
Results: A total of 465 participants completed the Brief IPQ. Scores were higher in those with advanced compared to mild fibrosis in only NAFLD and SVR patients (Figure). Among low fibrosis patients, the

mean score for SVR patients was significantly lower when compared to mean scores for all other groups (30.64 for HBV, 33.91 for HCV, and 30.37 for NAFLD; $p < 0.0005$ for all three comparisons). As well, among high fibrosis patients, the mean score for NAFLD patients was significantly higher than mean scores for all other groups (33.18 and $p = 0.001$ for HBV, 35.04 and $p = 0.017$ for HCV, and 32.07 and $p < 0.0005$ for SVR). Lastly, for the question assessing how much patients perceived treatment to help their illness, both the high and low fibrosis NAFLD groups had significantly greater mean scores compared to all other high ($p = 0.002$ for HBV, $p < 0.0005$ for HCV and SVR) and low fibrosis groups ($p = 0.057$ for HBV and $p < 0.0005$ for HCV and SVR) respectively.

Conclusion: Patients with chronic liver disease seen generally have accurate perception of their disease severity and the efficacy of treatment. The Brief IPQ proved to be a useful and reliable test for assessing disease perception, which may have value for assessing individuals' understanding of and engagement in their disease management.

THU-306

Liver function tests in NAFLD: Changes in upper normal limits, does it really matter?

Roberta Forlano[1], Benjamin H. Mullish[1], Michael Yee[1], Ameet Dhar[1], Mark Thursz[1], Pinelopi Manousou[1]. [1]*Liver Unit/Division of Integrative Systems Medicine and Digestive Disease, Imperial College London, London, United Kingdom*
Email: r.forlano@imperial.ac.uk

Background and aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is the commonest cause of abnormal liver function tests (LFTs). The current Upper Normal of Limit (UNL) of LFTs was derived from an apparently "healthy" population, where a high rate of undiagnosed NAFLD and chronic viral hepatitis may be suspected. We aimed to evaluate potential implications of changes in UNL of ALT in patients with NAFLD.

Method: We retrospectively assessed consecutive first referrals with a clinical or histological diagnosis of NAFLD from 2010 to 2017. The high UNL of ALT was set at 45 IU/L for men and 34 IU/L for women, while the low UNL of ALT was set at 30 IU/L for men and 19 IU/L for women. The UNL of AST was 40 IU/L for both men and women. Liver biopsies were scored according to the NASH CRN Scoring System. All patients underwent Liver Stiffness Measurement (LSM).

Results: 436 patients were enrolled; of these, 288 underwent liver biopsy. Lowering the UNL of ALT reduced the percentage of patients who had liver fibrosis or NASH despite normal ALT from 10% to 4% and from 28% to 4% respectively. However, the percentage of those with increased ALT and no evidence of liver fibrosis or NASH increased from 27% to 33% and from 3% to 19% respectively. There were no differences in terms of demographic, anthropometric and metabolic features.

Conclusion: Liver function tests might both under- and overestimate NASH-related liver disease. Reducing the UNL might not beneficial and lead to an increase in overall healthcare burden. Risk stratification in NAFLD should rely on a combination of risk factors, not on LFTs alone.

THU-307

Whipple procedure increases the risk for non-alcoholic fatty liver disease

Jordan Goldstein[1], Andrew Scheinberg[1], Bryan Stover[2], David To[2], Kathleen Corey[3], Cynthia Levy[4]. [1]*University of Miami/Jackson Memorial Hospital, Department of Medicine, Miami, United States;* [2]*University of Miami/Jackson Memorial Hospital, Department of Radiology, Miami, United States;* [3]*Massachusetts General Hospital, Division of Gastroenterology, Boston, United States;* [4]*University of Miami Hospital, Division of Hepatology, Miami, United States*
Email: jordan.goldstein@jhsmiami.org

Background and aims: Asian studies report an increased incidence of non-alcoholic fatty liver disease (NAFLD) post pancreaticoduodenectomy (PD), ranging from 7.8% to 40.0%. We sought to investigate the incidence and predictors of NAFLD after PD in an ethnically diverse population in the United States.

Method: We conducted a retrospective study of patients who underwent PD between 12/2010 and 12/2016, as well as patients who underwent a cholecystectomy (CH) or distal pancreatectomy (DP) serving as controls. Various imaging modalities were used to detect NAFLD with CT scans comprising 97.3%. Using Hounsfield units (HU), NAFLD was defined as a liver:spleen ratio < 0.9, or in patients who had a splenectomy, an absolute value of < 40 HU. We abstracted information on demographics, comorbidities, type and indication of surgery, post-operative use of pancrelipase and insulin, and use of chemotherapy. Patients who had NAFLD prior to surgery and those without post-operative imaging were excluded. Chi-square test was used to evaluate for associations, with a p value < 0.05 considered significant. Nominal logistic regression was used for multivariate analysis.

Results: A total of 123 patients were included: 66 controls (29 CH + 37 DP) and 57 PD. Sixty-one (49.6%) were male, 95 (80.5%) Caucasian, 57 (47.1%) Hispanic, median age at the time of surgery of 64 years and average BMI of 26.2 kg/m^2. Median follow-up time was 2.2 years. The proportion of patients developing NAFLD within the first 3 years post CH and DP versus PD was 30.3%, and 70.2%, respectively. Race, ethnicity, age, BMI, hypertension, diabetes, use of pancrelipase or insulin post-operatively, or use of chemotherapy were not associated with increased frequency of NAFLD post-operatively. After adjusting for age, gender, ethnicity, BMI, surgery indication and comorbidities, the type of surgery was the only independent predictor of NAFLD.

Table 1: Preoperative and postoperative variables associated with the development of NAFLD

	NAFLD present (N = 60)	NAFLD not present (N = 63)	P value
Age, median (range)	62 (18-87)	64 (35-89)	1.00
Female, n (%)	32 (53.3)	30 (47.6)	0.59
BMI >30, n (%)	13 (24.1)	14 (25.0)	1.00
Hispanic, n (%)	28 (46.7)	29 (47.5)	1.00
Type 2 diabetes, n (%)	17 (28.3)	15 (23.8)	0.68
Hypertension, n (%)	26 (43.3)	34 (54.0)	0.28
Hyperlipidemia, n (%)	15 (25.0)	14 (22.2)	0.83
Type of surgery (N = 123)			< 0.0001
Control group (Cholecystectomy + Distal Pancreatectomy), n (%)	20 (33.3)	46 (73.0)	
Pancreaticoduodenectomy, n (%)	40 (66.7)	17 (27.0)	
Diagnosis (n = 123)			0.11
Malignancy (n = 73), n (%)	39 (65.0)	34 (54.0)	
Benign (n = 36), n (%)	10 (16.7)	26 (41.3)	
Neuroendocrine tumor (n = 14), n (%)	11 (18.3)	3 (4.8)	

Conclusion: Patients who undergo a pancreaticoduodenectomy are at increased risk for the development of NAFLD post-operatively. The natural history of this post-op NAFLD is unclear and additional studies are warranted.

THU-308

More than 4 times higher healthcare costs for end-stage liver disease patients with non-alcoholic fatty liver disease/non-alcoholic steatohepatitis

Stuart C Gordon[1], Nandita Kachru[2], Shreay Sanatan[2], Diane Martinez[3], Meghan Moynihan[3], Robert Wong[4]. [1]*Henry Ford Hospital, Wayne State University School of Medicine, Detroit, United States;* [2]*Gilead Sciences, Health Economics Outcomes Research, Foster City, United States;* [3]*IBM Watson Health, Washington, DC, United States;* [4]*Division of Gastroenterology and Hepatology, Alameda Health System, Highland Hospital, Oakland, United States*
Email: Nandita.Kachru@gilead.com

Background and aims: NAFLD/NASH patients who progress to advanced liver disease (AdvLD) [compensated cirrhosis (CC)/ decompensated cirrhosis (DCC)/liver transplant (LT)/hepatocellular

carcinoma (HCC)], have significantly higher healthcare resource utilization and costs as compared to NAFLD/NASH patients who do not progress. However, previous studies have not comprehensively adjusted for baseline patient and disease characteristics. This study evaluated adjusted costs associated with progression among NAFLD/NASH patients using a large generalizable US claims database.

Method: NAFLD/NASH patients aged ≥ 18 years from 2006-2016 were identified retrospectively from the IBM Watson Health MarketScan® Commercial healthcare claims database using ICD-9/10-CM codes. Following the initial NAFLD/NASH diagnosis, development of CC, DCC, LT or HCC was identified using their first diagnosis date for each severity stage (index date). Annual healthcare costs for each liver severity stage were obtained from per patient per month estimates, adjusted for baseline demographics and comorbidities through generalized linear models.

Results: Of the total 153, 323, 509 individuals in the database, 468, 017 NAFLD/NASH patients who met inclusion/exclusion criteria were identified. Among this NAFLD/NASH cohort, 96.9% (453, 564) were without AdvLD, 1.6% (7, 665) had CC, 3.4% (15, 833) had DCC, 0.1% (696) had LT and 0.1% (428) had HCC. Patients across all liver stages had a mean age of 48-52 years and >50% females. The comorbidity burden was high across all liver stages with more than 57% patients having ≥ 1 co-morbidity, including hypertension, hyperlipidemia, cardiovascular disease, type-2 diabetes (T2DM) and renal impairment. The adjusted annual healthcare costs increased significantly as patients progressed through liver severity stages. As compared to NAFLD/NASH without AdvLD (adjusted costs: $23, 860), the cost of CC, DCC, LT and HCC was 1.22, 5.64, 8.27 and 4.09 times higher respectively, with adjusted costs being $29, 078, $134, 448, $197, 392 and $97, 563 respectively (p < 0.001)[Figure]

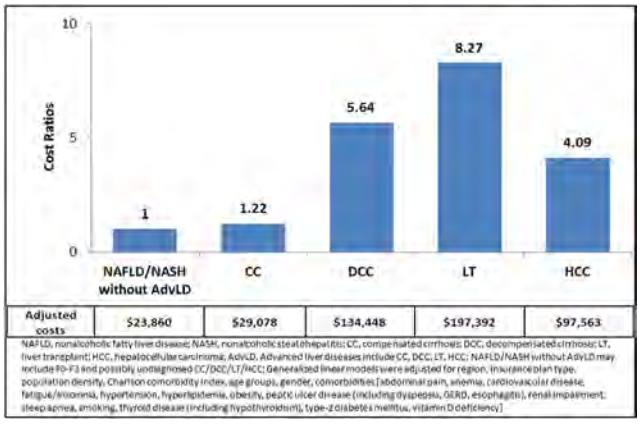

Figure: Generalized Linear Models for Adjusted Annual Healthcare Costs among NAFLD/NASH Patients with AdvLD

Conclusion: Amongst a large cohort of commercially insured NAFLD/NASH patients in the US, adjusted healthcare costs for NAFLD/NASH patients who progress to DCC/LT/HCC were 4-8 times higher than in patients who do not progress. Halting or reversing fibrosis to prevent progression to DCC/LT/HCC in CC patients due to NAFLD/NASH is imperative to limit the increasing healthcare costs.

THU-309

Cardiovascular risk assessment and management improves outcomes in a specialist multidisciplinary non-alcoholic fatty liver disease clinic

Atul Goyale[1], Marta Guerrero[2], Laura Iogna Prat[2], Davide Roccarina[2], Devaki Nair[1], Emmanuel Tsochatzis[2]. *[1]Royal Free Hospital, Department of Clinical Biochemistry, London, United Kingdom; [2]Royal Free Hospital and University College London, UCL Institute for Liver and Digestive Health, London, United Kingdom*
Email: atul.goyale@nhs.net

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease in the developed world and is predicted to become the leading indication for liver transplantation by 2030.

Patients with NAFLD usually have features of the metabolic syndrome as well as myriad of other cardiovascular risk factors. The majority of deaths among the NAFLD population are attributable to cardiovascular events such as myocardial infarction and cerebral vascular events.

Therefore, it is imperative that patients diagnosed with NAFLD undergo cardiovascular risk assessment and that where found, these risk factors should be managed proactively.

Here we assess the effectiveness of cardiovascular risk assessment and management as part of a Specialist Multidisciplinary NAFLD clinic.

Method: Data from 120 patients whom underwent a cardiovascular risk assessment as part of their routine care in a multidisciplinary NAFLD clinic were included. We assessed the impact of this service by assessing changes in LDL cholesterol, HbA1c and QRISK-3 score.

Results: Baseline data, mean age was 55.7 (9.3) years with mean weight of 90.7 kg and mean BMI of 32.3 kg/m^2. 17.5% were current smokers. Rates of known pre-existing comorbidities including hyperlipidaemia, hypertension and diabetes were 65.8%, 59.1% and 21.7%, respectively. Those with established cardiovascular disease (CVD) equated to 10%.

The 10-year QRISK-3 score for CVD in 17.6% of the patients was >20%; 53.7% had a score between 10 and 20% and 28.7% had a score of < 10% (Figure 1).

Hyperlipidaemia management was suboptimal in 67% of patients at baseline. Lipid lowering treatment was altered or commenced in 44% of patients. For primary prevention 68.3% achieved the LDL reduction of < 3 mmol/L. For secondary prevention, 75% reached the LDL target of < 2 mmol/L.

An additional 13 patients with undiagnosed type 2 diabetes were detected. The mean HbA1c prior to intervention was 77.6 mmol/mol. Diabetes treatment was commenced or altered in 34/39 (87.2%) patients in total. The mean HbA1c post intervention were 62.3 mmol/mol, representing a mean improvement of 15.3 mmol/mol.

Overall, the mean reduction for 10-year QRISK-3 score for CVD was 5.2% with a mean gain in CVD free years of 2.1 years (Figure 1).

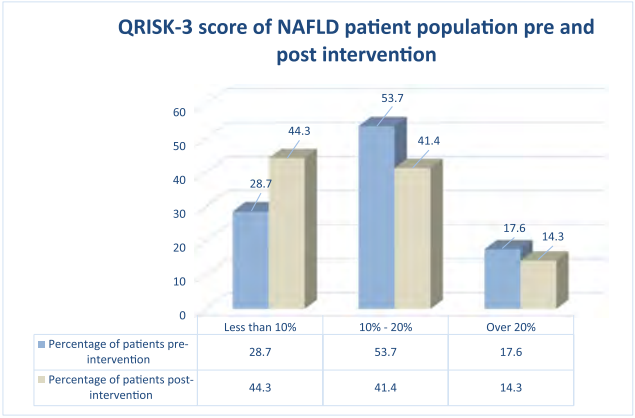

Figure 1: The QRISK-3 score for 10-year CVD risk of NAFLD patient population, pre and post intervention.

Conclusion: Cardiovascular risk assessment in the multidisciplinary NAFLD clinic aides the detection and treatment of conditions such as hyperlipidaemia and type 2 diabetes mellitus, creating an opportunity to optimise the management of these comorbidities and hence reducing the cardiovascular risk profile in the NAFLD population.

THU-310

Non-alcoholic steatohepatitis is associated with a higher risk of advanced colorectal neoplasm

Jimin Han[1], GwangPyo Ko[2], Won Kim[1]. [1]*Seoul national university college of medicine, Seoul metropolitan government boramae medical center, Department of internal medicine, Seoul, Korea, Rep. of South;* [2]*Graduate school of public health, Seoul national university, Department of environmental health sciences, Seoul, Korea, Rep. of South*
Email: wonshiri@yahoo.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is known to increase the risk of adenomatous colonic polyps. However, the role of screening colonoscopy in patients with biopsy-proven NAFLD in detecting advanced colorectal neoplasm is not clearly evidence-based. Therefore, we investigated whether the histological severity of NAFLD is associated with advanced colorectal neoplasm.
Method: This study included patients >18 years old who underwent routine colonoscopy between 2013 and 2018 within a biopsy-evaluated prospective NAFLD cohort. Advanced colorectal neoplasm was defined as an adenomatous polyp greater than 10 mm in diameter and/or with villous histology and/or with high-grade dysplasia or adenocarcinoma.
Results: Among the 476 subjects with biopsy-proven NAFLD (n = 379) and healthy controls without any evidence of NAFLD (n = 97) who underwent colonoscopy, the prevalence of advanced colorectal neoplasm was 11.1% (n = 53). Patients with advanced colorectal neoplasm had higher grade of steatosis (p = 0.004) and higher stage of hepatic fibrosis (p = 0.044) than those with normal colonoscopic findings or low-grade adenomatous polyp. Multivariable logistic regression analysis revealed that the presence of non-alcoholic steatohepatitis (NASH) was an independent risk factor for both colorectal polyp (odds ratio [OR], 2.08; 95% confidential interval [CI], 1.12-3.86; p = 0.020) and advanced colorectal neoplasm (OR, 2.81; 95% CI, 1.01 –7.87; p = 0.049).
Conclusion: The presence of biopsy-proven NASH was significantly associated with an increased risk of advanced colorectal neoplasm among patients with NAFLD. This finding may alert physicians to conduct screening colonoscopy in patients with NASH to detect advanced colorectal neoplasm early.

THU-311

Liver enzymes cut offs in patients with advanced non-alcoholic fatty liver disease: A multi-center study

Ma Ai Thanda Han[1], Rola Saouaf[2], Nabil Noureddin[3], Jonathan Grotts[4], Vinay Sundaram[1], Andrea Scott[5], Mahsa Mansouri[5], Mary Barbara[6], Matthew Tjahja[5], Emmanuel Thomas[7], Zeid Kayali[8], Edward Mena[9], Naim Alkhouri[5], Mazen Noureddin[10]. [1]*Cedars-Sinai Medical Center, Gastroenterology and Hepatology, Los Angeles, United States;* [2]*Cedars-Sinai Medical Center, Imaging, Los Angeles, United States;* [3]*University of Nevada, Internal Medicine, Las Vegas, United States;* [4]*UCLA, Los Angeles, United States;* [5]*Texas Liver Institute, Liver, San Antonio, United States;* [6]*UT Health, San Antonio, United States;* [7]*University of Miami, Miami, United States;* [8]*Inland Empire Liver Foundation, Rialto, United States;* [9]*California Liver Research Center, Pensadena, United States;* [10]*Cedars-Sinai Medical Center, Fatty Liver Program, Division of Digestive and Liver Diseases, Los Angeles, United States*
Email: maaithandahan@gmail.com

Background and aims: Primary care physicians rely on liver enzymes to assess non-alcoholic fatty liver disease (NAFLD) severity however the reliability of abnormal enzymes for determining this is uncertain. The prevalence of normal and abnormal liver enzymes and their cut offs with advanced NAFLD are not well determined. Aim is to assess the prevalence of abnormal alanine aminotransferase (ALT), aspartate aminotransferase (AST) and alkaline phosphatase (ALP) in patients with advanced NAFLD.
Method: In this multi-center cross-sectional study, we calculated the percentage of abnormal ALT, AST and ALP based on lab references and AASLD recommended references (normal ALT and AST ≤ 35 U/L for males and £ 25 U/L for females) in NAFLD patients with MR elastography (MRE) ≥ 2.5 kPa (possibly correlated with NASH), those with MRE ≥ 3.62 kPa (advanced fibrosis) and those with MRE ≥ 4.7 kPa (correlated with cirrhosis). Fisher's exact test was used for testing association strength.
Results: The cohort included 245 patients: 53% female; 47% DM or pre DM; mean BMI 32 (3.7) kg/m^2, ALT 43 (22.5) U/L, AST 32 (14.8) U/L, and ALP 78 (20) U/L). Normal ALT, AST and ALP were found in 49%, 51%, and 81% of patients with MRE ≥ 2.5 kPa, in 40%, 43%, and 78% of patients with MRE ≥ 3.62, and in 40%, 53%, 77% of patients with MRE ≥ 4.7 kPa, respectively. We analyzed associations of abnormal ALT, AST, ALP and patients with MRE ≥ 2.5, ≥ 3.62 and ≥ 4.7 kPa respectively based on lab references or AASLD recommended references as shown in table. AUC of ALT to detect advanced fibrosis was 0.55 and 0.68 respectively when we used local lab references. Using AASLD references, AUC of increased to 0.59 for ALT and 0.72 for AST respectively.

Table:

	Local labs reference range			AASLD reference range		
	MRE ≥ 2.5 (%)	MRE < 2.5 (%)	P vale	MRE ≥ 2.5 (%)	MRE < 2.5 (%)	P vale
Abn ALT	51	43	0.32	74	64	0.16
N ALT	49	57		26	36	
Ab AST	49	23	**0.0001**	64	47	**0.016**
N AST	51	77		36	53	
Abn ALP	19	6	**0.009**	N/A		
N ALP	81	94				
	MRE ≥ 3.62	MRE < 3.62		MRE ≥ 3.62	MRE < 3.62	
Abn ALT	60	44	**0.0247**	76	68	0.27
N ALT	40	56		24	32	
Abn AST	57	32	**0.0006**	69	53	**0.03**
N AST	43	68		31	47	
Abn ALP	22	11	0.05	N/A		
N ALP	78	89				
	MRE ≥ 4.7	MRE < 4.7		MRE ≥ 4.7	MRE < 4.7	
Abn ALT	60	45	**0.05**	73	69	0.64
N ALT	40	55		27	31	
Abn AST	47	36	0.15	60	56	0.66
N AST	53	64		40	44	
Abn ALP	23	12	0.06	N/A		
N ALP	77	88				

Conclusion: Significant number of patients with normal liver enzymes based on local lab references had NASH (~50%) and/or advanced fibrosis (~40%). Lower cut offs such as the AASLD reference range need to be used in NAFLD/NASH.

THU-312

Physician-recommended lifestyle interventions and associated effects among non-alcoholic steatohepatitis patients with and without cardiovascular-metabolic related comorbidities: A European real-world study

Kate Hallsworth[1,2], Victoria Higgins[3], Nathan Williams[3], Claudia Knight[3], Quentin Anstee[1,2]. [1]*Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom;* [2]*The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom;* [3]*Adelphi Real World, Bollington, United Kingdom*
Email: nathan.williams@adelphigroup.com

Background and aims: Patients who have non-alcoholic steatohepatitis (NASH) should receive the same degree of lifestyle management from their physicians regardless of whether they have additional comorbidities. This analysis aims to establish if additional cardiovascular-metabolic (CVM) related comorbidities affect the way NASH patients are managed in a real-world setting.
Method: Data were derived from the 2018 5EU Adelphi NASH Disease Specific Programme, a real-world, cross-sectional survey. Physicians completed questionnaires describing five consecutive NASH patients. These same five patients were asked to provide additional

information. Physicians reported comorbidities and clinical values. Patients reported weight/lifestyle-related factors. Patients were classified by absence versus presence of CVM comorbidities (type 2 diabetes, hypertension, dyslipidaemia, myocardial infarction, congestive heart failure, peripheral vascular disease and cerebrovascular disease).
Results: 270 physicians (48% hepatologists, 52% gastroenterologists) provided data on 1, 353 NASH patients. Of these, 238 had both physician and patient responses available comprising of NASH+CVM (45%) and NASH-only (55%). NASH+CVM had higher mean BMI vs. NASH-only (33.5 vs 29.4 kg/m^2), with physicians more likely to advise weight-loss (86% vs 75%). Whilst NASH+CVM patients reported higher physician-recommended weight maintenance (71% vs 52%), increased exercise (75% vs 54%) and dietician visits (49% vs 33%), they are less likely to be happy with their weight progress (10% vs 35%). NASH+CVM patients felt lifestyle changes had helped improve their overall health (58% vs 46%), control blood sugar (25% vs 13%) and lose weight (41% vs 29%). Conversely, NASH-only patients were more likely to self-report no perceived benefit via lifestyle changes compared to NASH+CVM patients (20% vs 6%).
Conclusion: The EASL-EASD-EASO Clinical Practice Guidelines advocate lifestyle change in all patients with NAFLD/NASH. Real-world evidence suggests this is most frequently implemented amongst NASH+CVM, not NASH-only patients. NASH+CVM patients self-report more benefit from implemented changes complementing the notion that NASH-only patients warrant additional targeted lifestyle management. Additionally, this may highlight differences in lifestyle management approaches between specialist groups, with non-diabetologist influence and infrastructure less likely to advocate and support lifestyle change.

THU-313
Differences between non-alcoholic steatohepatitis patient characterisation and management approaches: A multinational real-world study

Quentin Anstee[1,2], Kate Hallsworth[1,2], Niall Lynch[3], Adrien Hauvespre[3], Eid Mansour[4], John-Paul Marino[5], Juliana Bottomley[3], Claudia Knight[6], Nathan Williams[6], James Piercy[6], Victoria Higgins[6]. *[1]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; [2]The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [3]Gilead Sciences, Uxbridge, United Kingdom; [4]Gilead Sciences, Dubai, United Arab Emirates; [5]Gilead Sciences, Mississauga, Canada; [6]Adelphi Real World, Bollington, United Kingdom*
Email: nathan.williams@adelphigroup.com

Background and aims: Whilst global Non-Alcoholic Steatohepatitis (NASH) prevalence is currently unknown, differing healthcare systems, physician and patient factors equally pose regional challenges when managing NASH. This analysis aims to describe the characteristics of consulting NASH patients across Europe (EU), Canada (CAN) and the Middle East (ME) and establish any differences in current management approaches.
Method: Data were derived from the 2018 Adelphi NASH Disease Specific Programme, a real-world, cross-sectional survey. Physicians completed questionnaires describing five EU/CAN and ten ME consecutive NASH patients alongside completing an attitudinal physician survey. Diagnosis was via liver biopsy (LB) or non-invasive test (NIT) assessment, with physicians reporting diagnostic tests, clinical values and associated management.
Results: 444 physicians (35% hepatologists, 43% gastroenterologists, 22% diabetologists) provided data on 2, 267 NASH patients. ME patients are younger (47.3 vs 55.7/EU vs 55.3/CAN) with a higher proportion unemployed (13% vs 5%/EU vs 3%/CAN). Staging via LB is most likely in EU (48% vs 35%/CAN vs 20%/ME), via Fibroscan in ME (72% vs 60%/EU vs 44%/CAN). Diagnostic "liver screens" to exclude other diagnoses were more consistently completed in CAN, e.g. testing serum ferritin/transferrin saturation (85% vs 61%/EU vs 10%/ME). ME is least likely to assess levels of alcohol intake at diagnosis (9% vs 70%/EU vs. 89%/CAN). ME perform the greatest variety of tests to monitor NASH (10.0 tests vs 5.8/EU vs 5.3/CAN) and were most likely to prescribe off-label Vitamin E as NASH therapy (49% vs 19%/EU vs 12%/CAN). ME physicians more frequently reported treating the underlying cause of disease via other related comorbidities (76% vs 54%/EU vs 35%/CAN). EU physicians target NASH via weight-loss approach (GLP-1: 25% vs 6%/CAN vs 6%/ME). CAN physicians likely to address NASH via referral to nutritionist (65% vs 45%/EU vs 55% ME). All results $p \leq 0.05$.
Conclusion: NASH management approaches vary across EU, CAN and ME. Despite standard LB diagnostic recommendation, in a real-world setting LBs more likely in EU, Fibroscans more likely in ME with similar application of both in CAN. ME physicians monitor NASH more regularly and attempt off-label treatment approaches targeting underlying causes of disease, CAN physicians more likely to rely on lifestyle changes. Regional differences may be influenced by healthcare systems and culture and need to be accounted for across geographies.

THU-314
Serum Zinc levels as a prognostic factor for extra-hepatic carcinogenesis in Japanese patients with non-alcoholic liver disease

Takanori Ito[1], Masatoshi Ishigami[1], Yoji Ishizu[1], Teiji Kuzuya[1], Takashi Honda[1], Mitsuhiro Fujishiro[1]. *[1]Nagoya University Graduate School of Medicine, Department of Gastroenterology and Hepatology, Nagoya, Japan*
Email: tahkun56@gmail.com

Background and aims: Chronic liver diseases are associated with zinc (Zn) deficiency. However, no previous studies have examined the relationship between serum Zn levels and the incidence of hepatic and extra-hepatic malignancies in patients with non-alcoholic fatty liver disease (NAFLD). The aim of this study was to investigate the prognosis based on serum Zn levels in biopsy-proven NAFLD patients.
Method: A total of 179 NAFLD patients who underwent liver biopsy were enrolled. Firstly, we identified laboratory markers and pathological findings associated with serum Zn levels. Secondary, we assessed the factors, including serum Zn levels, associated with the incidence of hepatocellular carcinoma (HCC) and extra-hepatic malignancies.
Results: Zn level significantly decreased along with progression of hepatic fibrosis ($p = 0.012$), but there were no significant differences among inflammatory grades. Zn levels were most strongly correlated with albumin levels ($r = 0.432$, $P < 0.001$). In addition, Zn levels were significantly correlated with homeostasis model assessment of insulin resistance (HOMA-IR) ($r = -0.300$, $P < 0.001$) and branched chain amino acid/tyrosine molar ratio (BTR) ($r = 0.337$, $P < 0.001$). On the other hand, HCC and extra-hepatic malignancies developed in 7 (3.9%) and 10 (5.6%) during follow-up period (median 7.9 years), respectively. When Zn deficiency was defined as serum level < 70 μg/dL, 39 of our patients (21.8%) were classified as Zn-deficient. Patients with Zn deficiency had significantly higher incidental rate of extra-hepatic malignancies ($p = 0.026$). The majority of extrahepatic malignancies in this patients' population were breast cancer and digestive malignancies. Conversely, serum Zn levels were not able to predict hepatocarcinogenesis ($p = 0.141$). Multiple logistic regression analyses revealed the following risk factors associated with the incidence of extra-hepatic malignancies: serum Zn level < 70 μg/dL (hazard ratio [HR] 3.504, 95% confidence interval [CI] 1.010-12.157, $P = 0.048$) and liver inflammation (A2-3) (HR 3.445, 95% CI 0.886-13.395, $P = 0.074$).
Conclusion: The progression of liver fibrosis was associated with lower serum Zn levels, and serum Zn levels were correlated with nutrition markers and insulin resistance in biopsy-proven NAFLD patients. Importantly, Zn deficiency was an independent risk factor of extra-hepatic carcinogenesis in NAFLD.

THU-315

Non-cirrhotic patients with non-alcoholic fatty liver disease have impaired quality of life: Independently predicted by body mass index, diabetes and liver stiffness

Benjamin Kadler[1], James Hallimond Brindley[1], Victoria Berryman[1], Johanna Preston[1], Wing-Kin Syn[2], William Alazawi[1]. [1]*Blizard Institute, London, United Kingdom;* [2]*Ralph H Johnson Va Medical Center, Charleston, United States*
Email: benjamin.kadler@gmail.com

Background and aims: Patient related outcome measures are important determinants of cost-effectiveness of therapies. Quality of life is significantly impaired in patients with non-alcoholic fatty liver disease (NAFLD) and cirrhosis. However, the extent to which it is impaired before the development of cirrhosis and the factors that contribute to impairment have been less well studied.
Method: In a prospective study, set in a secondary care specialist clinic, we assessed quality of life (QOL) using the SF-36v2 questionnaire in 142 patients with NAFLD (n = 50 female, n = 92 male) and 9 healthy controls diagnosed by ultrasound and fibroscan. In a subset of patients, NASH was diagnosed histologically and staged according to the NASH CRN. Patients with cirrhosis were excluded from this study. QOL data was analysed with stepwise multiple regression models to identify factors independently affecting QOL scales.
Results: Non-cirrhotic patients with NAFLD had significantly reduced physical health QOL (mean 35.72) compared to healthy controls (mean 47.21, p = 0.016) and the normative UK population (n = 7984, mean 50, p < 0.001) (1). Patients with liver stiffness >7.9kPa (n = 53) had reduced physical health QOL compared to those with liver stiffness ≤ 7.9kPa (n = 80) (mean rank 56.3 vs 74.1, p = 0.009). However, we did not see differences in QOL domains when comparing results from patients with biopsy-proven NASH (n = 49) with patients who did not have NASH on biopsy (n = 18) or those whose non-invasive scores were too mild to warrant biopsy (n = 75). Moreover, there was no significant difference in QOL scales when comparing patients with biopsy-proven F3 or F2 fibrosis (n = 31) with those with F0 or F1 fibrosis (n = 36) or when comparing F3 fibrosis (n = 20) to F0, F1 and F2 fibrosis (n = 47). The factors independently associated with impaired physical health-related QOL in non-cirrhotic patients with NAFLD were age (B = – 6.082, p < 0.001) and high BMI (B = – 3.848, p = 0.008), whereas type 2 diabetes mellitus (B = – 9.356, p = 0.019), fibroscan score >7.9kPa (B = – 9.635, p = 0.013) and female gender (B = –9.813, p = 0.014) were associated with reduced general health QOL.
Conclusion: QOL is an important patient-related outcome measure in liver disease. Even before the onset of cirrhosis, NAFLD significantly reduces QOL. Understanding the independent predictors of impaired QOL may target existing and future therapies to those who are most likely to benefit.

THU-316

Cognitive impairment or hepatic encephalopathy? A prospective cross-sectional study in patients with non-alcoholic fatty liver disease

Nir Bar[1,2], Shira Deri[1,2], Muriel Webb[1,2], Jenny Rutenburg[1,2], Fadi Younes[1,2], Oren Shibolet[1,2], Shira Zelber-Sagi[1,2], Helena Katchman[1,2]. [1]*Tel Aviv Sourasky Medical Center, Gastroenterology and Hepatology, Tel Aviv, Israel;* [2]*Tel Aviv University, Tel Aviv, Israel*
Email: hkatchman@gmail.com

Background and aims: Recently, we are facing major changes in the landscape of liver cirrhosis. HCV with predominant liver damage is replaced by non-alcoholic fatty liver disease (NAFLD) with inherent multi-organ involvement due to metabolic syndrome (MS). We hypothesized that diagnosing hepatic encephalopathy (HE), may be challenging in the presence of cognitive dysfunction secondary to increasing age, diabetes mellitus (DM), hypertension (HTN), obstructive sleep apnea (OSA) and other MS associated conditions.
Method: a prospective cross-sectional study. Patients with NAFLD diagnosed by US were asked to report 5 HE related complaints (confusion, sleep-wake disturbance, day time somnolence, lack of concentration or energy) and underwent laboratory tests, transient elastography and HE testing by pen-and-paper tests, Stroop test, inhibitory control test and critical flicker frequency. Patients with a history of overt HE were excluded.
Results: Sixty eight patients were included. Mean age was 54.3 ± 13.6, 38 (56%) were female. Advanced fibrosis level (F3-F4) was found in 28 (41%) patients. MS, HTN, DM and diabetic microvascular complications were found in 49 (72.1%), 32 (47%), 26 (38%) and 8 (12%) patients, respectively. Six (9%) patients had OSA.
Diagnosis of MHE was considered when at least two HE tests were abnormal-found in 12 (17.6%) patients. In addition to fibrosis level, having HTN, duration of DM and age were associated with abnormal MHE tests (Table). In multivariate analysis, only age was independently associated with 2 abnormal HE tests.
Two thirds of patients had at least one HE complaint, while 33 (49%) had 2, and 19 (28%) had 3 or more complaints. Having 3 and more HE complaints was not associated with parameters of severity of liver disease: advanced fibrosis, steatosis, ALT level or platelet count. However, hypercholesterolemia and diabetic microvascular complications were predictive of having 3 HE complaints (Table). Frequency of OSA was higher in patients with 3 and more HE complaints:4 (21%) vs 2 (4%) p = 0.059.

Table:

	Logistic regression OR [95% CI]	Adjusted for age
Predictors of 2 MHE tests		
Fibrosis level	2.0 [1.2-3.5]	NS
HTN	7.7 [1.5-38.6]	NS
Duration of DM	1.17 [1.06-1.3]	NS
Age (per year)	1.15 [1.04-1.26]	1.2 [1.05-1.4]
Predictors for having 3 HE complaints		
F3-4	1.16 [0.39-3.45]	
Steatosis	0.4 [0.1-1.7]	
ALT	1 [0.98-1.02]	
Platelets	1 [0.99-1.01]	
Hypercholesterolemia	3.6 [1.1-12.7]	
Diabetic microvascular complications	5.5 [1.3-25.8]	

Having 2 abnormal MHE tests was more common in patients with 3 HE complaints compared to those with less (37% and 10% p = 0.028), but still, 12/19 patients with HE complaints did not have 2 abnormal MHE tests.
Conclusion: In patients with NAFLD clinical symptoms of HE and even specialized tests of MHE may be less specific due to related comorbidities affecting cognitive status and alertness. Further studies for optimal MHE tests in NAFLD are needed.

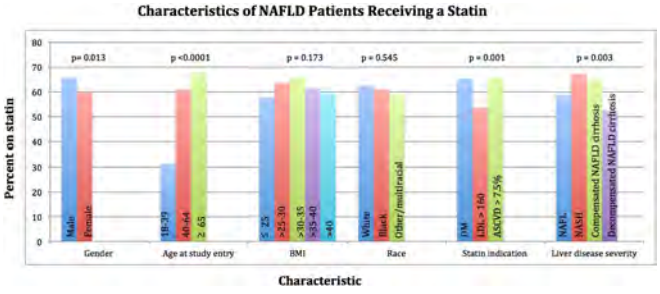
THU-317

The prescribing patterns and use of statins in patients with non-alcoholic fatty liver disease

Vandana Khungar[1], Anna LOK[2], L. Michael Weiss[3], Kalyan Ram Bhamidimarri[4], Paul J. Thuluvath[5], Derek Gazis[6], Laura Malahias[6], Rajender Reddy[7]. [1]*University of Pennsylvania, Philadelphia, United States;* [2]*University of Michigan, Ann Arbor, United States;* [3]*Gastro Florida, Clearwater, United States;* [4]*University of Miami, Miami, United States;* [5]*Mercy Medical Center, Baltimore, United States;*

[6]TARGET PharmaSolutions, Inc., Chapel Hill, United States; [7]University of Pennsylvania, Philadelphia, United States
Email: lmalahias@targetpharmasolutions.com

Background and aims: NAFLD, often encountered in the background of metabolic syndrome, represents a spectrum of progressive liver disease. Among NAFLD patients with metabolic syndrome, the most common cause of death is arteriosclerotic cardiovascular disease (ASCVD). Although statins are considered safe in liver disease, and even potentially beneficial in patients with cirrhosis, many patients are not prescribed a statin or other lipid-lowering agent despite one being indicated because of concerns about hepatic enzyme elevations. We aim to determine whether statins are underprescribed in NAFLD patients with indications for lipid-lowering agents, and whether this effect is magnified in patients with cirrhosis.
Method: TARGET-NASH, a longitudinal observational study of participants followed at 55 sites (41 academic/14 community) in the US, includes patients across the entire spectrum of NAFLD as defined by pragmatic case definitions. Data from medical records are centrally abstracted and monitored for completeness and accuracy. A cross-sectional analysis was performed to measure indications and prescriptions for lipid-lowering agents in patients with NASH, NAFL, compensated NAFLD cirrhosis and decompensated NAFLD cirrhosis.
Results: A total of 3, 284 adult participants (1279 NAFLD cirrhosis, 1317 NASH, and 688 NAFL) were studied. 1923 (58.6%) had one or more of the following indications for lipid lowering therapy: diabetes, LDL ≥ 160, or ASCVD score ≥ 7.5%. 62.1% of patients with an indication were prescribed a lipid lowering medication (58.6% with NAFL, 67.1% with NASH, 64.9% with compensated cirrhosis and 52.5% with decompensated cirrhosis). Men (65.6% vs 59.9%), patients ≥ 40 (64.0% vs 31.3%), those with any CV disease history (74.4% vs. 59.3%) and those with a CV event (79.7% vs. 59.4%) were more likely to be prescribed a statin. Similar proportions of patients managed in academic and community centers, 62.4% and 61.5%, of those with indications were prescribed a statin. Statins were used in 65% of those prescribed lipid lowering therapy.



Conclusion: Statins and other lipid-lowering agents are underprescribed in adult patients with NAFLD despite clear indications, particularly those with decompensated cirrhosis. Underprescribing is more common among women and younger patients. A shift in treatment paradigm is essential to ensure optimal use of statins and other lipid lowering agents in patients with NAFLD to reduce cardiovascular outcomes.

THU-318

Elevated urinary bisphenol A levels are associated with non-alcoholic fatty liver disease among adults in the United States

Donghee Kim[1], Eric Yoo[2], Andrew Li[1], George Cholankeril[1], Sean Tighe[1], Won Kim[3], Stephen Harrison[4], Aijaz Ahmed[5]. [1]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, Stanford, United States; [2]Santa Clara Valley Medical Center, San Jose, United States; [3]Seoul National University College of Medicine, Seoul, United States; [4]University of Oxford, Radcliffe Department of Medicine, Oxford, United States; [5]Stanford University School of Medicine, Department of Medicine, Stanford, United States
Email: aijazahmed@stanford.edu

Background and aims: The relationship between bisphenol A (BPA) and non-alcoholic fatty liver disease (NAFLD) is undefined. We studied the impact of BPA on NAFLD.
Method: We performed a cross-sectional analysis of data from the National Health and Nutrition Examination Survey (NHANES) 2005-2014 among adults in the United States (US). NAFLD was diagnosed using the hepatic steatosis index (HSI) and the US fatty liver index (USFLI) in the absence of other causes of chronic liver diseases. The first sample using HSI consisted of 7, 605 adults. The second sample using USFLI consisted of 3, 631 participants with availability of fasting data.
Results: Of the first 7, 605 participants (mean age 47 years, 48.4% male), the prevalence of NAFLD and abnormally elevated alanine aminotransferase (ALT) levels was correlated with urinary BPA levels ($p < 0.05$). Compared to the reference group with lowest quartile of urinary BPA levels, those with 3rd quartile and 4th quartile were 81% and 53% more likely to develop NAFLD defined by HSI. In a multivariate model, the ORs for NAFLD in 3rd quartile and 4th quartile were 1.69 (95% CI 1.39-2.04) and 1.44 (95% CI 1.19-1.76), respectively (*P* for trend < 0.001). In the second sample using USFLI, high BPA levels (4th quartile) remained an independent predictor of NAFLD (OR 1.44 95% CI 1.05-1.98, *P* for trend = 0.012).
Conclusion: High levels of urinary BPA were associated with NAFLD in a nationally representative sample of adults in the US. The pathophysiology remains unclear and warrants further investigation.

THU-319

Association between body size-metabolic phenotype and non-alcoholic steatohepatitis and significant fibrosis

Won Kim[1], Donghee Kim[2], Stephen Harrison[3], Zobair Younossi[4], Aijaz Ahmed[2]. [1]Boramae Medical Center, Seoul, Korea, Rep. of South; [2]Stanford University, Palo Alto, United States; [3]University of Oxford, Radcliffe Department of Medicine, Oxford, United Kingdom; [4]Center for Liver Diseases, Inova Fairfax Hospital, Department of Medicine, Virginia, United States
Email: wonshiri@yahoo.com

Background and aims: Body size-metabolic phenotype may help predict whether or not individuals with non-alcoholic fatty liver disease (NAFLD) develop advanced liver disease. We studied the association of body size-metabolic phenotype and non-alcoholic steatohepatitis (NASH) and significant fibrosis.
Method: Our cross-sectional study included 559 subjects (mean age of 53 years; women 51%) with biopsy-proven NAFLD. Clinical, genetic, and histological characteristic features of NAFLD were evaluated. The metabolically unhealthy phenotype was defined by the presence of two or more metabolic components, while body size was categorized based on body mass index: obese (≥ 25 kg/m^2) or non-obese (<25 kg/m^2). Body sizemetabolic phenotypes were divided into four study groups: (1) metabolically-healthy/non-obese (MHNO), (2) metabolically-unhealthy/nonobese (MUNO), (3) metabolically-healthy/obese (MHO), and (4) metabolically-unhealthy/obese (MUO).
Results: MHO and MUNO groups demonstrated comparable levels of insulin resistance, adipose tissue insulin resistance indexes, and visceral adipose tissue (VAT) areas. The VAT area was significantly higher in the MUO group versus MHO group. However, the VAT to subcutaneous adipose tissue (SAT) ratio was highest in the MUNO group. There was no difference in histology between the MUNO, MHO, and MUO groups. Multivariate analyses adjusted for age, sex, smoking status, PNPLA3, TM6SF2, and VAT/SAT areas demonstrated an independent and dose-dependent relationship between the body size-metabolic phenotype and NASH or significant fibrosis. After excluding MHNO, re-analysis did not demonstrate a significant difference between the MHO, MUO, and MUNO groups in terms of increased risk for NASH and significant fibrosis.

Conclusion: The MUNO group displayed similar degree of hepatic histological severity compared to their MHO counterparts. Metabolic milieu beyond obesity may play a pathogenic role in MUNO individuals who develop NASH with significant hepatic fibrosis.

THU-320

Evaluation of atherosclerosis and coronary artery stenosis of non-alcoholic fatty liver disease

Yoshihito Kubotsu[1], Hirokazu Takahashi[1], Chika Inadomi[1], Kenichi Tanaka[1], Yuka Fujioka[2], Michiaki Okada[1], Hiroshi Isoda[2], Satoshi Ooeda[2], Takumi Akiyama[1], Shinji Iwane[2], Keizo Anzai[1], Yuichiro Eguchi[2]. *[1]Saga University, Department of Metabolism and Endocrinology, Faculty of Medicine, Saga-ken, Japan; [2]Saga University, Liver Center, Faculty of Medicine, Saga-ken, Japan*
Email: y.05211027@gmail.com

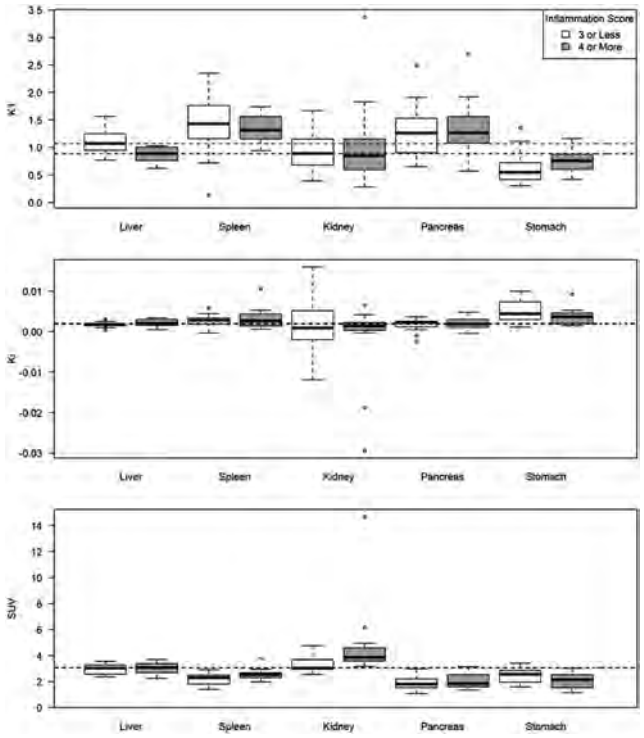
Background and aims: Cardiovascular disease (CVD) is the most common cause of death of non-alcoholic fatty liver disease (NAFLD) patients. CVD surveillance should be important in the management of NAFLD whereas it has not been well established. Moreover, association between the pathogenesis of CVD and NAFLD remains unclear. We evaluated carotid atherosclerosis and coronary artery stenosis (CAS) and tested utility of carotid ultrasonography for the surveillance of CAS in NAFLD.
Method: A total of 100 patients (56 females and 44males; median age, 60 years old: median body mass index, 28.2 kg/m^2) with liver biopsy-proven NAFLD were enrolled in this study. Liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) were examined with FibroScan® in all patients. Maximum intima-media thickness including plaque (max IMT) was measured using ultrasonography. Coronary CT angiography was performed to detect CAS if max IMT >1.0 mm. Association between pathogenesis of NAFLD and atherosclerosis/CAS was evaluated.
Results: Median of max IMT was 1.3 mm, and 60 patients showed max IMT >1.0 mm and 39 patients showed max IMT >1.5 mm. Max IMT significantly correlated with age ($r = 0.39$, $p < 0.001$). Max IMT of patients with advanced liver fibrosis (Kleiner fibrosis stage ≥ 2) was thicker than those with liver fibrosis ≤ 1 (1.62 mm vs. 1.13 mm, $p < 0.05$). Multivariate analysis indicated that age, sex and LSM were significant factors associated with max IMT. In the patients with max IMT ≥ 1.0 mm, 38.9% patients showed significant (75% stenosis or severe) CAS in coronary CT angiography. All patients with significant CAS showed max IMT ≥ 1.5 mm, and median max IMT of the patients with significant CAS was thicker than those without significant CAS (2.16 mm vs. 1.79 mm, $p < 0.05$) and liver fibrosis tended to be advanced in the patients with CAS (LSM, 16.3 kPa vs. 10.5 kPa: Fibrosis stage ≥ 2, 22.7% vs. 8.3%) whereas there were no differences in CAP (265 dB/m vs. 261 dB/m). In the multivariate analysis, max IMT was risk of significant CAS independent to diabetes.
Conclusion: Prevalence of advanced carotid atherosclerosis is surprisingly high and carotid atherosclerosis and CAS relate to liver fibrosis in NAFLD. Surveillance of NAFLD with advanced liver fibrosis is important and carotid ultrasound could be useful to identify the patients with high risk of CAS and CVD.

THU-321

Fluorodeoxyglucose perfusion and uptake in abdominal organs is associated with hepatic disease state in patients with non-alcoholic fatty liver disease

Alexander Kuo[1], Chung Heng Liu[1], Benjamin Spencer[2], Blythe Durbin-Johnson[3], Michael Corwin[4], Guobao Wang[2], Souvik Sarkar[1]. *[1]University of California, Davis, Internal Medicine/Gastroenterology and Hepatology, Sacramento, United States; [2]University of California, Davis, Radiology/Nuclear Medicine, Sacramento, United States; [3]University of California, Davis, Public Health/Biostatistics, Davis; [4]University of California, Davis, Radiology, Sacramento, United States*
Email: ssarkar@ucdavis.edu

Background and aims: The effect of hepatic steatosis, inflammation and fibrosis in patients with non-alcoholic fatty liver disease (NAFLD) on extra-hepatic pathologies is appreciated yet poorly understood. Characterizing the metabolic interactions between liver and related organs in patients with NAFLD may define risk factors for liver inflammation and fibrosis. The aim of this study is to explore the relationship between glucose uptake and metabolic activity in the liver and other abdominal organs as they relate to the state of NAFLD, utilizing dynamic ^{18}F-fluorodeoxyglucose (FDG)-PET.
Method: Patients with biopsy-proven NAFLD underwent FDG-PET in a fasting state. Imaging parameters were measured using established 3-compartment model of hepatic FDG kinetics. Due to limited field of view of current PET scanners, we were able to extract kinetic data from surrounding abdominal organs- kidney, stomach, pancreas, and spleen. The FDG parameters were compared using linear mixed effect models. These were also compared with histologic parameters within and between organs. Spearman correlations amongst parameters were calculated.
Results: Of the 30 patients, 67% were female, mean age 55 years, BMI 32.9 kg/m^2, Hgb A1c 5.8% and pre-PET blood glucose 113 mg/dL. Eight patients had advanced fibrosis (fibrosis score ≥ 3) and 67% having steatohepatitis (NAFLD activity score >4). Compared to the liver, the fold change of FDG influx rate (K_i) was relatively similar across the organs other than stomach (0.0025, $p = 0.008$) and kidney (−0.0024, $p = 0.009$). The surrogate for perfusion, characterized by rate of FDG uptake to the tissue from blood, K_1 was significantly higher in the spleen ($p = 0.022$) and pancreas ($p = 0.042$) but lower in the stomach ($p < 0.001$). Metabolic activity, characterized by standardized uptake value (SUV), was lower in all organs except the kidney, when compared to the liver. SUV of the kidney and spleen showed weak positive correlation with liver inflammation ($r = 0.41$, $p = 0.038$) and NAS score ($r = 0.4$, $p = 0.036$), respectively. Patients with high inflammation had a greater difference in SUV between the liver and kidney than those with low inflammation ($p < 0.001$; Fig 1).



Conclusion: Here we present FDG kinetic data of extra-hepatic abdominal organs in relation to NAFLD disease state. Although our data is limited by its small size and lack of comparison to healthy subjects, it shows that FDG uptake and perfusion rates are differential in the abdominal organs, which may be driven by hepatic inflammation and fibrosis.

THU-322

Statin use on development and progression of non-alcoholic fatty liver disease: A nationwide cohort study

Jung Il Lee[1], Kwan Sik Lee[1], Hyun Woong Lee[1], Hye Young Chang[2].
[1]*Yonsei University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: mdflorence@yuhs.ac

Background and aims: Use of statins in non-alcoholic fatty liver disease (NAFLD) subjects may reduce cardiovascular morbidity, whereas evidences lack to show benefits of statins on development and progression of NAFLD. We aimed to investigate role of statins on development of significant liver fibrosis in NAFLD subjects and on occurrence of NAFLD among non-NAFLD population.
Method: From the nationwide cohort, this study included 176, 387 subjects that entered the National Health Insurance Service Physical Examination Cohort of the Republic of Korea in 2006 and followed up for 10 years. NAFLD was diagnosed by calculating hepatic steatosis index (HIS), and significant liver fibrosis was evaluated using BARD score.
Results: The subjects with HSI >36.0 and without previous statin use were selected as NAFLD cohort (n = 22, 337). The subjects that were exposed to statins during the 10-year follow-up (n = 6, 817) were age and sex matched with those that never had statin treatment (n = 15, 520). The NAFLD subjects that underwent statin therapy had significantly increased risk of advanced liver fibrosis (AHR [adjusted hazard ratio] 1.36; 95% CI [confidence interval] 1.18-1.58) independent of accompanying diabetes mellitus (DM) (AHR 1.40; 95% CI 1.12-1.74 with DM) (AHR 1.32; 95% CI 1.08-1.611 without DM). The subjects with HSI < 30.0 were included in non-NAFLD cohort (n = 41, 241). Among them, 5, 053 subjects eventually experienced statin treatment, and 36, 188 subjects never had statin therapy. Non-NAFLD subjects that experienced statin treatment had increased risk of developing NAFLD (AHR 1.36; 95% CI 1.18-1.58).
Conclusion: This nationwide population based study suggests that beneficial effects cannot be expected in NAFLD subjects regarding progression of liver fibrosis with statins. For those without evident NAFLD, correcting dyslipidemia with statin would not prevent NAFLD development.

THU-323

Impact of genetic polymorphisms associated with NAFLD on hepatic and vascular complications in diabetes

Rosa Lombardi[1], Lorena Airaghi[1], Giovanni Targher[2], Gaetano Serviddio[3], Paola Dongiovanni[1], Gabriele Maffi[1], Marica Meroni[1], Alessandro Mantovani[2], Claudio Maffeis[4], Antonio Colecchia[5], Rosanna Villani[3], Luca Valenti[1], Silvia Fargion[1], Anna Ludovica Fracanzani[1]. [1]*Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan Italy, Pathophysiology and Transplantation, Metabolic Liver Diseases Research Center, Milan, Italy;* [2]*University Hospital of Verona, Division of Endocrinology, Diabetes and Metabolism, Department of Medicine, Verona, Italy;* [3]*University of Foggia, Centro C.U. R.E, Dept. of Medical and Surgical Sciences, Foggia, Italy;* [4]*University Hospital of Verona, Pediatric Diabetes and Metabolic Disorders Unit, Department of Surgical Sciences, Dentistry, and Pediatrics, and Gynaecology, Verona, Italy;* [5]*Azienda Ospedaliera Universitaria Integrata of Verona, Gastroenterology Unit, Verona, Italy*
Email: rosalombardi@hotmail.it

Background and aims: Type 2 Diabetes (T2DM) and NAFLD share common metabolic risk factors. NAFLD is influenced by genetic polymorphisms, namely PNPLA3 and MBOAT7. The impact of these polymorphisms in the diabetic population is not fully explored, therefore we aimed at investigating their role with regard to liver and vascular complications in a T2DM multi-centric cohort.
Method: Three-hundred nineteen patients attending the diabetes clinic were enrolled. Genotyping for rs738409 C > G (I148M in PNPLA3) and rs641738 C > T (TMC4 in MBOAT7) polymorphisms was performed in all patients, as well as FibroScan® using liver stiffness measurement (LSM) ≥ 7.0 for M probe and 5.7 kPa for XL to define fibrosis ≥ 2, and ultrasound examination to assess steatosis.
Results: Mean age was 69 ± 9 years and 49% patients were males. Steatosis was present in 89%, hypertension in 78%, dyslipidemia in 84% (78% of whom on statins), obesity in 32%. The 64% of the cohort was on antidiabetic therapy, while the 36% on diet only (mean HbA1c 7 ± 1.1%); 85% of patients presented at least one vascular complication, 80% a macrovascular one (66% carotid plaques; 71% intima-media thickness (IMT) >0.9 mm; 18% coronary artery disease) and 29% a microvascular one (16% nephropathy; 14% microalbuminuria; 11% retinopathy; 3% neuropathy); LSM ≥ 7/5.7 kPa was present in 47 (15%) patients, PNPLA3 mutated allele (G) in 47% and 7% in heterozygous and homozygous state and MBOAT7 mutated allele (T) in 46% and 18% in heterozygous and homozygous state. Prevalence of at least one microvascular complication and of LSM ≥ 7/5.7 kPa (M/XL probe) was significantly higher in patients homozygous for PNPLA 3 G allele, and this association remained in multivariate analysis adjusted for age, sex, glycaemic control, duration of T2DM, smoke, hypertension, BMI, statins, ACE/ARBs and the other polymorphism studied (OR 3.6; 95% CI 1.2-10.4; p = 0.02; OR 3.7; 95% CI 1.4-9.7; p = 0.008); conversely prevalence of at least one macrovascular complications was significantly lower in patients homozygous for MBOAT7 T allele and this association remained in multivariate analysis adjusted for the same variables (OR 0.4; 95% CI 0.2-0.9; p = 0.03).
Conclusion: NAFLD genetic polymorphisms have an impact not only on liver fibrosis but also on vascular complications in T2DM.

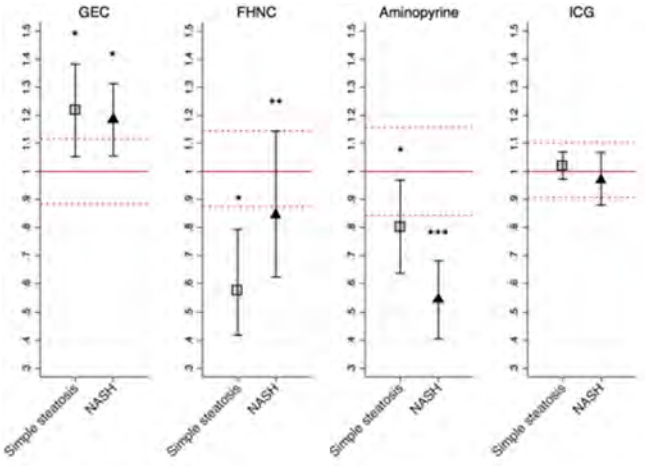
THU-324

Non-alcoholic fatty liver disease causes dissociated changes in metabolic liver functions

Peter Lykke Eriksen[1], Michael Soerensen[1], Henning Gronbaek[1], Stephen Hamilton-Dutoit[2], Hendrik Vilstrup[1], Karen Louise Thomsen[1]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark;* [2]*Aarhus University Hospital, Institute of Pathology, Aarhus, Denmark*
Email: ple@clin.au.dk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a major health concern affecting 25% of the world's population. It is generally held that a fatty liver does not influence liver function, but quantitative measurements of metabolic liver functions have not been systematically performed. We aimed to study selected hepatocellular metabolic functions in patients with different stages of NAFLD.
Method: Twenty-five non-diabetic, biopsy-proven NAFLD patients [12 with simple steatosis and 13 with non-alcoholic steatohepatitis (NASH)] and ten healthy controls were included in a cross-sectional study. Hepatocyte cytosolic function was assessed by the galactose elimination capacity (GEC), mitochondrial-cytosolic metabolic capacity by the functional hepatic nitrogen clearance (FHNC), microsomal function by the aminopyrine breath test, and excretory liver function by the indocyanine green (ICG) elimination test.
Results: GEC was 20% higher in NAFLD than in controls [3.15 mmol/min (2.9-3.41) vs. 2.62 (2.32-2.93); p = 0.02]. FHNC was 30% lower in NAFLD [23.3 l/h (18.7-28.9) vs. 33.1 (28.9-37.9); p = 0.04], more so in simple steatosis [19.1 l/h (13.9-26.2); p = 0.003] and non-significantly in NASH [27.9 l/h (20.6-37.8); p = 0.19]. Aminopyrine metabolism measured as the 2-hour cumulative percentage dose recovery was 25% lower in simple steatosis [8.9% (7.0-10.7)] and 50% lower in

NASH [6.0% (4.5-7.5)] than in controls [11.9% (9.3-12.8)] (p < 0.001). ICG elimination was intact.



Metabolic liver functions – normalised to healthy controls
Means with their 95% confidence interval shown.
■: Simple steatosis, ▲: NASH, red lines: healthy controls.
*: significantly different from controls, **: significantly different from simple steatosis,
***: significantly different from controls and simple steatosis.

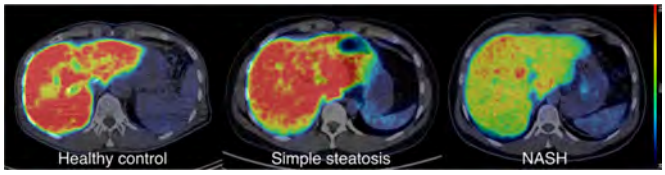
Conclusion: The hepatocellular metabolic functions were altered in a manner that was dissociated both by different effects on different liver functions and by different effects of different stages of NAFLD. Our results revealed a reduced mitochondrial and microsomal function and coexisting intact cytosolic and excretory function. This is compatible with the present pathophysiological understanding of the disease that some sub-hepatocellular compartments are more damage-prone to NAFLD than others. Our findings emphasise that even simple steatosis and early NASH are indeed hepatic diseases with organ function consequences, and do not simply represent innocuous fat accumulation in hepatocytes.

THU-325

Regional liver function investigated by galactose positron emission tomography is reduced in patients with non-alcoholic steatohepatitis

Peter Lykke Eriksen[1], Karen Louise Thomsen[1], Lars Peter Larsen[2], Henning Gronbaek[1], Hendrik Vilstrup[1], Michael Soerensen[1]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; [2]Aarhus University Hospital, Department of Radiology, Aarhus, Denmark*
Email: ple@clin.au.dk

Background and aims: Little is known about how the structural changes of non-alcoholic fatty liver disease (NAFLD) affect liver function. We investigated in vivo effects of hepatic fat fraction and morphological changes on regional (2-[^{18}F]fluoro-2-deoxy-D-galactose (^{18}F-FDGal) positron emission tomography (PET)) and global (galactose elimination capacity (GEC)) metabolic liver function in patients with non-alcoholic steatohepatitis (NASH), simple steatosis, and healthy controls.
Method: Twenty-five biopsy-proven, non-diabetic NAFLD patients (13 NASH, 12 simple steatosis) underwent ^{18}F-FDGal PET, GEC, and magnetic resonance imaging-derived proton density fat fraction (MRI-PDFF). Nine healthy controls were included.
Results: Mean hepatic ^{18}F-FDGal metabolism expressed as standardized uptake value (SUV), was 13.5 (95% CI, 12.1-14.9) in NASH, 16.0 (14.9-17.1) in simple steatosis, and 16.9 (15.8-17.9) in controls (p < 0.001) (Figure). Each 5 percentage point increment in liver fat fraction was associated with a 0.7 reduction in SUV (0.3-1.0; p < 0.001). The reduction of SUV in NASH was not attributable to fat alone as mean liver fat fraction was the same in NASH and simple steatosis (~30%; p = 0.5) and results remained unchanged after correction for the effect of fat (p = 0.008). The mean fat-free liver volume was larger in NASH than in simple steatosis and controls (p = 0.15) and exhibited a high functional heterogeneity with the coefficient of variation for SUV being 19% higher than in simple steatosis (p = 0.05) and 35% higher than in controls (p = 0.004), with no significant difference between simple steatosis and controls (p = 0.13) (Figure). GEC was unaffected by NAFLD (p = 0.9) while GEC per fat-free liver volume was reduced in NASH to 1.71 mmol/min/ml (1.58-1.84) vs. 1.95 (1.82-2.09) in simple steatosis and 1.91 (1.67-2.14) in controls (p = 0.05).



Conclusion: In NASH, while total capacity for galactose metabolism was maintained by an increased fat-free liver volume, regional metabolic capacity was markedly reduced with high functional heterogeneity that was not observed in the simple steatosis patients or the healthy controls. This was due not only to fat infiltration but also to other disease specific features of NASH such as ballooning and fibrosis. Thus, NASH, as opposed to simple steatosis, disturbs the uniform metabolic function of the liver.

THU-326

Relative fat mass: A new definition of obesity and NAFLD

Mariana Machado[1], Sara Policarpo[1], João Coutinho[2], Sofia Carvalhana[1], Jorge Leitão[3], Francisco Velasco[4], Isabel Medeiros[5], Catarina Alves[6], Mafalda Bourbon[6], Helena Cortez-Pinto[1]. *[1]Hospital de Santa Maria, Serviço de Gastrenterologia e Hepatologia, Lisbon, Portugal; [2]Hospital de Santa Maria, Serviço de Cirurgia, Lisbon, Portugal; [3]Centro Hospitalar e Universitário de Coimbra, Serviço de Medicina Interna, Coimbra, Portugal; [4]Centro Hospitalar do Algarve, Serviço de Gastrenterologia, Faro, Portugal; [5]Hospital Espírito Santo, Serviço de Gastrenterologia, Évora, Portugal; [6]Instituto Nacional de Saúde Dr. Ricardo Jorge, Center of Biodiversity Functional and Integrative Genomics, Lisbon, Portugal*
Email: mverdelhomachado@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the liver manifestation of adiposopathy. Recently, a new score was developed to estimate body fat percentage (relative fat mass, RFM). We aimed to evaluate the performance of RFM, as compared to other anthropometric measurements, in predicting the presence and severity of NAFLD.
Method: RFM, body mass index (BMI) and other anthropometric measurements were evaluated in two cohort of subjects: a cohort from a Portuguese prospective epidemiological study (e_Cor), and morbidly obese patients with biopsy-proven NAFLD. Associations were studied between RFM and BMI, and liver disease assessed by non-invasive tools in the first cohort and by liver histology in morbidly obese.
Results: In the general population cohort, 744 subjects (48% male) were enrolled. BMI-defined obesity was present in 23% and RFM-defined obesity in 86%. Insulin resistance (IR) associated with BMI-defined obesity (OR 4.37 [2.16-8.84]) and weight (OR 1.05 [1.02-1.08]) in men, and waist circumference (WC) (OR 1.07 [1.03-1.11]) in women. Dyslipidemia and hypertension associated with RFM-defined obesity in men (OR 2.96 [1.36-6.47] and OR 5.37 [1.31-22.06], respectively). Ultrasound-diagnosed NAFLD in 33%, associated with weight in men (OR 1.03 [1.003-1.06] and WC in women (OR 1.06 [1.02-1.10]). ALT elevation associated with weight in men (OR 1.04 [1.02-1.07]) and NAFLD Fibrosis Score-estimated advanced fibrosis with BMI-defined obesity in women (OR 42.43 [3.61-498.13]). In the

morbidly obese cohort, 152 subjects were enrolled, of whom 84% were female, 29% had steatohepatitis and 9.4% advanced fibrosis. Adiponectin associated inversely and leptin positively with RFM, in men. The severity of steatosis increased linearly with BMI and WC in women. Higher BMI associated with steatohepatitis in women and advanced fibrosis in men.
Conclusion: RFM-defined obesity better predicted dyslipidemia and hypertension (though not IR) and adipokines imbalance, however, it did not add value to BMI-defined obesity, in predicting NAFLD or liver injury.

THU-327
Lifestyle modification leads to a significant decline in aminotrasnsferase activity even without weight reduction in children with non-alcoholic fatty liver disease
Anna Mania[1], Pawel Malecki[1], Katarzyna Mazur-Melewska[1], Pawel Kemnitz[1], Wojciech Sluzewski[1], Magdalena Figlerowicz[1].
[1]Poznan University of Medical Sciences, Department of Infectious Diseases and Child Neurology, Poznań Poland
Email: maniaanna@hotmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is currently one of the most common health concerns due to a sedentary lifestyle and improper eating habits. Children develop fatty liver along with insulin resistance and metabolic syndrome.
Method: The study group consisted of 35 boys and 15 girls, age range 3-16 years (mean 10, 51 ± 3, 18 years), with the diagnosed non-alcoholic fatty liver disease. Differential diagnosis of the liver steatosis was performed to exclude underlying liver diseases. All patients underwent weight and height measurements, physical examination and blood collection for hematologic and biochemical parameters. APRI and PNFS were calculated basing on established formulas. Patients received lifestyle modification advice regarding diet and physical exercises. All children were followed during control visits for 2, 45 ± 1, 45 years. End point parameters were weight reduction and a decline in aminotransferase activity.
Results: 40/50 children were overweight, 7 had normal BMI. Weight loss was obtained in 22/50 children; 28 children gained weight after the follow-up period. ALT decline was observed in 36/50 children. Children with ALT reduction had lower BMI at the end of follow-up period (27, 29 ± 4, 84 vs 31, 01 ± 4, 93 kg/m$^{2;}$ p = 0, 035). Moreover, higher initial APRI value (0, 45 ± 0, 28 vs 0, 27 ± 0, 15; p = 0, 003) and more significant reduction of this parameter (− 0, 15 ± 0, 24 vs 0, 07 ± 0, 12) was observed in this group of patients. Decline in ALT activity was negatively related to PNFS (r = – 0, 61; p < 0, 05), APRI (r = – 0, 45; p < 0, 05), GTP activity (r = – 0, 41; p < 0, 05).
Conclusion: Although the decline in aminotransferase activity is related to lower BMI, it can be obtained due to lifestyle modification even without weight reduction in children with NAFLD. Higher initial markers of liver injury do not exclude an improvement in liver parameters after lifestyle modification.

THU-328
The prevalence of NAFLD in morbidly obese subjects revisited
Abraham Meijnikman[1], Natasha Bosma[1], Omrum Aydin[1], Maurits De Brauw[2], Hilde Herrema[1], Victor Gerdes[1], Max Nieuwdorp[1], Albert Groen[1], Dutch Liver Pathology Panel Dutch Liver Pathology Panel[1], Joanne Verheij[1]. *[1]Amsterdam UMC, Amsterdam, Netherlands; [2]MC Slotervaart, Amsterdam, Netherlands*
Email: a.s.meijnikman@amc.uva.nl

Background and aims: The global obesity epidemic is a driver for obesity-related complications such as non-alcoholic fatty liver disease (NAFLD). The active "hepatitic" subtype of NAFLD is non-alcoholic steatohepatitis (NASH) and potentially leads to liver fibrosis and cirrhosis. It is estimated that the prevalence of NAFLD in the general population is approximately 25% but increases to over 90% in morbidly obese subjects. It is important to validate the alarmingly high prevalence of NAFLD, including the occurrence of NASH, since these numbers are based on studies that differ in set-up (i.e. diagnostic tool, histological staging system). The aim of this study was to determine the prevalence of NAFLD in a cohort of morbidly obese subjects scheduled for bariatric surgery.
Method: In this prospective cohort study, 149 morbidly obese subjects scheduled for bariatric surgery were included. A standard metabolic work-up was performed and body composition was assessed using bioelectrical impedance analysis. Liver biopsies were obtained perioperatively and were evaluated by a panel of liver pathologists. Histological diagnosis was based on Steatosis Activity Fibrosis (SAF) score. NAFLD was categorized into simple steatosis when steatosis was present in >5% of hepatocytes without ballooning or NASH if ballooning and inflammation were both present in the biopsy.
Results: No NALFD was seen in 43.6%, simple steatosis in 47.7% and NASH in 8.7% of subjects. Subjects with NAFLD were older than subjects without NAFLD (48.7 ± 10.3 y. vs 42.7 ± 10.8 y; p < 0.001), had higher prevalence of hypertension (38.0% vs 18.5%; p = .012), type 2 diabetes (32.4% vs 10.8%; p = .002) and dyslipidemia (29.6% vs 12.3%; p = .014. Median (IQ range) BMI did not differ significantly: 38.0 (35.2-40.5) vs 38.4 (35.1-40.0) vs 38.5 (37.1-40.9) in subjects with healthy liver, NAFLD and NASH, respectively. Subjects with NAFLD had a lower percentage of total body fat (44.7 ± 5.5% vs 47.8 ± 4.8%; p = .005), and a higher fat-free mass (55.9 ± 5.5% vs 52.6 ± 5.4%; p = .002), than patients with a healthy liver. Of interest, preoperative weight loss was equal in subjects with healthy liver, NAFLD and NASH.
Conclusion: In sharp contrast to previous studies and to the general dogma that the prevalence of respectively NAFLD and NASH is 90% and 20% in subjects with (morbid) obesity, data from our large prospective cohort indicates that this prevalence is much lower in Dutch subjects.

THU-329
Opioid use is common in patients with non-alcoholic fatty liver disease and associated with severity of liver disease, hepatic encephalopathy and psychiatric comorbidities
Andrew Moon[1], Roberto J Firpi[2], Vandana Khungar[3], Justin Kupec[4], Anna LOK[5], Laura Malahias[6], Cheryl Schoen[6], Huy N. Trinh[7], A. Sidney Barritt[8]. *[1]University of North Carolina at Chapel Hill, Chapel Hill, United States; [2]University of Florida, Gainesville, United States; [3]University of Pennsylvania, Philadelphia, United States; [4]West Virginia University, Morgantown, United States; [5]University of Michigan, Ann Arbor, United States; [6]TARGET PharmaSolutions, Inc., Chapel Hill, United States; [7]San Jose Gastroenterology, San Jose, United States; [8]University of North Carolina at Chapel Hill, Chapel Hill, United States*
Email: lmalahias@targetpharmasolutions.com

Background and aims: Pain control is difficult in patients with non-alcoholic fatty liver disease (NAFLD) and particularly those with cirrhosis. Painful comorbidities are common in NAFLD and are often treated with opioids. We aimed to determine the prevalence of opioid use and associated characteristics in a real-world cohort of NAFLD patients.
Methods: TARGET-NASH, a longitudinal observational study at 55 sites in the United States, includes patients with NAFLD defined by pragmatic case definitions. Opioid use was defined as opioid use in the year prior to cohort enrollment. We compared opioid users and non-users by demographic factors, comorbidities and liver disease severity using univariate analyses and developed a stepwise logistic regression model of opioid use.
Results: The cohort included 3284 patients with NAFLD, including 1317 with non-alcoholic steatohepatitis (NASH) and 1279 with NAFLD cirrhosis. Opioid use was reported in 17.8% and was more common with females (20.2% vs 14.3%) and patients with advanced liver disease (10.3% NAFL, 17.5% NASH, 22.1% NAFLD cirrhosis), BMI ≥ 32 kg/m^2 (22.2% vs 13.0%), diabetes (21.9% vs 13.7%), depression (30.2% vs 10.2%), rheumatologic disease (34.5% vs 16.6%),

osteoarthritis (33.3% vs 16.1%) and fibromyalgia (47.1% vs 16.0%) ($p < 0.001$ for all). Among patients with cirrhosis, MELD was similar among opioid recipients and non-recipients (mean 10.1 vs 9.8, $p = 0.370$). Opioid use was more common among those with hepatic encephalopathy (30.6% vs 19.8%, $p < 0.001$) and ascites (27.0% vs 20.0%, $p = 0.006$). In a logistic regression model, liver disease severity, BMI ≥ 32 kg/m^2, diabetes, osteoarthritis, depression and rheumatologic disease were associated with opioid use. Age and race were not associated with opioid use.

Patient Characteristic	Odds Ratio (95% CI)
NAFL vs NAFLD Cirrhosis	0.64 (0.47, 0.87)
NASH vs NAFLD Cirrhosis	0.89 (0.72, 1.10)
BMI (≥ 32 vs < 32 kg/m^2)*	1.49 (1.22, 1.82)
Diabetes	1.21 (0.99, 1.49)
Osteoarthritis	1.93 (1.47, 2.52)
Depression	3.05 (2.51, 3.71)
Rheumatologic disease	2.11 (1.54, 2.88)

*Median BMI for cohort = 32 kg/m^2

Conclusion: Nearly 1/5 of NAFLD patients reported opioid use and, in patients with cirrhosis, usage was twice that of those with NAFL. Opioid use was associated with depression and presence of hepatic encephalopathy. Given safety concerns of opioids, alternative pain control options and treatment of mental health comorbidities should be pursued for patients with NAFLD.

THU-330
Biochemical liver tests reflect the genetic risk for fatty liver disease with increasing body weight but not with alcohol consumption

Elena Mueller[1], Ursula Huber-Schönauer[2], Georg Strebinger[1], Ludmilla Kedenko[1], Alexandra Feldmann[1], Bernhard Paulweber[1], Christian Datz[2], Elmar Aigner[1]. *[1]Landeskrankenhaus Salzburg, First Department of Medicine, 5020 Salzburg, Austria; [2]Hospital Oberndorf, 5110 Oberndorf, Austria*
Email: e.aigner@salk.at

Background and aims: Liver tests are commonly used as surrogates for liver health. We aimed to examine whether liver biochemistries are related to the genetic risk for fatty liver, conferred by PNPLA3 and TM6SF2 risk alleles, in groups stratified by weight and alcohol consumption on the population level.
Method: PNPLA3 and TM6SF2 genotypes were determined in 1814 Caucasian subjects from a colonoscopy screening program. Clinical and biochemical data were obtained by standard methods. Subjects were grouped according to BMI, alcohol consumption and genotypes.
Results: Carriers of the PNPLA3 or the TM6SF2 risk allele had a higher risk for fatty liver compared to wild type (PNPLA3: OR 1.252, TM6SF2: OR 1.586). Adiposity amplified the effects of the PNPLA3 risk allele on serum GGT and ALT levels on the population level. Liver biochemistries were not related to the genetic risk for fatty liver in groups stratified by alcohol consumption. Body weight and HOMA-IR are the determinants of GGT ($R = 0.250$, $p < 0.0001$ for women, $R = 0.196$, $p < 0.001$ for men) and ALT ($R = 0.318$, $p < 0.001$ for women, $R = 0.255$, $p < 0.001$ for men) independent of the underlying genetic risk.
Conclusion: This study confirmed that carriers of the PNPLA3 variant and the TM6SF2 variant exhibit an increased risk for developing fatty liver. The commonly used liver biochemistries are related to the underlying genetic risk for hepatic steatosis in the obese study cohort. However, liver biochemistries do neither reflect the genetic risk in the lean nor overweight group, nor with alcohol consumption. BMI and HOMA-IR are the determinants of liver tests, however, this relationship is independent from the underlying genetic risk.

THU-331
Derivation and validation of a cardiovascular risk score for prediction of major acute cardiovascular events in non-alcoholic fatty liver disease: The importance of an elevated mean platelet volume

Robin D. Abeles[1], Benjamin H. Mullish[1], Roberta Forlano[1], Maciej Adler[1], Nikos Giannakeas[2], Alexandros Tzallas[2], Michael Yee[1], Jamil Mayet[3], Robert D. Goldin[4], Mark Thursz[1], Pinelopi Manousou[1]. *[1]Liver Unit/Division of Integrative Systems Medicine and Digestive Disease, Imperial College London, London, United Kingdom; [2]Department of Computer Engineering, Technological Educational Institute of Epirus, Kostakoi, Greece; [3]National Heart and Lung Institute, Hammersmith Hospital, Imperial College London, London, United Kingdom; [4]Department of Cellular Pathology, Imperial College London, London, United Kingdom*
Email: r.forlano@imperial.ac.uk

Background and aims: Cardiovascular disease is a key cause of morbidity in non-alcoholic fatty liver disease (NAFLD) but appropriate means to predict major acute cardiovascular events (MACE) are lacking. We aimed to design a bespoke cardiovascular risk score in NAFLD.
Method: A retrospective derivation (2008-2016, 356 patients) and prospective validation (2016- 2017, 111 patients) NAFLD cohort study was performed. Clinical and biochemical data were recorded at enrolment and mean platelet volume (MPV), Qrisk2 and Framingham scores were recorded one year prior to MACE (Cardiovascular death, myocardial infarction, stroke, and transient ischaemic attack).
Results: The derivation and validation cohorts were well matched with MACE prevalence 12.6% and 12% respectively. On univariate analysis, age, diabetes, advanced fibrosis, collagen proportionate area >5%, MPV and liver stiffness were associated with MACE. After multivariate analysis, age, diabetes and MPV remained independently predictive. The "NAFLD CV-risk score" was generated using binary logistic regression: **0.06* (Age) + 1.2* (MPV) + 0.135* (DM[1])-19.46** [1] ***Diabetes mellitus: 0: absent; 1: present.***
(AUROC 0.882). A cut-off of < –3.2 gave a Sensitivity 98%, Specificity 63%, PPV 26%, NPV 99%. An MPV alone of >10.05 gave a sensitivity 97%, specificity 59%, PPV 24% and NPV 97% (AUROC 0.85). Validation cohort AUROCs were comparable at 0.75 (NAFLD CV-risk) and 0.72 (MPV). In the full cohort, the NAFLD CV-risk score and MPV outperformed both Qrisk2 and Framingham scores.

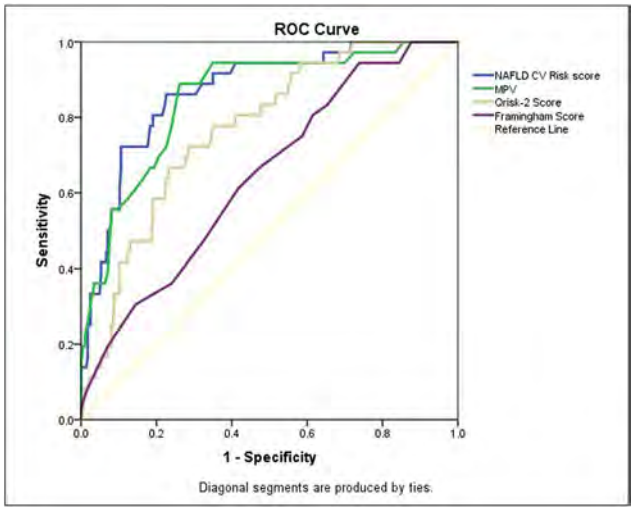


Figure: Diagnostic performance of NAFLD CV risk score and MPV vs traditional scores.

Conclusion: The NAFLD CV risk score and MPV accurately predict 1-year risk of MACE thereby allowing better identification of patients that require optimisation of their cardiovascular risk profile.

THU-332

Healthcare resource utilisation, demographics, and comorbidities by diagnosis codes and histological stage in non-alcoholic fatty liver disease/non-alcoholic steatohepatitis in a large integrated healthcare delivery system in the U.S

Lisa Nyberg[1], Heather Patton[1], Kevin Chiang[2], Su-Jau Yang[3], Susan Caparosa[3], Julie Stern[3], Anders Nyberg[1]. [1]*Kaiser Permanente, Hepatology Research, San Diego, United States;* [2]*Kaiser Permanente, Pharmacy Analytical Services, Downey, United States;* [3]*Kaiser Permanente, Research and Evaluation, Pasadena, United States*
Email: lisa.m.nyberg@kp.org

Background and aims: The increasing prevalence of non-alcoholic fatty liver disease/steatohepatitis (NAFLD/NASH) portends a large clinical and economic burden. However, there are limited data analysing Healthcare Resource Utilisation (HCRU) by diagnosis code and disease severity as determined by liver histopathology. Aims: 1) Describe prevalence, demographics, and comorbidities of NAFLD/NASH within Kaiser Permanente Southern California (KPSC); 2) Determine HCRU as quantified by stage of disease.

Methods: Retrospective cohort study of KPSC patients with diagnosis codes for NAFLD/NASH Jan 2006-Dec 2016. Exclusions: non-NAFLD/NASH liver disease diagnoses. Disease progression was determined by codes and procedures indicative of cirrhosis and portal hypertension. Comorbidities were determined by diagnosis codes and lab values. Liver biopsy reports were reviewed for steatosis, inflammation, ballooning and stage of fibrosis. HCRU was calculated over one-year post-index date including laboratory studies, office visits, hospitalisations, prescriptions dispensed, email and telephone encounters, and expressed as mean counts/person per/year. SAS EG 9.3 was used for statistical analyses.

Results: N = 103, 036 patients were included. Demographics, comorbidities, and HCRU are shown in the table. HCRU increases with progression of NAFLD/NASH to cirrhosis and decompensated cirrhosis with largest impact for hospitalisations (4-fold increase). Additionally, 505 biopsies were reviewed showing: Stage 0: 137 (27.1%), stage 1-2: 202 (40%), stage 3: 47 (9.3%), stage 4: 119 (23.6%). HCRU was significantly increased for labs, office visits, prescriptions, and telephone encounters in patients with cirrhosis vs non-cirrhosis.

	NAFLD, No cirrhosis	Compensated cirrhosis	Cirrhosis w/ portal hypertension	Decomp Cirrhosis
N	94716	1527	881	5912
Age	52.7	64.4	66.3	63.5
BMI >30 (%)	55.5	48.5	48.5	37.0
Diabetes (%)	33.6	47.9	56.3	39.3
Dyslipidaemia (%)	45.7	63.3	62.8	51.9
Hypertension (%)	70.6	78.0	70.1	79.1
Cardiovasc Dis (%)	41.0	57.8	59.6	47.4
Labs, mean (SD)	20.4 (35.6)	43.9 (63.7)	51.8 (72.2)	93.9 (153.1)
Office visits, mean (SD)	8.6 (9.4)	13.5 (12.5)	14.4 (12.0)	16.7 (15.0)
Hosp, mean (SD)	0.2 (0.5)	0.3 (0.8)	0.3 (0.8)	0.8 (1.5)
Rx, mean (SD)	7.3 (6.1)	10.9 (7.3)	11.0 (6.6)	13.5 (8.5)
Emails, mean (SD)	0.4 (1.2)	0.5 (1.4)	0.5 (1.3)	0.6 (1.7)
Tel enc, mean (SD)	1.3 (2, 4)	2.5 (3.6)	2.6 (3.6)	3.2 (4.8)

Conclusion: HCRU increases with progression to cirrhosis. This highlights the importance of identification and treatment at early stages of fibrosis to reduce the economical and clinical burden of this disease.

THU-333

The HSD17B13:TA (rs72613567) splice variant protects against severity of non-alcoholic fatty liver disease but not fibrosis

Rafael Paternostro[1], Katharina Staufer[1], Stefan Traussnigg[1], Albert Stättermayer[1], Emina Halilbasic[1], Omar Keritam[1], Judith Stift[2], Gerhard Prager[3], Petra Munda[1], Peter ferencl[1], Michael Trauner[1]. [1]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria;* [2]*Medical University of Vienna, Department of Pathology, Vienna, Austria;* [3]*Medical University of Vienna, Division of General Surgery, Department of Surgery, Vienna, Austria*
Email: rafael.paternostro@meduniwien.ac.at

Background and aims: Recently, the splice variant rs72613567:TA in the *17β-hydroxysteroid dehydrogenase 13* (*HSD17B13*) gene has been shown to be associated with a reduced risk for alcoholic liver disease, non-alcoholic liver disease (NAFLD) and of progression from steatosis to steatohepatitis. Aim of our study was to investigate the effects of rs72613567:TA carriage in a well-defined group of patients with biopsy-proven NAFLD.

Methods: Patients with NAFLD in a prospective registry study who underwent liver biopsy were genotyped for the *HSD17B13*- (minor allele:TA) and the *PNPLA3*-gene (minor allele: G). Furthermore, standard laboratory tests were measured. The NAFLD-activity score (NAS) was used to grade all liver biopsy samples.

Results: 239 patients with biopsy proven NAFLD were included in the study:Age 49 ± 13, 143 male (59.8%), BMI 33 (Median; range 28-41), NAS: ≤ 4:124 (51.9%); 5-8: 115 (48.1%); fibrosis: F0-2: 180 (75.3%); F3-4:59 (24.7%). 78 (32.6%) patients underwent bariatric surgery. 81 (33.9%) patients were rs72613567:TA heterozygotes and 17 (7.1%) homozygotes (overall allele frequency: 24.1%).NAS scores ≥ 5 in TA-allele carriers were less frequent than in T/T carriers (T/T: 77 [54.6%] vs. all TA carriers: 38[38.8%], p = 0.016; vs. TA/T:32 [39.5%] or TA/TA 6 [35.3%], p = 0.039). In PNPLA3 G-allele carriers NAS scores ≥ 5 were significantly more frequent than in C/C carriers (C/C 42[36.8%] vs. C/G 47[54.7%] vs. G/G 26[66.7%], p = 0.002]. The protective effect of the TA-allele was only observed in *PNPLA3* C/C homozygotes (NAS ≥ 5: TA-carriers 11 [23.4%] vs. T/T 31 [46.3%], p = 0.013)but not G-allele carriers (NAS ≥ 5: TA-carriers 27 [52.9%] vs. T/T 46[62.2%], p = 0.304). rs72613567 was not associated with more advanced fibrosis (F ≥ 3/4: TA-carriers 23[23.7%] vs. T/T 36[25.5%], p = 0.749). In a multivariate regression analysis (Table 1) harboring at least one TA-allele was associated with a reduced risk for NAS ≥ 5 independent of *PNPLA3* G-allele carriage, serum triglyceride-levels and fibrosis-stage. Diabetes mellitus and older age were independent markers of advanced fibrosis (F3/4).

Table 1:

	Univariate HR	95%CI	p value	Multivariate HR	95%CI	p value
Age	0.992	0.97-1.01	0.397			
Sex	0.822	0.49-1.38	0.459			
BMI	0.983	0.95-1.01	0.280			
HSD17B13 T/T vs. TA	0.526	0.31-0.89	0.016	0.43	0.24-0.76	0.004
PNPLA3 C/C vs. C/G	2.06	1.17-3.65	0.013	2.23	1.20-4.15	0.011
G/G	3.43	1.59-7.38	0.002	4.13	1.78-9.58	0.001
Fibrosis. Per Grade (0-4)	1.39	1.11-1.74	0.004	1.35	1.06-1.71	0.015
Diabetes	1.34	0.76-2.36	0.302			
Arterial Hypertension	1.53	0.89-2.62	0.127			
Total Cholesterol	0.999	0.993-1.004	0.640			
Triglycerides	1.004	1.001-1.007	0.011	1.006	1.002-1.009	0.001

Conclusion: In biopsy proven NAFLD patients the loss-of-function rs72613567 T >TA variant in the *HSD17B13*-gene is associated with significantly less severe fatty liver disease, irrespective of *PNPLA3* genotype and metabolic risk factors.

THU-334

PNPLA3 rs738409 C >G variant predicts liver-related events and death in non-alcoholic fatty liver

Stefania Grimaudo[1], Grazia Pennisi[1], Rosaria Maria Pipitone[1], Calogero Camma[1], Vito Di Marco[1], Roberta Boemi[1], Aurora Giannetti[1], Federica Spatola[1], Giulio Marchesini Reggiani[2], Antonio Craxi[1], Salvatore Petta[1]. Email: salvatore.petta@unipa.it

Background and aims: Patients with non-alcoholic fatty liver disease (NAFLD) are at higher risk of developing liver-related complications -hepatic decompensation (HD) and hepatocellular carcinoma (HCC)- including death, the severity of liver fibrosis and metabolic comorbidities being the main risk factors. Emerging evidences reported that a single nucleotide polymorphism in PNPLA3 gene is associated with a higher prevalence of liver damage and HCC, but prospective date are not available. We aimed to assess whether the common rs738409 variant in PNPLA3 gene can predict the occurrence of liver-related events and death in a large cohort of NAFLD patients.

Method: We considered 469 consecutive Italian individuals with histological diagnosis of NAFLD or with clinical diagnosis of compensated cirrhosis due to NAFLD, prospectively followed for at least 6 months. Hepatic events (HD and HCC) and death were recorded. The rs738409 G >C polymorphisms was genotyped by TaqMan assay.

Results: NAFLD patients had a mean age of 50 years with a higher prevalence of male gender (62.2%). Thirty-three percent were diabetic, and 35.6% had advanced fibrosis/compensated cirrhosis. During a median follow-up of 65 months (range 6.8-171 months) 27 HD, 12 HCC and 15 deaths (11 liver-related) were recorded. PNPLA3 C >G variant was associated with a higher risk of HD (HR 1.97, 95%C.I 1.14-3.41, p = 0.01) (Figure 1), this picture being confirmed (HR 1.82, 95%C.I 1.05-3.14, p = 0.02) after adjusting for age >50 years and diabetes, but being lost when including in the model the presence of advanced fibrosis/compensated cirrhosis (HR 1.55, 95%C.I 0.88-2.74, p = 0.12). A nonsignificant trend was also observed for the link between PNPLA3 variant and both HCC occurrence (HR 2.13, 95%C.I 0.92-4.92, p = 0.07) (Figure 2) and liver-related death (HR 2.18, 95%C.I 0.94-5.07, p = 0.06) (Figure 3), the strength of these associations being maintained after adjusting for age >50 years and diabetes (HCC || HR 2.6, 95%C.I 0.88-4.77, p = 0.9; Liver-related death || HR 1.95, 95% C.I 0.84-4.52, p = 0.1).

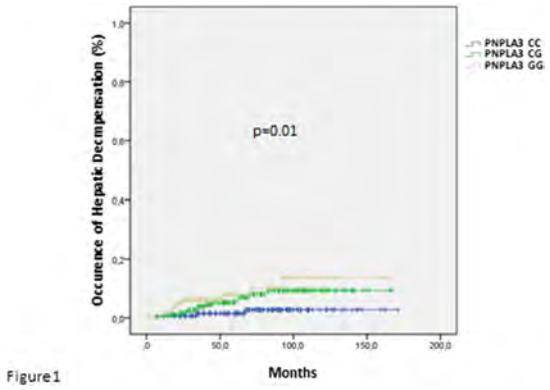

Figure1

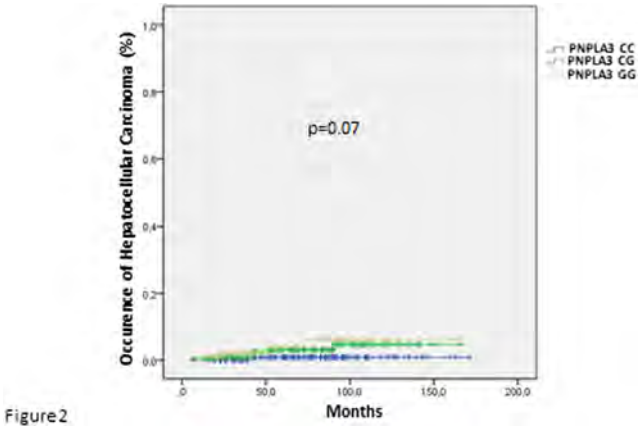

Figure2

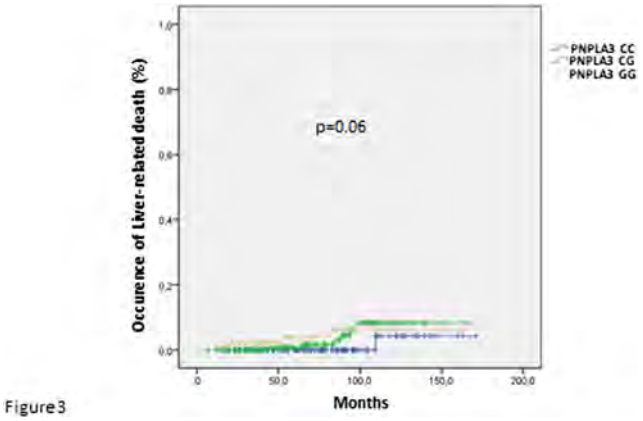

Figure3

Conclusion: Patients carrying PNPLA3 rs variant are at higher risk of liver-related events and death, this picture being mostly driven by developing advanced fibrosis/cirrhosis.

THU-335

FXR rs35724 C >G variant modulates cholesterol levels, carotid atherosclerosis and liver damage in non-alcoholic fatty liver

Stefania Grimaudo[1], Paola Dongiovanni[2], Rosaria Maria Pipitone[1], Guido Alessandro Baselli[2], Calogero Camma[1], Daniela Cabibi[3], Vito Di Marco[1], Miriam Longo[2], Grazia Pennisi[1], Silvia Fargion[2], Antonio Craxi[1], Luca Valenti[2], Salvatore Petta[1]. [1]*Sezione di Gastroenterologia e Epatologia, DiBiMIS, University of Palermo, Italy, Palermo, Italy;* [2]*Department of Pathophysiology and Transplantation, Section Internal Medicine, Università degli Studi, Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico, Milano, Italy, Milan, Italy;* [3]*Cattedra di Anatomia Patologica, University of Palermo, Italy, Palermo, Italy*
Email: salvatore.petta@unipa.it

Background and aims: Farnesoid X receptor (FXR) plays a key role in biliary acid and lipid homeostasis, and experimental evidence suggest that it can modulate atherosclerosis and liver damage due to non-alcoholic fatty liver disease (NAFLD). We examined the impact of FXR rs35724 variant on circulating cholesterol, carotid atherosclerosis and liver damage in a large cohort of patients at risk of non-alcoholic steatohepatitis (NASH).

Method: We considered 1, 447 consecutive Italian individuals at risk of NASH with liver histology. Common carotid arteries intima-media thickness (CC-IMT) was evaluated using ultrasonography in a subgroup (n = 703). The rs35724 G >C polymorphisms was genotyped by TaqMan assay. Gene expression was evaluated by RNASeq in a subset of patients (n = 124).

Results: Patients carrying FXR rs35724 variant had significantly higher hepatic mRNA levels of FXR, these last being associated with higher hepatic FGFR4 and Cyp39 in turn involved in bile acids synthesis. In the entire cohort of NAFLD patients, FXR rs35724 variant was independently associated with higher total circulating cholesterol (p = 0.01), while an inverse independent association was found for CC-IMT (p = 0.02). In patients with high circulating cholesterol (>200 mg/dl), FXR rs35724 was protective against NASH (OR 0.78, 95%C.I.0.61-0.99;p = 0.04) and severity of fibrosis (OR 0.81, 95%C. I.0.66-0.99;p = 0.04), these results being confirmed after adjusting for clinico-metabolic and genetic confounders.
Conclusion: Genetically induced increased FXR due to the rs35724 variant, while being linked to higher serum cholesterol, may not invariably results in more severe carotid atherosclerosis but may protect against NASH and hepatic fibrosis in patients with high cholesterol. The translational relevance of these results in terms of risk stratification and FXR-based target therapy is worthy of further investigation.

Possible ways of concomitant hypothyroidism effect on the course of non-alcoholic fatty liver disease

Vasyl Prysyazhnyuk[1], Olexander Voloshyn[1], Iryna Prysiazhniuk[2].
[1]*Higher State Educational Establishment Of Ukraine "Bukovinian State Medical University," Department of Internal Diseases, Chernivtsi, Ukraine;* [2]*Higher State Educational Establishment Of Ukraine "Bukovinian State Medical University," Department of Internal Medicine and Infectious Diseases, Chernivtsi, Ukraine*
Email: prysyaznyuk_v@ukr.net

Background and aims: Hypothyroidism is one of the common concurrent diseases in non-alcoholic fatty liver disease (NAFLD) patients. Moreover, hypothyroidism, even in subclinical form, is found to be associated with an increased risk of NAFLD development. The mechanisms of such dependence remain unclear. The aim of the study was to investigate influence of hypothyroidism on insulin resistance, adipokine profile and lipid metabolism in NAFLD patients.
Method: The study involved 188 NAFLD patients (average age 53.6 ± 12.34 years), including 20 NAFLD patients with subclinical hypothyroidism and 24 NAFLD patients with manifest hypothyroidism. 144 NAFLD patients with normal functional activity of the thyroid gland formed a comparison group. The control group consisted of 45 healthy individuals. Biochemical parameters, lipid profile, insulin, leptin, adiponectin blood levels were investigated.
Results: The study of lipid profile showed higher total cholesterol level in the blood by 10.7% (p = 0.04) and 12.5% (p = 0.02) as well as increased low density lipoprotein cholesterol concentration by 15.2% (p = 0.04) and 14.5% (p = 0.04) in NAFLD patients with both subclinical and manifested hypothyroidism as compared to NAFLD patients without thyroid dysfunction. NAFLD patients were shown to develop insulin resistance, which became more severe in case of concomitant subclinical or manifest hypothyroidism. In NAFLD patients with subclinical and manifested hypothyroidism J.F. Caro index was in 4.15 times (p < 0.001) and 3.38 times (p < 0.001) lower as compared to NAFLD patients without hypothyroidism. In NAFLD patients with manifested hypothyroidism HOMA IR index was at 67.7% (p = 0.04) higher in comparison with patients having normal thyroid activity. The patients with subclinical and manifested hypothyroidism were found to have a higher leptin level at 35.7% (p = 0.04) and 72.1% (p = 0.009), and those with NAFLD and manifested hypothyroidism also in 2.1 time (p = 0.004) lower adiponectin content in the blood as compared to patients without hypothyroidism. Our study shows that NAFLD patients with concomitant hypothyroidism are characterized by more pronounced changes of insulin resistance, adipokine and lipid profiles. Further investigations are required to examine the mechanisms of these findings.
Conclusion: Insulin resistance syndrome, adipokine imbalance and dyslipidemia can be aggravating factors of the course of NAFLD in patients with concomitant hypothyroidism.

THU-337
Cardiovascular risk factors and fibrosis severity in NAFLD: is there a link?

Davide Roccarina[1], Laura Iogna Prat[1,2], Marta Guerrero[1], Elena Buzzetti[1], Anna Mantovani[1,2], Atul Goyale[1], Francesco Arico'[1,3], Francesca Saffioti[1,4], Massimo Pinzani[1], Emmanuel Tsochatzis[1]. [1]*Royal Free London NHS Foundation Trust and UCL Institute for Liver and Digestive Health, University College of London, Sheila Sherlock Liver Centre, London, United Kingdom;* [2]*Azienda Ospedaliera Universitaria Integrata, University of Verona, Division of General Medicine and Hypertension, Department of Medicine, Verona, Italy;* [3]*University Hospital and School of Medicine of Messina, Department of Internal Medicine, Messina, Italy;* [4]*University of Messina, Department of Clinical and Experimental Medicine, Division of Clinical and Molecular Hepatology, Messina, Italy*
Email: davideroccarina@gmail.com

Background and Aims It is well documented that patients with NAFLD have an increased cardiovascular risk due to the presence of metabolic comorbidities. However, it is not clear whether cardiovascular risk is associated with an increased risk of liver disease in patients with NAFLD. Carotid artery intima media thickness (CCA IMT) can be used as a predictor of increased cardiovascular risk. Therefore, we evaluated if IMT correlates with the presence of NASH and fibrosis severity in such patients.
Method: We included consecutive patients with NAFLD. Transient elastography (TE) with FibroScan (Echosens) was performed in all patients and significant fibrosis was defined as a liver stiffness (LS) value ≥ 7.5 kPa. Abdominal fat thicknesses [(subcutaneous minimum and maximum (SCmin, SCmax), pre-peritoneal (PP), peri-renal (PR), visceral (VF) and abdominal fat index (AFI = PP/SCmin)], spleen size (SS) and CCAs IMT were measured using Affiniti 70G ultrasound (Philips). A right CCA IMT ≥ 75th percentile was considered as significant predictor of cardiovascular disease as per published data.
Results: 395 patients with NAFLD, mean age 55 ± 13y, 60% male, BMI 31.6 ± 5.8 kg/m^2, waist circumference (WC) 107 ± 15 cm, 43% with diabetes, 55% hypertension, 77% hyperlipidaemia.
Predictors of a right CCA IMT >75 percentile were increasing age (OR 1.088, 95%CI 1.058-1.188, p < 0.001) and male gender (OR 1.736, 95% CI 1.004-3.002, p = 0.048). In the subset of 126 patients with available liver biopsy, the presence of NASH or significant fibrosis was not associated with an increased CCA IMT.
Conversely, on univariate analysis, a LS value ≥ 7.5 kPa was associated with diabetes, hypertension, right CCA IMT ≥ 75th percentile, age, BMI, WC, VF, SS, total cholesterol, platelets, AFI, ALT and Hb1Ac. On multivariate analysis predictors of significant fibrosis were diabetes (OR 3.186, 95%CI 1.770-5.735, p = < 0. 001), AFI (OR 0.588, 95%CI 0.393-0.880, p = 0.010), SS (OR 1.370, 95% CI 1.173-1.600, p < 0.001) and ALT (OR 1.011, 95% CI 1.004 –1.017, p = 0.003).
Conclusion: Significant liver fibrosis is independent from increased cardiovascular risk in patients with NAFLD and is mainly associated with presence of diabetes, increasing ALT and reducing AFI. Targeted interventions for components of the metabolic syndrome should be offered to all NAFLD patients irrespective of the severity of the underlying liver disease.

Prevalence and dynamics of NAFLD-associated fibrosis among HIV+ from first presentation to last follow-up

Caroline Schmidbauer[1,2,3], David Chromy[1,2], David Bauer[1,2], Nikki Duong[4], Victor Schmidbauer[1,2], Mattias Mandorfer[1,2], Armin Rieger[5], Michael Trauner[2], Thomas Reiberger[1,2]. *[1]Vienna HIV and Liver Study Group, Vienna, Austria; [2]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [3]Wilhelminenspital der Stadt Wien, Wiener Krankenanstaltenverbund, Department of Internal Medicine IV, Vienna, Austria; [4]Medstar Georgetown University Hospital, Department of Gastroenterology, Washington, DC, United States; [5]Medical University of Vienna, Department of Dermatology, Vienna, Austria*
Email: schmidbauer.c@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has been reported to be highly prevalent in HIV+ individuals and if progressing to steatohepatitis (NASH) may induce liver fibrosis/cirrhosis. Additionally, some ART-regimens are known to cause metabolic alterations and thereby cause hepatic steatosis. Thus, we aimed to analyze epidemiological trends in the prevalence and severity of NAFLD in our Vienna HIV+ cohort.
Method: N = 1874 HIV+ patients attending our clinic between 2014 and 2016 were included. Epidemiological, clinical and laboratory parameters as well as ART regimens were retrospectively assessed at HIV-diagnosis (baseline) and at last contact. Patients with viral hepatitis or other chronic liver diseases were excluded. The prevalence of liver fibrosis according to NAFLD fibrosis scores (NFS) at first and at last visit were analyzed.
Results: After excluding n = 405/1874 (21.6%) due to viral hepatitis, NFS was available in n = 1283 (87.3%). At baseline, dyslipidemia and diabetes were diagnosed in 413 (32.2%) and 19 (1.5%) patients, respectively. 1074 (83.7%) patients showed NFS < −1.455 (absence of advanced fibrosis) and n = 17 (1.3%) showed NFS ≥ 0.676 (indicating F3/F4 NAFLD-fibrosis) at baseline, while n = 192 (15.0%) had intermediate NFS. Among patients with NFS-F3/F4 fibrosis, 1 (5.9%) had diabetes, 4 (23.5%) had dyslipidemia, and 5 (29.4%) were on HIV protease inhibitors (PI).
After a median follow-up of 5.9 years, 45/1469 (3.1%) patients had acquired viral hepatitis coinfection. Overall, 421 (31.8%) had dyslipidemia, 63 (4.8%) had diabetes and 188 (14.2%) were on PI-ART at follow-up. Data for NFS-calculation was available in 1325/1424 (93.0%) patients at last follow-up: n = 22 (1.7%) had NFS-F3/F4 fibrosis at last follow-up, including 10 (45.5%) with diabetes, 4 (18.2%) with dyslipidemia, and 9 (40.9%) on PI-containing ART.
Conclusion: Although dyslipidemia, diabetes and PI-containing ART were common in HIV+ patients without viral hepatitis coinfection, only 1.3 to 1.7% had suspected NAFLD-F3/F4 fibrosis. The study is limited by its retrospective design and lack of systematic imaging/elastography assessments. Thus, the true rate of NASH/NAFLD-fibrosis within the HIV+ patients remains to be established-especially for HIV+ patients with indetermined NFS scores.

THU-339

The relationship between the PNPLA3, TLL1 polymorphism combination and advanced fibrosis in Japanese patients with non-alcoholic fatty liver disease

Yuya Seko[1], Kanji Yamaguchi[1], Atsushi Umemura[1], Yoshito Itoh[1]. *[1]Kyoto Prefectural University of Medicine, Department of Gastroenterology and Hepatology, Kyoto, Japan*
Email: yuyaseko@koto.kpu-m.ac.jp

Background and aims: Hepatic fibrosis is an independent risk factor for mortality and liver-related events in patients with non-alcoholic fatty liver disease (NAFLD). PNPLA3 rs738409 has been associated with fibrosis in viral and nonviral hepatitis. TLL1 rs17047200 also has been associated with developing hepatocellular carcinoma probably via hepatic fibrogenesis. We estimated the impact of these genetic polymorphisms on hepatic fibrosis in Japanese patients with NAFLD.
Method: We analyzed the association between these genetic variants and the backgrounds of 817 individuals who received health checkups (health check cohort) from 2012 to 2014. Then, we investigated the relationship between genetic variants and liver histology in 258 consecutive patients with biopsy-proven NAFLD in Japan (NAFLD cohort) from 2012 to 2017.
Results: The prevalence of PNPLA3 CG/GG in the NAFLD cohort was higher than that in the health check cohort (p\0.001). The prevalence of patients with advanced fibrosis (stages 3-4) was higher for PNPLA3 genotype CG/GG than CC (p = 0.048) and for TLL1 genotype AT/TT than AA (p = 0.044). The high-risk group which had at least two risk alleles of these variants was more likely to have advanced fibrosis (p = 0.004). Multivariate analysis identified body mass index [odds ratio (OR) 1.123, serum AST (OR 1.037, p = 0.004], serum albumin (OR 0.247, p = 0.032), and genetic high risk (OR 2.632, p = 0.026) as predictors of advanced fibrosis.

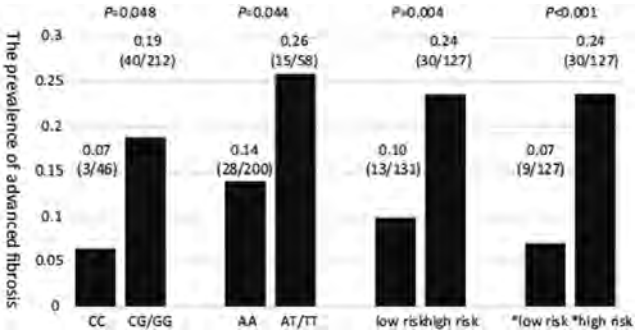

Figure: Prevalence of advanced fibrosis according to PNPLA3, TLL1 genotypes, genetic risk (low risk, \2; high risk, C2), and *genetic risk adjusted for sex and age

Conclusion: In Japanese patients with NAFLD, individuals with risk alleles of PNPLA3 and TLL1 may have a risk of advanced fibrosis.

THU-340

Epidemiology of NAFLD and advanced fibrosis in the French general population: A population-based cohort study in 118, 664 subjects (NASH-CO study)

Lawrence Serfaty[1], Oumarou Nabi[2], Jerome Boursier[3], Philippe Mathurin[4], Victor De Ledinghen[5], Marcel Goldberg[6], Marie Zins[6], Karine Lacombe[2]. *[1]Hôpital Hautepierre, Strasbourg, France; [2]Inserm UMRS_1136, Paris, France; [3]University Hospîtal, Anger, France; [4]CHU Lille, Lille, France; [5]Bordeaux University Hospital Branch, Bordeaux, France; [6]UMS 11 Inserm, Versaille, France*
Email: lawrence.serfaty@chru-strasbourg.fr

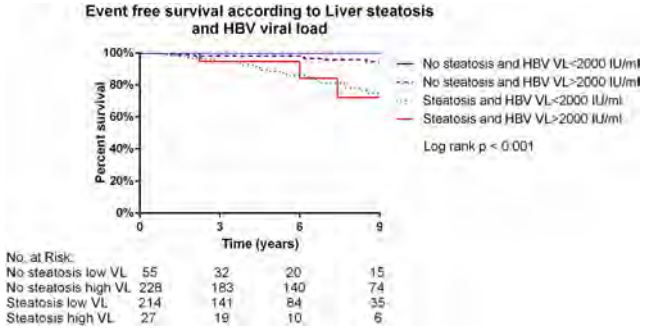
Background and aims: Assessment of the prevalence of NAFLD and NASH in the French general population is an important issue to quantify the disease burden. The aim of this study was to assess the prevalence and risk factors of NAFLD and associated liver fibrosis in a large French population-based cohort by using non-invasive markers.
Method: The study population consisted of 118, 664 participants from a sample drawn from the nationwide CONSTANCES cohort designed to be representative for age, gender and socioeconomic status of the French adult population. After exclusion of subjects with excessive alcohol consumption, viral hepatitis and other causes of liver diseases, 102, 344 subjects were analyzed. Non-invasive diagnosis of NAFLD and advanced fibrosis were performed using the Fatty Liver Index and Forns Index (FI). We used FI because in a previous work we observed it was as efficient as FIB4 for the detection of advanced fibrosis (AUC 0.8). Subjects with FLI >60 were considered as having NAFLD and those with FI >6.9 as having advanced fibrosis (NASH-CRN F ≥ 3).
Results: The global prevalence of NAFLD in the study population was 16.7% (CI95% 16.5-16.9), 24.6 and 10.1% among male and female

subjects, increased from 5.2% in subjects aged 18-28 yrs to 26.8% in subjects aged 68-78 yrs and reached 79.7% and 63% in obese and type 2 diabetic subjects, respectively. In the overall sample population, NAFLD was significantly associated (all $p < 0.001$) with older age (52.9 ± 11.7 vs 47.2 ± 13.6 yrs), male sex (66.8 vs 45.4%), obesity (58.2 vs 12.3%), diabetes (13.6 vs 3.7%), metabolic syndrome (59.8 vs 15.4%), high blood pressure (HBP) (28.6 vs 11.6%), hypertriglyceridemia (44.9 vs 12.3%) and ALT above normal threshold (33.9 vs 11.1%). In multivariate analysis, all factors remained significantly associated with NAFLD. Advanced fibrosis was only observed in NAFLD patients with a prevalence of 2.6% (IC95% 2.4-2.8), and a prevalence of 7.6% (IC95% 6.5-8.7) in NAFLD patients with diabetes. In multivariate analysis, independent risk factors of advanced fibrosis in NAFLD patients were age (OR = 4.1), male sex (OR = 7), obesity (OR = 1.4), diabetes (OR = 2.4), HBP (OR = 1.7) and elevated ALT (OR = 3.2).
Conclusion: NAFLD affects 1/6 of a large French population-based cohort with no excessive alcohol consumption or viral hepatitis. Advanced fibrosis is observed in 2.6% of NAFLD subjects, and in 7.6% of NAFLD subjects with diabetes. Age, male sex and metabolic disorders are independent risk factors of both NAFLD and advanced fibrosis.

THU-341
Liver steatosis is a strong predictor of mortality and cancer in chronic hepatitis B regardless of viral load

Noam Peleg[1], Assaf Issachar[1], Michal Cohen-Naftaly[2], Orly Sneh Arbib[2], Marius Braun[2], moshe leshno[3], alon barsheshet[4], Amir Shlomai[1]. *[1]Rabin Medical Center, Beilinson hospital, Medicine D, Petah-Tikva, Israel; [2]Rabin Medical Center, Beilinson hospital, Liver Institute, Petah-Tikva, Israel; [3]Tel Aviv University, Coller school of management, Tel Aviv, Israel; [4]Rabin Medical Center, Beilinson hospital, Cardiology, Petah-Tikva, Israel*
Email: shlomaiamir@gmail.com

Background and aims: Chronic hepatitis B (CHB) may co-occur with liver steatosis (LS) in up to 30% of patients. Both LS and HBV viral load (VL) are associated with poor outcomes in CHB patients. The present study was designed to investigate the association between LS and HBV viral load (VL) and their effects on a composite outcome of all-cause mortality and the development of cancer.
Method: This is a retrospective study of 524 CHB treatment naïve patients, who attended to the liver clinic of a tertiary hospital from January 2007 to December 2017. Mean follow-up of six years. LS was validated by at least 3 ultrasonographic (US) examinations in all patients. Liver biopsy was available for 170 patients. The primary end point of the study was the composite end point of all-cause mortality and development of cancer. Secondary end points included all-cause mortality, malignancy of any type, and the development of HCC. Kaplan-Meier survival estimate and Cox proportional hazards regression analysis were used to analyze the incidence of the primary end point.
Results: Out of 524 CHB patients, 241 (46%) had LS with a strong correlation between the degree of LS as assessed by US or by liver biopsy ($r = 0.9$, $p < 0.001$). Patients with LS were significantly older than patients without LS and had higher BMI. In addition, type 2 DM and hypertension were significantly more common in the LS population ($p < 0.05$ for all). Multivariate analysis showed that LS was associated with a significant 3-fold increased risk of all-cause mortality and the development of cancer (HR 3.18, 95% CI 1.64-6.16, $p < 0.001$), whereas baseline HBV VL was not significantly associated with this composite outcome (HR 1.44, $p = 0.33$). In addition, an inverse association between the degree of LS, assessed either by US or liver biopsy, and HBV VL was found.
Conclusion: CHB patients with LS have an increased risk for all-cause mortality and the development of cancer compared to CHB patients without LS, regardless of their baseline HBV VL. Although tending to have a lower baseline viral load, CHB patients with LS should be closely monitored irrespective of VL level.



THU-342
Development of a model to predict survival in recipients of liver transplant for non-alcoholic steatohepatitis

Ravikiran Sindhuvalada karnam[1,2], Nicholas Mitsakakis[3,4], Lilly Leslie[1], Nazia Selzner[1], Zita Galvin[1], Mamtha Bhat[1]. *[1]Toronto General Hospital, University Health Network and University of Toronto, Liver transplant unit, Multi organ transplant program, Toronto, Canada; [2]Ramaiah medical college and Hospitals, Bengaluru, India; [3]University Health Network and University of Toronto, Biostatistics Research Unit, Toronto, Canada; [4]Dalla Lana School of Public Health, University of Toronto, Institute of Health Policy, Management and Evaluation, and Division of Biostatistics, Toronto, Canada*
Email: drskravikiran@gmail.com

Background and aims: Non-alcoholic steatohepatitis (NASH) is projected to become the leading reason for liver transplantation (LT) in the near future. It is imperative to better understand the risk-benefit profile in an individual patient, so that we offer transplant to patients where there is a clear benefit as opposed to potential harm. The aim of our study was to develop a model to predict survival in recipients of LT for NASH.
Method: Liver transplant recipients whose primary indication was NASH were identified from the Scientific Registry of Transplant Recipients (SRTR) database (n = 11326, from 1987-2017). Patients with cryptogenic cirrhosis with a Body Mass Index (BMI) greater than 30 were also included. We excluded patients with hepatocellular carcinoma or those less than 18 years of age. Only recipient-specific factors were analysed. Data was analysed using univariate and multivariate Cox Proportional Hazard models. Through a series of covariate selection steps, a parsimonious set of independent predictors of survival were identified.
Results: Patient survival post liver transplantation for patients with NASH at 7 days, 30 days, 1 year, 3 year and at 5 years were 98%, 95%, 86%, 80% and 74% respectively. After univariate and multivariate analysis, the recipient factors found to be associated with the patient survival are shown in Table 1. Age and Serum Creatinine are analysed as continuous variables and other parameters are considered in binary. The model was internally validated and calibrated, giving Bootstrap-corrected errors of 0.0036, 0.0008, 0.0151, 0.0097 and 0.0048, for the survival probabilities for 7, 30 days, 1, 3 and 5 years respectively.

Survival Predictors	p value	Hazard Ratio (95% CI)
History of Diabetes	< 0.001	1.17 (1.08, 1.27)
History of Angina	0.051	1.17 (1, 1.36)
Recipient Age (at transplant)	< 0.001	1.02 (1.02, 1.02)
Portal vein thrombosis	0.034	1.12 (1.01, 1.24)
Mechanical ventilation at time of transplant	< 0.001	1.37 (1.19, 1.57)
Non hospitalised recipients	< 0.001	0.77 (0.71, 0.83)
Serum Creatinine before transplant	0.038	1.04 (1, 1.07)
History of TIPS procedure prior to transplant	0.028	1.13 (1.01, 1.26)

Figure: Table-1: Independent Predictors of Patient survival

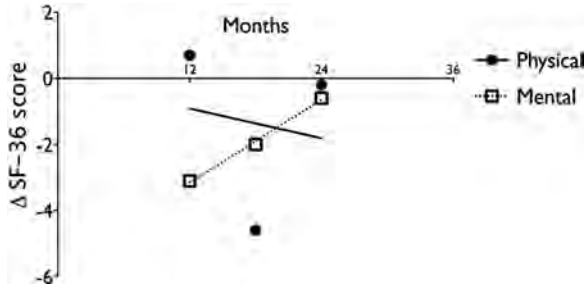
Conclusion: We have developed and validated a Cox model that is able to accurately predict patient survival post liver transplantation using recipient factors. Derivation of a practically useable risk calculator, along with validation in a local cohort at the University Health Network will further help in delineating risk assessment in an individual candidate for transplant.

THU-343

Systematic review: Patient reported quality of life outcomes in non-alcoholic fatty liver disease: Effect of disease severity and duration

Humaira Ud-Din[1], afiyah ajaz[2], Richard Parker[3]. [1]*University of Leeds, School of Medicine, Leeds, United Kingdom;* [2]*University of Leeds, School of Medicine, Leeds, United Kingdom;* [3]*St James University Hospital, Hepatology, Leeds, United Kingdom*
Email: um15hud@leeds.ac.uk

Background and aims: The objective of this review was to assess the impact of NAFLD on health related quality of life (HRQL) in both static (single time point) and dynamic (repeated over time) measures in patients with NAFLD.
Method: A systematic search was conducted in PubMed (1948-present). Primary articles were screened based on pre-specified inclusion criteria and papers with the highest relevancy were selected based on their abstracts. HRQL data was then extracted from relevant articles into a pre-prepared spreadsheet.
Results: A total of 553 papers were identified, of which 11 papers were included in the review. These studies included a total of 4495 patients had NAFLD (mean age 51, % male 44), of which 1127 subjects had biopsy-confirmed NASH. Seven studies were cross sectional, and four were longitudinal of which 3 were randomised control trials (RCT). HRQL was measured using 36-Item Short Form Survey (SF-36) in seven studies and the Chronic Liver Disease Questionnaire (CLDQ) in 3 studies and one study used the HRQOL-4 questionnaire. Scores were compared to normative US healthy population control data in six studies. Four studies reported dynamic outcomes whilst seven reported static outcomes. NAFLD was associated with reduced HRQL compared to control populations. When compared to non-alcoholic fatty liver (NAFL), HRQL in NASH or advanced fibrosis (AF) scores was significantly lower with the greatest impairment seen in domains concerning physical function (mean SF36 47.1 vs 44.4 vs 30.4 vs 44.4 vs 47.1 for NAFL, NASH and AF respectively, $p < 0.05$ for each comparison). Studies with repeated measures of HRQL over time showed improvement over time in mental aspects of HRQL in both treatment and placebo arms of therapeutic studies, whereas physical aspects showed no significant improvement.



Conclusion: NAFLD is associated with poorer HRQL, especially in domains relating to physical function. Mental HRQL was seen to improve over time in prospective studies, regardless of treatment arm. This may show that a diagnosis of NAFLD may cause initial distress which eases over time, or that repeated contact with liver services can ease patients' concerns without necessarily changing physical function. Further data is needed to be able to draw any firm conclusions.

THU-344

The influence of non-alcoholic fatty liver disease on a two year prognosis of the patients with stable coronary heart disease depending on SYNTAX score II

Nataliya Virstyuk[1], Iryna Vakalyuk[1]. [1]*Ivano-Frankivsk National Medical University, Internal Medicine, Ivano-Frankivsk, Ukraine*
Email: virstyukn@gmail.com

Background and aims: To evaluate the contribution of non-alcoholic fatty liver disease (NAFLD) in predicting risk of major cardiovascular events by cumulative proportion surviving depending on the SYNTAX score (SS) II in pts with stable coronary heart disease (CHD) who underwent coronary artery stenting.
Method: 150 pts (aged: 53.7 ± 3.5 years) with stable CHD who have had an acute coronary syndrome with an indication of coronary artery stenting more than 3 months ago were examined. Pts were categorized into 2 groups according to the SS II value: Group I-SS II value less than 29 (n = 97); Group II-SS II value more than 29 (n = 53). In each group, pts without NAFLD (subgroup A), with non-alcoholic steatosis (subgroup B), with non-alcoholic steatohepatitis (NASH) (subgroup C) were identified. General clinical examination, ECG, EchoCG, liver elastography, liver ultrasound, evaluation of the liver functional state were performed to all pts. Each coronary lesion based on angiogram at the time of acute coronary event was scored to SS I, than to SS II which were calculated by online calculators. Survival analysis based on Kaplan-Meier curves was evaluated by a two-year cumulative proportion surviving (%), the difference between groups was determined by Cox's F and Gehan's Wilcoxon tests.
Results: A two-year cumulative proportion surviving was the highest in pts without NAFLD: by reoccurring myocardial infarction (MI)-100.0% (Group IA) vs. 100.0% (Group IIA); by ischemic stroke-93.5% (Group IA) vs. 85.4% (Group IIA) ($p > 0.05$); by death from cardiovascular causes-96.8% (Group IA) vs. 88.9% (Group IIA) ($p < 0.05$); by re-revascularization-98.4% (Group IA) vs. 85.8% (Group IIA) ($p < 0.05$). In pts with non-alcoholic steatosis a two-year cumulative proportion surviving was significantly lower: by reoccurring MI-100.0% (Group IB) vs. 96.1% (Group IIB); by ischemic stroke-73.7% (Group IB) vs. 49.5% (Group IIB) ($p < 0.05$); by death from cardiovascular causes-74.1% (Group IB) vs. 49.5% (Group IIB) ($p < 0.05$); by re-revascularization-82.4 (Group IB) vs. 58.8% (Group IIB) ($p < 0.05$). The lowest a two-year cumulative proportion surviving in pts with NASH was observed: by reoccurring MI-78.6% (Group IC) vs. 60.0% (Group IIC) ($p < 0.05$); by ischemic stroke-54.5% (Group IC) vs. 33.3% (Group IIC) ($p < 0.05$); by death from cardiovascular causes-58.6% (Group IC) vs. 33.3% (Group IIC) ($p < 0.05$); by re-revascularization-71.8% (Group IC) vs. 31.8% (Group IIC) ($p < 0.05$).
Conclusion: The course of stable CHD in pts who underwent coronary artery stenting depends on the NAFLD presence and its severity and is the most prognostically unfavorable in pts with NASH. The severe course of NAFLD forms a high risk of major cardiovascular events by SS II values and causes a significant decrease of a two-year cumulative proportion surviving in pts with stable CHD who underwent coronary artery stenting combined with NAFLD.

THU-345

Lean NAFLD patients have lower prevalence of cardiovascular, metabolic and severe liver disease compared to overweight or obese patients with NAFLD

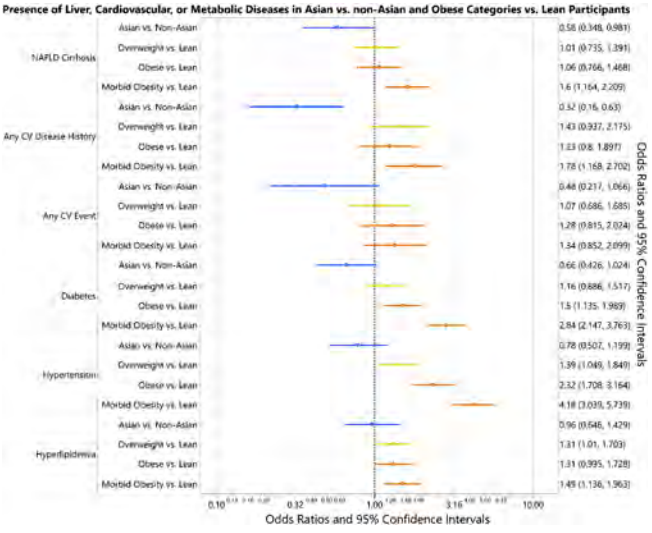
Ethan Weinberg[1], Huy N. Trinh[2], Roberto J Firpi[3], Kalyan Ram Bhamidimarri[4], Samuel Klein[5], Laura Malahias[6], Richard Zink[6], Anna Lok[7]. [1]*University of Pennsylvania, Philadelphia, United States;* [2]*San Jose Gastroenterology, San Jose, United States;* [3]*University of Florida, Gainesville, United States;* [4]*University of Miami, Miami, United States;* [5]*Washington University in St. Louis, St. Louis, United States;* [6]*TARGET PharmaSolutions, Inc., Chapel Hill, United States;* [7]*University of Michigan, Ann Arbor, United States*
Email: lmalahias@targetpharmasolutions.com

Background/Aim: Although non-alcoholic fatty liver disease (NAFLD) is associated with obesity, it is also seen in patients with

normal BMI (lean NAFLD). TARGET-NASH includes a large cohort of racially diverse patients including many with normal BMI, providing a unique opportunity to compare prevalence of NAFLD cirrhosis, cardiovascular (CV) and metabolic abnormalities among those with normal vs. high BMI.

Methods: TARGET-NASH, a longitudinal observational study of participants at 54 sites (39 academic/15 community) in the U.S, includes patients across the entire spectrum of NAFLD as defined by pragmatic case definitions. Data from medical records are centrally abstracted and monitored for completeness and accuracy. An analysis was performed to compare CV and metabolic abnormalities and severity of liver disease across BMI categories: Lean (>18.5-25, n = 436), Overweight (>25-30, n = 874), Obese (>30-35, n = 849), and Morbid Obesity (>35, n = 1069); and race (Asians vs non-Asians). Odds ratios and confidence intervals were adjusted by age, sex, center type (academic vs. community); site was included in models as a random effect.

Results: 436/3228 (13.5%) participants were lean. There was a clear decreasing trend ($p < 0.0001$) in the proportion of Asian patients (n = 401) across BMI categories: Lean (46%), Overweight (19%), Obese (5%) and Morbidly Obese (1%). Independent of BMI categories, Asian NAFLD had a significantly lower prevalence of cirrhosis (12% vs. 44%) and CV history (4% vs. 16%), and numerically less CV events (5% vs. 12%), diabetes (28% vs. 55%), hypertension (51% vs. 75%) or hyperlipidemia (48% vs. 63%) compared to non-Asians. Similar or more marked differences were observed when BMI cut-off of 23.5 was used to define lean Asians. Independent of race, lean participants had a significantly lower prevalence of hypertension (55% vs 66%) and hyperlipidemia (52% vs 62%), and numerically less NAFLD cirrhosis (24% vs. 36%), CV history (8% vs 15%), CV events (7% vs 10%), and diabetes (34% vs 43%) compared to overweight participants.



Conclusion: Lean NAFLD comprised 13.5% of our cohort and was significantly more prevalent among Asians. Across BMI categories, Asians had a significantly lower prevalence of cirrhosis and numerically lower prevalence of CV and metabolic abnormalities than their non-Asian counterparts. Longitudinal follow-up is ongoing to determine if lean NAFLD have slower progression of liver disease, in particular among lean Asians.

THU-346

Plasma ApoE levels are associated with non-alcoholic fatty liver disease: the PREVEND cohort study

Eline H. Wouters-van den Berg[1,2], James P. Corsetti[3], Stephan J.L. Bakker[4], Robin P. F. Dullaart[2]. [1]*University of Groningen, University Medical Center Groningen, Department of Gastroenterology and Hepatology, Groningen, Netherlands;* [2]*University of Groningen, University Medical Center Groningen, Department of Endocrinology, Groningen, Netherlands;* [3]*University of Rochester School of Medicine and Dentistry, Department of Pathology and Laboratory Medicine, Rochester, NY, United States;* [4]*University of Groningen, University Medical Center Groningen, Department of Nephrology, Groningen, Netherlands*
Email: e.h.wouters@umcg.nl

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is featured by increased plasma triglycerides, consequently to very low density lipoproteins (VLDL) elevations, but the extent to which plasma apolipoprotein E (ApoE) is elevated in NAFLD is unclear. Here we determined the relationship of plasma ApoE and its genotype with NAFLD.

Method: Plasma ApoE and genotypes were determined in 6, 762 participants of the Prevention of Renal and Vascular End-Stage Disease (PREVEND) cohort. Fatty Liver Index (FLI) $\geq$ 60 was used as a proxy of NAFLD.

Results: In total 1, 834 participants had a FLI $\geq$ 60, which coincided with increased prevalence of type 2 diabetes mellitus, metabolic syndrome, (central) obesity, elevated triglycerides, higher non-high density lipoprotein cholesterol and apolipoprotein B (all $p < 0.001$). ApoE was increased in subjects with an elevated FLI compared with subjects with a normal FLI (0.048 vs. 0.036 mmol/L, $p < 0.001$). In multivariable linear regression analysis, plasma ApoE levels were positively associated with an elevated FLI when taking account of ApoE genotypes and other clinical and laboratory covariates (fully adjusted model: beta = 0.201, $p < 0.001$). In a sensitivity analysis (n = 4, 730), which excluded subjects with positive cardiovascular history, impaired estimated glomerular filtration rate, elevated urinary albumin excretion and drug use, plasma ApoE was also independently associated with elevated FLI (beta = 0.221, $p < 0.001$). Stratified analysis for ApoE genotypes (ApoE ε3ε3 homozygotes, ApoE ε2 carriers, and ApoE ε3ε4 and ε4ε4 carriers combined), showed independent positive associations of plasma ApoE levels with an elevated FLI (all $p < 0.001$).

Conclusion: Increased plasma ApoE levels are associated with NAFLD, even when taking account of different ApoE genotypes. Increased plasma ApoE may contribute to altered VLDL metabolism in NAFLD.

THU-347

Economic and clinical burden of non-alcoholic steatohepatitis in patients with type II diabetes in the United States

Zobair Younossi[1,2], Radhika Tampi[2], Andrei Racilla[1,2], Ying Qiu[3], Leah Burns[3], Issah Younossi[4], Fatema Nader[4]. [1]*Center for Liver Disease-, Department of Medicine, Inova Fairfax Medical Campus, Falls Church, United States;* [2]*Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, United States;* [3]*Worldwide Health Economics and Outcomes Research, Bristol Myers Squibb, Princeton, United States;* [4]*Center for Outcomes Research in Liver Disease, Washington DC, United States*
Email: zobair.younossi@inova.org

Background and aims: NASH is the progressive form of non-alcoholic fatty liver disease (NAFLD) and is strongly associated with T2DM. Patients with both T2DM and NAFLD/NASH have increased risk for adverse clinical outcomes leading to higher risk for mortality and morbidity. Aim: To assess the economic burden of NASH and T2DM in the US.

Method: We built a Markov model with 1-year cycles and lifetime horizon to estimate the economic burden of NASH with T2DM in the adult US population from the health system perspective. Cohort size was determined by population size, prevalence of T2DM, and the prevalence and incidence of NASH in the US for 2017. Model includes 11 health states-NAFL, NASH-fibrosis stages 0, 1, 2, 3, compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), liver transplant (LT), one-year post-LT (1yPLT), post-LT (PLT), and 3 death states -liver-related (LRM), cardiovascular (CVM), and background mortality (BM). Transition probabilities (TPs) were

calculated from our meta-analyses and literature. TPs to LT and BM were age-related. Annual costs for NASH and diabetes were taken from literature or micro-costed using 2017 current procedural terminology (CPT) codes. Costs were discounted at 3% annually. Annual incidence rate of NASH in T2DM were assumed to be 5 times higher than the general population.

Results: We estimated that there were 17 million people in the US living with T2DM and NAFLD in the US, of which 3.9 million had both T2DM and NASH. Lifetime costs specifically related to NASH in these patients were $58.2 billion. Over the next 50 years, NASH with T2DM accounted for a large number of transplants, deaths (CV-related and liver related deaths), and cirrhosis complications (Table 1).

Table 1: Economic Burden of NASH with Type II Diabetes in the US in 2017

	T2DM and NASH
Lifetime Costs Associated with NASH	$58,176,567,817
Liver Transplants (N)	207,724
Liver-Related Deaths (N)	757,499
Cardiovascular Deaths (N)	1,340,158
DCC Person-Years (N)	1,011,764
HCC Person-Years (N)	271,221

Conclusion: Our model predicts an enormous clinical and economic burden due to NASH with T2DM over the next 50 years. It is highly likely that interventions that reduce morbidity and mortality in NASH with T2DM could potentially reduce this projected clinical and economic burden. In fact, these benefits may be greater since we assumed conservative inputs for our model and did not increase medical costs or the incidence of T2DM or NASH over time.

THU-348

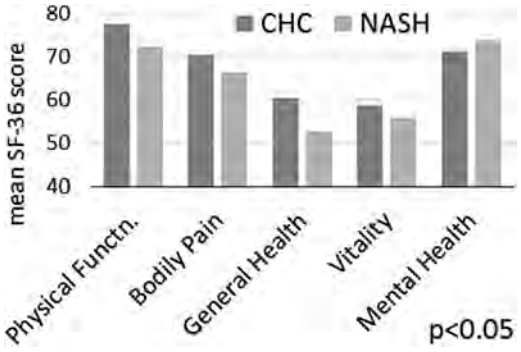
Patients with non-alcoholic steatohepatitis experience severe impairment of health related quality of life

Zobair Younossi[1,2], Maria Stepanova[3], Eric Lawitz[4], Rajender Reddy[5], Vincent Wai-Sun Wong[6], Alessandra Mangia[7], Andrew Muir[8], Stephen Djedjos[9], Anuj Gaggar[9], Robert Myers[9], Issah Younossi[3], Fatema Nader[3], Andrei Racilla[3]. *[1]Center for Liver Diseases-, Department of Medicine, Inova Fairfax Medical Campus, Falls Church, United States; [2]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, United States; [3]Center for Outcomes Research in Liver Disease, Washington DC, United States; [4]University of Texas Health, Texas Liver Institute, San Antonio, United States; [5]University of Pennsylvania, School of Medicine, Philidelphia, United States; [6]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong; [7]Casa Sollievo della Sofferenza Hospital, San Gi, Spain; [8]Duke Clinical Research, Durham, United States; [9]Gilead Sciences, Foster City, United States*
Email: zobair.younossi@inova.org

Background and aims: Chronic hepatitis C (CHC) and NASH are common causes of chronic liver disease. Although there is substantial evidence suggesting poor HRQL in CHC patients, similar data in NASH is lacking. AIM: Compare HRQL scores in patients with advanced fibrosis due to CHC to NASH.

Method: Patients with advanced fibrosis (bridging fibrosis and compensated cirrhosis) due to CHC and NASH were included. Prior to treatment, all patients had completed Short Form-36 (SF-36, score range 0-100), a disease-specific version of Chronic Liver Disease Questionnaire (CLDQ, range 1-7), Work Productivity and Activity (WPAI) (range 1-0), and extensive clinical data. Patients were matched 1:1 according to their age, gender, race, country of origin, and presence cirrhosis. The HRQL scores of matched CHC and NASH subjects were compared using a non-parametric Mann-Whitney test.

Results: We included 1338 patients with NASH with advanced fibrosis (mean age 57.2 years, 47% male, 76% white, 60% enrolled in the U.S., 55% with cirrhosis) and 1338 matched patients with CHC with advanced fibrosis. Patients with CHC and NASH had similar rates of psychiatric disorders (40 vs. 41%) and reported similar employment rates (52 vs. 54%) (both $p > 0.05$). As expected, patients with NASH had higher BMI (mean 33.7 vs. 27.6) and more type 2 diabetes (74% vs. 16%) (all $p < 0.01$). Patients with NASH had significantly lower HRQL scores related to physical health than CHC: Physical Functioning, Bodily Pain, General Health, Vitality, and Physical Summary of SF-36, and Fatigue of CLDQ (all $p < 0.02$). In contrast, patients with CHC had lower Mental Health score of SF-36 and Emotional score of CLDQ than NASH, and reported greater impairment in their daily activities as measured by WPAI (all $p < 0.002$). In multivariate regression analysis, after adjustment for demographic parameters, cirrhosis, and history of psychiatric disorders, having NASH was independently associated with lower physical HRQL scores (beta – 2.5 to – 7.5 for SF-36 domains, – 0.21 for Fatigue of CLDQ) and higher mental health-related scores (beta +2.7 for Mental Health of SF-36, +0.25 for Emotional of CLDQ) (all $p < 0.005$).



Conclusion: Patients with NASH and advanced fibrosis have more impairment of their physical health-related scores than patients with CHC and advanced fibrosis. These data should dispel the misconception that NASH is an asymptomatic disease with little negative impact on patient experience and well-being.

Lipid nanoparticle pre-treatment improves adeno-associated virus diffusion in the primate liver and enables an increase of therapeutic transgene expression

Karin L Kwikkers[1], Lukas Schwarz[1], Johannes de Laat[1], Anna Majowicz[1], Paula S. Miranda[1], Alexander W. Gielen[1], Martin de Haan[1], Harald Petry[1], Sander van Deventer[1], Valerie Ferreira[1]. *[1]uniQure B.V., Amsterdam, Netherlands*
Email: a.majowicz@uniqure.com

Background and aims: AAV vectors have been successfully used in preclinical studies and in clinical trials to express therapeutic proteins in the liver. Transduction of a limited percentage of hepatocytes can be sufficient for expression of secreted proteins. However, most hepatic metabolic monogenic disorders caused by the deficiency of an intracellular enzyme or membrane transporter would require a high percentage of hepatocytes to be transduced to achieve a therapeutic effect. This can be routinely achieved in rodents, but has proven to be a significant hurdle in large animals hampering the feasibility of such liver directed AAV based gene therapies

The liver has a very high capacity to remove particles from the circulation. The cells from the reticuloendothelial system (RES) play a central role in this clearance process. Those cells can ingest and destroy foreign material and therefore constitute the first cellular barrier between the blood flow and the liver tissue. The saturation of

the hepatic reticuloendothelial cells by nanoparticles or lipids has been shown to block uptake of particles from the circulation. We hypothesized that saturation of the RES could increase AAV-vector transduction and distribution in the liver, subsequently improving transgene expression, in large animals. Therefore, we explored the potential of pre-treatment with Intralipid, an FDA approved emulsion of soy bean oil, egg phospholipids and glycerin in non-human primates.

Method: Non-human primates (NHPs, n = 2) were injected intravenously with Intralipid one hour before intravenous administration of AAV5-hFIX. A control group (n = 2) was injected with AAV5-hFIX at the same dose after prior treatment with PBS. The levels of hFIX were measured in plasma. AAV vector DNA and transgene RNA copies numbers were assessed in the liver by QPCR and fluorescent in situ hybridization (FISH).

Results: After Intralipid pre-treatment, an increase in the levels of hFIX transgene expression was observed in the animals injected with AAV5-hFIX when compare to the control group (average of 3.5-fold). A similar increase was observed at the hFIX mRNA levels. Accordingly, the vector DNA copies numbers were higher in the liver tissues of the animals treated with Intralipid than in the control group (average of 2.6-fold). Remarkably, Intralipid pre-treatment resulted in an enhanced diffusion of AAV5 vector through the liver tissue. The percentage of transduced hepatocytes was up to 4-fold higher when Intralipid was used.

No adverse effect of Intralipid on the immunity against AAV5 capsid proteins or the transgene was observed.

Conclusion: Pre-treatment with a lipid emulsion prior to AAV5 administration improves significantly the efficacy of AAV vector delivery to the liver and enables a broader hepatic cell targeting throughout the tissue. This approach represents a valuable tool for liver-targeted gene therapies application.

THU-364

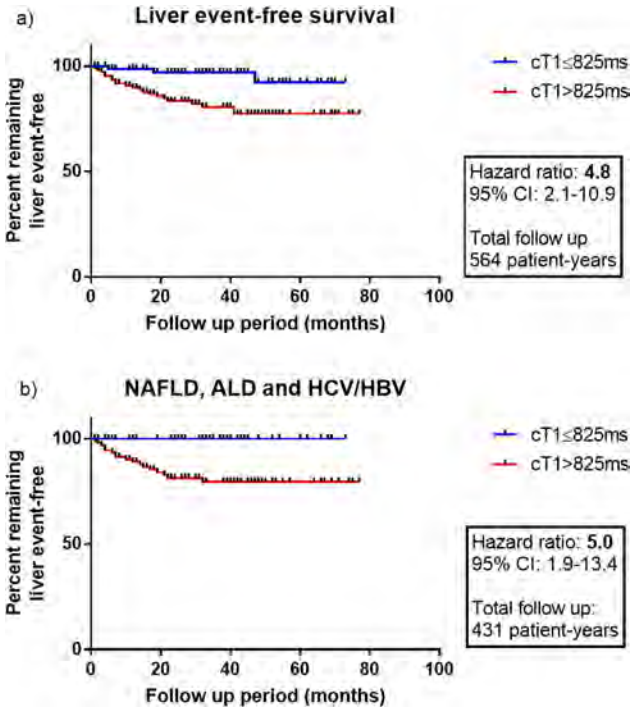
Liver cT1 predicts clinical outcomes in patients with chronic liver disease

Arjun Jayaswal[1], Michael Pavlides[1], Rajarshi Banerjee[2], Matthew Kelly[2], Ellie Barnes[1], Stefan Neubauer[1]. *[1]University of Oxford, Oxford, United Kingdom; [2]Perspectum Diagnostics Ltd, Oxford, United Kingdom*
Email: arjun.jayaswal@rdm.ox.ac.uk

Background and aims: The magnetic resonance imaging (MRI) parameter T1, when corrected for iron content (cT1) can quantify extracellular water content, which rises with fibrosis and inflammation. We have shown liver cT1 correlates with histological fibrosis and ballooning. Here we examine liver cT1 as a prognostic biomarker to predict clinical outcomes. Patients with varying liver disease aetiologies underwent multiparametric imaging (T1, T2* mapping (iron) and MR spectroscopy (fat)). Liver*MultiScan*™ software was used to obtain cT_1 liver maps and calculate the mean cT1 value from 3 regions of interest (ROIs) placed in the liver parenchyma.

Method: Patients were followed up for development of clinical outcomes by review of their medical records blinded to the imaging results. All-cause mortality, liver mortality, liver transplantation and liver-related events (ascites, variceal bleeding, hepatic encephalopathy, hepatocellular carcinoma) were considered as clinical end points. Analysis was carried out for mortality and liver event-free survival. Patients who developed multiple end points were censored at the index event for liver event-free survival analysis.

Results: 190 patients were followed up for 564 patient-years (median (IQR) 35 (19–51) months). 119 (72%) patients were male; mean age (± SD) was 52 (± 13) years. Liver biopsy was performed in 165 patients. Histologic fibrosis assessment by Ishak staging was none/mild (F0-2) in 85 (52%), moderate (F3-4) in 25 (15%) and severe (F5-6) in 55 (33%) patients. Main diagnoses were viral hepatitis (n = 54, 28%), NAFLD (70, 37%) and alcohol related liver disease (26, 14%). 24 new liver events occurred during follow-up, including 15 deaths. Using the equivalent cut-off (Pavlides et al, 2016), cT1 could significantly differentiate between all-cause mortality ($p = 0.021$), liver-related mortality ($p = 0.010$) and liver event-free survival ($p = 0.005$; Fig 1a). For prediction of liver events, cT1 > 825ms had a hazard ratio (HR) of 4.8 and correctly classified 21/24 (84%) liver events; liver iron and fat did not predict clinical outcomes. In NAFLD/ALD/HCV/HBV patients (n = 150), cT1 > 825ms correctly classified 17/17 liver events ($p = 0.001$; Fig 1b). ISHAK F5-6 predicted liver event-free survival ($p < 0.001$, HR: 19) correctly classifying 18/21 (89%) events.



Conclusion: We provide further evidence that liver cT1 can predict clinical outcomes in a larger cohort of patients with chronic liver disease of mixed aetiologies and particularly well in NAFLD, ALD and HCV/HBV patients.

THU-365

Adeno-associated virus-serotype-specific transduction patterns in mice and non-human primates liver tissue: Implications for therapeutic efficacy

Anna Majowicz[1], Lukas Schwarz[1], Johannes de Laat[1], Sander van Deventer[1], Valerie Ferreira[1]. *[1]uniQure B.V., Research, Amsterdam, Netherlands*
Email: a.majowicz@uniqure.com

Background and aims: AAV-based liver gene therapy has proven efficacious in mouse models of inherited disorders, but little is known about the transduction pattern of various AAV serotypes in the primate or human liver. To address this question, we assessed the AAV distribution pattern in the liver tissue of mice and non-human primates (NHPs) injected with either AAV serotype 1 or 5. The overall percentage of cells positive for the presence of AAV vector DNA/hFIX transgene RNA as well as the intensity and area of the positive signal were assessed. Additionally, AAV vector spatial distribution throughout the liver tissue was determined.

Method: Mice were injected intravenously (IV) with either AAV1-hFIX (human factor IX), AAV5^{ch}-hFIX or PBS, while NHPs were injected with either AAV1-hFIX, AAV5^{ch}-hFIX at dose or PBS. Liver tissues were collected post mortem and analyzed by fluorescent in situ hybridization (FISH) using probes specific for AAV vector DNA

and hFIX transgene mRNA. Hepatocytes were characterized based on Albumin RNA in mice and Serpina1 RNA in NHPs (FISH) while central veins were localized by Glutamine Synthetase (GS) protein detection by immunohistochemistry (IHC). Images were acquired with a slide scanner and analyzed with the use of an image analysis software (HALO, indica labs). For FISH image analysis, cells were scored from weak positive **(1+)** to strong positive **(4+)** based on combination of average positive signal area [μm^2] and average intensity of positive signal within cell [RFU].

Results: In mice, percentage of liver cells positive for the presence of AAV vector DNA/hFIX mRNA was similar for AAV1 and AAV5. However, liver cells positive for AAV5 vector DNA/hFIX RNA displayed a higher signal score than liver cells positive for AAV1 vector DNA/hFIX RNA suggesting more efficient transduction per cell by the AAV5 vector. Most cells transduced by AAV1 or AAV5 expressed Albumin and therefore were characterized as hepatocytes. Interestingly, spatial distribution of AAV vector DNA/hFIX RNA positive signal within the liver tissue was different for the two serotypes: AAV5 vector DNA/transgene RNA was more localized around the central veins whereas AAV1 was more homogenously distributed throughout the liver tissue.

In NHPs, the percentage of liver cells positive for AAV vector DNA/hFIX RNA was higher for $AAV5^{ch}$ than for AAV1, and like mice, AAV5 resulted in a higher AAV vector DNA/hFIX RNA probe signal score indicating a more efficient transduction per cell with AAV5 than with AAV1 in injected NHPs. Yet, in NHPs, unlike in mice, not only AAV1 but also AAV5 vector DNA/transgene RNA was homogenously distributed throughout the liver tissue.

Conclusion: These results indicate that mouse models may have a limited value to predict the efficacy of liver-targeted AAV-based gene therapy, in particular in the context of development of therapies for metabolic disorders.

THU-367

Linking diabetic cardiovascular disease with non-alcoholic fatty liver disease through L-carnitine: A hyperpolarized MRS study

Dragana Savic[1], Vicky Ball[1], Michael Pavlides[1], Lisa C. Heather[1], Damian J. Tyler[1]. [1]*University of Oxford, Oxford, United Kingdom*
Email: dragana.savic@dpag.ox.ac.uk

Background: Diabetes increases the incidence of non-alcoholic fatty liver disease (NAFLD) and cardiovascular disease (CVD).

NAFLD can progress to NASH and into cirrhosis. NAFLD has been shown to be associated with CVD and insulin resistance. However, the underlying mechanisms linking NAFLD and CVD in the context of diabetes need to be elucidated in order to improve quality of life for patients. Studies have shown that L-carnitine levels are decreased in diabetic patients, and that L-carnitine supplementation protects cardiac as well as liver function.

Method: Male Wistar rats were treated with streptozotocin (STZ, 55mg/kg; n = 20) to induce diabetes or act as controls by injecting citrate buffer (CTR; n = 20). Daily intra-peritoneal injections of either saline or L-carnitine (3 g/kg/day) were initiated and continued for three weeks. Following treatment, cardiac function was assessed with MRI and metabolism with hyperpolarized magnetic resonance spectroscopy (MRS) respectively. Liver tissue was extracted for metabolomics analysis.

Results: L-carnitine treated control and diabetic animals had reduced blood TAG levels (**Fig.1A**). L-carnitine resulted in higher liver choline (**Fig.1B**) and decreased glutamate levels, the latter only in the diabetic group (**Fig.1C**). Cardiac function was depressed in the diabetic group and L-carnitine improved diastolic function through elevation of end-diastolic lumen, EDL (**Fig.1D**). This functional improvement was accompanied by increased flux through pyruvate dehydrogenase (PDH) in the diabetic heart, while L-carnitine reduced PDH-flux in the control group (**Fig.1E**).

Conclusion: We show a linkage between diabetic heart and the liver. Metabolism in both the heart and liver was modulated by L-carnitine. The liver is critical for choline metabolism, and studies have shown that NASH is associated with lower choline concentrations. This study

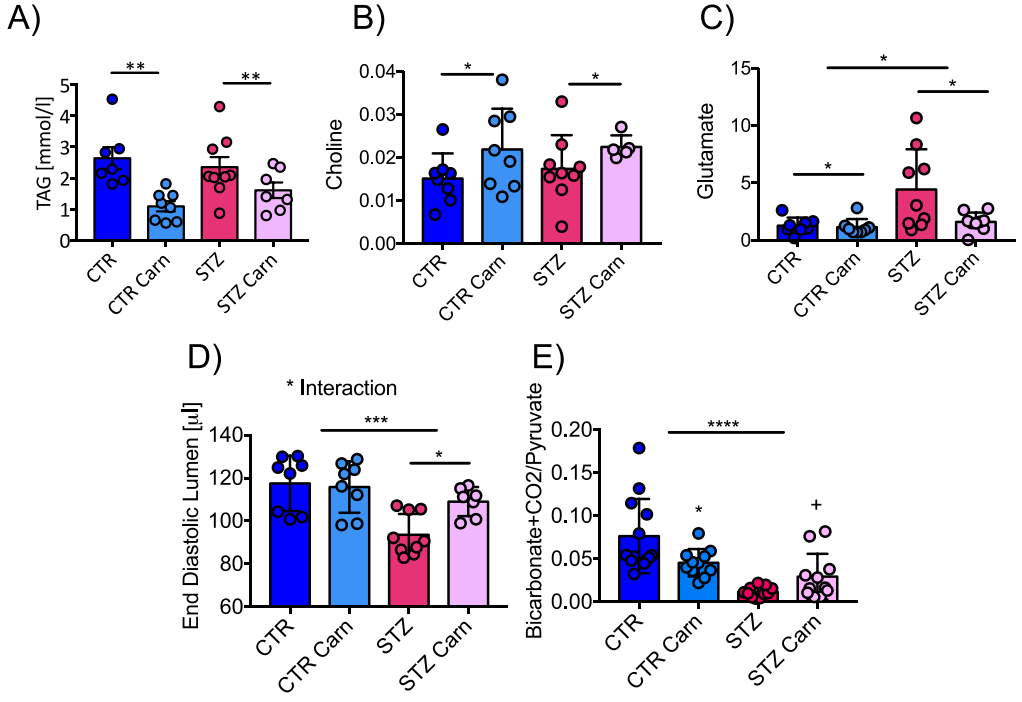


Figure: (abstract: THU-367): A)Serum triglycerides (TAG) levels in fasted state BC)Liver metabolites. D)End diastolic lumen (EDL) obtained from CINE MRI. E)Pyruvate dehydrogenase flux (Bicorbonate+CO2/pyruvate ratio) obtained from hyperpoalrized MRI.

demonstrates that some of the beneficial effects of L-carnitine could be mediated through increased liver choline levels, in addition to improving cardiac function and metabolism. Investigating cardiac function and metabolism in patients with NAFLD could provide an understanding of the interactions between the liver and heart and provide insights into novel therapeutics.

THU-368
Multimodal pre-clinical imaging of liver inflammation and fibrosis

Anja Schmidt-Christensen[1], Julia Nilsson[1], Sofia Mayans[2], Dan Holmberg[1]. [1]*Lund university, LUDC-IRC, EMV, Malmö Sweden;* [2]*inficurebio, Umeå Sweden*
Email: anja.schmidt-christensen@med.lu.se

Background and aims: Formation and remodeling of the extracellular matrix (ECM) is critical during wound healing and scar formation but excessive connective tissue formation, as seen in fibrosis, can be detrimental and lead to organ failure. Besides massive ECM accumulation, fibrosis also involves the formation of new vessels and the establishment of abnormal angio-architecture of the liver.
We have recently developed a spontaneous animal model, the NIF mouse, that recapitulates the process of persistent inflammation leading to tissue remodeling and fibrosis that is commonly observed in human fibrotic disorders. Liver fibrosis is a slow progressing disease requiring large and long costly clinical trials. Current non-invasive clinical and pre-clinical imaging systems are unable to access the spatial resolution domain to reliably detect fibrosis in its early stages. Thus, there is great potential and need for developing time efficient new approaches that can accurately diagnose the early-stages of liver fibrosis and in combination with a relevant preclinical *in vivo* model will identify the most promising drugs at an early stage of disease.
Method: Here we apply magnetic resonance imaging (MRI), optical projection tomography and synchrotron radiation imaging in a multimodal imaging approach that exploits the different strengths of these modalities to establish a method for longitudinal, high resolution, and global evaluation of the inflammatory and fibrosis component of the disease phenotype spontaneously developing in the N-IF mouse model.
Results: Eight-week-old NIF and control mouse liver samples revealed the potential of using SWI MRI for identifying fibrotic liver tissue. Liver fibrosis and cirrhosis involves the accumulation of scar tissue, which impedes blood circulation in the liver, leading to portal hypertension and as consequence the formation of new vessels (also called angiogenesis) and the establishment of abnormal angio-architecture of the liver that can be visualized by OPT, obtaining quantitative 3-D images of total organ fibrosis. Further, we have performed synchrotron radiation micro-CT on 8-week old NIF liver tissue. In comparison to healthy liver tissue we could detect a changed microstructure with less and disrupted sinusoids which can be distinguished in 3D images of the hepatic vessel network. This could give an Implication for the impaired exchange between sinusoids and hepatocytes in fibrotic livers.
Conclusion: This data will serve as baseline observation for determining the impact of therapeutic regimes targeting inflammation and/or fibrosis. Advances in the elucidation of the biology of fibrosis, combined with improved technologies for assessment will provide a comprehensive framework for design of antifibrotics and their analysis in well-designed clinical trials.

THU-369
Efficacy and safety of endoscopic ultrasound-guided liver biopsies in parenchymal liver diseases: A systematic review and meta-analysis

Anup Shah[1], Isabel Guerrido Martinez[1], Nelson Valentin[1], Melissa Hershman[2], Kelsey Collins[1], Shmuel Golfeyz[1], Ilan Weisberg[2]. [1]*Mount Sinai Beth Israel, Department of Medicine, New York, United States;* [2]*Mount Sinai Beth Israel, Division of Gastroenterology and Hepatology, New York, United States*
Email: anup.shah@mountsinai.org

Background and aims: Percutaneous and trans-jugular biopsies are the primary methods of obtaining liver tissue. While the utility of endoscopic ultrasound (EUS) guided liver biopsies for focal liver lesions is established, the role of EUS-guided random liver biopsies in the diagnosis of parenchymal liver diseases is of interest. We conducted a systematic review and meta-analysis to determine the efficacy and safety of EUS-guided liver biopsy in patients with suspected parenchymal liver diseases.
Method: Multiple databases were searched from 1988 through January 2008 incorporating retrospective chart reviews, prospective trials (randomized and non-randomized), and case series. The primary study outcomes were procedural success, determined by number of complete portal tracts (CPTs) and total specimen length (TSL). Secondary outcomes assessed safety of EUS-LB, including complications of pain, bleeding, peritonitis and death. Estimates were pooled across studies using the random effects model.
Results: A comprehensive search of the literature identified 1, 578 potential studies. Twenty studies with a total of 885 adult patients who underwent EUS-LB were included in the analysis. The most common indication for EUS-LB was elevated liver function tests (LFTs) without biliary obstruction. No studies included patients with thrombocytopenia (defined by platelets < 50, 000), coagulopathy (INR > 1.5), decompensated liver disease or pregnant subjects. The mean number of CPTs ranged between 3.5–38.4 with a pooled mean of 15.2 (95% CI = 11.5–18.9). The mean TSL ranged between 10.5 mm-77.0 mm with a pooled mean of 41.4 mm (95% CI = 30.2–52.6). Complication rates were low, including: bleeding 0.6%–5.0% (pooled 2.2%; 95% CI = 1.3%–3.8%) and pain 0.9%–33.3% (pooled 4.0%; 95% CI = 2.6%–6.2%). There were no reported adverse events of peritonitis or death.
Conclusion: EUS-guided liver biopsy is an effective alternative to percutaneous liver biopsy that meets the standard specifications for an optimal liver biopsy as defined by the European Association for the Study of the Liver (25 mm TSL) and the American Association for the Study of Liver Diseases (20 mm TSL and > 11 CPTs). This meta-analysis concludes that EUS-guided liver biopsies can provide evaluable samples with low complication rates. Additional studies evaluating various types of biopsy needles may provide further support for the use of EUS-guided liver biopsies.

Quantification of hepatic metal overload by laser ablation inductively coupled plasma mass spectrometry imaging (LA-ICP-MSI)

Sabine Weiskirchen[1], André Viveiros[2], Heinz Zoller[2], Uta Merle[3], Wolfgang Stremmel[3], Ralf Weiskirchen[1]. [1]*RWTH University Hospital Aachen, Institute of Molecular Pathobiochemistry, Experimental Gene Therapy and Clinical Chemistry, Aachen, Germany;* [2]*Medical University of Innsbruck, Department of Internal Medicine II, Innsbruck, Austria;* [3]*University Hospital Heidelberg, Internal Medicine IV, Heidelberg, Germany*
Email: rweiskirchen@ukaachen.de

Background and aims: Metal overload plays an important role in the development of liver diseases. Wilson's disease (WD) and hereditary hemochromatosis (HH) are good examples how metal buildups lead to organ damage and liver failure. They induce oxidative stress, severe dysfunction of mitochondrial energy production, and alterations in sterol metabolism resulting in severe molecular impairments. Precise metal quantitation and the identification of metal accumulates is still challenging. We have established novel LA-ICP-MSI protocols that allow quantitating various metals and metalloids in liver specimens of experimental metal overload models and in clinical samples obtained from patients suffering from WD or HH.

Method: All human samples have been collected in the course of routine clinical care and were obtained by a standardized protocol. WD and HH genotyping was carried out using validated TaqMan allelic discrimination assays and LightCycler technology. Liver samples were cryo-cut into 30 µm thick slices with a CM3050S cryomicrotome (Leica Biosystems) on −18°C cryo-chamber temperature and −16°C object area temperature, and thaw-mounted onto adhesive StarFrost® microscope slides (Knittel Glass). For the LA-ICP-MSI, we used a quadrupole-based inductively coupled plasma mass spectrometer (ICP-MS, XSeries 2, Thermo Scientific) coupled to a laser ablation system (NWR 213, New Wave Research). 30 µm thick tissue sections were ablated by a focused Nd:YAG laser beam in the scanning mode (wavelength 213 nm, repetition frequency 20 Hz, laser spot diameter 60 µm, scanning speed 60 µm/s).
Results: We demonstrate that LA-ICP-MSI technique allows precise measurement and visualization of copper and iron deposits with high spatial resolution, sensitivity, quantification ability, and exceptional reproducibility in liver tissue. Moreover, our measurements revealed that hepatic iron and copper overload are associated with large variations in other trace metals.
Conclusion: LA-ICP-MSI has multi-element capability suitable to simultaneously measure and quantify a large variety of different metals and metalloids within liver tissue. Therefore, this method is an important diagnostic option in hepatology. The established workflow is straightforward and creates metal maps that are easy to interpret. Furthermore, the simultaneous measurement of various metals offers unique opportunities for a deeper understanding of the biology and changes in metal fluxes during metal-associated liver diseases.

Liver development, physiology and regeneration

Modulation of H3K27 methylation by EZH2 and UTX/JMJD3 small molecules inhibitors impacts on proliferation and differentiation of hepatic progenitor cells and differentiated hepatocytes plasticity

Laura Belloni[1], Natalia Pediconi[1], Leonardo Lupacchini[2], Debora Salerno[1], Annapaola Angrisani[3], Giovanna Peruzzi[1], Enrico De Smaele[3], Massimo Levrero[1,4]. *[1]IIT, CLNS-Sapienza, Rome Italy, Rome, Italy; [2]IRCCS San Raffaele Pisana, Rome, Italy; [3]Sapienza, University of Rome, Rome, Italy; [4]Centre de Recherche en Cancérologie de Lyon (CRCL), UMR 1052-CNRS 5286, Lyon, France*
Email: laura.belloni@gmail.com

Background and aims: Histones methylation at specific lysine and arginine residues is dynamically regulated by different histone methyltransferases and demethylases and plays a critical role in many biological processes. The methyltransferase EZH2, as part of the Polycomb Repressive Complex 2 (PRC2), controls the di-trimethylation of H3K27 (H3K27me2/3) and triggers gene suppression, whereas the lysine demethylases Jumonji D3 (JMJD3, KDM6B) and the UTX (KDM6A) demethylate H3K27me2/3, leading to transcriptional activation. An increased expression of Ezh2 is frequently detected in HCC tissues. It correlates with aggressiveness and/or poor prognosis of HCCs and may help to discriminate between liver pre-neoplastic/dysplastic lesions from cancer. Here, we investigate the impact of the pharmacological modulation of H3K27 methylation on hepatic cells proliferation, differentiation and plasticity using the human bipotent progenitor cell line HepaRG.
Method: Proliferating HepaRG (pHepaRG), DMSO/low serum-differentiated HepaRG cells (dHepaRG) and primary human hepatocytes (PHHs) were treated with the epigenetic drugs GSK-126 (EZH2 inhibitor) and GSK-J4 (JMJD3/UTX inhibitor). RNA-Seq libraries were prepared using the TruSeq® Stranded RNA HT (w/Ribo-Zero™) and sequenced (75×2 cycles) on an Illumina HiSeq platform.
Results: EZH2 methyltransferase and JMJD3/UTX demethylases are differentially regulated in dHepaRG cells, resulting in a strong reduction of H3K27 methylation levels. RNA-seq analysis of GSK-J4 treated dHepaRG cells showed that the inhibition of JMJD3/UTX demethylase activity strongly downregulated several metabolic and differentiation pathways, whereas cell cycle and DNA replication pathways were upregulated. RT-PCR analysis confirmed that GSK-J4 treatment induces a drastic decrease of hepatic differentiation markers, such as Albumin and Cyp3A, 4 and a significant increase of proliferation markers, such as Ki67 and CCNB1. The inhibition of JMJD3 and UTX demethylase activity in human primary hepatocytes induced their partial de-differentiation with a reduction in albumin expression and secretion and Cyp3A4 activity. GSK-J4 treatment of dHepaRG cells and PHHs induced cell cycle re-entry and increased cell mobility in scratch wound assays. Conversely, the inhibition of EZH2 methyltransferase activity with GSK-126 decreased cell proliferation and upregulated several hepatic markers in pHepaRG cells.
Conclusion: Our results indicate that the balance of EZH2 and JMJD3/UTX activities plays an important role in the control of cell proliferation and differentiation in hepatic progenitor cells and that the pharmacological modulation of H3K27 methylation using small molecule inhibitors of EZH2 and JMJD3/UTX activity may be exploited to induce hepatic progenitor cells differentiation and differentiated hepatocytes plasticity and proliferation.

Exosomes from human umbilical cord mesenchymal stem cells promote liver regeneration in aged mice after major hepatectomy via activating sirtuin1 pathway

Liang Chen[1], Jun Zheng[1], Qing Yang[1], Jianye Cai[1], Jiebin Zhang[1], Tongyu Lu[1], Jia Yao[1], Yingcai Zhang[1], Yang Yang[1]. *[1]Department of Hepatic Surgery and Liver Transplantation Center of the Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*
Email: yysysu@163.com

Background and aims: Aging is known to negatively influence liver regeneration, which restrict the extent of hepatectomy in the elderly population. Exosomes are small double-membrane vesicles participating in intercellular communication. Previous studies have shown the ability of exosomes from umbilical cord-derived mesenchymal stem cells (UC-MSC-Exo) to promote hepatocyte proliferation. However, little is known about their biological function on aging liver. Thus, we aim to determine whether UC-MSC-Exo contribute to liver regeneration in aging mice after major hepatectomy.
Method: Exosomes from human umbilical cords-derived mesenchymal stem cell were isolated and characterized. In vivo study, we used model of 70% partial hepatectomy to evaluate whether UC-MSC-Exo promote hepatocyte proliferation and liver regeneration in aging C57BL/6 mice. In addition, primary hepatocytes were isolated and cultured to determine whether UC-MSC-Exo enhanced proliferation of senescent hepatocytes in vitro.
Results: Compared with young (8–10 weeks) mice, old (> 16 months) mice were more susceptible to oxidative stress and showed decreased hepatocytes regeneration after major hepatectomy. In addition, hepatic expression of sirtuin 1 (SIRT1) was significantly reduced in old mice compared with that in young mice. UC-MSC- Exo exhibit dose-dependent ability to promote proliferation of aging hepatocyte in vitro and in vivo. Mechanistically, UC-MSC-Exo fuse with the hepatocytes directly and increase synthesis of SIRT1. Finally, ablation of SIRT1 expression within aging hepatocytes abolished the proliferative effect of UC-MSC-Exo.
Conclusion: Exosomes from umbilical cord-derived mesenchymal stem cells could deliver the synthetic component to stimulate SIRT1 expression in senescent hepatocytes, resulting in their proliferation

and liver regeneration after major hepatectomy. These results represent a potentially new contributing mechanism of MSC-Exo in liver regeneration and have important indications for novel therapeutic approaches in age-related diseases.

THU-373

IL-6 trans-sginaling controls liver regeneration after partial hepatectomy

Nastaran Fazel Modares[1], Robin Polz[1]. [1]*Heinrich heine university, Institute of Biochemistry and Molecular Biology II, Düsseldorf, Germany*
Email: nastaran.fazel@gmail.com

Background and aims: Interleukin-6 (IL-6) is critically involved in liver regeneration after partial hepatectomy (PHX). PHX-induced generation of the soluble IL-6R by ADAM proteases strengthens IL-6 trans-signaling in which IL-6 forms an agonistic complex with the soluble IL-6 receptor (sIL-6R) to activate all cells expressing the signal-transducing receptor chain gp130. In contrast, without activation of ADAM proteases, IL-6 in complex with membrane-bound IL-6R and gp130 activates classic signaling. It has been suggested that IL-6 trans-signaling *via* the soluble IL-6/IL-6R complex is involved in liver regeneration. However, long-term contribution of IL-6 trans-signaling for liver regeneration after PHX is unknown. In this study we try to investigate the long term contribution and the importance of IL-6 trans-signaling for liver regeneration after PHX by using novel IL-6 trans-signaling mice. We survey the long-term consequences of global IL-6 signaling inhibition versus IL-6 trans-signaling selective blockade after partial hepatectomy on liver regeneration by IL-6 monoclonal antibodies and sgp130Fc, respectively. For first time we studied the importance of IL-6/IL-6R in the liver regeneration after partial hepatectomy by using IL-6R knockout mice.
Method: We generated novel IL-6 trans-signaling mice, which were genetically engineered to only execute IL-6 trans-signaling and abrogated classic signaling by *genetic* conversion of all membrane-bound IL-6R into sIL-6R proteins. The compensatory role of IL-6 trans-signaling in liver regeneration was then identified by monitoring stat-3 phosphorylation and hepatocyte proliferation.
Results: In this study we could show whereas IL-6R deficient mice were strongly affected by PHX, survival and regeneration of IL-6 trans-signaling mice was indistinguishable from control mice. Both global IL-6 blockade and selective inhibition of IL-6 trans-signaling results in strong decrease of overall survival after PHX, accompanied by decreased STAT3 phosphorylation and proliferation of hepatocytes. We could also show that IL-6 trans-signaling induces hepatocyte growth factor (HGF) production by hepatic stellate cells (HSC).
Conclusion: By using two independent strategies we demonstrate that IL-6 trans-signaling fully compensates for the loss of IL-6 classic signaling in liver regeneration after PHX.
In addition expression of HGF by hepatic stellate cells (HSCs) is under the control of IL-6 trans-signaling after PHX.

The INCRNA H19-dervied MIR-675 promotes liver necroptosis by targeting fadd

Eithan Galun[1], Rona Harai-Steinfeld[1], Meytal Gefen[1], Alina Simerzin[1], Elina Zorde-Khvalevsky[1], Mila Rivkin[1], Ezra Ella[1], Tomer Friehmann[1], Mordeachy Gerlic[2], Jessica Zucman-Rossi[3], Stefano Caruso[3], Melissa Leveille[4], Jennifer Estall[4], Daniel S Goldenberg[1], Hilla Giladi[1], Zohar Bromberg[1]. Email: eithang@hadassah.org.il

Chronic inflammation is closely linked to cancer formation. Many molecular pathways are involved in the inflammatory response and some of these including microRNAs, have been connected to liver cancer development. The H19 derived microRNA-675 (miR-675) has been implicated as both tumor promoter and tumor suppressor and also plays a role in liver inflammation, which is not yet fully understood. We found that miR-675 promotes cell death in human hepatocellular carcinoma (HCC) cell lines. We show that FADD, a mediator of apoptotic signaling, is a miR-675 target and is down regulated by this miRNA. Importantly, we found a negative correlation between miR-675 and FADD expression in mouse models of HCC as well as in human samples. We demonstrate in a mouse model of liver inflammation that over expression of miR-675 represses FADD expression and promotes necrosis. We confirm both *in vitro* and *in vivo* that this necrotic cell death is necroptosis which can be inhibited by the necroptosis specific inhibitor Nec-1/Nec-1 s. We also show that necroptosis induced by miR-675 expression, is mediated by p-MLKL (Mixed Lineage Kinase Domain Like Pseudokinase) in a lipopolysaccharide (LPS) induced liver inflammation. Furthermore, miR-675 enhanced MLKL binding to RIP3 (receptor-interacting protein 3) a key signaling molecule in necroptosis. In conclusion, down regulation of FADD by miR-675 promotes liver necroptosis in response to inflammatory signals. We propose that this regulation cascade could stimulate and enhance the inflammatory response in the liver, making miR-675 an important regulator in liver inflammation and potentially also in HCC.

THU-375

Transcription factor TRIM33 controls liver progenitor cell towards hepatocyte differentiation through synergizing with SMAD2/3 following massive parenchymal loss

Tao Lin[1], Shanshan Wang[2], Chen Shao[3], Xiaodong Yuan[1], Franziska Wandrer[4], Heike Bantel[4], Alexander Marx[5], Matthias Ebert[1], Huiguo Ding[2], Steven Dooley[1], Honglei Weng[1]. Email: honglei.weng@medma.uni-heidelberg.de

Background and aims: In liver disease with severe parenchymal loss, e.g. acute-on-chronic liver failure (ACLF), liver progenitor cells (LPC), the local stem cells, are the main cell source to replenish lost hepatocytes through cell reprogramming. The molecular mechanisms underlying LPC towards hepatocytes differentiation in ACLF largely remain unknown to date. Tripartite motif protein (TRIM) 33 is a crucial transcription factor for differentiation of embryonic stem cells through the formation of transcription factor complexes with p-Smad2/3, the downstream substrates of activated TGF-β signaling. This transcription factor complex opens binding sites at promoters of master regulators of differentiation, e.g. goosecoid (GSC), for the additional transcription factor complexes, such as Smad4-pSmad2/3-FoxH1. The current study investigated the role of TRIM33 in LPC differentiation towards hepatocytes.
Method: We enrolled 113 liver tissue specimens from patients with compensated cirrhosis, 20 ACLF with liver transplantation and 3 ACLF spontaneously recovered. Expression of TRIM33, FoxH1, GSC and presence of p-Smad2 was measured by immunohistochemistry. *In vitro*, BMOL cells, a murine LPC line, were used as an LPC towards hepatocyte differentiation model.
Results: Given that more than 70% hepatocyte buds derive from LPC in cirrhotic liver, patients with cirrhosis are ideal candidates to observe successful LPC differentiation towards hepatocytes. In 90 HBV-associated compensated cirrhotic patients, most buds showed

strong immune positivity for p-Smad2, TRIM33, FoxH1 and GSC in the same hepatocytes. However, in 20 ACLF patients, who received liver transplantation, expression of TRIM33, FoxH1 and GSC were undetectable. In contrast to these patients, 3 spontaneously recovered ACLF patients showed strong nuclear FoxH1 and p-Smad2 staining in LPC and hepatocyte-like cells. *In vitro*, BMOL cells differentiated into hepatocyte-like cells, expressing hepatocyte specific proteins, e.g. albumin and transferrin, synthesizing glycogen, and losing cholangiocyte phenotype as evident from reduced CK19 and SOX9 expression over time. In this transdifferentiation process, phosphorylation of Smad2 and Smad3, and expression of TRIM33 and FoxH1 were induced and maintained at high levels. Immunoprecipitation analysis revealed the presence of TRIM33/p-Smad2/3 complexes. Knockdown of Smad2, Smad3, TRIM33 or FoxH1 significantly reduced expression of albumin and transferrin. TRIM33 expression was upregulated by EGF, whereas blocking the EGF receptor reduced expression of TRIM33, albumin and transferrin.
Conclusion: Transcription factor complexes TRIM33/Smad2/3, which are driven by EGF and TGF-β signaling, mediate differentiation of LPC towards hepatocyte in severe liver disease with massive parenchymal loss, e.g. liver cirrhosis and ACLF.

THU-376
A viral mediated liver repopulation assay without the use of transgenic animals

Wei-Yu Lu[1,2], Tak Yung Man[2], Stuart Forbes[2]. [1]*Centre for Liver and Gastrointestinal Research, Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom;* [2]*The MRC Centre for Regenerative Medicine, The University of Edinburgh, Edinburgh, United Kingdom*
Email: stuart.forbes@ed.ac.uk

Background and aims: Animal models of liver repopulation assay is the ''gold standard'' to determine the functionality of transplanted cells. Most liver repopulation assays require genetic modifications to the recipients to provide selective advantage for the donor cells to outcompete the host cells during regeneration. Currently, the generation of these assays involve extensive breeding of transgenic animals, such as the urokinase plasminogen activator (uPA) mice, the fumaryl acetoacetate hydrolase (FAH) deficient mice, and the $Mdm2^{fl/fl}$ mice. Here, we developed an alternative strategy using a viral mediated method to inhibit hepatocyte proliferation in wild type mice as recipients for liver repopulation assay. This method reduces the number of transgenic animals required, time and cost for conducting therapeutic liver repopulation assay.
Method: We packaged a partial coding region of p21 into an Adeno-Associated Virus Serotype 8 (AAV8-p21) Vector under the control of the hepatocyte specific Thyroxine binding globulin (TBG) promoter. Due to the hepatotropism of the AAV8 and the hepato-specificity of the TBG promoter, this will confine the p21 overexpression in hepatocytes specifically. Recipient wild type C57Bl6 mice were administrated with AAV8-p21 or AAV8-Ctrl by tail vein injection at a concentration of 2.5×10^{11} GC/ml. Mice were then given a dose 1.5 mg/kg of Carbon Tetrachloride (CCl4) through intraperitoneal injection 7 days after the AAV8-p21 injection to induce hepatocyte damage. 10^6 freshly isolated TdTomato (tdTom) hepatocytes were transplanted into the recipient mice 2 days after the CCl4 injection. Recipient mice received weekly injection of 1.5 mg/kg CCl4 after transplantation and tissue were analysed one month after transplantation.
Results: p21 protein expression was observed in mice received AAV8-p21 injection and the lack of hepatocyte proliferation was observed after CCl4 injection. Similar engraftment of donor cells was observed 1-week post-transplantation in the AAV8-p21 injected mice compared to controls. When repetitive CCl4 was administrated weekly up to a month, transplanted hepatocytes repopulated 10 times better in the AAV8-p21 injected group than the controls and reconstitute around 30 percent of the liver. Transplanted cells are functional from the expression of CYP2D enzymes and HNF4a expression. The donor cells repopulate the liver uniformly without zonal preference and picrosirius red staining shows similar level of scar deposition in both groups suggesting the injury and regenerative mechanism is unaltered in the AAV8-p21 mediated liver repopulated model.
Conclusion: Here, we report a novel and rapid method to investigate the liver repopulating capacity of cells without using genetic modified animals.

THU-377
Systemic blood pressure is not associated with hepatic perfusion and metabolic activity by 18F-FDG PET in patients with NAFLD

Chung Heng Liu[1], Benjamin Spencer[2], Blythe Durbin-Johnson[3], Guobao Wang[2], Souvik Sarkar[1]. [1]*University of California, Davis, Internal Medicine/Gastroenterology and Hepatology, Sacramento, United States;* [2]*University of California, Davis, Radiology/Nuclear Medicine, Sacramento, United States;* [3]*University of California, Davis, Public Health/Biostatistics, Davis, United States*
Email: ssarkar@ucdavis.edu

Background and aims: ^{18}F-Fluorodeoxyglucose (FDG) positron emission tomography (PET) has the potential to quantitatively characterize fatty liver disease states. However, the effect of change in systemic hemodynamics on hepatic and splenic FDG-PET parameters in humans is not yet well understood. In the present study, we aim to examine the relationship between systemic blood pressure with perfusion and metabolism of the liver and spleen in non-alcoholic fatty liver disease (NAFLD) patients by FDG PET.
Method: Systolic (SBP), diastolic (DBP) blood pressures, and mean arterial pressure (MAP) were measured from biopsy-proven NAFLD patients. FDG PET was performed on all fasting patients and analyzed using 3-compartment modeling. Regions of interests (ROIs) were placed on eight individual liver segments and the spleen to obtain the surrogate of perfusion as characterized by the FDG blood-to-tissue rate K_1 and the overall metabolic activity as characterized by standardized uptake value (SUV). Associations between the FDG parameters and systemic blood pressure were determined by linear regression, adjusting for body mass index (BMI), age, gender, and use of beta and calcium channel blockers.
Results: 30 NAFLD patients were enrolled (67% female). Mean age 55 years, SBP 125 mm Hg, DBP 76 mm Hg, and MAP 70.5 mm Hg. 27% of the patients had advanced fibrosis (Kleiner Fibrosis ≥ 3). There was no association between blood pressure (s) and FDG K_1 and SUV in the liver and the spleen. Similarly, blood pressure (s) did not associate with the K_1 of each segment of the liver. Significant effect of SBP and DBP was observed only in a single segment with change in fibrosis. Among those with advanced fibrosis (> stage 3), K_1 in segment 5 increased with increasing SBP (p = 0035) and decreased marginally

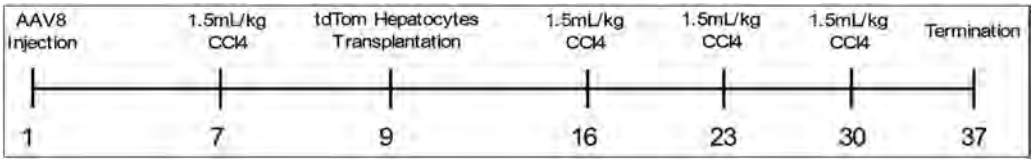

Figure 1: (abstract: THU-376): Schematic illustration showing the experimental setup

with increasing DBP (p = 0.049). However, no association between systemic blood pressure with other segments of the liver and the spleen for K_1 and SUV were observed among subjects with early or advanced fibrosis.
Conclusion: Although our study is limited by the number of patients, it provides preliminary data on the effect of changes in blood pressure on liver/spleen perfusion and glucose metabolism. We present data to show that systemic blood pressure did not appreciably affect either hepatic perfusion or overall metabolic activity in NAFLD patients. Future analysis in larger cohorts are needed to further define the effect in individual liver segments and relation to disease state.

THU-378
Messenger RNA transcriptome profiling reveals a distinct phenotype of human bone marrow mesenchymal stem cell-derived hepatocytes
Jun Li[1], Dongyan Shi[1], Jiaojiao Xin[1], Wenchao Ding[1], Jing Jiang[1], Qian Zhou[1], Suwan Sun[1], Yinyun Lu[1], Beibei Guo[1], Xingping Zhou[1].
[1]*The first affiliated hospital, Zhejiang university school of medicine, State key laboratory for diagnosis and treatment of infectious diseases, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: The hepatocytes differentiated from stem cells are promising alternatives of primary human hepatocytes (PHHs) to treat liver disease. However, the differentiation mechanism is still unclear, and the in vitro differentiated immature hepatocytes limit the further clinical translation. In this study, we aimed to clarify the transcriptome characteristics of hepatocytes differentiated from human bone marrow mesenchymal stem cells (hBMSCs) for future clinical application.
Method: Human BMSCs were isolated from bone marrow of health volunteers, and differentiated into hepatocytes. After 20 days differentiation, hBMSC differentiated hepatocytes (hBMSC-Hep) were harvested for mRNA sequencing (mRNA-seq), using hBMSCs and PHHs as controls. The significantly differentially expressed genes (DEGs) were identified via bioinformatics analysis, and validated in hBMSC transplanted fulminant hepatic failure (FHF) pigs.
Results: hBMSC-Heps exhibited a polygonal morphology, and were positive for albumin staining and glycogen accumulation. The transcriptome profiling of hBMSC-Hep showed specific hepatic functional pathways. Comparing with hBMSCs, 630 DEGs were identified to be significantly upregulated in hBMSC-Heps and PHHs, while 1082 DEGs were downregulated. Functional annotation clustering analysis showed that the upregulated DEGs were involved in hepatic functions, such as sterol metabolism, lipid transport, oxidation reduction, inflammatory and immune responses,. And the downregulated DEGs were related with stem cell characteristics, such as multipotent differentiation, cell cycle regulation and cytoskeleton reorganization. Total 18 DEGs (9 up- and 9 down-regulated) with > 5 fold changes were confirmed by quantitative real-time PCR in three independently experiments, which showed a similar results of mRNA-seq. Further validation of hBMSCs transplantation with FHF model in pigs showed that the implanted hBMSCs completely differentiated into hepatocytes within 7 days, and the 5/9 upregulated DEGs (*TDO2*, *HP*, *SERPINA3*, *LBP* and *SAA1*) exhibited a same expressed trend. Such 5 DEGs with > 150-fold change of increase were mostly contributed to the liver metabolism and inflammation, which imply a differentiation ability of mature hepatocytes.
Conclusion: The mRNA transcriptome profiling demonstrated a mechanical direction of hBMSC differentiation into hepatocytes, and five DEGs may contribute to improving strategies of hBMSC-derived hepatocytes.

THU-379
Deficiency of apoptosis-stimulating protein two of p53 promotes liver regeneration in mice by activating mammalian target of rapamycine
Hongbo Shi[1]. [1]*Beijing Youan Hospital, Beijing, China*
Email: shb411@126.com

Background and aims: Although liver regeneration has been intensively studied in various ways, the mechanisms underlying liver regeneration remain elusive. Apoptosis-stimulating protein two of p53 (ASPP2) was discovered as a binding partner of p53 and plays an important role in regulating cell apoptosis and growth. However, the role of ASPP2 in hepatocyte proliferation and liver regeneration has not been reported.
Method: The expression profile of ASPP2 was measured in a mouse model with 70% partial hepatectomy (PH_X). Liver regeneration and hepatocyte proliferation were detected in wild-type ($ASPP2^{+/+}$) and ASPP2 haploinsufficient ($ASPP2^{\pm}$) mice with PH_X. The mammalian target of rapamycin (mTOR) and autophagy pathways were analyzed in the $ASPP2^{+/+}$ and $ASPP2^{\pm}$ mice with PH_X. After rapamycin or 3-methyladenine (3-MA) treatment, hepatocyte proliferation and liver regeneration were analyzed in the $ASPP2^{+/+}$ and $ASPP2^{\pm}$ mice with PH_X.
Results: ASPP2 expression was shown to be upregulated at the early stage and downregulated at the late stage. Compared to the $ASPP2^{+/+}$ mice, liver regeneration was enhanced in $ASPP2^{\pm}$ mice with 70% PH_X. In addition, compared to the $ASPP2^{+/+}$ mice, the mTORC1 pathway was significantly upregulated and the autophagic pathway was downregulated in $ASPP2^{\pm}$ mice with 70% PH_X. Inhibition of the mTORC1 pathway significantly suppressed liver regeneration in $ASPP2^{\pm}$ mice with 70% PH_X. In contrast, disruption of the autophagic pathway further enhanced liver regeneration in $ASPP2^{\pm}$ mice with 70% PH_X.
Conclusion: ASPP2 deficiency can promote liver regeneration through activating the mTORC1 pathway, which further regulates downstream molecules, such as those related to autophagy and p70S6 K expression in mouse model post-PH_X.

THU-380
DLL4 restores damaged liver by protecting hepatocytes and enhancing cholangiocyte differentiation
Jun Li[1], Suwan Sun[1], Dongyan Shi[1], Jiaojiao Xin[1], Jing Jiang[1], Qian Zhou[1], Jiang Li[1], Li Shao[1], Lingling Yang[1], Hozeifa Mohamed Hassan[1], Yinyun Lu[1], Beibei Guo[1], Xingping Zhou[1].
[1]*The first affiliated hospital, Zhejiang university school of medicine, State key laboratory for diagnosis and treatment of infectious diseases, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Hepatocyte necrosis and intrahepatic cholangiolar injury are the main pathological mechanisms of fulminant hepatic failure (FHF). Delta-like ligand 4 (DLL4)-mediated Notch activation contributes to reversing hepatic and biliary injury. However, its detailed mechanism is still unclear. This study aimed to clarify the role of DLL4 in restoring damaged liver by protecting hepatocytes and enhancing cholangiocyte differentiation.
Method: The efficacy of DLL4 was evaluated in a rat model of FHF by determining the survival rate, observing the liver structure and examining the biochemical index. The human hepatocyte line QSG-7701 was transfected with pcDNA-DLL4 and si-DLL4 to evaluate the protective effects of DLL4. The potency of DLL4 in inducing cholangiocyte differentiation from human bone marrow mesenchymal stem cells (hBMSCs) was assessed by measuring the expression of cholangiocyte-specific genes and proteins.
Results: DLL4 treatment significantly prolonged the survival of rats with FHF (p < 0.05). Liver tissue structure and biochemical functions were significantly improved in rats in the DLL4 treatment group. The hepatocyte-specific markers albumin (ALB), alpha fetoprotein (AFP), cytokeratin 18 (CK18), hepatocyte nuclear factor 4 alpha (HNF4

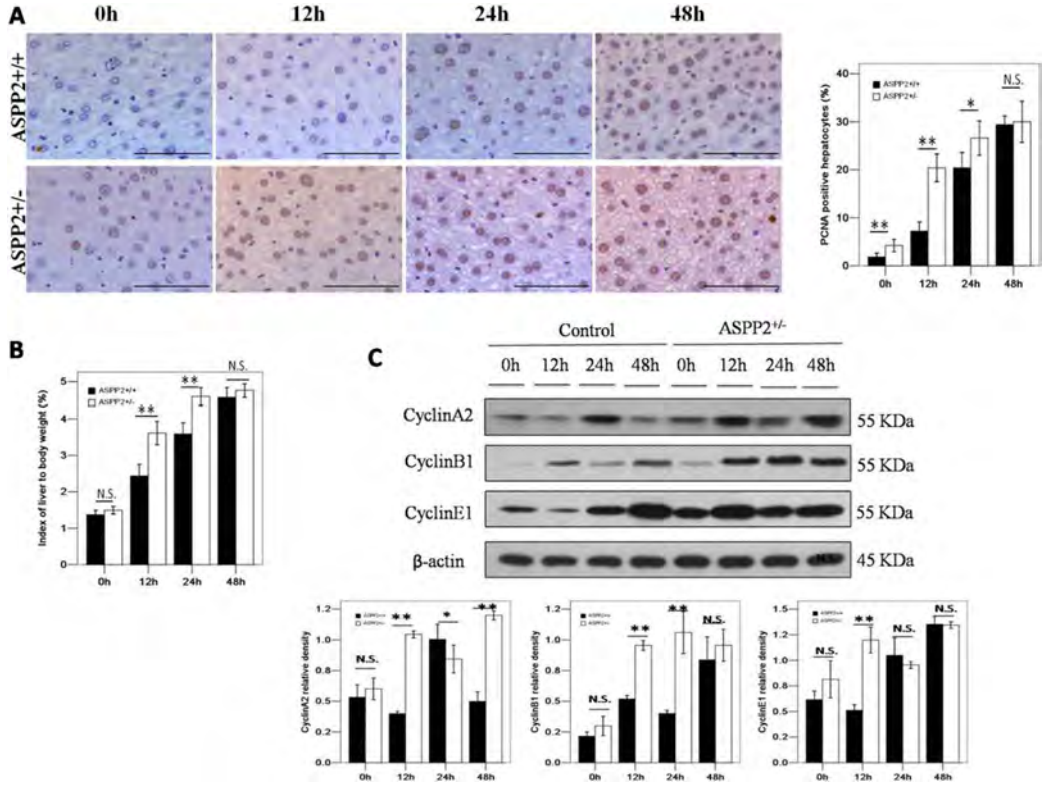

Figure1: (abstract: THU-379): Enhanced liver regeneration in ASPP2 ± mice after 70% PHX.

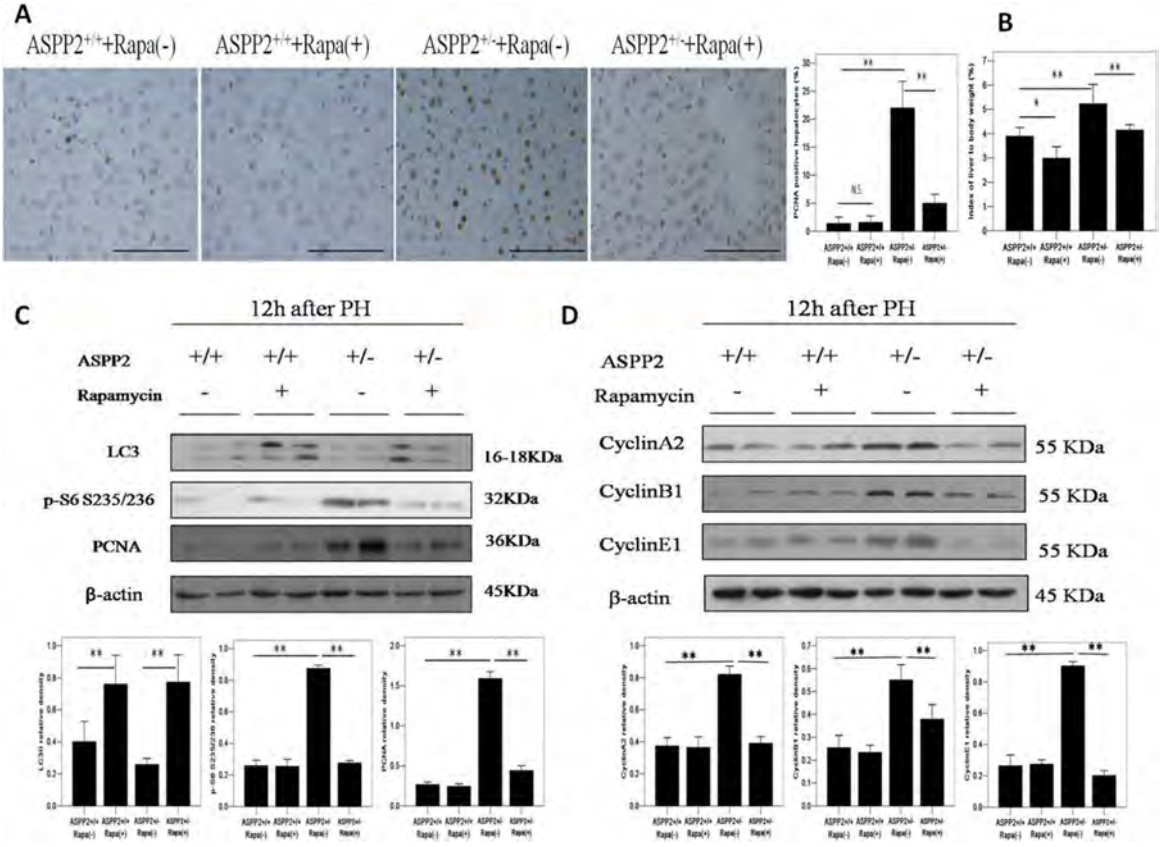

Figure 2: (abstract: THU-379): Inhibition of the mTORC1 pathway significantly suppresses liver regeneration in ASPP2 ± mice.

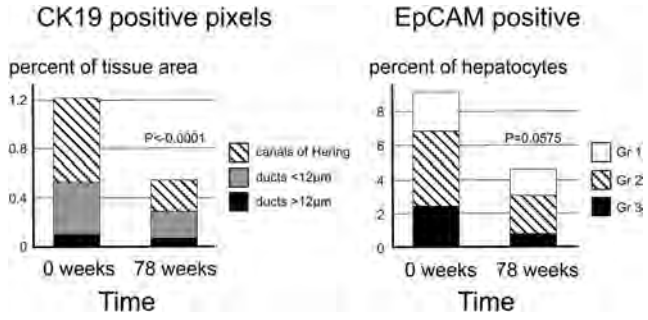
alpha) and cytochrome P-450 (CYP450) were upregulated by *DLL4* overexpression and downregulated by *DLL4* knockdown in cultured QSG-7701 hepatocytes. Furthermore, hBMSC-derived cholangiocyte-like cells induced by DLL4 showed a specific increase in the expression of cholangiocyte-specific genes (e.g., *CK19*, SRY-BOX 9 [*Sox9*] and cystic fibrosis transmembrane conductance regulator [*CFTR*]).
Conclusion: DLL4 restores damaged liver by protecting hepatocytes and enhancing cholangiocyte differentiation from hBMSCs, and DLL4 has the potential to be used in future clinical therapeutic applications.

THU-381
Characterization of regeneration in chronic hepatitis B before and after entecavir treatment in 20 patients
Ian Wanless[1], Bingqiong Wang[2], Yameng Sun[3], Hong You[3], Ji-Dong Jia[3], Shuyan Chen[3], Xiaoning Wu[3], Jialing Zhou[3], Xiaojuan Ou[3], Ashley Stueck[1]. *[1]Dalhousie University, Pathology, Halifax, Canada; [2]Beijing Friendship Hospital, Liver Research Center, Beijing; [3]Liver Research Center, Beijing Friendship Hospital, Beijing, China*
Email: iwanless@eastlink.ca

Background and aims: Human chronic liver disease is characterized by regions of collapsed parenchyma resulting in septa composed of approximated tissue structures and associated fibrosis. After cessation of primary injury, progenitor activity causes repopulation of these septa with bud-derived hepatocytes. Although the natural history of buds has been studied with various markers (Stueck A, Hepatology 2015), the timing of hepatocyte repopulation and maturation is unknown. The present study clarifies timing by examination of biopsies obtained during the course of a therapeutic trial of entecavir in chronic hepatitis B (Sun Y et al, Hepatology 2017;65:1438).
Method: Liver biopsies were obtained before (0 weeks) and after viral eradication had been achieved (78 weeks). 20 pairs of biopsies were stained for CK19 and EpCAM. CK19 positive pixels were counted with ImageJ software (NIH). Positive pixels were subclassified by location in large tubular ducts (> 12 µm), small tubular ducts (< 12 µm), and non-tubular structures (canals of Hering = COH). EpCAM positivity in hepatocytes were graded 0-3 and expressed as percent of total hepatocyte area.
Results: CK19+ pixels in COH decreased 62% with time ($p < 0.0001$). EpCAM expression was found in 8.7% of hepatocytes at 0W and 3.9% at 78W ($p = 0.0575$) (Figure 1). EpCAM correlated with CK19 in COH ($p = 0.0022$). EpCAM expression was less intense after therapy with adjacent domains of various intensities present concurrently. At 78 weeks, both markers remained at higher than normal levels.



Conclusion: The progenitor-derived budding process is easily observed with CK19 and EpCAM expression in most biopsies with active chronic hepatitis B. The process has largely subsided at 78 weeks, especially where damaged foci have regained near-normal parenchymal appearance. Hepatocyte division continues for a time after bud initiation so that cytoplasmic CK19 and EpCAM are diluted (or degraded) after new synthesis of the markers has ceased. The marked change in COH number with time confirms that many are transient structures in regions of incompletely healed injury. As such, they are likely residual tags of distal ducts resulting from the budding process. EpCAM expression related to regeneration may be distinguished from pre-neoplastic expression by the gradients of intensity (fading) with eincreasing distance from the duct centers. We expect to further clarify the time course of healing as 5-year biopsies from this trial become available in coming months.

Public Health

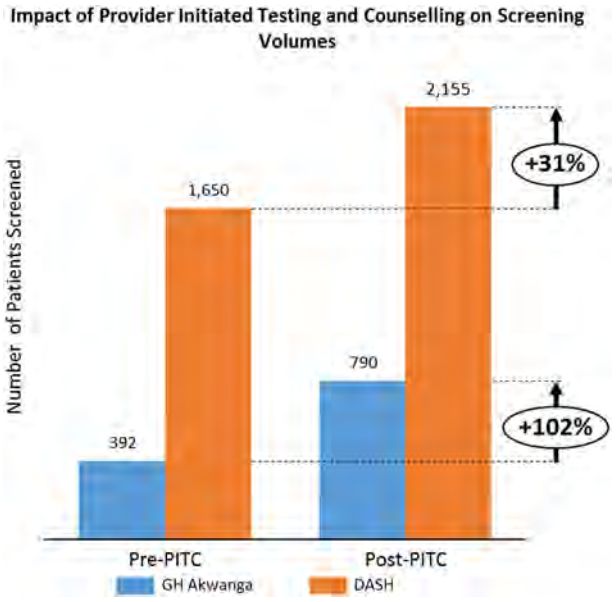
Use of facility-based provider initiated testing and counselling approach to ascertain viral hepatitis C status in high burden populations in Nigeria
Chukwuemeka Agwuocha[1], Jilian Sacks[2], Caroline Boeke[2], Ena Oru[1], Adamu Ibrahim[3], Namita Bansal[1], Justus Jiboye[1], Folu Lufadeju[1], Owens Wiwa[1]. *[1]Clinton Health Access Initiative, Abuja, Nigeria; [2]Clinton Health Access Initiative, New York, United States; [3]Nasarawa State Ministry of Health, Lafia, Nigeria*
Email: jsacks@clintonhealthaccess.org

Background and aims: In Nigeria, an estimated 24 million persons chronically infected with HBV and/or HCV could proceed to develop advanced liver diseases, and pose a risk of disease transmission if untreated. Despite the high burden of the disease and opportunities available for treatment, approximately 95% of people infected with HCV are unaware of their status. To improve case identification, Provider Initiated Testing and Counselling (PITC) used in the HIV program and approved/recognized by the World Health Organisation was employed across two facilities in Nasarawa State, to drive HCV case detection. Using this approach, patients visiting the facility outpatient clinics were offered screening for HCV to ascertain their status. This analysis aimed to highlight the impact of PITC at these pilot facilities in Nasarawa as a model to improve case identification in high burden environments.
Method: This analysis utilized retrospective data from facilities to determine access to and volume of HCV screenings successfully conducted using Rapid Test Kits (RTKs). Two facilities, Dalhatu Araf Specialist Hospital (DASH) and General Hospital (GH) Akwanga in Nasarawa were selected as initial pilot sites to demonstrate impact with two different health facility tiers. While healthcare worker trainings were conducted for physicians on HCV management during this timeframe, all other relevant facility-level factors including human resource capacity, laboratory and clinic workflow remained the same. Six months of retrospective data on adult HCV screening through outpatient departments (OPD) were compared pre- and post-PITC intervention and screening volumes and seropositivity were assessed. Pre-PITC data was collected from January to July 2017 for DASH and July to December, 2017 for GH Akwanga. Post-PITC data was collected from October 2017 to March 2018 for DASH and March to August 2018 for GH Akwanga.
Results: Six months retrospective data were compared across two facilities pre- and post-PITC intervention (2017-2018). At DASH, 1650 individuals (mean:275/month) were screened pre-PITC with 14% HCV seropositive while post-PITC, 2155 individuals (mean:359/month) were screened with 15% HCV seropositive. In GH Akwanga 392 persons (mean:65/month) were screened pre-PITC with 17% seropositive while post-PITC, 790 persons (mean:132/month) were screened with 16% seropositive.
Conclusion: Implementation of PITC led to a 31% and 103% increase in patients referred for HCV screening services from the OPD clinics at DASH and GH Akwanga respectively. Sero-positivity remained relatively stable across timeframe, implying a net increase in the volume of positive patients identified and referred for confirmatory

testing. Outcomes of the study shows that the PITC model may be critical to expanding access to early diagnosis to enable persons ascertain HCV status in high burden environments.



THU-383

Dried blood spots: A useful tool for virologically caracterising the hepatitis C virus epidemic

Adrian Antuori Torres[1], Vincent Montoya[2], Verónica Saludes[1,3], Jeffrey Joy[4], Sara González-Gómez[1], Cinta Folch[3,5], Jordi Casabona[3,5], Núria Ibáñez[6], Joan Colom[6], Elisa Martró[1,3]. *[1]Germans Trias i Pujol University Hospital, Germans Trias i Pujol Research Institute (IGTP), Microbiology Department, Clinical Laboratory North Metropolitan Area, Badalona (Barcelona), Spain; [2]BC Centre for Excellence in HIV, Vancouver, BC, Canada; [3]Instituto de Salud Carlos III, Biomedical Research Networking Centre in Epidemiology and Public Health (CIBERESP), Madrid, Spain; [4]University of British Columbia, Department of Medicine, Vancouver, BC, Spain; [5]Catalonia Public Health Agency (ASPCAT), Centre for Epidemiological Studies on Sexually Transmitted Infections and HIV/AIDS of Catalonia (CEEISCAT), Badalona (Barcelona), Spain; [6]Catalonia Public Health Agency (ASPCAT), Program on Substance Abuse, Barcelona, Spain*
Email: emartro@igtp.cat

Background and aims: Incident hepatitis C virus (HCV) cases identified in Europe occur mostly among people who inject drugs (PWID). The identification and characterization of recent infections is necessary for understanding mechanisms of current HCV transmission in this population. Dried blood spot (DBS) samples have demonstrated their usefulness in facilitating the HCV diagnosis and could help to characterize the local epidemic among PWID. Thus, we aimed to (i) establish the validity of DBS to assess HCV genetic variability by next-generation sequencing (NGS), (ii) identify acute infections through genetic variability estimates, and (iii) identify transmission clusters.
Method: HepCdetect II is a cross-sectional study of 410 active PWID in four harm reduction settings in Barcelona. DBS were collected from all participants, and plasma was additionally collected in 300 cases. DBS were qualitatively tested for HCV RNA [Saludes V, J Viral Hep 2018], and viral loads were quantified from plasma (Abbott). For positive samples, a 389-bp region of the HCV NS5B gene was amplified. Sequence libraries were indexed and subjected to Illumina paired-end sequencing (2x250 cycles, MiSeq). Inter and intra-host HCV genetic variability estimates and cluster analysis based on patristic distances were performed from NGS data [Montoya V, Infect Genet Evol 2016]. NGS was performed from plasma when available or from DBS when not; for 16 participants both plasma and DBS were sequenced.
Results: Excluding samples with viral loads <10, 000 UI/ml, 98.8% of 173 plasmas and 89.8% of 59 DBS were successfully characterized by NGS. The major circulating subtypes were 1a (39.3%) and 3a (33.3%), followed by 1b (16.4%) and 4d (6.8%). Two mixed infections were identified. The genetic variability estimates (Shannon entropy and single nucleotide variants) were not significantly different between plasma-DBS pairs. Based on Shannon entropy measures observed in acute and chronic infection controls, 34 (14.6%) cases were identified as acute, and 27 (79.4%) of them were identified as part of a transmission cluster.
Conclusion: DBS represent a valuable tool for facilitating HCV diagnosis, and also for characterising and monitoring HCV epidemics, since they can be successfully used to identify acute HCV infections and transmission clusters. HCV preventive strategies directly targeted to PWID populations currently experiencing ongoing HCV transmission could inform public health interventions.

THU-384

Clinical Performance of determine TM HBsAg 2 rapid test for hepatitis B detection

Ana Avellon Calvo[1], Aftab Ala[2], Antonio Diaz[3], Daniel Domingo[4], Rosario Gonzalez[3], Lorena Hidalgo[5], Paul Kooner[6], Sabarinathan Loganathan[7], Loli Martin[8], Stuart McPherson[9], Milagros Munoz-Chimeno[1], Stephen Ryder[10], Gabrielle Slapak[6], Pablo Ryan[11], Marta Valbuena[12], Patrick Kennedy[13]. *[1]National Center of Microbiology. Email: p.kennedy@qmul.ac.uk

Background and aims: Hepatitis B virus (HBV) infection is estimated to affect 292 million people worldwide. Approximately two thirds of chronically infected patients in the EU and 90% of patients worldwide are unaware of their hepatitis B status. There is a major need for a reliable near patient test to help enhance diagnostic rates globally. DetermineTM HBsAg 2 is a rapid test for the detection of HBsAg, since it is capable of detecting the 0.1 IU/ml WHO International Standard for HBsAg (NIBSC code 12/226), giving results in 15 minutes. The aim of this study is the evaluation of the clinical performance of DetermineTM HBsAg 2 rapid test for hepatitis B detection.
Method: We conducted a prospective, multi-centre study to establish the clinical performance of the DetermineTM HBsAg 2 rapid test in venous whole blood, plasma and serum as well as fingerstick whole blood. The DetermineTM HBsAg 2 test (Alere Medical Japan, Tokyo, Japan (now Abbott), Chiba, Japan) is an in-vitro, visually read, qualitative, immunochromatographic assay for the detection of HBsAg in 50 µL sample. The reference method for the study was the Abbott ARCHITECT® quantitative HBsAg assay. This study enrolled 351 evaluable subjects, 145 of these subjects were HBsAg-positive (age ranging 2-86 years) across 5 clinical sites in the UK and 1 clinical site in Spain.

Results: The sensitivity and specificity were 97.2% and 98.5% for fingerstick whole blood at 15 minutes when using the reference assay cut-off 0.05 IU/ml, and the sensitivity increased to 97.9% when using the pre-specified cut-off 0.13 IU/ml, which is required by the European regulations. At the 15-minute reading, the sensitivity was 97.2%, 97.9% and 98.6% and the specificity was 99%, 99.5% and 100% for venous whole blood, serum and plasma, respectively. An algorithm following up a positive fingerstick test result with a Determine™ HBsAg 2 plasma or serum test demonstrates 100% specificity.
Conclusion: The Determine™ HBsAg 2 test gives a result with high sensitivity and specificity at 15 minutes, making it an ideal tool for point-of-care testing in HBV screening programmes. The Determine™ HBsAg 2 test has the potential to enable large-scale population-wide screening, to reach the WHO target of 90% of HBV patients diagnosed by 2030.
Disclosures: Alere Medical Japan, (now Abbott), provided materials and expenses to perform the study.

THU-385
Targeted screening for hepatitis C and predictors of advanced liver disease in the birth cohort in a tertiary primary care clinic

Sophie Bersoux[1], Aqel Bashar[2], Lanyu Mi[3], Rolland Dickson[4]. *[1]Mayo Clinic, Division of Community Internal Medicine, Scottsdale, United States; [2]Mayo Clinic, Division of Gastroenterology and Hepatology, Scottsdale, United States; [3]Mayo Clinic, Department of Biomedical Statistics and Informatics and Division of Health Sciences Research, Scottsdale, United States; [4]Mayo Clinic, Division of Gastroenterology and Hepatology, Scottsdale, United States*
Email: bersoux.sophie@mayo.edu

Background and aims: : Hepatitis C virus (HCV) associated complications have been decreasing since the advent of highly effective antiviral medications and the recommendation of universal screening by the CDC (8/2012) and USPSTF (6/2013) for the 1945-1965 birth cohort (BC). NASH is now increasing in prevalence and as the etiology of complications of liver disease. The aim of our study is to determine the impact of HCV screening and risk factors for advanced fibrosis in the BC in a tertiary primary care practice.
Method: Data was extracted from the electronic medical record of all BC patients panelled to a primary care provider who underwent HCV screening between 9/8/2010 and 03/05/2018. If more than one HCV Ab screen was performed, only data associated with first testing was collected. Fib4 and APRI scores were calculated to screen for advanced fibrosis.
Results: 7097 BC pts were screened during the study period, 3462 (48.8%) male, 6435 (92.0%) white, 1028 (14.5%) had Diabetes, 2389 (34.1%) had BMI ≥30. From 2011 to 2017 there was a marked increase in the number of patients screened [188 (2.6% of screened) vs. 2009 (28.3%) of screened)]. 6876 (96.9%) were screened on or after 2012. Of the patients screened, 124 (1.7%) were HCV Ab+, of those 33 (26.6%) were HCV RNA +. ALT was available in 5578 patients. ALT was ≤ 30 U/L in 3544 (63.5%), between 30-60 U/L in 1499 (26.9%) and >60 U/L in 535 (9.6%). There was a correlation between ALT level and RNA + (TABLE). 3 out of the 4 patients with HCV RNA and ALT ≤ 30 had risk factors for HCV. Risk for intermediate or advanced fibrosis determined by APRI using multivariate analysis were HCV RNA + OR (95% CI) as 8.27 (3.30, 20.7) with p < 0.0001), Diabetes OR (95%CI) as 1.61 (1.29, 2.02) with p < 0.0001, ALT > 30 (OR (95%CI) as 13.0 (10.3, 16.4) with p < 0.0001) but not BMI ≥ 30 OR (95%CI) as 0.86 (0.71, 1.05) with p = 0.1342). BMI ≥ 30 was significant on univariate but not multivariate analysis. Fib4 score (not included) correlated with APRI (Pearson Correlation as 0.77, p < 0.0001).

HCV RNA detection/quant PCR	ALT (≤ 30, (30, 60], > 60)				
	ALT ≤ 30	30 < ALT ≤ 60	ALT > 60	Total	P Value
Positive	4 (0.11%)	13 (0.87%)	16 (2.99%)	33	< 0.0001
Negative	3540 (99.89%)	1486 (99.13%)	519 (97.01%)	5545	
Total	3544	1499	535	5578	

Figure: Association between HCV RNA and ALT.

Conclusion: The number of BC patients screened for HCV in primary care clinics increased following the CDC and USPSTF recommendations. EMR risk based assessment to determine screening for HCV in patients with an ALT ≤ 30 U/L could decrease the cost of HCV screening. Screening for advanced fibrosis in patients with DM or elevated ALT within the BC should be considered. Confirmation in other large primary care clinic data sets will be needed.

THU-386
Interim results of hepatitis prevention, control and elimination program in Ulaanbaatar, Mongolia

Purevjargal Bat-Ulzii[1], Oyungerel Lkhagva-Ochir[1], Delgerbat Boldbaatar[1], Zolzaya Davaadorj[1], Byambasuren Ochirsum[1], Khatantuul Boldbaatar[2], Uurtsaikh Baatarsuren[2], Altankhuu Murdorj[1], Dahgwahdorj Yagaanbuyant[1], Zulkhuu Genden[1], Naranbaatar Dashdorj[1,2], Naranjargal Dashdorj[1,2]. *[1]Liver Center, Ulaanbaatar, Mongolia; [2]Onom Foundation, Ulaanbaatar, Mongolia*
Email: b.purevjargal@onomfoundation.org

Background and aims: Mongolia has the world's highest rate of liver cancer mortality—nearly 12 times the global average. Prevalences of chronic hepatitis B, C, and D in Mongolia are at an endemic level and constitute the main cause for Mongolia's world-leading liver cancer mortality rate. Cirrhosis and liver cancer mortalities currently account for 15% of total annual mortalities in Mongolia. The Onom Foundation and partners initiated the Hepatitis Prevention, Control, and Elimination (HPCE) Program on September 8, 2014. The Parliament of Mongolia officially adopted the HPCE Program into the 2016-2020 Action Plan of the Government of Mongolia (GoM) on September 9, 2016. HPCE Program of Mongolia aims to eliminate HCV in Mongolia by 2020 and to significantly reduce hepatitis-induced liver cirrhosis and HCC mortalities. Within the program, free general population hepatitis screening, two free-of-charge HCV viral load testing and no-out-of-pocket-cost HCV treatment campaigns have been initiated nationwide. This study aimed to evaluate the progress of the program by comparing the HCV prevalence of 2013 and 2018 among the apparently healthy population of Ulaanbaatar, Mongolia.
Method: A cross-sectional study design was used to randomly select 552 participants aged 20 years and older from Ulaanbaatar city population of Mongolia. Anti-HCV screening was performed by rapid test (OraQuick, USA). Anti-HCV positive samples were further tested for HCV-RNA using RT-PCR (Cepheid GeneXpert, USA).
Results: In this study, total of 552 subjects were enrolled including 296 (53.6%) men and 256 (46.4%) female. HCV prevalence and detectable HCV-RNA percentage are shown in Table 1. In addition, results of 2013 Ulaanbaatar population HCV prevalence study are shown (Dashtseren et al). The overall prevalence of anti-HCV was 7.4% in 2018, while it was 9.9% in 2013. Furthermore, percentage of detectable HCV-RNA was 46.3% (19) in 2018 and it was almost 2 times higher (87.7%) in 2013 before started using DAA treatment in Mongolia. A number of treated people in 2018 were 10 (24.4%).

Table 1: Comparison of HCV prevalence and detectable HCV-RNA in 2013 and 2018

Years	2013	2018
Total number of samples	573	552
Anti-HCV prevalence % (n)	9.9 (57)	7.4 (41)
Percentage of detectable HCV-RNA (n)	87.7 (50)	46.3 (19)
Percentage of spontaneously cleared HCV-RNA	12.2 (7)	24.4 (10)
Percentage of treated people with DAA	0	24.4 (10)

Conclusion: This study clearly shows successful implementation of HPCE Program. It also shows that in order to reach the target to eliminate HCV by 2020 Mongolia has to accelerate the implementation progress.

THU-387

Eliminating viral hepatitis C in Belgium: A mathematical model of the micro-elimination approach

Dana Busschots[1,2], Samira Toghanian[3], Rob Bielen[1,2], Stina Salomonsson[3], Özgür Koc[1,2,4], Greet Hendrickx[5], Michel Jadoul[6], Frederik Nevens[7], Etienne Sokal[8], Christian Brixko[9], Kathelijne Peerlinck[10], Ludwig Apers[11], Geert Robaeys[1,2,7], Jeffrey Lazarus[12]. *[1]Faculty of Medicine and Life Sciences, Hasselt University, Hasselt, Belgium; [2]Department of Gastroenterology and Hepatology, Ziekenhuis Oost Limburg, Genk, Belgium; [3]MSD, Center of Observational Real-World Evidence (CORE), Stockholm, Sweden; [4]Medical Microbiology, School of NUTRIM, Maastricht University Medical Centre, Maastricht, Netherlands; [5]Viral Hepatitis Prevention Board, Centre for the Evaluation of Vaccination, Vaccine and Infectious Diseases Institute, University of Antwerp, Antwerp, Belgium; [6]Service de Néphrologie, Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium; [7]Department of Gastroenterology and Hepatology, University Hospitals KU, Leuven, Belgium; [8]Service Gastroentérologie Hépatologie Pédiatrique, Cliniques Universitaires St. Luc, Université Catholique de Louvain, Brusssels, Belgium; [9]Department of Gastroenterology and Digestive Oncology, CHR Citadelle, Liège, Belgium; [10]Division of Cardiovascular Disorders, Haemophilia Center, UZLeuven, Leuven, Belgium; [11]Department of Clinical Sciences, Institute of Tropical Medicine Antwerp, Antwerp, Belgium; [12]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain*
Email: Jeffrey.Lazarus@isglobal.org

Background and aims: The hepatitis C virus is one of the leading causes of chronic liver disease and liver-related deaths worldwide, prompting the World Health Organization to define targets for eliminating it by 2030. Belgium has had a 'Hepatitis C Plan' since 2014, yet elimination efforts remain unclear. The estimated prevalence is low in the general population (0.57%), though higher in several subgroups. This study sets out to employ the best available data to construct a micro-elimination model to guide national efforts.
Method: A constrained optimization modelling approach was applied for developing the "HepC Countdown" model in Excel with the objective to demonstrate how many patients need to be treated to reach elimination of hepatitis C by 2030, based on reported or estimated prevalence, incidence and reinfection rates (just for PWID) and current versus alternative treatment rates. Six subgroups with increased risk of hepatitis C were studied: people living with HIV, haemodialysis patients, migrants, patients with advanced liver disease, people who inject drugs and prisoners.
Results: According to the model, none of the subgroups would achieve hepatitis C elimination by 2030 at current treatment rates (Table 1). With the current rate of 3%, hepatitis C elimination would be reached by 2057 at the earliest in all subgroups with the exception of PWID (2314). For Belgium to meet the WHO targets, the average percentage of patients to treat per year out of the total pool of patients to be treated needs to be fixed at 8% of the current patient pool.

Table 1.: Mathematical modelling results based on current Belgian hepatitis C situation

	CURRENT SITUATION					
	Patients to treat at 80% of the reported/ estimated patient pool in 2030	Patients treated by 2030	Patients left untreated by 2030	Patients not treated (%)	Average number of patients treated per year (2018-2030)	Year of elimination
PEOPLE LIVING WITH HIV*	282	92	190	67%	7.0	2057
HAEMODIALYSIS PATIENTS*	238	78	160	67%	6.0	2056
MIGRANTS**	14, 969	4, 882	10, 087	67%	375	2056
PATIENTS WITH ADVANCED LIVER DISEASE**	17, 500	5, 722	11, 778	67%	440	2057
PEOPLE WHO INJECT DRUGS**	3656	996	2, 660	73%	77	2314
PRISONERS**	1, 422	465	957	67%	36	2056

*Reported.
**Estimated.

Conclusion: In order to reach the WHO elimination targets much greater efforts are required in Belgium, including removing hepatitis C treatment reimbursement restrictions. Improving surveillance and prevention would further facilitate efforts.

THU-388

Annual healthcare costs double for non-alcoholic fatty liver disease/non-alcoholic steatohepatitis patients who progress to advanced liver disease: A multivariable analysis of German real-world data

Ali Canbay[1], Nandita Kachru[2], Dominic Meise[3], Jennifer Scarlet Haas[3], Ahmet Burak Ozbay[2]. *[1]Department of Gastroenterology, Hepatology and Infectiology, University of Magdeburg Medical School, Magdeburg, Germany; [2]Gilead Sciences, Health Economics Outcomes Research, Foster City, United States; [3]Xcenda GmbH, Hannover, Germany*
Email: Nandita.Kachru@gilead.com

Background and aims: Healthcare resource utilization (HCRU) and costs significantly increase among NAFLD/NASH patients who progress to compensated cirrhosis (CC). This study evaluated comorbidities, HCRU and associated costs among NAFLD/NASH patients who progress to advanced liver disease (including CC, decompensated cirrhosis [DCC], liver transplantation [LT], hepatocellular carcinoma [HCC]) in Germany.
Method: Adult patients with NAFLD/NASH (ICD-10-GM) were identified retrospectively from 2011-2016 in the InGef database containing claims data of >4 million individuals. Patients with other causes of liver diseases were excluded. Following the prevalent NAFLD/NASH diagnosis, patients were identified with liver severity stages (NAFLD/NASH non-progressors (NN/NP), CC, DCC, LT, HCC) using their first diagnosis date (index date). Per patient per quarter values were annualized. A generalized estimating equation model was used to derive adjusted costs. Patients were censored at disease progression, end of continuous enrolment, death, or end of follow-up.
Results: Of 4, 580, 434 individuals in the database, the study identified 215, 655 (5%) prevalent NAFLD/NASH patients. During the follow-up, 100, 644 incident events of different liver severity stages were reported (NN/NP [79, 245 (78.7%)], CC [411 (0.4%)], DCC [20, 614 (20.5%)], LT [11 (0.01%)] and HCC [363 (0.4%)]). Comorbid burden was high, with 33-67% patients across liver severity stages having ≥3 conditions of hypertension, hyperlipidemia, type-2 diabetes, renal disease and cardiovascular disease. Mean annual hospitalizations were significantly higher for NAFLD/NASH patients with advanced liver disease [CC (2.51), DCC (3.49), LT (2.38), HCC (4.95)] than NN/NP (1.75) ($p < 0.05$ except for LT). Additionally, mean annual costs among

NAFLD/NASH patients with advanced liver disease were significantly higher than NN/NP [€10, 291 (CC), €22, 561 (DCC), €34, 089 (LT), €35, 910 (HCC) vs. €3, 818 (NN/NP)] ($p < 0.05$ except for LT); inpatient costs were the primary driver. Multivariable analyses adjusted for demographics and comorbidities confirmed this trend.

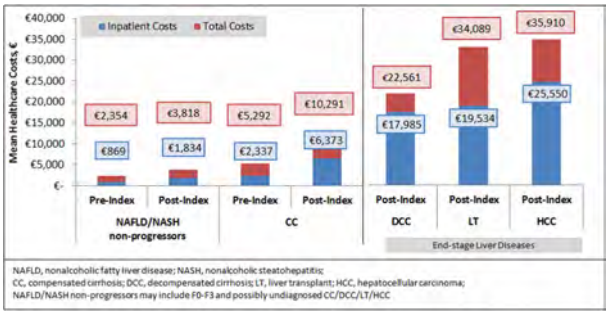

Figure: Annual Mean Healthcare costs for NAFLD/NASH patients with Advanced Liver Disease

Conclusion: Underdiagnosis of CC was apparent among NAFLD/NASH patients. Those who progress to advanced liver disease have high comorbidity burden with costs increasing by over 800% when compared to NN/NP. Early identification and effective treatment options to halt or reverse fibrosis are needed to prevent disease progression and the associated long-term costs.

THU-389

Assessment of hepatitis C screening strategies in different community settings in a Canadian metropolitan area

Camelia Capraru[1,2], Bettina Hansen[1,3,4], Aaron Vanderhoff[1,2], Steven Friedman[5], Kathy Bates[5], Tony Mazzulli[6,7,8], Danielle Porplycia[5], Bentley McCormack[1,2], Joshua Juan[1,9], Hsiao-Ming Jung[9], Hemant A Shah[1,2], Jordan Feld[1,2,10], Harry Janssen[1,2]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]VIRCAN Care and Research, Toronto, Canada; [3]Erasmus University Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands; [4]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; [5]University Health Network, Department of Emergency Medicine, Toronto, Canada; [6]Mount Sinai Hospital, Pathology and Lab Medicine, Toronto, Canada; [7]University of Toronto, Department of Laboratory Medicine and Pathology, Toronto, Canada; [8]Public Health Ontario, Toronto, Canada; [9]Albany Medical Clinic, Toronto, Canada; [10]University of Toronto, Sandra Rotman Centre for Global Health, Toronto, Canada*
Email: camelia.capraru@uhnresearch.ca

Background and aims: It is estimated that over 45% of individuals with chronic hepatitis C virus (HCV) infection in Canada remain undiagnosed. Understanding current rates of HCV diagnosis and linkage to care in different community settings is critical information for developing future screening strategies.
To evaluate HCV screening strategies in three different community settings: emergency department (ED), medical walk-in clinic (MC) and community outreach (CO).
Methods: We implemented birth cohort (1945-1975) HCV testing in the ED and MC, and universal testing during CO. Blood samples in the ED were collected by finger prick on Dried Blood Spot (DBS) collection cards and tested for anti-HCV with reflex to HCV RNA. In the MC and CO, we used anti-HCV point-of-care testing followed by HCV RNA on DBS card. Patients with positive HCV RNA were linked to care.
Results: 5, 144 individuals were tested during 1.5 years; 142 (2.8%) were HCV reactive (Table). Seropositivity varied among all three groups: 1.8% (95%CI 1.2%-2.4%) in the ED, 0.4% (95%CI 0.1%-0.7%) in the MC and 5.3% (95%CI 4.3%-6.3%) in the CO. Of Ab positives, 117 (82.4%) underwent HCV RNA testing. 61 (82.4%) out of 74 HCV RNA positives were linked to care. Compared to the general population the HCV prevalence was significantly higher in the CO (5.3% vs. 0.7%; $p < 0.0001$), and in the ED (1.8% vs. 0.7%; $p < 0.0001$). The MC group exhibited similar seropositivity as the general population (0.4% vs. 0.7%; $p = 0.12$).

Characteristics	HCV Ab tests				p value
	Total N = 5114	ED N = 1639 (32.0%)	MC N = 1452 (28.4%)	CO N = 2023 (39.6%)	
Age (median, range)	56 (15-97)	58 (35-74)	51 (15-97)	54 (16-97)	<0.0001
Male n (%)	2354 (46.0)	850 (51.9)	591 (40.7)	913 (45.2)	<0.0001
HCV Ab Positives n (%)	142 (2.8)	29 (1.8)	6 (0.4)	107 (5.3)	<0.0001
HCV RNA Tests n/HCV Ab positives (%)	117/142 (82.4)	26/29 (89.7)	5/6 (83.3)	86/107 (80.4)	0.531
HCV RNA Positives n/HCV RNA tests (%)	74/117 (63.2)	18/26 (69.2)	4/5 (80.0)	52/86 (60.5)	0.443
Linkage to Care n/HCV RNA positives (%)	61/74 (82.4)	14/18 (77.8)	3/4 (75.0)	44/52 (84.6)	0.474

Conclusions: The HCV prevalence in the CO and ED was significantly higher than the general Canadian population. Using DBS for HCV testing ensured high HCV RNA test uptake. Screening efforts in populations with higher prevalence, such as the ED and outreach programs, were higher yield and still resulted in good linkage to care.

THU-390

Results of a birth cohort hepatitis C screening program in an academic emergency department in Canada

Camelia Capraru[1,2], Steven M. Friedman[3], Kathy Bates[3], Tony Mazzulli[4,5,6], Danielle Porplycia[3], Bentley McCormack[1,2], Aaron Vanderhoff[1,2], Hemant A Shah[1,2], Harry Janssen[1,2], Jordan Feld[1,2]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]VIRCAN Care and Research, Toronto, Canada; [3]University Health Network, Department of Emergency Medicine, Toronto, Canada; [4]Mount Sinai Hospital, Pathology and Lab Medicine, Toronto, Canada; [5]University of Toronto, Department of Laboratory Medicine and Pathology, Toronto, Canada; [6]Public Health Ontario, Toronto, Canada*
Email: camelia.capraru@uhnresearch.ca

Background and aims: Epidemiologic and modeling studies suggest that between 45 and 70% of individuals with chronic hepatitis C virus (HCV) infection in Canada remain undiagnosed. The Canadian Association for the Study of the Liver (CASL) recommends one-time screening of baby boomers (1945-1975), based on data showing HCV prevalence is highest in this cohort and screening is cost-effective. Screening programs in the US have shown a very high prevalence of previously undiagnosed HCV among patients seen in the Emergency department (ED). The utility of ED screening has not been evaluated in Canada.
To assess the feasibility of implementing a targeted birth-cohort HCV screening program in the ED setting.
Method: Patients born from 1945 to 1975 presenting to the ED of a tertiary care hospital were offered HCV testing. Patients with life-threatening conditions and unable to provide verbal consent in English were excluded. Blood samples were collected by finger prick on Dried Blood Spot (DBS) collection cards and tested for anti-HCV with reflex to HCV RNA. Patients with positive HCV RNA were referred to a liver specialist.
Results: During a 14-month period, 6, 613 patients in the birth cohort presented to the ED during daytime hours. 77% (5, 117) met the eligibility criteria, 52% (2, 817) were offered testing: 269 (11%) were previously tested, 487 (20%) declined. 1639 (66%) individuals

underwent testing: median age 58.2 (35-74), 850 male (51.9%). Of these, 29 patients (1.8%; 95%CI 1.2%-2.4%) were anti-HCV positive: 18 (69.2%) were HCV RNA positive, 7 (26.9%) negative and 3 not done due to inadequate DBS sample. Screening was successfully done by non-medical staff (mean 8/day, median spots on DBS 3). 14 patients (78%) were linked to care and 4 lost to follow-up. The HCV prevalence in the ED was significantly higher than the general Canadian population (1.8% vs 0.7%; $p < 0.0001$) but much lower than reported rates in American EDs (1.8% vs 10.3%; $p < 0.0001$).

Conclusion: Acceptance of HCV screening in the ED birth cohort was high and easily performed using DBS to ensure the majority of positive samples were tested for HCV RNA. Challenges with implementation limited the number of people tested. HCV prevalence among this ED birth cohort was higher than the general population but lower than seen in the ED in the US. This may in part be due to exclusion of individuals with more severe medical issues or possibly due to population and healthcare system differences between countries.

Impact of early screening and treatment of hepatitis C virus and improvements in risk reduction on HCV transmission among HIV-infected men who have sex with men in France: A modeling approach

Mathieu Castry[1], Anthony Cousien[2,3,4], Virginie Supervie[5], Annie Velter[6], Jade Ghosn[1,7], A. David Paltiel[8], Yazdan Yazdanpanah[1,7], Sylvie Deuffic-Burban[1,9]. *[1]IAME, UMR 1137, INSERM, Paris, France; [2]Mathematical Modelling of Infectious Diseases Unit, Institut Pasteur, Paris, France; [3]CNRS UMR2000 : Génomique Evolutive, Modélisation et Santé Institut Pasteur, Paris, France; [4]Center of Bioinformatics, Biostatistics and Integrative Biology, Institut Pasteur, Paris, France; [5]INSERM, Sorbonne Université Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France; [6]Santé Publique France, Saint-Maurice, France; [7]Bichat Claude Bernard Hospital, Department of Infectious Diseases, APHP, Paris, France; [8]Yale School of Public Health, New Haven, United States; [9]Univ. Lille, Inserm, CHU Lille, U995-LIRIC, Lille, France*
Email: mathieu.castry@inserm.fr

Background and aims: Hepatitis C virus (HCV) incidence has increased recently among HIV-positive men who have sex with men (MSM) in France. This epidemic is associated with high-risk sexual behaviours, notably chemsex (the use of psychoactive substances during sexual encounters). We assessed the impact of alternative strategies to prevent HCV transmission-including screening, immediate treatment with direct acting antivirals (DAAs) and risk reduction-among HIV-positive MSM in France.

Method: We developed a deterministic dynamic compartmental model to simulate HCV transmission among HIV+ MSM, accounting for HIV and HCV care cascade, natural history and low- and high-risk groups (no versus chemsex practices). The model was calibrated to an initial HCV incidence of 0.92 per 100 person-years (PY) among French HIV+ MSM in 2016 (Dat'AIDS cohort). We assessed the impact of 8 strategies on HCV incidence and prevalence over a 10-year period starting in 2019, including: current practices (S0), current recommendations (S1), more frequent HCV screening with treatment at diagnosis (S2-S3), reduction in high-risk sexual behaviours (S4), and combined strategies (S5-S7; see Table).

Results: Current practices (S0) produced HCV prevalence of 0.94% and incidence of 0.298/100 PY in 2029. Strategies aimed solely at expanding screening and treatment (S1-S3) all yielded ~30% reductions in both HCV prevalence and incidence. Greater reductions in both prevalence/incidence (~40% and ~54%, respectively) were obtained via risk reduction (S4). Strategies combining screening, treatment, and risk reduction (S5-S7) produced the greatest possible reductions in both prevalence (53%) and incidence (65%).

Strategies	Prevalence (%) in 2029	Incidence/100 PY in 2029
S0 (Baseline) Current practices of HCV screening (annual) and treatment initiation (3 months after diagnosis)	0.94	0.298
S1 HCV screening every 6 months and immediate treatment initiation at diagnosis (current recommendations)	0.68	0.216
S2 HCV screening every 3 months for high-risk group* and immediate treatment initiation at diagnosis Keeping S1 for low-risk group	0.64	0.202
S3 S2 for all HIV+ MSM	0.62	0.196
S4 50% decrease of high-risk behaviours by 2022 S0+S4	0.57	0.136
S5 S1+S4	0.45	0.108
S6 S2+S4	0.44	0.104
S7 S3+S4	0.42	0.101

*High-risk group corresponds to individuals with "chemsex" practices

Conclusion: Implementing the current HCV screening and treatment recommendations among HIV+ MSM in France would have a marked impact on HCV transmission. Combining these recommendations with interventions to decrease high-risk sexual behaviours would make it possible to reach very low levels of HCV prevalence and incidence. These findings underscore the relevance of combining both approaches to eliminate HCV in this population.

THU-392

Building capacity within a hepatitis C treatment model. the validation process for a hepatitis C pre-treatment pharmacist assessment complex intervention toolkit

Miriam Coghlan[1,2], Aisling O'Leary[3], Gail Melanophy[1], Colm Bergin[2,4], Suzanne Norris[2,5]. *[1]St. James's Hospital, Pharmacy Department, Dublin, Ireland; [2]Trinity College, School of Medicine, Dublin, Ireland; [3]National Centre for Pharmacoeconomics, Dublin, Ireland; [4]St. James's Hospital, Department of GU Medicine and Infectious Diseases, Dublin, Ireland; [5]St. James's Hospital, Department of Hepatology, Dublin, Ireland*
Email: coghlam@tcd.ie

Background and aims: Knowledge relating to use of direct-acting antivirals is confined to specialist centres in Ireland. The pre-treatment pharmacist assessment is a novel complex intervention toolkit which has been designed and optimised with the aim of supporting devolvement of Hepatitis C treatment to primary care providers including pharmacists, nurses and clinicians. It combines all aspects of pre-treatment assessment (E.g. fibrosis staging, drug-drug interactions) into a user-friendly proforma to ensure optimum Hepatitis C treatment selection. Feasibility and acceptability of the toolkit has been assessed using survey methodology. Healthcare interventions which facilitate devolved Hepatitis C care must ensure that optimum clinical outcomes are maintained for patients and that evidence of their effectiveness is determined through robust research studies. This study describes the validation process for this toolkit for pharmacist use.

Method: Pharmacists were invited to participate in this matched cohort study to review Hepatitis C case vignettes using the toolkit or standard of care. Participants were divided into two groups using a concealed randomisation method. A random sample of anonymised test cases were selected from the Irish Hepatitis C treatment registry using selected co-variates (E.g. fibrosis stage). A sample size of 58 cases per group was calculated with 7 participants per group to complete 8 cases each. Group A utilised the toolkit and group B

completed the cases as per standard of care. The primary end point was selection of an optimum treatment regimen as per national guidelines. Secondary end points included time to completion, detection of drug-drug interactions and identification of patient interventions. T-test analysis was completed to assess variation in results between groups.

Results: A total of 56 cases were completed per group. Use of the toolkit was associated with selection of an optimum treatment regimen in 92.9% of cases as compared with 60.7% of cases in group B ($p < 0.05$). Drug-drug interaction detection rates were significantly higher with toolkit use (75% vs 47%;$p < 0.05$). Participants utilising the toolkit suggested an average of 3.4 interventions per case versus 2 per case in Group B. The toolkit was associated with a longer median time to completion (20 versus 15 minutes), however this was not found to be statistically significant (p:0.060).

Conclusion: Study findings confirm the effectiveness of the toolkit in aiding pharmacists in selecting the optimum Hepatitis C treatment regimen. The potential for pharmacists working in all practice environments in Ireland, including community, to make a robust contribution to treatment of Hepatitis C, is something that can be supported using this toolkit. This type of capacity building within our limited healthcare resources is key to upscaling the model of care in Ireland to achieve elimination targets.

THU-393

HCV infection in Canadian immigrants: Characteristics and treatment outcomes of the CANUHC cohort

Curtis Cooper[1,2], Marie-Louise Vachon[3], Brian Conway[4], Alexander Wong[5], Alnoor Ramji[6], Sergio Borgia[7], Edward Tam[8], Lisa Barrett[9], Daniel Smyth[9], Heidy Morales[10], Chrissi Galanakis[2], Jordan Feld[10], Samuel Lee[11]. *[1]The Ottawa Hospital-University of Ottawa, Ottawa, Canada; [2]Ottawa Hospital Research Institute, Ottawa, Canada; [3]Université Laval, Département de microbiologie-infectiologie et d'immunologie, Québec, Canada; [4]Vancouver Infectious Disease Centre, Vancouver, Canada; [5]University of Saskatchewan, Saskatoon, Canada; [6]University of British Columbia, Ottawa, Canada; [7]William Osler Health System, Toronto, Canada; [8]Liver Health Centre, Vancouver, Canada; [9]Dalhousie University, Halifax, Canada; [10]Toronto General Hospital Research Institute, Toronto, Canada; [11]University of Calgary, Calgary, Canada*
Email: ccooper@toh.ca

Background and aims: HCV-infected patients from endemic regions of the world immigrate to Canada and are subsequently referred to viral hepatitis clinics for management. Cultural differences and language barriers are potential obstacles to receiving HCV treatment. We set out to describe the diversity of the Canadian HCV-infected immigrant population and assess HCV DAA therapy outcomes.

Method: The Canadian Network Undertaking against Hepatitis C (CANUHC) Cohort contains prospectively collected demographic information and HCV DAA treatment information collected at 10 Canadian sites. Information on immigration history, country of origin and race is collected. Characteristics and outcomes (SVR) were compared by immigration status and race using Chi square, Student's t test and median test at significance levels of $p < 0.05$.

Results: Between January 2016 and May 2018, 725 HCV-infected patients initiating DAA therapy were enrolled in CANUHC (overall mean age: 53 (SD 12.7); 66% male; 78% white, 3% black, 4% South East Asian, 4% East Indian, 5% Indigenous). 19% were born outside of Canada (17% South East Asia and Indian Subcontinent, 7% Sub-Saharan Africa). Mean age was similar [54 (SD 13.9) years in immigrants versus 52 (SD 12.4) years in Canadian-born, $p = 0.09$]. A greater proportion of DAA treated immigrants were female. HIV co-infection was less common in immigrants (1% vs 6%, $p = 0.04$). The genotype distribution mirrored the country of origin/regional genotype distribution prevalence. The overall median baseline fibrosis stage (F2) was similar among Canadian and foreign-born patients. Fibrosis stage remained similar by groups when stratified by sex (male, $p = 0.68$; female, $p = 0.53$). SVR rates of 91% and 93% were similar in immigrants and Canadian-born patients respectively ($p = 0.80$) and did not differ by race ($p = 0.67$).

Variable	Immigrant to Canada (n = 134) n (%)	Canadian-Born (n = 591) n (%)	P Value
Male Sex	70 (52)	406 (69)	< 0.001
Race			
White	53 (40)	460 (88)	< 0.001
Black	10 (8)	11 (2)	
South East Asian	24 (18)	5 (1)	
East Indian	26 (20)	3 (1)	
Indigenous	1 (1)	32 (6)	
Other	18 (14)	11 (2)	
Genotype			
1a	24 (19)	311 (55)	< 0.001
1b	38 (30)	53 (9)	
1 (ab or unknown)	4 (3)	9 (2)	
2	13 (10)	59 (10)	
3	32 (25)	134 (24)	
4	13 (10)	2 (< 1)	
6	5 (4)	2 (< 1)	
Mixed	---	1 (< 1)	
Fibrosis Stage			
F1	49 (41)	209 (40)	0.59
F2	20 (17)	117 (22)	
F3	18 (15)	71 (14)	
F4	32 (27)	126 (24)	
Treatment Naive	40/69 (58)	244/345 (71)	0.04
Achieved SVR	32/35 (91)	140/151 (93)	0.80

Conclusion: Despite a diverse immigrant population in Canada access to and success with DAA therapy appear to be equitable.

THU-394

Cancer risk among people with HIV, HBV, and/or HCV infections

Maryam Darvishian[1,2], Carmine Rossi[1,2], Stanley Wong[2], Amanda Yu[2], Ryan Woods[1,3], Mawuena Binka[1,2], Zahid A Butt[1,2], Jane Buxton[1,2], Sofia Bartlett[1,2], Dr. Margo Pearce[1,2], Dr. Jason Wong[1,2], Dr. Mark Gilbert[1,2], Troy Grennan[1,2], Maria Alvarez[2], Darrel Cook[2], Eric Yoshida[1], John Spinelli[1,3], Mark Tyndall[1,2], Mel Krajden[1,2], Naveed Janjua[1,2]. *[1]University of British Columbia, Vancouver, Canada; [2]BC Centre for Disease Control, Vancouver, Canada; [3]Population Oncology, BC Cancer, Vancouver, Canada*
Email: maryam.darvishian@bccdc.ca

Background and aims: HIV, hepatitis B virus (HBV) and hepatitis C virus (HCV) infections each are associated with increased cancer risk. However, data on viral co-infection's synergistic effects on cancer incidence are limited. In this study we assessed the effect of co-occurrence of HIV, HBV and HCV on all cancers, anal cancer, non-Hodgkin Lymphoma (NHL) and liver cancer.

Method: The British Columbia Hepatitis Testers Cohort includes all individuals (~1.7 million) tested for HCV or HIV, or diagnosed with HCV, HIV, or HBV linked with data on medical visits, hospitalizations, cancers, prescription drugs and vital statistics. We included individuals tested for all three infections since 1990 and followed them from the date of their last test until the first cancer diagnosis, death, or 12/31/2015. Diagnostic codes from the population-based BC Cancer Registry were used to ascertain cancer occurrence. We utilized the Fine and Gray competing risks regression model to estimate adjusted sub-distributional hazard ratios (aHRs) for all cancers, anal cancer, NHL, and liver cancer, with death as a competing risk.

Results: Among 514, 501 individuals tested for all infections, 12, 586 (2.45%) had any cancer, 100 (0.02%) had anal cancer, 552 (0.11%) had NHL and 1, 081 (0.21%) had liver cancer during a median follow-up of 4.19 years (interquartile range: 2.11, 8.47). Compared to individuals with no infection, aHR for all cancers was highest for HIV/HBV co-infections (aHR 2.55, 95% CI: 1.91–3.42), followed by triple infections (aHR 2.29, 95% CI: 1.80-2.89) (Figure). The risk of anal cancer was

higher among individuals with HIV (e.g. triple infection aHR 22.61, 95% CI: 7.27-70.33), while risk of liver cancer was higher among those with HBV or HCV mono or co-infections and triple infections (aHR 41.40, 95% CI: 21.95-78.05). The risk of NHL was the highest among HIV/HBV co-infections followed by triple infection and hazard remained elevated in all infection groups (Figure).

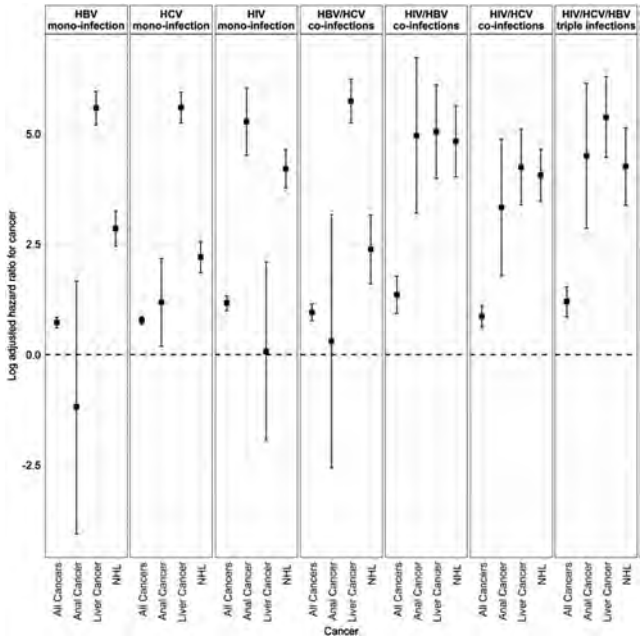

Figure: Log of adjusted hazard ratios for association of infections with cancers.

