4 patients without

SVR) (RR 1.75; 95% CI 0.92–3.32; p < 0.02). Three patients were treated with DAAs during chemotherapy and none presented transaminases flares or liver decompensation compared to patients treated after chemotherapy. All the characteristics of the patients are reported in Table.
Conclusion: Antiviral therapy for HCV during or after chemotherapy is an important strategy to prevent relapse of DLBCL in HCV infected patients when the patients reached a SVR. Our results also suggests that HCV treatment with DAAs reduces the risk of liver decompensation when given during chemotherapy in patients with advanced liver fibrosis.

FRI-388

Prospective follow up of 80 patients with addictive behaviors and advanced fibrosis after treatment of chronic HCV infection with DAA: a suboptimal management

C. Barrault[1], Régine Truchi[2], J.-B. Trabut[3], D. Carmona[4], F. Roudot[5], E. Gelsi[6], A. Bachelard[7], Stéphanie Dominguez[7], I. Rosa[1], C. Costentin[5], C. Hezode[5], A. Tran[2]. *[1]CH Intercommunal de Créteil, gastroenterology and hepatology unit, CRETEIL, France; [2]Chu l'archet, hepatology unit, nice, France; [3]Hopital Emile Roux, addictology unit, Limeil Brevannes, France; [4]CSAPA Epice, addictology unit, creteil, France; [5]Hopital Henri Mondor, hepatology unit, creteil; [6]Chu l'archet, hepatology unit, nice, France; [7]Hopital H. Mondor, clinical immunology, creteil, France*
Email: camille.barrault@chicreteil.fr

Background and Aims: Chronic HCV infection in drug-user (DU) and/or alcohol-dependent patients can effectively be treated with DAA. However, follow up of the liver disease and addiction behaviours remains complex due to associated psychosocial problems. The aim of the study was to assess the regularity of the liver disease follow-up in these patients and the evolution of their addictological behaviour after treatment with DAA.
Method: DU and/or alcohol-dependent patients with chronic HCV infection were prospectively followed during and after DAA treatment. Liver disease follow-up was planned according to EASL recommendations (ultrasound (US) for HCC screening, biological assessment and consultation every 6 months if fibrosis ≥ F3). Data were retrieved from 2 pooled French cohorts.
Results: Between January 2014 and December 2016, 80 patients (68% male) aged 49 (±9) years started DAA. Severe fibrosis (F3) or cirrhosis was observed in 40% and 60% of the patients, respectively. Housing was precarious in 42% of the patients, 62% lived alone, 79% were unemployed, 49% had psychiatric disorders and 49% received OST. Alcohol misuse was identified in 66 cases (82%). Viral eradication rate was 92.5%. The mean duration of follow-up was 65 ± 42 weeks. At 6 months, 13 patients (16%) were lost to follow-up, among the 66 alcohol-dependent patients, 42% had excessive alcohol intake. Addiction follow-up was regular in 47.5%, irregular in 25.5%. Factors associated with addiction follow-up were patient sent from an addiction care centre (p = 0.005), not receiving alcohol withdrawal medication (p = 0.023) and unemployment (p = 0.077). Follow-up of the liver disease was regular in 46%, irregular in 34.5%, absent in 19% of the cases. US at 6 months were available in 45 cases (58%), HCC was diagnosed in 5 cases (6%). Factors associated with liver monitoring were alcohol withdrawal before treatment (p = 0.23), stable housing (p = 0.038) and employment (p = 0.014).
Conclusion: Follow-up of liver disease after HCV treatment was suboptimal in DU and alcohol-dependant patients although advanced fibrosis at risk of HCC. Treatment seems to have a moderate impact on alcohol consumption. These results warrant close cooperation between hepatologists and addictologists after HCV eradication to improve patient's compliance to advanced fibrosis follow-up guidelines. Updated results including 12 months recontamination data will be presented in April 2018.

FRI-389

Predictors of clinical improvement among HCV patients with advanced liver disease treated with DAA: a single center experience

C. Mazzarelli[1,2], I. Carey[1], K. Childs[1], A. Suddle[1], M.A. Manini[1], G. Dusheiko[1], K. Agarwal[1], M.D Cannon[1]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]ASST Ospedale Niguarda, Hepatology and Gastroenterology, Milan, Italy*
Email: chiaramazzarelli@hotmail.com

Background and Aims: Patients with cirrhosis have been consistently shown to have lower rates of sustained virologic response (SVR) with direct-acting antiviral (DAA) therapy than those without fibrosis. However, registration trials and real-life cohorts have demonstrated that a large number of patients with advanced liver disease may experience clinical improvements following HCV eradication. We aimed to identify factors predictive of clinical improvement in patients with advanced liver disease.
Method: Retrospective analysis of cirrhotic patients treated with SOF + NS5A inhibitors (daclatasvir or ledipasvir) from 2015–17 at King's College Hospital was performed. Data was analyzed using SPSS version 22.0.
Results: 187 cirrhotic patients, including 45 with decompensated liver disease, were treated with SOF+NS5A-inhibitors for 12 weeks. 16% of those with CP-A had a prior history of decompensation with ascites or encephalopathy which had resolved with medical management. 89 patients (48%) were treatment experienced. 13 patients (6.9%) had an active HCC at the start of therapy. 13% of patients had a pretreatment MELD score >14. All the patients received a weight-based ribavirin with a mean dose of 1000 (800–1200 mg), lower in those with impaired eGFR. The demographic and clinical characteristics of the patients are reported in table below. 175/187 (93.6%) achieved SVR12. Only 6 patients failed the treatment (3 CP-A and 3 CP-B). 6 patients died or were lost to follow up. Consistent with published reports, we observed a lower SVR rate in the decompensated cohort (SVR12: 86%) compared to those with CP-A cirrhosis (SVR12: 95%). Despite the high dose of RBV, severe anemia (Hb < 10) was recorded in only 27 patients (14%). Patients with advanced liver disease had a greater risk of ribavirin-related-anaemia during the treatment (p = 0.049). Improvement in MELD occurred in 40%, 45% and 47% at week 12, 24 and 48 weeks post-treatment completion.The improvement in MELD function was more significant only in patients with MELD >14: the improvement in MELD occurred in 68.1%, 77.7% and 83.4% at week 12/24/48 post-treatment. Male sex, bilirubin and ALBI at baseline were identified as predictors of improvement at 24 or 48 weeks of follow-up. Moreover, a change in albumin at week 4 of treatment >0.4 g/L compared to baseline, as well as changes in ALBI class were both associated with improvement in liver function during the follow-up time. Albumin <3.5 and ALBI 3 were associated to a greater risk (p > 0.001) of adverse events (death, transplant, hospital admission, sepsis, HCC).
Conclusion: Viral eradication was associated in with clinical and biochemical improvement, which was maintained during longer term follow-up. A rapid improvement in albumin after only 4 weeks of treatment was the strongest predictor (p = 0.02) of long-term improvement in our patient cohort.

FRI-390

Sustained virologic response leading to improved long-term metabolic outcomes

B. Emmanuel[1], K.A. Stafford[1], L.S. Magder[2], M.E. Charurat[3], S.S. El-Kamary[2], S. Kottilil[1]. *[1]Institute of Human Virology, University of Maryland School of Medicine, Division of Clinical Care and Research, Baltimore, United States; [2]University of Maryland School of Medicine, Division of Epidemiology and Public Health, Baltimore, United States; [3]Institute of Human Virology, University of Maryland School of Medicine, Division of Epidemiology and Public Health, Baltimore, United States*
Email: ben.emmanuel@umaryland.edu

Background and Aims: Hepatitis C virus (HCV) clearance has shown rapid changes in metabolic pathways during direct-acting antiviral (DAA) therapy suggesting a direct effect of HCV viral suppression. However, long-term changes beyond sustained virologic response (SVR) and the modifying effect of HIV-coinfection remains unknown. We investigated the distribution of change over time from pre-DAA therapy to post-SVR in metabolic and inflammatory parameters among chronic HCV patients.
Method: Chronic HCV genotype 1 patients (N = 301) received DAA therapy in four clinical trials in Washington, D.C. Low-density lipoprotein (LDL), high-density lipoprotein (HDL), triglycerides, hemoglobin A1C (HbA1C), alanine aminotransferase (ALT), and aspartate aminotransferase (AST) were measured at pre-DAA therapy (baseline) and repeatedly measured during the duration of: DAA therapy, pre-SVR, at SVR, and post-SVR. Statistical analyses were conducted using linear mixed effects models, adjusting for age, sex, race, fibrosis, and HIV antiretroviral therapy in SAS 9.4.
Results: 269 chronic HCV patients (194 HCV and 75 HIV/HCV) achieved SVR (89%) and were predominately male (67%), black (79%), non-cirrhotic (93%), with a mean post-SVR follow-up of 2 years. Mean LDL significantly increased from pre-DAA to during DAA therapy (90 to 111 mg/dl, $p < 0.001$). After completing DAA therapy, mean LDL decreased between SVR and each yearly post-SVR period up to year 4 (107 mg/dl at SVR to 95 mg/dl at post-SVR year 4, $p = 0.01$). During DAA therapy, 20% of patients had LDL ≥130 mg/dl, which dropped to 9% at the last post-SVR follow-up. Mean triglycerides decreased between pre-DAA and SVR (107 to 94 mg/dl, $p = 0.005$), then continued to decrease between SVR and post-SVR year 4 (94 to 73 mg/dl, $p = 0.04$). HDL and HbA1C did not significantly change between pre-DAA and post-SVR. Both mean ALT and AST decreased significantly between pre-DAA and during DAA therapy (ALT 64 to 23U/l, $p < 0.0001$; AST 54 to 22U/l, $p < 0.0001$). ALT levels continued to decrease between SVR and post-SVR year 4 (19 to 13U/l, $p = 0.04$), while AST was constant. There was no significant difference by HIV-coinfection for all parameters.

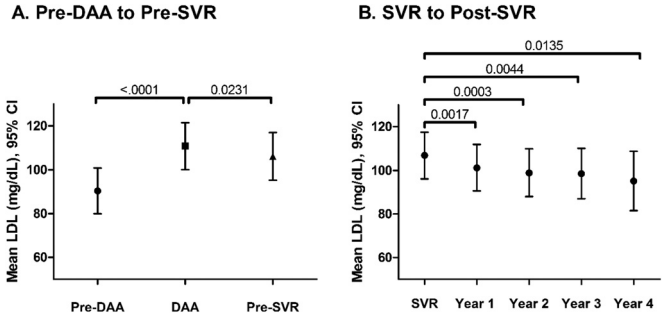

Figure: Mean LDL estimates from pre-DAA therapy to pre-SVR (A) and SVR to post-SVR (B).

Conclusion: Our longitudinal study showed chronic HCV patients treated with DAA therapy had continued improvements of metabolic (LDL and triglycerides) and inflammatory (ALT and AST) parameters after achievement of SVR.

FRI-391

High virological cure rate and low rate of reinfection in a project to eradicate HCV in people who inject drugs at risk for non-adherence to direct-acting antivirals in Vienna

A. Schütz[1], C. Schwanke[1], E. Gutic[2], T. Lang[2], R. Schubert[1], J. Luhn[1], S. Moser[2], H. Haltmayer[1], M. Gschwantler[2]. *[1]Suchthilfe Wien gGmbH, Ambulatorium Suchthilfe Wien, Vienna, Austria; [2]Wilhelminenspital, Department of Internal Medicine Iv, Vienna, Austria*
Email: michael.gschwantler@wienkav.at

Background and Aims: An important subgroup of people who inject drugs (PWID) receiving opioid agonist therapy (OAT), cannot be treated in the setting of a hepatologic center and would not regularly ingest their medication when handed to them for self-administration. Our hypothesis was that chronic hepatitis C in these patients could be ideally managed if modern, interferon-free regimens were administered together with OAT under direct observation of a pharmacist, physician or nurse at a pharmacy or a low-threshold facility.
Method: 166 PWID on stable OAT with chronic hepatitis C and high risk for non-adherence to DAA-therapy (male/female: 128/38; mean age: 38.2 ± 8.3 years; genotype (GT) 1/2/3/4: 103/2/55/6; HIV-coinfection: 13 patients; liver cirrhosis: 38 patients) started interferon-free treatment of chronic hepatitis C. Patients received antiviral therapy together with OAT under direct observation of a pharmacist, physician or nurse at a pharmacy or low-threshold facility. The DAA-regimen was selected according to GT, fibrosis stage, pretreatment and current reimbursement policy of insurances.
Results: Following this concept of directly observed therapy, adherence to antiviral therapy was excellent: Only 0.15% of scheduled dates for ingestion of the antiviral therapy in combination with OAT were missed by the 166 patients. Till now, 104 patients have completed treatment and a 12-week follow-up period. Virological cure of hepatitis C infection (sustained virologic response, SVR12) could be confirmed in all 104 patients (SVR12 rate: 100%, 95%CI: 96.5–100.0). During follow-up reinfections occurred in 6 patients. The cumulative rate of reinfection 12, 24, 48 and 72 weeks after end of therapy was 1.9%, 5.6%, 8.7% and 8.7%, respectively.
Conclusion: Directly observed therapy of chronic hepatitis C at a pharmacy or a low-threshold facility is highly effective in PWID at risk for non-adherence to DAA. By this new concept, a group of difficult-to-treat patients can be cured, who could not have been treated in settings of studies published so far. In our cohort the rate of reinfection was relatively low.

FRI-392

Circulating microparticles and thrombotic risk in patients with HCV-related cirrhosis who underwent DAA treatment

A. Zanetto[1], Elena Campello[2], E. Franceschet[1], S. Shalaby[1], A. Ferrarese[1], S. Sciarrone[1], C. Becchetti[1], M. Gambato[1], G. Germani[1], M. Senzolo[1], P. Simioni[3], P. Burra[1], F.P. Russo[1]. *[1]Multivisceral Transplant Unit, Gastroenterology, Surgery, Oncology and Gastroenterology, Padova, Italy; [2]Padua University Hospital, Department of Medicine, Italy; [3]Thrombotic and Hemorragic Diseases Unit, Medicine, Padova, Italy*
Email: francescopaolo.russo@unipd.it

Background and Aims: microparticles (MP) have been investigated for their ability to induce coagulation cascade and participate in thrombosis because of the presence of tissue factor (TF). Several studies have analysed levels of MP in patients with diseases at high risk for thrombotic complications, but there is not enough data about MP in patients with HCV related cirrhosis. Moreover, the impact of HCV clearance after DAAs in MP profile is not known. Our aim was therefore to investigate the presence and cellular origins of MP in patients with HCV cirrhosis, before and after DAAs, as well as to evaluate the possible contribution of MP in portal vein thrombosis (PVT) occurrence.
Method: HCV cirrhotic patients, treated with DAAs, were prospectively followed for 48 weeks after the end of antiviral therapy (EOT). Endothelial (E)-MP, platelet (P)-MP, TF and thrombomodulin (TM)-MP were measured by cytoflowrimetry at baseline (B), 12 weeks and 48 weeks after EOT. Pro-coagulant activity of the MP was evaluated. During follow-up, PVT onset was recorded. Fifty healthy subjects were recruited as controls.
Results: 58 patients were enrolled (Child A/B 50/8). All of them achieved SVR. Patients showed B-levels of E-, P-, TF- and TM-MP significantly higher ($p < 0.05$) and lower ($p < 0.05$) than controls, respectively. SVR was associated with a significant decrease of E, P and TF-MP, with no statistical difference when compared with controls ($p = 0.2$). On the other hand, there was a significant increase in TM-MP ($p < 0.01$). Patients showed a baseline phospholipid-dependent (PPL)

clotting time significantly shorter than controls, reflecting an increase of pro-coagulant activity due to phospholipid presence ($p < 0.05$). SVR was associated with a significant reduction of PPL ($p = 0.4$). Child B patients showed a significant reduction of TF-MP ($p < 0.05$), which, however, was not associated with a concomitant increase of TM-MP ($p = 0.1$). Two PVTs (both in Child B class) were observed, being the absolute incidence 1.1% p-yrs (95%CI, 0.18–3.58).
Conclusion: sustained virological response is associated with a significant modification in MP profile, possibly related to an improvement of liver synthesis. However, in patients with advanced liver disease, the haemostatic imbalance was not significantly modified, with a decrease of pro-thrombotic MP not associated with a concomitant increase of anti-coagulant MP. Thus, these patients seem to remain at risk of developing PVT, at least in the short term after antiviral therapy.

FRI-393
A cost-effectiveness analysis of shortened direct-acting antiviral treatment for mild chronic hepatitis C virus
C. Fawsitt[1], P. Vickerman[1], G. Cooke[2], N.J Welton[1]. [1]*University of Bristol;* [2]*Imperial College*
Email: c.fawsitt@bristol.ac.uk

Background and Aims: Hepatitis C virus (HCV) is a blood borne virus that can infect the liver, causing cirrhosis and decompensation of the liver, and hepatocellular carcinoma, requiring liver transplantation. A new class of oral medicines, called direct-acting antivirals (DAAs), have been developed to treat HCV, with cure rates observed in over 95% of patients treated for 12 weeks. DAAs are expensive; 12 weeks of therapy costs approximately £15,000 per patient. Shortened treatment durations, which have lower cure rates, have been proposed to reduce costs. We evaluate the lifetime cost-effectiveness of short-course first-line and re-treatment DAA regimens for treatment of non-cirrhotic HCV in genotype 1 patients.
Method: Assuming a UK National Health Service perspective, we use a probabilistic decision tree and Markov model to compare eight, six, and four weeks of shortened treatment regimens against a standard 12-week treatment regimen; patients for whom shortened treatment is unsuccessful are retreated with a standard 12-week treatment regimen. Evidence on efficacy of treatment and retreatment, drug and healthcare costs and utilities are taken from a review of the literature.
Results: Shortening treatment to eight or six weeks saves £6,796 and £3,317 and generates 0.06 and 0.01 more quality-adjusted life years (QALYs), respectively, per 1,000 patients compared with 12 weeks treatment. Shortening treatment to four weeks, with a 38% cure rate, costs an additional £859 and results in a QALY loss of 0.05. The probability that any shortened treatment strategy was most cost-effective was greater than the 12 weeks treatment arm, at £20,000 willingness to pay, but considerable uncertainty was observed in the four- and six-week treatment strategies due to limited evidence on efficacy.
Conclusion: Shortening treatment to eight or six weeks with retreatment in those that fail is cost-effective in genotype 1 non-cirrhotic treatment-naïve patients. Four weeks treatment is likely not cost-effective. More robust evidence on the efficacy of shortened treatment is required. Future research should also identify patients for whom shortened treatment duration is likely to be effective.

FRI-394
HCV testing and linkage to care: expanding access to HCV care through electronic health engagement and linkage to C care program in the PWID population
Z. Alam[1], D. Cook[2], H. Bui[1], I. Alam[1]. [1]*Austin Hepatitis Center, Austin, United States;* [2]*Austin Hepatitis Center, Austin, Texas, Austin, United States*
Email: ztariq@linkagetocare.com

Background and Aims: Over 75% of new hepatitis C [HCV] infections in the United States result from injection drug use. Since people who inject drugs [PWID] are at an increased risk for contracting HCV, the Center for Disease Control (CDC) recommends HCV testing in this population. Therefore, we must increase education, screening, and linkage to care by working through environments such as methadone clinics, Sober Living Homes, and drug rehabilitation centers. One challenge in testing PWID, particularly in community settings, is screening and linkage to care following a positive test. Our aim is to screen the PWID population and increase linkage of HCV RNA positive individuals to care. To achieve this goal, we plan to utilize electronic health engagement through our online patient database management system (PDMS) with our Substance Abuse Treatment Center partners.
Method: Longitudinal prospective cohort study with HCV screening at the above centers and utilization of a HIPPA compliant online patient database management system (PDMS) (www.linkagetocare.com). A centrally located Linkage to Care Specialist (LTCS) is notified immediately when an individual's information is entered in the system by the treatment center. The LTC Protocol initiates with education provided by the LTCS and ends with initial appointment with provider.
Results: January – October 2017, 609 PWID population were screened at 6 facilities; 284 (47%) were HCV Antibody positive; of the 284 RNA tests performed 201 (71%) were HCV RNA positive; 72% were uninsured; 61% of patients are between the ages of 21–40; 61% males. 159 (79%) were contacted by LTCS; 42 (21%) are still in recovery and we are still in process of gathering their contact information; 61 (38%) patients referred by the LTCS to a medical provider; 28 (18%) were awaiting further lab results; while 24 (39%) patients made it to their first appointment; 10 (16%) are in process of being seen by the doctor. PWIDs were linked to a LTCS within 2 days after referral. On average, patients were contacted twice before scheduling their first appointment.
Conclusion: The study found a high prevalence of HCV in PWID treatment centers. Approximately, 40% of patients have been referred to a medical provider. In its early phase the LTC program has increased HCV screening and compliance with linkage to care as compared to other care models in the PWID population. Our study accentuates a promising role for PWID patient engagement in electronic portals and LTCS as a tool in linking patients to the HCV care cascade.

FRI-395
Autoantibody to apolipoprotein A-1 in hepatitis C virus infection: a role in atherosclerosis?
S. Bridge[1], S. Pagano[2], M. Jones[3], G. Foster[3], D. Neely[4], N. Vuilleumier[2], M. Bassendine[5]. [1]*Northumbria University, Faculty of Health and Life Sciences, Newcastle upon Tyne, United Kingdom;* [2]*Geneva University Hospitals, Department of Genetics and Laboratory Medicine, Geneva, Switzerland;* [3]*Queen Mary University of London, The Liver Unit, Blizard Institute, London, United Kingdom;* [4]*Newcastle upon Tyne Hospitals NHS Foundation Trust, Clinical Biochemistry, Newcastle upon Tyne, United Kingdom;* [5]*Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom*
Email: mbassendine@doctors.org.uk

Background and Aims: 1–3% of the world's population have hepatitis C virus (HCV) infection which is not only a major cause of liver disease and cancer but also associated with an increased risk of atherosclerosis, despite an ostensibly favourable lipid profile. Autoantibodies are frequent in HCV infection and emerging evidence shows that autoantibodies could be valuable for cardiovascular disease (CVD) risk stratification. This study investigated a novel independent biomarker of CVD, autoantibodies to apolipoprotein A-1 (anti-apoA-1 IgG) and lipids in patients with chronic HCV before, during and after direct-acting anti-viral (DAA) therapy.
Methods: 89 blinded serum samples from 27 patients with advanced chronic HCV were assayed for lipids and anti-apoA-1 IgG by ELISA.
Results: Pre-treatment HCV viral load correlated with high density lipoprotein cholesterol (HDL-C, $r = 0.417$; $p = 0.042$) and negatively

with apolipoprotein (apo)B (r = –0.497; p = 0.013) and markers of CVD risk, apoB/apoA-1 ratio (r = –0.490; p = 0.015) and triglyceride (TG):HDL ratio (r = –0.450; p = 0.031). There was no significant difference in the serum lipid concentrations at week 0 and 12 of DAA therapy, when all 27 patients had a virologic response (undetectable HCV RNA). 14/27 (52%) patients had detectable anti-apoA-1 IgG autoantibodies pre-treatment; only two became undetectable with virologic cure. Autoantibody positive sera had lower apoA-1 (p = 0.012), HDL-C (p = 0.009) and total cholesterol (p = 0.006) levels.

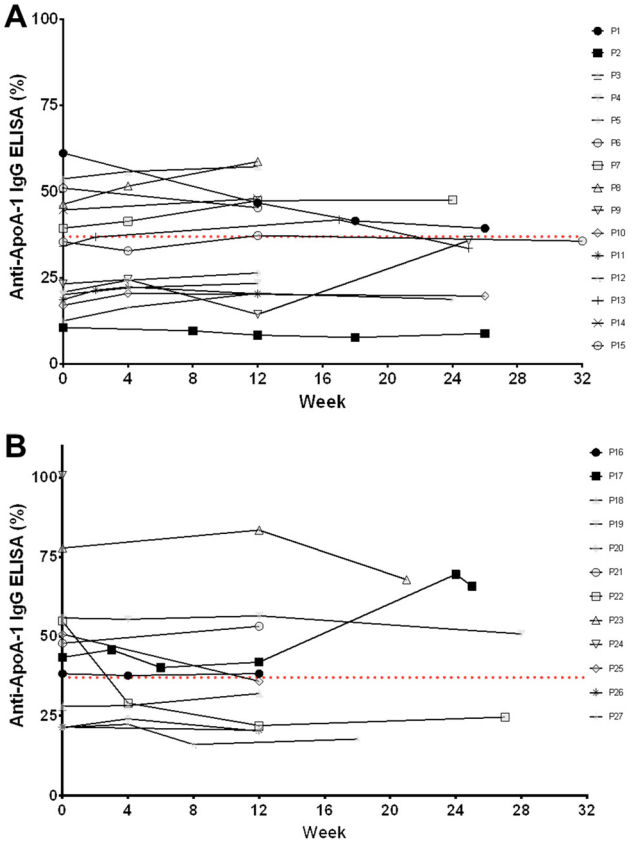

Figure: Autoantibody to apolipoprotein A-1 IgG ELISA reading [cut off 37%] in 27 patients with advanced chronic HCV before, during and after direct-acting anti-viral therapy, commenced at week 0. By week 12 all patients responded to antiviral treatment and were HCV RNA negative. **A.)** shows results in HCV genotype 1 patients, 2/15 relapsed after end of therapy; **B.)** shows results in HCV genotype 3 patients, 1/12 relapsed.

Conclusion: This is the first report of the presence of an emerging biomarker for atherosclerosis, anti-apoA-1 IgG, in some patients with HCV infection. They may be induced by apoA-1 on the surface of HCV lipoviral particles. The autoantibodies inversely correlate with apoA-1 and HDL levels and may render HDL dysfunctional. Whether these hypothesis-generating findings have clinical implications in HCV patients requires further study.

FRI-396

Treatment of HCV infection with DAAs is associated with lower HCC recurrence and improved survival after liver transplant

K. Willuweit[1], K. Piras-Straub[1], P. Andreas[2], G. Gerken[1], K. Herzer[1].
[1]*Department of Gastroenterology and Hepatology;* [2]*Department of General- Visceral- and Transplantation Surgery*
Email: kerstin.herzer@uk-essen.de

Background and Aims: High rates of sustained virological response (SVR) in patients with chronic hepatitis C (HCV) treated with direct-acting antivirals (DAAs) suggested a reduction of hepatocellular carcinoma (HCC). However, following antiviral treatment using DAAs, an unexpected high rate of HCC recurrence has been reported in certain settings. The aim of the current study was to identify the role of DAA-therapy on HCC recurrence after liver transplant (LT).
Methods: Clinical, laboratory and demographic data of 190 patients who had received LT between 2010 and 2016 at the university hospital Essen were retrospectively collected in a database. All patients received LT due to HCV cirrhosis with or without HCC or for HCC not related to HCV. Categorical data were analyzed by χ^2-tests with Pearson approximation or Fisher's exact test. The overall and HCC recurrence free survival was analyzed by Kaplan-Meier estimation and Log Rank test according to Mantel-Cox regression. The level of statistical significance was set at $p \leq 0.05$.
Results: To identify the role of DAA-therapy on HCC recurrence after LT, the cohort was divided into patients with HCV related HCC (n = 67) and patients with non-HCV related HCC (n = 74) that could be analyzed for HCC recurrence within the 2-year follow-up. HCC recurrence occurred in 21.9% (n = 31/141) of all patients. Of those patients with HCV, 50.7% (n = 34) received DAA-therapy. HCC recurrence occurred in only 9% (n = 3/34) of patients who received DAAs but in 33% (n = 11/33) of those patients who did not receive DAAs ($p \leq 0.017$). Moreover, patients who had received a DAA-therapy showed improved survival after LT compared to patients without treatment (11.6 vs 10.1 years).
Conclusion: DAA-based HCV-therapy before LT results in a significantly lower HCC recurrence risk after LT and improved patient survival. Exact mechanisms how DAAs alter the proliferative behavior of liver tumor cells and the specific immune responses in the liver influencing tumorgenesis remain to be elucidated.

Email: mromerogomez@us.es

Background and Aims: To analyze the impact of the sustained virological response after therapy with direct antiviral agents (DAAs) on the cardiovascular risk in patients with hepatitis C.
Methods: We recruited prospectively 71 patients with hepatitis C who achieved sustained virological response after DAAs treatment. The cardiovascular risk was evaluated according to a) subclinical atherosclerosis by the ankle brachial index (ABI); b) lipid profile; c) endothelial dysfunction through the laser Doppler flowmetry and the measurement of adhesion and angiogenesis soluble markers; d) markers of cell and endothelial damage including endothelial apoptotic microparticles (EMPs) and cell free DNA levels (cfDNA). Patients were evaluated before and one year after treatment with DAAs.
Results: Mean age was 54 ± 10 years, 67.6% were males, BMI 27 ± 4. 52.5% were cirrhotic, 77.5% genotype 1, 28% of patients presented hypertension, 20% Diabetes Mellitus and 7% dyslipidemia. There was no difference between first evaluation and the follow-up visit in the ABI, but the laser Doppler flowmetry showed a significant improvement in the peak flow (44.8 ± 5.7 vs 67.5 ± 17.4UP; p = 0.015). The

levels of VCAM (2317.8 ± 277.8 vs 1480.9 ± 202.5 ng/µl; p < 0.001) and E-selectin (64.9 ± 4.6 vs 43.5 ± 3.9 pg/ml; p < 0.001) also improved after the treatment. We observed that the levels of total cholesterol (170 ± 6 vs 183 ± 7 mg/dl; p < 0.001), LDL (98 ± 6 vs 110 ± 6 mg/dl; p < 0.001), ApoB (88.1 ± 5.4 vs 101.3 ± 5,3 mg/dl; p < 0.001) and PCSK-9 (624.9 ± 40.1 vs 770.9 ± 44.8 ng/ml; p < 0,001) were significantly increased after the treatment, instead HDL was not modified. Regarding to cell damage markers, there was a significant decrease in the EMPs number (317.7 ± 58.5 *vs* 212.4 ± 36,7U; p = 0,04) and also in the cfDNA level (613.6 ± 82.4 *vs* 401.6 ± 46.2 ng/ml; p = 0.02).
Conclusion: The new antivirals drugs improve the endothelial dysfunction one year after treatment, being another positive factor for HCV therapy indication.

FRI-398
The impact of direct antiviral agent therapy on liver fibrosis in patient with advanced fibrosis related chronic hepatitis C
B. Kutala[1], N.B. Darrigrand[1], C. Corinne[1], B. Pierre[2], T. Asselah[1], P. Marcellin[1]. *[1]Beaujon Hospital - APHP, Department of Hepatology, Clichy, France; [2]Beaujon Hospital - APHP, Department of Pathology, Clichy*
Email: nathalie.boyer@bjn.aphp.fr

Background and Aims: The impacts of sustained virologic response (SVR) after direct antiviral agents (DAA) therapy in patients with chronic hepatitis C virus (CHC) remain unclear. The regression of cirrhosis and portal hypertension demonstrated in interferon therapy, are expected in the DAAs therapies. Transient Elastography (TE) is a noninvasive method ultrasound based, for assessment liver stiffness (LS). The aims of this study were: (1) evaluated the changes in liver stiffness and fibrosis stage (2) to examine factors influencing changes in liver stiffness measurements after DAA treatment.
Methods: We prospectively consecutive patients treated with DAAs in our department between January 2013 and September 2016. 643 patients who received a DAA based treatment for CHC were screened and 417 were included. TE values recorded before therapy initiation and within 24 months after therapy were analysed. In addition, predictors of fibrosis regression were evaluated in multivariate analysis.
Results: A total of 417 patients (375 have TE and 42 have paired biopsy) were included. Baseline characteristic: 71% were men, 54% had cirrhosis and the median age was 53 years. Median TE before DAA treatment was 12.85 kPa (IQR 9.75–19.2 kPa) and decreased to 8.55 kPa (IQR 5.87–15.23) post-treatment. This finding is statistically significant (p < 0.001) and equals a TE regression of 33.5% after DAA treatment. Median FIB-4 and APRI values significantly decreased from 2.53 (IQR 1.64–4.42) and 1.13 (IQR 0.67–2.45) to 1.78 (IQR 1.27–2.90, p < 0.001) and 0.48 (IQR 0.33–0.81, p < 0.001) respectively. Cirrhosis regressed in 15/24 patients (62%), but advanced fibrosis regressed 14/18 cases (78%) among 42 patients with liver biopsy. Multivariate analysis found a lower BMI and gender female as factors independently associated with fibrosis regression [(odds ratio (OR) 0.68, 95%CI 0.48–0.97), p = 0.037 and [(OR: 0.51, 95%CI 0.36–0.89), p = 0.0221] respectively.
Conclusions: Patients with SVR after DAA therapy showed significant regression of TE values and fibrosis regression according liver biopsy. Rapid decrease in TE was in concordance with the improvement of liver function. It remains to be examined whether this indicates a true regression of fibrosis or merely resolution of chronic liver inflammation with subsequent improvement of biopsy values in large cohort.

