Publication information: *Journal of Hepatology* (ISSN 0168-8278). For 2019, volumes 70 and 71 are scheduled for publication. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this journal's website (http://www.elsevier.com/locate/jhep). Further information is available on this journal and other Elsevier products through Elsevier's website: (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Orders, claims, and journal enquiries: Please visit our Support Hub page https://service.elsevier.com for assistance.

Advertising information: Advertising orders and enquiries can be sent to: **USA, Canada and South America:** Elsevier Inc., 360 Park Avenue, Suite 800, New York, NY 10169-0901, USA; phone: (+1) (212) 989 5800. **Europe and ROW:** Robert Bayliss, Pharma Solutions, Elsevier Ltd., 125 London Wall, London EC2Y 5AS, UK; phone: (+44) 207 424 4454; e-mail: r.bayliss@elsevier.com.

Author enquiries: You can track your submitted article at http://www.elsevier.com/track-submission. You can track your accepted article at http://www.elsevier.com/trackarticle. You are also welcome to contact Customer Support via http://service.elsevier.com.

Funding body agreements and policies: Elsevier has established agreements and developed policies to allow authors whose articles appear in journals published by Elsevier, to comply with potential manuscript archiving requirements as specified as conditions of their grant awards. Registration of Clinical Trials
The *Journal of Hepatology* endorses the policy of the WHO and the International Committee of Medical Journal Editors (ICMJE) on the registration of clinical trials. Therefore, any trial that starts recruiting on or after July 1, 2005 should be registered in a publicly owned, publicly accessible registry and should satisfy a minimal standard dataset. Trials that started recruiting before that date will be considered for publication if registered before September 13, 2005.
More detailed information regarding clinical trials and registration can be found in New Engl J Med 2004; 351:1250–1251 and New Engl J Med 2005; 352:2437–2438.

GS-01

Efficacy, safety, and tolerability of lubiprostone for the treatment of non-alcoholic fatty liver disease: The LUBIPRONE, double-blind, randomized, placebo-controlled, phase II study

Takaomi Kessoku[1], Kento Imajo[1], Yuji Ogawa[1], Takashi Kobayashi[1], Yasushi Honda[1], Takayuki Kato[1], Wataru Tomeno[1], shingo Kato[1], Takuma Higurashi[1], Masato Yoneda[1], Hiroyuki Kirikoshi[2], Kazumi Kubota[3], Masataka Taguri[3], Takeharu Yamanaka[3], Haruki Usuda[4], Koichiro Wada[4], Satoru Saito[1], Atsushi Nakajima[1].

Email: takaomi0027@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disorder, and its progression is associated with increased gut-permeability. Lubiprostone is a type 2 chloride channel activator indicated as a laxative for the treatment of patients with constipation. We have previously reported that lubiprostone ameliorated the increased intestinal permeability (PlosOne 2016). This study is a first proof of concept study that uses lubiprostone to demonstrate improvement of NAFLD by controlling gut-permeability. The aim of study is to evaluate the efficacy, safety, and tolerability of lubiprostone on this disorder (Protocol Paper, Kessoku T, contemporary clinical trial 2018).
Method: In this double-blind, placebo-controlled, randomized, phase II trial, patients with NAFLD (ALT ≥ 40 IU/L, MRI-PDFF ≥ 5.2%, MR elastgraphy < 6.7kPa) were enrolled. 12μg or 24μg of lubiprostone or placebo were administered orally for 12 weeks. The primary end point was defined as the improvement in ALT level from the baseline to the end of treatment. A planned key secondary end point was defined as the improvement in the change of lactulose-mannitol ratio (LMR), which was used as the golden standard for the measurement of gut-permeability. The other end points were blood endotoxin activity, MRI-PDFF and liver stiffness measured by MR elastography. Analyses were done by intention-to-treat. This trial was registered with UMIN000026635.
Results: 150 NAFLD patients were randomly assigned. 41 patients in the placebo, 47 in the 12 μg lubiprostone, and 51 in the 24 μg lubiprostone were included in the full analysis population. After 12 weeks of treatment, the lubiprostone group showed significantly greater improvements in the mean ALT levels (placebo vs 12 μg lubiprostone: p = 0.0096, placebo vs 24 μg lubiprostone: p = 0.0025), LMR (placebo vs 12 μg lubiprostone: p = 0.0125, placebo vs 24 μg lubiprostone: P = 0.0017), blood endotoxin activity (placebo vs 12 μg lubiprostone: p = 0.0008, placebo vs 24 μg lubiprostone: P = 0.0002), MRI-PDFF (placebo vs 12 μg lubiprostone: p < 0.001, placebo vs 24 μg lubiprostone: P = 0.001) and liver stiffness (placebo vs 12 μg lubiprostone: p = 0.0207, placebo vs 24 μg lubiprostone: P = 0.0002). But no statistically significant difference was observed between the 12 μg and 24 μg lubiprostone group. In safety and tolerability, drop-out ratio of placebo, 12 μg lubiprostone, 24 μg lubiprostone, were 5%, 0%, and 9%, showing that 24 μg lubiprostone had significantly higher rates of adverse events (placebo vs 12 μg lubiprostone: no significant, placebo vs 24 μg lubiprostone: P = 0.0025), especially diarrhea, compared to the other groups.
Conclusion: Lubiprostone showed favourable efficacy and tolerability when administered at 12μg doses to NAFLD patients, suggesting manipulating gut permeability may be a promising novel treatment target for the treatment of NAFLD.

GS-02

Efficacy of GKT831 in patients with primary biliary cholangitis and inadequate response to ursodeoxycholic acid: Interim efficacy results of a phase 2 clinical trial

Background and aims: GKT831 is a potent inhibitor of the nicotinamide adenine dinucleotide phosphate oxidases 1 and 4 (NOX1/4). NOX1/4 produce reactive oxygen species and modulate intracellular signaling pathways through oxidation of target proteins. In response to cellular stress including cholestatic injury to cholangiocytes and hepatocytes, NOX1/4 coordinate the activation of multiple inflammatory and fibrogenic pathways. GKT831 has shown marked anti-inflammatory and anti-fibrotic activity in multiple models of advanced cholestatic diseases. We are conducting a 24-week, randomized, double blind, placebo controlled trial to assess the safety and efficacy of GKT831 in patients with primary biliary cholangitis (PBC) and inadequate response to ursodeoxycholic acid (UDCA).
Method: PBC patients on a stable dose of UDCA and with alkaline phosphatase (ALP) and gamma glutamyl transpeptidase (GGT) levels ≥ 1.5 times the upper limit of normal (ULN), and normal bilirubin were randomized to GKT831 400 mg once a day (QD), 400 mg twice a day (BID), or placebo. All subjects continued UDCA treatment during the treatment period. A predefined interim efficacy analysis was conducted when 92 patients completed 6 weeks of treatment.
Results: 111 patients with high baseline disease activity were randomized (female = 91%, mean ALp = 312 IU/L, mean GGT = 225 IU/L). Changes in the primary efficacy end point GGT, a marker of liver and bile duct injury, were-7%, –12%, and-23% in the placebo, 400 mg OD and 400 mg BID groups, respectively ($p < 0.01$ for 400 mg BID vs placebo). GKT831 achieved even greater GGT reductions (29% for GKT831 400 mg BID vs 8% for placebo, $p < 0.01$) in patients with higher baseline GGT (≥ 2.5 × ULN, n = 68), suggesting that GKT831 may also benefit patients with more advanced disease. Changes in ALP were-2%, –8% and –17% in the placebo, 400 mg OD, and 400 mg BID groups, respectively ($p < 0.001$ for 400 mg BID vs placebo). Although patients had low baseline levels of liver transaminases and high sensitivity C-reactive protein, dose dependent reductions were achieved. Total and conjugated bilirubin remained unchanged.
Conclusion: GKT831 achieved rapid, dose and time dependent reductions in markers of cholestatic bile duct and liver injury. These reductions in disease activity were highly significant for both ALP and GGT in the 400 mg BID group at week 6. Quality of life and markers of liver fibrosis will be assessed at week 24.

GS-03

Global real world evidence of sofosbuvir/velpatasvir as a simple, effective regimen for the treatment of chronic hepatitis C patients: Integrated analysis of 12 clinical practice cohorts

Pontevedra and IIS Galicia Sur-HEPA-C cohort, Vigo, Spain
Email: kim.vanstraelen@gilead.com

Background and aims: The WHO estimates that 71 million people are chronically infected with hepatitis C (HCV) globally and has a goal to eliminate HCV by 2030. SOF/VEL is a pangenotypic, panfibrotic, protease inhibitor (PI)-free, single duration, single tablet regimen (STR), offering a simplified treatment option to address this goal.
This integrated analysis of real-world data from clinical practice cohorts representing a heterogeneous patient population evaluates the efficacy of SOF/VEL for 12 weeks, without ribavirin (RBV), in patients with HCV across all genotypes (GT) and fibrosis stages, including patients with compensated cirrhosis (CC).
Method: Data from 12 clinical practice cohorts across North America and EU, representing 8 countries, are included. Adults were treated according to local standards of care, with CC determined by the treating physician according to local clinical practice. Data on GT1-6 patients with CC or without CC (NC), treatment naïve (TN) or treatment experienced (TE) [pegIFN + RBV±PI], who initiated SOF/VEL for 12 weeks prior to November 2018 were included. Patients with a history of decompensation, prior NS5A inhibitor exposure, treatment duration > 12 weeks or addition of RBV were excluded. For patients who completed treatment and with virological outcome data available at abstract submission, sustained virological response (SVR; ≥ 12 weeks after end-of-treatment) was assessed.
Results: Overall, 5760 patients with HCV GT1-6 were included. At abstract submission, virologic outcome was available for 4491 patients. The median age was 56 years, 58.4% were male and GT distribution was as follows: 31.5% GT1, 30.9% GT2, 30.8% GT3, 6.0% GT4-6, 0.9% mixed or unknown GT. CC was present in 889 (20%) patients. 1998 (44%) TE patients were included. 98.9% of patients (4442/4491) achieved SVR, with 99.1%; 98.4%; 98.4% SVR respectively in NC, CC patients and patients with unknown cirrhotic status, and 98.5%; 99.5% and 97.1% SVR respectively in TN patients, TE patients and DAA naïve patients with unknown treatment history. Demographics, SVR results and subgroup analyses of the full cohort will be available at the conference.
Conclusion: Simplicity is key in reaching the WHO goals for HCV elimination. SOF/VEL for 12 weeks is a simple and highly effective regimen that cures HCV patients, irrespective of GT, cirrhosis status or treatment history, with a manageable drug interaction profile, which will contribute to the implementation of test and treat strategies.

GS-04

Addition of stent placement to angioplasty for Budd-Chiari syndrome improves recanalization patency and reduces symptom recurrence with adequate safety: A randomised controlled trial

Qiuhe Wang[1], Xingshun Qi[1], Jiahao Fan[1], Chuangye He[1], Wenggang Guo[1], Kai Li[1], Xulong Yuan[1], Tianlei Yu[1], Bohan Luo[1], Zhengyu Wang[1], Jie Yuan[1], Xiaomei Li[1], Ying Zhu[1], Na Han[1], Jing Niu[1], Yong Lv[1], Jing Li[1], Shihao Tang[1], Shuai Guo[1], Enxin Wang[1], Dongdong Xia[1], Zhexuan Wang[1], Hongwei Cai[2], Zhanxin Yin[1], Jielai Xia[2], Daiming Fan[3], Guohong Han[1]. *[1]Department of Liver Disease and Digestive Interventional Radiology, National Clinical Research Center for Digestive Disease and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, China, Xi'an, China; [2]Department of Medical Statistics, Fourth Military Medical University, Xi'an 710032, China, Xi'an, China; [3]State Key laboratory of Cancer Biology, National Clinical Research Center for Digestive Disease and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, China, Xi'an, China*
Email: hangh@fmmu.edu.cn

Background and aims: Angioplasty is recommended by guidelines as the first-line interventional treatment for Budd-Chiari syndrome (BCS), the long-term patency of which consequently determines symptom recurrence, ensuing treatment and patient outcome. Although previous retrospective studies indicated that angioplasty with metal stents is conducive to maintain patency, this issue has not been investigated in prospective studies due to the rarity nature of the disease. We therefore designed the current randomized controlled trial to test the hypothesis that the addition of stent placement to angioplasty for BCS could improve patency and reduces symptom recurrence with adequate safety.
Method: From July 2014 to September 2017, 150 consecutive BCS patients were screened. Eighty-eight patients with short-length stenosis were finally enrolled and then randomly assigned to angioplasty (AP, n = 45) or angioplasty with stent placement group (AP+SP, n = 43). Primary end point was patency of recanalized veins. Secondary end points included symptom recurrence, procedure-related complications, hepatocellular carcinoma (HCC) incidence, and survival.
Results: During a median follow-up of 27 months in the entire cohort, incidence of recanalized veins restenosis were significantly lower in AP+SP group than in AP group (0% vs. 24% at 1 year and 4% vs. 40% at 3 years, respectively; HR = 21.5, 95% confidence interval [CI] 2.9-161.4, p < 0.001, Figure A, C). Noteworthy, symptom recurrences were also less frequent in AP+SP group (symptom recurrence-free survival being 5% vs. 33% at 1 year and 11% vs. 60% at 3 years, HR = 4.4, 95%CI 2.0-9.8, p < 0.001, Figure B, D). Meanwhile, procedure-related complications were not significantly different between the two groups (2% vs. 0%, p = 0.489), with no cases of stent fracture or migration during follow-up. HCC incidence (4.6% vs. 2.2%, p = 0.612) as well as 3-year survival (97% vs. 98%, p = 0.550) were similar between the two groups.
Conclusion: As the only randomised controlled trial regarding BCS to date, the current study indicated that the addition of metal stents to angioplasty significantly improves patency of recanalized veins and, more importantly, lessens symptom recurrence without increasing the risk of procedure-related complications, thereby relieving the burden of revision and reducing the necessity of procedures with higher invasiveness. Therefore, stent placement should be preferred in angioplasty for BCS patients.

Background and aims: A vaccine for HCV prevention is highly desirable. Pre-clinical studies in mice and non-human primates have shown that linking MCH class II invariant chain (li) to an immunogen encoded by viral vectors enhances immunogen-specific T-cell responses. We evaluated this strategy in humans for the first time, using viral vectors chimpanzee adenovirus 3 (ChAd3) and modified vaccinia virus Ankara (MVA) encoding the HCV non-structural immunogen (NSmut) linked to human (h)li.

Method: ChAd3-hliNSmut and MVA-hliNSmut were given 8 weeks apart in 17 healthy volunteers aged 18-65 in two doses i.m. (n = 6; ChAd3-hliNSmut 5×10^9/MVA-hliNSmut 5×10^7 viral particles[vp], n = 11; ChAd3-hliNSmut 2.5×10^{10}/MVA-hliNSmut 2×10^8vp). HCV specific T cell magnitude, breadth and polyfunctionality was assessed using fresh PBMCs in ex-vivo IFN-ɣ ELISpot assays, ICS and Class I multimers. We monitored anti-Ii T cell and antibodies. HCV immune responses were compared to those elicited using non-Ii vaccines. Adverse events (AEs) were reported.

Results: Side effects were typical of those observed after Ad/MVA vaccination and were generally mild. No serious AEs, persistent grade 3 solicited AEs, or clinically-significant changes in laboratory parameters were reported. Following low dose vaccination high magnitude HCV specific responses were observed (mean ±SD) 555SFU/10^6PBMC (±784) post prime and 4209SFU/10^6PBMC (±3968) post boost. At high dose, the magnitude and breadth of HCV specific T cell responses were further enhanced at 2538SFU/10^6PBMC (±2137) post prime and 6869SFU/10^6PBMC (±3667) post boost). These were significantly higher and more sustained than those seen at the same dose in non-Ii vaccines ($p = 0.015$). Polyfunctional HCV specific CD8+ and CD4+ responses were induced (> 20% CD8+/CD3+ in some individuals) (fig 1). Class I multimer analysis showed that up to 8% of CD8+/CD3+ targeted single HCV epitopes; these were mostly "effector memory" with high levels of T cell activation and cytolytic markers. No volunteers developed anti-Ii T cell or antibody responses.

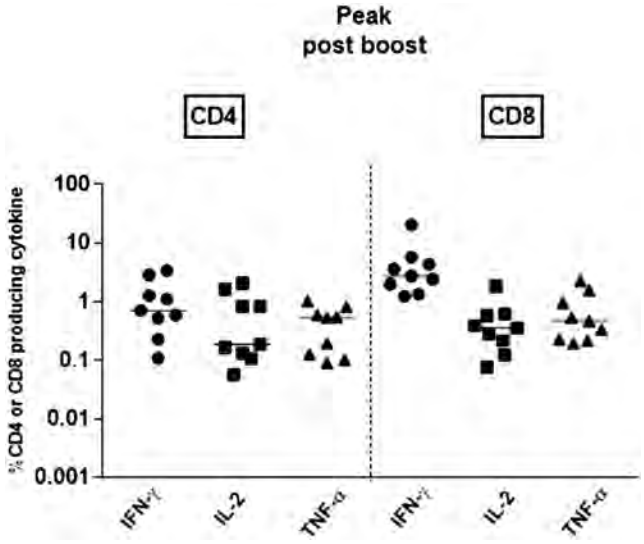

Figure 1: Functionality of vaccine induced HCV specific CD4+/CD8+ T cells.

Conclusion: Class-II invariant Ii adjuvanted chimpanzee adenoviral and MVA vaccines were well tolerated and elicited unprecedented levels of HCV specific T cell immune responses in humans. This new strategy could be developed to contribute to the HCV elimination targets, and paves the way for developing class-II Ii chain vaccines against cancer and other infections.

Background and Aims: Obeticholic acid (OCA), an FXR agonist, improved both fibrosis and histologic features of nonalcoholic steatohepatitis (NASH) in the Ph2 FLINT study. This Month 18 pre-specified interim analysis of the ongoing Ph3 REGENERATE study evaluated the effect of OCA on liver histology in patients (pts) with biopsy-confirmed NASH.

Method: Pts with NASH and fibrosis stages F2-3 (ITT), and an exploratory group of F1 pts with metabolic syndrome, were randomized to placebo (PBO), OCA 10 mg, or OCA 25 mg QD. Primary endpoints were fibrosis improvement (≥1 stage) with no worsening of NASH, or NASH resolution with no worsening of liver fibrosis per liver biopsy. The safety population included all randomized and dosed pts (F1-3, N = 1968). Clinical outcomes will be evaluated at the end-of-study.

Results: The ITT population included 931 pts (PBO [n = 311], OCA 10 mg [n = 312] or OCA 25 mg [n = 308]), comprised of 44% F2 and 56% F3. Baseline characteristics were well-balanced across groups. Results in Table. The primary fibrosis endpoint was met by 11.9% PBO, 17.6% OCA 10 mg (p = 0.0446 vs PBO), and 23.1% OCA 25 mg (p = 0.0002 vs PBO) pts (ITT). The primary NASH endpoint was not statistically significant (ITT); however, in a pre-specified analysis that included F1-F3 pts (N = 1218), more OCA 25 mg pts achieved NASH resolution. Significantly more pts on OCA 25 mg showed improvements in hepatocellular ballooning (p = 0.0011 vs PBO) and lobular inflammation (p = 0.0322 vs PBO). Dose-dependent reductions in ALT, AST and GGT were observed. Pruritus was the most common AE (19% PBO, 28% OCA 10 mg, 51% OCA 25 mg) and was predominantly mild to moderate in severity (severe pruritus: < 1% PBO, < 1% OCA 10 mg, 5% OCA 25 mg). More OCA 25 mg pts discontinued due to pruritus (< 1% PBO, < 1% OCA 10 mg, 9% OCA 25 mg; protocol mandated discontinuation of treatment with severe pruritus). SAEs occurred in 11% PBO, 11% OCA 10 mg and 14% OCA 25 mg pts. Increases in LDLc with OCA were observed by Week 4, but approached baseline by Month 18 (OCA 25mg: LS mean change Wk4 +22.6 mg/dL, M18 +4.0 mg/dL). Cardiovascular SAEs were similar across groups (2% PBO, 1% OCA 10 mg, 2% OCA 25 mg). Cholelithiasis or cholecystitis were reported in 1% PBO, 1% OCA 10 mg and 3% OCA 25 mg pts. Hepatic disorder SAEs were uncommon but occurred more frequently in OCA 25 mg pts (<1%). Three deaths occurred; none were considered treatment-related (PBO n = 2; OCA 25 mg n = 1).

	Placebo	OCA 10 mg	OCA 25 mg
Primary: ITT Population (F2 + F3)	n = 311	n = 312	n = 308
Fibrosis improvement + no worsening of NASH	11.9%	17.6% p = 0.0446	23.1% p = 0.0002
NASH resolution + no worsening of fibrosis	8.0%	11.2% p = 0.1814	11.7% p = 0.1268
Improvement in hepatocellular ballooning	23.2%	27.2% p = 0.2423	35.1% p = 0.0011
Improvement in lobular inflammation	35.7%	39.1% p = 0.3380	44.2% p = 0.0322
Additional: Full Efficacy Analysis (ITT + F1)	n = 407	n = 407	n = 404
Fibrosis improvement + no worsening of NASH	10.6%	15.7% p = 0.0286	21.0% p < 0.0001
NASH resolution + no worsening of fibrosis	7.9%	11.3% p = 0.0903	14.9% p = 0.0013

Overall study discontinuations (ITT): 16% PBO, 17% OCA 10 mg, 15% OCA 25 mg.

Conclusion: Treatment with OCA 25 mg improved liver fibrosis, key histologic features of steatohepatitis and liver biochemistry, demonstrating consistent efficacy with an overall AE profile similar to previous studies.

NAFLD Pathophysiology – Target identification

Roles of CC chemokine receptor 9 in the progression and carcinogenesis of murine non-alcoholic steatohepatitis

Rei Morikawa[1], Nobuhiro Nakamoto[1], Takeru Amiya[1], Po-Sung Chu[1], Nobuhito Taniki[1], Hirotoshi Ebinuma[1], Takanori Kanai[1]. *[1]Keio University, School of Medicine, Division of Gastroenterology and Hepatology. Institute of Internal Medicine, Tokyo, Japan*
Email: runrabbitrun1216@yahoo.co.jp

Background and aims: The number of non-alcoholic steatohepatitis (NASH) patients are increasing globally. Recently, many researches focus on CCR2/CCR5 for therapeutic target for NASH. Our group has demonstrated the pathogenic role of $CCR9^{+}$ macrophages in a murine model of acute hepatitis and its effect was greater than CCR2. This research aimed to examine a role of CCR9/CCL25 axis and reveal the therapeutic potential against NASH and NASH-based hepatocarcinogenesis.

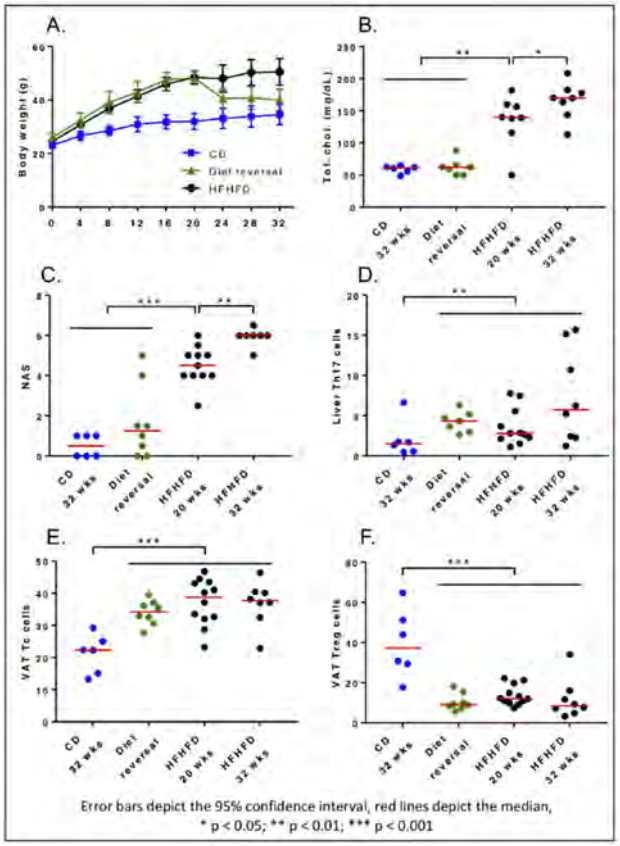
Method: 50 biopsy-proven NAFLD patients were recruited in this study. With written informed consent, blood sample were obtained and serum CCL25 level was measured by ELISA, which was compared

with healthy volunteers. For further study, Male C57BL/6 (WT) and CCR9 deficient ($CCR9^{-/-}$) mice were fed either a 60% high-fat and 1% high-cholesterol diet (HFHC) or a normal diet for 24 weeks as a NASH model. Bone marrow transplantation was performed to generate Ly5.1 mice with Ly5.1 or Ly5.2 $CCR9^{-/-}$ bone marrow (BM), and Ly5.2 $CCR9^{-/-}$ mice with Ly5.1BM, and they were fed with HFHC diet for 6 months. In other experiments, WT mice fed with HFHC diet for 18 weeks were subsequently administrated CCR9 antagonist for 6 weeks. Furthermore, we analyzed carcinogenesis with WT and $CCR9^{-/-}$ mice administrated diethylnitrosamine (DEN) intraperitoneally at 3 weeks old and fed 60% HF diet (HF+DEN) for 45 weeks.
Results: First, serum CCL25 level was significantly higher in NAFLD patients than that of healthy volunteer. To elucidate the role of CCR9, we analyzed WT and $CCR9^{-/-}$ mice fed with HFHC diet and found that $CCR9^{-/-}$ mice fed with HFHC demonstrated ameliorated NASH progression both in serologically and histologically compared with WT mice. To clarify the immunological mechanism, we analyzed liver infiltrating cells and found the increased TNF-α-producing $CCR9^{+}CD11b^{+}$ macrophages in WT mice fed with HFHC. Besides, CCR9 expression was significantly higher on hepatic stellate cell (HSC) in WT fed with HFHC by immunofluorescence analysis, and the expression of fibrosis-related genes were significantly decreased in HSCs derived from $CCR9^{-/-}$ mice fed with HFHC. WT mice reconstituted with $CCR9^{-/-}$ mice-derived BM developed severe steatohepatitis compared to $CCR9^{-/-}$ mice reconstituted with WT mice-derived BM, reinforced the role of CCR9 in resident liver cells rather than in BM cells in the progression of liver fibrosis. Reduction of liver fibrosis in mice administered with CCR9 antagonist further support the pathogenic role of CCR9 in NASH development. Finally, we investigated HF+DEN-induced carcinogenesis model, and revealed that development of hepatocellular carcinoma was suppressed both in the number and the diameter in $CCR9^{-/-}$ mice.
Conclusion: CCR9/CCL25 axis mainly in HSCs plays a pathogenic role both in murine NASH progression and NASH-based HCC development, suggesting a potential clinical therapeutic target against NASH in the future.

PS-002
Persistence of hepatic and adipose tissue alterations in T helper 17 cells, CD8+ cytotoxic T cells and regulatory T cells despite metabolic and histological improvement upon diet reversal in a high-fat high-fructose mouse model of NAFLD

Mikhail Van Herck[1,2], Luisa Vonghia[1,2], Peter Michielsen[1,2], Chris Bridts[3], Didier Ebo[3], Joris De Man[1], Benedicte De Winter[1], Sven Francque[1,2]. [1]*University of Antwerp, Laboratory of Experimental Medicine and Pediatrics-Gastroenterology and Hepatology, Antwerp, Belgium;* [2]*Antwerp University Hospital, Gastroenterology and Hepatology, Edegem, Belgium;* [3]*University of Antwerp, Antwerp University Hospital, Immunology-Allergology-Rheumatology, 2610, Belgium*
Email: mikhail.vanherck@uantwerpen.be

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a multisystem condition in which the liver, adipose tissue and the immune system are involved. T cells form a part of the adaptive immune system and can be subdivided in several subsets with distinct functions. We previously demonstrated that mice with severe NAFLD exhibit elevated hepatic T helper 17 cells (Th17, CD4+ RORγt+) cells, an abundance of visceral adipose tissue (VAT) CD8+ cytotoxic T cells (Tc) and a reduction of VAT regulatory T cells (Treg, CD4+ CD25+ Foxp3+). This study aimed at investigating the potential reversibility of these alterations upon diet reversal.
Method: Male 8-week old C57BL/6J mice were fed a high-fat high-fructose diet (HFHFD) for 20 weeks. Subsequently, a diet reversal (DR) was performed by substituting the HFHFD with control diet (CD) and continuing the CD for 12 additional weeks. Three control groups were included: mice fed CD for 32 weeks, HFHFD for 20 weeks and HFHFD for 32 weeks. Liver tissue was assessed histologically and the NAFLD Activity Score (NAS) was calculated. T-cell subsets were characterised in liver and visceral tissue (VAT) via flow cytometry. Tc cells were expressed as a percentage of CD45+ CD3+ cells, Treg and Th17 cells as a percentage of CD3+ CD4+ cells.
Results: HFHFD-feeding for 20 and 32 weeks confirmed the previous findings of metabolic alterations and NAFLD development (Figure 1A-C), and the associated hepatic and VAT T-cell alterations, specifically an increase in hepatic Th17 cells (Fig. 1D) and VAT Tc cells (Fig. 1E), as well as a reduction in VAT Treg cells (Fig. 1F), compared to CD-fed mice. DR induced weight loss (Figure 1A, $p < 0.001$), a decrease in cholesterol levels (Figure 1B, $p < 0.001$) and a decrease in NAS (Figure 1C, $p < 0.001$). No significant difference was observed in NAS between CD-fed mice and DR mice ($p = 0.160$). Conversely, the alterations in hepatic and VAT T cell subsets were not affected by DR. Hepatic Th17 cell and VAT Tc levels were significantly higher in DR mice compared to CD-fed mice ($p = 0.015$ and $p = 0.003$ resp.), whereas no difference existed between the DR group and mice fed HFHFD for 20 and 32 weeks (Figure 1D-E). VAT Treg levels were significantly lower in DR mice compared to CD-fed mice ($p = 0.003$), whereas no difference existed between the DR group and mice fed HFHFD for 20 and 32 wks (Figure 1F).



Conclusion: Although diet reversal induced a metabolic and histological normalisation in HFHFD-fed mice, the HFHFD-induced alterations in hepatic Th17 cells, VAT Tc cells and VAT Treg cells were not reversed within a timeframe of 12 weeks. This finding challenges our current understanding of the reversibility of NAFLD-related inflammation upon life style modification.

PS-003

Activation of the miR-34a/SIRT1:AMPK axis contributes for insulin resistance and mitochondrial dysfunction in the NAFLD muscle

André L. Simão[1], Marta B. Afonso[1], Pedro Miguel Rodrigues[1], Margarida Gama-Carvalho[2], Mariana V. Machado[3], Helena Cortez-Pinto[3], Cecília M. P. Rodrigues[1], Rui E. Castro[1]. *[1]Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal; [2]BioISI-Biosystems and Integrative Sciences Institute, Faculty of Sciences, Universidade de Lisboa, Lisbon, Portugal; [3]Gastrenterology, Hospital Santa Maria, Lisbon, Portugal*
Email: adlsimao@ff.ul.pt

Background and aims: Non-alcoholic fatty liver disease (NAFLD) pathogenesis associates with intramyocellular lipid deposition, mitochondrial dysfunction and insulin resistance (IR). microRNAs (miRNAs/miRs), including pro-apoptotic miR-34a, also contribute for disease progression and are found modulated in liver tissue and plasma.
We aimed to investigate the functional role of miR-34a-dependent signalling pathways in modulating mitochondrial function and IR in the skeletal muscle of human and experimental non-alcoholic steatohepatitis (NASH).
Method: Skeletal muscle biopsies were obtained from morbid obese NAFLD patients undergoing bariatric surgery. C57BL/6N mice were fed different NAFLD-inducing diets, including a fast food diet for 25 weeks; a choline-deficient, high-fat diet for 14 weeks; and a choline-deficient amino acid-defined diet for 32 weeks. C2C12 muscle cells were incubated with palmitic acid (PA) in the presence or absence of an AMP-activated protein kinase (AMPK) specific activator, or upon miR-34a functional modulation.
Results: Our results showed that different muscle miRNAs, including myomirs miR-1; –26a, –27a, and –27b, as well as miR-34a, increased with human NAFLD progression. Activation of the miR-34a/SIRT1:AMPK pathway, concomitant with the development of IR and deregulation of mitochondrial-shaping proteins, was evident in C2C12 cells incubated with PA, as well as in the skeletal muscle of all three diet-induced NAFLD mice models. Functional studies established the association between miR-34a- and PA-induced muscle cell deregulation. Of note, activation of AMPK almost completely prevented miR-34a- and PA-induced cellular stress. In addition, the miR-34a/SIRT1:AMPK pathway and mitochondrial dynamics dysfunction were also found amplified in the human NAFLD muscle. Finally, muscle miR-34a expression and Mitofusin 2 protein levels correlated with hallmarks of NAFLD and disease progression.
Conclusion: Our results indicate that activation of the miR-34a/SIRT1:AMPK pathway leads to IR and mitochondrial dynamics dysfunction in skeletal muscle of human and experimental NAFLD, representing an appealing prospective target in metabolic syndrome.

PS-004

Western diet triggers a unique inflammatory phenotype of myeloid leukocytes in bone marrow and liver

Jana Hundertmark[1,2], Krenkel Oliver[1,2], Trautwein Christian[1], Ivan G. Costa[3], Frank Tacke[1,2]. *[1]RWTH-University Hospital, Department of Medicine III, Aachen, Germany; [2]Charité University Medical Center, Department of Hepatology/Gastroenterology, Berlin, Germany; [3]RWTH-University Hospital, Institute of Computational Genomics, Aachen, Germany*
Email: jhundertmark@ukaachen.de

Background and aims: Changes in the composition and polarization of hepatic myeloid leukocytes, especially infiltrating monocytes and macrophages, are central features in the development and progression of metabolic diseases, such as non-alcoholic fatty liver disease (NAFLD). Single cell RNA sequencing has been emerged as a powerful method for analyzing gene expression profiles across distinct populations especially regarding disease associated changes. We therefore aimed to elucidate the characteristic changes in immune-metabolic pathways of myeloid leukocytes that promote the development of NAFLD.
Method: Experimental NAFLD was induced in C57BL/6J mice by feeding a high-fat, high-sugar, high-cholesterol Western diet for 16 weeks. Myeloid leukocyte populations from bone marrow and liver were then purified by fluorescence-activated cell sorting and subjected to single cell RNA sequencing. Further, bone marrow derived macrophages from lean and obese mice were stimulated *in vitro* towards an inflammatory or anti-inflammatory phenotype. To analyze the relevance of TLR4 mediated fatty acid recognition, an inhibitor of TLR4 signal transduction, TAK-242, was added to macrophages stimulated with fatty acids.
Results: Analyses of single cell RNA expression showed that Western diet feeding for 16 weeks induced a characteristic gene expression profile in myeloid leukocytes that was reflected across all myeloid subsets, comprising monocytes, macrophages and dendritic cells in liver as well as bone marrow. In the liver, the inflammatory phenotype was primarily characterized by a down-regulated expression of inflammation-associated markers *S100a8* and *S100a9* in Western diet fed mice, whereas differentiation markers like *Id3* and *Chil1* were highly expressed. Strikingly, myeloid populations in the bone marrow revealed similar changes. Moreover, *in vitro* experiments showed that macrophages isolated from lean and obese mice exhibited a unique polarization in response to inflammatory stimuli which was maintained even after cultivation for 7 days. *In vitro* stimulation of macrophages with fatty acids could partially mirror the *in vivo* observed phenotype and was found to depend on TLR4 signaling.
Conclusion: Hepatic myeloid leukocytes, as well as their precursors in the bone marrow, exhibit a unique NAFLD phenotype, consistent with an attenuated inflammatory response of monocytes and monocyte dependent liver macrophages. This phenotype was maintained *ex vivo* and could be partially mirrored by TLR4-dependent fatty acid stimulation of monocytes. Taken together, these data suggest that the diet-induced inflammatory polarization of monocytes and myeloid precursors is already stably imprinted in the bone marrow and determines pathogenic responses driving NAFLD in the liver.

PS-005

Evaluation of neuromedin-B receptor variants effect on iron metabolism and liver disease

Raffaela Rametta[1], Guido Alessandro Baselli[2], Paola Dongiovanni[3], Serena Pelusi[4], Marica Meroni[1], Anna Ludovica Fracanzani[1,4], Silvia Fargion[1,4], Luca Valenti[4,5]. *[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, General Medicine and Metabolic Disease, Milan, Italy; [2]University of Milan, Pathophysiology and Transplantation, Milan, Italy; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, General Medicine and Metabolic Disease, Milan, Italy; [4]University of Milan, Pathophysiology and Transplantation, Milan, Italy; [5]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Transfusional Center-Translational Medicine, Milan, Italy*
Email: luca.valenti@unimi.it

Background and aims: A significant proportion of iron overload heritability remains unexplained. By exploiting next generation whole exome sequencing in three cases of hereditary hemochromatosis (HH) and iron overload not accounted for by known genetic risk loci, we identified rare mutations predicted to alter protein activity in Neuromedin-B receptor (NMBR) in all patients. NMBR gene encodes for a G-protein-coupled receptor involved in the regulation of appetite, the hypothalamus-pituitary axis, cell contraction and proliferation. Aim was to validate the role of NMBR in the modulation of iron metabolism.

Method: *Genetic analysis:* NMBR coding sequence was fully sequenced in 129 unrelated HH/iron overload patients and 100 blood donors with normal iron metabolism. The L390M NMBR low-frequency variant was assessed in 191 patients with non-alcoholic fatty liver disease (NAFLD) and in 68 individuals who underwent oral iron tolerance test (OITT) with hepcidin measurement. *Functional analysis:* NMBR and its natural ligand Neuromedin B (NMB) gene expression was assessed by qRT-PCR on cDNA derived from human hepatoma HepG2 cells and murine primary hepatocytes. Serum NMB was assessed by ELISA.
Results: Rare NMBR mutations were significantly enriched in HH patients as compared to both local controls (15.5% vs. 5%, $p = 0.0038$) and 1000Genomes Non Finnish European subjects ($p = 0.02$ at burden test) and were associated with higher transferrin saturation in blood donors ($p = 0.04$). In patients at risk of iron metabolism alterations due to NAFLD, the L390M variant was independently associated with higher circulating ferritin ($p = 0.03$). In the OITT cohort, L390M-variant carriers without HH had higher iron absorption (s-iron-AUC 4016 ± 741 vs 2750 ± 844, $p = 0.002$; TS%-AUC 1057 ± 192 vs 716 ± 205, $p = 0.0006$) and lower hepcidin release index (0.26 ± 0.12 vs 0.43 ± 0.23, respectively, $p = 0.033$) as compared to non-carriers following iron challenge. In a subgroup of 20 individuals, serum NMB was significantly down-modulated by iron challenge at 8 hours, corresponding to the hepcidin release peak, and was decreased in L390M-variant carriers and HH individuals in parallel with increased TS%.
Conclusion: NMBR mutations may contribute to explain a fraction of still unexplained predisposition to iron overload.

PS-006
MBOAT7 downregulation induces hepatic lipid accumulation
Marica Meroni[1], Paola Dongiovanni[1], Miriam Longo[1], Guido Alessandro Baselli[2], Fabrizia Carli[3], Raffaela Rametta[1], serena pelusi[2], Sara Badiali[1], Marco Maggioni[1], Anna Ludovica Fracanzani[1,2], Stefano Romeo[4], Amalia Gastaldelli[3], Stefano Gatti[5], Luca Valenti[2,6]. *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; General Medicine and Metabolic Diseases, Milano, Italy; [2]University of Milan, Department of Pathophysiology and Transplantation, Milano, Italy; [3]Institute of Clinical Physiology National Research Council, Pisa, Italy; [4]University of Gothenburg, Department of Molecular and Clinical Medicine, Gothemborg, Sweden; [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; Center for Surgical Research, Milano, Italy; [6]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; Transfusional Center-Translational Medicine, Milano, Italy*
Email: luca.valenti@unimi.it

Background and aims: The rs641738 C > T variant in Membrane bound O-acyltransferase domain-containing 7 gene (MBOAT7), involved in phosphatidylinositol acyl-chain remodeling, increases the risk of non-alcoholic fatty liver disease (NAFLD), inflammation and fibrosis due to lower protein expression. Our preliminary results demonstrated that the Fatty Acid Transport protein 1 (FATP1) was upregulated upon Mboat7 silencing in mice. Aim of this study was to evaluate the impact of MBOAT7 downregulation and FATP1 overexpression on hepatic fat accumulation.
Method: We examined hepatic MBOAT7 and FATP1 in 119 obese patients. We silenced MBOAT7 in HepG2 hepatoma cells (MBOAT7$^{-/-}$) by Crispr/Cas9 technology. Then, MBOAT7$^{-/-}$ cells were exploited to produce a double stable model of full knockout MBOAT7 and heterozygous FATP1 (MBOAT7$^{-/-}$/FATP1$^{\pm}$).
Results: In obese patients, hepatic mRNA levels of MBOAT7 were inversely correlated with FATP1 ($p < 0.05$). As expected, MBOAT7 mRNA and protein levels were strongly dampened in MBOAT7$^{-/-}$ cells ($p < 0.01$). These cells showed also a phospholipidic composition pattern suggestive of altered MBOAT7 overall enzymatic activity, revealing reduced levels of lipid species associated to arachidonic and docosahexaenoic acids ($p < 0.05$). MBOAT7$^{-/-}$ cells displayed a spontaneous increase in intra-cellular fat content ($p < 0.05$), related to enhanced expression of genes involved in *de novo* lipogenesis (i.e. SREBP1, FAS, ACC) ($p < 0.05$) and increased FATP1 ($p < 0.01$). In addition, they retained activation of mTOR signaling in response to insulin (0.33μM), while AKT phosphorylation was hampered ($p < 0.05$), mirroring the condition of insulin resistant hepatocytes. FATP1 partial genetic deletion on this genetic background normalized FATP1 expression and rescued the phenotype, ameliorating fat accumulation ($p < 0.05$), *de novo* lipogenesis ($p < 0.01$) and improving insulin sensitivity.
Conclusion: These data suggest that downregulation of MBOAT7 is causally implicated in the pathogenesis of liver disease by inducing hepatocellular fat accumulation. Upregulation of FATP1 seems required to allow fat deposition associated with MBOAT7 downregulation. Further studies are needed to investigate the mechanisms linking reduced phosphatidyl-desaturation induced by MBOAT7 enzymatic activity impairment with the development of hepatic steatosis.

PS-007
Differential therapeutic effects of pan- and single PPAR agonists on steatosis, inflammation, macrophage composition and fibrosis in a murine model of non-alcoholic steatohepatitis
Sander Lefere[1,2], Tobias Puengel[2,3], Oliver Krenkel[2,3], Jana Hundertmark[2,3], Vanessa Adarbes[4], Céline Estavilet[4], Anja Geerts[1], Lindsey Devisscher[5], Guillaume Wettstein[4], Frank Tacke[2,3]. *[1]Ghent University, dpt. of Gastroenterology and Hepatology, Ghent, Belgium; [2]University Hospital Aachen, dpt. of Medicine III, Aachen, Germany; [3]Charité University Medical Center, Department of Hepatology/Gastroenterology, Berlin, Germany; [4]Inventiva, Daix, France; [5]Ghent University, dpt. of Basic and Applied Medical Sciences, Gut-Liver Immunopharmacology Unit, Ghent, Belgium*
Email: sander.lefere@ugent.be

Background and aims: Peroxisome proliferator-activated receptors (PPARs) are nuclear receptors essential for the regulation of glucose and lipid metabolism in the liver and adipose tissue. Furthermore, they are also expressed in immune cells, notably macrophages, where they act as modulators of inflammation and fibrogenesis. Various single or dual PPAR agonists have been clinically evaluated in non-alcoholic steatohepatitis (NASH), yielding variable effects on aspects of NASH pathogenesis. We aimed to compare selective PPARα, γ and δ agonists with the pan-PPAR agonist lanifibranor in a therapeutic setting.
Method: Male C57BL/6 mice were fed a choline-deficient, amino acid-defined high-fat diet (CDAA-HFD) with 2% cholesterol for 12 weeks. After 6 weeks of diet, mice were treated via oral gavage with lanifibranor (30mg/kg/day) or selective PPARα (fenofibrate, 100mg/kg/day), γ (pioglitazone, 30mg/kg/day) and δ (GW501516, 10mg/kg/day) agonists for 6 weeks. Outcomes were assessed by liver histology, serum biochemistry, gene expression profiling and hydroxyproline assay. Liver and blood immune populations were investigated using flow cytometry and F4/80 immunohistochemistry.
Results: PPAR target engagement was confirmed by elevated circulating adiponectin levels in lanifibranor and pioglitazone-treated mice, and reduced serum triglycerides in lanifibranor and fenofibrate-treated mice, respectively. Lanifibranor attenuated hepatocyte ballooning, whereas both lanifibranor and, to a lesser extent, fenofibrate significantly improved histological steatosis and lobular inflammation. Fibrosis quantified on sirius red staining was ameliorated in all treatment groups, which was associated with decreases in liver hydroxyproline content and fibrogenic gene expression, most pronounced in the lanifibranor group. Hepatic monocyte-derived macrophages (MoMFs) and monocytes as well as circulating monocytes were significantly decreased following lanifibranor and partially fenofibrate treatment, alongside a shift towards Ly6C+ and MHC-II+ macrophages. Hepatic and blood lymphocyte populations remained unaffected. This coincided with a lower hepatic expression of the inflammatory mediators CCL2 and TNF-α, of the MoMF marker

CCR2, as well as a decreased F4/80 immunopositivity, particularly in mice treated with lanifibranor and fenofibrate.
Conclusion: Our data suggest that different PPARs play distinct roles in the pathogenesis of NASH. Pan-PPAR agonists combine the beneficial effects of selective PPAR agonists and may counter inflammation and disease progression more potently.

PS-008
E2F2 mediated repression of fatty acid B-oxidation is mitigated through CREB1 in progressive non-alcoholic fatty liver disease
Francisco Gonzalez-Romero[1], Daniela Mestre[1,2], Igor Aurrekoetxea[1,2], Diego Sáenz de Urturi[1], Beatriz Gomez-Santos[1], Maitane Nuñez-García[1], Xabier Buqué[1,2], Igotz Delgado[1], Marta Palomo-Irigoyen[3], Miguel Tamayo-Caro[3], Ashwin Woodhoo[3,4], Marta Varela-Rey[3], María Luz Martínez-Chantar[3], Ainhoa Iglesias[5], Richard Lee[6], Sanjay Bhanot[6], Ana Zubiaga[5], Patricia Aspichueta[1,2].

Email: patricia.aspichueta@ehu.eus

Background and aims: Obese patients with non-alcoholic fatty liver disease (NAFLD) are at increased risk of developing hepatocellular carcinoma (HCC). However, the mechanisms involved in the progression of NAFLD to HCC are still unclear. The role of altered fatty acid oxidation (FAO) in NAFLD progression is controversial. However, it has been described that carnitine palmitoyl-transferase II (CPTII) is decreased in steatohepatitic-HCC, which contributes to carcinogenesis. E2f2 gene expression is increased in HCC according to the oncomine database and E2F1 controls oxidative metabolism in adipose tissue. Thus, the aims here were to evaluate if E2F2 is required for the metabolic rewiring of NAFLD-driven HCC and to investigate the role of E2F2 transcription factor modulating FAO in NAFLD progression.
Method: E2f2$^{-/-}$ and wild-type mice (WT) were used. Liver disease in mice was induced by administration of diethylnitrosamine (DEN) (25 mg/kg) at 14 days-old plus high-fat (HFD) or HFD alone until sacrificed at 3 or 9 months-old. A group of chow fed (CD) mice was used. To a subgroup of DEN HFD treated mice of each genotype, CREB1 antisense oligonucleotides were injected to knockdown gene expression. AAV8 were used to decrease expression of E2F2 in vivo in liver of WT mice. E2F2 was also silenced in HepG2 cells. Lipid content, ChiP analysis, gene expression, protein levels and FAO rate were analyzed.
Results: We observed that E2f2$^{-/-}$ mice were resistant to lipid accumulation and to HCC development, which was linked to increased FAO as the oxidation rate of palmitate and the transcriptome showed. Besides, levels of CREB1 and CPTII were increased in the DEN HFD E2f2$^{-/-}$ mice. This metabolic profile was also evident when E2F2 was silenced in livers of 3 month-old WT mice fed a CD or in HepG2 cells, which demonstrate that E2F2 plays a role regulating FAO in liver hepatocytes. Knockdown of CREB1 in DEN HFD WT mice, in which E2f2 gene expression is increased, results in decrease FAO rate and CPTII levels; however, it had no effect in DEN HFD E2f2$^{-/-}$ mice, in which FAO and CPTII levels remained increased. The ChIP analysis using E2F2 or CREB antibodies did not show enrichment in the corresponding binding sites of CPTII promoters when liver disease was induced or avoided in the E2f2$^{-/-}$ mice suggesting a E2F2-CREB mediated but indirect effect.
Conclusion: E2F2 transcription factor, required for NAFLD-HCC development, cooperates with CREB1 to regulate FAO in progressive NAFLD. Absence of E2F2 avoids the metabolic rewiring of NAFLD-driven HCC arising as a target for treatment.

Autoimmune and cholestasis I

Proteome of primary biliary cholangitis in naïve and UDCA treatment patients
Ben Millar[1], George Mells[2,3], John Brain[1,3], David Jones[1,3]. *[1]Newcastle University, Newcastle-upon-Tyne, United Kingdom; [2]University of Cambridge, Cambridge, United Kingdom; [3]NHS, Newcastle-upon-Tyne, United Kingdom*
Email: david.jones@newcastle.ac.uk

Background and aims: Primary Biliary Cholangitis (PBC) is a rare, autoimmune liver disease affecting women and men at a ratio of 9:1. Currently, there are two approved therapies: Ursodeoxycholic acid (UDCA) and Obeticholic acid to tackle the abnormal bile acid pool, cholestatic injury and chronic immune cell infiltrate. 40% of patients do not respond to UDCA thus increasing their predicted risk of liver failure according to the UK-PBC risk score.
Method: As part of the UKPBC consortium serial sampling from a prospective nested cohort of patients, proteomic profiling was carried out on (A) n = 444 UDCA-treated, (B) n = 68 Naïve treatment and (C) n = 102 controls via the Olink platform. Through a ΔΔ-Ct method 356 analytes were quantified in 4 µl serum. By multivariate analysis comparing cohorts and linear regression against risk scores and Alkaline Phosphatase (ALP) we have identified a distinct PBC proteome and close associations with biochemical responses.
Results: Interestingly, PBC proteome remains largely unchanged between naïve and treated patients. 44 analytes were significantly changed ($p < 0.05$) between these cohorts indicating that the cholestatic injury-based therapy is not affecting the systemic inflammatory profile in 77% of the protein panel. The UDCA-Modified PBC Proteome shows significant pathway clustering ($p < 5 \times 10^{-12}$). Cytokine/cytokine receptor interaction and chemokine signalling pathway remained significant (9 proteins @ FDR 2×10^{-9} and 4 proteins @ FDR 0.005). Highly significant clustering ($p < 1 \times 10^{-16}$) was seen for the proteins not significantly changed with UDCA treatment.
Correlation of this serum proteome in UDCA-treated patients with UK-PBC risk score demonstrated significant association of risk at 10 years with 172/356 (48%) proteins. Analytes such as uPA (adjusted p value = 1.52×10^{-14}) and MMP-2 (adjusted p value = 7.18×10^{-12}) correlating with risk at 5, 10 and 15 years. This is the first validation of the UK-PBC risk score utility with respect to PBC-central biological processes rather than just clinical end points. Delineating the risk score into its respective serum components has indicated the association of ALP with 197 analytes ($p < 0.05$). Of the 223 proteins in the PBC proteome unchanged in treated patients 60% showed a significant correlation with ALP.
Conclusion: This analysis is the first instance of a defined PBC Proteome. Cytokine/cytokine receptor interaction, chemokine signalling, TLR signalling, TNF signalling and JAK-STAT are associated with PBC, UDCA non-response and ALP presenting potential candidates for a mechanistically stratified second-line therapy.

PS-010
24-nor-ursodeoxycholic acid ameliorates inflammation by reshaping mTOR proteome and immunometabolism sensing programs in CD8 T-cells
Ci Zhu[1], Nicole Boucheron[2], André Müller[3], Peter Májek[3], Claudia D. Fuchs[1], Hatoon Baazim[3], Emina Halilbasic[1], Tatjana Stojakovic[4], Andreas Bergthaler[3], Wilfried Ellmeier[2], Michael Trauner[1]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria; [3]CeMM*

Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; [4]Medical University of Graz, Medical and Chemical Laboratory of Diagnostics, Graz, Austria
Email: michael.trauner@meduniwien.ac.at

Background and aims: Hepatic lymphocyte accumulation is a common immunopathological feature in many inflammatory liver diseases including primary sclerosing cholangitis (PSC) where nor-ursodeoxycholic acid (*nor*UDCA) has shown promising results. We previously reported anti-inflammatory mechanisms of *nor*UDCA via mTOR, distinct from UDCA in CD8 T cells. How *nor*UDCA potentially modulates dynamic signaling networks and bioenegergetic pathways underlying lymphocyte immunity remains unidentified. Therefore, we aimed to explore how *nor*UDCA impacts on CD8 T cell proteome, phosphoproteome and metabolic sensing programs in context of activation.
Method: Using mass spectrometry (MS) we generated in-depth profiling of *nor*UDCA shaped CD8 T cell proteome and phosphoproteome revealing a redirection of metabolic sensing programs, migration and functions. MS data were further validated in vivo, in lymphocytic choriomeningitis virus (LCMV) model of CD8 T cell driven hepatic immunopathology and in Mdr2 (Abcb4) KO model of PSC.
Results: Our MS data confirmed our previous finding of *nor*UDCA mTOR inhibitory effect as evidenced by reduced phosphorylation of mTOR substrate S6 kinase (Ser235/236) by 43% ($p < 0.05$). Consequently, *nor*UDCA reduced abundance of mTOR regulated glycolytic enzymes such as hexokinase2 and lactate dehydrogenase B ($p < 0.05$). Subsequently, *nor*UDCA treatment reduced abundance of effector molecules GranzymeB and IFNγ by 43% ($p < 0.005$) and 21% ($p < 0.05$), respectively and increased abundance of lymphatic retention patterns, like CD62L and CCR7 ($p < 0.05$). Conversely, fatty acid (FA) oxidation was enhanced by *nor*UDCA as shown by higher abundance of long-chain FA transport protein4, Fatty-acyl-CoA synthase, Cpt1α and Cpt2 ($p < 0.005$), while FA synthesis was reduced as shown by lower abundance of FA synthase. Interestingly, glutaminolysis was unaffected. Supporting MS finding, in vivo *nor*UDCA ameliorated hepatic injury and inflammation induced by LCMV as shown by lower ALT ($p < 0.005$), decreased liver expression of GranzymeB by 41% ($p < 0.005$) and Cxcl10 by 40% ($p < 0.005$), and reduced CD8 effector T cell hepatic infiltration without compromising virus control. Similarly, *nor*UDCA reduced CD8 T cell infiltration in liver of Mdr2 KO mice.
Conclusion: Overall, we unraveled novel metabolic modulatory potency of *nor*UDCA by reshaping mTOR proteome and phosphoproteome, indicating *nor*UDCA may represent a promising immunometabolic drug for treatment of T-cell based inflammatory liver diseases.

Email: jesus.banales@biodonostia.org

Background and aims: Polycystic liver diseases (PLDs) are inherited genetic disorders characterized by the development of multiple fluid-filled biliary cysts. We have previously shown that ursodeoxycholic acid (UDCA) inhibits hepatic cystogenesis in experimental models and patients with PLD. Furthermore, histone deacetylase 6 (HDAC6) inhibitors reduced hepatorenal cystogenesis in PCK rats. However, both therapies showed limited efficacy. Since UDCA does not display any HDAC6 inhibitory activity, and most of the available HDAC6 inhibitors are potentially toxic, we aimed to design new synthetic UDCA conjugates with selective HDAC6 inhibitory capacity (HDAC6i-UDCA) and evaluate their dual therapeutic potential for PLD.
Method: Eleven synthetic HDAC6i-UDCA#1-11 conjugates were designed, analysed *in silico*, synthesized and tested for their inhibitory activity on HDAC6 and HDAC1. After lead selection, PCK rats were orally administered 15 mg/kg day of HDAC6i-UDCA#1 for 5 months. After sacrifice, serum, bile, liver and kidney were collected and analysed. The molecular mechanisms of HDAC6i-UDCA#1 were investigated in PLD cholangiocytes.
Results: 4 of the 11 designed HDAC6i-UDCA conjugates presented highly selective HDAC6 inhibitory activity, with HDAC6i-UDCA#1 emerging as the most promising molecule. *In silico* experiments predicted an active contribution of UDCA to the HDAC6 inhibitory activity of HDAC6i-UDCA#1, which was confirmed by IC50 determination. HDAC6i-UDCA#1 treatment significantly reduced liver and kidney weights, respective tissue to body weight ratios and liver cystogenesis. In parallel, increased serum levels of albumin and reduced serum levels of urea were found in treated PCK rats. Administration of HDAC6i-UDCA#1 increased the liver and kidney alpha-tubulin acetylation, a HDAC6 target, and restored the related primary cilium length in cystic cholangiocytes. UDCA-HDAC6i#1 treatment also resulted in increased UDCA concentration in liver, bile, peripheral and portal blood. *In vitro*, HDAC6i-UDCA#1 inhibited the 2- and 3-dimentional growth of cystic cholangiocytes and decreased ERK1/2 phosphorylation, in a greater extent than its forming components [i.e. UDCA and 4- (aminomethyl)-N-hydroxybenzamide hydrochloride], alone or in combination. HDAC6i-UDCA#1 was transported into cells through NTCP, OCT1 and OCT3 transporters.
Conclusion: HDAC6i-UDCA#1 inhibited hepatorenal cystogenesis in an animal model of PLD and displayed greater antiproliferative effects on PLD cholangiocytes than UDCA alone, while retaining the UDCA hepatotropic characteristics. In addition to the HDCA6 inhibitory capacity, increased UDCA concentrations in treated animals, suggest a release of UDCA upon metabolism of HDAC6i-UDCA#1, minimizing potential toxicity of metabolites and highlighting the relevance of this promising dual therapy for the treatment of PLDs.

PS-012
Validation of histologic and non-invasive measures of fibrosis as surrogate end points of disease progression in patients with primary sclerosing cholangitis

Christopher Bowlus[1], Mitchell Shiffman[2], Harry Janssen[3], Aldo J Montano-Loza[4], Stephen Caldwell[5], Velimir Luketic[6], Xiaomin Lu[7], Gerald Crans[7], Chuhan Chung[7], Mani Subramanian[7], Robert Myers[7], Michael P. Manns[8], Cynthia Levy[9], Michael Trauner[10], Zachary Goodman[11], Andrew Muir[12]. *[1]University of California Davis, Davis, United States; [2]Liver Institute of Virginia, Richmond, United States; [3]University of Toronto, Toronto, Canada; [4]University of Alberta, Edmonton, Canada; [5]University of Virginia, Charlottesville, United States; [6]Virginia Commonwealth University, Richmond, United States; [7]Gilead Sciences, Inc., Foster City, United States; [8]Hannover Medical School, Hannover, Germany; [9]University of Miami, Miami, United States;*

[10]Medical University of Vienna, Vienna, Austria; [11]Inova Fairfax Hospital, Falls Church, United States; [12]Duke Clinical Research Institute, Durham, United States
Email: rob.myers@gilead.com

Background and aims: Surrogate end points that predict complications are necessary for approval of new therapies for PSC. We assessed associations between histologic and non-invasive fibrosis markers with disease progression in PSC.
Method: We included 209 adults with non-cirrhotic PSC from a 96-week phase 2 trial of simtuzumab. Liver fibrosis (baseline [BL], week 48 [W48], and W96) was staged by Ludwig classification, hepatic collagen and α-SMA expression were quantified by morphometry, liver stiffness (LS) was measured by transient elastography (TE), and ELF was calculated. Cox regression determined associations between these end points with PSC-related events (i.e. progression to cirrhosis, decompensation, transplantation, ascending cholangitis).
Results: Median age was 44 years, 62% were male, 48% had ulcerative colitis, 61% were on UDCA, and the median serum ALP was 248 U/L. At BL, 29% had F0-1 fibrosis, 71% had F2-3, and median LS by TE (n = 52) was 8.2 kPa. By W96, 56 (27%) developed a PSC-related event (progression to cirrhosis [n = 29], ascending cholangitis [25], ascites [1], variceal hemorrhage [1]). Among BL factors, F2-3 fibrosis (HR 4.13; 95% CI 1.77-9.64) and greater hepatic collagen, α-SMA expression, and ELF were associated with disease progression (Table). After adjustment for BL factors, non-worsening of fibrosis (HR 0.31; 95% CI 0.18-0.53) and fibrosis improvement (HR 0.04; 0.01-0.31) were associated with a reduced risk of progression. On the contrary, increases in hepatic collagen, α-SMA, ELF (and TIMP-1, PIII-NP, and hyaluronic acid), and LS by TE were associated with an increased risk of events. BL ALP, but not its change, was associated with progression.

Table: Predictors of Disease Progression

	HR (95%CI)*	P value
Ludwig stage		
BL F2-3 vs F0-1	4.13 (1.77-9.64)	**0.001**
Non-worsening vs worsening	0.31 (0.18-0.53)	**< 0.001**
Improvement vs no change/ worsening	0.04 (0.01-0.31)	**0.002**
Hepatic collagen, %		
BL	1.09 (1.03-1.16)	**0.006**
Change	1.14 (1.10-1.17)	**< 0.001**
α-SMA, %		
BL	1.15 (1.07-1.24)	**< 0.001**
Change	1.05 (1.04-1.07)	**< 0.001**
ELF		
BL	1.80 (1.47-2.22)	**< 0.001**
Change	1.86 (1.37-2.53)	**< 0.001**
LS by TE, kPa		
BL	1.02 (0.99-1.05)	0.21
Change	1.08 (1.03-1.13)	**0.003**
Serum ALP, per 10-U/L		
BL	1.02 (1.01-1.03)	**< 0.001**
Change	1.01 (1.00-1.03)	0.16

*Hazard ratios for changes from BL adjusted for BL value.

Conclusion: Disease progression in non-cirrhotic patients with PSC is associated with more advanced fibrosis at baseline and greater increases in fibrosis, measured histologically or with non-invasive markers.

PS-013
Evaluation of serological markers of extracellular matrix remodeling in primary sclerosing cholangitis

Lasse Langholm[1], Christine Zhang-Hagenlocher[2], Robert Voitl[2], Petra Kloeters-Plachky[2], Peter Sauer[2,3], Karl Heinz Weiss[2], Tina Manon-Jensen[1], Christian Rupp[2,3]. [1]Nordic Bioscience A/S, Herlev, Denmark; [2]University Hospital Heidelberg, Internal Medicine IV, Heidelberg, Germany; [3]University Hospital Heidelberg, Interdisciplinary Endoscopy Unit, Heidelberg, Germany
Email: christian_rupp@med.uni-heidelberg.de

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease with progression to liver cirrhosis in the majority of patients. PSC shows a remarkably variable course making it challenging for clinicians to identify patients at risk for rapid disease progression. We aimed to evaluate the prognostic utility of three biomarkers of interstitial extracellular matrix (C3M, PRO-C3) and fibril-associated collagen (PRO-C16) remodeling in patients with primary sclerosing cholangitis.
Method: Serum samples from 250 large-duct primary sclerosing cholangitis patients (of which 183 [72.3%] with IBD) recruited 2004-2016 and 20 healthy controls were analyzed. In 27 PSC patients a follow-up serum samples (mean 5.5 years, 3-10 years) were assessable. neo-epitope biomarkers of collagen type III formation and degradation (PRO-C3 and C3M, respectively) and type XVI formation (PRO-C16) were assessed and compared with regard to laboratory and clinical parameters.
Results: The final study cohort comprises 250 PSC patients. 183 (73.2%) patients had concomitant IBD and 69 (27.6%) patients presented dominant strictures at time of serum collection. Of the evaluated biomarkers PRO-C3 and PRO-C3/C3M ratio were significantly elevated in PSC patients compared to healthy controls (24.6 ng/ml vs. 8.1 ng/ml, $p < 0.0001$). PRO-C3 and PRO-C3/C3M were elevated in all PSC subtypes, independent of presence of concomitant IBD phenotypes (PRO-C3: control: 8.1 ng/ml; no IBD: 20.4 ng/ml; UC: 26.8 ng/ml; CD: 20.1 ng/ml, $p < 0.01$; PRO-C3/C3M ratio control: 0.8; no IBD: 2.0; UC: 2.5; CD: 1.8, $p < 0.05$;). Only PRO-C16 could separate PSC patients with and without IBD, ($p = 0.007$) After a mean follow-up period of 5.5 years in a subgroup of 27 patients C3M showed an significant increase during the course of disease, when compared to baseline (C3M: baseline 10.4 ng/ml vs. FU 12.7 ng/ml, $p = 0.04$) In patients with presence of dominant strictures in the bile ducts at serum collection PRO-C3/C3M ratio were significantly elevated (PRO-C3/C3M: no DS 1.79 vs. DS 3.32; $p = 0.003$).
Conclusion: Serum markers of extracellular matrix remodeling are elevated in primary sclerosing cholangitis patients compared to healthy controls. Collagen type III formation and turnover (PRO-C3, PRO-C/C3M) is significantly elevated in PSC patients with dominant strictures, while PRO-C16 specifically related to the IBD phenotype of the patients irrespective of PSC status. These results indicate that specific ECM biomarkers might relate to different pathophysiological aspects of PSC-IBD, and assessement of serum markers of extracellular matrix remodeling might be a valuable tool for early identification of patients at risk for rapid disease progression.

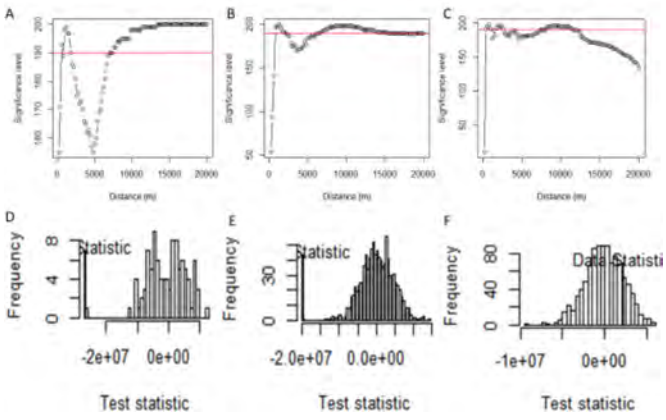
PS-014
Disease clustering in autoimmune liver diseases points towards environmental factors being important in their aetiology

Jessica Dyson[1,2], Mark Shirley[3], Alasdair Blain[3], Mark Hudson[1,2], Steven Rushton[3], David Jones[1,2]. [1]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; [2]Newcastle upon Tyne Hospitals NHS Foundation Trust, Hepatology, Newcastle upon Tyne, United Kingdom; [3]Newcastle University, School of Biology, Newcastle upon Tyne, United Kingdom
Email: jessicadyson@doctors.org.uk

Background and aims: Autoimmune liver diseases have a complex aetiology with the interplay of genetic and environmental factors. Disease clustering has been reported in primary biliary cholangitis (PBC) but equivalent studies have not been performed in autoimmune hepatitis (AIH) or primary sclerosing cholangitis (PSC). This study aimed to examine if there is spatial and/or temporal clustering in a comprehensive cohort of patients in the North-East of England and North Cumbria with PBC, AIH and PSC.

Method: All patients with PBC (n = 2150), AIH (n = 963) and PSC (n = 472) in a defined geographical region within England were identified using multi-source case-finding methodology. Spatial point analyses (k function) were used to investigate for the presence and patterns of disease clustering (using postal addresses) after controlling for population size. For those with a known year of diagnosis (1780 PBC, 889 AIH and 451 PSC), spatio-temporal analyses were undertaken. The time range was based on first and last years of diagnosis in 1-year steps.
Results: Significant spatial clustering was found at approximately 1-2 km in all 3 diseases (Figure 1A/B/C-red line defining 95%). Further clustering was identified for AIH and PSC with a peak distance of approximately 10 km. In PBC, the clustering appeared again at 7.5 km and was sustained to the limits of the spatial range (20 km). No significant temporal clustering was found in any of the diseases (Figure 1D/E/F). However, for PSC the test statistic was in the right hand tail of the histogram suggesting some evidence of temporal clustering.

Figure 1. A: Spatial clustering in PBC, B: Spatial clustering in AIH, C: Spatial clustering in PSC, D: Temporal clustering in PBC, E: Temporal clustering in AIH, F: Temporal clustering in PSC



Conclusion: Evidence of spatial clustering in PBC, AIH and PSC implies that exposure to an environmental agent may play a role in disease pathogenesis, with increased prevalence in areas reflecting increased exposure risk or exposure levels. The lack of temporal clustering does not support the theory of more transient environmental components such as infection. The presence of spatial, but not temporal, clustering suggests a persistent and low level environmental trigger for disease. Varying distances of peak clustering between the diseases raises the concept of different environmental factors being important in PBC, AIH and PSC. The suggestion of temporal clustering in PSC needs further exploration in a larger cohort and analyses for 'acute' AIH should be undertaken using shorter time steps (months versus years). Confirmation of spatial clustering emphasises the need to explore potential environmental factors that are associated with areas of high disease prevalence.

PS-015

Role of methylation-controlled J-protein, endogenous repressor of the mitochondrial respiratory chain, in cholestatic liver disease

Background and aims: Mitochondrial dysfunction contributes to CLD pathogenesis, in fact bile acids are cytotoxic, capable of emulsifying lipid membranes such as mitochondrial, causing ROS overproduction and hepatocyte death. MCJ is a mitochondrial protein that represses the function of the mitochondrial respiratory chain (MRC), so that its deficiency could mitigate the oxidative stress caused by cholestasis. Our aim is to study the effect of MRC inhibition by MCJ on bile acids induced liver toxicity.
Method: Bile duct ligation (BDL) in WT and MCJ-KO mice was used as an animal model of cholestasis. Liver injury was assessed by histology. The protein and gene expressions were measured by Western blot and qPCR respectively. The MCJ expression in WT mice was transiently knockdown injecting MCJ siRNA (siMCJ). In vitro studies, primary hepatocytes were treated with deoxycholic acid (DCA), MCJ was silenced using a ShRNA for MCJ (shMCJ), assessing the apoptosis by caspase3 activity. Total ROS and superoxide production, and active mitochondria were measured by CellROX®, MitoSOX® and MitoTraker® stain respectively. Mitochondrial membrane potential was analysed by flow cytometry, and ATP levels were measured by luminescence. MCJ levels were analysed by immunohistochemistry in patient liver biopsies with primary biliary cholangitis (PBC).
Results: Hepatic MCJ expression are significantly induced in PBC patients and WT mice after BDL. *In vivo*, we saw greater survival of MCJ-KO mice after BDL compared with WT, and lower inflammatory hepatic infiltrate at 48 hours after BDL. The liver injury was evaluated 7 days after BDL showed minimal levels of necrotic areas and inflammation in mice treated with siMCJ relative to those that did not receive siMCJ. Both *in vivo* and *in vitro*, MCJ-KO have lower JNK activation. In fact, we found less apoptosis after adding DCA in hepatocytes MCJ-KO and ShMCJ. This lower apoptosis is due to lower depolarization of mitochondrial membrane, lower ROS production and higher ATP production that we saw in hepatocytes MCJ-KO after DCA treatment. In addition, MCJ-KO hepatocytes showed higher expression of genes related to bile acids transport (MDR2, FXR), and lower expression of inflammatory genes (IL1b, TNF).
Conclusion: Loss of MCJ protects hepatocytes against JNK activation, ROS production, mitochondrial membrane depolarization, and ATP depletion as a result of bile acid toxicity. Our results identify MCJ as a potential therapeutic target to mitigate liver injury in CLD.

Background and aims: Serum alkaline phosphatase [ALP] is a prognostic biomarker in primary sclerosing cholangitis [PSC], however biovariability as part of the natural history of disease has not been formally or prospectively studied. Herein, we quantify, using high-quality controlled clinical trial data, the degree of ALP variability in patients [pts] with PSC.
Method: Data were analysed from 234 PSC pts enrolled in a 96-week, placebo-controlled trial of simtuzumab [SIM] (64% men, median age 45 yrs, 61% taking ursodeoxycholic acid, cumulative follow-up 371 pt-yrs) to evaluate the magnitude of ALP fluctuation and associations with clinical outcome. Since SIM did not influence ALP or other end points, treatment arms were combined.
Results: At study entry, baseline [BL] ALP values were widely distributed: ≤ 1xULN (n = 57), > 1xULN (n = 177), > 1.5xULN (n = 145), > 2xULN (n = 121), and 3xULN (n = 71). 26% of pts with normal BL ALP developed elevation > ULN at week-96 (W96). Conversely, a decrease by ≥ 30% occurred in 18%, 18%, 21%, and 25% of pts with a BL ALp > 1xULN, > 1.5xULN, > 2xULN, and > 3xULN, respectively. Overall, ALP spontaneously declined to ≤ 1.5xULN in 10.4% of pts at the end of study. Median intra-individual (per-pt) coefficients of variation approximated 12%, irrespective of fibrosis stage and BL value, with ranges exceeding 30% over a 4-week period (Fig 1A). Mean serum ALP did not improve significantly from BL to W96; however, variability as reflected by the standard deviation of relative change progressively increased from 25% at W12, to 37% at W48, and 42% at W96. The observed variability in ALP was applied to create a reference tool to power future clinical trials according to target ALP thresholds, end points, and magnitude of effect size (1B). Of 209 pts with a BL Ishak fibrosis stage 0-IV, 30 developed cirrhosis by W96. In univariate logistic regression analysis, changes in serum ALP by W12, W24 or W48 were not associated with progression to cirrhosis (all p > 0.05). In total, 47 pts (20%) experienced a PSC-related clinical event. However, changes in ALP at W12, W24, or W48 were not predictive of event-free survival (Cox regression, all p > 0.05).

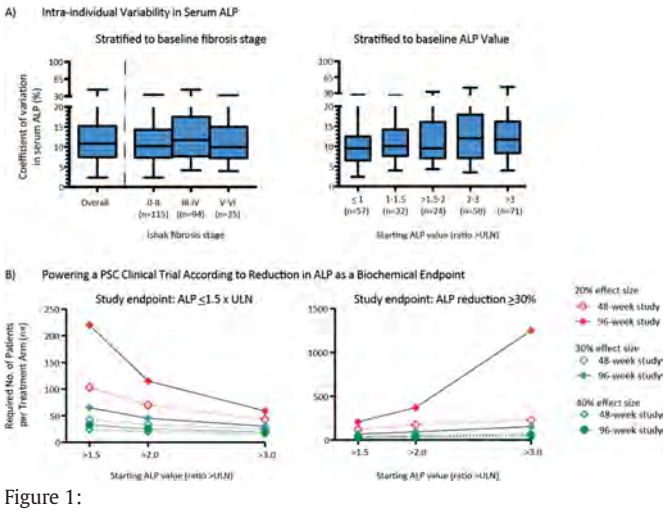

Figure 1:

Conclusion: The degree of fluctuation in ALP, wide per-pt coefficients of variation, and substantial proportion of pts who spontaneously attain specific thresholds, highlight significant implications relevant to the design of future trials in PSC, using ALP as part of a treatment efficacy end point.

Portal Hypertension – Refining risk stratification and therapy

PS-017
Long-term impact of sustained virological response on systemic and pulmonary hemodynamics in HCV-cirrhotic patients with portal hypertension

Email: slens@clinic.ub.es

Background and aims: Some case series suggest an association between antiviral therapy and the development of pulmonary hypertension (PH:mPAP ≥ 25mmHg) (Chest, 2016). Our previous data showed that early after therapy there was an improvement in systemic parameters but an increased prevalence of PH, although without fulfilling criteria for porto-pulmonary hypertension (PHH) (Gastroenterology, 2017). We aimed to assess the long-term impact of HCV cure (SVR) on systemic and pulmonary hemodynamics in patients with clinically significant portal hypertension (CSPH, HVPG ≥ 10mmHg).
Method: Prospective multicenter study of patients with HCV-related cirrhosis and CSPH at baseline (BL) who obtained SVR after treatment with all-oral antivirals (n = 226). Patients with CSPH 24 weeks after therapy underwent a new hemodynamic evaluation at 96 weeks (SVR24 and SVR96, respectively). Data from the subgroup of patients with right-heart catheterization at BL, SVR24 and SVR96 (n = 84) are presented.
Results: The majority (79%) were Child-A; 84% had esophageal varices and 31% previous hepatic decompensation. Most (70%) received sofosbuvir based-regimens. BL-HVPG 15.5 (13-18) mmHg decreased – 2 ± 3mmHg at SVR24 and – 4.1 ± 4mmHg at SVR96 (both, p <.01). However, 76% of patients still presented CSPH at SVR96. At this time point, an increase in mean arterial pressure (+7%, p = .07) and systemic vascular resistance (+12%, p <.05) as well as a reduction in cardiac output (– 9%, p <.01) were observed. There was also a significant increase (p <.05) in mean pulmonary arterial pressure (mPAP:16 ± 5 to 19 ± 6mmHg, +12%), pulmonary vascular resistance (PuVR:98 ± 52 to 110 ± 58 dyn/s/cm-5, +10%) and pulmonary capillary wedged pressure (10 ± 4 to 11 ± 4mmHg, +20%). At baseline, 7 (8%) patients had pulmonary hypertension, although none met the PPH criteria. At SVR96, pulmonary hypertension remained in 4/7 patients and developed in 12 additional patients. Only 4 presented high PuVR (> 240 dyn/s/cm-5). Two other patients had elevated PuVR but no significant PH (mPAP 22 and 21 mmHg). Neither the type of treatment nor the presence of previous decompensation or persistent CSPH had an influence on the hemodynamic response.
Conclusion: SVR after all-oral antiviral therapy is associated with an improvement in systemic hemodynamics in patients with CSPH. However, an increase in the prevalence of pulmonary hypertension was detected, although of post-capillary characteristics. No association with the type of antiviral therapy was found.

PS-018

Paroxysmal nocturnal hemoglobinuria and Budd Chiari syndrome: Impact of Eculizumab therapy on survival and liver outcome in 54 patients: A multicentric valdig study

Email: aurelie.plessier@aphp.fr

Background and aims: Paroxysmal nocturnal hemoglobinuria (PNH) is characterized by intravascular haemolysis and in 2-10% by Budd Chiari syndrome (BCS). This study aimed at assessing characteristics and outcome of patients with PNH and BCS, with the impact of Eculizumab (currently indicated in PNH with hemolysis with clinical symptom indicative of high disease activity (ie thrombosis), while administration varies according to availability in each country).
Method: Retrospective analysis of patients with PNH and BCS diagnosed in centers of the VALDIG network between 1987 and 2017. Primary end point was survival. Data are presented as median [IQR] and n (%). Features associated with survival were assessed using univariate Cox proportional hazards model. Survival curves were obtained using the Kaplan-Meier methods, and compared treated patients using the log-rank test.
Results: Fifty-four BCS patients (28men, 52%) were included (16 with portal vein thrombosis), 23 [0-51] months after PNH diagnosis, aged 40 [33-52] and followed-up after BCS diagnosis 5 years, 95%CI [1-11]. In 22 patients, PNH was revealed by BCS. Clone size was 87% [74-4], hemoglobin 10 [8-11] g/dl, LDH 783[564-16071]IU. Three had associated myeloproliferative neoplasms. Thirty-five (62%) had ascites, 20 (37%) oesophageal varices (6 variceal bleeding). All received a stepwise therapeutic strategy, including, anticoagulation (n = 50; 92%), vein angioplasty/stent (n = 4; 6%), transjugular Intrahepatic Portosystemic Shunt (n = 20, 37%) and/or liver transplantation (n = 2; 4%). Venous thrombosis elsewhere at diagnosis and during follow-up occurred in respectively 9 and 15 patients including 6 and 2 cerebral thrombosis. Arterial thrombosis occurred in 8 patients at diagnosis and 6 during follow-up. Complications were severe bleeding n = 17, sepsis n = 14, recurrent thrombosis n = 15; Overall, 17 (31%) patients died (infection, cancer, multiple organ failure, haemorrhage and other causes), including 8 from liver complications and 4 (7%) treated with Eculizumab. Thirty-three (61%) patients received Eculizumab treatment, for 1254 days, CI 95% [766-2130], 73 days[37-210] after BCS diagnosis in 31 patients. In univariate analysis, Eculizumab treatment was significantly associated with a better survival (HR 0.29 IC 95% (0.09-0.90) p = 0.03).Of note, patients treated or not with Eculizumab had similar prognosis scores at BCS diagnosis: Meld score 13 [12-16] vs 15 [13-22], Child-Pugh score 9 [7-10] vs9 [7- 10], Clichy score 6[4- 6] vs 5 [4- 6]

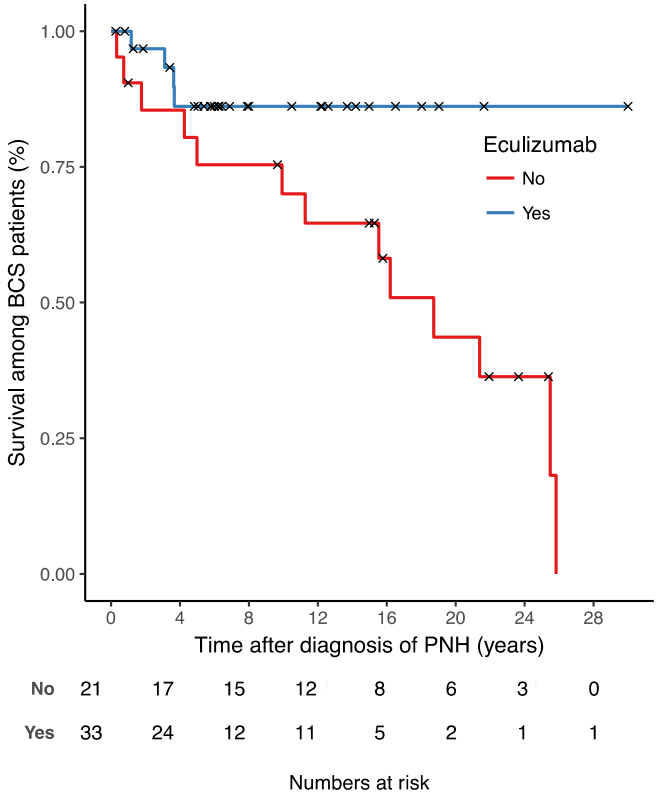

Figure: Overall survival according to Eculizumab therapy

Conclusion: Patients with PNH and BCS have frequent thrombosis outside the splanchnic vascular bed, bleeding and severe septic complications. Patients treated with Eculizumab have a significantly better survival. Nevertheless, close follow-up is still needed in these patients who may still have severe, lethal complications

PS-019

Response of liver and spleen stiffness to portal pressure lowering drugs in a rat model of cirrhosis

Omar Elshaarawy[1], Shami Alquzi[1], Johannes Mueller[1], Vanessa Rausch[1], Ines Silva[1], Teresa Peccerella[1], Karl H. Seitz[1], Sebastian Mueller[1]. *[1]University of Heidelberg, Salem Medical Center and Center for Alcohol Research, Heidelberg, Germany*
Email: sebastian.mueller@urz.uni-heidelberg.de

Background and aims: Liver stiffness (LS) is increasingly used to screen for liver fibrosis, in addition, spleen stiffness (SS) is an established parameter to assess portal hypertension which is tightly related to the hemodynamics of blood flow and vascular resistance. Little is known about the response of LS and SS to vasoactive

substances. We here studied LS and SS in an TAA-induced cirrhosis rat models after exposure to various vasoactive drugs using a miniaturized Fibroscan platform (µFibroscan).

Methods: We induced cirrhosis in 24 wildtype 8 weeks old adult male Wistar rats with 200 mg/Kg dosage of Thioacetamide (TAA) through intraperitoneal injection of 50 mg/ml solution 2 times per week for 6 weeks. The six groups consisted of control (sodium chloride), metoprolol, udenafil, enalapril, terlipressin and carvidelol. LS and SS were measured by µFibroscan (Echosens, Paris). The rats underwent general anesthesia with isoflurane inhalation. After anesthesia, abdominal aorta, inferior vena cava and portal vein were cannulated with 24-gauge cannula and connected to Power lab device (AD instruments) to continuously measure the mean arterial pressure (MAP), heart rate (HR) and portal vein pressure (PVP). Drugs were injected systemically and data were collected at time points 0, 15 and 30 mins.

Results: LS and SS was significantly higher in TAA treated rats than in the control group (23.8 vs 3.8 kPa and 19.6 vs 47.8 kPa, P < 0.0001). In addition, they had significantly bigger and heavier spleens (6 vs 4 cm and 2.7 vs 1 gm, P < 0.0001, respectively). In all drugs, LS and SS followed tightly the change of the portal vein pressure (r = 0.681and 0.622, P < 0.01, respectively). Also, SS was significantly correlated with spleen size and weight (r = 0.723 and 0.663, respectively < 0.01). Noteworthy, a significant decrease of PVP ranging from 22% to 34% (p < 0.05) was seen after 15 to 30 minutes with metoprolol, udenafil, enalapril and carvedilol which was accompanied with a significant decrease in LS and SS ranging from 18.2 to 44% (p < 0.05). (see the Table) Interestingly, with terlipressin, LS and SS only slightly decreased which could be explained by counteracting PVP and MAP. Thus, while PVP decreased by 20% (p < 0.001), MAP increased by 35% (p < 0.001). Overall, carvedilol showed the best response regarding the decrease of PVP, LS and SS. Of note, the heart rate increased after metoprolol and udenafil injection (ca. 10%, P < 0.05), while it decreased in response to terlipressin and carvedilol by ca 30% (p < 0.01).

Drug/Parameter	Delta LS (P Value)	Delta SS (P Value)	Delta PVP (P Value)	Delta MAP (P Value)	Delta HR (P Value)
Metoprolol	-19% (<0.05)	-21.9% (<0.001)	-22% (<0.001)	-20.1% (<0.01)	+7.5% (<0.01)
Udenafil	-18.2% (<0.05)	-27.7% (<0.001)	-26.2% (<0.001)	-16.5% (<0.05)	+7.9% (0.105)
Enalapril	-34% (<0.05)	-22.3% (<0.001)	-25.4% (<0.001)	-13.5% (<0.01	-0.3% (=0.125)
Terlipressin	-3.7% (=0.08)	-15.8% (=0.19)	-20.1% (<0.001)	+35.2% (<0.01	-27.6% (<0.01)
Carvedilol	-44.6% (<0.05)	-29.7% (<0.001)	-33.1% (<0.001)	-35.8% (<0.05)	-42.1% (<0.01)

Conclusion: LS and SS strongly correlates PVP and responded differently to various vasoactive drugs. Combined non-invasive LS and SS measurement could be useful to monitor the patient's response and compliance to portal pressure lowering drugs.

PS-020

Spleen T1 and spleen diameter criteria can identify and exclude oesophageal varices accurately

Christina Levick[1,2], Michael Pavlides[1,2], David J Breen[3], Kathryn Nash[3], Matthew Robson[4], Stefan Neubauer[2], Eleanor Barnes[1,5]. [1]*University of Oxford, Translational Gastroenterology Unit, Oxford, United Kingdom;* [2]*University of Oxford, Oxford Centre for Clinical MRI Research, Oxford, United Kingdom;* [3]*University Hospitals Southampton NHS Foundation Trust, Southampton General Hospital, Southampton, United Kingdom;* [4]*Perspectum Diagnostics Ltd, Oxford, United Kingdom;* [5]*University of Oxford, Peter Medawar Department, Oxford, United Kingdom*
Email: christina.levick@gmail.com

Background and aims: Application of Baveno VI criteria (platelets > 150 × 10^9/l, liver stiffness < 20 kPa) can avoid 10-34% of screening endoscopies for oesophageal varices needing treatment (VNT) in compensated advanced chronic liver disease (cACLD), but still > 46% endoscopies will be performed unnecessarily with no VNTs detected. Magnetic resonance imaging (MRI)-derived spleen T1, cT1, extracellular fluid volume fraction (ECV) and size measures have been associated with portal hypertension. This study explores these spleen MRI measures to improve the identification of patients with cACLD with and without VNTs.

Method: Ninety-one patients with cACLD of mixed aetiologies had spleen MRI, blood and liver stiffness assessment within median 30 days (IQR 11-117) of endoscopy screening for varices. MRI with gadoxetic acid administration was used to measure spleen T1, extracellular fluid volume fraction (ECV), volume and diameter. Measures were explored for the identification of VNTs. New criteria were derived to minimise the number of screening endoscopies for VNTs subject to accepting that < 5% of VNTs will be missed. Baveno and other published criteria were also tested.

Results: Patients had median age 61 years and 70% were male. VNT prevalence was 14%. Spleen T1 × spleen diameter had the highest accuracy for the identification of VNTs (area under the receiver operator curve 0.87, p < 0.001). Spleen T1 < 1307 ms or spleen diameter < 137 mm was the best performing criteria to avoid screening endoscopies for VNTs, saving 66% of endoscopies (table 1).

Table 1: Ability of non-invasive criteria to avoid endoscopy screening for VNTs in cACLD.

	Endoscopies avoided (%)	VNTs missed (%)
New criteria		
Spleen T1 < 1307 ms or spleen diameter < 137 mm	60 (66%)	0
Spleen diameter < 159 mm and platelets > 112 × 10^9/l	52 (57%)	0
Platelet/spleen volume < 0.267 × 10^9/l/ml	49 (54%)	0
Spleen T1 × spleen diameter < 185088 msmm	46 (51%)	0
Spleen T1 < 1307 ms	41 (45%)	0
Spleen cT1 < 1252 ms	37 (43%)	0
Spleen diameter < 137 mm	36 (40%)	0
Spleen volume < 403 ml	33 (36%)	0
Platelet/spleen diameter < 1.27 × 10^9/l/mm	24 (26%)	0
Platelets > 213 × 10^9/l	15 (16%)	0
Spleen ECV < 0.317	13 (14%)	0
Published criteria		
Baveno VI (platelets > 150 × 10^9/l and liver stiffness < 20 kPa)	16 (20%)	0
Expanded Baveno (platelets > 110 × 10^9/l and liver stiffness < 25 kPa)	39 (48%)	2 (5%)
MELD = 6 and platelets > 150 × 10^9/l	15 (16%)	0
LSPS < 1.33	23 (28%)	1 (4%)

Abbreviations: MELD, modified end stage liver disease score; LSPS, liver stiffness and platelet count/spleen diameter ratio score; ECV, extracellular volume fraction.

Conclusion: Spleen T1 and spleen diameter criteria have high accuracy for the identification of VNTs and could reduce endoscopy screening requirements for VNTs compared with published criteria.

PS-021

The development of portosystemic shunts depends on liver dysfunction rather than on PlGF-driven neoangiogenesis

Katharina Lampichler[1], Lukas Reider[1], Alek Stadlmann[2,3], Benedikt Simbrunner[2,3], Mattias Mandorfer[2,3], Theresa Bucsics[2,3], Rafael Paternostro[2,3], Ulrika Asenbaum[1], Thomas Reiberger[2,3].
[1]*Department of Biomedical Imaging and Image-guided Therapy, Vienna, Austria;* [2]*Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria;* [3]*Vienna Hepatic Hemodynamic Laboratory, Medical University of Vienna, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Portosystemic shunts (PSS) are common in patients with advanced chronic liver disease (ACLD). However, the relative impact of liver dysfunction, portal pressure and splanchnic neoangiogenesis in the pathophysiological development of PSS remains unclear. The pro-angiogenic placental growth factor (PlGF) has been associated with the development of liver fibrosis and portal hypertension in experimental studies. We assessed the association between the extent of PSS and hepatic dysfunction, portal pressure and PlGF levels in ACLD patients.
Method: 107 patients with ACLD were prospectively enrolled. Portal hypertension was evaluated by hepatic venous pressure gradient (HVPG), severity of hepatic dysfunction was evaluated by ALBI score, FIB-4 score, MELD score and Child-Pugh score (CPS). PSS were semiquantitatively categorised as mild, moderate and severe on contrast-enhanced computed tomography (CT) and magnetic resonance imaging (MRI) scans by two experienced radiologists.
Results: N = 51 (47, 7%) showed mild PSS, while n = 38 (35, 5%) showed moderate and n = 18 (16, 8%) severe PSS. The extent of PSS (mild vs. moderate vs. severe) correlated with a higher prevalence of portal vein thrombosis (PVT: 3.9% vs. 26.3% vs. 44.0%; $p < 0.001$), higher ALBI score (-2.41 vs. – 1.96 vs. – 1.90; $p = 0.002$) and FIB-4 score (3.9 vs. 5.2 vs. 8.8; $p < 0.001$). There was a significant association of PSS severity with HVPG (12 vs. 19 vs. 15 mmHg; $p = 0.0095$) and MELD score (10 vs. 13 vs. 14; $p = 0.0022$). However, there was no significant association between PSS and CPS ($p = 0.1024$). Also, PlGF levels were not significantly different between patients with mild vs. moderate vs. severe PSS.
Conclusion: The development and extent of portosystemic shunts seems to be determined by severity of portal pressure and hepatic dysfunction. Importantly, the presence of PVT, i.e. prehepatic portal hypertension may be a major trigger for PSS development. Surprisingly, PlGF levels did not correlate with the extent of PSS.

PS-022

Optimal timing of endoscopy is associated with lower 42-day mortality in variceal bleeding

Background and aims: The optimal timing of endoscopy in patients with variceal bleeding from the upper gastrointestinal tract is unknown. Current guidelines recommend performance of endoscopy within 12–24 hours from hospital admission, but the evidence is limited. Our aim was to describe the association between timing of endoscopy and 42-day mortality in variceal bleeding.
Method: Analyses were performed on prospective collected data on patients admitted with variceal bleeding at 34 centres in Europe and Canada during in the period October 2011 to May 2015. Patients transferred with bleeding from other hospitals and patients bleeding from post-banding ulcers, or non-specified sources, were excluded. Logistic regression analyses were used to investigate the association between timing of endoscopy and 42-day mortality following adjustment for confounding factors including age, sex, comorbidities, liver function, previous decompensation, laboratory values, haemodynamic parameters, and treatment with vasopressors. We evaluated the association in: 1. All patients with variceal bleeding; 2. Patients with Child-Pugh A or B-cirrhosis; and 3. Patients with systolic blood pressure (SBP) < 90mmHg.
Results: A total of 2, 138 patients were considered for inclusion. Following exclusion of transferred patients (n = 607) and patients with other sources of bleeding (n = 163), 1, 373 patients were included with mean age 59 years, and mean Child-Pugh score 8.2. 69%, 18%, 8% and 5% underwent endoscopy in the periods < 6, 6-12, 12-24, and > 24 hours, respectively. Mortality at 42 days was 26.2%. Following adjustment for confounding factors, performance of endoscopy within 24 hours from time of hospital admission was associated with lower mortality in patients with Child-Pugh A or B cirrhosis (Odds ratio (OR) 95% confidence interval (CI): 0.38 [0.16-0.86]; p = 0.020) and patients with SBp < 90 mmHg (OR [95% CI]: 0.053; [0.006-0.51]; p = 0.011). Performance of endoscopy within 6 or 12 hours was not associated with further reduction in mortality compared with endoscopy within 24 hours. We did not find a significant association between timing of endoscopy and mortality in the overall group of patients (OR [95% CI]: 0.51 [0.24-1.09]; p = 0.082).
Conclusion: Our data suggest that in patients presenting with variceal bleeding, performance of endoscopy within 24 hours is associated with reduced 42-day mortality in patients with Child-Pugh A or B cirrhosis and in those with SBp < 90mmHg.

Email: deborangrisani@hotmail.it

Background and aims: Pre-emptive TIPS (p-TIPS) improves outcomes in patients with acute variceal bleeding and high-risk of treatment failure (HR-VB) compared to those receiving medical/endoscopic treatment (Drug+Endo). However, current studies have included a low number of p-TIPS patients precluding the evaluation of factors predicting outcome after TIPS that may optimize its use.
The aim of the study is to identify prognostic factors in patients with HR-VB treated with p-TIPS. In addition, if different risk-groups are identified, the outcome observed in patients with p-TIPS will be compared with that in patients sharing the same prognostic factors, but receiving Drug+Endo.
Method: Individual data of all patients with HR-VB treated with p-TIPS included in 4 published studies (2 randomized, 2 observational) comparing p-TIPS vs Drug+Endo were analyzed to identify prognostic factors of survival. Liver transplant was considered as a competing event. Different prognostic models were developed avoiding redundant variables. Continuous variables were considered as continuous but also as categorical according to cut-off values identified by Youden index.
Results: 169 HR-VB p-TIPS patients were included. At one year, 30 died and 15 were transplanted. Cumulative survival at 6 weeks and at a 1 year was 91.2% and 76% respectively. At Cox uni and multivariate analysis, age, alcoholic etiology, bilirubin, creatinine, Child and MELD were associated with p-TIPS survival. From all significant models, the one with best "c-statistic" index, and consequently with better adjusted survival, entailed age ≥ 65; Creatinine ≥ 1.3 mg/dl; Child ≥ 12 and alcoholic etiology. A score of 3.5, 3.5, 4 and 4 points was given to each variable respectively. The model classified p-TIPS patients in low (total score < 4 points: n = 46), medium (score from 4-7.5; n = 68) and high (score > 7.5; n = 55) risk groups with a 1-year survival of 91, 83 and 55% respectively. Survival for all these 3 groups were better for p-TIPS when, by using the same scoring system, we classified the 692 patients treated with Drug+Endo included in the previous studies (low risk; n = 383: 70%: p < 0.02; Medium; n = 124: 53%:p < 0.01; High; n = 185; 44%:p < 0.05).
Conclusion: In HR-VB patients treated with p-TIPS, 3 different prognostic risk groups can be identified. For all 3 groups of risk, prognosis is better using p-TIPS than Drug+Endo. This fact strengthens and reinforces the use of p-TIPS in patients with cirrhosis and HR-VB.

Early TIPS with covered stent versus standard treatment for acute variceal bleeding among patients with advanced cirrhosis: A randomised controlled trial

Yong Lv[1], Zhiping Yang[2], Chuangye He[1], Kai Li[1], Zhengyu Wang[1], Jing Niu[1], Wengang Guo[1], Wei Bai[1], Hongbo Zhang[3], Huahong Xie[3], Liping Yao[3], Jianhong Wang[4], Hui Chen[1], Qiuhe Wang[1], Tainlei Yu[1], Xulong Yuan[1], Enxin Wang[1], Dongdong Xia[1], Bohan Luo[1], Xiaomei Li[1], Na Han[1], Ying Zhu[1], Hongwei Cai[5], Jielai Xia[5], Zhanxin Yin[1], Kaichun Wu[2], Daiming Fan[2], Guohong Han[1]. *[1]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Liver Diseases and Digestive Interventional Radiology, Xi'an, China; [2]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, State Key Laboratory of Cancer Biology, Xi'an, China; [3]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Digestive Endoscopy, Xi'an, China; [4]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Ultrasound, Xi'an, China; [5]Fourth Military Medical University, Department of Medical Statistics, Xi'an, China*
Email: hangh@fmmu.edu.cn

Background and aims: Early placement of transjugular intrahepatic portosystemic shunt (TIPS) has been shown to improve survival in high-risk patients (Child-Pugh B + active bleeding at endoscopy or Child-Pugh C10-13) with cirrhosis and acute variceal bleeding (AVB). However, whether the same results can be validated and achieved in a broader population remains to be assessed.
Method: Consecutive patients with advanced cirrhosis (Child-Pugh B or C) and AVB who had been treated with vasoactive drugs plus endoscopic therapy (ET) were randomly assigned in a 2:1 ratio to receive early TIPS treatment (performed within 72hours after initial endoscopy, early TIPS group) or continuation of vasoactive drug therapy to day 5, followed by propranolol plus long-term endoscopic band ligation for the prevention of rebleeding and a TIPS placement as rescue therapy when needed (ET+ Drug group), respectively. Primary end point was transplantation-free survival. Secondary end points included failure to control bleeding or rebleeding, new or worsening ascites, overt hepatic encephalopathy (OHE), other complications of portal hypertension and adverse events.
Results: From May 2011 to September 2017, a total of 129 patients were randomly assigned to the early TIPS group (n = 84) or the ET+ Drug group (n = 45). The transplantation-free survival rate was higher in the early TIPS group compared with the ET + Drug group (6 weeks: 99% vs 84%; 1 year: 86% vs 73%; 2 years: 79% vs 64%; p = 0.039, Figure A). Similar results were observed in a post-hoc competing risk sensitivity analysis (Figure B). After adjusting the severity of liver disease in the Cox regression analysis, early TIPS was associated a 56% relative risk reduction in the mortality or transplantation at 2 years (adjusted HR, 0.44; 95% CI: 0.22 to 0.88). Moreover, the beneficial effect tending to favour the early TIPS was homogeneous across the most of subgroups (Figure C). Finally, early TIPS placement was associated with decreased risks of failure to control bleeding or rebleeding as well as new or worsening ascites, without increasing the frequency and severity of overt hepatic encephalopathy and other adverse events.
Conclusion: Among patients with advanced cirrhosis and AVB, early TIPS is superior to drugs plus endoscopic treatment in improving transplantation-free survival rates, reducing failure to control bleeding and new or worsening ascites without increasing the risk of overt hepatic encephalopathy. Our results favour the early use of TIPS in patients with advanced cirrhosis and AVB. (Trial registration: ClinicalTrials.gov: NCT01370161)

Email: cathrin.gudd@gmail.com

Background and aims: Checkpoint inhibitors (CPIs) targeting cytotoxic T lymphocyte antigen-4 (CTLA-4) and programmed cell death-1 (PD-1) are a novel class of cancer treatment which stimulate anti-tumour immune responses. CPI treatment is frequently complicated by immune-related adverse events, including CPI-induced hepatitis (CPI-Hep) in up to 25% of patients on dual therapy. Here, we sought to characterise the profile of circulating and hepatic immune cells of patients with CPI-Hep.