Conclusion: HIV, HBV and HCV infections are associated with an overall higher risk of cancer. The highest risks for anal cancer and NHL were among those living with HIV infection and the highest risk for liver cancer was among HBV/HCV co-infected individuals. The observed association between HCV and anal cancer, which may be due to the presence of human papillomavirus and/or residual confounding, requires further investigation.

THU-395

Hepatitis C elimination by enhancing care and treatment among HIV co-infected individuals (the co-EC study): Real world evidence of decreasing HCV incidence and prevalence

Joseph Doyle[1,2,3], Daniela van Santen[2], David Iser[3,4], Joe Sasadeusz[3,5], Mark O'reilly[6], Brendan Harney[2], Janine Roney[3], Julia Cutts[2], Anna Bowring[2], Rebecca Winter[2], Nick Medland[7], Christopher Fairley[7], Richard Moore[8], Tee Bk[9], Jennifer Hoy[3], Edward Gane[10], Gail Matthews[11], Maria Prins[12], Mark Stoove[2], Margaret Hellard[2,3]. *[1]Monash University, Infectious Diseases, Melbourne, Australia; [2]Burnet Institute, Melbourne, Australia; [3]Alfred Health, Infectious Diseases, Melbourne, Australia; [4]St. Vincent's Hospital Melbourne, Gastroenterology, Melbourne, Australia; [5]Royal Melbourne Hospital, Melbourne, Australia; [6]Prahran Market Clinic, Melbourne, Australia; [7]Melbourne Sexual Health Centre, Melbourne, Australia; [8]Northside Clinic, Melbourne, Australia; [9]Centre Clinic, Melbourne, Australia; [10]The University of Auckland, Auckland, New Zealand; [11]The Kirby Institute, Kensington, Australia; [12]Public health service of Amsterdam, Department of Infectious Disease Research and Prevention, Amsterdam, Netherlands*
Email: joseph.doyle@monash.edu

Background and aims: Gay and bisexual men are the key population affected by HIV and hepatitis C (HCV) coinfection in Australia. The co-EC Study supports general practitioners to initiate treatment in primary care settings, aiming to provide proof-of-concept that treatment scale-up could eliminate HIV/HCV coinfection among gay and bisexual. This analysis describes the co-EC cohort and reports on HCV treatment outcomes in primary and tertiary care sites, and the population impact (incidence and prevalence) of HCV over time.
Method: A nurse-led, clinician-directed trial of HCV directly acting antiviral treatment among people with HCV/HIV co-infection was performed in Melbourne, Australia. At six key primary and tertiary care sites for HIV clinical care, providing care for 75% of people with HIV in our jurisdiction, all HCV/HIV coinfected people meeting standard prescribing guidelines were eligible for treatment. Primary HCV incidence and prevalence among the primary care population was measured using a state-wide surveillance system that electronically collects HCV and HIV testing data from 2012 to present. Poisson regression was used to determine change in incidence.
Results: 200 participants were recruited, 55% reporting recent injecting drug use and 76% condomless sex, of whom 177 initiated treatment in the study period 2016-2018. SVR12+ (SVR at or after 12 weeks post treatment) per protocol among people treated using any regimen in primary care was 97.1% (95% CI: 91.4-99.1%), which was not significantly different to tertiary care, SVR12 100% (95% CI: 92.1-100%). Twenty-six percent (46/177) required specialist referral for HCV prescribing, primarily for advanced liver disease or other non-HIV co-morbidities.
Over 9100 HCV tests were performed in primary care among gay and bisexual men living with HIV in Victoria since 2012; between 50 and 60% were tested annually. At the population level, HCV RNA prevalence among people with detectable HIV and HCV antibodies was 57% in 2016, which declined to 8% (an 86% reduction) in 2018 ($p < 0.01$). HCV incidence significantly decreased by a factor of 0.79 (95%CI = 0.69-0.92, p = 0.002) (a 21% reduction) each year.
Conclusion: HCV treatment in primary and tertiary care was highly effective in this real-world cohort of HIV/HCV coinfected men, many who have high-risk sexual and drug-use behaviour. This study provides proof of concept that expanding HCV treatment access is feasible and can lead to rapid HCV elimination among gay and bisexual men.

Hepatitis C screening among the population of Georgia within the national elimination program

David Sergeenko[1], Maia Lagvilava[2], Ana Aslanikashvili[3], Maia Tsereteli[3], Davit Baliashvili[4], Vladimer Getia[5], Alexander Turdziladze[6], Irma Khonelidze[6], Maia Alkhazashvili[7], Ekaterine Adamia[8], Paata Imnadze[6], Amiran GAMKRELIDZE[9]. *[1]Ministry of Internally Displaced Persons from the Occupied Territories, Labour, Health and Social Affairs of Georgia, Minister, Tbilisi, Georgia; [2]Ministry of Internally Displaced Persons from the Occupied Territories, Labour, Health and Social Affairs of Georgia, Deputy Minister, Tbilisi, Georgia; [3]National Center for Disease Control and Public Health Georgia, Department of Communicable Diseases, Tbilisi, Georgia; [4]Emory University, Rollins School of Public Health, Department of Epidemiology, Atlanta, United States; [5]National Center for Disease Control and Public Health Georgia, Department of State Programs, Tbilisi, Georgia; [6]National Center for Disease Control and Public Health Georgia, Deputy Director, Tbilisi, Georgia; [7]National Center for Disease Control and Public Health Georgia, Richard Lugar Center for Public Health Research, Tbilisi, Georgia; [8]National Center for Disease Control and Public Health Georgia, Department of Healthcare, Tbilisi, Georgia; [9]National Center for Disease Control and Public Health Georgia, Director General, Tbilisi, Georgia*
Email: a.aslanikashvili@ncdc.ge

Background and aims: Georgia is high hepatitis C (HCV) prevalence country. According to the latest nationwide seroprevalence study conducted in 2015, 7.7% of the population is anti-HCV antibody

positive and 5.4% has chronic hepatitis C infection. Since the launch of the National HCV Elimination Program in 2015, the country of Georgia has stepped up its efforts to achieve the goals of the National HCV Strategy and identify 90% of the HCV infected population by 2020. Therefore, screening campaigns became massive and rigorous in the country, with the active involvement from public and private organizations. Over 800 sites provide HCV screening across the country free-of-charge, following the National HCV Screening Protocol approved by the Ministry of Health. Full coverage is achieved among blood donors, pregnant women, hospitalized patients and military recruits.

Method: This analysis was prepared based on the data from the unified electronic HCV screening database, which is being used by all screening provider sites. The database is administered by the National Center for Disease Control and Public Health and it captures information of each HCV screening performed in the country. We looked at the numbers of screened individuals by different populations, as well as positivity rates among them.

Results: Since the launch of the Elimination Program in April 2015 through April 2018, more than 1.2 million individuals have been screened on HCV, with the overall positivity rate-9%. Positivity rates vary through the population groups, with the lowest rate among pregnant women (0.5%) to the highest prevalence in state opioid-substitution therapy beneficiaries (91.3%) (See the figure). Infection is also highly prevalent in people with hemophilia (62.5%) and people living with HIV (39.7%).

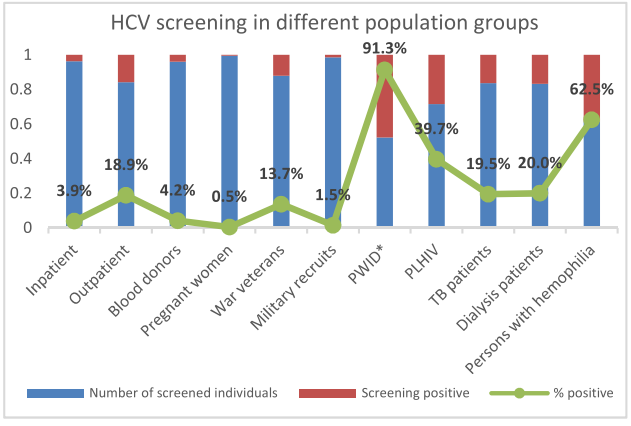

Figure: HCV screening in different population groups (April 2015-April 2018) * State Opioid-Substitution Program beneficiaries screened on HCV

Conclusion: More than one third of the adult population has been screened in Georgia and about half of estimated number of anti-HCV positive adult population were identified. Although, to reach the national strategy goals, it is required to increase screening coverage and reach the people who have never been tested, as well as raise awareness among population and improve infection control in medical and non-medical facilities to prevent transmission and reduce the number of new infections.

THU-397

Screening strategies for hepatitis C virus elimination in Italy

Ivane Gamkrelidze[1], Loreta Kondili[2], Andrea Marcellusi[3], Sarah Robbins[1], Sarah Blach[1], Antonio Craxi[4], Massimo Puoti[5], Homie Razavi[1], Francesco Saverio Mennini[3]. [1]*CDA Foundation, Lafayette, United States;* [2]*Istituto Superiore di Sanità Rome, Italy;* [3]*University of Rome Tor Vergata, Rome, Italy;* [4]*University of Palermo, Rome, Italy;* [5]*Niguarda Hospital, Milan, Italy*
Email: sblach@cdafound.org

Background and aims: Hepatitis C virus (HCV) elimination could be achieved in Italy by newly linking 36, 400 patients to care and treating 38, 000 patients annually by 2025. However, cost-effective screening strategies are needed to make elimination a reality. HCV is more prevalent in the older Italian population, so our objective was to determine if birth cohort-based screening could be cost-effective in Italy.

Method: A Markov disease burden model was populated with Italian data to quantify the annual HCV-infected population by liver disease stage, sex, and age. An economic impact module was added to quantify medical costs (costs of screening, antiviral treatment, including assessment and monitoring, and liver-related complications) and health effects, denominated in quality-adjusted life years (QALYs), associated with HCV infection. Prevalence of undiagnosed, asymptomatic HCV infection was used to calculate the number of HCV antibody screens needed annually. The cost-effectiveness threshold was set at €25, 000 as commonly accepted in the Italian guidelines. Modeled outcomes for disease burden, medical costs, and health effects of HCV infection were assessed under the status quo and as well as a scenario to achieve the World Health Organization's Global Health Sector Strategy targets for eliminating HCV by 2030 under four screening strategies. The screening strategies included universal or targeted screening by birth cohort: the 1948-78 cohort, the 1958-78 cohort, and graduated birth cohort screening (birth years 1958-78 over 2021-23, 1948-78 over 2024-27, and 1948-84 over 2028-30).

Results: All screening scenarios were found to be highly cost-effective (less than €3, 000 per QALY gained) compared with the status quo. The 1948-78 birth cohort screening scenario was the least costly, with €5.5 billion in total medical costs by 2031. This was €24.7 million less than screening in the 1958-78 birth cohort, €37.6 million less than universal screening, and €55.3 million less than graduated screening. Screening the 1948-78 birth cohort would gain approximately 140, 000 QALYs by 2031, compared to 134, 000, 127, 000, and 123, 000 QALYs for the universal, 1958-78 birth cohort, and graduated birth cohort, respectively.

Conclusion: In Italy, implementing screening in the 1948-78 birth cohort was the most cost-effective option, and showed the greatest reductions in overall disease burden by 2030. This strategy should be considered to sustain Italy's momentum towards achieving HCV elimination goals.

Circulating HCV resistant strains may result in long-term challenges to HCV elimination: A modeling study

Ilias Gountas[1], Georgios Nikolopoulos[2], Stefanos Bonovas[3], Angelos Hatzakis[1], Alessio Aghemo[4]. [1]*National and Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Medical School, Athens, Greece;* [2]*University of Cyprus, Medical School, Nicosia, Cyprus;* [3]*Humanitas University, Department of Biomedical Sciences, Milan, Italy;* [4]*Humanitas University, Liver Unit and Department of Biomedical Sciences, Rozzano, Italy*
Email: eliagoun@gmail.com

Background and aims: Significant developments in antiviral treatment of hepatitis C virus (HCV) have improved the management of the infection, making HCV curable. Cohorts of real-life patients treated with direct-acting antivirals (DAAs) have reported sustained virologic response rates (SVR) exceeding 95%. However, the retreatment of the ~5% that have failed to the first course of DAA treatment may be challenging, as treatment failure is associated with selection of resistant associated substitutions in the viral genome. The aim of the study is to assess the risk of potential rebound of a resistant HCV among people who inject drugs (PWID).

Method: A dynamic stochastic model was developed to simulate HCV transmission, incorporating the effect of treatment and harm reduction (HR) strategies. Two chronic hepatitis C (CHC) prevalence settings (45% and 60%) were considered, with population of 10.000 PWID and baseline HR coverage of 40%. We defined PWID with resistance infection as those who have two consecutive failures both in first DAA treatment (SVR 95%) and in retreatment with first-line or PI regimens (SVR ~85%) or in retreatment with SOF/VEL/VOX (SVR 90-95%). The time horizon of the analysis was 25 years (2018-2043).

Results: Our results highlighted that a potential rebound of resistant HCV is likely to occur under a first-line or PI-based regiments retreatment strategy, primarily in settings with high baseline prevalence in long-term. Specifically, under this strategy, the model anticipates that only patients with resistant virus would remain after 2029 (Figure a). Annual HCV incidence would exceed the levels of the elimination target after 2036 (Figure b). Under a SOF/VEL/VOX retreatment strategy, annual HCV incidence would be barely above elimination targets by 2043. Expanding harm reduction coverage from 40% to 75% by 2030 would be sufficient to maintain the results of elimination and control the spread of resistant virus.

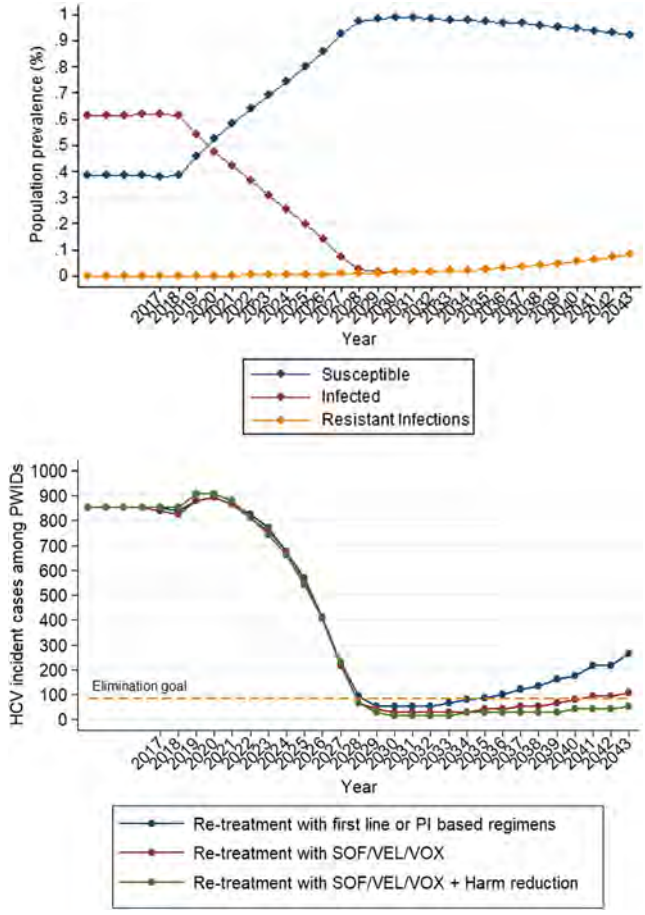

Figure: Model predictions concerning a 60% baseline chronic HCV prevalence under various re-treatments options. A. Distribution of the population under retreatment with first-line or PI regimens, B. Incident cases

Conclusion: A potential rebound of resistant HCV is likely, beyond 2035 and mainly, in high baseline prevalence settings. To prevent the emergence of resistant virus, retreatment of people with multiple DAAs failures should be optimized and harm reduction measures should be implemented to control the spread of resistant HCV.

THU-399

First Belgian hepatitis E seroprevalence study shows low stable birth-cohort specific seroprevalence until 2014, with recent 2016-2018 increase in single centre estimates

Erwin Ho[1,2], Veronik Hutse[3], Vera Verburgh[3], Marjorie Jacques[3], Heidi Theeten[4], Amber Lizroth[5], Vanessa Suin[3], Steven Van Gucht[3], Stéphanie Blaizot[4], Abbas Rahman[4], Niel Hens[4], Pierre Van Damme[4], Peter Michielsen[1,2], Thomas Vanwolleghem[1,2,6]. *[1]University Hospital Antwerp, Gastroenterology and Hepatology, Edegem, Belgium; [2]University of Antwerp, Laboratory of Experimental Medicine and Paediatrics, Antwerpen, Belgium; [3]Sciensano, Viral Diseases-National Reference Center for Measles, Mumps, Rubella, Viral Hepatitis and Human Papillomavirus, Ixelles, Belgium; [4]Vaccine and Infectious Disease Institute, Antwerpen, Belgium; [5]Sciensano, Epidemiology of infectious diseases, Ixelles, Belgium; [6]Erasmus MC, Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: erwin.husin@gmail.com

Background and aims: Recent studies have shown rising seroprevalence of hepatitis E virus (HEV) in younger age cohorts in Europe, but substantial regional differences are found. We aimed to evaluate trends in time in birth cohort-specific HEV seroprevalence and regional differences in Belgium.
Method: Firstly, we performed a retrospective analysis of HEV IgG seroprevalence on two national serum banks obtained from sentinel laboratories in 2006 and 2014. Five to ten-year age cohorts held equal amounts of samples and were equally distributed in sex and regional origin. Secondly, a prospective, single centre HEV IgG evaluation was performed of 1200 patients visiting the Hepatology department between 2016 and 2018. Wantai anti-HEV IgG ELISA assays were performed. Results equal or above 1.1 OD/cutoff were considered positive, below 1.1 as negative. Statistical analysis with R included a one-sided power analysis to specifically estimate required sampling for birth cohort-specific seroprevalence evaluation (1604 and 2087 samples respectively). Chi-square analysis or Fisher's Exact Test was performed in SPSS 25 to compare sex, region and birth cohort proportions.

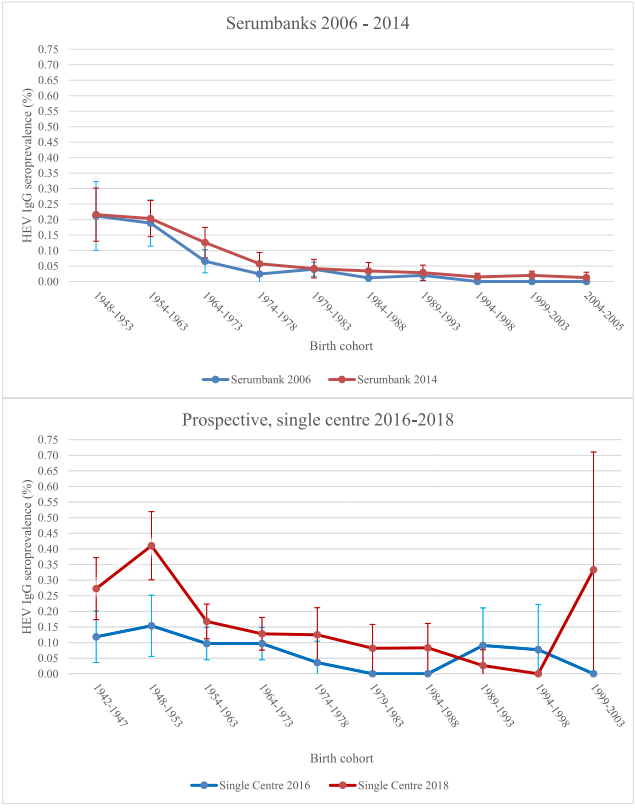

Figure: HEV IgG birth cohort-specific seroprevalence in Belgium, between 2006 and 2014 and 2016 and 2018

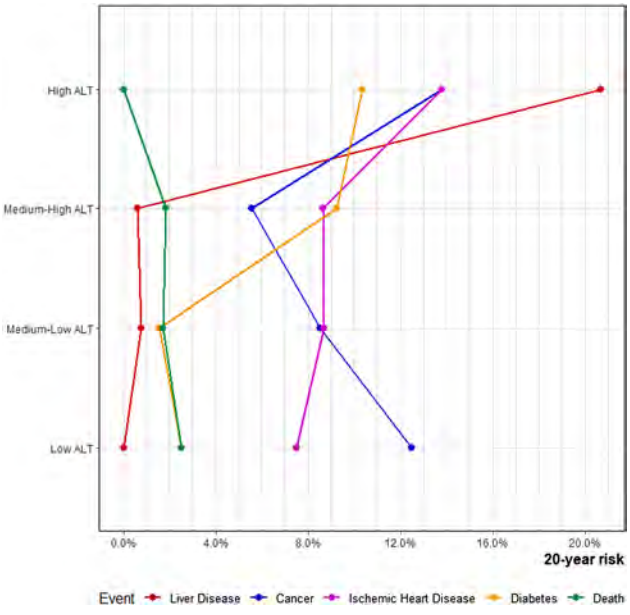
Results: Overall HEV IgG seroprevalences were 4.7% (76/1604, CI 3.2-6.3) and 5.8% (121/2087, CI 4.5-7.1) in 2006 and 2014 ($p = 0.161$), respectively. In the single centre analysis, HEV IgG seroprevalences were 8.6% (43/499, CI 6.2-11.1) and 17.1% (120/701, CI 14.3-19.9) in 2016 and 2018 ($p < 0.001$), respectively. No significant differences between sexes were found for any of the years ($p = 0.603$, $p = 0.942$, $p = 0.944$, $p = 0.657$). Significant regional differences were found in

2014 (p = 0.021) with a significant rise between 2006 and 2014 in two provinces: Hainaut (1.5% to 6.0%, p = 0.043) and Namur (3.7% to 14.7%, p = 0.037). We found no significant birth cohort-specific differences between 2006 and 2014, but in the single centre analysis we found a significant increase between 2016 and 2018 in the two oldest birth cohorts (born 1942-1947: 11.9% to 27.3%, p = 0.028 and born 1948-1953: 15.4% to 41%, p = 0.002).
Conclusion: Compared to reported seroprevalences in surrounding countries, initial analysis of Belgian nationwide HEV IgG seroprevalence shows stable and rather low rates. No birth cohort-specific increase in seroprevalence is seen between 2006 and 2014. A regional increase of seroprevalence was however found in two south-western provinces. In addition, single centre analysis between 2016 and 2018 suggests a recent rising seroprevalence, especially in older birth cohorts.

THU-400
Alanine-aminotransferase and 20-year risk of liver disease, cancer, ischemic heart disease, and diabetes in a Danish general population sample aged 30-49 years

Morten Daniel Jensen[1,1], Torsten Lauritzen[2], Hendrik Vilstrup[1], Henrik Toft Sørensen[3], Peter Jepsen[1,3]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark;* [2]*Institute of General Medical Practice, Aarhus University, Department of Public Health, Aarhus, Denmark;* [3]*Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark*
Email: mortenjensen_92@hotmail.com

Background and aims: Alanine-aminotransferase (ALT) is an enzyme chiefly found in the liver, and serum ALT is the most frequently used marker of liver cell injury. We examined the association between ALT levels and long-term risk of liver disease, cancer, ischemic heart disease, diabetes, and death in a general population sample of persons aged 30-49.

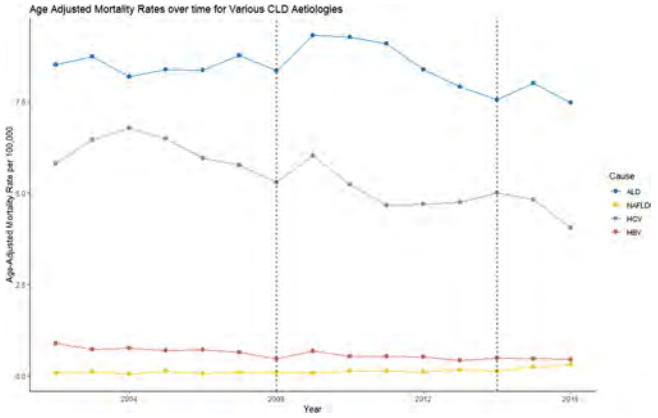


Method: We obtained the data from the Ebeltoft Health Promotion Project, a randomized controlled trial examining the value of health examinations in the general population aged 30-49 years. We used Danish healthcare registries to follow the 905 trial participants for up to 20 years. We divided the participants into four ALT categories based on their baseline values: low (ALT ≤ 10 U/l), medium-low (ALT 11-34 U/l for men, 11-22 U/l for women), medium-high (ALT 35-69 U/l for men, 23-44 U/l for women), and high (≥ 70 U/l for men, ≥ 45 U/l for women). We calculated the absolute risks of each event by ALT category using the cumulative incidence function, with the other events considered as competing risks. We also calculated all-cause mortality using the Kaplan-Meier estimator.
Results: For men and women with "high ALT," the 20-year risk of a hospital diagnosed liver disease was 20.7% (95% CI: 8.4-36.7). Patients with a lower ALT had a 20-year risk of 0.8% or less. Risk of cancer was highest for participants with "low ALT" or "high ALT" (20-year risk: 12.5% [CI: 4.6-24.6] and 13.8% [CI: 4.3-28.6], respectively). The 20-year risk of ischemic heart disease was highest in the "high ALT" group, with a risk of 13.8% (CI: 4.3-28.6). Risk of diabetes was highest for patients with "medium-high ALT" or "high ALT" (20-year risk: 9.3% [CI: 5.4-14.3] and 10.3% [CI: 2.6-24.3], respectively). The probability of being alive after 20 years without having developed liver disease, cancer, ischemic heart disease, or diabetes was highest in the "low ALT" (75.0% [CI: 58.5-85.7]), "medium-low ALT" (78.7% [CI: 75.3-81.7]), and "medium-high ALT" (74.1% [CI: 66.6-80.1]) groups, compared to participants with "high ALT" (41.4% [CI: 23.7-58.3]).
Conclusion: Members of the general population with a high ALT value at age 30-49 years had an increased 20-year risk of liver disease, cancer, ischemic heart disease, and diabetes. Those with a low ALT had a high risk of cancer. These findings may be valuable for patient counselling in the general practice or outpatient settings.

THU-401
Changes in mortality due to chronic liver diseases in Spain during the period 2002-2016

Isabel Graupera[1], Mathew Keys[2], Miquel Serra-Burriel[2], ELISA Pose[1], Elsa Solà[1], Sabela Lens[1], Zoe Mariño[1], Xavier Forns[1], Pere Ginès[1]. [1]*Liver Unit, Hospital Clínic, University of Barcelona, Barcelona, Catalunya, Spain and Institut d'Investigacions Biomèdiques August-Pi-Sunyer (IDIBAPS), CIBEREHD, Barcelona, c, Spain;* [2]*Center for Research in Health Economics, Universitat Pompeu Fabra, Barcelona, Catalunya, Spain*
Email: igraupe@clinic.ub.es

Background and aims: Chronic liver disease (CLD) is responsible for a significant burden of disease worldwide. The objective of the present study was to estimate the burden of disease in terms of mortality by each of the 4 most common aetiologies of CLD, alcoholic-liver disease (ALD), non-alcoholic fatty liver disease (NAFLD), hepatitis C virus (HCV) and hepatitis B virus infections (HBV) in Spain from 2002 to 2016.
Method: We collected data from the Spanish Institute for Statistics (INE) 2002-2016 mortality records and selected individuals with a primary cause of death of ALD, NAFLD, HCV and HBV using ICD-10 codes. We obtained temporal age-adjusted mortality rates using trend analysis. Deaths with unspecified aetiology of chronic liver disease were proportionally distributed among the 4 aetiologies.



Results: A total of 91, 664 deaths were included in the analysis, yielding an aggregated age-standardized yearly mortality of 14.5 per 100, 000 for the 2002-2016 period. ALD mortality remained stable at

8.4 deaths per 100, 000 persons from 2002 to 2008, increased an average 3% yearly from 2009 to 2011 to 9.0/100, 000p, and steadily decreased to 7.5 deaths per 100, 000 persons up to 2016. HCV-related mortality peaked at 2004 at a 6.8 per 100, 000 persons and slowly decreased at a 2.6% yearly average rate till 2014 to 5.0/100, 000p. From 2014 to 2016, HCV related mortality has had a reduction to 4.04/100, 000p, which represent a decrease in mortality of 19.2%. HBV-related mortality has reduced 50% from 0.89 to 0.44 per 100, 000. Although still low in comparison with other aetiologies, NAFLD-related mortality has increased from 0.07 to 0.3 per 100, 000p representing a 297% increase from 2002 to 2016.

Conclusion: In our population analysis of CLD mortality in Spain, we find three relevant time-frames that coincide with the economic expansion of 2000-2008, the financial crisis and the 2014 introduction of novel HCV therapies. ALD remains the main cause of death for CLD, NAFLD has increased and both HBV and HCV-related mortality have decreased. Accuracy of death certificates based upon ICD-10 codes is subject to misreporting and misclassification.

Tailored message interventions using social marketing approach versus traditional message for increasing participation in viral hepatitis screening for Japanese workers

Masaaki Korenaga[1], Tatsuya Ide[2], Chieko Ooe[3], Keiko Kamimura[3], Keiko Korenaga[1], Tatusya Ide[2], Takako Inoue[4], Jun Fukuyoshi[5].
[1]National Center of Global Health and Medicine (NCGM) at Kohnodai, Research center for hepatitis and Immunology, Ichikawa, Chiba, Japan; [2]Kurume University School of Medicine, Division of Gastroenterology, Department of Medicine, Kurume, Fukuoka, Japan; [3]Japan Health Insurance association, Fukuoka, Japan; [4]Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; [5]Keio University, Tokyo, Japan
Email: dmkorenaga@hospk.ncgm.go.jp

Background and aims: Although community residents have been provided an opportunity to undergo hepatitis B virus (HBV) and hepatitis C virus (HCV) screening by the Japanese government, actions against hepatitis at work sites in Japan have not yet been fully implemented, and the prevalence of hepatitis virus infections at work sites remains unknown. In Japan Health Insurance Association, which is belonged to about 37 million Japanese who are working in Medium and Small Sized Companies, the attendance rates of hepatitis screening was less than 2% of workers even the cost of only $ 5. The aim of this study was to examine whether the effectiveness of a tailored message intervention based on a social marketing approach increased viral hepatitis screening.

Method: A leaflet which was a tailored message condition for the screening was individually sent to 398, 636 Japanese workers of Japan Health Insurance Association who wish to get annual general check-up in 2017. For control subjects, we simultaneously enrolled about 338, 145 workers with a non-tailored message condition. In addition, we sent the leaflet which mentioned having the screening for free of charge to some workers. A thorough examination of the participants who screened positive was encouraged by forwarding to them a referral letter by Japan Health Insurance Association to specialized medical institutions. The main outcome measure was attendance rates in HBV and HCV screening.

Results: There was a significant difference in viral hepatitis screening attendance rates at follow-up assessments between the tailored matched-message condition (n = 54, 052, 16.0%) and the control (n = 4,794, 1.2%; $p < 0.001$). In cost free subjects, the rates significantly increased (49.3%; $p < 0.001$) compared with the message condition and control group. Six hundred two workers (1.1%) were positive for HBV (n = 382, 0.7%) and HCV (n = 222, 0.4%), respectably. Among them, two hundred fifty-six (42.6%) were confirmed to medicate within 6 mounts after the screening by medical bill checking system of Japan Health Insurance Association.

Conclusion: A tailored-message intervention designed to increase the viral hepatitis screening rates in the Medium or Small Sized Companies. Promoting hepatitis virus screening for workers by using social marketing approach may help detect carriers who are unaware of their infection and require treatment.

THU-403

The consensus hepatitis C cascade of care: Methodology and initial findings from three countries

Email: Jeffrey.Lazarus@isglobal.org

Background and aims: The World Health Organization (WHO) has called for the elimination of hepatitis C virus (HCV) as a public health threat by 2030. Efforts to monitor progress toward HCV elimination are hampered by the lack of a unified approach to defining HCV cascade stages, data sources and methodologies. The aims of this study were to develop a cascade of care for use in national and sub-national monitoring worldwide with well-defined stages, and to pilot the new instrument. The ultimate goal was to support strategic decision-making aimed at maximising the progression of HCV-infected individuals from diagnosis to cure.

Method: Leading clinical and public health experts reviewed the published literature on existing HCV cascade of care methodologies, as well as relevant information about cascade monitoring in the HIV field. Key methodological issues were discussed and agreed by consensus, and cascade stages and definitions formulated. Experts on the epidemiology of HCV in Denmark, Norway and Sweden applied the resulting HCV cascade of care instrument to national and-in the case of Denmark-sub-national data to report on progress toward HCV elimination in these countries.

Results: The proposed consensus cascade is comprised of four stages: infected, diagnosed, treated and cured. The four stages were defined in relation to an annual period beginning 1 January. Definitions took into account spontaneous clearance and the time lag between treatment initiation and sustained viral response. Norway and Sweden completed the cascade using national data and estimates for the three years of interest, 2015-2017, while Denmark reported using subnational data from three of its five regions. The cascades from all three settings showed high levels of fall-off from the diagnosed to the treated stage; an estimated 3%-18% of those diagnosed in 2017 received treatment (Figure 1). Large proportions of the estimated HCV-infected populations in Norway and Sweden

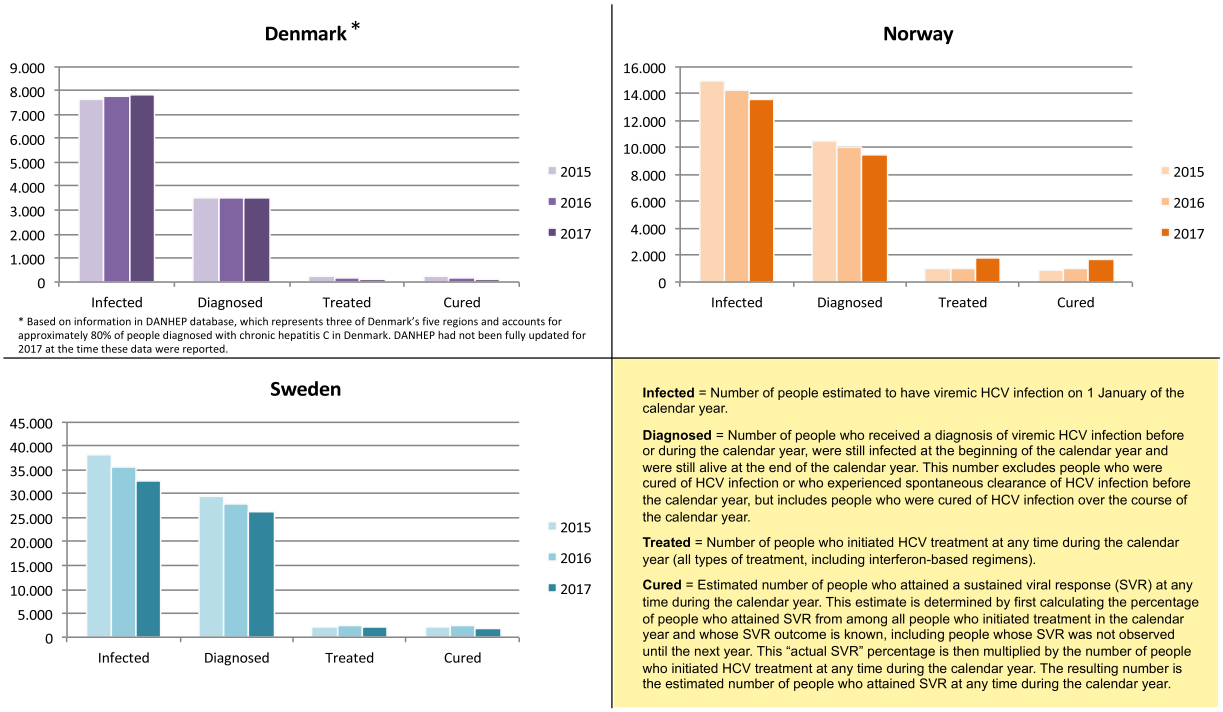

Figure 1: (abstract: THU-403): Estimated hepatitis C cascades of care for Denmark, Norway and Sweden, 2015–2017

are diagnosed-70% and 80%, respectively-while fewer are diagnosed in the Danish regions represented.
Conclusion: The Consensus HCV Cascade of Care is an effective instrument for monitoring progress toward WHO elimination targets and we recommend its use for national and subnational reporting. Reporting entities should describe any assumptions that informed the estimates reported for each cascade stage.

THU-405
Complications of chronic hepatitis B: Prevalence and disparities in a US health system cohort 2006-2016

Mei Lu[1], Yueren Zhou[1], Jia Li[1], Loralee B Rupp[2], Joseph A. Boscarino[3], Yihe G Daida[4], Mark A Schmidt[5], Sheri Trudeau[1], Stuart C Gordon[6].

Email: mlu1@hfhs.org

Background and aims: There are no recent reports of longitudinal trends in chronic hepatitis B (CHB)-related complications among routine clinical care patients in the US. Using data from the Chronic Hepatitis Cohort Study (CHeCS), we analyzed longitudinal rates of cirrhosis, decompensated cirrhosis, and all-cause mortality as well as disparities by age, sex, and race.
Method: Join-point and Poisson regression (univariate and multivariate) were used to estimate the annual percent change (APC) in each outcome from 2006 to 2016.
Results: A total of 5528 unique CHB patients were included. Prevalence of cirrhosis (including decompensated cirrhosis) doubled from 6.7% in 2006 to 13.7% in 2016. Rates among female patients were roughly half that of male patients (Rate ratio [RR] 0.47; $p < 0.001$). Cirrhosis rates were lowest among the youngest patients and highest among the oldest; rates increased over time in all age groups (adjusted APC (aAPC) 3.8-10.8; $p < 0.001$). Overall prevalence of decompensated cirrhosis increased from 2.3% to 5%; as with cirrhosis, rates were lowest among the youngest patients and highest among the oldest. aAPC increased (aAPC = +6.2%; $p < 0.001$) but did not differ by sex, age, or race. Incidence of all-cause mortality remained flat across the study period (1.4% to 1.7%), but varied by sex (female vs male RR = 0.61; $p < 0.001$) and age. APC increased among African Americans (aAPC = +6.2%; $p = 0.01$) but remained flat among Asian American/Pacific Islander (AAPI) and White patients ($p > 0.70$).

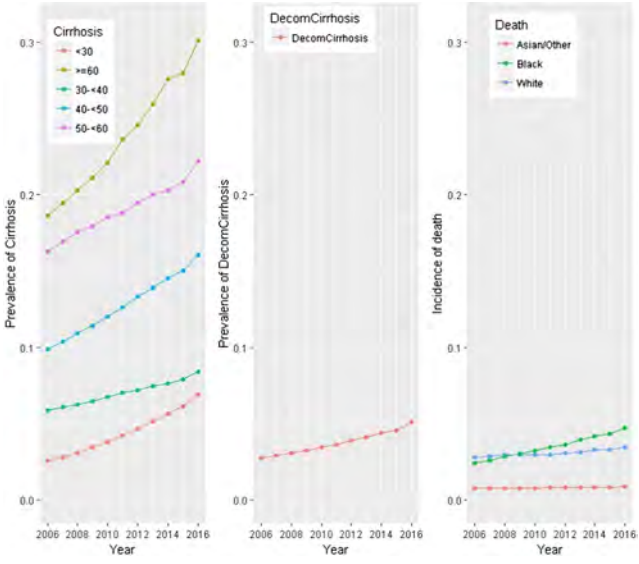

Figure: Rates of cirrhosis and decompensated cirrhosis, and incidence of mortality among patients with chronic hepatitis B.

Conclusion: From 2006 to 2016, prevalence of cirrhosis among CHB patients doubled; rates were highest among older, male, and African American patients. Rates of decompensated cirrhosis also doubled

over the study period. Incidence of all-cause mortality was steady in both AAPI and White patients, but increased among African Americans.

Cost-effectiveness analysis of "treat all" guidelines for chronic hepatitis C in Brazil

Everton Macêdo Silva[*,1,2,3], Constance Marie Meiners-Chabin[*,1,4], Liliana Sampaio Costa Mendes[3], Ray Costa Portela[3], Yazdan Yazdanpanah[1,5], Sylvie Deuffic-Burban[1,6]. [1]*IAME, UMR 1137, Inserm, Université Paris Diderot, Sorbonne Paris Cité Paris, France;* [2]*Ministry of Health, Brasilia, Brazil;* [3]*Instituto Hospital de Base do Distrito Federal, Brasilia, Brazil;* [4]*Ministry of Planning, Development and Management, Brasilia, Brazil;* [5]*Service de Maladies Infectieuses et Tropicales, Hôpital Bichat Claude Bernard, Paris;* [6]*Univ. Lille, Inserm, CHU Lille, U995-LIRIC, Lille, France*
Email: ms.everton@gmail.com

Background and aims: Home to over 1 million HCV-infected individuals, the Brazilian public health system incorporated direct-acting antivirals (DAAs) in 2015 for advanced liver disease. By 2017, DAAs had been delivered to about 65, 000 people. Recently, the Ministry of Health (MoH) decided to expand treatment to all patients regardless of liver damage. Our aim was to evaluate the cost-effectiveness of universal treatment for chronic hepatitis C in Brazil, which remains lacking.
Method: A Markov model simulated natural disease progression and treatment intervention for adult HCV mono-infected patients, from diagnosis to death, with characteristics drawn from a public hospital cohort (Hospital de Base, Brasilia). Costs and outcomes were compared for 3 scenarios: treat from Metavir fibrosis stage F3 (S1), treat from F2 (S2) or treat all patients (S3). Rates for background and liver disease-related mortality, disease progression, sustained virologic response (SVR) and quality-adjusted life years (QALYs) were based on official data and literature review. Direct costs, including ambulatory and hospital fees, and drug prices (US$ 6, 212.64 per 12-week therapy) were estimated from public payer perspective, considering MoH guidelines and databases. Discount rate was 5% for costs and outcomes. Incremental cost-effectiveness ratios (ICERs) were interpreted according to GDP per capita (US$ 9, 821). Extensive sensitivity analysis was performed.
Results: At baseline, 80% of patient population was in stages F3 or F4. S3 was the most effective strategy with mean gain of 0.01 and 0.03 QALYs compared to S2 and S1, respectively. However, due to cost, S3 was not cost-effective against S2 (US$ 16, 980/QALY), nor was S2 against S1 (US$ 12, 352/QALY). Varying the gender's distribution, fibrosis stage and age distribution at diagnosis, probabilities of progression, ambulatory and hospital costs and probabilities of svr did not hold much impact on ICERs. By contrast, results were highly sensitive to QALY and drug price variation. At US$ 1506, 75 per 12-week therapy, according to new prices under negotiation at the MoH, S1 became dominated and S3 highly cost-effective against S2 (US$ 429/QALY).
Conclusion: At current drug prices, expanding hepatitis C treatment eligibility is not cost-effective. However, universal treatment can be highly cost-effective or even cost-saving, compared to delaying treatment till F2 or F3 stages, once therapy costs are considerably reduced. Efforts to lower DAA prices are key to put Brazil on track with World Health Organisation targets to eliminate HCV infection by 2030.

THU-407

Implementation of a hepatitis C testing and linkage to care program in the Philadelphia jail system

Lora Magaldi[1], Ebonee Allen[1], Jolie Anderson[1], Carla Coleman[1], Jalina Evans[1], Bruce Herdman[2], Jay Kostman[1], Ta-Wanda Preston[1], Alexandra Ripkin[1], Ricardo Rivera[1], Nabori Rosario[1], Stacey Trooskin[1]. [1]*Philadelphia FIGHT, Viral Hepatitis, Philadelphia, United States;* [2]*Philadelphia Department of Prisons, Curran-Fromhold Correctional Facility, Philadelphia, United States*
Email: lmagaldi@fight.org

Background and aims: Hepatitis C (HCV) infection disproportionately affects those in correctional institutions. The HCV seroprevalence n incarcerated populations ranges from 17.4%-23.1% and in Philadelphia jails is estimated to be 17%. HCV-associated liver disease is a frequent cause of inmate death and has recently surpassed HIV deaths. International societies recommend that all incarcerated persons undergo HCV testing. HCV testing is not universally performed in this setting and treatment is provided only to those with advanced liver disease who meet sobriety and behavioural criteria.
Method: In October 2017 the Philadelphia Department of Prisons (PDP) partnered with Philadelphia FIGHT Community Health Centres to develop an HCV testing and linkage to care program for sentenced inmates. PDP leadership requested a staged roll out of the program due to concerns about the downstream costs of treatment. The first six months of the project consisted of providing HCV education and protocol training for PDP medical staff, securing necessary contracts, and hiring one FIGHT linkage coordinator. The following six months required an iterative process of developing inclusion criteria and modifying protocols.
Results: On 2 April 2018 a list of the 14 inmates expected to be released within six weeks was provided for testing. The PDP medical staff requested the FIGHT linkage staff to be present at the time of testing to provide patient education. On 1 May 2018 the PDP expanded eligibility to include all inmates who were expected to be released within six months (n = 246).

	eligible for testing	released before testing	refused testing	available for testing	tested within the month of eligibility	tested within 1 month of being declared eligible	total number tested between 1.4.18-15.11.18
April	14	4 (29%)	3 (21%)	7 (50%)	6 (43%)	6 (43%)	7 (50%)
May	112	32 (29%)	11 (10%)	69 (62%)	54 (48%)	63 (56%)	69 (62%)
June	80	35 (44%)	5 (6%)	40 (50%)	11 (14%)	38 (48%)	40 (50%)
July	56	18 (32%)	1 (2%)	37 (66%)	24 (43%)	37 (66%)	37 (66%)
August	914	324 (35%)	44 (5%)	546 (60%)	175 (19%)	304 (33%)	433 (47%)
September	201	85 (42%)	3 (1%)	113 (56%)	12 (6%)	68 (35%)	78 (39%)
October	218	68 (31%)	6 (3%)	144 (66%)	56 (26%)	68 (31%)	68 (31%)
Total	**1595**	**566 (35%)**	**73 (5%)**	**956 (60%)**	**338 (21%)**	**584 (37%)**	**732 (46%)**

Conclusion: To achieve the WHO HCV elimination targets by 2030 we must be testing for and treating HCV in correctional settings. Building an HCV testing program in correctional settings in the US is feasible but can be challenging and is influenced by concerns regarding the downstream cost of medication. Ideally all correctional settings should provide routine opt-out testing to all individuals upon intake.

THU-408

Screening for viral immunity prior to immunosuppressive or biologic therapy

Richard Manfready[1], Jack Husney[2], Michael Ma[1], Ilan Weisberg[2]. [1]*Mount Sinai Beth Israel, Icahn School of Medicine, Medicine, New York, United States;* [2]*Mount Sinai Beth Israel, Icahn School of Medicine, Digestive Diseases, New York, United States*
Email: richard.manfready@mountsinai.org

Background and aims: Immunosuppressive therapies and biologic agents are increasingly used as first-line treatments for inflammatory conditions across multiple specialties. Patients on these therapies are particularly susceptible to viral infections, while live vaccines may be contraindicated or rendered less effective. Major society guidelines recommend reviewing immunization history prior to initiation of immunosuppressive or biologic agents, in addition to screening for latent hepatitis B virus and tuberculosis. Routine pre-treatment screening for measles, mumps, and rubella immunity has been recommended but is not well-established. The purpose of this study

was to assess current pre-treatment screening practices, with the goal of better informing the standard of care.
Method: A retrospective review of patients on immunosuppressive or biologic agents was conducted within a single multi-hospital health system over a seven-year period (2011–2017, inclusive). Each treated patient was screened for selected laboratory values recorded at any point prior to treatment. These values included rubella IgG, measles IgG, mumps IgG, varicella zoster IgG, hepatitis B serology, and interferon-gamma release assay for tuberculosis.
Results: A total of 771 patients were included, representing 838 unique initiations of infliximab (54.5%), azathioprine (37.5%), adalimumab (6.8%), ustekinumab (0.6%), etanercept (0.2%), certolizumab (0.2%), and apremilast (0.2%). Screening rates were highest for hepatitis B surface antibody and antigen (80–100%), and lowest for varicella zoster IgG (10–40%), interferon-gamma release assay (0–20%), measles IgG (0–30%), mumps IgG (0–30%), and rubella IgG (0–30%). Screening rates were similar across all drugs surveyed.

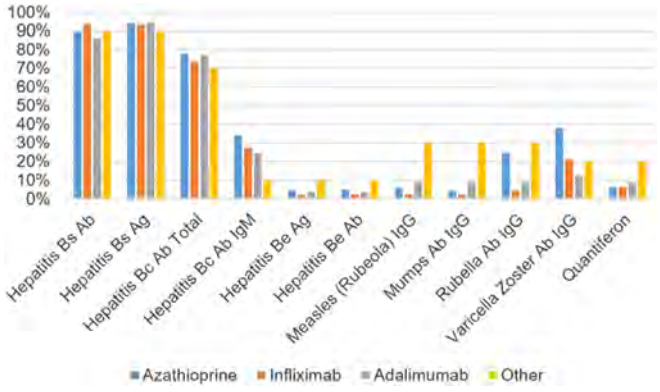

Figure: Rates of laboratory assays conducted for patients on immunosuppressive or biologic agents.

Conclusion: Among patients treated with immunosuppressive or biologic agents in a multi-hospital health system over a seven-year period, screening compliance was relatively high for hepatitis B serology, however was considerably lower for assessment of measles, mumps, rubella, and varicella immunity. These results are in agreement with our previous analyses of survey data, and highlight the need for improved pre-treatment screening guidelines.

THU-409

Progress on scaling up testing and treatment for hepatitis C elimination in Punjab, Pakistan: Hepatitis prevention and treatment program

Ammara Naveed[1,2], Amjad Khan[3], Asif Butt[1], Shabbar Ali[3], Farooq A. Khan[1,4], Khurram Anis[1], Arif Mahmood Siddique[1], Kamran Shafiq[1], Ahmad Karim Malik[1], Nauman Zakir[1], Amer Yar Khan[1], Saeed Akhter[1], Naveed Janjua[5,6], Abdul Nadir[1], Faisel Yunus[3]. *[1]Pakistan Kidney and Liver Institute and Research Center, Lahore, Pakistan; [2]University of Illinois at Chicago, Chicago, United States; [3]Hepatitis Prevention and Treatment Program, Pakistan Kidney and Liver Institute and Research Center, Lahore, Pakistan; [4]University Hospitals of Leicester, NHS Trust, Leicestershire, United Kingdom; [5]British Columbia Centre for Disease Control, Vancouver, Canada; [6]School of population and public health, University of British Columbia, Vancouver, Canada*
Email: ammara.naveed@gmail.com

Background and aims: The province of Punjab, Pakistan has one of the highest burdens of hepatitis C (HCV) in the world. 90% remain undiagnosed. Punjab government funded Hepatitis Prevention and Treatment Program (HPTP), by Pakistan Kidney and Liver Institute and Research Center (PKLIandRC), to scale-up testing and treatment. Between March 2017 and October 2018, 24 community clinics for viral hepatitis care were opened across Punjab, Pakistan. Two doctors without specialty training, supported by a nurse, laboratory technician and a pharmacist formulate the core team at a clinic. Guidance is provided by hepatologists at the central hub in Lahore. On the first visit, testing for HCV antibody (anti-HCV) and hepatitis B surface antigen, is done by rapid testing. Results are reported in 20 minutes. Positive cases are counselled for further testing. For HCV, blood samples are taken for HCV PCR, blood picture, liver and renal function, to confirm and stage disease. AST to Platelet Ratio Index and Fibrosis-4 Index is used for staging. Pakistan is Genotype (GT) 3 predominant region (>85%), hence GT is not performed. At follow-up, treatment is initiated with Sofosbuvir (SOF) and daclatasvir (DCV) using standard protocols. All steps are recorded in centralized electronic medical records. This paper describes overall program and its initial progress.
Method: We constructed a care cascade by performing an analysis on screening, confirmation testing and uptake of treatment up to November 10, 2018. Treatment completion rates were assessed for those who received their last refill on April 30, 2018.
Results: As of November 10, 2018, a total of 224, 687 patients had sought care across the 24 centers. 47.4% male and 52.6% female. 82% (n = 183, 370) were tested for anti-HCV, 37% (n = 84, 067) were found positive. 23% (n = 51, 778) were found to have chronic HCV. 16% (n = 36, 663) were enrolled in SOF based treatment. As of May 31, 2018, 7, 659 people have completed treatment. Sustained Virolgical Response (SVR) 12 was available in 63% of those that completed treatment (n = 4841). SVR12 for the overall program was 97.3% in those with SVR 12 data. (Figure 1).

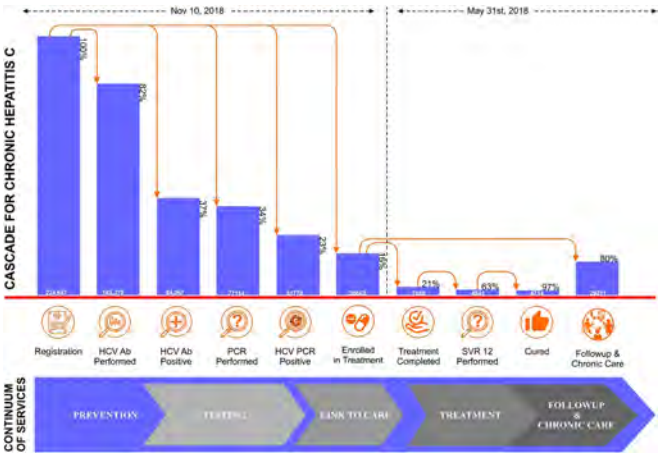

Figure 1: Treatment cascade for care, of patients presenting to Hepatitis Prevention and Treatment Program, Pakistan.

Conclusion: This program highlights community-based scale up of testing and treatment to achieve WHO elimination goals in high burden setting. Lessons learnt could be used for scale-up in other settings.

THU-410

Hepatitis B prevention of mother to child transmission integrated into antenatal care services in Mozambique

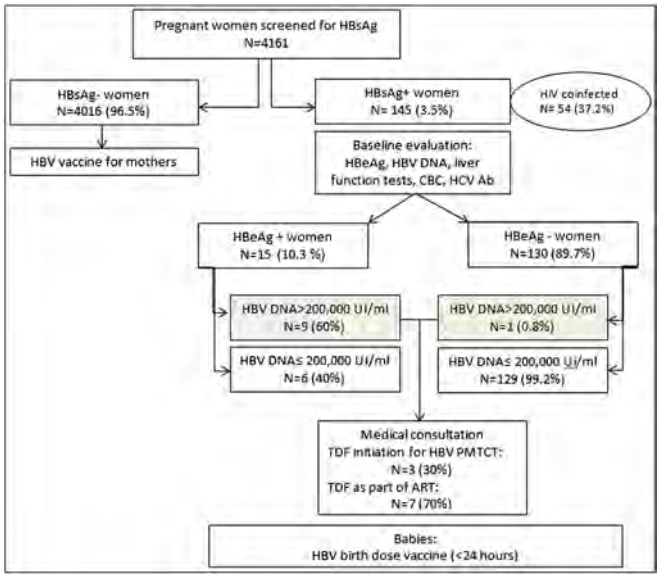
Aude Nguyen[1,2], Natalia Tamayo Antabak[3], Maira Chanase Rodrigues Marra[4], Natercia Madeira[5], Lucas Molfino[5], Nelly Staderini[1], anne Loarec[6]. *[1]Médecins Sans Frontières, Genève, Switzerland; [2]Geneva University Hospital, Geneva, Switzerland; [3]Médecins Sans Frontières, Mozambique mission, Maputo, Mozambique; [4]HIV program, Maputo, Mozambique; [5]Médecins Sans Frontières, Maputo, Mozambique; [6]Epicentre, Paris, France*
Email: aude.nguyen@geneva.msf.org

Background and aims: Hepatitis B (HBV) is mostly transmitted in endemic areas during peripartum and early childhood.

Implementing strategies to prevent mother-to-child transmission (PMTCT) is important to achieve WHO HBV elimination goals by 2030. Currently, neither HBV screening during pregnancy nor birth vaccination are available in Mozambique. The Ministry of Health (MOH) is developing national hepatitis guidelines which will include a PMTCT component. In response, Médecins Sans Frontières (MSF) and MOH have piloted a Hepatitis B prevention strategy in a maternity unit of Maputo to establish a sustainable model of care.

Method: In an existing MOH maternity unit, we implemented systematic point-of-care HBV screening (Alere Determine®) by nurses at initial antenatal visits, in addition to standard-of-care HIV and syphilis testing. Women testing positive for HBsAg were further tested for HBV viral load (VL), HBeAg, HCV Antibodies (SD Bioline®), liver function, creatinine and full blood count. Tenofovir (TDF) was prescribed for women who: a) were co-infected with HIV, b) had high HBV VL (>200, 000 IU/ml) for PMTCT or c) met WHO treatment criteria. Midwives provided HBV birth dose vaccine within 24 hours for all exposed babies. Women who underwent testing between Novembers, 2017-18 were included in this analysis.

Results: 4161 pregnant women were screened for HBV. Of these, 145 (3.5%) were HBsAg positive, and their median age was 27.4 years (IQR 23.1-32.6). Of these, 54 (37.2%) were co-infected with HIV, and none with HCV. The median APRI score was 0.3 (IQR 0.2-0.4); only 3 women had APRI >1. Among HBsAg positive women, 15 (10.3%) were HBeAg positive. Of these, 9 (60%) had high HBV VL (>200 000 IU/ml); only one HBeAg negative woman had high VL. Among the ten patients with high VL, seven were receiving TDF as part of a regular ART (antiretroviral therapy) regimen, and three were initiated as HBV PMTCT.



Conclusion: The prevalence of HBV in our cohort (3.5%) exceeds the WHO threshold (2%) recommended for systematic HBV screening during antenatal care. In this high HIV endemic context, most women in need of HBV PMTCT were already receiving TDF. This intervention highlights the feasibility of incorporating HBV screening and care into existing MOH maternity services, including birth dose vaccination. Future analysis, including HBV testing of infants, will be conducted to evaluate outcomes and propose interventions in resource-limited settings.

THU-411

Effectiveness of direct: Acting antivirals for the treatment of viral hepatitis C in Rwanda

janvier serumondo[1], michael penkunas[2], Alida Ngwije[2], eric remera[1], Carol Liu[2], dieudonne sebuhoro[1], Justine Umutesi[1], clarisse musanabaganwa[3], prosper karame[3], gentille musengimana[1], corneille killy ntihabose[1], sabine umuraza[2], augustin mulindabigwi[1], julienne niyikora[2], soline mugeni[2], Cyprien Ntirenganya[4], athanase kiromera[5], Sabin Nsanzimana[1]. *[1]Rwanda biomedical center, HIV/AIDS, STIs and other blood borne infections division, kigali, Rwanda; [2]Clinton health access initiative, kigali, Rwanda; [3]Rwanda biomedical center, Medical research center, kigali, Rwanda; [4]Butare university teaching hospital, Internal medecine, huye, Rwanda; [5]University of Maryland, kigali, Rwanda*

Email: angwije@clintonhealthaccess.org

Background and aims: Direct-acting antivirals were first introduced in Rwanda in November 2015 replacing interferon-based therapies. Clinical trials conducted mainly in high-income settings have reported up to 95% of sustained virological response 12 weeks post treatment (SVR12). However, little is known about the real-world effectiveness of these drugs for treating chronic Hepatitis C (HCV) in resource-constrained settings. The aim of this study was to evaluate the effectiveness of DAAs recently implemented in Rwanda. In addition, factors associated with virological failure and non-virological due to premature treatment discontinuation are presented.

Method: De-identified demographic, clinical and HCV treatment data were extracted from national HCV program monitoring database. Data for all patients who initiated DAA-based treatment between November 2015 and March 2017 were included. Our primary outcomes consisted of patients who achieved SVR12 and those who were classified as non-virologicial failure. Univariable and multivariable logistic regression models were fit to estimate the relationship between patients' clinical and demographic characteristics and virological outcome.

Results: 894 patients initiated treatment during the study period and 590 completed the full treatment sequence. In our analysis, 91.5% (540/590; 95% CI = 88.9-93.6) of patients achieved SRV12. In an intention-to-treat analysis, 60.4% of patients achieved SVR12 (540/894; 95% CI = 57.1-63.6), 50 patients (5.6%; 95% CI = 4.2-7.4) experienced virological failure and 304 patients (34.0%; 95% CI = 30.9-37.2) were considered as discontinuing treatment prematurely. Having a pre-treatment viral load above the median split (800.000 copies/cml was associated with virological failure (aOR = 2.6; 95% CI = 1.3-5.1; $p < 0.01$). Patients residing in Western Province were more likely to discontinue care (aOR = 1.8; 95% CI = 1.14-2.98; $p = 0.01$) compared to those in Kigali, and the association between paying out-of-pocket and earlier discontinuation was trending towards statistical significance (OR = 1.6; 95% CI = 0.9-2.8; $p = 0.05$).

Conclusion: DAAs treatment was found to be effective when implemented through Rwanda's national health system. Decentralization and enhanced financing efforts are underway in Rwanda, which could improve access to treatment and clinical follow-up as the country embarks on its journey towards HCV elimination.

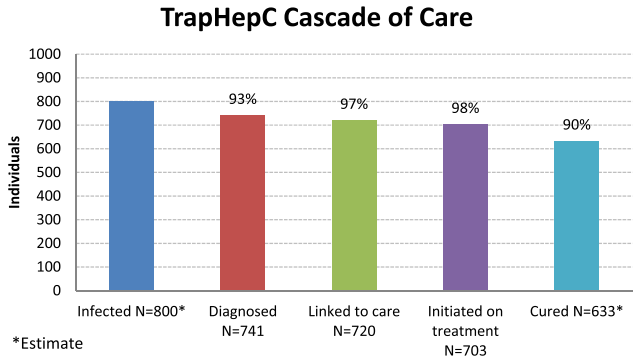
THU-412

Iceland may already have reached the WHO 2030 targets for diagnosis and treatment of hepatitis C virus infection: Results from the treatment as prevention for hepatitis C (Trap HepC) program

Sigurdur Olafsson[1,2], Ragnheidur H. Fridriksdottir[1], Thorarinn Tyrfingsson[3], Valgerdur Runarsdottir[3], Ingunn Hansdottir[3,4], Ottar M. Bergmann[1], Einar S. Björnsson[1,2], Birgir Johannsson[5], Bryndis Sigurdardottir[5], Arthur Löve[2,6], Gudrun Sigmundsdottir[7], Kamilla S Josefsdottir[7], Ubaldo Benitez Hernandez[8], Thorvardur Jon Love[2,8], Maria Heimisdottir[2,9], Magnús Gottfredsson[2,5,8,8]. *[1]Landspitali University Hospital, Department of Gastroenterology and Hepatology,*

Reykjavík, Iceland; [2]University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland; [3]SAA National Center for Addiction Medicine, Reykjavik, Iceland; [4]University of Iceland, Faculty of Psychology, School of Health Sciences, Reykjavík, Iceland; [5]Landspitali University Hospital, Department of Infectious Diseases, Reykjavík, Iceland; [6]Landspitali University Hospital, Department of Virology, Reykjavík, Iceland; [7]Directorate of Health, Chief Epidemiologist, Reykjavik, Iceland; [8]Landspitali University Hospital, Department of Science, Reykjavík, Iceland; [9]Icelandic Health Insurance, Reykjavik, Iceland
Email: sigurdol@landspitali.is

Background and aims: To achieve elimination of hepatitis C virus (HCV) as a major health threat, the World Health Organization (WHO) has set treatment service coverage targets of 90% diagnosis and treatment of 80% of eligible patients by the year 2030. Injection drug use (IDU) accounts for 90% of existing and almost all new HCV infections in Iceland. Most people who inject drugs (PWID) are routinely tested for HCV. Therefore, it is estimated that a small number of patients remain undiagnosed. Reporting to a national HCV registry is mandatory.
Method: Starting in 01/2016 with the TraP HepC program, all patients in Iceland infected with HCV are offered direct acting antivirals (DAAs), aiming for elimination of domestic transmission of HCV. PWID and prisoners are prioritized and various strategies are employed to enhance testing, linkage to care, and harm reduction. Untreated patients are identified and linked to care by cross-referencing several data sources including The HCV registry and Vogur Addiction Hospital database.
Results: In 2016, a total of 1287 HCV antibody positive individuals were identified in the HCV registry with additional 161 cases until 6/2018 for a total of 1448. When accounting for PCR negative, including previously treated and excluding temporary visitors, a total of 741 HCV PCR positive individuals currently living in Iceland were identified. The number of HCV tests increased from 5500 in 2015 to 8700 in 2017. No new infections were identified by outreach point-of-care testing among risk groups. Testing revealed a 30% infection rate among prison inmates, however, all had been diagnosed previously. As of November 2018, 720 patients (97% of those diagnosed) were linked to care. DAAs were initiated for 703 patients (98% of linked to care). Among 558 patients treated during the first 24 months, overall cure rate with first treatment attempt was 89%. Recent IDU was reported by 189 (34%). The majority of patients not achieving cure were retreated. On the basis of extensive screening among risk groups it is likely that >90% of domestic HCV infection have been diagnosed.



Conclusion: A major scale-up in testing and treatment for HCV in Iceland has resulted in a high rate of engagement and treatment. Iceland may already have reached the 2030 WHO service coverage targets of 90% diagnosis and treatment of 80% of eligible patients. Hopefully these results will translate into the elimination of HCV as a major health threat in Iceland.

THU-413

Service delivery for hepatitis C care: A systematic review and meta-analysis

Ena Oru[1], steve kanters[2], rohan shirali[2], Philippa Easterbrook[1]. *[1]World Health Organization, Global Hepatitis Programme, Geneva, Switzerland; [2]Precision Xtract, Boston, United States*
Email: orue@who.int

Background and aims: Worldwide, only a small proportion of those HCV infected persons have been diagnosed and treated. Increasing access to care in low-middle income countries (LMICs) will require adoption of simplified service delivery models such as decentralization and task shifting to non-specialists, and integrated testing and treatment at harm reduction sites. We conducted a systematic review and meta-analysis to establish their effectiveness on outcomes across the continuum of HCV care in different populations
Method: Bibliographic databases and conference abstracts were searched for clinical trials or observational studies published between 01/2008 to 02/2018 that evaluated interventions and outcomes along the HCV care cascade in PWID, prisoners (Pris), PLHIV, and general population (GenPop). Decentralisation was defined as either full (**FD**)-testing and treatment at same site, or partial (**PD**)- testing and referral for treatment**,** and task-shifting as HCV treatment by non-specialist physicians or nurses. Data was pooled using random effects meta-analysis
Results: 85 eligible studies from 19 countries (9 from LMICs) were included. 36 were in PWID, 12 in Pris, 2 in PLHIV, and 35 in the GenPop. 21 (25%) reported outcomes across the continuum of care, 21 (25%) the pre-treatment cascade only, and 43 (50%) treatment only. There was considerable heterogeneity in outcomes- Testing uptake (n = 18) 72% (95%CI 35-100) in PWID; 39% (95% CI 3-75) in GenPop; 40% (95%CI 21-59) in Pris. Linkage to care (n = 31) 58% (95%CI 41-75) in PWID; 72% (95% CI 58-86) in GenPop; 62% (95% CI 36-88) in Pris. Treatment uptake (n = 33) 69% (95%CI 46-72) in PWIDs; 52% (95%CI 36-67) in GenPop; and 71% (95%CI 60-80) in Pris. Among PWID, FD compared to PD had higher testing uptake: 88% (95%CI 78-98) vs. 47% (95%CI 4-99), and linkage to care: 80% (95%CI 62-98) vs. 53% (95%CI 30-76), but similar SVR rates: FD 93% (95%CI 89-97) vs PD 88% (95% CI 84-93). Results were similar for FD and PD in the GenPop. Task-shifting achieved similar SVR in both PWID 92% (95%CI 88-97) vs. 92% (95%CI 85-99) and GenPop 92% (95%CI 87-96) vs. 91% (95%CI 87-95)
Conclusion: Integration of testing and treatment with harm reduction for PWID achieved high levels of testing uptake and linkage to care. Decentralization and task-shifting achieved high levels of HCV cure in all populations. There is a need for more studies from LMICs and a more systematic approach to reporting outcomes across the continuum of care.

THU-414

Low rate of treatment uptake amongst recently released prisoners with active HCV infection

Tim Papaluca[1,2], George Tambakis[1], Anne Craigie[1], Lucy Mcdonald[1], Amy Edwards[1], David Iser[1], Jessica Howell[1], Paul Desmond[1], Mark Stoove[3], Margaret Hellard[3], Joseph Doyle[3], Alexander Thompson[1,2]. *[1]St. Vincent's Hospital Melbourne, Department of Gastroenterology, Fitzroy, Australia; [2]University of Melbourne, Parkville, Australia; [3]Burnet Institute, Melbourne, Australia*
Email: tim.papaluca@svha.org.au

Background and aims: There is high prevalence and incidence of HCV amongst prisoners. Prison treatment programs therefore provide an excellent opportunity to treat a marginalised population at high risk for transmission. However, short prison sentences mean that not all prisoners can be treated even in the context of comprehensive prison management programs (McDonald, J Hepatol, 2017; 66 (1) : S70 (PS-126)). There are no data about the rate of successful linkage to HCV care amongst recently released prisoners, a group who face many social challenges. We aimed to

determine the proportion commencing HCV therapy in the community amongst a group of recently released prisoners.
Method: Prisoners with HCV infection, who had been assessed as suitable for DAA therapy by our prison hepatitis program, but released prior to starting therapy, were included. Prior to release, prisoners were assessed by a hepatitis nurse; tests included HCV RNA and transient elastography. On release, all prisoners were referred to a local healthcare service for HCV treatment. All Australians are eligible for reimbursed HCV treatment, which can be dispensed in the community by primary care physicians. The primary outcome of this analysis was dispensing of HCV therapy within 6 months of release from prison, confirmed by the national medication prescribing database.
Results: Seventy-five HCV RNA positive prisoners were followed for 6 months post release. The mean age was 40 yrs, 66 (88%) were male, and 11 (15%) had cirrhosis. 59 (78%) prisoners identified as a person who injects drugs in the month prior to incarceration. 27 (36%) received opioid substitution therapy (OST) while incarcerated and psychiatric comorbidity was self-reported by 56 (75%). Only 19 (25%) were prescribed HCV therapy within 6 months of release. Of these, 7/19 (37%) were prescribed treatment on reincarceration. Predictors of treatment commencement were reincarceration ($p = 0.02$) and absence of cirrhosis ($p = 0.01$), but was not associated with OST, injecting drug use in the month prior to incarceration or psychiatric comorbidity.
Conclusion: The rate of HCV treatment post-release was low, despite all prisoners having been assessed as suitable for HCV treatment in prison, and HCV treatment being freely available in the community. The most important predictor of HCV treatment was reincarceration. These data emphasize the importance of maximizing treatment uptake during the period of incarceration. New models of care to improve linkage to community HCV treatment among recently released prisoners are required.

THU-415

Changing patterns of liver disease in Wales: First results from the Wales liver disease registry

Tom Pembroke[1,2], Gareth John[3], Berry Puyk[3], Jane Salmon[4], Andrew Yeoman[5]. *[1]Cardiff University, Cardiff, United Kingdom; [2]University Hospital of Wales, Cardiff, United Kingdom; [3]NHS Wales Informatics Service, Cardiff, United Kingdom; [4]Health Protection Division, Cardiff, United Kingdom; [5]Royal Gwent Hospital, Newport, United Kingdom*
Email: pembroket@cardiff.ac.uk

Background and aims: Liver disease is the third most common cause of premature death in the UK. At present major epidemiological studies have been based upon mortality data limiting our understanding of the true burden of liver disease and potential targets for service improvement. The Wales Liver Registry has been created as part of the Liver Disease Delivery Plan for Wales 2015-2020 to inform the effective provision of hepatology services within Wales.
Method: The Registry is populated by ICD10 code diagnoses from ONS mortality data and Patient Episode Database for Wales (PEDW) capturing all coded diagnoses of liver disease of inpatient and day case activity in Wales between 2001 and 2016. Data is pseudo anonymised with linking of recorded diagnoses, epidemiological and mortality data.
Results: Between 2001 and 2016 the number of new diagnoses of liver disease in Wales, based on relevant ICD10 coding, increased from 3354 in 2001 to 8115 in 2016. The incidence of each individual liver disease diagnosis increased during this period. Between the first 3 years (2001-3) and the final 3 years (2014-16) of the registry there was a 6-fold increase in fatty liver disease, 1.23 fold increase in alcohol related liver disease and 1.7 fold increase in viral hepatitis. Diagnoses of cirrhosis and portal hypertension, decompensated cirrhosis and primary liver cancer increased 2.1-, 1.7- and 2-fold respectively during this period.
Overall mortality of patients with liver disease remained static in Wales between 2001 and 2016 (mean = 1522 deaths per annum). Between 2001-3 and 2014-6 deaths in patients with fatty liver disease and liver cancer increased by 2.3 fold and 1.75 fold respectively. In contrast there was a decrease in deaths in those with alcohol related liver disease (30.2% reduction) and viral hepatitis (21.6% reduction) during this period.
Conclusion: Early analysis of the Wales Liver Disease Registry demonstrates a 2.5 fold increase in the number of new diagnoses of liver disease since 2006. There was a shift to fatty liver disease as the most common diagnosis within the defined groupings used for this analysis. Strikingly in spite of this increase in liver disease mortality rates have been static with improvements in mortality in individuals with alcohol related liver disease and viral hepatitis. We aim to further develop the Wales Liver Disease Registry with prospective data collection, incorporating all Wales primary care data and developing time to event analyses to identify opportunities for health interventions.

THU-416

Use of telemedicine as a cost-effective program to achieve microelimination of hepatitis C virus infection among patients in a public healt care system in a low-income country

Jose Luis Perez Hernandez[1], Marco Antonio Navarrete Prida[2], Fernando Rogelio Espinosa Lopez[2], Lourdes De la Cruz[2], Carlos Araiza Casillas[2], Alberto Castillo Fierro[2], Fatima Higuera De La Tijera[3,4]. *[1]Mexico City, hospital central sur de alta especialidad, Mexico City, Mexico; [2]Mexico City, Gerencia de servicios Medicos PEMEX, Mexico City, Mexico; [3]Mexico City, Gastroenterology, Mexico City, Mexico; [4]Mexico City, Gastroenterology, Mexico City, Mexico*
Email: josluiperez@hotmail.com

Background and aims: Direct antiviral agents (DAAs) are highly effective and safe; them have simplified the treatment of patients with hepatitis C virus infection (HCV). The use of communication technology allows avoiding the displacement of patients from remote places, reducing costs in health-care. *The Medical Services of Mexican Petroleum* (PEMEX) have 700, 000 health-care insured beneficiaries located throughout the country; the institution counts with 30 medical units divided into 8 regions throughout the country, including primary-care, regional centers, and specialty-care hospitals. Moving all the patients of the different regions of the country to Mexico City to receive antiviral treatment and follow-up by the gastroenterologist would be extremely expensive.
Aim: To evaluate the cost-effectiveness of a telemedicine as a part of an hepatitis C microelimination program among the Mexican insured population of PEMEX.
Method: A coordinator of the program in Mexico City, with experience on DAAs therapy was in charge to train through telemedicine using an internet platform, all primary-care physicians (PCP) responsible for treating HCV in the 8 different regions of the country. They were instructed on the criteria for selecting patients and how to prescribe the DAAs and their follow-up.
All patients diagnosed with HCV and susceptible to receive DAA therapy were included. They were prescribed: sofosbuvir/ledipasvir, sofosbuvir/velpatasvir, elbasvir/grazoprevir.
All of them were studied, treated and followed-up in their own region for their PCP with support of the coordinator of the program by telemedicine, all the decisions made by the PCP were supervised throughout the internet platform, phone-call or chat by the coordinator of the program and a group of specialists in Mexico City.
Results: We included for the analysis 116 patients, 83 F, 33 M, mean age 61.3 ± 11.40. Genotype 1 = 73, genotype 2 = 42, Genotype 3 = 1. 43 patients without significant fibrosis, and 73 cirrhotic: Child Pugh A = 63, B = 9, C = 1. All the viral loads at the end of treatment were reported negative (100% response), all patients were treated in a minimum of 4 visits in place of adscription through telemedicine, which saved $ 2400 per patient (includes the payment of per diem,

transportation, and disability) that makes a total of 324 800 dollars in total only by way of transfer to the capital. There were no serious side effects, so no treatment should be discontinued

Conclusion: It was possible to cure all patients (100%), there were no serious side effects. It stands out that 41 (35%) did not have significant fibrosis in such a way that they did not develop cirrhosis saved in the medium and long term economic and human resources for not developing this complication, as well as an excellent prognosis for all these patients. The use of telemedicine also generated significant savings because patients were not invested in their transfer.

THU-417

CURE-IT Program-Introducing equity, removing barriers and treating patients hepatitis C close to home: The Queensland experience

Hayley Thompson[1], Sarah Kentwell[1], Asim Khokhar[1], Tianhong Wu[1], Davoud Pourmarzi[2], James Thomas[1], Tony M Rahman[1,3]. *[1]The Prince Charles Hospital, Gastroenterology and Hepatology, Chermside, Australia; [2]Queensland University of Technology, Institute of Health and Biomedical Innovation, Medical Engineering Research Facility, Department of Public Health, Chermside, Australia; [3]James Cook University, Cairns Campus, Smithfield, Australia*
Email: tonyrahman@gmail.com

Background and aims: Background and aims: Healthcare delivery in Queensland has geographical challenges including distance, transport and distribution of specialists and services. HCV affects approximately 230 000 people in Australia. In 2016, the Pharmaceutical Benefits Scheme facilitated primary care prescribing of the new DAA's. Traditional HCV treatment occurred in tertiary hospitals, requiring patient travel, multiple attendances and missed appointments.

The "CURE IT Program" facilitates a shared model of care between community prescribers, hospital specialists, whilst providing clinical, financial and a best practice governance encouraging appropriate treatments. The "CURE IT" Program is "echo-lite," utilising a clinical nurse and hospital consultant offering daily advice to municipal, regional and remote communities, needle exchange workers and hospital prescribers. All patient treatments are facilitated by the treating GP close to home. Patients with advanced liver disease were referred pre or after treatments.

Method: From March 2016 all referrals to The Prince Charles Hospital were reviewed for suitability for CURE-IT. Simultaneously, community providers were engaged and provided with written and verbal education regarding HCV treatment and the "CURE IT" Program. Completed proforma's containing relevant information (patient demographics, medical history, ultrasound and laboratory results) were returned to the specialist, whereupon, following review patients were commenced on treatment in 1-2 business days. The average time taken for the specialist to review each request was 5-7 minutes.

Results: Between March 2016 and November 2018, 380 remote treatment requests were assessed:

371/380 (97.6%) patients approved for community based treatment.	350/380 (92.10%) patients GP commenced DAA therapy.	371/380 (97.63%) avoid hospital visits
9/380 (0.02%) patients referred for specialist review.	220/350 (62.85%) patients completed therapy.	218/220 (99%) achieving SVR
38/380 (10%) lived 70 –647km from Brisbane	>1200-1600 outpatient appointments avoided	>44, 000 kms of travel avoided

Conclusion: CURE-IT has redefined specialist healthcare delivery achieving SVR in 99% of patients, not one of whom have attended hospital. PROM's- Other end points have resulted in a "patient centred, patient focused program" factors most important to patients-treatment closer to home, treatment by a trusted GP, reduction of hospital visits, reduction in time lost from work, reduction in financial loss for patients, distance travelled by patients and this may all be doubled if partners also attended. The "CURE IT" Program has also had unintentional network gains including: dynamic collaborative relationships with primary care, increased awareness of HCV, liver disease, cirrhosis liver cancer and treatments, leading to upskilling of regional and rural healthcare workers.

THU-418

Community-based screening for significant liver fibrosis among apparently asymptomatic adults in Delhi

Archana Ramalingam[1,1], Bharathnag Nagappa[2], Ekta Gupta[3], Shantanu Dubey[4], Shiv Kumar Sarin[5]. *[1]Institute of Liver and Biliary Sciences, Assistant Professor, Epidemiology, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Senior Resident, Epidemiology, New Delhi, India; [3]Institute of Liver and Biliary Sciences, Additional Professor, Virology, New Delhi, India; [4]Institute of Liver and Biliary Sciences, Medical Operations, New Delhi, India; [5]Institute of Liver and Biliary Sciences, Senior Professor, Hepatology and Director, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: Community-based screening for liver fibrosis using non-invasive methods like Transient Elastography (TE) can play a major role in enabling early diagnosis of Chronic Liver Diseases (CLD). This study aims to find out (i) the proportion of subjects with significant liver fibrosis and its predictors, (ii) the number needed to screen (NNS) to detect one subject with significant fibrosis among apparently asymptomatic adults in the community.

Method: A cross-sectional study was done among asymptomatic adult volunteers (age ≥ 18 years) from the catchment areas of 72 randomly chosen "*Mohalla clinics*" (Primary healthcare clinics in Delhi), using a mobile screening van. A pre-tested questionnaire was used to collect demographic data and past and personal history of the subjects. Post the interview; a trained research team performed TE to obtain liver stiffness measurement (LSM), HBsAg, Anti-HCV and a venous blood sample was collected to test for alanine aminotransferase (ALT) and Total Cholesterol (TC). LSM ≥ 8.0 kPa and >13.0 kPa were taken as cutoffs suggesting clinically relevant/significant liver fibrosis and cirrhosis, respectively. Data were entered in Microsoft Excel and analysed using STATA ver. 14.

Table 1: Predictors of significant liver fibrosis among study subjects using multivariable logistic regression

Predictor	Reference	Adjusted Odds Ratio with 95% Confidence Intervals (CI)	p value
Age		1.02 (1.01-1.03)	< 0.001*
Gender			
Male	Reference		
Female		0.43 (0.35-0.51)	< 0.001*
ALT levels			
Normal	Reference		
Raised ALT		3.28 (2.71-3.97)	< 0.001
BMI			
18.5-22.9 (Normal)	Reference		
< 18.5 (Underweight)		2.22 (1.24-3.97)	0.007*
23-24.9 (Overweight)		1.21 (0.80-1.84)	0.36
25-29.9 (Obese)		1.87 (1.34-2.61)	< 0.001*
≥ 30 (Morbidly obese)		4.06 (2.95-5.60)	< 0.001*
History of DM and/or HTN			
No	Reference		< 0.001*
Yes		1.85 (1.52-2.26)	
Anti-HCV			
Non-Reactive	Reference		
Reactive		2.96 (1.18-7.38)	0.02*

*significant; Model R^2: 13.3%.

Results: A total of 4928 subjects were screened; 54.6% were men and the median age of subjects was 41 years. Significant liver fibrosis was seen among 13.9% of the study subjects and 3.4% had cirrhosis. The NNS to detect one subject with significant fibrosis was 7.1. Table 1 describes the independent predictors for significant liver fibrosis.
Conclusion: Almost 14% of asymptomatic adults were found to have significant liver fibrosis in New Delhi, indicating the urgent need for mass screening campaigns to detect asymptomatic patients.

THU-419

Prevalence of hepatitis B and C virus infections in Mongolian children and adolescents

Khishigtogtokh Sereenendorj[1], Maralmaa Enkhbat[1], Miriam Eichner[2], Khatantuul Boldbaatar[2], Bekhbold Dashtseren[1], Purevjargal Bat-Ulzii[1], Zulkhuu Genden[1], Anir Enkhbat[1], Myagmarjav Budeebazar[1], Naranjargal Dashdorj[1,2], Naranbaatar Dashdorj[1,2], Dahgwahdorj Yagaanbuyant[1]. *[1]Liver center, Ulaanbaatar, Mongolia; [2]Onom foundation-Оном сан, Ulaanbaatar, Mongolia*
Email: m.eichner@onomfoundation.org

Background and aims: Since decades Mongolia ranks among the countries with highest prevalence of hepatitis B (HBV) and C (HCV) virus infection. In 2013 HBV and HCV prevalence among the general adult population was estimated to be 11.1 and 8.5%, respectively. To tackle the burden of disease the Mongolian government took several measures. An HBV vaccination program for newborns was already introduced in 1991 and has been further improved since then. In 2016 the Parliament of Mongolia officially adopted the Hepatitis Prevention, Control, and Elimination (HPCE) Program into the 2016-2020 Action Plan aiming to eliminate viral hepatitis by 2020. Free hepatitis screening for the population aged 15 years and older as well as two treatment campaigns providing access to affordable HCV treatment were initiated.
We determined the current HBV and HCV prevalence among Mongolian children and adolescents, to assess whether there is need for further action specifically targeting this age group.
Method: A total of 3403 randomly selected children and adolescents (aged 0 to 24 years) from 17 Mongolian provinces were enrolled in a cross-sectional study. HBV surface antigen (HBsAg) and HCV antibody (anti-HCV) was tested on site using rapid diagnostic tests (CTK Biotech) on finger stick blood.
Results: Among a total of 3403 individuals aged 0 to 24 years we found 64 HBsAg- and 44 anti-HCV-positives, which were distributed unevenly between different age groups (**Table**).

Table: HBsAg and anti-HCV prevalence among Mongolian children and adolescent.

Age group	0-4n = 715	5-9n = 720	10-14n = 700	15-19n = 672	20-24n = 596	totaln = 3403
HBsAgn, (%)	6 (0.73)	7 (1.0)	11 (1.6)	4 (0.6)	36 (6.0)	64 (1.9)
anti-HCVn, (%)	7 (1.0)	3 (0.4)	8 (1.1)	10 (1.5)	16 (2.7)	44 (1.3)

Prevalence of HBsAg among the four age groups of individuals aged 0 to 19 years was low. While HBsAg-prevalence was comparable between these age groups, it was higher in individuals aged 20 to 24. This might be explained by lower quality and technique of vaccination 20 years ago. Anti-HCV-prevalence was generally low and tendentially increasing with age.
Conclusion: Overall HBsAg- and anti-HCV-prevalence within Mongolian children and adolescent was relatively low.
We therefore see no urgent need for further improvement of the HBV vaccination program or the inclusion of individuals below 15 years of age group in the population-wide hepatitis screening.

THU-420

Examination of patient and provider perceptions of hepatitis C care in Rwanda

janvier serumondo[1], Alida Ngwije[2], michael penkunas[3], Justine Umutesi[1], julienne niyikora[2], sabine umuraza[2], Gentille Musengimana[1], colton halverson[2], Makuza Jean Damascene[1], clarisse musanabaganwa[4], Prosper Karame[4], cyprien ntirenganya[5], Soline Mugeni[2], Athanase Kiromera[6], Sabin Nsanzimana[1]. *[1]Rwanda biomedical center, HIV/AIDS, STIs and other blood borne infections, kigali, Rwanda; [2]Clinton health access initiative, Hepatitis program, kigali, Rwanda; [3]Clinton health access initiative, kigali, Rwanda; [4]Rwanda biomedical center, Medical Research Center, Kigali, Rwanda; [5]Butare university teaching hospital, Internal medecine, huye, Rwanda; [6]University of Maryland, kigali, Rwanda*
Email: angwije@clintonhealthaccess.org

Background and aims: In Rwanda, estimates suggest that hepatitis C seroprevalence ranges between 3.1% to 4.1% in the general population and 4.5%-4.7% among people living with HIV. Direct-acting antivirals (DAAs) were introduced in Rwanda in November 2015 with four specialist physicians prescribing DAAs at four tertiary hospitals, one specialized laboratory for viral load testing, and one pharmacy supplying DAAs. The current study aimed to explore patients and healthcare providers' perceptions and experiences of the barriers and facilitators to DAA-based treatment in Rwanda in the early days of this major shift in service delivery.
Method: Semi-structured, face-to-face interviews were conducted with 39 patients treated with DAAs and 10 healthcare providers who managed HCV treatment from November 2015 to March 2017. Patients within each treatment outcome classification (achieved SVR12, virological failure and treatment discontinuation) were assigned a randomly generated number in Microsoft excel, stratified by hospital. Interview transcripts were translated into English and analysis was guided by a general inductive approach.
Results: According to patients**,** the availability of DAAs in Rwanda was in itself a motivator patients were grateful that they could access these drugs. The positive relationship patients shared with health-care providers and the support received from family and friends were reported as the main facilitators to treatment. From the perspective of healthcare providers, the lack of stigma around HCV, a motivated healthcare staff and mild side effect profile of DAAs increased patients' adherence to treatment. Barriers reported by patients included limited knowledge around liver health and HCV, difficulties in accessing testing and treatment services due to financial hardship and the centralized nature of treatment services. Healthcare providers reported heavy workloads, need for additional HCV-specific training for nurses and occasional communication break-downs with the central-level as barriers.
Conclusion: To our knowledge, this is the first study to identify barriers and facilitators to DAA-based treatment from the perspectives of patients and healthcare providers in sub-Saharan Africa. We found a suite of interrelated factors that enabled and impeded care at both the individual-and system-level. There was a high-degree of consistency between patient's and healthcare providers, suggesting that these factors were represented widely in the healthcare system. Results from this study can be used to design and enact evidence-informed interventions to help maximize the impact of DAAs as Rwanda moves towards HCV elimination.

THU-421

Lower alcohol taxes are associated with increased liver transplant listing

Nicole Shen[1,2], Michael Raver[1], Nicholas Hutchison[1], Arun Jesudian[1], Jeremy Bray[3], Bruce Schackman[4], Robert Brown[1]. *[1]New York Presbyterian Hospital-Weill Cornell, Medicine-Division of Gastroenterology and Hepatology, New York, United States; [2]Weill Cornell Medicine, Medicine-Division of Clinical Epidemiology and*

Evaluative Sciences Research, New York, United States; [3]University of North Carolina at Greensboro, Bryan School of Business and Economics, Economics, Greensboro, United States; [4]Weill Cornell Medicine, Medicine-Division of Health Policy, New York, United States
Email: nts9004@nyp.org

Background and aims: Alcoholic liver disease (ALD) is a leading indication for liver transplantation worldwide with rising prevalence. Whether relationships exist between transplant listing for ALD and changes in state alcohol tax rates or alcohol consumption has not been explored.
Method: State-level alcohol per capita consumption of spirit, wine, and beer was determined from published United States 2003-2015 data. Excise and ad valorem on- and off-premise tax rates of spirit, wine, and beer were calculated following standard practices. Using the United Network for Organ Sharing (UNOS) database, we analyzed 2003-2015 state-wide patient-level data to determine if transplant listing for ALD was associated directly with alcohol consumption per capita and inversely with alcohol taxes. Univariate and multivariate regression was performed with clustering at the state level controlling for the pre-specified variables age, sex, race, education, employment, and insurance.
Results: Of 137, 440 patients listed for liver transplant, 21.2% (29, 161) were for ALD, with increasing prevalence over time, up to 25.0% in 2015. Compared to all other patients, patients listed for ALD were more likely to be older, men, of White, Hispanic, or American Indian/Alaska Native race/ethnicity, unemployed, and with less education and private insurance ($p < .01$). Multivariate analysis indicated increased listing for ALD was associated with increased consumption of spirit (OR 1.67, 95% CI 1.12-2.49, $p = .01$); for each additional gallon of ethanol per capita of spirit consumed, patients were more likely to be listed for liver transplant for ALD. Multivariate analysis including consumption and taxation did not significantly affect consumption findings, and suggested a significant inverse relationship of spirit excise tax on-premise (OR.85, 95% CI.72-1.00, $p = .05$) and off-premise (OR.85, 95% CI.72-.99, $p = .04$) (Table 1); i.e. as spirit excise tax decreased, listing for ALD increased.

Table 1: Multivariate regression for liver transplant listing for Alcoholic Liver Disease (ALD) by alcohol consumption and tax, controlling for age, sex, race, education, employment, and insurance

	On-premise			Off-premise		
	OR	95% CI	p	OR	95% CI	p
Spirit						
Consumption	1.73	1.14, 2.62	.01	1.71	1.11, 2.64	.02
Tax, excise	.85	.72, 1.00	.05	.85	.72,.99	.04
Wine						
Consumption	1.52	.96, 2.41	.08	1.50	.99, 2.27	.06
Tax, excise	.43	.11, 1.64	.22	.44	.13, 1.42	.17
Beer						
Consumption	1.29	.79, 2.11	.30	1.27	.80, 2.03	.32
Tax, excise	.04	.00, 1.44	.08	.04	.00, 1.44	.08

Conclusion: Listing for liver transplantation for ALD was directly associated with alcohol per capita consumption and inversely associated with spirit excise taxes. These findings suggest a possible public health benefit of increasing spirit taxes.

THU-422

Referral, treatment uptake and self-reported barriers in drug users diagnosed with active hepatitis C attending a low-threshold methadone program in Lisbon

Mario Jorge Silva[1], Cláudia Pereira[2], Rafaela Loureiro[1], Paulo Lopes[2], Ivone Água-Doce[3], Elsa Belo[2], Helena Cores Martins[3], Rodrigo Coutinho[2], Filipe Calinas[1,4], Elizabeth Padua[3].
[1]Gastrenterologia, Hospital Sto. António dos Capuchos, Centro Hospitalar de Lisboa Central, Lisboa, Portugal; [2]Associação de Recuperação de Toxicodependentes Ares do Pinhal, Lisboa, Portugal; [3]Laboratório Nacional de Referência VIH/VHC e B, Instituto Nacional de Saúde, Lisboa; [4]Serviço de Gastrenterologia, Hospital Sto. António dos Capuchos, Centro Hospitalar de Lisboa Central, Lisboa, Portugal
Email: elizabeth.padua@insa.min-saude.pt

Background and aims: A previous study conducted between June 2015 and May 2016 on 825 drug users attending a mobile low-threshold methadone program (LTMP) in Lisbon, revealed that 68.4% of individuals with antibodies to HCV had active hepatitis C (n = 307) and among them, 30.0% had advanced liver fibrosis (*Eur J Gastroenterol Hepatol 2017*). At that time, a referral to conventional medical care for all participants with active hepatitis C was performed. After two years' time passed, the aim of the study is to evaluate the referral and treatment uptake of those HCV infected patients and to characterize possible barriers to treatment.
Method: Cross-sectional rollover study in previously selected drug-users with active hepatitis C (n = 307) performed during October 2018 and implemented by a self-completion of a questionnaire. The Ethics Committee of the National Institute of Health approved the study.
Results: Of the 307 individuals with hepatitis C diagnosed in the previous study, 191 were still attending the LTMP and of those, 150 individuals agreed to participate in this evaluation.
Among patients with advanced liver fibrosis in 2015-2016 assessment, 62.0% (26/42) reported to remember having mild liver disease or not to remember their liver disease stage.
Since the previous diagnosis and referral, only 67.1% (n = 100) were evaluated at least once in a hospital consultation due to hepatitis C, 45.0% (n = 67) initiated treatment and 27.5% (n = 41) were successfully treated, while 15.4% (n = 23) wait for assessment of treatment response.
The most frequent barriers to referral and treatment reported by treatment-naïve patients not followed-up in hospital consultations (38.3%; n = 57) were: costs of transport to hospital (53.8%; n = 28); long wait for consultation (50.0%; n = 26); costs of consultation fees (48.1%; n = 25) and perception that hepatitis C is not a severe medical problem (35.8%; n = 19).
Additionally, 73.7% (n = 42) of these untreated and unfollowed patients would prefer to be treated for hepatitis C at the low-threshold program rather than on a hospital-basis.
Conclusion: More than 2 years after confirmed diagnosis of hepatitis C and referral to conventional health care, a significant proportion of the patients did not access specialized care and therefore were not treated for hepatitis C, mainly due to economic and social barriers. Individualized medical-social strategies are needed to timely treat these individuals at their specific contexts.

THU-423

Patient group monitoring of implementation of WHO viral hepatitis C recommendations: Identifying the gaps between policy and practice in Europe

Samya R Stumo[1], Adam Palayew[2], Mojca Maticic[3,4], Ammal M Metwally[5,6], Greet Hendrickx[7], Tatjana Reic[8], Jeffrey Lazarus[1]. *[1]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain; [2]McGill University Department of Epidemiology, Biostatistics, and Occupational Health, Montreal, Canada; [3]Clinic for Infectious Diseases and Febrile Illnesses, University Medical Centre, Ljubljana, Slovenia; [4]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [5]National Research Centre, Giza, Egypt; [6]Association of Liver Patient Care, Dakhlyia, Egypt; [7]Viral Hepatitis Prevention Board, Centre for the Evaluation of Vaccination, Vaccine and Infectious Diseases Institute, University of Antwerp, Antwerp, Belgium; [8]European Liver Patients' Association (ELPA), Brussels, Belgium*
Email: Jeffrey.Lazarus@isglobal.org

Background and aims: The viral hepatitis C continuum of care (CoC) was adopted by WHO in 2016 to define the major steps in comprehensive care for viral hepatitis: prevention, testing, linkage

to care, treatment, and chronic care. This study aims to determine patient perspectives on the discrepancies between policy and practice to support efforts to eliminate viral hepatitis as a public health threat.

Method: Twenty-five organisations from the European Liver Patients' Association, each representing one country, were engaged in a survey in October 2018 to monitor implementation of national viral hepatitis policies. The cross-sectional survey was disseminated electronically via REDCap. Respondents received questions based on validated data sources that confirmed the existence of that policy in their country or, where unavailable, based on specific WHO policy recommendations. Participants were queried using a 5-point Likert scale on the degree to which the policies were functioning or implemented in practice. Questions were distributed between four components of the HCV CoC: 4 prevention questions (n = 61 total responses), 2 testing (n = 28), 23 linkage to care (n = 575), and 5 treatment (n = 52). Results were analysed descriptively using R.

Results: Among policies pertaining to the four domains (Fig 1) of the viral hepatitis CoC, patient groups reported the highest level of positive implementation for HCV treatment policies (67.3%), followed by prevention (54.1%), linkage to care (53.4%), and testing (46.5%). Linkage to care received the largest share of strong negative responses (12.5%) compared to testing (10.7%), treatment (3.8%), and prevention (3.3%). Data from individual questions in the linkage to care component revealed that patient groups reported the highest negative response on targeting of viral hepatitis services for transgender people (64%), and for migrants and sex workers (56%); while integration of HCV care within existing services was reported to be negative, "not at all" or "slightly" integrated, in the case of migrant health services (60%), alcohol use (52%), and non-communicable disease services (48%) (data not shown).

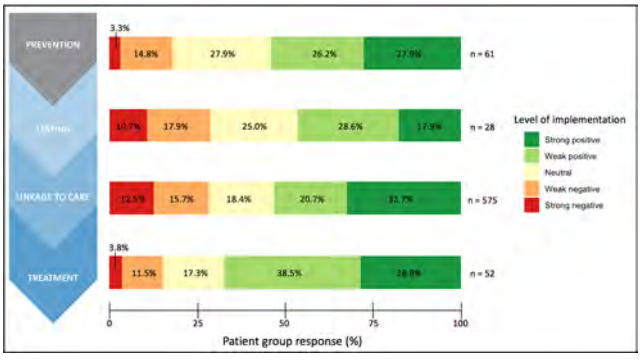


Figure 1: Level of implementation of policies across the viral hepatitis continuum of care in 25 European countries

Conclusion: Patient group respondents in 25 countries reported that the level of implementation of HCV policies and recommendations in practice in Europe remains incomplete across the continuum of care, especially in areas of linkage to care, testing, and services for vulnerable populations.

THU-424

HCV care cascade of PWIDs reached within the Global Fund needle and syringe program in Georgia

Ketevan Stvilia[1], Irma Khonelidze[2], Amiran Gamkrelidze[3], Alexander Asatiani[2], Marine Gogia[4], Guranda Jikia[4], Khatuna Kutateladze[4]. *[1]National Center for Disease Conctrol and Public Health, Tbilisi, Georgia; [2]National Center for Disease Conctrol and Public Health, Global Fund Programs Implementation Unit, Tbilisi, Georgia; [3]National Center for Disease Conctrol and Public Health, Director General, Tbilisi, Georgia; [4]Georgian Harm Reduction Network, Tbilisi, Georgia*
Email: k.stvilia@ncdc.ge

Background and aims: Within the Global Fund HIV Program HCV screening is integrated in the PWID comprehensive service package to support Georgian hepatitis C elimination program. HCV AB screening positive PWIDs were followed across the HCV care to develop PWID HCV care cascade for 2018.

Method: HCV AB rapid test screening is provided by nurses at the Needle and Syringe Program (NSP) Drop-in centers (16 sites) and mobile ambulatories (6 units) as well as by peer PWIDs countrywide in Georgia. PWIDs who agree to provide personal ID are registered in the National hepatitis C elimination database, others are registered in the HIV prevention program database with 15 digit unique identifier number.

All HCV AB positive PWIDs are referred for HCV RNA testing to HCV treatment sites or collected samples for core-Ag confirmatory testing are sent to the National Reference Laboratory (Lugar Center). The National Hepatitis C Elimination Database allows tracking of those PWIDs who are registered by personal ID across full continuum of HCV care.

Results: During 10 months of 2019 total 23914 PWIDs were reached within the NSP program out of which 13, 836 were screened on HCV AB with 3324 (24%) positive results. 1221 PWIDs agreed to provide personal ID for registration in hepatitis C elimination database, out of which 865 (70.8%) were HCV AB positive and were enrolled in the HCV care cascade analysis. HCV RNA testing was performed for 608 (70.2%) PWIDs with 84% (511) positivity rate. 255 (49.9%) PWIDs were enrolled in HCV treatment with a mean of 59.7 (± 54) days of led time from confirmation to treatment. Mean time from HCV AB testing to RNA testing was 16.7 days (± 37.8 days). Mean time for full HCV care cascade of PWIDs from screening to enrollment in treatment program was 74 days (± 51.1 days), with the minimum the same day enrollment and the maximum of 298 days prior initiation of treatment.

Conclusion: Despite the continues efforts to support hepatitis C elimination program through the Global Fund Needle and Syringe Program in Georgia, the number of PWIDs enrolled in HCV treatment remains small. Due to criminalization of drug use PWIDs are reluctant to provide personal information that complicates the monitoring of PWIDs across HCV care. More community based peer accompanied referral interventions and/or NSP integrated HCV treatment programs are necessary to increase the number of PWIDs enrolled in the treatment as well as to decrease the time from HCV AB screening to HCV treatment initiation.

THU-425

Questioning the concept of cure: The morbidity and mortality of a homeless population following HCV treatment

Julian surey[1,2], Dee Menezes[3], Marie Francis[1,2], John gibbons[2,4], Binta Sultan[1], Alistair Story[2], Ibrahim Abubakar[1]. *[1]University College London, Institute of Global Health, London, United Kingdom; [2]UCLH NHS Trust, FindandTreat, London, United Kingdom; [3]University College London, Institute of Health Informatics, London, United Kingdom; [4]Groundswell, London, United Kingdom*
Email: j.surey@ucl.ac.uk

Background and aims: Underserved populations such as the homeless have high rates of both hepatitis C (HCV) and alcohol use. Difficulties in accessing specialist care services means that they have a high risk of liver disease. Treating homeless populations for HCV is possible if services reach-out into the community however morbidity and mortality can remain disproportionately high compared with the general population. We studied the morbidity and mortality rates of homeless and underserved individuals infected with HCV.

Methods: The HepCare project, co-funded by the European Commission, aims to outreach HCV screening to at-risk underserved populations. In London, we worked alongside the FindandTreat team's mobile health unit, using HCV point-of-care tests and a portable Fibroscan to determine liver fibrosis, to individuals accessing homeless and drug services. Chronically infected HCV

individuals and those with severe fibrosis or cirrhosis were referred and supported into specialist care. Peer support workers were trained alongside the clinical team to screen individuals and improve linkage to care. Information was gathered on demographics and risk factors, plus linkage to care, treatment outcomes, SVR and all-cause mortality
Results: Over 20 months 461 individuals attending homeless or drug services in London were screened, the majority (78.7%) were male; the median age was 45.7 years (IQR 39-52); most were UK born (76.6%) and a total of 197 people (42.7%) were found to be chronically infected with HCV. Drug use was common with 329 (71.4%) having ever injected and 125 (27.1%) currently injecting. Problem alcohol use was high with a third (33.6%) consuming more than 50 units per week. Fibroscan was carried out on 283 individuals and over 1 in 4 (22.7%) had advanced fibrosis or liver cirrhosis (>F3). We found that the age-standardised all-cause mortality rate for our cohort was much higher than the general population (SMR 3.8, 95% CI 1.8-8).
Conclusions: There is a high burden of morbidity and mortality in this group compared with the general population. It is also likely that the above estimate is conservative, given that deaths were only recorded for those who were identified as being chronically infected, and not the entire screened cohort. This population clearly has a high burden of disease and will need specialist strategies to improve the cascade of care, integration with other services and will require a re-appraisal of the concept of cure.

THU-426
Further validation of a liver "traffic light" test as a prediction model for survival and development of serious liver-related events

Rochelle Sylvester[1], nick sheron[1]. [1]*University Hospital Southampton NHS Foundation Trust, CES Division Faculty of Medicine, Level E South Block, Southampton, United Kingdom*
Email: rds1g15@soton.ac.uk

Background and aims: Deaths from liver disease are continuing to rise despite huge advances in healthcare. Many non-invasive methods for liver fibrosis detection have been created, including the Southampton Liver Traffic Light (SLTL) test. However, few are sufficiently validated, especially in predicting serious liver-related events (SLE) or effectiveness in the community; the SLTL aims to achieve this.
Method: Clinical data from 4854 patients (community and secondary-care) with suspected liver disease were prospectively analysed over a mean follow-up period of 54 months (range 1-181 months). The SLTL is an algorithm incorporating hyaluronic acid, procollagen-3 N-peptide (P3NP), and platelet count results. It ultimately grades patients for liver fibrosis: green (low risk), amber (intermediate risk), red (high risk). AUROC analysis and survival graphs were established for predicting mortality and development of SLE, including varices and ascites.
Results: More deaths were observed within the red group of patients 280/1585 (17.7%) compared to amber 31/873 (3.6%) and green 49/2396 (2%) groups. A higher proportion of SLE was observed within the red group (29.5%) compared to amber (5.6%) and green (2%) groups. Survival plots demonstrated significantly increased mortality and development of SLEs in the red group compared with green and amber groups (Mantel-Cox, $p < 0.001$), with a further finding of significant increase in development of SLE in the amber group compared to green (Mantel-Cox, $p < 0.001$). Additionally, patients whose grade remained red over the follow-up period had lower survival than those who improved to amber (Mantel-Cox, $p < 0.001$) or green (Mantel-Cox, $p = 0.001$). AUROC analysis of the graded and continuous SLTL test results achieved prognostic values of 0.75 and 0.82 for mortality, respectively, and 0.80 and 0.87 for development of SLE, respectively. SLTL further demonstrated the ability to rule out risk of death and development of SLE based on achieving NPVs of 98% and 97%, respectively.
Conclusion: The SLTL test has been validated for predicting survival and development of SLE in the community. It could aid primary care decisions for risk management and referrals to specialists in the overall hope to detect liver disease earlier in the general population.

THU-427
A community-based fast-track seek-test-treat program to enhance diagnosis and linkage to care for hepatitis C infection among people who inject drugs in Athens, Greece (ARISTOTLE HCV-HIV program)

Vana Sypsa[1], Georgios Kalamitsis[2], Dimitrios Paraskevis[1], Mina Psichogiou[3], Sotiris Roussos[1], Georgios Daikos[4], George Papatheodoridis[5], Angelos Hatzakis[1]. [1]*National and Kapodistrian University of Athens, Dept. of Hygiene, Epidemiology and Medical Statistics, Athens, Greece;* [2]*Hellenic Liver Patient Association "Prometheus," Athens, Greece;* [3]*First Department of Medicine, Medical School, National and Kapodistrian University of Athens, Greece, Athensq, Greece;* [4]*First Department of Medicine, Medical School, National and Kapodistrian University of Athens, Greece, Athens, Greece;* [5] *National and Kapodistrian University of Athens, Greece, Department of*

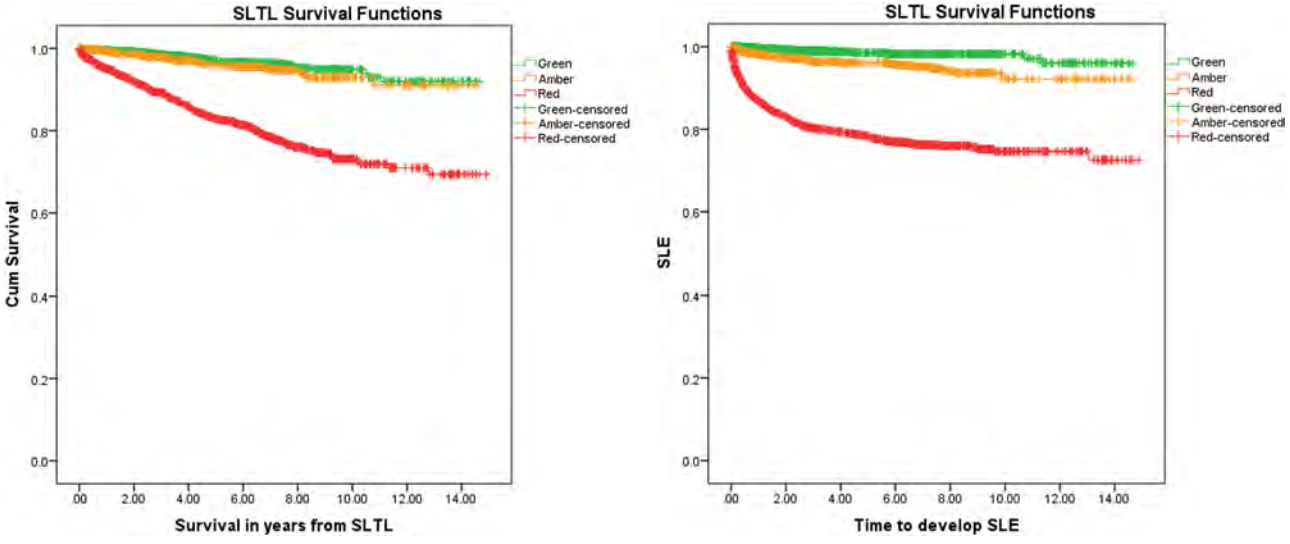

Figure: (abstract: THU-426)

Gastroenterology, Medical School, Athens, Greece
Email: vsipsa@med.uoa.gr

Background and aims: Approximately 80% of PWID who seek opioid substitution treatment (OST) in Athens are anti-HCV (+). It is estimated that annual treatment rates with DAAs of 4%-8% would reduce HCV prevalence in this population by 46%-90% in 2030. However, diagnosis and treatment rates remain low. We aim to describe a program designed to increase diagnosis and linkage to HCV care among active PWID in Athens.
Method: ARISTOTLE HCV-HIV is a "seek-test-treat" community-based program where PWID are recruited using chain-referral sampling with monetary incentives. Participation includes interviewing, fibroscan evaluation, blood testing (anti-HCV/HBsAg/anti-HIV, genotype in case of HCV/HIV coinfection or fibroscan ≥ 7.0 kPa, i.e. fibrosis ≥ F2, biochemical evaluation), counseling and linkage to care. PWID eligible for DAAs with available social security number are entered to the national HCV treatment registry to obtain treatment approval. A network of collaborating clinicians was set up and a peer-navigator accompanies patients to their first appointment with them. We present data until September 2018, i.e. before fibrosis-based treatment restrictions were removed in Greece.
Results: In a period of 5 months (April 2018-September 2018), 1, 088 PWID were recruited; 75.6% were active injectors (injecting in the past month) and 22.4% were on OST. Prevalence of anti-HCV and of HCV/HIV coinfection was 78.1% and 16.6%, respectively. At baseline, only 2.4% of anti-HCV (+) reported DAAs treatment. Out of 1088 PWID, 159 (14.6%) fulfilled treatment criteria due to HCV/HIV coinfection. In the remaining 665 PWID with HCV monoinfection, 37.9% had chronic hepatitis C/fibroscan ≥ 7.0 kPa whereas a substantial proportion (56.7%) had fibroscan < 7.0 kPa and, thus, were not eligible for treatment. Genotypes 1, 3 and 4 were identified in 34.0%, 53.6% and 11.4% of patients, respectively. Out of those with HCV monoinfection, 70.6% had available social security number and were entered to the treatment registry.
Conclusion: Community-based peer-driven chain referral allowed to reach rapidly a large number of active PWID not linked to OST. In the presence of treatment restrictions, approximately 4 out of 10 PWID with HCV monoinfection were eligible for DAAs; this would increase to 9 out of 10 if restrictions were removed. The majority of patients fulfilling treatment criteria were entered in the national treatment registry and efforts to issue social security numbers for the remaining is ongoing.

THU-428

Routine point of care antenatal screening of hepatitis B virus in windhoek, Namibia: Feasibility of implementation

Cynthia Tamandjou[1], Susan Cleary[2], Charles Wiysonge[3], Josef Mufenda[4], Dorothea Diergaardt[5], Wolfgang Preiser[1,6], Monique Andersson[1,7]. *[1]Stellenbosch University, Division of Medical Virology, Cape Town, South Africa; [2]University of Cape Town, Health Economics Unit, Cape Town, South Africa; [3]South African Medical Research Council, South African Cochrane Centre, Cape Town, South Africa; [4]Windhoek Hospital Complex, Department of Obstetrics and Gynaecology, Windhoek, Namibia; [5]Ministry of Health and Social Services, Division of Family Health, Directorate of Primary Health Care Services, Windhoek, Namibia; [6]National Health Laboratory Services, Virology, Cape Town, South Africa; [7]Oxford University Hospitals NHS Foundation Trust, Department of Infectious Diseases and Microbiology, Oxford, United Kingdom*
Email: 16959531@sun.ac.za

Background and aims: Elimination of mother-to-child transmission (MTCT) of hepatitis B virus (HBV) infection in sub-Saharan Africa is achievable. Identifying pregnant women at high risk of transmitting the infection to their infants is a key step in implementing prophylaxis. Currently, hepatitis B surface antigen (HBsAg) screening for pregnant women in Namibia is performed using a laboratory-based immunoassay. This study aimed to determine the feasibility and costs associated with implementing rapid test-based screening for HBV in pregnant women in Namibia.
Method: Consented pregnant women were counselled and screened for HBsAg by trained healthcare workers at participating antenatal clinics in Windhoek, using the Determine™ HBsAg rapid test. Venous blood was collected from all positive patients and a subset of negative patients for confirmatory laboratory-based HBsAg testing on the ARCHITECT i2000SR analyser to infer the diagnostic performance of the rapid test. Acceptance and usability of the rapid test from the perspective of the healthcare workers were assessed through a user-appraisal questionnaire. All resources including consumables, health-care workers' time, building space and facilities (and their quantity) were measured and valued to determine the costs of providing HBsAg screening at the clinics, in comparison to laboratory testing.
Results: A total of 515 pregnant women participated in the study; 28 (5.4%) tested HBsAg-positive. All 28 positive and 268 out of 487 negative results were laboratory-confirmed to be true, giving a sensitivity and specificity of 100%. All six healthcare workers involved in the study found the test simple to use. They showed preference for rapid testing over laboratory testing for routine antenatal screening of HBV; believing that this method would improve the care of pregnant women. The full cost of rapid testing was approximately US$6 in comparison to US$18 for the HBsAg test at the laboratory.
Conclusion: Screening using rapid testing is a cost-effective and feasible alternative for detecting HBV infection in pregnant women. The rapid test used in this study showed acceptable performance, and its roll-out was supported by the healthcare workers participating in the study. Implementation of this intervention, as part of the strategy for eliminating MTCT of HBV infection, is therefore feasible in a low resource setting like Namibia.

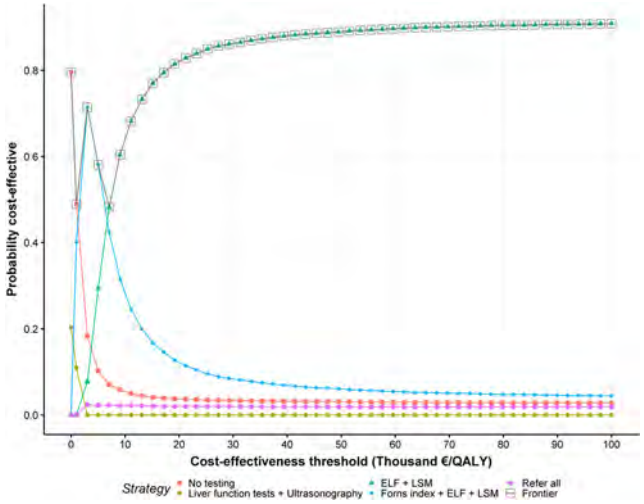
THU-429

Serial testing with the enhanced liver fibrosis test and liver stiffness is cost-effective for detection of advanced alcoholic liver disease in primary care

Maja Thiele[1,2], Lars Asphaug[3], Aleksander Krag[1,2], Hans Olav Melberg[3]. *[1]Odense University Hospital, Department of Gastroenterology and Hepatology, Odense C, Denmark; [2]University of Southern Denmark, Department of Clinical Research, Odense C, Denmark; [3]University of Oslo, Institute of Health and Society, Oslo, Norway*
Email: maja.thiele@rsyd.dk

Background and aims: Alcoholic liver fibrosis is a preventable disease that is largely asymptomatic until decompensated cirrhosis occurs. Primary care based screening of individuals with excessive alcohol consumption could reveal those with progression to advanced fibrosis earlier. We therefore aimed to evaluate the cost-effectiveness of screening for advanced fibrosis in primary care patients with an excessive alcohol consumption, using the Danish health care sector as examplar.
Method: The target population was 45-year olds with a history of excess drinking for at least one year. We evaluated screening with three strategies: 1) standard-of-care using routine liver function tests applied in parallel with follow-up ultrasonography for test-positives, 2) the enhanced liver fibrosis (ELF test) serum marker, with follow-up liver stiffness measurement (LSM) for positives above 10.5, and 3) three-tier strategy using the indirect marker Forns Index to control before strategy two. We compared the screening strategies to no testing and direct referral of all to outpatient FibroScan. We used a decision model of linked decision trees and Markov state-transition models informed by extracted data from published literature. The primary outcomes were lifetime quality-adjusted life-years (QALYs) and direct health care costs.
Results: The optimal screening strategy was ELF test and LSM follow-up, which correctly identified the true disease status of 97.9%. At an incremental cost-effectiveness ratio of €5, 707 per QALY gained, the strategy had an 80% chance of being cost-effective. This result was

robust to probabilistic sensitivity analysis. The Forns-index followed by ELF and LSM had the best positive predictive value and the lowest incremental cost-effectiveness ratio (€1, 005 per QALY gained), but a lower negative predictive value and resulted in worse patient outcomes over the lifetime according to our model. The strategy of referring all to LSM had the best negative predicted value, but lower effectiveness and higher costs. Standard-of-care had lower effectiveness and higher incremental cost-effectiveness ratio.



Conclusion: Primary care based screening for advanced alcoholic fibrosis is likely a cost-effective intervention. The optimal strategy was serial testing with the ELF test, followed by liver stiffness measurement if positives, while the cheapest strategy included adding Forns test first in the sequence.

THU-430

Changing prevalence of aetiological factors among Australians hospitalized for cirrhosis

Patricia Valery[1], Richard Skoien[2], Tony Rahman[3], Paul Clark[4], James O'beirne[5], Gunter Hartel[1], Katherine Stuart[6], Steven Mcphail[7], Rohit Gupta[8], Elizabeth Powell[6]. *[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia; [2]Royal Brisbane and Women's Hospital, Brisbane, Australia; [3]The Prince Charles Hospital, Brisbane, Australia; [4]Mater Hospitals, Brisbane, Australia; [5]Sunshine Coast University Hospital, Sunshine Coast, Australia; [6]Princess Alexandra Hospital, Brisbane, Australia; [7]Queensland University of Technology, Brisbane, Australia; [8]Logan Hospital, Logan, Australia*
Email: patricia.valery@qimrberghofer.edu.au

Background and aims: Cirrhosis is a major global public health problem, due largely to obesity-related non-alcoholic fatty liver disease (NAFLD), hazardous alcohol consumption and chronic viral hepatitis B (HBV) and C (HCV). In the past two decades, important preventive and treatment strategies have been put in place in many countries to halt transmission HBV and HCV. However, decreases in the number of new cases of cirrhosis due to these causes may be offset by increasing levels of obesity and its metabolic complications, and sustained alcohol consumption in many countries. In a population-based study of patients with cirrhosis, we examined changes in aetiology of liver disease leading to hospital admission over the 9-year period.
Method: Hospital data on all patient admissions during 2008-2016 in the state of Queensland were obtained. We identified 30, 327 hospital admissions for cirrhosis in 10, 254 adult patients.
Results: The commonest aetiology was alcohol-related cirrhosis (49.5%), followed by cryptogenic cirrhosis (28.5%), HCV (14.6%), NAFLD/NASH (4.8%) and HBV (3.3%). Males were most commonly admitted than females apart from in NAFLD/NASH cirrhosis (55.9%). Whilst the prevalence of alcohol-related cirrhosis remained stable over the 9-year period ($p = 0.410$), there were increases in the prevalence of HCV, HBV, NAFLD/NASH and cryptogenic for men and women (see Figure for men), and the proportion of patients allocated two or more aetiological factors increased from 17.1% in 2008-2010 to 30.0% in 2014-2016 ($p < 0.001$). The average prevalence of chronic HCV nearly doubled between 2008 and 2010 (11.2%) and 2014-2016 (21.4%; $p < 0.001$), that of cryptogenic was 26% higher in 2014-2016 (25.8% vs. 32.6%, $p < 0.001$) and the prevalence of chronic HBV and NAFLD/NASH were about 60% higher (2.6% vs. 4.1% for HBV, $p = 0.003$ and 3.8% vs.6.0% for NAFLD/NASH, $p < 0.001$). The prevalence of patients not allocated to any aetiology decreased during this time-period (21.3% vs 16.3%, $p < 0.001$).

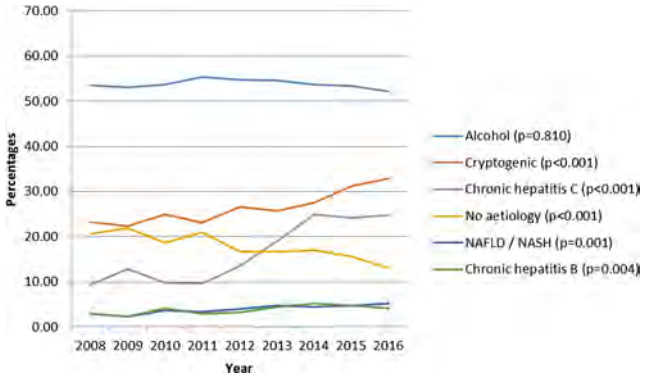


Figure: Trends in prevalence of selected aetiology among men

Conclusion: Our data highlights the increasing importance of HCV and cryptogenic/NASH/NAFLD, and to a lesser extent HBV, as contributing factor for cirrhosis. Strategies to prevent cirrhosis should be a major public health priority. The large number of cryptogenic cirrhosis suggests that more diagnostic support and specialist input may be important to help refine diagnosis for patients and to better understand the epidemiology of liver disease.

THU-431

The burgeoning growth in cirrhosis-related hospitalization in Australia, 2008-2016

Elizabeth Powell[1], Richard Skoien[2], Tony Rahman[3], Paul Clark[4], James O'beirne[5], Gunter Hartel[6], Katherine Stuart[1], Steven Mcphail[7], Rohit Gupta[8], Peter Boyd[9], Patricia Valery[10]. *[1]Princess Alexandra Hospital, Brisbane, Australia; [2]Royal Brisbane and Women's Hospital, Brisbane, Australia; [3]The Prince Charles Hospital, Brisbane, Austria; [4]Mater Hospitals, Brisbane, Australia; [5]Sunshine Coast University Hospital, Sunshine Coast, Australia; [6]QIMR Berghofer Medical Research Institute, Brisbane, Australia; [7]Queensland University of Technology, Brisbane, Australia; [8]Logan Hospital, Logan, Australia; [9]Cairns Base Hospital, Cairns, Australia; [10]QIMR Berghofer Medical Research Institute, Population Health, Brisbane, Australia*
Email: patricia.valery@qimrberghofer.edu.au

Background and aims: While chronic liver disease is a major global public health problem, it has not been recognized as a National Health Priority Area in Australia. A population-based study using hospital admission data for cirrhosis in the large state of Queensland, Australia during 2008-2016 was performed.
Method: Hospital data on all patient admissions (public and private) and deaths during 2008-2016 in the state of Queensland were obtained. Queensland is a large state in the north-east of Australia with a population of 4.9 million. We identified all hospital admissions for cirrhosis for patients aged 20 years or older. We reported age-standardized hospitalization rates/10, 000 person-years by gender and per calendar year, in-hospital case fatality rate among these admissions (n = 30, 327) and examined the factors associated with hospital deaths.

Results: Age-adjusted hospitalization rates increased by 32% between 2008 and 2016, from 8.50/10, 000 (95%CI 8.18-8.82) to 11.21/10, 000 (95%CI 10.87-11.54). Admission rates peaked in men at 34.03/10, 000 in 55-59 year-olds. The age-standardized admission rate for Indigenous Australians was 32.79/10, 000 (95%CI 31.28-34.31). Alcohol misuse was a contributing factor in over half (55.1%) of all admissions, and in 26.8% of admissions patients resided in most socio-economically disadvantaged areas. The overall in-hospital case fatality rate was 9.7% for males and 9.3% for females, and decreased significantly in males from 10.25% in 2008 to 8.32% in 2016 ($p < 0.001$). Admissions associated with hepatorenal syndrome (AOR = 7.24, 95%CI 5.99-8.75), HCC (AOR = 2.53, 95%CI 2.20-2.91), hepatic encephalopathy (AOR = 1.94, 95%CI 1.61-2.34), acute peritonitis (AOR = 1.93, 95%CI 1.61-2.33), jaundice (AOR = 1.82, 95%CI 1.20-2.75) and age ≥ 70 years (AOR = 1.63, 95%CI 1.38-1.92) were significantly associated with in-hospital mortality. A higher Charlson comorbidity index ($p = 0.021$), longer length of hospitalization ($p < 0.001$) and residence outside of a "major city" ($p < 0.001$) were also significantly associated with in-hospital mortality.

Conclusion: Our data highlights the increasing healthcare use by Australians with cirrhosis and this has major resource and economic implications. Greater awareness and emphasis on preventive care is needed to reduce the increasing prevalence of cirrhosis and the personal, social and economic burden of its complications.

THU-432

Viral sustained response in chronic hepatitis C did not reduce short term heatlh expediture

Mercedes Vergara Gómez[1,2], Emili Vela[3], Montserrat Clèries[4], Caridad Pontes[3], Mireia Miquel[5,6]. [1]*Parc Tauli Sabadell Hospital Universitari. Institut d'Investigació i Innovacio 3PT. Universitat Autonoma de Barcelona, Hepatology Unit. Digstive Disease System, Sabadell, Spain;* [2]*Instituto Carlos III, CIBERehd, Madrid, Spain;* [3]*Servei Catala de la Salut, Area del medicament, Barcelona, Spain;* [4]*Servei Catala de la Salut, Unitat d'Informació i coneixements, Barcelona, Spain;* [5]*Parc Tauli Sabadell Hospital Universitari. Institut d'Investigació i Innovació 3PT. Universitat Autònoma de Barcelona, Hepatology Unit. Digestive Disease Service, Sabadell, Spain;* [6]*Instituto Carlos III, Madrid, Spain*
Email: mvergara@tauli.cat

Background and aims: Viral sustained response in chronic hepatitis C virus seems to reduce the health expenditure by diminishing the hepatic and extrahepatic complications. The aim of our study was to analyse health-expenditure of these patients before and after antiviral treatment.

Method: The health expenditure of patients treated from 2015 to 2017 in Catalonia (an area of Spain) with direct-acting antiviral agents was analysed comparing the period pre-treatment (until the end of treatment) and post-treatment period. Data source: Registry of Patients and Treatments (RPT) and Registry of Morbidity and Use of Health Services of Catalonia (MUSSCAT).

Results: 12, 683 patients were treated in Catalonia for chronic hepatitis C by direct antiviral agents (2, 740 in 2015, 5, 782 in 2, 016, 4, 161 in 2017). Of these, 11.9% did not have fibrosis (F0-F1), 25.2% moderate fibrosis (F2), 59.6% significant fibrosis or cirrhosis (F3-F4) and 3.3% fibrosis not determined (ND). The median time of follow-up after treatment was 16.5 ± 8.5 months. Service's use (rates per 100 patients/year) before and after treatment was as follows: hospital admissions: 30.2 vs 36.4; Hospital admissions due to complications of cirrhosis: 2.9 vs 2.7; hospital days: 172.8 vs 183.3; visits to Primary Care: 1, 112.0 vs 1, 220.3, visits as outpatient's hospital: 743.6 vs 694.1; medications dispensed: 436.6 vs 580.1. When stratified by fibrosis-degree, a significant decrease of 12.2% in the number of admissions due to complications of cirrhosis is observed. A decrease in outpatient visits is also observed in F2 (11.9%), F3-F4 (8.9%) and ND (19.5%); and days of hospitalization in the F0-F1 (10.1%) and in the F2 (27.1%).

Conclusion: Antiviral treatment of chronic hepatitis C virus does not reduce the use of short-term health resources, except for the number of admissions due to complications of cirrhosis, number of out-patient's visits for patients with advanced liver fibrosis, and hospitalization's days for patients with a milder degree of fibrosis

THU-433

Availability of information in drug labels for appropriate prescribing in patients with hepatic impairment

Rianne A. Weersink[1,2], Lotte Timmermans[1,3], Margje H. Monster-Simons[1,4], Peter G.M. Mol[1,4], Herold J. Metselaar[5], Sander D. Borgsteede[2,5], Katja Taxis[1]. [1]*University of Groningen, Groningen, Netherlands;* [2]*Health Base Foundation, Houten, Netherlands;* [3]*Catholic University of Leuven, Leuven, Belgium;* [4]*Dutch Medicines Evaluation Board (CBG-MEB), Utrecht, Netherlands;* [5]*Erasmus University Medical Centre, Rotterdam, Netherlands*
Email: rianne.weersink@healthbase.nl

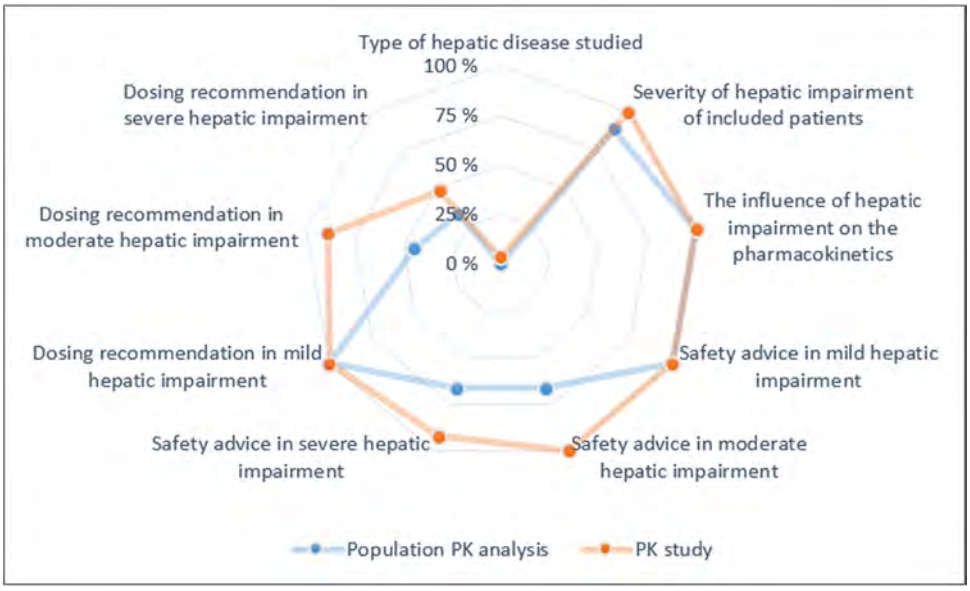

Figure: (abstract: THU-433): Available information in drug labels on use in hepatically impaired patients, based on PK study (n = 27) or population PK analysis (n = 9), expressed in percentage of available information.

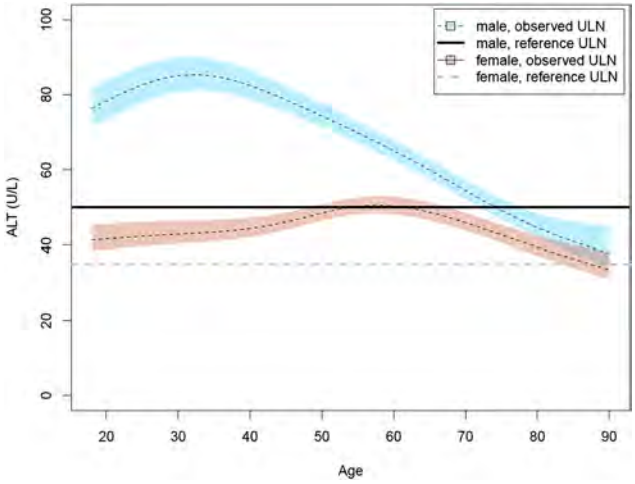
Background and aims: Before new drugs are authorized, the influence of hepatic impairment on the pharmacokinetics (PK) needs to be determined. In Europe, these PK studies are performed and described in the label, i.e. the Summary of Product Characteristics (SmPC) according to the European Medicines Agency (EMA) guideline from 2005. We aim to evaluate the availability of information on hepatic impairment in drug labeling and the relevance of this information for clinical practice.
Method: We reviewed the information on patients with hepatic impairment included in SmPCs of new medicines authorized by the EMA between 2015 and 2017. We evaluated the completeness and clarity based on nine required information items described in the EMA guideline. This evaluation resulted in an availability and an applicability score.
Results: The SmPCs of 51 medicines were analysed. A PK study in patients with hepatic impairment was conducted in 27 (53%), the impact of hepatic impairment was evaluated using population PK analysis in nine (18%) and for 15 (29%) medicines no study was conducted. The SmPCs contained 81% (range 67-100%) of required information for medicines with a dedicated PK study, and 67% (range 44-89%) for those using population PK analyses (Figure 1). For these 36 medicines with PK data, 59% of the information was conclusive, 16% ambiguous and 25% was not available. Low scoring items were: "definition of hepatic impairment" (no conclusive SmPC) and "safety advice in severe hepatic impairment" (14 conclusive SmPC). This safety advice was often ambiguously described as "use with caution" or "not recommended to use."
Conclusion: While the labels score well in terms of completeness of information, the definition and description of the patients with hepatic impairment is often unclear and inconsistent. This can negatively influence the practical use by healthcare professionals.

THU-434

Poorly chosen upper limits of normal for alanine aminotransferase may burden the patient and health system unnecessarily

David Petroff[1], Olaf Bätz[2], Katrin Jedrysiak[2], Jan Kramer[2], Thomas Berg[3], Johannes Wiegand[3]. [1]*University of Leipzig, Clinial Trial Center, Leipzig, Germany;* [2]*LADR Laboratory, Geesthacht, Germany;* [3]*University of Leipzig, Department of Gastroenterology, Leipzig, Germany*
Email: johannes.wiegand@medizin.uni-leipzig.de

Background and aims: Upper levels of normal (ULN) for alanine aminotransferase (ALT) generally take sex into account, but not age. This simplification may lead to misclassification in a relevant proportion of the population and may burden the patient and health system unnecessarily.
Method: Consecutive blood samples from 2015-2017 were analysed from a large laboratory (LADR Geesthacht) servicing medical practices. All blood samples were considered in which ALT, AST, or GGT were measured. The definition "upper limit of normal" of a laboratory value often corresponds to the 95th percentile of a healthy population. In our analysis, the ULN for ALT is 35 U/L for women and 50 U/L for men. Sensitivity analyses included healthy subsets (excluding patients with hepatitis B (HBsAg or anti-HBc positive) or at risk for non-alcoholic fatty liver disease (NAFLD) presenting with either elevated GGT, triglycerides, cholesterol, HbA1c, or glucose (according to Prati, Ann Intern Med 2002) and one random sample per patient). A subset of healthy subjects was considered that was being checked up because of occupational regulations and not for health reasons. Age was categorized in decades (18-24, 25-34, 35-44, etc.).
Results: A total of 1, 369, 162 blood samples were available from 601, 780 adult patients (51% female, mean age 58). ALT was measured in 1, 000, 486 of these blood samples. There is an extreme age dependence in ALT values for men: Elevated values were seen in 20.0% (95% CI 19.5% to 20.4%) of patients between the ages of 25 and 34, but only 6.7% (95% CI 6.4% to 7.0%) between the ages of 65 and 74. The 95th percentile reaches values above 80 U/L instead of 50 U/L at the age of 35 and falls to below 50 U/L by the age of 75 (Figure 1). Results do not change if one sample per patient is considered. The sub-population of healthy individuals showed similar qualitative results. Here, elevated ALT values were seen in 11.5% (95% CI 11.1% to 12.0%) of patients between the ages of 25 and 34 and 2.7% (95% CI 2.4% to 3.0%) between the ages of 65 and 74. These results were very similar in the healthy "occupational" subset.
There is only a weak age dependence in women in contrast to men (Figure 1).



Conclusion: Currently used reference values for ALT imply that subsequent diagnostics are needed for a large proportion of young men. Our data beg the question whether age-adapted reference values for ALT are needed.

THU-435

A threshold analysis for the cost-effectiveness of hepatitis B and hepatitis C testing in emergency departments in the UK

Jack Williams[1,2], Peter Vickerman[2,3], Sam Douthwaite[4], Gaia Nebbia[4], Laura Hunter[5], Terry Wong[6], Murad Ruf[7], Alec Miners[1,2]. [1]*London School of Hygiene and Tropical Medicine, Department of Health Service Research and Policy, London, United Kingdom;* [2]*The National Institute for Health Research Health Protection Research Unit (NIHR HPRU) in Blood Borne and Sexually Transmitted Infections at University College London, London, United Kingdom;* [3]*University of Bristol, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom;* [4]*Guy's and St Thomas' NHS Trust, Department of Infection, London, United Kingdom;* [5]*Guy's and St Thomas' NHS Trust, Emergency Department, London, United Kingdom;* [6]*Guy's and St Thomas' NHS Trust, Department of HIV/GU Medicine, London, United Kingdom;* [7]*Gilead Sciences, Medical Department, London, United Kingdom*
Email: jack.williams@lshtm.ac.uk

Background and aims: The prevalence of blood borne viruses (BBVs) is higher in emergency department (ED) attendees compared to the general population, due to higher attendance of marginalised populations. Studies have suggested prevalence up to 2% and 2.9% for hepatitis B (HBV) and hepatitis C (HCV) in EDs in England, although this varies considerably across regions. HIV testing in EDs in the UK is recommended in high prevalence areas (prevalence of 0.2% or higher), but there is no defined threshold for hepatitis testing. Hepatitis testing for those already receiving blood tests in EDs could provide an efficient setting to diagnose and treat those living with hepatitis.
Method: A Markov model was developed to analyse the impact of opt-out hepatitis C (HCV) and hepatitis B (HBV) testing in EDs in the UK. The model used data from studies of ED testing in the UK to

parameterise test costs and intervention effects (contact rates and linkage to care). For HCV we used an antibody test cost of £3.64 and RNA test cost of £68.38, and assumed a direct acting antiviral treatment cost of £10, 000. For HBV, we used a HBsAg test cost of £3.51 and annual treatment costs of £3, 672 for pegylated interferon-alpha and £578 for tenofovir disoproxil fumarate. We considered what prevalence of HCV (RNA-positive) and HBV (HBsAg) would be required to make ED testing cost-effective at a threshold of £20, 000 willingness to pay (WTP) per quality adjusted life year (QALY) gained. The model used a lifetime time horizon.

Results: The prevalence required for ED testing to be cost-effective was 0.3% HCV RNA prevalence, and 0.2% HBsAg prevalence, under our base case parameters (Figure). The prevalence thresholds were sensitive to the cost of the diagnostic tests and the linkage to care achieved (proportion of patients contacted with diagnosis, attend referral and receive treatment).

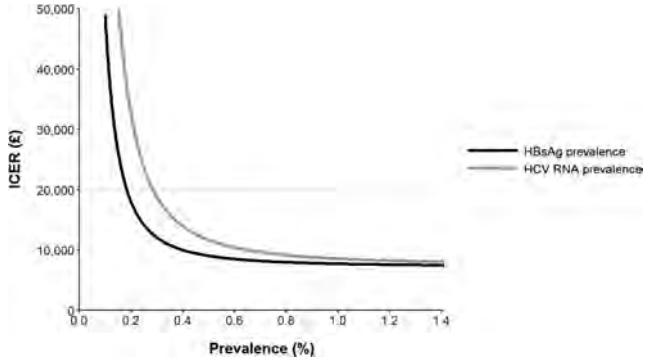


Figure: Incremental cost-effectiveness ratio (ICER) by HCV Ag and HBsAg prevalence

Conclusion: Early evidence suggests that ED testing and ED based linkage to care for HCV and HBV is likely to be cost-effective in many geographical areas across the UK, based on current studies of prevalence amongst ED attendees. Additional studies are required to evaluate ED testing across regions, using epidemiological, linkage to care and cost data specific to each region. This can help provide robust estimates to inform public health guidelines in the UK.

THU-436

The cost-effectiveness of one-time birth cohort screening for hepatitis C as part of the National Health Service health check programme for 40 to 74 year olds in England

Jack Williams[1,2], Alec Miners[1,2], Ross Harris[3], Sema Mandal[2,3], Ruth Simmons[2,3], Georgina Ireland[2,3], Matthew Hickman[4,5], Charles Gore[6], Peter Vickerman[2,4,5]. *[1]London School of Hygiene and Tropical Medicine, Department of Health Service Research and Policy, London, United Kingdom; [2]The National Institute for Health Research Health Protection Research Unit (NIHR HPRU) in Blood Borne and Sexually Transmitted Infections at University College London, London, United Kingdom; [3]Public Health England, National Infection Service, London, United Kingdom; [4]University of Bristol, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom; [5]NIHR HPRU in Evaluation of Interventions at University of Bristol, Bristol, United Kingdom; [6]The Hepatitis C Trust, London, United Kingdom*
Email: jack.williams@lshtm.ac.uk

Background and aims: Hepatitis C (HCV) birth cohort screening has been implemented in the US, but there is little evidence of its cost-effectiveness in England. The national health service (NHS) offers a health check for 40 to 74 years olds in primary care in England every five years, to assess and reduce a person's risk of heart disease, diabetes, kidney disease and stroke. This health check could provide a platform for HCV testing.

Method: A Markov model was developed to estimate the cost-effectiveness of adding HCV testing to the NHS health check, for individuals in birth cohorts between 1950 and 1979. The model also aimed to identify areas of uncertainty in the model and the key drivers of cost-effectiveness. Prevalence estimates were derived from a population based model of HCV burden in England (0.1% to 0.27% amongst attendees). We assumed the intervention costs were a HCV antibody test and nurse time. Due to uncertainty, two data sources were used for disease transition probabilities; published estimates used in other economic evaluations, and transition probabilities estimated from the population based model. We assumed direct acting antiviral (DAA) treatment costs of £10, 000. Results are presented as incremental cost-effectiveness ratios (ICERs) per quality adjusted life year (QALY) gained, with a £20, 000 per QALY willingness to pay threshold. We estimated the value of information (VoI), representing the maximum value for future research to reduce all uncertainty in the model.

Results: Base case ICERs ranged from £7, 394 to £24, 388 and £17, 517 to £45, 803 across birth cohorts for the two sources of HCV transition probabilities, respectively (Figure). The intervention is most likely to be cost-effective for those born in the 1970's, with lowest ICERs in this birth cohort. The model was most sensitive to the HCV transition probabilities, the probability of referral and receiving treatment, and the prevalence of HCV. The maximum VoI across all birth cohorts was £10.5 million, with the highest value for future research in the probability of referral and receiving treatment, HCV transition probabilities, and the utility associated with achieving a sustained virological response.

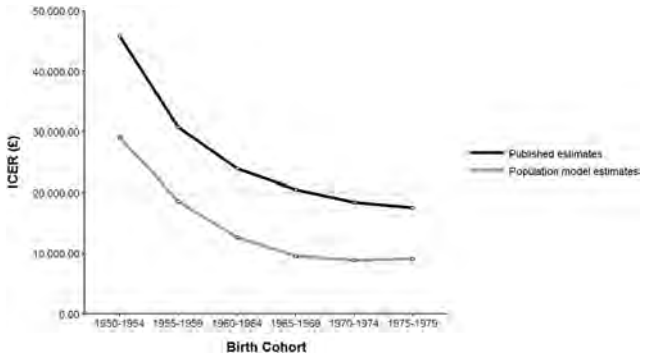

Figure: Cost-effectiveness of birth cohort screening across birth cohorts, by source of transition probability

Conclusion: There is considerable uncertainty in the cost-effectiveness of birth cohort screening for HCV as part of the NHS health check in England. We show further studies are warranted to reduce uncertainty in cost-effectiveness estimates, particularly for younger birth cohorts (1970s) in which the intervention is most likely to be cost-effective.

THU-437

The Global Epidemiology on non-alcoholic fatty liver disease and non-alcoholic steatohepatitis in patients with type 2 diabetes mellitus: A systematic review and meta-analysis

Zobair Younossi[1,2], Pegah Golabi[2], Leyla Deavila[2], James Paik[2], Manirath Srishord[2], Natsu Fukui[1], Ying Qiu[3], Leah Burns[3], Arian Afendy[4], Fatema Nader[4]. *[1]Center for Liver Diseases-, Department of Medicine, Inova Fairfax Medical Campus, Falls Church, United States; [2]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, United States; [3]Worldwide Health Economics and Outcomes Research, Princeton, United States; [4]Center for Outcomes Research in Liver Disease, Washington DC, United States*
Email: zobair.younossi@inova.org

Background and aims: Although NAFLD and NASH are closely associated with T2DM, the global prevalence of T2DM and NAFLD is

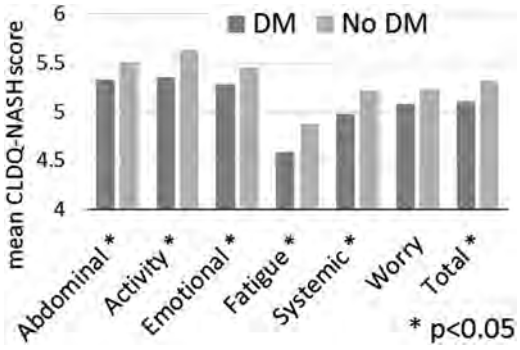
not well described. Aim: To assess the global prevalence of NAFLD in patients with T2DM.
Method: PubMed, Ovid-Medline, EMBASE and Web of Science were searched from January 1989 to September 2018 for terms involving NAFLD, NASH and T2DM. Strict exclusion criteria was applied. Review articles, abstracts, population including pediatric, bariatric surgery, type 1 diabetics, and non-English articles were excluded. Pooled NAFLD prevalence was calculated using random-effects models. Prevalence rates for NAFLD were stratified according to geographic region. Potential sources of heterogeneity were investigated using sub-group analyses and meta-regression.
Results: Of the 1685 studies, 99 met criteria (N = 222, 816 subjects with T2DM) from 25 countries. Pooled overall global NAFLD prevalence among diabetics was 61.1% (95% CI: 57.2 to 64.8, I2 = 99.5%). The predicted rate of T2DM+NAFLD was 5, 185 per 100, 000 global population. Meta-regression models showed that region, age and diagnostic method ($p < .05$) were associated with NAFLD prevalence and jointly accounted for 75.9% of heterogeneity. Among T2DM, South America (73.8% [52.4-87.8]) had the highest prevalence of NAFLD, followed by Europe (70.0% [65.7-73.9]), Oceania (70.3% [59.0-80.0]), South Asia (61.1% [53.0-68.6]), West Asia (59.1% [33.8-80.4]), East Asia (55.3% [51.2-59.3]), United States (53.1% [26.1-78.4]), and Africa (32.0% [10.6-65.0]). Over a follow-up of 5-10.9 years, pooled all-cause, CVD, and liver-related mortalities among T2DM+NAFLD patients were 11.9% (95% CI: 2.7 to 40.2, I2 = 95.2%), 2.1% (95% CI: 0.4 to 9.7, I2 = 73.8%), and 1.6% (95% CI: 0.2 to 13.8, I2 = 78.0%). A total of 808 biopsies (9 studies) documented a pooled overall NASH prevalence of 64.0% (95% CI: 53.4-73.4, I2 = 86.3%) in NAFLD patients with T2DM. This NASH prevalence rates were 56.8% (95% CI: 40.7-71.6) for United States, 61.1% (95% CI: 36.3-81.2) for South America, 56.4% (95% CI: 46.2-66.0) for East Asia, 66.9% (95% CI: 49.1-80.9) for South Asia, and 93.8% (95% CI: 66.5-99.1) for Oceania. Also, in this group, advanced fibrosis (stages F3-F4) was reported in 10 articles comprising 1, 250 subjects with the pooled overall prevalence of 10.4% (95% CI: 5.2-19.9, I2 = 92.6).
Conclusion: This study provides global prevalence rates for NAFLD, NASH and fibrosis in T2DM that can inform models to estimate its clinical and economic burden.

THU-438

The presence of type 2 diabetes is independently associated with impairment of patient-reported outcomes in patients with non-alcoholic steatohepatitis

Zobair Younossi[1,2], Maria Stepanova[3], Manuel Romero Gomez[4], Takeshi Okanoue[5], Michael Trauner[6], Stephen Djedjos[7], Robert Myers[7], Issah Younossi[8], Andrei Racilla[8], Fatema Nader[8].
[1]Center for Liver Diseases-, Department of Medicine, Inova Fairfax Medical Campus, Falls Church, United States; [2]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, United States; [3]Center for Outcomes Research in Liver Diseases, Washington DC, United States; [4]Hospital Universitario Virgen del Rocio, Sevilla, Spain; [5]Saiseikai Suita Hospital, Osaka, Japan; [6]Medical University of Vienna, Division of Gastroenterology and Hepatology, Vienna, Austria; [7]Gilead Sciences, Foster City, United States; [8]Center for Outcomes Research in Liver Disease, Washington DC, United States
Email: zobair.younossi@inova.org

Background and aims: Non-alcoholic steatohepatitis (NASH) is highly prevalent in patients with type 2 diabetes (T2DM). Patients with NASH and T2DM experience higher rates of adverse clinical outcomes. Aim: To assess the impact of T2DM on Patient-Reported Outcomes (PROs) of patients with NASH.
Method: Patients with NASH and bridging fibrosis or compensated cirrhosis were enrolled in the phase 3 STELLAR trials of selonsertib. PROs were assessed using Short Form-36 (SF-36), Chronic Liver Disease Questionnaire-NASH (CLDQ-NASH), EQ-5D, and Work Productivity and Activity Index (WPAI) prior to treatment initiation and compared between NASH patients with and without T2DM using Mann-Whitney test.
Results: There were 1667 NASH patients with PRO data (age: 58 ± 9 years, 40% male, 73% white, 52% cirrhotics, and 74% with T2DM). Patients NASH and T2DM were older (mean 58.4 vs. 56.3 years), had greater BMI (mean 33.7 vs. 32.7), had more cirrhosis (54.5% vs. 45.5%), higher haptoglobin, C-reactive protein, GGT, and greater liver stiffness by Fibroscan, but lower MELD score (mean 7.0 vs. 7.3) as well as lower AST, bilirubin, hemoglobin, and apolipoprotein B (all $p < 0.05$). Out of 23 calculated PRO scores from the 4 instruments, 12 scores were lower in NASH with T2DM: Physical Functioning, Bodily Pain, General Health, Vitality, and Physical Summary of SF-36, 5 out of 6 domains of CLDQ-NASH (Figure), and EQ-5D utility score (all $p < 0.03$). The average magnitude of impairment was from −2.6% to −6.3% of a PRO range size. In multiple regression analysis with adjustment for demographics, location of enrollment site, smoking, BMI, cirrhosis, and history of comorbidities, the presence of T2DM was independently associated with a significant impairment in 11 PRO scores (betas ranging from −1.9% to −6.1% of a PRO range size; $p < 0.05$).



Conclusion: In patients with NASH, T2DM is independently associated with PRO impairment. This suggests that NASH with T2DM is not only associated with substantial clinical burden, but also PRO and potentially economic burden.

THU-439

Variability in liver function test results and the risk of heart disease and mortality: A nationwide population-based study

Su Jong Yu[1], Eun Ju Cho[1], Kyungdo Han[2], Dong Wook Shin[3]. *[1]Seoul National University Hospital, Seoul, Korea, Rep. of South; [2]The Catholic University of Korea, Seoul, Korea, Rep. of South; [3]Samsung Medical Center, Seoul, Korea, Rep. of South*
Email: ydoctor2@hanmail.net

Background and aims: Variability in metabolic parameters such as fasting glucose levels, blood pressure, and body weight can affect health outcomes. In this study, we investigated the association between variability in liver function test results and the risk of mortality and cardiovascular outcomes in the general population.
Method: Using nationally representative data from the Korean National Health Insurance System, 8, 376, 860 people who were free of chronic liver disease, malignancy, congestive heart failure (CHF), myocardial infarction (MI), atrial fibrillation (AF), heavy drinking and who underwent ≥ 3 health examinations between 2009 and 2012 were followed to the end of 2017. Variability in alanine aminotransferase (ALT), aspartate aminotransferase (AST) and gamma-glutamyl transpeptidase (GGT) was measured using the average real variability, standard deviation (SD), and variability independent of the mean (VIM). High variability was defined as the highest quartile of variability. Cox proportional hazards models adjusting for age, sex, body mass index (BMI), smoking, alcohol, regular **exercise, income, presence of comorbidities, and respective liver enzyme level were used.**

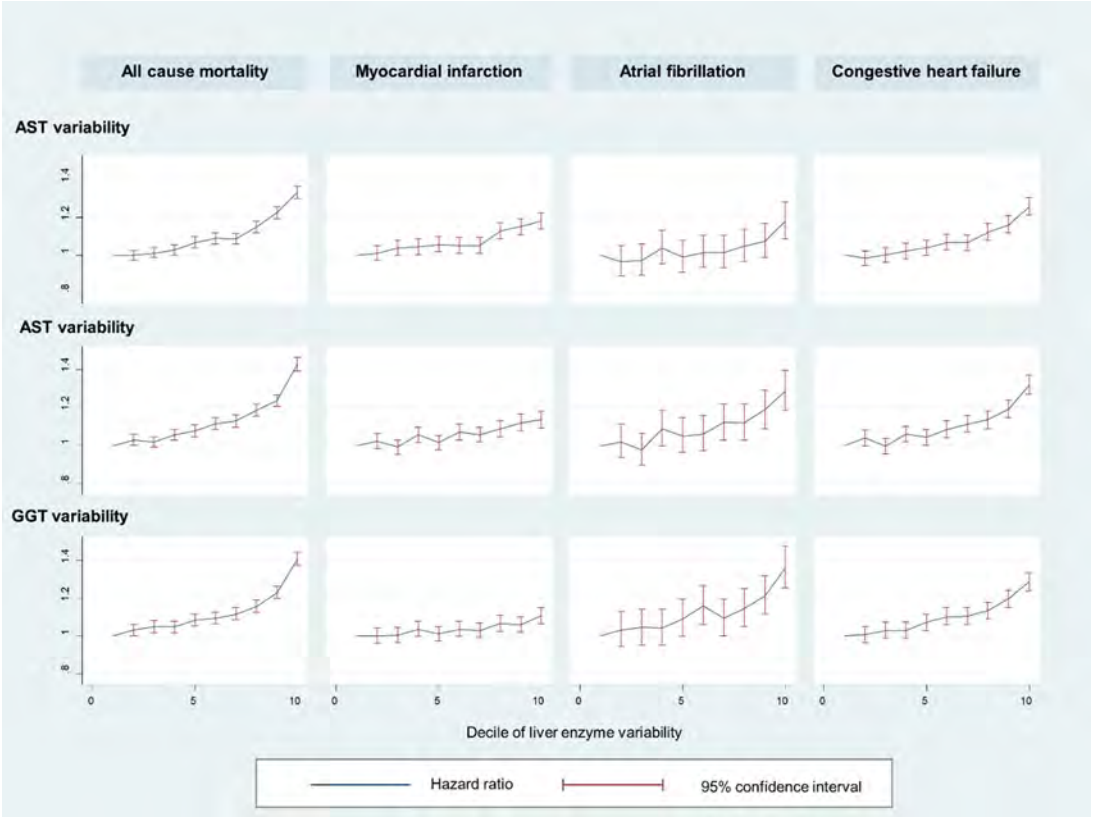


Figure 1: (abstract: THU-439): Risk of mortality and heart disease by deciles of liver enzymes variability

Results: There were 134, 345 deaths (1.5%), 64, 753 CHFs (0.7%), 67, 370 MIs (0.8%), and 81, 914 AFs (0.9%) during a median follow-up of 5.4 years. In the multivariable analysis, there was increasing trends of the association between liver enzyme variability and all study outcomes. The degrees of association were largest for GGT variability which were more marked in subjects with lower BMI and non-drinkers: all-cause mortality [HR (95% CI): Q2, 1.05 (1.03-1.07); Q3, 1.11 (1.09-1.13); Q4, 1.27 (1.25-1.29)]; CHF [Q2, 1.04 (1.02-1.07); Q3, 1.12 (1.09-1.15); Q4, 1.20 (1.18-1.23)]; MI [Q2, 1.03 (1.01-1.06); Q3, 1.07 (1.04-1.09); Q4, 1.10 (1.07-1.12)]; and AF [Q2, 1.07 (1.01-1.13); Q3, 1.16

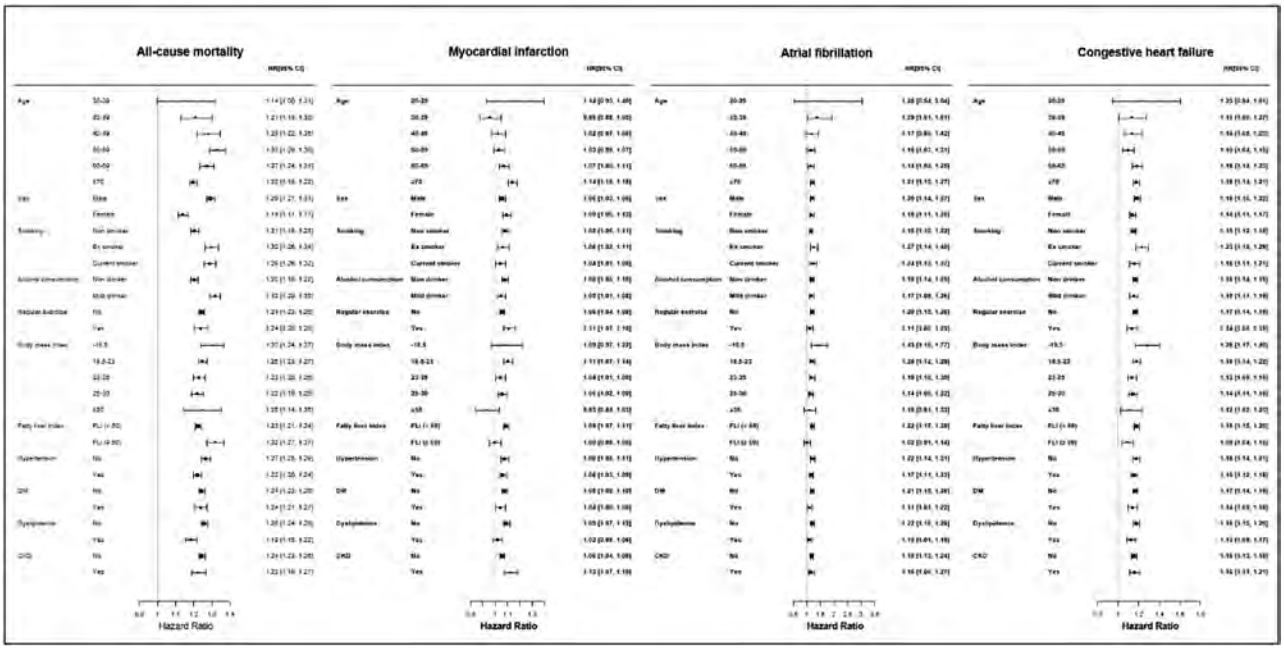

Figure 2: (abstract: THU-439): Risk of mortality and heart disease by level of liver enzymes variability with stratification by baseline characteristics

(1.11-1.23); Q4, 1.26 (1.20-1.32)]. Similar results were obtained when modeling the variability using the SD and VIM, and in various sensitivity analyses.
Conclusion: Higher visit-to-visit variability of liver enzyme was an independent predictor of all-cause mortality and cardiovascular events.

THU-440
Changing incidence of reported hepatitis B and its different trends amongest age groups in china from 2004-2016
Mingyuan Zhang[1], Ruihong Wu[1], Hongqin Xu[1], Junqi Niu[1]. [1]*First Hospital of Jilin University, Hepatology department, Changchun, China*
Email: junqiniu@aliyun.com

Background and aims: To provide a detailed national-level description of the reported incidence of hepatitis B in China during 2004–2016, and analysis the changing trend difference among age groups.
Method: Data were obtained from China's National Notifiable Disease Report System, reported trends were estimated by Joinpoint regression analysis.
Results: Overall, there were 13, 543, 137 new cases of hepatitis B reported in China from 2004 to 2016, among the new reported cases of viral hepatitis in total, the majority (80%) was ascribed to hepatitis B infections. The reported incidence of hepatitis B rose from 2004 (67.96/100, 000) to 2009 (88.82/100, 000), and then decreased in 2016 (68.74/100, 000). From 2004 to 2007, APC of hepatitis B reported incidence was 10.3% (95% CI 4.1 to 16.9, $P < 0.05$), indicating an increased trend, while, from 2007 to 2016, APC was –3.5% (95% CI –4.5 to –2.5, $P < 0.05$), indicating a significant decrease, overall, the AAPC of hepatitis B was –0.2% (95% CI –1.6 to 1.2, P = 0.8), indicating a stable trend. Age distribution in the first decade of this period was analyzed, average reported incidence of HBV was highest in the 20~29 age group, the lowest reported incidence was in age group between 1 and 9 years old. The reported incidence changing trend of "Age < 1," "30-39," "40-49" age groups kept stable, the "1~9," "10-19," "20-29"age groups showed a significant descending trend, all of the age groups of people more than 50 years old showed increased trend from 2004 to 2013. Generally, most of the age groups showed significant decreased or stable trend after 2007 or 2008, however, for the "50-59" age group, the changing trend kept increasing in all stages.
Conclusion: This study indicates that hepatitis B infections continue to constitute the majority of viral hepatitis cases in China, the changing trend of hepatitis B was kept stable nin recent years. For the young (Age < 19 years old), HBV reported incidence showed a significant descending trend, which consistent with the application of HBV vaccine. For the elders (Age >50 years old), the incidence changing trend showed increasing, which indicated that for the elders, the risk for infecting with hepatitis B is still high, after successfully vaccination for children, to decrease the prevalence of hepatitis B, vaccination among adults should also be conducted.
(APC: Annual percentage change; AAPC: average annual percentage change)

Email: natasha_snider@med.unc.edu

Background and aims: Hepatocellular carcinoma (HCC), the predominant form of primary liver cancer, is a leading cause of

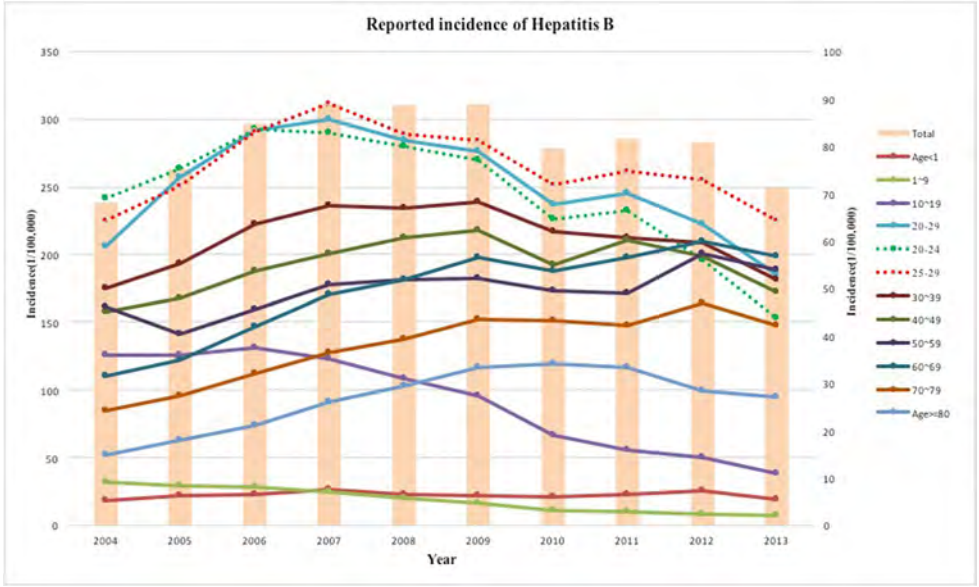

Figure: (abstract: THU-440): Age distribution of reported incidence of hepatitis B from 2003-2013

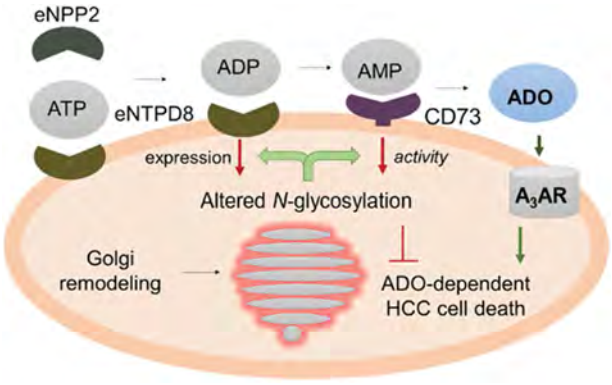
cancer-related deaths globally. Adenosine-3 receptor (A3R) activation blocks HCC progression in rodents, and small molecule A3R agonists are undergoing clinical development for HCC patients. Here, we examined the regulation of *ecto*-5´-nucleotidase (CD73), a novel target of cancer immunotherapy that produces extracellular adenosine, in human HCC.

Methods: We analyzed CD73 expression and correlation with tumor characteristics and patient outcomes using The Cancer Genome Atlas (TCGA). In addition, we extracted CD73 from paired surgical specimens of HCC tumor and non-tumor adjacent liver tissues and normal control liver tissues collected under approved protocols, and performed glycopeptide mass spectrometry analysis. RNAseq analysis was performed to compare the expression of glycoprotein-encoding genes in addition to molecular, biochemical, and cell biological assays using multiple human HCC cell lines.

Results: High expression of the CD73-encoding gene (*NT5E*) correlated with poor survival in HCC patients ($N = 365$; $p = 0.012$) but did not correlate with a specific HCC immune subtype, based on TCGA data. We show using analysis of surgical specimens from HCC and adjacent liver tissues similar CD73 protein levels between normal and tumor hepatocytes. However, tumor-associated CD73 was primarily intracellular and exhibited altered *N*-linked glycosylation, independently of HCC etiology or fibrosis presence. The altered CD73 glycosylation correlated with a 2.7-fold decrease in tumor associated 5´-nucleotidase activity ($p < 0.0001$), which was otherwise necessary to induce cell death in HCC cultured cells. Mass spectrometry profiling of CD73 from tumors demonstrated a significant increase in high-mannose CD73 glycans on residues N311/N333. Blocking CD73 N311/N333 glycosylation caused intracellular CD73 accumulation and decreased 5´-nucleotidase activity *in vitro*, similar to the phenotypes observed in the primary human HCC tumors. Aberrant Golgi function was implicated as a potential mechanism, based on altered tumor expression and organization of the structural protein GM130 and genes encoding other *N*-linked glycoproteins, as determined by RNAseq analysis.



Conclusion: Our results reveal a novel glycosylation mechanism for regulating endogenous purinergic signaling in HCC tumors.

THU-442

Role of drug transporters in the chemoresistance of hepatoblastoma

Maitane Asensio[1], Elisa Lozano[1,2], candela cives[1], Juan Carrillo[3], Lorena Abete[4], Oscar Briz[1,2], Stefano Cairo[5], Jordi Bruix[2,6], Carolina Armengol[2,3], Jose Marin[1,2], Rocio IR Macias[1,2]. Email: jjgmarin@usal.es

Background and aims: Hepatoblastoma (HB) is the predominant form of liver cancer in childhood. Although 80% of HB patients respond to standard neoadjuvant preoperative chemotherapy based on doxorubicin and cisplatin, in the remaining 20% the response is very poor and the prognosis is bad. The lack of response can be due to the presence of mechanisms of chemoresistance (MOCs), including the reduction of intracellular content of drugs as a result of changes in uptake/efflux proteins involved in the transport of drugs. We have investigated the role in HB chemoresistance of the so-called "transportome," i.e., the set of plasma membrane transporters expressed at a given time by tumour cells.

Method: Genes involved in drug transport were analyzed by RNA-sequencing in 18 HB specimens and their matched non-tumour (NT) tissues and results were confirmed by RT-QPCR. Selected genes were studied by RT-QPCR, western blot and immunofluorescence in HB-derived HepG2 and HuH6 cell lines in basal conditions and after 72 h of exposure to cisplatin and doxorubicin. Drug sensitivity of HB cell lines was determined by Sulforhodamine B test. Transport activity of ABC efflux pumps was analyzed by flow cytometry using specific substrates and inhibitors.

Results: Significant changes in the expression of drug transporters in HB as compared with surrounding NT tissue were found. SLCO1B1/3 (OATP1B1/3) and SLC22A1 (OCT1) genes were markedly down-regulated in tumours, and lower levels correlated with worse prognosis. Regarding ABC pumps, several ABCC transporters were highly expressed in HB. Interestingly, ABCC4 (MRP4) was up-regulated in tumours of patients with more aggressive phenotype (C2 vs C1). The expression levels of uptake (SLCO1B1, SLCO1B3, SLC22A1, SLC22A3, SLC31A1) and efflux (ABCB1, ABCC1–5, ABCG2) transporters found in cell lines suggested that both HuH6 and HepG2 cells presented a multidrug resistant phenotype, since they had very low expression levels of uptake transporters together with high or very high expression levels of export pumps. Moreover, the exposure of cells to 0.1 µM doxorubicin or 5 µM cisplatin for 72 h increased the resistant-phenotype of HB-derived cells, mainly by up-regulation of ABCG2 in HuH6 and ABCC3 in HepG2 cells.

Conclusion: Drug transportome can play an important role in HB chemoresistance and several transport proteins have been selected as potential candidates for HB prognosis and to develop novel therapies to overcome chemoresistance.

THU-443

Unexpected pro-tumorigenic effect of the chemokine Cxcl10 by modulation of tumor stroma in a murine model of HCC

Elisa Fabiana Brandt[1], Janine Koehncke[1], Daniel Heinrichs[1], Theresa Hildegard Wirtz[1], Petra Fischer[1], Thomas Longerich[2], Christian Trautwein[1], Hacer Sahin[1], Marie-Luise Berres[1]. [1]*University Clinic RWTH Aachen, Medical Clinic III, Aachen, Germany;* [2]*Heidelberg University Hospital, Institute of Pathology, Heidelberg, Germany*
Email: elisa.brandt@rwth-aachen.de

Background and aims: HCC progression is linked to the dynamic crosstalk between tumor cells and the surrounding tumor stroma. Tumor stroma is a complex, modifiable composition of fibroblast, extracellular matrix, immune cells and vasculature. The pro-inflammatory chemokine Cxcl10 is implicated in the crosstalk between parenchymal as well as non-parenchymal cells e.g. infiltrating immune cells and plays a key role during acute and chronic liver injury. Here we aimed to investigate the role of Cxcl10 in HCC progression.

Method: Hepatocellular carcinoma (HCC) was induced in *Cxcl10*$^{-/-}$ and wild-type (WT) mice via a single i.p. injection of N-Diethylnitrosamin (DEN, day 14) and weekly i.p. injections of low dose carbon tetrachloride (CCl_4, week 4–26). Liver tissue was characterized by histologically staining for proliferation (Ki67),

apoptosis (cleaved caspase 3) and vascularization (VEGF-R2). The HCC-related immune response was analyzed by comprehensive multicolor flow cytometry and immunofluorescence (IF)/-histological (IHC) staining with specific focus on tumor associated T cells (e.g. CD3, CD4, CD8). *In vitro,* the HCC cell line Hepa1–6 was stimulated with Cxcl10 and proliferation was assessed by BrdU incorporation.

Results: Treatment of WT mice with DEN/CCl_4 showed an enhancement of Cxcl10 expression in tumor tissue as compared to control tissue (qRT-PCR, $P < 0.05$). The deletion of *Cxcl10* in a HCC model led to a decreased tumor burden (number + size, $P < 0.05$) compared to WT mice, which was linked to a slight reduction of proliferative tumor cells ($p < 0.07$). *In vitro,* the stimulation of a Hepa1–6 with Cxcl10 did not alter cell proliferation implicating no direct effects of Cxcl10 on tumor cell proliferation. As CXC chemokines are implicated in cancer hallmarks e.g. angiogenesis and immune cell recruitment, we hypothesized that Cxcl10 exert its pro-tumorigenic effects. Indeed, *Cxcl10*$^{-/-}$ tumors showed a lower amount of microvessel density ($p < 0.05$). By flow cytometry analysis and IHC staining, we revealed significant differences in stromal $CD3^+$ T cell accumulation ($p < 0.001$) with an enhancement of $CD4^+$ T helper cell ($p < 0.01$) as well as $CD8^+$ cytotoxic T cell ($p < 0.05$) subsets in DEN/CCl_4 treated *Cxcl10*$^{-/-}$ mice in comparison to treated WT mice. Of note, the boost of T cells and the improvement of HCC phenotype was not associated with a compensational enhancement of Cxcl9-the other ligand of the Cxcl10 receptor Cxcr3.

Conclusion: Interestingly, our results revealed an unexpected pro-tumorigenic function of Cxcl10 in a murine HCC model. Cxcl10 stimulates tumor neovascularization and suppresses the accumulation of T cells with potential anti-tumoral properties. Hence, these data implicate CXCL10-directed stroma modification as novel target for HCC treatment.

THU-444

Alteration of miRNAs expression in patients with HCV-related cirrhosis who developed HCC after therapy with DAAs

Antonietta Romano[1], A. Brocca[1], Giulio Ceolotto[1], Valeria Calvino[1], Luisa Cavalletto[1], Zoe Mariño[2], Sofía Pérez-del-Pulgar[2], Sabela Lens[2], Loreto Boix[3], María Reig[3], Jordi Bruix[3], Ranka Vukotic[4], Valeria Guarneri[4], Pietro Andreone[5], Francesco Paolo Russo[6], Saverio Parisi[7], Paolo Angeli[1]. *[1]University of Padova, Department of Medicine, Padova, Italy; [2]Liver Unit, Hospital Clinic Barcellona, CIBEREHD, IDIBAPS, Universitat de Barcelona, Barcelona, Spain; [3]Barcelona Clinic Liver Cancer (BCLC) Group, Liver Unit, Hospital Clinic Barcelona, CIBEREHD, IDIBAPS, Universitat de Barcelona, Barcelona, Spain; [4]University of Bologna, Department of Medical and Surgical Sciences, DIMEC, Bologna, Italy; [5]Alma Mater Studiorum-University of Bologna, Department of Medical and Surgical Sciences, DIMEC, Bologna, Italy; [6]University of Padova, Gastroenterology and Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padova, Italy; [7]University of Padova, Department of Molecular Medicine, Padova, Italy*
Email: alessandra.brocca@gmail.com

Background and aims: Hepatitis C virus (HCV) is still one of the causes of hepatocellular carcinoma (HCC) related to liver disease. The treatment of HCV infection has radically changed by the new direct acting antiviral drugs (DAAs) that have shown to be effective and well tolerated. The impact of DAA on the risk of HCC development in cirrhotic patients is still controversial. Several studies have shown a correlation between serum and tissue levels of specific miRNAs and the development of HCC in patients with chronic hepatitis C; therefore they have been suggested as biohumoral markers for early and non-invasive diagnosis of HCC.

Our aim is to report miRNAs differentially regulated in HCV+ patients with or without de novo HCC after DAA treatment

Method: We enrolled a total of 80 patients with HCV+ cirrhosis treated with DAAs. Of these, 40 patients developed HCC (HCC group) in the six months after the end of therapy and 40 didńt (non-HCC group). Plasma and serum were recorded at the start (baseline) and the end of therapy. 8 patients of each group were selected for a screening phase, where 172 miRNAs were detected in the baseline samples in microarray plates. The miRNAs with significantly different expression between the 2 groups were selected and validated in the whole cohort, in samples at baseline and at the end of therapy by RT-q-PCR.

Results: In screening phase, 10 miRNAs with significantly different expression between HCC and non-HCC group at baseline were selected: miR-382-5p, miR-132-3p, miR-584-5p, miR-221-3p, miR-28-5p, miR-324-3p, miR-133b, miR-122-5p, miR-130b-3p, miR-27a-3p. Validation of results in the whole groups showed that: miR-382-5p, miR-132-3p, miR-584-5p and miR-221-3p were more expressed in HCC group compare to non-HCC group at baseline. Instead, in samples at the end of therapy, only miR-382-5p was more expressed in HCC group compare to non-HCC group.

Furthermore, within non-HCC group the expression of miR-324-3p, miR-133b and miR-122-5p was significantly decreased at the end of therapy compared to baseline. The same differences were obtained in HCC group in addition to a decreased expression of miR-132-3p and miR-221-3p in patients at baseline vs end of therapy (all $p < 0.05$).

Conclusion: These are preliminary results that should be refined according to the baseline characteristics of patients and the evolutionary confounding factors.

THU-445

Beta-catenin signaling controls NKG2D ligands expression in liver tumorigenesis

Mathilde Cadoux[1,2,3], Sandrine Pham[1,2,3], Stefano Caruso[2], Gabrielle Couchy[2], Jessica Zucman-Rossi[2], Chantal Desdouets[1,2], Nadia Guerra[4], Jean-Pierre Couty[1,2]. *[1]Institut Cochin, Paris, France; [2]Centre de Recherche des Cordeliers, Paris, France; [3]University Paris Descartes, Paris, France; [4]Imperial College, London, United Kingdom*
Email: mathilde.cadoux@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC) has emerged as the second leading cause of cancer-related death worldwide. Due to the advanced stages of HCC at the time of diagnosis, conventional treatments for solid tumors frequently end with treatment failure, recurrence, or poor survival. However, due to the impressive role of the immune microenvironment during tumorigenesis, approaches targeting immune effectors represents an exciting prospect for therapeutic.

In these lines, our goal is to understand immunosurveillance mechanisms taking place during HCC using both murine models and human samples.

These mechanisms are based on the expression of ligands for example after oncogenic stress on epithelial cells that are recognized by the receptor on immune cells. We focused to study NKG2D system described as very efficient anti-tumoral process in several tumors.

Method and Results: First, we monitored the expression of NKG2D ligands in a vast cohort of HCC patients ranged according to HCC classification groups. Genomic functional studies helped to define two major HCC tumor groups based on chromosomal stability: G1/G2/G3 groups associated with high chromosomal instability, inflammation and poor prognosis (*TP53* mutated); G4/G5/G6 groups associated with low chromosomal instability and good prognosis (G5/G6 *CTNNB1* mutated)

We showed that NKG2D ligands mRNA expression was higher in HCC tumors harboring chromosomal instability (G1/G2/G3) compared to G4/G5/G6 groups suggesting that NKG2D ligands expression associates with chromosomal instability.

Accordingly, we validated these results in our murine HCC models, one mimicking G1/G2/G3 groups of aggressive tumors (DEN induced HCC model) and the other harboring *ctnnb1* mutated HCC tumors mimicking G5/G6 groups.

Moreover, we observed a strong downregulation of NKG2D ligands both at the mRNA and the protein level in our *ctnnb1* mutated HCC. In addition, we observed the same behavior in other β-catenin activated context e.g. in the Apc KO mouse model that recapitulates a drastic activation of β-catenin signaling and β-catenin mutated αML cell line by CRISPR-Cas 9 technology. These results evidenced that β-catenin signaling controls negatively NKG2D ligands expression.
To get into the mechanism, we identified by ChIP-seq immunoprecipitation that β-catenin directly controls NKG2D ligands.
Conclusion: Collectively, these results identified β-catenin as a strong regulator of NKG2D ligands expression in the liver.
We are currently investigating whether the reintroduction of NKG2D ligands expression in *ctnnb1* dependent liver tumorigenesis will worsen the course of tumorigenesis in terms of inflammation, proliferation and grade of tumors.

THU-446

AMPK/PGC-1α-mediated metabolic reprogramming of hepatic stellate cells promote stemness of hepatocellular carcinoma via metabolite lactate shuttle

Jia Yao[1], Jianye Cai[1], Qing Yang[1], Jun Zheng[1], Liang Chen[1], Tongyu Lu[1], Yingcai Zhang[1], Yang Yang[1]. [1]*Organ Transplantation Institute, Department of Hepatic Surgery and Liver Transplantation Center of the Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*
Email: yysysu@163.com

Background and aims: Hepatic stellate cells (HSCs), as important interstitial cells in liver cancer microenvironment, play an important role in the malignant process of liver cancer. We previously found that the metabolic shifts of mitochondria drove the malignant transformation of tumors, suggesting that the mitochondrial metabolism mode might affect the cell fates in the tumor microenvironment. However, the role of HSCs in hepatocellular carcinoma (HCC) stem cell pool and its regulatory mechanism is not fully demonstrated.
Method: Glucose uptake ability, oxygen consumption rate, lactate accumulation and ATP production, as well as AMPK activity, PGC-1α expression of HSCs were measured in a co-culture system with HCC cells. The expression of MCT1, the abilities of side population, sphere formation and tumor incidence and metastasis were detected to explore the stemness of HCC cells after co-culture. The glycolytic phenotype and pro-fibrotic capacity of HSCs, as well as stemness of HCC cells, were determined using AMPK agonists metformin or inhibitors of lactate accumulation.
Results: We found that after co-culture with HCC cells, HSCs were activated with the metabolic phenotype switch from oxidative phosphorylation to glycolysis mediated by the AMPK/PGC-1α signaling inactivation, characterized by increased glucose uptake, oxygen consumption rate and lactate production. Interestingly, the metabolic intermediate lactate transferred to and took up by HCC cells via the lactate transporter MCT1, promoted the stemness of HCC cells. AMPK agonists metformin or inhibitors of lactate accumulation administrated in HSCs not only converted myofibroblasts to quiescent HSCs, but also reduced the side population, sphere formation and inhibited tumor incidence and metastasis of HCC in an *in vivo* tumor model. In agreement, pharmacologic inhibition of MCT1-mediated lactate upload dramatically affected tumor outgrowth of HCC.
Conclusion: In this study, we explored the mechanisms of AMPK/PGC-1α signaling pathway in HSCs mitochondrial metabolic shifts and demonstrated a reciprocal metabolic interplay between HSCs and cancer cells through metabolite lactate shuttle in HCC microenvironment, providing a novel cue of metabolism-based approaches to enhance the efficacy of cancer therapy.

DNA damage response CHK2 activates senescence cellular program and supports oxidative metabolism to drive hepatocellular carcinoma development

Matteo Lulli[1], Lorenzo Cavallini[2], Laura Gragnani[2], Caecilia Sukowati[3], Tommaso Mello[4], Andrea Galli[4], Veronica Ghini[5], Krista Rombouts[6], Vinicio Carloni[7]. [1]*University of Florence, Department of Experimental and Clinical Biomedical Science, General Pathology Unit, Florence, Italy;* [2]*University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy;* [3]*Italian Liver Foundation, Trieste, Italy;* [4]*University of Florence, Department of Experimental and Clinical Biochemical Sciences, Gastroenterology Unit, Florence, Italy;* [5]*University of Florence, CERM and Department of Chemistry, Florence, Italy;* [6]*University College London, University College London (UCL) Institute for Liver and Digestive Health, London, United Kingdom;* [7]*University of Florence, Experimental and Clinical Medicine, Florence, Italy*
Email: vinicio.carloni@unifi.it

Background and aims: Hepatocellular carcinoma (HCC) arises in most cases in a context of chronic hepatic inflammation. The causes for the underlying liver disease are diverse and comprise chronic viral infection, alcohol toxicity or non-alcoholic steatohepatitis. In these conditions, senescence constitutes a cellular response triggered by insults associated with DNA damage, oxidative stress and telomere attrition. It has been described that DNA damage response triggers senescence as a response to suppress transformed cells, but this phenomenon remains obscure. Aim of the study was to elucidate the mechanisms linking DNA damage response proteins such as CHK2 to cellular program of senescence and its role in HCC development.
Method: Human hepatocytes immortalized with hTERT (HuS), and p53 mutated HCC cell line Huh7 were used in biochemical studies. A transgenic TG (ALB1HBV)44BRI/J and a metabolic (STAM) HCC mouse model were employed. Finally, microparticles were isolated from blood of cirrhotic patients and normal subjects to evaluate CHK2 mRNA expression levels.
Results: Liver of 15–18 month old TG mice and 16 week old STAM mice showed expression of proteins CHK2, γ-H2AX, both markers of DNA damage response and $p21^{CIP1}$a marker of senescence. These findings coincided with de novo expression of glycolytic enzymes hexokinase I and pyruvate kinase M2 (PKM2). In vitro, CHK2 and γ-H2AX negative Huh7 cells expressed low levels of hexokinase I, PKM2, and phosphoglycerate kinase 1 (PGK1). Conversely, CHK2 and γ-H2AX positive HuS cells overexpressed hexokinase I, PKM2, and PGK1 and the glycolytic enzymes paralleled the markers of senescence SA-β-gal and $p21^{CIP1}$. Furthermore, measurements of oxygen consumption and metabolomic analysis by NMR spectroscopy revealed that overexpression of CHK2 increased mitochondrial oxidation of tricarbossylic acid cycle intermediates and stimulated elevated mitochondrial reactive oxygen species (ROS) production. Knockdown of CHK2 expression blocked mitochondrial ROS production, re-established ATP synthesis and reduced the expression of DNA damage marker γ-H2AX. CHK2 mRNA significantly increased in a cohort of cirrhotic patients in comparison to normal subjects.
Conclusion: The metabolic alterations that occur upon activation of DNA damage response lead CHK2 to repurpose mitochondria from ATP synthesis into ROS production. Together, these findings identified a dysfunction of senescence as a factor fueling HCC development.

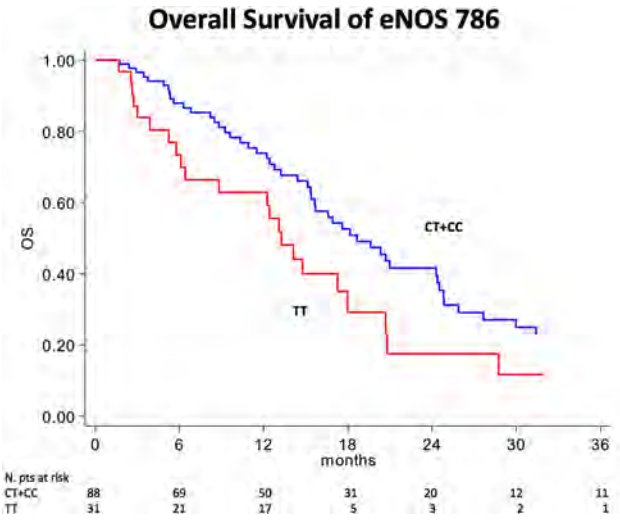
Multicentric prospettive study of validation of angiogenesis-related gene polymorphisms in hepatocellular carcinoma patients treated with sorafenib: Interim analysis of INNOVATE study

Andrea Casadei Gardini[1], Giorgia Marisi[1], Luca Faloppi[2], Vincenzo Dadduzio[3], Emanuela Scarpi[1], Luca Ielasi[4], Francesco Foschi[5], Caterina Vivaldi[6], Giovanni Cardellino[7], Emiliano Tamburini[8], Marianna Siletta[9], Francesca Negri[10], Paola Ulivi[1], Mario Domenico Rizzato[3], Laura Gramantieri[4], Fabio Conti[5], Lorenzo Fornaro[6], Annamaria Porfiello[11], Britt Rudnas[12], Daniele Santini[9], Alessandro Leonetti[10], Nicola Silvestris[13], Sabina Murgioni[3], Francesca Fornari[4], Irene Pecora[6], Antonella Argientiero[13], Sara Lonardi[3], Stefano Cascinu[14], Mario Scartozzi[2]. *[1]IRST, Meldola, Italy; [2]University of Cagliari, Cagliari, Italy; [3]IOV veneto, Padova, Italy; [4]UNIBO, Bologna, Italy; [5]ASL Romagna, Faenza, Italy; [6]University of Pisa, Pisa, Italy; [7]Azienda universitaria di Udine, Udine, Italy; [8]Hospital of Tricase, tricase, Italy; [9]UNICAMPUS, Roma, Italy; [10]University Hospital, Parma, Parma, Italy; [11]University of Udine, Udine, Italy; [12]ASL Romagna, Rimini, Italy; [13]IRCCS Bari, Bari, Italy; [14]UNIMORE, Modena, Italy*
Email: andrea.casadei@irst.emr.it

Background and aims: Although sorafenib is the upfront standard care of treatment for advanced hepatocellular carcinoma (HCC), molecular predictors of efficacy have not been identified yet. In the ePHAS study we analyzed three *eNOS* polymorphisms and at univariate analysis, patients with *eNOS*-786 (rs2070744) TT genotype had significantly shorter median Progression Free Survival (PFS) and Overall Survival (OS) compared to those with other genotypes. In the ALICE-1 and ALICE-2 studies, *VEGF-A*, *VEGF-C*, *VEGFR* and *HIF-1α* polymorphisms resulted independent prognostic factors for PFS and OS at multivariate analyses. On the basis of these preliminary results, our aim is to validate in a prospective study these data in patients with HCC treated with sorafenib (NCT02786342).
Method: This is a prospective Italian multicenter study, that includes 160 HCC patients receiving sorafenib. For this interim analysis we analyzed *eNOS-786* polymorphism on 119 patients. *eNOS*-786 T > C was analyzed by Real Time PCR in relation to the primary end point (OS). Event-time distributions were estimated using the Kaplan-Meier method and survival curves were compared using the log-rank test.
Results: 119 HCC patients (102 males and 17 females), prospectively treated with sorafenib from May 2015 to September 2018 were included. Median age was 69 years (range 28–88 years). 95 patients had Child-Pugh A and 23 had Child-Pugh B7. 42 had BCLC-B and 77 patients had BCLC-C.



At univariate analysis, we confirmed that *eNOS*-786 TT genotype were significantly associated with a lower median OS than the other genotypes (13.3 vs 18.7 months respectively $p = 0.021$, HR 1.96, 95% CI 1.08–2.94 $p = 0.023$). Moreover, patients carrying a TT genotype for *eNOS*-786 showed a lover percentage of Disease Control Rate at the first CT re-evaluation than those carrying other genotypes (50.5% vs. 25%).
Conclusion: This preliminary date confirms the prognostic role of *eNOS*-786 in advanced HCC patients treated with sorafenib. Previous studies have suggested that DNA variant at the *eNOS* gene can quantitatively regulate eNOS expression. The point variation at nucleotide −786 bp was associated with a significant reduction in the *eNOS* gene promoter activity resulting in lower levels of eNOS mRNA, eNOS protein and enzyme activity.
In conclusion, our data show that *eNOS* polymorphisms may identify patients who are more likely to benefit from sorafenib treatment.

THU-449

Nuclear orphan receptor COUP-TF2 increases the resistence to anoikis and induces amoeboid movment and metastatic potential in hepatocellular carcinoma

Elisabetta Ceni[1], Tommaso Mello[2], Simone Polvani[3], Mirko Tarocchi[2], Mireille Vasseur-Cognet[4], Stefano Milani[2], Andrea Galli[2]. *[1]Department of Experimental and Clinical Biomedical Sciences "Mario Serio" University of Florence, Florence, Italy; [2]Department of Experimental and Clinical Biomedical Sciences "Mario Serio" Florence, Italy; [3]d, Florence, Italy; [4]Institut Cochin, Paris, France*
Email: elisabetta.ceni@unifi.it

Background and aims: Hepatocellular carcinoma (HCC) is the second cause of cancer-related death worldwide. In the last few years, the role of nuclear receptors in hepatocarcinogenesis has received great attention. The orphan nuclear receptor COUP-TF2 regulates important biological processes such as glucose and lipid metabolic homeostasis. Recent studies indicate that COUP-TF2 is a pro-oncogenic factor but its role in HCC is still controversial. Aim of this study was to evaluate the role of COUP-TF2 in HCC.
Method: COUP-TFII expression on primary HCC samples was evaluated by immunohistochemistry. Overexpressing COUP-TFII HCC cells lines were created through stable transfection with pcR3.1/COUP-TF2 (Hepa1–6/COUP-TF2, HuH7/COUP-TF2, HepG2/COUP-TF2). The migration and the ability to colonize sites at a distance from the growth front were evaluated by Time-Laps microscopy. Finally, we studied the role of COUP-TFII in an in vivo models of mouse carcinogenesis (TgN (Alb1HBV)44Bri) realizing a triple transgenic animal where the liver-specific Cre expression deletes COUP-TF2 in hepatocytes and in xenograft model where mice were inoculated with human smmc7721 hepatocarcinoma cells stable transfected with COUP-TF2 or silenced by specific short hairpin.
Results: COUP-TFII is over-expressed in primary HCC samples and Kaplan-Meier and Cox regression analysis show that it may be an independent prognostic factor of worst outcome. Overexpression of COUP-TF2 has no significant effects on cell proliferation, but Live cell imaging experiments showed that COUP-TF2 induces a pro-metastatic phenotype characterized by an increased resistance to anoikis and amoeboid migration. Moreover, we found that several proteins involved in the organization of the cytoskeleton, cell-cell or cell-substrate adhesion (i.e. FAK, P-FAK, T-cadherin, β-catenin, αV-integrin, VCAM and α-tubulin), were differently modulated in COUP-TF2 overexpressing *vs* control cells. Finally, COUP-TF2 deletion in hepatocytes of HBV-transgenic mice (Tg[HBV]CreKOCOUP-TF2) reduces tumour growth and in xenograft model reduces pulmonary metastasis compared to control animals.
Conclusion: Our study uncovers COUP-TFII as a critical new player in hepatocarcinogenesis and HCC progression. The evidence that COUP-TFII deletion has a little impact in adult physiological functions and its transcriptional activity could be potentially regulated by ligands, indicates that this nuclear receptor is a promising target for HCC therapy.

THU-450

RFX5 promotes hepatocellular carcinoma progression via transcriptional activation of YWHAQ

Dongbo Chen[1], Xingwang Xie[1], yangjing zhao[2], xueyan wang[1], Weijia Liao[3], pu chen[3], kangjian deng[3], Lai Wei[1], hongsong chen[1]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing, China;* [2]*School of Medicine, Jiangsu University, Zhenjiang, China;* [3]*Laboratory of Hepatobiliary and Pancreatic Surgery, Affiliated Hospital of Guilin Medical University, guilin, China*
Email: chendongbo338@163.com

Background and aims: We previously identified that RFX5, a classical transcription regulator of MHC II genes, was significantly upregulated in hepatocellular carcinoma (HCC) tumors and cell lines. This study aims to reveal its biological significance and the underlying mechanism in HCC.
Method: The role of RFX5 in HCC was investigated by monitoring the colony forming and subcutaneous tumor growth ability of HCC cells after knocking down RFX5 with lentiviral CRISPR/Cas9 system. The transcriptional target of RFX5 in HCC cells was determined by ChIP-seq analysis in HepG2 and then validated with ChIP-PCR and luciferase assay in a set of HCC cell lines. The involvement of RFX5 transcriptional activated genes in HCC development was further determined by colony formation rescue experiment.
Results: We found that overexpression of RFX5 promoted HCC cell proliferation and colony formation, while knocking down RFX5 greatly inhibited the colony formation and subcutaneous tumor growth of several HCC cell lines. Moreover, we identified a group of transcriptional target genes of RFX5. Among these genes, YWHAQ, a member of the 14-3-3-protein family, was closely regulated by RFX5 both in HCC tissues and cell lines. Some study has been proved YWHAQ could interact with many signaling pathways that are critical for apoptosis and cell proliferation, mainly through binding phosphoserine/threonine motifs. We found that RFX5 could directly bind to the promoter of YWHAQ by ChIP-seq and ChIP-PCR assay in HCC cell lines. We also found that RFX5 could enhance the transcriptional activity of YWHAQ promoter by luciferase assay. Modulating the expression of RFX5 in HCC cell lines could subsequently alter the expression level of YWHAQ. Most importantly, the mRNA expression level of YWHAQ was elevated in HCC and tightly correlated with that of RFX5, and linked to the bad prognosis of HCC patients. Notably, YWHAQ overexpression largely rescued the growth inhibitory effects of RFX5 depletion in HCC cells, indicating that YWHAQ is a downstream effector of RFX5.

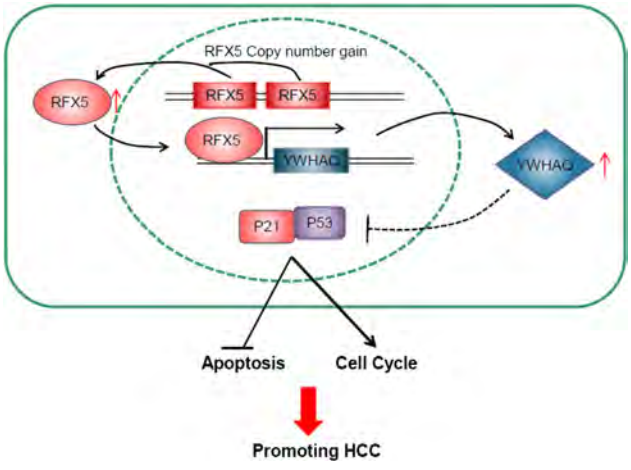


Figure: Graphical Abstract

Conclusion: RFX5 could promote hepatocellular carcinoma progression via transcriptional activation of YWHAQ.

Email: margherita.correnti@gmail.com

Background and aims: Cholangiocarcinoma (CCA) is an extremely heterogeneous adenocarcinoma arising from malignant transformation of biliary tree. Cancer Stem Cells (CSCs) are a subset of tumor cells responsible for tumor initiation, recurrence and metastasis. Spread of stem-like Circulating Tumor Cells (CTCs) in the blood plays a major role in tumor recurrence, metastasis initiation and drug unresponsiveness. Thus, we hypothesized the existence of CCA stem-like relapse-initiating cells. The present study aimed to explore the evolution of stemness features during CCA progression.
Method: Enrichment of CCA stem-like subset by sphere culture (SPH) in established CCA cell lines (HUCCT1) and primary CCA cell culture (MTCHC-01). Adherent monolayer (MON) cells as control. *Mouse:* set up of CCA orthotopic mouse model by using Luciferase-GFP (Luc-GFP) transfected SPH and MON HUCCT1/MTCHC-01 cells. Isolation of GFP+ tumor cells from primary and metastatic tumors by FACS sorting. Molecular characterization by qRT-PCR. *Human:* spiking experiments with low concentrations of GFP+ MTCHC-01 added to healthy peripheral blood mononuclear cells (PBMC). Identification of MTCHC-01 cells by FACS, after CD45 depletion. Same CTC-isolation setting used on 1 CCA and 1 hepatocellular carcinoma (HCC) patient blood sample. Isolated CCA-CTCs characterized by qRT-PCR.
Results: *Mouse:* CCA SPH-primary tumor derived GFP+ cells showed CSC and EMT-related gene enrichment compared to MON-primary tumors. In accordance, SPH cells were responsible for enhanced tumor spread in secondary organs (lungs, spleen, mesenteric lymph nodes) and bloodstream. Notably, SPH-disseminated cells showed up-regulation of almost all tested CSC- and EMT-related gene compared to SPH-primary tumor cells. *Human:* set of the better CTC isolation conditions with spiking experiments. HCC-CTCs identified by FACS as CD45-CD34- cells. Interestingly, 79 CD133+ CTCs were identified in HCC sample. In accordance with these results, CCA-CTCs revealed up-regulation of selected CSC-like genes.
Conclusion: These findings suggest that CCA SPH cells are enriched in stem-like disseminating tumor cells responsible for metastasis formation. Moreover, very preliminary results obtained in human samples indicate the possible presence of CTCs with stem-like traits in liver cancer patients.

THU-452

TFOX, a novel TGF-beta target gene, switches TGF-beta activity toward EMT during tumor progression of human hepatocellular carcinoma

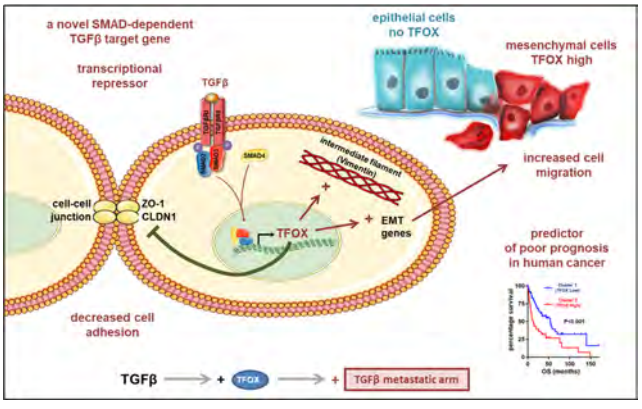
Bévant Kévin[1,2], Angenard Gaelle[1,2], Stefano Caruso[3,4,5], Jessica Zucman-Rossi[3,4,5], Cedric Coulouarn[1,2]. [1]*Inserm UMR-1241, Nutrition, Metabolims and Cancer, Rennes, France;* [2]*Université de Rennes 1, Rennes, France;* [3]*Inserm UMR-1162, Génomique fonctionnelle des Tumeurs solides, Paris, France;* [4]*Labex Immuno-Oncology, Paris, France;* [5]*Hôpital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Paris, France*
Email: cedric.coulouarn@inserm.fr

Background and aims: Transforming Growth Factor beta (TGFb) is a pleiotropic cytokine which controls fundamental cellular processes

associated with tumor onset and progression (e.g. proliferation, migration). In hepatocellular carcinoma (HCC), we previously highlighted TGFb signatures to discriminate patients with good and poor prognosis (Coulouarn, Hepatology, 2008), suggesting that TGFb may represent a relevant therapeutic target. However, targeting TGFb in cancer is complex given that it exhibits onco-suppressive or pro-tumorigenic properties, depending on the tumor stage. At an early stage TGFb induces cytostasis but at an advanced stage TGFb promotes metastasis, as a potent inducer of epithelial-mesenchymal transition (EMT). So far, the molecular mechanisms switching the actions of TGFb during tumor progression are not fully understood. The aim of our study was to characterize TFOX, a predicted transcriptional factor that we hypothesize to be involved in the functional duality of TGFb in cancer.

Method: Gene expression profiling was used to identify TFOX as a novel TGFb target gene in 8 HCC cell lines. Transient and stable TFOX gain and loss of function (lentivirus, siRNA, Crispr/Cas9) combined with functional assays (e.g. cell adhesion, migration) were used to determine the function of TFOX. Expression of EMT markers was determined by western blot and immunofluorescence. Clinical relevance of TFOX in human cancer was performed by integrative genomics.

Results: We show that i) TFOX is a novel canonical SMAD-dependent target of TGFb; ii) TFOX expression correlates with a mesenchymal phenotype, as exemplified by the expression of epithelial (e.g. CDH1/E-Cadherin) and mesenchymal (e.g. VIM/Vimentin) markers; iii) TFOX acts as a transcriptional repressor, as demonstrated by the endogenous TFOX loss of function gene signature made of 87% up-regulated genes; iv) TFOX mediates pro-metastatic properties of TGFb, by reducing cell adhesion, increasing cell migration and inducing EMT markers (e.g. VIM); v) TFOX correlates with VIM expression in human HCC (2 independent datasets: n = 81 and n = 193 HCC); and vi) TFOX expression predicts a poor prognosis (e.g. reduced patient survival), not only in liver cancer, but also in colon, stomach and kidney cancer. In HCC, TFOX is highly expressed in poor prognosis G1 subtype (Boyault, Hepatology, 2007) associated with a poor differentiation but is lowly expressed in good prognosis G5–6 subtypes associated with *CTNNB1* mutations.



Conclusion: Altogether, TFOX is identified as a novel effector of TGFb and its deregulation in cancer is clinically relevant being associated with the pro-tumorigenic properties of TGFb in poor prognosis tumors. Determining the expression of TFOX in advanced tumors in which the pro-metastatic arm of TGFb is activated could help to identify patients who may benefit from targeted therapies using TGFb inhibitors.

Email: cczauder@uni-mainz.de

Background and aims: Development of primary liver cancer is a multi-stage process. Pre-neoplastic dysplastic lesions emerge on the basis of chronic liver damage and evolve into early hepatocellular carcinoma (eHCC) and, subsequently, progressed HCC (pHCC). Detailed molecular characterization and prediction of pre-neoplastic lesions at high risk for malignant transformation would significantly advance our diagnostic and therapeutic approaches. We here utilized integrative molecular analyses to characterize the sequential evolution of liver cancer and aimed to define key epigenetic drivers and biomarkers of HCC development and progression.

Method: Methylation 450k-beadchip analyses were performed on cirrhotic liver (n = 7), low- (n = 4) and high-grade (n = 9) dysplastic lesions, eHCC (n = 5) and pHCC (n = 3) from 8 HCC patients with chronic hepatitis B infection. Differentially methylated gene regions (DMGR) were identified in comparison to non-cirrhotic and non-infected liver (n = 9). Potential epi-drivers and biomarkers were identified by integrative analyses of transcriptomic changes and validated in an independent cohort from the TCGA database.

Results: The proportion of hypermethylated DMGR progressively increased from cirrhosis over dysplastic- to HCC and peaked in eHCC lesions. Early epigenetic alterations involved signaling pathways related to cell death, apoptosis and immune regulation, while late changes centered on cell survival, growth and migration. A common regulation of stem cell-associated pathways including Wnt/b-catenin signaling was revealed in dysplastic as well as eHCC potentially predisposing tumor progression. Moreover, we identified 101 genes with significant methylom changes in dysplastic and cancerous lesions with concomitant progressive gene expression alterations in cancer tissue. We further defined an epi-panel of early epigenetic marks in dysplastic lesions including selected CpG-sites with confirmed differential methylation in cancer tissue and consequential transcriptional alterations of the target genes using an independent cohort of 362 HCC and 49 surrounding liver samples. Unsupervised hierarchical clustering confirmed a robust classification in malignant and non-malignant lesions.

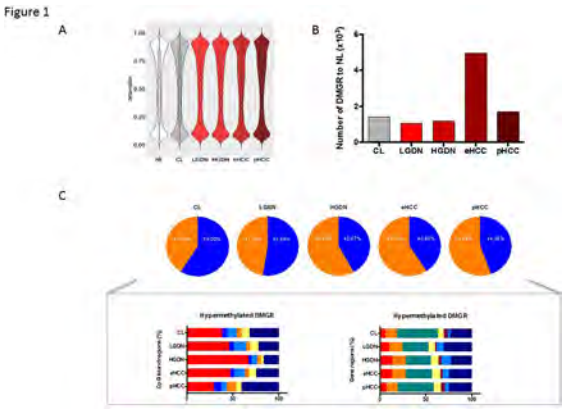

Figure:

Figure 2

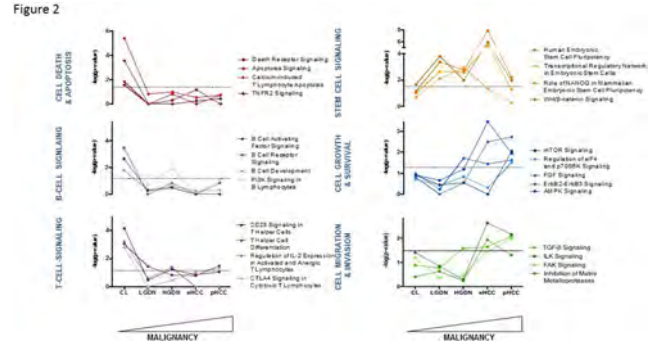

Figure 3

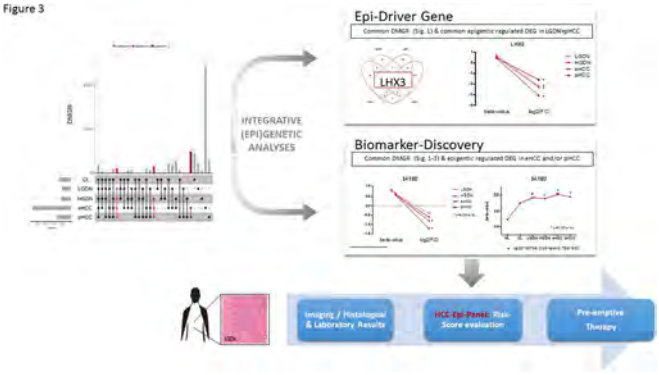

Conclusion: Our results confirm that epigenetic changes occur early during hepatocarcinogenesis. Epigenetic modifications, therefore, might be of high diagnostic/predictive utility for the identification of dysplastic lesions at risk for cancer progression. The identified (epi-) panel of oncogenic epigenetic marks might be useful to complement phenotypic classifications and facilitate selection of lesions amenable to early therapeutic interventions.

THU-454

Dual CCR2/CCR5 antagonism as macrophage targeted therapy in experimental hepatocellular carcinoma

Helena Degroote[1], Astrid Vandierendonck[2], Verhelst Xavier[1], Geerts Anja[1], Van Vlierberghe Hans[1], Lindsey Devisscher[2]. [1]*Ghent University hospital, Gastroenterology and hepatology, Ghent, Belgium;* [2]*Ghent University, Basic and Applied Medical Sciences, Gut-Liver Immunopharmacology unit, Ghent, Belgium*
Email: helena.degroote@ugent.be

Background and aims: Hepatocellular carcinoma (HCC) is an inflammation-associated cancer and characterized by specific tumor-associated macrophages (TAMs) which sustain tumor development. The chemokine-receptors CCR2 and CCR5 are involved in attraction and polarization of TAMs. The possibility to target monocyte infiltration and/or their pro-tumoural polarization was investigated by using Cenicriviroc (CVC), a selective dual CCR2/CCR5 antagonist.
Method: HCC was induced in 5-week-old male sv129 mice by weekly diethylnitrosamine (DEN)-injections for 20 weeks. Mice were treated with CVC 100 mg/kg or vehicle by daily oral gavage for 5 weeks (25–30 weeks of age). Liver damage and HCC development were analyzed by liver histology and qPCR, multiplex and flow cytometry analyses on serum and liver tissue. Life CD45+Ly6G-CD11b+F4/80+Ly6C+ infiltrated monocytes, CD45+Ly6G-CD11b+F4/80+Ly6C-Tim4- monocyte-derived macrophages and CD45+Ly6G-CD11bintF4/80+Ly6C-Tim4+ Kupffer cells (KC) were isolated from the liver by fluorescence activated cell sorting (FACS) and analysed for inflammatory and pro-tumorigenic markers by qPCR. The effect of CVC was further investigated in vitro on bone-marrow derived macrophages (BMDM).
Results: CVC treatment was well tolerated and mice showed reduced weight loss compared to vehicle treated mice. Treatment efficacy was confirmed by elevated serum CCL2 levels in CVC treated mice. CVC treatment did not result in a better survival rate or reduced tumor load. However, CVC treated mice showed a tendency to reduced fibrosis, evaluated on sirius red staining, with significant lower expression of MMP9 and MMP12 and the cytokines TNFalpha and IL-10. Flow cytometric analyses did not reveal significant differences between liver monocyte/macrophage populations between CVC and control treated mice while FACS-isolated KCs from CVC-treated mice showed reduced expression of TNFalpha and IL6 and an increased anti-tumoural CD86/CD206 balance compared to KCs from vehicle treated mice. The latter was confirmed in vitro on BMDM were CVC resulted in reduced expression of CD206, Arg-1, iNOS and CCR2.
Conclusion: CVC treatment in DEN-induced HCC did not result in better survival rate or reduced tumor load although the therapy influenced the tumoural micro-environment and might shifted liver KCs towards an anti-tumoural phenotype. Further research with combination therapy seems mandatory.

THU-455

Metabolomic analysis by 1H-nuclear magnetic resonance spectroscopy suggest that there are 2 phenotypes of human hepatocellular carcinoma developed in non-alcoholic fatty liver disease according to fibrosis level (F0F1 vs F3F4)

Camille Teilhet[1,2], Christelle Reynes[3], Robert Sabatier[4], Anne Sophie Biesse Martin[5], Marie Paule Vasson[6], Armand Abergel[7], Aicha Demidem[8]. [1]*Médecine Digestive, Hopital D'estaing, Clermont Ferrand, France;* [2]*medecine Digestive, Hopital D'estaing, Clermont Ferrand, France;* [3]*Stats Up, Montpellier, France;* [4]*Universite De Montpellier, Montpellier, France;* [5]*Universite D 'Auvergne, Clermont Ferrand, France;* [6]*Unversite Auvergne, Umr 1019, Clermont Ferrand, France;* [7]*medecine Digestive, Hopital D'estaing, Clermont Ferrand, France;* [8]*Inserm, Unite De Nutrition Humaine Umr 1919, Clermont Ferrand, France*
Email: aicha.demidem@inra.fr

Background and aims: There is a rising incidence of Non-alcoholic Fatty Liver Disease (NAFLD) as well as of the frequency of Hepatocellular Carcinoma (HCC) associated with NAFLD which occurs in 40% of cases in the absence of cirrhosis. There is no study reporting the impact of fibrosis on metabolic profile of HCC developed in NAFLD. The aim of this study is to highlight new biomarkers and propose metabolic pathways of HCC according to fibrosis stages (F0F1 *versus* F3F4).
Method: A non-targeted metabolomics strategy was applied. The analysis included 52 pairs of human liver tumoral tissue (HCC) and non tumoral tissue collected from the French Liver biobank. Among the 52 HCC, 26 were developed in severe fibrosis or cirrhosis (F3F4) and 26 no or mild fibrosis (F0F1). Tissue extracts (aqueous and lipid) were analyzed by ^{1}H-Nuclear Magnetic Resonance spectroscopy at 400 MHz. An optimization evolutionary method (genetic algorithm, Linear Discriminant Analysis and cross-validation) has been used to identify metabolites associated to HCC *vs* non tumoral tissue (NTT).
Results: We compared each group of HCC tissue with their own NTT. The metabolomic analysis revealed in HCC-F0F1, an increase in the level of derivatives of choline (phosphocholine and glycerophosphocholine) and a decrease in phosphoethanolamine corresponding to an alteration of phospholipid membranes synthesis, increased levels of glutamine suggesting the activation of glutamine synthetase. Lipids extracts analysis indicated a decreased of fatty acids suggesting an up-regulation of beta oxidation of fatty acids into Krebs cycle. In contrast, HCC-F3F4 is characterized by an accumulation of branched amino acids (Valine, Leucine and Isoleucine) suggesting an activation of the mTOR pathway as well as an increase in creatine and sarcosine which may reflect methylation disorders involving up-regulation of Glycine N Methyl Transferase (GNMT). Moreover, lipids analysis indicated an increase in free and total cholesterol content as

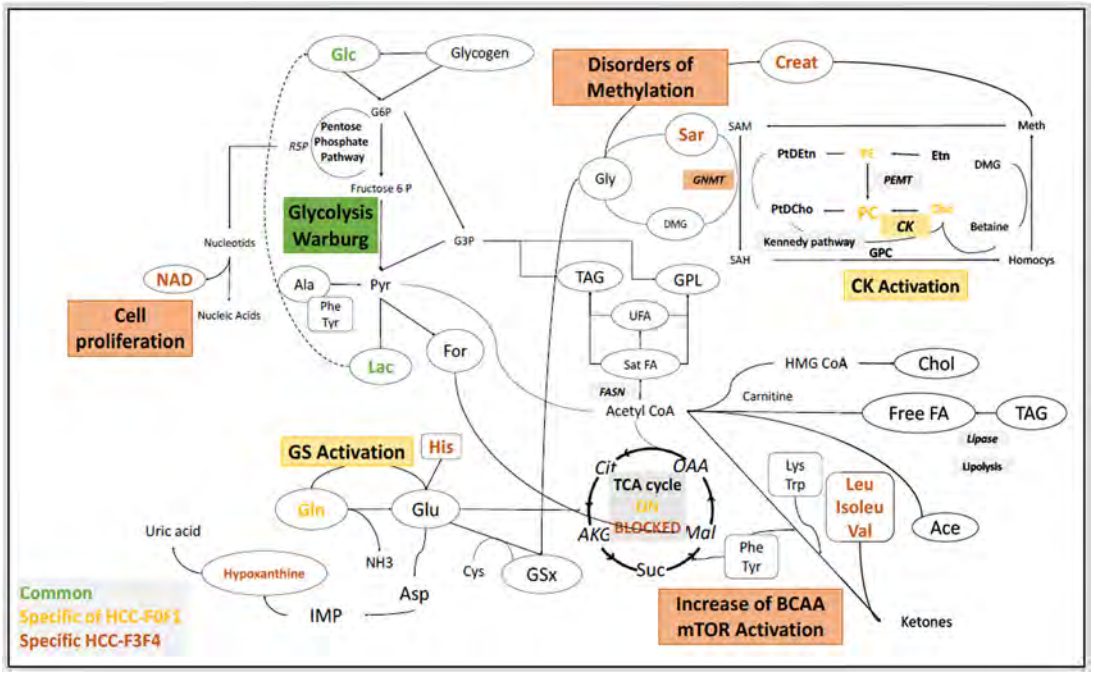

Figure: (abstract: THU-455): Hypothetic mechanistic pathways of HCC-NAFLD according to fibrosis severity.

well as an increase of saturated fatty acid levels suggesting an up-regulation of fatty acid synthase activity (FASN) which may contribute to tumor growth and proliferation.

Conclusion: In conclusion, metabolomic analysis of aqueous and lipid extracts allow us to suggest for the first time that there are two phenotypes of HCC developed in NAFLD according to the fibrosis level. This study highlights the impact of underlying pathology on metabolic reprogramming of the tumor.

Polyploidy spectrum: a new marker of molecular HCC tumour classification

Myriam Bou Nader[1], Stefano Caruso[1,2], Julien Calderaro[3,4], Romain Donne[1,2], Mathilde Cadoux[1,2], Thomas Guilbert[5], Christophe Klein[1,6], Gabrielle Couchy[1], Jean-Pierre Couty[1], Severine Morizur[1], Jessica Zucman-Rossi[1,2], Chantal Desdouets[1,2,5,6]. *[1]Centre de Recherche des Cordeliers, UMR 1138 Inserm, Genetic and Cancer, Paris, France; [2]Université Paris Descartes, Sorbonne Paris Cité Paris, France; [3]Inserm U955, Team 18, Créteil, France; [4]Département de Pathologie, Assistance Publique Hôpitaux de Paris, Groupe Hospitalier Henri Mondor, Créteil, France; [5]Inserm U1016, Institut Cochin, Paris, France; [6]Sorbonne Universités, Université Pierre et Marie Curie Paris 06, PARIS, France*
Email: chantal.desdouets@inserm.fr

Background and aims: Polyploidy is a fascinating characteristic of liver parenchyma. Hepatocytes polyploidy depends on the DNA content of each nucleus (nuclear ploidy) plus the number of nuclei per cell (cellular ploidy). Which role can be assigned to polyploidy during human HCC development is still an open question. Here, we investigated whether a specific ploidy spectrum is associated with clinical and molecular features of HCC.

Method: Ploidy spectra were determined on a total of 85 paired (tumor/adjacent) surgically resected tissues from HCC patients as well as 5 tissues from healthy control. To define ploidy profiles, quantitative and qualitative *in situ* imaging approach was used on paraffin tissue liver sections.

Results: We first demonstrated that polyploid hepatocytes are major components of human liver parenchyma, polyploidy being mainly cellular (binuclear hepatocytes). Across liver lobules, polyploid hepatocytes do not exhibit specific zonation pattern. During liver tumorigenesis, cellular ploidy is drastically reduced; binuclear polyploid hepatocytes being barely present in in HCC tumors. Remarkably, nuclear ploidy is specifically amplified in HCC tumors. In fact, nuclear ploidy is more amplified in HCCs harboring low grade of differentiation and related to p53 mutations. Our results finally demonstrated that highly polyploid tumors are associated with poor prognosis and higher proliferation rate.

Conclusion: Our results underscore the importance of quantification of cellular and nuclear ploidy spectrums as an accurate diagnostic test for HCC tumorigenesis.

Email: sabina.dimatteo@uniroma1.it

Background and aims: Cholangiocarcinoma (CCA) is a very aggressive cancer with high chemoresistance. We demonstrated that CCA is enriched of Cancer Stem Cells (CSCs); this feature is associated with aggressiveness and drug resistance. Recently, DCLK1 was validated as a CSC marker in different gastrointestinal tumors.
Our aims were to evaluate: i) DCLK1 expression and biological function in primary cell cultures of CCA subtypes iCCA (intrahepatic) and pCCA (perihilar) and; ii) DCLK1 expression in human CCA samples *in situ* and its serum concentration.
Method: Primary cell cultures were prepared from surgical specimens of human iCCA and pCCA and CSCs were immunosorted for specific markers (LGR5, CD13, CD90, EpCAM, CD133). hBTSC and hHPSC physiological primary stem cell cultures were used as controls of iCCA and pCCA respectively. DCLK1 expression was analysed by RT-qPCR, western blot and immunofluorescence. In functional studies, the effects of a selective DCLK1 inhibitor (LRRK2-IN-1, 72hrs of treatment) on cell proliferation (MTS Assay, population doubling time-PDT), apoptosis (AnnessinV-FITC/PI) and colony formation capacity were evaluated. DCLK1 gene expression in surgical resected CCA and healthy samples was evaluated by RT-qPCR. DCLK1 serum concentration was measured in CCA, HCC, cirrhotic and healthy patients by ELISA.
Results: For the first time, we demonstrated DCLK1 mRNA and protein expression in iCCA and pCCA. An increased expression of DCLK1 in CCA was evidenced in association with other CSC markers and its highest expression was observed in specific subpopulations of CCA-CSCs (i.e. $pCCA^{LGR5+}$ and $iCCA^{CD133+}$). DCLK1 showed cytoplasmic localization in $pCCA^{LGR5+}$, $iCCA^{CD133+}$, unsorted pCCA and iCCA cell cultures. LRRK2-IN-1 (5 μM) added to CCA cultures increased PDT, decreased proliferation, colony formation capacity and colony size, and induced apoptosis in both iCCA and pCCA compared with controls ($p < 0.01$). LRRK2-IN-1 showed a dose-dependent anti-proliferative effect (2.5μM-20 μM) by MTS assay with an IC_{50} of 9.61 μM in unsorted pCCA, 14.72 μM in unsorted iCCA, 4.51 μM in $pCCA^{LGR5+}$ and 9.61 μM in $iCCA^{CD133+}$ cells. Furthermore, LRRK2-IN-1 did not influence hBTSC and hHPSC primary cell cultures viability. DCLK1 gene expression was lower in healthy tissues than in specimens of iCCA and pCCA ($p < 0.01$). Interestingly, DCLK1 was detected in serum samples of iCCA and pCCA patients. DCLK1 serum levels were lower in cirrhotic and HCC patients compared to CCA patients ($p < 0.05$), but we have never observed DCLK1 protein into serum samples of healthy controls.
Conclusion: In conclusion, DCLK1 expression characterizes specific CCA-CSC subpopulations and could represent a serum biomarker for CCA. DCLK1 inhibition exerts anti-neoplastic effects in primary CCA cell cultures.

THU-458

Identification of relevant oncogenes in RAS-activated primary liver cancer using a targeted screening approach

Christian Lechler[1], Shuang Dong[1], Saumya Manmadhan[1], Thomas Rösner[1], Birgit Kohnke-Ertel[1], Katja Steiger[2], Carolin Mogler[2], Julien Sage[3], Roland Schmid[1], Ursula Ehmer[1]. *[1]Klinikum rechts der Isar, Department of Medicine II, Munich, Germany; [2]Klinikum rechts der Isar, Institute of Pathology and Unit of Comparative Experimental Pathology, Munich, Germany; [3]Stanford University, Departments of Pediatrics and Genetics, Stanford, CA, United States*
Email: ursula.ehmer@tum.de

Background and aims: Gene mutations within the RAS signaling pathway occur with a frequency of 15–20% in human hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (ICC). Activation of RAS signaling is associated with a poor prognosis. However, it remains unclear if specific targeted therapies could be beneficial in this subgroup of patients. In the RPK mouse model, liver-specific expression of oncogenic *Kras* and genetic inactivation of the tumor suppressors *Rb* and p53 mimics genetic changes found in a subgroup of human primary liver cancers. Hepatic tumors in this model resemble human HCC and ICC, as well as tumors of mixed HCC/ICC differentiation. We used a targeted *in vitro*-screening approach to identify relevant oncogenes in our model, followed by *in vivo*-transfection of mouse hepatocytes with transposon-based shRNA constructs.
Method: RNA and protein from microdissected liver tumors of $Rb^{lox/lox};p53^{lox/lox};Kras^{LSL-G12D/+}$ (*RPK*) mice and liver tissue of age matched control mice were analyzed by mRNA microarray, qPCR and western blot. Gene knock-down in primary cell lines from RPK tumors was achieved using lentiviral *shRNA* constructs. Proliferation and clonogenic assays were used to test for the functional relevance of target genes. Transposon *CreER*-constructs harboring inducible *shRNAs* were injected by hydrodynamic tail vein injection to achieve target gene knock-down *in vivo*.
Results: Highly upregulated genes in *RPK* tumors were identified by mRNA microarray analysis. Of all genes tested, only shRNA constructs against *Dmbt1* significantly decreased cell proliferation and clonogenic capacity. Knock-down of *Dmbt1* was verified by mRNA and protein analysis. *In vivo* experiments using *CreER-shDmbt1* transposon constructs showed a significantly longer survival of RPK mice in comparison to controls injected with a random shRNA construct.
Conclusion: Activation of RAS signaling is found in up to one in five patients with primary liver cancer and is associated with a poor prognosis. Using a targeted screening approach in a mouse model with RAS-dependent liver tumors, we identified *Dmbt1* as a relevant oncogene. Of note, DMBT1 functions as a tumor suppressor in other cancers probably through suppression of anti-cancer immunity. Here, we identified a novel oncogenic role of *Dmbt1* in the liver cancer. Interestingly, *DMBT1* is upregulated in a subset of human HCC and many ICC, where it could present a possible target for cancer therapy.

THU-459

Non-parenchymal TREM2 halts hepatocarcinogenesis through the inhibition of liver inflammation and hepatocyte proliferation

Aitor Esparza-Baquer[1], Ibone Labiano[1], Omar Sharif[2,3], Fiona Oakley[4], Pedro Miguel Rodrigues[1], Elizabeth Hijona[1,5], Raul Jimenez-Aguero[1], Adelaida La Casta[1], Marco Youssef William Zaki[4], Colm O Rourke[6], Patricia Munoz-Garrido[6], Jesper Andersen[6], Sylvia Knapp[2,3], Derek A Mann[4], Luis Bujanda[1,5], Jesús María Banales[1,5,7], María Jesús Perugorria[1,5,7]. *[1]Biodonostia Health Research Institute, Donostia University Hospital, University of the Basque Country (UPV-EHU), Department of Liver and Gastrointestinal Diseases, San Sebastian, Spain; [2]Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; [3]Medical University of Vienna, Department of Medicine I, Laboratory of Infection Biology, Vienna, Austria; [4]Newcastle University, Institute of Cellular Medicine, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom; [5]CIBERehd, Instituto de Salud Carlos III, Madrid, Spain; [6]Biotech Research and Innovation Centre (BRIC), University of Copenhagen, Department of Health and Medical Sciences, Copenhagen, Denmark; [7]IKERBASQUE, Basque Foundation for Science, Bilbao, Spain*
Email: matxus.perugorria@biodonostia.org

Background and aims: Hepatocellular carcinoma (HCC) is a prevalent and aggressive cancer that usually arises on a background of chronic liver injury where liver regenerative and inflammatory processes are involved. The triggering receptor expressed on myeloid cells 2 (TREM2) is predominantly expressed in hepatic non-parenchymal cells and inhibits Toll-like receptor (TLR)-derived signalling, protecting the liver from various types of hepatotoxic injury. However, its role in liver cancer is unknown. Here, the role of

TREM2 in hepatocarcinogenesis and liver regeneration was investigated.
Methods: TREM2 expression was analysed in liver tissue samples of 2 independent cohorts of HCC patients compared to control individuals. Experimental models of HCC and liver regeneration in wild type (WT) and *Trem2*$^{-/-}$ mice, and *in vitro* studies with hepatic stellate cells (HSCs) and HCC spheroids were conducted.
Results: *TREM2* expression was induced in human HCC tissue compared to normal liver tissue. In addition, *Trem2* expression was upregulated in the livers of DEN-induced carcinogenic liver injury mouse model as well as during liver regeneration after partial hepatectomy (PHx). *Trem2*$^{-/-}$ mice developed more liver tumours irrespective of size after diethylnitrosamine (DEN) administration, displayed exacerbated liver damage, inflammation, oxidative stress and hepatocyte proliferation. Notably, administration of an anti-inflammatory diet blocked DEN-induced hepatocarcinogenesis in *Trem2*$^{-/-}$ mice. Moreover, *Trem2*$^{-/-}$ livers showed increased hepatocyte proliferation and inflammation after partial hepatectomy (PHx). Supernatant from human hepatic stellate cells that overexpress TREM2 inhibits human HCC spheroid growth *in vitro*.
Conclusion: *TREM2* expression in non-parenchymal cells protects the liver from inflammatory-related hepatocarcinogenesis, representing a novel therapeutic target.

Longitudinal monitoring of cell-free DNA predicts for transarterial chemo-embolization failure in hepatocellular carcinoma
Joanne Evans[1], David Pinato[1], Caroline Ward[2], Mark Thursz[3], rohini sharma[1,2]. [1]*Imperial College London, Surgery and Cancer, London, United Kingdom;* [2]*Imperial College Healthcare NHS Trust, Medical Oncology, London, United Kingdom;* [3]*Faculty of Medicine Imperial College London, Gastroenterology and Hepatology, London, United Kingdom*
Email: joanne.evans@imperial.ac.uk

Background and aims: Level 1 evidence supports the use of transarterial chemo-embolization (TACE) in intermediate stage hepatocellular carcinoma (HCC), however survival outcomes are heterogeneous. Alpha-fetoprotein (AFP) is a well-established and widely used biomarker for HCC, however the sensitivity of AFP as a diagnostic and prognostic tool is limited by the existence of non-AFP-secreting tumours. Plasma derived cell-free DNA (cfDNA) is a compelling novel biomarker for monitoring cancer outcomes in both the curative and palliative setting. Here, we describe our preliminary experience of cfDNA monitoring in hepatocellular carcinoma (HCC) patients treated with transarterial chemoembolisation (TACE).
Method: A total of 54 patients with HCC who received TACE were identified within the PRECISION biobank at Imperial College Healthcare NHS Trust. Of these, 18 patients had matched plasma samples taken at baseline, post-TACE and on subsequent progression, with matched full demographic information available. Relevant plasma samples were retrieved, and cfDNA was extracted and quantified at all three time points. Mutational load by next generation sequencing (NGS) was carried out.
Results: Of the 18 patients identified, 72% were male and 28% female. 50% had Childs Pugh B disease (7–9), and 50% Childs Pugh A (5–6). 10 patients (55%) secreted AFP, defined as a value above the normal range. 72% of our cohort had documented cirrhosis. Across all 18 patients, there was a reduction in cfDNA levels following TACE, which increased subsequently on progression (median cfDNA levels of 921 (185.9–4804) ng/ml at baseline, 845 (251–2300) ng/ml following TACE and 1084.5 (80.3–72155) ng/ml on progression. Patients whose post-TACE cfDNA levels were higher than their baseline levels (31%) had a poorer overall survival (OS), with a median OS of 47.1 months compared to 116.8 months for those who saw any reduction in their cfDNA titre following treatment (Figure 1). Of note, in AFP non-secretors (n = 8), cfDNA had an obvious added utility in monitoring response to treatment, with a baseline median cfDNA of 1011.9 (185.9–2250) ng/ml; post-TACE median cfDNA of 843 (251–2300) ng/ml and on-progression median cfDNA of 1165 (369.6–3341) ng/ml, compared to AFP values of 2.5 (1–9) ng/ml; 5 (1–8) ng/ml and 3 (2–7) ng/ml respectively. NGS results will also be reported.

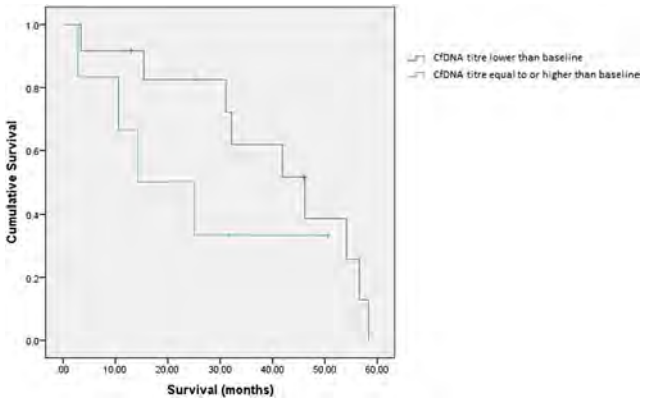

Figure 1: Overall survival in patients undergoing treatment with TACE, stratified by cfDNA response.

Conclusion: Plasma cfDNA analysis represents a potential strategy to monitor disease progression in HCC patients treated with TACE, particularly in those who do not secrete AFP. This technology can easily be applied to the clinic.

THU-461
A diet-induced lean non-alcoholic steatohepatitis-associated hepatocellular carcinoma mouse model
Paraskevi Farazi[1], Shilpa Karanjit[1], Elizabeth Keuter[1], Dong Liu[1], Geoffrey Talmon[2]. [1]*University of Nebraska Medical Center, Epidemiology, Omaha, United States;* [2]*University of Nebraska Medical Center, Pathology and Microbiology, Omaha, United States*
Email: evi.farazi@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has 24% prevalence globally. Its progressive form (non-alcoholic steatohepatitis; NASH) can lead to hepatocellular carcinoma (HCC) development. Interestingly, NAFLD can develop in the absence of obesity and diabetes, with a prevalence of 7% in lean individuals in the US and 25–30% in some Asian countries as a result of a diet high in fructose/fat/cholesterol and genetic predisposition affecting lipid export from the liver. Currently, there is limited understanding of lean NAFLD/NASH HCC pathogenesis, necessitating the development of mouse models for this disease. The aim of this work is to develop a diet-induced lean NASH-HCC mouse model.
Method: Thirty-five mice were fed a choline deficient, high trans-fat, sucrose, cholesterol (CD-HFSC) diet and fifteen mice were fed an isocaloric control low fat diet starting at 4 weeks of age. Choline deficiency is associated with triglyceride accumulation in the liver similar to genetically susceptible human NAFLD patients. Mice were weighed weekly, plasma liver enzymes and lipids were assessed at 17 and 26 weeks of age and glucose tolerance tests were performed at 8, 20, 32, and 44 weeks. Liver tissue was analyzed post mortem to assess nodule development and liver histology in order to determine the development of NAFLD, NASH, fibrosis and HCC.
Results: Mice fed the CD-HFSC diet developed HCC as early as 46 weeks of age with high penetrance (60.7%) at 56 weeks in the absence of obesity. 92.9% of these mice developed hyperplastic nodules and 89.3% had dysplastic nodules. 100% of the mice fed the CD-HFSC diet developed NASH and 51.8% had fibrosis stage 2–3. Mice fed the CD-HFSC diet experienced liver damage as evidenced by the significantly higher plasma ALT and AST levels ($p < 0.05$). Mice fed the CD-HFSC diet had lower plasma cholesterol and triglyceride levels compared to

mice fed the control diet, suggestive of retention of these lipids in the liver. Glucose tolerance was similar in both diet groups. Interestingly, nodule size at the end point was positively correlated with higher plasma liver enzyme (AST) and glucose levels at earlier time points.
Conclusion: Mice fed a diet deficient in choline and high in trans-fat, sucrose, and cholesterol experience liver damage and develop lean NASH-HCC in the absence of cirrhosis by 56 weeks of age. This mouse model is expected to aid in further understanding the pathogenesis of lean NASH-HCC.

THU-462

StARD1 is induced in human HCC and its overexpression aggravates cholesterol-mediated hepatocarcinogenesis in vivo

Laura Conde de la Rosa[1], Vicent Ribas[1,2], Carmen García-Ruiz[1,2], José Carlos Fernández-Checa[1,2]. [1]*Liver Unit, Hospital Clinic, CiBEREHD, IDIBAPS, Barcelona, Spain;* [2]*IIBB-CSIC, Barcelona, Spain*
Email: lcondedelarosa@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death worldwide and the end-stage of chronic liver disease. Hypercholesterolemia is also a growing health concern and a critical factor in the progression of fatty liver disease. StARD1, which transports cholesterol to mitochondria, has a role in the transition from steatosis to steatohepatitis which can progress to HCC. Obesity and hepatic steatosis promotes tumorigenesis, but the role of cholesterol and StARD1 overexpression in HCC progression has not been elucidated yet. **Aim**: To examine the homeostasis of StARD1 in human HCC and to study the role of cholesterol and StARD1 in chemically-induced HCC and the therapeutic effect of ezetimibe *in vivo*.
Method: 14 days-old wild type mice were injected i.p. with a single dose of the carcinogen diethylnitrosamine (DEN). Mice were fed high fat diet (60%) containing cholesterol (0.5%) (HFHC) supplemented or not with ezetimibe (Ez) for 32 weeks. In some cases, DEN-treated mice fed HFHC were injected with adenovirus to overexpress StARD1. Liver samples were analyzed for inflammation, fibrosis and tumor markers by WB, IHC and qRT-PCR. StARD1 expression was examined in samples from HCC patients.
Results: Liver cholesterol levels were higher in the HFHC fed group compared to HFHC+Ez group. Moreover, inflammation (IL-6, Ly6D, Ly6c), proliferation (PCNA, Ki-67) and fibrosis (collagen 1A1, αsma, TGFβ) markers were elevated in the HFHC group compared to HFHC+Ez group. In addition, tumour markers (AFP, CK-19, GP-73, Birc5) induced by DEN were elevated in mice fed the HFHC, and ezetimibe reversed this increase. Interestingly, adenovirus-mediated StARD1 overexpression (5–10 fold) 3–4 months after DEN treatment doubled the multiplicity and area of tumors in mice fed HFHC and increased the expression of tumor, fibrosis and inflammation markers. These findings were accompanied by increased activation of HIF-1α-mediated gene expression. Finally, liver biopsies from patients with HCC exhibit increased levels of StARD1 and HMGCR, which catalyzes the rate-limiting step in the synthesis of cholesterol, compared to samples from control subjects.
Conclusion: Cholesterol aggravates HCC and ezetimibe reversed this effect. StARD1 overexpression increases hepatocarcinogenesis, in part by stimulating HIF signaling. As patients with HCC exhibit increased StARD1 expression, these findings suggest that targeting StARD1 may be of potential relevance in HCC.

Role of natural killer cells receptors on the development and progression of hepatocellular carcinoma

Francesco Figorilli[1], Cristina Manieli[2], Simona Onali[3], Michele Casale[3], Balestrieri Cinzia[4], Giancarlo Serra[4], Teresa Zolfino[1], Lucia Barca[3], Elena Congeddu[5], Paola Ragatzu[5], Roberto Littera[5], Andrea Perra[6], Gualtiero Catani[2], Luchino Chessa[3,4]. [1]*SC Gastroenterologia, Azienda Ospedaliera Brotzu, Cagliari, Italy;* [2]*SC Anatomia Patologica, Azienda Ospedaliera Brotzu, Cagliari;* [3]*Dipartimento di Scienze Mediche e Sanità Pubblica, University of Cagliari, Cagliari, Italy;* [4]*Medicina Interna, AOU Cagliari, Cagliari, Italy;* [5]*Genetica Medica, Ospedale Binaghi, Cagliari, Italy;* [6]*Dipartimento di Scienze Biomediche, University of Cagliari, Cagliari, Italy*
Email: francesco.figorilli@gmail.com

Background and aims: NK cells play a crucial role in tumour immunosurveillance. Killer immunoglobulin-like receptors (KIRs) are key regulators of NK-mediated immune responses and their expression, which is genetically determined, is highly heterogeneous and regulated by different aplotypes. In this study we assessed the genetic pattern of KIRs and their human leukocyte antigen (HLA) ligands in liver transplanted patients with and without hepatocarcinoma (HCC) in order to identify a potential correlation between the frequency of inhibitory/activating KIRs and development/progression of the tumour.
Method: We analysed a single centre cohort of transplanted cirrhotic patients with and without HCC. Clinical data were collected along with the histological features of the explanted livers. The immunogenetic profile of the patients were compared to those of healthy individuals. High resolution (4 digits) typing of HLA A, B, C and 14 KIRs gene loci was performed. Subjects were divided into 2 groups according to homozygosity for KIR haplotype A (AA), heterozygosity (AB) or homozygosity for KIR haplotype B (Bx). They were also stratified according to the numbers of activating/inhibitory KIRs, the type of KIRs related HLA-ligands and the combinations with their receptors.
Results: 87 patients were included: 52 (60%) had HCC. HCV infection was the primary cause of liver disease (82.8%). No significant difference was observed in the frequency of HLA alleles and activating/inhibitory KIR genes and KIR aplotypes between patients and controls. The frequency of KIR2DS4, the only activating KIR gene of aplotype A, was similar between HCC and non-HCC group. However, homozygosis for the deletion variant of KIR2DS4 was more common in HCC group (23% vs 3% p = 0.009), indicating that a higher proportion of HCC patients with KIR haplotype A did not express any activating KIR genes compared to only 1 non-HCC patient. In contrast, HCC patients outside Milan criteria or with microvascular invasion showed a higher prevalence of the activating KIR gene 2DS2 (100% vs 30%; p = 0.003) and a lower frequency of the inhibitory KIR gene 2DL1 (40% vs 83%; p = 0.039).
Conclusion: Loss of activating KIR2DS4 was more frequently observed among HCC patients, suggesting a decreased cytotoxic function of NK cells and therefore a negative impact on tumour immunosurveillance. However, the higher frequency of activating KIR2DS2 observed in patients with a more aggressive tumour suggest that NK could play a potential dual role in HCC development and progression.

THU-464

NASH-related liver carcinogenesis is critically affected by hypoxia-inducible factor 2 alpha

Beatrice Foglia[1], Salvatore Sutti[2], Stefania Cannito[1], Erica Novo[1], Marina Maggiora[1], Claudia Bocca[1], Elisabetta Morello[1], Stefania Bruzzì[2], Naresh Naik Ramavath[2], Chiara Rosso[3], Ramy Younes[3], Elisabetta Bugianesi[3], Emanuele Albano[2], Maurizio Parola[1]. [1]*University of the studies of Turin, Dept. Clinical and Biological Sciences, Turin, Italy;* [2]*A. Avogadro University, Dept. Health Sciences, Novara, Italy;* [3]*University of the studies of Turin, Dept. Medical Sciences, Turin, Italy*
Email: bfoglia@unito.it

Background and aims: Hypoxia and hypoxia inducible factors (HIFs) are believed to significantly affect the progression of chronic liver diseases (CLD). Recently, we showed that hepatocyte HIF-2α activation is a key feature in both human and experimental NAFLD and significantly contributes to disease progression in both experimental animals and human patients. In the present study, we investigated the contribution of hepatocyte HIF-2α in promoting the

development of NAFLD/NASH-associated hepatocellular carcinoma (HCC).
Method: The role of HIF-2α was investigated: a) in human HCC liver specimens from NAFLD/NASH patients, b) in mice carrying hepatocyte-specific deletion of HIF-2α (HIF-2α fl/fl/Alb-Cre mice) receiving diethyl-nitrosamine (DEN) administration plus choline-deficient L-amino acid refined (CDAA) diet (DEN/CDAA protocol); c) in HepG2 stably transfected to overexpress HIF-2α vs cells transfected with the empty vector.
Results: HIF-2α as detected by immunohistochemistry (IHC), was expressed in HCC specimens from NAFLD/NASH patients, with higher expression in patients experiencing early tumour recurrence. Following the treatment with the DEN/CDAA protocol, mice carrying hepatocyte specific deletion of HIF-2α showed a significant decrease in the volume and number of neoplastic liver tumour masses in transgenic mice vs control littermates. Liver tumours in HIF-2α transgenic mice were also characterized by a significant decrease in: a) transcripts levels of tumour associated macrophages and fibroblasts/myofibroblasts markers (including F4/80 and α-smooth muscle actin); b) transcript levels for critical and HIF2α-related target genes, including EPO, c-Myc and CXCR4. In vitro data indicate that HIF-2α is also able to significantly induce cell proliferation, a process that seems to be impaired in the HIF-2α fl/fl/Alb-Cre mice compared to the control littermates.
Conclusion: These results indicate that the activation of HIF-2α in hepatocytes has a critical role in the development of experimental liver carcinogenesis in a dietary NAFLD/NASH-related environment.

THU-465
Variation of different histone deacetylases and the functional effects of HDAC inhibitors in hepatocellular carcinoma
Kim Freese[1], Peter Dietrich[1], Anja Bosserhoff[1,2], Claus Hellerbrand[1,2]. [1]*Friedrich-Alexander University Erlangen-Nürnberg, Institute of Biochemistry (Emil-Fischer Zentrum), Erlangen, Germany;* [2]*Comprehensive Cancer Center (CCC) Erlangen-EMN, Erlangen, Germany*
Email: kim.freese@fau.de

Background and aims: Histone deacetylases (HDACs) comprise in humans currently 18 members divided in 4 classes. HDAC inhibitors (HDACi) appear as promising therapeutic strategy for cancer treatment. The aim of this study was to comprehensively analyze HDAC expression and to functionally analyze the effect of HDACi in HCC.
Method: HDAC expression levels were analyzed in primary human hepatocytes (pHH) and HCC cell lines (Hep3B, HepG2, PLC and Huh7) with qRT-PCR. HDAC activity was measured with fluorometric activity assay (Biocat). HDAC inhibitors SAHA, TSA and TPX were purchased from Sigma. Cytotoxicity was measured with LDH Assay (Roche). Migration was measured with Trevigen Migration assay. Clonogenic assay was performed by seeding at low density, and colony counting after 7 days treatment. Apoptosis was measured with FACS with ANNEXIN V-FITC Kit (Invitrogen).
Results: qRT-PCR analysis revealed significantly increased expression of HDAC 1/2/3/8 (class I); HDAC 4/5/7/9 (class IIa); HDAC 6/10 (class IIb) and HDAC 11 (class IV) in 4 human HCC cell lines and 11 human HCC tissues compared to pHH. Biochemical analysis showed significantly higher HDAC-activity in HCC cells compared to PHH. In human HCC samples, expression levels of individual HDACs varied significantly but particularly HDACs of classes IIa showed significant correlations, i.e. it appeared that there are “high” and “low” HDAC-expressers. TCGA (The Cancer Genome Atlas) data set analysis of 377 HCC patients revealed that high HDAC1/2/8, (Class I), HDAC4/7/9 (Class IIa) or HDAC6 (Class IIb) correlated with poor patient survival. Next, we analyzed the effects of 3 different HDACi: SAHA (irreversible inhibitor of predominantly Class-I), trichostatin A (TSA; reversible inhibitor of foremost Class-IIb; less effective against Class-I, with the exception of HDAC5), and trapoxin (TPX; irreversible pan-inhibitor acting at nanomolar concentrations). All 3 HDACi caused dose-dependent toxicity in HCC cells, while the same doses did not exhibit any toxicity in PHH. Functional analysis of HDACi in sub-toxic doses showed a dose-dependent reduction of proliferation, with TSA and TPX inducing a complete growth arrest, while SAHA inhibited proliferation only approximately 50%. Furthermore, all 3 HDACi reduced the migratory potential and clonogenicity of HCC cells but also this with different efficacy. Moreover, combination with HDACi enhanced the efficacy of sorafenib in killing sorafenib susceptible cells. Furthermore, treatment with HDACi reestablished sorafenib sensitivity in resistant HCC cells.
Conclusion: HDACs promote different facets of tumorigenicity of HCC cells and HDACi showed qualitatively similar but quantitatively different inhibitory effects on HCC cells, which may be exploit to develop therapeutic approaches. HDACi and sorafenib combination appears as novel approach to break sorafenib resistance of HCC cells.