FRI-399
Effects of direct-acting antiviral treatment of chronic hepatitis C on macrophage activation, liver stiffness, metabolic liver function and portal hypertension in cirrhosis patients
T.L. Laursen[1], K. Kazankov[1], T.D. Sandahl[1], H.J. Møller[2], L. Hagelskjær Kristensen[3], C. Holmboe[4], C. Sølund[5], H. Arildsen[6], A. Laursen[6], H. Grønbæk[1]. *[1]Aarhus Universitetshospital. Email: tealaurs@rm.dk

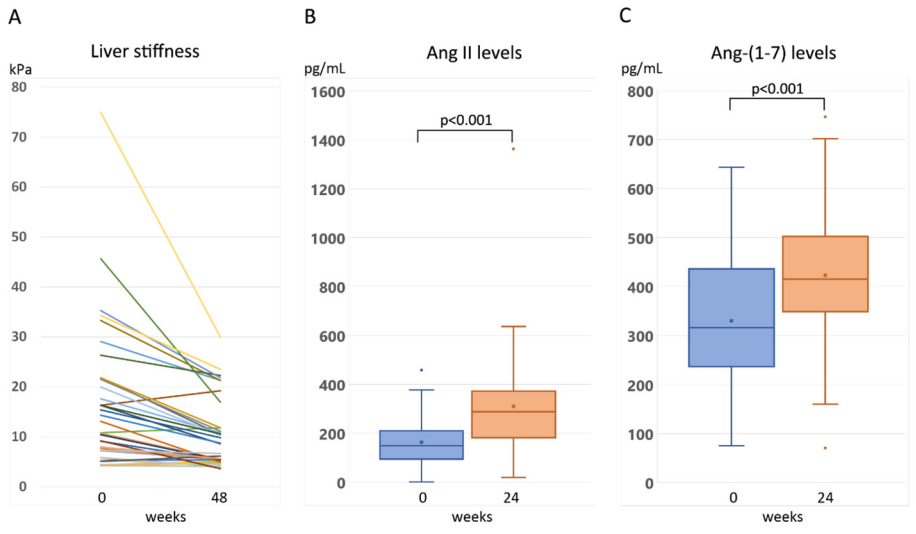
Background and Aims: The new all-oral direct-acting antiviral (DAA) treatments of chronic hepatitis C (CHC) cure >95% of the affected patients. However, it is unclear how features of liver cirrhosis change after DAA-treatment. Soluble (s)CD163 is released from activated liver macrophages and serum levels reflects liver disease severity. We aimed to investigate changes in sCD163, liver stiffness, metabolic liver function, and portal hypertension with DAA-treatment in CHC patients with liver cirrhosis.
Method: Between 2015–2017, we assessed 14 Danish CHC patients with cirrhosis before and immediately after DAA-treatment including ombitasvir, paritaprevir, ritonavir, and dasabuvir ± ribavirin for 12 weeks. Serum sCD163 levels were quantified by an in-house ELISA. Liver stiffness was measured by transient elastography (FibroScan). Metabolic liver function was assessed by the galactose elimination capacity (GEC) test. Portal hypertension was estimated by the hepatic venous pressure gradient using lever vein catheterisation.
Results: The patients had a mean age of 56 years (SD 9); 9 males and 5 females. Eleven had genotype 1a hepatitis C virusand 3 had genotype 1b. Five were abstinent from alcohol, 8 had a previous over-intake and one drank 1 unit/week of alcohol until enrolment. All patients had Child-Pugh A cirrhosis with a mean MELD-score of 8 (1.7). All patients received 12 weeks of DAA-treatment except for one patient, who died within two months of treatment initiation. All patients, who completed treatment, achieved sustained virological response (SVR) 12 weeks after treatment cessation. The mean sCD163 level decreased from 6.8 mg/L (4.8) to 4.5 (4.9) (p = 0.005). The mean liver stiffness decreased from 22.8 kPa (11.8)–11.0 (3.5) (p = 0.008). There was a trend for improved metabolic liver function (GEC) (60.0 (11.5) vs. 55.6% (9.1), p = 0.10). There was no significant effect on the hepatic venous pressure gradient after treatment (11.6 mmHg (5.9) vs. 9.8 (3.0), p = 0.50).
Conclusion: DAA-treatment leads to SVR associated with decreased macrophage activation and reduced liver stiffness indicating reduced inflammation and beneficial effects in the liver right after DAA-treatment. Further, DAA-treatment had no significant effects on metabolic liver function or portal pressure; however, long-term follow up studies may demonstrate further improvements in these parameters.

FRI-400
Involvement of angiotensin II/angiotensin-(1–7) fibrinolytic pathway in improvement of liver fibrosis in chronic hepatitis C patients who had sustained virological response by direct-acting antiviral therapy: a prospective trial
N. Teeratorn[1], K. Thanapirom[1], S. Suksawatamnuay[1], P. Thaimai[1], S. Sittisomwong[1], K. Sonsiri[1], N. Srisoonthorn[2], S. Sriphoosanaphan[1], N. Tanpowpong[3], B. Chaopathomkul[3], S. Komolmit[1,2]. *[1]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]Center of Excellence in Liver Diseases, King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [3]Department of Radiology, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [4]Center of Excellence in Clinical Virology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*
Email: pkomolmit@yahoo.co.uk

Background and Aims: There is growing evidence that angiotensin II (Ang II)/angiotensin-(1–7) [Ang-(1–7)]/Mas receptor axis, a counter regulatory arm of renin angiotensin system (RAS), involves in fibrinolysis in *vitro*/animal models. Eradication of hepatitis C (HCV)



LSM	Median (Q1-Q3) kPa	
Week 0	14.3 (7.3-21.8)	p<0.001
Week 48	8.5 (5.3-11.8)	

Ang II	Median (Q1-Q3) pg/mL	
Week 0	149.0 (94.6-210.0)	p<0.001
Week 24	286.9 (181.3-372.4)	

Ang-(1-7)	Median (Q1-Q3) pg/mL	
Week 0	315.6 (236.1-435.9)	p<0.001
Week 24	414.3 (348.3-502.3)	

Figure: (abstract: FRI-400): Changes of liver stiffness, serum Ang II and Ang-(1–7) levels in CHC patients at baseline and after having SVR (A) Median LSM (kPa) at baseline (0 week) and 48 weeks, (B) and (C) Box plot graphs of serum Ang II and Ang-(1–7) levels (pg/ml) at baseline (0 week) and 24 weeks (SVR 12 weeks), respectively.

results in improvement of liver fibrosis by multi-mechanisms, including viral factors and stellate cells deactivation through the reduction of TGF-beta 1 stimulation and matrix enzymes changes toward the fibrinolytic stage. We hypothesize that this newly established pathway, to some extent, might involve in the improvement of liver fibrosis in chronic hepatitis C (CHC) patients who had sustained virological response (SVR) by direct acting antiviral drugs (DAA).

Methods: After exclusion of factors that might affect RAS, forty CHC patients with compensated liver disease (mean age: 57 ± 1.7 years; 52% male) were enrolled prospectively for 12-week DAA therapy and achieved SVR between July 2016 and September 2017. Baseline characteristics, HCV viral load (mean 6.2 ± 0.1 logIU/mL), HCV genotypes [1 (64.1%), 3 (23.1%) and 6 (12.8%)], liver enzymes and liver stiffness measurement (LSM) using Fibroscan® were assessed before starting the therapy. Blood samples for Ang II/Ang-(1–7) levels were collected at baseline, 12 and 24 weeks (SVR 12 weeks). LSM were repeated at 48 weeks. All patient samples (–70C storage) were evaluated simultaneously. Standard ELISA methods were used for the assays.

Results: The alanine aminotransaminase (ALT) levels were significantly decreased from 83 ± 12.6 IU/ml at baseline to 22 ± 2.2 IU/ml (p < 0.001) at 24 weeks. Mean and median LSM were significantly decreased from 17.4 and 14.3 kPa at baseline to 10.5 and 8.6 kPa at 48 weeks, respectively (Figure 1A). Baseline mean of Ang II level was 162.4 ± 17.4 pg/ml. The level at 24 weeks (SVR 12 weeks) was significantly increased to 309.0 ± 34.9 pg/ml (p < 0.001) (Figure 1B). By the same period, the mean Ang-(1–7) levels were significantly increased from 329.6 ± 22.2 pg/ml to 422.1 ± 21.4 pg/ml (p < 0.001) (Figure 1C).

Conclusion: Supporting the *in vitro and vivo* evidences, increased Ang II and Ang-(1–7) serum levels are demonstrated in CHC patients who achieved SVR from DAA therapy along with the improvement of liver fibrosis. This RAS counter regulatory axis pathway might, in part, involve in the promotion of hepatic fibrosis regression in this scenario.

FRI-401

The lack of improvement in liver stiffness after SVR in HCV compensated advanced chronic liver disease is associated with the risk of presenting liver related events

M.P. Delgado[1], J.I.E. Mur[1,2], Víctor M.V. Blasco[1,2], M.B. Ferret[1,2], R. Esteban[1,2], M.R. Barciela[1,2], B. Minguez[1,2], S. Augustin[1,2], J. Genesca[1,2]. Email: monica_xina@hotmail.com

Background and Aims: Sustained virological response (SVR) after hepatitis C virus (HCV) therapy improves prognosis in cirrhotic patients. However, the risk of decompensation and hepatocellular carcinoma may persist in some patients. The aims of our study were to identify which factors were associated with liver stiffness improvement at 1 year after finishing treatment and which factors were associated to the development of liver related events in HCV compensated advanced chronic liver disease (cACLD) patients cured with oral antivirals.

Method: We included 290 cACLD patients who achieved SVR after oral antiviral therapy. All of them had a baseline liver stiffness measurement (LSM) ≥10 kPa, were Child-Pugh class A and had no prior liver decompensation. We performed LSM, laboratory work-up and an abdominal ultrasound at 1 year after finishing therapy and we registered the occurrence of liver related events during the follow-up. Improvement in LSM at follow-up was defined as a decrease ≥20% in LSM from baseline.

Results: Seven patients were lost during the follow-up and in 2 patients follow-up-LSM was not reliable. Data from 281 patients were collected during a median follow-up of 20.7 months (IQR 17.8–24.4 months). At 1 year of follow-up, mean LSM decreased significantly (baseline-LSM 19.3 kPa (SD 10.5) vs follow-up-LSM 13.7 kPa (SD 9.7); p < 0.001) with a mean decrease of 35.8% from baseline. Forty-seven

percent of patients had LSM < 10 kPa at 1 year after finishing therapy. A total of 202 patients (71.9%) presented a significant improvement in LSM (decrease ≥ 20%). Baseline predictors associated to LSM improvement were body mass index (OR 0.93; 95%CI: 0.87–0.99; p = 0.033), MELD = 6 (OR 2.3, 95%CI: 1.2–4.3, p = 0.010) and albumin (OR 2.3; 95%CI: 1.3–5.3; p = 0.008). During follow-up 6 patients (2.1%) developed de novo hepatocellular carcinoma and 1 patient presented a variceal bleeding. None of these patients had a follow-up-LSM < 10 kPa. In multivariate analysis only the lack of a significant improvement in LSM (decrease ≥20%) during follow-up (HR 12.7; 95%CI: 1.5–111.1; p = 0.020) was related to the risk of presenting liver related events.

Conclusion: In HCV cACLD patients successfully treated with oral antivirals, liver stiffness decreases significantly during the first year of follow-up. Patients without significant improvement in LSM are more likely to develop liver related events during follow-up.

Project code: PI15/00066. ISCIII-FEDER CO-FUNDING.

FRI-402

Health utilities in Spanish chronic hepatitis C patients treated with direct acting antivirals in real life conditions

R. Juanbeltz[1,2], Iván Martínez-Baz[2,3,4], Jesús C. Catalán[2,3,4], S.Goñi Esarte[5], J. Úriz[2,5], José M. Zozaya[2,5], Ramón S. Miguel[1,2].

Email: regina.juanbeltz.zurbano@navarra.es

Background and Aims: Health utilities are global measurements of quality of life, which are typically used to estimate quality-adjusted life years in the cost-utility analyses of therapeutic interventions. The aim of this study was to assess EQ-5D health utilities scores in Spanish patients with chronic hepatitis C treated with direct acting antivirals (DAAs), previous, during and after treatment. Predictors of health utilities after the end of treatment were identified.

Method: Prospective, observational study. Patients treated with all direct acting antiviral regimens, between May 2016 and April 2017, were included. Health utilities were assessed by using the EuroQol survey (EQ-5D-5L) at baseline, week 4 of treatment and 12 weeks after the end of therapy (post12). Analysis was limited to patients with sustained virological response.

Results: 206 patients were enrolled, 32% HIV/HCV co-infected and 28% with cirrhosis. The most prescribed combinations were ombitasvir/paritaprevir/ritonavir+/-dasabuvir (39%), sofosbuvir/ledipasvir (33%) and sofosbuvir + daclatasvir (22%). Ribavirin was used in 52% of regimens. Median baseline utility value was 0.857, with no change after 4 weeks of treatment and 6.2% of relative improvement in post-12 (0.857 baseline vs 0.910 post-12, p < 0.001). This increment in utility scores was observed in F4 patients (0.809 baseline vs 0.857 post-12, p = 0.027) and F2-F3 (0.857 baseline vs 0.910 post-12, p = 0.002), without statistical signification in mild fibrosis (0.893 vs 0.932, p = 0.061). HIV/HCV co-infected patients also had a higher score after treatment (0.871 vs 0.910, p = 0.036). In multivariate analyses, age > 64 years (β = 0.13; CI95% 0.01–0.26), comorbidity by Charlson ≥ 2 (β = –0.14; CI95% –0,22 to –0,05), problems of baseline mobility (β = –0.25; CI95%–0.32––0.17), cirrhosis (β = –0.11; CI95% –0.19 to –0.04), baseline depression (β = –0.11; CI95%, –0.19 to –0.04) and ribavirin use (β = 0.06; CI95% 0.01–0.12) were the most consistent predictors of post-12 utilities. Ribavirin had no impact on week 4 utility score (–0.01; p = 0.276).

Conclusion: The cure of chronic hepatitis C infection with DAAs has a short term positive impact on HRQoL. This study provides utility values derived directly from HCV patients treated with DAAs in real-life setting, which contributes to future cost-utility studies.

FRI-403

Hepatitis C virus infection a new reversible cardiovascular risk factor in cirrhotic patients after viral eradication?

T. Cuciureanu[1], A.-M. Singeap[1], S. Chiriac[1], C.-M. Muzîcă[1], L. Huiban[1], I. Girleanu[1], C. Stanciu[2], A. Trifan[1]. *[1]University of Medicine and Pharmacy Gr.T.Popa, Gastroenterology, and, Hepatology, Iasi, Romania; [2]Institute of Gastroenterology and Hepatology, Iasi, Romania*
Email: drcuciureanutudor@gmail.com

Background and Aims: The increase of the cardiovascular risk was recently recognized among a large spectrum of extrahepatic manifestations of chronic hepatitis C virus (HCV) infection. Recent studies evaluate its involvement in cardiovascular pathology due to its proatherogenic effects on the vascular endothelium and metabolic alterations. The aim of this study was to evaluate the role of HCV as a proatherogenic cardiovascular risk factor, and to verify if the alterations induced by the virus are reversible after therapy with interferon free direct acting antivirals.

Methods: 130 patients (female 59%, median age 56 years) with genotype 1b and chronic HCV infection, with 4 cardiovascular risk factors (dyslipidemia, hypertension, sedentariness, obesity), treated with paritaprevir/ritonavir, ombitasvir and dasabuvir (PrOD) ± ribavirin were prospectively included in the study group, from January 1st 2016 to October 31 2017. The control group included 50 patients with the same 4 cardiovascular risk factors and no history of liver or cardiovascular disease. The patients were completed evaluated according to the national protocol, the degree of fibrosis was determined by transient elastography, concomitant we assessed the intima media thickness (IMT) and the ankle arm index (AAI) as markers of subclinical atheromatosis.

Results: At the baseline the study group registered higher values of IMT compared with the control group (0.98 ± 0.4 vs 0.92 ± 0.28, p = 0.001). After the sustained viral response (SVR) the IMT decreased in 56 patients (43%). The AAI registered lower values in the study group compared with controls (0.93 ± 0.2 vs 1.0 ± 0.2, p = 0.034). After SVR the AAI was improved in only 20 patients (15.3%). The lipid profile improved in only 41 subjects (31.5%), triglycerides decreased in 48 patients (33%). An abnormal increase after SVR in LDL cholesterol was assessed in almost 30 patients (23%). The degree of fibrosis had a major role in the prediction of subclinical atherosclerosis. Thirty patients (23%) with liver stiffness greater than 30 kPa registered higher values of IMT.

Conclusion: An increase of incipient carotid atherosclerosis and peripheral arterial disease was observed in case of patients with HCV cirrhosis compared to subjects without hepatic disorders and improvement of the IMT, AAI and lipid profile confirmed the possible reversibility of the atherosclerotic lesions after antiviral treatment.

FRI-404

Controlled attenuation parameter values of Fibroscan® compatible with steatosis in patients with chronic hepatitis C and changes after sustained virological response

T. Broquetas, L. Canillas, M. Puigvehí, R. Fernández, G. Díaz, S. Coll, M.G. Retortillo, N. Cañete, X. Bessa, R.S. Lamoglia, J.A. Carrión. *Hospital del Mar, IMIM (Hospital del Mar Medical Research Institute), UAB, (Universitat Autònoma de Barcelona), Liver Section, Gastroenterology Department, Barcelona, Spain*
Email: 95565@parcdesalutmar.cat

Background and Aims: Steatosis worsen the prognosis of chronic hepatitis C (CHC) *(Everhart et al; Gastroenterology 2009).* Controlled attenuation parameter (CAP) of FibroScan® evaluates and quantifies steatosis non-invasively. In patients with CHC a CAP (db/m) value >250, correlates with significant steatosis (over 33% of hepatocytes). Aim of the study was to identify significant steatosis by CAP before and after achieving sustained viral response (SVR12) in patients with CHC and to recognize independent variables related to steatosis increase.

Method: Patients with CHC, treated with direct acting antivirals (DAA) between April 2015 and December 2016, were retrospectively included. Steatosis was defined as a CAP >250 at baseline (CAPb) or after SVR12 (CAPf).
Results: 350 patients with SVR were evaluated. 60 (17%) patients were excluded due to the lack of CAPb and/or CAPf. The median (range) age was 55 (24–86). The median (range) body mass index (BMI), waist circumference (WC) and skin-capsule distance (SCD) at baseline were 26.5 (16–41) kg/m², 98 (70–128)cm and 16 (8–30)mm, respectively. At baseline, transient elastography (TE) was 9.8 (2.8–72) kPa and CAPb was 229 (129–374) db/m. Patients with a CAPb >250 (n = 94, 32%) showed independently (OR, 95% CI, p) higher values of WC (1.5, 1.01–1.09, p = 0.011), SCD (1.3, 1.2–1.5, p < 0.001) and GGT (1.01, 1.01–1.01, p < 0.001). After SVR12, values of TE decreased to 7.1 kPa (2.8–57) (p < 0.001). However, median (range) CAPf did not change after SVR12 being 234 (100–394) (p = ns). Among patients with a CAPb <250 the CAPf increased in 21.4%. Patients with increasing CAPf showed higher values of WC (1.11, 1.06–1.16, p < 0.001) at baseline and weight increasement during antiviral treatment (1.12, 1.054–1.195, p < 0.001).
Conclusion: A third of patients with chronic hepatitis C have significant steatosis according to the Controlled Attenuation Parameter (CAP) values with FibroScan®. Moreover, around 21% of patients with low values of CAP before antiviral treatment showed steatosis after SVR12, especially in those with a high waist circumference or weight gain during treatment. Long-term follow-up of these patients would be recommended to know the clinical implication of these findings.

FRI-405
Recurrent viremia after successful hepatitis C virus therapy with direct-acting antivirals in a cohort of people who use drugs
A. Alimohammadi, J. Holeksa, A. Bassi, Y. Bhutani, A. Thiam, B. Conway. *Vancouver Infectious Disases Centre*
Email: arshia.alimohammadi@vidc.ca

Background and Aims: People who use drugs (PWUD) are disproportionately represented within the hepatitis C virus (HCV)-infected population of Canada. Ongoing risky injection practices and sharing of equipment increase the risk of recurrent viremia (RV) after successful HCV therapy. Long-term engagement of this vulnerable population within a multidisciplinary care program with enhanced long-term follow-up post-SVR may be critical to reducing the rate of HCV re-infection in a population of "core transmitters".
Methods: An observational, retrospective analysis was conducted among HCV-infected patients who achieved cure of HCV infection with all-oral regimens initiated between 06/15–05/17. The cohort of interest has continued to use recreational drugs on an ongoing basis (documented by urine drug screen) and has also continued to receive multidisciplinary care at our centre to address medical, psychiatric, addiction-related, and social needs prior to, during and after HCV therapy. The endpoint of this analysis was the occurrence of RV by serial measurement of HCV RNA every 6 months after the achievement of SVR.
Results: A total of 134 active or recent PWUD (66/40% heroin/cocaine use in the past 6 months) achieved SVR and are included in this analysis. Key demographic characteristics include: median age 69 years, 79% male, 63% GT1a, 23% cirrhotic, 10% HIV co-infected, 33% treatment-naive. Treatment regimens included SOF/LDV (n = 46), PrOD (n = 46), EBV/GZV (n = 13), SOF/VPV (n = 6), others (n = 23). Follow-up period ranges from 24–105 weeks (mean 66 weeks). To date, there were no documented cases of recurrent viremia.
Conclusion: We have previously documented high SVR rates among PWUD receiving HCV treatment at our centre. We hypothesized that maintenance in long-term multidisciplinary follow-up post-SVR may serve to consolidate SVR and reduce the RV rate despite ongoing risk behaviors. No cases of RV were documented in our most recent cohort, treated with all oral agents. This supports the hypothesis that maintenance of more intensive follow-up post-SVR may reduce the likelihood of RV in the weeks/months that follow successful HCV therapy. The long-term benefits and feasibility of this intervention requires further ongoing study.

FRI-406
Changes in liver steatosis and lipid metabolism accompanied by successful interferon-free DAAs therapy in HCV infected patients; a comprehensive analysis
N. Kawagishi, G. Suda, K. Morikawa, K. Ogawa, N. Sakamoto. *Hokkaido University, Gastroenterology and Hepatology, Sapporo, Japan*
Email: gsudgast@pop.med.hokudai.ac.jp

Background and Aims: HCV hijack hepatocyte lipid metabolism, resulting in liver steatosis and decrease in serum LDL level. After successful HCV eradication, existence of liver steatosis is associated with hepatocarcinogenesis, and elevated LDL might cause vascular event. Thus, to clarify the factors associated with those disorders after successful HCV eradication is required. We conducted comprehensive analysis to clarify the factors associated with those disorders after HCV eradication in patients treated with IFN-free DAAs.
Method: Patients who were treated with IFN-free DAAs therapy between 2014 and 2016 in Hokkaido University Hospital, and were conducted transient elastography including Controlled Attenuation Parameter (CAP) at pre- and post-treatment, and achieved SVR were enrolled. Liver steatosis was evaluated by CAP value. Changes in liver steatosis, lipid metabolism, blood test, and genetic factor, including PNPLA3:rs738409, MTP493:rs1800591, TMS6FS2:rs58542926, ALDH2:rs671 were analyzed.
Results: A total of 117 patients were included. 79 and 38 patients were infected with genotype 1 and 2 respectively and treated with DCV/ASV, SOF/RBV, SOF/LDV or OBT/PTV/r. Overall, mean CAP value and serum LDL levels were significantly elevated at post treatment point. However, in patients with baseline CAP value ≥220 dB/m, mean CAP value were significantly decreased. In patients with baseline LDL value ≥108 mg/dl, mean LDL values were significantly decreased. At baseline, LDL value and CAP value didn't have significant association, however, after HCV eradication both values were significantly associated (r = 0.317 p = 0.01). Univariate analysis revealed that patients with liver steatosis (CAP > 248 dB/m, n = 21 (18%)) after HCV eradication had significantly higher baseline BMI and lower HDL level. Patients with LDL more than 140 mg/dl at post-treatment had significantly higher baseline T-chol, LDL level, and non-LC. Patients with ALDH2 GG allele had significantly higher CAP value at baseline and post-treatment (p = 0.03, GG vs AG/AA) and MTP493 T allele was significantly associated with baseline lower LDL and higher ratio of HDL elevation at post-treatment.
Conclusion: Successful HCV eradication by IFN-free DAAs restored liver steatosis in patients with baseline higher CAP value, except for patients with baseline high BMI and/or low HDL level. Patients with non-LC and/or higher baseline T-chol level should be paid attention for hyperlipidemia after HCV eradication.

FRI-407
Impact of direct acting antiviral drugs on HCV- related decompensated liver cirrhosis
M. Essa, A. Sabry, E. Abdelsameea, E.-S. Tharwa, M. Salama. *National Liver Institute, Hepatology and gastroenterology, Shebin El Kom, Egypt*
Email: salamamohsen@yahoo.com

Background and Aims: HCV was considered as a major health problem in Egypt before evolution of direct acting antiviral drugs (DAAs). The benefit of treatment of HCV with DAAs in patients with decompensated liver cirrhosis (DLC) is still unclear. We aimed to evaluate the degree of improvement in hepatic decompensation events and quality of life in treated and untreated patients with DLC.
Methods: One hundred and fifty patients with HCV related DLC were included, 75 of them received treatment (group I) in form of sofosbuvir with either daclatasvir or ledipasvir for 24 weeks

without ribavirin or for 12 weeks with ribavirin while the other 75 patients didn't receive treatment as a comparable group (group II). Patients achieved SVR at 12 weeks were assessed regarding to decompensation events, MELD score, Child Turcotte Pugh (CTP) score, biochemical changes and quality of life (applied on Mcguill quality of life questionnaire) before starting treatment and 6 months after treatment and compared them with untreated patients.

Results: Forty two patients (56%) received sofosbuvir with daclatasvir for 24 weeks without ribavirin and 19 (25.3%) patients received sofosbuvir with ledipasvir for 24 weeks without ribavirin. MELD score improved in treated patients (mean change was −1.73) but worsened in untreated patients (mean change was + 11.8) before and after 6 months. Also, CTP score improved significantly ($p < 0.001$) [table 1]. Serum albumin, prothrombin time, bilirubin, alpha fetoprotein and ALT improved in treated patients ($p < 0.001$). Health related quality of life improved in treated patients (mean change was + 17.65) and worsened in untreated ones (mean change was −18.68) [$p < 0.001$].

Table: Comparison between the two studied groups according to Child Turcotte Pugh (CTP) score before and after 6 months

	Group I				Group II			
	Before		After		Before		After	
	No.	%	No.	%	No.	%	No.	%
CTP class	(n = 75)		(n = 75)		(n = 75)		(n = 75)	
A	0	0.0	30	40	0	0.0	0	0.0
B	58	77.3	34	45.3	57	76	42	56
C	17	22.7	11	14.6	18	24	33	44
Significance	$p_1 < 0.00^*$, $p_2 < 0.001^*$, $p_3 < 0.001^*$							
CTP score	(n = 75)		(n = 75)		(n = 75)		(n = 75)	
Min.–Max.	7.0–11.0		5.0–11.0		7.0–11.0		7.0–15.0	
Mean ± SD.	8.37 ± 1.19		7.14 ± 1.58		8.41 ± 1.22		10.16 ± 2.64	
Median	8.0		7.0		8.0		9.0	
Significance	$p_1 < 0.001^*$, $p_2 < 0.001^*$, $p_3 < 0.001^*$							

p_1: p value for Mann Whitney test for comparing between before and after 6 months in cases group.
p_2: p value for Mann Whitney test for comparing between before and after 6 months in control group.
p_3: p value for Mann Whitney test for comparing between cases and control after treatment.
*: Statistically significant at $p < 0.05$.

Conclusion: Treated patients with DLC showed improvement in their liver functions and health related quality of life. Those patients need longer durations of follow up for decompensation events.

FRI-408

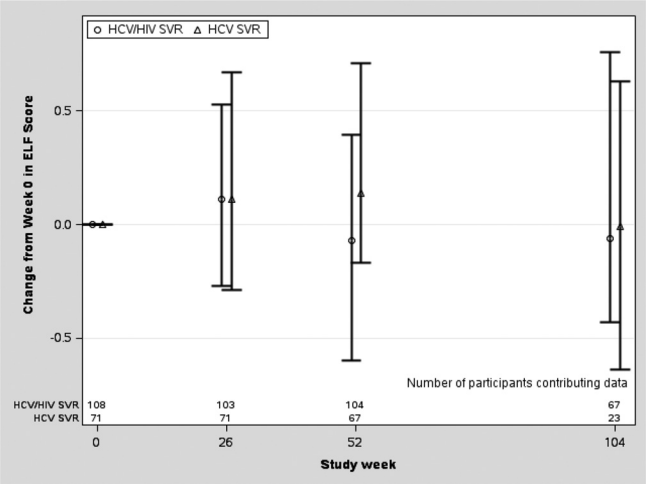
No evidence of fibrosis regression in HCV/HIV co-infected and HCV monoinfected participants up to 3 years after achieving SVR with DAA treatment: Interim results for the ACTG A5320 Viral Hepatitis C Infection Long-term Cohort Study (V-HICS)

M. Peters[1], M. Kang[2], R. Murphy[3], R. Matining[2], W. Rosenberg[4], D. Wyles[5]. [1]*University of California San Francisco, Gatroenterology, San Francisco, United States;* [2]*Harvard School of Public Health;* [3]*Northwestern University;* [4]*University College London, Medicine;* [5]*Denver Health, Infectious Diseases*
Email: Marion.peters@ucsf.edu

Background and Aims: A5320/V-HICS is an observational, prospective, long-term follow-up study in HCV/HIV and HCV participants enrolled within 1 year of completion of DAA-based HCV treatment. Enhanced Liver Fibrosis (ELF) test, validated in HCV mono-infection, utilizes direct measures of extra-cellular matrix components. ELF was shown to be superior to APRI and FIB-4 in predicting all-cause mortality in HIV/HCV co-infected women. We sought to study long-term fibrosis outcomes following sustained virologic response (SVR) in V-HICS. Changes from baseline in APRI of 0.25, FIB-4 0.5, and ELF 0.5 are considered clinically significant.

Method: Participants who achieved SVR, enrolled in V-HICS within a year of treatment completion and had at least 1 year of follow-up in V-HICS were included. ELF test used stored serum specimens at weeks 0 (entry), 26, 52 and 104 in V-HICS. APRI and FIB-4 were calculated at weeks 0, 52 and 104. Absolute score changes from week 0 were calculated and summarized by infection group.

Results: Of the 111 HCV/HIV and 71 HCV participants: 44% Black non-Hispanic, 22% female, 46% prior IV drug users, 62% genotype 1a; with a median of 30 weeks between DAA treatment completion and V-HICS entry. HCV/HIV participants had median CD4+ T-cell count 703 cells/mm^3, and 95% had undetectable HIV-1 RNA. APRI, FIB-4 and ELF scores were low and similar between the two groups at V-HICS entry: median ELF score was 8.93 and 9.01 in HCV/HIV and HCV groups. Overall, 1% had APRI > 1.5, 7% FIB-4 > 3.25 and 4% ELF ≥ 11.3 (cirrhosis cutoffs). At week 104, 1% by APRI, 6% by FIB-4 and 2% by ELF showed cirrhosis: median changes from baseline in APRI were −0.04 and −0.06 in HCV/HIV and HCV groups, respectively; similarly, −0.14 and −0.2 for FIB-4, −0.06 and −0.01 for ELF. There were no clinically significant changes from baseline in fibrosis scores. The figure shows the median (Q1, Q3) change from week 0 in ELF Score by group at study weeks



Conclusion: While "indirect" fibrosis tests have been reported to decrease during the 1st year post SVR, this may be mainly due to loss of inflammation. Fibrosis decreased over time but changes out to week 104 were small and likely not clinically important. The low number of participants with advanced fibrosis may have limited our ability to detect clinically important decreases in fibrosis. Whether fibrosis continues to decrease 3–5y after SVR is not clear and patients should be followed to determine long-term outcomes.

FRI-409

Direct acting anti-viral treatment for hepatitis C results in a rapid reduction in MRI measures of hepatic microstructure

R. Scott[1], C. Bradley[2], N. Palaniyappan[1], S. Ryder[1], G. Aithal[1], W. Irving[1], S. Francis[2], N. Guha[1]. [1]*National Institute for Health Research (NIHR) Nottingham Biomedical Research Centre at the Nottingham University Hospitals NHS Trust and University of Nottingham, Nottingham Digestive Diseases Centre, University of Nottingham, Nottingham, United Kingdom;* [2]*Sir Peter Mansfield Imaging Centre, School of Physics and Astronomy, University of Nottingham, Nottingham, U. Kingdom*
Email: robertscott@doctors.org.uk

Background and Aims: Direct acting antivirals (DAAs) for the treatment of hepatitis C virus (HCV) infection achieve high sustained virological response (SVR) rates, even in patients with cirrhosis. However, the effect of viral clearance on the liver and clinical outcomes are inadequately described. We aimed to prospectively characterise changes in serial quantitative MRI measures of

microstructure and haemodynamics within the liver and splanchnic system in patients accessing DAA therapy.

Method: Patients eligible for DAA therapy were invited to attend research MRI scans pre- and post- DAA treatment in a single UK research centre. Multiparametric MRI scans were performed on a Philips 1.5T Achieva (16-channel SENSEXL Torso receive coil) using a previously published protocol. DAA therapy consisted of treatment with sofosbuvir, plus either ledipasvir or daclatasvir, with or without ribavirin. Data was tested for normality (Shapiro-Wilk test). Paired t-test and Wilcoxon signed rank tests were used to compare pre- and post-treatment measures.

Results: 17 HCV patients with cirrhosis (10 HCV genotype 1, 6 genotype 3 and 1 genotype 2) had a MRI scans pre- and post- DAA treatment. 8/17 had decompensated cirrhosis (4 previous variceal haemorrhage, 2 ascites, 2 jaundiced). All patients underwent DAA therapy within 1 week of their pre-treatment MRI scan. Post-treatment MRI scans were performed at a median of 22 days (3–79 days) after the last dose of DAA. 16/17 (94.1%) achieved SVR. Changes in paired study data are summarised in Table 1. No significant changes were observed in any haemodynamic MRI measure (hepatic, splenic, superior mesenteric artery or portal vein flow, or liver perfusion) following DAA therapy.