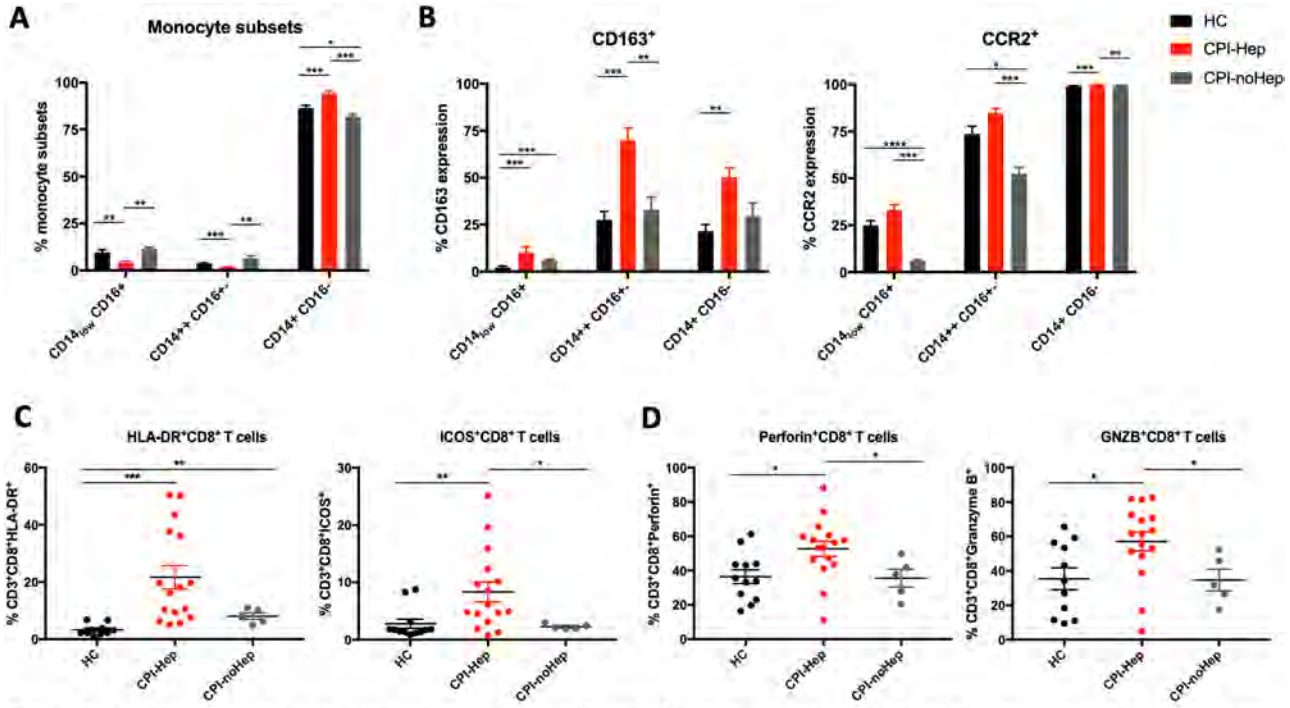

Figure. Flow cytometry analysis of circulating monocytes and T cells of healthy controls (HC), CPI-treated cancer patients with hepatitis (CPI-Hep) and without hepatitis (CPI-noHep). **A)** Frequency of circulating monocyte subsets. **B)** Expression levels of CD163 and CCR2 in monocyte subsets. **C)** Expression of HLA-DR and ICOS in CD8+ T cells. **D)** Granzyme B and Perforin production by CD8+ T cells. Non-parametric (Mann-Whitney) statistical analysis was used. Data shown as median values with IQR. *p<0.05, ** p<0.01, *** p<0.0001, **** p<0.0001.

Figure: (abstract: PS-025)

Method: Using multi-colour flow cytometry, we phenotypically and functionally characterized circulating immune cells from healthy controls (HC; n = 12), CPI-treated cancer patients with and without hepatitis [CPI-Hep, grade 3-4 hepatitis, (n = 16); CPI-noHep, (n = 5)]. Monocytes were screened for activation and tissue-homing markers as well as microbial clearance (phagoburst, pHrodo). Lymphocytes were monitored for activation (HLA-DR, CD25, ICOS) and function [CD127, perforin, granzyme B (GZMB)]. Immunohistochemistry (IHC) was performed on liver tissue from CPI-Hep/noHep (n = 3 each) and pathological controls (PC) [resection margins of colorectal metastases, (n = 2)].
Results: Patients with CPI-Hep had a lower proportion of non-classical and intermediate and a higher frequency of classical monocytes, compared to controls **(A)**. Circulating monocytes in CPI-Hep showed a higher proportion towards a $CD163^{high}CCR2^{high}$ phenotype **(B)**, but unaltered microbial clearance capacity. Proportions of CD4, CD8 and Tregs were comparable between CPI-Hep/noHep and HC. However, in CPI-Hep, $CD8^+$ T cells presented an activated $HLA\text{-}DR^{high}ICOS^{high}$ phenotype **(C)** with increased GZMB and perforin production, compared to controls **(D)**. Patients with CPI-Hep showed lobular liver inflammation and focal aggregates of CD68 with CD3/CD8/CD25/GZMB positive cells whereas macrophages and $CD8^+$ T cells were evenly distributed in PC and CPI-noHep. Double-IHC revealed colocalization of cytotoxic $CD8^+$ T cells with $CD68^+$/$CCR2^+$ macrophages in livers of patients with CPI-Hep.
Conclusion: CPI-Hep is an emerging problem with the development and wider application of cancer immunotherapy. Our novel data suggest that CPI-Hep is associated with changes in both the myeloid and $CD8^+$ T cell compartments. The coexistence of activated circulating monocytes and increased $CCR2^+$ hepatic macrophages, suggests monocyte recruitment to the liver may be important in disease pathogenesis. Further studies will focus on the interaction between cytotoxic T cells and monocyte-derived macrophages within the liver and mechanisms of altered immune cell phenotype and dysfunction during CPI-Hep.

PS-026
FOXO1-activitiy controls effector function of CXCR6+CD8+ T-cells and prevents liver immune pathology during viral hepatitis and non-alcoholic steatohepatitis

Michael Dudek[1], Dominik Pfister[2], Nina Kallin[1], Dirk Wohlleber[1], donakonda sainitin[1], Mathias Heikenwälder[2], Percy A. Knolle[1].
[1]Institute of Molecular Immunology and Experimental Oncology, Technical University of Munich, Munich, Germany; [2]German Cancer Research Center, DKFZ, Munich, Germany
Email: michael.dudek@tum.de

Background and aims: Recognizing foreign antigens as peptides in a complex with MHC class I is indispensable for $CD8^+$ T-lymphocytes to eliminate infected cells. Tight cellular co-regulation of metabolism and immunity is required to control effector function, but the mechanisms regulating organ-specific immunity in tissues rich in nutrients such as liver remained unclear. $CD8^+$ T cells expressing the chemokine receptor CXCR6 are important for staying as tissue-resident memory T cells (T_{rm}) in the liver and providing front-line defense for infections. T_{rm} express high levels of effector molecules like GzmB or IFN-γ but how T_{rm} regulates their effector function in order to avoid immune pathology is largely unknown. Here we identify Foxo1-activity in $CXCR6^+CD8^+$ T cells as critical regulator of CXCR6 expression, metabolism and effector function during liver disease states.
Method: Extracellular flux analysis, cytokine expression, cytotoxicity assays were performed to study co-regulation of metabolism and immunity of $CXCR6^+CD8^+$ T cells and its dependence on Foxo1 in vitro and ex vivo studies. Murine models of viral hepatitis and non-alcoholic steatohepatitis (NASH) were used to explore Foxo1-dependent T cell immunopathology.
Results: RNA-seq and KEGG pathway analysis of $CXCR6^+$ memory $CD8^+$ T cells of the liver compared to memory $CD8^+$ T cells from other tissues revealed high GzmB level accompanied with downregulation of Foxo1-dependent pathways. Flow cytometric analysis of liver-specific lymphocytes revealed a $Foxo1^{low}CXCR6^+GzmB^{high}CD69^+CD8^+$ T cell population. Using germ-free mice and *in vitro* studies we found that high GzmB level in Foxo1lowCXCR6+ CD8+ T cells were dependent on the the presence of microbiota. We further identified TGFβ and IL15 as critical cytokines that downregulate Foxo1 via PI3 K/pAkt pathway and inducing $CXCR6^+CD8^+$ T cells derived from $CXCR6^-CD122^+CD8^+$ T cells. To address the functional consequence of $CXCR6^+Foxo1^{low}Gzmb^{high}$ $CD8^+$ T cells we performed in vitro killing assays of infected and non-infected hepatocytes demonstrating antigen-independent immune pathology against hepatocytes in the presence of elevated levels of IL15 and acetate. This development of autoimmune $CD8^+$ T cell effector function was also be observed in NASH where we detected high numbers of $Foxo1^{low}CXCR6^+GzmB^{high}CD69^+CD8^+$ T cells that caused liver damage. Since TCR sequencing of hepatic T cells did not reveal presence of particular T cell-clones in NASH, we assume that increased effector function in $CXCR6^+$ $CD8^+$ T cells in the absence of Foxo1-control caused antigen-independent hepatic immunopathology.
Conclusion: Our results provide evidence for a critical role of Foxo1 in controlling metabolism in $CD8^+$ T cells that is required to prevent liver immunopathology and may explain metabolic $CD8^+$ T cell activation in NASH causing sterile inflammation.

PS-027
The LLT1-CD161 interaction : An important inhibitory interaction for NK cells in cirrhosis

Naveenta Kumar[1], Fouzia Sadiq[1], Sujit Mukherjee[1], Wafa Khamri[1], Fanny Lebossé[1], Ameet Dhar[1], Marco Purbhoo[1], Robert D. Goldin[1], Mark Thursz[1], Harry Antoniades[1], Salim Khakoo[2]. *[1]Imperial College London, London, United Kingdom; [2]University of Southampton, Southampton, United Kingdom*
Email: n.kumar@imperial.ac.uk

Background and aims: Immune profiling is important to understand the increased risks of hepatocellular carcinoma (HCC) in cirrhosis. Lectin-like transcript 1 (LLT1) interacts with CD161, a receptor expressed on most NK cells. Here we investigate LLT1 in the liver and determine its effect on NK cell function.
Method: LLT1 expression in the liver was characterised with immunohistochemistry (IHC) on formalin fixed liver tissue, and quantified with real-time PCR using RNA extracted from liver tissue snap frozen at the time of liver resection. GAPDH was the housekeeping gene. Peripheral blood mononuclear cells (PBMCs) from healthy donors and cirrhotic patients were surface stained for CD3, CD56, CD161. Function was assessed against K562 targets (PBMCs:K562, 5:1) with intracellular staining for Interferon gamma (IFNγ), and staining for degranulation (CD107a). CD107a was also measured on healthy donor NK cells (n = 3) cocultured with target cells expressing different surface levels of LLT1: Huh7 cells (low levels of LLT1), Huh7 cells overexpressing LLT1 (achieved by transfection), and Jurkat cells (lacking LLT1). Statistical analysis of variance (ANOVA) was performed to compare each condition.
Results: Relative quantification (RQ) demonstrated a significant upregulation of LLT1 in cirrhotic liver (median RQ of LLT1:371.7 vs. 1.0, cirrhotic liver (n = 5) vs. normal liver (n = 6), $p < 0.001$). IHC confirmed a homogenous expression of LLT1 on cirrhotic liver hepatocytes, but no expression on normal hepatocytes (n = 23 cirrhotic livers vs. n = 18 normal liver margins). Circulating NK cells had a significantly higher proportion expressing CD161 in cirrhosis compared to healthy donor NK cells (91.3% vs. 87.2%, p = 0.05, n = 29 vs. n = 25). NK cells from cirrhotic donors also had attenuated functional responses when co-cultured with K562 targets (cirrhotic (n = 25) vs. healthy donors (n = 24): percentage positive expressing

CD107a 59.8%vs69.3%, $p < 0.05$; percentage positive producing IFNγ 41.8%vs48.3%, $p < 0.05$). CD161+NK cells from healthy donors had reduced CD107a expression, compared to CD161-NK cells, when cocultured with Huh7 cells expressing LLT1. When cocultured with transfected Huh7 s overexpressing LLT1, as seen in cirrhotic livers, there was a further significant reduction in the proportion of healthy donor CD161+NK cells expressing CD107a ($p < 0.05$) compared to CD161+ NK cells cultured with non-transfected Huh7s. In contrast, CD107a expression in CD161+ and CD161-NK cells was not significantly different when the target cell did not express LLT1 (Jurkat cells).

Conclusion: LLT1 inhibits NK cytotoxicity via the CD161 receptor. Upregulation of LLT1 in cirrhotic livers, coupled with the increase in circulating CD161+NK cells contribute to the inhibitory NK cell profile in cirrhosis. Future NK-mediated HCC immunotherapies may need to overcome this inhibitory LLT1-CD161 interaction in cirrhosis.

Email: valerie.oberhardt@uniklinik-freiburg.de

Background and aims: Hepatitis D virus (HDV) super-infection of hepatitis B virus (HBV)-infected patients is associated with rapid progression to liver cirrhosis and hepatocellular carcinoma. Treatment options are limited, and no vaccine is available. Although HDV-specific CD8+ T cells are thought to mediate viral control, little is known about the repertoire of targeted epitopes, and it remains unclear why HDV-specific CD8+ T cells ultimately fail during persistent infection. We aimed to define how viral escape impacts the efficacy of HDV-specific CD8+ T-cells.

Method: 104 patients with chronic HDV/HBV infection were analyzed for HLA class I associated viral sequence polymorphisms. Candidate HDV-specific CD8+ T-cell epitopes overlapping these sequence polymorphisms were predicted, tested, and characterized in patients with resolved (n = 12) or chronic (n = 13) HDV infection. One of the validated epitopes was used for phenotypical characterization of HDV-specific CD8 T cells using a highly sensitive tetramer-based enrichment strategy.

Results: 21 HLA class I-associated viral sequence polymorphisms were identified as highly significant ($p < 0.005$). Five of these polymorphisms were found to co-localize with experimentally confirmed HDV-specific CD8+ T-cell epitopes. Importantly, variant peptides were only partially cross-recognized, indicating viral escape. Similarly, CD8+ T cells targeting escape variants display a 'memory-like' phenotype, indicating a loss of antigen drive. These newly identified epitopes were restricted by relatively infrequent HLA class I allotypes, with a preference for HLA-B. In contrast, frequent HLA class I alleles were not associated with viral sequence polymorphisms.

Conclusion: Using a viral sequence-based approach, we identified new HDV-specific CD8+ T-cell epitopes, indicating a role for viral escape as a determinant of immune failure. In turn, viral escape was associated with uncommon HLA class I alleles, suggesting population-level evolution of HDV.

Eradication of HCV by DAAs provides patients with immunological benefits by the restoration of antigen-presenting dendritic cells

Sachio Yoshio[1], Yuzuru Sakamoto[1], Hironari kawai[1], Michitaka Matsuda[1], Taizo Mori[1], Yoshihiko Aoki[1], Yosuke Osawa[1], Tatsuya Kanto[1]. [1]*National Center for Global Health and Medicine, Ichikawa, Japan*
Email: sachiyo@hospk.ncgm.go.jp

Background and aims: In an era of DAA against HCV, controversial arguments have been prevailed in the recurrence and/or occurrence of post-SVR HCC. Rapid and complete clearance of HCV from infected hepatocytes by DAAs is reported to reduce the expression of ISGs, thus probably resulting in the impairment of anti-malignancy potential. An interaction between BDCA3$^+$ dendritic cells (BDCA3$^+$DC/cDC1/mDC2) and NK cells is recently reported to play important roles in immune surveillance against cancer cells. We thus aimed to clarify whether the gene expression and function of antigen-presenting DCs, including BDCA3$^+$ subset, are restored or not in patients with HCV infection after successful DAA treatment.

Method: At the baseline before the DAA therapy, we enrolled 53 patients with chronic HCV infection and age-matched 21 healthy volunteers. In addition, we enrolled 14 patients with chronic HCV infection who achieved SVR with glecaprevir/pibrentasvir. PBMCs were collected at before, end of treatment (EOT) and 12 weeks thereafter. Phenotypes of immune cells and degree of apoptosis were analyzed by FACS. We performed the focused gene expression analysis on peripheral DCs (CD3-CD14- CD19- CD56-HLA-DR+) by single-cell RNA-seq (10X system). Alternatively, plasmacytoid DCs (pDCs) and BDCA3$^+$DCs were sorted from PBMCs and subjected to qPCR and functional analyses with TLR ligands.

Results: At the baseline, the frequency of pDCs and BDCA3$^+$DCs was significantly lower in HCV-infected patients than in healthy volunteers (HVs) (pDCs, 0.18 vs 0.28%; BDCA3$^+$DCs, 0.03 vs 0.06%). The proportion of apoptotic cells were significantly higher in pDCs and BDCA3$^+$DCs in HCV-infected patients, suggesting that HCV provides pro-apoptotic nature to DCs. IFN-α production by pDCs and IFN-λ production by BDCA3$^+$DCs were decreased in patients with HCV infection. RNA-seq revealed that, after DAA, downregulation of ISGs (IFI44L, ISG15, LY6E), cancer-related genes (KLF6, PRMT9, MALAT1) and maturation markers (NR4A2, CXCR4) were observed in BDCA3$^+$DCs. In this setting, enrichment analysis showed that pro-apoptotic pathway gene sets were downregulated. By the qPCR analysis at the baseline, we found that BCLX expression on BDCA3$^+$DCs was significantly decreased in patients compared with

HVs, while the expressions of the other anti- or pro- apoptotic genes, BCL2, MCL1, and BIM were comparable. After attaining SVR in treated patients, the frequency, function, and BCLX expression on BDCA3$^+$DCs were restored to the pretreatment levels.
Conclusion: In patients with chronic HCV infection, dendritic cells are decreased and functionally impaired, one of the reasons of which is apoptosis-prone nature of immune cells. Attaining SVR with DAAs restored the number, function and pro-survival BCLX expression in BDCA3$^+$DCs, supporting the notion that the eradication of HCV by DAAs provides some immunological benefits to patients.

PS-030
Cure of hepatitis C virus has limited impact on the functional and mitochondrial impairment of HCV-specific CD8+ T-cell responses
Amare Aregay[1], Solomon Owusu Sekyere[1], Katja Deterdig[2], Kerstin Port[1], Julia Dietz[3], Caterina Bertowski[3], Michael P. Manns[4], Markus Cornberg[1], Heiner Wedemeyer[2]. *[1]Hannover Medical School, Gastroenterology Hepatology and Endocrinology, Hannover, Germany; [2]Essen University Hospital, Gastroenterology and Hepatology, Essen, Germany; [3]University Hospital Frankfurt, Department of Internal Medicine, Frankfurt, Germany; [4]Hannover Medical School, Gastroeneterology Hepatology and Endocrinology, Hannover, Germany*
Email: wedemeyer.heiner@uk-essen.de

Background and aims: Hepatitis C virus (HCV)-specific CD8+ T cells are functionally impaired in chronic hepatitis C. Even though HCV can now rapidly and sustainably be cleared from chronically infected patients, reverberation of HCV clearance on virus-specific CD8+ T cells still remains elusive. Here, we aimed to investigate if HCV clearance by direct acting antivirals (DAA) could restore the functionality of exhausted HCV-specific CD8+ T cell responses.
Method: HCV-specific CD8+ T cells in PBMC obtained during and 6 months following IFN-free DAA therapy of 36 chronically HCV infected patients were analyzed for comprehensive phenotypes, proliferation, cytokine production, mitochondrial function and response to immune-check-point blockades.
Results: We show that, unlike activation markers that decreased, surface expression of multiple co-regulatory receptors on exhausted HCV-specific CD8+ T cells remained unaltered after clearance of HCV. Likewise, cytokine production by HCV-specific CD8+ T cells remained impaired following HCV clearance. Proliferative capacity of HCV multimer-specific CD8+ T cells was not restored in the majority of patients. However, enhanced proliferative expansion of CD8+ T cells after in-vitro HCV peptide stimulation was more likely in women, patients with low liver stiffness and low ALT levels. Interestingly, HCV-specific CD8+ T cells that did not proliferate following HCV clearance could preferentially re-invigorate their proliferative capacity upon in-vitro immune-check-point inhibition. Remarkably, altered mitochondrial dysfunction exhibited by exhausted HCV-specific CD8+ T cell could not be normalized after HCV clearance.
Conclusion: Taken together, our data implies that exhausted HCV-specific CD8+ T cells during chronic HCV still remain functionally and metabolically impaired at multiple levels following HCV clearance in most patients. Our results might have possible implications for re-infection with HCV.

PS-031
RNAseq of liver biopsies following DAA-based therapy reveals a greater enrichment in immune, interferon, cytokine and cell cycle pathways compared to IFN-based therapy: Implications for DAA-related sequelae
Jacinta Holmes[1,2], Ming-Lung Yu[3], Shu-Chi Wang[3], Meghan Sise[4], Chung-Feng Huang[3], Chia-Yen Dai[3], Wan-Long Chuang[3], Ching-Chin Lin[3], Steve Rwema[1], Esperance Schaefer[1], Batul Kaj[1], Dong Chen[1], Quijiu Sheng[1], Wenyu Lin[1], Raymond Chung[1]. *[1]Massachusetts General Hospital and Harvard Medical School, Gastrointestinal Division, Boston, United States; [2]St Vincent's Hospital, Gastroenterology, Melbourne, Australia; [3]Kaohsiung Medical University Hospital and Kaohsiung Medical University, Hepatobiliary and Internal Medicine, Kaohsiung City, Taiwan; [4]Massachusetts General Hospital and Harvard Medical School, Renal, Boston, United States*
Email: jacinta.holmes@svha.org.au

Background and aims: HBV reactivation (HBVr) and autoimmune disease (AID) are unexpected sequelae that emerged during interferon (IFN)-free direct-acting antiviral (DAA) therapy for HCV. The mechanism is unknown, particularly considering DAAs do not posses direct immunomodulatory properties. In contrast, HBVr and AID are well-recognized complications of IFN-based therapy, as IFN is directly immunomodulatory, and has some but limited anti-HBV activity. We sought to compare intrahepatic transcriptomic profiles before and after IFN-free DAA-based and IFN-based (DAA-free) therapy.
Methods: DAAs or pegIFN+ribavirin (PR)-treated patients who underwent liver biopsy before and at time of SVR assessment were retrospectively identified. RNA was extracted from RNAlater liver tissue and subjected to RNAseq. Pre and post-treatment transcriptomes were compared according to treatment group and response.
Results: 39 patients were enrolled: DAA-treated with SVR (n = 13), PR-treated with SVR (n = 13) and PR-treated non-SVR (n = 13). Patients were matched for sex, HCV genotype, HCV RNA, fibrosis stage and treatment history within each group. DAA patients were slightly older and had lower ALT levels ($p < 0.05$). At baseline, intrahepatic transcriptomic profiles did not differ among the three treatment groups. There was no difference in transcriptomic profiles before and after PR therapy in non-SVR patients. However, in DAA-treated patients, 518 genes were differentially expressed between pre and post-treatment liver biopsies. The top over-represented enriched pathways involved the immune system, IFN signaling, cytokine signaling, cell cycle and Rho effector pathways (FDR < 0.05). More than 1, 550 genes were differentially expressed between pre and post-treatment liver biopsies in PR SVR patients. The top over-represented pathways were immune system, cytokine signaling, IFN signaling, adaptive immune system, and cell cycle pathways. Interestingly, the fold enrichment of these pathways was significantly greater in DAA-treated patients.
Conclusion: We observed different patterns of changes in intrahepatic transcriptomic profiles between DAA-treated and PR-treated patients who achieved SVR, with significantly greater induction of immune-related and cell cycle pathways with DAA therapy. These findings may have implications for the mechanisms of several unexpected sequelae of DAA-based therapy, including HBVr itself and the severity of HBVr, as well as the development of AID.

PS-032
Impact of antigen recognition on memory-like HCV-specific CD8+ T-cells
Nina Hensel[1], Dominik Wieland[1], Zuguang Gu[2], Sagar Sagar[3], Katharina Jechow[2], Janine Kemming[1], Bertram Bengsch[1], Christoph Neumann-Haefelin[1], Ralf Bartenschlager[4], Christian Conrad[2], Dominic Gruen[3], Naveed Ishaque[2], Maike Hofmann[1], Robert Thimme[1]. *[1]University Hospital Freiburg, Department of Medicine II, Freiburg, Germany; [2]German Cancer Research Center/BioQuant, Department of Theoretical Bioinformatics, Heidelberg, Germany; [3]Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany; [4]German Cancer Research Center, Department of Infectious Diseases, Molecular Virology; Division of Virus-Associated Carcinogenesis, Heidelberg, Germany*
Email: nina.hensel@uniklinik-freiburg.de

Background and aims: In chronic HCV infection, T-cell exhaustion is described as a functional impairment of virus-specific T cells. We have previously reported that exhausted HCV-specific CD8+ T cells are comprised of terminally exhausted CD127-PD1hi and memory-like CD127+PD1+ subsets. However to what extent memory-like HCV-specific CD8+ T cells resemble conventional memory or

exhausted cells and which impact viral antigen recognition has on the phenotype of these cells remain unclear.
Method: In order to define the molecular determinants of memory-like subsets, we conducted low-input RNAseq analyses of CD127/PD1-based HCV-specific CD8+ T-cell subsets obtained during and after chronic HCV infection targeting consensus and escaped epitopes (n = 5 patients) and after spontaneous resolution of acute HCV infection (n = 3 patients). Via unsupervised clustering, DESeq2 analyses and WGCNA, we investigated the similarities and differences among the different subsets and clinical conditions.
Results: Although in chronic HCV infection memory-like HCV-specific CD8+ T cells clearly exhibit characteristics of memory T cells, on a transcriptional level, however, an exhausted signature is dominant even after DAA-mediated viral clearance. Thus, memory-like HCV-specific CD8+ T cells are distinct from conventional memory T cells and rather resemble exhausted T cells. Furthermore, HCV-specific CD8+ T cells targeting escaped epitopes also showed a clear exhausted profile revealing an imprinted dysfunction and a fate of exhaustion.
Conclusion: Thus, chronic HCV infection is strictly linked to an "exhaustive" T-cell differentiation that is not simply reverted by removal of viral antigen or loss of antigen recognition. This has potential implications for the control of re-infection and therapeutic vaccines.

Mechanism of regeneration response to injury

PS-033
Hepatocyte-specific deletion of ERK5 modulates liver regeneration in mice

Giovanni Di Maira[1], Benedetta Piombanti[1], Andrea Lombardo[1], Marilena Fazi[1], Carmen Berasain[2], Matías A Avila[2], Fabio Marra[1].
[1]University of Florence, Florence, Italy; [2]Universidad de Navarra, Pamplona, Spain
Email: fabio.marra@unifi.it

Background and aims: Liver regeneration induced by partial hepatectomy (PH) involves several cell types and the activation of multiple signaling pathway. The extracellular signal-regulated kinase 5 (ERK5) is a member of the Mitogen-Activated Protein Kinase (MAPK) family implicated in cell survival, angiogenesis, differentiation and proliferation. ERK5 is critical for the development and growth of HCC, and we recently generated hepatocyte-specific ERK5 knock-out mice (ERK5ΔHep). The aim of this study to investigate the contribution of hepatocyte ERK5 to liver regeneration, in a model of PH.
Method: ERK5ΔHep mice were generated crossing ERK5 floxed mice with mice expressing Cre-recombinase under the control of albumin promoter. ERK5ΔHep mice animals of 16–24 weeks of age along with Alb-Cre littermates (control mice) were subjected to a 70% partial hepatectomy (PH). Mice were sacrificed at different time points. Serum ALT and AST in the serum were measured using standard assays. Intrahepatic gene expression was assayed by quantitative real time PCR. ERK5 activation was assessed using phosphor-specific antibodies.
Results: First we evaluated the activation state of ERK5 during liver regeneration, Increased phosho-ERK5 signal was found between 6 and 9 hours after PH, corresponding to transition from the priming phase, where hepatocytes prepare for cell cycle re-entry to the progression phase of DNA replication and hepatocyte proliferation. Next control and ERK5ΔHep mice were subjected to PH and sacrificed at 24, 48 and 168 hours. Liver-to body weight ratio showed that liver recovery was similar at 24 and 48 hours after PH, whereas at a late time point (168 hours) a reduced hepatic regeneration in ERK5ΔHep mice was observed. This late decrease of regenerative response of ERK5ΔHep mice correlated with reduced hepatic expression of cell proliferation markers such as PCNA and cyclin B1. Reduced liver regeneration was accompanied by severe liver damage at 24 and 48 hours, as indicated by elevated ALT and AST levels. Histologic analysis showed that ERK5ΔHep exhibited hepatic necrosis, associated with monocyte infiltration as indicated by evelevated intrahepatic expression of CD14 and CCL2 were elevated in ERK5ΔHep livers.
Conclusion: This study indicates for the first time that ERK5 exerts an important role in the liver regeneration process participating in the priming phase, that involves the activation of several proinflammatory pathways, and in the progression phase that activates the cell cycle machinery of hepatocytes.

PS-034
MCJ: A therapeutic target in hepatic ischemia and reperfusion injury

Email: mlmartinez@cicbiogune.es

Background and aims: Ischemia/reperfusion (IR) injury, a frequent pathological process during liver resection, is a leading cause of post transplantation organ dysfunction. The extent of the injury can determine the success of the procedure and the survival of the patient. Therefore, attenuation of pathology caused by the injury and improving liver function after the procedure would be critical for clinicians to diminish IR injury prevalence and improve the outcome. Mitochondria play a key role in liver homeostasis; indeed, more functional mitochondria induce hepatic regeneration. MCJ, also known as DNACJ15, is an endogenous negative regulator of complex I, located in the mitochondrial electron transport chain. While under normal conditions MCJ deficiency does not result in an altered phenotype in mice, its absence improves mitochondrial activity without increasing mitochondrial ROS. We present MCJ as a new target to minimize hepatic damage caused by IR injury and enhance the efficiency of liver regeneration during liver resection.
Method: Partial hepatectomies (PH) and PH combined with IR injuries were performed in MCJ-KO mice and in WT mice after *MCJ* silencing.

Results: We observed that the lack of MCJ reduced liver damage and induced hepatic regeneration after IR injury; MCJ-KO mice showed lower levels of Caspase 3 and a significantly higher Cyclin D1 expression. Moreover, we saw an improved metabolic response to hepatic insufficiency and an accelerated cell cycle progression during liver resection, which led to a faster recovery of the hepatic mass. In the initial phase after the PH, glucagon response was amplified in MCJ-KO mice, characterized by increased cAMP and AKT signaling, along with higher Ca^{+2} release from the endoplasmic reticulum (ER), glycogen synthase kinase (GSK-3beta) inhibition and nuclear factor-Kbeta (NFKbeta) translocation to the nucleus. In the proliferative phase, ablation of MCJ accelerated the induction of proliferative markers. Indeed, after MCJ silencing, an improved phenotype was detected in an aging mice model that underwent partial hepatectomy. Hepatic insufficiency was ameliorated, PCNA expression increased and steatosis reverted. Importantly, the combined procedure of PH and IR injury that resemble liver transplant procedure resulted in a 100% survival rate for MCJ-KO mice while just the 33% of MCJ-WT mice survived the operation. Increased levels of MCJ were found in liver biopsies from all liver donors at 60 minutes after normothermic regional perfusion (nRP) was started.
Conclusion: Overall, MCJ silencing during liver resection emerges as a promising therapy for IR injury and restoration of hepatic mass.

PS-035

The role of pericentral hepatocytes in homeostatic liver regeneration: Caveats to lineage tracing from Axin2

Callum Livingstone[1], Stephanie May[1], Miryam Mueller[1], Christos Kiourtis[1], Tom Drake[1], Colin Nixon[1], Owen Sansom[1,2], Thomas Bird[1,3]. [1]*Cancer Research UK Beatson Institute, Glasgow, United Kingdom;* [2]*Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom;* [3]*Medical Research Council (MRC) Centre for Regenerative Medicine, University of Edinburgh, Edinburgh, United Kingdom*
Email: c.r.livingstone@dundee.ac.uk

Background and aims: The liver is a paradigm for organ regeneration, however there is still an incomplete understanding of which hepatocytes regenerate the liver. This has implications for liver regenerative therapy.
Quiescent hepatocytes repopulate the liver parenchyma after partial hepatectomy. However, during homeostasis or injury at least three new sub-populations of hepatocytes have been reported to have particular potential to regenerate. One is self-renewing Axin2+ hepatocytes which are adjacent to the pericentral veins. Lineage tracing has suggested these hepatocytes, with active Wnt signalling and Glutamine synthetase (GS) expression, are a major source of homeostatic liver regeneration.
Method: Our aims were to 1) examine regional differences in homeostatic hepatocyte proliferation and 2) to retest the role of pericentral hepatocytes using Axin2+ lineage tracing studies. Wild type and transgenic murine models, including lineage tracing from Axin2CreER mice, were given BrdU and analysed via multiplex immunohistochemistry, in-situ hybridisation and high throughput image acquisition/analysis. qRT-PCR was used for analysis of Wnt target gene expression.
Results: Quantification of homeostatic hepatocyte proliferation identified the area between periportal and pericentral zones, zone 2, as the area in which hepatocytes are most likely to proliferate (BrdU labelled/%total zonal hepatocytes: Ecad+ve zone 1, zone 2 and GS+ve zone 3; 0.13, 0.15 and 0.02 respectively). These phenotype was also seen with long term BrdU. When using established Axin2+ lineage tracing methodology we observed preferential labelling of zone 3 hepatocytes (GS+ve), however hepatocytes from all zones were labelled acutely in Axin2CreER LSL-tdTom mice. Increasing rates of hepatocyte labelling occurred between days 2 and 5 across multiple zones (labelled hepatocytes/%total zonal hepatocytes; GS+ve Days 2 and 5, 3.6 and 26.6 and GS-ve Days 2 and 5, 0.4 and 1.9 respectively). Finally we examined the effects of the presence of an Axin2CreER knock-in construct on the Wnt pathway, observing reductions in both Lgr5 and GS.
Conclusion: This study identifies zone 2, and not the pericentral zone 3, as the zone in which hepatocytes are most likely to proliferate. Previous Axin2 based lineage tracing reports pericentral restriction of these hepatocytes. However, we show that Axin2 is expressed across the lobule and the Axin2 reporter also labels hepatocytes across the lobule without pericentral restriction. Following induction, progressive labelling occurs which confounds attributing lineage tracing specifically to the pericentral population. Finally, we demonstrate that the Axin2CreER does not accurately reflect liver homeostasis, as it affects the Wnt pathway. These results help reconcile the discrepancies between differing lineage tracing studies in the liver.

PS-036

Optimization and validation of a novel three-dimensional co-culture system in decellularized human liver scaffold for the study of liver fibrosis and cancer

Kessarin Thanapirom[1], Luca Frenguelli[1], Walid Al-Akkad[1], ZhenZhen Zhang[1], Massimo Pinzani[1], Giuseppe Mazza[1], Krista Rombouts[1]. [1]*University College London, Institute for Liver and Digestive Health, London, United Kingdom*
Email: k.rombouts@ucl.ac.uk

Background and aims: Development of anti-fibrotic and anti-cancer therapies suitable for human use remains an elusive goal due to limitations in in vitro and in vivo models. Hence there is an urgent need for improved preclinical models using 3 Dimensional (3D) tissue-specific and disease-specific extracellular matrix (ECM) with co-culture systems to preserve the level of complexity found in human liver pathophysiology. The aim of this study was to develop and validate a co-culture model using human liver 3D healthy and cirrhotic scaffolds as a platform for drug testing.
Method: Decellularized 3D scaffolds obtained from healthy and cirrhotic human livers were recellularized with human hepatic cell lines LX2 and HEPG2 as single and co-cultures for up to 14 days. Protein secretion, gene/protein expression involved in fibrogenesis, hepatocyte functions and cytokine expression were compared between mono-and co-culture models in both 3D ECM models. To validate the system as a new drug testing platform, cultures were treated with Sorafenib (7 µM) w/wo TGF-b1 (5 ng/ml) for 48hrs.
Results: Gene and protein secretion/expression was significantly upregulated in co-cultures when cells were grown in 3D cirrhotic scaffolds in comparison to 3D healthy scaffolds indicating specific ECM-induced effects. Compared to the LX-2 monoculture in both 3D ECM models, LX2 co-cultures secreted significantly less pro-collagen1a1, and mRNA expression of *PDGFR-b*, *COL1A1*, *COL3A1*, *LOX* and *IL-6* was downregulated, whereas being upregulated upon TGF-b1 exposure. In contrast, HepG2 gene expression of *ALB*, *UGT1A1* and *HNF4a* was similar when grown in mono or co-cultures.
To optimize Sorafenib's anti-fibrotic effect, cell viability was not affected in co-cultures treated with Sorafenib and w/wo TGF-b1. In both 3D ECM scaffolds, co-cultures treated with Sorafenib showed a significant reduction in *PDGFR-b* protein expression and pro-collagen1a1 synthesis w/wo TGF-b1 exposure and demonstrated to significantly abrogate TGF-b1-induced upregulation of *COL1A1*, *LOX*, *FN-1* and *IL-6* gene levels. Ongoing experiments are performed to investigate Regorafenib's anti-fibrotic/anti-cancer effect.
Conclusion: Acellular human healthy and cirrhotic liver 3D ECM scaffolds represent a suitable platform that mimic the natural physio-pathological microenvironment. This new 3D platform constitute a more reliable platform to screen anti-fibrotic and anti-cancer drugs when compared to the standard 2D cell culture on plastic.

PS-037

SMURF1 aggravates liver steatosis by stabilizing SREBP-1C in an E3 catalytic activity independent manner

xin zhang[1], Wei An[2], Hong-Rui Wang[1], Ping Xie[3]. *[1]Xiamen University, School of Life Sciences, Fujian, China; [2]Capital Medical University, Department of Cell Biology, Beijing, China; [3]Capital Medical University, Department of Cell Biology, Beijing, China*
Email: xpxp922@163.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disorder characterized by the accumulation of excessive lipid in liver. Although disturbance in energy homeostasis is the main cause of the disease, the precise pathogenesis of NAFLD is very complicated and remains largely unknown. Sterol regulatory element binding protein-1c (SREBP-1c) is the main transcription factor that mediates de novo lipogenesis. Smad ubiquitination regulatory factor 1 (Smurf1) is crucial for numerous processes including bone homeostasis, embryogenesis and pathogenic autophagy. However, the role of Smurf1 in NAFLD remains unknown.
Method: We generated *Smurf1*-deficient mice fed with high-fat-diet (HFD) to verify the function of Smurf1 in liver steatosis. Oil Red O staining was performed to reveal the liver steatosis in *Smurf1*-deficient mice or in *Smurf1*-knockdown cells. TG and ALT were measured in *Smurf1* WT or knockout mice. Immunohistochemistry and western blot were used to detect the changes of SREBP-1c and its target proteins. Gene expression patterns were characterized by quantitative reverse transcription PCR. The interaction of Smurf1 with SREBP-1c was identified by *in vivo* protein-protein interaction assays. The protein stability and ubiquitination modification of SREBP-1c was assessed by *in vivo* ubiquitination assay.
Results: Here we demonstrated that liver steatosis was obviously alleviated in Smurf1-deficient mice fed with high-fat-diet (HFD). Smurf1 deletion significantly reduced the accumulation of lipid droplets and triglycerides in hepatocytes. We showed that SREBP-1c levels were dramatically reduced in *Smurf1*-KO mice. Further investigation found that Smurf1 interacted with SREBP-1c both *in vivo* and *in vitro*. Smurf1 protected SREBP-1c from ubiquitination and degradation probably through inhibiting its binding with Fbw7a, which is a major ubiquitin E3 ligase for SREBP-1c. Additionally, Smurf1 stabilized SREBP-1c in an E3 ligase catalytic activity-independent manner.

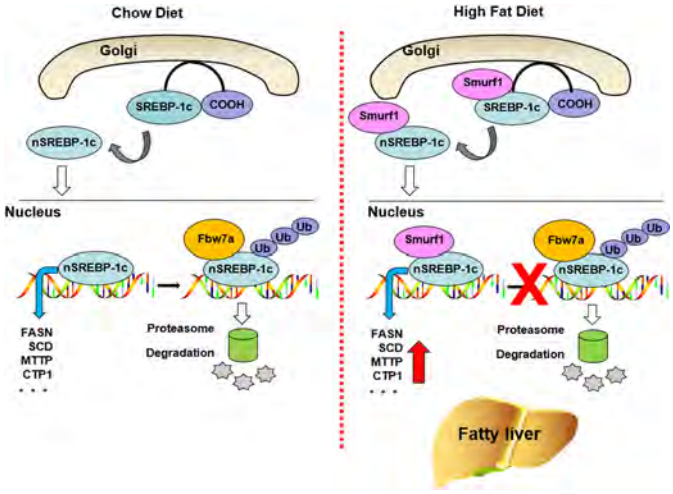

Figure legend: The proposed model for Smurf1 stabilizes SREBP-1c in E3-independent manner in fatty liver.

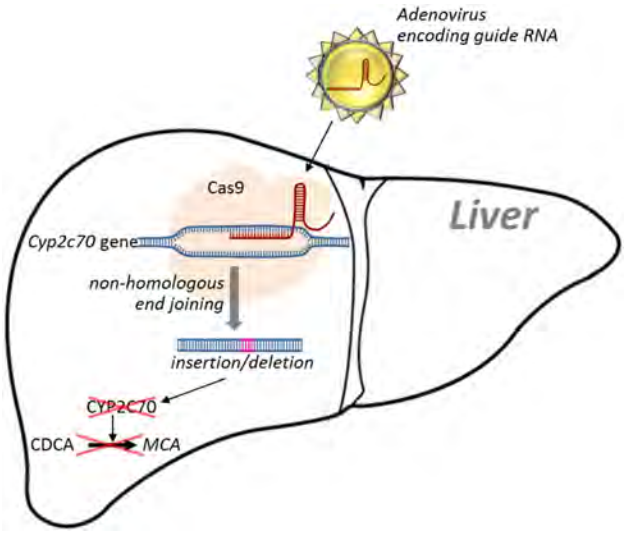
Conclusion: Results described in this study identify a previously unknown function of the Smurf1 in an E3-independent manner to regulate fatty liver development. Our findings unveil a novel mechanism underlying pathogenesis of liver steatosis and also provide a therapeutically potential target to combat NAFLD.

PS-038

A humanized bile acid pool induced by somatic CRISPR/Cas9-mediated deletion of Cyp2c70 modulates effects of pharmacological FXR activation in mice

Jan Freark de Boer[1,2], Esther Verkade[2], Niels L. Mulder[2], Hilde D. de Vries[1], Nicolette Huijkman[2,3], Martijn Koehorst[2], Theo Boer[1], Justina C. Wolters[2], Vincent W. Bloks[2], Bart van de Sluis[2,3], Folkert Kuipers[1,2]. *[1]University Medical Center Groningen, University of Groningen, Department of Laboratory Medicine, Groningen, Netherlands; [2]University Medical Center Groningen, University of Groningen, Department of Pediatrics, Groningen, Netherlands; [3]University Medical Center Groningen, University of Groningen, iPSC/CRISPR Center, Groningen, Netherlands*
Email: j.f.de.boer@umcg.nl

Background and aims: Bile acids (BAs) facilitate fat absorption but also modulate various metabolic pathways through activation of the BA receptors FXR and TGR5, which have been identified as targets for therapeutic interventions. However, fundamental differences in BA metabolism between humans and mice complicates translation of preclinical data. CYP2C70 was recently proposed to catalyze the formation of rodent-specific muricholic acids (MCAs). We generated an acute hepatic *Cyp2c70* knock-out mouse model, using somatic genome editing (see figure), to clarify the role of CYP2C70 in BA metabolism *in vivo* and to evaluate whether its activity modulates effects of pharmacological FXR activation on cholesterol homeostasis.
Method: The *Cyp2c70* gene was acutely ablated in adult mouse livers (*Cyp2c70*^{ako}) by CRISPR/Cas9-mediated somatic genome editing employing adenovirus-mediated delivery of single-guide RNA to Cas9-transgenic mice.
Results: Hepatic CYP2C70 protein levels were reduced by ~95% in *Cyp2c70*^{ako} mice. This translated into strongly increased contributions of chenodeoxycholic (CDCA) and ursodeoxycholic (UDCA) acids and a concomitantly reduced contribution of mouse-specific beta-MCA, resulting in a more hydrophobic BA pool ($p < 0.001$). Evaluation of *in vivo* CDCA and UDCA metabolism using D4-labeled tracers revealed 6beta-hydroxylase as well as C7-epimerase activity of CYP2C70, delineating its importance in generating the characteristic murine BA pool. Next, we assessed the impact of the humanized BA pool on the response to pharmacological FXR activation. The reduction of fractional cholesterol absorption observed in control mice upon FXR activation with PX20606 (54% to 20%, $p < 0.001$) was blunted in *Cyp2c70*^{ako} mice (47% to 34%, $p < 0.01$). Additionally, augmented fecal cholesterol disposal in response to FXR activation was impaired in *Cyp2c70*^{ako} mice ($p < 0.05$), predominantly due to reduced stimulation of transintestinal cholesterol excretion (TICE).



Conclusion: CRISPR/Cas9-mediated deletion of hepatic *Cyp2c70* in adult mice translates into a human-like BA pool composition and impacts the response to pharmacological FXR activation, emphasizing the importance to carefully consider the consequences of species-specific (BA) metabolism in pre-clinical studies.

PS-039

Role of ductular reaction on the hepatic microenvironment in chronic liver disease

Silvia Ariño Mons[1], Beatriz Aguilar-Bravo[1], Mar Coll[1,2], Ester Garcia-Pras[1,2], Javier Gallego[1,2], Elisa Pose[1,3], Delia Blaya[1], Isabel Graupera[1,3], Júlia Vallverdú[1], Teresa Rubio-Tomás[1], Juan José Lozano[1,2], Joan Caballería[1,2,3], Mercedes Fernández[1,2], Pere Ginès[1,2,3], Pau Sancho-Bru[1,2]. [1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain;* [2]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain;* [3]*Liver Unit, Hospital Clínic, Faculty of Medicine, University of Barcelona, Barcelona, Spain*
Email: psancho@clinic.cat

Background and aims: Ductular reaction (DR) expands in response to the loss of hepatocyte replicative capacity in chronic liver diseases. Yet, the role of DR in liver regeneration and its influence on the hepatic microenvironment is still not well understood. The aim of this study was to investigate the role of DR in tissue repair mechanisms such as inflammation, angiogenesis and fibrosis in the context of chronic liver disease.
Method: The hepatic transcriptomic profile was performed in normal liver tissue (n = 6) and patients with different stages of alcoholic liver disease (ALD) (n = 22). DR was obtained by laser microdissection of KRT7+ cells (n = 6) and analyzed by RNASeq. Hepatic organoids were generated from cirrhotic liver samples (n = 8), characterized by qPCR and ELISA and used as in vitro model of DR. The effect of organoids on: vasculogenesis was assessed on HUVEC cells cultured on Matrigel; neutrophils was evaluated by qPCR and Migratest; hepatic stellate cells (HSC) was evaluated by qPCR and wound-healing assay.
Results: Transcriptomic analysis of ALD samples showed the correlation of DR with the expression of inflammation, angiogenesis and fibrosis markers. Moreover, transcriptomic analysis of microdissected DR cells showed the expression of genes related to inflammation (*CXCL chemokines*), fibrogenesis (*LOXL, TIMP1, ACTA2*) and angiogenesis (*SLIT2, VWF, PECAM, VEGF*). Histological assessment showed that DR is associated with neutrophil infiltration, increased angiogenesis and fibrosis. Liver organoids generated from cirrhotic liver tissue expressed key markers of DR cells and showed a gene expression profile similar to DR cells. Moreover, organoids secreted inflammatory (CXCL5) and angiogenic factors (SLIT2), thus suggesting the potential of liver organoids as an in vitro system to model DR. Organoid conditioned medium promoted neutrophil migration and an increased expression of inflammatory cytokines (*IL1β* and *TNFα*). In addition, neutrophil conditioned medium up-regulated the expression of inflammatory chemokines (*CXCL chemokines*) in organoids, suggesting a crosstalk between DR and neutrophils. Regarding the potential role of DR in angiogenesis, organoid conditioned medium induced tubule formation in HUVEC cell cultures, which was dependent on SLIT2 production by organoids. Finally, organoid conditioned medium enhanced HSC activation and wound-healing response.
Conclusion: These results suggest that DR interacts with inflammatory cells, HSCs and vascular cells. In the context of chronic liver diseases, DR may exert an influence on the hepatic microenvironment and tissue repair mechanisms such as inflammation, angiogenesis and fibrosis.

PS-040

Bacterial infection upregulates TGR5 expression in a Krüppel-like-factor 5-dependent manner

Maria Reich[1], Kathleen Deutschmann[1], Jan Stindt[1], Haifeng C. Xu[2], Philipp Lang[2], Dieter Häussinger[1], Verena Keitel[1]. [1]*Clinic for Gastroenterology, Hepatology and Infectious Diseases, University Hospital Düsseldorf, Düsseldorf, Germany;* [2]*Department of Molecular Medicine II, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany*
Email: maria.reich@uni-duesseldorf.de

Background and aims: G protein-coupled bile acid receptor 1 (GPBAR1, TGR5) is one of the major effectors in bile acid sensing with demonstrated influence on metabolic, inflammatory, and proliferative processes. TGR5 is abundantly expressed in monocytes/macrophages and its activation in these cells is associated with a reduced nuclear factor kappa B (NFkB)-dependent inflammatory responses. The transcription factor Krueppel-like factor 5 (KLF5) has been shown to associate with NFκB to regulate genes involved in inflammation. Aim of our study was to investigate the role of KLF5 in the upregulation of TGR5 in inflammatory liver disease using different mouse models.
Method: TGR5 and KLF5 mRNA expression in *bone marrow-derived macrophages* (BMDMs) as well as in mice livers and human peripheral blood mononuclear cells (PBMC) were quantified by real-time PCR in relation to an endogenous control (HPRT1). Binding of the transcription factor KLF5 to the TGR5 promoter was verified by Chromatin Immunoprecipitation (ChIP). The survival of the TGR5 knockout (KO) and wildtype (WT) mice was monitored after the injections with 22, 5 µg/g BW lipopolysaccharide (LPS) or infection with 8×10^4 CFU/ml *Listeria monocytogenes (L.m.)*. Serum levels of AST and ALT were analyzed by using Spotchem-biochemical analyzer. Flow cytometry has been used to examine immune cells in non-lymphoid tissues.
Results: TGR5 and KLF5 mRNA expression was significantly upregulated in murine BMDMs or human PBMC as well as in livers from WT mice after LPS injection or *L.m.* infection. Furthermore, TGR5 staining in CD11 positive macrophages in the mouse liver was increased. Chromatin immunoprecipitation confirmed binding of KLF5 to the TGR5 promotor region. KLF5 increased the TGR5 promoter activity and the effect was lost when the binding sites for KLF5 in the TGR5 promoter region were mutated. LPS and L.m. injection resulted in severe liver injury in TGR5 deficient mice as determined by AST and ALT elevation. Moreover, mortality was significantly increased in TGR5 knockout mice. This phenotype was mirrored by immune-cell specific TGR5 knockout mice.
Conclusion: The TGR5 and KLF5 mRNA expression was significantly upregulated in murine and human macrophages and livers of WT animals after LPS injection or Listeria infection, indicating that TGR5 may confer protective effects in the WT animals, most likely through KLF5. In contrast, TGR5 deficient mice manifest increased mortality after LPS or L.m. injection underscoring the important role of TGR5 in inflammatory liver disease.

Liver tumours – Experimental

Email: stefan.thomann@med.uni-heidelberg.de

Background and aims: In hepatocarcinogenesis capillary endothelial cells (CECs) gradually replace liver sinusoidal endothelial cells (LSECs) in a tumour-supportive process termed capillarization. An in-depth molecular characterization of LSECs, CECs and liver macrophages in hepatocarcinogenesis is however still missing.
Method: An inducible mouse model with hepatocyte-specific expression of the constitutively active oncogene yes-associated protein (YAPS127A) was used to purify primary LSECs, CECs and liver macrophages. RNA was subjected to transcriptomic profiling. Predicted paracrine interactions were functionally tested in vitro. Kinase inhibition by Cabozantinib in vivo served as a model of HGF/c-Met axis perturbation.
Results: A progressive expansion of CECs from 4 ± 2% in healthy livers to 61 ± 30% in YAP induced hepatocellular carcinomas (HCCs) was observed. Transcriptome data revealed an intense paracrine crosstalk between CECs and LSECs including the ligand/receptor pairs VEGFC/Flt4, CXCL12/CXCR4, and the HGF/c-Met. Interestingly, a dynamic upregulation of c-Met was detected in CECs, while HGF was exclusively expressed by LSECs. Functionally, HGF stimulation of endothelial cells was associated with increased cell motility. In vivo, perturbation of the HGF/c-Met axis by Cabozantinib led to a 67% reduction of CEC sprouting. CEC expansion was also associated with an upregulation of myeloid recruiting genes. Indeed, a perivascular recruitment of CD11b+ F4/80+ macrophages was observed that lacked the typical Kupffer cell expression signature. Lastly, capillarization served as a prognostic biomarker in human HCCs and was associated with increased M0 macrophage infiltration.
Conclusion: A crosstalk between LSECs and CECs in hepatocarcinogenesis initiates capillarization. Angiogenesis perturbation could synergistically prevent tumour progressive capillarization and inhibit an influx of disease-modifying myeloid cells.

PS-042
Interventional targeting of cyclin E1 during hepatocarcinogenesis limits stem cell traits and hepatic myeloid cell homing and attenuates cancer progression

Roland Sonntag[1], Marlene Kohlhepp[1], Antje Mohs[1], Ute Haas[1], Daniela Lambertz[1], Frank Tacke[1], Christian Trautwein[1], Christian Liedtke[1]. *[1]University Hospital Aachen, RWTH Aachen University, Department of Medicine III, Aachen, Germany*
Email: rsonntag@ukaachen.de

Background and aims: Hepatocellular carcinoma (HCC) is one of the most severe tumor diseases with increasing incidence and limited treatment options. HCC initiation and progression are associated with persistent proliferation of hepatocytes and non-parenchymal cells. Proliferation is related to cell cycle activity, which is basically regulated by cyclins and Cyclin-dependent kinases (Cdks). E-Type cyclins (Cyclin E1, E2) and their canonical binding partner Cdk2 are key mediators of early cellular DNA replication. Own work demonstrated an essential role of Cyclin E1 and Cdk2 specifically for initiation of HCCs in a murine prevention model (Sonntag et al., PNAS 2018 Sep 11;115 (37):9282-9287). In the present study, we investigated the therapeutic benefit of Cyclin E1 or Cdk2 gene targeting after onset of hepatocarcinogenesis (intervention model).
Method: In this study, conditional Cyclin E1 (CcnE1f/f) or Cdk2 (Cdk2f/f) mice in a C57B6/J background with inducible Cre-recombinase under control of the Mx-gene promoter were used. For HCC induction, 14 days old male mice were intraperitoneally (i.p.) injected with diethylnitrosamine (DEN). Cre-negative littermates were used as controls. After 22 weeks (stage of early HCC), interventional inactivation of Cyclin E1 or Cdk2 in hepatocytes and the hematopoietic cell compartment was performed by three i.p. injections of poly-I:poly-C. Two weeks and 16 weeks after intervention, mice were analyzed for tumor burden, proliferation, stemness, DNA repair and the microenvironment composition to determine immediate and long term treatment effects.
Results: At the age of 40 weeks, interventional inactivation of Cyclin E1 resulted in a significant reduction of tumor numbers and size compared to DEN-treated control mice. This finding was associated with a decreased overall hepatic proliferation and intratumoral down-regulation of cell cycle activators, tumor markers, stem cell traits and vascularization. Already two weeks after intervention, Cyclin E1 deletion significantly reduced the expression of pro-proliferative genes. Importantly, Cyclin E1-independent growth in remnant tumors was associated with sustained expression of DNA repair genes. Moreover, Cyclin E1 inactivation also changed the composition of the myeloid HCC microenvironment (e.g. myeloid-derived suppressor cells) pointing to a new role of Cyclin E1 for immune progenitor cell homing during liver cancer development. In sharp contrast, interventional inactivation of Cdk2 after onset of hepatocarcinogenesis did not reveal any beneficial effect on tumor burden.
Conclusion: Cdk2 is essential for HCC initiation, but surprisingly fully dispensable for HCC progression. However, interventional inactivation of Cyclin E1 during early HCC progression attenuates disease development. Hence, Cyclin E1 presents a promising therapeutic target for treatment of HCC patients.

PS-043
Dual targeting of G9a and DNM-methyltransferase-1 for the treatment of experimental cholangiocarcinoma

Email: maavila@unav.es

Background and aims: Cholangiocarcinoma (CCA) is a deadly disease usually diagnosed at advanced stages when treatment options are limited. CCAs are histologically and molecularly heterogeneous tumors highly resistant to systemic therapies, and targeted drugs are yet to prove their efficacy. Identification of novel targets for CCA treatment is therefore necessary. Epigenetic alterations are increasingly recognized in CCAs which may constitute druggable targets. DNA and histone methylation reactions functionally cooperate in fostering tumor growth. We evaluated the therapeutic efficacy of a first-in-class substrate-competitive dual G9a H3K9-methyltransferase and DNA-methyltransferase 1 (DNMT1) inhibitor in different *in vitro* and *in vivo* CCA models.
Method: G9a and DNMT1 mRNA and protein levels were examined in human CCA tissues by qPCR and immunohistochemistry. Dual targeting of G9a and DNMT1 was examined in CCA cells by

combination treatment with the G9a and DNMT inhibitors BIX-01294 and decitabine. Anti-CCA efficacy of our G9a/DNMT1 inhibitor lead compound, CM-272, was tested in human CCA cells, alone and in combination with cisplatin, Mcl-1 or ErbB inhibitors. Microarray transcriptomic analyses were performed in two CCA cell lines treated with CM-272. CM-272 was also tested in subcutaneous and orthotopic mouse xenografts of human CCA cells, and in a new model of cholangiocarcinogenesis (mice with JNK1/2 deletion in hepatocytes, $JNK^{\Delta hepa}$).

Results: G9a and DNMT1 expression was increased in human CCA samples and CCA cell lines compared to non-transformed tissues and cells. Combined treatment of CCA cells with BIX-01294 and decitabine resulted in synergistic growth inhibition. CM-272 showed GI50 values in the nanomolar range in six human CCA cell lines and markedly inhibited their colony formation capacity. CM-272 synergized with cisplatin, an Mcl-1 inhibitor, or the ErbB pathway inhibitors afatinib or lapatinib in the inhibition of CCA proliferation. CM-272 inhibited the growth of subcutaneous and orthotopic CCA xenografts, and the development of preneoplastic CCA lesions in $JNK^{\Delta hepa}$ mice. In CM-272 treated mice no systemic or hepatic toxicity were observed. Mechanistically, microarray analyses showed that CM-272 induced a strong metabolic reprogramming and interfered with growth factor signaling pathways in CCA cells

Conclusion: Pharmacologic interference with G9a and DNMT1 might be a promising strategy for the development of effective therapies against CCA

PS-044

Identification of a pan-gamma-secretase inhibitor response signature for notch-driven cholangiocarcinoma

Colm O Rourke[1], Matthias Matter[2], Chirag Nepal[1], Phuongnga Ton[3], Valentina Factor[4], Jesper Andersen[1]. [1]*Biotech Research and Innovation Centre (BRIC), University of Copenhagen, Copenhagen, Denmark;* [2]*Institute of Pathology, University Hospital Basel, Basel, Switzerland;* [3]*Molecular Imaging Program, National Cancer Institute, NIH, Bethesda, MD, United States;* [4]*Laboratory of Molecular Pharmacology, Center for Cancer Research, National Cancer Institute, NIH, Bethesda, MD, United States*
Email: colm.rourke@bric.ku.dk

Background and aims: Cholangiocarcinoma (CCA) mortality rates are increasing. NOTCH pathway reactivation has been reported in CCA to conflicting degrees, hindering prioritization of therapeutic targets and identification of candidate responder patients for NOTCH-directed therapies. As 40% of NOTCH-directed clinical trials in cancer have been terminated or withdrawn, thorough guidelines for patient selection are clearly required. Here, we identified a transcriptomic signature capable of predicting pan-γ -secretase inhibitor (GSi) response across multiple patient cohorts and CCA models, as well as diverse cancer types.

Method: Transcriptomes were analyzed from 341 CCA patients. Models of GSi-sensitivity and -resistance were initially identified from 13 CCA cell lines *in vitro*, followed by subcutaneous CCA xenograft models. The responder signature was developed by transcriptome profiling of murine tumors and tested for enrichment across diverse hydrodynamic models and patient subgroups. Pan-cancer analysis of this signature was also pursued in 9409 patient tissues (31 cancer types) and 60 cancer cell lines.

Results: A *NOTCH1*^{high} CCA patient subgroup was identified, characterized by distinct stromal infiltration and lymph node metastasis. Extensive NOTCH network imbalance, including multiple ligand and receptor usage, identified the γ-secretase (GS) complex as an optimal therapeutic target. Treatment using two GSi classified HuCCT-1 and WITT as models of sensitivity and resistance, respectively. Subcutaneous transplantation of sensitive and resistant CCA cell lines pre-treated with a GSi cocktail demonstrated anti-neoplastic effects in the sensitive model only and led to development of a 225-gene responder signature. This signature was enriched in intrahepatic tumors developed by hydrodynamic injections of activated NOTCH as compared to AKT-RAS-driven tumors ($p < 0.001$), as well as in a subgroup of CCA patients ($p = 0.0232$). Candidate GSi-responder patients were characterized by grossly unique intra-tumoral stromal reaction and signaling pathways, as well as metastasis ($p = 0.0078$) and cancer stemness ($p = 0.0142$) signatures. Pan-cancer analysis identified 41.9% cancers to harbor prospective GSi-responder patients. This signature was also capable of discriminating nanomolar versus micromolar sensitivity of 60 tumor lines to GSi with an AUC of 1 (versus AUC:0.50-0.61 for *NOTCH* receptor expression).

Conclusion: Identification of this pan-GSi-responder signature may facilitate precision medicine application of NOTCH-directed therapy in CCA as well as prospectively across diverse malignancies. This is supportive of basket trial approaches using this theranostic signature.

PS-045

HCC promotes autophagy in hepatic stellate cells, leading to HCC progression via IL-6/STAT3 signaling

Yuta Myojin[1], Hayato Hikita[1], Takahiro Kodama[1], Yuki Makino[1], Ryoko Yamada[1], Yoshinobu Saito[1], Tasuku Nakabori[1], Ryotaro Sakamori[1], Tomohide Tatsumi[1], Tetsuo Takehara[1]. [1]*Osaka University, Graduate School of Medicine, Department of Gastroenterology and Hepatology, Suita, Osaka, Japan*
Email: myojin@gh.med.osaka-u.ac.jp

Background and aims: Autophagy, a system of degradation of proteins and organelles, in hepatoma cells is supposed to promote the progression of cancer. However, the effect of autophagy in hepatic stellate cells on hepatocellular carcinoma (HCC) has not yet been clarified.

Method: HepG2 cells were used as human hepatoma cells and LX2 cells as human HSCs. Autophagy was examined from the ratio of the fluorescence intensities of GFP and RFP using LX2 cells overexpressing GFP-LC3-RFP-LC3ΔG probe. HSC-specific Atg7 knockout (G-Atg7 KO mice) mice were generated by crossing GFAP-Cre mice and Atg7 fl/fl mice. These mice were administered streptozotocin at the age of 2 days followed by a high-fat diet feeding.

Results: When co-culturing LX2 cells with HepG2 cells, autophagy in LX2 cells was promoted and cell viability in HepG2 cells were increased. TaqMan Array using chemokine panel revealed WNT2, CER1, IL1B and IL6 expression levels were significantly increased in LX2 cells co-cultured with HepG2 cells. Among them, only IL-6 was detected by ELISA in co-cultured medium of LX-2 and HepG2 cells. Their IL-6 levels were significantly higher than those in LX2 mono-cultured medium, while IL-6 in HepG2 mono-culture medium was not detected. siRNA-mediated knockdown of Atg7 in LX2 cells decreased IL-6 levels in cultured medium. Co-culture with LX2 cells increased cell viabilities with pSTAT3 activation in HepG2 cells, which was attenuated by siRNA-mediated knockdown of Atg7 in LX2 cells. HepG2 cells, but not LX2 cells, were successfully engrafted into NOG mice. The growth of xenograft tumor of HepG2 cells in NOG mice was accelerated by co-transplantation with LX2 cells. The acceleration was suppressed by Atg7 KO using CRISPR-Cas9 system in LX2 cells.
Wild-type (WT) mice or HSC-Atg7 KO mice were administrated with streptozotocin, and fed a high fat diet. Atg7 was efficiently inhibited in stellate cells isolated from HSC-Atg7 KO mice. At 20 weeks of age, there was no significant difference in fat body weight ratio, body weight, blood glucose level, serum ALT and insulin levels between them. Macroscopic tumor formation rate was lower in G-Atg7 KO mice than WT mice. The maximum size of liver tumors were significantly suppressed in G-Atg7 KO mice (2.0 ± 2.1mm v.s. 10.0 ± 5.8mm ($p = 0.002$)) with decrease in pSTAT3 expression levels of tumor lesions.The number of liver tumors were also significantly suppressed in G-Atg7 KO mice.

Conclusion: HCC promotes autophagy in stellate cell, which modulates inflammatory cytokine such as IL-6, leading to progression of HCCs.

PS-046

Suppression of complex protumorigenic phenotypes in chronic injury-associated hepatocarcinogenesis is dependent on IL-6/STAT3 signaling

Anat Shriki[1], tali lanton[1], Amir Sonnenblick[2], Orr Levkovitch[1], Rinat Abramovitch[1], Lina Mizrahi[1], Devorah Olam[1], Orit Pappo[2], Sharona Elgavish[3], Amnon Peled[1], Stefan Rose-John[4], Eithan Galun[1], Jonathan Axelrod[1]. [1]*Hadassah Hebrew University Hospital, Goldyne Savad Inst. of Gene Therapy, Jerusalem, Israel;* [2]*Hadassah Hebrew University Hospital, Jerusalem, Israel;* [3]*Hebrew University of Jerusalem, Jerusalem, Israel;* [4]*University of Kiel, Kiel, Germany*
Email: axelrod@hadassah.org.il

Background and aims: Hepatocelluar carcinoma (HCC) typically develops on a background of chronic hepatitis. Evidence from chemical-induced HCC associated experimental models with acute liver injury indicates that interleukin-6 (IL-6) is a crucial factor driving hepatocarcinogenesis. However, in chronic liver injury, where IL-6 is an established hepatoprotective factor, its role in hepatocarcinogenesis remains unresolved. We investigated the roles of IL-6 and signal transducer and activator of transcription 3 (Stat3) in liver cancer in multidrug resistant gene 2 knockout mice ($Mdr2^{-/-}$), which develop primary sclerosing cholangitis and are a physiologically relevant model of hepatitis-associated HCC.
Method: IL-6 knockout ($IL\text{-}6^{-/-}$) mice, and hepatocyte-targeted Stat3 knockout mice ($Stat3^{\Delta hep}$), were crossed into $Mdr2^{-/-}$ mice generating $Mdr2^{-/-}IL6^{-/-}$ and $Mdr2^{-/-}Stat3^{\Delta hep}$ mice, respectively. Additionally, the transgene encoding sgp130Fc (a selective inhibitor of soluble IL-6 receptor sIL-6R mediated trans-signaling) was introduced to generate $Mdr2^{-/-}$sgp130Fc mice. Mice were followed for the development of hepatitis and tumorigenesis over the course of 14 months.
Results: IL-6/Stat3 signaling deficient $Mdr2^{-/-}$ mice of both genders displayed increased liver injury (ALT) and fibrosis from an early age together with increased dysplastic nodule formation and uniformly presented with accelerated and increased tumorigenesis. Gene expression and bioinformatics analyses of female WT, $Mdr2^{-/-}$, and $Mdr2^{-/-}IL6^{-/-}$ mice revealed close associations of the aggravated tumorigenesis with the presence of four aberrant, HCC-linked phenotypes in the IL-6 deficient mice: i) reduced hormone-mediated protection; ii) hepatosteatosis; iii) inflammation and iv) cellular senescence. But, ovariectomy of $Mdr2^{-/-}$ mice reduced liver injury and tumorigenesis, and dietary restriction experiments, although reducing steatosis, did not affect tumorigenesis; thus ruling out loss of hormonal-protection and hepatosteatosis as underlying causes. Immunostaining analysis confirmed the increased inflammatory status, particularly involving macrophage (F4/80) infiltration. Cellular senescence, as indicated by levels of p21, γH2AX, and SASP factors (TGFβ, Mmp2, Timp1 and Timp2), was strongly reduced in young (3 months) IL-6 signaling deficient $Mdr2^{-/-}$ mice, but surprisingly increased in older mice (14 months). In contrast, expression of other SASP factors, including PAI-1, Cxcl14, cGAS and STING, were significantly reduced at all ages; together suggesting a strong, age-dependent disruption in cellular senescence and the SASP in IL-6 deficient strains.
Conclusion: Loss of IL-6/Stat3 signaling strongly aggravates hepatocarcinogenesis in $Mdr2^{-/-}$ mice associated with a profound age-dependent disruption in cellular senescence and increased macrophage infiltration.

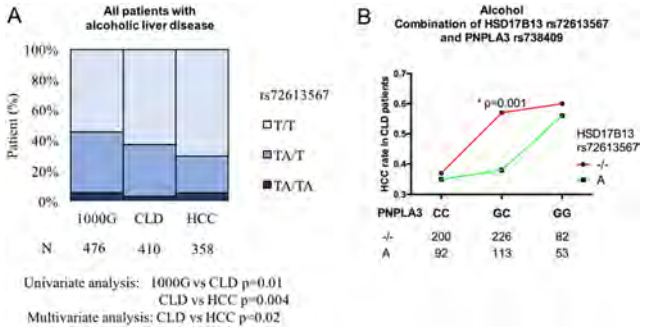
Email: naultjc@gmail.com

Background and aims: Recently, a loss of function variant (rs72613567) of 17-beta-hydroxysteroid dehydrogenase 13 (HSD17B13) has been identified as protective in non-alcoholic and alcoholic liver disease. However, the role of this SNP in hepatocellular carcinoma (HCC) development is currently unknown. We aimed to assess the impact of this variant in European patients with HCC developed on chronic liver disease (CLD) of various severities and etiologies.
Method: HSD17B13 rs72613567, PNPLA3 rs738409 and TM6SF2 rs58542926 were genotyped using a case control study design including 1018 patients with HCC (mean age 64 years, 83% of male, alcoholic liver disease 35%, hepatitis C 25%, non-alcoholic liver disease (NAFLD) 12%), 988 patients with CLD without HCC (mean age of 55 years, 68% of male, alcoholic liver disease 42%, hepatitis C 33% and NAFLD 18%) as well as 503 healthy individuals from 1000genome project all from European descent. We compared the genotype distribution between CLD patients and healthy controls from the 1000genome project, and between HCC patients and CLD patients using Chi-square test and logistic regression.
Results: Heterozygous T/TA of HSD17B13 were significantly less frequent in patients with CLD (32%, P = 0.001) and in cirrhotic patients (31%, P = 0.0008) compared to healthy control of 1000genome population (40%). Among etiologies of CLD, heterozygous T/TA of HSD17B13 was less frequent in patients with CLD due to chronic alcohol intake (34%; p = 0.03), chronic hepatitis C (32%, p = 0.01) and chronic hepatitis B (23%, p = 0.005) compared to healthy population (40%) suggesting a protective role of HSD17B13 rs72613567 in the progression of chronic liver disease.
In patients with HCC developed on alcoholic liver disease, T/TA genotype of HSD17B13 rs72613567 was less frequent (24%) than in CLD patients with alcoholic liver disease and without HCC (34%, P = 0.004) and the protective effect of the T/TA genotype remains significant after adjustment for age, gender and the stage of fibrosis in multivariate analysis (OR = 0.6 CI95% = 0.4-0.9 P = 0.03). In contrast, no robust association between HSD17B13 genotype and HCC risk was identified in other etiologies. PNPLA3 rs738409 (GC vs. CC: OR = 2.4 [1.6-3.6]; GG vs. CC: OR = 3.8 [2.3-6.3]) and TM6SF2 rs58542926 (CT +TT vs. CC: OR = 1.9 [1.3-2.9]) were both strongly associated with the risk of alcohol related HCC. Interestingly, the T/TA genotype of HSD17B13 rs72613567 was protective of HCC in patients with alcoholic liver disease harboring the at-risk CG allele of PNPLA3 rs738409 (OR = 0.4[0.2-0.7]; p = 0.001) but not in patients harboring the at-risk allele of TM6SF2.



Conclusion: Loss of function variant of HSD17B13 (rs72613567) is protective of HCC development on alcoholic liver disease, especially in patients harboring the at-risk allele of PNPLA3 rs738409.

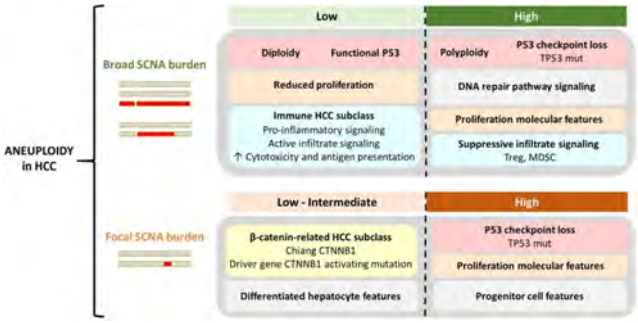
Email: jmllovet@clinic.cat

Background and aims: Aneuploidy is a hallmark of cancer that includes broad somatic copy-number alterations (SCNAs), being whole chromosome- or arm-level events, and smaller focal SCNAs. Pan-cancer studies suggest that distinctive molecular/clinical traits are linked to either broad or focal SCNA loads, with the first potentially interfering with tumor immune infiltrates. We aimed at assessing broad and focal SCNA burdens in hepatocellular carcinoma (HCC) to unveil associated clinic-molecular characteristics and immune cell profiles. We propose SCNA scores that predict low/high burdens and chromosomal instability.

Method: The study includes 520 paired tumor/adjacent surgically resected HCC samples: 150 of a training cohort (HEPTROMIC) and 370 of a validation cohort (TCGA). We extracted tumor ploidy and SCNAs from SNP array data using ASCAT and SAASCNV. Based on SCNA number, amplitude and length, we created a Broad SCNA Score (BSS) to assess broad SCNA loads in each sample, and a Focal SCNA Score (FSS) to determine focal SCNAs loads (being broad and focal those alterations spanning ≥ 50% and < 50% of a chromosome arm, respectively). The scores were integrated with gene expression profiling, clinic-pathological data from tumors and the composition of the tumor immune infiltrate, which was determined using the Immunophenoscore.

Results: HCC tumors characterized by a low BSS (25% of Heptromic, 15% of TCGA) were associated with the HCC Immune class and upregulation of genes related to inflammation, active infiltrate signaling, antigen presentation and cytolytic activity (FDR < 0.1, p < 0.05). Conversely, high BSS tumors (25% Heptromic, 45% TCGA) were linked to polyploidy, TP53 loss of function, were enriched in DNA repair and proliferation gene signatures and presented upregulation of genes from immune suppressor cells. On the other hand, tumors with high FSS (25% Heptromic, 49% TCGA) were associated with *TP53* loss of function and upregulation of genes related to proliferation and progenitor cells, whereas low-intermediate FSS tumors displayed higher β-catenin pathway activity, with enrichment in *CTNNB1* mutations. FSS was not associated with immunity profiles.



Conclusion: Broad are more informative than focal SCNA burdens in terms of molecular features and immune status. Tumors with low Broad SCNA Scores, thus with chromosomal stability, are enriched in the immune class of HCC, and might correspond to those tumors responding to checkpoint inhibitors.

Hepatitis B/D/E – Clinical aspects

Tenofovir alafenamide for hepatitis B virus prophylaxis post-liver transplantation is associated with improved renal function: An interim analysis of a multicenter real-world experience

Ryan Perumpail[1], Saro Khemichian[2], Krutika Lakhoo[3], Alexander Do[1], Gina Choi[1], Francisco Durazo[1], Mohamed El-Kabany[1], Sammy Saab[1], Ronald Busuttil[4], Steven-Huy Han[1]. *[1]David Geffen School of Medicine at UCLA, Vatche and Tamar Manoukian Division of Digestive Diseases and Pfleger Liver Institute, Los Angeles, United States; [2]University of Southern California, Liver Transplantation Program, Los Angeles, United States; [3]Cedars-Sinai Medical Center, Medicine, Los Angeles, United States; [4]David Geffen School of Medicine at UCLA, Surgery and Pfleger Liver Institute, Los Angeles, United States*
Email: rperumpail@mednet.ucla.edu

Background and aims: Tenofovir alafenamide (TAF) has been shown to be equally efficacious in suppressing hepatitis B virus (HBV) but with less renal toxicity than tenofovir disoproxil fumarate (TDF). Post-liver transplantation (LT) patients are especially prone to renal effects due to calcineurin inhibitor immunosuppression. Therefore, we conducted a multicenter real-world study to evaluate renal function in post-LT patients on TAF.

Method: Post-LT patients receiving HBV antiviral therapy at 3 tertiary liver transplant centers in Southern California (University of California Los Angeles [UCLA], Cedars-Sinai [Cedars], University of Southern California [USC]) were enrolled. There were two arms: the intervention cohort underwent crossover from existing HBV antiviral agent to TAF; the control cohort remained on existing HBV antiviral agent. Study assessments were based on 48-week follow-up from baseline or time of conversion to TAF-based prophylactic therapy. We used the two-sample t-test to compare mean differences in serum

creatinine following one year of TAF therapy compared to the control group. 23 additional patients have yet to complete 48 weeks of TAF therapy and are not included in this interim analysis.
Results: There were 52 patients (UCLA: n = 26; Cedars: n = 13; USC: n = 13) in the intervention (TAF) cohort and 47 patients in the control cohort (TDF 70%; entecavir 26%; lamivudine 4%) (Table). Patients who transitioned to TAF had a significant mean decrease in serum creatinine, compared to the control cohort (-0.07 mg/dL 95% CI [−0.14 to −0.01] vs. 0.04 mg/dL [0.01 to 0.08]; p = 0.0043) after 48 weeks of therapy (Figure). In the TAF cohort, the mean serum creatinine decreased after 48 weeks at each center: UCLA −0.08 range [−0.58 to 1.03]; Cedars −0.08 [−0.31 to 0.06]; USC −0.03 [−0.36 to 0.18]. There were no differences in post-LT outcomes (rejection episodes, re-LT, death) between the two cohorts.

Table: Baseline characteristics

	Intervention (n = 52)	Control (n = 47)
Age	61 (9)	60 (10)
Sex		
Female	7 (13%)	15 (32%)
Male	45 (87%)	32 (68%)
Race/Ethnicity		
Asian	39 (75%)	28 (60%)
White	10 (19%)	11 (23%)
Hispanic	2 (4%)	8 (17%)
Black	1 (2%)	0 (0%)
Serum Cr at baseline	1.42 (0.44)	1.12 (0.31)
Serum Cr after 48 weeks	1.35 (0.45)	1.17 (0.32)

Data are n (%) or mean (standard deviation). Cr = creatinine.

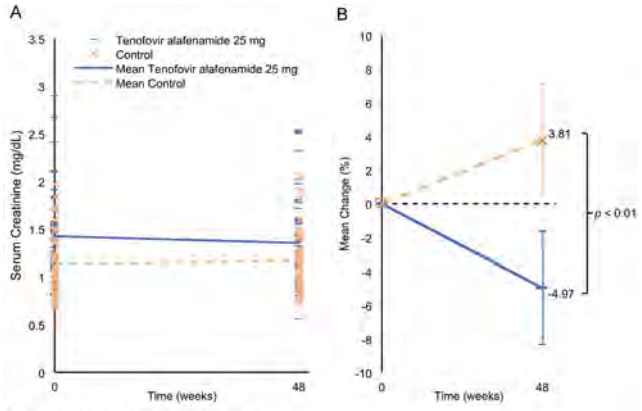

Figure: **Changes in serum creatinine**
(A) Mean serum creatinine and serum creatinine per patient at baseline and after 48 weeks of treatment.
(B) Mean percent change in serum creatinine at baseline and after 48 weeks of treatment. Bars are 95% CI.

Conclusion: Conversion to TAF in post-LT patients requiring HBV prophylaxis is associated with significant improvement in renal function, compared to a control cohort.

PS-050
Integrated analyses of both human and HBV genome to predict HCC Development

Masaya Sugiyama[1], Nishida Nao[1], Katsushi Tokunaga[2], Mizokami Masashi[1]. [1]*National Center for Global Health and Medicine, Ichikawa, Japan;* [2]*The University of Tokyo, Tokyo, Japan*
Email: msugiyama@hosp.ncgm.go.jp

Background and aims: Hepatitis B virus (HBV) infection is a major cause of hepatocellular carcinoma (HCC). Clinical outcomes are induced by interactions between viral and host factor. Especially, a prediction marker of HCC development provides great benefits for clinician and patients. In the present study, we determined a host genetic factor associated with HBV-derived HCC, and discovered viral genetic factors corresponding to the host genetic variation.
Method: Total 2, 996 individuals were enrolled from 10 hospitals, 408 chronic hepatitis B (CHB) patients, 307 HBV-derived HCC patients, and 2, 281 healthy volunteer (HV). Human genetic data were obtained from SNPs array and Luminex method for HLA genotype. These genetic data were filled up by imputation techniques. For viral genome analysis, HBV DNA was extracted from serum of CHB or HCC patients and was prepared for next-generation sequencing (NGS). All sequence reads were converted from nucleic acid into amino acid (AA) sequences. Multiple comparisons were counteracted by statistical method.
Results: By genome-wide association study using SNPs and HLA genotype, HLA-DPB1*02:01 was an independent protection factor against HCC development ($p < 4.53x10-9$, OR = 0.53). HLA-DPB1*04:01 was statistically associated with the protection against CHB establishment ($p < 6.49x10-6$, OR = 0.31). Next, we focused on viral genomic factor related with HCC development. Patients with HLA-DPB1*02:01 homozygote were divided into HCC and non-HCC group with age-, sex-, HBV genotype-matched condition. The half of the samples was used for test set. AA variations of HBV protein were restricted to particular patterns in PreS/S protein in the HCC group with the HLA-DPB1*02:01. The ratio of S166 in CHB and HCC was 51.5% and 0%, respectively ($p < 0.05$). However, the ratio of L166 in CHB and HCC was 34.3% and 99.4%, respectively ($p < 0.05$). The mutation was confirmed using validation sample set. S166L mutation was also associated with HCC development ($p < 0.02$, OR = 18.2). In addition, we determined the effect of S166L mutation in HLA-DPB1*02:01 heterozygote with or without HCC. S166L mutation was statistically associated with HCC patients with the heterozygotes ($p < 0.05$, OR = 1.6). But, S166L mutation in PreS/S didn't change AA sequence in HBV polymerase.
Conclusion: We detected host and viral genetic factors related with clinical outcomes. Hepatitis B patients with both HLA-DPB1*02:01 allele and S166 in PreS/S were low risk for HCC development. However, when they had L166 mutation, they had high risk for HCC. A specific AA change in the HBV antigen could affect HCC development by interaction change between host and virus. This is a proof of concept study in order to predict a prognosis using genomic data in hepatitis B.

PS-051
Mortality and morbidity of hepatitis E in scotland: A multicentre study

Sebastian Wallace[1], Rachael Swann[2], Linda Kemp[3], Leanne Stratton[4], Mhairi Donnelly[4], Aimee Murray[2], Johannes Spoor[2], Michael Miller[3], Harry Dalton[5], Kenneth J. Simpson[4], Adrian Stanley[2], Andrew Fraser[1]. [1]*NHS Grampian, Gastroenterology, Aberdeen, United Kingdom;* [2]*N H S Greater Glasgow and Clyde, Gastroenterology, Glasgow, United Kingdom;* [3]*NHS Tayside, Gastroenterology, Dundee, United Kingdom;* [4]*NHS Lothian, Gastroenterology, Edinburgh, United Kingdom;* [5]*Royal Cornwall Hospital, Gastroenterology (retired), Truro, United Kingdom*
Email: basswallace86@gmail.com

Background and aims: In the past decade Hepatitis E virus (HEV) infection has become the most common acute viral hepatitis in Scotland. Little is known about the burden of morbidity and mortality, which can be high in chronic liver disease and Immunosuppressed patients. Infection is also associated with nerve and kidney injury. The study aims to record the morbidity and mortality for all cases of HEV in four Scottish health boards.
Method: Demographic, clinical and laboratory data were collected retrospectively from all cases of HEV reported to virology departments within NHS Greater Glasgow and Clyde, NHS Grampian, NHS Tayside and NHS Lothian. Hospital records were reviewed by clinicians working within each hospital. Data was anonymised at hospital level.

Results: A complete, five-year dataset was obtained from Glasgow (n = 187) and Grampian (n = 96) between January 2013 and January 2018, further cases were included from Tayside (n = 72) and Lothian (n = 16) with data collection ongoing (n = 371, Mean age of 60yrs, 63% male). 41 (11.1%) cases had cirrhosis and 86 (23.2%) had diabetes. HEV infection affected 13 transplant patients in a total of 58 immunosuppressed cases (15.6%).
242 (65%) patients required admission, totalling 2255 inpatient-bed-days (median stay 3 days). 13 (3.5%) HEV related deaths were recorded, 10 with pre-existing liver disease and 3 with immunosuppression. 21 (5.7%) patients required admission to critical care. 27 (7.3%) patients developed acute, acute-on-chronic or decompensated liver failure with 2 requiring transplantation.
35 (9.4%) reported neurological symptoms with 8 developing neuralgic amyotrophy, 6 Guillain-Barré, and 2 encephalitis. 36 (9.7%) patients had a documented Acute Kidney Injury. 14 (3.8%) cases were documented as chronic HEV, 12 received Ribavirin therapy.

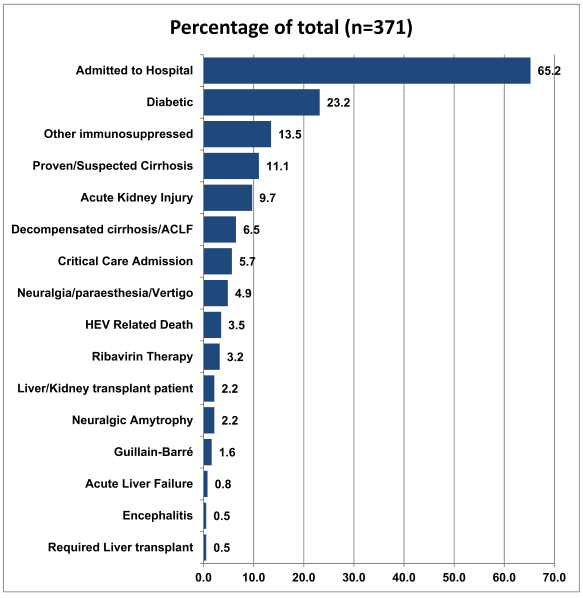

Figure: Morbidity and mortality expressed as percentage total of cases (n = 371)

Conclusion: Locally-acquired HEV causes a significant burden of disease, with a high number of inpatient days and a risk of organ failure or death. Cirrhosis, diabetes and immunosuppression are associated with symptomatic infection. Neurological and renal complications occur in a minority.

PS-052

End of study results from LIMT HDV study: 36% durable virologic response at 24 weeks post-treatment with pegylated interferon lambda monotherapy in patients with chronic hepatitis delta virus infection

Ohad Etzion[1], Saeed Sadiq Hamid[2], Yoav Lurie[3], Edward Gane[4], Nimrah Bader[2], David Yardeni[2], a Nevo-Shor[1], sm channa[5], Minaz Mawani[2], Om Parkash[2], Kyunghee Yang[6], Diane Longo[6], Robert G. Gish[7], Jeffrey Glenn[7], David Apelian[8]. *[1]Soroka University Medical Center, Beer-Sheva, Israel; [2]Aga Khan University Hospital, Karachi, Pakistan; [3]Shaare Zedek, Jerusalem, Israel; [4]Auckland City Hospital, Auckland, New Zealand; [5]Ghulam Mohammad Mahar Medical College Sukkur, Sukkur, Pakistan; [6]Dilisym, Research Triangle Park, United States; [7]Stanford University, Stanford, United States; [8]Eiger BioPharmaceuticals, Inc, Palo Alto, United States*
Email: ohadet34@yahoo.com

Background and aims: Hepatitis Delta Virus (HDV) infection leads to the most aggressive form of human viral hepatitis. There is no approved therapy. Worldwide prevalence of HDV infection is 15-20 million. PEG IFN-lambda-1a (Lambda) has previously demonstrated a good tolerability profile in >3000 HBV and HCV patients, with fewer cytopenias, flu-like and psychiatric symptoms compared to PEG IFN-alfa (Alfa). The goal of LIMT was to evaluate safety and efficacy of Lambda monotherapy in patients with HDV.
Method: Randomized, open-label study of Lambda 120 or 180 μg, weekly SC injections for 48 wks follow by 24 wks post-tx in patients with chronic HDV, conducted in Pakistan, Israel, and New Zealand. Major inclusion criteria: positive HDV RNA by qPCR (Robogene® 2.0, BLQ 14 IU/ml), ALT<10×ULN, and compensated liver disease. Tenofovir or entecavir were started at baseline (BL).
Results: 33 patients were randomized to Lambda 180 μg (n = 14) or 120 μg (n = 19). BL mean values: HDV RNA 4.1 log IU/ml (SD±1.4); ALT 106 IU/L (35-364) and bilirubin 0.5 mg/dL (0.2-1.2).

				48 Wk On-Treatment		24 Wk Post-Treatment	
Dose		N	Mean Wk 48 Log HDV RNA Decline	2 Log Decline or BLQ	BLQ	2 Log Decline or BLQ	BLQ
180 μg	All	14		9/14 64%	5/14 36%	7/14 50%	5/14 36%
	High BL VL	8	-2.3	7/8 88%	3/8 38%	4/8 50%	2/8 25%
	Low BL VL	6		2/6 33%	2/6 33%	3/6 50%	3/6 50%

ITT rates of durable virologic response (DVR = BLQ at 24 wks post-tx) for Lambda 180 μg (5 of 14, 36%) compare favorably to historic rates for Alfa 180 μg (28%) (Wedemeyer, NEJM, 2011). 50% DVR in low BL viral load (VL) patients ($\leq 4 \log_{10}$). Common on-treatment AEs included mild to moderate flu-like symptoms and elevated transaminase levels. Patients previously treated with Alfa noted significantly less side effects on Lambda. Cases of jaundice and increased incidences of bilirubin elevations were observed in the Pakistani cohort. No patients showed symptoms of decompensation, and all responded favorably to dose reduction or dose discontinuation. DILIsym® modeling of ALT and bilirubin dynamics indicate a transporter-based mechanism for the observed bilirubin elevations.
Conclusion: Lambda 180 μg had comparable antiviral activity with better tolerability, compared to historical data for Alfa. Durable BLQ virologic responses have been observed 24 weeks post-treatment. Lambda is a promising agent for mono or combo treatment of HDV. The LIFT study with Lambda + Lonafarnib is on-going at NIH.

PS-053

A rapid point-of-care device for the diagnosis of hepatitis delta virus infection

Florian A. Lempp[1,2], Volkan Sakin[1], Shirin Nkongolo[1,3], Paul Schnitzler[4], Heiner Wedemeyer[5], Frédéric Le Gal[6], Emmanuel Gordien[6], Cihan Yurdaydin[7], Stephan Urban[1,3]. *[1]University Hospital of Heidelberg, Infectious Diseases, Molecular Virology, Heidelberg, Germany; [2]*Current Adress, Vir Biotechnology, San Francisco, United States; [3]German Center for Infection Research (DZIF), partner site Heidelberg, Heidelberg, Germany; [4]University Hospital of Heidelberg, Infectious Diseases, Virology, Heidelberg, Germany; [5]University Hospital of Essen, Clinic for Gastroenterology and Hepatology, Essen, Germany; [6]Hôpital Avicenne, Laboratoire de Microbiologie Clinique, Bobigny, France; [7]Ankara University, Department of Gastroenterology, Ankara, Turkey*
Email: stephan.urban@med.uni-heidelberg.de

Background and aims: Chronic Hepatitis Delta Virus (HDV) infection represents the most severe form of viral hepatitis. The detection of anti-HDV antibodies against Hepatitis Delta Antigen (HDAg) represents the recommended initial step in the diagnosis of HDV infection. Current assays for anti-HDV detection rely on manual ELISAs, which are time consuming and require laboratory equipment and trained

staff. Our aim was to develop a rapid pan-genotypic point of care (POC) test that allows fast and reliable detection of anti-HDV antibodies for all eight HDV genotypes and that can be used in hospitals and doctors' practices but also in remote areas.
Method: Using multiple sequence alignments, we designed and optimized a pan-genotypic consensus sequence of HDAg. The corresponding recombinant protein was expressed, purified and implemented as a detection antigen to assemble a POC device, based on the principle of lateral flow assay. The POC device was validated with a panel of 332 HDV-positive and 142 HDV-negative patient samples. Additionally, 18 serum samples from patients with non-genotype 1 HDV infection were used to evaluate pan-genotypic test performance.
Results: Application of serum containing anti-HDV antibodies to the POC test strips led to a visible positive test result already after 10-20 minutes of incubation. Positive signals could be detected even if the patient sera were diluted 100-fold, while no false positive signals were detected when HDV-negative control sera were applied. POC test validation on 476 samples led to a sensitivity of 94, 6 % and specificity of 100 %. All 18 serum samples from non-genotype 1 HDV-infected patients were positive in the POC test indicating pan-genotypic sensitivity. Multiplexing the test strip with HBsAg-specific antibodies allowed simultaneous detection of HBsAg and HDV infection on the same strip.
Conclusion: In light of the several novel HDV-specific drugs that are currently entering registration trials and might be available in the near future, fast and reliable diagnostics for HDV infection are of utmost importance. Here, we have developed and successfully validated a rapid test device for POC diagnosis in hospitals and remote areas or for epidemiological field studies.

PS-054

Quantitative antibodies against hepatitis B core antigen differ in NUC suppressed caucasian HbeAG-negative patients compared to patients who achieved either "NUC induced" or "spontaneous" functional cure of HBV

Alessandro Loglio[1], Floriana Facchetti[1], Corinna Orsini[2], Alberto Perego[2], Riccardo Perbellini[1], Sara Colonia Uceda Renteria[3], Simone Segato[1], Giovanna Lunghi[3], Ferruccio Ceriotti[3], Pietro Lampertico[1]. *[1]CRC "A. M. and A. Migliavacca" Center for Liver Disease Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Fujirebio Italia Srl, Pomezia, Italy; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Virology, Milan, Italy*
Email: ale.loglio@gmail.com

Background and aims: IgG-antibodies against Hepatitis B core antigen (anti-HBc) persist lifelong in HBV subjects, independently of HBsAg loss. However, their quantitative assessment in different clinical settings of HBV including patients long-term treated with nucleos (t)ide analogs (NUC) or those who achieved a function cure, is lacking.
Method: This retrospective cross-sectional study evaluated three patients' groups: 1) 189 Caucasian HBeAg-negative HBV monoinfected patients under long-term TDF/ETV therapy; 2) 25 patients who cleared HBsAg after NUC therapy (functional cure group); 3) 60 HBsAg negative, anti-HBc patients referred for anti-HBV prophylaxis due to onco-hematological disease ("isolated anti-HBc" group). Quantitative anti-HBc levels (LG HBcAb-N, Fujirebio) and its ratio to WHO International Standard (Human NIBSC code 95/522) were evaluated.
Results: In the former group [age 66 (28-90) years, 75% male, 47% compensated cirrhosis, 100% HBeAg negative, 95% gt D, 65% NUC-experienced, TDF/ETV treated from 100 (15-127) months, undetectable HBV DNA since 118 (11-203) months, HBsAg 517 (1-11, 781) IU/ml] median anti-HBc levels were 127 IU/ml (6-282). Anti-HBc levels < 127 IU/ml were associated with older age, cirrhosis, longer TDF duration and HBV DNA suppression, and higher BMI; at multivariate analysis, only with longer HBV DNA suppression (OR 1.02, $p < 0.001$) and BMI (OR 1.10, $p = 0.047$).
In patients who achieved a functional cure following NUC therapy [age 59 (43-84) years, 80% male, 40% gt D, 36% compensated cirrhosis, 36% NUC-exp, treated from 67 (5-122) months, HBV DNA undetectable since 85 (0-153) months, 100% HBeAg neg, 84% anti-HBe, 44% with anti-HBs > 10 IU/ml (64 (13-461) IU/ml)], anti-HBc levels were 154 IU/ml (1-285).
In the "isolated" anti-HB-core positive patients [age 69 (46-84), 50% male, 25% anti-HBe, 93% with anti-HBs > 10 IU/ml (188 (11-1000) IU/ml)], median anti-HBc levels were 9 IU/ml (1-112). Anti-HBc levels < 9 IU/ml were associated only anti-HBe positivity ($p = 0.001$).
Among NUC suppressed CHB patient, anti-HBc levels were widely distributed independently of HBsAg levels. Despite a similar serological profile, anti-HBc levels were significantly higher in patients with NUC-induced compared to those with spontaneous-induced functional cure.
Conclusion: IgG anti-HBc levels differ in different phases of HBV infection suggesting that it may be useful to further characterize NUC suppressed patients and those achieving functional cure.

PS-055

The markers of HBV transcriptional activity-HBcrAg and pre-genomic HBV DNA during antiviral therapy with nucleos (t)ide analogue help to predict optimal timing of therapy withdrawal

Ivana Carey[1], Jeffrey Gersch[2], Matthew Bruce[1], Christiana Moigboi[1], Bo Wang[1], Mary Kuhns[2], Gavin Cloherty[2], Geoffrey Dusheiko[1], Kosh Agarwal[1]. *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Department of Infectious Diseases, Abbott Diagnostics, Chicago, United Kingdom*
Email: ivana.kraslova@kcl.ac.uk

Background and aims: Nucelos (t)ide analogue (NA) withdrawal is a potential therapeutic strategy in long-term supressed HBeAg-negative non-cirrhotic chronic hepatitis B (CHB) patients. We previously demonstrated in 15 patients that 20% patients had severe post-withdrawal ALT flare (> 10 UNL) and required to re-start NA therapy. At time of NA withdrawal all patients with significant flare after stopping NA had detectable HBcrAg and pre-genomic (pg)HBV RNA, both markers of cccDNA transcriptional activity. Data regarding changes of HBV serological/virological markers during NA therapy prior to NA withdrawal are lacking and might provide valuable information about the timing of NA withdrawal. We aimed to compare the levels of HBV DNA, HBsAg, HBcrAg and pgHBV RNA and their kinetics during long-term NA therapy prior to NA withdrawal to evaluate whether on-treatment markers can help with timing of successful NA withdrawal.
Methods: We studied 25 CHB non-cirrhotic patients (64%males, median age 48yrs) were treated for a median duration 6.9 yrs (3.2-11.2) with tenofovir (TDF) and had undetectable HBV DNA for at least 3 years. TDF was stopped and patients were followed for at least 52 weeks (median 78, range 52-78). Based on type of ALT flare post NA withdrawal, patients were divided into 3 groups: no flare (n = 9), mild ALT flare (> 2 < 5 UNL and > 2 from NA stop baseline, n = 11) and 5 with severe flare (> 10UNL with HBV DNA > 100, 000IU/ml). Serum samples from NA therapy at baseline, years 1, 2 and 3 on therapy and at time of withdrawal were tested for HBV DNA and HBsAg levels, HBcrAg concentrations (by were CLEIA Fujirebio assay [LLDQ 2 $\log_{10}$U/ml]) and pgHBV RNA (using a real-time PCR research assay Abbott Diagnostics [LLDQ 1.65 $\log_{10}$U/ml]). The markers were compared between patients according to post withdrawal ALT flare status.
Results: At time of starting NA therapy patients with severe flares had significantly higher levels of HBV DNA, HBcrAg and pgHBV RNA, but quantitative HBsAg, ALT and degree of liver damage were similar. All serological/virological markers declines did not differ across the groups. By year 1 only HBcrAg and pgHBV RNA levels were higher in patients with subsequent severe flares and this remained the case until NA withdrawal (Figure 1). The proportions of patients with

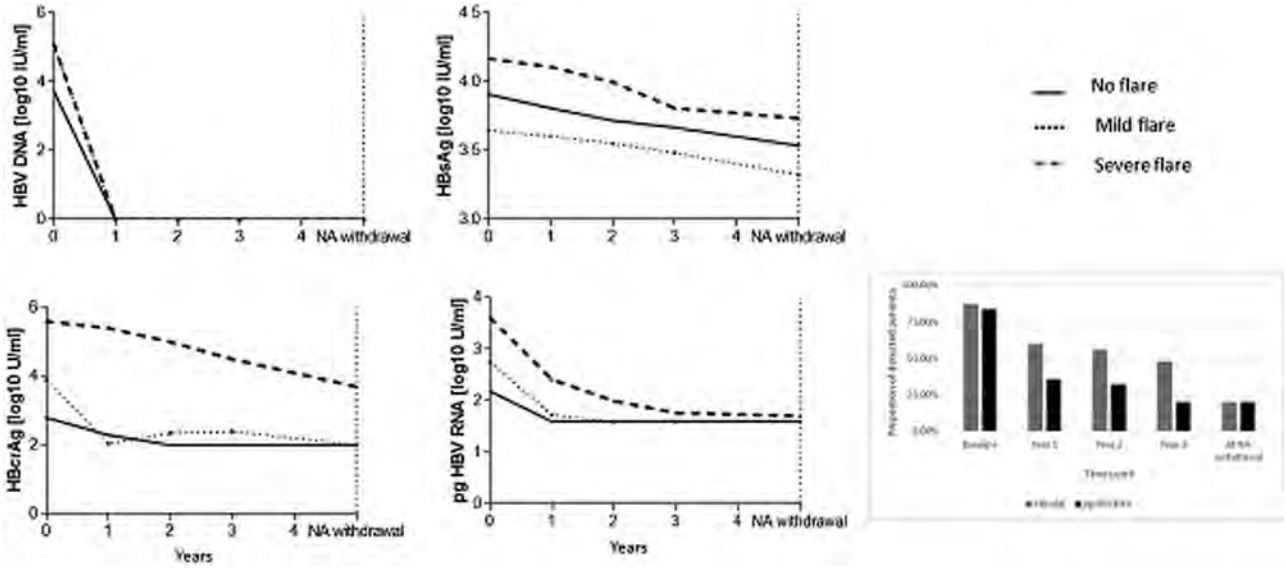

Figure 1: (abstract: PS-055): Medians of serological/virological markers during NA therapy

detectable HBcrAg and pgHBV RNA reduced during NA therapy (Figure 1); only patients who developed severe flares had detectable HBcrAg and pgHBV RNA at time of withdrawal.

Conclusion: During NA treatment of HBeAg negative patients, serum levels of HBcrAg and pgHBV RNA, ostensibly markers of transcriptional cccDNA activity were strong predictors of subsequent significant ALT flares after NA withdrawal and their monitoring on NA therapy might assist with appropriate timing of NA withdrawal to avoid relapse and related disease after NA withdrawal.