Epigenetic regulation of gene expression in a HCC-NASH murine model
Antonio Gil-Gomez[1], Ángela Rojas[1], Rocio Munoz hernandez[1], Rocío Gallego-Durán[1], Rocío Montero-Vallejo[1], Javier Ampuero[1,2], Manuel Romero Gomez[1,2]. [1]*SeLiver Group. Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla. CIBERehd., Seville, Spain;* [2]*UGC Enfermedades de enfermedades Digestivas. Hospital Universitario Virgen del Rocío, Seville, Spain*
Email: mromerogomez@us.es

Background and aims: Epigenetics play an important role in the progression from non-alcoholic fatty liver disease (NAFLD) to hepatocellular carcinoma (HCC). The aim of our study was to unravel how the interaction between genes and miRNAs expression could affect the development of HCC in a murine model.
Method: Twenty-five male six-weeks mice C57BL/6J were fed a HFHCC diet (40% Kcal fat, 1% cholesterol and 42 g/L glucose/fructose in drinking water) for 52 weeks. Anatomorphological features, histological, biochemical and metabolic parameters were measured. Total RNA from liver tumors and surrounding non-tumorous areas (n = 3) was extracted and the transcriptomic and epigenetic profile were studied by ClarionS and miRNA4.0 arrays including > 22, 000 transcripts and > 3, 000 miRNAs (mature and pre-miRNA) (ThermoFisher, CA, USA). The interaction was evaluated by using TAC software (ThermoFisher, CA, USA).
Results: HFHCC diet induced NASH in mice, characterized by macro-microvesicular steatosis, inflammatory foci at lobular, portal and periductal levels, followed by presence of hepatocyte degeneration (ballooning) and moderate fibrosis. The model also showed a progressive increase in the hepatic, lipidic and glucidic parameters. Besides, we also detected several foci of cellular alterations in > 40% animals and nodules in >20%, which were classified into adenomas or well-differenciated HCC Gpc3+. The transcriptomic analysis of HCC showed up to 20 genes differentially expressed ($p < 1 \times 10^{-9}$; fold ± 2; FDR < 0.05) compared to the surrounding areas. Similarly, the epigenetic profile revealed 32 miRNAs with differences ($p < 0.01$; fold ± 2;FDR < 0.05). Finally, by analyzing the target gene prediction of miRNAs we could confirm the interactions miRNA-genes (miRNAome).
Conclusion: miRNAs modulate the expression a great number of genes at the time that one gene could be differentially expressed by the combined action of several miRNAs. Here, we associated the expression of potential markers such as Spink1 or Gpc3 to HCC, and hypothesize that both genes (Tstd1, Adck4) and miRNAs (miR-21a, miR-27a) could play a role in its development. By deciphering miRNAome in NAFLD-HCC patients new biomarkers and therapeutic target could be developed and detected.

THU-467

Comparison of the immune tumour microenvironment between primary and metastatic hepatocellular carcinoma: Implication for biomarker research of immunotherapy

Da-Liang Ou[1], Chia-Lang Hsu[2], Yung-Ming Jeng[3], Li-Yuan Bai[4], Ann-Lii Cheng[5], Chiun Hsu[1]. *[1]National Taiwan University College of Medicine, Graduate Institute of Oncology, Taipei, Taiwan; [2]National Taiwan University Hospital, Medical Research, Taipei, Taiwan; [3]National Taiwan University Hospital, Pathology, Taipei, Taiwan; [4]China Medical University Hospital, Internal Medicine, Taichung, Taiwan; [5]National Taiwan University Cancer Center, Taipei, Taiwan*
Email: hsuchiun@gmail.com

Background and aims: Biomarker research of immunotherapy for HCC is often hindered by availability of tumor samples and concerns of quality of archival samples. TME of different anatomical sites may differ in composition of immune cells or expression of immune-related genes and confound the analysis.
Method: Archival formalin-fixed paraffin embedded tumor samples were obtained from (1) HCC patients who underwent surgery for both the primary HCC and metastatic HCC to lungs; and (2) HCC patients who received anti-program cell death-1 (anti-PD1)-based immunotherapy for advanced/metastatic diseases. Expression of immune-related genes were measured by the Cancer Immune Panel (Nanostring). Composition of immune cells in TME was evaluated by multiplex immunofluorescence staining (OPAL 7, Perkin Elmer). The response to immunotherapy was evaluated according to Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 and a clinical benefit response (CBR) was defined as complete (CR) or partial response (PR) according to RECIST 1.1 or stable disease (SD) lasting for > 16 weeks.
Results: For the 31 patients who had adequate paired tumor samples for analysis (median age 50.5 years, male/female 27/4, duration between liver and lung tumor resection 0–80.9 months), the median Pearson's correlation coefficient of the immune gene expressions between the primary liver and metastatic lung tumors was 0.87 (range 0.39–0.96), suggesting that TME between liver and lung tumors was similar in most patients. The proportion of CD4+FoxP3+ T cells was significantly higher in lung (metastatic) vs. liver (primary) HCC (1.2 ± 1.9% vs. 0.3 ± 0.8%, p = 5.4e-5), whereas the proportions of other tumor-infiltrating immune cells were similar. For the 27 patients who received antiPD1-based immunotherapy (0 CR, 8 PR, 11 SD, 8 progressive disease), patients with CBR (n = 16) had significantly higher proportion of tumor infiltrating CD8 T cells (24.2 ± 16.4% vs. 7.9 ± 8.1%, p = 0.02) and a 2.3-fold increase in the expression score defined by genes associated with CD8 T cell exhaustion (LAG3, CD244, EOMES, PTGER4).
Conclusion: Archival tumor tissue may be used to identify CD8 T cell exhaustion in TME that may be associated with better efficacy of antiPD1-based immunotherapy in HCC. The similarity of TME between primary liver and metastatic lung HCC suggested that anatomical site may not be a critical confounding factor in biomarker exploration for HCC immunotherapy.

THU-468

SLU7 controls genome integrity: New role of truncated SRSF3 proteins

Maddalen Jimenez[1], Raquel urtasun[1], María Elizalde[1], María Azkona[1], Maria Arechederra[1], Maria U Latasa[1], Iker Uriarte[1,2], Marina Bárcena-Varela[1], Gloria Álvarez-Sola[1], Leticia Colyn[1], Eva Santamaria[1,2], Bruno Sangro[2,3], Carlos Rodriguez-Ortigosa[1,2], Maite G Fernandez-Barrena[1,2], Matías A Avila[1,2], Carmen Berasain[1,2]. *[1]CIMA. University of Navarra, Hepatology, Pamplona, Spain; [2]CIBERehd, Madrid, Spain; [3]Navarra University Clinic, Hepatology Unit, Pamplona, Spain*
Email: cberasain@unav.es

Background and aims: The metabolic capacities of hepatocytes are maintained by the expression of a complement of genes that support hepatocellular differentiation and quiescence. However, the liver is endowed with an unparalleled regenerative capacity which entails hepatocellular proliferation while maintaining life-supporting metabolic functions. We previously identified the splicing regulator SLU7 as an essential gene in the maintenance of the quiescent, differentiated and metabolically functional liver. Importantly, SLU7 expression is reduced in the chronically injured human liver, and in hepatocellular carcinoma (HCC) cells and tissues. However, we also found that SLU7 expression was essential for the survival of HCC cells and this survival dependency on SLU7 was not observed in non-transformed hepatocytes. One major difference between transformed and normal cells is their proliferative activity, we have now further characterized the role of SLU7 in HCC cell cycle progression.

Method: Cell cycle analysis, detection of DNA:RNA hybrids (R-loops), sister chromatid cohesion analysis (SCC), RT-PCR, Western blot, IHQ, RNA-pull down, partial hepatectomy (PH).
Results: We found that SLU7 prevents the formation of R-loops and the generation of DNA damage and is required for the maintenance of SCC and progression through mitosis. We provide direct evidence demonstrating that SLU7 regulates the splicing and expression of sororin (CDC5A), a key gene in proper chromosome segregation. Mechanistically, these activities involve SLU7-mediated regulation of miR-17–92 and SRSF3 splicing to prevent the generation of aberrant truncated isoforms of SRSF3 (SRSF3-TR). In vivo we found that hepatocyte-specific knockdown of *Slu7* expression in mouse livers resulted in enhanced DNA damage and in impaired liver regeneration after PH. Importantly, SRSF3-TR isoforms are detected in the cirrhotic liver and in HCC.
Conclusion: We have gathered *in vitro* and *in vivo* evidence showing that SLU7 is essential for the preservation of chromosomal stability and DNA integrity during cell proliferation, as well as for mitotic progression. Our findings on reduced SLU7 expression in liver disease may contribute to understand the mechanisms of chromosomal instability, which is an early event in carcinogenesis. However, our findings also identify this splicing regulator as a new molecular target for HCC therapy, given its herein demonstrated key function in the mitotic progression of cancer cells.

THU-469

Nanoparticular bisphosphonate to selectively target and repolarize liver macrophages for efficient anti-tumour response

Leonard Kaps[1,2], Detlef Schuppan[1,3], Lutz Nuhn[4], Muhammad Ashfaq-Khan[1], Misbah Aslam[1], Adrian Klefenz[1], Niklas Choteschovsky[1]. *[1]Institute of Translational Immunology, Mainz, Germany; [2]First Department of Medicine University Medical Center, Mainz, Germany; [3]Division of Gastroenterology Beth Israel Deaconess Medical Center, Harvard Medical School Boston, Boston, United States; [4]Max Planck Institute for Polymer Research, Mainz, Germany*
Email: detlef.schuppan@unimedizin-mainz.de

Background and aims: Bisphosphonates, such as Alendronate (AL) or Zoledronate, were developed as anti-osteoporotic drugs that inhibit osteoclasts, a specialized population of macrophages. Prior studies suggested macrophage repolarizing and thus antitumor activity of zoledronate in rat hepatocellular carcinoma [J Transl Med. 2011, Zhou DY et al]. However, after oral or iv application, bisphosphonates rapidly bind to bone or are excreted by the kidneys. Therefore, we aimed to develop biodegradable and nontoxic nanogel particles (NP) with covalently linked Alendronate (AL-NP) that primarily home to the liver.
Method: NP with diameters below 100 nm were synthesized by controlled-radical polymerization combined with polymer-induced self-assembly and post-polymerization modification. Alendronate was efficiently incorporated by coupling its nonfunctional primary amine group to a squaric acid group of the NP to generate AL-NP.
Results: In M1/M2-polarized murine macrophages, unloaded NP did not show cytotoxicity even at high concentrations, while AL-NP induced a 50% reduction of cell viability at 1 mM AL loading, equal to free AL. Low concentrations of AL-NP (30, 60 µM Alendronate) repolarized putative profibrotic and cancer promoting M2-polarized bone-marrow derived macrophages towards anti-fibrotic and anti-tumorous M1 macrophages, increasing their expression of TNF-a and Interferon-g and decreasing CD206 (mannose receptor), as determined on the transcript and protein level via qPCR and FACS analysis. AL-NP repolarized macrophages more efficiently as equal doses of free AL, while NP alone had no effect. After intravenous injection in healthy Balb/c mice, more than 80% of near-infrared fluorescence labeled CS800-AL-NP rapidly accumulated in the liver, whereas CS800 labeled AL was readily cleared via the kidneys. CS800-AL-NP were effectively taken up by CD45+ F4/80+ CD11b+ liver macrophages (>90%), CD31+ endothelial cells (>40%), albumin+ hepatocytes (>40%), CD90+/TH1 portal myofibroblasts (>40%), NK1.1+ NKT cells (>90%), CD11c+ dendritic cells (>40%) and to a minor degree in CD3+ T-cells (< 10%), as determined by flow cytometry. CS800-AL-NP were well tolerated and showed no toxicity at high concentrations up to

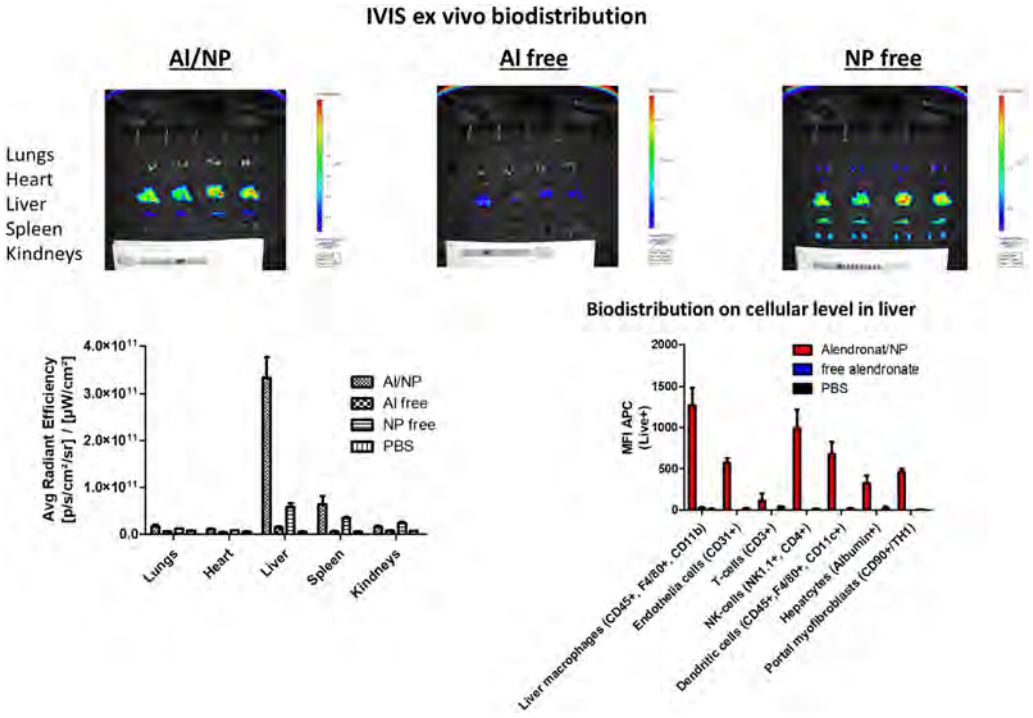

Figure: (abstract: THU-469): Biodistribution of AL/NP on macroscopic and cellular level

12.5 mg/kg AL as assessed-histology and by routine blood tests for liver/renal toxicity.
Conclusion: We have designed AL-NP as novel biocompatible nanocarriers for the bisphosphonate AL. Nanocarrier-coupled AL was almost exclusively sequestered by the liver and showed promising repolarizing effects on M2-type primary macrophages, shifting their cytokine levels towards a putative anti-fibrotic and anti-tumor M1 phenotype. CS800-AL-NP were efficiently taken up by liver macrophages, endothelial, fibroblastic and parenchymal cells, NKT cells, dendritic cells but not by T cells.

THU-470

The mRNA-binding protein tristetraprolin promotes hepatocarcinogenesis but inhibits tumour progression in liver cancer

Sonja Kessler[1], Kevan Hosseini[1], Tarek Kröhler[1], Ahmad Barghash[2,3], Sonika Patial[4], Jessica Hoppstädter[1], Katja Gemperlein[5], Johannes Haybäck[6,7,8], Markus List[9,10], Rolf Müller[5], Volkhard Helms[3], Marcel Schulz[10,11], Stephan Laggai[1], Perry Blackshear[4], Alexandra K. Kiemer[1]. *[1]Saarland University, Department of Pharmacy, Pharmaceutical Biology, Saarbruecken, Germany; [2]German Jordanian University, School of Electrical Engineering and Information Technology, Amman, Jordan; [3]Saarland University, Center for Bioinformatics, Saarbruecken, Germany; [4]National Institute of Environmental Health Sciences, The Laboratory of Signal Transduction, Research Triangle Park, United States; [5]Helmholtz Institute for Pharmaceutical Research Saarland, Helmholtz Centre for Infection Research, Department of Microbial Natural Products, Saarbruecken, Germany; [6]Otto-von-Guericke University Magdeburg, Department of Pathology, Magdeburg, Germany; [7]Medical University of Innsbruck, Department of Pathology, Neuropathology and Molecular Pathology, Innsbruck, Austria; [8]Medical University of Graz, Institute of Pathology, Saarbruecken, Austria; [9]Technical University of Munich, Big Data in BioMedicine Group, Chair of Experimental Bioinformatics, TUM School of Life Sciences Weihenstephan, Freising, Germany; [10]Max Planck Institute for Informatics, Saarland Informatics Campus, Department for Computational Biology and Applied Algorithmics, Saarbruecken, Germany; [11]Saarland Informatics Campus, Cluster of Excellence in Multimodal Computing and Interaction, Saarbruecken, Germany*
Email: s.kessler@mx.uni-saarland.de

Background and aims: The RNA-binding protein (RBP) tristetraprolin (TTP/*ZFP36*) has been shown to be downregulated in several cancer types but has also been described to promote metabolic disturbances. Since HCC frequently develops within metabolically disturbed livers, we aimed to elucidate the effect of TTP on liver carcinogenesis and tumor progression. Using a liver-specific *Ttp* knockout mouse model (ls*Ttp*-KO) and *in vitro* TTP overexpression, tumour initiation and progression were analysed in order to elucidate the mechanistic role of TTP in HCC.
Methods: TTP expression was analysed in three large human data sets (TCGA and GEO) comprising almost 400 samples. Effects tumour initiation, inflammation, and hepatic lipids were determined in ls*Ttp*-KO mice *via* HE staining, flow cytometry, and GC-MS. Effects of TTP overexpression was analysed *via* MTT-assay (chemosensitivity), scratch assay (migration), flow cytometry (proliferation), and qPCR (TTP target identification) in HepG2, PLC/PRF/5, and Huh7 cells.
Results: *ZFP36* expression was downregulated in tumour samples compared to non-tumour or cirrhotic tissue in all three of the analysed large human data sets. ls*Ttp*-KO mice had a significantly decreased tumour burden upon treatment with the carcinogen diethylnitrosamine (DEN). No difference was observed between wild-type and ls*Ttp*-KO animals regarding DEN-induced changes in hepatic leukocyte numbers ($CD45^+$). DEN short-term treatment led to an increase of hepatic fatty acids, which was almost abrogated in the DEN-treated ls*Ttp*-KO mice. In the long-term DEN model no difference between the genotypes was observed in the DEN-treated group, but within the control group ls*Ttp*-KO showed elevated levels of saturated and monounsaturated fatty acids. Regarding chemosensitivity only a minor effect of TTP overexpression was observed in Huh7 cells. However, TTP overexpression distinctly decreased migration ability in PLC/PRF/5 and Huh7 cells, and proliferation in HepG2, PLC/PRF/5, and Huh7. Several oncogenes were downregulated in TTP-overexpressing HCC cells, e.g. B-cell lymphoma 2 (*BCL2*), c-Myc (*MYC*), and vascular endothelial growth factor A (*VEGFA*).
Conclusion: Our data suggest that hepatocytic TTP promotes hepatocarcinogenesis, while it shows tumour-suppressive actions in hepatic tumour progression.

THU-471

Establishment of a short-termed orthotopic transplantation model in C57/B6 mice that recapitulates characteristic features of human intrahepatic cholangiocarcinoma

Janine Koehncke[1], Theresa Hildegard Wirtz[1], Christian Holland[2], Elisa Fabiana Brandt[1], Thomas Philipp Ritz[3], Daniel Heinrichs[1], Petra Fischer[1], Christian Trautwein[1], Thomas Longerich[4], Julio Saez-Rodriguez[2], Marie-Luise Berres[1]. *[1]University Clinic Aachen, Medical Clinic III, Aachen, Germany; [2]University Hospital Heidelberg, Medical Bioinformatics and Data Analysis, Heidelberg, Germany; [3]University Clinic Aachen, Aachen, Germany; [4]University Hospital Heidelberg, Institute of Pathology, Heidelberg, Germany*
Email: thwirtz@ukaachen.de

Background and aims: Intrahepatic cholangiocarcinoma (ICC) is a highly aggressive cancer ranking the second most common liver cancer worldwide and is associated with very poor prognosis and limited treatment options. To identify and understand molecular mechanisms of the rise and progression of cholangiocarcinoma animal models that recapitulate human disease are needed. Until today only few allograft or xenograft transplant ICC models that claim challenging operative techniques or longer time periods for tumor development are available. Here we present a murine orthotopic transplant model on B6 background resulting in ICCs with high molecular homology to human ICC within two to four weeks.
Method: 6–8 weeks old C57/B6 male mice were injected with $2^{*}10^{6}$ Hep55.1C cells in the left liver lobe and tumor growth was followed by weekly ultrasound. Mice were sacrificed after two and four weeks after cell injection. Immunohistological liver stainings were performed to determine protein expression of cholangiocyte and hepatocyte markers. mRNA sequencing and qPCR was performed to analyze gene expression of tumor and surrounding tissue. Intrahepatic as well as systemic immune response was characterized by flow cytometry analysis.
Results: Mice developed liver tumors after two or four weeks of Hep55.1C cell transplantation with a 100% incidence. Tumors had a size of 0.6cm² or 1cm² on average and showed features of highly differentiated biliary adenocarcinomas with tubular structures. Immunohistological stainings revealed a ubiquitous signal for pan-cytokeratin within tumor tissue with a loss of HNF4α expressing highlighting the ICC phenotype of the tumors. Supportively, real-time PCR analysis showed high expression of cholangiocyte markers (CK7, CK19, SOX9) but not of hepatocyte (HNF4 α, transthyretin) or hepatocellular carcinoma markers (α-Fetoprotein, albumin) in tumor tissue. Characterization of intrahepatic cell composition by flow cytometry displayed an induction of both innate and adaptive immune response as reflected by an increase of neutrophils, B-cells, and myeloid cells in the tumor tissue after two weeks. Surprisingly, this effect was partially reversed after four weeks following transplantation. Moreover, comparing transcriptomic analysis following RNA sequencing of tumor tissue from our mouse model with published data sets from human ICC tissue using gene set enrichment analysis, we were able to identify high similarities between our model and human ICC.
Conclusion: Here we present a highly reproducible ICC mouse model characterized by two advantages from the experimental point of view: 100% success rate of tumor induction with fast progression and

characteristic molecular features of human ICC. Our model is therefore most suitable to define and evaluate interventional therapies in ICC.

THU-472

Pharmacological inhibition of PIM1 suppresses tumor progression and enhances chemosensitivity in hepatocellular carcinoma

Ming Sum Leung[1], Kwan Shuen Chan[1], Cheuk Lam Lo[1]. [1]*The University of Hong Kong, Hong Kong, Hong Kong*
Email: lmshk2002@hotmail.com

Background and aims: Hepatocellular carcinoma (HCC) is a common and aggressive malignancy worldwide. Targeted therapies provide new strategic treatment options for HCC. PIM1, a serine/threonine kinase, is upregulated in the hypoxic microenvironment of HCC and promotes tumor progression through regulating glycolysis. In the current study, we will evaluate the preclinical efficacy of targeting PIM1 by specific inhibitor in vitro and in vivo.
Method: PIM kinase inhibitor 1SGI-1776 was used to treat HCC cell lines including MHCC97L and Huh7. Altered expression of downstream targets of PIM 1 was confirmed by western blotting. IC50 was determined by MTT assay. Cell proliferation, cell motility and matrigel invasion assays were employed to study the effects of proliferation and metastasis upon altered PIM1 functions. Glucose uptake assay and apoptosis assay with Annexin V/PI staining were carried out to examine the effects of glucose uptake and chemosensitivity, respectively. In vivo tumor growth was investigated by a subcutaneous injection model using MHCC97L cells coupled with inhibitor treatment by oral lavage.
Results: Treatment of HCC cells with SGI-1776 resulted in a concentration-dependent reduction in cell proliferation, migration and invasion. SGI-1776 treatment also sensitized HCC cells to cisplatin and suppressed PKM2 and glucose uptake in vitro. In vivo tumor growth was suppressed upon administration of SGI-1776.
Conclusion: Targeting PIM1 by PIM inhibitor demonstrates efficacy in suppressing HCC progression, hampering glucose metabolism, and enhancing chemosensitivity of HCC cells. It is a potential targeted therapy for HCC.

THU-473

Role of intracellular lysyl oxidase in progression of primary liver cancer

Monika Lewinska[1], Deepak Kumar Bhatt[1], Letizia Satriano[1], Douglas VNP Oliveira[2], Friederike Mahn[3], Jens Marquardt[3], Matthias Matter[4], María Jesús Perugorria[5], Jesús María Banales[5], Jesper Andersen[1]. [1]*Biotech Research and Innovation Centre (BRIC), Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark;* [2]*Harlev Hospital, Department of Pathology, Harlev, Denmark;* [3]*Department of Medicine, University Medical Center Johannes Gutenberg University Mainz, Mainz, Germany;* [4]*Institute of Pathology, University Hospital of Basel, Basel, Switzerland;* [5]*Biodonostia Research Institute, Donostia University Hospital, San Sebastian, Spain*
Email: jesper.andersen@bric.ku.dk

Background and aims: Lysyl oxidases (LOX) are a family of extracellular proteins involved in collagen and elastin crosslinking causing stiffening and modulation of the extracellular matrix (ECM). LOX genes have been shown to play both tumour promoting and suppressive roles, but function of intracellular LOX in primary liver cancer (PLC) is largely unknown.
Method: To evaluate the expression of LOX, we have analysed the transcriptomes from 158 intrahepatic cholangiocarcinoma (iCCA), 53 hepatocellular carcinoma (HCC) and 197 matched surrounding liver (SL) tissues. Data was confirmed using TCGA (CHOL and LIHC) and correlated with clinical features. Microdissection of intra-tumour stroma and epithelium compartments in CCA (n = 23) and HCC (n = 8) was used to generate a stromal signature and in cellular deconvolution with CIBERSORT. LOX gene and protein expression was measured in tumours, primary and established cell lines (HCC = 17, iCCA = 11), hepatic stellate cells (HSC), and cancer associated fibroblasts (CAFs). Functional analysis was performed on cells exposed to recombinant LOX (rLOX), CAF and HSC conditioned media (CM) and LOX inhibitor (BAPN). LOX immunoprecipitation (IP) followed by mass-spectrometry (MS) was used to identify novel interaction partners.
Results: LOX is significantly overexpressed in PLCs compared to SL (HCC; $P = 0.005$, iCCA; $P < 0.0001$) and high expression of LOX is associated with poor survival (HCC; $P = 0.035$, iCCA; $P = 0.017$). Analysis of tumour stromal and epithelial compartments showed a significant correlation of LOX expression with stroma in both iCCA ($p < 0.0001$, $r = 0.5$) and HCC ($p < 0.0001$, $r = 0.75$). In normal murine liver, LOX is predominantly expressed by HPCs compared to hepatocytes, cholangiocytes and Kupffer cells ($p < 0.0001$). Similar, human hepatic CAFs and HPCs express significantly higher levels of LOX compared to PLC cells ($p < 0.0001$). Immunohistochemical staining of LOX in tumour tissue showed high abundance in cancer cells contrary to mRNA expression in cell lines, suggesting it can have extracellular origin. LOX-negative cells challenged by CM or rLOX showed an intracellular location (including in the nucleus), suggesting its functional role beyond ECM organization. LOX IP followed by MS identified LOX binding partners in both nuclear and cytoplasmic components in rLOX-treated cancer cells. Using BAPN to inhibit LOX resulted in a reduced stromal cells proliferation.
Conclusion: We have shown in PLC that increased expression of LOX is driven by CAFs and associated with diminished survival. Nuclear location of tumour-specific LOX can be mimicked by exposing primary cancer cells with CM or rLOX, suggesting LOX may play important roles in tumour progression beyond collagen crosslinking. LOX may present a putative target in treating PLC.

Existence of intratumoral teriary lymphoid structures predicts better prognosis in Barcelona clinic of liver cancer stage 0-a hepatocellular carcinoma

Hui Li[1], Xing Chen[1], Jinjiu Wang[1], Genshu Wang[2], Kefei Yuan[1], Hong Wu[1]. [1]*West China Hospital, Liver Surgery, Liver Transplantation Division, Chengdu, China;* [2]*The Third Affiliated Hospital of Sun Yat-sen University, Hepatic Surgery and Liver Transplantation Center, Guangzhou, China*
Email: 445613487@qq.com

Background and aims: Tumor-associated tertiary lymphoid structures (TLS) are associated with favorable clinical outcomes in various solid tumors. However, their prognostic value in hepatocellular carcinoma (HCC) remain controversial. This study aimed to investigate clinical relevance of intratumoral TLS in HCC patients treated by surgical resection.
Method: Tissue arrays and immunohistochemistry were used to evaluate the existence and degree of TLS in specimens from a total of 303 HCC patients. Clinical relevance of intratumoral TLS was investigated in patients with Barcelona Clinic of Liver Cancer stage 0-A HCC. The results were verified in a public data set and an independent cohort of 149 patients with early stage HCC.
Results: TLS were identified in 102 (33.7%) cases after pathological reviewing, among which 83 (27.4%) and 19 (6.3%) cases were lymphoid aggregated and lymphoid follicles, respectively. No correlation was detected between existence of intratumoral TLS and overall survival ($p = 0.088$) as well as late tumor recurrence ($p = 0.308$), whereas a significant positive association was found between TLS and early relapse ($p = 0.004$). Univariate and multivariate

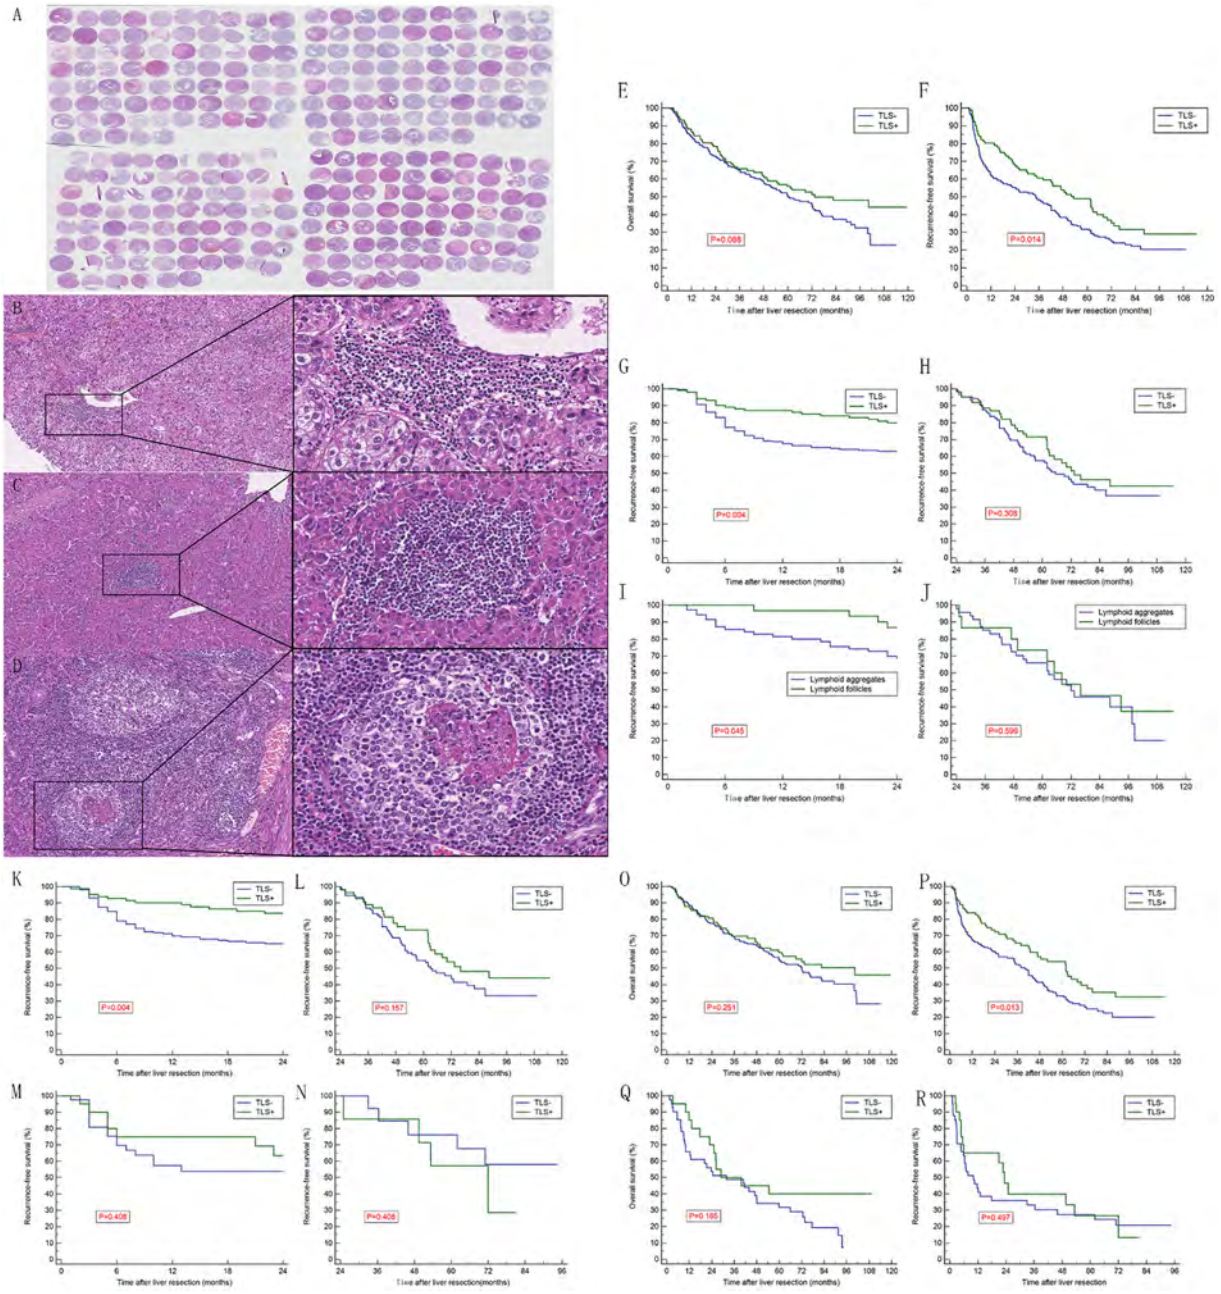

Figure: (abstract: THU-474): Characterization of tertiary lymphoid structures within hepatocellular carcinoma (A-D); Clinical relevance of intratumoral tertiary lymphoid structures in 303 patients with hepatocellular carcinoma (E-F); Association between intratumoral tertiary lymphoid structures and tumor relapse (G-J); Association between intratumoral tertiary lymphoid structures and tumor relapse for HCC patients with different tumor stages (K-N); Association between intratumoral tertiary lymphoid structures and tumor relapse for HCC patients with different tumor stages (O-R).

analyses identified TLS as a favorable factor for early tumor relapse (hazard ratio, HR = 0.501, P = 0.005). Patients with more mature TLS were associated with better clinical outcomes (p = 0.045). Importantly, the prognostic value of TLS was limited to BCLC stage 0-A HCC (p = 0.004), other than more advanced tumor (p = 0.408).
Conclusion: Our study suggested that the existence of intratumoral TLS was associated with a decreased risk of early tumor relapse for patients with BCLC stage 0-A HCC. TLS-targeted immune-modulating therapies might be potential strategies for effective immune-mediated tumor control.

THU-475

CENPF translocation for autoantigen presentation and autoimmune activation in hepatocellular carcinoma

Xiaojin Li[1,1], Anjian Xu[1], Donghu Zhou[1], Bei Zhang[1], Yanmeng Li[1], Jian Huang[1]. [1]*Beijing Friendship Hospital, Capital Medical University, Experimental Center, Beijing, China*
Email: huangj1966@hotmail.com

Background and aims: Tumor-associated antigen autoantibodies have advantages in early diagnosis of tumor. We have screened out CENPF autoantibody with high sensitivity and specificity in early hepatocellular carcinoma (HCC) diagnosis, but the mechanism of CENPF induced autoimmune activation and autoantibody production

is unclear. We found it might be associated with abnormal expression and localization of CENPF and cell apoptosis. We undertook this study to reveal the mechanism of CENPF antigen exposure and autoantibody production.

Method: The expression levels of CENPF in HCC cell lines, normal liver cell, tumor tissue and adjacent normal tissue were analyzed by real-time PCR and Western blot. The autoantibody level induced by HCC cells with different CENPF expression was assayed in tumor mouse model. The cellular localization of CENPF in HCC cells and normal liver cell was analyzed using confocal microscopy. By ELISA method, we assayed the secretion of CENPF into intercellular space in tumor tissue and adjacent normal tissue. After cell apoptosis induction, we studied the translocation and localization of CENPF by confocal microscopy and flow cytometry. The phagocytosis of apoptotic bodies and blebs by DC cells was analyzed by confocal microscopy.

Results: CENPF was overexpressed in HCC as compared with non-tumor cell or tissue. Highly expressed CENPF induced more autoantibody production in tumor mouse. Overexpressed expressed CENPF distributed in both nucleus and cytoplasm of HCC cells, whereas in normal liver cell CENPF mainly localized in the nucleus of dividing cell. In tumor tissue and adjacent normal tissue, no significant difference was seen in secretion of CENPF into intercellular space. The cell membrane expression level of CENPF was in direct proportion to cell apoptosis rate and was independent with cell necrosis. During apoptosis, apoptotic blebs were formed and CENPF was translocated from apoptotic cell bodies to apoptotic blebs. Apoptotic blebs and bodies seemed to be a preferred target of DC phagocytosis.

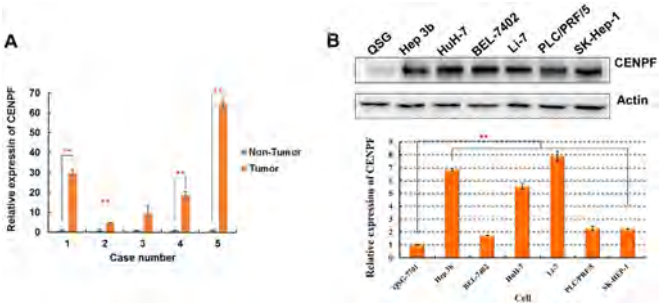

Figure 1: CENPF was overexpressed in HCC as compared with non-tumor tissue (A) or cells (B).

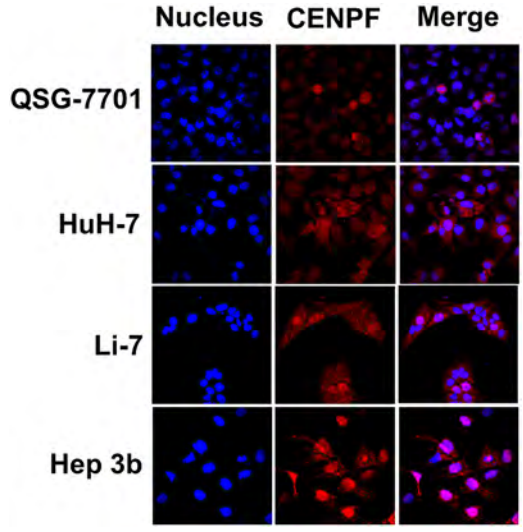

Figure 2: The distribution of CENPF in HCC cells HuH-7, Li-7, Hep 3b, and normal liver cell QSG-7701.

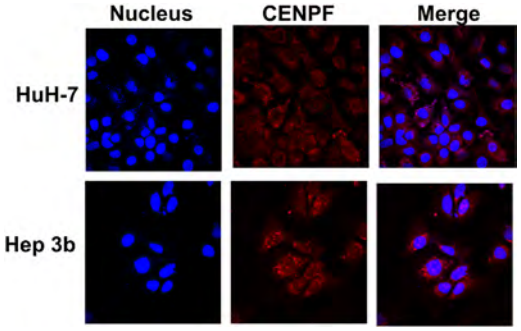

Figure 3: apoptotic blebs were formed and CENPF was translocated from apoptotic cell bodies to apoptotic blebs.

Conclusion: The overexpressed and abnormal localization of CENPF in HCC were key factors in autoantibody generation. Cell apoptosis induced the subcellular translocation and surface exposure of CENPF antigen, thus might result in antigen capture and autoantibody production.

THU-476

Modeling cancer stem cell and differentiated cancer cell phenotypes in liver cancer organoids

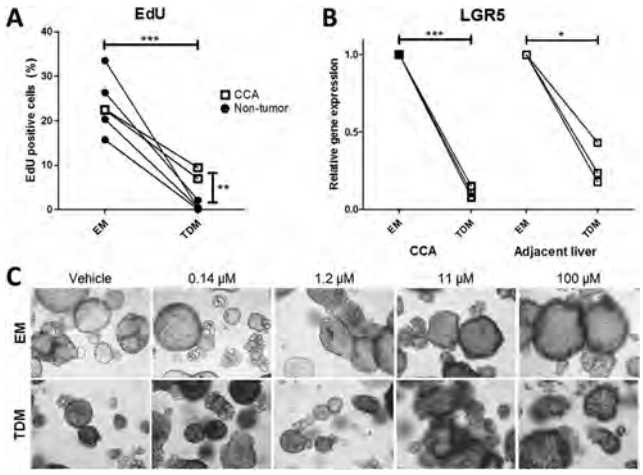
Ruby Lieshout[1], Monique M.A. Verstegen[1], Yik Y. Kan[1], Terry Jorna[1], Demy van Gilst[1], Jan IJzermans[1], Luc J.W. van der Laan[1]. [1]*Erasmus MC University Medical Center, Department of Surgery, Rotterdam, Netherlands*

Email: r.lieshout@erasmusmc.nl

Background and aims: Cholangiocarcinoma (CCA) is a biliary-type liver tumor with a dismal prognosis, due to late diagnosis, high chemo-resistance and tumor heterogeneity. Recently, we established long-term 3D CCA organoids which retain the histological architecture, gene expression profile and genomic landscape of the original tumor and are amenable to drug screening approaches. Due to the stem cell characteristics of organoids, CCA organoids represent a cancer stem cell (CSC)-like phenotype. CSC's are known to be resistant to chemo- and radiation therapy. However, the bulk of cancer cells in a tumor have a differentiated (non-stem cell) phenotype and are more therapy-sensitive. The aim of our study is to establish a model to study both the CSC and differentiated cancer cell phenotypes in CCA organoids and apply this in drug sensitivity screening.

Method: Organoids from CCA, non-tumorous adjacent liver and healthy liver tissue (all n = 3–6) were differentiated by blocking cancer stem cell signaling pathways. At day 5, cell viability, proliferation, cell death and differentiation potential was tested on gene expression (qPCR) and protein (immunohistochemistry) level and compared to CSC-like organoids. Drug sensitivity of differentiated and CSC-like CCA organoids was tested with sorafenib.

Results: Live/dead staining revealed that the level of cell death in differentiated organoids was similar to CSC-type cultures. Differentiated CCA organoids had a reduced proliferative rate, as demonstrated by reduced EdU incorporation (fig. A) and down-regulation of Ki67 gene expression ($p < 0.001$). Even though proliferation is inhibited, metabolic activity was stable, indicating a higher metabolic activity per differentiated cell. Gene expression analysis showed that known CSC markers LGR5 (fig. B), CD44 ($p = 0.01$) and CD133 ($p < 0.01$) were downregulated upon differentiation. Preliminary results from a drug sensitivity assay suggested that differentiation of CCA organoids increased their sensitivity to sorafenib (fig. C).



Conclusion: This study shows that it is feasible to differentiate liver tumor-derived organoids from a CSC-like phenotype towards a differentiated cancer cell phenotype. Differentiated CCA organoids are less proliferative, downregulate CSC markers and are more sensitive to sorafenib. More elaborate drug screenings are ongoing in order to more accurately identify effective compounds to treat CCA.

THU-477

Sumoylation/acetylation drives forward oncogenic role of LKB1 in Liver

Fernando Lopitz Otsoa[1], Imanol Zubiete-FRanco[2], Juan Luis García Rodríguez[2], Marina Serrano-Macia[2], Jorge Simón[2], Pablo Fernández Tussy[2], Lucía Barbier Torres[2], David Fernandez-Ramos[1], Virginia Gutiérrez de Juan[1], Sergio López de Davalillo[2], Onintza Carlevaris[3], Adolfo Beguiristain Gomez[4], Julio arrizabalaga[4], Diego F Calvisi[5], Cesar Martin[6], Edurne Berra[3], Patricia Aspichueta[7], Naiara Beraza[2], Marta Varela-Rey[2], Matías A Avila[8], Manuel S Rodriguez[9], José M. Mato[1], Irene Diaz-Moreno[10], Antonio Diaz-Quintana[10], Teresa Cardoso Delgado[2], María Luz Martínez-Chantar[2]. *[1]CIC bioGUNE, Liver Metabolism Lab, Derio, Spain; [2]CIC bioGUNE, Liver Disease Lab, Derio, Spain; [3]CIC bioGUNE, Derio, Spain; [4]Osakidetza, 20014 Donostia, Spain; [5]University of Greifswald, Greifswald, Germany; [6]Unidad de Biofisica, Leioa, Spain; [7]UPV/EHU, Departamento De Fisiologia, Leioa, Spain; [8]Universidad de Navarra, Pamplona, Spain; [9]ITAV-Centre Pierre Potier, 31106 Toulouse Cedex 1, France; [10]Universidad de Sevilla, Sevilla, Spain*
Email: mlmartinez@cicbiogune.es

Background and aims: In contrast with the commonly accepted model that describes Liver kinase B1 (LKB1) as a tumor suppressor in a wide variety of tissues, our group and also others have reported its oncogenic role in the liver. Indeed, LKB1 aberrant expression is associated with low survival in hepatocellular carcinoma (HCC) by unknown mechanisms.
SUMOylation is a reversible post-translational modification (PTM) with a crucial role on the control of nucleocytoplasmic signaling and transport of its target proteins. Even though loss-of-function mutations in components of the SUMO pathway are rare due to the fact that SUMOylation is an essential process to cells, expression of the SUMO E2 conjugating enzyme (UBC9) and other E3 SUMO-protein ligases are found to be upregulated and related to poor prognosis in HCC. In this work, we have explored the mechanism underlying the oncogenic behavior of LKB1 in HCC. New insights of SUMOylation/acetylation in LKB1 regulation are discussed in the context of tumor driver *vs* tumor suppressor in the liver.
Method: To address this, we have overexpressed LKB1 in human hepatoma cells and by using histidine pull-down assay we have investigated the role of the hypoxia-related SUMOylation/acetylation in the regulation of LKB1 oncogenic role. High affinity SUMO binding entities-based technology has been used to validate our findings in an in vivo pre-clinical mouse model and in liver cancer patients. Finally, we have performed a molecular modeling between SUMOylated LKB1 and its formal interactors STe20-Related ADaptor (STRADα) cofactor involved in the regulation of LKB1 nucleocytoplasmic shuttling and its activity.
Results: In human hepatoma cells under hypoxic stress, LKB1 overexpression induces deregulated cell growth and changes in its cellular localization. By using site-directed mutagenesis, we have shown that SUMO-2 LKB1 at Lys178 is the responsible to hamper LKB1 nucleocytoplasmic shuttling and fuel hepatoma cell growth. Importantly, we have identified that acetylation at Lys48 is required by LKB1 SUMOylation. Molecular modelling of SUMO modified LKB1 further confirmed steric impedance between SUMOylated LKB1 and the STe20-Related ADaptor cofactor, involved in LKB1 export from the nucleus. Finally, we provide evidence that endogenous LKB1 is modified by SUMO/acetylation in preclinical mouse models of HCC, complemented with clinical HCC biopsies.
Conclusion: In conclusion, we have shown that SUMO-2 modifications of LKB1 at Lys178 after its acetylation at Lys48 occur in human hepatoma cells and HCC, thus inhibiting the binding of LKB1 to STRADα and hampering its nucleocytoplasmic shuttling. The nuclear localization of LKB1 by SUMO modification is the main and differential driver of its oncogenic role in liver.

THU-478

CXCL5 induced by transforming growth factor-beta and Axl signalling causes neutrophil extracellular trap formation in hepatocellular carcinoma

Elisa Holstein[1], Eva Řezníčková[1], Teresita Flores[1], Huber Heidemarie[1], Gerhard Weber[1], Thomas Mohr[1], Gerald Timelthaler[1], Wolfgang Mikulits[1]. *[1]Institute of Cancer Research, Department of Medicine I, Vienna, Austria*
Email: wolfgang.mikulits@meduniwien.ac.at

Background and aims: Transforming growth factor (TGF)-beta and the receptor tyrosine kinase Axl that is activated by its ligand Gas6 are crucially involved in the development of hepatocellular carcinoma (HCC). Gas6/Axl interacts with 14-3-3-zeta to aberrantly activate TGF-beta/Smad3 linker region at serine 213 via c-Jun N-terminal kinase, causing the activation of pro-metastatic genes and autocrine TGF-beta signaling. In addition, the synergy of TGF-beta and Gas6/Axl induces the expression and secretion of CXCL5. Notably, CXCL5 is almost exclusively expressed in TGF-beta-positive HCC patients, correlating with neutrophil infiltration into the HCC microenvironment and poor patient survival. In this study, we aimed at investigating the TGF-beta/Axl/CXCL5-dependent attraction and activation of neutrophils.
Method: We employed human HCC models upregulating CXCL5 in response to long-term TGF-beta exposure. TCGA datasets of HCC patients (n = 400) were analyzed in tumor-, stroma- and immune-compartments by in silico microdissection. Formation of neutrophil extracellular traps (NETs) was studied by confocal immunofluorescence analysis and enzyme-linked immunosorbent assays by detecting citrullinated histone 3 (cit-H3) and neutrophil-specific enzymes. Inhibition of Axl and TGF-beta signaling in HCC cells was performed by pharmacological intervention, CRISPR/Cas9 genomic editing and RNA interference.
Results: The analysis of novel TCGA datasets revealed upregulation of CXCL5 in a large HCC patient cohort expressing Axl and TGF-beta. Loss of either Axl or TGF-beta signaling in human HCC cells abrogated CXCL5-dependent migration and attraction of neutrophils. Co-cultivation of CXCL5-secreting HCC cells with neutrophils induced NET formation as detected by the release of DNA associated with cit-H3 and neutrophil elastase as well as by the release of neutrophil DNA linked to myeloperoxidase. NET formation induced by the exposure of neutrophils to supernatants of CXCL5-positive HCC cells was

diminished by treatment with neutralizing CXCL5 antibody. Pharmacological or genetic inhibition of either TGF-beta/Smad or Axl signaling reduced NET formation, suggesting that Axl/TGF-beta is essentially involved in regulating the immunophenotype. In HCC patient samples Axl, TGF-beta and CXCL5 expression correlated with neutrophil infiltration and NET formation.
Conclusion: The molecular collaboration between TGF-beta and Axl induces the CXCL5-dependent NET formation in HCC. Disruption of TGF-beta/Axl/CXCL5 signaling provides a promising therapeutic strategy to interfere with HCC progression in TGF-beta-positive patients.

THU-479
The hepatocyte specific role of the NRF2/KEAP1 axis for HCC Progression during chronic liver disease

Antje Mohs[1], Tobias Otto[1], Roland Sonntag[1], Kai Markus Schneider[1], Mark Boekschoten[2], Christian Trautwein[1]. [1]*University Hospital RWTH Aachen, Department of Internal Medicine III, Aachen, Germany;* [2]*Wageningen University and Research, Department of Agrotechnology and Food Sciences, Wageningen, Netherlands*
Email: amohs@ukaachen.de

Background and aims: Hepatocellular carcinoma (HCC) occurs as a consequence of malignant transformation of hepatocytes frequently triggered during chronic inflammation and consecutive liver fibrosis. Oxidative stress has been considered as a conjoint pathological mechanism, and it contributes to initiation and progression of liver injury. The KEAP1 (Kelch-like ECH-associated protein-1)/NRF2 (erythroid 2-related factor 2) axis is a major regulator system of cellular redox balance. We investigated whether activation of the NRF2 pathway, by inactivation of the negative regulator KEAP1, affects the development of liver injury, fibrogenesis and HCC development.
Method: Hepatocyte specific NEMO ($NEMO^{\Delta hepa}$) knockout- mice were crossed with hepatocyte specific KEAP1 ($KEAP1^{\Delta hepa}$) knock-out mice to generate $NEMO^{\Delta hepa}$/$KEAP1^{\Delta hepa}$ mice. Primary hepatocytes as well as liver were subjected to microarray analysis. Furthermore, liver injury, DNA damage, proliferation as well as liver fibrogenesis and HCC development were analysed.
Results: Microarray analysis of primary hepatocytes of $NEMO^{\Delta hepa}$ and $NEMO^{\Delta hepa}$/$KEAP1^{\Delta hepa}$ and their controls revealed that particularly two signalling pathways were differentially regulated. Hepatocyte specific KEAP1 deletion upregulated genes involved in glutathione metabolism and xenobiotic stress (e.g. HO-2, Nqo1). Secondary, genes involved in cell cycle regulation and DNA replication were dramatically downregulated in $NEMO^{\Delta hepa}$/$KEAP1^{\Delta hepa}$ compared to $NEMO^{\Delta hepa}$ primary hepatocytes.
Accordingly, 8-week old $NEMO^{\Delta hepa}$/$KEAP1^{\Delta hepa}$ mice showed significantly elevated hepatic GSH levels and genes involved in the oxidative stress response compared to $NEMO^{\Delta hepa}$ mice. Furthermore, deletion of KEAP1 in $NEMO^{\Delta hepa}$ mice resulted in reduced apoptosis, proliferation and DNA damage. Subsequently, $NEMO^{\Delta hepa}$/$KEAP1^{\Delta hepa}$ mice displayed decreased fibrogenesis and in late disease stage a lower tumour incidence, a reduced tumour number and decreased tumour size.
Conclusion: Hepatocyte specific inactivation of KEAP1 in $NEMO^{\Delta hepa}$ livers attenuated apoptosis, DNA damage and hepatic fibrosis progression. Consequently, deletion of KEAP1 in $NEMO^{\Delta hepa}$ mice ameliorated HCC progression. Hence, KEAP1 is an attractive target to treat chronic liver disease.

Imaging mechanical stiffness and molecular landscapes of cancer stem cell niches in human hepatocellular carcinomas

François Tiaho[1], Denis Rouède[2], Frédéric Ezan[1], Georges Baffet[1], Orlando Musso[3]. [1]*INSERM, Institut de Recherche en Santé, Environnement et Travail (IRSET), Rennes, France;* [2]*CNRS, Univ Rennes, Institute of Physics of Rennes, RENNES, France;* [3]*INSERM, Univ Rennes, INRA, Institut Nutrition Metabolisms and Cancer, Rennes, France*
Email: orlando.musso@inserm.fr

Background and aims: Hepatocellular carcinoma (HCC) is the 3rd cause of cancer death worldwide and its heterogeneity challenges patient management. HCC heterogeneity distributes across a continuum of decreasing tumour differentiation and increasing proliferation. Proliferative-type HCCs exhibit a rich extracellular matrix (ECM) network, cancer cell plasticity and clinically aggressive stem/progenitor cells. These features are histologically observed as ECM-rich hotspots embedding cancer stem/progenitor cells. They are called "fibrous nests." The aim of this work is to image and model the plasticity of ECM and cancer cells and to obtain a dynamic picture of the mechanical forces in tumour tissues. In fibrous nests, cancer cells may be arranged as "Indian files" aligned along collagen fibres and myofibroblasts. This alignment may involve ECM-cell interactions and mechanical forces affecting cell fate through 3-dimensional ordering of collagen fibrils.
Method: we applied second harmonic generation (SHG), which is very performant for imaging human liver fibrosis, and two-photon-excited fluorescence microscopy (TPM), which combines SHG with fluorescence immunodetection. By Polarization-dependence SHG, the geometric organization of collagen fibrils can be studied and correlated to ECM stiffness. Then, we *in vitro* modelled fibre alignment in Huh-7 human liver cancer cells cultured in collagen matrices of varying mechanical properties.
Results: CD44, HAPLN1 and LGR5 (+) cancer stem/progenitor cells and ACTA2 (+) myofibroblasts were aligned along collagen fibres in human HCCs. By SHG combined with TPM, we co-localized collagen fibres with CD44 (+) cancer stem/progenitor cells and ACTA2 (+) myofibroblasts. The number of collagen pixels and the rates of fibre alignment were higher in high-grade than in low-grade fibrous nests. Fibre alignment rates related to ECM stiffness were then modelled *in vitro* in Huh-7 human liver cancer cells cultured in collagen matrices of varying mechanical properties. In these in vitro models, TPM and SHG showed that the longitudinal axis of tumour cells aligned parallel to collagen fibres, reproducing "Indian files."
Conclusion: cancer cell invasion along oriented collagen fibres seems to be a general mechanism whereby tumour cells make up the trails along which they infiltrate. These tools will allow further studies on the molecular landscapes and signalling pathways underlying mechanical forces in human HCC fibrous nests.

THU-481
Classification of intrahepatic cholangiocarcinoma microenvironment based on immune cell and tumor stromal features

Hiep Nguyen Canh[1], Kenta Takahashi[1], Kazuto Kosaka[2], Yasunori Sato[1], Kenichi Harada[1]. [1]*Kanazawa University Graduate School of Medicine, Human Pathology, Kanazawa, Japan;* [2]*Kanazawa University Graduate School of Medical Sciences, Department of Radiology, Kanazawa, Japan*
Email: kenichih@med.kanazawa-u.ac.jp

Background and aims: Intrahepatic cholangiocarcinoma (ICC) is characterized by an abundant stroma. Different components of the tumor microenvironment (TME) have been correlated with poor outcomes of patients. However, there are no systemic histological classifications for ICC stroma applied in daily practice. Here we classified stroma of ICC into four histological subtypes (early, activated, mature or inflammatory stroma) using formalin-fixed and paraffin-embedded samples and correlated with its pathology features.
Method: A total of 60 primary mass forming ICCs treated by resection were collected. Components of tumor microenvironment including tumor-infiltrating lymphocytes (TILs), cancer-associated fibroblasts

(CAFs, classified as normal or activated) and tumor fibrosis were evaluated, based mainly on routine staining methods. Immunohistochemistry stains detecting alpha-smooth muscle actin (α SMA), CD3 and CD276 were performed to support histological evaluation. Areas of the stromal subtypes in each tumor were separately evaluated and the prominent component (≥ 50% stroma area) was considered as the final stromal type of each case. The number of CD3 positive lymphocytes were counted and TILs were analysed at the invasive margin (IM) and tumor center (TC) using standardized assessment methods.

Results: ICC cases with activated, early, mature and inflammatory stroma accounted for 53.3%, 23.3%, 18.3%, and 5%, respectively. The early subtype was characterized by a loose stroma with low fibrotic and CAFs densities; activated stroma had a high number of activated CAFs; mature stroma consisted of high collagen density and low number of CAFs while inflammatory stroma contained prominent and diffuse lymphocyte infiltration. ICCs with activated stroma were associated with higher frequency of vascular invasion (29/32 cases), compared to those with early stroma (7/14 cases), mature stroma (6/11 cases), and inflammatory stroma (1/3 case) ($p = 0.004$). However, ICC showed widely intratumoral stromal diversity including differences in the numbers, distribution, and components of inflammatory infiltration. The infiltration of lymphocytes was mainly found at the invasive margin of ICCs with mature or activated stroma. The mean percentages of TILs (40%, 12%, 8%, and 5%) and mean number of CD3 positive lymphocytes (122, 40, 28 and 6 cells/mm^2) at the TC, but not at IM, showed significant difference among stromal subtypes (inflammatory, activated, early and mature stroma, respectively, $p = 0.02$). Furthermore, activated stroma was associated with large bile duct histological type. CD276 expression was found on activated stroma of 20/27 (74%) ICC cases, but not on background liver.

Conclusion: We have identified four stromal subtypes of ICC correlated with histological subtypes, tumor invasion and tumor immune features, which may be useful to predict patient outcomes.

A human anti-MICA/B antibody boost NK cell responses in hepatocellular carcinoma

STEFANIA MANTOVANI[1], Matteo Donadon[2], Cristiana Soldani[3], Barbara Franceschini[3], Roberto Santambrogio[4], Claudia Cigala[5], Marcello Maestri[6], Camillo Porta[7], Stefania Varchetta[1], Dalila Mele[1], Mario Umberto Mondelli[8], Barbara Oliviero[1,1]. *[1]Fondazione IRCCS Policlinico San Matteo, Division of Infectious Diseases II and Immunology, Pavia, Italy; [2]Humanitas Clinical and Research Center, Department of Hepatobiliary and General Surgery, Milan, Italy; [3]Humanitas Clinical and Research Center, Milan, Italy; [4]San Paolo Hospital, University of Milan School of Medicine, Milan, Italy; [5]San Paolo Hospital, University of Milan School of Medicine, Milan, Italy; [6]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [7]Fondazione Salvatore Maugeri IRCCS, Pavia, Italy; [8]Fondazione IRCCS Policlinico San Matteo and University of Pavia, Division of Infectious Diseases II and Immunology Department of Medical Sciences and Infectious Diseases and Department of Internal Medicine and Therapeutics, Pavia, Italy*
Email: mario.mondelli@unipv.it

Background and Aims. Natural Killer (NK) cells play a key role in tumor immunity, their function being tightly regulated by NK receptors and their ligands. Current evidence indicates that hepatocellular carcinoma (HCC) cells express several NKG2D ligands, including major histocompatibility complex class I chain-related protein A and B (MICA/B). We investigated whether a human anti-MICA/B monoclonal antibody (mAb) and *in vitro* treatment with drugs able to enhance MICA/B expression on tumor cells could boost NK cell responses toward HCC cells.

Method: Peripheral blood mononuclear cells (PBMC) were obtained from healthy donors (HD) or HCC patients. Liver-infiltrating lymphocytes were simultaneously obtained from tumorous (TIL) and surrounding non-tumorous (LIL) tissue by mechanical and enzymatic treatment. NK cell degranulation was assayed after coculture of unstimulated or IL15-stimulated PBMC, LIL or TIL with Huh7.5 or primary HCC cells. MICA/B expression on target cells was examined before and after bortezomib or gemcitabine treatment. Antibody-dependent cellular cytotoxicity (ADCC) was assayed by 7-aminoactinomycin D (7-AAD) release from target cells in the presence of a humanized MICA/B-specific mAb.

Results: Anti-MICA/B mAb significantly enhanced degranulation of circulating NK cells toward Huh7.5 cells in HD. Similar results were obtained when Huh7.5 cells were treated with gemcitabine or bortezomib that were shown to induce MICA/B expression. Similar findings were observed with circulating NK cells from HD and HCC subjects using primary HCC cells as target. Interestingly, TIL, but not LIL, showed increased degranulation for autologous untreated HCC cells. However, when anti-MICA/B was tested for its ability to mediate ADCC toward primary HCC cells, significantly increased 7-AAD release was found in HD only, in agreement with reduced CD16 receptor expression on patients' circulating and intra-hepatic NK cells.

Conclusion: A MICA/B-specific mAb significantly increased peripheral and tumor-infiltrating NK cell degranulation in HCC patients. Moreover, the same mAb was able to promote significant ADCC by HD NK cells for primary HCC cells, suggesting a possible use in immunotherapy for primary liver cancer based on allogeneic NK cell infusion.

THU-483

Blood based weighted gene co-expression network analysis identifies miRNA prognostic biomarkers for HCC

Devis Pascut[1], Francesca Gilardi[1], Muhammad Yogi Pratama[1,2], Riccardo Patti[3], Saveria Lory Croce'[1,3,4], Claudio Tiribelli[1]. *[1]Fondazione Italiana Fegato-ONLUS, Centre for Liver Studies, Trieste, Italy; [2]Hasanuddin University, Faculty of Medicine, Makassar, Indonesia; [3]University of Trieste, Departmento of Medical Sciences, Trieste, Italy; [4]Azienda Sanitaria Universitaria Integrata di Trieste (ASUITS), Clinica Patologie Fegato, Trieste, Italy*
Email: devis.pascut@fegato.it

Background and aims: Hepatocellular Carcinoma (HCC) ranks fifth as most common cause of cancer related death worldwide. Although treatment options have improved in the past 30 years, prognosis remains unsatisfactory. The lack of effective outcome prediction models prevent the opportunity for individualized treatment protocols. The potential role of microRNAs (miRNA) as prognostic biomarker has witnessed an increasing interest, owing to the non-invasive nature of miRNA-based screening assays. In this study, we used the weighted miRNA co-expression network analysis (WGCNA) to identify circulating miRNA clusters and miRNA candidates as predictive biomarkers for therapy response and overall survival.

Methods: Twenty patients with early/intermediated stage HCC were enrolled and treated according to the EASL/AASLD practice guidelines. Patients were staged at time 0 and 1, 6, 12 month from therapy with CT scan and/or MR; the longest follow-up was 48 month. Blood samples were collected at the admission time and the whole blood miRNome was analysed thought miRNA 3.0 gene array (Affymetrix). Expression data were used for the WGCNA. Network modules associated with clinical parameters were identified and Hub miRNAs were selected as biomarker candidates. Biomarkers were internally validated through a bagging out of bag predictive model with a bootstrap sampling.

Results: Six miRNA modules were identified and associated with clinical data such as treatment response, recurrence time, survival. Two modules were associated with treatment response, and one to survival. Within these modules, five hub miRNAs have a significant association with treatment response and survival ($p < 0.01$ and Module Membership > 70%), miR-194-5p, miR-3150b-3p, miR-4526, miR-574-5p, miR-4462. The selected miRNA were included in a

bagging out of bag predictive modelling procedure with bootstrap sampling of 1000 cycles. When considering the model including miR-3150b-3p, miR-4526 and miR-4462 as predictor for therapy response the AUC was 0.84 with a specificity and Sensibility of 85.7% and 83.3%, respectively.
Conclusions: WGCNA identified several key circulating miRNAs that may be used as potential biomarkers to predict therapy response in HCC patients.
Funding: The study was supported by the project surface-enhanced Raman microRNA for cancer (SERMI4CANCER) POR FESR 2014 2020 Friuli Venezia Giulia, decree no.3028 05/05/2017 and no. 4526 16/06/2017.

Mass spectrometric analysis of serum haptoglobin fucolysation in patients stratified according to fibrosis stages, and the presence of hepatocellular carcinoma

Valentina Peta[1], Prof. David Lubman[2], Dr Jianhui Zhu[2], Rezai Keyvan[3], Huguet Samuel[3], Imbert-Bismut Francoise[4], Bolbach Gerard[5], Codic Gilles[5], Matheron Lucrece[5], Chantal Housset[6], Thierry Poynard[7,8]. *[1]BioPredictive, Paris, France; [2]University of Michigan, Ann Arbor, United States; [3]Curie Institute, St Cloud, France; [4]APHP, Paris, France; [5]Sorbonne University, Paris, France; [6]INSERM, Paris, France; [7]APHP, Paris, France; [8]Sorbonne University, INSERM 938, Paris, France*
Email: thierry@poynard.com

Background and aims: Serum haptoglobin (Hp) is a reporter molecule for aberrant glycosylation in liver disease. Bifucosylated tetra-antennary haptoglobin glycan (fHp), has been used as a potential marker for primary liver cancer (HCC), but its specificity according to severity of fibrosis has never been assessed.
The aim was to assess if fHp was associated with HCC independently of the fibrosis stage and could increase the performance of the standard test (AFP), and not-standard tests (AFPL3, PIVKA).
Methods: From a prospective cohort, we retrospectively selected patients (Pts) with available frozen serum, 110 with contemporaneous HCC for assessing the sensitivity, and for assessing the specificity in versus 140 controls without HCC, including 81 with non-cirrhotic stages (F0 to F3) and 59 Pts with cirrhosis with the 3 classes of severity (F4.1, F4.2, F4.3), according to FibroTest cutoffs (JHepatol 2008). Applicability was defined as Hp ≥0.3 mg/L enabling the identification of fHp. LCR3- Algorithms (patent pending) were constructed (logistic regression) combining fHp, total Hp, GGT, apoA1, alpha-2-macroglobulin, with and without AFP-AFPL3-PIVKA, adjusted for age and gender. AFP and AFP-L3 were measured on a μTASi30 analyzer (Wako) and PIVKA by Lumipulse® G120 analyzer (Fujirebio). The presence of fHp was assessed by MALDI-TOF analysis of Hp purified using an anti-Hp antibody immobilized HPLC column. The N-glycans were released with PNGaseF, desialylated with neuraminidase, purified and permethylated prior to MALDI-TOF-TOF MS analysis.
Results: (Table)

Conclusion: Hp-F was strongly associated with the presence of HCC and permitted to improve the performances of current HCC biomarkers.

Email: david.pinato09@imperial.ac.uk

Background and aims: Modulation of adaptive immunity is postulated to underscore the efficacy of TACE. We evaluated the influence of TACE on T-cell function by assessing the phenotypic characteristics of lymphocyte populations from archival liver explants of patients who underwent orthotopic liver transplantation (OLT) with (T^+) or without (T^-) prior-TACE treatment using multi-parameter immunohistochemistry and targeted transcriptomics.
Method: We profiled tumoural and non-tumoural cirrhotic background tissue to evaluate regulatory $CD4^+/FOXP3^+$ (T-reg) and immune-exhausted $CD8^+/PD1^+$ T-cells in relationship with the expression of actionable drivers of anti-cancer immunity including PD-L1, IDO-1, CTLA-4, Lag-3, Tim-3 and CD163. Expression of candidate biomarkers was compared across T^+ and T^- patients and correlated with clinico-pathologic characteristics. We utilised Nanostring PanCancer Immune profiling to broadly characterise the differential enrichment of 770 immune-related transcripts across T^+ versus T^-.
Results: We analysed archival samples from 20 OLT recipients (T^+ n = 11, T^- n = 9), 80% males, 75% with HCV-cirrhosis. Median tumour size was 2.3 cm, 75% of patients had T1-T2 tumours, 85% were within Milan criteria, 70% grade 2 with micro-vascular invasion in 35%. Median percentage of necrosis post TACE was 30% (range 0–90%). T^+ and T^- groups were similar by size, stage, grade, etiology of cirrhosis and MVI ($p > 0.05$). T^+ specimens had evidence of significantly lower density of $CD8^+/PD1^+$ immune-exhausted T-cells within the tumour (9 versus 21 cells/mm^2, p = 0.03) but higher $CD4^+/FOXP3^+$ density of T-regs in cirrhosis (7.5 versus 0 cells/mm^2, p = 0.01). We found no significant difference in the expression of a number of drivers of T-cell

Table 1: (abstract: THU-484): Applicability, sensitivity (Se), specificity (Sp) of FfHp according to fibrosis stage, age and gender

Fibrosis stage	HCC n	fHp+ True positive NA (%)/n (% = Se)	Age ≥ 50 yr (%)	Male (%)	controls n	fHp+ False positive NA %/n (% = 1-Sp)	Age ≥ 50 yr (%)	Male (%)

NA: not applicable [1]P < 0.001 between HCC and controls [2] P = 0.005 between HCC and controls
FfHp alone had in intention to diagnose Se = .57, Sp = .89 and per protocol Se = .74, Sp = .88
Among these fibrosis-adjusted Pts the best AUROC (95%CI) was obtained by LCR3 algorithm with fHp-AFPL3-PIVK (.92;.86-.95) vs.82 (.75–0.87;P = .006) for standard AFP,.84 (.77-.89;P = 0.02) for AFPL3 and.85 (.78-.90;P = 0.04) for PIVKA. The false positive rate was 33% among Pts with severe cirrhosis.

exhaustion including PD-L1, IDO-1, Lag-3, Tim-3 or CD163 across T+ versus T- samples. Targeted transcriptomic profiling revealed differential regulation of genes reflective of adaptive and innate anti-cancer immune responses across T^+ versus T^-.
Conclusion: Pre-treatment with TACE is associated by lower density of immune-exhausted intra-tumoural T-cells and stronger T-reg infiltration in the peri-tumoural infiltrate. This highlights the pleiotropic effects of TACE in modulating the tumour microenvironment and strengthens the rationale for developing immunotherapy alongside TACE to improve clinical outcomes of patients with HCC.

A pro-regenerative environment triggers premalignant to malignant transformation and pinpoints new therapeutic targets

Anna Potapova[1], Viktoriia Iakovleva[1], Agnes Bee Leng Ong[1], Lars Zender[2,3,4], Torsten Wuestefeld[1,5]. Email: wustefeldt@gis.a-star.edu.sg

Background and aims: Aging, chronic tissue damage and inflammation are main risk factors and contributors to cancer. We investigated the interactive relationship of premalignant senescent hepatocytes, a regenerative environment and the influence of secreted factors for liver tumorigenesis in a mouse model.
Method: Through hydrodynamic tail vine injection of transposon based constructs for the expression of oncogenic NRasG12 V we triggered oncogene induced senescence in 5–10% hepatocytes of C57Bl6/j mice. In wt mice these senescent cells are eliminated by immunosurveillance. We then performed 2/3 partial hepatectomy (PH) as well as thioacetamide treatment to induce acute liver regeneration or chronic liver damage/regeneration respectively. We further applied transcriptomic and proteomic analysis to identify mechanisms of premalignant to malignant transition and for its suppression. Results were also validated in oxidative stress induced senescence and human cells.
Results: Interestingly, senescent hepatocytes are attenuating the regenerative process, indicated by less proliferation and a higher amount of cell cycle arrested cells. However, under regenerative pressure immunosurveillance is aborted. Even a single acute damage by PH is sufficient, leading to expansion of premalignant senescent hepatocytes already 40 days post PH and finally liver tumor development. Immune surveillance is not reinitiated after tissue regeneration finished, but liver tumor development still takes time, as first mice succumb to cancer around 150 days post tissue damage. The same situation we saw in case of chronic liver damage. Through investigating the transcriptomic signature we identified TFF3 as a potential player and could show that TFF3 knockdown abrogates the transformation of premalignant hepatocytes upon liver damage. The animals which still got a tumor showed no knockdown in the tumor tissue for TFF3. Through further transcriptomic as well as proteomic analysis we identified IGFBP5 as a mediator of tumor suppression. Tff3 knockdown leads to a strong upregulation of IGFBP5 which then suppresses IGFR1 signalling and blocks pro-oncogenic downstream pathways. The relation of Tff3 knockdown and IGFBP5 upregulation is conserved in humans and also suppresses human cancer cell proliferation.
Conclusion: We showed that liver damage triggers premalignant to malignant transformation of hepatocytes, immunosurveillance escape and liver tumor formation. This can be suppressed by inhibiting TFF3, leading to a strong upregulation of IGFBP5. Furthermore this mechanism is conserved in humans and represents a therapeutic target.

Email: yogi.pratama@fegato.it

Background and aims: One of the most crucial strategies to improve prognosis of patients with Hepatocellular Carcinoma (HCC) involves the discovery of predictive non-invasive biomarkers. This study aimed to investigate the potential role of serum miR-4492 as a prognostic biomarker in the cohort of patients with HCC.
Method: A total of 100 HCC patients were enrolled and treated according to the ESSL/AASLD practice guidelines. Serum samples were collected at the admission time. Twenty serum samples (discovery cohort) were profiled through miRNA 3.0 gene array (Affymetrix). miRNAs associated to therapy response and disease-free survival (DFS) were further validated in 80 HCC serum samples (validation cohort). miRNAs were profiled by qRT-PCR. Relative quantification (fold of change) was determined using the $2^{(-\Delta\Delta Ct)}$ method. MiR-1280 was used as an internal control. Statistical analysis was performed by using NCSS software for non-parametric test (Whitney-Mann).
The receiver operating characteristic (ROC) curves were plotted to estimate the prognostic value of the miRNA.
Results: Among the miRNA selected from the discovery phase, miR-4492 was significantly associated to therapy response and DFS. Mir-4492 showed a decreased expression in patients with no or partial response to treatments ($p = 0.006$) and with a DFS lower than 24 months ($p = 0.035$). The significance level improves in patients treated with transarterial chemoembolization (TACE) ($p = 0.002$). The receiving operating curve (AUC of serum miR-4492 for therapy response) was 0.68 (0.54–0.78 95%CI), with a 70.0% sensitivity and 64% specificity. The AUC for therapy response improves to 0.81 (0.54–0.94 95% CI) with a 83% sensitivity and 73% specificity when considering the TACE-treated patients. When considering the predictive value of serum miR-4492 of DFS longer than 24 month the AUC was 0.67 (0.47–0.79 95%CI) with a 63% sensitivity and 72% specificity.
Conclusion: Serum miR-4492 is as a novel biomarker for predicting treatment response and DFS in HCC patients.

Email: fabio.marra@unifi.it

Background and aims: Compared to tumor-bulk, cancer stem cells (CSC) are resistant to drugs and responsible for tumor initiation as well as relapse. However, mechanisms underlying CSC state in cholangiocarcinoma (CCA) remain largely unknown. Growing evidence indicated that deregulated cellular metabolism is linked to acquisition of tumor stem-like properties as well as drug resistance. The present study aimed to explore alterations of glucose metabolism in CCA stem-scenery.

Method: Stem-like compartment was enriched by sphere culture (SPH) in established human intrahepatic CCA cells (HUCCT1, CCLP1, SG231). CCA-SPH extracellular flux analysis was examined by seahorse technology. CCA-SPH expression of hexokinase II (HKII), pyruvate kinase M1 (PKM1), PKM2 and Peroxisome proliferator activated receptor gamma coactivator 1-α (PGC-1α) was investigated by western bottling. Metformin effect on survival was examined by MTT. Glucose uptake was quantified by incorporated (U-14C) deoxy-D-glucose.

Results: In contrast to parental cells grown as adherent monolayers (MON), metabolic analyses by seahorse technology revealed that CCA-SPH have a more efficient respiratory phenotype by mitochondrial oxidative phosphorylation (OXPHOS). In agreement, CCA-SPH cells showed down-regulation of the glycolytic marker HKII, indicating adaptation toward mitochondrial respiration. Also, PKM1 overexpression and PKM2 repression in CCA-SPH cells correlated with decrease of glucose uptake as well as with reduction of GLUT-1 expression. Finally, over-expression of PGC-1α in CCA-SPH indicated that mitochondrial biogenesis and respiration was functionally relevant in CCA stem-like cells. These data were corroborated by FACS analysis showing in CCA-SPH a higher mitochondrial membrane potential (MitoTracker Red) as well as elevated mitochondrial mass (MitoTracker Green). Consequently, CCA-SPH survival was impaired after targeting mitochondrial complex I (by administration of metformin, phenformin, rotenone), complex III (antimycin) or ATP sintase (oligomycin). More importantly, metformin drastically affected expression of CSC-like (CD13, CD133, EpCAM) and pluripotency genes (KLF4, NANOG, BMI1) as well as epithelial mesenchymal transition (EMT)-signaling (E-cadherin, Vimentin, ZEB1, ZEB2, Slug, Snail), suggesting its possible contribution to the CCA-stem subset. In an in vivo xenograft model, metformin limited the growth of CCA-SPH-derived tumors in immunocompromised mice, confirming the OXPHOS-associated phenotype of CCA-stem-like subset. Analysis of published microrarray-based data in 59 CCA vs. surrounding liver confirmed significant (FDR q-val < 0.2) signals of stemness and OXPHOS.

Conclusion: Our findings indicate that CCA stem-like cells undergo a metabolic reprogramming resulting in OXPHOS addiction to meet energy demands.

THU-489

Mixed HCC-ICC liver cancer derives from hepatic progenitor cells: A lineage tracing investigation in a mouse liver inflammation model

Nofar Rosenberg[1], Matthias Van Haele[2], tania roskams[2], Mathias Heikenwälder[3], Klaus Kaestner[4], hilla giladi[1], Eithan Galun[1]. *[1]The Hebrew University, Goldyne savad institute of gene therapy, Jerusalem, Israel; [2]University of Leuven, Department of translational cell and tissue Research, Leuven, Belgium; [3]German Cancer Research Center, Chronic Inflammation and Cancer, Heidelberg, Germany; [4]University of Pennsylvania Perelman School of Medicine, Molecular Studies in Digestive and Liver Diseases, Philadelphia, United States*
Email: nofar.ros@gmail.com

Background and aims: Primary liver cancer is the second leading cause of cancer-related death worldwide. Primary liver cancers include: Hepatocellular carcinoma (HCC), intrahepatic cholangiocarcinoma (ICC) and Mixed HCC-ICC tumor. Preceding the development of primary liver cancer, there is usually cirrhosis which results from a prolonged period of chronic inflammation. It has been proposed that hepatic progenitor cells (HPCs) could contribute to hepatocarcinogenesis. However, this has not yet been proven. These cells proliferate in response to injury and chronic inflammation in the liver. In this study, we aimed to determine whether HPCs contribute to liver cancer development in the MDR2 KO mouse model of inflammation-induced HCC.

Method: In order to enable tracing of progenitor cells, we generated a transgenic mouse based on the MDR2 KO that harbours a YFP reporter gene driven by the Foxl1 promoter, the promoter of a liver progenitor specific marker. These mice (MDR2 KO$^{Foxl1CRE;\ RosaYFP}$) develop chronic inflammation by the age of 1 month and HCCs by the age of 16 months followed by Mixed HCC-ICC tumors at the age of 18 months.

Results: At the age of 3 months, upon severe inflammation, YFP positive HPCs proliferate and differentiate, giving rise to both cholangiocytes and hepatocytes. In addition, at the age of a year and later, HPCs are present in the chronically inflamed livers and within dysplastic nodules (DN). Within the livers of 16-month old MDR2 KO$^{Foxl1CRE;RosaYFP}$ only a minority of DNs were positive for YFP expression. Furthermore, the HCC tumors that have developed, were YFP negative, but contained scattered YFP-positive HPCs. At later stages (18-month) these mice developed Mixed HCC-ICC tumors and very few ICC. Interestingly, the Mixed tumors were YFP positive, implying that they were derived from HPCs. These HCC-ICC YFP positive tumors accounted for 45% of the total tumors observed and they also express stem cells markers including Epcam, Cd24a, Cd133 and Krt19. These findings recapitulate the characteristics of human Mixed ICC-HCC tumors which also shown to have stem cell-like features. Next generation sequencing (NGS) analysis of human and mouse Mixed ICC-HCC tumors, revealed the presence of HPCs gene signature, implying that they originate from Foxl1 HPCs cells. In addition, RNA seq analysis revealed that both, human and mouse Mixed HCC-ICC tumors have a very similar pro-survival pathway signature. Most significantly, IL6 signalling was found to be up-regulated in these Mixed tumors at the RNA and protein levels.

Conclusion: Taken together, our results suggest that mixed HCC-ICC but not HCC tumors, originate from HPCs in the inflammation induced liver cancer model, and that the driver of this process involves the IL6 signalling pathway.

THU-490

Liver NK cells from NLG4 KO mice inhibit progressions of hepatocellular carcinoma of C57BL/6 mice model through decrease in p53 and AKT expressions

Ahmed Salhab[1], Johnny Amer[1], Rifaat Safadi[1]. *[1]Hadassah Hebrew University Hospital, Liver Unit, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: Cirrhosis is a main risk factor for hepatocellular-carcinoma (HCC) development. However, direct role of NK cell in HCC-progression is not fully understood. Therefore, we aimed to study the role of neuroligin-4 (NLG4) receptor of NK cells in models of HCC in C57BL/6 mice.

Method: HCC cell-line (Hep3B) secreted high levels of alpha-fetoprotein (αFP) were injected in the back of irradiated C57BL/6 (sub-lethal dose) and liver NK cells from both WT and homozygous NLG4$^{-/-}$ (KO) mice were transplanted at day 5 following HCC injections. Hepatic tumor sizes and serum αFP were then assessed from day 6 till day 14. Liver P53 and AKT expressions by RT were tested at day of sacrifice.

Results: Tumor mass increase in animals with HCC injections and was associated with elevated αFP serum levels in all tested time intervals. Mice receiving the liver NKs from the NLG4$^{-/-}$ animals showed a significant decrease in tumor at days 10, 12 and 14. Liver NKs from the WT animals did not alter tumor progressions. At the day of sacrifice, serum αFP levels maintained were almost not significant in all tested groups as the WT mice showed an elevations in their αFP levels and ended to similar levels of the groups probably attributed to lost effects of irradiations. Liver p53 showed to be significantly high (1.5 fold increase) in the mice groups with HCC alone while almost decreased in mice receiving liver NKs from the NLG4$^{-/-}$ to levels similar to the animals with no HCC. These results were associated with decrease in AKT only in animals receiving liver NKs from the NLG4$^{-/-}$ ($p = 0.001$).

Conclusion: p53 is a more sensitive marker for HCC tumorigenesis than αFP in C57BL/6 mice in advanced stages of tumor. The

mechanism of p53-mediated repression of αFP levels may be active during hepatic differentiation and lost in the process of tumorigenesis. NK from NLG4$^{-/-}$ mice showed to decrease tumor through p53 inhibitions and decrease in AKT indicating its associations with pathways decreasing proliferations of HCC and reinforces the importance of NLG4 modulation as a therapeutic target for HCC.

Email: jesper.andersen@bric.ku.dk

Background and aims: The high mortality rate associated with hepatocellular carcinoma (HCC) is mainly due to lack of effective markers for early detection of the disease. In the Western world, metabolic syndromes and the causal rearrangements are increasingly associated with HCC. However, we have limited understanding on how these aberrations contribute to liver tumorigenesis. The aim of this study is to characterize novel metabolic pathways inducing HCC onset and progression.
Method: We have analyzed the transcriptomes of HCCs obtained from a murine model of liver cancer (*Mdr2* knock out), followed by exposure to the carcinogen DEN. We analyzed the transcriptomes of 458 HCC patients and performed immunohistochemical staining and metabolic analysis on 164 HCC patients. Furthermore, we analyzed the methylation status of *AGXT*. To understand the role of *AGXT* on HCC progression, we genetically modified HCC cells by knocking out (KO) *AGXT* by CRISPR/Cas9 and also restored its expression by knock-in. On these HCC clones, we performed transcriptomics, metabolomics and functional assays.
Results: The transcriptomic analysis of *Mdr2*$^{-/-}$/DEN model showed *AGXT* among the top scored differential expressed genes. In 458 HCCs, *AGXT* was shown to be significantly downregulated in a subset of patients. Analysis of the clinical variables revealed a correlation between low *AGXT* and poor overall survival as well as high grade tumors. Moreover, impaired *AGXT* expression inversely correlated with the methylation status of its promoter. Association between the level of *AGXT* expression and tumor grading was confirmed at protein level by immunohistochemical staining of 95 HCC tissues, showing a pericentral location of the protein. Importantly, *AGXT* KO cells had a higher rate of proliferation, migration and colony formation compared to the parental cells, and KO phenotypes were normalized in *AGXT* restored cells. Integration of transcriptomics and metabolomics between *AGXT*-defined subsets of patients showed a dysregulation of key components in fatty acid, amino acids and energy metabolism. Also, this relationship of *AGXT* level and metabolic rearrangements was seen in the transcriptomic analysis of *AGXT* KO cells.
Conclusion: *AGXT* is a key enzyme in the glyoxylate cycle. However, here we show that depletion in HCC cells cause a significant reduction of lipids and rearrangement of the amino acid metabolism. Thus, this study contributes to unravel additional roles for *AGXT* and advance our understanding of how metabolic imbalances can affect HCC tumorigenesis.

THU-492

Role of regulatory T cells and checkpoint inhibition in hepatocellular carcinoma

Bettina Langhans[1], Hans Dieter Nischalke[1], Benjamin Kraemer[1], Leona Dold[1], Philipp Lutz[1], Raphael Mohr[1], Annabelle Vogt[1], Marieta Toma[2], Anna-Maria Eis-Hübinger[3], Jacob Nattermann[1], Christian Strassburg[1], Maria Gonzalez-Carmona[1], Ulrich Spengler[1]. *[1]University Hospital of Bonn, Department I of Internal Medicine, Bonn, Germany; [2]University Hospital of Bonn, Department of Experimental Pathology, Bonn, Germany; [3] University Hospital of Bonn, Institute of Virology, Bonn, Germany*
Email: bettina.langhans@ukbonn.de

Background and aims: Immune checkpoint inhibition suggests promissing progress for treatment of advanced hepatocellular carcinoma (HCC). However, the underlying cellular mechanisms remain unclear because liver cancer cells apparently do not upregulate inhibitory checkpoint molecules. Here, we analysed whether CD4$^+$ regulatory T cells (Tregs) can alternatively trigger checkpoint inhibition pathways in HCC.
Method: Using flowcytometry we analysed expression of checkpoint molecules (PD-1, PD-L1, CTLA-4, GITR, Tim-3) on peripheral CD4$^+$CD25$^+$Foxp3$^+$ Tregs as well as their secretion of inhibitory mediators (IL-10, IL-35, TGF-beta, galectin-9) in 108 individuals (50 patients with HCC, 41 non-tumour bearing liver disease controls, 17 healthy controls). Functional activity of Tregs on T effector cells (IFN-gamma production, cytotoxicity) was characterized *in vitro* using a lectin-dependent cellular cytotoxicity (LDCC) assay against checkpoint inhibitor-negative P815 target cells.
Results: Unlike liver patients without malignancy and healthy controls, the frequency of checkpoint inhibitor-positive Tregs in the blood inversely correlated to age of patients with HCC (PD-L1, $p = 0.0080$; CTLA-4, $p = 0.0029$) and corresponded to enhanced numbers of Tregs producing IL-10 and IL-35 ($p < 0.05$ each). Tregs inhibited IFN-gamma secretion and cytotoxicity of CD8$^+$ T cells when added to LDCC against P815 cells. Treg-induced inhibition of IFN-gamma secretion could be partially blocked by neutralizing PD-1 and PD-L1 antibodies specifically in the patients with HCC.
Conclusion: In HCC peripheral Tregs upregulate checkpoint inhibitors and contribute to systemic immune dysfunction and antitumoural activity by several inhibitory pathways, presumeably facilitating tumour development at young age. Blocking PD-L1/PD-1 interactions *in vitro* selectively interfered with inhibitory Treg-T effector cell interactions in the patients with HCC and resulted in improved antitumoural activity also against checkpoint inhibitor-negative tumour cells.

THU-493

Reciprocal changes in ARID1A and EZH2 are associated with cholangiocarcinoma development in a mouse model of caroli disease with high Yap expression

Eleanna Kaffe[1], Carlo Spirli[1], Romina Fiorotto[1], Valeria Mariotti[2], Massimiliano Cadamuro[2], Luca Fabris[2], Mario Strazzabosco[1]. *[1]Yale University, Internal Medicine, Section of Digestive Diseases and Liver Center, New Haven, United States; [2]University of Padova, Molecular Medicine, Padova, Italy*
Email: carlo.spirli@yale.edu

Background and aims: Congenital Hepatic Fibrosis (CHF) and Caroli disease (CD) are genetic cholangiopathies caused by mutations in the

PKHD1 gene. In about 15% of patients, CD may progress to Cholangiocarcinoma (CCA). *ARID1A* is a component of the SWI/SNF complex that blocks YAP regulators (i.e E2F1 or AKT) and EZH2, the catalytic subunit of polycomb repressive complex 2; EZH2 it has been shown to be overexpressed in several malignancies. We aimed to investigate if these epigenetic regulators are involved in the development of CCA in *Pkhd1*$^{del4/del4}$ mouse, an orthologous model of CD.

Method: Mucous production was examined by Alcian blue staining. EZH2, YAP and ARID1A protein expression was evaluated by immunohistochemistry and western blot. The DNA aneuploidy was examined by FACS. *Arid1a, Pik3pi, Sca-1, Nanog, Ctgf, Cdk1* gene expression levels were evaluated by RT-PCR. Silencing of ARID1A was performed using siRNA. Thioacetamide (TAA) was administrated in the drinking water (300 mg/L).

Results: *Pkhd1*$^{del4/del4}$ mice but not their WT controls, display an age-dependent increase of mucous production and nuclear YAP expression. DNA aneuploidy and EZH2 protein expression were detected only in aged (9- 12-months-old) *Pkhd1*$^{del4/del4}$ mice. *Pkhd1*$^{del4/del4}$ mice treated with TAA developed high grade dysplasia after 4 months and CCA after 7 months, whereas WT controls showed only ductular reaction and fibrosis. Gene expression of EZH2 and of YAP target genes increased in TAA treated *Pkhd1*$^{del4/del4}$ mice as respects to untreated *Pkhd1*$^{del4/del4}$ mice. Gene expression of *Arid1a* and its target gene *Pik3pi* decreased in the liver of TAA treated *Pkhd1*$^{del4/del4}$ mice, compared to TAA treated WT mice. ARID1A silencing in *Pkhd1*$^{del4/del4}$ cholangiocytes *in vitro* increased nuclear levels of YAP and the expression of YAP target genes (*Nanog, Sca-1, Cdk-1*).

Conclusion: Cholangiocytes of aged *Pkhd1*$^{del4/del4}$ mice show pre-malignant features of dysplasia. Treatment with TAA accelerated the progression to CAA in *Pkhd1*$^{del4/del4}$ but not in WT mice, indicating that *Pkhd1*$^{del4/del4}$ mice are prone to develop CCA. The progression from low grade dysplasia to CCA is accompanied by an increase in EZH2 expression and YAP transcriptional activity and by a concomitant decrease of *Arid1a* gene expression. Interestingly, the latter is known to be frequently mutated in human CCA.

Email: mtake0402@gmail.com

Background and aims: We have shown by genome-wide DNA methylation analysis that regions corresponding to microRNA clusters including the miR-183/96/182 cluster were hypomethylated in non-B non-C hepatocellular carcinoma (NBNC-HCC) tissues samples compared to their adjacent liver tissues. The aim of this study is to investigate the roles of the miR-183/96/182 cluster in NBNC-HCC development.

Method: We collected frozen or paraffin-embedded 122 pairs of tumor and adjacent background samples obtained from patients undergoing surgery. We quantified the expression levels of miRNA-96, miRNA-182 and miRNA-183 in tumor and background tissues and compared with clinical data. We then transfected these miRNAs into Hep G2 cells, and their effects on cell proliferation, invasion capacity, and apoptosis were determined.

Results: We found that the expression of miR-96, miR-182, and miR-183 was upregulated in tumor tissues compared to background tissues ($p = 0.0241$, $p = 0.0011$, and $p = 0.0035$ respectively). Surprisingly, when NBNC-HCC patients were divided into two groups according to the level of miR-96 expression in tumor tissues, those with relatively high level of miR-96 expression exhibited longer disease-free survival compared with the others ($p = 0.0321$). Transfection of miR-96 in Hep G2 cells resulted in the suppression of cell growth and invasion capacity. We also found that the apoptotic cells were increased in miR-96-treated Hep G2 cells. Microarray and quantitative PCR analyses showed that some genes related to invasion such as GPC3, ZEB1, SNAI1, and those related to negative regulation of apoptosis such as NPM1 were decreased in miR-96-treated cells.

Conclusion: Elevated expression of antitumor miR-96 in tumor tissues were significantly associated with disease-free survival in NBNC-HCC patients.

Real-time, intravital imaging of diethylnitrosamine-induced hepatocellular carcinoma

Alexandra Thompson[1], Kylie Conroy[1], Stephen Greenhalgh[1], Martin Lee[2], Kenneth Simpson[3], John Iredale[1], Jacco Van Rheenen[4], Alan Serrels[1], Neil Henderson[1]. [1]*Queen's Medical Research Institute, MRC Centre for Inflammation Research, Edinburgh, United Kingdom;* [2]*Cancer Research UK Edinburgh Centre, Edinburgh, United Kingdom;* [3]*Scottish Liver Transplant Unit, Edinburgh, United Kingdom;* [4]*Hubrecht Institute, Utrecht, Netherlands*
Email: aithompson@doctors.org.uk

Background and aims: The role of the microenvironment in hepatocarcinogenesis is complex, comprising interactions between immune, angiogenic and cancer-associated fibroblasts. Intravital microscopy (IVM) techniques allow direct visualisation of tumour cells interacting with their microenvironment. This can provide insights into the ability of tumour cells to migrate, metastasize, and induce angiogenesis. In the liver, IVM cancer models to date have been confined to studying colorectal cancer metastasis, or hepatocellular carcinoma (HCC) by imaging inoculated cancer cell lines. These models have obvious limitations in terms of studying the true tumour microenvironment. We previously developed an IVM protocol for directly imaging mouse liver in real-time, using a range of imaging modalities including multiphoton (MP) and Coherent Anti-Stokes Raman Scattering (CARS) microscopy. We hypothesized that a similar approach could be used in the setting of hepatocarcinogenesis.

Method: The diethylnitrosamine (DEN) model of HCC is well established. We have combined this model with a novel IVM approach, allowing sequential, real-time imaging of the liver via a surgically implanted titanium abdominal imaging window (AIW). This technique, in conjunction with MP microscopy and other label-free imaging modalities, allows us to image DEN-induced HCC in fluorescent reporter mice, at cellular and subcellular resolution.

Results: We show for the first time, that DEN-induced HCC can be directly imaged under terminal anaesthesia. We present data using the Albumin Cre$^{\pm}$;Confetti mouse, in which hepatocytes express one of four different fluorescent reporters. An AIW can be surgically

implanted on an area of HCC, to allow live imaging. Use of CARS microscopy demonstrates that this technique could be used to analyse blood flow and angiogenesis within HCCs and the surrounding tumour niche.

Conclusion: To the best of our knowledge, mature tumours from the DEN-induced murine HCC model have not previously been imaged in real-time *in vivo*. This provides a novel opportunity to undertake experiments designed to interrogate subtle differences in tumour biology and blood flow, which might only be detectable using an IVM system. This could also facilitate in-depth study of the efficacy of novel chemotherapeutic agents, allowing both assessment of topography of intra-tumoural drug delivery, and also the relative efficacy of targeting specific cell lineages within the setting of HCC.

THU-497

Molecular fingerprint of hepatocellular carcinoma in patients with non-alcoholic steatohepatitis

Llovet[1,3,9]. *[1]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clínic, Universitat de Barcelona, Liver Cancer Translational Research Laboratory, Barcelona, Spain; [2]Sema4, a Mount Sinai venture, Stamford, United States; [3]Icahn School of Medicine at Mount Sinai, Tisch Cancer Institute, Mount Sinai Liver Cancer Program (Divisions of Liver Diseases, Department of Hematology/Oncology, Department of Medicine, Department of Pathology), New York, United States; [4]Singapore General Hospital, Department of Anatomical Pathology, Singapore, Singapore; [5]University of São Paulo-School of Medicine, Departments of Gastroenterology and Pathology, São Paulo, Brazil; [6]Bern University Hospital, University of Bern, Department of Visceral Surgery and Medicine, Bern, Switzerland; [7]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; [8]Hospital Universitari Vall d'Hebron, Vall d'Hebron Institut of Research (VHIR), CIBERehd, Universitat Autonoma de Barcelona, Liver Unit, Department of Internal Medicine, Barcelona, Spain; [9]Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain*
Email: torrecilla@idibaps.org

Background and aims: Non-alcoholic steatohepatitis (NASH) is emerging as one of the leading risk factors for hepatocellular carcinoma (HCC), but its molecular pathogenesis is still ill-defined. This study aims to identify unique molecular traits that differentiate NASH-HCC from other aetiologies through an integrative molecular characterization.

Method: A total of 225 tissue samples were collected, including samples from 125 biopsied/transplanted NASH patients; and 100 resected/transplanted NASH-HCC patients. Molecular characterization of FFPE samples, comprised expression array (n = 53 NASH-HCC; n = 74 NASH), whole exome sequencing (n = 50 NASH-HCC), and SNP array (n = 44 NASH-HCC).

Results: NASH-HCC patients compared to NASH non-HCC patients were prevalently males (82% vs 42%, $p < 0.001$), with older age (67 years vs 54, $p < 0.01$), higher diabetes incidence (72% vs 50%, $p = 0.004$), hypertension (80% vs 52%, $p < 0.01$) and cirrhosis (69% vs 29%, $p < 0.001$). When exploring the transcriptome of non-tumour tissues, NASH cases showed enrichment of liver metabolism pathways, whereas NASH-HCC cases were enriched in hallmarks of inflammation (TNFα-NFkβ, IL6, STAT3), epithelial-mesenchymal transition (TGFβ1), proliferation (AKT, mTOR), as well as poor-prognosis liver signatures ($p < 0.05$). Regarding NASH-HCC neoplastic tissues, gene expression profiles demonstrated that they can be classified in proliferation (50%) and non-proliferation (50%) molecular classes. Mutational analysis identified genes with mutations in ≥ 10% of NASH-HCC tumours: *TERT* (52%), *CTNNB1* (28%), *TP53* (18%) and the TGFβ-receptor *ACVR2A* (10%). Unsupervised clustering of mutational signatures showed that NASH-HCC tumours are clustered in 2 groups, enriched in liver-cancer signatures #16 (44%) and #5 (22), respectively; and that a third cluster (15%) was enriched in signature #3, which is novel in liver cancer. When conducting signature clustering in 42 viral/alcohol-related HCCs, signature #3 cluster emerged as specific of NASH-HCC.

Conclusion: Non-tumour liver tissue of NASH-HCC patients is characterized by a cancer-field enriched in inflammatory, epithelial-to-mesenchymal transition and proliferation signalling pathways. NASH-HCC tumours showed high frequency of *TERT*, *CTNNB1*, *TP53* and *ACVR2A* mutations; and a novel liver-cancer mutational signature (#3, 15%), suggesting genotoxic factors specifically associated to this entity.

THU-498

Mass-spectrometric analysis of deregulated proteins in gallbladder carcinoma

Felicia Truckenmueller[1], Benjamin Goeppert[1], Stefan Pusch[2], Ivonne Heinze[3], Joanna Kirkpatrick[3], Peter Schirmacher[1], Alessandro Ori[3], Stephanie Roessler[1]. *[1]Institute of Pathology, Heidelberg, Germany; [2]Institute of Pathology, Department of Neuropathology, Heidelberg, Germany; [3]Leibniz Institute on Aging-Fritz Lipmann Institute, Jena, Germany*
Email: Felicia.Truckenmueller@med.uni-heidelberg.de

Background and aims: This study focuses on gallbladder carcinoma (GBC) which is a rare and understudied cancer entity. The main risk factors are female gender, age, ethnicity, obesity, cholelithiasis and chronic gallbladder inflammation. GBC treatment options are very limited and 2-year survival rates of unresectable GBC is less than 10%. Radical surgery is the only potentially curative treatment option but due to late diagnosis few patients are eligible. Therefore, the development of new treatment options, including targeted therapy for GBC is required to improve patient outcome.

Method: We performed quantitative LC-MS-based proteomics of a total of 18 FFPE tumors, 5 healthy gallbladder and 5 tumor stroma specimens from a German GBC cohort. The quantitative proteomic analysis was performed in three sets: healthy vs tumor, tumor vs stroma and long vs short survival. The analysis revealed differentially expressed proteins in the distinct groups, which were further subjected to pathway analysis. Candidate genes representing potential tumor suppressors were selected.The role of these candidate genes in proliferation, migration and clonogenicity was investigated in GBC cell lines to evaluate their specific function.

Results: We detected approximately 5, 000 proteins. Between long and short surviving patients 611 proteins with a significant difference (adj. p value < 0.05) were found. Among the enriched pathways in patients with worse survival are the cellular defense response and regulated exocytosis. Downregulated pathways are the ECM organization and cell/biological adhesion.

We also found 1766 proteins to be differentially expressed between healthy gallbladder and GBC (adj. p value < 0.05). Interestingly, pathways for RNA processing and inflammatory response were upregulated, whereas, cytoskeleton organization and biological/cell adhesion were downregulated.

In order to identify potential tumor suppressor candidates, we selected genes of the significantly downregulated pathways with at least 4-fold decrease in tumors. This led to the identification of FHL1 and ANK3. Both proteins were strongly downregulated in the 5 tumor samples, compared to the 5 healthy gallbladder samples. FHL1: fold difference: 8.6, $p < 0.001$, FDR = 0.008 and ANK3: fold difference: 4.5, $p < 0.001$, FDR = 0.0002. Based on intermediate to low endogenous expression of the respective genes, cell lines were selected to induce stable overexpression to study the biological functions of the genes. FHL1 overexpression in NOZ and G-415 cells significantly reduced the velocity of wound closure and the ability to form colonies, supporting a tumor suppressive role in GBC.

Conclusion: Proteomic profiling of a well-characterized German GBC cohort identified many differentially expressed proteins and tumor-relevant downregulated pathways. Functional validation confirmed the tumor suppressive function of FHL1.

THU-499

Angiotensin receptor blockade attenuates cholangiocarcinoma cell growth by inhibiting the oncogenic activity of Yes-associated protein

Yuki Tsuji[1], Kosuke Kaji[1], Soichiro Saikawa[1], Kenichiro Seki[1], Shinya Sato[1], Keisuke Nakanishi[1], Hideto Kawaratani[1], Mitsuteru Kitade[1], Kei Moriya[1], Tadashi Namisaki[1], Hitoshi YOSHIJI[1]. *[1]Nara medical university, Nara, Kashihara, Japan*
Email: tsujih@naramed-u.ac.jp

Background and aims: Cholangiocarcinoma (CCA) is a destructive malignancy with limited responsiveness to conventional chemotherapy. Yes-associated protein (YAP), a transcriptional co-activator, is a critical oncogene in several cancers. It has been shown that oncogenic YAP occurs in both human CCA cell lines and patient specimens, with nuclear YAP showing potential for use as an independent prognostic marker of overall survival in CCA. Moreover, recent evidence has also shown that it is regulated by angiotensin II (AT-II). Thus, this study aimed to elucidate the effect of angiotensin receptor blocker (ARB) on human CCA cell growth.
Method: WST-1 and TUNEL assays were performed to examine the effects of AT-II and/or ARB, losartan, on *in vitro* human CCA cells (KKU-M213 and HuCCT-1) proliferation and apoptosis, respectively. To create a xenograft model, we injected 1×10^6 of human CCA cells into the flanks of BALB/c nude mice. After the tumor was established, losartan was administrated at dose of 30 mg/kg per day. Immunohistochemistry was performed for analysis of intracellular cell proliferation, YAP activation and angiogenesis. Western blotting was carried out to evaluate the phosphorylation of YAP. Quantitative real-time PCR was also performed to assess the mRNA levels of YAP transcriptional genes and selected genes related to epithelial-mesenchymal transition (EMT), differentiation, and stemness. Immunohistochemistry was performed for analysis of intratumor cell proliferation, YAP activation and angiogenesis. Additionally, we investigated the effects of AT-II and/or losartan *in vitro* endothelial tubular formation.
Results: Losartan not only suppressed CCA cell proliferation stimulated by AT-II in a dose-dependent manner but also induced apoptosis, decreased phosphorylation of YAP (Ser127), and down-regulated YAP target genes (i.e., *CTGF*, *CYR61*, *ANKRD1*, and *MFAP5*). However, losartan did not affect EMT, differentiation, or stemness in the CCA cells. A xenograft tumor growth assay showed that oral administration of losartan at a low clinical dose significantly reduced subcutaneous tumor burden and attenuated intratumor vascularization in CCA cell-derived xenograft tumors in BALB/c nude mice. Furthermore, losartan inhibited AT-II-stimulated *in vitro* endothelial tubular formation.
Conclusion: These results indicate that ARB therapy could offer a potential novel strategy for the treatment of CCA.

THU-500

EGFR is a preventative target for NASH-induced liver cancer

Atsushi Umemura[1], Keiichiro Okuda[1], Yoshito Itoh[1]. *[1]Kyoto Prefectural University of Medicine, Gastroenterology and hepatology, Kyoto, Japan*
Email: aumemura2002@yahoo.co.jp

Background and aims: Non-alcoholic steatohepatitis (NASH) has become a serious health problem with the increase of metabolic syndrome. NASH is one of the major causes of liver cancer, however, the mechanism how NASH develops hepatocellular carcinoma (HCC) remains unclear. In addition, genetic analyses have not proposed any treatment or prevention so far, because there are no targetable driver mutations found in HCC.
In the background liver which is chronically injured, typically cirrhotic, gene alterations accumulate for 20–30 years, and hepatocytes demand anti-stress and regenerative responses to survive under stressed-condition. One of the key molecules is p62, a multifunctional adaptor protein. Previously, we reported that p62 accumulates in a variety of chronic liver diseases and activate Nrf2 and mTORC1 to adapt pre-cancerous cells to stress (Cancer Cell 2016, PMID: 27211490). These responses necessary for survival in chronic liver injury may drive hepatocarcinogenesis, so that we are focusing on the NASH-background liver.
Method: Using a genetic mouse model in which high fat diet induces HCC highly relevant to human NASH-HCC (Cancer Cell 2014, PMID: 25132496), we searched genes altered in the background liver by RNA sequence analysis, then examined the protein expression of the genes. Finally, we tested whether a natural product could reduce the incidence of HCC in this animal model.
Results: From results of RNA sequence and immunoblotting analyses, we found that EGFR signaling was hyperactivated in the mouse NASH liver. For liver cancer, the use of EGFR inhibitors has not been successful so far. For example, a phase III trial of sorafenib plus a major EGFR inhibitor erlotinib for the treatment of advanced-HCC did not show clear benefits compared with the sorafenib plus placebo arm (J Clin Oncol 2015, PMID: 25547503). However, the preventative effect of EGFR inhibition has not been explored yet. In this mouse study, we found that inhibition of EGFR signaling by a natural compound drastically attenuated NASH-HCC incidence. Mechanistically, this treatment induced EGFR degradation, not its dephosphorylation, leading to robust tumor suppression.
Conclusion: We show that EGFR inhibition significantly suppressed HCC induction in the mouse NASH-HCC model. EGFR signaling may be highly active in pre-cancerous cells which form dysplastic nodules and this signaling may facilitate these cells develop into liver cancer. Our results support the concept that EGFR signaling is a driver of liver carcinogenesis and is a suitable target for NASH-HCC prevention.
This is the first report showing that EGFR inhibition could prevent NASH-induced HCC and a natural compound could be a potential drug candidate.

Myeloid-specific IRE1 alpha deletion reduces tumour development in a non-alcoholic steatohepatitis-induced hepatocellular carcinoma mouse model

Sanne Van Campenhout[1], Sander Lefere[1], Astrid Vandierendonck[1], Xavier Verhelst[1], Anja Geerts[1], Hans Van Vlierberghe[1], Lindsey Devisscher[2]. *[1]Ghent University, Internal Medicine and Pediatrics, Ghent, Belgium; [2]Ghent University, Basic and Applied Medical Sciences, Ghent, Belgium*
Email: Sanne.VanCampenhout@UGent.be

Background and aims: Obesity, diabetes and associated non-alcoholic steatohepatitis (NASH) are characterized by adipose tissue and hepatic fat accumulation and inflammation and are rising causes of hepatocellular carcinoma (HCC). Macrophages are important immune cells involved in inflammation and tumour development. Macrophage inositol-requiring enzyme 1 alpha (IRE1a), an ER-stress protein, has shown to be involved in macrophage cytokine production and myeloid-specific IRE1a knock-out (KO) mice showed reduced weight gain during high fat diet feeding. However, the effect on NASH and subsequent HCC development has not been examined. Here, we investigated the effect of myeloid-specific IRE1a deletion on experimental NASH-HCC development.
Method: Mice with non-functional myeloid IRE1a were created by crossing IRE1a floxed mice with LysM-Cre mice. Two-day old KO and wild type (WT) mice were subcutaneously injected with streptozotocin (STZ) and male mice were fed a high-fat, -sucrose, -cholesterol diet (shortly called HFD) from the age of 4 weeks till 21 weeks. Control KO and WT mice received a PBS injection and matched

control diet. Mice were evaluated for obesity, diabetes, NASH and HCC by analyses of serum, fat and liver samples.
Results: STZ injection resulted in lower body weights at the age of 4 weeks (start of HFD) compared to control mice and resulted in elevated fasting glucose levels in STZ-WT mice, which was not observed in STZ-KO mice. HFD feeding resulted in more fat accumulation (p = 0.009) and a higher body weight (p = 0.05) but attenuated glucose intolerance (p = 0.01 at peak glucose levels) in STZ-KO mice compared to STZ-WT mice. While no difference was observed in the NAFLD activity score between STZ-KO and STZ-WT mice after HFD feeding, STZ-KO mice presented with significant lower tumour loads (p = 0.009) and reduced alpha fetoprotein gene expression both in tumour and surrounding tissue compared to STZ-WT mice. Liver monocyte infiltration was significantly higher (p = 0.01) and pro-inflammatory cytokine induction tended to be more pronounced in STZ-KO mice compared to STZ-WT mice after HFD feeding whereas the control KO mice showed a tendency to lower levels of pro-inflammatory markers and liver monocytes compared to control WT mice under homeostatic conditions.
Conclusion: Our results indicate that myeloid-specific IRE1a deletion attenuates diabetes induction and results in reduced NASH-induced HCC without significant influence on HFD-induced NASH development.

THU-502

ZEB1 expression in myofibroblasts regulates their interaction with cholangiocarcinoma cells promoting tumour progression

Javier Vaquero[1,2], Chantal Housset[1], Laura Fouassier[1]. [1]*Sorbonne Universite, Inserm, Centre de Recherche Saint Antoine, CRSA, AP-HP, Hôpital Saint-Antoine, Paris, France;* [2]*LPP, CNRS, Ecole Polytech., Univ. Paris-Sud, Observatoire de Paris, Univ. Paris-Saclay, Sorbonne University, PSL Research University, Paris, France*
Email: javiervr84@hotmail.com

Background and aims: Cholangiocarcinoma (CCA) is characterized by a prominent fibrous stroma which gene signature has been associated with a poor prognosis. CCA stroma is mainly composed of myofibroblasts (MF) thought to be derived from hepatic stellate cells (HSC). This activation is a well-orchestrated process controlled by epithelial-mesenchymal transition-inducing transcription factors (EMT-TF). The role of ZEB1 in MF function is largely unknown. Therefore, the main objective of this study was to elucidate the role of ZEB1 expressed by MF in the progression of CCA.
Method: Immortal activated human HSC, generated by ectopic telomerase expression, were used as MF model. Knockdown of ZEB1 was performed by lentivirus infection of shRNA-ZEB1 (MF-shZEB1) (and the corresponding shRNA-Control (MF-shCtr)). EGI-1 and HuCCT1 cell lines were used as CCA cell models. Conditioned media (CM), obtained from either MF or CCA cells, was used to mimic tumor-stroma crosstalk communication. *In vivo* experiments were performed using a xenograft tumor model in immunodeficient mice.
Results: ZEB1 knockdown in MF caused a downregulation of fibrotic markers (α-SMA, COL4A1 and vimentin) and soluble factors, including growth factors (TGF-β, IGF2, EGF, HB-EGF, PDGFB and osteopontin) and pro-inflammatory cytokines (IL-6 and IL-8), as compared to MF-shCtr. On the contrary, TNF-α and IL-1B, involved in cell death promotion, were upregulated in MF-shZEB1. Upon TGF-β stimulation fibrotic markers were upregulated both in MF-shCtr and MF-shZEB1 cells, while the expression of soluble factors was increased only in MF-shCtr cells, and remained unchanged in ZEB1-depleted MF. Moreover, MF-shCtr cells were more resistant to the toxic effect of gemcitabine than MF-shZEB1. Crosstalk communication experiments showed that CM from CCA cells increased cell viability of MF-shCtr but induced cell death of MF-shZEB1 cells, along with an increase of p53 and p21 protein expression. The inverse experiment showed that CM from MF-shCtr caused an increase in viability and STAT3 phosphorylation of CCA cells, as compared to CM from MF-shZEB1. *In vivo*, subcutaneous injection of EGI-1+MF-shCtr to immunodeficient mice led to generation of larger tumors than EGI-1+MF-shZEB1 or EGI-1 alone.
Conclusion: ZEB1 expression in MF plays a key role in CCA progression by inducing proliferative and survival signaling both in CCA tumor cells and MF, which may impact effectiveness of current therapy regimens with gemcitabine.

THU-503

Macrophage migration inhibitory factor shows a pro-proliferative and anti-apoptotic effect on hepatoma cells in vitro and promotes tumour growth in vivo

Theresa Hildegard Wirtz[1], Daniel Heinrichs[1], Saal Alena[1], Bergmann Irina[1], Petra Fischer[1], Janine Koehncke[1], Elisa Brandt[1], Jürgen Bernhagen[2], Christian Trautwein[1], Marie-Luise Berre[1]. [1]*University Hospital RWTH Aachen, Medical Department III, Aachen, Germany;* [2]*University Hospital Munich, Institute for Stroke and Dementia Research, Munich, Germany*
Email: thwirtz@ukaachen.de

Background and aims: Macrophage Migration Inhibitory Factor (MIF) is a proinflammatory cytokine and has been characterized in different chronic diseases as well as solid tumors. Here, MIF reflects a carcinogenic role as it drives neo-angiogenesis and metastasis but inhibits apoptosis. Referring to the MIF receptors, CD74 was identified as an important target of MIF in malignant diseases. In this study we first analyze the role of MIF and its receptor CD74 in murine hepatoma cells *in vitro*. Next we apply a toxic model of murine hepatocellular carcinoma (HCC) to study the role of MIF and CD74 in HCC *in vivo*.
Method: BrdU assay was performed to analyze the influence of recombinant mMif on the proliferative capacity of Hepa 1–6 cells. Next, the role of mMif in sorafenib-induced apoptosis of Hepa 1–6 cells was investigated by an Annexin V-assay as well as TUNEL-staining. In both assays, an anti-CD74 antibody was used to investigate a dependence on CD74 signalling. To examine the role of MIF in murine HCC the DEN/CCl_4 model was applied to mice with a hepatocyte-specific *Mif* depletion (*AlfpCre*$^{+}$*Mif*$^{flox/flox}$ mice, *Mif*^{1hep}), *CD74* deficient mice and respective control mice. Tumor size and number were analysed. Next, qPCR of *Mif* and *CD74* was executed in dissected liver and tumor tissue of control mice whereas qPCR of proliferation markers was conducted in control as well as *Mif*^{1hep} and *CD74* deficient mice. Immunohistochemical staining of Mif and Ki67 was complemented.
Results: mMif promotes the proliferation of Hepa 1–6 cells in a dose-dependent manner. Moreover, mMif inhibits sorafenib-induced cell death of Hepa 1–6 cells as evidenced by decreased Annexin V- and TUNEL-staining. Both effects can be reversed using a CD74 neutralizing antibody. In WT mice, qPCR and immunohistochemical staining of dissected liver tissue showed an increased expression of Mif and CD74 in tumor tissue as compared to fibrotic liver tissue. DEN/CCl_4 treatment of *Mif*^{1hep} as well as *CD74* deficient mice results in a decreased number and size of tumors compared to respective controls. Furthermore, tissue of *CD74*$^{-/-}$ mice showed a reduced proliferation rate in the Ki67 staining replicating the *in vitro* results *in vivo*.
Conclusion: In this study we present first data on MIF´s pro-proliferative and anti-apoptotic impact on hepatoma cells and identify CD74 as a possible partner of MIF in murine HCC *in vivo*. As a conclusion, the inhibition of the MIF/CD74 axis could present a promising target for the improvement of HCC directed therapies.

THU-504

lncRNA HOTAIR promotes cancer stem cell properties in hepatocellular carcinoma via the STAT3/NANOG pathway

Jiajia Zhou[1], Junge Deng[1], Di Cheng[1], Bin Zhang[1], Xiaogeng Deng[1], Rufu Chen[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*
Email: jiajiazh2004@126.com

Background and aims: lncRNA HOTAIR has been proved to play an essential oncogenic role in tumor initiation and progression, including hepatocellular carcinoma (HCC). However, the regulatory role of HOTAIR in liver cancer stem cells (LCSCs) properties remains largely elusive. The aim of this study was to investigate whether HOTAIR could modulate LCSCs properties in HCC.
Method: CD133 (+) LCSCs were purified from HCC cell lines Huh7 and HepG2 by FACS analysis. pHOTAIR or shHOTAIR were employed to ectopically increase or decrease HOTAIR expression. Then cell proliferation, colony formation, migration, and self-renewal capacity of LCSCs, as well as expression of NANOG, OCT4, SOX2 and STAT3 were analyzed. ChIP was used to detect the interaction of STAT3 on its target gene.
Results: Here we showed that lncRNA HOTAIR was highly expressed in LCSCs. Knockdown of HOTAIR markedly repressed the proliferation, colony formation, migration, and self-renewal capacity of LCSCs, whereas ectopic expression of HOTAIR dramatically promoted LCSCs properties. Furthermore, HOTAIR upregulated a panel of stemness genes, in which NANOG was found to be among the most significant one. Mechanically, HOTAIR activated STAT3 signaling via EZH2, leading to activation of NANOG expression and maintenance of LCSCs properties. Moreover, Treatment with STAT3 inhibitor abolished the effects of HOTAIR on the processes of LCSCs, as well as the expression of NANOG. In addition, phosphorylated-STAT3 directly binds to the NANOG promoter and regulates its expression.
Conclusion: Collectively, our findings suggest that lncRNA HOTAIR might play a critical role in the maintenance of LCSCs properties by activating the STAT3/NANOG signaling. Targeting HOTAIR would provide a novel therapeutic strategy for HCC.

Autoimmune and chronic cholestatic liver disease: Clinical aspects

FRI-001

The PBC-10: A validated short clinic symptom screening tool for primary biliary cholangitis

Laith Alrubaiy[1,2], George Mells[3], Helen Bosomworth[4], Steven Flack[3], Hayley Hutchings[2], John Gordon Williams[2], David Jones[4]. *[1]St Mark's Hospital, London, United Kingdom; [2]Swansea University, Swansea, United Kingdom; [3]University Of Cambridge, Department of Medical Genetics, Cambridge, United Kingdom; [4]Newcastle University, Institute of Cellular Medicine, Newcastle, United Kingdom*
Email: laithalrubaiy@gmail.com

Background and aims: The impact of symptoms in PBC is increasingly appreciated and the recent EASL guidelines recommend annual symptom assessment. At present, however, there are no validated short assessment tools. The existing tools such as the PBC-40 being research tools which are too cumbersome for normal clinic use. Therefore we need a valid, short and practical Quality of life (QoL) measure and symptom screening tool for use in patients with PBC at the point of care. The aim of this study was to develop a short version of the PBC-40 QoL measure that can be easily used in clinical practice.
Methods: We analysed a total of 4721 completed PBC-40 QoL questionnaires from the UK-PBC cohort database. We used a dataset of completed PBC-40 questionnaires in 2013 (n = 2219) to derive the short PBC-QoL and carry out the initial validation. We then confirmed the validation of the short PBC-QoL on a second cohort of patients with PBC who returned the PBC-40 questionnaire in 2017 (n = 2502). We carried out stepwise regression psychometric analysis to identify the items for the short version of PBC-QoL. We selected those items that contributed 95% of the variation in the scores. We assessed the internal consistency, item-total correlation, frequency of endorsement, principal component analysis (PCA) and construct validity for the short PBC-QoL questionnaire.
Results: We identified the 10 most important questions to derive the short form PBC-QoL questionnaire (PBC-10). Further testing showed that PBC-10 had good internal consistency (Cronbach's Alpha of 0.905), item-total correlations between 0.2–0.8 (Table 1), good construct validity (r = 0.5583). Principal component analysis showed that the 10 questions provided good representation of 6 different QoL aspects of patients with PBC: fatigue, psychological, cognitive, physical, skin and eating or drinking domains. Further validation on the second cohort of patients with PBC (n = 2502), confirmed the validity and reliability of PBC-10. There were no ceiling effects and skewness values of all 10 items ranged were acceptable between –1 to 1.

Table: PBC-10 items and their psychometric properties.

	PBC-10 items	% cumulative variance	Item total correlations
1	Fatigue interfered with my daily routine	.688	0.803
2	Because of PBC, I found it difficult to concentrate on anything	.816	0.779
3	PBC has reduced the quality of my life	.868	0.791
4	I have felt embarrassed because of the itching	.903	0.542
5	I feel guilty that I can't do what I used to do because of having PBC	.921	0.792
6	I had to force myself to do the things I needed to do	.936	0.804
7	My mouth was very dry	.945	0.574
8	My social life has almost stopped	.951	
9	I ate or drank only a small amount and still felt bloated	.958	0.571
10	If I was busy one day I needed at least another day to recover	.963	0.802

Conclusion: PBC-10 is a new short and valid quality of life measure that has the potential to be used in usual clinical practice for patients with PBC.

FRI-002

Sustained remission after treatment withdrawal in autoimmune hepatitis: A multicenter retrospective study

Yasmina Ben Merabet[1], Coralie Barbe[2], Alexandra Heurgue-berlot[1], Thierry Thévenot[3], Anne Minello Franza[4], François Habersetzer[5], Didier Samuel[6], Brigitte Bernard Chabert[1], Delphine Weil-Verhoeven[3], Pascal Renard[7], Hélène Clot[1], Vincent Di Martino[3], Hervé Louvet[7], Solange Bresson hadni[8], Gérard Thiéfin[1]. *[1]Reims University Hospital, HepatoGastroenterology Unit, Reims, France; [2]Reims University Hospital, Department of Research and Public health, Reims, France; [3]Besançon University Hospital, HepatoGastroenterology Unit, Besançon, France; [4]Dijon University Hospital, HepatoGastroenterology Unit, Dijon, France; [5]Strasbourg University Hospital, HepatoGastroenterology Unit, Reims, France; [6]Paul-Brousse Hospital APHP, Centre Hépato-Biliaire, Paris, France; [7]Polyclinique Reims-Bezannes, HepatoGastroenterology Unit, Reims, France; [8]Besançon Private Practice Medical Center, Hepatology, Besançon, France*
Email: gthiefin@chu-reims.fr

Background and aims: In patients with autoimmune hepatitis (AIH), relapse rates up to 90% after treatment withdrawal have been reported. The main objective of this study was to assess in AIH patients with prolonged complete biochemical response the relapse rate after treatment discontinuation and to identify the factors associated with relapse. Secondary objectives were to identify the predictive factors of histological remission and to evaluate the evolution of hepatic fibrosis.
Method: Data from patients with AIH followed between 1988 and 2018 in 7 centers from France were reviewed retrospectively. Patients

who had reached sustained biochemical remission on first-line immunosuppressive treatment were included. Relapse was defined as any elevation of aminotransferases or gammaglobulins/immunoglobulins G after treatment withdrawal. The relapse rate was analyzed using Kaplan Meier analysis. The predictive factors of histologic remission were analyzed by univariate and multivariate logistic regression analysis.

Results: Sixty-two AIH patients (47 female, median age: 44 years) were included. Thirty-nine stopped therapy after a median treatment duration of 64 months (25–265) and a median biochemical response of 47 months (13–155), among which 24 had a biopsy before withdrawal: 21 had a Metavir score A0 and three A1. During follow-up, 7 relapsed with a median time of 9.4 months. The cumulative rate of relapse was 12% at 12 months and 25% at 64 months. Only one patient with Metavir score A0 at treatment withdrawal relapsed, Other relapsers were 2 patients Metavir A1 and 4 without biopsy before treatment withdrawal. In univariate analysis, the only significant difference was a higher prevalence of anti smooth muscle antibodies in relapsers than in sustained responders (100% vs 50%, p = 0.005). Among the 62 included patients, 47 had a biopsy after a median treatment duration of 65 months (20–265) and a median biochemical response of 48 months (9–149). Twenty-five (53%) were Metavir A0 and 22 (47%) ≥ A1. Multivariate analysis showed that independent predictors of histological remission were older age (OR1.11 CI95% (1.03;1.2) P = 0.007), mild to moderate fibrosis at diagnosis (OR = 8.06 CI95% (1.4;47.6) p = 0.02) and AST level < 0.6 × ULN at the time of control biopsy (OR = 7.05 CI95% (1.3;36.7) p = 0.02). Regarding the course of fibrosis after a median time of 48 months of biochemical remission, there was a significant improvement in the stage of fibrosis (p = 0.007).

Conclusion: This retrospective study indicates that the relapse rate after treatment withdrawal in AIH patients is limited (25% at 64 months) when the treatment is stopped after a prolonged period of biochemical remission and a complete histological response. Older age, mild to moderate fibrosis at diagnosis and lower serum concentration of transaminases AST at the time of control biopsy are independent predictors of histological response.

FRI-003

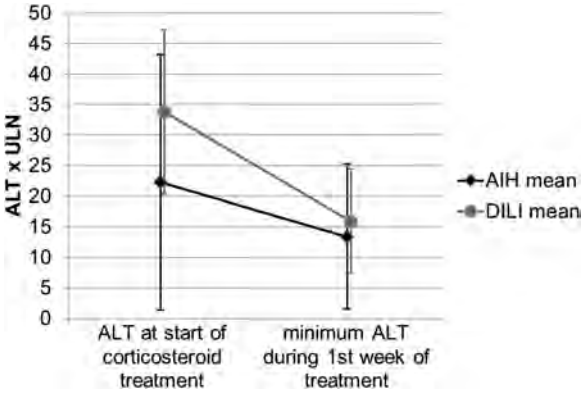
Early response to corticosteroid treatment supports differentiation of drug-induced liver injury and autoimmune hepatitis

Sabine Weber[1], Andreas Benesic[1], Isabelle Rotter[1], Alexander Gerbes[1].
[1]University Hospital, LMU Munich, Germany, Department of Medicine II, Liver Centre Munich, Munich, Germany
Email: andreas.benesic@med.uni-muenchen.de

Background and aims: Drug-induced liver injury (DILI) and idiopathic autoimmune hepatitis (AIH) are competing diagnoses in patients with acute liver injury and drug intake. In absence of markers unequivocally identifying DILI or AIH, scores like RUCAM and the AIH score are used to distinguish both entities at initial presentation. However, in some cases the diagnosis remains ambiguous. Consequently some DILI patients unnecessarily receive longterm corticosteroid treatment. Our aim was investigate a simple parameter to discriminate DILI and AIH shortly after starting steroid treatment.

Method: For the present analysis, 43 patients with acute liver injury who took at least one drug and who received corticosteroids were included and comprised 22 DILI and 21 AIH cases. AIH score and RUCAM were calculated at initial presentation, the final diagnosis was made from analyzing the course of disease. Changes in the serum alanine aminotransferase (ALT) concentrations after starting corticosteroid treatment were determined and compared between the DILI and AIH groups.

Results: While 58% of patients (n = 25) were correctly classified at presentation by AIH score and RUCAM, respectively, in nearly one third (n = 13) of the 43 patients results were inconclusive. Five other patients were misclassified by the scores. The decrease in ALT levels one week after the initiation of steroid therapy was significantly more pronounced in patients with the final diagnosis of DILI than in AIH patients (accuracy 81%). This difference was also observed in the 18 patients misclassified or with inconclusive results at initial presentation (accuracy 94%).



Conclusion: Short-term response of ALT to steroid therapy helps to differentiate DILI and AIH. This may be helpful to determine the duration of corticosteroid treatment, particularly in patients with inconclusive diagnostic scores.

FRI-004

Cirrhosis status at diagnosis, non-Caucasian descent, treatment response and age determine long term survival in autoimmune hepatitis

Maaike Biewenga[1], Martine Baven-Pronk[1,2], Aad van den Berg[3], Karin van Nieuwkerk[4], Gerd Bouma[4], Henk Van Buuren[5], Bart Van Hoek[1]. *[1]Leiden University Medical Center (LUMC), Gastroenterology and Hepatology, Leiden, Netherlands; [2]Groene Hart Hospital, Gastroenterology and Hepatology, Gouda, Netherlands; [3]University Medical Center Groningen, Gastroenterology and Hepatology, Groningen, Netherlands; [4]VUmc, Gastroenterology and Hepatology, Amsterdam, Netherlands; [5]Erasmus University Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: b.van_hoek@lumc.nl

Background and aims: Treated autoimmune hepatitis (AIH) has a ten year survival between 80 and 96%. Conflicting reports exist on predictors of long term survival. The aim of this study was to evaluate the influence of baseline parameters and treatment response on long term survival in AIH patients.

Method: In this retrospective cohort study patients with AIH were included in 4 university hospitals in the Netherlands. Baseline and survival data were collected by chart review. Survival was defined as survival free of liver transplantation or liver-related death. For the influence of treatment response on survival a landmark analysis was used in which follow-up started 12 months after start of treatment. Uni- and multivariate Cox regression and Kaplan-Meier and logrank analysis were performed.

Results: In total 396 AIH patients with median follow-up of 110 months (range: 1–560 months) were included. Cirrhosis was present in 124 (31%) of which 39 (10%) were decompensated at diagnosis. During follow-up 18 patients received a liver transplantation and 18 patients died from liver related causes. Univariately higher age, non-Caucasian descent, low ALAT, low albumin and low platelets were correlated to worse survival (p = 0.027; p = 0.004; p = 0.017; p < 0.001 and p < 0.001 respectively), and ten year survival was worse in compensated vs decompensated cirrhotic patients vs non-cirrhotic patients (84% vs 51% vs 98%; p < 0.001). Patients reaching complete biochemical remission in the first 12 months of treatment had a better survival compared to patients who did not (p = 0.002).

In multivariate analysis age, non-Caucasian descent and cirrhosis status at diagnosis remained significant predictors for survival. If treatment response after 12 months was added this, cirrhosis status and non-Caucasian descent remained significant, but age was not significant anymore.
Conclusion: At diagnosis presence of (de)compensated cirrhosis, non-Caucasian descent and age predict long term survival in autoimmune hepatitis. Reaching biochemical remission within 12 months after diagnosis replaces age as significant factor in landmark analysis. This is the only identified modifiable factor and should be a treatment goal to prevent progression of disease and improve long term survival.

FRI-005

Characteristics and outcome of autoimmune hepatitis-primary biliary cholangitis and autoimmune hepatitis-primary sclerosing cholangitis overlap patients compared to autoimmune hepatitis patients

Maaike Biewenga[1], Aad van den Berg[2], Henk Van Buuren[3], Bart Van Hoek[1]. *[1]Leiden University Medical Center (LUMC), Gastroenterology and Hepatology, Leiden, Netherlands; [2]University Medical Center Groningen, Gastroenterology and Hepatology, Groningen, Netherlands; [3]Erasmus University Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: b.van_hoek@lumc.nl

Background and aims: In 10% of the autoimmune hepatitis (AIH) patients features of primary biliary cholangitis (PBC) or primary sclerosing cholangitis (PSC) are present, called overlap or variant syndromes. The aim of this study was to characterize AIH-PBC and AIH-PSC patients and compare outcome to AIH patients.
Method: In a retrospective cohort study all patients with AIH-PBC and AIH-PSC were included in 3 university hospitals. AIH-PBC patients had to fulfil the strict Paris criteria. AIH-PSC patients needed a definite diagnosis of AIH according to the simplified criteria and signs of PSC on ERCP, MRCP or onion ring fibrosis on liver biopsy. Characteristics and outcome were compared to AIH in a case-control design matched on age and cirrhosis.
Results: Twelve AIH-PBC, 25 AIH-PSC and 74 AIH patients were included. AIH-PSC patients were more often males compared to AIH patients (56% vs 28%; $p = 0.007$) and had large duct PSC in 92%. AIH-PBC patients had higher AF and GGT ($p < 0.001$ and $p = 0.006$) and presence of AMA antibodies in 75%. AIH-PSC and AIH-PBC had lower ALAT than AIH at diagnosis ($p = 0.014$) but IgG levels and SMA antibodies did not differ ($p = 0.79$ and $p = 0.58$).
Treatment with prednisone, azathioprine and ursodeoxycholic acid (UDCA) was started in all AIH-PBC and AIH-PSC patients, except UDCA in 2 patients. Complete AIH remission was obtained in 8 (67%), 16 (64%) and 61 (82%) of the AIH-PBC, AIH-PSC and AIH patients ($p = 0.12$).
The median GLOBE score in AIH-PBC patients was −0.41 (range: −1.57–2.91) resulting in an expected median 10 year survival of 89% (range: 4–97%). The median Amsterdam Oxford score was 2.45 (range: 0.95–3.75) in AIH-PSC patients resulting in an expected median 10 year survival of 59% (range: 14–88%).
At the end of median follow-up of 107 months (range: 1–353) 4 (33%) AIH-PBC, 8 (32%) AIH-PSC and 8 (11%) AIH patients had progressed to liver transplantation or liver related death ($p = 0.023$). Four (16%) AIH-PSC developed a cholangiocarcinoma.
Conclusion: In 12 AIH-PBC patients and 25 AIH-PSC patients using strict criteria no difference was found regarding IgG, SMA antibodies and response to therapy compared to AIH patients. Survival was worse in AIH-PSC and AIH-PBC patients than AIH patients. Survival of AIH-PBC patients was worse than expected according to the GLOBE score and survival of AIH-PSC patients was better than expected according to the Amsterdam Oxford score although AIH-PSC patients are at risk for developing cholangiocarcinoma.

FRI-006

Soluble CD163 and mannose receptor as markers of liver disease severity and long term prognosis in patients with primary biliary cholangitis

Lars Bossen[1,2], Paola Rebora[3], Francesca Bernuzzi[2], Chiara Aloise[2], Peter Jepsen[1,4], Alessio Gerussi[2], Holger Jon Møller[5], Maria Grazia Valsecchi[3], Marco Carbone[2], Henning Grønbæk[1], Pietro Invernizzi[2]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark; [2]University of Milan Bicocca, Division of Gastroenterology and Center for Autoimmune Liver Diseases, Milan, Italy; [3]University of Milan Bicocca, Center of Biostatistics for Clinical Epidemiology, Milan, Italy; [4]Aarhus University Hosptial, Department of Clinical Epidemiology, Aarhus N, Denmark; [5]Aarhus University Hospital, Department of Clinical Biochemistry, Aarhus N, Denmark*
Email: larsbossen@clin.au.dk

Background and aims: In primary biliary cholangitis (PBC) activated macrophages are involved in liver inflammation and fibrosis. The macrophage activation markers soluble (s)CD163 and sMR are associated with liver disease severity and prognosis in other chronic liver diseases. However, sCD163 and sMR have never been investigated in PBC patients.
Method: We included 202 patients with PBC from the Italian PBC Study Group cohort. Blood samples from study inclusion were used to estimate correlation between the macrophage activation markers and ALP, ALT and bilirubin. Further, the patients were followed from enrolment until they experienced an event or censoring at the last known hospital visit. Events were defined as follows: (1) death from a liver-related cause, meaning liver failure, variceal haemorrhage, or hepatocellular carcinoma (HCC); or (2) LT for PBC.
Results: Ninety-three percent were women and median age was 62 (IQR 53–71) at enrolment. Median sCD163 was 3.43 mg/L (IQR 2.48–5.35) and median sMR was 0.35 mg/L (IQR 0.28–0.45). There was a significant increase in sCD163 and sMR with increasing baseline ALP, but not with increasing ALT or bilirubin. sCD163 and sMR was lower in patients with treatment response to UDCA compared to the non-responders (3.25 vs. 4.37). The 179 patients in the follow-up analysis were followed for a median of 8.6 years, and sCD163 and sMR predicted long-term risk of LT or liver related death. Finally we showed an increasing in the prediction accuracy of poor outcome gained by adding sCD163 to the UK-PBC risk score.
Conclusion: The macrophage activation markers correlate with ALP in PBC patients and are prognostic markers of liver related death or LT.

FRI-007

Serum markers of macrophage activation CD163 and Mannose receptor predict transplant-free survival in primary sclerosing cholangitis

Lars Bossen[1], Mette Vesterhus[2,3], Johannes Hov[2,4,5,6], Holger Jon Møller[7], Kirsten Boberg[2,4,5,6], Tom Karlsen[2,4,5,6], Henning Grønbæk[1]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark; [2]Oslo University Hospital, Norwegian PSC research Center, Oslo, Norway; [3]Haraldsplass Deaconess Hospital, Oslo, Norway; [4]University of Oslo, Institute of Clinical Medicine, Oslo, Norway; [5]Oslo University Hospital, Department of Transplant Medicine, Oslo, Norway; [6]Oslo University Hospital, Research Institute of Research Medicine, Oslo, Norway; [7]Aarhus University Hospital, Department of Clinical Biochemistry, Aarhus N, Denmark*
Email: larsbossen@clin.au.dk

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive and remarkably variable liver disease characterized by bile duct inflammation and fibrosis. Biomarkers predicting outcome are currently not established. Soluble (s)CD163, a macrophage specific activation marker, and mannose receptor (sMR) is associated with disease severity and outcome in other liver diseases but has not

been investigated in PSC. *Aim:* To evaluate the prognostic utility of sCD163 and sMR in patients with PSC.
Method: Plasma samples were available from 138 large-duct PSC patients (102 [74%] also had inflammatory bowel disease) recruited 2008–2012. The median follow-up time was 2.2 (range 0–4.3) years. Macrophage activation markers sCD163 and sMR were assessed by ELISA. The Enhanced Liver Fibrosis (ELF) Test as well as the Mayo score were assessed for comparison.
Results: Both markers showed incremental elevation in groups of PSC patients with increasing disease severity as defined by either Mayo score or ELF test ($p < 0.001$). Patients with high baseline plasma levels of sCD163 or sMR had shorter survival compared to patients with low baseline plasma levels whether divided into groups defined by tertiles, established upper limit of normal, or optimal cut-off value defined by Youden ($p < 0.001$). Both sCD163 and sMR were associated with transplant-free survival in univariate Cox-regression analyses but not in multivariate analyses.
Conclusion: Specific markers of macrophage activation are elevated according to disease severity in PSC patients. Furthermore, sCD163 was identified as a potent prognostic marker and predictor of transplant-free survival in PSC.

FRI-008
Incidence, prevalence and mortality of primary sclerosing cholangitis in Italy: A population-based study
Marco Carbone[1], yllka kodra[2], adele rocchetti[2], valerio manno[3], giada minelli[3], Alessio Gerussi[1], Vincenzo Ronca[1], Federica Malinverno[1], Laura Cristoferi[1], Annarosa Floreani[4], Pietro Invernizzi[1], susanna conti[3], domenica taruscio[2]. *[1]University of Milan Bicocca, Milan, Italy; [2]National Center for Rare Diseases, Istituto Superiore di Sanità, Rome, Rome, Italy; [3]Service of Statistics Istituto Superiore di Sanità, Rome, Rome, Italy; [4]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy*
Email: marco.carbone@unimib.it

Background and aims: Studies on primary sclerosing cholangitis (PSC) are mainly based on tertiary referral, retrospective case series with relevant selection bias, and population-based epidemiologic studies are scarce. To estimate prevalence, incidence and mortality rates of PSC in Italy, using population-based data sources.
Method: Two data sources were used: i) the National Rare Diseases Registry (RNMR) run by the National Center for Rare Diseases of the Italian National Institute of Health (ISS); ii) the National Mortality Database (NMD), run by the Unit of Statistics of ISS, based on official data from the Italian National Institute of Statistics. In the period 2001–2014, all PSC cases (defined according to RNMR criteria) were selected. A deterministic linkage between RNMR and NMD was performed to evaluate the vital status and causes of death of the selected cases. Given that PSC does not have a specific code in ICD-10, the larger group "cholangitis" (code K83.0) was investigated.

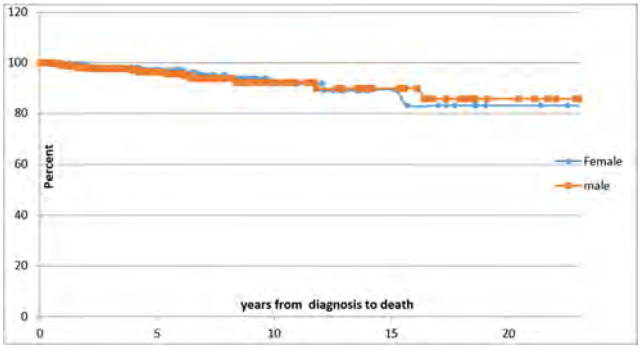


Figure: Survival time in years from diagnosis using Kaplan Meier estimator

Results: In the study period 502 PSC cases were identified (40% females). Since the RNMR reached full national coverage in 2011, PSC patients registered before where excluded; the mean number of new PSC patients registered in 2012–2014 was 61/year with a mean crude annual incidence of 0, 10 per 100.000 persons. The estimated crude prevalence of PSC was 0.78 per 100.00. Mean age at disease onset and at diagnosis were 33 and 37 years, respectively, highlighting a mean diagnostic delay of 4 years. We reported interregional mobility with overall 12% of patients moving in other regions. Ten-year survival was 92%; in 52% of deaths, the cause was PSC-related.
Conclusion: This is the first description of epidemiology of PSC in Italy. For rare conditions such as PSC, population-based cohorts studies are of paramount importance. Incidence and prevalence rates of PSC in Italy, using a population-based study design, are markedly lower and survival much longer than the ones reported from tertiary, single-centre series. Moreover, the diagnostic delay and the patient interregional mobility highlights the need for increasing awareness on the disease and for resource reallocation among regions within the National Health Service system.

FRI-009
Bezafibrate add-on therapy in high-risk primary biliary cholangitis is associated with prolonged predicted survival even in patients with incomplete biochemical improvements
Christophe Corpechot[1,2], Alexandra Rousseau[3], Sara Lemoinne[1,2], Gaouar Farid[1], Karima Ben Belkacem[1], Raoul Poupon[1], Olivier Chazouillères[1,2]. *[1]Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis (MIVB-H), Paris, France; [2]Sorbonne University, INSERM UMR_S938, Paris, France; [3]Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Clinical Research Platform of East of Paris, Paris, France*
Email: christophe.corpechot@aphp.fr

Background and aims: Data from the BEZURSO trial showed that bezafibrate therapy in addition to ursodeoxycholic acid (UDCA) increased the rate of complete biochemical response in patients with high-risk primary biliary cholangitis (PBC). However, not all patients from this trial equally responded to bezafibrate add-on and the efficacy of this treatment in incomplete responders remains uncertain. This post-hoc analysis of the BEZURSO trial aimed to characterize the factors predictive of, and the predicted outcomes associated with, an incomplete response to bezafibrate add-on therapy in high-risk PBC patients.
Method: The study population included 100 patients with an incomplete response to UDCA (Paris-2 criteria) who were randomly assigned to bezafibrate 400 mg/d ($n = 50$) or placebo ($n = 50$), in addition to continued UDCA, for 24 months. Incomplete response to bezafibrate was defined at the end of study (EOS) based on Paris-2 criteria. The predictive factors of incomplete response to bezafibrate were studied using a logistic regression model. The Globe and UK-PBC risk scores were used to estimate the predicted mortality or need for liver transplantation (LT) in complete and incomplete responders from each treatment group. The Kruskal-Wallis and Dwass-Steel-Critchlow-Fligner tests were used for the comparison of groups.
Results: The rate of incomplete Paris-2 response to bezafibrate was 30%. At baseline, the factors individually associated with an incomplete response to bezafibrate included significant pruritus (VAS > 3), portal hypertension (PH), and high values of liver stiffness, total bilirubin, ALP, or AST. In multivariate analysis, PH and high ALP levels (> 2.53 xULN) were independent predictors of incomplete response to bezafibrate. At EOS, median levels of ALP in bezafibrate complete responders (BCR), bezafibrate incomplete responders (BIR), and placebo patients (PP) were 0.90 xULN, 1.52 xULN, and 2.62 xULN, respectively. Median (IQR) changes from baseline to EOS in 15-year predicted mortality or need for LT of BCR, BIR, and PP were –45% (–58%; –25%), –16% (–41%; –3%), and 14% (–1%; 47%), respectively with the Globe score and –43% (–61%; –16%), –13% (–32%; 13%), and

22% (7%; 50%), respectively with the UK-PBC score ($p < 0.001$ for both models; Figure). The predicted mortality or need for LT was significantly reduced in BIR as compared to PP ($p < 0.01$ and $p < 0.05$ for Globe and UK-PBC models, respectively).

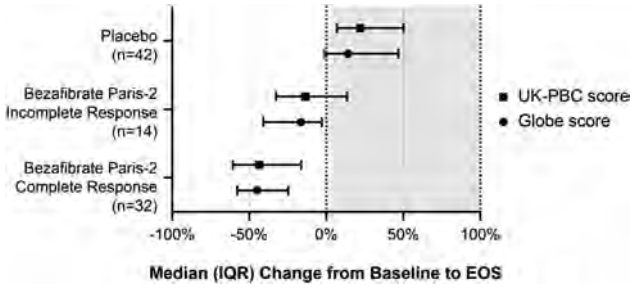

Figure: Predicted changes in 15-year mortality or need for LT

Conclusion: A third of PBC patients with an incomplete UDCA Paris-2 response still exhibits an incomplete biochemical response after 24 months of bezafibrate add-on therapy. These patients present more frequently at baseline with PH or ALP levels > 2.53 xULN. Their predicted mortality or need for LT is lower than that of UDCA plus placebo-treated patients suggesting that bezafibrate therapy should be continued in those patients.

FRI-010

Bezafibrate add-on therapy in high-risk primary biliary cholangitis is associated with an improvement of fibrometer and fibrometer-VCTE, two high-accuracy non-invasive fibrosis tests extensively validated in frequent chronic liver diseases

Christophe Corpechot[1,2], Alexandra Rousseau[3], Sara Lemoinne[1,2], Gaouar Farid[1], Karima Ben Belkacem[1], Raoul Poupon[1], Olivier Chazouillères[1,2], Paul Cales[4]. *[1]Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, Paris, France; [2]Sorbonne University, INSERM UMR_S938, Paris, France; [3]Saint-Antoine Hospital, Assistance Publique-Hôpitaux de Paris, Clinical Research Platform of East of Paris, Paris, France; [4]University Hospital of Angers, Hepatology Department, Angers, France*
Email: christophe.corpechot@aphp.fr

Background and aims: Data from the BEZURSO trial showed that 2 years of bezafibrate therapy in addition to ursodeoxycholic acid (UDCA) improved the measures of vibration-controlled transient elastography (VCTE) and of enhanced liver fibrosis (ELF) score in patients with high-risk primary biliary cholangitis (PBC). The number of sequential liver biopsies, however, was too limited to show an effect on histology. The present post-hoc analysis aimed to assess the effect of bezafibrate add-on therapy on the measures of Fibrometer and Fibrometer-VCTE, two high-accuracy non-invasive fibrosis tests, [1, 2] and of Inflameter, a necro-inflammatory activity score.
Methods: The study population included 100 patients with an incomplete response to UDCA (Paris-2 criteria) who were randomly assigned to bezafibrate 400 mg/d (n = 50) or placebo (n = 50), in addition to continued UDCA, for 24 months. Fibrometer^{2G}, Fibrometer^{2G}-VCTE, and Inflameter were measured at baseline, 12 months, and end of study (EOS). Associations with histological fibrosis stage or hepatitis activity grade (METAVIR classification) were evaluated using the Kruskal-Wallis test. The performance for the diagnosis of cirrhosis was determined using the C-statistic. Longitudinal changes were analyzed in each treatment group using linear mixed models.
Results: A total of 235, 210, and 235 measures of Fibrometer^{2G}, Fibrometer^{2G}-VCTE, and Inflameter were analyzed in 82, 75, and 82 patients, respectively. Concordance analysis was made based on 105 liver biopsies collected in 82 patients. Fibrometer^{2G} and Fibrometer^{2G}-VCTE were significantly associated with histological fibrosis stage ($p < 0.001$ for both) but not with hepatitis activity grade. Inflameter was associated with high hepatitis activity grade ($p = 0.07$). The diagnostic performance of Fibrometer^{2G} and Fibrometer^{2G}-VCTE for cirrhosis was 0.83 and 0.92, respectively. Longitudinal analysis showed a significant reduction in the slope of Fibrometer^{2G}, Fibrometer^{2G}-VCTE, and Inflameter in the bezafibrate group as compared to the placebo group ($p < 0.001$ for all). The median differences (95% CI) between bezafibrate and placebo groups in percent changes from baseline to EOS in Fibrometer^{2G}, Fibrometer^{2G}-VCTE, and Inflameter were −42% (−69%; −14%), −37% (−83%; 8%), and −35% (−52%; −17%), respectively.
Conclusion: Two years of bezafibrate add-on therapy in high-risk primary biliary cholangitis is associated with a significant improvement of Inflameter, Fibrometer, and Fibrometer-VCTE, thus supporting a long-term beneficial effect on both hepatic inflammation and fibrosis.

Ductular reaction, intermediate hepatocites and fibrosis extension correlate with prediction of treatment failure to ursodeoxycholic acid in primary biliary cholangitis

Laura Cristoferi[1], Guido Carpino[2], Vincenzo Cardinale[3], Cristina Rigamonti[4], Diletta Overi[5], Nicola Zucchini[6], Monica Leutner[7], Mauro Viganò[8], Alessandra Nardi[9], Alessio Gerussi[1], Vincenzo Ronca[1], Massimiliano Cadamuro[10], Giulia Bonato[1], Domenico Alvaro[11], Eugenio Gaudio[5], David Jones[12,13], Pietro Invernizzi[1], George Mells[14], Marco Carbone[1,14]. *[1]University of Milan Bicocca, Division of Gastroenterology, Department of Medicine and Surgery, Milan, Italy; [2] University of Rome "Foro Italico", Department of Movement, Human and Health Sciences, Division of Health Sciences, Rome, Italy; [3]Sapienza University of Rome, Department of Medico-Surgical Sciences and Biotechnologies, Latina, Italy; [4]Azienda Ospedaliero-Universitaria Maggiore della Carità, Division of Internal Medicine, Novara, Italy; [5]Sapienza University of Rome, Department of Anatomical, Histological, Forensic Medicine and Orthopedics Sciences, Rome, Italy; [6]San Gerardo Hospital, Department of Pathology, Monza, Italy; [7]Azienda Ospedaliero-Universitaria Maggiore della Carità, Department of Pathology, Novara, Italy; [8]University of Milan, Division of Hepatology, Ospedale San Giuseppe, Milan, Italy; [9]Tor Vergata University of Rome, Department of Mathematics, Rome, Italy; [10]University of Padua, Department of Molecular Medicine, Padua, Italy; [11]Sapienza University of Rome, Department of Internal Medicine and Medical Specialties, Rome, Italy; [12]Newcastle University, NIHR Biomedical Research Centre, Newcastle upon Tyne, United Kingdom; [13]The Newcastle upon Tyne NHS Foundation Trust, Department of Hepatology, Freeman Hospital, Newcastle upon Tyne, United Kingdom; [14]University of Cambridge, Academic Department of Medical Genetics, Cambridge, United Kingdom*
Email: laura.cristoferi@unimi.it

Background and aims: We recently derived and validated a model including alkaline phosphatase (ALP), bilirubin, aminotransferase, age at diagnosis, and waiting time before receiving ursodeoxycholic acid (UDCA), i.e. the *UDCA-response score* (*URS*). This score predicts future response to UDCA prior to initiation of therapy in patients with primary biliary cholangitis (PBC) and enables pre-treatment selection of high-risk PBC patients for second-line therapy earlier in the disease course, hence delivering effective care. Aim of this study was to validate the correlation of the predictive model *URS* with histological features in PBC patients.
Method: We evaluated formalin-fixed, paraffin-embedded liver biopsies from treatment-naive PBC patients, performed at diagnosis. Biopsies with fewer than nine complete portal tracts were excluded. Sections were stained with hematoxylin-eosin and Sirius red. We used the Ishak system to grade portal inflammation, interface hepatitis, lobular inflammation. Sirius Red stain was used for

quantitative assessment of fibrosis using an image analysis algorithm. Cytokeratin 7 (K7) immunoreactivity was used to evaluate ductular reaction (DR) and intermediate ($K7^+$) hepatocytes (IH). The area occupied by $K7^+$ DR was quantified by an image analysis algorithm. IH were defined as hepatocytes positive by immunofluorescence for K7 and albumin. Histological evaluation was done independently by two authors blinded to the clinical data.

Results: In 46 liver biopsy samples from treatment-naive PBC patients, the *URS* was associated with DR ($r = -0.830$, $p < 0.0001$, **figure 1**), IH ($r = -0.544$, $p < 0.0001$) and fibrosis extension ($r = -0.707$, $p < 0.0001$). Moreover, there was correlation between the extent of DR and ALP at diagnosis ($r = -0.514$, $p < 0.0001$), interface hepatitis ($r = -0.554$, $p < 0.0001$), and fibrosis extension ($r = -0.609$, $p = 0.0060$). No statistically significant correlation was found between the *URS* and interface hepatitis, portal and lobular inflammation.

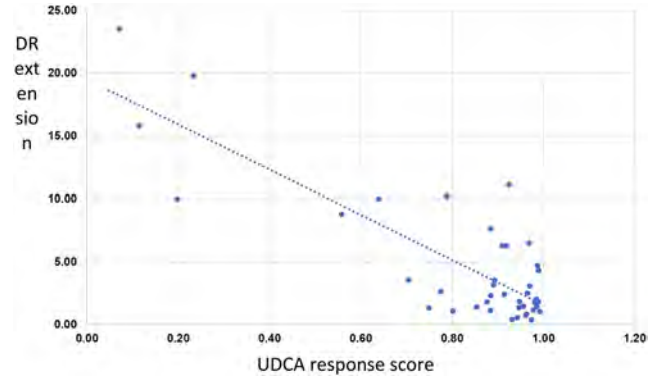

Figure 1: Correlation of estimated probabilities of response to UDCA based on the UDCA Response Score with the extent of ductular reaction expressed as volume fraction of liver parenchyma.

Conclusion: We identified that ductular reaction, intermediate ($K7^+$) hepatocytes and fibrosis extension correlate with prediction of treatment failure to UDCA in PBC. Ductular reaction and intermediate hepatocytes are a hallmark of severe biliary injury. This emphasizes the value of liver biochemistry at diagnosis as accurate surrogate biomarker for biliary injury in PBC and suggests that the severity of biliary injury and fibrosis are major determinants of treatment failure to choleretic treatment.

Analysis of clinical and histological factors to differentiate autoimmune hepatitis of drug induced liver injury

Lidia Cuevas del Campo[1], Elena Gómez-Domínguez[1], Yolanda Rodriguez Gil[2], Maria Luisa Manzano Alonso[1], Ana Martin Algibez[1], Gregorio Castellano Tortajada[1], Inmaculada Fernández Vázquez[1]. [1]*Doce de Octubre University Hospital, Liver Unit, Madrid, Spain;* [2]*Doce de Octubre University Hospital, Pathological Anatomy Department, Madrid, Spain*
Email: egdominguez@salud.madrid.org

Background and aims: The differential diagnosis between AIH and DILI is a clinical challenge due the lack of specific diagnostic tests. Our aim was to investigate clinical and/or histological factors which may facilitate the differential diagnosis of these entities.

Method: Retrospective observational study of histologic registers of AIH and DILI in our institution (2007–17), reviewed by an expert pathologist. Diagnosis was based in AIH diagnostic scores, CIOMS-RUCAM and evolution parameters. Comparative analysis was made by Chi-Square and non-parametric tests, Odd ratio (CI 95%).

Results: Forty-six patients (50% men):20 DILI, 26 HAI, mean age: 53.8 ± 14, 6. Hepatocellular biochemical pattern, IgG elevation and a chronic course were associated with AIH. Presence of autoantibodies was associated with AIH, but 38% of these patients had a negative immunological study. DILI was associated with cholestasic syndrome, fever and hypersensibility, and with a higher phosphatase alkaline, bilirubin and leucocytes serum levels. In the histological study, the presence of interface hepatitis and linfoplasmocitary infiltrate were the best predictive factors of AIH while cholestasis was of DILI. There weren't differences in neutrophilic infiltrate, hepatic russets, necrosis nor endothelitis.

Conclusion: In our study histological features were the ones which determine more accurately the diagnosis of AIH, because a relevant percentage of these patients had a negative autoantibody study. Biopsy remains the most important diagnosis test in the differential diagnosis between both entities.

Figure 1: (abstract: FRI-012): Independent factors of AIH.

Variables	DILI (n = 20)	HAI (n = 26)	p (< 0, 05)	OR (IC 95%)

FRI-013

A combined blood and MR imaging risk score for monitoring liver inflammation in paediatric AIH

Kamil Janowski[1], Andrea Dennis[2], Maciej Pronicki[3], Wieslawa Grajkowska[3], Małgorzata Woźniak[1], Piotr Pawliszak[4], Elżbieta Jurkiewicz[4], Matt Kelly[2], Stefan Neubauer[5], Rajarshi Banerjee[2], Piotr Socha[1]. *[1]The Children's Memorial Health Institute, Department of Gastroenterology, Hepatology, Nutritional Disorders and Pediatrics, Warsaw, Poland; [2]Perspectum Diagnostics, Oxford, United Kingdom; [3]The Children's Memorial Health Institute, Department of Pathology, Warsaw, Poland; [4]The Children's Memorial Health Institute, Department of Diagnostic Imaging, Warsaw, Poland; [5]University of Oxford, Oxford, United Kingdom*
Email: andrea.dennis@perspectum-diagnostics.com

Background and aims: Management of autoimmune hepatitis (AIH) is highly variable in practice, with lack of consensus on optimal follow-up strategies for patients, including the utility of on-treatment liver biopsy. Patient preference does not support serial biopsies, and blood based measures alone lack the sensitivity to subtle inflammation.
Liver*MultiScan*™ is a multiparametric MRI method which measures iron-corrected T1 (cT1). This has been shown to correlate with the key histological features of liver disease (ballooning, inflammation and fibrosis), and to predict clinical outcomes. Here, we evaluate the utility of cT1 in AIH, in combination with circulating biomarkers, for the stratification patients experiencing flares of liver inflammation.
Method: Forty-six AIH patients (19 male; mean age 13.8 [6–18yrs]; underwent Liver*MultiScan*™, with comparison to liver biopsy and liver enzymes (ALT, AST, GGT and bilirubin). Correlation with the imaging and blood biomarkers against biopsy was explored using Spearman's Rho. The ability of these biomarkers to identify individuals with histologically confirmed portal inflammation was evaluated using AUROC analysis, with step-wise logistic regression used to combine biomarkers into a risk score.
Results: All biomarkers correlated with Ishak fibrosis (Table 1-top) and all except total bilirubin correlated with portal inflammation (Table 1-bottom). Pairwise comparisons identified different patterns for cT1 compared to blood biomarkers, with stronger separation between Ishak scare 2–3 and 5–6 ($p < .001$) and equally a more stepwise pattern with portal inflammation.
Independently, both cT1 and ALT were the best predictors of portal inflammation ≥ 2 (cT1 AUROC: 0.70 (0.55–0.85, se: 39%, sp: 100%, NPV:61%, PPV: 100%)); ALT AUROC 0.73 (ci: 0.58–0.88), se: 61%, sp: 77%, NPV: 56%, PPV: 81%). Interestingly, the superior model with the strongest predictor of those with current portal inflammation ≥ 2 was a risk score combining cT1, total bilirubin and AST, (AUROC of 0.84 (0.7–0.94)) that was able rule-in those currently experiencing a "flare" with 100% specificity (PPV 100%, NPV 57%, Sensitivity 50%).

Table 1:

	cT1	ALT	AST	GGT	Bilirubin
Ishak Fibrosis	Rho = 0.43 p = 0.003	Rho = 0.43 p = 0.001	Rho = 0.45 p = 0.001	Rho = 0.43 p = 0.003	Rho = 0.52 p = 0.000
Portal Inflammation	Rho = 0.34 p = 0.022	Rho = 0.47 p = 0.001	Rho = 0.39, p = 0.081	Rho = 0.38 p = 0.001	Rho = 0.04 p = 0.785

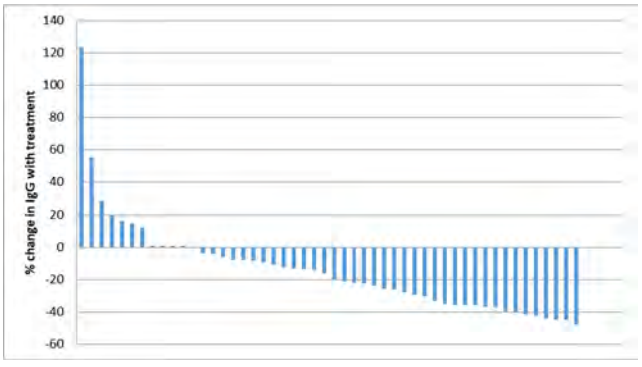
Conclusion: Both ALT and cT1 are effective biomarkers for identifying portal inflammation. This performance for identifying low level inflammation however is further enhanced when cT1 is used in composite with AST and total bilirubin, highlighting the potential of multiparametric MRI when used in conjunction with circulating markers of disease for monitoring paediatric patients with AIH. Further research is warranted.

FRI-014

Diagnostic criteria for autoimmune hepatitis: what is a normal "IgG"?

Jessica Dyson[1,2], Alasdair Blain[3], Mark Hudson[1,2], Steven Rushton[3], David Jones[1,2]. *[1]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; [2]Newcastle upon Tyne Hospitals NHS Foundation Trust, Hepatology, Newcastle upon Tyne, United Kingdom; [3]Newcastle University, School of Biology, Newcastle upon Tyne, United Kingdom*
Email: jessicadyson@doctors.org.uk

Background and aims: Simplified diagnostic criteria for autoimmune hepatitis (AIH) have been established by the International Autoimmune Hepatitis Group (IAIHG). These comprise autoantibodies, IgG level, histological parameters and the absence of viral hepatitis. "Probable" AIH is defined as a score ≥ 6 and "definite" AIH as a score of ≥ 7. Previous work has shown these criteria to have high sensitivity and specificity but a false negative diagnosis rate of 11%. The aim of this study was to apply the simplified IAIHG criteria to a cohort of AIH patients in a well-defined region of North-East England and North Cumbria to establish the false negative rate of diagnosis and examine the individual parameters in more detail.
Method: Clinical data was collected on 490 patients with an *a priori* clinical diagnosis of AIH. Information included demographic details, antibody status, IgG levels at diagnosis and follow-up and treatment response.
Results: The median age at diagnosis was 52 (4–87) years with 389 (79%) females. The majority (361 patients, 82%) were anti-nuclear or smooth muscle antibody positive, consistent with Type 1 AIH. 96% of patients had a diagnostic liver biopsy confirming AIH.
There were 62/335 (19%) patients with complete data available who did not meet the simplified IAIHG criteria for "probable" or "definite" AIH. IgG at diagnosis was available in 369 patients (median 22.3g/L (5.6–64.8), normal range 5.8–15.4) but 55 patients had normal IgG (15%), 24 (6%) had elevated IgG < 1.1xULN and 290 (79%) had elevated IgG > 1.1xULN. IgG at diagnosis and post-treatment were available for 277 patients, of whom 50 (18%) had normal IgG at the time of diagnosis (13.0g/L (5.6–15.4)). These patients would not have accrued "points" for IgG using the current criteria. However, IgG values at follow-up were significantly lower; median 10.1 (6–22) ($p = 0.0002$) (Figure).



Conclusion: Nearly a fifth of patients in this cohort had normal or sub-normal IgG values at the time of diagnosis with AIH. After treatment, 78% had experienced a decrease in their IgG. This suggests that the upper limit of normal being used currently may be too high and that delta change in IgG with therapy (rather than absolute values) is important. Patients are at risk of not being diagnosed in a timely manner with delayed treatment and potential under-treatment which are known to lead to higher morbidity and mortality in patients with AIH. Larger studies are needed to redefine the "normal" ranges for IgG.

FRI-015

Environmental triggering in primary biliary cholangitis: Disease risk relates to coal mining activity

Jessica Dyson[1,2], Alasdair Blain[3], Mark Hudson[1,2], Steven Rushton[3], David Jones[1,2]. [1]*Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom;* [2]*Newcastle upon Tyne Hospitals NHS Foundation Trust, Hepatology, Newcastle upon Tyne, United Kingdom;* [3]*Newcastle University, School of Biology, Newcastle upon Tyne, United Kingdom*
Email: jessicadyson@doctors.org.uk

Background and aims: Primary biliary cholangitis (PBC) has a complex aetiology with the interplay of genetic and environmental factors. Spatial disease clustering suggests there may be an environmental trigger but its nature remains elusive. This study explored the role of putative environmental risk factors in a comprehensive cohort of PBC patients in the North-East of England and North Cumbria, using primary sclerosing cholangitis (PSC) and autoimmune hepatitis (AIH) as comparator autoimmune liver diseases. The aims were to see if disease clustering was associated with environmental factors local to the cases and if there were differences between PBC, PSC and AIH.
Method: All patients with PBC (n = 2150), PSC (n = 472) and AIH (n = 963) in a defined geographical region within England were identified using multi-source case-finding methodology. Besag-York-Mollie models were used to estimate relative risk (RR) in postcode districts. The null model examined for areas of high and low disease prevalence and models were then fitted with single spatial covariates. These were selected based on data from previous studies regarding triggering of autoimmunity: urban-ness, traffic, landfill sites, coal/lead mines, sandstone/limestone quarries, social deprivation scores and heavy metals. Deviance Information Criterion (DIC) was used to compare the fits of models.
Results: Different postcode districts with high and low prevalence were identified for each disease (Figure). When spatial covariates were added to the null model, coal mining was strongly associated with a higher prevalence of PBC (change in DIC 9.885). In contrast, high prevalence of PSC was seen in more rural and less socioeconomically deprived areas (change in DIC 2.308 and 2.784, respectively). No associations were found in AIH.
Conclusion: This work confirms that high and low prevalence areas are seen in PBC, PSC and AIH but with different postcode districts being "high risk" in each disease. The associated environmental risk factors for PBC and PSC were strikingly different. No associations with the putative risk factors were seen in AIH. The relationship between coal mining and PBC suggests that exposure to environmental entities through mining activity (due to specific use in the mining industry or altered exposure through micro-environment disruption) is linked to disease development. Further assessment is needed to investigate potentially modifiable pathological mechanisms or triggers for autoimmune liver diseases.

Validation of the PREsTo machine learning algorithm for the prediction of disease progression in patients with primary sclerosing cholangitis

John Eaton[1], Konstantinos Lazaridis[2], Pietro Invernizzi[3], Olivier Chazouillères[4], Gideon Hirschfield[5], Herold Metselaar[6], Henning Grønbæk[7], Xiaomin Lu[8], Chuhan Chung[8], Mani Subramanian[8], Robert Myers[8], Bryan Mccauley[2], Elizabeth Atkinson[2], Brian Juran[2], Zachary Goodman[9], Michael P. Manns[10], Christopher Bowlus[11], Cynthia Levy[12], Andrew Muir[13]. [1]*Mayo Clinic, Gastroenterology and Hepatology, Rochester, United States;* [2]*Mayo Clinic, Rochester, United States;* [3]*University of Milan-Bicocca, Milan, Italy;* [4]*Hôpital Saint-Antoine, Paris, France;* [5]*University of Toronto, Toronto, Canada;* [6]*Erasmus MC University Hospital, Rotterdam, Netherlands;* [7]*Aarhus University, Aarhus, Denmark;* [8]*Gilead Sciences, Inc., Foster City, United States;* [9]*Inova Fairfax Hospital, Falls Church, United States;* [10]*Hannover Medical School, Hannover, Germany;* [11]*University of California Davis, Sacramento, United States;* [12]*University of Miami, Miami, United States;* [13]*Duke Clinical Research Institute, Durham, United States*
Email: eaton.john@mayo.edu

Background and aims: PREsTo is a machine learning-based algorithm that accurately predicted the risk of hepatic decompensation in patients with non-advanced PSC. Our objective was to prospectively validate the PREsTo algorithm for the prediction of disease progression in a randomized trial of PSC patients.
Method: We included 234 adults with large-duct PSC enrolled in a phase 2b, placebo-controlled trial of simtuzumab (SIM). Since SIM was ineffective in this 96-week study, treatment groups were combined for this analysis. The estimated risk of hepatic decompensation at 2 years was calculated according to the PREsTo algorithm using baseline (BL) age, alkaline phosphatase (ALP), AST, bilirubin, albumin, sodium, hemoglobin, platelets, and PSC duration. Liver fibrosis was staged according to the Ishak classification at BL, week 48, and week 96. Discrimination of PREsTo for hepatic decompensation, PSC-related clinical events (i.e. decompensation, ascending cholangitis, cholangiocarcinoma, transplantation), and progression to cirrhosis was determined using c-statistics. Model calibration was evaluated according to tertiles of predicted risk using the Hosmer and Lemeshow goodness-of-fit statistic.
Results: The median age was 45 years, 64% were male, 48% had UC, 62% were on UDCA, 51% had bridging fibrosis or cirrhosis, and the median (IQR) serum ALP and bilirubin at BL were 260 U/L (129–401) and 0.7 mg/dL (0.5–1.1), respectively. Over a median follow-up of 23.0 months (range, 2.8, 27.8), 10 subjects (4.3%) developed hepatic decompensation (ascites [n = 6], encephalopathy [n = 2], variceal hemorrhage [n = 2]), 47 subjects (20%) developed a PSC-related clinical event (first events of ascending cholangitis [n = 27], decompensation [n = 6], cholangiocarcinoma [n = 3], and other [n = 11]), and 36 of 209 (17%) non-cirrhotic subjects progressed to cirrhosis. PREsTo accurately predicted hepatic decompensation (c-statistic, 0.87 [95% CI

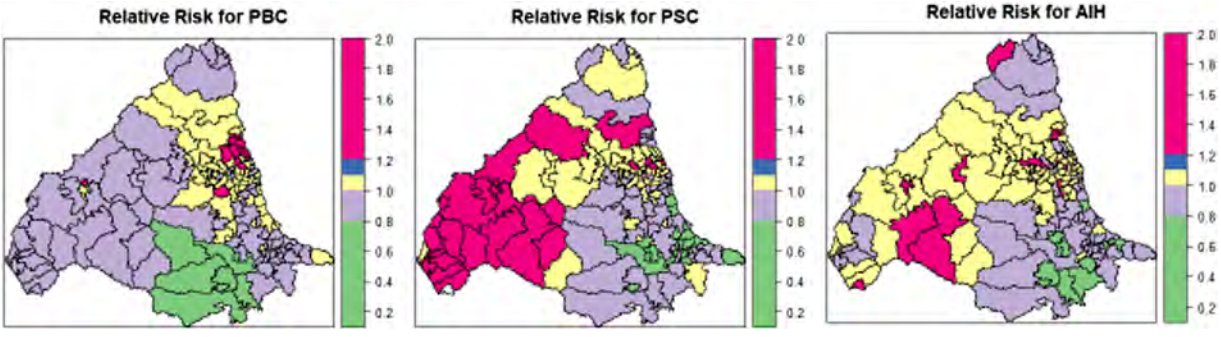

Figure: (abstract: FRI-015)

0.79–0.96]), but discrimination was lower for PSC-related clinical events (0.74 [95% CI 0.67–0.82]) and progression to cirrhosis (0.62 [95% CI 0.52-0.73]). Calibration of PREsTo for hepatic decompensation was good (observed vs expected events: low-risk: 0 vs 0.8; medium-risk: 1 vs 1.0; high-risk: 9 vs 8.4; p = 0.36).
Conclusion: In this prospective clinical trial of patients with PSC, the PREsTo algorithm accurately predicted the risk of hepatic decompensation, but had reduced performance for other PSC-related complications including progression to cirrhosis.

FRI-017
High prevalence of possible PSC recurrence post transplant evaluated by protocol biopsies
Lise Katrine Engesæter[1,2,3,4], Henrik Reims[5], Krzysztof Grzyb[5], Andreas Abildgaard[6], Tom H. Karlsen[1,2,3,4], Kristian Bjøro[1,3,4], Kirsten Muri Boberg[1,3,4], Johannes Roksund Hov[1,2,3,4], Espen Melum[1,2,3,4]. *[1]Norwegian PSC Research Center, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo University Hospital, Oslo, Norway; [2]Research Institute of Internal Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [4]Section of Gatroenterology, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo University Hospital, Oslo, Norway; [5]Department of Pathology, Oslo University Hospital Rikshospitalet, Oslo, Norway; [6]Department of Radiology, Oslo University Hospital Rikshospitalet, Oslo, Norway*
Email: lisek78@hotmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is one of the leading indications for liver transplantation (LTX) in the Nordic countries. Recurrent PSC (rPSC) is estimated to affect at least 20-30% and is associated with reduced graft survival. The diagnosis is challenging and true prevalence figures are so far not available. We therefore aimed to evaluate the incidence and impact of rPSC on graft- and patient-survival using protocol biopsies.
Method: We evaluated all transplanted PSC patients with protocol liver biopsies in the time period 2008–2017. Clinical routine histology reports were classified as possible rPSC or no rPSC. Prevalence was calculated at 1, 3 and 5 years following LTX. Patient and graft survival were estimated by Kaplan-Meier plots, and the log rank test was used for comparison.
Results: Two hundred and fifty-one PSC patients receiving a liver allograft were evaluated for inclusion. Fifteen patients (6%) were excluded due to treated hepatic artery stenosis/thrombosis or early biliary strictures/anastomotic strictures. Out of the remaining 236 patients 48, 56 and 70 patients had liver biopsies at 1, 3 and 5-years post-LTX respectively. Histology was classified as possible rPSC in 27 (56.3%) 29 (51.8%), and 44 (62.9%) at 1, 3- and 5 years. In time-to-event analyses from the time of liver biopsy, there were no differences in re-transplantation-free survival between patients with possible rPSC and no rPSC at histology.
Conclusion: The prevalence of possible rPSC based on routine pathological evaluation of liver biopsies was above 50% at all time points, but this did not affect outcome in terms of graft and patient survival in a 5 years perspective. A structured approach to classification of rPSC in terms of histology and MRI is warranted in order to further evaluate the role of these modalities in predicting outcome.

FRI-018
High risk of no response and poor prognosis of immunosuppressive therapy in patients of pbc-aih overlap syndrome
Xiaoli Fan[1], ruoting men[1], zhichao hu[1], li yang[1]. *[1]West China Hospital, Sichuan University, Chengdu, Sichuan 610041, China, Department of Gastroenterology and Hepatology, Chengdu, China*
Email: fxl0833@163.com

Background and aims: The aim of this study was to elucidate the clinical and histological features, response to corticosteroid therapy and long-term outcome of PBC-AIH overlap syndrome.
Methods: A cohort study was performed to evaluate the usefulness of immunosuppressive therapy and UDCA combination in this unique group. This cohort study was performed prospectively between October 2013 and May 2018 and included 96 biopsy-proven patients diagnosed according to strict criteria. The primary end points were biochemical response and outcome. Logistic regression analysis was performed to identify factors significantly associated with biochemical response.
Results: 49.0% of patients did not respond to treatment. The baseline values of total bilirubin, alkaline phosphatase, gamma-glutamyl transpeptidase, IgG, and presentation of cirrhosis differed significantly between the responders and non-responders ($p < 0.05$). The presence of cirrhosis ($p = 0.013$; odds ratio = 0.280) and IgG values ($p = 0.003$; odds ratio = 0.871) were associated with lack of response to the combination of UDCA and immunosuppression. Adverse event-free survival differed significantly between the two groups, according to the Kaplan-Meier estimate. Second-line immunosuppressive agents (mycophenolate mofetil and tacrolimus) led to biochemical remission in 33.3% of patients who did not respond to initial immunosuppression. Liver transplants were given to 2 patients with PBC-AIH. Eleven patients died from liver-related causes during follow-up.
Conclusions: There is a high risk of no-response and bad prognosis of PBC-AIH overlap syndrome in Asians. Early identification of no-response may allow timely intervention to prevent clinical deterioration. Second-line immunosuppressive agents only lead to 33.3% of response.

FRI-019
Readmission in hospitalized patients with autoimmune hepatitis in nationwide inpatient setting
Xiaowen Fan[1], Melissa Hershman[2], Ilan Weisberg[2]. *[1]Mount Sinai St. Luke's and Mount Sinai West, New York, United States; [2]Mount Sinai Beth Israel, Mount Sinai St. Luke's and Mount Sinai West, New York, United States*
Email: xiaowen.fan@mountsinai.org

Background and aims: Autoimmune hepatitis (AIH) is an autoantibody mediated chronic inflammatory disease of the liver with a variety of different clinical phenotypes. AIH presentation can vary from asymptomatic elevations of liver enzymes, to nonspecific symptoms associated with chronic liver disease, to acute liver injury including rarely, fulminant liver failure. While typically managed in the outpatient setting, we aimed to study risk factors in hospital readmission among AIH.
Method: This is a retrospective cohort study using the 2014 NRD. We included non-elective hospitalizations with a diagnosis of AIH. Hospitalizations with age less than 18, or liver transplantation performed during same hospitalization were excluded, transfers to other hospitals and patients who left against medical advice were excluded as well. We also identified hospitalizations with cirrhosis, which was defined as hospitalizations with a diagnostic code of cirrhosis or any complications of cirrhosis (table 1). Readmission was defined as the first admission to hospital for any non-trauma cause within 90 days of the index admission. The primary outcome was the 90-day readmission rate. Secondary outcomes included mortality rate, causes for readmission, and readmission risk factors.
Results: The total number of admissions with AIH was 9, 153. The mean age was 57.7 (56.8-58.5), 77.8% were female, 43.9% had coexisting cirrhosis, and 10.6% underwent liver biopsy during hospitalization. The in-hospital mortality rate was 3.7%. The all-cause 90-day readmission rate was 25.2%. The in-hospital mortality rate for readmitted patients was 4.7%. The top causes for readmission were (1-5): hepatic encephalopathy, AIH, unspecified septicemia, non-alcohol-related cirrhosis, acute kidney failure. AIH with cirrhosis population had an in-hospital mortality rate of 6.1% and 90-day readmission rate of 31.1%. Various risk factors were tested using univariate and multivariate regression analysis. The odds ratios (ORs)

and p values were calculated using multivariable logistic regression and independent factors for readmission were identified: Medicaid (OR 2.24; 1.53-3.26) and Medicare (1.54; 1.20-1.98) with private insurance as reference, cirrhosis (1.42; 1.18-1.71), and higher Charlson Comorbidity Index (1.13; 1.08-1.19) were associated with higher odds of readmission, while liver biopsy (0.69; 0.51-0.94) was associated with lower odds of readmission after adjusting for multiple factors (table 2).

Table 1: Supplement

	Diagnostic/Procedure Codes (ICD 9)
Autoimmune Hepatitis	571.42
Liver Transplantation	50.51, 50.59
Liver Biopsy	50.11, 50.13
Cirrhosis	571.2, 571.5, 571.6
Esophageal Varices	456.1, 456.21
Variceal Bleed	456.20, 456.0
Hepatocellular Carcinoma	155.0
Portal Hypertension	572.3
Hepatic Encephalopathy	572.2
Hepatorenal Syndrome	572.4
Hepatopulmonary Syndrome	573.5
Ascites	789.59
Spontaneous Bacterial Peritonitis	567.23

Table 2: Independent Predictors of Readmission

Factor	Odds Ratio (OR)	Lower 95% CI	Upper 95% CI	p-value
Age	0.99	0.99	1.00	0.06
Female Sex	1.00	0.82	1.22	0.99
Cirrhosis	1.42	1.18	1.71	**<0.01**
Charlson Comorbidity Index	1.13	1.08	1.19	**<0.01**
Liver biopsy	0.69	0.51	0.94	**0.02**
Prolonged Length of Stay (>10 days)	1.08	0.85	1.38	0.53
Primary Insurance				
Private	Reference			
Medicaid	2.24	1.53	3.26	**<0.01**
Medicare	1.54	1.20	1.98	**<0.01**
Uninsured	1.20	0.76	1.86	0.41
Median Household Income in Patient's Zip Code				
1st Quartile ($1-39,999)	Reference			
2nd Quartile ($40,000-50,999)	0.89	0.71	1.11	0.30
3rd Quartile ($51,000-65,999)	0.86	0.68	1.07	0.17
4th Quartile (≥$66,000)	1.00	0.80	1.26	0.97
Hospital Quintile (low-high)				
1st Quartile (1-20%)	Reference			
2nd Quartile (21-40%)	0.88	0.56	1.39	0.58
3rd Quartile (41-60%)	1.08	0.72	1.61	0.72
4th Quartile (61-80%)	0.99	0.67	1.45	0.95
5th Quartile (81-100%)	1.09	0.76	1.56	0.64

Conclusion: A quarter of AIH hospitalizations cause readmissions within 90 days. Readmissions were mostly for AIH, cirrhosis, and related comorbidities. The decreased readmission rate associated with liver biopsy may suggest that in the appropriate clinical setting, earlier utilization of tissue diagnosis prompts appropriate and effective therapy.

FRI-020

Identification of risk factors for histological progression with sequential liver biopsies in primary cholangitis patients

Yukihisa Fujinaga[1], Tadashi Namisaki[1], Takemi Akahane[1], Kosuke Kaji[1], Hiroaki Takaya[1], Shinya Sato[1], Kei Moriya[1], Hideto Kawaratani[1], Yasuhiko Sawada[1], Masanori Furukawa[1], Yuki Tsuji[1], Hitoshi Yoshiji[1]. [1]*Third Department of Internal Medicine, Nara Medical University, Kashihara, Japan*
Email: namisakitadashi1@yahoo.co.jp

Background and aims: Clinical outcomes of primary biliary cholangitis (PBC) remain vague despite improvements in the understanding of its natural history and prognosis. We previously reported that biochemical response to ursodeoxycholic acid (UDCA) according to the Nara criteria predicted the histological progression of PBC. The aim of this study was to determine factors associated with histologic progression in PBC patients using sequential liver biopsies.

Method: Thirty-five patients with PBC who received UDCA treatment underwent sequential liver biopsies. UDCA was administered in all patients after the initial liver biopsy. Accordingly, the patients were categorized into those demonstrating histological progression (progression group, PG) and those lacking histological progression (non-progression group, NPG). Pathologic staging was performed according to the Scheuer (SC) and Nakanuma (NA) systems. The NA system included grading of liver fibrosis (fibrosis score) and bile duct loss (BDL score). Univariate and multivariate analyses were conducted to assess factors distinguishing the PG and the NPG.

Results: Average patient age at the initial liver biopsy was 53.5 years, and patients were female. A mean of 2.7 liver biopsies per patient were obtained over a mean follow-up period of 6.7 year. There were 6, 12, 17, and 0 patients with SC stages 1, 2, 3, and 4, respectively, whereas 0, 7, 24, and 4 patients were categorized into NA stages 1, 2, 3, and 4, respectively. According to the SC system, 13 patients had histological progression, whereas 22 patients did not exhibit histological progression. According to the NA system, 9 and 26 patients were in the PG and NPG, respectively. The fibrosis and BDL scores progressed in 13 and 8 patients, respectively, whereas 22 and 27 patients did not exhibit progression, respectively. In univariate analysis, gamma-glutamyl transpeptidase (γ-GTP) level at two year after UDCA treatment initiation and pretreatment alanine aminotransferase (ALT) level were identified as risk factors for SC and NA stage progression, respectively. Univariate analysis also identified pretreatment γ-GTP level as significant factor associated with the increase in fibrosis score and ALT level at one and two year and aspartate aminotransferase level at two year after UDCA treatment initiation as significant factors associated with the increase in BDL score. However, in the multivariate analysis, there were no significant differences between PG and NPG for the serum liver enzymes. Multivariable logistic regression analysis showed that the rates of change in the γ-GTP levels after one year of UDCA treatment was an independent factor associated with the increase in NA stage progression.

Conclusion: The rates of change in the γ-GTP levels after one year of UDCA treatment is a significant factor for the increase in NA stage progression in PBC patients with sequential liver biopsies.

FRI-021

Comparing the predictive performance of the Mayo risk score and the GLOBE score in a large cohort of patients with primary biliary cholangitis

Background and aims: The Mayo Risk Score (MRS) is the traditional risk prediction model in patients with primary biliary cholangitis (PBC), but its utility in clinical practice may be hampered by the use of peripheral edema as a subjective parameter. In contrast, the GLOBE score only includes readily available objective parameters. We aimed to assess and compare predictive performance of the MRS and GLOBE score in a large international cohort of patients with PBC.
Method: This study included patients of 7 centers of the GLOBAL PBC Study Group. By retrospective chart review, additional data were collected on diuretic use, peripheral edema and prothrombin time (PT), enabling calculation of the MRS. A combined end point of death or liver transplantation (LT) was used. Discriminatory performance of the MRS and GLOBE score was assessed with C-statistic at yearly intervals up to 5 years of UDCA therapy. Prediction accuracy of both models was assessed by comparing predicted survival with the actual observed survival in Kaplan-Meier analyses.
Results: A total of 1100 UDCA-treated PBC patients were included, with a mean (sd) age of 53.6 (12.0) years, of whom 1003 (91%) were females. During a median follow-up of 7.6 (IQR 4.1-11.7) years 169 patients reached an end point: 42 patients underwent LT and 127 patients died. At 1 year of UDCA treatment, the C-statistic for the MRS was 0.77 (95% confidence interval [CI] 0.73-0.81) and for the GLOBE score 0.80 (95% CI 0.76-0.84) ($p > 0.05$). The C-statistics was similar for both scores when recalculated from 2 to 5 years following initiation of UDCA. For the MRS the observed minus the predicted 5-year transplant-free survival in the < 20th, 20th –80th and > 80th percentile was +0.3%, +3.9%, and +13.2%, respectively. For the GLOBE score these differences were +0.3%, +1.8% and –0.8%, respectively. In patients with abnormal bilirubin ($n = 124$), the C-statistic was 0.73 (95% CI 0.66-0.80) for the MRS and 0.75 (95% CI 0.67-0.82) for the GLOBE score. Within this subgroup the observed minus the predicted transplant-free survival at 3 years and 5 years of follow-up was –6.3% and –9.6% for the MRS, and –3.4% and –2.7% for the GLOBE, respectively.
Conclusion: In this large cohort of patients with PBC, the MRS and GLOBE score had comparable discriminating performance for LT or death. However, the GLOBE score showed better prediction accuracy and may therefore be better applicable in daily clinical practice for optimal management of individual patients.

Characteristics of autoimmune hepatitis with acute presentation

Ana Gomez[1], Carmen Álvarez-Navascués[1], Andrés Castano-Garcia[1], María Torner[1], Maria Varela[1], Valle Cadahía-Rodrigo[1], Maria Luisa Gonzalez Dieguez[1], Manuel Rodríguez[1]. *[1]Hospital Universitario Central de Asturias, Liver Unit. Division of Gastroenterology and Hepatology, Oviedo, Spain*
Email: canavascues99@movistar.es

Background and aims: Autoimmune hepatitis (AIH) is a heterogeneous disease with a broad clinical spectrum. The aim of this study was to analyze the characteristics of patients with AIH with acute presentation in our area.
Method: 179 patients diagnosed of AIH from 1995 to 2018 were included; 113, prospectively recorded, had acute presentation (AP) and 66, retrospectively recorded, other patterns of presentation (non-AP). AIH diagnosis was based on Simplified Criteria or clinical judgment. A liver biopsy was obtained in 143/179 patients (79.8%; 81.4% AP, 77.2% non-AP). AP was defined by ALT > 10xULN, severe acute hepatitis (SAH) by prothrombin < 50% and acute liver failure (ALF) when encephalopathy was added to the previous findings.
Results: Among 113 patients with AP, 10 (9%) were diagnosed in the period 1995-2002, 43 (38%) in 2003-2010 and 60 (53%) in 2011-2018. 25 of them (22.1%) had SAH and 10 (8.8%) ALF; no differences were found in the proportion of SAH or ALF in the three periods of time (20%/25.5%/36.6%; $p = 0.35$). Comparing patients with AP and non-AP there were no differences in sex (female 71.6% vs 80.3%; $p = 0.20$) or age [55 (45-65) vs 53.5 (36.7-64.5); $p = 0.28$)]. Features of other autoimmune diseases were more frequent in non-AP than in AP patients, but without statistical significance (37.8% vs 25.6%; $p = 0.086$). AP were more frequently seronegative (18.6% vs 7.2%; $p = 0.007$) while IgG levels were similar in AP and non-AP (19 vs. 18 g/L; $p = 0$, 44). The proportion of patients with atypical histology was higher in AP than in non-AP (31.5% vs. 7.8%; $p = 0.001$). Simplified Criteria score was ≥ 6 in 60% in AP and 69% in non-AP ($p = 0.31$). Although there were no differences in the proportion of patients with ≥ 1 acute exacerbation during follow-up (39.8% in AP vs 28.7% in non-AP; $p = 0.13$), patients with AP needed more frequently second line treatment (15.9% vs 4.5%; $p = 0.022$). During a median follow-up of 77 months (26-131), 15 patients were transplanted and 30 died. Free transplant survival at 5, 10, 15 and 20 years was 78.4%, 75.4%, 69.1% and 49.1% in patients with AP and 90.8%, 84.8%, 74.2% and 66.8% in those with non-AP ($p = 0.090$).
Conclusion: In our area, acute presentation of AIH is increasing. Nearly one third of AIH with AP develop severe acute hepatitis or acute liver failure. Patients with AP are frequently seronegative and with atypical histology, which makes diagnosis difficult. Response to standard treatment and free transplant survival are lower in patients with HAI with AP than in the rest.

FRI-023

Inadequate response to UDCA among PBC patients under routine care in the US: Rising serum bilirubin even in the normal range is a risk factor and subsequent clinical follow-up differs based on treatment response

Stuart C Gordon[1,1], Talan Zhang[2], Christopher L. Bowlus[3], Keith D. Lindor[4], Robert J Romanelli[5], Irina V. Haller[6], Heather Anderson[7], Jeffrey J. Vanwormer[8], Joseph A. Email: mlu1@hfhs.org

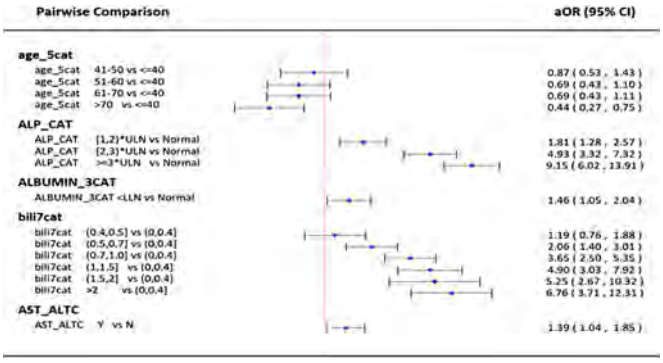
Background and aims: Ursodeoxycholic acid (UDCA) is a first line treatment in patients with primary biliary cholangitis (PBC) that is often followed by second-line therapy if there is inadequate response (IR). Previous analyses by the Fibrotic Liver Disease Consortium showed that pre-treatment total bilirubin, even within the normal range, is associated with increased risk of mortality. In the present

study, we analyzed the effect of pre-treatment bilirubin and other covariates associated with the risk of IR, and compared follow-up care between patients with/without IR.
Method: Baseline data were collected for PBC patients at time of UDCA initiation between 2006 and 2015. Total bilirubin was categorized as > 2, 2 > 1.5, 1.5 > 1.0, 1.0 > 0.7, 0.7 > 0.4, and ≤ 0.4 mg/dL. IR was defined using Paris II criteria 12 months after UDCA initiation. Logistic regression was used to estimate the adjusted risk for IR; model accuracy was assessed using area under the receiver operator characteristic curve (AUROC). Z-statistic was used to compare rates of follow-up care and treatment modification per person-year (PPY) between IR and non-IR patients.
Results: Among 1578 UDCA treated patients (13% men; 8% African American, 9% Asian American/American Indian/Pacific Islander (ASINPI); 25% Hispanic), 706 (45%) had IR to UDCA at 12 months post-baseline. The multivariate model (AUROC = 0.79) showed that younger age, increasing alkaline phosphatase (ALP), low albumin, and a ratio of aspartate to alanine aminotransferase (AST/ALT) > 1.1 were independently associated with an increased risk of IR. Bilirubin—even in the high-normal (1.0 > 0.7) and mid-normal (0.7 > 0.4 mg/dL) ranges—was also significantly associated with increased risk of IR compared to low-normal levels (≤ 0.4 mg/dL; Figure). A sensitivity analysis that defined IR as ALp > 1.67xULN yielded similar results. Compared to responders, patients with IR were more likely to: discontinue UDCA (0.08 vs 0.04 PPY; p < 0.01); add obeticholic acid (0.023 vs 0.004 PPY; p < 0.01); and were more likely to see a specialist (5.12 vs 3.16 visits PPY; p < 0.01), undergo liver imaging (1.23 vs 0.56 tests PPY; p < 0.01), have liver-related laboratory testing (18.4 vs 10.2 tests PPY; p < 0.01), be hospitalized (0.11 vs 0.07 PPY; p < 0.01), and seek emergency care (0.13 vs 0.08 PPY; p < 0.01).



Conclusion: Almost half of PBC patients (45%) in a routine clinical care cohort showed IR to UDCA. Baseline bilirubin > 0.4 mg/dL is associated with increasing risk of IR. Patients with IR had higher rates of specialist follow-up and health care utilization.

Incidence and prevalence of autoimmune hepatitis in England 1997-2015. A population-based cohort study

Lisbet Grønbæk[1,2,3], Harmony Otete[3,4], Lu Ban[5,6], Colin Crooks[3,5], Timothy Card[3,5], Peter Jepsen[1,2,3], Joe West[3,5]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; [2]Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark; [3]University of Nottingham, Division of Epidemiology and Public Health, Nottingham, United Kingdom; [4]University of Central Lancashire, School of Medicine and Dentistry, Lancashire, United Kingdom; [5]The Nottingham University Hospitals NHS and University of Nottingham, National Institute for Health Research Nottingham Biomedical Research Centre, Nottingham, United Kingdom; [6]University of Nottingham, Nottingham Digestive Diseases Centre, Nottingham, United Kingdom*
Email: groenbaek.lisbet@gmail.com

Background and aims: There are few population-based studies of the incidence of autoimmune hepatitis over long time periods. The burden of the disease and how it has changed over time has therefore not been fully explored. We conducted a population-based cohort study on the incidence of autoimmune hepatitis in England, 1997-2015.
Method: From the Clinical Practice Research Datalink, we included 882 patients diagnosed with autoimmune hepatitis in primary or secondary care in England between 1997 and 2015. We followed the patients through 2015 and calculated the sex- and age- standardised incidence and prevalence of autoimmune hepatitis. We examined variations in incidence by sex, age, calendar year, geographical region, and socioeconomic status. We calculated incidence rate ratios with Poisson regression.
Results: The overall standardised incidence rate of autoimmune hepatitis was 2.08 (95% confidence interval 1.94-2.22) per 100, 000 population per year, higher in women than in men, higher in older age, and independent of region of residence and socioeconomic status. The incidence doubled from 1.27 (95% confidence interval 0.51-2.02) per 100, 000 in 1997 to 2.56 (95% confidence interval 1.79-3.33) per 100, 000 population per year in 2015. The standardised point prevalence on 31 December 2015 was 19.24 (95% confidence interval 18.08-20.41) per 100, 000 population.
Conclusion: This population-based study showed a high incidence of autoimmune hepatitis which has doubled over an eighteen-year period. The incidence in England was particularly high in older women and was similar across all regions of England and independent of socioeconomic status.

FRI-025

Long-term outcome in autoimmune hepatitis: The second twenty years

Laura Harrison[1,2], Barbara Hoeroldt[1], Elaine Mcfarlane[1], Asha Dube[3], Dermot Gleeson[1]. *[1]Liver Unit, Northern General Hospital, Sheffield Teaching Hospitals NHS Foundation Trust, Hepatology, Sheffield, United Kingdom; [2]University of Sheffield Medical School, Infection, Immunity and Cardiovascular Diseases, Sheffield, United Kingdom; [3]Sheffield Teaching Hospital's NHS Foundation Trust, Histopathology, Sheffield, United Kingdom*
Email: laura.harrison11@nhs.net

Background and aims: Liver disease can progress in AIH despite treatment, but follow-up data beyond 20 years are sparse. Here, we aimed to assess outcomes over the 2nd twenty years of follow-up and to compare these with outcomes in patients followed up from initial diagnosis.
Method: Survival analysis and standardised mortality ratio (SMR), considering liver transplant as death; group comparisons using Kaplan-Meier and Cox regression analysis.
Results: 65 consecutive patients (diagnosed 1971-96), who had already been followed up for 20 years were followed up for a further (median (range)) 6.1 (0.3-26) years. Age at start of year 21 was 63 years (mean). Six patients were untreated (one had inactive cirrhosis; later transplanted, when AIH was confirmed; 5 had mild disease). Two patients had previously discontinued immunosuppressive treatment (IST) and a third did so after 27 years.
Two patients moved away after 28 and 39 years and were censored, 13 were discharged to primary care and remained alive until the end of follow-up. Of these, five were on IST, four were not and data were unavailable in four. The other 41 patients remained on IST until end of follow-up.
Of the 65 patients, 34 had cirrhosis by year 20 (22 at initial diagnosis) and 5 more developed cirrhosis after 20 years. Five patients (four on IST) suffered their first relapse after 20 years.
At end of follow-up (31/12/16), 42 of the 65 patients were alive, 3 had undergone liver transplantation, and 20 had died: 3 from liver disease (one hepatocellular carcinoma) and 17 from extra-hepatic causes (7 malignancy, 6 infection, 4 other causes). Survival from all-cause

death or transplant was lower in these 65 patients during the 2nd 20 years than in 327 consecutive patients followed from initial diagnosis (1987-2016); age at diagnosis 54 years): 68+7% (SEM) vs. 76+3% after 10 years and 38+10% vs. 47+4% after 20 years. However this was due to the older age of the 2nd 20-year cohort at start of follow-up (63 v 54 years), as the survival difference disappeared when adjusted for age. Survival from liver-related death/transplant was similar in the two cohorts (figure). SMR over the second 20 years was 1.45 (0.84-2.65) not significantly different from SMR in the 327 patients followed from diagnosis: 1.60 (1.21-1.91).

Figure: Survival from liver related death or transplant during the 2nd 20 yr of follow-up (n = 65) compared to those followed up from diagnosis (n = 327)

Conclusion: During the 2nd 20 years of follow-up, patients with AIH continue to have disease relapse and to develop cirrhosis. They have similar survival to patients followed from initial diagnosis.
Survival from liver related death or transplant during the 2nd 20 yr of follow-up (n = 65) compared to those followed up from diagnosis (n = 327)

FRI-026

Long-term assessment of the effects of obeticholic acid in patients with primary biliary cholangitis on immune and inflammatory markers

Gideon Hirschfield[1], Frederik Nevens[2], Mitchell Shiffman[3], Joost Ph Drenth[4], Christopher Bowlus[5], Víctor Manuel Vargas Blasco[6], Pietro Andreone[7], Alexander Liberman[8], Elizabeth Smoot Malecha[8], Leigh Macconell[8], Michael Trauner[9]. Email: g.hirschfield@bham.ac.uk

Background and aims: Obeticholic Acid (OCA) is a potent and selective farnesoid X receptor agonist approved for the treatment of primary biliary cholangitis (PBC). PBC is a chronic liver disease characterized by the immune mediated destruction of bile ducts resulting in cholestasis, cirrhosis and liver failure. The POISE study was a randomized, placebo-controlled phase 3 study investigating daily OCA 5-10 mg in PBC patients with an ongoing open label extension (OLE). The purpose of this analysis was to assess the long-term effects of OCA on key markers of liver damage and inflammation.

Method: Patients enrolled in the double-blind phase had an inadequate response to UDCA or were intolerant of UDCA. Upon completion of the 12-month double-blind phase, 198 patients enrolled in the OLE and received OCA. For this analysis, patients were pooled and assessed from the time of first dose of OCA. Data are shown through 48 months of OCA exposure, for patients randomized to placebo in the double-blind phase, only 36 months of data are included.

Results: At baseline (N = 198), patients were 92% female, mean age was 55 years, PBC disease duration was 9 years, and 93% received UDCA (mean dose: 16 mg/kg/day). As observed in the Table, there were sustained and significant reductions in immunoglobulins (Ig) A, G and M throughout 48 months of OCA treatment. In addition, significant reductions were observed in tumor necrosis factor (TNF)-α, c-reactive protein (CRP), and cleaved cytokeratin (CK)-18 throughout the duration of the OLE. No clinically meaningful changes were observed with transforming growth factor (TGF)-β and interleukin (IL)-12, both remained within the normal range.

Median (Q1, Q3)	Baseline	Δ From Baseline to 36 Months OCA (N = 161)	Δ From Baseline to 48 Months OCA (N = 120)
CRP mg/L	3 (2, 7)	−0.7*** (−2, 0.3)	−0.6** (−2, 0.5)
TNF-α pg/m)	11 (9, 14)	−3*** (−4, −1)	−2*** (−3, −0.4)
TGF-β ng/ml	25 (19, 35)	2 (−7, 11)	0 (−5, 7)
Ck-18 U/L	124 (83, 201)	−28*** (−78, 15)	−3 (−52, 40)
IL-12 pg/ml	138 (94, 198)	9 (−21, 28)	21** (−6, 43)
IgA g/L	2 (2, 3)	−0.2*** (−0.5, −0.1)	−0.3*** (−1, −0.1)
IgG g/L	13 (11, 15)	−1*** (−2, −0.03)	−1*** (−2, 0.2)
IgM g/L	4 (2, 6)	−1*** (−2, −0.4)	−1*** (−2, −0.4)

*p < 0.05; **p < 0.01; ***p < 0.0001. p values for the comparisons to baseline were obtained using a Wilcoxon signed rank test. Normal ranges: CRP 0-3 mg/L, TNF-α 8.1 pg/ml, TGF-β 18.3-63.4 ng/ml, Ck-18 80 U/L, IL-12 34-246 pg/ml, IgA 0.7-4 g/L, IgG 7-16 g/L, IgM 0.4-2.3 g/L

Conclusion: These results demonstrate that OCA has a durable anti-inflammatory effect in patients with PBC as observed by reductions on key markers of apoptosis (TNF-α and CK-18) and inflammation (CRP). Furthermore, a sustained reduction is observed in IgM, which is classically elevated in PBC patients. The clinical significance of OCA mediated reductions in IgA and IgG continues to remain unknown.

FRI-027

Serum bile acids significantly associate with the fibrogenesis biomarker Pro-C3: analysis of a randomized, placebo-controlled trial of NGM282 in patients with primary sclerosing cholangitis

Gideon Hirschfield[1], Lei Ling[2], Mark Jaros[3], Kathline H. Kim[2], Bryan Baxter[2], Alex Depaoli[2], Marlyn J. Mayo[4], Ulrich Beuers[5]. [1]*Toronto Centre for Liver Disease, University Health Network, University of Toronto, Toronto, Canada;* [2]*NGM Biopharmaceuticals, South San Francisco, United States;* [3]*Summit Analytical, Denver, United States;* [4]*University Texas Southwestern Medical Center, Dallas, United States;* [5]*Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*
Email: lling94080@yahoo.com

Background and aims: PSC is an inflammatory, cholestatic and progressively fibrotic liver disease devoid of effective medical interventions. NGM282, a non-tumorigenic FGF19 analogue, reduces levels of 7alpha-hydroxy-4-cholesten-3-one (C4, a marker of bile acid synthesis) and fibrosis biomarkers, including Pro-C3, in patients with PSC and NASH. To assess the impact of NGM282 on bile acid (BA) species which may be implicated in fibrosis, we evaluated the correlation of individual BAs with C4 and Pro-C3 (a marker of fibrogenesis) using our placebo-controlled trial data from patients with PSC treated with either NGM282 or placebo.

Method: As previously reported, sixty-two patients, with PSC by EASL criteria and an elevated ALP > 1.5xULN at baseline (BL), were randomized to NGM282 1mg, 3mg or placebo for 12 weeks (W12). Serum concentrations of BA species and C4 were determined by mass spectrometry (Mayo Clinic). Serum Pro-C3 was measured by an ELISA method (Nordic Bioscience). Correlation coefficients were calculated using Spearman's method.

Results: Serum concentrations of individual BAs significantly correlated with Pro-C3, but not C4, at W12 (Table 1). Placebo-adjusted reductions from BL to W12 were observed in hydrophobic (toxic) BAs, including DCA ($p < 0.001$ for both NGM282 1mg and 3mg groups), GDCA ($p = 0.003$ for 1mg, $P < 0.001$ for 3mg) and TDCA ($p = 0.03$ for 3mg). At W12, relative changes in Pro-C3 from BL were – 21% ($p = 0.008$) and – 27% ($p < 0.001$) with NGM282 1mg and 3mg, respectively, versus +11% ($p = 0.08$) with placebo.

Figure: Table 1: Correlation of individual bile acids with Pro-C3 and C4 concentrations at week 12

	Pro-C3		C4	
	P value	P value	r value	P value
Conjugated primary bile acids				
GCA	0.62	< 0.0001	–0.03	0.83
TCA	0.52	< 0.0001	–0.12	0.37
GCDCA	0.55	< 0.0001	–0.25	0.06
TCDCA	0.46	0.0003	–0.28	0.032
Conjugated secondary bile acids				
GDCA	0.31	0.020	0.27	0.038
TDCA	0.28	0.038	0.22	0.09
Unconjugated primary bile acids				
CA	–0.18	0.18	0.09	0.49
CDCA	–0.21	0.12	–0.01	0.92
Unconjugated secondary bile acids				
DCA	–0.06	0.65	0.52	< 0.0001

Conclusion: Circulating concentrations of the major hydrophobic BAs strongly correlate with the fibrosis marker Pro-C3 in PSC patients treated with NGM282. Both serum BAs and Pro-C3 are lowered by NGM282 suggesting that the effects of NGM282 on bile acid synthesis may be pathophysiologically linked to its anti-fibrotic effects in PSC. Our data confirm the need for further consideration of using markers such as BAs and Pro-C3 in the determination of efficacy of new therapies for patients with PSC.

Spleen stiffness and liver stiffness measurements as surrogate markers of liver fibrosis in patients with autoimmune hepatitis: prospective, single-center study

Maciej K. Janik[1], Konrad Kostrzewa[2], Raszeja-Wyszomirska Joanna[1], Frank Lammert[3], Małgorzata Milkiewicz[4], Piotr Milkiewicz[1,5], Marcin Krawczyk[3,6]. *[1]Medical University of Warsaw, Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery, Warsaw, Poland; [2]Warsaw School of Economics, Warsaw, Poland; [3]Saarland University Medical Center, Saarland University, Department of Medicine II, Homburg, Germany; [4]Pomeranian Medical University, Medical Biology Laboratory, Szczecin, Poland; [5]Pomeranian Medical University, Translational Medicine Group, Szczecin, Poland; [6]Medical University of Warsaw, Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Warsaw, Poland*
Email: mjanik24@gmail.com

Background and aims: Shear-wave elastography allows reliable measurements of LSM and SSM in patients with AIH, and they both are of help in identifying patients with cirrhosis. For fibrosis staging, SSM results seem to be however less biased by hepatic inflammation as compared to LSM rendering SSM potentially a more reliable tool in patients with AIH.

Method: We analysed two cohorts of patients with AIH: 34 patients (24 women, mean age 40.5 years) who had SWE done within 1.6 months from liver biopsy (19 with cirrhosis) and 91 consecutive, treated AIH patients (74 women, mean age 38.4 years) without flare. LSM and SSM measurements were done with SuperSonic Imagine Aixplorer®. Serum CD163, a macrophage activity marker, was measured by ELISA to assess the impact of liver inflammation on SSM.

Results: The optimal cut-off for detecting liver cirrhosis for LSM was 16.1 kPa (AUROC 0.9, 95% CI 0.79-1.01, $p < 0.01$, sensitivity 89% and specificity 87%). The optimal SSM cut-off for cirrhosis was 30.4 kPa (AUROC 0.98, 95% CI 0.93-1.04, $p = 0.02$) and had 92% sensitivity and 100% specificity. In the treated group without flare, a total of 26 (29%) had cirrhosis, applying the LSM cut-off ≥ 16.1 kPa. Comparison of patients with and without cirrhosis showed robust differences in fibrosis indices (FIB-4, FibroQ), markers of portal hypertension (platelet count, spleen diameter, esophageal varices) and liver injury surrogates (MELD) between both groups (all $p < 0.001$). Notably, LSM showed a significant correlation with all inflammatory markers: ALT and IgG (both $p < 0.01$) and CD163 ($p < 0.001$). In contrast, SSM correlated with CD163 ($p < 0.01$), but not with the other markers of hepatic inflammation.

Conclusion: Shear-wave elastography allows reliable measurements of LSM and SSM in patients with AIH, and they both are of help in identifying patients with cirrhosis. For fibrosis staging, SSM results seem to be however less biased by hepatic inflammation as compared to LSM rendering SSM potentially a more reliable tool in patients with AIH.

FRI-029

Non-alcoholic fatty liver disease and steatohepatitis in autoimmune hepatitis: important player or innocent bystander?

Kalliopi Zachou[1,2], Kalliopi Azariadi[1,2], Ellina Lytvyak[3], Nikolaos Gatselis[1,2], Atsushi Takahashi[4], Mercedes Robles[5], Raul J. Andrade[5], Christoph Schramm[6], Ansgar W. Lohse[6], Atsushi Tanaka[7], Aldo J Montano-Loza[3], George N. Dalekos and on behalf of the IAIHG[1,2]. *[1]Institute of Internal Medicine and Hepatology, Larissa, Greece; [2]Department of Medicine and Research Laboratory of Internal Medicine, University Hospital of Larissa, Larissa, Greece; [3]Division of Gastroenterology and Liver Unit, University of Alberta Hospital, Edmonton, Alberta, Canada; [4]Department of Gastroenterology, Fukushima Medical University School of Medicine, Fukushima, Japan; [5]Unidad de GestiónClínica del AparatoDigestivo, Servicio de FarmacologíaClínica, Instituto de InvestigaciónBiomédica de Málaga-IBIMA, Hospital Universitario Virgen de la Victoria, Universidad de Málaga, CIBERehd, Málaga, Spain; [6]I. Department of Medicine and Martin Zeitz Centre for Rare Diseases, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany; [7]Department of Medicine, Teikyo University School of Medicine, Tokyo, Japan*
Email: zachoukalliopi@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) and steatohepatitis (NASH) affect 17-46% of western countries population, making coexistence with other liver diseases inevitable. Our aim was to investigate the prevalence and clinical significance of NAFLD/NASH in patients with autoimmune hepatitis (AIH), in a multicentric large cohort.

Method: Prospectively collected data from patients with well-established AIH from 6 academic centers (Greece, Canada, Japan, Germany and Spain) were evaluated retrospectively. The presence of NAFLD and NASH in liver biopsy reports was recorded in detail in order to compare the clinical and laboratory data as well as the outcome between AIH patients with and without NAFLD/NASH.

Results: 580 patients (433 females, 74.7%; age at AIH diagnosis 46 ± 18 years; 175 from Greece, 309 from Canada, 44 from Japan, 29 from Germany, 13 from Spain; follow-up 103 ± 86 months) were included. NAFLD was present in 123/580 (21.2%) baseline biopsies. In more detail, 107/580 (18.4%) had NAFLD (64/107 steatosis only; 43/107 steatosis and lobular inflammation) and 16/580 (2.7%) NASH. Patients

with AIH-NAFLD/NASH were older at AIH diagnosis (p = 0.004), had higher BMI (p < 0.001), lower AST, ALT, ALP and bilirubin (p < 0.05 for each), but higher albumin (p < 0.001), triglycerides (p = 0.05) and lower simplified score (p = 0.02) compared to those without NAFLD/NASH. AIH-NAFLD/NASH patients suffered more frequently from hypertension, diabetes and obesity (p < 0.001 for each). AIH-NAFLD/NASH patients were less likely to be anti-SLA/LP positive (p = 0.005), but more likely to be anti-LKM positive (p = 0.02). Although progression to cirrhosis was not associated with NAFLD/NASH presence, AIH-NAFLD/NASH cirrhotic patients (39/197) were more likely to decompensate during follow-up (p = 0.01). The presence of NAFLD/NASH did not affect response to treatment or overall prognosis (liver related death or liver transplantation).
Conclusion: Despite the high prevalence of NAFLD/NASH in one fifth of AIH patients, there is no evidence that NAFLD/NASH acts as an aggravating factor since response to treatment and the overall prognosis of AIH patients were not affected. However, the low number of patients with AIH and NASH could be responsible for these findings. Nevertheless, special attention might be needed for those with established AIH-related cirrhosis and concurrence NAFLD/NASH.

FRI-030
Treatment choice and long-term prognosis for elderly PBC
Hiroteru Kamimura[1], Masaaki Takamura[1], Kenya Kamimura[1], Atsunori Tsuchiya[1], Shuji Terai[1]. *[1]Niigata University, Division of Gastroenterology and Hepatology, Niigata Japan, Japan*
Email: hiroteruk@med.niigata-u.ac.jp

Background and aims: Primary biliary cholangitis (PBC) is a chronic and progressive cholestatic liver disease of presumed autoimmune pathogenesis that usually affects middle-aged women. PBC onset is increasing in the ageing population of Japan.
Method: We compared differences in characteristics, clinical findings, treatment choice and prognosis with UK-PBC score between elderly and younger-onset PBC patients.359 patients were enrolled from 2005 to2018 and divided into > 65 and < 65 years groups. We retrospectively examined the treatment choice and long-term prognosis for elderly PBC. This multifacility observational study in the Niigata prefecture had an ethical screening committee in each facility.

Factors (Median) (range) (n)	< 65 y.o.	≥ 65 y.o.	p value
n	260	99	-
Gender (Male / Female)	26 / 234 (90%)	20 / 79 (79.8%)	0.013
Age (years)	52 (28-64)	69 (65-92)	-
Male (years)	55 (38-64)	69 (65-92)	-
Female (years)	52 (35-64)	70 (65-79)	-
Family history of PBC (+ / - / unknown)	7 (2.6%) / 235 / 18	4 (4.0%) / 87 / 8	0.678
mother, daughter / sister, brother / father	4 / 2 / 1	2 / 2 / 0	-
Symptoms (+ / -)	52 (20%) / 208	16 (16%) / 83	0.453
itching / jaundice / ascites / edema / EV	45 / 5 / 7 / 7 / 2	15 / 1 / 5 / 9 / 7	-
s1-PBC / s2-PBC	47 / 5 (1.9%)	15 / 1 (1.0%)	>0.999
Other autoimmune diseases (+ / -)	89 (34.2%) / 171	29 (29.2%) / 70	0.450
SjS / Thyroiditis / RA / SLE	40 (15.3%) / 20 / 12 / 3	15 (15.1%) / 3 / 3 / 0	-
AIH / CREST / PSS / Myositis / Others	8 (3%) / 5 / 7 / 3 / 11	3 (3%) / 4 / 0 / 1 / 3	-
Malignancies (+ / -)	24 (9.2%) / 236	14 (14.1%) / 85	0.187
HCC / Colon / Gastric / MMK / Lung / Others	2 / 6 / 3 / 6 / 2 / 5	1 / 5 / 3 / 3 / 0 / 3	-

Figure: Background (at the time of diagnosis)

Results: 99 cases, age > 65 years, were defined as elderly PBC and 260 cases, age < 65 years, were defined as younger-onset PBC. The symptomatic PBC ratios were 16% vs 20%. There was no significant difference in ALP and γ-GT levels. However, Alb and platelet levels were decreased in elderly PBC (p = < 0.001). There were AMA/M2 antibody negative cases (14.8% vs. 10.7%, p = 0.457) as well as Scheuer stage 4 cases (11.1% vs. 0%, p = 0.084) As for the treatment choice observation, there were 4 vs. 17 cases. For UDCA treatment only, there were 81 vs. 171 cases and did not exit significant difference. For UDCA and Bezafibrate (BF) combination treatment, there were 11 vs. 71 cases and there were significantly few cases in elderly patients. UDCA alone dosage example, the UDCA + BF combination treatment had good reactivity in both groups. Treatment reactivity did not exit the significant difference in UK-PBC risk score. However, the elderly group had lower weight than the younger group, so the UDCA dose per weight was higher in the elderly group. Regarding long-term prognosis between liver transplant and liver-related death, the significant difference did not exist. UK-PBC score and GLOBE score have high sensitivity and specificity in both groups (AUC 0.987 P < 0.001 vs. AUC 0.987 P < 0.001)
Conclusion: There was no significant difference in laboratory data at the time of diagnosis, treatment reactivity, and long-term prognosis. The prognosis of liver-related death as an end point was equal and the factors for prognosis were not identified. It is necessary to try the problem of treatment policy for the elderly person PBC case and the long-term convalescence should be re-examined.

FRI-031
Association between serum immunoglobulin G levels and intrahepatic plasmacytic gene signature in human autoimmune hepatitis
Atsumasa Komori[1], Asami Hori[1], Yuki Kugiyama[1], Shigemune Bekki[1], Tomoyuki Suehiro[1], Satoru Hashimoto[1], Akira Saeki[1], Shinya Nagaoka[1], Kazumi Yamasaki[1], Seigo Abiru[1], Masahiro Itoh[1], Hiroshi Yatsuhashi[1]. *[1]National Hospital Organization Nagasaki Medical Center, Clinical Research Center, Ōmura, Japan*
Email: atsuriko1027@yahoo.co.jp

Background and aims: Atypical autoimmune hepatitis (AIH) without a hallmark hypergammaglobulinemia are on the increase in number and their association with acute onset cases is an emerging topic. The aim of the study is to define specific gene signature in the human AIH liver that associates with serum immunoglobulin G (IgG).
Method: The patient cohort consisted of 17 cases of AIH, including ones with acute manifestation. According to the International Autoimmune Hepatitis Group simplified criteria, patients whose serum IgG exceeded over 1.1 × upper limit normal were classified into high IgG group (n = 8). Hepatic RNA were extracted from biopsy samples and microarray hybridization was performed on Human Oligo chip 25k array (TORAY, Japan). Commercially available hepatic RNA from 4 healthy volunteers were used as controls (CON). Normalization of raw intensity values, followed by analysis of data were performed using GeneSpring (Agilent Technologies, U.S.A.). We first extracted genes whose expression differed 1.5 folds < between AIH and CON (FDR corrected $p < 0.05$, Genes A: n = 2067). Next, gene signatures between high and non-high IgG group were compared (FDR corrected $p < 0.05$). For deconvolution of disease activity with regard to plasma cell gene signature, gene probes whose expression profile were correlated (Pearson, $r_s > 0.85$) with both with *TNFRSF17* and *POU2AF1* were extracted among Genes A (B, n = 48). For personalized analyses, each patient sample was compared to the average of CON for each gene probe in Genes B. The level of regulation of plasma cell gene signature was calculated as the percentage difference: % up-regulated minus % down-regulated gene probes. Canonical pathways analysis was performed using Ingenuity (version 01-10, Q3 2018, QIAGEN, GmbH)
Results: Significantly upregulated canonical pathways among Genes A (Z score > 2.0) were identified exclusively as those with immune-inflammatory function, that is, Neuroinflammation Signaling Pathway, Dendritic Cell Maturation, Th1 Pathway, Calcium-Induced T Lymphocyte Apoptosis, Th2 Pathway, ICOS-ICOSL Signaling of T Helper Cells, and Role of NFAT in Regulation of the Immune Response, in ascending order of p value. Serum IgG (mg/dl) values (median, range) among IgG high and non-high group were as follows: 2270, 1900-4310 vs 1590, 923-1860, $p < 0.01$. Although genes fulfilling FDR corrected $p < 0.05$ between high and non-high IgG group were not demonstrated, the activity of plasma cell gene signature was correlated with levels of serum IgG, but not with those of ALT (r_s = 0.554, $p < 0.05$, vs r_s = -0.271, *not significant*).

Conclusion: AIH transcriptome in the liver may not be distinguished by serum IgG levels. Nevertheless, serum IgG is likely a useful surrogate marker for the plasma cell activation and infiltration in the AIH liver in situ.

Liver transplantation ameliorates chronic fatigue and improves quality of life in patients with primary sclerosing cholangitis

Marcin Krawczyk[1,2], Karolina Wronka[3], Katarzyna Kotarska[4], Marta Przedniczek[3], Maciej K. Janik[3], Raszeja-Wyszomirska Joanna[3], Maciej Wójcicki[3], Piotr Milkiewicz[3,5]. [1]*Department of Medicine II, Saarland University Medical Center, Homburg, Germany;* [2]*Laboratory of Metabolic Liver Diseases, Center for Preclinical Research, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland;* [3]*Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland;* [4]*Department of Physical Culture and Health Promotion, University of Szczecin, Szczecin, Poland;* [5]*Translational Medicine Group, Pomeranian Medical University, Szczecin, Poland*
Email: marcin.krawczyk@uks.eu

Background and aims: A significant proportion of patients with primary sclerosing cholangitis (PSC) requires liver transplantation (LTx). Although an improvement of pruritus has been found after LTx in patients with chronic cholestatic liver diseases, the effect of this procedure on chronic fatigue, which is supposed to be central in its origin, remains controversial. PBC-40 questionnaire, initially designed for the assessment of health related quality of life (HRQoL) in primary biliary cirrhosis (PBC), has also been found to be a reliable tool in patients with PSC (Liver Int 2015;35:1764-71). Here we aim to assess the effects of LTx on chronic fatigue and other measures of HRQoL in patients with PSC

Method: Seventy patients (47 males, mean age at LTx 35 ± 11) who underwent LTx for PSC in our centre between 02/2012 and 04/2018 were prospectively enrolled. SF-36 and PBC-40 were applied before LTx and at 2 time points after LTx, the first one (time point P1) at median 11 months after the procedure in all 70 patients and at median 28 months (time point P2) in 19 patients. Matched control group included of 72 adults without chronic or acute liver diseases (46 males, age 36 ± 10 years). Kolmogorov-Smirnov test was used to determine whether data were normally distributed. Quantitative traits were assessed using Mann-Whitney or Student's t-test, as appropriate.

Results: Liver transplantation caused a significant improvement of chronic fatigue assessed with fatigue domain of PBC-40 (30 ± 10 before OLTx vs 20 ± 8 at P1; $p < 0.0001$) with further improvement at P2 (18 ± 8). Significant improvement in all domains of PBC-40, in particular itch ($p < 0.0001$) cognitive ($p < 0.0006$) and social/emotional ($p < 0.0001$), was seen after LTx. In terms of general well-being, evaluated with SF-36, a significant improvement caused by LTx was also observed ($p < 0.001$ for all its domains). HRQoL assessed with SF-36 remained significantly worse in transplanted patients with PSC at both P1 and P2 when compared to healthy controls.

Conclusion: Liver transplantation in patients with PSC leads to significant decrease of chronic fatigue. It also improves other measures of health related quality of life which include itching, cognitive and emotional functions. Quality of life in these patients remains however worse as compared to matched healthy controls.

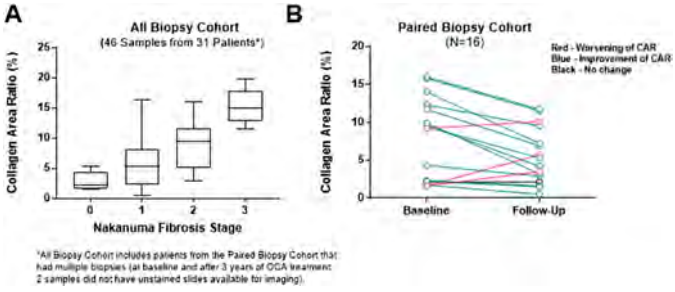
Long-term obeticholic acid treatment is associated with improvements in collagen morphometry in patients with primary biliary cholangitis

Andreas E Kremer[1], Christopher Bowlus[2], Pierre Bedossa[3], Albert Parés[4], Lisa Forman[5], Joost Ph Drenth[6], Stephen Ryder[7], Luigi Maria Terracciano[8], Yuying Jin[9], Alexander Liberman[9], Richard Pencek[9], Leigh Macconell[9], Paul Pockros[10]. [1]*Friedrich-Alexander-University Erlangen-Nürnberg, Department of Medicine I, Erlangen, Germany;* [2]*University of California Davis, Sacramento, United States;* [3]*University Paris Diderot, Department of Pathology, Physiology and Imaging, Paris, France;* [4] *University of Barcelona, CIBERehd, IDIBAPS, Hospital Clinic, Barcelona, Spain;* [5]*University of Colorado, Division of Gastroenterology-Hepatology, Aurora, United States;* [6]*Radboud University Medical Center, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands;* [7]*NIHR Nottingham Biomedical Research Centre at Nottingham University Hospitals NHS Trust, Queen's Medical Centre, Nottingham, United Kingdom;* [8] *University of Basel, Department of Pathology, Basel, Switzerland;* [9]*Intercept Pharmaceuticals, Inc., San Diego, United States;* [10]*Scripps Clinic and Scripps Translational Science Institute, Division of Gastroenterology/ Hepatology, La Jolla, United States*
Email: andreas.kremer@uk-erlangen.de

Background and aims: Obeticholic acid (OCA) is a potent, selective FXR agonist approved for the treatment of PBC based upon biochemical improvements predicted to improve transplant-free survival. An optional liver biopsy substudy was conducted in a subset of patients from the Phase 3 POISE trial to determine the impact of OCA treatment on progression of liver fibrosis. Results, using standard histologic grading, showed that the majority of patients treated with OCA either improved or had no worsening of fibrosis over 3 years. New technologies, such as second harmonic generation (SHG) microscopy, allow quantitative measurement of the molecular features of fibrosis using high-resolution stain-free imaging of collagen 1 and 3. This post-hoc analysis assessed the impact of OCA treatment on collagen morphometry using biopsy samples from the POISE substudy.

Method: Patients included in this analysis had an inadequate response or intolerance of UDCA, biopsies ≤ 1 year from double-blind baseline and after ~3 years of OCA treatment. Unstained slides were used to quantify collagen using SHG and 2-photon microscopy. Stained biopsy samples were masked, randomized and scored by consensus of 2 blinded pathologists utilizing Nakanuma Staging for histologic evaluation. Two cohorts were identified: an All Biopsy Cohort, defined as all adequate biopsy samples (determined by the pathologists) with collagen data, and a Paired Biopsy Cohort, defined as patients with both a baseline and follow-up biopsy and collagen data.

Results: The All Biopsy Cohort was composed of 31 patients (46 samples total, mean age 56 years, 90% female, 97% received UDCA), and the Paired Biopsy Cohort was composed of 16 patients (59 years, 94% female, 100% received UDCA). In the All Biopsy Cohort, trends were observed between increasing median Collagen Area Ratio (CAR) (Fig A), Collagen Fiber Density (CFD), and Collagen Reticulation Index (CRI) and increasing Nakanuma Fibrosis Stage. In the Paired Biopsy Cohort, the majority of patients (12/16) had a reduction in CAR after 3 years of OCA treatment (Fig B). The median (Q1, Q3) change and percent change from baseline was CAR −2.1 (−4.6, −0.3) and −31.1% (−46.1,−11.4), CFD −0.8 (−2.5, 0.0) and −35.3% (−57.0, −2.5), and CRI −0.1 (−0.3, 0.0) and −7.4% (−20.8, −1.1).



Conclusion: In this analysis, 3 years of OCA treatment resulted in a reduction in CAR, CFD and CRI, supporting the overall trend of improvement or no progression in the histologic components of PBC

FRI-034

Clinical phenotype of significantly elevated serum IgG4: Single center experience

Hadi Kuriry[1], Marwa Ismail[1], Orlando Cerocchi[1], Aliya Gulamhusein[1].
[1]*Toronto General Hospital-, UHN, Toronto Centre for Liver Disease, Toronto, Canada*
Email: h.kuriry@live.com

Background and aims: Elevated serum IgG4 has been associated with multiple diseases. For that, elevated serum IgG4 level is an insufficient single diagnostic tool. The appropriate cutoff for serum IgG4 not well establishes. Although elevated IgG4 level more than 2xULN has better specificity around 90%. Our aim of this study to determine the clinical, imaging, and serological features of patients with elevated IgG4 more than 2xULN.

Method: We conducted a retrospective study using computerized search to identify all patients with elevated serum IgG4 level at the Toronto Centre for Liver Disease during the 5-year period from January 1, 2013 to February 28, 2018. Subjects with elevated serum IgG4 equal or more than two times the upper limit of normal (≥ 2xULN) were included. Demographic data, clinical features, imaging study and laboratory test results at presentation were retrieved.

Results: A total of 89 patients with elevated serum IgG4 were reviewed. 38 cases (42.7%) had elevated serum IgG4 levels ≥ 2 × the upper limit of normal were included in this cohort. In all, 68% of patients were males with median age 56 at time of presentation. Fifty percent of patients were non-Caucasian and two-thirds of them were Asians. Prevalence of IBD was 24% (n = 9) with similar prevalence of other autoimmune disease, including RA, Sjogren's disease, vitiligo, hypothyroidism. Prior history of malignancy observed in 4 cases colon cancer, laryngeal cancer and MALT lymphoma.

Majority of cases were diagnosed with IgG4 related disease 42% (n = 16). PSC was accounted for 26% of cases (n = 10), followed by autoimmune pancreatitis 18.4% (n = 7). Other etiologies were also observed in this cohort, such as AIH, AIH overlap with PSC, PBC, PVT with liver cirrhosis and secondary sclerosing cholangitis.

Although PSC patients tend to be younger than the others, 9 out of 10 PSC cases developed advanced fibrosis or cirrhosis. Three cases required liver transplantation for PSC cirrhosis. Surprisingly, two out 3 them were found to have incidental HCC and cholangiocarcinoma on explanted liver. Further comparison between AIP, IgG4RD and PSC patients is in table 1.

Conclusion: Serum IgG4 measurement has insufficient accuracy and established cut-off values are lacking. PSC patients with elevated serum IgG4 could present with more aggressive disease. IgG4/IgG1 ratio tend to differentiate between PSC and IgG4 RD although cut off is not well defined.

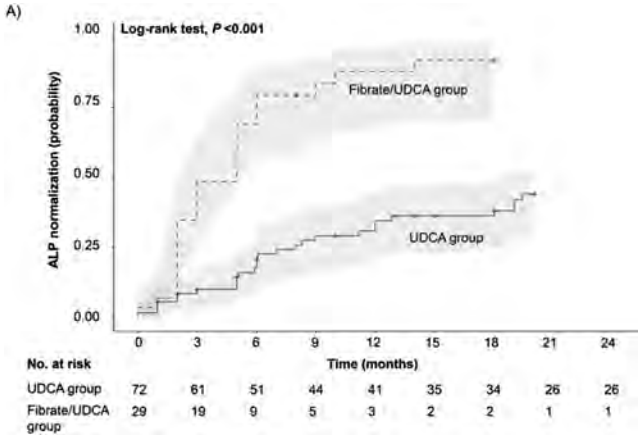
FRI-035

Clinical outcomes associated with additional fibrate treatment in UDCA-refractory PBC patients: A multicenter study

Jeonghoon Lee[1], Sungwon Chung[1], Cheol-Hyung Lee[1], Minseok Albert Kim[1], Galam Leem[2], Sun Woong Kim[1], Young Chang[1], Hyo Young Lee[1], Jun Sik Yoon[1], Jun Yong Park[2], Yun Bin Lee[1], Eun Ju Cho[1], Su Jong Yu[1], Yoon Jun Kim[1], Jung-Hwan Yoon[1]. [1]*Seoul National University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Yonsei University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of South*
Email: pindra@empal.com

Background and aims: There is no proven treatment for ursodeoxycholic acid (UDCA)-refractory primary biliary cholangitis (PBC) except obeticholic acid. Although fibrates have been reported to improve biochemical parameters, the long-term effects remained unclear. This study evaluated the effect of fibrate on clinical outcomes of UDCA-refractory PBC.

Method: Patients whose alkaline phosphatase (ALP) was not normalized with at least 13 mg/kg of UDCA treatment for > 1 year were included from two tertiary referral centers. The primary outcome was ALP normalization. Secondary outcomes included the development of liver cirrhosis and hepatic deterioration. Immortal time bias was adjusted using the Mantel-Byar method.



Results: A total of 101 UDCA-refractory PBC patients were included: 72 patients received UDCA alone (the UDCA group) and 29 patients received UDCA plus additional fibrate treatment of 160 mg/day fenofibrate (n = 26) or 400 mg/day bezafibrate (n = 3) (the fibrate/UDCA group). The baseline differences between two groups were not significant except for UDCA dose [median 900 mg/day (interquartile range (IQR) 600-1400 mg) in the UDCA group and 1200 mg/day (IQR 800-1200 mg) in the fibrate/UDCA group, P < 0.001], serum aspartate transaminase levels [median 39 IU/L (IQR 31-62 IU/L) in the UDCA group and 32 IU/L (26-44 IU/L) in the fibrate/UDCA group, P = 0.02] and albumin levels [median 4.2 g/dL (IQR 3.8-4.3) in the UDCA group and median 4.3 g/dL (IQR 4.1-4.4) in the fibrate/UDCA group,

Figure: Table 1: (abstract: FRI-034)

		AIP (n=7)	IgG4RD (n=16)	PSC (n=10)	p-Values
Age, median (range)		71 (52-78)	64 (38-85)	40 (23-62)	**<0.001**
% male		4 (57.1%)	14 (87.5%)	7 (70.0%)	0.259
Ethnicity, n (%)	Caucasian	2 (28.6%)	10 (62.5%)	6 (60.0%)	0.609
	Non-Caucasian	5 (71.4%)	6 (37.5%)	4 (40.0%)	
IgG4 (mean+SD)		5.8+4.5	5.5+3.4	2.9+1.7	0.117
IgG4/IgG1 ratio (mean+SD)		0.73+0.60	0.89+0.26	0.26+0.12	**0.037**
ALT (mean+SD)		29+20	51+60	76+60	0.257
ALP (mean+SD)		92+65	154+143	326+192	**0.009**
Bilirubin (mean+SD)		9+3	44+79	12+6	0.292

P = 0.002]. During the follow-up period, the probability of ALP normalization was significantly higher in the fibrate/UDCA group [hazard ratio (HR) = 4.78, 95% confidence interval (CI) = 2.75-8.27, P < 0.001]. Among 59 non-cirrhotic patients (44 in the UDCA group and 15 in the fibrate/UDCA group), 19 patients (43.2%) in the UDCA group and none in the fibrate/UDCA group developed cirrhosis (HR = 0.12, 95% CI = 0.001-0.90, P = 0.04). Hepatic deterioration (Child-Pugh score increase of ≥ 2 points or signs of decompensated liver cirrhosis) occurred in 17 patients (23.6%) of the UDCA group and none in the fibrate/UDCA group which the difference was significant (HR = 0.12, 95% CI = 0.001-0.90, P = 0.04). Neither the risk of hepatocellular carcinoma development (p = 0.31) nor that of transplantation-free survival differ significantly (p = 0.26).

Conclusion: In patients with UDCA-refractory PBC, additional fibrate treatment is associated with a higher probability of ALP normalization and a lower risk of cirrhosis development and hepatic deterioration.

FRI-036

Perception by patients with autoimmune and chronic cholestatic disease of their own health condition: Results of a survey led by the French patient association (ALBI)

Sara Lemoinne[1], Philippe Durand[2], Daniel Leburgue[2], Angela Leburgue[2], Gaouar Farid[1], Christophe Corpechot[1], Olivier Chazouillères[1]. [1]*Assistance Publique-Hôpitaux de Paris (AP-HP), Reference Centre for Inflammatory Biliary Diseases and Autoimmune Hepatitis (CRMR, MIVB-H), Department of Hepatology, Saint-Antoine Hospital, Paris, France;* [2]*ALBI France (Association pour la Lutte contre les Maladies Inflammatoires du Foie et des Voies Biliaires), Paris, France*
Email: sara_lemoinne@yahoo.fr

Background and aims: Primary Biliary Cholangitis (PBC), Primary Sclerosing Cholangitis (PSC), Autoimmune Hepatitis (AIH) and Low-Phospholipid Associated Cholelithiasis (LPAC) syndrome are rare chronic liver diseases affecting people of all ages with various outcomes. The purpose of this study was to assess the burden of symptoms for patients and the impact on their daily life.

Method: A survey, with 57 questions, was designed by the French Association for Patients with Inflammatory Biliary Diseases (ALBI) in collaboration with the Medical Reference Center in Saint-Antoine Hospital. Out-patients were invited to respond by Emails and advertising on ALBI website. Results are self-reports by patients.

Results: 585 patients completed the survey: 304 PBC, 149 PSC, 63 AIH, 51 LPAC syndrome and 18 without established diagnosis. Most patients were from France, 10% living in other countries (French-speaking countries such as Belgium, Switzerland or Canada). The global health condition was judged good, fair and bad in 64%, 28% and 8% by PBC patients, 57%, 31% and 12% by PSC patients, 60%, 31% and 10% by AIH patients and 39%, 47% and 14% by LPAC syndrome patients. When asked to compare their global heath condition to people their age, patients reported it was altered in 40%, 62%, 50% and 65% for PBC, PSC, AIH and LPAC syndrome, respectively. The proportion of patients feeling that their daily life activities were quite or very disrupted because of their liver disease was 51%, 63%, 70% and 72% in PBC, PSC, AIH and LPAC syndrome patients, respectively. The 3 most frequent reported symptoms were, in decreasing order of frequency: fatigue, joint pain, and disturbed intestinal transit by PBC patients; fatigue, disturbed intestinal transit and abdominal pain by PSC, AIH and LPAC syndrome patients. Pruritus was only 8th rank after insomnia and abdominal bloating.

Conclusion: The impact of autoimmune and chronic cholestatic liver diseases on the patient's life varies a lot depending on individuals. A majority perceive themselves in reasonably good conditions, noting however that their daily life has been altered. A minority consider that their health has deteriorated significantly. Global perception is more positive for PBC patients, whereas patients with LPAC syndrome have mostly negative perceptions. This study demonstrates that the perception of the liver disease varies significantly between patients and encourages a better listening of physicians to their patient feeling.

FRI-037

Change in lipids: Characteristics and response to obeticholic acid in TARGET-PBC, a diverse, large United States real-world cohort

Cynthia Levy[1], Marlyn J. Mayo[2], Elizabeth Carey[3], Ester Little[4], W. Ray Kim[5], Karen Deane[6], Richard Zink[6], Robert Sandefur[6], Christopher Bowlus[7]. [1]*University of Miami, Schiff Center for Liver Diseases, Division of Gastroenterology and Hepatology, Miami, United States;* [2]*University of Texas Southwestern, Division of Gastroenterology and Hepatology, Dallas, United States;* [3]*Mayo Clinic, Division of Gastroenterology and Hepatology, Phoenix, United States;* [4]*Advanced Liver Disease and Transplant Institute, Banner-, University of Arizona, Division of Gastroenterology and Hepatology, Phoenix, United States;* [5]*Stanford University Medical Center, Division of Gastroenterology and Hepatology, Stanford, United States;* [6]*TARGET PharmaSolutions, Chapel Hill, United States;* [7]*University of California Davis, Divison of Gastroenterology and Hepatology, Sacramento, United States*
Email: cLevy@med.miami.edu

Background and aims: Hyperlipidemia is often associated with primary biliary cholangitis (PBC) but does not appear to increase cardiovascular risk. Use of obeticholic acid (OCA) in PBC has been associated with a reduction in total cholesterol (TC) primarily related to lowering high-density lipoproteins (HDL). A mild increase in low-density lipoproteins (LDL) is also observed. The aim of this study was to determine the impact of OCA on lipid profile when treating patients with PBC in a real-world setting.

Method: TARGET-PBC is a longitudinal observational study of PBC patients at 35 U.S. sites. Data is captured from redacted medical records within a database utilizing centralized data abstraction. All clinical diagnoses and treatment decisions are at the discretion of the treating provider.

Results: Out of 516 enrolled patients, 82 participants were treated with OCA for at least 3 months and constituted our study population. The median duration of OCA treatment was 15.5 months, median age at diagnosis 48; 91.5% were female, 85.4% White, 26.8% Hispanic, 84% AMA positive, 14.6% with autoimmune hepatitis overlap syndrome. Twenty-eight participants (34.1%) were taking statins. Seventeen patients (20.7%) discontinued use of OCA primarily due to pruritus (n = 8, 47.1%). Forty-two patients (51.2%) were cirrhotic, of whom 14 (33.3%) had evidence of prior decompensation. The following median percent changes were observed in all OCA patients: alkaline phosphatase −25.7% (n = 70, p < 0.0001), −8.59% TC (n = 33, p = 0.0098), −13.1% HDL (n = 32, p = 0.0057), −3.08% LDL (n = 31, p = ns) and −9.59% in triglycerides (n = 32, p = ns). The median percent changes for statin and non-statin users on OCA were as follows: TC (−4.93% (n = 14) vs. −10.0% (n = 19), CI −8 (−24.5, 8.29)), HDL (−8.89% (n = 15) vs. −15.0% (n = 17), CI.37 (−13.6, 14.34)), LDL (1.56% (n = 13) vs. −9.92% (n = 18), CI −19 (−46.5, 9.06)) and triglycerides (−9.81% (n = 15) vs. −9.38% (n = 17), CI.47 (−21.9, 22.80)). Median LDL change after OCA treatment was greater among cirrhotics (−12.4%) compared to non-cirrhotic patients (0%, p = 0.046).

Conclusion: In addition to a clear improvement in liver chemistries, use of OCA was associated with a significant reduction in HDL and TC. OCA was not associated with an increase in LDL among non-cirrhotic PBC patients, but rather a decrease in LDL among cirrhotics, possibly related to natural history of disease. Additional studies are required to understand the impact of OCA on the lipid profile of patients.