Table 1: Comparison of paired serum markers and quantitative MRI measures of 17 patients pre- and post- HCV treatment with DAAs.

Variable	Pre-treatment	Post-treatment	Significance
Serum markers			
ALT	86.3 ± 104.3	32.5 ± 25.3	p = 0.038
Fib4	4.7 ± 3.0	2.9 ± 1.5	p = 0.006
APRI – median (inter-quartile range)	2.2 (1.0–3.9)	0.8 (0.6–1.2)	p = 0.006
MELD	7.8 ± 2.2	9.3 ± 2.9	p = 0.032
Structural MRI measures:			
Liver T_1 (ms)	762 ± 22.6	728.8 ± 23.6	p < 0.0001
Liver T_2 (ms)	44.3 ± 7.6	41.9 ± 7.7	p = 0.01
Liver T_2^* (ms)	29.1 ± 8.4	26.0 ± 8.9	p < 0.001
Splenic T_1 (ms)	1251.8 ± 21.7	1254.7 ± 22.9	p = 0.75

Conclusion: We observed changes in liver relaxation times (T_1, T_2, T_2^*) reflecting hepatic microstructure in a short time window following DAA therapy. These MRI changes are a likely a result of reduced pro-inflammatory milieu, including interstitial oedema, within the liver after viral clearance. The ability of MRI to characterise changes in the angio-architecture of patients with cirrhosis after intervention in the short term will enhance our understanding of the natural history of regression of liver disease and potentially influence clinical decision algorithms.

FRI-410

Clinical consequences of occult HCV infection in a post-liver transplant population

B.R. Bang[1], B. Kim[1], T. Harper[1], S. Chopra[2], G. Kanel[2], K. Jerome[3,4], L. Cook[3,4], T. Saito[1], B. Lee[1], Y. Genyk[5], J. Emamaulee[5], J. Kahn[1]. *[1]Keck School of Medicine of USC, Medicine, Division of Gastrointestinal and Liver Diseases; [2]Keck School of Medicine of USC, Pathology; [3]Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division; [4]University of Washington, Laboratory Medicine, Seattle, United States; [5]Keck School of Medicine of USC, Department of Surgery, Division, Hepatobiliary/Pancreatic Surgery and Abdominal Organ Transplantation, Los Angeles, United States*
Email: jkahn@usc.edu

Background and Aims: Post-transplant recurrent HCV infection develops in most patients with viremia at the time of orthotopic liver transplant (OLT). Antiviral therapy with direct acting agents (DAA) is indicated to preserve graft longevity. We have observed that up to 11% of patients who achieve a sustained virologic response (SVR) with DAA therapy continue to exhibit clinical and histological features of viral hepatitis, while HCV RNA remains undetectable in the serum. HCV is capable of persisting in the liver and peripheral blood mononuclear cells (PBMC) after attaining SVR, defined as occult HCV infection (OCI), however, the prevalence and clinical significance of the phenomenon remain elusive, especially in immunocompromised hosts. To better understand this emerging clinical entity, this pilot study focused on the prevalence and clinical outcomes of OCI.

Methods: Patients who were post-OLT with liver test abnormalities after achieving SVR and were having liver biopsies were enrolled under an approved IRB protocol. A portion of liver biopsy and PBMC were collected, followed by total RNA extraction. The RNA was then applied for one-step RT-qPCR with TaqMan probe for the detection and quantification of HCV-RNA. In addition, DNA was extracted for IL-28B genotyping from liver tissue and PBMC.

Results: 12 patients who underwent OLT and had SVR after DAA treatment participated in the study. Of those, 6 had OCI, 4 with adverse clinical outcomes: 1 with frequently abnormal liver tests requiring intervention, 1 with graft failure requiring re-transplant, 1 with IgA nephropathy likely due to HCV infection and 1 with chronic aminotransferase, alkaline phosphatase and bilirubin elevation. Most of the 6 patients without OCI had no significant clinical event except for 1 patient who had intermittent liver test abnormalities responding to immunosuppression modulation. Of those patients with OCI, 4/6 were IL-28B genotype TT, 1 was TC and 1 unknown. Of the 6 patients without OCI, 3 were TC, 1 was CC and 2 were unknown.

Conclusions: We found an unexpectedly high prevalence of OCI in patients who attained SVR with DAA for recurrent HCV post-OLT. Our preliminary results also suggest that the presence of OCI is correlated with an increased risk of adverse clinical consequences despite attaining serologic SVR, especially in recipients who are IL-28B TT genotype. The prevalence and clinical outcomes of OCI should be investigated in larger clinical cohorts in the post OLT population.

FRI-411

Incidence of de-novo hepatocellular carcinoma after treatment with direct antiviral agents for hepatitis C: A multicenter prospective cohort study from Latin America

Email: fpinerof@cas.austral.edu.ar

Background and Aims: Information about the development of de-novo hepatocellular carcinoma (HCC) after achieving sustained virologic response (SVR) with all-oral direct antiviral agents (DAA) in Latin America is scarce. The aim of this study was to evaluate the incidence of HCC after therapy with DAA in patients with advanced fibrosis.

Methods: A prospective cohort from the Latin-American Liver Research, Educational and Awareness Network (LALREAN) was analyzed. Patients from Argentina, Brazil, Chile, Uruguay and Colombia who received DAAs since their approval in 2015–2016 were included. Advanced fibrosis was defined as liver fibrosis grade 3 or 4 (METAVIR F3-4/LSM > 9.5 kPa). De-novo HCC was defined as the newly development of HCC after DAA regimens. All patients underwent routine ultrasound screening every 6 months before, during and after DAAs therapy.
Results: Of the 378 patients who received DAA therapy, a total of 229 patients with F3 (n = 45) and F4 (n = 184) were included for the analysis. Baseline patient characteristics were: age 55 ± 11, male sex 48.5%, HIV co-infection 3.5%, HBV co-infection 0.4%. Proportion of genotypes was as follows: 1a 19%, 1b 57%, 2 10%, 3 4% and 4 1% (genotype 1 without subgenotype in 8%). Median elastography assessment before treatment was 33 kPa (IQR 15–55 kPa), with a pre-treatment MELD score of 9 ± 3, Child Pugh A 84%, B 15% and C 1% (32 patients were listed for liver transplantation). Overall, 88.3% of the initial cohort completed DAAs treatment, with an SVR12 of 96.9%. During post-SVR12 follow-up 3 patients developed ascites, 2 encephalopathy and 2 variceal hemorrhage. Seven (22%) patients were delisted. Cumulative incidence of HCC in the overall cohort was 3% (n = 7) during a median follow-up since end of treatment of 14.5 weeks (IQR 8.6–31.3 weeks) with an incidence rate of 0.003 per person/weeks (HCC per Child Pugh A 2.7% and Child Pugh B 7.4%; p = NS). All patients who developed de-novo HCC achieved SVR12; only one was F3. At HCC diagnosis, 2 patients presented with extrahepatic HCC with a median major tumor size of 40 mm.
Conclusions: Our study demonstrates that there still exists a high-risk of newly HCC development in patients with advanced fibrosis treated with DAA. Routine screening of HCC in this population should be strict during the first months after treatment with DAAs.

FRI-412
Impact of sustained virological response in the use of concomitant drugs in hepatitis C virus infected patients with comorbidities

E. González-Colominas[1], M. Batlle[2], Inés Monge-Escartín[1], M. Puigvehí[2], T. Broquetas[2], N. Cañete[2], M.G. Retortillo[2], S. Coll[2], R.S. Lamoglia[2], S.G. Cerrato[1], J.A. Carrión[2]. *[1]Hospital del Mar, Pharmacy Department, Barcelona, Spain; [2]Hospital del Mar, IMIM (Hospital del Mar Medical Research Institute), Hepatology Unit, Gastroenterology Department, Barcelona, Spain*
Email: 95565@parcdesalutmar.cat

Background and Aims: More than 70% of patients with chronic hepatitis C virus infection (CHC) whom start direct-acting antivirals (DAAs) take concomitant drugs (*Gonzalez-Colominas E et al; doi:10.1111/jgh.14014).* Sustained virological response (SVR) reduces both hepatic and extrahepatic morbidity and mortality. Our objective was to evaluate the impact of SVR with DDAs (SVR12) in the use of concomitant drugs.
Method: Prospective study (January 2015–September 2016) including patients treated with DAAs. Routine medication (RM) was collected at the beginning of treatment and at least after one year of achieving the SVR12. The RM was defined as those drugs prescribed for a chronic disease (>6 months). Patients were classified according to treatment changes: (A) no change (B) change (B.1: increase; B.2: decrease; B.3: same number of drugs).
Results: 343 patients with median age (range) of 58 (30–87) were included, 39.1% women, 20.1% HIV co-infection and 46.6% with cirrhosis. Out of 336 (98%) patients with SVR, 79.5% (n = 267) were receiving concomitant treatment before starting DDAs with a median of 4 (1–14) drugs per patient. After a follow-up of 98 (56–147) weeks, a change in the usual treatment was seen in 205 (61%) of the patients, with a median of 2 (1–10) changes per patient. Of them, 49.8% (n = 102) increased (B.1), 28.3% (n = 58) decreased (B.2) and 22% (n = 45) maintained the same number of drugs (B.3). Patients increasing the number of drugs presented in a higher proportion: cirrhosis (61.8% vs 39.5%; p < 0.001), advanced age >65 (42.2% vs 29.6%; p = 0.025) and high Charlson Index (4.7 vs 3.6; p < 0.001). Charlson Index (OR = 1.19; 95CI% = 1.04–1.36) and cirrhosis (OR = 1.84; 95%CI = 1.05–3.22) were associated with an increase on the number of drugs after SVR. Decrease (B.2) in the number of drugs was due to diuretics (14%), anxiolytics (12.5%), antiacids (10.7%) and antihypertensives (8.9%).
Conclusion: Half of patients with CHC increased the number of drugs received after achieving SVR, especially in patients with comorbidities. However, a quarter of patients achieving the SVR show a decrease in the number of drugs taken. Further follow-up is needed to know the impact of the SVR in comorbidities of patients with CHC.

FRI-413
Noninvasive diagnosis of fibrosis in the patients with hepatitis C virus infection treated with direct-acting antivirals

H. Numao, K. Shimaya, K. Hasui, K. Igarashi. *Aomori Prefectural Central Hospital, Gastroenterology, Aomori, Japan*
Email: qqqc2c79@celery.ocn.ne.jp

Background and Aims: Noninvasive biomarkers are widely used in assessing liver fibrosis; however, there is lack of knowledge about changes in their values during the course of disease. The aim of this study is to assess the chronological changes of fibrosis using noninvasive biomarkers in patients with HCV treated with direct-acting antivirals (DAA).
Method: One hundred fourteen patients with biopsy-proven HCV infection who attained sustained virological response (SVR) with DAA (57 men; mean age, 66.6 ± 10.5 years; mean body mass index, 23.3 ± 3.56 kg/m^2) were enrolled. The liver biopsy specimen was evaluated according to the METAVIR system. Liver fibrosis was assessed at the baseline (BL), SVR12, SVR24, SVR48, and SVR72 using real-time shear wave elastography (SWE), magnetic resonance elastography (MRE), mac-2 binding protein glycosylation isomer (M2BPGi), fibrosis-4 index (FIB-4), and platelet count (PLT). Albumin (ALB) and alanine transaminase (ALT) were also evaluated at the same time.
Results: Inflammatory activity was A0/A1/A2/A3 in 2/60/47/5 patients respectively, and fibrosis severity was F0/F1/F2/F3/F4 in 5/45/24/22/18 patients respectively. The mean SWE (m/s), MRE (kPa), M2BPGi (COI), FIB-4, PLT (×10^4/μl), ALB (g/dL), and ALT (IU/l) at BL/SVR12/SVR24/SVR48/SVR72 were 1.75/1.66/1.65/1.64/1.65, 4.85/4.44/3.54/3.65/3.71, 3.25/2.08/1.75/1.51/1.28, 4.13/3.28/3.19/2.90/2.73, 14.5/15.2/15.2/15.7/16.1, 4.01/4.26/4.26/4.31/4.24, and 57.4/22.5/21.3/22.8/21.0 respectively. Significant differences were observed between BL/SVR12 in SWE, M2BPGi, and FIB-4 and SVR12/SVR72 in M2BPGi. In a cohort of significant fibrosis (F2-F4), significant differences were observed between BL/SVR12 in M2BPGi and FIB-4, SVR12/SVR72 in M2BPGi, and BL/SVR48 in MRE. ALB and ALT showed significant difference between BL/SVR12 and no significant changes thereafter. The rates of change in SWE and M2GPGi during the period between BL and SVR12 showed no correlation with those in ALB and ALT. Only FIB-4 showed correlation with ALT (r = 0.51).
Conclusion: SWE, M2BPGi, and FIB-4 suggested improvement in fibrosis at SVR12. Although these changes were accompanied with significant changes in ALB and ALT, the rates of change in SWE and M2BPGi did not correlate with those in ALB and ALT. All the fibrosis markers except for M2BPGi showed no significant changes between SVR12 and SVR72.

FRI-414

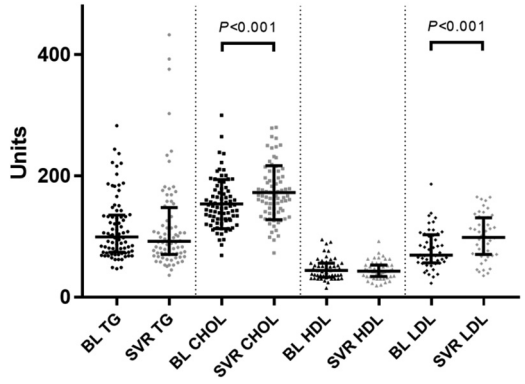
Impact of SVR to IFN-free DAA therapy on steatosis in HIV/HCV coinfected patients

D. Chromy[1], P. Schwabl[1], T. Bucsics[1], B. Scheiner[1], C. Schmidbauer[1], M. Aichelburg[2], P. Ferenci[1], M. Trauner[1], T. Reiberger[1], M. Mandorfer[1].
[1]*Medical University of Vienna, Department of Internal Medicine Iii, Division of Gastroenterology and Hepatology, Vienna, Austria;* [2]*Medical University of Vienna, Dermatology, Immunology, Allergy and Infectious Diseases, Vienna, Austria*
Email: n1142399@students.meduniwien.ac.at

Background and Aims: Hepatic steatosis (HS) and dyslipidemia contribute to the burden of liver disease among HIV/hepatitis C (HCV) coinfected patients (HIVHCV). Previous studies suggested a steatogenic effect of HCV. We evaluated the impact of sustained virologic response (SVR) to IFN-free direct-acting antivirals (DAAs) on HS and dyslipidemia in HIVHCV.

Methods: HIVHCV attending our HIV/Liver outpatient clinic and achieving SVR to IFN-free DAA treatment were assessed. Patients with paired controlled attenuation parameter (CAP®, FibroScan®, Echosense, France) measurements pre and post SVR were included in this retrospective study. CAP® values were adjusted according to Karlas et al (J Hepatol 2017).

Results: The majority of all HIVHCV (73%; 62/85) were male and (52%; 44/85) had intravenous drug abuse as suspected route of transmission. Patient characteristics: Median age at baseline (BL): 50 (15) years; mean BMI: 23.9 kg*m-2 ± 4.52; *PNPLA3* genotype (GT): C/G 41% (34/82) and G/G 4% (3/82); HCV-GT-1a 51% (43/85), HCV-GT-1b 14% (12/85), HCV-GT-3 20% (17/85) and HCV-GT-4 14% (12/85). Liver transaminases and bilirubin levels showed a significant decrease after SVR. Furthermore, total cholesterol (CHOL; 154 ± 40.6 vs. 172 ± 44.6; $p < 0.001$) and low density lipoprotein (LDL; 69.4 (46.3) vs. 98.6 (60.4); $p < 0.001$) levels significantly increased after SVR (Figure), while no changes in triglycerides (TG), high density lipoprotein (HDL) levels, or CAP® were observed. The prevalence of HS (defined by CAP® ≥ 248 dB/m) at BL and SVR was 35% (30/85) and 41% (35/85), respectively. Predictive factors for a decrease in HS after SVR were high BL CAP® values (253 dB/m ± 55.7 vs. 210 dB/m ± 47.6; $p < 0.001$) as well as protease inhibitor (PI) intake (47% (18/38) vs. 20% (9/46); $p = 0.007$) as part of antiretroviral therapy (ART) at BL. Noticeably, HIV PI were discontinued in 16% (14/85) to avoid drug-drug interactions with DAAs. In these patients, CAP® values decreased from 252 dB/m ± 51.3 at BL to 210 ± 64.3 dB/m ($p = 0.046$) at SVR.



Conclusions: In HIV/HCV, achieving SVR to IFN-free therapies had no impact on CAP® values. Thus, the proportion of HIV/HCV affected by HS remained high after SVR. Moreover, HCV eradication increased CHOL and LDL levels. Hence, further studies investigating metabolic changes in HIVHCV post SVR are warranted. Interestingly, switching from a HIV PI to an integrase inhibitor based regimen was associated with a significant decrease in CAP®, which might indicate a beneficial effect on HS.

FRI-415

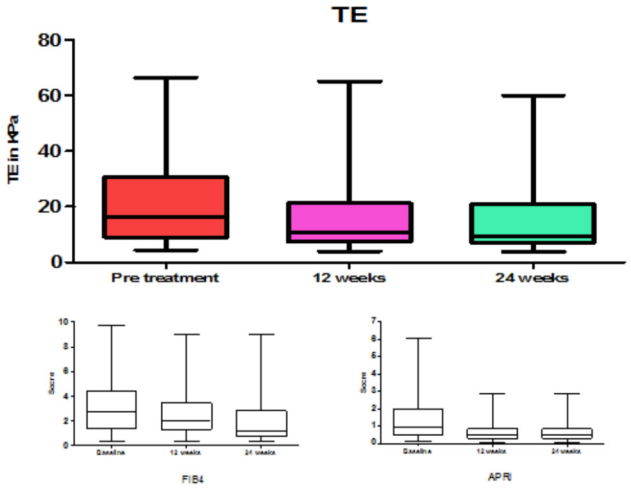
Sustained virological response predicts fibrosis regression in chronic hepatitis C patients treated with direct acting antivirals-a single tertiary care centre experience

R. Gunjal, K. Devadas, V. Tadkalkar. *Government Medical College, Medical Gastroenterology, Trivandrum, India*
Email: dr.rajendragunjal@gmail.com

Background and Aims: Treatment with Direct Acting Antivirals (DAA) results in sustained viral response (SVR) in more than 90% of treated individuals with subsequent improvement in liver function and fibrosis. The aim of our study was to assess changes in liver fibrosis by transient elastography (TE) and fibrosis-4 (FIB-4) score and AST-Platelet ratio (APRI) in patients with chronic hepatitis C (CHC) treated with DAA.

Method: Between April 2015 to April 2017, 110 consecutive CHC patients treated with DAAs at our centre were included. TE, FIB4, APRI score were performed before treatment and after 12 weeks of completion of therapy, the time of assessing sustained virological response (SVR12) and after 24 weeks of completion of therapy. Changes in scores were analysed by paired t test.

Results: The median age of the patients was 51 years, 57% had compensated cirrhosis, 79% were treatment naïve, 92.7% achieved SVR12. Most common genotype was type 3 (62%). There was significant improvement in fibrosis scores among all patients. Median TE improved from 18 KPa to 13.4 KPa ($p < 0.01$), median FIB4 score from 2.85 to 1.90 ($p < 0.01$), median APRI score from 0.95 to 0.54 ($p < 0.01$) before treatment to 12 weeks post treatment. Patients with advanced fibrosis (F3-F4, TE > 9.5 KPa) had significant improvement in fibrosis scores compared to those without advanced fibrosis (F0-F2, TE < 9.5). For F3-F4 patients median TE, FIB4, APRI scores improved from 23.8 KPa, 3.97, 1.73 before treatment to 17.8 KPa, 2.44, 0.63 at 12 weeks post treatment respectively. For F0-F2 patients median TE, FIB4, APRI scores improved from 6.7 KPa, 1.17, 0.34 before treatment to 6.5 KPa, 0.97, 0.28 at 12 weeks post treatment respectively. Patients who have not achieved SVR12 had increment in fibrosis scores. Median TE increased from 19.7 KPa to 28.8 KPa, median FIB4 from 3.6 to 4.3, median APRI from 1.35 to 2.07 before treatment to 12 weeks post treatment respectively. In the patients who had completed 24 weeks post treatment (78.4%), median TE, FIB4, APRI scores improved from 10.6 KPa, 1.95, 0.52 at 12 weeks post treatment to 9 KPa, 0.85, 0.32 at 24 weeks post treatment respectively. Trend for these patients has been shown in figure below.



Conclusion: SVR12 using DAA therapy predicts a significant regression in liver fibrosis, particularly in those with advanced fibrosis. A nonsignificant trend towards continued regression of fibrosis was maintained at 24 weeks post treatment.

FRI-416

Long-term evolution of thrombocytopenia in patients with chronic hepatitis C and advanced fibrosis after sustained virological response with direct antiviral agents

J. Gómez- Camarero[1], P. Linares[2], S. Calvo[1,3], M.I. Martín Arribas[4], C. Almohalla[5], F. Jorquera[2,6,7], H.A.R. Rosario[1], F. Jiménez Vicente[8], M. de Benito[5], Belén B. Cabredo[1], Begoña A. Cuenllas[2], E. Badia-Aranda[1], F. Sáez-Royuela[1]. *[1]Hospital Universitario de Burgos; [2]Complejo Asistencial Universitario de Leon; [3]Fundacion Burgos Investigacion por la Salud; [4]Complejo Asistencial Universitario de Salamanca; [5]Hospital Universitario Rio Hortega, Valladolid; [6]CIBERehd, Madrid; [7]IBIOMEDLeon; [8]Hospital Universitario de Salamanca*
Email: jgomcam@hotmail.com

Background and Aims: Thrombocytopenia (TP) is frequent in patients with hepatitis C virus infection (HCV) and advanced fibrosis. The platelet count (PC) evolution after the elimination of HCV infection with direct antiviral agents (DAA) is fairly unknown. The aims of the present study were to analyse the changes of PC and TP in patients with sustained virological response (SVR) after treatment of HCV infection with DAA and their relationship with fibrosis evolution.

Methods: Multicentric, prospective, observational study performed in patients with HCV infection and advanced fibrosis (F3/F4 measured by transient elastography, TE, Fibroscan, EchoSens, Paris) who were treated with DAA in a real-world setting. The study was carried out in 4 hospitals from Castilla y León, Spain. PC and TE value at baseline, 24 (W24), 48 (W48) and 72 (W72) weeks after the end of treatment were collected. As patients without SVR were retreated during the follow-up period, we considered for the analysis only patients with SVR after the first DDA treatment. We studied the evolution of PC and TP (PC < 150 x109/l) along the time and the relationship between these variables and the changes in fibrosis (cut-off values: F3 ≥ 9. kPa, F4 > 12.5 kPa).

Results: From April 2015 to November 2016, 386 consecutive patients were included; 366 (95%) achieved SVR. A) Baseline characteristics: 67% men, mean (SD) age 57 (11.7) years, BMI 26 (4.4) kg/m2, ALT 81 (60)UI/ml and HCV RNA 2725329 (3879053)IU/ml; 74% of patients had genotype 1 HCV and 65% had received a previous treatment. Median (IQR) fibrosis was 16 (9.5–75) kPa; 71% of patients had cirrhosis (91% Child-Pugh A). The most frequently used AAD combinations were: SOF+SMV (32%), 3D/2D (26%) and SOF+LDV (19%). B) PC: At baseline, W24, W48 and W72 median (IQR) PC was 147.5 (100–189)x109/l, 151 (106–199)x109/l, 158 (108–197)x109/l and 159 (117–198)x109/l, (p = 0.000); median (IQR) fibrosis was 16 (12–23) kPa, 10.8 (11–18) kPa, 12 (8–20) kPa and 10.5 (7.5–15) kPa, respectively (p = 0.007). PC at W72 was directly correlated with baseline albumin (rho = 0.29; p = 0.001) and inversely correlated with baseline INR (rho = –0.20; p = 0.021), bilirubin (rho = –0.18; p = 0.036) and with W72 fibrosis (rho = –0.37; p = 0.002). At this time of the study, in W72 64 patients have TE measurement. Median (IQR) PC at W72 was 126 (84.5–167.5)x109/l in patients who remained at F3-F4 stage vs 176 (151–213) x109/l in those who moved to F0-F2 (p = 0.000). C) TP: TP was present in 191(52%) patients at baseline; at W72 only 26.5% had TP. The proportion of patients with TP decreased from 73% in those who stayed at F3-F4–19% in those who improved to F0-F2 stage (p = 0.000).

Conclusion: In clinical practice, PC increases progressively until W72 after the end of treatment in patients with chronic hepatitis C and advanced fibrosis who achieve SVR. Both PC and TP improve significantly in patients who obtain fibrosis decrease after DDA treatment.

FRI-417

Treatment of patients with decompensated cirrhosis with DAAs improves clinical symptoms without affecting their MELD score

J. Romano[1], O. Sims[2], J. Richman[3], M. Tansia[4], M. Shoreibah[5], P. Fitzmorris[5], Y. Guo[6], V. Kommineni[1], K. Lakshmi[1], O. Massoud[5]. *[1]University of Alabama at Birmingham, Medicine; [2]University of Alabama at Birmingham, Social Work; [3]University of Alabama at Birmingham, Surgery; [4]Birmingham Va, Medicine; [5]University of Alabama at Birmingahm, Division of Gastroenterology & Hepatology; [6]University of Alabama, School of Social Work*
Email: jaromano@uabmc.edu

Background and Aims: There is currently a paucity of data on the impact of HCV treatment with DAAs on the clinical manifestations of hepatic decompensation. The primary aim of this study was to assess the changes in ascites, hepatic encephalopathy (HE), and variceal bleed (VB) after achieving sustained virologic response (SVR). The secondary aim of this study was to compare pre-treatment and post-SVR MELD and CP scores and alpha-fetoprotein (AFP) levels.

Method: A retrospective analysis was conducted between November 2014 and January 2016 of all decompensated HCV cirrhosis patients who achieved SVR with all-oral DAAs at single tertiary medical center. The McNemar-Bowker test was used to assess changes in ascites, hepatic encephalopathy (HE), and variceal bleeding (VB) by comparing pre-treatment cases to cases 3 month post-SVR. Changes in MELD and CP scores and AFP levels were compared using the Wilcoxon Signed Rank test.

Results: 249 patients were reviewed. A sample of 37 patients met inclusion criteria. 81% of patients were treated with ledipasvir/sofosbuvir. The pre- and post- treatment prevalence of ascites were 65% and 29%, respectively (p < 0.01). The pre- and post- treatment prevalence of HE were 70% and 16%, respectively (p < 0.01). The pre- and post- treatment prevalence of VB were 35% and 3%, respectively (p < 0.01).There were no differences of statistical significance between pre-treatment and post-SVR median (interquartile range [IQR]) MELD scores 15 [8–28] vs. 15 [6–36] (p = 0.20) and median CP scores 7 [5–11] vs. 7 [5–15] (p = 0.60). Post-SVR median AFP levels 4.24, [0.06–15.7] were significantly lower than pre-treatment median AFP levels 6.45, [0.81–39.7] (p < 0.01).

	Pre-Treatment n (%)	3 Months Post-SVR n (%)	% Change
Ascites	24 (65%)	9 (29%)	36%
Hepatic Encephalopathy	26 (70%)	5 (16%)	54%
Variceal Bleeding	13 (35%)	1 (3%)	32%

Conclusion: This study showed achieving SVR was associated with significant improvement of clinical hepatic decompensation without significant change in MELD score. That means improvement of patients' quality of life without affecting their chance of obtaining liver transplantation. Further studies are needed to assess long-term sustainability of these reductions in a larger sample and over a longer study period.

FRI-418

Development of hepatocellular carcinoma following HCV eradication by direct-acting antivirals: Real-life experience from Japanese multicenter cohort

Email: eogawa@gim.med.kyushu-u.ac.jp

Background and Aims: Japanese HCV patients characteristically are older than patients in Europe and the United States. Advanced age has been proven to be an independent risk factor for the development of hepatocellular carcinoma (HCC). The purpose of this study was to evaluate the risk of HCC development among Japanese patients with chronic HCV infection, including compensated cirrhosis and previous HCC, following the achievement sustained viral response (SVR) by sofosbuvir-based regimens for 12 weeks.
Method: This large-scale, multicenter cohort study included 1,675 consecutive patients who achieved SVR by treatment with interferon-free sofosbuvir-based regimens, divided into groups with (n = 152) or without previous HCC (n = 1,523). The Kaplan-Meier method and Cox proportional hazard analysis were used to calculate the cumulative HCC incidence and related factors of HCC.
Results: During the follow-up period (median: 23 months), 76 (4.5%) patients developed HCC. The one-year cumulative rates of de novo HCC were 0.5% and 5.2% for the non-cirrhosis and cirrhosis groups, respectively (log-rank test: $p < 0.001$). Among the 565 patients without severe fibrosis/cirrhosis or metabolic disease including obesity (body mass index >25 kg/m^2) and/or diabetes, none developed de novo HCC. For cirrhotic patients, serum alpha-fetoprotein level at the end of treatment (EOT-AFP) was the strongest predictor of de novo HCC. The one-year cumulative de novo HCC rates were 1.3% and 14.1% in the EOT-AFP < 9.0 ng/ml and ≥9.0 ng/ml groups (cut-off value), respectively (log-rank test: $p < 0.001$). For patients with previous HCC, the one-year cumulative HCC recurrence rates were 9.7% and 21.2% in the non-cirrhosis and cirrhosis groups, respectively (log-rank test: $p < 0.05$). In multivariable Cox analysis, cirrhosis (HR 2.45, $p = 0.007$), time from previous HCC treatment to initiation of DAA of <1 year (HR 3.94, $p < 0.001$), number of HCC nodules ≥2 (HR 1.95, $p = 0.034$), and non-curative procedure with transarterial chemoembolization (HR 1.96, $p = 0.036$) were extracted as independent factors of HCC recurrence. Age, sex, ALT level, diabetes, and prior experience with interferon did not influence de novo HCC or recurrence in the short term.
Conclusion: The serum EOT-AFP level is a useful marker for predicting de novo HCC for cirrhotic patients. Moreover, close HCC surveillance should be required for patients with a past history of HCC, especially for patients treated with non-curative procedures.

NAFLD: Diagnostics and non-invasive assessment

FRI-421
Prevalence and stratification of NAFLD/NASH in a UK and US cohort using non-invasive multiparametric MRI

S. Harrison[1], H. Wilman[2], M. Kelly[2], V. Bachtiar[2], A. Dennis[2], C. Kelly[2], A. Paredes[3], J. Whitehead[3], S. Neubauer[2], R. Banerjee[2]. *[1]University of Oxford, Oxford, United Kingdom; [2]Perspectum Diagnostics Ltd, Oxford, United Kingdom; [3]San Antonio Military Medical Center, San Antonio, United States*
Email: henry.wilman@perspectum-diagnostics.com

Background and Aims: Given the societal impact of NAFLD, there is a clear need to accurately assess population prevalence, and approaches to non-invasively stratify those at risk. The MRI-derived quantitative Liver Inflammation and Fibrosis (LIF) score has been shown to correlate with liver inflammation and fibrosis, and can effectively stratify patients with NASH and cirrhosis [1, 2]. This study investigates the effectiveness of multiparametric MRI for the assessment and stratification of NAFLD/NASH in two large UK and US cohorts.
Method: 2825 individuals in the UK Biobank cohort and 402 individuals from the US San Antonio area received multiparametric MRI (Liver*MultiScan*™ protocol, <5 min) to estimate liver fat fraction (PDFF) and LIF. High risk participants in the US-cohort (PDFF ≥ 5%, LIF ≥ 2, MRE ≥ 3 kPa or FibroScan ≥ 7kPa) were asked for a liver biopsy (n = 140). Liver biopsies were double-blind evaluated with consensus using the NASH CRN scoring system by two expert pathologists. The US-cohort were individuals with no prior history of liver disease or alcohol abuse referred for routine colon cancer screening. Recruitment of UK-cohort were part of an ongoing national study that will collect imaging data from 100,000 individuals.

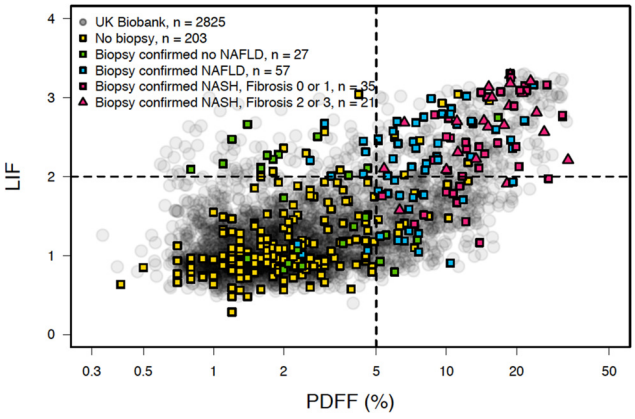

Figure 1: Distribution of cT1 and PDFF for UK-cohort (Grey) and US-cohort (Colour).

Results: Of the biopsied subjects from the US cohort, 99% with PDFF ≥ 5% & LIF ≥ 2 had NAFLD and 56% had NASH. 90% of NASH subjects with Kleiner-Brunt F2-3 had PDFF ≥ 5% & LIF ≥ 2. None of the subjects with PDFF < 5% & LIF < 2 had NASH and only 2% had NAFLD. Projecting onto the UK cohort would give an estimated NASH prevalence of 8.4%.
Conclusion: Multiparametric MRI is an effective non-invasive method to identify and stratify individuals with NAFLD and NASH at a population level. It can be used for high-throughput analysis of a general population and can identify individuals less likely to benefit from a liver biopsy.