PS-056

Higher relapse and retreatment rates in patients who started as HBeAg positive than negative after stopping long-term nucleos (t) ide analogue therapy: results from the randomized controlled STOP study

Seng Liem[1,2], Scott Fung[1], David Wong[1], Colina Yim[1], Jenny Chen[1], Seham Noureldin[1], Jordan Feld[1,3], Bettina Hansen[1,2,4], Harry Janssen[1].
[1]*University Health Network, Toronto Centre for Liver Disease, Toronto, Canada;* [2]*Erasmus University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands;*
[3]*McLaughlin-Rotman Centre for Global Health, Toronto, Canada;*
[4]*University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada*
Email: k.s.liem@erasmusmc.nl

Background and aims: Patients with chronic hepatitis B (CHB) often receive long-term nucleos (t)ide analogue (NA) therapy. We compared outcomes after stopping NA therapy between patients who started therapy HBeAg positive or negative.

Method: In this prospective single-center randomized controlled trial, patients were included if they had received tenofovir/entecavir therapy for ≥ 12 months and achieved virologic suppression (HBeAg seroconversion and undetectable HBV DNA ≥ 12 months in HBeAg positive patients, or undetectable HBV DNA ≥ 36 months in HBeAg negative patients). Patients were randomized 2:1 to either stop or continue NA therapy for 72 weeks. Retreatment criteria were: HBeAg seroreversion, HBV DNA > 20, 000IU/ml twice or HBV DNA > 2, 000 with ALT > 5xULN twice. Sustained response (HBeAg negative, HBV DNA < 2, 000 IU/ml and normal ALT) was determined at week 72.

Results: Of 67 patients (60% male, 97% Asian), 45 (67%) patients were assigned to stop and 22 (33%) to continue NA therapy. At start of therapy, 18/45 (40%) stop patients were HBeAg positive. At randomization the mean duration of NA therapy was 8 (3) vs. 7 (3) years, 82% vs. 100% was anti-HBe positive and HBsAg level was 3.2 (0.9) vs. 3.0 (0.6) log IU/ml in HBeAg positive vs. negative patients. Time since HBeAg loss was 3.8 (2.3) in patients who started therapy as HBeAg positive. Sustained response was observed in 3/18 (17%) HBeAg positive vs. 7/27 (26%) negative patients (p = 0.35) (Table). HBsAg loss occurred in 1 HBeAg-negative patient.

Among patients who stopped, the mean HBsAg change from randomization to week 72 was –0.1 (0.4) vs. 0.2 (0.2) log IU/ml in HBeAg positive vs. negative patients (p = 0.10). 11/18 (61%) of the HBeAg positive vs. 5/27 (19%) HBeAg negative patients were retreated by week 72 (p < 0.005). ALT > 1/2/5/10xULN occurred in 89/72/61/50% vs. 70/48/37/15 % of HBeAg positive vs. negative stop patients. One HBeAg positive patient developed a bilirubin of 68umol/L, but none decompensated or died.

	Start of therapy		
Week 72 outcomes (%)	HBeAg positiven = 27	HBeAg negativen = 18	P
Sustained response	17	26	0.35
HBsAg loss	0	4	-
ALT > 5xULN	61	37	0.26
ALT > 10xULN	50	15	0.03
Virologic reactivation (lone HBV DNA > 20, 000 IU/ml)	83	56	0.14
Clinical relapse (HBV DNA > 2, 000 IU/ml +ALT > 1.5xULN)	6	19	0.10

Conclusion: Start of therapy HBeAg positive patients were more likely to relapse and receive retreatment than HBeAg negative patients. These findings in an Asian majority cohort suggest that patients do not benefit from stopping long-term NA therapy, particularly those who are HBeAg positive at the start of therapy.

NAFLD – Clinical burden natural history

Redefining risk of liver disease in the general population: Analysis of the health survey for England 2016

Kate Glyn-Owen[1,2], Julie Parkes[2], Scott Harris[2], Richard Aspinall[3], Paul Roderick[2]. [1]*National Institute for Health Research (NIHR) Collaboration for Applied Health Research and Care (CLAHRC) Wessex, Southampton, United Kingdom;* [2]*University of Southampton, Primary Care and Population Sciences, Southampton General Hospital, Southampton, United Kingdom;* [3]*Portsmouth Hospitals NHS Trust, Hepatology, Portsmouth, United Kingdom*
Email: k.glyn-owen@soton.ac.uk

Background and aims: The health, financial and societal arguments for public health action to prevent lifestyle related liver disease are clear. Primary care has frequently been suggested as a key location for prevention strategies. Evidence on the most appropriate cut-offs for liver biochemistry and indirect fibrosis markers, which may be used for screening before more definitive assessment, has predominantly been gathered in patients with existing liver disease. These thresholds may not be suitable in community settings.
For the first time liver function tests, from a sample representative of the general population in England, are available. We explored the distribution of risk factors for liver disease, liver function test results and liver fibrosis scores in the Health Survey for England (HSE) 2016.
Method: Cross-sectional survey with interview, examination and blood tests. Multi-stage, stratified, random probability sample designed to be representative of the population living in private households in England.
Participants: 7, 826 adults aged 18 years and over, of whom 3, 791 had a blood test.
Exposures and markers: Risk factors were alcohol consumption > 14 units/wk, body mass index ≥ 25 and diabetes. Liver function tests were Alanine aminotransferase (ALT) and Aspartate Aminotransferase (AST). Liver fibrosis scores calculated were FIB–4 score (high >2.67), APRI score (high ≥ 1.0), AST:ALT ratio (high > 0.8), BARD score (high ≥ 2).
Results: 85.5% (84.4 to 86.7%, n = 5670) of the population representative sample have at least one risk factor for liver disease. 25.9% (24.4 to 27.5%, n = 4685) have two or more risk factors. 2.5% (2.0 to 3.1%, n = 3388) had a high FIB–4; 11.5% (10.3 to 12.8%, n = 3607) had a raised ALT; 86.0% (84.5 to 87.3%, n = 3424) had a high AST:ALT ratio. Only 5.1% (4.3 to 6.0%, n = 4031) of those with at least one risk factor and 7.9% (6.1 to 10.1%, n = 3749) of those with two or more risk factors had been told by a health professional that they were at risk of liver disease. 12.9% (11.8 to 14.1%, n = 4722) of the sample and 17.7% (10.9 to 27.3%, n = 85) of those with a high FIB–4 score report ever being tested for liver disease.

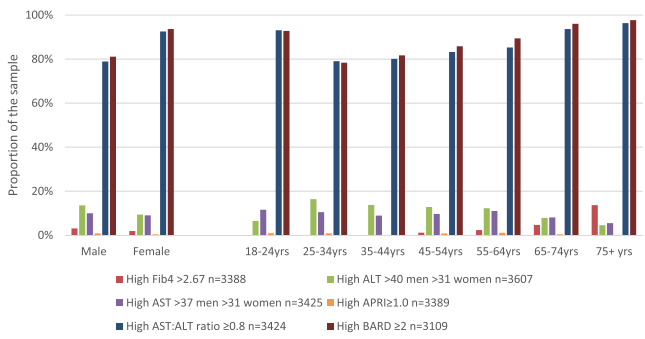

Figure 1: Distribution of 'high' liver function test and fibrosis marker results in the HSE 2016 sample, representative of the general population of England, by age and sex.

Conclusion: This is the first analysis of liver biochemistry and indirect fibrosis markers in a sample representative of the general population of England. Modifiable lifestyle risk factors for liver disease are present in more than 85% of participants. Multiple risk factors are common and may be synergistic. Commonly used liver function tests and fibrosis scores showed large variation in positivity. Awareness of risk and testing for liver disease was low, even in those with multiple risk factors. The best approach to achieve detection of liver disease in primary care remains unclear.

PS-058

The socio-economic burden of NASH in Europe and the United States: The gain study

leonardo Ruiz[1], Rosa Willock[1], Thomas Russell[1], George Morgan[1], Jamie O'hara[1], Quentin Anstee[2], Ingo Van Thiel[3], Alan Finnegan[4], Judy Rhys[5], Vanessa Hebditch[5], Mzwandile Mabhala[4], PD Dr. Schattenberg Jörn[6], Manuel Romero-Gómez[7], Elisabetta Bugianesi[8], Vlad Ratziu[9], Tatjana Reic[10], Gregory Guzauskas[11], Bengt Jönsson[12], Anthony Hatswell[13]. Email: rosa.willock@hcdeconomics.com

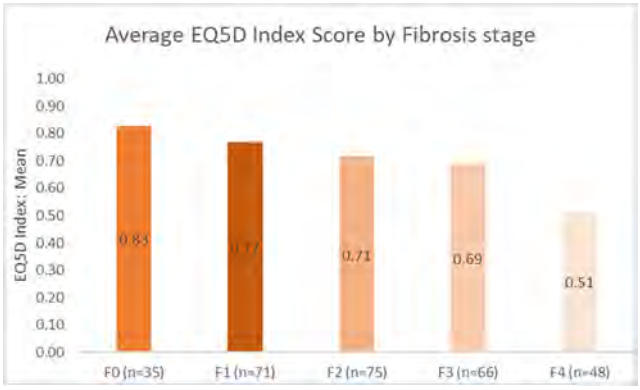
Background and aims: NASH is one of the most common chronic liver conditions yet, currently, no pharmacologic drug is available. The disease is associated with a significant socio-economic burden which, coupled with a steadily rising prevalence, is a growing public health threat. The Global Assessment of the Impact of NASH: a socioeconomic study (GAIN) study is a prevalence-based burden of illness study across Europe (France, Germany, Italy, Spain and the United Kingdom) and the United States to determine the socio-economic burden of NASH in the real-world.
Method: This study followed a retrospective and cross-sectional methodology that recruited a sample of physicians and provided demographic, clinical and economic information, including 12-month ambulatory and secondary care activity for patients via an online survey. Each patient was invited to provide corresponding patient questionnaire providing patient reported outcomes through validated tools (EQ–5DL, CLDQ-NAFLD, WPAI) as well as direct and indirect non-medical costs. Per-patient costs are calculated by multiplying the quantities of the resource use collected with the national unit price and then extrapolated to population level to calculate the economic burden. Patients with diagnosed by liver biopsy (n = 1, 619) were stratified by fibrosis score (F0-F4). Patients diagnosed by serum biomarkers and imaging techniques (n = 2, 135) were stratified with early (F0-F2) or advanced (F3-F4) fibrosis.
Results: Clinical reports for a total of 3, 754 patients were received. 767 patients (20% of the sample) provided information on indirect costs and health-related quality of life, of which 295 patients had a liver biopsy and confirmed fibrosis score (F0-F4). For these 295 patients, the average EQ–5D and CLDQ-NAFLD index scores were 0.70 and 4.70 respectively. Both indexes decreased with progression of fibrosis stage. For 2017, the total annual per patient cost of NASH was estimated at EUR 25, 512. The highest country per-patient costs were in the USA (mean EUR 73, 255) and the lowest were in France (mean EUR 4, 409). Costs increased with fibrosis stage driven by hospitalisations and a higher co-morbidity burden. Indirect costs are driven by patient and non-professional caregiver work loss.



Conclusion: The GAIN study significantly adds to the evidence base regarding the socio-economic burden in NASH. Results show a significant socio-economic burden associated with NASH that increases with progression of fibrosis stage.

PS-059

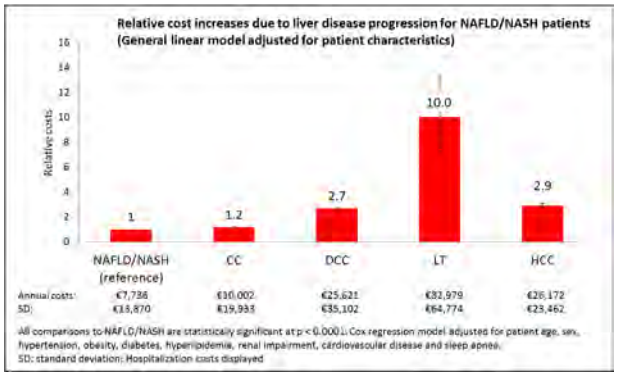
Increased healthcare resource utilization and costs in non-alcoholic fatty liver disease/non-alcoholic steatohepatitis patients with liver disease progression: A multivariate analysis of french national hospital care

Jerome Boursier[1], Jeremy Fraysse[2], Antoine Lafuma[3], Elodie Torreton[4], Ahmet Burak Ozbay[2]. [1]*Angers Hospital University, Angers, France;* [2]*Gilead Sciences, Health Economics Outcomes Research (HEOR), Foster City, United States;* [3]*CEMKA, Bourg La Reine, France;* [4]*CEMKA, Bourg La Reine, United States*
Email: jeboursier@chu-angers.fr

Background and aims: HCRU and healthcare costs increase in NAFLD/NASH patients who progress to compensated cirrhosis (CC). However, limited data on HCRU and costs exist for NAFLD/NASH patients with progression to decompensated cirrhosis (DCC), liver transplantation (LT), or hepatocellular carcinoma (HCC). This study evaluated increases in HCRU and costs in these hospitalized patients in France.

Method: Patients aged ≥ 18 years with NAFLD/NASH were identified from the French National Database on hospital care (PMSI) between 2009 and 2015, which captures all hospitalizations in France. Five study cohorts were identified via ICD–10-CM: (1) NAFLD/NASH overall, (2) CC, (3) DCC, (4) LT, and (5) HCC. Index date was defined as the earliest diagnosis date for each stage. Cohorts were not mutually exclusive; patients with other causes of liver disease were excluded. Patients followed from index date to earliest of 12 months, progression to new stage, death, or end of study. Costs were reported in 2015 €. Generalized linear models used to adjust for patient characteristics.

Results: 125, 052 hospitalized French NAFLD/NASH patients (mean age 55.9; 46.2% male) were identified, including 1491 CC (1.2%), 7846 DCC (6.3%), 52 LT (0.04%), and 1144 HCC (0.9%), with mean ages between 51.6 and 70.1. Rates of comorbidities were high across cohorts: ≥ 43% had diabetes, ≥ 41% had cardiovascular disease, ≥ 21% had renal impairment, ≥ 47% had hypertension. Mean length of stay generally increased with disease severity: NAFLD/NASH 4.1 ± 7.4 days, CC 3.5 ± 5.6, DCC 9.1 ± 15.4, LT 9.0 ± 7.6 and HCC 5.6 ± 6.3. Mean annual number of stays was 3.1 ± 5.6 in NAFLD/NASH and increased to 4.2 ± 8.6 in CC, 7.0 ± 11.1 in DCC, 7.1 ± 5.6 in LT and 5.5 ± 6.6 in HCC. Mean annual hospitalization costs were high for all groups and increased with disease progression: €7736±€13, 870 in NAFLD/NASH, €10, 002±€19, 933 in CC, €25, 621±€35, 102 in DCC, €82, 979±€64, 774 in LT, and €26, 172±€23, 462 in HCC. After multivariate adjustment, costs were 2.3 for DCC, 8.5 for LT, and 2.5 for HCC times significantly higher relative to CC (p < 0.0001). Similar significant increases were found relative to NAFLD/NASH (Figure).



Conclusion: Underdiagnoses of CC was apparent in hospitalized NAFLD/NASH patients in France. Along with a high comorbidity burden, HCRU and healthcare costs were significantly higher in patients with liver disease progression. Effective therapies to slow disease progression or reverse advanced disease are needed.

PS-060

Increasing risk of disease progression and mortality in non-alcoholic fatty liver disease/non-alcoholic steatohepatitis patients with advanced liver disease: A german real-world analysis

Ali Canbay[1], Nandita Kachru[2], Dominic Meise[3], Jennifer Scarlet Haas[3], Ahmet Burak Ozbay[2]. [1]*Department of Gastroenterology, Hepatology and Infectiology, University of Magdeburg Medical School, Magdeburg, Germany;* [2]*Gilead Sciences, Health Economics Outcomes Research, Foster City, United States;* [3]*Xcenda GmbH, Hannover, Germany*
Email: Nandita.Kachru@gilead.com

Background and aims: The presence of advanced fibrosis (F3/F4) is an independent predictor of all-cause mortality among NAFLD/NASH patients. This study aimed to quantify disease progression and all-cause mortality rates in NAFLD/NASH patients without and with advanced liver disease, including compensated cirrhosis (CC), decompensated cirrhosis (DCC), liver transplant (LT) and hepatocellular carcinoma (HCC), using a German claims database.

Method: Adult patients with NAFLD/NASH (ICD–10-GM) were identified retrospectively from 2011-2016 in the InGef database containing claims data of > 4 million individuals. Patients with other causes of liver diseases were excluded. Following NAFLD/NASH diagnosis, patients were identified with liver severity stages (NAFLD/NASH non-progressors (NN/NP), CC, DCC, LT, HCC) using first diagnosis as index date. Cohorts were not mutually exclusive with 6 years maximum follow-up. Patients were censored at disease progression to calculate the mortality rates. Kaplan-Meier curves were plotted for cumulative all-cause mortality rates for all liver stages except LT (low sample size).

Results: Of the 4, 580, 434 individuals in the database, the study identified 215, 655 (5%) NAFLD/NASH patients. Subsequent follow-up demonstrated, 100, 644 incident events of different liver severity stages were (NN/NP [79, 245 (78.7%)], CC [411 (0.4%)], DCC [20, 614 (20.5%)], LT [11 (0.01%)] and HCC [363 (0.4%)]). At 1 year follow-up, mortality rate was up to 50-times higher in patients with advanced liver disease than in NN/NP (p <.0001), including 1.2% in NN/NP, 8.8% in CC, 18.3% in DCC, 51.2% in HCC. This trend continued over 5 year follow-up, with significantly higher mortality in advanced liver disease patients than in NN/NP (p <.0001), with 2.8% in NN/NP deceasing, as compared to 14.8% in CC, 25.6% in DCC, and 64.5% in HCC. During the study period, 11.7% of the NAFLD/NASH patients progressed to advanced liver disease and 20.7% CC patients progressed to DCC.

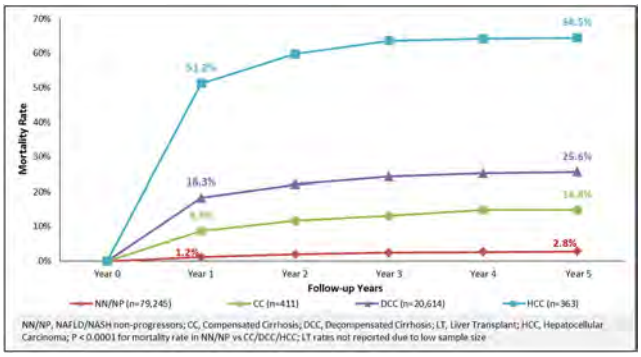


Figure: NAFLD/NASH Patients Cumulative All-cause Mortality Rate by Liver Severity Stages

Conclusion: Incident rates of CC and DCC indicate underdiagnosis of CC among NAFLD/NASH patients. Those with advanced liver disease in Germany had high mortality rate that significantly increased with disease progression ranging from 14.8% in CC to 25.6% in DCC to 64.5% in HCC. More than 20% of CC patients decompensate over 5 years of follow-up. Results suggest the need for early detection and effective interventions among NAFLD/NASH patients to prevent progression and potentially reduce mortality.

PS-061

Non-alcoholic fatty liver disease/Non-alcoholic steatohepatitis patients with advanced liver disease had high burden of comorbidities, healthcare resource utilization and costs: Results from Italian administrative databases

Salvatore Petta[1], Jie Ting[2], Stefania Saragoni[3], Luca Degli Esposti[3], Ahmet Burak Ozbay[2], Giulio Marchesini Reggiani[4]. [1]*University of Palermo, Section of Gastroenterology and Hepatology, Di.Bi.M.I.S., Palermo, Italy;* [2]*Gilead Sciences, Inc., Health Economics and Outcomes Research, Foster City, United States;* [3]*CliCon S.r.l. Health Economics and Outcomes Research, Ravenna, Italy;* [4]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy*
Email: jie.ting@gilead.com

Background and aims: NAFLD/NASH may progress to advanced liver disease (AdvLD), which includes compensated cirrhosis (CC), decompensated cirrhosis (DCC), liver transplant (LT), and hepatocellular carcinoma (HCC). This study characterized the comorbidities, HCRU and associated costs among hospitalized patients with AdvLD due to NAFLD/NASH.

Method: NAFLD/NASH patients ≥ 18 years from 2011-2017 were identified from 8 administrative databases of Italian local health units with over 9 million inhabitants using ICD–9-CM codes. Following NAFLD/NASH diagnosis, development of CC, DCC, LT, or HCC was identified using their first diagnosis date for each severity cohort (index date). Eligible patients were followed from index date until the earliest of disease progression, end of coverage, death, or end of study period. Within each cohort, per member per month values were annualized to calculate the annual all-cause HCRU or costs in 2017 €.

Results: This study identified 9, 729 hospitalized NAFLD/NASH patients (mean age 62.0 years, 43% female). The majority (97%, N = 9, 470) did not have AdvLD, 1.3% (N = 131) had CC, 3.0% (N = 303) had DCC, 0.1% (N = 11) had LT, and 0.8% (N = 79) had HCC. The comorbidity burden was high across all cohorts—type 2 diabetes (34%–49%), renal impairment (15%–36%), cardiovascular disease (82%–94%), and hypertension (35%–47%). Mean annual number of hospitalizations was greater in patients with AdvLD vs. those without (4.2–4.4 vs. 2.9, p ≤ 0.05). Similar trends were observed in outpatient visits and pharmacy fills. Mean total annual costs also increased with disease severity, with post-index costs among patients with AdvLD due to NAFLD/NASH at least 86% higher than patients without AdvLD, driven primarily by higher inpatient costs (NAFLD/NASH without AdvLD was €10, 576, vs. CC €19, 681, DCC €19, 808, LT €65, 137, and HCC €26, 220, p < 0.001 for all) [Figure].

Figure: Total mean annual healthcare costs of hospitalized NAFLD/NASH patients by severity cohort in Italy (2017 €)

Conclusion: NAFLD/NASH patients in Italy have high comorbidity burden. Patients with AdvLD had significantly higher costs compared to those without, and costs increased significantly in patients with more severe disease. The lower prevalence of CC compared to DCC in this study suggests missed opportunity to diagnose at earlier stages. Early identification and effective management is needed to reduce the risk of disease progression and subsequent healthcare utilization and costs.

PS-062

The increasing importance of non-alcoholic fatty liver disease in human deficiency virus (HIV) positive patients

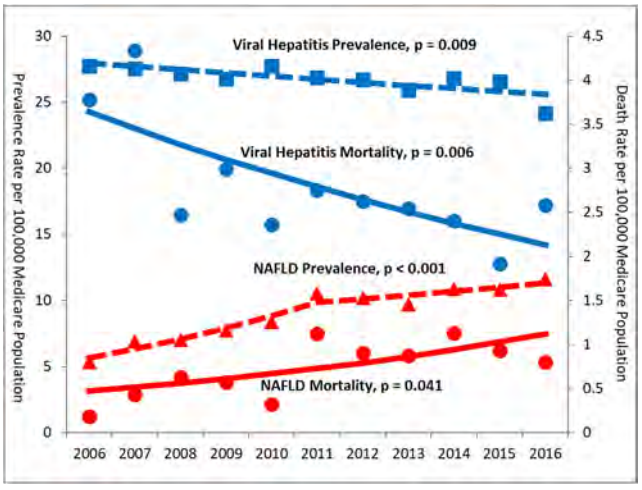
James Paik[1], Pegah Golabi[1,2], Greg Trimble[2], Leyla Deavila[1,2], Linda Henry[3], Zobair Younossi[1,2]. [1]*Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, United States;* [2]*Center for Liver Diseases- Department of Medicine, Inova Fairfax Medical Campus, Falls Church, United States;* [3]*Center for Outcomes Research in Liver Disease, Washington DC, United States*
Email: zobair.younossi@inova.org

Background and aims: The development of highly effective antiretroviral regimens for HIV led to a decrease in the associated mortality. On the other hand, mortality from hepatitis C virus (HCV)-related liver disease (LD) became a leading cause of death in HIV (+) patients. The recent approval of new anti-HCV drugs have resulted in high cure rates in HIV-HCV co-infected patients. As viral hepatitis is effectively treated in HIV (+) patients, NAFLD could become a prominent LD. We aimed to assess the prevalence and mortality trends of NAFLD, viral hepatitis and other LDs in HIV infected Medicare recipients in the US.

Method: We used inpatient and outpatient data (random 5%) for the Medicare beneficiaries (1/1/2006 to 12/31/2016) with ICD–9 and ICD–10 diagnostic codes, resource utilization, and mortality rates. Prevalence rates for HCV, HBV, NAFLD, and other LDs (such as alcohol-LD, cholestatic LD etc.) were determined. Logistic regression models were used to assess 1-year mortality risk in NAFLD, HBV, HCV, and controls without LD.

Results: Among the 28, 675, 887 unique Medicare beneficiaries, there were 47, 062 HIV (+) subjects with 10, 474 having LD (5, 628 HCV, 1, 374 HBV, 645 HCV+HBV, 2, 629 NAFLD, 198 other LDs.). Between 2006 and 2016, rates for viral hepatitis decreased from 27.75 to 24.17 (p =.009) while, the rate for NAFLD in HIV (+) Medicare recipients doubled from 5.32 to 11.62 per 100, 000 (p <.001). During the study period, there were 2, 882 deaths within one-year of the encounter. Of these, 36.2% were related to LD (49.5% dying from HCV, 14.4% from HBV, 11.9% from HCV+HBV, 20.3% from NAFLD, and 3.9% from other LDs). During the study period, the death rates related to viral hepatitis in HIV (+) Medicare recipients decreased from 3.78 to 2.58 (p =.006), while the mortality for NAFLD in this group increased from 0.18 to

0.80 for NAFLD (p =.041). After adjustments for calendar year, age, sex, race/ethnicity, region, and beneficiary entitlement, presence of HCV (Odds ratio [OR] = 1.89, 95% CI: 1.69–2.11), HBV (OR = 2.25, 95% CI: 1.85–2.72), HCV+HBV (OR = 4.17, 95% CI: 3.31–5.24), and NAFLD (OR = 1.54, 95% CI: 1.33–1.80) were associated with increased risk of 1-year mortality in the HIV (+) Medicare recipients [vs. HIV (+) without LD].



Conclusion: As highly effective regimens for HIV, HBV and HCV lead to a reduction in associated mortality in HIV (+) patients, NAFLD is increasing as an important cause of LD and reason for liver mortality in this group of patients.

PS-063

Screening diabetic patients for non-alcoholic fatty liver disease: Is it cost-effective

Yaakov Maor[1], Shira Zelber-Sagi[2,3], Moshe Leshno[4]. *[1]Kaplan Medical Center, Institute of Gastroenterology and Hepatology, Rehovot, Israel; [2]Tel-Aviv Medical Center, Department of Gastroenterology and Liver Diseases, Tel-Aviv, Israel; [3]University of Haifa, School of Public Health, Haifa, Israel; [4]Tel Aviv University, Coller School of Management, Tel-Aviv, Israel*

Email: leshnom@tauex.tau.ac.il

Background and aims: NAFLD is diagnosed in 70%–90% of diabetic patients. The EASL/EASD Guidelines recommend screening patients with diabetes for NAFLD. Recently, several novel interventions were shown to improve fibrosis stage. Our aim was to analyze whether screening individuals with diabetes for NAFLD may potentially be cost-effective.

Method: We constructed a Markov model (Figure 1) with an initial decision regarding screening diabetic patients for liver fibrosis (using elastography). The model is based on the natural history of NAFLD. We assumed that the hypothetical new treatment is relevant only for patients with NASH and significant fibrosis (F2-F3), whereas cirrhotics will be managed according to current guidelines. We assumed that the treatment will annually reduce the progression rate by 15% and increase the regression rate by 15%. The analysis was based on local costs and presented in USD. The annual cost of the new treatment ranged between 8, 000$ to 40, 000$. The primary outputs of the model included cost, life-years (LYs), and quality-adjusted LYs (QALYs), which were used to calculate the incremental cost-effectiveness ratio (ICER).

Results: For the base case where the new treatment cost was 10, 600$ the average cost of screening strategy was 54, 100$ and the No-screening strategy was 20, 454$, an increase of 33, 646$. The average QALY in the No-screening strategy was 15.25 QALY compared to 15.86 QALY in the screening strategy, an incremental of 0.61 QALY. The ICER was 55, 157$ per QALY. However, for annual cost of the new treatment of 40, 000$ the ICER increased to 208, 894$ per QALY. Sensitivity analysis of the annual cost of new treatment assuming annually reduce the progression rate and increase the regression rate by 15% and 20%, respectively, is shown (Figure 2).

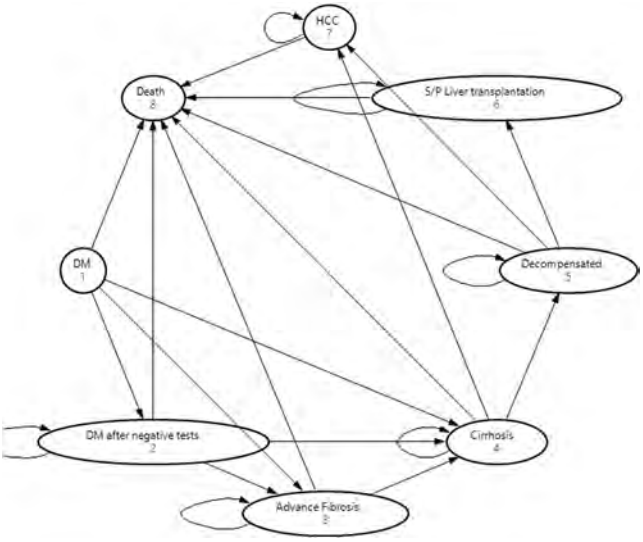


Figure 1: Markov Model for screening diabetics for NAFLD

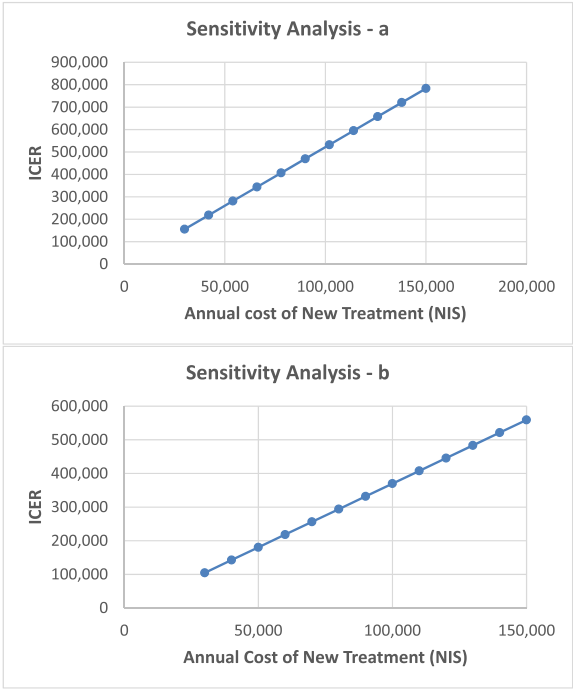

Figure 2: Cost-effectiveness of screening diabetic for NAFLD: a. 15% regression rate and 15% reduced progression rate b. 20% regression rate and 20% reduced progression rate

Conclusion: With the proposed screening strategy for NAFLD in diabetics the incremental QALY is marginal. Therefore, the costs of the novel therapeutic interventions have to remain relatively low (~10, 600$) to maintain cost-effectiveness. Cost-effectiveness of screening needs to be reassessed when more effective medications become available.

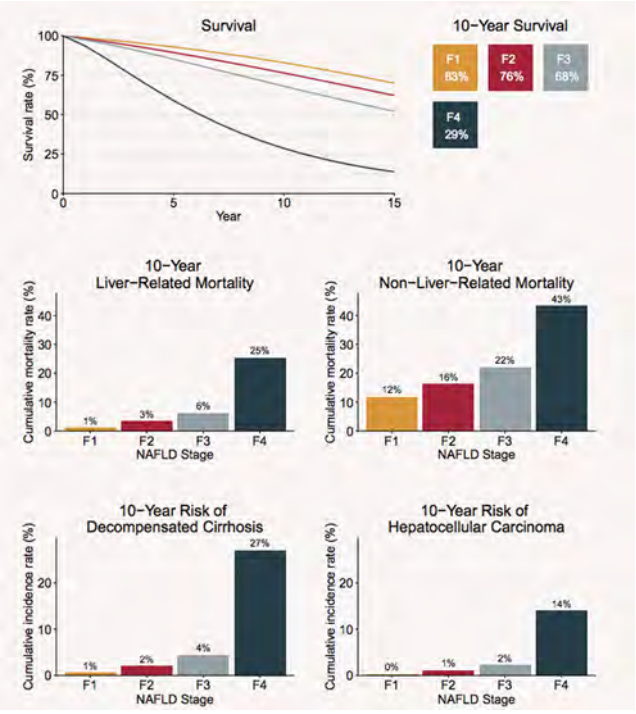
PS-064

NAFLD simulator: An interactive open-access tool for long-term risks of NAFLD and NASH

Jagpreet Chhatwal[1,2], Ozden Onur Dalgic[1,2], Sumeyye Samur[1,2], Emily Bethea[1,2], Mary Ann Ladd[1], Tiannan Zhan[1], Kathleen Corey[1,2], Rohit Loomba[3]. [1]*Massachusetts General Hospital, Boston, United States;* [2]*Harvard Medical School, Boston, United States;* [3]*University of California San Diego, La Jolla, United States*
Email: jagchhatwal@mgh.harvard.edu

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease worldwide, with an estimated prevalence ranging from 25% to 40%. Several pharmacological treatments that could potentially reduce the rising burden of non-alcoholic steatohepatitis (NASH), an aggressive form of NAFLD, are in early stages of development. Because NASH is a slow progressive disease, ongoing clinical studies use surrogate markers as primary end point. Our aim was to develop an open-access, interactive tool for patients and providers that help them understand the risk of short- and long-term adverse outcomes associated with NASH.

Method: We developed a mathematical model that simulated the life course of NASH patients as they progressed through the stages of the natural history: including NASH fibrosis states (F0-F4), decompensated cirrhosis, and hepatocellular carcinoma (HCC). Patient characteristics in the model were based on the NASH Clinical Research Network data. The model accounted for both liver-related and non-liver-related mortality in NASH patients. Disease progression rates and mortalities were derived from published meta-analyses and observational studies. Model-predicted patient survival was independently validated with three large observational studies. We created a large database of simulated NASH patients and their outcomes, and used it to create an interactive, web-based tool, NAFLD Simulator, that allows users to enter patient demographics and current NAFLD stage, and predicts survival, mortality (liver, non-liver, and background), cumulative incidence of liver cancer and decompensated cirrhosis.



Results: Figure 1 compares the predicted outcomes for a 50-year old patient having NASH fibrosis stages F1, F2, F3 and F4. For instance, the 15-year survival in patients with NASH F1, F2, F3, and F4 is 83%, 76%, 68%, and 29%, respectively. The 10-year non-liver-related mortality in these patients is 12%, 16%, 22%, and 43%, respectively. The NAFLD Simulator also shows that the 10-year risk of developing hepatocellular carcinoma increases from 2% to 14% in patients progress from F3 to F4.

Conclusion: NAFLD Simulator provides an innovative platform to disseminate the short and long-term risk associated with NAFLD and NASH to patients and providers. We envision that NAFLD Simulator will serve as an educational tool for patients and aid patient-physician decision-making; thereby increasing awareness of the long-term risks of NAFLD. The tool can be expanded to predict long-term outcomes of potential NASH treatments when they become available.

Cascade of care towards elimination of viral hepatitis

PS-065

The global investment case for hepatitis C elimination

Margaret Hellard[1], Alisa Pedrana[1], Jessica Howell[1], Nick Scott[1], Sophia Schroeder[1], Christian Kuschel[1], David Wilson[1], Jeffrey Lazarus[2], Ricardo Baptista Leite[3], Rifat Atun[4], Sharon Hutchinson[5]. [1]*Burnet Institute, Melbourne, Australia;* [2]*University of Barcelona, Barcelona Institute for Global Health, Barcelona, Spain;* [3]*Universidade Católica Portuguesa, Lisbon, Portugal;* [4]*Harvard University, Department of Global Health and Population, Boston, United States;* [5]*Glasgow Caledonian University, Glasgow, United Kingdom*
Email: margaret.hellard@burnet.edu.au

Background and aims: Approximately 71 million people globally are infected with hepatitis C, with an estimated 400, 000 deaths attributed to hepatitis C annually. Highly effective, well-tolerated treatment is available, making it possible to eliminate hepatitis C as a public health threat by 2030. Despite this, investment in hepatitis C programs has been slow. One potential reason for the limited investment in hepatitis C elimination is the lack of a strategic approach to investment in prevention, testing and treatment activities to achieve elimination. We proposed an investment framework, aligned with the Global Health Sector Strategy to guide policymakers and global funders in making investment decisions that will enable hepatitis C elimination.

Method: Our framework utilized a public health approach to identify national activities aimed at reducing hepatitis C transmission, morbidity, and mortality, and international activities necessary to provide an enabling environment for countries to achieve maximum effectiveness. Key enablers were highlighted including public support, community mobilization, and skilled workforces that can facilitate the rapid scale-up of national hepatitis C elimination activities.

We also modelled the health and economic (direct and indirect) benefits of scaling up hepatitis C elimination activities to meet the WHO global elimination targets of 90% of people diagnosed and 80% treated by 2030.

Results: Our models showed that investing to achieve elimination could reduce hepatitis C incidence by 85% and hepatitis C-related mortality by 68% by 2030, preventing a cumulative 2.1 million hepatitis C-related deaths and 12 million new hepatitis C infections. This required US $51 billion globally between 2018 and 2030, which included a peak of US $5.7 billion in 2021 before becoming cost-saving by 2027 due to substantive productivity gains (Figure 1). Overall, investing to achieve elimination produced a net US $19 billion return by 2030. Sharing staffing costs already invested within

the context of universal health coverage (UHC) reduced the cumulative costs of the elimination by $20.2 billion.

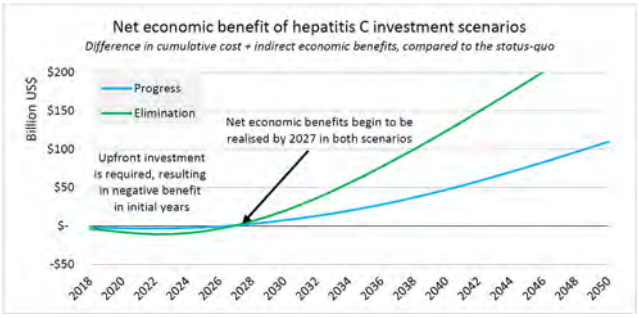


Figure: Net economic benefit of the elimination and progress investment scenarios compared to the status-quo

Conclusion: Achieving hepatitis C elimination requires a strategic approach nationally and internationally. However, investment in hepatitis C programs to achieve elimination is both cost-effective and becomes cost-saving by 2027.

PS-066

Patient flow across physician specialties over the course of the hepatitis C care cascade: A real-world analysis from the United States

Sanika Rege[1], Yuri Sanchez[2], Steven Marx[2], Shivaji Manthena[2], Nancy S Reau[3]. *[1]University of Houston, College of Pharmacy, Houston, United States; [2]AbbVie Inc., North Chicago, United States; [3]Rush University Medical Center, Chicago, United States*
Email: sanika.rege@gmail.com

Background and aims: Hepatitis C virus (HCV) infection is a major cause of hepatic and extrahepatic morbidity and mortality. In spite of recommendations for HCV screening, diagnosis, linkage to care and treatment, significant gaps remain in the cascade of care for HCV. As the role of physician specialties for closing these gaps is poorly understood, this study assesses the flow of HCV patients across physician specialties in the US, over the course of the care cascade.
Method: This retrospective real-world study used two large de-identified national laboratory datasets (2013–2016). Screened patients had a HCV antibody (AB) test and/or HCV RNA viral load test. Diagnosed patients had a positive HCV RNA viral load test, and among this group, fibrosis assessment, genotype test and treatment were evaluated. Treatment was inferred with an algorithm based on changes in viral load. The number/proportion of patients at each step in the care cascade was calculated by physician specialty. Patient flow by physician specialty over the course of care cascade was assessed using Sankey Diagrams.
Results: Approximately 17 million patients received HCV screening, and 913, 529 were diagnosed. Over the course of the care cascade, there was an increase in the proportion of patients switching to HCV specialists (gastroenterologist, hepatologist, and infectious disease specialist). Generalists (primary care, family practice, internal medicine) ordered 37% of the AB tests, and 15% initiated treatment. HCV specialists ordered 3% of screening tests and 37% initiated treatment. Most of the fibrosis assessment (30%) and genotype tests (29%) were ordered by HCV specialists. Obstetricians/gynecologists ordered 11% of screening tests but only 0.3% initiated treatment. Among 974, 277 patients who received a positive AB test, 46% did not receive a confirmatory RNA test. Among diagnosed patients, 57% did not receive fibrosis assessment, 47% did not receive genotype test and 90% did not receive treatment.

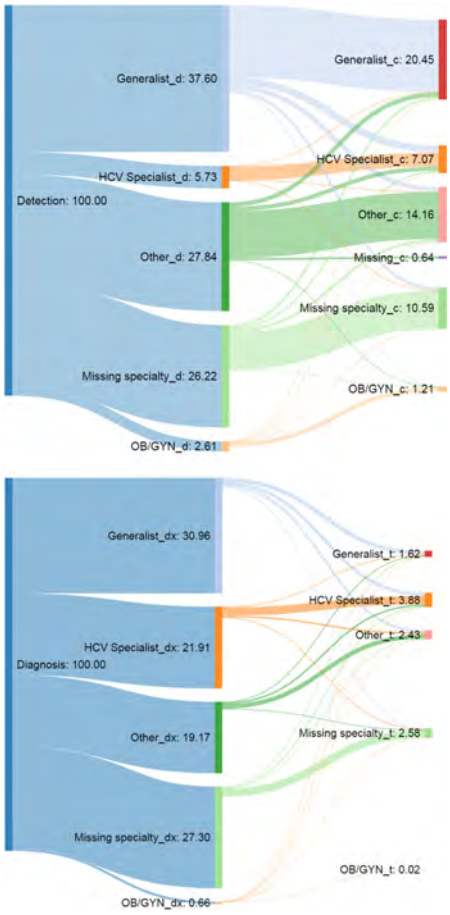

Figure: Sankey diagram of patient flow across physician specialties over the course of the care cascade. AB HCV detection to RNA confirmatory test (b) HCV diagnosis to treatment

Conclusion: Generalists account for more than one third of all HCV screening tests, however, HCV specialists play a more prominent role in patient assessment (fibrosis status, genotype testing) and treatment. Significant gaps remain in all stages of the cascade of care for HCV, and improved efforts are needed for every physician specialty to address them. Timely screening, monitoring and linkage to care by generalists coupled with early treatment by specialists could effectively reduce the hepatic and extrahepatic burden of HCV.

PS-067

Increasing incidence of HCV-GT2 as well as reinfections within the ongoing epidemic of acute HCV infections among MSM in Central Europe

David Chromy[1,2], David JM Bauer[1,2], Caroline Schmidbauer[1,2,3], Philipp Schwabl[1,2], Theresa Bucsics[1,2], Bernhard Scheiner[1,2], Gerold Felician Lang[4], Michael Gschwantler[3], Peter Ferenci[1], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2].
[1]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; [2]Medical University of Vienna, Vienna HIV and Liver Study Group, Vienna, Austria; [3]Wilhelminenspital, Wiener Krankenanstaltenverbund (KAV) der Stadt Wien, Department of Internal Medicine IV, Vienna, Austria; [4]Medical University of Vienna, Department of Dermatology, Division of Immunology, Allergy and Infectious Diseases, Vienna, Austria
Email: david.chromy@meduniwien.ac.at

Background and aims: An epidemic of acute hepatitis C virus (HCV) infections (AHC) among men who have sex with men (MSM) is currently observed in high-income countries. While a recent study reported a declining incidence of AHC, potentially due to the broad

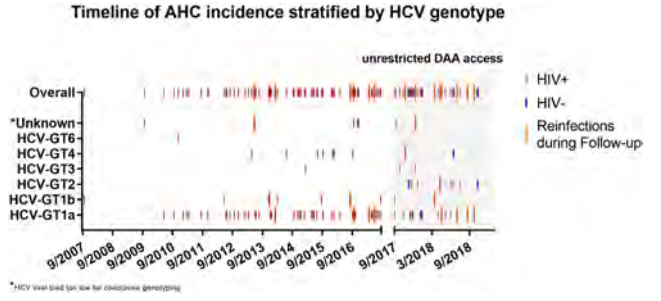
access to highly effective direct-acting antivirals (DAA), other studies found a further increase in AHC among MSM. As a consequence of these conflicting reports, we aimed to assess the characteristics of AHC patients at a large Central European tertiary care center in the era of unrestricted DAA-access.

Method: Patients presenting with AHC between 01/07 and 10/18 were retrospectively enrolled and followed after virologic clearance/eradication. AHC was defined by the European AIDS treatment network (NEAT) criteria.

Results: We identified 97 AHC patients with a mean age of 39 ± 8 years at inclusion. The majority of patients were male (95%, 92/97), HIV-positive (95%, 92/97), and MSM (87%, 84/97). After introduction of nationwide unrestricted DAA-access in Austria in 09/17 (DAA-era), a history of prior HCV infection at inclusion (i.e. previous episode of AHC or chronic HCV infection) was more frequent (33%, 8/24 vs. 7%, 5/73; p = 0.003). Importantly, when comparing infections occurring in the "pre-DAA-era" with infections after 09/17, we observed an increase in AHC incidence from 8.07 (95%-confidence interval (95-CI) 6.50–10.01) to 27.50 (95-CI 19.58–38.21) cases per year.

Patients were followed after spontaneous clearance or sustained virologic treatment response (SVR) for a total of 183.11 patient-years (PY; median 1.04). During follow-up, 15 reinfections were observed in 13 patients, corresponding to an incidence rate of 81.9 per 1000PY (95-CI 49.4-131.7) and a median time from SVR to reinfection of 1.51 years. Moreover, more than half of all reinfections (53% 8/15 vs. 47% 7/15) occurred in the DAA-era.

Interestingly, while HCV-genotype (GT)1a remained the most common HCV-GT (53%, 17/32 vs. 70%, 56/80), an outbreak of HCV-GT2 AHC was observed (25%, 8/32 vs. 0%, 0/80) in the DAA-era among both HIV+ and HIV- individuals (Figure).



Conclusion: We continue to observe a high incidence of AHC in Central Europe-primarily among HIV-positive MSM, but increasingly also in HIV-negative MSM. Notably, we also recorded an increasing number of reinfections and a significant rise in GT-2. Prevention strategies are urgently needed to confine further spread of HCV.

PS-068

The hepatitis C cascade of care and treatment outcomes among people who inject drugs in a Norwegian low-threshold setting: A real life experience

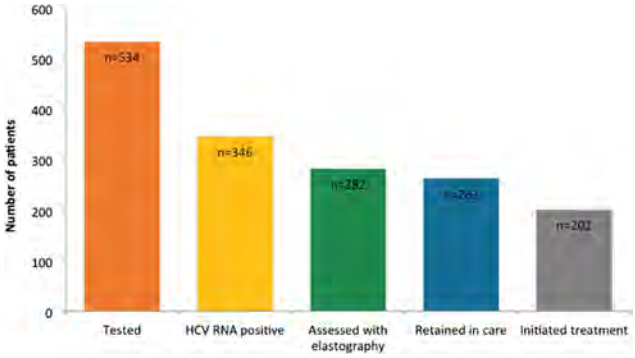
Håvard Midgard[1], Ulstein Kjersti[2], Backe Øystein[2], Tarjei Foshaug[2], Linda Elise Couëssurel Wüsthoff[2], Olav Dalgard[3]. *[1]Oslo University Hospital, Department of gastroenterology, Oslo, Norway; [2]Agency for Social and Welfare Services, City of Oslo, Oslo, Norway; [3]Akershus University Hospital, Department of Infectious Diseases, Lørenskog, Norway*

Email: havardmi@gmail.com

Background and aims: Improving hepatitis C virus (HCV) treatment uptake and outcomes among people who inject drugs (PWID) is crucial to achieve the World Health Organisation HCV elimination goals. The aim of this study was to describe the HCV cascade of care including treatment outcomes and reinfection rates in an urban cohort of PWID attending a low-threshold clinic.

Method: In 2013 a low-threshold clinic was established in downtown Oslo as an effort to provide HCV care for marginalised PWID. The clinic is located within the premises of the city's harm reduction services (including needle/syringe provision), and is staffed by a general practitioner and two nurses with specialist support. The nurses draw blood, operate a portable transient elastography device and provide individually tailored direct-acting antiviral (DAA) HCV treatment with emphasis on flexibility and ambulant work. In Norway, DAA treatment without fibrosis restrictions was available for all genotype 1 patients from February 2017, and for all HCV patients from February 2018.

Results: By September 2018 the clinic had tested 534 individuals, of whom 346 (65%) had chronic HCV infection. 282 of 346 (82%) were subsequently assessed with elastography (17% cirrhosis) and of those, 202 (72%) had initiated treatment. Cumulative treatment uptake among viremic individuals was 58% (202 of 346). Among 144 untreated individuals, 61 (42%) were retained in care, 76 (53%) were lost to follow-up and 7 (5%) had died. Among 110 individuals due for sustained virologic response (SVR) assessment by September 2018, mean age was 49 years, 76% were male, 29% had cirrhosis and 55% had genotype 1 infection. Injecting drug use during treatment was reported by 81% and 78% received opioid substitution treatment. In intent to treat analysis, SVR was observed in 93 of 110 (85%), one individual had virological failure, 6 discontinued treatment and 10 were lost to follow-up. In observed analysis, excluding discontinuations and loss to follow-up, 93/94 (99%) achieved SVR. Adherence of > 90% prescribed doses was reported by 91%. Follow-up data was available in 83 patients. Two cases of probable HCV reinfection (post-treatment HCV RNA recurrence in presence of risk factors) were observed over 71 PY of follow-up (incidence 2.8/100 PY [95% CI 0.34-10.2]).



Conclusion: HCV treatment uptake and virologic response was high among PWID attending a low-threshold clinic. This study provides real-life data on the feasibility of a model of care that could be disseminated to other urban areas.

PS-069

Towards HCV elimination: Feasibility of complete linkage to care by testing and treatment on the same day of screening: A pilot study

Gamal Shiha[1,2], Reham Elsayed[3,4], Nabiel Mikhail[5,6], Philippa Easterbrook[7]. *[1]Mansoura university, faculty of medicine, Hepatology, Mansoura, Egypt; [2]Egyptian liver research instiute and hospital, Mansoura, Egypt; [3]Egyptian liver research institute and hospital, mansoura, Egypt; [4]Faculty of Medicine Port Said University, Port Said, Egypt; [5]Assuit University Faculty of Medicine, Assuit, Egypt; [6]Egyptian liver research institute and hospital, Mansoura, Egypt; [7]Global Hepatitis Programme, HIV Department, World Health Organization, Geneva, Switzerland*

Email: g_shiha@hotmail.com

Background and aims: We developed a community-based outreach model (Educate, Test and Treat) for prevention, diagnosis and

treatment of hepatitis C infection. (Lancet Gastroenterol Hepatol, 2018). To date the model has been implemented in 73 villages across 7 governates in Egypt. The program achieved high uptake of HCV testing and linkage to HCV RNA confirmation and treatment. We estimate coverage of treatment and cure in about 84% of all adult HCV viraemic persons across the 73 villages. The median time from serological diagnosis to treatment initiation was 2.1 weeks (IQR: 0 to 3.3), The availability of an FDA and WHO pre-qualified GeneXpert instrument for measurement of HCV Viral load in less than two hours (105 mins) and in the absence of sophisticated lab requirements presents an opportunity to offer a same day "test, evaluate and treat" on the same day of screening. Our objective was to establish the feasibility of a same day "test and treat" model through provision of point-of-care HCV viral load confirmation using GeneXpert, and on-site Fibroscan and clinical evaluation in one village in northern Egypt

Method: This pilot study was conducted on 7th October 2018 at Beeden village, Tanah district, Dakahlia, in northern Egypt, preceded by an awareness raising campaign one week earlier. Key portable laboratory instruments were transferred from the Egyptian liver research institute and hospital (ELRIAH) to the village, and calibrated the day prior to screening: This included: GeneXpert IV for HCV RNA; Mindray BA-88A chemistry analyzer; FibroScan Echosens Mini System and routine abdominal ultrasound Siemens Acuson P300. A team of 3 physicians, 2 radiologists, 2 fibroscan operators, 1 pharmacist, 4 lab specialists, 7 nurses and 2 data entry personnel were mobilised for the same day test and treat pilot in the village. Screening was done using HCV antibody RDT.

Results: All staff arrived at 8:30 am, and screening commenced at 9:00 am. Results of the first 100 RDTs were available by 10:00am, and 16 were HCV antibody positive. Their PCR results were available by 12:00 pm, 11 cases were positive HCV RNA. Results of liver functions, renal functions, CBC, AFP, abdominal ultrasound and Fibroscan were obtained by 12:00 pm. Treatment was offered to the first 11 patients by 12:30 pm. so the 11 cases received treatment 3.5 hours after screening. The same process was repeated, by the end of the day (6:00 pm), 475 individuals were screened by RDT, 56 had their HCV PCR done, 43 were positive for HCV RNA by PCR, and 40 patients received their treatment. Three patients were excluded, 2 had hepatic focal lesions and one pregnant female.

Conclusion: We report the feasibility of implementation of screening, testing, clinical evaluation and treatment on the same day with almost complete linkage to care.

PS-070

Uptake of testing, linkage to care, and treatment for hepatitis C infection among people who inject drugs in Australia: The ETHOS Engage study

Heather Valerio[1], Maryam Alavi[1], David Silk[1], Carla Treloar[2], Andrew Milat[3], Adrian Dunlop[4,5], Jo Holden[6], Charles Henderson[7], Janaki Amin[8], Phillip Read[9], Louisa Degenhardt[10], Gregory Dore[1], Jason Grebely[1]. *[1]The Kirby Institute, UNSW Sydney, Sydney, Australia; [2]Centre for Social Research in Health, UNSW Sydney, Sydney, Australia; [3]Centre for Epidemiology and Evidence, NSW Health, Sydney, Australia; [4]Hepatitis NSW, Sydney, Australia; [5]Drug and Alcohol Clinical Services, Hunter New England Local Health District, Sydney, Australia; [6]Population Health Strategy and Performance, NSW Health, Sydney, Australia; [7]NSW Users and AIDS Association, Sydney; [8]Macquarie University, Sydney, Australia; [9]Kirketon Road Centre, Sydney, Australia; [10]National Drug and Alcohol Research Centre, UNSW Sydney, Sydney, Australia*

Email: hvalerio@kirby.unsw.edu.au

Background and aims: People who inject drugs (PWID) are at high risk of hepatitis C virus (HCV) infection but have poor access to HCV treatment in most settings. Unrestricted direct-acting antiviral (DAA) therapy has been available in Australia since March 2016. Our objective was to evaluate burden of HCV and the extent of, and factors associated with, engagement with the HCV cascade of care among PWID in an era of unrestricted DAA therapy access.

Method: ETHOS Engage is an observational cohort study collecting demographic, behavioural and clinical data among PWID attending drug treatment clinics and needle and syringe programs in Australia. All PWID underwent point-of-care (POC) HCV RNA testing via Xpert® HCV Viral Load Finger-Stick assay. Multivariate logistic regression models were used to identify demographic and behavioural factors associated with treatment uptake.

Results: Between May and November 2018, 507 PWID were enrolled. Overall, 70% had injected drugs in the last month, and 70% were currently receiving opioid substitution therapy (OST). Of all enrolled, 73% (n = 370) were ever HCV-infected (Ab positive), and 58% (n = 296) were ever chronic HCV-infected (RNA positive or prior treatment). Among those Ab positive (n = 370), 76% had previously been tested for HCV RNA. Among those with evidence of current or past chronic HCV (n = 296), 86% had ever been linked to care and 68% had ever received treatment for HCV. Uptake of HCV therapy was high across sub-populations, including those with current and no OST (71%, 59%) recent injecting (last month) (70%), and heroin (68%), other opioid (57%) and amphetamine (70%) injecting in the last month. In adjusted analysis, no factors were associated with treatment uptake. Among those with a POC HCV RNA result at enrolment, 26% had current HCV infection (HCV RNA+ve), 33% had treatment-induced clearance, 17% spontaneous clearance, and 23% were uninfected (HCV Ab-ve) (Figure). The proportion with current HCV infection was similar across demographic and behavioural sub-populations.

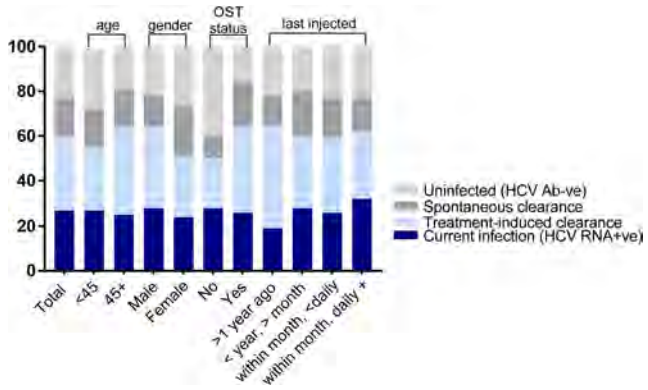


Figure: HCV prevalence among ETHOS Engage participants with known POC HCV RNA result at enrolment (n = 464)

Conclusion: The DAA era in Australia has produced high treatment uptake and lowered HCV viraemia among PWID attending drug treatment and needle syringe programs. To reach elimination targets, subgroups of PWID may require additional support to encourage further screening and engagement with HCV care.

PS-071

Piloting of integrated HCV, TB and HIV screening model at primary care level in Georgia

Irma Khonelidze[1], Amiran Gamkrelidze[2], Maia Lagvilava[3], Maka Danelia[4], Ketevan Stvilia[4], Ekaterine Ruadze[4], Maia Tsereteli[5], Irina Karosanidze[6], Vladimer Getia[7], Nana Odisharia[8], Anzor Kobalia[9]. *[1]National Center for Disease Control and Public Health, Global Fund Programs Implementation Unit, T'bilisi, Georgia; [2]National Center for Disease Conctrol and Public Health, Director General, Tbilisi, Georgia; [3]Ministry of Internally Displaced People from Occupied Territories, Labour, Health and Social Affairs, Tbilisi, Georgia; [4]National Center for Disease Conctrol and Public Health, Tbilisi, Georgia; [5]National Center for Disease Conctrol and Public Health, HIV, viral hepatitis, TB and STI unit, Tbilisi, Georgia; [6]National Family Medicine Training Center, Tbilisi, Georgia; [7]National Center for Disease Conctrol and Public Health, State*

Programs Department, Tbilisi, Georgia; [8]Public Health Unit of Samegrelo-Zemo Svaneti Region, Zugdidi, Georgia; [9]Public Health Unit of Samegelo-Zemo Svaneti Region, Head, Zugdidi, Georgia
Email: i.khonelidze@ncdc.ge

Background and aims: In 2018, With support of the Global Fund Georgia started a pilot project in one of the regions of Georgia (Samegrelo-Zemo Svaneti) to test the potential for integration of HCV, HIV and TB screening services at the regional level and to engage primary healthcare providers in detection and management of all three diseases under the "one umbrella."
Method: The integrated screening protocol and training module were developed and almost all primary healthcare providers (440 professionals) in the region were trained to ensure the quality of diagnostic procedures, ethical conduct, and accurate recording and reporting through web-based platform. Trained primary health care physicians currently offer triple screening to patients seeking for care at medical facilities, and also pursue active case finding using door to door approach for individual houses, congregate settings or public establishments. In case of AB positive test result, individuals were asked to provide vein blood samples for RNA testing at the point of care. Local government has invested in incentives for physicians and nurses providing screening. The horizontal integrated model has involved local public health department staff as well that along with the National Family Medicine Training Center was providing supportive monitoring and supervision.
Results: In three years before the pilot initiation only 58 500 people were screened for HCV in Samegrelo-Zemo Svaneti Region. In 7 months of the pilot project implementation 88, 178 people (90% of the annual target) were screened, including 66% tested in the rural areas of the region. 2279 (2.58%) were HCV antibody positive (anti HCV+), 1393 (61%) were RNA tested, out of which 1277 (91.7%) were confirmed, 718 (56.2%) were registered at HCV treatment sites and 499 (39%) were enrolled in treatment. The integrated screening program has allowed 60% increase of the local population number screened on HCV infection. In addition, within the pilot 37 HIV AB positive individuals and 192 presumptive TB cases were identified and referred for further confirmation and treatment.
Conclusion: The project implementation enabled development of sustainable public-private partnership for effective integration of TB/HIC/HCV screening and early disease detection with engagement of Central government, the local municipalities, the Global Fund as a donor and local service providers. It has also become the first precedent of local government contribution to priority health initiatives. The pilot motivated service providers to explore patient-centered approaches to case detection and supported decentralization of diagnostic services (HIV and HCV confirmation tests) to district level non-specialized facilities. Based the promising results obtained during the pilot in Samegrelo-Zemo Svaneti, It is planned to standardize and roll-out the approach countrywide in 2019–2020.

PS-072

Is homelessness the biggest hurdle to treatment success in the management of HCV in the era of direct acting antivirals? Results from the TraP HepC nationwide treatment initiative in Iceland

Email: magnusgo@landspitali.is

Background and aims: Hepatitis C virus (HCV) infection commonly affects people who inject drugs (PWID); injection drug use (IDU) is the driver of HCV transmission in many countries. Thus, special attention needs to be given to PWID in efforts to eliminate the disease. The Treatment as prevention for Hepatitis C (TraP HepC) program has provided access to direct acting antivirals (DAAs) without restrictions in Iceland since 2016, with the objective of eliminating domestic transmission of HCV in the country.
Method: From 01/2016 all HCV positive patients have been offered DAAs;-SOF/LDV ±RBV through 10/2016 and SOF/VEL±RBV thereafter. People with recent IDU, prisoners, and patients with advanced liver disease are prioritized. PWID receive additional support. Here, we analysed sustained virologic response rates at 12 weeks or later post treatment (SVR12+) using an intention to treat (ITT) design for all patients started on their first course of DAA during the first 24 months of TraP HepC.
Results: Treatment was initiated for 631 individuals, 80% of the estimated total HCV-infected patient population during the first 2 years of the project. Mean age was 43 years (range 19–83), males were 426 (67.5%). Recent (within 6 months) IDU was reported by 210 patients, 33.3% of the entire treatment cohort; of those 116 (55.2%) reported injecting within 30 days; 60 (28.6%) within 7 days. Overall, 40 (6.3%) were homeless, and 33 (5.2%) were incarcerated. Among those with history of recent IDU, stimulants were the preferred IV drugs by 86%, opiates by 14%, and 16% were receiving medication-assisted treatment. By ITT analysis, the overall cure rate (negative SVR12+) after the first treatment attempt was 89.2%, 82.9% among patients reporting recent IDU compared to 92.4% among those who did not ($p < 0.0001$). Those with recent IDU were more likely to discontinue treatment (15.2% vs 4.5%, $p < 0.0001$); if analysis is restricted to patients who completed treatment, their chance of cure on first attempt was nevertheless lower (89.9% vs 95.3%, $p = 0.025$). Homelessness was associated with a higher chance of persistent viremia at ≥ 12 weeks post treatment (relative risk RR, 2.42 (95%CI 1.34-4.37), $p = 0.007$), in contrast residence in a halfway house may be associated with lower risk (RR 0.37 (95%CI 0.12-1.16), $p = 0.068$). More than 90% of those who remained viremic after the first treatment attempt have been retreated.
Conclusion: Although rates of cure are lower among patients with recent history of IDU the vast majority of these patients are nevertheless cured on first treatment attempt with DAAs. Homelessness is associated with lower chance of treatment success, probably due to a higher chance of treatment discontinuation. This group needs to be targeted in order to curtail spread of HCV.

Real-world safety, effectiveness, and patient-reported outcomes in patients with chronic hepatitis C virus infection treated with glecaprevir/pibrentasvir: Data from the German Hepatitis C-Registry

Markus Cornberg[1], Albrecht Stoehr[2], Naumann Uwe[3], Hartwig Klinker[4], Lutz Thomas[5], Willibold Schiffelholz[6], Nazifa Qurishi[7], Andreas Pangerl[8], Kristina Lohmann[8], Bettina König[8], Karl-Georg Simon[9]. *[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]IFI Studien und Projekte GmbH, Hamburg, Germany; [3]UBN-Praxis, Berlin, Germany; [4]University Hospital Würzburg, Wurzburg, Germany; [5]Infektiologikum, Frankfurt, Germany; [6]Gastroenterologische Schwerpunktpraxis, Augsburg, Germany; [7]Gemeinschaftspraxis Gotenring, Cologne, Germany; [8]AbbVie, Inc, North Chicago, United States; [9]MVZ Dres Eisenbach/Simon/Schwarz/GbR, Leverkusen, Germany*
Email: cornberg.markus@mh-hannover.de

Background and aims: The coformulated direct-acting antivirals glecaprevir (identifed by AbbVie and Enanta) and pibrentasvir (G/P) are approved to treat chronic HCV infection. Recent real-world data show that G/P is safe and highly effective, but patient-reported outcomes (PROs) are limited, particularly in subgroups key to achieving HCV elimination. Here we report real-world data from the German Hepatitis C-Registry (DHC-R) on the safety and effectiveness of G/P, and PROs in patients with psychiatric disorders, alcohol abuse, active drug use, on opioid substitution therapy (OST), and/or with HIV coinfection, for whom treatment is sometimes deferred.
Method: The DHC-R is an ongoing, non-interventional, multicenter, prospective registry study. Data were documented by 135 sites in Germany. The analysis included adult patients with HCV genotype 1–6 infection treated with G/P according to the local label. The primary end point was SVR12, assessed in patients who received at least one dose of study drug. Safety, tolerability, and PROs were also assessed.
Results: The analysis included 1242 patients, the majority of whom were treatment-naïve and without cirrhosis (84%), and thus treated for 8 weeks. Reported comorbidities included on OST (N = 311; 25%), with psychiatric disease (N = 178; 14%), alcohol abuse (N = 78; 6%), HIV coinfection (N = 74; 6%) and active drug use (N = 33; 3%). The SVR12 (ITT) rate was 97% (592/609), including 100% SVR12 in 11 patients with active drug use. There were 2 reinfections; one treatment-naïve patient with GT3 infection without cirrhosis relapsed. Thirteen patients discontinued treatment; 3 due to an adverse event (AE) or serious AE. Excluding non-virologic failures, the modified SVR12 rate was 99.5% (584/587). Ten serious AEs have occurred; 3 were considered possibly related to treatment. Patients with available data in key subgroups reported improvements in both their mental and physical SF-36 component scores; generally, patients with comorbidities reported lower scores at baseline, and showed more improvement at end of treatment, than those without comorbidities (Table 1).

Table 1. SF-36 Components at Baseline and End of Treatment (EOT)

	Mental Component, mean (SD)		Physical Component, mean (SD)	
Subgroup (N)	Baseline	EOT	Baseline	EOT
No OST (N=198)	42 (13.0)	44 (12.4)	50 (9.4)	51 (8.5)
On OST (N=49)	37 (13.8)	43 (11.5)	48 (8.9)	51 (7.4)
No psychiatric disease (N=204)	42 (12.8)	46 (11.1)	50 (9.1)	51 (8.1)
Psychiatric disease (N=43)	34 (13.6)	35 (14.0)	48 (10.0)	51 (9.2)
No alcohol abuse (N=218)	41 (13.2)	44 (12.2)	49 (9.2)	51 (8.3)
Alcohol abuse (N=29)	37 (13.2)	43 (12.2)	48 (9.7)	51 (7.8)
Without HIV (N=227)	41 (13.4)	44 (12.1)	49 (9.4)	51 (8.4)
With HIV coinfection (N=20)	45 (10.3)	44 (13.7)	52 (7.6)	53 (5.9)
Total (N=247)	41 (13.3)	44 (12.2)	49 (9.3)	51 (8.3)
	p=0.000		p=0.001	

Conclusion: In this real-world analysis, G/P treatment was safe and highly effective, and led to significant improvements in SF-36 component scores, including in patients with key comorbidities. Updated safety and efficacy data, including healthcare resource utilization data and PROs at time of follow-up, will be presented.

GS-08

The prevalence of non-alcoholic fatty liver disease in young adults: An impending public health crisis?

Kushala Abeysekera[1,2], Gwen Fernandes[1], Gemma Hammerton[1], Fiona Gordon[2], Andrew Portal[2], Jon Heron[1], Matthew Hickman[2]. *[1]University of Bristol, Population Health Sciences, Bristol, United Kingdom; [2]Bristol Royal Infirmary, Bristol, United Kingdom*
Email: k.abeysekera@bristol.ac.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has an estimated worldwide prevalence of 20%. This has major implications: increased cardiovascular disease related morbidity; greater burden on transplant services; a rising prevalence of hepatocellular carcinoma. The impetus is on early preventative measures to halt cirrhotic change. A cross-sectional analysis performed on the Avon Longitudinal Study of Parents and Children (ALSPAC) cohort in late teens, identified a NAFLD prevalence of 2.5% by ultrasound criteria. The aim of this study was to identify the prevalence of NAFLD within the same cohort, now young adults, using transient elastography to measure fibrosis and steatosis with controlled attenuated parameter (CAP).
Method: 4020 study participants (SPs) had fibroscans using the Echosens 502 Touch®. SPs with known alcohol use disorder or excessive daily alcohol intake were excluded. Results with interquartile range/median ratio (IQR/M) greater than 30% were excluded when analysing fibrosis, but not CAP. Data was collated on multiple variables including Metavir fibrosis (F) score, steatosis grade, body mass index (BMI), and serology including alanine transaminase (ALT), aspartate aminotransferase (AST), and gamma-glutamyl transferase (GGT). Statistical analysis was performed using Stata MP 15.1.
Results: Mean age was 24 years (± 0.8). 3128 fibroscans were eligible for fibrosis analysis. 72 (2.4%) had fibrosis. 8 (0.3%) SPs had F4. ALT, AST and GGT were all associated with rising F score ($p = 0.002$, $p = 0.001$, $p < 0.001$ respectively). 3283 were eligible for analysis of steatosis. 780 (20.7%) SPs had steatosis; 377 (10.1%) had S3 steatosis. Females had significantly more steatosis than males ($p < 0.001$). ALT, AST and GGT all rose with CAP score ($p < 0.001$). CAP score was positively associated with F score ($p < 0.031$). Cholesterol levels,

ELSEVIER

triglycerides, and low-density lipoprotein rose with increasing steatosis grade ($p < 0.001$) whilst high-density lipoprotein levels fell ($p < 0.001$). BMI rose significantly with F score ($p = 0.019$) and CAP score ($p < 0.001$).
Conclusion: This is the largest study to date to analyse fibrosis and steatosis in young adults with suspected NAFLD using transient elastography. 1 in 5 had steatosis and 1 in 40 had fibrosis at 24yrs. This is raised from previous estimated prevalence of NAFLD within the same cohort 6 years prior. The results suggest greater public health awareness of NAFLD is needed in young adults in the UK.

GS-09

Ramucirumab for patients with advanced hepatocellular carcinoma and elevated alpha-fetoprotein following sorafenib: Outcomes by liver disease aetiology from two randomised, placebo-controlled phase 3 studies (REACH-2 and REACH)

Email: peter.galle@unimedizin-mainz.de

Background and aims: Two global, randomized, blinded, placebo (PL)-controlled phase 3 trials have studied ramucirumab (RAM) in patients (pts) with advanced hepatocellular carcinoma (HCC) following sorafenib, with the REACH-2 (NCT02435433) study limiting enrolment to pts with an alpha-fetoprotein (AFP) ≥ 400 ng/ml. REACH-2 met its primary end point of overall survival (OS) for RAM treatment compared to PL, consistent with the benefit observed in the pre-specified population of pts with baseline AFP ≥ 400 ng/ml in REACH (NCT01140347). An exploratory analysis on pooled individual pt data (IPD) of REACH-2 and REACH pts with baseline AFP ≥ 400 ng/ml was performed by liver disease aetiology subgroups.
Method: Eligible pts had advanced HCC, Child-Pugh A, ECOG PS 0 or 1, AFP ≥ 400 ng/ml, and prior sorafenib. Pts received RAM 8 mg/kg or PL every 2 weeks. A pooled IPD meta-analysis (stratified by study) of REACH-2 pts and REACH pts with AFP ≥ 400 mg/ml was performed. Results are reported by aetiology subgroup (Hepatitis [Hep]B, HepC, Other [e.g. significant alcohol use, steatohepatitis, and cryptogenic cirrhosis]). In each subgroup, OS and progression-free survival (PFS) were evaluated using Kaplan-Meier method and Cox proportional hazard model. Aetiology subgroup-by-treatment interaction was tested using Wald test in the Cox model. Overall response rate (ORR) and disease control rate (DCR) were reported by treatment arms within each subgroup.
Results: Baseline pt characteristics were generally balanced between treatment arms in each aetiology subgroup. A consistent treatment benefit for RAM v PL (Table) was observed across aetiology subgroups (OS interaction p value = 0.29). Grade ≥ 3 adverse events (AEs) were consistent with observations from both individual studies; hypertension was the most frequent grade ≥ 3 AE.

	HepB	HepC	Other
Analysis Population (RAM v PL)	N = 225 (RAM 124, PL 101)	N = 127 (RAM 76, PL 51)	N = 190 (RAM 116, PL 74)
OS median, months	7.7 v 4.5	8.2 v 5.5	8.5 v 5.4
HR (95% CI)	0.74 (0.55, 0.99)	0.82 (0.55, 1.23)	0.56 (0.40, 0.79)
PFS median, months	2.7 v 1.4	3.6 v 2.7	2.8 v 1.6
HR (95% CI)	0.55 (0.41, 0.74)	0.58 (0.39, 0.88)	0.57 (0.41, 0.79)
ORR, %	3.2 v 1.0	7.9 v 2.0	6.0 v 0.0
DCR, %	53.2 v 28.7	65.8 v 52.9	53.4 v 37.8

Conclusion: A treatment benefit with RAM was observed for pts with advanced HCC and a baseline AFP ≥ 400 ng/ml, regardless of aetiology. RAM was well tolerated with no new safety concerns.

GS-10

A germline mutation in SEMA4D leads to a familial syndrome of sclerosing cholangitis

Email: espen.melum@medisin.uio.no

Background and aims: Primary sclerosing cholangitis (PSC) is a severe chronic cholestatic disease with unknown etiology and lacking effective treatment options. A group of PSC risk genes have been described in previous studies, but none are PSC specific or causal. Here we report the first monogenic form of PSC in a Swedish family and clarify the mechanism for disease causality.
Method: Germline DNA from 5 family patients and 19 controls were subjected to whole-exome sequencing to identify causal mutations. 3178 unrelated PSC patients and 5024 healthy controls were screened for the same mutation. Then functional studies were carried out on peripheral blood mononuclear cells by flow immune-phenotyping, functional tests, and RNA sequencing after cell subset purification. DDC diet was employed to induce cholangitis in CD100 deficient mice or mutation knock-in mice generated using CRISPR.
Results: The inheritance pattern in the family was consistent with an autosomal dominant disease. We identified a heterozygous missense mutation private to this family which affects a highly conserved region at the cytoplasmic tail of SEMA4D/CD100. Patients carrying the mutation had no obvious change in major immune subsets, but displayed altered T cell function by means of increased proliferation

and TLR1/2 dependent responses. CD100 deficient mice and mutation knock-in mice exhibited abnormal bile flow rate and were more sensitive to DDC-induced cholangitis. More body weight loss, higher serum cholestatic markers, and more server histological phenotypes were observed in them. Mutant mouse T cells also showed similar functional alterations as T cells from familial patients. Finally, adoptive transfer of wild type T cells to CD100 genetically modified mice attenuated cholangitis.

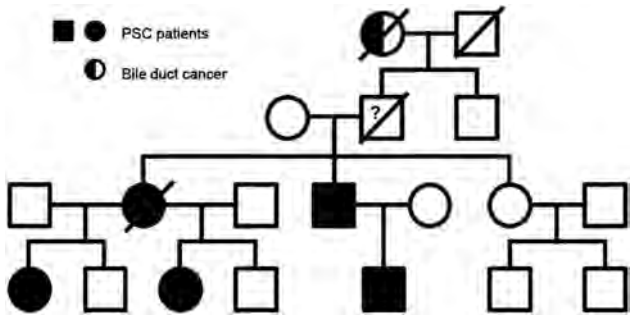

Figure: Pedigree of the Swedish PSC family. Squares: male subjects; circles: female subjects; black filled symbols: patients with PSC; half-filled symbols: patient with bile duct cancer but without a confirmed diagnosis of PSC; crossed-out symbols: deceased subjects.

Conclusion: We have identified the first monogenic variant of PSC and clarified potentially causal alterations in T cells. These findings suggest a role of CD100 in cholangitis pathogenesis which may represent a putative therapeutic target.

GS-11

Baseline neutrophil-to-lymphocyte ratio indicates both prevalent and incident infection and acute kidney injury, and is related to corticosteroid Lille response in alcoholic hepatitis

Ewan Forrest[1], Natasha Storey[1], Rohit Sinha[2], Stephen Atkinson[3], Nikhil Vergis[3], Michael Allison[4], Paul Richardson[5], Steven Masson[6], Mark Thursz[3], Peter Hayes[2]. *[1]Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom; [2]Royal Infirmary of Edinburgh, Liver Unit, Edinburgh, United Kingdom; [3]Imperial College, Liver Unit, London, United Kingdom; [4]Addenbrooke's Hospital, Cambridge Biomedical Research Centre, Cambridge, United Kingdom; [5]Royal Liverpool Hospital, Liver Unit, Liverpool, United Kingdom; [6]Freeman Hospital, Liver Unit, Newcastle, United Kingdom*
Email: ewanforrest@hotmail.com

Background and aims: The Neutrophil-to-Lymphocyte Ratio (NLR) has been shown to reflect sepsis and inflammation in a variety of illnesses. We assessed the role of NLR in the prognosis of alcoholic hepatitis.

Method: The NLR was calculated from 789 patients who participated in the STOPAH trial with patients randomised to receiving prednisolone or not. Prevalent Acute Kidney Injury (AKI) was defined by an initial creatinine ≥ 133μmol/l and incident AKI was defined as either an increase of serum creatinine by 26.5μmol/l or by 50% by Day 7 in those without baseline AKI. Patients presenting with infections (prevalent infection) were treated prior to randomisation; incident infections were determined after inclusion in the trial. Odds ratio and *t*-tests were used for comparative analysis. with 95% confidence intervals shown.

Results: Those with prevalent AKI had higher NLR than those without (11.1 *cf.* 6.0; p = 0.001 [2.6, 7.6]) as did those with prevalent infection compared with those without (7.8 cf. 6.3; p = 0.02 [0.2, 2.8]). Higher NLR values were seen in those with both incident AKI and infection (Table). A favourable Lille score with Prednisolone treatment was more likely if NLR ≥ 5 *cf.* < 5: (56.5% *cf.* 41.1%: p = 0.01; OR 1.86 (1.16, 2.99)). The risk of developing infection after Prednisolone treatment was greater if NLR > 8 *cf.* < 8 after 7 days (17.3% *cf.* 7.4%: p = 0.006; OR 2.60 (1.32, 5.14)) and 28 days (30.6% *cf.* 20.0%: p = 0.031; OR 1.76 (1.05, 2.96)). The risk of incident AKI after Prednisolone treatment was greater for those with NLR > 8 *cf.* < 8: 20.8% *cf.* 7.0%: p = 0.008; OR 3.46 (1.39, 8.62).

	NLR		
Incident AKI	Present (n = 67)	7.5 (6.4, 8.7)	p = 0.0056
	Absent (n = 403)	6.0 (5.6, 6.4)	(0.5, 2.6)
Incident infection Day 7	Present (n = 94)	7.8 (6.3, 9.2)	p = 0.035
	Absent (n = 695)	6.1 (5.8, 6.5)	(0.1, 3.1)
Incident Infection Day 28	Present (n = 185)	7.1 (6.3, 8.0)	p = 0.025 (0.1, 2.0)
	Absent (n = 604)	6.1 (5.6, 6.5)	

*p < 0.05, **p < 0.01, ***p < 0.001

Conclusion: High NLR is associated with both prevalent and incident AKI and infection in alcoholic hepatitis. A Lille response to prednisolone is more likely if NLR ≥ 5, but development of infection or AKI after prednisolone treatment is greater if NLR > 8.

GS-12

Ascending dose cohort study of inarigivir - A novel RIG I agonist in chronic HBV patients: Final results of the ACHIEVE trial

People's Rep. of; [16]Spring Bank Pharmaceuticals, Hopkinton, United States; [17]VIDRL, Melbourne, Australia; [18]Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong*
Email: cmacfarlane@springbankpharm.com

Background and Aims: Inarigivir, an oral dinucleotide RIG-I agonist has demonstrated anti-viral activity against HBV via a combination of activation of innate immunity and a DAA effect as a Non Nucleotide reverse transcriptase inhibitor (NNRTI). We report here the final results of the ACHIEVE trial, an ascending dose cohort study of 12 weeks of inarigivir followed by a switch to 12 weeks of tenofovir (TDF) 300 mg daily in treatment naïve HBV patients.

Method: 80 patients were randomized to inarigivir (25,50,100 and 200 mg) daily or placebo in a 4:1 ratio for 12 weeks and then all patients were switched to TDF. Primary endpoints were safety and efficacy measured by reduction in HBV DNA at week 12 from baseline. Secondary endpoints included HBV RNA, quantitative HBsAg, peripheral serum cytokines and change in ALT.

Results: Patient demographics are given in the table. Primary endpoint of HBV DNA reduction was achieved in a dose dependent fashion for both HBeAg positive and negative patients with a maximal reduction of 3.26 $\log_{10}$ in the 200 mg dose. HBV RNA paralleled HBV DNA reductions, with greater reduction in HBeAg

negative patients. Quantitative HBsAg response with a predefined threshold of a >0.5 log_{10} reduction at either week 12 or week 24 was seen in 22% of patients with a mean reduction of 0.8 log_{10} and a maximal reduction of 1.4 log_{10}. Unlike HBV DNA, HBsAg decline was not dose dependent and indicates the potential importance of the host response to inarigivir. Tolerability of treatment was good with 1 unrelated SAE of knee pain and 1 grade 3 non-sustained laboratory abnormality of hypertriglyceridemia. ALT flares (>200 IU) were seen in 6 treated patients (10%) and 4 placebo patients (25%) and 1 patient required dose discontinuation for ALT > 400 IU. No significant increases in bilirubin or INR were seen.

	Pbo E + ve	Pbo E – ve	Epos 25 mg	Eneg 25 mg	Epos 50 mg	Eneg 50 mg	Epos 100 mg	Eneg 100 mg	Epos 200 mg	Eneg 200 mg
n	8	8	9	7	11	5	13	4	8	7
Age	35	48	37	43	36	47	34	46	42	52
M: F	7:1	5: 3	5:5	3:3	9:2	5:0	7:6	3:1	4:4	2:5
ALT	85	53	82	75	75	65	75	90	54	73
HBVDNA	7.6 4	4.75	7.86	5.69	7.79	4.55	8.20	5.95	7.88	4.95
GTA		1		1						
GTB	2	6	4	3	3	4	4	3	2	5
GTC	6	1	5	1	7	1	8	1	6	2
GTD				2	1		1			

Conclusion: The ACHIEVE trial confirms the safety and anti-viral efficacy of inarigivir up to 200 mg daily and further studies at doses of up to 400 mg daily in combination with TDF or added to NUC suppressed patients are underway.

Hepatitis B – drug development

PS-073

Preclinical profile of HBV core protein inhibitor, ABI-H3733, a potent inhibitor of cccDNA generation in HBV infected cells

Qi Huang[1], Simon Haydar[1], Yi Zhou[1], Dawei Cai[1], Xiang Xu[1], Ran Yan[1], Lida Guo[1], Esteban Carabajal[1], Xuman Tang[1], Michael Walker[1], Roopa Rai[1], Mark Bures[1], Leping Li[1], Richard Colonno[1]. [1]*Assembly Biosciences, San Francisco, United States*
Email: richard@assemblybio.com

Background and aims: Clinical cure remains elusive in chronic HBV (CHB) patients, despite prolonged treatment with current therapies. Core protein Inhibitors (CPIs) represent a novel class of direct acting antivirals that target multiple aspects of the viral life cycle. Here we characterize a newly identified CPI with enhanced potency in blocking cccDNA establishment.
Method: Antiviral activities were determined using the induced HepAD38 cell line (Gt D), and infection of HepG2-NTCP cells and Primary Human Hepatocytes (PHH). Pan-genotypic activity was established using transient transfection assays or HBV stable cell lines. Combination studies were performed using a range of inhibitory concentrations in HepAD38 cells. HBV DNA was quantified by Taqman PCR (qPCR) using primers and a probe specific to the HBV core gene. HBeAg and HBsAg were quantified by ELISA. HBV total RNA/encapsidated pgRNA, capsids and capsid-associated core DNA were detected by either RT-qPCR, Northern Blot or b-DNA, Western Blot, Enzyme Immunoassay (EIA) and Southern Blot, respectively, as previously described.
Results: ABI-H3733 exhibited potent inhibition of viral DNA replication in HepAD38 cells and PHH (EC_{50} 5 and 12 nM, respectively), and reductions in HBeAg, HBsAg and pgRNA in infected HepG2-NTCP cells and PHH (EC_{50} 43 and 61 nM, respectively). ABI-H3733 antiviral activity was pan-genotypic and activity was retained against a panel of known CPI resistant variants. No significant activity was observed against other viruses (EC_{50}s > 10 µM) or in cytotoxicity assays (CC_{50}s > 10 µM). Combination studies predict additive to synergistic inhibition when combined with Nuc therapy. ABI-H3733 possesses promising physical properties, low drug-drug interaction potential and favorable PK profiles in multiple species. Mechanism of action studies suggest enhanced potency in blocking encapsidation of pgRNA, and disruption of pre-formed capsids (EC_{50} 133 nM), leading to premature disassembly during trafficking of rcDNA containing capsids to the nucleus during infection. Using Southern blot analysis, ABI-H3733 inhibited cccDNA formation with an EC_{50} of 125 nM.
Conclusion: ABI-H3733 is a novel CPI, derived from a new chemical scaffold. It possesses potent inhibitory activity against multiple steps in the HBV infectious cycle, particularly those related to cccDNA generation. The enhanced potency and favorable preclinical profile support advancement of this next generation CPI into clinical development.

PS-074

A first-in-class orally available HBV cccDNA destabilizer ccc_R08 achieved sustainable HBsAg and HBV DNA suppression in the HBV circle mouse model through elimination of cccDNA-like molecules in the mouse liver

Li Wang[1], Qihui Zhu[1], Jing Zeng[1], Zhipeng Yan[1], Andrew Feng[1], John Young[2], Lu Gao[1]. [1]*Roche Innovation Centre Shanghai, Shanghai, China;* [2]*Roche Innovation Centre Basel, Basel, Switzerland*
Email: lu.gao@roche.com

Background and aims: The persistence of covalently closed circular DNA (cccDNA) in the nuclei of infected hepatocytes is a major barrier for achieving cure with existing therapies in chronic hepatitis B (CHB) patients. Therapeutic agents that can reduce the level of pre-existing cccDNA are needed to achieve the goal of cccDNA eradication. Here we report the discovery of a novel small molecule, ccc_R08, which reduces pre-existing cccDNA both *in vitro* and *in vivo*.
Method: Primary human hepatocytes (PHH) were used for HBV infection experiments and evaluation of antiviral activities. The HBVcircle mouse model was used to study in vivo efficacy. Compound treatment was initiated after viral persistence established. The levels of HBV DNA, pgRNA, HBsAg, HBeAg were measured by quantitative polymerase chain reaction (qPCR), HBsAg chemiluminescent immunoassay (CLIA), and HBeAg CLIA kits, respectively. cccDNA from infected hepatocytes and mouse liver was measured with Southern Blot or qPCR after Hirt DNA extraction.
Results: We observed potent and dose-dependent inhibition of HBV DNA, HBsAg, and HBeAg upon ccc_R08 treatment initiated two days after HBV infection in PHH. More importantly, the pre-existing level of cccDNA was reduced significantly by ccc_R08 in HBV infected PHH. ccc_R08 did not show any significant cytotoxicity in PHH or in multiple proliferating cell lines at up to 100 µM. No significant effect on mitochondrial DNA was observed, indicating a specific effect on cccDNA. In vivo efficacy was evaluated in the HBVcircle mouse model, in which HBV replication was driven by cccDNA-like molecules. ccc_R08 was orally dosed twice daily for two weeks. Notably, the levels of serum HBV DNA, pgRNA, HBsAg, HBeAg were significantly reduced, and sustained during the off-treatment follow-up period. Moreover, at the end of follow-up, levels of cccDNA molecules in the liver of ccc_R08 treated mice were reduced to below lower limit of quantification (LLOQ). As a control, entecavir did not impact cccDNA level in this model. In summary, these results demonstrate that ccc_R08 can reduce pre-existing cccDNA.
Conclusion: We have reported results that a novel small molecule ccc_R08 can substantially reduce cccDNA levels in HBV infected hepatocytes and in HBVcircle mouse model. These data encourage exploration of this type of molecule in the clinic to evaluate its potential for curing CHB infection.

PS-075

AAV-delivered IL-21 activates CD8+ T-cells to clear HBV replicon plasmid and cccDNA in mice

Zhongliang Shen[1], Jing Liu[2], Jingwen Wu[1], Yuanfei Zhu[2], Gaiyun Li[2], Jun Wang[2], Mengjun Luo[2], Qiang Deng[2], Jiming Zhang[1], Youhua Xie[2]. [1]*Huashan Hospital, Fudan University, Shanghai, China;* [2]*School of Basic Medical Sciences, Fudan University, Shanghai, China*
Email: yhxie@fudan.edu.cn

Background and aims: Chronic hepatitis B virus (HBV) infection causes hepatitis, liver cirrhosis and hepatocellular carcinoma. HBV covalently closed circular DNA (cccDNA) is the sole viral transcription template in infected hepatocytes and is not cleared by current treatment options, thus constituting a key factor underlying HBV persistence in vivo. Previously, we established a mouse HBV persistence model based on hydrodynamic injection of HBV replicon plasmid and identified interleukin-21 (IL-21) as a potent regulator of HBV clearance in mice. We also recently described another HBV persistence mouse model based on cccDNA mimic termed recombinant cccDNA (rcccDNA) that is produced in vivo. Novel therapeutics with demonstrable effectiveness against cccDNA need to be developed.
Method: Antiviral effects of IL-21 were evaluated in HBV persistence models via adeno-associated virus (AAV)-IL-21 injection. Antibody block and adoptive transfer of immune cells were performed to investigate the cells involved in IL-21-mediated HBV clearance. To determine the long-lasting memory of antiviral effects, the cured mice were re-challenged with HBV.
Results: AAV-IL-21 treatments efficiently clears serum HBV markers and intrahepatic HBV replicon and rcccDNA. Antibodies against CD8+ T cells delayed IL-21-mediated HBV clearance. Adoptive transfer of splenic CD8+ T cells from the cured mice engenders clearance of HBV persistence in acceptor mice. IL-21-induced CD8+ T cell response harbors long-lasting memory that provides prolonged protection for the cured mice.
Conclusion: Our results demonstrate IL-21 as a sound basis for novel therapeutics against chronic HBV infection, with potential in removing cccDNA-harboring hepatocytes via activated CD8+ T cell responses and establishing subsequent long-term protection.

PS-076

Antiviral activity of JNJ-4964 (AL-034/TQ-A3334), a selective toll-like receptor 7 agonist, in AAV/HBV mice after oral administration for 12 weeks

Florence Herschke[1], Chris Li[2], An De Creus[1], Ren Zhu[2], Qinglin Han[2], Qing Lu[2], Tse -I Lin[3]. [1]*Janssen Pharmaceutica NV, Beerse, Belgium;* [2]*Janssen China RandD Center, Shanghai, China;* [3]*Janssen Biopharma, San Francisco, United States*
Email: adecreus@its.jnj.com

Background and aims: JNJ-64794964 (JNJ-4964), an oral toll-like receptor 7 (TLR7) agonist in clinical development for the treatment of chronic hepatitis B (CHB), may play an important role in restoring immune responses to hepatitis B virus (HBV). The ability of JNJ-4964 to restore anti-HBV immune responses was assessed preclinically in an adeno-associated virus/replicable HBV genome (AAV/HBV) mouse model.
Method: C57BL/6 mice infected with rAAV8-1.3HBV (genotype D) were treated orally with 20 mg/kg of JNJ-4964 weekly for 12 weeks and followed up for 4 weeks. The anti-HBV activity of JNJ-4964, and the capacity to induce HBV-specific immune responses, were evaluated by T and B-cell ELIspot assays.

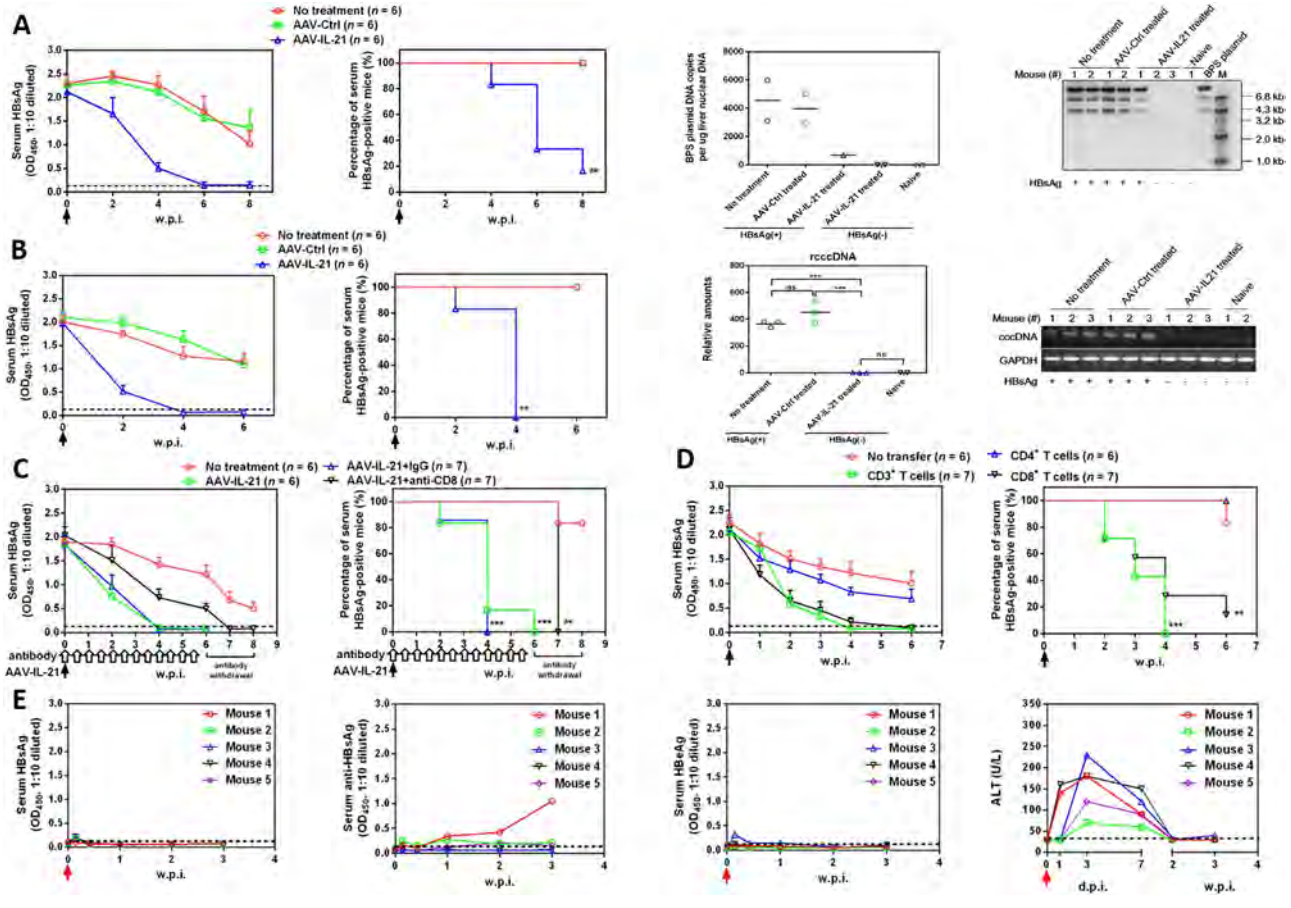

Figure: (abstract PS-075)

Results: JNJ-4964 showed potent anti-HBV activity in AAV/HBV mice treated for 12 weeks. HBV DNA and HBV surface-antigen (HBsAg) concentrations were undetectable for all animals 14 days after start of treatment with no alanine aminotransferase elevations. No rebound in HBV DNA and HBsAg was observed until the end of follow-up. Seroconversion (HBsAg under detection limit and with detectable anti-HBsAg antibody) was observed from 21 days after start of treatment through to the end of follow-up by which time liver HBV DNA and HBV RNA levels had dropped by 1.17 $\log_{10}$ and 0.5 $\log_{10}$, respectively. Four weeks after the last dose, HBV core-antigen expression was decreased and HBsAg became undetectable in the liver in half of the animals. Detectable T-cell and B-cell responses against HBsAg were observed at the end of treatment and the end of follow-up, suggesting sustained T and B-cell immunity in JNJ-4964-treated mice.
Conclusion: Oral administration of JNJ-4964 in AAV/HBV mice for 12 weeks resulted in potent and sustained anti-HBV activity resulting in HBsAg seroconversion and detectable HBsAg-specific T-cell and B-cell responses, supporting further investigation of JNJ-4964 in patients with CHB.

PS-077
Lenvervimab, a monoclonal antibody against HBsAg, can induce sustained HBsAg loss in a chronic hepatitis B mouse model
Jung-Hwan Kim[1], Hyunjin Kim[1], Tae-Hee Kim[1], Woohyun Kim[1], Jaesung Jung[1], Ara Lee[1]. [1]*Mogam Institute for Biomedical Research, Youngin, Korea, Rep. of South*
Email: lmv338@gamil.com

Background and aims: Two billion people worldwide have been infected with hepatitis B virus (HBV) and 240 million people live with the chronic infection. Chronic hepatitis B (CHB) patients are at high risk of death, accounting for more than 750, 000 deaths each year. Sustained loss of HBV surface antigen (HBsAg) is regarded as a marker for functional cure. Since HBsAg is known to suppress immune responses against HBV, it was hypothesized that removal of HBsAg might result in restoration of the immune responses.
Method: Therapeutic potential of Lenvervimab was evaluated in hydrodynamic injection (HDI) based CHB mouse model with surrogate Lenvervimab (sLenvervimab) in this study.
Results: Sustained HBsAg loss for 6 months was observed after cessation of the sLenvervimab treatment in 5 out of 12 mice (41.7%). The replication of HBV and HBV core antigen positive hepatocytes was hardly detectable in the liver of those mice. More than 1 log reduction in the copy number of the injected DNA (pAAV-HBV1.2), which act as a template for HBV replication as cccDNA does in natural infection, was observed and the level attained was comparable to that of self-limited mice. Immunohistochemistry of liver tissues showed infiltration of lymphocytes and structural changes of hepatocytes, resembling ballooning degeneration. Also, upregulation of inflammatory markers, such as Cox-2, interleukin-1β and prostaglandin E2, were observed. Statistically meaningful increase of ALT level was observed in the mice. However, the level could be classified as mild or moderate. The existence of protective immunity was confirmed by further challenge experiments to the HBsAg loss mice.
Conclusion: These results indicated that removal of HBsAg by Lenvervimab resulted in the restoration of immune responses against HBV and sustained HBsAg loss was caused by elimination of HBV positive hepatocytes. This study provides proof of concept for applying antibody based therapeutics to achieve a functional cure of CHB.

PS-078
A phase 1b evaluation of HepTcell HBV-specific immunotherapy in nuc-controlled, eAg negative chronic HBV infection
Young-Suk Lim[2], David Mutimer[3], Jeong Heo[4], Won Young Tak[5], William Rosenberg[6], Byoung Kuk Jang[7], Yoon Jun Kim[8], Dan Forton[9], Sybil Tasker[10], Bertrand Georges[11]. Email: stasker@altimmune.com

Background and aims: It is well understood that cellular immunity is key to HBV control. HepTcell is an immunotherapeutic synthetic

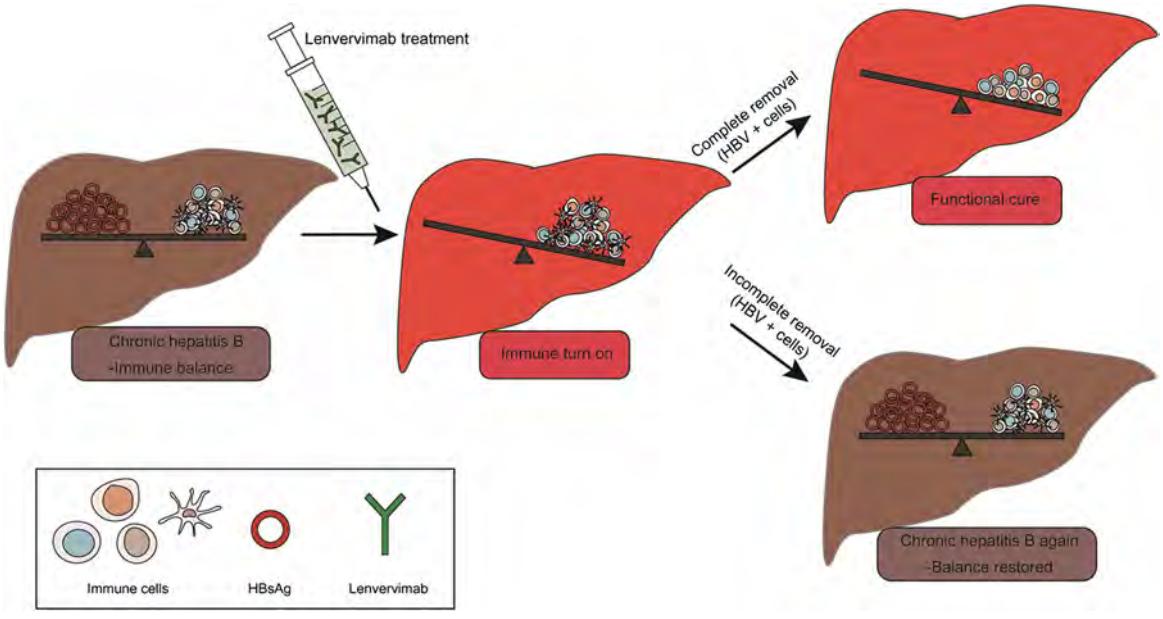

Figure: (abstract PS-077)

product composed of 9 peptides designed to drive T cell-immune responses against conserved regions of several HBV antigens. IC31® is a TLR-9 agonist-based adjuvant formulation designed to minimize systemic exposure.
Method: 60 HBeAg- subjects well controlled on entecavir or tenofovir were randomized to low and high dose peptides, with and without IC31, placebo, and IC31 alone across 3 dose-escalating cohorts. All subjects received 3 injections 28 days apart and were followed for 6 months after last injection. End points included patient and physician assessment of reactogenicity, adverse events including changes in transaminase levels, IFNγ-ELISpot of cultured PBMCs, and quantitative HBsAg.
Results: All doses were well tolerated with no SAEs or liver flares. The placebo group had higher baseline ELISpot responses, making immunology results difficult to interpret, but after the 3 injections, both adjuvanted peptide groups had increases in ELISpot spots/10^6 PBMC against the vaccine peptides compared to baseline values: Low + IC31 = +5608 (95% CI 0, +17483); High+ IC31 = +4804 (95% CI +2933, +10192); Placebo = +167 (95% CI −6717, +6692). Most of the response was driven by peptides derived from HBV polymerase antigen. Only one subject, a placebo recipient, had quantitative HBsAg decline > 0.5 log.
Conclusion: HepTcell immunotherapy was well tolerated and elicited HBV-specific immune responses in patients with well controlled HBeAg-negative chronic HBV. No effect on HBsAg was seen in this short course monotherapy study, but the safety and immunogenicity supports further evaluation in additional HBV populations and in combination with other novel products.