FRI-038

Good performance of the biochemical response criteria after three months of ursodeoxycholic acid treatment in patients with primary biliary cholangitis

Laura Patricia Llovet[1], Anna Reig[1], Oswaldo Ortiz[1], Maria Carlota Londoño[1], Albert Parés[1]. [1]*Hospital Clinic Barcelona. IDIBAPS. CIBERehd. University of Barcelona, Liver Unit, Barcelona, Spain*
Email: llovet@clinic.cat

Background and aims: Response to ursodeoxycholic acid (UDCA) therapy in patients with primary biliary cholangitis (PBC) is assessed by different validated biochemical criteria, which identify those patients that could benefit from further therapies. Nevertheless, these criteria have been evaluated at 12 and 24 months of treatment and, therefore this may delay the start the use of new agents in patients with suboptimal response. The aim of the current study has been to evaluate the performance of the known criteria three months after starting UDCA therapy.
Method: The study was carried out in cohort of PBC patients from a single centre, who started UDCA therapy with 13-16 mg/kg/d. The clinical features and liver biochemistries were assessed before and after 3, 6, 12 and 24 months of UDCA therapy. Ludwig's histologic stage was documented in 87 patients. The biochemical criteria (Barcelona, Paris I, Toronto and Paris II) were calculated at 3, 6, 12 and 24 months. The performance of these criteria was evaluated at 3 months as compared with those validated at 12 months (Toronto at 24 months).
Results: 95 patients (age 53 (44-65 years, 90.4% female) were included with alkaline phosphatase (AP) of 1.45 (1.1-2.9) times upper normal levels (UNL). After a year of treatment, non-response to UDCA was: Paris I 25.5%, Barcelona and Paris II 42.1%, and Toronto 21.4%. Lack of response was also evaluated with the aforementioned criteria at 3 months: Barcelona 52%, Paris I 28.8%, Paris II 48.6% and Toronto 31.8%. The sensitivity (S), specificity (Sp) and area under de curve (AUC) at 3 months were: Barcelona 72.7% S, 82.5% Sp and AUC 0.76; Paris I 88.6%S, 83.3% Sp and AUC 0.86; Toronto 100% S, 64.7% Sp and AUC 0.84; Paris II 80% S, 87.5% Sp and AUC 0.84. When patients with Ap < 1.5 ULN were excluded, the specificity of all criteria at 3-months increased over 80%, with a decrease in sensitivity below 70%, except Paris I with S 77.5%. Patients with no response at 3 months that became responders at 12 months had early disease (histologic stage I 100% vs 50%, p = 0.01), lower median bilirubin (0.75 [0.6-0.9] vs 1.2 [0.8-1.3]mg/dL, p = 0.04), and bilirubin < 1mg/dL (87.5% vs 40%, p = 0.02). No other clinical, histological and biochemical differences were observed.
Conclusion: The good performance of the biochemical response criteria to UDCA after 3-months suggests that these criteria are able to identify early non-responders and therefore, patients requiring additional therapies.

FRI-039

Autoimmune hepatitis-related cirrhosis: The importance of treatment response and the utility of Baveno VI criteria

Laura Patricia Llovet[1], Oswaldo Ortiz[1], Montserrat García-Retortillo[2], Raquel Vinuesa[3], Judith Gómez- Camarero[3], María García Eliz[4], Diana Horta[5], Conrado Fernández- Rodríguez[6], Ana Gomez[7], Carmen Álvarez-Navascués[7], Albert Parés[1], Maria Carlota Londoño[1]. [1]*Hospital Clinic Barcelona. IDIBAPS. CIBERehd. University of Barcelona, Liver Unit, Barcelona, Spain;* [2]*Hospital del Mar, Universitat Autonoma de Barcelona, Medicine Department, IMIM, Liver Section, Gastroenterology Department, Barcelona, Spain;* [3]*Hospital Universitario de Burgos, Gastroenterology and Hepatology Department, Burgos, Spain;* [4]*Hospital Universitario La Fe, University of Valencia, CIBERehd, Liver Transplantation and Hepatology Unit, Valencia, Spain;* [5]*Hospital Universitario Mútua de Terrassa, Department of Gastroenterology, Terrassa, Spain;* [6]*Hospital Universitario Fundación Alcorcón, Gastroenterology and Hepatology Department, Madrid, Spain;* [7]*Hospital Universitario Central de Asturias, Gastroenterology and Hepatology Department, Oviedo, Spain*
Email: llovet@clinic.cat

Background and aims: The information regarding diagnosis and prognosis of autoimmune hepatitis-related cirrhosis (AIH-C) is scarce. We aimed: 1) to describe patients with AIH-C and their prognosis, 2) to determine the utility of elastography (FS) in the diagnosis of AIH-C, and 3) to evaluate the performance of Baveno VI and expanded Baveno VI criteria in predicting the absence of varices needing treatment.
Method: 112 patients with AIH-C (defined by radiological and histological criteria) were included in a retrospective, multicentre, cohort study. Clinical, histological and laboratory data were analysed. Liver stiffness was evaluated using FS. Baveno VI (platelets > 150, 000 and elastography < 20kPa) and expanded Baveno VI (platelets > 110, 000 and elastography < 25kPa) criteria were evaluated in 63 patients (95 endoscopies). Portal hypertension (PHT) was defined by radiological and laboratory data, and presence of varices.
Results: Median age was 56 years-old (42-65). Most of the patients had advanced fibrosis at diagnosis (F3-F4, n = 81, 73%). Fourteen patients (15%) were non-responders to standard treatment, and 7 required second line therapy. Median FS was 12, 2kPa (IQR 7.4-17.3), 59% and 51% of patients had a FS below the usual cut-offs for the diagnosis of cirrhosis (14kPa and 12.5kPa, respectively). After a median of 3.9 years, 52 (46%) patients presented PHT, more frequently in non-responders (71.4% vs 43%, p = 0.05). Sixteen patients (16%) had varices needing treatment. Negative predictive value of Baveno VI and expanded Baveno VI criteria was 100%, suggesting that 35% and 52% of the endoscopies could have been saved, respectively. Within a median time of 6.9 years (IQR 3.8-14.5) of follow-up, 24 patients (21%) presented decompensation (more frequently in non-responders; 42% vs 13%, p = 0.01), 1 (1%) had hepatocellular carcinoma, 3 (3%) underwent liver transplantation and 5 (5%) died. Cumulative 20-year survival was significantly higher in responders to treatment (86% vs 54% in non-responders, p = 0.04).
Conclusion: Patients with AIH-C are diagnosed in an advanced stage of the disease. Lack of response to standard therapy has a negative impact on disease course and patient survival. Elastography does not seem to correlate with severe fibrosis stage in AIH. Baveno VI criteria are useful and could save an important number of endoscopies.

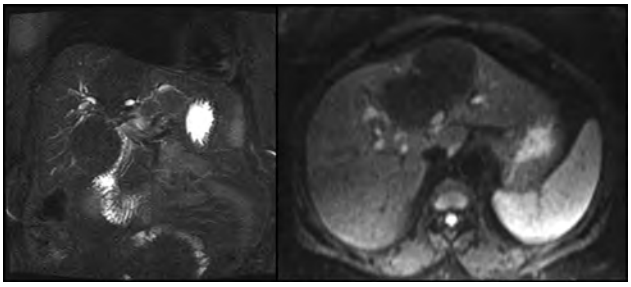
FRI-040

Imaging and clinical correlations of macro regenerative nodules in primary sclerosing cholangitis

Beatrice Madrazo[1], Leonardo Pisani[2], Andres Morgado[3], Priscila Santiago[4], Ingrid Schwartz[4], Emmanuel Thomas[2], Cynthia Levy[2]. [1]*University of Miami Miller School of Medicine, Radiology Department, Miami, United States;* [2]*University of Miami Miller School of Medicine, Miami, United States;* [3]*Jackson Memorial Hospital/University of Miami, Radiology Department, Miami, United States;* [4]*Jackson Memorial Hospital/University of Miami, Miami, United States*
Email: lp.leonardopisani@gmail.com

Background and aims: Primary Sclerosing Cholangitis (PSC) is a progressive cholestatic disorder of unclear pathogenesis. An association of macro regenerative nodules (MRN) and PSC has been vaguely described in the literature. In this study we further assess their frequency, characteristics on MRI and relationship with clinical features.
Method: This is a retrospective study including patients with PSC and at least one MRI done between 2000 and 2018. Two radiologists reviewed all MRI imaging. Patients status post partial hepatectomy or liver transplantation were excluded. We collected demographic, clinical and laboratory information within 3 months of the MRI and outcomes data. Chi-square and Wilcoxon sign rank tests were used to evaluate associations between these characteristics and MRNs.

Results: A total of 97 patients were included. Fifty-two (54%) were male, 45 (46%) female, 71 (74%) Caucasian, 78 (80%) with large duct PSC, and 47 (49%) with IBD. Median disease duration at the time of first MRI was 4.9 years (range 0.03-49.1). MRNs were present in 63 (70%).
MRNs were hypertrophic hepatic nodules with healthy bile ducts, associated with architectural distortion of surrounding areas and of the biliary system. They are distinguishable from other entities by lacking copper, zync, fat and iron within nodules. When available, gadoxetate disodium contrast-enhanced studies revealed functioning hepatocytes within MRN. Segments 4b and 3 were most frequently involved. For 61/97 patients a subsequent MRI was available; 38 (62.2%) had MRNs on both studies; 5 additional patients developed MRNs on follow-up study.
Presence of MRN was not associated with age at diagnosis, gender, race, cirrhosis, platelet count, bilirubin or INR. MRNs were associated with spleen size > 12 cm (81.2% vs. 58%, p = 0.024), use of UDCA (75% vs. 50%, p = 0.027) and with alkaline phosphatase above the upper limit of normal (65.7% vs 45%. P = 0.08). There was no association between MRNs and clinical outcomes including gastrointestinal bleeding, ascites, encephalopathy, malignancies, liver transplantation or death.



Conclusion: MRN's exhibit specific characteristics on MRI imaging of PSC patients and should not be confused with cirrhotic nodules or malignancy. In our 3 cases evaluated with hepatobiliary imaging, functioning hepatocytes were present in MRN's. Their etiology and significance remain unclear; further studies are required to elucidate their significance.

FRI-041

Pharmacokinetics, safety, and tolerability of seladelpar in subjects with hepatic impairment

Lily Mao[1], Robert Martin[1], Alexandra (Sasha) SteinbergMD, PhD[1], Patricia Rohane[1], Jaidyn Nguyen[1], Mary Standen[1], Pol Boudes[1].
[1]CymaBay Therapeutics, Newark, United States
Email: pboudes@cymabay.com

Background and aims: Primary Biliary Cholangitis (PBC) is a rare autoimmune disease manifested by chronic cholestasis. Patients can progress to cirrhosis, particularly if they do not respond adequately to UDCA treatment. Seladelpar, a potent and selective peroxisome proliferator-activated receptor-delta (PPARδ) agonist, has demonstrated potent anti-cholestatic and anti-inflammatory activity in patients with PBC. Seladelpar decreases the synthesis of bile acids in hepatocytes and also reaches cholangiocytes as it is cleared through the biliary system. We evaluated the pharmacokinetics (PK) and safety of a single 10 mg dose of seladelpar in subjects with varying degrees of hepatic impairment (HI).
Method: Subjects with mild, moderate, or severe HI (defined per Child-Pugh score) and healthy control subjects matched to the moderate HI subjects were enrolled in an open-label, non-randomized, parallel-group, single-dose PK study. Blood samples were collected to assess the PK of seladelpar. Safety and tolerability were assessed throughout the study.
Results: Thirty-two subjects completed the study and were analyzed for PK: 8 subjects with mild, moderate, and severe HI, and 8 healthy controls. Mild HI did not significantly impact seladelpar PK comparing to controls: seladelpar C_{max} increased by 20%, while seladelpar AUC increased by 10%, while $T_{1/2}$ did not change. However, moderate and severe HI impacted seladelpar PK comparing to controls: seladelpar C_{max} increased to 5-fold, AUC increased to 2-fold, while $T_{1/2}$ did not change. Single doses of 10 mg seladelpar were well-tolerated by subjects with varying degrees of hepatic impairment. All adverse events were mild in severity, except for 1 severe SAE of esophageal varices hemorrhage in a subject with a history of intermittent bleeding from esophageal varices. This SAE was considered unlikely related to study treatment. No clinically important changes in vital signs, physical examination findings, or laboratory values were observed.
Conclusion: Mild HI did not significantly change the PK of seladelpar and dose adjustments in this population do not appear necessary. However, given the magnitude of the increases in seladelpar exposure in the moderate and severe HI subjects, dose adjustments in these populations might be necessary. Single-dose administration of seladelpar appeared to be well tolerated and safe in subjects with varying degrees of hepatic impairment.

FRI-042

Prevalence and male/female ratio of autoimmune liver diseases are increasing over time in Japan: Hospital-based epidemiological study

Kosuke Matsumoto[1], Atsushi Tanaka[1], Mitsuru Mori[2], Hiromasa Ohira[3], Susumu Tazuma[4], Hajime Takikawa[1]. *[1]Teikyo University School of Medicine, Department of Medicine, Tokyo, Japan; [2]Hokkaido Chitose College of Rehabilitation, Chitose, Japan; [3]Fukushima Medical University, Gastroenterology, Fukushima, Japan; [4]Hiroshima University, Graduate School of Medical Science, Department of General Medicine, Hiroshima, Japan*
Email: a-tanaka@med.teikyo-u.ac.jp

Background and aims: Prevalence of autoimmune liver diseases (AILD, including autoimmune hepatitis; AIH, primary biliary cholangitis; PBC, primary sclerosing cholangitis; PSC) is reported to be increasing worldwide. In addition, change of male-female ratio is another notable trend in AIH and PBC. We conducted epidemiological studies of AIH and PBC in 2004 and of PSC in 2007. In 2018, we again performed a nation-wide, hospital-based epidemiological study to clarify prevalence of AIH, PBC and PSC, to clarify time trend in epidemiology of AILD in Japan.
Method: The hospitals used in the study were selected randomly from a list of all hospitals in Japan. The selection rate was determined according to a stratification based on the number of beds in the hospital. Thus, hospitals with a high number of beds had a greater probability of being selected. The selection rate was 100% for hospitals with 500 beds or more or university hospitals, whereas only 5% of hospitals with fewer than 100 beds were selected at random. In addition, all specialized hospitals that had previously reported patients with AILD were selected for the study. After selection, we sent questionnaires describing the diagnostic criteria for AILD and asked to describe the number and gender of patients with AILD. The epidemiological study was performed in an identical method for AIH/PBC in 2004 and for PSC in 2007, and we compared the results.
Results: We selected 1, 793 hospitals or departments of paediatrics, internal medicine, gastroenterology, hepatology and surgery were selected from all over Japan. Of them, 1, 078 (60.1%) responded to the questionnaires. The number of reported patients with AIH, PBC and PSC were 7, 679, 10, 847, and 906, respectively, and the statistically-estimated number of patients were 30, 325 (95%CI, 29, 586-31, 063) for AIH, 37, 045 (36, 172-37, 917) for PBC, and 2, 306 (2, 247-2, 365) for PSC. The prevalence of AILD was calculated as 23.9 for AIH (8.7 in 2004), 33.8 for PBC (11.6 in 2004), and 1.80 for PSC (0.95 in 2007) per

100, 000 Japanese population. Furthermore, female/male ratio of AILD in the current study was 3.89 for AIH (6.94 in 2004), 4.26 for PBC (7.06 in 2004) and 0.88 for PSC (1.36 in 2007).
Conclusion: The current and previous epidemiological studies demonstrate that increasing trend of prevalence as well as male/female ratio of all AILD, AIH, PBC and PSC in Japan. These results suggest alteration of environmental triggering factors and provide definite needs for case-control studies.

FRI-043
Primary biliary cholangitis-Autoimmune hepatitis overlap syndrome: Characteristics and response to obeticholic acid in TARGET-PBC, a diverse, large United States real-world cohort
Marlyn J. Mayo[1], Christopher Bowlus[2], Elizabeth Carey[3], Ester Little[4], Karen Deane[5], Richard Zink[5], Robert Sandefur[5], W. Ray Kim[6], Cynthia Levy[7]. [1]*University of Texas Southwestern, Division of Gastroenterology and Hepatology, Dallas, United States;* [2]*University of California Davis, Division of Gastroenterology and Hepatology, Sacramento, United States;* [3]*Mayo Clinic, Divison of Gastroenterology and Hepatology, Phoenix, United States;* [4]*Advanced Liver Disease and Transplant Institute, Banner-, University of Arizona, Phoenix, United States;* [5]*TARGET PharmaSolutions, Chapel Hill, United States;* [6]*Stanford University Medical Center, Division of Gastroenterology and Hepatology, Stan\, United States;* [7]*University of Miami, Schiff Center for Liver Diseases, Division of Gastroenterology and Hepatology, Miami, United States*
Email: marlyn.mayo@utsouthwestern.edu

Background and aims: A subset of PBC patients have an overlap syndrome with AIH. Patients with overlap may have poorer response to ursodeoxycholic acid (UDCA) and higher rates of progression to cirrhosis. The aim of this study was to compare clinical characteristics and outcomes in PBC patients with and without overlap.
Method: TARGET-PBC is an ongoing observational study of PBC patients at 35 U.S. sites. Data is captured from redacted medical records. All clinical diagnoses and treatment decisions are at the treating provider's discretion.
Results: Overlap was reported in 71/485 patients (14.6%). Median age at diagnosis was 52 years for both groups; gender (85.9% vs. 90.1% female), race (74.6% vs. 86.4% white), ethnicity (21.1% vs. 17.1% Hispanic) and frequency of ≥ 1 autoimmune conditions (55% vs. 59%) were similar between groups. The autoantibodies in overlap vs. PBC patients at study enrollment were: antimitochondrial (73.8% vs. 87.5%, p = 0.004), antinuclear (64.4% vs. 47%, p = 0.035), and smooth muscle (51.4% vs. 21%, p = 0.0002). Median IgG levels at study entry did not differ: overlap 1393 vs. PBC 1256, possibly because most overlap patients were on immunosuppressant treatment. Liver biopsy reports were available for 74.6% and 61.4% of overlap and PBC patients. Interface hepatitis was more common (81.8% vs. 43.8%, p < 0.0001) and median fibrosis score was greater (3 vs. 2, p = 0.002) in overlap patients. Cirrhosis was present in more overlap patients (47% vs. 36%, p = ns) and evidence of prior decompensation was present in more of the overlap cirrhotic patients (60.6% vs. 48%, p = ns). The frequency of pruritus and fatigue was similar between groups. Fifty-one patients (72%) with overlap were treated at last follow-up with UDCA and 11 (15.5%) with UDCA + OCA. The mean alkaline phosphatase reduction in OCA-treated overlap patients was 20.3% vs. 24.7% in OCA-treated PBC patients. The mean total bilirubin reduction in OCA-treated overlap patients was 14% compared to a 10.4% increase in OCA-treated PBC patients. The most common adverse event and reason for discontinuation with OCA was pruritus for both groups.
Conclusion: AIH overlap was diagnosed in 15% of this cohort. Overlap patients were more likely to have antinuclear and smooth muscle antibodies, interface hepatitis, and advanced fibrosis, but were otherwise similar to PBC patients. OCA was administered to 11 overlap patients with safety and efficacy comparable to PBC patients.

FRI-044
PNPLA3 polymorphism is associated with disease progression in patients with autoimmune hepatitis
Young-Seon Mederacke[1], Martha Kirstein[1], Silke Marhenke[1], Metzler Frauke[1], Michael P. Manns[1], Arndt Vogel[1], Ingmar Mederacke[1]. [1]*Medizinische Hochschule Hannover, Gastroenterology, Hepatology, and Endocrinology, Hannover, Germany*
Email: mederacke.ingmar@mh-hannover.de

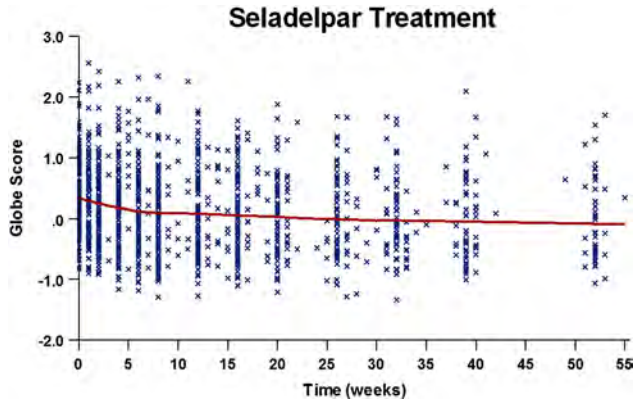
Background and aims: Autoimmune hepatitis (AIH) is an inflammatory liver disease leading to liver fibrosis and cirrhosis. Immunosuppressive treatment can attenuate disease progression. However, patients may develop significant liver fibrosis/cirrhosis over time, some despite biochemical response to immunosuppressive therapy. Single nucleotide polymorphisms (SNPs) such as PNPLA3 (rs738409), TM6SF2 (rs58542926), and MBOAT7 (rs641738) are associated with liver fibrosis progression. Recently, a splice-variant in HSD17B13 (rs72613567:TA) has been shown to be protective in liver disease patients. Aim of this study was to analyze, whether these SNPs play a role in the clinical course of patients with AIH.
Method: We included 242 patients into this study who were treated between 1982 and 2018 for AIH in our department. Genomic DNA was isolated from whole blood. SNPs were determined by PCR analysis using Primers/Probes (Thermofisher). Data at first visit and at the end-of follow-up were analyzed and non-invasive fibrosis scores were calculated. Statistical analysis was performed using SPSS, a p value < 0.05 was considered significant.
Results: Mean age at diagnosis was 39.2 ± 18.2 years with 25.6% being male. The median follow-up was 10 years (range 32 days-34 years), 12.4% of the patients died or required liver transplantation. The allelic frequencies of the four determined SNPs are presented in Table 1. Patients with the homozygous variant HSD17B13 had a later onset of disease (49 vs 36 years, p < 0.01). At the end of follow-up 35.2%, 20% and 53.3% of all patients presented with significant fibrosis as determined by an APRI-score > 0.7, a Fib-4 score > 3.25 and a DeRitis-score > 1, respectively. Homozygous presence of the PNPLA3 variant was associated with significant fibrosis as determined by APRI (80% vs. 32.6%, p < 0.01) and Fib-4 score (50% vs 18.6%, p < 0.05) as well as significantly diminished liver function as determined by CHE, albumin, prothrombin test and higher bilirubin levels (all p < 0.01) and increased liver related mortality or liver transplantation (p < 0.05). Neither TM6SF2, MBOAT7 nor HSD17B13 had an influence on the development of significant fibrosis/cirrhosis or parameters of liver inflammation/synthesis at the end-of follow-up.

	PNPLA3	TM6SF2	MBOAT7	HDS17B13
homozygous ancestral	141	206	87	136
heterozygous variant	89	32	110	79
homozygous variant	12	4	45	25

Conclusions: While AIH patients with detectable HSD17B13 splice variants were diagnosed at an older age, patients with the homozygous PNPLA3 variant had an increased risk of liver disease progression. Determination of PNPLA3 variants in patients with AIH may help to identify patients at risk for a more progressive natural course.

FRI-045
Treatment of patients with primary biliary cholangitis with seladelpar for 52 weeks improves predicted transplant-free survival
Carla Fiorella Murillo Perez[1], Pol Boudes[2], Alexandra (Sasha) SteinbergMD, PhD[2], Monika Varga[2], Yun-Jung Choi[2], Harry Janssen[1], Aliya Gulamhusein[1], Gideon Hirschfield[1], Bettina Hansen[1]. [1]*Toronto General Hospital, University Health Network, Toronto, Canada;* [2]*Cymabay Therapeutics, Newark, United States*
Email: bettina.hansen@utoronto.ca

Background and aims: Treatment options for patients with primary biliary cholangitis (PBC) are still needed. The Globe score is a validated prognostic tool that can be implemented to estimate transplant-free survival. Seladelpar is a peroxisome proliferator-activated receptor δ agonist in development. Our aim was to evaluate the predicted changes in transplant-free survival associated with treatment with seladelpar based on the Globe score.
Methods: Patients with an incomplete response to ursodeoxycholic acid (UDCA) that were enrolled in an ongoing Phase 2 trial of seladelpar and who were treated with either 2mg (n = 11), 5mg (n = 53), or 10mg (n = 55) of seladelpar were included (n = 119). The Globe score was calculated at baseline, 26 weeks, and 52 weeks of treatment to estimate transplant-free survival at 3, 5, 10, and 15 years.
Results: The mean age of patients enrolled was 57.8 (SD 9.0), 94% (n = 112) were female, and the majority were treated with UDCA. Median baseline alkaline phosphatase and bilirubin were 261 u/L and 11.5 µmol/L, while mean baseline albumin and platelets were 40 g/L and 228 × 10^9/L. The Globe score decreased over time in patients treated with seladelpar (**Figure**). For those with an available Globe score, 76 patients received treatment for least 26 weeks, while 48 patients received treatment for 52 weeks. At baseline, 26 weeks, and 52 weeks, the mean Globe score was 0.419, 0.018, and −0.006, respectively. This represents a total decrease of 0.425 from baseline to 52 weeks (p < 0.001). The decline in Globe score at 52 weeks was more pronounced in the 5mg and 10mg treatment groups (−0.443 and −0.434) compared to the 2mg group (−0.271). There were improvements in the predicted transplant-free survival at 3 years (93.6 vs 95.6%), 5 years (89.0% vs 92.3%), 10 years (74.2% vs 81.4%), and 15 years (60.2% vs 70.4%).



Conclusion: Longer-term use of seladelpar improves the estimates of transplant-free survival assessed by the Globe score.

FRI-046

Raising awareness and messaging risk in patients with primary biliary cholangitis: The rapid Global PBC Screening Test

Mayo[10], Kris V. Kowdley[11], Cyriel Ponsioen[12], George Dalekos[13], Douglas Thorburn[14], Andrew L. Mason[15], Nikolaos Gatselis[13], Verhelst Xavier[16], Tony Bruns[17], Harry Janssen[1], Keith D. Lindor[18], Olivier Chazouillères[5], Pietro Invernizzi[2], Bettina Hansen[1,19], Gideon Hirschfield[1]. *[1]Toronto General Hospital, University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]University of Milan-Bicocca, Milan, Italy; [3]University of Birmingham, Birmingham, United Kingdom; [4] Erasmus University Medical Center, Rotterdam, Netherlands; [5]Hôpital Saint-Antoine, Paris, France; [6]Università degli Studi di Milano, Milan, Italy; [7]University of Padua, Padua, Italy; [8]University of Barcelona, Barcelona, Spain; [9]University Hospitals Leuven, KU Leuven, Leuven, Belgium; [10]UT Southwestern Medical Center, Dallas, United States; [11] Swedish Medical Center, Seattle, United States; [12]Academic Medical Center, Amsterdam, Netherlands; [13]University of Thessaly, Larissa, Greece; [14]The Royal Free Hospital, London, United Kingdom; [15]University of Alberta, Edmonton, Canada; [16]Ghent University Hospital, Ghent, Belgium; [17]University of Jena, Jena, Germany; [18]Arizona State University, Phoenix, United States; [19]University of Toronto, Toronto, Canada*
Email: gideon.hirschfield@uhn.ca

Background and aims: Primary biliary cholangitis (PBC) is slowly progressive but impactful, and there is an increasing choice of effective therapies. Too many risk scores however exist, and such tools can appear complex. We sought to simplify risk evaluation with the goal of early triaging patients to specialist clinics.
Method: We utilized patient data from the Global PBC Study group. Ursodeoxycholic acid-treated patients with available bilirubin and alkaline phosphatase (ALP) at baseline (n = 2643) or 1 year (n = 2681) were included. Patients were categorized into colour risk groups (red, amber, and green) based on age at the start of treatment, bilirubin, and alkaline phosphatase. Those with abnormal bilirubin, ALP > 3 × ULN, and under 50 years old were categorized as red (high risk); those with normal bilirubin, ALP ≤ 3 × ULN, and above 50 years old were categorized as green (low risk). Meanwhile, other combinations were denoted as amber (intermediate risk). The transplant-free survival rates associated with each group were estimated with Kaplan-Meier curves and the Globe score.
Results: At baseline, there were 156 (6%) patients identified as red, 1451 (55%) as amber, and 1036 (39%) as green. The 10-year transplant-free survival rates associated with each colour was 60.7%, 77.2%, and 88.2%, respectively (p < 0.001). The corresponding median 10-year survival when estimated by the Globe score was 64.5%, 85.4%, and 84.4%. Similarly, at 1 year there were 72 (3%) red, 1199 (45%) amber, and 1410 (52%) green categorizations. While the 10-year transplant-free survival rates associated with each was 43.0%, 74.9%, and 83.8% (p < 0.001), median 10-year survival estimates by the Globe score were 68.3%, 90.7%, and 86.5%. Of those who were categorized at baseline and 1 year (n = 2122), 471 experienced a change in categorization from baseline to 1 year. The red group had the highest proportion of patients who changed (61% [86/140]) primarily to the amber group (n = 80). Furthermore, 32% (375/1171) of patients in the amber group changed, of which the majority were to a green categorization (n = 354). Lastly, only 3% (22/811) of patients in the green group changed, but none to the red highest-risk group.

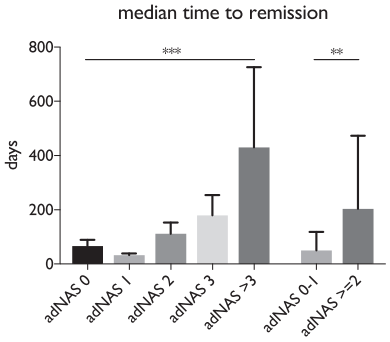
Conclusion: Clinicians can easily, rapidly and effectively stratify risk of future events in PBC using a simple "traffic light" test. Applying this at baseline and at 1-year adequately identifies risk; we propose "Red" patients at baseline, and "Red and Amber" patients after 1 year of UDCA be offered referral to dedicated PBC clinics.

FRI-047

Metabolic syndrome delays biochemical remission in autoimmune hepatitis

Alyn Cratchley[1], Alexander Hinkson[1], Emily Hughes[1], Palak Trivedi[2,3], Judy Wyatt[1], Richard Parker[1,4]. *[1]Leeds Teaching Hospitals NHS Trust, Leeds Liver Unit, Leeds, United Kingdom; [2]University of Birmingham, Centre for Liver Research, Birmingham, United Kingdom; [3]University Hospitals Birmingham NHS Foundation Trust, Liver and Hepatobiliary Unit, Birmingham, United Kingdom; [4]University of Leeds, Leeds Institute for Medical Research at St. James's, Leeds, United Kingdom*
Email: richardparker@nhs.net

Background and aims: In this study, we examine the prevalence of metabolic syndrome in patients with autoimmune hepatitis (AIH), including the impact on histological findings and efficacy of treatment response.
Method: Patients with biopsy-proven AIH were identified from a departmental database at a single centre, using Systemetized Nomenclature of Medicine (SNOMED) codes. Medical records were reviewed for anthromorphic, biochemical and histological data. The presence of fatty liver disease was graded using an adjusted NAS (aNAS) score that included steatosis and ballooning but not lobular inflammation. Response to corticosteroid treatment was examined with regard to the time to normalization of transaminases.
Results: Between the years of 2010 and 2017, 70 patients with biopsy-proven AIH were identified. Median age at diagnosis was 55 years and 80% of patients were women. At presentation, the median ALT value was 268 U/L and median IgG was 22.5 g/L. Two patients were cirrhotic according to Ishak stage. Observing the cohort in entirety, the median BMI was 26 kg/m^2: 23 patients were overweight (BMI 25.0-29.9kg/m^2) and 9 were obese (BMI > 30kg.m^2). Six patients had diabetes mellitus. In addition to AIH, 42 patients had histological evidence of fatty liver on biopsy. Hepatic steatosis was seen in 28 biopsies and ballooning was seen in 26 biopsies. Patients with a greater aNAS score took longer to respond to corticosteroid therapy (log rank p = 0.066) (**figure 1**), with a median time to remission in of 50 (± 12) vs. 203 (± 65) days in patients with a NAS 0-1 vs. NAS ≥ 2, respectively (p = 0.003).



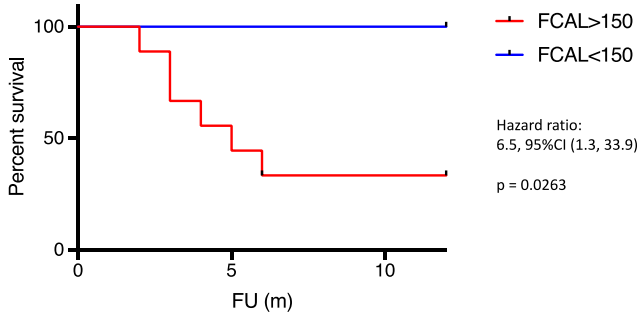
Conclusion: Obesity and diabetes are common amongst patients with AIH. Co-exisiting NAFLD is frequently seen on biopsy in addition to AIH, and may delay response to induction therapy.

FRI-048

Faecal calprotectin in PSC-IBD is a prognostic marker of cholangitis associated complications

Polychronis Pavlidis[1], Yasser El-Sherif[1], Ben Warner[1], Shraddha Gulati[1], Konstantinos Sarras[1], Ellie Alberts[1], Joe Segal[1], Tamir Rashid[1], Phil Harrison[1], John Devlin[1], Gwion Emlyn[1], Hadil Abu Arqoub[1], Patrick Dubois[1], Alberto Sanchez-Fueyo[1], Michael Heneghan[1], Deepak Joshi[1], Nick Powell[1], Bu Hayee[1]. *[1]King's Health Partners, London, United Kingdom*
Email: polychronis.pavlidis@kcl.ac.uk

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic inflammatory condition of the bile ducts leading to fibrosis and end stage liver disease. A lack of robust non-invasive biomarkers has been hindering disease monitoring and development of optimal therapies. We have previously noted that the high levels of faecal calprotectin (fcal) seen in PSC-IBD patients belie the mild or quiescent intestinal inflammation. An unsupervised proteomics study identified biliary calprotectin as a potential biomarker. Here, we test the hypothesis that fcal is a marker of biliary injury in PSC.
Method: We analysed paired endoscopic activity data (UCEIS) and fcal results of patients with PSC-IBD (n = 20) or UC (n = 20) who underwent colitis surveillance in the context of a colitis surveillance pilot study. Relevant clinical data was recorded prospectively. Recruiting consecutive patients attending for ERCP (n = 8) allowed for the concomitant testing of biliary and faecal calprotectin.
Results: As expected, fcal strongly correlated with severity of mucosal injury (UCEIS) in UC [r = 0.82, 95%CI (0.58, 0.92), p < 0.0001]. However, the correlation was weaker in PSC-IBD [r = 0.59, 95%CI (0.19, 0.82), p = 0.006]. Moreover, in patients with PSC-IBD and quiescent colitis (UCEIS: 0-1) fcal concentration was significantly higher in comparison to UC patients with comparable endoscopic activity [279ug/g (10, 1560) vs. 30 (10, 161), p = 0.015)]. A trend towards abnormal liver biochemistry was seen in those PSC-IBD with higher fcal [ALP: 250IU/L (113, 561) vs. 83 (59, 170), p = 0.06, GGT: 351U/L (117, 1014) vs. 51 (29, 153) p = 0.02, AST: 53U/L (26, 85) vs. 37 (22, 43), p = ns]. UC patients with quiescent colitis and fcal > 150 had a higher risk of colitis relapse in 12 months [HR = 7.6, 95%CI (1.8, 33.6)] in comparison to those with fcal < 150. However, in patients with PSC-IBD and quiescent colitis a fcal > 150 was associated instead with a higher risk of cholangitis associated complications (need for antibiotics or stent insertion), HR = 6.5, 95%CI (1.3, 33.9). Strikingly, biliary calprotectin concentration showed a strong correlation with fcal concentration (r = 0.90, p = 0.04).



Conclusion: In patients with PSC-IBD and quiescent colitis the identification of a raised fcal is likely to herald complications of inflammation in the bile ducts rather than the colon. In this setting, fcal may be a valuable prognostic biomarker of cholangitis.

FRI-049

Real world experience of obeticholic acid (Ocaliva) for the treatment of primary biliary cholangitis in the secondary care setting

Anthony Pratt[1], Lucy Turner[1], John Hutchinson[1], Laura Maher[1], Dawn Orange[1], Charles Millson[1]. *[1]York Teaching Hospital NHS Foundation Trust, York, United Kingdom*
Email: anthonypratt@nhs.net

Background and aims: Primary biliary cholangitis (PBC) is a condition that involves the destruction of interlobular bile ducts, which can lead to end-stage chronic liver disease. PBC activity is monitored through serum alkaline phosphatase (ALP) and bilirubin levels. Increased ALP and bilirubin levels have been shown to correlate with disease progression and disease outcome, respectively. The POISE Study Group demonstrated that obeticholic acid (OCA) reduces these biochemical parameters but was also associated with

side effects (SE). We evaluated the use of OCA in the treatment of PBC patients at our Trust.

Method: PBC patients who had not responded to, or who were intolerant to ursodeoxycholic acid (UDCA) monotherapy at a dose of 13-15mg/kg/day were discussed at our Hepatology multi-disciplinary team meeting. Twenty nine patients were started on OCA between July 2017 and November 2018. Patient's bloods were sampled one, three and six months after starting OCA; a patient telephone helpline was also made available and SE were recorded.

Results: The mean patient age was 62 years (range, 31-79); 25/29 (86%) patients were female and 4/29 patients (14%) were male. 18/29 (62%) patients had not responded biochemically to UDCA and 11/29 (38%) patients had stopped UDCA due to SE; prior to OCA use.

15/29 (52%) patients have so far received at least six months of OCA; of these patients we identified an ALP reduction (mean, 80.5 u/L; p = 0.006; range, −307 to +71) and a trend in bilirubin reduction (mean, 1.6 µmol/L; p = 0.137; range, −11 to +5).

The most commonly reported SE was pruritus, reported in 19/29 (66%) patients; 12/29 (41%) patients described mild to moderate pruritus which was tolerable; 7/29 (24%) patients experienced severe pruritus; of these seven patients, only 3/7 (43%) restarted and tolerated OCA at a lower dose following a two week interruption. Furthermore three patients experienced liver decompensation leading to a dose reduction in two patients and discontinuation in one patient. In total SE leading to discontinuation occurred in 9/29 (31%) of patients.

Figure: Comparison of YTHT and Poise 5-10mg Titration Arm Results

	York Teaching Hospital Trust	Poise 5-10mg Titration Arm
Mean age	62 years	56 years
Mean Fibroscan	10.7 kPa	10.7 kPa
UDCA usage	18/29 (62%)	65/70 (93%)
Mean baseline ALP	291 IU/L	326 IU/L
Mean ALP reduction	80.5 IU/L	87.7 IU/L
Mean baseline bilirubin	14.3 µmol/L	10.3 µmol/L
Mean bilirubin reduction	1.6 µmol/L	0.34 µmol/L
Reports of pruritus	19/29 (66%)	39/67 (58%)
Discontinuations due to SE	9/29 (31%)	4/67 (6%)

Conclusion: Six months of OCA treatment was associated with a significant reduction in ALP but not bilirubin, similar to the POISE study group. We found the incidence of pruritus to be only slightly higher than the POISE study group but more of our patients withdrew from OCA due to the SE. We continue to monitor our OCA patient group and await our longer term clinical outcomes with interest.

FRI-050

Antibodies to human beta-tubulin isotype 5 in autoimmune liver disorders-re-evaluation of their specificity and clinical relevance

Beate Preuss[1], Amelie Frank[1], Birgit Terjung[2], Christoph Berg[3], Ulrich Spengler[4], Reinhild Klein[1]. [1]*University of Tuebingen, Internal Medicine II, Tuebingen, Germany;* [2]*St. Josef-Hospital Bonn-Beuel, Bonn, Germany;* [3]*University of Tuebingen, Internal Medicine I, Tuebingen, Germany;* [4]*University of Bonn, Department of Internal Medicine I, Bonn, Germany*

Email: reinhild.klein@med.uni-tuebingen.de

Background and aims: From previous studies there was strong evidence that human beta-tubulin isotype 5 (TBB-5) is the corresponding antigen for pANCA (perinuclear antineutrophil cytoplasmic antibodies) in autoimmune liver diseases (AILD) (1, 2). Thus, anti-TBB-5 antibodies (abs) have been found in 88% of patients with pANCA-positive autoimmune hepatitis (AIH) and 72% of pANCA-positive patients with primary sclerosing cholangitis (PSC). Aim of the present study was to re-evaluate their diagnostic relevance.

Method: Sera from 350 patients with pANCA-positive or -negative AIH, 41 patients with pANCA-positive or -negative PSC, 250 patients with primary biliary cholangitis (PBC), 49 patients with viral hepatitis, 57 patients with alcoholic liver disease (ALD), 52 patients with non-alcoholic fatty liver disease or non-alcoholic steatosis hepatitis (NAFLD/NASH), 8 patients with storage diseases and 62 healthy individuals were analysed by ELISA for anti-TBB-5 abs of the IgG- and IgA-type. Recombinant human TBB-5 was expressed in E.coli as a histidine-tagged protein.

Results: The incidence of IgG anti-TBB-5 abs was significantly higher in patients with AIH (33%) and PSC (27%) than in the other groups of patients (up to 18%; $p < 0.05$) and healthy controls (3%; $p < 0.0001$). Also reactivity towards this antigen was significantly higher in patients with AIH as compared to patients with other liver disorders. However, there was no correlation with the presence or absence of pANCA. Interestingly, IgA anti-TBB-5 abs were predominantly found in patients with ALD (40%) but hardly in patients with AILD or NAFLD (up to 12%; $p < 0.005$), and also reactivity was significantly higher in the ALD-patients as compared to the other groups.

Conclusion: We could confirm the high association of IgG anti-TBB-5 abs with AIH and PSC. However, they were found also in pANCA negative patients; vice versa, strongly pANCA positive patients were anti-TBB-5 negative, indicating that TBB-5 is not the only target of pANCA. In contrast, IgA anti-TBB-5 antibodies were strongly associated with ALD. I.e. the determination of anti-TBB-5 abs of the IgG- and IgA-type may be helpful in the serological differential diagnosis of autoimmune and alcoholic liver disorders as well as NAFLD.

Pregnancy outcomes in women with autoimmune hepatitis

Mussarat Rahim[1], Munira Altarrah[1], Tiong Yeng Lim[1], Cannon Mary D[1], Michael Heneghan[1]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom*

Email: michael.heneghan@nhs.net

Background and aims: A significant proportion of female patients with autoimmune hepatitis (AIH) are of child-bearing age. With the advent of in vitro fertilization, improved drug safety profiles and publication of positive outcome data, pregnancy in AIH is increasingly common. Despite a few Scandinavian population-based studies, there is a paucity of conclusive data for certain pregnancy related outcomes in AIH. There is reproducible data on the increased risk of pre-term births, with miscarriage (MC) rates seemingly unaffected. Stillbirth rates and impact of immunosuppression (IS) are not fully defined. This study will aim to look at the incidence and severity of adverse pregnancy outcomes in our cohort of females with AIH.

Method: Pregnancies in patients with a diagnosis of "definite" AIH were identified through an earlier prospectively collated database and subsequent clinic consultations. Details on baseline pre-conception characteristics, diagnosis, histology, medications and fibrosis stage were obtained from medical records. Maternal complications and MCs were documented, along with gestation length and live birth rates. Statistical analysis was performed with Chi squared test. A p value of < 0.05 was statistically significant.

Results: Since 1983, 99 self-reported pregnancies were identified in 61 mothers with AIH at King's College Hospital. Median age of conception was 28 years (range 16-44). Cirrhosis or advanced fibrosis was present in 31/99 (31%) pregnancies. There were 77/99 (78%) pregnancies on IS at conception; 34 on monotherapy, 40 on dual therapy and 3 on triple therapy. In 99 pregnancies, 76 live births (77%) occurred, with 10 early MCs, 10 terminations and 2 intrauterine deaths. The miscarriage rate in cirrhotics was 10% versus 12% in non-cirrhotics (p = 0.82).

Of the live births, 51 (67%) were term (> 37 weeks), 7 (9%) were pre-term (32-37 weeks) and 3 (4%) were very pre-term (< 32 weeks). Of the cirrhotic pregnancies, 13/33 were pre-term. In the non-cirrhotic group, 7/31 were pre-term (p = 0.15). In our cohort, IS did not affect pre-term rates (36/55 vs 8/9, p = 0.16).
Liver related complications occurred in 12/99 (12%) pregnancies, including flares, decompensation and cholestasis. There was no difference in the rate of liver complications between cirrhotic and non-cirrhotic groups (12% vs 12%, p = 0.91). IS during pregnancy was not a risk for developing liver related complications (12/82 vs 0/17, p = 0.09). A flare during/after pregnancy occurred in 24/82 (29%) on IS, compared to 8/17 (47%) not on IS (p = 0.15).
Conclusion: Pregnancy in AIH, with or without cirrhosis, appears to have favorable outcomes in most patients. Larger corroborative studies could elucidate which pre-conception factors predict poor outcomes. High risk patients may warrant in depth pre-conception counselling and closer follow-up with the Hepatologists and Obstetricians, ideally in a combined clinic.

FRI-052

Long-term bezafibrate therapy does not prevent the progression of primary biliary cholangitis in patients with advanced disease

Anna Reig[1], Laura Patricia Llovet[1], Pilar Sesé[1], Maria Carlota Londoño[1], Albert Parés[1]. *[1]Liver Unit, Hospital Clínic. CIBERehd. IDIBAPS. University of Barcelona., Barcelona., Spain*
Email: anna.rg86@gmail.com

Background and aims: Combined treatment with ursodeoxycholic acid (UDCA) and fibrates has the potential both to improve liver biochemistries and to reduce the symptoms of primary biliary cholangitis (PBC), but the long-term effects of this regimen has not been completely evaluated. The current study was addressed to explore the outcome of the combined treatment is terms of survival free of transplantation and development of events of PBC progression.
Method: 54 PBC patients (51 female, age 53 -IQR 36-58- years) treated with UDCA for at least a year and alkaline phosphatase (ALP) above 1.5 times upper normal levels (× UNL) were treated with bezafibrate (400 mg/day) plus UDCA (13-16 mg/kg/day). Changes in clinical features, liver biochemistries and outcome after therapy were assessed. In 48 patients, liver stiffness (LS) as an index of fibrosis was assessed before and at the end of observation. The globe score (GS) as a prognostic index was measured as well.
Results: After a median of 5.9 (4.4-5.8) years a significant improvement of biochemical cholestasis was observed, although without changes in LS (9.4 ± 1.1 vs 10.9 ± 1.7, kPa, p:n.s). ALP normalized in 28 patients (52%) after a median of 17 months. Sixteen patients (33%) have a baseline LS ≥ 9.6 kPa, and 17 patients (31%) a GS > 0.3. Eight patients (15%) progressed to more advanced disease and died (2), were transplanted (3), developed hepatocellular carcinoma (1) or had events of decompensation (2). All of these patients did not normalize ALP, six had a baseline LS ≥ 9.6 kPa and six (75%) had a baseline GS > 0.3. In the patients with poor outcome, improvement of liver biochemistries was observed as well (ALP: 3.9 ± 0.6 to 2.3 ± 0, 5, p = 0.04; ALT: 105 ± 13 to 69 ± 13 u/L, γGT: 480 ± 131 to 131 ± 39 u/L, p = 0.03), but a significant decrease in albumin (39.2 ± 1.3 to 32.9 ± 1.3 g/L, p = 0.008) and platelet count. Moreover, the probability of poor outcome according to the Kaplan-Meir analysis was significantly higher in the patients with lack of ALP normalization (p = 0.005), and baseline LS ≥ 9.6 kPa (p = 0.002) or GS > 0.3 (p = 0.004).
Conclusion: Long-term treatment with bezafibrate in addition to UDCA resulted in biochemical response with normalization of ALP in a short period of time in more than half of the patients. However, this treatment does not prevent the progression of primary biliary cholangitis in the patients with more advanced disease, despite of the improvement of biochemical cholestasis.

Email: anna.rg86@gmail.com

Background and aims: Primary biliary cirrhosis (PBC) and autoimmune hepatitis (AIH) occurring concurrently is called "overlap syndrome" (OS). It may be diagnosed in a previously healthy subject, or may arise in the course of PBC. The natural history and prognosis are not fully established, nor the characteristics of PBC patients who develop OS across the course of the cholestatic disease. Then, this study was aimed at assessing the course and prognosis of the OS in PBC.
Method: Data from 2120 patients with PBC included in the Col-Hai registry were analyzed. 1955 patients were diagnosed as PBC and 165 as OS (7.8%). Clinical and laboratory data at presentation, and features of cirrhosis or portal hypertension (PH), decompensation events and liver related death or transplantation were recorded. Moreover, patients with no overlap at diagnosis who develop this condition during the course of PBC were evaluated separately. There were 3 groups: no overlap (PBC), overlap at diagnosis (OS) and overlap diagnosed within the PBC follow-up (OS-PBC).
Results: At diagnosis OS patients were younger (49.8 ± 14 vs 54.8 ± 13 years, p < 0.001) with higher transaminases (2.7 ± 2.4 vs 1.6 ± 1.5 UNL, p < 0.001) and γGT (6.6 ± 7 vs 6.1 ± 6 UNL; p = 0.001) and lower bilirubin (0.9 ± 1.5 vs 1.5 ± 2 mg/dl, p = 0.03). Global and UK-PBC scores were similar, but in OS patient's prognosis stratified by age was poorest (67 vs 92%, p < 0.001), and with lower UDCA response to Paris I, Paris II and Rotterdam criteria than in PBC. Time to cirrhosis or PH was shorter (11.8 ± 1.5 vs 18.1 ± 0.7 years, p = 0.07), with no differences in time to death or transplantation. 25 PBC patients (1.3%) had OS-PBC, within a period of 7.9 ± 4 years. OS-PBC patients were younger at diagnosis of PBC (44.2 ± 12 vs 54.8 ± 13 years,

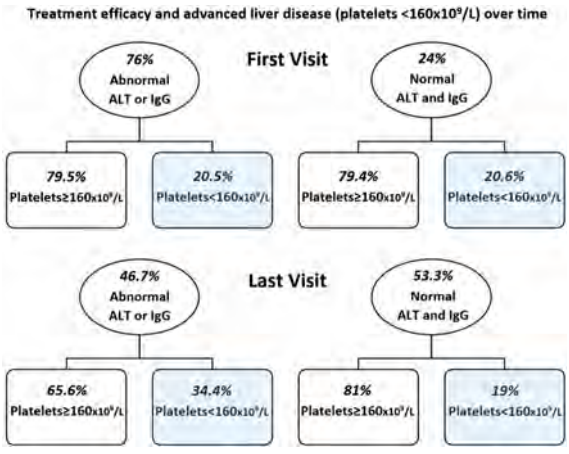
p < 0.01) with similar response to UDCA and Global and UK-PBC scores than in patients who did not developed OS. OS-PBC patients developed more features of cirrhosis or PH during follow-up (54% vs 21%, p < 0.001) in a shorter period (6.5 ± 1.2 vs 18.1 ± 0.6 years, p < 0.001) and lower time to liver-related death or transplantation (p = 0.05) than the PBC patients. No significant differences in survival free of transplantation were observed between PBC and OS groups.
Conclusion: Overlap PBC-AIH syndrome is observed in younger patients and associated with faster progression of the disease. Prognosis scores and response to treatment do not predict overlap development in during the course of PBC.

FRI-054
Immune-related hepatitis as an independent entity from autoimmune hepatitis: clinical, prognostic and therapeutic differences
Mar Riveiro-Barciela[1,2], Judit Vidal-González[1], Ana Barreira-Díaz[1], Eva Muñoz-Couselo[3], Lluís Viladomiu[1], Carolina Ortiz Velez[3], Fernando Martínez-Valle[4], Lluís Castells[1,2], Rafael Esteban[1,2], Maria Buti[1,2]. *[1]Liver Unit, Internal Medicine Department, Hospital Universitario Vall de Hebrón, Barcelona, Barcelona, Spain; [2]CIBERehd, Barcelona, Spain; [3]Oncology Department, Instituto de Oncología Vall d'Hebron (VHIO), Hospital Universitario Vall de Hebrón, Barcelona, Barcelona, Spain; [4]Systemic Autoimmune Diseases Unit, Internal Medicine Department, Hospital Universitario Vall d'Hebron, Barcelona, Spain, Barcelona, Spain*
Email: mar.riveiro@gmail.com

Background and aims: Immunotherapy has revolutionized Oncology. However, patients can develop adverse events that mimic autoimmune conditions. Real-world data concerning immune-related hepatitis (irH) is lacking. The aim of the study was to describe the characteristics, prognosis and treatment of a cohort of irH.
Method: Retrospective study including all cases of irH referred from 2013 and diagnosed according to the Oncology guidelines. Patients were compared with autoimmune hepatitis (AIH) diagnosed within the same period.
Results: 63 cases were recorded: 25 (40%) irH and 38 (60%) AIH. 59% women, 94% Caucasian, mean age 58 ± 15. At diagnosis, 86% presented acute hepatitis. irH were older (64 vs 54, p = 0.04) and less severe at presentation (9% acute liver injury or failure vs 32%, p = 0.046). Symptoms were less frequent in irH (32% vs 68%, p = 0, 005), including fatigue (p = 0.002) and jaundice (p = 0, 015). Bilirubin (p = 0, 001), proteins (p = 0, 02), γglobulins (p < 0, 001) and IgG (p < 0, 001) values were lower in irH, as well as the presence of ANAs ≥ 1:80 (p < 0, 001). The majority of irH had received antiPD1/L1 (72%) and/or antiCTLA (36%). Liver biopsy did not show signs of cirrhosis in any irH vs 16% of AIH (p = 0.04). The majority of AIH were classified at least as probable according to the AIH score, but it was not useful for irH (94% vs 11%, p < 0.01). Initial dose of corticoids in irH was higher (64 vs 40mg, p < 0.001) but duration was shorter (2.5 vs 10 months, p < 0.001). Weeks to decrease corticoids < 20mg/d was similar, as well as the proportion of flares. A lower percentage of irH received a second immunossupressant (41% vs 97%, p < 0, 001) and just 1 case required second line therapies vs 28% of AIH (p = 0.05). IrH achieved complete remission sooner (2.8 vs 6 months, p = 0.049). Rate of infections was 18% and similar between the two groups, although prophylaxis with cotrimoxazole was more common in irH (p < 0.02). Mortality was higher in irH (p = 0.04), although liver-related ones were similar (10% vs 9%, p = 0.67). Among AIH, 19% developed decompensation during follow-up, 2 (5%) hepatocarcinoma and 2 (5%) required transplantation.
Conclusion: AntiPD1/L1 and antiCTLA were the immunotherapies more commonly associated with irH, 9% presenting as severe acute hepatitis and mortality rate of 10%. Diagnostic scores for AIH are not useful in irH. Most cases resolved with corticoids and though the initial dose tends to be higher, duration of treatment is shorter than AIH.

FRI-055
Failure to normalize ALT and IgG in Autoimmune Hepatitis is associated with more advanced liver disease: Perspectives from a multi-ethnic Canadian AIH registry
Surain Roberts[1,2], Aliya Gulamhusein[1,2], Marwa Ismail[2], Andrew L. Mason[3], Mark G Swain[4], Catherine Vincent[5], Eric Yoshida[6], Cynthia Tsien[7], Jennifer Flemming[8], Harry Janssen[2], Bettina Hansen[1,2], Gideon Hirschfield[2]. *[1]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; [2]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [3]University of Alberta, Edmonton, Canada; [4]University of Calgary, Calgary, Canada; [5]University of Montreal, Montreal, Canada; [6]University of British Columbia, Vancouver, Canada; [7]University of Ottawa, Ottawa, Canada; [8]Queen's University, Kingston, Canada*
Email: surain.roberts@mail.utoronto.ca

Background and aims: Autoimmune hepatitis (AIH) is infrequent but impactful, with management that remains heterogeneous. We sought to define diversity of disease in Canadian practice.
Method: Data on patients with a clinical diagnosis of AIH within the Canadian Network for Autoimmune Liver disease were abstracted for demographic, clinical, and biochemical data between November 1999 and October 2018. Paired T-tests/Wilcoxon tests were used for continuous data and chi-square/McNemar's tests for categorical data. Logistic regression and receiver operator characteristic were applied.
Results: The cohort included 412 patients with follow-up of at least 1 year. Median age was 54.6 years (39.4-69.6), 75.2% were female, and 18.0% had clinical features of overlap with either PBC (56.8%) or PSC (43.2%). Our multi-ethnic cohort was 63.6% Caucasian, 11.9% Asian, 8.9% Black, 4.4% Middle Eastern, 2.7% Latin American, 1.7% Indigenous Canadian, and 3.9% mixed ethnicity. 78.6% of patients had Type 1 AIH and 1.2% had Type 2 AIH. ANA, SMA, and LKM were negative in 20.1%. At first visit, median ALT was 59 U/L (31-156), IgG 16.9 g/L (12.6-23.8), AST 56 U/L (30-142), total bilirubin 12 µmol/L (8-24), and platelets 232x10^9/L (175-287). Median ALP was 101 U/L (66-160) and GGT 82 U/L (33-188). 76% of patients had abnormal ALT or IgG at first visit; at last visit 53% had normal ALT and normal IgG. Thrombocytopenia (platelets < 160x10^9/L), as a sensitive marker for cirrhosis, identified 20.5% of patients at first visit with advanced disease compared to 26.2% at last follow-up (p = 0.006). Of those at last visit with abnormal ALT or IgG, 34.4% had a surrogate of cirrhosis compared to 19.0% in patients with normal ALT and IgG (p < 0.01; Figure). Across follow-up, median ALP of patients with clinical overlap features was 178 U/L (95-222) compared to 79 U/L (61-108) in patients with AIH alone (p < 0.0001). Across follow-up, patients with overlap features had GGT of 130 U/L (47-218) compared to 44 U/L (24-97) in those without (p < 0.01). Univariate logistic regression demonstrated that higher GGT values were associated with increased odds of overlap features (p < 0.0001), but GGT demonstrated only moderate ability to discriminate overlap features (AUC = 0.677).



Conclusion: In a multi-ethnic Canadian registry of overwhelmingly Type 1 adult AIH, the majority of patients are over the age of 50. When stratified by achievement of established treatment goals, the burden of advanced liver disease is significantly increased in those without normal ALT or IgG.

Obeticholic acid as adjunctive therapy in Primary Biliary Cholangitis: A review of early real-world experience

Surain Roberts[1,2], Marwa Ismail[1], Gowthami Kanagalingam[1], Andrew L. Mason[3], Mark G Swain[4], Catherine Vincent[5], Eric Yoshida[6], Cynthia Tsien[7], Jennifer Flemming[8], Harry Janssen[1], Gideon Hirschfield[1], Bettina Hansen[1,2], Aliya Gulamhusein[1,2].
[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; [3]University of Alberta, Edmonton, Canada; [4]University of Calgary, Calgary, Canada; [5]University of Montreal, Montreal, Canada; [6]University of British Columbia, Vancouver, Canada; [7]University of Ottawa, Ottawa, Canada; [8]Queen's University, Kingston, Canada
Email: surain.roberts@mail.utoronto.ca

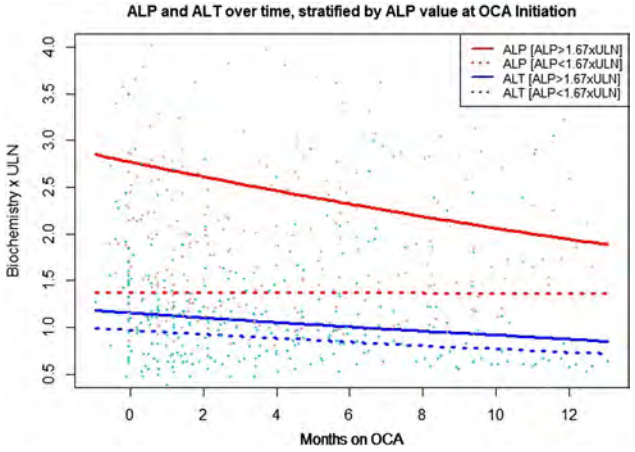
Background and aims: Patients with Primary Biliary Cholangitis (PBC) with incomplete response to UDCA are at risk of progressive liver injury and in need of alternative therapy. In May 2017, obeticholic acid (OCA) was approved in Canada as adjunctive therapy for PBC. We sought to describe our experience of the real world use of OCA use in high risk PBC.

Method: Available data on patients initiated on OCA within the Canadian Network for Autoimmune Liver disease were included. Medical records were abstracted for patient demographics. Clinical and biochemical data were collected at baseline and at defined intervals in follow-up. Repeated measures models (SAS 9.4) were used to assess changes in alkaline phosphatase (ALP), aspartate aminotransferase (AST), alanine aminotransferase (ALT), and total bilirubin over time.

Results: 40 patients were initiated on OCA between August 2017 and October 2018 based on treating hepatologists' clinical evaluation of individual risk of disease progression. Mean age was 54.7 (± 9.8) years, 92.5% (n = 37) were female, 90% (n = 36) were AMA positive, and median liver stiffness was 10.6 kPa (7.8-15.0). Median follow-up time of OCA-treated patients was 7.0 (3.6-10.6) months. At OCA initiation, median ALP was 264 U/L (IQR 190-379), ALT was 43 U/L (30-57), AST was 44 U/L (36-57), total bilirubin was 13 µmol/L (9-16), and platelets were $229x10^9$/L (174-268). After 12 months of OCA treatment, ALP had decreased by a mean of 64 U/L ($p < 0.01$) and ALT had decreased by 11 U/L ($p < 0.04$). AST showed a decreasing trend of 5.1 U/L (p = NS) while total bilirubin remained stable (decrease of 0.03 µmol/L; p = NS).

13 patients had ALP < 1.67xULN at OCA initiation, one of whom also had total bilirubin > 2xULN. In these patients with lower ALP at initiation, ALP remained stable ($p = 0.98$) while ALT showed a significant decline ($p < 0.05$) similar to that observed in patients with ALP ≥ 1.67xULN ($p = 0.25$; Figure). AST and total bilirubin showed the same non-significant trends in patients with lower ALP at OCA initiation.

Worsening of itch occurred in 52.5% (n = 21) patients. 7.5% (n = 3) of patients discontinued therapy, 2 due to worsening pruritus and 1 due to variceal bleed. Dose reduction to 5 mg weekly occurred in 7.5% (n = 3) of patients due to clinical suspicion of progressive disease.



Conclusion: In this real word cohort, use of OCA in addition to UDCA in patients with high risk PBC was associated with improvement in biochemical markers of cholestasis and inflammation.

Email: lavan.0819@gmail.com

Background and aims: Therapeutic advances in primary biliary cirrhosis (PBC) make assessment of treatment response a critically important issue. We studied the clinical practice around PBC in Wales. Population of Wales is over 3 million people with rural/urban diversity. Clinical services reflect the diversity with small district hospitals and large liver units.

Method: We developed a clinical audit tool with UK-PBC and EASL guidelines. Data was retrospectively collected by specialist trainees in each health board, including demographic information, clinical management and differences in adherence to standards between clinicians. We interrogated ursodeoxycholic acid (UDCA) use, appropriate dosing, documentation of symptoms, prevalence of cirrhosis and referral for transplant.

Results: Total of 406 living patients with diagnosis of PBC were identified across five Welsh health boards.
Out of 406 patients, majority were females (n = 297, 73%), mean age at diagnosis of 59.7 years (± 13.5). Serological testing for PBC (AMA > 1/40) was present in 88.5% patients at time of diagnosis. Mean Alkaline Phosphatase (ALP) at diagnosis was 334U/L (56-2020). Liver biopsy was performed in 26.6% of patients and was more likely to be requested by a hepatologist than a general gastroenterologist, p = 0.039 (Chi Square).
Mean follow-up since diagnosis was 7.9 ± 6years.
Symptoms of pruritus and fatigue were documented in 29.2% and 32.9% of recent clinic records respectively.
Hepatologists followed PBC patients up more frequently with 70.7% of their patients seen at 6 monthly intervals whereas general gastroenterologists were more likely to follow-up patients annually, p < 0.001.
Of 214 patients with recent clinic letters, 179 (83.6%) were on UDCA. Patients managed by hepatologists were more likely on the appropriate dose of UDCA (92.9%) compared to gastroenterologists (39.3%), p = 0.018. Hepatologists were better in recording assessment of response at 1 year (86.8%) compared to gastroenterologists (62.5%), p = 0.024.
Of the total cohort, 47.8% patients had cirrhosis, with screening performed for hepatocellular cancer in 54.3% and varices in 38%. Out of 82 patients with documentation of conversation about transplant, 26 patients were considered with 12 undergoing liver transplant.
Conclusion: This study provides a unique insight into current services for PBC patients across Wales. Despite widely available guidelines, there were significant discrepancies in adherence to standards between hepatology and gastroenterology managed patients. In particular, patients managed by hepatology were likely to receive optimal UDCA dosing and have response documented at 1 year. This study has also uncovered areas requiring improvement like documentation of fatigue and pruritis. These findings will be used to review the PBC care pathway in Wales to improve adherence to standards and access to new therapies.

FRI-058

Randomized controlled trial to compare efficacy of albumin dialysis using MARS versus new adsorbent recirculation for pruritus treatment

Jan Stange[1], Hartmut Schmidt[2], Steffen Mitzner[3], Sebastian Koball[3], Christian Wilms[2], Hans Ulrich Gerth[4], Michael Hinz[5], Tarek Hassanein[6], Andreas Kortgen[7], Christoph Sponholz[7], Matthias Dollinger[8], Raoul Benedikt Sauer[9], Alexandra Rivera Luna[9], Victoria Rivera Luna[9]. *[1]Internal Medicine, Nephrology, Rostock, Germany; [2]Hepatology, Muenster, Germany; [3]Internal Medicine, Rostock, Germany; [4]Nephrology, Muenster, Germany; [5]Nephrology, Rostock, Germany; [6]Liver Centers, Coronado, United States; [7]University of Jena, Jena, Germany; [8]University of Ulm, Landshut, Germany; [9]University of Rostock, Rostock, Germany*
Email: jan.stange@web.de

Background and aims: Albumin Dialysis is a therapy option for pruritus in cholestatic liver disease. The aim was to compare the efficacy between MARS with a new albumin dialysis device.
Method: A Prospective randomized crossover study was conducted in 4 sites. Randomly subjects received either MARS first and new HepalbinCluster[12] albumin dialysis (OPAL) second or vice versa. Clinical scores, Visual Analogue Score, standard laboratory tests as well as albumin binding function, free fatty and bile acids were measured before and after each treatment.
Results: 8 subjects suffering from cholestatic liver disease and pruritus were enrolled. Subjects in both arms were comparable and results are listed in Figure 1 (Table):

Baseline	Mars 1st n = 4		Opal 1st(Hepalbin Cluster12) n = 4	
Gender (f/m)	(0/4)		(3/1)	
Age	44.50 + 21		47.25 ± 18	
	All Mars Therapies (n = 8)		All Hepalbin Cluster12 (n = 8)	
	Pre	post	pre	post
Mean Art. Pressure	93 ± 11	102 ± 20	96 ± 8	96 ± 16
Hemoglobin (mmol/l)	7.3 ± 1.6	7.0 ± 1.5	7.1 ± 1.5	6.8 ± 1.5
Platelets	226 ± 115	189 ± 92	214 ± 122	196 ± 115
Quick (%)	66 ± 30	63 ± 31	72 ± 31	71 ± 34
Antithrombine III	90 ± 42	90 ± 41	90 ± 48	89 ± 45
Creatinine	74 ± 23	47 ± 18	77 ± 25	50 ± 19
Bilirubin (umol/l)	254 ± 184	207 ± 148	291 ± 173	207 ± 110
Bile Acids (umol/l)	122 ± 88	67 ± 52	125 ± 121	35 ± 25
Free Fatty Acids-FFA	697 ± 618	1196 ± 715	828 ± 596	813 ± 534
Alb-Binding Capacity	64 ± 10	65 ± 14	63 ± 9	70 ± 6
Alb-Uptake FFA	14 ± 11	14 ± 14	15 ± 13	27 ± 31
Pruritus-VAS	4.9 ± 3.7	3.9 ± 3	6.5 ± 3.5	3.4 ± 3.3
Hepatic Encephalop.	0.5 ± 0.8	0.33 ± 0.5	0.57 ± 0.5	0.57 ± 0.5
MELD	20 ± 7	20 ± 6	22 ± 7	20 ± 9

Conclusion: With a new adsorbent albumin dialysis could reduce albumin bound toxins (e.g. bilirubin and free fatty acids) more effectively, which resulted in a significant improvement of albumin binding and fatty acid uptake. Which one of the changes are responsible for the more profound improvement of pruritus remains unknown and requires more research.
The procedure was safe in all subjects.

FRI-059

Systematic review and meta-analysis of bezafibrate in combination with ursodeoxycholic acid in patients with treatment refractory primary biliary cirrhosis

Ted Stoklosa[1], Simone Strasser[1]. *[1]Royal Prince Alfred Hospital, A W Morrow Gastroenterology and Liver Centre, Camperdown, Australia*
Email: tmstoklosa@gmail.com

Background and aims: Primary biliary cirrhosis (PBC) is a cholestatic liver disease characterised by chronic inflammation and accumulation of bile acids resulting in bile duct and hepatocyte damage. If untreated, ongoing inflammation and tissue damage can lead to progressive fibrosis, cirrhosis and end stage liver disease. Ursodeoxycholic acid (UDCA) has been shown to prolong transplant free survival for patients with PBC and is widely accepted first line therapy. However, patients who have progressive disease refractory to UDCA treatment have limited treatment options. Bezafibrate (BEZA) is a peroxisome proliferator-activated receptor alpha agonist with anticholestatic properties that has been used in this setting. We performed a systematic review and meta-analysis to assess the efficacy of BEZA in combination with UDCA for patients with PBC refractory to first line treatment.
Method: We performed a systematic review of randomised trials, crossover trials and self-controlled clinical trials for this indication. A systematic review of MEDLINE and the Cochrane Library was performed and an expert in the field was consulted. A meta-analysis of the results was performed for the outcomes of alkaline phosphatase (ALP), mortality, pruritus and adverse events prompting treatment cessation. For continuous variables a mean difference was calculated with 95% confidence intervals. For dichotomous outcomes a risk ratio (RR) was calculated. A random effects model was chosen. Heterogeneity of outcomes was assessed using the Chi-squared and I^2 tests.
Results: 181 papers were identified, and 10 papers included in the final analysis including 307 patients. Mean age of subjects was 57 years and 97% were female. 9/10 studies were deemed at a high risk of bias, predominantly due to issues with lack of randomisation and assessor or participant blinding. In the meta-analysis, compared with

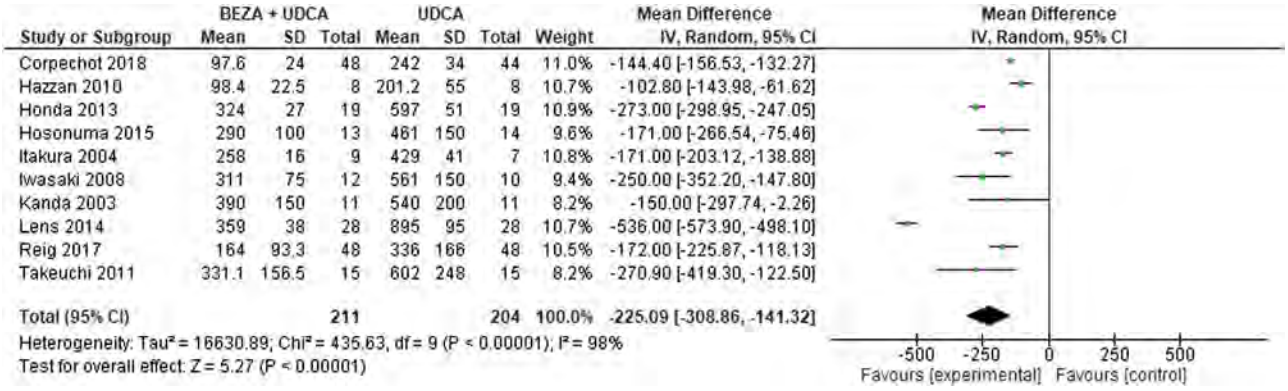

Figure 1: (abstract: FRI-059): Alkaline Phosphatase

UDCA alone, BENZA+UDCA demonstrated: a mean ALP reduction of 225 IU/L (95%CI 309 -141, p = < 0.001) (figure 1), an improvement in pruritus RR 0.41 (95% CI 0.24 to 0.70, p = 0.001), a significant number of adverse events prompting discontinuation of treatment 13 vs 1 (p = 0.01) and no significant difference in mortality (p = 0.11). There was evidence of heterogeneity for the outcome of ALP (I^2 = 98%, Chi-squared p = < 0.001), however all studies included demonstrated a significant reduction in ALP for BENZ + UDCA compared with UDCA alone.

Conclusion: We have demonstrated that based on the current literature, BEZA in combination with UDCA appears safe and efficacious treatment for PBC refractory to UDCA monotherapy to improve liver biochemistry and patient symptoms. Further studies are required to assess the long-term effectiveness of this therapy to demonstrate definitively that an improvement in liver biochemistry will result in improvement in progression of liver disease.

FRI-060

Effects of the ileal bile acid transport inhibitor A4250 on pruritus and serum bile acids in patients with biliary atresia: phase 2 study results

Ulrich Baumann[1], Ekkehard Sturm[2], Florence Lacaille[3], Emmanuel Gonzales[4], Henrik Arnell[5], Björn Fischler[5], Marianne Hørby Jørgensen[6], Richard Thompson[7], Jan Mattsson[8], Per-Goran Gillberg[8], Kristina Torfgard[8]. *[1]Hannover Medical School, Hannover, Germany; [2]niversity Children's Hospital Tübingen, Tübingen, Germany; [3]Necker-Enfants Malades Hospital, Paris, France; [4]University Hospitals of Paris-Sud, Bicêtre, France; [5]Astrid Lindgren Children's Hospital, Stockholm, Sweden; [6]Rigshospitalet, Copenhagen, Denmark; [7]Institute of Liver Studies, King's College London, London, United Kingdom; [8]Albireo AB, Gothenburg, Sweden*
Email: baumann.u@mh-hannover.de

Background and aims: Biliary atresia (BA) is an important cause of neonatal cholestasis, which may progress to biliary cirrhosis and end-stage liver disease. Management of cholestasis and pruritus is often limited to dietary support, supplementation of fat-soluble vitamins, treatment of cholangitis and symptomatic relief; new, non-invasive treatment options are needed. Ileal bile acid transporter (IBAT) inhibition is a novel therapeutic concept for the treatment of cholestatic pruritus and progression of cholestatic liver disease (CLD). The effects of A4250 (a potent, selective, reversible IBAT inhibitor that decreases enteric bile acid reuptake with minimal systemic exposure) are reported in BA patients.

Method: A phase 2, open-label, multi-centre study evaluating A4250 safety and tolerability in paediatric CLD with pruritus (including BA) was conducted. Efficacy end points were change in serum bile acid levels and pruritus. Patients received oral A4250 10-200 µg/kg/day for 4 weeks.

Results: Three female patients with BA were enrolled and received A4250 30 µg/kg/day; all 3 completed the study. No serious treatment-related adverse events (AEs) were reported. Most AEs, including some increased transaminases, were transient. Two BA patients had reductions in serum bile acids and pruritus captured by both visual analogue scale (VAS; 0-10) and Whitington scale (0-4; **Table**). These data, though limited, are consistent with results from the overall study population of paediatric patients with chronic CLD. A third patient who had relatively low baseline serum bile acids did not have reductions in serum bile acids or pruritus (**Table**).

Table:

Effects of A4250 on bile acids and pruritus in patients with biliary atresia

Patient	1	2	3
Age, years	14	4	2
Baseline parameters			
ALT, U/L	36*	151*	65*
Albumin, g/L	37*	36*	35*
Bilirubin, total, µmol/L	8.0	38.3*	19.3*
GGT, U/L	51*	326*	181*
Bile acids, µmol/L			
Baseline	42.8	136.2	131.5
End of treatment	42.6	57.8	64.7
VAS-Itch			
Baseline	6.59	5.07**	5.72
End of treatment	7.14	1.00	4.04
Whitington-Itch			
Baseline	2.57	2.57**	2.00
End of treatment	2.00	0.29	1.00

*Value outside normal limits.
**Patient had missing baseline diary entries; value is mean from days 1-7 after single dose.

Conclusion: Orally administered A4250 was well tolerated in these patients, and the reductions in serum bile acids and improved pruritus observed suggest that further investigation of A4250 in children with BA is warranted.

FRI-061

Colorectal cancer, colectomy rates and inflammatory bowel disease activity following liver transplantation in primary sclerosing cholangitis: A systematic review and meta-analysis

Tom Thomas[1], Rachel Cooney[2], tariq iqbal[2,3], subrata ghosh[2,3], James Ferguson[3,4], Gideon Hirschfield[5], Palak Trivedi[3,4,6,7]. [1]*University of Oxford, Translational Gastroenterology Unit, Oxford, United Kingdom;* [2]*Queen Elizabeth Hospital, Department of Gastroenterology, Birmingham, United Kingdom;* [3]*National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre (BRC), Birmingham, United Kingdom;* [4]*Queen Elizabeth Hospital, Liver Unit, Birmingham, United Kingdom;* [5]*University Health Network, University of Toronto, Toronto Centre for Liver Disease, Toronto, Canada;* [6]*University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom;* [7]*University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom*
Email: tom.thomas@nhs.net

Background and aims: Primary sclerosing cholangitis [PSC] is the classical hepatobiliary manifestation of inflammatory bowel disease [IBD] for which liver transplantation [LT] is the only curative therapy. We provide pooled incidence rates [IR] and time trends of (1) colorectal cancer [CRC], (2) flares in IBD activity and (3) colectomy rates post LT, through systematic review and meta-analysis.
Method: A systematic literature search of Medline and Embase was undertaken to identify studies that were pertinent to our research objectives from 1981 to 2014. Included studies were assigned to one or more of the three analytical streams (indicated above). The "meta" package (R Studio (V.1.1.463)) and Revman was used to pool IRs and HRs from individual studies using a random effects model.

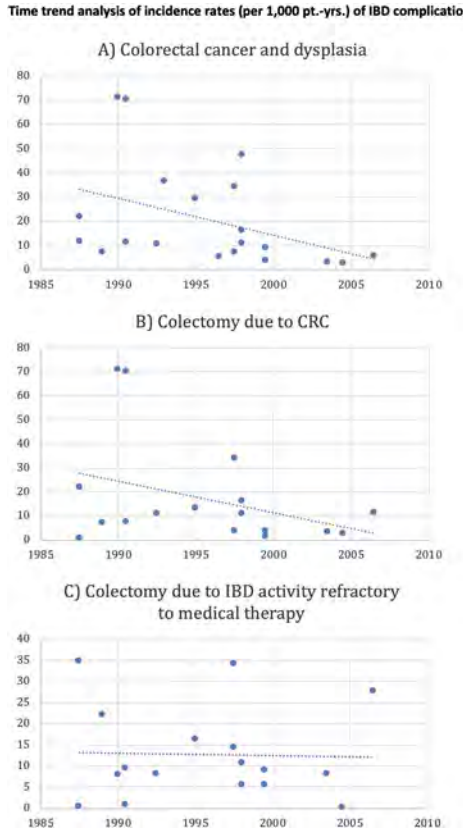

Figure 1:

Results: Forty-two studies qualified for inclusion in the systematic review. Twenty studies detailing the clinical course of 1994 patients (cumulative 9874 patient years) were pooled to assess the incidence of dysplasia or CRC (combined end point) and CRC only; IR 14.97 cases (95%CI 9.74-23.02) and 9.21 (95%CI 6.01-14.09) per 1000 person years, respectively. Heterogeneity was considerable (I^2 = 86%). The incidence of post LT CRC was seen to be decreasing over time **(Fig 1A)**. Colectomy rate following OLT was 23.18 per 1000 person years (95% CI 16.74-32.08) (I^2 = 84%). The IR for colectomy due to dysplasia/CRC was 11.25 cases per 1000 person years (95% CI 6.43-19.68) and seen to be decreasing over time (**1B**). By contrast, deterioration in IBD activity necessitated colectomy in 13.26 cases per 1000 person years (95% CI 9.95-17.66), with no change over time (**1C**). Nine studies reported clinical course of IBD post LT according to endoscopy findings/ escalation in IBD therapy. 27.6% of patients (n = 584) experienced deterioration in IBD activity post LT. The effect of 5-aminosalicylates [5ASA] on risk of CRC (2 studies), colectomy (1 study) and IBD activity (2 studies) was examined. Due to study heterogeneity, this data could not be analysed. The effect of ursodeoxycholic acid [UDCA] on the risk of CRC after LT was examined by 3 studies. Due to data availability, only 2 studies could be pooled. UDCA increased the risk of CRC post LT; HR 2.90 (95%CI 1.37-6.11). Studies examining the impact of UDCA on colectomy and IBD activity post LT were inconclusive. No study examined the role of anti-TNF therapy in context of study objectives.
Conclusion: This is the first comprehensive systematic review and meta-analysis of IBD related outcomes post LT in the PSC cohort (CRC, dysplasia, colectomy overall and by indication and IBD activity). The risk of CRC mandates ongoing colonoscopic surveillance in the PSC/ IBD LT population, although the incidence appears to be decreasing. Identification of risk predictors impacting IBD course is of critical importance, given that IBD deterioration appears to be the principal indication for colectomy post LT.

FRI-062

Identifying research priorities in primary sclerosing cholangitis: Driving clinically meaningful change from the patients' perspective

Martine Walmsley[1], Angela Leburgue[2], Douglas Thorburn[3], Gideon Hirschfield[4], Palak Trivedi[5,6,7,8]. [1]*PSC Support, Oxford, United Kingdom;* [2]*Albi France, Albi, France;* [3]*Royal Free Hospital, Sheila Sherlock Liver Centre and UCL Institute of Liver and Digestive Health, London, United Kingdom;* [4]*University Health Network, University of Toronto, Toronto Centre for Liver Disease, Toronto, Canada;* [5]*University of Birmingham, National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre, Birmingham, UK, Birmingham, United Kingdom;* [6]*University Hospitals Birmingham, Birmingham, UK, Liver Unit, Birmingham, United Kingdom;* [7]*University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom;* [8]*University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom*
Email: p.j.trivedi@bham.ac.uk

Background and aims: Primary sclerosing cholangitis [PSC] is a disease with no curative medical treatment, a progressive yet often unpredictable clinical course, and complex symptom burden. Our aim was to prospectively inform basic and targeted outcomes' research in PSC, by examining the opinions, attitudes and experiences of those living with the disease.
Method: This was a cross-sectional study led by the UK charity "PSC Support" in partnership with "**albi**" France. Participants were invited to detail the most difficult aspects of living with PSC and develop a hierarchy of key research priorities based on present unmet need. Concurrently, we gauged patient willingness to undergo specific interventions as part of PSC research and attribute confidence levels to currently proposed therapeutic end points.
Results: Between 10/2014 and 03/2017 we captured the views of 636 respondents (450 patients, 186 caregivers) who collectively reported 1318 concerns relating to the most difficult part of living with PSC-the most prevalent theme related to the emotional impact of disease (**Fig. 1A**). 79% of emotional impact responses related to "uncertainty;" specifically the unpredictable nature of disease progression, and

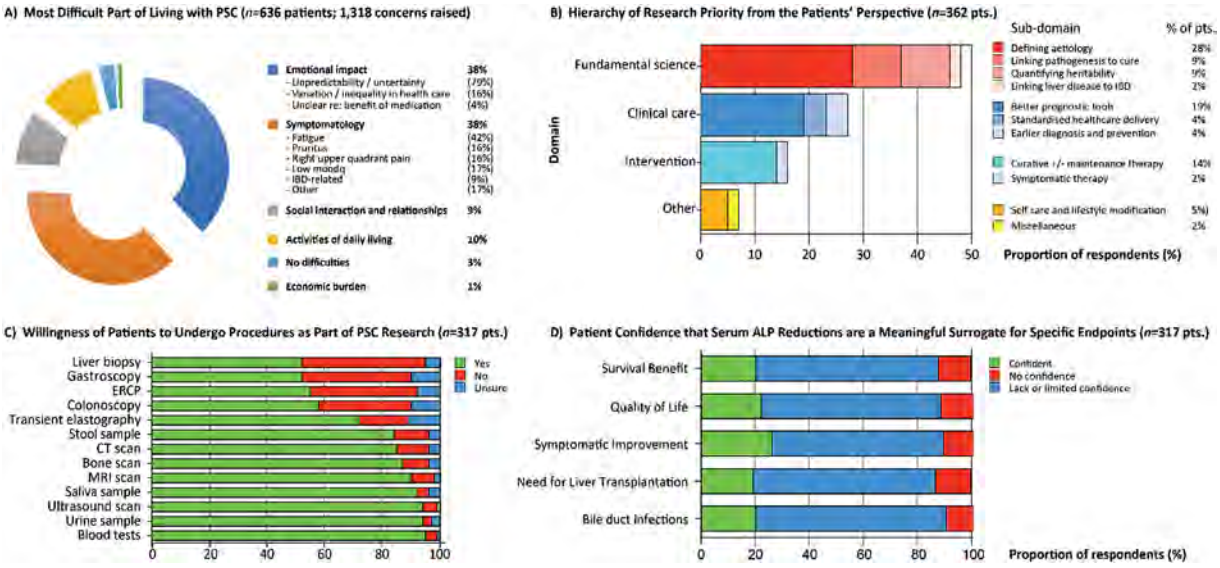

Figure: (abstract: FRI-062)

inability to be given a clear individual prognosis. A further 16% of emotional impact responses related to variation and inequality in healthcare delivery. When asked to identify future PSC research questions important to them, 362 participants responded. The most common questions were deemed "fundamental," specifically to identify cause of disease and magnitude of heritability, in addition to strengthening efforts toward more effective risk stratification/ prognostic models that operate at a high degree of confidence (**1B**). 317 patients detailed their readiness to undergo specific procedures as part of research (**1C**); 52% being willing to undergo liver biopsy. When asked specifically about serum alkaline phosphatase, fewer than 25% of participants were confident that a reduction would lead to less acute cholangitis episodes, confer symptomatic benefit, or improved transplant-free survival **(1D**).

Conclusion: For patients, the unpredictable nature of PSC results in far-reaching feelings of helplessness and uncertainty, including toward the inconsistencies and variation in healthcare delivery. The low confidence in currently proposed surrogate end points, suggest need to develop novel non-invasive end points for clinical trials.

FRI-063

Low-dose prednisone increases the risk of adverse events in autoimmune hepatitis patients

Floris van den Brand[1,1], Ynto de Boer[1], Karin van Nieuwkerk[1], Birgit Lissenberg-Witte[2], Gerd Bouma[1]. *[1]Amsterdam UMC, location VUmc, Gastroenterology and Hepatology, Amsterdam, Netherlands; [2]Amsterdam UMC, location VUmc, Epidemiology and Biostatistics, Amsterdam, Netherlands*
Email: f.vandenbrand@vumc.nl

Background and aims: Autoimmune hepatitis (AIH) requires long-term immunosuppressive therapy. Studies on dose-related side-effects of steroids are predominantly performed in rheumatic diseases whereas data in patients AIH is scarce. We aim to assess cataract, diabetes mellitus and osteoporotic fractures during the long-term treatment of patients with AIH.

Method: Medical charts of 480 patients (77% women) with an established diagnosis of AIH were reviewed for cataract, diabetes mellitus and fractures occurring after diagnosis. Prednisone was assessed per follow-up year per mg per day and correlated with adverse events in a multivariate longitudinal generalized estimated equations model, corrected for age, gender, cirrhosis and concomitant features of primary sclerosing cholangitis (AIH-PSC) or primary biliary cholangitis (AIH-PBC). Patients who were prescribed budesonide, were censored from the date of initiation of budesonide onwards.

Results: A total of 5813 years with a median of 13 years per patient (range 1-40) were recorded. The median age at diagnosis was 44 years (range 2-88). Prednisone use increased the odds ratio for new-onset cataract and diabetes mellitus (Table) in a dose related pattern, but not of fractures. Prednisone was used by 435 (91%) patients in a median dose of 7 mg/day (1.7-34.0) during 5 years (1-39). Cataract developed in 38 (8%) and diabetes mellitus in 46 (10%) patients. In 61 (13%) patients, 88 fractures occurred including fractures of; vertebral compression (n = 31), femur and hip (n = 9), tibia or fibula (n = 8), humerus or radius or ulna (n = 18), (meta)carpal (meta)tarsal or phalanx bones (n = 14), or other (n = 8). Patients with cirrhosis at diagnosis (n = 65; 18%) were not at greater risk of fractures (p = 0.4) compared with patients without cirrhosis (n = 302; 82%).

Table: Multivariate analysis of corticosteroid related adverse events

	Cataract		Diabetes mellitus		Fracture	
	OR (95% CI)	p value	OR (95% CI)	p value	OR (95% CI)	p value
No prednisone	1.0	0.03	1.0	< 0.001	1.0	0.08
Prednisone 0.1-5.0 mg/day	1.7 (0.7-3.7)		3.7 (1.3-11.0)		2.3 (1.2-4.2)	
Prednisone 5.1-10 mg/day	2.1 (0.9-5.1)		6.7 (2.4-18.6)		1.5 (0.7-3.0)	
Prednisone > 10 mg/day	4.9 (1.7-14.2)		26.0 (8.8-76.9)		2.0 (0.7-5.8)	

Corrected for age, gender, and AIH-PSC and AIH-PBC variant syndromes.

Conclusion: Patients with AIH who were treated with prednisone had an increased risk of cataract and diabetes mellitus, but not of fractures. A dose-relation with prednisone and adverse events was observed.

FRI-064

Systematic review and meta-analysis of risk factors for recurrent primary sclerosing cholangitis

Kerem Sebib Korkmaz[1], Iris Steenstraten[1], Palak Trivedi[2,3,4], Akin Inderson[1], Bart Van Hoek[2], Mar Rodriguez Girondo[5], Jeroen Maljaars[1]. [1]*Leiden, Gastroenterology and Hepatology, Leiden, Netherlands;* [2]*Birmingham, University Hospitals Birmingham, Birmingham, United Kingdom;* [3]*Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom;* [4]*Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom;* [5]*Leiden, Department of Biomedical Data Sciences, Leiden, Netherlands*
Email: k.sebib@lumc.nl

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic inflammation of the bile ducts leading to fibrosis and eventually cirrhosis. Aetiology of PSC remains unknown and no specific treatment can delay or arrest the progressive course of the disease with orthotopic liver transplantation (OLT) remaining the only curative option. Nonetheless, recurrent primary sclerosing cholangitis (rPSC) can occur after liver transplantation (rPSC) with considerable morbidity often leading to retransplantation. In the past decade large cohorts of patients with PSC undergoing OLT were analysed to identify risk factors for rPSC. The current systematic review and meta-analysis was conducted to summarize all available data to define risk factors for rPSC.
Method: The search of the following databases was performed: Pubmed, Embase, Web of Science, Cochrane library for articles published until March 2018 using the medical subject headings sclerosing cholangitis, recurrence, liver transplantation, risk and risk factors. Studies addressing risk factors for developing rPSC after liver transplantation were eligible for inclusion in the review. Studies able to provide data to calculate hazard ratios (HR) and 95% confidence intervals (95% CI) were included in the meta-analysis. Quality of included studies was independently evaluated by two authors with the Newcastle Ottawa Scale (NOS) for cohort studies. Statistical analysis was performed using Cochrane Review Manager.
Results: The electronic database search yielded 449 results. Sixteen retrospective cohort studies met the inclusion criteria for the review. Twelve studies were included for meta-analysis. Studies scored a median of 8 points (6-9) on the NOS. After excluding possibly overlapping cohorts we analysed recurrence a total cohort of 1899 patients, with median age ranging from 31 to 49 years, 1330 were male (70.0%) and 321 developed rPSC (16.9%). We found that colectomy before OLT, HR 0.63 (95% CI: 0.41-0.99), presence of cholangiocarcinoma (CCA) before OLT, HR 2.81 (95% CI: 1.34-5.87), presence of inflammatory bowel disease (IBD), HR 1.76 (95% CI: 1.19-2.61), donor age, HR 1.02 (95% CI 1.01-1.04), MELD score per point, HR 1.05 (95% CI: 1.02-1.08) and development of acute cellular rejection (ACR), HR 2.37 (95% CI: 1.30-4.32) were associated with the risk of rPSC.
Conclusion: IBD presence, CCA before transplantation, donor age, MELD score and development of ACR were risk factors for rPSC. Performing a colectomy before liver transplantation was protective for rPSC.

FRI-065

The Amsterdam cholestatic complaints score is a valid patient reported outcome measure for cholestatic symptoms in PSC patients

Kim van Munster[1], Marcel Dijkgraaf[2], Ulrich Beuers[1], Cyriel Ponsioen[1]. [1]*Amsterdam UMC, Gastroenterology and hepatology, Amsterdam, Netherlands;* [2]*Amsterdam UMC, Clinical reseach unit, Amsterdam, Netherlands*
Email: k.n.vanmunster@amc.nl

Background and aims: The presence and intensity of symptoms such as pruritus, fatigue, abdominal pain and fever in primary sclerosing cholangitis is highly variable. In both patient care and clinical trials there is need for a validated questionnaire that accurately measures disease burden. Several studies have used the Amsterdam Cholestatic Complaints Score (ACCS), which evaluates pruritus, fatigue, abdominal pain and fever, as patient reported outcome measure. Still, the ACCS has not yet been validated. The aim of this study is to prospectively validate the ACCS in a Dutch PSC cohort.
Method: Two hundred and twelve patients from the EpiPSC 2 prospective registry were approached for a digital survey. The ACCS was compared to several validated questionnaires: The 5D-itch scale, Liver Disease Symptom Index (LDSI), a Visual Analog Scale (VAS) for itch, fatigue and pain and the EuroQol-5D-5L (EQ-5D) to measure general quality of life. Construct validity was determined using Spearman's rho correlation. To investigate if the sensitivity of the ACCS could be increased by introducing distinct questions for symptom severity and frequency, an adapted version of the ACCS was developed and tested in parallel.
Results: A total of 154 PSC patients (73%) completed the survey. The itch, fatigue and pain score and the ACCS sum score showed mostly high correlations with relevant domains of the different validated questionnaires (table 1). The item fever showed only low correlations. The adapted version of the ACCS was not superior to the original version.

Table 1: Correlations of the ACCS with other questionnaires.

		Spearman's rho (confidence limit closest to 0)			
ACCS item	Domain	ACCS		Adapted ACCS	
Itch	VAS Itch	0, 699	0, 592	0, 717	0, 622
	LDSI Itch	0, 860	0, 785	0, 831	0, 745
	5D Itch score	0, 841	0, 753	0, 860	0, 780
	EQ-5D Index	–0, 418	–0, 279	–0, 395	–0, 523
Fatigue	VAS Fatigue	0, 772	0, 685	0, 832	0, 771
	LDSI Sleepiness	0, 658	0, 543	0, 675	0, 570
	LDSI Sleepiness impact	0, 719	0, 615	0, 711	0, 609
	EQ-5D Index	–0, 641	–0, 530	–0, 628	–0, 509
Pain	VAS RUQ-A pain	0, 665	0, 548	0, 682	0, 566
	LDSI RUQ-A pain	0, 833	0, 737	0, 835	0, 739
	EQ-5D Pain	0, 540	0, 405	0, 534	0, 395
	EQ-5D Index	–0, 412	–0, 266	–0, 402	–0, 255
Fever	EQ-5D Pain	0, 255	0, 089		
	EQ-5D Index	–0, 142	–0, 284		
Sum score	EQ-5D Health status	–0, 605	–0, 486		
	EQ-5D Index	–0, 644	–0, 541		

VAS = visual analog scale, LDSI = liver disease symptom index, EQ-5D = EuroQol-5D-5L, RUQ-A = right upper quadrant abdominal

Conclusion: The ACCS is a simple and valid instrument to quantify cholestatic symptoms in PSC patients. The sum score mirrors impairment of quality of life.

FRI-066

Rituximab therapy is effective for inducing remission in IgG4-RD hepatobiliary disease: A retrospective case series

Bertus Eksteen[1], Danielle T Vannan[1], Stephanie Gysel[1,2]. [1]*Aspen Woods Clinic, Calgary, Canada;* [2]*University of Alberta, Faculty of Pharmacy and Pharmaceutical Sciences, Edmonton, Canada*
Email: bertus_eksteen@hotmail.com

Background and aims: IgG4-related disease (IgG4-RD) is a multi-organ inflammatory condition that affects the hepatobiliary system and leads to sclerosing cholangitis and autoimmune pancreatitis. First line therapy includes corticosteroids followed by immunomodulator use. However, case reports suggest that Rituximab (RTX) may be an option for corticosteroid-dependent cases following first line therapy failure. Given the paucity of data using RTX for IgG4-RD, we report our experience of RTX treatment efficacy to induce remission in our patient population.

Method: We performed a retrospective case series review of patients from our clinic with hepato-biliary IgG4-RD who had received RTX treatment. After excluding patients with overlapping PSC, we selected five cases of IgG4-RD sclerosing cholangitis who received RTX between 2014 and 2018. Patient charts were reviewed for serum IgG4 treatment response and overall outcomes. Statistical differences were compared using ratio paired t tests with significance set at $P < 0.05$.
Results: All patients were male with a mean age of 72.2 ± 1.9 years. Previous immunosuppressive exposure included prednisone dependence (5/5), azathioprine failure (5/5) and patients were maintained on either mycophenolate (4/5) or 6-Mercapto Purine (1/5) post-RTX treatment. All patients achieved clinical IgG4 remission following two 1000mg RTX infusions two weeks apart. There was a significant reduction in serum IgG4 levels ($p = 0.02$). None of the patients developed infection nor required hospitalization. There were no infusion reactions
Conclusion: Rituximab therapy is effective for inducing remission in IgG4-RD hepatobiliary disease. Patients tolerated the treatment well with no reported side effects. Larger cohort studies are required to confirm these initial findings.

FRI-067

Management of primary biliary cholangitis in the pre-obeticholic acid era, and the rate of non-response to ursodeoxycholic acid (UDCA), in a large real-world cohort of PBC patients in Italy: The CLEO-AIGO database

Umberto Vespasiani Gentilucci[1], Floriano Rosina[2], Luchino Chessa[3], Valeria Pace Palitti[4], Antonio Picardi[1], Michela Barlattani[5], Angelo Barlattani[6], Valentina Feletti[7], Alessandro Musetto[7], Teresa Zolfino[8], maurizio russello[9], Maria rita Cannavò[9], Raffaele Cozzolongo[10], Francesco Losito[10], Giovanni Garrucciu[11], Grazia Niro[12], Rosanna Fontana[12], Donato Bacca[13], Giada Cardinale[13], Alessandro Grasso[14], Silvia Storato[15], Gaetano Bertino[16], Evelise Frazzetto[16], Gaetano Scifo[17], Giuseppe D'adamo[18], Basilio Fimiani[19], Rodolfo Sacco[20], Angelo Ricchiuti[20], Antonio Ascione[21], Tundo Paolo[22], Marco Distefano[23], Pierluigi Tarquini[24], Aldo Marrone[25], Valeria Bardon[26], Francesco Di Candilo[27], Ruggiero Francavilla[25], Salvatore Madonia[28], Ernesto Claar[29], Luigi Elio Adinolfi[30], Claudio Puoti[31], Raffaele Mazziotti[32], Giuseppina Ubalducci[33], Maria D'antò[34], Carlo Clementi[35], Adriano Pellicelli[36], Antonio Izzi[37]. *[1]University Campus Bio-Medico of Rome, Internal Medicine and Hepatology, Rome, Italy; [2]Medical Team Torino, Torino, Italy; [3]University Hospital of Cagliari, Liver Unit, Cagliari, Italy; [4]ASL Pescara, Pescara, Italy; [5]ASL RM A, Rome, Italy; [6]ASL RM A, Roma, Italy; [7]Santa Maria delle Croci Hospital, Gastroenterology Unit, Ravenna, Italy; [8]Brotzu Hospital, Gastroenterology, Cagliari, Italy; [9]Arnas Garibaldi, Liver Unit, Catania, Italy; [10]National Institute of Gastroenterology "S de Bellis" Reseach Hospital, Gastroenterology Unit, Castellana Grotte (Bari), Italy; [11]Sassari University Hospital, General Medicine and Medical Pathology, Sassari, Italy; [12]Casa Sollievo della Sofferenza Institute, Gastroenterology, San Giovanni Rotondo (Foggia), Italy; [13]Casarano Hospital, Internal Medicine Unit, Lecce, Italy; [14]ASL2 Savonese, Gastroenterology, Savona, Italy; [15]Sacro Cuore Institute Don Calabria, Gastroenterology, Verona, Italy; [16]University Hospital Policlinico Vittorio Emanuele, Hepatology, Catania, Italy; [17]Umberto I Hospital, Infectious Diseases, Siracusa, Italy; [18]Umberto I Hospital ASL Salerno, General Medicine, Nocera Inferiore (Salerno), Italy; [19]Nocera Inferiore Hospital, Nocera Inferiore, Italy; [20]University Hospital, Gastroenterology, Pisa, Italy; [21]Fatebenefratelli Hospital, Hepatology, Napoli, Italy; [22]S.Caterina Novella Hospital, Infectious Diseases Unit, Galatina (Lecce), Italy; [23]Umberto I Hospital, Infectious Diseases Unit, Siracusa, Italy; [24]G. Email: u.vespasiani@unicampus.it

Background and aims: Until the recent advent of obeticholic acid (OCA), UDCA has been the only drug approved for the treatment of PBC. Response to UDCA was proved crucial for the prediction of PBC prognosis, and different response criteria were proposed by some reference centres for PBC. However, rates of non-response to UDCA from real-world series are poor or absent. Here we aimed to evaluate PBC management in the pre-OCA era, and the rate of non-response to UDCA, in a large real-world cohort of PBC patients.
Methods: Hepatology/Gastroenterology centres belonging to "Club Epatologi Ospedalieri" (CLEO) and "Associazione Italiana Gastroenterologi Ospedalieri" (AIGO) were invited to participate to the study, and asked to: 1) extract all patients followed for PBC, without any selection or exclusion, and fill in the database provided; 2) for patients already on OCA, give data concerning the last control pre-OCA.
Results: Thirty-three centres were enrolled throughout Italy, with a total of 681 patients. After excluding 74 patients (11%) diagnosed as overlap PBC/autoimmune hepatitis, 607 patients were analysed, mean age: 64.5 ± 11.9 yrs; 91.4% females; F/M 10.7/1; mean age at PBC diagnosis: 55.6 ± 12.1 yrs, mean disease duration: 8.9 ± 7.6 yrs. Ninety-six% of patients were on treatment with UDCA at a mean dose of 14.8 ± 3.9 mg/kg/day. In patients with at least 1 year of UDCA treatment (561), rates of non-response to UDCA were evaluated according to the computable ncriteria (Table). Only 3.4% of patients received second-line off-label treatments (fibrates, budesonide etc.). Compared to patients in reference studies[1-4], mean alkaline phosphatase levels on UDCA treatment, and the age-adjusted prevalence of F3/F4 fibrosis, appeared lower.

Table.:

	CLEO-AIGO UDCA NON-RESPONDERS	UDCA NON-RESPONDERS IN ORIGINAL COHORTS	REFERENCE
PARIS-I	26.4%	39%[1]	[1]Corpechot C et al, Hepatology 2008
PARIS-II	39.1%	52%[2]	[2]Corpechot C et al, J Hepatol 2011
TORONTO	20.3%	43.5%[3]	[3]Kumagi T et al, Am J Gastroenterol 2010
GLOBE (Age-specific)	15%	30%[4]	[4]Lammers W et al, Gastroenterology 2015

Conclusion: A mildly better response to UDCA is observed in a real-world PBC population from Italian centres not specifically focused on PBC/autoimmune liver diseases, probably due to migration of some of most severe/advanced cases towards reference centres. UDCA dose and compliance were optimal and, in the pre-OCA era, increasing UDCA daily dose was most common than second-line off-label treatments for non-responsive patients.

FRI-068

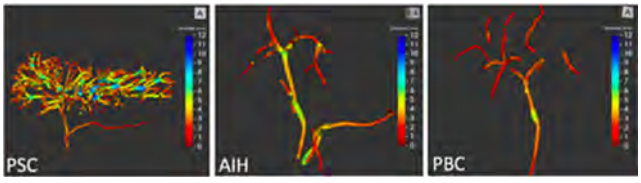
Quantitative biliary tree imaging by MRI: Evaluating new technology across patient cohorts with autoimmune liver disease

Katherine Arndtz[1], James Hodson[1], Peter Eddowes[1], Gary Woodward[2], Marija Mavar[2], Ged Ridgway[2], Carlos Ferreira[2], Andrea Borghetto[2], Matt Kelly[2], John Michael Brady[2], Rajarshi Banerjee[2], Gideon Hirschfield[3]. [1]*University of Birmingham, Centre for Liver and Gastrointestinal Research, Birmingham, United Kingdom;* [2]*Perspectum Diagnostics Ltd, Oxford, United Kingdom;* [3]*University of Toronto, Toronto Centre for Liver Disease, Toronto, Canada*
Email: gary.woodward@perspectum-diagnostics.com

Background and aims: Magnetic resonance cholangiopancreatography (MRCP) is a non-invasive imaging technique for the evaluation of biliary disease. Despite widespread use there remain limitations such as variable quality bile duct depiction and subjective assessment. We sought to understand the potential utility of quantitative MRCP (MRCP+), particularly in Primary Sclerosing Cholangitis (PSC), evaluating a well characterised cohort of prospectively imaged patients.

Method: Patients with PSC, autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC) were recruited for heavily T2-weighted MRCP imaging at base-line and 1-year follow-up. Scans were processed with MRCP+ to enhance and quantify the tubular structures. The underlying algorithms combine multi-scale Hessian analysis, gradient vector flow analysis, an intelligent path search algorithm and novel duct modelling algorithms.

Results: A total of 284 MRCP images were processed, consisting of PSC (44), AIH (35) and PBC (59) patients with both baseline and follow-up scans. PSC patients had higher biliary tree volumes (11.3ml; $p = 0.006$) and stricture scores (21; $p = 0.015$) than those with AIH (6.5ml and 10.9, respectively) and PBC (7.1ml and 10.2, respectively). Higher-risk PSC patients (ALP > 1.5xULN) had a significantly higher number of dilated ducts (14.8; $p = 0.04$) than the lower-risk PSC patients (6.9; ALP < 1.5xULN without cirrhosis). Increases in MRI-derived iron corrected T1 (cT1) whole liver inter-quartile range (a proposed measure of heterogeneous fibro-inflammation) was associated with increases in biliary tree volume (Pearson correlation $R = 0.78$-0.85, $p < 0.001$).



Conclusion: We demonstrate that quantitative MRCP (MRCP+) provides measures that have the potential to objectively differentiate patients with PSC. Quantitative biliary tree imaging, furthermore warrants investigation prospectively as a standardised application for disease and therapy monitoring in PSC.

FRI-069

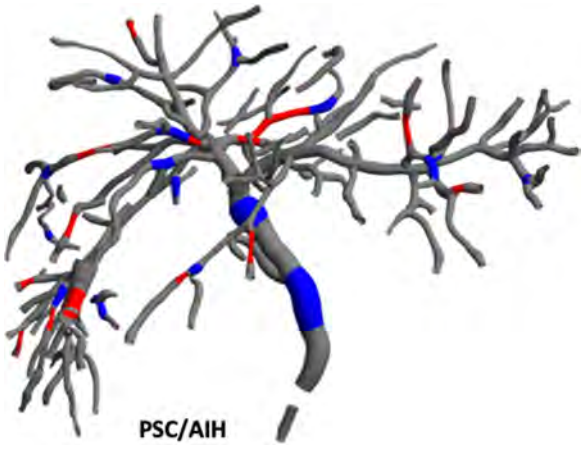
Quantitative MRCP imaging: Preliminary observations in a cohort of paediatric patients with liver and biliary diseases

Kamil Janowski[1], Gary Woodward[2], Marija Mavar[2], Ged Ridgway[2], Matt Kelly[2], Carlos Ferreira[2], Andrea Borghetto[2], Maciej Pronicki[1], Wieslawa Grajkowska[1], Malgorzata Wozniak[1], Piotr Pawliszak[1], Elzbieta Jurkiewicz[1], John Michael Brady[2], Rajarshi Banerjee[2], Piotr Socha[1]. [1]*The Children's Memorial Health Institute, Department of Gastroenterology, Hepatology, Nutritional Disorders and Pediatrics, Warsall, Poland;* [2]*Perspectum Diagnostics Ltd, Oxford, United Kingdom*
Email: K.Janowski@IPCZD.PL

Background and aims: Magnetic resonance cholangiopancreatography (MRCP) is commonly used for the evaluation of biliary disease but has significant limitations, including variable quality bile duct depiction and subjective assessment. This is particularly true in paediatric assessment, where biliary changes may be less advanced. We sought to understand the potential utility of quantitative MRCP (MRCP+™)in paediatric patients, particularly those with overlapping autoimmune hepatitis (AIH) and Primary Sclerosing Cholangitis (PSC).

Method: Recruited patients (6-18 yrs; AIH (51), AIH/PSC (10), Wilson's disease (6), other (7)) and 21 healthy controls underwent multi-parametric MRI with LiverMultiScan™ and heavily T2-weighted three-dimensional MRCP imaging for MRCP+ processing to enhance and quantify the tubular biliary structures and assess liver parenchyma. The underlying algorithms combine multi-scale Hessian analysis, gradient vector flow analysis, an intelligent path search algorithm and novel duct modelling algorithms.

Results: PSC patients had an increased number of candidate strictures and dilatations (defined as a change in diameter > 30%) than healthy controls ($p = 0.007$) and AIH patients ($p = 0.019$). Furthermore, the percentage severity of strictures and total length of dilated and strictured regions were greater in PSC patients than healthy controls ($p = 0.019$; $p = 0.008$) and AIH patients ($p = 0.045$; $p = 0.035$). AUROCs of 0.80-0.95 were observed for a range of quantitative biliary metrics assessing AIH/PSC against Health or AIH patient groups. Increases in MRI-derived iron corrected T1 (cT1) whole liver inter-quartile range (which can reflect heterogeneity of fibro-inflammation) was associated with increases in the total length of dilated and strictured regions (Pearson's correlation $R = 0.88$; $p = 0.05$), suggesting parenchymal disease association with biliary metrics.



Conclusion: We report findings demonstrating that quantitative MRCP (MRCP+) provides measures that could objectively differentiate patients with PSC from healthy or other liver disease patients, with potential for monitoring and severity assessment applications.

FRI-070

Long-term clinical outcomes in patients with autoimmune hepatitis according to treatment response in Asian country

Sun Yoo[1], Jonggi Choi[2], Gwang Hyun Choi[2], Danbi Lee[2], Ju Hyun Shim[2], Young-Suk Lim[2], Han Chu Lee[2], Young-Hwa Chung[2], Yung-Sang Lee[2], Kang Mo Kim[2]. [1]*Asan Medical Center, University of Ulsan College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South*
Email: kimkm70@amc.seoul.kr

Background and aims: As surrogate markers for autoimmune hepatitis (AIH), serum alanine aminotransferase (ALT) and immunoglobulin G (IgG) are convenient to measure and follow-up under immunosuppression by international guidelines. However, the long-term prognosis of patients who achieve complete biochemical

remission (CBR) in comparison with patients who achieve only biochemical remission (BR) is uncertain.
Method: A total of 291 patients (89.7% female) diagnosed with AIH were retrospectively evaluated by reviewing electronic medical records. Liver biopsy was done in 231 (79.4%) of patients. According to International Autoimmune Hepatitis Group revised criteria, 200 (68.7%) and 91 (31.3%) patients met criteria for definite and probable AIH, respectively. BR was defined as normal serum ALT levels after starting treatment, while CBR was defined as normal serum ALT and IgG levels. Liver-related outcomes included liver-related death, liver transplantation, and development of hepatocellular carcinoma.
Results: With immunosuppressive treatment, 168 (57.7%) patients achieved CBR, 87 (29.9%) patients achieved only BR, and 36 (12.4%) patients did not achieve remission within 1 year after starting treatment. With a median follow-up duration of 6.6 years (range: 0.6—21.2 years), the annual incidence of liver-related mortality was lower in patients with CBR (0.25/100 person-years [PY]) than in patients with BR (0.72/100 PY), although this difference was not statistically. Twenty-seven liver-related adverse outcomes occurred. The annual incidence of liver-related adverse outcomes was significantly higher in patients with BR than in patients with CBR (2.06/100 PY vs 0.58/100 PY, P = 0.003)
Conclusion: Patients who achieved CBR had a lower risk of liver-related adverse outcomes than patients who only achieved BR, suggesting that CBR is a more reliable surrogate marker to reflect long-term clinical outcomes in AIH patients.

FRI-071

AMA-positives without PBC and healthy subjects have similar bile acid profiles but are different from PBC patients

Stephan Zandanell[1], Julia Tevini[2], Alexandra Feldman[1], Michael Strasser[1], Thomas Felder[2], Christian Datz[3], Elmar Aigner[1].
[1]Paracelsus Medical University, First Department of Medicine, Salzburg, Austria; [2]Paracelsus Medical University, Institute for Medical-Chemical Laboratory Diagnostics, Salzburg, Austria; [3]Oberndorf Hospital, Department of Internal Medicine, Oberndorf, Austria
Email: e.aigner@salk.at

Background and aims: Antimitochondrial antibody (AMA) positivity may precede the development of primary biliary cholangitis (PBC). It is unclear whether changes in serum bile acid (BA) composition already occur in subjects with AMA but without the clinical diagnosis of PBC. We therefore aimed to determine the serum BA profile across the clinical spectrum of AMA-positivity including subjects with known PBC (UDCA responders and non-responders), newly diagnosed PBC, AMA-positives without PBC, AMA-negatives (negative AMA at second testing) and healthy controls in order to identify potential changes in BA homeostasis that may be linked to early mechanisms of disease in AMA-positivity.
Method: We identified 446 subjects (85 males, 361 females) tested positive for AMA over a ten-year period. To assess the subsequent clinical and biochemical course, these subjects were invited for a follow-up visit. Clinical follow-up data were determined in 271 subjects after 6.8 ± 5.1 years. Serum BA profiles were available in 161 subjects. By the time of follow-up, 87 patients had died. Composition of the BA pool in those 161 patients was compared to 59 age-matched healthy controls (28 males, 31 females). Concentrations of 20 serum bile acids were measured using a commercially available mass spectrometry based kit (Biocrates Lifesciences®, Innsbruck, Austria).
Results: AMA-positives without PBC showed similar CDCA concentrations compared to healthy controls, but only controls were significantly lower than PBC patients ($p < 0.05$).
Conjugated primary BAs glycocholic acid (GCA), glycochenodeoxycholic acid (GCDCA), taurocholic acid (TCA) and taurochenodeoxycholic acid (TCDCA) were all higher in treated PBC patients compared to AMA-positive subjects without PBC and healthy controls ($p < 0.05$). Regarding conjugated secondary serum bile acids glycodeoxycholic acid (GDCA) and taurodeoxycholic acid (TDCA), AMA-positive subjects without PBC had similar concentrations compared to PBC groups and were higher compared to healthy subjects ($p < 0.05$). Glycoursodeoxycholic acid (GUDCA) was higher in UDCA treatment responders compared to AMA-positives without PBC and controls ($p < 0.001$), while tauroursodeoxycholic acid (TUDCA) was higher in both PBC groups compared to AMA-positives without PBC ($p < 0.001$) but not controls ($p = 0.30$).
Conclusion: AMA-positive subjects were characterized by a serum BA profile similar to that of healthy controls except increases of conjugated secondary bile acids GDCA and TDCA, which showed similar concentrations to those in PBC patients.
Patients with PBC (UDCA responders and non-responders) have significantly increased primary and secondary conjugated serum BA concentrations.
These findings suggest that rises in GDCA and TDCA may represent an early finding of altered BA homeostasis in AMA positives without clinically overt PBC.

FRI-072

Alteration of glucocorticoid metabolism in patients with cholestasis

Verena Schwetz[1], Hansjörg Schlager[2], Barbara Obermayer-Pietsch[1], Tatjana Stojakovic[3], Günter Fauler[3], Peter Fickert[2], Gernot Zollner[2].
[1]Medical University of Graz, Division of Endocrinology and Diabetology, Department of Internal Medicine, Graz, Austria; [2]Medical University of Graz, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Graz, Austria; [3]University Hospital Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostic, Graz, Austria
Email: gernot.zollner@medunigraz.at

Background and aims: Cholestasis might lead to an impairment of adrenal function. Bile acid and adrenal steroid metabolism share the precursor cholesterol. In addition, the bile acid receptors farnesoid X receptor (FXR) and the G protein-coupled bile acid receptor 1 (TGR5) are expressed in the adrenal glands. Previous findings from our group have shown that mice fed bile acids or subjected to common bile duct ligation develop hypercortisolemia. We thus aimed to assess adrenal gland function in patients with cholestasis.
Method: Adrenal gland function was assessed in 36 patients with cholestasis and in 33 hospitalized patients without cholestasis. Total serum cortisol, adrenocorticotropic hormone (ACTH), aldosterone and dehydroepiandosterone-sulfate (DHEAS) were measured. In addition, relative increase of cortisol (delta cortisol) was calculated in 39 patients 20 and 30 minutes after administration of 1 µg-ACTH as a marker of relative adrenal insufficiency. Bile acid levels and bile acid pool composition were determined by high-resolution mass spectrometry.
Results: Patients with cholestasis per definition had markedly elevated levels of alkaline phosphatase (AP) (median 403 U/L, interquartile range (IQR) 229-664), bilirubin (median 7.4 mg/dL, IQR 2.8-12.2) and serum bile acids (median 157 µmol/L, IQR 23-223). Baseline cortisol (223.2 ± 59.4 versus 186.1 ± 62.3 ng/ml, $p = 0.014$) and maximum cortisol after ACTH stimulation (331.2 ± 56.4 versus 285.9 ± 47.8 ng/ml, $p = 0.015$) was significantly higher in patients with cholestasis compared to controls. Levels of delta cortisol, ACTH, DHEAS and aldosterone were comparable between both groups. In the cholestasis group, baseline cortisol correlated with bilirubin (Spearman's rho = 0.503, $p = 0.002$), but not with AP, total serum bile acids and levels of conjugated and unconjugated bile acid species. Patients with duration of cholestasis < 6 months ($n = 30$) had significantly higher baseline cortisol levels than those with long standing cholestasis (> 6 months, $n = 6$; 232.3 ± 59.9 versus 178.1 ± 31.2 ng/ml, $p = 0.04$).
Conclusion: Glucocorticoid but not mineralocorticoid homeostasis is altered in patients with cholestasis. Elevated serum cortisol levels in patients with cholestasis correlate with bilirubin as a marker of disease severity. ACTH stimulation leads to an adequate rise in cortisol levels thus excluding relative adrenal insufficiency. Lack of

ACTH increase in cholestasis indicates a direct effect of cholestasis on adrenals and not on the pituitary gland. Further studies are needed to elucidate the mechanism of cortisol elevation in patients with cholestasis and its clinical significance.

Acute liver failure and drug induced liver injury

FRI-076

On the role of inflammation in acute paracetamol injury

Saleh Alabbas[1,2], Ramya Movva[2], Jakob Begun[1,2], Timothy Florin[1,2], Iulia Oancea[1,2]. [1]*Faculty of Medicine, University of Queensland, Brisbane, Australia;* [2]*Mater Medical Research Institute, Brisbane, Australia*
Email: s.alabbas@uq.edu.au

Background and aims: Paracetamol (acetaminophen; APAP) is one of the most commonly used medications and is generally considered a safe analgesic, although misuse and overdoses do occur with serious consequences. APAP is primarily metabolized in the liver, and overdose causes hepatic injury that is mediated by APAP-generated metabolites triggering oxidative stress and inflammation. We are interested in the role of the gut-liver axis in acute hepatic injury because it has been implicated as a possible contributory factor in the development of chronic liver diseases such as alcoholic liver disease. We investigated the effect of APAP injury in a rodent model with gut inflammation, the *Winnie* (*Win*) mouse model.
Method: 5 to 6-week-old C57Bl/6 (WT) and *Win* mice were challenged with i.p. injections of 500 mg/kg of vehicle control (saline only) or APAP. Mice were euthanized 9-hour post administration. Colon length and weight were measured. Liver weights were measured, and samples were collected for HandE staining. Visiopharm™ software used to quantify area of liver necrosis. Cytokine expression measured using qPCR from liver samples.
Results: Our data show that 9-hours after APAP administration there is significant liver necrosis in WT and *Win* mice compared to vehicle controls ($p = 0.0001$ and $p = 0.0004$, respectively). Interestingly, the amount of liver necrosis was significantly higher in *Win* mice compared to WT mice ($p = 0.008$). Liver weights were not affected by APAP challenge. Inflammatory cytokines expressions were upregulated in liver tissues following APAP challenge. In this experiment, colon sizes were significantly different following APAP administration. There was a statistically significant reduction in the colon lengths of animals challenged with APAP compared to saline control (WT, $p = 0.004$; *Win*, $p = 0.001$). The weights of shorter colons were comparable to the weights of saline mice.
Conclusion: In our study, we have demonstrated that APAP can induce significant liver injury as shown by the total area of necrosis as early as 9-hour post administration. Interestingly, the amount of liver injury due to APAP was significantly higher in *Win* compared to WT mice. It is important to note that *Win* mice develop spontaneous colitis leading to a point mutation in the Muc2 gene, and this leads to increased intestinal inflammation and gut permeability. These differences between WT and *Win* mice highlight the potential impact of the liver-gut axis on the severity of liver disease and injury. These findings raise the question of how altered gut permeability and inflammation leads to enhanced injury and whether it is due to an already primed immune system due to gut inflammation or due to enhanced bacterial translocation occurring. It also raises the question of whether patients with chronic gut inflammation may be at increased risk for paracetamol induced liver injury.

FRI-077

Influence of drug categorization according to labelling information in the phenotypic presentation of drug-induced liver injury (DILI): An analysis in the Spanish DILI registry

Laura Sanz-Villanueva[1], Cecilio Parra-Martinez[1], I Medina-Caliz[1], J Sanabria-Cabrera[1], M Robles-Díaz[1], A Ortega-Alonso[1], J Gasca[1], Rocío Sanjuan-Jimenez[1], MR Cabello[1], Miren Garcia Cortes[1], Maria Isabel Lucena[1], A González-Jiménez[1], Raul J. Andrade[1]. [1]*UGC Aparato Digestivo y Servicio de Farmacología Clínica, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Universitario Virgen de la Victoria, Universidad de Málaga, CIBERehd, Malaga, Spain*
Email: laurasanz@uma.es

Background and aims: The Liver Toxicity Knowledge Base (LKTB) has classified the hepatotoxic potential of drugs according to drug-labelling information into four categories (Chen M. et al 2011). We aimed to analyze the performance of this classification and its clinical correlation using the Spanish DILI Registry database.
Method: We classified demographics, clinical and laboratory data of 864 DILI cases from the Spanish DILI Registry induced by 188 causative drugs into the four LTKB groups: "adverse reactions," "warning and precautions," "box warning" and "withdrawn." Of the total number of drugs included in the Spanish DILI Registry, 7 were unclassified by LKTB and 49 were not included in LTKB.
Results: One hundred one cases (22%) had safety information included in the adverse reactions group; 269 (54%) in warnings and precautions; 72 (14%) in box warning; and 48 (10%) in the withdrawn group. Age and sex distribution were similar between groups with mean values of 53-57 years and 39-57% female, respectively. Diabetes mellitus ($p = 0.058$) and hypertension ($p = 0.010$) were more frequent in drugs with less stringent regulatory status. Except for median daily dose that was significantly lower in DILI cases related to drugs in the adverse reactions group ($p < 0.001$), this group and the warning and precautions group did not differ in any of the other variables analyzed. DILI cases related to drugs in the box warning and withdrawn groups presented with longer latency ($p < 0.001$), hepatocellular damage ($p = 0.004$) and higher TBL and ALT and lower ALP values ($p < 0.001$), more frequently fulfilling Hy's Law ($p = 0.016$) compared to the remaining groups. The fraction of cases with physicochemical properties linked to a higher risk of hepatotoxicity (lipophilicity + daily dose $\geq$ 100 mg [R02], R02 + reactive metabolite formation [R03]) was low across the 4 groups with percentages of 11-27 and 0-16, respectively.
Conclusion: Classification of drug hepatotoxic potential according to the LTKB system shows good correlation with standard clinical and laboratory parameters of severity in DILI. Overall, the drugs with physicochemical properties believed to be associated with DILI risk were scarcely represented and did not correlate with increasing hepatotoxic potential according to labelling information in the Spanish DILI Registry. Analysis of hepatotoxicity drug-labeling information in bona fide DILI cases may help to refine liver safety drug classification.

Email: bessonefernando@gmail.com

Background and aims: Nimesulide (N) is a potent non-steroideal antiinflamatory drug with analgesic and antipyretic properties, that is still marketed in many countries around the world. **Aim:** To analyze the clinical phenotype, outcome, and histological features in the largest series of N-induced liver injury (N-DILI) reported so far.
Method: We analyzed 57 Argentinian and Spanish N-DILI cases, recruited from 1988 to 2009. Other causes of liver diseases (viral, autoimmune, metabolic, obstructive, alcohol and ischemic) were ruled out. Demographics, clinical presentation, laboratory findings, and outcome were analyzed. Causality was assessed by RUCAM scale.
Results: Forty six (81%) patients were women (59 ± 16 years). Mean N dose was 200 mg/day, mostly prescribed for pain (arthritis and traumatisms). Mean time to onset 68 ± 81 days (range: 3-466 days). Forty six patients (81%) presented jaundice, and 60% of them required hospitalization. Hepatocellular, mixed and cholestatic patterns were present in 37 (65%), 12 (21%)and 8 (14%) of patients, respectively. Liver test mean values (xULN) were: ALT 17 ± 19, AST 19 ± 26 andALP 2.0 ± 1.5, whereas total bilirubin was13 ± 11 mg/dL. Liver histology was obtained in 14/57 (25%) patients, with a wide spectrum of liver lesions observed including: hepatocellular (hepatitis, massive and submassive necrosis), mixed (cholestatic hepatitis with and without eosinophilia), and pure cholestasis patterns. Mean time to recovery in 49 (86%) patients was 79 ± 88days (range: 6-550 days). Severity index was severe in11 (18%) and fatal in 6 (10.5%)patients. Eleven (19%) patients developed acute liver failure (ALF) of whom 5 recovered spontaneously. RUCAM scale was "probable" in 18 (32%), "possible" in 12 (21%), and "highly probable" in 27 (48%) patients. Comparing the cases with latency < 15 days (n = 12) with those with > 15 days (n = 45) did not show significant differences in terms of age, gender, symptoms, liver tests, results, and presence of ALF. Immunoalergic features were not detected in any case at presentation.
Conclusion: Nimesulide-induced DILI presented mainly in women with hepatocellular damage and was associated with ALF and death in a high proportion of patients. Latency < 15 days did not lead to less severe forms of liver injury aspreviously reported.

FRI-079

HLA B*14:01 is associated with Trimethoprim-sulfamethoxazole induced liver injury

YI-JU Li[1], Andrew Dellinger[2], Paola Nicoletti[3], Robert FONTANA[4], Paul Watkins[5], Huiman Barnhart[1], Elizabeth Phillips[6], Naga Chalasani[7]. [1]Duke University Medical Center, Department of Biostatistics and Bioinformatics, Durham, United States; [2]Duke Molecular Physiology Institute, Durham, United States; [3]Icahn School of Medicine at Mount Sinai, Department of Genetics and Genomic Science, New York, United States; [4]University of Michigan, Ann Arbor, United States; [5]University of North Carolina, Chapel Hill, UNC Eshelman School of Pharmacy, Chapel Hill, United States; [6]Vanderbilt University, Nashville, United States; [7]Indiana University School of Medicine, Division of Gastroenterology and Hepatology, Indianapolis, United States
Email: nchalasa@iu.edu

Background and aims: Trimethoprim-sulfamethoxazole (TMP-SMZ) is a common cause of drug induced liver injury (DILI). Variations in the HLA locus are the most common genetic risk factor for idiosyncratic forms of DILI, but their role in the pathogenesis of TMP-SMZ DILI is unclear. We conducted a study to investigate the relationship between genetic variants in the HLA I and II loci and TMP-SMZ DILI.
Method: We studied Caucasian TMP-SMZ DILI cases with definite, highly likely, or probable causality scores enrolled into the DILIN and population controls from eMERGE-I (phs000360.v3.p1 in dbGaP). We performed HLA sequencing on all TMP-SMZ DILI cases by Illumina MiSeq platform, and imputed the HLA for eMERGE-1 controls using the variants in the MHC region by HLA genotype imputation with attribute bagging (HIBAG) program. Fisher exact tests were used to test the allele frequency (AF) difference between cases and controls. Considering the rare nature of TMP-SMZ DILI, we used Firth logistic regression to test HLA effect with sex adjusted. We selected top alleles based on false discovery rate (FDR) ≤ 0.2, and performed haplotype association tests by haplotype score tests (haplo.stats R package) for two and three loci windows within Class I and II, respectively.
Results: There were 51 TMP-SMZ DILI cases and 12, 402 eMERGE-I controls of European descent. Selected characteristics of DILI cases were: 55% female, mean age 48.6 years, median peak ALT 506 IU/L, and median peak bilirubin 7 mg/dL. Thirteen HLA alleles met the FDR ≤ 0.2 threshold, with *B*14:01*, *DQA1*05:01*, and *DQA1*05:05* exhibiting the most significant associations (FDR < 0.05). However, the imputed *DQA1* alleles in controls were unreliable due to the discrepancy of their AF to published population AF (eg, AF = 0.126 vs. 0.25 for *DQA1*05:01*). The *B*14:01* was significantly more frequent among cases than controls (4.9% vs 0.09%, p = 0.002), and differences remained significant in Firth models (OR = 8.69; 95% CI: (3.18, 19.45); $p = 2.3 \times 10^{-4}$). Interestingly, all five *B*14:01* carriers also possessed *C*08:02*. This pattern was further confirmed by the significant association between the *C*08:02-B*14:01* haplotype and TMP-SMZ DILI ($p = 1.33 \times 10^{-5}$). Latency, serum enzyme levels, severity scores, and outcomes of individuals carrying *HLA B*14:01* were not different from others without this variant.
Conclusion: *HLA B*14:01* is significantly associated with TMP-SMZ DILI in Caucasians. This relationship may be linked to *HLA B*14:01-C*08:02* haplotype.

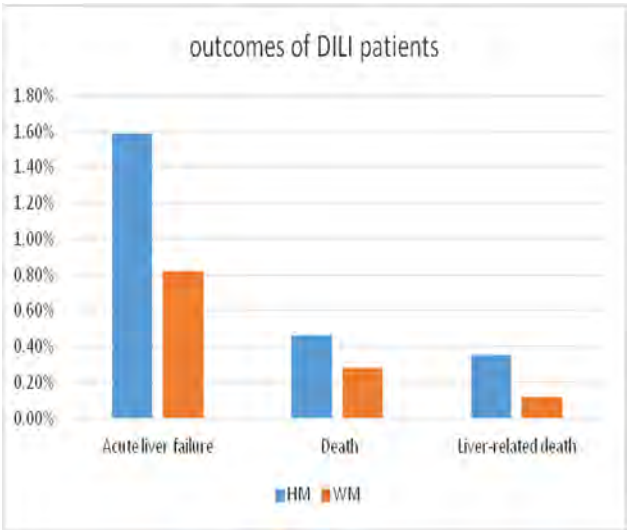
Herbal medicines induces severe liver injury than western medications: A nationwide multicenter retrospective research

Jun Chen[1], Xinyu Liu[2], Rongtao Lai[3], Yimin Mao[4], Chengwei Chen[5]. [1]The third Hospital of Shenzhen, Department of Liver Diseases, Shenzhen, China; [2]Third Xiangya Hospital, Changsha, China; [3]Ruijin Hospital, Shanghai, China; [4]Renji Hospital, Shanghai, China; [5]85th Hospital, Shanghai, China
Email: chenjun66@csu.edu.cn

Background and aims: Herbal medicines (HM) are widely used, however, the clinical features of HM-induced liver injury are not yet clarified. This study aims to intensive investigate the differences between HM DILI and western medications (WM) DILI.
Method: A nationwide multicenter retrospective research among 308 medical centers in major cities of China.29, 478 DILI patients, who were hospitalized from January 1, 2012 to December 31, 2014. Patients whose RUCAM scores are more than 6 just took either only HM or only WM as causative agent of DILI were analyzed. The data on demographics, clinical characteristics, suspicious drugs, and outcome assessments of eligible cases were collected and systematically evaluated.
Results: A total of 3711 HM and 8859 WM cases were enrolled in the study. The mean age of the HM group was 48.24 ± 14.64 years, and that of the WM group was 44.70 ± 17.19 years (p < 0.0001). Females (59.3%)were predominant in the HM group. The average serum level of ALT, AST, ALP, TBIL and DBIL at baseline and peak value was significantly higher in the HM group (p < 0.0001). Although the general mortality of the two groups did not differ significantly (p = 0.1491), the liver-related death varied significantly between HM group and WM group (0.35%vs0.12%, p = 0.0369). The incidence of Hy's cases, acute liver failure, and chronic DILI was more frequent in

the HM than the WM group (45.03% vs.14.13%, 1.59% vs.0.82%, 14.4% vs.8.78%, respectively).



Conclusion: Depending on clinical characteristics and outcomes, HM might cause severe liver injury and liver-related mortality than WM.

FRI-081

Characterisation of severe liver injury induced by immune checkpoint inhibitors

Yana Davidov[1], Afif Yaccob[2], Orit Pappo[3], Nora Balint-Lahat[3], Oranit Cohen-ezra[1], Maria Lihter[1], Itai Kalisky[1], Ziv Ben Ari[1,4], Ella Veitsman[2,5]. *[1]Sheba Medical Center, Tel Hashomer, Ramat Gan, Liver Diseases Center, Ramat Gan, Israel; [2]Rambam Health Care Campus, Center for Liver Disease, Haifa, Israel; [3]Sheba Medical Center, Tel Hashomer, Ramat Gan, Ramat Gan, Israel; [4]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel; [5]Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel*
Email: y.davidov@gmail.com

Background and aims: Immune checkpoint inhibitors (ICI) are established treatment for different oncologic disease. Immune-relate adverse events associated with ICI are rare complication. Immune mediated hepatitis (IMH) is detected in 3.5% of cases. The aim of our study was to detect an association between the clinical presentation, pattern of histological findings and treatment.
Method: A multicenter retrospective observational study of 10 patients treated with ICI that were referred to the liver units for grade ≥ 3 hepatitis. Of them, 4 received anti-programmed cell death protein 1 (PD-1) (nivolumab, pembrolisumab), 3 received anti-cytotoxic T lymphocyte antigen 4 (CTLA-4) in combination with anti-PD-1 (nivolumab, ipilumumab), 2 received anti-PD-1 in combination with adenosine A2a receptor antagonists (pembrolisumab, preladenat) and 1 received anti PD ligand 1 in combination with paclitaxel. Liver investigations were undertaken in all patients, including viral assays, autoimmune tests and liver biopsy, histological review. Immunostaining of liver specimens was performed in few.
Results: Ten patients were included, median age was 58 years, 6 (60%) were male. Median time between immunotherapy initiation and the development of IMH was 4 (range, 1-7) weeks and median number of immunotherapy injections was 2 (range, 1-3). 7 patients (70%) developed grade 4 IMH (AST or ALT > 20 times ULN, bilirubin > 10 times ULN), all of them demonstrated similar histologic pattern: portal edema, cholangiolar proliferation accompanied by neutrophils and bile duct damage. 6 of the 7 patients had pericentral necrosis as well. 3 patients developed grade 3 IMH (AST or ALT > 5 and < 20 times of ULN, bilirubin > 3 times ULN). Liver biopsy performed in 2, disclosed a distinguished histologic pattern: lobular hepatitis with ill formed granuloma in one (combination of CTL-4 and PD-1) and minimal portal and lobular hepatitis in the second (combination of PD-L1 with paclitaxel). 5 patients (three grade 4 IMH and two grade 3) improved after oral corticosteroids. 5 patients (50%) (four grade 4 IMH patients and one grade 3) failed to improve after methylprednisolone pulse therapy 500 mg/day and required the addition immunosuppressive drug; 4 patients improved. 2 patients died; one due to liver failure associated with the IMH and the second due to the progression of the primary oncological disease after cessation of ICI treatment. In one patient, immunotherapy was reintroduced with IMH recurrence.
Conclusion: ICI for metastatic cancer can be associated with IMH. Liver biopsy is helpful for the evaluation of the severity of injury and diagnosis. IMH may have different clinical and histological pattern. The management is tailored according to the severity of the IMH. The severe liver injury and outcome detected in our study might reflect the late referral of severe cases. Larger studies are required to confirm our results.

FRI-082

Super stealth immunoliposomes as a strategy to overcome liposome-induced liver toxicity

Daniela Gabbia[1], Elena Canato[1], Valentina Carraro[2], Lorenzo Tomasini[1], Guido Maria[2], Gianfranco Pasut[1], Sara De Martin[1,1]. *[1]University of Padova, Dept. Pharmaceutical and Pharmacological Sciences, Padova, Italy; [2]University of Padova, Dept. of Medicine, Padova, Italy*
Email: sara.demartin@unipd.it

Background and aims: Immunoliposomes (ILs) are nano-delivery systems functionalized with monoclonal antibodies or antibody fragments, with the double aim of ameliorating the pharmacokinetics and tolerability of incapsulated drugs and permitting targeted therapy. Binding poly-ethylene-glycol (PEG) chains to their surface, thus obtaining stealth ILs, delays their elimination, which is mainly due to the clearance operated by the reticuloendothelial system (RES). Recently, to further improve their biopharmaceutical and pharmacokinetic features, the so called "super stealth liposomes" have been proposed, by adding mPEG-dendron-phospholipids. However, these nano-sized materials can accumulate in the liver and cause hepatic toxicity. On the basis of these considerations, the aim of this study was to evaluate, at the histological and molecular level, the *in vivo* liver toxicity of two formulations, one of stealth (SIL) and one of new super-stealth IL ($SSIL_2$), both loaded with doxorubicin, in Sprague-Dawley rats.
Method: A dose of 2.5 mg/kg of doxorubicin-loaded immunoliposomes (SIL and $SSIL_2$) was administered via caudal vein to Sprague-Dawley female rats (n = 3 per group) and vehicle-administered rats were used as controls. Rats were sacrificed 48 hours after the treatment. Hepatic toxicity of the formulations was assessed by: 1) standard histological analysis performed on 5-µm sections of liver tissues stained with HandE; 2) mRNA hepatic expression of IL-1β, IL-6 and TNF-α; 3) reactive oxygen species (ROS) concentration in liver tissues. The results were compared by one-way ANOVA followed by Dunnett's *post-hoc* test. $p < 0.05$ was considered statistically significant.
Results: Rats treated with SIL showed hepatic histological alterations, i.e. numerous granulomatous lesions, sometimes associated with apoptotic bodies, whereas in rats treated with $SSIL_2$ only few isolated granulomas could be observed in the otherwise healthy livers. The expression of both IL-1β and TNFα was significantly increased only in in SIL-treated rats ($p < 0.001$ vs controls) and did not change in $SSIL_2$-treated rats with respect to controls. Accordingly, the concentration of hepatic ROS increased significantly in SIL-treated rats ($p < 0.001$ vs controls) and was comparable to that of controls in $SSIL_2$-treated rats.
Conclusion: SILs are able to induce dramatic alterations of the hepatic parenchyma, probably due to their preferential deposition in hepatic tissue, which is particularly rich in RES cells. Conversely, $SSIL_2$

caused only limited histological liver alterations. Therefore, $SSIL_2$s, besides their pharmacokinetic advantages, permit to overcome the hepatic toxicity caused by SIL administration, thus representing a smart strategy to improve the tolerability of cancer therapy.

Background and aims: Acute liver failure (ALF) is a rare but serious condition but no specific etiology is found in 20 to 30% of cases. These undetermined cases have a poor prognosis and higher death rate post transplantation. The aim of this study was to evaluate if in patients who develop ALF of unknown cause (ALF-UC) acetaminophen use below toxicity threshold impacts on the prognosis.
Method: This study is an ancillary program from HASIPRO: a multicenter prospective French cohort study aimed to investigate prognostic factors related to ALF-UC and looking for new etiologies. ALF-UC is defined by INR up to 1.5 without any identified cause at diagnosis. To be enrolled in the cohort, patients should have not taken more than 3 g/day of acetaminophen and acetaminophen would not be the cause of ALF according to physicians' discretion.
Results: From june 2013 to dec 2016, 70 patients with ALF-UC were included: 27 patients (median age: 42y[22-80]; women: 51, 85%) took acetaminophen and 43 (45y[18-82); 74, 42%] with no acetaminophen use. In the acetaminophen group, patients used a median dose of 3 [0, 85-8] g/day. At baseline there is no significant difference between both group except for median AST level (acetaminophen: 2442UI/L [21-18 330]; non-acetaminophen: 610UI/L [46-12 788]; P = 0.007), ALT level (acetaminophen: 2150UI/L [30-10 349]; non-acetaminophen: 732UI/L [71-8506]; P = 0.005) and phosphatemia level (acetaminophen: 0, 65 mmol/L [0, 35-1, 6]; non-acetaminophen: 0.9 [0.4-1.6]; P = 0.039). Median MELD score was 27 [11-40], no statistically different between both groups. Survival rate without transplantation at 3 month wasn't different between both groups (p = 0.15). In the acetaminophen group, 10 patients were transplantated and 20 in the other group (p = 0.43). Median time to transplantation was 4.5 [1-33] days versus 3 [1-48] days (p = 0.47). Death rate in the acetaminophen group was 11.1% and 16.3% in the other group (p = 0.73).
Conclusion: In patients with ALF-UC, use of acetaminophen does not impact the prognosis. Despite a clinical-biological profile compatible with an ALF induced by acetaminophen with higher AST level and lower phosphatemia, acetaminophen alone could not explain patient's phenotype.

GST and NRf2 gene mutations predisposing to acetaminophen toxicity are currently on going. Results will be presented during the meeting.

FRI-084

Targeting Toll-Like Receptor 4 signalling with TAK-242: A novel therapy for acute liver failure

Cornelius Engelmann[1,2], Mohammed Sheikh[1], Simone Novelli[1], Thomas Berg[2], Annarein Kerbert[1], Abeba Habtesion[1], Nathan Davies[1], Fausto Andreola[1], Rajiv Jalan[1]. *[1]Liver Failure Group-ILDH, University College London, London, United Kingdom; [2]Section Hepatology, University Hospital Leipzig, Leipzig, Germany*
Email: cornelius.engelmann@medizin.uni-leipzig.de

Background and aims: Acute liver failure (ALF) is associated with multi-organ injury and poor prognosis. Toll-like receptor 4 (TLR-4) ligands, lipopolysaccharides (LPS) and damage associated molecular patterns (DAMPs), are increased in ALF and knocking out TLR4 protects from ALF. This study aimed to evaluate whether the TLR4 signalling pathway was altered in a rodent ALF model and whether TLR4 inhibition would be a potential therapy.
Method: ALF was induced in Sprague Dawley rats (n = 10/group) by injecting Galactosamine (GalN) (400 mg/kg) and LPS (0.05 mg/kg i. p.). Animals were treated with TAK242 (TLR4 Inhibitor, 10 mg/kg) or saline i.p. 45 min after ALF induction. Biochemistry, ELISA, mRNA TLR-pathway expression, brain water content, TUNEL staining and immunohistochemistry were used to assess the effect of treatment on organ injury. Immortalised human monocytes (THP-1) and hepatocytes (HHL5) were incubated with LPS (100 and 2000ng/ml)±TAK242 (200nM) *in vitro* and their responses were measured with IL1b-ELISA or TUNEL staining, respectively.
Results: LPS incubation led to a dose-dependent increase in IL1b secretion and apoptosis in THP-1 and HHL5 cells, respectively. LPS response in both cell lines could be abrogated by co-incubation with TAK242 (THP-1 LPS100 ng/ml: IL1b 42.4pg/ml±8.3 vs. 24.7pg/ml±9.1; HHL5 LPS100 ng/ml: TUNEL positive cells 72%±21.6 vs. 20.7%±9.5). TAK242 reduced the severity of acute liver injury evidenced by lower ALT levels (355.1IU±155.7 vs. 275.6IU±176.9, p = 0.246) and declined apoptotic areas within the liver (p = 0.004). Circulating cytokines IL1b (p < 0.001), TNFa (p = 0.002) and IL10 (p = 0.306) were reduced by TAK242. Whilst the brain water content was lower (p = 0.004), creatinine levels remained unchanged but apoptotic areas within the kidney were reduced (p = 0.06) by treatment. mRNA expression of TLR4-related genes, Fos (p = 0.008), TRAF6 (p = 0.008) and MyD88 (p = 0.03), were significantly down-regulated after GalN/LPS injection but remained unchanged after TAK242. Hepatic TNFa and IL6 gene expression was up-regulated in ALF and significantly reduced by TAK242 (TNFa p = 0.004, IL6 p = 0.004). Liver TLR4 expression (mRNA and protein) remained unchanged in all groups.
Conclusion: The data highlights the importance of TLR4 signalling in the development and maintenance of ALF. TLR4 inhibition with TAK242 reduced the severity of hepatic injury and inflammation as well as systemic inflammation suggesting that TLR4 is a potential therapeutic target for ALF.

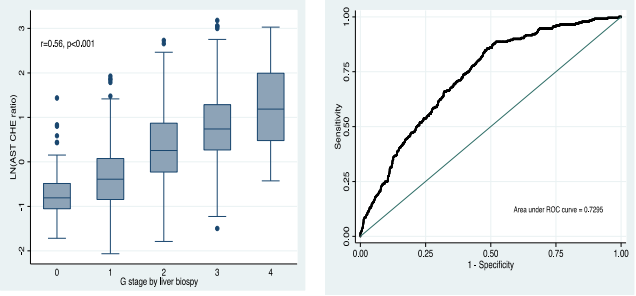
FRI-085

Development and validation of a novel non-invasive model to predict drug-induced liver injury recurrence

Dong Ji[1], Chun-yan Wang[1], Shuai Wang[2], Zhong-bin Li[1], Ping Han[1], QING SHAO[1], Guofeng Chen[1]. *[1]The Fifth Medical Center of Chinese PLA General Hospital, Second Liver Cirrhosis Diagnosis and Treatment Center, Beijing, China; [2]The Seventh Medical Center of Chinese PLA General Hospital, Department of liver diseases, Beijing, China*
Email: jidg302@126.com

Background and aims: The incidence of drug-induced liver injury (DILI) is increasing, and it is hard to be cured due to high recurrence rate in many cases. In the present study, we aimed to develop a novel

non-invasive model to predict the recurrence of DILI, so as to increase its therapeutic effect.
Method: The retrospective cohort study enrolled DILI patients who underwent liver biopsy (LB) in our hospital from January 2008 to December 2017. All the patients were followed up at least 3 times with an interval of 3 to 6 months. The end point was the recurrence of DILI, defined as aminotransferase (ALT or AST) or bilirubin rising at least 2 times of its upper limit of normal value (ULN) within 6 months after the end of treatment. The prediction model was established based on Logistic regression, and its diagnostic performance was evaluated by ROC analysis.
Results: All of 2201 patients were randomly split into two sets (1467 in training set and 734 in validation set). The recurrent rate in training set was 15.6%, comparable to that in the validation set (12.8%, p = 0.08). Univariable analysis showed that recurrent patients had a higher proportion of female, older age, higher AST, lower cholinesterase (CHE) and PLT compared to those without recurrence. Moreover, G3 or above were 14 times more likely to relapse. Furthermore, a novel non-invasive model (AST/CHE ratio index, ACRI) was established based on the results of multivariable analysis, which was calculated by AST (/ULN)/CHE (/lower limit of normal value, LLN). ACRI was correlated significantly with G stage, with a higher correlation coefficient than CHE or AST level alone (r = 0.56, p < 0.001). The area under ROC for ACRI to predict the recurrence was 0.73 (95% CI: 0.70-0.76) in the training set, using ACRI of 1 as the cut-off point, the sensitivity and specificity were 85.6% and 51.3% (see Figure). The corresponding values in the validation set were 0.71 (95% CI: 0.66-0.76), 80.0%, and 49.1%, respectively.



Conclusion: Liver inflammation grade G3 or above is a robust predictor for recurrence of DILI, meanwhile ACRI provides an alternative non-invasive approach with a better diagnostic accuracy than currently available parameters. More than 80% recurrent DILI patients could use this algorithm without resorting to LB, which might help clinicians to initiate steroid treatment at an appropriate time or without delay, thus to decrease the recurrence rate of DILI.

Stem cell treatment on acute liver failure model using semipermeable Poly Lactic-co-Glycolic Acid membrane pouch

Bo-Kyeong Kang[1], Mi Mi Kim[1], Dae Won JUN[2], Jinhwa Park[2], Jaeyoon Jeong[3], Joo Hyun Sohn[3], Hyunwoo Oh[4], Hyo Young Lee[5], Sang Bong Ahn[6], Yong Kyun Cho[7], Dong Hee Koh[8]. *[1]Hanyang University School of Medicine, Radiology, Seoul, Korea, Rep. of South; [2]Hanyang University School of Medicine, Internal Medicine, Seoul, Korea, Rep. of South; [3]Hanyang University School of Medicine Guri, Internal Medicine, Guri, Korea, Rep. of South; [4]Medical corp, 7th division, Republic of Korea army, Hwacheon, Korea, Rep. of South; [5]Seoul National University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of South; [6]Eulji University School of Medicine, Internal Medicine, Seoul, Korea, Rep. of South; [7]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Internal Medicine, Seoul, Korea, Rep. of South; [8]Hallym University College of Medicine, Internal Medicine, Hwaseong, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and aims: It is very well known that stem cell treatment was effective in liver failure condition. Although most studies suggest stem cell injection via systemic vein was generally safe, there is still some concern with cell therapies of creating a cell embolus. We tried to check possibility and feasibility using semipermeable Poly Lactic-co-Glycolic Acid (PLGA) membrane pouch whether it can minimize cell embolus and maximize paracrine effects in acute liver failure model as well as it's possible mechanism.
Method: Animal model was induced by injecting thioacetamide (TAA) (100 mg/kg, i.p.) three times every other day. The mice were divided in 3 groups: 1) TAA; 2) mesenchymal stem cell (MSC) injected via tail vein; 3) PLGA-membrane including MSCs implanted on dorsum, to evaluate histological improvement and liver function. Moreover, quantitative RT-PCR was performed for evaluating gene expression level.
Results: Necrotic area, portal inflammation of liver was reduced in both MSC treatment groups (tail vein, and membrane pouch) compare to control group. But there was no difference between tail vein injection group and PLGA membrane pouch group. More giant cells which seem to be related with cell proliferation were observed in PLGA membrane group compare to the TAA group. Migration of stem cells to lung and liver was detected in tail vein injection group, but did not observe in membrane pouch group. Large portion of injected stem cell in membrane pouch changed cell morphology, and stained with PAS and CYP2E1. Stem cells survived in membrane pouch until 3 weeks in In vitro setting, and secretes more human growth factor, and fibroblast growth factor compared to monolayer cultured MSCs.
Conclusion: MSCs injected into membrane had beneficial effect via secreting growth factors on acute liver failure model.

FRI-087
The good use of paracetamol: prospective assessment of the knowledge of prescribers (practitioners, residents), pharmacists, care providers (nurses, others) and students in an university medical center

Dominique Larrey[1], Lucy Meunier[2], Nadine Deshormière[3]. *[1]Liver Unit Hôpital Saint-Eloi; INSERM 1183; COSEMED; CHU Montpellier, Montpellier, France; [2]Liver Unit Hôpital Saint-Eloi; CHU Montpellier, Montpellier, France; [3]COSEMED; CHU Montpellier, Montpellier, France*
Email: dom-larrey@chu-montpellier.fr

Background and aims: Paracetamol is the most commonly used drug in Western countries. Its use is markedly commonplace since it may be obtained without any prescription. A recent nationwide study (SALT III) showed that paracetamol-induced acute liver failure is an increasing and main cause of acute liver failure leading to registration for liver transplantation (42.1% including 17.6% of paracetamol misuse) (EASL2018). The study is aimed to assess the knowledge of prescribers (practitioners, residents), care/drug providers (nurses, pharmacists, others) and students about paracetamol use in an university medical center.
Method: Prospective study performed using a questionnaire comprising 5 questions regarding paracetamol prescription in adult patients, focused on the place of paracetamol among causes of acute liver failure; the maximum unitary dose; the time intervalle between dosing; the maximum daily dose in chronic usage; the potential co-factors promoting paracetamol hepatotoxicity. The questionnaire has been validated by the Committee for the security of medication use (COSEMED) of the hospital and submitted since November 2017 during professional meetings or via hospital intranet website.
Results: To date, 1118 questionnaires have been completed by 130 medical practitioners from all specialities, 201 medicine residents, 30 pharmacists, 408 nurses, 248 others care providers, 101 medicine students. The global quantitative and quantitative results are shown in the table.

Table: Percentage of correct answers to global and specific questions according to professional category

	Medical practitioners n = 130	Residents n = 201	Pharmacists n = 30	Nurses n = 408	Other care providers n = 248	Students n = 101
Global correct responses to all questions	72.5	66.7	73.7	65.9	60.5	54.6
Paracetamol as cause of liver failure	82.6	78.1	77.3	74.1	60.4	66.1
Maximum unitary dose	98.3	99.4	100	99.1	95.9	84.5
Minimum intervalle between doses	93.0	97.7	95.5	98.2	97.2	83.5
Maximum dose in chronic use	47.8	14.4	50.1	36.9	32.3	10.1
Promoting factors of hepatotoxicity	40.9	43.9	45.5	21.3	16.9	28.9

Conclusion: The knowledge regarding the good use of paracetamol is insufficient for the maximum chronic dosage, the risk of paracetamol hepatotoxicity and its contributing factors. These results encourage to promote a more intensive and specific teaching of all care providers involved in the use of this drug.

FRI-088

The good use of non steroidal anti-inflammatory drugs (nsaids): prospective assessment of the knowledge of prescribers (practitioners, residents), care providers (nurses), pharmacists and students in an university medical center

Dominique Larrey[1], Lucy Meunier[2], Nadine Deshormière[3]. *[1]Liver Unit Hôpital Saint-Eloi; INSERM 1183; COSEMED; CHU Montpellier, Montpellier, France; [2]Liver Unit Hôpital Saint-Eloi; CHU Montpellier, Montpellier, France; [3]COSEMED; CHU Montpellier, Montpellier, France*
Email: dom-larrey@chu-montpellier.fr

Background and aims: NSAIDs are among the most commonly used drugs in western countries. Their use is markedly commonplace since some of them may be obtained without any prescription such as ibuprofen and naproxen. NSAIDs are responsible of various adverse events and are frequently associated with paracetamol, the main drug causing acute liver failure. The study is aimed to assess the knowledge of prescribers (practitioners, residents), care/drug providers (nurses, pharmacists) and students about NSAID adverse effects and their risk factors in an university medical center.

Table: Percentage of correct answers to global and specific questions according to professional category.

	Medical Practioners n = 95	Residents n = 180	Pharmacists n = 25	Nurses n = 113	Students n = 101
Global % of correct responses	59.1	56.2	60.2	41.6	38.1
Overall adverse effects of NSAIDs	66.7	59.0	47.8	13.7	17.9
Hepatotoxicity effects of NSAIDs	75.9	45, 5	52.1	45.1	32.7
Relationship of adverse effects with the dose	43.7	45.5	39.1	29.4	23.2
NSAID hepatotoxicity when combined to paracetamol	55.1	44.5	78.2	54.9	47.4
No specific safety of NSAIDs not requiring prescription	99.1	98.1	95.7	96.1	97.9
Mechanisms of NSAID adverse effects	39.0	31.8	30.4	13.7	4, 2

Method: Prospective study performed using a questionnaire comprising 5 questions regarding NSAID prescription and their adverse effects in adult patients, focused on: the types of NSAID adverse effects; their dose relationship; the hepatotoxic risk when combined with paracetamol; the safety of NSAIDS not requiring a medical prescription; the mechanisms of adverse effects towards the stomach, skin and liver. The questionnaire has been validated by the Committee for the security of medication use (COSEMED) of the hospital and submitted since November 2017 during professional meetings or via the hospital intranet website.
Results: To date, 514 questionnaires have been filled by 95 practitioners from all specialities, 180 medicine residents, 113 nurses, 25 pharmacists, 101 medical students. The global and qualitative quantitative results are shown in the table. Overall, the knowledge for all questions is limited even in medical practitioners.
Conclusion: The knowledge regarding the adverse effects of NSAIDs and their promoting factors is insufficient in all professional category. These results encourage to promote a more intensive and specific teaching of all care providers involved in the use of these drugs.

FRI-089

Genetic deletion of Keap in hepatocytes improves liver damage, but triggers hepatitis in an Nrf2-dependent manner, in experimental toxic liver injury

Laura Moran Blanco[1], Nuria López-Alcántara[1], Olga Estévez[2], Pierluigi Ramadori[3], Christoph J. Wruck[4], Iris Asensio[5,6,7], Javier Vaquero[5,6,7], Rafael Bañares[5,6,7], Yulia Nevzorova[2,3,8], Francisco Javier Cubero[8,9]. *[1]Complutense University School of Medicine, Department of Immunology, Ophthalmology and ORL, Madrid, Spain; [2]Faculty of Biology, Complutense University, Department of Genetics, Physiology and Microbiology, Madrid, Spain; [3]University Hospital RWTH Aachen, Department of Internal Medicine III, Aachen, Germany; [4]University Hospital RWTH Aachen, Department of Anatomy and Cell Biology, Aachen, Germany; [5]Hospital General Universitario Gregorio Marañón, Servicio de Aparato Digestivo, Madrid, Spain; [6]Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Madrid, Spain; [7]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain; [8]12 de Octubre Health Research Institute (imas12), Madrid, Spain; [9]Complutense University School of Medicine, Department of Immunology, Ophthalmology and ORL, Madrid, Spain*
Email: fcubero@ucm.es

Background and aims: Drug-induced liver injury (DILI) is an increasing health problem in developed countries. Acetaminophen (APAP) toxic liver injury is characterized by extensive oxidative damage. The Kelch-like ECH-associated protein 1/Nuclear factor erythroid 2-related factor (Keap1/Nrf2) system is a master regulator of the defense against oxidative stress. In the current study, we examined the contribution of Nrf2 in hepatocytes to DILI.
Method: Animals with hepatocyte-specific deletion of Keap1 ($Keap1^{\Delta hepa}$) and floxed mice ($Keap1^{f/f}$) were challenged *i.p.* with carbon tetrachloride (CCl_4, 0.6 ml/kg) and acetaminophen (APAP, 500 mg/kg) and sacrificed at different time points ranging from 0 to 28 days. Liver samples were processed for histopathological examination, and protein (IF, IHC and WB) and mRNA expression were evaluated. In parallel, the Nrf2/Keap1 axis was thoroughly studied in human HepaRG cells.
Results: Toxic challenge caused reduction of markers of liver damage (eg: AST, ALT) and decreased levels of reactive oxygen species (ROS) as observed in DHE and 4-HNE in $Keap1^{\Delta hepa}$ and $Keap1^{f/f}$ mice. Furthermore, toxicity caused significantly increased body vs liver weight (LW/BW) ratio in $Keap1^{\Delta hepa}$ mice. In addition, toxic liver injury triggered necroinflammation in periportal areas in $Keap1^{f/f,}$

whilst it was dramatically enhanced in Keap1$^{\Delta hepa}$. Concomitantly, reduced necrosis in Keap1$^{\Delta hepa}$ was linked with decreased number of TUNEL-positive cells. Interestingly, collagen deposition evaluated as Sirius red (SR) staining was significantly elevated in mice with deletion of Keap1 (Keap1$^{\Delta hepa}$) in hepatocytes compared with Keap1$^{f/f}$ animals. These results were associated with elevated markers of fibrosis and hepatic stellate cell (HSC) activation including αSMA and Collagen IA1. Deletion of Keap1 in hepatocytes suggested an overexpression of Nrf2 which led to increased inflammatory milieu in these animals.

Conclusion: Deletion of Keap1 in hepatocytes triggered overexpression of Nrf2 leading to increased inflammation and fibrogenesis but reduced cell death and liver damage. These data highlight the important role of Nrf2 in hepatocytes in DILI.

FRI-090

Enhanced ASPP2 improves liver injury by way of an inflammatory immune regulatory mechanism in acute liver failure

Xiangying Zhang[1], Hongbo Shi[1], Yu Chen[1], Zhongping Duan[1], Dexi Chen[1], Feng Ren[2]. [1]*Capital Medical University, Beijing YouAn Hospital, Beijing, China;* [2]*Capital Medical University, Beijing YouAn Hospital, Beijing, China*
Email: renfeng7512@hotmail.com

Background and aims: Acute liver failure (ALF), an inflammation-mediated hepatocellular injury process, is a clinical syndrome that results from hepatocellular apoptosis and hemorrhagic necrosis. The apoptosis stimulating protein of p53-2 (ASPP2), a haploinsufficient tumor suppressor, is a pro-apoptotic member of the p53 binding protein family. However, the role of ASPP2 in the pathogenesis of ALF and its regulatory mechanisms remain unclear.

Method: The expression of ASPP2 were analyzed using the liver biopsy samples from HBV-related hepatocarcinoma (HCC) patients and ALF patients. ASPP2$^{\pm}$ and ASPP2$^{+/+}$ Balb/c mice were used to examine the effects of ASPP2 on liver injury induced by D-galactosamine (D-GalN)/lipopolysaccharide (LPS) in vivo. The inflammatory immune mechanism of ASPP2 were also explored in bone marrow-derived macrophages (BMDM) in vitro.

Results: The expression of ASPP2 was significantly upregulated in liver tissue of ALF patients with HBV infection and ALF mice induced by D-GalN/LPS, and significantly down-regulated in HCC patients. Compared with wildtype mice, the ablation of ASPP2 (ASPP2$^{\pm}$) significantly ameliorated the hepatocellular damage, evidenced by reduced serum alanine aminotransferase (sALT and sAST) levels, well-preserved liver architecture compared with controls. The liver protective effect of ASPP2± was dependent on an inflammatory immune regulatory mechanism, because ASPP2 is required to regulate liver inflammation by selectively depressing tumor necrosis factor-α (TNF-α) and promoting interleukin-6 (IL-6) in vivo and in vitro, moreover, the luciferase assay results showed that overexpression of ASPP2 could bind to the promoter sequence of TNF-α and IL-6. The molecular mechanistic investigations elucidated that the enhanced ASPP2 promoted liver injury by regulating PPARα-autophagy pathway, because inhibition of PPARα by siRNA abrogated liver protection and decreased autophagy again induced by ASPP2±.

Conclusion: Our novel findings document the key inflammatory immune regulatory function of ASPP2 in the pathophysiology of ALF, and provide a rationale to target ASPP2 as a refined therapeutic strategy to ameliorate acute liver injury.

Email: esss2491@gmail.com

Background and aims: Cholestasis is a common syndrome in a large number of hepatic diseases such as drug-induced cholestasis, which is produced due to a primary lesion of the bile ducts, either functional or obstructive, generating oxidative stress in the liver. Hepatocyte growth factor (HGF) and its receptor c-Met represent the first defense line against hepatotoxic factors inducing Nrf2 activation which, in turn, activates its target genes leading to an antioxidant and repair response. The aim of this work was to characterize the anticholestatic molecular mechanisms deployed by HGF in a murine model of inflammatory cholestasis induced by the α-naphthil-isothiocyanate (ANIT).

Method: CD1 mice were, treated or not with ANIT (60 mg/kg, ig) for 48 h. After 24 h of ANIT treatment, HGF (10 μg/kg, iv) was administrated. Forty-eight hours after ANIT treated animals were euthanized. Blood, bile and liver tissue were obtained. Liver function test (AST, ALT, ALP, GGT, bile salts and bilirubin), histology studies (H-E staining), analysis of gene expression of ABC transporters by qRT-PCR, content of antioxidant proteins by Western blot, immunofluorescences and collection of bile (excretion of bile salts) were performed.

Results: ANIT treated animals, showed hepatomegaly, and cholecystitis, effects reverted by HGF administration. The increment in liver function test induced by ANIT, significantly diminished to control values under HGF treatment. Histology revealed extensive necrotic foci and inflammatory infiltration; HGF induced a significant decrement in necrotic areas, and less inflammation. HGF also restored the bile flux and bile salts excretion. These findings, could be related to the HGF-induced expression of key genes related to liver protection, in fact, HGF alone, induced the expression of *Abcc3,*

Gpx1/2, HO1, and catalase. Most of them directed by Nrf2 activation, which in addition was increased, judged by an EMSA assay. Furthermore, HGF preserved the canalicular structure ("double rail"), disturbed by ANIT treatment, remarkably HGF treatment alone, induced the canalicular width. To gain more confidence, we extended the ANIT treatment time up to 108 h and we noticed renal damage, judged by proteinuria and the content in urine of HSP72, HGF induced renal protection improving such kidney damage marker, in addition to a damage prevention in the liver, similar findings were observed in the pancreas.
Conclusion: Our results clearly show that HGF induces a wide anti-cholestatic response, protecting the liver and commonly compromised organs in this liver disease such as the kidneys and pancreas. HGF/c-Met could be of interest as a key target of therapeutically relevance.

Email: m.sebode@uke.de

Background and aims: Drug-induced liver injury (DILI) is a heterogenous entity leading to acute liver damage. Large multicentre DILI registries have identified the most frequent agents causing DILI, among which antimicrobials are the leading causes. Metamizole or Dipyrone is banned from the market in some countries such as the United States but is approved and frequently applied in other countries including Germany. Elevation of liver enzymes is not listed as a potential side effect on the label of metamizole in Germany. Since metamizole can cause allergic reactions we hypothesized that it may also cause immune-mediated DILI. We here determined the frequency and pattern of metamizole-induced DILI at our tertiary care centre in Germany.
Method: Consecutive DILI cases who presented to the I. Department of Medicine at the University Medical Centre Hamburg-Eppendorf were analysed retrospectively. Cases of acute hepatitis other than DILI were excluded. Notably, autoimmune hepatitis was ruled out by clinical follow-up of DILI cases to assure that liver enzymes did not rise again after the drug had been stopped.
Results: 154 DILI cases with acute icteric hepatitis were admitted to our centre from 2008 to 2017. After phenprocoumon, metamizole was the second most frequent putative agent causing DILI (23 of all 154 DILI cases, 14, 9%). In 14 cases, metamizole was the sole drug causing DILI, in the other 9 cases concomitant drugs like statins or NSAIDs were also potential causative agents. In 4 of the 23 metamizole-induced DILI cases, patients were accidently re-exposed to metamizole resulting in another episode of acute icteric hepatitis, stressing the lack of awareness of metamizole being a DILI-causing drug. The biochemical pattern on admission of all metamizole cases was hepatocellular with median levels of ALT (823U/l) by far exceeding median ALP levels (131U/l). Median MELD score on admission was 12. 61% of metamizole-induced DILI cases showed the presence of autoantibodies such as ANA and/or anti-SMA. 15 of 23 patients with metamizole-induced DILI received a liver biopsy. The histological pattern of an acute hepatitis with infiltrating lymphocytes was present in all metamizole cases and 8 of 15 patients showed centrilobular necrosis. Interface hepatitis, the histological hallmark of autoimmune hepatitis, was not present in metamizole-induced DILI cases. 68% of metamizole DILI cases were treated with steroids. In 21 of the 23 metamizole-induced DILI cases liver damage resolved. 2 patients developed acute liver failure, received liver transplantation and are still alive.
Conclusion: Acute icteric hepatitis or acute liver failure are not mentioned in the German label of metamizole or dipyrone as side effects. Our study reveals that in Germany, metamizole is a frequent and underrated agent causing DILI, and can lead to acute liver failure.

FRI-093
Low volume plasma exchange in patients with acute liver failure: A real world study
Mohammed Sheikh[1], Michael James[2], Jennifer Ryan[2], Rajiv Jalan[1], Andrew Davenport[3], Banwari Agarwal[1,4]. *[1]University College London, Institute of Liver and Digestive Health, London, United Kingdom; [2]Royal Free Hospital, Department of Hepatology, London, United Kingdom; [3]University College London, UCL centre for nephrology, London, United Kingdom; [4]Royal Free Hospital, Intensive Care Unit, London, United Kingdom*
Email: mfaisal1@doctors.org.uk

Background and aims: High volume plasma exchange (HVPLEX) (8-12 litres per procedure) can improve transplant free survival in acute liver failure (ALF). HVPLEX is expensive, blood bank resource intensive and can be associated with complications such as volume overload. It is not known whether using smaller volumes for PLEX is efficacious in ALF. The aim of this study was to determine the efficacy of low volume PLEX (LVPLEX).
Method: Consecutive patients with ALF admitted to a single intensive care unit (ICU) between 2013 and 2018 (n = 58) were studied. The decision to use LVPLEX was made by the duty hepatologist. Daily volume exchange was 5-7.5% of ideal body weight (average 3 litres) and replacement fluid was either Fresh Frozen Plasma (FFP) or a combination of FFP, albumin or a crystalloid solution. Outcome measures included resolution of ALF, bridge to liver transplantation (OLTx), death, and changes in the biochemical, physiological and organ function status. Outcomes were compared to ALF patients admitted to ICU (2008-2012) prior to the introduction of LVPLEX at our centre (PrePLEX) (n = 61).
Results: 59% (n = 34/58) of patients with ALF were treated with LVPLEX (age 40 [32-54], 68% female). 71% (n = 24/34) met Kings College poor prognostic criteria (KCppc). 24/58 patients did not receive PLEX (NoPLEX) (age 41 (35-49), 54% female). LVPLEX was commenced in the first 24 hours of ICU admission (n = 27), within 48 hours (n = 4) or after 48 hours (n = 3). Median length of treatment was 3 (IQR 2-3) days. The main clinical effect of LVPLEX was a significant reduction in average noradrenalin requirement from 0.25 (0.14-0.59) mcg/kg/min prior to starting to PLEX to 0.07 (0.02-0.27)mcg/kg/min after PLEX treatment (p = 0.004). 69% (n = 11/16) of those receiving LVPLEX were successfully bridged to transplantation compared to 76% (n = 10/13) in the NoPLEX group and 67% (n = 12/18) PrePLEX. There was no difference in overall transplant free survival with LVPLEX 38% (n = 5/13) vs. 35% (n = 8/23) PrePLEX, and (n = 0/3) in the NoPLEX group survived. However, in those that met KCppc and were not listed for OLTx, use of LVPLEX was associated with numerical improvement in survival; 63% (n = 5/8) vs. 47% (n = 8/17) PrePLEX.
Conclusion: LVPLEX did not impact the survival of patients listed for OLTx but numerically improved survival of ALF patients who met KCppc but were ineligible for OLTX listing. Further clinical trials are required to define patient selection and the ideal treatment dose for PLEX in ALF.

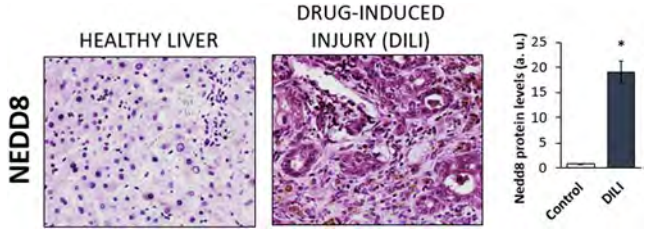
Email: jsimon@cicbiogune.es

Background and aims: Drug induced liver disease (DILI) is the leading cause of liver transplantation in the USA and most of Europe. Only in the USA, each year, 30000 patients are admitted to the intensive care units because of an acetaminophen overdose (APAP) from which 10000 need of a transplant. Until date, the only effective therapy available is the treatment with N-acetylcysteine, with low chances of rescuing the liver, making new therapies a need. Our group has been focused on the NEDDylation process, a post-translational modification already reported to be altered in HCC and previous stages such as cirrhosis.

Method: NEDD8 has been determined in human sample sections by IHC and a pre-clinical assay has been developed with DILI animal models by APAP overdose (500 mg/kg) in wild-type (Wt) and NAE1 heterozygote (NAE1$^{\pm}$) mice. *In vitro* experiments with primary hepatocytes have also been developed.

Results: NEDDylation is induced in human patients, *in vivo* DILI models and *in vitro* primary hepatocytes and its inhibition prevents liver from APAP-induced damage both in *in vivo* and *in vitro* models. As a consequence of NEDDylation inhibition, IκBα is downregulated and p65 translocation into the nucleus, inhibited by APAP overdose, is allowed. Proteomics analysis suggest IκBα as a possible NEDDylation target.



Conclusion: NEDD8 inhibition prevents liver from being damaged by a drug overdose by promoting IκBα degradation, which allows p65 or NF-κB to be internalized into the nucleus in presence of APAP.

FRI-095

The overweight role in the occurrence of hepatotoxic reactions during chemotherapy of chronic lymphocytic leukaemia

Igor Skrypnyk[1], Ganna Maslova[1]. [1]*Ukrainian Medical Stomatological Academy, Poltava, Ukraine*
Email: inskrypnyk@gmail.com

Background and aims: Chemotherapy (CT) in pts with chronic lymphocytic leukemia (CLL) is followed by risk of hepatotoxic reactions onset that limit further full-scale program treatment and can cause inefficiency of the therapy.

The aim-to determine the role of overweight and obesity in hepatotoxic reactions occurrence in pts with CLL dynamically during CT.

Method: 73 pts with CLL, who were given 6 courses of CT according to FCR (fludarabine, cyclophosphamide, rituximab) regimen were examined. The average age was 67.4 ± 11.7 years, 19 (26%) pts were women, 54 (74%)-men, ECOG I-II. The pts were classified by Rai System: II stage-22 (30.1%), III-18 (24.7%), IV-33 (45.2%) pts. The body mass index (BMI) was determined. The pts were followed-up during 6 courses of CT. The liver function was assessed by the activity of ALT, AST, ALP, GGT, bilirubin, protein in the blood serum, which were carried out twice during each CT course: at baseline and on the 5th day after starting CT. To assess the severity of hepatotoxic reactions the CTCAE scale was used.

Overweight was detected in 26 (35.6%) pts: BMI = 25-29.9-in 21 (28.8%), BMI > 30-in 5 (6.8%). Depending on the overweight presence the pts were divided into 2 groups: I (n = 47) -CLL with normal body weight, II (n = 26)-CLL and overweight.

Results: Before the CT all of the 47 pts with CLL and BMI within normal ranges of the Ist group had normal values of functional liver state. Among 4 (15.4%) pts with CLL of the IInd group having overweight, ALT activity was elevated up to the grade I according to CTCAE.

Dynamic follow-up of pts with CLL of the Ist group revealed hepatotoxic reactions in 11 (23.4%) pts after II CT course according to FCR regimen, 6 (12.7%) patients out of them had elevation of ALT activity, 3 (6.4%)-increase of GGT activity, 2 (4.2%) decrease of total protein level. Defined hepatotoxic reactions were characterized by grade I of the CTCAE and were isolated and reversible. Further abnormalities in biochemical blood tests during next CT courses were not determined.

Hepatotoxic reactions among the pts of the IInd group with overweight were defined during the dynamic follow-up in 12 (46.2%) pts, in 8 (30.7%) out of them-after the 2nd CT course and in 4 (15.4%)-after the 4th CT course according to the FCR regimen. Elevation of ALT activity took place in 12 (46.2%) pts: in 10 (38.5%)-up to the grade I, in 2 (7.7%)-up to the grade II according to the CTCAE, which in 4 (15.4%) pts was associated with AST increase up to the grade I, in 4 (15.4%)-GGT increase, in 3 (11.5%)-total bilirubin grade I increase, in 1 (3.8%)-total protein decrease. Hepatotoxic reactions in the pts of the IInd group were irreversible and had tendency to severity increase on the background of cytostatics' cumulative dosage rise.

Conclusion: Overweight is the leading risk factor of hepatotoxic reactions onset, which are characterized by increase of their severity associated with cumulative CT dosage rise.

FRI-096

Technetium-99m-GSA within the first 3d after admission as an early predictor of outcome in severe acute liver injury

Yuji Suzuki[1], Keisuke Kakisaka[1], Takuro Sato[1], Hiroaki Abe[1], Tokio Sasaki[1], Takehiro Akiyama[1], Yasuhiro Takikawa[1]. [1]*Iwate Medical University School of Medicine, Morioka, Japan*
Email: yusuzuki@iwate-med.ac.jp

Background and aims: Patients with severe acute liver injury (SLI) without pre-existing chronic liver disease usually recover spontaneously. However, some SLI patients progress to acute liver failure (ALF), with varying degrees of hepatic encephalopathy. ALF is associated with high mortality, which can be substantially reduced by liver transplantation. Therefore, distinguishing SLI patients who might progress to ALF and are at risk of death is important when evaluating patients needing liver transplantation. Technetium-99m-diethylenetriaminepentaacetic acid galactosyl human serum albumin (^{99m}Tc-GSA) scintigraphy is a method used to evaluate liver function. The present study aimed to determine whether ^{99m}Tc-GSA scintigraphy could predict the prognosis of SLI patients.

Method: This prospective observational study included 54 SLI patients with a prothrombin time-international normalized ratio ≥ 1.5. ^{99m}Tc-GSA scintigraphy was performed within the first 3 d after admission. For the procedure, 185 MBq of ^{99m}Tc-GSA was injected into a cephalic vein, and images were then obtained using a dual-head gamma camera with a 20-min scan time (15 s/frame). Time-activity curves were generated from regions of interest for the entire liver and

heart. The hepatic accumulation index was calculated by dividing the radioactivity of the liver regions of interest by that of the liver-plus-heart regions of interest after 15 min (i.e. LHL15). The relationship between each variable and SLI prognosis was evaluated using a univariate analysis, followed by a multivariate statistical analysis.
Results: Twelve (22.2%) patients died or underwent liver transplantation (poor outcome), and the LHL15 value was significantly lower in these patients (0.678) versus those who survived (0.848; $p < 0.0001$). The optimal LHL15 cut-off for distinguishing a poor outcome and survival was 0.737, with a sensitivity of 91.7%, specificity of 92.9% and area under the curve of 0.976 (95% confidence interval, 0.917-1.007). At the cut-off, positive and negative predictive values were 78.6% and 97.5%, respectively. In the multivariate analysis, LHL15 was the only independent predictor of a poor outcome (95% confidence interval, −0.559 to −0.063, $p = 0.0141$).
Conclusion: ^{99m}Tc-GSA scintigraphy may help predict the prognosis of SLI patients. In clinical practice, ^{99m}Tc-GSA scintigraphy may be an adjunctive diagnostic tool for indicating those SLI patients at risk of progressing to ALF and requiring liver transplantation.

FRI-097
PBI-4050 treatment decreases sepsis-induced liver injury in mice
Jean-François Thibodeau[1,2], Brigitte Grouix[1], Jean-Christophe Simard[1], Chet Holterman[2], Alex Gutsol[2], Alexandra Blais[1], Alexandre Laverdure[1], Richard Hébert[2,3], François Leblond[1], Pierre Laurin[1], Chris Kennedy[2,3], Lyne Gagnon[1]. *[1]Prometic Biosciences Inc., Laval, Canada; [2]Kidney Research Center, Ottawa Hospital Research Institute, Ottawa, Canada; [3]Department of Cellular and Molecular Medicine, University of Ottawa, Ottawa, Canada*
Email: j.thibodeau@prometic.com

Background and aims: Prometic's lead drug candidate, 2- (3-pentylphenyl)acetic acid (PBI-4050), is a dual G protein-coupled receptor GPR40 agonist/GPR84 antagonist that exerts antifibrotic, anti-inflammatory, and antiproliferative action. Previous studies found that PBI-4050 reduces carbon tetrachloride and bile-duct ligation induced fibrosis. Here, we tested whether PBI-4050 would offer hepatic protection in an acute model of liver injury induced by sepsis-related endotoxemia.
Method: Eight-week old male C57BL/6N mice were given either vehicle (H_2O) or PBI-4050 (200 mg/kg) daily by gavage for 2 weeks and challenged with a single intraperitoneal dose of bacterial lipopolysaccharides (LPS; 10 mg/kg) and sacrificed after 24 hours.
Results: LPS-induced sepsis was confirmed by significant elevations in several circulating pro-inflammatory cytokines (IL-6, TNF-α, IL-1β, CXCL1, RANTES, MCP-1, INFγ), all of which were significantly decreased by PBI-4050 treatment. LPS was associated with hypoalbuminemia, which was significantly prevented in PBI-4050-treated mice. Histological assessment revealed mild microsteatosis in both groups, while hepatocyte morphology (size, cytoplasmic density) was increased in vehicle-treated LPS mice, but not in PBI-4050-treated mice. Interestingly, Kupffer cells were also increased in PBI-4050-treated mice compared to vehicle-treated LPS mice. Gene expression analysis revealed that PBI-4050 modulated several pro-inflammatory (NOS2, IL-6 and CXCL1) and ER-stress related genes (DDIT3, ATF4 and PDIA4). Finally, PBI-4050 reduced ER-stress proteins CHOP, phospho-eIF2α and GRP78 induced by LPS in the liver.
Conclusion: Taken together, PBI-4050 treatment in septic mice decreased systemic inflammation and liver injury, improved plasma albumin levels and dampened the ER-stress pathway. These data suggest PBI-4050 treatment may offer protection from sepsis-mediated acute liver injury.

FRI-098
Targeting cholesterol with atorvastatin protects against valproic acid-induced sensitization to acetaminophen hepatotoxicity
Sandra Torres[1,2], Susana Núñez[1,2], Naroa Insausti-Urkia[1,2], Estel Solsona-Vilarrasa[1,2], Vicent Ribas[1,2], Carmen García-Ruiz[1,2,3], José Fernandez-Checa[1,2,3]. *[1]August Pi i Sunyer Biomedical Research Institute-IDIBAPS, Mitochondrial regulation of cell death and steatohepatitis, Barcelona, Spain; [2]Institute of Biomedical Research of Barcelona, Cell Death and Proliferation, Barcelona, Spain; [3]USC Research Center for ALPD, Keck School of Medicine, Los Angeles, United States*
Email: sandra88tn@gmail.com

Background and aims: Mitochondrial cholesterol (mChol) accumulation is associated with chronic liver diseases, including fatty liver disease and hepatocellular carcinoma. Increased cholesterol trafficking to mitochondria alters membrane physical properties, including the transport of cytosol GSH into mitochondrial matrix, which results in mitochondrial GSH (mGSH) depletion. As GSH is a critical player in drug-induced liver injury (DILI), we hypothesized that altered mChol homeostasis contributes to DILI. Valproic acid (VPA) is a widely prescribed epileptic and anticonvulsant drug, and patients under VPA therapy have been shown to develop acetaminophen (APAP) hepatotoxicity. Therefore, our aim was to examine the role of targeting cholesterol by statins and its trafficking to mitochondria mediated by StARD1 in VPA sensitization to APAP-mediated hepatotoxicity and acute liver failure.
Method: WT C57BL/6J male mice were fed with normal chow (Ctrl) or high-cholesterol diet (2% Cholesterol and 0, 5% Sodium Cholate, HC) followed by a single dose of APAP (300 mg/Kg, ip). Mice were dosed daily by oral gavage with atorvastatin (Pfizer, 10 mg/kg) or vehicle 7 days before being treated three times every 12 h with VPA (400 mg/Kg, sc) followed by a single dose of APAP (300 mg/Kg, ip). Moreover, mice with hepatocyte-specific StARD1 deletion (StARD1$^{\Delta Hep}$) were analysed for VPA sensitization to APAP mediated hepatotoxicity. Liver damage by ALT and HandE, cholesterol trafficking and GSH homeostasis were examined following VPA plus APAP cotreatment. Expression of StARD1, MLN64, ER stress markers and lipogenic transcription factors were examined by qPCR and WB.
Results: Mice fed a cholesterol-enriched (HC) diet, which exhibited enhanced hepatic cholesterol loading in mitochondria, were highly sensitive to APAP-induced liver injury, determined by serum ALT levels and HandE. Livers from HC+APAP displayed increased mChol transporters and ER stress markers expression and mChol accumulation, resulting in GSH depletion. Interestingly, atorvastatin therapy prevented the mChol loading and reduced the expression of StARD1, MLN64 and ER stress markers in mice treated with VPA+APAP. Atorvastatin therapy protected mice from VPA plus APAP liver injury, revealed by the HandE staining and the significant serum ALT decrease. Moreover, StARD1$^{\Delta Hep}$ mice were resistant to VPA+APAP mediated hepatotoxicity, exhibiting decreased mChol accumulation and mGSH repletion compared to StARD1 $^{f/f}$ mice.
Conclusion: Cholesterol exacerbates liver toxicity following APAP administration and its targeting by atorvastatin protects against the hepatotoxic effects of VPA-induced sensitization to APAP hepatotoxicity. Similar findings are observed in StARD1$^{\Delta Hep}$ mice indicating that the selective mChol pool plays an important role in DILI.

FRI-099
PD-1+ monocytes and macrophages contribute to impaired microbial clearance following acute liver failure
Evangelos Triantafyllou[1,2,3], Cathrin Gudd[1,2], Rooshi Nathwani[1], Francesca Trovato[3], Lucia Possamai[1,2], Rebecca Morrison[4], Christine Bernsmeier[3,5], Vishal Patel[6], Wafa Khamri[1], Robert Goldin[4], Julia Wendon[3], Mark McPhail[3], Kevin Woollard[2], Mark Thursz[1], Charalambos Antoniades[1]. *[1]Imperial College London, Integrative Systems Medicine and Digestive Disease, London, United Kingdom; [2]Imperial College London, Immunology and Inflammation, London, United Kingdom; [3]King's College London, Institute of Liver Studies,*

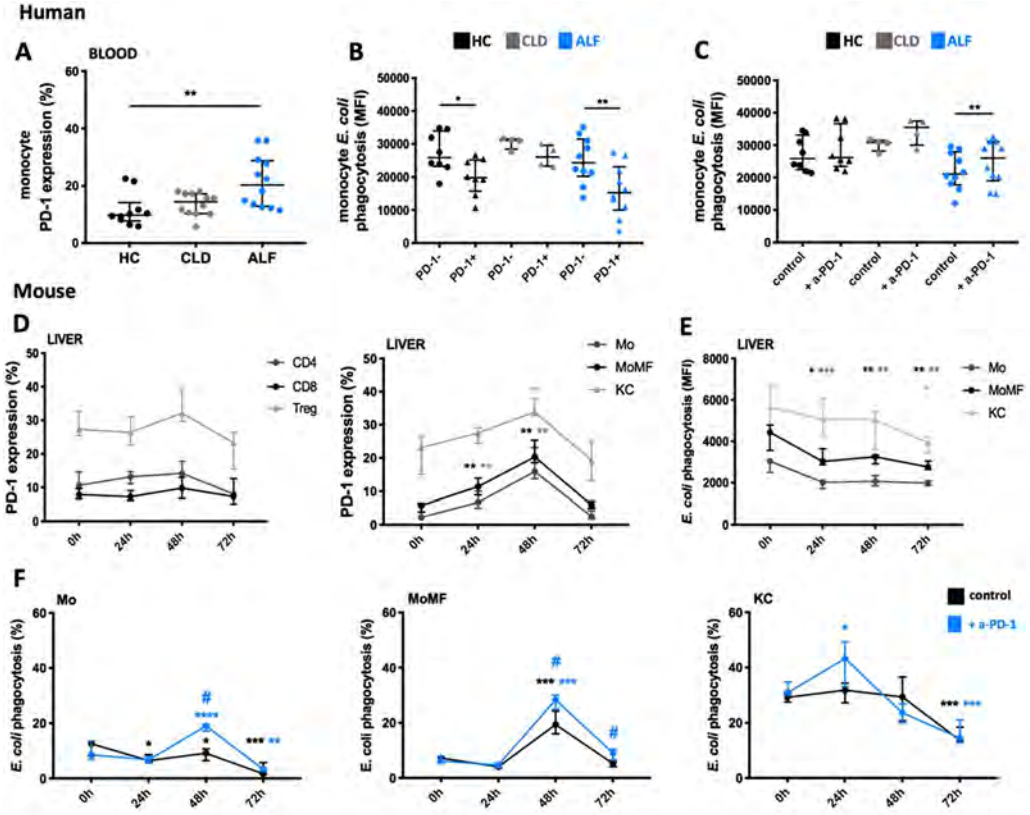


Figure. (**A**) PD-1 expression levels of blood monocytes in healthy controls (HC), chronic liver disease (CLD) and acute liver failure (ALF) patients. (**B**) Phagocytosis of *E. coli* (pHrodo) in PD-1- versus PD-1+ monocytes in HC, CLD and ALF. (**C**) Phagocytosis of *E. coli* (pHrodo) in HC, CLD and ALF monocytes with/without anti-PD-1 mAb pre-treatment. (**D**) PD-1 expression levels of mouse liver CD4+, CD8+ T cells, Tregs, monocytes (Mo), monocyte-derived macrophages (MoMF) and Kupffer cells (KC) after APAP overdose. (**E**) Phagocytosis of E. coli (pHrodo) by mouse liver Mo, MoMF and KC after APAP overdose. (**F**) Phagocytosis of E. coli (pHrodo) by mouse liver Mo, MoMF and KC after APAP overdose in mice treated with isotype control or anti-PD-1 mAb . Non-parametric (Mann-Whitney) statistical analysis was used. Data shown as median values with IQR. *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001. # p<0.05, comparison between groups. Programmed-cell-death-protein-1 (PD-1).

London, United Kingdom; [4]Imperial College London, Centre for Pathology, London, United Kingdom; [5]University of Basel, Biomedicine, Basel, Switzerland; [6]The Foundation for Liver Research, Institute of Hepatology, London, United Kingdom
Email: e.triantafyllou@imperial.ac.uk

Background and aims: Patients with paracetamol (APAP)-induced acute liver failure (ALF) show defective innate immune responses to microbial cues, promoting increased susceptibility to infections and mortality. Interestingly, recent studies in sepsis and cancer have associated the expression of programmed-cell-death-protein-1 (PD-1) by monocytes and macrophages with reduced phagocytosis. Therefore, we examined the expression of PD-1 and its role in regulating microbial clearance in human and murine ALF.
Methods: Using flow cytometry, we determined PD-1 expression in circulating T cells, Tregs and monocytes isolated from healthy controls (HC, n = 10), chronic liver disease (CLD, cirrhosis; n = 12) and ALF (n = 12) patients. Monocyte *E. coli* (pHrodo) phagocytosis was assessed *ex vivo* and *in vitro* after anti-PD-1 monoclonal antibody (mAb, 10μg/ml) treatment. WT mice dosed with APAP (250 mg/kg) were treated with isotype control or anti-PD-1 mAb (200μg) at 24 h before and after APAP (n = 5/group). Using liver intravital confocal imaging and flow cytometry, we measured and visualized: (a) PD-1 expression of Tcells, Tregs, monocytes and macrophages, (b) macrophage phagocytosis following *E. coli* (pHrodo) systemic administration.
Results: Patients with ALF showed a higher proportion of PD-1+ monocytes than HC and CLD (**A**) whereas PD-1+ Tcells and Tregs were similar between groups. PD-1+ monocytes have reduced *E. coli* uptake when compared to PD-1- cells (**B**). PD-1 expression correlated negatively with phagocytosis index (r = -0.70, p < 0.001) and anti-PD-1 treatment increased phagocytosis in ALF (**C**). In mice, Tcell and Treg PD-1 expression remained unaltered while PD-1 was up-regulated in liver monocytes (Mo), monocyte-derived macrophages (MoMF) and Kupffer cells (KC) at 24 h and 48 h (**D**). Following injury, there was impaired *E. coli* uptake in the liver by these subsets (**E**), with PD-1+ cells phagocytosing less. Anti-PD-1 treatment led to similar liver injury (ALT levels, necrosis) and increased Mo and MoMF phagocytosis, compared to control group (**F**).
Conclusions: We reveal the expansion of human and murine PD-1+ monocytes and liver macrophages following ALF. These PD-1+ cell subsets contribute to impaired microbial clearance, thus targeting PD-1 may provide novel therapeutic strategies in ALF. Future work will better characterize the importance of PD-1 on monocytes and macrophages and its mechanisms underlying innate immunosuppression in human and experimental liver injury.

Protective effects of glutathione and lipoic acid against cadmium-induced oxidative stress in rat's liver

Andrej Veljkovic[1,1], Gordana Kocic[1], Dusan Sokolovic[1], Branka Djordjevic[1], Tatjana Jevtovic[1], Jelena Basic[1], Milena Despotovic[1], Tatjana Cvetkovic[1], Ivana Stojanovic[1], Ruzica Nikolic[2], Jasmina Jovanovic[3], Dusica Pavlovic[1]. *[1]Medical faculty, Biochemistry, Nis, Serbia; [2]Faculty of Science and Mathematics, Chemistry, Nis, Serbia; [3]High medical school, Physiology, Cuprija, Serbia*
Email: veljkovicandrej@yahoo.com

Background and aims: Cadmium is a widespread, toxic industrial pollutant, which is introduced into the organs through food, air and

tobacco smoke. Cd poisoning leads primarily to damage of the liver tissue and testes in laboratory animals. We analyzed the effects of cadmium exposure on the model system of experimental animals, the thiobarbituric acid (TBA)-reactive substance (TBARS) level, and the activity of xanthine oxidase (XO) and catalase in liver of rats, with and without glutathione and lipoic acid (LA).
Method: The experimental animals were divided into six groups, regarding cadmium, glutathione, and LA intake. The concentration of TBARS in the homogenate was determined by spectrophotometric method according to Andreeva et al. The specific activity of XO was determined spectrophotometrically by the method of Hashimoto et al. Catalase activity in tissues was determined by spectrophotometric method according to Goth.
Results: The increased level of TBARS and the increased activity of XO in rat liver in cadmium poisoning are statistically significant compared to control ($p < 0.001$). Glutathione and LA applied along with cadmium lowered TBARS level and reduced XO activity ($p < 0.001$). Catalase activity in the liver tissue was increased in the group, which was administered cadmium ($p < 0.001$).
Conclusion: Glutathione and LA, as physiological antioxidants have reduced the level of lipid peroxides and the activity of XO, in conditions of cadmium poisoning, and can be used as protectors.

FRI-101
FGL2 deficiency resists viral fulminant hepatitis through abrogating inflammatory macrophage activation
Fang Xiao[1], Hongwu Wang[1], Ran Tao[1], Xinxin Weng[1], Peng Wang[1], Di Wu[1], Xiaojing Wang[1], Weiming Yan[1], Dong Xi[1], Xiaoyang Wan[1], Qin Ning[1]. [1]*Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*
Email: qning@vip.sina.com

Background and aims: Virus-induced acute liver failure (or viral fulminant hepatitis, VFH), is devastating liver disease without specific intervention agents. Understanding the molecular and immune mechanism underlying VFH progression will give implications on therapeutic targets. Fgl2 is a membrane protein expressed on macrophages and promotes fulminant hepatitis progression, however, the detailed mechanism underlying immune alterations and through which Fgl2 modulates immune response during VFH remains unclear.
Method: Hepatic macrophages were analyzed in *fgl2*$^{-/-}$ mice and wild type littermates infected with murine hepatitis virus strain 3 (MHV-3) which induced VFH in mice. Liver damage was assessed in mice with macrophage depletion after infection. Phagocytosis, polarization, and inflammatory signaling were evaluated in fgl2$^{-/-}$ macrophages in response to Lipopolysaccharide or viral stimulation.
Results: In patients of HBV-associated liver failure, inflammatory macrophages were accumulated in periportal region with high level of Fgl2 expression. In murine VFH model, macrophages predominated infiltrating leukocytes. Kupffer cells (KCs) were replaced of by infiltrating monocyte-derived macrophages (MoMFs) in which Ly6C^{high} MoMFs dominated macrophage population. Fgl2 was robustly induced on proinflammatory MoMFs and KCs following viral infection. Depletion of macrophages ameliorates liver damage in wild type mice and synergically in fgl2$^{-/-}$ mice after viral infection. In Fgl2-deficient mice, infiltrating macrophages were significantly reduced with lower portion of Ly6C^{high} MoMFs and more Ly6C^{low} MoMFs during VFH. Fgl2 depletion impaired macrophage activation by attenuating IRF3, NF-κB, and p38 activation in response to either lipopolysaccharide stimulation or viral infection.
Conclusion: Proinflammatory infiltrating macrophages were the major source of inflammation during VFH progression. Fgl2 induction on these cells orchestrates a positive feedback look for macrophages-derived inflammatory expansion leading to VFH progression by directly promoting classical inflammatory signaling.

FRI-102
Metabolomic and inflammatory mediator based biomarkers analysis for identification of severe drug induced liver injury
Zhongyang Xie[1], Ermei Chen[1], Xiaowei Xu[1], Lanjuan Li[1]. [1]*The First Affiliated Hospital, School of Medicine, Zhejiang University, Infectious, Hangzhou, China*
Email: ljli@zju.edu.cn

Background and aims: To describe the differences of serum metabolomics and immune mediators between Severe and Non-severe idiosyncratic drug-induced liver injury (DILI) patients, and to select biomarkers for identifying the severity of DILI.
Method: A gas chromatography-mass spectrometry (GC-MS) and an ultra-performance liquid chromatography-mass spectrometry (UPLC-MS)-based metabolomics approach were used to explore metabolomics differences in serum samples from 29 DILI patients at disease severity grade 3 (Non-severe) and 27 patients at severity grade 4 (Severe), while 36 controls were also included. Full length and fragmented keratin-18 and 27 immune mediators were determined by ELISA.
Results: Between Severe and Non-severe groups, alkaline phosphatase ($p = 0.021$) and International Normalized Ratio (INR) ($p < 0.001$) were significantly different. Severe group showed a higher M30 serum level than Non-severe group. Multivariate analysis of GC-MS and UPLC-MS both showed a good separation between any two of health control, Non-severe and severe groups. According to the OPLS-DA model, 14 metabolite of GC-MS and 17 metabolites of LC-MS were selected. Among them, 16 metabolites upgraded and 15 downgraded in Severe group. Pathway analysis revealed major changes in primary bile acid biosynthesis, alpha-Linolenic acid metabolism, etc. PDGF-bb, IP-10, IL-1Ra, MIP-1b and TNF-a showed significant difference between severe and non-severe groups, and most of the metabolites had negatively correlation with these immune mediators. Then the representative metabolites and immune mediators were integrated in an OPLS-model and the model revealed clear separation of Severe and Non-severe groups ($R^2Y = 706$, $Q2 = 0.674$, $AUC = 0.983$).
Conclusion: We identified thirty-one differentially expressed metabolites and five immune mediators implicated in different severity of idiosyncratic drug-induced liver injury. Primary bile acid biosynthesis, alpha-Linolenic acid metabolism, etc. were involved in the severity progression. The model of metabolites and immune mediators showed clear separation of different severity of DILI, indicating that these biomarkers could be potential to identify the severity of DILI.

FRI-103
A sublethal dose of acetaminophen suffices to induce the unfolded protein response in hepatocytes through an IRE1alpha-JNK1-XBP1s-dependent mechanism
Hui Ye[1,2], Kang Zheng[1,2], Yulia Nevzorova[2,3,4], Beatriz Martin[1,2], Leonard J Nelson[5], Manuel Gómez del Moral[6], Iris Asensio[7,8,9], Javier Vaquero[7,8,9], Rafael Bañares[7,8,9], Eduardo Martínez-Naves[1], Francisco Javier Cubero[1,2]. Background and aims: Acetaminophen (APAP) overdose is the leading cause of acute liver failure (ALF) in developed countries.

Figure: (abstract: FRI-102)

Activation of the unfolded protein response (UPR) as a consequence of endoplasmic reticulum (ER) stress has recently reported in APAP toxicity. However, the role of the UPR in APAP toxicity remains unclear. In this study, we investigated the role of the UPR during ALF.
Method: Overnight fasted C57/BL6 male mice aged 12-14 weeks, were challenged with a sublethal injection of APAP [0, 75, 150 and 300 (mg)/kg)]. Control mice received an equivalent volume of vehicle (PBS). In parallel, human liver HepaRG cells were challenged with APAP [10 mM]. Twenty-four hours later mice were sacrificed, and tissue collected. Histopathological examination of liver and HepaRGs, immunofluorescence and immunohistochemistry, Western Blot and Real time (RT)-qPCR studies and transmission electron microscopy (TEM) were performed.
Results: Mice: Serum ALT increased proportionally to the concentration of APAP reaching its peak at 300 mg/kg whilst APAP triggered strong hepatic damage further characterized by necrotic foci in the liver parenchyma and massive hepatocyte death (quantified by TUNEL-positive staining). Interestingly, markers of inflammasome formation such as NRLP3, IL-1β and TNF were significantly elevated, which was associated with strong infiltration of $CD11b^{+}$, F4/80+ and CD45+ macrophages. Importantly, increased mRNA and protein expression of pIREα, and XBP1 s, BIP and CHOP-markers of UPR, were observed in mice challenged with 300 mg/kg APAP together with elevated phosphorylation of JNK1. Interestingly, Oil-Red-O and triglyceride content revealed further cellular stress through ER-induced hepatic steatosis and lipogenesis. Moreover, specific inhibition of XBP1 in hepatocytes reversed APAP-induced injury. Animal studies were validated in human HepaRG cells.
Conclusion: Our study strongly suggests that high concentrations of APAP induce the UPR associated with ER stress-induced lipogenesis, ultimately leading to hepatocyte death and ALF. This mechanism is linked to the activation of IRE1α-JNK1-spliced X-box binding protein-1 (XBP1 s) in hepatocytes.

Cirrhosis and its complications: Experimental and pathophysiology

Combining endozepine-4 and blood ammonia: Does it improve the diagnosis of hepatic encephalopathy in patients with liver cirrhosis?

Ayman El Shayeb[1], Akram Deghady[2], Marwa Ibrahim[1], Mohamed Abaza[3]. [1]*Alexandria faculty of medicine, Tropical medicine department, Alexandria, Egypt;* [2]*Alexandria faculty of medicine, Clinical and Chemical Pathology department, Alexandria, Egypt;* [3]*Alexandria fever hospital, Alexandria, Egypt*
Email: aymanelshayeb65@gmail.com

Background and aims: Hepatic encephalopathy (HE) is a neuropsychiatric syndrome that covers a wide range of disturbances in which cerebral function deteriorates. Although the pathogenesis of HE is multifactorial, ammonia has a pivotal role in the genesis of the disease and has been demonstrated to exert a glutamate-related neurotoxicity which in turn may alter the γ-aminobutyric acid (GABA) receptor system. Endozepine-4, an endogenous ligand for the benzodiazepine recognition site of the GABA receptor, may play an important role in the pathogenesis of HE and can be useful in the monitoring of patients with hepatic coma.

The purpose of this work was to evaluate the serum levels of endozepine-4 in patients with hepatic encephalopathy. Moreover, its relation with grading of encephalopathy and ammonia level was studied

Method: This study was carried out on eighty individuals classified into three groups: Group I: Forty patients with hepatic encephalopathy. Group II: Twenty patients with liver cirrhosis without hepatic encephalopathy. Group III: Twenty apparently healthy volunteers as controls. Serum endozepine-4 was measured by ELISA.

Results: Serum endozepine-4 was significantly higher in hepatic encephalopathy patients than in those with liver cirrhosis and controls (Z = 4.69, 5.48) (p = 0.000). Moreover, it was significantly higher in liver cirrhosis patients than controls (Z = 3.03, P = 0.002). Grading of hepatic encephalopathy according to the West Haven Criteria revealed: Grade 1 in 2 patients, Grade 2 in 18 patients, Grade 3 in15 patients and Grade 4 in 5 patients. Significant positive correlation was observed between endozepine-4 and grading of HE (r = 0.52, P = 0.001). Also Significant positive correlation was observed between endozepine-4 and blood ammonia levels (r = 0.48, P = 0.001). Roc curve analysis revealed that endozepine-4 at a cut off > 51 pg/ml is diagnostic of hepatic encephalopathy (AUC 0.83) with a sensitivity of 82.5%, PPV of 89.1, NPV of 69.56% and accuracy of 81.66%. While blood ammonia level at a cut off > 133 mcg/dl is diagnostic of HE (AUC 0.83) with a sensitivity of 77.5%, PPV of 86.11%, NPV of 62.5% and an accuracy of 76.6%. Binary regression analysis model of combined endozepine-4 and ammonia is significant (X^2 32.15, P = 0.000) in predicting hepatic encephalopathy with sensitivity of 92.5%, PPV 86%, NPV 82% and accuracy of 85%.

Conclusion: Serum Endozepine level is a useful marker for diagnosis and grading of hepatic encephalopathy. Moreover, combined measurement of both blood ammonia and serum endozepine-4 have a good predictive value of occurrence of hepatic encephalopathy in patients with liver cirrhosis.

FRI-107

Emerging role of taurine conjugated bile acids in the gut liver axis and on hepatic bile acid receptors in chronic hepatitis C

Rabab Oun Ali Anwar Ali[1], Gabriella quinn[1], kareen hill[1], Grace Zhang[1], Christopher Koh[1], Elliot Levy[1], David E Kleiner[1], Ohad Etzion[1], Theo Heller[1]. [1]*National Institutes of Health, Liver Disease Branch, Bethesda, United States*
Email: rabab.ali@nih.gov

Background and aims: Bile acids (BA) are mediators in gut-liver cross talk and impact host metabolism through BA receptors (BARs). Many BARs have higher affinity for conjugated BA. The aim was to evaluate conjugated BA in the gut liver axis in chronic liver disease.

Method: HCV patients had liver biopsy with portal vein cannulation; portal and peripheral blood obtained before (P1) and 1 year after DAA therapy (P2). Ultrahigh Performance Liquid Chromatography-Tandem Mass Spectroscopy and ELISA assessed 24 BA, taurine and glycine amino acids (AA); and FGF19, respectively. Fecal microbiome and liver transcriptome were evaluated by 16S-rRNA and RNA-Seq, respectively. BA were summed as free, taurine, glycine conjugated (Free-BA, Tau-BA, Gly-BA). All correlations after FDR correction (p < 0.1).

Results: In P1 (n = 29), 16 were Non-Cirrhotic (NC) and 13 Cirrhotic (Cir) by Ishak Fibrosis. Peripheral Tau-BA (not Gly-BA or Free-BA) were higher in Cir compared to NC (Mann-Whitney p < 0.05). Peripheral Tau-BA (not Gly-BA or Free-BA) were inversely linked to portal glycine AA. Of 177 microbial genera, portal glycine AA correlated inversely with Lachnospira, Lachnobacterium, Veillonella, and Hemophilus, and positively with Dorea and Ruminococcus. In portal serum, Tau-BA (not Gly-BA or Free-BA) were associated with higher FGF19. Among classic BARs i.e. FXR, TGR5, LXR, PXR, VDR, CAR, S1PR2, peripheral Tau-BA correlated with hepatic mRNA expression of FXR, LXR beta, and S1PR2; and portal Tau-BA with FXR, TGR5, LXR beta, and S1PR2. Peripheral and portal Gly-BA only correlated with S1PR2. Free-BA showed no link with BARs. In P2 (n = 23), all achieved SVR with no change in fibrosis. Tau-BA and Gly-BA decreased overall (Wilcoxon paired p < 0.05). Tau-BA was higher in Cir than NC, even after SVR.

Conclusion: Among all peripheral BA groups, only Tau-BA were elevated in cirrhosis. Our findings suggest a link between gut microbiome and portal glycine levels, and an influence of portal glycine levels on hepatic Tau-BA conjugation. Association of hepatic BA receptors and portal FGF19 predominantly with Tau-BA is an important finding as BARs and FGF19 mediate host responses of immunity and metabolism. Despite an overall reduction, elevated Tau-BA in cirrhotics even after SVR suggests a relationship between Tau-BA and cirrhosis, independent of HCV. Overall, these findings highlight pathological and possibly therapeutic implications of Tau-BA and BA receptors in chronic HCV and in cirrhosis.

FRI-108

Gut-derived GABA is strongly linked with cognitive impairment in cirrhosis

Jasmohan S Bajaj[1], Qinglong Wu[2], Andrew Fagan[1], Prapaporn Boonma[2,3], Edith Gavis[1], Melanie White[1], Aiswarya Aravamudhanramanujam[2], Michael Fuchs[1], Nazli Yalcinkaya[2], Binu John[1], Anthony Haag[2], Tor Savidge[2]. Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Hepatic encephalopathy (HE) consists of a subclinical minimal (MHE) and clinically apparent overt (OHE) stage. Both stages demonstrate significant alterations in the gut-brain axis that can worsen outcomes and are hypothesized to be due to hyperammonemia and inflammation. However, the gut microbiota produce other neurotransmitters such as tryptophan metabolites and GABA (gamma aminobutyric acid), which need to be evaluated in HE.

Aim: Determine association of HE and cognitive performance with ammonia and gut-derived neurotransmitters in cirrhosis.

Method: Outpatients with cirrhosis underwent cognitive testing, ammonia, cirrhosis severity testing and stool collection. Cognitive testing was performed using the psychometric hepatic encephalopathy score (PHES < -4 = MHE, high score is good). Stool was analyzed for neurotransmitters GABA and tryptophan derivatives (tryptophan, serotonin, melatonin, 5-hydroxytryptophan, N-acetyl serotonin, 5-hydroxyindoleacetic acid (5-HIAAA) and kynurenine). In the entire group, we compared patients with/without MHE with respect to MELD score, ammonia, and neurotransmitters, which were also correlated with PHES scores. Similar analyses were performed in patients without prior OHE. Multi-variable analysis for PHES scores as dependent variables using demographics, cirrhosis details, OHE, ammonia and gut-derived neurotransmitters was performed for each group.

Results: *Entire group*: 63 pts (MELD 10.4, age 58.8, 20 alcoholic cirrhosis, 21 prior OHE who were on rifaximin) were enrolled. 34 pts (21 OHE) had MHE on PHES. Patients with MHE had higher fecal GABA concentrations but statistically similar levels of other neurotransmitters and ammonia (Table). PHES score was negatively correlated with GABA (–0.44, p < 0.001) but not with ammonia (–013, p = 0.37), MELD score (–0.23, p = 0.08) or other neurotransmitters. On multi-variable analysis, PHES was predicted by GABA (p = 0.001) and age (p = 0.022). *Patients without prior OHE*: In these patients, there was a greater increase in fecal GABA concentrations in MHE *vs*. no-MHE with similar levels of other neurotransmitters and ammonia (Table). A similar relationship continued in this subgroup, where the correlation of PHES with GABA was stronger

(–0.72, p < 0.001). No linkage with ammonia (0.06, p = 0.91), MELD score (0.07, p = 0.63) or other neurotransmitters was recorded. On multi-variable analysis, PHES score was predicted by GABA (p < 0.0001) and age (p = 0.039).

mean±SD unless specified	All patients (n=63)			Patients without prior HE (n=42)		
	No-MHE (n=22)	MHE (n=41)	P value	No-MHE (n=16)	MHE (n=26)	P value
Age	57.2±8.2	59.6±7.2	0.13	55.6±8.9	59.1±5.4	0.09
Gender(M/F)	19/3	34/7	0.72	13/3	20/6	0.74
Alcoholic etiology	8/14	12/29	0.33	5/11	6/20	0.56
MELD score	11.1±4.1	10.0±3.9	0.84	9.9±4.1	8.3±2.4	0.92
Venous Ammonia	43.5±23.8	44.1±25.1	0.47	40.9±22.5	37.1±19.3	0.69

PHES median(IQR)	**-0.5 (3.00)**	**-6.0 (6.5)**	**<0.001**	**0.0(3.75)**	**-6.0 (5.5)**	**<0.0001**
Fecal neuro-transmitters (ng/ml)						
GABA	**725±1497**	**2060±4645**	**0.05**	**214±237**	**1336±1697**	**0.001**
Tryptophan	1792±1989	1756±1364	0.53	1632±882	1763±1233	0.37
Serotonin	3.29±3.95	3.92±4.25	0.30	4.24±4.54	4.33±5.05	0.48
Melatonin	0.82±0.84	0.72±0.82	0.66	0.96±0.84	0.73±0.83	0.77
5-hydroxytryptophan	1.89±3.58	6.1±14.0	0.054	2.42±4.15	8.0±16.8	0.08
N-acetyl serotonin	0.67±0.78	0.91±0.96	0.17	0.64±0.81	1.06±1.0	0.10
5-HIAAA	0.70±1.54	0.46±1.67	0.70	0.90±1.81	0.18±0.49	0.90
Kyunerine	0.12±0.09	0.11±0.09	0.59	0.12±0.10	0.09±0.08	0.76

Conclusion: Gut-derived GABA was associated with impaired cognitive performance in cirrhosis independent of prior OHE, lactulose/rifaximin therapy, cirrhosis severity or hyperammonemia, while tryptophan-based neurotransmitters were not linked. Strategies focused on GABA reduction in the gut could form an additional strategy to improve HE severity and progression.

FRI-109

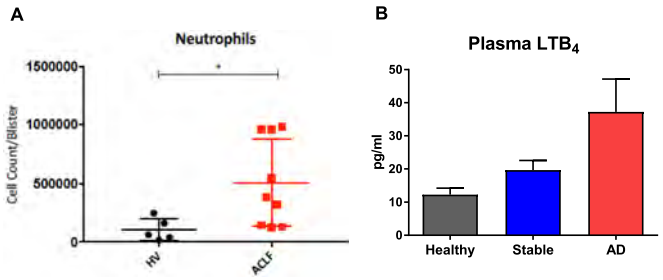
Increased plasma leukotriene B4 in decompensated cirrhosis associates with disease progression and leads to increased skin window neutrophil infiltration

Natalia Becares[1], Alexander A Maini[1], Romain A Colas[2], Jesmond Dalli[2], Derek W Gilroy[1], Alastair O'brien[1]. [1]*University College London, London, United Kingdom;* [2]*Queen Mary University of London, London, United Kingdom*
Email: a.o'brien@ucl.ac.uk

Background and aims: Patients with advanced liver disease are highly prone to bacterial infection secondary to immune dysfunction combined with increased systemic inflammation. Recent studies have shown several circulatory chemokines involved in leukocyte migration and chemotaxis to be increased in decompensated cirrhotic patients, which correlated with survival. Leukotriene B_4 (LTB_4) is a pro-inflammatory lipid mediator that displays strong chemoattractant properties, and we aimed to investigate if its circulating levels were altered in outpatients with ascites and acute decompensation/Acute-on-chronic liver failure (AD/ACLF) inpatients, and whether this correlated with disease progression.

Method: Plasma LTB4 levels from AD/ACLF, outpatients with ascites and healthy volunteers were quantified by High Performance Liquid Chromatography. Expression of enzymes and receptors involved in synthesis and signaling of LTB_4 was assessed by real-time qPCR in primary monocytes and neutrophils. ACLF patients underwent forearm cantharidin blister formation (Cantharone, Dormer Laboratories) with cells counted and stained for flow cytometry.

Results: Neutrophil numbers were significantly increased in our *in vivo* skin blister model of sterile inflammation in AD/ACLF patients compared to healthy volunteers (Figure A). This associated with elevated plasma LTB_4 in both outpatients with ascites and AD/ACLF patients, being highest in AD/ACLF (Figure B). In addition, increased expression of several genes involved in the LTB_4 synthetic pathway was observed in outpatients with ascites and AD/ACLF circulating neutrophils and monocytes, as well as significantly higher levels of the LTB_4 receptor (BLT1) in neutrophils with levels correlating with disease progression.



Conclusion: Contrary to previous studies, we have shown that AD/ACLF patients display significantly higher neutrophil recruitment to a site of inflammation than healthy volunteers. Moreover, plasma levels of the chemotactic LTB_4 increased according to disease progression. We also found that the LTB_4 synthetic machinery was increased in cirrhotic patients, again related to disease progression. This human *in vivo* study supports a novel role for increased LTB_4, causing exuberant leukocyte transmigration in AD/ACLF perhaps underlying the increased systemic inflammatory response that denotes a poor prognosis in these patients. Further studies are required to determine whether this lipid mediator represents a potential therapeutic target.

FRI-110

A nutraceutical supplement rich in docosahexaenoic acid improves portal hypertension in a pre-clinical model of chronic liver disease

Zoe Boyer-Diaz[1], Nicolo Manicardi[2], Peio Aristu[1], Laia Abad[2], Begoña Cordobilla[3], Anabel Fernández Iglesias[2,4], Martí Ortega Ribera[2], Joan Carles Domingo[3], Paloma Morata[5], Jaime Bosch[2,4,6], Jordi Gracia-Sancho[2,4,6]. Email: jordi.gracia@idibaps.org

Background and aims: High levels of oxidative stress in the liver play a key role in the physiopathology of chronic liver disease and portal hypertension (PH). Previous studies demonstrated the effectivity of pharmacological and genetic antioxidant strategies improving PH. However, said strategies have not moved to the bedside. Considering the lack of effective and safe treatments for PH, in this study we evaluated the effects of an antioxidant nutraceutical supplement rich in docosahexaenoic acid triglycerides (DHA-TG) as a possible novel therapy to improve PH.

Method: *In vitro*. The phenotype of human hepatic stellate cells (LX-2) incubated 72h with DHA-TG (10-50 µM) was evaluated in terms of activation (α-SMA and TGFβR) and proliferation markers (PDGFRβ and proliferation assay).
In vivo. Male Wistar rats with chronic liver disease induced by chronic administration of thioacetamide (12 weeks) were treated for two weeks with DHA-TG (500mg/kg/day) or placebo (olive oil) (n = 12 per group). At the end of the treatment the following parameters were evaluated: hepatic and systemic DHA-TG bioavailability using GC-MS, hepatic and systemic hemodynamics (portal pressure, mean arterial pressure, portal blood flow), hepatic oxidative stress (dihydroethidium staining), hepatic fibrosis (sirius red staining), hepatic stellate cell phenotype (HSC: collagen I and α-SMA) and biochemical analysis of serum.

Results: *In vitro*. DHA-TG promoted HSC deactivation in a concentration-dependent manner (data for 50 µM: –93% in α-SMA, –92% in TGFβ, –98% in PDGFRβ, all p < 0.05) without altering their viability.
In vivo. Rats with chronic liver disease treated with DHA-TG showed significantly increased omega-3 index and decreased the omega-6: omega-3 fatty acid ratio in erythrocytes and liver, thus confirming the effectiveness of the treatment. Importantly, rats receiving DHA-TG

exhibited a significant improvement in PH (−14% in portal pressure; p = 0.03) without changes in portal blood flow, suggesting a reduction in intrahepatic vascular resistance (−25%; p = 0.15). The mechanisms underlying this hemodynamic improvement included a reduction in intrahepatic oxidative stress (−21%; p = 0.02), HSC deactivation (−46% in α-SMA protein expression; p = 0.05), together with a tendency to improve hepatic fibrosis (−17%; p = 0.1) with no changes in biochemical parameters.

Conclusion: The present pre-clinical study demonstrates that an antioxidant nutraceutical supplement rich in DHA-TG improves moderately, but significantly, PH and chronic liver disease. These results encourage the evaluation of this type of non-pharmacological therapeutic strategy as a new treatment for PH and cirrhosis.

Email: jclaria@clinic.cat

Background and aims: Human serum albumin (HSA) is an effective therapy in patients with advanced liver disease at risk of developing acute-on-chronic liver failure (ACLF), a clinical condition characterized by recurrent infections and intense systemic inflammation that lead to organ failure (s) and high short-term mortality. Recent studies have demonstrated that HSA downplays systemic inflammation independently of its oncotic properties, although the mechanisms underlying these anti-inflammatory actions are unknown. In the current study, we investigated the molecular mechanisms of HSA in peripheral innate immune cells exposed to a bacterial pathogen-associated molecular pattern molecule (PAMP).

Method: Plasma levels of 42 cytokines-chemokines were measured by bead-based Luminex panels in a group of patients with acute decompensated (AD) cirrhosis under HSA therapy. Peripheral leukocytes (PBMC and PMN) from patients with AD cirrhosis and healthy donors were challenged with bacterial DNA rich in unmethylated CpGs (2 μM) in absence or presence of HSA at 15 mg/ml. Experiments were performed in both preventive and therapeutic modes. The expression of cytokine and interferon stimulated genes (ISGs) was determined by real-time PCR. Cytokine levels were measured by Luminex immunoassay. Phagocytosis was assessed by a fluorimetric assay and respiratory burst by flow cytometry. Leukocyte HSA uptake and intracellular trafficking were monitored by confocal microscopy.

Results: Patients with AD receiving albumin therapy showed significantly reduced circulating levels of tumor necrosis factor (TNF) alpha, interleukin (IL) 6, IL-10 and granulocyte colony-stimulation factor (G-CSF). Similar anti-inflammatory effects were observed *in vitro* in PBMC and PMN stimulated with CpGs and incubated with HSA. No changes in phagocytosis and respiratory burst were detected, indicating that HSA therapy did not compromise leukocyte defensive mechanisms against pathogens. Immunofluorescent confocal microscopy analysis revealed that FITC-labeled HSA was taken up by leukocytes and internalized in intracellular vesicles that were positively stained with EEA1, a marker of early endosomes. Moreover, FITC-labeled HSA colocalized with CpGs in the endosome, the intracellular compartment where CpGs bind to its receptor, TLR9. Consistent with this, HSA also blocked the expression of poly- (I:C)-induced ISG genes (i.e. OAS and CXCL10), which is exclusively mediated by endosomal TLR3. The immunomodulatory effects of HSA were partially mediated by FcRn and independent of its oncotic and/or scavenging properties.

Conclusion: These findings demonstrate that HSA interferes with the leukocyte endosomal TLR signaling pathway, thus providing a mechanism for the anti-inflammatory properties of HSA infusions in patients with AD cirrhosis.

FRI-112

Prediction of treatment failures in a multicentre feasibility trial using human albumin solution to prevent infection in acute decompensation of liver cirrhosis

Louise China[1], Natalia Becares[1], Derek Gilroy[1], Alastair O'brien[1]. *[1]University College London, LONDON, United Kingdom*
Email: louise.china@ucl.ac.uk

Background and aims: Infection is a major cause of death in advanced liver disease. We previously identified PGE_2 mediated immune suppression in acute decompensation patients and its effects were antagonised by albumin. In a single arm, 10-centre study to pilot daily HAS in order to prevent infection, 22/79 patients developed nosocomial infection in the 14 day treatment period. This study aims to link clinical characteristics with laboratory immune assays to predict treatment failure when using HAS as an immunorestorative agent.

Method: Inpatients (n = 79) with complications of cirrhosis and serum albumin < 30g/L were recruited. Daily 20% HAS was infused according to serum albumin level. We evaluated patients that developed a nosocomial infection (NI, n = 22) vs. those that did not (NO, n = 57). Ex vivo immune function was assessed by measuring TNFα production from LPS and *S.Aureus* stimulated monocyte derived macrophages (MDMs) in the presence of patient plasma taken on different treatment days. Albumin-PGE_2 binding function was assessed using ^{3}H-PGE_2 equilibrium dialysis with patient plasma.

Results: 59% of nosocomial infection (NI) patients had a baseline infection at hospital admission as opposed to 25% of patients without nosocomial infection (NO). Mean MELD score was high in both groups (20-22). A higher number of NI patients had ACLF at baseline (32%vs.23%). There were no significant differences in mean volume of HAS infused (≈115mls/day) or baseline serum albumin. In both groups there was a significant improvement in LPS-induced MDM TNFα production in the presence of post HAS treatment plasma (NI:+15.2% (4.6, 25.9, p = 0.008) NO:+8.7% (2.6, 14.8, p = 0.006) when serum albumin had reached > 30g/L. However following this improvement the NI patients had a mean 45.4% decrease in LPS-induced MDM TNFα production at the time of infection (−18.6 to −72.3, p = 0.002) which improved with MDM PGE_2 receptor antagonism. Gram-positive stimulated cells mirrored these results with an even larger impact of PGE_2 receptor blockade. Plasma albumin PGE_2 binding capacity initially improved after patient IV HAS treatment, but significantly dropped in the NI group the day prior to infection (−17.9% (−3.9, −31.9, p = 0.014)) despite serum albumin concentrations remaining > 30g/L.

Conclusion: HAS has been shown to have immunomodulatory potential ex-vivo, however in this study 28% developed NI despite initial improvements in ex vivo immune function and albumin binding. NI patients had a downwards reversal of this initial improvement in both assays, which was PGE_2 dependent. It may be that over time albumin-PGE_2 binding sites become saturated (e.g. with drugs, bilirubin or endotoxin) that renders HAS ineffective or infusions are unable to fully reverse the effects of PGE_2 in end stage liver disease. A future approach may be to use of PGE_2 receptor antagonists in combination with HAS therapy to restore immune function.

Matrix stiffness modulates the phenotype of hepatic cells in cirrhosis and modifies the sinusoidal effects of statins

Sergi Guixé-Muntet[1], Marti Ortega-Ribera[2], Cong Wang[1], Jaime Bosch[1], Jean-François Dufour[1], Annalisa Berzigotti[1], Jordi Gracia-Sancho[1,2,3]. [1]*Inselspital, Hepatology, Bern, Switzerland;* [2]*IDIBAPS, Barcelona, Spain;* [3]*CIBEREHD, Madrid, Spain*
Email: jordi.gracia@idibaps.org

Background and aims: During chronic liver disease (CLD), continued injury induces activation/dedifferentiation of liver cells, leading to formation of scar tissue and stiffening of the liver. Measurement of liver stiffness is an accurate diagnostic tool for fibrosis assessment in CLD. Since stiffness predicts prognosis within each stage of CLD, and since cells may change their phenotype when cultured *in vitro* on matrices with different stiffness, it is **hypothesized** that increased liver stiffness may not only be a consequence of CLD but a primary factor driving its progression.
Method: Primary liver cells (hepatocytes: Hep; stellate cells: HSC; sinusoidal endothelial cells: LSEC) were isolated from healthy and cirrhotic (CCl_4 or thioacetamide) rats and cultured for 72h on polyacrylamide gels with increasing stiffness mirroring healthy and fibrotic/cirrhotic liver matrix (0.5kPa, 13.5kPa, 30kPa). Cells' phenotype was assessed by quantitative morphology, mRNA, protein and functional analyses. Validation experiments were performed in primary human liver cells. In addition, influence of matrix stiffness on the protective effects of simvastatin (SMV) was determined in rat cirrhotic cells.
Results: Phenotypical changes of healthy sinusoidal cells were proportional to stiffness. Indeed, healthy cells at 30kPa displayed larger area, altered morphology, significantly worsened mRNA expression of activation markers [Hep: hepatocyte nuclear factor 4α (HNF4α), albumin; HSC: collagen I, α-smooth muscle actin (α-SMA); LSEC: laminin b1, eNOS] and impaired functionality (Hep: −80% albumin and urea synthesis, HSC: +150% α-SMA fiber formation, LSEC: −40% nitric oxide (NO) synthesis and decreased fenestrae) compared to healthy cells on 0.5kPa gels. On the other hand, cirrhotic cells displayed a significant amelioration of the same markers of phenotype and functionality when cultured on soft surfaces compared to stiffer ones (Hep: +570% albumin, +94% urea synthesis; HSC: −70% α-SMA fiber; LSEC: +90% NO synthesis). Finally, SMV showed statistically significant greater effects deactivating cirrhotic HSC at lower stiffnesses [greater morphology change and higher reduction of α-SMA (−82% in 30kPa vs −94% in 0.5kPa) and collagen I (−19% in 30kPa vs −55% in 0.5kPa)], while its effects on Hep's phenotype were mostly evident on stiff matrices [greater morphology shift, increased HNF4α (+56% in 30kPa vs +13% in 0.5kPa)].
Conclusion: Stiffness determines the phenotype of liver cells; a stiffer environment (mirroring CLD progression) prompts deregulation of healthy cells, while a softer environment (mirroring CLD improvement) leads to improved phenotype of cirrhotic cells. Importantly, efficacy of statins is modulated by matrix stiffness. Thus, targeting liver stiffness may represent a novel therapeutic strategy for CLD management to be added to the existing armamentarium.

FRI-114

Progression of splenic fibrosis in cirrhotic patients with portal hypertension

Yuji Iimuro[1,2], Toshihiro Okada[2], Jiro Fujimoto[2]. [1]*Yamanashi Central Hospital, Department of Surgery, Kofu, Japan;* [2]*Hyogo College of Medicine, Department of Surgery, Nishinomiya, Japan*
Email: siimuro@hyo-med.ac.jp

Background and aims: Among several non-invasive evaluation of portal hypertension (PH), measurement of spleen stiffness by ultrasound is becoming a reliable method to predict esophageal variceal bleeding, while underlying mechanisms for the increased spleen stiffness remain unclear. We aimed to elucidate the pathological changes of spleen and the underlying mechanisms in patients with PH accompanied by thrombocytopenia and splenomegaly.
Method: Histological examination was performed using splenic tissues from 42 HCV-positive patients with PH who underwent laparoscopic splenectomy (platelet counts; 59.5 (21-111) × $10^3/\mu l$), in comparison with those from patients without PH. All research protocols of this study were approved by the institutive Ethics Committee.
Results: In addition to splenic sinus congestion; dilatation of splenic sinus and narrowing of splenic cord, diffuse fibrosis was detected in the splenic cords in the red pulp of patients with PH. The degree of the fibrosis well correlated with severity in thrombocytopenia ($p = 0.011$) and splenomegaly ($p < 0.001$). Cells expressing α-smooth muscle actin (SMA) dramatically increased in the cord of patients with PH, and its expression was network-patterned. Morphological analysis showed that reticular cells in the splenic cord most likely expressed α-SMA, suggesting transformation of reticular cells to myofibroblastic cells. Expressions of nicotinamide adenine dinucleotide phosphate oxidases (NOXs) 2 and 4, oxidative stress markers such as nitrotyrosine, and transforming growth factor (TGF)-β were markedly upregulated in the red pulp of patients with PH, suggesting significant contribution of oxidative stress to the mechanism of the splenic fibrosis.
Conclusion: Splenic fibrosis progresses along with advancement of portal hypertension. This fibrosis progression possibly contributes to the increased spleen stiffness in patients with PH. Reticular cells in the splenic cord possibly participate in this process through the mechanism including oxidative stress.

Toll-like receptor 4: A novel therapeutic target for the treatment of hyperammonemia

Annarein Kerbert[1], Yalda Sharifi[1], Mohammed Sheikh[1], Cornelius Engelmann[1,2], Fausto Andreola[1], Rajiv Jalan[1]. [1]*University College London, Institute for Liver and Digestive Health, Rowland Hill Street, United Kingdom;* [2]*University Hospital Leipzig, Department of Gastroenterology and Rheumatology, Leipzig, Germany*
Email: a.kerbert@ucl.ac.uk

Background and aims: In cirrhosis, lipopolysaccharide (LPS) acts synergistically with ammonia in mediating the severity of hepatic encephalopathy (HE). Although LPS results in neuroinflammation, it is not clear whether it induces hyperammonemia (HA) contributing to HE. This study addressed the following: 1) Does LPS worsen HA in a rodent model of cirrhosis 2) Does treatment with an antagonist (TAK242) of the LPS receptor, toll-like receptor-4 (TLR4), prevent HA and 3) Is a TLR4 knock out ($TLR4^{-/-}$) animal protected from HA.
Method: *Study 1:* Sprague Dawley rats were treated with LPS (0.025 mg/kg, ip.) 4 weeks after bile duct ligation (BDL). 4 groups of rats were studied: sham (n = 4), BDL (n = 4), BDL+LPS (n = 6) and BDL+TAK242 (10 mg/kg ip.) 3 hours before LPS injection (n = 7). *Study 2:* 4 groups of mice were studied: wild type control (WTC, n = 5), WT with HA (WTH, n = 5), $TLR4^{-/-}$ control ($TLR4^{-/-}$C, n = 5) and $TLR4^{-/-}$ with HA ($TLR4^{-/-}$H, n = 5). HA was induced by addition of 0.28M ammonium chloride to drinking water for 3 days. For both studies, plasma ammonia levels and liver gene expression of the 5 urea cycle enzymes (UCEs; OTC, CPS1, ASS1, ASL, ARG1) were assessed. Gene expression was assessed using qPCR and shown as relative gene expression ($2^{-\Delta\Delta CT}$) compared to sham/WT.
Results: *Study 1:* There was a stepwise increase in plasma ammonia throughout the sham, BDL and BDL+LPS groups ($p < 0.001$). Rats pretreated with TAK242 had significantly lower plasma ammonia as compared to the BDL+LPS group ($p < 0.01$, **figure**) and a lower coma rate (85% vs. 0%). Gene expression of all UCEs showed a stepwise decrease in sham, BDL and BDL+LPS rats (all $p < 0.05$), which was prevented by TAK242 treatment (all $p < 0.05$). This was most pronounced for the key, rate-limiting enzyme carbamoyl phosphate

synthetase 1 (CPS1), for which expression levels in the TAK242 group were restored to that of the sham animals (**figure**). *Study 2:* In the TLR4$^{-/-}$ mice, the increase in plasma ammonia levels was lower compared to WT mice ($p < 0.001$). HA resulted in a significant increase in relative expression levels of CPS1 and Argininosuccinate Syntethase 1 (ASS1) in both WT and TLR4$^{-/-}$ animals (both $p < 0.05$).

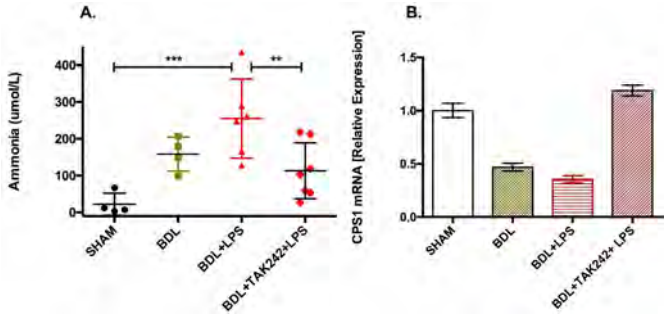

Figure: Plasma ammonia levels (A) and relative gene expression ($2^{-\Delta\Delta CT}$) of the rate-limiting UCE CPS1 (B).

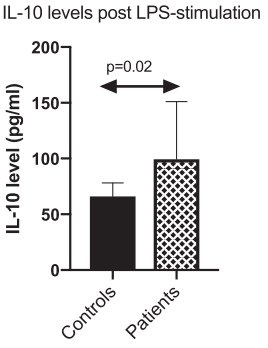
Conclusion: This study shows for the first time that UCE gene expression and the consequent HA is modulated by the LPS-TLR4 pathway. Inhibition of TLR4 with TAK242 offers a novel therapy for HA in cirrhosis.

FRI-116

Capturing the complexities of the immune system in patients with advanced cirrhosis using a whole blood culture system reveals a robust inflammatory response to endotoxin stimulation

Victoria Kronsten[1], Charlotte Woodhouse[1], Tiong Yeng Lim[1], Marc Martinez-Llordella[1], Alberto Sanchez-Fueyo[1], Debbie Shawcross[1]. [1]*Institute of Liver Sciences, King's College Hospital, London, United Kingdom*
Email: victoria.kronsten@nhs.net

Background and aims: Systemic inflammation and cirrhosis-associated immune dysfunction (CAID) in cirrhosis contribute to the development of complications, infection and organ failure. CAID shifts from a pro-inflammatory phenotype in compensated cirrhosis to a state of immune paresis in decompensated cirrhosis and acute-on-chronic liver failure (ACLF).
To date, immune responses in cirrhotic patients have been studied *ex-vivo* using peripheral blood mononuclear cells or isolated immune cell subsets, poorly reflecting the complex interactions between circulating cells, cytokines and metabolites. The TruCulture® (Myriad RBM, Austin) system uses whole blood preserving physiological cellular interactions. It captures global immune cell activity at the time and place of sample collection, thus minimizing bias and variability introduced by cell subset isolation. This study aimed to assess the global immune response of patients with advanced cirrhosis, without evidence of sepsis or organ failure.
Method: 19 patients with cirrhosis (underlying aetiology of alcohol-related liver disease, non-alcoholic fatty liver disease or treated viral hepatitis) were recruited and compared to healthy controls (HC) (n = 7). Median Model for End-Stage Liver Disease (MELD) score was 14 (10-16). Exclusion criteria included other causes of liver disease, active infection, antibiotic or immunomodulator use, immunodeficiency, malignancy, organ failure and hepatorenal syndrome.
Whole blood was drawn directly into 3 TruCulture® tubes (unstimulated, pre-loaded with lipopolysaccharide (LPS) or heat-killed *E.Coli* 0111:B4 (HKEB)) and incubated in dry heat blocks at 37°C for 24 hours. A mechanical separator was used to stop the reaction. Analysis of the supernatant was performed in batch by multiplex assay.
Results: Patients with cirrhosis exhibited a robust pro-inflammatory response to HKEB and LPS with production of interferon (IFN) gamma 1, IFN alpha 2, IFN gamma 2/3 and IFN beta that was not seen in HCs. Patients had significantly higher IL-6 ($p = 0.005$) and IL-10 ($p = 0.02$) levels post LPS-stimulation compared to HCs. IL-10 production negatively correlated with MELD score ($r = -0.51$; $p = 0.02$).



Conclusion: In cirrhotic patients exposed to bacterial products, the response of the un-manipulated circulating compartment is characterised by an exaggerated inflammatory response orchestrated by IL-10, interferons, and IL-6. IL-10 is most significantly influenced by the degree of liver failure, suggesting it plays a key role in the inflammatory events associated with end-stage liver disease.

FRI-117

The gain of function mutation of SerpinB3 (SCCA-PD) is associated with the severity of portal hypertension and complications onset in patients with advanced liver disease

Andrea Martini[1], Filippo Marafatto[1], Cristian Turato[2], Erica Novo[3], Maurizio Parola[3], Alessandra Biasiolo[1], Santina Quarta[1], Mariagrazia Ruvoletto[1], Paolo Angeli[1], Patrizia Pontisso[1]. [1]*University of Padua, Dept. of Medicine, Padua, Italy;* [2]*Veneto Institute of Oncology, IOV-IRCCS, Padua, Italy;* [3]*University of Turin, Dept. of Clinical and Biological Sciences, Turin*
Email: martiniandrea86@gmail.com

Background and aims: Hepatic fibrosis and portal hypertension are determinants of clinical outcome in chronic liver disease and TGF-beta is the key fibrogenic cytokine involved in the activation of hepatic stellate cells. SerpinB3 (or SCCA1) can directly activate stellate cells and SerpinB3 transfected cells up-regulate TGF-beta, an effect that requires the integrity of the reactive site loop of this serpin. The polymorphic variant SCCA-PD presents a substitution in the reactive center loop (Gly351Ala), determining an improved anti-protease activity. Our aim was to assess the effect of SCCA-PD on TGF-beta expression *in vitro* and the clinical characteristics and outcome of a cohort of cirrhotic patients carrying or not this polymorphic variant.
Method: TGF-beta mRNA and protein levels were determined in Huh-7 and HepG2 cells transfected with either wild-type SerpinB3 (SCCA-WT) or SCCA-PD. TGF-beta expression was also evaluated in the human stellate cell line LX2 in response to recombinant SCCA-WT or SCCA-PD proteins. SCCA polymorphism was determined in 86 cirrhotic patients, prospectively followed up for a median period of 81 months. The results were analyzed in relation to clinical data at baseline and the onset of new complications during follow-up.
Results: Transfected cells showed increased TGF-beta, compared to controls and this finding was more prominent in cells transfected with SCCA-PD (SCCA-WT vs SCCA-PD, mRNA: $p = 0.027$, protein: $p = 0.009$). Accordingly, in LX2 cells recombinant SCCA-PD induced higher TGF-beta production, compared to SCCA-WT protein ($p = 0.01$). SCCA-PD was detected in 30% of the enrolled patients that at baseline presented more severe thrombocytopenia (60 vs. 109 x10^9/L, $p = 0.012$) and varices F2-F3 (36% vs. 15%, $p = 0.041$), despite having similar age to SCCA-WT patients (53 + 8 vs 55 + 9 years). Patients carrying SCCA-PD presented a higher MELD score (14 vs. 11 $p = 0.02$) and during follow-up they developed a higher number of cirrhosis complications (56% vs. 20.3%, $p = 0.016$). SCCA-PD (HR = 2.80, p =

0.021), MELD score (HR = 1.17; p = 0.002) and ascites (HR = 3.99; p = 0.003) were identified as independent predictors of cirrhosis complications by Cox regression analysis.
Conclusion: SCCA-PD is able to induce TGF-beta synthesis *in vitro* more efficiently than SCCA-WT. Patients with cirrhosis carrying the SCCA-PD polymorphism present signs of more severe portal hypertension and develop more frequently cirrhosis complications during follow-up, supporting a role of this polymorphic variant in liver disease progression.

Email: cmontoliu@incliva.es

Background and aims: Patients with minimal hepatic encephalopathy (MHE) show mild cognitive impairment associated with cognitive alterations and changes in connectivity. We assessed the relationship of abnormalities of resting-state functional connectivity (rs-FC) and gray matter (GM) volume with cognitive alterations and biochemical parameters associated to MHE. We also evaluated the relationship between memory in MHE and structural and functional connectivity (FC) changes in the hippocampal system.
Method: Twenty-six cirrhotic patients without MHE (NMHE), 13 with MHE, and 24 controls were cognitive assessed with a battery of psychometric tests. Atrophy was determined using Voxel-Based Morphometry and rs-FC was assessed by ICA analysis. Receiver operating characteristic (ROC) curves was performed to assess the diagnostic utility of rs-FC and GM reduction for the discrimination of patients with and without MHE. We also assessed the relationship between alterations in memory and the structural integrity and FC of the hippocampal system.
Results: MHE patients showed significant decrease of GM volume and lesser degree of rs-FC in different networks related to attention and executive functions as compared to controls and NMHE. There is a progressive reduction in rs-FC in the default mode network with the progression of cognitive impairment. MHE patients showed GM reduction in right frontal lobe, right insula and right cerebellum compared to NMHE patients. Alterations in GM volume and rs-FC correlated with cognitive tests.
MHE patients showed impairments in learning, memory, and recognition, compared to NMHE and controls. Cirrhotic patients showed reduced fimbria volume compared to controls. Larger volumes in hippocampus subfields were related to better memory performance in NMHE patients and controls. MHE patients presented lower FC between the L-presubiculum and L-precuneus than NMHE patients, and a reduced FC between L-presubiculum and subiculum seeds and bilateral precuneus, which correlated with cognitive impairment and memory performance.
Conclusion: Decreased cognitive performance is associated by reduced rs-FC and GM atrophy in MHE patients. These changes could have predictive value for detecting MHE.
Alterations in the FC of the hippocampal system could contribute to learning and long-term memory impairments in MHE patients. This study shows the association between alterations in learning and long-term memory and structural and FC disturbances in hippocampal structures in cirrhotic patients.

FRI-119

Distinct salivary microbiome profile in patients with decompensated cirrhosis

Theodora Oikonomou[1], Ioannis Goulis[1], Evangelos Cholongitas[1,2].
[1]Aristotle University of Thessaloniki, 4th Department of Internal Medicine, Thessaloniki, Greece; [2]National and Kapodistrian University, Athens, Greece
Email: oikotheod@yahoo.gr

Background and aims: Patients (pts) with cirrhosis have altered salivary and enteric microbiome, characterized by the presence of dysbiosis. Invasion of the gut by oral bacterial species, may contribute to changes of gut microbiota and consequently to the development of decompensating events.
Method: We collected salivary samples from 28 pts with stable DeCi [20 males, MELD: 12 ± 4, Child-Pugh score: 7 ± 2, viral cause of cirrhosis: 11, hepatocellular carcinoma: 5 pts] along with 26 healthy controls. Exclusion criteria were active or recent infection, use of antibiotics or recent (last 6 months) decompensating event. DNA was extracted and next-generation sequencing of the samples was conducted on the Ion Torrent instrument.
Results: There was no difference between pts and controls in gender, age, or smoking. Overall, 14 phyla and 113 families were identified in the 54 study subjects; 13 phyla and 95 families in controls, 13 phyla and 103 families in pts. The most abundant phyla were Firmicutes (38.43%) and Bacteroidetes (29.88%); in controls Firmicutes accounted for 36.12% of total abundance and Bacteroidetes 31.96%, in patients Firmicutes accounted for 40.86% and Bacteroidetes 27.69%. In family level, Micrococcaceae detected to be more abundant in patients (p value = 0.024); Clostridiaceae (p = 0.004) and Clostridiales Family XIII Incertae Sedis (p = 0.0006), Sphingomonadaceae (p = 0.001), Enterobacteriaceae (p = 0.004), Spirochaetaceae (p = 0.025) were more abundant in controls. Beta diversity assessed by PERMANOVA test confirmed statistically significant differences in community composition between controls and pts (p = 0.008). PERMDISP2 procedure resulted to insignificant results (p = 0.32), which means that these differences are not due to dispersions of the samples within the groups. Sensitivity analysis on Boruta wrapper algorithm selected the most representative genera able to classify controls from patients; Rothia, Serratia, Atopobium, Butyrivibrio, Neisseria, Alloprevotella and Mogibacterium were indicative of DeCi (AUC = 0.815).
Conclusion: Abundances of bacterial taxa showed differences in DeCi pts compared to healthy controls. Salivary microbiome of pts was significantly different from controls. We first report a distinct salivary microbiome profile related to the presence of DeCi.

FRI-120

Structural liver disease rather than portal hypertension is the predominant factor for hepatic macrophage activation in patients with cirrhosis, portal vein thrombosis and idiopathic portal hypertension

Nikolaj Worm Orntoft[1], Michel Blé[2], Anna Baiges[2], Claudia Berbel[2], Virginia Hernández-Gea[2], Fanny Turon[2], Søren Møller[3], Holger Jon Møller[4], Juan Carlos Garcia-Pagan[2], Henning Grønbæk[1].
[1]Aarhus University Hospital, Dept. of Hepatology and Gastroenterology, Aarhus, Denmark; [2]Hospital Clinic de Barcelona, Barcelona Hepatic Hemodynamic Lab, Barcelona, Spain; [3]Copenhagen University Hospital

Hvidovre, Department of Clinical Physiology and Nuclear Medicine, Hvidovre, Denmark; [4]Aarhus University Hospital, Department of Clinical Biochemistry, Aarhus, Denmark
Email: norntoft@gmail.com

Background and aims: Macrophage activation is involved in the development and progression of chronic liver disease and may play a role in portal hypertension. We have demonstrated associations between portal hypertension and the macrophage activation markers soluble CD163 (sCD163) and soluble mannose receptor (sMR) in patients with liver cirrhosis. It is unknown whether this association is only seen in the presence of structural liver disease or also present in patients with non-cirrhotic portal hypertension e.g. idiopathic portal hypertension (IPH) or portal vein thrombosis (PVT). We aimed to investigate the association between macrophage activation markers and portal hypertension in IPH patients and PVT patients with and without cirrhosis.
Method: In a cross-sectional design, we studied plasma levels of sCD163 and sMR in 26 patients with IPH, 20 patients with non-cirrhotic PVT, 17 patients with cirrhosis without PVT, 31 patients with cirrhosis and PVT and 15 healthy controls. All patients and healthy controls had liver vein catheterisation for measurement of hepatic venous pressure gradient (HVPG) and additional clinical and biochemical data was obtained.
Results: Median sCD163 concentration was 1.51 mg/L (95%CI: 1.24; 1.83) in healthy controls, 2.16 mg/L (1.75; 2.66) in patients with IPH and 1.96 mg/L (1.49; 2.56) in patients with non-cirrhotic PVT. There was no difference between IPH and non-cirrhotic PVT patients; but IPH patients had higher levels than controls ($p < 0.05$). These groups had all significantly lower sCD163 levels compared to patients with cirrhosis without PVT (5.19 mg/L (4.18; 6.46)) and cirrhosis with PVT (6.31 mg/L (5.16; 7.73)) ($p < 0.01$, all). Similar significant differences were observed for the sMR. There was no correlation between HVPG and sCD163. Soluble MR was only correlated to HVPG in patients with cirrhosis with PVT (Rho = 0.455, P = 0.01).
Conclusion: Soluble CD163 and sMR levels were higher in patients with cirrhosis with or without PVT compared to patients with IPH and patients with non-cirrhotic PVT. This suggests that hepatic macrophage activation and elevated sCD163 and sMR levels are primarily driven by the structural liver disease per se and not portal hypertension.