FRI-422
Serum bile acids are markedly elevated in patients with compensated cirrhosis due to nonalcoholic steatohepatitis (NASH)

A. Sanyal[1], S. Harrison[2], M. Charlton[3], S. Caldwell[4], J. Chuang[5], L. Wang[5], G. Chen[5], C. Chung[5], S. Djedjos[5], R. Myers[5], N. Afdhal[6], J. Bosch[7,8], V. Ratziu[9], R. Loomba[10]. *[1]Virginia Commonwealth University, Richmond, VA, United States; [2]Pinnacle Clinical Research, San Antonio, TX, United States; [3]University of Chicago, Chicago, IL, United States; [4]University of Virginia, Charlottesville, VA, United States; [5]Gilead Sciences, Inc., Foster City, CA, United States; [6]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States; [7]Inselspital, Bern University, Bern, Switzerland; [8]IDIBAPS, University of Barcelona, Barcelona, Spain; [9]Hôpital Universitaire Pitié-Salpêtrière, Paris, France; [10]University of California, San Diego, United States*
Email: asanyal@mcvh-vcu.edu

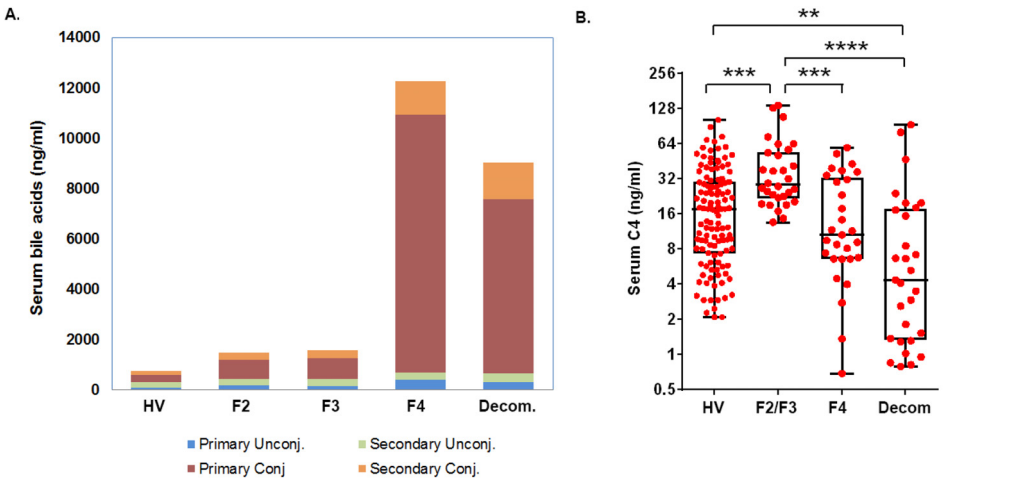

Figure1. Serum bile acid profiles are significantly altered in patients with NASH. (A) Primary conjugated bile acids are the main species that are elevated in cirrhotic subjects that subsequently developed liver decompensation. (B) Serum C4 levels are increased in patients with F2-F3 NASH, but are decreased in compensated cirrhotic subjects and at the time of decompensation.**p<0.01, ***p<0.001, ****p<0.0001. Decom, decompensated F4; HV, healthy volunteer.

Figure 1: (abstract: FRI-422)

Background and Aims: Bile acid (BA) metabolism is altered in NASH. Data describing the association between circulating BAs and NASH-related fibrosis, particularly cirrhosis, are limited. Our aim was to characterize circulating BAs and the intermediate, 7α-hydroxy-4-cholesten-3-one (C4), in patients across the spectrum of NASH severity.
Methods: Levels of 15 BAs were quantified by LC-MS/MS (Agilent 1290/Sciex, Metabolon) in fasting serum samples from healthy controls (n = 118), NASH patients with F2-F3 fibrosis (n = 68), and NASH patients with compensated cirrhosis (n = 29). In cirrhotic patients, analysis of serum BA was performed at BL and following hepatic decompensation (median 14.8 months [IQR 10.0, 22.3] from BL). Serum C4 levels were measured by LC-MS/MS to assess bile acid synthesis. Differences in BA and C4 levels between groups were determined using Kruskal-Wallis tests.
Results: Median total fasting serum BA levels in patients with NASH were greater than in healthy controls (2,533 vs. 878 ng/mL; $p < 0.0001$) and increased with fibrosis stage: F2, 1,619 (IQR 1,078–2,508); F3, 1,825 (1,226–2,848); and F4, 12,160 ng/mL (5,614–22,112) ($p < 0.0001$; Figure A). An increase in BAs in patients with compensated cirrhosis was primarily due to increased conjugated BAs (median: F4, 12,117 vs. F2-F3, 1,277 ng/mL; $p < 0.0001$). Primary conjugated bile acids (glycocholate [GCA], taurocholate [TCA], glycochenodeoxycholate [GCDCA], and taurochenodeoxycholate [TCDCA]) were the major BA species elevated in F4 vs. F2-F3 NASH. GCA and TCA were ~15 and 34-fold higher, respectively, in F4 vs. F2-F3 NASH. The ratio of secondary to primary bile acids in subjects with NASH (F2-F4) was lower than in healthy controls (15% vs. 56%; $p < 0.0001$). In patients with cirrhosis, serum BA levels were numerically lower at the time of hepatic decompensation ($p = 0.48$ vs. BL), but still at levels ~10-fold higher than in controls ($p < 0.0001$; Figure A). In contrast, BA synthesis as reflected by median serum C4 levels was lower in patients with cirrhosis vs. F2-F3 fibrosis (10.5 vs. 28.4 ng/mL; $p < 0.001$) and decreased further upon decompensation (4.3 ng/mL; $p < 0.05$ vs. BL; Figure B). C4 levels were in higher in NASH F2-F3 patients compared with healthy controls (28.4 vs. 17.4 ng/mL; $p < 0.001$).
Conclusions: BA profiles are altered in patients with NASH. In cirrhosis, decreased BA synthesis is accompanied by a relative increase in primary BA and decrease in secondary BA. These changes likely reflect decreased canalicular BA transport and/or impaired dehydroxylation in the intestine.

FRI-423

Non-invasive liver tests in electronic health records of patients with non-alcoholic fatty liver disease: combined analysis from four European countries

N. Dhalwani[1], M. Alexander[2], K. Loomis[3], N. Sattar[4], D. Waterworth[5], M. Mosseveld[6], P. Rijnbeek[6], J. van der Lei[6], T. Duarte-Salles[7], D. Prieto-Alhambra[7], D. Ansell[8], A. Pasqua[9], F. Lapi[9], P. Egger[10], S. Kendrick[2], W. Alazawi[11]. *[1]Diabetes Research Centre, Leicester, United Kingdom; [2]GlaxoSmithKline, Stevenage, United Kingdom; [3]Pfizer, United States; [4]BHF Glasgow, Glasgow, United Kingdom; [5]GlaxoSmithKline, United States; [6]Erasmus Medical Centre, Netherlands; [7]IDIAP Jorgi Gol, Spain; [8]Quintile Ims, United Kingdom; [9]Health Search, Italy; [10]GlaxoSmithKline, Uxbridge, United Kingdom; [11]The Blizard Institute, London, United Kingdom*
Email: myriam.n.alexander@gsk.com

Background and Aims: International guidelines for the management of non-alcoholic fatty liver disease (NAFLD) recommend the use of non-invasive liver tests (NILTs). NILTs utilise routinely collected clinical parameters as a primary screen for fibrosis risk and require very little or no extra investigations. We aimed to assess the proportion of patients in whom each NILT could be calculated, the concordance between the tests in terms of risk categories and the differences between European territories in the risk category of patients with a recorded diagnosis of NAFLD.
Method: We combined data on NAFLD patients from The Health Improvement Network (THIN, UK), the Integrated Primary Care Information (IPCI, The Netherlands), the Health Search Database (HSD, Italy) and the Information System for Research in Primary Care (SIDIAP, Spain). AST/ALT Ratio, FIB-4, NAFLD Fibrosis Score (NFS) and BARD Score were calculated and categorised using the recommended cut-offs. Markers were compared to NFS in patients with complete data on all four markers.
Results: Of the total 143,384 NAFLD patients included, AST/ALT ratio could be calculated for 54.4% patients, followed by FIB-4 (46.8%), BARD (36.3%) and NFS (8.1%). AST/ALT ratio was the most complete in HSD (67%), FIB-4 and BARD score were the most complete in SIDIAP (62.8% and 46.9% respectively), and NFS was the most complete in THIN (11.4%). In the 11,731 (8.1%) patients with complete data, 50.3% and 8.8% were low and high risk respectively using NFS; 59.6% and 7.6% using FIB4; 42.8% and 32.5% using AST/ALT ratio, and 33.3% and 66.7% using BARD score. There was good concordance between NFS and FIB-4 for patients in high or low risk categories (Table 1).

Table 1: Concordance between NILTs

	Low NFS N= 5897		Indeterminate NFSN = 4808		High NFSN = 1026		N = 11731	
	N	%	N	%	N	%	N	%
FIB-4								
Low	5069	86.0	1849	38.5	79	7.7	6997	59.6
Indeterminate	822	13.9	2586	53.8	428	41.7	3836	32.7
High	6	0.1	373	7.8	519	50.6	898	7.7
AST/ALT								
Low	3235	54.9	1591	33.1	189	18.4	5015	42.7
Indeterminate	1392	23.6	1299	27.0	215	21	2906	24.8
High	1270	21.5	1918	39.9	622	60.6	3810	32.5
BARD								
Low	3014	51.1	827	17.2	64	6.2	3905	33.3
High	2883	48.8	3981	82.8	962	93.8	7826	66.7

Conclusion: Less than half of NAFLD patients had sufficient data to calculate most NILTs. Good concordance at extremes of risk suggests that the choice of NILT should be pragmatic and based on availability of data. Lack of concordance in patients with indeterminate risk supports use of a second, alternative modality (e.g. biomarker or transient elastography) in this group.

FRI-424

Algorithm to identify patients with an activity grade > 2 in type 2 diabetic patients with non-alcoholic fatty liver disease (NAFLD)- development in a large prospective multicenter UK study

P. Eddowes[1], M. Allison[2], E. Tsochatzis[3], Q. Anstee[4], D. Sheridan[5], I.N. Guha[6], J. Cobbold[7], Valérie Paradis[8], P. Bedossa[8], P. Newsome[1].

Email: p.n.newsome@bham.ac.uk

Background and Aims: To address the problem of high screen failure rates NAFLD clinical trials, we aimed to develop a simple algorithm to detect the presence of NASH with an activity (A) from SAF score >2 in patients with diabetes.

Method: FibroScan examination was undertaken within 2 weeks of a clinically indicated liver biopsy (LB) for suspected NAFLD. Recruitment took place (Mar 2014-Jan 2017) at seven UK centres. LB were read in a blinded manner with consensus by two expert pathologists using the (steatosis, activity, fibrosis) SAF score. Activity was the sum of ballooning (graded 0-2) and lobular inflammation (graded 0-2) scores. NASH was diagnosed using the FLIP algorithm. Only those patients with T2DM were considered in this analysis.

An algorithm was developed to identify patients with A > 2 with the following objectives:

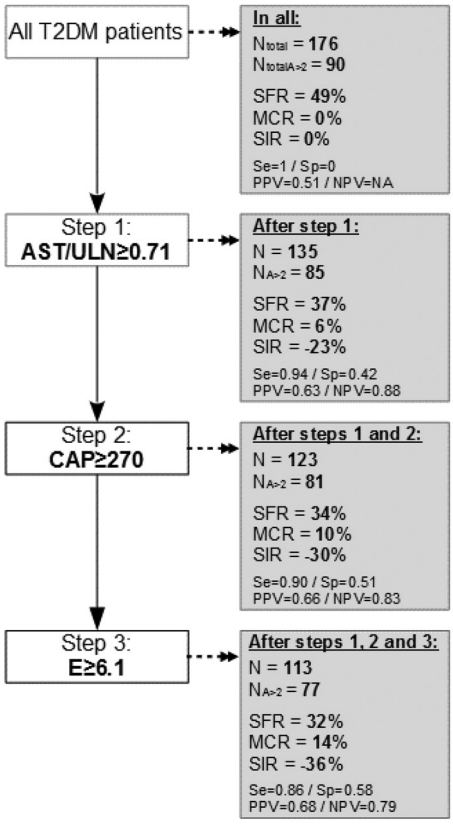
- Improve the screen failure rate (SFR = 1-PPV) of at least 30%,
- Keeping the missed cases rate (MCR = 1-sensitivity (Se)) below 15%.

The following steps were repeated 3 times:

(1) Univariable analysis between the patients with A > 2 and the bio-clinical parameters (E, CAP (controlled attenuation parameter), Fib-4, NAFLD fibrosis score, Forn score, BARD score, AST to Platelet Ratio Index (APRI), body mass index (BMI), age, liver enzymes normalized by the upper limits for normal (ULN), fasting glucose, lipid parameters, platelet, albumin, creatinine, urea, phosphatase alkaline, ferritin, hypertension, hypercholesterolemia and gender),
(2) Keep for comparison parameters significantly different in the target patients (at the given step+those initially significantly associated),
(3) Compute cutoffs based on high Se ≥ 0.95 for all parameters in the comparison list,
(4) Select the parameters that has the highest sum Se+specificity (Sp),
(5) Exclude patients with parameters value < cutoff,
(6) Compute performances: SFR and MCR.

Results: Among the 408 patients who completed the study, 188 were diabetic (46%). 176 were considered in the present analysis due to missing data. 49% were female, with a median age 58 [IQR 14] years and BMI 34.4 [8.7] kg/m². 77% had NASH. 51% had A > 2.

The algorithm was devised with the 3 optimally determined parameters: ALT /ULN ≥ 0.71, CAP ≥ 270 dB/m and E ≥ 6.1 kPa. Performance is presented in the figure below.



Legend:
SFR: screen failure rate (1-PPV)
MCR: missed cases rate (1-Se)
*SIR: screen improvement rate ((N-Ntotal)/Ntotal*100)*
Se: sensitivity / Sp: specificity
PPV-NPV: positive and negative predictive values
ULN: upper limit of normal

Conclusion: A simple algorithm based on FibroScan E, CAP and ALT was developed to improve detection patients with A > 2 in NAFLD diabetic patients. If applied as a pre-screening tool in clinical trials, it

improved the SFR by 35% and reduced the number of patients that would undergo a LB by 35% with missed cases being below 15%.

FRI-425

Noninvasive mapping of fibrosis and inflammation in nonalcoholic fatty liver disease: isolating fibrogenesis in the Space of Disse with MRI R2 multicomponent relaxometry

P. Clark[1], W. Chua-Anusorn[1], C. Oliveira[2], M. Rocha[3], F.J. Carrilho[2], F. Lima[4], V. Alves[4], B. Oliveira[3], H.L. Filho[3]. *[1]MagnePath Pty Ltd, Perth, Australia; [2]Universidade de Sao Paulo, School of Medici, Sao Paulo, Brazil; [3]Universidade de Sao Paulo, Department of Radiology, Sao Paulo, Brazil; [4]Universidade de Sao Paulo, Department of Pathology, Sao Paulo, Brazil*
Email: paul@magnepath.com

Background and Aims: Magnetic resonance relaxometry techniques sensitive to the increase in extracellular water with fibrosis and inflammation offer MRI biomarker maps of these pathologies. However, blood vessels in the maps require thresholding or exclusion by defining vessel-free regions, the placement of which is hampered by the heterogeneity of fibrosis and inflammation in the liver.
Our aim is to isolate the Space of Disse (focal to fibrogenesis) by eliminating contribution of the blood pool in extracellular water fraction maps. Moreover, relaxation parameters for the Space of Disse and blood pool may provide further biomarkers for discriminating fibrosis from inflammation.
Method: 109 NASH patients with liver biopsy were selected within 6 months for MRI exam. A spoiled multi-gradient echo sequence was used to derive fat fraction maps, and a multi-spin echo sequence was used for R2 multicomponent relaxometry (3T Philips Achieva, ~8 minutes). Images were analysed by a radiologist and physicist with ~15 years of experience each in liver imaging. Biopsies were reviewed by a pathologist with 15 years of experience using the NASH-CRN score. In total, 104 paired biopsy and MRI results were obtained. 16 volunteers with no known liver disease were used for control.
Results: MRI fat fraction (ρ_{fat}) was well correlated with biopsy fat grading (Spearman's $r_s = 0.72$), and quantified steatosis ($\rho_{fat} > 5.6\%$) with a specificity (Sp) of 93% and sensitivity (Sn) of 92% (AUROC = 0.98). The proton density of free water associated with blood in the sinusoids and vessels (ρ_{blood}) was ~16% regardless of fibrosis score ($r_s = 0.00$). The proton density of water bound to the extracellular matrix and endothelium in the Space of Disse (ρ_{Disse}) was well correlated with fibrosis, ballooning, and lobular inflammation (r_s = 0.80, 0.66 and 0.52 respectively). ρ_{Disse} was able to distinguish fibrosis from healthy liver with a Sp of 93% and Sn of 87% (AUROC = 0.95). 2-parameter predictive models incorporating ρ_{Disse} and the next most significant MR parameter for a given pathology showed improved discrimination of healthy liver from fibrosis (Sp = 94%, Sn = 87%, AUROC = 0.96), ballooning (Sp = 90%, Sn = 83%, AUROC = 0.94), and lobular inflammation (Sp = 94%, Sn = 94%, AUROC = 0.98).
Conclusion: MRI R2 multicomponent relaxometry isolating the Space of Disse from the liver blood pool provides improvements in quantifying fibrosis and inflammation, and allows entire liver slices to be assessed.

FRI-426

The EPoS staging system is a reproducible 7-tierfibrosis score for NAFLD adapted both to glass slides and digitized images (e-slides)

P. Bedossa[1], J. Arola[2], D. Susan[3], A.S. Gouw[4], G. Maria[5], K. Lackner[6], P. Schirmacher[7], L.M. Terracciano[8], Q. Anstee[9], V. Ratziu[10], T. Dina[11]. *[1]University Paris-Diderot, Pathology, Paris, France; [2]University of Helsinki, Pathology, Helsinki, Finland; [3]Cambridge University Hospitals, Pathology, Cambridge, United Kingdom; [4]University Medical Center Groningen, Dept of Pathology & Medical Biology, Groningen, Netherlands; [5]University of Padova, Dept of Pathology, Padova, Italy; [6]Medical University of Graz, Institute of Pathology, Graz, Austria; [7]Universitätsklinikum Heidelberg, Institute of Pathology, Heidelberg, Germany; [8]Institute of Pathology, Molecular Pathology Division, Basel, Switzerland; [9]Institute of Cellular Medicine, Newcastle-upon-Tyne, United Kingdom; [10]Hôpital Pitié Salpêtrière and Université Pierre et Marie Curie, Hôpital Pitié Salpêtrière and Université Pierre et Marie Curie, Paris, France; [11]Newcastle University, Institute of Cellular Medicine, Newcastle, United Kingdom*
Email: pierre.bedossa@inserm.fr

Background and Aims: Liver fibrosis is a major independent prognostic factor in NAFLD. Despite its wide use, the NASH CRN staging system is insufficiently accurate in advanced fibrosis stages (stages 3 and 4) which are the ones most strongly linked to liver-related outcomes. The aim of the study was to develop and validate a linear and expanded staging system that mirrors more accurately the different stages of liver fibrosis during NAFLD progression
Method: In a first step, 9 European liver pathologists (EPoS Histopathology consortium) and 2 hepatologists jointly reviewed a set of NAFLD liver biopsies to define consensually the various stages of the new EPOS score of fibrosis. Then, each participant reviewed independently the same set of 45 cases (glass slides) with the EPoS staging system to evaluate inter-observer variability. Three months later, the glass slides were digitized (e-slides) and re-evaluated electronically by each pathologist, blinded to their first assessment on glass slides. The inter-observer agreement was evaluated using Kappa score.
Results: The EPoS staging system includes 7 stages (from 0 to 6) that cover the whole spectrum of fibrosis in NAFLD. Compared to NASH CRN, stage 1a, b and c were grouped together while stage 3 and 4 were each expanded into 2 stages. The inter-observer agreement for EPoS staging system using glass slides was almost perfect (Kappa score = 0.84) when only pathologists were considered. It remained substantial when both pathologists and hepathologists were considered together (Kappa score = 0.72). When e-slide reading was considered, inter-observer agreement between pathologists was almost perfect (0.80). When comparing Epos scoring on glass slide and on e-slide, agreement was also almost perfect (mean Kappa coefficient = 0.85, range 0.79–0.89)
Conclusion: The EPoS fibrosis staging system provides a robust and expanded scoring system which might prove useful to assess fibrosis variation in natural history or therapeutic trials. E-slides provide material as suitable as glass slides for staging fibrosis reproducibly. The relevance of the EPoS staging system is currently being evaluated in relation to disease outcome.

FRI-427

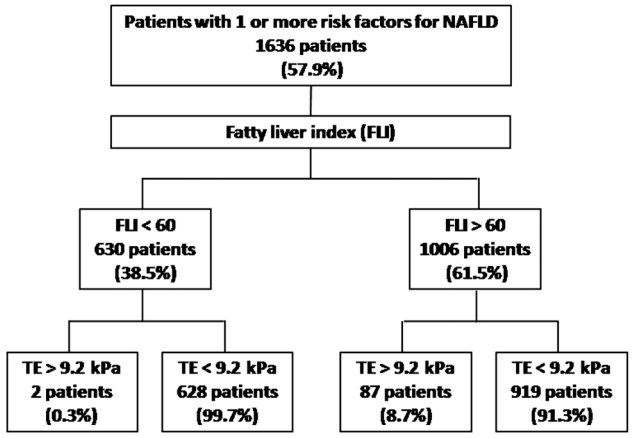
An algorythm for screening for liver fibrosis in primary care using population-based data

Llorenç Caballeria[1], I. Graupera[2], G. Pera[1], I. Arteaga[1], Lluís Rodríguez[1], Núria Fabrellas[3], C. Expósito[1], P. Torán[1], J. Caballería[2], P. Ginès[2]. *[1]Institut Català de la Salut, USR Metropolitana Nord. IDIAP Jordi Gol, Mataró, Spain; [2]Hospital Clínic. Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBPAS). Centro de Investigación en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD). Barcelona, Liver Unit, Barcelona, Spain; [3]Universitat de Barcelona, Escola d'Infermeria, Barcelona, Spain*
Email: lcaballeria.bnm.ics@gencat.cat

Background and Aims: Liver cirrhosis is one of the main causes of death worldwide. Currently, most cases of cirrhosis are diagnosed when patients develop complications. Diagnosis of liver diseases in early stages of fibrosis, may help prevent development of complications and improve survival. In that regard, screening for liver fibrosis in primary care may be a useful approach. Although several algorithms have been proposed, they are not built on data from population-based studies.
Method: We used data from a population-based study including 3014 subjects aged 18–75 years, without known liver disease, identified randomly from the general population through phone calls. The assessment of liver fibrosis was performed by measuring liver stiffness (LS) with transient elastography (TE). The best cut-off of LS

for diagnosis of liver fibrosis (F2 or greater) was 9.2 kPa and was determined by analyzing LS in 92 subjects in whom liver fibrosis was assessed by liver biopsy.

Results: The overall prevalence of liver fibrosis in the whole series was 3.2%, and was due to non-alcoholic fatty liver disease (NAFLD) in most cases. The prevalence of liver fibrosis in patients with at least one risk factor for NAFLD (obesity, type-2 diabetes, hyperlipidemia, arterial hypertension or metabolic syndrome) was 5.0%, compared to only 0.4% in patients with no risk factors (1,269 subjects, 42.1%). We then analyzed the accuracy of the following variables in predicting liver fibrosis in patients with risk factors for NAFLD: AST/ALT, NAFLD fibrosis score, FIB-4, and FLI (fatty liver index, a score that estimates the amount of fat in the liver that includes body mass index, waist circumference, and serum GGT and triglycerides). Among these factors, FLI had the best negative predictive value 99.7%. Patients with a FLI value lower than 60 had very low prevalence of liver fibrosis (2 out of the 628 subjects, 0.3%). By contrast, the prevalence of liver fibrosis among subjects with FLI > 60 was of 8.6% ($p < 0.001$). With this approach, only 35.7% of the population from our series (18–75 years) would have to be screened for presence of liver fibrosis with TE. The algorithm performed equally well if subjects younger than 45yrs were excluded.



NAFLD, nonalcoholic fatty liver disease.
FLI, fatty liver index
TE, transient elastography

Conclusion: An algorithm based on assessment of liver fibrosis using TE in subjects with risk factors of NAFLD and FLI > 60 allows the identification of the majority of subjects with liver fibrosis and reduces markedly the number of subjects to be screened.

FRI-428

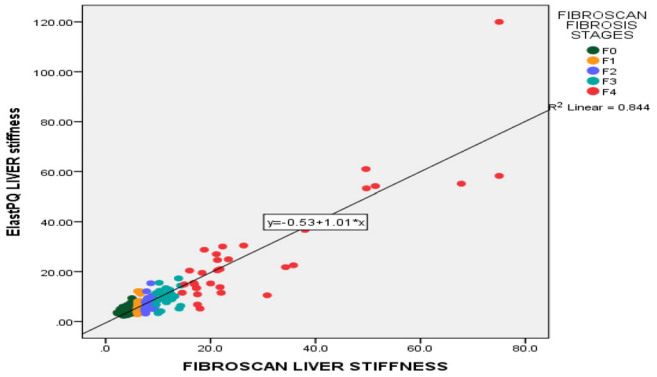
Comparison of ElastPQ Shear-wave Elastography (ElastPQ-SWE) and FibroScan Transient Elastography (F-TE) for liver fibrosis staging in patients with NAFLD

D. Roccarina, L.I. Prat, M. Guerrero, E. Buzzetti, M. Rosselli, M. Pinzani, E. Tsochatzis. *UCL Institute of Liver and Digestive Health, Sheila Sherlock Liver Centre, Royal Free Hospital, London, United Kingdom*
Email: davideroccarina@gmail.com

Background and Aims: Shear wave Elastography with ElastPQ (ElastPQ-SWE) is a recently introduced elastography-based technique for non-invasive fibrosis assessment.
We compared liver stiffness evaluation by ElastPQ-SWE and Fibroscan (F-TE) in a cohort of consecutive patients with NAFLD. We further evaluated the performance of ElastPQ-SWE in a subgroup of patients with available histology.

Method: Anthropometric parameters (weight, height, BMI and waist circumference (WC)) were measured together with routine bloods including a lipid profile. Transient elastography (TE) was measured by FibroScan (Echosens) and ElastPQ-SWE (Affiniti 70G, Philips) in all recruited patients.

Results: We enrolled 319 consecutive patients with NAFLD, mean age 54 ± 13y, BMI 31.7 ± 5.8 kg/m^2, waist circumference (WC) 107 ± 15 cm, 56.3% male, 44% with diabetes, 55.7% hypertension, 81% hyperlipidaemia.
ElastPQ had a good correlation with F-TE (Spearman's = 0.740, $p < 0.0001$), which was better for mild and moderate stages of fibrosis (Figure 1). A ≥2 kPa difference between the two techniques was found in 89 patients. On the univariate analysis predictors of such a difference were diabetes ($p = 0.004$), BMI ($p = 0.032$), AST (0.021) and F-TE ≥ 10 kPa ($p < 0.0001$) compatible with advanced fibrosis. On the multivariate analysis the only independent predictor was F-TE ≥ 10 kPa (OR: 6.891, 95% CI 3.538–13.422, $p < 0.0001$).



In the subgroup of 112 patients with available histology, the distribution of fibrosis was as follow: F0 = 14 (12%), F1 = 40 (36%), F2 = 21 (19%), F3 = 17 (15%), F4 = 20 (18%).

	ElastPQ				FIBROSCAN			
	Cut-off (kPa)	Sensitivity (%)	Specificity (%)	AUC	Cut-off (kPa)	Sensitivity (%)	Specificity (%)	AUC
F ≥ 2	6.8	81	76	0.855	7.9	82	72	0.810
F ≥ 3	8.2	89	82	0.927	10.1	76	83	0.878
F4	12.5	100	93	0.992	13.2	86	87	0.935

The optimal cut-off values of ElastPQ-SWE for individual stages of fibrosis were lower than those of F-TE. ElastPQ showed the same diagnostic performance for F ≥ 2 and a better diagnostic performance for F ≥ 3 and F4 compared to F-TE (Table 1).

Conclusion: ElastPQ and F-TE showed a good correlation in patients with NAFLD, which is better for low values of liver stiffness. The optimal cut-off values of ElastPQ are lower than those of F-TE for individual stages of fibrosis. ElastPQ seems to have a better diagnostic accuracy than F-TE in diagnosing advanced fibrosis and cirrhosis but this finding needs to be confirmed in larger cohorts.

FRI-429

Establishing reliability criteria forLiver ElastPQ Shear-wave Elastography (ElastPQ-SWE): Comparison between 3, 5 and 10 measurements

D. Roccarina, L.I. Prat, M. Guerrero, E. Buzzetti, M. Rosselli, A. Marshall, D. Thorburn, M. Pinzani, E. Tsochatzis. *UCL Institute of Liver and Digestive Health, Sheila Sherlock Liver Centre, Royal Free Hospital, London, United Kingdom*
Email: davideroccarina@gmail.com

Background and Aims: Shear wave Elastography with ElastPQ (ElastPQ-SWE) is a recently introduced elastography-based technique for non-invasive assessment and staging of liver fibrosis. However, despite its increasing use there is a lack of validated reliability criteria for the liver stiffness measurement and thus the FibroScan criteria are currently applied.

We evaluated the reliability of 5 and 3 measurements compared to 10 measurements in a cohort of patients with different aetiologies of liver disease.
Method: All patients underwent liver stiffness measurement using ElastPQ-SWE (Affiniti 70G, Philips). The average, median, standard deviation (SD) and SD percentage (SD%) of 3, 5 and 10 measurements were collected for each patient and compared to each other.
Results: We enrolled 334 consecutive patients with different liver disease aetiologies (NAFLD, PBC, PSC and AIH). The median kPascal (kPa) value of average, median, SD and SD% for 10, 5 and 3 measurements were 5.58, 5.43, 1.27, 23–5.44, 5.47, 1.17, 19 and 4.72, 4.8, 0.55, 11, respectively. The correlation of averages and medians was better between 10 and 5 measurements (Spearman's 0.958 and 0.944, respectively) than between 10 and 3 measurements (Spearman's 0.932 and 0.922, respectively).
The difference of SD and SD% was significant comparing 10 measurements to 5 and 3. However, the difference of averages and medians was significant only in the comparison between 10 and 3 measurements. No significant difference of averages and medians was found between 10 and 5 measurements when considering NAFLD and other aetiologies separately. (Tab.1)

N. of ElastPQ measurements	ElastPQ 10	ElastPQ 5	P value	ElastPQ 10	ElastPQ 3	P value
Average	5.58	5.44	0.573	5.58	4.72	<0.0001
Median	5.43	5.47	0.575	5.43	4.8	<0.0001
SD	1.27	1.17	0.001	1.27	0.55	<0.0001
SD%	23	19	<0.0001	23	11	<0.0001

Conclusion: The median of 5 valid liver stiffness measurements using ElastPQ-SWE does not significantly differ from 10 measurements and is sufficient for the reliable estimation of liver stiffness using this technique.

FRI-430

Gender differences in body composition in lean and overweight non-alcoholic fatty liver disease: The Rotterdam Study

L. Alferink[1], K. Trajanoska[2], N. Erler[1,3], J. Schoufour[2,4], R. de Knegt[5], A. Ikram[4], H. Janssen[6], O. Franco[4], H. Metselaar[4], F. Rivadeneira[2,4], S.D. Murad[1]. *[1]Erasmus Medical Centre, Hepatology, Rotterdam, Netherlands; [2]Erasmus Medical Centre, Internal medicine, Rotterdam, Netherlands; [3]Erasmus Medical Centre, Global Public Health, Rotterdam, Netherlands; [4]Erasmus Medical Centre, Epidemiology, Rotterdam, Netherlands; [5]Erasmus MC, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [6]University Health Network, Toronto, Canada*
Email: l.alferink@erasmusmc.nl

Background and Aims: Body composition is important in identifying the risk of NAFLD. Yet, evidence on the association between muscle mass, fat mass, fat distribution, and NAFLD is scarce. We therefore aimed to study the body composition, assessed by Dual-Energy X-Ray Absorptiometry (DXA), in relation to lean and overweight NAFLD, while accounting for known risk factors.
Method: Participants in the population-based Rotterdam Study underwent an extensive work-up with DXA and ultrasonography. NAFLD was defined as hepatic steatosis in absence of alcohol abuse, steatogenic drug use and viral hepatitis. Skeletal muscle index (SMI) was defined as appendicular lean mass/height^2. Fat mass (FM) was adjusted for height and fat free mass (FFM) and vice versa, to derive FM and FFM residuals, FMr and FFMr respectively. All analyses were stratified by sex and BMI (at 25 kg/m^2) and adjusted for (1) age; (2) BMI, weight and height, or weight only; 3) socio-demographic, lifestyle, and metabolic confounders; and 4) waist-to-hip ratio (WHR) in stepwise logistic regression.
Results: We included 4455 Caucasian participants (57% women) with a mean age of 69 ± 9 years and BMI of 27 ± 4 kg/m^2. NAFLD was present in 1552 participants (35%), of which 153 were lean and 1399 overweight. SMI (in kg/m^2) was lowest in the lean NAFLD group (6.6 vs. 8.0 in overweight NAFLD, and 7.3 in no NAFLD; $p < 0.001$). An increase in SMI was consistently associated with less NAFLD in lean women (OR 0.5 CI 0.3–0.9), but not in overweight women ($p = 0.17$), nor in lean ($p = 0.88$) or overweight men ($p = 0.12$). Sensitivity analyses using alternative proxies for SMI, adjusting for weight and fat mass, yielded similar results. FMr was associated with both lean (OR 2.3 CI 1.6–3.2) and overweight NAFLD in women (OR 1.2 CI 1.0–1.4), and with overweight NAFLD in men (OR 1.3 CI 1.1–1.5) after adjustment for well-known confounders. FMr association attenuated after further adjustment for WHR, particularly in men, in which it did not remain significant. FFMr was associated consistently with less NAFLD in lean women only (OR 0.6 CI 0.4–0.8).
Conclusion: Body composition is different in lean and overweight NAFLD, particularly in women, in which both an excess of fat mass and a lack of muscle mass were associated with NAFLD. In men, fat distribution, measured by WHR, appears important. These findings could help identify NAFLD in lean individuals and add to the rationale of resistance training without the aim of weight loss in this group.