PS-079

HDV co-infection modifies the immunoproteasome profile of HBV infected hepatocytes leading to increased CD8 T-cell recognition: Implication for immunotherapy

Christine Y. L. Tham[1,2], Janine Kah[3], Anthony Tan[2], Alessandro Loglio[4], Camille Sureau[5], Marc Lütgehetmann[6], Pietro Lampertico[4], Maura Dandri[3,7], Antonio Bertoletti[1,2]. *[1]Singapore Immunology Network, A*STAR, Singapore, Singapore; [2]Duke-NUS Medical School, Program Emerging Infectious Diseases, Singapore, Singapore; [3]I. Medical Department, Center for Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]CRC "A. M. and A. Migliavacca" Center for the Study of Liver Disease, Gastroenterology and Hepatology Division, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [5]Institut National de Transufusion Sanguine (INTS), Paris, France; [6]Institute of Microbiology, Virology and Hygiene, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [7]German Center for Infection Research, Hamburg-Lübeck-Borstel Partner Site, Hamburg, Germany*
Email: antonio@duke-nus.edu.sg

Background and aims: Patients with HBV/HDV co-infection are at risks to develop liver cirrhosis and cancer. Immunological therapy utilizing engineered virus-specific T cells might eradicate HBV/HDV infected hepatocytes. However, the impact that HDV might exert on the T cell recognition of HBV infected hepatocytes is unknown. Here we first analyzed *in vitro* how HDV modifies HBV antigen presentation to CD8 T cells. We then tested the antiviral efficacy of engineered T cells in HBV/HDV co-infected humanized chimeric mice.
Method: Quantity of HBV CD8 T cell epitopes were measured on primary human hepatocytes (PHH) infected with HBV alone or co-infected with HBV/HDV using antibodies and CD8 T cells specific for either core or envelope HLA-A0201 restricted HBV epitopes. HDV infection was concomitantly stained with a Primeflow RNA assay and expression of innate immunity genes were analyzed using Nanostring technology. HBV-specific TCR T cells were engineered using TCR mRNA electroporation on T cells of healthy and HDV chronically infected subjects. HBV/HDV co-infected uPA-SCID/beige/IL2rg$^{-/-}$ (USG) mice repopulated with HLA-A02-matched primary human hepatocytes were used for *in vivo* adoptive T cell transfer experiments.
Results: HBV/HDV co-infected hepatocytes displayed a selected increase presentation of HBV envelope (~100 times) but not of core CD8 T epitopes. The increased epitope presentation was linked with activation of type I IFN genes and modification of immunoproteasome profile, leading to an enhanced target recognition by HBV-envelope specific CD8 T cells. Adoptive transfer of T cells engineered with TCR specific for envelope/A0201 complexes into HBV/HDV co-infected human liver chimeric mice triggered a rapid decrease of both HDV (> 0.5 log) and HBV viremia (> 1 log) in only 12 days. Intrahepatic analysis indicated that the amplitude of anti-HDV effects correlated to the amount of HBV/HDV co-infected cells present at baseline. Of note, TCR-redirected T cells engineered utilizing T cells of HBV/HDV co-infected patients display identical functional profiles with TCR-T cells of healthy controls.
Conclusion: The ability of HDV to activate immunoproteasome activity in HBV infected hepatocytes and boost the presentation of envelope derived HBV epitope support the therapeutic use of HBV envelope specific TCR engineered T cells in HBV/HDV co-infection.

PS-080

Short term RNA interference therapy in chronic hepatitis B using JNJ-3989 brings majority of patients to HBsAg < 100 IU/ml threshold

Man-Fung Yuen[1], Stephen Locarnini[2], Tien Huey Lim[3], Simone STRASSER[4], William Sievert[5], Wendy Cheng[6,7], Alex Thompson[8], Bruce Given[9], Thomas Schluep[9], James Hamilton[9], Gavin Cloherty[10], Danny Wong[1], Christian Schwabe[11], Kathy Jackson[2], Carlo Ferrari[12], Ching Lung Lai[1], Robert G. Gish[13,14], Edward Gane[11]. *[1]The University of Hong Kong, Hong Kong, China; [2]Victorian Infectious Disease Reference Laboratory, Victoria, Australia; [3]Middlemore Hospital, Auckland, New Zealand; [4]Royal Prince Alfred Hospital, Sydney, Australia; [5]Monash Health and Monash University, Melbourne, Australia; [6]Royal Perth Hospital, Perth, Australia; [7]Linear Clinical Research, Perth, Australia; [8]St. Vincent's Hospital, Melbourne, Australia; [9]Arrowhead Pharmaceuticals, Pasadena, United States; [10]Abbott Diagnostics, Abbott Park, United States; [11]Auckland Clinical Studies, Auckland, New Zealand; [12]University of Parma, Parma, Italy; [13]Stanford University, Palo Alto, United States; [14]The Hepatitis B Foundation, Doylestown, United States*
Email: mfyuen@hku.hk

Background and aims: RNAi with JNJ-3989 (previously ARO-HBV) has shown promising reductions in circulating CHB viral parameters based on its design to silence mRNA from cccDNA and integrated sources (AASLD 2018). The ongoing phase 2 portion of AROHBV1001 assesses 3 doses of JNJ-3989 administered weekly to monthly in HBeAg pos (e pos) or neg (e neg) CHB patients. Herein we report reductions in HBsAg levels below important literature proposed thresholds and exploration of loading dose effect.
Method: CHB patients (n = 56) received 3 subcutaneous doses of JNJ-3989. CHB cohorts 2b–5b (n = 4, e pos or neg, NUC treated or not) received monthly doses of 100, 200, 300 or 400 mg. Cohorts of e pos, NUC naïve and experienced CHB (cohorts 8, 9 respectively, n = 4 each) received 300 mg monthly. Loading dose cohorts (all n = 4, e pos or e neg, NUC treated or not) received bi-weekly or weekly doses of 100 mg (cohorts 6 and 7) or weekly doses of 200 mg (cohort 10) or 300 mg (cohort 11). Baseline NUC untreated CHB in any cohort receive NUCs from day1, continuing after JNJ-3989 dosing ends. HBsAg results reported are through day 113, 56 days after 3rd monthly dose when available or most recent in patients with data at least 14 days data following 3rd dose. In total, current HBsAg data is reported for 40 patients and safety for 56. Further data will be available at time of presentation.
Results: No serious AEs or dropouts have been reported. Injection site AEs (all mild) occurred in ~12% of 171 injections. Mean max log10 declines in HBsAg were: 100 mg 1.9, 200 mg 1.7, 300 mg 1.7 and 400 mg 2.0 logs in cohorts 2b–5b and 2.3 in cohort 8, 2.5 in cohort 9.

Giving JNJ-3989 more frequently (cohorts 6, 7, 10, 11) did not increase rate or extent of HBsAg knockdown; duration persisted at least 6 weeks after last dose. 97% (34 of 35) of patients reaching day 85 after first dose have > 1.0 log HBsAg reduction. Of 40 patients with ≥ 14 days follow-up after 3rd dose 3 had HBsAg < 100 IU/ml at baseline while currently 32 have achieved HBsAg < 100, 14 ≤ 10, 5 ≤ 1. Other viral parameters (HBV DNA, RNA, HBcrAg, HBeAg) above LLOQ at baseline improved.
Conclusion: Monthly RNAi reduced all measurable viral products, including HBsAg in e pos and e neg CHB. JNJ-3989 rapidly reduces HBsAg to thresholds associated with improved chances of HBsAg sero-clearance with characteristics desirable for a cornerstone therapy in finite regimens aimed at HBsAg clearance in CHB. JNJ-3989 has been safe and well tolerated.

Cirrhosis – Clinical aspects

PS-081
Systemic arterial blood pressure determines the therapeutic window of non selective betablockers in patients with decompensated liver cirrhosis

Tammo Lambert Tergast[1], Markus Cornberg[1,2,3], Michael P. Manns[1,2,3], Benjamin Maasoumy[1,2]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]German Centre for Infection Research (Deutsches Zentrum für Infektionsforschung DZIF), Partner-site Hannover-Braunschweig, Hannover, Germany; [3]Centre for Individualised Infection Medicine (CIIM), CRC Hannover, Hannover, Germany*
Email: tergast.tammo@mh-hannover.de

Background and aims: Non-selective β-blockers (NSBB) remain the cornerstone of primary and secondary prophylaxis of variceal bleeding. However, the safety of NSBB has been questioned in patients with advanced liver cirrhosis and ascites. It has been suggested that there is a limited therapeutic window. Yet, the specific limits of this window still need to be better defined. This study aimed to evaluate different potential limits of the therapeutic window of NSBB treatment in patients with liver cirrhosis and ascites.
Method: The impact of NSBB on 28day (d)-mortality was analyzed in a cohort of 624 consecutive patients with decompensated liver cirrhosis and ascites. Four potential limits of the therapeutic window were investigated: development of a spontaneous bacterial peritonitis (SBP), acute-on-chronic liver failure (ACLF), mean arterial blood pressure (MAP) ≤ 82 mmHg and < 65 mmHg. To adjust for potential confounding factors a multivariate Cox regression, including MELD, platelet count, presence of esophageal varices and leukocyte count, was performed.
Results: NSBB treatment was independently associated with a lower 28d-mortality in the overall cohort as well as in the subgroup of patients with ACLF (adjusted HR: 0.621; p = 0.035 and adjusted HR: 0.578; p = 0.031, respectively). Of note, even in the group of patients with SBP a numerical lower mortality was documented among NSBB users (adjusted HR: 0.594, p = 0.073). In contrast, survival benefits were markedly extenuated in those with a MAP ≤ 82 mmHg and completely lost in those with MAp < 65 mmHg (p = 0.536). However, NSBB was still not associated with an increased mortality in these patients. Similar results were documented in ACLF and SBP patients with a MAp < 65 mmHg. In SBP patients with MAp < 65 mmHg NSBB treatment was associated with renal impairment as indicated by an increase in serum creatinine (p = 0.027) as well as a numerically higher risk of grade 3 acute on kidney injury (HR: 2.266, p = 0.078). In patients with a MAP ≥ 65 mmHg NSBB treatment was independently associated with a lower 28d-mortality regardless of the presence of SBP or ACLF (overall cohort: adjusted HR: 0.582; p = 0.029, SBP cohort: adjusted HR: 0.435; p = 0.028 and ACLF cohort: adjusted HR: 0.480; p = 0.034, respectively).
Conclusion: Neither ascites, ACLF nor SBP per se seem to limit the safe usage of NSBB in patients with cirrhosis. In contrast, a low MAP might be a more valid indicator to determine the therapeutic window of NSBB treatment.

PS-082
Plasma metabolomic changes modulate the impact of Middle Eastern versus Western Diet in an international cirrhosis cohort

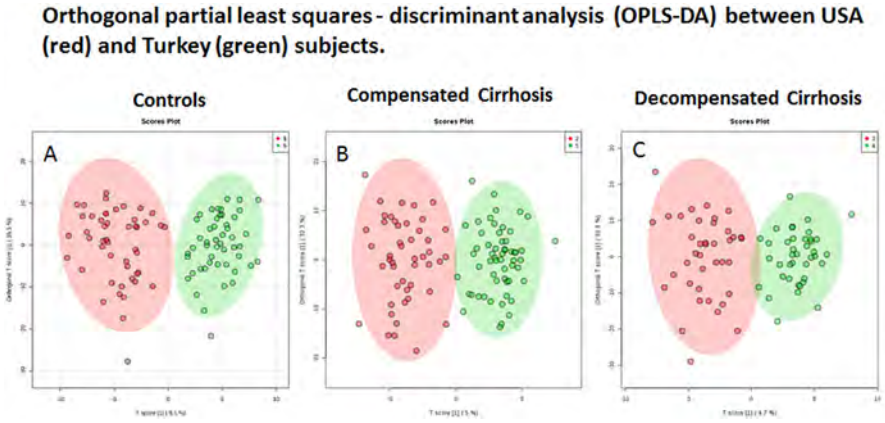
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Diet affects gut microbiota and modulates hospitalization risk in a Turkish versus USA cirrhosis cohort, and these may also influence the metabolite composition of blood. This study aimed to define circulating metabolites in plasma associated with Western and Middle-Eastern diet in healthy and cirrhotic subjects across USA and Turkey.
Method: Compensated (Comp) and decompensated (Decomp) cirrhotic outpts and healthy controls (ctrls) were enrolled from Turkey and USA. A dietary history, cirrhosis severity (MELD score), stool (16srRNA diversity) and plasma (NMR spectroscopy at 600MHz) were obtained. Plasma metabolomics were compared between and within the country-based cohorts and $Q^2 > 0.4$ indicated good separation on multivariate analysis.
Results: 296 age-balanced subjects (157 USA [8 ctrls, 59 comp, 50 decomp]; 139 Turkey [46 ctrls, 50 comp, 43 decomp] were included. Cirrhotics between cohorts had similar MELD scores (11 vs 12) metabolic syndrome and diabetes (p = 0.42). Diet: All of the USA cohort consumed a high-fat Western diet. Coffee intake was higher in US subjects, while tea, fermented milk and chocolate intake were higher in the Turkish group (all p < 0.05). Microbiota: We found a significantly higher diversity in Turkish cohort than USA group regardless of cirrhosis; diversity similar in Turkish group between controls and cirrhotics (p = 0.16), but altered within the US-cohort being lowest in decomp pts (p < 0.001). Metabolomics: *Between countries*: There were differences between controls, comp and decomp pts of US vs Turkey (Figure, Q^2 0.62, 0.41 and 0.60 respectively) due to a higher lactate and lipid differences in Turkey compared to US. CH2 and CH3 lipids were higher in earlier stages but lower in decomp in Turkey compared to US (Figure). *Within countries:* there were differences in plasma metabolites within the Turkish cohort, despite similar microbial diversity, which was greatest between ctrls vs cirrhosis (Q^2 ctrl-comp 0.44, ctrl-decomp 0.70 and comp-decomp 0.26). Within the US group, the difference was greatest between ctrl-decomp (Q^2 0.58) rather than ctrl-comp (Q^2 0.21) and comp-decomp (Q^2 0.28). Phosphocholine and CH2 lipids were lowest in decomp followed by comp and ctrls regardless of country, suggesting systemic lipid derangement related to cell regeneration.
Conclusion: Plasma metabolomics showed systemic differences in circulating lipid metabolites in Turkish vs US cirrhosis and healthy cohort related to the dietary changes. These could modulate the potential benefits of the Middle Eastern diet in cirrhosis.



D. Turkey grouping compared to USA grouping: Relative metabolite levels contributing to differences

Metabolite Turkey Vs USA	Control	Comp	Decomp
Lipid CH_2	↓	↓	↑
Lipid CH_3	↓	↓	↑
Lactate	↑	↑	↑
Choline compounds	-	↑	-

Email: paolo.caraceni@unibo.it

Background and aims: The ANSWER trial[1] recently showed that long-term administration of human albumin (HA) to patients with cirrhosis and uncomplicated ascites significantly improves 18-mo survival. Under such treatment, mean serum albumin level (SA) increased from 3.1 to 3.7-3.8 g/dl within 1 month, remaining stable thereafter. This post-hoc analysis aims to determine whether SA at baseline and during treatment predicts patient outcomes.
Method: The entire ITT population (431 pts randomized to standard medical treatment [SMT] or SMT+HA) of the ANSWER trial was included in the analysis. 3rd grade polynomial regression was used to smooth K-M survival probability estimate for each SA. Factors influencing the achievement of 1-mo SA thresholds were determined with logistic regressions. Survival analysis (K-M estimation and Cox regression) was then performed on SMT+HA pts grouped by 1-mo SA.
Results: Baseline SA ranged from 2.2 to 3.9 g/dl in both arms. According to the different baseline SA (0.1 g/dl increase), 18-mo survival ranged from 35 to 98% in SMT arm and from 70 to 98% in SMT+HA arm. A survival benefit was seen in SMT+HA arm for baseline SA up to 3.7 g/dl, which was associated with a 84% survival in both arms.
To identify on-treatment SA associated with an improved survival, 1-mo SA was first assessed in the entire population. SA of 3.8 and 4.1 g/dl corresponded to 80 and 85% survival, respectively. Factors independently associated with these 1-mo SA thresholds were baseline SA, baseline MELD score, and HA treatment with the latter being the most powerful predictor (3.8 g/dl: OR 24.77 [95% CI 11.72-52.35], $p < 0.0001$; 4.1 g/dl: OR 33.69 [95% CI 10.03-113.11], $p < 0.0001$). In the SMT+HA arm, the survival probability was 86% in pts with 1-mo SA > 3.8 g/dl (n = 82) and 67% in those with 1-mo SA ≤ 3.8 g/dl (n = 96) ($p = 0.007$), while it was 93% in pts with 1-mo SA > 4.1 g/dl (n = 59) and 70% in those with 1-mo SA ≤ 4.1 g/dl (n = 122) ($p = 0.002$). Patients not reaching these 1-mo SA thresholds had lower SA and higher MELD score at baseline.
Conclusion: Long-term HA administration provides a survival benefit in patients with uncomplicated ascites presenting SA even in the low-normal range. More important, a 1-mo on-treatment SA of approximately 4 g/dl is associated with a significantly higher survival. Baseline SA and disease severity influence the response to treatment. These data can be used to guide dosage and timing of long-term HA treatment.

PS-084

Pregabalin for muscle cramps in patients with liver cirrhosis: A randomized, double-blind, placebo-controlled trial

Won Kim[1], Jimin Han[1], Yoon-Ho Hong[1]. *[1]Boramae Medical Center, Seoul, Korea, Rep. of South*
Email: wonshiri@yahoo.com

Background and aims: Muscle cramps are defined as a paroxysmal, involuntary, and painful contraction of skeletal muscle. Cirrhotic patients can encounter with muscle cramp frequently, which might

be associated with poor quality of life. However, cirrhotic patients have limited access to many therapeutic drugs metabolized primarily in liver due to decreased liver function. Indeed, to date, a well-established therapy for cramp in liver cirrhosis is still lacking. This is the first randomized placebo-controlled trial of pregabalin in the treatment of muscle cramps in patients with liver cirrhosis. Here, we aimed to assess efficacy and safety of pregabalin against frequent muscle cramp with liver cirrhosis. And we also investigate the relationship of muscle cramps with quality of life (QOL) using 36-item Short-Form Health Survey (SF-36) and Liver Disease Quality of Life instrument (LDQOL).

Method: In our randomized, double-blind, placebo-controlled study, we enrolled participants up to 75 years old with diagnosed liver cirrhosis at the Seoul Metropolitan Government Boramae Medical Center from July 2011 to Dec 2017. The patients randomly allocated into the treatment (pregabalin) and placebo (dummy) groups, by a web-based randomization program. The primary outcome was the reduction rate of the frequency of muscle cramps in both groups. We assessed the primary outcome in all participants who received at least one dose and had at least one LDQOL and SF 36 measurement. We monitored adverse events in all participants. This study is registered with ClinicalTrials.gov, number NCT01271660

Results: Between July 2011, and February 2018, we enrolled 63 participants (30 randomly allocated pregabalin, 30 randomly allocated placebo, and 3 withdrew). In the pregabalin group, the reduction rate of the frequency of muscle cramps was significantly higher than placebo group ($p < 0.005$). The reduction rate of pain and frequency of muscle cramp during sleep did not differ in both groups. Two domains of SF-36, "Role limitations due to physical health" and "Pain", and one domain of LDQOL scores, "Symptoms", showed significant differences between the placebo and the pregabalin group ($p < 0.05$).

Conclusion: Pregabalin is generally well tolerated in cirrhotic patients and reduces the frequency of muscle cramp over placebo. Our trial showed pregabalin will be good candidate for cramp treatment in cirrhotic patients.

PS-085

The impact of ABO blood group on von Willebrand factor levels and the prevalence of portal vein thrombosis in patients with advanced chronic liver disease

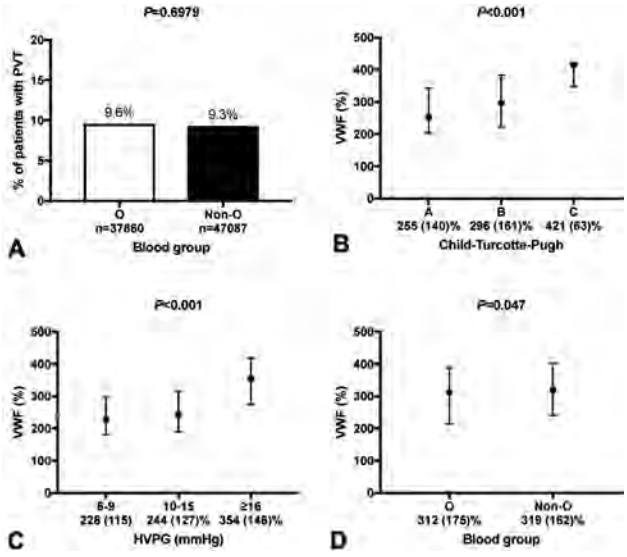
Bernhard Scheiner[1], Prof. Patrick G. Northup, M.D.[2], Anselm B. Gruber[1], Gerda Leitner[3], Prof. Peter Quehenberger, MD[4], Michael Trauner[1], Thomas Reiberger[1], Ton Lisman[5], Mattias Mandorfer[1]. *[1]Medical University of Vienna, Department of Gastroenterology and Hepatology, Vienna, Austria; [2]University of Virginia, Division of Gastroenterology and Hepatology, Charlottesville, United States; [3]Medical University of Vienna, Department of Blood Group Serology and Transfusion Medicine, Vienna, Austria; [4]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria; [5]University of Groningen, Surgical Research Laboratory and Section of Hepatobiliary Surgery and Liver Transplantation, Department of Surgery, Groningen, Netherlands*
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Non-O ABO blood group (BG) is a risk factor for arterial and venous thromboses in the general population, which has been attributed to the effect of BG on von Willebrand factor (VWF) plasma levels. Patients with cirrhosis commonly develop venous thrombosis, especially portal vein thrombosis (PVT). Procoagulant alterations, such as high VWF plasma levels, have been suggested as a risk factor. We aimed to assess **(1)** if BG is a risk factor for PVT and **(2)** whether BG impacts VWF plasma levels in patients with advanced chronic liver disease (ACLD).

Method: Retrospective analysis including two patient cohorts: **(1)** 'US' cohort including all adult liver transplantations in the US between 2002-2017 and **(2)** 'Vienna' cohort comprising patients undergoing hepatic venous pressure gradient (HVPG)-measurement at the Medical University of Vienna between 2006-2018 who had an HVPG ≥ 6mmHg and available information on BG and VWF plasma levels.

Results: (1) The 'US' cohort comprised 84947 patients. 55% had a non-O BG and except for ethnicity, we observed no relevant differences in patient characteristics between patients with BG O and non-O. Importantly, the prevalence of PVT at the time of liver transplantation was similar between groups (O: 9.6% vs. non-O: 9.3%; panel A).

(2) 420 patients were included in the 'Vienna' cohort; 64% with a non-O BG. Mean HVPG was 18 ± 6mmHg and 90% of patients had clinically significant portal hypertension (HVPG ≥ 10mmHg). VWF plasma levels were markedly increased, in a manner proportional to the degree of hepatic impairment (Child-Turcotte-Pugh: +16.5% VWF per point in adjusted analysis; panel B) and severity of portal hypertension (HVPG: +4.1% VWF per mmHg in adjusted analysis; panel C). VWF plasma levels were slightly higher in patients with a non-O BG (319 (162)% vs. 312 (175)%, p = 0.047 in unadjusted analysis; +23.6% VWF in adjusted analysis; panel D).



Conclusion: Elevated VWF plasma levels are related to the severity of liver disease with only a minor contribution of BG. BG was not a risk factor for PVT in a very large dataset, and this lack of association could be explained by the minor effect of BG on VWF plasma levels. Alternatively, hypercoagulability, for example caused by elevated VWF levels may only have a minor impact on PVT risk in patients with ACLD.

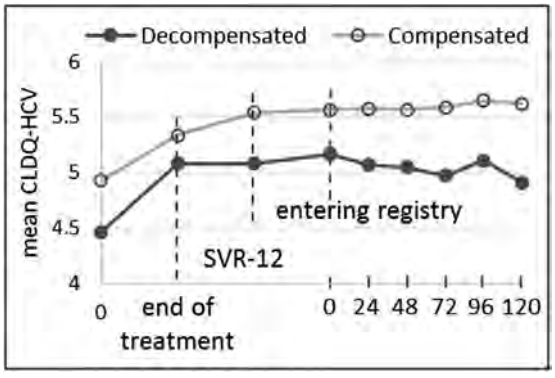
PS-086

Sustained virologic response in patients with cirrhosis from chronic hepatitis C leads to sustained and long-term improvement of health-related quality of life, fatigue, and work productivity

Zobair Younossi[1,2], Maria Stepanova[3], Andrei Racilla[3], Ira Jacobson[4], Andrew Muir[5], Stefan Zeuzem[6], Eric Lawitz[7], Stanislas Pol[8], Anuj Gaggar[9], Robert Myers[9], Issah Younossi[3], Fatema Nader[3]. *[1]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, United States; [2]Center for Liver Diseases-Department of Medicine, Inova Fairfax Medical Campus, Falls Church, United States; [3]Center for Outcomes Research in Liver Disease, Washington DC, United States; [4]NYU Langone Health, New York, United States; [5]Duke Clinical Research, Durham, United States; [6]Universitatsklinikum, Frankfurt, Germany; [7]Texas Liver Institute, San Antonio, United States; [8]Hopital Cochin, Paris, France; [9]Gilead Science, Foster City, United States*
Email: zobair.younossi@inova.org

Background and aims: Patients with chronic hepatitis C (CHC) and cirrhosis have severe impairment of health-related quality of life

(HRQL) and other patient-reported outcomes (PROs). Although achieving sustained virologic response (SVR) leads to improvement in PROs, the long-term sustainability of this improvement in patients with cirrhosis has not been well established.
AIM: To assess long-term changes in PRO scores in patients with cirrhosis who have achieved SVR after treatment with a direct-acting antiviral.
Method: Patients with HCV and cirrhosis who had been treated in 14 clinical trials and had achieved SVR-12 were prospectively enrolled in a long-term registry (#NCT02292706). PROs were collected every 24 weeks for 120 weeks using Short Form-36 (SF-36), Chronic Liver Disease Questionnaire (CLDQ)-HCV, and Work Productivity and Activity Impairment (WPAI) instruments which collectively return 20 PRO domain scores.
Results: Data was available for 785 HCV cirrhotics with SVR-12: 659 compensated (CC) and 126 decompensated cirrhosis (DCC). Their pre-treatment characteristics include age 57.6 ± 7.3 years, 69% male, 22% with type 2 diabetes, 50% employed. Prior to their initial treatment, DCC patients had severely impaired PRO scores in comparison to CC patients (by average 5.8% to 15.6% of a PRO range size; $p < 0.05$ for 15/20 PRO domain scores); the most pronounced difference between DCC and CC patients was in physical health- and activity-related domains. After achieving SVR and enrollment into the registry, significant PRO improvements from their pre-treatment scores were noted in 19/20 PRO domains in CC patients (ranging from average +2.2% to +17.0% of a PRO range size) and in 10/20 PRO domains in DCC patients (from +4.4% to +20.5% of a PRO score range) (all $p < 0.05$). These PRO gains persisted or continued to improve over time up to 120 weeks after entering the registry in patients with both CC and DCC (Figure). In DCC patients, the presence of hepatic encephalopathy was the most important contributor to PRO impairment (up to −10.2%, $p < 0.01$ for 12/20 PRO scores).



Conclusion: Achieving SVR leads to significant and sustainable improvement of PRO scores in patients with pre-treatment cirrhosis.

PS-087
Fecal microbiota capsules are safe and effective in patients with recurrent hepatic encephalopathy: A randomized, blinded, placebo-controlled trial
Jasmohan S Bajaj[1], Nita Salzman[2], Chathur Acharya[1], Richard Sterling[1], Andrew Fagan[1], Melanie White[1], Edith Gavis[1], Majdi Osman[3], Michael Hayward[2], Mary Holtz[2], Scott Matherly[1], Richard Todd Stravitz[1], Mohammad Siddiqui[1], Michael Fuchs[1], Binu John[1], Masoumeh Sikaroodi[4], Patrick Gillevet[4]. *[1]Virginia Commonwealth University and McGuire VA Medical Center, Richmond, United States; [2]Medical College of Wisconsin, Milwaukee, United States; [3]OpenBiome, Somerville, United States; [4]George Mason University, Manassas, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: Recurrent hepatic encephalopathy (HE) can cause major morbidity despite standard of care (SOC; rifaximin/lactulose). Fecal microbial transplant (FMT) enema can be useful but patients prefer capsular FMT. FMT without pre-intervention antibiotics also needs to be studied with emphasis on small intestinal barrier function. Aim: Determine the safety, tolerability and impact on brain function and mucosal/stool microbiota in recurrent HE after capsular FMT vs placebo.
Method: Cirrhotic outpts with recurrent HE on SOC were randomized 1:1 into receiving 15 FMT capsules vs placebo from a single donor enriched in beneficial Lachnospiraceae and Ruminococcaceae. Endoscopies with duodenal/sigmoid Bx and stool analysis, cognitive function (EncephalApp and Psychometric hepatic encephalopathy score PHES) and duodenal anti-microbial peptide (AMP) mRNA expression were performed pre-, 2/4 weeks post with 5 mth follow-up. Pts remained blinded and those assigned to FMT underwent repeat endoscopies 4 weeks post-FMT.SOC was continued throughout the trial.
Results: 20 subjects on lactulose/rifaximin were randomized 1:1. MELD score was similar at baseline (9.6 vs 10.2) and study end (10.2 vs 10.5). Hospitalizations/Death: 6 pts in the placebo group required hospitalizations/died compared to one in FMT ($p = 0.05$). The number of hospitalizations was higher in placebo vs FMT (median 1.5 vs 0, $p = 0.02$). Infection/HE episodes not requiring admission was similar (median 1 vs 1, $p = 0.5$, Fig 1A). Microbiota changes: Baseline diversity was similar between gps in stool, sigmoid and duodenal mucosa ($p > 0.05$). Post-FMT, there was a significant increase in duodenal mucosal diversity [2.1 vs 2.6, $p = 0.01$) and relative abundance of Ruminococcaceae and Bifidobacteriaceae with decrease in Streptococcaceae and Veillonellaceae in FMT pts (Fig 1B). No change in stool/sigmoid diversity was seen pre/post FMT but reductions in

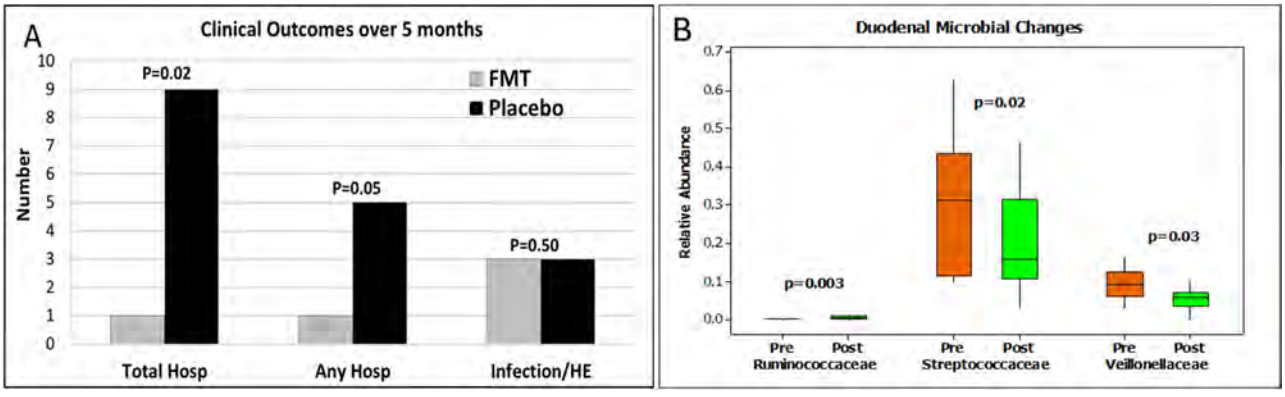


Figure: (abstract PS-087)

Veillonellaceae were seen post-FMT in sigmoid (p = 0.04) and stool (p = 0.05). Stool results over time were similar for placebo pts.
Duodenal inflammation/AMP expression: Baseline expressions were similar between groups. There was a significant increase in E-cadherin protein [pre 26700 (35500) vs post 43600 (35500) p = 0.03], reduced IL-6 [pre 146.4 (310.3) vs post 90.6 (117.4), p = 0.02] and increased Defensin A5 [pre 1821916 (271832) vs post 2430000 (3352500), p = 0.03] expression.
Brain function: Baseline EncephalApp scores were similar between groups (p = 0.57), which improved in the FMT group [250.2 (237.2) vs 224.9 (98.5), p = 0.02). PHES changes were similar at baseline and remained similar between groups post-intervention.
Conclusion: Oral FMT capsules were safely tolerated and associated with lower hospitalizations, improvement in duodenal mucosal diversity, dysbiosis and barrier function, and enhanced EncephalApp performance in cirrhosis and recurrent HE compared to placebo.

PS-088
Impaired cardiac contractile reserve on dobutamine stress echocardiography predicts development of hepatorenal syndrome

Anoop Koshy[1], Benjamin Cailes[1], Omar Farouque[1], Adam Testro[2], Jithin Sajeev[1], Jay Ramchand[1], Paul Calafiore[1], Hamid Salehi[1], Piyush Srivastava[1], Matthew Peverelle[2], Han Lim[1], Hui-Chen Han[1], Andrew Teh[1], Paul Gow[2]. *[1]Victorian Liver Transplant Unit, Austin Health, Cardiology, Melbourne, Australia; [2]Victorian Liver Transplant Unit, Austin Health, Gastroenterology and Hepatology, Melbourne, Australia*
Email: ankoshy@gmail.com

Background and aims: Development of hepatorenal syndrome (HRS) in end stage liver disease is associated with poor outcomes. Identifying early predictors of HRS may allow an opportunity for intervention. Preliminary studies in small cohorts have suggested a potential role of myocardial dysfunction in its pathogenesis. We hypothesized that a diminished cardiac contractile reserve was associated with development of HRS.
Method: Consecutive patients without known cardiac disease that underwent dobutamine stress echocardiogram (DSE) for pre-liver transplant (LT) workup between 2010-2017 were recruited. HRS was diagnosed based on guideline-based criteria. Cardiac output (CO) (stroke volume by left ventricular outflow tract velocity time integral × heart rate; HR) was prospectively recorded at baseline and low-dose (10 μg/kg/min) dobutamine.
Results: Among the 560 patients that underwent DSE, 27 were excluded (cardiomyopathy n = 14, beta-blocker use n = 5, arrhythmias n = 8). Overall, 85 (15.9%) patients developed HRS over a mean follow-up of 1.8 (±2.4) years. The HRS cohort had higher baseline CO (7.9 L/min vs 6.7 L/min, p < 0.001) but demonstrated a significantly blunted response to dobutamine (% ΔCO; 29.7% vs 44.6%, p = 0.002). This was primarily driven by an impaired heart rate (HR) response in the HRS cohort (ΔHR: 13bpm vs 18bpm, p = 0.004). Impaired contractile reserve was defined as < 22% increase in CO with low-dose dobutamine (derived from the lowest quartile of % ΔCO at low-dose dobutamine). A significantly higher proportion of patients with impaired contractile reserve developed HRS, 34 (40%) vs 87 (25%), p = 0.006. On multivariable logistical regression, after adjusting for age, gender, model of end stage liver disease (MELD) and Child-Pugh score, impaired contractile reserve was the strongest predictor for development of HRS (Odds ratio 2.2 95%CI 1.2-4.0, p = 0.02).
Conclusion: Patients that developed HRS demonstrate an attenuated rise in CO with low dose dobutamine, driven primarily by an impaired chronotropic response. Impaired cardiac contractile reserve identified on DSE was the strongest predictor for HRS and may offer a novel non-invasive method for early identification of patients at risk for HRS.

Liver fibrosis

PS-089
Development of advanced alcoholic liver fibrosis involves intensive remodelling of a wide range of extracellular matrix proteins and is characterised by imbalance between collagen formation and -degradation and dysfunctional wound-healing

Stine Johansen[1], Natasja Gudmann[2], Bjørn Stæhr Madsen[1], Maria Kjærgaard[1], Mette Juul Nielsen[2], Diana Leeming[2], Suganya Jacobsen[1], Sönke Detlefsen[3], Aleksander Krag[1,4], Morten Karsdal[2], Maja Thiele1[4]. *[1]Odense University Hospital, University of Southern Denmark, Department of Gastroenterology and Hepatology, Odense, Denmark; [2]Nordic Bioscience A/S, Herlev, Denmark; [3]Odense University Hospital, University of Southern Denmark, Department of Pathology, Odense, Denmark; [4]Odense University Hospital, OPEN, Odense Patient Data Exploratory Network, Odense, Denmark*
Email: stine.johansen@rsyd.dk

Background and aims: Liver fibrosis is the driver of liver related mortality in alcoholic liver disease (ALD). In search of key mechanisms for progression, we aimed to investigate remodelling of extracellular matrix (ECM) proteins as a function of the histological severity of asymptomatic ALD.
Method: We measured 21 markers of fibrosis and ECM remodelling in a biopsy controlled study of 305 ALD patients and 50 gender, age and BMI matched healthy controls. We excluded decompensated cirrhosis or alcoholic hepatitis patients. We evaluated total fibrosis by elastography (FibroScan) and serum hyaluronic acid (HA). Specific ELISAs quantified collagen type III, V and VI formation (PRO-C3, PIIINP, PRO-C5, PRO-C6), tissue inhibitor of MMP1 (TIMP1), collagen type IV and V degradation (C4M, C5M), and collagen cross-linking (LOXL2, PRO-C3X). Additionally, we evaluated vascular and elastin remodelling (PRO-C18, ELM, ELM7, EL-NE), and wound-healing by markers of fibrinolysis (D-Dimer), fibrin formation (FPA), thrombin inactivation (F1) and activation (F1 + 2), von Willebrand factor degradation (vWF-A) and formation (vWF-N). We correlated all markers with central histological scoring of fibrosis, inflammation, ballooning and steatosis, as well as with alcohol consumption, age and gender (figure).

		Histological characteristics								
		Fibrosis stage (0-4)	Lobular inflammation (0-3)	Portal inflammation (0-1)	Ballooning (0-2)	Steatosis (0-3)	Healthy controls	Abstinent at inclusion (yes-no)	Age*	Gender

Spearman's rho for pairwise correlations between the 21 markers and semiquantitative histological scores for fibrosis, inflammation and ballooning, together with drinking status at inclusion, age and gender. *Age in decades (<30, 30-39, 40-49, 50-59, 60-69 and ≥70)

Results: Mean age was 55 ± 10 years, 75% male, BMI 27 ± 7 kg/m^2. Compared to healthy controls, ALD patients had elevated levels of total fibrosis, collagen formation and degradation, and vascular and elastin remodelling, as a sign of ongoing ECM remodelling. This was irrespective of whether patients were actively drinking or abstinent

at inclusion. Patients with fibrosis stage F3-F4 showed an imbalance favouring collagen formation over degradation (34% higher PRO-C5 in F3-4 vs F0-2, compared to 6% higher C5M). A similar observation was seen in patients with severe ballooning and lobular inflammation (18% higher PRO-C5 vs 7% higher C5M). Also, fibrosis stage, lobular inflammation and ballooning correlated significantly with higher concentrations of fibrin degradation, low fibrin formation, lack of thrombin inactivation and more von Willebrand factor formation, as sign of a dysfunctional wound-healing cascade.
Conclusion: Alcoholic liver disease is characterised by extensive extracellular matrix remodelling, even after abstaining from alcohol. This study indicates that development of advanced fibrosis involve more collagen formation than degradation and dysfunctional wound-healing.

PS-090
SOX9 regulates extracellular matrix proteins in liver fibrosis that correlate with severity of fibrosis
Varinder Athwal[1,2], James Pritchett[1,3], Jennifer Scott[1,2], Katherine Martin[1,2], William Irving[4], Neil Guha[4], Neil Hanley[1,2], Karen Piper Hanley[1]. [1]*The University of Manchester, Manchester, United Kingdom;* [2]*Manchester University NHS Foundation Trust, Manchester, United Kingdom;* [3]*Manchester Metropolitan University, Manchester, United Kingdom;* [4]*University of Nottingham, Nottingham, United Kingdom*
Email: varinder.athwal@manchester.ac.uk

Background and aims: Extracellular matrix (ECM) deposition and resultant scar play a major role in the pathogenesis and progression of liver fibrosis. Identifying core regulators of ECM deposition may lead to urgently needed diagnostic and therapeutic strategies for disease. The transcription factor Sex determining region Y box 9 (SOX9) is actively involved in scar formation and its prevalence in patients with liver fibrosis predicts progression. We hypothesised that SOX9 regulated gene products could be utilised to predict severity of liver fibrosis.
Method: Primary rodent HSCs were isolated, and culture activated. Gene silencing was performed using short interfering RNA. Microarray was performed on *in vitro Sox9*-abrogated activated rat hepatic stellate cells (HSCs). *Sox9* deletion *in vivo* was induced in ROSACreER:*Sox9*$^{fl/fl}$ mice and fibrosis induced with injection of carbon tetrachloride or bile duct ligation. Chromatin immunoprecipitation (ChIP) assays were performed with a SOX9 antibody. Protein-DNA complexes were eluted, crosslinks reversed, and protein degraded prior to DNA purification and PCR. Serum paired with liver biopsy samples were obtained from chronic hepatitis C infected patients and assayed with sandwich ELISA for discrete proteins.
Results: In this study, transcriptomic approaches using *Sox9*-abrogated myofibroblasts identified > 30% of genes regulated by SOX9 relate to the ECM. Further scrutiny of these data identified a panel of highly expressed ECM proteins, including Osteopontin (OPN), Osteoactivin (GPNMB), Fibronectin (FN1), Osteonectin (SPARC) and Vimentin (VIM) as SOX9 targets amenable to assay in patient serum. *In vitro*, all identified proteins increased during HSC activation. SOX9 knockdown resulted in a commensurate reduction, suggesting regulation by SOX9. Moreover, *in silico* analysis revealed conserved SOX9 binding motifs in all identified ECM proteins, with 4 of the 5 demonstrating enrichment with ChIP. *In vivo,* all SOX9-regulated targets were increased in human disease and in mouse models of fibrosis and decreased following *SOX9*-loss in mice with parenchymal and biliary fibrosis. In patient serum samples, SOX9-regulated ECM proteins were altered in response to fibrosis severity.
Conclusion: These data support SOX9 as a key driver of the mechanisms underlying fibrosis and highlight SOX9 and its down-stream targets as new measures to stratify patients with liver fibrosis.

PS-091
Targeted disruption of TGF-B activation by an AVB1 integrin inhibitor significantly reduces liver fibrosis in CCl4 mice and Human NASH liver slices
johanna schaub[1], Martin Decaris[1], Maureen Reilly[1], Gail Lee[1], Shamra Martin[1], Vickram Rao[1], Chun Chen[1], Meghi Rexhepaj[1], Perna Kotak[1], Lisa Hooi[1], Katarina Leftheris[1], Jake Cha[1], Irene Lepist[1], Patrick Andre[1], Scott Turner[1]. [1]*Pliant Therapeutics, South San Francisco, United States*
Email: sturner@pliantrx.com

Background and aims: For many years, $\alpha_V\beta_1$ has been an elusive integrin as its distribution and expression levels were hindered by the lack of selective tools (integrin α_V can pair with 5 β integrins while β_1 integrin can pair with 12 α integrins). Although data in human tissue has been lacking, studies with a semi selective small molecule inhibitor has shown efficacy across multiple mouse models of fibrosis and suggested a prominent role of $\alpha_V\beta_1$ in TGF-β promotion of liver fibrosis.
Method: We have developed a sensitive electrochemiluminescence assay for the quantitation of $\alpha_V\beta_1$ in mouse models of liver fibrosis as well as human tissue samples from NASH and PSC patients. The efficacy of selective inhibition of $\alpha_V\beta_1$ was evaluated using an orally available, selective small molecule inhibitor of $\alpha_V\beta_1$ in vivo in CCl_4-treated mice and in precision cut liver slices from CCl_4-treated mice and explanted human cirrhotic liver tissue.
Results: In human livers $\alpha_V\beta_1$ expression (fig A) and SMAD3 phosphorylation (fig B) were significantly elevated in NASH and increased with increasing liver fibrosis stage. Integrin inhibition in precision cut human cirrhotic NASH liver slices reduced the expression of fibrosis related genes (fig C). In CCl_4 treated mice $\alpha_V\beta_1$ expression, SMAD3 phosphorylation, collagen gene expression and OHP concentration were significantly elevated. In vivo $\alpha_V\beta_1$ inhibition reduced SMAD3 phosphorylation, fibrotic gene expression and liver collagen content.

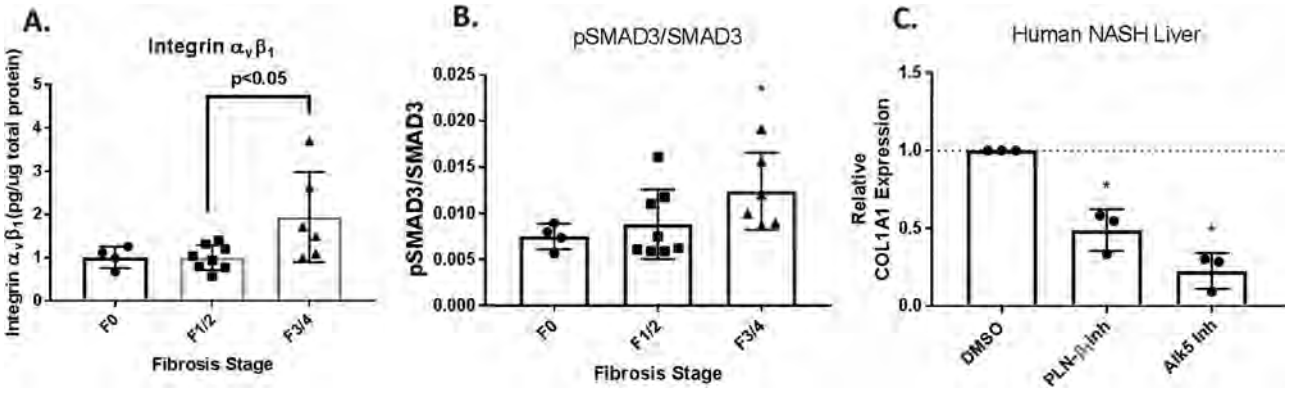

Figure: (abstract PS-091)

Conclusion: Inhibition of $\alpha_V\beta_1$-mediated activation of TGF-β significantly reduced expression of fibrotic genes in human precision cut liver slices and supressed liver fibrosis in mice warranting further evaluation.

PS-092

Lack of monoacylglycerol lipase protects from MCD-induced hepatic inflammation and fibrosis

Francesca Bruschi[1], Matteo Tardelli[1], Thierry Claudel[1], Robert Zimmermann[2], Sophie Lotersztajn[3], Michael Trauner[1].
[1]Medical University of Vienna, Vienna, Austria; [2]Medical University of Graz, Graz, Austria; [3]Université Paris XII-Val de Marne, Paris
Email: francesca.bruschi@meduniwien.ac.at

Background and aims: Monoacylglycerol lipase (MAGL) is the rate limiting step in the degradation of monoacylglycerols. It contributes to the production of arachidonic acid from endocannabinoid 2-arachydonoyl-glycerol (2-AG), thereby representing a metabolic hub between endocannabinoid and lipid signaling. NAFLD can progress to NASH and fibrosis with activation of hepatic stellate cells (HSC) as cellular source of fibrosis. Therefore, our aim was to explore the contribution of MAGL in HSC activation and metabolic liver fibrosis.
Method: Primary HSC and bone marrow derived macrophages (BMDMs) were isolated from wild type (WT) and MAGL knock-out (MAGL KO) mice and cultivated in vitro. To mimic NASH-induced fibrosis in vivo, we fed WT and MAGL KO mice a methionine-choline deficient diet (MCD) for 4 weeks. Fibrotic and metabolic markers were evaluated in primary HSC and total liver tissue by RT-PCR, western blot, immunohistochemistry (HandE, F4/80, Sirius Red, Oil Red O) and migration assays.
Results: After 4 weeks of MCD diet MAGL KO mice developed less steatosis (HandE), less inflammation (F4/80) and fibrosis (Sirius Red), compared to WT mice. In addition, analysis of hydroxyproline content (μg/mg) and total liver expressions of fibrogenic markers such as Collagen1α1, TGF-β, PDGFRβ and MCP-1 were significantly ($p < 0.05$) decreased in MAGL KO mice. Moreover, hepatic expression of de-novo lipogenesis related genes, such as SREBP-1c and FASN were significantly downregulated in mice lacking MAGL ($p < 0.05$), whereas PPARγ and its target gene CD36 were induced ($p < 0.05$), but there were no difference in bile acid synthesis (CYP7A1) and transporters expressions (BSEP, NTCP, MRP2, 3, 4) and cholesterol synthesis (SREBP-2, HMGCR). Interestingly, primary HSC isolated from MAGL KO mice displayed slower activation in vitro compared to WT HSC, supported by significant reduction of the fibrogenic markers Collagen1α1, PDGFRβ and α-SMA ($p < 0.05$) during the first 7 days of culture after isolation. Moreover, MAGL KO HSC showed less migration capacity and even stimulation with TGF-β (5 ng/ml) resulted in reduced amount of MCP-1, TIMP-1, Collagen1α1, SREBP-1c expressions in these cells ($p < 0.05$). BMDMs lacking MAGL have less migratory ability, also when stimulated with conditioned medium collected from activated HSC, compared to WT cells ($p < 0.05$). In addition, primary MAGL KO HSC accumulated less lipid droplets ($p < 0.05$) when challenged with oleic acid (100μM) and showed reduction of autophagic gene expression ATG7.
Conclusion: Lack of MAGL contributes to protect from hepatic inflammation and fibrogenesis in vivo and in vitro by reducing steatosis, inflammation and de-novo lipogenesis, thereby resulting in reduced HSC activation. Thereby, inhibition of MAGL may become a potential therapeutic strategy for NASH.

PS-093

The dynamics of elastin in collagen-based liver fibrosis: Accumulates late during progression and degrades slowly in regression

Wei Chen[1], Xuzhen Yan[2], Anjian Xu[1], Yameng Sun[2], Bingqiong Wang[2], Ai Ting Yang[2], Min Cong[2], Ji-Dong Jia[2], Hong You[2]. *[1]Experimental and Translational Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China; [2]Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China*
Email: youhong30@sina.com

Background and aims: Excessive deposition of elastin in advanced liver fibrosis may contribute to the declining reversibility of the disease. Our previous study has found that elastin crosslinking inhibition can effectively arrest liver fibrosis progression. To further understand the roles of elastin involved in liver fibrosis, we systematically investigated the expression, accumulation and degradation, and the ultrastructure of liver elastin and collagen, based on dynamic and bidirectional CCl_4-induced liver fibrosis mouse models.
Method: Dynamic and bidirectional liver fibrosis mouse model was established by CCl_4-intoxication. Multiple modalities were employed to observe and quantify liver elastin and collagen including cyto- and immunohistochemistry, immunofluorescence with 3D analysis, quantitative real-time PCR, western blot assays, biochemical analysis of collagen and elastin, and scanning electron microscopy.
Results: We found that the expression pattern of tropoelastin (soluble elastin) and collagen I was not completely comparable at both the transcriptional and posttranscriptional levels during liver fibrosis progression and regression. Elastin mainly accumulated onto the internodular fibrous septa and enlarged portal areas and intertwined with collagen I at the late stage of liver fibrosis. 3D analysis of elastin and collagen I by confocal immunofluorescence coupled, with biochemical analyses revealed that, with respect to collagen, elastin deposition was characterized by late aggregation in progression and slow turnover in regression. Based on the decellularized ECM scaffolds and in vitro models, scanning electron microscope analysis of the dynamic ultrastructures of elastin during ECM modeling and remodeling suggested that elastin globules physically interacted with collagen fibers in extracellular matrix.

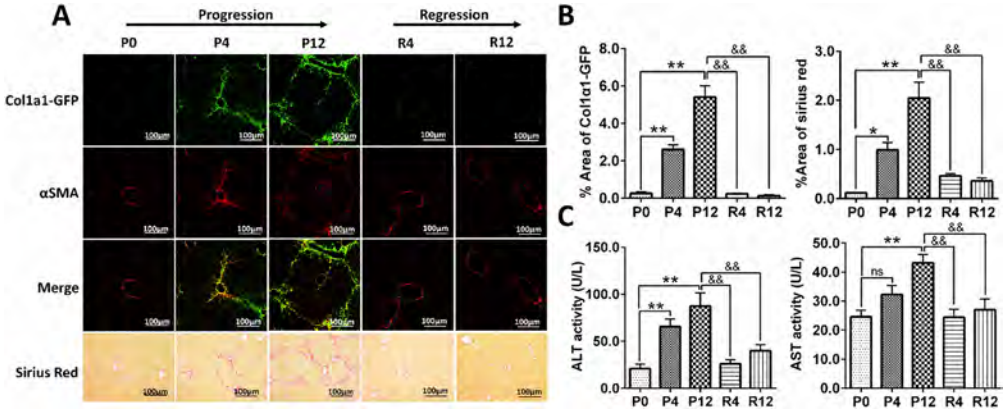

Figure 1: (abstract PS-093) Successful establishment of CCl4-induced liver fibrosis and spontaneously reversal model.

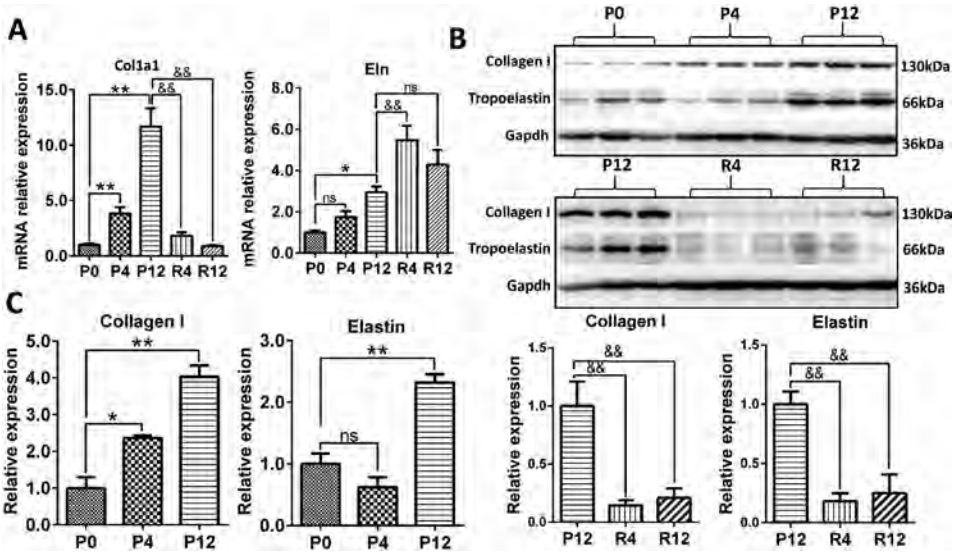

Figure 2: (abstract PS-093) Comparison of the expression pattern of collagen I and tropoelastin.

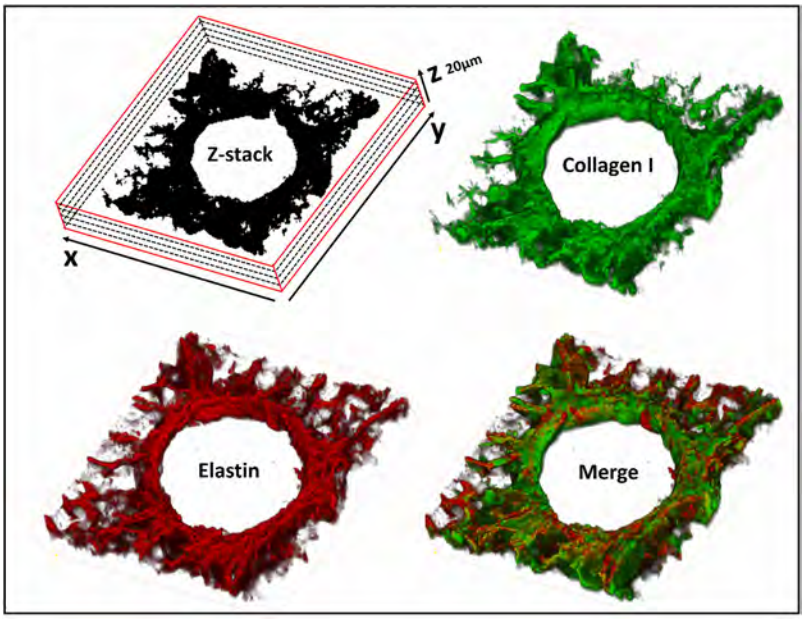

Figure 3: (abstract PS-093) 3D imaging model by laser scanning confocal microscopy.

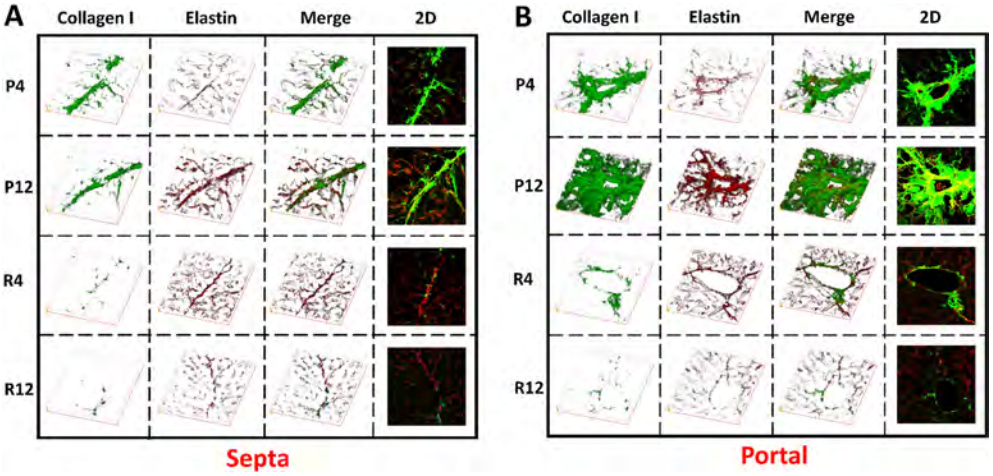

Figure 4: (abstract PS-093) 3D perspective views of extracellular collagen I and elastin colocalization in fibrotic and fibrolytic mouse livers.

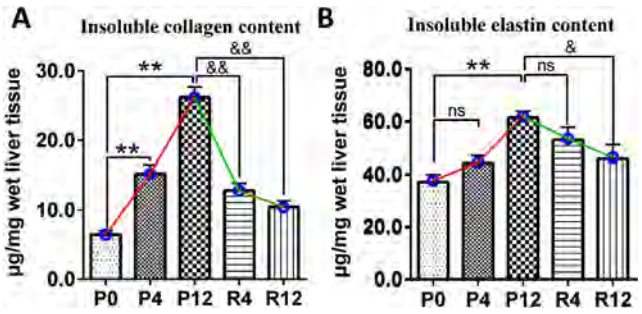

Figure 5: (abstract PS-093) Detection of liver insoluble collagen and elastin contents in bidirectional mouse models.

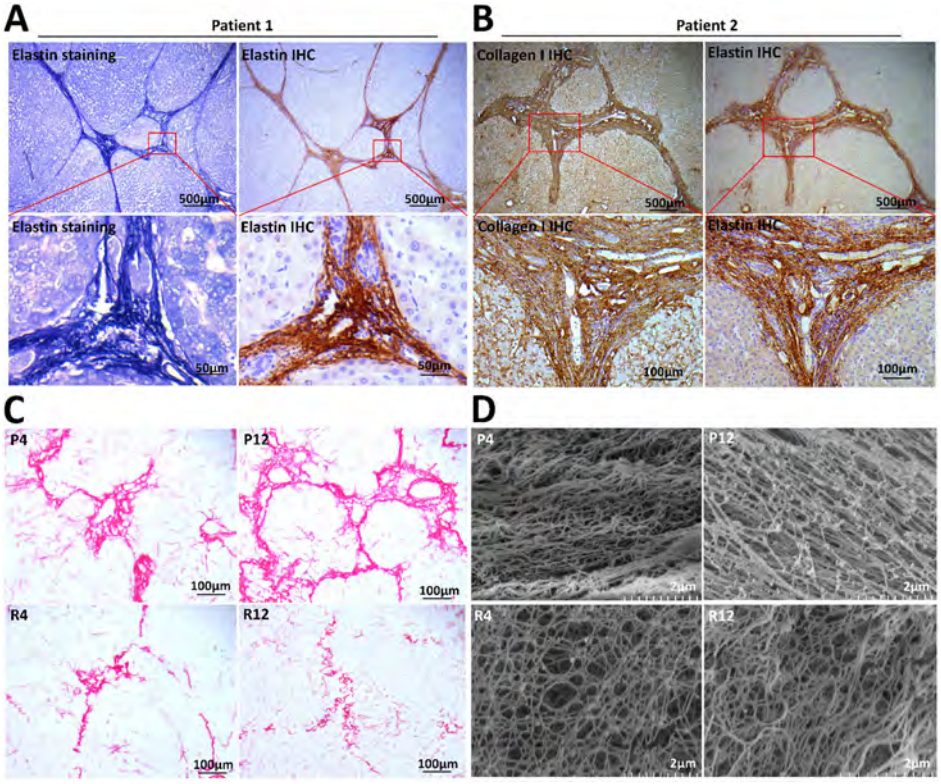

Figure 6: (abstract PS-093) Spatial localization of fibrotic liver collagen and elastin.

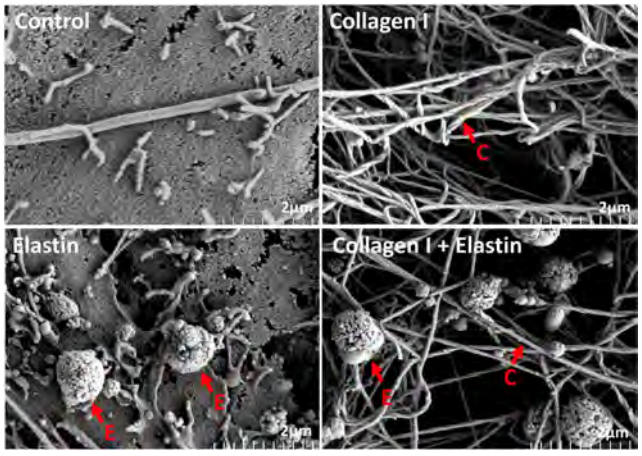

Figure 7: (abstract PS-093) Direct interaction between elastin globules and collagen fibers in ECM.

Conclusion: Our current study established new general hallmarks of elastin levels and forms in progressive and regressive liver fibrosis, and provided a foundation for further experimental investigation of the growing role of elastin in liver fibrosis regression.

PS-094

Selective activation of JAK-STAT1-mediated apoptosis in hepatic stellate cells as a new therapeutic option for liver fibrosis: Role of rilpivirine

Alberto Martí-Rodrigo[1], Ángela B. Moragrega[1], Aleksandra Gruevska[1], Anabel Fernández-Iglesias[2], Jordi Gracia-Sancho[2], Juan V. Esplugues[1,3,4], Nadezda Apostolova[1,4], Ana Blas-García[1,4].
[1]Departamento de Farmacología, Facultad de Medicina, Universitat de València, Valencia, Spain; [2]Liver Vascular Biology Research Group, Barcelona Hepatic Hemodynamic Laboratory, IDIBAPS Biomedical Research Institute-CIBERehd, Barcelona, Spain; [3]FISABIO-Hospital Universitario Dr. Peset, Valencia, Spain; [4]CIBERehd, Valencia, Spain
Email: alberto.marti-rodrigo@uv.es

Background and aims: Increasing incidence of chronic liver disease and lack of effective therapeutic options represent a serious health problem worldwide. JAK-STAT1 and 3 signaling pathways have been proposed as possible therapeutic targets since they regulate cell proliferation and death within the liver. In general, JAK-STAT1 activation induces apoptosis, whereas JAK-STAT3 promotes cell proliferation. Rilpivirine (RPV) is a widely used antiretroviral drug whose beneficial effects in the liver have been previously described by our group. We aimed to study the involvement of JAK-STAT1 and JAK-STAT3 signaling pathways in the hepatoprotective effect of RPV, analyzing its actions on hepatic stellate cells (HSC) and hepatocytes.
Method: A nutritional model of non-alcoholic fatty liver disease (NAFLD) and a CCl_4-induced liver fibrosis model (both in C57BL/6 mice) were used; RPV was daily administered at clinical doses. Human cell lines of hepatocytes (Hep3B) and HSC (LX-2), as well as human primary HSC (hHSC) were also treated with RPV. Standard molecular biology and histology techniques were used to assess the progression of liver damage and the activation of STATs. Gene silencing and conditioned medium experiments were carried out to evaluate the implication of STATs and the crosstalk between different cell types in response to RPV.
Results: RPV significantly reduced hepatic inflammation and fibrosis *in vivo*, and produced an increase of STAT3 activation in hepatocytes and of STAT1 in HSC. These effects were accompanied by augmented numbers of proliferating hepatocytes and apoptotic HSC. *In vitro*, RPV did not directly alter the viability or STAT3 activation in hepatocytes, but it did induce a clear pro-apoptotic effect in LX-2 cells, together with a decrease in STAT3 and collagen 1 protein expression, and an increase in STAT1 activation. Interestingly, this selective cytotoxic effect completely disappeared when STAT1 was silenced. In addition, STAT3 was activated in hepatocytes incubated with conditioned medium from apoptotic LX-2 cells. All these results were reproduced in hHSC.
Conclusion: The hepatoprotective effect of RPV is directly mediated by the selective STAT1-dependent induction of apoptosis in HSC. Additionally, RPV activates STAT3 in hepatocytes, increasing its proliferation and favoring liver regeneration. These effects could be of great clinical relevance in the development of new effective therapies for liver diseases with a fibrotic component.

PS-095
MerTK-mediated cytokine secretion mediates a cross-talk between M2c macrophages and hepatic stellate cells to induce fibrosis

Mirella Pastore[1], Alessandra Caligiuri[1], Chiara Raggi[1], Elisabetta Rovida[1], Giovanni Di Maira[1], Salvatore Petta[2], Fabio Marra[1].
[1]University of Florence, Florence, Italy; [2]University of Palermo, Palermo, Italy
Email: fabio.marra@unifi.it

Background and aims: Liver fibrosis is the consequence of chronic liver diseases caused by distinct etiologies, which can ultimately lead to cirrhosis and hepatocellular carcinoma. Among the main events initiating the fibrogenic process is the recruitment of inflammatory cells such as monocytes and macrophages, besides the activation of resident macrophages (Kupffer cells). These cells release several soluble mediators which induce the activation of various cells, including hepatic stellate cells (HSCs).
MerTK (Myeloid-epithelial-reproductive Tyrosine Kinase) is a receptor tyrosine kinase belonging to the TAM (Tyro3, Axl, Mer) subfamily of receptors and it is mainly expressed in M2c macrophages. In this study we evaluated a potential involvement of MerTK in the cross-talk between HSCs and M2c macrophages.
Method: Primary human HSCs and peripheral monocytes-derived macrophages were employed. M2c (CD206 + CD163 + CD209-) cells were differentiated by M-CSF, IL-10 and TGF-β and inhibition of MerTK expression was performed by UNC569, the first small-molecule Mer inhibitor. HSCs were exposed to Conditioned Medium (CM) of Gas-6-stimulated M2c macrophages. HSC Migration of was assessed by modified Boyden chamber, viability was measured by MTT assay, proliferation was evaluated by BrdU incorporation assay and gene expression by Real Time PCR.
Results: MerTK was phosphorylated in macrophages terminally differentiated towards the M2c phenotype, resulting in the activation of STAT3 and AKT, two downstream pathways. Moreover, exposure of M2c macrophages to Gas-6 further increased the phosphorylation of MerTK, that was reverted by pretreatment with UNC569. MerTK activation in M2c macrophages promoted HSC profibrogenic features, by inducing a significant increase in cell migration, viability, proliferation and in expression of profibrogenic genes, such as TIMP1, TGF-β1, IL-8 and VEGF-A. Furthermore, the treatment of HSCs with conditioned medium of Gas-6-stimulated M2c macrophages induced the activation of STAT3 and of two mitogen-activated protein kinases, ERK 1/2 and p38. These effects were specifically related to MerTK activity as indicated by pharmacologic inhibition.
Conclusion: Altogether, these data suggest the potential role of MerTK activation in M2c macrophages on HSC phenotype modulation.

PS-096
Validation study of the impact of hepatic iron concentration on the development of advanced hepatic fibrosis in HFE hemochromatosis

Justin Chin[1], Lawrie Powell[2], Louise Ramm[3], Elizabeth Mckinnon[4], Grant Ramm[2,3], John Olynyk[1,5]. *[1]Fiona Stanley Hospital, Department of Gastroenterology and Hepatology, Murdoch, Australia; [2]The University of Queensland, Faculty of Medicine, Brisbane, Australia; [3]QIMR Berghofer Medical Research Institute, Hepatic Fibrosis Group, Brisbane City, Australia; [4]Telethon Kids Institute, Nedlands, Australia; [5]Edith Cowan University (ECU), Joondalup Campus, School of Medical and Health Sciences, Joondalup, Australia*
Email: chinjustin@hotmail.com

Background and aims: HFE hemochromatosis (HH) is a common inherited disorder of iron overload in Caucasian populations. Phenotypic expression is variable with a minority of patients developing end organ damage such as liver fibrosis or cirrhosis, which when present reduces survival. Prior studies have shown that the hepatic iron concentration (HIC), and the product of HIC × age are associated with risk of advanced fibrosis. The aim of this study was to validate these predictors of the risk of fibrosis in an independent cohort.

Table 1: (abstract: PS-096).

	Mean HIC (umol/g)	95%CI	Mean HIC × age ([umol/g] × years)	95%CI	
Males	210.2	187.1–233.3	9066	7916–10217	P <
Females	155	126.8–183.1	7210	5719–8683	0.001
Males with advanced fibrosis	328.5	281–376	14443	12253–16634	p <
Males with no advanced fibrosis	173.9	153.4–194.4	7176	6143–8209	0.001
Females with advanced fibrosis	394.2	162.8–625.6	22061	12018–32104	p <
Females with no advanced fibrosis	135.4	114.4–156.3	5983	4988–6979	0.001

Method: We conducted a retrospective analysis of 140 male and 66 female subjects with HH who had undergone liver biopsy for diagnostic purposes. Baseline demographic data, alcohol consumption, biochemical results and liver biopsy histological assessments were available on all subjects. Statistical analyses including receiver-operator-curve (ROC) analyses and analysis of variance were performed using GraphPad Prism software and SPSS.
Results: The mean age at diagnosis was 42 yrs for males and 46 yrs for females. The mean values of HIC and the product of HIC × age in males were significantly higher compared with females (Table 1). In both males and females, these values were higher in the patients with advanced fibrosis (≥ F3) compared with those who did not have advanced fibrosis ($p < 0.001$). ROC curve analysis in males demonstrated that HIC alone had a sensitivity and specificity of 74% and 68% using a cut-off ≥ 200umol/g for diagnosis of advanced fibrosis (AUC = 0.79). In females, HIC alone had both a sensitivity and specificity of 80% using a cut-off > 197umol/g (AUC = 0.93). The ROC curve analysis in males for the product of HIC × age had both a sensitivity and specificity of 70% using a cut-off > 9152[mmol/g] × year for diagnosis of advanced fibrosis (AUC = 0.79). In females, the sensitivity and specificity for the product of HIC × age was 100% and 87% using a cut-off > 10400[mmol/g] × year (AUC = 0.97).
Conclusion: Levels of HIC above certain thresholds are predictive of increased risk of advanced fibrosis in HH. The product of HIC × age improves the prediction of advanced fibrosis predominantly in females, but adds little to predictions in males.

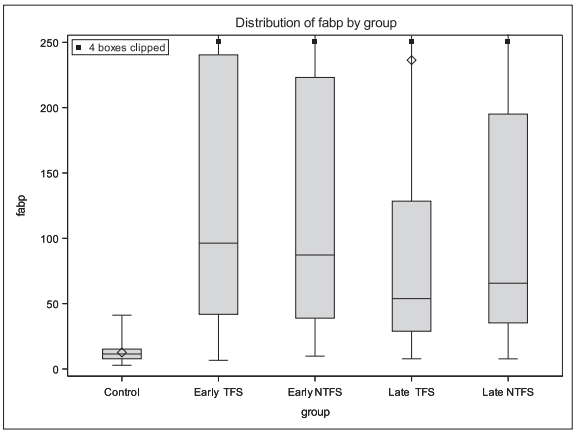
Acute and acute-on-chronic liver failure Translational aspects

PS-097

The association between liver type fatty acid binding protein serum levels and clinical outcomes in patients with non-acetaminophen acute liver failure: A cohort study

Constantine Karvellas[1], Jaime Speiser[2], Melanie Tremblay[3], William M. Lee[4], Christopher F Rose[3]. *[1]University of Alberta, Critical Care Medicine/Hepatology, Edmonton, Canada; [2]Wake Forest, Biostatistics, Wake Forest, United States; [3]Université de Montréal, Hepato-neuro Laboratory, CRCHUM, Montréal, Canada; [4]UT Southwestern, Medicine/Hepatology, Dallas, United States*
Email: dean.karvellas@ualberta.ca

Background and aims: Acute liver failure (ALF) is associated with significant mortality. Failure to identify non-survivors results in preventable deaths, while misclassifying prospective survivors may lead to unnecessary transplants (LT). Liver-type fatty acid binding protein (FABP1) is a 15 kDa protein expressed in hepatocytes. It has previously been demonstrated to improve prognostic discrimination in acetaminophen (APAP)-induced ALF but has not been investigated in other etiologies of ALF. Our primary aim was too determine if serial FABP1 levels (early; admission or late; day 3–5) are associated with 21-day transplant-free survival in non-APAP ALF.
Method: FABP1 was measured in serum samples from 384 ALF patients (n = 88 transplant-free survivors (TFS), n = 296 died/LT~ NTFS) using solid-phase enzyme-linked immunosorbent assay (ELISA) and analysed with US ALFSG registry data.
Results: Of 384 patients, etiologies of ALF included autoimmune hepatitis (AIH, n = 125), drug-induced liver injury (DILI, n = 141) and Hepatitis B (n = 118). Overall, 177 (46%) ALF patients received LT. Transplant-free survivors (n = 88) were less likely to require mechanical ventilation (21 vs. 66%), vasopressors (10% vs. 35%) and or have Grade III/IV hepatic encephalopathy (30% vs. 73%, $p < 0.0001$ for all) compared with patients who died/required LT. FABP1 levels were significantly lower in TFS patients at day 3–5 (TFS 54 vs. NTFS 66 ng/ml; $p = 0.049$; see Figure) but not admission (TFS 96 vs. NTFS 87 ng/ml; $p = 0.67$). After adjusting for significant covariates, increased FABP1 levels at late time points (day 3–5) were significantly associated with worse outcomes (death/LT) in AIH patients (Log FABP1 Odds Ratio (OR) 3.93 (1.50–10.32), P = 0.0055; AUROC 0.89). Increased late FABP1 was associated with worse outcomes in HBV (Log FABP1 OR 1.85 (0.96–3.59), P = 0.068; AUROC 0.82) and DILI (Log FABP1 OR 1.36 (0.97–1.91), P = 0.079; AUROC 0.72), but these were not statistically significant after adjusting for covariates. Similarly, FABP1 on admission was not significant (adjusted $p > 0.15$ for all subgroups).



Conclusion: This is the first report of FABP-1 in non-APAP-ALF. Used in combination with existing prognostic scores, FABP1 may potentially help identify ALF patients with higher recovery potential at later time points after a period of organ support.

PS-098

Prevalence and risk factors of first line anti-tuberculosis drug induced liver injury: Large cohort study involving 4652 patients

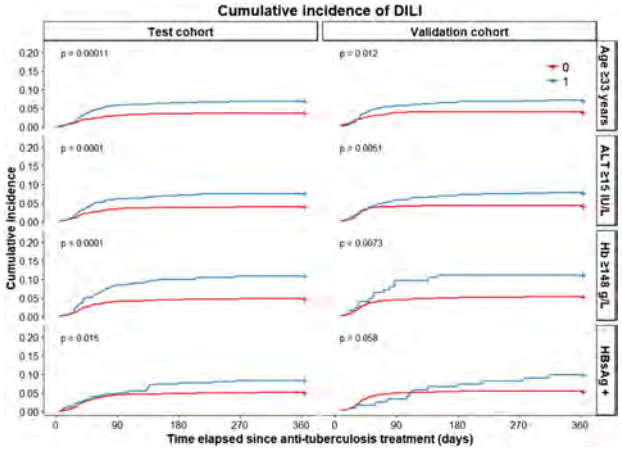
Lili Liang[1], Yan HUADONG[1], JingYuan Du[1], Jin susu[1], Yaoren Hu[1], Guruprasad Aithal[2]. *[1]Ningbo NO.2 hospital, hepatology, Ningbo, China; [2]Nottingham university, Nottingham Digestive Diseases Centre, Queen's Medical Centre Campus, Nottingham, United Kingdom*
Email: huadongy588@163.com

Background and aims: Reported prevalence of anti-tuberculosis drug-induced liver injury vary widely in the literature. The aim of this study was to investigate prevalence and risk factors associated with first-line anti-tuberculosis drug induced liver injury (DILI) in a large cohort of consecutive TB patients receiving first line intensive therapy.
Method: All patients diagnosed with tuberculosis from July 2011 to December 2015 in Ningbo No.2 hospital receiving a combination of isoniazid, rifampicin, ethambutol and pyrazinamide were enrolled. DILI was defined by serum alanine transaminase (ALT) levels of ≥ 5 times the upper limit of normal (ULN), or ≥ 3 times with 2 times ULN bilirubin or 2 times ULN levels of alkaline phosphatase (ALP). Risk factors for DILI were investigated using Cox regression analysis. A validation cohort (from January 2016 to July 2017) in Ningbo No.2 hospital was used to confirm our findings.

Table 1: Independent risk factors associated with DILI by multivariate Cox proportional hazard model in the training cohort

Variables	Regression coefficient	Hazard ratio (HR)	95% confidence interval (CI)	P value
Age	0.013	1.014	1.005–1.023	0.003
ALT	0.014	1.014	1.003–1.024	0.009
Hemoglobin (g/L)	0.012	1.011	1.002–1.020	0.02
HBsAg positive	0.461	1.516	1.004–2.290	0.05

Results: Of 3155 patients identified and followed, 170 (5.4%) developed DILI after a median 42.9 days from start of treatment. 143 (84.1%) was mild DILI; 27 (15.9%) developed jaundice; 9 (5.3%) was severe DILI (acute liver failure) and 2 died. Age, baseline ALT, hemoglobin and HBsAg positivity were independent risk factors for DILI. Age, baseline AST, active drinking and previous anti-TB treatment were independent risk factors for developing jaundice. In the validation cohort of 1497 patients, 87 (5.8%) developed DILI, age ≥ 33 years, baseline ALT (≥ 15 IU/l), hemoglobin (≥ 148 g/l) and HBsAg positivity were strongly predictive of DILI.



Conclusion: First-line anti-tuberculosis DILI and related death are lower than that has been reported in a large cohort of patients in China. Age, baseline ALT, hemoglobin and HBsAg positivity are risk factors for the development of DILI and these factors can be useful in choosing patients for close monitoring during therapy.

PS-099

PP100-01 (calmangafodipir) for overdose of paracetamol (The POP trial): Principal results

Emma Morrison[1], Katherine Oatey[2], Polly Black[3], Bernadette Gallagher[3], Julia Grahamslaw[3], Rachel O'Brien[3], Wilna Oosthuyzen[1], Robert Lee[2], Christopher Weir[2], Dennis Henriksen[4], The POP Trial Investigators[5], James Dear[1].
[1]University of Edinburgh, Pharmacology, Therapeutics and Toxicology, Edinburgh, United Kingdom; [2]Edinburgh Clinical Trials Unit, Edinburgh, United Kingdom; [3]EMERGE, Edinburgh, United Kingdom; [4]PledPharma AB, Stockholm, Sweden; [5]Edinburgh, Edinburgh, United Kingdom
Email: james.dear@ed.ac.uk

Background and aims: Paracetamol (APAP) overdose is a common cause of acute liver failure. Calmangafodipir (trial drug PP100-01) is a superoxide dismutase mimetic that prevents APAP toxicity in mice. The POP Trial was a phase 1, open label, rising dose, randomised study which explored the safety and tolerability of PP100-01 co-treatment with a 2 bag, 12 h, N-acetylcysteine (NAC) regimen in APAP overdose.
Method: Patients were recruited in the Emergency Department of the Royal Infirmary of Edinburgh from 8th June 2017 to 10th May 2018 with full ethical and regulatory approval. The inclusion criterion was: adults within 24 h of a single or staggered APAP overdose that required NAC treatment. Patients were randomly assigned, with concealed allocation, into one of 3 sequential dosing cohorts of 8 patients (NAC+PP100-01 n = 6; NAC alone n = 2). The intravenous doses of PP100-01 were 2, 5 and 10µmol/kg, administered between NAC bags 1 and 2. Participants, study and clinical teams were not blinded. The primary outcome was the safety and tolerability of PP100-01 combined with NAC. Pre-defined secondary outcomes included alanine transaminase (ALT) activity, full-length keratin-18 (FLK18) and microRNA-122 (miR-122), measured at baseline, 10 and 20 h after starting NAC. FLK18 and miR-122 are hepatotoxicity biomarkers that have regulatory support for exploratory use in trials.
Results: All 24 participants received their allocated dose of PP100-01 and NAC. All were included in the analysis. All participants experienced at least 1 adverse event (AE). The numbers experiencing at least 1 serious adverse event (SAE) were: NAC alone, 2/6; NAC +PP100-01 (2µmol/kg), 4/6; NAC+PP100-01 (5µmol/kg), 2/6; NAC +PP100-01 (10µmol/kg), 3/6. There were no AEs or SAEs probably or definitely related to PP100-01.No treatment group had an increase in ALT (baseline to 20 h). Median FLK18 at 20 h was: NAC alone, 306U/L (range 118-2606); NAC+PP100-01 (2µmol/kg), 212U/L (98-572); NAC +PP100-01 (5µmol/kg), 163U/L (100-287); NAC+PP100-01 (10µmol/kg), 155U/L (103-508). The median fold increase in FLK18 (baseline to 20 h) with NAC alone was 1.71 (1.24-3.57). With NAC+PP100-01 co-treatment the fold increase in FLK18 was smaller (2µmol/kg: 1.41 (0.53-2.80); 5µmol/kg: 1.02 (0.43-1.45); 10µmol/kg; 1.17 (0.74-4.34)). miR-122 was similar to FLK18.
Conclusion: PP100-01 was tolerated in patients treated with NAC for APAP overdose and may reduce liver injury.
Clinicaltrials.gov NCT03177395

PS-100

Bench-to-clinical development of plasminogen as a novel prognostic biomarker for patients with hepatitis B virus related acute-on-chronic liver failure

Daxian Wu[1], zeyu sun[1], sainan zhang[1], qunfang rao[1], Zhouhua Hou[2], Bingjie Liu[3], Hainv Gao[4], Lanjuan Li[1]. *[1]The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [2]Xiangya Hospital, Central South University, Changsha, China; [3]The First Affiliated Hospital, Nanhua University, Hengyang, China; [4]Shulan Hospital, Hangzhou, China*
Email: ling7080@126.com

Background and aims: HBV related acute-on-chronic liver failure (HBV-ACLF) deteriorates rapidly in short term, which necessitates accurate initial clinical decision-making. Present study aims to develop a novel prognostic biomarker for HBV-ACLF patients.
Method: Three batches of Tandem Mass Tag (TMT) labelled quantitative proteomic were executed with 10 acute exacerbation (AE) and 20 ACLF patients. The biomarker candidates were preliminarily verified by a cross-sectional cohort (n = 144) and further verified by two prospective cohorts (n = 207, and n = 121 respectively).
Results: Plasminogen, a novel prognostic biomarker for HBV-ACLF patients, was identified by TMT quantitative proteomic and preliminarily verified by the cross-sectional cohort. In the further verification with a prospective cohort (n = 207), plasminogen was significantly lower in ACLF non-survivors than survivors ($p < 0.001$). The cumulative survival time in patients with higher plasminogen was significantly longer than whom with lower plasminogen ($p < 0.001$). During the 14-day longitudinal observation, the plasminogen level significantly decreased in the deterioration groups ($p = 0.008$), but significantly increased in the improvement group ($p < 0.001$). Additionally, the plasminogen level gradually increased in survivors ($p < 0.001$) but gradually decreased in non-survivors ($p = 0.019$) during patients' hospitalization. PHAIT, a novel prognostic score based on plasminogen, hepatic encephalopathy, age, international normalized ratio, total bilirubin was significant better than Child-Pugh, MELD, CLIF-C ACLF, COSSH, and HINT (all $p < 0.05$). This score was validated by another multi-centred prospective cohort (n = 121).
Conclusion: Plasminogen is a novel promising biomarker for HBV-ACLF, sequential plasminogen measurements may facilitate prediction of the clinical course of ACLF. PHAIT is a novel prognostic score and superior to Child-Pugh, MELD, CLIF-C ACLF, COSSH, and HINT.

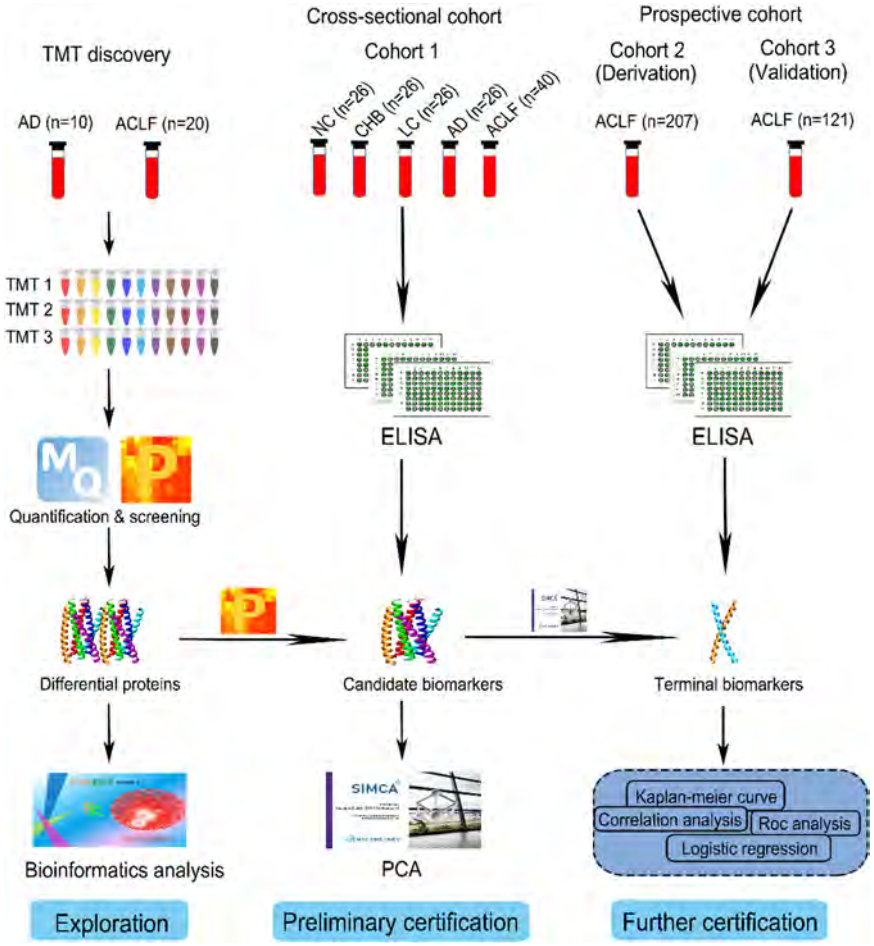

Figure: (abstract PS-100)

PS-101

Inhibition of toll-like receptor 4 using TAK-242 is a novel therapy for prevention and treatment of acute-on-chronic liver failure

Mohammed Sheikh[1], Cornelius Engelmann[1,2], Abeba Habtesion[1], Shreya Sharma[1], Stewart Macdonald[1], Nathan Davies[1], Tauhid Ali[3], Saurabh Gupta[4], Fausto Andreola[1], Rajiv Jalan[1]. *[1]University College London, Institute of Liver and Digestive Health, London, United Kingdom; [2]University Hospital Leipzig, Department of Gastroenterology and Rheumatology, Leipzig, Germany; [3]Takeda Pharmaceuticals International Co, London, United Kingdom; [4]Takeda Pharmaceuticals Internatioanl C0, Cambridge, United States*
Email: mfaisal1@doctors.org.uk

Background and aims: ACLF is characterized by acute deterioration of cirrhosis, systemic inflammation and multi-organ failure. Bacterial translocation, lipopolysaccharide (LPS) and cell death damage associated molecular patterns (DAMPS) are crucial players in the pathogenesis of ACLF. LPS and DAMPS transactivate toll-like receptor 4 (TLR4) resulting in pro-inflammatory cytokine release and systemic inflammation. The aims of this study were to assess whether inhibiting TLR4 signalling using a specific TLR4 antagonist, TAK242, can prevent the occurrence of ACLF and serve as potential treatment.
Method: Two models of ACLF were studied; (1) Bile duct ligated (BDL) SD rats, 4-weeks after ligation were administered LPS (i.p; 0.025 mg/Kg). TAK-242 (Takeda) (10 mg/Kg) or saline were given i.p 3 hours pre LPS injection (prophylactic [PX]) or at 30/60 minutes after ACLF induction (treatment [TX]) (n = 6-8 per group).
(2) C57BL/6 mice were gavaged carbon tetrachloride (CCl_4) over 6 weeks followed by i.p LPS (4 mg/Kg) (n = 4 per group). I.p TAK-242 (10 mg/Kg) was given 60 minutes and 22 hours post LPS (n = 4 per group). End points were: coma free survival at 6 hours after LPS injection (BDL) and at 24 hours (CCl_4), severity of liver and renal injury (biochemistry and TUNEL staining), plasma cytokines (LUMINEX), liver TLR4 protein (immunohistochemistry) and TLR signaling mRNA expression (qPCR).

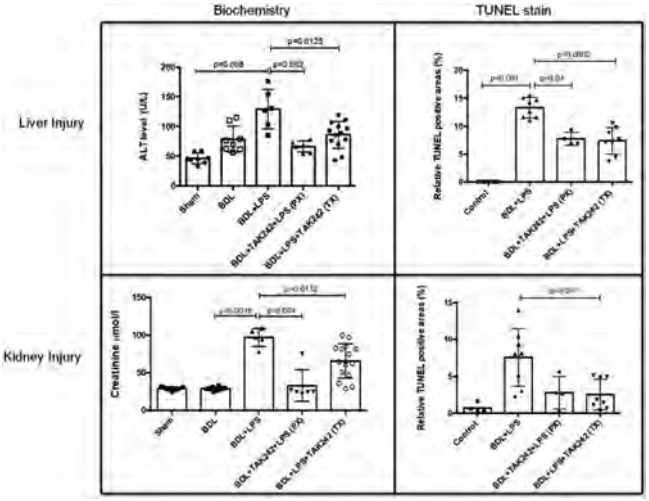

Figure: TAK242 reduces liver and kidney injury

Results: In the BDL model treatment with TAK-242 improved coma free survival from 13% to 100% (PX) and 53% (TX) and reduced the severity of liver and kidney injury (ALT, creatinine and TUNEL) significantly (Figure 1). TAK-242 led also to a reduction in plasma cytokines (pg/ml); TNF alpha 466 (± 137) vs 16 (± 0) (p = 0.001) [PX] vs 200 (± 50) (p = 0.04) [TX], IL-6 1518 (± 486) vs 36 (± 0) (p = 0.001) [PX] vs 3052 (± 1603) (p = 0.01) [TX] and IL −1 beta 1518 (± 486) vs 136 (± 43) (p = 0.005) [PX] vs 234 (± 72) (p = 0.012) [TX]. TAK-242 diminished significantly the severity of liver and kidney injury (TUNEL) in the CCl4 model. Hepatic TLR4 expression was upregulated in both models; TAK-242 modulated hepatic expression of genes in the TLR signaling (including TNFalpha, IL-6) (p < 0.05).
Conclusion: These data show for the first time an important role of TLR4 in the pathogenesis of ACLF. Inhibition of TLR4 signaling was associated with reduction in hepatic, renal and systemic inflammation, amelioration of organ injury in two ACLF rodent models and reduction in mortality providing a strong rationale for clinical evaluation.

PS-102

Circulating native albumin in patients with cirrhosis admitted to hospital for acute decompensation and acute-on-chronic liver failure: Relation to serum albumin levels, albumin function, and patient outcomes

Maurizio Baldassarre[1], Marina Naldi[2], Michele Bartoletti[3], Agnese Antognoli[1], Maristella Laggetta[1], Martina Gagliardi[1], Giacomo Zaccherini[3], Giulia Iannone[3], Dario Pratelli[3], Marco Domenicali[3], Katja Waterstradt[4], Manuela Bartolini[2], Franco Trevisani[3], Mauro Bernardi[3], Paolo Caraceni[1]. *[1]University of Bologna, Department of Medical and Surgical Sciences-Center for Applied Biomedical Research (CRBA), Bologna, Italy; [2]University of Bologna, Department of Pharmacy and Biotechnology-Centre for Applied Biochemical Research (CRBA), Bologna, Italy; [3]University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [4]MedInnovation GmbH, Berlin, Germany*
Email: paolo.caraceni@unibo.it

Background and aims: Serum albumin (SA) of patients with cirrhosis undergoes oxidative and non-oxidative damages, so that the molecules with a fully preserved structure, termed "native albumin" (NA), are substantially reduced. As the SA routinely measured in clinical practice includes both the NA and its altered isoforms, this study aimed to assess the relative changes of NA and SA in patients with cirrhosis and their relationships with albumin function and patient outcomes.
Method: 319 out of 516 patients with cirrhosis, enrolled in a prospective observational study on hospitalized patients for acute decompensation (AD) or acute-on-chronic liver failure (ACLF), were included in this analysis because of the availability of blood samples within 36 hours from admission. 18 outpatients with compensated cirrhosis were also enrolled as reference population. Serum NA concentration was derived from its relative abundance, as assessed by LC-ESI-MS analysis, and normalized on SA concentration. Albumin binding efficiency (BE) and detoxification efficiency (DTE) were determined by electron paramagnetic resonance analysis.
Results: NA concentration progressively declined from outpatients (2.1 mg/dl [1.6-2.3]) to AD (1.1 mg/dl [0.9-1.4]) and ACLF (0.9 mg/dl [0.6-1.2]) (p < 0.001). NA concentration was significantly correlated with SA levels (r_s: 0.649, p < 0.001) and MELD score (r_s: −0.430, p < 0.001). Covariance analysis showed that NA concentration significantly decline from outpatients to hospitalized patients with AD and ACLF independently from SA concentration (p < 0.001). BE and DTE were both significantly correlated with MELD score (r_s: −395, p < 0.001), NA (r_s: 0.516, p < 0.001) and SA (r_s: 0.524, p < 0.001). Multiple linear regression analysis showed that MELD score, NA and SA are independent predictors of dysfunctional BE and DTE. Finally, Cox regression analysis showed that NA, but not SA, was an independent predictor of ACLF (HR: 0.322, 95%CI 0.116-0.896, p = 0.030) and 90-day mortality (HR: 0.465, 95%CI 0.236-0.915, p = 0.027).
Conclusion: Both NA and SA are reduced in advanced cirrhosis. However, these data indicate that the decrease of NA is independent from and proportionally greater than that of the SA assessed by routine method. NA independently predicts albumin dysfunction, the onset of ACLF and short-term mortality. Whether albumin treatment should aim to increase not only SA, but also NA concentration is an attractive topic for future research.

PS-103

BTLA expression contributes to HBV-related acute-on-chronic liver failure morbidity and mortality by inducing CD4+ T-cell exhaustion

Xueping Yu[1,2], Feifei Yang[2], Richeng Mao[2], Haoxiang Zhu[2], Qirong Jiang[2], Jingwen Wu[2], Zhu Beidi[2], Zhijun Su[1], Jiming Zhang[2]. *[1]the First Hospital of Quanzhou Affiliated to Fujian Medical University, Department of Infectious Diseases, Quanzhou, China; [2]Huashan hospital affiliated to Fudan University, Department of Infectious Diseases, Shanghai, China*
Email: jmzhang@fudan.edu.cn

Background and aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is characterized by susceptibility to infection and T cell immune exhaustion. B and T lymphocyte attenuator (BTLA) maintain T-cell immune tolerance and were increased on liver-infiltrating lymphocytes in HBV-ACLF patients. However, whether BTLA could lead to T cell immune exhaustion in patient with HBV-ACLF remains unknown.
Method: The blood samples were collected from 83 healthy subjects, 148 chronic hepatitis B (CHB) and 86 patients with HBV-ACLF admitted to Huashan hospital and the first hospital of Quanzhou; and liver tissues were collected from Huashan hospital. The expression of BTLA on peripheral blood mononuclear cells (PBMCs) and liver-infiltrating lymphocytes were detected by flow cytometry and immunohistochemistry. The gene expression profiles of $BTLA^+CD4^+$T cells and $BTLA^-CD4^+$T cells, as well as PBMCs treated or not with anti-BTLA were compared by RNA-seq. The plasma cytokines were detected by Luminex and ELISA. Recombinant cytokines or their inhibitors were used to identify specific cytokines that induce the up-regulation of BTLA. BTLA activator (anti-BTLA) or BTLA shRNA was used to determine whether BTLA could promote $CD4^+$T cell immune exhaustion.
Results: The expression of BTLA were significantly increased on Tem subtype, all subgroups of circulation $CD4^+$T cells and on intrahepatic $CD4^+$T cells in HBV-ACLF patients, but not on theirs $CD8^+$T cells. Moreover, $BTLA^+CD4^+$T cells were positively correlated with severity of disease, prognosis and infection complication. Compared to $BTLA^-CD4^+$T cells, $BTLA^+CD4^+$T cells manifest a more mature and more exhaustion phenotype. IL-6 and TNF-alpha could prompt the up-regulation of BTLA on $CD4^+$T cells and blocking IL-6 and TNF-alpha signalling pathways decrease BTLA expression. Cross-linked BTLA can inhibit the activation, proliferat0069on, cytokines production of $CD4^+$T cells, but promote the $CD4^+$T cells apoptosis. Knockdown of BTLA level can promote the activation, proliferation of $CD4^+$T cells. Cross-linked BTLA on one hand activates suppression signalling by phosphorylation of SHP1/2, and on the other hand, provides a pro-survival signal upon activating the PI3K-Akt-GSK-3bata signalling pathway.
Conclusion: Under the double whammy of SIRS and infection, BTLA was induced to deplete $CD4^+$T cells function and to weaken its ability of removing pathogen, and eventually contribute to secondary infection and aggravate HBV-ACLF patients' death. This study is helpful to elucidate the pathogenesis of HBV-ACLF and provide a new drug target.

Email: haili_17@126.com

Background and aims: The most accepted diagnostic criteria of ACLF have been developed by the European CANONIC study in patients with acutely decompensated (AD) alcoholic or hepatitis C virus-related cirrhosis. We aimed to design diagnostic criteria of ACLF specific for patients with hepatitis B virus (HBV)-related cirrhosis.
Method: Prospective, observational study in 1, 402 patients with AD HBV-related cirrhosis admitted at 14 Chinese hospitals using an evidence-based methodology similar to that used for the European CANONIC study.
Results: We developed a new 5-variable organ failure (OF) score. Circulatory failure was excluded due to its low (0.9%) prevalence. Definitions of individual OFs (coagulation [INR ≥ 2], liver [bilirubin ≥ 22.0 mg/dL], kidney [creatinine ≥ 1.5 md/dL], respiratory [respiratory support], brain [overt encephalopathy]) and ACLF, based on associated mortality and number of OFs, respectively, differed from European definitions. The prevalence of ACLF, ACLF-1 (1 OF), ACLF-2 (2 OFs) and ACLF-3 (3-5 OFs) were 40.9%, 25.4%, 11.1%, and 4.4%, respectively. The 28-day transplant-free mortality were, respectively, 22.0%, 11.9%, 32.9% and 66.1%; it was 1.8% in patients without ACLF. The relative risk of 28-day mortality of ACLF-1 was 6.6, compared with no ACLF patients. Using either COSSH criteria (developed in HBV-related cirrhosis but largely based on the CANONIC Criteria) or European CANONIC criteria in our patients resulted in 37.2% and 65.8% false negative and 15.7% and 0.9% false positive diagnoses, respectively. Our criteria were validated in a cohort of 890.
Conclusion: ACLF in patients with AD HBV-related cirrhosis requires specific diagnostic criteria. The criteria developed in the European CANONIC study are inaccurate for ACLF diagnosis in these patients.
Registration number: NCT02457637.