FRI-121
Portal hypertension in nodular regenerative hyperplasia is caused by vascular remodeling with extensive regression of portal vein branches

Christian Perez Shibayama[1], Mario Novkovic[2], Ruslan Hlushchuk[3], David Haberthür[3], Burkhard Ludewig[2], Valentin Djonov[3], David Semela[4]. *[1]Kantonsspital St. Gallen, Liver Biology Lab, St. Gallen, Switzerland; [2]Kantonsspital St. Gallen, Institute of Immunobiology, St. Gallen, Switzerland; [3]University of Bern, Institute of Anatomy, Bern, Switzerland; [4]Kantonsspital St. Gallen, Division of Gastroenterology and Hepatology, 9007, Switzerland*
Email: david.semela@kssg.ch

Background and aims: Non-cirrhotic portal hypertension (NCPH) is the main complication in nodular regenerative hyperplasia (NRH). The pathophysiology of NCPH remains unclear. Animal studies suggest that remodeling of the sinusoidal vasculature may induce NCPH. However, sinusoidal changes cannot fully explain NCPH since most NRH patient with NCPH have (false) normal hepatic venous pressure gradients (HVPG) suggesting an additional pre-sinusoidal component for the increased vascular resistance in the portal vein (PV). This concept is supported by biopsy findings in NCPH patients, which often show malformed portal vein branches in the portal tracts. We therefore hypothesize that vascular remodeling of the pre-sinusoidal PV vasculature is the driver in the development of NCPH and represents the site of hemodynamic resistance.
Method: Notch1−/− MxCre mice developing NRH with NCPH (histologic verification of NRH by reticulin/HE/CD34, intravascular PV pressure measurement) were used (Dill et al. Gastroenterology). Whole livers of mice (NRH vs. C57BL/6 controls, n = 4 each) were perfused using a novel polymerizing contrast agent (µAngiofil®) and scanned *ex vivo* by latest generation high-resolution microangio-computed tomography (HR microCT, voxel size 5 um; SkyScan, Bruker). MicroCT-based 3-dimensional (3D) reconstruction was then generated to analyze the complete PV vasculature. Next, filament tracer-based analysis (Imaris®) was used for quantitative and

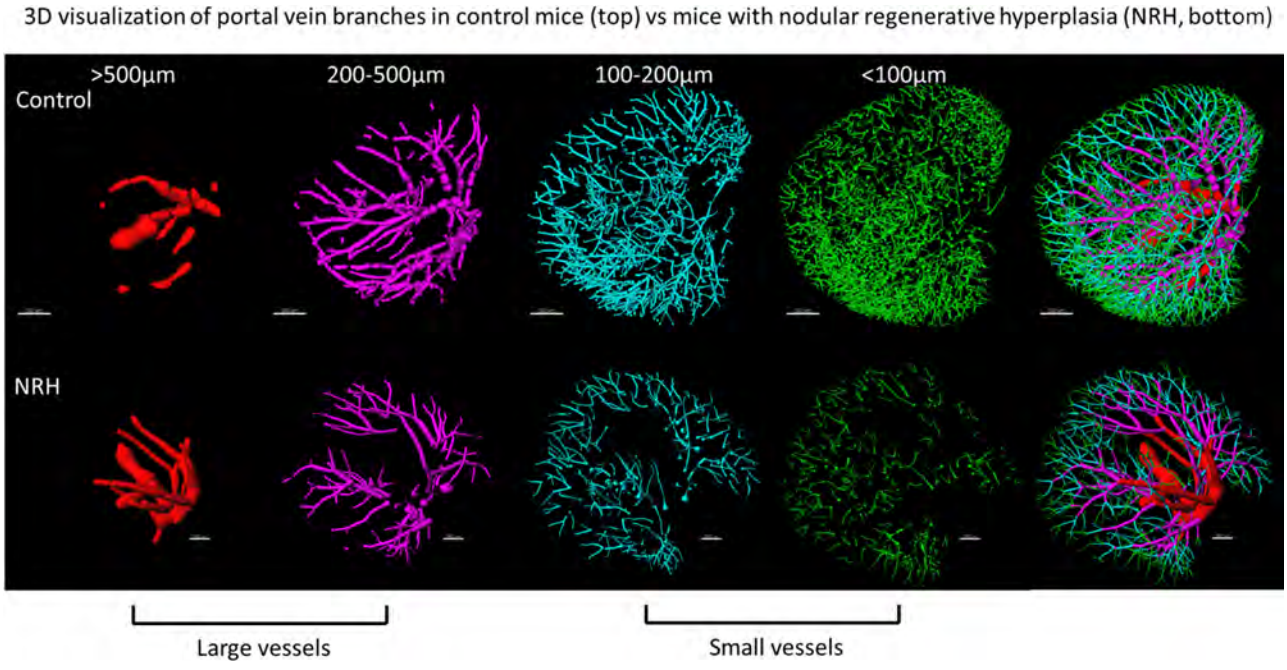

Figure: (abstract: FRI-121)

qualitative morphometry of the vasculature followed by hemodynamic analysis *in silico*.
Results: Whole liver microCT-based imaging allowed detailed imaging of the complete PV vasculature down to pre-sinusoidal PV branches. Subsequent 3D visualization revealed a highly aberrant vascular network in NRH mice. Filament tracer analysis showed extensive reduction (figure) in the number of PV branches by 30%, massive decrease by 80% of small vessels (< 200 um diameter) and terminal (pre-sinusoidal) PV branches as well as a significant reduction of the cumulative PV vascular diameter by 64% leading to increased vascular resistance by hemodynamic analysis located in the pre-sinusoidal PV branches.
Conclusion: Whole organ HR microCT allows unprecedented detailed analysis of the complete PV vasculature and insight into the pathogenesis of vascular liver diseases. NRH mice show substantial vascular remodeling with massive regression of portal vein branches leading to increased pre-sinusoidal vascular resistance and portal hypertension.

FRI-122

Sarcopenia improves after sustained virologic response to DAAs in chronic hepatitis C patients with cirrhosis, but not in those who develop HCC

Colombatto Piero[1], Laura Crocetti[2], Riccardo Gattai[1], Gabriele Ricco[1,3], Antonio Salvati[1], Piercarlo Rossi[2], Barbara Coco[1], Filippo Oliveri[1], Veronica Romagnoli[1], Daniela Cavallone[1], Ferruccio Bonino[4,5,6], Davide Caramella[2], Maurizia Brunetto[1,3]. [1]*Hepatology Unit and Laboratory of Molecular Genetics and Pathology of Hepatitis Viruses, Reference Center of the Tuscany Region for Chronic Liver Disease and Cancer, University Hospital of Pisa, Pisa, Italy;* [2]*Department of Diagnostic and Interventional Radiology, University Hospital of Pisa, Pisa, Italy;* [3]*Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [4]*Italian Liver Foundation (FIF), Science Park, Basovizza, Trieste, Italy;* [5]*Institute of Biostructure and Bioimaging, National Research Council, Naples, Italy;* [6]*University of Pittsburgh Medical Center Institute for Health, Chianciano Terme, Siena, Italy*
Email: p.colombatto@ao-pisa.toscana.it

Background and aims: Sarcopenia is frequently observed in cirrhotic patients and is associated with increased morbidity and mortality. In NASH patients, sarcopenia is associated with insulin resistance, and parallels the progression of liver fibrosis and the risk of developing HCC. Data are scanty in HCV cirrhotic patients. We assessed the impact of HCV clearance on sarcopenia in DAA treated patients with cirrhosis.
Method: The loss of skeletal muscle mass was evaluated by measuring the L3 skeletal muscle index (L3SMI) in 23 consecutive patients (median age 68.9 years, range:42.5-80.8) with HCV (genotype 1a: 5; 1b: 11; 2: 1; 3: 5 and 4: 1) compensated cirrhosis (MELD:6-12) who had CT scans available within 6 months pre-therapy (PT) with DAAs and 6-18 months after completion. The cut-off value used to define sarcopenia was 50 cm^2/m^2 in males (16) and 39 cm^2/m^2 in females (7). Liver function test and metabolic parameters (Cholesterol, Glucose, Insulin, HOMA index, BMI, NAFLD score) were measured at PT, end of therapy (EOT) and at week 48 of post-treatment follow-up.
Results: All patients achieved SVR with 24 week SOF+LDV (17) or SOF+DCV (7) treatment. Twelve patients had previously treated HCC: in 8 of them HCC recurred during or after DAAs therapy. In other 4 patients HCC occurred de novo. In post-treatment follow-up a significant increase of serum cholesterol ($p = 0.038$), and a decrease of BMI ($p = 0.038$) and of NAFLD score ($p = 0.012$) were observed. Sarcopenia was present in 19 (82.6%) patients before and in 14 (60.9%) after DAAs ($p = 0.014$). Overall, median muscle density improved post-DAAs [36.5 (11.4-55.6) pre-DAAs vs 41.0 (20.6-65.9) post-DAAs, $p = 0.003$], increasing in 19 (82.6%) patients. Muscle density increased significantly ($p = 0.003$) in patients who did not develop HCC, remaining stable in those developing HCC (Figure). HCC developed in 0/4 patients without PT-sarcopenia, in 8/15 (53.3%;1 de novo, 7 recurrent) with PT-sarcopenia who increased muscle density and in 4/4 (100%; 3 de novo, 1 recurrent) with PT-sarcopenia who decreased muscle density ($p = 0.018$).

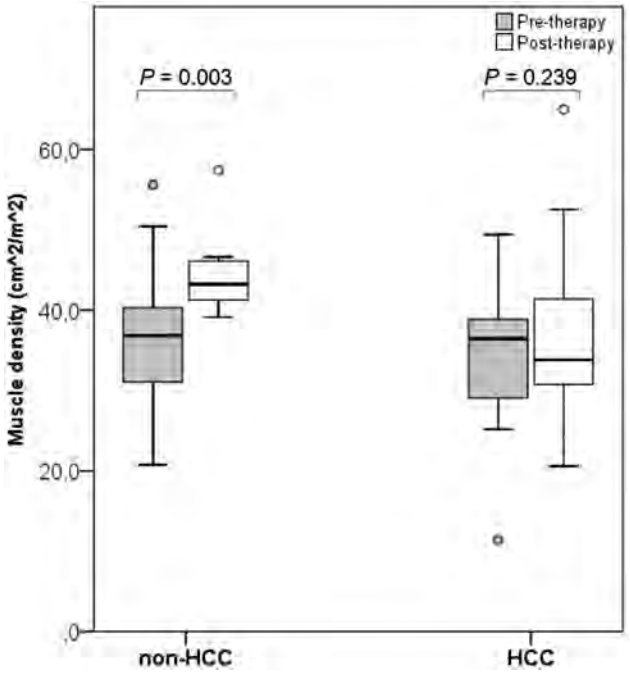

Figure: Muscular density by time-point (pre/post-DAAs) and HCC status

Conclusion: DAAs therapy in cirrhotic patients induces a significant increase of muscle density, even if reverses sarcopenia only in a minority (26.3%) of them within 6-18 months from EOT. The lack of muscle density increase is associated with a higher incidence of HCC. Further studies are required to confirm our observation and to understand the underlying physiopathology.

FRI-123

Transcriptomic and functional analysis of Kupffer cells in patients with cirrhosis reveals a tumour associated macrophages profile and an impaired immune response that are associated with increased risk of infections

Elisa Pose[1], Mar Coll[2], Isabel Graupera[1], Javier Pavía[3], David Fuster[3], Elsa Solà[1], Pau Sancho-Bru[4], Pere Ginès[1]. Email: EPOSE@clinic.cat

Background and aims: Patients with decompensated cirrhosis are at high risk of bacterial infections. During homeostasis, resident macrophages from the liver (Kupffer cells [KCs]) play a key role in the phagocytosis of circulating bacteria. The aim of this study was to characterize the transcriptomic and functional profile of KCs in liver cirrhosis and their relationship with the risk of infections.
Method: KCs were isolated from livers of patients with cirrhosis ($n = 4$) and controls ($n = 5$) and the profile was determined by RNAseq. Molecular pathways of KCs were analysed through GSEA and GO. Protein-protein interaction network (PPIN) was generated with the top 100 de-regulated genes from KCs of cirrhotic compared to KCs from control livers. Protein analysis was performed by FACS from KCs from patients with cirrhosis ($n = 8$) and controls ($n = 6$). Pro-inflammatory response was evaluated in vitro with LPS in KCs from patients with cirrhosis ($n = 5$) and controls ($n = 5$). In vivo phagocytic

capacity of KCs by SPECT with 99mTc-phytate in patients with cirrhosis (n = 21) and in a control group (n = 5).
Results: The expression profile of KCs is different depending on whether they reside in a cirrhotic or control liver. GO analysis revealed that pathways differentially expressed in KCs from cirrhotic livers are involved in immune response. GSEA showed that KCs from patients with cirrhosis have greater expression of M1 markers with respect to M2 (NES: 1.68, p < 0.01 vs. NES: 0.8, p < 0.01). PPIN revealed that most connected nodules corresponded to tumour associated macrophages (TAM) markers, associated with immunosuppression. Over-expression of TAM markers (PDL1, MARCO, CD80, CD163) in cirrhotic KCs was confirmed by FACS. KCs from cirrhotic livers showed a reduced expression of pro-inflammatory cytokines (IL6, CCL20, TNFα) in response to LPS. In vivo phagocytic capacity of KCs was reduced in patients with cirrhosis as shown by a decrease in hepatic uptake and blood clearance of 99mTc-phytate. Patients who presented infections within a 3-month follow-up had an impaired baseline phagocytic capacity (liver/spleen +bone marrow uptake ratio 0.29 vs 0.88, p = 0.02).
Conclusion: KCs from patients with cirrhosis have a TAM profile, with an altered functionality consistent of a reduced pro-inflammatory response and poor phagocytic capacity, which is associated with an increased risk of infections. Restoration of the immune profile and response of KCs may be a good strategy to prevent infections in patients with cirrhosis.

FRI-124
Increased prevalence of low-frequency and rare NOD2 variants in patients with liver cirrhosis
Matthias Reichert[1], Cristina Ripoll[2], Markus Casper[1], Paul Horn[3], Tony Bruns[3], Frank Grünhage[1], Robin Greinert[2], Beate Appenrodt[1], Alexander Zipprich[2], Frank Lammert[1]. *[1]Saarland University Medical Center, Department of Medicine II, Homburg, Germany; [2]Martin-Luther University, Department of Medicine I, Halle, Germany; [3]Gastroenterology, Hepatology and Infectious Diseases, Department of Internal Medicine IV, Jena, Germany*
Email: matthias.reichert@uks.eu

Background and aims: In recent years, genome-wide association studies (GWAS) have robustly identified common genetic risk variants for cirrhosis of various etiology (Karlsen and Lammert J Hep 2015). However, heritability is not fully explained, since low-frequency and rare variants are typically missed by GWAS (Auer et al. Genome Med 2015). Hence, we explored the association of common low-frequency and rare variants in the Nucleotide-binding oligomerization domain containing 2 (*NOD2*) gene with cirrhosis, investigating the three known risk variants and two novel single nucleotide variants (SNV) recently identified by high-resolution mapping (Huang et al. Nature 2017) in patients being screening for the INCA trial (Impact of NOD2 genotype-guided antibiotic prevention on survival in patients with liver Cirrhosis and Ascites, EudraCT 2013-001626-26).
Method: In 17 tertiary care hepatology referral centers throughout Germany, potential study participants were genotyped for the three *NOD2* (p.R702W, p.G908R and c.3020insC) and the two additional variants p.N289S and rs72796367 (intronic), using PCR-based allelic discrimination assays. Prevalence rates and allelic frequencies of the *NOD2* variants were correlated with clinical phenotypes in patients with compensated and decompensated cirrhosis.
Results: Overall, 2, 952 patients were identified and genotyped for the five *NOD2* variants. The most common risk variant was p.R702W (allele frequency 5.8%, 340 patients), followed by c.3020insC (3.6%, 211 patients), and p.G908R (1.8%, 108 patients). The allele frequencies of the rare variants were 2.8% (rs72796367, 167 patients) and 1.0% (p.N289S, 57 patients). Within a subgroup of patients recruited at the academic medical centers Homburg and Halle (n = 750), the prevalence of these variants did not differ when stratified for Child-Pugh classes A-C, compensated/decompensated cirrhosis, or liver stiffness measurements (transient elastography).
Conclusion: According to available data in healthy adults, the *NOD2* variant allele frequencies in the ExAC and dbSNP databases are 3.5% (p.R702W), 2.0% (c. 3020insC), 1.5% (p.G908R), 0.7% (rs72796367) and 0.6% (p.N289S). In our patients with liver cirrhosis treated in tertiary care hepatology centers, the prevalence of the three common *NOD2* risk variants as well as p.N289S is about twice as high as the frequency in the general population, and about four times higher for SNV rs72796367. Investigation of the molecular mechanisms of this association, in particular pathological bacterial translocation and alteration of gut microbiota, is warranted.

FRI-125
The phase angle determined by bioelectrical impedance is a predictive factor of hospitalization, falls and mortality in patients with cirrhosis
Eva Roman[1,2,3,4], Maria Poca[5], Gerard Amorós[6], Javier Rosell[7], Cristina Gely[2], Berta Cuyas[5], Silvia Vidal[2], Eulalia Urgell[8], Elvira Hernández[1], Rosalia Santesmases[1], Candido Juárez[9], Carlos Guarner[3,5,10], German Soriano[3,4,5]. *[1]Escola Universitària d'Infermeria de Sant Pau, Barcelona, Spain; [2]Institut de Recerca Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [3]Autonomous University of Barcelona, Bellaterra, Spain; [4]Instituto de Salud Carlos III, Madrid, Spain; [5]Hospital de la Santa Creu i Sant Pau, Gastroenterology, Barcelona, Spain; [6]Institut de Recerca Hospital de la Santa Creu i Sant Pau, Cardiology, Barcelona, Spain; [7]Universitat Politècnica de Catalunya, Electronic Engeenering, Barcelona, Spain; [8]Hospital de la Santa Creu i Sant Pau, Biochemistry, Barcelona, Spain; [9]Hospital de la Santa Creu i Sant Pau, Immunology, Barcelona, Spain; [10]Instituto de Salud Carlos III, Madrid, Spain*
Email: eroman@santpau.cat

Background and aims: Patients with cirrhosis often present alterations in body composition. The measurement of the phase angle (PA) is a quick method for the evaluation of the corporal composition calculated from the resistance (linked to the state of hydration of tissues) and the reactance (linked to the cellular mass). The PA can be a more precise tool than other nutritional, biochemical or anthropometric parameters to assess the frailty and prognosis in patients with chronic diseases. However, data in patients with cirrhosis are still very scarce. The aim of our study was to analyze the prognostic value of the PA to predict events related to frailty (hospitalization, falls and mortality) in patients with cirrhosis.
Method: Outpatients with cirrhosis were consecutively included, and the PA was determined by bioelectrical impedance with the BIA 101 system (Bodygram TM 1.31, Akern). The measurement was made after 10 minutes of rest in supine position with 4 conventional electrodes: 2 placed on the hand and 2 on the contralateral foot. Patients were prospectively followed to determine the incidence of hospitalizations, incidence of falls, and mortality.
Results: We included 100 patients (age 63.8 ± 9.3, men 68%, alcohol etiology 63%, frailty according to the Fried Index 25%, MELD 9.0 ± 2.5 and PA 5.4 ± 1.5°). During a mean follow-up of 21.1 ± 5.9 months, 30% of patients required hospitalization, 23% presented falls and 15% died. In the multivariate analysis, the PA ≤ 4.6° and the degree of comorbidity (Charlson) were independent predictive factors of hospitalization (HR 3.787, 95%CI 1.437-9.984, p = 0.007, and HR 1.713, 95%CI 1.038-2.828, p = 0.035, respectively). The PA ≤ 4.6° was the only predictive factor for falls (HR 4.755, 95%CI 1.831-12.343, p = 0.001), and serum sodium and PA ≤ 4.6° were predictive factors of mortality (HR 0.728, 95%CI 0.606-0.876, p = 0.001, and HR 9.165, 95% CI 1.894-44.349, p = 0.006, respectively). Patients with PA ≤ 4.6° (n = 31) showed a higher probability of hospitalization, falls and mortality at 2-years follow-up than patients with PA > 4.6° (n = 69) (36% vs 11%, p = 0.002, 44% vs 11%, p < 0.001, and 25% vs 3%, p = 0.001, respectively). The PA showed a positive correlation with muscle strength and

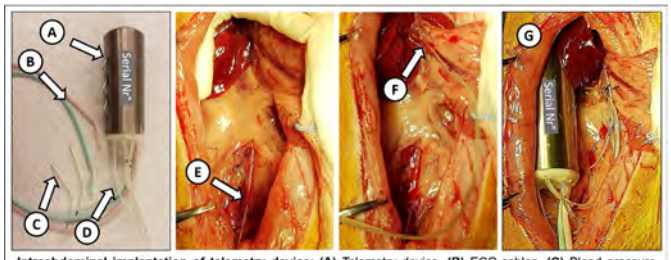
testosterone concentration; and a negative correlation with Fried Index, MELD, albumin, creatinine and cystatin C.
Conclusion: The phase angle is a predictive factor of hospitalization, falls and mortality in outpatients with cirrhosis.

FRI-126
Innovative potential biomarkers in spontaneous bacterial peritonitis from ascitic fluid
Sophia Scherm[1], Haderer Marika[1], Aschenbrenner Elisabeth[1], Pollinger Kirstin[1], Schlosser Sophie[1], Kunst Claudia[1], Martina Mueller-Schilling[1]. [1]*University hospital Regensburg, Internal Medicine I, Regensburg, Germany*
Email: gn.scherm.sophia@live.de

Background and aims: Spontaneous bacterial peritonitis (SBP), a bacterial infection of ascitic fluid without intra-abdominal, surgically treatable focus, is a severe complicationindecompensatedliver cirrhosis with a 1-year-mortality of 70%. Translocation of intestinal bacteria from the gut to mesenteric lymph nodes into the ascitic fluid is regarded to be the underlying process. Diagnosis of SBP is assured with detection of > 250 polymorphonuclear (PMN)cells per µl. Since patients need an immediate antibiotic treatment, molecular markers indicating a beginning SBP need to be identified to improve early diagnosis of SBP.
Method: To identify novel potential biomarkers for SBP, ascitic fluid was collected from patients suffering liver cirrhosis. Protein levels of lactoferrin, C3a, IP-10, IL-6, IL-8 and IL-10 within ascitic fluids were determined by ELISA.
Results: In total, 69 ascitic fluid samples from 41 patients between 36 and 77 years of age (87% male, 22% female) were analyzed. Genesis of liver cirrhosis was alcohol-toxic (58.5%), cryptogenic (19.5%), nutritiv-toxic (7.3%), viral (4.9%), autoimmune (2.4%), PBC (2.4%), non-alcoholic steatohepatitis (2.4%) and Budd Chiari Syndrome (2.4%). In 11.6% of the samples diagnosis of SBP was confirmed. Lactoferrin levels in ascitic fluids of SBP samples (mean 1006 ng/ml) were higherthan in ascitic fluids without SBP (mean 75ng/ml). Follow-up samples indicated that lactoferrin concentrations were elevated in early stages of SBP and coincided with the course of the disease and therapeutic response.C3a levels also correlated with the course of disease, but were reduced in infected ascitic fluids (mean 511ng/ml) compared to non-SBP samples (mean 975 ng/ml). IP-10 was detected in all samples, but did not display any correlation with disease activity. Although relevant amounts of cytokines IL-6, IL-8 and IL-10 were detected in ascitic fluid of liver cirrhosis patients, an association of these parameters with early onset of SBP was not observed.
Conclusion: Lactoferrin and C3a levels in ascitic fluid of liver cirrhosis patients correlate with the onset and course of SBP. Notably, a lower PMN-cutoff resulted in an enhanced specificityfor SBP. High levels of inflammatory molecules and cytokines highlight the tremendous inflammatory activity in ascitic fluids of liver cirrhosis patients. These results put SBP in a novel perspective and provide options for earlier diagnosis and treatment.

FRI-127
Measuring dynamics of portal pressure and vital parameters in conscious rats using real-time telemetry
Philipp Königshofer[1,2], Benedikt Simbrunner[1,2], Ksenia Brusilovskaya[1,2], Bruno Podesser[3], Michael Trauner[1], Thomas Reiberger[1,2], Philipp Schwabl[1,2]. [1]*Medical University of Vienna, Dept. of Internal Medicine III, Div. of Gastroenterology and Hepatology, Vienna, Austria;* [2]*Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Vienna, Austria;* [3]*Medical University of Vienna, Center for Biomedical Research, Vienna, Austria*
Email: philipp.schwabl@meduniwien.ac.at

Background and aims: Portal pressure represents an excellent integrative readout for severity of liver disease. Thus, an improvement of portal hypertension is an accepted surrogate parameter in clinical trials. In cirrhotic rodent models, evaluation of the portal hypertensive syndrome is usually performed under anaesthesia at a terminal end point due to invasive measurements. Thus, we aimed to establish a system for telemetric pressure measurements in conscious cirrhotic rats.
Method: After median laparotomy, we implanted a telemetric device (PPBTA-L2, TSE Systems) into the abdomen of Sprague-Dawley rats of 350-400g bodyweight (see Figure). One solid state pressure tipped sensor was implanted into the abdominal aorta, while the second was placed in the portal vein. Intravascular pressure probes were secured with tissue glue and specifically aligned to compensate for tension forces due to body movements and intestinal peristalsis. Two ECG leads were subcutaneously sewed to the thoracic and abdominal wall to measure heart rate. Moreover, temperature and X/Y/Z-axis activity were recorded via integrated sensors. In a subgroup, the bile duct was ligated to induce cholestatic cirrhosis. Portal and arterial pressure, heart rate, temperature and activity level were longitudinally monitored every 6 hours.



Intraabdominal implantation of telemetry device: **(A)** Telemetry device, **(B)** ECG-cables, **(C)** Blood pressure probes, **(D)** Temperature probe **(E)** Blood pressure probe in the abdominal aorta, **(F)** Blood pressure probe in the portal vein **(G)** Implanted telemetry device.

Results: Surgical implantation required microsurgery skills and yielded in high success rates (85%). Healthy rats presented a long-term survival of > 8 weeks without complications. In healthy rats, mean arterial pressure (90 ± 9 mmHg), heart rate (311 ± 33 bpm) and portal pressure (9.7 ± 2.8 mmHg) were within physiological ranges and followed a circadian rhythm. In bile duct ligated rats, experiments are currently ongoing. First readouts showed a steady increase in portal pressure.
Conclusion: Telemetric hemodynamic measurements allow monitoring of dynamic and circadian changes of portal pressure, arterial pressure and heart rate in cirrhotic rats in real-time without anaesthesia. This new method requires precise surgical skills, yet facilitates a detailed long-term follow-up and provides a setting for studying pharmacodynamics of novel compounds for the treatment of portal hypertension. On top, it supports the 3Rs by methodological refinement and reduction of required animals if multiple timepoints need to be analysed.

FRI-128
Mesenchymal stem cells cultured in hypoxic conditions had multi-directional effects on mice with liver cirrhosis through prostaglandin E2 and miR210 production
Atsunori Tsuchiya[1], Yuichi Kojima[1], Masahiro Ogawa[1], Shunsuke Nojiri[1], Suguru Takauchi[1], Takayuki Watanabe[1], Hiroteru Kamimura[1], Masaaki Takamura[1], Shuji Terai[1]. [1]*Niigata University, Gastroenterology and Hepatology, Niigata, Japan*
Email: atsunori@med.niigata-u.ac.jp

Background and aims: Mesenchymal stem cells (MSCs) are easily expanded; can be acquired from medical waste such as adipose and umbilical cord tissues; are influenced by culturing conditions; and have multiple functions, such as anti-inflammatory, anti-oxidative, and anti-fibrosis effects as well as angiogenesis. We analyzed the multi-directional effects of MSCs cultured in hypoxic conditions and their underlying mechanisms in treating liver cirrhosis model mice.
Method: Human bone marrow-derived MSCs cultured in hypoxic (5% O_2; hypo-MSCs) and normal oxygen conditions (21% of O_2; nor-MSCs) were compared by cap analysis of gene expression (CAGE), with or

without serum from liver cirrhosis patients. The therapeutic effects of MSCs such as serum liver enzymes, fibrosis regression and oxidative stress in the liver were evaluated by administering 1×10^6, 2×10^5, or 4×10^4 cells/mouse of hypo- and nor-MSCs from the tail vein into a CCl_4-induced liver cirrhosis model mouse. Intra-vital imaging was performed using a two-photon excitation microscope to confirm different migration paths of the MSCs to the liver.

Results: CAGE analysis revealed that mRNA expression levels of prostaglandin E synthase *Ptges* and miR210 in hypo-MSCs were significantly higher than those in nor-MSCs. *In vivo* analysis revealed that, while both hypo-MSCs and nor-MSCs reduced the serum levels of ALT, oxidative stress, and fibrosis compared to the control mice in a dose-dependent manner, hypo-MSCs had more therapeutic effects compared to nor-MSCs. We further confirmed this by an *in vitro* study wherein hypo-MSCs had effectively changed the polarity of macrophages to an anti-inflammatory phenotype via prostaglandin E2 (PGE2) and miR210 reduced the rate of apoptosis of hepatocytes. Intra-vital imaging after administration showed that both hypo- and nor-MSCs were trapped mainly in the lungs and minor population of both cells had migrated into the liver, with no difference between their distributions.

Conclusion: Hypo-MSCs had a greater therapeutic effect, mediated by PGE2 and miR210 production, compared to nor-MSCs. These results revealed that MSCs can be manipulated to induce better therapeutic effects in liver cirrhosis, which can be used for effective cell therapy in the future. MSCs produce multiple factors that can affect multi-directional effects; that Is MSCs are working as "conducting cells" in the liver cirrhosis.

A defect in the Nrf2/HO-1 pathway and Nox2 activation results in regulatory T cell mitochondrial dysfunction in alcohol related cirrhosis

Niloufar Safinia[1,2], Trishan Vaikunthanathan[1], Silvia Cellone Trevelin[3], Marco Romano[1], Qi Peng[1], Mark Thursz[2], Alberto Sanchez-Fueyo[3], Robert Lechler[1], Giovanna Lombardi[1]. [1]*MRC Centre for Transplantation, Division of Transplantation Immunology and Mucosal Biology, King's College London, London, United Kingdom;* [2]*Department of Hepatology, Division of Surgery and Cancer, Imperial College London, London, United Kingdom;* [3]*Institute of Liver Studies, King's College London, London, United Kingdom*
Email: niloufar_safinia@yahoo.com

Background and aims: Alcoholic liver disease is a major cause of chronic liver disease in the western world with mortality continuing to rise. The molecular and cellular events underlying the progression of liver disease remain poorly understood, with immune-mediated injury and oxidative stress highlighted as factors driving disease progression.

The effects of oxidative stress are mediated, in part, by nuclear factor E2-related factor 2 (Nrf2), a transcription factor regulating an array of antioxidant genes in the liver. Here we report a previously unrecognized functional deficit in circulating regulatory T cells (Tregs) isolated from patients with alcohol-related cirrhosis (ARC), correlating with disease severity. We propose a mechanism to explain this defect, showing that a dysregulated Nrf2 pathway and subsequent NADPH oxidase 2 (Nox2) activation leads to Treg mitochondrial dysfunction and loss of suppressor function.

Method: Tregs were isolated from peripheral blood of patients with ARC (abstinent > 6 months) and healthy controls (HC). CFSE dilution assay was used to assess Treg suppressor function. Western blots/ELISA were used to quantify Nrf2 and Heme Oxygenase-1 (HO-1) expression. Imagestream® assessed Nrf2 translocation. Tregs isolated from spleens of Nrf2 KO/WT mice were assessed by flow cytometry and CFSE dilution assay. Intracellular reactive oxygen species (ROS) production, lipid peroxidation and apoptosis rate of ARC Tregs were determined by flow cytometry. The Seahorse Platform was used to measure glycolysis (extracellular acidification rate; ECAR) and oxidative phosphorylation (oxygen consumption rate; OCR) post 24hrs stimulation with anti-CD3/CD28. Nox2 activation was studied by confocal microscopy, assessing the co-localization of p47phox and gp91phox.

Results: ARC Tregs displayed reduced suppressor function with a lower expression of HO-1 and a defect in Nrf2 transnuclear migration as compared to HC Tregs. In agreement, Tregs isolated from $Nrf2^{-/-}$ mice displayed reduced expression of regulatory markers and suppressive function compared to WT mice. Additionally, culture of HC Tregs with a specific inhibitor of HO-1 reduced their suppressive function.

ARC Tregs also demonstrated higher baseline ROS production, lipid peroxidation and apoptosis rate as compared to HCs and exhibited a higher ECAR and OCR, after oligomycin injection, indicative of mitochondrial uncoupling. Furthermore, we demonstrate activation of Nox2, secondary to increased intracellular heme build up, as a mechanism for the intracellular ROS production and mitochondrial dysfunction [figure].

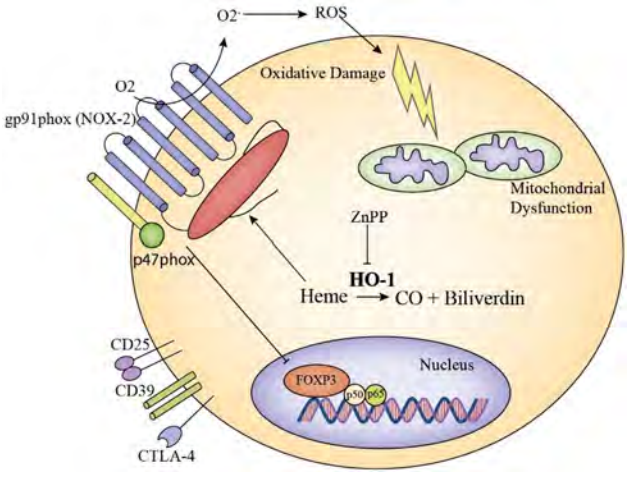

Figure: Dysregulated Nrf2/HO-1 pathway leads to build up of intracellular heme, activation of Nox2 and Treg mitochondrial dysfunction

Conclusion: Modulation of the Nrf2 pathway provides a therapeutic target to enhance Treg function in order to halt/prevent liver disease progression.

FRI-130

Changes in the extracellular matrix of the heart and the liver assessed by MRI with T1-mapping are closely linked in cirrhosis: Is inflammation the shared pathway?

Signe Wiese[1], Andrei Voiosu[1,2], Jens Hove[1], Ove Andersen[1], Flemming Bendtsen[1], Søren Møller[1]. [1]*Copenhagen University Hospital Hvidovre, Copenhagen, Denmark;* [2]*Colentina Clincial Hospital, Bucharest, Romania*
Email: signeswiese@gmail.com

Background and aims: Changes in the composition of the hepatic extracellular matrix are well-established in cirrhosis. Novel MRI with T1-mapping and extracellular volume (ECV) quantification directly reflects intrinsic tissue changes. Recently, we reported an increased cardiac ECV in patients with cirrhosis reflecting alterations in the myocardial extracellular matrix. The relation between hepatic and cardiac ECV has never been addressed. Our aim was therefore simultaneously to investigate changes in liver ECV and myocardial ECV in patients with cirrhosis, and to study the role of inflammation.

Method: We performed a prospective study including 52 patients with cirrhosis (8 Child class A/37 Child B/7 Child C) and 14 healthy controls. Contrast-enhanced MRI with T1-mapping and ECV quantification was performed with a 3.0-Tesla scanner and myocardial ECV and liver ECV were calculated. Inflammatory markers (IL-6, IL-8, IL-

1b, IL-18, TNF-α and stromal-cell derived factor 1α (SDF1α) were measured from plasma samples. In the controls, contrast-enhanced MRI alone was performed.
Results: Liver ECV and myocardial ECV, both, were significantly increased in cirrhotic patients compared to controls (liver ECV: 44.4 ± 11% vs. 33.7 ± 7%, p = 0.001 and myocardial ECV: 31.2 ± 6 vs. 27.4 ± 3%, p = 0.04) and were individually correlated (r = 0.484, p = 0.001). Liver ECV was correlated with Child score (r = 0.421, p = 0.003), MELD (r = 0.410, p = 0.004), IL-6 (r = 0.37, p < 0.01), and SDF-1α (r = 0.56, p < 0.001). Similarly, myocardial ECV significantly correlated with Child score, MELD, IL-6 and IL-8.
Conclusion: Cardiac ECV as well as liver ECV in cirrhosis are increased and mutually related. This may reflect altered extracellular matrix composition of both the heart and the liver and low-grade inflammation most likely seems to be a common pathway for these changes.

Impact of HBsAg level on cellular immune responses in HBeAg negative patients with chronic hepatitis B virus infection

Elmira Aliabadi[1,2], Carola Mix[1,2], Michael P. Manns[1,2,3], Anke Kraft[1,2], Markus Cornberg[1,2,3]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, 30625, Hannover, Germany; [2]German Centre for Infection Research (Deutsches Zentrum für Infektionsforschung DZIF), Partner-site Hannover-Braunschweig, 30625, Hannover, Germany; [3]Centre for Individualized Infection Medicine (CIIM), c/o CRC Hannover, 30625, Hannover, Germany*
Email: aliabadi.elmira@mh-hannover.de

Background and aims: Worldwide 250 million people are persistently infected with hepatitis B virus (HBV) leading to 686.000 deaths annually. The level of hepatitis B surface antigen (HBsAg) produced by HBV-infected hepatocytes could have an immunomodulatory role in HBV infected patients. However, the correlation between HBsAg level and HBV-specific T cell immune responses in patients with chronic HBV (CHB) and HBeAg negative has not been well defined. We investigated HBV-specific immune responses in HBeAg negative patients with different levels of HBsAg during the natural course of chronic hepatitis B.
Method: 44 HBeAg negative patients were categorized into 4 groups based on their HBsAg level (HBsAg < 100 IU/ml, HBsAg 100–999 IU/ml, HBsAg 1, 000-9, 999 IU/ml, HBsAg ≥ 10, 000 IU/ml). PBMCs were isolated from these patients and different subsets of immune cells were phenotypically characterized using 14 color flow cytometry. Furthermore, IFNγ+ HBV-specific T cell responses were measured after in vitro culture with overlapping peptides covering polymerase, surface and core of HBV genotype D in the presence or absence of anti-PD-L1 antibody.
Results: Patients with different levels of HBsAg showed similar frequencies of memory, naïve and effector T cells, γδ T cells, Treg cells, MAIT cells, B cells, NK cells, monocytes and DCs. Interestingly, the frequency of γδ T cells, Treg cells and CD1c- myeloid DCs was significantly increased in CHB patients compared to healthy individuals.
Stimulation of PBMCs with HBV overlapping peptides induced core- and polymerase-specific T cell responses. However, surface-specific T cell responses were hardly detectable. We observed a trend towards higher HBV-specific T cells in patients with HBsAg < 100 IU/ml. In patients with HBsAg ≥ 10, 000 IU/ml a high variability of T cell responses were detected. Interestingly, in these patients stronger T cell responses were associated with young age, female gender and low HBV DNA. In general, CD4+ T cell response to in vitro stimulation with HBV overlapping peptides was stronger than CD8+ T cell responses. Blocking the PD-1/PD-L1 pathway during in vitro culture significantly increased the core-specific T cell response in patients with HBsAg < 100 IU/ml.
Conclusion: Our data suggests that HBsAg level per se may have only a minor impact on the cellular immune responses. Patients with HBsAg < 100 IU/ml, showed slightly stronger T cell responses to in vitro HBV peptide stimulation especially after using checkpoint inhibitors. Therefore, patients with low HBsAg levels may demonstrate better responses to immune-modulatory treatment.

FRI-132
In vitro modulation by TLR8 agonist GS-9688 of multiple regulatory cell types in patients with chronic hepatitis B

Oliver E Amin[1], Emily Colbeck[1], Stephane Daffis[2], Divya Pattabiraman[2], Colette Sitali[3], William Rosenberg[4], Simon Fletcher[2], Mala Maini[1], Laura J Pallett[1]. *[1]UCL, Infection and Immunity, London, United Kingdom; [2]Gilead Sciences, Foster City, United States; [3]UCL, Infection, Immunity and Transplantation, London, United Kingdom; [4]UCL, Infection, Immunity and Transplantation, London, United Kingdom*
Email: laura.pallett@ucl.ac.uk

Background and aims: HBV-specific T cell responses are characterised by functional exhaustion and premature deletion. Immunosuppressive cell types targeting this antiviral T cell response include granulocytic myeloid-derived suppressor cells (gMDSC), CD4 + regulatory T cells (Tregs), and regulatory TRAIL + NK cells. Signalling through different toll-like receptors (TLR) induces selective cytokine profiles capable of differentially modulating immune cell subsets. Here we have tested the impact of a selective small molecule agonist of TLR8 (GS-9688), currently in Phase 2 trials for the treatment of chronic HBV infection (CHB), on these three different regulatory populations and on HBV-specific CD8 + T cells *in vitro*.
Method: PBMC obtained from a cohort of CHB patients were treated with 1-500 nM GS-9688 for 2-7 days. Cytokine responses were measured by luminex assay. Sixteen-colour flow cytometry was used to analyse changes in the frequency and phenotype of gMDSC (CD11bhighCD33+HLADR-CD14-CD15+, n = 14 CHB patients), Tregs (CD4+CD25hiCD127loFoxp3+, n = 8 CHB patients), NK cells (CD3-CD56+, n = 20 CHB patients) and HBV-specific CD8+ T cells (binding a panel of HLA-A2/peptide dextramers, n = 12 CHB patients).
Results: In line with previous studies, GS-9688 induced cytokines in PBMC cultures (e.g. TNF-α, IFN-γ, IL-12p70 and IL-18) with the potential to modify regulatory cell subsets. Consistent with this cytokine profile, GS-9688 treatment induced gMDSC to switch to a more mature and less suppressive phenotype, resulting in a > 50% reduction in the frequency of this regulatory cell type ($p < 0.001$). Similarly, GS-9688 treatment induced a dose-dependent reduction in the frequency of conventional Tregs ($p < 0.05$). In contrast, GS-9688 triggered dose-dependent activation of CD56bright and CD56dim NK cells, and a rapid upregulation of their expression of the death ligand TRAIL ($p < 0.05$). Despite this, HBV-specific CD8+ T cell frequencies remained stable, suggesting they were protected from NK cell TRAIL-mediated deletion in the presence of GS-9688.
Conclusion: Overall, these in vitro data suggest that GS-9688 has the potential to reduce the suppressive activity of regulatory populations in the liver that collectively limit the antiviral response of HBV-specific T cells. Further studies will explore how HBV-specific T cells are protected from deletion by the GS-9688-driven expansion of TRAIL+ NK cells and whether these changes are recapitulated using intrahepatic lymphocytes.

Email: thomas.pietschmann@twincore.de

Background and aims: Characterization of HIV patients with elite neutralizing antibody responses led to discovery of broadly neutralizing antibodies and their epitopes, thus promoting vaccine design. Here we aimed to develop an HCVcc-based screening panel for identification of elite neutralizers.
Method: Polyclonal immunoglobulins from more than 100 patients infected with HCV genotype 1-6 were purified and HCVcc neutralization was quantified across 14 isolates representing 6 viral genotypes. Metric multidimensional scaling was used for HCV neutralization cartography to plot neutralization maps. Various normalization methods and weighted-stress schemes across different dimensions were explored and leave-one-out (LOO) errors were computed to select the best normalization/weighing method. K-means clustering combined with elbow method, silhouette error, and gap statistics were employed to guide virus clustering and selecting representative strains.
Results: Vast differences in neutralization sensitivity of HCV strains were detected, with Jc1 (GT2) being most resistant and SA13 (GT5a) being most sensitive. Viruses mapped to six neutralization clusters, in part composed of viruses from different subtypes and genotypes. There was no correlation with the genetic distance of strains, suggesting that neutralization clustering differs from sequence-based clustering. Antibodies from GT1 infected individuals formed a compact cluster whereas antibodies from other genotypes were intermixing and varied broadly in neutralization capability.
Conclusion: Representative isolates from six neutralization clusters reconstructed the neutralization space with even slightly lower LOO error than the full panel of isolates. Viruses representing these clusters are well suited for high resolution profiling of virus-antibody neutralization and they may reflect viral functional and antigenic properties important to consider in HCV vaccine design.

Comparative analysis of intrahepatic and peripheral chemokine responses in chronic hepatitis B, C and D in vivo

Jan-Hendrik Bockmann[1], Matin Kohsar[1], Lena Allweiss[1], Tassilo Volz[1], Janine Kah[1], Marc Luetgehmann[2], Ansgar W. Lohse[1], Julian Schulze zur Wiesch[1], Maura Dandri[1]. [1]*University Medical Center Hamburg-Eppendorf, I. Department of Internal Medicine, Hamburg, Germany;* [2]*University Medical Center Hamburg-Eppendorf, Department of Medical Microbiology, Virology and Hygiene, Hamburg, Germany*
Email: j.bockmann@uke.de

Background and aims: While the important role of chemokines in disease progression has been analysed for several liver diseases, less is known about the differences in chemokine expressions between hepatitis B and D.
Method: Serum levels of various chemokines were analysed by Bead Conjugation Assay in the sera of 29 chronic hepatitis B (CHB) patients and compared to other hepatitis virus infections (21 HDV, 12 HCV) and 16 healthy controls. To analyse the intrahepatic chemokine expression in human hepatocytes, chemokine levels were analysed in the livers of chimeric uPA/SCID/beige (USB) mice measuring gene expression of human hepatocytes using species-specific RT-qPCR assays.
Results: Proinflammatory chemokines CXCL8, 9, 10 and 11 as well as CCL5 were highly induced in human hepatocytes of HDV (7.7-, 5.4-, 68.1-, 82.5- and 86.1- fold median induction) and HCV infected (62.1-, 10.2-, 696.7-, 525.6- and 154.9-fold) USB mice. In comparison, only mild (CXCL10: 8.7- and CXCL8: 3-fold) or no significant inductions (CXCL9, 11 and CCL5) could be observed in HBV infected hepatocytes. Despite the absence of adaptive immunity, high chemokine induction elicited by infected human hepatocytes was accompanied by significant induction of the human fibrotic marker hTIMP-1 in HBV, HDV and HCV infected mice. Notably, hTIMP-1 enhancement was highest in HBV/HDV infected chimeric mice ($p = 0.0034$). Compared to the RNA expression levels in hepatocytes of infected mice, we found significant up-regulation of CXCL8, 9, 10, 11 and CCL5 not only in serum of chronic hepatitis C and D but also in CHB patients compared to healthy controls, even if CXCL10 levels were higher in hepatitis C and D patients. Of note, chemokine increase did not correlate with viremia, but with fibrosis, since levels of CXCL8, 10 and 11 were higher in patients with F3-F4 compared to those with F0-F2 fibrosis.
Conclusion: HBV, HDV and HCV trigger a pattern of chemokine induction in patients, which can be observed also in human hepatocytes of chimeric mice lacking adaptive immunity. HDV induced expression of CXCL8-11 and CCL5 in human hepatocytes is substantially higher than in HBV monoinfection and resembled that determined in HCV infection. Correlation of CXCL8-11 with fibrosis in chronic viral hepatitis suggests their potential role as indicators for chronic hepatitis B and D disease progression.

Toll-like receptor signalling induces changes in the Hippo signalling pathway that counter regulates innate immune responses in hepatocytes

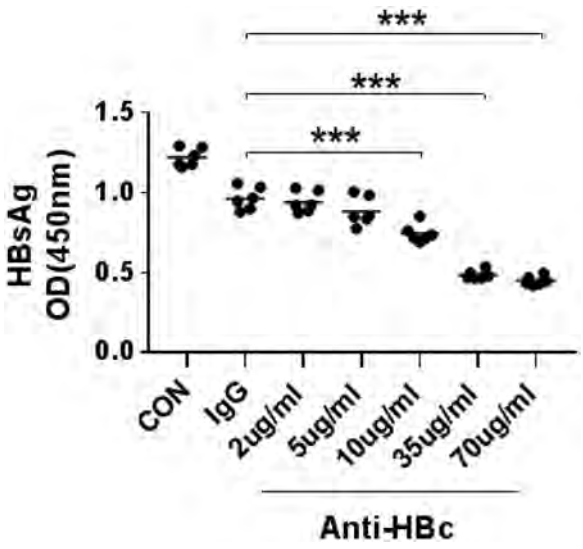
Luo Xufeng[1], Lu Mengji[2], Baba Hideo A[3], Wedemeyer Heiner[1], Ruth Broering[1]. [1]*University Duisburg-Essen, Medical faculty, Dept. of Gastroenterology and Hepatology, Essen, Germany;* [2]*University Duisburg-Essen, Medical faculty, Institute for Virology, Essen, Germany;* [3]*University Duisburg-Essen, Medical faculty, Dept. of Pathology, Essen, Germany*
Email: ruth.broering@uni-due.de

Background and aims: Chronic hepatitis B virus (HBV) infection is a key risk factor for the development of hepatocellular carcinoma. Our previous work showed that immune genes as well as oncogenes are induced in primary murine hepatocytes (PMH) exposed to HBV particles. Another remarkable study showed that Hippo signalling is activated by Toll receptor in *Drosophila* and regulates innate immune response. We here investigated the relation between Hippo signalling and innate immune responses in liver cells.
Method: Reanalysis of GEO (GSE69590) data was performed to search for eligible pathways associated with HBV infection. PMH were isolated and treated with TLR ligands (LPS, PAM3CSK4) and HBV particles. Immunocytochemistry (ICC) was performed to intracellularly locate YAP and P65 proteins. Dual-luciferase reporter (DLR) assay, chromatin immunoprecipitation (ChIP) and electrophoretic mobility shift assay (EMSA) were combined to prove the direct regulation of the *Nfkbia* promoter by the YAP/TEAD4 transcription factor complex. Short hairpin RNA (shRNA)-induced gene knock down and over expression of selected factors were analyzed.
Results: Reanalysis of Chip data showed that Hippo signalling and NF-kB signalling were affected in primary human hepatocytes 40 hours after HBV infection. To verify these results, PMH were exposed to HBV particles for different time points. ICC and Western blot results showed that YAP and P65 time-dependently translocated into nucleus. Interestingly, IkBa was entirely disappeared 30 minutes after exposure to HBV, then its expression recovered constantly,

representing a rapid innate immune control mechanism. Bioinformatic analysis of *Nfkbia* promoter indicated the presence of several TEAD4 bind sites. ChIP assay, binding site mutated DLR assays and EMSA confirmed that Yap/Tead4 transcription factor complex bound and activated the *Nfkbia* promoter. Hepa1-6 cell line was transfected with an RFP-reporter plasmid containing the *Nfkbia* promoter region. The treatment with LPS, PAM3CSK4 or the MST1/2 inhibitor (XMU-MP1) led to increased RFP signals. Overexpression and knockdown of YAP in the transduced Hepa1-6 cell line directly affected RFP/IkBa expression, shown by ICC and flow cytometry.
Conclusion: The Hippo signalling pathway harbours regulatory tasks in the rapid innate immune response. These findings directly links inflammation and growth control, and might explain tumor progression in non-cirrhotic HBV-infected patients.

FRI-136
Hepatitis B core antibody (anti-HBc) mirrors activation of hepatitis B virus-specific immune responses and exhibits direct effect on hepatitis B virus control
Chengcong Chen[1], Yongyin Li[1], Ling Guo[1], Yang Zhou[1], Xuan Yi[1], Xiaoyi Li[1], Weibin Wang[1], Xieer Liang[1], Rong Fan[1], Libo Tang[1], Jian Sun[1], Jinlin Hou[1]. [1]*state key laboratory of organ failure research, guangdong provincial key laboratory of viral hepatitis research, department of infectious diseases, nanfang hospital, southern medical university, Guangzhou, China*
Email: jlhou@fimmu.com

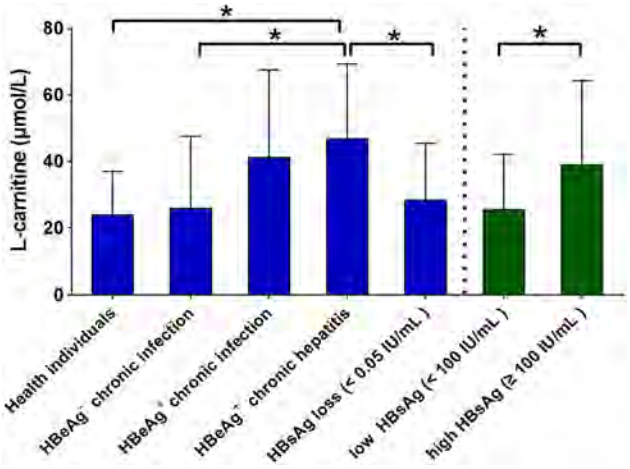
Background and aims: Our previous work has shown that quantitative levels of hepatitis B core antibody (qAnti-HBc) at baseline is a useful predictor of antiviral therapy efficacy in HBeAg-positive CHB patients (GUT, 2016). However there is little known whether Anti-HBc is only a biomarker or it also plays a role in controlling HBV, therefore, we aim to investigate the role of Anti-HBc in chronic HBV infection.
Methods: Mouse model with hepatitis B virus (HBV) was established by tail vein injection of pAAV8-HBV1.3 plasmid. After one month, the stable HBV carrier mice were intraperitoneally injected with acetaminophen (APAP). The serum levels of qAnti-HBc, ALT and hepatitis B core-related antigen (HBcrAg), and the frequency and function of intrahepatic CD8+ T cells from mice were detected. Moreover, serum qAnti-HBc, the phenotype and function of lymphocytes in peripheral blood and HBcAg expression in the liver tissue from patients with chronic HBV infection were analysed by ELISA, flow cytometry and Immunohistochemistry respectively. In addition, *in vitro* assays were performed to examine the ability of Anti-HBc in suppressing HBV replication.
Results: The levels of ALT and HBcrAg were significantly elevated at day 1 after APAP injection in the HBV mouse model, and the levels of qAnti-HBc were sequentially elevated. A significant correlation was found between the serum qAnti-HBc levels and the frequency of intrahepatic effector CD8+ T cells (CD44-CD62L-), and there was also a positive correlation between serum qAnti-HBc levels and the frequencies of intrahepatic IFN-gamma+CD8+ T cells and IL-21+CD8+ T cells in the mouse model. Moreover, in patients with chronic HBV infection, serum levels of qAnti-HBc were correlated with the intrahepatic levels of HBcAg, the frequencies of periphery effector CD8+T cells (CCR7-CD45RO-), and HBcAg-specific CD8+ T cells respectively. An *in vitro* assay revealed that high levels of Anti-HBc were able to directly suppress HBV replication in HepG2.2.15 cells. Furthermore, Anti-HBc mediated the activation of complement to lyse HepG2.2.15 cells and resulted in significantly reduced the levels of HBsAg and HBeAg in the culture supernatant.
Conclusion: The generation of Anti-HBc mainly results from the release of HBcAg from HBV-infected hepatocytes, and this marker mirrors the activation of CD8+ T cell responses against HBV. The notable demonstration of the direct antiviral effect of Anti-HBc suggests that this antibody may have a potential value in the treatment of chronic HBV infection.



FRI-137
l-carnitine impedes hepatitis B surface antigen loss through immunosuppressive effect in chronic hepatitis B virus infection
Shuqin Gu[1], Ling Guo[1], Chengcong Chen[1], Shihong Zhong[1], Weibin Wang[1], Libo Tang[1], Jinlin Hou[1], Yongyin Li[1]. [1]*state key laboratory of organ failure research, guangdong provincial key laboratory of viral hepatitis research, department of infectious diseases, nanfang hospital, southern medical university, guangzhou, China*
Email: yongyinli@foxmail.com

Background and aims: Achievement of hepatitis B surface antigen (HBsAg) loss represents the hallmark for functional cure of chronic hepatitis B (CHB). Previous study has documented an association between lower baseline levels of plasma L-carnitine (L-Cn) and treatment-induced HBsAg loss in CHB patients. Herein, we aimed to investigate the profile of plasma L-Cn in patients with chronic HBV infection and its effect on immunological function of lymphocytes.
Method: Seventy-four patients with chronic HBV infection were classified into 4 groups according to the EASL guidelines (2017): hepatitis B e antigen (HBeAg) negative chronic infection (n = 28), HBeAg positive chronic infection (n = 13), HBeAg positive chronic hepatitis (n = 17), and HBsAg loss (n = 16). According to the HBsAg levels, these patients were also classified into 2 groups: low HBsAg < 100 IU/ml (n = 28) and high HBsAg ≥ 100 IU/ml (n = 46). Another 22 healthy individuals were enrolled as controls. Plasma L-Cn levels were measured by enzyme-linked immunosorbent assay. *In vitro* assays were performed to assess the effect of L-Cn on distinct lymphocytes; the frequency and function of lymphocytes were analyzed by flow cytometry. In addition, HepG2.2.15 cells were lysed and mouse model with acute liver injury was established by intraperitoneal injection of acetaminophen (APAP) to investigate the origin of L-Cn, and the levels of L-Cn in supernatant or serum were detected.
Results: The plasma levels of L-Cn in the HBeAg-positive chronic hepatitis group were significantly higher than that in the groups of HBsAg loss, HBeAg-negative chronic infection and HCs. Intriguingly, compared with the low HBsAg group, high HBsAg group has significantly elevated plasma levels of L-Cn (figure). Moreover, a negatively correlation between plasma levels of L-Cn and HBV DNA load, while a positive correlation between plasma levels of L-Cn and liver pathological inflammatory grades were found. Of note, plasma L-Cn levels were significantly increased after the second administration of APAP injection in mouse model with acute liver injury, and HepG2.2.15 lysates exhibited an ascending level of L-Cn in a cell-density-dependent manner. *In vitro* assays revealed that L-Cn significantly suppressed the proliferation and IL-21production of

circulating chemokine (C-X-C motif) receptor 5+CD4+ T cells, and reduced the production of immunoglobulin G by B cells. In contrast, L-Cn upregulated the frequencies of arginase-expressing granulocytic myeloid-derived suppressor cells (gMDSC) and IL-10-secreting regulatory T cells, as well as the expression of eomesodermin (Eomes) in CD8+ T cells.



Conclusion: Excess L-Cn released from the injured hepatocytes displays immune suppressive properties, thus may impede the achievement of HBsAg loss in chronic HBV infection, implicating that L-Cn may serve as a potentially therapeutic target for HBV infection.

Email: kathrin.heim@uniklinik-freiburg.de

Background and aims: Chronic Hepatitis B virus (HBV) infection is characterized by the presence of impaired HBV-specific CD8+ T-cell responses. T-cell exhaustion induced by persistent antigen stimulation is considered a major mechanism underlying HBV-specific CD8+ T-cell failure. However, due to low frequencies of detectable HBV-specific CD8+ T-cell populations in chronically HBV-infected patients, it is currently unknown whether HBV-specific CD8+ T cells targeting different epitopes are similarly impaired and share molecular profiles indicative of T-cell exhaustion.
Method: To enhance detection of HBV-specific CD8+ T-cell responses, we performed pMHCI tetramer-based enrichment of circulating CD8+ T cells specific for HBV core- and polymerase-derived epitopes in 88 cHBV patients with low viral loads. Subsequently, phenotypic and functional in-depth analyses were performed using multicolor flow cytometry. Patients were pre-selected for autologous viral sequences that matched the targeted epitopes by the analyzed HBV-specific CD8+ T cells.
Results: We were able to detect HBV-specific CD8+ T cells *ex vivo* in the majority (> 80%) of tested patients. Specifically, core- and polymerase-, but not envelope-specific CD8+ T cells were frequently found. Interestingly, these HBV-specific CD8+ T cells exhibited a predominantly less differentiated memory-like phenotype characterized by CD127+PD1+, showed low TOX expression and lacked signs of terminal exhaustion, possibly reflecting weak ongoing cognate antigen recognition. However, within the HBV-specific population, we found significant differences in phenotype and function between core- and polymerase-specific CD8+ T cells. Indeed, more core-specific CD8+ T cells displayed the CD127+PD1+ memory-like phenotype compared to polymerase-specific CD8+ T cells. This observation is in line with the advanced differentiation of polymerase-specific CD8+ T cells towards more severe T-cell exhaustion marked by higher CD38, KLRG1 and Eomes expression accompanied by low T-bet levels and down-regulation of CD127. Polymerase-specific CD8+ T cells also exhibited a reduced expansion capacity compared to core-specific CD8+ T cells that was linked to dysregulated TCF1/BCL2 and high Eomes expression in polymerase-specific CD8+ T cells. These differences were only detectable in HBV-specific CD8+ T cells obtained from chronically infected patients and not from patients who resolved HBV.
Conclusion: Overall, the results of our study show different molecular mechanisms underlying impaired T-cell responses with respect to the targeted HBV antigens core versus polymerase in cHBV infection. This may have potential implications for the design of immunotherapeutic approaches in HBV cure.

FRI-139

Intrahepatic transcriptional profiling of chronic hepatitis B patients during interferon-alpha treatment

Ning Li[1], Kangkang Yu[1], Minhui Dong[1], Feizhen Wu[2], Jiming Zhang[1].
[1]Huashan Hospital, Fudan University, Shanghai, China; [2]Institute of Biomedical Sciences, Fudan University, Shanghai, China
Email: jmzhang@fudan.edu.cn

Background and aims: Interferon-alpha (IFN-alpha) treatment for chronic hepatitis B (CHB) is favored for inducing long-term immunological control with a finite duration treatment, but high variability of response has been observed. The interplay between viral replication and host immune responses during IFN-alpha treatment remains to be clarified. We aimed to comprehensively analyze the changes of intrahepatic host gene expression during pegylated IFN-alpha (PegIFN-alpha) treatment in CHB patients.
Method: Gene expression profile of seventeen CHB patients with paired liver biopsies at baseline and week 24 of PegIFN-alpha treatment were compared. Changes of immune cell composition during PegIFN-alpha treatment were estimated by cell-type identification by estimating relative subsets of RNA transcripts (CIBERSORT). Gene set enrichment analysis (GSEA) of innate and adaptive immunity were correlated to treatment response.
Results: Intrahepatic transcriptional profiling revealed a significant upregulation of antiviral effectors. Immune cell composition analysis showed that CD8 T cells significantly reduced, while B cells significantly increased after 24 weeks of PegIFN-alpha treatment. GSEA results suggested an enhanced regulation of both innate and adaptive immune responses, and comparison of several most significant differentially expressed genes (DEGs), including RSAD2, DDX60, CD8A, IL18A, between responders and non-responders suggested that PegIFN-alpha treatment had boosted innate immune response in both groups of patients, while some adaptive immune effectors almost remained at the same levels in responders but were significantly downregulated in non-responders after treatment.
Conclusion: These data show a remarkable alteration of intrahepatic gene expression profile in CHB patients during PegIFN-alpha treatment. Innate immune response is enhanced, while T cell response is estimated to be unchanged, or even attenuated, which might also correlate to poor treatment response. With further validation, this study would help achieve better understanding of the antiviral mechanisms of IFN-alpha treatment and facilitate patient selection.

FRI-140

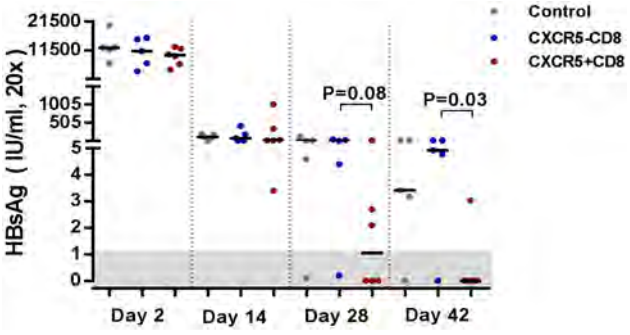
Chemokine (C-X-C motif) ligand 13-mediated recruitment of intrahepatic chemokine (C-X-C motif) receptor 5+CD8+ t cells contribute to viral control in chronic hepatitis B patients and hepatitis B virus mouse model

Yongyin Li[1], Libo Tang[1], Chengcong Chen[1], Shuqin Gu[1], Yang Zhou[1], Ling Guo[1], Weibin Wang[1], Jian Sun[1], Jie Peng[1], Jinlin Hou[1]. [1]*state key laboratory of organ failure research, guangdong provincial key laboratory of viral hepatitis research, department of infectious diseases, nanfang hospital, southern medical university, guangzhou, China*
Email: jlhou@fimmu.com

Background and aims: Exhausted CD8+ T cells are not a homogeneously dysfunctional population, while instead consist of phenotypically and functionally distinct subpopulations during chronic viral infection. Recent publications demonstrate that a special subset of CD8+ T cells expressing chemokine (C-X-C motif) receptor 5 (CXCR5) exhibits more potent antiviral efficacy. However, there are limited data regarding its impact in chronic hepatitis B virus (HBV) infection.

Methods: The frequency of circulation CXCR5+CD8+ T cells and the levels of chemokine (C-X-C motif) ligand 13 (CXCL13) were detected in a clinical trial cohort of chronic hepatitis B (CHB) patients with nucleotide drugs based therapy. A series of membrane markers on peripheral and intrahepatic CXCR5+ and CXCR5- CD8+T cells obtained from patients with chronic HBV infection were analyzed by flow cytometry, as well as the expression of HBV-specific interferon (IFN)-gamma. Additionally, purified CXCR5+ and CXCR5- CD8+T cells from mice with pAAV-HBV1.2 injection were adoptively transferred to the recipient HBV mice and then serum levels of HBsAg were sequentially monitored.

Results: An expansion of circulation CXCR5+CD8+ T cells were observed in patients with chronic HBV infection and this population maintained decent antiviral ability; moreover, high frequency of circulation CXCR5+CD8+ T cells was associated with virological response in CHB patients with antiviral therapy. Although the CXCR5+ subset have higher expression of PD-1 than the CXCR5- subset, they demonstrated a status of activation with memory potential by the evidence of enhanced expression of CD69 and CD38 as well as CD62L and CCR7. Additionally, high expression of intrahepatic CXCL13, which recruits CXCR5+CD8+ T cells, were presented in patients with chronic HBV infection and high levels of serum CXCL13 were also observed in CHB patients with a complete treatment response. Notably, intrahepatic CXCR5+CD8+ T cells obtained from patients with HBV infection displayed higher expression of IFN-gamma upon stimulation with HBV peptides. More strikingly, this CXCR5+ subset exhibited more potent ability in the control of HBV replication because recipient infected mice showed significantly decreased levels of serum HBsAg compared with CXCR5- subset (figure).



Conclusion: CXCL13 promotes the recruitment of CXCR5+CD8+ T cells to the live and this population contributes to viral control in chronic HBV infection. These data reveal a novel CD8+ T cell subset that may play an important role in future strategies for treatment of chronic HBV infection.

Email: imago@isciii.es

Background and aims: Hepatitis C virus (HCV) has an envelope crowned by the E1-E2 envelope proteins, which are the main target for neutralizing anti-HCV antibodies (HCV-nAbs). In this study, we have analyzed the titers, breadth, and dynamics of HCV-nAbs in HIV/HCV-coinfected individuals who achieved sustained virological response (SVR) with HCV therapy.

Methods: We carried out a retrospective study (before-and-after design) in 29 patients from GESIDA 3603b study. All patients were treated with peg-IFNα+ribavirin or peg-IFN-α/ribavirin/DAAs between February 2012 and February 2014. Neutralization assays were performed for five chimeric HCV expressing E1-E2 glycoproteins from 1a (H77), 1b (J4), 2a (JFH1), 3a (S52) and 4a (ED43) genotypes. The 50% inhibitory dose (ID50) and the area under the curve (AUC) were assessed at baseline (before anti-HCV treatment) and at 24 weeks after SVR.

Results: All patients were on combined antiretroviral therapy (cART), the median of CD4+ T-cells was 695 cells/mm^3, 14 patients were F4 ($\geq$ 12.5 Kpa), the median of $\log_{10}$ HCV-RNA was 6.62 IU/ml, and 13 patients were coinfected with HCV-GT1a, 3 GT1b, 8 with HCV-GT3 and 5 with HCV mixed infection. At baseline, most plasmas were able to neutralize 1a (H77), 1b (J4), 2a (JFH1), and 4a (ED43) genotypes, while 3a (S52) was barely neutralized. At week 24 after SVR, the majority of neutralizing titers decreased significantly ($p \leq 0.05$), becoming undetectable against 3a (S52) in all patients and 2a (JFH1) in several of them. Patients with high HCV-nAbs titers against a specific recombinant virus also had high titers against the other chimeric viruses ($r > 0.4$; $p \leq 0.05$). Patients with the highest titers a baseline also had the highest titer at the end of follow-up. A positive correlation between the values of $CD4^+/CD8^+$ ratio and the HCV-nAbs titers against H77 (1a) [AUC ($r = 0.454$; $p = 0.013$) and ID50 ($r = 0.450$; $p = 0.014$)] was found.

Conclusion: Although high titers of broad-spectrum HCV-nAbs were found in HIV/HCV-coinfected patients, a significant decrease in those titers took place shortly after SVR. Our findings should be considered in the design of future prophylactic measures against HCV infection, since the preservation of protective HCV antibody levels against HCV reinfections could be questioned in HIV/HCV-coinfected individuals who eliminated HCV after HCV therapy.

Email: nghiemxuanhoan@108-icid.com

Background and aims: The host immune responses are believed to regulate the hepatitis B virus (HBV) infection and subsequently liver disease progression. Interferon regulatory factor 5 (IRF5) is a transcriptional mediator, vital for virus-mediated activation of interferon and Fibrinogen-like protein 2 (FGL2), secreted by T cells is an important effector molecule in the regulation of T and B cells mediated immunity. The *IFR5* locus specific genetic variants and the sFGL2 plasma levels in acute and chronically infected patients with HBV were investigated. Also, *FGL2* mRNA was quantified among 32 dyads (tumor and non-tumor) of liver biopsy tissues.
Method: *IFR5* genetic variants (*rs13242262A/T, rs77416878C/T, rs10488630A/G, and rs2280714 T/C*) were genotyped by direct sequencing among 379 patients with HBV and 242 healthy individuals. The plasma levels of sFGL2 were quantified by ELISA among 296 patients with HBV and 258 healthy individuals. Quantification of FGL2 mRNA was performed using real-time PCR.
Results: *IRF5* alleles rs13242262 T and rs10488630G contributed to an increased risk of liver cirrhosis (LC vs. CHB: OR = 1.5, 95%CI = 1.1-2.3, adjusted P = 0.04; LC vs. CHB: OR = 1.7, 95%CI = 1.1-2.6, adjusted P = 0.019, respectively) and the reconstructed haplotype *IRF5*TCGT* had a significant association with liver cirrhosis occurrence. The sFGL2 levels were significantly elevated in HBV patients with acute hepatitis and liver cirrhosis, and clinical outcomes of HBV-related liver diseases. *FGL2* mRNA was up-regulated in tumor compared to adjacent non-tumor tissues (p = 0.043) (Figure).

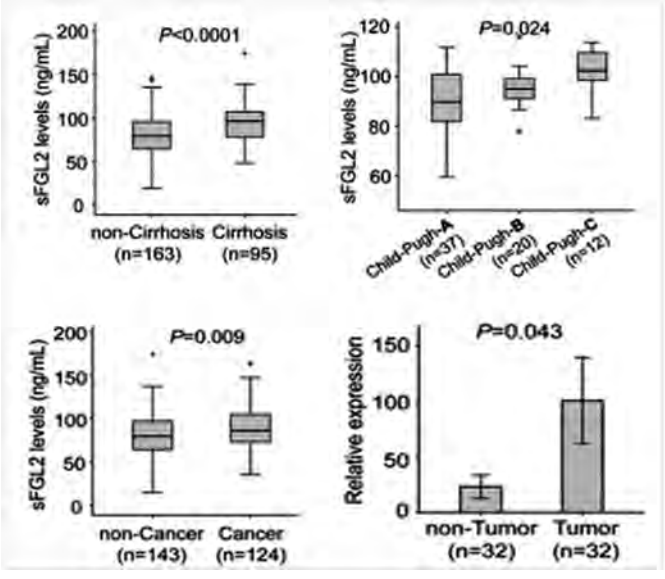

Figure: Association of FGL2 expression with clinical outcomes of HBV patients. FGL2 expression in serum and tumour among different classified groups. NS: Not significant; AST and ALT: Aspartate and alanine amino transferase. P values were calculated by Whitney-Wilcoxon test or Kruskal-Wallis test where appropriate while comparisons of *FGL2* mRNA relative expression were performed using Paired-samples t-test.

Conclusion: The *IRF5* variants may contribute as a host factor in determining the pathogenesis in chronic HBV infections and the sFGL2 levels are induced by HBV infection and correlated with the progression and clinical outcomes.

FRI-143

Liver-resident HBV-specific CD8+ T cells are long-lived and can be replenished by allogenic responses following transplantation

Laura J Pallett[1], Alice Burton[1], Oliver E Amin[1], Nekisa Zakeri[1], Douglas Thorburn[2], Simon Yona[3], Mala Maini[1]. [1]*UCL, Infection and Immunity, London, United Kingdom;* [2]*UCL, London, United Kingdom;* [3]*UCL, Division of Medicine, London, United Kingdom*
Email: laura.pallett@ucl.ac.uk

Background and aims: We recently identified a population of tissue-resident memory CD8 T cells (TRM) expressing liver homing/retention markers (CXCR3+CXCR6+, CD69+CD103+), adapted to maintain efficient non-cytolytic antiviral function in the human liver. These CD8 TRM were absent from the circulation, preferentially expanded in patients with partial HBV immune control (HBeAg-chronic infection), remained in the liver after resolution of infection and contained HBV-specific CD8 T cells directed against epitopes from all major HBV proteins (Pallett LJ. et al J Exp. Med. 2017).
Method: To definitively investigate the lifespan and derivation of global and HBV-specific CD8 TRM, we took advantage of access to a liver allograft explanted after 11 years in an HLA-mismatched recipient, where monoclonal antibodies were available to distinguish donor-derived (HLA-A2+) and recipient-derived (HLA-A2- A3+) leukocytes. The donor had resolved HBV infection (anti-HBcAb+) that reactivated following liver transplantation.
Results: Remarkably, global and HBV-specific donor-derived CD8 TRM were still detectable within the explanted liver 11 years post-transplantation, confirming the long-lived nature of CD8 TRM within their local microenvironment. Furthermore, a significant proportion of recipient-derived CD8 T cells within the allograft had acquired a tissue-resident phenotype, revealing that repopulation from the peripheral compartment can contribute to the pool of intrahepatic CD8 TRM. We also identified recipient-derived, HLA-A3+ CD8 T cells able to bind HBV-specific HLA-A2-restricted multimers, implying that allogeneic CD8 T cell responses can be directed against HBV within an infected liver allograft. Further samples are being used to distinguish donor versus recipient derivation of different hepatic antigen presenting cells.
Conclusion: In summary, analysis of this case of HLA-mismatched liver allograft/recipient T cells in the setting of HBV infection suggests that hepatic CD8 TRM can be long-lived, replenished from the periphery and therefore contribute to antiviral immunity.

FRI-144

Performance study of new geenius HCV supplemental assay

Anthony Palvadeau[1], Muriel Costaille[1], Catherine Bachard[1], Catherine Bonchamp[1], Matthieu Ferret[1], Marie-Pierre Branger[1], Patrice Sarfati[1], Muriel Cardona[1]. [1]*Bio-Rad, Marnes-la-Coquette, France*
Email: anthony_palvadeau@bio-rad.com

Background and aims: The new Bio-Rad Geenius™ HCV Supplemental Assay is a qualitative single-use immunochromatographic test for the confirmation of individual antibodies associated with infection caused by the Hepatitis C Virus (HCV) in human venous whole blood, serum or plasma samples.
Geenius™ HCV Supplemental Assay is intended for use as an additional screening and/or diagnostic test to confirm the presence of antibodies to HCV for specimens found to be reactive by screening procedures.
It is associated with Geenius™ system (reader and software) and results are automatically interpreted.
The aim of this study, performed by Bio-Rad RandD department was to evaluate the performance of this new assay and to compare with reference assays.

Method: A full validation of this new rapid test has been performed. Specificity has been evaluated on fresh negative blood bank samples (n = 500) as well as on samples from hospitalized patients (n = 200). Sensitivity has been tested on specimens from chronic HCV infected patients (n = 276) and on 20 commercial seroconversions panels. Performance of Geenius™ HCV Supplemental Assay has been compared with INNO-LIA® HCV Score.
All results were obtained using automatic reading with Geenius™ system.
Results: Regarding specificity, we obtained no false positive result and only 1, 60% (8/500) and 1, 50% (3/200) indeterminate results were found among blood bank samples and hospitalized patient samples respectively.
A comparative study has been realized between Geenius™ HCV Supplemental assay and INNO-LIA® HCV Score. On 250 blood donor specimens, 249 were found negative and 1 was found indeterminate with Geenius™ HCV Supplemental Assay. On the same population, 240 were found negative and 10 were found indeterminate with INNO-LIA® HCV Score. On 200 hospitalized patients, specimens, 197 were found negative and 3 were found indeterminate with Geenius™ HCV Supplemental Assay; 181 were found negative, 16 were found indeterminate and 3 were found positive with INNO-LIA® HCV Score. Overall, specificity for Geenius™ HCV Supplemental Assay is 99% and 92.75% for INNO-LIA® HCV Score respectively.
A sensitivity of 100% was obtained with Geenius™ HCV Supplemental Assay (276/276) on samples from chronic HCV infected patients.
Sensitivity obtained on the 20 seroconversion panels tested was equivalent to INNO-LIA® HCV Score Assay.
Conclusion: Performance obtained with the Geenius™ HCV Supplemental Assay during evaluations met the required specifications in terms of specificity and sensitivity. Results have shown a better specificity and an equal sensitivity than INNO-LIA® HCV Score. The new Geenius™ HCV Supplemental Assay is the first unitary and quickest one assay for the confirmation of the presence of antibodies to HCV with automatic reading and interpretation. The expert software allows a complete automation of the reading and a complete traceability.

Direct acting antiviral treatment decreases inhibitoryTIM-3 immune checkpoint receptor expression on NK cells in patients with chronic HCV

Gabriella Par[1,1], Szereday Laszlo[2], Meggyes Matyas[2], Miseta Attila[3], Par Alajos[1]. [1]*University of Pecs, First Department of Medicine, Pecs, Hungary;* [2]*University of Pecs, Department of Medical Microbiology and Immunology, Pecs, Hungary;* [3]*University of Pecs, Department of Laboratory Medicine, Pecs, Hungary*
Email: pargabriella@gmail.com

Background and aims: In chronic HCV hepatitis immune cells have increased expression TIM-3 checkpoint inhibitor receptor that downregulates T cell activation, resulting T cell exhaustion. In contrast to immune dysfunction of adaptive immune response high levels of TIM-3 expression on NK cells was associated with an activated phenotype towards cytotoxicity. Elimination of hepatitis C virus with direct-acting antiviral (DAA) treatment may modify host immune response via changing TIM3 immune checkpoint molecule expression. In this prospective study we aimed to analyse changes in TIM3 receptor expression by peripheral blood mononuclear cells in chronic HCV hepatitis patients during DAA treatment.
Method: Methods: Phenotype distribution and expression of TIM-3 by peripheral blood CD3+, CD4+, CD8+ T cells, regulatory T cells, NK, NK dim, NK bright, NKT cells and monocytes were determined by multicolor flow cytometry in 14 patients with chronic hepatitis C pretreatment and after 12 weeks of dasabuvir, ombitasvir, paritaprevir/ritonavir combination treatment. Blood samples were collected baseline (BL), at the end of treatment (EOT) and at 12 weeks after EOT (SVR12) All patients achieved sustained virological response (SVR12).
Results: Results: While the percentage of NK bright cells significantly decreased during DAA therapy (BL: 3, 1%, SVR12: 1, 7%), the percentage of peripheral blood CD3+ T lymphocytes was significantly higher at SVR12 compared to baseline values (BL: 47% vs SVR12: 56, 3%). TIM-3 expression by NKT (BL: 4, 9% vs SVR12: 3, 5%) and by NK bright cells (BL: 64% vs SVR12: 50, 4%) decreased significantly after treatment. DAA treatment did not alter TIM-3 expression by CD3+, CD4+ and CD8+ T cells.
Conclusion: Sustained virological response was associated with increased percentage of peripheral CD3+ T cells and with decreased inhibitory TIM-3 checkpoint inhibitor expression by NKT and NK bright cells. Our data suggest that DAA therapy via decreasing the expression of TIM-3 inhibitory immune checkpoint molecules on specific NK cell subpopulations may modulate NK cell activity and via decreasing cytotoxicity agains T cells may contribute to the recovery of exhausted adaptive immune responses.

FRI-146

Long-term nucleos (t)ide-analogue treatment in chronic hepatitis B eAg (−) together with a low level of HBsAg leads to a non-exhausted HBV-specific T CD8+ response

Julia Peña Asensio[1], Eduardo Sanz de Villalobos[1], Joaquín Míquel[1], Antonio Madejón[2], Antonio Olveira Martin[2], Alejandro González Praetorius[1], Andrea Martínez de la Guerra[1], Francisco Javier Garcia-Samaniego Rey[2], Juan Ramón Larrubia[1]. [1]*University Hospital of Guadalajara, Translational Hepatology Unit., Guadalajara, Spain;* [2]*University Hospital La Paz. CIBERehd, Hepatology Unit. Gastroenterology Service., Madrid, Spain*
Email: hlnd.julia@gmail.com

Background and aims: HBV-specific T CD8 cell response is exhausted in chronic viral Hepatitis B (HBV) eAg negative (CHBe (−)). Nucleos (t) ide-analogue (NA) treatment can control viral replication but it must be administered indefinitely. Nevertheless, a non-exhausted specific T CD8 HBV response could allow functional cure and consequently NA discontinuation. To this end, we have compared the specific T CD8 HBV response of CHBe (−) patients in treatment with NA depending on the duration of treatment and the HBsAg level.
Methods: 37 HLA-A2+ CHBe (−) patients were included: 25 patients in treatment for less than 6, 5 years (< 6, 5y) and 12 patients for more than 6, 5 years (> 6, 5y). Serum levels of HBs antigen (HBsAg) were determined. Peripheral HBV-Core epitope18-27 CD8 T cells were visualised by flow cytometry, using co-staining with pentameric complexes, anti-CD3 and anti-CD8 (CD8+/Pent+). In CD8 +/Pent+ cells, the following was analysed: the PD-1/CD127 phenotype; interferon-gamma production (IFNg); CD107a mobilization; specific antigen proliferation capacity.
Results: The level of HBsAg was negatively correlated with the duration of the treatment ($r = -0.333$; $p = 0.044$) and was higher in the group of < 6.5y (3.36log IU; Interquartile range (IQR) 1.2) than in the > 6.5y group (2.7log IU; IQR 2.9), ($p = 0.023$). The frequency of CD8+/Pent+ cells out of total CD8+ cells was higher in the > 6.5 y group (0.9%; IQR 0.08) than in the < 6.5y (0.006%; IQR 0.02) group ($p = 0.001$). CD8+/Pent+ cells were detected in 100% of cases in the > 6.5y group, whereas only in 20% of the < 6.5y group ($p = 0.001$). Moreover, in the > 6.5 y group, the HBsAg level was negatively correlated with the frequency of CD8+/Pent + cells ($r = -0.786$; $p = 0.036$). > 6.5y treatment and < 3.2log IU HBsAg level was positively correlated with proliferative capacity of the CD8 +/Pent+ cells ($r = 0.668$; $p < 0.001$). The degranulation capacity of CD8 +/Pent+ cells was positively correlated with > 6.5y treatment and < 3.2log IU HBsAg level ($r = 0.794$; $p = 0.006$). Globally, the > 6.5y group was able to express a higher CD107a (277 median fluorescence intensity (MFI); IQR 278) than the < 6.5y group (MFI 166, IQR 84), ($p < 0.05$). IFNg production was higher in the > 6.5y group with < 3.2log IU HBsAg (111MFI; IQR 174) than in the other groups (MFI 48; IQR 52), ($p < 0.05$). CD8+/ Pent + cells in both groups expressed a PD-1+/CD127+phenotype

Conclusion: Treatment with NA for more than 6, 5 years and HBsAg level lower than 3.2log IU is associated with the presence of an HBV-specific T CD8 cell population, with a PD-1+/CD127+phenotype and restored effector capacity that could impact the development of a functional cure.

FRI-147

Gradual restoration of HCV-specific CD8+ T cell frequency but persistence of altered phenotype in cirrhotic HCV-infected patients after successful direct-acting antiviral therapy

Elena Perpiñan[1], Sofía Pérez-del-Pulgar[1], Maria Carlota Londoño[1], Patricia González[1], Zoe Mariño[1], Sabela Lens[1], Concepció Bartres[1], Mireia García-López[1], Xavier Forns[1], Georgios Koutsoudakis[1].
[1]*Hospital Clinic, University of Barcelona, IDIBAPS and CIBEREHD, Liver Unit, Barcelona, Spain*
Email: perpinan@clinic.cat

Background and aims: Chronic hepatitis C virus (HCV) infection impairs the phenotype and function of CD8+ T cells specific for HCV or other unrelated pathogens such as Cytomegalovirus (CMV) or Epstein Barr Virus. Nonetheless, it has been shown that these alterations could be partially restored following interferon-free therapy. Here, we focused on the potential restoration of HCV-specific CD8+ T cells in patients with established cirrhosis after successful therapy.
Method: 29 HLA-A*02:01 positive patients with chronic HCV infection and liver cirrhosis were prospectively included in the study. Peripheral blood was collected at the beginning of treatment (BL), at week 4 during therapy and at weeks 12 and 48 after end-of-therapy (FU12 and FU48, respectively). HCV-specific CD8+ T cells were analysed by flow cytometry after *in vitro* expansion in the presence of HLA-A2-restricted HCV peptides. HCV epitope sequencing was performed by Sanger method. As controls, CMV and Influenza (Flu)-specific CD8+ T cells were analysed in HCV-infected patients and in 10 healthy individuals, matched by age and sex.
Results: The frequency of HCV-specific CD8+ T cells increased gradually from BL to FU48 (p = .0001) in the majority of patients (72%), as well as the number of patients with more than one positive response against the analysed HCV epitopes (41%, *P* <.0001). This restoration was observed in CD8+ T cells targeting either conserved or variable HCV epitopes. However, despite viral clearance during the first weeks of therapy, CD8+ T exhausted cells, defined by co-expression of co-inhibitory receptors PD-1 and TIM-3/CTLA-4, persisted until FU48.
Interestingly, the frequency of CMV-, but not Flu-specific CD8+ T cells, was greater in HCV-infected patients than in controls even at FU48 (p = .03). In addition, patient CMV- and Flu-specific CD8+ T cells expressed higher levels of PD-1, Tim-3 and CTLA-4 compared to controls (p < .05).
Conclusion: Despite the rapid on-therapy viral eradication, restoration of HCV-specific CD8+ T cell response was gradual and continued up to FU48, even though not in all patients. Expression of co-inhibitory receptors persisted altered not only in HCV- but also in CMV-/Flu-specific CD8+ T cells. These results suggest that, HCV may leave a sustained imprint in antiviral CD8+ T cell responses in cirrhotic patients, whose clinical relevance remains unknown and requires further investigation.

Email: s.phillips@researchinliver.org.uk

Background and aims: Host-virus interactions during early phase of Hepatitis B virus (HBV) infection are not well understood and studies are hampered by lack of good models. We have recently developed an immunocompetent model of HBV infection, human Precision-Cut Liver Slices (hPCLS), which we have shown to recapitulate alcohol mediated liver injury/inflammation and fibrosis. Using hPCLS, our aims were to investigate:1) host immunity during early phase of HBV infection. 2)role of host protein/profibrogenic factor Osteopontin (OPN) in virus-host interactions.
Method: hPCLS were produced from healthy portion of post-resection liver tissue and infected with HBV inoculum at 2×10^{10} genome equivalents/slice. Infected hPCLS were cultured for 7 days ± recombinant OPN (rOPN) at 1000 ng/ml. Media was replaced every day post infection. Intracellular and secreted HBVDNA were quantified by qPCR, cccDNA and HBsAg levels were measured by high-sensitivity Droplet Digital PCR and ELISA respectively. In addition, total RNA from the slices was extracted, reverse-transcribed and run on 96 human innate and adaptive immunity PCR array (Qiagen).
Results: HBV infection in hPCLS was successfully attained and viral replication maintained for 7 days. In each, 24hr period we observed secreted HBVDNA levels of 5-6 Log copies/ml; intracellular HBVDNA of 5-7 Log copies/ml and cccDNA levels at 2 Log copies/ml. The early phase of HBV infection (day2/3) resulted in the abolition of type I Interferon and RIG1/IRF3 signalling when compared to non-infected hPCLS. In addition, a marked impairment of the expression of chemokine involved in recruitment of innate and adaptive immune cells to the liver was observed including CCL2, CXCL10. We also observed significant reduction of pathogens recognition receptors (PPR) such as TLR2, TLR8, NOD2 and in pro- and anti-inflammatory cytokines IL-1, IL-2, IL-18 and IL-5, IL-4, IL-13. rOPN led to 4-fold increase in HBVDNA, HBsAg and cccDNA inducing 13-fold increase in expression of antiviral genes including potent anti-HBV genes such IFN-inducible protein MX1 and in chemokines genes favouring a pro-fibrogenic milieu including CCL2 and CCL5.
Conclusion: Here we describe a novel and robust immunocompetent model HBV infection and reveal that during the early phases of infection, HBV actively inhibits immunity. We confirm the immune and fibrogenic modulatory functions of OPN and show its active involvement in driving HBV replication. We identify OPN as a new antiviral and anti-fibrotic target for HBV infection.

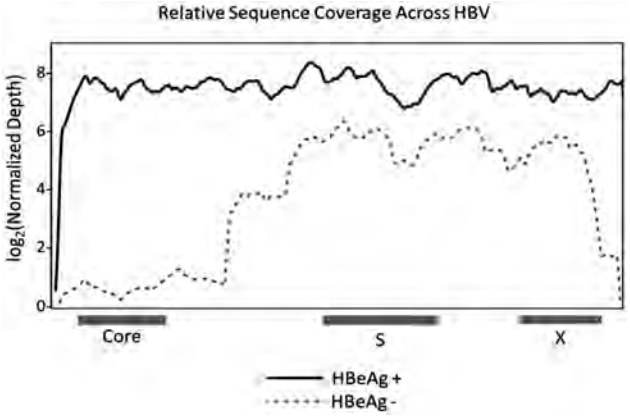
FRI-149

Comprehensive transcriptome analysis of liver biopsies from chronically infected HBV patients

Ricardo Ramirez[1], Nick van Buuren[2], Vithika Suri[1], Neeru Bhardwaj[1], Nam Bui[1], Li Li[1], Patrick Marcellin[3], Henry Chan[4], Maria Buti[5], Anuj Gaggar[1], Becket Feierbach[2]. [1]*Gilead Sciences, Inc., Foster City, United States;* [2]*Gilead Sciences, Inc., Clinical Virology, Foster City, United States;* [3]*Hospital Beaujon, Viral Hepatitis Research Unit, Clinchy, France;* [4]*Chinese University of Hong Kong, Hong Kong, Hong Kong;* [5]*University Hospital Vall d'Hebron, Barcelona, Spain*
Email: becket.feierbach@gilead.com

Background and aims: Our current knowledge of the interaction between chronic HBV infection and the immune microenvironment comes from animal models and patients with human hepatocellular carcinoma (HCC). Here, we describe the intrahepatic transcriptomes from chronically HBV (CHB)-infected, non-HCC patients to characterize the host immune cell phenotypes and viral transcripts.
Method: Liver biopsies were obtained from chronic hepatitis B patients enrolled in an open-label Phase 4 trial with TDF and/or

PEG-IFN-alpha (GS-US-174-0149).Next-generation sequencing was performed on 54 samples from 46 patients with high quality mRNA libraries, which included 8 pairs of longitudinal biopsies baseline and 96 weeks post-antiviral treatment. A multimodal bioinformatics pipeline was used to analyze both host and viral transcriptomes including viral transcript quantification, detection of HBV integration events, and cell-type enrichment analysis using the xCell algorithm.
Results: Using gene set enrichment analysis we found two unique immune signatures in baseline samples: 1) high CD4+ memory T cells, high CD8+ TCM, high Th2, high PD-L1, and 2) low CD4+ memory T cells, low CD8+ TCM, high Th1, low PD-L1. Preliminary correlations found a trend toward ALT levels ($p = 0.052$), however, a complete analysis of baseline and disease factors is ongoing. Additionally, a subset analysis of the paired liver biopsy samples revealed an enhancement of the latter immune signature. Our deep sequencing approach also enabled detection of viral transcripts. In HBeAg positive patients, we see coverage across the entire HBV genome, suggestive of transcription from cccDNA (Figure 1). However, in HBeAg negative patients, we observe loss of coverage in the core region and downstream of DR1, suggestive of transcription largely from HBV integration (Figure 1). This suggests that the contribution of viral transcripts from cccDNA is dramatically reduced in HBeAg negative patients, thereby revealing the contribution of viral transcripts from HBV DNA integration. We also observed this pattern of HBV transcription in patients following who lost HBeAg following antiviral treatment.



Conclusion: Here, we report the first transcriptome characterization of intrahepatic immune and viral signatures in CHB patients without HCC. RNA-seq analysis of longitudinal biopsies will allow for an understanding of how the immune microenvironment and viral transcripts are affected by treatment which will provide insight into necessary steps needed for a functional cure.

FRI-150

Association of the immunodominant HLA-B35:01 restricted CD8+ T cell epitope with clustered viral evolution in HBV polymerase

Elahe Salimi Alizei[1], Michael Muthamia Kiraithe[1], Philipp Ehrenmann[1], Maike Hofmann[1], Robert Thimme[1], Christoph Neumann-Haefelin[1]. [1]*University Hospital Freiburg, Internal Medicine II, Freiburg, Germany*
Email: elahe.salimi.alizei@uniklinik-freiburg.de

Background and aims: CD8+ T-cell exhaustion and viral escape are considered as the main mechanisms in chronic HBV infection; however, the relative role of viral escape herein is not well defined. Until now, viral escape has been mainly described for the core protein. In this study, we aimed to address the role of viral escape from CD8+ T cell responses targeting HBV polymerase.
Method: 114 patients chronically infected with HBV genotype D were analyzed by HLA class I typing and HBV full-genome sequencing. HLA class I associated HBV polymorphisms were identified. Corresponding to a cluster of three HLA-B35:01 associated HBV polymerase sequence mutations, the optimal epitope peptide was determined. Tetramer-based enrichment of CD8+ T-cells specific for the novel HLA-B35:01 polymerase epitope as well as two previously described HLA-A01:01 and HLA-A11:01 restricted core- epitopes was performed. A cohort of 51 patients with chronic HBV genotype D infection was screened.
Results: Several HLA class I associated sequence polymorphisms were observed in the polymerase protein, including a striking cluster of three HLA-B35:01 associated polymorphisms (pol174, 180 and 181) located within a single predicted HLA-B35:01 restricted CD8+ T cell epitope. The epitope was confirmed after peptide-specific expansion followed by intracellular interferon-gamma staining in 3 HLA-B*35:01+ patients. By using a sensitive ex vivo tetramer-based enrichment protocol, we were able to detect polymerase-specific CD8+ T cells responses in 4/20 HLA-B35:01+ patients. The frequency was similar to the detection rate of CD8+ T cells targeting a previously described immunodominant HLA-A01:01 and a HLA-A11:01 epitope with 2/9 HLA-A01:01+ and 3/22 HLA-A11:01+ patients, respectively. Phenotypical analysis of the CD8+ T cells targeting the polymerase-specific HLA-B*35 restricted epitope differs from CD8+ T cells targeting the core- specific HLA-A11 restricted epitope. HLA B35:01 polymerase- specific CD8+ T cells expressed higher levels of KLRG1 and Eomes and lower levels of T-bet. Furthermore, less HLA B35:01 polymerase-specific CD8+ T cells revealed the CD127+PD1+ memory-like phenotype in comparison to HLA-A11:01 core-specific CD8+ T cells.
Conclusion: We identified a novel HLA-B35:01 restricted HBV-specific CD8+ T cell polymerase epitope. This epitope was associated with viral escape mutations at several positions, indicating that viral escape in polymerase may be more constrained compared to viral escape in the core protein. In conclusion, these results could provide the basis for the development of novel therapeutic vaccination strategies targeting non-escaping epitopes and immunomodulatory therapies restoring the function of HBV -specific CD8+ T cells with the aim of virus elimination.

FRI-151

Characterization of regulatory T cells and the role of PD-1 and TNF-alpha in spontaneous hepatitis B surface antigen seroclearance in chronic hepatitis B

Fen Liu[1], Saisai Zhang[1], Fung Yu Huang[1], Danny Wong[1], Lung-Yi Mak[1], Ka-Shing Cheung[1], Ching Lung Lai[1], Man-Fung Yuen[1], Wai-Kay Seto[2]. [1]*The University of Hong Kong, Medicine, Hong Kong, Hong Kong;* [2]*The University of Hong Kong, Medicine, Hong Kong, Hong Kong*
Email: wkseto@hku.hk

Background and aims: Spontaneous seroclearance of hepatitis B surface (HBsAg) is associated with enhanced HBV-specific T cell response. $CD4^{+}CD25^{high}$ $CD127^{low/-}$ regulatory T cells (Tregs) possess HBV-specific immunoregulatory effects. Whether Tregs are involved in HBsAg seroclearance remains to be determined. We aimed to investigate the changes of Tregs in chronic hepatitis B (CHB) patients achieving spontaneous HBsAg seroclearance.
Methods: We recruited CHB patients who achieved spontaneous HBsAg seroclearance for at least 6 months (experimental group), and treatment-naïve age- and sex-matched hepatitis B e antigen-negative controls. Peripheral blood mononuclear cells (PBMCs) were isolated using Ficoll-Pague density gradient centrifugation method. The frequency, transcriptional factor (FoxP3), different inhibitory phenotypes (PD-1, CTLA-4, LAG-3 and GITR), and immunoregulatory cytokines (TNF-alpha, IFN-gamma, TGF-beta, IL-10 and IL-17A) of Tregs were detected by multicolor flow cytometry (BD LSR Fortessa Analyzer, San Jose, CA).
Results: Twenty-seven patients with HBsAg seroclearance were recruited (mean age 53.70 ± 7.93 years, 55.6% male). Median duration from achieving HBsAg seroclearance to PBMCs collection was 1.47

(interquartile range 0.72–2.73) years. Median HBsAg and HBV DNA levels in the control group (n = 27) were 2.74 (1.59-3.42) log IU/ml and 3.22 (1.96-3.81) log IU/ml, respectively. The mean frequency of Tregs and the expression of FoxP3 in the experimental group were comparable to the control group (3.39% vs. 3.35% and 65.95% vs. 65.37%, respectively; both p > 0.05). The mean expression of PD-1 on Tregs was significantly lower in the experimental group than that in the control group (9.65% ± 3.27 vs. 12.03% ± 4.49; p = 0.03). No significant differences were found for CTLA-4, LAG-3 and GITR phenotypes (all p > 0.05). In the experimental group, Tregs had a greater expression of TNF-alpha when compared to the control group (37.89% ± 9.50 vs. 28.87% ± 9.04; p = 0.001), with no significant differences noted in the production of IFN-gamma, TGF-beta, IL-10 and IL-17A (all p > 0.05). In the control group, a significant inverse correlation was observed between the proportion of TNF-alpha-expressing Tregs and serum level of HBsAg (r = -0.669, p < 0.001).
Conclusion: The reduced expression of PD-1 and/or increased production of TNF- alpha may attenuate the immunosuppressive capability of Tregs, and may contribute to the "functional cure" of CHB.

FRI-152

Immunoregulatory activity of preimplantation-factor on HCV stimulated primary human hepatocytes demonstrates preclinical activity for treating inflammatory liver diseases

Emmanuel Thomas[1], Jasmine Edwards[1], Alejandro Badilla[1], Christopher O'brien[2], Krassimira Todorova[3], Soren Hayrabedyan[3], Eytan Barnea[4]. *[1]University of Miami, Miller School of Med., Microbiology and Immunology, Miami, United States; [2]University of Miami, Miller School of Med., Miami, United States; [3]Institute of Biology and Immunology of Reproduction, Bulgarian Academy of Sciences, Sofia, Bulgaria; [4]BioIncept, New York, United States*
Email: ethomas1@med.miami.edu

Background and aims: Liver disease can be driven by chronic inflammatory processes that damage the liver over many years. Currently, effective immunomodulatory agents, with minimal side effects, that can regulate inflammation in the liver to promote liver health in the setting of chronic liver disease have not been developed. PreImplantation-Factor (PIF) a non-viral therapeutic protein that is currently in phase II clinical trials, is an endogenous embryo-derived peptide that comprehensively (i.e. locally and systemically) imparts this determining immune regulatory activity safely. A better understanding of the effects of PIF on models of inflammatory liver disease will provide strong justification for later-phase therapeutics discovery and development efforts in appropriate patient populations with liver disease. The aims of this study are focused on understanding the potential benefits of PIF for patients with viral liver diseases by specifically focusing on inflammatory responses activated in primary human hepatocytes (PHHs).
Method: To determine the mechanisms through which PIF modulates the antiviral response in HCV infected PHHs, multiple techniques were employed. RNAseq and qPCR analyses were performed on HCV treated PHHs, with and without sPIF, to determine which inflammatory pathways are modulated. M.O.Is of 0.5, 1.0, 5.0 and 50 and multiple time points including 24 and 48-hour infections were utilized in the presence of multiple doses of PIF. Further analysis was performed on the genes and pathways identified by RNAseq that were affected by sPIF. Proteomics was performed to identify PIF binding partners in hepatocytes.
Results: HCV infected PHHs demonstrated a robust induction of inflammatory genes that was significantly impacted following treatment with sPIF. RNAseq analysis demonstrated a broad and reproducible modulation of HCV regulated genes. Specifically, downregulation of Interferon Regulatory Factor 3 (IRF3) and Peroxisome proliferator-activated receptor alpha (PPAR-alpha) dependent pathways (p < .001) was observed. qPCR analysis verified downregulation of inflammatory genes including CXCL10 and CCL5 (p < .001) in HCV infected PHHs following sPIF administration. Mass spectrometry was utilized to identify PIF binding partners, in uninfected primary hepatocytes, that may mediate these effects.
Conclusion: These studies provide strong data, using well-validated and predictive human cell-based models, that there is a high likelihood that PIF treatment will be beneficial for viral-induced liver disease. Collectively, we expect the outcomes of these experiments to greatly add to our understanding of PIF activity while providing a significant contribution to the data supporting the validity of PIF for the efficacious treatment of viral-induced liver disease through a non-viral biologic approach (PIF Proprietary).

Potent hepatitis B core-specific B cell responses associate with clinical parameters in untreated and virally suppressed chronic HBV patients

Thomas Vanwolleghem[1,2], Anthony Grooshuismink[2], Kim Kreefft[2], Magdeleine Hung[3], Nikolai Novikov[3], Andre Boonstra[2]. *[1]Antwerp University Hospital, Gastroenterology and Hepatology, Antwerp, Belgium; [2]Erasmus University Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands; [3]Gilead Sciences, Biology, Foster City, United States*
Email: t.vanwolleghem@erasmusmc.nl

Background and aims: Exhaustion of virus-specific T cells is a hallmark of chronic HBV (cHBV) infections, but the HBV-specific B cell response is less well studied. Previously, we identified B cell-related transcriptomic changes in blood and liver of cHBV patients in different clinical phases. We now examined, the number, phenotype and function of HBcAg-specific B cells during cHBV, in comparison to HBsAg-specific B cells.
Method: Serum and PBMC were obtained from 137 cHBV patients, both untreated (n = 114) belonging to different clinical phases as NUC treated (n = 23), and 22 healthy HBsAg-vaccinated controls. The phenotype of overall and HBV-specific B lymphocytes was studied by FACS using DyLight650 and DyLight550 dual fluorescently labelled HBsAg and HBcAg in combination with antibodies against CD3, CD10, CD19, CD27, CD21, CD38, and FcRL5. In vitro anti-HBs and anti-HBc antibody production was measured after polyclonal PBMC stimulation by ELISPOT assays. Anti-HBs and anti-HBc antibodies were measured in serum and in supernatant by ELISA.
Results: Serum levels of anti-HBc, but not anti-HBs antibodies associate with the clinical phases of cHBV, characterized by increasing titers in patients with ALT rise (p < 0.0001). In vitro, a similar profile is seen for the number of spot-forming anti-HBc-producing cells and their levels in the supernatant of these cultures (p < 0.0001). Also the number of HBcAg-specific B cells in blood followed this pattern (p = 0.0035). In contrast, HBsAg-specific B cells show no typical numeric or functional changes in cHBV and are vastly outnumbered by HBcAg-specific B cells in blood (92.8-fold, P < 0.0001). HBcAg-specific B-cells are enriched for a CD21- and CD21 + CD27 + memory B cell profile compared to total B cells (3.6-fold and 2.0-fold, P < 0.0001 respectively), but demonstrate a less activated phenotype (activation marker CD38: 0.8-fold, P = 0.0017; inhibitory IgG co-receptor FcRL5: 2.3-fold, P < 0.0001). Interestingly, complete viral suppression in the NUC cohort, led to reduced numbers of HBcAg-binding B cells and in vitro production of anti-HBc antibodies (all P < 0.05). For the total chronic HBV cohort, HBV DNA levels positively correlated with in vitro anti-HBc production levels (r = 0.388, P = 0.0008) and with the number of HBcAg-binding B cells (r = 0.323 P < 0.05).
Conclusion: HBcAg-specific B cells vastly outnumber HBsAg-specific B cells in blood of chronic HBV patients, are enriched for a classical memory B cell phenotype and show no impairment with increasing HBV DNA titers.

FRI-154

Augmentation of HBV-specific CD4 T cell responses via combined OX40 stimulation and PD-L1 blockade

Katharina Wild[1], Felix Jacobi[1], Maike Smits[1], Katharina Zoldan[1], Tobias Flecken[1], Julia Lang[1], Philipp Ehrenmann[1], Florian Emmerich[2], Maike Hofmann[1], Christoph Neumann-Haefelin[1], Robert Thimme[1], Tobias Böttler[1]. Email: katharina.wild@uniklinik-freiburg.de

Background and aims: Chronic hepatitis B virus (cHBV) infection is a common cause of progressive liver disease that eventually may lead to hepatocellular carcinoma. Antiviral therapeutic options are still limited and aren't able to induce viral clearance. HBV-specific T cells are crucial for HBV control and have recently been shown to be protective in patients following discontinuation of antiviral therapy. Thus, T-cell based immunotherapy appears to be a promising therapeutic approach. In this project, we aimed to identify immunological pathways that are able to improve functionality of HBV-specific CD4 T cells.
Methods: The expression of relevant costimulatory and coinhibitory molecules (e.g. CD127, OX40 and PD-1) on HBV- and Influenza (Flu)-specific CD4 T cells were analyzed using MHC class II- tetramer technology in 11 cHBV patients and 11 healthy volunteers, respectively. Using overlapping peptides (OLPs) spanning the entire HBV-polyprotein, we screened 66 patients (cHBV, genotype D) for CD4 T cell responses. Control responses (Flu, Epstein-Barr virus [EBV] and tetanus toxoid [TT]) were analyzed in 59 healthy donors (HD). Stimulation with recombinant IL-7, an agonistic OX40-antibody or blockade of PD-L1 was performed in antigen-specific *in vitro* cultures. Cytokine secretion and expression of transcription factors were analyzed by flow cytometry.
Results: CD127, OX40 and PD-1 were more strongly expressed on HBV- compared to Flu-specific CD4 T cells. HBV-specific CD4 T cells were identified in 27% of chronically infected patients and predominantly targeted the HBV polymerase and core proteins whereas responses to the surface protein were not detectable in cHBV patients. Consistent with the elevated *ex vivo* surface expression combined OX40 stimulation and PD-L1 blockade resulted in an increased frequency of IL-21 and IFN-g secreting CD4 T cells after antigen-specific *in vitro* culture. In addition, Tfh- and Th1-associated transcription factors Bcl6 and T-bet were strongly expressed in cytokine producing cells. In line with a lower expression of OX40 and PD-1 on Flu-specific CD4 T cells *ex vivo*, the augmentation of cytokine production was observed to a lesser extent for viral control responses to Flu and also EBV epitopes in HD.
Conclusion: Collectively, our observations demonstrate that synergistic effects of combined OX40 stimulation and PD-L1 blockade augment the secretion of Th1 and Tfh signature cytokines IFN-g and IL-21, suggesting that these pathways are promising candidates for immunotherapeutic interventions during cHBV infection.

Email: karin.wisskirchen@tum.de

Background and aims: Hepatitis B virus (HBV) infection remains a severe health problem with chronically infected patients being at increased risk of developing liver cirrhosis and hepatocellular carcinoma. Current treatment options control viral replication. However, viral clearance is not achieved. Since virus eradication is known to be accompanied by a strong T-cell response in patients with resolved HBV infection, adoptive T-cell therapy represents a promising therapeutic approach. We have recently demonstrated that CD8+ T cells grafted with T-cell receptors (TCR) restricted by major histocompatibility complex (MHC)-I have the potential to cure HBV infection in vitro and in vivo. Nevertheless, also CD4+ T cells are known to play an important role in resolving HBV infection and may therefore potentially benefit adoptive cell therapy. We thus aimed at identifying, cloning and characterizing MHC-II restricted TCRs from HBV-specific CD4+ T cells.
Method: HBV peptides derived from surface, core or polymerase antigens were selected by in silico prediction and used to stimulate PBMC from donors who had cleared HBV infection. HBV-specific CD4+ T cells secreting TNF-α were sorted by flow cytometry and clonally expanded from a single-cell level. Subsequently, sequences of TCR α- and β-chains of MHC-II restricted TCRs were identified, codon-optimized and cloned into a retroviral vector combined with murine constant domains. After retroviral transduction, all TCRs were expressed on primary T cells and characterized in depth regarding their MHC-II restriction, specificity, binding affinity and functionality.
Results: A total of 23 TCRs specific for seven different epitopes from HBV surface, core or polymerase antigens were generated. Through co-culture with a panel of partially matched lymphoblastoid cell lines (LCL), six different MHC-II restrictions were identified. They included HLA-DRB1*01, *07, *04 and *13 or HLA-DPB1*02 and *04, with worldwide phenotype frequencies ranging from 5 to 35% each. Seventeen TCRs recognized at least three peptide variants of HBV genotypes A-D and twelve TCRs had a high binding affinity with EC50 values in a low nanomolar range. Similarly, a strong activation by intracellularly processed viral antigen was observed for twelve TCRs. Interestingly, most TCRs were equally able to activate both CD4+ and CD8+ TCR-transduced T cells. Upon antigen recognition, CD4+ T cells secreted predominantly TNF-α and IL-2, whereas CD8+ T cells produced almost exclusively IFN-γ.
Conclusion: Taken together, we generated and characterized a set of 23 MHC-II restricted TCRs recognizing epitopes derived from HBV core, surface and polymerase antigens. These TCRs enabled CD4+ as well as CD8+ T cells to recognize antigen on MHC-II in a nanomolar range, resulting in antigen-specific T-cell activation.

Email: dr.wu@nju.edu.cn

Background and aims: To determine expression profiling of circulating B cells from patients with HBeAg-positive chronic hepatitis B virus (HBV) infection and healthy volunteers with the history of HBV vaccine immunization.
Method: Peripheral blood CD19+ B cells isolated from 4 HBeAg-positive CHB patients and 4 HBV vaccinated healthy controls were analyzed by high-through RNA sequencing. GO analyses and signaling pathway enrichment analysis including KEGG pathway analysis and Reacome pathway analysis were used to identify differentially expressed genes (DEG) among different groups. Our interested gene expressions were further validated by both of qPCR and Flow cytometry.
Results: 1401 differentially expressed genes (DEG) were identified from B cells of HBsAg positive CHB patients versus HBV vaccinated

healthy controls. Interestingly, the DEGs were enriched in biological progress especially in immune system process. The ribosome pathway was down regulated in HBsAg positive chronic hepatitis B patients may result in p53 suppression leading to B cells activation and proliferation. Specifically, we identified that cell activation and proliferation related genes including BACH2, CTLA4, TLR4, NFAM1, ZAP70, NOD2, PELI1 and PRDM1 were upregulated in HBsAg positive CHB patients.

Conclusion: For the first time, we identified a panel of potential genes and signaling pathways associated with the hyperactivation and proliferation of B cells in CHB patients, which might serve as promising targets for novel therapies to treat chronic hepatitis B infection.

Viral hepatitis B/D: therapy

FRI-157

Novel HBV capsid assembly modulator inhibits pregenomic RNA encapsidation by accelerating capsid assembly kinetics and disrupting core protein dephosphorylation

Leda Bassit[1], Kiran Verma[1], Suzane Kioko Ono[2], Bryan Cox[1], franck amblard[1], Raymond F Schinazi[1]. *[1]Emory University School of Medicine, Pediatrics, Atlanta, United States; [2]University of São Paulo School of Medicine, Gastroenterology, Sao Paulo, Brazil*
Email: rschina@emory.edu

Background and aims: Currently approved anti-HBV agents do not eliminate cccDNA from infected cells, whereas, some experimental capsid assembly modulators (CAMs) have an important impact in several steps of HBV viral replication including capsid assembly, reverse transcription, and pregenomic RNA (pgRNA) and polymerase protein packaging. Importantly, the dynamic of HBV core protein phosphorylation/dephosphorylation also controls several steps of viral replication and can be altered by these modulators. To better understand how our novel CAM blocks pgRNA encapsidation or cccDNA amplification, we evaluated their impact on core phosphorylation dynamics and HBeAg secretion.

Method: HepAD38 cells were cultured with 5 µM CAMs, (GLP-26 or GLS4). After 7 days, HBV capsids were purified and resolved into fast [DNA-containing capsids = hyperphosphorylated (hyper-P)] and slower migration [(empty capsids or core protein free dimers = hypophosphorylated (hypo-P)] in native agarose gel electrophoresis. Particles were transferred to nitrocellulose membrane, and immunoprobed for capsid imaging. Additionally, HBeAg antigen production (EIA), and pgRNA (RT-PCR) were quantified. Combinations with GLP-26, ETV and TAF were performed in AD38 cells.

Results: GLP-26 enhanced kinetics of capsid assembly that were hyperphosphorylated (Hyper-p = empty capsids and/or core-protein-free dimers), inhibited pgRNA (EC_{50} = 0.11 µM) and HBeAg production (EC_{50} = 0.003 µM). In contrast, GLS4, misdirected capsid assembly to form noncapsid polymers, however with lower inhibition of pgRNA or HBeAg *vs* GLP-26 (28-fold or > 33-fold greater potencies of pgRNA and HBeAg *vs* GLS4. GLP-26-treated cells maintained 2-2.3 log reduction in HBV DNA for 9 days post GLP-26 washout, vs 0.9-1.2 log reduction for ETV or TAF, independent of presence of ETV, TAF or media alone.

Conclusion: These results demonstrate that 1) GLP-26 accelerates capsid assembly kinetics of empty capsids, preventing viral DNA replication via inhibition of pgRNA encapsidation, and 2) GLP-26 alters both capsid structures and core protein dephosphorylation dynamics, which can interfere with pgRNA encapsidation and cccDNA amplification. GLP-26 confers sustained viral suppression for 9 days after removal of drug, similar to reduction in HBV observed for cells maintained with ETV or TAF. These data support additional studies in animals and eventually in humans to evaluate the ability of these agents to control and/or eliminate HBV *in vivo*.

Email: vithika.suri@gilead.com

Background and aims: TAF, a novel prodrug of tenofovir, has shown similar efficacy to TDF in Phase 3 studies with less bone and renal effects. As part of a protocol amendment to extend double blind (DB) treatment for 1 additional year (Week 96 to Week 144), only ~50% consented in time for this change; the remainder had already been receiving open-label (OL) TAF after Week 96. Here, we evaluate the 4 year (Week 192) safety and efficacy of switching to OL TAF in patients who had received DB TDF treatment for either 2 or 3 years.

Method: In 2 identically-designed studies, 1298 HBeAg-negative and HBeAg-positive CHB patients (873 TAF, 425 TDF) were randomized and treated with either TAF or TDF. In the TDF group, 180 patients were switched to OL TAF at Week 96 (OL TAF 96 Wk), while 202 patients switched from DB TDF to OL TAF at Week 144 (OL TAF 48 Wk). Safety assessments including changes in bone (hip and spine BMD) and renal (CrCl by Cockcroft-Gault [$eGFR_{CG}$]) parameters, viral suppression, and biochemical responses were assessed at Week 192 using the time of rollover to TAF as the respective OL baseline (BL). Within group changes in bone and renal parameters were assessed by paired t test or Wilcoxon signed rank test.

Renal and Bone Safety at Year 4 (Week 192)

	OL TAF 96 Wk. (N=180)	OL TAF 48 Wk. (N=202)
$eGFR_{CG}$, median (Q1, Q3) change (mL/min)	+3.0 (-2.4, +10.2) p<0.0001[a]	+1.5 (-4.8, +9.6) p=0.0212[a]
Hip BMD, mean (SD) % change	n=134 +1.25% (2.69%) p<0.0001[b]	n=190 +0.83% (2.39%) p<0.0001[b]
>3% increase / >3% decrease in hip BMD	18.7% / 5.2%	11.6% / 2.6%
Spine BMD, mean (SD) % change	n=133 +1.56% (3.39%) p<0.0001[b]	n=190 +1.62% (3.12%) p<0.0001[b]
>3% increase / >3% decrease in spine BMD, (%)	34.6% / 9.0%	27.9% / 5.8%

All results expressed as change from open-label (OL) baseline (defined as Week 96 for OL TAF 96 Wk and Week 144 for OL TAF 48 Wk patients). $eGFR_{CG}$ is creatinine clearance by Cockcroft-Gault method, BMD is bone mineral density by dual energy x-ray absorptiometry (DXA), Q is quartile. [a]Week 192 vs OL baseline by Wilcoxon signed rank test; [b]Week 192 vs OL baseline by paired t test.

Results: Patient characteristics were similar for those receiving OL TAF for 1 or 2 years following DB TDF treatment. Significant increases in $eGFR_{CG}$ from OL BL were observed within each group at Week 192 (Table). Significant increases in hip and spine BMD from OL BL occurred within each group, the magnitude was greater after 2 years of OL TAF only for hip BMD. Within each group, virologic suppression (HBV DNA < 29 IU/ml) was maintained from OL BL to Week 192 in patients who remained on TAF treatment (OL TAF 96 Wk group: 88% and 88%; OL TAF 48 Wk group: 94% and 93%, respectively), while at Week 192, within each group the rate of ALT normalization by 2018 AASLD criteria increased from OL BL after switching to TAF (55% OL TAF 96 Wk and 37% OL TAF 48 Wk).
Conclusion: In CHB patients treated with TDF for 2 or 3 years, recovery of renal and bone parameters occurred at Year 4 suggesting reversibility of these parameters. Virologic control was maintained and ALT normalization increased following the switch from TDF to TAF.

FRI-159

Can HBcrAg and pre-genomic HBV RNA predict the risk of ALT flares after nucleoside analogue therapy withdrawal: delineating the clinical utility of new biomarkers?

Ivana Carey[1], Jeffrey Gersch[2], Matthew Bruce[1], Bo Wang[1], Mary Kuhns[2], Gavin Cloherty[2], Geoffrey Dusheiko[1], Kosh Agarwal[1]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom;* [2]*Infectious Diseases Department, Abbott Diagnostics, Chicago, United States*
Email: ivana.kraslova@kcl.ac.uk

Background and aims: We have previously demonstrated that significant ALT flares after nucleos (t)ide analogue (NA) withdrawal in HBeAg-negative non-cirrhotic chronic hepatitis B (CHB) patients who were suppressed on NA therapy for at least 3 years are associated with detectable HBcrAg (> 2 log_{10}U/ml) and detectable pregenomic (pg) HBV RNA (> 1.65 log_{10}U/ml). The proportion of patients with significant ALT flares after stopping NA was 20% in our pilot cohort (n = 15), but data from "real-life" cohorts are lacking. We have evaluated the proportion of non-cirrhotic HBeAg-negative treated patients (fully suppressed with undetectable HBV DNA for at least 5 years on NA) with detectable HBcrAg and pgHBV RNA after 3 and 5 years of therapy.
Method: We have studied 66 HBeAg-negative, tenofovir (TDF) treated non-cirrhotic CHB patients across HBV genotypes (A:18%, B:3%, C:15%, D:15% and E:49%), who had suppressed HBV DNA for at least 5 years (median duration 7.5 yrs, range 5.5 –11.5 yrs). 73% were male, and their median age was 45 years. Plasma samples at baseline, year 3 and year 5 on-treatment were tested for serological/virological markers: HBV DNA by TaqMan (Roche, log_{10}IU/ml); quantitative HBsAg by Abbott Architect [log_{10} IU/ml], HBcrAg levels by CLEIA Fujirebio [log_{10}U/ml] and concentrations of pgHBV RNA were measured using the Abbott Diagnostic real-time PCR assay (Butler E et al, Hepatology 2018) [LLQD = 1.65 log_{10}U/ml]. Baseline and on-treatment levels of serological/virological markers were compared between patients according to detectable HBcrAg/pgHBV RNA vs. undetectable HBcrAg/pgHBV RNA status at year 3 and year 5.
Results: All patients with HBcrAg < 2 log_{10}U/ml had simultaneously levels of pgHBV RNA < 1.65log_{10}U/ml. All patients achieved persistently HBV DNA < 20IU/ml after 6 months of therapy. While at baseline only 4 (6%) patients had undetectable HBcrAg and pgHBV RNA, by year 3, 46 (70%) patients and at year 5, 57 (86%) of treated patients had undetectable HBcrAg and pgHBV RNA. Patients with detectable HBcrAg at year 3 had significantly higher median baseline concentrations of HBV DNA (4.91 vs. 3.99 log_{10}IU/ml), HBsAg (4.01 vs. 3.67 log_{10}IU/ml), HBcrAg (4.45 vs. 3.15 log_{10}U/ml) and pgHBV RNA levels (2.1 vs. 1.79 log_{10}U/ml) (all p < 0.01). At year 3 and year 5 the patients with detected HBcrAg/pgHBV RNA had significantly higher HBsAg, HBcrAg and pgHBV RNA at these time-points than HBcrAg/pgHBV RNA negative patients.
Conclusions: After 3 years on treatment 30% patients have still detectable HBcrAg and pgHBV RNA, suggesting viable transcriptional activity despite nucleoside analogue inhibition of HBV DNA. These data suggest heterogeneity of this cohort and warranting individual approach if NA stopping therapy is considered. Including biomarkers of transcriptional activity, HBcrAg and pgHBV RNA, into the treatment/disease management algorithms should be considered.

FRI-160

The role of soluble propragmmed cell death protein 1 on HBV relapse after cessation of entecavir therapy in HBeAg-negative non-cirrhotic patients

Chien-Hung Chen[1], Jing-Houng Wang[1], Tsung-Hui Hu[1], Chao-Hung Hung[1], Sheng-Nan Lu[1]. [1]*Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan*
Email: e580306@ms31.hinet.net

Background and aims: Recent study showed serum soluble programmed cell death protein 1 (sPD-1) is an important immune-related marker for assessment of HBV activity. However, it remains unclear whether serum sPD-1 levels could predict HBV relapse or HBsAg loss after cessation of nucleos (t)ide analogues (NAs) therapy. The aim of this study is to investigate the role of sPD-1 on HBV relapse and HBsAg loss after discontinuation of entecavir therapy.
Method: A total of 252 HBeAg-negative non-cirrhotic patients who had stopped entecavir treatment for at least 12 months were recruited. sPD-1 levels were check at baseline, end of treatment and post-treatment 6 months. All patients fulfilled the stopping criteria proposed by the Asian Pacific Association for the Study of the Liver (APASL) 2012 guideline.
Results: The mean of sPD-1 levels were 4.81 ± 0.81, 4.19 ± 0.80, 4.20 ± 0.81 log pg/ml, respectively, at baseline, end of treatment and post-treatment 6 months. During entecavir treatment (mean: 169.2 ± 40.1 weeks), sPD-1 decline from baseline to end of treatment was 0.62 ± 0.48 log pg/ml. HBsAg decline levels, HBV genotype C, and higher baseline HBV DNA levels were independent factors of sPD-1 decline. sPD-1 decline levels were correlated with HBsAg decline levels during entecavir therapy (R^2 = 0.55, P < 0.001).
The 6-year cumulative rates of virological relapse, clinical relapse, and HBsAg loss were 70.8%, 57.3%, and 31%, respectively, after cessation of entecavir therapy. Older age, HBV genotype B, higher baseline HBV DNA and end-of-treatment HBsAg levels, and higher sPD-1 levels at post-treatment 6 months were independent factors of virological relapse. Older age, HBV genotype B, and higher sPD-1 levels at post-treatment 6 months were independent factors of clinical relapse. End-of-treatment HBsAg levels was an independent factor of HBsAg loss.
We utilized a sPD-1 at post-treatment 6 months of 3500 pg/ml as the optimal values for predicting HBV relapse and HBsAg loss after cessation of entecavir therapy. Of the patients who achieved sPD-1 < 3500 and ≥ 3500 pg/ml, the 5-year cumulative rates of virological and clinical relapse, and HBsAg loss were 37.6% vs. 81.7%, 27.1% vs. 67.4%, and 49.7% vs. 12.3%, respectively (all p < 0.001).
Conclusion: sPD-1 decline was highly correlated with HBsAg decline during entecavir therapy. sPD-1 levels at post-treatment 6 months was a useful marker to predict HBV relapse and HBsAg loss after discontinuation of entecavir treatment.

Email: qning@vip.sina.com

Background and aims: Cirrhosis is a unique entity of chronic liver disease which is still a controversial determinant to mortality of hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF).
Method: In this prospective-retrospective study, 709 patients with HBV-ACLF defined by the Asian Pacific Association for the Study of Liver ACLF Research Consortium (AARC) criteria were enrolled from 12 Asian-Pacific countries. Cirrhosis were evaluated as a risk factor intervening short-term (28 and 90 days) transplant-free mortality. Meanwhile, Current main prognostic models Tongji prognostic predictor model score (TPPMs), Chinese Group on the Study of Severe Hepatitis B-ACLF score (COSSH-ACLFs), CLIF consortium organ failure score (CLIF-C OFs), CLIF-C acute-on-chronic liver failure score (CLIF-C ACLFs), Model for End-Stage Liver Disease score (MELDs) and MELD-sodium score (MELD-Nas) were measured for predicting ability of mortality with area under the receiver operating characteristic curves (AUROCs).
Results: Among 709 HBV-ACLF patients, cirrhotic group (62.91%) showed significantly higher mortality and complications (ascites, infection and gastrointestinal bleeding) than non-cirrhotic group. Only 36.1% and 40.1% of patients met CLIF-C criteria in non-cirrhotic and cirrhotic group respectively, who showed significantly higher mortality and complications than those who did not satisfy the CLIF-C criteria. Furthermore, in major patients who did not meet CLIF-C criteria, cirrhotic group exhibited higher mortality and complication occurrence than non-cirrhotic group, without significant difference of organ failures. TPPMs (0.870, 0.792), who set number of complications as determinants, showed prior ability than COSSH-ACLFs (0.843, 0.773), CLIF-Cs (0.819, 0.753), CLIF-OFs (0.735, 0.698), MELDs (0.784, 0.727) and MELD-Nas (0.773, 0.733), in cirrhotic patients. Number of complications more than 1 was an independent risk factor in cirrhotic HBV-ACLF patients.
Conclusion: Cirrhosis has its advantages in HBV-ACLF risk stratification. TPPMs possess high predicting ability in cirrhotic HBV-ACLF patients. Complication other than organ failure is the major risk factor for mortality of cirrhotic HBV-ACLF patients.

Email: senthil.chinnakannan@ndm.ox.ac.uk

Background: Current therapies for HBV suppress viral load but rebound occurs on cessation of therapy; novel therapeutic strategies are urgently required.
Aim: To develop a potent therapeutic HBV vaccine that will induce B and T-cells to all major HBV antigens.
Method: First generation HBV immunogens (HBV-$CP_{mut}S$) with and without class II shark invariant chain (SIi), were designed to encode precore (PreC), core, non-functional polymerase (P_{mut}) and large surface antigen in chimpanzee adenoviral (ChAd) vectors [Figure 1a (i)]. These were then modified for incorporation into ChAds and Modified Vaccina Ankara (MVA): SIi, PreC, core, P_{mut}, NΔPreS1 and PreS2 were generated under a CMV (ChAd) or F11 (MVA) promoter to induce HBV specific T cells, whilst tissue plasminogen activator (TPA), CΔPreS1 and surface was generated separately using F2A (in ChAds) or mH5 promoter (in MVA) in order to generate envelope protein and anti-HBV B cell responses [Figure 1a (ii)]. The order of the HBV (core, pol and Pre-S1 and pre-S2) genes were rearranged within the ChAd and MVA to prevent the generation of immune responses to inter-gene regions when used in prime boost strategies. Vaccines were tested in CD1, Balb/c and C57BL6 mice. HBV-specific T-cell responses were assessed using IFN-ϒ ELISpot and intracellular cytokine (ICCS) assays. Anti-HBs antibodies were assessed using ELISA.
Results: The inclusion of SIi significantly enhanced T-cell magnitude of spleen lymphocytes (3821 vs. 386 mean total SFU/10^6 splenocyte, $p < 0.0001$, in CD1 mice). ChAd vaccine alone generated very high magnitude of CD8+ HBV specific T-cell responses to all HBV antigens, but CD4+ responses and HBsAb responses were not detected. MVA prime vaccination alone induced low level T-cell response at 878 SFU/10^6 splenocytes in Balb/c mice. However, ChAd prime/MVA boost showed induction of high magnitude of T cells (4022 and 6063 mean total SFU/10^6 splenocytes in Balb/c and C57BL6 respectively) (Figure 1b) and anti-HBs antibodies. ICCS showed that HBV specific CD8+ and CD4+ T cells were highly polyfunctional producing IFN-ϒ, TNF-α, and IL-2. Importantly, T cells to the non-HBV SIi, F2A and the inter-gene regions were not generated.
Conclusion: We have generated genetically adjuvanted ChAd and MVA vectored HBV vaccines that induce high-magnitude B and T cells, for use in prime/boost vaccination strategies. These pre-clinical studies pave the way for new studies of HBV immunotherapy in humans with chronic HBV infection.

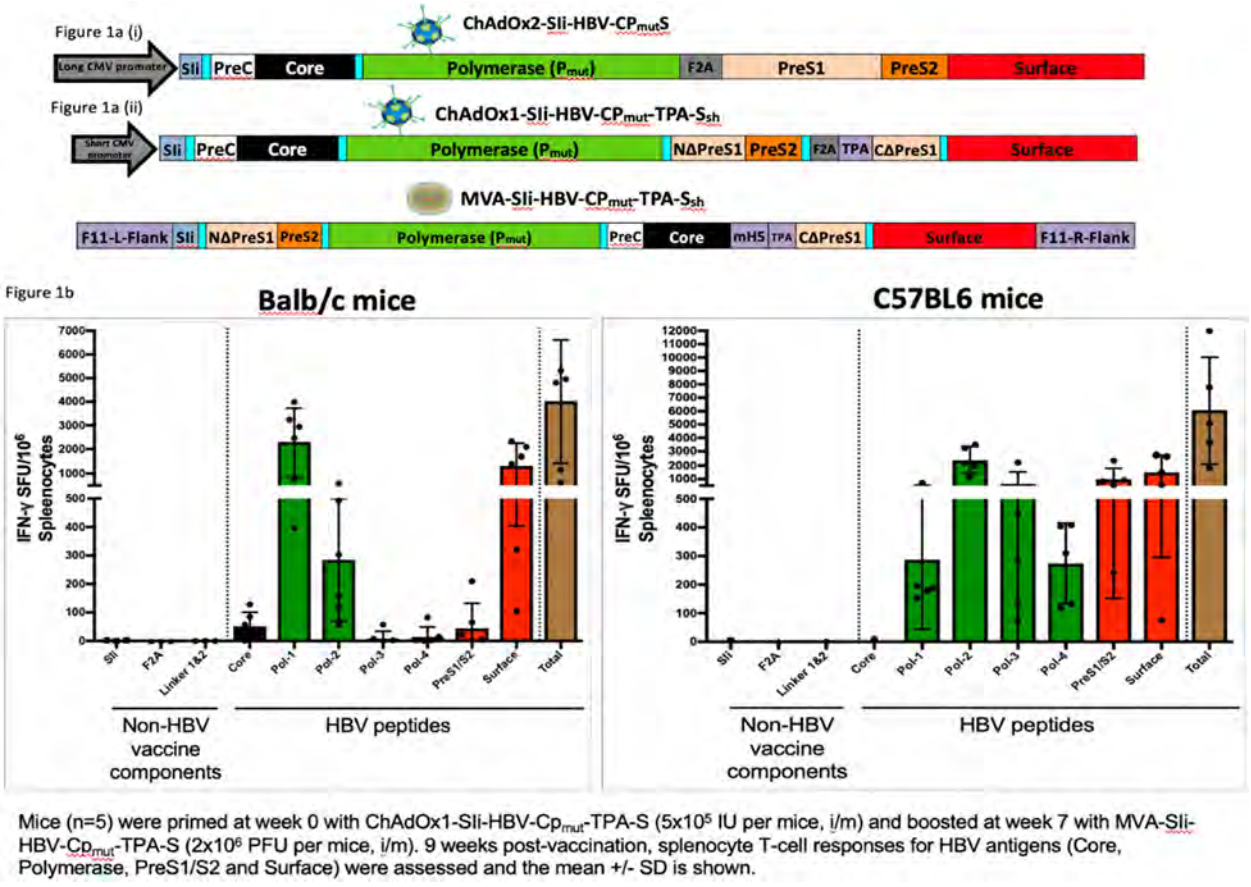

Figure 1: (abstract: FRI-162): (a) ChAd/MVA HBV vaccines. (b) IFN-ϒ ELISPOT response to ChAdOx1-SIi-HBV-CP_{mut}-TPA-S_{sh} prime and MVA-SIi-HBV-CP_{mut}-TPA-S_{sh} vaccination

Reduced liver-related complications after 13 years of follow-up of interferon-alpha treatment for HBeAg-positive chronic hepatitis B: The ELITE-B study

Hannah S.J. Choi[1,2], Margo J.H. van Campenhout[3], Cedric de Jong[3], Hanneke van Vuuren[4], Milan Sonneveld[3], Robert De Knegt[3], Bettina Hansen[1,3,5], Harry Janssen[1]. *[1]Toronto Centre for Liver Disease, Toronto, Canada; [2]University of Toronto, Institute of Medical Science, Toronto, Canada; [3]Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [4]Erasmus University Medical Center, Department of Public Health, Rotterdam, Netherlands; [5]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada*
Email: sjchoi0731@gmail.com

Background and aims: Interferon-alpha (IFN-α) treatment of chronic hepatitis B (CHB) is finite and leads to relatively high loss of serum HBeAg and HBsAg compared to nucleo (s)tide analogue (NA) therapy. Response to IFN-α treatment and its long-term clinical outcomes are of great interest for current drug development.
Method: All consecutive HBeAg-positive patients treated with IFN-α or PEG-IFN-α at a European tertiary center between 1978 and 2014 were included. We reviewed medical charts and consulted the Municipal Person Records Database for patient information. Patients were invited for a single visit at the outpatient clinic in case of missing follow-up data. The end points included serologic (HBeAg/HBsAg loss), biochemical (ALT normalization), and virologic response (HBV DNA < 2000 IU/ml) at long-term follow-up (LTFU) and incidence of liver-related clinical events (decompensation/HCC), stratified by presence or absence of response. Person-years and 95% confidence intervals (CI) were used to analyze the incidence of liver-related events. Lookback period was used to prevent overestimation of incidence. Patients were excluded if events were reported < 6 months of the first IFN-α treatment start date (baseline).
Results: A total of 261 HBeAg-positive patients treated with (PEG) IFN-α were included in the analysis. The mean follow-up duration was 13 years. The cohort was mostly male (67%), with a median age of 31 years, and 57% Caucasian vs. 34% Asian. The median duration of the first (PEG)IFN-α treatment course was 27 weeks. At LTFU, HBeAg loss was found in 169 (65%) and HBsAg loss in 64 (25%) patients. The incidence of HBsAg loss was 2.3 per 100 person-years during a total follow-up of 2927 person-years. The incidence of liver-related events per 100 person-years was significantly lower in patients who achieved biochemical response (0.3 (0.1-0.6) vs.1.3 (0.7-2.3)), virologic response (0.2 (0.1-0.5) vs 1.8 (1.0-3.4)) and HBeAg loss (0.2 (0.1-0.5) vs 1.5 (1.0-2.5)). There was no reduction in the incidence of liver-related events with respect to HBsAg loss (0.5 (0.2-1.5) vs 0.6 (0.4-1.1)). Patients who achieved HBsAg loss were significantly older at baseline compared to those who did not have HBsAg loss, and the 3 patients who lost HBsAg but experienced a liver-related event during follow-up were all cirrhotic at baseline.
Conclusion: In our large single tertiary centre cohort with the longest follow-up duration to date, the risk of liver-related adverse outcomes was profoundly reduced, however not fully eliminated with HBeAg loss, and biochemical and virologic response to (PEG)IFN-α treatment. HBsAg loss did not lower the risk, presumably due to presence of cirrhosis and older age at the start of treatment.

FRI-164

Prognostic value of various liver scoring systems in cirrhotic chronic hepatitis B patients with and without tenofovir disoproxil fumarate treatment

Jonggi Choi[1], Ken Liu[2], An Le[3], Vincent Wai-Sun Wong[4], Stephen L. Chan[5], Mindie Nguyen[3], Young-Suk Lim[1], Grace Lai-Hung Wong[4]. *[1]ASAN Medical Centre, University of ULSAN, Department of Gastroenterology, Seoul, Korea, Rep. of South; [2]Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Sydney, Australia; [3]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, Palo Alto, United States; [4]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong; [5]The Chinese University of Hong Kong, Department of Clinical Oncology, Hong Kong, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: Various scoring systems predict risk of decompensating events and deaths (Child-Pugh, model for end-stage liver disease [MELD], albumin-bilirubin [ALBI]) and chronic hepatitis B (CHB)-related hepatocellular carcinoma (CU-HCC, REACH-B, PAGE-B). The performance of these scores in CHB patients with cirrhosis treated with tenofovir disoproxil fumarate (TDF) is unclear. We aimed to investigate the predictive value of these scores for hepatic decompensation, hepatocellular carcinoma (HCC) and death.

Method: Two CHB cirrhotic cohorts were retrospectively studied. Cirrhosis was defined by liver histology, thrombocytopenia (< 150×10^9/L) and/or features of portal hypertension on imaging. TDF cohort included consecutive patients from 3 tertiary centres (Hong Kong, South Korea, United States) who received TDF 300 mg/day for ≥ 12 months. Control cohort included historical untreated patients.

Results: 808 TDF-treated and 291 control patients were studied. There were 72 decompensating events, 113 HCC and 41 deaths at 5 years follow-up. Among untreated controls, baseline Child-Pugh, MELD and ALBI scores were predictive for decompensation and death at 5 years (**Table 1**). Child-Pugh, MELD, REACH-B and CU-HCC scores were predictive for HCC. The best areas under receiver operator characteristics curve for decompensation, HCC and death were Child-Pugh, CU-HCC and ALBI, respectively. Among TDF-treated patients, scores lost their predictive value for events except Child-Pugh, and CU-HCC was still predictive for HCC and PAGE-B became predictive for HCC. TDF treatment led to significant improvements after 1-year follow-up compared to baseline which were sustained at 5 years follow-up in all scores except PAGE-B and ALBI.

Table 1: Predictive value of each scoring system based on univariate Cox regression model for liver events and deaths at 5-years follow-up

SCORE	UNTREATED PATIENTS			TDF-TREATED PATIENTS		
Decompensation	**HR**	**95% CI**	***P***	**HR**	**95% CI**	***P***
Child-Pugh	2.32	1.76–3.05	**< 0.001**	1.25	0.39–4.00	0.712
MELD	1.22	1.13–1.31	**< 0.001**	1.10	0.92–1.30	0.288
ALBI	6.18	4.14–9.22	**< 0.001**	1.66	0.62–4.47	0.318
HCC	**HR**	**95% CI**	***P***	**HR**	**95% CI**	***P***
Child-Pugh	1.84	1.38–2.45	**< 0.001**	1.37	1.03–1.82	**0.032**
MELD	1.16	1.04–1.29	**0.008**	1.02	0.93–1.11	0.696
CU-HCC	1.09	1.03–1.15	**0.002**	1.05	1.02–1.08	< 0.001
REACH-B	1.31	1.04–1.64	**0.021**	1.04	0.96–1.12	0.393
PAGE-B	1.03	0.93–1.15	0.556	1.09	1.03–1.16	**0.007**
Death	**HR**	**95% CI**	***P***	**HR**	**95% CI**	***P***
Child-Pugh	2.18	1.54–3.09	**< 0.001**	0.85	0.18–4.00	0.832
MELD	1.35	1.19–1.52	**< 0.001**	0.97	0.69–1.38	0.883
ALBI	4.89	2.84–8.74	**< 0.001**	1.22	0.23–6.41	0.816

Conclusion: Baseline liver prognostic scores have predictive value for decompensation, HCC and death in untreated CHB patients with cirrhosis which is diminished or lost in TDF-treated patients. TDF treatment led to sustained improvements in most prognostic scores.

FRI-165

No detectable resistance to tenofovir in patients with Adefovir- and Entecavir-resistant chronic hepatitis B after 240 weeks of treatment with tenofovir disoproxil fumarate monotherapy

Jonggi Choi[1], Young-Suk Lim[1], Han Chu Lee[1], Yung Sang Lee[1], Kwan Soo Byun[2], Yoon Jun Kim[3], Byung Chul Yoo[4], So Young Kwon[4], Geum-Youn Gwak[5]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South; [2]Korea University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [3]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South; [4]Konkuk University School of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [5]Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South*
Email: limys@amc.seoul.kr

Background and aims: A major challenge in the treatment of chronic hepatitis B (CHB) patients is to maintain long-term viral suppression without emerging the drug-resistant mutations. Monotherapy with tenofovir disoproxil fumarate (TDF) is efficacious in patients with lamivudine-, entecavir- (ETV), or adefovir (ADV) resistant hepatitis B virus.

Method: We conducted two multicenter, randomized, open-label trials (IN-US-174-0202 and IN-US-174-0205) designed to compare the efficacy and safety of TDF monotherapy with that of TDF + ETV combination therapy in multiple-drug CHB patients with multiple drug failure and persistent viremia. Patients were randomized 1:1 to receive TDF monotherapy or TDF + ETV combination therapy for 48 weeks, and then to maintain TDF monotherapy or to switch to TDF monotherapy. One study enrolled patients with ETV-resistance without ADV-resistance (n = 90), and the other patients with ADV-resistance (n = 102). Resistance mutations were determined by restriction fragment mass polymorphism analyses and direct sequencing of the pol/RT. Resistance profile was surveilled for patients who experienced virologic breakthrough (VB: increases in HBV DNA levels ≥ 1 $\log_{10}$ IU/ml from nadir on two consecutive tests) or persistent viremia (HBV DNA > 60 IU/ml) at Week 240 or discontinuation.

Results: Over the 240-week treatment period, 94 patients with ADV-resistance and 82 patients with ETV-resistance completed up to 240 weeks of TDF monotherapy. Three (3.3%) patients in the ETV-resistance group and 4 (3.9%) patients in the ADV-resistance group experienced VB ($p > 0.99$). All of which were associated with decreased adherence to study medication (less than 80%) and were transient requiring no treatment modification. During VB, some of the baseline resistance mutations, but no additional substitutions, were detected in pol/RT region of HBV in the patients. Among the 12 patients who discontinued the study, none had VB at drop-out, but 2 had HBV DNA > 60 IU/ml at the last time point of treatment, where no additional substitutions were detected in pol/RT gene compared to baseline. At week 240, 1 and 8 patients in the ETV-resistance and ADV-resistance groups, respectively, had HBV DNA levels > 60 IU/ml ($p = 0.04$). Among them, 2 patients in the ADV-resistance group had at least one detectable HBV resistance mutation at week 240, all of which were present at baseline. No patients developed additional substitutions in pol/RT compared to baseline.

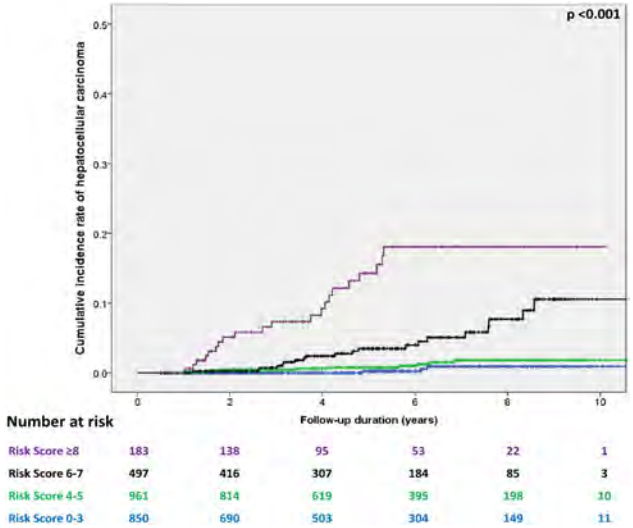
Conclusion: TDF monotherapy maintains effective suppression of HBV DNA through 240 weeks of treatment with no evidence of additional resistance mutations in patients with ADV- and ETV-resistant CHB.

FRI-166

Treatment recommendations for chronic hepatitis B and the risk of hepatocellular carcinoma

Sung Eun Kim[1], Dong Hyun Sinn[2], Beom Kyung Kim[3], Ji Hoon Kim[4], Byung Chul Yoo[5], Moon Seok Choi[2]. *[1]Hallym University Sacred Heart Hospital, Seoul, Korea, Rep. of South; [2]Samsung Medical Center, Seoul, Korea, Rep. of South; [3]Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [4]Korea University College of Medicine, SEoul, Korea, Rep. of South; [5]Konkuk University School of Medicine, Seoul, Korea, Rep. of South*
Email: sinndhn@hanmail.net

Background and aims: Ideally, those who are not indicated for antiviral therapy for chronic hepatitis B virus (HBV) infection should be at null risk of developing hepatic complication. We assessed the incidence of hepatocellular carcinoma (HCC) in those outside of current treatment recommendations and risk factors associated with HCC development.
Methods: A multi-center, retrospective cohort of 3, 624 patients who were monitored without antiviral treatment was analyzed. Incident HCC risk according to the Asian Pacific Association for the study of the Liver (APASL), the American Association for the Study of Liver Disease (AASLD) and the European Association for the Study of the Liver (EASL) treatment recommendations was assessed. Risk score was developed using independent factors associated with HCC development among patients who were outside current treatment criteria.
Results: During a median follow-up of 4.6 years, incident HCC was diagnosed in 161 (4.4%) patients. Proportions of patients developed HCC outside treatment recommendation according to APASL, AASLD, and EASL criteria were 64.0%, 46.0%, and 33.5%, respectively. The 5-years cumulative HCC incidence rate was 13.9% for cirrhotic patients with low-level viremia and 6.1~7.3% for chronic hepatitis patients with elevated HBV DNA levels plus mildly elevated alanine aminotransferase levels. Among patients who were outside treatment recommendation, age, sex, hepatitis B e antigen, cirrhosis, alanine aminotransferase, and platelet levels were independent factors associated with HCC development. When these factors were used to calculate risk score for each patient, those with score ≥ 8 showed high HCC incidence rate (14.3% at 5-year), although they were currently outside treatment recommendation.



Conclusion: HCC was observed among patients who were outside current treatment criteria indicating careful attention for HCC and efforts to identify patient at risk are required.

Effectiveness and safety with tenofovir alafenamide (TAF) for hepatitis B in US clinical practice

Michael Curry[1], Ho Bae[2], Douglas Dieterich[3], Victor Ankoma-Sey[4], Rajender Reddy[5], Calvin Pan[6], Hie-Won Hann[7], Myron Tong[8], W. Ray Kim[9], Paul Kwo[9], Lynn Frazier[10], Scott Milligan[11], Keith Spitz[11], Nezam Afdhal[1]. *[1]Beth Israel Deaconess Medical Center, Boston, United States; [2]St. Vincent Medical Center, Asian Pacific Liver Center, Los Angeles, United States; [3]Mount Sinai School of Medicine, New York, United States; [4]Liver Associates of Texas, P.A., Houston, United States; [5]University of Pennsylvania, Philadelphia, United States; [6]NYU Langone Health, NYU School of Medicine, New York, United States; [7]Thomas Jefferson University Hospital, Philadelphia, United States; [8]Huntington Medical Research Institute Liver Center, Pasadena, United States; [9]Stanford University School of Medicine, Stanford, United States; [10]Liver Wellness Center, Little Rock, United States; [11]Trio Health Analytics, La Jolla, United States*
Email: scott.milligan@triohealth.com

Background and aims: TAF provides similar efficacy to tenofovir disoproxil fumarate (TDF) but with an improved safety profile particularly for renal injury. Here, we assess clinical experience with TAF for patients with HBV in US Clinical Practice.
Method: The TRIO HBV Registry, consisting of 1078 enrolled patients from 6 academic and 4 community-based centers serving 17 US States, was created to understand real-world HBV treatment. Data presented here are limited to 250 registry patients who initiated TAF between Nov 2016 and Apr 2018, received ≥ 6 months of TAF therapy, and were followed up to 18 months. Baseline measures were closest to but between −30 to +60 days from regimen start. Measures in other time periods were those with the maximum date while on TAF. Comparisons to baseline were made using paired 2-tailed T-Tests. eGFR was calculated using the CKD-EPI equation.
Results: Characteristics of the study population: median age 52 years, BMI 24.3 kg/m2, male (147/250, 59%), Asian ethnicity (220/250, 88%), HBeAg positive (54/250, 22%), osteopenia/osteoporosis (47/250, 19%), and FIB-4 > 3.25 (17/250, 7%). Mean and median TAF duration was 13 months as of data collection. 233/250 (93%) of patients receiving TAF switched from TDF (214/233, 92%), entecavir (16/233, 7%), or other therapies (3/233, 1%). At TAF initiation, 17/250 (7%) patients had baseline HBV DNA ≥ 2000 IU/ml. Of the 17, 16 patients had controlled HBV (< 2000 IU/ml) after 6 or 12 months of TAF therapy. One patient had a 50% viral reduction to 30, 000 IU/ml after 6 months of therapy but did not achieve suppression. 233/250 (93%) patients had baseline HBV DNA < 2000 IU/ml; of these, 226 were assessed after 6 or 12 months of therapy and all had maintained HBV suppression (< 2000 IU/ml). 224/250 (90%) patients had baseline eGFR ≥ 60 ml/min and 26/250 (10%) < 60 ml/min with minimum 28 ml/min. In paired comparisons, mean eGFR increased 5% from baseline 85.7 to 90.1 ml/min ($p < 0.001$) after 6 months of TAF therapy ($n = 213$). Of 158 patients with eGFR measures after 12 months of TAF, the mean eGFR increase was 4% from baseline 86.9 to 90.5 ml/min ($p = 0.001$). For patients with baseline eGFR < 60 ml/min, mean eGFR increased 16% from 48.4 to 56.0 ml/min after 6 months ($n = 24$, $p < 0.001$). In the eGFR < 60 ml/min subset with 12+ months of TAF, the change in eGFR was 14% from baseline 54.0 to 61.4 ml/min though this change did not reach significance ($n = 11$, $p = 0.066$).
Conclusion: In US, clinical practice experience with TAF indicates effective HBV suppression after switching and improved renal function in real-world application. Continued long-term monitoring is critical to assess potential effects of prolonged treatment with lower dose tenofovir.

FRI-168

Understanding HDV and HBsAg kinetics during nucleic acid polymer REP 2139 mono-therapy in HBeAg-negative chronic HBV/HDV co-infected patients via mathematical modeling

Louis Shekhtman[1,2], Scott Cotler[1], Susan Uprichard[1], Michel Bazinet[3], Victor Pantea[4], Valentin Cebotarescu[4], Lilia Cojuhari[4], Pavlina Jimbei[5], Adalbert Krawczyk[6], Andrew Vaillant[3], Harel Dahari[1]. [1]*Loyola University Medical Center, Maywood, United States;* [2]*Bar-Ilan University, Ramat Gan, Israel;* [3]*Replicor Inc., Montreal, Canada;* [4]*N. Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova;* [5]*Toma Ciorba Infectious Clinical Hospital, Chisinau, Moldova;* [6]*Universitätsklinikum Essen, Essen, Germany*
Email: harel.dahari@gmail.com

Background and aim: REP 2139-Ca and REP 2139-Mg were previously shown to clear hepatitis B surface antigen (HBsAg) and establish functional control/cure in chronic HBV infection. In a recent study (REP 301) REP 2139-Ca also eliminated detectable HDV viral load in chronic HBV/HDV co-infection and established functional control/cure of HDV. Here we sought to estimate HDV-HBsAg-host parameters and REP 2139-Ca efficacy against HDV and HBsAg using mathematical modeling.

Method: Twelve treatment naive HBeAg negative participants with high serum HDV RNA and serum HBsAg concentrations of more than 1000 IU/ml with documented chronic HDV infection for 10 months to 18 years were recruited as described (Lancet Gastroenterol Hepatol.2017;2 (12):877–889). Serum HDV and HBsAg levels were measured every two weeks. A dual mathematical model of HDV and HBsAg dynamics (Hepatol. 2014; 60 (6): 1902–1910) was modified to account for a direct effect of REP 2139-Ca in blocking HDV production consistent with the direct interactions of REP 2139 with HDAg reported in a recent in vitro study (Hepatol. 2017;66 (Suppl1): 504A). The model was simultaneously fit to measured data during REP 2139-Ca monotherapy. Two patients were excluded from modeling due to late response or early fluctuations in HDV during REP 2139-Ca monotherapy.

Results: Mean baseline values for HDV and HBsAg were 6.6 [IQR 6.08–7.1] Log U/ml and 4.2 [4.0–4.4] log IU/ml, respectively. The model was able to simulate/estimate the simultaneous decline of HDV and HBsAg at 25 days [16–35] in 8 of 10 participants as well as the earlier HDV decline at 25 [19–30] days compared to HBsAg decline at 32 [20–33] days observed in the remaining 2 participants. HBsAg and HDV clearance rates were estimated to be 0.42 [0.34–0.53] and 0.31 [0.27–0.38]/d corresponding to HBsAg half-life of $t_{1/2}$ = 1.65 d and HDV $t_{1/2}$ = 2.2 d, respectively. The HDV-infected cell death/loss was estimated to be 0.056 [0.024-0.078]/d corresponding to an infected cell $t_{1/2}$ = 12.4 d. The overall efficacies of blocking HDV and HBsAg production were 98.3 [97.0–99.9] % and 96.5 [94.1–99.6]%, respectively, with both efficacies over 99% in 50% of patients.

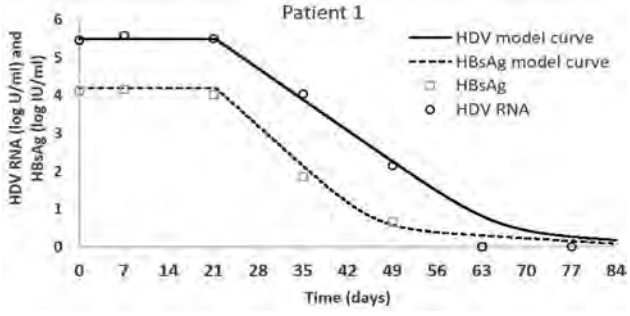

Figure: A representative model fit with measured HDV and HBsAg data during REP 2139-Ca monotherapy. ALT and anti-HBs remained unchanged (not shown)

Conclusion: During REP 2139-Ca monotherapy, inhibition of both HDV and HBsAg production was observed in 83% of REP 2139-Ca treated participants. The decrease in HDV RNA prior to the decline in HBsAg observed in 2 participants is consistent with a direct effect of NAPs on HDV independent of blocking HBsAg production, however the ability of the model to support this direct effect is limited by the sampling frequency available. Modeling provides important new insight into HDV and HBsAg kinetic parameters and REP 2139-Ca efficacy in blocking HDV and HBsAg. This modified dual model could be used to guide treatment duration.

FRI-169

Liver transplantation for hepatitis B induced end stage liver disease: Is it possible to do away with anti virals after liver transplantation?

Rajesh Dey[1], Subhash Gupta[2]. [1]*Max Super Speciality Hospital, Liver and biliary sciences, New Delhi, India;* [2]*Max Super Speciality Hospital, New Delhi, India*
Email: drrajeshdey@gmail.com

Background and aims: Hepatitis B induced end stage liver disease/ hepatocellular carcinoma is one of the leading causes of liver transplantation in Asian countries. Recurrence of Hepatitis B (HBV) has always been a concern in patients undergoing liver transplantation (LT) for HBV. Most strategies revolve around use of peri operative HBV immune globulin (HBIG) and long term use of antivirals (entecavir/tenofovir). Our group has previously shown that successful LT is possible without the use of HBIG[1], and such patients have remained recurrence free in the long term. This study aims to demonstrate that even withdrawal of antivirals is possible in patients undergoing LT for HBV.

Method: All patients undergoing LT for HBV induced end stage liver disease/HCC between January 2014 and June 2017 were included in the study. Pre operative anti viral treatment status, HBV DNaA levels were assessed as well as the MELD score where applicable. Demographic characteristics like sex, age distribution, country of residence was included. Post operative antiviral treatment and immunization status was recorded as well as anti HBs antibody titres to detect sero conversion. HBV DNA levels in the post operative period were assayed. Survival rate, HBV recurrence rate were assessed.

Results: 963 LT were performed in our center between Jan 2014 and June 2017, out of which 173 cases (17%) were due to HBV either alone or in combination with HDV/HCV or both. 155 (90%) were on antivirals prior LT. None of the recipients received HBIG perioperatively. All recipients received antivirals (entecavir-85%, tenofovir-15%) after LT. Post operative immunization was given to all recipients, first dose of the three dose regimen being given at least 3 months after transplant. Anti HBs antibody titres were measured 4 to 6 weeks after the last dose of vaccine. Patients who achieved an anti HBs antibody titres of more than 10 IU/ml underwent a HBV DNA quantitative analysis and 100% were found to have undetectable levels. Such patients accounted for upto 6% of the total LT recipients. No increase in HBV recurrence was seen in this subgroup of patients on follow-up.

Conclusion: Post LT anti virals can be discontinued in upto 6% of recipients in our series without any increase in recurrence in this subgroup of patients.

Email: mi.farag@mail.utoronto.ca

Background and aims: Tenofovir alafenamide fumarate (TAF), a new prodrug of tenofovir, has recently been approved for chronic hepatitis B (CHB) treatment. In phase 3 studies with highly selected patients, TAF resulted in fewer renal adverse changes compared to tenofovir disoproxil fumarate (TDF). We aimed to study the effectiveness and renal safety of TAF therapy in a real world setting among CHB patients in Canada.
Method: CHB patients from 9 academic institutions across Canada who received TAF (either Nucleot (s)ide Analogue (NA) naïve or experienced) were studied as part of the Canadian Hepatitis B Network (CanHepB). Kidney function was measured by serum creatinine, estimated glomerular filtration rate (eGFR) as per Cockcroft-Gault and serum phosphate. Patients who received TDF with eGFR between 60 and 90 ml/min/1.73m^2 before switching to TAF were followed 72 weeks before and after switching.

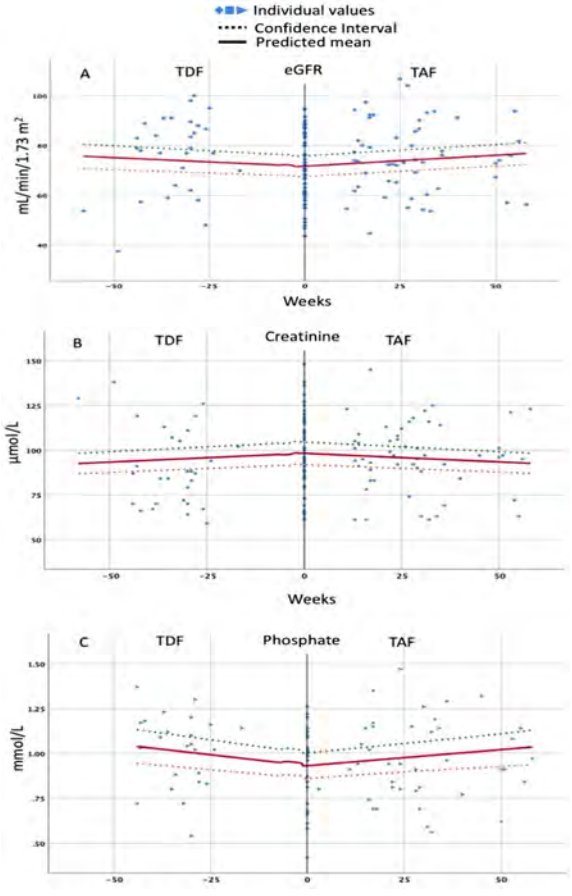

Figure: A. Changes in eGFR; B. Changes in Creatinine; C. Changes in Phosphate

Results: Of 170 patients receiving TAF, 107 (63%) switched from TDF, 43 (25%) switched from another NA and 20 (12%) were NA naïve. Overall, at start of TAF treatment (baseline), the mean (SD) age was 52 (12) years, 122 (74%) patients were male and 66/16/10% of patients were Asian/Caucasian/Black. Majority had HBV DNA < 20 IU/ml (82%), 51 (38%) were HBeAg positive and mean eGFR (SD) 82.7 (21.4).

Among the TDF switch group, eGFR declined within the mild renal impaired group (−0.01 [95 CI% −0.1-0.0] per week; P = 0.05) and creatinine increased during TDF therapy (+0.10 [0.04-0.16] µmol/L per week; P < 0.001). After TAF switching, creatinine decreased significantly (−0.10 [95 CI% 0.04–0.16] µmol/L per week; P = 0.04) and eGFR increased significantly (+0.09 [0.02- 0.15] per week; P = 0.01). Serum phosphate decreased during TDF therapy (−0.002 [−0.005–0.0001] mmol/L per week; P = 0.03) and increased following TAF switch (+0.001 [0.00-0.003] mmol/L per week; P = 0.03). Patients with eGFR > 90, showed no significant change after switching to TAF (+4.26 [10.70–2.43; P 0.73). ALT showed a declining trend after switching (−0.002 [−0.003–0.0002] $\log_{10}$ IU/ml per week; P = 0.08) and HBV DNA remained suppressed. Among the other NA switch group, ALT showed a declining trend from baseline to 24 weeks (−0.6 [−1.4–0.2] × upper limit normal (ULN), p = 0.1).
Among NA naïve group, serum HBV DNA and ALT levels declined significantly from baseline to 24 weeks (mean [95% CI]: −3.8 [−4.8–2.8] $\log_{10}$ IU/ml, P < 0.001; −1.8 [-2.6–1.0] (ULN), p < 0.001).
Conclusion: In CHB patients previously on TDF with mild renal impairment, switching to TAF led to a significantly improved kidney function. Viral load remained suppressed and ALT levels minimally declined. NA Naïve patients showed a significant decline in DNA and downward trend in ALT levels. Extended follow-up in a larger population will be presented at the meeting.

A phase 1 single ascending dose study of the safety, tolerability and pharmacokinetics of CRV431

Danielle Armas[2], Michael Snyder[3], Daniel Trepanier[1], Daren Ure[1], Jill Greytok[3], Robert Foster[1]. [1]*ContraVir Pharmaceuticals, Inc., Research and Development, Edmonton, Canada;* [2]*Celerion, Clinical Research, Tempe, United States;* [3]*ContraVir Pharmaceuticals, Inc., Research and Development, Edison, United States*
Email: jgreytok@contravir.com

Background and aims: CRV431 is a non-immunosuppressive cyclosporine A (CsA) analog that displays a variety of therapeutic activities in experimental models as a result of its potent inhibition of cyclophilin isomerases. In a mouse model of non-alcoholic steatohepatitis CRV431 reduced liver fibrosis and tumor burden. In cellular and *in vivo* models of HBV infection CRV431 reduced HBV DNA, HBsAg, HBeAg, pregenomic RNA and cccDNA. Single dose rat and monkey studies demonstrated dose-dependent CRV431 exposures and half-lives ($t_{1/2}$) greater than 24 hours. These experiments along with other preclinical safety, ADME, and early toxicology results led to the development of a clinical program. The present, single human dose study was designed to investigate safety, tolerability, and pharmacokinetics of CRV431.
Method: In this phase 1 study, single ascending oral doses of 75, 225, 325, and 525 mg CRV431 were administered sequentially to cohorts of 8 healthy subjects randomized 6:2, active: placebo. CRV431 was administered orally in a self-microemulsifying drug delivery system (SMEDDS) formulation in an aqueous medium. Placebo consisted of the SMEDDS formulation, without CRV431. Serial evaluations of adverse events (AEs), physical examinations (PE), concomitant medications, vital signs, clinical safety laboratory tests, and ECGs were collected. Whole blood levels of CRV431 were quantitated using a validated LC-MS/MS methodology.
Results: Data from the 75 mg, 225 mg 325 mg and 525 mg healthy volunteer cohorts showed that CRV431 was rapidly absorbed with T_{max} values ranging from 1-4 hours. Whole blood exposure, $AUC_{inf\text{-}obs}$ and C_{max}, of CRV431 was dose-related up to the 325 mg and ranged from 20, 917-103, 833 hr.ng/ml and 334-1655 ng/ml, respectively, across the four cohorts. Terminal elimination t½ was approximately 100 hours.
Safety results demonstrated that CRV431 was well tolerated with no serious adverse events (SAE), no dose-limiting toxicities or dose-dependent adverse events. Overall, the incidence of adverse events

and laboratory abnormalities was low and similar among cohorts. All AEs were mild and not drug related.
Conclusion: CRV431 appeared to be safe and well tolerated. The favorable safety profile, pharmacokinetic profile and *in vitro* anti-viral results warrant further clinical development of CRV431 in HBV-infected patients.

FRI-172
Outcomes of response guided therapy with pegylated interferon alpha 2a in chronic hepatitis B and D
George Sebastian Gherlan[1,2], Stefan Lazar[1,2], Augustina Culinescu[2], Smadu Daniela[2], Andreea Ruxandra Cazan[1,2], Corneliu Petre Popescu[1,2], Adelina Paunescu[1], Laurentiu Filip[2], simin florescu[1,2], Petre Calistru[1,2], Emanoil Ceausu[1,2]. [1]*Universitatea de Medicina si Farmacie "Carol Davila," Infectious Diseases, Bucharest, Romania;* [2]*Spitalul Clinic de Boli Infectioase si Tropicale "Dr. Victor Babes," Infectious Diseases, Bucharest, Romania*
Email: gherlanus@gmail.com

Background and aims: Pegylated Interferon alpha is currently the only available drug for the treatment of chronic hepatitis D. The reported on-treatment virologic response varies between 17 and 47% with relapses in more than 50% of these patients. No stopping rules have been defined and the duration of the treatment is not clearly established, but should be within 48 and 96 weeks.
Method: 76 patients with compensated liver disease treated with peginterferon according Romanian National protocol for the treatment of hepatitis D were retrospectively analysed. According to our protocol, the duration of treatment is up to 96 weeks, with the following stopping rules: less than 2 log HDV RNA decrease by week 24 and less than 1 log decrease every 6 months afterwards. 6 months after stopping the treatment, it can be restarted for unlimited cycles. We monitored our patients for a total period of 4 years (including those that repeated the cycle).
Results: 45 men and 31 women, with a mean age of 44 years and a mean body mass index of 26.2 were included. 13 patients had HBV DNA values greater than 20000 IU/ml, in the others HBV was supressed. 4 patients were HBe Ag positive. 16 patients had cirrhosis, 18 F3, 7 F2 and 35 F0 or F1 according to non-invasive assessments prior treatment.
During the first course of therapy, 45 patients had at least one moderate adverse reaction to treatment, most frequently neutropenia. In one patient, the treatment was stopped due a serious adverse event (osteomyelitis). Treatment doses had to be reduced in 19 patients.
After the first 6 months of treatment, 27 patients (35.5%) had a greater than 2 log HDV RNA decrease, 19 of them achieving undetectable HDV RNA. 17 patients (22.3%) had undetectable HDV RNA 24 weeks after stopping 96 weeks of treatment and none relapsed in the following 2 years. Of these 17 patients, 6 were cirrhotic, 4 had F3. Lower fibrosis stage was not a predictor for a favourable virologic response. Undetectable HDV RNA at 24 weeks was the only parameter that predicted a long-term suppression of HDV RNA. In 49 patients, the treatment was stopped after 6 months according to our national guidelines, but it was restarted 6 months after. 5 of these patients finished a 48 weeks course of treatment, none achieved undetectable HDV RNA.
Conclusion: Using stopping rules like the one we used might select the patients in which long term suppression can be achieved. Undetectable HDV RNA at week 24 is an independent predictor for long term HDV suppression.

Background and aims: Current antiviral treatment do not eradicate virus and need to be taken lifelong to present virus resurgence. The main obstacle to cure is the fact that the virus is able to escape from the immune response, via the production of a large amount of subviral particles (SVPs) coated with HBs-antigen (HBsAg) that act as a decoy for the immune response. In order to stimulate the immune response, a promising strategy is to use a toll-like receptor 7 (TLR7) agonist, that induces the production of IFN-α and cytokines and stimulates antigen presentation. Here we aimed to use a viral dynamic model to characterize for the first time the antiviral response during treatment with a TLR7 agonist used alone or in combination with ETV
Method: We used data collected by Hoffmann-La Roche in a mouse model. A total of 118 animals were analyzed, treated with either a placebo (n = 24), ETV (n = 6), TLR7 agonist (n = 76), or the combination of both (n = 12) at various dosing regimen and for period of 6 to 9 weeks of treatment. We developed a viral dynamic model that describes the interplay between virions, SVPs and antibodies. We hypothesized that TLR7 agonist may induce the production of anti-HBs. However, a low amount of anti-HBs may be rapidly occupied by binding to virions and SVPs and forming immune complexes, and such immune complex-associated antibodies can be difficult to detect. The immune complexes may be eliminated and cause an extra decay of their kinetics.
Results: A model of chronic hepatitis B, integrating the role of anti-HBsAg in virus elimination, could successfully reproduce all the observed data in both monotherapy and combination groups. ETV efficiently blocked HBV DNA production (ε = 99.9999%) but had no effect on HBsAg or anti-HBs titers. In contrary, the TLR7 agonist had a triple mechanism of action, whereby production of both virions and SVPs were successfully blocked. Production of virions could be reduce 93.80% for and 99.70% at the dose of 100 mg/kg QW and QOD, respectively, whereas reduction of the production of SVPs could be reduced by 99.70% up to 99.97%. In addition, our model suggested that the treatment led to an increase in anti-HBs concentrations, thereby allowing for further reduction of viremia and HBsAg titers on the long run. Eventually, a model assuming a Loewe additivity of ETV and the TLR7 agonist in reducing virion production could well reproduce the data observed during combination therapy.
Conclusion: The model provides a novel framework to analyze the effect of immunomodulatory drugs that is consistent with destabilization of viral production and stimulation of antibody production, which may contribute as combination partner in the perspective of a cure. Future analyses including other drugs in combination with TLR7 agonist and clinical studies are needed to confirm the potential of this therapeutic class.

FRI-174
Discovery of novel therapeutic targets for decreasing HBsAg, focusing on host proteins binding to HBV RNAs
Ryota Haba[1], Kazuki Shimane[1], Takaki Kawano[2], Nozomi Nakajima[1], Toshiyuki Nakatani[2], Shingo Mizunaga[1], Shinji Hagiwara[2], Takefumi Hara[2], Yasuhito Tanaka[3]. Email: ryota.haba@fujifilm.com

Background and aims: Chronic hepatitis B virus (HBV) infection remains a major health concern, with an estimated 240 million chronically infected patients worldwide. The indications of chronic HBV infection are high levels of viral load (HBV DNA) and significantly larger numbers of noninfectious particles containing viral S antigen

(HBsAg). Currently approved drugs, nucleos (t)ide analogues, effectively reduce HBV DNA but only rarely result in a functional cure (defined as sustained HBsAg loss). Therefore, a critical need arises for novel therapies that reduce HBsAg levels and restore virus-specific immune responsiveness in patients. We have found that two subregions in 3' untranslated region of 2.1/2.4 kb HBV RNAs, here referred as "region X" and "region Y," regulate HBsAg production (unpublished data). Here, focusing on region X and Y, we aimed to screen host proteins to identify novel therapeutic targets reducing HBsAg.

Method: Host proteins binding to region X and Y were determined by following two methods. (1) The lysate of HepG2.2.15 hepatoblastoma cells was incubated with *in vitro*-transcribed RNA corresponding to above two regions, and binding proteins were pulled-down. The proteins pulled-down were identified by SDS-PAGE and LC-MS/MS. (2) Host proteins binding to region X and Y were presented by searching an RNA-binding protein database. siRNAs specific to the proteins determined by above two methods were transfected into HepG2.2.15 cells, and the effects on the HBsAg production were analyzed.

Results: Among those proteins either identified by pull-down assays or presented by database search, knockdown of 7 proteins showed potent anti-HBsAg effects, more than 90% reduction in HBsAg, without affecting cell viability. Interestingly, these were all nuclear-localizing proteins. Some of them were reported to regulate RNA splicing, stability or nuclear export of mRNA while the others were functionally unknown. Then, expression levels of 2.1/2.4 kb HBV RNAs were quantified, and silencing of these proteins showed less than 80% reduction in those RNAs, that was slightly milder reduction compared with that in HBsAg protein. These data suggested that the proteins identified here could regulate HBsAg production by affecting RNA processing or dynamics.

Conclusion: Host proteins binding to region X and Y in 2.1/2.4 kb HBV RNAs were shown to be attractive therapeutic targets to reduce HBsAg, suggesting novel insights for better understanding of HBV virology.

FRI-175

Frequency, severity and impact of Peg-IFNa-associated flares in HDV infection: Results from the HIDIT-II study

Email: hardtke.svenja@mh-hannover.de

Background and aims: Treatment with PEG-IFNa is currently the only treatment option of hepatitis D virus (HDV) infection. ALT flares may occur during and after interferon-based therapies of hepatitis B monoinfection and are considered as beneficial. However, hepatitis flares could represent a concern in hepatitis D which is frequently associated with more advanced disease stages. We analyzed the frequency, severity and impact of hepatitis flares in the HIDIT-2 study.

Method: HIDIT-2 has been a randomized multicenter study performed in 14 sites in Germany, Greece, Romania and Turkey. 120 patients were treated for 96 weeks with PEG-IFNa2 with tenofovir dipivoxil (TDF) or placebo (Wedemeyer et al., Lancet ID 2019). Hepatitis flares were defined as ALT increases above ten times the upper limit of normal or increases of more than 2.5 fold above baseline or nadir values.

Results: ALT flares occurred in 28 patients during treatment (< week 96) and in 17 patients post-treatment until follow-up week 24. While there was no differences between the two treatment arms in ALT flare patients during treatment (37.8% PEG-IFNa+Placebo vs. 31.1% PEG-IFNa+TDF), ALT flares tended to be more frequent after treatment in TDF-treated patients (17.9% PEG-IFNa+Placebo vs. 8.5% PEG-IFNa+TDF ($p = 0.1$). The majority of flares happened between treatment week 8 and 24 (20 patients; median flare week 12). Flare frequency was similar in patients with and without cirrhosis (31% and 32%, respectively), none of the cirrhotic patients experienced hepatic decompensation due to flares. ALT flares were associated with HDV RNA declines (> 1log10 cop/ml) within the next two visits in 53.5% (15/28) of patients and with HBsAg drops (0.5 > log10 IU/ml) in 8 patients (3 PEG-IFNa+Placebo and 5 PEG-IFNa+TDF). Post-treatment week 120 HDV RNA levels were similar in patients who had experienced flares and in patients w/o flares (2.25E+05 cop/ml vs. 2.29E+05 cop/ml). ALT flares during treatment were associated with undetectable HDV RNA at week 120 in 11 patients.

Conclusion: ALT flares occur frequently during and after PEG-IFNa therapy of hepatitis D. Flares are associated with virological responses in some patients. These findings are of relevance for combination therapies with antiviral agents and PEG-IFNa.

FRI-176

Orally administered TQ-A3334 to evaluate the safety, tolerability, pharmacokinetics and pharmacodynamics single and multiple ascending doses in healthy Chinese subjects

Yue Hu[1], Hong Zhang[1], Min Wu[1], Dandan Huo[2], Hong Chen[1], Xiaojiao Li[1], Zhongnan Xu[2], Yanhua Ding[1], Junqi Niu[3]. *[1]The First Hospital of Jilin University, Phase I Clinical Research Center, Changchun, China; [2]Chiatai Tianqing Pharmaceutical Co. Ltd, Changchun, China; [3]The First Hospital of Jilin University, Changchun, China*
Email: 18343117193@163.com

Background and aims: TQ-A3334 activated toll-like receptor (TLR)-7 to induce specific cytokines and chemokines to inhibit HBV, such as IFN-α and IFN-inducible protein-10 (IP-10). The primary objectives are to evaluate the tolerability, pharmacokinetics, and pharmacodynamic (PD) biomarkers of orally TQ-A3334 administered to healthy chinese subjects.

Method: This is a randomized, double-blind, placebo-controlled SAD study in 32 healthy adult subjects. A total of four cohorts (0.2 mg, 0.5 mg, 1.0 mg, 1.8 mg). The first cohort, 2 subjects in 0.2 mg dose were randomly assigned to TQ-A3334 treatment. Other cohorts (0.5 mg, 1.0 mg, 1.8 mg), 8 subjects was randomly assigned to TQ-A3334 treatment, and 2 subjects to placebo treatment, and the ratio of male and female was 1:1. For single-dose administration, a sentinel group of 2 subjects, will be evaluated at least 3 days prior to any subsequent dosing. Safety, PK and PD data will be collected at each cohort. Pharmacodynamic biomarker include cytokines (IFN-α, TNF-α, IL-6, IL-1RA, MCP-1 and IP-10) and ISG expression (ISG-15, MX-1, and OAS-1).

Results: Pharmacokinetics

The plasma concentration of the TQ-A3334 increased rapidly and reached its peak at 0.5 h after drug administration on day 1. The Cmax and AUC of TQ-A3334 increased near proportional (the ration : 1.53-

2.9) to the dose TQ-A3334 from 0.2 mg to 0.5 mg. The linear PK properties was characterized by moderate to high clearance (CL), high volume of distribution (Vd), and moderate to slow elimination (half-life [t1/2] = 56-169 hours). No sex differences were apparent.

Pharmacodynamics

TQ-A3334 could induced the expression of ISG (MX1, ISG15, OAS1), IFN-α, IP-10, IL-1RA and MCP-1 between 12 and 72 hours postdose above 0.2 mg cohort, and it was dose-related, whereas no relevant changes of cytokines could be detected in 0.2 mg cohort.

Safety

Clinical safety assessment available for all 32 subjects, TQ-A3334 was well tolerated. Main drug-related adverse events (AEs) were grade 1 or 2. No drop-outs, no serious adverse event (SAE). Most AEs were lymphopenia, neutropenia, fever, rigors, headache, dizziness, and nausea after 7-12 hours post dose. 2 female subjects only experienced transient lymphopenia and neutropenia in grade 3, proximal to dosing suggestive of on-target effects of TQ-A3334.

Conclusion: TQ-A3334 was well tolerated from 0.2 mg to 1.8 mg, and induced changes of cytokines and chemokines that will be benefit for patients chronic infected with HBV. Meanwhile, TQ-A3334 response in females was more obvious than males based on above data. And more information needs to be explored in clinical studies in future.

FRI-177

Association of prophylactic anti-HBV therapy with improved long-term survival in patients with hepatocellular carcionoma undergoing transarterial therapy

Jeong Won Jang[1], Sun Hong Yoo[1], Hee Chul Nam[1], Pil Soo Sung[1], Sung Won Lee[1], Jung Hyun Kwon[1], Si Hyun Bae[1], Seung Kew Yoon[1], Jong Young Choi[1]. [1]*The Catholic University of Korea, Internal Medicine, Seoul, Korea, Rep. of South*
Email: garden@catholic.ac.kr

Background and aims: The effect of prophylactic antiviral therapy (AVT) on survival of patients with hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) remains unknown. The aim of this study was to determine whether prophylactic AVT could improve long-term survival in patients undergoing transarterial therapy (TAC).
Method: Between 2000 and 2016, 2, 890 newly diagnosed HBV-related HCC patients treated with TAC as the initial therapy were screened to analyze two groups based on prophylactic use of antivirals. Treatment effects were analyzed using propensity score (PS) matching (1:1) separately for the entire cohort and each subgroup. The primary end point was overall survival.
Results: A total of 1, 547 patients met the inclusion criteria and 1, 084 were PS-matched for the two groups. Mean follow-up duration was 16.55 months (IQR range: 4.97-46.67). In the entire unmatched cohort, patients receiving prophylactic AVT survived significantly longer than those not, with 10-year overall survival rates of 26.8% vs. 9.6%, respectively. Among AVT-untreated patients, baseline high-viremia and HBV reactivation during treatment were significantly associated with shorter survival. Regarding types of antivirals, survival was significantly longer for patients receiving high-potency antivirals than those receiving low-potency antivirals. In the PS-matched cohort, the prophylactic AVT group survived significantly longer than the non- prophylactic group, irrespective of viral status or tumor stage. Prophylactic AVT remained an independent factor for survival. The association of prophylactic AVT with decreased risk of mortality persisted in patient subgroups after adjusting for baseline risk factors. Sensitivity analyses also confirmed estimated treatment effects.
Conclusion: Prophylactic AVT is associated with significantly improved long-term survival among patients undergoing TAC. High-potency antivirals are indicated for this approach.

FRI-178

The clinical significance and predictors for precipitous HBsAg decline in off entecavir therapy HBeAg negative patients

Rachel Wen-Juei Jeng[1,2], Ming-Ling Chang[1,2,3], Yun-Fan Liaw[1,3]. [1]*Chang Gung University, College of Medicine, Taoyuan, Taiwan;* [2]*Chang Gung Memorial Hospital, Linkou branch, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan;* [3]*Chang Gung Memorial Hospital, Linkou branch, Liver research unit, Taoyuan, Taiwan*
Email: liveryfl@gmail.com

Background and aims: Increased HBsAg loss in off Nuc therapy HBeAg negative patients has been observed in several studies. A study further showed off therapy gradual decrease of HBsAg level with a "precipitous HBsAg decline" (> 0.5 $\log_{10}$IU/ml in 1 year) prior to HBsAg loss was noted. However, whether such HBsAg kinetics also present in off Nuc un-treated patients who remained HBsAg seropositive and the predictors for precipitous HBsAg decline were unknown. This comparative study aimed to address these issue.
Method: From CGMH off Nuc cohorts, patients stopping entecavir monotherapy with subsequent HBsAg loss ("study group") and an 1:1 "control group" with persistent HBsAg seropositivity matched in age, gender, end-of-treatment (EOT) qHBsAg and follow-up duration were recruited. Serial serum samples were assayed retrospectively for quantitative HBsAg (qHBsAg) and compared. Cox regression analysis was applied for predictor (s) of "precipitous HBsAg decline." All statistical analysis were performed by SAS 9.4.
Results: Study group and control group each included 36 patients with sustained response (SR) and 12 patients with un-retreated clinical relapse (CR). All study patients showed similar trend of gradual qHBsAg decrease with a "precipitous HBsAg decline" (> 0.5 log10IU/ml in 1 year) prior to HBsAg loss. Control group" patients also showed gradual qHBsAg decrease but "precipitous HBsAg decline" occurred less frequently (39.6% vs 100%; P < 0.001), with later onset (from EOT: 15.1 vs 5.7 months; P = 0.003) and less steep slop (−0.6 vs −1.65 log10IU/year; P < 0.001). The sensitivity, specificity, positive (PPV) and negative predictive value (NPV) of "precipitous HBsAg decline" for HBsAg loss was 100%, 60.42%, 71.21% and 100%. Lower EOT HBsAg level [aHR: 0.999 (0.998-1.000), P = 0.015] and genotype C [aHR: 1.947 (1.098–3.453); P = 0.023] were two independent factors associated with the occurrence of "precipitous HBsAg decline." Among patients with "Precipitous HBsAg decline," a decline > 0.76 $\log_{10}$ IU/ml/year predicted HBsAg loss with AUROC: 0.882 (0.801–0.964; P < 0.0001) and a PPV of 92.9%, NPV of 66.7%.
Conclusion: Steep "precipitous HBsAg decline" is a pre-requested event for HBsAg loss.

FRI-179

Antiviral therapy might not be required for chronic hepatitis B patients in the immune-tolerant phase with a significantly low incidence rate of liver-related events

Mi Young Jeon[1], Tae Seop Lim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1], Kwang-Hyub Han[1], Beom Kyung Kim[1], Seung Up Kim[1]. [1]*Yonsei College of Medicine, Seoul, Korea, Rep. of South*
Email: beomkkim@yuhs.ac

Background and aims: Antiviral therapy (AVT) for chronic hepatitis B (CHB) patients in the immune-tolerant (IT) phase has been controversial. We assessed whether AVT for CHB patients in the IT-phase contributed to a better prognosis by comparing the risks of hepatocellular carcinoma (HCC) and liver transplantation (LT) among patients in the persistent IT-phase, those in the IT-phase, but who later received AVT due to a change in status, and those in the immune-active (IA) phase treated with AVT.
Method: A total of 3, 467 patients with CHB between 2007 and 2016 were enrolled. The IT-phase was defined as hepatitis B e antigen positivity, HBV-DNA level > 20, 000 IU/ml, and normal ALT. The incidence rates was estimated using the Kaplan-Meier method, and compared between groups using the log-rank test.
Results: The median age of the study population (2, 510 men and 957 women) was 49.8 years. Of the 129 patients in the IT phase at enrolment, 57 (44.2%) were in the persistent IT phase, whereas 72 (55.8%) subsequently received AVT due to a change in viral status. A total of 3, 338 patients in the IA phase were treated with AVT. During the follow-up period (median 56.3 months), there were 57 (44.2%) patients in the persistent IT phase, 72 (55.8%) in the IT phase who later were treated with AVT, and 282 (8.1%) who developed HCC. The 72 patients in the IT phase at enrolment who started AVT due to a change in viral status were later grouped with the 57 patients in the persistent IT phase group. The incidence rates of HCC and LT and the mortality rate were significantly higher in patients in the IA phase treated with AVT than in those in the IT phase (both P < 0.001, log-rank test). When the study population was stratified into three groups, (1) persistent IT phase, (2) IT phase at enrolment and later receiving AVT due to a change in viral status and (3) IA phase treated with AVT, the rates of HCC and LT incidence and mortality were highest in patients in group (3), followed by group (2), and lowest in group (3) (log-rank P = 0.027 for HCC; P = 0.044 for LT and mortality).
Conclusion: In our study, patients in the IT phase had an extremely low rates of HCC, LT and mortality compared with those in the IA phase treated with AVT (0.8% vs. 8.4% for HCC; 0.8% vs. 11.3% for LT and mortality; all P < 0.05). Thus, patients who require AVT should receive surveillance for HCC development, whereas patients in the IT phase receiving AVT may not be considered.

JNJ-64530440, a novel capsid assembly modulator: single- and multiple-ascending dose safety, tolerability and pharmacokinetics in healthy volunteers

Thomas Kakuda[1], Jeysen Yogaratnam[1], Christopher Westland[1], Edward Gane[2], Christian Schwabe[3], Megha Patel[1], Willem Talloen[4], Oliver Lenz[4], Pieter van Remoortere[5]. *[1]Janssen BioPharma Inc., South San Francisco, United States; [2]University of Auckland, New Zealand Liver Transplant Unit, Auckland, New Zealand; [3]Auckland Clinical Studies, Auckland, New Zealand; [4]Janssen Pharmaceutica NV, Beerse, Belgium; [5]Janssen Pharmaceuticals, Titusville, United States*
Email: tkakuda@its.jnj.com

Background and aims: JNJ-64530440 (JNJ-0440) is a potent hepatitis B virus capsid assembly modulator with a dual mechanism of action. The safety, tolerability and PK of single and multiple doses of 1° and 2°-generation tablet formulations of JNJ-0440 were evaluated in healthy adults in a double-blind Phase 1 study (NCT03439488).
Method: Adults (n = 10 per cohort) were randomized 8:2 to receive a single dose of JNJ-0440 or placebo under fasted (50, 150, 300 and 900 mg) or fed (300, 750, 1000, 2000 and 4000 mg) states. Multiple once-daily doses of 750 and 2000mg JNJ-0440 with food were evaluated over 7 days. JNJ-0440 plasma concentrations were determined using liquid chromatography-tandem mass spectrometry and PK parameters estimated using non-compartmental analysis (WinNonlin, Certara, Princeton NJ). Safety and tolerability were assessed throughout.
Results: 100 adults have completed dosing. There were no withdrawals due to adverse events (AEs), serious AEs, or dose limiting toxicities. AEs and lab abnormalities were mostly Grade 1 or 2. Related AEs (n ≥ 2) included headache (n = 8), fatigue (n = 2) and contusion (n = 2). No clinically relevant changes in electrocardiograms were observed.
PK results are presented in the table.
Conclusion: Single-doses of JNJ-0440 up to 4000 mg, and multiple once-daily doses up to 2000mg for 7 days, were safe and well tolerated in healthy adults. PK was less than dose proportional and achieved concentrations expected to have antiviral activity. Evaluation in HBV-infected patients is ongoing.

FRI-181

Efficacy and safety of switching therapy from tenofovir disoproxil fumarate to tenofovir alafenamide for hepatitis B virus infection

Shun Kaneko[1], Masayuki Kurosaki[1], Nobuharu Tamaki[1], Jun Itakura[1], Sakura Kirino[1], Keiya Watakabe[1], Leona Osawa[1], Mao Okada[1], Wang Wan[1], Takao Shimizu[1], Mayu Higuchi[1], Kenta Takaura[1], Yutaka Yasui[1], Kaoru Tsuchiya[1], Hiroyuki Nakanishi[1], Yuka Takahashi[1], Namiki Izumi[1]. *[1]Musashino Red Cross Hospital, Tokyo, Japan*
Email: skangast@tmd.ac.jp

Background and aims: Hepatitis B virus (HBV) infection is a major public health threat that increases the risk of developing liver failure and hepatocellular carcinoma. Nucleos (t)ide analogs suppress HBV replication and reduce the risk of HCC and HBV-associated mortality. Tenofovir alafenamide (TAF) is a new prodrug of tenofovir that has been developed to treat patients with chronic hepatitis B at a lower dose than tenofovir disoproxil fumarate (TDF) via a more efficient delivery of tenofovir to the hepatocytes. We compared the efficacy and safety of TDF and TAF, investigated the switching therapy from TDF to TAF.
Method: Consent for TDF and TAF therapy was obtained from 117 and 67 patients, respectively, from August 2014 to January 2018. Total 45 and 14 patients were administrated TDF and TAF, respectively, as naïve therapy for > 48 weeks. 36 patients were switched from TDF to TAF. Antiviral effect and renal function safety were assessed.
Results: At week 48, the differences in the antiviral effect of patients receiving TDF and TAF as naïve therapy were similar in terms of reduction in the HBV deoxyribonucleic acid (DNA) (–5.6 ± 1.8 log IU/L vs. – 5.0 ± 1.7 log IU/L; p = 0.34) and Hepatitis B surface antigen (HBsAg) (– 0.29 ± 0.64 log IU/ml vs. – 0.15 ± 0.42 log IU/ml; p = 0.71). The proportion of patients who received TDF and TAF and had higher than normal levels of alanine aminotransferase (ALT) by AASLD criteria at baseline that normalized at week 48 were 45.2% and 57.1%, respectively. Decrease in the estimated glomerular filtration rate (eGFR) using the Cockcroft-Gault method was significantly observed in 48w TDF treatment (– 5.34 ± 7.69 ml/min/1.73 m2 ; p < 0.001).
The switching therapy from TDF to TAF did not increase the HBV DNA and HBsAg at 24 weeks. Although the eGFR worsened after TDF (– 4.36 ± 6.22 ml/min/1.73 m2) irrespective of TDF administration period, it improved significantly at week 4 (+1.12 ± 5.41: p = 0.002) and week 24 (+1.06 ± 7.20; p = 0.006) after switching from TDF to TAF.
Conclusion: TDF and TAF showed adequate antiviral effect as naïve therapies. Furthermore, switching the therapy from TDF to TAF contributed to the maintenance of antiviral effect and the renal dysfunction recovery in real world.

FRI-182

Anti-viral treatment in patients with immune tolerant-phase chronic hepatitis B may be cost-effective

Hye-Lin Kim[1], Gi-Ae Kim[2], Jae-A Park[3], Hye-Rim Kang[3], Eui-Kyung Lee[3], Young-Suk Lim[4]. *[1]Sahmyook University, College of Pharmacy, Seoul, Korea, Rep. of South; [2]Asan Medical Center, University of Ulsan College of Medicine, Health Screening and Promotion Center, Seoul, Korea, Rep. of South; [3]Sungkyunkwan University, School of Pharmacy, Suwon, Korea, Rep. of South; [4]Asan Medical Center, University of Ulsan College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: limys@amc.seoul.kr

Background and aims: Currently, antiviral therapy for chronic hepatitis B (CHB) patients in immune tolerant (IT, chronic HBV infection) phase is generally not recommended. There has been a need for studies assessing benefits of antiviral therapy in IT-phase. A recent study showed that untreated IT-phase patients had higher risk

of hepatocellular carcinoma (HCC) than treated immune active (IA, chronic hepatitis B) phase patients. We aimed to evaluate the cost-effectiveness of starting antiviral treatment from IT-phase (IT-Tx) compared to delaying the treatment to immune active phase (IA-Tx).
Method: We designed a Markov model to compare expected costs and quality-adjusted life-years (QALYs) between IT-Tx group and IA-Tx group from healthcare system and societal perspectives. Transition probabilities and costs were obtained from a cohort of 4, 965 HBeAg-positive, treatment-naive CHB patients at Asan Medical Center. Literature review was conducted for other parameters. The starting age of the simulated cohort was 30 years old, and the cycle length was 1 year. Cost and effectiveness were discounted at a 5% annual rate, and incremental cost-effectiveness ratio (ICER) was calculated for 10-year horizon and evaluated with various HCC risks.
Results: The cost-effectiveness analysis showed that IT-Tx group had $6, 532 incremental costs and additional 0.288 QALY per patient compared to IA-Tx group with 10-year cumulative HCC risk of 10%. Through the base-case analysis ICER was $22, 642/QALY. The result indicated that IT-Tx was borderline high cost-effective based on the implicit ICER threshold of $20, 000/QALY in Korea. As HCC risk increased, IT-Tx became acceptable in cost-effectiveness. When the HCC risk increased over 11.3%, ICER went below the threshold. The analysis including the cost of lost productivity showed that IT-Tx was dominant, which had superior effectiveness and less costing, with HCC risk greater than 6.8% (ICER < 0).

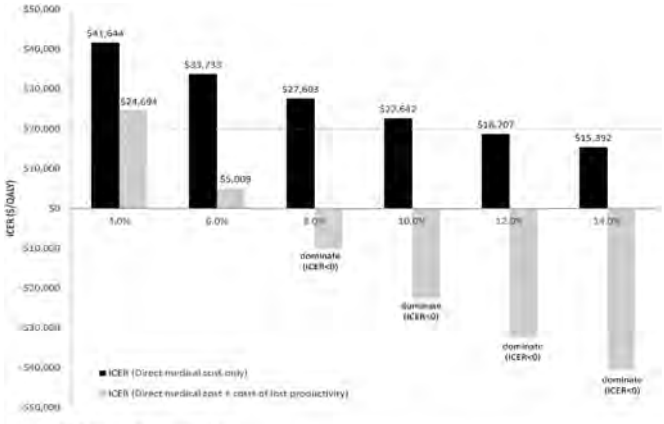

Figure 1. ICER change with various HCC risk.
When an intervention showed superior efficacy and less costing and consequently the ICER had a negative value, it is referred to as a 'dominant' strategy. In case of dominant strategy, usually ICER was not estimated. But in the current work, to compare the difference according to an addition of the costs of lost productivity ICERs were calculated even though below zero

Conclusion: To start antiviral therapy for CHB patients in IT-phase was borderline high cost-effective from healthcare system perspective dealing with the only medical costs, however, it was a dominant strategy in view of societal perspective covering also the costs for lost productivity.

Email: pietro.lampertico@unimi.it

Background and aims: TAF, a novel prodrug of tenofovir (TFV), was recently approved for treatment of CHB. TAF has greater plasma stability, more targeted delivery of TFV to the liver, and reduced circulating levels of TFV compared to TDF at approved doses. TAF has shown efficacy non-inferior to TDF with improved renal and bone safety in viremic CHB patients at Weeks 48 and 96. We evaluated efficacy and safety in stable, virally-suppressed patients who were switched from TDF to TAF vs. continued TDF for an additional year.
Method: In this Phase 3 study (NCT02979613), CHB patients on TDF for ≥ 48 weeks with HBV DNA < LLOQ (local laboratory) for ≥ 12 weeks and < 20 IU/ml at screening were randomized (1:1) to TAF 25 mg QD or TDF 300 mg QD, each with matching placebo, and treated for 48 weeks. After this, all patients received open-label TAF for an additional 48 weeks. The primary efficacy analysis was the proportion of patients with HBV DNA ≥ 20 IU/ml at Week 48 based on the modified US FDA-defined Snapshot algorithm; the study was powered to show non-inferiority in efficacy of TAF compared to TDF, with a 4% margin. Key prespecified secondary safety end points were assessed sequentially: changes in hip and spine bone mineral density (BMD), and changes in estimated creatinine clearance by Cockcroft-Gault ($eGFR_{CG}$). Markers of bone turnover and renal tubular function were serially assessed. Viral resistance was evaluated by population sequencing those patients who experienced virologic breakthrough or viremia at the time of discontinuation.

Table. Efficacy and Safety at Week 48

n/N (%)	TAF (N=243)	TDF (N=245)	P value
Efficacy parameters			
HBV DNA ≥20 IU/mL[a]	1/243 (0.4)	1/245 (0.4)	0.95[b]
HBV DNA <20 IU/mL	234/243 (96.3)	236/245 (96.3)	0.98
No virologic data in Week 48 window	8/243 (3.3)	8/245 (3.3)	–
ALT normal (central laboratory)[c,d]	217/243 (89.3)	208/245 (84.9)	0.14
ALT normal (2018 AASLD criteria)[e]	192/243 (79)	184/245 (75.1)	0.31
HBeAg seroconversion[f]	2/78 (2.6)	0	0.13
HBsAg seroconversion	0	0	–
Safety parameters			
Hip BMD, mean (SD) % change (g/cm^2)	+0.66 (2.08)	-0.51 (1.91)	<0.001
Spine BMD, mean (SD) % change (g/cm^2)	+1.74 (3.46)	-0.11 (3.13)	<0.001
CTX, median (Q1, Q3) % change (ng/mL)[g]	-29.4 (-44.2, -14.3)	+7.1 (-14.8, 32)	<0.001
P1NP, median (Q1, Q3) % change (ng/mL)[h]	-19.4 (-32.2, -7.5)	+1.70 (-12.5, 17)	<0.001
$eGFR_{CG}$, median (Q1, Q3) change (mL/min)	+0.99 (-4.47, 6.31)	-2.74 (-7.87, 1.98)	<0.001
RBP/Cr, median (Q1, Q3) % change[i]	-17.7 (-41.3, 17.2)	+18.6 (-15.3, 67.3)	<0.001
β2MG/Cr, median (Q1, Q3) % change[i]	-36.0 (-61.9, -1.1)	+10.7 (-33.9, 90.6)	<0.001

[a]HBV DNA results are by modified US FDA-Snapshot algorithm; other efficacy results are missing=failure. [b]By stratified Cochran-Mantel-Haenszel tests. [c]ALT normal is the proportion with ALT ≤ULN at Week 48 regardless of baseline status (i.e. includes those ≤ and >ULN at baseline). [d]Central lab ULN 43 U/L males, 34 U/L females; [e]2018 AASLD ULN 35 U/L males, 25 U/L females. [f]Only includes patients HBeAg-positive at baseline. [g]C-type collagen sequence (bone resorption marker); [h]Procollagen type 1 N-terminal propeptide (bone formation marker); [i]Retinol binding protein/creatinine (tubular marker); [i]Beta-2 microglobulin/creatinine (tubular marker).

Results: 488 patients were randomized and treated at 42 sites in 8 countries. At baseline the groups were similar: median age 52 y

(22% ≥ 60 y), 71% male, 82% Asian, 68% HBeAg-negative, and median ALT 23 U/L. Median $eGFR_{CG}$ was 90.5 ml/min; 45% and 50% had low BMD by T scores at hip and spine, respectively. Median (Q1, Q3) duration of prior TDF was 222 (145, 305) weeks. Key efficacy/safety results are summarized in the Table. TAF demonstrated non-inferior efficacy to TDF with a similar rate (0.4%) having HBV DNA ≥ 20 IU/ml at Week 48, (difference in proportions: 0.0%, 95% CI, −1.9% to +2.0%). TAF treatment resulted in increases in hip/spine BMD with less impact on bone turnover makers; switching from TDF to TAF also resulted in increased $eGFR_{CG}$ and decreases in markers of tubular function. Rates of ≥ Grade 2 adverse events (AEs) and serious AEs were low and similar between groups. No viral resistance was observed in the 3/243 (1.2%) and 2/245 (0.8%) TAF and TDF patients, respectively, who qualified for testing.

Conclusion: Virologically-suppressed CHB patients who were switched to TAF demonstrated noninferior efficacy to continued TDF with improved bone and renal safety.

FRI-184

Function and drug combination studies in cell culture models for AB-729, a subcutaneously administered siRNA investigational agent for chronic hepatitis B infection

Amy C.H. Lee[1], Emily P. Thi[1], Andrea Cuconati[1], Andrzej Ardzinski[1], Richard Holland[1], Hui Huang[1], Andrew S. Kondratowicz[1], Rose Kowalski[1], Lorne Palmer[1], Chris Pasetka[1], Rene Rijnbrand[1], Holly M. Steuer[1], Xiaohe Wang[1], Xin Ye[1], Michael J. Sofia[1]. [1]*Arbutus Biopharma, Warminster, United States*
Email: alee@arbutusbio.com

Background and aims: Developing a cure for chronic hepatitis B must address viral persistence and likely requires combination of drugs with different modes of action. AB-729 is a siRNA agent that acts on all HBV RNA transcripts, enabling inhibition of HBV replication and suppression of all viral antigens including HBsAg; this may facilitate reinvigoration of host immune responses. A novel high avidity N-acetylgalactosamine (GalNAc) moiety mediates targeting of AB-729 to hepatocytes, the site of HBV infection. Here we describe HBV cell culture models capable of demonstrating both cellular entry and gene silencing functionalities of GalNAc-siRNA, and present in vitro characterization of AB-729 anti-HBV activities as monotherapy as well as in combination with approved and investigational drug modalities.

Method: AB-729 activity was studied in adeno-associated virus-transduced HBV-expressing primary mouse hepatocytes (PMH), HBV-infected primary human hepatocytes (PHH) and transiently- and stably-transfected HBV cell lines. Drug combination studies were conducted using three-dimensional modeling for drug-drug interactions and analyzed using MacSynergy II software.

Results: Asialoglycoprotein receptor (ASGPR) levels decreased rapidly during in vitro culture of primary hepatocytes, providing a narrow time window for GalNAc-mediated cellular entry of AB-729. Congruent with this, EC50 shifts of 24- and at least 478-fold were observed in PMH and PHH treated with GalNAc-siRNA at 4 h compared to 24 h or 4 days post-plating. AB-729 reduced HBV RNA, HBeAg and HBsAg expression, with 5.6-19.4 nM EC50 values in PMH. Commercial transfection agent had to be utilized to conduct a standard HBV genotype and resistance mutant susceptibility panel for the siRNA component of AB-729. Pairwise testing with tenofovir alafenamide, peg-interferon-alpha-2a and AB-506, a next-generation investigational capsid inhibitor, showed that AB-729 was able to combine productively with each of these drug modalities and without significant effects on cell viability.

Conclusion: Standard HBV cell lines can be used to characterize the activity of the AB-729 siRNA whereas two primary hepatocyte systems were able to model both the cell entry functionality and anti-HBV activities of AB-729. Preclinical investigations demonstrate that AB-729 and AB-506 when combined have distinct but mechanistically compatible antiviral activities and may feasibly be used in future combination therapeutic regimens.

FRI-185

Virological and immunological predictors of long-term ouctomes of peginterferon alfa-2a therapy for HBeAg-negative chronic hepatitis B

I-Cheng Lee[1], Chien-Wei Su[2], Keng-Hsin Lan[2], Han-Chieh Lin[2], Ming-Chih Hou[2], Yi-Hsiang Huang[2]. [1]*Taipei Veterans General Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan;* [2]*Taipei Veterans General Hospital, Taipei, Taiwan*
Email: iclee@vghtpe.gov.tw

Background and aims: Predictors of long-term outcomes of peginterferon (PegIFN) therapy for chronic hepatitis B (CHB) remain to be explored. The aim of this study was to evaluate the predictive value of virological and immunological biomarkers and long-term outcomes of PegIFN therapy for HBeAg-negative CHB.

Method: 57 HBeAg-negative CHB patients receiving 48 weeks PegIFN therapy were prospectively followed for a median period of 5.3 years after the end of treatment (EOT). Serum HBsAg, HBV DNA, CXCL9 and IP-10 levels were measured in all patients. Flow cytometry analysis for frequencies of regulatory T cells, $CD4^+CD69^+$, $CD8^+CD69^+$, $CD8^+PD\text{-}1^+$, $CD4^+CXCR3^+$ and $CD8^+CXCR3^+$ cells were performed in 23 patients with available peripheral blood mononuclear cells. The definition of viral relapse and clinical relapse after EOT followed APASL guidelines. Factors associated with long-term HBsAg loss, viral relapse and clinical relapse were analyzed.

Results: Baseline CXCL9 levels significantly correlated with frequencies of $CD4^+CXCR3^+$, $CD8^+CXCR3^+$ and $CD4^+CD69^+$ cells, while $CD8^+PD\text{-}1^+$ cells population significantly correlated with HBV DNA, ALT levels and frequencies of $CD8^+CD69^+$ and $CD8^+CXCR3^+$ cells. The cumulative incidences of HBsAg loss and clinical relapse at year 7 were 31.6%, and 0%, respectively, in patients with sustained off-treatment virological response (SVR), and 6.7% and 67.4%, respectively, in patients without SVR. In patients with SVR, the viral relapse rate was 18.1% at year 7. By multivariate analysis, CXCL9 > 200 pg/ml (HR = 8.154, p = 0.038) and HBsAg < 750 IU/ml (HR = 10.507, p = 0.036) were baseline predictors of HBsAg loss, while HBsAg decline at EOT > 1 log (HR = 23.296, p = 0.005) was the on-treatment predictor of HBsAg loss. Baseline CXCL9 > 80 pg/ml (HR = 0.092, p = 0.047), $CD8^+PD\text{-}1^+$ cells > 21% (HR = 25.618, p = 0.007), HBsAg decline > 10% at week 12 (HR = 0.026, p = 0.024) and HBsAg decline > 50% at EOT > 1 log (HR = 0.075, p = 0.033) were independent predictors of viral relapse. $CD4^+CD69^+$ cells > 2.5% (HR = 0.167, p = 0.020) and HBsAg decline > 10% at week 12 (HR = 0.180, p < 0.001) were independent predictors of clinical relapse.

Conclusion: Baseline serum CXCL9 levels could predict HBsAg loss and viral relapse after PegIFN therapy for HBeAg-negative CHB. Populations of T cell subsets, such as $CD8^+PD\text{-}1^+$ and $CD4^+CD69^+$ cells, might predict viral and clinical relapses. Combining virological and immunological biomarkers could predict long-term outcomes of PegIFN therapy for HBeAg-negative CHB.

FRI-186

Entecavir plus pegylated interferon alfa-2a and sequential HBV vaccination increases the chance of HBsAg-seroclearance: Results from a randomized controlled E+VIP trial

Jeonghoon Lee[1], Yun Bin Lee[1], Eun Ju Cho[1], Su Jong Yu[1], Jung-Hwan Yoon[1], Yoon Jun Kim[1]. [1]*Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South*
Email: yoonjun@snu.ac.kr

Background and aims: HBsAg-seroclearance is considered as a functional cure in chronic hepatitis B patients, but is rarely achievable with oral nucleos (t)ide analogs (NAs) alone. We conducted a randomized controlled trial to evaluate the efficacy and safety of additional pegylated interferon alfa-2a (Peg-IFN) plus sequential hepatitis B virus (HBV) vaccination.
Method: A total of 111 patients who achieved serum HBV DNA < 20 IU/ml and quantitated HBsAg (qHBsAg) < 3, 000 IU/ml with entecavir were randomly assigned (1:1:1) to the treatment group (entecavir +Peg-IFN [180 μg every week over 48 weeks] +sequential HBV vaccination [20 μg of HBsAg; at weeks 52, 56, 60, and 76]), the control group (entecavir only), or the explorative group (entecavir +Peg-IFN +concurrent HBV vaccination [at weeks 4, 8, 12, and 28]). The primary end point was HBsAg-seroclearance at week 100 and secondary end points included change in qHBsAg titer and safety.
Results: There was no difference in baseline qHBsAg and HBV DNA among groups. In intention-to-treat analysis, the treatment group showed significantly higher chance of HBsAg-seroclearance at week 100 than control group (16.2% vs 0%, $P = 0.025$), but the explorative group (5.4%) failed to reach significant difference ($p = 0.54$). The changes in median qHBsAg titer from baseline to week 100 was −67.7% in the treatment group and −36.3% in the control group (Figure 1). Adverse events were significantly more frequent in the treatment group than the control group (81.1% vs 2.7%, $P < 0.0001$). However, the frequency of serious adverse events did not differ significantly between groups (2.7% vs 2.7%, $P = 1.00$).

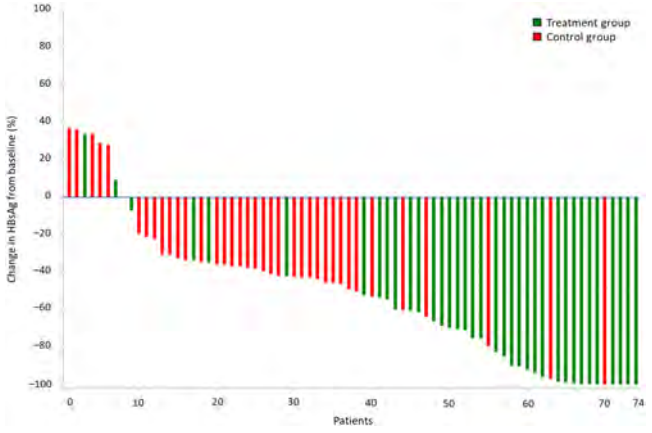

Figure 1: Maximal change of qHBsAg titer in each patient.

Conclusion: Entecavir plus an additional Peg-IFN treatment followed by sequential HBV vaccination with intensified schedule significantly increases the chance of HBsAg-seroclearance compared to entecavir alone. ClinicalTrials.gov number: NCT02097004.

FRI-187

Comparison of tenofovir and entecavir on the risk of hepatocellular carcinoma and liver-related events in patients with chronic hepatitis B: A propensity score analysis

Sung Won Lee[1,1,2], Jung Hyun Kwon[1,2], Hae Lim Lee[1,2], Sun Hong Yoo[1,2], Hee Chul Nam[1,2], Pil Soo Sung[1,2], Soon Woo Nam[1,2], Si Hyun Bae[1,2], Jong Young Choi[1,2], Seung Kew Yoon[1,2], Nam Ik Han[1,2], Jeong Won Jang[1,2]. [1]*College of Medicine, The Catholic University of Korea, Division of Hepatology, Department of Internal Medicine, Seoul, Korea, Rep. of South;* [2]*The Catholic University Liver Research Center, Seoul, Korea, Rep. of South*
Email: garden@catholic.ac.kr

Background and aims: The use of tenofovir (TDF) and entecavir (ETV) in chronic hepatitis B (CHB) patients has led to a decrease in the incidence of hepatocellular carcinoma (HCC) and liver-related events. However, whether there is a difference between the two agents in the extent of improving such clinical outcomes has not been clarified thus far. We aimed to compare the effects of TDF and ETV on HCC risk reduction and liver-related events.
Method: A total of 7, 015 CHB patients who were treated with TDF or ETV between February 2007 and January 2018 at the liver units of the Catholic University of Korea were screened for study eligibility. We have excluded the patients with HCV or HIV co-infection, antiviral therapy less than 6 months, HCC or liver transplantation (LT) prior to or within 6 months since the initiation of antiviral therapy, other malignancies at baseline, TDF and ETV combination therapy, and conversion from TDF to ETV or from ETV to TDF. The remaining 3, 282 treatment-naïve patients (1541 TDF, 1741 ETV) were finally analyzed using the inverse probability of treatment weighting (IPTW) method. Primary end points were HCC development and occurrence of liver-related events within 5 years since the initiation of antiviral therapy. Liver-related event was defined as the occurrence of either HCC, LT or liver-related death.
Results: The mean age was 47.4 years and 59% of the patients were male. 60.5% of the patients had chronic hepatitis, 31.6% compensated liver cirrhosis (LC) and 7.9% decompensated LC. Both in the unmatched and IPTW models, no difference was observed in HCC incidence rates (HR 0.962; 95% CI, 0.707-1.308, IPTW model). Also, although a marginally lower tendency in the occurrence of liver-related events was observed in the TDF group, no statistically significant difference was observed in both models (HR, 0.867; 95% CI, 0.651-1.154, IPTW model). In the multivariate analysis, male sex, old age, cirrhosis and platelet count less than 150, 000/mm^3 were identified to be the independent predictors of both HCC and liver-related events.
Conclusion: This large observational cohort study has demonstrated that intermediate-term clinical outcomes including HCC and liver-related events do not differ according to the use of either TDF or ETV. However, a further long term analysis should be carried out before we conclude whether TDF or ETV may result in different clinical outcomes in any aspect.

FRI-188

Sequence analysis of baseline and on-treatment samples from HBV-infected chronic hepatitis B patients treated for 28 days with JNJ-56136379 monotherapy

Thierry Verbinnen[1], Moana Hodari[1], Willem Talloen[1], Jan Martin Berke[1], David Blue[1], Jeysen Yogaratnam[2], Umesh Shukla[3], Sandra De Meyer[1], Oliver Lenz[1]. [1]*Janssen Research and Development, Beerse, Belgium;* [2]*Janssen Biopharma Inc., South San Francisco, United States;* [3]*Janssen Pharmaceuticals RandD, Titusville, United States*
Email: olenz@its.jnj.com

Background and aims: JNJ-56136379 (JNJ-6379) is a potent capsid assembly modulator (CAM) currently in Phase 2a clinical development. In a Phase 1b study (NCT02662712), treatment-naïve chronic hepatitis B HBeAg-positive and -negative patients received oral JNJ-6379 (25, 75, 150, and 250 mg once-daily) for 4-weeks. Potent

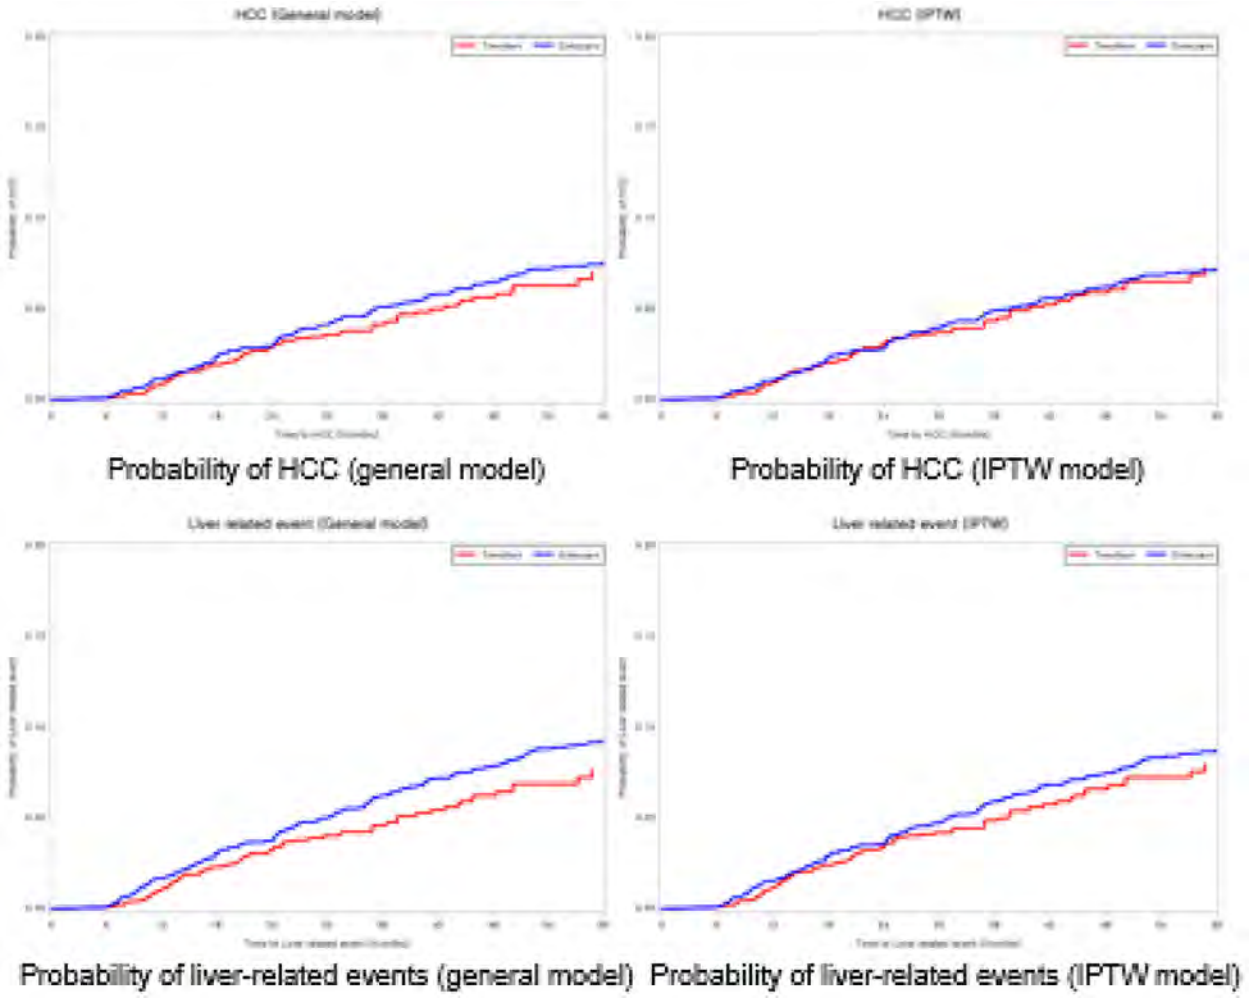

Figure: (abstract: FRI-187)

antiviral activity was observed. Here we present the resistance analysis of this study.

Method: HBV DNA was extracted from serum samples collected over the study period and the HBV full genome was sequenced using next generation sequencing (NGS). Baseline amino acid (aa) polymorphisms were defined as changes versus the universal HBV reference sequence (frequency > 15%). Emerging mutations were defined as aa changes from patient-specific baseline sequences (frequency < 1% at baseline and > 15% post-baseline). The analysis focused on 28 HBV core protein aa positions described as part of the CAM binding pocket. Impact of aa substitutions on JNJ-6379 *in vitro* activity was assessed in a transient replication assay using a genotype (GT) D backbone.

Results: Overall, 27 of 51 patients with baseline NGS data available had ≥ 1 polymorphisms at any of the 28 HBV core protein positions of interest. The highest prevalence of baseline polymorphisms was observed at Positions 38 (31.4%), 105 (21.6%), and 109 (15.7%). Polymorphisms at these positions tested as site-directed mutants did not reduce JNJ-6379 *in vitro* activity. One of 51 (2.0%) patients (GT-A, JNJ-6379 75 mg treated) carried a baseline polymorphism known to reduce JNJ-6379 *in vitro* activity (Y118F, 6.6-fold change in EC_{50} value). This patient had a pronounced decline in HBV DNA levels of 2.77 log_{10} IU/ml from baseline to levels below quantification by the end of 4 weeks' treatment. In 1 of 22 JNJ-6379 treated patients with post-baseline NGS data available, an emerging substitution at 1 of the 28 HBV core protein positions of interest was detected. This patient (GT-E, JNJ-6379 150 mg treated) had an emerging Y118F mutation at Day 8, which persisted until the end of follow-up. HBV DNA decline in this patient was slower but continued until the end of treatment with a maximum decline of 2.19 log_{10} IU/ml.

Conclusion: Baseline polymorphisms reducing JNJ-6379 *in vitro* activity were rare. One patient carried a baseline polymorphism which reduced JNJ-6379 activity *in vitro* and the same aa substitution was emerging in another patient without a clear impact on JNJ-6379 virological response.

FRI-189

HBcrAg decline in JNJ-56136379-treated chronic hepatitis B patients: Results of a phase 1 study

Oliver Lenz[1], Thierry Verbinnen[1], Moana Hodari[1], Willem Talloen[1], Joris Vandenbossche[2], Umesh Shukla[3], Françoise Berby[4], Caroline Scholtes[4], David Blue[1], Jeysen Yogaratnam[5], Sandra De Meyer[1], Fabien Zoulim[4]. *[1]Janssen Research and Development, Beerse, Belgium; [2]Janssen Pharmaceuticals NV, Beerse, Belgium; [3]Janssen Pharmaceuticals RandD, Titusville, United States; [4]INSERM U1052-Cancer Research Institute of Lyon, Lyon, France; [5]Janssen Biopharma Inc., South San Francisco, United States*
Email: olenz@its.jnj.com

Background and aims: JNJ-56136379 (JNJ-6379) is a potent capsid assembly modulator which binds to HBV core protein, interfering with capsid assembly and formation of cccDNA. In a Phase 1b study (NCT02662712), patients with HBeAg-positive or -negative chronic hepatitis B received once-daily oral JNJ-6379 or placebo for 28 days.

JNJ-6379 was well tolerated and resulted in potent HBV DNA and HBV RNA reductions. Here we present an exploratory analysis of hepatitis B core-related antigen (HBcrAg) changes during JNJ-6379 treatment.
Method: Treatment-naïve chronic hepatitis B patients with screening serum ALT levels < 2.5x ULN were included in this study. ALT, HBV DNA, HBeAg, and HBsAg levels were assessed using standard assays. Exploratory analysis included serum HBV RNA assessed with qRT-PCR assay, and HBcrAg assessed using the Lumipulse platform (Fujirebio). The HBcrAg assay detects HBeAg, HBcAg and p22cr protein with a LLOQ of 3.0 logU/ml and LOD of 2.0 logU/ml.
Results: Fifteen of 57 (26%) patients were HBeAg-positive and were enrolled in the 25 mg (N = 6), in the two 75 mg (N = 8) and the 250 mg (N = 1) sessions. Mean (SD) baseline HBcrAg levels were 7.8 (1.3) logU/ml and 3.3 (1.5) logU/ml in HBeAg-positive and -negative patients, respectively. 15/15 and 17/42 (40%) HBeAg-positive and -negative patients, respectively, had HBcrAg levels ≥ 3.5 logU/ml at baseline, sufficient to determine a ≥ 0.5 logU/ml reduction in HBcrAg. Treatment with JNJ-6379 for 28 days resulted in ≥ 0.5 logU/ml (range 0.7 to 1.7) declines in HBcrAg from baseline in 6/12 (50%) HBeAg-negative patients with baseline HBcrAg ≥ 3.5 logU/ml and Day 28 data available, compared to 0/4 receiving placebo (range 0.1 to -0.2). Among JNJ-6379-treated HBeAg-positive patients, 1/10 (10%) experienced on-treatment decline of ≥ 0.5 logU/ml in HBcrAg, compared to 0/5 placebo-treated subjects.
Interestingly, patients with HBcrAg decline had either ALT levels > 1xULN at baseline or transient on-treatment ALT elevations. No relevant changes in HBeAg (in HBeAg-positive patients) or HBsAg were noted following short-term JNJ-6379 treatment, suggesting that the HBcrAg reductions observed in some patients might be due to direct inhibition of release of the HBV core protein.
Conclusion: Following 28 days of treatment with JNJ-6379, a reduction in HBcrAg levels occurred in a subset of patients, while no changes in HBeAg or HBsAg were observed. This will be examined further in the ongoing Phase 2a JNJ-6379 (JADE) study.

FRI-190

Incidence and predictors of flares after discontinuing nucleos (t) ide analogue therapy in HBeAg negative patients with chronic hepatitis B: Results from the randomized controlled STOP study

Seng Liem[1,2], Scott Fung[1], David Wong[1], Colina Yim[1], Jenny Chen[1], Seham Noureldin[1], Jordan Feld[1,3], Bettina Hansen[1,2,4], Harry Janssen[1].

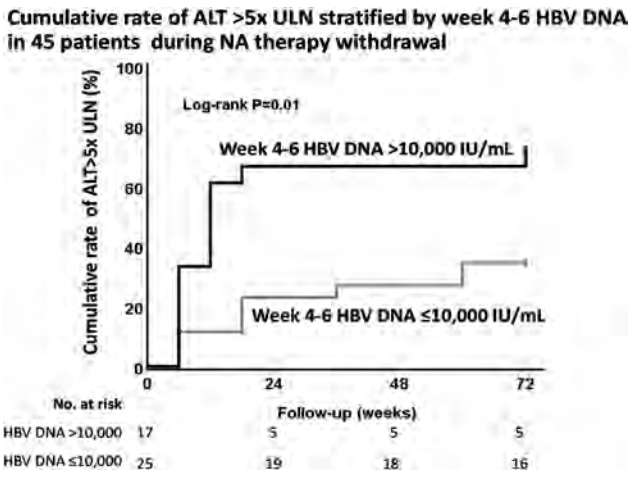
Email: k.s.liem@erasmusmc.nl

Background and aims: HBeAg negative patients with chronic hepatitis B (CHB) often develop flares after stopping nucleos (t)ide analogues (NA) therapy, but early prediction of off-therapy flares remains difficult. In this prospective randomized controlled trial, we determined the cumulative incidence of flares and evaluated response-guided prediction after stopping long-term NA therapy.
Method: Patients at a North-American hospital were eligible if they had received entecavir/tenofovir therapy for ≥ 1 year and achieved virologic suppression (HBeAg seroconversion combined with undetectable HBV DNA ≥ 12 months in HBeAg positive patients, or undetectable HBV DNA ≥ 36 months in start of therapy HBeAg negative patients). Patients were randomized 2:1 to stop or continue NA therapy for 72 weeks. Patients were retreated in case of HBeAg seroreversion, persistent HBV DNA > 20, 000IU/ml or HBV DNA > 2, 000 with ALT > 5xULN. Predictors of flares (ALT > 5x ULN) were studied by Cox proportional-hazards regression.
Results: Of 67 included patients (60% male, 97% Asian), 45 (67%) patients were assigned to stop and 22 (33%) to continue NA therapy. NA-induced HBeAg loss occurred in 37/67 (55%) patients. At randomization the mean duration of NA therapy was 8 (4) years and HBsAg level was 3.0 (0.7) log IU/ml. Within the stop group 24/45 (53%) patients continued to have a normal ALT and HBeAg negative status compared to 95% in the continue group. By week 72 off-therapy, 38 (84%) NA stop patients developed ALT > ULN, of whom twenty (49%) had ALT > 5xULN and fourteen (31%) had ALT > 10x ULN. Among patients with an ALT > 10x ULN, the median ALT was 16 (13-23)×ULN (peak: 40). Although one patient developed a bilirubin of 68 umol/L, none decompensated or died.
Independent predictors of ALT > 5xULN were male sex (OR: 6.5 (4.0-10.4); p < 0.005) and serum HBV DNA (1.3 (1.1–1.5); p < 0.005) at week 6 off-therapy. Specifically, a week 4-6 HBV DNA > 10, 000 IU/ml predicted a higher risk of ALT > 5xULN compared to ≤ 10, 000 IU/ml (3.0 (1.3-7.1); p = 0.01; see Figure). Quantitative HBsAg at the end of therapy was not predictive for ALT > 5xULN (p > 0.05).



Conclusion: In this prospective randomized controlled trial, the cumulative rate of off-therapy flares was 49% in HBeAg negative patients with CHB. Male sex and week 4-6 HBV DNA values independently predicted a flare. The proposed threshold of HBV DNA > 10, 000 IU/ml facilitates off-therapy identification of patients with a high risk of flares who may need more intensive follow-up and earlier retreatment.

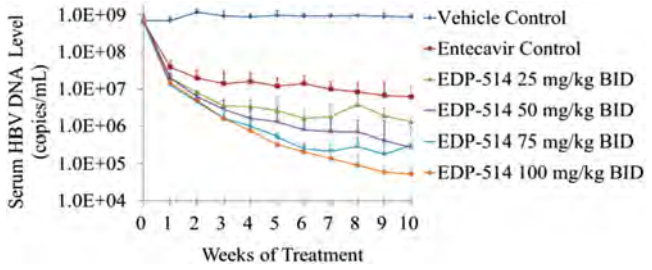
EDP-514, a novel HBV core inhibitor with potent antiviral activity both in vitro and in vivo

Michael Vaine[1], Victor Dellisola[1], Susan Clugston[1], Hui Cao[1], Xuri Gao[1], Jorden Kass[1], Wei Li[1], Xiaowen Peng[1], Yao-Ling Qiu[1], Lijuan Jiang[1], Kellye Daniels[1], Yat Sun Or[1], Bryan Goodwin[1], Kai Lin[1].
[1]*Enanta Pharmaceuticals, Inc., Watertown, United States*
Email: kailin@enanta.com

Background and aims: Current therapies for hepatitis B virus (HBV) can effectively suppress viral replication but rarely lead to a functional cure, which necessitates the development of new antiviral drugs. The HBV core protein plays an essential role in multiple steps of viral life cycle and has been proposed as a potential therapeutic target. EDP-514 is a novel HBV core inhibitor with favorable pharmacokinetic and safety profile. Here, we describe the anti-HBV activities of EDP-514 *in vitro* and in a chimeric mouse model with humanized liver.
Method: The effect of EDP-514 on viral capsid assembly was determined *in vitro*. Its anti-HBV activities at different stages of the viral lifecycle were characterized in stable cell lines (HepG2.2.15, HepAD38 and HepDE19) and primary human hepatocytes. Activities against different HBV genotypes and resistance mutants were assessed in transiently transfected HepG2 cells. The *in vivo* efficacy of EDP-514 was evaluated in HBV genotype C-infected PXB mice

which were generated by transplantation of urokinase-type plasminogen activator/severe combined immunodeficiency (uPA/SCID) mice with human hepatocytes.

Results: EDP-514 induced the assembly of empty capsids *in vitro* and in HBV infected cells but did not lead to core protein aggregation or degradation, confirming it is a class II core inhibitor. EDP-514 inhibited HBV DNA replication with an EC_{50} of 18, 27 and 17 nM in HepAD38, HepDE19 and HepG2.2.15 cells, respectively. In addition, EDP-514 prevented the *de novo* formation of cccDNA in primary human hepatocytes with an EC_{50} of 35 nM. The compound was active across HBV genotypes A-H with potencies ranging from 9-32 nM and its efficacy was not affected by known nucleos (t)ide resistant variants. Combination of EDP-514 with nucleos (t)ide or class I core inhibitors led to synergistic antiviral effect *in vitro*. Moreover, EDP-514, given orally at 25, 50, 75 and 100 mg/kg BID, reduced HBV DNA by 2.75, 3.42, 3.27 and 4.13 logs, respectively, in PXB mice after 10 weeks of treatment.



Conclusion: EDP-514 is a novel HBV core inhibitor with an attractive preclinical profile. It is a potent inhibitor of HBV replication and prevents *de novo* cccDNA formation. *In vivo*, EDP-514 treatment of HBV-infected PXB mice results in a rapid and sustained viral load reduction of > 4-log. Overall, these data support the further development of EDP-514 as a therapeutic candidate for the treatment of HBV.

FRI-192

Tenofovir disoproxil fumarate treatment in chronic hepatitis B patients with cirrhosis reduces hepatic decompensation, hepatocellular carcinoma and death

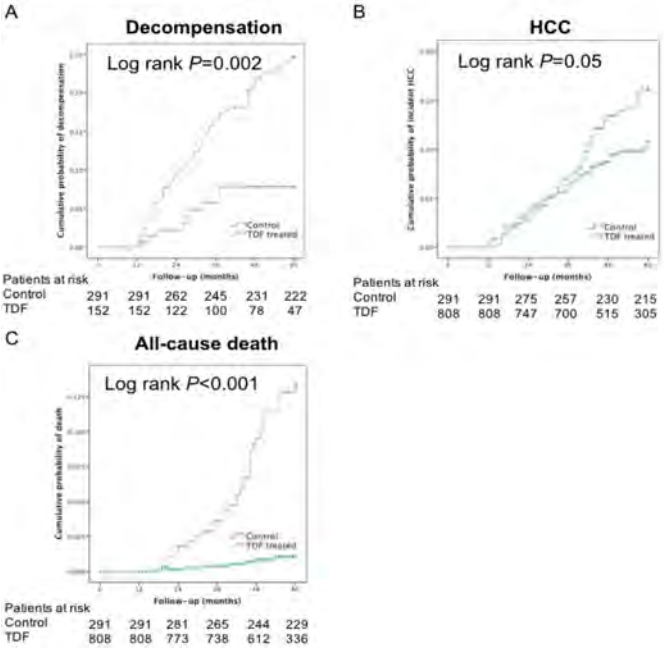
Ken Liu[1], Jonggi Choi[2], An Le[3], Vincent Wai-Sun Wong[4], Stephen L. Chan[4], Mindie Nguyen[3], Young-Suk Lim[2], Grace Lai-Hung Wong[4]. *[1]Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Sydney, Australia; [2]ASAN Medical Centre, University of ULSAN, Department of Gastroenterology, Seoul, Korea, Rep. of South; [3]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, Palo Alto, United States; [4]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: Lamivudine and entecavir have been shown to reduce decompensation, hepatocellular carcinoma (HCC) and death in chronic hepatitis B (CHB) patients with cirrhosis. Tenofovir disoproxil fumarate (TDF) is a potent antiviral agent with no documented resistance to date, but its impact on cirrhotic patients is unclear. We aimed to investigate the effectiveness of TDF therapy in CHB patients with cirrhosis.

Method: We studied 808 TDF-treated and 291 untreated CHB cirrhotic patients from 3 tertiary centres (Hong Kong, South Korea, United States). Cirrhosis was defined by liver histology, thrombocytopenia ($< 150 \times 10^9$/L) and/or features of portal hypertension on imaging. TDF cohort included consecutive patients from three tertiary centres who received TDF 300 mg/day for ≥ 12 months. Control cohort included historical untreated patients

Results: TDF-treated patients were 69% men, mean age 54 ± 10 years, and 47% hepatitis B e antigen (HBeAg) positive, 55% had prior (non-TDF) antiviral therapy. Untreated controls were 78% men, mean age 50 ± 9 years and 24% HBeAg positive. At 5-years follow-up, there were 72 decompensating events, 113 HCCs and 41 deaths (28 liver-related) from both groups combined. Undetectable Hepatitis B virus DNA was achieved in 90.8% of TDF-treated patients. 5-year cumulative probabilities in TDF-treated vs. control cohorts were (**Figure 1**): 8% vs. 22% for decompensation (p = 0.002), 10% vs. 15% for HCC (p = 0.05) and 1% vs. 12% for death (p < 0.001). On multivariate Cox regression, TDF treatment was independently associated with reduced risks of decompensating events (hazard ratio [HR] 0.41, *P* = 0.046), HCC (HR 0.42, *P* = 0.001), all-cause death (HR 0.05, *P* < 0.001) and liver-related death (HR 0.09, *P* < 0.001). Other independent predictors for events were: decompensating events (albumin [HR 0.92, *P* = 0.015], platelet count [HR 0.99, *P* < 0.017] and INR [HR 9.89, *P* = 0.002]), HCC (albumin [HR 0.94, *P* < 0.001]), all-cause death (INR [HR 21.24, *P* < 0.001]) and liver-related death (albumin [HR 0.89, *P* = 0.012]). A sensitivity analysis performed including only patients who received no prior antiviral therapy before TDF showed TDF was still independently protective for HCC (HR 0.49, *P* < 0.001), all-cause death (HR 0.05, *P* < 0.001), liver-related death (HR 0.06, *P* < 0.001), and almost for decompensating events (HR 0.49, *P* = 0.068).

Figure 1. Kaplan-Meier analysis of cumulative probability of (A) Decompensation, (B) HCC, and (C) death in TDF-treated vs. untreated CHB patients with cirrhosis



Conclusion: Among patients with cirrhosis, TDF treatment reduces risks of hepatic decompensation and HCC by more than 2-fold and death by 95% at 5 years

FRI-193

Long-term renal and bone safety of tenofovir disoproxil fumarate in chronic hepatitis B patients with cirrhosis

Ken Liu[1], Jonggi Choi[2], An Le[3], Vincent Wai-Sun Wong[4], Stephen L. Chan[5], Mindie Nguyen[3], Young-Suk Lim[2], Grace Lai-Hung Wong[4]. *[1]Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Sydney, Australia; [2]ASAN Medical Centre, University of ULSAN, Department of Gastroenterology, Seoul, Korea, Rep. of South; [3]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, Palo Alto, United States; [4]The Chinese*

University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong; [5]The Chinese University of Hong Kong, Department of Clinical Oncology, Hong Kong, Hong Kong
Email: wonglaihung@cuhk.edu.hk

Background and aims: Although real-life data suggest that TDF is generally safe, there are renal and bone safety concerns. Long-term data in patients with cirrhosis is limited. We aimed to investigate long-term renal and bone toxicity of TDF therapy in chronic hepatitis B (CHB) patients with cirrhosis.
Method: We studied two CHB cirrhotic cohorts: one treated with TDF and one untreated historical control group. Cirrhosis was defined by liver histology, thrombocytopenia ($< 150 \times 10^9$/L) and/or features of portal hypertension clinically or on imaging. TDF cohort included consecutive patients from 3 tertiary centres (Hong Kong, South Korea, Unites States) who received TDF 300 mg/day for ≥ 12 months. Estimated glomerular filtration rate (eGFR) as calculated by CKI-EPI and 5-year cumulative probabilities of chronic kidney disease (CKD) progression ≥ 1 stage and fracture were compared.
Results: For renal outcomes, we analysed 935 TDF-treated (baseline mean eGFR 92 ml/min/1.73m^2) and 69 untreated cirrhotics (baseline mean eGFR 85 ml/min/1.73m^2). At 5-years follow-up, there was less eGFR decline in TDF-treated patients vs. controls (−5 ml/min/1.73m^2 vs. −13 ml/min/1.73m^2, $P < 0.001$) (**Figure 1**). 5-year probability of CKD progression was lower in TDF-treated patients vs. controls (19% vs. 42%, $P < 0.001$). TDF treatment was associated with less CKD progression (hazard ratio 0.4, $P < 0.001$) even after adjusting for age, baseline eGFR and prior antiviral therapy. For bone outcomes, we analysed 443 TDF-treated and 291 untreated cirrhotic patients. During the study period there were 21 fractures in both groups combined. The 5-year probability of fracture was similar in TDF-treated patients vs. controls (5% vs. 3%, $P = 0.174$). There was no significant change in serum phosphate levels in TDF-treated patients during follow-up.
Conclusion: Among CHB patients with cirrhosis, TDF treatment appears safe with no significant increase in eGFR decline, CKD progression, or fracture risk compared to untreated patients.

FRI-194

The novel antiviral agent inarigivir inhibits both nucleos (t)ide analogue and capsid assembly inhibitor resistant HBV in vitro

Danni Colledge[1], Kathy Jackson[1], Vitina Sozzi[1], XIn Li[1], Michael Beard[2], Nicholas Eyre[2], JunJie Zhang[3], Haitao Guo[3], Nezam Afdhal[4], Radhakrishnan Iyer[4], Stephen Locarnini[1]. *[1]VIDRL, Melbourne, Australia; [2]University of Adelaide, Adelaide, Australia; [3]Indiana University, Indianopolis, United States; [4]Spring Bank Pharmaceuticals, Hopkinton, United States*
Email: danni.colledge@mh.org.au

Background and aims: Inarigivir is a synthetic dinucleotide that activates the RIG-I antiviral pathway resulting in inhibition of HBV replication. Inarigivir has been demonstrated to also have direct antiviral activity against HBV *in vitro* by inhibiting reverse transcription following the packaging of its pgRNA into the nucleocapsid. The study aim was to test the *in vitro* antiviral potency of Inarigivir against a panel of nucleos (t)ide analogue resistant, capsid assembly inhibitor resistant and precore stop codon variants of HBV.
Method: Huh7 cells were transfected with replication competent clones of HBV known to be resistant to lamivudine (rtL180M + rtM204 V and rtM204I), adefovir (rtA181 V + rtN236 T) or entecavir (rtL180M + rtT184G + rtS202I + rtM204 V) as well as a panel of HBVs with substitutions in the core protein (cT33I or cY109A or cT118F or cV124A) and also the HBeAg-negative G1896A stop codon variant. The amount of HBsAg secreted into the cell culture supernatant was measured by quantitative EIA, whilst HBV DNA replication was evaluated by Southern blot. Following transfection, cells were incubated for 5 days with daily medium change of Inarigivir and scored as drug sensitive if a dose-response in antiviral effect at 2 or 25 or 50μM Inarigivir on HBsAg secretion/HBV DNA replication was seen and the inhibition exceeded 20% compared to the untreated control. Resistance was defined as < 20% reduction in HBsAg or HBV DNA levels compared to untreated controls with no dose response in antiviral effect observed at the drug concentrations tested.
Results: Inarigivir effectively inhibited replication of all HBV isolates associated with antiviral drug resistance and to a level comparable to the wild-type HBV whilst lamivudine had no effect. Inarigivir also inhibited all four of the capsid variants tested compared to wild-type HBV whilst the BAY 41-4109 anti-HBV compound had no antiviral effect on these isolates. Finally, Inarigivir retained its antiviral activity against HBV containing the G1896A stop codon mutation that is needed for HBeAg production.
Conclusion: Inarigivir was active, at the level of HBsAg production and secretion as well as active HBV DNA replication, against a panel of

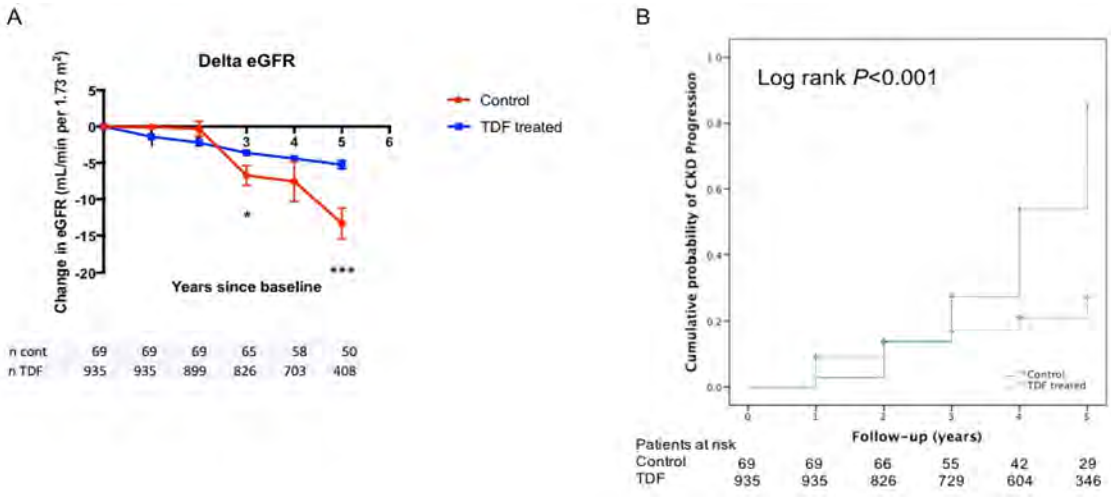


Figure: (abstract: FRI-193)

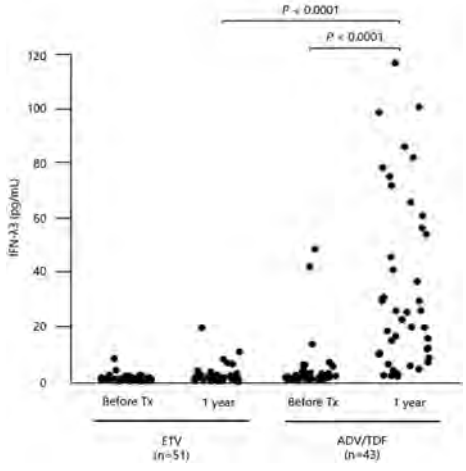
antiviral drug and capsid inhibitor resistant variants and also HBV with the G1896A substitution. This indicates that treatment with Inarigivir should result in retention of antiviral activity against isolates of HBV that are resistant to these two groups of antiviral agents.

FRI-195

Long-term effect of nucleos (t)ide analogs on hepatitis B surface antigen in chronic hepatitis B patients

Kenichi Morikawa[1], Machiko Umemura[1], Koji Ogawa[1], Taku Shigesawa[1], Kazuharu Suzuki[1], Akihisa Nakamura[1], Masatsugu Ohara[1], Naoki Kawagishi[1], Tomoe Shimazaki[1], Megumi Kimura[1], Takaaki Izumi[1], Masato Nakai[1], Takuya Sho[1], Goki Suda[1], Mitsuteru Natsuizaka[1], Kota Ono[1], Kazumoto Murata[1], Masaya Sugiyama[1], Mizokami Masashi[1], Naoya Sakamoto[1]. [1]*Hokkaido University Faculty of Medicine and Graduate School of Medicine, Department of Gastroenterology and Hepatology, Sapporo, Japan*
Email: kenichi.morikawa@med.hokudai.ac.jp

Background and aims: Nucleos (t)ide analogs (NAs) treatment against chronic hepatitis B (CHB) has ability to reduce liver disease progression, the risk of HCC development, and HBV-related mortality However, long-term benefits of NAs on hepatitis B surface antigen (HBsAg) reduction are still not known. This study aimed to investigate the long-term effect of NAs on HBsAg reduction and evaluate the effect of interferon-lambda3 (IFN-λ3) induction by NAs on HBs Ag reduction.
Method: A total of 176 patients [121 treated with nucleoside analog entecavir hydrate (ETV) and 55 treated with nucleotide analog adefovir dipivoxil (ADF) or tenofovir disoproxil fumarate (TDF) with clinically evident chronic hepatitis B (chronic hepatitis, 121; liver cirrhosis, 55) were enrolled in this study. Among them, a total of 94 patients (ETV, 51; ADV/TDF, 43) were measured IFN-λ3 before the initiation of therapy and 1 year post-therapy.
Results: The change (mean±SD) in serum HBsAg levels from baseline to year 9 was −0.47 ± 0.60 and −1.57 ± 1.17 $\log_{10}$ IU/ml in ETV and ADV/TDF groups, respectively ($p = 0.0064$). The proportions of patients with HBV DNA lower limit of quantification, alanine aminotransferase normalization, the rate of hepatitis e seroconversion were not significantly different between ETV and ADV/TDF groups during the study period. Serum IFN-λ3 levels were significantly higher in patients receiving nucleotide analogs (ADV/TDF: 25.5 pg/ml) than in the patients receiving nucleoside analog (ETV: 1.3 pg/ml) at 1 year post-therapy ($p < 0.0001$).