FRI-431

New diagnostic method for hepatic steatosis using attenuation measurement by B mode ultrasound: Comparison with controlled attenuation parameter

Y. Koizumi[1], H. Masashi[1], N. Yada[2], T. Nobuharu[3], O. Nakashima[4], N. Izumi[3], M. Kudo[2], Y. Hiasa[1]. *[1]Ehime University Graduate School of Medicine, Departments of Gastroenterology and Metabology, Toon City, Japan; [2]Faculty of Medicine, Kindai University, Department of Gastroenterology and Hepatology, Higashiosaka City, Japan; [3]Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Tokyo, Japan; [4]Kurume University Hospital, Department of Clinical Laboratory Medicine, Kurume-city, Japan*
Email: masashihirooka@gmail.com

Background and Aims: Findings such as hepatic kidney contrast etc. have been used to diagnose fatty liver in B mode ultrasound, but they are based on subjective interpretation by the operator, and diagnostic accuracy is unsatisfactory. In recent years, it has become possible to measure hepatic steatosis (Controlled Attenuation Parameter: CAP) by measuring liver hardness using vibration-controlled transient elastography (VCTE) and attenuation of the ultrasonic signal. However, since VCTE cannot observe the measured section in real time, it has the disadvantage that it cannot be measured in postoperative cases or ascites. To overcome these disadvantages, we have developed a function (Attenuation: ATT) that transmits ultrasonic waves of different frequency components when measuring in B mode, and it estimates hepatic steatosis from the difference in attenuation of the received signal. The aim was to clarify the usefulness of ATT by comparing fat quantitative diagnosis by ATT and by CAP.
Method: All participants provided written, informed consent, and the study protocols were approved by the institutional ethics committee. Liver biopsies were performed from July 2015–March 2017, and 366 ATT and 105 CAP measurements were conducted. ATT measurements were performed five times with the ultrasonic diagnostic apparatus (HI VISION Ascendus; Hitachi, Ltd., Tokyo, Japan) with a convex probe (EUP-C715), avoiding the vessels in the liver from the right intercostal space, and the median was calculated. The CAP measurement was measured using M and XL probes. Steatosis grades obtained from pathological tissues were compared with the ATT and CAP values.
Results: The steatosis grades of the cases were: S0 303 cases; S1 43 cases; S2 14 cases; and S3 15 cases. In all cases, ATT measurement was possible. The area under the receiver operating characteristic curve (AUC-ROC) for ≥ S1 was 0.77, 0.80, and 0.83 for ATT, CAP M probe, and CAP XL probe, respectively. The AUC-ROC for ≥ S2 was 0.85, 0.83, and 0.84, respectively. The AUC-ROC for S3 was 0.95, 0.98,

and 0.92, respectively. Significant differences in AUC-ROC between ATT and CAP were examined by the DeLong test, and no significant differences were found for ≥ S1 (ATT vs M probe: p = 0.257, ATT vs XL probe: p = 0.061), ≥S2 (ATT vs M probe: p = 0.385, ATT vs XL probe: p = 0.717), and S3 (ATT vs M probe: p = 0.515, ATT vs XL probe: p = 0.143). From these results, the diagnostic ability for hepatic steatosis was considered to be comparable between ATT and CAP.

Conclusion: The steatosis diagnostic grade ability of ATT was similar to that of CAP. ATT does not require dedicated equipment for lipid diagnosis, it can be measured simultaneously with normal observation in B mode, and it is a useful modality considered to be measurable even in cases where measurement is impossible or difficult by CAP.

Evaluation of SOMAscan as a discovery platform to identify noninvasive protein biomarkers for diagnosis and monitoring of NASH

M. Lai[1], T. Libermann[1], M. Charlton[2], A.M. Diehl[3], L. Ngo[1], S. Dillon[1], E. Lawitz[4], N. Chalasani[5], B. Hameed[6], S. Caldwell[7], M. Rinella[8], T. Nguyen[9], A. Billin[9], S. Djedjos[9], M. Subramanian[9], R. Myers[9], Z. Goodman[10], R. Loomba[11], N. Afdhal[1]. *[1]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, United States; [2]University of Chicago, Chicago, United States; [3]Duke Clinical Research Institute, Durham, United States; [4]Texas Liver Institute, University of Texas Health San Antonio, San Antonio, United States; [5]Indiana University School of Medicine, Indianapolis, United States; [6]University of California San Francisco, San Francisco, United States; [7]University of Virginia, Charlottesville, United States; [8]Northwestern Medicine, Chicago, United States; [9]Gilead Sciences, Foster City, United States; [10]Inova Fairfax Hospital, Falls Church, United States; [11]University of California at San Diego, Division of Gastroenterology, Department of Medicine, San Diego, United States*
Email: stephen.djedjos@gilead.com

Background and Aims: Circulating proteins that are secreted, shed, or leak from the liver may reflect hepatic pathophysiology and are potentially useful biomarkers for NASH. Our aim was to evaluate the utility of SOMAscan, an aptamer-based proteomics platform, for identifying serum proteins associated with NASH-related liver histology and monitoring treatment response.

Methods: Using the SOMAscan assay (SomaLogic; Boulder, CO), serum proteomic signatures were analyzed in 72 subjects with NASH (NAS ≥ 5 and NASH CRN F2-3 fibrosis) enrolled in a Phase 2 trial of selonsertib (SEL). Subjects were treated with SEL alone or in combination with simtuzumab (SIM), or SIM alone for 24 weeks (W24). SOMAscan was assayed at baseline (BL) and W24, and also in 74 NASH subjects who failed screening due to ineligible fibrosis stage (F0-1, F4). Associations between the 1,310 proteins detected with SOMAscan and centrally-read liver histology (NAS and NASH CRN fibrosis stage) were assessed using both Kruskal-Wallis and Jonckheere-Terpstra trend tests. Multivariate analyses using a two-step approach were performed to combine markers for the discrimination of F0-2 vs. F3-4 fibrosis at BL, and prediction of ≥1-stage/grade improvements in fibrosis and NAS components at W24.

Results: Univariate analysis identified 28 proteins significantly associated with fibrosis stage and 32 proteins associated with the NAS at BL (all p < 0.001). Multivariate analysis identified a panel of 7 proteins at BL (C7, CL-K1, IGFBP7, spondin 1, IL-5Ra, MMP-7, and TSP2) that accurately discriminated between early and advanced fibrosis (F0-2 [n = 72] vs F3-4 [n = 74]: AUROC 0.83 [95% CI 0.77, 0.90]). Longitudinal changes in a panel of 7 proteins (PTEN, CD70, caspase 2, cathepsin H, LAG1, PDXK, and GITR) accurately predicted fibrosis improvement at W24 (AUROC 0.90 [95% CI 0.83, 0.98]; Figure). Longitudinal analysis of other circulating proteins revealed additional panels that effectively identified improvements in hepatocellular ballooning (AUROC 0.97 [95% CI 0.93, 1.00]), lobular inflammation (AUROC 0.88 [0.78, 0.98]), or hepatic steatosis (AUROC 0.89 [0.82, 0.97]).

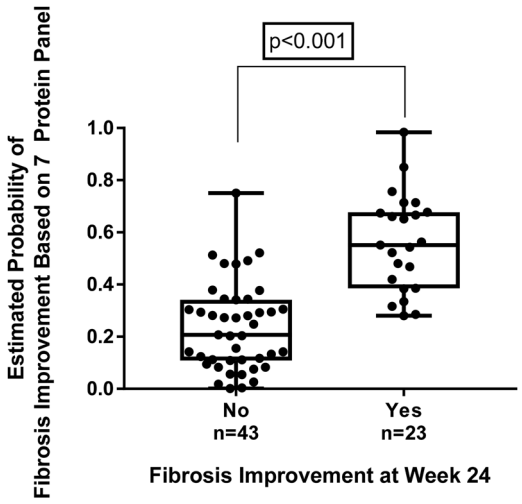

Figure 1: SOMAscan identified a panel of 7 serum proteins that accurately predicted fibrosis improvement after 24 weeks of SEL treatment in subjects with NASH.

Conclusion: The SOMAscan platform identified novel circulating protein biomarkers that correlated with disease severity and were responsive to changes in liver histology in patients with NASH. The utility of these protein biomarkers for the diagnosis and monitoring of NASH requires validation in future studies.

Electronic-nose breath print distinguishes non-alcoholic fatty liver disease from healthy lean control: A pilot study

R. Sinha[1], I. Gallagher[2], K.A Lockman[1], R. Chamuleau[3], A. Jaap[4], P. Hayes[1], J. Plevris[1]. *[1]Royal Infirmary and The University of Edinburgh, Hepatology Laboratory and Centre of Liver and Digestive Diseases, Edinburgh, United Kingdom; [2]University of Stirling, Health & Exercise Research Group, Stirling, United Kingdom; [3]Academic Medical Centre, University of Amsterdam, Surgical Laboratory and Tytgat Institute for liver and intestinal research, Amsterdam, Netherlands; [4]Royal Infirmary and The University of Edinburgh, Edinburgh Centre for Endocrinology & Diabetes, Edinburgh, United Kingdom*
Email: rohit.sinha@nhs.net

Background and Aims: Human breath contains numerous volatile compounds which reflect metabolic activity. Electronic nose (eNose) technology can rapidly detect these volatile metabolites to provide breath prints non-invasively. Non-alcoholic fatty liver disease (NAFLD) is the hepatic manifestation of metabolic syndrome. We hypothesized breath prints obtained from eNose could distinguish healthy individuals from those with NAFLD.

Method: The study was prospective single-center cohort study (ClinicalTrials.gov: NCT02950610) with training cohort and one-against all (leave-one out) cross validation verification (CVV). eNose (SpiroNose) is a custom-made device made up of five-sensor arrays each containing four sensors, previously validated in respiratory and liver disease [1, 2]. eNose on exhaled breath was performed on well characterised NAFLD patients; (a) NAFLD Child's A cirrhosis (n = 30; n = 4, liver biopsy; n = 20, endoscopic features of portal hypertension; n = 6, radiological features), (b) NAFLD non-cirrhosis [n = 30; n = 8, liver biopsy; n = 22, non-invasive markers e.g. NAFLD fibrosis score, Fib4, hyaluronic acid, transient elastography etc. and (c) self-declared healthy subjects [n = 30]. Data were analyzed using R (v 2.3.2) and Orange (v 3.4.1) software. Data reduction to 3 principal components (PCs) explained 97.8% of total variance. Data was further classified by *k*-nearest neighbor's (k-NN) algorithm, a non-parametric machine learning algorithm for classification.

Results: In patients with NAFLD cirrhosis, eNose was able to accurately classify with 100% sensitivity ($p < 0.001$, cross-validation verification [CVV] 96%) from healthy subjects, independent of age and gender. Sensor 1, Sensor 2, Sensor 3 and Sensor 4 identified NAFLD cirrhosis patients with AUC 0.96 (standard error = 0.043; $p < 0.001$), 0.89 (standard error = 0.046; $p < 0.001$), 0.98 (standard error = 0.016; $p < 0.001$) and 0.96 (standard error = 0.022; $p < 0.001$) respectively. eNose was able to differentiate between healthy from; non-cirrhotic NAFLD ($p < 0.001$, CVV 96.8%) and NAFLD cirrhotic ($p < 0.001$, CVV 95.1%). However, it could not differentiate non-cirrhotics from cirrhotic in NAFLD ($p = 0.88$). 60 participants (30 healthy and 30 NAFLD cirrhotic) were analyzed using a leave-one-out CVV for creating training sets and validation sets. This method, designed to reflect the generalization property of the k-nearest neighbor's classifier, scored a classification rate of 96%.

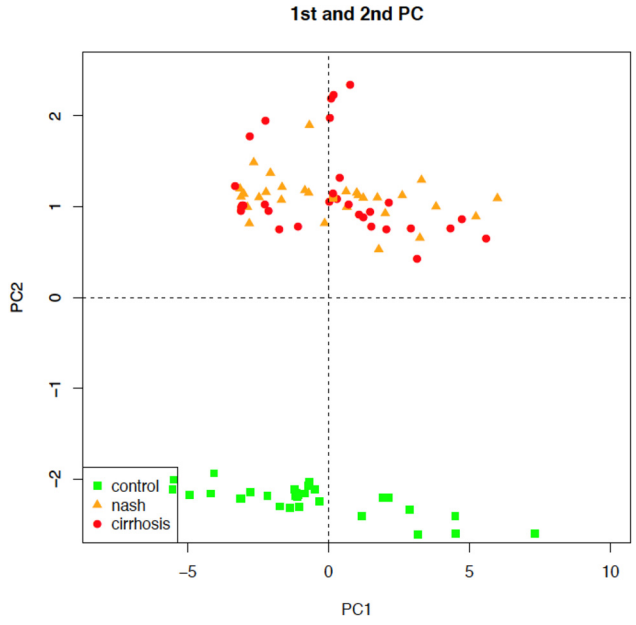

Figure 1: Principal component analysis of 3 study groups

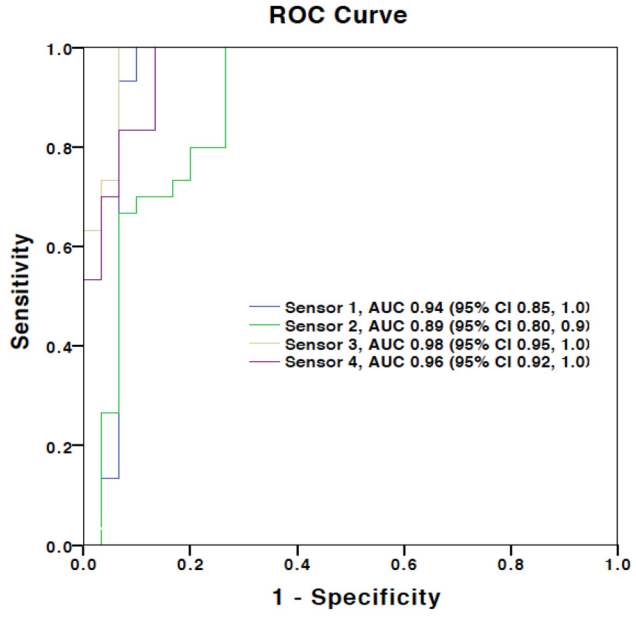

Figure 2: Individual sensor ROC curve in in discriminating NAFLD cirrhosis

Conclusion: Our study demonstrates the ability of eNose to accurately distinguish NAFLD from healthy individuals. Thus, eNose technology can provide rapid, non-invasive point-of-care screening to risk stratify patients, which can reduce the burden of liver biopsy.

FRI-434

A study of breath metabolome in Non-alcoholic fatty liver disease

R. Sinha[1], K.A Lockman[1], N. Homer[2], E. Bower[2], P. Brinkman[3], H. Knobel[4], R. Chamuleau[5], A. Jaap[6], P. Hayes[1], J. Plevris[1]. *[1]Royal Infirmary and The University of Edinburgh, Hepatology Laboratory and Centre of Liver and Digestive Diseases, Edinburgh, United Kingdom; [2]Edinburgh Clinical Research Facility and Queen's Medical Research Institute, Mass Spectrometry, Edinburgh, United Kingdom; [3]Academic Medical Centre, University of Amsterdam, Dept. Respiratory Medicine, F5-259, Amsterdam, Netherlands; [4]Philips Innovation Labs, Material Analysis, Eindhoven, Netherlands; [5]Academic Medical Centre, University of Amsterdam, Surgical Laboratory and Tytgat Institute for liver and intestinal research, Amsterdam, Netherlands; [6]Royal Infirmary and The University of Edinburgh, Edinburgh Centre for Endocrinology & Diabetes, Edinburgh, United Kingdom*
Email: rohit.sinha@nhs.net

Background and Aims: Breath-omics is gaining popularity as a method for non-invasive measure of biomarkers for various diseases. Breath metabolome is a multitude of volatile organic compounds (VOCs) reflecting pathological metabolic processes. The purpose of this study was to compare breath VOCs in patients with non-alcoholic fatty liver disease (NAFLD) and healthy controls.

Method: Breath samples were collected from well characterised NAFLD patients; a) NAFLD Child's A cirrhotics ($n = 15$; $n = 14$, endoscopic features of portal hypertension; $n = 1$, radiological feature), b) NAFLD non-cirrhosis [$n = 14$; $n = 3$, liver biopsy; $n = 11$, elevated transient elastography and fibrosis scores and c) self-declared healthy subjects [$n = 15$]. Exhaled breath collection and breath condensate analysis has been previously well described [1]. VOCs were identified using mass spectrometry analysis; comprising of abundant and trace compounds. Compounds based on the mass spectra and a peak appearing at a retention time that was consistent in all samples. The mass spectra of each compound were matched in the chromatogram and further identified using AMDIS® software. The peak areas of the compounds were collected from extracted ion chromatograms of the most dominant parent ion of the compound and the peak automatically integrated using Xcalibur®. All compound peak areas were normalised by internal standard (d8-toluene), which was added to all samples when it was analysed. Data were analysed by non-parametric ANOVA (Kruskal–Wallis) and Dunns *post-hoc*. Receiver Operating Characteristic (ROC) curves were used to determine the diagnostic accuracy of the volatiles compound.

Results: Body mass index adjusted exhaled breath levels of acetone, dimethyl sulphide, d-limonene, acetophenone and alfa-terpinene were significantly higher ($p < 0.001$, $p < 0.01$, $p = 0.005$, $p < 0.001$, $p = 0.001$, $p < 0.001$) in patients with NAFLD cirrhosis than that seen with healthy subjects. D-limonene is found to provide the most discriminatory power for NAFLD cirrhosis, AUROC = 0.91(95% CI 0.79, 1.0; standard error 0.06) (Figure 1). Additionally, breath acetone and d-limonene concentrations can differentiate NAFLD non-cirrhosis from NAFLD cirrhosis ($p < 0.001$ and $p < 0.05$). Breath acetone level can distinguish between NAFLD non-cirrhotic and NAFLD cirrhotic; AUROC = 0.88 (standard error 0.07) and achieves a sensitivity of 90% with a specificity of 70% (Figure 2).

Conclusion: Breath VOCs have a promising future as biomarkers for a non-invasive diagnostic and prognostic tool in the management of NAFLD. D-limonene and acetone can identify NAFLD non-cirrhosis from NAFLD cirrhosis with confidence. Future validation of our finding to external cohort is needed.

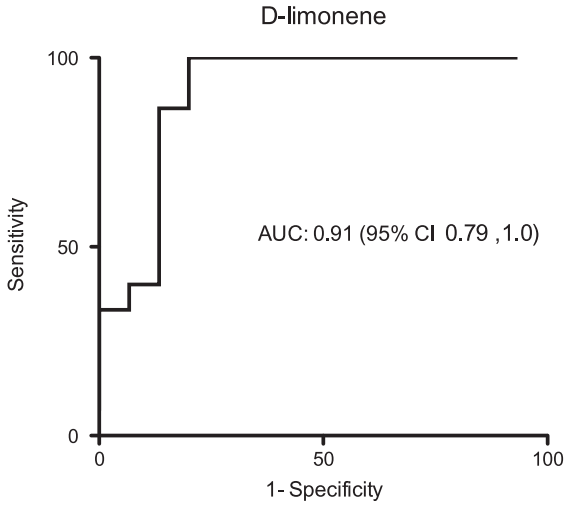

Figure 1: Receiver operating characteristic curve for D-Limonene.

Email: tpoynard@teaser.fr

Background and Aims: In NASH diagnostic studies, biopsies are performed for routine clinical care in the investigation of abnormal liver function tests, often defined as "increased ALT" (iALT). This criteria, which varied according to age and gender, can impact the estimation of NASH-test performances by selecting risk factors not representative of the T2D context of use. The risk of significant fibrosis (F2F3F4), a recognized definition of significant liver disease, according to ALT value, is unknown (DiabetesCare 2017). To assess this risk, we compared T2D with and without iALT using non-invasive tests such as FibroTest (FT), routinely used in France since 2002 and validated as alternatives to biopsy for F2F3F4 diagnosis (LancetGastro 2017).

Method: We retrospectively analyzed T2D (receiving T2D treatment, or with fasting glucose > = 7, in the prospective FibroFrance cohort (NCT01927133). iALT was defined as ALT > 30 IU for men, and >20 IU for women. T2D were followed by liver tests to assess F2F3F4 with standard cut-offs (Fibrotest 0.48, Elastography TE-M, TE-XL or SWE, all 7.1 kPa). The primary endpoint was the presence of F2F3F4 ing non-iALT, and any significant difference in the main prognostic characteristics between the 2 groups: gender, age, and severity defined as the Kaplan-Meier overall survival at 10 yr. Prognostic value of iALT was also assessed after taking into account age and gender by Cox model.

Results: 230 consecutive T2D without other cause of liver diseases, were included. During a mean follow-up of 7 years 157/230 (68%) had iALT and 73/230 (32%) had non-iALT. 77 pts had at least one liver biopsy. The risk of significant liver disease in the non-iALT was not negligible, with 45% of significant activity A2A3A4 among pts with biopsy, and prevalence of F2F3F4 35%, 30% and 62%, by biopsy, FT and TE, respectively. The spectrum was significantly different, with more women, more pts younger than 65 years of age, and with a higher 10-year overall survival rate in iALT group (26 deaths) vs non-iALT group (35 deaths) (Table 1), but the significant difference disappeared when adjusted by age and female gender, risk-ratio = 0.69 (95%CI 0.40–1.16; p = 0.16).

Table 1: characteristics of T2D patients with or without increased ALT transaminases

	Increased ALT n = 133	Not increased ALT n = 97	P value
10-yr cumulative survival (95% CI)	70% (58–82)	56% (43–69)	0.02
Age younger than 65 years	95/1133 (71%)	57/97 (59%)	0.04
Female gender	65/133 (49%)	24/97 (25%)	0.0002
F2F3F4 FibroTest >0.48	58/133 (44%)	29/97 (30%)	0.04
F2F3F4 Elasticity >=7.1 kPa	62/80 (78%)	28/45 (62%)	0.10
Stage F2F3F4 FLIP-CRN biopsy	31/52 (60%)	8/23 (35%)	0.08
Grade A2A3A4 FLIP biopsy	40/52 (77%)	10/22 (45%)	0.01
No steatosis or steatosis <5% biopsy	6/54 (17%)	4/23 (11%)	0.45

Conclusion: T2D without increased ALT should be included in diagnostic studies evaluating NASH-tests to prevent a spectrum effect and a biased control population.

FRI-436

Performance and reliability of non-invasive fibrosis scores in non-alcoholic fatty liver disease with and without morbid obesity

A. Drolz, S. Wolter, M. Wehmeyer, F. Piecha, T. Horvatits, J.S.Z. Wiesch, A. Lohse, O. Mann, J. Kluwe. *University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
Email: a.drolz@uke.de

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a leading etiology of chronic liver disease. Transient elastography is widely used for fibrosis-assessment, but has limitations in morbid obesity. Non-invasive scores, such as the NAFLD Fibrosis Score (NFS), are increasingly used for non-invasive fibrosis assessment.
Aim of this study was to assess the applicability and reliability of non-invasive fibrosis scores in NAFLD patients with and without morbid obesity.

Method: Patients with biopsy-proven NAFLD (143 conventional and 225 morbidly obese) were retrospectively studied. Clinical and laboratory data obtained prior to biopsy were collected, and fibrosis scores were calculated.

Results: Three hundred sixty-eight patients were analyzed. Median age was 47 years, 57% were female. Median BMI was 42.9 kg/m^2 with significant differences between our conventional and morbidly obese patients (BMI 29.0 kg/m^2 vs. 50.8 kg/m^2, p < 0.001). Overall, 42% showed mild/moderate fibrosis, and 16% advanced fibrosis (stage III/IV). All tested scores were significantly linked to fibrosis stage (p < 0.001 for all). FIB-4 (AUROC 0.904), APRI (AUROC 0.848) and NFS (AUROC 0.750) were identified as most potent predictors of advanced fibrosis, although NFS overestimated fibrosis stage in morbid obesity (Figure 1). Limiting BMI to a maximum of 40 kg/m^2 improved NFs' overall performance (AUROC 0.838). A FIB-4 value of >1.0 was

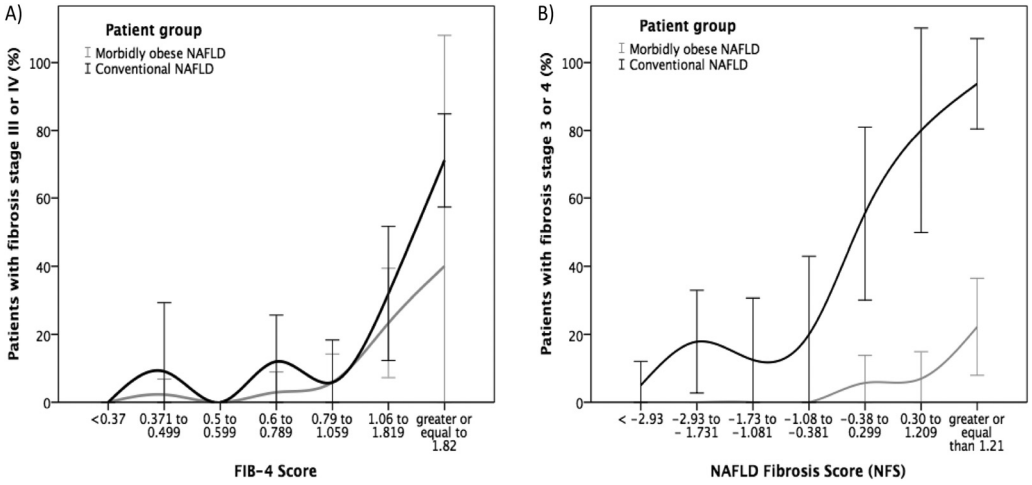

Figure: (abstract: FRI-436)

dramatically associated with presence of advanced fibrosis (OR = 29.1). FIB-4 predicted advanced fibrosis independently from age, sex, BMI and presence of morbid obesity.

Conclusion: Non-invasive scoring systems are effective tools for assessing fibrosis stage in NAFLD with and without morbid obesity. Our data suggest that FIB-4 and APRI can be applied to patients in all BMI ranges, whereas NFS may require modification in morbid obesity.

FRI-437

Controlled attenuation parameter is useful in the diagnosis of fatty liver disease and allows to identify patients with high vascular risk as well as those with advanced liver disease

M. González[1], J.A. Guerra[2], D. Escudero-García[3], María T.A. Loste[1], M. Hernández Conde[2], P. Iruzubieta[1], Ángel Estébanez[1], L. Puchades[3], E. Llop[2], J.C. Gonzalez[1], M. Serra[3], José L.C. Panero[2], J. Crespo[1].

Email: mgonzalezmtnez@gmail.com

Background and Aims: Fatty liver disease (FLD) has increased its prevalence concurrently to the rise in obesity and metabolic syndrome. Our aim is to establish FLD prevalence in Spanish general population as well as the factors associated with advanced liver disease.

Method: Population and cross-sectional study carried out between July 2015 and May 2017. Two-stage cluster sampling was performed, with stratification by gender, socioeconomic status and rural/urban area. Clinical, anthropometric and analytical data were collected. Transient elastography (TE) with controlled attenuation parameter (CAP) were performed. All subjects with abnormal liver blood test and/or TE >7 kPa underwent abdominal ultrasound and liver chronic disease etiological study.

Results: A total of 5,520 subjects were evaluated (age 49.4; male 45%). CAP was feasible in 4,761 cases, resulting in steatosis of any aetiology in 2,328 (48.9%). Diagnosis of FLD was based in CAP > 248 and/or increased liver echogenicity by ultrasound in the absence of other causes of liver disease, resulting in a prevalence of 44,8% (2420 cases). Between them, 30,8% have abnormal liver blood test and 6,3% TE >7 kPa. Most patients with high vascular risk, defined as

	Subjects without steatosis (n=2338)	P (1)	Non-advanced FLD (n=2267)	Advanced FLD (n=153)	P (1)
Male gender	865 (37)	0.00	1213 (53.5)	106 (69.3)	0.00
Age (years)	47 (20-80)	0.00	54 (18-80)	58 (23-80)	0.00

High vascular risk: >50 years + hypertension + HOMA > 2.6 + dyslipidemia.
BMI (Body Mass Index). sPD (systolic blood pressure). sPD (diastolic blood pressure). DM2 (Diabetes Mellitus type 2). HOMA-IR (homeostasis model assessment); na (not available); ns (no statistical significance)

Figure: (abstract: FRI-437)

age >50, hypertension, dyslipidaemia and HOMA-IR >2.6, showed CAP > 280 (42/57). Age, waist circumference and the presence of diabetes mellitus were associated with advanced FLD in multivariate analysis.
Conclusion: Hepatic steatosis measurement by CAP, does not only identify patients with FLD, but can also characterise a group of patients with high vascular risk. Moreover, when it is associated to TE, allows to detect patients with advanced FLD, even in those with normal liver blood test. This high prevalence shows the need of an early diagnosis in order to plan early therapeutic strategies.

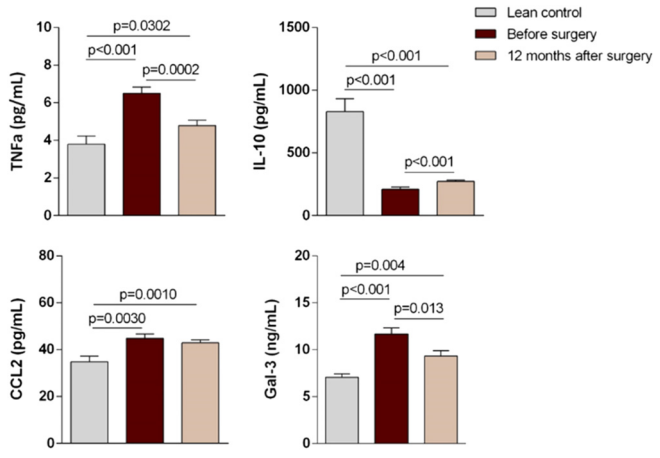
Effects of bariatric surgery on Non-alcoholic fatty liver disease: The role of macrophage-mediated the systemic inflammation
Noemí Cabré[1,2], F. Luciano-Mateo[1,2], P.J. Águila-Hervás[1,2], M. Català[1,2], A. Hernández-Aguilera[1,2], J. Camps[1,2], J. Joven[1,2]. *[1]Unitat de Recerca Biomèdica, Institut d'Investigació Sanitària Pere Virgili, Universitat Rovira i Virgili, Reus, Spain; [2]Instituto de Salud Carlos Iii (Grant Pi15/00285 co-founded by the European Regional Development Fund (FEDER)), Madrid, Spain*
Email: noemi.cabre@urv.cat

Background and Aims: Obesity is a pathologic condition that is characterized by a state of chronic low-grade systemic inflammation that contributes to development of comorbidities, including non-alcoholic fatty liver disease (NAFLD). The microenvironment generated by NAFLD in the liver tissue influences the proliferation and activation of a type of macrophages and the release of certain molecules that promote tissue damage. Macrophages play a major role in the immune system, especially because liver tissue homeostasis is maintained through an adequate balance of pro- and anti-inflammatory state. In order to identify potential therapeutic approaches, the aims of our study were to investigate how bariatric surgery modulates the inflammation and, in addition, whether this fact influences the pathogenesis of NAFLD.
Method: We carried out an observational, prospective, single-site and cross-sectional study with a pre-set duration of 1 year with patients who underwent bariatric surgery (n = 120) as a model of obesity-induced NAFLD and lean healthy (n = 50) as a control group. Liver biopsy and a blood collection were obtained immediately before bariatric surgery and after a 12-month period. We performed immunohistochemical, western blot and ELISA analysis to evaluate several inflammatory changes such as infiltration of macrophages (CD68) and expression/location of Chemokine (C-C motif) Ligand 2 (CCL2), Tumor Necrosis Factor alpha (TNF- alpha), Interleukin 10 (IL-10) and Galectin-3 (Gal-3).



Results: After bariatric surgery there was a significant improvement of liver tissue corresponding with a significant decrease in the presence of hepatic steatosis, acute inflammation and fibrosis after one year. These results contrasted with a significant profile change regarding the presence of macrophages in the liver, on the same line the alterations in the expression/secretion of CCL2-CCR2 axis, TNF-α, IL-10 and Gal-3. In addition, plasma levels of CCL2, TNF-α, IL-10 and Gal-3 showed significant differences after 12 months in patients who underwent bariatric surgery.
Conclusion: Bariatric surgery modulates the proliferation and activation of macrophages, especially, it modifies the secretion/release of molecules associated with the progression of NAFLD. Therefore, the expression of CCL2, TNF-α, IL-10 and Gal-3 has been proposed as possible therapeutic targets and biological markers of the stages of NAFLD.