NAFLD – Clinical Therapy

PS-105
Significant regression in fibrosis in paired liver biopsies following a 12-week aerobic exercise intervention in individuals with non-alcoholic fatty liver disease

Philip O'Gorman[1], Sara Naimimohasses[2,3], Ann Monaghan[1], Megan Kennedy[1], Stephen Finn[4], John Gormley[1], Suzanne Norris[2,3]. *[1]Discipline of Physiotherapy, School of Medicine, University of Dublin, Trinity College, Dublin, Ireland; [2]Department of Clinical Medicine, University of Dublin, Trinity College, Dublin, Ireland; [3]Hepatology Department, St James's Hospital, Dublin 8, Ireland; [4]Histopathology Department, St. James's Hospital, Dublin 8, Ireland*
Email: pogorma@tcd.ie

Background and aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is a rapidly growing health epidemic. Individuals with NAFLD often present with multiple comorbidities including; obesity, type 2 diabetes, metabolic syndrome and cardiovascular disease. In the absence of approved pharmacological treatments, lifestyle modifications are the first line of treatment. This study examined the benefits of a 12-week, aerobic exercise intervention (EI) on hepatic and extrahepatic outcomes in individuals with NAFLD and the sustainability of the benefits 12 weeks after completion.
Method: Individuals with biopsy proven NAFLD consented to take part in the EI. Pre-exercise assessments included review of liver biopsies by a single pathologist, baseline pre-exercise CAP and liver stiffness scores (Fibroscan, FS), cardiovascular fitness ($\dot{V}O_{2max}$), physical activity levels (PAL), anthropometry, blood profile and frailty measures. These measures were recorded before the EI (T0), immediately after the EI (T1) and three months after T1 (T2). The EI consisted of two supervised and three unsupervised aerobic exercise sessions per week with increasing intensity (45-75% heart rate reserve) and duration (24-45 minutes) for 12-weeks. Control participants completed only three physical assessments. A repeated measures ANOVA and Wilcoxon signed rank test were used to examine for significant differences in parametric and non-parametric measures, respectively.
Results: 25 individuals (16 exercise, 9 controls) completed the EI with 96% mean adherence. At T1, there was a significant regression of fibrosis ($p = 0.025$) in the exercise group which corresponded to a significant reduction in CAP ($p = 0.015$) and stiffness scores ($p = 0.025$) via FS. Additionally, there was a significant increase in $\dot{V}O_{2max}$ ($p = 0.034$), PAL ($p = 0.022$) and the number of individuals achieving WHO PAL guidelines ($p = 0.046$) at T1. There were significant reductions in BMI ($p = 0.01$), fat mass ($p = 0.001$), waist circumference (WC, $p < 0.0001$), HbA1c ($p = 0.047$) and in self-reported ($p = 0.034$) and test based ($p = 0.025$) frailty measures. At T2, CAP score ($p = 0.005$), BMI ($p = 0.04$) and WC ($p = 0.001$) remained significantly improved from T0. The remaining improvements at T1 were not sustained at T2.
Conclusion: This study demonstrates a significant regression in hepatic fibrosis in response to exercise therapy as assessed by paired liver biopsy and FS, with additional improvements in $\dot{V}O_{2max}$, anthropometry and frailty measures. That the benefits were not maintained at T2 indicates a need for strategies to integrate exercise and physical activity into a community-based setting to promote long term adherence to the therapy.

PS-106
An international, randomized, placebo-controlled phase 2 trial demonstrates novel effects of DGAT2 antisense inhibition in reducing steatosis without causing hypertriglyceridemia in T2DM patients

Rohit Loomba[1], Erin Morgan[2], Maple Fung[2], Lynnetta Watts[2], Richard Geary[2], Sanjay Bhanot[2]. *[1]University of California, San Diego, NAFLD Research Center, Division of Gastroenterology, La Jolla, United States; [2]Ionis Pharmaceuticals Inc., Clinical Development, Carlsbad, United States*
Email: emorgan@ionisph.com

Background and aims: DGAT2 catalyzes the terminal step in the synthesis of triacylglycerols from de novo synthesized fatty acids and newly formed diglycerides. We previously reported that specific inhibition of DGAT2 caused a marked improvement in hepatic steatosis (Hepatology 2005; 42: 362-371). In this clinical trial we examined the efficacy of a novel antisense inhibitor of DGAT2, IONIS-$DGAT2_{RX}$ versus placebo in T2DM patients with MRI-PDFF ≥ 10% in a double-blind placebo-controlled design.
Method: This international trial included 44 patients with NAFLD and T2DM, HbA1c, 8.1% BMI, 34.3 kg/m^2 and mean baseline MRI-PDFF of 18.8% who were randomized 2 :1 (Active: PBO) to either a once weekly subcutaneous injection of IONIS-$DGAT2_{RX}$ 250 mg or PBO (0.9% saline solution) for 13 weeks. MRI-PDFF was conducted prior to initiation of dosing and 2 weeks after the last dose. Primary end point was absolute reduction in liver fat content by MRI-PDFF.
Results: Treatment with IONIS-$DGAT2_{RX}$ resulted in a significant absolute reduction in liver fat of –5.37% (± 5.4) compared to –0.04% (± 5.8) in patients treated with placebo ($p = 0.003$). The relative percent reduction from baseline was also significantly higher –26.4% in ISIS-$DGAT2_{RX}$ treated patients compared to 1.0% in placebo treated patients ($p = 0.003$). Importantly, 50% (13/26) of the treated patients had at least a 30% relative reduction in liver fat ($p = 0.02$), Table 1; 30% or higher fat reduction has been associated with histologic

improvement in NASH in longer term studies. IONIS-DGAT2$_{RX}$ was well tolerated. There were no treatment related deaths or serious adverse events, no changes in hepatic or renal function and no thrombocytopenia. Liver fat reduction was not accompanied by hypertriglyceridemia or GI side effects and no elevations in serum transaminases, plasma glucose or body weight.

Table 1:

	Randomized Population (N = 44)	
	Placebo (N = 15)	ISIS DGAT2RX (N = 29)
Number of Patients who had Post-Treatment Liver Fat Percentage Assessment	15	26
Percent Reduction in Liver Fat Percentage ≥ 20%	2 (13.3%)	15 (57.7%)
p =		0.0052
Percent Reduction in Liver Fat Percentage ≥ 30%	2 (13.3%)	13 (50.0%)
p =		0.0188
Percent Reduction in Liver Fat Percentage ≥ 40%	1 (6.7%)	8 (30.8%)
p =		0.0804

Conclusion: These data suggest that DGAT2 inhibition may be a novel, safe and effective strategy for treatment of NAFLD and associated disorders. These data support further investigation of this agent's efficacy in biopsy-proven NASH.

PS-107

SGLT2 inhibition does not reduce hepatic steatosis in overweight, insulin resistant patients without type 2 diabetes

Thomas Marjot[1,2], Charlotte Green[1], Catriona Mcneil[1], Thomas Cornfield[1], Jonathan Hazlehurst[1,3], Ahmad Moolla[1], Sarah White[1], Jane Francis[4], Stefan Neubauer[4], Jeremy Cobbold[2], Leanne Hodson[1], Jeremy Tomlinson[1]. *[1]University of Oxford, Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom; [2]University of Oxford, Translational Gastroenterology Unit, NIHR Oxford Biomedical Research Centre, University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom; [3]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [4]University of Oxford, Oxford Centre for Clinical Magnetic Resonance Research, Oxford, United Kingdom*
Email: thomas.marjot@ouh.nhs.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is rapidly becoming the leading indication for liver transplant and is associated with increased cardiovascular and liver mortality, yet there are no licensed therapies. Sodium-glucose co-transporter 2 (SGLT2) inhibitors are now widely used for their glucose lowering effects in patients with type 2 diabetes (T2D). Pre-clinical models have suggested a beneficial impact on NAFLD, but clinical data are limited and there are currently no data in patients without type 2 diabetes. We aimed to investigate the impact of SGLT2 inhibition on NAFLD in overweight, non-diabetic patients and establish the effect these agents may have on the processes that regulate hepatic steatosis *in vivo*.

Methods: We conducted an open-label, experimental medicine pilot study in insulin resistant overweight/obese individuals (n = 10), using gold-standard non-invasive assessments of NAFLD phenotype including hepatic magnetic resonance spectroscopy, 2-step hyperinsulinaemic euglycaemic clamps and stable isotope tracers to assess lipid and glucose metabolism. Investigations were performed before and after 12-weeks of treatment with the SGLT2 inhibitor, Dapagliflozin.

Results: Despite a body weight reduction of 4.4 kg, hepatic steatosis was unchanged following treatment. Hepatic glucose production rates increased and there was impairment of glucose disposal during the low-dose insulin infusion. Although circulating non-esterified fatty acid levels did not change, the ability of insulin to suppress lipolysis was reduced.

Conclusions: SGLT2 inhibition for 12 weeks does not improve hepatic steatosis in patients without T2D. Additional studies in patients with established T2D or impairments of fasting or post-prandial glucose homeostasis and needed to determine whether SGLT2 inhibition represents a viable therapeutic strategy for NAFLD.

PS-108

NGM313, a novel activator of beta-Klotho/FGFR1c: A single dose significantly reduces steatosis (liver fat by MRI-PDFF), inflammation (ALT, AST) and fibrogenic activity (Pro-C3) in NAFLD subjects

Alex DePaoli[1], Mustafa Bashir[2], Van Phung[1], Andrew Yan[1], Lei Ling[1], Bryan Baxter[1], Hui Tian[1]. *[1]NGM Biopharmaceuticals, South San Francisco, United States; [2]Radiology and Medicine (Gastroenterology), Duke University, Durham, United States*
Email: lling94080@yahoo.com

Background and aims: NGM313 is a once-monthly humanized monoclonal antibody activator of β-klotho/FGFR1c. Insulin sensitizers have demonstrated decreases in hepatic steatosis, inflammation and fibrosis in patients with NASH, but pioglitazone (PIO) has limited use due to heart failure, weight gain, edema and fractures. This study compared the effects of a single dose of NGM313 *vs.* daily PIO on liver fat content (LFC), ALT, AST, Pro-C3, lipids, insulin sensitivity (HOMA-IR) and safety in insulin resistant patients with NAFLD.

Method: Twenty-five subjects were randomized 2:1 to either a single dose of NGM313 240 mg SC (n = 17) or PIO 45 mg PO QD (n = 8) for 36 days. Inclusion criteria included fasting glucose < 125 mg/dL, fasting

Table 1: (abstract: PS-108): Change from Baseline.

	Day 23[§] or 28[#]		Day 36	
	NGM313 240 mg × 1	PIO 45 mg QD	NGM313 240 mg × 1	PIO 45 mg QD
MRI-PDFF (Absolute) [§]	−5.1%***	−1.2%	−6.3%***	−4.0%**
% of pts with ≥ 5% ↓	38%	13%	63%	25%

*p < 0.05, **p < 0.01, ***p < 0.001

insulin > 10 mIU/ml, BMI > 30 kg/m^2 and NAFLD with ≥ 8% LFC by MRI-PDFF. MRI-PDFF was performed at Day 1, Day 23 and Day 36 and read centrally by a radiologist blinded to treatment sequence. Metabolic studies were performed at Day 1 and Day 28. One subject did not complete the Day 28 metabolic study.

Results: (Table 1) Significant reductions in absolute and relative LFC were seen. HOMA-IR and lipids improved with both treatments, consistent with insulin sensitizing activity. NGM313 and PIO improved HbA1c. ALT and AST were decreased significantly by both drugs. Pro-C3 was reduced with a single dose of NGM313 and not with PIO. The safety and tolerability profile was favorable for both drugs, with all AEs being mild and no safety signals observed. Mild increase in appetite was observed in two NGM313 subjects. Body weight increased by 1.6 kg with NGM313 *vs*. 2.4 kg with PIO.

Conclusion: A single dose of NGM313 demonstrated improvements in insulin sensitivity, FPG and lipids coupled with rapid and significant reductions in LFC, ALT, AST and Pro-C3. There were no identified safety or tolerability signals. These data support further evaluation of NGM313 in patients with biopsy-confirmed NASH.

PS-109

Partial inhibition of de novo lipogenesis with the acetyl-CoA carboxylase inhibitor PF-05221304 does not increase circulating triglycerides in humans and is sufficient to lower steatosis in rats

William Esler[1], Trenton Ross[1], Arthur Bergman[1], Collin Crowley[1], Santos Carvajal Gonzalez[1], David Beebe[1], Jeffrey A Pfefferkorn[1], Neeta Amin[1]. [1]*Pfizer Worldwide Research and Development, Cambridge Massachusetts, United States*
Email: william.esler@pfizer.com

Background and aims: Increased hepatic de novo lipogenesis (DNL) and reduced fatty acid oxidation are hypothesized to contribute to steatosis and lipotoxicity in non-alcoholic steatohepatitis (NASH). Acetyl-CoA carboxylase (ACC) catalyzes the first step in DNL, and modulates mitochondrial fatty acid oxidation. Inhibition of ACC by MK-4074 was shown to inhibit DNL and reduce steatosis in patients with NAFLD along with unexpected increases in circulating triglyceride (TG) levels (*Cell Metab.* 2017;26:576). That study evaluated a dose of MK-4074 which fully inhibited hepatic DNL. We sought to determine if partial inhibition of hepatic DNL with the liver-targeting ACC inhibitor PF-05221304 could decouple DNL inhibition from circulating TG elevations in rats and humans.

Method: The dose-response for hepatic DNL inhibition, circulating TG levels and steatosis was evaluated following administration of PF-05221304 for 4 weeks in Western-diet-fed rats. The dose response for hepatic DNL inhibition and serum TG levels was also evaluated in healthy adult humans administered oral PF-05221304 or matching-placebo for 14 days.

Results: Administration of PF-05221304 to healthy adult humans inhibited hepatic DNL in a dose-dependent manner, with a maximum average inhibition of 98%. At doses of PF-05221304 sufficient to inhibit DNL by > 90%, fasting and 24 hour serum TG levels were increased relative to baseline. However, increases in serum TG levels were not observed at doses which inhibited hepatic DNL by an average of ≤ 80%. To determine if doses which partially inhibit hepatic DNL are sufficient to reduce steatosis, studies were conducted in Western-diet-fed rats. Oral administration of PF-05221304 at 1, 3, and 10 mg/kg to Western-diet-fed rats inhibited hepatic DNL by 47%, 58% and 73% respectively relative to vehicle ($p < 0.001$). Mean reduction in steatosis of 60% ($p < 0.0001$) at the 2 higher doses were observed despite only partially inhibiting hepatic DNL.

Conclusion: Doses of PF-05221304 which only partially inhibit hepatic DNL (≤ 80% inhibition) did not elevate fasting or 24 hour serum TG levels in adult humans. Partial inhibition of hepatic DNL (58% and 73%) was sufficient to robustly lower steatosis in Western-diet-fed rats. Additional studies are needed to determine if these findings translate to patients with NASH.

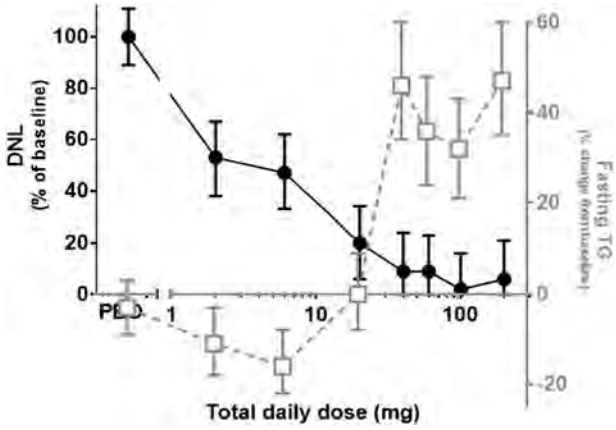

Figure 1: Dose-response relationship for hepatic DNL inhibition (% of baseline; mean ± 90% confidence interval) and % change from baseline (mean ± 80% confidence interval) in fasting serum triglyceride levels in healthy adult humans.

PS-110

Ketohexokinase inhibitor PF-06835919 administered for 6 weeks reduces whole liver fat as measured by magnetic resonance imaging-proton density fat fraction in subjects with non-alcoholic fatty liver disease

Roberto Calle[1], Arthur Bergman[2], Veena Somayaji[2], Kristin Chidsey[2], David Kazierad[2]. [1]*Pfizer Inc, Internal Medicine Research Unit, Cambridge, MA, United States;* [2]*Pfizer Inc, Early Clinical Development, Cambridge, MA, United States*
Email: roberto.a.calle@pfizer.com

Background and aims: Preclinical studies show that fructose rapidly enriches glycolytic metabolite pools, leading to activation of the Carbohydrate Response Element Binding Protein (ChREBP), a highly lipogenic transcription factor, that can promote steatosis and insulin resistance. Excessive fructose consumption has been shown to cause features of metabolic syndrome and NAFLD. KHK catalyzes phosphorylation of fructose to mediate its entry into the glycolytic pool. PF is a potent, reversible inhibitor of human KHK, and is expected to decrease hepatic de novo lipogenesis and steatosis, thereby ameliorating the pathogenesis of NAFLD. This clinical study was designed to test the hypothesis that KHK inhibition would lead to reduction in WLF.

Method: 53 subjects with NAFLD (> 6% WLF by MRI-PDFF) were randomized and 48 subjects completed the trial. Subjects were stratified by presence or absence of diabetes and baseline WLF. Participants received placebo (17), PF 75 mg (17) or PF 300 mg (14) once daily for 6 weeks.

	Week 6 Percent Change from Baseline [LS Mean (90%CI)]		
	Placebo	75 mg/day	300 mg/day
WLF PDFF	−7.78 (−17.72, 2.17)	3.67 (−6.32, 13.66)	−26.50 (−38.15, −14.86)*
Hs−CRP	8.33 (−9.82, 30.12)	−16.42 (−30.39, 0.36)	−31.01 (−44.00, −15.01)
Uric Acid #	6.52 (1.01, 12.03)	4.44 (−4.15, 13.04)	−11.53 (−16.48, −6.57)
Adiponectin	−14.25 (−25.12, −1.79)	18.29 (3.10, 35.73)	38.59 (18.63, 61.92)
HOMA-IR	0.13 (−0.43, 0.69)	−0.61 (−1.34, 0.12)	−0.53 (−1.16, 0.10)
IL−6	8.48 (−11.51, 32.98)	−0.72 (−19.43, 22.32)	−7.14 (−26.51, 17.34)

*$p < 0.0395$; #median (90% CI)

Results: Incidence of treatment emergent adverse events was low and similar across treatment groups. No SAEs were reported. Pharmacodynamic observations are summarized below.

Conclusion: PF administered for 6 weeks is well-tolerated with an acceptable safety profile in adults with NAFLD. PF 300 mg showed a statistically greater reduction from baseline compared to placebo in WLF. Dose-dependent percent changes from baseline were observed for hs-CRP (reductions), and adiponectin (increases) in PF treated groups. A trend for a dose-dependent decrease in insulin resistance (by HOMA-IR) was observed. Small numerical decreases in ALT, AST and GGT change from baseline were observed in the PF 300 mg group relative to placebo (not shown). No notable differences were found for changes from baseline in IL-6. These results suggest that additional studies are warranted to assess the potential of PF for the treatment of NAFLD/NASH.

PS-111

Six month interim results of MSDC-0602 K in a large phase 2b NASH study demonstrate significant improvement in liver enzymes and glycemic control (NCT02784444)

Stephen Harrison[1], Guy Neff[2], Julie Iwashita[3], Jules Lee[3], Don Lazas[4], Kenneth Cusi[5], Arun Sanyal[6], Rohit Loomba[7], Naim Alkhouri[8], Juan Frias[9], Sam Moussa[10], Howard Dittrich[3]. *[1]University of Oxford, Radcliff Department of Medicine, Oxford, United Kingdom; [2]Florida Research Institute, Lakewood Ranch, United States; [3]Cirius Therapeutics, San Diego, United States; [4]Digestive Health Research, Nashville, United States; [5]University of Florida, Medicine, Orlando, United States; [6]VCU, Medicine, Richmond, United States; [7]University of California at San Diego, San Diego, United States; [8]Texas Liver Institute, San Antonio, United States; [9]National Research Institute, Los Angeles, United States; [10]Adobe Gastroenterology, Tucson, United States*
Email: stephenharrison87@gmail.com

Background and aims: MSDC-0602 K, a 2nd generation thiazolidinedione is designed to selectively modulate the mitochondrial pyruvate carrier relative to PPAR-γ, thus reducing PPAR-γ-induced adverse effects while mitigating deleterious effects of nutrient excess in NASH. The drug is being evaluated in the EMMINENCE Study, a 12-month, placebo-controlled trial in biopsy-confirmed NASH.
Method: 402 patients were enrolled from 57 US sites. Entry criteria included NAFLD Activity Score of ≥ 4 that included ballooning and inflammation ≥ 1, and fibrosis score F1-F3. Stratification required ≥ 50% F2/F3 and ≥ 50% type 2 diabetes. Randomization was 1:1:1:1 to daily oral doses of MSDC-0602 K (62.5, 125, and 250 mg) or placebo. An interim analysis of non-biopsy safety and efficacy was conducted in the first 328 patients completing 6 months of therapy.
Results: the 4 cohorts were well balanced with 58.8% female, median age 57 (range 20-82), 51.8% diabetic, mean NAS of 5.3 (SD 1.02), 39.9% F1, and 60.1% F2/F3. Baseline alanine transaminase was 56.4 U/L and placebo corrected change at 6 mos was 10.1%, 27.0% and 20.1% (p = 0.24, < 0.001, and = 0.004) for 62.5, 125, and 250 mg doses, respectively). Aspartate transaminase (baseline 43.8 U/L) decreased at 6 mos with placebo corrected reductions of 9.1, 21.3, and 11.4% (p = 0.36, = 0.012, and 0.2 for 62.5, 125, and 250 mg, respectively). Statistically significant reductions in bilirubin, alkaline phosphatase, and gamma glutamyl transferase were also seen at 6 months at the 125 mg dose. Markers of fibrosis APRI, CK-18, ELF, FIB-4, and FibroTest showed improvement with several reaching statistical significance at the 125 mg dose. In the diabetes cohort, baseline HbA1c (6.83-7.09%), decreased by 0.03, 0.49, 0.62, and 0.55% at 6 months for placebo, 62.5, 125, and 250 mg groups, respectively (p = 0.022, p = 0.001, and p = 0.006, respectively compared to placebo). Overall adverse event rates and rates of peripheral edema were similar across all 4 cohorts. As expected with an insulin sensitizing agent, there was a modest placebo-corrected dose-dependent increase in weight of up to 2% (significant for 125 and 250 mg doses).
Conclusion: The interim results from 328 of 402 NASH patients in the Phase 2b EMMINENCE study demonstrate significant positive effects on liver enzymes and glycemic control, suggesting that MSDC-0602 K may result in improvement of NASH and fibrosis on liver biopsy while also improving glycemic control in type 2 diabetes.

PS-112

Endoscopic duodenal mucosal resurfacing improves hepatic fat fraction, glycemic and lipid profiles in type 2 diabetes

Guruprasad Aithal[2], Naomi Sakai[3], Manil Chouhan[3], David Hopkins[4], Rachel Batterham[5], Rehan Haidry[6], Bu Hayee[7], Jacques Deviere[8], Manoel Galvao Neto[9], Geltrude Mingrone[10]. *[1]Nottingham University Hospitals and University of Nottingham, NIHR Nottingham Digestive Diseases Biomedical Research Unit, Nottingham, United Kingdom; [2]Nottingham University Hospitals NHS Trust and University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; [3]University College London, UCL Centre for Medical Imaging, London, United Kingdom; [4]King's College Hospital NHS Foundation Trust, Diabetes and Endocrinology, London, United Kingdom; [5]University College Hospital, Centre for Obesity Research, Department of Medicine, London, United Kingdom; [6]University College Hospital, Gastroenterology, London, United Kingdom; [7]King's College Hospital, Gastroenterology, London, United Kingdom; [8]Erasme University Hospital, Gastroenterology, Brussels, Belgium; [9]Herbert Wertheim College of Medicine at Florida International University, Department of Surgery, Florida, United States; [10]Catholic University, Department of Internal Medicine, Rome, Italy*
Email: Guru.Aithal@nottingham.ac.uk

Background and aims: High fat/sugar diet leads to duodenal hyperplasia in rodent models. In the foregut of subjects with type 2 diabetes (T2D), abnormal entero-endocrine cell population and co-expression of glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic peptide (GIP) has been described.
The present study was designed to investigate the effects of endoscopic Duodenal Mucosal Resurfacing (DMR) involving circumferential hydrothermal ablation of post-papillary duodenal mucosa on liver fat and key metabolic end points in T2D.
Method: Revita-2 (NCT02879383) is a multi-center, randomized, double-blind, sham controlled trial involving T2D subjects. In an open-label training cohort, liver fat content was estimated using local MRI facilities and proton density fat fraction (PDFF) acquisition protocols, before and 12 weeks following DMR.
Results: Among 24 subjects (28-75 years; 17/7 male/female; BMI 24-40 kg/m^2) with T2DM on oral antiglycemic agents (HbA1c: 7.5-10.0%), 17 (85%) had > 5% liver fat at baseline. Following DMR, mean (±SEM) weight fell (89.7 ± 1.9 vs 86.6 ± 2.0 kg, p < 0.001). Significant improvements were also observed in alanine transaminase (ALT) levels: 35.75 ± 4.08 vs 25.35 ± 1.67 U/L, p < 0.001; HbA1c 8.4 ± 0.2% vs 7.4 ± 0.2%, p = 0.001; fasting-C-peptide 3.22 ± 0.29 vs 2.66 ± 0.16 ng/ml, p = 0.01; HOMA-IR 5.96 ± 0.73 vs 4.14 ± 0.61, p = 0.01; ferritin 90.8 ± 16.6 vs 69.4 ± 15.5 ng/ml, p < 0.001 and TG/HDL ratio 5.44 ± 1.15 vs 3.92 ± 0.92U/L, p = 0.02.
Among the 17 subjects with > 5% liver fat at baseline, there was a marked reduction in absolute liver fat from 19 ± 2.0% to 12 ± 2.0%, (p < 0.001) and relative (−35.8 ± 7.8%, p < 0.001) liver fat at 12 weeks. No serious adverse events or unanticipated adverse device effects were observed.
Conclusion: Substantial reduction in liver fat and hepatic transaminase indicates therapeutic potential of DMR in non-alcoholic fatty liver disease. In addition, procedure improves insulin sensitivity, glycemic control and lipid profile in T2D.
Baseline (Left) and 12 week (Right) post treatment PDFF images from a single subject. Reduction in signal in the liver reflects a reduction in the PDFF following treatment.

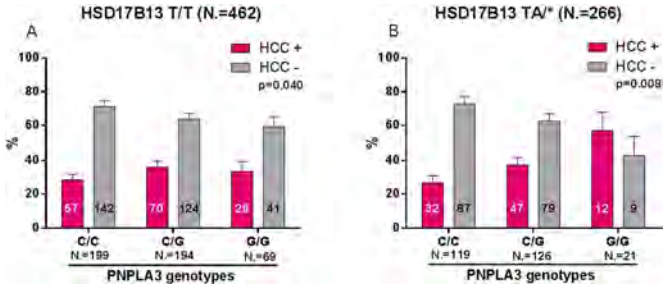
Liver cancer – From Prognosis to locoregional treatments

PS-113

Analysis of the HSD17B13: TA allelic variant as a putative protective factor towards hepatocellular carcinoma in patients with and without chronic hepatitis C

Martina Fazio[1], Carla De Benedittis[1], Michela Emma Burlone[2], Matteo Nazzareno Barbaglia[1], Ramana Mallela Venkata[1], Antonio Panero[1], Rosalba Minisini[1], Mario Pirisi[1]. *[1]Università del Piemonte Orientale, Translational Medicine, Novara, Italy; [2]AOU Maggiore della Carità, Medico, Novara, Italy*
Email: rosalba.minisini@med.uniupo.it

Background and aims: The PNPLA3 single nucleotide polymorphism rs738409 (C > G) is a major genetic factor for steatosis, fibrosis progression and hepatocellular carcinoma (HCC). In fact, carriers of the G allele with chronic liver disease are more likely to progress to cirrhosis and HCC, especially when affected by alcoholic or non-alcoholic fatty liver disease (NAFLD). However, these same patients have been shown to be relatively protected against developing cirrhosis by carriage of the HSD17B13:TA variant (rs72613567) (Abul-Husn NS et al. N Engl J Med. 2018;378:1096-106). Since cirrhosis is by far the strongest risk factor for HCC, it is conceivable that such protection might extend to HCC. We aimed to verify this hypothesis.
Method: The study population included N. = 728 patients, among whom N. = 246 had a diagnosis of HCC (Group 1; 135 with hepatitis C virus infection, HCV, 55%); N. = 180 HCV infected patients (Group 2) and 302 NAFLD (Group 3) patients had chronic liver disease with and without advanced fibrosis/cirrhosis, not complicated by HCC. Restriction fragment length polymorphism analysis was performed to determine the allelic variants frequency of PNPLA3 and HSD17B13.
Results: The PNPLA3:G frequencies were 0.40, 0.31 and 0.32 for Group 1, Group 2 and Group 3, respectively ($p = 0.004$). The HSD17B13:TA frequencies were 0.21, 0.28 and 0.16 for Group 1, Group 2 and Group 3, respectively ($p < 0.001$). The figure shows the distribution of PNPLA3 genotype frequencies, according to the presence or absence of HCC and HSD17B13 status. By considering only the subgroup of patients negative for HCV (N. = 416/728, 57%), similar results were observed: based on PNPLA3 genotype, patients with HCC were 22/118 (19%) vs. 10/55 (18%) (C/C), 35/131 (27%) vs. 21/55 (38%) (C/G), and 20/45 (44%) vs. 6/12 (50%) (G/G), among HSD17B13 wild-type ($p = 0.002$) vs. HSD17B13 variant carriers ($p = 0.006$), respectively.



Conclusion: The HSD17B13:TA allelic variant does not appear to decrease appreciably the risk of developing HCC conferred by carriage of the PNPLA3:G allele, neither among HCV positive nor among HCV-negative patients.

PS-114

Stabilization of UBQLN1 by circRNA_104797 mediates acquired sorafenib resistance in hepatocellular carcinoma

Lin Ji[1,2,3], Junjie Xu[1,2,3], Zhongjie Lin[1,2,3], Qijiang Mao[1,2,3], Bin Zhang[1,2,3], Xiujun Cai[1,2,3]. *[1]Key Laboratory of Laparoscopic Technology of Zhejiang Province, hangzhou, China; [2]Sir Run-Run Shaw Hospital, Department of General Surgery, hangzhou, China; [3]Zhejiang University School of Medicine, hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) is the fifth most common tumor around the world. Sorafenib is a famous drug to treat HCC. However, sorafenib resistance commonly occurs within one year. The mechanism behind sorafenib resistance is still unveiled. Recently, some studies found that sorafenib may target mitochondrial electron transport chain complexes, resulting in ROS increase and cell death. How HCC cell develops to escape mitochondria damage is an interesting question.
Method: Sorafenib resistant (SR) cell lines were established by sustained treatment of small dose of sorafenib. Effects of sorafenib

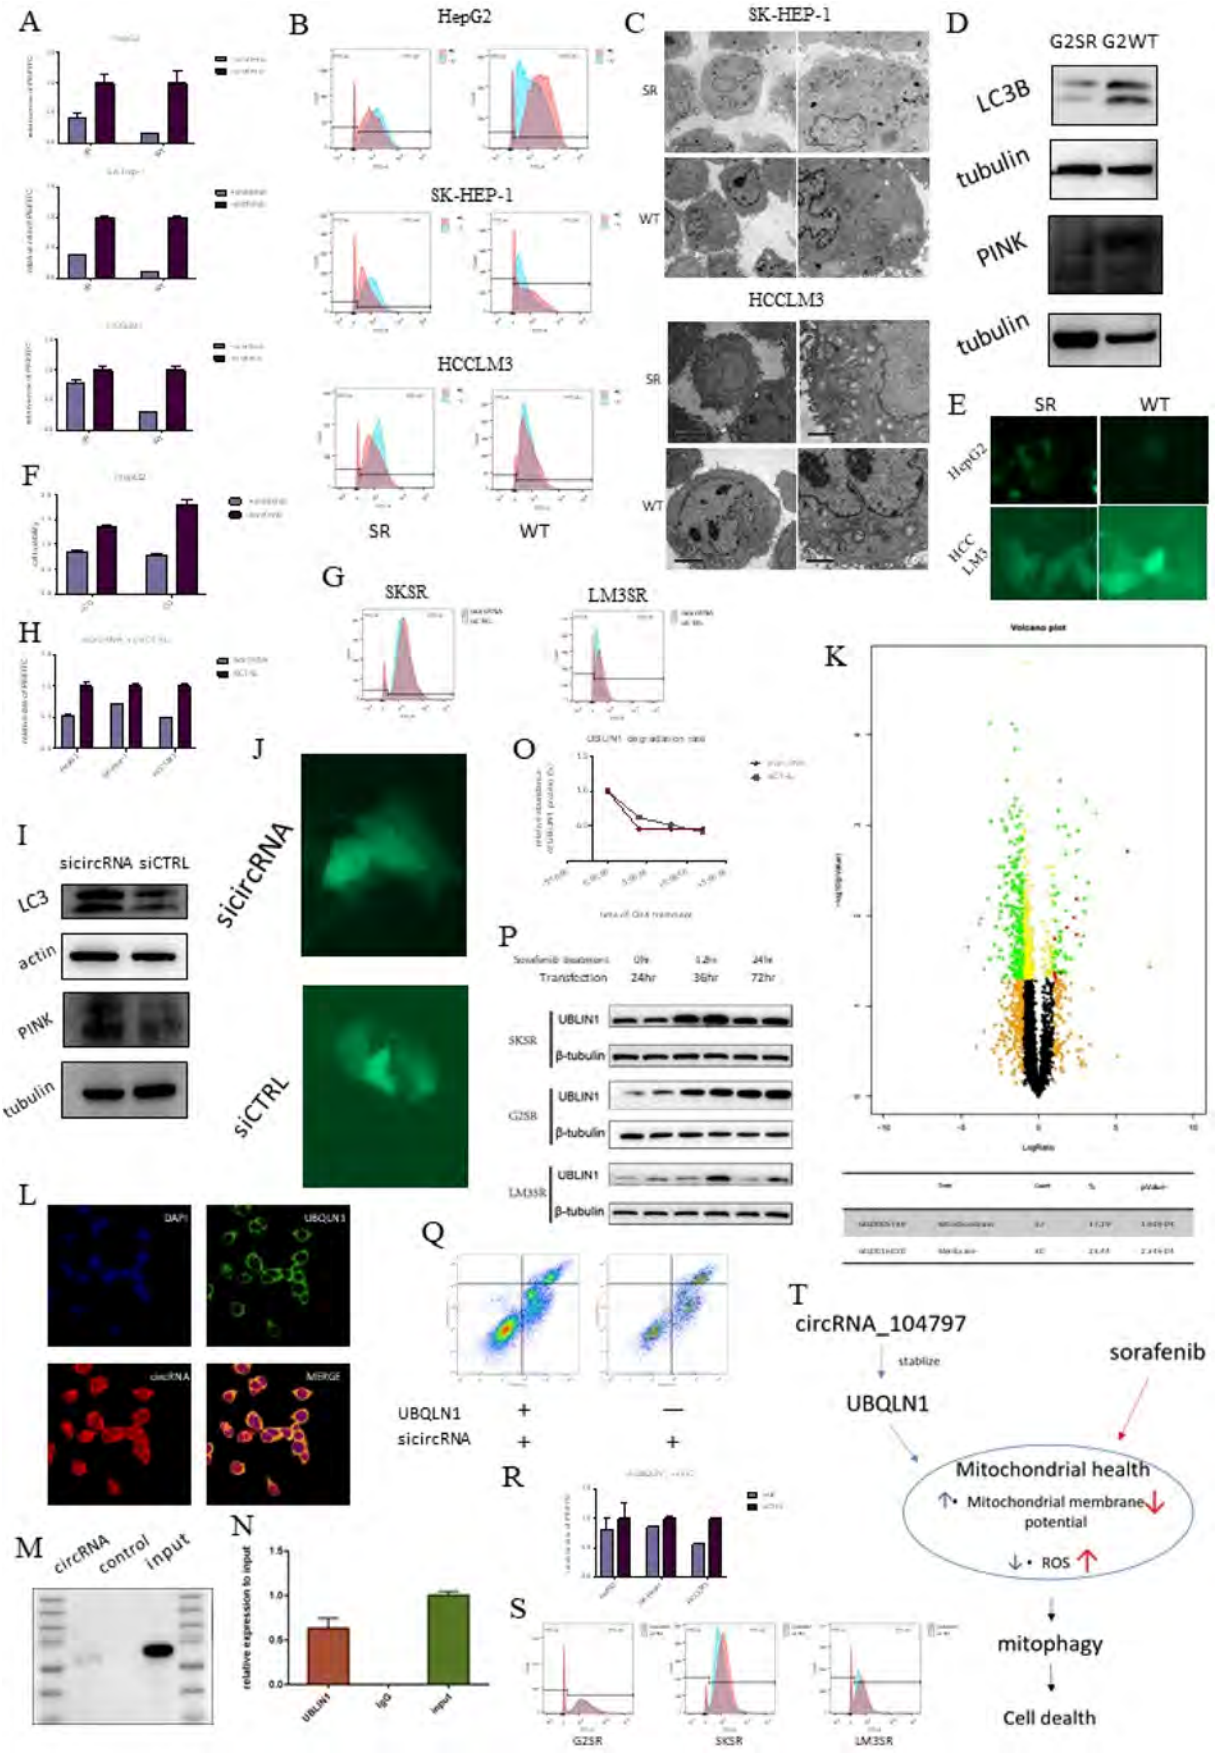


Figure: (abstract: PS-114)

was analyzed in cell viability by Cell Counting Kit-8 assay, ROS and mitochondrial transmembrane potential (MTP) by flow cytometry, cell morphology by transmission electron microscope (TEM). A CircRNA Array analysis and mass spectrum were carried out to detect possible interacting molecules.
Results: We established three pairs of SR cell lines. In accordance with variant cell growth inhibition rates, we found that ROS increased dramatically after sorafenib treatment in wild type HCC cell lines but decreased in SR cell lines. Correspondingly, MTP change was minor in SR cell lines. TEM also confirmed that mitochondria morphology was more integrated in SR cell lines after sorafenib treatment. We also observed that sorafenib induced less mitophagy in SR cell lines and autophagic inhibitor could partly reduce sorafenib induced cell death. Then an Arraystar Human CircRNA Array analysis showed that a circRNA named circRNA_104797 was upregulated in HepG2 SR cell line compared with WT cell line. Depletion of circRNA_104797 by siRNA transfection could increase cellular ROS, reduce MTP, and induce mitophagy. GO analysis of a mass spectrometric result revealed that mitochondria protein was enriched after siRNA transfection. Besides, comparing with the mass spectrometric result of circRNA_104797 pulldown protein, we found that UBQLN1 decreased after siRNA transfection. In consideration of UBQLN1's function, we supposed circRNA_104797 could mediate sorafenib resistance through binding to UBQLN1, which was confirmed by RNA immunoprecipitation, RNA pulldown and confocal fluorescence microscopy results. UBQLN1 degradation was accelerated after circRNA_104797 depletion. UBQLN1 depletion by siRNA transfection could also increase ROS and reduce MTP in SR cell lines. Furthermore, overexpression UBQLN1 could partly protect SR cell line from circRNA depletion induced cell death.
Conclusion: Our results uncovered a type of sorafenib resistance mechanism. In SR cell lines, circRNA_104797 increased to stabilize UBQLN1, while UBQLN1 can regulate MTP and ROS. Therefore, circRNA_104797 and UBQLN1 may offer to be potential targets to overcome sorafenib resistance.

PS-115
Evaluation of LI-RADS v2018 by magnetic resonance in US-detected nodules < 2 cm in cirrhotics
Alejandro Forner[1,2], Anna Darnell[3], Carla Caparroz[3], Jordi Rimola[3], Maria Ángeles García-Criado[3], Ernest Belmonte[3], Maria Reig[1,2], Carnen Ayuso[2,3], Jordi Bruix[1,2]. *[1]Hospital Clínic of Barcelona. Fundació Clínic per a la Recerca Biomédica (FCRB). IDIBAPS. University of Barcelona. Spain, BCLC group. Liver Unit, Barcelona, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd)., Barcelona, Spain; [3]Hospital Clínic of Barcelona. IDIBAPS. University of Barcelona. Spain, BCLC group. Radiology Department, Barcelona, Spain*
Email: aforner@clinic.ub.es

Background and aims: Liver Imaging Reporting and Data System (LI-RADS) was developed to classify the observations in six categories from LR-1 (definitively benign) to LR-5 (definitively HCC), stratifying the probabilities of HCC diagnosis to assist the clinicians in the decision making. Since its implementation in 2011, LI-RADS has been updated according the results of several studies evaluating its diagnostic performance. In the last version in 2018, aimed to be implemented by AASLD, nodules between 10-19 mm displaying non-rim arterial phase hyperenhancement and non-peripheral washout were assigned as LR-5. The objective of this study was to evaluate the diagnostic accuracy of LI-RADS v2018 when using magnetic resonance imaging (MRI) for hepatic nodules ≤ 20 mm detected during ultrasound (US) surveillance in cirrhotic patients, with particular interest in those observations categorized as LI-RADS 3.
Method: Between November 2003 and February 2017 we included 262 cirrhotic patients with a newly US detected solitary ≤ 20 mm hepatic nodule who were prospectively examined by MRI and fine-needle biopsy (reference-standard) and followed-up with MRI every 6 months if initial definitive diagnosis was not achieved. A LI-RADS (LR) category according to v2018 was retrospectively assigned. The diagnostic accuracy for each LR category was described and the main MRI findings associated with HCC diagnosis were analyzed.
Results: Final diagnoses were: 197 HCC (75.2%), 5 intrahepatic cholangiocarcinoma (1.9%), 2 metastasis (0.8%) and 58 benign lesions (22.1%). 0/15 (0%) LR-1, 6/26 (23.1%) LR-2, 51/74 (68.9%) LR-3, 11/12 (91.7%) LR-4, 126/127 (99.2%) LR-5, and 3/8 (37.5%) OM were HCC. LR-5 category displayed a sensitivity of 64.5% (CI95%: 57.4–71.1), very similar to the sensitivity achieved by EASL criteria (62.9% [CI95%: 55.8–69.7]). Considering also LR-4 as diagnostic for HCC, the sensitivity slightly increased to 69.5% (CI95%:62.6–75.9) with minor impact on specificity (96.2%; CI95%:89.3–99.6). Regarding LR-3 observations, 51 out 74 were HCC, 2 were non-HCC malignancies, and twenty-one out 22 LR-3 nodules > 15 mm (95.5%) were finally categorized as HCC.
Conclusion: In cirrhotic patients with nodules ≤ 20 mm detected on US, distinction between LR-4 and LR-5 according to v2018 has minor impact. A relevant proportion of LR-2 and LR-3 lesions corresponded to an HCC and thus, an active diagnostic work-up including biopsy is recommended.

PS-116
Use of cyclooxygenase inhibitor and the risk of hepatocellular carcinoma in patients with chronic hepatitis B: A nested case-control study using a nationwide population-based data
Sohn Won[1], Kyoung Sun Cho[2], Jung Hee Kim[3], Ju-Yeon Cho[4], Yong Han Paik[2]. *[1]Wonkwang University Sanbon Hospital, Gunpo, Korea, Rep. of South; [2]Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South; [3]Hallym University Hangang Sacred Heart Hospital, Seoul, Korea, Rep. of South; [4]Chosun University Hospital, Gwang-Ju, Korea, Rep. of South*
Email: hand0827@naver.com

Background and aims: Recent studies showed the cyclooxygenase (COX) inhibitors are associated with reduced cancer development in various malignancies. This study aimed to investigate the relationship between the use of COX inhibitors and the risk of hepatocellular carcinoma (HCC) development in patients with chronic hepatitis B (CHB) using a nationwide population-based data.
Method: The nested case-control study was conducted using the National Health Insurance Service-National Sample Cohort (NHIS-NSC) from January 2003 to December 2013 in Korea. The use of COX inhibitors was measured using the cumulative defined daily dose (cDDD) which is the sum of prescribed dosages of drug in the exposed duration. All kinds of COX inhibitors that are available in Korea were included. We compared the use of COX inhibitors between HCC cases and the matched controls by categorizing 5 groups according to cDDD (< 28, 28–90, 91–180, 181–360, and > 360) adjusting the use of antiviral agents.
Results: A total of 4, 980 patients with CHB were analyzed as 996 HCC cases and 3, 984 matched controls. Matching variables were age at index date, sex, alcoholic liver disease, diabetes mellitus, liver cirrhosis, and follow-up duration. The number of COX inhibitor users (≥ 28 cDDD) was 358 patients (36%) and 1, 814 patients (45%) in HCC group and control group, respectively. The use of COX inhibitors was significantly associated with the decreased risk of HCC development compared to non-users (adjusted odds ratio [OR] 0.62, 95% confidence interval [CI] 0.52-0.73, $p < 0.001$). There was a dose-dependent inverse relationship between the use of COX inhibitors and the risk of HCC. The adjusted ORs were 0.75 (95% CI: 0.63–0.90), 0.41 (95% CI: 0.31–0.56), 0.38 (95% CI: 0.25–0.57), and 0.49 (95% CI: 0.31–0.79) in 28–90, 91–180, 181–360, and > 360 cDDD, respectively ($p < 0.001$).
Conclusion: The use of COX inhibitors was associated with reduced risk of HCC in CHB. COX-inhibitor may have a chemopreventive role in HCC development in patients with chronic liver disease.

PS-117

Multiplatform analysis of HCC tumors uncovered molecularly distinct subtypes

JiHyun Shin[1], YunSeong Jeong[1], Bo Hwa Sohn[1], Ju-Seog Lee[1]. [1]*UT MD Anderson Cancer Center, Systems Biology, Houston, United States*
Email: jlee@mdanderson.org

Background and aims: While recent genomic profiling studies of HCC identified many genetic alterations, these studies are limited by a loose correlation between genetic alterations and their functional products such as proteins and metabolites. Reverse-phase protein array (RPPA) allows us to simultaneously measure multiple protein features, such as expression, modification of proteins, and interaction with ligands from the samples. To overcome current limitation of genomic studies, we generated genomic and proteomic data together from HCC tumors and performed integrated analysis of both data sets.
Methods: We generated gene expression profile data and proteomic data from 300 HCC tumors by using expression microarrays and RPPA platform. Supervised and unsupervised approaches were applied to analyze proteomic data and multiple genomic data such as somatic mutations, mRNA expression, miRNA expression, and copy number alterations were integrated with proteomic data to uncover most correlated genomic alterations with functional products. Clinical significance of identified key protein features were validated in multiple independent cohorts of HCC patients.
Results: Integrative analysis of genomic and proteomic data uncovered three subtypes of HCC with substantial difference in clinical outcomes. Interestingly, one of HCC subtype has strong mesenchymal characteristics as reflected in low expression of epithelial marker like CDH1 and CTNNB1. When assessed clinical relevance, the overall survival rate of patients in mesenchymal subtype was significantly worse than those in other two subtypes ($p = 0.001$). For validation of clinical association, we collected additional genomic and proteomic data from independent cohort of patient. Poor clinical outcomes of mesenchymal subtype is validated in multiple independent cohorts (in total of > 500 patients). Gene network analysis with integrated genomic and proteomic data further revealed association of subtypes with currently available treatments of HCC such as sorafenib and immunotherapy. In addition, multiple in-depth analysis of integrated data identified potential therapeutic target candidates for each subtype. Functional validation with cell lines demonstrated that some of candidates are essential for growth and survival of HCC cells.
Conclusion: HCC can be classified into distinct subtypes by analyzing integrated genomic and proteomic data. These analyses has identified potential therapeutic targets as well as biomarkers associated with therapeutic targets. Our study demonstrated merit of integrated analysis of proteomic data with genomic data to uncover potential driver genes of HCC development.

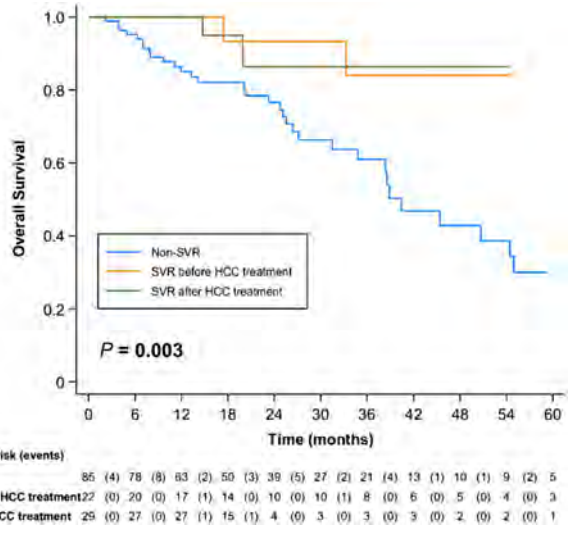
PS-118

HCV eradication before or following curative management of HCC in patients with cirrhosis allows optimal tumour management and improves survival: The French multicentre prospective ANRS CO12 CirVir cohort experience

Pierre Nahon[1], Layese Richard[2], Cagnot Carole[3], Marcellin Patrick[4], Dominique Guyader[5], Pol Stanislas[6], Roudot Francoise[2], Etienne Audureau[2]. [1]*APHP Jean Verdier, Bondy, France;* [2]*APHP Henri Mondor, Créteil, France;* [3]*ANRS, Paris, France;* [4]*APHP Beaujon, Clichy, France;* [5]*CHU Rennes, Rennes, France;* [6]*APHP Cochin, Paris, France*
Email: pierre.nahon@aphp.fr

Background and aims: This study aimed to accurately assess the impact of HCV eradication on HCC recurrence, liver decompensation and overall survival in patients with compensated cirrhosis included in the French prospective multicentre ANRS CO12 CirVir cohort who were curatively treated for an incidental HCC.

Method: Data were collected from 1323 patients with compensated Child-Pugh A biopsy-proven HCV-cirrhosis recruited between 2006 and 2012 in 35 centres and prospectively followed-up, including achievement of a sustained virological response (SVR) and the occurrence of HCC during the study period. The primary outcomes for the present analysis were HCC recurrence, liver decompensation and overall survival measured from the time of HCC treatment.
Results: During a median follow-up (FU) of 67.5 months, 218 patients developed an HCC among whom 128 received a curative procedure [percutaneous ablation (n = 90) or a liver resection (n = 31]). At HCC diagnosis, patients were mostly males (58.7%), mean age was 63.9 yrs, Child-Pugh A status in 52.5%. HCC was mostly uninodular (75.7%), less than 20 mm in 66.7%, BCLC 0/A in 93.7%. 71 patients (52.9%) never achieved SVR, while 47 patients (38.8%) achieved SVR either before (n = 27; 20.7%) or after HCC occurrence (n = 23; 18.1%) [missing data = 7]. After a median FU of 27.1 months following HCC treatment, 55 (43.0%) experienced an HCC recurrence. SVR was not significantly associated with lower HCC recurrence risk, whether considering final SVR status (HR = 0.94 [0.51; 1.73], $P = 0.84$) or according to its time to achievement (before or after HCC emergence, global $P = 0.29$). During the same time-frame, 48 (37.6%) patients died (liver failure: 42%, HCC recurrence: 33%, extra-hepatic cause 25%). In univariate (Figure) and multivariate analysis, SVR was associated with an improved overall survival (HR = 0.19 [0.07; 0.48], $P = 0.001$), whether obtained before (HR = 0.24 [0.07; 0.79], $P = 0.018$) or after (HR = 0.14 [0.03; 0.58], $P = 0.007$) HCC diagnosis. Survival benefit was explained by a lower incidence of liver decompensation in case of SVR (HR = 0.26 [0.09; 0.75], $P = 0.013$) and higher rates of HCC recurrence re-treatment using sequential percutaneous ablation (83% vs 50% in non-SVR, $P = 0.01$). DAAs intake (n = 50, including 23 after HCC treatment) was not associated with a higher risk of HCC recurrence (HR = 0.56 [0.24; 1.30], $P = 0.18$) but with an improved overall survival (HR = 0.19 [0.04; 0.79], $P = 0.022$).



Conclusion: SVR achievement before or after HCC occurrence is not associated with a modified risk of tumour recurrence following implementation of a curative procedure in patients with cirrhosis. However, HCV eradication allows optimal HCC management by preventing potential deterioration of liver function and increasing rates of HCC recurrence re-treatment, leading to improvement of overall survival.

PS-119

Time-varying mHAP III is the most accurate score in predicting survival in patients wit hepatocellular carcinoma undergoing trans-arterial chemoembolization

Claudia Campani[1], Alessandro Vitale[2], Sami Aburas[1], Gabriele Dragoni[1], Umberto Arena[1], Edoardo Giovanni Giannini[3], Umberto Cillo[2], Franco Trevisani[4], Fabio Marra[1], Ita.Li.Ca. Group[1]. *[1]University of Florence, Florence, Italy; [2]University of Padua, Padua, Italy; [3]University of Genoa, Genoa, Italy; [4]University of Bologna, Bologna, Italy*
Email: fabio.marra@unifi.it

Background and aims: TACE is the most widely used treatment for patients with unresectable HCC. The prognosis of these patients is extremely variable due to differences in liver function, tumor burden and performance status and a median survival of around 40 months has been reported for well-selected candidates. Many prognostic scores have been proposed to identify those more likely to benefit from TACE. Moreover, albumin-bilirubin (ALBI) and platelet-albumin-bilirubin (pALBI) grades have not been specifically evaluated in patients undergoing TACE.
An important confounding effect is that TACE is often repeated several times, but there are no studies evaluating prognostic scores as time-varying variables, i.e. recalculating the scores before each TACE procedure. The aim of this study was to compare different prognostic and staging systems in patients undergoing TACE in a large series of patients with HCC.
Methods: We retrospectively evaluated the accuracy of HAP, mHAP II, mHAP III, ALBI, and pALBI in estimating overall survival (OS) in patients with HCC undergoing TACE. We considered 1610 TACE performed in 1058 patients recorded in the Ita.Li.Ca database from 2008 trough 2016. Exclusion criteria were CPT score > 7 and/or refractory ascites. We carried out a time-dependent analysis to consider prognostic scores as time-varying variables, and calculated OS from the time of TACE to the time of the subsequent treatment. The total follow-up time for each patient was therefore split into several observations accounting for each TACE procedure, where appropriate. Values of the likelihood ratio test (LRT) and Akaike information criterion (AIC) were used to compare different systems.
Results: The median OS was 36 months. Comparing LRT and AIC values of the prognostic scores, mHAP III achieved the highest $\chi 2$ and lowest AIC values (39, 6 and 4638 respectively, $p < 0.0001$), indicating an improved predictive performance compared with HAP ($\chi 2$ 16.3, AIC 4665, $p = 0.0010$), mHAP ($\chi 2$ 19.9 AIC 4662, $p = 0.0003$), ALBI ($\chi 2$ 4.34, AIC 4673, $p = 0.0373$), whereas pALBI was not significantly different ($\chi 2$ 1.47, AIC 4676, $p = 0.2254$). The prognostic performance of mHAPIII was also superior to that of other HCC prognostic systems (BCLC, ITALICA, CLIP, MESH, MESIAH, JIS and HKLC). In time-varying multivariable Cox proportional hazards model, mHAP III maintained an independent effect on OS (hazard ratio 1.34, 95% CI 1.15-1.56). Other significant variables in the multivariable model resulted age, alcoholic etiology, radiologic response to TACE, and performing ablation or surgery after TACE.
Conclusion: In a large series of patients with HCC undergoing TACE, mHAP III was identified as the most accurate scoring system for predicting OS, using an innovative, time-dependent analysis of patients comprised in the Ita.Li.Ca. database.

PS-120

Post progression survival in patients with intermediate-stage hepatocellular carcinoma after receiving transarterial chemoembolization

Yukiko Shima[1], Sadahisa Ogasawara[1], Yoshihiko Ooka[1], Kazufumi Kobayashi[1], Susumu Maruta[1], Hiroaki Kanzaki[1], Kengo Kanayama[1], Takahiro Maeda[1], Yuko Kusakabe[1], Soichiro Kiyono[1], Masato Nakamura[1], Tomoko Saito[1], Eiichiro Suzuki[1], Shingo Nakamoto[1], Shin Yasui[1], Akinobu Tawada[1], Tetsuhiro Chiba[1], Makoto Arai[1], Tatsuo Kanda[1], Hitoshi Maruyama[1], Naoya Kato[1]. *[1]Chiba University, Graduate School of Medicine, Department of Gastroenterology, Chiba, Japan*
Email: sadahisa@me.com

Background and aims: Correlations between progression patterns and post progression survival (PPS) in patients with advanced hepatocellular carcinoma (HCC) treated with sorafenib have been reported. These results are helpful for not only understanding the prognosis of patients who do not respond to sorafenib but also designing clinical trials. So far, several novel compounds have been developed in patients with HCC and some may be used in combination with transarterial chemoembolization (TACE) or compared with TACE. The aim of this study was to evaluate correlations between progression patterns and PPS in patients with intermediate-stage HCC after receiving TACE.
Method: From 2003 to 2016, 441 patients with intermediate-stage HCC, who received TACE as initial treatment at our institution, were enrolled in this study. Radiological responses were evaluated according to modified Response Evaluation Criteria in Solid Tumors (mRECIST).
Results: The patient cohort was 77% male, a median age 71 years (range, 30-92 years). Concomitant conditions included hepatitis C virus (67%), alcohol abuse (16%), and hepatitis B virus (11%). The median overall survival was 27.2 months [95% confidence interval (CI); 23.6-30.8], and the median time to progression was 5.7 months (95% CI; 5.2–6.3). We observed progression in 378 patients (86%), intrahepatic growth in 187 patients (42%), new intrahepatic lesions (NIH) in 251 patients (57%) (with ≤ 3 lesions noted in 161 patients, 4–7 lesions in 34 patients, and with ≥ 8 lesions in 56 patients), and new extrahepatic lesions (NEH) in 47 patients (11%). In patients with ≥ 8 NIH lesions, PPS was significantly worse than that in 4–7 NIH lesions and ≤ 3 NIH lesions [≥ 8 lesions, 11.7 months (95% CI, 8.7–14.7 months), 4–7 lesions, 17.7 months (95% CI, 11.0–24.4), ≤ 3 lesions, 26.1 months (95% CI, 20.3–31.9), $p = 0.003$]. Similarly, PPS in patients with NEH lesions was significantly lesser than without NEH lesions [with NEH lesions, 7.7 months (95% CI, 4.9–10.5); without NEH lesions, 22.2 months (95% CI, 20.1–27.9 months); $p < 0.001$]. Following multivariate Cox hazard analysis, ≥ 8 NIH lesions and NEH lesions were independent prognostic factors of PPS in patients with intermediate-stage HCC after receiving TACE.
Conclusion: We indicated the strong positive correlations between progression pattern (≥ 8 NIH lesions and NEH) and PPS in patients with intermediate-stage HCC after receiving TACE as initial treatment. These results may be beneficial for designing future clinical trials related to TACE in patients with intermediate-state HCC.

Autoimmune and cholestasis II

PS-121

Obeticholic acid limits cholestasis induced cognitive decline by maintaining blood-brain barrier integrity and preserving neuronal health

Lucy Gee[1], Ben Millar[1], Jack Leslie[1], Claire Richardson[2], Diana Jurk[3], Saimir Luli[1], Marco Youssef William Zaki[4], Fiona LeBeau[2], Elizabeth Stoll[2], David Jones[1], Fiona Oakley[1]. *[1]Newcastle University, Institute of Cellular Medicine, Newcastle Upon Tyne, United Kingdom; [2]Newcastle University, Institute of Neuroscience, Newcastle Upon Tyne, United Kingdom; [3]Newcastle University, Campus for Ageing and Vitality, Newcastle Upon Tyne, United Kingdom; [4]Newcastle University, Northern Institute of Cancer Research, Newcastle Upon Tyne, United Kingdom*
Email: l.m.gee@ncl.ac.uk

Background and aims: Primary Billiary Cholangitis (PBC) is an autoimmune disease of the bile duct and liver. Biliary epithelial cell injury causes cholestasis, fibrosis and systemic circulation of toxic bile acids. PBC patients often experience significant central fatigue with associated cognitive symptoms Including impaired short-term

memory and problems with concentration. Likened by patients to "brain fog" this under-recognised complex of central nervous system symptoms is a major contributor to poor quality of life and is currently untreatable.
The study aims to utilise the Bile Duct Ligation (BDL) model to investigate mechanisms of cholestasis-induced memory impairment in mice and explore the potential therapeutic benefit of the second-generation, FDA approved anti-cholestatic agent Obeticholic Acid (OCA).
Method: C57BL/6 mice underwent either BDL or sham surgery. A sub-group of BDL were treated prophylactically or therapeutically with OCA. Activity and cognitive function was evaluated by standardised behavioural tests. Fluorescence imaging and Transmission Electron Microscopy assessed hippocampal cell populations, cellular senescence and the Blood-Brain Barrier (BBB). Flow cytometry was used to measure FXR expression in the BBB. Gamma oscillation in the hippocampal slices were evoked by the cholinergic agonist Carbachol (10 uM).
Results: Spatial memory was significantly decreased in BDL mice. OCA therapy rescued the decline, returning cognitive function to near sham level. Astrocytes are key mediators of BBB integrity and neuronal function. Astrocyte coverage of the BBB was significantly reduced in BDL mice compared to sham controls, indicating damage to the BBB, likely mediated by bile acids. Neuronal senescence was increased in the hippocampus of BDL mice. OCA therapy restored astrocyte coverage of the BBB and reduced neuronal senescence, suggesting improved neuronal health. Hippocampal slices from BDL mice had impaired gamma frequency oscillations as only 20% had stable oscillations compared to 69% of slices from sham animals, indicative of deficit.
The Farnesoid X Receptor is expressed on microvascular endothelial cells of the BBB but decreased with BDL, suggesting that OCA, an FXR agonist could directly regulate BBB health during cholestasis.
Conclusion: OCA limits and reverses cholestasis induced cognitive decline through preserving BBB integrity and neuronal health. We propose that OCA may be an effective intervention for cognitive deficit in PBC patients if used early in the disease process.

PS-122
Seladelpar for the treatment of primary biliary cholangitis: Experience with 26 cirrhotic patients

Email: marlyn.mayo@utsouthwestern.edu

Background and aims: Primary biliary cholangitis (PBC) is a progressive liver disease that leads to cirrhosis. Seladelpar, a selective PPAR delta agonist, demonstrates potent anti-cholestatic and anti-inflammatory activity in PBC. We evaluated the efficacy and safety of seladelpar in PBC patients with clinically diagnosed compensated cirrhosis.
Method: PBC patients were enrolled into an ongoing, randomized, open-label Phase 2 study (EudraCT 2016-002996-91) and evaluated for the effect of oral seladelpar 5 and 10 mg. Eligible patients had inadequate response (alkaline phosphatase [AP] ≥ 1.67 × upper limit of normal (ULN)) or an intolerance to ursodiol and a total bilirubin ≤ 2 mg/dL. Cirrhosis was diagnosed using liver biopsy, imaging tests, or liver elastography. After 12 weeks, patients on 5 mg were dose-escalated to 10 mg when the AP threshold was not met (5/10 mg group). The primary outcome was AP % change from baseline. Secondary outcome measures included AP responder analyses (< 1.67xULN), changes in hepatic function, inflammatory markers, and pruritus using the visual analogue scale (VAS). Safety analysis included adverse events and laboratory parameters.
Results: 119 patients were exposed to at least one dose of seladelpar, 26 of whom had compensated cirrhosis (5/10 mg n = 15 and 10 mg n = 11). Analysis was performed with a July 2018 data cut. At this time 15 of 26 cirrhotic patients received seladelpar for 3 months, 13 of 26 for 6 months, and 8 of 26 for 1 year.
In cirrhotic patients, the baseline values for the 5/10 and 10 mg groups were: mean AP-277 U/L and 309 U/L, median total bilirubin-0.73 mg/dL and 0.80 mg/dL, median ALT-32 U/L and 50 U/L, and median VAS 20 and 37, respectively. Mean decreases in AP (%) were −25% and −39% at 3 months, −24% and −41% at 6 months, and −36% and −43% at 1 year in the 5/10 mg and 10 mg groups, respectively. After 1 year, all patients in 5/10 mg and 3 of 5 patients in 10 mg had Ap < 1.67 × ULN; the median decreases in ALT (%) were −31% and −50%, and the median absolute changes in pruritus VAS were 0 and −25 in 5/10 mg and 10 mg groups, respectively.
Three patients with cirrhosis experienced an SAE, all unrelated to seladelpar. Total bilirubin, platelets, albumin, and INR remained stable. No liver decompensation events were observed.
Conclusion: In PBC patients with compensated cirrhosis, seladelpar was shown to be safe and well tolerated and demonstrated anti-cholestatic and anti-inflammatory effects.

PS-123
Biliary tree stem/progenitor cells mediate the regeneration in biliary lining after injury

Lorenzo Nevi[1,2], Vincenzo Cardinale[3], Wei-Yu Lu[4], Sabina Di Matteo[2], Samira Safarikia[2], Daniele Constantini[2], Fabio Melandro[5], Pasquale B. Berloco[5], Eugenio Gaudio[6,7], Stuart Forbes[1], Domenico Alvaro[2]. *[1]The University of Edinburgh, MRC Centre for Regenerative Medicine, Edinburgh, United Kingdom; [2]Sapienza University of Rome, Department of Translational and Precision Medicine, Rome, Italy; [3]Sapienza University of Rome, Department of Medical Surgical Science and Biochnologies, Latina, Italy; [4]University of Birgmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom; [5]Sapienza University of Rome, Department of General Surgery and Organ Transplantation, Rome; [6]Sapienza University of Rome, Department of Anatomical, Histological, Forensic Medicine and Orthopedics Sciences, Rome, Italy; [7]Sapienza University of Rome, Division of Human Anatomy, Department of Anatomical, Histological, Forensic Medicine and Orthopedics Sciences, Rome, Italy*
Email: lorenzo.nevi@uniroma1.it

Background and aims: In extrahepatic biliary tree (EHBT) are found the Peribiliary Glands (PBGs), these contain cells showing phenotype and biological properties of primitive endoderm called Biliary Tree Stem/Progenitor Cells (BTSCs). There are very few knowledges on the repair of injured biliary epithelium. Our aim was to evaluate *in vitro* and *in vivo* the BTSCs role in the regeneration of the biliary epithelium after injury and the pathways involved.
Method: Krt19CreTdTomato^{LSL} C57BL6/J mice were treated with 3, 5-Diethoxycarbonyl-1, 4-dihydrocollidine (DDC) for 14 days to induce biliary injury. Mice were sacrificed after 14 days of DDC treatment

(DDC) or after 14 of recovery after injury (DDC+14-R). EHBTs were collected and analyzed by immunohistochemistry (IHC) and immunoluorescence (IF). Human BTSCs (hBTSCs) were isolated from organ donors and were cultured in NOTCH, WNT or BMP pathway-inducing media using sDLL-1, RSPO-1 and Hegdehog respectively. Cell extracts were examined by RT-qPCR to analyze stem and mature cell gene expression. NICD, actived β-Catenin and Phospho-SMAD1/5 were quantify by Western Blot (WB).
Results: Significant increase of PBG area in DDC and DDC+14-R mice compared to and controls ($p < 0.05$; $N = 5$) was detected by IHC. Further, PBGs are still activated 2 weeks after DDC injury as demonstrated by $Ki67^+$ PBG cells. SOX9 was observed highly expressed in PBGs and biliary epithelium of DDC mice. Stimulation of NOTCH signaling by Jagged1 was observed in PBGs and biliary lining of DDC+14-R. Co-localization of Wnt3A/β Catenin were found in PBGs and biliary epithelium of DDC but not in control mice. Finally, very few $\alpha SMA^+/TdTom^+$ cells were detected in PBGs of DDC+14-R mice. *In vitro*, NOTCH pathway activation in hBTSC cultures induced a significative increase ($p < 0.01$; $N = 6$) of mature cholangiocyte genes expression while the endodermal stem cell genes expression was decreased. Instead, WNT pathway induction in hBTSC cultures enhanced SOX17 ($p < 0.05$; $N = 6$) and PCNA ($p < 0.01$; $N = 6$) gene expression. BMP pathway stimulation in hBTSCs cultures induced an increase ($p < 0.05$; $N = 6$) of gene expression of TWIST1, an EMT marker, compared to hBTSCs cultured in basal condition. *In vitro* pathway activations were confirmed by WB.
Conclusion: In conclusion, our results demonstrated that BTSCs have a key role in modulating the regeneration of biliary epithelium after injury and that NOTCH, WNT and BMP pathways are involved in the BTSCs activation.

PS-124
Cholestasis-induced kidney injury is ameliorated in Nlrp3 deficient mice
Mick Frissen[1], Liao Lijun[1], Veerle Bieghs[1], Eicke Latz[2], Alexander Wree[1], Peter Boor[1], Christian Trautwein[1]. [1]*University Clinic RWTH Aachen, Aachen, Germany;* [2]*Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn, Germany*
Email: mfrissen@ukaachen.de

Background and aims: Induction of cell death after cholestasis-induced hepatotoxicity caused by toxic bile acids starts in, but is not limited to, the liver. Another organ affected by cholestasis is the kidney, undergoing sever tubular epithelial injury and consecutive kidney injury and fibrosis. Since Nlrp3 inflammasome deficiency played a protective role after bile duct ligation (BDL) and BDL-associated kidney injury reflects bile cast nephropathy we studied the role of Nlrp3 inflammasome.
Method: We performed BDL on WT and NLRP3 knockout (Nlrp3-/-), as well as treatment with inflammasome inhibitor MCC950 5 days after BDL. Mice were sacrificed after acute (48 hours) or chronic (28 days) BDL injury. Livers and kidney were taken and inflammation, fibrosis and cell death were evaluated.
Results: Acute BDL induced liver injury was exacerbated in Nlrp3-/- mice compared to WT mice, as evidenced by liver injury markers such as serum transaminases as well as inflammatory markers. Remarkably, we found an increase in Cyp7a1 and Fxr in Nlrp3-/- mice compared to WT mice before BDL, in line with the increase of bile infarcts in Nlrp3-/- animals. After chronic BDL induced liver injury however, Nlrp3-/- as well as MCC950 treated mice showed a remarkable improvement with a decrease in liver injury as well as inflammation and fibrosis. Kidney injury however showed an improvement both after acute as well as chronic BDL-induced injury in Nlrp3-/- mice compared to WT mice. After acute kidney injury Nlrp3-/- kidneys showed reduced granulocyte infiltration and tubular damage marker KIM-1 and NGAL. Long-term impact of BDL on kidney injury showed full blown bile cast nephropathy with significantly less bile casts in Nlrp3-/- kidneys compared to WT mice, as well as a decrease in associated tubular damage as shown by KIM-1 and NGAL. Furthermore, F4/80 positive cells were significantly decreased in Nlrp3-/- kidneys. Finally, we also found reduced kidney fibrosis assessed by collagen accumulation in Nlrp3-/- kidneys compared to WT controls after BDL.
Conclusion: These results show that Nlrp3 is involved in triggering cholestasis induced kidney damage in the acute, but also in the chronic phase independent of ongoing liver injury and can be treated by an oral Nlrp3 inhibitor. A possible explanation of the difference between kidney and liver could be the increase of bile infarcts due to the higher bile acid synthesis in livers of Nlrp3-/- mice.

PS-125
Gut pathobionts underlie intestinal barrier dysfunction and liver Th17 immune response in primary sclerosing cholangitis
Nobuhiro Nakamoto[1], Nobuo Sasaki[1], Ryo Aoki[1], Kentaro Miyamoto[1], Toshiaki Teratani[1], Takahiro Suzuki[1], Yuzo Koda[1], Po-Sung Chu[1], Nobuhito Taniki[1], Toshiro Sato[1], Takanori Kanai[1]. [1]*Keio University School of Medicine, Department of Internal Medicine, Tokyo, Japan*
Email: nobuhiro@z2.keio.jp

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic inflammatory liver disease and its frequent complication with ulcerative colitis (UC) highlights the pathogenic role of epithelial barrier dysfunction, yet its underlying mechanism remains unknown. Here, we aimed to identify the specific microbiota that contribute to the pathogenesis of PSC using humanized gnotobiotic mice.
Method: Patients with PSC/UC (n = 18), UC (n = 16), and healthy controls (HCs) were included in this study. 16s rRNA metagenome analysis and quantitative PCR to detect specific microbiota in human fecal samples were performed. We generated gnotobiotic mice by inoculating fecal samples from patients with PSC/UC (PSCUC mice), UC (UC mice), or Healthy controls (HCs) (HC mice). Gut barrier function, immunophenotyping, and the susceptibility to experimental hepatobiliary injury by DDC feeding in these mice were examined. To examine the interaction between bacteria and the intestinal epithelium, a monolayered human intestinal organoids were cultured with the specific bacteria in vitro.
Results: Metagenomic analyses revealed lower diversity and a distinct taxonomic trend with a higher prevalence of *Enterobacteriaceae* in the microbiota of PSC/UC patients. In contrast to germ-free (GF) or HC gnotobiotic mice, PSCUC mice demonstrated higher Th17 response in the liver and strong susceptibility to the experimental hepatobiliary inflammation, which was reversed by administration with RORgt inverse agonist. We identified three bacterial species, *Klebsiella pneumoniae*, *Proteus mirabilis*, and *Enterococcus gallinarum from* the mesenteric lymph nodes of PSCUC mice by bacterial culture. Importantly, these pathobionts were specifically enriched in the feces of PSC/UC patients both in our cohort (*K. pneumoniae*, 17/18, *P. mirabilis*, 5/18, *E. gallinarum*, 12/18) and European validation cohort. The mono-inoculation of GF mice with PSC mice-derived *K. pneumoniae* caused mucosal invasion detected by fluorescence in situ hybridization with an EUB338 probe and the induction of $RORgt^+IL17^+CD4^+$ T cells in the liver, but was insufficient to induce a robust Th17 response, as was observed in mice inoculated with the three mixed strains. Using a mono-layered organoid culture system, we demonstrated that PSC/UC-derived *K. pneumoniae* unlike commercially available *K. pneumoniae* strains, directly induced epithelial-pore formation with apoptosis-related genes upregulation. Finally, we confirmed that antibiotic treatment targeting *K. pneumoniae* and *E. gallinarum* was effective in the reduction of pathogenic Th17 response in the liver in PSCUC mice.
Conclusion: Our results identified specific pathobionts in PSC/UC patients that collude in intestinal barrier disruption and subsequent Th17-priming in the liver, and provide insights into the implication of the gut microbiota in the pathogenesis of PSC.

Email: harry.sokol@aphp.fr

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease, most often associated with inflammatory bowel disease (IBD). PSC patients have been shown to display a bacterial gut dysbiosis but fungal microbiota has never been studied in these patients. The aim of this study was to explore the fungal gut microbiota in PSC patients.
Method: We analyzed the fecal microbiota of: patients with PSC and concomitant IBD (n = 27), patients with PSC and no IBD (n = 22), patients with IBD and no PSC (n = 33) and healthy subjects (n = 30). Bacterial and fungal composition of the fecal microbiota was determined using 16S and ITS2 sequencing, respectively. To assess if microbiota features were associated with disease phenotype, a multivariate association test with linear models (MaAsLin) was used to override the effect of potential confounding factors such as age, gender, smoking or treatment.
Results: We found that patients with PSC exhibited bacterial dysbiosis characterized by a decreased biodiversity, an altered composition and a decreased correlation network density. These microbiota alterations were associated with PSC, independently of IBD status. For the first time, we showed that patients with PSC displayed a fungal gut dysbiosis, characterized by a relative increase in biodiversity and an altered composition. Notably, we observed an increased proportion of *Exophiala* and a decreased proportion of *Saccharomyces cerevisiae*. Compared to patients with IBD and healthy subjects, the gut microbiota of patients with PSC exhibited a strong disruption in bacteria-fungi correlation network suggesting an alteration in the inter kingdom crosstalk.
Conclusion: This study demonstrates that PSC is characterized by an altered fungal gut microbiota associated with an impaired fungi-bacteria correlation network. The implications of these findings remain to be defined but pave the way for the development of microbiota-based biomarkers and treatments in PSC.

PS-127

Analysis of liver infiltrating lymphocytes in primary sclerosing cholangitis by surface antigen and single cell RNAseq

Kate Lynch[1], Fabiola Curion[2], Hing-Yuen Yeung[2], Eve Fryer[3], Andrew Slater[4], Helen Ferry[1], Moustafa Attar[2], Hubert Slawinski[2], Roger W.G. Chapman[1], Rory Bowden[2], Calli Dendrou[2], Paul Klenerman[1], Satish Keshav[1]. *[1]University of Oxford, Translational Gastroenterology Unit, NDM Experimental Medicine, Oxford, United Kingdom; [2]University of Oxford, Wellcome Centre for Human Genetics, Oxford, United Kingdom; [3]University of Oxford, Nuffield Division of Clinical Laboratory Sciences, Oxford, United Kingdom; [4]John Radcliffe Hospital, Radiology Department, Oxford, United Kingdom*
Email: katewilly@hotmail.com

Background and aims: Little is known about the nature of liver infiltrating lymphocytes (LIL) in primary sclerosing cholangitis (PSC). Fine needle aspiration (FNA) of the liver has emerged as a safe, minimally invasive technique to obtain LILs for immunophenotyping. We evaluated whether FNA could be used to differentiate LIL in patients with PSC and other liver conditions (LC). and tested the hypothesis that cells expressing chemokine receptor CCR9 were preferentially enriched in PSC.
Methods: We obtained PBMC and LIL using FNA from patients with PSC and LC and performed multicolour flow cytometry, and single cell RNA sequencing on CD45+ sorted cells using the 10X Chromium Single Cell 3′ platform. We also performed immunohistochemistry (IHC) for CCR9 and CD3 on formalin fixed paraffin embedded (FFPE) liver biopsy sections from patients with PSC with and without inflammatory bowel disease (IBD), and LC.
Results: A median 12, 333 LIL were obtained from 31 patients (16 PSC, 15 LC). These displayed specific hepatic characteristics compared to PBMC including greater proportions of CD56+ NK cells, and more CD8+, CD69+, and CD161+ T-cells (respectively: 47.4%±3.4 vs. 37.3%±3.5; 37.5%±1.9 vs. 30.3%±2.3; 15.7%±2.0 vs. 4.5%±1.2; mean ±SEM, p < 0.0001 for all). There was no difference of CCR9 expression among CD4+ CD45RA- LIL between PSC/IBD and LC (4.6%±0.7 vs. 4.0% ±0.5, mean±SEM, p = ns).
IHC was performed on 36 FFPE liver biopsies (10 PSC/IBD, 12 PSC/no IBD, 14 LC). There was a trend towards higher mean CCR9 counts in

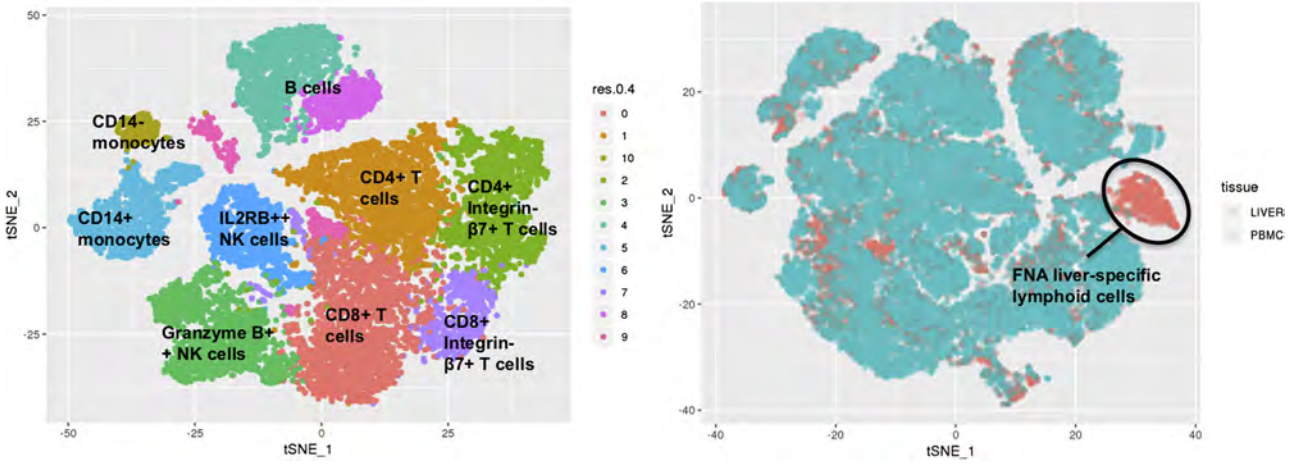

Figure 1: (abstract: PS-127): tSNE plots characterising and comparing FNA liver immune cells relative to PBMCs. Left panel: FNA liver immune cell types include CD8+ and CD4+ T cell, NK cell, B cell and myeloid cell populations (n = 4, 16, 867 cells analysed in total). Right panel: A lymphoid cell cluster (circled) is observable that is highly enriched in FNA liver (blue, n = 4) compared to matched PBMCs (red, n = 4).

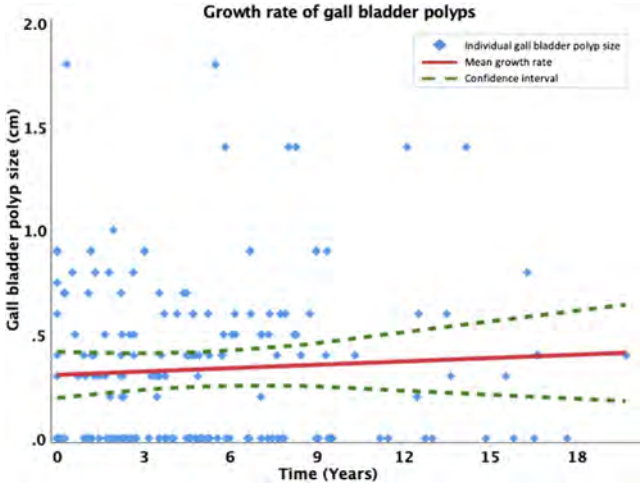
PSC/IBD (3.4/5HPF [IQR 0.2-5.2]) vs. PSC/no IBD (0.5 [0.1-3.0], p = 0.334) vs. LC (2.0/5HPF [0.6-6.0], p = 0.92). CCR9+ T-cells were centred around the portal tracts.
On transcript analysis (n = 4;16, 867 liver immune cells), 11 clusters were identified including lymphoid and myeloid cell subsets displaying differential expression of cell adhesion molecules (e.g. ITGB7) and activation markers (e.g. granzyme B, CD69). One lymphoid population was highly enriched in LIL, expressing transcription factors such as IRF1 and FOXP1 and cell surface markers including CD2 and lymphotoxin β (see Fig 1).
Conclusion: FNA of the liver could isolate a liver-specific lymphoid cell population that is not found in PBMC. There was no clear difference in CCR9 expression between PSC and LC. Single cell RNAseq can also determine gene expression in LIL, and with refinement of the technique, could be used to ascertain if tissue-homing molecules such as CCR9, ITGB7, and CD161 are also differentially expressed in PSC.

PS-128

Risk of gall bladder cancer in patients with primary sclerosing cholangitis and gall bladder polyps: an opportunity to revisit the guidelines

Liselot van Erp[1,2], Morven Cunningham[1], Manasa Narasimman[3], Hamideh Aleali[4], Kartik Jhaveri[4], J.P.H. Drenth[2], Harry Janssen[1], Cynthia Levy[3], Gideon Hirschfield[1], Bettina Hansen[1], Aliya Gulamhusein[1]. *[1]Toronto General Hospital, Toronto Centre for Liver Disease, Toronto, Canada; [2]Radboud University Medical Center, Department of Hepatology, Nijmegen, Netherlands; [3]University of Miami, Department of Hepatology, Miami, United States; [4]Toronto General Hospital, Department of Radiology, Toronto, Canada*
Email: liselotvanerp@gmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is a premalignant cholestatic liver disease associated with a risk of gall bladder cancer (GBC). International guidelines recommend cholecystectomy for gall bladder polyps of any size. We aimed to characterize the risk of GBC in PSC patients with gall bladder polyps.
Method: A retrospective review of patients with PSC followed at the Toronto Centre for Liver Disease between 2008–2018 was performed. All imaging and histology reports were reviewed for presence of gall bladder abnormalities. Descriptive statistics were used to characterize the cohort. The polyp growth as assessed by imaging was analyzed with repeated measurement methods using SAS.
Results: 366 PSC patients diagnosed between 1980 and 2017 were included. Mean age (SD) at diagnosis was 34 (± 15) years, 57% were male and 80% had large duct PSC. Mean follow-up time (SD) was 8.0 (± 5.9) years. Median number of imaging reports (IQR) per patient was 7 (4-13). A gall bladder polyp was seen in 17% (61/366) with median size (range) when first detected of 4 (2 –18) mm. At time of PSC diagnosis the median (IQR) ALT was 81 (35-135) U/l, AST 52 (32-73) U/l, ALP 231 (137-341) U/l, total bilirubin 12 (8-17) µmol/L and platelets 237 (180-279) × 10^9/L. Cholecystectomy was performed in 30% (18/61) of which pathology was available for 72% (13/18). Benign or no polyp was reported in 77% (10/13) and dysplasia or malignancy in 23% (3/13). In the 2 patients with adenocarcinoma, preoperative imaging described high risk features with an enlarging polyp or gall bladder mass. Low grade dysplasia was identified on explant in 1 patient with repeatedly stable 7-9mm polyp. Patients with gall bladder polyp who did not have cholecystectomy (43/62) were followed for median (IQR) 5 (2-9) years since the polyp was first detected. In this group 5% (2/43) had enlarging polyps (none greater than 8mm), 12% (5/43) stable or decreasing polyp size, and in 79% (34/43) the polyp was not reported on subsequent imaging. In 5% no subsequent imaging was available. In this cohort, gall bladder polyps did not show significant growth over time (Figure). After detection of a gall bladder polyp, the risk of developing GBC was 1.6 per 100 person years.



Conclusion: In the context of current screening recommendations, many gall bladder polyps in PSC patients are benign. Short term surveillance imaging may be considered prior to recommending immediate cholecystectomy in PSC patients without high risk imaging features.

Email: schoeneweis@myr-pharma.com

Background and aims: Myrcludex B/Bulevirtide (MyrB) is a first-in-class entry inhibitor to treat HBV/HDV infection. MyrB monotherapy resulted in HDV RNA decline and improvement of ALT levels (MYR 202). In a follow-up phase II study (MYR203) we reported end of treatment data in HBV/HDV infected patients receiving MyrB alone or combination with peg-interferon α 2a (PEG-IFNα) for 48 weeks (Wedemeyer et al. Hepatology 2018, DOI:10.1002/hep.30256). Here we present the 24-week (w) treatment-free follow-up data.

Method: 60 patients with HBV/HDV co-infection were randomized in 4 arms, receiving: 180 µg PEG-IFNα (A) or 2 mg MyrB plus PEG-IFNα (B), 5 mg MyrB plus PEG-IFNα (C), or 2 mg MyrB (D) for 48 w followed by a treatment-free period of 24 w. PEG-IFNα was given once weekly, and MyrB once daily, both as s.c. injection. The primary end point was undetectable serum HDV RNA at w72; secondary end points included ALT normalization, a combined treatment response (≥2log serum HDV RNA decline + normal ALT levels), and HBsAg reduction > $1\log_{10}$.
Results: *Safety:* MyrB was well tolerated with 155 drug-related AEs until w72 (mild n = 122, moderate n = 28, severe n = 5) primarily caused by an increase in total bile salts. Most AEs (n = 524) were related to PEG-IFNα. Two SAE (anal fistula and proctitis) occurred in one patient of arm B during follow-up, not-related to MyrB. All AEs resolved without sequelae; bile salts returned to baseline levels already at follow-up w50. *Efficacy:* Efficacy results are shown in the table below.
Conclusion: In contrast to PEG-IFNα monotherapy, a combination of MyrB with PEG-IFNα demonstrated high rates off-treatment HDV RNA suppression. HBsAg loss was achieved in a substantial proportion of patients, indicating a potential role of Myrcludex B in future HBV cure regimens.

Table: (abstract: GS-13)

Virological response	Time point	Arm A (n = 15) PEG-IFNα	Arm B (n = 15) 2 mg MyrB + PEG-IFNα	Arm C (n = 15) 5 mg MyrB + PEG-IFNα	Arm D (n = 15) 2 mg MyrB
Undetectable HDV RNA	w48	2/15	9/15	6/15	2/15
	w72	0/15	8/15	4/15	0/15
Median HDV RNA log reduction	w48	−1.14	−3.62	−4.48	−2.84
	w72	−0.26	−3.00	−1.38	−1.16
ALT normalization	w48	4/15	4/15	7/15	10/15
	w72	1/15	7/15	5/15	3/15
HBsAg: > 1log decline or undetectable	w48	0/15	7/15	2/15	0/15
	w72	0/15	6/15	2/15	0/15
Undetectable HBsAg	w48	0/15	3/15	0/15	0/15

Background and aims: Acute Hepatic Porphyrias (AHPs) are rare genetic diseases due to enzyme deficiencies involved in heme biosynthesis. AHPs include acute intermittent porphyria (AIP), variegate porphyria (VP), and hereditary coproporphyria (HCP). Induction of aminolevulinic acid synthase 1 (ALAS1) can lead to accumulation of neurotoxic heme intermediates aminolevulinic acid (ALA) and porphobilinogen (PBG), resulting in potentially life-threatening, neurovisceral attacks and debilitating chronic symptoms. Givosiran is an investigational RNAi therapeutic targeting ALAS1 to reduce ALA and PBG levels in AHP patients and ameliorate disease manifestations.
Method: ENVISION (NCT03338816) is a Phase 3 global, multicenter, randomized, double-blind, placebo-controlled trial in AHP patients to evaluate the effect of givosiran (2.5 mg/kg, given subcutaneously once-monthly) compared to placebo, on attack rate over six months. Eligible patients were aged ≥ 12 years with an AHP diagnosis and history of ≥ 2 attacks in the six months prior to enrollment. Patients also had to be willing to discontinue or not initiate hemin prophylaxis. The primary end point is annualized rate of attacks requiring hospitalization, urgent care, or home IV hemin. Secondary end points are safety/tolerability, ALA and PBG levels, hemin usage, symptoms, and quality of life measures.
Results: Study enrollment has been completed (N = 94, 18 countries, 36 sites). An interim analysis of safety and urinary ALA, a biomarker likely to predict clinical benefit, was conducted in 43 patients (41 AIP, 1 VP, 1 HCP; 23 randomized to givosiran, 20 to placebo) who were on study for at least three months. No deaths were reported. Serious adverse events were reported in 5/23 (22%) of patients on givosiran, and 2/20 (10%) on placebo. One patient on givosiran was discontinued due to > 8x ULN increase in liver transaminases (a protocol-stopping rule), which later resolved. Patients on givosiran showed a statistically significant urinary ALA reduction, compared to placebo group ($p < 0.001$). The study is ongoing, and results from the complete six-month double-blind period, including the primary end point of annualized attack rate, will be presented.
Conclusion: Givosiran is an investigational RNAi therapeutic under study for the treatment of AHP. An interim safety analysis of an ongoing Phase 3 study demonstrated a safety profile supportive of continued development and a significant reduction of the disease biomarker.

GS-15

Deficiency of the ABC transporter ABCC12/MRP9 is associated with chronic cholestasis syndromes and causes bile duct paucity in zebrafish and mouse model organisms

Lingfen Xu[1,2], Duc Hung Pham[1], Tiffany Shi[1], Jillian Ellis[1], Mary Mulen[1], Alexander Valencia[3], Sujit Mohanty[4], Sami Wali[5], Alexander Miethke[1], Chunyue Yin[1]. *[1]Cincinnati Children's Hospital Medical Center, Pediatric Gastroenterology, Hepatology and Nutrition, Cincinnati, United States; [2]Shengjing Hospital of China Medical University, Pediatric Gastroenterology, Shenyang Shi, China; [3]Cincinnati Children's Hospital Medical Center, Human Genetics, Cincinnati, United States; [4]Cincinnati Children's Hospital Medical Center, Pediatric Surgery, Cincinnati, United States; [5]Prince Sultan Military Medical City, Pediatric Gastroenterology, Riyadh, Saudi Arabia*
Email: alexander.miethke@cchmc.org

Background and aims: Despite recent advances in understanding the genetic underpinning of progressive familial intrahepatic cholestasis (PFIC), the etiology for cholestasis remains unknown in many children. We surveyed the genome of children with chronic cholestasis for variants in genes not previously associated with PFIC and validated their biological relevance in zebrafish and murine models.
Method: Whole exome and candidate gene sequencing was performed in 38 children with normal GGT cholestasis without disease causing mutations in the genes *ABCB11, ATP8B1 or ABCB4*. Crispr/Cas9 gene editing was employed to induce truncating mutations in the candidate gene in C57BL/6 mice and zebrafish.
Results: A homozygous, truncating mutation (c.198del.Gly67Alafs*6) was detected in *ABCC12* encoding MRP9, a member of the superfamily of ATP-binding cassette (ABC) transporters, in a 1yo female patient with normal GGT cholestasis and bile duct paucity by liver histopathology. 3 more subjects were found to harbor compound heterozygous mutations in this gene. The biological functions of this transporter are largely undefined, and it has not been associated with liver disease before. Using IHC we found it to be expressed in bile duct epithelial cells (Fig 1a). Adult, male mice lacking *Abcc12* due to a 100 bp deletion in exon 3 displayed higher serum ALP (mean: 180 vs 86 IU/L, $p < 0.01$) and ALT levels (77 vs 37 IU/L, $p < 0.01$) compared with age matched WT controls. IHC for panCK revealed a higher percentage of bile ducts without lumen (36 vs 17%, $p < 0.05$). When younger mice were challenged by feeding

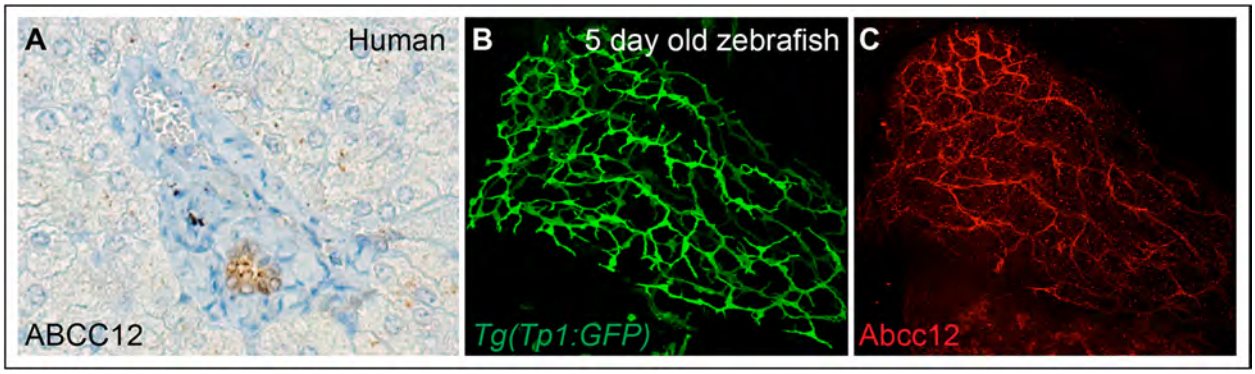

Figure: (abstract: GS-15) Liver tissue from an infant without liver disease (**A**), and 5-day-old zebrafish larvae expressing the transgene Tg (Tp1bglob:GFP) in biliary epithelial cells (**B**) were stained with an antibody against ABCC12 (**C**).

of 1% cholic acid admixed to the chow for 7 days, biliary injury was aggravated in Abcc12$^{-/-}$ mice compared with age/sex matched WT mice, as indicated by increased bile duct proliferation (area CK19+: 0.38 vs 0.32%, p < 0.05), higher serum total bilirubin levels, and more periportal fibrosis (Sirius Red stained area: 0.97 vs 0.72%, p = 0.05). In zebrafish, we detected conserved expression of the homolog of ABCC12 in cholangiocytes (Fig 1b/c). The zebrafish mutant harboring similar truncating mutations exhibits a significant reduction in cholangiocyte number compared to WT during juvenile stage and had elevated total bile acid and ALT levels at adult stage.

Conclusion: *Abcc12*/Mrp9 is a novel transporter expressed by cholangiocytes, and its loss is associated with bile duct paucity in humans, mice and zebrafish. The substrates for this transporter and mechanisms for cholangiocyte injury are under investigations.

GS-16

Safety and tolerability of liver-derived stem cells (HepaStem) infused in patients with acute-on-chronic liver failure or acute decompensation: a European phase I/IIa open-labelled study

Nevens Frederik[1], Gustot Thierry[2], Laterre Pierre-François[3], Lasser Luc[4], Haralampiev Lyudmil Enev[5], Vargas Victor[6], Barthel Virginie[7], Nathalie Clerget-Chossat[7], Etienne Sokal[3,7].

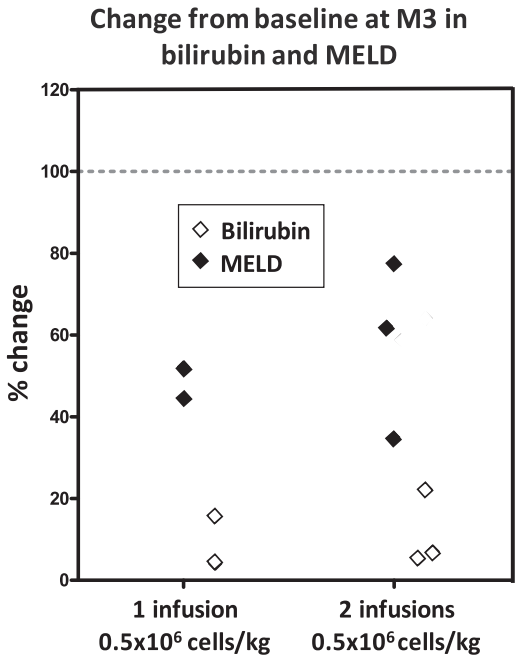
Email: etienne.sokal@promethera.com

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by acute decompensation (AD) of cirrhosis associated with failure of one or more organs. HepaStem™ (Promethera) is a suspension of liver stem cells derived and expanded from the parenchymal fraction of collagenase-digested adult human liver. The immunomodulatory properties of HepaStem is expected to restore the immunological disturbances and functional impairment in patients with ACLF or AD. The main objective is the safety of single or double infusions of various doses in patients with ACLF or AD at risk of developing ACLF up to day (D)28 post treatment. Secondary objectives include safety and efficacy up to month (M)3.

Method: The study is composed of 6 dose-cohorts: 250 × 10^6 cells (n = 3); 0.25 × 10^6 cells/kg (1 dose, N = 3); 0.5 × 10^6 cells/kg (1 dose, N = 3; or 2 doses, N = 3); 1 × 10^6 cells/kg (1 dose, N = 3; or 2 doses, N = 3). Twelve patients were included in the first 4 cohorts and followed up to M3 after treatment.

Results: The 1st patient (ACLF) received no cells due to technical issue. The 2nd and 3rd patients (both ACLF) received 1 or 2 infusions of 250 × 10^6 cells (around 3.5 × 10^6 cells/kg/infusion). Nine patients (3 ACLF and 6 AD) received 1 infusion of 0.25 × 10^6 cells/kg, or 1 or 2 repeated infusions 1 week apart of 0.5 × 10^6 cells/kg. The 2nd and 3rd patients had severe epistaxis and one bled at the insertion side of the transjugular biopsy. They all suffered at baseline from severe coagulation disturbances. Both patients recovered; one of them had liver transplantation. After dose reduction in the subsequent cohorts, no serious events causally related to HepaStem were reported. Reported AEs were in line with those expected in regards underlying diseases and comorbidities. No drop in platelets, fibrinogen, or coagulation factors were observed. From the patients with transplant-free survival at M3, bilirubin and MELD decreased by respectively 80% and 50%.

Conclusion: At high HepaStem doses, 2 out of the 3 ACLF patients with severe coagulation disturbances experienced bleedings possibly related to study medication. HepaStem expresses tissue factor, which can activate the coagulation cascade and lead to consumption of coagulation factors; this effect is dose-dependent according to preclinical studies. Repeated infusions of 0.5 × 10^6 cells/kg were shown safe in this AD/ACLF patient population, and clinically significant MELD and bilirubin improvement is considered as an encouraging sign of efficacy.



GS-17

The integration of Hepatitis B virus into human genome is a common event in the setting of HBeAg negative disease: Implications for the treatment and management of CHB

Email: valentina.svicher@uniroma2.it

Background and aims: HBV Integration in the human genome is associated with hepatocarcinogenesis, a factor which should be considered in the initiation of treatment. We recently demonstrated HBV DNA integration in the early phases of HBV infection (*Mason et al., Gastroenterology 2012).* Here we analysed integration events in eAg negative disease with low to moderate levels of viraemia including those who currently do not meet treatment criteria.

Method: Liver tissue from 40 eAg negative CHB patients was studied. Patients were classified according to level of viraemia: group 1 (HBV DNA < 2, 000IU/ml; n = 8), group 2 (HBV DNA 2, 000-20, 000IU/ml; n = 14), group 3 (HBV DNA > 20, 000IU/ml; n = 18). cccDNA and pgRNA were evaluated by qPCR. HBV integration was identified by recognition of chimeric HBV human sequences by NGS [Illumina, median (IQR) coverage:114x (92x-138x)]. The threshold of parameters predicting HBV integration was defined by AUROC.

Results: Median (IQR) serum HBV DNA and HBsAg were 3.9logIU/ml (3.4-5.3) and 3980IU/ml (1260-10000) respectively. Patients in group 1 and 2 had comparable intrahepatic reservoirs of cccDNA and pgRNA. Conversely, compared to group 2, group 3 was characterised by higher cccDNA [median (IQR): 2.6 (2.3-2.7)] vs 2.0 (0.9-2.3) log copies/1000 cells, p = 0.01] and pgRNA [190 (7-775) vs 3.3 (1.5-12.2) copies/1000 cells, p = 0.02]. HBV integration was detected in all

3 groups with an overall prevalence of 32.5%: 50% in group 3, 14.3% in group 2 and 25% in group 1. Among the 15 recognised integration events; 10 involved the HBx-encoding region, followed by HBs (n = 3), core (n = 1) and pol (n = 1). HBV integration preferentially occurred within intronic regions (9/15), critical for RNA splicing and mRNA production. Notably, in 6 patients, HBV integration localised in human genes, regulating cell proliferation. Amongst them, NUP85, COL18A1, AGBL5 and ANKRD52 are specifically involved in hepatocarcinogenesis. Integrated HBV was also found in genes regulating lipid metabolism (CYP2UI, LMF-1) and the ISG, IFITM-1. By AUROC, HBsAg > 5, 000IU/ml identified the occurrence of HBV integration with the best diagnostic accuracy (86.5%), 100% sensitivity and 80% specificity.