Conclusion: Long-term nucleotide analog (ADV/TDF) treatment rapidly reduced HBsAg levels compared with nucleoside analog (ETV). Serum IFN-λ3 levels is negatively correlated with HBsAg reduction in patients limited to initial HBsAg, HBV genotype, and therapeutic response.

FRI-196

The development of HCC in chronic hepatitis B patients with nucleos (t)ide analogs: Focus on hepatitis B surface antigen and core-related antigen

Itaru Ozeki[1], Hirokazu Suii[1], Ryoji Tatsumi[1], Masakatsu Yamaguchi[1], Mutsuumi Kimura[1], Tomohiro Arakawa[1], Tomoaki Nakajima[1], Yasuaki Kuwata[1], Takumi Ohmura[1], Shuhei Hige[1], Yoshiyasu Karino[1], Joji Toyota[1]. [1]*Sapporo-kousei general hospital, Sapporo, Japan*
Email: 3767759101@jcom.home.ne.jp

Background and aims: Although overseas reports indicate that a high HBs antigen (sAg) level is a risk factor for HCC in chronic HBV patients (pts) treated with nucleoside analogs (NAs), HCC often occurs in pts with low sAg levels in Japan, where many elderly pts develop this condition. The HBV core-related antigen (crAg), a similar risk factor, is derived from covalently closed circular DNA, like sAg. However, sAg and crAg levels differ in some NA-treated pts. We aimed to examine the association between sAg and crAg levels after NA therapy and the development of HCC.
Method: We included 356 pts who had received entecavir (ETV) or tenofovir for ≥ 3 years and achieved sustained viral suppression of HBV DNA (mean age at 3 years of NA therapy, 54 years; men, 212; HBeAg positive, 77; and genotype C, 267). Exclusion criteria included an adefovir treatment history, resistant with lamivudine and/or ETV, HCC history, and HCC development within 3 years of NA therapy. Cumulative HCC incidence and contributing factors for HCC were assessed. According to sAg (IU/ml) and crAg (U/ml), levels at 3 years of NA therapy, the pts were stratified into 4 groups: group 1, sAg ≥ 1300 and crAg < 3.0; group 2, sAg < 1300 and crAg < 3.0; group 3, sAg ≥ 1300 and crAg ≥ 3.0; group 4, sAg < 1300 and crAg ≥ 3.0. Cumulative HCC incidence was analyzed in each group; log-rank test was performed to assess differences among the groups. We used sex, genotype, diabetes mellitus-treatment history, familial history, presence or absence of steatosis, alcohol consumption, and HBeAg, sAg, crAg, M2BPGi, FIB-4 and AFP levels at 3 years of treatment as factors in the Cox proportional hazards model. Cut-off values were calculated by receiver operating characteristic curve analysis. Numerical values were expressed as mean; p < 0.05 was considered to indicate significance.
Results: The Cumulative HCC incidence was 3.1% and 10.8% at 5 and 10 years, respectively. An sAg level < 1300 (hazard ratio [HR], 5.9; p = 0.005), a crAg level ≥ 3.0 (HR, 4.0; p = 0.004), age ≥ 55 years (HR, 11.3; p = 0.002), and presence of diabetes mellitus (HR, 3.4; p = 0.003) were identified as contributing factors for HCC. The cumulative HCC incidence in groups 1, 2, 3, and 4 were 0%, 0%, 1.9%, and 10.3% at 5 years and 0%, 5.8%, 4.4%, and 31.3% at 10 years, respectively. Group 4 showed a significantly higher incidence rate than groups 1, 2, and 3.
Conclusion: Analysis stratified by sAg and crAg levels showed that HCC did not occur in pts with an sAg level ≥ 1300 and a crAg level < 3.0 at 3 years after NA therapy initiation, whereas HCC incidence was the highest in those with an sAg level < 1300 and a crAg level ≥ 3.0. Pts at high risk of HCC after NA therapy can be mainly identified by sAg and crAg levels.

FRI-197

Prediction of elastographic reversion of cirrhosis after 5 years of entecavir or tenofovir disoproxil fumarate therapy in caucasian chronic hepatitis B patients

Email: gepapath@med.uoa.gr

Background and aims: Long-term follow-up of phase III clinical trials has shown that reversion of histological cirrhosis may be achieved in CHB patients after ≥ 5 years of ETV or TDF therapy. However, predictors of such reversion of cirrhosis have not been well defined, while a follow-up liver biopsy cannot be routinely performed in clinical practice. We assessed predictors of elastographic reversion of cirrhosis at 5 years of ETV/TDF in CHB patients.
Method: We included 348 adult Caucasian CHB patients of the PAGE-B cohort who had compensated cirrhosis before ETV/TDF and available reliable liver elastography at 5 years of therapy. Compensated cirrhosis before ETV/TDF was diagnosed mostly by histological findings or by well accepted ultrasonographic and/or endoscopic findings. Elastographic reversion of cirrhosis at 5 years of ETV/TDF therapy was diagnosed in cases with reliable liver stiffness measurements (LSM) < 12 kPa.
Results: At 5 years, LSM < 12 and ≥ 12 kPa was observed in 246 (71%) and 102 (29%) patients. In univariable analyses, elastographic reversion of cirrhosis was associated with lower BMI (p = 0.002) or BMI ≤ 30 vs > 30 kg/m^2 (77% vs 49%, p < 0.001), current alcohol use < 20 vs ≥ 20 g/day (80% vs 67%, p = 0.049), absence vs presence of diabetes (80% vs 58%, p = 0.006), higher platelets (p < 0.001) or platelets ≥ 150 vs < 150 x10^9/L at baseline (76% vs 64%, p = 0.014), higher platelets (p = 0.001) or platelets ≥ 150 vs < 150 x10^9/L at year 5 (75% vs 62%, p = 0.017), lower HBV DNA at baseline (p = 0.012), prior use of interferon (p = 0.001) or other nucleos (t)ide analogues (p < 0.001), normal (≤ 40 IU/L) vs elevated ALT at year 1 (74% vs 50%, p = 0.002), therapy with TDF vs ETV (74% vs 62%, p = 0.038), but not with age, gender, smoking, HBeAg status at baseline or year 5, normal ALT at baseline or year 5, baseline albumin levels, virological on-therapy remission. Logistic multivariable regression analysis showed that elastographic reversion of cirrhosis was independently associated with baseline BMI ≤ 30 kg/m^2 [OR: 2.92 (95% CI: 1.23-6.94), p = 0.015], absence of diabetes [OR: 3.16 (1.21-8.27), p = 0.019] and TDF therapy [OR: 3.21 (1.38-7.46), p = 0.007].
Conclusion: Elastographic reversion (LSM < 12 kPa) of compensated cirrhosis after long-term antiviral therapy can be achieved in > 70% of CHB patients and appears to be associated with absence of obesity and diabetes, as previously reported in clinical trials with histological follow-up, as well as with TDF compared to ETV therapy.

FRI-198

A Phase 1, double-blind, randomized, placebo-controlled, first-in-human study of the safety, tolerability, pharmacokinetics and pharmacodynamics of oral JNJ-64794964, a toll-like receptor-7 agonist, in healthy adults

Ed Gane[1], Mina Pastagia[2], An De Creus[3], Christian Schwabe[4], Joris Vandenbossche[3], Leen Slaets[3], Bart Fevery[3], Liviawati S Wu[2], Rui Li[5], Samia Siddiqui[5], Abbie Oey[2], Clark Musto[2], Bruce Bryan[2], Pieter Van Remoortere[5]. *[1]University of Auckland, New Zealand Liver Transplant Unit, Auckland, New Zealand; [2]Janssen BioPharma Inc., South San Francisco, United States; [3]Janssen Pharmaceutica NV, Janssen Research and Development, Beerse, Belgium; [4]Auckland Clinical Studies, Auckland, New Zealand; [5]Janssen Research and Development LLC, Titusville, United States*
Email: mpastagi@its.jnj.com

Background and aims: JNJ-64794964 (JNJ-4964) is an oral toll-like receptor-7 agonist in clinical development to treat chronic hepatitis B infection. This first-in-human study assessed the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of single- (presented here) and multiple ascending doses of JNJ-4964 in healthy adults with/without food.
Method: In this ongoing study, subjects received a single oral dose of 0.2 (N = 6), 0.6 (N = 6), 1.25 (N = 8) or 1.8 mg (N = 6) JNJ-4964 or placebo (N = 2/dose group) in a fasted state and were followed up for 4 weeks. The 1.25-mg group were evaluated for food effect in a cross-over manner with ≥ 6 weeks' interval. PD analyses comprised an IFN-alpha ELISA, a Luminex panel of 13 other cytokines including IP-10, TNF-alpha and MCP-1, and an IFN-stimulated gene (ISG) expression analysis for ISG15, MX1 and OAS1 using qPCR.
Results: All single doses were safe and well tolerated. No serious adverse events (AEs) occurred. 10/34 adults reported mild (≤ Grade 2), transient and reversible AEs at least possibly related to study drug: 5 had fever and flu-like symptoms that resolved within 24-48 hours; 4 had transient, asymptomatic lymphopenia (< 0.9×10^9/L). In the 1.25 mg group, the incidence of AE reporting was lower for the fed compared to the fasted state.
JNJ-4964 exposure post-administration was dose proportional for 0.2-1.8 mg doses. Individual profiles showed rapid JNJ-4964 uptake with an early t_{max} (0.5-1 h), followed by a rapid distribution phase, but with a variable and long median terminal half-life of 190-540 h. $AUC_{0\text{-}24h}$ was ~20% lower in the 1.25-mg fed compared to the fasted state.
ISG and cytokine levels peaked within 12-24 h and returned to predose levels 48-96 h post-administration. Induction of all 3 ISGs was observed in every group, including all dosed subjects in the 1.25 and 1.8-mg groups. Increased cytokine expression was observed in 0/6, 1/6, 5/6 and 7/8 dosed subjects in the 0.2, 0.6, 1.25, and 1.8 mg fasted dose groups, respectively. IFN-alpha increased ≥ 2-fold in 4/8 and 2/6 dosed subjects in the 1.25 and 1.8-mg groups, but not in the 0.2 and 0.6-mg groups. Cytokine and ISG expression were reduced in the 1.25-mg fed compared to the fasted state.
Conclusion: Single oral doses of 0.2-1.8 mg JNJ-4964 in healthy adults were generally safe, well tolerated, exhibited dose proportional PK and induced cytokines/ISGs. AEs were mild and reversible. Preliminary data supports continued development of JNJ-4964.

FRI-199

First in Human, single ascending dose clinical trial of AIC649 in patients with chronic hepatitis

Ibironke Addy[1], Alen Jambrecina[2], Thomas Berg[3], Florian van Bömmel[3], Dirk Kropeit[1], Christiane Vank[1], Alexandra Bigge[1], Katja Nedoschinsky[1], Hans-Peter Stobernack[1], Manickam Rangaraju[1], Silke Kummer[4], Urte Matschl[5], Adam Gehring[6], Johanna Eberhard[4], Marcus Altfeld[5], Julian Schulze zur Wiesch[4], Holger Zimmermann[1], Daniela Paulsen[1]. *[1]AiCuris Anti-infective Cures GmbH, Wuppertal, Germany; [2]CTC North GmbH and Co. KG, Hamburg, Germany; [3]University Hospital Leipzig, Clinic for Gastroenterology and Rheumatology, Section Hepatology,*

Leipzig, Germany; [4]University Medical Center Hamburg-Eppendorf, Department of Medicine, Infectious Disease Unit, Hamburg, Germany; [5]Heinrich-Pette-Institut, Department of Viral Immunology, Hamburg, Germany; [6]Toronto General Hospital Research Insitute, Toronto Centre for Liver Disease, Toronto, Canada
Email: ibironke.addy@aicuris.com

Background and aims: AIC649 is an immunomodulator known to induce loss of woodchuck hepatitis surface antigen (WHsAg) and induce anti-WHsAg antibodies, suggesting that AIC649 may achieve functional cure in chronic hepatitis B (CHB) patients (pts). This randomized, multi-center, double-blind, placebo-controlled trial was conducted to assess the safety, tolerability and pharmacodynamics of single ascending intravenous doses of AIC649 in CHB pts.
Method: In total, 32 male and female, 18 to 65-year-old, treatment-naïve and -experienced, HBeAg-negative and -positive pts with CHB were included. At each of the 4 dose steps, 8 pts received a single dose of AIC649 (6 pts) or placebo (2 pts) and were followed for 3 months. Safety assessments included overall tolerability, clinical laboratory and adverse events. HBV parameters were assessed over the whole time course, immunological parameters between baseline and day 14. The high dose groups 3 and 4 were additionally assessed for HBV parameters at 6 and 12 months post-treatment.
Results: Treatment-emergent adverse events (TEAEs) were reported for fewer AIC649-treated pts (20/24, 83.7%) than for placebo (8/8, 100%). No pt receiving AIC649 had drug-related, severe, or serious TEAEs. There were no apparent effects of AIC649 upon vital signs, electrocardiography, hematology, clinical chemistry, or urinalysis. There were no hepatic flares.
Following a single dose of AIC649, there was evidence of innate activation with increases in IL-1β, IL-6, IL-8, IFN-γ and reduction in IL-10 plasma levels. IFN-γ showed a consistent response in the highest dose group. The CD4 T cell effector memory population appeared to consistently expand from dose group 2 upwards.
HBV DNA and HBsAg levels did not substantially change in most pts. However, 2 pts (1 placebo, 1 dose group 3) showed a clear reduction in HBV DNA at the end of follow-up. The AIC649-treated pt achieved HBeAg loss with anti-HBe seroconversion and despite unchanged HBsAg levels, became transiently anti-HBs Ab positive. In dose groups 3 and 4, a total of 3 pts had marked peaks in HBV DNA levels post-treatment: In 2 pts HBsAg levels did not change but in 1 pt (dose group 4) this was followed by a continuous reduction in HBsAg levels to 32% at 1 year post-treatment.
Conclusion: A single intravenous dose of AIC649 was safe and well tolerated in all dose groups. Despite the heterogeneity of the pts in the trial, there was evidence that a single dose of AIC649 stimulates immunity.

Email: jeyamani.ramachandran@sa.gov.au

Background: With its unrestricted access to directly acting antiviral drugs, Australia is committed to eradicating hepatitis C (HCV) infection.The strategies used to augment treatment uptake include innovations in models of care (MOC) and decentralization of care.
Aims: To study the short (24 weeks) and long-term (lifetime) cost-effectiveness of four different MOC in HCV treatment.
Method: A cohort Markov model-based probabilistic cost-effectiveness analysis (CEA) was undertaken extrapolating upto 30 years from cost and outcome data collected from a 24-week study in which patients, initiated on HCV therapy for a year from 1st March 2016 at four major public hospitals in South Australia after excluding those with cirrhosis and after liver transplantation, were studied. The MOC were classified depending on the person providing patient workup, treatment and monitoring into: MOC1 (specialist); MOC2 (mixed specialist and nurse); MOC3 (nurse); MOC4 (General Practitioner, GP).Incremental costs were estimated from a Medicare perspective. Incremental outcomes were estimated based on the sustained viral response (SVR) and quality adjusted life years (QALY) gained. A cost-effectiveness threshold of $50, 000 per QALY gained, the implicit criterion used for assessing the cost-effectiveness of new pharmaceuticals and medical services in Australia, was assumed for QALY outcomes. Net monetary benefit (NMB) estimates based on this threshold were also calculated.
Results: 1373 patients, 64% males, mean age 50 (SD 11) years were studied. At 24 weeks, the SVR of 97% was not different between MOCs ($p = 0.093$). In CEA, MOC4 and 2 clearly dominated MOC1 both at 24 weeks and over 30 years with higher QALYs and lower costs. Similarly, NMB were highest in MOC 4, followed by MOC2 as shown in the table below.

Table:

Time Horizon	Costs (AUD)/QALY	MOC 1	MOC 2	MOC 3	MOC 4
10 years	Mean total health care costs	$77, 479	$77, 217	$77, 395	$77, 003
	Mean QALYs gained	6.3801	6.3856	6.3788	6.3857
	Net Monetary Benefit	$241, 527	$242, 063	$241, 547	$242, 283
20 years	Mean total health care costs	$77, 812	$77, 341	$77, 779	$77, 121
	Mean QALYs gained	10.2725	10.2830	10.2701	10.2833
	Net Monetary Benefit	$435, 812	$436, 811	$435, 725	$437, 043
30 years	Mean total health care costs	$77, 953	$77, 393	$77, 942	$77, 170
	Mean QALYs gained	12.5134	12.5279	12.5100	12.5283
	Net Monetary Benefit	$547, 715	$549, 003	$547, 560	$549, 242

Conclusion: Decentralized models of care using GP (MOC4) and mixed consultant nurse model (MOC2) were cost effective ways of promoting HCV treatment uptake.

Email: adrianapalom@gmail.com

Background and aims: Anti-HBc+ subjects are at risk of HBV reactivation when undergoing immunosuppression. Some studies have shown that anti-HBs titles < 100mUI/L are associated with a higher rate of reactivation. Our aim was to assess the immunogenicity of HBV vaccine in immunocompromised anti-HBc+ patients with anti-HBs < 100mUI/L.

Method: Hepbare is a post-authorization effectiveness study whose primary aim is to assess the immunogenicity of HBV vaccine (anti-HBs > 100mUI/L) in immunocompromised anti-HBc+ adults with low anti-HBs titers. Secondary aim: to assess the efficacy of HBV vaccine to prevent reactivation. Inclusion criteria: immunocompromised subjects HBsAg-/anti-HBc+ with anti-HBs < 100mUI/L and undetectable HBV DNA. Exclusion criteria: previous HBV vaccination or criteria for antiviral prophylaxis (anti-CD20 therapy, chemotherapy, stem cell transplant or anti-HBc+ liver graft). Patients were randomized to control or vaccination group (0-1-2 months, plus booster in case of response or revaccination at double dose if antiHBs < 100 mUI/ml).

Results: To date 65 subjects have been recruited: 65% male, median age 62 years (IQR 50-68), 90% Caucasians, median time of immunosuppression 3 years (IQR 2-7). Conditions: 52% solid organ transplantation, 19% rheumatological, 17% dermatological and 9% IBD. Immunosuppression: 26% monoclonal antibodies, 19% calcineurin inhibitors, 18% purine inhibitors, 16% methotrexate, 14% calcineurin + purines inhibitors. 39% also received corticoids. Randomization: 33 (51%) vaccine and 32 (49%) control group. Baseline, 44% presented anti-HBs < 10mUI/L. In the vaccine group, 58% developed anti-HBs > 100mUI/L after the first vaccination schedule and anti-HBs statistically increased (18 vs 205 mUI/ml, p = 0.05). Response was higher in subjects with basal anti-HBs 10-100 mIU/L than anti-HBs < 10mUI/L (75% vs 20%, p = 0.08). Among non-responders, only 25% developed anti-HBs > 100mUI/L after the second schedule (overall response 64%). Follow-up showed a progressive decrease on anti-HBs levels, with 50% of subjects persisting anti-HBs > 100mUI/L. No changes in anti-HBs were observed in the control group (p = 0.67). To date, no subjects have shown HBV reactivation.

Conclusion: Preliminary analysis of Hepbare showed that 64% of the subjects develop anti-HBs > 100mUI/L after HBV vaccination, although the titers tended to decrease during follow-up. Further data is needed to assess the clinical impact of vaccination on the risk of HBV reactivation.

Outcomes of hepatitis B patients transplanted without hepatitis B immunoglobulin

Sheetal Shah[1], James O'beirne[2], William Rosenberg[3], Esther Gathogo[1], Rachel Westbrook[3]. *[1]Royal Free London NHS Foundation Trust, Pharmacy Department, London, United Kingdom; [2]Sunshine Coast University Hospital, Birtinya, Australia; [3]Royal Free London NHS Foundation Trust, Sheila Sherlock Liver Centre, London, United Kingdom*
Email: tinashah@nhs.net

Background and aims: Hepatitis B immunoglobulin (HBIG) is routinely used in conjunction with nucleoside analogues (NA) following liver-transplantation (LT) in patients with hepatitis B virus (HBV) to reduce the risk of donor graft infection from recipient HBV. This treatment regimen was established prior to the routine incorporation of NA into clinical care. Data are emerging which question the role of HBIG post LT when NA's with a high barrier to resistance are being co-administered.

Method: All patients undergoing LT for HBV related cirrhosis between November 2015-17 were maintained on their NA therapy (Entecavir or Tenofovir). Only those patients with a HBV DNA > 10, 000iu/ml received high dose intravenous HBIG for 8 days in the immediate post-operative period with hepatitis B surface antibody (HBsAb) monitoring. Post LT, HBV DNA and HBsAg status were recorded and compared to a historic cohort treated with both HBIG and NA therapy to assess safety and efficacy.

Results: Over the 2-year period 18 patients with HBV were treated post-LT with the new protocol. Median age was 56-years (31-68 years). All patients were receiving NA therapy at the time of LT and had a HBV DNA of < 10, 000 copies/ml. At the time of LT, 15 patients had an undetectable HBV DNA and the remaining 3 patients had VL of 23, 84, and 23 copies/ml. Patient and graft survival at 1-year was 88% (16/18) and 78% (14/18) respectively. All deaths and graft failure were surgical or sepsis related. Following LT, HBV DNA was undetectable in 94% (15/16) of patients. The patient with detectable HBV was on entecavir, having previously been exposed to lamivudine, on switching to tenofovir viral suppression was achieved. HBsAg status was available in 11/18 patients and negative in 9/11.

Comparison was made to a retrospective control group treated post-LT with both HBIG and NA. This group were matched to age (p = NS), HBV viral load (p = NS), disease severity (UKELD) (p = NS) and indication for LT. Patient and graft survival at 1-year was 100%. Following LT, HBV DNA was undetectable in all patients and HBsAg status was available in 14/18 patients and negative in 13/14.

Conclusion: Omitting HBIG peri- and post-LT in patients with a low viral load appears a safe and effective treatment strategy in this small cohort. The cost of HBIG is £15, 000 per patient which produced a cost saving of £270, 000 in this cohort. Larger and longer term studies are required to confirm this observation.

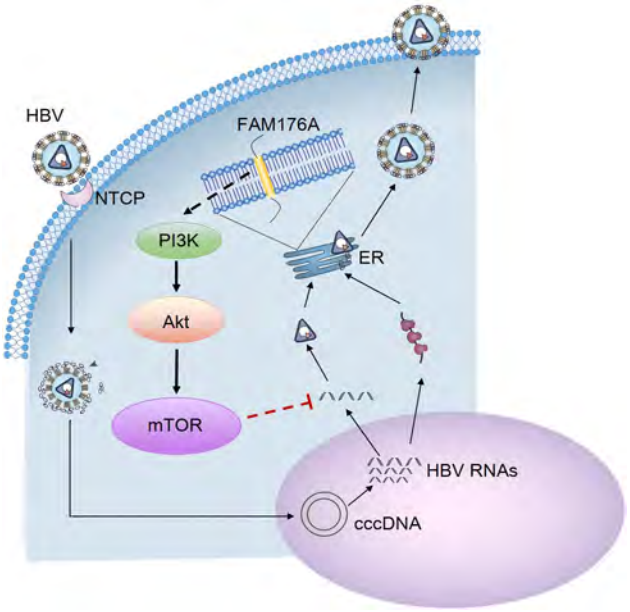
FRI-203

Inhibition of hepatitis B virus replication by FAM176A via activation of PI3K-AKT-mTOR signaling pathway

Jie Yu[1], zhongliang shen[1], Jiming Zhang[1], Youhua Xie[2]. *[1]Huashan sub-hospital of Fudan University, department of infectious disease, Shanghai, China; [2]fudan university, Shanghai, China*
Email: yujie11@fudan.edu.cn

Background and aims: Hepatitis B virus (HBV) replication activity is much higher in immune tolerant phase than in inactive carrier phase, however, the immune responses are comparable between these two phases. We previously reported mRNA levels of several intrahepatic genes were higher in inactive carriers, including FAM176A, MANEAL, TOMM34, ZMYM3, and CSTF2. In these study, we focused on FAM176A and aimed to investigate whether FAM176A inhibits HBV gene expression and replication. If so, the mechanism by which FAM176A regulates HBV needs to be further explored. Current antiviral therapies for chronic hepatitis B (CHB) patients are limited.

We also evaluated whether FAM176A could be used as a candidate for treating CHB.
Method: Histochemistry analysis of FAM176A expression between above two CHB phases; Serial cell models and animal models were used to investigate whether FAM176A regulates HBV replication; RNA sequence analysis of signal pathway involved in FAM176A-mediated HBV regulation; FAM176A functional domain analysis through targeted mutagenesis; CHB mouse models were used for evaluation of FAM176A's antiviral activity based on gene therapy.
Results: FAM176A protein levels are higher in in inactive carrier patients than in immune tolerant patients. FAM176A inhibits HBV gene expression and replication in vitro and in vivo. FAM176A induces activation of PI3K-Akt-mTOR pathway to decay HBV RNA. Transmembrane domain of FAM176A in endoplasmic reticulum is indispensable for FAM176A-mediated antiviral activity. FAM176A is a promising candidate in treating CHB mice.



Conclusion: FAM176A activates PI3K-Akt-mTOR pathway to inhibit HBV replication, and harbors robust potential in treating CHB.

ASPP2: A potential strategy to inhibit HBV replication through reducing hepatocytes autophagy
Ying Shi[1,2,3], Luxin Qiao[2], Yang Wang[2], dexi chen[2]. *[1]Beijing Youan Hospital, Capital Medical University, Beijing Institute of Hepatology, Beijing, China; [2]Beijing Youan Hospital, Capital Medical University, Beijing Institute of Hepatology, Beijing, China; [3]Beijing Youan Hospital, Capital Medical University, Beijing Institute of Hepatology, Beijing, China*
Email: 953898534@qq.com

Background and aims: Hepatitis B virus is such a virus that can induce cell basal autophagy and use cell autophagy to facilitate its own replication. Alteration of hepatocytes autophagy was found to have impacts on cellular HBV replication.
Method: Liver cell models (HepG2, HepG2.2.15 and Hep3B cells) were used to investigate the function of ASPP2 on the autophagy of HBV infected hepatocytes, as well as its indirect effects on HBV replication. GFP-LC3 puncta, autophagy related gene mRNA and protein expressions were used to evaluate the level of cell autophagy.
Results: Overexpression of ASPP2 was found to inhibit HBV induced cell autophagy, thus reduce HBV replication and HBsAg and HBeAg release. This function of ASPP2 on autophagy was prominent in p53-null liver cells (Hep3B cells). Overexpression of ASPP2 reduced Atg7 transcription, whereas reduction of ASPP2 increased Atg7 transcription. Atg7 silence restricted the function of ASPP2 on autophagy reduction evidently.
Conclusion: ASPP2 reduced cell autophagy and inhibited HBV replication by reducing Atg7 transcription in a p53 independent manner. ASPP2 could be a novel strategy to inhibit HBV replication.

FRI-205
Entecavir improves liver function and fibrosis in hepatitis B virus-associated cirrhosis: A 6 years-multicenter study
Seung Kak Shin[1], Oh Sang Kwon[1], Jeong Han Kim[2], Chan Uk Lee[3], Jong Eun Yeon[3], Sang Jun Suh[4], Hyung Joon Yim[4], Yun Soo Kim[1], Ju Hyun Kim[1]. *[1]Gil Medical Center, Gachon University College of Medicine, Department of Internal Medicine, Incheon, Korea, Rep. of South; [2]Konkuk University School of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [3]Korea University Guro Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of South; [4]Korea University Ansan Hospital, Department of Internal Medicine, Ansan, Korea, Rep. of South*
Email: kos@gilhospital.com

Background and aims: Previously we reported that entecavir (ETV) improves liver function and non-invasive fibrosis markers in patients with HBV-associated cirrhosis after 2 years of treatment. This study extended observational period and aimed to confirm that 6 years of ETV treatment continuously improve liver function and fibrosis in patients with hepatitis B virus (HBV)-associated cirrhosis.
Methods: Previously enrolled 283 naïve patients with HBV associated-cirrhosis who completely finished 2 years of ETV study, were treated further by ETV (more than 4 years) between March 2007 and December 2017 in 4 tertiary institutions. Among them, the patients with HCC development (n = 61) and frequently skipping medication (n = 17) were excluded. For the evaluation of liver function or fibrosis, laboratory findings, model for end stage liver disease (MELD) score, Child-Pugh (CP) class, AST platelet ratio index (APRI), FIB-4 index, and liver stiffness measurement (LSM) value on Fibroscan were compared among at baseline, at 2 years, and 6 years after ETV treatment.
Results: A total 205 patients (mean age of 50 ± 9 years; 64.2% of male; 50.2% of HBeAg-positive; mean ALT of 139 ± 205 U/L; mean HBV DNA of 6.9 ± 1.2 $\log_{10}$ copies/ml) were finally enrolled. The ALT normalization rates were 78% at 2 years and 87.3% at 6 years. The undetectable HBV DNA rates were 95.6% at 2 years and 99.0% at 6 years. The HBeAg loss rate was 39% at 2 years and 86% at 6 years. Total bilirubin levels (1.9 ± 2.7 at baseline; 1.2 ± 0.6 at 2 years; 1.1 ± 0.6 mg/dL at 6 years, $P < 0.005$), platelet counts (105 ± 44 at baseline; 109 ± 46 at 2 years; 124 ± 53 x10^3/mm^3 at 6 years, $P < 0.001$), and APRI (3.7 ± 5.4 at baseline; 1.2 ± 1.1 at 2 years; 0.8 ± 0.7 at 6 years, $P < 0.001$) were continuously improved. The distribution of CP class was also continuously improved (A:74.1%, B:21.0%, C:4.9% at baseline; A:92.7%, B:6.8%, C:0.5% at 2 years; A:96.1%, B:3.4%, C:0.5% at 6 years, $P < 0.05$). Albumin levels (3.7 ± 0.6 to 4.2 ± 0.4 g/dL, $P < 0.001$), INR (1.26 ± 0.29 to 1.09 ± 0.12, $P < 0.001$), MELD score (10.9 ± 4.3 to 8.9 ± 3.0, $P < 0.001$), FIB-4 index (6.5 ± 6.4 to 3.6 ± 2.4, $P < 0.001$), and LSM value (28.8 ± 19.8 to 14.5 ± 9.2, $P < 0.001$) were initially improved from baseline to 2 years-treatment. However, the improvement rates of those were very slow after 2 years of ETV treatment.
Conclusion: ETV rapidly improves liver function and fibrosis in patients with HBV-associated cirrhosis after 2 years-treatment. After that, liver function and fibrosis were slowly improved.

Relationship between hepatitis B core related antigen levels and sustained HBeAg seroconversion in patients treated with nucleos (t)ide analogues

Milan Sonneveld[1], Gertine Oord[1], Margo J.H. van Campenhout[1], Robert De Man[1], Harry Janssen[2], Robert De Knegt[1], Annemiek Van Der Eijk[3], Andre Boonstra[1]. [1]*Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands;* [2]*Toronto General Hospital, Division of Gastroenterology, toronto, Canada;* [3]*Erasmus MC University Medical Center Rotterdam, Viroscience, Rotterdam, Netherlands*
Email: m.j.sonneveld@erasmusmc.nl

Background and aims: HBeAg seroconversion experienced during nucleo (s)tide analogue (NUC) therapy is often not sustained. We aimed to study whether hepatitis B core related antigen (HBcrAg) levels predict sustained HBeAg seroconversion.
Method: We studied HBeAg-positive patients treated with NUCs for at least six months. We quantified HBcrAg at baseline and at the time of HBeAg seroconversion and studied the relationship with HBeAg seroconversion and subsequent relapse.
Results: HBcrAg was quantified at baseline in 196 patients (130 treated with entecavir or tenofovir). Baseline HBcrAg levels correlated with HBV DNA (r 0.658, p < 0.001), HBeAg (r 0.738, p < 0.001) and HBsAg (r 0.247, p = 0.001), and varied by HBV genotype (7.30/7.70/8.14/7.65 log U/ml for genotypes A/B/C/D; p = 0.001 by ANOVA). Baseline HBcrAg levels were lower in patients who achieved HBeAg seroconversion (n = 55) than in those who did not (7.42 versus 7.86 log U/ml, p = 0.017); the unadjusted hazard ratio (HR) was 0.802 (95% CI: 0.656-0.980, p = 0.031). The association was however not sustained in multivariate analysis (adjusted HR 0.972, p = 0.883). HBcrAg remained detectable in all patients at the time of HBeAg seroconversion. Higher HBcrAg at the time of HBeAg seroconversion was an independent predictor of subsequent HBeAg relapse (observed in 16 patients; adjusted HR 1.855 (95% CI: 1.099-3.133, p = 0.021). None of the patients with HBcrAg < 4.90 log U/ml (n = 13) experienced relapse. Fifteen patients discontinued treatment after at least 6 months consolidation therapy and 5 (33%) experienced HBeAg relapse subsequently. HBcrAg levels at the time of HBeAg seroconversion were higher in patients who experienced relapse than in those who did not (5.89 versus 5.42 log U/ml, p = 0.039)
Conclusion: Baseline HBcrAg level is not an independent predictor of HBeAg seroconversion during NUC therapy. HBcrAg remains detectable in patients after HBeAg seroconversion. Patients with high HBcrAg levels at the time of HBeAg seroconversion have a high risk of relapse.

Email: kathrin.sprinzl@kgu.de

Background and aims: Infinite duration of nucleos (t)ide (NUC) treatment of chronic hepatitis B (cHBV) prones longterm toxicity. In the prospective BONIKA Study (NCT-Nr. 02267473) hepatitis **B** patients under **o**ral **N**UC treatment undergo **i**ntermittent **k**idney function **a**ssessment with a combination of serum and urine parameters to detect early renal tubular dysfunction (RTD).
Method: Between 10/2014 and 01/2017 in Frankfurt 179 mono-infected HBV patients under NUC treatment consented and were regularly screened for RTD by analyses of serum phosphate (**sPh** < 2, 6 mg/dl)), serum uric acid (**sUA** < 3, 4 mg/dl), urine alpha-1 microglobuline (**uMG** > 12 mg/l) and urine glucosis (uGlc positive). By definition a RTD is diagnosed when at least 2 of the above abnormalities are given. Here a subgroup of patients with NUC treatment changes till 05/2018 was monitored over 12 months after switching.
Results: In this subcohort of 179 patients under NUC-treatment (115 Tenofovir Disoproxil [TDF]/47 Entecavir [ETV]/12 Lamivudine [LAM]/5 other NUCs) a total of 20 patients had a treatment switch. 10 patients were switched due to deterioration of renal tubular function (2x Fanconi syndrome, 7x RTD per definition, 1x proteinuria + elevated creatinine). All these 10 patients were on treatment with TDF before switching. 9 patients were changed to ETV and one to Tenofovir Alafenamide (TAF). Renal parameters were further monitored (see table 1). Viral replication was persistently suppressed after switch to ETV/TAF. 10 patients were switched for other reasons (6x insufficient viral suppression, 1x family planning, 1x elevated liver enzymes, 1x patient wish, 1x gastrointestinal side effects) to either TDF or ETV.
Conclusion: Relevant RTD requiring a change in treatment was only observed under TDF treatment. Switching to ETV in case of RTD improves the renal condition and shows reliable viral suppression. Serum phosphate is normalizing, but tubular proteinuria often persists in case of progressed RTD, which emphasizes the relevance of early detection of RTD.

Median (*m*)	Prä-switch	3 months post-switch	6 months post-switch	1 year post-switch	p prä-switch vs 1 y post switch

Email: martin.sprinzl@unimedizin-mainz.de

Background and aims: Addition of pegylated interferon alfa-2a (Peg-IFN) to an ongoing NUC therapy accelerates HBsAg decline and clearance in patients with chronic hepatitis B (cHB). However, decision for Peg-IFN should be well-balanced, as its drug-related side effects are more frequent compared to nucleos (t)ide treatment. Here we report about predictors of treatment response from the PADD-ON study to guide treatment decision

Method: HBeAg-negative cHB patients (HBsAg > 100 IU/ml) under effective NUC treatment for ≥ 1 year were randomized to receive additional Peg-IFN (180 µg/week) for 48 weeks (Peg-IFN group, n = 112) or continuing NUC monotherapy (control group, n = 58) in a prospective open-label phase IIb study (EudraCT-Nr: 2011-002812-10). The modified intention-to-treat (mITT) population (n = 165), covering ≥ 1 post-baseline HBsAg assessment is reported. Primary response after 48 weeks of treatment was defined by reduction of ≥ 1log10 in serum HBsAg concentration compared to baseline. Secondary end points were HBsAg seroconversion and overall HBsAg concentrations. Adverse events (AEs) were assessed. Predictors for treatment response were analysed by multivariate cox regression. Fisher's Exact test#, T test$, chi2-test§.

Results: Primary response (HBsAg log drop) was achieved in 24.5% (n = 26/110) of the Peg-IFN group compared to 1.9% (n = 1/55) in the control group (p < 0.0001#). Six patients (5.5%) in the Peg-IFN group developed an HBsAg-seroconversion, whereas none occurred in the control group (p > 0.05#). In the Peg-IFN group HBsAg loss was observed in 15.8% (n = 16/110), whereas the control group failed HBsAg clearance (p < 0.05§). Most patients (94.6% in the Peg-IFN- and 58.6% in the control- group) experienced at least one AE. No death was reported.

Multivariate analysis confirmed the treatment group (p = 0.0038§) and baseline HBsAg < 1000 U/ml (p = 0.0002§) as predictors for the primary response. HBsAg loss was associated with the treatment group (p = 0.0014), baseline HBsAg < 1000 U/ml (p = 0.042§) and overall NUC treatment duration (p = 0.048§). Anti-HBsAg seroconversion only correlated with baseline HBsAg < 1000 U/ml (p = 0.047§) and overall NUC treatment duration (p = 0.041§). In all explorative settings gender, age, serum transaminases, liver function as well as the NUC regimen (tenofovir versus entecavir) had no impact on treatment response.

Conclusion: The addition of Peg-IFN to an ongoing NUC regimen accelerates HBsAg reduction in comparison to standard NUC therapy of HBeAg negative cHB patients. Particularly patients with longer NUC pre-treatment duration and lower baseline HBsAg levels show better response rates.

FRI-209

Exploring TH1/TH2 adjuvants to improve the efficacy of the therapeutic vaccination against chronic hepatitis B

Jinpeng Su[1], Anna Kosinska[1], Livia Brunner[2], Julia Sacherl[1], Géraldine Frank[2], Katrin Singethan[1], Julia Hasreiter[1], Frank Thiele[1], Nicolas Collin[2], Ulrike Portzer[1]. *[1]Institute of Virology, Technical University of Munich/Helmholtz Zentrum München, Munich, Germany; [2]Vaccine Formulation Laboratory, University of Lausanne, Lausanne, Switzerland*

Email: protzer@tum.de

Background and aims: With the limitation of current treatments to cure HBV infection, therapeutic vaccination becomes an interesting new strategy to treat chronic hepatitis B. To this end, we have developed a therapeutic hepatitis B vaccine, termed *TherVacB*, which is based on two protein immunizations using particulate, recombinant HBV S and core antigens (HBsAg, HBcAg) and a boost using a modified vaccinia virus Ankara (MVA) vector expressing HBV antigens. We found success of therapeutic vaccination largely depends on an appropriate adjuvant for the protein priming, which simultaneously generates neutralizing antibody responses and elicits potent CD4 and CD8 T-cell responses.

In order to improve the efficacy of our *TherVacB* regimen, we composed and investigated a series of novel HBsAg/HBcAg adjuvants formulations based on either liposomes, or squalene-in-water emulsion enriched by saponin QS21 and optionally by monophosphoryl lipid A (MPL).

Method: Firstly, HBsAg/HBcAg adjuvants formulations were tested for their stability and antigen integrity *in vitro*.Afterwards, the immunogenicity of selected adjuvants formulations was evaluated in the C57BL/6 wild type and AAV-HBV transduced mice, where persistent HBV replication was established. In addition, the secreted cytokine profiles by *in vitro* re-stimulated splenocytes were determined to assess the adjuvant effects on Th1/Th2 immune response pattern.

Results: Six selected vaccine formulations proved to be stable and antigens remained intact for at least 2 weeks. Immunogenicity study in naive mice showed the new formulations elicited not only very high anti-HBs levels, but also robust HBV-specific CD4 and CD8 T-cell responses outcompeting previously tested adjuvants. In AAV-HBV mice, immunization with four most promising liposomal as well as non-liposomal formulations resulted in a 3-log decrease in serum HBsAg levels, accompanied by very high anti-HBs titers. In addition, high percentages of IFNγ-secreting HBV-specific T cells were detected in the livers of mice after immunization with most of the novel HBsAg/HBcAg formulations. After immunizations, overall 40-70% decrease in serum HBeAg and numbers of HBV-positive hepatocytes was shown. The highest antiviral effect was observed for the optimized liposomal formulation containing QS21 and MPL. *Ex vivo* stimulation of isolated splenocytes with HBV antigens resulted in

detection of not only IFNγ, but also IL4 and IL5, suggesting that the new vaccine formulations induced a balanced Th1/Th2 response in mice. Similarly, immunizations elicited comparable HBsAg-specific IgG1 and IgG2a antibody levels. Last but not least, all vaccine formulations were safe and well tolerated.
Conclusion: The liposome based adjuvant formulations improved the efficacy of therapeutic vaccination in chronic hepatitis B mouse models, and thereby are promising candidates for the *TherVacB* regimen.

FRI-210

Establishment of high rates of functional cure of HBeAg negative chronic HBV infection with REP 2139-Mg based combination therapy: Ongoing follow-up results from the REP 401 study

Michel Bazinet[1], Victor Pantea[2], Gheorghe Placinta[2], Iurie Moscalu[3], Valentin Cebotarescu[2], Lilia Cojuhari[2], Pavlina Jimbei[4], Liviu Iarovoi[2], Valentina Smesnoi[4], Tatiana Musteata[4], Alina Jucov[2,3], Adalbert Krawczyk[5], Andrew Vaillant[1,1]. *[1]Replicor Inc., Montreal, Canada; [2]Nicolae Testemițanu State University of Medicine and Pharmacy, Department of Infectious Diseases, Chișinău, Moldova; [3]Arensia Exploratory Medicine, Republican Clinical Hospital, Chișinău, Moldova; [4]Toma Ciorbă Infectious Clinical Hospital, Chișinău, Moldova; [5]Universitätsklinikum Essen, Institute for Virology, Essen, Germany*
Email: availlant@replicor.com

Background and aims: The REP 401 study (NCT02565719) is assessing the safety and efficacy of REP 2139-Mg (clinical lead) or REP 2165-Mg combined with tenofovir disoproxil fumarate (TDF) and pegylated interferon α-2a (pegIFN) in Caucasian patients with HBeAg negative chronic HBV infection.
Method: Lead-in TDF therapy in 40 patients was followed by randomization into an experimental group (48 weeks of TDF, pegIFN and REP 2139-Mg or REP 2165-Mg) or an adaptive control group (24 weeks of TDF + pegIFN followed by cross over to 48 weeks of experimental therapy). All patients were subsequently entered into a treatment-free follow-up scheduled for 48 weeks. Viremia is monitored on the Abbott Architect and Realtime platforms.
Results: Baseline HBsAg was > 1000 IU/ml in all patients and 14775.7 ± 9302 and 9018 ± 8743 IU/ml in adaptive control and experimental groups. Therapy was well tolerated except for one withdrawal due to pegIFN-related depression. Two additional participants withdrew where therapy was well tolerated. Antiviral responses between REP 2139-Mg and REP 2165-Mg were indistinguishable and not related to HBV genotype or HBsAg, ALT or fibrosis (Fibroscan) at baseline. Following the introduction of TDF, HBV DNA was well controlled in all patients during therapy. Following the introduction of NAPs, HBsAg reduction was > 1 log in 36/40 patients and became < 1 IU/ml in 28/40 and < 0.05 IU/ml in 24/40 participants. Transaminase flares occurred in 38/40 patients and were correlated with reductions in HBsAg, were self-resolving during therapy and not accompanied by any evidence of liver dysfunction. Transaminase flares were especially pronounced (400-1748 U/L) in patients where HBsAg became < 1 IU/ml and were accompanied by profound elevations in anti-HBs (up to 255, 055 mIU/ml).
As of the date of submission, treatment-free follow-up has been extended to 24 or 48 weeks in 34/40 patients completing treatment. Persistent and stable inactive chronic HBV (HBV DNA < 2000 IU/ml with normal ALT) is present in 15/34 (44%) of participants. An additional 14/34 (41%) participants have functional cure (HBsAg and HBV DNA target not detected). Liver function has normalized in 94% of patients (versus 47% at baseline) and median hepatic stiffness consistent with F0 (≤ 7kPa) is present in 81% of patients (versus 52% at baseline).
Conclusion: A finite REP 2139-Mg based combination therapy with TDF and pegIFN is well tolerated and results in a high proportion of patients achieving control of infection not requiring further therapy under current guidelines. Transaminase flares appear therapeutic in nature and may reflect an immune mediated clearance of infected hepatocytes essential in establishing persistent control of chronic HBV infection.

FRI-211

Evaluation of the safety and tolerability of transaminase flares during antiviral therapy in patients with HBeAg negative chronic HBV infection or HBV/HDV co-infection

Michel Bazinet[1], Victor Pantea[2], Gheorghe Placinta[2], Iurie Moscalu[3], Valentin Cebotarescu[2], Lilia Cojuhari[2], Pavlina Jimbei[4], Liviu Iarovoi[2], Valentina Smesnoi[4], Tatiana Musteata[4], Alina Jucov[2,3], Adalbert Krawczyk[5], Andrew Vaillant[1]. *[1]Replicor Inc., Montreal, Canada; [2]Nicolae Testemițanu State University of Medicine and Pharmacy, Department of Infectious Diseases, Chișinău, Moldova; [3]Arensia Exploratory Medicine, Republican Clinical Hospital, Chișinău, Moldova; [4]Toma Ciorbă Infectious Clinical Hospital, Chișinău, Moldova; [5]Universitätsklinikum Essen, Institute for Virology, Essen, Germany*
Email: availlant@replicor.com

Background and aims: The onset of transaminase flares during antiviral therapy of chronic HBV infection or HBV/HDV co-infection is an important consideration in the pursuit of functional cure of HBV and HDV infection. The high proportion of transaminase flares observed during NAP-based therapy in HBV infection (REP 401 study NCT02565719) or HBV/HDV co-infection (REP 301 study NCT02233075) affords a unique opportunity to evaluate factors predicting transaminase flares during therapy, the tolerability of different flare geometries during therapy and how flares correlate with antiviral response during therapy and the establishment of functional cure.
Method: Data from all 52 participants from the REP 301 (12) and REP 401 (40) studies were included in the analysis. Baseline data used in the analysis was HBsAg, ALT, AST, GGT and median hepatic stiffness (MHS, as measured by Fibroscan). Serial on-therapy biochemistry data included ALT, AST, GGT, Alk. Phos, bilirubin, albumin, INR and MHS at the end of treatment and during follow-up. Serial virologic data included HBsAg, anti-HBs, HBV DNA and HDV RNA.
Results: Three different transaminase flare geometries were observed during therapy: a single flare self-resolving during therapy, a single flare with a persistently elevated transaminase tail during therapy and a "double" flare with two distinct peaks.
Flare geometries, transaminase maxima or transaminase AUC during therapy were not correlated with baseline HBsAg, ALT, AST, GGT or MHS (up to 30.7 kPa in this participant population). No alterations in bilirubin, albumin or INR were observed with any flares and patients were asymptomatic throughout these flares including the absence of jaundice. Increased MHS at end of therapy was asymptomatic and correlated with transaminase AUC but decreased or normalized during follow-up.
The occurrence of transaminase flares was correlated with the introduction of pegIFN in patients who experienced HBsAg reduction and was more pronounced in patients where HBsAg reduction became < 1 IU/ml. Flares were also accompanied by pronounced increases in circulating anti-HBs during therapy. The strength of transaminase flares was also correlated with the establishment of functional cure of HBV or HDV or the establishment of inactive chronic HBV.
Conclusion: Transaminase flares are very common during NAP-based therapy of HBV infection or HBV/HDV co-infection and appear well tolerated, suggesting that in the context of these infections, transaminase flares can occur without impacting liver function. Flares are also correlated with HBsAg reduction, increases in circulating anti-HBs and the establishment of functional control/cure of HBV and HDV infection, suggesting they are a component of a restored immunological control of these infections.

FRI-212

HBV RNA can be detected more frequently than HBcrAg but decreases during long term treatment with nucleos (t)ide analogues up to 14 years in patients with HBeAg negative chronic hepatitis B

Florian van Bömmel[1], Danilo Deichsel[1], Alessandro Loglio[2], Floriana Facchetti[2], Maria Pfefferkorn[1], Martin Brehm[3], Thomas Berg[1], Pietro Lampertico[2]. [1]*University Hospital Leipzig, Department for Gastroenterology and Rheumatology, Section of Hepatology, Leipzig, Germany;* [2]*University of Milan, CRC "A. M. e A. Migliavacca" Center for Liver Disease, Division of Gastroenterology and Hepatology, Fondazione Irccs Ca" Granda Ospedale Maggiore Policlinico, Milan, Italy;* [3]*Laborpraxis Dessau, Dessau-Roßlau, Germany*
Email: florian.vanboemmel@medizin.uni-leipzig.de

Background and aims: Hepatitis B virus (HBV) RNA is a new serological marker that correlates with intrahepatic cccDNA. HBV RNA levels were shown to remain detectable in HBeAg positive patients in spite of suppression of HBV DNA by treatment with nucleos (t)ide analogues (NAs). However, in HBeAg negative patients the kinetics of HBV RNA during long term NA treatment are yet unknown. The aim of our study was to examine whether HBV RNA may still be detectable after long term treatment with NA and how it correlates with other HBV replication markers.
Method: A total of 96 patients with HBeAg negative chronic HBV infection (mean age 65 ± 9 [range, 40-84] years, 74 (77%) male, 50 (52%) with liver cirrhosis, 96 (100%) HBV genotype D) who had achieved undetectable HBV DNA levels for > 8 years (mean 117 ± 32 [range, 71-172] months) during NA treatment were retrospectively analyzed. All had achieved normal ALT during NA treatment over at least 6 years. Thirty-four patients (35%) had achieved undetectable HBV DNA for longer than 10 years. The current treatment consisted either of tenofovir (TDF, n = 90) or entecavir (ETV, n = 6) and had been conducted for a mean duration of 89 ± 11 [range, 43-119] months. HBV biomarker levels were measured from 288 serum samples stored at –20°C at the time points year 4, 7 and 10-14 (mean 117, range 120-172 months) of undetectable HBV DNA during NA treatment. HBV RNA was quantified after reverse transcription using a specific real-time PCR (LOD 160 copies/ml), HBV DNA by real time PCR (Roche, LOD 9 IU/ml), HBcrAg and HBsAg by ELISA (Lumipulse G, Fujirebio, LOQ 3 log U/ml and Abbott Architect, LOD 0.05 IU/ml, respectively).
Results: HBV RNA levels were above the LOD at years 4, 7 and 10-14 in 32%, 18% and 5% of samples by a mean of 2.8 ± 0.8 (2.2-5), 2.6 ± 0.5 (2.2-4), and 2.3 (2.2-4) $\log_{10}$ copies/ml. Mean HBsAg levels 3.1 ± 0.5 (1.3-4.3), 2.7 ± 0.6 (0.9-4.2) and 2.5 ± 0.7 (0.6-4.1) while HBcrAg levels were below LOQ in all but 4 samples. Correlation of HBV RNA with HBsAg levels was weak at all time points (r = 0.1, 0.2 and 0.1, respectively). Detection of HBV RNA was not associated with HBsAg levels, patient age, presence of cirrhosis, development of hepatocellular carcinoma (p = n.s.).
Conclusion: In HBeAg negative patients achieving long term suppression of HBV DNA during NA treatment HBV RNA can frequently be detected even after long treatment periods, but its quantity seems to decline over time. More sensitive detection methods for HBV RNA should be validated for its characterization as HBV replication marker on long term NA treatment.

FRI-213

HBV RNA at 6 months predicts HBeAg loss in nucleos (t)ide analogue treated HBeAg positive patients: Demonstration of clinical utility?

Bo Wang[1], Jeffrey Gersch[2], Mary Horner[1], Mary Kuhns[2], Gavin Cloherty[2], Geoffrey Dusheiko[1,3], Kosh Agarwal[1], Ivana Carey[1]. [1]*King's College Hospital, Institute of Liver Studies, London, United Kingdom;* [2]*Abbott Laboratories, Illinois, United States;* [3]*UCL Medical School, London, United Kingdom*
Email: bo.wang@nhs.net

Background and aims: HBeAg loss in patients with HBeAg-positive chronic hepatitis B is an important treatment end point and a pre-requisite for functional cure. Only around half of patients achieve HBeAg loss after five years of treatment with nucleos (t)ide analogues (NUC), despite nearly all achieving profound HBV DNA suppression. It is still unclear, but critical to understand, whether newer biomarkers differentiate patients who will achieve serological end points such as HBeAg loss. In this single-centre retrospective longitudinal cohort study, we evaluated HBV RNA and hepatitis B core-related antigen (HBcrAg) concentrations in NUC treated HBeAg-positive patients, with the aim of characterising differences that predict HBeAg loss.
Methods: Consecutive HBeAg-positive patients started on NUC therapy in 2012 with adequate stored serum samples were analysed. Baseline characteristics included age, sex, HBV genotype, ALT and liver fibrosis assessment by transient elastography or histology. Serum from baseline, 3, 6 and 12 months into NUC therapy and last follow-up were tested for HBV DNA, quantitative hepatitis B surface antigen (HBsAg), HBcrAg and HBV RNA concentrations.
Results: 28 patients received treatment with tenofovir disoproxil fumarate. After median follow-up of 64 months, 17 patients (61%) achieved HBeAg loss and 26 patients (93%) were HBV DNA negative. There were no significant differences at baseline between patients who subsequently lost HBeAg and those who remained positive. There was a strong correlation at baseline between HBV DNA and HBcrAg (r = 0.862, p < 0.001), and HBV DNA and RNA (r = 0.704, p < 0.001). This correlation was subsequently lost with treatment.
During treatment, median HBV DNA and quantitative HBsAg were similar between the groups at all time points (Figure 1). In contrast, early differences in HBcrAg concentrations were seen at 3 months (p = 0.019) and HBV RNA at 6 months (p = 0.006); by last follow-up, patients who achieved HBeAg loss had significantly lower HBcrAg and HBV RNA levels (median HBcrAg 5.8 vs 3.8 logU/ml, p = 0.026; median HBV RNA 3.94 vs. 0.83 logU/ml, p < 0.001). HBV RNA decline from baseline at 6 months was greater in those who achieved HBeAg loss (p = 0.038). Furthermore, HBV RNA decline had good predictive value for HBeAg loss; a 1 logU/ml decline at 6 months had a positive predictive value of 71.4% and area under the receiver operating curve of 0.747.
Conclusion: In this study, HBV RNA decline after 6 months of NUC therapy predicted HBeAg loss with good performance. HBV RNA decline presents an important goal for novel therapies, with HBV RNA suppression potentially being associated with favourable treatment end points.

FRI-214

Novel hepatitis B virus X gene mutants emerge during antiviral therapy to increase covalently closed circular DNA accumulation conferring pseudo-drug-resistance and increaing hepatocellular carcinoma risk

Chau-Ting Yeh[1], Yu-De Chu[1], Rong-Nan Chien[2], Chih-Lang Lin[2]. [1]*Linkou Chang Gung Memorial Hospital Hospital, Taoyuan, Taiwan;* [2]*Keelung Chang Gung Memorial Hospital, Keelung, Taiwan*
Email: chautingy@gmail.com

Background and aims: Hepatitis B virus (HBV) × (HBx) gene mutants have been found in late stage HBV infection and play a critical role in hepatocarcinogenesis. However, little is known about whether HBx mutants can emerge during long-term antiviral therapy to adapt for antiviral drug-induced stress. The aim of this study was to identify and characterize previously unrecognized HBx mutants developed in patients conferring lamivudine (LAM) resistance or suboptimal response to entecavir (ETV).
Method: From January 2006 to December 2012, 46 patients with phenotypic and genotypic LAM resistance and 6 with suboptimal response to ETV were enrolled. HBx gene was sequenced. The identified HBx mutants were characterized in hepatocytes. Patients were followed until development of hepatocellular carcinoma (HCC) or loss-to-follow-up.

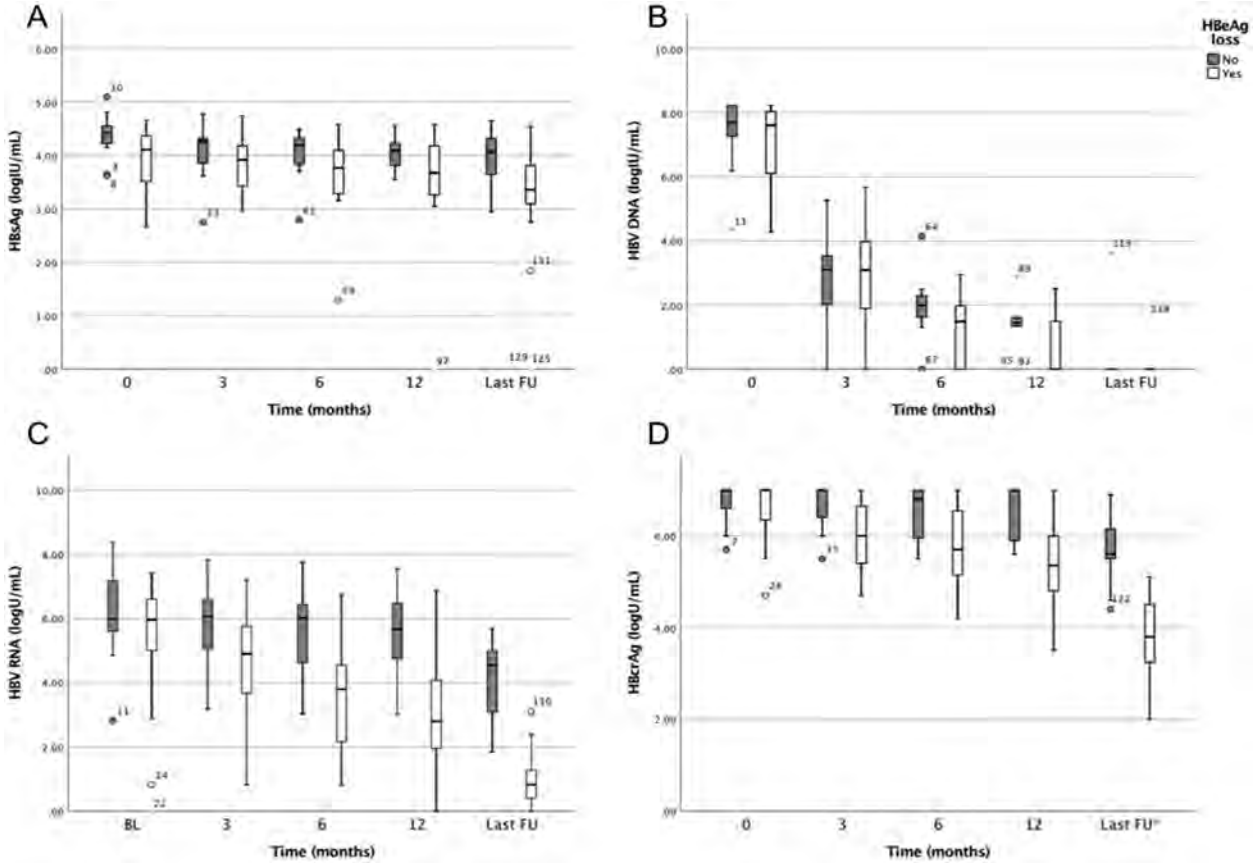

Figure 1: (abstract: FRI-213): Box plots of HBsAg (A), HBV DNA (B), HBV RNA (C) and HBcrAg (D) concentrations during treatment with nucleos (t)ide analogues in HBeAg-positive patients (*last FU; median duration 64 months).

Results: HBx sequence analysis identified novel HBx mutants, including 15 with asynonymous mutations, 11 with deletion mutations and 2 with insertion mutations. Transactivation assays showed that these HBx mutants manifested a significant decrease of transactivation ability on pre-S1 promoter with an increase of transactivation ability on HBx promoter. Transfection of plasmids expressing HBx mutants into HepG2 cells containing a replication-competent clone resulted in altered intracellular small to large and middle surface protein ratios, increased nuclear fractions of core protein, increased nuclear-to-cytoplamic HBV-DNA ratios, and increased covalently closed circular DNA (cccDNA). Consequently, antiviral drug sensitivity assays revealed a pseudo-drug-resistance phenotype. Longitudinal follow-up for these patients revealed that 5 patients developed HCC. Characteristics of HBx mutations shared by these HCC patients were analyzed.

Conclusion: In conclusion, novel HBx mutants emerged during LAM or ETV therapy. They manifested an altered transactivation activities on HBV pre-S1 and X promoters, leading to increased nuclear fractions of core protein, HBV-DNA, and cccDNA, which conferred a drug-resistance-like phenotype. Some of these mutants might be responsible for subsequent development of HCC.

Background and aims: Besifovir dipivoxil maleate (BSV) is an acyclic nucleotide phosphonate with a potent antiviral activity against hepatitis B virus (HBV). An antiviral efficacy of BSV for forty-eight week was shown to be comparable to tenofovir disoproxil fumarate (TDF) with improved renal and bone safety. We evaluated the efficacy and safety of BSV in treatment-naïve chronic hepatitis B patients in 144 weeks follow-up study.
Method: After 48 weeks of double-blind comparison of BSV to TDF, patients continued to participate in the open-label BSV study. We evaluated antiviral efficacy and drug safety for both BSV group (BSV-BSV) and the group switched from TDF to BSV (TDF-BSV) up to 144 weeks. The primary end point was the proportion with HBV DNA < 400 copies/ml (virological response).
Results: Among 197 patients who received randomized treatments, 170 (87%) patients entered the open-label phase, and 153 (78%) completed 144 weeks of the study. The virological response rate of those who have taken BSV over 144 weeks is 87.65% while 92.11% of patients who switched the treatment from TDF were respondent (p = 0.36). HBeAg seroconversion and ALT normalization rates were similar between the groups. There were no drug resistant mutations to BSV and no adverse events related to bone mineral density or renal function.
Conclusion: BSV maintained efficacy in both suppression of HBV DNA and ALT normalization over 144 weeks without any evidence of resistance to BSV. Also, BSV is safe, well tolerated, and effective for those who have switched to BSV from TDF.

Email: gudwns21@korea.ac.kr

Background and aims: For the management of multidrug resistant (MDR) chronic hepatitis B (CHB), tenofovir (TDF) monotherapy or tenofovir plus entecavir (ETV) or tenofovir monotherapy for MDR CHB has been suggested However, long term data comparing TDF monotherapy and TDF plus entecavir are limited. Herein, we report a multicenter cohort study for the evaluation of TDF-based therapy for MDR CHB.
Method: The inclusion criteria were CHB patients with resistance to more than 2 nucleos (t)ide analogues and hepatitis B virus (HBV) DNA level over 200 IU/ml. Patients with decompensated cirrhosis or hepatocellular carcinoma were excluded. Primary end point was cumulative virologic response defined by undetectable HBV DNA (< 20 IU/ml) until month 60.
Results: A total of 256 patients were enrolled and 230 patients were included for analysis. Mean age of patients were 49 years and 77.8% were male. Mean baseline HBV DNA level was 4.2 ± 1.4 log IU/ml. Genotypic resistance to L-nucleoside analogues (L-NA)+adefovir (ADV) (75 patients), L-NA+ETV (103 patients), L-NA+ADV+ETV (50 patients) were confirmed at enrollment.
Initial treatments for MDR CHB were TDF monotherapy (n = 52) or TDF+ETV combination therapy (n = 178). Virologic response rates of the whole cohort at year 1, year 2, year 3, year 4, and year 5 were 77.4%, 87.0%, 90.1%, 89.2%, and 92.2%, respectively. At year 5, virologic response rate was not significantly different between the TDF monotherapy group and TDF-based combination group (87.5% vs. 92.9%, respectively, p = 0.499 by Fisher's exact test). The cumulative virologic response rate of TDF monotherapy was not significantly different at year 5 (96.2% vs. 97.8%, respectively, p = 0.881), and was not inferior to combination therapies considering that 95% confidence interval (−3.3% ~ 6.5% at year 5) did not include the 10% of non-inferiority margin.
Conclusion: TDF based therapy was effective for the treatment of MDR CHB for during 5 years of follow-up. The efficacy of TDF monotherapy was not inferior to the TDF based combination therapy.

FRI-217

Safety, antiviral activity, and pharmacokinetics of a novel hepatitis B virus capsid assembly modulator, JNJ-56136379, in Asian and non-Asian patients with chronic hepatitis B

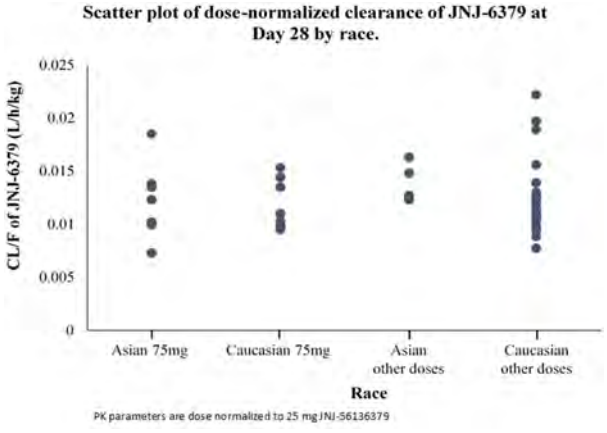
Email: jeysen.yogaratnam@hotmail.com

Background and aims: The capsid assembly modulator, JNJ-56136379 (JNJ-6379), was well tolerated in healthy volunteers and patients with chronic hepatitis B (CHB) in a first-in-human study. Significant antiviral activity was observed in patients with CHB at doses up to 250 mg QD (NCT02662712). Here we compare safety, antiviral activity, and pharmacokinetics of JNJ-6379 in Asian and non-Asian patients with CHB.
Method: Non-cirrhotic, treatment-naïve, HBeAg-positive or -negative patients with CHB were enrolled to receive single daily doses of JNJ-6379 of 25, 75, 150 or 250 mg, or placebo, for 4 weeks with 8 weeks' follow-up. 57 patients participated in European and Asian sites across doses. There were two 75 mg groups; 12 patients (8 JNJ-6379:4 placebo) in European sites, and 9 patients (7:2) in Asian sites.
Results: In the overall study population, 14 patients were Asian, and 38 were Caucasian. All patients were Caucasian in the 75 mg European group, and Asian in the 75 mg Asian group. There were 3 Asian patients in the 25 mg group, and 1 in each of the 150 mg and 250 mg groups.
Amongst patients treated with the 75 mg dose, 57% in the Asian group and 50% in the European group reported an AE. No serious AEs or deaths occurred.
After 4 weeks dosing at 75 mg, mean (SD) HBV DNA decreased by 2.89 (0.48) $\log_{10}$ IU/ml in the Asian group, and by 2.92 (0.58) $\log_{10}$ IU/ml in the European group; serum HBV DNA was below the lower limit of quantification for the assay for 2 and 3 patients, respectively.
Mean apparent clearance was lower in the 75 mg Asian group (0.754 L/h) compared to the 75 mg European group and other dose groups (mean apparent clearance ranged from 0.928 to 0.982 L/h). This resulted in higher dose normalized C_{max} and AUC values in the 75 mg Asian group than the 75 mg European group. However, after correction for body weight, CL/F was comparable between Caucasian and Asian patients (Figure). Dose-proportionality was observed over the entire dose range of 25 mg to 250 mg QD. Mean $t_{1/2}$ was long, and similar for all dose groups, ranging from 103.3 to 148.0 hours.



Conclusion: JNJ-6379 was well tolerated, and resulted in similar pharmacokinetics over the entire dose range. Antiviral effects were comparable in Asian and non-Asian CHB patients receiving daily 75 mg doses for 4 weeks. These data support further evaluation of the same dose of JNJ-6379±nucleos (t)ide analogs in a larger cohort of patients at European and Asian sites in a Phase 2a study (NCT03361956).

FRI-218

Dynamic changes of serum hbv pgrna levels in patients with chronic hepatitis B treated with entecavir or peg-interferon

Xiaoqi Yu[1], Demin Yu[1], Peizhan Chen[2], Qiming Gong[3], Xinxin Zhang[1,2].
[1]Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Research Laboratory of Clinical Virology, shanghai, China; [2]Ruijin Hospital North, Shanghai Jiao Tong University School of Medicine, Translational Medicine Research Center, shanghai, China; [3]Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Department of Infectious Diseases, shanghai, China
Email: xin-xin-zhang@163.com

Background and aims: Serum hepatitis B virus (HBV) pregenome RNA (pgRNA) levels may independently predict virological and serological response during antiviral therapy. This study aimed to find the correlation between serum HBV pgRNA levels and other biomarkers, further investigate the dynamic changes of serum HBV pgRNA levels and its clinical significance during treatment.
Method: A real-time polymerase chain reaction (PCR) was developed for quantitative analysis. HBV pgRNA levels were retrospectively determined in serial serum samples from 136 patients with chronic HBV infection who have received entecavir or peg-interferon treatment. Receiver operating characteristics (ROC) analysis was performed to evaluate the prediction value in HBeAg seroconversion of individual biomarkers.
Results: The mean serum HBV pgRNA level was 6.41 [1.94] copies/ml at baseline, which was higher in HBeAg-positive patients of 7.20 [1.54] copies/ml than in HBeAg-negative patients of 4.60 [1.51] copies/ml ($p < 0.001$). Baseline HBV pgRNA levels correlate strongly with HBV DNA levels ($r = 0.82$, $p < 0.001$), moderately with HBsAg levels ($r = 0.69$, $p < 0.001$), and weakly with serum alanine aminotransferase ($r = 0.28$, $p < 0.05$). Peg-IFN treatment induced a stronger decline in HBV pgRNA level from baseline to week 4 of 1.36 [1.28] copies/ml, to week 24 of 2.20 [1.48] copies/ml, and to week 48 of 2.87 [1.53] copies/ml in comparison to entecavir (ETV) monotherapy ($p < 0.05$). ETV treated patients with HBeAg seroconversion showed a stronger decline in HBV pgRNA level at week 4, 12, 24 and 48. At baseline, the area under ROC (AUC) of HBV pgRNA was 0.68, comparable to those of HBV DNA (AUC = 0.66) and HBsAg (AUC = 0.64) in ETV treated patients; however, in peg-IFN treated parents, the AUC of HBV DNA was highest in predicting seroconversion, followed by HBV pgRNA and HBsAg (AUC = 0.63 and 0.60, respectively). No significant difference was noted for AUCs among these biomarkers ($p > 0.05$). During treatment, the best prediction of HBeAg seroconversion in ETV treated patients was HBV pgRNA at week 4 (AUC = 0.71, the corresponding cut-off value, sensitivity, specificity, PPV and NPV were 7.95 log10copies/ml, 83%, 56%, 40%, 91%), while in peg-IFN treated patients, HBV pgRNA level at week 24 allowed the best prediction (AUC = 0.70, the corresponding cut-off value, sensitivity, specificity, PPV and NPV were 3.55 log10copies/ml, 89%, 62%, 44%, 94%).
Conclusion: Serum HBV RNA levels may serve as a brand new biomarker in the evaluation of patients with chronic HBV infection during antiviral therapy.

RO7049389, a core protein allosteric modulator, demonstrates robust decline in HBV DNA and HBV RNA in chronic HBV infected patients

Edward Gane[1], Man-Fung Yuen[2], Qingyan Bo[3], Christian Schwabe[4], Tawesak Tanwandee[5], Sudip Das[6], Yuyan Jin[3], Lu Gao[3], Xue Zhou[3], Yifan Wang[3], sheng feng[3], dominik meinel[7], mingfen zhu[3]. [1]*The University of Auckland, Auckland, New Zealand;* [2]*The University of Hong Kong, Hong Kong, China;* [3]*Roche Innovation Centre Shanghai, Shanghai, China;* [4]*Auckland Clinical Studies, Auckland, New Zealand;* [5]*Mahidol University, Bangkok, Thailand;* [6]*Roche Products Limited, Shire Park, United Kingdom;* [7]*Roche Innovation Centre Basel, Basel, Switzerland*
Email: edgane@adhb.govt.nz

Background and aims: RO7049389 is a small molecule, Class I HBV core protein allosteric modulator (CpAM) resulting in formation of aberrant core protein aggregates. RO7049389 is expected to interrupt viral assembly, inhibit HBV replication, and potentially restore host immune response to HBV. RO7049389 effectively suppresses HBV replication in in-vitro cell-based assays and in-vivo animal models.
Method: The ongoing Phase I study investigates the safety, tolerability, pharmacokinetics (PK) of RO7049389 and explores the anti-HBV effects in untreated chronic HBV infected patients.
Results: The safety, PK and tolerability data from SAD and MAD in healthy volunteers (HV) has been previously reported (EASL 2018). PK, safety and pharmacodynamic data are presented from 3 proof of mechanism cohorts in chronic HBV infected patients: 200 mg BID (n = 7) and 400 mg BID (n = 7) with standard meal and 600 mg QD fasted (n = 7) for 28 days.
Patients had a similar PK profile to that of HVs with no evidence of accumulation in C_{max} and AUC_{tau} of RO7049389.
Substantial decline in HBV DNA and RNA was shown in all POM cohorts (Table 1). HBV DNA was reduced to below the lower level of quantification (HBV DNA < 20IU/ml) in 8/18 patients who took active drug. No viral breakthrough during dosing was observed. There were no significant changes in the HBsAg or HBeAg antigen level during 28 days of dosing.
Overall, blinded data review showed similar safety profile in both HVs and patients. A total of 39 adverse events (AEs) were reported in 14 of 22 HBV patients, 3 patients had treatment emergent Grade 3 ALT/AST increase which resolved without treatment in follow-up. One pre-dose SAE was reported and the patient was replaced. No AEs leading to drug discontinuation were reported and no clinically significant changes in any safety parameters tested were observed.

Table:

Table1:Median decline (range) from baseline	200mg BID	400mg BID	600mg QD
HBV DNA log10 IU/ml	2.7 (0.6–3.4)	3.2 (2.2–5.3)	2.9 (2.0–3.7)
HBV RNA log10 copies/ml	1.6 (0-2.5)	2.3 (0-4.0)	Pending

Conclusion: RO7049389 demonstrated robust anti-HBV activity over 28 days of dosing in patients with chronic HBV infection and is well tolerated. This agent will be further evaluated in combination with other agents.

FRI-220

Antiviral effect and predictors of hepatitis B surface antigen seroconversion in children of 1-6 years old with chronic hepatitis B

Min Zhang[1]. [1]*The Fifth Medical Center of General Hospital of PLA, Children's liver Disease Department, Beijing, China*
Email: gcmw2001@163.com

Background and aims: This study was aimed to observe the long-term antiviral therapeutic outcome in patients with chronic HBV infection and explore the factors related to HBsAg sero-conversion in children of 1-6 years old.

Method: Two hundred and thirty six children aged 1-6 years old with chronic hepatitis B were admitted to the Children's liver Disease Department from January 2012 to May 2018, and were enrolled into our study. After follow-up study, all the data were collected and a retrospective analysis was performed. Meanwhile, the clinical data of 148 patients aged 7-18 years old were also collected and analyzed as control.
Results: 1) A total of 384 patients with chronic HBV were enrolled. Among them, 236 patients were 1-6 years old, 148 patients were 7-18 years old. The positive rate of HBeAg in two groups was 90.8% and 85.5%, respectively. In 1-6 years old group, 44.5% achieved HBsAg seroconversion and the mean seroconversion time was 60.8 ± 42 weeks; in 7-18 years old group, 6.9% achieved HBsAg seroconversion and the mean seroconversion time was 114.8 ± 70.5 weeks. 2) In the baseline, the numbe of total lymphocytes、T cell、CD4+T cell、B cell in peripheral blood of HBsAg seroconversion patients at the age of 1-6 years old were higher than that of 7-18 years old patients ($p < 0.05$). 3) The number of CD4+T cell、B cell in peripheral blood of HBsAg seroconversion patients at the age of 1-6 years old were higher than that of HBsAg non-seroconversion patients ($p < 0.05$). 4) In group 1-6 years old, the age of treatment、sex、HBeAg、AST、the number of peripheral total lymphocytes、T cell、CD4+T cell、B cell were significantly associated with the achievement of HBsAg seroconversion by univariate analysis. 5) Among children aged 1-6 years, only the age of treatment was significantly associated with the achievement of HBsAg seroconversion by multivariate analysis.
Conclusion: The age of treatment was a predictor for HBsAg seroconversion, higher HBsAg seroconversion rate can be obtained before 6 years old. The detection of peripheral lymphocyte subsets has certain clinical predictive value for understanding the immune status and disease outcome of patients.

Viral hepatitis C: Clinical aspects except therapy

Email: stephanie.coulon@merck.com

Background and aims: The new generation of oral direct-acting antivirals (DAAs) demonstrate both high efficacy and high

tolerability. However, none of the DAAs are completely free of drug-drug interactions (DDIs), which can significantly alter the drugs exposure, efficacy and toxicity. The aim of the study was to describe the use of comedications and the changes made before starting DAA treatment and assessing prevalence of patients at risk for potential DDIs.

Methods: 405 patients were included in an observational study at 11 centers in Belgium from Jan17 till Oct17. Data were collected on patients' characteristics, previous and most recent HCV treatment, comorbidities (MedDRA), comedications (ATC code) and changes made in comedications at start of DAA treatment. Patients received following DAAs: EBR/GZR; OBV/PTV/r±DSV; SOF/DCV; SOF/LDV; SOF/VEL. Potential clinically relevant DDIs were assessed based on information available at www.hep-druginteractions.org.

Results: Median age was 55 years, 60.5% were male, and 20.5% were cirrhotic. Patients were treated with SOF/VEL (31.1%), EBR/GZR (27.4%), SOF/DCV (26.4%), OBV/PTV/r±DSV (8.4%) or SOF/LDV (6.7%). Most common comorbidities were arterial hypertension (27.2%), HIV co-infection (22.5%) and type 2 diabetes mellitus (14.3%). Ninety percent of the patients took comedications, ranging from 1 to 16 per patient. The predominant therapeutic classes were psycholeptics (28.6%), antivirals for systemic use (24.2%) and drugs for acid related disorders (21%). Of the 365 patients on comedications, 20.3% required an adaptation of their comedication. Drugs used for acid related disorders (31%) and antiviral drugs (33%) were most frequently changed prior to DAA treatment. Lipid modifying agents (43%) and drugs for acid related disorders (21%) were most frequently stopped. Modifications to the comedications of patients at the start of their DAA treatment decreased the risk for potential clinically relevant DDIs from 34% (136/405) to 22% (91/405). Patients treated with EBR/GZR (11%); SOF/DAC (19%) and SOF/VEL (22%) were the least exposed to potential clinically relevant DDIs. Patients treated with SOF/VEL underwent the most adaptations (29%) to their medication scheme compared to patients treated with EBR/GZR (12%).

Conclusion: This study suggest that physicians are aware of potential DDIs between comedications and DAAs but that there is still a clear gap between the clinical practice and the theoretical recommendations.

FRI-222

Redundancy of elastography in mono-infected HCV individuals less than 30 years old -Development of Dillon's Rule

Paul Brennan[1], Asthika Amirthalingam[2], Emma Robinson[3], John Dillon[3]. *[1]University of Dundee, Department of Molecular and Clinical Medicine, Dundee, United Kingdom; [2]University of Dundee, School of Medicine, Dundee, United Kingdom; [3]University of Dundee, Department of Molecular and Clinical Medicine, Dundee, United Kingdom*
Email: Brennap9@gmail.com

Background and aims: The Hepatitis C Virus (HCV) is a blood-borne, causing chronic infection, defined as the persistence of HCV RNA for at least 6 months after initial infection. Chronic HCV infection predisposes individual patients to liver fibrosis, cirrhosis and hepatocellular carcinoma. Of those with chronic HCV infection; it is estimated that 16–20% of individuals will go on to develop liver cirrhosis within 20 years.

There has been a revolution in the treatment of chronic HCV infection with almost universal cure. The issue is now to minimise the steps required to start treatment, especially as we seek to treat younger more difficult to engage groups. Currently fibrosis is assessed before starting treatment. We sought to validate the theory that those individuals who were mono-infected with HCV; young and with no additional hepatic insult were unlikely to have significant fibrosis.

Method: We performed a retrospective analysis of the Tayside Hepatitis C dataset; with collation of relevant basic demographics including age, sex and baseline Fibroscan© measurements pre-treatment. Previous validation of transient elastography (TE) in HCV has suggested that a cut off of less than 11kPa would significant fibrosis.

Results: Our complete cohort consisted of 719 individuals with HCV who had elastography performed before undergoing HCV therapy. We stratified for age across 5 year intervals. The results are summarized in the figure below.

Within this patient cohort we established that no patient under 30 had a TE score > 9 kPa without a co-existent history of hazardous alcohol consumption; and only a single individual within the 31–35 group had a fibroscan > 11kPa in absence of hazardous alcohol ingestion or co-infectivity with a hepatotropic virus.

Age Range	*Total (n =) (M/F)*	*Transient Elastography (Mean; Range)*	*Transient Elastography > 9kPa*	*Transient Elastography > 11kPa*
< 30 Years	99 (62/37)	5.71 (3.2–10.6)	1	0
30–35	111 (82/29)	8.9 (2.1–26.6)	6	4

Conclusion: Going forward we therefore propose that those patients < 30 years old do not necessitate elastography prior to treatment. The vast majority of patients between 30 and 35 years (> 95% in our dataset) are also likely to be suitable for treatment without elastography in the absence of other co-existent factors for fibrosis; most notably alcohol in this cohort.

Contribution of HBV and HCV infection in mortality of B-NHL subjects

Myagmarjav Budeebazar [1], Delgerbat Boldbaatar[1], Sukhbaatar Myadagsuren[2], Tungalag Saruul[2], Uurtsaikh Baatarsuren[3], khishigjargal Batsukh[2], Erdeenetsogt Dungubat[4], Andreas Bungert[3], Altankhuu Mordorjyn[5], Dahgwahdorj Yagaanbuyant[5], Duger Davaadorj[4], Naranbaatar Dashdorj[3,5], Naranjargal Dashdorj[3,5]. *[1]Liver Center, Ulaanbaatar, Mongolia; [2]First Central Hospital of Mongolia, Ulaanbaatar, Mongolia; [3]Onom Foundation, Ulaanbaatar, Mongolia; [4]Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia; [5]Liver Center, Ulaanbaatar, Mongolia*
Email: b.myagmarjav@onomfoundation.org

Background and aims: Lymphoma, especially the Non-Hodgkin's B Lymphoma (B-NHL) is one of the globally prevalent type of cancer with rapidly increasing prevalence. Hepatitis B and C virus (HBV, HCV) is found to increase the risk of NHL development with some geographical differences. Mongolia is a country with very high prevalence of HBV, HCV and HBV/HDV infection. However, it is not known if the viral hepatitis infections are higher in the B-NHL subjects and if these chronic infections affect the survival of the B-NHL subjects. In this study we aim to determine the prevalence of HCV, HBV and HBV/HDV among the B-NHL subjects and its influence on the survival rate of these patients.

Method: We have done a retrospective analysis of patients diagnosed with B-NHL, at the Hematology Center of the First State Hospital of Mongolia between 2015 and 2017. Patients were divided into two groups with survival rate less and more than 12 months, after being diagnosed with B-NHL and comparatively analyzed by age group, Ann Arbor staging of lymphoma and HBV, HCV infection. HBV and HCV prevalence of B-NHL patients were compared with general population survey results.

Results: Overall, 178 B-NHL patients (77 males, 101 females) with average age 53.9 were enrolled in the study. In total, 24 (13.5%) patients had HBV infection and 13 (7.3%) had HBV/HDV double infection which was similar to the general population prevalence. However, HCV prevalence among B-NHL subjects was 5 times higher

than the general population prevalence (Table 1). As shown in Table 1, 46 (25.8%) subjects had survival rate less than 12 months after being diagnosed with B-NHL including 15 (19.5%) in B-NHL group without viral hepatitis infection, 5 (20.8%) in HBV positive B-NHL group, and 26 (33.8%) in HCV positive B-NHL group. Furthermore, HCV positive B-NHL group mortality rate was doubled in comparison to B-NHL group without viral hepatitis infection in Ann Arbor stages.

Table 1: B-NHL groups by Ann Arbor staging comparing with general population prevalence

	B-NHL group without HBV or HCV		HBsAg positive B-NHL group		Anti-HCV positive B-NHL group	
	Ann Arbor		Ann Arbor		Ann Arbor	
Survival rates	1 and 2	3 and 4	1 and 2	3 and 4	1 and 2	3 and 4
≤ 12 months	2 (6.4%)	13 (28.2%)	0	5 (33.3%)	3 (13%)	23 (42.5)
> 12 months	29 (93.6%)	33 (71.8%)	9 (100%)	10 (66.7%)	20 (87%)	31 (57.5%)
Total	31 (100%)	46 (100%)	9 (100%)	15 (100%)	23 (100%)	54 (100%)
Total n/ (%)	77/ (43.3%)		24 (13.4%)		77 (43.3%)	
Healthy people	930/1158 (80.3%)		128/1158 (11.1%) HDV pos 77/128 (60%)		100/1158 (8.6%)	

Conclusion: Our study demonstrated very high prevalence of HCV among B-NHL subjects, but the prevalence of HBV and HBV/HDV infection rate was similar to the general population. In addition, 12 months' survival rate of B-NHL patients is negatively affected by the hepatitis C but not by the HBV infections as shown in Table 1. These results indicate that clinicians need to pay extra attention to the B-NHL patients with chronic HCV infections.

FRI-224

Reaching out to the undiagnosed people with hepatitis C infection in Belgium: A pilot study

Dana Busschots[1,2], Rob Bielen[1,2], Özgür Koc[1,2,3], Eefje Dercon[1,4], Tessa Windelinckx[5,6], Griet Maertens[5,6], Stefan Bourgeois[7], Catharina Mathei[5,8], Geert Robaeys[1,2,9]. *[1]Hasselt University, Faculty of Medicine and Life Sciences, Hasselt, Belgium; [2]Ziekenhuis Oost-Limburg, Departement of Gastroenterology, Genk, Belgium; [3]Maastricht University Medical Centre, Medical Microbiology, School of NUTRIM, Maastricht, Netherlands; [4]Center for Alcohol and other Drugs (CAD) Limburg, Hasselt, Belgium; [5]Free Clinic ngo, Antwerp, Belgium; [6]Harm Reduction, coordinator Needle Exchange, Antwerp, Belgium; [7]ZNA Antwerp, Departement of Gastroenterology, Antwerp, Belgium; [8]University Hospitals KU Leuven, Department of Public Health and Primary Care, Leuven; [9]University Hospitals KU Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium*
Email: dana.busschots@uhasselt.be

Background and aims: Whereas the prevalence of hepatitis C virus (HCV) infection in the general population is low (0.57%), data for HCV antibody (Ab) prevalence in Belgium show rates of 60-80% in people who inject drugs (PWID). Despite the severe health and economic burden, targeted screening is not yet broadly executed in Belgium, and if executed for PWID, it is mostly focussed on PWID receiving opiate substitution therapy. In this pilot study we want to reach subgroups who are often completely isolated from care such as young opiate injectors and amphetamine injectors. By contacting the community of drug injectors, we want to outreach to PWID who avoid drug treatment centers, using the screening for HCV as a bridge to re-integration in society.

Method: The participants were recruited by outreaching. For this pilot study we organised three screening events in Antwerp and Hasselt, Belgium. The location of these events were communicated in advance, using posters and flyers to inform possible candidates and planned in accordance with the local authorities, health care workers, pharmacists and general practitioners. Possible candidates were 18 years of age or older, were not in follow-up at Freeclinic Antwerp or CAD Limburg and had a history of drug use. The eligible candidates were tested by fingerprick for HCV Ab using the Oraquick® test. While waiting on the results (20 minutes), an encoded questionnaire was filled out and a Fibroscan® was performed to score the grade of fibrosis. Participants received a fee of 10 euros.

Results: During the first three screening days at Hasselt, 96 persons were included. Of those participants 24 (25.0%) tested HCV Ab positive using the fingerprick test. One result was false positive after blood analyses. Out of the 23 (24.0%) HCV Ab positives confirmed by blood sample, five (21.7%) persons were not aware of their HCV Ab status. In total, 15 out of 23 (65.2%) were HCV RNA positive. Whereas three are starting treatment, the remaining 12 (80.0%) could not be treated yet due to the strict reimbursement criteria in Belgium. In Antwerp 26 persons were screened of whom two (7.7%) tested positive for HCV Ab.

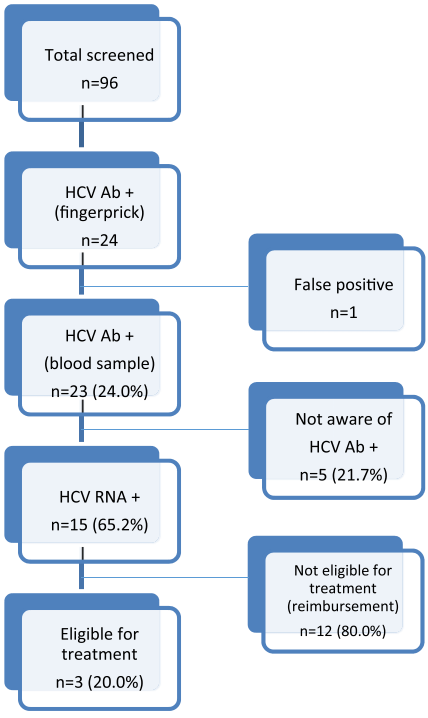

Figure: Results of three days screening in Hasselt, Belgium

Conclusion: The outreach method does work in Belgium and allows to reach isolated subgroups. However, the Belgian reimbursement criteria remain a burden in treating those screened and potentially new diagnosed people. This pilot project will be continued and validated by another team in Belgium during the next year.

FRI-225

Universal access to direct-acting antivirals treatment is not not enough to prevent late stage presentation of hepatitis C infection

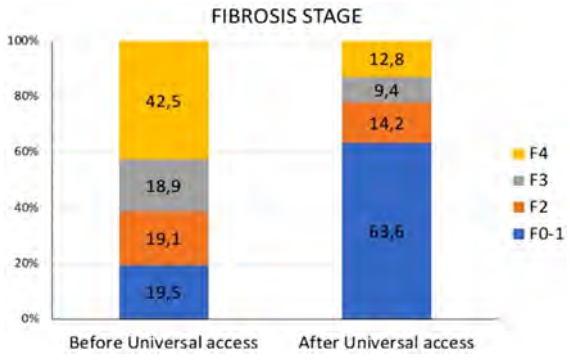
Email: joweycabezas@gmail.com

Background and aims: Hepatitis C virus (HCV) infection is asymptomatic for a long period of time. Previous antiviral treatments in the period prior to direct antiviral agents (DAA) had low efficacy and many side effects. Therefore, patients were typically referred and treated by the hepatologist in advanced stages. Nowadays, The National Strategic Plan for HCV in Spain, from July 1st 2017, allows universal access to treatment with DAAs with no restrictions.
To study the application of the national plan and its impact in the management of new HCV infected patients. To describe features of this group with no restrictions to be treated.
Method: Hepa-C database is the National registry of HCV patients, directed by the Spanish Association for the Study of the Liver. Naive patients from the Hepa-C cohort who were treated with DAA were included in the study. Only the first antiviral treatment was analyzed. Data collected from May 2011 to present time was analyzed.



Results: We included 6053 naïve HCV infected patients. Before the universal access to DAA, 61.8% of the whole cohort started treatment (Group A). This group included 61.4% patients with advanced fibrosis (F3 or greater). Patients treated during non-restriction period (Group B) showed lower proportion of advanced fibrosis, 22.2% ($p < 0.001$). Regarding this group with advanced fibrosis, we found a high proportion of patients with advanced liver diseases (clinical signs of cirrhosis or portal hypertension, and/or previous liver decompensation or hepatocellular carcinoma [HCC]), 55.6% [group A] vs 31.2% [group B] ($p < 0.001$). Including these patients with advance liver disease, there is a significant decline in the proportion of subjects presenting with esophageal varices (group A, 56.9% vs group B, 38.9%, $p < 0.001$), hepatic encephalopathy (A- 11.3% vs B- 5.3%, $p = 0.05$) and HCC (A- 9.6% vs B- 5.3%, $p = 0.002$).
Conclusion: There is a clear switch in fibrosis stage and liver disease features at the time of starting HCV treatment triggered by a wide access to DAA. Despite this policy allowing universal access to DAA antiviral treatment in Spain, there is still a significant number of patients who are diagnosed and treated with advanced fibrosis stages (F3-4). This issue may suggest the importance of establishing universal screening programs for the detection of cases in earlier stages of liver disease.

FRI-226

Modeling early viral kinetics during observed HCV acute infection in post lung transplantation recipients

Upendra Kumar[1], Rafaela Ribeiro[2], Susan Uprichard[1], Marcos Galasso[2], Marcos Cypel[3], Atul Humar[3], Scott Cotler[1], Harel Dahari[1], Jordan Feld[2]. *[1]Loyola University Medical Center, Maywood, United States; [2]University of Toronto, Toronto, Canada; [3]University Health Network, Toronto, Canada*
Email: harel.dahari@gmail.com

Background and aims: Lung transplantation from HCV-infected donors to uninfected recipients allows a unique opportunity to evaluate very early HCV kinetics during acute infection. The aim of this study was to use agent-based modeling to characterize viral-host dynamics from infection to steady state in immunosuppressed transplant recipients.
Method: HCV^+ donor lungs were transported in cold static preservation, placed on normothermic ex-vivo lung perfusion for 6 h, and transplanted into HCV-uninfected recipients. HCV was tested daily for 1 week, then weekly for 12 weeks. Detailed viral kinetics are currently available for 16 of the 21 participants, of whom 7 (3M, 4F) reached HCV steady-state prior to antiviral treatment, which was initiated at 21 days (median) post-transplant. In the model, hepatocytes are represented as individual agents with the introduction of free virus into the blood. When uninfected agents are exposed to HCV, they become infected and enter an eclipse phase in which they do not secrete virus. Infected hepatocytes then proceed to a productive phase in which they release virions that go on to infect additional cells/agents. Viral and host parameters were defined based on trial design, measured kinetics and previous estimates.
Results: HCV had 3 kinetic phases: (i) lower plateau (i.e. viral eclipse), (ii) amplification and (iii) steady state. The viral eclipse phase (median 2 log IU/ml) lasted for about 2 days. Individual viral amplification kinetics (phase ii) could be stratified into rapid ($n = 2$) and slow ($n = 5$) viral spread groups with median slopes of 1.03 vs 0.46 log IU/ml/day, reaching viral plateau (median 6.22 vs 7.76 log IU/ml) at 7 vs 14 days post infection, respectively. Preliminary modeling simulations reproduce the HCV kinetics pattern well when: (1) the eclipse phase lasts between 10 and 48 hours, (2) a median initial transmitted HCV viral load of 4 log IU/ml is predicted, and (3) the following parameters were assumed to be different in the rapid vs. slow HCV spread patients: (i) ~4-fold higher HCV infection rate, (ii) ~1 day shorter production cycle with HCV reaching its max production, in a given infected cell, within ~3 vs ~4 days pi, and (iii) ~7/10-fold lower steady state production rate (~7 vs 10 virions/h) assuming the same number of infected cells at steady state.
Conclusion: HCV exhibits a simple infection pattern (i.e. viral eclipse, exponential amplification, culminating in viral steady state) that provides a framework to understand viral-host dynamics in acute HCV infection. We hypothesize that observed interpatient variability in kinetic parameters may be related to differences in innate antiviral responses among patients. Considering the relatively small amount of HCV expected to be introduced into the recipient from the perfused

lung, the surprising high initial transmitted virus load predicted by the model (4 log IU/ml) also needs further investigation.

FRI-227

Interleukin-6 −174G/C genotype and interleukin-10 ATA haplotype are associated with clinical comorbidities in chronic hepatitis C patients

Cliviany Borges da Silva[1], Diego Alves Vieira[1], Luciana Rodrigues da Cunha[1], Adriana Dias Gomes[2], César Lúcio Lopes de Faria, Jr [2], Rosângela Teixeira[1,3], Gifone Aguiar Rocha[2], Dulciene Maria Magalhães Queiroz[2], Juliana Maria Trindade Bezerra[1], Luciana Diniz Silva[1,3]. *[1]Faculdade de Medicina da Universidade Federal de Minas Gerais, Viral Hepatitis Ambulatory, Instituto Alfa de Gastroenterologia, Hospital das Clínicas, Belo Horizonte, Brazil; [2]Faculdade de Medicina da Universidade Federal de Minas Gerais, Laboratory of Research in Bacteriology, Belo Horizonte, Brazil; [3]Faculdade de Medicina da Universidade Federal de Minas Gerais, Internal Medicine, Belo Horizonte, Brazil*
Email: lucianadinizsilva@gmail.com

Background and aims: Patients with chronic hepatitis C (CHC) have both higher prevalence of diabetes mellitus type 2 and increased cardiovascular risk compared to individuals without the infection. More recent studies have pointed that an imbalance between pro-inflammatory and anti-inflammatory cytokines might induce some extrahepatic manifestations. Taking into account the scarcity of data about the influence of cytokine gene polymorphisms on the clinical comorbidities such as diabetes and hypertension (high blood pressure), we determined the genotypic and allelic frequencies of the Interleukin (IL) *IL6* (−174G/C), *IL*-10 (−1082G/A), *IL*-10 (−592A/C) and *IL*-10 (−819C/T) single nucleotide polymorphisms (SNP), and their association with clinical characteristics in CHC patients.
Method: In this cross sectional study, we prospectively enrolled 255 consecutive CHC patients and 186 age- and sex-matched healthy blood donors who underwent a detailed clinical evaluation. *IL*6 and *IL*10 SNP polymorphisms were evaluated by Taqman SNP genotyping assay. The *IL*10 haplotypes GCC, ACC and ATA are associated with high, intermediate and low production of IL-10, respectively. The *IL*6-174GG and −174GC genotypes are associated with higher IL-6 plasma levels but, the genotype −174CC is linked to a low production of this cytokine. Plasma concentrations of IL-6 and IL-10 were determined using the Human Th1/Th2 Cytometric Bead Array kit. Multivariate analysis evaluated the associations. The study was approved by the Ethics Committee of UFMG.
Results: The frequencies of the *IL*6 and *IL*10 SNPs did not differ between the CHC patients and controls. Diabetes mellitus was independently associated with the IL6-174G/C (OR = 0.40; 95%CI = 0.21-0.77; $P = 0.006$) and hypertension (OR = 7.00; 95%CI = 3.38-14.49; $p < 0.001$). *IL*10 ATA haplotype was associated with liver cirrhosis (OR = 2.23; 95%CI = 1.03-4.86; $P = 0.04$). The median [interquartile range (IQR)] of IL-6 plasma levels [8.94 (6.34-11.97) vs. 6.44 (5.60-7.74) pg/ml; $p < 0.001$] was significantly higher in patients with cirrhosis than in those without cirrhosis.
Conclusion: The *IL*6-174G/C and *IL*10 ATA haplotype provoke an imbalance between pro-inflammatory and anti-inflammatory cytokines, which may influence the clinical course of hepatitis C and CHC-related extrahepatic comorbidities.

FRI-228

Community-based hepatitis C treatment of people who inject drugs and their injecting network is feasible and effective: Results from the TAP (Treatment And Prevention) study

Joseph Doyle[1,2,3], Paul Dietze[1,3], Mark Stoove[3], Peter Higgs[3,4], Paul Desmond[5,6], David Iser[5], Emma Mcbryde[7], Brendan Harney[2], Alisa Pedrana[3], Tim Spelman[3], Sally Von Bibra[3], Janine Roney[2], Alexander Thompson[5,6], Margaret Hellard[1,2,3]. *[1]Monash University, Melbourne, Australia; [2]Alfred Health, Infectious Diseases, Melbourne, Australia; [3]Burnet Institute, Melbourne, Australia; [4]La Trobe University, Melbourne, Australia; [5]St. Vincent's Hospital Melbourne, Melbourne, Australia; [6]University of Melbourne, Melbourne, Australia; [7]James Cook University, Townsville, Australia*
Email: joseph.doyle@monash.edu

Background and aims: People who inject drugs (PWID) are at risk of hepatitis C virus (HCV) infection and transmission of HCV within their injecting network. However, many barriers have limited engagement of PWID in specialist-led care. The HCV Treatment and Prevention (TAP) Study aimed to test the feasibility and effectiveness of treating PWID and their injecting partners concurrently in community settings using a nurse-led model of care.
Method: The TAP Study is a community-based trial using a networks-based approach to treatment (clinicaltrials.gov, NCT02363517). Eligible PWID were those with chronic HCV mono-infection, who injected drugs in the same time and place with ≥ 1 person in the previous six months. Participants were randomised to receive sofosbuvir/velpatasvir treatment individually, or concurrently with their HCV-infected injecting partners. Participants were recruited via mobile street-based vans or primary health clinics. Nurses performed study assessments including FibroScan and venepuncture, and delivered treatment from the mobile clinic after case discussion with clinical investigators. We report pooled SVR12+ (co-primary outcome) and treatment uptake. Follow-up to 72 weeks post-treatment for reinfection incidence by randomised group (co-primary outcome) is ongoing.
Results: The TAP Study screened 336 PWID and enrolled 241 participants; 114 primary participants with 127 injecting partners. Median age of participants was 39 years (range 20-59 years), most were male (167, 69%), unemployed (189, 78%), had previously been incarcerated (144, 60%), and 22% (52) reported unstable housing. Treatment was commenced in 93 (85%) primary participants and 37 (55%) viraemic injecting partners; prior incarceration was associated with failing to enroll or start treatment. There were no study or drug related serious adverse events. In per-protocol analysis, among 130 participants who started treatment, 114 had HCV RNA measured at or after SVR12, and 96 (84%) achieved SVR12+. There were six known relapses, two non-responders, three unspecified treatment failures and 10 confirmed reinfections. During 98 person years of follow-up to date, reinfection incidence is 10.2/100 person years. In modified intention to treat analysis, 74% achieved SVR12+, mostly due to failure to attend for assessment.
Conclusion: Nurse-led HCV treatment for active PWID is feasible and effective for community-based active PWID. Recruiting and treating injecting partners is challenging but is potentially an important model to interrupt HCV transmission-longer follow-up is needed before assessing the randomised impact of treatment on reinfection.

FRI-229

Reflex testing in patients with chronic hepatitis C in Spain improves healthcare outcomes and is cost effective

Federico Garcia Garcia[1], Raquel Dominguez[2], Juan Carlos Alados Arboledas[3], Marta Casado[4], Juan Macias Sanchez[5], Francisco Téllez Pérez[6], Juan Manuel Pascasio[7], Miguel Ángel Casado[8]. *[1]Department of Microbiology, Hospital Universitario San Cecilio. Email: fegarcia@ugr.es

Background and aims: To achieve the goal towards hepatitis C virus (HCV) elimination proposed by the World Health Organization

(WHO), interventions to improve testing, facilitate linkage and treatment are necessary. Our analysis estimated the impact on healthcare and economic outcomes of reflex testing in chronic HCV diagnosis (single blood sample, one-step diagnosis) in Andalucía, Spain (8.39 million people), from a National Health System perspective.

Method: A decision tree model was developed to estimate the impact on detection, referral to specialists, loss of follow-up and access to treatment comparing one-step diagnosis versus standard diagnosis, in which HCV viremia is not investigated in the first visit. A total of 269, 526 individuals were estimated to be screened for HCV (67% outpatient and 33% inpatient care). In both scenarios, diagnosis was based on HCV antibody testing, HCV-RNA (viral load) and genotyping. Patient follow-up included: initial visit, diagnosis testing, referral or not to specialists and, where appropriate, treatment. The unit costs (€, 2018) of the health resources were obtained from databases of the Andalusian Health Service. The pharmacological cost was not considered. All data for the model were obtained from literature or, if not available, from an Expert Panel.

Results: In the analysis, a total of 2, 830 individuals of the tested population would be detected as positive for HCV antibody, of whom 1, 876 would be HCV-RNA+ve. From this population, using one-step diagnosis, 1, 389 chronic HCV patients were referred to specialised care (1, 320 treated) and 1, 063 patients (1, 009 treated) with standard diagnosis. No HCV-RNA-ve patient were referred to specialist using one-step diagnosis versus 540 with standard diagnosis. Compared to one-step diagnosis, using standard diagnosis 63% more patients were not referred to specialists and 30% more patients were considered a lost to follow-up. When compared reflex testing to standard diagnosis, savings of €184, 928 linked to one-step testing are obtained, and savings of €3, 634 per patient with HCV-RNA+ referred to specialised care.

Conclusion: Reflex testing simplifies the HCV diagnosis procedure, enhancing linkage to care as more patients with chronic infection are identified and treated, making better use of healthcare outcomes, and contributing to achieve the WHO HCV elimination target. In addition, reflex testing would generate economic savings to the Health System.

FRI-230

Rapid starts to stop hepatitis C: Same day hepatitis C treatment starts enhancing patient engagement and follow-up in a vulnerable, treatment naïve group living with hepatitis C

Shawn Greenan[1], George Carruthers[2,3], Lisa Barrett[2,4,5]. [1]*Health PEI, Charlottetown, Canada;* [2]*Dalhousie University, Halifax, Canada;* [3]*Memorial University of Newfoundland, St. Johns, Canada;* [4]*Nova Scotia Health Authority, Halifax, Canada;* [5]*Canadian Center for Vaccinology, Halifax, Canada*
Email: lisa.barrett@nshealth.ca

Background and aims: Hepatitis C virus (HCV) elimination requires alternate care models for key populations. Beyond diagnosis, engaging people in HCV treatment that leads to treatment completion and cure is one of the greatest barriers to HCV elimination. Human immunodeficiency virus (HIV) research has demonstrated better HIV and non-HIV health care engagement with rapid, same day treatment start. Our aim is to determine if rapid access to HCV treatment improves engagement in HCV and non-HCV health care.

Method: Prince Edward Island, Canada is a Canadian province with a Phase 2 provincial, coordinated HCV elimination program. Patients are identified and referred to the program through the public health department, community providers, or "bring a friend" strategies. Program staff facilitate baseline blood work, do pre-visit drug-drug interaction checks, and book a first appointment within 1-2 weeks of bloodwork. Treatment naïve patients without contraindications are offered glecaprevir/pibrentasvir treatment at the first visit. Self-reported medication adherence, side effects, sustained virological response (SVR12), and attendance at scheduled opioid substitution therapy (OST) clinic visits are recorded.

Results: Patients assessed between February and October 2018 were included. 102 patients were referred and 73 (71.5%) were seen for initial visits. 71/73 (97.2%) treatment naïve individuals started treatment, 67/71 (94.3%) on the first visit. Of those who attended the first visit and did not start immediately, 5 had medication interactions requiring adjustment, and 1 person was pregnant. There were 3 discontinuations for non-HCV related medical reasons, and 1 person was lost to follow-up before SVR. To date, all 52 people past the treatment completion date finished treatment, and 23/32 have documented SVR12 (9 people did not have SVR12 bloodwork but completed full treatment course). Importantly, individuals with difficulty attending opioid substitution clinic (OST) appointments before HCV treatment had improved attendance at appointments after HCV treatment start. Attendance at other health care appointments was variably improved. No safety issues were noted.

Conclusion: Rapid treatment start is safe, and has a very high rate of successful HCV and non-HCV care engagement. Same day, first visit HCV treatment start should be explored as an HCV elimination tool.

FRI-231

Hostel-based models can improve the engagement of homeless individuals with liver services: VALID (vulnerable adults liver disease) study

Ahmed Hashim[1,2], stephen bremner[2], Lucia Macken[1,2], Tim Worthley[3], Guruprasad Aithal[4], Sumita Verma[1,2]. [1]*Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom;* [2]*Brighton and Sussex Medical School, Brighton, United Kingdom;* [3]*The Arch Healthcare, Brighton, United Kingdom;* [4]*Nottingham Digestive Diseases Centre, Nottingham Biomedical Research Centre, Notingham, United Kingdom*
Email: ahmedsir37@hotmail.com

Background and aims: Homeless adults, a disenfranchised cohort, are particularly at risk of chronic liver disease (CLD) though they not engage with hospital services. Our aim was to establish a liver clinic at homeless hostels and assess service uptake, prevalence of CLD including hepatitis C virus (HCV) and HCV treatment outcomes

Methods: The liver service was set up in October 2015, at two large homeless hostels in SE England. Consecutive individuals aged > 18 yrs were offered alcohol (AUDIT) questionnaire and substance misuse assessment, blood borne virus (BBV) testing, mobile Transient Elastography (TE) and focussed treatment. Clinically significant hepatic fibrosis (CSHF) was defined as liver stiffness measurement (LSM) ≥ 8 kPa.

Results: To date 127/131 (97%) individuals approached have been enrolled. Mean age of participants was 47.6 (SD = 9 yrs), 76% being male. At baseline 89 (70%) were homeless/living in hostels/supported accommodation. Positive hepatitis C virus (HCV) antibody was detected in 59 (46%) participants, 81% (48/59) being HCV PCR positive [genotype 1 (48%) and 3a (48%)]. The majority (65%) were drinking alcohol more than recommended, the AUDIT questionnaire revealing alcohol dependency (scores of ≥ 20/40) in 61 (48%). One hundred and three (81%) had history of current/past substance misuse [68/127 (54%) IDU] with 91/127 (72%) having a diagnosis of a mental health illness. Of the 127 participants, 33 (26%) had CSHF (LSM ≥ 8 kPa) with 21 (17%) having cirrhosis (LSM ≥ 13 kPa). The aetiological factor/s for Cirrhosis were alcohol (n = 12, 57%), HCV (n = 1, 5%) and HCV+ alcohol (n = 8, 38%). Independent predictors of CSHF were a positive HCV RNA (OR: 1.90, 95% CI: 1.20-3.00, p = 0.006) and Alcohol AUDIT score > 20 (OR: 5.53, 95% CI: 2.13-14.33, p < 0.001). Of the 48 individuals with positive HCV RNA, 28 (58%) have commenced HCV treatment with direct acting antiviral (DAA) (26 in the community and two clinical trials). Of those with SVR12 data available (n = 17), 82% (n = 14) have achieved sustained virological response (SVR12). Thirteen patients (including 3 being retreated) are still on treatment/awaiting SVR results and one discontinued DAA. Compliance with treatment has been 97%.

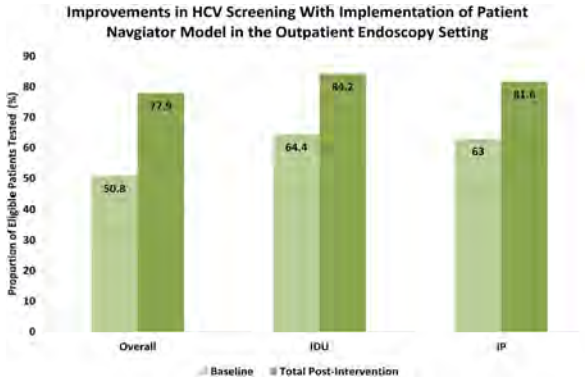
Conclusion: This study reflects the high CLD burden in homeless individuals. In contrast to a common perception that homeless individuals do not engage with health services, 97% accepted the community service with 97% being compliant with DAA therapy. In a cohort of vulnerable adults, high alcohol AUDIT score and HCV RNA positivity were clinical predictors of CSHF.

FRI-232

An outpatient endoscopy-based patient navigator model improves hepatitis C virus screening among high risk patients: A 3-year prospective observational study among a safety-net health system

Grishma Hirode[1], Benny Liu[1], Taft Bhuket[1], Robert Wong[1]. [1]*Alameda Health System, Oakland, United States*
Email: rowong@alamedahealthsystem.org

Background and aims: Despite guidelines recommending hepatitis C virus (HCV) screening among high-risk groups, overall HCV screening remains poor, and it is clear that novel models are needed to achieve WHO 2030 elimination targets. We aimed to evaluate the feasibility and real-world effectiveness of an outpatient endoscopy-based patient navigator model to improve screening among high risk populations.
Method: Consecutive adults undergoing outpatient endoscopy from July 2015-September 2018 at a safety-net hospital were prospectively assessed for HCV screening eligibility using U.S. Preventative Services Task Force guidelines. Eligible patients not previously tested were offered HCV antibody testing via a patient navigator intervention, and were followed to analyze test completion outcomes. The main outcomes evaluated were the proportion of patients screened, and HCV antibody positive (HCV Ab+). We further stratified patients by two high-risk groups: former/current injection drug users (IDU), and previously/currently incarcerated patients (IP). We compared outcomes among those previously tested at baseline (control), and the intervention group (tested). Between-group comparisons used chi-squared testing. Statistical significance was established by a p value < 0.05.
Results: Among 3, 264 patients evaluated, 69.2% (n = 2, 257) were eligible for HCV screening (mean age 57.2 ± 9.8, 48.7% male, 89.8% 1945-1965 birth cohort, 30.4% with ≥ 1 HCV risk factor (2.8% HIV positive, 3.5% chronic hepatitis B, 4.5% IDU, 18.8% IP, 6.4% pre-1992 blood transfusion). The overall proportion of eligible patients tested increased from 50.8% to 77.9%, from 64.4% to 84.2% among IDU, and from 63.0% to 81.6% among IP. Compared to the control group, the intervention group had lower proportions of IDU (5.8% control vs. 3.3% tested, p = 0.02), and IP (23.7% control vs. 12.9% tested, p < 0.001), as well as HCV Ab+ (13.8% control vs. 3.11% tested, p < 0.001). When stratified by risk factors, while the proportion of newly identified HCV Ab+ was still high, it did not vary significantly between the two groups among IDU (60% control vs. 40% tested, p = 0.17), or IP (19.5% control vs. 7.6% tested, p = 0.01). Among those not previously tested and thus in need of HCV screening, 41.2% and 45.5% of IDU and IP, respectively, did not complete HCV testing.



Conclusion: While a novel patient navigator-based model of HCV screening in the outpatient endoscopy setting is feasible and effective to improve HCV testing among the safety-net population, challenges remain in effectively engaging these high-risk and vulnerable patients into the HCV care cascade.

FRI-233

The impact of community-based rapid point-of-care testing on enhancing uptake of hepatitis C treatment for people who inject drugs in needle and syringe services

Jessica Howell[1,2,3,4], Bridget Williams[1], Alisa Pedrana[1], Michael Traeger[1], Joseph Doyle[1,4,5], Ned Latham[1], Bridget Draper[1], Chloe Layton[6], Frances Bramwell[6], Dean Membrey[6], Margaret Mcpherson[7], Janine Roney[5], Alexander Thompson[3,8], Margaret Hellard[4,5,9]. [1]*Burnet Institute, Disease Elimination, Melbourne, Australia;* [2]*St Vincent's Hospital Melbourne, Gastroenterology, Fitzroy, Australia;* [3]*University of Melbourne, Medicine, Parkville, Australia;* [4]*Monash University, Preventive health and epidemiology, Melbourne, Australia;* [5]*Alfred Hospital, Infectious Diseases, Melbourne, Australia;* [6]*Cohealth General Practice, Melbourne, Australia;* [7]*North Richmond Community Health, Richmond, Australia;* [8]*St Vincents Hospital Melbourne, Gastroenterology, Fitzroy, Australia;* [9]*Burnet, Disease Elimination, Melbourne, Australia*
Email: jessica.howell@svha.org.au

Background and aims: Point-of-care (POC) diagnostics overcome barriers to conventional hepatitis C (HCV) testing in people who inject drugs by allowing testing outside of traditional health services, provision by non-clinical staff and same-day diagnosis. This study assessed the feasibility and impact on treatment uptake of POC HCV testing in needle and syringe exchange programs (NSPs).
Method: Rapid EC was a single arm interventional pilot study conducted in three inner-city community clinics with NSPs. Clinic staff offered clients not currently engaged in HCV care an OraQuick HCV antibody mouth swab test followed by a serum Gene Xpert HCV viral load. Same-day results were offered onsite, via phone, or at return visit. Participants received confirmatory standard-of-care blood tests and a follow-up appointment for liver fibrosis assessment, results provision and linkage to care. Six months after the intervention, a retrospective clinical audit was performed to determine the number of HCV RNA positive participants who initiated HCV treatment.
Results: 70/174 people (40%) who underwent POC testing for HCV were HCV RNA positive on laboratory testing. Of these, 44/70 participants (63%) were prescribed HCV therapy and 31 participants (44%) commenced therapy. 22 participants completed treatment at six months (31% of those who were HCV RNA positive), of whom 11 had documented SVR12; 5 people did not complete treatment. Treatment initiation varied by clinic service model, highest at clinics A (76%) and B (71%) where NSPs were embedded within community clinics compared with clinic C (27%) where the NSP was co-located but separate to the clinic (p < 0.001).
Conclusion: Provision of POC testing through NSPs was effective for linking people diagnosed with hepatitis C into care and treatment. Further studies are needed to define how best to incorporate POC testing into models of care for people who inject drugs to increase HCV treatment uptake and completion rates.

FRI-234

Viral interference between dengue virus and hepatitis C virus infections

Po-Cheng Liang[1], Jee-Fu Huang[1], Ming-Lun Yeh[1], Chung-Feng Huang[1], Chia-Yen Dai[1], Ming-Lung Yu[1], Wan-Long Chuang[1]. [1]*Kaohsiung Medical University Hospital, Kaohsiung, Taiwan*
Email: jf71218@gmail.com

Background and aims: Dengue virus (DENV) and hepatitis C virus (HCV) infections are two members of Flaviviridae with global health concern. Both of them may lead to acute hepatitis episodes. Southern

Taiwan, is an HCV endemic region and has faced several dengue fever (DF) outbreaks in the past decades. We aimed to investigate the virological interaction between the two viral infections.
Method: We examined the disease courses of the DF patients during Jan 2014 through Dec 2015. The baseline and follow-up characteristics of virology and clinical profiles were retrospectively reviewed. For those with hepatitis B virus (HBV) or hepatitis C virus (HCV) infection, molecular diagnostic tests for HBV DNA and HCV RNA were conducted for further analysis. We also conducted a cell line study to survey viral interaction utilizing HCV Con1 cells infected with DENV1.
Results: A total of 1, 192 DF patients who were diagnosed by positive nonstructural protein 1 (NS1) tests were consecutively enrolled. Among them, 515 DF patients with HBV and/or HCV infections were recruited into the analysis. HCV prevalence was 6.21% (32/515) in these DF patients. HBV/HCV coinfection rate was 21.9% (7/32) in HCV patients. Positive HCV RNA was noted in 14 cases (43.8%, 14/32). HCV with viremia or not during DF did not determine dengue-related complications (dengue hemorrhagic fever or severe dengue). Of 14 positive HCV RNA patients, 11 were rechecked for viral loads (VL) at least one time after DF with the median follow-up interval of 23 months (range 12-35 months). The post-dengue VL was significantly higher than that during DF [5.43 (± 0.77) vs 3.09 (± 1.24) log IU/ml, p = 0.003]. The mean VL difference was 2.34 (± 1.15) log IU/ml. All had an elevation of VL by 0.5 logs. Moreover, we arranged an HCV gene sequencing examination for one subject using his serum samples during and after DF. The analysis reported a 99.8% identical genomic sequence between the two samples, so the possibility of HCV reinfection could be excluded. The experimental study showed DENV could infect con1 cells. HCV NS5A expression was significantly downregulated along with the increase in DENV NS1.
Conclusion: HCV is suppressed by DENV via viral interference.

FRI-235
Hepatitis C virus risk factors and test uptake in an English prison
Kathryn Jack[1], Paul Linsley[2], Brian Thomson[3], William Irving[1].
[1]University of Nottingham, School of Life Sciences, Nottingham, United Kingdom; [2]University of East Anglia, School of Health Sciences, Norwich, United Kingdom; [3]University of Nottingham, School of Medicine, Nottingham, United Kingdom
Email: kathryn.jack@nottingham.ac.uk

Background and aims: Prisons are a key demographic in the drive to eradicate hepatitis C virus (HCV) as a major public health threat. High rates of testing prisoners for HCV infection will therefore be a crucial determinant of the outcome of any elimination strategy, however rates of testing in the East Midlands region of England remain far below the targets set by NHS England of 50-75%. There is insufficient knowledge detailing the extent of risk factors for HCV amongst the prisoner population which may explain prisoners' choice in not accepting a test and to inform harm reduction activity. The aim of this study was to understand details of the risk factors present in an English prison and HCV test uptake.
Method: Men incarcerated in a category C prison in the East Midlands of England were surveyed. An anonymous questionnaire was distributed to the prisoners and returned to the healthcare department. The questions included length of time and number of prisons spent in current sentence, whether they had been tested in current sentence, reasons for not being tested, and risk factors for HCV.
Results: A survey response rate of 10.7% (n = 109/1018) was obtained from men aged 21 to 68 years. The time spent in their current prison ranged between less than 1 and 60 months and the number of different prisons stayed in during current sentence was between 2 and 9. 71% (78/109) had not been tested in their current prison and 45% (49/109) not tested at all in their current sentence. Only 35% (38/109) reported ever injecting drugs, of whom 21% (8/38) had not been tested during current sentence. Additional key risk factors for HCV reported were; 76% (83/109) sharing prison hair clippers), 69% (75/109) inhaled drug use and 44% (48/109) fighting in prison. Only 7% (8/109) reported no risk factors for HCV. Of those not tested who supplied a rationale (n = 70) 43% (30/70) reported a previous negative test result, 23% (16/70) were needle-phobic and 11% (8/70) were scared of being diagnosed with HCV.
Conclusion: Our study found evidence that prisoners with risk factors were not tested for HCV. Routine testing on admission to prison will ensure all those with risk factors for HCV are tested. Further, testing methods such as dried blood spots may overcome the resistance to testing due to venous blood sampling. The role of intra-prison risks such as fighting and sharing hair clippers warrants further exploration.

FRI-236
Hepatitis C virus related liver fibrosis in people who inject drugs at the Stockholm Needle Exchange evaluated with liver elasticy
Martin Kåberg[1,2], Erika Edgren[2], Anders Hammarberg[3,4], Ola Weiland[1]. *[1]Karolinska Institutet, Karolinska University Hospital Huddinge, Department of Medicine Huddinge, Division of Infectious Diseases, Stockholm, Sweden; [2]Stockholm Centre for Dependency Disorders, Stockholm Needle Exchange, Stockholm, Sweden; [3]Karolinska Institutet, Centre for Psychiatry Research, Department of Clinical Neuroscience, Stockholm, Sweden; [4]Stockholm Centre for Dependency Disorders, Stockholm Health Care Services, Stockholm, Sweden*
Email: martin.kaberg@ki.se

Background and aims: Sharing of unsterile injection equipment among people who inject drugs (PWID) is the major transmission route for hepatitis C (HCV). HCV is highly prevalent in PWID in the Stockholm needle exchange program (NEP). The frequency of advanced liver fibrosis among the participants is, however, unknown.
Method: From December 2016 to April 2018 all patients with chronic hepatitis C infection (CHC), defined as positive HCV RNA tests > 6 months, were offered liver fibrosis evaluation at the Stockholm NEP. This included liver stiffness measurement (LSM), and a medical history with expanded blood tests to evaluate the APRI and FIB-4 scores.
Results: A total of 2037 individuals were enrolled in the Stockholm NEP, during the study period, of which 1159 (57%) were HCV RNA positive. 964 (47%) participants had CHC. LSM was performed in 203 (21.1%) of eligible participants of whom 85% had mild fibrosis (Metavir F0-F2) and 15% advanced fibrosis (Metavir F3-F4). APRI score > 1 and FIB-4 > 3.25 only identified 30% of participants with advanced fibrosis. All 31 (100%) participants with advanced fibrosis on the other hand were detected when APRI score > 1 was combined with age of ≥ 40 years and an injection drug use (IDU) duration of ≥ 15 years.
Conclusion: All PWID with advanced fibroses in the Stockholm NEP were detected when age ≥ 40 years and IDU duration of ≥ 15 years were combined with an APRI score > 1. We found that the diagnostic work-up for advanced fibrosis can be simplified with this combination of easily available factors. This allows identification of PWID in need of immediate HCV treatment to prevent further disease progression. Furthermore, LSM can be avoided among PWID with mild fibrosis, identified by age < 40 years combined with IDU duration of < 15 years and APRI score < 1. This strategy enhances the HCV care cascade where LSM is not easy available, and will thus facilitate HCV treatment initiation.

FRI-237
Triple E (engagement, education and eradication) for patients chronically infected with hepatitis C: Results of a self-sustaining, comprehensive education, screening and treatment program for patients in substance abuse treatment facilities
Marcelo Kugelmas[1], Michael Taglienti[2], Stacey Shellenhamer[2], Jane Ranagan[2], Rachel Bejarano[3]. *[1]south denver gastroenterology, englewood, United States; [2]focus medical communications, Parsippany, United States; [3]r.b. scientific sciences, llc., Fanwood, United States*
Email: rachel.bejarano@gmail.com

Background and aims: The United States (US) opioid epidemic has led to increases in hepatitis C viral (HCV) infections. Despite HCV

being recognized as prevalent in patients with substance use disorders (SUDs), the vast majority of substance abuse treatment facilities in the US do not screen for HCV. Lack of clinical staff and/or access to knowledgeable HCV experts limits screening and disease management.
The Chronic Liver Disease Foundation (CLDF), a non-profit educational organization dedicated to increasing awareness of the effects of chronic liver disease in the US, designed an integrated program to improve the care of patients with SUDs.
Method: This program provided 4 important fundamentals to substance abuse center sites: staff education, patient education and counselling, antibody (Ab) screening and secondary blood draw (if Ab positive) and linkage to care. Linkage to care links the patient directly to a hepatitis specialist (onsite or via telemedicine in areas where HCV providers are limited) and a CLDF healthcare provider for onsite counselling and management. Patient screening and outcomes data are measured and the results are reported here.
Results: This initiative encompassed 19 substance abuse center sites located in New Mexico (n = 13), Kentucky (n = 5) and Arizona (n = 1). Data were collected March, 2017 and the results as of November, 2018 are summarized in the Figure. Overall, 658 of the 1475 SUD patients (pts), who were unaware of their HCV status, tested positive for HCV Ab. Furthermore, 384 pts who had HCV RNA testing (n = 531) were linked to HCV care.

Figure: Patient Screening and Outcome Results

	Ab Screened	Ab Positive	Blood Draw Completed (on Ab Positive Patients)	Linked to Care (Patients who had Blood Drawn)	HCV RNA Detectable
Number of Pts	1475	658	531	384	369

Conclusion: Promising new direct-acting antiviral drug regimens offer the possibility of eradication of HCV. However, patient and provider HCV education, screening and effective linkage to care are necessary to effectively integrate these treatments into disease management. Based on these results, the CLDF anticipates that broadening the reach of this self-sustaining, comprehensive HCV education, screening and treatment model could result in recovery center-focused eradication of HCV. This will have an invaluable effect on public health. This initiative was supported by an educational grant from AbbVie.

FRI-238
Shifty business: Task shifting is essential to sustained increases in hepatitis C care engagement
Danielle Leblanc[1], Nicholas Bartlett[1,2], Yvonne Lynch-Hill[1], Morgan Macneil[1], Barbara Goodall[1,2], Sharon Oldford[2,3], Lisa Barrett[1,2,3]. *[1]Nova Scotia Health Authority, Halifax, Canada; [2]Canadian Center for Vaccinology, Halifax, Canada; [3]Dalhousie University, Halifax, Canada*
Email: lisa.barrett@nshealth.ca

Background and aims: Hepatitis C virus (HCV) elimination requires a marked, contemporaneous scale-up of both HCV diagnostics and therapeutics. To do this in publicly funded health systems, finding maximum efficiencies is paramount. In particular, revision of medically complex HCV care models is needed. One strategy is task shifting non-nursing roles to other skilled individuals, such as clerical staff who are supported and encouraged to work at full scope. Our objective is to determine the effect of skilled clerical staff on overall HCV wait times and treatment initiations.
Method: A publicly funded provincial HCV elimination strategy was developed in a medium sized Canadian province. Key elements include: centralized triage and referral, rapid treatment start, inclusion of incarcerated individuals, harm reduction strategies, and patient self-referral. Intrinsic to the low cost business plan is each individual working to full scope of practice. In particular, a medical clerk with advanced skills in database management and telephone based patient engagement was added to the HCV clinical team to complement an HCV experienced nurse and physician. The required amount of time to engage each patient, as well as the wait times before and after engagement were measured.
Results: We collected data from 3 time periods: pre-clerk (Jan-Dec 2017), clerk (Dec 2017- Aug 2018), and post-clerk (Oct 2018). Treatment initiations were an average of 2.25, 15.3, and 3 patients per month respectively during each of the periods. Median wait time, in days, for the pre-clerk and clerk period was 140 (IQR 84-235) and 35 (IQR 21-63.75), respectively. First appointment attendance was 54.5%, 82.2%, and 14.3% ($p < 0.05$, clerk vs post clerk period) respectively for the pre-clerk, clerk, and post-clerk time periods. The average per patient clerk time from consult received to patient booked was 165 minutes, with 55% of patients requiring greater than 2 phone calls to successfully engage in care.
Conclusion: Task shifting initial HCV patient engagement from a nurse to skilled clerical personnel is a successful tool to gain rapid scale-up of patient treatment initiation, despite being time intensive for the clerical person. Without this resource, wait times rapidly increase and do not promote HCV treatment, despite expert nurses and physicians. Models that encourage task shifting need to be supported longitudinally to maintain benefit in HCV elimination.

FRI-239
SAMBA II HCV: A new point of care molecular assay for HCV diagnostics and DAA monitoring
Helen Lee[1], Allyson Ritchie[1], Sonny Michael Assennato[1], Hiroshi Sembongi[1]. *[1]Diagnostics for the Real World Ltd, Cambridge, United Kingdom*
Email: hl207@cam.ac.uk

Background and aims: SAMBA II is a point of care (POC) nucleic acid testing platform designed for developing countries and for use in low-level health care settings such as district hospitals and health centres. The SAMBA II instrument system is a fully automated system for sample extraction, nucleic acid amplification, detection and interpretation of the results. The lyophilized reagents are non-toxic and the kits are stable for up to one month at 55°C and at 7-9 months at 2-37°C, thus, no cold chain transport or storage of reagents is required. DRW have now developed a SAMBA II HCV test to identify and monitor chronic HCV infections using venous or finger-prick whole blood. The HCV test is intended for high-risk groups such as HIV-1 infected individuals, assessing DAA eligibility for anti-HCV seropositive blood donors worldwide and, in developed countries, for niche populations such as prisoners and IV drug abusers in prisons or rehabilitation facilities. The aim of this study was to assess the performance of the test.
Method: Based on NASBA technology with HCV core region primers, amplified nucleic acids are detected by specific anti-hapten conjugate labeled with colored particles wicked up on a test strip. Colored amplicon-conjugate are immobilized on a test line by hybridization to a specific capture probe; a control line indicates valid performance of the test. The test has been evaluated for sensitivity, specificity and subtype coverage using the WHO standard and genotyped samples prepared in whole blood.
Results: The limit of detection was assessed using the 5th WHO International Standard for HCV NAT diluted in K_2EDTA whole blood. Probit analysis determined that the concentration of HCV RNA in whole blood detected with 95% probability, was 751 IU/ml (95% confidence interval (CI): 592-1, 268 IU/ml). Three to seven samples of each of the six HCV genotypes were consistently detected by the test showing coverage of all genotypes.. In specificity studies no cross-reaction was observed with HIV-1, HIV-2, HTLV-1 HTLV-2, HBV or Epstein Barr virus and testing of 100 individual negative whole blood samples was 100%.

Conclusion: SAMBA II HCV whole blood preliminary data are consistent with a POC assay able to detect at least 1000 IU/ml of HCV of all genotypes in whole blood with excellent specificity. Field studies will be conducted in relevant geographic areas to demonstrate similar performance in patient/blood donor capillary whole blood prior to and post-DAA treatment.

FRI-240

Comparison of Abbott RealTime HCV genotype II, Abbott HCV genotype plus RUO with Roche Cobas HCV genotyping assays for hepatitis C virus genotyping

Chen-Hua Liu[1,2,3], Tung-Hung Su[1,3], Chun-Jen Liu[1,3,4], Chun-Ming Hong[5], Hung-Chih Yang[1,3,6], Tai-Chung Tseng[1,3], Pei-Jer Chen[1,3,4], Ding-Shinn Chen[1,3,7], Jia-Horng Kao[1,3,4]. *[1]National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan; [2]National Taiwan University Hospital, Yun-Lin Branch, Internal Medicine, Douliou, Taiwan; [3]National Taiwan University Hospital, Hepatitis Research Center, Taipei, Taiwan; [4]National Taiwan University College of Medicine, Graduate Institute of Clinical Medicine, Taipei, Taiwan; [5]National Taiwan University Hospital, Traumatology, Taipei, Taiwan; [6]National Taiwan University College of Medicine, Microbiology, Taipei, Taiwan; [7]Academia Sinica, Genomics Research Center, Taipei, Taiwan*
Email: jacque_liu@mail2000.com.tw

Background and aims: Data comparing the diagnostic accuracy for Abbott RealTime Genotyping II with/without RUO testing and Roche Cobas HCV genotyping are limited.
Method: 342 HCV-viremic patients receiving Abbott RealTime HCV Genotype II and Roche Cobas HCV genotyping assays were consecutively enrolled. Patients with indeterminate and unsubtypable HCV genotype 1 (HCV-1) results by Abbott RealTime HCV Genotype II assay were tested by Abbott HCV genotype plus RUO assay to discriminate HCV-1a, 1b, or 6 infection. Direct sequencing at the core and NS5B regions was performed for patients with inconsistent and unsubtypable HCV-1 results by either Abbott RealTime HCV Genotype II or Roche Cobas HCV genotyping assay.
Results: 328 (95.9%) showed consistent results between Abbott RealTime HCV Genotype II and Roche Cobas HCV genotyping assays. Eleven patients with indeterminate results by Roche Cobas HCV genotyping assay had HCV-6e, 6 g, 6n and 6w infections. Abbott RealTime HCV Genotype II assay can correctly diagnose HCV-6w infection, but showed unsubtypable HCV-1 and indeterminate results HCV-6 g and HCV-6n infections, which were correctively diagnosed by Abbott HCV genotype plus RUO assay. In two HCV-1b patients, 1 and 2 of them showed indeterminate results by Abbott RealTime HCV Genotype II and Roche Cobas HCV genotyping assays, which were correctively diagnosed by Abbott HCV genotype plus RUO assay.
Conclusion: Abbott RealTime HCV Genotype II and Roche Cobas HCV genotyping assays show high consistent results. High indeterminate rates were found in HCV-6 infection by Roche Cobas HCV genotyping assay. Most patients with indeterminate and unsubtypable HCV-1 results by Abbott RealTime HCV Genotype II assay can be accurately diagnosed by plus RUO assay.

FRI-241

Barriers to HCV elimination among drug users: HepCare-Spain

Juan Macias Sanchez[1], María Iglesias[1], Beatriz Rioja[2], Bartolomé Baena[3], Evangelina Claro[4], Edmundo Cartagena[5], Juan C. Hornillos[6], MªMar Vázquez[7], José Osuna[8], MªCarmen Gordillo[9], Coral Guerrero[9], Carmen Sánchez[3], Jesús Gómez-Mateos[1], Juan A. Pineda[1]. *[1]Hospital U. de Valme, Seville, Spain; [2]AFAR, Seville, Spain; [3]Comunidad Terapeútica Los Palacios (FADAI), Seville, Spain; [4]ANTARIS España, Sevilla, Spain; [5]Centro de tratamiento de adicciones Maicena del Alcor, Seville, Spain; [6]Centro de tratamiento de adicciones Alcalá de Guadaira, Seville, Spain; [7]Centro de tratamiento de adicciones Ecija, Seville, Spain; [8]Centro Restauración y Centro Nuevo Día. Carmona, Seville, Spain; [9]Centro de tratamiento de adicciones Polígono Sur, Seville, Spain*
Email: juan.macias.sanchez@gmail.com

Background and aims: Active drug users, as people at risk of social exclusion with problems to access health care, may not be aware of their HCV status. To reach the objective of HCV elimination, it is necessary to detect nearly all individuals with HCV infection and give them access to treatment. The HepCare Europe (a collaboration between Bucharest, Dublin, London and Seville) project aims to assess in a new model of care for hepatitis C, which facilitates access to diagnosis and treatment of HCV infection in disadvantaged groups. We present data from HepCare-Spain with the aim of evaluating the prevalence of infection in these groups and the linkage to care of patients with active HCV infection.
Method: Within HepCare, the HepCheck subproject aims at improving HCV testing. As part of it, a health team travels to addiction treatment centers, therapeutic communities and non-governmental organizations to detect markers of HCV infection in blood or saliva. The HepLink subproject is designed to facilitate access to specialized care for patients with detectable HCV RNA. We describe the process of screening, the prevalence of positive anti-HCV and of detectable HCV-RNA among individuals invited to participate in HepCheck. We also describe the cascade of care of those with active HCV infection and engaged in HepLink.
Results: We invited 784 individuals to participate (January 2017-November 2018), 32 (4%) refused and 228 (29%) did not attend appointments. Of the 524 individuals screened, 415 (79%) of them were unaware of their HCV status. 452 (86%) participants were previous drug users, and 209 (40%) current drug users. Overall, 185 (35%) individuals showed positive anti-HCV, and 99 (19%) had detectable HCV RNA. 68 (69%) of those with active HCV infection attended the appointment to be fully evaluated for treatment, 15 (22%) of them failed their next appointment to start or plan DAAs. Treatment was initiated in 41/68 (60%) patients with these Results: SVR12, 36; relapsed, 2; dropped-out, 1; treatment ongoing, 10. Overall, HCV infection was eliminated in 36% (36/99) viremic patients.
Conclusion: In a population mainly constituted by drug users in Spain, a fifth of the subjects have active HCV infection. It is possible to link to specialized care and give access to DAA to HCV-infected patients who were not followed up or were unaware of their HCV status. However, the elimination of HCV infection in this group could not be possible, with the described strategy, due to losses to follow-up.

FRI-242

Absence of hepatitis C infection despite high-risk sexual behavior in a cohort of men who have sex with men screened in the community: preliminary results of SEXCHECK study

Pietro Malosso[1], Lorenzo Badia[1], Viola Guardigni[1], Renato Pascale[1], Alessandro Di Felice[1], Gabriella Verucchi[1], Pierluigi Viale[1], Alessandro Mattioli[2]. *[1]Alma Mater Studiorum-University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [2]PLUS Onlus, Bologna, Italy*
Email: pietro.malosso@gmail.com

Background and aims: Over the last decade, an outbreak of sexually transmitted acute HCV infection has been documented among HIV positive men who have sex with men (MSM). Specific sexual practices have been associated with the risk of HCV infection in this population. However, data about HCV in HIV-negative MSM population are scarce, and community screening programs may be helpful. Our purpose was to assess HCV prevalence in a cohort of HIV-negative MSM with high risk sexual behaviour.
Method: We recruited HIV-negative cis-men or trans-women who have sex with men and that presented one or more risk factors for sexual acquisition of HCV and/or HIV infection. Recruited individuals filled in a survey about sexual habits and underwent screening tests

for sexual transmitted infections (STIs), including HCV-RNA and anti-HCV. The study was conducted at the community-based, peer-lead "BLQ Checkpoint" managed by PLUS Onlus (Bologna, Italy), using rapid test (Oraquick HCV® on saliva for HCV-Ab and Xpert® HCV viral load on blood for HCV-RNA).
Results: 56 cis-men and 1 trans-woman were enrolled in this analysis. Median age was 40 (range 19-59). 46 individuals (80.7%), reported 10 or more partners in the last 6 months; 47 (82.5%) reported sporadic use of condom and in this subgroup 70% of insertive intercourses and 51.1% of receptive ones were with partner of unknown serological status. 27 individuals were on PrEP. 45 (78.9%) reported at least one high-risk sexual practice (sex toys sharing, group sex participation, fisting) in the last 3 months; group sex was the most common (70%). 17 (29.8%) reported chemsex use, 12 (21.1%) straws or needle sharing in the last 3 months. No active or previous HCV infections were found. 44 individuals (77.2%) reported a previous STI; 32.8% had positive syphilis test. At first evaluation, in 14 subjects PCR for *Chlamydia trachomatis* (6) *Neisseria gonorrhoeae* (5) or both (3) was positive.
Conclusion: Despite an high prevalence of risk factors in our cohort, no silent HCV infections were detected at baseline. Data about incidence of new infections will be obtained through prospective evaluation of the cohort and will help to understand the epidemiology of HCV in HIV-negative MSM population in Italy. Community-based screening with rapid tests was an effective and reliable way to reach this target population.

FRI-243
Utility of simple serum based tests to exclude cirrhosis prior to HCV treatment in non-hospital based settings
Lauren Burrage[1], Henry Zimmerman[2], Sarah Higgins[1], Kerrin Param[1], Clare Orme[1], Jonathan Mitchell[1], James O'beirne[1,3]. *[1]Sunshine Coast University Hospital, Hepatology, Birtinya, Australia; [2]The University of Queensland, School Of Medicine, Saint Lucia, Australia; [3]USC Sunshine Coast, Sippy Downs, Australia*
Email: James.obeirne@health.qld.gov.au

Background and aims: Current guidelines suggest using transient elastography (TE) or APRI with a cut-off of < 1 to exclude cirrhosis prior to HCV therapy. An efficient serum based test could reduce the need for TE allowing more streamlined treatment in non-hospital settings. Recently FIB-4 (cut off 0.93) has been shown to have a high negative predictive value (NPV) for the presence of cirrhosis and to reduce the need for TE. We aimed to assess FIB-4 and APRI in our cohort of HCV patients and to validate FIB-4 < 0.93 in populations of HCV infected individuals with differing cirrhosis prevalence including those assessed and treated in primary care and prison.
Method: From our treatment database we identified patients with complete data. (n = 793) We calculated FIB-4 and APRI and correlated this with the presence of cirrhosis TE (> 12.5kPa). We analysed performance of FIB-4 and APRI using AUROC. We then calculated sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and number of patients misclassified using published cut-offs in various populations with differing prevalence of cirrhosis.
Results: FIB-4 was superior to APRI for the diagnosis of cirrhosis (AUROC 0.868 vs 0.80). In secondary care (cirrhosis 32%) APRI < 1 had a NPV of 80% and misclassified 14% of patients with cirrhosis. FIB-4 < 0.93 had a NPV of 97% and misclassified 1%. In primary care patients and prisoners who had a lower prevalence of cirrhosis (15 and 8%) the NPV for APRI < 1 was 93% and 96% respectively but still 5% of patients with cirrhosis were misclassified. FIB-4 < 0.93 had excellent NPV in primary care (97%) and prisoners (100%).
Conclusion: The recently described FIB-4 cut off of 0.93 is highly efficient at ruling out cirrhosis in HCV patients. These patients can safely avoid TE thus streamlining treatment in primary care and other populations with a low prevalence of cirrhosis.

FRI-244
Platelet-derived growth factor alpha might mediate hepatic fibrosis by enhancing insulin resistance in patients with hepatitis C
Anna Mrzljak[1,2], Davorka Dusek[3], Kristina Blaslov[4], Snjezana Zidovec Lepej[3], Ivana Grgić[5], Lana Gorenec[5], Iva Košuta[6], Adriana Vince[2,3]. *[1]University Hospital Merkur, Dept. of Gastroenterology, Zagreb, Croatia; [2]School of Medicine, University of Zagreb, Zagreb, Croatia; [3]University Hospital of Infectious Diseases, Department for Viral Hepatitis, Zagreb, Croatia; [4] University Hospital Center "Sestre Milosrdnice," Department of Endocrinology, Diabetes and Metabolic Diseases "Mladen Sekso," Zagreb, Croatia; [5]University Hospital for Infectious Diseases, Department of Imunological and Molecular Diagnostics, Zagreb, Croatia; [6]Univeristy Hospital Merkur, Department of Medicine, Zagreb, Croatia*
Email: anna.mrzljak@gmail.com

Background and aims: Insulin resistance (IR) represents one of the key regulatory mechanisms in the development of hepatic steatosis, the consequent hepatocyte injury and finally hepatic fibrosis. Both conditions represent a common feature in hepatitis C virus (HCV) infection and type 2 diabetes mellitus (T2DM). The platelet-derived growth factors (PDGFs) are key regulators of the connective tissue formation and potent mitogens for hepatic stellate cells. It was recently demonstrated that higher plasma PDGF-A concentration is associated with increased hepatic steatosis and fibrosis in T2DM. We aimed to investigate whether there is an association between PDGF-A serum concentration, IR and HCV mediated hepatic steatosis and fibrosis.
Method: This cross-sectional study comprised 107 non-diabetic participants aged 50.85 ± 1.57 years, 77 (71.96%) with HCV infection. The fasting PDGF-A concentration was determined by enzyme-linked immunoadsorbent assay. Homeostatic Model Assessment of Insulin Resistance (HOMA-IR) score over 1.64 was categorised as IR. Fibrosis and steatosis were evaluated by ultrasound elastography (FibroScan®). The participants were divided into 4 groups: HCV negative group with IR (HCV^-/IR^-, N = 12), HCV positive group without IR (HCV^+/IR^-, N = 34), HCV positive group with IR (HCV^+/IR^+, N = 44) and 18 healthy controls. One-way ANOVA or Kruskall-Wallice test followed by Bonferroni's correction were used to test the differences on multiple levels by a single factor (independent) variable.
Results: There was a significant difference in liver stiffness indicating the degree of fibrosis with the highest mean value of 15.9 kPa in the HCV^+/IR^+ ($p < 0.001$ for all) and steatosis severity accessed by Controlled Attenuation Parameter ($p < 0.001$, for all) revealing the highest value in HCV^-/IR^+ (296.5 dB/m). The PDGF-A concentration correlated positively with steatosis ($r = 0.341$, $p = 0.007$) and fibrosis ($r = 0.264$, $p = 0.071$) severity. Both IR positive groups had higher PDGF-A compared to HCV^+/IR^- group ($p = 0.006$). In accordance with more pronounced steatosis, the HCV^-/IR^+ group revealed the highest PDGF-A concentration.
Conclusion: We demonstrated that PDGF-A concentration is associated with the severity of hepatic steatosis in HCV and non-HCV patients with IR; i.e. that PDGF-A could represent one of the key regulatory mechanisms in the pathway from hepatic steatosis towards fibrosis. These results provide better understanding of pathways that regulate fibrosis which might have a good potential in future therapeutic options development.

FRI-245
Improvement in cognitive impairment following 12 weeks of aerobic exercise in individuals with non-cirrhotic, chronic hepatitis C
Philip O'gorman[1], Damien Ferguson[2,3], Orla Strahan[4], Ann Monaghan[1], Megan Kennedy[1], Colm Bergin[5], Susan Mckiernan[6,7], Robert Coen[8], Colin Doherty[2,3], Cuisle Forde[1], John Gormley[1], Suzanne Norris[6,7]. *[1]Discipline of Physiotherapy, School of Medicine, University of Dublin, Trinity College, Dublin, Ireland;*

Email: pogorma@tcd.ie

Background and aims: Cognitive impairment (CI) is reported to occur in 30-50% of individuals with non-cirrhotic, chronic hepatitis C (HCV). A virally induced, chronic inflammatory state is thought to be the main contributor to HCV related CI. In other chronic inflammatory diseases, aerobic exercise has been utilised to improve disease related CI. This study aimed to examine the effects of an aerobic exercise intervention (EI) on cognitive function in individuals with HCV.
Method: DAA-naïve HCVRNA positive individuals with proven CI were recruited to take part in a 12-week aerobic EI. A comprehensive assessment including measures of; cognitive function, cardiovascular fitness ($\dot{V}O_{2max}$), anthropometry and objective physical levels (PAL) was undertaken before the EI (T0), post completion of the EI (T1) and reassessed three months after T1 (T2). The EI consisted of two supervised and three unsupervised sessions per week with increasing intensity (45-75% heart rate reserve) and duration (24-45 minutes) for 12 weeks. Control participants did not participate in the EI. A two-way ANOVA with repeated measures was used to examine for significant differences compared to controls. Values are displayed as mean difference±standard deviation.
Results: 42 participants enrolled in the EI with 13 exercise and 20 control participants completing the EI with 76% mean adherence. In the exercise group, there was a significant improvement in the Trail Making Test A and B (TMT-A and B), the Montreal Cognitive Assessment (MOCA) and $\dot{V}O_{2max}$ at T1 (Figure 1) compared to T0 but these improvements were not maintained at T2 (p = NS).

Mean difference between T0 and T1	Group		*Time X Group Effect*
	Exercise Group	Control Group	
TMT-A (s)	-12.5 ± 5.85 *	-2.9 ± 13.58	p = 0.037
TMT-B (s)	-18.6 ± 24.4 *	8.1 ± 34.41	p = 0.035
MOCA	2.8 ± 2.04 ***	-0.4 ± 2.55	p = 0.001
Digit Symbol Test	6.7 ± 7.32	3.8 ± 4.61	p = 0.210
$\dot{V}O_{2max}$ (ml.min.kg)	6.3 ± 5.50 *	-0.4 ± 7.26	p = 0.013
PAL (min/week)	42.8 ± 241.00	-14.1 ± 257.90	p = 0.553

*, *** Indicates significantly different from T0 in the EG (p < 0.05, p < 0.001, respectively).

Conclusion: This is the first study to report the potential of aerobic exercise in ameliorating symptoms of HCV-related CI. Future studies investigating strategies to promote long term adherence to exercise to address extrahepatic manifestations of HCV infections are warranted.

FRI-246

Elimination of HCV in a Large Urban Health System in the United States: A Big-data Approach

Ponni Perumalswami[1], Brooke Wyatt[1], Alyson Harty[1], Anna Mageras[1], Li Li[2,3], Mark Miller[1], Maxence Vandromme[1], Joel Dudley[2], Douglas Dieterich[1], Andrea Branch[1]. [1]*Icahn School of Medicine at Mount Sinai, Department of Medicine, Division of Liver Diseases, New York, United States;* [2]*Icahn School of Medicine at Mount Sinai, Institute for Next Generation Healthcare, New York, United States;* [3]*Sema4, A Mount Sinai venture, Stamford, United States*
Email: ponni.perumalswami@mountsinai.org

Background and aims: Chronic hepatitis C virus (HCV) infection leads to progressive liver disease that can result in liver failure and liver cancer. Innovative case-finding strategies are needed to make use of the highly effective direct acting antiviral drugs that are now available to cure HCV. The Aims of this study are to develop and apply methods for identifying HCV-infected patients across a large urban healthcare system and for linking them to HCV treatment.
Method: Electronic medical records (EMR) of the approximately 7.6 million patients in the Mount Sinai Health System (2000-2017) were queried and a list was generated of 27, 814 patients with International Classification of Diseases 9/10 diagnosis codes for HCV and/or records of HCV antibody or HCV RNA testing (see Fig. 1). A team of computer specialists, liver disease providers, care coordinators, and patient navigators is investigating the status of these patients and offering navigation/care coordination when appropriate.

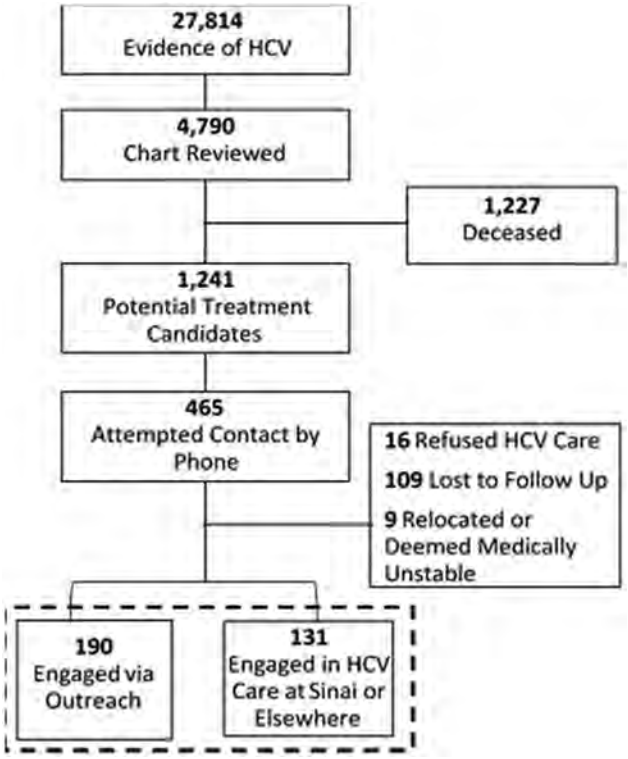

Figure: Patient Outreach Outcomes

Results: Of the 27, 814 patients, the records of 4, 790 (17%) have been reviewed thus far. Of those reviewed, 1, 227 (26%) were deceased and 1, 241 (26%) were HCV RNA positive treatment candidates. Thus far, we have attempted to contact 465/1, 241 (37%) patients by phone and succeeded in engaging 190/465 (41%) in the scheduling pipeline and/or in HCV treatment. Among the others, 131/465 (28%) were already actively engaged in HCV care at Mount Sinai or elsewhere; 16 (3%) said they did not want to pursue HCV treatment; nine (2%) had moved out of the geographic region and/or were too medically unstable for HCV treatment; and 109 (23%) could not be reached. Extrapolating from these results, as of 2017, there were approximately 3, 000 patients in the Mount Sinai System with positive HCV test results or an HCV-related diagnosis in need of outreach for engagement in HCV care.
Conclusion: Many patients in our urban healthcare system who had EMR data indicative of HCV infection had either died (26%) or failed to access HCV treatment by the end of 2017. Based on data collected using computer algorithms, manual chart review, and contact by telephone, we estimate that about 3, 000 patients with chronic HCV infection could be engaged in HCV care with adequate care coordination and patient navigation. Our findings of high mortality of HCV-positive patients who are left untreated highlight the urgent need for large-scale HCV case finding and care coordination.

FRI-247

Influence of HCV coinfection and HCV treatment on risk of diabetes mellitus in HIV infected persons

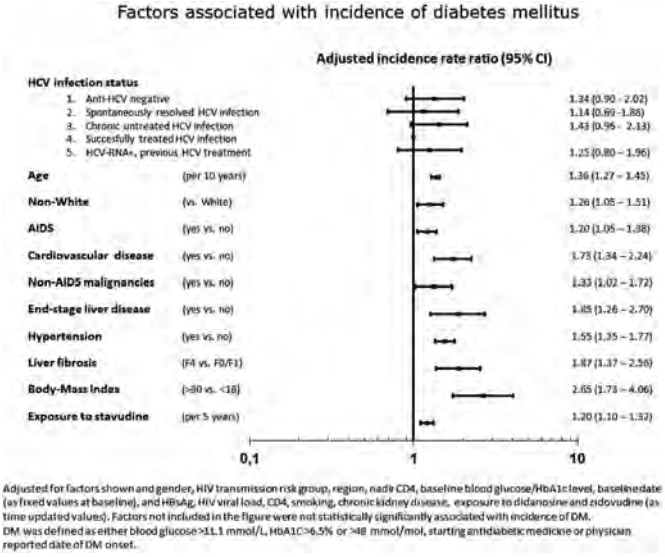
Email: Lars.peters@regionh.dk

Background and aims: HCV infection has been associated with an increased risk of diabetes mellitus (DM). In how far this may change after successful HCV therapy as well as the contribution of fibrosis stage and HIV related risk factors in DM development remains unclear.

Method: All HIV positive individuals in the EuroSIDA cohort with known HCV status after January 2001 were included in one of five groups based on time-updated HCV-RNA and use of HCV treatment: 1) HCV-uninfected, 2) spontaneously resolved HCV infection, 3) chronic untreated HCV infection, 4) successfully treated HCV infection, 5) HCV-RNA positive despite previous HCV treatment. Individuals with DM at baseline were excluded. Poisson regression was used to investigate the association between HCV groups and DM.

Results: We included a total of 16, 034 HIV positive persons of which 6109 (38.1%) were anti-HCV positive and 460 (2.9%) had cirrhosis at baseline. The majority were male (74%), White (85%), and on ART (85%) with a median (IQR) age of 41 (35-49) years and CD4 cell count of 446 (290-639) cells/µl. During 123610 person-years of follow-up (PYFU); median 6 years (IQR 3-12) per person, 1019 (6.4%) developed DM. The crude incidence rate/1000 PYFU (95% CI) of DM was 8.7 (8.1-9.3), 6.3 (4.2-8.5), 7.4 (6.1-8.7), 6.7 (4.4-8.9), 7.4 (5.4-9.5) in group 1-5, respectively. In multivariable analysis (figure), there was a 43% increased incidence of DM in those with chronic untreated HCV compared to those successfully treated, although this was marginally significant ($p = 0.08$). Other HCV groups had similar incidence of DM compared to those successfully treated. The incidence of DM was significantly higher among persons with cirrhosis vs. F0/1 fibrosis and in those with end-stage liver disease (ESLD) vs. no ESLD. In addition, development of AIDS or serious non-AIDS events (cardiovascular events, malignancies) and hypertension, as well as older age, non-white ethnicity, higher body-mass index and increased exposure to stavudine were associated with increased incidence of DM.



Conclusion: In a large cohort of HIV/HCV coinfected persons, cirrhosis and ESLD were associated with increased risk of DM. There was some evidence that those successfully treated had a lower incidence of DM that those with chronic untreated HCV, but our results did not reach statistical significance, potentially due to limited power. Increased risk of DM was also associated with both HIV related and well-known general risk factors for DM.

FRI-248

Cost-effectiveness of elbasvir/grazoprevir (EBR/GZR) for treatment-naive (TN) patients with chronic hepatitis C virus (HCV) genotype 1b (GT1b) infection in Russia

Shelby Corman[1], Amy Puenpatom[2], Andrey Kulikov[3], Roza Yagudina[3]. *[1]Pharmerit International, Bethesda, MD, United States; [2]Merck and Co., Inc., Kenilworth, NJ, United States; [3]Sechenov University, Moscow, Russian Federation*
Email: scorman@pharmerit.com

Background and aims: An estimated 4.1% of the population in Russia is infected with HCV, of which GT1b is the most common. EBR/GZR is a direct-acting antiviral (DAA) indicated for the treatment of GT1b in Russia. The objective of this study was to compare the cost-effectiveness of EBR/GZR to regimens currently used in Russia for the treatment of TN patients with GT1b HCV infection.

Method: A Markov model was constructed to evaluate the cost and effectiveness of EBR/GZR over a lifetime time horizon. The target population was TN patients infected with HCV GT1b, stratified by presence of cirrhosis. The model consists of 16 health states encompassing METAVIR fibrosis score (F0-F4), treatment success or failure, decompensated cirrhosis (DC), hepatocellular carcinoma (HCC), liver transplant, and liver-related death. The proportions of patients achieving sustained virologic response (SVR) were obtained from clinical trials. Other inputs were obtained from published sources. The primary outcome was incremental cost-utility ratio (ICUR) for EBR/GZR vs. each comparator.

Results: EBR/GZR is less costly and more effective (economically dominant) over all comparators in cirrhotic patients (Table). In non-cirrhotic patients, EBR/GZR was cost-saving vs. all comparators and economically dominant over all comparators except OMB/PAR/RIT +DAS and GLE/PIB, for which QALY differences were negligible.

Conclusion: EBR/GZR is economically dominant over other DAA regimens in cirrhotic patients, and is economically dominant or cost-saving vs. comparators in non-cirrhotic patients.

Table: Costs, QALYs, and the ICUR for EBR/GZR vs. Comparators

Treatment Regimen	Total Discounted Costs (RUB)	Total Discounted QALYs	Incremental Costs	Incremental QALYs	ICUR, EBR/GZR vs. Comparator (RUB/QALY)

FRI-249

HCV in french prisoner, the study 2017: Fewer patients but more treatment than in 2015

André-Jean Remy[1], Valérie Canva[2], Chaffraix Frederic[3], Terrail Nicolas[4], Christine Silvain[5], Laura Harcouet[6], Melanie Gaillet[7], Sannier Olivier[8]. *[1]Centre Hospitalier, Hospitalogy Unit, Perpignan, France; [2]CHRU de Lille, Hepatology Unit, Lille, France; [3]CHRU STRASBOURG, Hepatology Unit, Strasbourg, France; [4]CHU Montpellier, USMP, Villeneuve les Maguelone, France; [5]CHU Poitiers, Hepatology Unit, Poitiers, France; [6]CHU Cochin, Pharmacy, Paris, France; [7]APHP, US FRESNES, Fresnes, France; [8]Liberal Office, Paris, France*
Email: andre.remy@ch-perpignan.fr

Background and aims: Prevalence of HCV infection is high among prisoners. In France, medical units in prison (unite de soins en milieu pénitentiaire USMP) are under the responsibility of public hospital since 1994. In 2015, a French national 2015 survey describes the state of play of diagnosis and treatment of HCV prisoners. From 2016, all the prisoners can be treated whatever their liver fibrosis is. Objective: Describe national HCV diagnostic and therapeutic practices in french prisons in 2017 and to compare with the 2015 results according to an identical questionnaire.
Method: email survey about practices in 168 USMP.
Results: 71/168 (43%) of questionnaires were usable, covering 46% of prisoners in France. The number and prevalence (%) of HCV patients decreased from 1145 (4.3%) to 928 (2.8%); (average from 20 to 16 in each USMP) There was no significant differences in proposal and performing of HCV screening; systematic announce of HCV results increased from 72% to 79%. HCV DBS (n/n prisoners; 54%) was possible in 18% USMP. FIBROTEST (89%) was more frequently performed than FIBROSCAN (68%) in 2017. Number of on-site performed FIBROSCAN was similar. On-site hepatologist consultations decreased from 56% to 46% USMP with a frequency falling from 3.4 to 1.6 a month. Same proportion of USMP (67%) introduced at least one AAD treatment in 2017, number of treated prisoners increased from 145 to 260 (+79%) with a rate of treatment increasing from 12.7% to 28.1% (+126%); In 2017, 72% USMP compared to 59% in 2015 introduced DAA even if release was scheduled before the end of treatment. Weekly DAA dispensing was more frequent (27% versus 19% in 2015) however remained mostly daily (67% versus 79%). Treatment and post-release follow-up after were similar. Discussion: HCV care in prison was more efficient in 2017 than in 2015. Considering screening, systematic announce of the results remained low. Use of FIBROSCAN* to assess hepatic fibrosis was restricted. the number and percentage of treated patients increased. But, 1/3 of the USMP did not introduce any treatment during the incarceration of the prisoner. DAA dispensing surveillance remains low because of their high cost.
Conclusion: Prison environment constitutes a suitable environment for vulnerable population to access to HCV treatment. However DAA access remains limited.

FRI-250

Test to cure: Increase outreach linkage to care by use of real time HCV viral load

André-Jean Remy[1], Bouchkira Hakim[1], Jeremy Hervet[1], Arnaud Happiette[1]. *[1]Centre Hospitalier, Mobile Hepatitis Team, Perpignan, France*
Email: andre.remy@ch-perpignan.fr

Background and aims: HCV treatment for all was effective in France since 2017. HCV testing, diagnosis and treatment of drugs users and precarious people remain low. Lost follow-up was too important since several stages are necessary. Pangenotypic DAA were available and did not require no determination of viral genotype before treatment. Point-of-care HCV RNA testing offers advantage over antibody testing, enabling diagnosis of active infection with real time measure in a single visit. It is missing link between HCV DBS, liver fibrosis evaluation by FIBROSCAN and treatment. An Australian team concerning 210 drug users (30% positive HCV viral load) validated Xpert HCV Viral Load assay CEPHEID system with 100% feasibility, 95% sensibility, and 98% specificity. This technique of fast training can allow to develop projects of diagnosis to treatment session. Objective: estimate feasibility of test session to treat real time allowing the access in 5 hours to an antiviral treatment to vulnerable populations (drug users, migrants, psychiatric patients) to increase outreach screening and treatment.
Method: Eligible patients had to have known positive serology or risk behavior, an unknown or unchecked viral load after antiviral treatment; 5 to 7 patients were recruited by social or nursing interview. Between 9 am and 2 pm these patients had access to measure of the hepatic fibrosis by FIBROSCAN, HCV viral load in real time by Xpert HCV Viral load finger-stick samples, social interview, shared educational evaluation, collective workshops, specially harm reduction. Depiction of results by hepatologist and prescription of AAD allowed delivery of 1st month of treatment on-site or with support to pharmacy. A report was sent to GP.
Results: From March to October 2018, 73 patients were eligible; 11 sessions were realized on 8 sites: one drug unit, one prison, 6 social units; 4 patients did not come; 69 measures of viral load in real time were realized; 38 were positive (55%); 36 treatments were begun same day, only 2 were delayed due to default social rights; 19 patients had a negative viral load spontaneously and 12 following prior treatment. Social and nursing follow-up was made during and after the treatment according to procedures and biological tests standardized.
Conclusion: With these new mobile clinic model, by screening and real time measure in unity of place, adapted to precarious public, patients distant from system of care had access immediately to treatment.

FRI-251

Impact of hepatitis C treatment on patterns of drug use and subsequent treatment outcomes: High SVR rates despite increasing intravenous drug use in the post treatment period

Trina Ritchie[1], Alison Boyle[2], Fiona Marra[2], Erica Peters[2], John Campbell[1], Carole Hunter[1], Stephen Barclay[3]. *[1]Glasgow Alcohol and Drug Recovery Services, Glasgow, United Kingdom; [2]Gartnavel General Hospital, Brownlee Centre for Infectious Diseases, Glasgow, United Kingdom; [3]Glasgow Royal Infirmary, Walton Liver Clinic, Glasgow, United Kingdom*
Email: catriona.ritchie@ggc.scot.nhs.uk

Background and aims: HCV treatment involves interaction with healthcare professionals with the potential to alter health behaviours. Little information exists on patterns of drug use post vs pre

treatment. We sought to identify changes in drug use and utilisation of Injecting Equipment Provision (IEP) amongst our patients.
Method: Non trial patients commencing Glecaprevir/Pibrentasvir in Glasgow prior to 01/05/2018 were identified from the Scottish HCV database. Data on baseline demographics, Opiate Replacement Therapy (ORT), and SVR12 were obtained. For patients on ORT, review of addictions notes identified (where available) self reported intravenous drug use (IVDU), non-IVDU, and toxicological evidence of drug use in the 3 months pre (PRE) and post (POST) treatment. Those attending specialist addictions clinics (not primary care ORT clinics) were linked with local IEP database by identifiers based on name/date of birth. Anonymous data was returned on; number of registered patients, and number/nature of IEP exchanges in the PRE and POST periods.
Results: 355 patients (251 (70.7%) male, mean age 45.2 (± 9.3), 33 (9.4%) with cirrhosis) met the inclusion criteria, of whom 222 (62.5%) were on ORT. Self reported drug use/positive toxicology was unchanged POST vs PRE period (table 1). POST there was a trend to increased self reported IVDU. 97/144 (67.4%) patients attending specialist addictions clinics linked to the IEP database. There was a numerical rise in patients accessing IEP. More patients accessed needles only, and fewer accessed foil (for heroin inhalation, an IVDU alternative) alone or in combination with needles. To date ITT SVR rates are high amongst those with and without drug use PRE: 114/121 (94.2) vs 62/64 (96.8), $p = 0.65$ or POST: 107/115 (93.0%) vs 57/58 (98.3%) $p = 0.14$. 3 patients died of probable drug related causes. There was one probable and one possible reinfection.

Drug Use	PRE (%)	POST (%)	*p*
Self reported drug use	114/197 (57.9)	117/193 (60.6)	0.58
Self reported IVDU	17/197 (8.6)	28/193 (14.5)	0.07
Any evidence of drug use (self reported or toxicology)	135/201 (67.2)	142/201 (70.6)	0.45
Patient with IEP Transactions	46/144 (31.9)	53/144 (38.8)	0.38
Patients with IEP needle only transactions	32/46 (69.5)	50/53 (94.3)	0.001
Patients with IEP foil transactions (± needles)	14/53 (26.4)	3/53 (5.7)	0.006

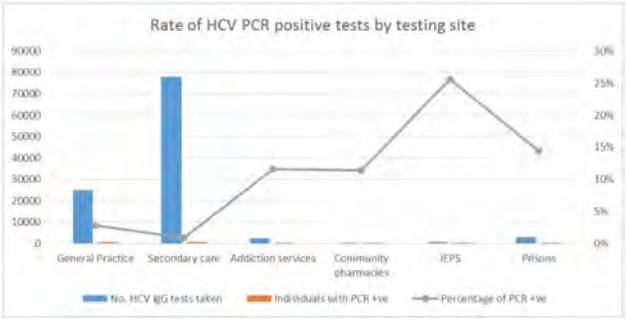
Conclusion: Overall drug use was stable between the PRE and POST periods, however there was a trend towards increased reported IVDU, numerically higher numbers attending for IEP, and a rise in patients accessing needle only IEP. Further qualitative work is required to explore these changing patterns, however these changes, together with the drug related deaths and reinfection observed, reinforce the need for promotion and linkage to harm reduction/IEP as a core part of HCV treatment. SVR rates remain high irrespective of drug use in the PRE or POST treatment period.

FRI-252
Comparing the efficacy of hepatitis C diagnostic pathways: Standard testing vs. targeted testing

Emma Robinson[1], Paul Brennan[1], John Dillon[1]. *[1]School of Medicine-University of Dundee, Hepatology, Dundee, United Kingdom*
Email: e.robinson7@nhs.net

Background and aims: NHS Tayside is committed to eradicating the Hepatitis C virus (HCV) by 2030 in line with the World Health Organisation recommendations. This includes diagnosing at least 90% of those infected. With an estimated prevalence of 0.55% we anticipate that we should have 2700 people with chronic HCV. 2300 are known to the team and have either been treated and cured or are in line to be treated. A further 400 are not known to us. It is vital that we diagnose and treat these people in order to prevent further transmission of the virus and achieve elimination.

NHS Tayside have instituted a number of specialised pathways for testing and treatment of HCV amongst the most at-risk populations, including people who inject drugs (PWID), those on opiate substitution therapy and prison inmates. Widespread testing occurs in injecting equipment provision sites (IEPS), community pharmacies, substance misuse centres and the prison service. These models operate in addition to the standard viral hepatitis service.
Our aim was to analyse the efficacy of the new directed diagnosis pathways compared with standard testing.
Method: Data was collected for every Hepatitis C IgG and PCR test ever done in NHS Tayside. We attributed each test to a diagnosis pathway according to the testing source. Clinical records show the testing source for each individual in Tayside with positive antibody results. Pooling this data allowed us to assess pathway efficacy.
Results: Overall the diagnostic activity for HCV has increased over the last two decades. More markedly since 2012 when DAAs were becoming available. The standard diagnostic pathways (General practice and secondary care) show large volume testing with a low rate of PCR positivity. In contrast testing pathways aimed at high risk individuals show a higher PCR positive rate. See figure.



Conclusion: Utilisation of diagnostic pathways targeting populations most at risk of HCV are more effective at yielding new HCV diagnoses than standard pathways. These tailored diagnostic pathways will also resolve some of the health inequalities around drug use and provide methods of ensuring entry to treatment. We believe using targeted testing will find the majority of our undiagnosed population, as we are exhausting the standard pathways. This will help us to direct resources and achieve our aim of elimination by 2030.

FRI-253
Changing epidemiology of hepatitis C: A Hospital-level study

Joana Roseira[1], Mario Jorge Silva[2], Rita Corte-Real[3], Sara Santos[2], Manuel Rocha[2], Helena Pacheco[4], Fernando Maltez[5], Filipe Calinas[2]. *[1]Algarve University Hospital Center, Gastroenterology and Hepatology, Algarve, Portugal; [2]Centro Hospitalar Lisboa Central-Hospital dos Capuchos, Gastroenterology and Hepatology, Lisbon, Portugal; [3]Centro Hospitalar Lisboa Central-Hospital dos Capuchos, Pathology, Lisbon, Portugal; [4]Centro Hospitalar Lisboa Central-Hospital dos Capuchos, Internal Medicine, Lisbon, Portugal; [5]Centro Hospitalar Lisboa Central-Hospital dos Capuchos, Infectiology, Lisbon, Portugal*
Email: jsr_roseira@hotmail.com

Background and aims: After the mass treatment of the longstanding Hepatitis C virus (HCV) patients from the Hepatology clinics, there should be considerable variation in the prevalence and epidemiology of HCV infection. To update HCV epidemiology is critical, because different strategies are required to interrupt different patterns of HCV transmission. Our aim was to characterize the recently newly identified HCV patients for in-hospital treatment.
Method: Analysis of all the confirmed HCV infection cases (defined by positive HCV viral load) between September 2017 and September 2018, at a Tertiary hospital centre. Patient demographical and clinical characterization, including genotype, liver disease stage, transmission patterns and co-infection status, was performed.

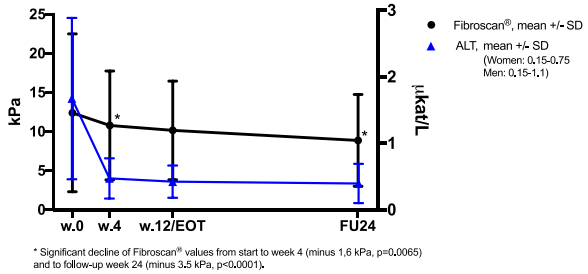
Results: Initially retrieved 276 newly confirmed HCV infections. 48 cases were excluded due to previously confirmed infection (n = 16), ongoing follow-up at other hospitals (n = 4) or lack of information (n = 28). 228 patients (167 males [73.2%]; mean age 51.0 ± 11.2 years old) were identified for further analysis.
Patients were mainly referred to the hospital from primary care (n = 80, 35.1%), other in-hospital outpatient clinics (n = 77, 33.8%) and community support associations for drug users (n = 48, 21.1%). From antibody screening to hospital referral, there was an overall 5-year mean delay. Primary care accounted for the biggest referral delay (7.5 years) followed by community (4.8 years) and in-hospital outpatient clinics (1.2 years). Drug use was the predominant risk factor identified (n = 142, 62%). Liver fibrosis stage distribution was as follow: F0-1, n = 72 (31.6%); F2-3, n = 71 (31.1%); F4, n = 58 (25.4%). Genotype was also identified: G1a/b, n = 83/29 (49.1%); G2, n = 5 (2.2%); G3, n = 63 (27.6%); G4, n = 33 (14.5%); G5, n = 1 (0.4%). Human immunodeficiency virus co-infection was present in 10.9% of the sample.
Conclusion: Unexpectedly, there are only subtle temporal variations concerning HCV epidemiology. There is an even striking expression for drug use as an infection transmission route, and a weightier fraction of patients are being referred to the hospital by non-conventional health care institutions. However, the genotypes distribution did not change and there are still many cirrhotic patients being newly identified for treatment. Still, patients keep experiencing a long delay between screening to in-hospital treatment.

FRI-254
The impact of virally induced hepatic inflammation and low to moderate alcohol consumption on liver transient elastography (Fibroscan) in patients with chronic hepatitis C virus infection treated with direct-acting antivirals

Christoffer Ruus[1], Gunnar Norkrans[1], Magdalena Ydreborg[1], Rune Wejstål[1]. [1]*Inst. for Biomedicine, Dept. of Infectious Diseases, Gothenburg, Sweden*
Email: christoffer.ruus@vgregion.se

Background and aims: Fibrosis assessment using liver transient elastography (Fibroscan®) is important to discriminate patients with moderate or advanced fibrosis. Elastography might overestimate fibrosis for several reasons. This study evaluates the impact on Fibroscan® of DAA treatment and inflammation.
Method: 115 patients treated with DAA were included and repeatedly evaluated by Fibroscan®, HCV-RNA and ALT levels. Alcohol use was evaluated by a modified AUDIT-C questionnaire and phosphatidylethanol 16:0/18:1 (B-PEth), 2 times 3-4 weeks apart, before starting DAA.
Results: 22 patients were excluded mostly because of blood sampling difficulties, unwillingness to continue or breakthrough viremia (n = 3). 98 of the patients fulfilled the pretreatment part of the study concerning alcohol use and 85 patients, all with sustained virologic response (SVR), had complete data including Fibroscan® until follow-up 24 weeks after treatment (FU24).
ALT normalized at week 4 of treatment, together with HCV-RNA levels becoming undetectable or very low. In all 85 patients Fibroscan® mean values declined from baseline 12.4 kPa, week 4 10.8 kPa, EOT/week 12 10.1 kPa and FU24 8.85 kPa (Figure 1).

Figure 1: ALT and Transient Elastography (Fibroscan®) During and After DAA Treatment



* Significant decline of Fibroscan® values from start to week 4 (minus 1.6 kPa, p=0.0065) and to follow-up week 24 (minus 3.5 kPa, p<0.0001).

AUDIT-C evaluating the last 4 weeks of alcohol consumption at first visit correlated moderately with B-PEth levels (r: 0, 54), 56 had undetectable levels while 39 had light to moderate elevation (B-PEth 0.05-0.7 µmol/L). The mean alcohol consumption in the 98 evaluated patients did not change during the pretreatment period (p = 0.53, paired t-test), and mean Fibroscan® values also remained unchanged (p = 0.91, paired t-test). No significant change in liver stiffness was seen in 28 patients who reduced drinking, according to B-PEth, during the pretreatment period.
Conclusion: These new data with Fibroscan® evaluation early during DAA treatment, reveal a 2-phase decline with a first phase of almost 2 kPa, probably due to quickly resolving virally induced inflammation. After 4 weeks a second phase with slower decline is seen during continuing treatment up to 24 weeks after treatment (FU24), probably representing a true decline in fibrosis. Thus, DAA induced reduction of the Fibroscan® value 24 weeks after treatment, is a combined effect of reduced inflammation and fibrosis, representing approximately 50% each. Inflammation must be considered when using Fibroscan® for fibrosis assessment. AUDIT-C can be used to assess alcohol use in patients with chronic hepatitis C. However, a low to moderate alcohol consumption had no significant impact on Fibroscan® values in this study.

FRI-255
Dynamics of HCV epidemiology among HIV+ patients in Vienna

Caroline Schmidbauer[1,2,3], David Chromy[1,2], David Bauer[1,2], Victor Schmidbauer[1,2], Mattias Mandorfer[1,2], Armin Rieger[4], Florian Mayer[5], Heidemarie Holzmann[6], Michael Trauner[2], Michael Gschwantler[3], Thomas Reiberger[1,2]. [1]*Vienna HIV and Liver Study Group, Vienna, Austria;* [2]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria;* [3]*Wilhelminenspital der Stadt Wien, Wiener Krankenanstaltenverbund, Department of Internal Medicine IV, Vienna, Austria;* [4]*Medical University of Vienna, Department of Dermatology, Vienna, Austria;* [5]*Medical University of Vienna, Division of Virology, Department of Laboratory Medicine, Vienna, Austria;* [6]*Medical University of Vienna, Center for Virology, Vienna, Austria*
Email: schmidbauer.c@gmail.com

Background and aims: HIV/HCV coinfection used to be mostly restricted to people who inject drugs (PWIDs), but recently, "high-risk" sex practices among HIV+ men who have sex with men (MSM) have been reported as routes of HCV transmission. At the same time, novel direct acting antivirals (DAAs) against HCV achieved sustained virologic response (SVR) rates > 95%. We retrospectively analyzed changes in HCV epidemiology in our cohort of n = 1874 HIV+ patients.
Method: HCV serology/PCR results were recorded at HIV diagnosis (baseline, BL) and at last visit (follow-up, FU) for all HIV+ patients with a clinical visit at our HIV-clinic between January 2014 and December 2016. The proportions of HIV+ patients with anti-HCV (+) and HCV viremia (HCV-RNA+) were assessed and stratified by the suspected route of transmission. Finally, rates of spontaneous or treatment-induced HCV clearance (anti-HCV (+) and HCV-RNA (–)) were calculated.
Results: N = 1806/1874 (96.4%) patients were tested for HCV. 359/1793 (20.0%) were anti-HCV (+) and 208/343 (60.6%) showed HCV viremia. The discrepancy between the total numbers of patients in the individual subgroups results from the retrospective study design, due to which HCV-testing did not follow a universal standardized protocol.
At BL, anti-HCV (+) was observed in 93.2% (276/296) of PWIDs and in 3.0% (25/823) of MSMs.
1644/1806 (91.0%) of the patients had an HCV test at FU. 50/1508 (16.6%) were anti-HCV (+) and 132/397 (33.2%) showed HCV viremia. 195/208 of the initially HCV-coinfected patients (93.8%) underwent FU HCV-testing: 30 (15.4%) had spontaneously cleared HCV, 76 (39.0%) had achieved SVR due to antiviral therapy and 89 (45.6%) were still HCV viremic. 168/187 (89.8%) of PWIDS and 43/715 (6.0%) of

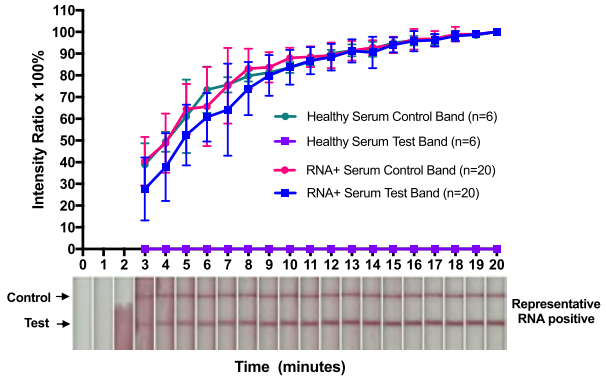
MSM showed anti-HCV (+) at FU. Among the 1433 initially HCV-naive patients, 45/1294 (3.5%) acquired de-novo HCV infection.
Conclusion: HCV testing has been sufficiently implemented among HIV+ patients. Over a median FU period of 6.9 years, anti-HCV (+) prevalence remained stable (89.8 to 93.2%) in PWIDs and increased (3.0 to 6.0%) in MSM. Spontaneous and treatment-induced HCV clearance occurred in 15.4% and 39.0% of HCV/HIV+ patients, respectively. 89 (45.6%) patients remained untreated and 45 new cases of HCV (3.5% of the HIV+ population) were observed.

FRI-256
Procoagulant imbalance in chronic hepatitis C and its relationship with cardiovascular and liver damage
Giordano Sigon[1], Giuseppina Pisano[1], Roberta D'ambrosio[2], Mariagrazia Clerici[3], Veena Chantarangkul[3], Pietro Lampertico[2], Roberta Sollazzi[1], Flora Peyvandi[3], Armando Tripodi[3], Silvia Fargion[1], Anna Ludovica Fracanzani[1]. *[1]Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan Italy, Pathophysiology and Transplantation, Metabolic Liver Diseases Research Center, Milan, Italy; [2]Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan Italy, CRC AM e A Migliavacca Center for liver diseases Gastroenterology and Hepatology, Milan, Italy; [3]Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan Italy, Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Milan, Italy*
Email: gio.sigon@virgilio.it

Background and aims: Chronic C Hepatitis (CHC) is one of the most important causes of morbidity and mortality not only for liver but also for cardiovascular diseases, the last occurring mainly in the presence of metabolic syndrome and steatosis. A procoagulant imbalance, potentially responsible for cardiovascular disease has been reported in patients with NAFLD as well as in subjects with any causes of cirrhosis. Aim: to evaluate the complex interplay between the procoagulants and anticoagulants in naïve, non-cirrhotic CHC patients, the role of coexisting steatosis and the relationship among coagulation imbalance, liver and cardiovascular damage.
Method: From 2014 to 2018, 205 patients with CHC were enrolled. Clinical and biochemical parameters, cardiovascular assessment, (carotid and cardiac ultrasound), presence of steatosis (ultrasound), severity of liver damage [transient elastography and non-invasive fibrosis scores (FIB-4 and NAFLD fibrosis score)] and coagulation balance through the evaluation of procoagulants (FII and FVIII, anticoagulants [antithrombin and protein C (PC)], endogenous thrombin potential (ETP) and peak-thrombin ratio with/without thrombomodulin were determined at enrollment. Coagulation parameters of CHC patients were compared to those of 188 control subjects, enrolled among hospital employers and healthy patients" relatives.
Results: Ultrasound evidence of steatosis was detected in 87 patients (42%). No difference in carotid and cardiac parameters and in severity of liver fibrosis was observed in CHC patients with or without steatosis despite higher BMI, triglycerides, prevalence of hypertension, diabetes, use of statin and lower HDL values in patients with steatosis. Indexes of procoagulant imbalance defined as high FVIII, FVIII/PC ratio, ETP-ratio and peak-thrombin-ratio (with/without thrombomodulin) were significantly higher in CHC patients than in controls without differences between CHC with or without steatosis. Indexes of procoagulant imbalance were independently associated with liver fibrosis [FVIII and FVIII/PC ratio with FIB-4 (coefficient 7.6, SE 3.7, p = 0.04 and coefficient 0.1, SE 0.07, p = 0.03, respectively) and with carotid intima-media thickness (IMT) [FVIII/PC ratio with IMT (coefficient 0.8, SE 0.4, p = 0.05)].
Conclusion: Patients with non-cirrhotic CHC have a procoagulant-imbalance that may play a role both in their increased risk of cardiovascular disease and in severity of fibrosis.

FRI-257
Making OraQuick quicker: A hepatitis C point-of-care assay reduced to five minutes for viremic individuals
Aaron Vanderhoff[1,2], David Smookler[1,2], Mia Biondi[1,2], Camelia Capraru[1,2], Bettina Hansen[1,3,4], Hemant A Shah[1,2], Harry Janssen[1,2], Jordan Feld[1,2,5]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]VIRCAN Care and Research, Toronto, Canada; [3]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; [4]Erasmus University Medical Centre, Gastroenterology and Hepatology, Rotterdam, Netherlands; [5]University of Toronto, Sandra Rotman Centre for Global Health, Toronto, Canada*
Email: david@vircan.ca

Background and aims: Point-of-care testing for hepatitis C virus (HCV) increases access to screening for hard-to-reach populations and in settings with high test volumes or limited laboratory facilities. OraQuick HCV Rapid Antibody Test (OQ) is an FDA-approved lateral flow-based enzyme linked immunosorbent assay (ELISA) that detects anti-HCV antibodies (Ab) in whole blood or serum. The approved assay requires results be determined 20-40 minutes after test initiation; however, field observations suggest it may be possible to decrease read-time (RT) for viremic individuals (VIs). Our aim is to determine whether a RT prior to 20 minutes can be established for VIs that is non-inferior to the required 20-40 minutes RT.
Method: Blood samples from 46 HCV VIs and 11 long term resolvers (defined as clearing HCV > 5 years prior) were tested with the OQ assay. Serial photos were taken for up to 20 minutes, and the time of first appearance of a positive band was recorded and confirmed by a second reader. Intensity ratio analysis was used to compare positive test bands at each time point to their final intensities. Negative controls included 6 uninfected subjects. Data collection is ongoing.
Results: By 5 minutes, 46/46 VIs had a positive result. The mean time to positivity was 2.6 minutes in VIs, compared to 7.4 minutes in the long-term resolvers ($p < 0.0001$). VIs were 65% male, median age of 59, median HCV RNA of 1.91×10^6 IU/ml, and 16 had cirrhosis. The long-term resolvers cleared the virus 5-14 years ago, following treatment, and all were cirrhotic. In contrast to the VIs, only 6 of 11 long-term resolvers were positive at 5 minutes. Based on these results, the probability of a VI testing positive by 5 minutes was 100% (95% CI, 92.3-100). Intensity analysis demonstrated that test bands from VI samples darken within 5 minutes to 52% (± 14%) of their final intensities, which is easily detectable (see figure). Kinetics of band intensity in viremic samples are shown in the figure, accompanied by a representative example.



Conclusion: Our results demonstrate that the OraQuick HCV Rapid Antibody test can reliably detect anti-HCV Abs by lateral flow in 5 minutes among viremic individuals. Although there may be value in documenting past HCV infection, the main goal of screening is to identify those infected. This shortened read time for testing may have important implications to improve engagement and linkage to care by facilitating follow-up HCV RNA in as little as 5 minutes.

FRI-258

Sustained virologic response among non-cirrhotic persons who inject drugs: Results from the CanHepC retrospective hepatitis C registry

Daniel Smyth[1], Lisa Barrett[1], Julie Bruneau[2], Leeanna Bulinckx[3], Carla Coffin[4], Brian Conway[5], Shariq Haider[6], Samuel Lee[4], Gisela Macphail[4,7], Stefanie Materniak[8], Heidy Morales[9], Alnoor Ramji[10], Kristoffer Stewart[11], Edward Tam[12], Duncan Webster[1,8]. *[1]Dalhousie University, Halifax, Canada; [2]Centre Hospitalier de l'Université de Montréal, Montreal, Canada; [3]PerCuro Clinical Research Ltd., Victoria, Canada; [4]University of Calgary, Calgary, Canada; [5]Vancouver Infectious Diseases Centre, Vancouver, Canada; [6]McMaster University, Hamilton, Canada; [7]Calgary Urban Project Society, Calgary, Canada; [8]Centre for Research, Education and Clinical care of At-Risk Populations, Saint John, Canada; [9]University Health Network, Toronto, Canada; [10]GI Research Institute, Vancouver, Canada; [11]Saskatchewan Infectious Disease Care Network, Saskatchewan, Canada; [12]LAIR Center, Vancouver, Canada*
Email: dr.daniel.smyth@horizonnb.ca

Background and aims: In Canada, most incident cases of hepatitis C virus (HCV) occur in those engaged in high risk activities including injection drug use (IDU). Limited data exists on characteristics and treatment outcomes in this population in Canada. The current study assessed baseline characteristics and treatment outcomes in those with a history of IDU in the Canadian Network on Hepatitis C (CanHepC) retrospective registry which includes patients from diverse clinical settings across Canada. Outcomes were compared to those without a history of IDU.
Method: The CanHepC retrospective registry has combined demographic and outcome data on patients with chronic HCV who were assessed at 13 academic and community sites across Canada. All non-cirrhotic individuals who had information available on current or past IDU as well as results for sustained virologic response (SVR) from the CanHepC retrospective registry were included in the current analysis.
Results: Between January 1, 2015 and December 27, 2017 a total of 1169 non-cirrhotic individuals were treated with direct-acting antiviral (DAA) regimens and had SVR results available at 13 sites across Canada. Of those, 610 (52.2%) had data available on IDU. Findings demonstrated that those with a history of IDU were younger (47.5 vs. 56.0 years, $p < 0.001$), more likely to be male (36.7% vs. 23.5%, $p = 0.001$) and were significantly less likely to be Caucasian (56.8% vs. 93.5%, $p < 0.001$). Genotype 1a was more common in those with a history of IDU (60.5% vs. 46.6%), as was the presence of mixed genotypes 1 and 3 (6.1% vs. 3.2%). SVR rate was found to be 94.4% (95% CI 92.2-96.6) in those with history of IDU which did not significantly differ from those without a history of IDU where SVR rates were found to be 97.0% (95% CI 94.6-99.4).
Conclusion: Individuals with a history of IDU in the CanHepC retrospective registry were more likely to be younger, male, and non-Caucasian. Despite IDU history, overall SVR12 rates in this Canadian cohort are excellent and do not differ significantly from those without any history of IDU.

FRI-259

Characteristics and sustained virologic response of persons reporting illicit substance use in the past 6 months: Results from the CANUHC prospective patient registry

Daniel Smyth[1], Lisa Barrett[1], Sergio Borgia[2], Brian Conway[3], Curtis Cooper[4], Jordan Feld[5], Samuel Lee[6], Stefanie Materniak[7], Heidy Morales[8], Alnoor Ramji[9], Marie-Louise Vachon[10]. *[1]Dalhousie University, Halifax, Canada; [2]Osler Hepatitis Centre, Brampton, Canada; [3]Vancouver Infectious Diseases Centre, Vancouver, Canada; [4]University of Ottawa, Ottawa, Canada; [5]Toronto Center for Liver Disease, Toronto, Canada; [6]University of Calgary, Calgary, Canada; [7]Centre for Research, Education and Clinical Care of At-Risk Populations, Saint John, Canada; [8]University Health Network, Toronto, Canada; [9]GI Research Institute, Vancouver, Canada; [10]CHU de Québec-Université Laval, Québec, Canada*
Email: dr.daniel.smyth@horizonnb.ca

Background and aims: In Canada, most incident cases of hepatitis C virus (HCV) occur in those engaged in high risk activities including injection drug use (IDU). Limited data exists on disease characteristics and treatment outcomes in this population in Canada. The current study assessed baseline characteristics and treatment outcomes in those with a history of IDU in the CANUHC prospective registry.
Method: The Canadian Network on Hepatitis C (CanHepC) prospective registry is collecting demographic and outcome data on patients with chronic HCV who are assessed at academic and community sites across Canada. The prospective registry is enriched with populations of interest in Canada including persons who inject drugs (PWIDs). All individuals who reported illicit substance use within the 6 months prior to baseline were included in the current analysis.
Results: Between January 2016 and May 2018, 445 individuals who reported illicit substance use were enrolled in the registry. Of those, 97 (21.8%) reported use of one or more illicit substances in the prior 6 months. Those with recent substance use were significantly younger (47.6 vs. 51.6 years, $p = 0.005$), and less likely to be currently employed (10.8% vs. 38.0%, $p < 0.001$). This group also reported higher rates of past or current injection drug use (79.4% vs. 56.6%, $p < 0.001$) and were more likely to be Canadian-born (99.0% vs. 90.2%, $p = 0.005$). There were no significant differences in biological sex or proportion who identified as indigenous. Sustained virologic response (SVR) was available at the time of this abstract for 111 patients. Overall, SVR rate was 93.8% [95% CI 85.4-100.0], and did not significantly differ from those without reported recent substance use (96.2% [95% CI 92.0-100.0]).
Conclusion: Individuals with recent substance use in the CANUHC prospective registry were more likely to be younger, Canadian-born and unemployed. Despite current substance use, overall SVR12 rates in this Canadian cohort are excellent and do not differ significantly from those without recent reported substance use.

FRI-260

Improving hepatitis C care cascade through electronic health engagement

Imtiaz Alam[1], Zohha Tariq Alam[2], Imran Alam[1]. *[1]Austin Hepatitis Center, Austin, United States; [2]Austin Hepatitis Center, Austin, United States*
Email: ialam@drimtiazalammd.com

Background and aims: There are multiple challenges in the hepatitis C [HCV] care cascade. Electronic health engagement could emerge as a tool in linking patients to the HCV care cascade. There is an emerging epidemic of people who inject drugs (PWID), contract HCV and then fail to seek treatment for this curable illness. One challenge in testing PWID, particularly in community settings, is linkage to care and treatment following a positive test. Our aim is to link individuals that are HCV RNA positive to care and utilize our online patient database management system (PDMS) with Substance Abuse Treatment Centers to fulfil the linkage portion.
Method: Longitudinal prospective cohort study with HCV screening at the above centers and utilization of a HIPPA compliant PDMS (www.linkagetocare.com). A centrally located Linkage to Care Specialist (LTCS) is notified immediately when an individual's information is entered in the system by the treatment center or self-referred. The LTCS educates the individual and proceeds to link them to care.
Results: January 2017-October 2018, 1838 patients were referred to LTC; 53% self-referred and 47% referred from 38 facilities in 27 states; 94% Texas; 69% were uninsured; 55% were between the ages of 21-40; 59% males. 855 HCV RNA positive patients; 680 (80%) patients were contacted by LTCS; 470 (69%) referred to a medical provider; 22% patients awaiting lab results; 9% lost contact. Patients were connected with an LTCS within 2 days after referral and were contacted twice

before scheduling their first appointment. 172 (37%) patients made it to their first appointment; 83 (48%) initiated therapy; 52% were completing evaluation; 62 (75%) finished therapy or achieved SVR12; 88% were seen in office vs. 12% through telemedicine. Additionally, 55% of patients were from sober living homes, 33% from treatment facilities and 12% from medical clinics.
Conclusion: Targeting PWID is an effective way of reducing the prevalence of HCV infection and ultimately eliminating HCV in our communities. Our study accentuates a promising role for patient engagement in electronic health portals as a tool in linking patients to the hepatitis C care cascade. With the LTC program, there is an increase in patient compliance with linkage to care as compared to current care models. Therefore, continued efforts are needed to increase and improve PWID HCV patient electronic health engagement.

FRI-261
Large-scale screening is not useful to identify individuals with hepatitis B or C virus infection: Final results of a Swiss prospective study

Aicha Trabelsi[1], Astrid Marot[1,2], Cyril Andre[3], Pierre Deltenre[3,4,5].
[1]*Centre Hospitalier Universitaire Vaudois, Division of Gastroenterology and Hepatology, Lausanne, Switzerland;* [2]*CHU UCL Namur, Department of Gastroenterology and Hepatology, Yvoir, Belgium;* [3]*Centre Hospitalier Universitaire Vaudois, Division of Immunology and allergology, Lausanne, Switzerland;* [4]*CUB Hôpital Erasme, Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Brussels, Belgium;* [5]*Clinique St Luc, Department of Gastroenterology and Hepatology, Bouge, Belgium*
Email: pierre.deltenre01@gmail.com

Background: Current treatments are able to control HBV replication and to eradicate HCV in almost all cases. Further improvements in the management of HBV and HCV infections will be possible by focusing on treatment impact at a population level for which screening is an essential step. As many patients with HBV or HCV infection are still undiagnosed, large-scale screening could be useful.
Aim: To investigate whether large-scale screening for HBV or HCV infection (e.g. risk-based vs. age-based) could identify infected individuals.
Method: Individuals between 18 and 80 years attending the pre-operative consultation prior to minor surgery in a general surgical outpatient clinic were tested for HBsAg, anti-HBc and anti-HCV from November 2014 to November 2018. The presence of anti-HCV was confirmed by an Immunodot test. HBV DNA and HCV RNA were determined in HBsAg- and anti-HCV-positive individuals.
Results: Among 3000 individuals tested, 7 were positive for HBsAg (0.26%) and 4 had detectable HBV DNA. Twelve individuals were positive for anti-HCV antibodies (0.44%). Two of them had detectable HCV RNA (0.07%) and 10 had undetectable HCV RNA (5 spontaneously and 5 after a successful antiviral treatment). When compared to HCV negative people, HCV positive individuals had already been screened more frequently for HCV (83.3% vs. 12.8%, $p < 0.001$) as well as for HBV infections (66.7% vs. 21.5%, $p = 0.001$), had more frequently anti-HBc antibodies (33.3% vs. 4.2%, $p = 0.001$), had more frequently HCV household members (16.7% vs. 1.7%, $p = 0.02$), and had used more frequently intravenous drugs (66.7% vs. 0.1%, $p < 0.001$), nasal drugs (58.3 vs. 6.2%, $p < 0.001$) or cannabis (58.3% vs. 7.9%, $p < 0.001$). None of HCV positive individuals were immigrant from an endemic area. The median age of HCV positive individuals was not different from that of those who were HCV-negative (52 years [range: 39-59] vs. 44 years [95% CI: 43-45], $p = 0.1$). Most of the positive individuals were already aware that they were infected (86% of the HBV positive individuals and 100% of the HCV viremic individuals).
Conclusion: In this prospective study performed in a general surgical outpatient clinic, a large-scale screening was not useful to identify individuals with undiagnosed HBV or HCV infection. Screening for HBV and HCV infection should focus on individuals with well-known risk factors.

FRI-262
Genetic variants in the promotor region of the macrophage migration inhibitory factor are associated with severity of HCV-induced liver fibrosis

Theresa Hildegard Wirtz [1], Backhaus Christina[2], Petra Fischer[1], Bergmann Irina[1], Eggermann Thomas[2], Kurth Ingo[2], Christian Stoppe[3], Jürgen Bernhagen[4], Thomas Berg[5], Christian Trautwein[1], Marie-Luise Berres[1]. [1]*University Hospital RWTH Aachen, Medical Department III, Aachen, Germany;* [2]*University Hospital RWTH Aachen, Institute for Human Genetics, Aachen, Germany;* [3]*University Hospital RWTH Aachen, Department of Intensive Care Medicine, Aachen, Germany;* [4]*University Hospital Munich, Institute for Stroke and Dementia Research, Munich, Germany;* [5]*University Hospital Leipzig, Department for Gastroenterology and Hepatology, Leipzig, Germany*
Email: thwirtz@ukaachen.de

Background and aims: Macrophage migration inhibitory factor (MIF) is a proinflammatory cytokine, which is characterized as an important regulator of the innate immune system in different diseases. Two polymorphisms of the MIF promotor-the single nucleotide polymorphism (SNP) –173 G/C and the microsatellite polymorphism –794 $CATT_{5-8}$-show a prognostic relevance in different inflammatory diseases including chronic liver diseases. The aim of the underlying study is to investigate a correlation between these two MIF promotor polymorphisms and the severity of HCV-induced liver fibrosis.
Methods: First, the genotypes of the SNP –173 G/C (rs755622) are determined using taqman genotyping assay in DNA samples extracted from whole blood from 500 patients with HCV-induced liver fibrosis. Second, the repeat number of the microsatellite 794 $CATT_{5-8}$ (rs5844572) is analyzed by specific PCR-based DNA-amplification followed by high resolution gel electrophoresis and fragment length analysis. A correlation between the genotypes of both polymorphisms and the histological grading and staging of HCV-induced fibrosis is investigated.
Results: Concerning the genotypic distribution of the SNP polymorphism only 3% of all patients show the C/C genotype compared to a higher frequency of the G/G and G/C genotype (66%; 31%). Accordingly, a higher repeat number in the microsatellite (7/X) shows only a low prevalence (2%) in our cohort. Interestingly the C/X genotype in the –173 G/C-SNP is associated with a significant lower stage of fibrosis than the G/G genotype (mean fibrosis stage 1.87 vs. 2.06); this effect is even more pronounced regarding the C/C genotype vs. G/G genotype (1.54 vs. 2.06). Additionally, there is a positive correlation between a low repeat number in the microsatellite –794 $CATT_{5-8}$ (genotype CATT5/5; 5/6; 6/6) and the presence of stage 2 and higher levels of fibrosis.
Conclusion: The mentioned MIF promotor polymorphisms correlate with the severity of HCV-induced liver fibrosis. Here, the C/C genotype in the –173 G/C-SNP is associated with a significantly lower fibrosis stage. Our results therefore argue for a prognostic relevance of these two promotor polymorphisms that therefore could represent promising biomarkers in HCV-induced liver disease.

FRI-263
The VirA+EmiC project: Opt out hepatitis B and C testing of 38704 patients in an urban emergency department

Terence Wong[1], Sam Douthwaite[1], Sooria Balasegaram[2], Basel Karo[2], Laura Hunter[3], Susanne Johanssen[1], Ranjababu Kulasegaram[1], Antonio Querol-Rubiera[1], Murad Ruf[4], Gaia Nebbia[1]. [1]*St. Thomas' Hospital, London, United Kingdom;* [2]*Public Health England, London, United Kingdom;* [3]*St. Thomas' Hospital, Department of Emergency Medicine, London, United Kingdom;* [4]*Gilead Pharmaceuticals Inc, Foster, United Kingdom*
Email: wongter@btinternet.com

Background and aims: Previous studies of screening attendees to urban emergency departments (ED) have indicated high detection

rates of hepatitis B (HBV) and hepatitis C (HCV). The current study evaluated the feasibility and detection rates in a large urban emergency department in the United Kingdom.

Method: Over a 9 month period consecutive attendees to an urban ED, who had clinically indicated blood sampling, underwent opt out testing for HBV surface antigen (HBsAg) and HCV (Antibody [Ab]) using an electronic preselected blood order set. All HCV Ab reactive results were followed by reflex HCV antigen (Ag)testing (Abbott Architect). Attendees who were identified as either HBsAg, or HCV Ag were then linked to care by the study team. Seroprevalence estimates and risk factors (age, sex, ethnicity, homelessness, and HIV) associated with seropositivity were estimated using univariable and multivariable Poisson regression.

Results: 81, 088 patients attended the ED, of whom 38, 704 patients (49% male, median age 45yrs [31-62yrs]) had blood sampling. 29, 240 (75.5%) underwent testing for HBV and/or HCV. Of the 28, 941 patients tested for HBsAg, 244 (0.8%, 95% confidence interval [CI] 0.7%-0.9%) were positive. Of the 28, 939 patients tested for HCV, 539 (1.9%, 95%CI 1.7%-2.0%) were HCV Ab positive. Of these 462 patients had HCV Ag measured, of whom 264 (adjusted seroprevalence 1.1%) were HCV Ag positive.

A high HBsAg seroprevalence was observed among patients aged 50-59 years (1.6%), with Black or Asian ethnicity (1.9%, 95%CI 1.6-2.4%), and with HIV infection (4.3%, 95%CI 2.1-8.7%). In the adjusted model, risk factors for infection were being male (relative risk (RR): 1.6, 95%CI 1.2-2.1%), of non-White British ethnicity (RR > 4), being homeless (RR: 1.9, 95% CI 1.0-3.5) or being HIV positive (RR: 4.1, 95%CI 1.9-8.9%). A high HCV Ab seroprevalence was observed in patients aged 30-49 years (2.9%, 95% CI 2.6-3.3%), male (2.9%, 95% CI 2.6-3.2%), homeless (22.1%, 95%CI 19.2-25.3%) and HIV infection (12.3%, 95%CI 8.0-18.4%). In the adjusted model risk factors for HCV Ab positivity were being male (RR:2, 95% CI 1.6-2.5), age 30-49 years (RR:4.4, 95% CI 3.1-6.4), homeless (RR:10.1, 95% CI 8.7-13.0), and being HIV positive (RR:3.6, 95% CI 2.2-5.8)

To date 35 HCV Ag patients have been contacted, 24 were eligible for linkage, and of there 20 have attended clinic.

Conclusion: In this large study of opt out Hepatitis B and C testing good uptake rates are achievable, with a high detection rate of hepatitis B and C. For hepatitis B the greatest risk factor was being of non-white ethnicity, and for hepatitis C being homeless. Linkage to care remains a challenge.

FRI-264

Silencing clusterin supress the progression of hepatitis C virus-related HCC by regulating autophagy and attenuating HCC cell properties

Yuemin Nan[1], Xiaoxiao Zhang[1], Na Fu[1]. [1]*Department of Traditional and Western Medical Hepatology, Third Hospital of Hebei Medical University, Hebei Province, Shijizhuang, China*
Email: nanyuemin@163.com

Background and aims: Hepatitis C virus (HCV) induced hepatocellular carcinoma (HCC) threatens human health worldwide. At present, effective therapeutic target for HCV-HCC is still absent.

Method: Twelve patients with HCV-related HCC and 3 age- and gender-matched liver transplant donors were included in the study. Differentially expressed mRNAs in plasma of the patients with HCV-HCC were detected by digital gene expression (DGE) profile analysis. Hepatic clusterin and autophagy-related genes were detected through qRT-PCR and Western blot. Meanwhile, we set up HCC cell lines stably expressed HCV core protein, and detected the expression of CLU and autophagy-related genes by qRT-PCR and Western blot, and also observed autophagy by transmission electron microscopy. Furthermore, we knocked down CLU by siRNA transfection and then detected cell autophagy by transmission electron microscopy, cell apoptosis and cell cycle by flow cytometry, cell proliferation by Cell Counting Kit-8 (CCK-8) kit, and cell invasion by Transwell assay, as well as the expression of related genes were detected by qRT-PCR and Western blot.

Results: We found that CLU was dramatically increased in tumor tissues of HCV-HCC and HCC cell lines stably expressed HCV core protein, which accompanied with the increased autophagy and pro-autophagy gene expression. When knockdown of CLU in HCC cell lines, we found that cell autophagy was dramatically decreased, autophagy marker LC3B II/I ratio was decreased, and the pro-autophagy genes like Beclin1, Atg7 and lamp2 was downregulated. On the other hand, the anti-autophagy genes or regulators including p62, p-mTOR were notably upregulated. Meanwhile, cell apoptosis was increased, pro-apoptosis gene BAX, PARP, AKT, Caspase3 and Caspase9 were dramatically increased, and anti-apoptosis gene Bcl2 was decreased. Also, knockdown of CLU could regulate cell cycle and inhibit proliferation, and inhibit cell invasion, which accompanied with downregulated matrix metalloproteinase (MMP) 2 and N-cadherin and upregulated tissue inhibitor of metalloproteinase (TIMP) 1, E-cadherin and Vimentin.

Conclusion: CLU could promote the progression of HCV-related HCC by regulating autophagy. Knockdown of CLU could attenuate tumor properties of HCC cell lines, which might be a potential therapeutic target of HCV-related HCC.

Gut microbiota and liver disease

FRI-265

Twelve weeks of effective resistance training did not change the gut microbiota in patients with cirrhosis

Luise Aamann[1,1], Gitte Dam[1], Hendrik Vilstrup[1], Meghana Malyala[2], Patrick Gillevet[2], Jasmohan S Bajaj[3], Niels Kristian Aagaard[1]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark;* [2]*George Mason University, Microbiome Analysis Center, Manassas, United States;* [3]*Virginia Commonwealth University and McGuire VA Medical Center, Division of Gastroenterology, Hepatology and Nutrition, Richmond, United States*
Email: luise.aamann@gmail.com

Background and aims: Increasing evidence demonstrates that physical activity may modulate the gut microbiota composition and stimulate a health-promoting effect in healthy individuals and in patients with chronic diseases e.g. diabetes. In cirrhosis, the composition and changes of the gut microbiota affect disease severity and complications, including higher relative abundance of gram-negative proteobacteria. We examined if 12 weeks of resistance training could alter the microbiota in patients with cirrhosis.

Method: 39 patients with cirrhosis Child Pugh A/B were randomized 1:1 to either an exercising group performing 12 weeks of progressive resistance training three times per week or a non-exercising control group. Diet was protein-rich Northern European. Stool samples were collected at week 0 and 12 from 17 exercisers and 14 controls and analyzed using 16S rRNA sequencing. Microbial taxa at the family level were studied between and within groups at baseline and post-exercise.

Results: Diet, use of antibiotics and hepatic encephalopathy treatment (lactulose, BCAA, rifaximin) were equal among groups and the resistance training increased muscle mass and strength. There were no changes in Shannon diversity or UniFrac between groups at baseline and study-end. Two patients in the exercise group did not improve their muscle strength. These patients had a higher relative abundance of Proteobacteria (Piscirickettsiaeae, Hyphomonadaceae, Caulobacterales) compared to those who improved muscle strength (n = 15). Interestingly Proteobacteria were higher in these patients at baseline as well.

Additionally, patients with diabetes (n = 9), showed no difference in their microbiota versus patients without diabetes. Former versus current smokers showed an increase in Rikenellaceae and a decrease in Firmicutes and Clostridia.
Conclusion: Although based on a secondary outcome of a randomized clinical trial, our findings lend no support to the hypothesis that the beneficial effects of physical activity to involve gut microbiota.
Yet, the microbiota may affect the results of resistance training and exercise-improved muscle strength may be associated with lower Proteobacteria constituents at baseline and at study-end.

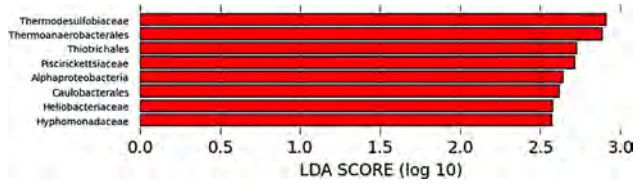


Figure 1: Taxa showing higher relative abundance at 12 weeks in those who ultimately did not improve after resistance training compared to those who improved

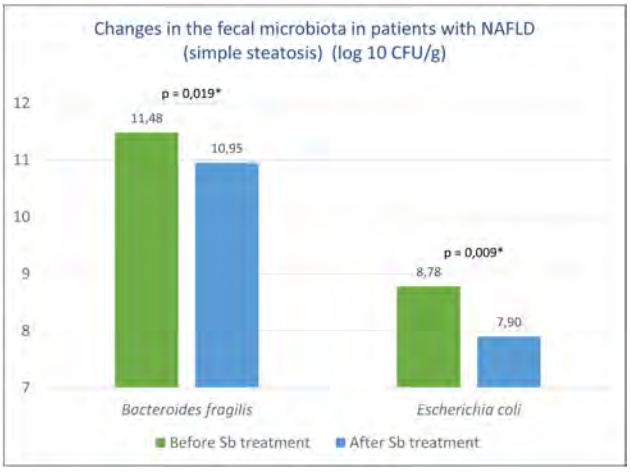
FRI-266
Saccharomyces boulardii modulates the colonic microbiota towards a more favourable composition in patients with non-alcoholic fatty liver disease (simple steatosis)
Pavel Seliverstov[1], Stanislav Sitkin[2,3], Elena Avalueva[2], Timur Vakhitov[3], Elena Demyanova[3], Maria Suvorova[4], Valeriy Radchenko[1]. [1]*North-Western State Medical University named after I.I. Mechnikov, Department of Internal Medicine and Nephrology, St. Petersburg, Russian Federation;* [2]*North-Western State Medical University named after I.I. Mechnikov, Department of Internal Diseases, Gastroenterology and Dietetics named after S.M. Ryss, St. Petersburg, Russian Federation;* [3]*State Research Institute of Highly Pure Biopreparations of FMBA, Department of Microbiology, St. Petersburg, Russian Federation;* [4]*Institute of Experimental Medicine, St. Petersburg, Russian Federation*
Email: drsitkin@gmail.com

Background and aims: Recent experimental studies show that *Saccharomyces boulardii* maintains the integrity of the intestinal barrier and exerts some anti-inflammatory effects. The aim of this study is to investigate changes in the composition of fecal microbiota and some clinical parameters following treatment with lyophilized *Saccharomyces boulardii* in patients with NAFLD (steatosis only).
Method: 25 adult patients with NAFLD (steatosis only) were enrolled in the study. The quantitative real-time polymerase chain reaction (qRT-PCR) was used for fecal microbiota assessment. All patients were treated with oral lyophilized *Saccharomyces boulardii* CNCM I-745® for 90 days (3 capsules 250 mg per day).
Results: The count of *Escherichia coli* in patients with NAFLD steatosis was initially higher than the reference values obtained from healthy volunteers. Lyophilized *S. boulardii* (Sb) for 90 days significantly reduced *Bacteroides fragilis* group and *Escherichia coli* (Figure) There were no significant changes in other fecal microbiota (total bacterial count, *Lactobacillus* group, *Bifidobacterium* spp., *Faecalibacterium prausnitzii*, etc.). Treatment with *S. boulardii* improved symptoms and quality of life in patients with NAFLD steatosis and significantly reduced VLDL and atherogenic index. Patients with overweight or obesity showed a decrease in body weight. In all patients, steatosis showed no progression as assessed by FibroMax® test, liver ultrasonography and telomere test.



Conclusion: *Saccharomyces boulardii* CNCM I-745® significantly reduced initially elevated fecal *Escherichia coli* in patients with NAFLD steatosis to normal values, thus reducing the risk of additional liver damage by endogenous ethanol and inhibiting the choline deficiency. *S. boulardii* significantly lowered *Bacteroides fragilis* group, thus reducing the risk of endotoxemia. The lack of progression of steatosis after 90 days suggests the effectiveness of *S. boulardii* in patients with NAFLD. Lyophilized *Saccharomyces boulardii* modulates the composition of the gut microbiota in patients with NAFLD steatosis and restores intestinal barrier integrity, thus preventing the progression of the disease.

FRI-267
Serial measurement of serum dextran absorption by novel competition ELISA demonstrates larazotide acetate significantly improves "leaky gut" in a Western diet murine model of metabolic liver disease
Rebecca Caffrey[1], Jonathon Marioneaux[1], Madhavi Bhat[1], Christopher Prior[2], Jay Madan[2], Sandeep Laumas[2], Arun Sanyal[3]. [1]*Sanyal Biotechnology, Norfolk, United States;* [2]*Innovate Biopharmaceuticals, Raleigh, United States;* [3]*Virginia Commonwealth University, Richmond, United States*
Email: rebecca@sanyalbio.com

Background and aims: Integrity of the gut epithelial barrier is critical to preventing bacterial translocation; increased Gut Permeability (GP) ("leaky gut") contributes to inflammation and the development of numerous liver diseases. Larazotide Acetate is a gut-specific intestinal permeability re-normalizing agent that acts by regulating tight junctions. The purpose of the study was to test efficacy of larazotide at high and low doses via drinking water and oral gavage in the DIAMOND™ mouse model, which develops significantly leaky gut that worsens with advancing liver disease status.
Method: 60 DIAMOND™ mice were weight randomized to 8 groups, placed on either normal chow (NDNW) or Western Diet (42% fat, 4% sugar water, WDSW) and aged up to baseline 8 wks (NAFLD) then dosed with larazotide at 1 mg/ml or.1 mg/ml ("HD" and "LD," respectively) in sugar water, or gavaged twice daily with.3 mg or.03 mgs ("HD" and "LD," respectively) in aqueous vehicle. Pioglitazone, an insulin sensitizer lacking impact on gut permeability, was gavaged at 27 mg/kg. Mice were dosed from baseline 8 wks to study end at 16 wks. GP was assessed at baseline and end with modified competition ELISA for serum dextran; mice were gavaged with 4 kDa dextran @ 600 mg/kg and 20 µL of serum was taken by tail vein nick 4 hours later for dextran measurement. Serum and liver were collected at necropsy and LFTs and histology were assessed.
Results: Serum dextran levels at baseline were very low in all groups; as expected GP increased by 16 wks on WDSW and in pair-wise comparison, average serum dextran in the bottle VC, gavage VC, and

pioglitazone groups increased 16x (p = .005), 63x (p = .084) and 6x (p = .032) over their respective baselines. Larazotide treatment significantly attenuated GP deterioration; in paired T-tests HD bottle and LD gavage groups were not statistically different from their baselines. Comparison of serum dextran levels between groups at end of study showed that the biggest effects were in the HD bottle and LD gavage groups (both groups were significantly lower than either VC, pioglitazone, LD bottle and HD gavage; see P value matrix). The LD bottle group did not differ statistically from VC groups or pioglitazone.

Conclusion: This study demonstrated that leaky gut develops rapidly between 8–16 wks on WDSW in the DIAMOND™ mouse model, and that oral administration of larazotide effectively retards the deterioration in gut permeability; administration by high-dose bottle or low-dose gavage was the most effective. Since the time course did not allow development of histologic liver disease indicative of non-alcoholic steatohepatitis, it was not possible to evaluate the impact on liver function and longer duration on a high fat diet which are being investigated in ongoing studies.

FRI-268

Microbiota signature differs significantly between NAFLD and healthy controls but not between NAFL and NASH

Münevver Demir[1], Sonja Lang[1], Fedja Farowski[2], Hilmar Wisplinghoff[3], Maria J.G.T. Vehreschild[2,4], Marcin Krawczyk[5,6], Angela Nowag[3], Frank Lammert[5], Anna Martin[1], Tobias Goeser[1], Hans-Michael Steffen[1]. *[1]Clinic for Gastroenterology and Hepatology, University Hospital of Cologne, Cologne, Germany; [2]Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany; [3]Wisplinghoff Laboratories Cologne, Cologne, Germany; [4]Department of Medicine II, University Hospital Frankfurt, Frankfurt, Germany; [5]Department of Medicine II, Saarland University Medical Center Homburg, Homburg, Germany; [6]Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland*
Email: muenevver.demir@uk-koeln.de

Background and aims: Previous studies have shown that gut dysbiosis is associated with non-alcoholic fatty liver disease (NAFLD). However, the data regarding differences in microbiota composition between the two NAFLD phenotypes, i.e. non-alcoholic fatty liver (NAFL) and non-alcoholic steatohepatitis (NASH) are inconsistent. In this prospective cross-sectional study we aimed to evaluate the association between gut bacterial dysbiosis and the presence of NAFLD in general and NAFL and NASH in particular.

Method: Ninety patients with NAFLD (n = 21 NAFL, n = 47 NASH; n = 23 without liver biopsy) and 21 healthy controls (HC) were enrolled. Taxonomic composition of gut microbiota was determined using 16S rDNA gene sequencing of stool samples. Linear discriminant analysis (LDA) effect size (LEfSe) analysis, followed by multivariate logistic regression was performed to detect differences in the bacterial composition of gut microbiota between the groups.

Results: Mean age of all study subjects (n = 111) was 44.5 years (SD±14.3) and 54 (49%) were women. Comparing NAFLD to HC we observed three phyla and nine families to differ significantly (p < 0.05) between the two groups. After multivariate analysis only the differences in abundance of *Bacteroidetes* (phylum) and *Ruminococcaceae* (family) between NAFLD and HC remained significant. LEfSe found no phyla but twelve families to be significantly different between biopsy-proven NAFL and NASH (p < 0.05). However, after multivariate logistic regression (adjusted for the presence of metabolic syndrome) the difference in gut microbiota composition between NAFL and NASH was no longer statistically significant.

Conclusion: The gut microbiota composition seems to differ significantly between NAFLD and HC but not between NAFL and NASH. Thus, whereas bacterial gut microbiota signature could serve as a biomarker for the diagnosis of NAFLD, this might not be sufficient to accurately distinguish between NAFL and NASH.

FRI-269

Regulation of lymphangiogenesis by Paneth cells in normal physiology and experimental portal hypertension

Mohsin Hassan[1], Andrea De Gottardi[2], Sheida Moghadamrad[2]. *[1]University Hospital, Bern, Department of Biomedical Research, Hepatology, Bern, Switzerland; [2]University Hospital, Bern, University Clinic for Visceral Surgery and Medicine and Department of Biomedical Research, Hepatology, Bern, Switzerland*
Email: sheida.moghadamrad@dbmr.unibe.ch

Background and aims: The mesenteric lymphatic network contributes to the transport of fluid and intestinal mucosal associated immune cells along the gut-liver axis. We hypothesized that Paneth cells, as part of the innate intestinal immune system, regulate the development of lymphatic vessels and affect portal pressure under the control of intestinal bacteria.

Method: We induced Paneth cell depletion in Math-1 Lox/LoxVillcre^{ERT2} mice by injecting three consecutive doses of tamoxifen and performed partial portal vein ligation (PPVL) to induce portal hypertension. After 14 days, intestinal and mesenteric lymphatic vessels were assessed by immunohistochemistry (IHC) using lymphatic vessel endothelial hyaluronic acid receptor 1 (Lyve-1) antibody. The lymphatic vessels were quantified using Metamorph to calculate pixel ratio. Expression of genes involved in the regulation of lymphatic vessels was evaluated by RT^2 profiler PCR array in intestinal tissue. Intestinal organoids from control and Paneth cell depleted mice were exposed to different bacterial derived products. Proteomic analysis of conditioned media was performed using MaxQuant to analyse differentially regulated proteins in lymphangiogenesis in the absence of Paneth cells and/or in portal hypertension.

Results: Portal pressure was significantly attenuated in Paneth cell depleted mice compared to control mice after PPVL (n = 11/group, 9.78 ± 1.23 cmH_2O vs 11.45 ± 1.41 cmH_2O, respectively, $p < 0.002$). Depletion of Paneth cells resulted in a significantly decreased density of lymphatic vessels compared to control as assessed by IHC (n = 5, pixel ratio), in the intestine (0.176%±0.12 vs 0.367%±0.15, p = 0.01) and in the mesentery (0.160%±0.06 vs 0.404%±0.20 p = 0.001). Quantitative PCR showed a decreased expression of genes involved in the regulation of lymphangiogenesis, including VEGF-C, VEGF-D, VEGF-A, Nrp2, Angpt-2, Tie-1, Tie-2, TGF-α, HGF and CXCL-1 in Paneth cell depleted mice. In the absence of Paneth cells, proteomic analyses showed a significant downregulation of several proteins involved in lymphatic vessel development and morphogenesis, as well as in processes of lipid metabolism and transport.

Conclusion: In the absence of Paneth cells, the intestinal and mesenteric lymphatic vessel networks were significantly underdeveloped. This resulted in an attenuated portal hypertension. These findings suggest that Paneth cells not only play an antimicrobial role in the intestine, but also contribute to the regulation of lymphatic vessels and portal pressure

FRI-270

Association between gut microbiota and hepatocellular carcinoma in patients with chronic liver disease

Takashi Honda[1], Masatoshi Ishigami[1], Kenta Yamamoto[1], Takanori Ito[1], Yoji Ishizu[1], Teiji Kuzuya[1], Mitsuhiro Fujishiro[1]. *[1]Nagoya University Graduate School of Medicine, Gastroenterology and Hepatology, Nagoya, Japan*
Email: honda@med.nagoya-u.ac.jp

Background and aims: It has been reported that insulin resistance and high fat diet and dysbiosis of gut microbiota are possible causes of carcinogenesis of NASH and NAFLD in animal models. Moreover, it has been reported that there are changes of gut microbiota in patients with hepatocellular carcinoma (HCC) compared with that in patients

without HCC. Therefore, in order to investigate whether gut microbiota is associated with HCC, we determined the differences of gut microbiota by using the next generation sequencer between patients with and without HCC in patients with chronic liver disease.
Method: One hundred and twenty-five out of 133 patients with chronic liver disease have participated in this study. We analyzed fecal samples from 82 patients with HCC and 43 patients with non-HCC in 125 patients suffering from chronic liver diseases and 16 healthy controls. After extracting DNA from feces, the V3-4 region of the 16S rRNA gene was amplified and measured by Illumina Miseq. QIIME and Lefse (Linear discriminant analysis effect size) were used for statistical analysis, and PICRUSt (Phylogenetic Investigation of Communities by Reconstruction of Unobserved States) was used to predict metagenome functional profile of microbial community based on marker genes. We determined the difference in relative abundance of each microbiota among the patients with HCC and non-HCC in patients with chronic liver diseases. Furthermore, we selected the key microbiota, it has gradually decreased relative abundance with significant difference in the following order; HCC > non-HCC > controls.
Results: Characteristics of the patients showed following results in chronic liver disease: male/female = 78/47, Child A/B/C = 98/23/3, among 82 patients with HCC, hepatitis C/hepatitis B/non B non C = 39/12/31, and there was no significant difference in alpha-diversity among patients with HCC and non-HCC. In patients with HCC, *Veillonella, Klebsiella, Pseudoramibacter Eubacterium, Enterococcus* were significantly increased and *Sutterella* was significantly decreased compared with patients with non-HCC ($p < 0.05$). *Veillonella* was selected as key microbiota at the genus level. Bacterial groups which have genes related to ketone body biosynthesis and degradation were increased in patients with HCC, and bacterial groups which have genes related to taurine degradation were decreased.
Conclusion: Increased oral indigenous bacteria such as *Veillonella* might be associated with the difference between patients with HCC and non-HCC.

FRI-271
Rifaximin alleviates endotoxemia with improved intestinal hyperpermeability with partially modified fecal microbiota in cirrhotic patients
Kosuke Kaji[1], Hiroaki Takaya[1], Soichiro Saikawa[1], Shinya Sato[1], Hideto Kawaratani[1], Kei Moriya[1], Tadashi Namisaki[1], Takemi Akanahe[1], Akira Mitoro[1], Hitoshi Yoshiji[1]. [1]*Nara Medical University, Third Department of Internal Medicine, Kashihara, Japan*
Email: kajik@naramed-u.ac.jp

Background and aims: Rifaximin is a minimally absorbed antibiotic effective for hepatic encephalopathy (HE). However, the mechanism of how rifaximin affects HE remains unclear. In this study, we assessed the mechanistic effect of rifaximin on intestinal permeability and gut microbiota in patients with decompensated cirrhosis.
Methods: Thirty clinically stable patients with decompensated cirrhosis (Child-Pugh score > 7) were assessed by cognitive neuropsychological testing, endotoxin activity (EA), and serum proinflammatory cytokines at baseline and after 4 weeks of rifaximin treatment (400 mg thrice a day). Intestinal permeability was assessed by serum levels of soluble CD163 (sCD163), mannose receptor (sMR), and zonulin. Fecal microbiome was analyzed by 16S ribosomal RNA (rRNA) gene sequencing.
Results: Treatment with rifaximin improved hyperammonemia and cognitive impairment, and decreased EA. Rifaximin also lowered serum levels of sCD163 and sMR, but not zonulin. Decreases in sCD163 and sMR were positively correlated with EA decrease (ΔsCD163: $R = 0.680$, $p = 0.023$; ΔsMR: $R = 0.613$, $p = 0.014$, *vs* ΔEA). Rifaximin did not change the diversity or major components of the gut microbiome, although the relative abundance of *Veillonella* was reduced. Serum levels of proinflammatory cytokines were also unchanged.
Conclusions: Rifaximin alleviated HE and endotoxemia with improvement of intestinal hyperpermeability in patients with decompensated cirrhosis. This effect is partially associated with a minor change in bacterial composition, although further investigation is required to clarify other key mechanisms to preserve intestinal barrier function.

FRI-272
Identification of novel glycans that target gut microbiota-associated ammonia production
Kelsey Miller[1], Jonathan W. Leff[1], Nicholas Beauchemin[1], Christopher Liu[1], Mitchell Antalek[1], David Belanger[1], Ruth Thieroff-Ekerdt[2], Michael A. Mahowald[1], Margaret J. Koziel[1], Madeline Hartman[1], Maxwell Hecht[1], Anastasia Murphy[1], Brian Meehan[1]. [1]*Kaleido Biosciences, Inc., Lexington, MA, United States;* [2]*Kaleido Biosciences, Inc. (former), Lexington, MA, United States*
Email: kelsey.miller@kaleido.com

Background and aims: The human gut microbiome impacts health and disease by affecting metabolism, nutrition, immune function, and other organ systems. The gut microbiome plays a significant role in the production and consumption of ammonia, which is central to the pathogenesis of hepatic encephalopathy (HE). Existing therapies, such as lactulose, reduce blood ammonia but are poorly tolerated. We sought to develop Microbiome Metabolic Therapies (MMTs) that include synthetic, novel oligosaccharide compositions (glycans) to reduce net ammonia production by the gut microbiome with good tolerability. Glycans are found in many food products, and many are Generally Recognized As Safe under US FDA regulation.
Method: Ex vivo screening of more than 200 glycans across healthy human microbiome samples identified glycans that reduced ammonia concentration to a variable degree. Ten glycans were further tested in an ex vivo assay with 19 fecal microbiome samples from hepatically impaired patients. One of the top-performing glycans was then evaluated in a placebo-controlled, randomized, double-blind clinical study in 47 healthy human subjects. Subjects were given a standard dose of lactose ^{15}N-ureide as a tracer for bacterial urease activity both at baseline and at the end of 21 days of oral administration of the test glycan or 1 of 3 comparator compounds. Total ^{15}N-nitrogen excretion in urine is indicative of hepatic exposure to ammonia produced by colonic gut bacteria. Assessment of GI tolerability included the Gastrointestinal Tolerability Questionnaire (GITQ), which assesses symptoms like flatulence and abdominal cramping, and the Bristol Stool Scale (BSS), which assesses stool consistency.
Results: One of the top-performing glycans in the ex vivo screen, KB195, reduced ammonia to levels equal to or less than lactulose in 74% (14/19) of the microbiome samples from hepatically impaired patients. In the clinical study, subjects showed a clinically relevant decrease in ^{15}N-nitrogen excretion after ingestion of KB195 vs the placebo control ($p = 0.002$). Tolerability of KB195 was comparable to that of placebo at all doses in both GITQ and BSS.
Conclusion: An ex vivo screening in human microbiome samples was effective in identifying an MMT that showed a clinically relevant reduction of gut-derived ammonia in a clinical study and was well tolerated. Future clinical studies aim to demonstrate improved management of patients with HE by reducing ammonia and targeting other unmet needs.

Email: 363111396@qq.com

Background and aims: The occurrence of hepatitis B e antigen (HBeAg) seroconversion is a landmark event indicating immune control on hepatitis B virus (HBV). Currently, there is limited knowledge regarding the association between the composition of intestinal microbiota and HBeAg seroconversion after oral antiviral therapy.
Method: In this cross-sectional study, we collected information on fecal microbiota from the patients with CHB who have oral antiviral therapy and evaluated whether these were associated with HBeAg seroconversion. Thirty-five of these subjects displayed HBeAg seroconversion in the first 3 years after the initiation of oral antiviral therapy, while the remaining 39 subjects remained HBeAg positive even after over 3 years of therapy. Samples were analyzed using 16S ribosomal DNA sequencing. The HBeAg and anti-HBeAg levels were measured for each subject, and the HBV DNA was measured by quantitative PCR.
Results: Using classical approaches, no differences were found between the microbiota from patients with and without HBeAg seroconversion. However, a computational statistical and machine learning approach allowed us to identify a microbial signature for HBeAg seroconversion, consisting of 47 bacterial operational taxonomic units. The microbial signature was able to discriminate patients who achieved HBeAg seroconversion from those who

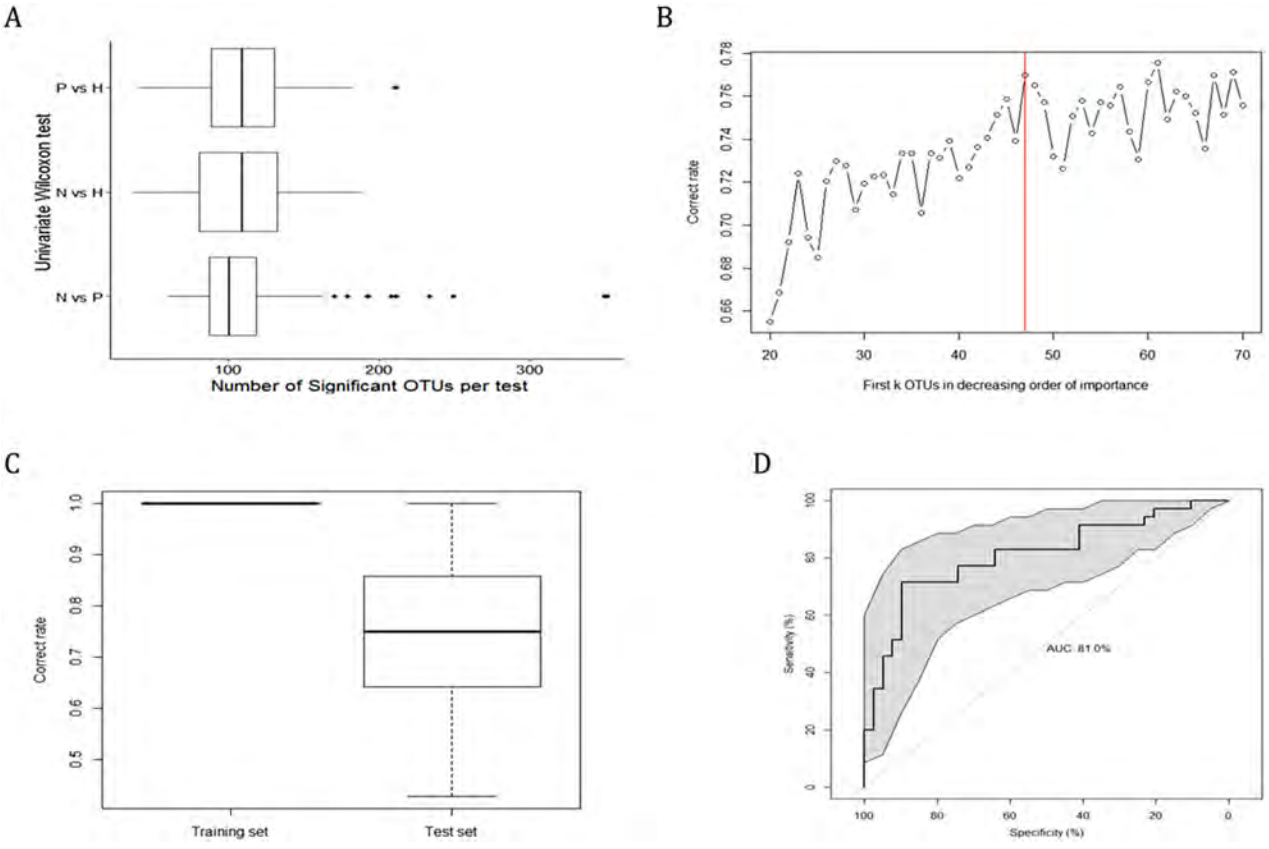

Fig. 2: (abstract: FRI-273): Univariate comparison and machine learning based on HBeAg seroconversion.

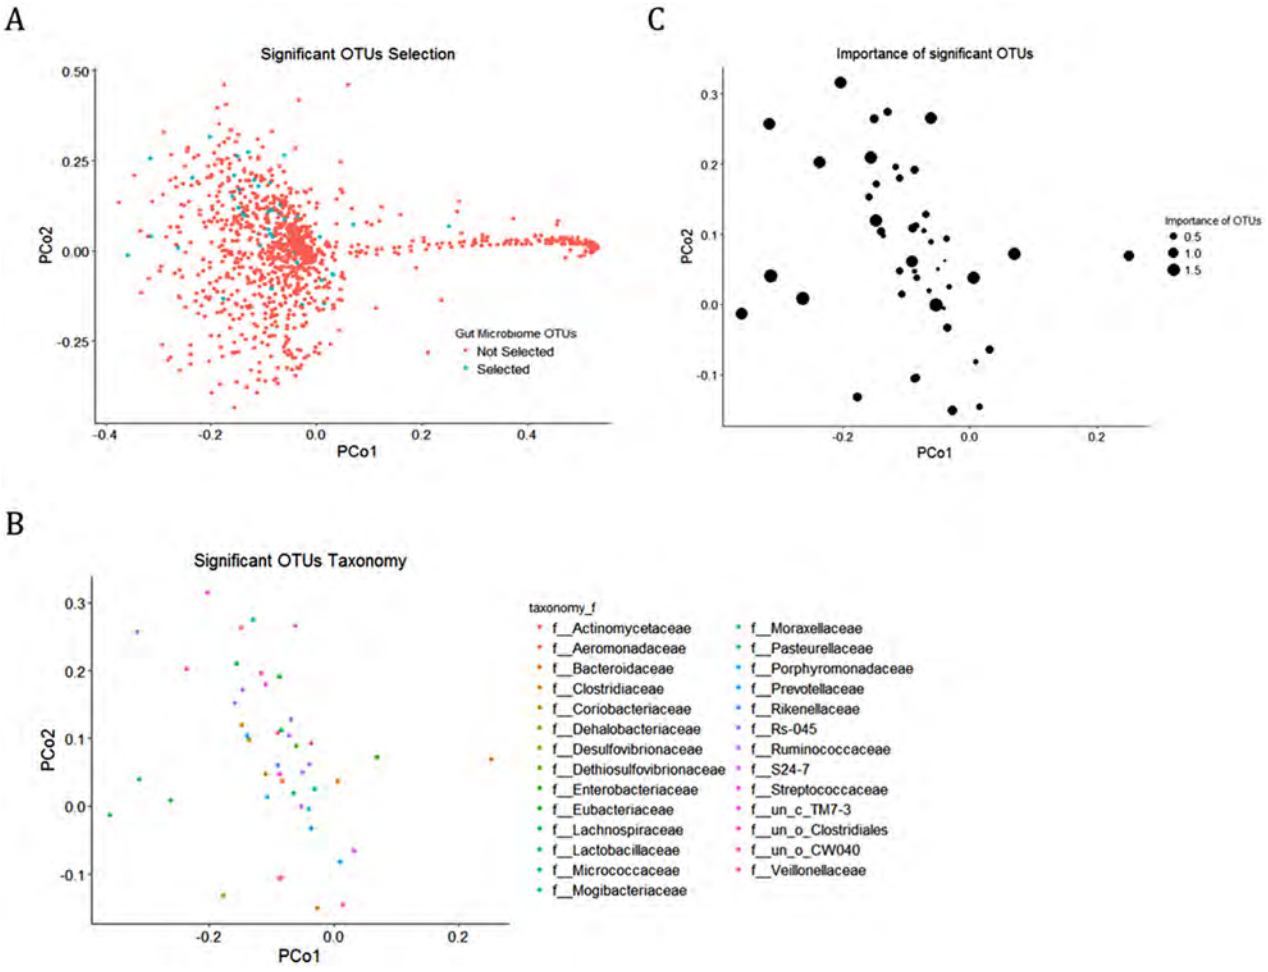

Fig. 3: (abstract: FRI-273): Taxonomic assessment of OTU microbiota signature for HBeAg seroconversion.

remained HBeAg-positive. Using random forest method, we further constructed a prediction model based on the gut microbial signature, with the area under curve being 0.81 for the test set. Based on our results, HBeAg seroconversion was found to be associated positively with AST, and several genera belonging to *TM7-3,* and *Actinomycetaceae* families.

Conclusion: By analyzing the fecal microbiota from the patients with and without HBeAg seroconversion, we identified intestinal microbiota signatures that is associated with HBeAg seroconversion after oral antiviral therapy.

FRI-274

Exercise modulates gut microbiota and intestinal barrier functionality counteracting early obesity and NAFLD in an in vivo model

Email: ssanc@unileon.es

Background and aims: Childhood obesity has reached epidemic levels, representing one of the most serious public health concerns associated with metabolic syndrome, non-alcoholic fatty liver disease (NAFLD) and gut microbiota alterations. Physical exercise is known to counteract obesity and NAFLD progression and modulate gut microbial balance. We aim to evaluate the benefits of exercise on metabolic status, gut microbiota composition and intestinal barrier functionality in an *in vivo* model of early obesity and NAFLD.

Method: 21 days old male Wistar rats fed with control or high fat diet (HFD) were subjected to an interval aerobic training protocol. Fecal microbiota was sequenced by Illumina MiSeq system and parameters related to metabolic syndrome, fecal metabolome, including bile acids (BAs) profile, and gut-liver axis alteration were measured.

Results: Exercise decreased HFD-induced body weight gain, metabolic syndrome and hepatic steatosis, as a result of its lipid metabolism modulatory capacity. The microbiome and metabolome were substantially modified as a consequence of diet, age, and exercise intervention. Training protocol counterbalanced a subset of changes in microbial composition and functionality associated with early obesity and NAFLD, showing a modulatory effect on gut microbiota composition related to a specific metabolomic function that could counteracts dysbiosis caused by HFD. Thus, exercise triggered a microbiome and metabolome pattern similar to the control group, allowing to identify a bacterial genera profile associated with a specific metabolomic signature which correlated with clinical outcomes in our study. Moreover, exercise intervention also reduced TLR-4-dependent inflammatory response, downregulating NF-kappa B transcriptional activity induced by HFD. These effects of exercise appear to be mediated by its capacity to preserve

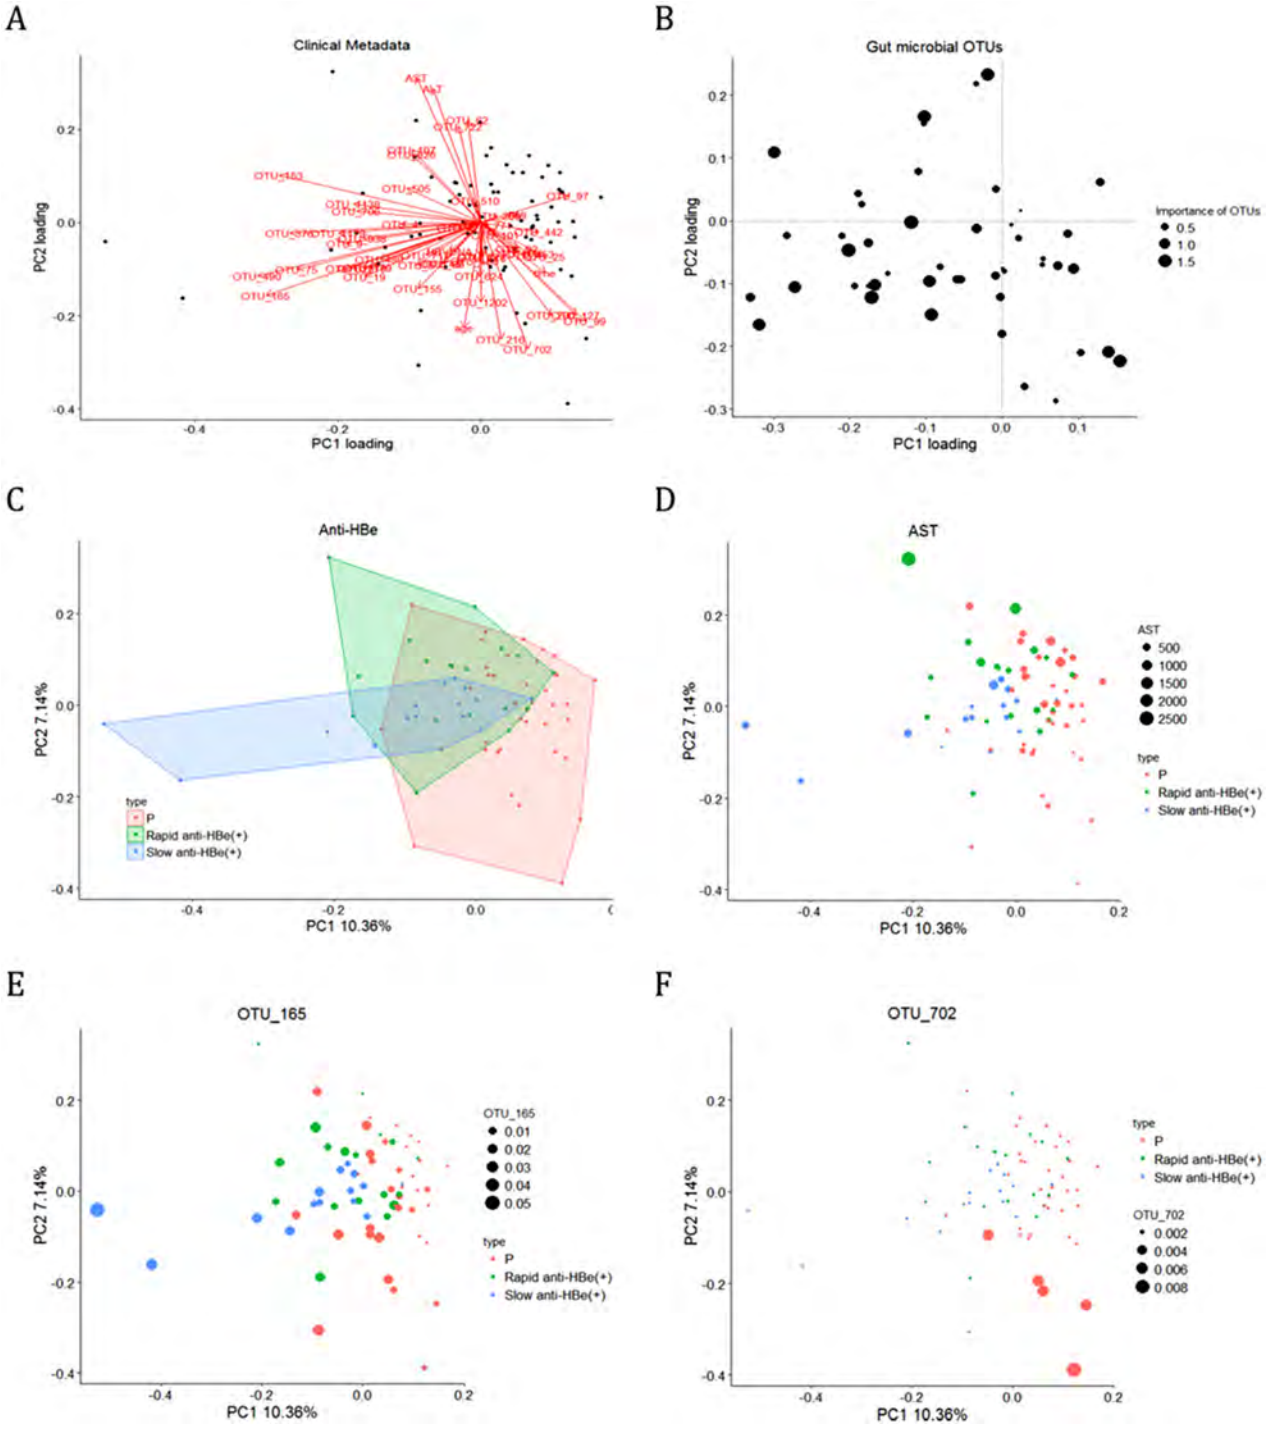

Fig. 4: (abstract: FRI-273): Interactions between clinical, microbial ecology parameter and microbial signatures for HBeAg seroconversion.

intestinal barrier functionality, which in turn prevented gut-liver axis deregulation and improved BAs homeostasis.