FRI-439
Magnetic Resonance Elastography versus Transient Elastography in detection of fibrosis in nonalcoholic fatty liver disease: A systematic review and meta-analysis of individual participant date
C. Hsu[1], C. Caussy[1,2], K. Imajo[3], J. Chen[4], S. Singh[1], K. Kaulback[5], M. Le[1], J. Hooker[6], R. Bettencourt[1], M. Yin[4], C. Sirlin[6], R.L. Ehman[4], A. Nakajima[3], R. Loomba[7]. *[1]University of California at San Diego, Nonalcoholic Fatty Liver Disease Research Center, Department of Medicine, La Jolla, United States; [2]Université Lyon; [3]Yokohama City University Graduate School of Medicine, Department of Gastroenterology, Yokohama, Japan; [4]Mayo Clinic, Department of Radiology, Rochester, United States; [5]Research in Practice, Toronto, Canada; [6]University of California at San Diego, Liver Imaging Group, Department of Radiology, La Jolla, United States; [7]University of California at San Diego, Division of Gastroenterology, Department of Medicine, San Diego, United States*
Email: c6hsu@ucsd.edu

Background and Aims: Magnetic resonance elastography (MRE) and transient elastography (TE) are noninvasive imaging techniques used to diagnose liver fibrosis in patients with nonalcoholic fatty liver disease (NAFLD). Previous studies comparing the efficacy of MRE versus TE have been single-center studies. Therefore, we aimed to perform a meta-analysis of individual participant data from published studies to compare the diagnostic performance of MRE versus TE for the staging of liver fibrosis in NAFLD using liver biopsy as the gold standard.
Method: A computer-aided systemic literature search of multiple databases from January 1, 2005 to September 05, 2017 identified 3 studies (Imajo et al. Gastroenterology 2016, Park et al. Gastroenterology 2017, Chen et al. Radiology 2017) with MRE and TE assessment for the detection of liver fibrosis in patients with NAFLD, using liver biopsy as a reference. Data for 318 participants, including baseline characteristics, histologic fibrosis stage, MRE, and TE measurements, were collected by contacting the study authors and of those, data from 230 participants with MRE, reliable TE measurement and liver biopsy available were included in the analysis using a pre-specified meta-analysis protocol. Through pooled analysis, the cluster-adjusted area under the curve (AUROC) of MRE and TE was calculated for the detection of each stage of fibrosis, and AUROC comparisons between MRE and VCTE were performed using the Delong test.
Results: The pooled analysis included 230 participants with biopsy proven NAFLD with mean (± sd) age and BMI of 52.2 (± 13.9) years and 31.9 (± 7.5) kg/m^2, respectively. The distribution of stage 0, 1, 2, 3 and 4 fibrosis was 31.7%, 27.8%, 15.7%, 13.9%, and 10.9%, respectively. The AUROC (95% CI) of TE versus MRE for the detection of fibrosis stages ≥1 was 0.82 (0.76–0.88) vs. 0.87 (0.82–0.91), p <0.05, fibrosis stage ≥ 2 was 0.87 (0.82–0.91) vs. 0.92 (0.88–0.96), p < 0.05, fibrosis stage ≥ 3 was 0.84 (0.78–0.90) vs. 0.93 (0.89–0.96), p < 0.001, and fibrosis stage ≥ 4 was vs.0.84 (0.73–0.94) vs. 0.94 (0.89–0.99), p < 0.01, respectively.
Conclusion: In this pooled analysis of data from individual participants with NAFLD in 3 independent studies, MRE

demonstrated a higher diagnostic accuracy than TE for the detection of individual stages of fibrosis using liver biopsy as a reference. Both MRE and TE have a role in the detection of fibrosis in NAFLD depending upon the desirability for accuracy.

FRI-440

Gut-liver interactions in celiac disease: FGF-19 and GLP-1 link disease activity to hepatic steatosis and liver injury

S. Sydor[1], P.P. Manka[2], J. Schänzer[2], I. Messerschmidt[2], S. Kinner[3], A. Link[1], H. Moshage[4], K.N. Faber[4], G. Gerken[2], A. Canbay[1], L.P. Bechmann[1]. *[1]Otto-von-Guericke-University Magdeburg, Department of Gastroenterology, Hepatology and infectious diseases, Magdeburg, Germany; [2]University Hospital Essen, Department of Gastroenterology and Hepatology, Essen, Germany; [3]Universitätsklinikum Essen, Institut für Diagnostische und Interventionelle Radiologie und Neuroradiologie, Essen, Germany; [4]University of Groningen, University Medical Center Groningen (UMCG), Faculty of Medical Sciences Gastrointestinal and liver diseases, Groningen, Netherlands*
Email: svenja.sydor@med.ovgu.de

Background and Aims: We and others have previously identified celiac disease (CD) as a risk factor for hepatic steatosis and non-alcoholic steatohepatitis (NASH). NASH in CD is associated with cellular stress and hepatocellular apoptosis. The underlying mechanisms leading to hepatic steatosis in CD have yet to be shown. Bile acid (BA) signaling has recently been identified as an important mediator in gut-liver interactions and the pathogenesis of NASH. With this study, we aim to analyze parameters of BA signaling and liver injury in patients with CD compared to healthy controls (HC).
Method: We included 20 patients with known CD and 20 healthy volunteers and analyzed transaminases, cell death markers (M30, M65) as well as markers of BA and fatty acid metabolism (FGF-19, serum BA, FGF-21, GLP-1). Hepatic steatosis was determined using controlled attenuated parameter (CAP) via Fibroscan and by MRI-HFF.
Results: In CD, ALT and hepatocellular apoptosis (M30) were increased compared to HC (ALT: 19.3 vs. 26.5 U/l; $p < 0.0001$; M30: 88.9 vs. 142.4 U/l; $p = 0.03$). Accordingly, in CD hepatic steatosis was abundant as indicated by higher CAP and MRI-HFF. In order to associate steatotic liver injury with disease activity in CD, we further analyzed CD subgroups (anti-transglutaminase antibody positive (tTg-Ab-pos; $n = 10$) vs. negative (tTg-Ab-neg; $n = 10$). In tTg-Ab-pos individuals, M30 as indicator of hepatocellular injury was significantly induced (88.9 vs. 158.7 U/l; $p = 0.043$). CD patients with a CAP $\geq$ 283 dB/m (established cutoff for diagnosis of fatty liver) were exclusively tTG-Ab-pos. While total BA were not different between groups, FGF-19 levels were significantly lower in CD compared to HC, which was not related to CD activity. In contrast, GLP-1 levels were significantly higher in tTG-Ab-pos compared to tTG-Ab-neg and controls (1144.0 vs. 616.9 pg/ml; $p = 0.02$). In this cohort increased CAP was positively correlated to an increase of MRI-HFF, M30, ALT, fecal calprotectin, and GLP-1. In contrast increased FGF-19 serum levels were negatively correlated to steatosis as assessed by MRI-HFF.
Conclusion: In this cohort, CD was associated with steatosis, hepatocellular injury, hepatic inflammation, and reduced FGF-19 serum levels. Abundance of tTG-Ab in CD was associated with steatosis, liver injury and increased GLP-1 levels as an indicator of metabolic alterations in CD. Both, FGF19 and GLP-1 (via TGR5 receptor) are associated with BA signaling. Thus, we hereby elucidate a novel role for BA signaling in CD associated fatty liver.

FRI-441

Utility and limitation of non-invasive fibrosis markers for predicting the prognosis in biopsy-proven Japanese NAFLD patients

T. Ito, M. Ishigami, Y. Ishizu, T. Kazuya, T. Honda, K. Hayashi, T. Ishikawa, Y. Hirooka, H. Goto. *Nagoya University Graduate School of Medicine, Department of Gastroenterology and Hepatology, Nagoya, Japan*
Email: tahkun56@gmail.com

Background and Aims: Fibrosis stage of nonalcoholic fatty liver disease (NAFLD) is closely associated with long-term prognosis. Non-invasive fibrosis markers used in lieu of liver biopsy have been reported to be useful for assessing the liver fibrosis and prognosis, especially liver-related mortality. However, it is not yet clear whether these markers can predict the incidence of non-liver-related complications. In the present study, we clarified the prognosis including non-liver-related diseases based on hepatic pathology and non-invasive fibrosis markers in Japanese NAFLD patients.
Method: A total of 246 patients with Japanese NAFLD diagnosed by liver biopsy were enrolled. We investigated the mortality and the prognosis based on hepatic pathology and non-invasive fibrosis markers, FIB-4 index and NAFLD fibrosis score (NFS).
Results: The cumulative incidental number of death, hepatocellular carcinoma (HCC), complications related to liver cirrhosis (LC) other than HCC, extrahepatic malignancies, and cardiovascular disease (CVD) were 8 (3.3%), 9 (3.7%), 10 (4.1%), 16 (6.5%) and 12 (4.9%) during follow-up period (median 7.0 years), respectively. When these patients were categorized based on the severity of liver fibrosis as F0-2 ($n = 196$) and F3-4 ($n = 50$), the patients with F3-4 had significantly poorer prognosis in overall survival rate and all complications ($p < 0.05$) other than CVD. Non-invasive fibrosis markers, FIB-4 index and NFS, were useful to predict overall survival, the incidence of HCC and complications related to LC, but not extrahepatic malignancies and CVD. Multiple logistic regression analysis revealed severe liver fibrosis was independently associated with overall survival and malignancies including HCC: hazard ratio (HR) 6.512 (95% confidence interval [CI], 1.433–29.592) for survival; HR 7.622 (95% CI, 1.401–41.459) for HCC; HR 3.989 (95% CI, 1.335–11.913) for extrahepatic malignancies, respectively. Although FIB-4 index was an independent risk factor of complications related to LC (HR 26.560, CI, 3.320–212.494), both FIB-4 and NFS were not selected as an independent risk factors of extrahepatic malignancies and CVD.
Conclusion: The progression of liver fibrosis was associated with not only liver-related complications but also extrahepatic malignancies in Japanese NAFLD. NFS and FIB-4 were useful for predicting liver-related complications, but they had limitation for extrahepatic malignancies and CVD.

FRI-442

FibroScan stiffness and CAP in the evaluation of cardiovascular risk assessment in patients with NAFLD

R. Lombardi[1], S. Petta[2], A. Giannetti[2], R. Boemi[2], G. Pisano[1], C. Bertelli[1], A. Craxi[2], S. Fargion[1], A.L. Fracanzani[3]. *[1]Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy; [2]University of Palermo, Department of Gastroenterology and Hepatology Di.Bi.M.I.S, Palermo, Italy; [3]Department of Pathophysiology and Transplantation, Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan, Italy, Department of Pathophysiology and Transplantation, Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan, Italy, Italy*
Email: anna.fracanzani@unimi.it

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) may progress to advanced fibrosis and exposes patients to high

cardiovascular mortality, independently of other metabolic factors. FibroScan® is a widely used tool to detect both hepatic steatosis and fibrosis, but its role in defining a cardiovascular risk profile is still unexplored. To evaluate if FibroScan® is able to detect NAFLD patients at higher cardiovascular risk.

Method: Four-hundred thirty-three biopsy proven NAFLD were enrolled in two Italian hepatology centres. All patients underwent FibroScan®, carotid Doppler US and echocardiography. Controlled attenuation parameter (CAP) value ≥248 dB/m and liver stiffness measurement (LSM) ≥7.9 kPa defined the presence of steatosis and significant fibrosis, respectively.

Results: Mean age was 50 ± 14 years and 66% patients were males. Prevalence of diabetes was 29%, hypertension 38%, dyslipidemia 54%, 24% of whom on statins. Carotid plaques were present in 45% of patients, mean IMT was 0.8 ± 0.2. Mean epicardial adipose tissue was 7.5 ± 2.5 mm, diastolic dysfunction (E/A < 1) was present in 33%. Only 4% patients reported cardiovascular events. LSM ≥7.9 kPa was present in 195 patients (45%) and at univariate analysis correlated with carotid plaques ($p < 0.001$), IMT ($p = 0.007$), diastolic dysfunction ($p < 0.001$) and cardiovascular events ($p = 0.004$), at multivariate analysis adjusted for confounding factors, LSM ≥7.9 kPa remained independently associated with age (OR 1.055; 95% CI 1.001–1.111), waist circumference (WC) (OR 1.047; 95% CI 1–1.096), plasmatic insulin (OR 1.058; 95% CI 1.005–1.114) and histology stage F2 (OR 4.949; 95% CI 1.858–13.182). CAP ≥248 dB/m at multivariate analysis correlated with severe histology steatosis and inflammation (OR 7.9, 95% CI 1.6–63 and OR 6.4, 95% CI 1.01–126). Differently from fibrosis defined by LSM assessment, histological fibrosis was independently associated with IMT and history of cardiovascular events.

Conclusion: Transient elastography, a non-invasive method for the diagnosis and staging of NAFLD, confirms its association with metabolic parameters, showing a good correlation with histology. Our results indicate that FibroScan® is unable to detect NAFLD patients at higher cardiovascular risk, suggesting a complex and multifactorial underlying scenario predisposes to the cardiovascular disease.

FRI-443
Repeatability and reproducibility of multiparametric magnetic resonance imaging of the liver

H. Wilman, J. Jacobs, R. Newbould, M. Halberstadt, M. Gyngell, A. Herlihy, C. Fernandes, C. Kelly, M. Maguire, N. Jayaratne, S. Linden, K. Groves, V. Bachtiar, A. Mckay, M. Kelly, S. Neubauer, R. Banerjee.
Perspectum Diagnostics, Oxford, United Kingdom
Email: henry.wilman@perspectum-diagnostics.com

Background and Aims: MRI-based technology for quantitative analysis of hepatic fat, T2*, iron corrected T1 (cT1) and MR elastography has considerable utility in NASH clinical trials. To be clinically effective, a measurement should be consistent across sites with good reproducibility. Trout (Radiology 2016; 281:793) evaluated the cross-vendor performance of MRE, and demonstrated a CoV of 10.7%. cT1 has been shown to correlate with fibro-inflammatory disease and predict clinical outcomes. We test the robustness of Liver*MultiScan*-derived metrics across different MRI scanner manufacturers, models, software versions and field strengths.

Method: cT1, T2* and Proton Density Fat Fraction (PDFF) maps were acquired from 61 participants on combinations of three Siemens (1.5T Avanto-Fit, VE11C, MyoMaps; 3T Prisma, VE11C, MyoMaps; 3T Skyra, VE11C, MyoMaps) and two Philips (1.5T Ingenia, 5.3.0, CardiacQuant; 3T Ingenia, 5.3.0, CardiacQuant) scanners. Participants were adult volunteers with mixed liver disease aetiology and those without any history of liver disease to represent a range of physiological values of these metrics. Two acquisition repeats were conducted for each scan, with subjects leaving the scanner in between. Participants were scanned on at least two different scanner models and field strengths in pseudorandomised order with up to 1-week between scans. Standardisation of T1 maps across scanner models and software versions was based on phantom-derived mappings from 90 acquisitions on the above MRI systems. Phantoms were purpose built to span the clinically-relevant range of liver T1s.

Results: Standardised cT1 in participants demonstrated high reproducibility across different scanner models, software versions and field strengths (CoV 3.3%; bias 6.5 ms, 95% LoA of –76.3 ms–89.2 ms). Both T2* (CoV 6.6%; bias –1.7 ms, 95% LoA of –6.6 ms to 3.2 ms) and PDFF measurements (CoV 17%; bias 0.06%, 95% LoA of –0.69%–0.82%) also showed excellent reproducibility at both field strengths and across different scanners models. Bland-Altman analysis of the T1 phantom measurements showed a clear reduction in bias (from –20 ms–4.7 ms), tightening of the 95% Limits of Agreement (LoA: from –59.2 ms – 19 ms, to –25.3 ms – 15.9 ms) and reduction in mean coefficient of variation (CoV: 2.5%–1.0%) after standardisation.

Conclusion: We demonstrate standardised cT1 is a robust metric independent of vendor (Philips or Siemens) and field strength (1.5T or 3T). Combined with the excellent reproducibility of T2* and PDFF, LMS represents a robust and reliable non-invasive tool for characterising liver tissue.

FRI-444
The Community based management of NAFLD Study (COMMANDS): Improved diagnosis and referral using a novel integrated care pathway

L. Burke, B. Williams, G. Abouda, L. Corless. *Hull and East Yorkshire Hospitals*
Email: lynsey.corless@nhs.net

Background and Aims: In the United Kingdom, most non-alcoholic fatty liver disease (NAFLD) is diagnosed after identification of

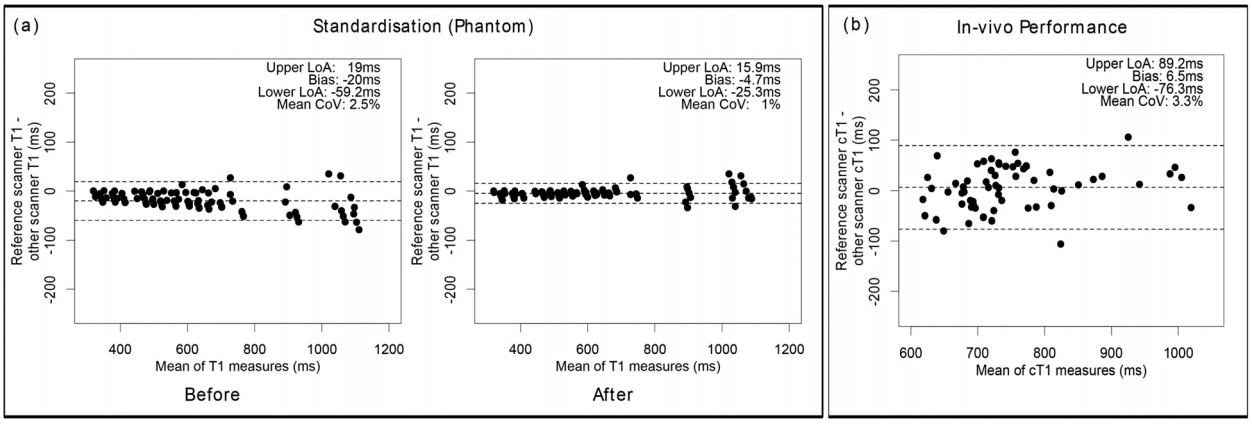


Figure: (abstract: FRI-443): Bland-Altman plots demonstrating **(a)** standardization of T1 in phantoms, and **(b)** reproducibility of *in vivo* cT1 measurements.

abnormal liver function tests (LFT) in primary care (PC), with subsequent referral to liver specialists (LS) for investigation. Despite high prevalence there is currently no standardized community management pathway for those with abnormal LFT and suspected NAFLD. Our previous study showed practice varies extensively leading to both unnecessary referrals and suboptimal identification of high-risk patients with advanced fibrosis requiring LS management. We created an electronic-Integrated Care Pathway (eICP) to support PC through a clear, concise diagnostic and staging process, including evidence-based management and referral advice.

Method: eICP effectiveness was tested against standard care (SC) in a randomised controlled trial in 3 domains: accuracy of diagnosis, adequate risk assessment, and appropriateness of referral decision (keep in PC or refer to LS). Patients with persistently deranged LFT (at least 2x ALT > 70) and suspected NAFLD were randomised by PC practice to either e-ICP or SC management. Enhanced Liver Fibrosis (ELF) testing was used to assess fibrosis severity in the cohort but was not part of standard PC management.

Results: 52 patients (29% female, median age 52 [26–76], median BMI 33 [25–49]) were included (eICP n = 22; SC n = 30). Patients were well matched for BMI, metabolic syndrome features and disease severity (median ELF 8.9 kPa eICP vs. 9.33 kPa SC).

Exclusion of alternate diagnosis was performed in significantly more eICP than SC: ultrasound 100% vs. 57.7%, hepatitis virus serology 86.3% vs. 6.7%, liver antibodies 90.9% vs. 20% and ferritin 100% vs. 23.3% respectively (all $p < 0.005$). This allowed secure PC NAFLD diagnosis in 64% (n = 14) of eICP, with median time from presentation to confirmed diagnosis of 40 days. In contrast due to incomplete investigation, no SC patients had a confirmed diagnosis ($p < 0.005$), including several who were not referred to LS and remained in PC with unexplained abnormal LFT.

Median NAFLD fibrosis score (NFS) was −2.1 [−2.5–−0.33] in the eICP arm. Notably, NFS could not be calculated in any of the SC group, as none had undergone all the required investigations, and therefore PC decision-making could not include fibrosis risk assessment. In the eICP moderate/high risk NFS triggered LS referral advice, which also captured all high risk ELF in the group (n = 4; 18.2%). Conversely, those in SC with high ELF were not identified until the trial team relayed results and advised LS referral (n = 3; 10%).

Conclusion: eICP use was associated with significant improvements in secure NAFLD diagnosis and risk stratification, and supported safe PC NAFLD management or appropriate LS referral. A 5-year prospective observational study of the cohort is underway to track clinical outcomes and factors associated with disease progression.

FRI-445

Enhanced liver fibrosis (ELF) score accurately detects advanced fibrosis in nonalcoholic fatty liver disease (NAFLD)

R.E. Stauber[1], K. Staufer[2], J. Stift[3], R. Marculescu[4], B. Obermayer-Pietsch[5], M. Trauner[6], K. Lackner[5]. *[1]Institute of Pathology, Graz, Austria; [2]Medical University of Vienna, Department of Surgery, Vienna, Austria; [3]Medical University of Vienna, Clinical Institute of Pathology, Vienna, Austria; [4]Medical University of Vienna, Department of Medical and Chemical Laboratory Diagnostics, Vienna, Austria; [5]Medical University of Graz, Department of Internal Medicine, Graz, Austria; [6]Medical University of Vienna, Division of Gastroenterology and Hepatology, Vienna, Austria*
Email: rudolf.stauber@medunigraz.at

Background and Aims: The Enhanced Liver Fibrosis (ELF) test is a noninvasive fibrosis panel composed of hyaluronic acid (HA), procollagen-3 N-terminal peptide (P3NP), and tissue inhibitor of metalloproteinase-1 (TIMP1). Nonalcoholic steatohepatitis (NASH) with advanced fibrosis (F3) or cirrhosis (F4) causes increased liver-related mortality. Noninvasive tests are needed to identify patients with these advanced stages of NASH who are eligible for enrolment in clinical trials. Aim of the present study was to determine the diagnostic accuracy of ELF score for prediction of advanced fibrosis/cirrhosis in non-alcoholic fatty liver disease (NAFLD) with or without NASH.

Method: We enrolled 122 consecutive patients with NAFLD admitted to two Austrian outpatient liver clinics who underwent liver biopsy. Histological NASH was defined as presence of steatosis >5%, hepatocellular ballooning and lobular inflammation. Fibrosis was staged according to the clinical research network (CRN) score. Serum samples obtained at the time of liver biopsy were used to perform ELF test (Siemens Health Care, Vienna, Austria). The predictive value of ELF score for diagnosis of fibrosis stage was assessed by receiver operating characteristic (ROC) analysis and compared to that of FIB-4, a simple fibrosis test based on age, AST, ALT and platelet count.

Results: Our study cohort contained 122 patients with NAFLD. On liver histology, NASH was present in 63 patients (52%) and advanced fibrosis stage (F3–4) in 34 patients (28%). ELF score was significantly higher in fibrosis stages F3-4 vs. F0-2 (10.5 ± 1.5 vs. 8.6 ± 1.3, $p < 0.001$). ROC analysis revealed superior diagnostic accuracy of ELF score (AUROC 0.88 [CI 0.81–0.95]) vs. FIB-4 (AUROC 0.78 [CI 0.68–0.89]) for prediction of fibrosis stage F3-4. At a cut-off of 9.1, ELF score accurately detected or excluded fibrosis stage F3-4 (sensitivity 94%, specificity 75%, PPV 58%, NPV 97%).

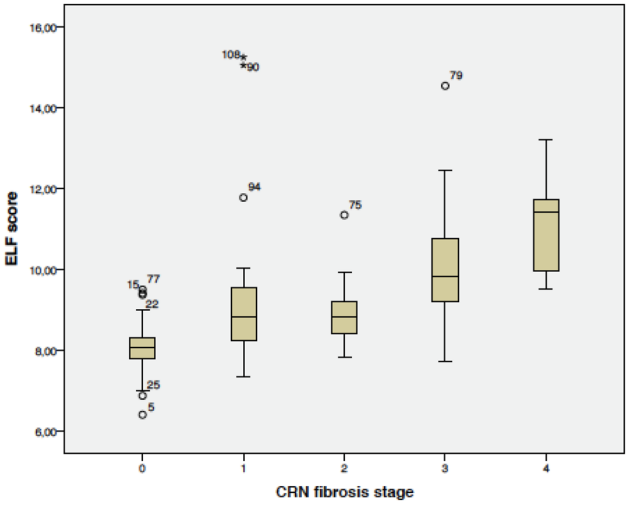

Figure: Boxplot of ELF score by CRN fibrosis stage.

Conclusion: Based on our findings, ELF score shows good diagnostic accuracy for detection or exclusion of advanced fibrosis in NAFLD and thus may be very useful to assess eligibility of NAFLD patients for clinical trials with anti-inflammatory and/or antifibrotic drugs.

FRI-446

Genetic variations of three important anti-oxidative enzymes: SOD2, CAT and CPX1 in non-alcoholic steatohepatitis

Y.-S. Huang. *Taipei Veterans General Hospital, Division of Gastroenterology and Hepatology, Taipei, Taiwan*
Email: yshuang@vghtpe.gov.tw

Background and Aims: Why only part of people under same predisposing factors progress to non-alcoholic steatohepatitis (NASH) remains to be elucidated. Steatosis may increase the reactive oxidative stress (ROS), which has been proposed as one crucial pathogenic factor of NASH. Superoxide anion radical, the main product of ROS, can be reduced by manganese superoxide dismutase (SOD2) to hydrogen peroxide, which is further reduced by catalase (CAT) and glutathione peroxidase (CPX) to water. Functional genetic polymorphisms of these 3 important anti-oxidative enzymes have been found; however, little is known regarding these genetic variants with the risk of NASH. We aimed to investigate the association of genetic variants of SOD2, CAT and CPX1 with the susceptibility to NASH.

Method: 122 adults with liver tissue-verified NASH, 54 patients with liver tissue-proved non-alcoholic fatty liver (NAFL), and 170 healthy controls were enrolled in this study. Their DNAs were retrieved for genotyping SOD2 47T > C (rs4880), CAT −262C > T (rs1001179) and GPX1 593C > T (rs1050450) variation by polymerase chain reaction.
Results: There was statistical difference in the frequency of SOD2 and CAT genotypes among NASH, NAFL and control groups, but there was no difference in CPX1 genotype. The NASH group had higher frequency of subjects with SOD2 C allele than NAFL and control groups had (36.9% vs. 25.9% and 22.9%, p = 0.03). Similarly, the NASH group had higher percentage of CAT T allele than NAFL and control groups had (20.5% vs. 11.1% and 6.5%, p = 0.001). After adjustment for confounders (age, body mass index, DM and hyperlipidemia), the CAT T allele still possessed the higher risk of NASH (OR: 2.57, 95% CI: 1.10–5.97, p = 0.029), followed by SOD2 C allele (OR: 2.10, 95% CI: 1.16–3.81, p = 0.014).
Conclusion: Functional genetic variations of anti-oxidative enzymes CAT −262C > T and SOD2 47T > C may affect the disposition of ROS, and increase the risk of NASH.

FRI-447

Comparison of conventional ultrasound signs to current state-of-the-art MRI method for detection of hepatic steatosis

M.M. Kim[1], D.W. Jun[2], B.-K. Kang[1], Y.C. Joo[3], H. Oh[2], E.C.J. Jang[4], J.H. Sohn[5], J.Y. Jeong[5], S.B. Ahn[6]. *[1]Hanyang University School of Medicine, Department of Radiology; [2]Hanyang University School of Medicine, Department of Internal Medicine; [3]Hanyang University Graduate school of Biomedical Science and Engineering, Department of Translational Medicine; [4]Soonchunhyang University College of Medicine, Department of Occupational and Enviroment Medicine; [5]Hanyang University, College of Medicine, Guri Hospital, Department of Internal Medicine; [6]Eulji university college of medicine, Department of Internal Medicine*
Email: noshin@hanyang.ac.kr

Background and Aims: To compare conventional ultrasound signs with MRI proton density fat fraction (PDFF) for detection of hepatic steatosis (HS) and to determine the diagnostic performance of ultrasound for the grading of HS using recently determined MRI PDFF cut offs.
Method: This study includes 182 patients who simultaneously underwent ultrasound and MRI PDFF between February 2014 and October 2016. Four ultrasound signs (abnormal hepatorenal echo, loss of echogenicity of the portal vein, poor diaphragm visualization, poor diaphragm visualization) were evaluated independently by two radiologists. The hepatic fat fraction is defined as the average of 24 non-overlapping regions of interest (ROIs) obtained by drawing three ROIs within each segment in MRI. The diagnostic performance in assessing the diagnosis and severity of HS was assessed using receiver operating characteristic (ROC) analyses.
Results: A sensitivity of 96.6%, a specificity of 74.8% and a negative predictive value (NPV) of 97.9% were achieved by using abnormal hepatorenal echoes to detect HS with a value of area under the ROC curve (AUROC) of 0.875. Combination of 2 signs (Abnormal hepatorenal echoes and loss of echogenicity of the portal vein) had a sensitivity of 100%, a specificity of 85.9%, and an AUROC of 0.930 in detecting moderate fatty liver. There was a strongly positive correlation between the sonographic findings and hepatic fat fraction (r = 0.754, p < 0.001).
Conclusion: The sensitivity and NPV for the detection of HS with abnormal hepatorenal echo were good and ultrasound is useful screening tool for "rule-out" of HS.

Loomba[14]. *[1]Cedars-Sinai Medical Center, Los Angeles, United States; [2]The Liver Institute at Methodist Dallas, Dallas, United States; [3]Pinnacle Clinical Research, San Antonio, United States; [4]Ruane Medical and Liver Health Institute, Los Angeles, United States; [5]Atlanta Gastroenterology Associates, Atlanta, United States; [6]Texas Liver Institute, University of Texas Health San Antonio, San Antonio, United States; [7]Medical Research Associates Group, San Diego, United States; [8]Indiana University School of Medicine, Indianapolis, United States; [9]Kansas City Gastroenterology and Hepatology, Kansas City, United States; [10]Gilead Sciences, Inc., Foster City, United States; [11]University of California at San Diego, San Diego, United States; [12]University of Chicago, Chicago, United States; [13]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, United States; [14]University of California at San Diego, Division of Gastroenterology, Department of Medicine, San Diego, United States*
Email: rob.myers@gilead.com

Background and Aims: CAP is a quantitative, ultrasound-based measure of hepatic steatosis. Our objectives were to assess the: (1) correlation between CAP and MRI-estimated proton density fat fraction (PDFF), and (2) responsiveness of CAP to change in a clinical trial of subjects with NASH.
Method: CAP (FibroScan; Echosens, France) and MRI-PDFF were measured at baseline (BL) and Week 12 (W12) in a Phase 2, multi-center trial of NASH subjects treated with the acetyl-CoA carboxylase (ACC) inhibitor GS-0976 20 mg, GS-0976 5 mg, or placebo orally once daily for 12 weeks. MRI-PDFF was read centrally and CAP was performed locally where available. A ≥30% relative reduction in MRI-PDFF between BL and W12 was considered clinically significant. Spearman correlations (ρ) were used to evaluate associations between CAP and MRI-PDFF, and changes in MRI-PDFF and CAP by treatment arm were evaluated using Wilcoxon rank-sum and Fisher exact tests.

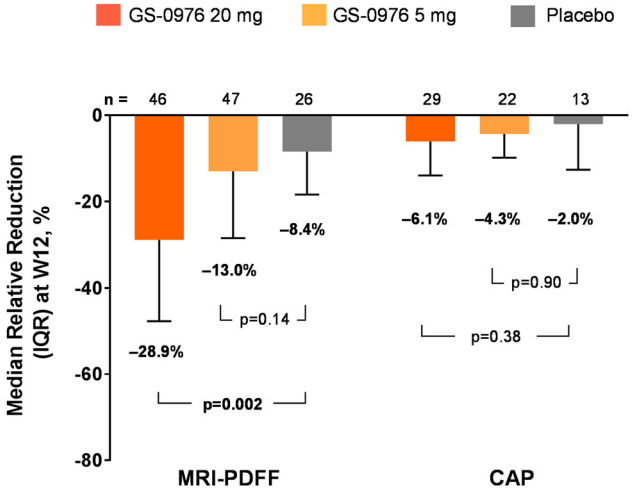

Figure: Relative Changes in MRI-PDFF and CAP between BL and W12.

Results: The majority of subjects were female (65%) and diabetic (60%); median BL MRI-PDFF (n = 126) and CAP (n = 69) were 14.37% (IQR 11.07, 18.98) and 329 dB/m (298, 359), respectively. 52% (72/138) of all CAP measurements were obtained using the FibroScan M probe. Among demographic and BL clinical parameters, CAP was correlated

with body mass index (ρ = 0.32, p = 0.008), waist circumference (ρ = 0.31, p = 0.010), and fasting serum glucose (ρ = 0.24, p = 0.046). CAP and MRI-PDFF were significantly correlated at BL (ρ = 0.29, p = 0.016) and W12 (ρ = 0.32, p = 0.009). However, absolute (ρ = 0.22, p = 0.094) and relative changes (ρ = 0.21, p = 0.096) in CAP and MRI-PDFF between BL and W12 were not significantly correlated. In subjects treated with GS-0976 20 mg daily, a 28.9% median relative reduction in MRI-PDFF was observed between BL and W12 (p = 0.002 vs. placebo); a 13.0% reduction in the 5 mg group was not statistically different from placebo (Figure). Relative reductions in CAP were smaller and did not differ between treatment groups (Figure). Relative reductions ≥30% in MRI-PDFF in the GS-0976 20 mg, GS-0976 5 mg, and placebo groups were observed in 48%, 23%, and 15% of subjects (p = 0.004 vs. GS-0976 20 mg; p = 0.43 vs. GS-0976 5 mg), respectively. Relative CAP reductions ≥30% were observed in 10%, 0%, and 7.7% of subjects, respectively (both p > 0.05 vs. placebo). The median relative change in CAP in 23 MRI-PDFF responders was −7.5% (IQR −14.8, 1.8) compared with −3.0% (−10.8, 9.9) among non-38 responders (p = 0.23).