Conclusion: HBV integration occurs across all patients with eAg negative disease including those with low HBV DNA (<2, 000IU/ml). Localisation of HBV integrants suggest that these events are not restricted to carcinogenesis, but also involved in mechanisms regulating hepatocyte metabolism and antiviral immunity.

Email: christophe.corpechot@aphp.fr

Background and aims: Primary biliary cholangitis (PBC) frequently recurs after liver transplantation (LT). Recent data have shown that PBC recurrence impairs graft and patient survival (1). Strategies to prevent PBC recurrence and its long-term impact are therefore needed. It has been suggested that ursodeoxycholic acid (UDCA) may prevent PBC recurrence after LT but data supporting this effect are limited (2). Our aim therefore was to assess in a large multicenter, international cohort the impact of UDCA administered preventively after LT on the incidence of PBC recurrence and long-term outcomes.

Method: Data from 941 patients (88% female; mean age: 54 years) who underwent LT for PBC over the past three decades among 16 centers and 9 countries were retrospectively analyzed. Among these patients, 211 (22%) have been treated with UDCA (10-15 mg/kg/d) continuously from the first 2 weeks post-LT (preventive UDCA). Recurrence of PBC was diagnosed based on liver histology. Adjusted Cox models, competing risk and restricted mean survival time analyses were used to study the factors associated with PBC recurrence and long-term outcomes.

Results: Over a mean follow-up period of 9.7 ± 7.7 years, 264 PBC recurrences, 111 graft losses, and 298 deaths occurred. Within the population of patients who had had at least 1 biopsy during follow-up (n = 667, 71%), the factors associated with PBC recurrence in a multivariate analysis included absence of preventive UDCA (p <.0001; Fig.1), younger age at LT (p <.0001), use of tacrolimus vs. cyclosporine regimen (p <.001), and use of protocol vs. clinically driven biopsies (p <.05). Preventive UDCA and cyclosporine use were the only 2 factors independently associated with survival without graft loss or PBC recurrence. Hazard ratios (95% CI) associated with preventive UDCA with respect to PBC recurrence, graft loss, and death were 0.42 (0.30-0.59), 0.44 (0.26-0.76), and 0.67 (0.51-0.89) respectively. Preventive UDCA was associated with a survival gain without graft loss or PBC recurrence of 21.1 months (95% CI: 12.6-29.5) at 12 years and 42.8 months (27.9-57.7) at 20 years.

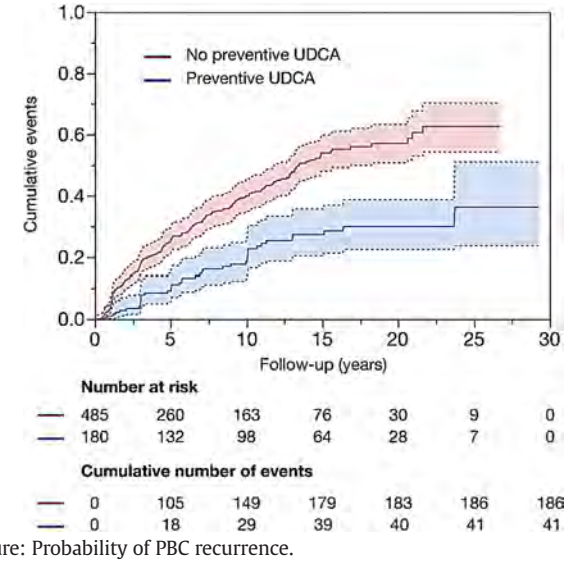

Figure: Probability of PBC recurrence.

Conclusion: Preventive administration of UDCA after LT for PBC prevents disease recurrence and prolongs graft survival.

NAFLD – Preclinical pipeline

PS-129

The glucocorticoid antagonist ST001 prevents development of NASH and improves aspects of the metabolic syndrome in the DIAMOND (TM) mouse model

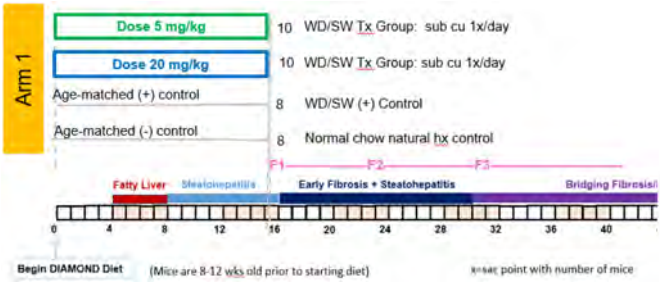
Rebecca Caffrey[1], Manohar Katakam[2], Arthur Schwartz[2], Bo Allen[2], Pierre Bedossa[3], Jonathon Marioneaux[1], Arun Sanyal[4]. *[1]Sanyal Biotechnology, Norfolk, United States; [2]SteroTherapeutics LLC, Spring House, PA, United States; [3]LiverPat, Paris, France; [4]Virginia Commonwealth University, Richmond, United States*
Email: rebecca@sanyalbio.com

Background and aims: The steroid ST001 (fluasterone, SteroTherapeutics) is a strong in vivo antagonist to glucocorticoids

that retains beneficial immunosuppressive effects. It is being evaluated as a treatment for Cushing's Syndrome, in which most patients are insulin resistant and obese and 20% develop NASH. We aimed to determine if ST001 could prevent development of NASH in the DIAMOND™ mouse model.

Method: Mice were randomized into 4 groups: high dose (HD 20 mg/kg), low dose (LD 5 mg/kg), WDSW positive (PC) and NCNW negative (NC) natural history controls. Mice were raised for 16 weeks on diet, corresponding to a baseline NASH with mild fibrosis in all WDSW groups. Treatment groups were then injected once daily with aqueous vehicle or drug in vehicle for the 16 wks they were on-diet. Serum biomarkers of insulin sensitivity, LFTs, lipids, and liver histology (HandE and Sirius Red) were assessed.

Results: At necropsy, the body weight and liver weight of the mice in the HD group were significantly lower than the PC and LD groups. Interestingly, steatosis percentage was higher in the fluasterone-dosed groups compared to PC, but steatosis grade did not differ. Fasting blood glucose was higher in the treated groups, but ketones and serum triglycerides were lower compared to PC. No statistically significant differences in serum insulin or HOMA-IR were observed, although there was a strong trend to lower insulin in the HD group. Serum LFTs and cholesterol did not differ between the PC and treatment groups. Fluasterone had significant anti-fibrotic effects; NASH CRN fibrosis scores were significantly lower in both treatment groups compared to WDSW positive controls ($P \leq 0.001$) and perisinusoidal fibrosis was also significantly lower in both treatment groups ($P \leq 0.01$). While 66% of the 16-wk positive control mice progressed to NASH, none of the mice being treated with fluasterone progressed beyond simple steatosis, and this lack of progression was highly statistically significant ($P \leq 0.001$). Fluasterone eliminated ballooning in both dose groups compared to PC ($P \leq 0.0001$). Lobular inflammation and NAS score did not differ between groups but the SAF activity score was lower in both dose groups.



Conclusion: Fluasterone successfully met the primary study end point of preventing NASH development. While not an insulin sensitizer, it did improve some measures of insulin sensitivity and metabolic syndrome, suggesting that the development of NASH in this model may be partly driven by glucocorticoids as with Cushing's disease. These results support the biological rationale for further testing of anti-glucocorticoid compounds with immunosuppressive effects like fluasterone as NASH therapeutics.

PS-130

Preclinical pharmacology of CJ-14199, a new and potent ileum bile acid transporter inhibitor for non-alcoholic steatohepatitis

Jin Woo Jung[1], Hyungjin Jun[2], Dong-Hyun Kim[1], Keun-Ho Lee[1], Ju Hyun Lee[1], Dong-Kyu Kim[1], Soo-Jin Kim[1], Byoung-Seok Moon[1], Won Kim[3], Shin-Young Ryu[1]. *[1]CJ HealthCare, RandD Center, Seoul, Korea, Rep. of South; [2]CJ HealthCare, Seoul, Korea, Rep. of South; [3]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea, Rep. of South*
Email: shinyoung.ryu@kolmar.co.kr

Background and aims: CJ-14199 is a novel and highly selective ileum bile acid transporter (IBAT) inhibitor in preclinical development for the next-generation treatment of the chronic liver diseases such as non-alcoholic steatohepatitis (NASH). In the present study, we investigated the *in vitro* and *in vivo* pharmacological properties of CJ-14199 and the effect of CJ-14199 in a diet induced mouse NASH disease model.

Method: *In vitro* cell assay was performed using IBAT- or LBAT (Liver BAT)-overexpressing cell line. *In vivo* pharmacological properties of CJ-14199 in normal ICR mice were determined by the changes of fecal bile acid and plasma 7αC4. *In vivo* efficacy of CJ-14199 on NASH was evaluated by NAS (Non-alcoholic fatty liver disease Activity Score) and fibrosis area in the various diet-induced mouse NASH diseases model. Tissue distribution of CJ-14199 was investigated using quantitative whole-body autoradiography (QWBA) in rats.

Results: CJ-14199 selectively inhibited IBAT with IC_{50} of IBAT was 1.83~3.6nM, which was about 4000 times lower than IC_{50} of LBAT. Following oral administration of CJ-14199 to ICR mice, the concentration of fecal bile acid was increased with dose-dependent manner and the increase of plasma 7αC4 was observed. CJ-14199 significantly improved NAS and prevented progression of fibrosis in the various diet-induced mouse models of NAFLD/NASH. In a QWBA study in which [^{14}C]CJ-14199 was orally administered to SD rats, CJ-14199 was highly distributed in the gastrointestinal tract such as stomach, small intestine, and large intestine.

Conclusion: CJ-14199 is a highly selective IBAT inhibitor, and is locally distributed in target organ, the gastrointestinal tract. CJ-14199 showed not only the increase of fecal bile acid and plasma 7αC4, but also the improvement of NAS and fibrosis area in the diet-induced NASH model. Therefore, CJ-14199 has the potential as a new therapeutics for NASH.

Email: robert.walczak@genfit.com

Background and aims: Drug combinations are increasingly required for the successful treatment of complex liver diseases. In NASH, drug combination has recently emerged as a new treatment paradigm to increase the proportion of patients that reach all treatment goals. The ideal NASH medication will both reverse NASH histology and stop the progression of fibrosis in patients at high risk of cirrhosis and complications.

Elafibranor (ELA), a PPARα/δ agonist can reverse NASH histology and decrease fibrosis, especially in patients with advanced disease (GOLDEN-505 phase 2b trial), and is currently being evaluated in the RESOLVE-IT phase 3 trial. We have recently identified nitazoxanide (NTZ), a phase-2 ready drug candidate with a good safety profile in man as a potent anti-fibrotic agent, by using an unbiased phenotypic screening approach.

The aim of this proof of concept study is to assess ELA/NTZ combination in a disease model of NASH to establish its potential value for treating human disease.

Method: Human primary stellate cells (HSC) were activated with TGFβ. The expression level of the profibrotic marker αSMA was measured by ELISA. A NASH phenotype was induced in C57Bl/6J mice by feeding a cholesterol-supplemented CDAA diet (CDAA/c) for 12 weeks. Animals received ELA alone (1 mg/kg/day), NTZ alone

(100 mg/kg/day) or ELA/NTZ combination for the entire study period of 12 weeks. Histological evaluation of NASH and fibrosis was performed in a blinded fashion.
Results: Nitazoxanide (NTZ) potently interfered with TGFβ-induced HSC activation in vitro. IPA analysis of transcriptional data showed that profibrotic signaling pathways (RhoA signaling, ILK signaling, Integrin signaling) were attenuated in HSC cells that received NTZ. At low doses, ELA and NTZ showed a modest inhibition (20–30%) of HSC activation, when used separately but this effect was doubled when both drugs were used as combination.
Histological examination *in vivo* revealed a severe NASH phenotype accompanied by perisinusoidal fibrosis. Liver fibrosis area was reduced by 41% and by 32% in mice treated with ELA and NTZ, respectively, whereas ELA/NTZ combination reduced the proportional fibrosis area by 60%. Transcriptomic analysis showed that ELA/NTZ combination created a synergistic beneficial action on multiple pathological mechanisms, involving liver cell death, inflammasone activation, immune cells recruitment and fibrosis.
Conclusion: Elafibranor and nitazoxanide synergize in vitro and in vivo to reduce liver fibrosis, opening interesting perspectives for further clinical development.

PS-132
The acetyl-CoA carboxylase inhibitor PF-05221304 exerts direct effects on hepatic inflammation and fibrosis independent of benefits on steatosis

Trenton Ross[1], Kenneth Kelly[1], Anthony Rinaldi[1], Matthew Lech[1], Robert Martinez[1], Collin Crowley[1], Santos Carvajal Gonzalez[1], Magalie Boucher[1], Dinesh Hirenallur Shanthappa[1], Jeffrey Morin[1], Alan C. Opsahl[1], Sarah R Vargas[1], Kendra Bence[1], Jeffrey A Pfefferkorn[1], William Esler[1]. [1]*Pfizer Worldwide Research and Development, Cambridge Massachusetts, United States*
Email: trenton.ross@pfizer.com

Background and aims: The molecular pathogenesis of non-alcoholic steatohepatitis (NASH) is complex, involving steatosis, lipotoxicity, hepatic inflammation and fibrosis. Acetyl-CoA carboxylase (ACC) regulates de novo lipogenesis (DNL) and fatty acid oxidation. ACC inhibitors reduce levels of steatosis in rodents and humans. In the present studies, the effects of a liver targeting, ACC1/ACC2 inhibitor (PF-05221304) on direct modulation of hepatic inflammation and fibrosis were evaluated in human-derived primary cells, and rat *in vivo* models, where improvements in steatosis do not contribute to efficacy.
Method: Effects of PF-05221304 on primary human T-cell and myofibroblast activation were assessed *ex vivo*. Effects of oral administration of PF-05221304 on markers of hepatic inflammation and fibrogenesis were evaluated in the diethylnitrosamine (DEN) chemical induced liver injury model and the choline deficient high fat fed rat model (CDAHFD).
Results: In primary human T-cells cultured under conditions to drive Th17 polarization, PF-05221304 inhibited DNL (EC_{50} 23 nM) and blocked polarization to Th17 pro-inflammatory cells (EC_{50} 151 nM) but not anti-inflammatory Treg cells. In primary human hepatic stellate cells treated with TGFβ1 to drive myofibroblast activation, PF-05221304 inhibited DNL (EC_{50} 31 nM) and attenuated myofibroblast activation as assessed by αSMA (EC_{50} 5 nM) and collagen (EC_{50} 23 nM) staining. In the rat DEN liver injury model, PF-05221304 administration reduced the %CD3 staining area, a marker of T-cell inflammation, by 33% ($p < 0.05$) and increased hepatic expression of the anti-inflammatory cytokine IL-10 ($p < 0.01$) without modulating steatosis, relative to vehicle. In the CDAHFD model, PF-05221304 administration reduced liver stiffness by 35% ($p < 0.001$), decreased αSMA staining area by 41% ($p < 0.01$) and Picro Sirius red staining by 26% ($p < 0.05$), without altering steatosis relative to vehicle treated rats. Additionally, hepatic expression of the activated myofibroblast marker gene αSMA and the fibrosis marker genes Col1A1 and Col3A1 were reduced by 46% ($p < 0.01$), 40% ($p < 0.01$) and 44% ($p < 0.05$), respectively, indicative of a reduction in hepatic inflammatory and fibrotic tone.
Conclusion: The liver targeting, ACC1/ACC2 inhibitor PF-05221304 produced direct improvements in markers of inflammation and fibrosis in both human-derived primary cells and rodent models, demonstrating that ACC inhibition has potential to address multiple dimensions of NASH pathogenesis.

PS-133
LXR inverse agonists reduce steatosis and fibrosis in the STAM mouse model but also improve insulin sensitivity in a high fat diet mouse clamp study

Eva Hambruch[1], Christian Gege[1], Olaf Kinzel[1], Katharina Hauser[1], Manfred Birkel[1], Ulrich Deuschle[1], Claus Kremoser[1]. [1]*Phenex Pharmaceuticals AG, Heidelberg, Germany*
Email: eva.hambruch@phenex-pharma.com

Background: Nuclear receptors LXR alpha and beta are involved in the control of hepatic de novo lipogenesis and overall lipid and cholesterol homeostasis. We have developed potent, synthetic LXR inverse agonists (LXRias) which block transcriptional activity of both LXRs. The effects of PX-L788 and PX-L329 were tested in the STAM mouse model of progressive NASH and compared to a clinical stage ACC inhibitor (ACCi). Furthermore, we assessed the impact on glucose homeostasis and insulin signaling by LXR inverse agonist, PX-L665, in a mouse model of NAFLD as well as in a two-step euglycemic clamp study.
Methods: STAM model: C57BL/6 mouse pups were injected with streptozotocin 2 days after birth and were placed on high-fat diet at 4 weeks of age. From week 6 on, mice received PX-L788 (10 and 30 mg/kg), PX-L329 (1 and 5 mg/kg), ACC inhibitor (0, 3 and 10 mg/kg) or vehicle. HandE stained liver sections were assessed for NAS scoring, Sirius-red positive area (SRA) was analysed as a correlate of fibrosis. NAFLD Model: C57BL/6 mice (fed a high fat and cholesterol (1% by wt) diet for 6 wks) were dosed with PX-L665 (5 mg/kg) or vehicle for 3 wks and an oral glucose and pyruvate tolerance test (oGTT, PTT) were performed. Euglycemic clamp: C57BL/6 mice (fed a 60% high fat diet for 16 wks) were dosed with PX-L665 (5 mg/kg), Pioglitazone (30 mg/kg) or vehicle q.d. for 4 wks. During the two step euglycemic clamp (8 mU/kg/min and 18mU/kg/min insulin) the glucose infusion rate was recorded as a measure for insulin sensitivity.
Results: In the STAM mouse model all compound treatments reduced total NAS (NAS = 4.7; 3.9; 2.8; 3.0; 3.2; 3.0 for [cpd (dose in mg/kg)] vehicle, ´329 (1), ´329 (5), ´788 (10), ´788 (30), ACCi (10)) and resulted in reduced SRA (−41.15%, −42.56%, −18.36%, −48, 68%, −43.03% for ´329 (1), 329 (5), ´788 (10), ´788 (30), ACCi (10)). In the NAFLD model PX-L665 treatment reduced glucose production in a PTT (AUC blood glucose −21.5%) and decreased glucose-stimulated insulin secretion in an oGTT (AUC insulin: −34.7%) relative to vehicle. Clamp experiments revealed an improved insulin sensitivity, similar to Pioglitazone, upon PX-L665 treatment.
Conclusion: LXR inverse agonists demonstrate anti-steatotic and anti-fibrotic effects in the hypoinsulinemic STAM model, thus independent from insulin sensitisation. However, in HFD mice with elevated insulin resistance, an LXRia also substantially improved insulin sensitivity. Taken both effects together there is a strong biological rationale for the development of LXRias in NASH therapy

PS-134
Oral treatment with PBI-4547 promotes beta-oxidation and energy expenditure, and reverses liver damage and white adipose tissue fibrosis in high-fat diet and ob/ob mouse models of NAFLD.

Brigitte Grouix[1], Alexandre Laverdure[1], François Sarra-Bournet[1], Mikaël Tremblay[1], Marie-Pier Cloutier[1], Liette Gervais[1], Jonathan Richard[1], Alexandra Felton[1], Pierre Laurin[1], Lyne Gagnon[1]. [1]*Prometic Biosciences Inc., Laval, Canada*
Email: b.grouix@prometic.com

Background and aims: Obesity and its resulting metabolic disturbances are major health threats and the main cause of a host of diseases, including non-alcoholic fatty liver disease (NAFLD).

PBI-4547, a novel first-in-class orally active compound, has been shown to improve liver fibrosis resulting from CCl_4-induced liver injury. This study examined the effect of PBI-4547 in *ob/ob* and high-fat diet (HFD)-induced mouse models of NAFLD.
Method: Six-week old male *ob/ob* mice were treated with vehicle or PBI-4547 (10 or 50 mg/kg, oral once a day) from day 1 through 105. C57BL/6 mice were fed with either a standard or an HFD (Harlan, TD.06414) for 14 weeks. These mice were divided in three groups [Normal chow, HFD + Vehicle, and HFD + PBI-4547 (10 mg/kg, oral once a day)] and treated for an additional 6 weeks. Liver steatosis and ballooning as well as white adipose tissue (WAT) were assessed by hematoxylin and eosin (HandE) staining. Pro-inflammatory/profibrotic and fatty acid (FA) metabolism gene expression was measured in liver and WAT samples by qPCR. Blood glucose, serum triglyceride, and adiponectin levels were examined.
Results: Both *ob/ob* mice and HFD-mice displayed severe liver steatosis and ballooning, which was completely reversed with PBI-4547 treatment. PBI-4547 reduced collagen types I and III, MMP-2, and TIMP1 gene expression in liver of *ob/ob* mice and HFD-mice. Moreover, PBI-4547 treatment significantly reduced fibrosis and inflammatory cell infiltration in WAT for both animal models, and decreased profibrotic/inflammatory markers CTGF, MMP-2, Collagen I and MCP-1 in WAT of HFD-mice. To further characterize the activity of PBI-4547, quantitative RT-PCR analysis of the expression of FA transport, synthesis and oxidation markers was performed in liver and WAT of HFD-mice. In liver, PBI-4547 increased markers of mitochondrial FA transport and oxidation (ACOX-1, CD36, FABP4, CPT1β, PDK4) and FA synthesis (FASN). In WAT, PBI-4547 increased mitochondrial FA transport and oxidation markers CD36 and CPT1β, thermogenesis marker UCP-1 (by 16X, suggesting browning of adipose tissue) as well as glucose transporter GLUT4. Moreover, PBI-4547 completely inhibited Vaspin gene expression in WAT. Blood glucose and serum triglyceride levels were strongly reduced by PBI-4547 and serum level of adiponectin, which was reduced in *ob/ob* and HFD-mice, was significantly increased in PBI-4547-treated mice.
Conclusion: PBI-4547 is a potential novel therapy for NAFLD, obesity, and associated metabolic syndrome. PBI-4547 decreases liver and WAT profibrotic markers, and promotes β-oxidation and energy expenditure.

PS-135
MSDC-0602 K, a PPAR-gamma sparing modulator of the mitochondrial pyruvate carrier, improves NASH outcome in a diet-induced animal model of non-alcoholic steatohepatitis
Rebecca Caffrey[1], Jonathon Marioneaux[1], Jerry Colca[2], Pierre Bedossa[3], Arun Sanyal[4]. *[1]Sanyal Biotechnology, Norfolk, United States; [2]Cirius Therapeutics, Kalamazoo, MI, United States; [3]LiverPat, Paris, France; [4]Virginia Commonwealth University, Richmond, United States*
Email: rebecca@sanyalbio.com

Background and aims: MSDC-0602 K, a second generation TZD, is currently being evaluated in a 52-week, phase 2b dose-ranging clinical trial in subjects with biopsy proven NASH (EMMINENCE, NCT02784444). MSDC-0602 K is optimized for the mitochondrial target of thiazolidinedione (TZD), the mitochondrial pyruvate carrier (MPC) complex, which is required to import pyruvate into the mitochondrial matrix from the cytosol. Modulating mitochondrial pyruvate metabolism through attenuation of the MPC produces insulin-sensitizing effects. Unlike the first generation TZDs pioglitazone and rosiglitazone, MSDC-0602 was designed not to bind PPARγ. We postulated that MSDC-0602 K treatment would improve clinical laboratory indices and pathophysiological aspects of NASH in the DIAMOND™ mouse model.
Method: Male DIAMOND™ mice received high fat sugar water diet (WDSW) or chow diet normal water (CDNW) for 24 wks. Mice on WDSW were randomized to MSDC-0602 K (30 mg/kg/day) and Vehicle (VC) gavaged QD for 16-24 wks (n = 10/group), and results were compared to baseline WDSW positive controls (baseline PC, n = 5) and 24-week CDNW negative natural history controls (NC, n = 5). The end points included measures of insulin sensitivity, lipids LFTs, and liver histology with HandE and Sirius Red staining to quantify NASH progression.
Results: MSDC-0602 K dramatically reduced HOMA-IR compared to VC and PC groups ($P \leq 0.002$ and 0.021, respectively); this was driven mostly by decreased fasting insulin compared to VC and PC groups ($P \leq 0.0006$ and 0.08, respectively). Remarkably, the HOMA-IR and fasting insulin values in the MSDC-0602 K treated mice were comparable to NC mice, even though their fasting glucose, ketones, triglycerides, body/liver weights, and hepatic steatosis (% and grade) did not differ from the VC group. Average serum AST and ALT in the MSDC-0602K-treated group was halved compared to the VC but did not reach statistical significance ($P \leq 0.07$ and 0.12 respectively). Relative to VC, treatment with MSDC-0602 K significantly decreased ballooning ($P \leq 0.024$; the SAF activity score was significantly lower in the MSDC-0602K-treated group compared to the VC ($P \leq 0.04$) and was reduced to the level of baseline controls. The NAFLD Activity Score (NAS) trended lower compared to VC in the MSDC-0602K-treated group ($P \leq 0.11$) The NASH CRN fibrosis score in the MSDC-0602K-treated group was 0; the MSDC-0602K-treated group was equivalent to the NC group. Significantly fewer MSDC-0602K-treated mice (3/10, 30%) progressed from simple steatosis to NASH compared to the VC group ($P \leq 0.023$).
Conclusion: MSDC-0602 K met the primary study goal of ameliorating and preventing progression of NASH. The drug treatment improved insulin resistance, LFTs, ballooning, and NASH outcome independently of weight and steatosis. These study results support the biological rationale for use of MPC modulators like MSDC-0602 K to treat NASH.

Liver cancer – Systemic treatment and immunotherapy

Email: hirage@m.ehime-u.ac.jp

Background and aims: Although sorafenib (SOR) and regorafenib (REG) have been shown to contribute to improve survival of patients with unresectable hepatocellular carcinoma (u-HCC), effective therapeutic options for those patients, who show SOR intolerability or REG failure, have yet to be established. Recently, lenvatinib (LEN) was developed as a first-line tyrosine-kinase inhibitor (TKI) for treatment of u-HCC and made commercially available. Here, we examined the clinical efficacy of LEN in real-world practice.

Method: From March to August 2018, 109 u-HCC patients were treated with LEN at our hospitals. Following exclusion of those with a reduced dose at the start or with short the observation period (<2 weeks), 77 of 109 patients including those with an REG history (n = 11) were enrolled (72.0 ± 8.9 years old; 59 males, 18 females; HCV: HBV:alcohol:others = 38:14:12:13; dosage 8/12 mg = 49/28, TNM stage II/III/IVa/IVb = 8/28/4/37) and divided into 2 groups, TKI naïve (n = 33) and TKI experienced (n = 44). Therapeutic response was evaluated after 1, 2, and 3 months (M) using enhanced CT or MRI findings in accordance with modified RECIST guidelines, and the clinical therapeutic efficacy of LEN was retrospectively evaluated.
Results: The average observation period was 79.3 ± 40.7 days. The first evaluation of LEN therapeutic effect at 1 month was performed for 52 patients, which showed complete response (CR) in none, partial response (PR) in 20, stable disease (SD) in 22, and progressive disease (PD) in 10, for an overall response rate (ORR) of 38.5% and disease control rate (DCR) of 80.8%. Image findings of 37 patients at 3 months showed CR in 1, PR in 11, SD in 14, and PD in 11 (ORR 32.4%, DCR 70.3%). The 1- and 3-month progression free survival rates (PFSRs) were 90.1% and 80.1%, respectively, while 1- and 3-month overall survival rates (OSRs) were 98.6% and 93.4%, respectively. Hand-foot skin reaction was the most frequent adverse event in the present cohort [all grades, n = 31 (40.3%); grade 3, n = 7 (9.1%)], followed by general fatigue [grade 1/2, n = 26 (33.8%)], appetite loss [all grades, n = 22 (28.6%); grade 3, n = 5 (6.5%)], hoarseness [all grades, n = 17 (22.1%); grade 3, none], and hypothyroidism [all grades, n = 15 (19.5%); grade 3, none]. Although age was younger and TNM stage worse in the TKI experienced group (70.0 ± 5.9 vs. 75.6 ± 11.2 years, P = 0.040; II/III/IVa/IVb = 0/16/3/25 vs. 8/12/1/12, P = 0.006), there were no significant differences for Child-Pugh score (5/6/7/8 = 23/14/6/1 vs. 19/11/3/0, P = 0.512), PFSR (1-/3-month PFSR: 90.5%/80.1% vs. 89.7%/80.4%, P = 0.499), or OSR (1-/3-month OSR: 96.7%/96.7% vs. 100%/92.3%, P = 0.769).
Conclusion: Our results showed that early therapeutic response to LEN was favorable. LEN might be an important option for not only first-line but also second-/third-line therapy, thus helping to meet the present unmet need in regard to TKI treatment for u-HCC.

Background and aims: Nivolumab was granted accelerated approval by FDA for hepatocellular carcinoma (HCC) based on the results of the Checkmate 040 trial. We aim to describe the clinical/safety profile and outcomes of patients with HCC treated with nivolumab outside clinical trials (compassionate use).
Method: This is a retrospective, observational, multicentric study involving 10 healthcare centers with multidisciplinary teams led by hepatologists. Clinical and laboratorial data, previous treatments, adverse events (AE) and overall survival (OS) were recorded.
Results: 110 patients received nivolumab, of whom 74 in clinical trials and 36 outside clinical trials. Nivolumab was the first (1L), second (2L) and third-line (3L) treatment in 4 (11.1%), 18 (50%) and 14 (38.9%) patients, respectively. Sorafenib was the 1L in 100% of the patients who received nivolumab as 2L/3L and regorafenib was the 2L in 86% of the patients who received nivolumab as 3L. Regarding the 18 patients treated with nivolumab as 2L (61.1% Child-Pugh A; 38.9% Child-Pugh B and 100% PS0-1), 5 discontinued the 1L due to AE without radiologic progression and the remaining presented BCLCp-B (16.7%), BCLCp-C1 (27.8%) and BCLCp-C2 (27.8%). In the nivolumab-2L cohort, median follow-up and OS since the start of 1L was 12.5 months (IQR 7.7-28.9) and 28.5 months (95%CI 15.5-43.0) respectively. All, except 1 of 14 patients treated with nivolumab in the 3L (85.7% Child-Pugh A, 71.4% PS0 and 28.6% PS1) received nivolumab due to radiologic progression (BCLCp-B, C1 y C2: 7.1; 28.6 y 57.1%). In the nivolumab-3L cohort, median follow-up since 1L start was 21.3 months (IQR 15, 6-24, 4) and OS was not calculated owing to insufficient follow-up and number of events. Fifteen (46.8%) patients presented 25 AEs, of which 5 (20%) AEs were grade III-IV and 1 was grade V (rejection after liver transplantation). Corticosteroids were required for the management of AEs in 5 (15.6%) patients. There were 2 definitive discontinuations due to AEs (1 rejection after liver transplantation and 1 ascites).
Conclusion: The safety profile in this cohort is similar to that reported in clinical trials, despite the inclusion of patients in 2L and 3L. The heterogeneity in the patterns of progression before nivolumab and the fact that some patients started nivolumab due to intolerance to sorafenib/regorafenib without presenting radiologic progression highlights the need to consider these confounding factors when evaluating OS data.

PS-138

PD-1 targeted immunotherapy in advanced hepatocellular carcinoma: Efficacy and safety data from an international multicenter real-world cohort

Bernhard Scheiner[1], Martha Kirstein[2], Florian Hucke[3], Fabian Finkelmeier[4], Kornelius Schulze[5], Johann von Felden[5], Sandra Koch[6], Philipp Schwabl[1], Jan Hinrichs[7], Oliver Waidmann[4], Thomas REIBERGER[1], Christian Müller[1], Wolfgang Sieghart[1], Michael Trauner[1], Arndt Weinmann[6], Henning Wege[5], Jörg Trojan[4], Markus Peck[3], Arndt Vogel[2], Matthias Pinter[1]. *[1]Medical University of Vienna, Department of Gastroenterology and Hepatology, Vienna, Austria; [2]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [3]Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology including Centralized Emergency Department (ZAE), Klagenfurt, Austria; [4]University Hospital Frankfurt, Department of Gastroenterology, Hepatology and Endocrinology, Frankfurt/Main, Germany; [5]University Medical Center Hamburg-Eppendorf, Department of Internal Medicine, Gastroenterology and Hepatology, Hamburg, Germany; [6]University Medical Center of the Johannes Gutenberg University Mainz, Department of Internal Medicine, Mainz, Germany; [7]Hannover Medical School, Institute for Radiology, Hannover, Germany*
Email: matthias.pinter@meduniwien.ac.at

Background and aims: Programmed cell death protein-1 (PD-1)-targeted immunotherapy has shown promising results in phase II studies of hepatocellular carcinoma (HCC). We report safety and efficacy data of an international, multicenter, real-world cohort of patients with advanced HCC treated with nivolumab or pembrolizumab.

Method: Sixty-five patients treated with nivolumab (n = 34) or pembrolizumab (n = 31) between July 10, 2015 and May 31, 2018 (data cut-off) across 6 centers in Austria and Germany were retrospectively analyzed.
Results: Child-Pugh class A/B/C was 32 (49%)/28 (43%)/5 (8%). Immunotherapy was used as systemic first-, second-, third-, or fourth-line treatment in 9 (14%), 27 (42%), 26 (40%), and 3 (5%) patients, respectively. Forty-six patients had at least one follow-up imaging and were therefore available for radiological response assessment. The overall response and disease control rates were 13% and 59%, respectively. Of 44 evaluable patients, four (9%) had hyperprogressive disease. Twenty-six (40%) patients had radiological disease progression and 21 (32%) participants died during follow-up. Median time to progression was 4.8 (95%CI, 1.7–7.9) months, median progression-free survival was 4.6 (95%CI, 1.9–7.4) months, and median overall survival was 11.0 (95%CI, 5.3–16.6) months. Most common adverse events were infections (n = 5), rash (n = 5), pruritus (n = 3), fatigue (n = 3), and hepatitis (n = 3). Efficacy and safety results were comparable between Child-Pugh A and B patients as well as between patients who received immunotherapy as first-/second-line and third-/fourth-line, respectively.
Conclusion: PD-1 targeted immunotherapy with nivolumab or pembrolizumab was safe in patient with advanced HCC, including subjects with Child-Pugh stage B and patients with intensive pretreatment. Efficacy was comparable to that reported in phase II studies.

PS-139
Liver enzyme elevations and hepatotoxicity in patients treated with checkpoint inhibitor immunotherapy
Morven Cunningham[1], Marco Iafolla[2], Yada Kanjanapan[2], Orlando Cerocchi[1], Marcus Butler[2], Lillian Siu[2], Philippe Bedard[2], Kendra Ross[2], Anna Spreafico[2], Jordan Feld[1]. *[1]Toronto Centre for Liver Disease, Toronto, Canada; [2]Princess Margaret Cancer Centre, Toronto, Canada*
Email: morven_c@hotmail.com

Background and aims: Checkpoint inhibitors (CPi) are now standard of care in a variety of cancers. Various degrees of hepatic immune-related adverse events (LirAE) frequently occur, but diagnosis, clinical course and optimal management are poorly characterized. We sought to better understand causes of liver enzyme elevations (LEE) in patients treated with CPi, frequency of LirAE and impact on patient management.
Method: Patients enrolled in Phase I/II clinical trials within the Tumour Immunotherapy Program at Princess Margaret Cancer Centre from Aug 2012-Oct 2016 were included. Patients with a clinically significant LEE (ALT/AST > 3xULN and/or bilirubin > 1.5xULN) were identified and clinical records reviewed for cause, investigation, management and clinical outcomes.
Results: Of 338 patients treated with CPi, most (57.4%) received anti-PD-1 therapy whilst 17.4% received combination CPi. 74 (21.8%) had clinically significant LEE. Diagnostic evaluation included liver imaging in 52 (70.3%), HBV/HCV serologies in 13 (17.6%), autoimmune serologies in 6 (8.1%) and liver biopsy in 2 patients (2.7%). LEE was attributed to disease progression in 37 (50%), other drugs/toxins in 9 (12.2%), surgery in 5 (6.8%), other causes in 11 (14.9%) and to LirAE in 13 patients (18% of LEE and 3.8% of total cohort). LirAE was associated with prior CPi exposure (11.3% of patients with vs 2.4% of patients without prior CPi, p = 0.007) and other irAEs (occurring in 61.5% of patients with LirAE vs 19.8% of patients without, p = 0.002), but not with age, sex, primary malignancy, liver metastases or class or duration of CPi. Most patients with LirAE (12/13) received steroids with normalization of liver enzymes after a median of 37 days (range 7–102). 3 patients received further CPi with recurrent LirAE in 1 patient. During follow-up (median 8.2 months, range 0.6–51.8), 258 patients had disease progression and 100 patients died. Incidence of disease progression was lower in patients with LirAE (69.2% of patients with LirAE vs 92.9% of patients without, p = 0.015). No patient died of complications from LirAE.
Conclusion: LEE are common in patients receiving CPi and may be unrelated to cancer/CPi, requiring a full diagnostic evaluation. LirAE were more common in patients with previous CPi exposure and who had other irAEs. Those with LirAE had lower incidence of disease progression, possibly indicating more profound response to immunotherapy. Further work is required to identify risks for LirAE and optimize management.

PS-140
Association of gut microbiome with clinical response to nivolumab in advanced hepatocellular carcinoma: A pilot study
Pei-Chang Lee[1], ChiehJu Lee[1], Hsiu J Ho[2], Ming-Chih Hou[1], Yi-Hsiang Huang[1]. *[1]Gastroenterology and Hepatology, Medicine, Taipei, Taiwan; [2]Translational Research, Medical Research, Taipei, Taiwan*
Email: tympanum3688@gmail.com

Background and aims: Nivolumab (anti-programmed cell death-1, PD-1) is the first FDA-approved immune checkpoint inhibitor for advanced hepatocellular carcinoma (HCC). However, only ~20% of patients had an objective response to nivolumab; and the expression of PD-L1 could not predict the response. Gut microbiome was reported to modulate tumor response to checkpoint blockade immunotherapy in patients with melanoma. Whether the gut microbiome is also associated with clinical response to nivolumab in advanced HCC is unclear.
Method: From May 2017, 37 patients had received nivolumab treatment for advanced HCC in Taipei Veterans General Hospital. Among them, 20 patients were enrolled in this prospective study; and 12 of them completed fecal examination for gut microbiome analysis as well as already had radiographic assessment according to the RECIST criteria.
Results: The disease control rate was 50%, including three partial responses (25%) and three stable diseases (25%). The time to response was around 2 months (median interval 61 days, interquartile [IQR] 56–62). The median time to progression was 6.6 months (95% C.I. 0–15.5). Significant different composition of gut microbiome was observed between responders (R, n = 6) and non-responders (NR, n = 6). The responders had a relatively higher diversity in the fecal microbiome; and a significant clustering effect of the gut microbiome on response status was also observed in principal coordinate analysis according to either unweighted unifrac distance (p = 0.036) or Bray-Crutis distances (p = 0.019). Furthermore, the high dimensional class comparisons via linear discriminant analysis (LDA) of effect size also demonstrated differently abundant fecal bacteria between responders and non-responders to nivolumab therapy, with Aeromonadaceae enriched in NR and Burkholderiales enriched in R.
Conclusion: Gut microbiome has significant association with clinical response to nivolumab treatment in patients with advanced HCC. These findings highlight the therapeutic potential of modulating gut microbiome before immunotherapy.

PS-141
CyTOF-based immune monitoring of HBV-HCC patients receiving autologous anti-tumour T-cell therapy
Anthony Tan[1], Nina Le Bert[1], Thinesh Krishnamoorthy[2], Alicia Chua[3], Xinyuan Zhao[3], Huisi Tan[3], Adeline Chia[1], Hiang Keat Tan[2], Rajneesh Kumar[2], Farah Irani[2], Zi Zong Ho[3], Lu-en Wai[3], Sarene Koh[3], Evan Newell[4], William Hwang[2], Wan Cheng Chow[2], Antonio Bertoletti[1,4]. *[1]DUKE-NUS Medical school, Singapore, Singapore; [2]Singapore General Hospital, Singapore, Singapore; [3]Lion TCR Pte. Ltd., Singapore, Singapore; [4]Singapore Immunology Network, A*STAR, Singapore, Singapore*
Email: anthony.tan@duke-nus.edu.sg

Background and aims: Short HBV-DNA fragments are frequently integrated in HBV-related hepatocellularcarcinoma (HBV-HCC).

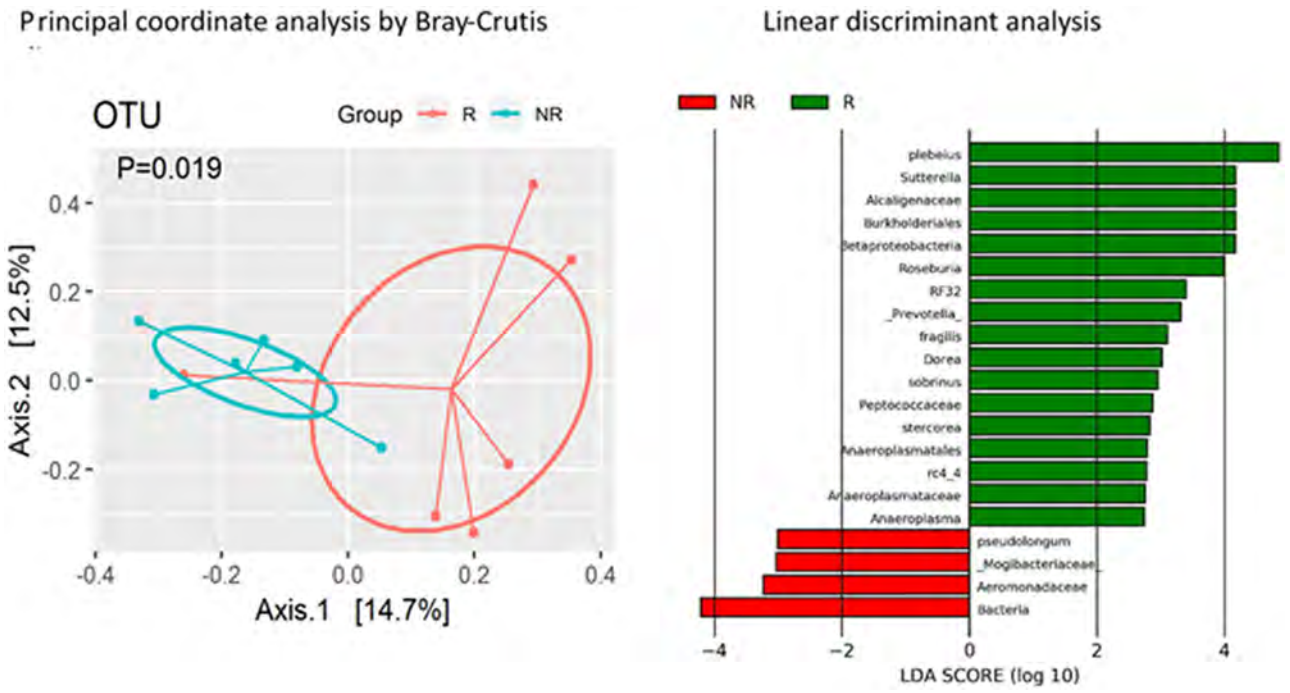

Figure: (abstract: PS-140)

These integrated HBV-DNA fragments can generate targetable CD8 T-cell viral epitopes allowing for the use of HBV-specific T-cells to eradicate HBV-HCC. Previously, we demonstrated how the analysis of HBV integrations in HBV-HCC tissues could be used to guide patient and HBV-specific TCR selection for use in HBV-HCC T-cell immunotherapy. Here, we focus on the immunological changes observed in patients during the course of the T-cell immunotherapy.

Method: HBV-HCC patients with metastases post liver transplantation were selected for T-cell immunotherapy. The metastases were analyzed for HBV integrations and the patients were treated with autologous mRNA electroporated T cells expressing HBV-specific TCRs. PBMCs from the patients were collected before and throughout the course of therapy consisting of multiple infusions of the transiently HBV-specific T-cells. Immune profiling of the PBMCs was performed by multi-parametric mass cytometry using 42 different markers.

Results: Despite the co-administration of immunosuppressive drugs due to the liver transplant, we detected a transient increase in the frequency of proliferating CD39+ CD8 T-cells within the first 5 days post T-cell infusion, which reached ~10% of total CD8 T-cells. This T-cell population was of effector memory phenotype (CD45AR-, CCR7-), co-expressing the activation markers Ki67, CD71, CD38 and HLA-DR, as well as the cytotoxic protease Granzyme A.

Conclusion: HBV-specific T-cell immunotherapy was able to induce detectable immunological changes in the peripheral blood of liver transplanted HBV-HCC patients under stable immunosuppression. Whether this is indicative of *in vivo* activation and proliferation of the infused HBV-specific T-cells, or a *de novo* induction of novel anti-tumour response warrants further monitoring and investigation.

PS-142

Analysis of sorafenib-regorafenib sequential therapy in patients with advanced hepatocellular carcinoma using baseline date of sorafenib

Sae Yumita[1], Sadahisa Ogasawara[1], Yoshihiko Ooka[1], Kazufumi Kobayashi[1], Susumu Maruta[1], Hiroaki Kanzaki[1], Kengo Kanayama[1], Takahiro Maeda[1], Yuko Kusakabe[1], Soichiro Kiyono[1], Masato Nakamura[1], Tomoko Saito[1], Eiichiro Suzuki[1], Shingo Nakamoto[1], Shin Yasui[1], Akinobu Tawada[1], Tetsuhiro Chiba[1], Makoto Arai[1], Tatsuo Kanda[1], Hitoshi Maruyama[1], Naoya Kato[1]. [1]*Chiba University, Graduate School of Medicine, Department of Gastroenterology, Chiba, Japan*
Email: sadahisa@me.com

Background and aims: Regorafenib is the second line drug after sorafenib in patients with advanced hepatocellular carcinoma (HCC), and has demonstrated a survival benefit compared to placebo in a Phase III trial (RESORCE trial). The RESORCE trial reported that median overall survival (OS) from the date of starting sorafenib for patients with the regorafenib arm to be over 26 months. However, the baseline clinical data at the time of starting sorafenib was not collected in the RESORCE trial. Therefore, the clinical benefit of sorafenib-regorafenib sequential therapy should be confirmed using data collected in field practice. This study aims to analyze the impact of sorafenib-regorafenib sequential therapy from the starting date of sorafenib in patients with advanced HCC.

Method: We retrospectively identified patients with advanced HCC who received sorafenib as the first line systemic therapy from June 2009 through December 2017. We excluded Child-Pugh B patients from this analysis.

Results: A total of 323 patients with Child-Pugh A liver function received sorafenib. Median age was 72 years, and the most frequent etiology was hepatitis C virus (n = 165, 50.3%), followed by hepatitis B virus (n = 45, 13.7%), and alcohol abuse (n = 43, 13.1%). A total of 94 (28.7%) patients had macrovascular invasion (MVI), and 142 (43.3%) had extrahepatic metastasis (EHM). The Majority of patients (89%) started a full dose of sorafenib (800 mg). The median OS for all patients was 13.7 months (95%CI, 11.8–14.2). During the observation

period, 29 patients were switched to regorafenib from sorafenib. The median OS in patients with sorafenib-regorafenib sequential therapy was 25.3 months (95%CI, 17.8–32.8) and which was higher than in patients who were treated with sorafenib therapy alone, i.e. they were unable to convert to regorafenib (median OS, 12.3 months; 95%CI, 10.4–14.2; P = 0.001). Not receiving regorafenib was an independent poor prognostic factor in the multivariate analysis with a cox hazard model, as well as for ECOG performance status, MVI, EHM, Child-Pugh score, and α-fetoprotein value.

Conclusion: Our results demonstrated the benefit of sorafenib-regorafenib sequential therapy in patients with advanced HCC using clinical data at the time of starting sorafenib. We recommend that it is necessary to increase the rate of conversion from sorafenib to regorafenib in patients with advanced HCC, although limited population of patients have switched sorafenib to regorafenib in the filed practice.

Email: esola@clinic.cat

Background and aims: Cirrhosis progression is associated with immune dysfunction. However, assessment of immune response in cirrhosis using high-resolution profiling has not yet been performed. The aim of the study was to use state-of-the art techniques for multiparametric characterization and unbiased analysis of immune phenotypes and functions across the entire spectrum of cirrhosis stages.

Method: single-cell mass cytometry profiling with 40 labels was performed on peripheral blood mononuclear cells from 30 patients with cirrhosis at different disease stages: compensated cirrhosis and decompensated cirrhosis (AD), with and without acute-on-chronic liver failure (ACLF). Unsupervised hierarchical clustering and regression analysis were performed to identify cell identities significantly different among disease stages. To further characterize the T cell compartment, single-cell T cell receptor (TCR) sequencing of activated CD8+ T cells was performed.

Results: mass cytometry data revealed that the only clusters of cells significantly different between patients with AD and those with compensated cirrhosis, regardless of the presence of ACLF, were clusters constricted to CD4+ and CD8+ T cells with activated phenotypes (CD69+ or CD38+HLA-DR+), that were significantly increased in AD. Patients with AD also showed significantly higher expression of PD1+ TIM3+ LAG3+ on CD8+ T cells and expansion of the CD4+CD25+CD127low Treg population, suggesting progression towards T cell exhaustion. Nonetheless, cytotoxic T cell activity (measured by in vitro IFNγ and IL-2 production) is preserved and significantly higher in AD compared to compensated patients. Analysis focused on patients with AD found that the only significant difference between patients with and without ACLF, was that those with ACLF had a markedly expanded monocyte population with significantly lower expression of HLA-DR and increase in PD-L1, compatible with a suppressor phenotype. TCR sequencing analysis showed that activated CD8+ T cells from patients with cirrhosis, independently of the disease stage, were markedly clonally expanded compared to healthy controls (48% vs 11% in cirrhosis vs controls; $p < 0.05$). We then analysed whether TCR sequences with common specificities were shared among different patients by clustering analysis. Among TCR sequences, we identified 13 clusters containing TCRs from multiple patients and from different disease stages, suggesting that T cell activation in cirrhosis may be driven by antigen recognition. Survival analysis showed that increase in activated CD8+ T cells and in CD8+TIM3+ T cells were associated with increased mortality.

Conclusion: high-dimensional profiling of immune responses in cirrhosis unveils a relevant role for CD8+ T cell activation in disease progression, that is associated with impaired outcomes.

PS-144

Autotaxin mediates lipid dysregulation in acute-on-chronic liver failure, promoting persistence of systemic inflammation via lysophosphatidic acid-mediated monocyte activation

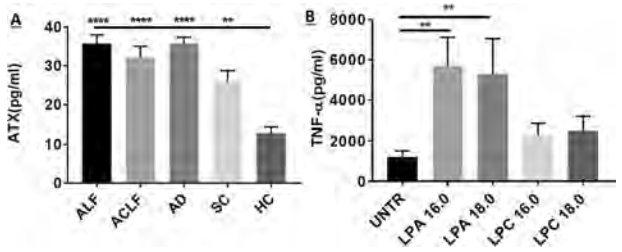
Mark J W McPhail[1,2], Francesca Trovato[1], Evangelos Triantafyllou[3], Rabiya Zia[3], Kate Wolfer[3,4], Xiaohong Huang[1], Liane Rabinowich[2], Vishal C Patel[4], Elaine Holmes[3], Nigel Heaton[2], Michael Heneghan[2], William Bernal[2], Georg Auzinger[2], Muireann Coen[3], Julia Wendon[2], Harry Antoniades[2,3]. *[1]King's College London, Inflammation Biology, London, United Kingdom; [2]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [3]Imperial College London, Integrative Systems Medicine and Digestive Diseases, London, United Kingdom; [4]Foundation for Liver Research, London, United Kingdom*
Email: mark.mcphail@kcl.ac.uk

Background and aims: Acute-on-chronic liver failure (ACLF) is characterised by systemic inflammation and increased susceptibility to infection. Phenotypic and functional impairment in peripheral monocytes, with increased expression of regulatory Mer-tyrosine kinase (MERTK), has previously been demonstrated in ACLF. Lysophosphatidylcholines (LPCs) are immune-active lipids down-regulated in ACLF. The metabolic regulation of LPC and its role in monocyte function in ACLF is unknown.

Method: Patients with stable cirrhosis (SC, n = 18), acute decompensation (AD, n = 50) and ACLF (n = 60)) had admission and sequential plasma samples characterised by lipidomics (using ultra-performance liquid chromatography-mass spectrometry), cytokine and autotaxin (ATX) levels (by ELISA). Peripheral blood mononuclear cells (PBMCs) and isolated CD14+ monocytes were cultured in the presence of LPC or its ATX-derived product lysophosphatidic acid (LPA) with or without LPS stimulation. Monocytes were assessed for surface marker phenotype, cytokine production and phagocytic (E. coli pHrodo) capacity. Healthy volunteers (n = 40) and acute liver failure (ALF) patients (n = 30) served as controls.

Results: Patients with ACLF demonstrated significantly higher levels of TNF-alpha and IL-6 ($p < 0.001$) compared to SC, AD or HC, although TNF-alpha responses in ACLF were lower than ALF. ACLF plasma was depleted in multiple LPCs ($p < 0.001$) with up-regulated LPA levels ($p < 0.001$ cf controls). Patients who died or had sepsis had lower LPC levels than survivors (AUROC 0.94, $p < 0.001$). ATX was confirmed as the primary source of LPC-LPA conversion, with higher concentrations in patients with AD, ACLF and ALF (Fig A, $p < 0.001$), correlating with MELD and CLIF-SOFA scores (rho = 0.59, 0.65, $p < 0.01$ for both), and LPC and LPA concentrations. ATX levels rose dynamically over the first 48 hours of ACLF evolution ($p < 0.01$). ACLF patients had lower baseline HLA-DR, and higher CD163 and MERTK regulatory marker expression in CD14+ monocytes than controls; however, both CD163 and MERTK expression was markedly reduced in ACLF patients following 24-hour incubation with LPA ($p < 0.001$) but not LPC. LPA also induced significant up-regulation of

TNF-alpha production by CD14+ cells without improving phagocytic capacity (Fig B).



Conclusion: We show for the first time that phospholipid dysregulation in ACLF is dynamically mediated by ATX. Downstream LPA production inhibits resolution phenotypes in peripheral monocytes perpetuating inflammatory activation but not bacterial clearance. The therapeutic potential of the ATX-LPA axis requires further exploration.

PS-145

Albumin protects the liver from tumour necrosis factor alpha-induced cell death

Marta Duran-Güell[1], Mireia Casulleras[1], Roger Flores-Costa[1], Cristina López-Vicario[1], Esther Titos[1,2], José Alcaraz-Quiles[1], Raquel Horrillo[3], Montserrat Costa[3], Vicente Arroyo[4], Joan Clària[1,2,4].
[1]Hospital Clínic-IDIBAPS, Biochemistry and Molecular Genetics Service, Barcelona, Spain; [2]Department of Biomedical Sciences, Barcelona, Barcelona, Spain; [3]Grifols Bioscience Research Group, Barcelona, Spain; [4]European Foundation for the Study of Chronic Liver Failure (EF-Clif), Barcelona, Spain
Email: jclaria@clinic.cat

Background and aims: Albumin infusions reduce systemic inflammation and prevent organ failure (s) in patients with advanced chronic liver disease by mechanisms not completely defined. In the current study we performed *in vivo*, *ex vivo* and *in vitro* experiments to uncover the potential mechanisms implicated in the tissue protective actions of albumin.
Method: Double transgenic humanized neonatal Fc receptor (FcRn)/albumin mice were induced to stable cirrhosis by administration of carbon tetrachloride for 6 weeks and acute liver injury was provoked by injection of lipopolysaccharides (LPS) and D-galactosamine after receiving either placebo or two albumin dosages (1.5 g/kg). Hepatic F4/80 and caspase-3 immunostaining were assessed by immunohistochemistry and the population of peripheral blood Ly6C+Cd11b+ monocytes were measured by flow cytometry. *Ex vivo* and *in vitro* experiments were performed in precision-cut liver slices (PCLS) and hepatocytes, respectively, challenged with TNF-alpha in the presence or absence of albumin (15 mg/ml). Caspase-3 activity and cytosolic cathepsin B levels were measured by luminescence and fluorometric assays, respectively. The release of cytochrome C from the mitochondria to the cytosol was visualized by confocal microscopy and validated by Western blot. Gene expression was determined by real-time PCR.
Results: Transgenic humanized FcRn/albumin cirrhotic mice receiving albumin showed reduced levels of hepatic F4/80 and caspase-3 immunostaining. In addition, these mice showed an augmented number of patrolling and tissue repair $Ly6C^{Lo}$ monocytes and a reduced $Ly6C^{Hi}$ inflammatory subpopulation. In PCLS from wild-type mice, both preventive and therapeutic albumin administrations, significantly reduced TNF-alpha-induced caspase-3 activity and up-regulated the expression of tissue repair genes. Reduction of caspase-3 activity in hepatocytes incubated with albumin was associated with reduced release of the cysteine protease cathepsin B from lysosomes and a lower expression of the apoptotic transcription factor CHOP. Confocal microscopy experiments confirmed that albumin reduces the leaking of cytochrome C from mitochondria in hepatocytes.

Conclusion: Taken together, these findings uncover novel mechanisms by which albumin could protect organs from tissue damage, contributing to the understanding of why albumin infusions are useful in patients with advanced liver disease at risk of developing organ failures.

PS-146

Intestinal mucus and vascular barrier: FxR-modulated entry sites for pathological bacterial translocation in liver cirrhosis independent from portal hypertension and lymphatic route

Reiner Wiest[1], Marcel Sorribas[2], Bathi Yilmaz[2], David Stutz[1], Yannick Noser[1], Andrea De Gottardi[3], Sheida Moghadamrad[2], Mohsin Hassan[2], Agustin Albillos[4], Maria Rescigno[5].
[1]Gastroenterology, UVCM, Inselspital, Bern, Switzerland; [2]Department Biomedical Research, Bern, Switzerland; [3]Hepatology, UVCM, Inselspital, Bern, Switzerland; [4]Servicio de Gastroenterología y Hepatología, Hospital Universitario Ramón y Cajal, Madrid, Spain; [5]Department of Biosciences, Università degli Studi di Milano, Milano, Italy
Email: reiner.wiest@insel.ch

Background and aims: Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality. Factors known to contribute to PBT in LC are among others an increased intestinal permeability of which however, the mucus layer has not been addressed. A clear route of translocation for luminal intestinal bacteria is yet to be defined but we hypothesize that the recently described gut vascular barrier (GVB)[1] is impaired in cirrhosis leading to increased accessibility of the gut-liver-axis for bacteria.
Method: We applied partial portal vein ligation (PVL) or liver cirrhosis induced by carbon tetrachloride (CCl4) inhalation or bile duct ligation (BDL). Probe-based confocal endomicroscopy (pCLE) was utilized to evaluate the GVB by assessing extravasation of pre-defined sized FITC-dextrans. By dualband pCLE bacteria were visualized while crossing the muco-epithelial and vascular endothelial barrier.

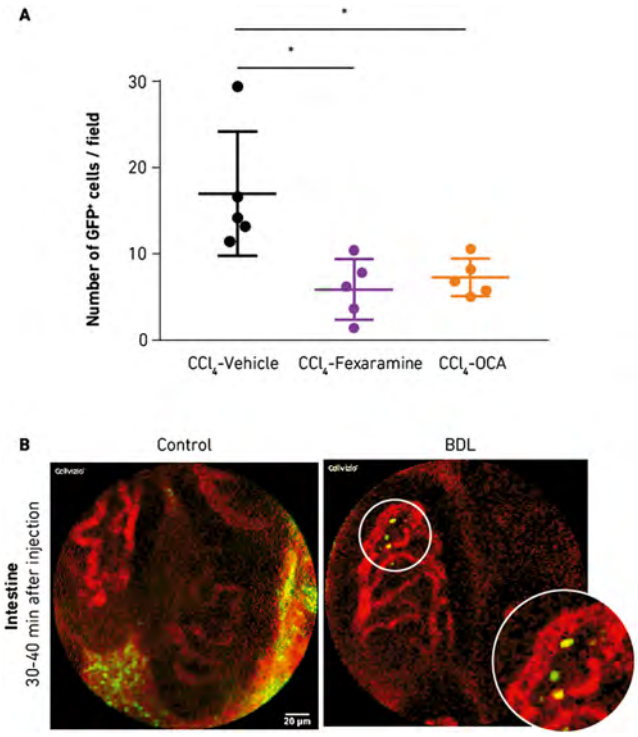


Figure: PBT from gut to liver of GFP-E.coli in CCl4-cirrhotic mice is reduced upon FXR agonists treatment (Fexaramine or obeticholic acid (OCA)) (A). GFP-E-coli crossed the muco-epithelial barrier and accessed the portal venous circulation in BDL but not in control mice.

Results: Healthy and pre-hepatic portal-hypertensive (PVL) mice lack translocation of FITC-dextran and GFP-E.coli from the small intestine to the liver whereas bile-duct-ligated (BDL) and CCl4-induced cirrhotic mice demonstrate PBT which is not altered by prior thoracic-duct ligation. Mucus layer is reduced in thickness with loss of goblet cells (GC) and *Muc2*-expression in cirrhotic but not PPVL-mice associating with a pathological translocation of GFP-E.coli through the ileal epithelium (Fig. 1B). GVB is profoundly altered in BDL and CCl4-mice with Ileal extravasation of large-sized 150 kDa-FITC-dextran but only minor in PPVL-animals. This pathological endothelial permeability and accessibility in cirrhotic mice associated with an augmented expression of PV1 in intestinal vessels. Pharmacological FXR-activation restores the normal GC density in CCl4-induced liver cirrhosis and improves GVB permeability ameliorating gut-liver-translocation of GFP-E.coli (Fig. 1A).
Conclusion: Liver cirrhosis but not portal hypertension per se grossly impairs the endothelial and muco-epithelial barrier promoting PBT to the portal-venous circulation. Both barriers appeared FXR-modulated with -agonists reducing PBT via the portal-venous route.

PS-147
Simvastatin-loaded nanoparticles are more effective and less toxic than conventional statins in a pre-clinical model of advanced chronic liver disease
Diana Hide[1], Mar Gil[1], Diana Fernandes de So Rafael[2], Fernanda da Silva Andrade[2], Salvador Augustin[1], Simo Schwartz[2], Joan Genesca[1], Maria Martell[1]. Background and aims: polymeric micelles (PM) are biodegradable, biocompatible and FDA-approved drug delivery systems (DDS), which are mainly directed to the liver and, due to its properties, can potentially load any type of molecule. Statins have demonstrated high potential to be considered a future treatment for chronic liver disease (CLD) but its side effects in patients with severely deteriorated hepatic function limit the administered dose and, thus, its effect. We aim at developing a drug delivery system based on PM to better target the liver sinusoidal endothelial cells (LSEC) and encapsulate simvastatin (PM-simva) in order to avoid muscular and hepatic toxicity and then improve the effectivity and safety of the drug.
Method: rats underwent bile duct ligation (BDL) and, 3 weeks after, cell isolation or in vivo treatment were performed. In cultured cells internalization was studied by flow cytometry after incubation with DTAF-labelled PM; to test its effect cells were treated for 16 h with empty PM, free simvastatin or PM-simv and gene expression was evaluated. In vivo, PM were i.v. administered once a day during one week and compared with vehicle or oral simvastatin treatments in haemodynamic studies.
Results: *In vitro*, LSEC derived from cirrhotic rats internalize PM-simva in similar way than healthy cells; after 10 min 50% of cells internalize PM and increased to 80% after 4 h. PM-simva have an effect increasing simvastatin target gene KLF2 in LSEC, Kupffer cells and hepatocytes. In LSEC this is associated with increased eNOS and reduced endothelin-1 expression. In KC and hepatocytes, KLF2 increased expression is associated with an increase in markers of cell phenotype maintenance.
In vivo, PM-simva biodistribution in BDL rats is mainly hepatic, 40% accumulate in the liver within 30minuts and importantly, have little muscular accumulation (2.4%). When administered for one week, hepatic toxicity is 70% in oral simvastatin vs. 0% in PM-simva and they reduce portal pressure (PP) from 16.8 in vehicle rats to 14.9 mmHg in PM-simva group ($p = 0.057$). PP in oral simvastatin treatment is 15.7 mmHg.
Conclusion: PM-simva show its effectiveness in improving liver cell phenotype in BDL-derived cells. Furthermore they cause less hepatic toxicity in this model and have greater effect in reducing portal hypertension being suitable DDS for treatments in CLD.

PS-148
Liver sinusoidal endothelial cells significantly cooperate in the phagocytic immune activities and activation of the adaptive T cell response in a model of experimental cirrhosis by CCl4
Esther Caparrós[1], Oriol Juanola[1], Paula Piñero[2], Isabel Gómez-Hurtado[3], Raquel Linares[1], Paula Boix[2], Rebeca García-Román[1], Jordi Gracia-Sancho[4], Rubén Francés[1,2,3]. [1]*Grupo de Inmunobiología hepática e intestinal, Dpto. Email: ecaparros@umh.es

Background and aims: Cells of the hepatic immune system play a fundamental role both in the detection and direct elimination of antigens, and in the activation of the adaptive response necessary for the maintenance of tissue homeostasis. Liver sinusoidal endothelial cells (LSECs) show functional capacity of antigenic presentation and activation of the adaptive T response. The objective was to determine the contribution of LSECs in hepatic immune function during experimental cirrhosis.
Method: Untreated Sprague-Dawley rats (Control group) and treated with intragastric CCl_4 for 12 weeks (CCl_4 group) were included. Perfused livers were collected, and Kupffer cells (KCs) and dendritic cells (DCs) were purified by beads. LSECs were isolated by differential centrifugation and adhesion on collagen pretreated plates. The phagocytic capacity was measured by internalization of LPS-FITC and posterior absorbance measurement (450 nm). For the evaluation of T lymphocytes activation, APCs were preactivated with bacterial LPS, and then co-incubated for 48 h with autologous CD4+ T lymphocytes isolated from spleen. The phenotypic expression of CD25 and CD71 on CD4+ T lymphocytes was analyzed.
Results: The innate immune response in controls is directed by the activity of LSEC cells. Its phagocytic capacity increases in cirrhosis and remains significantly above the phagocytic capacity of DCs and KCs in liver damage conditions (Table 1A). The expression of CD25 and CD71 as T cell activation markers is shown in Table 1B. The ability of induction of specific T cell responses increases in liver damage by all APCs. However, LSECs show an additional activation capacity in response to an acute stimulus in the pre-inflamed cirrhotic environment.
Conclusion: LSECs participate significantly in the regulation of the immune response in experimental cirrhosis by CCl_4.

Background and aims: In liver failure as well as UCD, there is an unmet clinical need for highly targeted, effective treatments for HA. When the urea cycle is compromised, alternative mechanisms of ammonia metabolism are triggered, such as the formation of glutamine by hepatic and muscle glutamine synthase (GS). However, the physiological upregulation of this enzyme is not sufficient to prevent HA. The aim of this study was therefore to

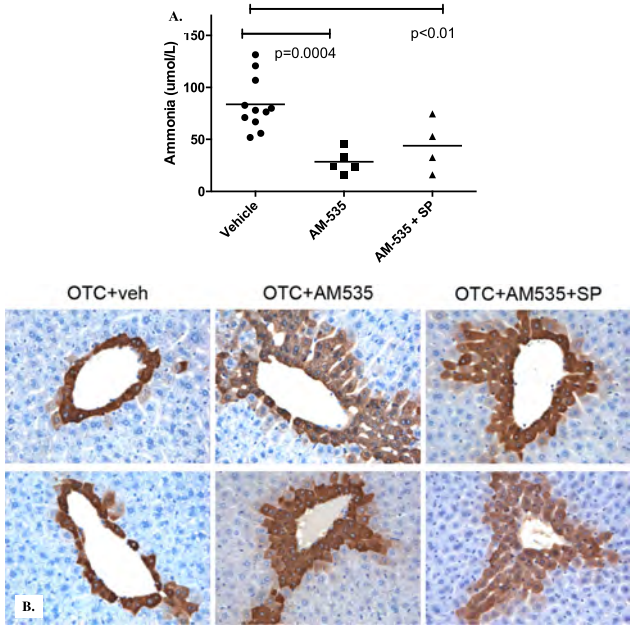
assess recombinant GS (recGS; AM535; supplied by Ammun Ltd.) as a potential novel treatment for HA.

Method: *Study 1. GS in a bile duct ligated (BDL) rat model of cirrhosis:* 3 weeks after BDL, HA was induced by high ammonia diet for 5-days. Rats were treated with vehicle (n = 12) or AM-535 (20 mg/dl, ip. n = 11) on day 1 and 3. Plasma ammonia levels, brain water content and GS activity were assessed. *Study 2. GS in hemizygous ornithine transcarbamoylase-deficient mice ($OTC^{spf\text{-}ash}$)*: Mice were treated with vehicle (n = 11), AM-535 (20 mg/kg, n = 5) or AM-535+sodium phenylbutyrate (SP), an ammonia scavenger (0.3 g/kg, n = 4) for 6 days. Plasma ammonia levels were assessed and liver immunohistochemistry for GS was performed. *Study 3. In vivo localisation of AM-535:* AM-535 was labelled with a fluorescent probe and administered to CD-1 mice, which were imaged with an in vivo fluorescent imaging system for 14 days.

Results: *Study 1.* Rats treated with AM-535 had lower plasma ammonia [144 (+15) vs. 91 (+13) umol/L, $p < 0.01$], which was associated with less severe brain edema as reflected by brain water content [82 (+1.2) vs. 79 (+1.2)%, $p < 0.01$]. In addition, AM-535 treatment resulted in higher GS-activity in both plasma and liver as compared to the vehicle group ($p < 0.001$). *Study 2.* Plasma ammonia was significantly lower in the $OTC^{spf\text{-}ash}$ mice treated with AM-535 compared with vehicle. No additional effect of SP on plasma ammonia was seen in the AM-535+SP group [$p < 0.001$, **fig A**]. The administered AM-535 was localised in the pericentral regions in the liver, corresponding with usual zonation pattern of GS (**fig B**). *Study 3.* The in vivo imaging study with fluorescent AM-535 showed that the i. p. administered AM-535 was visible in high concentrations in the liver for 3-days.



Conclusion: The results of this study suggest that AM-535 is an effective therapy for HA in both cirrhosis and UCD. Given the safety and efficacy of enzyme replacement therapies, AM-535 should be developed further for clinical use.

Evidence for the presence of infectious virus in the serum from chronic hepatitis B patients suppressed on nucleos (t)ide therapy with detectable but not quantifiable HBV DNA

Dara Burdette[1], Andrea Cathcart[1], Allyson Shauf[1], Rosanna Win[1], Shiva Zaboli[1], Charlotte Hedskog[1], Evguenia S Svarovskaia[1], Vivian Barry[1], David Inzunza[1], John F. Flaherty[1], Anuj Gaggar[1], Simon Fletcher[1], Henry Chan[2], Hongmei Mo[1], Scott Lazerwith[1], Becket Feierbach[1], Bill Delaney[1]. [1]*Gilead Sciences, Inc., Foster City, United States;* [2]*The Chinese University of Hong Kong, Shenzhen, Hong Kong*
Email: dara.burdette@gilead.com

Background and aims: We previously reported that after 240 weeks of TDF or TDF/FTC treatment the majority of chronic hepatitis B (CHB) patients had detectable but not quantifiable (DNQ) HBV DNA (LLOQ ≤ 29 IU/ml). While these data suggest that viral suppression is not absolute with the current NUC therapies, it is not known whether the DNQ serum HBV DNA represents infectious virus. To determine if DNQ HBV DNA represents virus capable of infecting new hepatocytes, we utilized the PhoenixBio (PXB) uPA/SCID chimeric mouse model to assess the infectivity of serum from patients prior to and after long-term NUC therapy.

Method: Serum from nine CHB patients from clinical trial GS-US-203-0101 evaluating TDF or TDF/FTC was evaluated in the PXB mouse model. The nine patients had HBV genotype B or C infections, were HBeAg/HBsAg positive at baseline, and achieved viral suppression (≤29 IU/ml) at a median of 72 weeks. Baseline sera (mean viral load of 1.5×10^9 copies/ml) were inoculated into PXB mice (n = 2/sample) either undiluted or diluted such that the total amount of virus per mouse was 100, 10, 5 and 1 genome equivalents. A separate group of PXB mice were subsequently inoculated five times over a two week period with sera from patients taken 12-32 weeks after NUC treatment (HBV DNA ≤ 29 IU/ml) to determine if DNQ HBV DNA was infectious. Mouse sera were analyzed biweekly for HBV DNA by quantitative PCR and HBsAg/HBeAg by ELISA.

Results: Baseline patient sera were capable of establishing infections in PXB mice, reaching maximal viremia and antigen production at 30 days post-infection (average 5.5×10^8 copies/ml HBV DNA, 4.5×10^4 IU/ml HBsAg, 3.3×10^3 COI HBeAg). Dilution studies demonstrate that 1-5 genome equivalents are sufficient to result in infection. Mice that received multiple inoculations of sera from patients on NUC therapy with DNQ HBV DNA resulted in viremia for 9/31 (29%) samples at a median of 66 days post infection. No clinical or virologic features predicted infectivity of DNQ samples.

Conclusion: Sera from patients on long-term NUC therapy are capable of infecting naïve hepatocytes in the PXB mouse model, confirming NUC therapy does not fully suppress viral replication. Low levels of circulating virus may be sufficient to infect naïve hepatocytes to maintain chronic HBV infection in the liver in CHB patients on long-term NUC therapy. Reducing viral replication further may contribute to increased HBsAg loss among long-tern NUC treated patients.

PS-151

Hepatitis E virus infection induces mitochondrial fusion to facilitate viral replication through induction of autophagy

Yijin Wang[1], Yiyun Jiang[1,2], Jingmin Zhao[1], Qiuwei Pan[2]. [1]*Beijing 302 hospital, Beijing, China;* [2]*Erasmus MC-University Medical Center, Rotterdam, Netherlands*
Email: q.pan@erasmusmc.nl

Background and aims: Mitochondrial morphological dynamics play important roles in physiology and pathogenesis. This study aimed to understand mitochondrial morphological alteration in response to hepatitis E virus (HEV) infection and its implication.

Method: Liver biopsies of 17 patients with hepatitis E and 5 controls with hepatic hemangioma were reviewed for mitochondrial morphology by Immunofluorescence. Huh-7 cells inoculated with infectious HEV viral particle or transfected with *in vitro* generated HEV RNA were used to model HEV infection. Mitochondrial dynamics were observed by transmission electron microscope (TEM) and Immunofluorescence. Lentiviral mediated RNAi or lipofectamine delivered plasmids were applied to silence targeted genes. Viral replication was quantified by qPCR.

Results: Immunofluorescent staining of liver biopsies showed that 11 out of 17 (65%) HEV infected patients presented aggregated and fused mitochondria; whereas mitochondria in all 5 uninfected controls displayed uniform and spotty distribution. Ultrastructuralanalysis of HEV-infected Huh7 cells by TEM displayed elongated mitochondria (mitochondrial fusion) with obscure cristae (Fig. 1A). In contrast, mitochondria in uninfected cells displayed short and rod-like mitochondria with clear cristae. Consistently, immunofluorescent observation of HEV infected cells substantiated tubular mitochondria, in contrast to dispersive and fragmented mitochondria in uninfected cells (Fig. 1B). Mitochondrial fusion is modulated by proteins Optic atrophy 1 (OPA1) and Mitofusion 1 (Mfn1). Consistently, western blot analysis demonstrated an increase of both OPA1 and Mfn1 and a decrease of Fis 1 and Drp1 (regulators of mitochondrial fission) in HEV infected cells, compared with uninfected cells (Fig. 2A). Importantly, silencing of OPA1 or Mfn1, with a concomitant persistent fragmentation of mitochondria, resulted in a significant suppression of HEV replication, suggesting that HEV-induced mitochondrial fusion facilitates viral infection (Fig. 1C). Mechanistically, we found HEV infection can stimulate autophagy by inhibiting mTOR (Fig. 2B-C). While interference of mitochondrial fusion potently abrogated HEV induced autophagy by rescuing mTOR (Fig. 2B). Our previous study demonstrated that pharmacological or genetic activation of mTOR can facilitate HEV replication. Taken together, these results suggested that induction of autophagy could contribute to mitochondrial fusion mediated pro-HEV activity.

Conclusion: HEV infection induces mitochondrial fusion to facilitate HEV infection by induction of autophagy through suppressing mTOR. Mitochondrial dynamics represents a viable option for prevention and treatment for hepatitis E.

PS-152

Formation of semi-enveloped particles as a unique feature of a HBV deletion mutant

Bingfu Jiang[1], Quingyan Wu[1], Lisa Kuhnhenn[2], Sami Akhras[1], Catrina Spengler[1], Klaus Boller[1], Kai-Henrik Peiffer[1,2], Eberhard Hildt[1]. [1]*Paul-Ehrlich-Institut, Virology, Langen, Germany;* [2]*J.W.Goethe University, Gastroenterology and Hepatology, Frankfurt, Germany*
Email: eberhard.hildt@pei.de

Background and aims: In addition to virions, Hepatitis B virus (HBV)-infected cells release large amounts of subviral particles (SVPs) as spheres and filaments. SVPs are exclusively formed by HBV surface proteins (HBsAg). Virions and filaments contain all three surface proteins LHBs, MHBs and SHBs, while the spheres are composed almost exclusively of SHBs. LHBs encompasses the N-terminal PreS1-domain, followed by the PreS2- and the C-terminal S-domain. A deletion mutant lacking 15 amino acids (aa 25-39) in the PreS1-domain was isolated from a chronically infected patient.

Methods: HBV genomes were transiently expressed in HepG2 and Huh7 cells. Subcellular distribution of viral proteins was studied by confocal immunofluorescence microscopy and subcellular fractionation. Viral and subviral particles were isolated by density gradient centrifugation and analyzed by electron microscopy and western blot analysis.

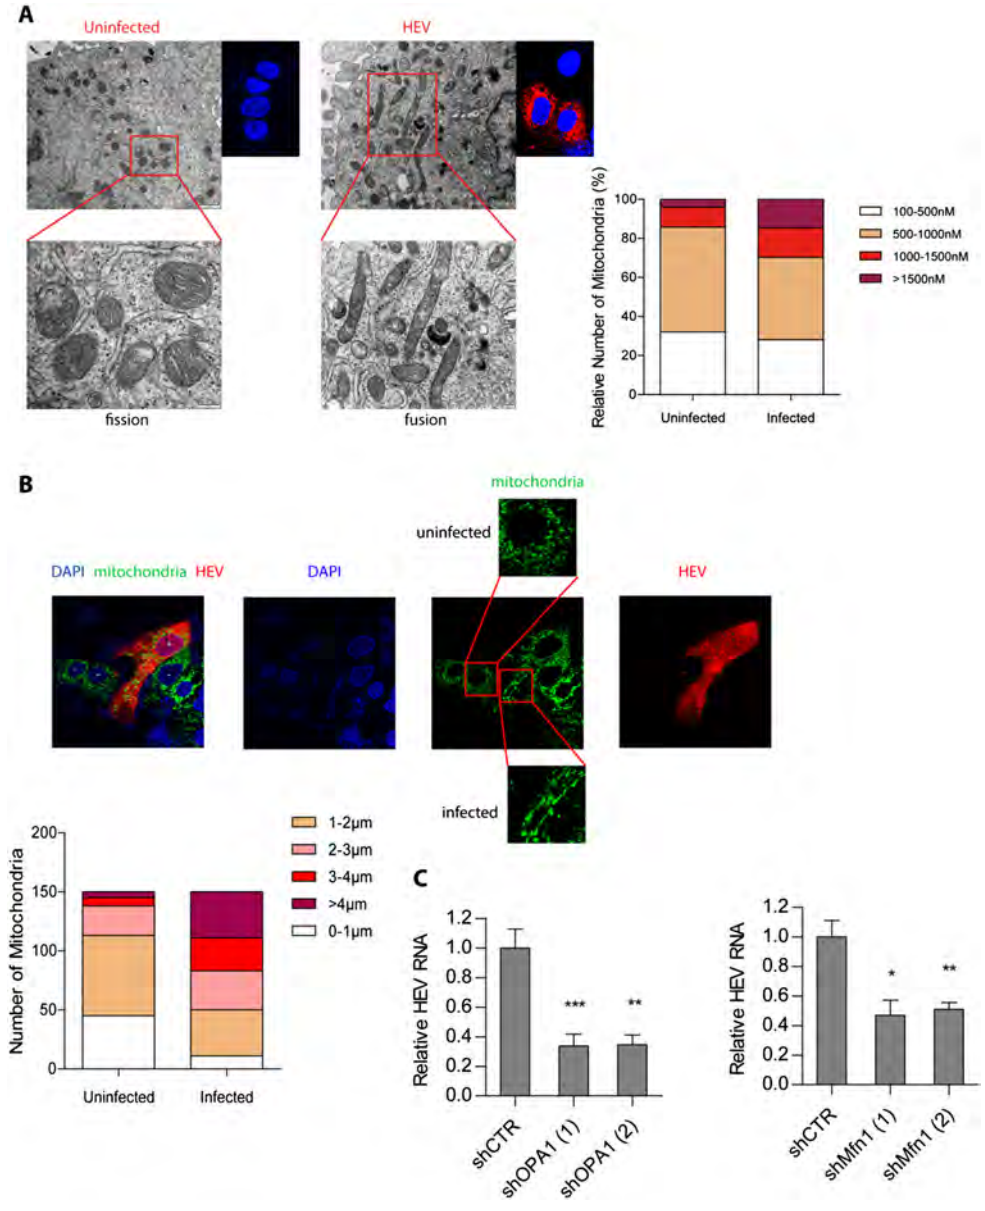

Figure 1: (abstract: PS-151)

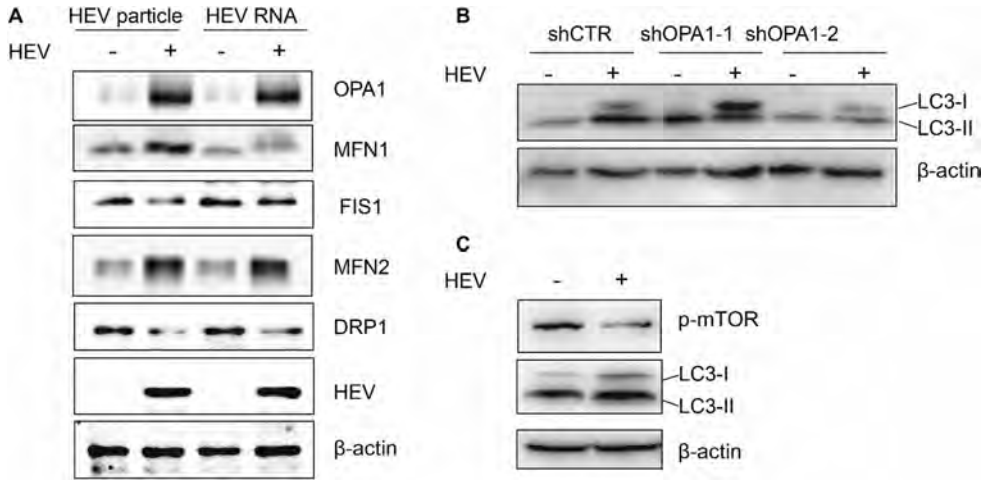

Figure 2: (abstract: PS-151)

Results: Expression of this mutant genome released higher amounts of LHBs in the form of shorter filaments as compared to the control. Morphology and release of spheres were not affected by this deletion. Most interestingly, a significant fraction of semi-enveloped virions was observed by electron microscopy that has been unprecedented so far. Stepwise insertion of aa 25-31, aa 32-39 and aa 25-39 increased the length of filaments. The rescue of aa 25-31 drastically decreased the fraction of semi-enveloped virions. Insertion of aa 32-39 had no effect on the rescue of the semi-enveloped virions, arguing against a simple spacer function of this region. Confocal immunofluorescence microscopy shows that deletion mutant and rescued mutants do not differ in subcellular HBsAg distribution and colocalization with ER, Golgi and MVB (multivesicular bodies) markers, arguing against differences in release pathways.
Conclusion: These data describe the first time formation of semi-enveloped HBV virions. In contrast to existing models, relevance of the N-terminal PreS1-domain (aa 25-31) for the morphogenesis and release of properly assembled virions and filaments is shown. As morphogenesis of virions (harbouring a nucleocapsid) and filaments (lacking a nucleocapsid) is affected by deletion of this region, it is concluded that this region triggers proper HBsAg-assembly independent of a direct interaction with the nucleocapsid.

PS-153

The pre-s2 deletion HBVmutants are responsible for the intracellular accumulation of the HBS protein, ER stress and mitochondria dysfunction

Jenny Yuh-Jin Liang[1], Rui-Dung Teng[2], Cheng-Pu Sun[3], Chien-Wei Su[4], Ming-Hua Tao[3], Jaw-Ching Wu[5]. *[1]Taipei Veterans General Hospital, Medical Research Department, Taipei City, Taiwan; [2]Taipei Veterans General Hospital, Taipei City, Taiwan; [3]Institute of Biomedical Science, Academia Sinica, Taipei City, Taiwan; [4]Medical Department, Taipei Veterans General Hospital, Taipei City, Taiwan; [5]Institute of Clinical Medicine, National Yang-Ming University, Taipei City, Taiwan*
Email: jcwu@vghtpe.gov.tw

Background and aims: Pre-S deletion HBV mutants are associated with HCC development and postoperative recurrence. Mitochondrial is related to lipid metabolism, liver diseases and HCC development. This study aimed to investigate the association of wild type and pre-S2 deletion HBV mutants with HBsAg retention, ER stress and mitochondrial dysfunction.
Methods: The HBV whole genome expression plasmids containing wild type or various pre-S2 deletion mutant sequences under the driving of HBV endogenous promoter or CMV promoter were transfected into Huh7 cells. The intracellular retention of HBsAg and the subsequent ER stress or mitochondria dysfunction were compared between Huh-7 cells transfected by plasmids expressing wild type HBV or various pre-S2 deletion mutants and hepatocytes of HBV infected FRG mice containing chimeric human hepatocytes.
Results: The ratio of intracellular to the HBsAg in culture medium were calculated. Intracellular HBsAg retention ratio was the lowest in the wild type, followed by the pre-S2 mutant with proline 142, and the highest in the HBV pre-S2 mutant without proline. The ER stress markers (pIRE1α, XBP1, CHOP) were significantly higher in Huh-7 cells transfected with plasmids of pre-S2 mutants by immunoblotting analysis. Colocalizations of HBsAg and an ER-marker calnexin were confirmed by confocal microscopy. In contrast to the diffuse and homogenous distribution of HBsAg expressed by wild type HBV, pre-S2 deleted HBsAg located over perinuclear area and aggregated into coarse granules or clumps in both transfected Huh-7 cells and HBV-infected human hepatocytes in FRG mice. Electron micrographs revealed that aberrant ER ultra-structures include ER dilation and fragmentation in HBV expressing cells. In addition, mitochondria fragmented with defects in cristae shape were also found in both wild type and pre-S2 mutants HBV expressing cells with different extents under transmission electron microscopy. Time lapse live imaging of mitochondria labeled with MitoTracker revealed that the mitochondria motility were impaired in wild type HBV expressing cells and even more severe in pre-S2 mutants-expressing cells. Using the human liver chimeric mouse model of Fah/Rag2/Il2rg (FRG), serum HBV DNA levels of FRG mice infected by the pre-S2 deletion HBV mutant were 2 logs lower than those infected by the wild type. The secretion of HBsAg in the serum of FRG mice infected with the pre-S2 deletion HBV mutant was also decreased.
Conclusion: Pre-S2 deletion HBV mutants are impaired in secretion which resulted in the retention of HBsAg inside the liver cells. The intracellular accumulation of HBsAg induces ER stress, mitochondria dysfunction which may subsequently impair lipid metabolism and contribute to HCC development.

PS-154

Dissecting the different roles of ORF3 in HEV spread and fecal shedding in a humanized mouse model

Gulce Sari[1], Xin Yin[2], Andre Boonstra[1], Zongdi Feng[2,3], Thomas Vanwolleghem[1,4]. *[1]Erasmus MC, Gastroenterology and Hepatology, Rotterdam, Netherlands; [2]The Research Institute at Nationwide Children's Hospital, Center for Vaccines and Immunity, Columbus, United States; [3]The Ohio State University College of Medicine, Pediatrics, Columbus, United States; [4]University Hospital Antwerp, Gastroenterology and Hepatology, Antwerp, Belgium*
Email: t.vanwolleghem@erasmusmc.nl

Background and aims: Hepatitis E viruses (HEV) are an important enterically transmitted cause of viral hepatitis. The HEV RNA genome is single-stranded, positive-sensed RNA encoding 3 ORFs. Although ORF3 has a viroporin structure and is required for viral propagation in macaques, its exact role remains unclear. In the present study, we dissect ORF3's function via reverse genetics and infectivity studies, both in vitro as in the liver humanized mouse model.
Method: A genotype 3 HEV strain (Kernow C1, P6) was used as backbone to construct ORF3 mutant viruses. Virus stocks were produced by transfecting in vitro transcripts into Huh-7 (clone S10-3) cells followed by gradient ultracentrifugation to purify intracellular non-enveloped virions. uPA-NOG and TK-NOG mice (n = 15) were transplanted with human hepatocytes from a single donor and inoculated iv with ORF3 mutant viruses (6 log geq/mouse) upon establishment of a stable graft. Weekly feces and serum samples were obtained during the 6-weeks infection course, after which animals were sacrificed and liver and bile were collected for viral load determination by multiplex qPCR.
Results: Three ORF3 mutants were generated: an ORF3del mutant that contains a mutation in the start codon, a PSAP mutant that contains mutations in the C terminal late domain, and a CCC mutant that contains mutations in the N terminal cysteines 11–13 (a putative palmitoylation site). Replication and infectivity of all 3 mutants were comparable to the wild type (WT) HEV in vitro. WT ORF3 and the PSAP mutant predominantly localized to the apical membrane of HepG2 cells, whereas the CCC mutant was predominantly cytoplasmic. At sacrifice, HEV RNA was detectable in livers of 9/14 animals (1 mouse died at 4 weeks pi) with HEV RNA titers (4–7 log IU/gr tissue) comparable between WT (n = 4/4), PSAP (n = 4/4) and CCC (n = 1/2) inoculated mice. None of the ORF3del mutants proved infectious in vivo (n = 4/4). While all WT inoculated mice had detectable HEV RNA in bile (5-7 log IU/ml) and feces (3–6 log IU/gr), only 1/4 PSAP mutant inoculated mice showed quantifiable HEV RNA in bile and feces. The HEV CCC mutant was barely detectable in bile (< 3.75 log IU/ml) and negative in fecal samples (n = 3/3). Despite this, serum titers between WT-HEV PSAP and HEV CCC mutant viruses were comparable.
Conclusion: Overall this corroborates the importance of ORF3 in HEV propagation in vivo and suggests a role of a putative palmitoylation site at the N-terminus of ORF3 in secretion of HEV into the biliary canaliculi.

PS-155

HBV entry inhibition after interferon alpha treatment hinders HBV rebound in hepatocytes that became negative for all HBV markers during interferon treatment

Lena Allweiss[1], Katja Giersch[1], Tassilo Volz[1], Ansgar W. Lohse[1,2], Jörg Petersen[3], Stephan Urban[2,4], Marc Luetgehmann[2,5], Maura Dandri[1,2]. *[1]University Medical Center Hamburg-Eppendorf, I. Department of Internal Medicine, Hamburg, Germany; [2]German Center for Infection Research (DZIF), Hamburg-Lübeck-Borstel and Heidelberg sites, Germany; [3]Asklepios Clinic St. Georg, IFI Institute for Interdisciplinary Medicine, Hamburg, Germany; [4]University Hospital Heidelberg, Department of Infectious Diseases, Molecular Virology, Heidelberg, Germany; [5]University Medical Center Hamburg-Eppendorf, Institute of Microbiology, Virology and Hygiene, Hamburg, Germany*
Email: lenaallweiss@hotmail.com

Background and aims: Treatment with interferon alpha (IFNα) can exert both immunomodulatory and antiviral effects, such as suppression of HBV transcription and cccDNA degradation. In this study, we aimed to investigate to which extent these antiviral effects take place in HBV-infected human hepatocytes in vivo and whether these effects can persist after treatment cessation. Moreover, we employed HBV entry inhibition to assess the role of new infection events in HBV rebound.
Methods: We treated HBV infected human liver chimeric mice with pegylated IFNα for 6 weeks (n = 13+5 untreated controls). Then, mice were either sacrificed (n = 5) or treatment was stopped to assess serological and intrahepatic viral changes for additional 6 weeks, either in the presence (n = 4) or absence of the entry inhibitor Myrcludex B (MyrB) (n = 4). MyrB treatment started 3 days before the last IFNα injection. HBV loads were analysed in serum and liver by qPCR. RNA in situ hybridization (RNA-ISH) and immunofluorescence were used to visualize both HBV transcription and the presence of SMC6, a component of the "structural maintenance of chromosomes complex" SMC5/6 which is degraded by the HBx protein, and hence may serve as a cellular marker of cccDNA suppression or clearance.
Results: Six weeks of IFNα treatment reduced median levels of viremia (1.2log), HBV transcripts (3.6fold) and cccDNA (4.3fold). As expected, SMC6 protein was degraded in most hepatocytes in the livers of HBV-infected control mice, but it was clearly detected in IFNα-treated mice. After stopping IFNα, HBV rebound occurred in 3 to 6 weeks and was accompanied by renewed SMC6 degradation in most human hepatocytes. Of note, we observed viremia increase also in MyrB-treated mice; however, entry inhibition blocked intrahepatic HBV rebound in a large proportion of human hepatocytes (>40%), which remained SMC6 positive and negative for HBcAg and HBV RNA (RNA-ISH). Interestingly, intrahepatic cccDNA levels in mice receiving MyrB during rebound remained as low as in mice sacrificed at the end of IFNα treatment.
Conclusion: Reappearance of the SMC5/6 complex in HBV-infected human hepatocytes in mice treated with IFNα did not hinder HBV reactivation after drug withdrawal in the setting of an established HBV infection. However, MyrB clearly maintained HBV negativity in a substantial proportion of human hepatocytes, suggesting that these cells had cleared cccDNA during IFNα treatment and that new infection events play a key role in HBV rebound post treatment.

PS-156

Antigen suppression effect of the core protein allosteric modulator RO7049389 in AAV-HBV mice is accompanied by transient upregulation of immune-cell gene signatures in the liver

Xue Zhou[1], Jitao David Zhang[2], Yuan Zhou[1], Xiaojun Tian[1], Youjun Yu[1], Lue Dai[1], Jie Zhao[1], John Young[2], Lu Gao[1]. *[1]Roche Innovation Centre Shanghai, Shanghai, China; [2]Roche Innovation Centre Basel, Basel, Switzerland*
Email: lu.gao@roche.com

Background and aims: The hepatitis B virus (HBV) core protein plays critical roles in multiple steps of the HBV life cycle, representing an attractive target for anti-HBV therapeutics. We have previously demonstrated that oral administration of RO7049389, a small molecule HBV core protein allosteric modulator (CpAM) in Phase I clinical development, can result in sustained suppression of not only serum HBV DNA, but also HBsAg and HBeAg levels in a mouse model infected with recombinant adeno associated virus carrying HBV genome (AAV HBV). Here we report follow-up studies aimed at a better understanding of the mechanisms of RO7049389 beyond its direct antiviral effect.
Method: In vivo efficacy of RO7049389 was studied in AAV-HBV infected immunocompetent (C57BL/6) as well as immunodeficient (CB17 SCID) mice. RNA-seq based transcriptome analyses were applied to liver tissues collected from AAV-HBV infected or uninfected mice dosed with or without RO7049389. Time points for tissue collection were selected to cover the time window before, during, and after the decline phase of HBV antigens.
Results: Oral administration of RO7049389 (20 mg/kg once daily) in AAV-HBV infected C57BL/6 mice rapidly reduced serum HBV DNA level, reaching the lower limit of quantification (LLOQ, 4.3 Log_{10} copies/ml) within 14 days of treatment. In contrast, the onset of HBsAg and HBeAg decline was much delayed, occurred only after maximal DNA suppression was achieved. RNA-seq analysis of liver tissues revealed that RO7049389 induced temporal effects on host gene expression exclusively in the AAV-HBV infected mice. While few genes are modulated at both early (day 3) and late (day 35) time points, gene-set enrichment analysis indicated upregulation of gene signatures specific to multiple immune cell types in the liver around day 14 and day 21, which coincide with the onset of serum HBV antigens decline. When similar studies were conducted in AAV-HBV infected CB17 SCID mice lacking functional T and B cells, HBsAg and HBeAg were also reduced by RO7049389 treatment, though the effect was slightly delayed. Taken together, these data indicated that although on the gene-expression level both innate and adaptive immune responses were temporarily enhanced in RO7049389 treated AAV-HBV infected C57BL/6 mice, mature T and B cells are likely dispensable for the antigen suppression effect of RO7049389.
Conclusion: Our study indicates that the antigen suppression effect of RO7049389 in AAV-HBV mice is accompanied by transient upregulation of immune-cell gene signatures in the liver, but nevertheless does not depend on T and B cell functions. These effects clearly differentiate RO7049389 from other direct-acting antiviral drugs and will be further studied both in preclinical models and in the clinical setting.

Gut-Liver Axis

Background and aims: The presence of cirrhosis in non-alcoholic fatty liver disease (NAFLD) is the most important predictor of liver-related mortality. Moreover, we have demonstrated that first-degree relatives of probands with NAFLD-cirrhosis have a high risk of advanced fibrosis. The gut-liver axis has recently emerged as a pivotal component of NAFLD but limited data exist concerning the diagnostic accuracy of gut-microbiome-derived signatures for detecting NAFLD-cirrhosis. We aimed at examining the familial similarity of gut-microbiome composition and to test whether a non-invasive stool-microbiome-derived signature accurately detects NAFLD-cirrhosis.
Method: We characterized by 16S rRNA amplicon sequencing gut-microbiome compositions of 203 uniquely well-characterized participants from a prospective twin and family cohort, including 98 probands encompassing the entire spectrum of NAFLD (NAFLD-cirrhosis (n = 26), NAFLD without AF (n = 18), non-NAFLD controls (n = 54)) and their first-degree relatives (n = 105), assessed using advanced magnetic resonance (MR)-imaging proton density fat fraction (MRI-PDFF) for quantifying hepatic steatosis and MR-elastography (MRE) for quantifying liver fibrosis.
Results: We observed a significant correlation within biologically related pairs compared to random-unrelated pairs at the level of the phyla (p = 0.023) and 16S sequences of bacterial strains (p = 2.4E-41). In addition related individuals with shared-housing had a lower phylogenetic dissimilarity than those who did not share housing (p = 0.045). We identified a panel of 30 features, including 27 bacterial features and age, sex and body mass index, which were used to build a Random Forest classifier for detecting NAFLD-cirrhosis. In a *derivation* cohort of probands with NAFLD-cirrhosis and non-NAFLD controls, the model had a robust diagnostic accuracy (receiver operating characteristic curve (AUROC) of 0.92) for detecting NAFLD-cirrhosis **Fig. 1a**, confirmed in a *validation* cohort of first-degree relatives of proband with NAFLD-cirrhosis (AUROC of 0.87) **Fig. 1b.**
Conclusion: This study reports a strong familial correlation of gut-microbiome driven by shared-housing and provides evidence for a novel fecal-microbiome-derived signature to detect NAFLD-cirrhosis.

PS-158
Paneth cells drive microbial induced signals to promote angiogenesis and regulate portal hypertension

Mohsin Hassan[1], Sheida Moghadamrad[1,2], Marcel Sorribas[3], Sergi Muntet[1], Philipp Kellmann[1], Coralie Trentesaux[4], Marie Fraudeau[4], Paolo Nanni[5], Witold Wolski[5], Beatrice Romagnolo[4], Siegfried Hapfelmeier[6], Prof. Dr. Reiner Wiest[3], Andrea De Gottardi[1,2].

Email: andrea.degottardi@gmail.com

Background and aims: The number of Paneth cells (PCs) is increased in portal hypertension and in the presence of bacteria, but the mechanisms by which these cells contribute to the regulation of splanchnic hemodynamics are unknown. We investigated their role in a model of conditional deletion of PCs in which we induced portal hypertension by partial portal vein ligation (PPVL).
Method: Math-1 Lox/LoxVillcreERT2 or control mice were injected three consecutive doses of tamoxifen before undergoing PPVL or sham surgery. Hemodynamic measurements were performed 14 days after PPVL. Intestinal and mesenteric angiogenesis was assessed by immunohistochemistry using CD-31 antibodies. Using a RT^2 profiler PCR array we quantified the expression of angiogenic genes in distal ileum. 3D enteroids from control and PC depleted mice were exposed to different bacterial derived products and E. *coli*. The conditioned media (CM) from these enteroids were co-cultured with endothelial cells (EC) to analyse tube formation activity on matrigel as well as wound healing responses. Proteomic analysis of CM was performed using MaxQuant v1.6.2.2.3 to quantify differentially regulated proteins.
Results: Portal hypertension was significantly attenuated in Paneth cell depleted mice compared to control mice and was associated with a decrease in portosystemic shunts (n = 8–11/group). Depletion of PCs also resulted in a significantly decreased density of blood vessels in ileum and mesentery. Tube formation and wound healing responses were significantly decreased in ECs treated with conditioned media from PC-depleted organoids. Proteomic results revealed that an important number of proteins associated with angiogenesis were downregulated in CM of enteroids lacking Paneth cells, confirming the data obtained from PCR arrays.

Conclusion: The in vivo and in vitro results presented here suggest that intestinal flora and microbial-derived factors activate Paneth cells to secrete proangiogenic signalling molecules to increase intestinal and mesenteric angiogenesis. These effects are abrogated in the absence of Paneth cells leading to a decrease in portal hypertension.