Conclusion: Our results suggest the existence of a HFD-determined deleterious microbiota profile that results positively modified by exercise intervention, leading to a functionally protective microbiome able to counterbalance altered gut-liver axis and BAs circulation.

Fecal microbiota profiles as a diagnosis marker in PSC and PSC-IBD patients compare to healthy controls

Yelena Lapidot[1,2], Shira Ben-Simon[3], Oranit Cohen-ezra[1], Yana Davidov[1], Peretz Weiss[1], Mariya Likhter[1], Ella Veitsman[1], Omry Koren[3], Michal Safran[1], Ziv Ben Ari[1,2]. *[1]Chaim Sheba Medical Center -Tel Hashomer, Liver Disease Center, Tel-Hashomer, Israel; [2]Tel Aviv University, The Sackler School of Medicine, Tel Aviv, Israel; [3]Bar Ilan University, Faculty of Medicine, Safed, Israel*

Email: michal.safran@sheba.health.gov.il

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease, strongly associated with inflammatory bowel disease (IBD). Neither the cause of PSC, nor the mechanisms by which PSC patients develop IBD are known. Previous studies found that the intestinal microbiota may play a role in disease pathogenesis. In this study, we explored the gut microbiome signature of PSC and PSC-IBD patients.
Method: In this study, patients with PSC (n = 17) or PSC-IBD (n = 18) and 30 healthy controls were recruited. Fecal samples were collected and analyzed using metagenomic methods based on 16 sRNA sequencing and bioinformatics analysis.
Results: Patients with PSC (with and without IBD) demonstrated a distinct microbiome signature as compared to healthy controls, including a significant decrease in bacterial quantity and diversity (Faith's PD p value = 1.211726e-08, unweighted Unifrac p value = 0.001). Significantly decreases in 261 species, alongside over-representation of 32 species was noted in patients with PSC as compared to controls. Patients with PSC demonstrated increased levels of Blautia (p value = 0.038) and Clostridium XlVa (p value = 0.0009). Patients with PSC-IBD showed a similar and significant decrease in bacterial quantity and diversity compared to controls (Observed OTU's p value = 3.9848E-07). Among patients with PSC, a significant decrease in bacterial quantity and diversity (Observed OTU's p value = 0.018) was documented in patients with FUT-2 secretor phenotype compared to non-secretor phenotype PSC. Moreover, patients treated with proton pump inhibitors, showed lower bacterial alpha diversity (p value = 0.038). Ursodeoxycholic acid had no significant effect on the microbiome of patients with PSC. In addition, a decrease in alpha diversity (p value = 0.0006) and an altered microbiome composition (p value = 0.004) were observed in smoking patients.
Conclusion: In this study, we observed significant alterations in the microbiome of patients with PSC and PSC-IBD compared to healthy controls. We observed a significant increase in Blautia and Clostridium XlVa, species that are correlated with significant decrease in bacterial amount and diversity. Moreover, PSC was characterized by dysbiosis (an increase in pathogenic bacteria and decreased levels of beneficial bacteria), with a stronger effect than the concomitant development of IBD. Many of the bacteria altered in PSC are pathogenic species, and associated with IBD. Our findings are expected to enhance our understanding of the specific microbial alterations in PSC, with and without IBD, and to advance the development of novel treatment strategies for PSC and PSC-IBD.

FRI-276

Effect of korean red ginseng on non-alcohlic steatohepatitis: Randomized controlled trial

Sang Joon Yoon[1], Nayoung Lee[1], Dae Hee Han[1], Haripriya Gupta[1], Gi Soo Youn[1], Ki Tae Suk[1], Dong Joon Kim[1], Young Lim Ham[2]. *[1]Hallym University College of Medicine, Internal Medicine, Chuncheon, Korea, Rep. of South; [2]Daewon University, Jaecheon, Korea, Rep. of South*
Email: ktsuk@hallym.ac.kr

Background and aims: Korea Red Ginseng (KRG) has been known as a natural product with anti-inflammatory and hepatoprotective effect in liver disease. Gut microbiota plays an important roles in the pathophysiology of non-alcoholic statohepatitis (NASH). We evaluated the effect and mechanism of KRG on patients with NASH.
Method: Between January 2017 and April 2018, a total of 94 patients (KRG: 45 and placebo: 49) were prospectively randomized to receive the 30 days of KRG (2, 000 mg/day, ginsenoside Rg1+Rb1+Rg3 4.5 mg/g) or placebo. Liver function test, fatigue score, pro-inflammatory cytokines, lipopolysaccharide (LPS), and stool microbiome analysis by 16S rRNA-based sequencing were examined and compared after therapy.
Results: In KRG group, the mean levels of alanine aminotransferase (75.6 ± 40.7→65.3 ± 41.9 IU/L, P = 0.040), gamma glutamyl-transferase (95.1 ± 78.0→80.2 ± 69.9 IU/L, P = 0.004), and fatigue score (34.2 ± 14.2 → 26.0 ± 12.7, P < 0.001) were significantly improved after the administration of KRG. The decline of LPS was seen in both groups but it showed a big drop in red ginseng group (p < 0.05). Changes in microbiome in the stool were observed in the KRG group. KRG group showed a rise in *Firmicutes* and *Proteobacteria* in patients with increased alanine aminotrasferase level. Placebo group revealed contrary results. In patients with improved alanine aminotrasferase, *Firmicutes* and *Proteobacteria* in KRG group were decreased and *Actinobacteria* in placebo group was increased in the stool analysis
Conclusion: KRG might be effective in improving liver enzymes, endotoxin, and fatigue by modulating gut-microbiota in patients with NASH. KRG can be used as a next therapeutic option in patients with NASH.

FRI-277

Effect of probiotics in the treatment of NASH: A randomized clinical trial

Gabriela Port[1], Cristiane Tovo[1], Sabrina Fernandes[1], Alessandra Peres[2,3], Gilson Dornelles[2], Giselle Pinto[1], Vanessa Houde[4,5], Thibault Varin[4,5], Genevieve Pilon[4,5], Andre Marette[4,5], Caroline Buss[1,6,7]. *[1]UFCSPA, 1Graduate Study Program (GSP) in Medicine: Hepatology, Porto Alegre, Brazil; [2]UFCSPA, 2Basic Health Sciences Department, Porto Alegre, Brazil; [3]Centro Universitário Metodista IPA, 3Laboratory of Immunology, Exercise Physiology, Porto Alegre, Brazil; [4]CRIUCPQ, 4Department of Medicine, Faculty of Medicine, Cardiology Axis of the Québec Heart and Lung Institute, Quebec, Canada; [5]Laval University, Institute of Nutrition and Functional Foods (INAF), Quebec, Canada; [6]UFCSPA, Nutrition Department, Porto Alegre, Brazil; [7]UFCSPA, Graduate Study Program in Health Sciences, Porto Alegre, Brazil*
Email: gabriela.port@hotmail.com

Background and aims: Same promising results in the improvement of NAFLD and NASH have been identified following the treatment with probiotics. The aim of this study was to evaluate the effect of probiotic supplementation on hepatic fibrosis, aminotransferases, systemic inflammatory markers, metabolic profile and microbiome composition in NASH patients.
Method: In a double-blind, placebo-controlled clinical trial, 43 NASH patients were randomized to receive probiotics (Lactobacillus acidophilus 1x109 CFU and Bifidobacterium lactis 1x109 CFU-Probiotic Group) or placebo (Placebo Group) for 6 months. Patients were evaluated at 0, 3 and 6 months, including BMI and laboratory tests (AST, ALT, HDL, LDL and total cholesterol, triglycerides, glucose, insulin, C-reactive protein, ferritin, interleukin-6, TNF-α, MCP-1 and leptin). Liver biopsy and/or Fibromax™ (non-invasive test to evaluate liver fibrosis), were performed at baseline and repeated after 6 months of treatment. Faecal DNA was extracted and 16S rRNA gene-based analysis was used to profile gut microbiota. Results are presented as medians.
Results: After 6 months of treatment, Probiotic Group presented a significant reduction in AST level (37.0 vs. 34.0 p = 0.012), APRI score (0.41 vs. 0.35 p = 0.042), C-reactive protein (6.6 vs. 4.5 p = 0.026) and ferritin (169.0 vs. 138.5 p = 0.008) compared to within group baseline values. Compared to within group baseline values, HDL (47.5 vs. 52.0 p = 0.020) and total cholesterol (186.0 vs. 205.0 p < 0.001) increased significantly in the Probiotic Group. There were no significant differences between groups after treatment.
Conclusion: This trial identified that NASH patients treated with probiotic supplementation presented reduced AST levels and APRI score and had some inflammatory and metabolic parameters improved. However, treated and untreated groups of NASH patients were not different at the end of the study in relation to main outcomes.

NAFLD: Experimental and pathophysiology

Email: mbafonso@ff.ulisboa.pt

Background and aims: Regulated necrosis or necroptosis was recently described as a novel cell death pathway activated downstream of death receptor stimulation and dependent on receptor-interacting protein 3 (RIP3) kinase activity. Although necroptosis has already been implicated in the pathogenesis of non-alcoholic fatty liver disease (NAFLD), its specific contribution remains poorly explored. Here, we aimed to evaluate the impact of RIP3 signalling in steatosis, inflammation, fibrosis and carcinogenesis associated with experimental NAFLD.
Method: C57BL/6 wild-type (WT) or RIP3-deficient ($RIP3^{-/-}$) mice were fed a choline-deficient L-amino acid-defined diet (CDAA; n = 14) or a control choline-sufficient L-amino acid-defined diet (CSAA; n = 14) for 32 and 66 weeks. Tissue samples were processed for histological and biochemical analysis of hepatic damage and carcinogenesis, insulin resistance and oxidative stress, and for lipidomic analysis.
Results: CDAA-fed WT mice exhibited all the typical histological features of liver injury associated with non-alcoholic steatohepatitis, including steatosis, hepatocellular ballooning, immune cell infiltration, and fibrosis, which became more prominent over time. RIP3 deficiency ameliorated CDAA-induced inflammation and fibrosis, and decreased the NAFLD activity score. In agreement, hepatic gene expression of pro-inflammatory mediators was also significantly decreased in CDAA-fed $RIP3^{-/-}$ mice, compared with WT, at both 32 and 66 weeks. Intriguingly, $RIP3^{-/-}$ mice displayed increased body weight gains, as well as increased liver fat accumulation at both time-points, compared with WT mice on the CSAA or CDAA diets. Lipidomic analysis showed that deletion of RIP3 shifted hepatic lipid species profiles, while increasing insulin resistance, as assessed by homeostasis model assessment-estimated insulin resistance, compared with WT mice on CSAA or CDAA diet. Concomitantly, insulin receptor phosphorylation in muscle tissue was decreased at 66 weeks. Finally, $RIP3^{-/-}$ mice on the CDAA diet for 66 weeks tended to display reduced incidence of macroscopic preneoplasic nodules, accompanied by significantly reduced Ki67 positive hepatocytes. Indeed, microarray analysis and subsequent validation studies showed that the absence of RIP3 hampered the expression of oncogenes and signalling pathways controlling tumour microenvironment.
Conclusion: Overall, hepatic RIP3 plays an opposing role in controlling steatosis versus inflammation and carcinogenesis in CDAA-fed mice, leading to dissociation between these phenomena that are usually considered linked in NAFLD.

FRI-279

Stat2 is a pathogenic factor in human non-alcoholic steatohepatitis and mouse models of liver injury and mediates fatty acid-induced Inflammasome activation in hepatocytes

Wenhao Li[1], Gary Britton[1], Hiromi Kudo[2], Robert D. Goldin[2], William Alazawi[1]. [1]*Barts Liver Centre, Queen Mary University of London, London, United Kingdom;* [2]*Department of Pathology, Imperial College London, London, United Kingdom*
Email: w.alazawi@qmul.ac.uk

Background and aims: Inflammation and liver cell injury drive the progression of non-alcoholic steatohepatitis (NASH) and lead to liver fibrosis. We have previously reported that loss of Stat2 is protective from LPS-induced NF-kB-mediated inflammatory cytokine production in mice. We hypothesised that Stat2 is a pathogenic factor in the response to liver injury in NASH. We tested this hypothesis using liver tissue from NASH patients, mouse models of liver injury, RNA sequencing of primary hepatocytes and siRNA-mediated knockdown in human liver cells.
Method: Expression of Stat2 in NASH and normal liver was assessed by immunohistochemistry. In vivo effects of stat2 loss on liver injury and inflammation were assessed using carbon tetrachloride (CCl_4)-induced liver injury in wild type, $Stat2^{-/-}$ mice. RNA sequencing was used to assess the global transcriptomic effects of Stat2 on inflammation in primary hepatocytes isolated from wild-type (WT) or $Stat2^{-/-}$ mice. Silencer RNA was used to knockdown Stat2 in the HepG2 human liver cell line prior to treatment with a 2:1 oleate: palmitate fatty acid mixture.
Results: Hepatocyte nuclear expression of Stat2 was significantly greater in NASH (n = 39) compared to normal liver (98% vs 35%, p < 0.0001). Similarly, Stat2 expression increased in WT liver tissue following treatment with CCl_4 and $Stat2^{-/-}$ mice were protected from CCl_4-mediated liver injury with reduced histological inflammation and necrosis, serum ALT (2165 vs 1090 iU/ml, p = 0.03) and IL-6 levels (562 vs 38 pg/ml p = 0.02). To model the Stat2-mediated inflammatory response, primary WT and $Stat2^{-/-}$ hepatocytes were treated with LPS and global gene expression was assessed by RNAseq. We found significant differences in genes involved in intracellular signal transduction, inflammation and metabolism. We found significant reduction in the production of secreted cytokines and chemokines (IL-6, IL-10, CCL3, CCL5, CXCL2, CXCL10) from $Stat2^{-/-}$ hepatocytes. Knockdown of Stat2 in HepG2 cells by two different siRNAs prior to fatty acid-induced injury resulted in inhibition of inflammasome activation; caspase-1 (by western blot) and IL1beta mRNA levels (7.4-fold, p < 0.0001) and reduced IL8 production (2-fold, p = 0.0002).
Conclusion: Stat2 is a pivotal mediator of inflammation and hepatic damage. Stat2 loss leads to reduced hepatocyte injury, inflammatory signalling and inflammasome activation, suggesting that Stat2 or a downstream mediator may be a therapeutic target in human NASH.

[1]*Institute of Translational Immunology, Mainz, Germany;* [2]*Dow university of medical sciences, Karachi, Pakistan;* [3]*Division of Gastroenterology, Beth Israel Deaconess Medical Centre, Boston, United States*
Email: m.ashfaq_biotech@yahoo.com

Background and aims: The gut-liver-axis has emerged an important driver of chronic liver disease. Accordingly, specific food derived immunogenic signals may be important contributors to non-alcoholic fatty liver disease (NAFLD) and liver fibrosis. A common immunogenic component in food are wheat amylase trypsin inhibitors (ATI) that resist intestinal degradation and activate intestinal macrophages and dendritic cells via toll like receptor 4. Once activated in the gut, these cells migrate to the peripheral organs such as liver to propagate the inflammatory stimulus. We therefore studied how far nutritional ATI would affect NAFLD and liver fibrosis in preclinical models.
Methods: Male C57Bl/6J mice received a carbohydrate and protein (zein from corn) defined low fat or high fat diet (HFD), with or without 30% of the protein being replaced by wheat gluten (G, naturally containing 0.15g ATI per 10g), or 0.7% of the replaced by purified ATI for 8 weeks. Male Mdr2−/− FVB mice were fed defined,

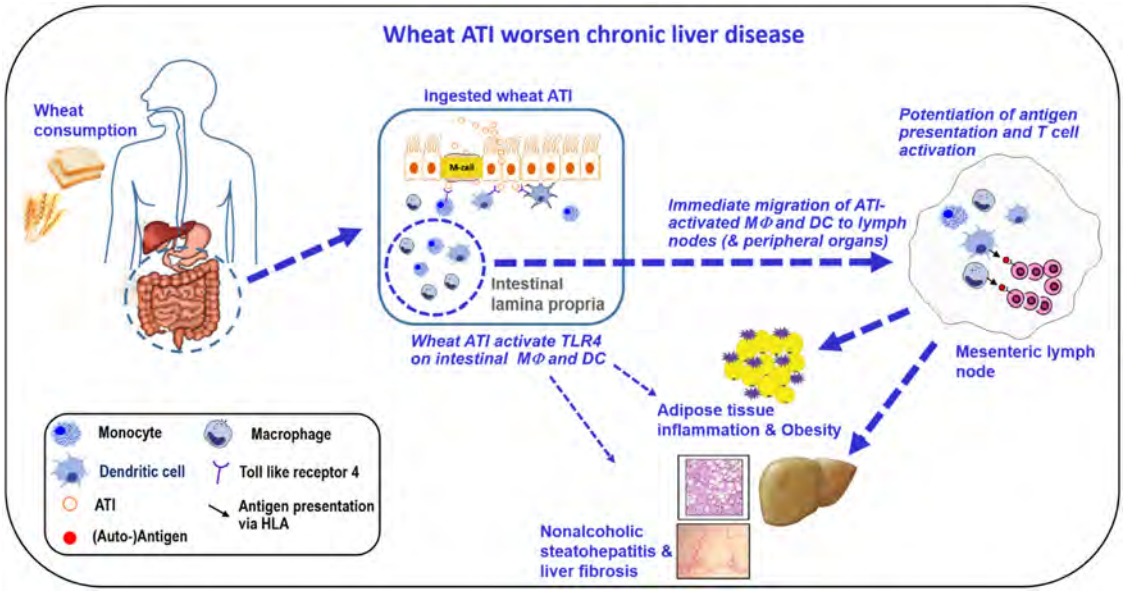

Figure: (abstract: FRI-280)

ATI containing and ATI free diets for 6 weeks. In the NASH model, insulin resistance (IR) was assessed test.

Results: Mice on the HFD gained weight and developed insulin resistance (IR) as determined by an intraperitoneal glucose tolerance test. Compared to the HFD alone, mice fed the HFD/G/ATI or the HFD/ATI diets gained significantly more weight and displayed significantly higher serum transaminases and triglycerides, increased liver, epididymal, mesenteric and inguinal fat, and a higher IR. ATI feeding promoted liver and adipose tissue inflammation, M1 macrophage polarization and infiltration, and enhanced the fibrogenic response in the liver. Moreover, there were significant increases in hepatic CD68+ macrophages, CD86+ dendritic cells and MHC-II+ cells in the distal part of the intestine of HFD/ATI compared to HFD diet fed mice. In biliary fibrotic Mdr2−/− mice, transaminases and liver weights in the ATI fed group were significantly increased compared to the ATI free group. Overall, liver transcripts for il1b, tnf-a, cd68, col1a1, a-sma and col3a1, mmp9, mmp13 and timp1 were significantly upregulated in the ATI fed vs ATI free groups. Moreover, in Mdr2−/− mice ATI feeding increased ductular reactions, hepatic CD68+ macrophage infiltration, and accelerated fibrosis progression as evidenced by a higher collagen deposition (Sirius red morphometry) and alpha-SMA+ myofibroblasts.

Conclusions: When ingested in quantities comparable to average human consumption, wheat ATI exacerbate the key features of rodent NAFLD and the metabolic syndrome despite their irrelevant caloric value. Moreover, dietary ATI promote liver fibrosis in the NASH and the Mdr2KO mouse model of PSC. The postulated mechanism is outlined in **Fig.1.**

FRI-281

IL-4 receptor alpha knock-out mice are protected against fibrotic NASH in a representative mouse model of non-alcoholic steatohepatitis

Muhammad Ashfaq-Khan[1], Misbah Aslam[1], Marcel Senkowski[1], Detlef Schuppan[1,2]. [1]*Institute of Translational Immunology and Research Center for Immunotherapy, Mainz, Germany;* [2]*Division of Gastroenterology, Beth Israel Deaconess Medical Center, Boston, United States*
Email: m.ashfaq_biotech@yahoo.com

Hepatic macrophages derive from resident phagocytes (Kupffer cells) or circulating monocytes (monocyte derived macrophages). They critically modulate fibrosis progression or regression depending on disease aetiology and stage, especially in NAFLD/NASH where massive proinflammatory macrophages recruitment to the liver can occur. It was reported that elevated serum levels of IL-4 and IL-13 correlate with the severity of liver fibrosis (F3-F4 > F0-F1) in NASH patients. IL-4 and IL-13 signal via two different but overlapping receptors having the IL-4 receptor alpha (IL-4Ra) as common subunit. We therefore studied mice with IL-4Ra deletion in a representative mouse model of NASH.

Methods: Male Balb/C wild type, IL-4Ra$^{-/-}$ and macrophage-specific deleted (LysM^{cre}IL-4Ra$^{-/lox}$) mice and their respective littermate controls (bearing either only the Cre or the floxed genes) were fed a choline-deficient, L-amino acid-defined (CDAA) vs a choline supplemented (CSAA) diet for 12 weeks.

Results: Both KO strains displayed a significant decrease in liver weights compare to their respective wild type controls upon CDAA diet feeding. This was accompanied by reduced NASH activity as evidenced by the NAS score (adapted for mice) in both IL-4R$^{-/-}$ and LysM^{cre}IL-4Rα$^{-/lox}$ mice vs their wildtype controls. CD68^{+} macrophages, MPO^{+} neutrophil inflammatory foci, infiltration by inflammatory monocytes (CD11b^{+}F4/80^{-}Ly6G^{-}Ly6c^{high}) were significantly decreased in the livers of the IL-4Ra KO mice. Based on Sirius Red morphometry, the fibrosis score was > 2 in the wildtype mice and reduced to < 1 in both KO strains. Accordingly, hydroxyproline content and the number of alpha-SMA+ myofibroblasts was significantly and comparably mitigated in both IL-4Ra deficient strains. This was paralleled by significantly suppressed hepatic transcript levels for col1a1, tgfb, mmp9 and tnfa.

Conclusion 1. General ablation of the IL-4Ra or its selective ablation in macrophages comparably suppressed steatosis, inflammation and fibrosis in the CDAA model of NASH; 2. IL-4Ra targeted therapies are a novel treatment option for fibrotic NASH and may be superior to therapies that block IL-4 and IL-13 cytokines.

FRI-282

Effect of the farnesoid X receptor agonist, obeticholic acid, in hepatocellular carcinoma: Is it NASH-dependent or -independent?

Yasmeen Attia[1], Rasha Tawfiq[1], Aya Adel[1], Abdullah Gibriel[2], Olfat Hammam[3], Mohamed Elmazar[1]. *[1]The British University in Egypt, Department of Pharmacology, Cairo, Egypt; [2]The British University in Egypt, Department of Biochemistry, Cairo, Egypt; [3]Theodor Bilharz Research Institute, Department of Pathology, Cairo, Egypt*
Email: yasmeen.attia@bue.edu.eg

Background and aims: Non-alcoholic steatohepatitis (NASH) has now become the second leading cause of hepatocellular carcinoma (HCC) making liver transplantation a compelling demand. Unlike other liver disorders, NASH-associated HCC (NASH-HCC) was not recognized until recently. Besides the identified multifaceted effects of the nuclear farnesoid X receptor (FXR) on metabolic disorders, it was also identified as a tumour suppressor acting as an intriguing bridge between metabolic regulation and carcinogenesis. Herein, the present study aimed at investigating the potential effect of obeticholic acid (OCA), a potent FXR agonist FDA-approved drug for primary biliary cholangitis, in two different etiology-based HCC animal models among which is NASH-HCC.

Method: Two animal models were used: (1) NASH-HCC induced by diethyl nitrosamine (DEN) and a high-fat choline-deficient diet (HFCD) [DEN+HFCD] and (2) HCC induced by DEN and carbon tetrachloride (CCl_4) [DEN+CCl_4]. In [DEN+HFCD], three-week-old male mice received a one-time i.p. injection of 25 mg/kg DEN and was kept on a HFCD diet during the entire experimental period. However, in [DEN+CCl_4], mice received a one-time i.p. injection of 1 mg/kg DEN and starting 8 weeks of age, they received a twice per week i.p. injections of 0.2 ml/kg CCl_4 till the end of experiment. OCA (10 mg/kg/day, p.o.) was started after 20 weeks of induction for a duration of 8 weeks for [DEN+HFCD] model and 12 weeks for [DEN+CCl_4] model. Histopathological and immunohistochemical analyses of liver sections against alpha fetoprotein (AFP), caspase-3, and signal transducer and activator of transcription-3 (STAT3) were performed. Tissue adiponectin, transforming growth factor (TGF)-beta1, and interferon (IFN)-gamma were determined by ELISA. Tissue FXR, small heterodimer partner (SHP), p53, AFP, and TGF-beta1 gene expression was determined using qRT-PCR.

Results: Gross appearance of mice livers showed nodules in control and not in treated groups. OCA showed significant amelioration in dysplastic foci compared to control groups of both models. IFN-gamma, TGF-beta1, AFP, and STAT3 levels were lower in treated groups. Meanwhile, caspase-3 and adiponectin were higher in treated groups compared to their respective controls. Moreover, OCA treatment showed elevation in FXR, SHP, and p53 gene expression levels.

Conclusion: Activation of FXR by OCA attenuated the development and progression of both NASH-dependent and -independent HCC which may suggest its potential use to prevent NASH progression to HCC besides a potential towards treatment of HCC patients independent of NASH.

FRI-283

Impact on NAFLD of long-term weight loss after bariatric surgery

Chiara Barbieri[1,2], Marianna Palumbo[3], Fabrizia Carli[1], Melania Gaggini[1], Barbara Patricio[1,4], Virna Zampa[5], Brenno Astiarraga[6], Ele Ferrannini[1], Stefania Camastra[3], Amalia Gastaldelli[1]. *[1]National Research Council (CNR), Institute of Clinical Physiology, Pisa, Italy; [2]University of Siena, Department of Biotechnology, Chemistry and Pharmacy, Siena, Italy; [3]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [4]Sant'Anna School of Advanced Studies, Institute of Life Sciences, Pisa, Italy; [5]University of Pisa, Department of Diagnostic and Interventional Radiology, Pisa, Italy; [6]University Hospital Joan XXIII, Pere Virgili Institute-Rovira i Virgili University, Diabetes and Metabolic Associated Diseases Research Group, Taaragona, Spain*
Email: Amalia@ifc.cnr.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a common characteristic of morbid obese patients, both diabetic (T2D) and non-diabetic (ND). Roux-en-Y Gastric Bypass (RYGB) leads to significant weight loss, improvement in metabolic profile and has been indicated as a possible treatment of NAFLD. Our aim was to evaluate presence of NAFLD 7 years after RYGB and significant weight loss.

Method: : The cohort comprised 21 subjects (11 T2D and 10 ND; BMI 50.2 ± 2.5 and 48.3 ± 2.3 kg/m^2) that were studied before RYGB and again after 7years with meal tolerance test (MTT) and the infusion of stable isotope tracers to measure glucose and lipid metabolism, hormone profile, endogenous glucose production (EGP), lipolysis (RaGlycerol) and insulin resistance (IR) in liver (Hep-IR = EGPxIns) and adipose tissue (Lipo-IR = RaGlycerolxIns). Magnetic resonance imaging (MRI) was performed to evaluate hepatic triglyceride accumulation (HTG), visceral (VF) and subcutaneous fat (SC). Imaging data were compared with Fatty Liver Index (FLI).

Results: At baseline the group included 11 T2D and 10 ND. Seven years after RYGB, all subjects were ND, and N = 7 were no NAFLD (HTG < 5.5%), N = 7 had moderate NAFLD (HTG 5.5–20%) and N = 7 severe NAFLD (HTG > 20%), despite similar distribution of T2D and BMI at baseline.

Subjects with no-NAFLD were the ones with higher weight loss (37% of original weight vs 35% in moderate and 26% severe NAFLD) reaching a BMI of 29.2 ± 0.9 vs 32.1 ± 2.0, 36.7 ± 2.0 in the other 2 groups. Moreover, across the 3 group there was a significant increase in VF (44.10 ± 15.4 76.7 ± 26.5; 106.1 ± 18.4 cm^2) and SC (184.2 ± 27.8; 339.2 ± 27.9; 354.9 ± 43.1 cm^2). VF and SC were correlated with HTG (r = 0.60 for VF and 0.68 for SC, p < 0.006) and BMI (r = 0.63 for VF and 0.62 for SC, p < 0.003). We observed a significant reduction in Hep-IR and Lipo-IR, ALT, AST and GGT and lipid profile with normalization of high values. No NAFLD showed lowest values of Hep-IR and Lipo-IR, due to a strong correlation between HTG with Hep-IR (r = 0.53; p = 0.002;) and Lipo-IR (r = 0.62; p = 0.008).

HTG at 7y was significantly associated with BMI (r = 0.63, p < 0.005), amount of weight loss (r = -0.48 p = 0.03). and FLI (r = 0.79; p = 0.0007).

Conclusion: Despite significant weight loss (> 25%) and resolution of T2D, 7y after RYGB only 30% of studied subjects had HTG within the normal ranges. Presence of NAFLD at 7y was associated with persistence, although decreased, insulin resistance both at the level of the liver and adipose tissue.

FRI-284

A combination of fenofibrate with a liver-targeted acetyl-CoA carboxylase inhibitor enhances efficacy while reversing plasma triglyceride increases in a murine model of NASH

Jamie Bates[1], Archana Vijayakumar[1], David Hollenback[1], Saritha Kusam[1], Harini Burri[1], David G. Breckenridge[1]. *[1]Gilead Sciences, Inc., Biology, Foster City, United States*
Email: jamie.bates@gilead.com

Background and aims: Acetyl-CoA Carboxylase (ACC) 1 and 2 catalyze the rate-limiting step in de novo lipogenesis (DNL) and

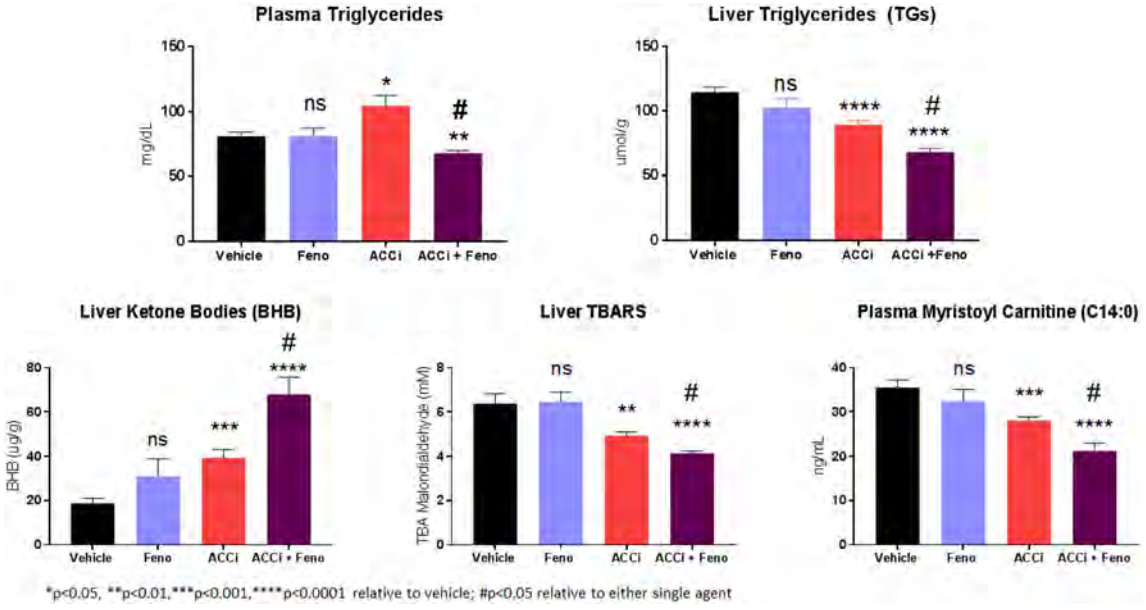

Figure: (abstract: FRI-284)

inhibit mitochondrial beta-oxidation, respectively. GS-0976, a liver-targeted ACC1/2 inhibitor, is in clinical development for NASH. In patients with NASH, GS-0976 reduces hepatic steatosis and liver biochemistry, but may increase plasma triglycerides (TGs), particularly in patients with pre-existing hypertriglyceridemia. We and others have shown repression of PPAR-alpha transcripts with ACC inhibition, which could contribute to the increased plasma TGs. A clinical study evaluating the safety of co-administration of fenofibrate, an approved PPAR-alpha agonist, with GS-0976 is ongoing. The aim of this study was to evaluate the preclinical efficacy of the combination in a murine model of NASH.

Method: Male C57BL/6 mice were administered a fast food diet (FFD) enriched in fat, cholesterol, and sugar for 9 months and were then treated with either vehicle, a liver-targeted ACCi inhibitor at 5 mg/kg PO QD (ACCi), fenofibrate at 50 mg/kg PO QD (Feno), or both, for 15 days (n = 11-14 per treatment). End points include hepatic TGs by a biochemical colorimetric assay, hepatic beta-hydoxybutyryl-CoA (BHB) and plasma acylcarnitines by quantitative LC/MS/MS, and lipid peroxidation by TBARS, and plasma TGs.

Results: Hepatic BHB, a measure of beta-oxidation, increased with fenofibrate (64%, ns) and was significantly increased with ACCi relative to vehicle (105%, $p < 0.001$). The combination significantly increased BHB relative to vehicle (260%, $p < 0.0001$) and relative to the levels of either single agent ($p < 0.01$). Conversely, hepatic TGs, plasma myristoyl carnitine levels (C14:0), and lipid peroxidation were non-significantly reduced with fenofibrate, significantly reduced with ACCi (22%, 21% and 23%, respectively, $p < 0.01$), and significantly reduced with the combination relative to vehicle (40%, 40% and 35%, respectively, $p < 0.0001$) and either single agent ($p < 0.05$). Plasma TGs were significantly increased with ACCi (30%, $p < 0.05$), not changed by fenofibrate, and decreased below baseline with the combination (16% inhibition, $p < 0.01$).

Conclusion: The addition of fenofibrate to an ACCi improved efficacy and reversed the increase in plasma TGs observed with ACC inhibition. These data support further investigation of fenofibrate in combination with GS-0976 in patients with NASH and hypertriglyceridemia.

FRI-285

The benchmarks obeticholic acid and elafibranor show variable effects on NASH and hepatic fibrosis in diet-induced or chemically-induced animal models

Francois Briand[1], Brousseau Emmanuel[1], Faresse Nourdine[1], Sulpice Thierry[1]. [1]*physiogenex, Labege, France*
Email: f.briand@physiogenex.com

Background and aims: To select relevant NASH and hepatic fibrosis models for drug efficacy studies, we here evaluated the curative effects of the benchmarks obeticholic acid (OCA, an FXR agonist) and elafibranor (GFT505, a PPARalpha/delta dual agonist) in various preclinical models.

Method: For each model, blood and liver were collected for biochemistry, liver histology and NAS scoring at the end of the treatment period to evaluate drug efficacy.

Results: Concomitant with a severe body weight loss, methionine choline deficient (MCD) diet for 4 weeks in mice resulted in liver steatosis, inflammation and perisinusoidal (stage 1) to periportal (stage 2) fibrosis. While OCA markedly increased plasma ALT/AST levels and only reduced steatosis, GFT505 strongly reduced ALT/AST and NAS score.

Diet-Induced NASH (DIN) using a 25-week high fat/cholesterol/fructose diet in mice, resulted in strong liver steatosis, limited inflammation and stage 1 to stage 2 fibrosis. In this obese and insulin resistant mouse model, both OCA and GFT505 significantly improved ALT/AST levels and NAS scoring. However, OCA better reduced fibrosis, but unlike humans, reduced LDL-cholesterol by 45% ($p < 0.001$ vs. vehicle)

DIN hamsters also developed obesity and insulin resistance, strong liver steatosis with evident inflammation and hepatocyte ballooning, and peri-portal to bridging fibrosis (stage 3). GFT505 reduced plasma ALT by 52% ($p < 0.01$ vs. vehicle) and significantly improved total NAS score, including fibrosis score (21% lower, $p < 0.01$ vs. vehicle). In this DIN hamster model, OCA showed limited benefits on NASH with concomitant dyslipidemic side effects, similar to humans (higher plasma LDL-cholesterol and lower HDL-cholesterol).

Thioacetamide intoxication for 13 weeks in rats induced stage 3 fibrosis, but both OCA and GFT505 failed to improve liver lesions.

Carbon tetrachloride intoxication for 4 weeks also resulted in stage 3 fibrosis in mice. Both OCA and GFT505 significantly reduced % Sirius

Red labelling in the liver, but GFT505 showed a more pronounced effect and was the only drug to reduce fibrosis score significantly (33% lower, $p < 0.001$ vs. vehicle).
Conclusion: OCA and GFT505 show variable effects in NASH and hepatic fibrosis animal models. Depending on the context and drugs mechanisms of action, the characteristics of each preclinical model have to be carefully considered, to better translate drug efficacy data to humans.

FRI-286
Integrated transcriptomic analysis of human NASH livers, rodent models and hepatic stellate cells reveals molecular mechanisms underlying ASK1-mediated hepatic fibrosis

Grant Budas[1], David Lopez[1], June Chen[1], Dmytro Kornyeyev[1], Fefe Wu[1], David Breckenridge[1]. [1]*Gilead Sciences, Foster City, United States*
Email: grant.budas@gilead.com

Background and aims: Apoptosis signal-regulating kinase 1 (ASK1) is a redox-sensitive protein kinase that promotes phosphorylation of JNK and p38 MAPK leading to hepatocyte apoptosis, inflammation, and fibrosis. Treatment with the ASK1 inhibitor selonsertib (SEL) was recently shown to reduce liver fibrosis in patients with NASH. Defining the mechanisms by which ASK1 promotes fibrogenesis is of clinical interest given that liver fibrosis is an important determinant of clinical outcome and mortality in NASH. We used a translational research approach to identify ASK1-dependent genes that are concordantly modulated in hepatic stellate cells (HSCs), in rodent models of NASH and in human NASH livers.
Method: HSCs (LX-2 cells) were transfected for 24 hours with an adenoviral construct containing human ASK1 in the absence or presence of SEL, then subjected to RNAseq to delineate differentially expressed genes (fold change > 2 compared to control, $p < 0.05$). These data were then integrated with liver RNASeq data from two rodent NASH models in which ASK1 inhibition was shown to reduce liver fibrosis (choline-deficient high-fat diet in rat and fast food diet in mice), and with liver RNAseq data from patients with NASH (comparison of F1 vs. F4 stages of fibrosis). The effects of ASK1 inhibition on HSC migration were evaluated by transwell chamber and gap-closure migration assays, and by confocal microscopy.
Results: Integrated analysis of RNASeq data sets revealed a 31-gene signature modulated by ASK1 activity in HSCs and in rodent NASH livers, which was concordantly dysregulated in human NASH livers at F4 stage. ASK1 activity significantly increased expression of multiple genes involved in cell migration, adhesion, and motility. For example, ASK1 activity concordantly upregulated the expression of CD44 and fibroblast growth factor-inducible 14 (Fn14), which are expressed on HSCs, promote cell migration, and have a causal role in liver fibrosis. SEL dose-dependently reduced HSC migration induced by either TGF-beta or PDGF-bb, and reduced the formation of lamellipodial protrusions, demonstrating a functional role for ASK1 in promoting cytokine-induced HSC migration.
Conclusion: Using a translational approach, we identified an ASK1-dependent hepatic gene signature in NASH and revealed cytokine-induced HSC migration as a novel fibrogenic mechanism mediated by ASK1. These data provide mechanistic insight into the anti-fibrotic effect of SEL in patients with NASH.

FRI-288
Physiological levels of cardiotrophin-1 (CT-1) contribute to fasting-induced free fatty acid mobilization

David Carneros Trujillo[1], Cristina Morilla[1], Emilio Jimenez[1], Matilde Bustos[1]. [1]*Ibis- Biomedicine Institute of Sevilla, Liver, Digestive and Inflammatory Diseases, Sevilla, Spain*
Email: mbustos-ibis@us.es

Background and aims: It is becoming clear that several human liver-related pathologies are caused by altered adipose tissue expansion and altered lipid metabolism. Cardiotrophin-1 (CT-1) is a member of the interleukin-6 (IL-6) family of cytokines. CT-1 is a nutritionally regulated metabolic gene with a key role in glucose and lipid metabolism and is expressed in several metabolic tissues such as white adipose tissue (WAT), skeletal muscle and liver. We have previously reported that CT-1 is induced after 48 hours fasting. Here, we aimed at analysing the role of CT-1 in fasting, a physiological stress that elicits well-known metabolic adaptations.
Method: A differential study was carried out with wild-type (WT) and CT-1 deficient mice in fed and fast conditions (24 and 48 hours). White adipose tissue (WAT), liver and skeletal muscle were examined. Biochemical data (glucose, free fatty acid and ketone bodies) were determined. Analysis of proteins was studied by Western-blot, mRNA levels were quantified by real-time PCR and histological studies were performed with HandE and oil-red staining. Adipocyte size was quantified using the software adiposoft.
Results: We observed that CT-1 mRNA was upregulated in WAT, liver and skeletal muscle upon fasting. By nutrient deprivation (24 and 48 hours), CT-1 knock-out mice exhibited less weight loss than WT animals, higher WAT mass with bigger adipocytes than WT. Physiological levels of CT-1 controlled lipid catabolism in WAT via induction of hormone sensitive lipase (HSL) phosphorylation, induction of lysosomal acid lipase (Lipa), autophagy and fatty acid oxidation. Concomitantly, circulating free fatty acids and levels of ketone bodies were significantly decreased in CT-1 null mice. The defective adaptation to fasting of young CT-1 null mice was associated with decreased lipid droplet accumulation and enhanced autophagy in the fasted livers.
Conclusion: We conclude that CT-1 plays a relevant role in fasting adaptation through the regulation of lipid metabolism. Physiological levels of CT-1 contribute to fasting-induced free fatty acid mobilization.

FRI-289
Effect of MSDC-0602K treatment on the metabolome of a diet-induced murine model

Cristina Alonso[1], Enara Arretxe[1], Jonathon Marioneaux[2], Rebecca Caffrey[2], Jerry Colca[3], Arun Sanyal[4]. [1]*OWL Metabolomics, Derio, Spain;* [2]*Sanyal Biotechnology, Richmond, VA, United States;* [3]*Cirius Therapeutics, Research and Development, San Diego, CA, United States;* [4]*Virginia Commonwealth University, Richmond, VA, United States*
Email: jcolca@ciriustx.com

Background and aims: MSDC-0602K is a second-generation thiazolidinedione (TZD) designed to selectively modulate the mitochondrial pyruvate carrier (MPC), which conducts pyruvate across the mitochondrial inner membrane to the matrix. MSDC-0602K is currently being evaluated in a 52-week, phase 2b dose-ranging clinical trial in subjects with biopsy-proven NASH. (EMMINENCE trial, NCT02784444). This study sought to characterize the changes of MSDC-0602K in the hepatic metabolome of a dietary mice model of NASH, and to determine potential circulating biomarkers that reflected the therapeutic effect on the liver.
Method: Male DIAMOND™ mice received either high fat sugar water diet (WDSW) or chow diet normal water (CDNW) for 24 wks. Mice on WDSW were randomized to MSDC-0602K (30 mg/kg/day) or Vehicle (VC) and gavaged QD from 16-24 wks ($n = 10$/group), and results were compared to baseline WDSW positive controls (baseline PC, $n = 5$) and 24-wks CDNW negative natural history controls (NC, $n = 5$). Metabolites were extracted from snap-frozen liver and serum samples and analyzed via ultra-high performance liquid chromatography coupled to mass spectrometry (UHPLC-MS).
Results: Relative to VC, histological improvement in ballooning occurred in mice treated with MSDC-0602K without changes in steatosis. However, triglyceride profile in the hepatic tissue was significant altered by the treatment, being changes dependent on the esterified acyl chains. While saturated and monounsaturated species decreased in MSDC-0602K group (vs. VC), polyunsaturated species

increased. Similarly, there was a significant decrease in saturated diglycerides in the treated group compared to VC group. MSDC-0602K also significantly lowered the levels of ceramides and lysophosphatidylcholines, species previously associated with hepatic lipotoxicity and NASH progression. Several metabolites significantly altered by MSDC-0602K in the liver were also lowered in serum samples (vs. VC). This is relevant, since serum and not liver should be the base for the non-invasive identification of human NASH responders to this treatment. Among them, several polyunsaturated fatty acids, triglycerides and lysophosphatidylcholines.
Conclusion: Administration of MSDC-0602K regulated the levels of triglycerides in the liver, reducing saturated and increasing polyunsaturated species, and reduced the levels of lipotoxic species. The results also revealed metabolites that are specifically altered by MSDC-0602K and that may be used as non-invasive biomarkers reflecting its therapeutic effect on the liver.

FRI-290

The role of bile acids profile and insulin reistance for the prediction of gallstone disease in a prospective cohort of blood donors

Francesco Azzaroli[1], Patrizia Simoni[1], Rosario Arena[1], Elton Dajti[1], Federico Ravaioli[1], Rocco Maurizio Zagari[1], Alberto Porro[1], Cecilia Camborata[1], Annarita Belardinelli[1], Silvia Spinozzi[1], Marco Montagnani[1], Franco Bazzoli[1], Davide Festi[1], Franco Placido[1], Aldo Roda[1], Giuseppe Mazzella[1]. [1]*University of Bologna, Bologna, Italy*
Email: francesco.azzaroli@unibo.it

Background and aims: Bile acids (BAs) play an important role in lipid and glucose homeostasis. The aim of this study is to evaluate the association between the single and total BAs' profile and the presence of gallstone disease (GD) in a large blood donor population.
Method: This is a prospective study (SOLENNE), in which 280 blood donors were consecutively enrolled. Subjects with previous cholecystectomy, overt gastrointestinal disease or assuming drugs were excluded. Routine laboratory tests, BA fraction quantification by high-performance liquid chromatography-mass spectrometry (HPLC-MC), as well as abdominal ultrasound (US), were performed for each patient. The HOMA-Index was calculated for each patient in order to assess insulin sensitivity. A propensity score was calculated and used as a co-variate at uni- and multivariate analysis, in order to adjust per known confounding factors (age, sex, Body Mass Index [BMI]). The study was approved by local ethical committee.

Table Legend: Predictors of gallbladder disease presence at ultrasound in healthy blood donors.

	Univariate analysis		Multivariate analysis	
	OR (95% IC)	p value	OR (95% IC)	p value
G-DCA	4.330(1.636-11.465)	0.003	3.942(1.443-10.773)	0.007
T-DCA	60.477(2.756-1327.281)	0.004		
HOMA-Index > 2	3.047(1.175-7.902)	0.022	1.443(1.012-7.015)	0.047
HOMA-Index > 2.5	2.5800.9781-6.807)	0.056		

#Adjusted for propensity score including: age, sex, BMI.

Results: Out of the 280 subjects included in the final analysis, GD was found in 20 (7.1%) of them. Subjects with GD were older and presented higher BMI, glucose levels and IR prevalence, when confronted to subjects without GD disease. Levels of tauro (T)- and glyco (G)-deoxycholic acid (DCA) were also significantly higher in the GD group ($p = 0.0018$ and $p = 0.007$, respectively); their association with GD presence was found significant at univariate analysis. At the multivariate analysis adjusted for the propensity score, G-DCA (OR, 3.942, 95%IC, 1.443-10.773) and insulin-resistance (IR) (OR, 1.433, 95% IC 1.012-7.015) were independent predictors of GD presence ( ). When stratified by G-DCA level's terciles, GD and IR prevalence progressively increased, and IR was independently associated with GD only in patients with higher levels of G-DCA (3rd tercile).
Conclusion: G-DCA is independently associated with presence of GD, and therefore could play a crucial role in the pathogenesis of gallstone formation. IR could play a role in the development of GD, especially in patients with higher levels of G-DCA.

FRI-291

Glucokinase sensitizes hepatocarcinoma cells to the lipogenic activity of fructose and controls accumulation of lipid droplets and secretion of triglyceride-rich lipoproteins

Olivier Diaz[1], Clémence Jacquemin[1], Baptiste Panthu[1], Bénédicte Elena-Herrmann[2], Gilles Rautureau[3], Patrice Andre[1], Vincent Lotteau[1]. [1]*Centre International de Recherche en Infectiologie (CIRI), INSERM U1111-CNRS UMR5308 Université Lyon 1, ENS de Lyon, LYON cedex 07, France;* [2]*Institute for Advanced Biosciences (IAB), La Tronche, France;* [3]*Institute of Analytical Sciences (ISA), UMR 5280, Villeurbanne, France*
Email: olivier.diaz@inserm.fr

Background and aims: Human hepatocarcinoma cell lines are in vitro models for the study of lipid metabolism, hepatic steatosis and carcinogenesis. However, these cells have an unbalanced lipid metabolism that is strongly dependent on exogenous fatty acids to synthesize triglycerides and lipoproteins. This motivates the need for a physiologically relevant hepatocyte *in vitro* model allowing a deep analysis of the cellular mechanisms that regulate glycolysis, *de novo* lipogenesis and lipoprotein synthesis in normal and pathological situations.
Method: Like virtually all cancer cells, hepatocarcinoma cells express the "cancer-type" hexokinase isoenzyme HK2. Here, we restored the hepatic hexokinase isoenzyme (glucokinase, GCK) expression in the paragon hepatocarcinoma cell line Huh7 invalidated for HK2 by CRISPR-Cas9. Endo- and exo-metabolites have been analysed by a combined approach of biochemistry and high-field Nuclear Magnetic Resonance metabolomics.
Results: Metabolomic analysis highlighted that although glucose consumption was not affected, a profound metabolic remodelling occurred following hexokinase isoenzyme switch. GCK induced lipid droplets accumulation as well as secretion of triglyceride-rich $ApoB^+$ lipoproteins. Accompanying the lipogenic activity of GCK, the TCA cycle is rewired at the level of pyruvate entry and succinate dehydrogenase and pentose phosphate pathway is activated. With this metabolic profile, GCK-expressing cells become responsive to fructose by accumulating intracellular lipids as well as secreting large amount of $ApoB^+$ lipoproteins.
Conclusion: Restoring GCK expression in hepatoma cells has induced a large scale metabolic remodelling with a balanced lipid metabolism mimicking *in vivo* lipogenesis. This physiologically-relevant hepatocyte model will certainly provide improved clues to control liver inflammation, NAFLD and tumorigenesis.

Liver polyploidization during NAFLD: A gatekeeper against the replication stress

Romain Donne[1], Maeva Saroul[1], Mounia Herrag[2], Patrick Revy[2], Philippe Gual[3], Valérie Paradis[4], Chantal Desdouets[1]. [1]*Inserm U1016, Cochin Institute, Paris, France;* [2]*UMR 1163, Imagine Institute, Paris, France;* [3]*Inserm U1065, Mediterranean Center for Molecular Medicine C3M, Nice, France;* [4]*INSERM U773, Centre de Recherche Biomédicale Bichat-Beaujon, Clichy, France*
Email: romain.donne@inserm.fr

Background and aims: Over the past decades, the rising incidence of HepatoCellular Carcinoma (HCC) has paralleled to the increase

prevalence of obesity. The liver is a central organ affected by high level of fat accumulation, defined as Non-Alcoholic Fatty Liver Diseases (NAFLD). Alarmingly, hepatic steatosis (NAFL) combined with chronic inflammation and liver injuries cause Non-Alcoholic Steatohepatitis (NASH), the more severe form of NAFLD and a precursor of HCC. Increasing evidence indicates that NAFLD strongly affects the intrinsic proliferative properties of hepatocytes. Several signs of impaired proliferation status were reported in fatty hepatocytes such as telomeres attrition and senescence's engagement. Recently, our team demonstrated that fatty hepatocytes divide preferentially by endoreplication (skip mitosis) due to the activation of the **D**NA **D**amage **R**esponse (DDR). Endoreplication is considered as an alternative division program in a context of genomic stress and leads to the genesis of polyploid contingents.

Methods and Results: We developed a powerful quantitative and qualitative technological approach to define ploidy profiles on tissue liver sections. We demonstrated a dramatic enrichment of highly polyploid hepatocytes (≥ 8n) in NASH murine models (**H**igh-**F**at **H**igh-**S**ucrose/**C**holine-**D**eficient **H**igh-**F**at **D**iets) but also in NASH human patients. Importantly, this population is barely seen in normal condition. Within fatty parenchyma, polyploid fraction co-localize with lipid droplets suggesting an adaptation process to store and/or metabolize lipids more efficiently. We go further to decipher why the DDR is activated in fatty parenchyma leading to the genesis of the polyploid fraction. Transcriptomic analysis reveals an enriched gene set involved in DNA repair in fatty hepatocytes. In this context, DNA synthesis parameters were measured in dividing primary hepatocytes cultures (HFHS/CTR). DNA combing assay reveals that NAFL hepatocytes exhibit a dramatic reduction of replication fork speed with the presence of stalled fork. Regarding the presence of DNA breaks by Comet assay, replicating NAFL hepatocytes display high level of breaks associated with a pan-nuclear of gamma-H2AX staining. Additional molecular analyses reveal a specific activation of ATR/pRPA^{S33} pathway, specifically activated by single-strand DNA Breaks. Interestingly, double-strand DNA Breaks are found in replicating NASH hepatocytes.

Conclusion: Collectively, our results showed that dividing fatty hepatocytes harbor Replication Stress; RS being recognized as a hallmark of cancer. We suggest that the genesis of polyploid hepatocytes could buffer these DNA lesions and thus represent a defense mechanism in NASH-HCC sequence.

FRI-293

Recipient PNPLA3 and TM6SF2 genotypes and risk of NAFLD folllowing liver transplantation

Carmen Ester[1], Razvan Cerban[1], Speranta Iacob[1], Razvan Iacob[1], Georgiana Constantin[2], Prof. Dr. Liliana Pislaru[2], Dr. Sorop Andrei[3], Dr. Mihaela Ghioca[1], Dr. Lorand Savu[4], Prof. Dr. Irinel Popescu[3], Prof. Dr. Liana Gheorghe[1]. *[1]Fundeni Clinical Institute, Gastroenterology and LIver Transplantation, Bucharest, Romania; [2]Fundeni Clinical Institute, Biochemistry, Bucharest, Romania; [3]Fundeni Clinical Institute, General Surgery and Liver Transplantation, Bucharest, Romania; [4]Genetic Lab, Molecular Biology, Bucharest, Romania*
Email: carmen.ghidu@gmail.com

Background and aims: Liver transplant recipients are more likely to develop de-novo or recurrent non-alcoholic fatty liver disease (NAFLD), most of them fulfilling the criteria for metabolic syndrome (MetSy). Our aim was to assess the impact of single nucleotide polymorphyisms of PNPLA3 rs738409 "M-variant" (43928847C > G) and TM6SF2 "K-variant" (19268740C > T) on the presence of metabolic syndrome and cardiovascular risk in these patients.

Method: We assessed 61 liver transplant recipients for clinical and biological features and genetic polymorphism. The cardiovascular risk was assessed using the Framingham risk score.

Results: HCV cirrhosis was the main indication for liver transplantation (69% of patients), 62.3% were males and the mean age at evaluation was 56 years. The rs738409 polymorphism of PNPLA3 I148M was encountered in 70.5% of the study population with 46% heterozygous I/M and 24.5% homozygous M/M mutation. The non-parametrical test (Mann-Whitney) identified a significant association between the PNPLA3 M-variant and higher BMI (> 25) ($p = 0.0063$) and higher Framingham cardiovascular risk score ($p < 0.001$). TM6SF2 rs58542926 K- variant (E167K) was present in a lower proportion of patients compared to PNPLA3 M-variant-24.5% (14.5% homozygous and 10% heterozygous). When tested with the same Mann-Whitney test for independent samples the TM6SF2 K-variant was significantly associated with higher Framingham risk score ($p < 0.0001$), BMI > 25 ($p = 0.0007$), and the presence of metabolic syndrome ($p = 0.0001$).

Conclusion: Recipient PNPLA3 and TM6SF2 genotypes confer a genetic predisposition to liver graft non-alcoholic fatty liver disease along with a higher post-LT cardiovascular risk, independent of the graft genotypes. Assessment of the PNPLA3 and TM6SF2 polymorphisms in LT recipients will possibly modify clinical practice in the future.

Background and aims: Non-alcoholic fatty liver disease is one of the major chronic liver diseases in developed countries, including alterations from steatosis and non-alcoholic steatohepatitis to advanced fibrosis in at risk patients. Non-alcoholic fatty liver disease patients with and without fibrosis may develop hepatocellular carcinoma. Non-alcoholic fatty liver disease -related mechanisms include impairments in lipid uptake, mitochondrial fatty acid beta-oxidation, de novo lipogenesis and/or inefficient very-low-density lipoprotein assembly and secretion.

Glycine-N-methyltransferase (GNMT) is the enzyme responsible for a large amount of transmethylation reactions, comprising 1% of the soluble protein in liver. The importance of GNMT is to maintain the SAMe/SAH ratio, which represents an indicator of the methylation

capacity of the cell. In this work we explore the involvement of GNMT in non-alcoholic fatty liver disease pathogenesis and the influence of the GNMT regulator miR-873-5p targeting in fatty liver progression.
Method: We evaluate the miR-873-5p as biomarker in serum samples and liver biopsies of non-alcoholic fatty liver disease patients. In addition, we employ *in vitro* and *in vivo* non-alcoholic fatty liver disease models to assess the role of GNMT in fatty liver progression, and the targeting of the miRNA miR-873-5p as non-alcoholic fatty liver disease therapy.
Results: In the present study, we describe for the first time the role of GNMT in the mitochondria, particularly interacting with the complex II in the electron transport chain, and increasing mitochondrial functionality and fatty acid beta-oxidation. There is also a decrease in hepatic oxidative stress, protecting it from fatty liver progression.
In particular, miR-873-5p was found to be upregulated in liver and serum from non-alcoholic fatty liver disease patients, correlating with GNMT depletion. Treatment of diet-induced non-alcoholic fatty liver disease in mice based on anti-miR-873-5p improved GNMT mitochondrial function.
Conclusion: In conclusion, we show the potential of miR-873-5p as novel non-alcoholic fatty liver disease biomarker and introduce a new therapy by targeting this microRNA, which results in the restoration of GNMT levels and the improvement of the newly identified GNMT function in mitochondria.

FRI-295

Advanced glycation end products (AGEs) exacerbate NAFLD progression to liver fibrosis via receptor for AGEs (RAGE) in high fat fed mice

Hettya Kandage Dinali Helan Fernando[1], Christopher Leung[2], Peter Angus[2], Chandana Herath[1]. [1]*The University of Melbourne, Department of Medicine, Heidelberg, Australia;* [2]*Austin Hospital, Heidelberg, Australia*
Email: hettiyaf@student.unimelb.edu.au

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease in the world, affecting up to 30% of the adult population. Advanced glycation end products (AGEs), formed as a result of non-enzymatic reaction between reducing-sugars and proteins, have been suggested as a second hit that drives NAFLD progression to liver fibrosis. We therefore investigated the role of the best characterized AGE receptor, RAGE, in mediating AGE effects in mice with NAFLD.
Method: Two groups of C57Bl/6 mice were fed a high fat (HF) diet for 40 weeks and one group was induced diabetes at 15 weeks of diet (HF+D) to increase endogenous AGE formation. Third group of mice was fed a baked HF diet to increase dietary AGE intake (HF+B, 1 hour at 160°C) and was made diabetic. Two groups of RAGE knockout mice were fed on either the HF or HF+B and were made diabetic. At 40 weeks, animals were sacrificed to collect liver tissues for gene expression analysis of RAGE, proinflammatory and profibrotic cytokines and collagen 1 by qPCR and quantification of fibrosis by picrosirius red staining. Plasma was harvested for liver function test. Dietary AGE content was determined by GC/MS. Gene expression of proinflammatory cytokines was determined after murine Kupffer cells (KUP5) were exposed to AGEs (200μg/ml) in the presence or absence of RAGE antagonists (RAP and FPS-ZM1).
Results: Baking increased AGE content in the diet. Long-term consumption of HF diet produced steatosis and mild fibrosis after 40 weeks. Both diabetes and high AGE diet caused upregulation ($p < 0.05$) of liver RAGE expression in wild type mice. The increased expression of tumour necrosis factor α (TNF-α) ($p < 0.01$), Toll like receptor-4 and CD14 ($p < 0.05$), transforming growth factor-β1 ($p < 0.0001$) and collagen I ($p < 0.05$) in HF+D or HF+B fed wild type mice was abrogated ($p < 0.01$) by RAGE deletion. Moreover, in wild type mice, diabetes and high dietary AGEs led to an increased ($p < 0.0001$) collagen expression, leading to severe liver fibrosis. Importantly, HF+D or HF+B-induced NAFLD progression to liver fibrosis was strongly inhibited by RAGE deletion. Increased ($p < 0.0001$) expression of RAGE, TNF-α, monocyte chemoattractant protein-1, interleukin-6 and −1β by KUP5 cells was completely ($p < 0.0001$) abrogated by incubation with RAGE antagonists.
Conclusion: Baking increases dietary AGE levels. Increased dietary AGEs, and diabetes which likely increases endogenous AGE production, trigger NAFLD progression to liver fibrosis by acting via RAGE. Blocking RAGE provides protection against AGE-induced NAFLD progression to liver fibrosis.

FRI-296

Interaction between the soluble guanylate cyclase and the NLRP3 inflammasome in Kupffer cells: Implications for the anti-inflammatory actions of sGC stimulation in liver

Roger Flores-Costa[1], Marta Duran-Güell[1], Mireia Casulleras[1], Cristina López-Vicario[1], Esther Titos[1,2], Joan Clària[1,2,3]. [1]*Hospital Clínic-IDIBAPS, Biochemistry and Molecular Genetics Service, Barcelona, Spain;* [2]*Hospital Clínic-IDIBAPS, Department of Biomedical Sciences, Barcelona, Spain;* [3]*European Foundation for the Study of the Chronic Liver Failure (EF-Clif), Barcelona, Spain*
Email: jclaria@clinic.cat

Background and aims: The inflammasome is a multiprotein complex that promotes the maturation of pro-interleukin (IL)-1 beta and pro-IL-18 to their active forms through the activity of caspase-1. The NLRP3 inflammasome, formed by NLRP3, ASC and caspase-1, is critical in initiating the "cytokine storm." Cyclic nucleotides, such as cyclic guanosine-3," 5'-monophosphate (cGMP), play a major role in cell signaling and tissue homeostasis. Soluble guanylate cyclase (sGC) is the enzyme that catalyzes the conversion of GTP into cGMP. We demonstrated that sGC expression and cGMP levels were significantly reduced in livers of mice with non-alcoholic steatohepatitis (NASH) and that could be corrected by the use of sGC stimulators, which produced a remarkable anti-inflammatory effect. Here, we explored whether the anti-inflammatory effects of sGC-cGMP stimulation are linked to the inactivation of the hepatic NLRP3 inflammasome.
Method: *In vitro* and *ex vivo* experiments were performed in primary Kupffer cells and precision-cut liver slices (PCLS), respectively, incubated with LPS+ATP. *In vivo* experiments were performed in mice with NASH induced by a choline-deficient L-amino acid-defined high-fat diet. Gene expression was analyzed by qPCR and protein expression by Western blot and ELISA. Ly6C+Cd11b+ monocytes were identified by flow cytometry.
Results: Kupffer cells showed constitutive expression of sGC and NLRP3 inflammasome components. Incubation of Kupffer cells with LPS+ATP significantly induced NLRP3 expression and triggered IL-1beta production, effects that were significantly attenuated by sGC stimulation. Interestingly, sGC stimulation reduced TIMP-1 and TGF-beta expression in Kupffer cells, indicating that sGC stimulation also has the ability to inhibit the production of pro-fibrogenic factors by liver macrophages. Similar effects were observed in PCLS. Anti-inflammatory actions were confirmed *in vivo*, in which sGC stimulation significantly abrogated protein expression of inflammasome components (i.e. NLPR3, ASC, caspase-1 and IL-1beta). Interestingly, flow cytometry analysis of peripheral blood revealed that sGC stimulation increased the number of patrolling and tissue repair $Ly6C^{Lo}$ monocytes, while reducing the population of pro-inflammatory $Ly6C^{Hi}$ monocytes.
Conclusion: These findings provide potential novel mechanisms of action for the anti-inflammatory properties of sGC stimulation in experimental NASH.

Trans-signaling blockade induces mature-onset obesity and insulin resistance in mice via suppression of PPARalpha

tali lanton[1], Orr Levkovitch[1], Rinat Abramovitch[1], Sharon Perles[2], Joseph Tam[3], Shiran Udi[3], Evan Williams[4], Ruedi Aebersold[4], Eran Elinav[5], Meirav Pevsner-Fischer[5], Jacob Rachmilewitz[1], Stefan Rose-John[6], Eithan Galun[1], Jonathan Axelrod[1]. [1]*Hadassah Hebrew University Hospital, Goldyne Savad Inst. of Gene Therapy, Jerusalem, Israel;* [2]*Raziel Therapeutics Ltd, Jerusalem, Israel;* [3]*Hebrew University of Jerusalem, Jerusalem, Israel;* [4]*ETH, Institute of Molecular Systems Biology, Zurich, Switzerland;* [5]*Weizmann Inst. of Science, Dept. of Immunology, Rehovot, Israel;* [6]*Christian-Albrechts-University of Kiel, Institute of Biochemistry, Kiel, Germany*
Email: axelrod@hadassah.org.il

Background and aims: IL-6 has been shown to play crucial roles in metabolic homeostasis and weight gain in experimental models; but the controlling molecular mechanism (s) and their physiological and clinical relevance remain unclear. Interestingly, evidence from clinical studies has revealed statistically significant correlations of body mass index in diabetic patients with increased levels of soluble gp130 (sgp130)-a specific inhibitor of IL-6/IL-11 signaling mediated via their respective soluble receptors (sIL-6R/sIL-11R), or so called trans-signaling. Paradoxically, while total IL-6 ablation in IL-6 knockout mice reportedly induces mature-onset obesity, hepatosteatosis and insulin resistance (Matthews et al., 2010; Wallenius et al., 2002), inhibition of trans-signaling in mice carrying a recombinant sgp130 transgene (sgp130Fc) prevented HFD-induced recruitment of adipose tissue macrophages and did not exacerbate weight gain, liver steatosis, or insulin resistance in young HFD-fed mice (Kraakman et al., 2015). Here we have examined the hypothesis that IL6 trans-signaling plays a protective role against mature-onset obesity and fatty liver in aging mice.
Method: Sgp130Fc transgenic mice and wild type littermate control mice were maintained under normal dietary conditions and analyzed at 2, 5 and 14 months-of-age, for weight gain, glucose tolerance, liver steatosis, and for differential expression of liver proteins by proteomics and bioinformatics analysis.
Results: Blockade of trans-signaling in sgp130Fc mice resulted in mature-onset obesity becoming apparent at about 6 months of age with increased adipose tissue visualized by MRI, increased gonadal fat pad size, adipocyte hypertrophy, and hyperleptinemia appearing at 12 months. Sgp130Fc mice also displayed hepatosteatosis and peripheral insulin resistance, without gut microbiota dysbiosis or defective mitochondrial fat oxidation. Proteomics analysis revealed a strong correlation between the metabolic phenotype in sgp130Fc mice and a profound decrease in hepatic PPARα activity from 2 months of age, as confirmed by qPCR and Western blot analyses, which was associated with increased hepatic miR-21 expression. PPARα is a known target of miR-21. Importantly, treatment with the PPARα agonist, fenofibrate rescued the sgp130Fc mice from obesity, steatosis, and insulin resistance.
Conclusion: Our findings reveal a profound PPARα-mediated role for IL-6 trans-signaling in the prevention of age-dependent obesity, insulin resistance, and fatty liver in mice.

FRI-298

Hypoxia-inducible factor 2 alpha drives lipid accumulation in human hepatocytes through the fatty acid translocase CD36

Carmelo García-Monzón[1,2], Esther Rey[1], Florinda Meléndez-Rodríguez[1,3,4], Patricia Marañón[1], Elvira Del Pozo-Maroto[1,2], Javier Rodríguez de Cía[1,2], Julián Aragonés[1,3,4], Águeda González[1,2]. [1]*Instituto de Investigación Sanitaria del Hospital Universitario de La Princesa, Research Unit, Hospital Universitario Santa Cristina, Madrid;* [2]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain;* [3]*Universidad Autónoma de Madrid, Madrid, Spain;* [4]*Centro de Investigación Biomédica en Red de Enfermedades Cardiovasculares (CIBERCV), Madrid, Spain*
Email: garcia-monzon@hotmail.com

Background and aims: Molecular mechanisms by which hypoxia might contribute to hepatosteatosis, the earliest stage in non-alcoholic fatty liver disease (NAFLD) pathogenesis, remain still to be elucidated. We aimed to assess the impact of hypoxia-inducible factor 2α (HIF2α) on the fatty acid translocase CD36 expression and function *in vivo* and *in vitro*.
Method: NASH features, and HIF2α and CD36 expression were evaluated in livers from animals in which von Hippel-Lindau (*Vhl*) gene is inactivated ($Vhl^{f/f}$ deficient mice) or both *Vhl* and *Hif2α* are simultaneously inactivated ($Vhl^{f/f}Hif2\alpha^{f/f}$ deficient mice), and from 33 biopsy-proven NAFLD patients and 18 subjects with histologically normal liver. Additionally, modulation of CD36 expression as well as intracellular lipid content was determined by qPCR and flow cytometry, respectively, in hypoxic HIF2α-silenced human liver cells.
Results: Livers from $Vhl^{f/f}$ deficient mice showed histologic features of non-alcoholic steatohepatitis (NASH) and increased *Cd36* mRNA and protein amounts, whereas both significantly decreased and NASH features markedly ameliorated in $Vhl^{f/f}Hif2\alpha^{f/f}$ deficient mice. Moreover, in hypoxic human liver cells, CD36 expression and intracellular lipid content were significantly augmented. Noteworthy, in these hypoxic liver cells, CD36 knockdown significantly reduced lipid accumulation, and HIF2α silencing markedly decreased both lipid accumulation and *CD36* gene expression. In addition, both HIF2α and CD36 were significantly overexpressed within the liver of NAFLD patients and, interestingly, a significant positive correlation between hepatic transcript levels of *CD36* and erythropoietin (*EPO*), a HIF2α-dependent gene target, was observed in NAFLD patients.
Conclusion: This study provides evidence that HIF2α drives lipid accumulation in human hepatocytes by upregulating CD36 expression and function, thus contributing to hepatosteatosis setup.

FRI-299

Transcriptomic and epigenetic characterization of a NAFLD murine model

Antonio Gil-Gomez[1], Ángela Rojas[1], Rocio Munoz hernandez[1], Rocío Gallego-Durán[1], Sheila Gato[1], Rocío Montero-Vallejo[1], Douglas Maya-Miles[1], Javier Ampuero[1,2], Manuel Romero Gomez[1,2]. [1]*SeLiver Group. Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla. CIBERehd., Seville, Spain;* [2]*UGC Enfermedades de enfermedades Digestivas. Hospital Universitario Virgen del Rocío,., Seville, Spain*
Email: mromerogomez@us.es

Background and aims: Epigenetics play an important role in the progression of non-alcoholic fatty liver disease (NAFLD). The aim of our study was to unravel how the interaction between genes and miRNAs expression could affect the development of non-alcoholic steatohepatitis (NASH) in a murine model.
Method: Fifty-two male six-weeks mice C57BL/6J were fed a HFHCC diet (40% Kcal fat, 1% cholesterol and 42g/L glucose/fructose in drinking water) (n = 40) or standard diet (n = 12) being sacrificed at 13, 26, 39 and 52 weeks. Anatomorphological features, histological, biochemical and metabolic parameters were measured. Liver RNA was extracted and the transcriptomic and epigenetic profile were studied by ClarionS and miRNA4.0 arrays including > 22, 000 transcripts and > 3, 000 miRNAs (mature and pre-miRNA) (ThermoFisher, CA, USA). The interaction was evaluated by using TAC software (ThermoFisher, CA, USA).
Results: HFHCC diet induced NASH in mice, characterized by a gain in weight and BMI, macro-microvesicular steatosis (> 90%), inflammatory foci at lobular, portal and periductal levels, followed by presence of hepatocyte degeneration (ballooning) and moderate fibrosis. The model also showed a progressive increase in the hepatic, lipidic and glucidic parameters. Besides, we also detected several foci of

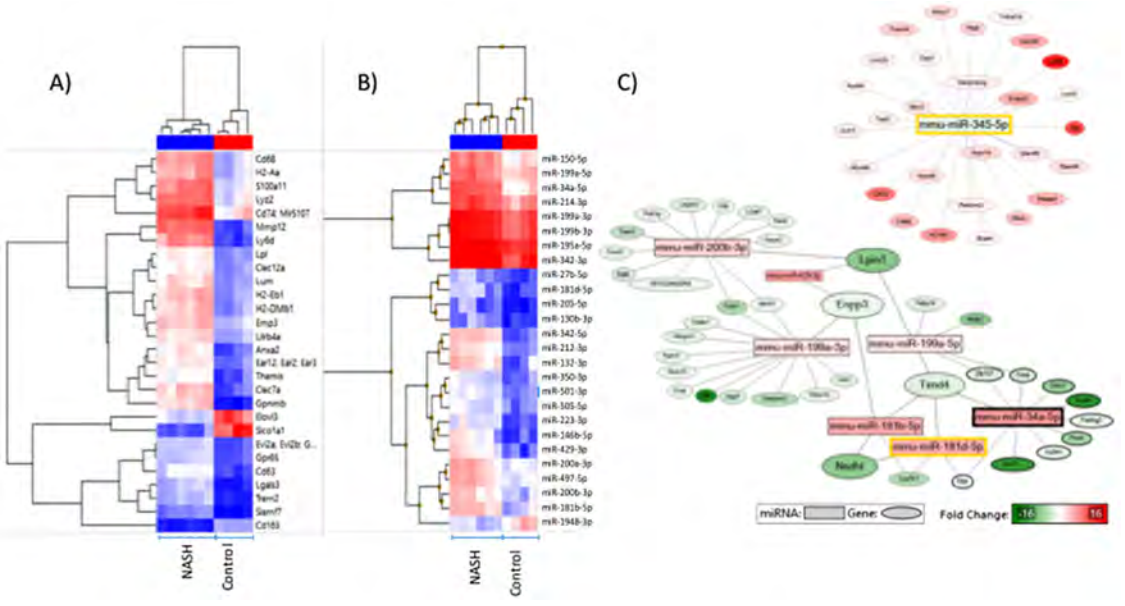

Figure: (abstract: FRI-299)

cellular alterations in > 40% animals and nodules in > 20%. The transcriptomic gene enrichment analysis allowed us to identify changes in pathways similar to human NASH. At early stages, changes in lipid metabolism, proliferation and inflammatory signaling were observed. Nevertheless, advanced stages showed an increase in oxidative stress, senescence and innate immune response pathways. Besides, we found upregulation of several pluripotency-related factors such as Sox2, Nanog and Klf4 at 52 weeks. In comparison to control, NASH animals showed up to 28 genes differentially expressed ($p < 1x10^{-8}$;fold±10;FDR < 0.05) Similarly, the epigenetic profile revealed 26 miRNAs with differences ($p < 0.001$;fold±2;FDR < 0.05). Finally, by analyzing the target gene prediction of miRNAs we could confirm the interactions miRNA-genes (miRNAome).

Conclusion: HFHCC model comprises the main clinical and histological characteristics of human NASH, including slow progression to fibrosis and hepatocellular carcinoma, covering the needs in the field for future preclinical studies. Besides, by deciphering the miRNAome of NAFLD new biomarkers and therapeutic targets could be developed and detected. In this sense, we found that overexpression of four miRNAs (miR-200b, miR-199a, mir181b and miR34a), through regulating several genes, could play a role in NAFLD pathogenesis.

FRI-301

The differential expression of the CIDE family is associated with NAFLD progression from steatosis to steatohepatitis

Sans Arnaud[1], Bonnafous Stéphanie[1], Rousseau Déborah[1], Patouraux Stéphanie[1], Canivet Clémence[1], Leclere Pierre[1], Tran-Van-Nhieu Jeanne[2], Luci Carmelo[1], Bailly-Maitre Béatrice[1], Minehira Kaori[3], Anty Rodolphe[1], Tran Albert[1], Iannelli Antonio[1], Philippe Gual[1]. *[1]INSERM, U1065, C3M, Team 8, Université Côte d'Azur, Nice, France; [2]HU Henri Mondor, Department of Pathology, AP-HP-Université Paris Est Créteil, Creteil, France; [3]University of Lausanne, Department of Physiology, Lausanne, Switzerland*
Email: gual@unice.fr

Background and aims: Improved understanding of the molecular mechanisms responsible for the progression from a "non pathogenic" steatotic state to Non-Alcoholic Steatohepatitis (NASH) is an important clinical requirement. The CIDE family members (CIDEA, B and FSP27α and β) regulate lipid homeostasis in the liver by controlling lipid droplet growth and/or VLDL production. However, CIDE proteins, particularly FSP27, have a dual role in that they also regulate cell death. Here, we aim to evaluate the relative expression level of the three CIDE members over the transition from simple steatosis to NASH, and to assess the contribution of CIDEC to hepatocyte steatosis and death.

Method: The CIDE family was studied in the livers of mice challenged with a high fat diet (33 weeks; exhibiting obesity and hepatic steatosis) or a methionine choline deficient diet (from 2 to 7 weeks; exhibiting progression of the NASH features) and in liver biopsies from 38 obese patients. FSP27 was downregulated or overexpressed in human and mouse hepatocytes to study its role in lipid droplet synthesis and cell viability.

Results: We here report that hepatic expression of CIDEA and FSP27α and β was similarly upregulated in a dietary mouse model of obesity and hepatic steatosis. In contrast, CIDEA expression decreased, whereas only FSP27β expression was strongly increased in a dietary mouse model of steatohepatitis. The inverse expression pattern of CIDEA and FSP27β was amplified with the increasing severity of the liver inflammation and injury. In morbidly obese patients, the hepatic expression of CIDEC2 (human FSP27β homologue) strongly correlated with the NAFLD activity score, hepatic inflammation, liver injury and hepatocyte apoptosis. The hepatic expression of CIDEA tended to increase with obesity but decreased with NAFLD severity. The hepatic expression of CIDEB was not modified with obesity or NAFLD in mouse and human. In hepatic cell lines, the downregulation of FSP27beta resulted in the fractionation of lipid droplets but overexpression of FSP27 decreased the anti-apoptotic BCL2 expression. This, in turn, sensitized cells to apoptosis at baseline and in response to oleic acid.

Conclusion: Considered together, our animal, human and in vitro studies indicate that modification of the FSP27β/CIDEC2 to CIDEA ratio is related to NAFLD progression and liver injury.

FRI-302

Impact of exercise on advanced fibrotic stage of NASH and liver carcinogenesis

Maria Guarino[1,2], Andrea Felser[3], Luigi Maria Terracciano[4], Sergi Guixé-Muntet[1], Jordi Gracia-Sancho[1,5], Jean-Marc Nuoffer[3], Marie V. St-Pierre[1], Jean-François Dufour[1,6]. *[1]University of Bern, Hepatology, Department for BioMedical Research, Bern, Switzerland; [2]University of Naples "Federico II," Gastroenterology, Department of Clinical Medicine and Surgery, Naples, Italy; [3]Bern University Hospital, University Institute of Clinical Chemistry, Bern, Switzerland; [4]University Hospital Basel, Institute of Pathology, Basel, Switzerland; [5]IDIBAPS Biomedical Research Institute, CIBEREHD, Liver Vascular Biology Research Group, Barcelona Hepatic Hemodynamic Laboratory, Barcelona, Spain; [6]Inselspital Bern, University Clinic of Visceral Surgery and Medicine, Bern, Switzerland*
Email: maria.guarino86@gmail.com

Background and aims: In the absence of approved pharmacotherapy, lifestyle interventions incorporating exercise remain the cornerstone of treatment for NASH. However, benefits of exercise on fibrotic NASH are unexplored. We queried whether exercise arrests the histological and carcinogenic progression of NASH in an experimental model.
Method: Male C57Bl/6N mice aged 10 weeks were assigned randomly to either control diet (CD, n = 11) or choline-deficient high-fat diet (HFD, n = 33). At 12 weeks, CD mice were harvested and the HFD mice were randomized either for harvest (n = 11) or for 8 further weeks of sedentariness (SED, n = 11) or treadmill exercise (EXE, n = 11) (1 h, 5 days/week, speed 12.5m/min). Changes in plasma biochemistry, protein expression and triglycerides in liver, histology and scanning electron microscopy, and mitochondrial bioenergetics (Oxygraph-2k Oroboros) were assessed. Fibrosis was quantified (MetaMorph software) on Sirius Red stained sections.
Results: Compared to SED mice, EXE showed reduced plasma ALT (138 vs 259 U/l), bilirubin (16 vs 29 µmol/l), triglycerides (0.67 vs 0.82 mmol/l), cholesterol (1.84 vs 2.57 mmol/l) and bile acids (58.9 vs 78.7 µmol/l), as well as liver triglycerides (1512 vs 2613 nmol/mg) ($p < 0.05$, EXE vs SED). Histologically, EXE livers showed less ballooning degeneration (median score 0 vs 2; $p = 0.0006$) and a lower NAS score (median 6 vs 8; $p = 0.0009$). Importantly, exercise prevented the progression of fibrosis (4.74 vs 9.17 pixel percentage ratio; $p < 0.0001$) [Fig.1]. Additionally, exercise activated AMPK with consequent inhibition of mTORC1, reducing the development of hepatocellular adenoma (70% vs 100%, $p = 0.0075$). Defenestration of endothelial cells was present in all HFD groups, regardless of exercise. In mitochondrial bioenergetics studies, maximum and complex IV driven respiration was reduced in NASH but only at 12 weeks commensurate with a down-regulation of cytochrome oxidase 4 protein. Leak respiration increased in all NASH groups and was unaffected by exercise.
Conclusion: Exercise improves biochemical and histological parameters in an experimental model of established NASH and impedes the progression of fibrosis and liver carcinogenesis. Our work supports the benefits of exercise independently of other lifestyle changes.

FRI-303

How to develop a differentiated FXR agonist: GS-9674 shows a reduced side effect profile in mice, monkeys amd human phase I studies compared to its predecessor Px-102

Eva Hambruch[1], David Hollenback[2], John Liles[2], Olaf Kinzel[1], Manfred Birkel[1], Gero Fink[1], Dorothy French[2], Christian Gege[1], Martin Hornberger[1], William Watkins[2], Claus Kremoser[1]. *[1]Phenex Pharmaceuticals AG, Heidelberg, Germany; [2]Gilead Sciences, Inc., Foster City, United States*
Email: eva.hambruch@phenex-pharma.com

Background: FXR agonists such as Obeticholic Acid (OCA) have proven to be effective pharmacotherapies in liver diseases such as

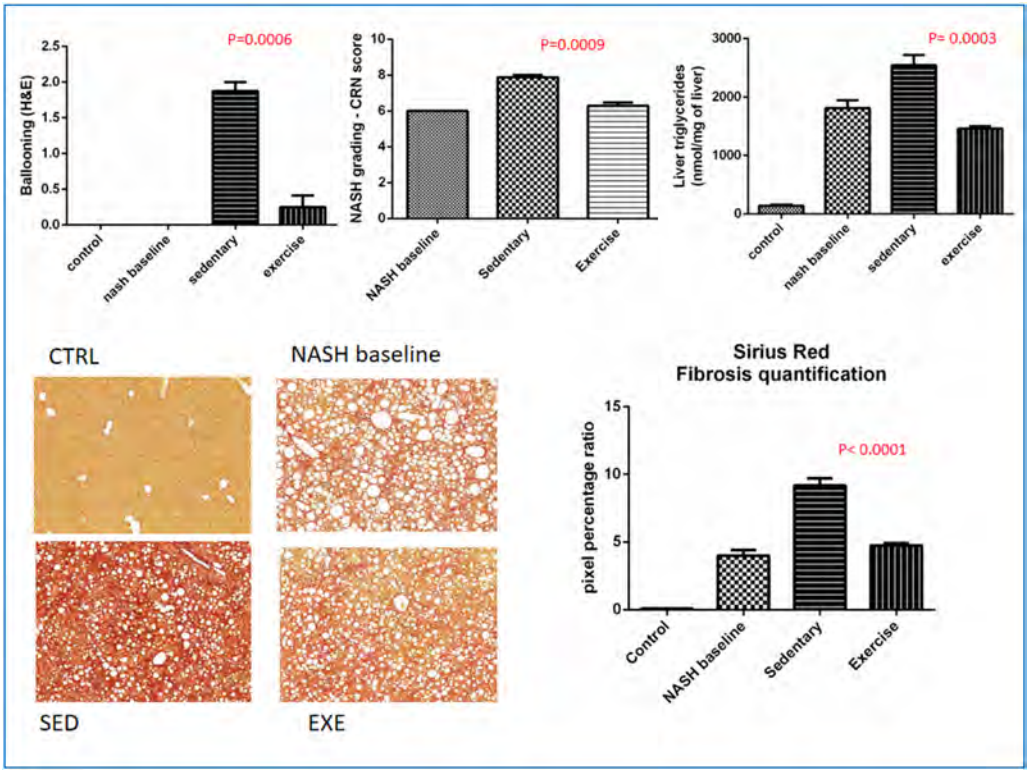

Figure: (abstract: FRI-302)

Primary Biliary Cirrhosis (PBC) or Non-alcoholic Steatohepatitis (NASH). With regards to NASH, FXR agonists have demonstrated anti-steatotic, anti-inflammatory and anti-fibrotic effects in preclinical studies and clinical trials. However, clinically, liabilities such as LDL-c increases, HDL-c lowering and pruritus have been reported with FXR agonists, with the first two suggestive of an increased atherogenic and thus cardiovascular risk.

Methods/Results: We initially developed a fully synthetic, non-steroidal FXR agonist, Px-102 and tested it in preclinical NASH animal models and in a single ascending (SAD) and seven-day multiple dose (MAD) phase I study. In the SAD study, Px-102 was given as oral suspension (0.05 to 4.5 mg/kg). FXR agonism was evident from dose-proportional increases in plasma FGF19. The MAD study revealed daily increases superimposed on the circadian rhythm. However, LDL-c and HDL-c also changed and time and dose-dependent increases of ALT and AST as well as individual cases of pruritus were noted. These unwanted side effects prompted a quest for a differentiated FXR drug candidate. To probe for less liabilities, we established an appropriate animal model recapitulating the pattern of FXR-induced changes to screen structurally related FXR agonists of similar potency. Here, C57BL/6J mice on a high fat diet (HFD) showed similar changes whereas $FXR^{-/-}$ mice of the same background showed no Px-102 induced effects.

The new candidate, GS-9674, showed no ALT increases and only very moderate cholesterol changes. Comparing the reduction in fibrosis of GS-9674 with Px-102 in a choline-deficient HFD rat model of fibrosis revealed similar efficacy at 30 mg/kg versus 10 mg/kg of Px-102. Moreover, GS-9674 had no effects on HDL-c whereas Px-102 lowered HDL-c in a HFD-monkey model despite similar FGF19 induction. Finally, GS-9674 was tested in a SAD and 21 days MAD human phase I study and displayed dose-dependent induction of FGF19 and repression of C4, whereas cholesterol parameters remained unchanged up to 300 mg/day.

Conclusion: In this translational effort the human side effects of Px-102 were recapitulated in an appropriate animal model. Using the model as a screen we identified GS-9674 as a differentiated FXR agonist with intestinally biased activity and clearly reduced side effects for further clinical development in NASH, PBC, and PSC.

FRI-304

Elafibranor and pioglitazone reduce NASH and fibrosis in a genetically-obese dietary-induced NASH mouse model

Katie R. Headland[1], Katie Dickinson[1], Sharon Cheetham[1]. [1]*RenaSci Limited, Nottingham, United Kingdom*
Email: katie.headland@renasci.co.uk

Background and aims: Dietary-deficient mouse models of NASH present limitations due to their associated weight loss resulting in an altered metabolic profile to man. To resolve this issue we have developed a genetically-obese dietary-induced mouse model (*ob/ob* H-FFC) of NASH and fibrosis which is more congruent with man. We have evaluated this paradigm with the clinically effective compounds elafibranor and pioglitazone.

Method: Elafibranor (30 mg/kg po, once daily) and pioglitazone (15 mg/kg po, bi-daily) were evaluated in male *ob/ob* (B6/Cg-Lepob/J, n = 11-13) mice fed a high fat/fructose/cholesterol diet (H-FFC) for 85 days. Genetically obese (*ob/ob*) mice on a standard rodent diet were also included. Plasma liver enzymes, liver lipids, liver collagen and liver histology including NAFLD activity scoring (NAS) were assessed at the end of the study.

Results: The *ob/ob* H-FFC mice had significantly ($p < 0.05$ vs. control *ob/ob* mice) increased fibrosis, total NAS (a combination of steatosis, hepatocellular ballooning and lobular inflammation) and lobular inflammation. Plasma AST and ALT were also significantly ($p < 0.05$) increased alongside liver collagen and liver lipids (triglyceride, cholesterol and NEFA). We observed a small reduction in body weight from day 60 onwards, no change to plasma glucose but a significant ($p < 0.001$) reduction in plasma insulin in the *ob/ob* H-FFC mice versus the *ob/ob* standard diet controls. A summary of the effects of elafibranor and pioglitazone can be seen in Table 1.

	ob/ob H-FFC + elafibranor vs ob/ob	*ob/ob* H-FFC + pioglitazone vs ob/ob
Hepatic Pathology		
Steatosis	↓	-
Lobular Inflammation	↓	↓
Hepatocellular Ballooning	-	-
Fibrosis	↓	↓
NAS	↓	↓
Liver analysis		
Collagen	↓	↓
Triglycerides	↓	↓
NEFA	↓	↓
Cholesterol	↓	-
Plasma analysis		
ALT	↓	↓
AST	↓	-
Glucose	-	↓
Insulin	-	↓
Other parameters		
Bodyweight	↓	↑

Conclusion: Elafibranor and pioglitazone both improved NAS and fibrosis in the *ob/ob* H-FFC mouse model. While both compounds also reduce the liver enzyme ALT, liver lipids and collagen, the improvements observed with elafibranor were more marked. Due to the minimal effect on body weight and plasma glucose the *ob/ob* H-FFC diet mouse model is an improvement on dietary deficient models for the assessment of potential treatments of NASH and fibrosis with translatability to the clinic.

FRI-305

Long acting GLP-1/Glucagon co-agonist ameliorates steatosis, inflammation and fibrogenesis in a rodent model of NASH

Jenny Egecioglu Norlin[1], Elisabeth Galsgaard[1], Anne Bugge[1], Thomas Hansen[1], Jesper Lau[1], Kirsten Raun[1], Markus Robert Latta[1], Dorte Holst[1]. [1]*Novo Nordisk A/S, Maaloev, Denmark*
Email: doho@novonordisk.com

Background and aims: Glucagon-like peptide 1 (GLP-1) analogues are utilized in the treatment of type 2 diabetes and obesity, due to their well-characterized effects on body weight, glycemic control and cardiovascular benefits. Glucagon could provide additional efficacy through direct effects on hepatocyte metabolism, cholesterol synthesis, and anti-oxidative pathways. In preclinical models, GLP-1/Glucagon receptor (GG) co-agonists have shown greater body weight reduction and anti-steatotic properties than GLP-1 alone, and human studies has shown antisteatotic effect without deleterious effects on fasting or postprandial blood glucose. Here we aimed to evaluate the efficacy of a novel, long-acting GG co-agonist in a rodent diet-induced model of NASH.

Method: Male C57Bl/6 mice fed a diet high in trans-fat, fructose and cholesterol (FFC) for 36 weeks and randomized on fibrosis score at baseline, received once daily s.c. administration of vehicle or three different doses of the long-acting (LA) GG co-agonist for 8 weeks. In addition a reference group of animals was treated with semaglutide, a GLP-1 analogue. Hepatic steatosis, inflammation and fibrosis were assessed from liver biopsies using immunohistochemistry and morphometric analyses. Plasma levels of lipids and liver enzymes

were determined, and hepatic gene expression was analyzed by RNA sequencing.
Results: The LA GG co-agonist dose-dependently reduced body weight by 0-22% as compared to vehicle treatment, while semaglutide induced a body weight loss of 18%. Plasma levels of ALT, as a measure of liver injury, were reduced in all treatment groups with body weight loss. The co-agonist reduced hepatic steatosis to a greater extent compared with semaglutide at equal body weight loss, as demonstrated by three independent methods. The co-agonist, as well as semaglutide, significantly decreased histological markers of inflammation such as CD11b and Galectin-3, in addition to markers of hepatic stellate activation (SMA) and fibrosis (collagen I). Results from pathway analyses at the mRNA level suggest that the LA GG co-agonist plays an additional role in preventing oxidative stress, as the glucagon component normalised expression of a genetic pathway, encoding enzymes involved in methionine metabolism and generation of glutathione.
Conclusion: We have shown that a long acting GG co-agonist reduces hepatic steatosis, inflammation and fibrosis in a mouse model of NASH, supporting evaluation in clinical trials.

FRI-306
RIP3 deficiency restores mitochondrial bioenergetics and function in experimental NAFLD
Tawhidul Islam[1], Marta B. Afonso[1], Véronique Lenoir[2], Rui E. Castro[1], Carina Prip-Buus[2], Cecília M. P. Rodrigues[1]. [1]*Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal;* [2]*Institut Cochin, INSERM U1016, CNRS UMR8104, Université Paris Descartes, Paris, France*
Email: tislam@ff.ulisboa.pt

Background and aims: Mitochondrial dysfunction, liver cell damage and inflammation constitute key pathogenic mechanisms underlying non-alcoholic fatty liver disease (NAFLD) progression to non-alcoholic steatohepatitis (NASH) and hepatocellular carcinoma. To curb hepatic fat accumulation, metabolic adaptation, such as increased mitochondrial fatty acid oxidation (mtFAO), may take place. Of note, increased mtFAO without collateral up-regulation of the mitochondrial respiratory chain (MRC) activity leads to reactive oxygen species (ROS) overabundance. In this regard, we have previously shown that receptor interacting protein 3 (RIP3) kinase deficiency attenuates diet-induced liver oxidative stress, injury, inflammation and fibrosis. Here, we aimed to evaluate the role of RIP3 depletion on restoration of the MRC activity in experimental NAFLD progressing from steatosis to the development of preneoplastic lesions.
Method: C57BL/6N wild-type (WT) and RIP3$^{-/-}$ mice were fed either a choline-sufficient, amino acid-defined control diet (CSAA; n = 38) or a choline-deficient, amino acid-defined diet (CDAA; n = 38) for 32 and 66 weeks. Liver samples were collected and processed for assessment of steatosis, inflammation, fibrosis and hepatocyte proliferation. Citrate synthase and MRC complex I, II, II+III and IV activities were investigated. Mitochondrial biogenesis markers (PGC1α, NRF1, TFAM), and ROS detoxification markers (SOD1, SOD2) and SIRT3 were also analyzed.
Results: RIP3 depletion ameliorated CDAA-induced inflammation, fibrosis and oxidative stress, while decreasing the NAFLD activity score and the incidence of preneoplastic lesions. Compared to CSAA-fed WT mice, citrate synthase activity was slightly diminished at both 32 and 66 weeks of CDAA feeding. In addition, at 32 weeks, the CDAA diet resulted in significantly decreased enzymatic activities of MRC complex I, II, II+III and IV in WT mice compared to CSAA-fed animals. Strikingly, RIP3$^{-/-}$ mice showed an overall protection against CDAA-induced impairment of MCR complex activity, notably at 32 weeks. mRNA expression of PGC1α, NRF1 and TFAM was downregulated in CDAA-fed WT mice at both 32 and 66 weeks, but significantly increased in RIP3$^{-/-}$ mice. Similarly, SOD1, SOD2 and SIRT3 mRNA levels were downregulated in CDAA-fed WT mice, while RIP3 depletion significantly abrogated this effect at 32 weeks.
Conclusion: In conclusion, impaired MRC complex activity correlates with inflammation, fibrosis and ROS overproduction in experimental NAFLD. RIP3 deficiency restores MRC complex activity, enhances mitochondrial biogenesis, increases ROS detoxification capacity and, collectively, halts NAFLD progression.

FRI-307
Metadoxine prevents diet-induced non-alcoholic steatohepatitis in mice
Du Jinghua[1], Wen Zhao[1], Yu Lu[1], Dongdong Li[1], Lingdi Liu[1], Luyao Cui[1], Yuguo Zhang[1], Yuemin Nan[1]. [1]*Third Hospital of Hebei Medical University, Shijiazhuang, China*
Email: nanyuemin@163.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is one of the most common chronic liver disorders worldwide. Metadoxine appears to be a effective strategy to manage alcoholic steatohepatitis. However, its role during non-alcoholic steatohepatitis (NASH) remains poorly defined. The study aimed to assess the therapeutic efficacy and mechanisms of metadoxine in NASH
Method: Male C57BL/6J mice were obtained at 8 weeks of age. Mice were randomly divided into three groups of six animals. The treatments were as follows: 1): Control group fed with standard diet. 2) NASH group received a 42% fat "high fat/western-style" diet (HF) ad libitum for 16 weeks. 3) Metadoxine group received HFD and a single oral dose of metadoxine (200 mg/kg) was administered. Mice body weight, liver weight, fat mass was measured. Sera were collected for the analysis of biochemical markers and livers were obtained for further histological staining and gene expression analysis. Each liver tissue specimen was scored based on the criteria proposed by Knodell, Lee for steatosis and inflammation. Transmission electron microscope (TEM) was used to investigate the effect of metadoxine on the cell ultrastructure. The expression of inflammation genes, lipogenesis genes, and oxidative stress genes were assessed by real-time PCR and western blot.
Results: After 16-week dietary intervention, metadoxine decreased the body weight and the liver weight compared to the HFD group. Liver sections showed that HFD mice developed marked macrovesicular and microvesicular steatosis, as well as multifocal necrosis compared to the control group. However, metadoxine treatment abolished steatosis in metadoxine treated mice. Consistent with the results on steatosis on HandE staining, less lipid droplets were observed in the metadoxine treated animals in Oil Red O-stained sections. As compared to the controls, HFD feeding increased serum concentrations of ALT, AST and marked accumulation of TC, LDL-C, and GLU. Metadoxine treated mice showed lower serum biochemical markers than HFD mice. Moreover, we found mRNA levels of TNF-α, IL-1β, NF-κB, IκBα were higher in HFD-fed mice than control group. However, metadoxine treatment could decrease these genes and protein expression. In addition, metadoxine significantly increase the expression of lipogenesis genes (PPAR-α/γ, SREBP1c, FASN and ACO). We also analyzed the effects of metadoxine on oxidative stress gens, such as NRF2, SOD1, HO-1, NQO1. Hepatic mRNA levels of these genes were increased in HFD group, and metadoxine treatment further enhanced the expression of oxidative stress factors.
Conclusion: Our data established a therapeutic role of metadoxine in NASH development. Metadoxine has a protective effect on NASH and its mechanims may be related to decrease the lipid accumulation, inhibit the oxidative stress and ultimately deduce inflammation.

Email: helen.jones@ucl.ac.uk

Background and aims: Fatty liver disease (NAFLD) is increasing worldwide. Patients with the inflammatory state of non-alcoholic steatohepatitis (NASH) have increased risk of developing cirrhosis and hepatocellular carcinoma. Noradrenaline (NE) may trigger development of NASH. NE increases the release of pro-inflammatory cytokines through alpha 2a subtype adrenergic receptors (Adra2a) on Kupffer cells (KCs) and Adra2a gene expression in KCs is upregulated in rats with systemic inflammation. We aimed to examine the role of the Adra2a in a rat model of NASH and investigate Adra2a antagonism as a possible treatment for progression of NAFLD.

Method: Male Sprague Dawley rats were fed either high fat high cholesterol (HFHC) to induce NASH or normal chow (NC) diet ad libitum for 16 weeks. Rats in the HFHC group were randomised to receive the Adra2a antagonist YoHCl (titrated to 0.4mg/kg daily) in drinking water for the final 8 weeks. Subsequently, formalin fixed

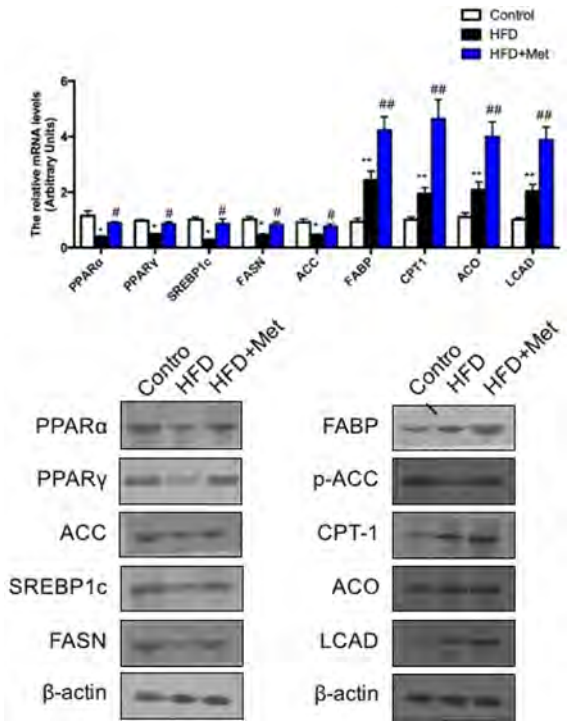

Figure 3

liver sections were stained with HandE for NAS scoring. Pro-inflammatory changes were investigated in liver tissue using qPCR, ELISA, and CD68 immunohistochemistry.

Results: HFHC diet increased liver/body weight ratio (6.51 (0.89) vs 2.76 (0.25); $p < 0.0001$), which was reduced by YoHCl (5.73 (0.44); $p = 0.034$). Histologically, HFHC-group livers showed severe steatosis and NASH with ballooning and increased NAS score (5.83 (0.41) vs 0.11 (0.33); $p < 0.0001$), that was reduced in YoHCl-treated HFHC animals (4.33 (1.12); $p = 0.001$).

HFHC diet increased CD68 stained area (3.92 (1.02) vs 0.70 (0.40) %; $p < 0.0001$) providing evidence of increased inflammatory cells of the monocyte/macrophage lineage. Also, qPCR analysis showed higher gene expression of chemokines involved in immune cell chemotaxis (Ccl3, Cx3Cl1, CxCl1, CxCl5; all $p < 0.001$) and ELISA analysis showed higher levels of CxCl5 (158.4 (34.7) vs 130.6 (11.4) pg/mg protein; $p = 0.014$) and Cx3Cl1 (1256 (225) vs 809 (114) pg/mg protein; $p < 0.0001$). Importantly, CD68 stained area (3.07 (0.56) %; $p = 0.034$), chemokine gene expression, and liver tissue levels of Cxcl5 (134.8 (10.8) pg/mg protein; $p = 0.014$) and Cx3cl1 (955 (112) pg/mg protein; $p = 0.0009$) were all reduced by YoHCL indicating a reduction in hepatic inflammation.

Conclusion: This study demonstrates that Adra2a antagonism reduces immune activation and inflammatory hepatic changes in NAFLD. This suggests Adra2a antagonism may slow progression of NAFLD. The potential for therapeutic translation in NAFLD patients warrants further investigation.

FRI-309

Hepatitis B virus B and T cell specific responses are reduced in adults with a body mass index > 35 and non-alcoholic fatty liver disease and in a mice model of NAFLD compared to adults with a BMI of < 35 patients and normal animals

Shivali Joshi[1], Rachelle Davis[1], Mang Ma[2], Edward Tam[3], Curtis Cooper[4], Alnoor Ramji[5], Erin Kelly[4], Saumya Jayakumar[6], Mark G Swain[7], Craig Jenne[7], Carla Coffin[7]. *[1]University of Calgary, Calgary, Canada; [2]University of Alberta, Edmonton, Canada; [3]LAIR Centre, Vancouver, Canada; [4]University of Ottawa, Ottawa, Canada; [5]University of British Columbia, Vancouver, Canada; [6]University of California, San Diego, San Diego, United States; [7]University of Calgary, Calgary, Canada*
Email: cscoffin@ucalgary.ca

Background and aims: Due to the obesity epidemic, many individuals are at risk of the metabolic syndrome and non-alcoholic fatty liver disease (NAFLD). Obesity and cirrhosis are associated with poor HBV vaccine responses, but vaccine efficacy has not been assessed in NAFLD.

Method: In this ongoing multi-site prospective study, HBV naïve NAFLD adults were given 3-dose HBV or HBV/HAV vaccine (Engerix B® or Twinrix®) and stratified based on body mass index (BMI) < or > 35. Anti-HBs levels were measured at 1-3 mo post 3rd vaccine dose. In subjects enrolled at the coordinating site, peripheral blood mononuclear cells (PBMC) were isolated from whole blood at baseline and post vaccination. Flow cytometry based T- cell proliferation assays with 10^7 CFSE labelled PBMC/sample and analysis of memory B and T cell phenotypes was done. In complementary pre-clinical studies, C57BL/6 mice were fed either a normal chow vs. high fat diet (HFD) for 20 weeks (N = 40;10/group) and given 2 doses of Engerix-B® either at baseline or after inducing NAFLD phenotype, and anti-HBs levels were assessed at 2 weeks' post 2nd dose.

Results: To date, 61 (32F, median age 49 y [26-63]), HBV naïve NAFLD adults were enrolled, of whom 33 completed the 3-dose HBV or HBV/HAV vaccine series. In total, 21 had BMI > 35 (13 F, median age 49y, 3 diabetic, median ALT 32 U/L, median liver stiffness measurement (LSM) 5.7 kPa, median BMI 38.2) and 40 patients had BMI < 35 (19 F, median age 51y, 7 diabetic, median ALT 40 U/L, median LSM 4.9 kPa, median BMI 30). In 33 NAFLD patients who completed HBV vaccination series to date, mean anti-HBs levels were significantly lower in the group with BMI > 35 compared to those with BMI < 35 (203.7 IU/L±92.2, N = 11 vs. 707.2 IU/L±92.6, N = 22, $p = 0.004$). T-cell recall response was assessed in 23 to date, only 1/8 with BMI > 35 vs. 13/15 with BMI < 35 showed stimulation index values > 2 suggesting HBsAg specific CD3+CD4+ T_H cell proliferative response *ex vivo*. The results of experiments in mice, vaccinated either prior to or after inducing HFD NAFLD phenotype, also showed lower anti-HBs levels vs. controls, $p < 0.05$.

Conclusion: Significantly reduced HBV vaccine specific antibody and T- cell responses were found in NAFLD patients with BMI > 35. In addition, a similar blunted anti-HBsAg response was observed in mice with HFD induced NAFLD. This clinical and animal model data will inform optimal immunization protocols in high risk obesity class individuals with NAFLD.

FRI-310

Alcohol dehydrogenase activity in liver and blood is altered in non-alcoholic fatty liver disease

Finn Jung[1], Ruth Ladurner[2], Katharina Staufer[3], Silvia Wagner[2], Anna Janina Engstler[1], Annette Brandt[1], Anika Nier[1], Anja Baumann[1], Vincent Winkler[1], Ina Bergheim[1]. *[1]University of Vienna, Department of Nutritional Sciences, Vienna, Austria; [2]University of Tübingen, Department of General, Visceral and Transplant Surgery, Tübingen, Germany; [3]Medical University Vienna, Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria*
Email: ina.bergheim@univie.ac.at

Background and aims: Results of studies in humans and animal models suggest that the development of non-alcoholic fatty liver disease (NAFLD) is associated with increased ethanol levels, even in the absence of any alcohol consumption. It further has been proposed that these elevated ethanol levels may results from an increased ethanol synthesis of intestinal microorganism. However, studies also suggest that activity of alcohol dehydrogenase (ADH), the key enzyme involved in alcohol metabolism, may be impaired in NAFLD. The aim of the present study was to determine if ADH activity is altered in

blood of patients with various stages of NAFLD and if these alterations reflect ADH activity in liver tissue.
Method: Fasting blood samples were obtained from 64 patients with biopsy proven NAFLD (simple steatosis: n = 20, non-alcoholic steatohepatitis (NASH): n = 44), and 16 age-matched controls. Furthermore, liver tissue and fasting blood samples were obtained from 10 patients with NAFLD (simple steatosis/NASH with beginning fibrosis) and 8 disease free controls all undergoing liver resection for different medical reasons. In addition, C57Bl6 mice were either fed a fat-, fructose- or cholesterol-rich (FFC) diet to induce NASH, or a control diet (C) for 13 weeks. ADH activity in serum and plasma, respectively as well as in liver tissue was determined using an enzyme assay and ADH 1 and 4 protein levels were determined using Western blot.
Results: While ADH 1 protein levels were significantly higher in serum of patients with NAFLD than in controls, the relative ADH activity was significantly lower in patients with NAFLD, decreasing with increased disease stage (control > steatosis > NASH). Furthermore, relative ADH activity in liver tissue of patients with NAFLD was also significantly lower than in disease-free controls whereas protein levels were similar between groups. In line with these findings, in livers and plasma of FFC-fed mice showing macrovesicular fat accumulation and hepatic inflammation, as well as significantly higher plasma ALT activity than C-fed mice, relative ADH activity in plasma and liver tissue was significantly lower than in control animals. Furthermore, fasting insulin levels were inverse correlated with relative ADH activity in plasma.
Conclusion: Taken together, our data suggest that relative ADH activity in liver tissue is markedly lower in settings of NAFLD and that similar alterations are also found in blood.

FRI-311

Gut lymphatic vascular disorder associates with severity of cirrhosis in non-alcoholic fatty liver disease

Savneet Kaur[1], Dinesh M Tripathi[1], Sumati Rohilla[2], Preety Rawal[2], Rajan Vijayraghavan[1], Archana Rastogi[1], Sm Shasthry[1], Shiv K Sarin[1].
[1]Institute of Liver and Biliary Sciences, Vasant Kunj, India; [2]Gautam Buddha University, Greater Noida, India
Email: savykaur@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is an important cause of cirrhosis. Enhanced intestinal/gut permeability is observed in about 40% patients with NAFLD. As there is a close association between altered gut permeability and its lymphatic system, in the current study, we investigated the gut lymphatic vessels in NAFLD patients.
Methods: Duodenal (D2) biopsies were collected from NAFLD patients with: compensated cirrhosis (n = 7), decompensated cirrhosis (n = 8) and non-cirrhotic controls (n = 5). Real time-PCR analysis for intestinal permeability and lymphatic marker genes including ZO1, OCLN, LYVE1, VEGFR3 and CCL2 were studied. Lymphatic vessel morphology was assessed by VEGFR3 immunohistochemistry (IHC) in the biopsies and plasma TNF-α levels were analyzed by ELISA.
Results: The expression of intestinal permeability gene, ZO1 was significantly downregulated (suggestive of increased intestinal permeability) in decompensated as compared to compensated and control groups ($p < 0.05$ versus both). The gene expression of lymphatic endothelial cell marker, VEGFR3 was substantially higher in decompensated as compared to controls ($p < 0.05$). A negative correlation was seen between the expression of ZO1 and VEGFR3 genes in decompensated patients. Gene expression of chemokine CCL2, an important marker of activated lymphatic endothelial cells, was upregulated in both groups as compared to controls. Histologically, VEGFR3 protein expression was evident in the lymphatic vessels which demonstrated a substantial increase in

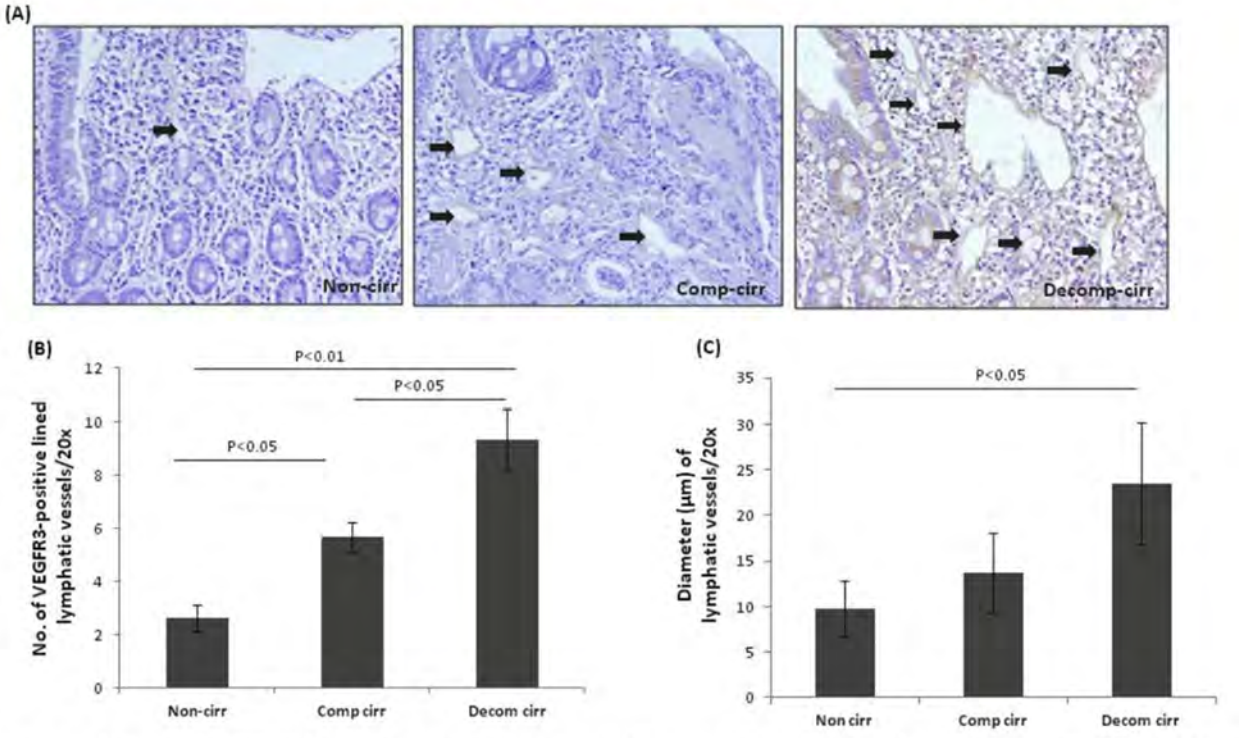

Figure: Lymphatic Vessels in NAFLD. (A) Representative images (20x) showing VEGFR3 immunohistochemical staining of duodenal biopsies in patients with NAFLD. (B) Histogram depicting quantification of VEGFR3-positive lymphatic vessels. (C) Histogram depicting diameter of lymphatic vessels. Data represents mean ± SD. n= 4 each.

decompensated as compared to compensated cirrhosis ($p < 0.05$). Morphologically, a marked dilation of VEGFR3-positive lymphatic vessels was observed in the mucosal and submucosal regions in biopsies of decompensated cirrhosis compared to controls (23.47 ± 6.6 versus 9.7 ± 3 μm, $P < 0.05$). Decompensated group also displayed higher plasma TNF-α levels as compared to other two groups ($p < 0.001$ versus both). Increased VEGFR3 protein expression correlated significantly with MELD scores ($r = 0.86$, $p = 0.01$).
Conclusion: Our results demonstrate that patients with decompensated NAFLD cirrhosis show increased intestinal permeability that correlates with deranged and altered VEGFR3-positive lymphatic vessel density. To summarize, gut lymphatic vascular disorder strongly associates with severity of cirrhosis in NAFLD.

Increased levels of bile acid in feces plays an important role in pathophysiology of non-alcoholic steatohepatitis
Takaomi Kessoku[1], Takashi Kobayashi[1], Kento Imajo[1], Yasushi Honda[1], Yuji Ogawa[1], Takuma Higurashi[1], Shingo Kato[1], Masato Yoneda[1], Yousuke Oikawa[2], Yoshiki Tanaka[2], Shunji Nakajima[2], Haruki Usuda[3], Koichiro Wada[3], Satoru Saito[1], Atsushi Nakajima[1]. [1]*Yokohama city university school of medicine, Gastroenterology and hepatology, Yokohama, Japan;* [2]*Biofermin Pharmaceutical Co., Ltd, Kobe, Japan;* [3]*Shimane University School of Medicine, Pharmacology, Shimane, Japan*
Email: takaomi0027@gmail.com

Background and aims: Recently, several evidences suggest that the bile acid (BA) plays important roles in the pathogenesis of (NASH). Previous reports demonstrated the increased serum BA in NASH patients compared to non-NASH patients. It is reported that the increased level of BA improves the gut-permeability which plays an important role in NASH pathogenesis. The aim of this study is to assess the change of fecal BA level in NASH patients and mechanism that explains the relationship between BA and the NASH pathogenesis.
Method: In the human study, 15 healthy control subjects and 30 patients with biopsy-proven NASH (15 mild fibrosis [F0-2] and 15 severe fibrosis [F3-4]). A single stool sample was collected from each participant. Metabolomics analysis was used to analyze the BA level contained in patient's fecal sample. In the animal study, Eight-week-old male C57BL/6J mice were randomly distributed into 7 groups, each containing 10 mice: a chow diet fed mice (B), a high-fat high-fructose high-cholesterol diet fed mice (H) which is diet-induced (NASH) model with liver fibrosis of mice, B + 0.5% cholic acid (CA)-fed mice (BC), and H + 0.5% CA fed mice (HC) group, and H + 0.3% cholestimide-fed mice (HCL), Chow-fed germ-free mice (GFB), CA-fed germ-free mice (GFC). Gut-permeability were assessed by using fluorescein isothiocyanate (FITC).
Results: In the human study, fecal cholic acid was significantly increased in NASH patients with F3-4 to the healthy control. Similarly, the fecal total bile acid level and cholic acid level were significantly increased in the H group compared to the B group in mouse study. Gut permeability measured by the FITC absorbance, serum endotoxin levels, hepatic free cholesterol, and CYP7a1 mRNA level were all significantly increased in the H, HC, and BC group compared with B group. All of them were improved in the HCL group. Moreover, Gut permeability measured by FITC absorbance as well as serum endotoxin level were increased in the BC group compared to the B group. Surprisingly, neither intestinal permeability in GFB nor GFC were altered significantly, suggesting that the increase in gut-permeability by CA is mediated by gut-microbiota, rather than by the direct action of CA. The significant decrease in fecal BA levels and increase in ALT/AST levels were observed in hepatic CYP7a1 (enzyme for BA synthesis) knock down by CYP7a1 SiRNA to H mice, despite the increased gut permeability in the same mice, suggesting that the inhibition of BA synthesis lead liver injury but improve the gut permeability in diet induced NASH model mice.
Conclusion: Our results suggest that the increase in bile acid synthesis may be a part of protective effect for liver damage that was triggered in reaction to the pathogenesis of NASH, which however, lead to the increased gut permeability. Taking together, removing the excess bile acid may be the novel therapeutic approach for the treatment of NASH.

FRI-313
A novel farnesoid X receptor agonist, TERN-101, reduces liver steatosis, inflammation, ballooning and fibrosis in a murine model of non-alcoholic steatohepatitis
Kevin Klucher[1], Yujin Wang[1], Randall Halcomb[1], Martijn Fenaux[1]. [1]*Terns Pharmaceuticals, San Mateo, United States*
Email: kklucher@ternspharma.com

Background and aims: The Farnesoid X Receptor (FXR) is a nuclear hormone receptor that controls the conversion of cholesterol into bile acids and maintains homeostasis of multiple metabolic pathways. Activation of the FXR pathway using synthetic FXR agonists may help control metabolic disorders such as non-alcoholic steatohepatitis (NASH). TERN-101, a novel non-steroidal agonist of FXR in early stage clinical trials, was tested in a mouse model of NASH.
Method: Male C57/Bl6J mice were fed a high fat diet (60% kcal) to induce obesity (> 36g mouse) prior to daily oral drug treatment and biweekly intraperitoneal carbon tetrachloride (CCL_4) treatment. Following 28 days of TERN-101 dosing, serum lipids, liver enzymes and liver tissue were analyzed for changes from baseline. Plasma 7-alpha-hydroxy-4-cholesten-3-one and RNA levels of genes known to be regulated by FXR in liver and intestinal tissue were measured as biomarkers of FXR activation.
Results: In diet-induced obese mice chronically treated with CCL_4 and TERN-101, TERN-101 caused a dose-dependent increase in FXR-mediated gene expression showing on-target activity inducing pathways that modulate lipid metabolism, inflammation and fibrosis. The NAFLD activity score was markedly reduced by all doses of TERN-101 tested with an 80%, 58% and 67% reduction from baseline at 100, 30 and 10mg/kg (mpk, $p < 0.0001$), respectively. Steatosis was reduced to healthy control (lean mice) levels at 30mpk and hepatocellular ballooning at 100mpk ($p < 0.001$). Hepatic inflammation was also reduced in TERN-101 treated mice ($p < 0.01$ at 10mpk). The reduction in liver steatosis seen by histopathology correlated with a reduction in liver triglycerides seen at all doses of TERN-101, with liver levels equivalent to healthy control mice at 30mpk ($p < 0.001$). Triglycerides and total cholesterol were also reduced in the serum of TERN-101 treated mice. In addition, TERN-101 reduced the liver fibrotic area, with a 32%, 26% and 26% reduction from baseline at 100, 30 and 10mpk ($p < 0.0001$), respectively. Finally, a dose-dependent reduction in the serum ALT and AST levels in TERN-101-treated mice was seen.
Conclusion: TERN-101 is a potent agonist of FXR that reduces liver steatosis, ballooning, inflammation and fibrosis in a mouse model of NASH while also lowering serum triglycerides, total cholesterol and alanine aminotransferase levels.

FRI-314
A novel semicarbazide-sensitive amine oxidase inhibitor, TERN-201, reduces NAS and fibrosis in rodent models of non-alcoholic steatohepatitis
Kevin Klucher[1], Yujin Wang[1], Yingzi Xu[1], Randall Halcomb[1], Martijn Fenaux[1]. [1]*Terns Pharmaceuticals, San Mateo, United States*
Email: kklucher@ternspharma.com

Background and aims: Semicarbazide-Sensitive Amine Oxidase (SSAO), also known as vascular adhesion protein (VAP-1), is a dual function cell adhesion molecule with a unique amine oxidase ecto-enzyme activity significantly increased in patients with Non-Alcoholic Steatohepatitis (NASH) and independently associated with liver fibrosis stage. SSAO catalyzes the oxidative deamination of aliphatic and aromatic primary amines, generating toxic products

that increase systemic oxidative stress and damage the vasculature, mediating leukocyte entry into inflammatory sites. SSAO inhibition is anticipated to reduce inflammation and fibrosis in NASH patients. TERN-201, a novel, selective SSAO inhibitor was tested in rodent models of NASH and fibrosis.
Method: Diet-induced obese (DIO) mice fed a high-fat diet or non-obese rats were orally dosed with TERN-201 daily and biweekly or triweekly intraperitoneal carbon tetrachloride (CCL_4) treatment, respectively. Following 28 days of dosing, liver tissue was analyzed by histology for changes from baseline in relevant parameters of the Non-Alcoholic Fatty Liver Disease (NAFLD) Activity Score (NAS) using hematoxylin and eosin staining and fibrosis using Sirius Red staining. RNA analysis of genes known to be induced in fibrosis and inflammation was used to study the mechanism of action of TERN-201.
Results: DIO mice chronically treated with CCL_4 and TERN-201 had a dose-dependent increase in plasma methylamine, showing SSAO target engagement in dosed mice. The NAFLD activity score was reduced by TERN-201 treatment with a 42% reduction from baseline at 20 mg/kg (mpk, $p < 0.005$), primarily driven by a reduction in hepatocellular ballooning (80% reduction from baseline at 20mpk, $p < 0.05$). Liver inflammation was elevated in CCL_4-treated rats and was reduced ~80% from baseline at 20mpk TERN-201 ($p < 0.0001$). This correlated with a similar reduction in liver CD11b RNA suggesting inflammation may be reduced by reduction in inflammatory cells infiltrating the liver. Fibrosis was also reduced ~57% at this dose ($p < 0.05$) with a reduction in collagen1a1 RNA of ~80% at 20mpk TERN-201 ($p < 0.0001$).
Conclusion: TERN-201 is a potent SSAO inhibitor effective in rodent models of NASH and fibrosis. Daily dosing of TERN-201 reduced the NAFLD activity score in a diet-induced obese mouse model of NASH, primarily through a reduction in hepatocyte ballooning. TERN-201 reduced liver inflammation and fibrosis in a rat CCL_4 model of liver fibrosis.

FRI-315

Lipoprotein lipase deficiency in myeloid cells aggravates the progression of non-alcoholic steatohepatitis

Anja Koop[1], Jörg Heeren[2], Ansgar W. Lohse[1], Johannes Kluwe[1].
[1]University Medical Center Hamburg-Eppendorf, I. Department of Internal Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Institute of Biochemistry and Molecular Cell Biology, Hamburg, Germany
Email: a.koop@uke.de

Background and aims: Lipoprotein Lipase (LPL), an enzyme that hydrolyses triglyceride-rich lipoprotein particles, is mainly expressed in macrophages, adipose and muscle tissue. Moreover, LPL may regulate macrophage polarization. While absent in healthy liver, hepatic LPL expression is upregulated in murine non-alcoholic fatty liver disease (NAFLD). Our aim was to evaluate the source of LPL in non-alcoholic steatohepatitis (NASH).
Method: LPL expression was assessed in samples from healthy liver tissue and human NASH by qPCR. Moreover, LPL expression was quantified in different liver cell populations isolated from mice. $LPL^{flox/flox}$ × Lysozyme2-Cre recombinase (LysM-Cre) mice were used to create a myeloid cell-specific LPL knockout. Crossing $LPL^{flox/flox}$ mice with Albumin-Cre recombinase (Alb-Cre) mice enabled a hepatocyte-specific LPL deletion. Mice were fed a high fat, high carbohydrate, high cholesterol diet for 24 weeks to induce NASH. The NASH phenotype was characterised by histology, qPCR and ALT levels.
Results: LPL expression in healthy liver was low but significantly increased in livers of patients with NASH. Liver macrophages were identified as the major source of the low basal LPL expression in healthy livers. Also in NASH, hepatocytes are not the source of the increased LPL expression as deletion of LPL in hepatocytes does not affect the hepatic LPL expression level in mice with NASH. Consistent with this, hepatocyte-specific LPL deletion did not affect NASH severity in mice compared to LPL-competent littermates. In contrast, LPL deletion in myeloid cells significantly blunted the NASH-induced increase of hepatic LPL expression. This lead to a more severe NASH phenotype in the LysM-Cre positive mice indicated by significantly higher expression levels of pro-inflammatory (like TNFalpha; 1.6 fold), pro-apoptotic (like Bim; 1.4 fold) and pro-fibrotic genes (like Col1alpha1; 1.9 fold). Sirius red staining of fibrillary collagen indicated enhanced NASH-induced liver fibrosis in mice with myeloid cell-specific LPL deficiency compared to wildtype littermates.
Conclusion: The enhanced hepatic LPL expression in NASH is caused by liver macrophages rather than hepatocytes. LPL in liver macrophages appears to attenuate NASH progression. According to the results, LPL alteration in liver macrophages could be a potential tool for NASH therapy.

FRI-316

Liver fetuin-A in activated macrophages is a key feature of non-alcoholic steatohepatitis in mice and humans

Quentin Etienne[1], Valérie Lebrun[1], Mina Komuta[2], Benoit Navez[3], Isabelle Leclerq[1], Nicolas Lanthier[1,4]. *[1]Université catholique de Louvain, Laboratory of Gastroenterology and Hepatology, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium; [2]Cliniques universitaires Saint-Luc, Department of Pathology, Brussels, Belgium; [3]Cliniques universitaires Saint-Luc, Department of Surgery, Brussels, Belgium; [4]Cliniques universitaires Saint-Luc, Service d'Hépato-gastro-entérologie, Brussels, Belgium*
Email: nicolas.lanthier@uclouvain.be

Background and aims: Fetuin-A, a plasma multifunctional protein known to play a role in insulin resistance, is usually presented as a liver secreted protein. However, fetuin-A adipose tissue production has been also described. Here, we evaluated fetuin-A production by the liver and the adipose tissue during NAFLD-NASH development.
Method: Male foz −/− mice fed a normal diet (ND) or a HFD for 4 (short term HFD or SHFD), 12 (long term HFD or LHFD) or 30 weeks (very long term HFD or VLHFD) were used to induce early steatosis, marked steatosis or definite fibrosing NASH, respectively. Fetuin-A was evaluated by ELISA, PCR, Western-blot and immunofluorescence in those animals and in NAFLD-NASH patients undergoing bariatric surgery (n = 5) and from the hepatology clinic (n = 49). Fetuin-A was also quantified in hepatocyte and adipocyte cell culture experiments.
Results: Foz −/− mice fed a SHFD developed liver steatosis and increased circulating levels of fetuin-A compared to ND fed mice. On liver slides, fetuin-A and steatosis were mainly located in the centrilobular region. In LHFD mice, macrophage activation was observed within the liver together with elevated fasted plasma glucose, raised fetuin-A blood levels and localization of fetuin-A immunostaining in steatotic hepatocytes. VLHFD mice were characterized by the occurrence of NASH. Fetuin-A was located at this time-point not only in steatotic hepatocytes but also in some macrophages forming lipogranuloma. A high quantity of fetuin-A protein was present within the adipose tissue. However, compared to the adipose tissue, liver fetuin-A mRNA expression was significantly higher.
In humans, fetuin-A was located in steatotic hepatocytes in NAFLD-NASH patients and within some lipogranuloma and macrophage clusters in NASH patients. Circulating fetuin-A was significantly correlated with blood glucose levels rather than with NASH severity in terms of fibrosis. Liver m-RNA expression was 5000 times increased compared to adipose tissue mRNA expression.
In cell culture, fetuin-A was evidenced only in the supernatant of hepatocytes but not in the supernatant of adipocytes.
Conclusion: Fetuin-A is produced by steatotic hepatocytes at early time points in NAFLD and correlates with insulin resistance both in mice and humans. In NASH, fetuin-A also co-localizes with activated liver macrophages. Future experiments on foz −/− mice will help to progress in the role of fetuin-A on NASH pathogenesis and macrophage activation.

FRI-317

Progression of fatty liver disease to steatohepatitis and liver fibrosis is associated with altered Oncostatin M type I and type II receptor expression

Philipp Lederer[1], Martin Roderfeld[2], Daniela Kroy[3], Elke Roeb[2], Andreas Geier[1], Heike Hermanns[1]. [1]*University Hospital Wuerzburg, Medical Clinic II, Hepatology, Wuerzburg, Germany;* [2]*Justus-Liebig University Gießen, Center for Inner Medicine, Gastroenterology, Gießen, Germany;* [3]*University Hospital RWTH Aachen, Medical Clinic III, Aachen, Germany*
Email: hermanns_h@ukw.de

Background and aims: One of the cytokine families most prominently associated with liver inflammation, obesity and metabolic response, is the family of IL-6-type cytokines, in particular IL-6 itself, but also its less well investigated relative oncostatin M (OSM). IL-6 and OSM have been shown to be intimately connected with our body's reaction to physical, metabolic and pathogen-induced stress. Reports over the last two decades have clearly pointed out that these cytokines have anti-inflammatory as well as pro-inflammatory signaling activities which very much depend on the cellular and physiological context in which they are released or the receptors they utilize for signaling. Much attention has been given to IL-6 as well as its mode of action, however, recent studies implicate that OSM is much more strongly involved in disease pathogenesis than anticipated so far. Its physiology, however, is far less well understood. Here, we investigate its potential contribution to the progression of liver diseases.
Method: Since OSM can signal via two receptor complexes which might have more pro- or anti-inflammatory activities, respectively, we characterized their expression profile in vivo in liver samples from different rodent models of liver inflammation and fibrosis or in vitro in hepatoma cell lines stimulated with different inflammatory cytokines using quantitative real-time PCR, Western blot analysis and flow cytometry.
Results: We found a distinct decrease of components of the type I OSM receptor complex in livers from mice fed different high fat diets, after intraperitoneal injection of pro-inflammatory cytokines or in Abcb4−/− mice. At the same time the type II OSM receptor complex appeared to be strongly upregulated. Similar observations were made in HepG2 cells treated with IL-1β. In vitro experiments carried out with pharmacological inhibitors of various signaling pathways indicated an important role of the mitogen-activated protein kinases ERK1/2 in the downregulation process for the type I receptor complex.
Conclusion: Dysregulation of the expression levels of the type I and type II OSM receptor complexes appears to be a conserved feature in the progression of inflammatory liver diseases. Consequently, alterations in OSM receptor levels might be a possible diagnostic marker for the assessment of progressive liver inflammation.

FRI-318

Effects of fatty acids and polyphenols from extra virgin olive oil in a murine animal dietary model knockout for the LDL receptor

Álvarez Amor Leticia[1,2], Amparo Luque-Sierra[1], Lourdes María Varela[1], Javier López-Beas[1], Rocío Gallego-Durán[3,4], Manuel Romero Gomez[3,4], Karim Hmadcha[1,2], Bernat Soria Escoms[1,2], Franz Martin[1,2]. Email: fmarber@upo.es

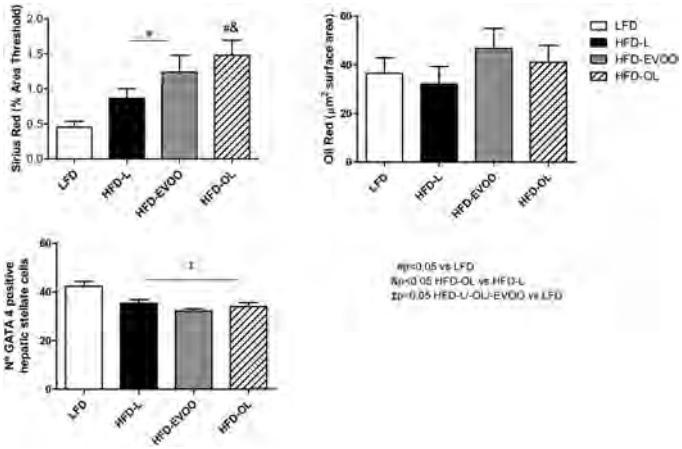
Background and aims: Metabolic syndrome (MS) is the combination of health risk factors which includes obesity, insulin resistance, dyslipidemia and non-alcoholic fatty liver disease. The consumption of olive oil can prevent its onset. Therefore, our aim was to evaluate the pathophysiological changes caused by MS in a murine animal model lacking from the LDL receptor that were fed with three different diets: high fat diet based on lard (HFD-L), high fat diet based on monounsaturated fats from extra virgin olive (HFD-MUFA-EVOO) and high fat diet based on monounsaturated fats from extra virgin olive oil rich in polyphenols (HFD-MUFA-OL).
Method: KO Leiden LDLR−/− female mice, 5 weeks of age (n = 120), were distributed in 4 groups of 30 animals and fed, during 8 months, with different diets: control, HFD-L (45% of caloric intake coming from lard), HFD-MUFA-EVOO (45% of caloric intake coming from olive oil) and HFD-MUFA-OL (45% of caloric intake coming from olive oil rich in polyphenols). We evaluated their body weight (BW), lipid profile (LDL, HDL, triglycerides and total cholesterol levels), glycemia, intraperitoneal glucose tolerance test (IPGTT), insulinemia, transaminases (AST and ALT) and liver histology (H-E, Oil red, GATA 4 and Sirius Red). Moreover, we studied the mechanisms involved in SM with a liver microarray analysis and we checked the expression of genes involved in these routes by RT-qPCR.
Results: KO Leiden LDLR−/− mice developed MS with severe hepatic damage. All mice fed with a HFD showed significant ($p < 0.001$) increased BW vs control fed mice. KO-HFD-MUFA-OL and KO-HFD-MUFA-EVOO mice showed significant increase in glycemia ($p < 0.05$), insulinemia ($p < 0.05$) and liver damage (transaminases, fatty liver and fibrosis) ($p < 0.05$) vs KO-HFD-SFA. KO-HFD-MUFA-OL mice showed significant increase in total-cholesterol ($p < 0.05$) vs KO-HFD-L. Ingenuity Pathway Analysis confirmed deregulation of metabolic routes such as non-alcoholic fatty liver disease and fatty acid degradation and metabolism in all high fat diets. Individual RT-qPCR confirmed the results of the Array.



Conclusion: Thus, the HFD-MUFAs did not improve the liver damage and not reduce metabolic abnormalities associated with HFD induced fatty liver disease in mice. Our data suggest that Leiden LDLR−/− strain are susceptible to suffer from to severe liver damage when fed with HFD, regardless of the lipid profile of the diets, including the HFD-MUFA-OL group.

FRI-320

TM6SF2 silencing impairs lipid metabolism and trafficking in HepG2 cells carrying the I148M PNPLA3 variant and MBOAT7 deletion

Miriam Longo[1], Marica Meroni[2], Raffaela Rametta[2], Veronica Erconi[2], Stefano Romeo[3], Anna Ludovica Fracanzani[1,4], Luca Valenti[5,6], Paola Dongiovanni[2]. Email: paola.dongiovanni@policlinico.mi.it

Background and aims: The inter-individual variability in phenotype observed in patients affected by non-alcoholic fatty liver disease (NAFLD) may be attributable to genetics. The I148M PNPLA3 and E167K TM6SF2 variants alongside the rs641738 polymorphism in MBOAT7/TMC4 locus represent the main genetic risk factors for NAFLD development and progression. We previously generated an in vitro model of steatosis by inducing full knockout of MBOAT7 in HepG2 hepatoma cells. Aim of this study was to investigate whether TM6SF2 silencing impacts on lipid homeostasis in this model.
Method: We silenced TM6SF2 in HepG2 cells which are homozygous for the I148M PNPLA3 variant and full knockout for MBOAT7 by Crispr/Cas9 technology (PNPLA3 148M/M MBOAT7−/− TM6SF2−/−). We further analyzed gene expression in 125 severely obese patients (Bariatric Cohort), of whom RNA-seq data were available.
Results: As expected, TM6SF2 mRNA and protein levels were reduced in PNPLA3 148M/M MBOAT7−/− TM6SF2−/− cells compared to PNPLA3 148M/M MBOAT7−/− ($p < 0.01$), along with the expression of genes involved in lipoprotein assembly (MTTP) and Triglycerides (TG) synthesis (DGAT2), usually co-expressed with TM6SF2 ($p < 0.05$). Moreover, cells lacking TM6SF2 showed a complete suppression of TG-rich lipoproteins secretion and a slight reduction in TG release ($p < 0.05$). The mRNA levels of genes-related to de novo lipogenesis (DNL), cholesterol biosynthesis and β-oxidation were also decreased ($p < 0.01$). Conversely, lipid droplets content was similar to those of PNPLA3 148M/M MBOAT7−/− cells, probably due to lipid synthesis and removal balancing. At univariate analysis, the expression of DNL ($p < 0.0001$), cholesterol ($p < 0.01$) and TG synthesis genes ($p < 0.001$) as well as circulating TG ($p < 0.05$) positively correlated with TM6SF2 mRNA levels in the Bariatric cohort. Similar to PNPLA3 148M/M MBOAT7−/− TM6SF2−/− cell model, at linear regression analysis TG synthesis was progressively decreased in patients who carry an increasing number of risk variants ($p = 0.02$).
Conclusion: We firstly generated a model of hepatocytes carrying mutations in genes involved in NAFLD predisposition. TM6SF2 silencing impairs lipid metabolism and trafficking, without altering lipid droplets content. Moreover, in obese patients, TG synthesis correlated with increasing number of risk variants. Further studies are required to investigate the impact of PNPLA3 148M/M MBOAT7−/−TM6SF2−/− phenotype to hepatic injury and/or malignant transformation.

FRI-321

Hepatocyte expression of the protein kinase ERK5 regulates insulin sensitivity

Giovanni Di Maira[1], Giulia Lori[1], Benedetta Piombanti[1], Maria Letizia Taddei[1], Matteo Parri[1], Elisabetta Rovida[1], Paola Chiarugi[1], Fabio Marra[1]. [1]*University of Florence, Florence, Italy*
Email: fabio.marra@unifi.it

Background and aims: Insulin resistance is a key element in the development of non-alcoholic fatty liver disease (NAFLD). The extracellular signal-regulated kinase 5 (ERK5) is a member of the mitogen-activated protein kinase (MAPK) family, and is highly expressed in the liver. ERK5 regulates the biologic actions of hepatocellular carcinoma cells and is critical for the development and growth of HCC. We recently generated hepatocyte-specific ERK5 knock-out mice (ERK5ΔHep). The aim of this study was to investigate the potential role of ERK5 in the insulin resistance associated with NAFLD.
Method: ERK5ΔHep and control mice were fed with a high-fat diet (HFD) for 16 weeks. At the end of the experiment, glucose tolerance test (GTT) and insulin tolerance test (ITT) were performed. A murine hepatocyte cell line was silenced for ERK5 using lentiviral vectors. Mitochondrial depolarization was assayed using the TMRE staining protocol. Measurement of mitochondrial mass was performed by flow cytometry using mitotracker dye and OXPHOS metabolism was measured with Seahorse analyzer.
Results: ERK5ΔHep mice subjected to HFD showed reduced insulin sensitivity in comparison to control group, as indicated by both GTT and ITT, whereas body weight was similar. In cultured hepatocytes ERK5 silencing led to reduced phosphorylation levels of Akt following insulin stimulation. Mitochondrial dysfunction is considered a critical component in the development of insulin resistance. Measurement of mitochondrial membrane potential showed a strong depolarization ERK5-silenced cells in comparison to control cells. We next evaluated the metabolic status of MMH through seahorse assay, and observed a clear shift from mitochondrial OXPHOS to glycolysis in cells with ERK knockdown. Moreover, flow cytometric assay showed an increased mitochondrial mass in ERK5-deficient cells. The transcriptional coactivator peroxisome proliferator-activated receptor-γ coactivator-1α (PGC-1α), a pivotal regulator of mitochondrial biogenesis and function, was overexpressed in ERK5-deficient cells, representing a possible link between ERK5 deficiency and the occurrence of insulin resistance.
Conclusion: Our study provides the first evidence that ERK5 loss induces insulin resistance in vivo in a NAFLD model. Impairment of mitochondrial function appears a major mechanism in mediating this effect.

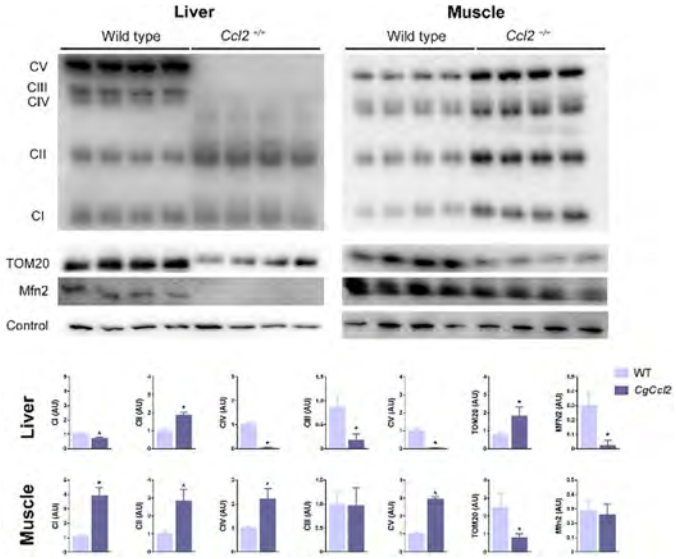
FRI-322

Metabolic inflammation: The role of chemokine C-C motif ligan 2 in the crosstalk between liver tissue and muscle

Fedra Luciano-Mateo[1,2], Noemí Cabré[1,2], Gerard Baiges[1], Elizabet Rodríguez-Tomàs[1,2], Salvador Fernández-Arroyo[1,2], Anna Hernández-Aguilera[1], Jordi Camps[1], Jorge Joven[1,2]. [1]*Reus, Unitat de Recerca Biomèdica, Hospital Universitari Sant Joan, Institut d'Investigació Sanitària Pere Virgili, Reus, Spain;* [2]*Reus, Universitat Rovira i Virgili, Reus, Spain*
Email: fedranicaury.luciano@urv.cat

Background and aims: Chronic low-grade systemic inflammation is a compromised management of excessive energy intake and represents a significant factor that contributes to development of comorbidities, including non-alcoholic fatty liver disease (NAFLD). NAFLD is a metabolic abnormality with a strict inter-relationship derived to metabolically compromised tissues, such as liver and muscle. Chemokines play an important role in NAFLD initiation by multiple pathogenic drives; including mitochondrial dysfunction, autophagy and acute alterations into metabolism. The aim of this study was to determine the effect of Chemokine (C-C motif) Ligand 2 (CCL2) overexpression, a proinflammatory chemokine, can influence in the metabolic homeostasis in liver and muscle to understand the origin and progression of NAFLD.
Method: We carried this study using a cisgenic *Ccl2* overexpression mouse and wild-type C57BL/6J as a control for 22 weeks. After this period, we determined the liver and muscle status by biochemical and histological examinations. We evaluate the state of the AMPK/mTOR pathway and performed target metabolomics assays of energy and one carbon metabolism intermediaries (UHPLC-ESI-QqQ-MS and GC-EI-QTOF-MS) to understand the metabolic response.
Results: *Ccl2* overexpression was associated with hepatic metabolic alterations, including steatosis, dyslipidemia, hyperglycemia and high concentration of liver injury markers. These histological and biochemical alterations were associated with a liver disturbance in the mitochondrial oxidative phosphorylation (OXPHOS) complex, TCA cycle and transmethylation pathway. All of them, induce disturbing in the hepatic ATP synthesis. Contrary, muscle metabolic

analysis showed an important metabolic flexibility from liver alterations. We observed an increase in the catabolism mechanisms involved in energy synthesis. Specially, by an hyperactivation of OXPHOS activity, significantly increase of β-Hydroxybutyrate and lactate concentration as an ATP alternative source; together with an upregulation of pAMPK activity and autophagy.



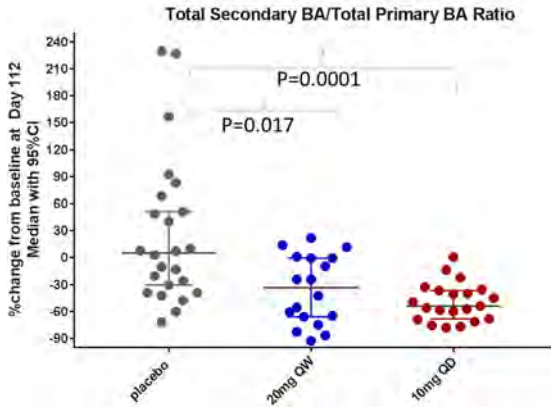
Conclusion: We report that CCL2 is a potent targetable approach to NAFLD progression. In the same way, understanding the ability of the organism to adapt according to changes in metabolic and energetic demand it is essential to comprehend the progression and evolution of this pathology.

FRI-323

Pegbelfermin (BMS-986036) reduces serum levels of secondary bile acids in patients with non-alcoholic steatohepatitis

Yi Luo[1], Edgar Charles[1], Petia Shipkova[1], Michael Reily[1], Gabor Jarai[1], Arun Sanyal[2]. *[1]Bristol-Myers Squibb, Princeton, United States; [2]Virginia Commonwealth University, Richmond, United States*
Email: yi.luo@bms.com

Background and aims: Bile acids (BAs) regulate cholesterol homeostasis and lipid digestion, and act as signalling molecules. Primary (1°) BAs (cholic acid [CA] and chenodeoxy-CA) are produced in the liver; the secondary (2°) BAs (deoxy-CA [DCA] and litho-DCA) are produced by the gut microbiome from 1° BAs. The 2° BA DCA and its conjugates glyco-DCA (GDCA) and tauro-DCA (TDCA) are elevated in patients (pts) with non-alcoholic steatohepatitis (NASH). Increases in DCA and related conjugates are linked to elevated hepatotoxicity, hepatocellular carcinoma (HCC), and colon cancer rates. Pegbelfermin (BMS-986036) is a PEGylated analogue of human fibroblast growth factor 21 (FGF21), a key regulator of energy metabolism. In the phase 2 trial MB130-045 (NCT02413372) in pts with NASH and fibrosis (stage 1-3), pegbelfermin significantly decreased hepatic steatosis and improved biomarkers of fibrosis, metabolic parameters, and markers of hepatic injury over 16 weeks. This exploratory, post hoc analysis of MB130-045 evaluated the effect of treatment (tx) with pegbelfermin on BAs.
Method: Serum samples were collected on Days 1, 57, and 112 during study MB130-045. Samples were analysed using ultra high-performance liquid chromatography and mass spectrometry to assess serum BA levels. Statistical analyses compared data from the pegbelfermin tx groups (once daily [QD] and once weekly [QW]) with the placebo (PBO) group using nonparametric comparisons with control using the Steel method; p values for each BA was adjusted for multiple comparisons using Bonferroni correction.
Results: Serum samples from 63 pts were available for analysis (PBO, n = 24; pegbelfermin QD, n = 21 and QW, n = 18). The median decrease from baseline in DCA, GDCA and TDCA ranged from 61%-84%. Significant reductions in serum concentrations of DCA, GDCA, and TDCA were observed in both pegbelfermin QD and QW groups vs PBO on Days 57 and 112 ($p < 0.005$). 1° BAs were not significantly changed following pegbelfermin tx. The ratio of total 2° BAs:total 1° BAs was significantly reduced with pegbelfermin QD and QW tx vs PBO ($p < 0.05$; figure). Additionally, decreases in 2° BAs resulted in a trend of lower total BAs ($p < 0.02$).



Conclusion: Pegbelfermin tx in pts with NASH and fibrosis resulted in the reduction of serum 2° BAs and the 2° BAs:1° BAs ratio. 2° BAs are associated with elevated risk of hepatotoxicity and HCC. Further investigation is needed to understand the mechanisms mediating the effects of pegbelfermin on BAs, such as BA synthesis and absorption, and microbiome activities.

FRI-324

Introducing a new pre-clinical model of advanced NASH that mimics the main pathophysiologic characteristics and transcriptomic signature of the human disease

Raquel Maeso Díaz[1], Zoe Boyer-Diaz[2], Carmen Peralta[3,4], Jaime Bosch[1,4,5], Jordi Gracia-Sancho[1,4,5]. *[1]IDIBAPS, Liver Vascular Biology Research Group, Barcelona, Spain; [2]Barcelona Liver Bioservices, Barcelona, Spain; [3]IDIBAPS, Barcelona, Spain; [4]CIBEREHD, Madrid, Spain; [5]Inselspital, Department of Biomedical Research, Bern, Switzerland*
Email: jordi.gracia@idibaps.org

Background and aims: The lack of proper NASH animal models represents a limitation for studying the pathophysiology of this disease and for generating new therapeutic strategies. In a previous communication we described the development of a new pre-clinical rat model of mild NASH following an experimental protocol called "Barcelona Nash (BarNa) model," which combines CCl_4 inhalation with a high fat and high cholesterol diet for 10 weeks. The main aim of the present study was to reformulate this procedure to obtain a wider and more severe spectrum of the disease.
Method: Male Wistar rats were exposed to a 24-week BarNa model protocol consisting in 8 weeks of CCl_4 inhalation + phenobarbital, followed by 16 weeks of high fat and cholesterol diet + CCl_4. The BarNa model was compared to control rats matched to age (n = 6 per group). The following parameters were evaluated: steatosis and metabolic syndrome, lipotoxicity, cell death, inflammation, hepatic fibrosis and portal hypertension. Moreover, and to identify the gene sets commonly de-regulated between NASH patients and rats undergoing the BarNa model, whole hepatic transcriptome sequencing was performed in rat liver tissue and data compared to two independent cohorts of NASH patients using pathway enrichment analysis.

Results: When compared to control animals, the BarNa rats exhibited ($p < 0.05$ in all comparisons):
1-Steatosis and metabolic syndrome (+45% in body and fat weight); −19% in relative hepatic weight; 45% of hepatic tissue positive for Oil-Red staining; NAS Score of 9.3; glucose intolerance accompanied by 110% in plasmatic insulin).
2-Lipotoxicity (+75% in lipid peroxidation) and cell death (+6-fold TUNEL; +300% cleaved-caspase 3; +90% transaminases).
3-Hepatic inflammation (+65%, +133% and +200% in the infiltration of macrophages positive for CD68 and CD163, and neutrophils, respectively).
4-Hepatic fibrosis (+47% in Collagen I protein expression with 15% of the hepatic tissue positive for Sirius-Red staining) and hepatic stellate cells activation (+500% protein expression of α-SMA and +200% in desmin).
5-Portal hypertension (+50% in portal pressure [13.26 ± 0.8 vs. 8.77 ± 0.4 mmHg] as a consequence of hepatic vascular resistance increase [12.7 ± 2.3 vs. 5.1 ± 0.7 mmHg·min·ml^{-1}·g].

Analysis of the whole hepatic transcriptome evidenced that the BarNa model shares de-regulations in a significant part of pathways involved in the human disease pathophysiology including: insulin resistance, lipid metabolism, cell death, inflammation, fibrosis, endothelial dysfunction and mitochondrial dysfunction.
Conclusion: The present study defines a pre-clinical model of advanced NASH that mimics a broader spectrum of the human disease and shares a significant part of its gene signature. We herein propose the BarNa model as a reliable tool for studying the pathophysiology of NASH and for the development of new therapies.

FRI-325

rs641738 C > T variant near MBOAT7-TMC4 increases risk of fibrosis, NASH, and HCC: A meta-analysis

Kevin Teo[1], Amedine Duret[1], Dana de Gracian Hahn[1], Harriet Hunter[1], Yu Ri Im[1], Madison Fairey[1], Mrudula Utukuri[1], Jiawen Dong[1], Hong Lim[1], Jake Mann[2]. *[1]University of Cambridge, Clinical School of Medicine, Cambridge, United Kingdom; [2]University of Cambridge, Paediatrics, Cambridge, United Kingdom*
Email: jm2032@cam.ac.uk

Background and aims: Several genetic variants have been associated with clinical outcomes and progression of non-alcoholic fatty liver disease (NAFLD). rs641738 C > T variant near MBOAT7-TMC4 was initially identified as reaching genome-wide significance on association with alcoholic liver disease and subsequently several cohorts have reported links to NAFLD, though data is not uniformly consistent with recent reports of no effect. MBOAT7 is proposed as an acyltransferase with influence on lipotoxicity via modulation of very long-chain phosphatidylinositols but how this intergenic variant influence MBOAT7 is unclear.
Therefore we performed a meta-analysis to establish the effect of rs641738 C > T on clinical, histological, and biochemical features of NAFLD.
Method: MEDLINE, Embase, Google Scholar, and abstracts from EASL and AASLD meetings were searched for 'MBOAT7,' 'rs641738,' and 'TMC4.' Two authors independently reviewed abstracts and extracted data. Studies were included if they used a validated method of genotyping and reported on clinical, radiological, histological, or biochemical features of NAFLD. Primary outcome was the association between advanced fibrosis (F3-4) and rs641738 C > T. Meta-analysis was performed using both fixed and random effects models, reporting heterogeneity between studies. Recessive and dominant models were tested throughout. GWAS meta-analysis data was searched using Phenoscanner and LocusZoom for clinical and biochemical outcomes associated with rs641738 C > T.
Results: 16 studies (24, 260 participants) were included in the meta-analysis. rs641738 C > T was associated with advanced fibrosis (odds ratio (OR) 1.34 (95% CI 1.04-1.74)) and the presence of fibrosis (F0 vs. F1-4): OR 1.37 (95% CI 1.11-1.68). rs641738 C > T was associated with increased odds of hepatocellular carcinoma: OR 1.47 (1.01-2.13) and T-allele was also associated with the presence of NASH: OR 1.37 (95% CI 1.08-1.72). However rs641738 C > T did not increase the chance of a diagnosis of NAFLD (OR 1.09 (95% CI 0.99-1.19) or change in hepatic fat fraction (mean difference +1.6% (95% CI −0.9% to +4.1%). rs641738 C > T was not correlated with biochemical traits of insulin resistance or dyslipidaemia.
Conclusion: rs641738 C > T variant near MBOAT7-TMC4 is associated with fibrosis, non-alcoholic steatohepatitis, and hepatocellular carcinoma, but not total hepatic fat. These data suggest rs641738 C > T variant affects lipotoxicity without influencing triacylglycerol accumulation. Further mechanistic work is needed to understand the function of this variant.

FRI-326

Preclinical evaluation of endothelial dysfunction by peripheral artery tonometry and its correlations with untargeted metabolomic profiles

Mario Masarone[1], Jacopo Troisi[2], Gemma Calvanese[1], Rosa Caruso[1], Angelo Colucci[2], Valerio Rosato[1], Andrea Aglitti[1], marcello persico[1]. *[1]Internal Medicine and Hepatology, Department of Medicine and Surgery, Baronissi (SA), Italy; [2]Theoreo SRL, Spin-off- Company-University of Salerno, Salerno, Italy*
Email: marcello.persico@sangiovannieruggi.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has been associated with Metabolic Syndrome, insulin resistance and diabetes. It represents also a cardiovascular risk factor. Endothelial Dysfunction (ED), the pathophysiological basis of Cardiovascular Diseases (CVD), is present in NAFLD pts. However, not all NAFLD patients have a clinically demonstrable ED. Untargeted Metabolomics is a novel and powerful method to discover biomarkers then was used to evaluate ED in NAFLD patients by PAT and to correlate it with metabolomic studies.
Method: Metabolomic signatures were obtained from 49 patients with biopsy proven NAFLD (33 NAFL;16 NASH)by means of mass spectrometry and were correlated with PAT scores performed with an EndoPAT 2000 device.
Results: A statistical analysis with the "Partial Least Square Discriminant Analysis" (PLS-DA) was used to class separation in metabolomic profiles between NAFL and NASH patients with and without ED (cut-off value of EndoPAT score of 0.51), and to reveal the metabolites principally contributing to class differentiation. PLS-DA score plot showed a significant differentiation of metabolomic profiles in patients with or without ED, both in NAFL and NASH ($R^2 = 0.985$, $Q^2 = 0.842$, $p < 0.001$ and $R^2 = 0.996$, $Q^2 = 0.939$, $p < 0.001$, respectively). In particular: Propionate, Butyrate, Fumarate, Phenilacetate, Erythrose, Stearic and Aspartic Acid in NAFL and Homovanillic acid, Choline, Stearic Acid, Linoleic Acid, Butyrate, Valeric Acid in NASH, were significantly impaired in patients with ED.
Conclusion: Metabolomic profiles of NAFLD patients showed a statistically different pattern in patients with and without ED. They could be a useful tool to predict CVD risk in both simple steatosis and NASH.

FRI-327

Liver mitochondrial hydrogen sulfide oxidation: From nutritional physiology to non-alcoholic fatty liver pathology

Inês Mateus[1], Véronique Lenoir[2], Frédéric Bouillaud[2], Carina Prip-Buus[2]. *[1]Institut Cochin, INSERM U1016, CNRS UMR8104, Université Paris Descartes, Early Stage Researcher at ETN "FOIE GRAS" Project funded by H2020-MSCA grant N°722619, Paris, France; [2]Institut Cochin, INSERM U1016, CNRS UMR8104, Université Paris Descartes, Paris, France*
Email: ines.mateus@inserm.fr

Background and aims: Non-alcoholic fatty liver disease (NAFLD) encompasses all liver lesions from isolated steatosis to non-alcoholic steatohepatitis (NASH). However, the mechanisms behind the

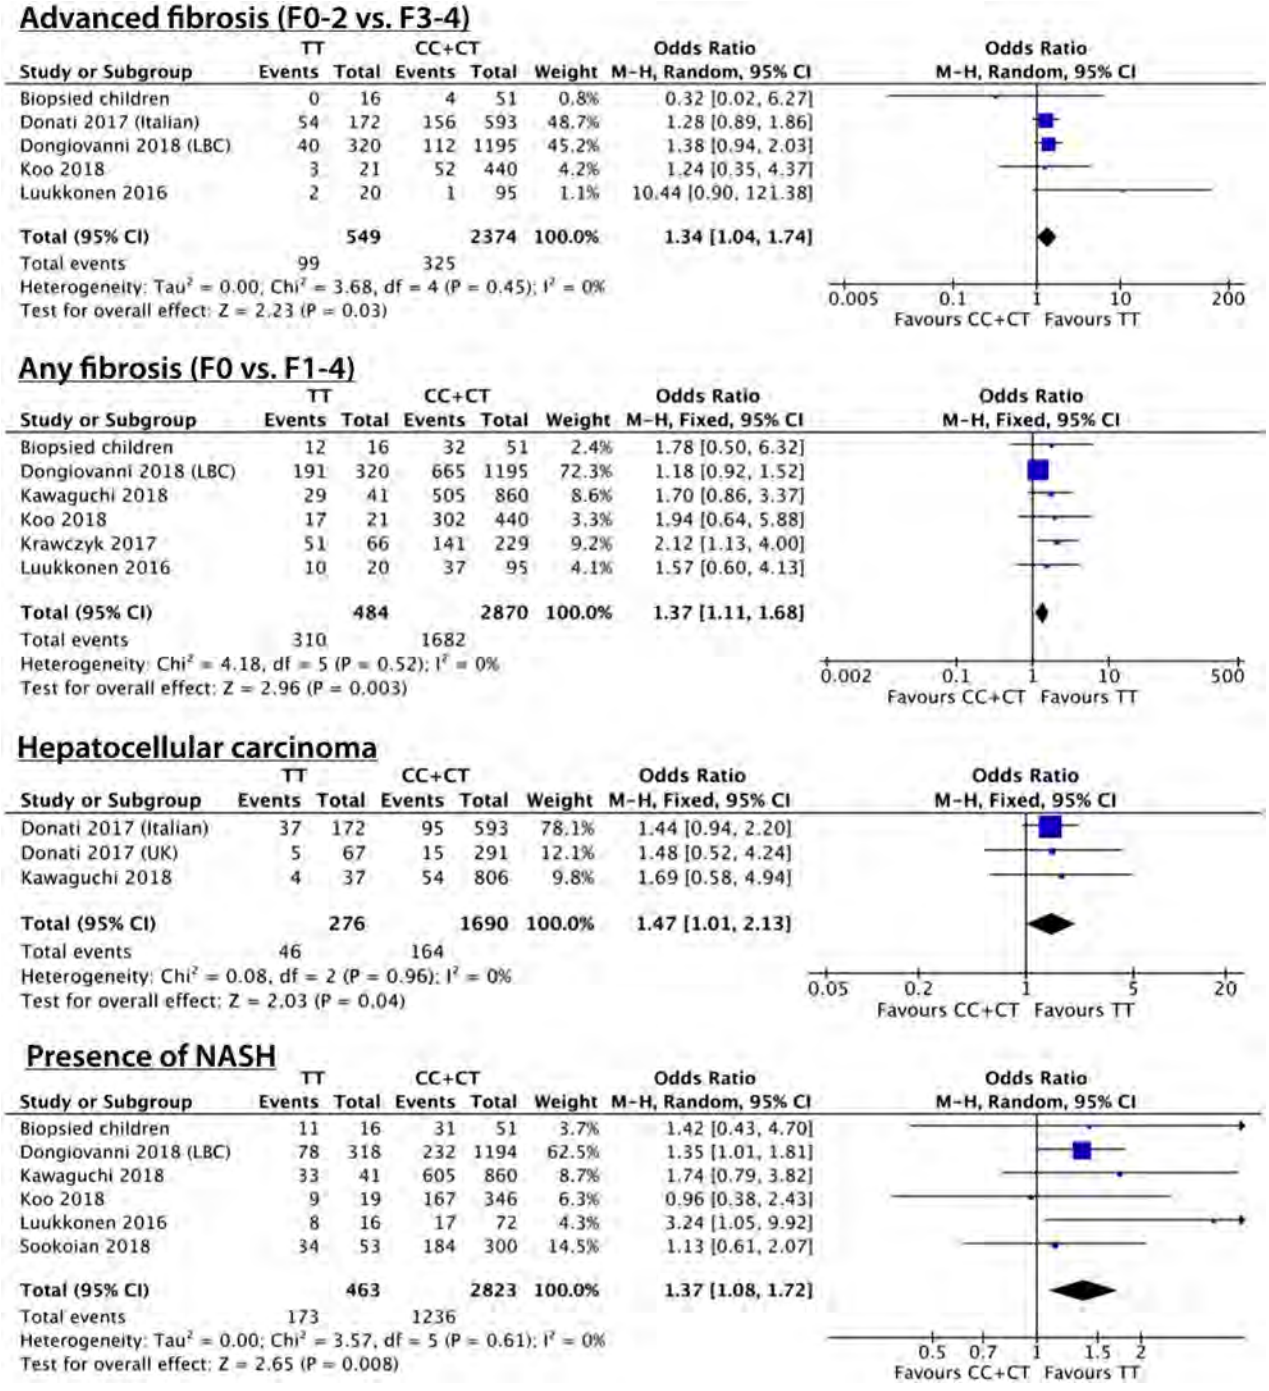


Figure: (abstract: FRI-325)

development of NAFLD are poorly grasped. Impaired liver biosynthesis of hydrogen sulfide (H_2S), the third gasotransmitter in mammals, has been reported in animal models of NAFLD, and H_2S supplementation was recently shown to prevent NASH development by decreasing hepatic steatosis, oxidative stress and inflammation. At high concentrations, H_2S blocks mitochondrial respiration through the inhibition of complex IV, whereas at low concentrations H_2S can be used as an inorganic energetic substrate for mammalian mitochondria. Our aim was to study if liver mitochondrial H_2S oxidation is regulated i) in different nutritional situations and ii) during NAFLD development, which currently remain totally unknown.

Method: Liver mitochondria were isolated from fed, 24h-fasted and re-fed C57Bl6/J mice as well as from mice fed a high fat-high sucrose (HFHS) diet to induce NALFD. Mitochondrial respiration and H_2S oxidation were measured using methods of oxygraphy (OROBOROS Instruments).

Results: Compared to fed mice, liver mitochondria from 24h-fasted animals presented a 2.4-fold decrease in the capacity to oxidize H_2S. Overnight refeeding after fasting restored mitochondria's ability of oxidizing H_2S, achieving values close to those observed in fed mice.

Regarding NAFLD development, mice fed a HFHS diet for 10 weeks, which led to increased body weight and adiposity, glucose intolerance but normal insulin sensitivity, exhibited unchanged liver mitochondrial H_2S oxidation capacity. However, after 20 weeks of HFHS diet that induced insulin resistance and NAFLD, liver mitochondrial H_2S oxidation was decreased by 1.3-fold. Importantly, the decrease in mitochondrial H_2S oxidation observed both in fasted and HFHS-fed mice occurred without any impairment of mitochondrial respiration.

Conclusion: In mouse liver, mitochondrial capacity to oxidize H_2S is under nutritional regulation and is impaired during NALFD development when insulin resistance is present.

FRI-329

Comparison of seladelpar and combinations with liraglutide or selonsertib for improvement of fibrosis and NASH in a diet-induced and biopsy-confirmed mouse model of NASH

Yun-Jung Choi[1], Jiangao Song[2], Jeff Johnson[1], Marc Hellerstein[3], Charles McWherter[1]. *[1]CymaBay Therapeutics, Inc, Newark, United States; [2]CymaBay Therapeutics, Inc, Newark, United States; [3]University of California, Berkeley, Nutritional Sciences and Toxicology, Berkeley, United States*
Email: ychoi@cymabay.com

Background and aims: Complete resolution of non-alcoholic steatohepatitis (NASH) is challenging due to a multifactorial etiology of this complex disease. Combining therapies with complementary mechanisms of action may achieve better outcomes. Seladelpar, a potent PPAR delta agonist, attenuates multiple pathophysiologic pathways in NASH mouse models. Here we evaluate combinations of seladelpar with the GLP-1-R agonist liraglutide or the ASK1 inhibitor selonsertib in a diet-induced and biopsy-confirmed mouse model of NASH.

Method: Male C57BL/6J mice were fed a diet high in fat, fructose and cholesterol for 43 weeks. Mice with histologically confirmed steatosis (score ≥ 2) and fibrosis (stage ≥ 1) were randomized and treated daily for 12 weeks. Seladelpar, liraglutide, selonsertib, and obeticholic acid (OCA) were tested alone as were combinations of seladelpar with liraglutide (S+L) or selonsertib (S+Se) for their effects on fibrosis and NASH pathology. D_2O was administered to allow measurement of hepatic collagen fractional synthesis rate (FSR). Biochemical (hydroxyproline, ALT, AST, total triglycerides (TG) and total cholesterol (TC)), and liver histological (NAFLD Activity Score (NAS) and fibrosis) and RNAseq analyses were performed.

Results: Treatment with seladelpar alone or the S+L and S+Se combinations resulted in stark reductions in liver fibrosis as measured by hydroxyproline content compared to NASH vehicle and the other single agents ($p < 0.0001$). Morphometric analysis of picrosirius red staining gave similar results. Col 1α1 mRNA and other mRNA indices of fibrosis were significantly reduced with seladelpar, liraglutide and the S+L and S+Se combinations compared to NASH vehicle ($p < 0.0001$). A significant decrease in FSR of collagen I protein was observed with seladelpar, S+L, S+Se and liraglutide ($p < 0.05$). The proportion of mice with a 2-point or greater improvement in NAS was 82%, 100%, 67%, 36%, 17%, 8% and 0% for seladelpar, S+L, S+Se, liraglutide, selonsertib, OCA and NASH vehicle, respectively. Robust reductions in liver steatosis were observed: −56%, −76%, −43%, −43% and −36% for seladelpar, S+L, liraglutide, S+Se and OCA, respectively ($p < 0.0001$). Seladelpar reduced plasma ALT, AST, TG, TC and liver TG and TC, but these were further lowered in the S+L combination ($p < 0.05$).

Conclusion: Seladelpar had substantial anti-fibrotic and anti-NASH efficacy in a mouse model, but the anti-NASH activity is enhanced by combination with liraglutide.

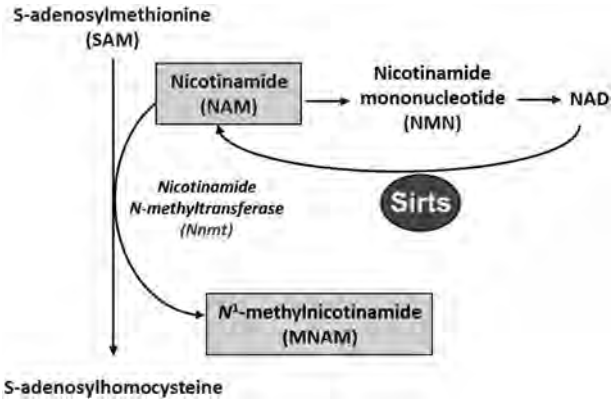
Do N1-methylnicotinamide and nicotinamaide administration defferentially alleviated hepatic steatosis?

Makoto Nakamuta[1], Kenji Ohe[2], Yusuke Murata[2], Masayoshi Mori[2], Shinichi Kiso[3], Yasushi Matsuzaki[4], Naoki Tanaka[5], Kazuhiro Tanabe[6], Nobuhiro Ookubo[6], Naoyuki Togawa[7], Akira Honda[4], Tadashi Ikegami[4], Kazufumi Dohmen[8], Munechika Enjoji[2]. *[1]National Hospital Organization Kyushu Medical Center, Gastroenterology, Fukuoka, Japan; [2]Fukuoka University, Clinical Pharmacology, Fukuoka, Japan; [3]Osaka University, Community Medicine, Osaka, Japan; [4]Tokyo Medical University Ibaraki Medical Center, Gastroenterology and Hepatology, Ibaraki, Japan; [5]Shinshu University, Metabolic Regulation, Matsumoto, Japan; [6]LSI Medience Corporation, Tokyo, Japan; [7]Mitsubishi Chemical Corporation, Tokyo, Japan; [8]Chihaya Hospital, Internal Medicine, Fukuoka, Japan*
Email: nakamuta.makoto.ya@mail.hosp.go.jp

Background and aims: We previously reported that nicotinamide (NAM), a metabolite of NAD catalyzed by Sirtuins (Sirts), ameliorated hepatic steatosis (NAFLD) via Sirtuins (Sirts) activation by inhibition of fatty acid synthesis (EASL the international liver congress 2018 and NASH summit 2018). Interestingly, NAM is turned to nicotinamide mononucleotide (NMN) to replenish the attenuated NAD level in high fat diet (HFD); by contrast, NAM is turned to N^1-methylnicotinamide (NNMT) in normal diet (ND) designated as "NAM metabolic switch." MNAM also ameliorates NAFLD via Sirts activation (Hong S, et al. Nat Med. 2015;21:887-94). Therefore, we investigated MNAM as a therapeutic alternative for NAFLD.

Method: C57BL/6J mice (n = 40) were divided into 8 groups and fed with ND: ND+NAM (NAM mixed with ND to 0.1% wt/wt); ND+MNAM (MNAM mixed with ND to 0.1% wt/wt); ND+NAM+MNAM or HFD containing fat of 40%: HFD+NAM; HFD+MNAM and HFD+NAM+MNAM for 8 weeks. The contents of NAM-related materials in the liver, NAM, NMN, NAD, and MNAM were measured by LC/MS (Fig. 1). The expression of lipid metabolism-related genes was evaluated by real-time RT-PCR.

Results: MNAM administration was more effective in the reduction of body weight than NAM in HFD mice, leading to a similar body weight as ND mice. Combining NAM and MNAM on HFD had a stronger effect than administrating independently. HFD mice treated with NAM decreased the levels of NAD without effecting of MNAM, NAM, and MNM; however, HFD mice treated with MNAM significantly increased those of MNAM, NMN and NAD but not NAM. HFD mice treated with NAM+MNAM strongly increased all these four components. Interestingly, both SAM and MNAM similarly and completely suppressed the HFD-upregulated genes involved in fatty acid synthesis such as SREBP1c and fatty acid synthase. Lastly, the treatment with MNAM as well as NAM activated Sirtuins.



Conclusion: MNAM evidently attenuated NAFLD indicating that the hepatic steatosis preventive feature of *NAM* N-methyltransferase (Nnmt) knockout mice (Kraus D, et al. Nature. 2014;508:258-62) was

not due to reduction of MNAM, and that MNAM might directly activate Sirts. It is intriguing that MNAM also increased the contents of NMN and NAD, and that MNAM might attenuate the function of Nnmt to increase NMN and concomitant NAD^+ level to activate the Sirts. We believe MNAM as well as NAM have promising potentials in treating NAFLD. We are now checking metabolites of the microbiota and bile acid metabolism because we found both of them dramatically change in ND+NAM where NAM is mainly converted to MNAM (EASL NASH summit 2018).

Effect of combined farnesoid X receptor agonist and angiotensin 2 receptor blocker on established liver fibrosis in rats

Tadashi Namisaki[1], Kosuke Kaji[1], Keisuke Nakanishi[1], Yuki Tsuji[1], Shinya Sato[1], Yasuhiko Sawada[1], Takemi Akahane[1], Masanori Furukawa[1], Yukihisa Fujinaga[1], Hiroaki Takaya[1], Hitoshi YOSHIJI[1]. *[1]Nara medical university, Kashihara, Japan*
Email: tadashin@naramed-u.ac.jp

Background and aims: It is important to find agents with therapeutic effect on the established liver fibrosis for future clinical application. This study is designed to investigate the combination effect of INT747 with losartan on established liver fibrosis in rats fed a choline-deficient, L-amino acid-defined (CDAA) diet.
Methods: Fischer 344 rats given a choline-deficient L-amino-acid-defined (CDAA) diet for 12 weeks. After 4-week administration of CDAA diet, rats were administered either INT747, losartan or a combination of each at the dose of 30mg/kg/day for 8 weeks by oral gavage. The therapeutic effect of INT747 and losartan was evaluated along with liver fibrosis development, lipopolysaccharide (LPS)-toll like receptor 4 (TLR4) regulatory cascade, and intestinal barrier function. The direct inhibitory effect of both INT747 and losartan on activated hepatic stellate cells (Ac-HSCs) was assessed in vitro.
Results: The F344 rats fed with CDAA diet developed marked liver fibrosis with deposition of collagen fibers. Single treatment either with INT747 and losartan significantly attenuated development of liver fibrosis induced by a CDAA diet. The combination treatment with both agents exerted a more potent inhibitory effect as compared with either single agent along with the inhibition of hepatic mRNA expression of α-smooth muscle actin (α-SMA), Transforming Growth Factor-β1 (TGF-β1) and Toll-like receptor 4 (TLR4). LPS binding protein (LBP) mRNA expression and intestinal permeability were significantly attenuated by INT747 monotherapy and combination treatment, but were not significantly altered by losartan monotherapy. Semi-quantitative immunofluorescence microscopy revealed that INT747 and combination treatment reduced CDAA-induced inhibition of the expression of zonula occludens (ZO)-1 tight-junction-associated protein in intestinal epithelium, whereas Losartan had no significant effect on ZO-1 expression. In vitro, AT-II- and LPS-induced proliferation of Ac-HSC was significantly attenuated by losartan monotherapy and combination treatment. However, there was no significant effect of INT747 on Ac-HSC proliferation. Contrarily, ATII- and LPS-induced mRNA expression of TGF-β1, TLR4, and Myd88 were individually suppressed by INT747 or losartan. Combined therapy exerted more potent suppression than monotherapy with either agent.
Conclusion: INT747 and Losartan have a synergistic repressive effect on established liver fibrosis by reversing LPS-induced gut barrier dysfunction and suppressing HSC activation and proliferation. Combined treatment may represent a promising novel therapeutic approach for NASH and advanced fibrosis.

FRI-333

ATG7 genetic variant and defective autophagy: A novel risk factor for non-alcoholic fatty liver disease progression in patients with type 2 diabetes mellitus

Serena Pelusi[1], Guido Alessandro Baselli[1], Annalisa Cespiati[1], Paola Dongiovanni[1], Misti McCain[2], Marica Meroni[1], Anna Ludovica Fracanzani[1], Renato Romagnoli[3], Salvatore Petta[4], Antonio Grieco[5], Luca Miele[5], Giorgio Soardo[6], Elisabetta Bugianesi[3], Silvia Fargion[1], Riccardo De Francesco[7], Stefano Romeo[8], Helen Reeves[9], Luca Valenti[1]. *[1]Università degli Studi di Milano, Milan, Italy; [2]Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom; [3]Università di Torino, Torino, Italy; [4]Università degli Studi di Palermo, Palermo, Italy; [5]Università Cattolica di Roma, Rome, Italy; [6]Università di Udine, Udine, Italy; [7]Istituto Nazionale di Genetica Molecolare (INGM), Romeo ed Enrica Invernizzi, Bioinformatic group, Milan, Italy; [8]University of Gothenburg, Gothenburg, Sweden; [9]Newcastle University, Newcastle upon Tyne, United Kingdom*
Email: serena.pelusi@unimi.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) represents an emerging cause of cirrhosis and hepatocellular carcinoma (HCC). Genetic factors play an important role in the pathogenesis of progressive NAFLD and HCC.
Method: We performed whole exome sequencing (WES) in 142 NAFLD-HCC cases from Italy and the UK, 59 Italian patients with NAFLD and advanced fibrosis, and 50 local healthy individuals. Clinical, biochemical data, personal and family history were also collected. Phenotypic characterization in carriers of the rs143545741 *ATG7* variant was performed.
Results: We have applied a novel bioinformatic pipeline for prioritization of rare variants predicted to severely impair protein function and increase the risk of progression to advanced NAFLD. Here we highlight a candidate loss-of-function variant in the ubiquitin-binding domain of *ATG7* as a novel risk factor for advanced fibrosis and NAFLD-HCC. ATG7 is involved in lipo-autophagy, a biological process of growing interest in liver biology and ATG7 deficient mice reportedly develop hepatomegaly and steatohepatitis. Moreover, autophagy may be involved in the pathophysiology of insulin resistance and type 2 diabetes mellitus (T2DM) through the regulation of pancreatic beta cells and insulin-target tissues (skeletal muscle, liver and adipose tissue). In our study, the rare rs143545741 variant (allelic frequency in the general population 0.001), encoding for the P426L protein variant, was associated with a 14-fold increased risk of advanced NAFLD ($p = 4.64*10^{-5}$, 95% CI = 4-33).
We identified 5 carriers of the *ATG7* variant. Four of them were male, 3 were overweight and two were obese; mean age was 66 ± 10 years. Two of these patients had NAFLD-HCC, while 3 had NAFLD and advanced fibrosis. There were no differences in the plasmatic concentrations of lipids, aminotransferases values, histological activity and BMI between carriers and non-carriers. Interestingly, a higher prevalence of T2DM in the group at risk was observed compared to patients negative for the genetic variant ($p = 0.04$) and all carriers had T2DM.
Conclusion: The rs143545741 C > T encoding for P426L variant in *ATG7* was associated with an increased risk of advanced NAFLD. The higher prevalence of T2DM in the mutated subjects supports a role of ATG7 in T2D development and/or a synergic effect with hyperglycemia in the progression of liver disease.

FRI-334

Cerium oxide nanoparticles present antilipogenic and anti-inflammatory effects in rats with diet-induced non-alcoholic fatty liver disease

Meritxell Perramon Corominas[1], Silvia Carvajal[1], Denise Oró[1], Eudald Casals[2], Guillermo Fernández Varo[1,3], Gregori Casals[1], Marina Parra-Robert[1], Jordi Ribera[1], Manuel Morales-Ruiz[1,3], Victor Puntes[2,4,5], Wladimiro Jiménez[1,3]. *[1]Biochemistry and molecular genetics of Hospital Clínic de Barcelona, Institut d'investigacions biomèdiques August Pí i Sunyer (IDIBAPS), Centro de investigación biomédica en red de enfermedades hepáticas y digestivas (CIBERehd), Barcelona, Spain; [2]Institut català de nanociència i nanotecnologia (ICN2), Barcelona, Spain; [3]Department of biomedical sciences, Faculty of medicine, University of Barcelona, Barcelona, Spain; [4]Institut català de recerca i estudis avançats (ICREA), Barcelona, Spain; [5]Vall d'Hebron insitute of research (VHIR), Barcelona, Spain*
Email: wjimenez@clinic.cat

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease worldwide. Oxidative stress and inflammation have been considered as key pathogenic mechanisms contributing to initiation and progression of injury. Cerium oxide nanoparticles (CeO_2NPs) have recently emerged as a powerful antioxidant, acting as ROS scavengers and anti-inflammatory agents. The current study was addressed to investigate the potential therapeutic effect of CeO_2NPs in an experimental model of NAFLD.

Method: Wistar rats were fed with a methionine and choline deficient diet (MCDD) for 6 weeks, receiving either 0.1 mg/kg of CeO_2NPs (n = 8) or vehicle (n = 7) twice a week during the 3rd and 4th week of MCDD intake. Biochemical parameters of liver function and hepatic fat content were assessed. Hepatic triglycerides (TG) and cholesterol esters (CE) were extracted and fatty acids (FAs) were quantified. Moreover, hepatic mRNA expression of genes involved in oxidative stress response and fatty liver metabolism was evaluated.

Results: As expected, in addition to having increased transaminases, hypercholesterolemia and hyperbilirubinemia, MCDD fed animals showed a dramatic increase in liver fat content as reflected by abundant intrahepatocellular lipid droplets (LD). CeO_2NPs administration to MCDD rats reduced the size and content of LD. This was associated with a decrease in the lipid components:TG and CE. TG monounsaturated fatty acids were significantly decreased after treatment, which was mainly due to a reduction in oleic acid. CeO_2NPs administration significantly decreased CE FAs, including saturated (myristic, pentadecylic and palmitic acids) and unsaturated FAs (palmitoleic, oleic, linolenic and gamma-linolenic acids). CeO_2NPs treatment also resulted in a significant increase in docosahexaenoic acid, a modulator of inflammatory response which has been considered as a potential treatment for NAFLD. Finally, CeO_2NPs administration reduced the expression of genes related to FA oxidation, adipokine signalling and antioxidant metabolism such as IL1b, Cpt1a and Ncf1.

Conclusion: CeO_2NPs attenuate inflammation, hepatic steatosis and partially revert the expression of genes involved in lipid metabolism and oxidative stress response in MCDD rats. These results demonstrate for the first time that CeO_2NPs have antilipogenic effect on rats with diet-induced NAFLD and suggest that they could be of therapeutic value in this condition.

FRI-335

Lect2, a new hepatokine regulating cholesterol metabolism in liver during non-alcoholic fatty liver disease

Sandrine Pham[1,2,3], Mathilde Cadoux[1,2], Fadila Rayah[1], Stéphanie Bonnafous[4], Nesrine Mabrouk[3], Valentin Derangère[5,6], Philippe Gual[4], TRAN Albert[4], Catherine Postic[1], Chantal Desdouets[1,2], Catherine Paul[3], Jean-Pierre Couty[1,2]. *[1]INSERM U1016, Cochin Institute, Paris, France; [2]INSERM UMR1138, Centre de Recherche des Cordeliers, Paris, France; [3]LIIC, EPHE EA7269, University of Burgundy, EPHE, PSL Research University, Dijon, France; [4]INSERM U1065, C3M, Nice, France; [5]Research Platform in Biological Oncology, Dijon, France; [6]GIMI Genetic and Immunology Medical Institute, Dijon, France*
Email: sandrine.pham@inserm.fr

Background and aims: **N**on-**A**lcoholic **F**atty **L**iver **D**isease (NAFLD) is becoming the most common disease worldwide due to the growing epidemic of obesity and metabolic syndrome. NAFLD encompasses a broad spectrum of chronic liver diseases ranging from simple hepatic steatosis (NAFL) to its aggressive manifestation called **N**on-**A**lcoholic **S**teato**H**epatitis (NASH), which is characterized by the occurrence of chronic liver inflammation, hepatocyte cell death and ongoing tissue damage sensitizing dramatically to HCC emergence. NAFLD is characterized by the accumulation of lipid species within hepatocytes, including lipotoxic agents such as cholesterol. These lipotoxic agents could in turn triggered chronic inflammation, a significant risk factor to develop HCC. Recently, our team demonstrated that the protein Lect2 was a key player of the liver immune microenvironment regulating the aggressiveness of HCC. Interestingly, Lect2 was also recently described as a hepatokine that could be involved in NAFLD, but little is known about its functional role in liver cells and its contribution to the severity of NAFLD. Thus, the goal of this work is to decipher the mechanistic role of LECT2 in the liver during NAFL/NASH/HCC progression.

Method and Results: First, using both mouse model and a cohort of human patients, we showed that Lect2 mRNA levels were higher in NAFL and NASH livers compared to controls. To understand the role of Lect2 in NAFLD, we first assessed its implication in lipid metabolism under physiological context, comparing Lect2-deficient and WT livers. Our results showed an upregulation of key actors of lipogenesis (*Srebp-1c, Fas, Acc*) in Lect2-deficient mice compared to WT. Transcriptomic analysis reveals an enrichment of genes involved in cholesterol metabolism, in the catabolism of cholesterol in bile acids (*Cyp7a1, Abcg5/Abcg8*). Mechanistically, we evidenced that this molecular signature is associated with an upregulation of the nuclear receptor LXR activity, in Lect2-deficient mice. Under pathological context of NASH, using a High Fat High Cholesterol Diet, we evidenced that Lect2 deletion worsens inflammatory process and fibrosis development, comparing Lect2-deficient and WT livers. Finally, using a CD-HFD that recapitulates key features of human NAFL/NASH/HCC progression, we demonstrated that Lect2-deficient mice develop liver tumors significantly more and faster than control mice (100% of Lect2-deficient versus 20% of Controls at 13 months of CD-HFD diet).

Conclusion: We demonstrated that Lect2 regulates cholesterol metabolism through a LXR-dependant manner, suggesting its contribution in lipotoxicity mechanisms that occurs during NAFL/NASH/HCC progression. Altogether, these findings illustrate the critical importance of Lect2 in NAFLD.

FRI-336

Lack of CCL2 limits the development of HCC in a model of obesity-associated carcinogenesis

Elisa Vivoli[1], Benedetta Piombanti[1], Chiara Raggi[1], Giovanni Di Maira[1], Stefania Madiai[1], Fabio Marra[1]. *[1]University of Florence, Florence, Italy*
Email: fabio.marra@unifi.it

Background and aims: Overweight and obesity are associated with increased cancer risk. Obesity-promoted HCC development is dependent on enhanced production of tumor- promoting cytokines IL-6 and TNF which cause hepatic inflammation and activation of the oncogenic transcription factor STAT3. CCL2 is a multifunctional chemokine involved in various aspects of the pathogenesis of chronic liver disease, including non-alcoholic steatohepatitis. Recently, the protective effects of the deficiency of CCR2, the receptor for CCL2, have been reported. However, the phenotype of ligand deficiency may be considerably different from that of chemokine

receptors. In this study, we investigated the role of CCL2 deficiency in a model of HCC associated with fatty liver.
Method: 14 days old CCL2+/+ and CCL2−/− mice were injected with DEN 25mg/kg IP or saline. After 4 weeks from the injection mice were fed with control (CD) or high-fat diet (HFD) for 38 weeks. Number and size of tumors were evaluated, Gene expression was measured by quantitative PCR.
Results: No differences in food consumption were observed across experimental groups. In CCL2−/− mice body weight was 1.5 fold lower than in CCL2+/+ mice. ALT levels were increased in all mice receiving HFD, whereas no effects of DEN were observed. The elevation was significantly higher in CCL2+/+ mice. No tumors developed in animals not receiving DEN. In those exposed to the carcinogen, the number of tumors was significantly higher in mice on a HFD than in those on CD. The number and mean size of tumor was dramatically and significantly decreased in CCL2−/− mice compared to wild-type. Gene expression analysis in the non-tumoral liver indicated that absence of CCL2 reduced the expression of TGF-beta and TNF-alpha. In the tumoral tissue, significantly reduced exoression levels of TNF-alpha, IL-18 and IL-6 were observed in CCL2−/− mice.
Conclusion: Genetic knock out of CCL2 is involved in tumor growth and progression in an obesity induced HCC murine model, and is associated with modulation of cytokine expression both in tumoral and non tumoral tissue.

FRI-338
Mitochondrial uncoupler HU6 reduces hepatic oxidative stress in the DIAMOND (TM) mouse model, thus abrogating NASH development
Francisco Portell[1], Stephen Eaton[1], Jameel Dennis[1], Rebecca Caffrey[2], Jonathon Marioneaux[2], Isaac Onyango[1], Omer Khan[1], Shaharyar Khan[1], Arun Sanyal[3]. *[1]Gencia LLC, Charlottesville, United States; [2]Sanyal Biotechnology, Norfolk, United States; [3]Virginia Commonwealth University, Richmond*
Email: frportell@genciabiotech.com

Background and aims: The Gencia mitochondrial uncoupler HU6 was evaluated for utility in treating NASH in a diet-induced animal model of metabolic syndrome and NASH (DIAMOND™ mice); development of NASH in this model is driven by insulin resistance, oxidative stress, inflammation, and leaky gut induced by Western Diet (WDSW). The aim of this study was to investigate effects of HU6 on ROS formation and correlate these with disease progression.
Method: Mice were grouped into 5 groups: vehicle control (VC), high dose HU6 (HD), 5 mg/kg), low dose HU6 (LD, 1 mg/kg), WDSW positive (PC) and NCNW negative (NC) natural history controls. Mice were raised for 12 weeks on diet, corresponding to a baseline NASH F0 in the WDSW groups. Treatment groups were then gavaged once daily with aqueous vehicle or drug in vehicle for 8 weeks. Serum and liver tissue were harvested, snap frozen and fixed, and LFTs, blood lipids and histology on FFPE section stained with HandE and Sirius Red was performed. DNA/RNA oxidative damage was measured via ELISA from representative liver samples. Key chemokines were also assayed from mouse livers utilizing Luminex Bead-based multiplex assays.
Results: Serum ALT, AST and ALP levels in the HD group were significantly lower than in the VC ($p = 0.001$, 0.0004, and 0.0002, respectively) and PC ($p = 0.03$, 0.01, and 0.00008, respectively) groups. In the HD group the significant reduction in ballooning ($p = 0.0000001$), lobular inflammation and liver transaminotransferase levels is accompanied by a 72% reduction in MCP-1, 37% reduction in IP-10, 50% reduction in MCP-3 and a 43% reduction in MCP-2. Additionally, HU6-treated mice have a near 30% reduction in baseline oxidative damage to nucleic acids. Steatosis percentage and grade ($p = 0.001$ and 0.01, respectively) were reduced in the HD group, which correlated with significantly lower body weights and liver weights compared to the VC and PC groups. Composite histology scores (NAS and SAF activity scores) were also significantly improved in the HD group compared to VC and PC groups. While all VC and PC mice progressed to NASH, HU6 at 5 mg/kg prevented NASH development in all but one mouse.
Conclusion: HU6 significantly reduced measures of oxidative stress and chemokines, correlating with decreases in ballooning, inflammation, and progression from simple steatosis to NASH. HU6 also produced significant reductions in body and liver weight, correlating with decreased hepatic steatosis. HU6 impacted multiple drivers of NASH in this study, thus supporting the rationale for further study of HU6's therapeutic potential in NASH.

FRI-339
Clinical translatability of a diet-induced obese mouse model of non-alcoholic steatohepatitis
Kristoffer Rigbolt[1], Sanne Veidal[1], Malte Suppli[2], Peter Lykke Eriksen[3], Michael Feigh[1], Filip Krag Knop[2,4,5], Henning Grønbæk[3], Karen Louise Thomsen[3], Jacob Jelsing[1], Niels Vrang[1]. *[1]Gubra, Hørsholm, Denmark; [2]Clinical Metabolic Physiology, Steno Diabetes Center Copenhagen, Gentofte, Denmark; [3]Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark; [4]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark; [5]Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*
Email: kri@gubra.dk

Background and aim: The Amylin (AMLN) diet-induced obese (DIO) mouse model has become one of the preferred preclinical animal models of non-alcoholic steatohepatitis (NASH). However, the translatable value of preclinical data in this model is still not properly validated. Our aim was to compare histology and liver transcriptome of AMLN DIO-NASH mouse liver samples with NASH patient biopsies.
Method: Liver samples were obtained from C57Bl/6J mice fed the AMLN diet (40% fat, 20% fructose, 2% cholesterol, AMLN DIO-NASH mice), a 60% high-fat diet (DIO mice) or chow (lean mice) for at least 30 weeks, and compared to human samples collected from lean (BMI < 25 kg/m^2), obese (BMI > 30 kg/m^2) and patients with histology-proven NASH (n = 12). Histopathological assessment of NAFLD activity score (NAS) and fibrosis stage was performed, and quantitative histology was used to analyze steatosis (HandE staining), inflammation (galectin-3 immunohistochemistry), and fibrosis (Pico-Sirius red staining). Global gene expression was finally characterized by next generation sequencing.
Results: Pathological evaluation showed no disease pathology in lean mice and human lean and obese subjects, while both normal DIO and AMLN DIO NASH mice, and human NASH patients, showed severe steatosis (score 3). Only AMLN DIO-NASH and NASH patients showed inflammation (score 1), ballooning (score 1 or 2) and fibrosis (score 1 or 2). The quantitative histology showed identical levels of liver lipid accumulation and similar levels of inflammation and fibrosis in AMLN DIO-NASH mice and human NASH patients, with slightly higher values in the mouse livers. RNAseq analyses from both mouse and human liver showed a pronounced shift in gene expression profile and perturbation of NASH-related pathways. In addition, prototypical NASH-related genes such as *Col1a1*, *Col3a1*, *Timp1* and *MCP-1* show analogous expression changes in mouse and human NASH samples.
Conclusions: A head-to-head comparison of the AMLN DIO-NASH mouse model and human NASH patients showed similar pathological scoring, quantitative histology, and gene expression validating the AMLN DIO-NASH mouse model as a clinically relevant model of human NASH.

FRI-340

In vivo effects of a novel inhibitor of apoptosis signal-regulating kinase 1 in mouse models of liver injury and metabolic disease

Manuel Roqueta-Rivera[1], Mary Chau[1], Guoqiang Wang[1], Kelsey Garlick[1], Bindu Ramachandran[1], Susanne Fyfe[1], Khanh Hoang[1], Yat Sun Or[1], Bryan Goodwin[1]. [1]*Enanta Pharmaceuticals, Inc., Watertown, MA, United States*
Email: bgoodwin@enanta.com

Background and aims: Apoptosis-Signal-Regulating-Kinase-1 (ASK1) is a redox-sensitive kinase. In the setting of oxidative stress, ASK1 activates mitogen-activated kinase (MAPK) signalling which, in turn, modulates the activity of apoptotic and inflammatory pathways. As a result, inhibition of ASK1 has been proposed as a therapeutic approach for the treatment of non-alcoholic steatohepatitis (NASH). EP-027315 is a novel, highly selective, and potent (IC_{50} < 1.25 nM) ASK1 inhibitor in cellular models of oxidative stress. Here, we evaluate the *in vivo* efficacy of EP-027315 in mouse models of liver injury (acetaminophen toxicity) and metabolic disease (diet-induced obesity).
Method: Inhibition of acute ASK1 activation was tested in C57BL/6 male mice (8 weeks of age) receiving a single dose of vehicle or EP-027315 (oral gavage) 1 hour prior to acetaminophen (APAP) administration (300mpk, i.p). Livers and plasma were harvested 6 hours after APAP treatment to evaluate the effects of EP-027315 on hepatic ASK1 signalling. To further characterize the pharmacologic effects of ASK1 inhibition on APAP-mediated hepatotoxicity, RNA-Seq analysis of livers was performed. In addition, inhibition of ASK1 was evaluated in diet-induced obese (DIO) mice fed a high-fat diet (D12492) for 24 weeks. MAPK signalling (ASK1, MKK4, JNK, p38) and apoptotic markers was evaluated using immunoblot or MSD assay in liver lysates. Hepatic injury and inflammation were assessed by plasma ALT, plasma IL-1beta, and histological evaluation of formalin-fixed tissues.
Results: In both the APAP liver injury and DIO mouse models, EP-027315 dose-dependently inhibited the activation of ASK1 and its downstream effector kinases. In addition, EP-027315, effectively suppressed multiple markers of apoptosis, including cytochrome-C release and cleaved PARP. Inhibition of ASK1 correlated with attenuation of liver damage by APAP (60% decrease ALT, $p < 0.05$) and reduced hepatocyte centrilobular degeneration. EP-027315 also exerted anti-inflammatory effects (75% decrease IL-1beta $p < 0.05$). RNA-Seq analysis confirmed the positive impact of EP-027315 on genes associated with apoptosis and inflammation.
Conclusion: EP-027315 effectively inhibited hepatic ASK1 activation induced by either acute liver injury or chronic metabolic stress. EP-027315 treatment suppressed liver injury, inflammation, and apoptotic pathways at both a transcriptional and protein level. These data support the further evaluation of EP-027315 for the treatment of NASH.

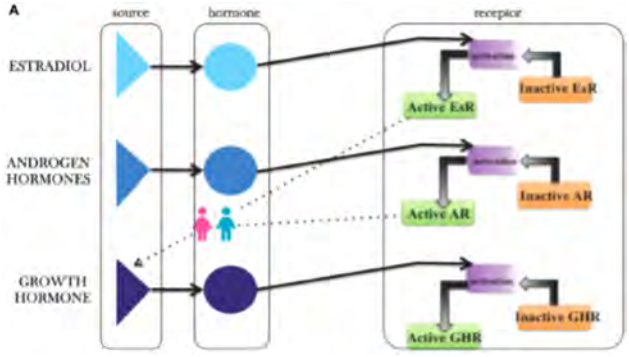
Sexual aspects of liver metabolism: A computational approach

Damjana Rozman[1], Tanja Cvitanivić Tomaš[1], Miha Moškon[2], Miha Moškon[2]. [1]*University of Ljubljana, Faculty of Medicine, Institute of Biochemistry, CFGBC, Ljubljana, Slovenia;* [2]*University of Ljubljana, Faculty of Computer and Informaiton Science, Laboratory for Computer structures and Systems, Ljubljana, Slovenia*
Email: damjana.rozman@mf.uni-lj.si

Background and aims: Liver is a known sexually dimorphic non-reproductive organ with over 1000 genes whose expression differs between females and males. This indicates that female and male livers are metabolically not identical organs. The liver pathologies usually prevail in one or the other sex, with different contributing genetic and environmental factors. Mathematical modelling can aid importantly in understanding the multifactorial liver disease etiology. The currently established computational models of hepatic metabolism that have proven to be essential for understanding of non-alcoholic fatty liver disease (NAFLD) and hepatocellular carcinoma (HCC) are limited to the description of gender-independent response or reflect solely the response of the males. Herein we present *LiverSex*, the first sex-based multi-tissue and multi-level liver metabolic computational model.
Method: We used object oriented modelling to contruct the *LiverSex* mode based on *in silico* liver model *SteatoNet*. The crucial factor in adaptation of liver metabolism to the sex is the inclusion of estrogen and androgen receptor responses to respective hormones and the link to sex-differences in growth hormone release. For experimental validation of the mathematical model we applied gene expression data from livers of female and male mice on western diet.
Results: The model was extensively validated on literature data and experimental data obtained from wild type C57BL/6 mice fed with regular chow and western diet. These experimental results show extensive sex-dependent changes and could not be reproduced *in silico* with the uniform model *SteatoNet*. The *LiverSex* model identified the most important sex dependent metabolic pathways which are involved in accumulation of triglycerides representing initial steps of NAFLD. PGC1A, PPARα, FXR, and LXR were identified as regulatory factors that could become important in sex-dependent personalized treatment of NAFLD.



Conclusion: *LiverSex* represents the first large-scale liver metabolic model, which allows a detailed insight into the sex-dependent complex liver pathologies, and how the genetic and environmental factors interact with the sex in disease appearance and progression.

FRI-342

Combining probiotics and an angiotensin-2 type 1 receptor blocker has beneficial effects on hepatic fibrogenesis in a rat model of non-alcoholic steatohepatitis

Yasuhiko Sawada[1], Hideto Kawaratani[1], Takuya Kubo[1], Yukihisa Fujinaga[1], Masanori Furukawa[1], Soichiro Saikawa[1], Shinya Sato[1], Kenichiro Seki[1], Hiroaki Takaya[1], Yasushi Okura[1], Kosuke Kaji[1], Naotaka Shimozato[1], Mitsuteru Kitade[1], Kei Moriya[1], Tadashi Namisaki[1], Takemi Akahane[1], Hitoshi Yoshiji[1]. [1]*Nara Medical University, Third Department of Internal Medicine, Kashihara Nara, Japan*
Email: yasuhiko@naramed-u.ac.jp

Background and aims: Intestinal endotoxin is important for the progression of non-alcoholic steatohepatitis (NASH). By improving the gut microbiota environment and restoring gut-barrier functions, probiotics are effective for NASH treatment in animal models. It is also widely known that hepatic fibrosis and suppression of activated hepatic stellate cells (Ac-HSCs) can be attenuated by using an angiotensin-II (AT-II) type 1 receptor blocker (ARB). We thus evaluated the effect of combination probiotics and ARB treatment on liver fibrosis using a rat model of NASH.
Method: Fisher 344 rats were fed a choline-deficient/L-amino acid-defined (CDAA) diet for 8 weeks to generate the NASH model. MIYAIRI 588 were used for probiotics and 30 mg/kg/day of losartan

was used for ARB. Animals were divided into probiotics, ARB, and probiotics plus ARB groups. Therapeutic efficacy was assessed by evaluating liver fibrosis (Sirius Red and α-SMA staining), the lipopolysaccharide (LPS)-Toll-like receptor (TLR)4 regulatory cascade, and intestinal barrier function (zonula occludens-1 (ZO-1) staining). Microbiome of the rats were assessed by analyzing new-generation sequencing.

Results: CDAA group showed moderate liver fibrosis by assaying Sirius Red and α-SMA staining. Liver fibrosis was suppressed in both probiotics and ARB group, compared to that in the CDAA group. A more potent inhibitory effect on liver fibrosis was observed in the combination group of probiotics plus ARB, compared to that with either drug alone.

Hepatic TGF-β and TLR4 expression were increased in CDAA group. On the other hand, hepatic TGF-β and TLR4 expression were decreased in both the probiotic and ARB groups, compared to that in the CDAA group. Notably, the combination of probiotics and ARB resulted in a stronger inhibitory effect than either drug alone. Hepatic LBP mRNA was increased in CDAA group. In the probiotics group, LBP mRNA decreased compared to that in the CDAA group. In contrast, no significant effect was observed in the ARB group. Regarding the combination group of probiotics and ARB, LBP mRNA was decreased compared to that in the CDAA group, however, there was no additional benefit compared to probiotics alone. As well as hepatic LBP, probiotics, not ARB, reduced intestinal permeability by rescuing ZO-1 disruption induced by the CDAA diet. CDAA group showed different cluster compared with control group. In addition, probiotics administration improved the microbiome disrupted by the CDAA diet.

Conclusion: Combination of probiotics and ARB are effective in suppressing liver fibrosis via different mechanisms (thorough HSC, intestinal tight junction, gut microbiome). Currently both drugs are in clinical use; therefore, the combination of probiotics and ARB is a promising new therapy for NASH.

FRI-343
NEDDylation inhibition as a new potential therapy of non-alcoholic fatty liver disease

Lu[8], José M. Mato[3,4], Felix Elortza[2], María Luz Martínez-Chantar[1,4]. *[1]CIC bioGUNE, Liver Disease Laboratory, Derio, Bizkaia, Spain; [2]CIC bioGUNE, Proteomic Platform, Derio, Bizkaia, Spain; [3]CIC bioGUNE, Liver Metabolism Lab, Derio, Bizkaia, Spain; [4]CIBERehd, Derio, Bizkaia, Spain; [5]University of Basque Country and Biocruces Health Research Institute, Physiology, Leioa and Barakaldo, Spain; [6]University of Basque Country, Physiology, Leioa, Bizkaia, Spain; [7]Marqués de Valdecilla University Hospital, Santander, Cantabria, Spain; [8]Cedars-Sinai Medical Center, Division of Digestive and Liver Diseases, Los Angeles (LA), United States*
Email: mserrano@cicbiogune.es

Background and aims: NASH is a complex and chronic liver disease in which multiple mechanisms are implicated in its progression that limit novel therapeutic approaches. Thus, multi-target models might be a better physiological approach to understanding NASH and its treatment. One of the cutting-edge research topics is the study of post-translational modifications (PTMs) that have emerged as a faster and effective mechanism to regulate signaling pathways and metabolic reactions. NEDDylation is an ubiquitin-like reversible PTM characterized by the conjugation of Nedd8 (neural precursor cell expressed developmentally down-regulated 8) to target proteins that promote their stabilization. Our laboratory has described a marked increase of NEDDylatied proteome in liver as well as serum in patients and mice model with NAFLD.

Method: Animal procedure was make using male adult C57BL/6 mice (3-month old) fed with methionine (0.1%) and choline (0%) deficient diet (MCD diet) and control group fed with regular diet. After 2 week of feeding with 0.1%MCD diet a group of mice were treated with Pevonedistat or MLN4924 (60 mg/Kg) by gavage (Takeda Oncology, Cambridge, MA, USA) each 4 days as total of 2 weeks. Proteomic analysis. Liver samples were digested with trypsin and analyzed by LC-MS/MS using an LTQ Orbitrap XL (Thermo). The differential expression analysis was carried out using Progenesis software (Nonlinear Dynamics). Only proteins quantified with at least 2 different peptides identified with a FDR < 1% were considered for further analysis. Functional analysis of the differential proteins ($p < 0.05$, ratio > 1.5 in either direction) was carried out using the DAVID Functional enrichment tool (https://david.ncifcrf.gov/) and with Ingenuity Pathway Analysis (IPA, QIAGEN).

Results: In preclinical studies using Pevonedistat (MLN4924), an already approved FDA inhibitor of NEDDylation, we have been able to reverse steatosis, inflammation and fibrosis in a preclinical NASH mice model. In addition, we describe the reversion of NEDDylation levels in serum samples and tissues after the treatment. We found β-oxidation activity and ketone bodies levels were increased in the treatment group. Noteworthy, the levels of reactive oxygen species (ROS) and lipid peroxidation showed a significantly reduction after Pevonedistat treatment. Hepatic proteomic analysis after Pevonedistat treatment showed regulation of multiple pathways including fatty acid metabolism, peroxisomes, bile acid metabolism, ribosomes and endoplasmic reticulum stress.

Conclusion: NEDDylation plays an important role in the physio-pathology of NAFLD and NASH progression. Hence, understand the complexity of the relation between NEDDylation and NASH will pave the way to develop new therapeutic option.

FRI-344
Preclinical characterization of FM101, a first-in-class A3 adenosine receptor modulator for the treatment of non-alcoholic steatohepatitis

Changho Shon[1], Su-Yeon Choi[1], Jeong-Su Park[1], Chong-Woo Park[2], Jiyoun Lee[2], Yoon-Seok Roh[1]. *[1]Chungbuk National Uniuversity, College of Pharmacy, Cheongju, Chungcheongbuk-do, Korea, Rep. of South; [2]Future Medicine, Research and Development Center, Seoul, Korea, Rep. of South*
Email: ysroh@cbnu.ac.kr

Background and aims: Adenosine and its receptor are involved in energy metabolism and immune response regulation. Notably, the activation of A3 adenosine receptor (A3AR) inhibits cyclic AMP (cAMP)-protein kinase A (PKA) pathway, which subsequently regulates mitochondrial electron transport chain (ETC) and apoptosis. However, the mechanism how a biased agonist of A3AR, FM101 modulates liver mitochondria and the severity of non-alcoholic steatohepatitis (NASH) remains unclear.

Method: C57BL/6N mice were treated with fast food diet (FFD, 40% calories from fat, 0.2% cholesterol, RD Western Diet, plus fructose 23.1 g/l and glucose 18.9 g/l added to the drinking water) for 25 weeks, and orally administrated either or FM101 (30 or 60mg/KG) or vehicle for last 6 weeks. Liver tissues, primary hepatic stellate cells (HSCs) and Kupffer cells (KCs) were collected and analyzed by histology and qPCR. Oxidative phosphorylation (OXPHOS), mitophagy and mitochondrial turnover were measured by Seahorse machine, Mt-Keima and pMitoTimer system, respectively.

Results: In functional assay, FM101 act an agonistic role of A3AR as assessed by cAMP with the homogeneous time-resolved fluorescence (EC_{50} = 104 nM). However, FM101 inhibited the β-arrestin translocation in response to A3AR activation (IC_{50} = 44 nM). A3AR was predominantly expressed in KCs, and HSCs compared with hepatocytes. *In vitro* treatment with FM101 significantly inhibited activation of KCs and HSCs as demonstrated by downregulation of inflammatory cytokines (TNF-alpha, IL-6, IL-1beta), and pro-fibrogenic (COL1A1,

TIMP1 and ACTA2) gene expressions, respectively. *In vivo* treatment of FM101 decreased liver weight, and ratio of liver to body weight. Moreover, FM101 decreased serum level of ALT and cholesterol induced by FFD. Consistently, FM101 effectively ameliorated steatofibrosis as assessed by quantification of collagen deposition and profibrogenic mRNA expressions. Mechanistically, FM101 treatment strongly blocked mitochondrial ETC in KCs. Moreover, FM101 increased accumulation of damaged mitochondria and subsequent mitophagic degradation in response to CCCP treatment using pMitoTimer and Mt-Keima system, respectively. Consequently, CCCP-induced cell death in mouse macrophages was enhanced by FM101 treatment.

Conclusion: The biased agonist of A3 adenosine receptor, FM101, could have therapeutic potential for the treatment of NASH through induction of mitochondria-mediated KCs death.

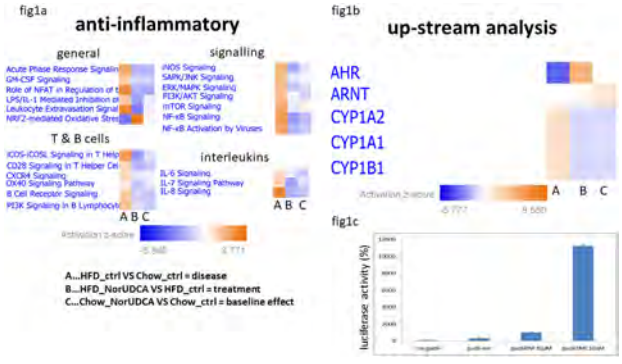
FRI-345

Whole transcriptome analysis uncovers NorUDCA as a ligand of the aryl hydrocarbon receptor

Daniel Steinacher[1], Johannes Grießner[2], Claudia Fuchs[1], Lorenz Hinterleitner[1], Thierry Claudel[1], Wulf Haubensak[2], Michael Trauner[1]. [1]*Medical University of Vienna, Wien, Austria;* [2]*Research Institute of Molecular Pathology (IMP), Wien, Austria*
Email: daniel.steinacher@meduniwien.ac.at

Background and aims: NorUrsodeoxycholicacid (NorUDCA) is a bile acid based drug currently in late clinical development for treatment of PSC and NASH. Despite its anti-inflammatory, anti-cholestatic/choleretic and anti-fibrotic effects, its molecular mechanism remains unknown. Therefore, we used unbiased whole transcriptome analysis to deepen our understanding of NorUDCA and explore its mechanism of action.

Method: Male C57BL/6J mice received either chow (A04, Safe Diets, France) or high-fat-diet (36% fat from butter, HF260, Safe Diets, France) ± 0.5% NorUDCA for 39 weeks. mRNA was extracted from livers (n = 5 per group). A Tn5 enzyme based RNA-seq library prep was performed and underwent Ilumina seq. Genes were ranked by log2FC and a p-adjusted threshold of < 0.05 was applied. Ingenuity Pathway Analysis (IPA, Quiagen) was used for further analysis. In vitro qPCR of AhR target genes hepa1c1c cells (mouse hepatocyte cell line) was done using NorUDCA±AhR ligands (ANF, BNF, 3MC, CH223191). In addition, we performed luciferase assays (gud6) and gel shifts in IHH (immortalized human hepatocytes) cells, either naive or co-transfected with mouse AhR±NorUDCA and compared it with BNF and 3MC.



Results: RNA-seq analysis revealed a striking differential regulation of canonical anti-inflammatory pathways (fig1a). Further, AhR was upregulated in HFD_NorUDCA vs HFD_ctrl (padj = 0.0058) and Chow_NorUDCA vs Chow_ctrl (padj = 0.0072), while its downstream targets cyp1a1 and cyp1a2 were downregulated (fig1b). A series of AhR-co-regulated pathways were clearly affected (e.g. fibrosis, inflammation, cell cycle). In hepa1c1c cells treated with both AhR ligands and NorUDCA, a mean suppression of cyp1a1 of at least 25% was observed. Luciferase assays in IHH cells demonstrated NorUDCA -binding to AhR, although weaker than BNF or 3MC (fig1c). Also, gel shifts confirmed the luciferase assays, as AhR was found less in the cytosol and more in the nucleus fraction of cells pre-treated with NorUDCA, BNF or 3MC.

Conclusion: Our data show that NorUDCA is a ligand of AhR in vitro and strongly affects it in vivo. This could explain several hepatoprotective effects seen in preclinical models and clinical studies. Moreover, RNA-seq data in mice hinted at more potential mechanisms and applications of NorUDCA like anti-proliferative and anti-inflammatory actions, which need to be evaluated in more detail in vivo and in clinical studies.

FRI-346

The effect of exercise training and canagliflozin on hepatic lipid metabolism of non-alcoholic fatty liver disease

Kenichi Tanaka[1], Hirokazu Takahashi[1], Yoshihito Kubotsu[1], Yuka Fujioka[1], Keizo MD, PhD[1], Yuichiro Eguchi[2]. [1]*Saga University, Metabolism and Endocrinology, Saga, Japan;* [2]*Saga Medical School, Liver center, Saga, Japan*
Email: kensmvc541112@gmail.com

Background and aims: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) is a possible pharmacological therapy for non-alcoholic fatty liver disease (NAFLD). Exercise is a robust treatment of obesity and NAFLD; however, effect of SGLT2i on exercise therapy is unclear. We investigated the effect of canagliflozin (CAN), exercise training and combination therapy on NAFLD and lipid metabolism in the liver.

Method: Male mice loaded with a high-fat diet for 4 weeks were housed in a normal cage (sedentary; Sed) or wheel cage (WCR). CAN was administrated for 4 weeks. Respiratory quotients (RQ) was analyzed in the metabolic cages. Pathological findings and mass spectrometry-based lipidomics were compared among 4 groups (Control/Sed, Control/WCR, CAN/Sed, and CAN/WCR).

Results: Body weight of Control/WCR and CAN/Sed was significantly lower than Control/Sed, and further weight loss was observed in CAN/WCR. RQ was significantly different among 4 groups (Control/Sed 0.80, Control/WCR 0.83, CAN/Sed 0.75, CAN/WCR 0.77, $p < 0.0001$). Hepatic steatosis and NAFLD activity score was ameliorated in Control/WCR, CAN/Sed and CAN/WCR comparing to Control/Sed (Control/Sed 2.25, Control/WCR 1.25, CAN/Sed 1.5 and CAN/WCR 0.25). In CAN/Sed and CAN/WCR, CPT1a and PGC1a expression was significantly increased and FAS and SCD1 were significantly decreased comparing to Control/Sed ($p < 0.05$), and these differences were more significant in CAN/WCR than CAN/Sed. Phosphorylated AMPK tended to increase in the order of Control/Sed, Control/WCR, CAN/Sed, and CAN/WCR. In lipidomics, CAN and/or WCR remarkably decreased triacylglycerols regardless chemical structure of triacylglycerols and average fold change in triacylglycerols of Control/Sed, Control/WCR, CAN/Sed, and CAN/WCR were 1.0 ± 0.08, 0.38 ± 0.21, 0.77 ± 0.11 and 0.46 ± 0.10. There was no significant difference in diacylglycerol, phosphatidylcholine and fatty acid including ω-3 and ω-6 polyunsaturated fatty acids. Erucic acid was significantly decreased only with CAN, and fold change of Control/Sed, Control/WCR, CAN/Sed, and CAN/WCR were 1.0 ± 0.23, 1.0 ± 0.15, 0.37 ± 0.08 and 0.47 ± 0.12.

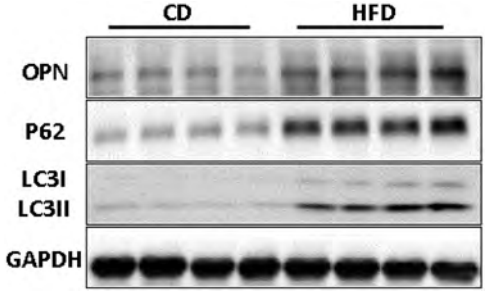
Conclusion: Canagliflozin and exercise independently decreases hepatic triglyceride and ameliorates NAFLD. Canagliflozin activates AMPK additively to exercise effect, and suppress lipid synthesis and up-regulates β-oxidation. In order to decrease erucic acid, which is known cardiac disease risk, SGLT2i is a potential therapeutic choice.

FRI-347

OPN inhibits autophagy and accelerates lipid accumulation in non-alcoholic fatty liver disease

min Tang[1], Changqing Yang[1]. [1]*Tongji hospital, Tongji University School of Medicine, Division of Gastroenterology and Hepatology, Institution of Digestive Diseases, shanghai, China*
Email: cqyang@tongji.edu.cn

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with insulin resistance and obesity and prevalent throughout the world. NAFLD ranges from pure steatosis to a more severe stage termed non-alcoholic steatohepatitis (NASH) by fatty inflammation, which may in turn progress to hepatic fibrosis and cirrhosis. Recent studies have demonstrated that hepatic autophagy is impaired in NAFLD. In the present study, we investigated the impact of osteopontin (OPN), a secreted phosphoprotein 1, negative regulation of autophagy in the progression of NAFLD.
Method: ① In the construction of NAFLD mice experiment, C57BL/6 mice were randomly assigned to a high fat diet (HFD) group, which was further subdivided into 4 groups (0, 4, 8, 12 weeks) (n = 4) according to time points. Control mice were fed with chow diet (CD) (n = 4). ② Expression of OPN and LC3II/I, P62 in liver tissues were detected. ③ In vitro experiment, HepG2 cells were induced by free fatty acids (FFA) to simulate high-fat environment in vivo. Real-time PCR and Western blot were used to detect the expression levels of OPN, LC3II/I and P62. ④ SIRNA was used to down-regulate OPN expression and recombinant OPN protein was exogenously added. LC3II/I, P62 and lipid accumulation in HepG2 cells. ⑤ LC3-II expression levels were compared in the presence and absence of CQ (chloroquine) in order to detect that whether FFA treatment suppressed net degradation via autophagy. ⑥ Wild-type (WT) and OPN knockout (OPN−/−) mice were fed a high fat diet to study OPN effects in obesity-driven hepatic alterations.
Results: ① OPN was upregulated in association with autophagy impairment in the livers of mice fed with a high-fat diet ($p < 0.05$). The most obvious change was detected at week 12. ② In vitro experiment, as the concentration of FFA increased, the expression of OPN was also increased unlike within the control group, and the level of autophagy was gradually suppressed ($p < 0.05$). ③ The upregulation of OPN was associated with suppression of the late stage of autophagy as evidenced by accumulation of both LC3-II and p62 expression levels as well as decreased autophagy flux ($p < 0.05$). Its blockade by siRNA attenuated autophagy impairment and reduced FFA-induced lipid accumulation. ④ CQ obviously increased the levels of LC3-II expression in control HepG2 cells. However, further accumulation was not observed in FFA-supplemented cells, which suggested that FFA treatment inhibited autophagic flux, most likely through blockade at the autophagosome maturation step. ⑤ OPN deficiency ameliorated liver steatosis, at least in part, by the regulation of autophagy.



Conclusion: OPN is up-regulated and plays a pathogenic role in NASH by accelerating hepatocellular lipid accumulation and inhibiting autophagy. OPN may be a novel therapeutic target for regulating NASH development and progression.

FRI-348

Monoacylglycerol lipase deletion protects against obesity-induced hepatic steatosis via PPARg regulation in adipose tissue and fatty acid malabsorption in the intestine

Matteo Tardelli[1], Francesca Bruschi[1], Thierry Claudel[1], Nicole Auer[1], Victoria Kunczer[1], Tatjana Stojakovic[2], Merima Herac[1], Sophie Lotersztajn[3], Michael Trauner[1]. [1]*Medical University of Vienna, Vienna, Austria;* [2]*Medical University of Graz, Graz, Austria;* [3]*Centre de Recherche sur l'Inflammation, Paris, France*
Email: matteo.tardelli@meduniwien.ac.at

Background and aims: Obesity is strongly associated with the development of non-alcoholic fatty liver disease (NAFLD). Accumulating evidence links metabolic lipases to the pathogenesis of NAFLD. Monoacylglycerol lipase (MGL) is the rate-limiting enzyme of the fatty acid (FA) degradation pathway hydrolyzing monoglycerides into glycerol and FAs but its role in NAFLD is still unclear. In the present study, we aimed to uncover the role of MGL in obesity-induced hepatic steatosis.
Method: Immunohistochemistry (IHC) for MGL was performed in lean and obese patients with NAFLD. Wild type (WT) and MGL knockout ($MGL^{-/-}$) mice were fed western diet for 12 weeks to study MGL effects in obesity driven hepatic alterations. Inflammation and fibrosis were assessed by serum biochemistry, liver histology and gene expression profile were analyzed in liver and adipose depots. Triglycerides (TG) were measured in liver tissue and FA in stools by colorimetric assays. Primary adipocyte progenitor cells (APC) and 3T3-L1 were processed for flow cytometry, rt-PCR and western blot analysis.
Results: We demonstrated that MGL abundance increased dramatically in livers of obese patients with NAFLD (IHC), whilst MGL deficiency in mice protects from obesity-induced hepatic steatosis (ALT −40%, AST −50%) by downregulating hepatic TG synthesis (TG content −40%, Pparg −60%, Srebp1c −70%, FAS −60%. Dgat1 −50% mRNA) and inflammation (F4/80 −50%, CCL2 −60%) without affecting fibrosis. Absence of MGL promoted fat storage in gonadal white adipose tissue (GWAT weight +70%, Pparg +70%, CD36 +40%, Dgat1 +50% mRNA), preventing ectopic accumulation in the liver, while favoring malabsorption of FAs in the intestine (+70% FA content in feces). Furthermore, in vitro experiments demonstrated increased APC size and lipid content (+70% BODIPY, Dgat1 +50%, Pparg +40%, adiponectin +40% mRNA), driven by PPARγ feedback regulation as further demonstrated in 3T3-L1 co-treated with GW-9662 and rosiglitazone (MGL mRNA −50%).
Conclusion: Our data emphasize that MGL deletion prevents NAFLD by lipid storage in GWAT and FFA malabsorption in the intestine, creating a futile cycle whereby the products of TG hydrolysis can be recycled into TG within the cell and/or sensed by PPARγ, finally resulting in a leaner phenotype.

FRI-349

Development of humanized non-alcoholic steatohepatitis model using chimeric mice with highly repopulated humanized livers

Chise Tateno[1,2], Go Sugahara[1], Keishi Kisoh[1], Yasumi Yoshizane[1], Suzue Furukawa[1], Michinori Kohara[3], Yuji Ishida[1,2]. [1]*PhoenixBio Co., Ltd., RandD Department, HigashiHiroshima, Japan;* [2]*Hiroshima University, Research Center for Hepatology and Gastroenterology, Hiroshima, Japan;* [3]*Tokyo Metropolitan Institute of Medical Science, Department of Microbiology and Cell Biology, Tokyo, Japan*
Email: chise.mukaidani@phoenixbio.co.jp

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the leading cause of chronic liver disease. Although a significant number of new drugs for NASH are already in the development pipeline, there are no animal models of human (h-) NASH to estimate the efficacy and safety of potential new drugs. We have been producing humanized chimeric mice (PXB-mice) with livers highly repopulated with h-hepatocytes (h-heps). These mouse (m-) models are used to study drug metabolism, pharmacokinetics, toxicity of new

drugs, and efficacy of anti-hepatitis B and anti-hepatitis C therapeutic agents. In the present study, to develop the h-NASH model, we tried a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) (A06071302; Research Diets, Inc.) in PXB-mice.

Method: PXB-mice were fed with either the CDAHFD or a control diet for 12 weeks and body weight and h-albumin levels were determined. Mice were euthanized at 8 and 12 weeks. Alanine aminotransferase (ALT) activity and h-ALT1 levels were measured in m-plasma. Liver sections were histologically analyzed by HandE staining, silver staining and immunostaining. h- and m-mRNA expressions in the liver were determined by real-time quantitative PCR (qPCR) method.

Results: Mean body weight was lower in CDAHFD group than that in the control group, maintaining about 80% of the initial level. Increase in ALT activity and hALT1 level were observed in m-plasma at 2 and 4 weeks, which were recovered to normal in the CDAHFD group. Both liver weight to body weight and h-albumin levels in m-blood in the CDAHFD group were lower compared to those in the control group at 8 and 12 weeks. At 12 weeks, ballooning of h-heps and Mallory body-like structures in h-heps were observed only in the CDAHFD group. Increase in alpha-smooth muscle actin-positive stellate cell area, tunnel-positive h-heps, Ki-67 positive h-heps, Gr-1 positive neutrophils, and F4/80-positive macrophages was noted in the CDAHFD group compared with those in the control group at 8 and/or 12 weeks. Furthermore, perisinusoidal/pericellular fibrosis were observed with Sirius red staining and silver staining with increase in Sirius red-positive areas in the CDAHFD group compared with the control group at 12 weeks. qPCR revealed higher levels of h-TGFbeta1, h-CCL2, m-Tgfbeta1, m-Cxcl2, m-Col1a1, m-Col1a2, m-Col3a1, and m-Acta2 mRNA expressions in the CDAHFD group than the control group.

Conclusion: We successfully developed humanized NASH model using h-hep chimeric mice with CDAHFD diet.

FRI-350

Dietary cholesterol mitigates bile acid toxicity in NASH and cholestatic mouse models

Oren Tirosh[1], Yula Kolesnikov[1]. [1]*The Hebrew University of Jerusalem, Institute of Biochemistry, Food Science and Nutrition, Rehovot, Israel*
Email: oren.tirosh@mail.huji.ac.il

Background and aims: It has been a long-standing observation from liver pathology that bile acids toxicity is associated with NASH and cholestasis disease progression. The effect of dietary cholesterol on phase 1 hepatocytes proliferation, degree of inflammation and fibrosis induced by bile acids is not clear. In our study we aimed to determine whether the dietary cholesterol can regulate bile acid toxicity in NASH and cholestasis models.

Method: The study was conducted using two models for bile toxicity, dietary induced NASH and MDR2ko mice model for cholestasis. Dietary induced NASH model used male wild type mice and was performed for 3 weeks. Mice were assigned to 4 groups (n = 32 mice) and were fed with one of the following diets: ND (standard AIN-93G diet, Control group), ND + cholesterol 1% (CHOL group), ND + Cholic Acid 0.5% (CA group), ND + Cholesterol 1% + Cholic Acid 0.5% (CHOL + CA group, atherogenic diet). In model of MDR2KO mice that prolonged for 6 weeks, mice were assigned to 2 groups, one that received standard AIN-93G diet and the second, was treated with ND + 1% cholesterol. After treatments, mice were euthanized, and blood serum and liver tissue were collected. Plasma serum was analysed for lipid profile, liver enzymes and blood glucose. Liver tissue damage was assessed by Masson Trichrome staining for fibrosis and histological analysis. Immune inflammatory response was determined by inflammatory parameters expression in hepatocytes and macrophages infiltration was represented by immunohistological analysis of the tissue with macrophage-specific antigen (F4/80). Furthermore, hepatocytes proliferation was analysed by determination proliferating cellular nuclear antigen (PCNA). Liver tissue hypoxia levels were assessed by immunohistological analysis of the tissue for hypoxia inducible factors expression (HIF-1α).

Results: It was observed that mice fed cholesterol enriched diets were significantly protected against cholic acid/bile acids-induced necrosis and liver damage. Bile acid treatments induced increased liver damage and increased peri-portal and intralobular fibrosis. Adding cholesterol dramatically attenuated liver damage and fibrosis. However, cholesterol induced liver inflammation and uncontrolled hepatocytes proliferation. HIF-1α and nuclear factor (erythroid derived 2) like 2 (Nrf2) defence genes were also activated by cholesterol. Interestingly, HIF-1α specific expression in Ito cells' nuclei was decreased by cholesterol treatment.

Conclusion: We are showing for the first time that dietary cholesterol may prevent the bile acid-induced damage by activating hepatocytes defence genes and proliferation. Moreover, cholesterol enriched diet attenuated liver fibrosis and cholestasis, through inhibition of HIF-1α in Ito cells.

DNA methylation pattern of TM6SF2 influences NAFLD progression in genotype-dependent manner

Burge Ulukan[1], Buket Yigit[1], Onur Yilmaz[1], Melis Cansu Comert[1], Mert Erkan[2], Gupse Adali[3], Murat Dayangac[4], Mujdat Zeybel[1]. [1]*Koc University, Gastroenterology and Hepatology, School of Medicine, Istanbul, Turkey;* [2]*Koc University, General Surgery, School of Medicine, Istanbul, Turkey;* [3]*Sancaktepe Education and Research Hospital, Gastroenterology, Istanbul, Turkey;* [4]*Medipol University, Liver Transplantation Unit, Istanbul, Turkey*
Email: mzeybel@ku.edu.tr

Background and aims: Non-alcoholic fatty liver disease (NAFLD) arises due to complex interaction of genetic and environmental factors. Evidence suggests that transmembrane 6 superfamily member 2 (TM6SF2) E167K variant is associated with NAFLD susceptibility and progression. The loss of function mutation in TM6SF2 plays a pivotal role in hepatic lipid accumulation, however, it remains unknown if there is an interplay between genetic and epigenetic mechanisms modifying disease pathogenesis. In this study, we aimed to investigate whether epigenetic marks of TM6SF2 could affect development of hepatic steatosis and fibrosis.

Method: Histologically proven NAFLD patients and control subjects (hepatic resection due to benign liver lesions) were included into the study. Liver samples from 22 cirrhotic-NASH (F4), 24 mild-intermediate fibrosis stage (F1-3) NASH and 9 control patients (F0) were used to perform hepatic DNA methylation profiling in TM6SF2 gene using bisulphite modification and pyrosequencing. TM6SF2 gene expression and genotyping were determined using digital PCR and TaqMan RT-PCR assays, respectively.

Results: Pyrosequencing targeting several CpGs in TM6SF2 gene indicated significant methylation differences (> 7%) in promoter and first intronic regions between controls, mild-intermediate stage and cirrhotic patients. Interestingly, this difference was more prominent between TM6SF2 CC group versus CT/TT group (> 10%) suggesting genotype dependent epigenetic changes. In addition, TM6SF2 gene expression was also significantly altered associating with CpG methylation pattern and the genetic variation.

Conclusion: Here we report for the first time the association of DNA methylation profile of TM6SF2 gene in NAFLD progression. Differential methylation levels according to the E167K variant suggests the crosstalk between genetic and epigenetic pathways controlling the disease susceptibility and progression. Epigenetic editing could be employed to attenuate hepatic steatosis and fibrosis.

Inflammation provokes hepatic but not adipose tissue diacylglycerol acyltransferase 2 expression and concomitant triglyceride synthesis in an experimental non-alcoholic fatty liver disease

Balasubramaniyan Vairappan[1], Anjana Chandrasekar[1]. [1]*Jawaharlal Institute of Postgraduate Medical Education and Research, Liver Diseases Research Lab, Department of Biochemistry, Pondicherry, India*
Email: balamaniyan@gmail.com

Background and aims: Triglycerides (TG) are the predominant energy storage molecules in eukaryotes, and the DGAT enzymes catalyse its synthesis. Two isoforms of DGAT (1 and 2) have been identified from a distinct gene family and are widely expressed in both human and rodent liver. Evidence suggesting that the two enzymes play different roles in TG metabolism in the milieu of fatty liver diseases indeed the molecular mechanism remains unclear. We aimed to investigate whether superimposed inflammation increases DGAT (1 and 2) overexpression and associated hepatic and adipose tissue TG synthesis in non-alcoholic fatty liver disease (NAFLD) and also to study the effect of FXR agonist INT-747 on the regulation of hepatic DGAT-TG pathway in NAFLD.
Method: 90 days after feeding HFD and chow, mice were orally administered INT-747 (Sigma, USA; 5mg/kg b.w. daily by gastric lavage) in the vehicle (corn oil) for 7 days or vehicle alone. In order to determine the effect of superimposed inflammation on the background of fatty liver, the treatment groups were given either lipopolysaccharide (LPS; 1 mg/kg in 0.8-1 ml of saline, IP) or vehicle (saline). The final study groups were as follows: (a) Chow fed control mice, (b) Chow + LPS, (c) HFD, (d) HFD + LPS, (e) HFD + INT-747, (f) HFD + INT-747+LPS. At the end of the study, at fourteen weeks, all mice were sacrificed. Blood, hepatic and adipose tissue were collected for various analysis.
Results: When compared to naïve mice, NAFLD mice showed markedly elevated hepatic ($p < 0.05$ and $p < 0.01$, respectively) and adipose tissue ($p < 0.05$) DGAT (1 and 2) protein expressions. LPS challenge to NAFLD mice showed further significant ($p < 0.05$) increase of hepatic DGAT 2, but not DGAT 1 whereas adipose tissue DGAT (1and2) were not altered significantly. INT-747 treatment to NAFLD mice and that received LPS showed significantly ($p < 0.05$) reduced DGAT 1 and 2 and hepatic TG synthesis. Moreover, cytokines (TNF α and IL-1 β), NFκB, iNOS, and 4-HNE protein expressions were significantly ($p < 0.05$) increased in NAFLD mice that received LPS. INT-747 treatment significantly ($p < 0.05$) lowered the above indices.
Conclusion: Our study is the first indication of evidence for an association between increased hepatic however not adipose tissue DGAT 2 and associated TG synthesis in NAFLD with superimposed inflammation. INT-747 treatment attenuated hepatic TG accumulation by downregulating DGAT 2 overexpression, thereby lowering the progression of NAFLD.

Email: mvarela.ciberehd@cicbiogune.es

Background and aims: We recently demonstrated that half of NAFLD patients have a serum metabolic profile similar to the one observed in mice lacking MAT1A enzyme (MAT1A-KO mice). We proposed that this subtype of patients (M-subtype) could have lower MAT1A activity, and this is supported by studies showing decreased MAT1A expression in NASH patients. Since MAT1A expression increases with fasting, and considering that intermittent fasting has been shown to ameliorate liver steatosis, our aim in this study was to determine the effect of fasting on NAFLD progression in situations where MAT1A expression is compromised, similar to what would happen in NAFLD patients with an M-subtype.
Method: We collected liver and serum samples from fed and starved two-month old wild-type C57BL/6J and MAT1A-KO mice, and from C57BL/6J mice after *in vivo* silencing of MAT1A.
Results: We observed that starvation induces a more pronounced weight loss and adipose lipolysis when hepatic MAT1A was not expressed. Lipid hepatic content was not significantly different between wild-type and MAT1A-KO mice during the first 24h of starvation, but was drastically reduced in MAT1A-KO mice if starvation persisted during 36h. We observed that despite the huge increase in MAT1A protein expression in WT livers during starvation, SAMe levels decreased dramatically during prolonged fasting, and no differences was seen between wild-type and MAT1A-KO mice in total liver extracts. On the other hand, we found a pronounced decrease in SAMe levels in crude mitochondria isolated from MAT1A-KO mice than in control mice. This decrease in mitochondrial SAMe levels was associated with increased hepatic beta-oxidation, endoplasmic reticulum stress (ERS) and liver transaminases in MAT1A-KO-starved mice, suggesting a detrimental effect of fasting in livers from MAT1A-KO mice.
Conclusion: Altogether, our work suggests that despite the beneficial effect of fasting on body weight loss observed in MAT1A-KO mice, the increase in ERS, beta-oxidation and liver transaminases observed after starvation under MAT1A deficient conditions could promote the progression of NAFLD.

FRI-354

Novel Gubra Amylin NASH diet-induced obese mouse model of biopsy-confirmed non-alcoholic steatohepatitis

Sanne Veidal[1], Michael Feigh[1], Michelle Boland[1], Denise Oro[1], Kirstine Tølbøl[1], Jacob Jelsing[1], Niels Vrang[1], Henrik B. Hansen[1], James Trevaskis[2]. [1]*Gubra, Horsholm, Denmark;* [2]*MedImmune, Gaithersburg, United States*
Email: ssv@gubra.dk

Background and aims: The Amylin Liver NASH (AMLN) diet-induced obese C57Bl/6J (DIO-NASH) and ob/ob (ob/ob-NASH) mouse models display clinical translatability with respect to key metabolic and liver pathological changes associated with non-alcoholic steatohepatitis (NASH). A recent FDA ban on trans-fats in foods has prompted the development of a new NASH diet capable of promoting a compatible level of disease, as AMLN diet contains trans-fat-containing Primex shortening. Here, we assessed the metabolic and liver pathological phenotype in C57Bl/6J and ob/ob mice fed a high-fat diet with a nutrient composition and caloric content comparable to the AMLN diet.
Method: Male ob/ob mice were fed AMLN diet (40% total fat kcal of which 18.5% were trans-fat kcal; 20% fructose; 2% cholesterol) for 16 weeks or a modified AMLN diet with Primex substituted by equivalent amounts of palm oil, termed Gubra Amylin NASH (GAN)

diet, for 8-12-16-24-30 weeks. C57 mice were fed GAN diet for 28 weeks.
Results: In ob/ob-NASH mice, the GAN diet was more obesogenic and adipogenic compared to the AMLN diet. GAN, but not AMLN, diet also impaired glucose tolerance in ob/ob-NASH mice compared to chow-fed C57Bl/6J mice. GAN and AMLN diets promoted comparable levels of steatosis, lobular inflammation and hepatocyte ballooning as well as similar fibrotic liver lesions and collagen-1a1 fractional area. Mild (stage F1) and moderate (stage F2) grade fibrosis was induced in DIO-NASH and ob/ob-NASH mice, respectively, when fed AMLN or GAN diet for 16 weeks. When fed GAN diet for ≥ 24 weeks, a significant proportion of ob/ob-NASH mice developed advanced fibrosis (stage F3). Also, the two diets promoted overlapping liver transcriptome changes.
Conclusion: Modification of the AMLN diet by substitution of Primex with palm oil results in a maintained NASH phenotype in C57 and ob/ob mice. Accordingly, the GAN diet induced clear metabolic and histopathological hallmarks of biopsy-confirmed NASH in both DIO-NASH and ob/ob-NASH mice, highlighting the suitability of these models for the characterization of novel drug therapies for NASH.

FRI-355
Elafibranor, a drug candidate for first line NASH monotherapy and a universal backbone for drug combination treatment

Hum[1], Dr. Sophie Mégnien[2], Prof. Bart Staels[3,4,5,6], Prof. Rohit Loomba[7], Prof. Stephen A. Harrison[8], Prof. Vlad Ratziu[9], Arun J. Sanyal[10], Robert Walczak[1]. *[1]GENFIT SA, Loos, France; [2]GENFIT CORP, Cambridge, MA, United States; [3]Inserm U1011, Lille, France; [4]Institut Pasteur De Lille, Lille, France; [5]CHU Lille, Lille, France; [6]EGID, University Lille, Lille, France; [7]NAFLD Research Center, UCSD, Division of Gastroenterology, La Jolla, United States; [8]Pinnacle Clinical Research Center, San Antonio, United States; [9]Pitié-Salpêtrière Hospital, Paris, France; [10]Virginia Commonwealth University, Richmond, United States*
Email: robert.walczak@genfit.com

Background and aims: Elafibranor (ELA), a PPARα/δ agonist, reverses NASH histology and decreases fibrosis in patients with advanced disease [1], and is currently being evaluated in the RESOLVE-IT phase 3 trial. Among other NASH treatment candidates, obeticholic acid (OCA), GS-0976 (GS), selonsertib (SEL) and cenicriviroc (CVC) have complementary actions with ELA.
Aim: to provide experimental evidence for ELA as a universal backbone for drug combination therapies in NASH.
Method: C57Bl/6J mice and Wistar rats were fed a fat and/or cholesterol supplemented choline deficient CDAA diet (modified CDAA) for 8-12 weeks to generate NASH with fibrosis. Histological evaluation was performed in a blinded fashion. NASH was assessed using the NASH Clinical Research Network Scoring System. Fibrosis area was determined by measuring the collagen positive area.
Results: The animals developed a severe NASH phenotype with abundant fibrosis.
Low doses of ELA (1 and 3 mg/kg) decreased NAFLD activity score (NAS) by 1 ($p < 0.0001$) and 2 points ($p < 0.0001$), respectively. Among the other compounds, only GS (10 mg/kg) reduced NAS by 1 point ($p = 0.04$) under conditions used in this study. Combination of ELA with GS (10 mg/kg) or CVC (10 mg/kg) but not with other compounds, improved NAS by 3 points ($p < 0.001$ for both compounds).
Monotherapy with ELA (1 mg/kg), ELA (3 mg/kg), OCA (10 mg/kg), SEL (30 mg/kg) and GS (10 mg/kg) reduced fibrosis area by 24% ($p = 0.0006$), 47% ($p < 0.0001$), 26% ($p = 0.15$), 32% ($p = 0.02$) and 38% ($p = 0.0001$), respectively. Further, OCA and SEL in combination with ELA decreased fibrosis area by 71% ($p < 0.0001$) and 49% ($p < 0.0001$), respectively. The effect of GS on fibrosis was not further potentiated by ELA.
PK studies in rodents did not show any relevant drug-drug interactions with respect to plasma exposure following ELA coadministration with OCA, SEL and CVC. The interaction with GS cannot be excluded and is currently under investigation.
Conclusion: Several NASH front-runner drug candidates can be safely coadministered with ELA in the advanced NASH model. ELA worked in synergy with most of the other candidates to efficiently attenuate fibrosis development despite a significant dose reduction for both drugs. We conclude that ELA is a universal backbone for combination drug therapies in NASH.