Conclusion: Among NASH subjects in this multi-center trial of GS-0976, measures of hepatic steatosis quantified by CAP and MRI-PDFF were moderately correlated. However, changes in these parameters were not correlated and CAP was less responsive to change than MRI-PDFF. Further validation of CAP is necessary before it can be considered a valid endpoint for use in clinical trials of interventions for NASH.

A non-invasive biomarker of hepatic inflammation based on magnetic resonance imaging

M. House[1,2], L.L. Lai[3], W.-K. Chan[3], N.R.N. Mustapha[4], A. Vijayananthan[5], S. Mahadeva[3], L. Adams[6], J. Olynyk[7,8], S. Boulos[2], T.S. Pierre[9]. *[1]The University of Western Australia, Physics, Australia; [2]Resonance Health Ltd, Australia; [3]University of Malaya, Gastroenterology and Hepatology Unit, Malaysia; [4]Hospital Sultanah Bahiyah, Department of Pathology, Malaysia; [5]University of Malaya, Department of Biomedical Imaging, Malaysia; [6]The University of Western Australia, Medicine and Pharmacology, Australia; [7]Fiona Stanley Fremantle Hospital Group, Department of Gastroenterology, Australia; [8]Edith Cowan University, School of Medical and Health Sciences, Australia; [9]The University of Western Australia, Physics*
Email: mikeh@resonancehealth.com

Background and Aims: Inflammation and ballooning are pathological hallmarks of non-alcoholic steatohepatitis (NASH), but their detection and the diagnosis of NASH relies on an invasive liver biopsy. The non-invasive detection of inflammation and ballooning would therefore be a significant step in diagnosing, monitoring and treating NASH. In this preliminary study, we report on a magnetic resonance imaging (MRI) approach for identifying patients with mild to severe grades of inflammation and ballooning.

Method: The participants for this research were drawn from two independent studies. The participants in the first study were from Australia (n = 39) and comprised 10 healthy controls with normal body mass index (18.4–24.9) and 29 patients with biopsy-confirmed NAFLD. The participants in the second study were from Malaysia (n = 51) and comprised patients with biopsy-confirmed NAFLD. An identical gradient echo MRI protocol was acquired for both cohorts and a non-invasive imaging biomarker of inflammation (NIIBI) was developed from the images via post-processing. From the histopathologists' grading of the biopsies, an inflammation score (IS) was generated from the sum of the lobular inflammation and ballooning components of the NAFLD activity score (NAS), with the healthy controls assigned an IS of 0. The data from two cohorts were then pooled before dividing participants with no inflammation (IS 0) from those with some inflammation (IS 1–5). The mean difference between the groups was assessed using the Student's t-test. Area under the ROC curve (AUROC) analysis was used to assess the diagnostic potential of the MRI biomarker for predicting inflammation.

Results: There were 28 participants with an IS of 0 (12 female, 16 male) and 62 participants with an IS between 1 and 4 (36 female, 27 male). No participant had an IS score of 5. The mean (standard deviation) NIIBI value was 0.25 (0.23) for the IS 0 group and 0.72 (0.36) for the IS 1-4 group (Figure 1). The difference between the mean NIIBI values of the two groups was statistically significant (p < 0.0001). The AUROC for distinguishing no inflammation from some inflammation was 0.87 (95% CI 0.80–0.95) and the sensitivity and specificity was 81% (95% CI 69% to 90%) and 79% (95% CI 59% to 92%) at an NIIBI cut-off value of 0.43.

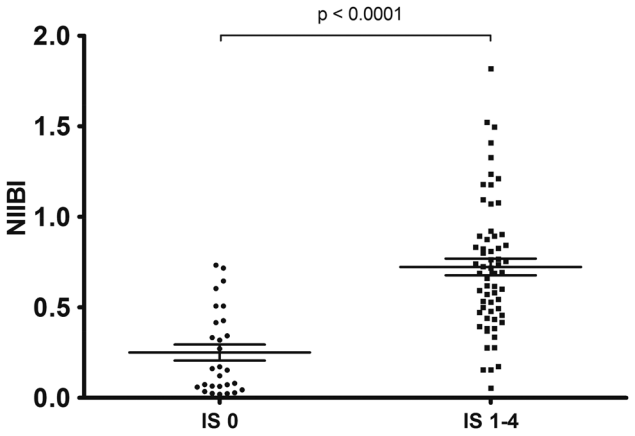

Figure 1 Scatter plot of NIIBI values for the two groups of subjects. The lines through the data are the mean and the standard error on the mean.

Conclusion: A new, rapidly acquired MRI-based parameter has been developed for detecting inflammation and ballooning in the liver. This new measurement tool has the potential to assist in the identification of patients with NASH and to help pre-screen patients for recruitment into NASH clinical trials.

FRI-450

Temporal assessment of the non-invasive fibrosis scores FIB-4 and Non-Alcoholic Fatty Liver Disease Fibrosis Score (NFS) in a retrospective cohort study among patients with Non-Alcoholic Fatty Liver Disease (NAFLD)

M. Pérez-Carreras[1], C. Muñoz Codoceo[1], M.M. Ortega[2], M.R. Castro[1], F.M. Alfonso[1], A.M. Algibez[1], Y.R. Gil[3], G.C. Tortajada[1]. *[1]University Hospital "12 de Octubre". Medicine Faculty. Spain, Epidemiology, Madrid, Spain; [3]University Hospital "12 de Octubre". Medicine Faculty. Complutense University of Madrid. Spain, Pathology, Madrid, Spain*
Email: mpcarreras@salud.madrid.org

Background: FIB-4 and NFS scoring systems have been validated to identify advanced liver fibrosis in patients with NAFLD. However, there are no longitudinal studies that support their usefulness in monitoring this disease.

Aims: To assess the diagnostic performance of both scoring systems in comparison to the liver biopsy (LB) in our setting and to analyze their temporal evolution.

Method: We included those patients who had baseline and follow-up visits at our specialized medical consultation for NAFLD from 1995 through 2016. Data on patient demographics, anthropometrics and metabolic risks, blood test results and fibrosis degree on LB were registered. NFS and FIB-4, their receiver operating curve (ROC) and their area under the curve (AUC) (95% CI) were calculated. Sensitivity (S), Specificity (Sp), Positive Predictive Value (PPV), and Negative Predictive Value (NPV) for the cut-off points (CP) suggested in the

literature were analyzed. According to those CP, the degree of fibrosis was classified as "advanced", "not advanced" or "indeterminate". Five evaluation periods were established: the moment of NAFLD diagnosis, 3–6 years later, 7–10 years later, 11–14 years later and 15 years after the diagnosis.

Results: 109 patients were included, 48% men, mean age 50 ± 12 years. Metabolic factors: 81% were obese (BMI 29.8 ± 5), 31% had diabetes. Histologic diagnosis: 70 patients had an initial LB: 36 (51%) showed fibrosis (F1: 16 patients, F2: 9, F3:7, F4: 4); NFS (62 patients): AUC 0.83 (95% CI: 0.67–0.98). Low CP (−1.455): S 87.5%; Sp 54.1%; PPV 29.2%; NPV 95.2%. High CP (0.676): S 25%; Sp 94.6%; PPV 50%; NPV 85.4%; FIB-4 (98 patients): AUC 0.58 (95% CI: 0.35–0.81). Low CP (1.3): S 80%; Sp 23%, PPV 16.7%, NPV 85.7%. High CP (2.67): S 30%; Sp 82.7%, PPV 25%, NPV 86%; NFS Temporal evolution: 29 patients (46.8%) had a basal NFS <−1.455 (F0-F2, no advanced fibrosis), and only one of them progressed to advanced fibrosis (NFS > 0.676, F3-F4) 11–14 years later. Among the 26 patients (41.9%) that had an initial indeterminate NFS value, 5 (19.2%) progressed to an advanced fibrosis according to NFS value, three of them after 11–14 years and two of them after 15 years of follow-up.

Conclusion: 1. We confirm the diagnostic value of the NFS as a non-invasive scoring system for advanced liver fibrosis, with a better diagnostic performance than FIB-4 in our sample of Spanish NAFLD patients 2. NFS values under −1.455 at diagnosis rarely progress to advanced fibrosis. However, those patients with an indeterminate NFS value at diagnosis seem to have a higher risk of developing an advanced fibrosis. In both cases, the progression was identified after 10 years of follow-up, suggesting this could be the optimal time to perform a LB 3. Our sample size and the number of patients lost during follow-up limit the extrapolation of our results. These should be confirmed in a larger cohort of patients.

FRI-451

In non obese NAFLD increased plasma saturated fatty acids and insulin resistance are metabolic signatures of severity of liver disease

F. Carli[1], M. Gaggini[1], C. Rosso[2], C. Saponaro[1], C. Barbieri[1], V.D. Latta[1], E. Buzzigoli[1], D. Ciociaro[1], M.L. Abate[2], M. Marietti[2], R. Younes[2], E. Bugianesi[2], A. Gastaldelli[1]. *[1]Institute of Clinical Physiology, CNR, Cardiometabolic Risk Unit, Pisa, Italy; [2]Division of Gastroenterology and Hepatology and Lab. of Diabetology, Dept. of Medical Sciences, University of Turin, Turin, Italy*
Email: amalia@ifc.cnr.it

Background and aims: Alterations in lipid metabolism and insulin resistance (IR) are related to the development and progression of NAFLD. Previous lipidomic analyses in morbid obese subjects with NAFLD have found that having a high prevalence of saturated fatty acids (FA) in hepatic triglycerides (TAGs) was related to HOMA-IR and worse histological profile. Given the need of biomarkers of NAFLD, we evaluated if if high plasma saturated FA were associated with Hepatic-IR and Adipose tissue IR and with severity of NAFLD in non obese and mild obese NAFLD.

Methods: In 44 subjects with biopsy proven NAFLD (29 non obese NAFLD-NO and 15 obese NAFLD-Ob, BMI= 25.6 ± 0.5 and 32.4 ± 2.2) and 9 non-obese CT without fatty liver we evaluated TAG composition by LC/MS-QTOF and FFA composition by GC/MS. We measured also several metabolic parameters: IR in adipose tissue (AT-IR = FFA × insulin), liver (Hep-IR = EGP × Insulin where EGP is the hepatic glucose production measured using stable isotope tracers) and HOMA-IR, plasma concentration of Monocyte Chemoattractant Protein-1 (MCP-1), hepatic fat in biopsy; we also calculated the index of de novo lipogenesis (DNL = palmitic/linoleic acid), the ratio of saturated to unsaturated FFAs (SFA/PUFA), SCD-1 activity (palmitoleate/palmitate). We then correlated SFA/PUFA and the percent of unsaturated FA in TAG (determined by the number double bonds, db) with the above measurements. We considered low plasma unsaturated FA if there were less than 2 db in each fatty acyl chain.

Results: Plasma TG (84 ± 8 vs 103 ± 8 mg/dl in CT vs NAFLD) were composed mainly by TAG (85% in both groups). Composition analysis showed that NAFLD-NO had more saturated TAG than NAFLD-Ob. In the whole cohort TAG with more saturated FA (1db and 2db) were associated with increased hepatic fat, DNL-index, SCD-1 activity, SFA/PUFA, MCP-1, AT-IR, HEP-IR and HOMA-IR. For the same analyses we found that TAG with higher % of unsaturated FA were inversely correlated with the above variables (p = 0.0001–0.03) indicating a more favourable profile. Severe fibrosis F3-4 was also associated with presence of more saturated TAG and FFA compared to F0-2 (all p < 0.05).

Table 1: association between % unsaturated FA in plasma TAG and FFA and metabolic profile

	SFA/PUFA	TAG 1db	TAG 2db	TAG 3db	TAG 4db	TAG 5db
Hepatic fat %	0.32	0.53	0.31	−0.49	−0.34	−0.35
DNL index	0.73	0.49	0.29	−0.48	−0.29	−0.30
SCD-1 activity	ns	0.50	0.43	−0.53	−0.48	−0.41
SFA/PUFA	–	0.58	0.30	−0.52	−0.35	−0.33
MCP-1	0.31	0.49	0.29	−0.45	−0.36	−0.36
AT-IR	0.33	0.46	0.24	−0.46	−0.36	−0.29
Hep-IR	0.43	0.51	ns	−0.53	ns	ns
HOMA-IR	0.39	0.48	ns	−0.52	ns	ns

Conclusion: In subjects with NAFLD, plasma composition of TAG and FFA revealed that the presence of saturated TAG is associated with a worse metabolic profile (higher IR) and increased fibrosis especially in non obese NAFLD.

Excess weight has a major impact on hepatic fibrosis by users of psychoactive substance

François Habersetzer[1,2,3], M. Doffoël[1,3], C. Frederic[3], H. Carmen[4], T. Baumert[1,2,3], L.J. Philippe[3], F.D. Nino[3], E. Florence[1,3]. *[1]Pôle Hépato-digestif, Hôpitaux Universitaires de Strasbourg, Strasbourg, France; [2]Unité 1110, INSERM, Strasbourg, France; [3]SELHVA - Service Expert de Lutte contre les Hépatites Virales d'Alsace, Hôpitaux Universitaires de Strasbourg, Strasbourg; [4]SOS Hépatites Alsace Lorraine, SOS Hépatites, Strasbourg, France*
Email: francois.habersetzer@chru-strasbourg.fr

Background and Aims: Excess weight may increase the risk of liver damage in patients addicted to psychoactive substances. This study aimed to investigate the impact of being overweight on hepatic fibrosis among drug users.

Method: Overall 1248 drug users from nine addiction treatment centers were included. Their mean age was 46 years and most of them (75%) were men. In total, 65% of them were addicted to alcohol, 74% to tobacco, 23% to cannabis, 11% to heroin, and 5% to cocaine. All our users were offered to undergo a FibroScan and screening tests for hepatitis B (HBsAg, anti-HBc Ab, and anti-HBs Ab), hepatitis C (HCV Ab), and HIV (HIV−1 and −2 serological screening).
They were then divided into two groups based on their body mass index (BMI): Group A included users whose BMI was <25 Kg/m² and Group B those whose BMI was >25 Kg/m².

Results: Overall, 524 drug users (42%) were overweight (BMI >5). The rates of opioid replacement therapy and addiction to alcohol and cocaine did not differ between the two groups. Addiction to tobacco, cannabis, and heroin, however, was less common in Group B (p < 0.01). Intravenous and intranasal drug abuse along with tattoos were also less common in Group B (p = 0.01). The other risk factors were less common but did not differ significantly between the two groups. Uptake of the FibroScan was 99% in both groups. The failure rate was 2% in Group A and 4.2% in Group B. Significant (F ≥ 2) and severe (F3–F4) fibrosis rates were higher in Group B than in Group A, respectively 31.6% *versus* 16.7% and 22.2% *versus* 10.1%, (p < 0.001). The detection

rates of hepatitis B, hepatitis C, and HIV were lower in Group B; respectively, 83.7% *versus* 89.9% for HBsAg; 86.9% *versus* 93% for HCV Ab; 85.6% *versus* 92.4% for the HIV serological tests, and 54.6% *versus* 62.7% for the three viruses ($p < 0.01$).

Conclusion: Excess weight is common among users of psychoactive substances and leads to increased hepatic fibrosis, with a severe fibrosis rate of more than 20% compared with users who were not overweight.

Email: zobair.younossi@inova.org

Background and Aims: Hepatic fibrosis in NASH can predict liver-related mortality. Phosphoproteomic and MicroRNAs (miRs) technologies can elucidate pathways involved in the pathogenesis of NASH-related fibrosis.

Method: The study included patients with biopsy-proven NAFLD and available liver specimens (N = 66). All liver biopsies were read by the study hepatopathologist. Hepatic % collagen was quantified using Computer Assisted Morphometry (CAM) after Sirius red staining of the liver specimens. Quantitative analysis of phospho-signaling proteins in the hepatic tissue was performed by Reverse Phase Protein Microarrays (RPMA). Using the same liver specimen, HTG EdgeSeq sequencing technology was used to sequence ~2200 miR on NextSeq®500 system. Phosphoproteins and miRNAs independently associated with hepatic % collagen (upper quartile >5.36%) were identified by generalized linear model with adjustment for cofounders. Correlations between predictive miR and phosphoproteins were performed.

Results: Using miR data, hepatic miR-let7c-5p (SE = 0.430, p = <0.001), miR-199a-5p (SE = 0.571, p = <0.001) and miR-6756-3p (SE = 0.209, p = <0.012) were independently associated with increased % hepatic collagen. Using RPMA data, ASK1 S83 (SE = 0.028, p = 0.02), the receptor tyrosine kinase, Met Y1234/1235 (SE = 0.17, p = 0.009), p38-MAPK T180/Y182 (SE = 0.07, p = <0.001), LIMK1T508/LIMK2 T505 (SE = 0.13, p = 0.004) were independently associated with increased % hepatic collagen. There were significant correlations between these phosphoproteins and miRs which were associated with hepatic collagen deposition. In fact, miR-let7c-5p positively correlated with ASK-1 S38 (rho = 0.425, p = <0.001) and p38 MAPK T180/Y182 (rho = 0.379, p = 0.002). Similarly, miR-199a-5p correlated with ASK-1 S38 (rho = 0.481, p = <0.001) and p38 MAPK T180/Y182 (rho = 0.375, p = 0.002). In contrast, miR-6756-3p negatively correlated with ASK1 S83 (rho = –0.409, p < 0.001) and p38 MAPK T180/Y182 (rho = –0.363, p = 0.003); respectively. After controlling for diabetes, gender and BMI, miR-199a-5p remained independently associated with p38 MAPK T180/Y182 (SE = 0.0000, p = 0.046). In fact, miR-199a-5p regulates ASK-1 pathway and targets the tyrosine-protein kinase Met (hepatocyte growth factor receptor (HGFR), which are both key players in development of hepatic fibrosis.

Conclusion: These data suggest that ASK-1 phosphoprotein and miR-199a-5p are associated with increased % hepatic collagen and may serve as promising diagnostic biomarker or treatment targets.

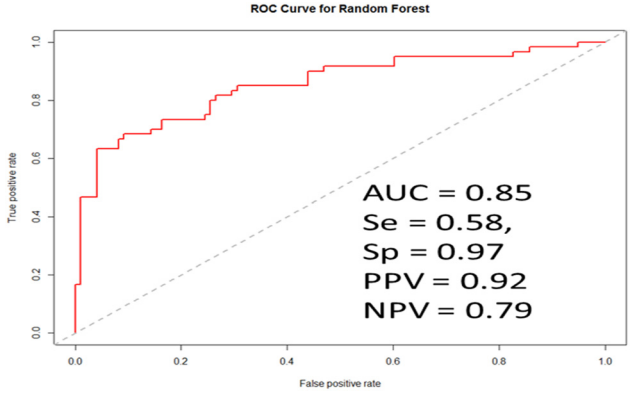
Serum metabolomics analysis to identify boilermakers for advanced fibrosis in NASH patients

Y. Luo[1], E. Charles[1], A. Oseini[2], R. Gagnon[1], P. Shipkova[1], M. Reily[1], K. Daita[2], G. Jarai[1], R. Christian[1], G. Rosen[1], A. Sanyal[2]. *[1]Bristol-Myers Squibb; [2]Viriginia Commonwealth University*
Email: yi.luo@bms.com

Background and Aims: Novel non-invasive biomarkers are needed to identify patients at high risk for NASH. Metabolomics quantifies small molecules in biofluids yielding a comprehensive view of the alterations in metabolic pathways in diseases. Previous studies have identified metabolic signatures discriminating NASH from simple steatosis or healthy control. This study aimed to explore the metabolomics biomarkers of advanced fibrosis (F3/F4) in NASH.

Method: This retrospective study comprised a cohort of 23 NAFLD patients with simple steatosis as non-NASH control and 141 NASH patients diagnosed by histologic assessment of liver biopsy according to NASH CRN criteria. The NASH cohort had fibrosis stages ranging from F0 to F4 and NAFLD Activity Score from 1 to7. Serum was collected within 6 months of liver biopsy and stored at –80°C. Metabolomics analysis was performed by Ultra-high performance liquid chromatography mass spectrometer. The Kruskal-Wallis test with FDR adjusted p-values, exploratory quantile analysis and t-test was used to test for statistically significant differences, Random Forest modeling was used to rank importance, and AUROCs to identify F3/4 were calculated.

Results: Significantly lower levels of dehydroepiandrosterone sulfate (DHEAS), taurine, uracil, and several amino acids were observed in F3/F4 patients. Lower levels of lysophosphatidylcholine and higher levels of unsaturated long chain acylcarnitines, gut microbiomes products (benzoic acid and phenylacetylglycine), as well as conjugated hydrophobic bile acids (glycodeoxycholic acid and glycochenodeoxycholic acid) were observed in F4 patients. By combining metabolomics biomarkers with previously identified collagen biomarkers Pro-C3 and Pro-C6, Random Forest analysis identified a biomarker panel with improved diagnostic performance for identification of advanced fibrosis (AUCROC 0.85, positive predictive value is 0.92, negative predictive value is 0.79) with glutamine, Pro-C3, DHEAS, Pro-C6, taurine and glycodeoxycholic acid the most important markers in the panel.



Conclusion: Metabolomics analysis suggest that advanced fibrosis in NASH patients is associated with altered metabolisms in amino acids, lipids and bile acids. The increase in gut microbiome products in these patients suggest changes in gut microbiomes and possibly intestinal barrier function. A biomarker panel which included Pro-C3, Pro-C6 and metabolites had improved diagnostic performance to identify advanced fibrosis.

FRI-455

Liver and pancreatic steatosis in children are both assosiated with metabolic syndrome but have different influence on insulin sensitivity and glucose metabolism

O. Lukianenko[1], N. Hravirovska, N.H. [2], V. Yagmur[2]. [1]*"Institute of gastroenterology of the National academy of medical sciences of Ukraine", Pediatric gastroenterology department, Dnipro, Ukraine;* [2]*"Institute of gastroenterology of the National academy of medical sciences of Ukraine", Diagnostic department, Dnipro, Ukraine*
Email: sirenkolga@gmail.com

Background and Aims: Children with obesity have high risk for ectopic fat accumulation both in liver and pancreas. It is known that liver steatosis can be independent risk factor for metabolic complications. We still don't have proved data about existence of independent association between metabolic complications and pancreatic fat. Aim of our study was to compare influence of liver and pancreatic steatosis on metabolic complications in children by estimation of the ultrasound attenuation.
Method: We examined 114 children aged 7–17 years, 67 with obesity, 48 without obesity. Anthropometry, lipid spectrum and insulin level with calculation HOMA1-IR and HOMA2-IR indices, oral glucose tolerance tests were assessed using standard techniques. Pancreatic and liver steatosis were diagnosed by ultrasound study (US). Also we estimated liver controlled attenuation parameter (CAP) with usage Fibroscan 502 Touch (France) and pancreatic ultrasound attenuation coefficient (UAC) with usage UltimaPAExpert® (Radmir, Ukraine).
Results: The prevalence of liver steatosis evaluated by ultrasound was 27.3%, pancreatic steatosis – 56.1%. CAP level positively correlated with degree of liver steatosis according to US ($r = 0.59$, $p < 0.05$), also UAC positively correlated with degree of pancreatic steatosis according to US ($r = 0.46$, $p < 0.05$). We found association between CAP and UAC in whole group and nonobese subcohorts. The CAP (233 [193.0; 263.0] dB/m^2) and UAC (2.58 [2.31; 2.75] dB/sm^2) were elevated in subjects with obesity. We found association between UAC and body mass index-standard deviation score (BMI-SDS) in whole group ($r = 0.42$, $p < 0.05$) and obesity subcohort ($r = 0.44$, $p < 0.05$), while no association between CAP and BMI-SDS was found in whole group neither in subcohorts. CAP correlated to fasting glucose level, fasting insulin level, HOMA1-IR and β-cell function (%b) (according to HOMA2-IR) in simple regression; UAC negatively correlated with glucose level 60 min after load in obese subcohort ($r = –0.40$, $p < 0.05$) and insulin sensitivity (%S) (according to HOMA2-IR) ($r = –0.38$, $p < 0.05$). Both CAP and UAC were associated with components of metabolic syndrome (MetS) such as waist circumference, systolic blood pressure. While CAP additionally correlated with level of TG ($r = 0.30$, $p < 0.05$). In nonobese subcohorts both CAP and UAC correlated with LDL and nonHDL level, also UAC negatively correlated with HDL.
Conclusion: In children with obesity, CAP is elevated and associated to MetS, fasting glucose, insulin resistance, beta-cell function, but not to glucose tolerance, or BMI-SDS. While UAC was associated with MetS, BMI-SDS, glucose 60 min after load in oral tolerance test, glucose sensitivity but not to beta-cell function. This study demonstrates that liver and pancreatic steatosis both are associated with MetS but have different influence on glucose metabolism and insulin sensitivity.

Email: clevy@med.miami.edu

Background and Aims: The utility of serum GGT as a surrogate endpoint in clinical trials for PSC is unclear. Our objective was to prospectively validate GGT for the prediction of disease progression in a randomized trial of PSC patients.
Method: We included 234 adults with PSC enrolled in a phase 2b, controlled trial of simtuzumab (SIM). Since SIM was ineffective in this study, treatment groups were combined. GGT was measured at BL and every 12 weeks through this 96-week study. Liver fibrosis was staged according to the Ishak classification (BL, W48 and W96). Cox proportional hazards regression determined associations between BL GGT and change at W12 with PSC-related clinical events (e.g. decompensation, ascending cholangitis, cholangiocarcinoma, liver transplantation). In non-cirrhotic patients at BL, logistic regression determined the association between serum GGT and progression to cirrhosis at W96. Discrimination of GGT was determined based on the area under the receiver operating characteristic (AUROC) curve.
Results: The median age was 45 years, 64% were male, 62% were on UDCA, and the median (IQR) GGT, alkaline phosphatase (ALP), and Enhanced Liver Fibrosis (ELF) scores at BL were 236 U/L (99–524), 260 U/L (129–401), and 9.46 (8.60–10.43), respectively. 40% (n = 94) of subjects had bridging fibrosis and 11% (n = 25) had cirrhosis. At BL, GGT was significantly correlated with ALP (Spearman $\rho = 0.80$), bilirubin ($\rho = 0.34$), ELF score ($\rho = 0.42$), and fibrosis stage ($\rho = 0.36$; all $p < 0.001$). By W96, 47 patients (20%) developed a PSC-related clinical event (ascending cholangitis [n = 27], jaundice [n = 10], cholangiocarcinoma [n = 3], ascites [n = 2], encephalopathy [n = 2], variceal hemorrhage [n = 2], sepsis [n = 1]) and 30/191 biopsied subjects (16%) progressed to cirrhosis. Median BL GGT was higher in patients with than without an event (430 [IQR 212–730] vs. 188 U/L [75–482]; $p < 0.001$), whereas median change in GGT at W12 was lower in patients with an event (-28 [IQR -100, 17] vs. 1 U/L [-23, 35; $p = 0.003$). The risk of clinical events increased with higher BL GGT (HR per 10-U/L: 1.007; 95% CI 1.001–1.013; $p = 0.015$), but change in GGT at W12 was not significant (HR per 10-U/L: 0.981; 0.962–1.001; $p = 0.065$) after adjustment for BL GGT. The AUROC for BL GGT to predict clinical events was 0.67 (95% CI 0.59–0.75). After adjustment for BL serum ALP, bilirubin, ELF, and fibrosis stage, GGT was not associated with PSC-related events (HR per 10-U/L: 0.995; 95% CI 0.985–1.006; $p = 0.37$). Progression to cirrhosis was not associated with GGT at BL or its change at W12.
Conclusion: In the clinical trial setting, serum GGT levels are not associated with PSC-related disease progression after adjustment for other prognostic factors. Based on these data, GGT cannot be considered a validated surrogate endpoint for use in clinical trials of this condition.

FRI-457

Metabolomics in the progression of fatty liver disease

J. Troisi[1,2], M. Masarone[1], R. Caruso[1], M. Persico[1]. [1]*University of Salerno, Department of Medicine and Surgery - Internal Medicine and Hepatology Division, Baronissi (Salerno), Italy;* [2]*Theoreosrl – Spin-off company of the University of Salerno, Salerno, Italy*
Email: mario.masarone@gmail.com

Background and Aims: Non-Alcoholic Fatty Liver Disease (NAFLD) encompasses a wide spectrum of diseases that range from simple steatosis (NAFL) to steatosis with inflammation and fibrosis (namely Non-Alcoholic Steato-Hepatits or NASH) up to cirrhosis and

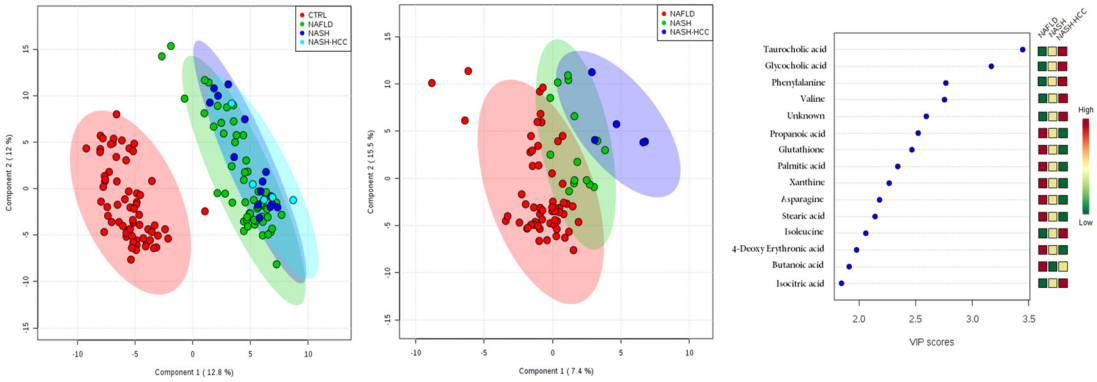

Figure 1: (abstract: 457)

hepatocellular carcinoma (HCC). The greatest challenge in this field is to recognize the patient with a more severe and/or progressive pathology. A reliable non-invasive method based on biomarkers does not exist. Metabolomics is a novel and powerful method to discover biomarkers and gives insights on diseases pathophysiology. Few studies have applied this technique to NAFLD patients.

Aims: to apply metabolomics to understand if simple steatosis, steatohepatitis and hepatocellular carcinoma occurred in NAFLD patients have a peculiar metabolites profile that can differentiate them among each other's and from healthy controls.

Method: Metabolomics signatures were obtained by means of mass spectrometry gas chromatography from 78 NAFLD patients, of whom 58 were diagnosed by liver biopsy (42 simple steatosis, 16 NASH) and 20 by clinical, instrumental and laboratory signs (15 NASH-cirrhosis, 5 NASH-HCC), and 67 age and sex matched healthy controls from a local blood bank.

Results: A statistical analysis with the "Partial Least Square Discriminant Analysis" (PLS-DA) was used to reveal class separation in metabolomics profiles between patients and controls and among each class of NAFLD, and to reveal the metabolites principally contributing to class differentiation. PLS-DA score plot showed a significant differentiation between NAFLD patients and controls (R^2 = 0.822, Q^2 = 0.743, $p < 0.001$), and also among the various clinical presentations of NAFLD (R^2 = 0.782, Q^2 = 0.698, $p < 0.05$). In particular: Glycocholic acid, Taurocholic acid, Phenylalanine, branched-chain amino acids increased at the increase of the severity of the disease from simple steatosis to NASH, NASH-cirrhosis and HCC, while glutathione decreased (ANOVA multiple comparisons with Tukey HSD correction $p < 0.001$ for each).

Conclusion: These preliminary results suggest that metabolomics profiles of NAFLD patients could be a useful tool to non-invasively diagnose NAFLD, discriminate among the various stages of the disease and give other insights into the pathophysiology of NAFLD.

FRI-458

Comparison of HepaFat-Scan and controlled attenuation parameter for the estimation of hepatic steatosis in patients with non-alcoholic fatty liver disease using histology as the reference standard

Email: wahkheong2003@hotmail.com

Background and Aims: We aimed to compare HepaFat-Scan, an MRI-based technology for the measurement of liver fat, with Fibroscan controlled attenuation parameter (CAP) for the estimation of hepatic steatosis in patients with non-alcoholic fatty liver disease (NAFLD).

Method: Consecutive NAFLD patients who underwent liver biopsy at the University of Malaya Medical Centre were enrolled in this study, and had MRI and Fibroscan examinations on the same day. Histopathological examination of liver biopsy specimen was performed by a single expert pathologist who was blinded to clinical data and reported according to Non-alcoholic Steatohepatitis Clinical Research Network scoring system. Area under receiver operating characteristic curve (AUROC) was used to evaluate the diagnostic accuracy of HepaFat-Scan and CAP for the estimation of hepatic steatosis using liver histology as the reference standard.

Results: Data for 72 patients were analyzed (mean age 58.3 ± 9.8 years, males 45.8%, mean body mass index 29.9 ± 4.0 kg per m^2, central obesity 95.8%). The distribution of steatosis grades was as follows: S1, 33%; S2, 57% and S3, 10%. The AUROC (95% confidence interval), sensitivity, specificity, positive predictive value and negative predictive value of HepaFat-Scan and CAP for the diagnosis of steatosis grades ≥ S2 and S3 using previously validated cut-offs are shown in Table 1.