PS-159

Intestinal dysbiosis fuels liver disease progression via NLRP3 in the Mdr2$^{-/-}$ mouse model of primary sclerosing cholangitis

Email: kai.markus.schneider@gmail.com

Background and aims: There is a striking association between human cholestatic liver disease (CLD) and inflammatory bowel disease. However, the implications for intestinal microbiota and inflammasome mediated innate immune response in cholestatic liver disease remain imprecise. Here we investigated the functional role of gut-liver crosstalk for cholestatic liver disease in PSC patients and the murine PSC-model the Mdr2 knockout (*Mdr2*$^{-/-}$) mice.
Method: *Mdr2*$^{-/-}$, *Mdr2*$^{-/-}$ crossed with hepatocyte-specific deletion of capsase-8 (*Mdr2*$^{-/-}$/Casp8$^{\Delta hepa}$) and wildtype (WT) control mice to characterize the impact of Mdr2 deletion on liver and gut including comprehensive bile acid and microbiota profiling. To block caspase activation, a pan-caspase inhibitor (IDN-7314) was administered. Finally, the functional role of *Mdr2*$^{-/-}$ associated intestinal dysbiosis was studied by microbiota transfer (FMT) experiments.
Results: *Mdr2*$^{-/-}$ mice displayed an unfavorable intestinal microbiota signature and pronounced NLRP3 inflammasome activation within the gut-liver axis, as found by immunostaining and western blot analysis in the intestine as well as in the liver. In addition, significant NLRP3 inflammasome activation was found in livers of PSC patients. Intestinal dysbiosis in *Mdr2*$^{-/-}$ mice prompted intestinal barrier dysfunction evidenced by reduced colonic mucus layers, reduction of tight junction expression and increased permeability evidenced by an in-vivo FITC-dextran assay. Loss of intestinal barrier integrity and bacterial translocation triggered the hepatic NLRP3 mediated innate immune response and fueled liver disease progression. Strinkingly, *Mdr2*$^{-/-}$ microbiota was transmissible to healthy WT mice, urged intestinal barrier impairment and induced significant liver injury in recipient mice, which resembled the inflammatory *Mdr2*$^{-/-}$ phenotype characterized by NLRP3 activation within the gut-liver axis.
This phenotype could not be rescued by introducing *Mdr2*$^{-/-}$/*Casp8*$^{\Delta hepa}$ indicating that hepatocytic caspase-8 activation is a downstream consequence and dispensable for the inflammatory response. In contrast, caspase inhibition via IDN-7314 dampened inflammasome activation, improved barrier function, ameliorated liver injury, reversed serum bile acid profile and cholestasis associated microbiota signature.
Conclusion: CLD in *Mdr2*$^{-/-}$ mice triggers intestinal dysbiosis, which is transmissible to healthy WT mice. In turn, translocation of endotoxin into the portal vein and subsequent NLRP3 inflammasome activation as also found in PSC patients contribute to higher liver injury in *Mdr2*$^{-/-}$ mice. This process does not essentially depend on hepatocytic caspase-8, but can be blocked by IDN-7314, highlighting the causal role of intestinal dysbiosis and the subsequent innate immune response for disease progression in *Mdr2*$^{-/-}$ mice, which might also be relevant in humans.

PS-160

miRNA-21 signals through a gut-liver axis to regulate experimental cholestasis

André A. Santos[1], Marta B. Afonso[1], Ricardo S. Ramiro[2], Rui E. Castro[1], Cecília M. P. Rodrigues[1]. *[1]iMed.ULisboa, Faculty of Pharmacy, Universidade de Lisboa, Portugal, Cellular Function and Therapeutic Targeting, Lisbon, Portugal; [2]Instituto Gulbenkian de Ciência, Oeiras, Portugal*
Email: afasantos@ff.ulisboa.pt

Background and aims: Gut microbiota plays an important role in gut-liver axis homeostasis. New evidence suggests that endogenous miRNAs, secreted into the intestinal lumen, may modulate gut microbiota function and abundance. For instance, loss of miR-21 alters gut microbiota composition in mice and protects against inflammatory bowel disease. Of note, we previously showed that miR-21 deletion ameliorates liver fibrosis in experimental cholestasis and improves adaptative response to bile acid dysregulation. Here, we aimed to characterize changes occurring in the gut microbiota of miR-21 knockout (miR-21KO) mice after bile duct ligation (BDL).
Methods: Three-month old C57BL/6 wild type (WT) and whole body miR-21KO mice were subjected to sham or BDL surgeries. After 3 days, the small intestine was collected for qRT-PCR analysis of intestinal permeability-related genes. Serum was also collected for biochemical analyses. Gut microbiota composition was evaluated by sequencing the 16S rRNA gene V3 region of bacterial DNA from the small intestinal lumen. In co-housing experiments, WT and miR-21KO animals were housed together for 1 month and then separated into different boxes for an additional month.
Results: Our results show that miR-21KO mice are protected against small intestinal dysbiosis induced by BDL. In particular, depletion of miR-21 in mice positively correlated with increased *Lactobacillus sp.* and diminished Proteobacteria. This effect is independent from the BDL, as miR-21KO co-housed mice display increased relative abundance of *Lactobacillus sp.* in the small intestine, compared with WT mice. Of note, separated miR-21KO animals showed higher amounts of *Lactobacillus sp.* when compared with co-housed miR-21KO. Further, mRNA expression of small intestinal tight junctions (ZO-1, JAM-A and Occludin-1) and stem cell markers (Lgr5 and Olfm4) are decreased in WT mice after BDL but remains unaltered in miR-21KO animals. Finally, miR-21 ablation also correlates with increased FXR mRNA expression in the small intestine, increased bile acid homeostasis and reduced liver injury.
Conclusion: Genetic ablation of miR-21 modulates small intestinal permeability and FXR expression, impacting on bile acid production and contributing for improved gut microbiota and host homeostasis. These results reinforce the importance of the gut-liver axis in protecting the liver after acute cholestasis.

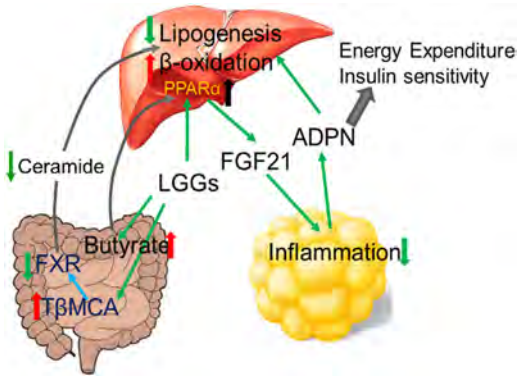
Lactobacillus rhamnosus GG culture supernatant improves energy expenditure and glucose tolerance in high-fat-high-fructose fed mice exposed to chronic intermittent hypoxia through regulation of intestinal microbiota and bile acid homeostasis

Qi Liu[1], Yiping Chen[1], Wenke Feng[2], Craig McClain[2]. [1]*The Second Affiliated Hospital and Yuying Children's Hospital Wenzhou Medical University, Department of Pediatrics, Wen Zhou, China;* [2]*University of Louisville School of Medicine, Departments of Medicine and Pharmacology and Toxicology, louisville, United States*
Email: wenke.feng@louisville.edu

Background and aims: OSAS has been recently connected to metabolic disorders such as NAFLD and type 2 diabetes. Our previous studies have demonstrated that the probiotic *Lactobacillus rhamnosus* GG cultural supernatant (LGGs) prevents ALD and fructose-induced NAFLD. In the current study, we aimed to examine the effects the mechanism of LGGs on glucose metabolisms and body energy expenditure in mice fed a high-fat-high-fructose (HFHF) diet and exposed to chronic intermittent hypoxia in order to understand the underlying mechanisms.

Method: C57BL/6 mice were fed HFHF diet or normal liquid diet (NLD) respectively for 15 weeks. After 3 weeks feeding, two groups of mice were exposed to chronic intermittent hypoxia (CIH) for 12 weeks, and one of the groups was supplemented with LGGs at a dose equivalent to 10^9 CFU bacteria/day.

Results: HFHF diet feeding significantly increased body fat mass, hepatic steatosis, glucose tolerance, and liver injury, and decreased energy expenditure. These indices of metabolic disorders were worsened in mice exposed to CIH, indicating that CIH has an additive effect on HFHF diet feeding. The HFHF-fed mice supplemented with LGGs showed marked improvements in indices of metabolic disorder including fat mass, energy expenditure and glucose and insulin tolerance. LGGs treatment decreased hepatic fat content and adipocyte size. Adipose expression of HIF-1α, a marker of tissue hypoxia, was increased in HFHF-CIH mice, which was reduced by LGGs treatment. The reduction of adipose tissue hypoxia was associated with decreased inflammatory cytokines such as TNFα, IL-1β and IL-6. HFHF-CIH mice had a markedly reduced circulating adiponectin, and was significantly elevated by LGGs treatment. Metabolomics study showed that intestinal butyrate was significantly elevated by LGGs leading to hepatic PPARα activation and a robust elevation of FGF21 expression in the liver and in circulation. Importantly, depletion of FGF21 significantly attenuated the beneficial effect of LGGs. Furthermore, LGGs significantly changed hepatic and fecal bile acid composition. Fecal concentrations of TαMCA and TβMCA, which are known FXR antagonists, were decreased in HFHF-CIH mice but were significantly increased by LGGs treatment. Intestinal and circulation ceramide, which is regulated by FXR and contributes to NAFLD, was reduced by LGGs.



Conclusion: LGGs treatment prevents NAFLD and increases energy expenditure and insulin sensitivity induced by diet and hypoxia in HFHF-CIH mice. The beneficial effects of LGGs are mediated by multiple mechanisms. LGGs increases intestinal butyrate and hepatic PPARα expression leading to increased hepatic FGF21 expression and adipose adiponectin production. LGGs increases TβMCA which inhibits intestinal FXR and likely ceramide production. LGGs may be used as a potential treatment strategy in subjects with OSAS and metabolic syndrome.

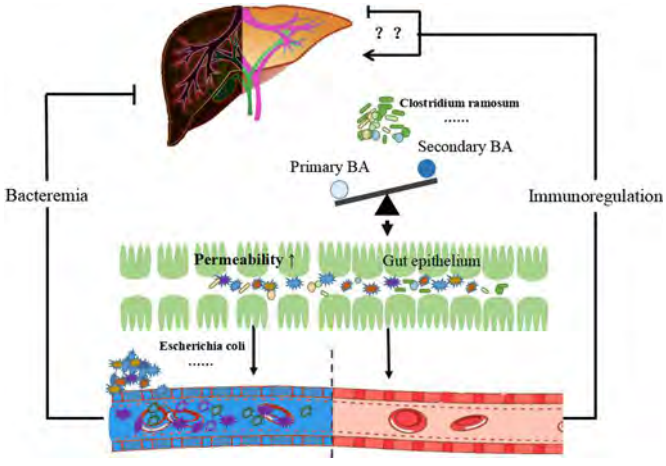
PS-162

Gut microbiota is closely involved in the prognosis of HBV-related acute-on-chronic liver failure

KE WANG[1], Zhao Zhang[2], Zhishuo Mo[1], Xiaohua Yang[1], Jian Wu[2], Tao Chen[2], Hanqi Yin[2], Zhiliang Gao[1]. [1]*The Third Affiliated Hospital of Sun Yat-Sen University, Department of Infectious Diseases, Guangzhou, China;* [2]*Guangdong Longsee Biomedical Corporation, Research and Development Department, Guangzhou, China*
Email: gaozhl@mail.sysu.edu.cn

Background and aims: The characteristic of HBV-related acute-on-chronic liver failure (HBV-ACLF) is the rapid progression and frequently high mortality. However the specific influence factors that contributed to this remains to be clarified. Emerging evidence have highlighted the role of gut microbiota in liver disease. This study focused on defining the changes of the gut microbiota in fecal and blood of HBV-ACLF patients.

Method: We recruited 128 patients with HBV-ACLF and 20 health controls (NC). The two of the HBV-ACLF patients were collected three times approximately every week (7 ± 2days) according to the degree of disease progression: one case as regression, the other case as progression. The gut microbiota composition was determined using 16S rRNA gene sequencing of stool samples. Metagenome sequencing of fecal, blood, white blood cells of the two dynamic HBV-ACLF patients. The species composition was identified and pathway analysis of the predicted genes were performed using geeNOG, GO, KEGG database. The content of bile acids in fecal and blood was determined by liquid chromatography-mass spectrometry.



Results: The fecal microbiota diversity of HBV-ACLF group was significantly lower compared with that of NC. Among these gut microbiota, HBV-ACLF regression group showed higher abundance of Streptococcus, Megamonas, Clostridium, Ruminococcus and Dorea, while the progression group showed increased Veillonella and Enterococcus. Faecalibacterium, Roseburia, Lachnospiraceae, et al were significantly increased in the NC group. Metagenomic sequencing revealed Ruminococcus and Lachnospiraceae with different abundance have the same trend showed in 16 s rRNA gene sequencing. Further, correlation analysis of bile acids and gut microbiota showed only two types of bile acids, cholate and deoxycholate were detectable in the first week samples of HBV-ACLF. While on the second and third week samples, the types of bile

acids in the regression patients increased mainly secondary bile acids while such phenomenon was not observed in the progression group. Interestingly, we also observed that enterococcus-faecalis, escherichia-coli, veillonella-unclassified were co-existed in the fecal, blood and white blood cells simultaneously when clinical blood culture test was negative in the HBV-ACLF.

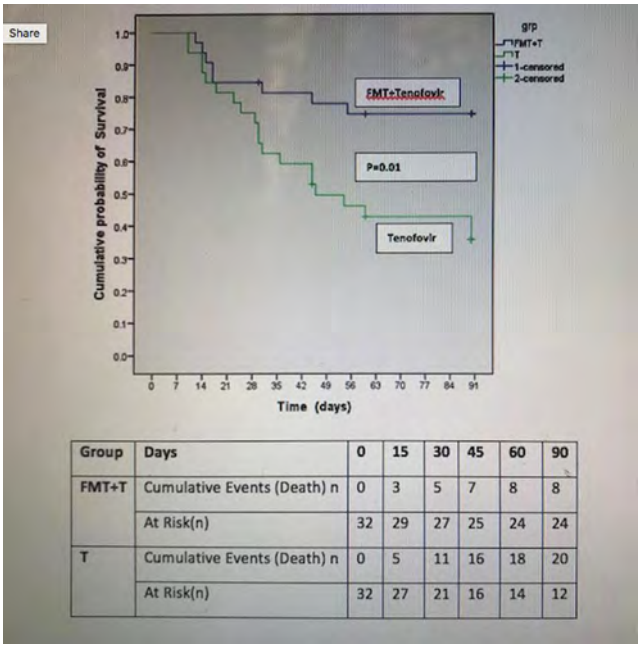
Conclusion: The abundance of different major gut microbiota, including Ruminococcus and Lachnospiraceae, may be a potential underlying mechanism of developing advanced HBV-ACLF. Bile acid metabolism indirectly influences the prognosis of HBV-ACLF through the regulation of intestinal flora. Besides, the co-exist of the several gut microbiota species in fecal and blood suggests that it may be very important to carry out antibiotic therapies ahead of the exactly evidences.

PS-163

Faecal microbiota transplantation with tenofovir is superior to tenofovir alone in improving clinical outcomes in acute-on-chronic liver failure due to hepatitis B: An open label randomized controlled trial (NCT02689245)

Juned Ahmad[1], Manoj Kumar[2], Shiv Kumar Sarin[2], Shvetank Sharma[2], Ashok Choudhury[2], Ankur Jindal[2], Nirupma Trehanpati[2], Anand Kulkarni[2], Shakti Choudhury[2], Dr. Abhinav Verma[2]. *[1]ILBS, New Delhi, Hepatology, New Delhi, India; [2]ILBS, Hepatology, New Delhi, India*
Email: ahmadjuned43.jk@gmail.com

Background and aims: Acute-on-chronic liver failure due to reactivation of hepatitis B (ACLF-B) has a high mortality despite antiviral therapy, and urgent liver transplantation is often needed. Gut dysbiosis is an important contributor for development of infections and liver failure in ACLF. It is plausible that manipulation of gut microflora may favourably influence the course and outcome of this severe liver disease due to ACLF-B. **Aims:** We investigated the efficacy and safety of combining FMT with antiviral therapy compared to antiviral alone in improving transplant free survival at 3 months in ACLF-B.



Group	Days	0	15	30	45	60	90
FMT+T	Cumulative Events (Death) n	0	3	5	7	8	8
	At Risk(n)	32	29	27	25	24	24
T	Cumulative Events (Death) n	0	5	11	16	18	20
	At Risk(n)	32	27	21	16	14	12

Method: Patients with spontaneous reactivation of hepatitis B presenting as ACLF according to the APASL criteria having MELD > 18 with < 2 organ failures were randomised to receive either FMT+ Tenofovir (FMT-T) or Tenofovir alone. Liver and kidney parameters, APACHE and SOFA scores were assessed at baseline and at day 7, 15, 30 and 90. HBV DNA/HBsAg, changes in gut microbiome and serum levels of proinflammatory and anti-inflammatory cytokines and endotoxin levels were measured in both the groups [baseline, day 7, 30, 90].

Results: Sixty-four ACLF patients (52 male, 43.87 ± 8.55 years) completed the study; 32 in each arm. Baseline parameters were comparable in 2 groups. After 3 months transplant free survival was significantly (p = 0.01) superior in FMT+T Gr (24/32, 75.0%) then Tenofovir alone (12/32, 37.5%). Improvement in MELD at day 15, 30, 60 and 90 was significantly higher in FMT+T Gr than Tenofovir Gr (p = 0.02). Improvement in SOFA/APACHEII at day 15, 30, 60 and 90 was significantly higher in FMT+T then Tenofovir Gr (p = 0.01). The HBV DNA was reduced from 12.99 ± 2.52 IU/ml to 1.75 ± 0.59 in FMT + T group (p value = 0.03) and 12.77 ± 1.95 to 1.6 ± 0.43 (p value = 0.02) in Tenofovir group at 3 months, the differences were not significant (p value = 0.17). At day 15, > 2 log reduction in the HBV DNA level was associated with improved survival (p = 0.03). SIRS significantly improved (p = 0.02) at day 7, 15, 30, 60 and 90 in FMT+T than Tenofovir Gr. Infectious complication significantly lower in FMT+T Gr (p = 0.04).No adverse effects of FMT noted.

Conclusion: FMT along with tenofovir is well tolerated and is more effective than tenofovir alone in ameliorating liver failure, infectious complications and improving transplant free survival.

Liver transplantation I

PS-164

Patients with non-alcoholic steatohepatitis have inferior liver transplant outcomes

Shunji Nagai[1], Kelly Collins[1], Lucy Chau[1], Michael Rizzari[1], Atsushi Yoshida[1], Marwan Abouljoud[1], Mohamed Safwan[1], Dilip Moonka[2]. *[1]Henry Ford Health Systems, Transplant Institute, Detroit, United States; [2]Henry Ford Health Systems, Division of Gastroenterology and Hepatology, Detroit, United States*
Email: snagai1@hfhs.org

Background and aims: Non-alcoholic steatohepatitis (NASH) is an increasing indication for liver transplantation (LT). Historically, patients with NASH are reported to have similar outcomes after LT compared to patients without NASH. The current study revisits this question. Post-transplant outcomes were evaluated among three major etiologies: NASH, hepatitis C (HCV), and alcoholic liver disease (ALD) to determine risks in LT associated with the NASH population.

Method: Data from the UNOS registry were analysed. Patients were divided into those with a diagnosis of NASH, HCV or ALD. Patients with overlapping diagnoses were excluded. LT was divided into four groups by era: Era 1: 2008–2010, Era 2: 2011–2013, Era 3: 2014–2015, Era 4: 2016–2017. Primary outcome was one year patient survival. Outcomes were compared among disease groups using Cox regression models adjusting for donor/recipient characteristics, except for recipient age, body mass index, and diabetes, which were considered NASH-associated characteristics. All patients had at least one year follow-up.

Results: There were 6, 344 patients with NASH, 17, 037 with HCV, and 9, 279 with ALD. The percent of patients with NASH and ALD rose significantly across eras from 14.0% to 27.9% and from 24.7% to 36.8%, respectively. The percent with HCV declined from 61.3% to 36.3%. In Era 1, the HCV group showed significantly worse one-year patient survival of 87.4% than the NASH and ALD groups at 90.3% (p = 0.007) and 90.6% (p < 0.001), respectively, whereas in Era 4, the NASH group showed significantly worse survival at 90.4% compared to 92.8% in the HCV (p = 0.004) and 93.5% in the ALD (p < 0.001) groups. The risk of one-year mortality in the NASH group became higher than the HCV and ALD groups in Era 4 with hazard ratios of 1.29 (p = 0.047) and 1.52; (p < 0.001). There was significant improvement in one-year

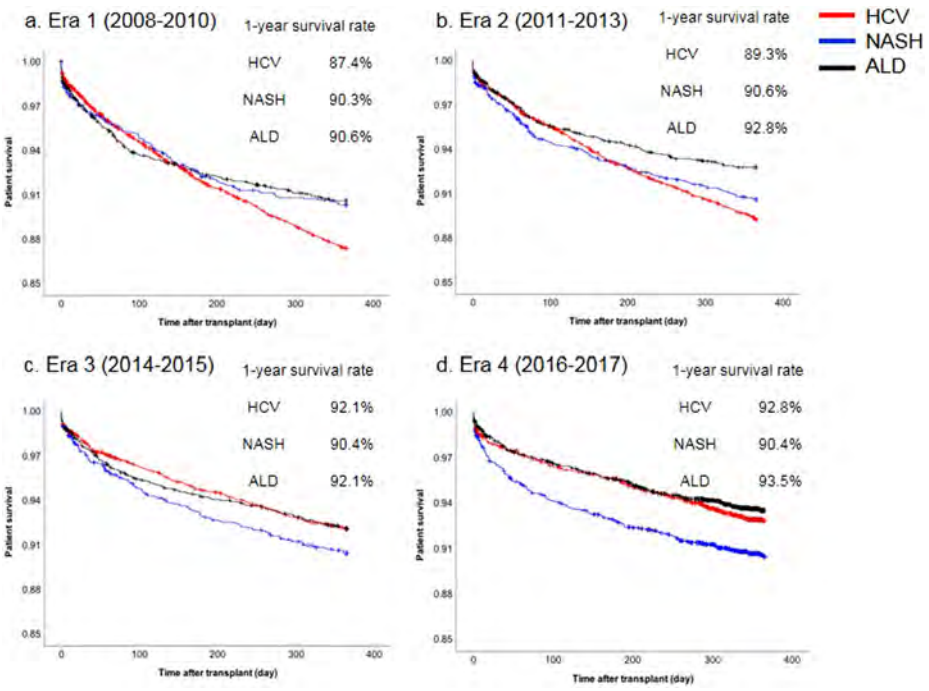


Figure: (abstract: PS-164) One year patient survival by diagnosis over eras.

patient survival over eras in the HCV (p < 0.001) and ALD groups (p = 0.001), whereas no improvement was seen in the NASH group.
The NASH group contained the fastest growing population of older patients. The annual number of patients over 65 years was largest in the HCV group in Era 1 at 144 per year compared to 103 in NASH and 94 in ALD. In Era 4, the NASH group has the largest number of patients over 65 at 422 per year compared to 369 in HCV and 227 in ALD. In addition, the effects of increasing age were most pronounced in the NASH group. Compared to patients < 50 years, the hazard of mortality in age 50-59, 60-64, 65-69 and ³70 years was 1.32 (p = 0.022), 1.64 (p < 0.001), 2.05 (p < 0.001), and 2.61 (p < 0.001). Mortality from cardiovascular/cerebrovascular disease was greatest in the NASH group accounting for 11.5% of deaths compared to 7.0% and 9.6% in HCV and ALD (p < 0.001).
Conclusion: The risk of LT in the NASH population has become higher than in HCV or ALD. This is likely to have profound implications in a time of shifting indications for LT.

PS-165

Handgrip strength adds more prognostic value to the MELD score than imaging-based measures of muscle mass in men awaiting liver transplantation

Marie Sinclair[1], Brooke Chapman[1], Rudolf Hoermann[2], Adam Testro[1], Thomas Scodellaro[1], Penelope Hey[1], Paul Gow[1]. *[1]The University of Melbourne, Liver Transplant Unit, Austin Hospital, Melbourne, Australia; [2]The University of Melbourne, Medicine, Melbourne, Australia*
Email: mariejsinclair@gmail.com

Background and aims: Sarcopenia is associated with mortality in cirrhosis yet there is no gold standard for diagnosis. Little is known about the comparative utility of different diagnostic methods in predicting mortality. The aim of this study was to compare the relative prognostic impact of three commonly employed measures of sarcopenia in a single cohort of men awaiting liver transplantation.
Method: This single centre observational cohort study investigated outcomes in 145 men referred for liver transplant evaluation between 2005 and 2012. Baseline demographics included Model for End-stage Liver Disease (MELD) score. Muscle mass was estimated by handgrip strength, Dual Energy Xray Absorptiometry (DEXA) lean mass and muscle area on single slice CT scan at the 4th lumbar vertebra. Recorded outcomes included time-to-death or liver transplantation.
Results: The median age was 54 years [47; 59] and median MELD score 17 [14; 23]. Of the 145 men, 56 died, with a median time to death of 7.44 months [3.48, 14.16] and 79 were transplanted, with median time to transplant of 7.2 months [3.96, 12.84]. Muscle mass measurements correlated only modestly using different methods with the strongest correlation being observed between CT-measured muscle area and DEXA-measured appendicular lean mass (APLM) (tau 0.41, p < 0.001). For each modality, reduced muscle mass was associated with increased mortality, including CT-measured muscle (HR 0.94 [0.90; 0.98], p = 0.002), APLM (HR 0.99 [0.99; 0.99], p = 0.003) and handgrip strength (HR 0.94 [0.91; 0.98], p = 0.002) and these results retained significance independent of the MELD score. In predicting mortality, the handgrip strength-MELD bivariable Cox model was superior to a MELD-CT Cox muscle model (p < 0.001).
Conclusion: This study for the first time compares three commonly employed techniques to quantify sarcopenia in a cohort of men cirrhosis. There was only modest correlation between methods, but in a bivariable model incorporating MELD score, each of CT scan, DEXA and handgrip strength had similar prognostic value. Given the radiation, cost and access issues often related to CT and DEXA scans, we propose that handgrip strength is a simple alternative with comparable utility. The ability to perform handgrip strength serially has the additional benefit of allowing identification of deteriorating muscle strength in patients awaiting liver transplant.

PS-166

Repopulation of decellularized porcine bile ducts with human cholangiocyte organoids for the generation of human-sized bioengineered biliary tissue

Teresa Brevini[1], Walid Al-Akkad[2], Alessandro F Pellegata[3], Olivia C Tysoe[4,5], Luca Frenguelli[2], Si Emma Chen[6], Paolo De Coppi[3], Massimo Pinzani[2,7], Kourosh Saeb-Parsy[4], Ludovic Vallier[4,5], Giuseppe Mazza[2], Fotios Sampaziotis[4,5,8,9]. *[1]Dipartimento di Biotecnologie Mediche e Medicina Traslazionale, Milan, Italy; [2]University College London, Division of Medicine, Institute for Liver and Digestive Health, Royal Free Hospital, London, United Kingdom;*

Email: teresa.brevini@studenti.unimi.it

Background and aims: We have demonstrated proof-of-principle for the use of bioengineered ducts for biliary reconstruction in mice. However, clinical translation requires up-scaling of this technology to human dimensions. To address this challenge, we combined decellularized porcine bile ducts with human cholangiocyte organoids to generate bioengineered biliary tissue resembling the dimensions, micro-architecture and properties of the human bile duct.
Method: Primary Extrahepatic Cholangiocyte Organoids (ECOs) were isolated and propagated using our established protocol. Pig bile ducts were decellularized by intra-luminal perfusion using our established methodology and characterized using histology, DNA quantification and Scanning Electron Microscopy. Acellular bile ducts were anastomosed to pig common bile ducts, perfused with bile ex-vivo and monitored for leakage of bile. Nutrient diffusion was assessed using FITC-Dextran. Decellularized bile ducts were seeded with ECOs using our established protocols. Cell survival and growth were assessed using Presto Blue. Bile acid permeability was assessed using Cholyl-L-lysyl-fluorescein (CLF).
Results: Intra-luminal perfusion resulted in high decellularization efficiency, while preserving key architectural features, including the basal lamina, peribiliary glands and vascular plexus. Decellularized bile ducts can be surgically manipulated for biliary reconstruction ex vivo with no immediate complications. Nevertheless, perfusion with bile resulted in tissue degradation and bile leak. ECOs seeded on decellularized ducts rapidly expand to reach confluence and form an epithelial monolayer. These constructs survive long-term in culture and maintain key biliary features including marker expression (CK7, CK19, Sox9) and function, such as ALP and GGT activity. Importantly, the ECO monolayer prevents bile acid diffusion and provides an adequate barrier to bile which protects the scaffold from bile degradation. Furthermore, decellularized scaffolds allow passive nutrient diffusion, which is crucial for supporting the viability of the epithelial layer post transplantation.
Conclusion: ECOs can be combined with decellularized porcine bile ducts to generate constructs closely resembling the structural and functional properties of the human common bile duct. These findings provide proof-of-principle for the feasibility of human-sized hollow organ tissue engineering and pave the road for future studies in large animal models.

PS-167
Bile as a non-invasive source of cholangiocyte organoids for developing patient-specific disease modelling and personalized regenerative medicine

Floris Roos[1], Monique Verstegen[1], Jan-Werner Poley[2], Marko Bruno[2], Geert Tetteroo[3], Jan IJzermans[1], Luc van der Laan[1]. [1]Erasmus MC, Surgery, Rotterdam, Netherlands; [2]Erasmus MC, Gastroenterology and Hepatology, Rotterdam, Netherlands; [3]IJsselland Ziekenhuis, Surgery, Capelle aan de IJssel, Netherlands
Email: f.roos@erasmusmc.nl

Background and aims: Bile duct related diseases are the leading cause for pediatric liver transplantation and adult re-transplantation of a liver graft. Studying biliary diseases has long-term been hampered by the inability to culture bile duct lining cholangiocytes long-term. Recently was shown that Extra-hepatic Cholangiocyte Organoids (ECOs) that are derived from extra-hepatic bile duct (EHBD) tissue can be long-term expanded in culture. However, disease modeling or personalized regenerative medicine applications are limited since highly invasive bile duct biopsies are required to obtain these ECOs from individual patients. Therefore the aim of the current study is to investigate whether ECOs can be cultured from less invasively acquired bile fluid.
Methods. Bile-derived cholangiocyte organoids (BCOs) were cultured, according to the previous published protocol and collected from gallbladder bile obtained from donor livers for transplantation and from bile obtained by endoscopic retrograde cholangiopancreatography (ERCP) or percutaneous transhepatic cholangiography drain (PTCD) in patients. In addition, ECOs were initiated from three different patients and compared to BCOs on the genetic level (qrt-PCR), protein level (either immunohistochemistry, immunofluorescence or Western blotting) and functional level by testing the cholangiocyte specific transporter channels (ussing chamber and transport assay).
Results. Cultures were initiated from 1 ml of bile obtained from all different sources. Bile-derived cholangiocyte organoids could be effectively (8/9 attempts) expanded from all sources of bile from patients with a variety of diseases (primary sclerosing cholangitis, cholangiocarcinoma, bile stones and biliary stenosis after liver transplantation). BCOs expressed similar cholangiocyte markers on gene and protein level as tissue-derived ECOs and both lacked either stem cell- or hepatocyte markers. Furthermore, these cells expressed and responded similarly to stimulation and inhibition of different cholangiocyte ion-channels. Interestingly, cholangiocyte-organoids from a patient with cystic fibrosis (CF) clearly lacked CFTR channel activity, showing that cholangiocyte-organoids can be used as a disease model to study biliary diseases.
Conclusion. Our study showed that bile provides a novel minimally-invasive source of patient-specific cholangiocyte organoids. This creates new opportunities to study autologous bile duct regeneration and develop patient-specific disease models.

PS-168
Novel real time prediction of liver graft function during hypothermic oxygenated machine perfusion prior to liver transplantation

Philipp Dutkowski[1], Xavier Muller[1], Andrea Schlegel[1], Philipp Kron[1], Dilmurodjon Eshmuminov[1], Michael Würdinger[1], David Meierhofer[2], Pierre-Alain Clavien[1]. [1]University Hospital Zurich, Department of Surgery and Transplantation, Zurich, Switzerland; [2]Max Planck Institute for Molecular Genetics, Mass Spectrometry Facility, Berlin, Germany
Email: philipp.dutkowski@usz.ch

Background and aims: *Ex situ* machine perfusion is a new method to potentially repair injured organs and assess organ function. In liver transplantation, however, no studies exist on reliable prediction of graft function during machine perfusion. We have developed a simple machine perfusion technique, hypothermic oxygenated perfusion (HOPE), which is applied after cold storage for 1-2 hours exclusively through the portal vein. The aim of this study was to analyze, whether liver graft function can be predicted during HOPE, besides optimizing of outcomes.
Method: We applied HOPE for DCD (donation after cardiac death) or extended criteria DBD (donation after brain death) human liver grafts in the past 5 years. Our entire series includes currently 100 HOPE treated liver transplanted patients with an overall tumor censored 5y graft survival of 89%. Based on recent reports on mitochondrial

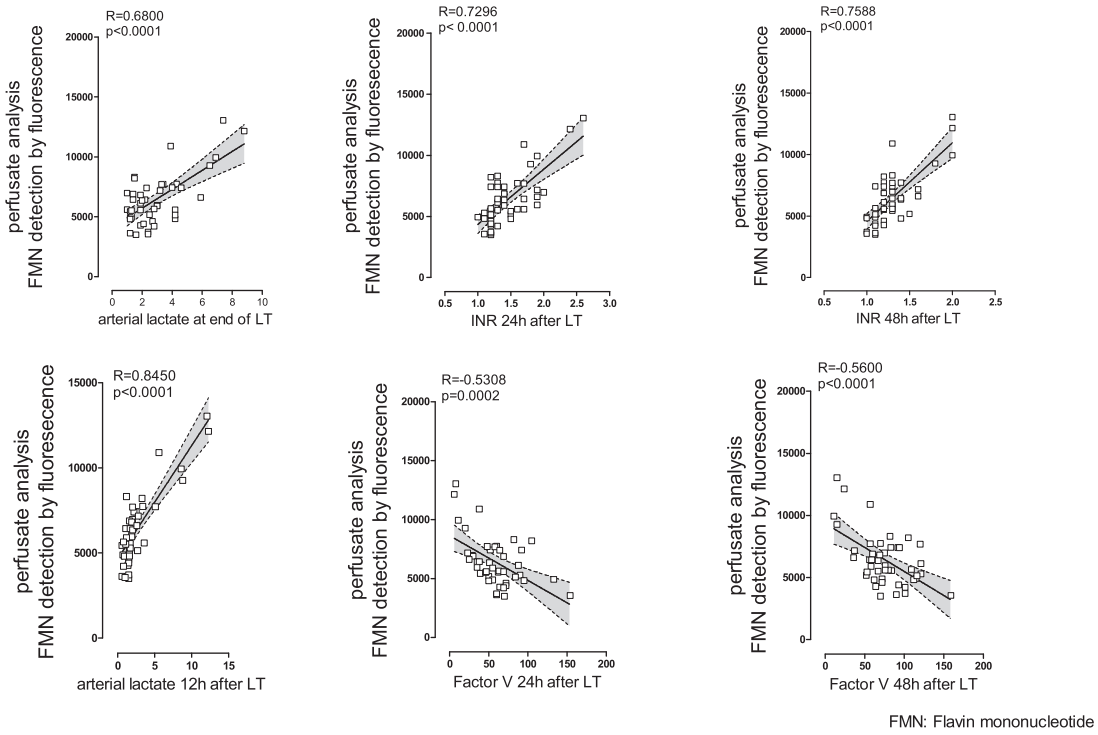

Figure: (abstract: PS-168) Prediction of graft function by machine perfusate analysis during HOPE.

metabolism, suggesting injury of mitochondrial complex I during re-oxygenation after ischemia, we monitored fifty livers during HOPE by fluometric analysis of released mitochondrial flavoproteins (flavin mononucleotide, FMN) in the machine perfusate. In detail, monochromal light with a wavelength of 450 nm was introduced to machine perfusate, and a spectroscopic detector quantified the proportion of fluorescent light, emitted at 90°. The peaks detected at a wavelength between 500 and 600 nm correspond to the emission spectrum of FMN, validated by additional NMR analysis. Perfusate measurements were correlated to liver graft function after transplantation, as determined by arterial lactate clearance, INR, factor V synthesis, and the L-GrAFT risk score (Agopian et al, 2018).
Correlation between fluometric perfusate analysis and liver graft function was calculated using Pearson's correlation coefficient. Reference values for strength of effect size were: "very weak" 0.00-0.19, "weak" 0.20-0.39, "moderate" 0.40-0.59, "strong" 0.60-0.79 and "very strong" 0.80-1.0.
Results: Real time optical measurement of mitochondrial FMN release in machine perfusates of fifty livers correlated strongly with lactate clearance and coagulation factors at day 1 and 2 after transplantation (Figure 1). Receiver operating characteristic curve analysis revealed an area under the curve (AUROC) of 0.80 (95% CI 0.67-0.93) for allograft dysfunction.
Conclusion: We demonstrate for the first time an accurate and fast prediction of liver graft function during ex situ machine perfusion before implantation, based on determining the level of mitochondrial complex I injury.
We expect a high clinical relevance of our results, as liver grafts from extended DBD or DCD donors potentially carry considerable risks for recipients. On-line estimation of outcome before implantation would therefore substantially increase safe utilization of liver grafts.

PS-169

Umbilical cords-derived mesenchymal stem cells ameliorated hepatocellular apoptosis mediated by PINK1-dependent mitophagy in liver ischemia/reperfusion injury dependent on AMPKα activation

Jun Zheng[1], Liang Chen[1], Jianye Cai[1], Jia Yao[1], Tongyu Lu[1], Xiaomei Zhang[1], Yingcai Zhang[1], Yang Yang[1]. [1]*Organ Transplantation Institute, Department of Hepatic Surgery and Liver Transplantation Center of the Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*
Email: yysysu@163.com

Background and aims: Hepatocyte apoptosis is a main pathophysiological process that underlies liver ischemia/reperfusion (I/R) injury. Mitochondrial abnormalities play a vital role in hepatocellular damage. It is well acknowledged the beneficial effects of umbilical cords-derived mesenchymal stem cells (UC-MSCs) on hepatocellular protection in response to liver I/R injury. However, the mechanism underlying these phenomena is still not fully clear.
Method: In the present study, a model of 70% liver I/R injury was used in vivo. UC-MSC (1×10^6 per mouse) was intravenously infused to the liver I/R injury mice. Hepatocellular anoxia/reoxygenation (A/R) model was established to mimic liver I/R injury and incubated with UC-MSCs conditioned medium (UC-MSCs-CM) for in vitro analyses.
Results: Mitochondrial dysfunctions of hepatocytes were observed in mice suffering from liver I/R injury, including mitochondrial reactive oxygen species (mtROS) overproduction, accumulation of mitochondrial fragmentation, lower ATP production and defective mitophagy. Meanwhile, along with reduced the protein expression of Parkin and PINK1, phosphorylated AMPKα (p-AMPKα) was dramatically downregulated. Loss of p-AMPKα was associated with ULK1 dephosphorylation and mTOR phosphorylation. These pathological changes were revered following a peripheral venous transfusion of UC-MSCs (1×10^6 per mouse). To validation, our results showed that the hepatocellular protective roles of UC-MSCs were abolished after added with 3-methyadenine (3-MA), an autophagy inhibitor, or

dorsomorphin, an AMPK antagonist, respectively. Furthermore, we used L02 hepatocyte line anoxia/reoxygenation (A/R) model to mimic liver I/R injury in vitro. UC-MSCs conditioned medium (UC-MSCs-CM) suppressed hepatocellular apoptosis and inhibited mtROS accumulation in the A/R environment. The reduced Parkin and PINK1 as well as suppressed PINK1-dependent mitophagy noted in L02 cells subjected to A/R condition were restored partially after L02 cultured with UC-MSCs-CM. And the effects of UC-MSCs-CM on cellular protection and induced mitophagy in L02 were weakened after L02 transfected with PINK1 siRNA or treated with dorsomorphin.

Conclusion: These results explored that UC-MSCs played beneficial effects on hepatocellular protection in liver I/R injury via PINK1-dependent mitophagy through activating AMPKα.

PS-170

A trend towards a lower patient survival is observed when either NAT+ve or NAT-ve donors with positive HCV Ab are transplanted into HCV negative recipients

Paul J. Thuluvath[1], Yulia Savva[2], David Bruno[3]. *[1]Mercy Medical Center and University of Maryland School of Medicine, Baltimore, United States; [2]Mercy Medical Center, Baltimore, United States; [3]University of Maryland School of Medicine, Baltimore, United States*
Email: thuluvath@gmail.com

Background and aims: The proportion of HCV RNA positive cadaver organs has increased (~15%) due to the opioid crisis in the USA. Recently it has been suggested that HCV RNA positive organs could be safely transplanted into HCV RNA negative recipients because of the availability of safer and highly efficacious DAA regimens. The modeling studies have claimed benefits with this strategy, but the real life data are very limited. The objective of our study was to determine whether there were graft and patient survival when HCV negative patients received HCV RNA (NAT+ve) positive liver grafts.

Method: We queried UNOS data sets from 2015-2018 and stratfied recipients into 5 groups based on the status HCV anitbody and RNA of recipient and donors (donor HCV RNA status was determined by NAT and data collected since 2015). During the study period, 957 recipients received NAT positive liver grafts, but of these only 45 RNA negative recipients received NAT+ grafts. During the same period, 487 anibody positive but NAT -ve grafts were transplanted into 386 HCV positive and 101 HCV negative recipients.

Results: Important characterisitics of recipients and donor are shown in the table below. MELD scores were higher in HCV negative recipients who received grafts from HCV positive donors (NAT +ve or -ve). There were no differences (p = 0.33) in survival in HCV positive recipients whether they received NAT positive (n = 912) or HCVAb and NAT negative (n = 5310) grafts (Figure 1). There was a lower survvial (p = 0.011) when HCV negative recipients (n = 101) received HCV Ab +ve/NAT -ve grafts (Figure 2) as compared to HCV postive recipients (n = 4924) receiving HCVAb -ve/NAT -ve grafts. Survival was also lower (p = 0.002) when HCV negative recipients (n = 101) received HCV Ab +ve/NAT -ve grafts when compared to HCV positive patients (n = 386) receiving similar grafts (Ab +ve/NAT-ve) (Figure 3). Survival was also lower (p = 0.03) when HCV negative recipients (n = 45) received NAT positive grafts as compared to HCV positive patients (n = 912) receiving NAT positive grafts (Figure 4).

Variable	Donor NAT+ Recipient HCV+	Donor NAT+ Recipient HCV-	Donor Ab+ and NAT-v Recipient HCV+	Donor Ab+ and NAT-v Recipient HCV-	Donor Ab and NAT- Recipient HCV+
N	912	45	386	101	4924
Mean Age (SD)	59.0 (6.7)	52.4 (12.7)	59.5 (6.3)	56.5 (11.3)	59.1 (7.1)
Dialysis (%)	142 (15.6)	5 (11.6)	33 (8.6)	6 (5.9)	585 (11.9)
MELD (SD)	18.4 (7.9)	23.5 (8.4)	17.7 (7.5)	23.5 (8.2)	19.2 (11.1)
DRI (SD)	1.64 (0.39)	1.6 (0.28)	1.72 (0.42)	1.84 (0.46)	1.77 (0.43)

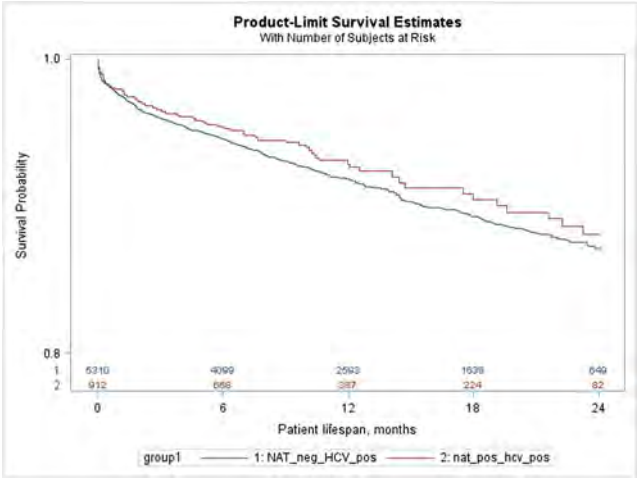

Figure 1

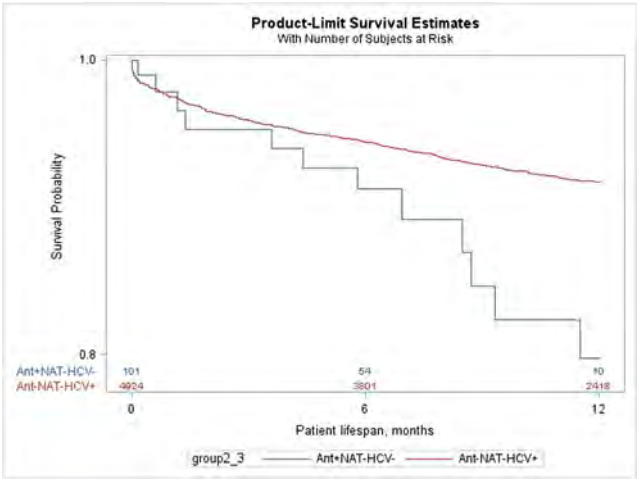

Figure 2

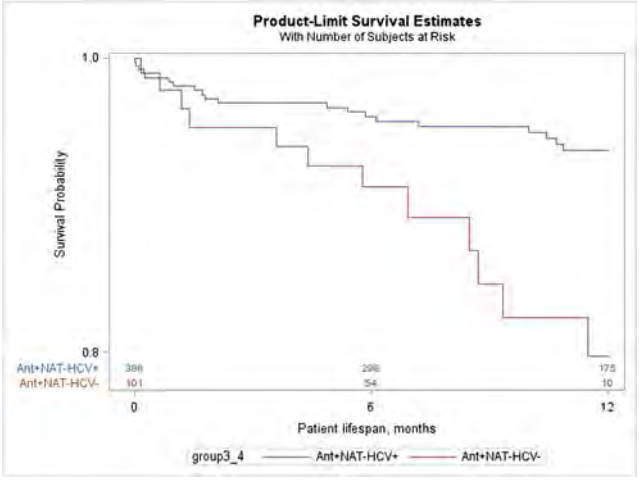

Figure 3

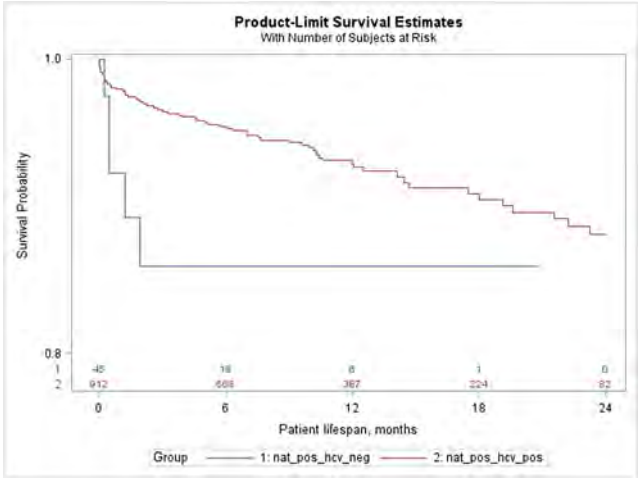

Figure 4

Conclusion: Early experience in HCV negative recipients receiving HCV positive liver grafts (antibody or NAT positive) suggests a trend towards a lower patient survival. This could be related to the higher risk profile of recipients, but caution should be exercised before routine transplant of liver grafts from HCV Ab +ve donors into HCV negative recipients.

Alcohol related liver disease

PS-171

Survival in a 10 year prospective cohort of heavy drinkers: Liver stiffness is the best long-term prognostic parameter

Johannes Mueller[1], Vanessa Rausch[1], Ines Silva[1], Teresa Peccerella[1], Felix Piecha[1], Christian Dietrich[1], Helmut-Karl Seitz[1], Sebastian Mueller[1]. [1]*Salem Medical Center and Center for Alcohol Research, University of Heidelberg, Heidelberg, Germany*
Email: sebastian.mueller@urz.uni-heidelberg.de

Background and aims: Alcoholic liver disease (ALD) is the most common liver disease in the western world. Although measurement of liver stiffness (LS) by transient elastography has been well established for early diagnosis of fibrosis, no prospective long-term data on survival exist so far in patients with ALD. We here present first data on the prognostic impact of LS on long-term survival of Caucasian heavy drinkers in a 10 year, prospective single center trial.
Method: Information of survival status was obtained in 675 (71.6%) of 943 screened patients that had presented for alcohol detoxification (6.0 days) over a 10-year period from 2007 to 2017 with a mean daily consumption of alcohol of 178 g. Mean observation time was 3.7 years and mean duration of heavy drinking was 14.0 years. All patients had LS measurements by transient elastography and routine laboratory tests.
Results: During the observation time, 106 patients (15.7%) died. The cause of death could be clarified in 42 patients (39%) and it was liver-related in 16 (38%). Overall death was highest associated with LS (r = 0.291, P = 1.3E-14), followed by hemoglobin and alkaline phosphatase (AP). In a multivariate proportional hazard model, LS next to age, AP and serum albumin was the most significant independent predictor of survival with a hazard ratio of 1.013 (1.003 to 1.023, P < 0.05). Using ROC analysis, LS was the best predictor of death in general with an AUROC of 0.72 and a cutoff value of 14.0 kPa, followed by AP and albumin. Moreover, LS was the top predictor of death starting from 2 to 5 years. In contrast, LS was preceded by bilirubin and albumin in predicting one-year-survival. AUROCs to predict death for 1, 3 and 5 years were 0.76, 0.74 and 0.73, respectively, with corresponding cut-off values (Youden index) of 26.3, 14.0 and 6.4 kPa, respectively. When stratifying patients according to standard LS cut-off values < 6 kPa, 6 to 12.5 kPa and > 12.5 kPa, the survival curves were significantly different (p < 0.0001), 3-year survival rate was 94%, 88% and 74% and 5-year survival rate was 90%, 78% and 64%, respectively.
Conclusion: We here identify LS as the best long-term prognostic parameter in patients who heavily consume alcohol. LS measurements should become an important parameter for the screening of alcoholics.

PS-172

Acute adipocyte death preferentially induces liver injury and inflammation via the activation of CCR2+ macrophages and lipolysis

Seung-Jin Kim[1], Dechun Feng[1], Adrien Guillot[1], Shen Dai[2], Fengming Liu[2], Seonghwan Hwang[1], Richard Parker[1,2,3], Wonhyo Seo[1], Yong He[1], Grzegorz Godlewski[4], Won-Il Jeong[1,2,3,4,5], Yuhong Lin[6], Xuebin Qin[2], George Kunos[4], Bin Gao[1]. [1]*Laboratory of Liver Diseases, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, United States;* [2]*Department of Neuroscience, School of Medicine, Temple University, Philadelphia, United States;* [3]*NIHR Centre for Liver Research, University of Birmingham, Birmingham, United Kingdom;* [4]*Laboratory of Physiologic Studies, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, United States;* [5]*Laboratory of Liver Research, Biomedical Science and Engineering Interdisciplinary Program, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Rep. of South;* [6]*Laboratory of Membrane Biochemistry and Biophysics, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, United States*
Email: bgao@mail.nih.gov

Background and aims: Adipocyte death occurs under various physiopathological conditions, including obesity and alcohol drinking, and can trigger organ damage particularly in the liver, but the underlying mechanisms remain obscure. The aim of this study was to evaluate the pathological role of adipocyte death *in vivo* by using a model of acute adipocyte death in mice.
Method: To explore these mechanisms, we developed a mouse model of inducible adipocyte death by overexpressing the human CD59 (hCD59) on adipocytes (adipocyte-specific *hCD59* transgenic mice).
Results: Injection of these mice with intermedilysin (ILY), which rapidly lyses hCD59 expressing cells exclusively by binding to the hCD59 but not mouse CD59, resulted in the acute selective death of adipocytes, adipose macrophage infiltration, and elevation of serum free fatty acid (FFA) levels. ILY injection also resulted in the secondary damage to multiple organs with the strongest injury observed in the liver, with inflammation and hepatic macrophage activation. Mechanistically, acute adipocyte death elevated epinephrine and norepinephrine levels and activated lipolysis pathways in adipose tissue in a CCR2+ macrophage-dependent manner, which was followed by FFA release and lipotoxicity in the liver. Additionally, acute adipocyte death caused hepatic CCR2+ macrophage activation and infiltration, further exacerbating liver injury.
Conclusion: Acute and selective adipocyte death predominantly induces liver injury and inflammation, which is probably due to the superior sensitivity of hepatocytes to lipotoxicity and the abundance of macrophages in the liver.

PS-173

Differential contribution of RIP3-mediated cell death in alcohol and non-alcohol related liver disease

Xiaoqin Wu[1], Jeanette Wat[1], Megan McMullen[1], Sanjoy Roychowdhury[1], Laura Nagy[1]. [1]*Cleveland Clinic, Cleveland, United States*
Email: len2@po.cwru.edu

Background and aims: Hepatocellular death is associated with the progression of both alcohol (ALD) and non-alcohol related liver

disease (NAFL/NASH); however, the pathogenic contributions of individual pathways of programmed cell death are not well understood. RIP3 kinase is a critical mediator of necroptosis, a regulated pathway of cell death. Recent data indicate that RIP3 kinase differentially contributes to liver injury in murine models of ALD and NAFL/NASH; *Rip3*-/- mice are protected from chronic ethanol-induced liver injury, but not high fat diet-induced liver injury. RIP3 contains two functional domains, a serine-threonine kinase domain and a RHIM domain that mediates interactions with other RHIM containing proteins; emerging evidence suggests that there are domain-specific functions for both the kinase and RHIM domain. Therefore, we tested the hypothesis that the kinase domain of RIP3 would differentially contribute to liver injury in murine models of ALD and NAFL/NASH.

Method: RIP3 kinase dead knock-in mice ($Rip3^{K51A/K51A}$) and wild-type controls were exposed to ethanol (chronic ethanol feeding or Gao-binge acute on chronic ethanol) or a diet high in fat, fructose and cholesterol (Western diet). All mice were on a C57BL/6J background.

Results: Interestingly, $Rip3^{K51A/K51A}$ mice were protected from Western diet-induced liver injury and inflammation, but not ethanol-induced liver injury. $Rip3^{K51A/K51A}$ on the Western diet gained weight at an equal rate to wild-type mice, but serum ALT and AST levels and hepatic triglycerides were reduced. Interestingly, inflammatory cytokine expression was still increased in the $Rip3^{K51A/K51A}$ mice in liver, but reduced in adipose tissue. In contrast, serum ALT/AST, hepatic triglycerides and inflammatory cytokine expression remained elevated in $Rip3^{K51A/K51A}$ on the ethanol diets.

Conclusion: Taken together, these data indicate that RIP3 plays a differential role in Western diet- versus ethanol-induced liver injury. In models of ALD, RIP3-mediated injury was independent of RIP3 kinase activity, while RIP3 kinase activity contribute to Western diet induced liver injury.

PS-174

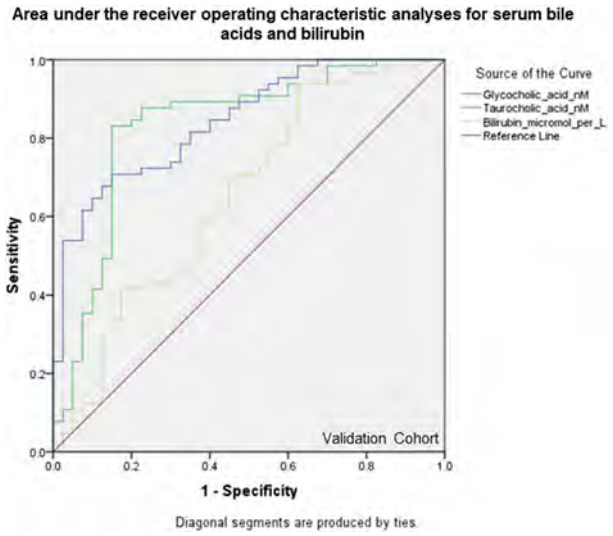
Serum bile acid profiles distinguish severe alcoholic hepatitis from decompensated alcohol-related cirrhosis

Luke D. Tyson[1,2], Stephen Atkinson[2], Alexandros Pechlivanis[2], Elaine Holmes[2], Nikhil Vergis[2], Rooshi Nathwani[2], James Maurice[2], Simon Taylor-Robinson[1,2], Benjamin H. Mullish[2], Roger Williams[3], Mark J W McPhail[4], Vishal Patel[3,4,5], Mark Thursz[1,2]. [1]*Imperial College Healthcare NHS Trust, London, United Kingdom;* [2]*Imperial College London, London, United Kingdom;* [3]*Institute of Hepatology, Foundation for Liver Research, London, United Kingdom;* [4]*Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom;* [5]*School of Immunology and Microbial Sciences, King's College London, London, United Kingdom*
Email: luke.tyson@nhs.net

Background and aims: Alcoholic hepatitis (AH) is characterised by recent onset jaundice in patients with ongoing alcohol misuse. Distinguishing AH from decompensated alcohol-related cirrhosis (DC) guides rational use of prednisolone but can be challenging. Demonstration of steatohepatitis on liver biopsy remains the gold standard. Liver biopsy is not universally available and both biopsy and prednisolone are associated with complications. Differences in the serum bile acid (BA) profiles of patients with AH and DC have been reported. The aim of this study was to determine whether serum BAs can non-invasively discriminate between AH and DC.

Method: Serum BAs were measured by ultraperformance liquid chromatography-mass spectrometry in exploratory and validation cohorts. Patients with AH had a Maddrey's Discriminant Function (DF) > 32 and steatohepatitis on liver biopsy. The exploratory cohort comprised 68 patients with AH (median Model for End-stage Liver Disease score, MELD, 23) and 21 with DC (defined as MELD > 18; median 26); the validation cohort comprised 65 patients with AH (median MELD 25) and 40 with DC and jaundice (defined as bilirubin > 80 micromol/L and DF > 32; median MELD 30). Mean age was 49 years; 69% were male. Data was analysed by orthogonal projection to least squares discriminant analysis (OPLS-DA) and area under the receiver operating curve (AUROC) analysis.

Results: OPLS-DA accurately discriminated AH from DC in both exploratory and validation cohorts. The AUROC for the full BA profiles was 0.93 (95%CI 0.87-0.99) and 0.93 (95%CI 0.88-0.98) respectively. Model diagnostics identified glycocholic (GCA) and taurocholic (TCA) acid as dominant metabolites. The AUROC for serum GCA was 0.90 (95%CI 0.83-0.97) in the exploratory and 0.85 (95%CI 0.77-0.92) in the validation cohorts. The AUROCs for TCA were 0.87 (95%CI 0.77-0.97) and 0.83 (95%CI 0.74-0.92). Both performed better than bilirubin (AUROC 0.79 (95%CI 0.67-0.91) and 0.65 (95%CI 0.54-0.76) respectively). In the validation cohort, TCA concentration more than or equal to 8300 nM had a sensitivity and specificity for AH of 83% and 85%.



Conclusion: AH has a serum BA profile distinct from patients with DC and similar liver dysfunction and jaundice. The discriminatory performance of both the entire bile acid profile and individual bile acids (GCA and TCA) indicates that they are promising non-invasive biomarkers for severe AH and may reduce the need for liver biopsy.

PS-175

The burden of alcoholic cirrhosis is critically increasing in Canada: A population-based study

Hassan Azhari[1], Jason Jiang[1], Mark G Swain[1], Abdel-Aziz Shaheen[1]. [1]*University of Calgary, Gastroenterology and Hepatology, Calgary, Canada*
Email: azshaheen@me.com

Background and aims: Alcohol is one of the most common causes of cirrhosis. Over the last two decades, efforts to increase awareness of heavy drinking and improve access to care for alcoholic cirrhosis patients have been implemented. However, the impact of these efforts on the natural history of alcoholic cirrhosis have not been fully evaluated. Therefore, we undertook this study to evaluate changes in the epidemiology of alcoholic cirrhosis in Alberta, Canada.

Method: We used validated codes to identify alcoholic cirrhosis (International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM): 571.2) in population-based administrative databases in Alberta, Canada (population ~4.3 million) from 2013-2017, with a washout period from 2009–2012. Multiple sources of data including inpatient, ambulatory care, and physician billing were linked. Annual prevalence and incidence were estimated using Poisson regression. Age/sex adjusted rate ratios were calculated. We used Kaplan-Meyer and Cox regression models to estimate all-cause mortality.

Results: During the study period, the overall annual age/sex adjusted alcoholic cirrhosis incidence was 38.9 cases per 100, 000 [23.2 (95%

CI: 22.4-24.1) and 55.6 (95%CI: 54.3-56.9) cases per 100, 000 for women and men, respectively], with a female to male incidence rate ratio (IRR) = 0.42 (95%CI: 0.37-0.48). The highest incidence rate was observed among men aged 40-59 (97.4 per 100, 000), with an IRR of 6.87 (95%: 6.78-6.96) compared to those aged ³ 80. While incidence rates remained stable across our study period (p = 0.37), prevalence rates increased significantly from 107.7 to 158.2 cases/100, 000 between 2013 and 2017 (p < 0.01). Prevalence rate was highest at 309.5 cases/100, 000 amongst men aged 60-79, with an IRR of 5.40 (95%: 5.31-5.49) compared to those aged ³ 80. During the study period we identified 5811 incident alcoholic cirrhosis cases, with a median age of 56 years (IQR 48-63) and 69.8% (n = 4053) were men. The age/sex standardized mortality rate was 13.1 per 100, 000 (95%CI: 12.5-13.7). Survival rates at 1, 3, and 5 years were 66.9% (95% CI: 65.6- 68.2), 60.7% (95%CI: 59.3-62.2), and 55.1% (95%CI:53.5-56.7) respectively, with 73% of our incident cohort presenting with decompensated cirrhosis at time of index diagnosis.

Conclusion: We report an increasing prevalence of alcoholic cirrhosis in this large representative Canadian population. Risk of developing alcoholic cirrhosis is highest among middle-age men, and the societal burden of alcoholic cirrhosis is significant with poor survival rates due to late diagnosis. Better surveillance, early detection of alcoholic liver disease patients, and the development of effective health care practices are warranted to facilitate preventative measures and avoid alcoholic liver disease and late diagnosis.

Background and aims: Hyperoxidized albumin promotes inflammation in severe alcoholic hepatitis (SAH). However its contribution in platelet activation, alteration of platelet phenotype and linked functions is yet not known.

Method: To explore 50 SAH patients, 20 alcoholic cirrhosis (AC) and 20 healthy controls (HC) were studied. Quantitative platelet proteomics in SAH was compared to HC (discovery), which led to the characterization of platelet phenotype (GO, KEGG, blood transcription modules-BTMs). Key dysregulated pathways were validated in a separate cohort of (n = 40) SAH patients. Platelets functions were correlated to severity of SAH. Causality of platelet activation/dysfunction was determined by in-vitro treatment of healthy platelets with patient plasma, purified albumin from the study groups or *ex-vivo* modified albumin (human mercaptalbumin-HMA, human nonmercaptalbumin-HNA1 and HNA2) in the presence or absence of CD36 (receptor for oxidised albumin) blockade.

Results: Quantitative platelet proteomics identified 202 proteins upregulated and linked to platelet activation, complement regulation, lipid transportation whereas 321 downregulated proteins related to platelet haemostasis and coagulation (FC ± 1.5, p < 0.01). Blood transcriptome module enrichment (BTM) showed inflammatory phenotype of SAH platelet. Validation studies confirmed increase in platelet-activation (PAC-1, P-selectin), intracellular-Ca^{2+} and aggregation in SAH (p < 0.05). Transcripts linked to platelet activation were increased and directly correlated (r2 > 0.3); whereas transcripts linked to granular secretions were decreased and inversely correlated (r2 > –0.3, p < 0.05) with severity. In-vitro stimulation of healthy platelets showed enhanced activation with patient plasma or purified albumin treatment, blocking of CD36 blunted this effect (p < 0.05). *Ex-vivo* modified albumin (mainly HNA2 – 1 mg/ml) showed markedly high activation/aggregation and intracellular ROS production in healthy platelets (p < 0.05), which significantly reduced after CD36 neutralization.

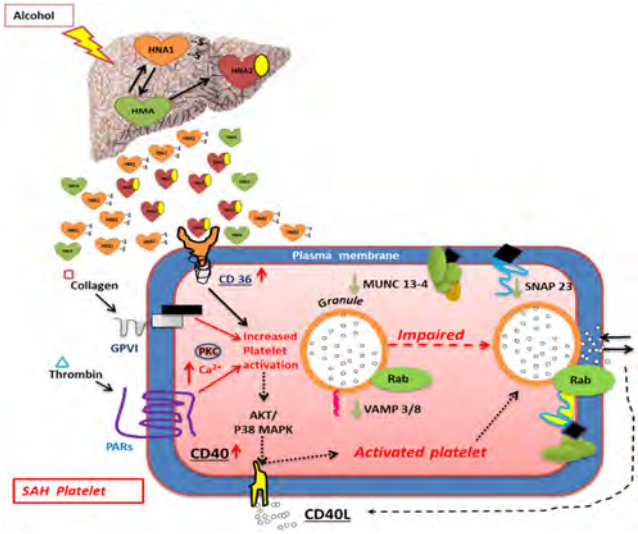

Figure: Proposed proinflammatory and prothrombotic platelet prototype in severe alcoholic hepatitis. Oxidised albumin majorly HNA2 over HNA1 promote platelet activation via scavenger receptor CD36. Platelet activation releases pro-inflammatory mediators, induces CD40L expression and ROS production in platelets per se to facilitate systemic inflammation in SAH.

Conclusion: Hyperoxidized albumin triggers platelet activation potentially through CD-36 receptor; promotes inflammation, oxidative-stress and may contribute to thrombotic events in SAH patients.

PS-177

HSD17B13 rs72613567 TA is associated with a reduced risk for developing hepatocellular carcinoma in patients with alcohol-related cirrhosis

Background and aims: Host genetic factors play an important role in the development of alcohol-related cirrhosis. Hepatocellular carcinoma (HCC) complicates the course of this disorder in approximately 20% of affected persons Variant rs738409 in *patatin-like phospholipase domain containing-3* (*PNPLA3*) is an established risk factors for the development of alcohol-related cirrhosis and HCC. Recently, a loss-of-function splice variant rs72613567:TA in the gene coding for hydroxysteroid 17-beta dehydrogenase 13 (*HSD17B13*) was reported to be associated with a reduced risk for developing cirrhosis in individuals with alcohol use disorders and non-alcoholic fatty liver disease (NAFLD). The aim of this study was to undertake a case control study to determine if carriage of *HSD17B13* rs72613567:TA is associated with a lower risk for developing HCC in patients with alcohol-related cirrhosis and whether it modulates the risk conferred by carriage of *PNPLA3* rs738409.
Method: The total study population comprised of 2202 individuals with alcohol-related cirrhosis recruited from Germany, Switzerland, Italy and United Kingdom. Of these 840 had HCC and were designated as cases whilst the remaining 1362 had no evidence of HCC and were considered as controls. Genomic DNA was extracted from whole blood and genotyped for risk variants in *PNPLA3* and *HSD17B13*. The associations between genotypes and the risk of developing HCC were analysed using multivariate logistic regression. Adjusted allelic and genotypic odds ratios were calculated. Gene-gene interaction was evaluated by including interaction terms to the regression model.
Results: The presence of HCC was inversely associated with carriage of allele rs72613567:TA in *HSD17B13* (OR 0.72 [CI 0.61 – 0.85], p = 1.00×10^{-4}) and positively associated with rs738409 G allele in *PNPLA3* (OR 1.83 [CI 1.60 – 2.09], p = 1.62×10^{-18}) when examined using an additive model and controlling for sex, age and country. The risk reduction in the development of HCC was evident in both heterozygous (OR 0.75; 95% [CI 0.61 – 0.93], P = 0.008) and homozygous carriers of rs72613567:TA (OR 0.47; 95% [CI 0.30 – 0.74], P = 0.001). The rs72613567-rs738409 SNP-SNP interaction term was not significant P = 0.12.
Conclusion: In patients with alcohol-related cirrhosis, carriage of *HSD17B13* rs72613567:TA is associated with a lower risk for developing HCC, independently of the increased risk conferred by carriage of *PNPLA3* rs738409. The HCC risk conferred of carriage on *PNPLA3* rs738409 was not attenuated by *HSD17B13* rs72613567:TA in this sample.

Hepatitis C – Treatment and resistance

Email: gdore@kirby.unsw.edu.au

Background and aims: Direct-acting antiviral (DAA) therapy for hepatitis C virus (HCV) infection has high efficacy and limited toxicity. We hypothesised that efficacy and tolerability of an 8-week glecaprevir-pibrentasvir regimen for chronic HCV would be equivalent with a simplified and standard treatment monitoring schedule.
Method: In this open-label randomised controlled trial, treatment-naïve adults with chronic HCV without cirrhosis were randomly assigned (2:1) to receive glecaprevir-pibrentasvir 300/120 mg once daily for 8 weeks administered with a simplified or standard monitoring strategy. Following screening, study visits occurred at baseline and post-treatment week 12 in the simplified arm, and at baseline, week 4, week 8, and post-treatment week 12 in the standard arm. Study nurse phone contact was at week 4 and week 8. Patients considered to require additional treatment adherence support were not eligible, including those reporting injecting drug use in the past 6 months. The primary end point was SVR12, with a non-inferiority margin for difference of 6% (lower bound of 95% confidence interval [CI] -6.0%).
Results: In total, 380 patients with chronic HCV were randomized and treated with glecaprevir-pibrentasvir in the simplified (n = 253) and standard (n = 127) arms. Overall, 60% were male, 48% genotype 1, 32% genotype 3, 7% HIV positive, and 10% on opiate agonist therapy. By intention-to-treat, SVR12 was 91% (95% CI 88%, 95%) in the simplified and 94% (95%CI 91%, 99%) in the standard arm (difference between arms, -3.2% [95%CI -8.5%, 2.0%]; p = 0.27) (Table). In the per-protocol population, SVR12 was 97% (95%CI 95%, 99%) in the simplified and 98% (95%CI, 96%, 100%) in the standard arm (difference between arms, -1.0% [95%CI -4.0%, 2.1%]; p = 0.57).

	Standard monitoring N = 127	Simplified monitoring N = 253
Outcome, n (%)		
SVR12	120 (94%)	231 (91%)
Virologic failure	2 (2%)	6 (2%)
Failure for other reasons		1 (0.5%)
Death	0	2 (1%)
Discontinuation	0	13 (5%)
Loss to follow-up	5 (4%)	
Safety parameters, n (%)		
Discontinuation due to adverse event	0	1 (0.5%)
Death	0	1 (0.5%)
Treatment emergent serious adverse event	0	3 (1%)
Related to treatment	-	0

Conclusion: Among patients with chronic HCV infection without cirrhosis, treatment with glecaprevir-pibrentasvir provided favorable virological outcomes and tolerability with a simplified monitoring schedule. Clinical judgement will be required to select patients without additional adherence or follow-up support needs.

PS-179

Analysis of long-term persistence of HCV resistance-associated substitutions within NS3, NS5A and NS5B in genotype 1 and 3 after DAA treatment failure

Email: julia.dietz@em.uni-frankfurt.de

Background and aims: Treatment of chronic hepatitis C virus (HCV) infection direct acting antivirals (DAAs) is highly effective. Virologic failure is associated with the selection of HCV resistance-associated substitutions (RASs) in the majority of patients. Persisting RASs are largely unknown and have implications for a retreatment especially in countries without available multiple target retreatment options. This study investigated the long-term kinetics of RASs in genotypes (GT) 1 and 3 after a DAA-failure.

Method: Samples were obtained from the European Resistance Database containing samples of 1080 DAA failure patients. We analyzed a subgroup of 468 GT1- or GT3-infected patients with a documented sampling time after end of treatment (EOT), including sequential samples of 127 patients. NS3, NS5A and NSB5 genes were sequenced population based and RASs conferring a > 2-fold increased DAA susceptibility were analyzed.

Results: Patients have failed to grazoprevir/elbasvir (n = 10, 2%), simeprevir (SMV)/sofosbuvir (SOF) (n = 43, 9%), 3D (paritaprevir/ombitasvir/dasabuvir) (n = 73, 16%), ledipasvir (LDV)/SOF (n = 196, 42%), daclatasvir (DCV)/SOF (n = 97, 21%) or velpatasvir (VEL)/SOF (n = 49, 10%). At end-of-treatment (EOT), NS3 RASs were present in 69% of GT1-infected patients, however vanished fast until follow-up (FU) month (mth.) 12 and were only detectable in 30% of patients anymore. In SOF-experienced patients, NS5B nucleotide inhibitor RASs were rare and S282 T was observed in one individual with GT3 at FU3 and was not detectable anymore thereafter. NS5B non-nucleoside inhibitor RASs were detected in 72% of patients with GT1 at EOT and RASs declined to 59% in patients until FU12. NS5A inhibitor failures harbored high rates of RASs at EOT reaching frequencies of > 90% in GT1 and GT3. At FU12, the rates of RASs were stable with prevalences of 90% in subtype 1b and GT3, while in subtype 1a NS5A RASs already declined to frequencies of 76%. At FU24, RAS further declined to frequencies of 72% in subtype 1a and at this time point first signs of vanishing NS5A RAS were observed in GT3 as well, as RASs were detected in 78% of patients anymore. However, in subtype 1b the frequencies of NS5A RASs remained stable and were still detectable at FU24 in 90% of patients.

Conclusion: NS3 and NS5B RASs vanished fast during the first 12 months after EOT. High rates of persisting NS5A RASs were detected in subtype 1b 24 months after EOT, while they started to disappear in subtype 1a and GT3.

PS-180

ns5a resistance profile of genotype 1b virological failures that impacts outcome of re-treatment by glecaprevir/pibrentasvir: Nation-wide real world study

Masayuki Kurosaki[1], Jun Itakura[1], Namiki Izumi[1]. *[1]Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Tokyo, Japan*
Email: kurosakim@gmail.com

Background and aims: Resistance-associated substitutions (RAS) are generated in chronic hepatitis C patients who failed direct-acting antiviral (DAA) treatment. Especially, RAS in NS5A may affect the efficacy of re-treatment since NS5A inhibitor is included in all available DAA regimens. This study examined the prevalence and specific pattern of NS5A RAS in patients who failed prior DAA and its impact on the efficacy of re-treatment by Glecaprevir (GLE)/Pibrentasvir (PIB) in the real-world.

Method: This nation-wide study involved 83 regional core centers for the treatment of liver disease and related hospitals. A total of 1, 420 genotype 1 patients who failed DAA treatment were registered, and RAS in NS3 and NS5A after virological failure was determined by population sequencing. The prevalence and patterns of NS5A RAS in these patients was compared to 1, 068 patients who are naïve to DAA. Association between RAS and sustained virologic response was analyzed in 545 patients who started re-treatment by GLE/PIB for 12 weeks.

Results: Among DAA failed patients, 83% of patients had failed 1 DAA regimen, 15% had failed 2 DAA regimens, and 2% had failed 3 DAA regimens. Daclatasvir (DCV)/Asunaprevir (ASV) was the most frequently used regimen (84%), followed by Ledipasvir (LDV)/Sofosbuvir (SOF) (13%) and Grazoprevir (GZR)/Elbasvir (EBR) (2%). The prevalence of NS3 RAS at positions 156 and 168, and NS5A RAS at positions 31, 32 and 93 was significantly high in DAA failed patients compared to DAA naïve patients. Dual RAS in NS3 plus NS5A was detected in 35% of DCV/ASV failed patients and in 20% of GZR/EBR failed patients. The prevalence of dual RAS in NS3 plus NS5A increased in parallel with the number of courses of prior DAA: 34% in 1 course of DAA failure, 55.3% in 2 courses of DAA failure and 86.7% in 3 courses of DAA failure. Among NS5A RAS, P32deletion was not found in any DAA naïve patient but was detected in 3.7%, 2.0%, and 4.3% of patients who failed prior DCV/ASV, LDV/SOF, and GZR/EBR, respectively. In 545 patients re-treated by GLE/PIB for 12 weeks, HCVRNA was negative at the end of treatment in 99.2% of patients (371/374), and SVR12 was 95.8% (227/237). The presence of any NS3 RAS or NS5A RAS at position 31 and 93 did not impact SVR. However, SVR was 25% in patients with P32deletion RAS compared to 97% in patients with wild type P32 ($p = 0.0002$).

Conclusion: This nation-wide study revealed highly complex nature of RAS after DAA failure. Re-treatment by GLE/PIB was highly effective except for patients having unique RAS P32deletion in NS5A.

PS-181

Unacceptably low SVR rates in African patients with unusual HCV sub-genotypes : Implications for global elimination

Kate Childs[1], Chris Davis[2], Mary D Cannon[1], Matthew Bruce[1], Geoff Dusheiko[1], Emma Thomson[2], Kosh Agarwal[1]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]MRC-University of Glasgow Centre for Virus Research, Glasgow, United Kingdom*
Email: kate.childs@nhs.net

Background and aims: Worldwide elimination of Hepatitis C (HCV) is attainable, but relies on efficacious first line therapy. Rare subtypes are underrepresented in clinical trials but exist as prevalent polymorphisms in some regions. We describe the genotype

distribution and antiviral treatment outcome in a south London cohort of African pts.
Methods: We identified all pts attending our service from 2015-2018 who were born in Africa. Information on HCV genotype, treatment regimen and outcome was obtained. Samples were analysed locally by VERSANT HCV Geno 2.0 Assay. Non-subtypeable samples were then analysed using Glasgow NimbleGen next-generation sequencing (NGS).
Results: Of 91 African pts, 47 (52%) had an unusual genotype, which includes non-subtypeable G1, non 1a/1b G1 or non 4a/4d G4. Of non-subtypeable samples that underwent NGS, 17 were classified as highly divergent G1a (div1a). These were closest in genetic sequence to G1a but the median p-distance was (sequence diverged by) 10.8%. 46/51 (90%) pts achieved SVR, however, SVR was only seen in 19/26 (73%) of those with unusual G1 subtypes, with failure in 4/16 div1a and 3/4 in G1L. SVR failure was associated with unusual G1 subtype and NS5a rather than PI based treatment. Following retreatment, 1 patient with divG1a has failed to achieve SVR after 16 weeks G/P. 2 patients with G1L have achieved SVR with G/P.

Age	54 (47, 64)	
Gender	42/91 (46%) female	
HIV +	8 (9%)	
Cirrhosis	20/91 (21.9%)	
Country of birth	n	Genotype
Cameroon	9	1, div1a, 1b, 2x1e, 1l, 2, 4, 4f
Congo	7	2, 4, 4c, 3x4k, 4r
Cote D'Ivoire	4	1a, 3xdiv1a
Egypt	3	2x1g, 4
Eritrea	3	1a, 4a, 5a
Ghana	6	1a, 2xdiv1a, 2a/c, 4, 6
Nigeria	26	2x1a, 4xun1, 3x1b, 1c, 2x1g, 1h, 3x1l, 5xdiv1a, 3a, 3x4a, 4f
Other African countries	33	8x1a, 3xdiv1a, un1, 3x1b, 1l, 1e, 1b/2k, 2k, 2a, 2x3h, 4x4a, 4r, 4x4e

Conclusion: In an unselected cohort of African pts the majority (52%) had an unusual genotype. The SVR rate of those with unusual genotype 1 was 19/26 (73%). This is unacceptably low in the current era. This was driven by 6 failures in pts taking sofosbuvir/ledipasvir, compared with only 1 failure on a PI based regimen and raises concerns about the roll out of first generation NS5a inhibitor based schemes across Africa. Depending on the chosen regimen, failure rates in African cohorts could be higher than in clinical trials, jeopardising HCV elimination agendas.

PS-182

Effectiveness of elbasvir/grazoprevir in patients with hepatitis C virus genotype 1 infection who receive opioid agonist therapy: Treatment utilization and the impact of concomitant psychiatric medications

Jennifer Kramer[1,2], Amy Puenpatom[3], Yumei Cao[1], Hashem El-Serag[1,2], Fasiha Kanwal[1,2]. [1]*Center for Innovations in Quality, Effectiveness and Safety (IQuESt), Michael E DeBakey VA Medical Center, Houston, TX, United States;* [2]*Baylor College of Medicine, Department of Medicine, Houston, TX, United States;* [3]*Merck and Co., Inc., Kenilworth, NJ, United States*
Email: puenpatom.amy@merck.com

Background and aims: Elbasvir/grazoprevir (EBR/GZR) for 12 weeks is an effective treatment for patients with hepatitis C virus (HCV) genotype (GT) 1 infection receiving opioid agonist therapy (OAT). This study assessed the real-world effectiveness of EBR/GZR in HCV GT1-infected patients receiving OAT.
Method: We conducted a nationwide retrospective observational cohort study of patients with chronic HCV infection in the US Department of Veterans Affairs who had received EBR/GZR for > 11 weeks between January 28, 2016, and August 31, 2017, and a diagnosis of opioid use disorder (ICD-10-CM code F11.x-) or ≥ 1 prescription for OAT (including methadone, buprenorphine, levomethadone, naloxone, and naltrexone) within 1 year prior to the index date through the end of treatment. Patients who had received buprenorphine transdermal patch, an undetermined HCV treatment regimen, or an NS5A inhibitor-containing regimen were excluded. SVR was defined as undetectable HCV RNA at ≥ 4 weeks after the end of treatment.
Results: 611 patients were included (male, 96%; black, 53%; mean age, 62 years), of whom 526 received EBR/GZR without ribavirin for 12 weeks and 85 received other EBR/GZR-based regimens. Forty-seven percent (n = 286) had GT1a and 50% (n = 303) had GT1b infection. Baseline viral load was < or ≥ 800, 000 IU/ml in 163 (27%) and 416 (68%) patients. Most patients were treatment-naive (n = 549, 90%), had chronic kidney disease stage 4–5 (n = 526, 86%), had received ≥ 1 OAT (59%; n = 363), had a history of alcohol abuse (77%; n = 471), had a history of drug abuse (90%; n = 548), or were receiving concomitant psychiatric medication (71%; n = 434). SVR was achieved by 586 of 611 patients (95.9% [95% confidence interval [CI], 94.0%, 97.3%), with high SVR rates in those who received EBR/GZR for 12 weeks (506/526, 96% [95% CI, 94.6%, 97.8%]). SVR in select subgroups is shown in the Figure.

SVR in select subgroups

Subgroup	n/N	SVR, % (95% CI)
Baseline viral load		
<800,000 IU/mL	156/163	96 (92.6, 98.8)
≥800,000 IU/mL	401/416	96 (94.6, 98.2)
HCV genotype		
GT1a	273/286	95 (93.0, 97.9)
GT1b	293/303	97 (94.7, 98.7)
Cirrhosis	205/216	95 (92.0, 97.8)
CKD stage 4–5	506/526	96 (94.6, 97.8)
History of alcohol abuse	455/471	97 (95.0, 98.2)
History of drug abuse	529/548	97 (95.0, 98.1)
Any concomitant psychiatric medication	417/434	96 (94.3, 97.9)
Benzodiazepines	60/61	98 (95.2, 100)
Mood stabilizer	184/192	96 (93.0, 98.7)
Antidepressant	327/342	96 (93.4, 97.8)
Antipsychotic	107/112	96 (91.7, 99.4)
Any OAT	343/363	94 (92.1, 96.8)

CKD, chronic kidney disease; GT, genotype; HCV, hepatitis C virus; OAT, opioid agonist therapy; SVR, sustained virologic response.

Conclusion: In this real-world population, EBR/GZR was highly effective in patients with HCV GT1 infection receiving OAT. SVR rates were consistently high regardless of baseline viral load, history of alcohol or drug abuse, or concomitant psychiatric medication.

PS-183

Association of patient-reported outcomes with cerebral metabolism in patients with chronic hepatitis C at baseline and post sustained virologic response

Leyla Deavila[1], Ali A Weinstein[2], Michael Curry[3], Maria Stepanova[4], Lynn Gerber[1,2], Zobair Younossi[1,5]. Email: zobair.younossi@inova.org

Background: CHC patients experience significant impairment of emotional health and fatigue as assessed by PROs, which improves after SVR.
Aim: We assessed association of PROs and cerebral metabolites prior to treatment and after SVR in CHC patients treated with ledipasvir/sofosbuvir (LDV/SOF).
Method: CHC patients with genotype 1 without cirrhosis (N = 40, age: 45.3 ± 11.5, 48% male, 90% white) received 12 weeks of LDV/SOF. Clinical, laboratory, and PRO data were collected. The PROs included Short-Form (SF-36), Chronic Liver Disease Questionnaire-HCV (CLDQ-HCV), and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) administered prior to treatment and after SVR-24. At the same time points, cerebral metabolism in the basal ganglia (BG) and frontal (FR) and dorsolateral prefrontal cortex (DL) was assessed using magnetic resonance spectroscopy (MRS). Metabolic markers measured included N-acetylaspartate (NAA), choline (Cho), and myoinositol (MI), in addition to Creatinine (Cr) as a control metabolite. Spearman's correlations between the PRO scores and the markers of cerebral metabolism were calculated.
Results: Of the entire cohort, 92% achieved SVR-24. Patients who achieved SVR experienced PRO improvement in 22 out of 26 calculated domains ($p < 0.05$). Prior to treatment, the ratio of MI in the BG was significantly and inversely correlated with Role Emotional of SF-36 ($r = -0.37$, $p = 0.02$). Similarly, the ratio of MI in the DL negatively correlated with Emotional Well-Being of FACIT-F ($r = -0.31$, $p = 0.05$). In contrast, post-SVR, the ratio of MI in the BG negatively correlated with different domains than at baseline, including Fatigue-FACIT-F and total CLDQ-HCV score ($r = -0.46$ and $r = -0.41$, both $p < 0.05$). Also, the ratio of MI in FR correlated with Emotional Well-Being-FACIT-F and Systemic Symptoms as measured by CLDQ-HCV ($r = -0.44$ and $r = -0.43$, both $p < 0.05$). Furthermore, post-SVR, the ratio of NAA in FR negatively correlated with Fatigue of FACIT-F, Emotional and total scores of CLDQ-HCV (r from -0.46 to -0.40, $p < 0.05$) while NAA in DL positively correlated with Bodily Pain-SF-36 ($r = 0.52$; $p < 0.01$). Lastly, choline metabolites in DL negatively correlated with Social Well-Being and total FACIT-F score ($r = -0.41$, $p < 0.05$).
Conclusion: Fatigue and emotional well-being PROs in CHC correlate with cerebral metabolites. This pattern changes after SVR, and may be related to viral clearance and changes in fatigue, pain and social well-being as assessed by PROs.

PS-184

Real-world effectiveness and safety of glecaprevir/pibrentasvir in adults with chronic hepatitis C virus infection: A meta-analysis

Markus Cornberg[1], Francesco Negro[2], Pietro Lampertico[3], Juan Turnés[4], Michael Curry[5], Ashley Brown[6], Heiner Wedemeyer[7], José Antonio Carrión[8], Nicole Wick[9], Andreas Pangerl[10], Lois Larsen[10], Yao Yu[10], Marcello Persico[11]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]University Hospital, Divisions of Gastroenterology and Hepatology and of Clinical Pathology, Geneva, Switzerland; [3]University of Milan, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy; [4]C.H.U. Email: andreas.pangerl@abbvie.com

Background and aims: Glecaprevir/pibrentasvir (G/P) is approved for adults infected with hepatitis C virus (HCV) genotypes 1-6. In clinical trials, G/P was associated with high rates of sustained virologic response at post-treatment Week 12 (SVR12) and was well tolerated. Currently, real-world evidence (RWE) regarding G/P use is being collected. A systematic review and meta-analysis of RWE reporting the effectiveness and safety of G/P were undertaken.
Method: Biosis, Derwent Drug File, Embase®, International Pharmaceutical Abstracts, Medline®, and SciSearch databases were searched using pre-defined terms for "G/P" and "RWE" to identify real-world prospective/retrospective studies (1 January 2017–15 October 2018) that reported SVR12 and/or safety parameters in HCV-infected adults ($N \geq 20$) treated with G/P. Congress presentations up to 12 November 2018 were included. Random effects meta-analysis was used to determine SVR12 and naïve pooling for adverse event (AE) rates. Intention-to-treat (ITT) SVR12 analyses included all patients dosed with G/P; modified ITT (mITT) excluded those who had non-virologic failure.
Results: 10, 048 adults treated with G/P in 16 studies were included; ITT SVR12 rates were reported in 14 studies and mITT SVR12 rates in 11 studies. SVR12 rates overall and by subgroups based on ITT and

mITT populations are shown (Table). AEs were summarised in 6 studies and reported in 12.7% (724/5685) of patients. Treatment discontinuations due to AEs were summarised in 5 studies and reported in 0.5% (24/4508) of patients. The most frequent AEs were pruritus (4.7%; 126/2698), fatigue (4.4%; 146/3305), and headache (2.7%; 102/3759). SVR12 and safety data will be updated in the final presentation.

Conclusion: Consistent with results observed in clinical trials, RWE indicates that G/P is a well-tolerated and highly effective pangenotypic treatment option for a broad range of HCV-infected patients.

Non-invasive assessment of liver disease

PS-185

Magnetic resonance risk score and liver stiffness by transient elastography have complementary prognostic values in patients with primary sclerosing cholangitis

Email: nora.cazzagon@gmail.com

Background and aims: Magnetic resonance (MR) risk scores and liver stiffness (LS) were previously shown to be associated with the clinical outcome in patients with primary sclerosing cholangitis (PSC)[1,2]. The aim of the current study was to assess the complementary value of the MR risk score without gadolinium[3] (Anali score without Gd) and LS to predict prognosis of PSC patients.

Method: Patients with large duct PSC from three European centers with three dimensional-MR cholangiography (3D-MRC) images available for central reviewing and a valid LS measurement assessed by Fibroscan performed within 6-month interval were included in a longitudinal retrospective study. Exclusion criteria consisted of decompensated cirrhosis, primary liver cancer, a history of acute cholangitis at study entry, PSC-autoimmune hepatitis variants. All 3D-MRC images were reviewed by two expert radiologists and the Anali score without Gd calculated according to the formula (1 × dilatation of intrahepatic bile ducts) + (2 × dysmorphy) + (1 × portal hypertension). The primary end point was survival without liver transplantation (LT) or cirrhosis decompensation. The prognostic value of LS and Anali score without Gd were assessed using Cox proportional hazard models.

Results: 162 patients were included. A total of 753 patient-years were available. Forty patients experienced an adverse outcome (4 LT, 6 liver-related deaths and 30 cirrhosis decompensations). LS and the Anali score without Gd were individually associated with the occurrence of an adverse outcome ($p < 0.001$ for both). Optimal prognostic thresholds were 10.5 kPa for LS and 2 for the Anali without Gd (Hazard Ratios: 2.07, $p = 0.03$ and 3.78, $p = 0.001$, respectively). The frequency of adverse outcomes according to the value of LS and Anali score without Gd was 8.3% in patients with LS ≤ 10.5 kPa and Anali ≤ 2, 24% in patients with LS > 10.5 kPa or Anali > 2 and 55% in patients with LS > 10.5 kPa and Anali > 2, respectively ($p = 0.001$). A significant difference in mean survival of these 3 subgroups of patients was observed (Log-Rank 26.8, $p < 0.001$) (Figure).

Conclusion: The combination of MR imaging and liver stiffness improves the stratification of PSC patients into groups with high, medium and low risk of developing adverse outcome.

Hodge[2], Federica Vernuccio[3], Claude Sirlin[4], Ahmed Ba-Ssalamah[2], Thomas Reiberger[1]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Department of Biomedical Imaging and Image-Guided Therapy, Vienna, Austria; [3]University of Palermo, Biomedical Department of Internal Medicine and Medical Specialties (Di.Bi.M.I.S), Palermo, Italy; [4]University of California, San Diego, Liver Imaging Group, Department of Radiology, La Jolla, United States*
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Non-invasive methods for stratifying the risks of first hepatic decompensation and mortality in patients with compensated (cACLD) and decompensated (dACLD) advanced chronic liver disease, respectively, might facilitate individualized therapy. In contrast to other MRI-based methods, the Functional Liver Imaging Score (FLIS) derived from the hepatobiliary phase (HBP) of gadoxetic acid-enhanced MRI (GA-MRI) does neither require tedious measurements or calculations, nor specific hard- or software, and thus, is easily applicable in clinical routine.
We aimed to investigate the predictive value of FLIS for hepatic decompensation and transplant-free survival in a large series of patients with chronic liver disease (CLD).
Method: Our study comprised 262 consecutive patients with CLD but without malignancy who underwent a standardized GA-MRI protocol. Two radiologists blinded to the clinical data evaluated the FLIS components (0-2points each) in the HBP 20min after contrast administration: (1) contrast enhancement and (2) excretion as well as (3) portal vein sign.
Patients were stratified into three groups according to FIB-4 and the history/presence of hepatic decompensation: non-advanced CLD (FIB-4 ≤ 1.45), cACLD (FIB-4 > 1.45), and dACLD. Within these strata, patients with FLIS indicative of poor (0-3points) and good (4-6points) liver function were compared.
Results: Intra- (κ = 0.983, 95% confidence interval [95%CI]:0.971-0.991) and inter-observer (κ = 0.893, 95%CI:0.864-0.916) agreement for FLIS was excellent.
Patients with non-ACLD (n = 56;0-3points:25%), cACLD (n = 110;0-3points:15%), and dACLD (n = 99;0-3 points:46%) were followed for a median of 40.7, 40.6, and 13.7months, respectively. As expected, patients with non-advanced CLD had a negligible risk of clinical events. In cACLD patients, the FLIS was independently predictive of hepatic decompensation (0-3vs.4-6points;adjusted hazard ratio [aHR]:3.724, 95%CI:1.098-12.635;*P* = 0.035;panel A). Moreover, a FLIS score of 0-3points emerged as an independent risk factor for transplant-free mortality in both cACLD (aHR:7.437, 95% CI:2.742-20.17;*P* < 0.0001;panel B) and dACLD patients (aHR:2.869, 95%CI:1.311-6.281;*P* = 0.008;panel C).
Conclusion: The FLIS is an easy-to-use and highly reproducible imaging biomarker for the development of first hepatic decompensation and mortality in patients with ACLD. Implementation of the FLIS into GA-MRI reports might refine prognostication, and thus, facilitate personalized medicine.

PS-187

Transient elastography is the most reliable non-invasive predictor of advanced liver fibrosis in fontan-associated liver disease: The VALDIG FONLIVER study

Luis Téllez[1], Payance Audrey[2], Valérie Paradis[2], Enrique Rodríguez-Santiago[3], Aurélie Plessier[2], Ana Clemente[4], Rafael Bañares[4], Dominique Valla[2], Agustin Albillos[3], PE Rautou[2]. *[1]Hospital Universitario Ramón y Cajal. CIBERehd., Gastroenterology and Hepatology, Madrid, Spain*
Email: luis.tellez@salud.madrid.org

Background and aims: Fontan surgery (FS) is a palliative treatment in congenital heart diseases with single ventricle physiology. FS creates a hemodynamic system characterized by systemic venous congestion and low cardiac output, which leads to liver damage in the long-term. Assessment of liver fibrosis is controversial in this setting, since transient elastography (TE) can overestimate liver stiffness due to sinusoidal congestion, and liver biopsy can be risky, particularly in patients on anticoagulation. Aim: To evaluate the accuracy of TE to assess advanced liver fibrosis in patients with FS.
Method: International, multicenter, observational, prospective and analytical study. 19 FS patients were evaluated by blood test, Fibroscan®, Doppler US, MRI/CT, liver biopsy and HVPG. Inclusion period: 01/01/2015-01/11/2018. All liver biopsy specimens were analyzed by expert pathologists who, as the TE operators, were blinded to clinical information. Only liver biopsy specimens ≥1.5cm and with ≥5portal tracts were accepted. Portal and sinusoidal fibrosis, periportal inflammation and sinusoidal dilation were evaluated. METAVIR and Congestive Hepatic Fibrosis Score (CHFS) were used to stage liver disease.
Results: (Median, range). 19 patients were included. In 16/19 (84%) there was some degree of fibrosis, being advanced (CHFS 3-4) in 9/19 (47%). Although liver stiffness was > 10kPa in all patients, those

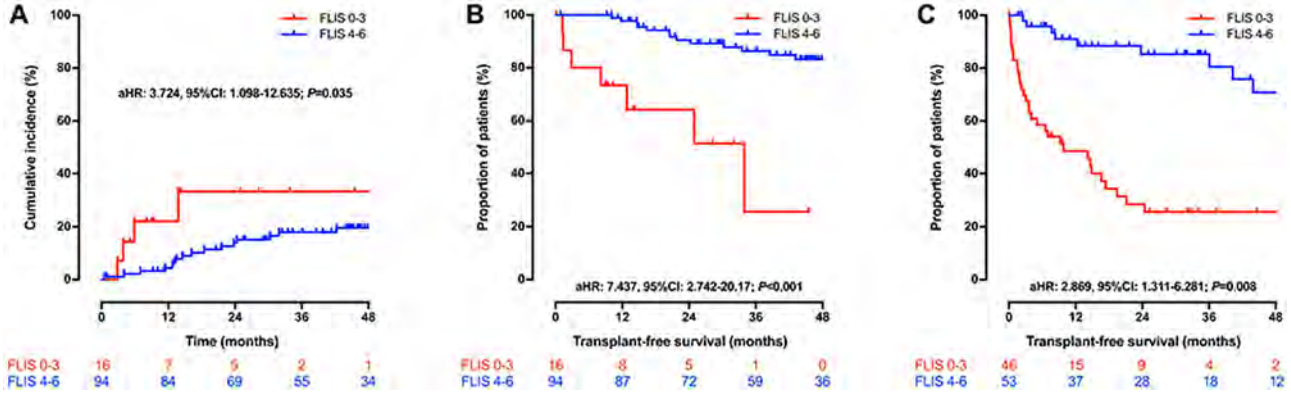

Figure: (abstract: PS-186)

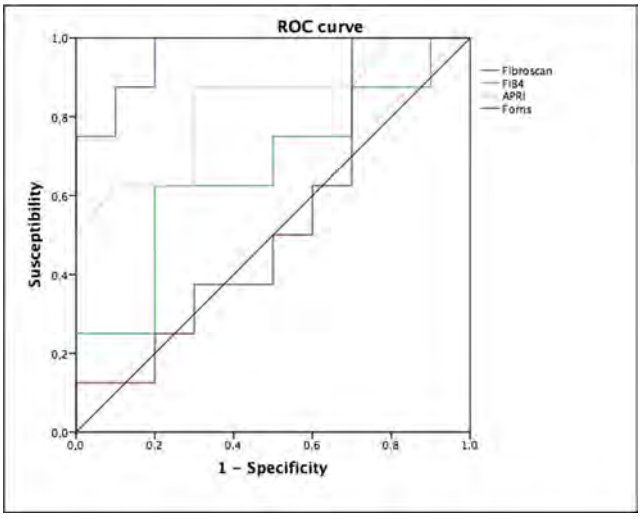
with mild fibrosis (CHFS 0-2) had lower stiffness than those with advanced fibrosis [15.8 (11.6-28.4) vs 48.9 (27.3-70.6)kPa, p < 0.001]. Liver stiffness correlated with the degree of portal fibrosis (rho = 0.74, p < 0.001), sinusoidal fibrosis (rho = 0.63, p = 0.004), METAVIR score (rho = 0.74, p < 0.001) and CHFS (rho = 0.82, p < 0.001). Wedged hepatic venous (rho = 0.52, p = 0.03) and inferior vena cava (rho = 0.59, p = 0.01) pressures, but not HVPG, correlated with sinusoidal fibrosis. Portal inflammation was minimal in 2/19 (11%) and absent in 89%. The presence of a heterogeneous hepatic parenchyma on US/reticular enhancement on MRI/CT were not associated with greater histological liver damage, although a nodular surface was associated with advanced fibrosis according to CHFS (p = 0.04). TE accurately discriminated between patients with mild fibrosis (CHFS 0-2) and those with advanced fibrosis (CHFS 3-4), with AUROC 0.96 (0.73-1.0, p < 0.001). When the best cut-off of 26.4kPa was used, the sensitivity was 100% and the specificity 80%. Among the other non-invasive methods analyzed (FIB-4, APRI and Forns), only APRI correlated with the severity of fibrosis (rho = 0.57, p = 0.01).



Conclusion: TE is the most reliable non-invasive method for the diagnosis of advanced liver fibrosis in FALD, and the best cut-off seems to be higher than in other etiologies. Radiological features and serological methods commonly used for the diagnosis of advanced fibrosis in other etiologies are suboptimal in FALD.

PS-188

A novel non-invasive technology for liver fibrosis detection

Hao Chen[1,1], Zhenyan Li[2], Sergey Klimov[1], Alton B. "Brad" Farris[3], Yi Jiang[1,1]. *[1]Georgia State University, Mathematics and Statistics, Atlanta, United States; [2]Shijiazhuang Fifth Hospital, Sjijiazhuang, China; [3]Emory University Hospital, Department of Pathology, Atlanta, United States*
Email: yijianggsu@gmail.com

Background and aims: Liver fibrosis results from chronic liver damage and is a significant public health problem. Early stages of liver fibrosis are difficult to diagnose [1]. While it has been well accepted that progression of hepatic fibrosis is strongly correlated with increasing rigidity of liver tissue [2], how fibrosis modifies the mechanical properties of liver and how that in turn affect the blood flow dynamics in the liver is still not understood. We hypothesize that tissue rigidity can affect the dynamics of blood flow and that non-invasive blood flow measurements can be used to detect fibrosis. The aims of this study is the test this hypothesis and develop a novel non-invasive method for liver fibrosis detection.
Method: A computational model of blood flow in portal and hepatic veins was developed to demonstrate the quantifiable modifications of flow dynamics as a function of fibrosis progression. Ultrasound Doppler measurements as well as ELF (enhanced liver fibrosis using Fibroscan®) were collected with the corresponding biopsy data from 200 patients with F0-F4, F0 indicating healthy people. Physics-based machine learning analysis of the Ultrasound Doppler images were trained to classify F1-F4 based on clinical biopsy staging. Leave-one-out method was used as validation.
Results: Mathematical modeling suggest that blood flow dynamics showed quantifiable differences for different stages of fibrosis, which is confirmed by ultrasound Doppler data. Our classification of Stage F0-F5 showed clear discrimination of fibrosis of all stages (Figure 1). Comparing our technology with existing non-invasive technology, e.g. ELF (enhanced liver fibrosis using Fibroscan®), our technology showed better specificity in differentiate early stage fibrosis (Table 1).

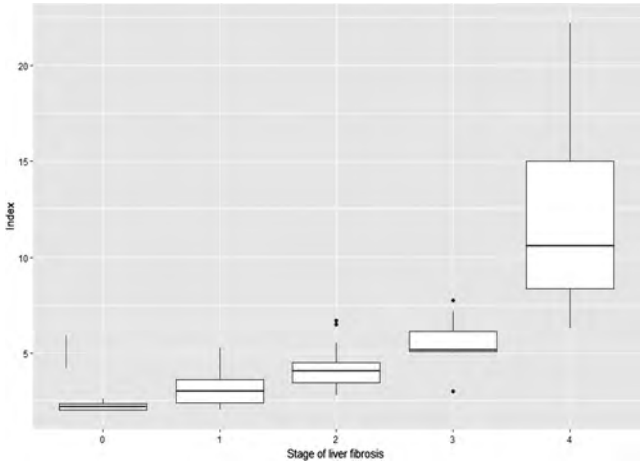


Figure 1. Stage liver fibrosis by Ultrasound Doppler measurement.