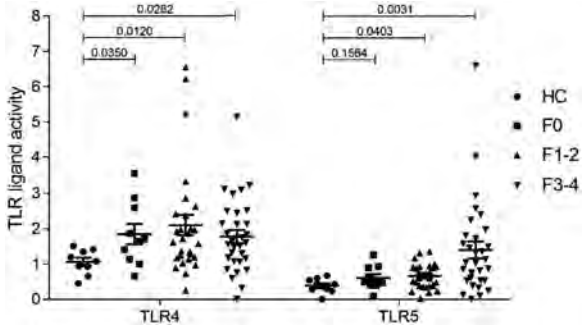
Single cell peripheral innate and adaptive immune signature of non-alcoholic steatohepatitis by cytometry time of flight

Kathryn Waller[1], Anja Versteeg-de Jong[1], Wenhao Li[1], Robert Lowe[2], Polychronis Kemos[3], Wing-Kin Syn[4], William Alazawi[1]. *[1]Barts Liver Centre Blizard Institute, Immunobiology, London, United Kingdom; [2]The Blizard Institute, Genomics and Child Health, London, United Kingdom; [3]The Blizard Institute, Immunobiology, London, United Kingdom; [4]Medical University of South Carolina, Medicine, Strom Thurmond Building, Charleston, United States*
Email: k.j.waller@qmul.ac.uk

Background and aims: Inflammation is a hallmark of non-alcoholic steatohepatitis (NASH). Multiple 'hits' including lipotoxicity trigger inflammatory responses and contribute to disease progression and fibrosis. However, the peripheral immune response to these triggers, particularly in the early stages of disease, has received scant attention to date. We studied the peripheral immune phenotype in patients with NASH to gain novel insights into the pathogenesis of disease.
Method: We isolated peripheral blood mononuclear cells (PBMCs) from 16 patients with biopsy-proven NASH and advanced fibrosis ($n = 8$), mild fibrosis ($n = 8$) and 3 healthy controls. We designed a panel of 36 antibodies conjugated to heavy metals for cytometry by time of flight (CyTOF). To determine the potential of patient plasma to activate Toll-like receptors (TLRs), we used HEK cell lines co-transfected with human TLR4 and 5 genes in combination with an inducible reporter gene. Specific inhibitors of TLR4 (CLI-095) or TLR5 (TH1020) were used in assays of lipotoxicity with a mixture of free fatty acids (palmitic acid/oleic acid, 1mM/2mM).
Results: Principal component analysis of single cell CyTOF data revealed a distinct peripheral immune signature in patients compared to controls that suggested a type 1 immune skew with increased $CD4^+$ Th1 and $CD8^+$ T cell populations. Global expression of TLR5, but not TLR2 or TLR4, was increased in patients with advanced fibrosis compared to those with mild disease or controls ($p = 0.0027$), which we confirmed with conventional flow cytometry. In a separate cohort of 69 patients, plasma TLR4 activity was elevated in both mild and advanced disease compared to controls, but TLR5 activity was only evident in patients with advanced fibrosis. Both TLR4 and TLR5 activity was reduced but not abrogated by pre-treatment with protease K, but not DNase or RNase. To confirm the role of TLR activity in lipotoxicity we pre-treated HepG2 cells with specific inhibitors prior to injury with palmitate/oleate mixture. Fatty acid-induced IL-8 mRNA was reduced by inhibition of TLR5 (1.7-fold, $p = 0.0002$) but not TLR4, although fatty acids themselves did not activate TLR5 in the reporter assay.
Conclusion: Single cell CyTOF shows a distinct immune signature for NASH and a role for TLR5, but not TLR4, in lipotoxicity in NASH. TLR5 is not activated by fatty acids and only partially through protein mediators but other agonists that are likely to play a role are yet to be defined.



FRI-357

Fibrinogen-like protein 2 aggravates non-alcoholic steatohepatitis by enhancing inflammatory signaling in macrophages

Junjian Hu[1], Hongwu Wang[1], Xitang Li[1], Xiaojing Wang[1], Qin Ning[1]. [1]*Tongji Hospital Affiliated to Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China*
Email: qning@vip.sina.com

Background and aims: Fibrinogen-like protein 2 (fgl2), which is critical for immune regulation in inflammatory state, leads to production of proinflammatory cytokines and hepatic injury. This study aims to investigate the role of fgl2 in the pathogenesis of non-alcoholic steatohepatitis (NASH) and to explore the mechanisms.
Method: The wild type and fgl2 (−/-)C57BL/6 mice were subjected to methionine/choline-deficient (MCD) diet or high fat diet (HFD) for establishing NASH models. Fgl2 expression in liver was detected by immunofluorescent staining and western blotting. Hematoxylin-eosin staining and Oil-red staining were performed to detect liver injury and steatosis. ALT, AST, LDH, triglyceride and cholesterol in serum were observed. Bone marrow-derived macrophages were stimulated with LPS or free fatty acids (FFA). The NF-kappa B, p38-MAPK and NLRP3 inflamasome signaling pathways as well as lipid metabolism related molecules were tested both in vivo and in vitro using RT-PCR and western blotting. The levels of proinflammatory cytokines in cell supernatant and homogenate of liver tissues were tested by ELISA.
Results: The hepatic expression of fgl2 was markedly increased in murine models of NASH, this change was associated with enhanced infiltration of macrophages in liver. Compared with WT mice NASH models, inflammatory liver injury and steatosis were dramatically attenuated, in parallel with significant decreases of ALT, AST and LDH in fgl2-deficient test groups. In both liver tissues and bone marrow-derived macrophages from the NASH models, fgl2 deficiency resulted in reduced secretion of proinflammatory cytokines including TNF-alpha, IL-1beta, MCP-1 and IL-6. Meanwhile, activation of NF- kappa B and p38-MAPK signaling pathways as well as expression of NLRP3, pro-caspase-1, caspase-1 and pro-IL-1beta were significantly decreased. Genes involved in lipogenesis (SREBP-1c, HMGCR) were downregulated while those involved in lipometabolism (PPARalpha, PGC-1alpha) were upregulated in fgl2-deficient test groups.
Conclusion: Fgl2 promotes inflammation and steatosis in NASH by enhancing inflammatory activity of macrophages via multiple signaling pathways. Inhibition of fgl2 could effectively attenuate liver injury and steatosis and prevent disease progression of NASH.

Background and aims: Non-alcoholic steatohepatitis (NASH), is the aggressive subtype of fatty liver disease, that is currently palliatively managed by metabolic control. Oxyntomodulin, a natural dual agonist of GLP-1 receptor (GLP1R) and glucagon receptor (GCGR), is central to metabolic controls and prevents NASH in preclinical studies. It is unclear whether the impact on liver is through GLP1R or GCGR agonism. In this study, we intend to evaluate effects of glucagon and GLP-1 on primary hepatocytes procured from NASH and healthy subjects.
Method: Primary hepatocytes from NASH (N = 6) and healthy (N = 5) were treated for 4 hours with liraglutide (GLP1R agonist) and G1437 (GCGR agonist). Gene and metabolite profiling were conducted to identify pathogenesis in NASH, and to differentiate GLP1R and GCGR effects.
Results: Four main pathogeneses were identified in NASH hepatocytes by IPA analysis. Fibrosis (PDGFA, TIMP1, collagen IV) was increased, while the redox reaction (GSTA1, GSTA3) was inhibited in NASH, suggesting enhanced oxidative stress. Hepatocyte health was affected due to the inhibition of LXR/RXR and PXR/RXR in NASH and increased p53 signaling, resulting in cell apoptosis.
After the treatment of liraglutide, gene expression profiles were identical to the vehicle. In G1437 group, 344 genes were altered compared to controls ($\pm$ FC $\geq$ 1.6, p $\leq$ 0.1). Cellular cAMP was not changed by liraglutide, but increased by G1437, suggesting GCGR was activated, but not GLP1R. In IPA analysis, G1437 increased G6PC expression (FC > 5, p < 5e-04) in glycolysis, confirming GCGR activation. Surprisingly, GCGR activation significantly induced Wnt/β-catenin signaling, e.g. TCF7L2 (FC = +1.9, p_{adj} = 1e-7) and cyclin D1 (FC = +1.7, p_{adj} = 3e-5). TCF7L2 is an effector of Wnt signaling. In liver, TCF7L2 plays a central role in Wnt signaling, leading to cell growth and proliferation, and enhanced lipid and amino acid metabolism in hepatocytes. Consistent with proliferation, 6-glucophosphonate and ribose-1 phosphate in pentose phosphate pathway was increased by 2.76-fold and 1.8-fold respectively (p < 0.05), suggesting a shift to pentose-nucleotide biosynthesis in parallel to glycolysis. Metabolites in arginine-urea cycle were increased in hepatocytes (arginine by 1.87-fold, p < 0.05; citrulline by 1.94-fold, p < 0.05). Single nucleotide polymorphisms (SNPs) in TCF7L2 were associated with risk in diabetes (e.g., rs7901695; OR = 1.37, p = 1e-48). The increase in TCF7L2 by G1437 can lead to improved β-cell function, which are beneficial effects of GCGR activation in diabetes control.
Conclusion: Gene expression profiling clearly identified four pathogeneses pathways in NASH hepatocytes. GLP1R agonism does not have direct impact on hepatocytes, while activation of GCGR results in upregulated Wnt signaling and increased TCF7L2, a modulator of hepatocyte homeostasis in liver.

FRI-359

Ductular reaction predicts the progression of non-alcoholic fatty liver disease

Ramy Younes[1,2], Stuart McPherson[2,3], Elisabetta Bugianesi[1], Quentin Anstee[2,3], Dina Tiniakos[2,4], Olivier Govaere[2]. [1]*University of Turin, Department of Medical Sciences, Division of Gastroenterology and Hepatology, Torino, Italy;* [2]*Newcastle University, Institute of Cellular Medicine, Newcastle Upon Tyne, United Kingdom;* [3]*Newcastle upon Tyne Hospitals NHS Foundation Trust, Liver Unit, Freeman Hospital, Newcastle Upon Tyne, United Kingdom;* [4]*National and Kapodistrian University of Athens, Dept of Pathology, Aretaieio Hospital, Athens, Greece*
Email: ramy.younes@unito.it

Background and aims: Ductular reaction (DR), which comprises an expansion of transit amplifying cells of the terminal branches of the

biliary tree, is often seen in advanced NAFLD and is believed to reflect hepatic progenitor cell (HPC) activation. This study aims to investigate the prognostic value of DR/HPCs in NAFLD for NASH development and fibrosis progression.

Method: We included 36 patients with biopsy-proven NAFLD at Freeman Hospital, Newcastle-Upon-Tyne Hospitals, UK, who underwent at least two liver biopsies more than a year apart. The histological semi-quantitative NAS CRN system was used to score steatosis (S0-3), ballooning (B0-2), lobular inflammation (I0-3) and to stage fibrosis (F0-4). HPCs were quantified in the portal/periportal area and parenchyma based on Keratin 19 immunostaining in the baseline biopsies and correlated with clinicopathological features. Parenchymal ductular cells were scored based on acinar zone topography (1-3) and pattern (single cells, ductular structures).

Results: In our cohort, the absolute number of periportal HPCs significantly correlated with elevated AST levels ($p < 0.01$). Moreover, the presence of HPCs into the parenchyma correlated with higher AST ($p < 0.01$), ALT ($p < 0.05$) and with the progressive increase of insulin levels ($p < 0.01$). The small sample size of the cohort did not allow us to highlight a significant association between the absolute number of either periportal or parenchymal HPCs and fibrosis progression or the occurrence of NASH, although a positive trend was reported. Comparing baseline and follow-up liver biopsies (mean time between biopsies 79 months, range 14-198), the presence of ductular structures in the parenchyma of the baseline biopsy was significantly associated with the progression of at least 1 stage of fibrosis (prevalence of 35% in progressors vs 6% in non-progressors, $p < 0.05$). In addition, a significant correlation with the increase of AST and ALT levels was noted (OR 1.028 and 1.026 respectively).

Conclusion: In a cohort of biopsy-proven NAFLD patients with follow-up biopsies, HPCs are associated with biochemical signs of inflammation and higher insulin levels. Moreover, the presence of parenchymal ductular structures predicts disease progression. Due to the lack of a prognostic biomarker for NAFLD, the development of this tool could acquire paramount importance for both stratifying patients at risk at baseline and the design of targeted therapies to patients with high likelihood of disease progression.

FRI-360

The role of Paneth cells in the pathogenesis of non-alcoholic fatty liver disease: A potential gut microbiota-associated mechanism

Saisai Zhang[1], Fen Liu[1], Fung Yu Huang[1], Danny Wong[1], Ching Lung Lai[1], Man-Fung Yuen[1], Wai-Kay Seto[1]. [1]*The University of Hong Kong, Medicine, Hong Kong, Hong Kong*
Email: wkseto@hku.hk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is currently the most common liver disease worldwide. Paneth cells are granulated epithelial cells clustered in the bottom of small intestinal crypts, which secrete a variety of antimicrobial peptides and lysozyme to regulate the commensal gut microbiota. Paneth cell function has been associated with the pathogenesis of chronic liver disease in general, but its specific role in the pathogenesis of NAFLD remains poorly understood.

Method: Eight-week old C57Bl/6J male mice ($n = 20$) were given a high-fat diet (HFD) (60% kcal fat, Research Diets, New Brunswick, NJ) or low-fat diet (10% kcal fat) for 12 weeks. Paneth cell granules were pharmacologically depleted by intravenous dithizone (10mg/kg) treatment for every three weeks. Hematoxylin and eosin (HandE) and Oil Red O staining were used to visualize the lipid accumulation in the liver. The fecal samples were collected to extract metagenomic DNA (QIAGEN, Hilden, Germany). PCR-Based Denaturing Gradient Gel Electrophoresis (Bio-Rad, Hercules, California) and principal component analysis (PCA) were used to compare the differences in microbial structure.

Results: The relative lysozyme level in the small intestine was significantly decreased in dithizone treated HFD mice when compared to those without ($30.02\% \pm 4.01$ vs. no decrease, $p = 0.0075$). Dithizone treated HFD mice, when compared to non-dithizone treated HFD mice, had a borderline significant increased body weight loss ($42.21g \pm 2.90$ vs. $48.95g \pm 0.70$, $p = 0.0864$), a significant reduction both in liver mass gain ($1.2g \pm 0.14$ vs. $1.94g \pm 0.02$, $p = 0.0007$) and hepatic lipid accumulation (steatosis grade $20.73\% \pm 9.71$ vs. $70.52\% \pm 4.09$, $p = 0.0115$). In dithizone treated HFD mice, the relative mRNA level of tight junction gene zonula occludens-1 (ZO-1), a marker of gut permeability, was significantly higher than that in non-treated HFD mice ($36.10\% \pm 7.88$ vs. $1.75\% \pm 0.87$, $p = 0.0493$). A PCA plot based on DGGE profile confirmed a clear separation between dithizone and non-dithizone treated HFD groups, which two principal components (PC1) and PC2 contributed 57.889% and 34.939% to the total variability respectively. The abundance of *Bacteroides thetaiotaomicron* in dithizone treated HFD mice was doubled compared to non-dithizone treated HFD mice, with a trend towards significance ($150.30\% \pm 23.25$ vs.$75.93\% \pm 7.87$, $p = 0.0939$).

Conclusion: Depletion of Paneth cell granule ameliorates the severity of NAFLD, which may involve a gut microbiota-associated mechanism and alterations in intestinal permeability. Further metagenomic sequencing may identify specific microbiota profiles associated with the disease process of NAFLD.

Liver transplantation and hepatobiliary surgery: Clinical aspects

FRI-361

Impact of cardiovascular complications on patients' outcome after orthotopic liver transplantation

Jan Zabel[1], Niklas Aehling[1], Adam Herber[1], Dr. Sebastian Rademacher[2], Robert Sucher[2], Daniel Seehofer[2], Thomas Berg[1], Cornelius Engelmann[1,3]. [1]*University Hospital Leipzig, Section Hepatology, Department of Gastroenterology and Rheumatology, 04103 Leipzig, Germany;* [2]*University Hospital Leipzig, Department of Visceral, Vascular, Thoracic and Transplant Surgery, 04103 Leipzig, Germany;* [3]*University College London, Institute for Liver and Digestive Health, London, United Kingdom*
Email: niklas.aehling@medizin.uni-leipzig.de

Background and aims: Long-term complications after orthotopic liver transplantation (OLT) majorly impact on patients' outcome. However, data evaluating specifically the role of cardiovascular complications is sparse. Therefore, we conducted a retrospective single center study to investigate its frequency and its effect in liver transplant recipients.

Method: Out of 424 patients, who were transplanted between 2000 and 2009 at the University Hospital Leipzig, 343 patients with cirrhosis±hepatocellular carcinoma could be included. Epidemiological and clinical data were obtained retrospectively from patients' records. Cross-sectional and longitudinal analyses including multivariate Cox-regression analyses were applied.

Results: Out of 343 patients 204 (59.5%) were men and the main indication for OLT was alcoholic liver disease. In total 62 (18.1%) patients were transplanted with HCC. The median age was 52 (19-73). In total 106 patients (30.9%) had a cardiovascular disease (CVD) before OLT, most commonly arterial hypertension (AHT) ($n = 97$, 91.5%). Patients with CVD were older (54.6 vs. 50.0 years; $p < 0.001$) and had a higher BMI ($27.8\ kg/m^2$ vs. $26.1\ kg/m^2$; $p = 0.005$). Diabetes mellitus was more common amongst patients with previous CVD (47.4% vs. 18.1%, $p < 0.001$). After transplantation 40.5% (139) patients incurred new cardiovascular events (figure 1), again most frequently AHT ($n = 91$, 51.7%).

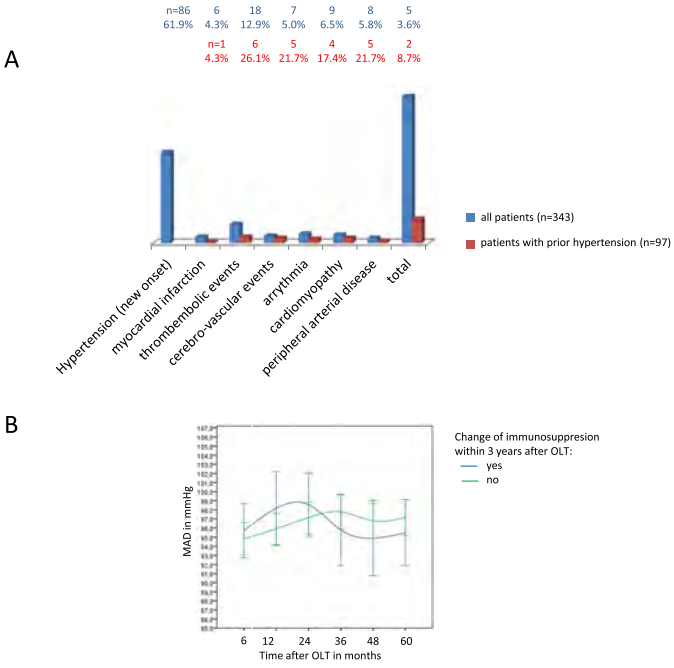

Figure: A: Cardiovascular complications after OLT listed for the overall cohort and patients with arterial hypertension before OLT. B: Absolute MAP in mmHg of patients with a change of immunosuppression (blue) and patients without change of immunosuppression (green) within 3 years after OLT.

28.6% of all patients died during the follow-up, of which 10.2% died of cardiovascular events. Patients' survival after transplantation with previous cardiovascular diseases, notably AHT, was significantly lower (112.2 vs. 148.4 months; p = 0.001). In long-term follow-up (>24 month) patient with new CVD had a trend towards a reduced survival time (171.3 vs. 184.2 month, p = 0.146).
The initial standard immunosuppression was based on calcineurin inhibitors (92.4%) ± mycophenolate (MMF; 67.3%). Patients, who were treated with MMF, had a trend towards lower prevalence of arterial hypertension (65% vs. 50%, p = 0.081). After switching the immunosuppression to an mTOR-inhibitor based regime (29.7% of all patients at year 5) there was a trend (delta MAP) in blood pressure compared to patients with standard CNI-based immunosuppression (p = 0.053).
Conclusion: Cardiovascular diseases have a significant impact on the outcome of patients after liver transplantation and are associated with metabolic complications. mTOR-inhibitors have the potential to be of benefit for patients with arterial. Whether this can be translated into an improved outcome should be the matter of future research.

FRI-362
Exercise training for liver transplant candidates

Bandar Aljudaibi[1], Roberto Hernandez-Alejandro[1], Ibrahim Alqalami[2], Michael Sey[2], Karim Qumosani[2], Paul Marotta[2], Natasha Chandok[3], Nancy Howes[4], Anouar Teriaky[2]. [1]*University of Rochester and London Health Sciences Centre, Rochester, United States;* [2]*London Health Sciences Centre, Solid organ Transplant, London, Canada;* [3]*Brampton, Osler Hepatitis Centre, Brampton, Canada;* [4]*Western University, Physical Therapy department, London, Canada*
Email: bandaraljudaibi@gmail.com

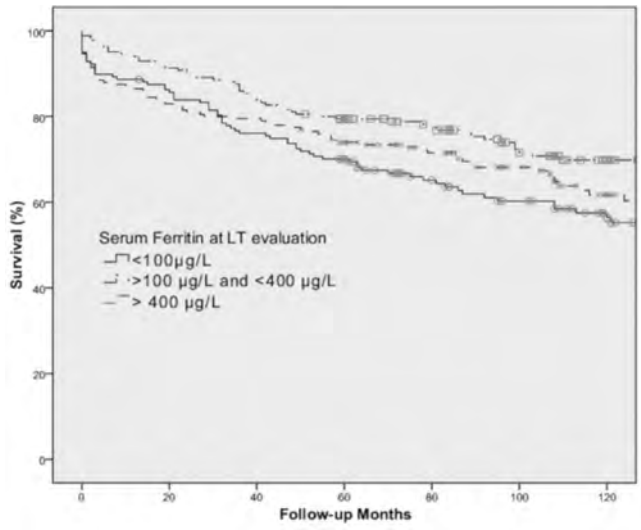
Background and aims: Frailty is associated with increased morbidity and mortality, as these are tightly linked to decompensation and increased complication rates among liver transplant (LT) candidates. The aim of the study was to evaluate the efficacy of structured in- and outpatient exercise training program for cirrhotic patients who were referred for liver transplant evaluation.
Method: We retrospectively reviewed 472 consecutive LT patients between 2007 and 2016 at our centre. There were 208 patients who underwent LT prior to the implementation of the exercise training program (non-ETP) and 264 LT patients who underwent a comprehensive exercise training program (ETP) from 2012 and forward. Baseline characteristics, readmission rate, length of hospital stay (LOS), and post-operative LT complications were analyzed and compared between the two groups.
Results: The mean age for the ETP group was 56.3 compared to 53.2 in the non-ETP group (p = 0.0006). The mean indication for liver transplant in the ETP was liver tumor (34.1%) compared to viral hepatitis in the non-ETP group (p < 0.001). The ETG group had more comorbidities compared to the non-ETG group, (diabetes mellitus; 20.7% vs 35.4%, p < 0.0001, coronary artery disease; 20.7% vs 35.4%, p < 0.001). The remaining baseline characteristics were not significant different between the two groups. In addition, there was no significant difference in the post-operative complications between the two groups except for a higher rate of infection in the ETP group compared to the non-ETP group (18.3% vs 7.7%, p = 0.001). LOS and 90-day readmission rate were lower in the ETP compared to the non-ETP (LOS; 14 vs 17 days, readmission rate; 17.5 vs 19.7%). However, the results were not statistically significant.
Conclusion: In this study, there was a trend towards shorter length of hospital stay and reduced 90-day readmission rate in the exercise training program group compared to the non-exercise training program group. Further studies are required to validate the result.

FRI-363
Iron metabolism imbalance is associated with increased mortality following orthotopic liver transplantation

Fallet Elodie[1], Rayar Michel[1], Camus Christophe[1], Houssel-Debry Pauline[1], Jezequel Caroline[1], legros Ludivine[1], Uguen Thomas[1], Robert-Bouchet Martine[1], Boudjema Karim[1], Guyader Dominique[1], Edouard Bardou-Jacquet[1]. [1]*CHU Rennes, Rennes, France*
Email: elodiefallet@yahoo.com

Background and aims: Liver transplantation (LT) is the best treatment for patients with end-stage liver disease. However there is a need for identification of factors associated with post-transplant mortality that could improve patient management. Results regarding the impact of iron metabolism in this setting are discrepant. The aim of our study was to evaluate in a large retrospective cohort the impact of pre-transplant iron metabolism markers on post-transplant survival.
Method: From 2001 to 2011, 553 patients who underwent LT between in our center with iron metabolism parameters available at LT evaluation were included. Data were prospectively recorded at the time of evaluation and at the time of LT. Follow- up data were obtained from local and national database.
Results: Median age at evaluation for LT was 55 [49-60.5] years. They were preferentially men (74.9%) with alcoholic related liver disease (61.5%). Hepatocellular carcinoma was present at evaluation in 214 patients. The median SF was 241[75.5-593.5] µg/L, 168 patients had SF < 100 µg/L and 200 had SF > 400 µg/L. The median TS was 43.6% [25.1-74.5] with 24.6% of patients having a TS higher than 75%. Median MELD was 15.1[10.6-20.7]. At the end of a 95 months follow-up 196 patients were dead, 38 because of infections. In multivariate analysis, overall survival was significantly associated with Transferrin Saturation (TS) > 75% (p = 0.007), Serum Ferritin (SF) (p = 0.005), hepatocellular carcinoma (p = 0.004), estimated glomerular filtration rate (CKD EPI Cystatin C equation) (p = 0.01), intensive care unit length of stay (p = 0.001) and number of packed red blood cell transfusion during surgery (p < 0.001). Kaplan Meier survival curves showed that patients with low SF (< 100 µg/L) and high SF (> 400 µg/L) have a lower survival than patients with normal SF, and show that TS > 75% was associated with an increased mortality at 6 months (p = 0.012) and at 12 months (p = 0.039). Increased TS (p = 0.042) and low SF (p = 0.015) were significantly associated with infection related

death. Neither TS nor SF were associated with higher risk of infection or pneumonia within 3 months after LT.



Conclusion: Our results show that imbalance in iron metabolism is significantly associated with post-transplant sepsis related mortality and overall mortality.

FRI-364

Frequency and impact of discordance between pre-transplant imaging and explant histology on post liver transplant outcomes for patients with hepatocellular carcinoma

Amine Benmassaoud[1], Giulia Quartini[1], Aileen Marshall[1]. [1]*The Royal Free Sheila Sherlock Liver Centre, Royal Free Hospital, Royal Free London NHS Trust, Hepatology, London, United Kingdom*
Email: amine.benmassaoud@mail.mcgill.ca

Background and aims: Hepatocellular carcinoma (HCC) is a major cause of morbidity and mortality in patients with chronic liver diseases. Eligibility for transplant is usually determined using pre-transplant imaging, however this may not stage disease accurately. The aim of this study was to evaluate concordance between pre-transplant radiology and explant histology, seeking to identify any impact of lack of concordance on post transplant outcome.
Method: We conducted a single center retrospective cohort study of patients who were transplanted for HCC at the Royal Free Hospital, London, UK, between January 1st, 2016 and April 31st, 2018. We assessed factors associated with lack of concordance between Milan Criteria (MC) at last imaging and explant pathology, and its impact on post-transplant outcomes.
Results: During our study period, 63 patients were transplanted for HCC. The median age at diagnosis was 60.6 (interquartile range [IQR], 8.1) years, 84.1% of cases were male, and the most common cause of liver disease was Hepatitis C Virus (41.5%). Imaging alone was the method of HCC diagnosis in 82.5% of patients, using MRI in 61.9%. Overall, 82.5% of patients received pre-transplant bridging therapy, with transarterial chemoembolization being the most common modality in 75.5%. Furthermore, time to first bridging therapy was 2.4 (IQR 2.4) months, while time from HCC diagnosis to transplant was 10.4 (IQR 8.5) months. Based on explant pathology, 54.8% of patients were within MC, compared to 93.5% at diagnosis ($p < 0.001$), and 95.2% at last imaging pre-OLT ($p < 0.001$). There was no difference between MC at diagnosis and at last imaging ($p = 1.000$). Discordance between MC based on explant pathology and last imaging occurred in 25 (40.3%) patients. Factors predicting discordance included total number of nodules at last imaging ($p = 0.002$), the total number of diagnostic HCC nodules at last imaging ($p = 0.015$), and older age ($p = 0.029$). Type of imaging modality, use of bridging therapy, type of bridging therapy, and time interval between imaging and OLT were not associated with presence of discordance. The 12-month survival was 91%, and 2-year survival was 87%. There was one recurrence, with one recurrence-related death. Discordance between radiology and pathology MC had no definite impact on short-term post-OLT survival (log-rank, $p = 0.119$) or recurrence (log-rank, $p = 0.207$). On multivariate cox regression analysis, explant total number of HCC was predictive of worse survival (HR1.66, $p = 0.008$), as well as longer duration from diagnosis to OLT (HR1.12, $p = 0.057$)-but not last number of diagnostic HCC at last imaging.
Conclusion: Discordance between MC at last imaging and explant pathology was frequent. Although follow-up was short, this discordance does not predict worse survival, where as explant total number of HCC nodules did.

FRI-365

Efficacy of combined partial hepatectomy and cyst fenestration on health-related quality of life in polycystic liver disease

Lucas H.P. Bernts[1], Myrte Neijenhuis[1], Marie E. Edwards[2,3], Rory L. Smoot[4], David M. Nagorney[4], Joost Ph Drenth[1], Marie C. Hogan[2,3]. [1]*Radboudumc, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands;* [2]*Mayo Clinic, Division of Nephrology and Hypertension, Rochester, MN, United States;* [3]*Mayo Clinic, Robert M. and Billie Kelley Pirnie Translational Polycystic Kidney Disease Center, Rochester, MN, United States;* [4]*Mayo Clinic, Department of Surgery, Rochester, MN, United States*
Email: lucas.bernts@radboudumc.nl

Background and aims: Polycystic liver disease (PLD) is a progressive hereditary condition which can result in severe and symptomatic hepatomegaly in a proportion of patients. We investigated symptom relief and improvement of health-related quality of life after combined partial hepatectomy and cyst fenestration in a cohort of individuals with moderate to severe PLD.
Method: We performed a prospective study between November 2014 and May 2018 at a referral center in the United States (Mayo Clinic, Rochester MN). Patients received a questionnaire before surgery and six months after surgery. Total liver volume was measured where post-operative imaging was available. Primary end point was change in symptoms six months after surgery, measured with the PLD Questionnaire (PLD-Q). Change in symptoms was defined as clinically relevant when decrease in score was larger than the Minimal Clinically Important Difference (MCID), defined as half the standard deviation of the mean change in score. Secondary end point was change in quality of life, measured with the 12-Item Short Form Survey (SF-12), and the EuroQoL Visual Analogue Scale (EQ-VAS). All questionnaire scores range from 0 to 100. Complications were scored according to the Clavien-Dindo classification (grade 1 to 5).
Results: Of 17 eligible patients, 16 (94%) were included (mean age 52 years, 81% female). Surgery reduced median liver volume from 4917 ml (IQR: 3680-6400) to 2120 ml (IQR: 1755-2533), corresponding to a median reduction of 58% (IQR: 45-67%) for 12 patients. PLD-Q assessed symptoms decreased from 76.9 (IQR: 41.0-83.0) at baseline to 34.8 (IQR: 17.0-43.8) six months after surgery ($p = < 0.001$). The MCID was −16.5, resulting in a clinically relevant response in 9/13 (69%) patients. Physical Component Scale of SF-12 improved from 24.9 (IQR:17.4-26.5) to 45.7 (IQR: 34.6-55.3) ($p = 0.004$), while SF-12 Mental Component Scale increased from 40.5 (IQR: 25.9-59.0) to 55.4 (IQR: 50.8-58.9) ($p = 0.02$). EQ-VAS increased from 40.0 (IQR:36.8-48.8) to 72.5 (IQR: 63.3-92.3) ($p = 0.003$). Minor post-operative complications (grade 1 or 2) occurred in 8 patients (50%), major complications (grade 4) in 2 patients (13%). There was no procedure-related mortality.

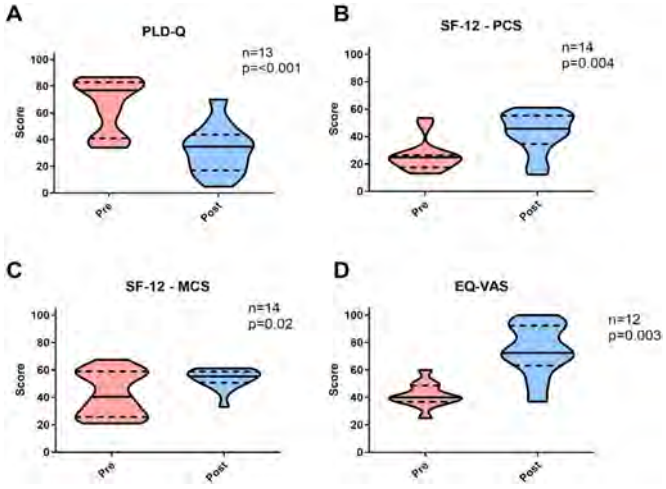


Figure: Patient-reported outcomes pre-surgery and six months post-surgery. Violin plots show the distribution of scores, median (solid line) and inter-quartile range (dashed lines) are superimposed. **Panel A** shows changes in polycystic liver disease questionnaire (PLD-Q) score. **Panel B and C** show changes in the physical component scale (PCS) and mental component scale (MCS) of the 12-Item Short Form Survey (SF-12) questionnaire. **Panel D** shows changes in EuroQol-Visual Analogue Scale (EQ-VAS) score.

Conclusion: Combined partial hepatectomy and cyst fenestration is effective in reducing symptom burden and substantially improved quality of life in selected patients with highly symptomatic PLD.

FRI-366

Portal vein thrombosis in patients on the waiting list for liver transplantation: A single center cohort study

Josephine Bert[1], Anja Geerts[1], Aude Vanlander[2], Luis Abreu De Carvalho[2], Frederik Berrevoet[2], Roberto Ivan Troisi[2], Xavier Rogiers[2], Hans Van Vlierberghe[1], Verhelst Xavier[1,1]. *[1]Ghent University Hospital, Gastroenterology and Hepatology, Gent, Belgium; [2]Ghent University Hospital, General and hepatobiliary surgery, Gent, Belgium*
Email: xavier.verhelst@uzgent.be

Background and aims: Portal vein thrombosis (PVT) is a well-recognized complication of end-stage liver disease. However, current literature is still inconclusive about its impact on the clinical course in liver transplant candidates.
The aim of this study was to identify the prevalence of and the risk factors for PVT, to assess the usefulness of anticoagulant therapy and to determine the impact of thrombosis as well as anticoagulation on postoperative outcomes, patient and graft survival.
Methods: We performed a single center retrospective cohort study in an expert liver transplant unit. Patient receiving liver transplantation between January 2006 and June 2016 were included. Relevant demographic, clinical and outcome data were retrieved from the medical records. For analysis, patients were stratified in two groups according to presence of PVT. Univariate and multivariate logistic regression analysis and survival analysis were performed.
Results: During the study period 390 adult patients underwent orthotopic liver transplantation. In 40 patients (10, 26%) PVT was diagnosed. In respectively 10 (2, 56%), 7 (1, 79%) and 23 (5, 9%) patients, the thrombus was identified at time of evaluation for transplantation, during waiting time and at time of transplantation. Among the 37 (9, 49%) cases who still had PVT at the time of transplantation, 20 (54, 05%) showed partial and 17 (45, 05%) showed complete thrombosis. In a multivariate analysis, body mass index (p = 0, 006; OR 1, 1; 95% CI: 1, 028-1, 177), previous treatment of portal hypertension (p = 0, 001; OR 3, 59; 95% CI: 1, 681-7, 671) and a history of encephalopathy (p = 0, 007; OR 2, 86; 95% CI = 1, 332-6, 142) were independently associated with the occurrence of PVT. A beneficial trend was present favouring the use of anticoagulation towards the accomplishment of recanalization (n = 3/7 versus 0/9; p = 0, 062). In the anticoagulated patients, only one mild bleeding episode (14, 3%) occurred. Operation time was increased (p = 0, 001) in patients where the thrombus was discovered incidentally during surgery. Length of stay was increased (p = 0, 012) in the presence of PVT. Patient and graft survival rates were similar between the groups with and without portal vein thrombosis after 5 year of follow-up. However, 1-year patient survival was significantly lower (p = 0, 031) in patients with PVT. Variables independently associated with the risk of 1-year and overall patient mortality included respectively the presence of portal vein thrombosis (p = 0, 032) and male gender (p = 0, 023).
Conclusion: PVT occurred in 10% of patients awaiting liver transplantation and had a deleterious effect on one year survival after liver transplantation. Anticoagulation is safe and showed a beneficial trend on recanalization of PVT and on the one year survival rate.

FRI-367

Pre-liver transplant profile of cardiovascular risk factors and its impact on early post-transplant outcome

Silvia Martini[1], Alessandra Risso[1], Elena Mosso[1], Federica Calvo[1], Claudia Chialà[1], Francesco Tandoi[2], Walter Grosso Marra[3], Angelo Panio[4], Antonio Ottobrelli[1], Giorgio Maria Saracco[1], Renato Romagnoli[2], Bruna Lavezzo[4]. *[1]Gastrohepatology Unit, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy; [2]Liver Transplant Center and General Surgery 2U, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy; [3]Cardiology Unit, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy; [4]Anesthesia and Intensive Care Unit 2, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, Italy*
Email: sivima21@hotmail.com

Background and aims: There are limited data about the optimal strategy of cardiovascular (CV) risk assessment during liver transplant (LT) candidate workup. We aimed to evaluate CV risk profile and its correlation with early post-LT cardiac events.
Method: We included 555 adult patients (pts) who consecutively underwent a first LT for cirrhosis at our Centre between January 2013 and December 2017, with a graft from brain-dead donor. CV risk factors (RF) were collected.
Pre-LT cardiac workup included electrocardiogram (ECG) and echocardiography (ECHO). Non-invasive stress testing was performed in pts with ≥ 1 CV RF. We recorded adverse cardiac events within 30 days post-LT.
Results: 78.2% were male; median LT age 56 years (y) [interquartile, IQR, 51-61]; median body mass index 25.3 kg/m^2 [23.2-27.8]. 47.4% affected by virus-related cirrhosis, 15.0% alcohol-induced, 11.5% alcohol+virus, 7.6% immune mediated, 4.1% NASH, 1.3% genetic haemochromatosis and 13.1% mixed etiology. Median time between listing and LT: 66 days [28-150]. Median MELD at LT: 14 [9-19], and 55.5% affected by hepatocellular carcinoma.
CV RF: 21.3% 60-64 y-old age, 11.7% ≥ 65 y; 8.8% body mass index > 30 Kg/m^2; 33.3% smoking abuse; 14.2% mellitus diabetes requiring insulin; 6.8% hyperlipidemia; 20.7% arterial hypertension; 0.7% ischemic heart disease (2 pts with coronary artery stent); 0.9% stroke/ischemic attack; 0.2% dialysis, 0.9% creatinine > 2 mg/dL.
26.3% of the pts had 0 CV RF; 42.7% 1 RF, 19.3% 2 RF, 8.8% 3 RF, 2.5% 4 RF and 0.4% 5 RF.
ECG showed ischemic changes in 1.1% and chronic atrial fibrillation in 0.4% of the pts.
ECHO showed: 96.6% with ejection fraction ≥ 55% and 96.4% with normal/stage 1 diastolic dysfunction.
44.7% of the pts underwent non-invasive stress testing (dobutamin/dipyridamole ECHO or myocardial scintigraphy), which was positive in 1.1% of the pts; all of them underwent coronary angiography which did not show coronary disease.
2 pts underwent pre-LT transcatheter aortic valve replacement for severe aortic stenosis.

4 pts were on successful vasodilator therapy for porto-pulmonary hypertension.
Within 30 days post-LT: 13 pts (2.3%) died, 1 of them for CV event (right heart failure in pt with pre-LT porto-pulmonary hypertension, on specific therapy); 12 pts (2.2%) underwent re-LT; *de novo* CV events (16 atrial fibrillation, 6 ventricular tachycardia/pulseless electrical activity, 1 ischemic heart disease, 2 cardiac failure, 1 Takotsubo syndrome, 1 pulmonary hypertension and 2 pulmonary edema) occurred in 27 pts (4.9%) who had a median number of CV RF of 1 *vs.* 1 in the 528 pts without post-LT CV events (p = 0.38, *t-test*).
None of the CV RF was significantly associated with early post-LT CV events.
Conclusions: Our 555 LT pts had a median number of 1 CV RF pre-LT. Within 30 days from LT, CV events occurred in only 4.9% of them and 1 pt died of heart failure. The number of pre-LT CV RF did not correlate with early post-LT CV outcome.

FRI-368
Clinical analysis of emergency liver transplantation in patients with high MELD score
Ho Joong Choi[1], Gun Hyung Na[2], Bong Jun Kwak[1]. [1]*Seoul St. Mary's hospital, The Catholic University of Korea, Surgery, Seoul, Korea, Rep. of South;* [2]*Bucheon St. Mary's hospital, The Catholic University of Korea, Surgery, Bucheon, Korea, Rep. of South*
Email: hopej0126@gmail.com

Background and aims: In general, patients with a high model for end-stage liver disease (MELD) score have a poor prognosis before and after liver transplantation. The current allocation system is based on the MELD score in emergency liver transplantation. Therefore, the mortality rate after liver transplantation in high MELD patients is an important consideration in future liver allocation system. This study was performed to identify poor prognostic factors and mortality rates in patients with high MELD score.
Method: From September 2001 to December 2017, living donor liver transplantation (LDLT) and deceased donor liver transplantation (DDLT) were performed in 851 and 157 patients in our center, respectively. The 81 patients with MELD score of 35 or more were analyzed. We divided 81 patients into postoperative survival group (POS) and postoperative mortality (POM) group. To assess the risks associated with high MELD score, we evaluated various preoperative and operative factors.
Results: Of the 81 patients, LDLT was performed in 49 (60.5%) patients and DDLT in 32 (39.5%) patients. Overall survival rates at 1, 3, and 5 years in 81 patients were 72.4%, 67.3%, and 67.3%, respectively. The POS group was 63 (77.8%) and the POM group was 18 (22.2%). In univariate analysis, the mean age of the POM group was higher (p = 0.028), the mean MELD score was higher (p = 0.045), the proportion of intubated patients was higher (p < 0.001) and the proportion of positive culture was higher (p = 0.042). There were more patients with mental status above stupor (p = 0.014). In multivariate analysis, age [p = 0.006, Exp (B) = 1.118], intubation status [p = 0.042, Exp (B) = 6.073], and culture positive [p = 0.036, Exp (B) = 5.218] were significant.
Conclusion: In patients with high MELD score, the 3-year and 5-year survival rates are not significantly deteriorated unless initial post-operative mortality is achieved. And the prognosis was poor in patients with old age, preoperative intubation or positive culture.

FRI-369
The role of adipose tissue in metabolic and cardiovascular complication after liver transplantation
Daria D'ambrosio[1], Nicoletta Fabrini[1], Daniele Tavano[1], Francesca Di Sario[1], Barbara Lattanzi[1], Vincenza Di Gregorio[1], Francesca Aprile[1], Manuela MERLI[1]. [1]*Gastroenterology Unit La Sapienza, ROMA, Italy*
Email: daria.damb@gmail.com

Background and aims: Metabolic and cardiovascular complications are an important burden in patients after liver transplantation (LT), for many reasons such as immunosuppressive therapy. Adipose mass is an independent predictor of morbidity in general populations; little is known in transplant setting. Therefore, the aim of this study is to evaluate the role of adipose mass at the time of LT, in the outcome for morbidity and mortality.
Method: We enrolled 173 patients (116 male and 56 female), liver transplanted for end-stage liver disease from 2000 to 2015. Nutritional assessment before LT was detected by the analysis of CT scan (L3-L4 slice), obtaining the area (cm2) of visceral, subcutaneous and intramuscular adipose tissue; we indexed them by height, getting SAT (for subcutaneous adipose tissue), VAT (for visceral adipose tissue) and IAT (for intramuscular adipose tissue).
Results: The most common cause of transplantation was viral hepatitis (43%), followed by alcohol disease (16%) and NASH (13%). At the time of LT, 42% of patients were obese or overweight according to BMI (corrected for ascites); 10% had cardiovascular diseases before LT (myocardial infarction, cerebral stroke, hemodynamically significant stenosis to major arterial vessels), 26% diabetes mellitus and 17% arterial hypertension.
After LT, there was a significant increase in cardiovascular complications (39%, vs. 10%; p = 0.03), diabetes mellitus (45%, vs. 26%; p = 0.02) and arterial hypertension (51% vs. 17%; p < 0.01).
Total fat area, IAT and SAT detected by CT scan before transplantation correlate significantly with the increase of cardiovascular complication after LT (p < 0.01), also in multivariate analysis (p < 0.01).
There were no correlations between fat and arterial hypertension or diabetes mellitus. Furthermore, adipose tissue did not play a role in mortality after LT.
BMI before transplantation, however, does not correlate with the increase in cardiovascular and metabolic complications after LT.
Conclusion: Patients after LT have increased metabolic and cardiovascular complications. Adipose tissue in CT before transplantation plays a fundamental role and correlates with the increase in cardiovascular complications, more than BMI, but not with mortality after LT. This could be useful in identifying patients at risk and in performing preventive treatments.

FRI-370
Application of an extended-release tacrolimus formulation allows dose reduction and stabilizes graft function after liver transplantation
Alexandra Frey[1], Fuat Saner[2], Anne Hörster[3], Heiner Wedemeyer[3], Kerstin Herzer[2]. [1]*Gastroenterology and Hepatology, Essen, Germany;* [2]*University Hospital Essen, General, Visceral- and Transplantation Surgery, Essen, Germany;* [3]*University Hospital Essen, Gastroenterology and Hepatology, Essen, Germany*
Email: alexandra.frey@uk-essen.de

Background and aims: Immunosuppressive (IS) regimens after liver transplantation (LT) are in general based on the Calcineurin Inhibitor (CNI) Tacrolimus (Tac), however, its low bioavailability can be a problem. Bioavailability of the extended-release Tac formulation Envarsus® (ENV) is about 40% higher than that of the rapid-release Tacrolimus, Prograf®, allowing a dose reduction of up to 30%. Reduction in dose and, thus, in adverse events can be anticipated. This analysis examines the tolerability of Envarsus®, with the extended-release formulation of Tacrolimus, in a large real-world cohort post LT.
Method: Clinical and laboratory data from 170 patients who were switched to an ENV-based regimen at our center, was collected retrospectively and statistically analysed. Currently, all patients have reached an observation period of 6 months.
Results: The most frequent reason to administer ENV was the intention to reduce nephro- and neurotoxic CNI effects. Liver values (GOT 21 (8-534) U/L, GPT 22 (8-190) U/L, GGT 25 (7-660) U/L, bilirubin 0.2 (0.1-2.2) mg/dL) and renal function (S-creatinine 1 (0.55-1.57) mg/dL) of all patients remained stable 6 months after the start of application. Sleep, concentration and tremor disorders improved in

all patients after conversion. In 47% of patients who were determined as fast Tac metabolizers (n = 83), the ENV dose could be reduced up to 25% (P ≤ 0.003). IS with ENV had to be discontinued in only 7% (n = 12) of the patients.
Conclusion: ENV has no negative impact on liver and kidney function. In approximately 50% of the fast metabolizers the daily Tac dose could significantly be reduced upon switching to ENV, thus decreasing the risk of side effects and better tolerability in the long-term course.

FRI-371
Correlation between classification of circulating tumor cells in peripheral blood and early recurrence in patients with hepatocellular carcinoma after liver transplantation
Binsheng Fu[1], Qing Yang[1], Shuhong Yi[1], Yi Zhang[1], Xiaomei Zhang[1], Yunliang Xie[1], Yang Yang[1], Guihua Chen[1]. [1]*The Third Affiliated Hospital of Sun Yat-sen University, Liver transplantation Center, Guangzhou, China*
Email: andyfu79@163.com

Background and aims: To investigate the detection and subtype identification of circulating tumor cells (CTC) in peripheral blood of patients with hepatocellular carcinoma, and to analyze the correlation with early recurrence after liver transplantation.
Method: A total of 25 recipients of liver transplantation for hepatocellular carcinoma were were enrolled in this study from January 2016 to January 2017. Extrahepatic tumor metastasis had not been found before 1iver transplantation by imaging examination, and the primary disease was diagnosed after liver transplantation by pathological examination. The CanPatrolTM CTC second generation capture technique combined with RNA in situ hybridization (RNA-ISH) was used to detect preoperative and postoperative peripheral blood CTC in patients undergoing liver transplantation. And the expression of related markers is classified and identified according to Epithelial-mesenchymal transition (EMT). Tumor recurrence and metastasis were recorded during follow-up.
Results: Of the 25 recipients, 3 patients (12%, 3/25) were negative for peripheral blood CTC before liver transplantation, and 22 (88%, 22/25) were positive. CTC has not been detected in peripheral blood of healthy volunteers. Univariate analysis showed that the total number of CTCs and the proportion of interstitial CTCs were closely related to the TNM stage of hepatocellular carcinoma and the degree of tumor differentiation. During follow-up, 8 of the 25 recipients relapsed (8 were positive for all CTCs, 7 of which were positive for interstitial CTC). The Cox risk ratio model showed that the number of interstitial CTCs could be used as an independent prognostic factor for predicting tumor recurrence after liver transplantation in patients with hepatocellular carcinoma. The recurrence time of interstitial CTC ≥ 1 was significantly earlier than that of interstitial CTCs ($p < 0.05$). The majority of CTC patients (19/25) had a decrease in the total number of CTCs after transplantation, but the proportion of peripheral blood CTC (6/8) in patients with postoperative tumor recurrence increased compared with the preoperative. Patients with an increased proportion of interstitial CTC after surgery had a shorter recurrence time than patients with a decreased (or constant) proportion of interstitial CTC.
Conclusion: The positive rate of CTC in peripheral blood of patients with hepatocellular carcinoma is high. The preoperative high CTC or high interstitial CTC ratio and the increase of postoperative interstitial CTC ratio are prone to tumor recurrence and interstitial type. CTC has stronger invasiveness and metastatic potential. Interstitial CTC can be used as an independent indicator to determine the time of tumor recurrence after liver transplantation in patients with hepatocellular carcinoma.

Next generation sequenzing outperforms standard microbiological cultivation for detection of bacteria in the biliary tract in patients with ischemic type biliary lesions and/or anastomotic stricture
Björn Grobe[1], Philipp Solbach[1,2], Freya Wellhöner[1], Friederike Klein[1], Vital Marius[3], Michael P. Manns[1,2], Dietmar H. Pieper[3], Von Hahn Thomas[1,2], Torsten Voigtländer[1], Henrike Lenzen[1,2,4], Benjamin Heidrich[1,2,3]. [1]*Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany;* [2]*Integrated Research and Treatment Center Transplantation (IFB-Tx), Hannover Medical School, Hannover, Germany;* [3]*Microbial Interactions and Processes Research Group, Helmholtz Center for Infection Research, Braunschweig, Germany;* [4]*Department of Gastroenterology and Hepatology, University Hospital Essen, University of Duisburg Essen, Essen, Germany*
Email: grobe.bjoern@mh-hannover.de

Background and aims: Recurrent bacterial cholangitis is a common complication in patients with ischemic type biliary lesions (ITBL) and/or anastomotic strictures (AS) after orthotopic liver transplantation. These patients frequently need antibiotic treatment and endoscopic retrograde cholangiography (ERC) to improve the bile flow. Antibiotic treatment is based on findings in standard microbiological cultivation (SMC) of bile samples. However, cultivations techniques are limited to a subset of bacteria easy to cultivate in human samples. Therefore, the aim of the present study was to evaluate the value of next generation sequencing (NGS) as additional diagnostic tool in patients with ITBL and/or AS compared to SMC.
Method: We sequenced the V1-2 region of the rRNA gene in stored bile samples of 242 patients with ITBL and/or AS on the Illumina MiSeq platform. Furthermore, in about one half of the patients SMC was performed (n = 135/56%).
Results: In patients with SMC performed, ERC revealed more often gallstones (27.1% vs. 39.3%; $p = 0.047$). Furthermore, stenosis were more often dilatated (69.2% vs. 82.2%; $p = 0.017$). These patients received more often antibiotic treatment before ERC (41.1% vs. 67.9%; $p < 0.001$) and had significantly higher cholestasis parameter (AP, $p = 0.007$ and GGT, $p = 0.001$). In patients with SMC results available, NGS, with a cut-off of at least 1% of relative abundance of detected genera, performed significantly better in detecting bacterial genera in bile samples than SMC (2.3 ± 1.2 vs. 6.9 ± 3.6; $p = 1.3^{*}10\text{-}32$). The discovery rate, defined as the total relative abundance in NGS of genera also detected in SMC, showed high variations with discovery rates ranging from 0.1% to 99.6%. Except of antibiotic treatment (62.6% vs. 91.7%; $p = 0.006$) only cholinesterase was associated with high discovery rates (> 80%) of SMC. Finally, NGS detected in almost all samples Fusobacterium spp. (99%), Bifidobacterium spp. (99%), Campylobacter spp. (89%) and Haemophilus spp. (87%) whereas these bacteria were not detected by SMC.
Conclusion: NGS is more sensitive in detecting bacterial genera in the biliary tract than SMC and no clinical parameters can be used to predict high discovery rates in SMC. NGS could be used for improved diagnostics for more specific and targeted antibiotic treatments in patients with ITBL and/or AS. However, more such studies are needed to deepen our understanding of microbes being involved in bacterial cholangitis.

FRI-373
Mismatch in C-locus Eplets between donor and recipient as independent factor of acute T-cell mediated rejection in liver transplantation
Sandra Guiral[1,1], David San Segundo[1,2], Antonio Cuadrado[2,3,4], Angela Puente Sanchez[3,4,5], Fernando Casafont[3,4,5], Jose Ignacio Fortea[3,4,6], Marcos López-Hoyos[1,5], Javier Crespo[3,4,5], Emilio Fabrega[3,4,5]. Santander, Spain; [3]Marqués de Valdecilla University Hospital, Department of Gastroenterology and Hepatology, Santander, Spain; [4]CIBER of Hepatic and Digestive Diseases (CIBERehd), Madrid, Spain; [5]Research Institute (IDIVAL), Santander, Spain; [6]Research Institute (IDIVAL), Santander, Spain
Email: emiliofabregagarcia@gmail.com

Background and aims: HLA matching in solid organ transplantation is essential, especially in kidney, heart and lung transplantation, because of the proven benefits of increased graft survival and decreased incidence of acute rejection. Currently, the HLA match between donor and recipient is suffering a change in the way to interpretate the mismatches with the eplets definition. Eplets are highly polymorphic regions of the HLA molecule and constitute essential components oh HLA epitopes recognized by antibodies that explain the cross-reactivity with different HLA antigens. In renal transplantation, class II HLA eplet mismatch determination has been shown to be a superior method of risk stratification compared with traditional HLA antigen mismatch for predicting class II de novo DSA development, allograft rejection, transplant glomerulopathy, and allograft survival. However, the effect of eplet-mismatch in liver transplantation (LT) has not been studied in detail. The aim of this study is to investigate the relationship between the eplet-mismatch in LT and assess the impact with post-LT outcomes.
Method: HLA typing of 46 consecutive liver graft receptor-donor pairs was performed in our center from January 2016. Follow-up was censored at October 2018. The quantification of antibody verified eplet (VerEp) mismatch in locus-A, B, C, DQA and DQB was performed with HLAMatchmaker software, version 2.0.
Results: A total of 9 patients suffered an episode of acute T cell mediated rejection (TCMR). No significant differences were observed in the number of VerEp mismatches at the HLA-A, B, DRB, DQA and DQB loci. However, the number of VerEp mismatches at the C locus (VerEpC) was significantly increased in patients with acute TCMR: 2 (0-3.5) vs 0 (0-1), p = 0.016. After pooling the patients depending on their load of VerEpC, those with high VerEpC (≥ 2) had an increased risk of acute TCMR in comparison to patients with low VerEpC (< 2) [OR 4; IC95% (1.68-9.49), p = 0.006]. The time free of acute TCMR after LT between low and high VerEpC load was significant (log rank test p = 0.007). In multivariate analysis, high VerEpC load remained as an independent risk factor of acute TCMR (p = 0.032).
Conclusion: The measurement of VerEpC mismatch between donor-recipient prior liver transplantation could identify those at risk of developing acute TCMR.

FRI-374

Von Willebrand factor independently predicts mortality on the waitlist for liver transplantation and facilitates additional risk stratification in low MELD patients

G. Gyoeri[1], David Pereyra[2], Benedikt Rumpf[2], Christoph Koeditz[2], Thomas REIBERGER[3], Gabriela Berlakovich[1], Patrick Starlinger[3].
[1]Medical University of Vienna, Division of Transplantation, Department of Surgery, Vienna, Austria; [2]Medical University of Vienna, Department of Surgery, Vienna, Austria; [3]Medical University of Vienna, Division of Gastroenterology and Hepatology, Departmnet of Internal Medicine III, Vienna, Austria
Email: georg.gyoeri@meduniwien.ac.at

Background and aims: To this date, liver transplantation (LTx) poses the gold standard in treatment of patients suffering from end-stage liver disease. Well-known limitations of the current MELD based liver allocation comprise the lack of functional assessment of liver insufficiency and underestimation of complications resulting from portal hypertension and infection while on the waitlist. Accordingly, further optimization of the organ allocation process seems inevitable in order to reduce mortality prior to LTx. vWF-Ag was previously shown to play a major role in predicting long-term outcome of patients with chronic liver disease. Accordingly we aimed to evaluate if vWF-Ag could close the obvious functional disabilities of the MELD score in risk assessment of patients listed for transplantation.
Method: Retrospective analysis of 1237 patients listed for liver transplantation at our center between 2003 and 2016. To assure clinical relevance, vWF-Ag was prospectively collected and analyzed as part of the routine laboratory analysis. Receiver operating characteristic (ROC) analysis was applied to assess the discriminatory

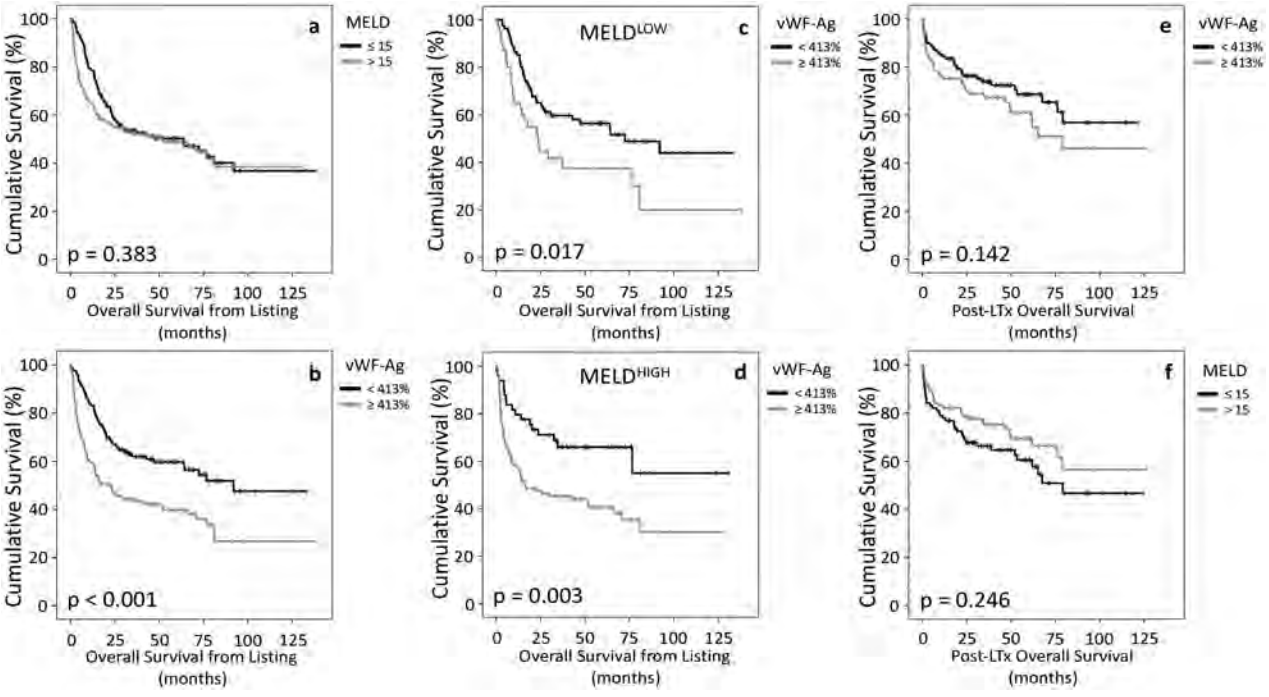

Figure: (abstract: FRI-374)

potential of vWF-Ag in patients listed for LTx. In addition, this statistical approach was used to identify the optimal cut-off level with the greatest accuracy of distinguishing high- and low-risk groups. Multivariable analysis (MVA) was used to investigate independency of predictive markers for waitlist mortality. Kaplan-Meier curves were plotted to visualize survival according to defined risk groups and log rank test was used to assess statistical differences.
Results: Detailed information on vWF-Ag at the time point of listing was available in 269 patients. Patients dying within 3 months on the waitlist displayed elevated levels of vWF-Ag (median vWF-Ag no mortality = 405%, median vWF-Ag mortality = 420%, $p < 0.001$). MELD and vWF-Ag seemed to be almost comparable in their predictive potential for 3-month DoL (AUC vWF-Ag = 0.739, AUC MELD = 0.770). we were able to define a cut-off using Youdens' J statistic at 413% of vWF at time of listing. The cut-off at 413% vWF-Ag was found to predict patients OS both when listed with low MELD score (median OS vWF-Ag^{LOW} = 72.4 months, median OS vWF-Ag^{HIGH} = 23.4 months, $p = 0.017$, Fig.3c) and high MELD score (median OS vWF-Ag^{LOW} = not reached, median OS vWF-Ag^{HIGH} = 16.2 months, $p = 0.003$, Fig. 3d)
Conclusion: vWF-Ag is able to independently predict on list mortality in patients listed for LTx. Importantly, vWF-Ag is able to further identify high risk patients despite a low MELD score and should therefore be incorporated in routine clinical decision making in patients on the waitlist. Ultimately, the data provided within this analysis suggests that the addition of vWF-Ag to the process of organ allocation could eventually result in a higher number of patients reaching the end point of transplantation and hence improve survival.

FRI-375

Direct oral anticoagulants are safe and effective in patients after liver/kidney transplantation

Adam Herber[1], Antje Weimann[2], Paulina Kreusler[3], Cornelius Engelmann[4], Niklas Aehling[1], Daniel Seehofer[2], Sirak Petros[3], Thomas Berg[1], Christian Pfrepper[3]. *[1]University Hospital Leipzig, Section Hepatology, Department of Gastroenterology and Rheumatology, Leipzig, Germany; [2]University Hospital Leipzig, Department of Visceral, Vascular, Thoracic and Transplant Surgery, Leipzig, Germany; [3]University Hospital Leipzig, Division of Hemostaseology, Leipzig, Germany; [4]University College London, Institute for Liver and Digestive Health, London, United Kingdom*
Email: adam.herber@medizin.uni-leipzig.de

Background and aims: The ideal anticoagulant therapy in patients after solid organ transplantation is still not clear due to lack of robust data for the use of direct oral anticoagulants (DOAC) in this population. The aim of our study was to describe the real-world effectiveness of DOAC after transplantation with a special emphasis on *in vivo* drug-drug interactions with the immunosuppressive therapy (IS).
Method: Patients after liver and kidney transplantation treated with DOACs between 2014 and 2018 in the out-patient clinic of the University Transplant Center Leipzig were included. Data regarding IS-dose adjustments and complications were collected from medical records and patient-questionnaire. In addition DOAC trough levels were measured.
Results: 42 Patients with liver (n = 21, 50%) kidney (n = 16, 38%) and combined (n = 5, 12%) transplantation were included. Mean age was 64.1 ± 9.6 years, 59.5% males. Mean glomerular filtration rate (GFR) at start of DOAC therapy was 46.6 ± 9.6 ml/min. Patients received either a CNI- (n = 32; 76%) or mTOR-inhibitor-based (n = 10, 24%) immunosuppressive therapy. 23 (55%) patients were treated with rivaroxaban, 19 (45%) with apixaban. The indication for anticoagulation was nonvalvular atrial fibrillation (n = 23), deep vein thrombosis (n = 9), pulmonary embolism (n = 5) and portal vein thrombosis (n = 5). DOACs were administered for a median of 16.0 (range 3.1-52.0) months (corresponding to 72.4 patient-years). No patient withdrew anticoagulation due to adverse events. The IS-dose after DOAC initiation was adjusted in 10 (26.2%) cases. In patients without IS-dose change (n = 27), mean IS plasma levels increased from baseline by 23.6 ± 35.4% (CNI: 25.7 ± 36.6%; mTORi 17.7 ± 33.7%). No rejection or ALT increase was observed in any patient. The mean change in GFR was +1.0 ± 7.1 ml/min in all patients.There were no documented major bleedings but one myocardial infarction in a patient with an underlying malignant disease. 18/30 (60%) patients who completed the questionnaire reported minor bleedings (gingival bleeding, hematoma) (12/15 with rivaroxaban and 6/15 with apixaban). Bleeding (epistaxis) was considered relevant in 3/30 (10%) cases. The trough DOAC levels were available in 22 patients and reached the therapeutic range in all patients.
Conclusion: Treatment with rivaroxaban and apixaban in our patients after liver and kidney transplantation was safe and effective. No major adjustments of immunosuppression were needed in our cohort. Although these data are encouraging, more data including also other DOACs are necessary to make a robust conclusion.

FRI-376

Early treatment with sorafenib and mTOR inhibitor in recurrent hepatocellular carcinoma after liver transplantation: Safety and survival

Federica Invernizzi[1], Massimo Iavarone[1], Claudio Zavaglia[2], Stefano Mazza[1], Umberto Maggi[3], lucia cesarini[2], Barbara Antonelli[3], Aldo Airoldi[2], Matteo Angelo Manini[4], Angelo Sangiovanni[1], Giorgio Rossi[3], Maria Francesca Donato[1], Luca Saverio Belli[2], Pietro Lampertico[1]. *[1]C.R.C. A.M. and A. Email: invernizzi.federica@gmail.com

Background and aims: Sorafenib (SOR) is currently used in hepatocellular carcinoma (HCC) recurring after liver transplantation (LT), generally in those patients unsuitable for surgical/locoregional treatments. The early introduction of SOR after HCC recurrence and its association with mTOR inhibitors (mTORi) are still debated. Therefore, we evaluated safety and effectiveness of SOR±mTORi in this setting.
Method: From January 2008 to June 2018 all the patients with HCC recurring after LT referring to two liver transplant centers were included if treated with SOR with or without mTORi. Surgical/locoregional treatments were performed before and during systemic treatment.
Results: Forty-eight non cirrhotic patients were enrolled (median age 58, 81% male, 77% on mTORi, 57% only extra-hepatic recurrence). Overall, SOR was started within 3 months after HCC recurrence and 2 months after surgery or locoregional treatments (65% of cases, 57% with curative intent). During 8 months (range 0.1-89) of administration, all patients had at least one SOR-associated adverse event (AE): 18 (38%) graded 1-2; 28 (58%) grade 3-4; 2 (4%) died, the first one due to massive gastrointestinal bleeding and the second one after the onset of severe diarrea. Dose was reduced in 32 (67%) patients, being AEs the main cause of reduction (median daily dose of sorafenib 494 mg). SOR was permanently discontinued in 42 (88%) for symptomatic progression (60%), AE (33%), liver graft dysfunction (5%), HCC complete response (2%). mTORi-associated AEs occurred in 45% (proteinuria 8%, oral ulcers 13%, hypertriglyceridemia 17%, ankle edema 13%), dose was reduced in 30% and withdrawn in 20%. Increase in liver functions tests was registered in 9 cases (19%), without evidence of drug-drug interaction. The best radiological response was objective response in 7 (15%) and stable disease in 23 (48%). The

median time to first radiological progression was 6 months (95%CI 5-7). Thirty-three patients (69%) died, all but two for HCC progression. The 1-, 3- and 5-year overall survival (OS) were 64% (95%CI 50-78%), 23% (95%CI 9-37%) and 18% (95%CI 4-32%). Median OS was 18 months (95%CI 8-27). Predictors of OS were SOR+mTORi (p = 0.03, HR 2.4, 95%CI 1.1-5.3) and HCC-curative treatment (p = 0.003, HR 3.0, 95%CI 1.4-6.2).
Conclusion: Early combination treatment with SOR and mTORi in HCC recurring after LT resulted in an acceptable safety profile and a role in increased patients' survival can be suggested.

FRI-377
Survival outcome after liver transplantation in US patients with hepatocellular carcinoma
Mohamed Saleh Ismail[1,2], Manal Hassan[1], Lydia Dawood[1], Kalpesh Patel[3], Prasun Jalal[1]. *[1]Baylor College of Medicine, Division of Abdominal Transplantation, Houston, United States; [2]Ain Shams University, Department of Internal Medicine, Gastroenterology and Hepatology, Cairo, Egypt; [3]Baylor College of Medicine, Department of Gastroenterology and Hepatology, Houston, United States*
Email: jalal@bcm.edu

Background and aims: The incidence of hepatocellular carcinoma (HCC) has been dramatically increased in the United States over the last 3 decades. Liver transplantation (LT) is the only curative option for patients with early-stage HCC. Despite the high cost and risk of LT, limited reports addressed the impact of patients' clinico-pathological characteristics on post-transplant overall survival (OS). We aimed at investigating the independent impact of different clinico-pathological factors on OS of HCC patients after LT.
Method: Between 1997 and 2016, total of 6425 cirrhosis-induced HCC patients received LT and had been registered in the United Network for Organ Sharing (UNOS) database. SAS software was used for data extraction and statistical analysis. OS was defined as the time between HCC diagnosis and death (as result of all causes) or end of follow-up (censored observation). To identify independent prognostic factors on OS, hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated by using Cox proportional models.
Results: The mean age (± SD) of all subjects was 60.5 (± 7.7) years. Majority of patients were men (77%). We observed 3% and 8% increase in the expected death hazard relative to each year increase in patients' age and each cm increase in tumor size. The HRs (95% CIs) were 1.03 (1.02-1.04) and 1.08 (1.05-1.11) respectively. Poor tumor differentiation and vascular invasion were significantly associated with poor survival. Multivariate HRs (95% CIs) were 1.38 (1. 25-1.52) and 1.42 (1.22-1.66) respectively; P < .01. No significant impact of other factors including, male gender, diabetes, BMI, portal thrombosis, lymph node involvement, number of tumors, year of listing, or days on waiting list. Stratifying the patients by cirrhosis etiology showed that patients with cryptogenic cirrhosis experienced the highest prevalence of HCC poor differentiation (9%).
Conclusion: Our analysis indicated that patients' age, poor tumor differentiation, and presence of vascular invasion are significant predictors of poor outcome in patients with cirrhosis-induced HCC who had LT. Giving the scarcity of organs, such model will pin point the high risk population for post-LT poor prognosis among HCC population. This may further assist in identifying and prioritization candidates for LT. Future validation of the results in prospective cohorts may be warranted.

FRI-378
Should we change the allocation policy for NASH patients?
Assaf Issachar[1,2], Michal Cohen-Naftaly[1], Orly Sneh Arbib[1], Ran Tur-Kaspa[1], Amir Shlomai[1,2], Sigal Cohen[3], Rachel Michowiz[3], Eytan Mor[3], Marius Braun[1]. *[1]Rabin Medical Center, Beilinson Hospital, Liver Institute, Petah Tikva, Israel; [2]Rabin Medical Center, Beilinson Hospital, Medicine D Department, Petah Tikva, Israel; [3]Rabin Medical Center, Beilinson Hospital, Transplant Department, Petah Tikva, Israel*
Email: assafissa@gmail.com

Background and aims: The need for liver transplants by far exceeds the current supply of cadaveric organs. The introduction of the MELD system reduced waiting list mortality. MELD does not account for liver disease etiology. Should certain diseases incur increased wait list mortality, their prioritization for transplant might need to be reconsidered.
The aim of this study is to assess the waiting time on our transplant list and survival rate from listing to transplantation and overall intention to treat survival.
Method: We analyzed data for all the patients listed in our center from 1/2013 till 09/2018 from our database. The death rate on the waiting list, wait time till transplant and death rate after transplant were calculated.
Results: During this period 406 pts were listed for liver transplantation, 20 patients were transplanted overseas and 55 patients were not include in the analysis (not eligible for liver transplantation due to HCC beyond Milan, significant comorbidity other than liver disease or improvement of the liver disease) so that 331 pts were available for analysis. 105 patients (31%) had NASH as primary liver disease. The mean waiting time was 26.2 months. Wait list mortality was 26% (86 pts) and the mean time from listing to death 11.5 m. The deceased patients suffered from NASH (41 pts, 48%) viral hepatitis (8), cholestatic diseases (4), alcohol related liver disease (3), HCC (2) and miscellaneous causes (7).
The survival at 1 and 3 years after transplantation was 78% and 77% respectively, however intention to treat survival from listing was only 63% and 55% respectively.
Conclusion: Almost half of the patients that died on the waiting list suffer from NASH. We suggest that this population might need other allocation policy or serious consideration of early LDLT.

FRI-379
Renal dysfunction between tenofovir and entecavir in patients with hepatitis B virus after liver transplantation
Jong Man Kim[1], Dong Hyun Sinn[2], Gyu-Seong Choi[3], Jae-Won Joh[3]. *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Surgery, Seoul, Korea, Rep. of South; [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [3]Samsung Medical Center, Sunkyunkwan University School of Medicine, Department of Surgery, Seoul, Korea, Rep. of South*
Email: jongman94@hanmail.net

Background and aims: Tenofovir, Nucleotide analogue polymerase inhibitor is already accepted as effective and tolerable drug for treatment of hepatitis B virus (HBV) as much as entecavir. There are some concerns about nephrotoxicity of tenofovir in patients with end-stage liver disease or liver recipients. We retrospectively investigated the renal function of tenofovir compare to entecavir in liver recipients with HBV.
Method: Among 468 patients with HBV who were underwent liver transplantation at Samsung Medical Center between 2008 January to 2015 December, tenofovir (n = 37) treated group was matched with entecavir (n = 132) group. (1:4, matching variables = age, pre-operative HBV DNA, eGFR, CTP score) Baseline characteristics and 1, 2, 3 year follow-up eGFR and creatinine levels after operation were compared between both group using GEE (Generalized estimating equation) analysis. Risk factors lowering eGFR value are also reviewed with univariate and multivariate analysis.

Results: Among baseline characteristics, age, pre-operative creatinine, eGFR and hepatic encephalopathy score showed statistical difference between tenofovir (n = 39) and entecavir (n = 429) group before propensity score matching. After matching, there was no statistical difference in pre-operative characteristics. Post-operative 1-year eGFR showed no statistical difference from pre-operative eGFR in both group. Post-operative 2-year eGFR (5.25 ml/min/1.73m^2 decrease, p = 0.04) and 3-year eGFR (7.43 ml/min/1.73m^2 decreased, p = 0.02) showed a little decreased from pre-operative eGFR, but there was no statistical difference and interaction between tenofovir and entecavir group (p = 0.42). Post-operative 1-year creatinine (0.28 mg/dl decreased, p = 0.02) and 2-year creatinine (0.24 mg/dl decreased, p = 0.049) showed improvement. 3-year creatinine showed decrease by 20 mg/dl without statistical difference (p = 0.10) from pre-operative creatinine. There was also no statistical difference and interaction between both group (p = 0.38) for creatinine change.
Conclusion: Tenofovir does not induce renal dysfunction in liver transplant patients with HBV compared to entecavir. The safety and renal dysfunction in tenofovir after liver transplantation will be investigated in the further studies.

FRI-380
Factors and models for predicting posthepatectomy liver failure in patients undergoing hepatic resection for hepatocellular carcinoma

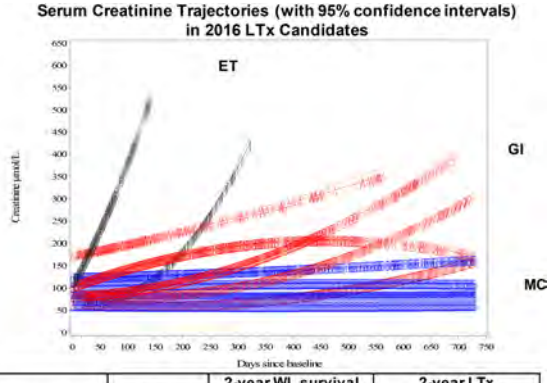
So-hyun Kim[1], Jonggi Choi[2], Gwang Hyun Choi[2], Danbi Lee[2], Ju Hyun Shim[2], Young-Suk Lim[2], Han Chu Lee[2], Young-Hwa Chung[2], Yung Sang Lee[2], Kang Mo Kim[2]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South*
Email: kimkm70@amc.seoul.kr

Background and aims: Hepatic resection has been a main treatment option for patients with hepatocellular carcinoma (HCC). The aim of this study was to seek predictive factors and to build predictive model for posthepatectomy liver failure (PHLF).
Method: A total of 1, 364 consecutive patients underwent hepatic resection between January 2016 and December 2017. Laboratory tests were assessed before, and 1, 2, 3, 5, 7, and 10 days after surgery. Posthepatectomy hepatic dysfunction was defined as an increase in the total bilirubin ≥ 2.9 mg/dL (50 μmol/L) or an increase INR on or after postoperative day 5, compared with the values of the previous day. PHLF includes posthepatectomy hepatic dysfunction, ICU stay, development of ascites requiring diuretics or drainage procedure, and mortality from any cause.
Results: Of 1, 256 patients with available data, mean age was 58.3 years and male comprised 80.6% of patients. 403 (32.1%) patients underwent major hepatic resection and 481 (38.3%) revealed cirrhosis at pathologic specimens. The mortality at 30 and 90 days were 0.3% and 0.9%, respectively. PHLF developed in 117 (9.3%) patients: posthepatectomy hepatic dysfunction in 62 (4.9%) patients, ICU stay in 18 (1.4%) patients, ascites in 42 (3.3%) patients, and death 11 (0.9%) patients. In multivariable logistic regression, age over 70 years (adjusted odds ratio [AOR]: 2.89, 95% confidence interval [95% CI]: 1.65-4.97), cirrhosis (AOR: 2.60, 95% CI: 1.67-4.08), albumin less than 3.5 (AOR: 2.17, 95% CI: 1.56-3.01), major hepatic resection compared with minor resection (AOR: 2.26, 95% CI: 1.41-3.62), and high indocyanine green (ICG) index at 15 minutes over 20% (AOR: 2.53, 95% CI: 1.21-5.46) were significantly associated with a high risk of PHLF. Interger values were assigned to each factor to develop a model that predicted PHLF, which presented an area under the curve of 0.780.
Conclusion: Cirrhosis, age over 70 years, major resection, lower albumin and high ICG level were associated independently with PHLF. A composite interger-based risk scoring model could accurately predict PHLF in patients undergoing hepatic resection for HCC.

FRI-381
Latent trajectory analysis of serum creatinine in patients with end stage liver disease: Predictors of pre- and post-transplant outcomes

W. Ray Kim[1], Sumeet Asrani[2], Scott Biggins[3], Pimsiri Sripongpun[1], Ajitha Mannalithara[1]. *[1]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, Redwood City, United States; [2]Baylor University, Liver Transplant, Dallas, United States; [3]University of Washington, Seattle, United States*
Email: wrkim@stanford.edu

Background and aims: Renal impairment remains an important determinant of outcome in patients with end stage liver disease (ESLD). We identify clusters of serum creatinine (sCr) trajectory for liver transplantation (LTx) candidates with which to determine predictors of outcomes before and after LTx.
Method: In the US Organ Procurement and Transplantation Network registry, all adult primary LT candidates on the waiting list as of Jan 1, 2016 were identified. In eligible (baseline MELD > 15 and sCr < 1.5 mg/dL and ≥ 3 sCr data) patients, the nearest date on which a MELD score was available within the preceding 180 days of Jan 1, 2016 was taken as baseline. Subpopulations with heterogeneous disease trajectories were identified, using latent class growth mixture modelling to group individuals based on changes in sCr over two years of follow-up. Statistical fit was determined by Bayesian information criteria and trajectories with similar patterns were categorized into separate groups for analysis. Patient characteristics predictive of the sCr trajectory were identified with the multiple logistic regression analysis. The impact of the pre-LTx sCr on post-LTx renal function was assessed by the generalized linear model (GLM) procedure adjusting for the sCr at LTx.
Results: Three distinct trajectory groups were identified among 2, 044 patients (Figure), including (1) early deterioration (ED, shown in black in Figure), (2) gradual increase (GI, red), and (3) minimal change (MC, blue). These trajectories had a significant impact on two-year waitlist survival (0.15, 0.26 and 0.79 for ED, GI and MC, respectively) and LTx probabilities (1.00, 0.82 and 0.46 for ED, GI and MC, respectively). In the multivariable analysis, predictors of ED included bilirubin (odds ratio [OR] = 1.10, p < 0.01) and albumin (OR = 0.47, p < 0.01), as well as baseline sCr (OR = 5.92, p < 0.01). There were 555 patients who underwent deceased donor, single organ LTx for ESLD and had complete data. The median sCr at LTx was 2.65 mg/dL for ED, 1.83 mg/dL for GI, 0.93 mg/dL for MC. These differences diminished over time-the median follow-up sCr ≥ 180 days after LTx was 1.37 mg/dL, 1.30 mg/dL and 1.10 mg/dL for ED, GI and MC, respectively. These trends persisted in the multivariable GLM: ED was associated with larger improvement in sCr (–0.25, p = 0.04) compared to GI and MC, adjusting for sCr at LTx (0.22, p < 0.01), age (0.006, p < 0.01) and female sex (–0.19, p < 0.01).



Trajectory groups	N (%)	2-year WL survival probability	2-year LTx probability
Early Deterioration	50 (2.5)	0.15	1.00
Gradual Increase	192 (9.4)	0.26	0.82
Minimal change	1802 (88.2)	0.79	0.46

Conclusion: Using latent class trajectory modelling methods, we were able to define three distinct trajectory groups for sCr in LTx candidates with ESLD. Based on the sCr trend and pre- and post-LTx renal function, the ED trajectory likely corresponds to hepatorenal syndrome (HRS) type I or acute tubular necrosis, whereas GI reflects HRS-2. Significant recovery in sCr is seen after LTx, particularly in ED.

FRI-382

Biological assessment comprising alpha-fetoprotein, albumin-bilirubin score and C-reactive protein provides better prognostic competence than tumor size criteria in liver transplant patients with HCC

Arno Kornberg[1], Martina Achernhammer[1], Jennifer Kornberg[2], Katharina Müller[3], Helmut Friess[1], Katharina Thrum[4]. [1]*Technical University Munich, Surgery, Munich, Germany;* [2]*Ludwig-Maximilians-University, Munich, Germany;* [3]*Friedrich-Schiller-University, Jena, Germany;* [4]*Helios-Klinikum, Berlin, Germany*
Email: arnokornberg@aol.com

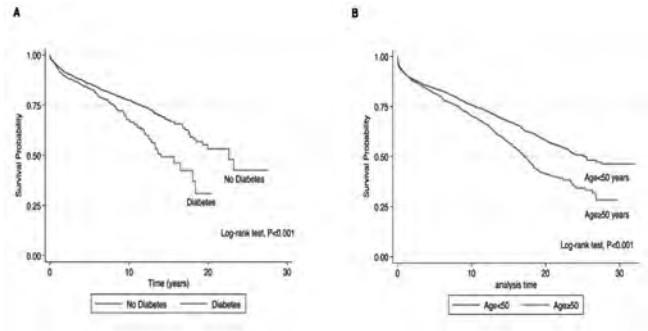
Background and aims: Recently, the albumin-bilirubin (ALBI) score was shown to correlate with overall and cancer-specific outcome following liver resection for hepatocellular carcinoma (HCC). Respective data in the liver transplant (LT) setting is completely lacking. The aim of this retrospective study was to determine the power of pretransplant ALBI score for predicting oncological prognosis after LT for HCC.
Method: 123 HCC patients following LT were analyzed. The ALBI score at LT was determined by standard calculation formula. At final pretransplant radiographic imaging, tumors were staged as meeting or exceeding the Milan (MC) and the Up-to-seven (UTS) criteria. Recurrence-free survival (RFS) rates were determined by the Kaplan-Meier method. Uni- and multivariable Cox regression analysis was used for identifying pre-LT available prognostic factors. Concordance statistics was applied to compare the prognostic competence in predicting post-LT HCC relapse.
Results: Median post-LT follow-up was 80 months (range: 5-190). Cumulative risk of HCC relapse at 7 years post-LT was comparable between ALBI-grade 1 (10.5%) and ALBI-grade 2 patients (15.9%; p = 0.459), while being significantly higher in ALBI-grade 3 recipients (68.2%; $p < 0.001$). In multivariable analysis, AFP level $\leq$ 100 ng/ml (HR = 4.99; $p < 0.001$), ALBI-grade 1/2 (HR = 3.52; $p = 0.002$) and C-reactive protein level $\leq$ 1 mg/dl (CRP; HR = 2.61; $p = 0.026$) were identified as independent clinical promoters of disease-free outcome. RFS at 7 years post-LT was comparable between MC In patients (86.8%) and MC Out patients with ALBI-grade 1 (75.5%) or ALBI-grade 2 (75%; $p = 0.296$), and between UTS In patients (81.6%) and UTS Out recipients with ALBI-grade 1 (75%) or ALBI-grade 2 (67%; $p = 0.408$). In contrast, it was only 17.6% in MC Out and 30% in UTS Out patients with ALBI-grade 3 ($p < 0.001$), respectively. According multivariate significance, the following oncological risk scores were assigned: AFp > 100 ng/ml: 3; ALBI-grade 3: 2; CRp > 1 mg/dl: 1, finally leading to a summarized minimum of 0 (lowest oncological risk) and a maximum of 6 (highest oncological risk) risk points. Actuarial RFS rates at 7 years post-LT were 89% in the low risk group (score 0 to 3; n = 101), but only 27% in the high risk subset (score 4 to 6; n = 22; $p < 0.001$). C-indexes for predicting post-LT HCC recurrence were 0.79 for biological risk scoring, 0.67 for MC and 0.65 for UTS criteria, respectively.
Conclusion: The ALBI score is an important and easy available prognosticator of oncological outcome in liver transplant patients with HCC and should, therefore, be implemented in individual decision making process. Tumor biological risk assessment based on AFP value, ALBI-grade and CRP level identifies a subset of HCC patients that may benefit from LT independent from tumor size limitations.

FRI-383

Role of traditional cardiovascular risk factors in predicting long term survival after liver transplantation

Anoop Koshy[1], Omar Farouque[1], Jay Ramchand[1], Adam Testro[2], Peter Angus[2], Robert Jones[2], Matthew Peverelle[2], Mandy Byrne[2], Matias Yudi[1], Benjamin Cailes[1], Paul Gow[2]. [1]*Victorian Liver Transplant Unit, Austin Health, Cardiology, Melbourne, Australia;* [2]*Victorian Liver Transplant Unit, Austin Health, Hepatology, Melbourne, Australia*
Email: ankoshy@gmail.com

Background and aims: Cardiovascular (CV) death is a leading cause of long-term mortality following liver transplantation (LT). Identifying pertinent CV risk factors that impact on long-term survival may allow an opportunity for intervention.
Method: Outcome data was prospectively collected for all adult LT performed in Australia and New Zealand between 1985 and 2017, from the Australian and New Zealand Liver Transplant Registry. Risk factors including hypertension, diabetes, age, sex, obesity (body mass index $\geq$ 30 kg/m^2), pre-existing coronary artery disease (CAD) and non-alcoholic fatty liver disease aetiology were collected and entered in a multivariable Cox regression model.
Results: Among, 4, 538 adult LT performed, 1433 (31.6%) deaths including 240 CV deaths (17%) occurred during a median follow-up of 10.5 years (IQR: 4.9-17.9 years). On univariate analysis, age $\geq$ 50 years (log-rank test, p < 0.001), diabetes (p < 0.001) and obesity (p = 0.006) were associated with all-cause mortality (**Figure**). After Cox multivariable adjustment, diabetes (Hazard ratio [HR] 1.4, 95%CI 1.07-1.8, p = 0.01) and age $\geq$ 50 (HR 1.5 95%CI 1.2-1.9, p < 0.001) remained as independent predictors for all-cause mortality. Notably, pre-existing CAD did not predict long-term mortality (p = 0.24).



Conclusion: Presence of diabetes and age $\geq$ 50 independently increased the risk of long term mortality following LT. Whether intensive risk factor modification in high-risk populations improves long-term survival after LT remains to be tested.

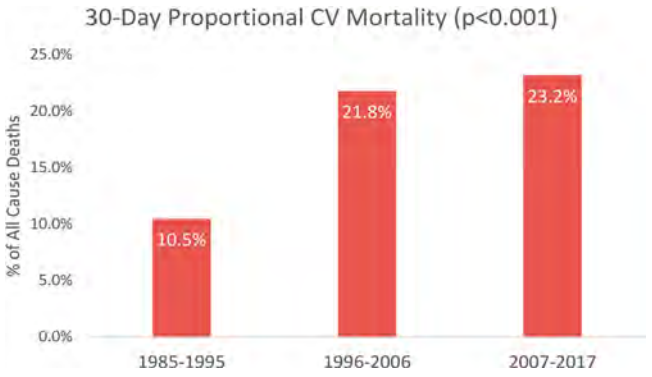
FRI-384

Early cardiovascular mortality following liver transplantation: 30-year temporal trends from the Australian and New Zealand liver transplant registry

Anoop Koshy[1], Omar Farouque[1], Jithin Sajeev[1], Adam Testro[2], Matthew Peverelle[2], Peter Angus[2], Robert Jones[2], Mandy Byrne[2], Benjamin Cailes[1], Hui-Chen Han[1], David Clark[1], Han Lim[1], Andrew Teh[1], Paul Gow[2]. [1]*Victorian Liver Transplant Unit, Austin Health, Cardiology, Melbourne, Australia;* [2]*Victorian Liver Transplant Unit, Austin Health, Hepatology, Melbourne, Australia*
Email: ankoshy@gmail.com

Background and aims: Liver transplantation (LT) poses significant cardiovascular (CV) risk for patients. Given the rising prevalence of non-alcoholic fatty liver disease and advancing age of LT candidates, delineating CV risk is increasingly important. We sought to characterize the incidence and modes of intraoperative and early ($\leq$ 30days) CV death post-LT.

Method: Prospectively recorded clinical and outcome data were collected for all adult LTs in Australia and New Zealand between 1985 and 2017. Data was collected from six participating centres and compared between Era 1 (1985-1995), Era 2 (1996-2006) and Era 3 (2007-2017).
Results: Among, 4, 538 adult LT performed, 201 (4.4%) deaths including 38 (19.0%) CV deaths occurred within 30-days. All-cause mortality fell across the 3 Eras. A significant reduction in all-cause mortality and overall early CV death was noted (1.1%-1.2%-0.6%, p < .001, Era 1-3). However, CV death as a proportion of all-cause 30-day mortality increased significantly (10.5%-21.8%-23.2%, *p < 0.001, Era 1-3, respectively- **Figure**). CV events were the leading cause of intra-operative mortality (40%) and second leading cause of overall early death (31.8%). Most common modes of CV death were cardiac arrest and congestive heart failure (44.7% and 23.7%, respectively, of CV deaths).



Conclusion: CV events are a leading cause of operative and early mortality following LT. Despite reductions in absolute all-cause mortality over 30 years, the proportion of deaths due to CV causes continues to rise. Improvements in preoperative risk stratification are needed.

FRI-385
Use of machine learning algorithms to predict HCC recurrence after liver transplantation: A proof of concept
Lawrence Lau[1], Walter Nelson[2], Andre Gorgen[1], Lauren Erdman[2], Phillipe Abreu[1], Anna Goldenberg[2], Gonzalo Sapisochin[1]. *[1]Toronto General Hospital, Multiorgan Transplant, Toronto, Canada; [2]Sick Kids (The Hospital for Sick Children), Center for Computational Medicine, Toronto, Canada*
Email: thelau@gmail.com

Background and aims: The liver transplant listing criteria for hepatocellular carcinoma (HCC) is controversial. Policies aim to prevent tumor recurrence but it has been difficult to encompass the numerous contributive factors. This study takes advantage of machine learning algorithms to incorporate all available features in a post-transplant recurrence prediction calculator.
Method: The calculator was developed using the University of Toronto HCC database, which is a comprehensive dataset including all patients with HCC listed for liver transplantation between 2000 and 2016. The dataset includes comprehensive features including serial imaging morphology, AFP, details of bridging therapy, treatment response, and post-transplant outcome.
A Cox proportional hazards model was used to model time to recurrence following transplant. The model was estimated through a least absolute shrinkage and selection operator (LASSO) penalized maximum likelihood procedure in order to encourage sparsity of the coefficients, thereby discouraging overfitting. The coefficients were learned on 90% of the data (the training set). The regularization hyperparameter was learned on the same set of training data. Performance was evaluated over 1000 iterations by assessing the area under the receiver operating curve (AUC) and concordance on the held-out data (the testing set). Variables selected by LASSO in over 50% of iterations were selected to run the analysis of the 5-year recurrence risk in the model. The same dataset was then used to train alternative recurrence risk algorithms (AFP score and MORAL) to compare its predictive power.
Results: The dataset included 694 patients who underwent liver transplant for HCC. The overall concordance of score with disease-free survival was satisfactory (concordance 0.706, sd: 0.075). The AUC for prediction of recurrence show the predictive power of the model (Figure 1). Including all variables meeting the selection criteria, the AUC at 5 years post transplantation was 0.756 (95% CI 0.708-0.804). By comparison, the AUC for AFP score at 5 years post transplantation was 0.616 (95% CI 0.558-0.675) and that of MORAL was 0.595 (95% CI 0.536-0.655).

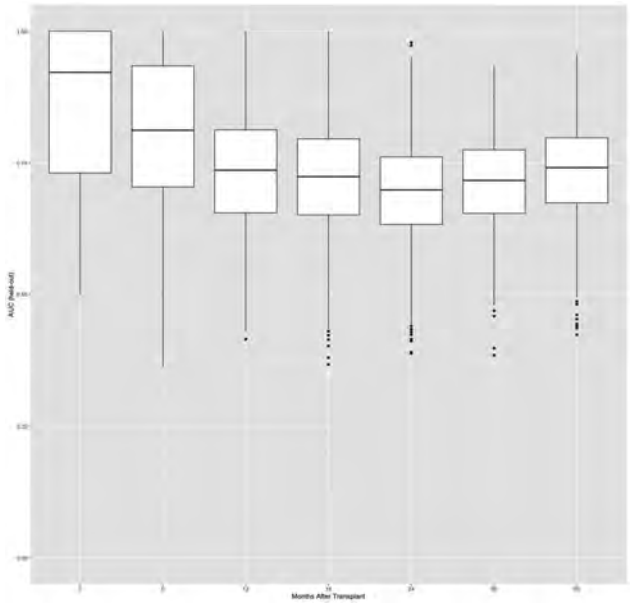


Figure 1: AUC of the Toronto HCC Recurrence Calculator at specific times.

Conclusion: A comprehensive HCC recurrence risk calculator using machine learning is possible with higher accuracy than other available scores.

FRI-386
Impact of acute-on-chronic liver failure on survival after liver transplantation
Sebastián Marciano[1], Liliana P Rojas-Saunero[2], Ezequiel Mauro[3], Maria C Torres[3], Maria N Gutiérrez-Acevedo[3], Carla Bermudez[3], Juan M Díaz[3], Adrián Narvaez[3], Jorge Ortíz[3], Melisa Dirchwolf[4], Florencia Pollarsky[5], Adrián C Gadano[1]. *[1]Hospital Italiano de Buenos Aires, Liver Unit and Department of Research, Buenos Aires, Argentina; [2]Erasmus MC, Epidemiology Department, Rotterdam, Netherlands; [3]Hospital Italiano de Buenos Aires, Liver Unit, Buenos Aires, Argentina; [4]Hospital Privado de Rosario, Liver Unit, Rosario, Argentina; [5]Hospital Dr. Carlos Bonorino Udaondo, Liver Unit, Buenos Aires, Argentina*
Email: sebastian.marciano@hospitalitaliano.org.ar

Background and aims: The post-liver transplant (LT) survival of patients with an episode of Acute-on-Chronic Liver Failure (ACLF) has not been evaluated in depth. We aimed to estimate the effect of ACLF on survival at 365 days post-LT.
Method: Retrospective cohort of patients with cirrhosis aged > 17 years who underwent a liver transplant from Jan/2010 to May/2016. Follow-up started the date of LT until death, liver re-transplantation, loss to follow-up or for a total of 365 days. ACLF was defined according to CLIF-SOFA, evaluated on the day of transplantation. The risk of

post-transplant death is presented as a Hazard Ratio (HR) and was estimated using a Cox model weighted with inverse probability weighting (HR_{IPW}) taking into account the following receptor's potential confounders: MELD-Na, age, detectable HCV viremia and hospitalization in intensive care unit at the time of LT and Donor Risk Index (DRI).

Results: Of a total of 336 patients who underwent liver transplantation 185 met the selection criteria and were included: 125 (68%) underwent transplant without ACLF, and 60 (32%) with ACLF. ACLF grades: 1: 34 (57%); 2: 18 (30%); 3, 8 (13%). Main etiologies were HCV and alcohol-related cirrhosis. Survival at 365 days in patients who were transplanted without ACLF was 91% (95% CI: 84% –95%) vs 85% (95% CI: 73% –91%) in patients with ACLF, p = 0.2005. No effect of ACLF was observed on post-LT survival in the bivariate analysis [crude HR 1.76 (95% CI: 0.73-4.25, p = 0.207)], nor adjusted by confounders [HR_{IPW}1.38 (95% CI: 0.47-4.06, p = 0.548)].

Table: Characteristics according to the absence or presence of ACLF at LT

	Without ACLF N = 125	With ACLF N = 60	p
Donor			
Donor Risk Index	1.59 (1.28-1.94)	1.58 (1.28-1.94)	0.339
Recipient			
Male gender	77 (61.80)	36 (60)	0.834
Age-years	59.5 (54.2-64.9)	60 (50.4-64.6)	0.381
Intensive care unit at transplant	4 (3.2)	10 (16.67)	0.001
Child-Pugh score	10 (7-11)	11 (10.5-12.5)	< 0.0001
MELD Score	17 (12-23)	27 (23-30)	< 0.0001
Hepatocellular carcinoma	59 (47.20)	9 (15)	< 0.0001
HCV RNA positive at LT	51 (41.13)	15 (25)	0.032
HIV	4 (3.20)	4 (6.67)	0.277
Pre LT Hypertension	33 (26.40)	15 (25)	0.839
Pre LT Diabetes	36 (28.80)	14 (23.33)	0.433
Previous abdominal surgery	57 (46.34)	16 (27.12)	0.013
Leukocytes-x10^3/μL	5.0 (3.7-63)	4.4 (3.2-6.7)	0.899
Platelets count-x10^3/μL	74 (51-104)	63 (44-104)	0.572
Total Bilirubin-mg/dL	3 (1.4-5.8)	12.9 (4.5-21)	< 0.0001
Albumin-gr/dL	2.9 (2.6-3.5)	2.8 (2.4-3.27)	0.022
INR	1.6 (1.28-1.9)	2.46 (1.75-3.2)	< 0.0001
Creatinine-mg/dL	0.79 (0.68-0.96)	0.9 (0.75-1.14)	0.0137
Serum sodium-mEq/L	136 (132-138)	132 (128-136)	0.0472
Total psoas volume-cm^3	12.4 (6.9-27.3)	11.2 (5.95-17.67)	0.0125

Categorical variables are expressed in absolute numbers (percentages); continuous variables in median and IQR

Conclusion: No differences in post-LT survival was observed in patients with and without ACLF at the time of LT. Our study supports LT of these patients.

FRI-387

Risk factors associated with early post-operative acute kidney injury requiring renal replacement therapy following liver transplantation

Jeremy Nayagam[1], Oliver Tavabie[1], Benjamin Norton[1], Deepak Joshi[1], Abid Suddle[1], John O'grady[1], Wayel Jassem[1], Krishna Menon[1], William Bernal[1], Nigel Heaton[1], Kosh Agarwal[1], Michael Heneghan[1], Varuna Aluvihare[1]. [1]*King's College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: shanika.nayagam@doctors.org.uk

Background and aims: Liver transplant (LT) recipients are at high risk of developing post-operative acute kidney injury (AKI). Patient, graft and perioperative factors have been associated with this insult. Although the majority recover from this early post-operative AKI, the development of AKI is associated with increased incidence of chronic kidney disease, reduced graft and patient survival. We sought to evaluate risk factors associated with the severe phenotype of AKI requiring renal replacement therapy (RRT).

Method: All liver transplants performed at a high volume centre from 1/1/17 to 31/12/17 were reviewed. Patients who were aged under 18, received multi-organ transplants or had acute liver failure were excluded. Patient demographics, clinical and biochemical parameters pre-LT, organ characteristics and surgical technique utilised, post-LT biochemistry and use of RRT were collected from clinical notes. Univariate statistical analysis was performed between RRT and RRT free groups.

Results: A total of 164 patients were included with a median age at transplant 55.7 years. The incidence of AKI requiring RRT was 22.6%. The RRT group had: more severe liver disease at listing (UKELD ($p = 0.01$), MELD ($p = 0.004$)); a higher incidence of diabetes (*OR 3.03 CI 1.37-6.62 p = 0.006*), non-alcoholic fatty liver disease (NAFLD, *OR 3.3 CI 1.38-7.51 p = 0.007*), ascites (*OR 3.02 CI 1.36-7.18 p = 0.008*); lower eGFR at assessment ($p = 0.0009$) and immediately prior to LT ($p < 0.0001$); higher utilisation of DCD grafts (*OR 3.77 CI 1.74-8.34 p = 0.0008*); and higher opening AST ($p = 0.01$). Decrease in eGFR from assessment to LT was seen in 42 patients and associated with RRT ($p = 0.0002$). There was no significant difference in age, sex, re-do LT or use of a caval replacement.

Conclusion: A significant proportion of patients develop AKI requiring RRT following LT. A number of risk factors for this have been identified in this subgroup of patients, emphasising the multifactorial nature of the process. Few of these factors are modifiable in the setting of LT. Strategies to preserve renal function prior to LT in all recipients, with particular attention to those with more severe liver disease, NAFLD, diabetes and ascites, and minimising early allograft dysfunction may reduce post-LT AKI requiring RRT. Identifying patients at high risk of AKI informs post-LT immunosuppression strategy. The use of DCD grafts should also be carefully considered in this cohort to preserve renal outcomes.

FRI-388

Hepatitis C iInfected liver grafts transplanted into non-infected recipients are safe in the era of highly effective direct-acting antiviral therapy

Heather O'dell[1], Alison Rafferty[2], Natasha Schneider[1], Andrew Scanga[1], J. Kelly Wright[1], Sunil Geevarghese[1], Lea Matsuoka[1], Sophoclis Alexopoulos[1], Seth Karp[1], Roman Perri[1], Joseph Awad[1,2], Lee Gorden[1]. [1]*Vanderbilt University Medical Center, Nashville, United States;* [2]*Tennessee Valley Healthcare System, Veterans Affairs, Nashville, United States*
Email: heather.odell@vumc.org

Background and aims: Availability of effective direct-acting antiviral therapy has raised the possibility of safely transplanting hepatitis C infected organs into hepatitis C naïve recipients. This study aimed to (1) determine the incidence of post-liver transplant hepatitis C infection in previously uninfected patients transplanted with hepatitis C infected liver grafts, and (2) assess response to therapy using direct-acting antiviral agents for hepatitis C naïve patients who develop hepatitis C post-transplant with hepatitis C infected liver grafts.

Method: Hepatitis C non-infected patients awaiting liver transplantation were given the option of consenting to accept a hepatitis C infected graft that was otherwise deemed programmatically to be an acceptable organ for transplantation. These patients followed the same post-transplant treatment algorithms using direct acting antiviral agents that were utilized in recipients who were hepatitis C infected prior to transplant.

Results: A retrospective chart review from March 2016 to July 2018 noted 15 patients that underwent liver transplantation with hepatitis C infected grafts defined as positive donor hepatitis C nucleic acid testing into HCV naïve recipients. All 15 recipients developed hepatitis C infection post-transplant documented by a quantifiable viral load post-transplant with genotypes 1a, 2, and 3. Direct-acting antiviral therapy was initiated between 19 and 138 days (median 51 days) after liver transplantation. All 15 recipients completed treatment for hepatitis C using one of the following regimens: ledipasvir/sofosbuvir, glecaprevir/pibrentasvir, or sofosbuvir/

velpatasvir. Nine recipients have achieved a sustained viral response 12 weeks post treatment, one recipient has achieved a sustained viral response 4 weeks post treatment, and post treatment data is pending on the remaining 5 recipients. All transplanted recipients in this cohort are recovering expectedly.

Conclusion: Hepatitis C uninfected patients on the liver waitlist transplanted with hepatitis C infected grafts universally develop infection with hepatitis C post-transplant. Fortunately, these patients can be successfully cleared of hepatitis C post-transplant. In short term follow-up, hepatitis C non-infected patients who receive hepatitis C infected grafts do not have a higher mortality than non-infected liver recipients transplanted with non-hepatitis C infected donor grafts.

FRI-389

Impact of coronary artery disease on long term mortality after liver transplantation

Samarth Patel[1], Viviana Rodriguez[2], Mohammad Bilal Siddiqui[1], Masoud Faridnia[3], Joseph Clinton[4], Fei-Pi Lin[4], John Laurenzano[4], Anchalia Chandrakumaran[3], Trevor Reichman[5], Chandra Bhati[5], Mohammad Siddiqui[1]. *[1]Virginia Commonwealth University, Division of Gastroenterology, Hepatology and Nutrition, Richmond, United States; [2]Virginia Commonwealth University, Department of Bio-statistics, Richmond, United States; [3]Virginia Commonwealth University, Department of Internal Medicine, Richmond, United States; [4]Virginia Commonwealth University School of Medicine, Richmond, United States; [5]Virginia Commonwealth University, Department of Transplant Surgery, Richmond, United States*

Email: patelsamarth@gmail.com

Background and aims: Cardiovascular disease (CVD) is an important cause of post liver transplantation (LT) mortality and is higher than age-and gender matched cohorts. This happens despite careful pre-LT selection where patients deemed to be high risk for CVD are excluded from LT consideration. Thus, the key driver of this post-LT mortality is not known. We hypothesized that patients after LT have accelerated atherosclerosis and therefore, pre-LT coronary artery disease (CAD) would not be able to predict overall and CVD associated mortality post-LT.

Method: Protocol coronary angiography is performed in all patients aged > 50 years or risk factors (diabetes, hypertension, obesity, family history, smoking history) prior to LT. Those without risk factors and < 50 years old have non-invasive cardiac stress test and coronary angiography was limited to those with positive stress test. All adult patients receiving LT from 1/2007 to 1/2017 were included (N = 495). The primary and secondary outcomes were all cause mortality and CVD mortality, respectively. A Cox proportional hazards model was conducted on survival after LT adjusting for age, etiology of chronic liver disease, CAD, smoking, and diabetes.

Results: A total of 495 LTR were enrolled. The mean age of the LT recipients (LTR) was 55 ± 9 years and 358 (72%) were males. The prevalence of CAD as noted on angiography was 26% prior to LT. After median follow-up of 4.5 years (range:0-11 years), 120 (24.2%) deaths occurred, 29 (5.9%) of which were related to CVD. The 1-, 3- and 5-year survival rates were 91.5%, 84.4%, and 75.4%%, respectively. The overall mortality rates were similar between those with and without CAD at baseline (Figure 1). No association between presence, severity or history of CAD intervention with overall mortality was found. The etiology of liver disease was not related to overall mortality (Table 1). While NASH is closely associated with CAD (38.5% vs. 23.7% p = 0.009), in sub-group analysis CAD did not impact survival in patients transplanted for NASH cirrhosis [HR:1.47, 95%CI:0.47, 4.62].

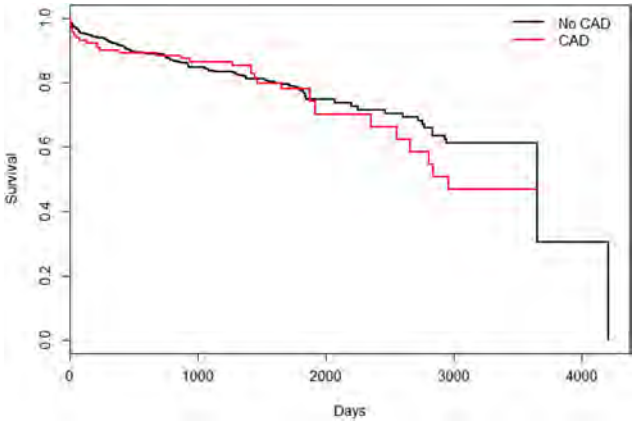

Figure 1: Survival curves of patients post-LT by presence of CAD.

Table 1: Cox proportional hazards model for overall survival post-LT

Characteristics	Hazard Ratio (95% CI)	p values
CAD present	1.00 (0.66, 1.53)	0.972
NASH	0.65 (0.37, 1.14)	0.131
Age	1.03 (1.00, 1.05)	0.034
Smoking	1.36 (0.94, 1.97)	0.106
Diabetes	1.37 (0.93, 2.02)	0.111

Conclusion: Despite aggressive attempts to risk stratify patients prior to LT, cardiovascular risk is not fully captured on pre-LT cardiac evaluation, lending further support to factors that are exacerbated post-LT. More importantly the prevalence of CVD mortality post-LT was much higher than the reported general population suggesting potential limitation in clinical management that need to be overcome if we are to improve long-term survival in LTR.

FRI-390

Management of dyslipidemia after liver transplantation

Samarth Patel[1], Viviana Rodriguez[2], Mohammad Bilal Siddiqui[1], Fei-Pi Lin[3], Masoud Faridnia[4], Joseph Clinton[3], John Laurenzano[3], Anchalia Chandrakumaran[4], Trevor Reichman[5], Chandra Bhati[5], Mohammad Siddiqui[1]. *[1]Virginia Commonwealth University, Division of Gastroenterology, Hepatology and Nutrition, Richmond, United States; [2]Virginia Commonwealth University, Department of Bio-statistics, Richmond, United States; [3]Virginia Commonwealth University, School of Medicine, Richmond, United States; [4]Virginia Commonwealth University, Department of Internal Medicine, Richmond, United States; [5]Virginia Commonwealth University, Department of Transplant Surgery, Richmond, United States*

Email: patelsamarth@gmail.com

Background and aims: Cardiovascular disease (CVD) remains a major cause of long-term mortality in liver transplant recipients (LTR). Adequate control of CVD risk factors like hypertension, diabetes, and dyslipidemia is therefore essential in this population. Although there is robust data supporting aggressive use of statin therapy in patients with documented CVD or dyslipidemia in general population, there is currently no data regarding post-liver transplantation (LT) CVD management or adherence to societal guidelines for management of dyslipidemia.

Method: Patients undergoing at liver transplantation at Virginia Commonwealth University from January 2007 to January 2017 were reviewed. All LTR had a thorough evaluation for coronary artery disease (CAD) prior to listing. Patients were considered eligible to be prescribed a statin if they had documented CAD on angiography or dyslipidemia. The primary end point consisted of percentage of eligible LTR receiving statins. Secondary end points were adverse events from statin use and patient survival. Associated factors to

statin use and mortality were assessed using a logistic regression and Cox proportional hazards models, respectively.
Results: The mean age of the 495 LTR patients in the sample was 55.3 ± 9.3 years. The median follow-up period was 4.5 years (range:0-11 years). In the post-LT period, 245 patients were eligible for statin therapy, and statin use was noted in 106 (43%) eligible patients. CAD was noted in 129 (26.1%) patients during the pre-LT evaluation, and 45% of these were on statin therapy post-LT. In the post-LT period 116 patients had dyslipidemia requiring statin therapy and 53% of them were on statin therapy. Factors associated with post-LT statin use included gender, CAD, diabetes (DM) and hypertension (HTN) (Table 1). Lower levels of alanine transaminase (ALT), aspartate transaminase (AST) and total bilirubin were observed in patients using statins. Finally, no patients developed liver failure or acute liver injury from statin use. Statin was related to longer survival time [HR:0.20, 95%CI:0.11, 0.38]

Table 1: Adjusted effect for statin use and overall mortality

Characteristics	Statin Use		Overall Mortality	
	OR (95% CI)	p value	HR (95% CI)	p value
Age	1.00 (0.98, 1.02)	0.899	1.04 (0.99, 1.08)	0.066
Male	0.48 (0.31, 0.74)	< 0.001	0.74 (0.41, 1.33)	0.315
CAD present	1.57 (1.00, 2.45)	0.046	1.66 (0.99, 2.76)	0.053
NASH	1.65 (0.97, 2.81)	0.064	0.86 (0.43, 1.72)	0.662
Hypertension	1.62 (1.08, 2.43)	0.021	1.20 (0.72, 1.98)	0.490
Diabetes	1.96 (1.28, 3.02)	0.002	1.81 (1.07, 3.04)	0.026
Statin	-	-	0.20 (0.11, 0.38)	< 0.001

Conclusion: The statin therapy is underutilized in LTR. The use of statin therapy after LT did not cause significant elevations in liver enzymes. There was no increased in hepatic complications with statin use. There was survival benefit noted with statin use.

FRI-391

Biliary calprotectin, lactoferrin and dimeric pyruvate kinase after liver transplantation are markers for biliary damage and predict graft survival

Conrad Rauber[1,2,3], Miriam Awad[3], Ronald Koschny[3], Peter Sauer[3], Arianeb Mehrabi[4], Philip Gath[5], Karl Heinz Weiss[3], Daniel Gotthardt[3], Christian Rupp[3]. *[1]Universite Paris-Sud, Universite Paris-Saclay, Paris, France; [2]Gustave Roussy Cancer Campus (GRCC), Villejuif, France; [3]University Hospital Heidelberg, Internal Medicine IV, Heidelberg, Germany; [4]University Hospital Heidelberg, Department of General, Visceral and Transplantation Surgery, Heidelberg, Germany; [5]Hospital Ludwigshafen, Department of Gastroenterology and Hepatology, Ludwigshafen, Germany*
Email: christian_rupp@med.uni-heidelberg.de

Background and aims: Biliary complications are an important cause of mortality and morbidity after liver transplantation. Endoscopic management is the mainstay for biliary strictures complicating LT. The prognosis of anastomotic strictures is largely beneficial and they resolve upon repeat endoscopic intervention. By contrast non-anastomotic strictures are often related to increased donor ischemia time and reperfusion injury while in many patients none of these risk factors can be identified. They carry a dismal prognosis with almost inevitable graft failure and need for re-transplantation. A reliable biliary marker for the assessment of irreversible versus reversible biliary damage would be of great value for patient triage and early consideration for re-transplantation.
Method: A cohort of 111 patients with liver graft complications after LT, who received ERC during 2006-2014 was analyzed. Bile fluid was collected during first ERC after LT. The cohort comprised 23 controls, 7 CMV infections, 8 biopsy proven acute rejections (ACR), 20 anastomotic strictures (AS), 15 non-anastomotic strictures (NAS) and 26 ischemic type biliary lesions (ITBL). Biliary calprotectin, lactoferrin and dimeric pyruvate kinase was measured by ELISA. Biliary markers were correlated with regard to the primary end point of re-transplantation free survival.
Results: Median calprotectin level in bile was 1426 pg/ml (range: 26-203100 pg/ml). Calprotectin was significantly higher in bile of ITBL and NAS compared to control, bile leakage, CMV infection, AS or ACR patients ($p < 0.001$) independent of serum liver values at ERC. Median biliary lactoferrin concentration was 153 pg/ml (range: 0-2714pg/ml). Lactoferrin was significantly higher in ITBL patients compared to the NAS ($p < 0.05$), AS or controls ($p < 0.001$). Median M2PK concentration was 296 pg/ml (range: 0-654pg/ml). Median M2PK values in ITBL were significantly higher compared to NAS ($p < 0.05$), AS ($p < 0.01$) and controls ($p < 0.001$). Calprotectin had the best predictive value for ERC diagnosed ITBL with an AUC of 0.838 at an optimal cutoff of > 3940 pg/ml for ITBL with a sensitivity of 81% and a specificity of 76%. Median re-LT-free-survival in the highest calprotectin and lactoferrin tertial was significantly reduced (24.5 months vs. not reached, $p < 0.01$ and 16.0 months versus not reached, $p < 0.01$). In multivariate analysis including age, gender, cold ischemia time, ERC radiographic classification of the biliary damage only biliary calprotectin ($p = 0.02$) and serum gGT ($p = 0.03$) were independent risk factors for reduced re-TL free survival.
Conclusion: Calprotectin and lactoferrin are bile markers for biliary damage and predict re-transplantation free survival. They can differentiate progressive biliary damage from reversible biliary damage or non-biliary liver value alterations after LT.

FRI-392

Sarcopenia associated with worse pre-transplant psychosocial status and predicted post-transplant diabetes

Yael Milgrom[1], Samir Abu Gazala[2], Abed Khaliala[2], Reem Gawi[2], Yusef Azraq[3], Mina Rowe[1], Mohamad Masarwah[1], David Hakimian[1], Hadar Merhav[2], Rifaat Safadi[1]. *[1]Hadassah Hebrew University Hospital, Liver Unit, Jerusalem, Israel; [2]Hadassah Hebrew University Hospital, Surgery Dept., Jerusalem, Israel; [3]Hadassah Hebrew University Hospital, Imaging Dept., Jerusalem, Israel*
Email: Safadi@hadassah.org.il

Background and aims: suggested as an objective surrogate marker for frailty and functional performance. Debatable associations reported between Sarcopenia and Pre or post-transplant morbidity and mortality outcomes. CT scan is an acceptable modality to assess sarcopenia via Whole-body Lean Muscle Mass (WLMM); although lacks standardization. This study assessed the correlation between Sarcopenia and liver transplant outcome in the Israeli population.
Method: An observational retrospective study included 26 adult transplants (deceased donors) at the Hadassah Medical center 2008-2011; with feasible adequate quality Pre transplant abdominal CT. WLMM assessed, adjusted to stature and correlated to transplant outcomes.
Results: mean age at transplant 51 ± 12.3 years (81% males), mean Model for End-Stage Liver Disease 21.4 ± 4.96. The majority (77%) of patients had viral hepatitis. Patients grouped in relation to the WLMM threshold of 650. There were no significant differences in mean post-transplant survival (28.44 ± 16.9 vs. 23.43 ± 16.92), death (83.33% vs. 78.57%), graft rejections (33.33% vs. 64.29, $p = 14$), infections (50% vs. 53.8%), biliary complications (41.7% vs. 35.7%) or recurrence of liver disease (33.33% vs. 21.43%) between the high and low WLMM, respectively. However, the low Muscle Mass significantly correlated with worse Pre transplant psychosocial assessment including compliance ($p = 0.02$), insight ($p = 0.01$) and support ($p = 0.0001$). Moreover, the high Muscle Mass significantly correlated with increased post-transplant diabetes (41.67% vs. 0%, $p < 0.001$).
Conclusion: Sarcopenia (WLMM) prior to Liver transplantation correlated with Pre transplant psychosocial assessment. Whole high LMS predicted post-transplant diabetes. Larger transplant population and post transplant WLMM will be provided at presentation.

FRI-393

Arterial stiffness in the assessment of cardiovascular risk after liver transplantation

Lydia Sastre[1], Raquel García[1], Julián Gonzalo Gándara[1], Marta Martínez-Picola[1], Pablo Ruiz[1], Jordi Colmenero[1], Miquel Navasa[1], Gonzalo Crespo[1]. [1]*Hospital Clínic, IDIBAPS, CIBERehd, University of Barcelona, Liver Transplant Unit, Liver Unit, Barcelona, Spain*
Email: gcrespo@clinic.ub.es

Background and aims: Liver transplant (LT) recipients have a higher cardiovascular risk (CVR) than the general population. Assessment of CVR is based in clinical algorithms whose usefulness after LT is unclear. Before causing major cardiovascular events, atherosclerosis induces asymptomatic vascular lesion that can be quantified through the estimation of arterial stiffness, or by measuring the ankle-arm index (AAI), among others. We aimed to evaluate these markers of early atherosclerosis and their association with clinical cardiovascular risk factors after liver transplantation.
Method: Cross-sectional single-center study in which we included, during one year, all LT recipients with a follow-up of 12 (± 3), 60 (± 6) and 120 (±6) months after LT. The presence of CVR factors (diabetes, arterial hypertension, dyslipemia, smoking status, obesity) and their control was assessed, and the algorithms SCORE and REGICOR were calculated. Arterial stiffness was estimated by measuring wave pulse velocity with the Mobil-O-Graph® device, and AAI was calculated with a double digital oscilometer (WatchBP OfficeABI®).
Results: We included 122 liver transplant recipients with 12 (n = 39), 60 (n = 45) y 120 (n = 38) months of follow-up, at a median age of 58, 60 and 66 years, respectively (p = 0.02). The prevalence of arterial hypertension increased significantly with the time of follow-up after LT (51%, 67% and 82% at 12, 60 and 120 months, respectively, p = 0.01). On the contrary, we did not find significant differences in the prevalence of the remaining CVR factors. Similarly, there were no statistically significant differences either in clinical algorithms or in AAI according to the time of transplant follow-up. Wave pulse velocity significantly increased, being 8.2 m/s at 12 months, 8.9 m/s at 60 months and 9.4 m/s at 120 months (p = 0.014). Wave pulse velocity was significantly associated with age (p < 0.001), time of transplant follow-up (p = 0.007), the REGICOR algorithm (p = 0.05), and the grade of control of blood pressure (p = 0.02).
Conclusion: Quantitative estimation of arterial stiffness by measuring wave pulse velocity is associated with variables related to cardiovascular risk and its grade of control after liver transplantation and thus it may be a good marker of such risk in this population. Longitudinal studies are required in order to test its capacity to predict major cardiovascular events.

FRI-394

Impact of early kidney dysfunction in the incidence of major cardiovascular events after liver transplantation

Lydia Sastre[1], Raquel García[1], Julián Gonzalo Gándara[1], Julissa Lombardo[1], Jonathan Aguirre[1], Pablo Ruiz[1], Jordi Colmenero[1], Miquel Navasa[1], Gonzalo Crespo[1]. [1]*Hospital Clínic, IDIBAPS, CIBERehd, University of Barcelona, Liver Transplant Unit, Liver Unit, Barcelona, Spain*
Email: gcrespo@clinic.ub.es

Background and aims: Major cardiovascular events (MACE) are increasingly frequent after liver transplantation (LT), and their risk factors are not well defined. Recent research has suggested an association between renal dysfunction and MACE, particularly in the short-term. We aimed to investigate the incidence of MACE after LT and evaluate their risk factors, both before and after LT, focusing on the relationship between renal dysfunction and the risk of MACE in the long-term.
Method: We designed a retrospective, single-centre study in which we included all recipients of a first, single-organ LT between January 1st 2007 and December 31st 2017. The incidence of MACE (arrythmia, coronary artery disease, cerebrovascular disease, peripheral artery disease) after LT was investigated, and risk factors before LT (cardiovascular risk factors, kidney function, characteristics of liver disease, age, gender), at discharge from transplant episode and 12 months after LT (cardiovascular risk factors, kidney function, immunosuppression) were evaluated.
Results: We included 627 patients, 117 (19%) of whom suffered at least one MACE at a median time of 18 (IQR 1-46) months after LT follow-up. Cumulative incidence of MACE was 8% and 20% at 12 and 60 months after LT, respectively. Most MACE episodes were arrhythmia (53%), coronary artery disease (27%) and cerebrovascular disease (19%). Age at LT, male gender and serum creatinine at LT were associated with the risk of presenting a MACE during the first month after LT at univariate analysis, with age (p < 0.001) and serum creatinine (p = 0.014) being independent risk factors at multivariate analysis. Male gender, age at LT, personal history of diabetes, arterial hypertension and MACE before LT, immunosuppression with cyclosporine A at transplant episode discharge, arterial hypertension 12 months after LT and serum creatinine at transplant discharge and 12 months after LT were associated with the incidence of MACE > 12 months after LT at univariate analysis. At multivariate analysis, age at LT (p = 0.019), male gender (p = 0.025), pre-LT personal history of MACE (p = 0.03) and serum creatinine 12 months after LT (p = 0.05) were independent predictors of the risk of MACE > 12 months after LT.
Conclusion: Our data suggest that renal dysfunction during the first months after LT is an early marker of cardiovascular risk in LT recipients. Whether renal-sparing immunosuppressive regimens also result in a decreased incidence of MACE should be evaluated in prospective, longitudinal studies.

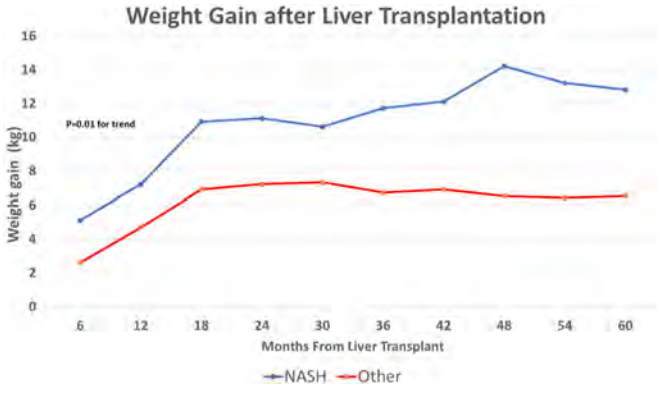
FRI-395

Etiology of liver disease affects weight gain after liver transplantation

Mohammad Bilal Siddiqui[1], Samarth Patel[1], Anchalia Chandrakumaran[2], John Laurenzano[2], Fei-Pi Lin[2], Joseph Clinton[2], Trevor Reichman[2], Chandra Bhati[2], Mohammad Siddiqui[1]. [1]*Virginia Commonwealth University, Gastroenterology and Hepatology, Richmond, United States;* [2]*Virginia Commonwealth University, Richmond, United States*
Email: mohammad.b.siddiqui@vcuhealth.org

Background and aims: Weight gain after liver transplant (LT) is a key driver of cardiometabolic disease and associated mortality. There is little known about trends in post-LT weight gain including liver disease specific differences in weight gain after LT. The published data is limited by epidemiological studies linked to the SRTR database and with relatively short follow-up. Patient level data are needed to better understand weight gain after transplant to optimize management. Thus, the aim of the current study was to evaluate long-term weight trends after LT.
Method: All patients who had a LT between 2010 and 2016 were evaluated. To minimize the confounding effects of perioperative fluid weight, the baseline weight was the 1st weight after hospital discharge for LT. Body weights were collected at 6-month intervals from LT to end of follow-up to 1/2018. Patients with combined organ transplants and those who died within 1 year after LT were excluded. To keep the analysis focused, we evaluated patients transplanted for either NASH, alcohol or HCV related cirrhosis since these are the most common indications for LT.
Results: A total of 496 patients had a LT over the study period and met study criteria. The baseline distribution of etiology of liver disease was: HCV (N = 227), NASH (N = 78), and alcohol (N = 79). At the time of LT, the mean weight for patients transplanted for HCV, NASH, and alcoholic cirrhosis was 81 ± 18 kg, 84 ± 15 kg and 75 ± 17 kg, respectively (p = 0.004). The weight gain experienced by patients transplanted for NASH cirrhosis was higher than other etiologies of chronic liver disease (**Figure 1**). Patients with NASH started to gain weigh early after LT where they gained 7.3 ± 13 kg compared to 6.3 ±

9.8 kg for HCV and 3.5 ± 12.1 kg for alcohol (p = 0.05). This trend persisted for up to 60 months where patients gained the greatest degree of weight (p = 0.029). This trend persisted, and the difference was more pronounced at 60 months after LT (12.8 ± 13.1 kg for NASH vs. 6.5 ± 13.3 kg for other indications, p = 0.01). In patients with NASH, male gender was predictive of weight gain but this association was no longer significant after 24 months. In patients transplanted for NASH cirrhosis, age, diabetes, hypertension, and dyslipidemia at the time of LT were not predictive of future weight gain.



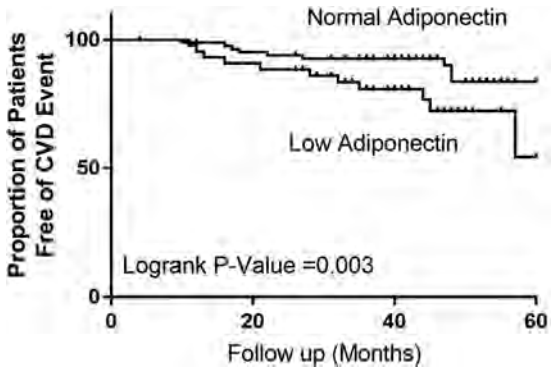
Conclusion: Weight gain after transplant is common in LT recipients regardless of etiology of liver disease. However, there is a liver disease specific impact on weight gain after LT in which patients transplanted for NASH cirrhosis are likely to gain the most weight after LT.

FRI-396

Hypoadiponectinemia as a predictor of cardiovascular events in liver transplant recipients

Mohammad Bilal Siddiqui[1], Samarth Patel[1], Fei-Pi Lin[1], Joseph Clinton[1], John Laurenzano[1], Anchalia Chandrakumaran[1], Trevor Reichman[1], Chandra Bhati[1], Mohammad Siddiqui[1]. [1]*Virginia Commonwealth University, Richmond, United States*
Email: mohammad.b.siddiqui@vcuhealth.org

Background and aims: Cardiovascular disease (CVD) is an important cause of morbidity and mortality after liver transplantation (LT). Serum adiponectin levels inversely correlate with CVD related outcomes, but the relationship between hypadiponectinemia and CVD after LT is unknown. Thus, the aim of the present study was to prospectively evaluate this relationship in LT recipients (LTR).
Method: LTR were prospectively enrolled (N = 130) between 1/1/2012 and 1/1/2014. Baseline adiponectin levels were drawn at enrollment and patients were followed for CVD events. Hypoadiponectinemia was defined as serum adiponectin < 10 µg/ml. The primary end point was a composite CVD outcome consisting of myocardial infarction, angina, need for coronary revascularization, stroke or cardiac death.
Results: The mean age was 58 ± 11 years and prevalence of obesity, diabetes and dyslipidemia was 40%, 35% and 40%, respectively. A total of 20 CVD events were noted after median follow-up of 45 months. Hypoadiponectinemia was significantly associated with future risk of CVD event (HR 3.519, 95% confidence interval 1.180, 10.499, p = 0.024). This association was independent of traditional CVD risk factors including age, gender, obesity, hypertension, diabetes and choice of immunosuppression.
Conclusion: Hypoadiponectinemia is a strong independent predictor of future cardiovascular events in LTR can be incorporated in clinical practice to assess CVD risk assessment after LT.



FRI-397

Sepsis is a major risk factor for delirium post liver transplantation

Oliver Tavabie[1], Robert Adamson[1], Deepak Joshi[1], Abid Suddle[1], William Bernal[1], Wayel Jassem[1], Michael Heneghan[1], Varuna Aluvihare[1], Kosh Agarwal[1]. [1]*King's College Hospital NHS Foundation Trust, Institute of Liver Studies, London, United Kingdom*
Email: oliver.tavabie@nhs.net

Background and aims: The aetiology of delirium post liver transplantation (LT) is typically multifactorial with pre-LT and post-LT risk factors. The presence of delirium in this cohort has been demonstrated to be associated with increased morbidity and mortality. This study aims to evaluate individual aetiologies of post-LT delirium and review the effect on intensive care unit (ICU) and hospital length of stay (LOS).
Method: We retrospectively analysed all adult LTs from 08/2016-08/2017 for chronic liver disease performed at King's College Hospital. We recorded patients' age, liver disease aetiology, previous neurological history, pre-LT; serum sodium, UKELD, encephalopathy and post-LT; evidence of sepsis, tacrolimus levels at day 5 and use of a renal sparing strategy. We analysed ICU LOS and ward LOS. Inclusion criteria were defined as a documentation of confusion or delirium post-LT in the absence of structural neurological abnormality. Data was collected and univariate and multivariate analysis were performed.
Results: 186 LTs were performed fulfilling inclusion criteria during this time. The incidence of post-LT delirium was 13.4%. ICU LOS was prolonged in patients with post-LT delirium (*Mdn = 5.0 v 3.0, U = 1442, n_1 = 25, n_2 = 160, P < 0.05 two tailed*) as was hospital LOS (*Mdn = 14.0 v 10.5, U = 1390, n_1 = 25, n_2 = 160, P < 0.05 two tailed*). Sepsis was diagnosed more frequently in patients with post-LT delirium than those without (*OR 4.6, CI 1.96-10.5, p < 0.005*). No significant associations were observed for patients with post-LT delirium and; serum sodium, UKELD, age or day 5 tacrolimus levels. Although not reaching clinical significance, post LT delirium may be associated between pre-LT encephalopathy (*OR 1.9, CI 0.82-4.32, p = 0.13*) and post LT acute kidney injury (*OR 2.2, CI 0.94-4.95, p = 0.08*). There were no significant differences seen in prevalence of underlying liver disease aetiology in patients with post-LT delirium although numbers were small for meaningful statistical analysis. Delirium was typically short-lived and did not affect survival.
Conclusion: Delirium post-LT is associated with increased ICU and hospital LOS. Sepsis post-LT was significantly associated with post-LT delirium. A high clinical suspicion for sepsis in patients with post-LT delirium should be advised.

FRI-398

Impact of sarcopenia and myosteatosis on post-transplant complications and survival

Daniele Tavano[1], Francesca Di Sario[1], Daria D'ambrosio[1], Simone Di Cola[1], Nicoletta Fabrini[1], Vincenza Di Gregorio[1], Barbara Lattanzi[1], Manuela Merli[1]. [1]*Sapienza University of Rome, Rome, Italy*
Email: danieletav92@gmail.com

Background and aims: Several studies have reported that sarcopenia is associated with a poor prognosis before transplantation. Recent data suggest that also myosteatosis is an important emerging prognostic factor in cirrhosis. However there is not definitive evidence about the role of sarcopenia and myosteatosis after liver transplantation. The aim is to investigate the correlation of sarcopenia and myosteatosis with complications and mortality after liver transplantation.
Method: 173 liver transplanted cirrhotic patients were enrolled between 2000 and 2015 at "Policlinico Umberto I" of Rome. Sarcopenia and myosteatosis were analyzed by CT scan (performed before transplantation) using the third lumbar vertebrae skeletal muscle and attenuation indexes, using previously validated gender- and body mass index-specific cutoffs.
Results: Patients were predominately men (n = 116, 67%). The most represented aetiologies were viral hepatitis (43%), alcohol (16%) and NASH (13%). The average age was 55.6 ± 9.1 years. The mean follow-up after liver transplantation was 55.6 ± 51.6 months. At the time of transplantation sarcopenia was present in 73 patients (42, 2%) and myosteatosis in 71 patients (41.2%). Days of hospitalization in intensive care, acute and chronic rejection, graft loss, neoplasia, cardiovascular events, dyslipidemia, arterial hypertension and diabetes were considered during the follow-up and there were no differences between patients with or without myosteatosis and sarcopenia. The presence of myosteatosis is not associated with mortality after transplantation (p = 0.9). The Kaplan-Meier curve showed a significantly higher mortality in the pre-liver transplant sarcopenic population vs non sarcopenic patients (p = 0.01).

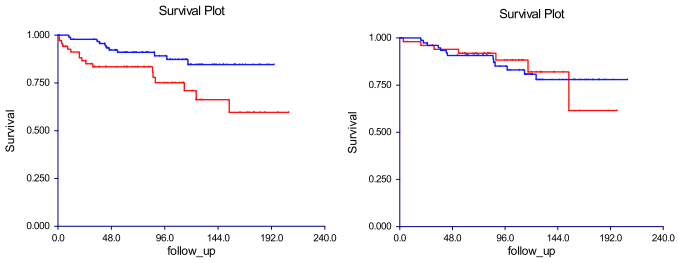


Figure: Survival after transplantation in sarcopenic patients Survival after transplantation in patients with myosteatosis p = 0.01 p = 0.9.

Conclusion: Neither myosteatosis nor sarcopenia are associated with a higher rate of post-transplant complications. Patients with myosteatosis do not have a worse prognosis after the liver transplant. Pre-transplant sarcopenia is a negative prognostic factor for post-transplant survival.

FRI-399

Impact of a temporary cardiac arrest in a brain dead liver donor on liver transplantation results

Elodie Timsit[1], Eric Savier[1], Yann De-Rycke[1], Meriem Khalfallah[2], Frederic Charlotte[1], Rousseau Geraldine[1], Perdigao Fabiano[1], Corinne Vezinet[1], Olivier Scatton[1], Filomena Conti[1]. [1]*84 Boulevard de l'Hôpital, Paris, France;* [2]*Boulevard Tonnellé, Tours, France*
Email: elodietimsit0890@gmail.com

Background and aims: The use of hepatic allografts from donors who have suffered a temporary cardiac arrest (TCA) is considered as a risk factor of liver failure following liver transplantation (LT) because he could lead to graft dysfunction. Conversely, some studies suggested a protective effect. The aim is to study the influence of TCA in brain dread donors (BDD) on LT outcome.
Method: Single institutional retrospective study on 429 consecutive LT (01/2008-06/2017). Exclusion criteria: retransplantation, multi-organ transplantation, splits and domino graft, controlled cardiac dead donors. A group of LT from TCA donor (n = 111) was compared to a group of no TCA (n = 318). Primary end point: arteriobiliary complications free survival (ABC free survival) during the first year post-LT.
Results: patients of the TCA group were younger than patients of the no-TCA group. Main cause of death was anoxia in the TCA group and vascular in the no-TCA group. The following characteristics donor were higher in the TCA group: AST and ALT levels (peak), γGT and ALP at day 1 after ICU admission, creatinine, PT and peak of lactate and bilirubin. Patient survival, graft survival and Early Graft Dysfonction were not different between the 2 groups. AST and ALT level at postoperative day 2 were lower in the TCA group. The ABC free survival was significantly higher in the TCA group compared to the no-TCA group (81% versus 70% at 1 year, p = 0, 044) at univariate analysis. However, this difference disappeared at multivariate analysis.
Conclusion: We failed to observe any deleterious effect of a TCA in BDD on LT outcome. On the contrary, some results were suggestive of a protective influence.

FRI-400

Poor long term outcome of patients undergoing liver transplantation with preterminal renal dysfunction

Marcel Touma[1], Thomas Horvatits[1], Sven Pischke[1], L Fischer[2], Ansgar W. Lohse[1], Martina Sterneck[1]. [1]*University Hospital Hamburg-Eppendorf, Gastroenterology and Hepatology, Hamburg, Germany;* [2]*University Hospital Hamburg-Eppendorf, Department of visceral Transplantation, Hamburg, Germany*
Email: marcel.touma91@gmail.com

Background and aims: With introduction of the Model of End Stage Liver Disease (MELD) based allocation system the number of patients undergoing orthotopic liver transplantation (OLT) with severely impaired renal function has significantly increased. Due to organ shortage nowadays, combined renal transplantation (KTx) and OLT are not routinely performed. Therefore, we here investigated long term outcome of patients undergoing OLT with advanced renal dysfunction.
Method: In this retrospective study all patients were included who underwent OLT at the University Hospital Hamburg-Eppendorf between 2011 and 2015 with chronic kidney disease (CKD) stage 4/5. Course of kidney function, need for dialysis, risk factors for poor renal outcome as well as patient survival were assessed.
Results: Altogether 60 patients (CKD 4: n = 22, 37%, CKD 5: n = 38, 63%) were included in the study. Median follow-up was 1099 days (IQR 66-1817). Directly postoperatively, 42 (70%) patients required dialysis for median 21 days (IQR 8-61). On long term follow-up 18/60 (30%) remained on dialysis, 5 of these patients (28%) subsequently underwent KTx after a median period of 274 days (IQR 201-1461). 29 patients (48%) had CKD 4/5 or had undergone KTx at end of follow-up. There was no difference in terms of age, CKD stage or time on dialysis prior to OLT or length of stay on ICU between patients with compensated renal function and those with poor renal outcome (CDK 4/5 or KTx) at last follow-up (p = n.s.). Furthermore, neither type of immunosuppression (CNI-free vs. CNI-based, mono, dual or triple immunosuppression), nor presence of diabetes, arterial hypertension or hyperlipidemia during follow-up were associated with poor renal outcome (p = n.s.). The only risk factor for poor renal outcome post OLT was post-operative need for dialysis.
Overall 3- and 5-year patient survival after OLT was 60% and 42% respectively. 1- and 5- year mortality was significantly higher in patients with poor compared to compensated renal outcome (59% vs.

13%, p < 0, 001 and 72% vs. 28%, p < 0.001 respectively), as illustrated in figure 1.

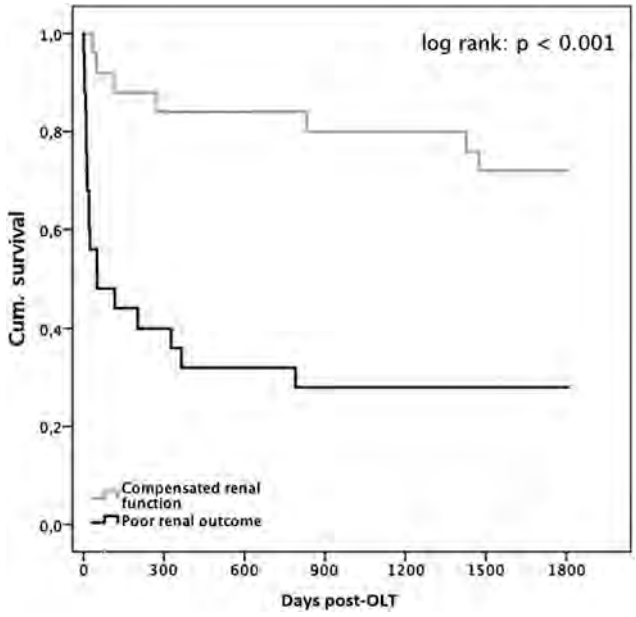

Figure 1: Kaplan-Maier plot of patient survival according to renal function after OLT (compensated: CKD 1/2/3; poor renal outcome: CKD 4/5 or KTx)

Conclusion: In this long-term follow-up study, about half of the patients with CKD 4 and 5 prior to OLT had poor long term renal outcome post transplantation, going along with a very low 5 year patient survival rate of only 28%. Only necessity of renal replacement therapy after OLT was associated with this poor outcome. Therefore, further studies should investigate if survival improves with combined OLT and KTx.

FRI-401

Direct-acting antiviral agents are not associated with an increased risk of hepatocellular carcinoma recurrence in liver transplant recipients with hepatitis C

Chung Sang Tse[1,2], Judong Yang[3], Omar Mousa[3,4], Surakit Pungpapong[4], Andrew Keaveny[4], Kevin Nelson[3], Aqel Bashar[5], Rolland Dickson[5], Hugo E. Vargas[5], Gregory Gores[3], Lewis Roberts[3], Michael Leise[3]. *[1]Brown University, Gastroenterology, Providence, United States; [2]Mayo Clinic, Internal Medicine, Rochester, United States; [3]Mayo Clinic, Gastroenterology and Hepatology, Rochester, United States; [4]Mayo Clinic, Gastroenterology and Hepatology, Jacksonville, United States; [5]Mayo Clinic, Gastroenterology and Hepatology, Scottsdale, United States*
Email: Tse.Chungsang@brown.edu

Background and aims: Prior data demonstrated a possible association between direct acting antiviral (DAA) and heightened risk of HCC recurrence after liver transplantation for individuals with hepatitis C virus related hepatocellular carcinoma (HCV-HCC). The aim of this study was to determine the relationship between direct-acting antiviral (DAA) treatment and post-transplant HCC recurrence.
Method: We conducted a retrospective cohort study of HCV-active patients (with detectable viral load subsequent to interferon-based therapy, or treatment naïve) who underwent liver transplantation for HCC at three centers between January 1, 2014 and June 30, 2017. The study group received DAA-containing therapy prior to liver transplantation while the control group did not. The primary outcome was the rate of recurrence of HCC post-transplant. Secondary outcomes were the rate of sustained virologic response (SVR12), HCV recurrence post-transplant, liver allograft failure, and death. Statistical analyses with t-test and chi-square were used to compare baseline variables. Kaplan Meier analysis and Cox proportional hazard models were used to investigate the risk of HCC recurrence.
Results: A total of 171 patients were included in the study (99 DAA; 72 controls). Post-transplant HCC recurrence rate was 9% (n = 15). The median follow-up time was 24 months (IQR 12, 26). DAA-treated patients and the control group were not statistically different for Model for End Stage Liver Disease (MELD) scores, wait time on the transplant list, and histologic assessment of the explanted liver.
Pre-transplant DAA was not associated with HCC recurrence (RR 0.40; 95% CI 0.12, 1.15; p = 0.09) while lymphovascular invasion (HR 4.36; 95% CI, 1.16, 28.3; p = 0.03) was associated with increased risk of HCC recurrence. SVR12 pre-transplant was 75% (39/52), which is significantly lower (p < 0.01) than the post-transplant SVR12 rate of 97% (59/61). Liver transplant graft failure (7% vs 3%; p = 0.21) and death (12% vs 14%; p = 0.19) were not statistically different among the DAA treatment group and the controls.

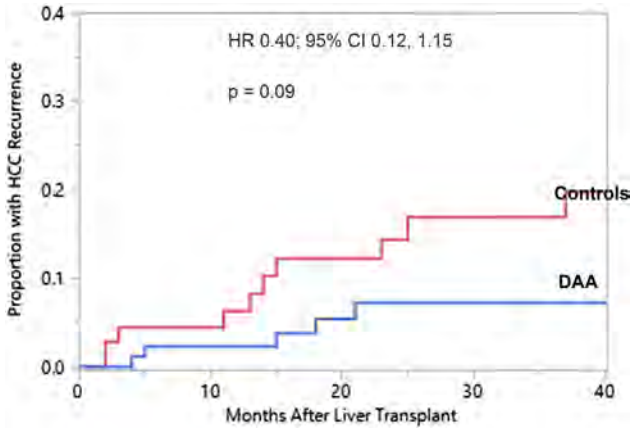

Figure: Inverse Kaplan Meier Curve for Hepatocellular Carcinoma Recurrence Post-Liver Transplant, by Pre-Transplant Direct-Acting Antiviral Therapy

Conclusion: DAA therapy for HCV is not associated with an increased risk of post-transplant HCC recurrence.

FRI-402

Outcomes after liver transplantation for argininosuccinate lyase deficiency: A longitudinal study

Nipun Verma[1,2], Patrick Mckiernan[1,3], Diana Shellmer[3], Pamela Kachmar[3], James E. Squires[1], Robert Squires[1], Gerard Vockley[4], George V. Mazariegos[3], Kyle Soltys[3]. *[1]UPMC Children's Hospital of Pittsburgh, Pediatric Gastroenterology, Hepatology and Nutrition, Pittsburgh, United States; [2]Post Graduate Institute of Medical Education and Research, Chandigarh, Hepatology, Chandigarh, India; [3]UPMC Children's Hospital of Pittsburgh, Hillman Center for Pediatric Transplantation, Pittsburgh, United States; [4]UPMC Children's Hospital of Pittsburgh, Medical Genetics, Pittsburgh, United States*
Email: nipun29j@gmail.com

Background and aims: Argininosuccinate lyase deficiency (ASLD) is a rare urea cycle defect, manifesting as recurrent hyperammonemia, neurocognitive decline, liver fibrosis and hypertension. Liver transplantation (LT) corrects the defect in liver and abolishes hyperammonemia, but its impact on extrahepatic manifestations is uncertain and poorly reported. We describe the outcomes of children undergoing LT for ASLD in our Centre.
Method: Retrospective analysis of the impact of LT on 7 patients with ASLD was done. Development and behavioral functioning were assessed by the Adaptive Behavior Assessment System-II (ABAS-II) and the Child Behavior Checklist (CBCL). Quality of life [QoL] assessments for the patients were done using the Pediatric Quality

of Life Inventory (PedsQL) and for the family using the Family Impact Module of the PedsQL.
Results: The primary indication for LT was poor metabolic control and developmental delay. Pre-transplant CBCL scores were impaired in internalizing, externalizing and/or total problems in 4/7 children. ABAS-II scores fell in the low average, below average, or borderline range of functioning in 6/7 children. PedsQL revealed impaired physical functioning in 5/6 subjects and impaired family functioning in 5/7 families. Median [range] age at LT was 4.2 years [2.4-6.6]. All 7 are alive and well with recent follow-up of 3.7 years [1-5.2]. No new seizures have occurred and currently all are receiving tacrolimus monotherapy. Current diet is unrestricted without any need of ammonia scavengers. Plasma amino acids and ammonia have normalized except for persistent hypercitrullinemia. One child has developed hypertension; well controlled with a single drug. All 7 demonstrated developmental progress and of those with school age participate in mainstream education. Three children had formal post-transplant assessment. ABAS-II global scores for 2/3 children improved to the Borderline range of functioning. CBCL scores improved to the normal range with 2/3 children signifying improvement in attention or somatic problems. PedsQL parent report revealed improved physical functioning, but mildly impaired school functioning in 3/3.
Conclusion: LT abolishes the hyperammonemia in ASLD and in the short term hypertension is unusual. The early impact of LT on developmental outcomes and QoL in ASLD suggests stabilization and diminished likelihood for continued decline. Longer follow-up is required to ascertain the ultimate impact of LT in ASLD.

FRI-403
Impact on post liver transplant outcomes of response to treatment with terlipressin and albumin in patients with hepatorenal syndrome
Elia Vettore[1], Salvatore Piano[1], Marta Tonon[1], Antonietta Romano[1], Carmine Gambino[1], Eleonora Bertoli[1], Silvano Fasolato[1], Giacomo Zanus[2], Patrizia Boccagni[2], Patrizia Burra[3], Umberto Cillo[2], Paolo Angeli[1]. *[1]Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine-DIMED, University of Padova, Italy, Padova, Italy; [2]Hepatobiliary Surgery and Liver Transplantation Unit, Department of Surgery, Oncology and Gastroenterology, Padua, Italy, Padova, Italy; [3]Gastroenterology/Multivisceral Transplant Unit, Padua, Italy, Padova, Italy*
Email: martatonon11@gmail.com

Background and aims: Hepatorenal syndrome (HRS) is a relevant complication of cirrhosis and is associated with a poor prognosis. Terlipressin and albumin are effective in resolving HRS, but liver transplantation (LT) is still the best treatment of HRS. However, it is not clear of an effective treatment with terlipressin and albumin may improve outcomes after LT in patients with HRS. The aim of this study was to evaluate the impact of response to treatment with terlipressin and albumin on post-transplant outcomes in patients with HRS.
Method: We analyzed 2 cohorts of patients with liver cirrhosis listed for LT at our Centre between 2012 and 2016: a) patients who developed HRS before LT which were treated with terlipressin and albumin an b) patients without HRS transplanted during the study period (control group). Patients with HRS were classified as responders or non-responders to the treatment. We excluded patients with previous liver transplant or indication for combined liver and kidney transplantation.
Results: 82 patients with HRS before transplant were treated with terlipressin and albumin (first cohort) and the rate of response to therapy was 52%. Responders had a better transplant free survival (60% vs 33%, p = 0.006) 30 days after HRS, longer LT waiting list time (37 vs 17 days, p = 0.041) and lower MELD-score at the time of LT (23 vs 29, p = 0.007). Among patients with HRS who were transplanted (n = 63), non-responders showed a worse renal function in the first week after LT, higher need for RRT (0% vs 26%, p < 0.001) and higher rate of post-transplant infections (63% vs 87%, p = 0.037) than responders. There were no differences in length of stay, graft dysfunction, immunosuppressive protocols and trough levels of calcineurin inhibitors between responders and non-responders. Non-responder had a significantly higher incidence of CKD 1 year after liver transplantation than responders (60% vs 33%, p = 0.019). When also the control group was included in the analysis of predictors of CKD at 1 year, age (sHR = 1.04; p = 0.024), diabetes (sHR = 1.64; p = 0.048), AKI post-transplant (sHR = 1.81; p = 0.012), MELD at the time of transplantation (sHR = 1.03; p = 0.028), and no responder to terlipressin and albumin were found to be independent predictors for CKD, while responders had a similar risk of CKD than control group. There were no difference in term of survival between responder, no responder and control group.
Conclusion: Treatment with terlipressin and albumin improves renal function before LT, reduced need for RRT use and is associated with a lower prevalence of CKD at 1 year after LT. Non-response to terlipressin and albumin is an independent predictor of CKD at 1 year.

FRI-404
Multicenter experience evaluating outcomes of HCV-seropositive donors to HCV-seronegative recipients liver transplantation
Karn Wijarnpreecha[1], Surakit Pungpapong[1], Aqel Bashar[2], Kunam Reddy[3], Burcin Taner[4], Michael Leise[5], Rolland Dickson[2]. *[1]Mayo Clinic, Gastroenterology and Hepatology, Jacksonville, United States; [2]Mayo Clinic, Gastroenterology and Hepatology, Scottsdale, United States; [3]Mayo Clinic, Transplant and Hepatobiliary Surgery, Scottsdale, United States; [4]Mayo Clinic, Transplant, Jacksonville, United States; [5]Mayo Clinic, Gastroenterology and Hepatology, Rochester, United States*
Email: dr.karn.wi@gmail.com

Background and aims: The introduction of direct-acting antiviral agents (DAA) in the context of organ shortage and high waitlist mortality among liver transplant (LT) candidates has resulted in increased interest in using grafts from hepatitis C virus (HCV)-seropositive donors. We report here our multicenter experience evaluating the outcome of HCV-seropositive donors to HCV-seronegative recipients LT.
Method: This is a retrospective analysis of prospectively collected database of ongoing multicenter IRB-approved research study expanded into clinical protocol to evaluate adult HCV-seronegative LT recipients who received grafts from HCV-seropositive donors.
Results: Since January 2018, 10 HCV-seronegative LT recipients received grafts from HCV-seropositive brain dead donors [3 with negative nucleic acid testing (NAT) and 7 with positive NAT] with the median allocated MELD-Na score of 20 (range 11-30). Three underwent simultaneous liver-kidney transplant (SLK) and 3 underwent repeat LT. The median waiting time prior to listing for HCV-seropositive donor was 266 days (range: 0-988). The median waiting time after listed for HCV-seropositive donor to LT was 57 days (range: 9-238). None of the patients who received HCV-NAT negative grafts developed HCV viremia at the median follow-up of 48 days (range 45-181) after LT. All 7 patients who received HCV-NAT positive grafts had HCV viremia confirmed within 5 days after LT with the median peak HCV RNA of 33.1 million IU/ml (range 1-97.5 millions). DAA treatment was started at the median time of 32 days (range 6-62) after LT: 5 patients received glecaprevir/pibrentasvir (G/P) for 12 weeks, 1 patient received 12 weeks of ledipasvir/sofosbuvir (LDV/SOF) and ribavirin (RBV), and 1 patient is waiting for insurance approval. HCV RNA decreased after 1 week of treatment and all patients achieved negative HCV RNA by week 4 (range 1-4). Mild AST/ALT elevation was observed, but it was not associated with graft dysfunction. Two patients had mild biopsy-proven acute rejection. No graft loss or death was observed.
Conclusion: LT using HCV-seropositive grafts to HCV-seronegative recipients resulted in excellent short-term outcomes in our multicenter experience. The acceptance of HCV-seropositive grafts may

improve the chance of LT and reduce waitlist morbidity and mortality, especially in the certain population such as those awaiting SLK or repeat LT.

Table:

Patient	Age/ Sex	Allocated MELD-Na Score	Blood Type	Organ	Waiting Time before HCV+ Listing (days)	Waiting Time after HCV+ Listing (days)	HCV Genotype	DAA Regimen	Interval from LT to DAA Treatment (days)

Predictors of outcomes for patients with non-alcoholic steatohepatitis undergoing liver transplantation in the United States

Maria Stepanova[1], Alita Mishra[2], Issah Younossi[1], Donghee Kim[3], Aijaz Ahmed[3], Zobair Younossi[2,4]. *[1]Center for Outcomes Research in Liver Diseases, Washington DC, United States; [2]Center for Liver Disease-, Department of Medicine, Inova Fairfax Medical Campus, Falls Church, United States; [3]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, Palo Alto, United States; [4]Inova Health Systems, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States*
Email: zobair.younossi@inova.org

Background and aims: NASH is currently among the leading causes of liver transplantation (LT) in the U.S. **Aim:** To assess predictors of LT outcomes in NASH.
Method: We used the Scientific Registry of Transplant Recipients, and included all adult (18+) LT candidates waitlisted in 2001-2017 in the U.S. with the primary listing diagnosis of NASH with available clinical, demographic, and outcomes data. Independent predictors of receiving a LT were assessed using multiple logistic regression; independent predictors of post-transplant mortality were assessed using Cox proportional hazard model; patients were followed till March 2018.
Results: 27, 117 NASH patients were listed for LT (2001-2017) with complete data: 58.5 ± 9.2 years, 53% male, 77% white, 21% employed, 43% pre-LT type 2 diabetes (DM), 10% hepatocellular carcinoma (HCC), 58% were covered with private insurance, 29% with Medicare, and 10% with Medicaid. After listing, 54.8% of NASH patients were eventually transplanted (mean wait time 226 days), 24.4% dropped out of the list, and 3.3% improved. Factors independently associated with a lower chance of receiving a LT were older age (odds ratio (OR) (95% confidence interval) = 0.989 (0.985-0.993) per year), Hispanic ethnicity (0.78 (0.71-0.85)), being covered by Medicare (0.82 (0.75-0.88)) or Medicaid (0.74 (0.66-0.83)), being on life support (0.60 (0.47-0.76)), having hepatic encephalopathy (0.83 (0.75-0.91)), and prior history of non-liver transplants (0.59 (0.39-0.90)). Factors independently associated with a higher chance of receiving a LT were male gender (1.42 (1.33-1.52)), having listing status 1 (2.39 (1.34-4.25)) or HCC (2.15 (1.89-2.44)), ascites (1.68 (1.49-1.90)) or higher MELD score (1.005 (1.001-1.009) per 1 point) or being on dialysis (1.26 (1.15-1.37)) (all $p < 0.02$). Post-LT mortality was as follows: 11.9% at 1 year, 18.3% at 3 years, 23.8% at 5 years, 40.3% at 10 years. Independent predictors of higher post-LT mortality were an earlier year of LT (adjusted hazard ratio (aHR) = 0.94 (0.92-0.95) per year), older age (1.025 (1.019-1.031) per year), having Medicare (1.14 (1.03-1.26)) or Medicaid (1.23 (1.05-1.44)), being on life support, higher MELD score (1.006 (1.000-1.013) per point), pre-LT DM (1.14 (1.04-1.26)), re-transplant (1.90 (1.49-2.42)), and HCC (1.46 (1.23-1.73)) (all $p < 0.05$).
Conclusion: Comorbidities and socio-demographic factors are associated with waitlist and post-transplant outcomes in patients with NASH.

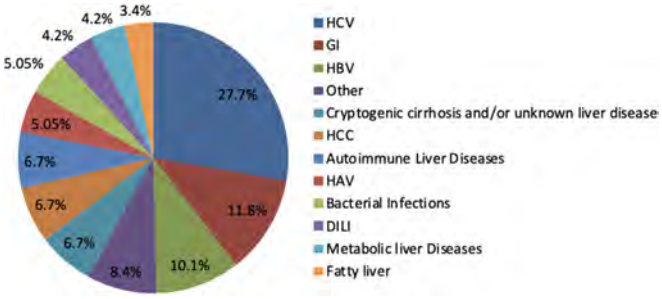
Elevating liver disease management in Egypt: A Project Echo® experience

Noha Abdelgelil[1], Fatma Barakat[1], Tarek Hassanein[1]. *[1]International Liver Centers Foundation, Inc., Coronado, United States*
Email: ilcfecho@livercenters.com

Background and aims: Chronic Hepatitis C infection (CHC) continues to be a major health burden in Egypt, with almost 10% of the general population affected. Despite efforts on eradicating CHC in Egypt, there are limited resources. Patients still suffer from complications of liver disease and a complex of health conditions, especially those living in underserved areas. *"Project ECHO®* [Extension for Community Healthcare Outcomes] *is a movement to demonopolize knowledge and amplify the capacity to provide best practice care for underserved people all over the world. The ECHO model™ is committed to addressing the needs of the most vulnerable populations by equipping communities with the right knowledge, at the right place, at the right time."* https://echo.unm.edu/wp-content/uploads/2018/07/ECHO_One-Pager_07.24.2018.pdf Using videoconferencing, International Liver Centers Foundation (ILCF) in Southern California replicated the ECHO Model™ with clinicians and researchers in Egypt. The goals of the ILCF-Egypt ECHO® are to guide Egyptian clinicians in the management of CHC and its complications, connect clinicians practicing in major cities in Egypt with those in rural areas and link senior practitioners with their junior peers.
Method: ILCF-Egypt ECHO® started in October 2017 with 3 clinicians (spokes) from Alexandria. The spokes are practicing at community hospitals in Alexandria and independent clinics in the surrounding communities. Sessions are held bi-monthly. A typical session lasts 2 hours and consists of 5 case presentations and a 20-minute didactic given by ILCF or an invited expert (Hub). Case presentations are sent in advance in a de-identified standard format with pertinent medical information. Each case presentation is followed by a discussion between the spokes and Hub. The Hub then forwards its final recommendations to the spoke.
Results: Initially, our focus was on Alexandria and its surroundings. The number of spokes steadily grew. Case presentations were focused on complicated cases of CHC. Currently, based on the spokes" requests, the majority of the cases and didactics are on other aetiologies of liver disease (see figure). The spokes and Hub also developed collaborative research projects including a 23-case report of leptospirosis.
Conclusion: ILCF-Egypt Project ECHO®: 1) is successful in connecting GI/Transplant Hepatology experts in the U.S. with clinicians in Egypt offering them world-class mentoring that would not otherwise be easily accessible; 2) addresses the void of guidance on unique, rare and complex cases; 3) provides linkages between senior and junior clinicians as well as those serving in cities and their counterparts in underserved communities in Egypt. This will ultimately provide

better access to much-needed specialized healthcare especially to those in underserved communities.



FRI-408

Self-stigma among patients with hepatitis B and C and its association with delayed diagnosis and treatment

Shireen Abu Elhija[1]. [1]*bnai zion hospital, gastroentrology unit, haifa, Israel*
Email: shireen.1683@gmail.com

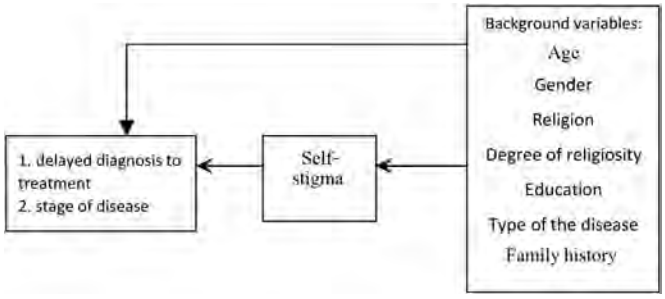
Background Stigma is one of the main issues that patients with hepatitis cope with (Paterson, Backmund, Hirsch and Yim, 2007). Hepatitis is linked to stigma because of disease transmission routes, namely, drug abuse or unsafe sex that are perceived to characterize groups of people who are not well accepted in society (Drazic and Caltabiano, 2013). Such stigma may cause serious psychological, social, economic and even health related repercussions (Cotler et al., 2012; Drazic and Caltabiano, 2013; Li et al., 2012). Timely diagnosis and referral to treatment is of utmost importance for hepatitis patients, in order to prevent disease progression and complications, improve quality of life, and prevent further transmission of the disease (Ben Ari, 2016; Modabbernia, 2013). Nevertheless, the effect of self-stigma on delayed diagnosis and treatment in patients with hepatitis B and C was scarcely studied (Li et al, 2012; Paterson et al, 2007; Poll, Allmark, Tod, 2017; Skeer et al, 2018; Subic, Zoulim, 2018; Sweeney et al, 2015; Veldhuijzen, 2010).

Aims of the study: To investigate the association between perceived self-stigma in patients with hepatitis B and C and the stage of disease at diagnosis and the time lag between diagnosis and first visit to the liver clinic.

Method: A cross-sectional study was conducted among patients and carriers of hepatitis B and C, who are followed and treated in the outpatient liver clinic of an academic hospital in Northern Israel.
Eligible patients fill a questionnaire that included items on socio-demographic information, and a rating of statements reflecting self-stigma (adapted from Li et al, 2012). Further clinical data were collected from patients' medical records.

Results: Enrolled in the study were 120 patients with hepatitis B or C. Patients with hepatitis C reported significantly higher levels of self-stigma (39.1 ± 11.9) than patients with hepatitis B (34.0 ± 10.4) {t (113) = -2.245, p < 0.05}.
A significant association was found between the level of self-stigma and the stage of the disease at diagnosis {t (98) = -2.590, p < 0.05}. Higher levels of self-stigma were reported by Hepatitis C patients with advanced disease (39.1 ± 11.4) compared to Hepatitis B patients with early disease (32.6 ± 11.5). No significant correlation was found between self-stigma and the lag-time from diagnosis to first visit to the liver clinic {t (113) = -0.584, p = 0.56}.

Conclusion: We found that patients with higher levels of self-stigma are diagnosed at more advanced stages of their disease. This highlights the importance of interventions to foster disease prevention and early diagnosis in populations at risk, in order to improve awareness, reduce self-stigma, encourage screening, and prevent morbidity from a curable disease.



FRI-409

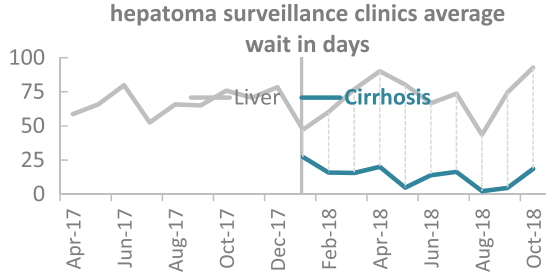
Measuring the impact of a new liver specialist nursing service on patient care

dianne backhouse[1], George Abouda[1], Lynsey Corless[1]. [1]*Hull and East Yorkshire Hospitals NHS Trust, Gastroenterology, Hepatology and Endoscopy, Hull, United Kingdom*
Email: dianne.backhouse@hey.nhs.uk

Background and aims: Mortality is high in patients admitted with decompensated chronic liver disease (DCLD). Management in the first 24 hours is critical to outcome. Historically, all hepatology reviews were by medical staff, and were frequently delayed due to competing service pressures. A pilot scheme for a specialist nurse-led in-reach and follow-up service was launched in April 2018, and the impact assessed.

Method: The nurse-led service provided daily input the acute medical unit, emergency department and non-specialist wards, and followed early management recommendations from the BSG/BASL DCLD care bundle, ensuring all appropriate investigations were completed. Appropriate patients were identified for specialist transfer, early discharge or day-case procedure. In addition, dedicated nurse-led hepatoma surveillance clinics for all cirrhotic patients were opened, as well as doubling capacity of the existing consultant-led early discharge clinic. The impact of the service on time from admission to specialist review, overall length of stay and out-patient surveillance waiting lists was audited at 6 months post-inception.

Results: The liver specialist nurse is now an integral part of hepatology reviews in the acute medical unit (AMU), with a major increase in use of the BSG/BASL DCLD care bundle by all clinical staff (82.5% of DCLD patients in the AMU between May to September 2018 had care bundle in place). Post-discharge clinic follow-up is now occurring within the required timeframe, along with more structured and timely cirrhosis surveillance clinics. The average waiting time for cirrhosis surveillance appointments is now 14 days compared to 71 days prior to the new service, an improvement of 80.3%. The introduction of the nurse-led paracentesis service significantly reduced length of stay for suitable patients by 90% (4.5 day, reduced to 12.5 hours, $P < 0.0001$). Importantly, the service has received excellent feedback from both patients and colleagues.



Conclusion: The introduction of a liver specialist nurse has had a positive impact on both inpatient and outpatient care. This is demonstrated by increased compliance to the BSG/BASL DCLD care

bundle, reduced length of stay-particularly in patients requiring large volume paracentesis, timely surveillance clinics, and increased availability of post discharge liver reviews.

FRI-410

Health literacy in outpatients with liver cirrhosis

Palle Bager[1], Thea Pinderup[1], Maria Freudlich[1]. [1]*Aarhus University Hospital, Hepatology and Gastroenterology, Aarhus N, Denmark*
Email: pallbage@rm.dk

Background and aims: Health literacy (HL) is a concept covering a range of cognitive and social skills that comprises aspects necessary for patients to navigate in the healthcare system. Our study aimed to investigate HL in patients with liver cirrhosis and determine factors associated with low HL.
Method: Face validity of 3 HL questionnaires (paper versions): the Single Item Literacy Screener (SILS) [1question (Q)], the Brief Health Literacy Screening Tool (BRIEF) [4Q], 3 dimensions of the Health Literacy Questionnaire (HLQ) [15Q] were tested in a random order in 108 outpatients with liver cirrhosis. Patients were ask to complete the 3 questionnaires themselves, but could ask a nurse for help if needed
The 3 dimensions used from the HLQ were 'Social support for health' (S-scale), 'Ability to actively engage with healthcare providers' (E-scale), and 'Understand health information well enough to know what to do' (I-scale). Unpaired t-test was used to investigate differences on the HLQ scale scores. The effect sizes (ES) were calculated between groups using the Cohen's d.
Results: 105 patients (55% male; mean age 60 years; 65% alcohol-related liver disease) completed all 3 questionnaires. 39 patients (37%) needed help to complete even the 1Q SILS questionnaire. They were charaterised by: male gender, low level of education, no work, alcohol-related liver disease and severe cirrhosis. The HLQ revealed low level of HL in males (S-scale), and patients with low level of education (S-scale). The largest ES were found for employment (I-scale) (0.49), education (S-scale) (−0.43), comorbidity (I-scale) (0.42), and male (S-scale) (0.41).
Conclusion: One third of patients needed help to complete one single question about HL. Assistance is needed if asking about HL using questionnaires.
Subgroups of patients had both difficulties with the questionnaires and had low level of HL. The subgroups were mainly characterised by: male gender, low level of education, and alcohol-related liver disease.

FRI-411

Nurse-led out-patient-clinic for patients with cirrhosis

Hanne Bennick[1], Anne Kjaergaard Danielsen[1], Lene Dupont[1], Marthe Forbord Huss Joensson[1], Marie Louise Sjoedin Hamberg[1], Ane Soegaard Teisner[1], Mette Lehmann Andersen[1]. [1]*Herlev Hospital, Department of Gastroenterology and Hepatology, Herlev, Denmark*
Email: hanne.bennick@regionh.dk

Background and aims: The burden of liver disease continues to rise and the main driver for morbidity and mortality are the complications of decompensated cirrhosis. Increased patient participation and out-patient access, close monitoring for complications and early preventive interventions are presumed to improve survival.
In March 2017 we established a nurse-led out-patient-clinic for patients with cirrhosis with a patient-centered approach aiming at health promotion. The nurses working in the clinic were highly competent with several years of practice in clinical hepatology.
Local clinical guidelines were set up for treatment-related interventions i.e. medicine titration of diuretics and nonselective betablockers. Clinical and paraclinical limits requiring supervision were well defined. Furthermore, the nurses had access to supervision from specialized medical doctors also working in the clinic.
The aim is therefore to describe the patient population, type of visits, and the nurse interventions within 12 months after implementation of the clinic.
Method: All patient files with visits from August 1st 2017-July 31st 2018 were screened. Patients with first visit to the clinic from August 1st were included.
Data were processed using descriptive statistical methods, and results are presented using median (min-max) or percentages were relevant. All analyses were done using IBM SPSS statistics 22.
Results: 146 patients were screened, and 97 patients were included with a total of 296 visits in the period with a median visit of 2 (1-12). 29 patients (29.9%) of the patients were admitted during the period. The visits were distributed on 75% ascites control, 11% screening for minimal HE, HE controls 5, 5% diagnostic interview and 4% to adjustment of betablockers. Diuretics were adjusted in 86 visits (29%) of all the visits.
According to the defined limits for the need for supervision 30% of the visits were interdisciplinary discussed.

Table 1: Baseline data on included patients (results are median and min, max or percentages in parenthesis)

Age (years)	66 (45-92)
Gender (female/male)	46 (47.4%)/51 (52.6%)
Etiology	
Alcohol	74 (76.3%)
NASH	6 (6.2%)
Viral	7 (7.2%)
Cryptogenic cirrhosis	7 (7.2%)
Other reasons	3 (3.2%)
Child Pugh Score 1. visit	7 (5-12)

Conclusion: This study shows that the nurse-led out-patient-clinic is highly functional in monitoring for complications and medicine titration in an interdisciplinary setting. Further studies on outcomes are needed.

FRI-412

A collaborative approach to increase access to hepatitis C treatment for the homeless population in Cornwall

Mary Mckenna[1], Helen Hampton[2], Malcolm Putko[3], Kate Heath[3], Adele Igoe[3]. [1]*Royal Cornwall Hospital, Treliske, United Kingdom;* [2]*Addaction, Truro, United Kingdom;* [3]*Cosgarne Hall, St Austell, United Kingdom*
Email: mary.mckenna1@nhs.net

Background and aims: There is a higher prevalence of Hepatitis C (HCV) amongst the homeless population (Beijer, 2012). Within Cornwall in 2017, our homeless population had a high number of known HCV positive people, but none entering treatment. There is a long standing community treatment program within Cornwall, offering testing, staging and treatment throughout the county by drug services supported by the hepatology department at the local hospital (Hampton, 2015). Competing priorities, including finding somewhere to stay each night has been recognised as a barrier to HCV treatment (Lambert et al, 2017). The aim of this project was to provide safe accommodation to enable access to HCV treatment and treat six homeless people over a 12 month period.
Method: A partnership was formed between local drug and alcohol services, Addaction, secondary care hepatology services and a housing provider who support homeless people in Cornwall. Cosgarne Hall would provide a room and support for people on HCV treatment and for two weeks after treatment to facilitate them moving to stable accommodation post treatment. Treatment would be delivered by community blood borne virus nurse in partnership with hepatology services in secondary care. All potential residents were assessed as suitable for the accommodation using their standard assessment. All people who were housed and underwent treatment were given a questionnaire post treatment to assess the psychosocial impact the project had. Data was also collected to see if the project had an impact on the housing situation of those treated. The final piece of data collected was the response to treatment using a

negative viral load at 12 weeks post treatment as a sustained virological response to treatment.
Results: The project has been running for six months and already there have been six homeless people who were offered and accepted accommodation through this project. They all commenced treatment and the table below shows the results.

Genotype	Fibrosis	Completed Treatment	SVR	Social situation pretreatment	Social situation post treatment
3a	Cirrhosis	Yes	Yes	Homeless	In Prison
3a	Non cirrhotic	Yes	Awaited	Recent move to supported housing	Remains in supported housing
3a	Cirrhosis	Yes	Awaited	Recent move to supported housing	Remains in supported housing
1a	Non cirrhotic	Yes	Awaited	Homeless	Remains in supported housing
1b	Non cirrhotic	On treatment	Awaited	Homeless	On treatment
1a	Cirrhosis	On treatment	Awaited	Recent move to supported housing	On treatment

Conclusion: Ensuring that homeless people have secure accommodation can help them to engage in HCV treatment. It is necessary to have a supportive housing provider who can both offer support to the people staying there and to have good community support to ensure that people do not need to travel to appointments and that the treatment easily accessible.

FRI-413
Integrating nurses in the management and care of patients with NAFLD: Better adherence and outcomes
Anna Marie Hefner[1], Fatma Barakat[2], Katherine Hall[1], Renee Pozza[1], catherine hill[1], Tarek Hassanein[1]. *[1]Southern California Liver Centers, Coronado, United States; [2]Southern California Research Center, Coronado, United States*
Email: ahefner@livercenters.com

Background and aims: Non-alcoholic Fatty Liver Disease (NAFLD) has risen to epidemic proportions in the United States. It is estimated 30-40% of all Americans are obese, paralleling the rate of diagnosed NAFLD. The primary recommendation is lifestyle changes. There is no current medication approved regimen. It has been shown that asking a patient to change their lifestyle behaviours is difficult with inconsistent and poor results to making these changes. With the overwhelming burden of this disease, it is crucial for the Hepatologist (MD) to integrate their provider-extenders including nurses/nurse practitioners/allied health professionals (AHP) into the management and care of NAFLD patients. This is a single center experience in the role of AHP in a specialized community-based clinic in improving the health and outcome of patients with NAFLD.
Method: In a single community Hepatology center, we have set up a standardised protocol for patients referred for NAFLD. Patients with a confirmed NAFLD diagnosis are placed in "NASH-ville" clinics. These dedicated clinics encompass the concept of HALO (Health and Liver Optimization). At the first visit, the patient is asked to complete questionnaires identifying their lifestyle, diet, sleep patterns, fatigue levels, medications, and perception of BMI. Anthropometric measurements were also taken. Subsequent visits evaluated depression, nutrition, and changes in waist circumference, BMI, and physical well-being. Patients are seen every 1-3 months based on mutual goal setting between patient and AHP. Focus groups discussing diet, exercise can occur during scheduled clinic time, individual time is given for the nuances of each person, and the HALO approach was instituted for each patient and family member present.
Results: Patients with NAFLD needed more extended visits and time spent with them to allow for in breadth discussions of their lifestyle changes. Having the patient on board with their current disease state, setting goals and a tailored plan together with them was critical. This had a positive impact on their adherence to their management plan and ultimately their health outcomes. Implementing a dedicated "NASH-Ville" clinic has allowed our community-based clinic to see patients with a similar diagnosis together and individually.
Conclusion: Each NAFLD patient brings their family history, culture, habits, and co-morbidities to the situation requiring an individualized plan of care to assist in their improvement of health and lifestyle behaviours. MDs have extensive responsibilities and limited availability to spend adequate time with NAFLD patients. AHP have the ability to be more flexible/spend time in their schedules to accommodate the holistic needs of the patients. Both complement each other in the care of the patients and management of the disease. AHP's role had a positive impact on the continuity of care in NAFLD patients.

FRI-414
The impact of self and parental perception of body image on management in patients with NAFLD
Anna Marie Hefner[1], Katherine Hall[1], Renee Pozza[1], catherine hill[1], Noha Abdelgelil[1], Fatma Barakat[2], Tarek Hassanein[1]. *[1]Southern California Liver Centers, Coronado, United States; [2]Southern California Research Center, Coronado, United States*
Email: ahefner@livercenters.com

Background and aims: Treating patients with Non-Alcoholic Fatty Liver Disease (NAFLD) has been difficult as there is no standardized management plan except primarily improving healthy lifestyle measures. The environment in which one was raised in influences one's weight and perception. Understanding self-perception of body weight in this population provides an opportunity to understand the patient and their perception to help them improve healthy lifestyle changes. The aim of our analysis was to examine the role of perception of body image of patients with NAFLD of one-self to that of the patient's perception of their parents' body image.
Method: Between September 2017 and May 2018, 367 consecutive patients with a confirmed diagnosis of fatty liver were seen at a NASH-ville clinic in a hepatology practice in Southern California. Body size perception was assessed using the Stunkard Adult Image Figure scale. The Stunkard scale consists of 9 silhouette figures -two-specific gender scales that increase in size from very thin (figure 1) to very obese (figure 9). These figures were classified into underweight (figures 1 and 2), normal weight (figures 3 and 4), overweight (figures 5- 7) and obese (figure 8 and 9). The patient identified the silhouette figure most consistent with their perception of self and that of each of their parents. Other questionnaires and information about their medical records was collected.
Results: Based on BMI, 0.8% were classified as underweight, 10.5% normal, 27.4% overweight, 28.8% obese, and 32.5% morbidly obese. Table represents the correlation of self-perception of body image and grouped BMI. There was a statistical significant correlation between patient's BMI and their self-perception ($p < 0.05$). Same applies with patient's perception of their father's body image ($p < 0.05$). But that was not the case with the mothers.

		Self Perception					
		Underweight	Normal	Overweight	Obese	Morbidly Obese	**Total**
BMI	Underweight	0	0	0	0	2	**2**
	Normal	0	12	15	1	0	**28**
	Overweight	0	12	48	12	1	**73**
	Obese	0	6	33	27	11	**77**
	Morbidly Obese	0	3	18	29	37	**87**
Total		**0**	**33**	**114**	**69**	**51**	**267**

Conclusion: One's perception of self influences one's behaviour and motivation to change lifestyle. This analysis found that NAFLD patients had an accurate perception of their body weight and that of their parents unless one was morbidly obese or underweight. Looking at one's perception offers potential opportunities for clinicians to incorporate understanding of the unique challenge and potential obstacles in weight loss strategies. Identifying weight perception is a key tool in developing interventions to reduce obesity, ameliorate liver disease and improve overall health. Incorporating the family into the plan of care may influence all family members to improve healthy lifestyle behaviours.

FRI-415

"People are scared: what they don't know don't hurt them". A qualitative exploration of reasons for low uptake of hepatitis C virus testing in an English prison

Kathryn Jack[1], Paul Linsley[2], Brian Thomson[3], William Irving[1].
[1]University of Nottingham, School of Life Sciences, Nottingham, United Kingdom; [2]University of East Anglia, School of Health Sciences, Norwich, United Kingdom; [3]University of Nottingham, School of Medicine, Nottingham, United Kingdom
Email: kathryn.jack@nottingham.ac.uk

Background and aims: The prison population are central to the campaign to eliminate hepatitis C virus (HCV) as a public health threat. In the UK this has led to the introduction of a national 'opt-out' policy, requiring prisoners to be tested for HCV unless they decline, with a target to test 50-75% of those admitted. However, in a representative prison estate in the East Midlands of England (20, 000 prison entrants per annum) this policy has resulted in testing rates of only 13.4%. This qualitative exploration seeks to understand why the rates of test uptake are so far short of target.
Method: This qualitative study examines the experiences of 45 prisoners and 6 nurses of Hepatitis C testing in an English category C prison accommodating men nearing the end of their custodial sentence. The data collection method was face to face audio-recorded semi-structured interviews. The data were coded and analysed according to the research questions. This formed part of a larger study conducted in a realistic framework of evaluation. Interpretation of the data was aided by the use of NVivo and a thematic network approach.
Results: The key themes of *Fear*, *Insufficient Knowledge*, *Stigma*, *Privacy*, *Choice* and *Prison Life* have emerged as the principal barriers to test uptake. *Test Uptake Facilitators* were however identified by participants and a positive notion presented of prison healthcare being a *Health Farm*. It was highly evident that prisoners did not speak to each other about HCV and were fearful of catching this infection. Further, if identified as infected, social rejection by other prisoners was experienced, so fears of being found out were high. Privacy was highly valued and being seen attending the specialist hepatitis nurse clinic led to concerns by some prisoners. Levels of knowledge about all aspects of HCV by both prisoners and nurses were low and there were misunderstandings about the definition of an opt-out approach to testing, contributing to missed opportunities. Furthermore the prison regime, which necessarily prioritises security, can hamper opportunities for healthcare. Utilising time in prison positively to improve health was identified and most prisoners were accepting of the concept of routine testing on arrival.
Conclusion: In order to increase HCV test uptake a significant uplift in all factors affecting prison healthcare delivery, including nurse and prisoner education and support from the prison regime, are required. Providing information to prisoners aimed at allaying fears may encourage test uptake.

FRI-416

Assessment of written patient information pertaining to cirrhosis and its complications: A pilot study

Lea Ladegaard Grønkjær[1,2], Kirsten Berg[1], Rikke Søndergaard[1], Majbritt Møller[1]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; [2]Hospital of South West Jutland, Department of Gastroenterology, Esbjerg, Denmark*
Email: lea.ladegaard.gronkjaer@rsyd.dk

Background and aims: Written patient information may play an important role in the patient compliance of the cirrhosis disease but little is known on the quality and patients understanding of them. The aim of this pilot study was to assess the quality of written patient information pertaining to cirrhosis and its complications, and to explore patients' understanding of the written information.
Method: A web-based search was performed to retrieve written patient information from different Danish Gastroenterology and Hepatology departments. Baker Able Leaflet Design (BALD) criteria's and Ensuring Quality Information for Patients (EPIQ) questionnaire was applied to assess design, layout characteristics, and information quality of the written information. Readability was calculated using the Læsbarhedsindex (LIX) and the Simple Measure of Gobbledygook (SMOG). In addition, a cross-sectional study with a mixed-method design was carried out among eleven outpatients with cirrhosis at the Department of Hepatology and Gastroenterology, Aarhus University Hospital, Denmark, using a questionnaire consisting of 28 closed and open questions regarding written patient information. Descriptive statistics were used for assessing the quality of the written information and for the closed-ended responses. Data from the open-ended responses were analysed in accordance with Kvale and Brinkmanns meaning condensation.
Results: The mean BALD score was 24 and the mean EQIP score was 70%. The mean LIX score was 46 and the mean SMOG score 15.8. Fifty percent of the patients stated that they had received written patient information, but only one patient was able to recall advices and/or instructions from the written information. Sixteen identical phrases from the written information were selected to explore patients' understanding. Four phrases were understood by 100% of the patients, six phrases by more than 50% of the patients, and six phrases were understood by less than 50% of the patients. The meaning condensation showed that knowledge and understanding of cirrhosis and its complications were not enhanced by the availability of the written information.
Conclusion: The written patient information had good design, layout, and information quality but was difficult to read. Patients appeared to relate poorly to the written information and demonstrated limited health literacy. These results suggest awareness among healthcare professionals in the importance of matching written patient information and patients' level of health literacy in order to ensure effective patient understanding and thereby disease compliance. Further studies on intervention to improve patients' health literacy are recommended.

FRI-417

Impact of a nurse educational program and accessibility in the management of patients with hepatocellular carcinoma under systemic treatment

Neus Llarch[1], Gemma Iserte[1], Víctor Sapena[1], Alvaro Diaz-Gonzalez[1], Marco Sanduzzi Zamparelli[1], Leonardo Gomes da Fonseca[1], Cassia Regina G Leal[1], Jordi Bruix[1], Maria Reig[1]. *[1]Barcelona, BCLC Group. Liver Unit. Hospital Clínic of Barcelona. University of Barcelona. IDIBAPS. CIBERehd, Barcelona, Spain*
Email: nllarch@clinic.cat

Background and aims: Management of sorafenib therapy in hepatocellular carcinoma patients (HCC) requires dose modifications due to adverse events (AE) and multiple visits until reaching the tolerated dose for each patient. Thus, a multidisciplinary approach

including expert nurses for patient education and counseling is key to improving treatment compliance.
Our study evaluates the impact of expert nurses in handling unscheduled phone-call visits regarding doubts and symptom management at the start of treatment. (≤ 60 days).
Method: A descriptive retrospective study based on prospective data of the nurse educational program and its impact during systemic therapy. The program includes an on-site educational appointment before starting sorafenib, on-site visits every month and unscheduled phone-call visits. We collected the number, causes, type of issues raised by patients and the resolution of the unscheduled phone-call visits.
Results: From Jan/2015 to Sept/2018 101 patients started sorafenib at BCLC. 93 of them made 357 unscheduled phone-call visits. 163 calls were excluded because of their administrative nature or lack of information. The remaining 194 unscheduled phone-call visits from 76 (75.25%) of the 101 patients were analyzed.
The median number of issues for each unscheduled phone-call visit was 1 (range; 1-4) and 424 types of issues were the cause of consultation. 52.5% (n = 137) of the issues were solved only by nurses and 47.5% (n = 124) needed physician intervention. The issues solved by nurses were classified as sorafenib-related AEs (43%), non-sorafenib related AEs (53%) and cirrhotic decompensations (4%). The most frequent treatment-related AEs solved by nurses were hypertension 13.9% (n = 19) and deposition alterations 12.4% (n = 17). Nurse interventions were care counseling (50%), educational intervention (28%) and resource management (22%).
5% of the patients were referred to the emergency department due to fever, hemorrhage, ascites and pain and 60% of them were admitted to the hospital.
Conclusion: The nurse educational program and the follow-up monitoring registered the use of unscheduled phone-call visits by 92% of sorafenib-treated patients. More than 50% of the issues were solved only by the expert nurse. Thus, this program reduces on-site visits, optimizes health resources and secures patient compliance to treatment. Therefore, our results demonstrate the key role of the expert nurse in the optimal management of patients under systemic treatment.

FRI-418
Evaluating patient's experience in liver transplantation: Role of the focus group technique

Eva Lopez-Benages[1], Raquel Garcia[1], Carmen Cierco[1], Miquel Sanz[1], Ana Alonso[2], Inma Perez[1], Miguel Navasa[3]. *[1]Hospital Clinic de Barcelona, Liver Surgery and Liver Transplant Unit, Institut Clínic de Malalties Digestives i Metabòliques, Hospital Clinic de Barcelona, Barcelona, Spain; [2]Hospital Clinic de Barcelona, Liver Unit, Institut Clínic de Malalties Digestives i Metabòliques, Hospital Clinic de Barcelona, Barcelona, Spain; [3]Hospital Clinic de Barcelona, Liver Transplant Unit, Hospital Clinic, Institut d'Investigació Biomèdiques Pi i Sunyer (IDIBAPS), Biomedical Research Networking Center Consortium-Digestive and Liver Diseases (CIBERehd), University of Barcelona, Barcelona, Spain*
Email: elopezb@clinic.cat

Background and aims: Liver transplantation (LT) is the treatment of choice for patients with acute or chronic liver disease without other therapeutic alternatives. This is a common procedure in our environment and it is evaluated periodically using objective data. More recently, patients' feedback is also assessed to know the patients' subjective aspects (feelings, impressions, perceptions) of LT, and it is known as "the patient's experience". The aim of this study was to know the experiences in patients undergoing liver transplantation, and to identify improvement opportunities in this procedure.
Method: In order to know the experiences of the patients/relatives during the LT process, the technique of the focus group (FG) was applied. To prepare this group, the professionals involved in LT carried out the following activities: 1) a brainstorming session, applying the metaplan© technique, to gather the most relevant ideas and opinions about the process, 2) preparation of a document, based on the metaplan information, so that outside psychologist could moderate the FG; and 3) the selection of the participants in the FG: 4 caregivers and 8 transplanted patients. This group was held on 11/29/2016. Subsequently, the psychologist, who prepared a document with the information gathered from the FG, met with the transplant team to analyze the data and to identify possible improvement opportunities, which could be implemented in the daily work of the team.
Results: Transplant patients and their relatives considered the LT process well structured. They pointed out that the information about the process provided by the different professionals of the transplant team is unified, and refer a high degree of satisfaction with the staff. On the other hand, they emphasize the feeling of isolation in the Intensive Care Unit (ICU) and the lack of psychological support throughout all the process. Accordingly an intercom was used to enhance patient communication and visiting hours were more flexible. In addition, efforts are being made to incorporate a psychologist into the team, to help patients and relatives.
Conclusion: The FG has been an effective technique to identify important patient's subjective aspects in LT. That has allowed us to implement measures aimed at improving the patients' experience.

FRI-419
Is a lack of patient awareness holding back self-management of NAFLD?

Bronwen Williams[1], Nurun Tania[1], Lynsey Corless[1]. *[1]Hull and East Yorkshire Hospitals NHS Trust, Hepatology Research Department, Hull, United Kingdom*
Email: bronwen.williams@hey.nhs.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) affects 25% of the UK population and is a frequent manifestation of the metabolic syndrome (MetS). Lifestyle change can ameliorate the negative impact of NAFLD/MetS on long-term health, but requires patient engagement. Lack of NAFLD/MetS awareness in patients may act as a barrier to making healthy lifestyle choices. A questionnaire was developed to explore knowledge of NAFLD in our local population.
Method: Questionnaires were distributed at random to 100 patients attending various medical specialty outpatient clinics over a 12 week period. Questions explored understanding of causes and management of NAFLD.
Results: Respondents were 47% (n = 47) female; 52% (n = 52) male; 1% (n = 1) other; Age ranged from < 21 years (11%; n = 11); 21- 40 years (24%; n = 24); 41-60 years (39%; n = 39); > 60 years (26%; n = 26). Ethnic origin and educational achievement were representative of the local population: Most respondents had at least one self-reported risk factor for NAFLD/MetS: obesity (30%;n = 30); fatigue (30%; n = 30); hypertension (19%; n = 19); dyslipidaemia (15%; n = 15); depression (14%; n = 14); Type 2 diabetes (13%; n = 13); low exercise levels (12%; n = 12); high fat/processed diet (11%; n = 11).
39% (n = 39) of patients had heard of NAFLD. 7% (n = 7) self-reported having NAFLD and 6% (n = 6) knew someone with NAFLD lower than expected prevalence suggesting a lack of awareness. Overall awareness of NAFLD was poor; only 80% (n = 80) thought NAFLD could be harmful and 43% (n = 43) did not know that it could cause cirrhosis. Only 39% (n = 39) knew NAFLD is preventable, with no significant difference in knowledge between those with and without NAFLD (p = 0.49). Once established, 21%; (n = 21) thought NAFLD was irreversible.
Understanding the impact of lifestyle on NAFLD was limited. Only 25% (n = 25) correctly identified a target of 5-10% total body weight loss. Just over half (n = 54) recognised the Mediterranean diet as a

suitable dietary strategy. 21% (n = 21) incorrectly stated that rapid weight loss would be appropriate.
Conclusion: Despite high self-reported incidence of MetS risk factors, surprisingly few respondents had, or were aware of someone with NAFLD. Awareness of the impact and management of NAFLD was poor in people with and without NAFLD. Greater public education on NAFLD prevention and management by healthy lifestyle change is critical to long term reduction of prevalence and progression of NAFLD.

FRI-420
A nurse-led advice and lifestyle intervention shows high levels of patient-reported satisfaction and motivation in community-based management of NAFLD

Bronwen Williams[1], Lynsey Corless[1], George Abouda[2]. *[1]Hull and East Yorkshire Hospitals NHS Trust, Hepatology Research Department, Hull, United Kingdom; [2]Hull and East Yorkshire Hospitals NHS Trust, Hepatology Research Department, Hull, United Kingdom*
Email: bronwen.williams@hey.nhs.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) affects 25% of the UK population but only a fraction develop advanced liver disease. For most, management focuses on cardiovascular risk reduction with responsibility increasingly devolved to primary care (PC). However PC is poorly resourced to discuss the diagnosis and importance of lifestyle change. We explored acceptability of nurse-led clinics to support PC management of NAFLD.
Method: As part of a randomised trial of a NAFLD Integrated Care Pathway participants in control and intervention arms were given information about diagnosis and healthy lifestyle change by a NAFLD specialist nurse. Interview and questionnaires at 1-year follow-up explored understanding of NAFLD, disease management and patient reported outcomes.
Results: 52 patients were recruited, (29% [n = 15] female; 71% [n = 37] male) with median age 48 (26-62) and 52 years (24-76), respectively. 19% (n = 10) withdrew before 1 year: 90% (n = 9) could not be contacted or declined; 10% (n = 1) moved away. 2 patients had pending visits at the time of data collection. 40 patients completed 1 year of follow-up, and were included in the analysis. Baseline patient awareness and knowledge of NAFLD was poor, but 100% (n = 40) said the nurse-led clinic had improved their understanding: 65% (n = 27) rated the information very helpful, with nobody rating it unhelpful (p = 0). 93% (n = 27) said discussing their Enhanced Liver Fibrosis test result aided understanding of their stage on the NAFLD spectrum, and encouraged self-management. All participants found the nurse helpful in discussing plans for sustainable lifestyle change. At 1-year, 22% (n = 9) reported psychosocial improvement, 54% (n = 21) better diet and 40% (n = 16) increased exercise. Objectively, 67% (n = 18) had reduced BMI by median 0.9 (–6.37-2.45), with 20% (n = 8) and 8% (n = 3) achieving > 5% or > 10% weight loss respectively. Worryingly, a questionnaire for healthcare professionals (HCP) conducted in parallel also revealed poor knowledge, with 27% (n = 40) unaware NAFLD is preventable, and 28% (n = 41) not realising NAFLD can cause cirrhosis.
Conclusion: Poor HCP and patient knowledge of disease impedes effective clinical management. Time spent discussing NAFLD and necessary lifestyle change with a trained nurse led to patient reported improvements in knowledge, and was considered helpful by all participants. Sustainability of change will be monitored at future follow-up. Nurse-led clinics could become a valuable part of community-based NAFLD services.

Genetic and pathophysiological factors leading to deficient acyl-CoA oxidase 2 (ACOX2) activity in hepatocytes, an alteration which causes oxidative and endoplasmic reticulum stress in liver cells

Marta Alonso-Peña[1,2], Heike Hermanns[2], Elisa Herraez[1,3], Oscar Briz[1,3], Maria Monte[1,3,3], Manuel Sánchez-Martín[4], Pablo Berrocal[4], Ignacio Garcia-Tuñon[4], Ricardo A. Espinosa-Escudero[1], Jesus Prieto[3,5], Andreas Geier[2], Jose Marin[1,3]. *[1]University of Salamanca, Experimental Hepatology and Drug Targeting (HEVEFARM), IBSAL, Salamanca, Spain; [2]University Hospital Würzburg, Medical Clinic II, Division of Hepatology, Würzburg, Germany; [3]Carlos III National Institute of Health, Center for the Study of Liver and Gastrointestinal Diseases (CIBERehd), Madrid, Spain; [4]University of Salamanca, Transgenic Facility, Nucleus, IBSAL, Salamanca, Spain; [5]University of Navarra, Department of Medicine, Clinica Universidad de Navarra and Center for Applied Medical Research (CIMA), Pamplona, Spain*
Email: jjgmarin@usal.es

Background and aims: Acyl-CoA oxidase 2 (ACOX2) is a key enzyme in cholic acid biosynthesis. Its partial deficiency (APD) results in accumulation of trihydroxycholestanoic acid (THCA) and has been recently described as a cause of asymptomatic hypertransaminasemia. Here we have explored the mechanisms controlling ACOX2 expression and the pathogenic consequences of the absence of its enzymatic activity.
Methods: Human hepatocytes, either immortalized or freshly isolated, and human hepatoma cells (HepG2 and Huh7) were cultured in the presence of bile acids (BA), FXR or PPAR agonists, recombinant FGF19, oncostatin M (OSM), IL-6, IL-1beta and TNF-alpha. ACOX2 expression was determined by quantitative real-time PCR and immunoblot. Specific inhibitors were used to investigate the signalling pathways involved in gene regulation. Predicted genetic variants in *ACOX2* ORF were generated by site-directed mutagenesis and overexpressed in Huh7 cells using lentiviral vectors. Their ability to metabolize THCA was measured by HPLC-MS/MS. Oxidative stress was determined by flow cytometry using specific probes. Endoplasmic reticulum (ER) stress was studied by measuring CHOP and GRP78 up-regulation plus spliced XBP1 generation by immunoblot and PCR, respectively.
Results: Several genetic variants of ACOX2 were able to retain its enzymatic activity, although others partially or completely blocked THCA biotransformation resulting in oxidative and ER stress. In human hepatocytes, ACOX2 expression was downregulated by BA, FGF19 and OSM. Similar but weaker effect was exerted by IL-6, IL-1beta and TNF-alpha, whereas PPAR agonists had no effect. After washing-out OSM from de culture, ACOX2 down-regulation persisted for more than 24 h, which was associated to strong OSM adhesion to extracellular collagen. Abrogation of the Janus kinase activity completely blocked the suppressive effect of OSM, while inhibition of the MAPKs p38 and JNK had no effect. Inhibition of ERK1/2 pathway partially overcame OSM-induced ACOX2 down-regulation, whereas it was able to completely block FGF19-mediated effect.
Conclusion: Inflammatory processes and cholestasis may affect ACOX2 expression. Moreover, the presence of inactivating mutations in *ACOX2* gene leads to altered BA metabolism and enhanced oxidative and ER stress.

FRI-423

Role of antithrombin deficiency in splanchnic vein thrombosis

Anna Baiges[1,1], M Eugenia Morena-Barrio[2], Fanny Turon[1], José Ferrusquia[1], Marta Magaz[1], Juan Carlos Reverter[3], Virginia Hernandez-Gea[1], garcia pagan juan carlos[1]. [1]*Hospital Clínic de Barcelona, Barcelona Hepatic Hemodynamic Laboratory, Liver Unit, Universitat de Barcelona, Hospital Clínic de Barcelona, Spain, Barcelona, Spain;* [2]*Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación. Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer. IIMIB-Arrixaca. Universidad de Murcia, Murcia, Spain, Murcia, Spain;* [3]*Hospital Clínic de Barcelona, Department of Haemotherapy and Haemostasis, Hospital Clínic de Barcelona, Spain, Barcelona, Spain*
Email: abaigesa@clinic.cat

Background: The most frequent causes of splanchnic thrombosis (ST) are thrombophilia disorders and local inflammation-induced thrombosis, but in 30% of patients it is not possible to identify its aetiology. The most severe thrombophilia disorder is antithrombin deficiency (AT) caused by mutations in SERPINC1 gene. Recently, transitory AT deficiency triggered by the combination of molecular defects and inflammatory events have been described. Alterations in the N-glicosilation pathways have also been reported to cause AT deficiency. However, clinical screening of AT deficiency only includes anti-factor Xa activity. Patients requiring anticoagulation could remain untreated if a thrombophilia disorder was misdiagnosed. In addition, the incidence of ST among patients with AT deficiency has not been established.
Aim: Assess the role of molecular AT analysis in ST and evaluate the incidence of ST in patients with ATdeficiency.
Methods: 89 patients with ST in whom AT deficiency was ruled out by conventional methods underwent molecular and gene sequencing analysis of AT. Additionally, the incidence of ST was evaluated in 715 patients with known congenital deficiency of AT.
Results: AT variations were identified in 4 out of the 89 patients with ST: one patient with locally induced thrombosis had glicosilation alterations (he did not receive anticoagulation and presented with pulmonary thromboembolism 2 years later) while the remaining 3 presented heterozygote mutations in SERPINC1 gene: one with a previously unreported genetic variation (*p.Gly199Arg; c.595G > A*) with pathogenic potential. This patient did not receive anticoagulation and did not develop new thrombotic events. The other 2 patients presented ST in the setting of myeloproliferative neoplasms. One of them had the variation c.438C > T (p.Ala156Ala), scarcely reported in general population, and the thrombosis progressed despite anticoagulation. The last patient had the c.89 T > A (p.Val30Glu) variation enabling transitory loss of anticoagulant activity in stress conditions. This patient began anticoagulation and did not present new thrombotic events.
14 of the 715 patients (2%) with AT deficiency developed ST.
Conclusion: The molecular analysis of SERPINC1 in patients with ST could enhance the detection of AT deficiency. Detecting these variations could modify the therapeutic approach and prevent future thrombotic events. In addition, our results show that the incidence of ST in patients with AT deficiency is relevant (2%)

FRI-424

Estrogen-containing oral contraceptives are associated with polycystic liver disease severity in pre-menopausal patients

Lucas H.P. Bernts[1], René van Aerts[1], Tom Gevers[1], Wietske Kievit[2], Lisanne Koopmans[1], Bertho Nieboer[3], Frederik Nevens[4], Joost Ph Drenth[1]. [1]*Radboudumc, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands;* [2]*Radboudumc, Department for Health Evidence, Nijmegen, Netherlands;* [3]*Radboudumc, Department of Obstetrics and Gynecology, Nijmegen, Netherlands;* [4]*University Hospital Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium*
Email: lucas.bernts@radboudumc.nl

Background and aims: Polycystic liver disease (PLD) is a progressive disease that occurs predominantly in females. It is hypothesized that exposure to estrogen results in higher liver volume but supporting evidence for this concept is contradictory. We aimed to assess the association between oral estrogen-containing contraceptives and history of pregnancies with disease severity in females with PLD.
Method: We performed a cross-sectional cohort study. Female PLD patients were identified from the International PLD Registry and included when imaging was available prior to any liver volume reducing therapy. Patients received a questionnaire to collect detailed information on estrogen use and pregnancies. We used multiple

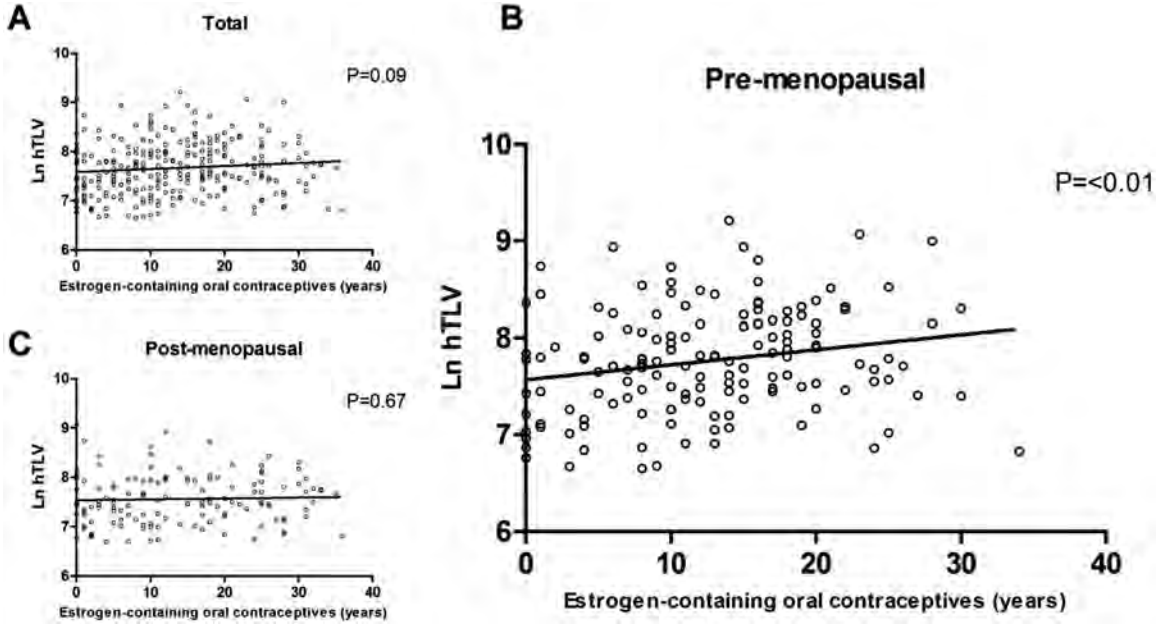

Figure: (abstract: FRI-423): Scatter plots and univariable regression lines, without correction for confounders, for estrogen-containing oral contraceptives in the total group (A) and pre-menopausal (B) and post-menopausal (C) subgroups. Natural logarithmic transformed height-adjusted total liver volume (Ln hTLV) is presented on the Y-axis.

regression analyses to assess associations of exposure to estrogen-containing contraceptives (years) and duration of pregnancies (months) with height-adjusted liver volume (hTLV) and adjust for confounders. Preplanned subgroup analyses were performed on pre-menopausal and post-menopausal patients.
Results: The questionnaire was returned by 287 out of 360 selected patients (80%). There was no significant association between estrogen-containing oral contraceptives and hTLV in the total group (B = 0.0068, P = 0.06) and post-menopausal subgroup (B = 0.00173, P = 0.70). By contrast, in pre-menopausal females use of estrogen-containing oral contraceptives led to higher polycystic liver volumes (B = 0.0144, P = 0.02). Each year of exposure corresponds with a 1.45% higher hTLV, equivalent to 15.5% higher hTLV for every 10 years of use. hTLV was independent of duration (B = -0.00113, P = 0.69) and number of pregnancies (B = 0.0485, P = 0.56).
Conclusion: Exposure to estrogen-containing oral contraceptives is associated with a higher hTLV in pre-menopausal females. Pre-menopausal PLD patients should avoid exogenous estrogens.

FRI-425

Maintenance therapy for Wilson disease with zinc: A comparison between zinc acetate and alternative zinc salts

Michelle Camarata[1,2,3], Aftab Ala[1,2], Michael Schilsky[3]. [1]*Royal Surrey County Hospital, Gastroenterology and Hepatology, Guilford, United Kingdom;* [2]*University Of Surrey, Department of Clinical and Experimental Medicine, Guilford, United Kingdom;* [3]*Yale University, Department of Digestive Diseases, Transplant and Immunology, New Haven, United States*
Email: michellecamarata@gmail.com

Background and aims: Our study evaluates treatment of Wilson Disease (WD) with zinc (Zn) acetate (FDA approved) and alternative Zn salts. Studies examining the effectiveness of Zn in WD are few and data on alternative Zn salts is limited. We describe one of the largest recent cohort studies of WD patients on Zn therapy and aim to improve our understanding of Zn as a treatment option.
Method: Single center retrospective review of 59 WD patients (age 6-88y, 32 females) treated with Zn (50-150 mg) from 0.8 to 52 years (median 26y). Most patients (n = 39) were on prior chelation therapy. An online survey was used to explore patients' experience using different Zn salts. We contacted 56 subjects; 31 completed the survey.
Results: Treatment response was evaluated using ALT and 24 h urine Cu. Urine Cu excretion (µg/24 h) was categorized as low < 25, target 25-100, or elevated > 100. Levels > 100 suggest medication or diet non-compliance, or treatment failure. Levels < 25 may indicate overtreatment. Target range was reached in 60% on Zn acetate, 65% on Zn gluconate and 50% on alternative Zn. Low urine Cu was not associated with a high ALT. Serum ALT was expressed as normal or a multiple (1-2, 2-3 or > 3 x) of the upper limit of normal (ULN). ALT was normal in 75% with target urine Cu but only in 16% with urine Cu > 100 µg. ALT elevations were not significantly different between Zn Salts (34% Zn acetate, 21% Zn gluconate and 28% alternative Zn, Kruskal-Wallis, p = 0.26).
Our online survey showed the mean age at diagnosis to be 18 years (2-43y). The average age of starting Zn was 26.8 years (3.5-65y). Most were on Zn acetate (45%) followed by Zn gluconate (42%). The majority were taking non-prescription Zn. Prior to Zn treatment 45% were symptomatic (45% neuro, 25% liver and 20% psychiatric). The majority (80%) had no WD symptoms on Zn. Only one person took Zn incorrectly. Most (80%) had previously been on alternative WD treatment. Patients switched from a different Zn salt (38%) mainly due to GI side effects (Zn acetate n = 11, Zn gluconate n = 5, Zn sulfate n = 1). Most reported no side effects on current Zn therapy (67%). Gastric side effects were experienced in 32%.

		Zn Acetate (n = 26)			Zn Gluconate (n = 19)			Alternative Zn (n = 7)		
Urine Cu (mcg/24 h)		< 25	25-100	>100	< 25	25-100	>100	< 25	25-100	>100
ALT	Normal	2	15	0	2	12	1	2	3	0
	1-2xULN	0	5	0	0	2	0	0	1	1
	2-3xULN	0	1	1	0	0	0	0	0	0
	3-4x ULN	0	0	2	0	1	1	0	0	0

Conclusion: Effective treatment with Zn preparations is possible in many WD patients. The potential for treatment failure in some suggests close monitoring is paramount for individuals on zinc therapy without both a normal ALT and an appropriate urine Cu excretion. More clearly defined parameters determining treatment success or failure will inform our clinical decision making for continuation of Zn treatment or a timely change to alternative therapy.

FRI-426

Overexpression of c-Jun N-terminal Kinase-1 coincides with the acquisition of cholangiocytic markers in experimental cholangiocarcinoma

Chaobo Chen[1], Leonard J Nelson[2], Matías A Avila[3,4,5], Francisco Javier Cubero[1,6]. [1]*Complutense University School of Medicine, Immunology, Ophthalmology and ORL, Madrid, Spain;* [2]*Institute for Bioengineering (IBioE), Faraday Building, The University of Edinburgh, Edinburgh, United Kingdom;* [3]*Cima, University of Navarra, Hepatology Program, Pamplona, Spain;* [4]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain;* [5]*Instituto de Investigaciones Sanitarias de Navarra-IdiSNA, Pamplona, Spain;* [6]*12 de Octubre Health Research Institute (imas12), Madrid, Spain*
Email: fcubero@ucm.es

Background and aims: Cholangiocarcinoma (CCA) is an aggressive malignant adenocarcinoma characterized by biliary tract differentiation and the second most common primary liver tumour in Europe, with around 13, 000 new CCA cases diagnosed each year. However, the pathogenesis of CCA remains elusive and lack of a diagnostic tools impede a better outcome for patients. In the present study, we aimed to understand the molecular events that drive CCA initiation and development.
Method: HepG2 cells, and undifferentiated and differentiated HepaRG cells were cultured in presence of thioacetamide (TAA, 0-40 mM) and harvested for 0-24 h. D-JNK1-I [2 µM], an inhibitor of JNK, was used. In parallel, wildtype mice bred in a C57BL/6 background were injected *i.p.* with diethylnitrosamine (DEN, 25 mg/kg b/w) at day 14 postnatally. At 8 weeks of age, TAA (300 mg/l) was added into the drinking water. A second experimental group was treated only with TAA. All mice were sacrificed 28-35 weeks after the start of the treatment. Histopathological examination of cells and livers, immunofluorescence and immunohistochemistry, protein expression and real time (RT)-PCR studies were performed.
Results: The median lethal dose (LD50) of TAA was 34.53 mM and 36.11 mM for HepG2 and HepaRG cells, respectively (calculated using CCK8 and TUNEL staining). Since HepaRG progenitor cells (HPC) are able to differentiate into hepatocytes or cholangiocytes, we next studied phenotypic markers. Interestingly, high concentrations of TAA induced overexpression of JNK1 but blocked JNK2 activation in both HepG2 and HepaRG cells, and this effect was blocked by adding D-JNK1-I. This was coincident with the acquisition of cholangiocytic markers (A6, CK19) and loss of the hepatocytic phenotype (HFN-4α, ALB). This was further reversed by the addition of D-JNK1-I. Furthermore, these results were validated in both experimental models of CCA. Mice treated with DEN/TAA, acquired phenotypic markers of cholangiocyte differentiation which were concomitant with overexpression of JNK1 but loss of JNK2 phosphorylation.
Conclusion: Dysregulation of the JNK signaling pathway coincides with the acquisition of phenotypic markers of cholangiocytes. Addition of an inhibitor of JNK, reversed HPC differentiation. These findings may open up new therapeutic avenues for the treatment of CCA.

FRI-427

Liver humanized mouse as models for human metabolic liver diseases

Stephen STROM[1], Raghuraman chittoor srinivasan[1], Mihaela Zabulica[1], Christina Hammarstedt[1], Tingting Wu[1], Roberto Gramignoli[1], Kristina kannisto[2], Ewa Ellis[1], ahmad karadagi[1], Johannes Häberle[3], Gabriella Allegri[3], Veronique Ruefenacht[3], Beat Thöny[3], ralph fingerhut[3], Jean-Marc Nuoffer[4]. *[1]Karolinska Institutet Campus Huddinge, laboratory medicine, Huddinge, Sweden; [2]Karolinska Institutet Campus Huddinge, CLINTEC, Huddinge, Sweden; [3]Children's Hospital Zurich-Eleonore Foundation, Division of Metabolism and Children's Research Centre (CRC), Zürich, Switzerland; [4]Institute for Clinical Chemistry and University Childrens Hospital, Bern, Switzerland*
Email: stephen.strom@ki.se

Background and aims: The objectives of these studies were to create liver-humanized mice where the liver is highly repopulated with hepatocytes from patients with severe urea cycle defects (UCD).
Patients with genetic defects in any of the urea cycle enzymes or two inner mitochondrial transport proteins can result in urea cycle defects. Two of the most common urea cycle defects are, carbamoyl phosphate synthetase I (CPS-I), ornithine transcarbamylase (OTC). Many animal models do not faithfully reproduce rare human disease. We propose the best model for diseases that affect metabolic activities in hepatocytes should utilize disease-affected human hepatocytes. If those studies can be conducted *in vivo*, the value of the model is enhanced.
Method: Mice that are immune and *Fumarylacetoacetate hydrolase*-deficient (FRGN) produce tyrosine metabolites that are toxic to mouse liver cells, and transplantation of human hepatocytes at that time, leads to the replacement of the mouse cells and high-level repopulation of the liver with human hepatocytes. Hepatocytes were isolated from two normal donors and from patients who received liver transplants for severe urea cycle defects, carbamoyl phosphate synthatase-1 (CPS-1) or ornithine transcarbamylase (OTC)-deficiency. Isolated mutant or normal human hepatocytes were transplanted into the liver of FRGN mice.
Results: When compared to mice highly repopulated with, normal, CPS1-proficient human hepatocytes, mice repopulated with CPS1-deficient human hepatocytes exhibited characteristic symptoms of human CPS1 deficiency including an 80% reduction in CPS1 metabolic activity, delayed clearance of an ammonium chloride infusion, elevated glutamine and glutamate levels and impaired metabolism of ^{15}N-ammonium chloride into urea. Mice repopulated with OTC-deficient human hepatocytes displayed an increase in blood ammonia levels on a regular protein diet and a delayed clearance of an ammonia challenge. Amino acid levels and ureagenesis studies with OTC-deficient, liver-humanized mice are ongoing.

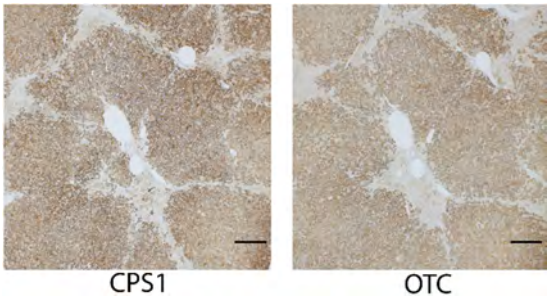

Figure: Humanized mice liver tissue after 80% humanization

Conclusion: We conclude that CPS1- or OTC-deficient, liver-humanized mice provide a faithful model for the human urea cycle deficiencies. The model reported here is expected to be useful for investigations of modified RNA, gene, cellular and small molecule therapies for CPS1-deficiency. Liver-humanized models for this and other monogenetic liver diseases affords the ability to assess the therapy on actual disease-affected human hepatocytes, *in vivo,* for long periods of time and will likely provide data that is highly relevant for investigations of the safety and efficacy of gene editing technologies and their translation to the clinic.

Prevalence and impact of sarcopenia in non-cirrhotic portal hypertension

Simone Di Cola[1], Barbara Lattanzi[1], Daria D'ambrosio[1], Stefania Gioia[1], Daniele Tavano[1], Angelo Bruni[1], Manuela Merli[1], Oliviero Riggio[1].
[1]Sapienza University of Rome, Rome, Italy
Email: simonedicola92@hotmail.it

Background and aims: little is known on nutritional parameters in patients with chronic portal vein thrombosis (PVT) and idiopathic non-cirrhotic portal hypertension (INCPH).
The aim of this study is to assess the prevalence of sarcopenia, measured by the skeletal muscle index (SMI) at CT-scan, in patients with non-cirrhotic portal hypertension (NCPH). A control group of cirrhotic patients was also studied. Both groups were followed up to establish the relationship between sarcopenia and clinical outcomes.
Method: sixty-seven patients with NCPH (51 PVT and 16 INCPH) were included in the study group and 104 patients with liver cirrhosis in the control group. The axial plane passing through the intersomatic disk between L3 and L4 was evaluated for the quantitative analysis of muscle mass and the skeletal muscle index was calculated (SMI).
Results: sarcopenia was present in the 37.5% of patients with INCPH, 41.2% of patients with chronic PVT. In the control group it was registered a 40% of prevalence in patients with compensated cirrhosis and 61% in patients with decompensated cirrhosis.
During a mean follow-up of 51 ± 62 months, there was no difference in sarcopenic and non-sarcopenic patients with NCPH for episodes of ascites, hepatic encephalopathy, oesophageal varices and death. However, the incidence of refractory variceal bleeding requiring TIPS placement was significantly higher in comparison with non-sarcopenic ones (26% vs 8% p = 0.01). After TIPS placement (5 out of 10 patients who undergone TIPS had a CT-scan control after the placement), SMI significantly improved from 42.7 ± 8.9 to 47.5 ± 8.3 (p = 0.05) with an average increase of 4.7 ± 3.9 cm2/m.
Conclusion: in patients with NCPH sarcopenia is similar to that observed in compensated cirrhotic patients. Instead cirrhotic patients with MELD ≥ 15 present a higher prevalence of sarcopenia, suggesting that portal hypertension per se might play a role in the development of sarcopenia. This is supported by the significant amelioration of SMI value observed after TIPS placement. Moreover, sarcopenic patients seem may be more prompt to develop complication related to portal hypertension particularly a higher rate of refractory bleeding causing TIPS placement in the follow-up.
Our results suggest the importance of nutritional assessment in patients with NCPH and, in case of detection of sarcopenia, measures finalized to the amelioration in nutritional status should be taken into consideration.

FRI-429

Impact of allelic variants of platelet receptors and coagulation system genes in the development of clinical manifestations of Wilson's desease

Teona Rozina[1,2], Saglara Fastovets[1], Ekaterina Starostina[1], Larisa Samokhodskaya[1], Tatiana Krasnova[1,2]. *[1]Federal state budget educational institution of higher education M.V.Lomonosov Moscow State University, Moscow, Russian Federation; [2]Federal state autonomous educational institution of higher education I.M. Sechenov First Moscow state medical university of the Ministry of Health of the Russian Federation, Moscow, Russian Federation*
Email: s.v.fastovets@gmail.com

Background and aims: A variety of phenotypic Wilson's disease (WD) manifestations with the same mutations in ATP7B gene implies that there are some modifier genes that might influence the pathogenic mechanism and the WD clinical symptoms. We assess the effect of various genes polymorphisms combinations, including FII 20210G/A, FV 1691G/A, FVII 10976G/A, FXIII 103G/T, ITGA2 807C/T, ITGB3 1565 T/C, FBG −455G/A, PAI −6755G/4G, MTHFR 677C/T, on the clinical course of WD.
Method: The research includes 85 patients with Wilson's disease: 51 patients with predominant liver disease without neurological symptoms (abdominal form) and 34 patients with concomitant neurological symptoms (mixed form). Assessment of gene polymorphisms was carried out by PCR.
Results: Genotypes GA FII 20210 G/A and GA FV 1691G/A were more frequently observed in patients with neurological manifestations. The frequency of these genotypes nearly approached statistical significance (p = 0, 157 and p = 0, 061). The 4G allele of PAI −675 5G/4G gene was more common in the group with neurological symptoms than in the group without signs of CNS damage (OR 1.374; 95% CI 0.739-2.553). In the group with neurological manifestations, genotype 4G4G was observed more frequently (47.06%) than in patients with liver disease only (23.53%) (OR 2.889; 95% CI 1.135-7.350). The minor T allele of the ITGA2 807 C/T gene was observed more often in the group with mixed form of WD than in the group with abdominal form of WD (p = 0.018; OR 2.172, 95% CI 1.163-4.058). The combined genotype CT+TT was significantly more frequent in the group with neurological manifestations (82.35%) compared with the group without such symptoms (54, 90%) (p = 0.010; OR 3.833; 95% CI 1.355-10.846).
Conclusion: In Wilson's disease patients, genotypes FII 20210 G/A, FV 1691G/A, PAI-675 5G/4G, ITGA2 807 C/T are associated with development of neurological symptoms.

FRI-430
Preclinical validation of copper 64 as a translational tool for evaluating the pharmacodynamics of VTX-801 genen therapy in Wilson's disease
Gloria González-Aseguinolaza[1,2], Maria Collantes[3], Margarita Ecay[3], Daniel Moreno[4], Oihana Murillo-Sauca[1], Cristina Gazquez[1], Veronica Ferrer[2], Anne Douar[2], Jean Philippe Combal[2], Ruben Hernandez[1], Ivan Peñuelas[3], Bernard Benichou[2]. *[1]CIMA, Pamplona, Spain; [2]Vivet Therapeutics, Paris, France; [3]Clinica Universidad de Navarra, Nuclear Medicine, Pamplona, Spain; [4]CIMA, Gene Therapy and Regulation of Gene Expression, Pamplona, Spain*
Email: ggasegui@unav.es

Background and aims: Wilson's disease is an autosomal recessive metabolic defect of hepatocyte copper excretion into the bile, caused by absent or reduced ATP7B copper transporter function. The ATP7B transporter has dual role: it transports copper into the trans-Golgi compartment for incorporation into the plasma protein ceruloplasmin, and into the bile for excretion of excess copper stores. Recently, we have demonstrated that the administration of an adeno associated vector (AAV) encoding a mini version of the human *ATP7B* cDNA (AAV-miniATP7B) provides long-term correction of copper metabolism in Wilson's disease (WD) mice. In anticipation of a future gene therapy clinical trial, we considered the value of using biliary copper excretion as a pharmacodynamic biomarker. For that purpose, we have evaluated the excretion of radiocopper (^{64}Cu) into the faeces as an alternative biomarker in AAV-miniATP7B-treated WD mice.
Method: Male and female WD mice were injected with AAV-miniATP7B at 6 weeks of age. Three months later, radiocopper was injected intravenously in treated mice as well as in control mice of the same age (WT and Atp7B ±). Abdominal PET analyses were performed 24 and 48 h later. 24 h faeces, 24 h urine and serial blood samples were collected over a period of 72 h post radiocopper injection, at which time animals were sacrificed and organs collected (liver, kidney, lung, brain and spleen); the radioactive signal was then measured for each biological sample in a gamma counter.
Results: Faecal radiocopper excretion was significantly higher in control mice in comparison to WD mice, in which a signal was barely detectable; while in AAV-miniATP7B treated WD animals, radiocopper faecal elimination was restored. The overall kinetics of radiocopper in blood was also very different in controls and WD mice, and it was restored in treated WD mice. Finally, the radioactive signal in the liver was much higher in untreated WD mice compared to controls, and was reduced in treated WD mice.
Conclusion: In conclusion, faecal excretion of radiocopper represents a very promising biomarker to evaluate the therapeutic efficacy of *ATP7B* gene supplementation in WD patients.

FRI-431
Clinical spectrum of congenital hepatic fibrosis in children: 15 year experience from a tertiary care centre in north India
Sadhna Bhasin Lal[1], Vybhav Gummadi[1], ashim das[2], Jagadeesh menon[1], shruti sharma[1], rishi kumar bolia[1]. *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, Pediatric gastroenterology, Hepatology and Nutrition, Chandigarh, India; [2]Post Graduate Institute of Medical Education and Research, Chandigarh, Histopathology, Chandigarh, India*
Email: sadhnalal2014@gmail.com

Background and aims: Congenital hepatic fibrosis (CHF) is a fibrocystic liver disease associated with ductal plate malformation (DPM) of the intrahepatic bile ducts. Normal liver parenchyma is separated by broad bands of bland fibrosis and DPM consisting of irregular shaped bile ducts along with abortive portal venules. Literature pertaining to various presentations of CHF in children is limited; this study aims at providing insights into the same.
Method: A retrospective case review of 125 children with CHF diagnosed at a tertiary care center in Northern India from 2003-2018, on the basis of clinical, radiological, endoscopic evidence of portal hypertension, and histopathological findings on liver biopsy, was performed. Percutaneous liver biopsy was done in all cases and the biopsies were reviewed by a single observer.
Results: At presentation, 60% had cholangitic variant with infantile cholestasis and predominantly intermittent pale coloured stools. 72.8% were boys. Median age at presentation was 5 months, 48 months and 8 years for cholangitic, mixed and portal hypertensive variants respectively. Presentation was with jaundice in 56%, abdominal distension in 22.4% and upper GI bleed in 17.6%. Majority of them had striking left liverlobe enlargement and moderate splenomegaly confirmed on ultrasound.1.6% (2), developed hepato-pulmonary syndrome. 5.6% had positive family history. In contrast to the published literature, our cohort had low frequency of associated syndromes. 15.2% had kidney disease of which 11.2% had Autosomal Recessive Polycystic Kidney Disease (ARPKD), 3.2% had Medullary Sponge Kidney; 5.6% had Caroli syndrome.
Conclusion: Sporadic isolated CHF without associated renal manifestations is a common presentation. Cholangitic CHF is an underrecognized entity and should be considered in the differential diagnosis of infantile cholestasis.

attention to identify potential candidates for transjugular intrahepatic portosystemic shunt (TIPS).

Method: Between March 2002 and June 2016, all consecutive adults with EHPVO were screened from our prospectively acquired database. The strategy for cirrhotic portal hypertension was applied for all the patients. For those with recurrent variceal bleeding and without fibrotic main portal vein and complete superior mesenteric vein and splenic vein thrombosis (EHPVO-TIPS criteria), TIPS was attempted.

Results: 302 patients were included into the study and the median follow-up was 58.8 months. With similar treatment strategy to cirrhosis, the 5-year cumulative incidences of development of large varices, first variceal bleeding, and rebleeding was 25.1%, 34.9%, and 33.6%, respectively. TIPS was attempted in 41 patients with recurrent bleeding meeting EHPVO-TIPS criteria and 37 (90.2%) were successful with a reduced risk of recurrent variceal rebleeding (HR = 0.36, 95% CI: 0.16-0.83, p = 0.017). Shunt dysfunction and HE were observed in ten (27.0%) and seven (18.9%) patients, respectively. 41 (13.6%) patients died and only nine (22%) were related with variceal bleeding. The 5-year cumulative survival rate were 91.9% with age the only predictor.

Conclusion: The current outcome of EHPVO is good. In addition, EHPVO-TIPS criteria can improve the technical success rate of TIPS and reduce rebleeding rate in patients with recurrent bleeding.

FRI-433

Bevacizumab for the treatment of liver involvement in patients with hereditary hemorrhagic telangiectasia

Assaf Issachar[1,2], Michal Cohen-Naftaly[1], Orly Sneh Arbib[1], Ran Tur-Kaspa[1], Amir Shlomai[1,2], Marius Braun[1], Meir Mei-Zahav[3].
[1]Rabin Medical Center, Beilinson Hospital, Liver Institute, Petah Tikva, Israel; [2]Rabin Medical Center, Beilinson Hospital, Medicine D Department, Petah Tikva, Israel; [3]Schneider Children's Medical Center, The National Israeli HHT Center, Petah Tikva, Israel
Email: assafissa@gmail.com

Background and aims: Liver involvement of HTT is related to the type of vascular shunting present and can be manifest clinically as high-output cardiac failure, portal hypertension or biliary disease There is increasing evidence that treatment with Bevacizumab can be efficient for high cardiac output (CO) heart failure secondary hepatic involvement of HHT but there isn't data about this treatment in other manifestations of liver involvement in HHT.

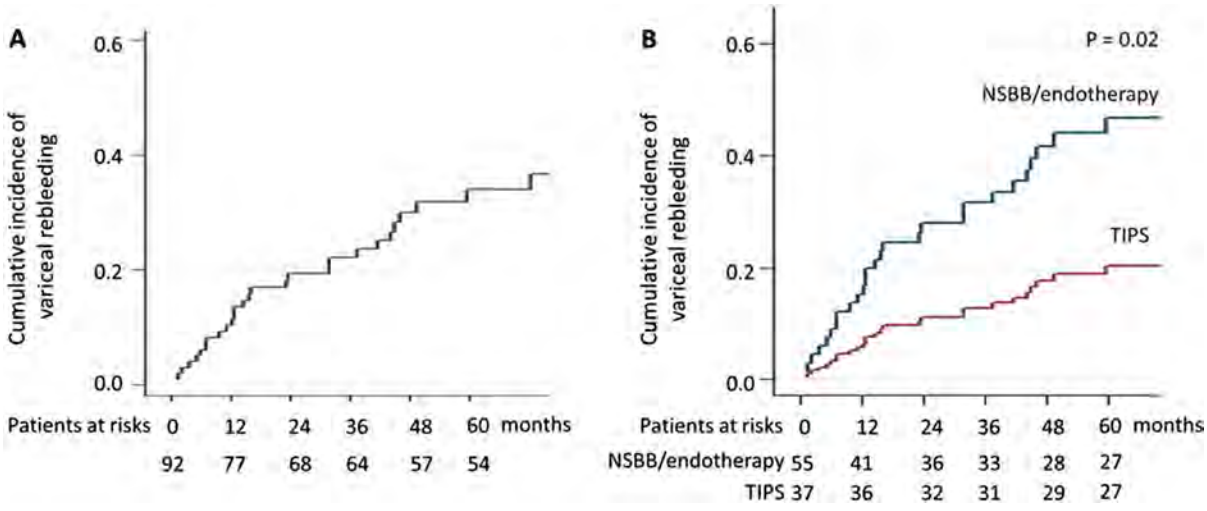

Figure 1: (abstract: FRI-432): Cumulative incidence of variceal bleeding under primary prophylaxis (A) and variceal rebleeding under secondary prophylaxis (B).

The aim of this study is to describe the successful outcome of patients with hepatic manifestations Of HHT treated with Bevacizumab.
Method: Retrospective case series using the patient's electronic data.
Results: Eleven patients were treated with Bevacizumab for clinical significant liver involvement of HHT. Ten of them were patients with high CO failure and one with liver decompensation only (portal HTN-ascites and encephalopathy). From the patients with high CO failure one had severe hepatic encephalopathy, one had severe ischemic cholangiopathy and one had refractory ascites with features compatible with portal HTN. All patients were treated with Bevacizumab 5 mg/kg every 2 weeks for 6 courses and then every 4-8 weeks for up to 3 years (3m-3years). All patients had significant clinical improvement of the heart failure and the other hepatic manifestations (ascites and encephalopathy).
Conclusion: Bevacizumab may be beneficial for the treatment of hepatic manifestation of HHT other than high cardiac output.

FRI-434

Role of next generation sequencing in the etiological diagnosis of splanchnic venous thrombosis

Marta Magaz[1], Alberto Álvarez-Larrán[2], Dolors Colomer[2], Mónica López[2], Gabriel Mezzano[1], Fanny Turon[1], Anna Baiges[1], José Ferrusquia[1], Michel Ble[1], Lara Orts[1], Claudia Berbel[1], Francisco Cervantes[1], Virginia Hernandez-Gea[1], Juan-Carlos Garcia-Pagan[1]. *[1]Hospital Clínic de Barcelona, Hepatic Hemodynamic Laboratory Liver Unit, Barcelona, Spain; [2]Hospital Clínic de Barcelona, Department of Haemotherapy and Haemostasis, Barcelona, Spain*
Email: jcgarcia@clinic.ub.es

Background and aims: Myeloproliferative neoplasms (MPN) are the most frequent cause of PVT. The mainstay of MPN diagnosis is based on the detection of mutations at JAK2V617F, JAK2 exon12, Calreticulin (CALR) or MPL. However, in some instances traditional techniques (Sanger sequencing) had low sensitivity, as they require at least 20% mutated leucocytes. Moreover, in up to 30-40% patients with PVT the etiological workup remains negative or only a local factor is identified (idiop/local-PVT). NGS allows the simultaneous evaluation of multiple genes associated with myeloid neoplasms even at low mutational levels, leading to a higher sensitivity than Sanger sequencing. Our aim was to explore the potential role of NGS identifying mutations/new etiological factors in a group of 44 patients with PVT that were negative for molecular markers using conventional techniques.
Method: We analyzed 44 DNA samples (4 MPN-PVT patients without mutations in JAK2/CALR/MPL genes by conventional techniques and 40 idiop/local-PVT patients). A panel of genes associated with myeloid pathology including TET2, ASXL1, CSF3R, RUNX1 and TP53 among others (Myeloid SolutionTMSOPHiAGENETICS®) was used. The analysis of the detected variants was carried out using SOPHiA DDM® software considering those non-synonymous variants with variant allele frequency (VAF) > 2%.
Results: In 2/4 (50%) with triple negative MPN-PVT, a mutation was identified in the "hotspot" region of exon 12 of JAK2. In addition, JAK2-exon12 was identified in 2/40 (5%) of idiop/local-PVT. No MPL mutations were detected. Of the remaining idiop/local-PVT, in 13/38 patients (34.2%) significant mutated genes were identified: 4 ASXL1 (2 associated with TET2), 4 CSFR3 (1 associated with TET2) and 5 isolated TET2. Interestingly, 3/13 (23%) patients with idiop/local-PVT with significant mutations had rethrombosis during follow-up while this only happened in 1/25 without significant mutations (4%) (p = 0.1).
Conclusion: NGS identified JAK2-exon12 mutations not previously detected by Sanger sequencing in 4 patients with PVT. In addition, NGS detected significant clonal mutations in approximately a third of patients with idiop/local-PVT. These patients seem to be exposed to a higher risk of rethrombosis. This preliminary result suggests NGS could be an useful diagnostic tool in patients with idiop/local-PVT and may lead to consider the use of long-term anticoagulation in those patients with significant mutations to prevent rethrombosis.

Email: xforns@clinic.cat

Background and aims: Wilson's disease (WD) has a very low prevalence. Thus, data on phenotipe/genotype at diagnosis and particularly on clinical outcomes in patients on therapy are scarce. We evaluated the clinical characteristics of patients with WD in a multicentric cohort comprising 4 centers in Spain.
Method: Clinical and laboratory variables, treatment and outcomes during follow-up were recorded. Categorical and quantitative variables were expressed in n (%) and median/IQR (25-75), respectively. Analysis extended from WD diagnosis until September 2018 or the development of events (transplantation/death). Molecular analysis was performed by Sanger and MLPA sequencing.
Results: 89 WD patients were included: 52.7% men, age at diagnosis 19 (12-31.5) years. The main phenotypic presentation was chronic liver disease (Leipzig H2) (69.2%); 79% of patients presented with ≥ 4 points in the Leipzig diagnostic score. WD was suspected mainly due to abnormal ALT levels (54.9%; ALT 87.5 UI/L [42-175]), whereas diagnosis due to neurological symtomps was infrequent (15.4%). Six patients (6.7%) presented as fulminant liver failure requiring liver transplantation. Up to 9.9% of cases were detected in a presymtomatic phase during family screening. Genetic analysis detected 1 (n = 30) or 2 (n = 29) mutations responsible for the disease in 95% of cases with available data (n = 62). The most prevalent mutations were p. Met645Arg (25.8%), p.His1069Gln (16.1%) and c.1708-1G > A (21%). First treatment was mainly penicilamine (68.5%), although 35 patients (57.4%) were discontinued, mainly due to adverse events. During clinical follow-up (70.3% adherence) the most frequent therapy was zinc (n = 44, 49.4%). In the last control, up to 60.4% of patients had normal ALT levels[median 30 (21-51)IU/L]. Nevertheless, after a median follow-up of 14.7 (9.6-25.5)years, 26 (28.6%) patients had developed liver cirrhosis, 13 (14.3%) patients presented gastro-esophageal varices and 2 (2.2%) cases were complicated with liver cancer; 12 patients received a liver transplantation (13.2%) and 3 (3.3%) died due to liver disease decompensation.
Conclusion: Hepatic phenotype was the most prevalent at diagnosis in this multicentric cohort of WD patients, and three recurrent mutations in the *ATP7B* accounted for 63% of patients. Despite medical therapy, cirrhosis development was remarkable, suggesting the need for a stricter monitoring of treatment adherence.

FRI-436

Congenital porto-systemic shunts in children: Preliminary results from the IRCPSS

Email: valerie.mclin@hcuge.ch

Background and aims: Our aim was to use data patients from centers participating in the first International Registry for Congenital Porto-Systemic Shunts (IRCPSS) to identify trends that might inform therapeutic strategies according to the anatomy of the shunt.
Method: Data were collected retrospectively (descriptive patient data, mode of presentation, complications, management). Intrahepatic (IH) was defined as porto-hepatic and extrahepatic (EH) as a porto-systemic communication occurring either upstream of the portal vein or originating at the portal vein. Persistent ductus venosus were considered EH.
Results: 246 children were identified and are summarized in Figure 1. IH and EH shunts were equally frequent. 24% of all CPSS were identified pre-natally and 76% post-natally. Among patients diagnosed pre-nataly, a majority had with IH shunts (75%). Among those diagnosed post-natally, EH CPSS were diagnosed later than IH CPSS. IH shunts were more often identified incidentally than EH shunts.
Symptoms: were equally frequent among patients with IH (57%) or EH (61%) CPSS. Hypoglycemia or cholestasis was more frequent in patients with IH CPSS. Patients with EH CPSS were more likely to have several symptoms than patients with IH CPSS. They were also more likely to have liver nodules on imaging.
Closure: 54% of IH CPSS and 5% of EH CPSS closed spontaneously. 35% of IH CPSS required medical or surgical closure of which nearly 40% for a preventive indication. 70% of patients with EH CPSS were closed through a procedure, of which 41% were preventive.
Conclusion: IH and EH shunts were equally frequent in this multicenter retrospective cohort of CPSS in children. CPSS are a cause of severe symptoms in children and should be sought in infants with hypoglycemia or cholestasis. In older children, they should be considered in the differential diagnosis of liver nodules, cardiopulmonary symptoms or neurocognitive deficits. Given the potential severity of complications, preventative closure was often performed, although timing and approach need further study, something which the IRCPSS aims to address.

Diagnosis of sickle cell liver disease may be aided by non-invasive tests

Jibran Mecci[1], Maria-Emanuela Maxan[2], Polychronis Kemos[1], Paul Telfer[2], Filipa Barroso[2], Graham Foster[1], Kaya Banu[2]. *[1]Blizard Institute, Barts and The London School of Medicine and Dentistry, London, United Kingdom; [2]The Royal London Hospital, London, United Kingdom*
Email: alij16@hotmail.com

Background and aims: Sickle cell liver disease (SCLD) continues to be poorly defined with most patients not being diagnosed whilst alive with reports of between 7 and 10% prevalence of cirrhosis in autopsy studies. The role of haemosiderosis, and historically, hepatitis C further clouded our diagnostic ability. With life expectancy increasing for patients suffering with sickle cell disease the burden of SCLD is expected to rise. The use of non-invasive tests may lead to a jump in our understanding thereby allowing earlier and more effective diagnosis and treatment. We hypothesise, non-invasive tests will aid the diagnosis of SCLD.
Method: All patients treated within a large tertiary center were screened for SCLD. Inclusion criteria consisted of all patients > 16 years old with genotype HbSS or HbSβ-thalassaemia with at least 1 episode of either a raised bilirubin (> 100μmol/L), ALT, ALP or clinical suspicion between Jan 15-Jun 16 regardless of treatment. We excluded patients who were pregnant. Blood tests were extracted with the mean calculated, excluding hospitalised episodes and post-transfusion tests. Patients were offered a Fibroscan® performed by experienced operators. Those within 1 week of an acute sickle crisis were not tested. Ferriscan® was performed at the clinicians discretion to measure liver iron concentration (LIC). All correlations were assessed using the non-parametric Spearman's rho in SPSS. The confidence intervals were calculated using the arctanh Fisher transformation in Python using the Python math module.
Results: 76 patients were examined with a mean age of 31.8yo and 74 with HbSS. 18 received no treatment, 10 hydroxyurea and 48 transfusions. Mean Hb was 87 (min. 66-max. 107)g/dl and Ferritin was 1976 (10-11626)μg/L. Liver function tests were grossly normal, Bilirubin-66 (10-219)μmol/L, ALT-29 (10-77) units/L, ALP-118 (28-473)IU/L and albumin 45 (34-78)g/L. Mean stiffness was 7.5 (3.4-36.2)kPa and LIC 13.2 (0.6-43)mg/g. Any fibrosis (> 6kPa) was found in 40 patients with 7 cirrhotics (> 12.3kPa). We correlated these with Fibroscan® to find a weak/moderate signal with ALP (r = 0.275, 95%CI: 0.05 to 0.47, p = 0.017), a weak signal for albumin (r = 0.238, 95%CI:

−0.44 to −0.01, p = 0.039) and no correlation with LIC (r = 0.149, 95% CI: −0.18 to 0.44, p = 0.37).
Conclusion: We can infer that Fibroscan® can aid the diagnosis of SCLD whilst not being affected by LIC and we are currently collecting biopsies to verify these correlations.

FRI-438
Histone deacetylase 5 methylation changes in mice and patients with Wilson disease

Gaurav Vilas Sarode[1], Charles Mordaunt[2], Noreene Shibata[1], Christopher Bowlus[1], Anna Czlonkowska[3], Tomasz Litwin[3], Karl Heinz Weiss[4], Janine LaSalle[2], Valentina Medici[1,1]. *[1]Sacramento, Internal Medicine, Sacramento, United States; [2]University of California Davis, Department of Medical Microbiology and Immunology, Genome Center, and MIND Institute, Davis, United States; [3]Institute of Psychiatry and Neurology, 2nd Department of Neurology, Warsaw, Poland; [4]University Hospital Heidelberg, Department of Internal Medicine IV, Heidelberg, Germany*
Email: vmedici@ucdavis.edu

Background and aims: Wilson disease (WD) is a genetic disease due to copper accumulation in the liver and brain. The clinical presentation is variable and suggests that environmental factors through epigenetic mechanisms may contribute to the disease phenotype. Histone deacetylases (HDACs) remove acetyl moieties from lysine residues of histone tails, resulting in transcriptional repression. Class II HDAC5 levels are believed to be greatly influenced by dietary factors, therefore lying at the interface between nutrition and epigenetic regulation of gene expression. The aim of the present study was to explore the methylation levels of HDAC5 in patients with WD and in an animal model of hepatic copper accumulation.
Method: Whole-genome bisulfite sequencing was performed on DNA from liver and whole blood of patients with WD compared to healthy subjects, primary sclerosing cholangitis, and non-alcoholic fatty liver disease patients (liver n = 21, blood n = 72). HDAC5 protein levels were confirmed in tx-j mice as model of spontaneous hepatic copper accumulation and compared to C3H control mice. Both tx-j and C3H female mice were started on choline-supplemented (choline 36 mmol/Kg of diet) and control diets (choline 8 mmol/Kg of diet) 2 weeks before mating and through pregnancy. The progeny was continued on the same diets until week 24 of age when mice were euthanized and livers were obtained.
Results: About one third of the genes near blood differentially methylated regions significantly overlapped with those identified in liver. Among overlapping genes, *HDAC5* gene was significantly hypermethylated both in the liver and blood from patients with WD with similar direction and gene body locations (FDR < 0.05). *HDAC5* hypermethylation was observed in patients with WD compared to healthy subjects and to subjects with other liver diseases. HDAC5 protein levels were more than twice reduced in livers of tx-j mice compared to wild-type mice but increased to control levels after penicillamine or choline supplementation. Concomitantly, the relative expression of acetylated histone 3 was increased in tx-j mice livers.
Conclusion: Our results suggest that *HDAC5* is a regulator of the interaction between nutrition factors and epigenetic mechanisms in WD and its levels appear to be affected by methyl groups availability.

Background and aims: Clinical guidelines do not recommend long-term anticoagulation in patients with non-cirrhotic splanchnic thrombosis of local or idiopathic etiology (NC-PVT) unless there is evidence of intestinal ischemia or recurrence. The aim of our study is to describe the risk of splanchnic and extra-splanchnic rethrombosis in these patients and the identification of predictors of recurrence.
Method: We prospectively included 64 patients with NC-PVT from the REHEVASC registry that, after discarding an underlying pro-thrombotic disorder, were classified as of local/idiopathic etiology. All these patients were not receiving long-term anticoagulation and had scheduled follow-up angioTAC/angioRMN studies during follow-up. Patients were censored at the time of rethrombosis or when the last imaging study was performed. Additionally, a detailed coagulation study was performed in 48 patients.
Results: During a median follow-up of 97 (10-206) months, 14/64 (22%) patients developed rethrombosis (50% asymptomatic) with an incidence of 1.6%, 8.4%, 17.4% and 27.3% at 1, 2, 5 and 10 years respectively. No clinical, biochemical or imaging parameters could predict development of rethrombosis. In the subgroup of 48 patients with a coagulation study, 10 (21%) had rethrombosis. Levels of factor V (being the best cut-off point by Youden 91%) and factor VIII ≥ 150% (value associated with recurrence of thrombosis in other territories) were significantly higher in patients who had rethrombosis. The incidence of splanchnic rethrombosis was 4.8% in patients with factor V < 91% and factor VIII < 150% at 10 years and 44.5% in patients with factor V ≥ 91% or factor VIII ≥ 150% (p < 0.01). Seven patients also had extrasplanchnic thrombosis (5 had also had splanchnic rethrombosis), then a total of 12 patients had the end point composed of rethrombosis and/or extrasplanchnic thrombosis. A factor VIII ≥ 150% and/or a factor V ≥ 91% confirmed its predictive capacity of new thrombotic events.
Conclusion: Risk of recurrent thrombosis in patients with idiopathic/local NC-PVT not receiving long-term anticoagulation treatment is not an exceptional event. Levels of factor V ≥ 91% and factor VIII ≥ 150% can help to select patients at high risk of rethrombosis who could benefit from long-term anticoagulacion.