Table 1: The AUROC (95% confidence interval), sensitivity, specificity, positive predictive value and negative predictive value of HepaFat-Scan and CAP for the diagnosis of steatosis grades ≥ S2 and S3 using previously validated cut-offs.

	≥S2	S3
HepaFat-Scan		
AUROC (95% confidence interval) (0.74–0.93)	0.90 (0.80–0.96)	0.85
Optimal cut-off, %	12.08	16.23
Sensitivity, %	84.1	27.3
Specificity, %	81.8	72.9
Positive predictive value, %	90.2	27.3
Negative predictive value, %	72.0	97.7
Controlled attenuation parameter		
AUROC (95% confidence interval) (0.47–0.71)	0.71 (0.58–0.81)	0.60
Optimal cut-off, dB/m	268	280
Sensitivity, %	95.6	100
Specificity, %	18.2	15.1
Positive predictive value, %	70.5	12.1
Negative predictive value, %	66.7	100
p for comparison of AUROC of HepaFat-Scan and controlled attenuation parameter	0.016	0.019

Conclusion: The HepaFat-Scan has higher accuracy for the estimation of hepatic steatosis in NAFLD patients compared with the CAP.

FRI-459

Measuring what matters to patients: the development of the NASH-CHECK, a new patient-reported outcome instrument for nonalcoholic steatohepatitis

L. Doward[1], M.M. Balp[2], J. Twiss[1], C. Slota[3], D. Cryer[4], A. Langford[5], R. Collen[6], N. Agashivala[7], C. Brass[7], Q. Anstee[8], A. Sanyal[6]. *[1]RTI-Health Solutions, Patient-Centered Outcomes Assessment, Manchester, United Kingdom; [2]Novartis Pharma Ag, HEOR, Basel, Switzerland; [3]RTI-Health Solutions, Patient-Centered Outcomes Assessment, Research Triangle Park, United States; [4]Global Liver Institute, Washington DC, United States; [5]British Liver Trust, Bournemouth, United Kingdom; [6]Virginia Commonwealth Univertsity, Medical College of Virginia, Richmond, United States; [7]Novartis Pharmaceuticals Corporation, East Hanover; [8]Newcastle University, Newcastle, United Kingdom*
Email: ldoward@rti.org

Background and Aims: Nonalcoholic steatohepatitis (NASH) is a progressive form of fatty liver disease characterized by excessive liver fat accumulation, inflammation, cell injury and fibrosis. Aim was to develop a NASH-specific patient-reported outcome (PRO) measure (NASH-CHECK) suitable for clinical practice and clinical trials with NASH patients.
Method: A NASH conceptual model was developed based on review of published/grey literature, social media patient narratives and medical/patient expert (US/UK) review. The model guided concept elicitation (CE) interviews with NASH patients recruited via a tertiary care centre (USA). NASH-CHECK content was generated via thematic analysis of CE data and review by clinical experts and patient representatives. Cognitive debriefing (CD) interviews evaluated NASH-CHECK content validity.
Results: Literature/social media review confirmed that NASH profoundly impacts patient functioning and health-related-quality-of-life (HRQOL). 23CE/15CD interviews were conducted. CE sample: 18 females; mean age = 55.9(31.0–73.0 yrs); biopsy-diagnosed NASH = 11(F1 = 1; F2 = 5; F3 = 10); mean yrs since diagnosis = 3.9; mean BMI = 36.4(26.1–43.3). CD sample: 7 females; mean age = 53.6 (31.0–68.0 yrs); biopsy-diagnosed NASH = 11[F1 = 3; F2 = 2; F3 = 6]; mean yrs since diagnosis = 3.2; mean BMI = 36.4(26.1–43.3). No patients had evidence of hepatic decompensation. CE interviews: key symptoms reported included pain in upper right abdomen (n = 14), fatigue (n = 18), poor sleep quality (n = 12), and cognition problems (impaired memory [n = 13; reduced focus [n = 11]); key HRQOL impacts included impaired physical functioning (reduced capacity to walk short distances), ability to conduct daily living tasks (e.g. household chores/personal care), reduced quality of relationships (e.g. pain/fatigue limited willingness/ability to engage in social activities), low mood, anxiety and self-consciousness. The 1st draft NASH-CHECK included 52 items including some duplication to allow patient-selection of preferred phrasing. CE interviews reduced NASH-CHECK to 31-items based on patient preferences for item relevance, acceptability and comprehension. The final version was considered relevant and acceptable to the CD patients.
Conclusion: The study was successful in producing a US English NASH-specific PRO measure assessing symptoms and HRQOL (NASH-CHECK) suitable for psychometric evaluation. Further work is underway to translate and validate this tool in UK and other European territories.

Spatial systems lipidomics reveals nonalcoholic fatty liver disease heterogeneity

K. Scupakova[1], Z. Soons[2], G. Ertaylan[3], K.A. Pierzchalski[1], G.B. Eijkel[1], S.R. Ellis[1], J.W. Greve[4], A. Driessen[5], T.M De Kok[6], S. Rensen[2], S.O. Damink[7], R.M.A. Heeren[8]. *[1]Maastricht University, M4I Institute, Maastricht, Netherlands; [2]Maastricht University, Department of Surgery, Maastricht; [3]Maastricht University, The Maastricht Centre for Systems Biology, Maastricht, Netherlands; [4]Zuyderland Medical Center, Department of Surgery, Heerlen, Netherlands; [5]Maastricht University, Department of Pathology, Maastricht, Netherlands; [6]Maastricht University, Department of Toxicogenomics, Maastricht, Netherlands; [7]Maastricht University Medical Centre, Maastricht University Medical Center, Maastricht, Netherlands; [8]M4I Institute, M4I Institute, Maastricht, Netherlands*
Email: k.scupakova@maastrichtuniversity.nl

Background and Aims: Hepatocellular lipid accumulation is the hallmark of nonalcoholic fatty liver disease. However, the types of lipids associated with disease progression are debated, as is the impact of their localization. Traditional lipidomics analysis using liver homogenates or plasma dilutes and averages lipid concentrations, and does not provide spatial information about lipid distribution. We aimed to characterize the distribution of specific lipid species in relation to fatty liver disease severity by performing label-free molecular analysis by mass spectrometry imaging (MSI).
Method: Fresh frozen liver wedge biopsies from severely obese subjects undergoing bariatric surgery (n = 23) with various degrees of nonalcoholic fatty liver disease were cryosectioned and analyzed by matrix-assisted laser desorption/ionization (MALDI)-MSI. Molecular

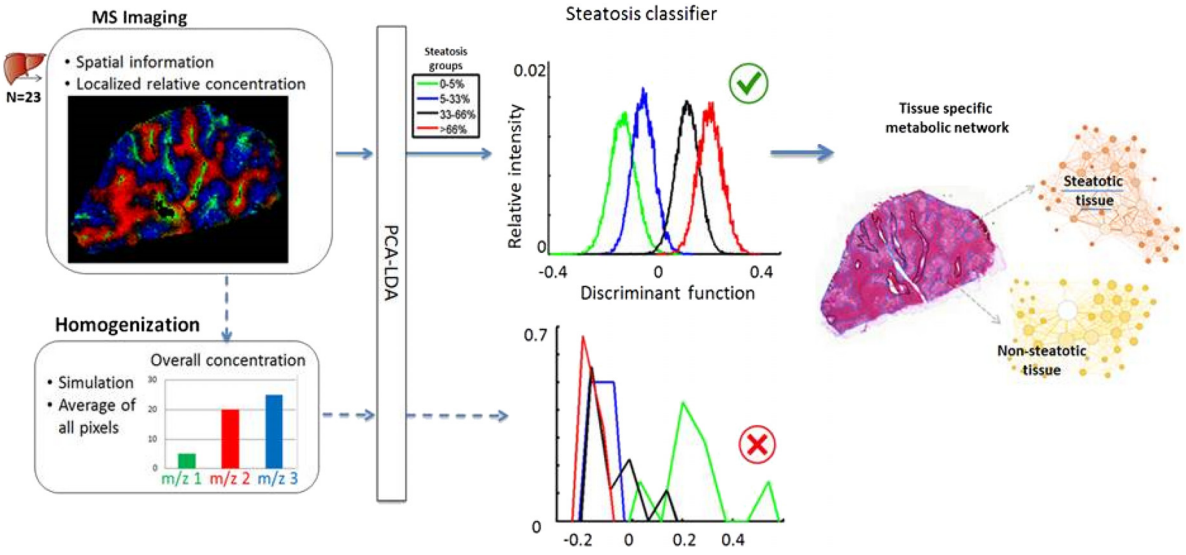

Figure 1: (abstract: 460)

identification was verified by tandem MS. Tissue sections were histopathologically stained and annotated according to the Kleiner classification before co-registration with the MSI dataset. Lipid pathway analysis was performed and linked to local proteome networks.

Results: Spatially resolved lipid profiles showed pronounced differences between non-steatotic and steatotic tissues. Lipid identification and network analyses revealed phosphatidylinositols and arachidonic acid metabolism in non-steatotic regions, whereas (very) low–density lipoprotein (LDL) and VLDL metabolism was associated with steatotic tissue regions. Supervised and unsupervised discriminant analysis using lipid based classifiers outperformed simulated analysis of liver tissue homogenates in predicting steatosis severity.

Conclusion: We conclude that lipid composition of steatotic tissue and non-steatotic tissue is highly distinct, implying that spatial context is important for understanding the mechanisms of lipid accumulation in nonalcoholic fatty liver disease. MSI combined with principal component – linear discriminant analysis linking lipid and protein pathways represents a novel tool that enables detailed and comprehensive studies of the heterogeneous nature of nonalcoholic fatty liver disease.

Validation of a quantitative imaging assessment biomarker metric for MRI-estimated proton density fat fraction in a large multi-center clinical trial

M. Middleton[1], W. Henderson[1], J. Cui[1], A. Mamidipalli[1], R. Myers[2], S. Djedjos[2], C. Yeaton[2], B. Mccolgan[2], R. Loomba[3], C. Sirlin[4]. *[1]Liver Imaging Group, Department of Radiology, San Diego, United States; [2]Gilead Sciences Inc., Liver Diseases Therapeutic Area, Foster City, United States; [3]UCSD School of Medicine, Department of Gastroenterology, La Jolla, United States; [4]Liver Imaging Group, Department of Radiology, La Jolla, United States*
Email: msm@ucsd.edu

Background and Aims: Drug development clinical trials increasingly rely on quantitative imaging biomarkers to support study aims. In addition to rigorous imaging intake quality control and site qualification, there is also a need to determine whether individual analyses are acceptable. For a 29-site clinical trial in adults with nonalcoholic steatohepatitis (NASH) and fibrosis stages F2-F3 (Gilead Sciences, GS-1497; NCT02466516), in a retrospective analysis we found that using a per-segment coefficient of determination (r^2; a measure of goodness of least-squares fitting to estimate proton density fat fraction [PDFF] values) cutoff value of 0.985 resulted in exclusion of 1–6 (of 9) segments per MRI in 54/204 MRIs, with no loss of reportable results (Middleton et al, AASLD poster # 2110, Washington D.C., October 20–24, 2017). We now need to validate that result in a separate, independent cohort. Thus, the aim of this analysis was to validate that there is minimal or no loss of reportable results using a PDFF-fitting r^2 cutoff value of 0.985 in an independent, multi-center study of adults with inferred NASH (PDFF ≥ 8%, MRE liver stiffness ≥ 2.5 kPa), or with biopsy-determined NASH (Gilead Sciences, GS-3989; NCT02856555).

Method: For each of the 424 study MRIs obtained across 40 study sites, ROIs were placed in each of the nine Couinaud liver segments for images acquired from a magnitude six-echo gradient-echo PDFF-estimation MRI sequence. To compare to the prior study, segmental data was deemed adequate if the r^2 value was ≥ 0.985. MRI PDFF values were calculated as the mean of PDFF values of all adequately analyzed segments. An MRI PDFF value was considered analyzable if three or more of the nine segmental PDFF values were deemed adequate.

Results: For the 414/424 (97.6%) MRIs where the correct PDFF sequence was acquired and ROIs were placed in all 9 segments, using an r^2 value of 0.985 we found that all but 2 MRIs were deemed analyzable. 129/414 (31.2%) of those MRIs showed segmental inadequacy in 1–6 segments (for those cases, there were 2.13 ± 1.52 inadequate segments/MRI, compared to 2.07 ± 1.41 inadequate segments/MRI for the prior analysis). One additional MRI in this analysis would have been marginally analyzable if the cutoff was 0.982, and one MRI was not analyzable under any circumstances. Excluding those 2 cases, the mean PDFF value of those 129 MRIs was 0.05% higher using the r^2 = 0.985 cutoff, than using no cutoff; which is not clinically meaningful.

Conclusion: This study validates in an independent study that setting a conservative, high r^2 cutoff value of 0.985 for MRI-exam PDFF analyzability to exclude segmental analyses of lesser quality can be accomplished in a large multi-center clinical trial setting without appreciable loss of reportable results. Further work is needed to determine the effect of using an r^2 cutoff on PDFF accuracy, repeatability, and reproducibility.

FRI-462

FIBROSpect®NASH serum test identifies advanced liver fibrosis in patients with nonalcoholic steatohepatitis: Results of a validation study

M. Abdelmalek[1], C. Guy[1], A.M. Diehl[1], X. LI[2], L. Mimms[2], K. Hester[2], A. Jain[2], R. Loomba[3]. *[1]Duke University, Division of Gastroenterology, Durham; [2]Prometheus Laboratories Inc., Research & Development, San Diego, United States; [3]University of California at San Diego, Division of Gastroenterology, San Diego, United States*
Email: roloomba@ucsd.edu

Background and Aims: In patients with nonalcoholic steatohepatitis (NASH), advanced (stage 3–4) hepatic fibrosis is the primary predictor for liver-related morbidity and mortality. FIBRO*Spect* NASH (Prometheus Laboratories Inc., San Diego, CA) has been developed as a potential non-invasive serum blood test to risk-stratify patients with NASH. The aim of this study was to validate the diagnostic performance of FIBRO*Spect* NASH in a second independent cohort of patients with biopsy-proven NASH.

Method: In a cohort of patients with biopsy-proven NASH (n = 396), results of FIBRO*Spect* NASH were trained against fibrosis stage (as defined by NASH CRN criteria) using serum acquired on the same day as liver biopsy. A logistic regression model was developed using concentrations of three serum biomarkers (alpha2-macroglobulin, hyaluronic acid and tissue inhibitor of metalloproteinase-1). The FIBRO*Spect* NASH test was validated in a combined independent cohort (n = 640) of patients with biopsy-proven NASH obtained from two geographically distinct locations.

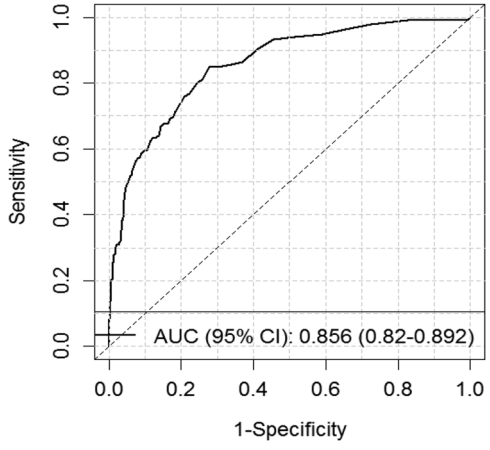

Figure 1: ROC Curve of F0-F2 vs. F3-F4 in Validation Cohort of NASH patients

Results: The mean age of the 640 patients was 49.6 ± 12.8 years and 39% were of male gender. The distribution of fibrosis stages 0, 1, 2, 3, and 4 was 209 (33%), 168 (26%), 130 (20%), 115 (18%) and 18 (3%), respectively. The prevalence of advanced hepatic fibrosis (F3/F4) of 21% in this cohort was comparable to the reported literature. The

model had an AUROC of 0.86 (95% CI: 0.82–0.89) (Figure 1). Sensitivity and specificity for identifying NASH patients with advanced hepatic fibrosis was 80% (95% CI: 72–86%) and 76% (95% CI: 72–79%), respectively.
Conclusion: FIBRO*Spect* NASH test proves to have robust performance when validated in an independent cohort of patients with biopsy-proven NASH. FIBRO*Spect* NASH can non-invasively identify those NASH patients with advanced hepatic fibrosis.

FRI-463
The association of circulating microRNAs (miRs) with liver fibrosis stage and the impact of selonsertib treatment in patients with NASH

M. Charlton[1], A.M. Diehl[2], N. Sarkar[3], B. Li[3], L. Wang[3], A. Billin[3], S. Djedjos[3], M. Subramanian[3], R. Myers[3], N. Afdhal[4], S. Caldwell[5], Z. Goodman[6], R. Loomba[7]. *[1]University of Chicago, Chicago, United States; [2]Duke Clinical Research Institute, Durham, United States; [3]Gilead Sciences, Foster City, United States; [4]Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, United States; [5]University of Virginia, Charlottesville, United States; [6]Inova Fairfax Hospital, Falls Church, United States; [7]University of California at San Diego, Division of Gastroenterology, Department of Medicine, San Diego, United States*
Email: stephen.djedjos@gilead.com

Background and Aims: Circulating miRs have been studied as potential biomarkers of NASH. We assessed: 1) associations between miRs and liver fibrosis and 2) the modulation of miR expression in response to selonsertib (SEL) treatment in patients with NASH enrolled in a Phase 2 trial.
Method: Plasma samples were collected from 72 subjects with biopsy-confirmed NASH (NASH CRN F2-3 fibrosis and NAFLD Activity Score [NAS] ≥5). Subjects were treated with SEL alone or in combination with simtuzumab (SIM) or SIM alone for 24 weeks. Liver biopsies were performed at baseline (BL) and week 24 (W24). Selected miRs (n = 301) were measured at BL, W12, and W24 by qPCR. Differential expression analysis using the Linear Models for Microarray Data (limma) method and Spearman correlations (r_s) were performed. The utility of miRs alone or in combination with other markers to discriminate advanced fibrosis (F3-4 vs. F1-2) or fibrosis response (≥1-stage reduction in fibrosis vs. no improvement at W24 vs. BL) was determined using areas under receiver operating characteristics (AUROC) curves.

Top 10 miRs associated with fibrosis stage F1-2 vs F3-4 at W24				Top 10 miRs with change in expression correlated with change in fibrosis stage at W24		
miRs	Fold Change (F3-4 vs F1-2)	AUROC	p-value	miRs	r_s	p-value
miR-125b-5p	1.45	0.71	0.01	miR-365a-3p	0.35	0.009
miR-29a-3p	1.27	0.71	0.01	miR-125b-5p	0.33	0.013
miR-136-5p	−2.08	0.69	0.01	miR-34a-5p	0.33	0.014
miR-30a-5p	1.37	0.67	0.02	miR-215-5p	0.30	0.025
miR-29c-3p	1.23	0.67	0.02	miR-194-5p	0.30	0.025
miR-378a-3p	1.30	0.67	0.03	miR-378a-3p	0.30	0.025
miR-34a-5p	1.60	0.66	0.03	miR-99a-5p	0.30	0.027
miR-99a-5p	1.35	0.65	0.04	miR-1260b	−0.39	0.006
miR-150-5p	1.46	0.64	0.04	let-7i-5p	−0.30	0.025
miR-375	1.46	0.63	0.05	miR-122	0.29	0.028

Results: At BL, miR-136-5p was 1.58 fold lower in patients with F2 compared to F3 fibrosis (p = 0.046). At W24, 10 miRs, including miR-136-5p, showed modest AUROCs (0.63–0.71) for distinguishing patients with advanced vs. mild fibrosis (F3-4 vs. F1-2; Table). Changes in expression of 12 miRs from BL to W24 were significantly correlated with change in fibrosis stage (all p < 0.05; Table). Expression of miR-136-5p alone or with CK18-M30 and MRE at W24 most accurately distinguished fibrosis responders from non-responders with AUROCs of 0.73 (95% CI 0.58, 0.89) and 0.89 (95% CI 0.79, 0.98), respectively. Twelve miRs were modulated by SEL treatment. Among them, miR-122-5p, miR-215-5p, miR-505-3p, miR-885-5p, and miR-34a-5p were down-regulated by SEL treatment with miR-885-5p having the largest fold change of −1.56 (p = 0.005).
Conclusion: In this Phase 2 trial, we identified a panel of miRs associated with hepatic fibrosis and changes in fibrosis following SEL treatment. The accuracy of a miR to determine fibrosis response was enhanced when combined with other biomarkers. These observations require validation in future studies.

ELF test in NAFLD: Poor concordance with liver stiffness values

L.I. Prat, M. Guerrero, E. Buzzetti, D. Roccarina, A. Goyale, M. Ismail, E. Tsochatzis. *UCL Institute for Liver and Digestive Health, Sheila Sherlock Liver Centre, Royal Free Hospital, London, United Kingdom*
Email: laura.iognaprat@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the leading cause for secondary care referrals in most western countries. Despite its high prevalence, only a minority of patients develops fibrosis and subsequent liver-related outcomes. The ELF test is a validated tool for non-invasive assessment of liver fibrosis and is recommended by the National Institute for Clinical Excellence (NICE) in the UK for screening NAFLD patients for advanced fibrosis. We explored the concordance of ELF with FibroScan and its diagnostic accuracy compared to liver biopsy in consecutive patients referred because of a high ELF score.
Method: We selected all patients who had been referred from 2014 to 2017 according to local referral pathways because of a suspicion of NAFLD and an ELF test ≥9.5. Clinical and laboratory data were collected. ELF test was compared to liver biopsy and/or liver stiffness assessed with FibroScan™.
Results: 170 patients fulfilled our inclusion criteria. Characteristics of the population were: 52% male, mean age 65 ± 10 years, mean BMI 32 ± 6 Kg/m^2, 49% T2DM, 69% dyslipidaemia, 69% hypertension. Liver biopsy was available for 56 (33%) patients and FibroScan™ measurements for 117 (69%) patients. 16 (28%) liver biopsies showed advanced fibrosis and 40 (70%) showed NASH. Liver stiffness values were <10 kPa in 95 (81%) of patients, <8 kPa in 85 (73%) and <6 kPa in 58 (50%). Therefore, the concordance of FibroScan and ELF for significant fibrosis was 19% and there was also a significant discordance in 50% of the cases. Based on biopsy confirmation of advanced fibrosis, the positive predictive value of ELF > 9.5 was 32%. Thirty-four patients with a high ELF score had no or minimal fibrosis (F0-F1) on liver biopsy; only three and one of these patients had FibroScan values above 8 kPa and 10 kPa respectively. All patients with biopsy proven advanced fibrosis had FibroScan values >8 kPa. We could not find independent predictors of a false positive ELF test.
Conclusion: The ELF test has a poor concordance with liver stiffness for the diagnosis of advanced fibrosis. When ELF is used as a screening tool, the use of a second non-invasive test is warranted for positive results, in order to better stratify patients needing a liver biopsy.

Aetiology and severity of liver disease in HIV positive patients with suspected NAFLD: Lessons from a cohort with available liver biopsies

L.I. Prat[2], D. Roccarina[2], R. Lever[3], A. Rodger[3], A. Hall[4], S. Bhagani[5], E. Tsochatzis[2]. *[1]UCL Institute for Liver and Digestive Health, Royal Free Hospital, London, United Kingdom; [2]UCL Institute for Liver and Digestive Health, Sheila Sherlock Liver Centre, Royal Free Hospital, London, United Kingdom; [3]Infectious Diseases/HIV Medicine, Royal Free Hospital, London, United Kingdom; [4]UCL Institute for Liver and Digestive Health, Cellular Pathology, Royal Free Hospital, London, United Kingdom;*

[5]*Infectious Diseases/HIV Medicine, Royal Free Hospital, London, United kingdom*
Email: l.prat@ucl.ac.uk

Background and Aims: The spectrum of liver injury among HIV positive people is variable; in particular non alcoholic fatty liver disease (NAFLD) seems to occur at a higher prevalence among HIV positive people compared to HIV negative. We retrospectively evaluated the aetiology and severity of liver disease in a group of HIV positive patients without viral hepatitis co-infection and with available liver biopsies. We further estimated the accuracy of two non-invasive tools (FIB4 and elastography) for the assessment of liver fibrosis.
Method: We evaluated all liver biopsies performed at Royal Free Hospital from 2000 to 2017 in HIV positive patients with abnormal transaminases. Exclusion criteria were: known viral hepatitis, opportunistic infections, liver malignancy, lack of sufficient clinical data or suboptimal histological samples. Clinical data were collected and FIB4 was calculated for every patient. Liver stiffness was assessed with FibroScan™.
Results: 97 biopsies fulfilled our criteria. Characteristics of the population were: 81% male, mean BMI 27 Kg/m^2, 11% diabetes, 47% dyslipidaemia. Median duration of HIV infection at time of biopsy was 126 months and 90% had undetectable viral load. The most common histological findings were in keeping with NAFLD (28%) and non specific changes (28%) followed by normal histological findings (13%). 19 (20%) patients had significant fibrosis and 11 (11%) had advanced fibrosis. The prevalence of FIB4 < 1.3, 1.3–2.67 and >2.67 were 38%, 46% and 16% respectively. The 1.3 FIB4 cut-off had a specificity of 82% and NPV of 95% for exclusion of advanced fibrosis. Fibroscan was available in 27 (28%) patients and 33% had a liver stiffness ≥ 7.5 kPa. Fibroscan showed a sensitivity of 80%, specificity of 77% and NPV of 94% for exclusion of significant fibrosis. Among patients with NAFLD (n = 27), 5 (18%) had advanced fibrosis while the majority (56%) did not have any fibrosis. The NPV of FIB4 and Fibroscan for advanced and significant fibrosis in these patients was 93% and 100% respectively.
Conclusion: Among HIV positive patients with elevated liver function tests and available histology, a surprisingly high number of patients had non-significant changes or even normal histological findings. The prevalence of NAFLD was lower than reported in other series. Use of non-invasive tools with a high NPV for significant fibrosis can help reduce the number of required biopsies.

Email: stephen.djedjos@gilead.com

Background and Aims: Fibrosis is the most important determinant of disease progression in patients with NASH. Our aim was to identify markers of disease progression using machine learning.
Methods: A Bayesian machine learning platform (REFS™; GNS Healthcare; Cambridge, MA) was applied to data from two trials of simtuzumab in adults with NASH and advanced fibrosis (NASH CRN F3-F4). The trials were stopped at Week 96 due to lack of efficacy, so treatment groups were combined for this analysis. At baseline (BL), we used clinical, histologic, serum fibrosis marker, and genetic data to construct an ensemble of models to predict risk of progression to cirrhosis in subjects with bridging fibrosis, and adjudicated clinical events in cirrhosis. The predictive performance of the models was assessed using the concordance index (C-index) in-sample and by internal 3-fold cross validation (CV) in the training set and further validated in a test sample (20% of the cohort).
Results: 477 subjects with advanced fibrosis were randomized; 248 subjects with complete genetic and histologic data were included in the training set and 77 in the test set. Predictive models that included full BL data including histology performed well (Table). Similar performance was observed in noninvasive models excluding histology and models excluding genetic data. Variables commonly identified in the predictive model ensemble for risk of progression to cirrhosis among subjects with bridging fibrosis were α-smooth muscle actin expression on biopsy (in 79% of ensembles), ELF score (64%), platelets (46%), and FIB-4 (34%) in the full model, and ELF (87%) and platelets (69%) in the noninvasive model. For the prediction of risk of clinical events in cirrhotic subjects, variables were similar in the full and noninvasive models, including direct bilirubin (94% and 92% of ensembles) and alkaline phosphatase (7.4% and 9.0%).

Table: Model Performance

		C-Index (95% CI)		
Cohort	Model*	In-sample	3-fold CV	Validation Set †
Bridging fibrosis (n = 124)	Full	0.92 (0.76–0.98)	0.79 (0.61–0.90)	0.77 (0.65–0.90)
	Noninvasive	0.90 (0.73–0.96)	0.80 (0.61–0.91)	0.79 (0.65–0.92)
Cirrhosis (n = 124)	Full	0.83 (0.64–0.93)	0.72 (0.52–0.86)	0.66 (0.55–0.78)
	Noninvasive	0.83 (0.64–0.93)	0.68 (0.48–0.83)	0.68 (0.58–0.78)

*Full models include all genetic, histologic, and clinical data at BL, including HVPG in patients with cirrhosis. Noninvasive models exclude histologic and HVPG data.
†33 subjects with bridging fibrosis and 44 with cirrhosis.

Conclusion: Models generated using machine learning utilizing only noninvasive data can accurately predict the risk of clinical disease progression in patients with advanced fibrosis due to NASH.

FRI-467
A new score to predict presence of advanced fibrosis in NAFLD and comparison with established scoring systems

H. Hagström[1], P. Nasr[2], M. Ekstedt[2], U. Hammar[1], R. Hultcrantz[1], P. Stal[1], S. Kechagias[2]. [1]*Karolinska Institutet, Sweden;* [2]*Linköping University, Sweden*
Email: hannes.hagstrom@ki.se

Background and Aims: Detection of advanced fibrosis in liver biopsy (stage 3–4) is the most robust predictor of mortality and liver-related morbidity in nonalcoholic fatty liver disease (NAFLD). Serum markers have been proposed as alternatives to biopsy but have shortcomings in diagnostic accuracy. We aimed to create a new non-invasive scoring system to identify advanced fibrosis in a well-defined cohort of biopsy-proven NAFLD patients, and to compare this to established scoring systems.
Method: We included 646 biopsy-proven NAFLD patients and investigated possible predictors of advanced fibrosis. Candidate predictors were age, sex, body mass index (BMI), type 2 diabetes, haemoglobin, platelets, glucose, creatinine, ferritin, ALT, AST, ALP, γGT, bilirubin, PK-INR, albumin, cholesterol, and triglycerides. All parameters were obtained at the time of biopsy. We used backward selection with an alpha of 0.20 to identify relevant predictors. Model performance was evaluated using 20-fold cross-validation. Missing values were imputed with predictive mean matching using 10-fold multiple imputation. AUC estimates from the different imputations were combined using Rubin's rules. The new score was compared to the FIB-4 index and the NAFLD fibrosis score (NFS).

Results: Age, AST, BMI, glucose, γGT and platelets were included in the final model. The new score was calculated as:

$$\text{Score} = -13.32 + 0.09^{*}\text{BMI} + 0.02^{*}\text{AST} + 0.31^{*}gGT - 0.008^{*}\text{TPK} + 0.04^{*}\text{age} + 1.27^{*}\text{glucose}$$

The score can be transformed into a probability for advanced fibrosis by the equation *exp(Score)/(1 + exp(Score))*.
The new score predicted advanced fibrosis with an AUC of 0.80, compared to 0.79 for the FIB-4 index and 0.76 for the NFS (figure 1). An upper cut-off for the score of –3.17 identified cases with advanced fibrosis with a sensitivity of 0.90 and a specificity of 0.39, while a lower cut-off of –0.57 had a specificity of 0.95 to exclude cases with advanced fibrosis, with a sensitivity of 0.28.

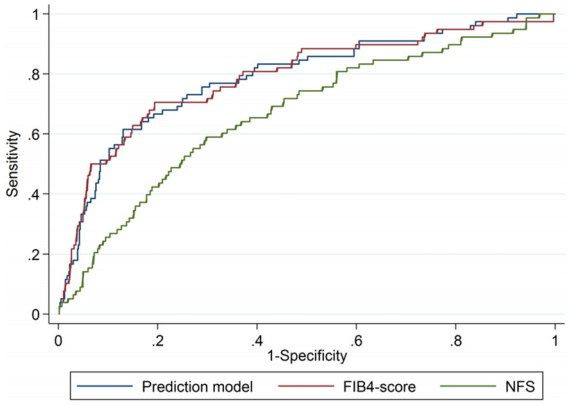

Figure 1: ROC curve for prediction of advanced fibrosis for the new score (Prediction model), the FIB-4 score and the NAFLD fibrosis score (NFS)

Conclusion: The new score performed similarly to established scoring systems for prediction of advanced fibrosis in NAFLD. Validation of the new score in other cohorts is needed in order to assess if it provides superior diagnostic accuracy compared to established algorithms.

FRI-468

Evaluation of severity of hepatic fibrosis and steatosis in biopsy-proven NAFLD patients using MR imaging, transient elastography, and serum biomarker

Y.-S. Lee[1], J.H. Kim[2], C.H. Lee[3], J.E. Yeon[4], K.S. Byun[5]. *[1]Department of Internal Medicine, Korea University College of Medicine, Seoul, Korea, Rep. of South; [2]Korea University Guro Hospital, Gastroenterology and Hepatology, Seoul, Korea, Rep. of South; [3]Korea University College of Medicine, Department of Radiology, Korea, Rep. of South; [4]Korea University Medical College, Gastroenterology, Seoul, Korea, Rep. of South; [5]Korea University College of Medicine, Department of Internal Medicine, Korea, Rep. of South*
Email: jeyyeon@hotmail.com

Background and Aims: As nonalcoholic fatty liver disease (NAFLD) is becoming a leading cause of chronic liver disease, non-invasive diagnosis of disease severity is urgently needed. For the diagnosis of liver fibrosis, transient elastography (TE) has acceptable accuracy in viral related liver disease. But in patients with severe steatosis, TE has shortage. Aim of our study was plan to analyze hepatic fibrosis, steatosis, and inflammation in patients with biopsy-proven NAFLD using MR imaging, TE, and serum biomarkers.
Method: This is a multicenter prospective study of patients with biopsy-proven NAFLD. The patients were underwent liver biopsy, MRI and TE 6 months before enrollment. MRI examination included mDIXON, MR spectroscopy (MRS), and MR elastography (MRE). TE measured liver stiffness and controlled attenuation parameter (CAP). Twenty serum biomarkers were analyzed using the Luminex Multiplex Assay.