Health	Our Diagnostic Model	ELF(Fibroscan)
Sensitivity	94.12	92.7
Specificity	90.74	42.2
PPV	76.19	66.2
NPV	98	82.6

F1	Our Diagnostic Model	ELF(Fibroscan)
Sensitivity	68	62.3
Specificity	91.4	39.1
PPV	80.95	77.4
NPV	84.16	23.7

Table 1. Diagnostic performance for F0 and F1, very early stage fibrosis.

Conclusion: We have developed a series of mathematical models that showed the relationship between the liver stiffness and change in blood flow patterns in the hepatic veins. Analysis of clinical data from 200 patients confirmed that the blood flow patterns measured by the ultrasound Doppler Imaging can quantitatively reflect the fibrosis stage with high accuracy, even for early stage fibrosis.

PS-189

Toronto HCC risk index and albumin predict low risk of hepatocellular carcinoma after sustained virological response in hepatitis C infection

Jason Lau[1,2,2], Lisette Krassenburg[1,2,3], Wayel R. Zanjir[1], Firas Georgie[1], Orlando Cerocchi[1], Emily Stotland[1], Heidy Morales[1], Harry Janssen[1,2], Bettina Hansen[1,4], Jordan Feld[1,2]. *[1]Toronto General Hospital, Toronto Centre for Liver Disease, Toronto, Canada; [2]University of Toronto, Institute of Medical Science, Toronto, Canada; [3]Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [4]University of Toronto, Institute of Health Policy, Toronto, Canada*
Email: mr.lau@mail.utoronto.ca

Background and aims: Current guidelines recommend hepatocellular carcinoma surveillance for all F3/F4 after sustained virological response, however not all patients with advanced fibrosis are at

equally high risk of hepatocellular carcinoma. Hepatocellular carcinoma surveillance is unlikely to be cost effective if the incidence is below 1.3%/year. This study aimed to identify factors associated with a low enough risk of hepatocellular carcinoma post-treatment to forego hepatocellular carcinoma surveillance.

Method: Data were collected from the Toronto Centre for Liver Disease from 06/2006 to 10/2018 for all patients with advanced fibrosis (AST-to-platelet ratio index ≥ 1, FIB-4 ≥ 1.45, liver stiffness ≥ 9.5 kPa or biopsy ≥ F3) who achieved sustained virological response. Toronto HCC risk index combines age, sex, etiology, and platelet count to categorize patients with F4 as low (Toronto HCC risk index < 120), intermediate (Toronto HCC risk index = 120-240), or high hepatocellular carcinoma risk (Toronto HCC risk index > 240). Baseline patient data were collected at start of treatment and patients were followed from end of treatment until hepatocellular carcinoma occurrence, transplant, or death. Cox regression was used to identify factors associated with a low risk of hepatocellular carcinoma post-treatment.

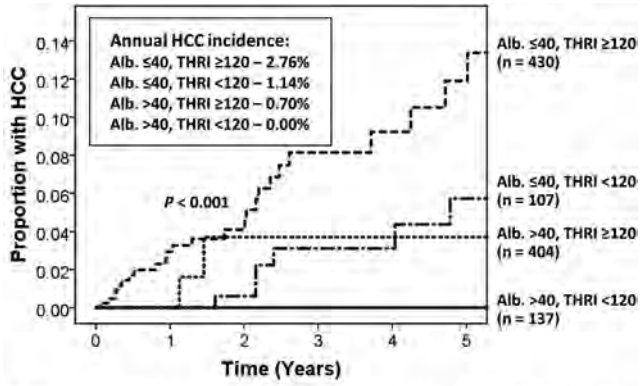

Figure 1. Albumin >40 g/L and Toronto HCC risk index (THRI) <120 independently predict low risk of hepatocellular carcinoma (HCC) after sustained virological response.

Results: Of 1, 093 F3/F4 patients who achieved sustained virological response, 397 (36.3%) received interferon-based and 696 (63.7%) received direct-acting antiviral therapy. Median age was 57.7 (IQR 52.1-63.1) years, 420 (38.4%) were female and 703 (64.3%) had cirrhosis. Patients were followed for median 1.4 (0.6-2.9) years: 4.1 (1.4-7.7) years for interferon patients and 1.0 (0.4-1.7) years for direct-acting antiviral patients. Forty-one (3.8%) patients developed hepatocellular carcinoma. By multivariable analysis, higher albumin and lower Toronto HCC risk index were associated with decreased hepatocellular carcinoma risk. Baseline albumin > 40 g/L (HR = 0.228 (0.101-0.516), P < 0.001) and Toronto HCC risk index < 120 (HR = 0.317 (0.098-1.029), P = 0.056) predicted a lower risk of hepatocellular carcinoma. Prognosis was improved in patients with albumin > 40 g/L or Toronto HCC risk index < 120, and best in patients with albumin > 40 g/L and Toronto HCC risk index < 120 (Fig. 1). Of 541 (49.5%) patients with albumin > 40 g/L, 7 (1.3%) developed hepatocellular carcinoma (incidence = 0.52% per person-year) and none of the 137 patients with albumin > 40 g/L and Toronto HCC risk index < 120 developed hepatocellular carcinoma.

Conclusion: Among hepatitis C patients with F3/F4 and sustained virological response, patients with baseline Toronto HCC risk index < 120 and albumin > 40 g/L have a very low risk of hepatocellular carcinoma. If confirmed with longer follow-up, hepatocellular carcinoma surveillance could be avoided in these individuals.

PS-190

Cirrhotic cardiomyopathy evaluated by myocardial deformation imaging and new diastolic dysfunction criteria: Prevalence and relationship with circulatory dysfunction

Juan Francisco Cueva[1], Trinidad Serrano[2], Isaac Lacambra[1], Alberto Lué[2], Daniel Abad[3], Luis Cortes Garcia[2], Sara Lorente[2].
[1]Hospital Clínico Universitario Lozano Blesa, Cardiology, Zaragoza, Spain; [2]Hospital Clínico Universitario Lozano Blesa. ISS Aragón, Liver Unit, Department of Gastroenterology, Zaragoza, Spain; [3]Hospital Clínico Universitario Lozano Blesa, Liver Unit, Department of Gastroenterology, Zaragoza, Spain
Email: jfcueva@salud.aragon.es

Background and aims: The prevalence of CCM is not well known due to the lack of a specific diagnostic test. In addition, it may vary depending on diagnostic criteria used. Myocardial strain imaging with speckle-tracking echocardiography (STE) is a new method that has been believed to be a sensitive marker of early subclinical systolic

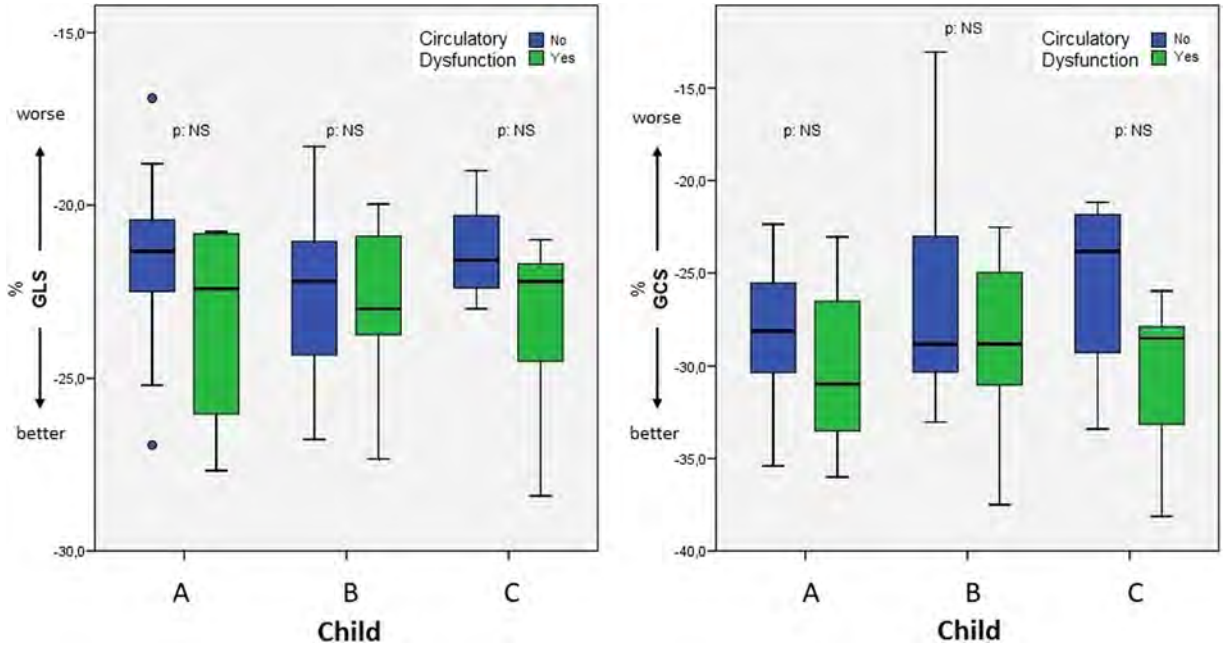

Figure: (abstract: PS-190)

impairment. However, studies are scarce and have shown variable results. The aim of this study was to investigate the prevalence of CCM evaluated by STE and its relationship with circulatory function.
Method: We conducted a prospective study enrolling patients with compensated and decompensated cirrhosis. Conventional and Tissue Doppler Imaging (TDI) echocardiography with myocardial deformation analysis (EPIQ7, QLAB v.10, Philips) were performed. Diastolic Dysfunction (DD) was assessed according to the latest defined criteria (Nagueh SF et al. 2016). Systolic function was estimate by STE with Global Longitudinal Strain (GLS, cut-off value: −20%) and Global Circumferential Strain (GCS, cut-off value: −22%). Plasma renin activity (PRA, cut-off value: > 4 ng/ml/hour) was determined as a surrogate of circulatory dysfunction (CD). Patients with structural heart disease and other cardiac conditions interfering with STE were excluded.
Results: A total of 88 subjects (male: 85%, age: 57, 5 ± 8, 2 years) were included. Child-Pugh class was distributed as follows: A, 31 (35.2%), B, 41 (46.6%) and C, 16 (18.2%). Alcoholic etiology was present in 58 cases (66.6%). Median MELD score was 13.4 ± 5.3. In ECG analysis, 11 (12.5%) subjects present QTc interval > 470ms. Regarding echocardiographic data, no patient was diagnosed of CCM by left ventricular (LV) ejection fraction, meanwhile, new criteria of DD identified 10 (11.3%) cases. GLS and GCS recognized CCM in 11 (12.5%) and 3 (3.4%) subjects, respectively. Prevalence of CCM did not differ between patients with or without decompensated cirrhosis (Child B-C: DD: 7/10 [70%] p:0, 17; GCS: 3/3 [100%] p:0, 19; GLS: 5/6[45, 5%] p:0, 15). Circulatory dysfunction was seen in 37 cases (42%), these patients showed better values of GLS and GCS but without statistical difference (Figure).
Conclusion: The prevalence of CCM is around 11-12% when the new diagnostic criteria are applied, lower than previously reported. STE did not show better diagnostic performance than DD. Circulatory dysfunction is likely to cause a compensatory increase of GLS and GCS, a hypothesis that requires further confirmation.

PS-191
External validation of an algorithm combining multi-analyte blood tests (FibroTest-LCR1-LCR2) for identifying subjects at risk of hepatocellular carcinoma among patients with chronic liver disease

Valentina Peta[1], Marianne Ziol[2], Imbert-Bismut Francoise[2], Angela Sutton[2], Mona Munteanu[1], Frederic Charlotte[2], Olivier Lucidarme[2], Tam Pham[1], Olivier Scatton[2], Yen Ngo[1], An Ngo[1], Olivier Deckmyn[1], Dominique Thabut[2], Vlad Ratziu[2], Chantal Housset[3], Thierry Poynard[2,4], Pierre Nahon[2]. *[1]Biopredictive, Paris, France; [2]APHP, Paris, France; [3]INSERM Sorbonne University, Paris, France; [4]Sorbonne University, Paris, France*
Email: thierry@poynard.com

Background and aims: The early non-invasive detection and prediction of hepatocellular carcinoma (HCC) in patients (pts) with chronic liver disease, without or with cirrhosis is needed. We hypothesized that certain FibroTest (FT) components mediating hepatoprotection could be associated with the development of HCC. The algorithm FT-LCR1-LCR2 sequentially combining, FT and two multi-analyte-tests (LCR1-LCR2 patents pending) which increased the performance of AFP alone were constructed and internally validated in the prospective FibroFrance cohort (NCT01927133; *APT 2018*). The aim was to externally validate the sensitivity (Se) and the 5-yr prognostic value of FT-LCR1-LCR2.
Method: Pts of the ongoing prospective cohort of Bondy-Hospital, France, who had paired frozen serum with HCC prospectively detected (cases) were matched to controls who had not developed HCC during a similar follow-up (≥1 control for 1 HCC) using gender, age and Fibrotest fibrosis stages, blindly to LCR1-LCR2 results. The performance of FT-LCR1-LCR2 algorithm {high LCR2 (LCR2+) in pts with cirrhosis (F4+/LCR2+), or in pts without cirrhosis but with high LCR1 (FO123/LCR1+/LCR2+)}, was assessed and compared (Se and 5-yr survivals without HCC) with the standard AASLD surveillance (F4+/+-AFP). HCC diagnosis was either confirmed by biopsy, or suggested by non-invasive Barcelona criteria, or reported by death certificate.
Results: 159 pts were followed prospectively (median 5.1yr (IQR 2.5-7.1)), including 51 who had developed HCC (31 with cirrhosis and 20 without) and 108 controls (56 with cirrhosis and 52 without). The Se of FT-LCR1-LCR2 algorithm was higher *vs* standard surveillance: 78.4 vs 60.8 (p = 0.002) (Table), and the 5yr-survival without HCC was.90 (.81-.99) *vs*..77 (.67-.86; Logrank P = 0.003) according to FT-LCR1-LCR2 predetermined cutoff respectively. Similar results were observed in patients of 50 years of age or older (Table). In pts with HCC occurrence only 4/51 (7.8%) had disappearance of the algorithm signal vs 15/108 (13.9%) of controls when repeated in the same 159 pts, 1.5 yr (IQR 1.1-2.4) later, associated with an increase per year of LCR2, +0.014 (SE = 0.02) for cases vs 0.00 (0.01) for controls (Kruskal-Wallis P = 0.003).

Table: Performance of LCR1 in F0123, and sequential LCR1-LCR2 algorithm in all.

	ALL n (%)		50 years of age and older	
	HCC	Controls	HCC	Controls
LCR1 in F0123	**20**	**52**	**19**	**42**
LCR1 + inclusion	20 (100)	49 (94.2)	19 (100)	42 (100)
LCR1- inclusion	0 (0)	7 (5.8)	0 (0)	0 (0)
FT-LCR1-LCR2 algorithm all	**51**	**108**	**47**	**92**
FT-LCR1-LCR2 + inclusion	40 (78.4)	66 (61.1)	37 (78.7)	62 (67.4)
FT-LCR1-LCR2-inclusion	11 (21.6)	42 (38.9)	10 (21.3)	30 (32.6)
Standard AASLD algorithm all	**51**	**108**	**47**	**92**
Cirrhosis	31 (60.8)	56 (51.9)	28 (40.4)	50 (54.3)
No cirrhosis	20 (39.2)	42 (48.1)	19 (59.6)	42 (45.7)

Conclusion: The FT-LCR1-LCR2 algorithm was validated in an independent external cohort for the prediction of HCC.

Clinical developments in rare liver disease

PS-192
Lanreotide reduces liver growth in autosomal dominant polycystic kidney disease: Data from a 120-week randomized clinical trial

René van Aerts[1], Wietske Kievit[2], Ron T. Gansevoort[3], Joost Ph Drenth[1]. *[1]Radboud University Medical Center, Dept. Gastroenterology and Hepatology, Nijmegen, Netherlands; [2]Radboud University Medical Center, Radboud Institute for Health Sciences, Nijmegen, Netherlands; [3]University Medical Center Groningen, Dept. Nephrology, Groningen, Netherlands*
Email: rene.vanaerts@radboudumc.nl

Background and aims: Polycystic liver disease (PLD) is the most common extra-renal manifestation in autosomal dominant polycystic kidney disease (ADPKD). There is need for robust long-term evidence on the volume reducing effect of somatostatin analogues. Therefore we evaluated the effect of lanreotide on height adjusted liver volume (hTLV) and combined height adjusted liver- and kidney volume (hTLKV) in ADPKD patients with PLD.
Method: The DIPAK-1 study, a 120-week open label, randomized clinical trial, compared lanreotide versus standard care in 305 ADPKD patients to evaluate its renoprotective effect. For this analysis we studied the 175 patients with PLD, defined as hepatic cysts on MRI and a liver volume ≥ 2000ml. Of these, 93 were assigned to lanreotide (120 mg subcutaneously every 4 weeks) and 82 to standard care. Primary end point was percentage change in hTLV

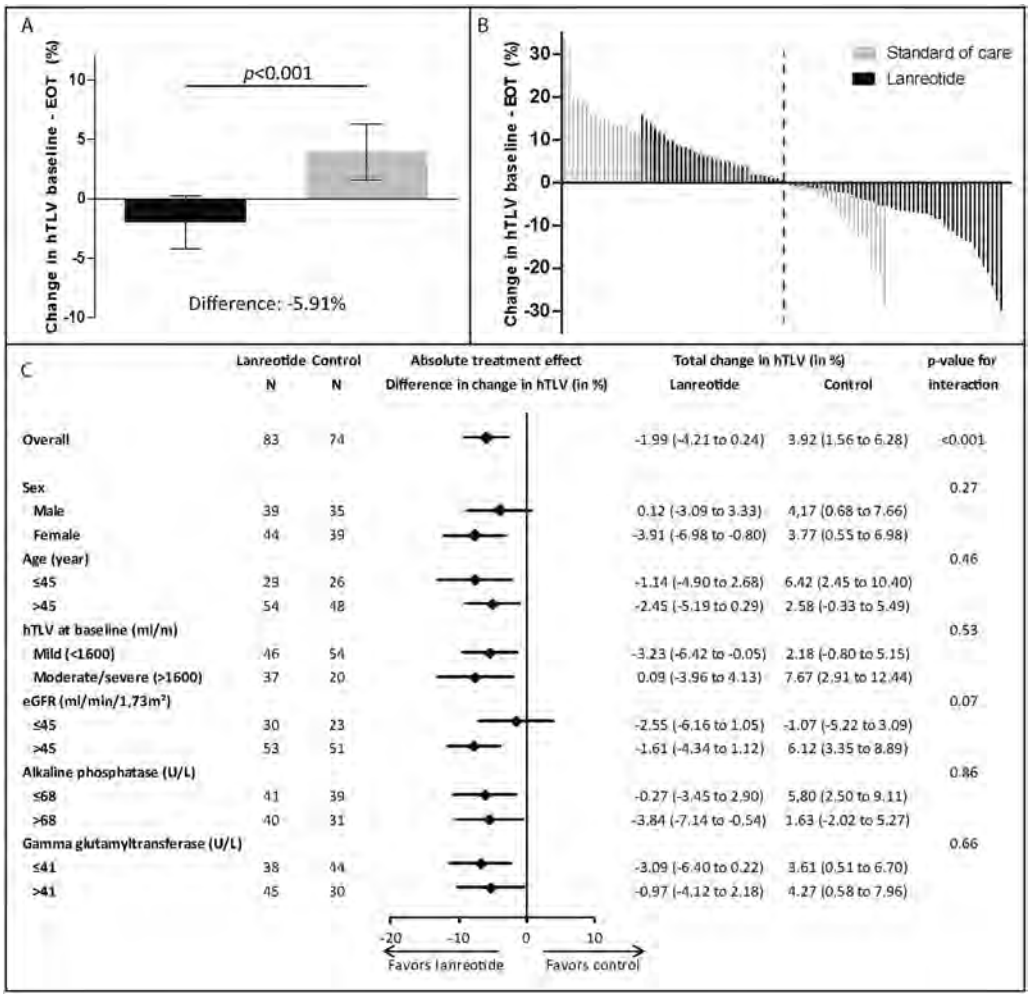

Figure: (abstract: PS-192): Change in hTLV between baseline and end of treatment A) Estimated percent change (mean ± 95% CI) in hTLV between baseline and end of treatment; B) percent change in hTLV, each bar represents 1 patient (dark bars-lanreotide, light bars-control group). All bars right from the scattered line represent decrease in hTLV, bars on the left represent increase in hTLV; C) subgroup analysis for the primary outcome.

between baseline and end of treatment (week 120). Secondary end point was change in hTLKV.

Results: At 120 weeks, hTLV decreased with 1.99% (CI −4.21 to 0.24) in the lanreotide group, whereas it increased by 3.92% (CI 1.56 to 6.28) in controls. Compared to controls, lanreotide reduced growth of hTLV by 5.91% (CI −9.18 to −2.63; p < 0.001). A beneficial treatment effect was still present 4 months after the last injection (−3.87%, CI −7.55 to −0.18; p = 0.04). Lanreotide resulted in an even stronger reduction in hTLKV compared to controls (−7.18%, CI −10.25 to −4.12; p < 0.001).

Conclusion: In patients with PLD due to ADPKD, lanreotide for 120 weeks reduced the growth of liver and combined liver- and kidney volume. This effect was still present four months after cessation of treatment; ClinicalTrials.gov number, NCT01616927

PS-193

Phase 2 open-label study with a placebo-controlled drug withdrawal period of the apical sodium-dependent bile acid transporter inhibitor maralixibat in children with Alagille Syndrome: 48-week interim efficacy analysis

Desai[11], Alejandro Dorenbaum[12], Ciara Kennedy[13], Alastair Baker[14], Emmanuel Jacquemin[1]. *[1]Hôpital Bicêtre, AP-HP, Université Paris Sud-Paris Saclay, Hépatologie Pédiatrique, Paris, France; [2]University Hospital for Children and Adolescents, Paediatric Gastronentrology/Hepatology, Tübingen, Germany; [3]The Children's Hospital at Westmead, Department of Gastroenterology, Westmead, Sydney, Australia; [4]Cliniques Universitaires Saint-Luc, Gastropédiatrie, Brussels, Belgium; [5]The Royal Children's Hospital Melbourne, Department of Gastroenterology, Parkville, Australia; [6]Hôpital Universitaire Necker-Enfants malades, Gastroenterology-Hepatology-Nutrition Unit, Paris, France; [7]Children's Memorial Health Institute, Department of Gastroenterology, Hepatology, Feeding Disorders and Pediatrics, Warsaw, Poland; [8]Hospital Universitario La Paz, Servicio de Hepatologìa y Transplante, Madrid, Spain; [9]Shire International GmbH, Zug, Switzerland; [10]Shire Pharmaceuticals, Lexington, MA, United States; [11]Shire Pharmaceuticals, Cambridge, MA, United States; [12]Stanford University, Palo Alto, CA, United States; [13]Reneo Pharmaceuticals, San Diego, CA, United States; [14]King's College London, Institute of Liver Studies, London, United Kingdom*
Email: emmanuel.gonzales@aphp.fr

Background and Aims: Maralixibat (SHP625/LUM001) is a potent, selective and minimally absorbed ileal apical sodium-dependent bile acid transporter (ASBT) inhibitor, in development for the treatment of pruritus in patients with Alagille Syndrome (ALGS).

Method: This was a pre-specified 48-week interim analysis of a phase 2 study in children with ALGS. After an 18-week maralixibat run-in period (6 weeks ascending doses up to 400 µg/kg daily and 12

weeks of stable dosing), subjects were randomized to placebo or continued maralixibat treatment for 4 weeks. After this all subject were treated with maralixibat. Change in serum bile acid (sBA), caregiver and patient reported Itch Reported Outcome (ItchRO) scores, Clinician Xanthoma Severity Scale and Pediatric Quality of Life Inventory (PedsQL) were evaluated during the randomization period and through 48 weeks of treatment.

Results: The 31 enrolled participants' mean age was 5.4 years (1-15 years), 19 (61%) were males, 30 had JAGGED1 and 1 not identified mutation. Twenty-nine completed the withdrawal period and 25 the 48-weeks treatment. There was a 31% sBA reduction during the run-in period (mean [SD]: −87 [120] µmol/L, p < 0.001) in the overall group. During the randomization period, sBA levels returned to baseline (BL) in the placebo but continued to decrease in the maralixibat group (94 [133] vs. −17 [110] µmol/L, p = 0.038). At the end of the 48 weeks there was a 36% sBA reduction from BL in the overall group (−101 [170] µmol/L, p = 0.003). This coincided with a −1.7 [0.9] point mean reduction in weekly average morning ItchRO (Obs) score (0 = none, 4 = severe itching) at week 18, a 1.7 [1.0] vs. 0.3 [0.8] point increase in the placebo vs. maralixibat group during the randomization period (p = 0.008), and a −1.6 [1.3] point reduction at week 48 (Figure). A total of 72% of subjects experienced an ItchRO reduction from BL of ≥ 1.0 point. Clinician Xanthoma Severity scores decreased by 44% and PedsQL scores improved by 9.5 points over 48 weeks of treatment. Maralixibat was generally safe, the most frequent adverse events were diarrhea, abdominal pain, vomiting and upper respiratory infections. During the study a small ALT increase (18 [84] U/L) was observed, while total bilirubin did not change.

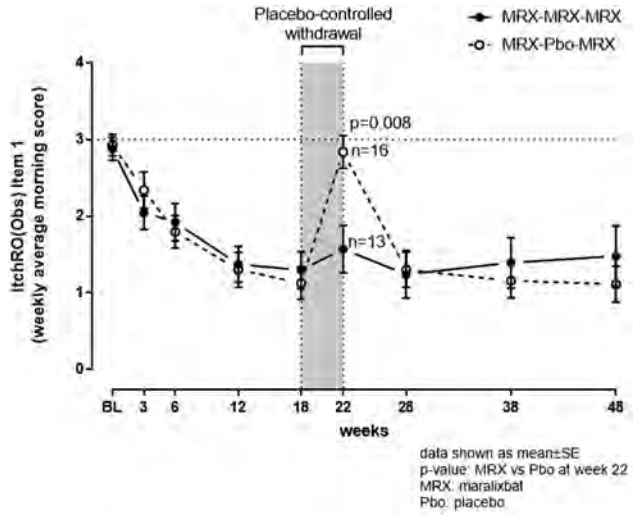

Figure: Pruritus change over time.

Conclusion: In cholestatic patients with ALGS, ASBT inhibition with maralixibat led to a significant reduction in sBA and improvement in pruritus compared to placebo and improvements in xanthoma severity and quality of life over 48 weeks of treatment.

PS-194

Effects of the ileal bile acid transport inhibitor A4250 on serum bile acids, pruritus and sleep in patients with Alagille syndrome: Phase 2 study results

Ulrich Baumann[1], Ekkehard Sturm[2], Florence Lacaille[3], Emmanuel Gonzales[4], Henrik Arnell[5], Björn Fischler[5], Marianne Hørby Jørgensen[6], Richard Thompson[7], Jan Mattsson[8], Per-Goran Gillberg[8], Kristina Torfgard[9]. *[1]Hannover Medical School, Hannover, Germany; [2]University Children's Hospital Tübingen, Tübingen, Germany; [3]Necker-Enfants Malades Hospital, Paris, France; [4]University Hospitals of Paris-Sud, Bicêtre, France; [5]Astrid Lindgren Children's Hospital, Karolinska University Hospital, Stockholm, Sweden; [6]Rigshospitalet, Copenhagen, Denmark; [7]Institute of Liver Studies, King's College London, London, United Kingdom; [8]Albireo AB, Gothenburg, Sweden; [9]Albireo AB, Gothenburg, Sweden*
Email: baumann.u@mh-hannover.de

Background and aims: Alagille syndrome (ALGS) may include chronic cholestatic liver disease with intractable pruritus and progression to end-stage cirrhosis. Current treatments include invasive surgical biliary diversion and liver transplantation. The effects of A4250 (a potent, selective, reversible ileal bile acid transporter inhibitor that decreases bile acid reuptake with minimal systemic exposure) are reported in patients with ALGS.

Method: A phase 2, open-label, multi-centre study evaluating A4250 safety and tolerability in paediatric cholestatic liver diseases with pruritus (including ALGS) was conducted. Efficacy end points included change in serum bile acid levels and pruritus. Patients received oral A4250 10-200 µg/kg/day for 4 weeks.

Results: Six patients with ALGS were enrolled. All had elevated baseline serum bile acids (~2 to > 40×ULN). After 4 weeks of A4250 treatment, 5 patients had marked reductions in serum bile acids (range: −39% to −92%) and 1 patient assigned to the lowest A4250 dose (10 µg/kg/day) had a slight increase of 4%. Pruritus scores improved on 3 daily reported itch tools: a visual analogue scale (VAS; 0-10), Partial Patient-Oriented Scoring Atopic Dermatitis scale (PO-SCORAD; 0-10) and Whitington scale (0-4), as did PO-SCORAD sleep scores (Table). A4250 was generally well tolerated. Liver enzymes varied in ALGS patients and 2 patients in the 200 µg/kg/day group had elevated liver transaminases at baseline that increased further during treatment. Although the levels observed were within baseline variability, the DSMB halted dose escalation and the planned 300 µg/kg/day dose was not administered. No serious treatment-related adverse events, deaths or discontinuations were reported in ALGS patients.

Effects of A4250 on bile acids and pruritus in patients with Alagille syndrome

	Baseline	End of Treatment	Change
Bile acids, µmol/L	237.5 ± 79.7 (25.7, 563.8)	139.8 ± 64.4 (12.2, 352.7)	−46.3 ± 12.8% (−92, 4.3%)
VAS-Itch	5.5 ± 0.8 (3.5, 8.1)	3.2 ± 1.0 (0.2, 6.9)	−2.3 ± 1.0 (−6.1, 0.7)
Whitington-Itch	2.0 ± 0.24 (1.0, 2.6)	1.6 ± 0.4 (0.5, 3.0)	−0.5 ± 0.4 (−1.6, 0.8)
PO-SCORAD-Itch	5.0 ± 1.0 (1.8, 8.3)	2.8 ± 0.8 (0.1, 5.5)	−2.3 ± 1.0 (−6.7, 0.2)
PO-SCORAD-Sleep	3.8 ± 1.0 (0.8, 6.3)	2.4 ± 0.8 (0.8, 5.0)	−1.5 ± 1.0 (−5.4, 0.7)

Values represent mean ± standard error (min, max).

Conclusion: Orally administered A4250 was generally well tolerated, and observed reductions in serum bile acids and improved pruritus and sleep scores suggest that further investigation of A4250 in children with ALGS is warranted.

PS-195

Predicting long-term outcome after surgical biliary diversion in Bsep-deficiency patients: Results from the NAPPED consortium

Email: d.b.e.van.wessel@umcg.nl

Background and aims: Progressive Familial Intrahepatic cholestasis type 2, or BSEP-deficiency (BSEP-def), results from mutations in the *ABCB11* gene. Mutations impair biliary bile salt secretion, leading to progressive liver disease. Symptoms do not always respond to medical therapy. Rather, patients are treated by surgical biliary diversion (SBD) and/or liver transplantation (LTx). We reported that SBD is associated with long-term native liver survival (NLS) in BSEP-def patients (Hepatol 2018, 68:S130). We now assessed if biochemical parameters after SBD could function as a reliable surrogate parameter for long-term NLS.

Method: From the global NAPPED database we analyzed patients with compound heterozygous or homozygous pathological mutations in *ABCB11*, who had undergone SBD (n = 51). Patients had mild (n = 34), moderate (n = 14) or severe (n = 3) mutations. For biochemistry analyses we used the most recent available sample pre-SBD and the first sample at > 2 months post-SBD. Continuous variables are expressed as medians and IQR. The association between serum bile acids (SBA), alanine aminotransferase (ALT) or total serum bilirubin (TSB), and NLS was analysed with cox-regression (corrected for sex and birthyear) and Receiver Operating Characteristic curve analysis.

Results: The major indication for SBD had been refractory, cholestatic pruritus (89%). SBD consisted of partial external biliary diversion (PEBD, n = 47), ileal exclusion (n = 3) or cholecystocolostomy (n = 1). Follow-up after SBD (at age 2.9 [1.3-6.0]yr) was 9.5 [2.5-12.5]yr. Pruritus was present in 94% pre- and in 41% post-SBD ($p < 0.001$). The diversion was closed in 6 patients (mild = 2, moderate = 3, severe = 1) at 2.0 [0.1-4.0]yr after SBD, followed by LTx in 5/6 patients at 6.3 [0.9-10.3]yr post-SBD. LTx was performed in 32% of all patients, 2.7[1.2-10.3]yr post-SBD. SBD was associated with a decrease in SBA (from 335 [195-459]μM pre-SBD to 44 [3-239]μM post-SBD; –91%, $p < 0.001$), ALT ($p < 0.0001$) and total serum bilirubin ($p < 0.0001$). Upon multivariate analyses, only SBA was significantly associated with NLS ($p < 0.001$). The figure shows NLS at the arbitrarily cut-off SBA level < or > 100μM ($p < 0.0001$) with an area under the ROC curve of 0.753 with an optimal cut-off point of 109μM with a sensitivity and specificity of 75%.

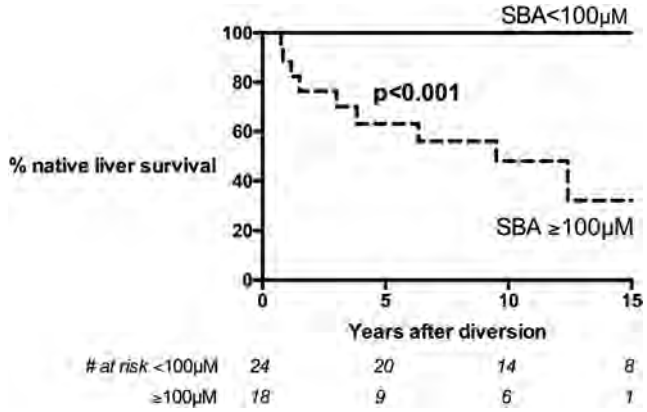

Figure: Native liver survival patients with BSEP-def with a post-SBD serum bile acid concentration below or equal to/above 100μM ($p < 0.001$). SBA: serum bile acid concentration.

Conclusion: SBD profoundly decreased SBAs in BSEP-def patients with mild or moderate genetic severity. Present data indicate that SBA levels below 100μM after surgical bile diversion predict a long-term NLS.

PS-196

Efficacy and safety of sebelipase alfa over 144 weeks in a diverse population of children and adults with lysosomal acid lipase deficiency

Barbara Burton[1], Alejandra Consuelo Sanchez[2], Maria Kostyleva[3], Ana Maria Martins[4], Sachin Marulkar[5], Florian Abel[6], Ivo Baric[7,8]. *[1]Ann and Robert H Lurie Children's Hospital, Chicago, United States; [2]Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico; [3]Russian Children's Clinical Hospital, Moscow, Russian Federation;*

Email: bburton@luriechildrens.org

Background and aims: Lysosomal acid lipase deficiency (LAL-D) is a rare, progressive disease characterized by accumulation of cholesteryl esters and triglycerides in the liver that leads to dyslipidemia, hepatomegaly, and liver cell damage. Sebelipase alfa (SA) is a recombinant human LAL indicated for the treatment of LAL-D. We report final results of LAL-CL06, a multicenter, open-label study designed to evaluate the safety and efficacy of SA.
Method: Eligible patients > 8 months of age with LAL-D were given SA 1.0 mg/kg by intravenous infusion every other week (qow). Dose escalation to 3.0 mg/kg qow and subsequently to 3.0 mg/kg weekly was allowed for patients who met protocol-defined criteria; dose reductions for tolerability were permitted to 0.35 mg/kg qow. No inferential statistical analyses were conducted.
Results: Of 31 patients enrolled and treated, 19 completed the 144-week study. At baseline, median age was 12 years (range, 3-55 y), 61% were male, 87% were white, and 55% were taking a lipid-modifying agent. Of 30 patients with a baseline liver biopsy, 20 had fibrosis and 8 had cirrhosis; of the remaining 2, 1 was < 4 years old and 1 had a prior liver transplant. Marked improvements in liver and lipid parameters and liver and spleen volumes were observed (Table). SA was generally well tolerated. Most adverse events (AEs) were mild to moderate in severity. Three patients (10%) experienced infusion-associated reactions that were mild (n = 1) or moderate (n = 2). One patient experienced anaphylactic reactions; the patient underwent desensitization and remained in the study through week 96. One patient discontinued due to a serious AE (liver transplant; unrelated to SA). Two patients (6%) tested positive for anti-drug antibodies (1 occasion each); neither developed neutralizing antibodies. No deaths occurred.

Parameter	Baseline (N = 31)	Week 144 (n = 19)	% Change From Baseline (n = 19)
ALT, U/L	63.5	38.0	−43.2
ALT ≤ 1.5 × ULN, n (%)	13 (42)	16 (84)	
AST, U/L	65.5	41.0	−32.7
AST ≤ 1.5 × ULN, n (%)	16 (52)	18 (95)	
GGT, U/L	31.5	16.0	−34.3
Liver volume, MN	1.4[a]	1.3[b]	−19.7[c]
Spleen volume, MN	2.6[a]	2.3[c]	−16.8[c]
Total cholesterol, mg/dL	233	193	−24.4
LDL-C, mg/dL	160[d]	121	−34.3
HDL-C, mg/dL	31	38	30.3
Triglycerides, mg/dL	159	112	−19.4

Data are medians. MN, multiples of normal.
[a]n = 27; [b]n = 13; [c]n = 12; [d]n = 30;

Conclusion: Long-term treatment with SA was well tolerated and resulted in sustained improvements in liver and lipid parameters in a broader patient population with LAL-D than was previously studied.

Email: cheimes@ukaachen.de

Background and aims: Homozygous carriers of the alpha1-antitrypsin (AAT) 'Pi*Z' variant (Pi*ZZ genotype) are susceptible to develop liver cirrhosis, whereas the heterozygous Pi*Z carriage (Pi*MZ genotype) acts as a disease modifier in patients with alcohol abuse or non-alcoholic fatty liver disease. However, the relevance of Pi*MZ in subjects without another etiology of chronic liver disease (CLD) remains unknown. Therefore, we evaluated the extent of liver disease in non-carriers (Pi*MM genotype) as well as Pi*MZ/Pi*ZZ carriers without other CLDs.
Method: Overall, 235 Pi*ZZ individuals, 299 Pi*MZ subjects and 205 matched controls without AAT mutations (Pi*MM), were recruited as a part of our European, multi-center registry study. At recruitment, participants underwent routine lab tests and AAT genotyping as well as measurement of liver stiffness (LSM) and controlled attenuation parameter (CAP) via transient elastography. The coexistence of CLD was excluded by a standardized workup.
Results: Compared to Pi*MM, Pi*MZ carriers displayed higher AST, GGT and LSM values, but lower platelet counts. In particular, 9% of Pi*MZ carriers presented with LSM ≥ 7.1 kPa compared to 4% of Pi*MM controls. However, Pi*MZ individuals had significantly lower AST, ALT, GGT serum levels as well as lower LSM and CAP values than Pi*ZZ participants, while displaying significantly higher platelet counts and serum triglyceride levels.
Conclusion: Compared to Pi*MM and Pi*ZZ individuals, Pi*MZ carriers display intermediate phenotype in terms of liver injury and LSM. Unlike Pi*ZZ subjects, Pi*MZ patients do not present with liver steatosis and metabolic alterations.

PS-198
Fibroscan improves diagnosis of cystic fibrosis related liver disease

Jennifer Scott[1,2], Elliot Jokl[1], James Pritchett[3], Andrew Jones[2], Peter Barry[2], Karen Piper Hanley[1], Varinder Athwal[1,2]. [1]The University of Manchester, Manchester, United Kingdom; [2]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [3]Manchester Metropolitan University, Manchester, United Kingdom
Email: jennifer.scott-11@postgrad.manchester.ac.uk

Background and aims: Cystic Fibrosis related liver disease (CFLD) is the 3rd biggest cause of death in Cystic Fibrosis (CF). As a result of improved pulmonary therapy and increasing survival age it is becoming more prevalent. With no single reliable physical, biochemical or radiological screening tool available for the diagnosis of CFLD, it is thought the current guidelines underdiagnose the presence of liver fibrosis, particularly in its early stages. Newer criteria have recently been proposed (Koh, et al, Hepatology, 2017). With improving technology better techniques are required to screen for liver disease. Newer modalities for the assessment of fibrosis may provide a more accurate assessment. The aim of this project is to assess the use of FibroScan and novel platforms in the diagnosis of CFLD and compare to current best practice tools.

Table 1: (abstract: PS-197): Features of heterozygous Pi*MZ carriers compared to non-carriers (Pi*MM) and homozygous carriers (Pi*ZZ).

	Pi*MM *n* = 205	Pi*MZ *n* = 299	Pi*ZZ *n* = 235	*P* value *Pi*MZ vs. Pi*MM*	*P* value *Pi*MZ vs. Pi*ZZ*
Age (years)	45 ± 12	45 ± 16	45 ± 10	.714	.759
Sex (% female)	59%	59%	59%	.969	.912
BMI (kg/m^2)	25.8 ± 5.3	25.8 ± 4.6	25.8 ± 4.1	.989	.900
Diabetes (%)	2%	4%	4%	.099	.789
Mean alcohol consumption (g/d)	5 ± 4	3 ± 3	4 ± 6	.422	.147
AAT serum level (mg/dl)	140.3 ± 28.8	88.7 ± 21.2	25.7 ± 21.5*	**<.0001**	**<.0001**

Fib4	0.24 ± 0.16	0.35 ± 0.72	1.10 ± 0.55	.056	**<.0001**

Quantitative measures are expressed as mean ± standard deviation range or as relative frequency (%). Abbreviations: ULN, upper limit of normal (sex-specific); FIB-4; Fibrosis4-score.
*only levels in non-augmented patients were considered.

Method: A cohort (n = 102) of genetically confirmed, fully phenotyped patients from the Manchester Adult Cystic Fibrosis Centre, UK were identified at annual assessment. Demographic data including co-morbidity, *CFTR* genotyping, biochemistry and recent imaging were assessed to group patients into those with CFLD and CF controls. All patients underwent transient elastography (TE) with Fibroscan and assessment of currently available serum-based biomarker panels (ie FIB-4) and novel serum biomarkers.
Results: 10 of 102 patient classified as CFLD according to the European Cystic Fibrosis Society best practice guidelines (hereafter called Debray criteria) compared with 33 patients using newer proposed diagnostic guidelines, incorporating elastography (hereafter referred to as Koh criteria). In line with previous cohorts, no specific risk factor for development of CFLD was identified, although presence of diabetes mellitus correlated with CFLD using Koh criteria ($p = 0.047$). Liver function test appeared to be lower in those without liver disease compared to those with CLFD using both criteria, including aspirate aminotransferase (25 vs 36 ($p = 0.002$) vs 29 ($p = 0.456$)), alkaline phosphatase (117 vs 144.5 (Debray; $p = 0.004$) vs 138.5 (Koh; $p < 0.001$)) but not alanine aminotransferase (24 vs 50 (Debray; $p = 0.018$) vs 23 (Koh; $p = 0.605$)). Median platelet count is higher in those without CFLD (283 vs 229 (Debray; $p = 0.010$) vs 266 (Koh; $p = 0.046$)). Using both criteria, median elastography was significantly raised (4.6 vs 8.5 (Debray; $p < 0.001$) vs 6.75 (Koh; $p < 0.001$)). Moreover, median liver stiffness was greater in patients with radiological evidence of portal hypertension (4.3 vs 8.6; $p < 0.001$). Biomarker panels, including FIB-4 and APRI, did not accurately predict the presence of liver disease.
Conclusion: Here we present the largest cohort of CF patients assessed for the presence of liver fibrosis using TE based platforms. Our data compares currently available diagnostic criteria for CFLD, Fibroscan may have a role as an adjunct to increase diagnostic accuracy.

Prevalence of mother-to-child transmission of hepatitis B virus: A systematic review and meta-analysis

Jinfeng Liu[1], Naijuan Yao[2], Tianyan Chen[1], Shan Fu[2], yuchao wu[2], Yali Feng[2], Zhen Tian[2], juan li[2], Fanpu Ji[3], yaolong chen[4], Yingren Zhao[1]. *[1]the First Affiliated Hospital of Xi'an Jiaotong University, Department of Infectious Diseases, Xi'an, China; [2]the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [3]the Second Affiliated Hospital of Xi'an Jiaotong University, Department of Infectious Diseases, Xi'an, China; [4]Lanzhou University, Evidence-based Medicine Center, Lanzhou, China*
Email: sourmilk2003@163.com

Background and aims: Prevention and control measures of hepatitis B virus (HBV) infection requires knowledge on the quantification of the burden of hepatitis B infection attributable to mother-to-infant transmission (MTCT).So far such data hasn't been comprehensively examined, we aim to estimate the exact risk and burden of MTCT of HBV.
Method: We systematiclly searched PubMed, Embase and the Cochrane Library from database inception to Oct 18, 2018, for primary data reporting MTCT of HBV among mothers (n≥10) with chronic HBV infection, in which definition of MTCT and measures against MTCT of HBV were descibebed. Search terms included strings pertaining to hepatitis B, mother, infant and vertical transmission. Two indenpent reviewers extracted data from eligible studies and assessed the quatity. We performed a meta-analysis with a DerSimonian-Laird random-effects model to calculate a pooled estimate of MTCT.
Results: Of the 118 studies inclued by our reserch, 1376 infants were diagnosed as MTCT from the total 28181 infants of chronic HBV infected mothers in 25 countries. The pooled MTCT rate of HBV in mother-infant pairs without any preventions was 29% (95% CI 13-49), ranged from 1% (0-6; Europe) to 34% (17-53; Asia), and HBeAg positive mothers showed significantly higher MTCT rate than HBeAg negative mothers (82% vs 4%). A significant deceasing in the pooled MTCT rate was shown in thoses infants received HBV vaccine soly (4% (95% CI 2-7)), including 8% (95% CI 4-10) in infants from HBeAg (+) mothers and 1% (95% CI 0-4) in infants from HBeAg (–) mothers. In

addition, the pooled MTCT rate in infants adopted combined immunoprophylaxis was 4% (95% CI 3-6), 6% (95% CI 6-9) in infants from HBeAg (+) mothers and 4% (95% CI 3-5) in infants from mothers unknown HBeAg status, what's more important, a pooled rate of 0% was observed in infants from HBeAg (−) mothers. Furthermore, the pooled MTCT rate were also 0% in infants with combined immuno-propgylaxis from mothers accepted antiviral intervention during pregnancy regardless HBeAg status of mothers and regions. 15 studies eligible for analysis of MTCT rate under various HBV DNA level, the pooled MTCT rate were 0%, 1% (95% CI 0-3), 1% (95% CI 0-3), 4% (95% CI 0-10), and 10% (95% CI 6-15) in infants from mothers with HBV DNA <4, 4-4.99, 5-5.99, 6-6.99, and 7-7.99 LogIU/ml, respectively.
Conclusion: This first global assessment revealed serious burden of MTCT of HBV, especially in high-endemic areas. Substantial variations between different regions, preventing measures, mothers with different HBeAg status, and HBV DNA level further highlighted the need of continued and individualizing prevention strategy against MTCT to achevie elimination of HBV infection in 2030.

The efficacy of two different dosages hepatitis B immunoglobulin in interrupting mother-to-infant transmission of hepatitis B virus: a systematic review and meta-analysis

Jinfeng Liu[1], Shan Fu[1], Naijuan Yao[1], Tianyan Chen[1], Yingren Zhao[1].
[1]*Department of Infectious Diseases, First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Xi'an 710061, Shaanxi Province, China, xi'an, China*
Email: sourmilk2003@163.com

Background and aims: Implementation of hepatitis B immuno-globulin (HBIG) combined with hepatitis B vaccine (HepB) has prevented mother-to-child transmission (MTCT) in a great degree, whereas, there is not consensus about the optimal dosage of HBIG for infants from chronic hepatitis B (CHB) infected mothers. Therefore, we did a systematic review and meta-analysis to compare the efficacy of two dosages of HBIG combined with HepB to interrupt mother-to-child transmission (MTCT) of CHB.
Method: We systematically searched MEDLINE, Embase, and Cochrane Library from database inception to Jan 16, 2019 for studies that infants accepted 100 or 200IU HBIG combined with HepB, while no intervention for their CHB mothers . We requested individual data from study authors and extracted primary data from published reports and online trial registries. The primary outcome was the rate of immonoprophylaxis failure, which was defined as HBsAg and/or HBV DNA positive of infants at 6-12 months old. Extracted data was caculated by random effects model
Results: 48 studies including 16121 infants were eligible for inclusion, 7478 infants in 100 IU group and 8643 infants in 200 IU group. No significant differences were found in the rates of immonoprophylaxis failure between 100 IU HBIG group (6%, 95% CI:4%–9%) and 200 IU HBIG group (7%, 95% CI :5%–8%). When further stratified according to HBeAg status and maternal HBV DNA load, comparable rates of immonoprophylaxis failure were shown in different HBIG dosage groups. In HBeAg (+) mothers, 7% (95% CI :4% −11%) infants became chronic HBV infection in 100 IU HBIG group compared to 8% (95% CI: 6%–10%) in 200 IU HBIG group. The rates were 1% in 100IU group (95% CI: 0%–2%) and 0% (95% CI 0%–0%)in 200IU group in infants born to HBeAg (−) mothers. Similarly in mothers with HBV DNA >106IU/ml, the rates were 8% (95% CI:5% −11%) versus 9% (95% CI :5%–14%) when accepted two different dosages of HBIG. Comparative analysis of 5 studies on two different dosages HBIG implicated consistent phenomenon (100IU vs 200IU: RR 1.16, 95% CI 0.82-1.64).
Conclusion: Our meta analysis highlighted that no significant difference was estimitated in the pure use of 100 and 200IU HBIG combined with HepB on blocking MTCT of HBV, regardless of maternal HBeAg status or viral load. It requires more large studies to examine whether100 IU HBIG should be recommended in preventing MTCT for infants born to CHB infected mothers.

FA-03

Caesarean section versus vaginal delivery to prevent mother-to-child transmission of hepatitis B virus: A meta-analysis

Zhen Tian[1], juan li[1], Jinfeng Liu[1], Tianyan Chen[1], Yingren Zhao[1].
[1]*Department of Infectious Diseases, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*
Email: tianzen1984@163.com

Background and aims: Mother-to-child transmission (MTCT) is the predominant mode of HBV infection, which accounts for 35-50% of HBV infection in China. Despite to appropriate passive and active immunization, perinatal transmission of hepatitis B virus (HBV) through MTCT occurs up to 5-10% of infants born to women with HBV infection. It remains unclear whether parturition method affects MTCT of HBV. The aim of this meta-analysis is to assess whether cesarean section reduces the risk of MTCT of HBV, compared to vaginal delivery.
Method: Two investigators independently searched PubMed, Embase, Cochrane Library, China Biological Medicine Database, China National Knowledge Infrastructure, and Wanfang Data Library database for relevant studies published prior to January 2019. The terms hepatitis B, hep B, hepatitis B virus, HBV, HBsAg, HBeAg, cesarean section, vaginal delivery, natural labour, natural childbirth, delivery mode were combined using the Boolean operators AND or OR. Randomized trials, cohort and case-control studies assessing the effect of delivery mode on vertical transmission of HBV were included. The main outcome of was HBV MTCT according to delivery mode.
Results: A total of 1264 records were collected, and 23 were finally included. A total of 7735 mothers were included in the analysis with 4012 undergoing caesarean section (51.87%) and 3723 undergoing vaginal delivery (48.13%). The MTCT rate of HBV was 5.09% (394 of 7735) overall, with individual rates of 3.41% (137 of 4012) for mothers who underwent cesarean section and 6.90% (257 of 3723) for those who underwent vaginal delivery. The summary RR was 0.57 (95% CI:0.46-0.69, P < 0.01), indicating a statistically significant decrease in HBV vertical transmission with cesarean section, as compared to vaginal delivery. In the analysis of the maternal HBeAg status subgroups, similar results were observed in the HBeAg positive mothers (RR = 0.36, 95%CI:0.19-0.71, P < 0.01); but in the HBeAg negative group, we found no significant differences (RR = 0.97, 95% CI:0.10-9.91, p = 0.98). There was an obvious decrease in HBV vertical transmission with cesarean section when maternal HBV DNA≥6 $\log_{10}$ copies/ml (RR = 0.41, 95%CI:0.25-0.67, P < 0.001), however, when maternal HBV DNA<6 $\log_{10}$ copies/ml, no significant difference was observed among the two delivery modes (RR = 1.18, 95%CI:0.48-2.94, p = 0.71).
Conclusion: Cesarean section could reduce the risk of MTCT of HBV in comparison to vaginal delivery. Performing cesarean in highly viremic mothers with pre-delivery HBV-DNA levels ≥6 log10 copies/ml and/or HBeAg positive may be considered with caution. Moreover, future well-designed randomized control trials are needed to confirm our findings.

FA-04

Tenofovir disoproxil fumarate use during pregnancy and maternal bone health: The tenofovir in pregnancy (TiP) pilot study

Athena Kourtis[1], Jeffrey Wiener[1], Bo Fan[2], Liming Wang[3], Marc Bulterys[3]. [1]*CDC, DRH, Atlanta, United States;* [2]*University of California San Francisco, San Francisco, United States;* [3]*CDC, China Office, Beijing, China*
Email: apk3@cdc.gov

Background and aims: There is very limited information on bone mineral density (BMD) of women exposed to tenofovir during pregnancy. However, tenofovir is increasingly used among pregnant

women with HIV and hepatitis B virus (HBV) infection for their own health and for prevention of transmission of these viral infections to their offspring. We assessed the effect of tenofovir disoproxil fumarate (TDF) initiated during pregnancy among HIV-HBV coinfected women in a clinical trial in China.

Method: The Tenofovir in Pregnancy (TiP) study was a pilot phase II randomized controlled trial of the safety of a regimen containing vs. one not containing TDF, starting from 14 weeks gestation, in HIV/HBV co-infected pregnant women in Guangxi, China, who were antiretroviral drug-naive. The other antiretroviral agents were emtricitabine and lopinavir/ritonavir in both study arms. Maternal spinal and hip BMD were assessed by Dual X-ray absorptiometry (DXA) scans at delivery and at 6 months postpartum.

Results: Fifteen TDF-exposed and 16 TDF-unexposed women had evaluable BMD measurements at delivery. TDF-exposed women were similar at delivery to unexposed women on mean age (28.8 vs 27.8 years), gestational age at delivery (38.1 vs. 38.4 weeks), body mass index (21.2 vs 22.3 kg/m^2) and CD4+ T lymphocyte count (326.6 vs 393.3 cells/mm^3). The mean difference in BMD at lumbar spine between TDF-exposed and unexposed women was –0.01 g/cm^2 (95% confidence interval = –0.09, 0.08) at delivery and –0.01 g/cm^2 (95% confidence interval = –0.08, 0.07) at 6 months postpartum. The mean difference in BMD of femur neck at delivery and 6 months postpartum between TDF-exposed women and unexposed women was –0.07 g/cm^2 (95% CI = –0.15, 0.01) and –0.04 (95% CI, –0.14, 0.06), respectively. The mean change from delivery to 6 months postpartum in BMD at femur neck was 0 g/cm^2 in TDF-exposed women vs. –0.03 g/cm^2 in unexposed women (p = 0.12), adjusted for relevant covariates.

Conclusion: HIV/HBV coinfected women exposed to TDF during the second and third trimester of their pregnancy had slightly lower BMD at delivery and at 6 months postpartum, compared to women not exposed to TDF, but these changes were not statistically significant in this small sample size. There was no change in BMD from delivery to 6 months postpartum in the TDF-exposed group. The observed potential differences in BMD in women exposed to TDF are of uncertain clinical significance.

FA-05

Tenofovir disoproxil fumarate treatment is safe and efficacy for chronic hepatitis B mothers from early pregnancy

Tianyan Chen[1], Yali Feng[1], Jinfeng Liu[1], Naijuan Yao[2], Yingren Zhao[1].
[1]the First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Department of Infectious Disease, Xi'an, China; [2]the First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Xi'an, China
Email: chentianyan@126.com

Background and aims: Tenofovir Disoproxil Fumarate (TDF) is recommended to prevent hepatitis B virus (HBV) mother-to-child transmission (MTCT) from the second to the third trimester. Whereas, data about the safety and efficacy of TDF administration during the entire pregnancy was insufficient.

Method: Chronic hepatitis B infected pregnant women accepted TDF treatment either before pregnancy or from early pregnancy were enrolled, and followed up to 28 weeks after delivery. Adverse events were prospectively continuous recorded during follow-up, as well as HBV DNA and HBV serological markers.

Results: A total of 69 CHB mothers were enrolled, including 2 cases with spontaneous abortion, 1 case with premature labor, and 66 cases of full-term delivery, and among which 45 cases had finished postpartum 28 weeks follow-up. During pregnancy, the most common adverse events included hyperemesis gravidarum (7/67, 10.4%), gestational diabetes (5/67, 7.5%) and ALT flare (ALT >40IU/ml) (3/67, 4.5%). In addition, lower bone mass was observed in 6.7% (3/45). Furthermore, 25% mothers shown postpartum ALT flare and all were resolved spontaneously. Congenital abnormalities and neonatal growth were comparable to the normal population, while 1 infant reported laryngeal cartilage dysplasia and recovered without treatment. Bone mineral density was also evaluated, the median SOS z-score of the children was 0.3 (range: –0.6-2.0). None of the infants was positive for HBsAg or HBV DNA at 28 weeks old.

Conclusion: TDF treatment from early pregnancy was safety and efficacy for chronic HBV-infected pregnant mothers and their infants.

FA-06

Maternal nucleoside analogues treatment and infant immunoprophylaxis to prevent chronic hepatitis B in children: A prospective eight-year real-world study

Yonglan Pu[1], Yiqi Yu[2], Yang Li[2], Jie Wang[1], Chao Qiu[2], Wenhong Zhang[2]. *[1]Taicang No.1 People's Hospital, Department of Infectious Disease, Taicang, China; [2]Huashan Hospital, Fudan University, Department of Infectious Disease, SHANGHAI, China*
Email: zhangwenhong@fudan.edu.cn

Background and aims: There has been an inconclusive debate about whether the use of nucleos (t)ide analogue during late pregnancy is necessary in pregnant women with high hepatitis B virus (HBV) DNA to prevent perinatal transmission in addition to immunoprophylaxis. In this eight-year study in real-world setting, we investigated the incidence of chronic HBV (CHB) infection in children born to CHB mothers and evaluated the efficacy of nucleos (t)ide analogue in the prevention of vertical transmission on long term follow-up.

Method: We prospectively enrolled pregnant CHB women in China. Women with HBV DNA level ≥2*10^6 IU/ml (highly viraemic) were recommended to receive telbivudine from week 28 of gestation until delivery and those with HBV DNA level <2*10^6 IU/ml (lowly viraemic) received standard care without nucleos (t)ide analogue. All infants received hepatitis B immune globulin and HBV vaccine within 24 hours postpartum. HBV serological markers and HBV DNA in umbilical cord blood were determined and children were followed up until December 2018.

Results: From January 2011 to December 2017, a total of 281 highly viraemic pregnant women presented to our hospital, of whom 161 agreed to receive telbivudine and 120 declined, while 105 lowly viraemic pregnant women were assigned to the control group. Among 233 completing the follow-up, 105 telbivudine-treated mothers, 61 untreated highly viraemic mothers and 67 lowly viraemic mothers gave birth to 111, 65 and 73 infants, respectively. Of these, 10 infants (4 born to telbivudine-treated mothers, 5 born to highly viraemic controls, 1 born to lowly viraemic controls) failed to receive HBV immunoprophylaxis owing to medical reasons and were excluded from the per-protocol analysis. HBV DNA levels declined significantly in the telbivudine treated mothers. In the intention-to-treat analysis, no children were infected in the telbivudine group or the lowly viraemic control group, as compared to nine children in the highly viraemic control group. The rate of CHB children were significantly higher in the highly viraemic control group than in the telbivudine-treated group and the lowly viraemic control group, both in the per-protocol analysis (6.7% [4/60] vs 0% [0/107], p = 0.016; 6.7% [4/60] vs 0% [0/72], p = 0.039) and the intention-to-treat analysis (13.8% [9/65] vs 0% [0/111], p < 0.001; 13.8% [9/65] vs 0% [0/73], p = 0.001). The proportion of the HBsAg-positive and the detectable level of HBV DNA in umbilical cord blood did not differ significantly between the telbivudine group and the highly viraemic control group. No hepatic flares were reported in the telbivudine-treated mothers after drug withdrawal.

Conclusion: The decline of HBV DNA levels after the use of telbivudine during late pregnancy was associated with lower incidence of CHB in children born to mothers with HBV DNA ≥2*10^6 IU/ml, probably by reducing the risk of perinatal transmission.

A Bayesian network analysis of the efficacy and safety of antiviral therapy for chronic hepatitis B infection during diferent trimesters of pregnancy

Yuchao Wu[1], Yali Feng[1], Yingren Zhao[1], Fanpu Ji[2]. [1]*First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China;* [2]*Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*
Email: zhaoyingren@mail.xjtu.edu.cn

Background and aims: Mother-to-child transmisson remains the major risk of hepatitis B virus infection worldwide. Antiviral therapy to reduce maternal HBV DNA viral load at different trimesters of pregnancy has been employed to block mother-to-infant tranmission. This research aimed to demonstrate the efficacy and safety of antiviral therapy at different trimester of pregnancy to prevent mother-to-infant tranmission of hepatitis B virus.

Method: Controlled studies were included from PubMed, EMBASE and Cochrane databases inception through December 6th, 2019. Eligible studies included randomized controlled trial and observational studies of third trimester or/and before trimester antiviral treatment vs. controls for patients with hepatitis B virus infection. Extracted data were analysized by pairwised and network meta analysis.

Results: We included 23 studies (three randomized controlled trial and 19 non-randomized controlled studies) that enrolled 5335 pregnant women. By pairwise meta-analysis using non-antiviral treatment as the reference, antiviral treatment reduced MTCT, as defined by infant hepatitis B surface antigen sero-positive or HBV DNA sero-positive, after initiated before third trimester (RR = 0.07, 95%CI 0.03-0.14) or at third trimester (RR = 0.07, 95% CI0.32-0.50). Using network analysis, lower MTCT were seen with antiviral therapy before third trimester compared with treated at third trimester (OR = 0.019, 95% CI 0.00034-0.19). No significant differences were found in the congenital malformation rate (OR = 0.98, 95% CI 0.77-12), prematurity rate (OR = 1.0, 95% CI 0.42-2.6), and Apgar scores (OR = 0.79, 95% CI 0.10-6.4). Compared to treatment used at third trimester, no significant difference were found in improved maternal HBV DNA suppression at delivery and during 4-8 weeks' postpartum follow-up after beginning treatment before third trimester (OR = 4.7, 95% CI 0.072-2000). No significant differences were found in postpartum hemorrhage (OR = 1.1, 95% CI 0.56-2.3), cesarean section (OR = 1.2, 95% CI 0.83-1.6), and elevated creatininekinase rates (OR = 0.022, 95% CI 1.0e-20-3.8e+14) during different trimester.

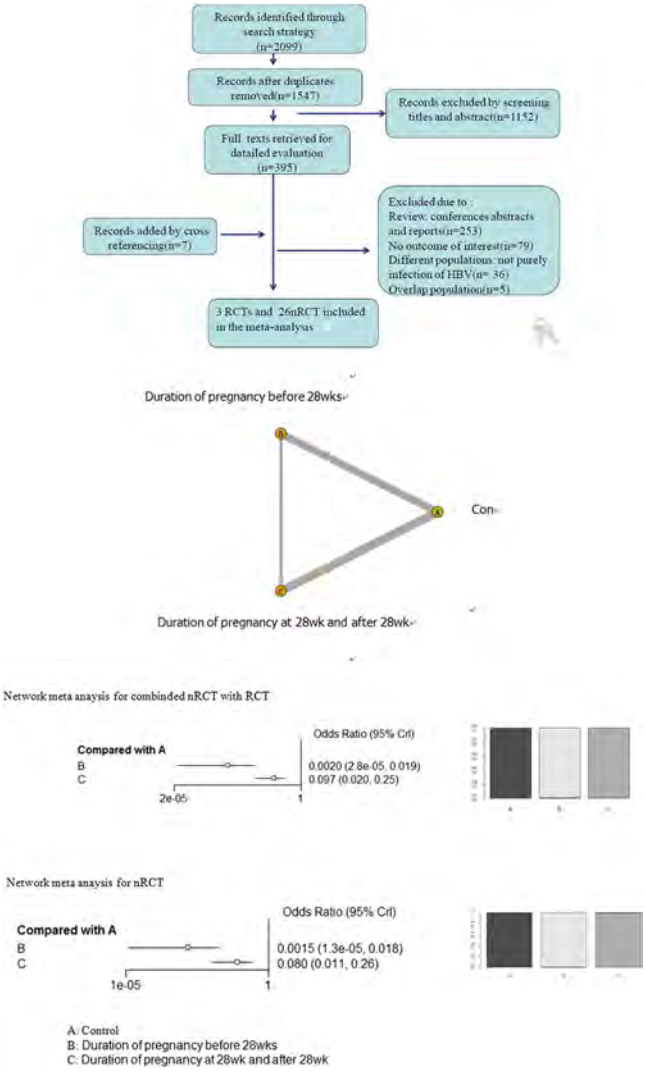

Figure: 1. The study selection process 2. Treatment networks 3. Forest plots and rank probabilities of infected infants for various interventions for perinatal hepatitis B virus transmission according network meta analysis.

Conclusion: Antiviral therapy improves HBV suppression and reduces MTCT in women with chronic HBV infection compared to the use of hepatitis B immunoglobulin and vaccination alone during different trimester of pregnancy. The earlier use of antiviral drug appears to be better to prevent MTCT of HBV in pregnancy without increased adverse maternal or fetal outcome.

FA-08

Hepatic flare after antiviral treatment withdraw in post-partum for pregnancy of chronic hepatitis B viral infection: A pairwise and Bayesian network meta-analysis

Yingren Zhao[1], Yali Feng[1], yuchao wu[2], Fanpu Ji[2], Tianyan Chen[2]. [1]*the First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Department of Infectious Disease, Xi'an, China;* [2]*the First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Xi'an, China*
Email: zhaoyingren@sohu.com

Background and aims: Antepartum anti-viral therapy has been well established to break vertical transmission of hepatitis B virus. However, the optimum duration to extend anti-viral therapy remains uncertain. Therefore, we aim to demonstrate the hepatic flares after antiviral therapy withdrawal at different time of post-partum.
Method: Controlled studies were included from PubMed, EMBASE and Cochrane databases inception through December 6th, 2019. Eligible studies included randomized controlled trial and observational studies of post-partum flares that pregnant women with chronic HBV infection treated with antiviral therapy and discontinued the treatment after post-partum 0 week, 4 weeks and 12 weeks. Extracted data were analyzed by pair-wised and network meta-analysis.
Results: We included 12 studies (three randomized controlled trials and nine non-randomized controlled studies) that enrolled 2336 pregnant women. By pairwise meta-analysis using non-antiviral treatment as the reference, no significant difference was suggested in women withdrawal post-partum anti-viral treatment (risk ratio = 1.22, 95% CI 0.94-1.60). Similar results were seen in the subgroup analysis of discontinued therapy at post-partum 0 week (risk ratio = 1.29, 95%CI 0.57-2.96), 4 weeks (risk ratio = 1.39, 95% CI 0.82-2.38) and 12 weeks (risk ratio = 1.62, 95% CI 0.71-3.71) when compared with controlled group. Using network analysis, similar results were demonstrated in direct or indirect comparisons. Stopped treatment at post-partum 4 weeks showed no significant reduced hepatic flares compared with post-partum 0 week in only indirect comparison (risk ratio = 0.72, 95% CI 0.20-3.1). Withdrawal treatment at post-partum 12 weeks was not different from the treatment discontinued at post-partum 0 week (combined direct and indirect comparison, risk ratio = 0.82, 95% CI 0.22-3.6) and 4 weeks (indirect comparison, risk ratio = 1.2, 95% CI 0.26-3.47).
Conclusion: It appears that extending anti-viral therapy from 0 weeks to 4 weeks and 12 weeks after delivery does not protect against post-partum flares. Well designed studies are needed to confirm the optimal Withdrawal treatment time of post-partum.

Late breaker: Orals

LBO-01

Multicenter, double-blind, placebo-controlled, randomized trial of emricasan in subjects with NASH cirrhosis and severe portal hypertension

Guadalupe Garcia-Tsao[1], Jaime Bosch[2,3], Zeid Kayali[4], Stephen Harrison[5], Manal Abdelmalek[6], Eric Lawitz[7], Sanjaya Satapathy[8], Marwan Ghabril[9], Mitchell Shiffman[10], Ziad H. Background and aims: NASH is a leading cause of cirrhosis and liver transplant, and severe PH is a key driver of decompensation and worse clinical outcomes. Lowering hepatic venous pressure gradient (HVPG) has been associated with clinical benefit. Emricasan (oral pan-caspase inhibitor) decreased portal pressure and improved survival in cirrhosis models and in an open-label study reduced HVPG in cirrhosis patients with HVPG ≥12 mmHg. This study aimed to confirm these results.
Method: Patients with NASH cirrhosis and baseline HVPG ≥12 mmHg were randomized 1:1:1:1 to emricasan 5, 25, 50 mg or placebo (pbo) orally twice daily for 48 wks, with 1 follow-up HVPG at Wk 24 (primary end point) and all HVPG tracings evaluated by a central reader.

Table: Least Squares (LS) Mean Change* from Baseline at Wk 24

	Emricasan 5 mg N = 65	Emricasan 25 mg N = 65	Emricasan 50 mg N = 66	Pbo N = 67
HVPG (Overall)	−0.6 p = 0.96	−0.8 p = 0.79	−1.0 p = 0.65	−0.4
HVPG (Compensated)	−0.8 p = 0.10	−0.9 p = 0.09	−0.5 p = 0.27	+0.2
HVPG (Compensated HVPG ≥ 16 mmHg)§	−1.6 p = 0.01	−1.7 p < 0.01	−1.5 p = 0.02	+0.5
Caspase 3/7	−4% p = 0.90	−31% p < 0.01	−37% p < 0.01	−4%
cCK18	−27% p < 0.01	−32% p < 0.01	−34% p < 0.01	−13%
ALT	−8 p < 0.01	−8 p < 0.01	−6 p = 0.02	−3
AST	−6 p < 0.01	−7 p < 0.01	−3 p = 0.18	−1

p values (descriptive) for difference in LS mean vs. pbo
*Adjusting for baseline value, cirrhosis status, and/or NSBB use (multiple imputation for overall, observed case for rest)
§Post-hoc

Results: Of 263 subjects (59 US/EU sites) randomized, 13 discontinued prior to Wk 24 and 7 more had no or unevaluable Wk 24 HVPG. Treatment groups were generally balanced. Overall, mean (SD) age was 60.8 (8.8) years, 57% female, 91% Caucasian, 84% T2DM, BMI 35.3 (6.9) kg/m2, 76% compensated vs. 24% decompensated (only 1 prior event, stable on study entry), 88% Child Pugh A, MELD 9.0 (2.5), HVPG 17.0 (3.6) mmHg. HVPG was reduced in subsets of patients (Table). Treatment-emergent AEs were similar (81.6% combined emricasan vs. 82.1% pbo), with SAEs in 17.9% (emricasan) vs. 11.9% (pbo) and no imbalance in routine labs, vitals, ECGs.
Conclusion: Although the primary end point was not met, these data suggest that caspase inhibition with emricasan for 24 wks reduced portal pressure in compensated NASH cirrhosis patients with severe PH, especially those with higher baseline HVPG, and support further studies in these patients. Decreases in transaminases suggest an intrahepatic effect with reduction of liver injury. Potential effects on clinical outcomes and full safety data will be evaluated after completion of the 48-wk study.

Background and aims: Ursodeoxycholic acid (UDCA) is the established treatment for patients with primary biliary cholangitis (PBC). Up to 40% of UDCA-treated patients have suboptimal response and remain at high risk for disease progression. Elafibranor (Ela), a dual PPAR alpha and delta agonist, has potential as a new anti-cholestatic treatment for such patients.
Method: We evaluated the added anti-cholestatic effects of Ela in a 12-week double blind randomized placebo-controlled phase 2a trial of non cirrhotic patients with PBC and with inadequate response to UDCA defined as an alkaline phosphatase (ALP) >1.67x upper limit of normal (ULN). Patients were randomly assigned to Ela 80 mg/day, 120 mg/day or placebo (Pbo) (15 patients per group: 43 women and 2 men; mean age 59 years). UDCA was continued in all patients. The primary end point was ALP percentage change from baseline to week 12.
Results: Both Ela doses demonstrated a significant decrease in the mean ALP: −48% for 80 mg, −41% for 120 mg with a 3% increase for Pbo, producing a highly significant treatment effect versus Pbo: −52% (95% CI: [−62.5;−41.5]) ($p < 0.001$) for 80mg and −44% (95% CI: [−55.7;−32.1]) ($p < 0.001$) for 120 mg. The composite end point of ALP < 1.67xULN and ALP decrease >15% and total bilirubin < ULN, was achieved in 67% patients at 80 mg and 79% patients at 120 mg ($p = 0.002$ and $p < 0.001$ respectively) as compared to 6.7% patients on Pbo. Effect on gamma-glutamyl transferase was also highly significant as compared to Pbo: −39% for 80mg and −40% for 120mg ($p = 0.001$ and $p = 0.002$ respectively). Ela-treated patients showed improvement in lipid markers including total cholesterol, low-density lipoprotein and triglycerides, as well as reduction of anti-inflammatory markers (IgM, CRP, haptoglobin and fibrinogen); a decrease in C4, an intermediate of bile acid synthesis, was noted. By self-reported visual analogue scale (VAS) in patients with pruritus at baseline (10/group), the VAS median percentage change from baseline to week 12 was −24%, −49% and −7% in the 80mg, 120 mg and Pbo groups respectively. Both doses of Ela were globally well-tolerated.
Conclusion: A 12 week course of Ela demonstrated a substantial anticholestatic effect in patients with PBC and with inadequate response to UDCA. This was associated with anti-inflammatory and potential antipruritic effects which make it a promising novel treatment candidate.

LBO-03

Tenofovir treatment has lower risk of hepatocellular carcinoma than entecavir treatment in patients with chronic hepatitis B

Terry CF Yip[1], Vincent Wai-Sun Wong[1], Yee-Kit Tse[1], Henry Chan[1], Grace Lai-Hung Wong[1]. *[1]Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: Both tenofovir disoproxil fumarate (TDF) and entecavir (ETV) have potent antiviral effect on hepatitis B virus, and are recommended as the first-line treatment for chronic hepatitis B (CHB). A recent study suggested that patients who received TDF treatment have lower risk of hepatocellular carcinoma (HCC) than those received ETV. We aimed to compare TDF and ETV on the risk of HCC in a territory-wide cohort of CHB patients.
Method: Consecutive adult CHB patients who initially treated by ETV or TDF for at least 6 months between January 2008 and December 2018 was identified using the Clinical Data Analysis and Reporting System that captures in-patient and out-patient data of all public hospitals and clinics in Hong Kong. Patients who had cancers or liver transplantation before or within the first 6 months of treatment were excluded. Missing data were replaced by multiple imputation (MI) by chained equations to create 20 complete data sets after 10 iterations. Propensity score (PS) weighting was used after MI to balance the baseline clinical characteristics between two treatment groups; PS included all covariates in the multivariable analysis (Table), serum creatinine, and renal replacement therapy. Fine-Gray model was used to adjust for competing risk of death.
Results: 29, 123 CHB patients were identified. Their mean age was 53.7 ± 13.3 years, 18, 492 (63.5%) were male; 1, 227 (4.2%) and 27, 896 (95.8%) first received TDF and ETV, respectively. At a median (interquartile range) follow-up of 3.3 (1.6-5.0) years, 9 (0.7%) TDF-treated and 1, 468 (5.3%) ETV-treated patients developed HCC. The 5-year cumulative incidence (95% confidence interval [CI]) of HCC in ETV and TDF-treated patients was 7.5% (7.1%−7.9%) and 1.3% (0.6% −2.6%), respectively (Figure). TDF use was associated with a lower risk of HCC than ETV use before (adjusted hazard ratio [aHR] 0.46, 95% CI 0.23-0.91, $p = 0.027$) and after multiple imputation, with (weighted HR 0.40, 95% CI 0.18-0.86, $p = 0.019$) and without (aHR 0.34, 95% CI 0.18-0.66, $p = 0.001$) PS weighting (Table).
Conclusion: TDF treatment is associated with a lower risk of HCC than ETV treatment in a territory-wide cohort of CHB patients.

Table:

Parameters	Univariate analysis			Multivariable analysis		
	HR	95% CI	*P* value	aHR	95% CI	*P* value
TDF *vs.* ETV	0.16	0.09-0.32	<0.001	0.34	0.18-0.66	0.001
Age	1.06	1.05-1.06	<0.001	1.05	1.04-1.05	<0.001
Male gender	2.30	2.02-2.62	<0.001	2.54	2.23-2.90	<0.001
Cirrhosis	5.05	4.56-5.60	<0.001	2.22	1.95-2.52	<0.001
Platelet*	0.37	0.33-0.41	<0.001	0.56	0.51-0.61	<0.001
Albumin	0.92	0.92-0.93	<0.001	0.98	0.97-0.99	<0.001

Email: cornberg.markus@mh-hannover.de

Background and aims: Chronic hepatitis E virus infection (cHEV) is an emerging problem in immunocompromised patients. Treatment is limited to ribavirin (RBV) but many patients cannot be treated because of contraindications. Thus, there is an unmet need for new antiviral therapies. *In vitro* studies have shown that the HCV polymerase inhibitor sofosbuvir (SOF) inhibits the HEV replication, however case reports on the use of SOF in cHEV patients showed conflicting results.

Method: We performed an investigator-initiated, multicentre phase II pilot trial (NCT03282474) at 3 centers in Germany. Ten patients with confirmed cHEV who either failed prior RBV therapy or had contraindications for RBV received 400mg sofosbuvir daily for 24 weeks. The primary end point was undetectable HEV RNA at week 24. Secondary outcomes included analysis of antiviral efficacy defined by $\log_{10}$ decline of HEV RNA.

Results: Ten patients with cHEV entered the study but one patient was excluded from further analysis because of exclusion criteria. Mean age of the nine patients was 44 ± 14 years. Seven patients failed prior treatment with RBV (median 15 months (4-40)) and two patients were ineligible to receive RBV. Eight patients had a history of organ transplantation and one patient had common variable immunodeficiency. Two patients had cirrhosis. Median ALT before start of SOF treatment was 126 U/l (38-624). Baseline HEV RNA was 6E5 IU/ml (range 8E4-5E6 IU/ml). Overall 5/9 (56%) patients experienced a decline of HEV RNA of at least 1log10 IU/ml. The

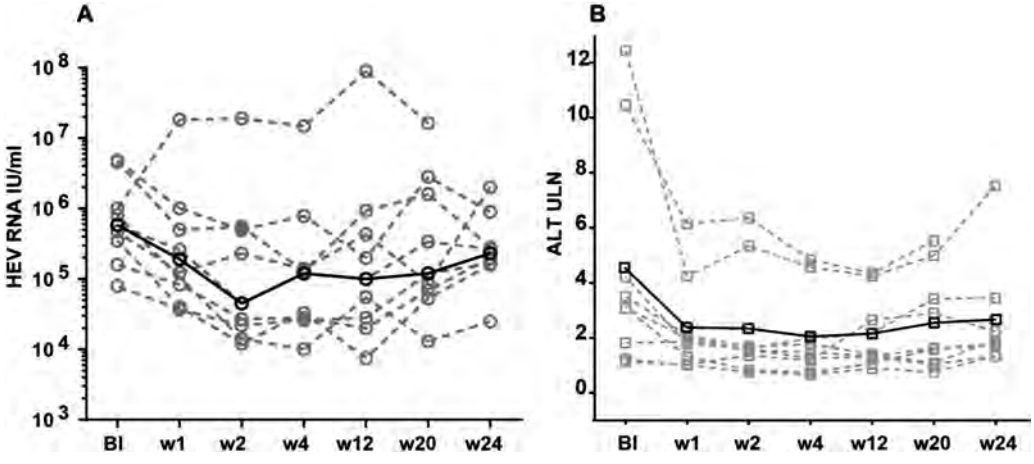

Figure: (abstract LB-04): A) Individual courses of HEV RNA in IU/ml of nine patients, black line represents median values B) Individual courses of ALT shown as upper limit of normal (ULN); black line represents mean values.

strongest median decline of HEV RNA was observed between baseline and week 2 (1.1 log10). However, no patient reached the primary end point and only two patients maintained a >1log10 reduction of HEV RNA at week 24. Importantly, ALT level showed a significant decline from 4.6 upper limit of normal (ULN) to 2.2 ULN at week 12 and 2.7 ULN at week 24. Treatment with SOF was well tolerated. Creatinine clearance was stable during therapy; all patients stayed above GFR 30 ml/min. Six serious adverse events were reported in three patients but only one (elevated lipase) was considered to be related to SOF. Sadly, this patient experienced a sepsis and died 4 weeks after SOF was stopped.
Conclusion: Sofosbuvir shows moderate antiviral efficacy but does not lead to cure of cHEV. HEV RNA decline was associated with ALT improvements. SOF should be further investigated in combination with RBV for the treatment of cHEV in immunocompromised patients.

LBO-05
Bezafibrate improves the effect of obeticholic acid on cholestasis in patients with primary biliary cholangitis
Lena Smets[1], Schrijvers Liliane[2], Korf Hannelie[1], van der Merwe Schalk[2], Nevens Frederik[2]. *[1]KU Leuven, Department chronic diseases, metabolism and ageing, Leuven, Belgium; [2]UZ Leuven, Department of gastroenterology and hepatology, Leuven, Belgium*
Email: lena.smets@kuleuven.be

Background and aims: Obeticholic acid (OCA) is the second line treatment for patients (pts) with primary biliary cholangitis (PBC) who have an inadequate response or are intolerant to ursodeoxycholic acid (UDCA) (1). Recently, bezafibrate treatment was also shown to improve biochemical responses in PBC pts (2). Here, we explored whether combining OCA and bezafibrate therapy normalised alkaline phosphatase (ALP) and bilirubin levels, since this is the strongest predictor of improved outcome.
Method: We included 16 pts of the POISE (PBC OCA International Study of Efficacy) study who received OCA (5 or 10 mg/d)±UCDA for 4-5 years (y). In 3 pts OCA treatment was terminated (pruritus n = 2). After 5 y, bezafibrate treatment (Eulitop 400 mg/d) in addition to OCA + UCDA was initiated in 11 pts (2 male, 9 female) with a mean age of 64 y and a median fibroscan value of 6.8 kPa (min: 4.7-max: 21.8). Due to myalgia, bezafibrate treatment was terminated in 2/11 pts. The effect on pruritus was assessed with the PBC-40 questionnaire. Our primary end point was a normalisation of ALP and bilirubin levels. p values were calculated per-protocol analysis.

Table 1: Biochemical parameters (Median [IQR])

	start OCA (n = 11)	6 m OCA (n = 11)	4-5 y OCA (n = 11)	6 m OCA + bezafibrate (n = 9)
ALP (U/L)	315.0 [275.0-408.4]	233.2 [194.4-259.4]	190.2 [157.4-252.0]	94.0 [90.0-143.5]
BILI (µMOL/L)	7.7 [6.8-20.9]	8.6 [5.8-18.0]	7.7 [6.8-14.7]	6.8 [5.0-10.5]
AST (U/L)	37.2 [27.9-67.9]	35.9 [23.8-69.0]	29.3 [26.3-47.8]	37.0 [27.5-48.5]
ALT (U/L)	45.6 [27.2-67.8]	29.3 [17.4-46.0]	21.9 [15.5-32.0]	27.0 [19.5-37.0]
GGT (U/L)	274.7 [97.3-397.7]	71.0 [52.1-189.9]	37.2 [27.6-87.8]	32.0 [26.5-103.0]

(1) Nevens F et al. N Engl J Med. 2016
(2) Corpechot C et al. N Engl J Med. 2018

Results: After 6 months (m) of OCA, ALP decreased in 73% ($p < 0.001$) and bilirubin in 64% ($p = 0.625$) of the pts. After 4-5 y of POISE, none of the pts reached the primary end point (normal ALP: 0/11 and normal bilirubin: 9/11) (see also Table 1). After 6 m of triple treatment, ALP further decreased in 100% ($p < 0.001$) and bilirubin in 67% ($p = 0.184$) of the pts. ALP was normal in 4/9 and bilirubin in 8/9 of the pts, reaching the primary end point in 44% of the pts. Itching decreased in 5/7 of the pts with bezafibrate therapy and their mean PBC-40 score decreased from 6.0 to 4.6 points ($p = 0.070$).
Conclusion: Combination therapy of OCA and bezafibrate in PBC pts had a strong additive effect on cholestasis and improved pruritus.

LBO-06
Interim safety and efficacy results of the ABI-H0731 phase 2a program exploring the combination of ABI-H0731 with Nuc therapy in treatment-naive and treatment-suppressed chronic hepatitis B patients

Email: urilopatin@gmail.com

Background and aims: Chronic Hepatitis B (CHB) infection is a major cause of morbidity and mortality worldwide. Nucleos (t)ide analogues (Nuc) are standard of care (SOC) but achieve low rates of sustained responses off therapy. The novel core inhibitor ABI-H0731 (731) exhibited potent anti-HBV activity over 28 days as monotherapy and is currently being tested in two phase 2a studies evaluating its potential benefit in combination with Nuc therapy.
Method: ABI-H0731-201 and ABI-H0731-202 are double blinded, placebo (pbo) controlled studies in F0-F2 fibrosis (or equivalent) CHB patients. In study 201, 47 HBeAg pos and 26 HBeAg neg subjects already suppressed on SOC Nuc randomized 3:2 for addition of 731 (300mg):Pbo to their SOC. In study 202, 25 treatment-naive HBeAg pos viremic subjects randomized 1:1 to Entecavir (ETV) + 300mg 731 or ETV + Pbo. Subjects randomized Day 1 and return to clinic weeks (wk) 2, 4 and then monthly up to wk 24 at which time they can enter an open-label long-term extension study of up to 1 additional year. Clinical labs, safety and PK are monitored, as well as HBV biomarkers including HBV DNA, HBV RNA, HBsAg and HBeAg. Primary efficacy end points are $\log_{10}$ decline in HBsAg/HBeAg at wk 24 (study 201), and $\log_{10}$ decline in HBV DNA at wks 12/24 (study 202).
Results: Enrolment is complete in both ongoing studies. 731 has been well tolerated; treatment emergent adverse events (AE) and

laboratory abnormalities have been few and generally mild or moderate. 3 subjects have had AE of rash (Grade (G)1 and G2) which did not limit 731 dosing: 2 self-resolved (G1) and 1 resolved on antihistamine (G2). No discontinuations due to AE or ALT flares have occurred. In study 201, 32 (suppressed) subjects have reached wk 12 and 2 subjects have reached wk 24. At wk 12, subjects on 731 + Nuc reduced HBV RNA levels by 2.6 $\log_{10}$ IU/ml vs an increase of + 0.2 $\log_{10}$ IU/ml in the Pbo + Nuc group. In study 202, 21 (naive) subjects have reached wk 12, and 4 subjects have reached wk 24. At wk 12 subjects on 731 + ETV reduced HBV DNA/RNA by 4.5/2.6 $\log_{10}$ IU/ml vs. 3.2/0.4 ($\log_{10}$ IU/ml) for the ETV + Pbo group. Individual subjects have shown decreases in HBeAg and HBsAg in both studies, but no meaningful conclusions can be drawn at this early timepoint.

Conclusion: Interim data suggest that ABI-H0731 + Nuc is well tolerated and provides early and enhanced antiviral benefit including HBV RNA reductions not seen on Nuc alone. Updated safety and efficacy data will be presented.

LBO-07

Effectiveness of therapy in 16, 567 directly-acting antiviral treated people in England: high response rates in genotype 3 hepatitis C infection regardless of degree of fibrosis, but ribavirin improves response in cirrhosis

Kate Drysdale[1], Ceri Townley[2], Faizel Mahomed[3], Graham Foster[1].
[1]*Barts Liver Centre, The Blizard Institute, Queen Mary University of London, London, United Kingdom;* [2]*NHS England, Specialised Services National Support Team, Southampton, United Kingdom;* [3]*NHS Arden and Greater East Midlands Commissoning Support Unit, Leicester, United Kingdom*
Email: k.drysdale@qmul.ac.uk

Background and aims: An estimated 100, 000 people in England have chronic hepatitis C (HCV) infection. Directly-acting antivirals (DAAs) are available, but drug choice is mandated centrally, based on national contracts, allowing comparison of regimens without confounding by clinician choice. A mandatory national registry monitors therapy. We examined sustained virological response at 12 weeks (SVR12) of different regimens.

Method: Anonymised data from 9 Jan 2019 was analysed using Stata 15. The null hypothesis was that there was no difference in SVR with different DAAs. Per protocol analyses assessed proportions with a valid outcome achieving SVR. Differences between SVR rates were statistically significant if $p < 0.05$ (Chi square or Fisher's exact tests).

Results: The registry lists 37, 693 people with HCV. 16, 756 DAA treated adults were due a 12-week post-treatment outcome eight weeks before this data extraction. 14, 603 patients had a per protocol outcome. Of these 13, 959 (95.59% [95% confidence interval (CI) 95.24% to 95.91%]) achieved an SVR12. Patients with some fibrosis had a significantly higher SVR12 (96.12% [95%CI 95.57% to 96.59%]), than those with compensated cirrhosis (94.21% [95%CI 93.45% to 94.89%]), or decompensated cirrhosis (90.02% [95%CI 87.16% to 92.29%]).

We focussed on genotype 3. For patients with moderate fibrosis, we compared SVR with 8 weeks Glecaprevir/Pibrentasvir (n = 92 (96.63% [95% CI 90.04% to 98.91%])) to 12 weeks Sofosbuvir/Velpatasvir (n = 214 (97.11% [95%CI 93.71% to 98.70%])) ($p = 0.793$). The SVR12 rate for patients with genotype 3 compensated cirrhosis given 12 weeks of Sofosbuvir/Velpatasvir and Ribavirin (n = 196 (97.96% [95%CI 94.67% to 99.23%])) was significantly higher than for those given Sofosbuvir/Velpatasvir (n = 218 (91.60% [95%CI 87.33% to 94.52%])) ($p = 0.005$), or Sofosbuvir/Daclatasvir and Ribavirin (n = 868 (92.17% [95%CI 90.18% to 93.78%])) ($p = 0.002$). 12 weeks of Glecaprevir/Pibrentasvir was not significantly different (n = 167 (96.41% [95%CI 92.23% to 98.38%])) to other regimens.

Conclusion: The English HCV treatment registry is a large, non-selective registry. SVR12 rates with Sofosbuvir/Velpatasvir and Ribavirin were higher than with Sofosbuvir/Velpatasvir or Sofosbuvir/Daclatasvir and Ribavirin in patients with genotype 3 HCV and compensated cirrhosis. No other significant differences were found.

LBO-08

Growth analysis in children with progressive familial intrahepatic cholestasis treated with the apical sodium-dependent bile acid transporter inhibitor maralixibat

Richard Thompson[1], Deirdre Kelly[2], Sanjay Rajwal[3], Alexander Miethke[4], Nisreen Soufi[5,6], Christine Rivet[7], Irena Jankowska[8], Cara mack[9], Thomas Jaecklin[10], Robert Squires[11], Kathleen Loomes[12]. [1]*King's College London, Londong, United Kingdom;* [2]*Birmingham Children's Hospital, Liver Unit, Birmingham, United Kingdom;* [3]*Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom;* [4]*University of Cincinnati College of Medicine, Cincinnati, United States;* [5]*Children's Hospital Los Angeles, Los Angeles, United States;* [6]*University of Southern California, Los Angeles, United States;* [7]*Hôpital Femme-Mère-Enfant, Bron, France;* [8]*Children's Memorial Health Institute, Warsaw, Poland;* [9]*University of Colorado School of Medicine, Colorado, United States;* [10]*Mirum Pharmaceuticals AG, Basel, Switzerland;* [11]*University of Pittsburgh Medical Center, Pittsburgh, United States;* [12]*University of Pennsylvania, Philadelphia, United States*
Email: loomes@email.chop.edu

Background and aims: Maralixibat is a potent, selective and minimally absorbed ileal apical sodium-dependent bile acid transporter (ASBT) inhibitor. Pharmacological inhibition of enterohepatic circulation may offer an alternative to surgery in progressive familial intrahepatic cholestasis (PFIC). A pre-specified 48-week interim analysis of a phase 2 open-label study of maralixibat in PFIC demonstrated a therapeutic response in a subset of PFIC2 patients. We describe a 72-week post hoc analysis of growth parameters (NCT02057718).

Method: Maralixibat doses were escalated up to 280 µg/kg/day over 13 weeks and maintained for ≥72 weeks. Serum bile acid (sBA) change from baseline was the primary, alanine transaminase (ALT), total bilirubin levels (TB), caregiver-rated pruritus (ItchRO[Obs]; 0 = none; 4 = most severe itch) were secondary end points. Height and weight z-score changes from baseline were compared in patients meeting sBA and ItchRO treatment response criteria and those who didn't.

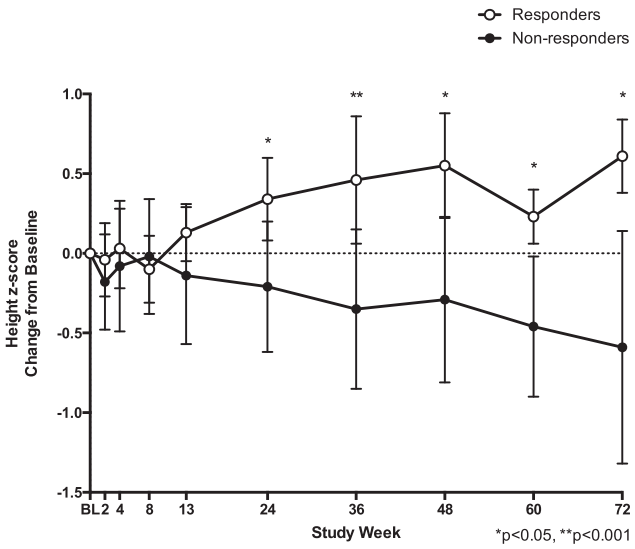

Figure: Height z-score change from baseline.

Results: Patients with PFIC2 (n = 25/33) were included; median age 4.0 years (range 1-13), 32% male. The primary end point of mean (SD) sBA reduction at week 13 was 29 (117) µmol/L; sBA reduction at week 48 was 59 (209) µmol/L. Six patients experienced sBA normalization (≤8.5 µmol/L) or reduction from baseline by ≥70% and ItchRO of 0 or

improvement ≥1.0 point (responders). Mean (SD) height and weight z-scores at baseline in responders/non- or partial responders were −1.33 (0.83)/−1.28 (1.23) and −0.63 (0.89)/−0.72 (1.07), respectively. After 48 and 72 weeks of treatment height z-score mean change from baseline was 0.55 (0.33) and 0.61 (0.23) in responders, compared to −0.29 (0.52) and −0.59 (0.73) in non- or partial responders ($p < 0.05$; Figure 1). Weight z-score mean change from baseline was 0.42 (0.29) and 0.32 (0.25) in responders and −0.29 (0.30) and −0.37 (0.51) in non-or partial responders ($p < 0.05$). Statistically significant differences were seen at 24 weeks of treatment and onwards. Treatment-emergent adverse events (TEAEs) were reported in all patients, 22 related to maralixibat, 15 had serious TEAEs, one led to discontinuation. The most frequent TEAEs were pyrexia, diarrhea, cough and abdominal pain.

Conclusion: Clinically relevant growth accelerations were observed in maralixibat treatment responders compared to non- or partial responders at 24 weeks and beyond, suggesting potential disease modification with ASBT inhibition.

NAFLD – Staging and prognosis

PS-199

sqFibrosis: A robust liver fibrosis scoring system for artificial intelligence telepathology

Yu Yang[1], Sakkarin Chirapongsathorn[2], Mongkon Charoenpitakchai[3], Nifadeelah Yalor[3], Hanry Yu[1]. [1]*Yong Loo Lin School of Medicine, National University of Singapore, Department of Physiology, Singapore;* [2]*Phramongkutklao Hospital, College of Medicine, Division of Gastroenterology and Hepatology, Department of Medicine, Bangkok, Thailand;* [3]*Phramongkutklao Hospital, College of Medicine, Pathology, Bangkok, Thailand*
Email: sakkarin33@gmail.com

Background and aims: Accurate assessment of liver fibrosis suffers from the data variations of the sampling error, staining and imaging heterogeneity in variable clinical lab settings. Experienced pathologists deal with such variations by comparing with other scoring samples in their memory to generate predictive decisions by selecting useful features and neglecting noises. Accordingly, we have developed fully a quantitative machine learning-aided algorithm (sqFibrosis) for liver fibrosis assessment using variable qualities/sizes of commonly available collagen-stains and imaging conditions of standard light microscopes from biopsy samples.
Method: A new staining index (sqFibrosis) for liver fibrosis evaluation was established as a combined index using 63 morphological features derived from tissue sections stained with conventional collagen dyes. Images acquired from 25 Thioacetamide-treated rat samples, 84 core biopsies of chronic hepatitis B (CHB), and 59-core biopsies with various etiologies (chronic hepatitis C (CHC), and autoimmune hepatitis (AIH)) were used to train and validate the index and to demonstrate its accuracy and reproducibility in the clinical settings.
Results: We showed that sqFibrosis reliably scores various fibrosis stages, as it can identify differences between all stages in animal samples and clinical biopsies ($p < 0.001$). Moreover, it is robust and unaffected by sampling error in image size, resolution and quality, allowing for sensitive scoring of fibrosis in animal samples (area under curve (AUC): 0.89–1.00 for fibrosis detection; 0.90–0.99 for significant fibrosis detection, 0.88–0.98 for advanced fibrosis detection, and 0.86–0.95 for cirrhosis detection) and can help elucidate the process of collagen deposition in fibrosis progression using different staining approaches. sqFibrosis could also address the staining quality and imaging platform variations (area under curve (AUC): 0.89–0.95 for significant fibrosis detection, 0.86–0.92 for advanced fibrosis detection, and 0.85–0.99 for cirrhosis detection) and has the ability to differentiate between Ishak stages 3, 4 and 5, 6 (AUC: 0.70) and P-I-R scores (AUC: 0.71), suggesting that it may be sensitive enough for monitoring intra-stage cirrhotic changes. Using patient samples, we further demonstrated that sqFibrosis also has the potential to stage liver fibrosis progression for other etiologies. Lastly, sqFibrosis demonstrates superior performance to CPA measurements on all counts.
Conclusion: Using only conventional collagen stained liver samples, sqFibrosis makes it possible to quantitatively score liver diseases in fully automated manner and partially correct the sampling error and variations.

Email: javi.ampuero@gmail.com

Background and aims: A) To identify the baseline features of patients with hidden advanced fibrosis by transient elastography (TE); B) To assess the diagnostic accuracy of TE by using HEPAmet Fibrosis Score (HFS); C) To develop a stepwise algorithm between HFS and TE to improve the non-invasive detection of advanced fibrosis.
Method: International multicentre study including 885 biopsy-proven NAFLD patients (Spain n = 212, France n = 330, Italy n = 250, China n = 93). HFS (age, gender, DM, HOMA, albumin, AST, platelets), considering <0.12 and >0.47 as cut-offs, and TE were evaluated. Hidden advanced fibrosis was defined as TE <9.5 kPa when F3 was shown in liver biopsy.
Results: Fibrosis distribution was: F0 24% (215/885), F1 28% (244/885), F2 22% (192/885), F3 20% (174/885), F4 7% (60/885).
A) Factors related to hidden advanced fibrosis (21% (48/234) were: BMI (>9.5 kPa 32.5 ± 5 *vs.* <9.5 kPa 29.7 ± 4 kg/m^2; p = 0.001), GGT (>9.5 kPa 169 ± 229 *vs.* <9.5 kPa 90 ± 89 UI/L; p = 0.0001), HOMA (>9.5 kPa 9.6 ± 9.5 *vs.* <9.5 kPa 5.7 ± 3.4; p = 0.0001), platelets (>9.5 kPa 191 + 62 vs. <9.5 kPa 231 ± 66; p = 0.0001).
B) TE values were: F0 6.4 ± 2.8 kPa, F1 7.1 ± 2.9 kPa, F2 9.6 ± 4.7 kPa, F3 14.8 ± 8.6 kPa, F4 25.1 ± 15.9 kPa (p = 0.0001). kPa values according to fibrosis stage and HFS: F0 (HFS < 12: 6.2 ± 2.7 *vs.* HFS 0.12–0.47: 8.3 ± 2.8 *vs.* HFS >0.47: 7.6 ± 1.7; p = ns), F1 (HFS < 12: 6.9 ± 2.6 *vs.* HFS 0.12–0.47: 7.8 ± 3 *vs.* HFS >0.47: 6.2 ± 2; p = ns), F2 (HFS < 12: 8.7 ± 3.5 *vs.* HFS 0.12–0.47: 10.6 ± 5.1 *vs.* HFS >0.47: 11.6 ± 3.6; p = 0.002), F3 (HFS < 12: 11.2 ± 4.2 *vs.* HFS 0.12–0.47: 13.4 ± 6.5 *vs.* HFS >0.47: 20.5 ± 11.5; p = 0.0001), F4 (HFS < 12: 16.8 ± 13.3 *vs.* HFS 0.12–0.47: 25.2 ± 14 *vs.* HFS >0.47: 29.2 ± 17.1; p = 0.005) (Figure).
C) A stepwise algorithm based on HFS and TE distinguished a lowest and highest risk group of advanced fibrosis that included 45% of the total population: a) HFS >0.47 and TE >17.8 kPa: advanced fibrosis in 97.7% (43/44); Se. 18% Sp. 99.9%, PPV 97.7%, NPV 77.3%, LR + 119, LR- 0.82; b) HFS < 0.12 and TE < 6.7 kPa: advanced fibrosis in 2% (6/303); Se. 97.4% Sp. 45.7%, PPV 39.2%, NPV 98%, LR + 1.79, LR- 0.06.
Conclusion: Around 25% of patients with advanced fibrosis were not detected by TE, showing less insulin resistance and BMI and also better liver function. Besides, kPa values were different in patients with the same fibrosis stage when classified according to their HFS value. The stepwise algorithm combining HFS and TE allowed the detection of advanced fibrosis with a diagnostic accuracy higher than 98% in around 50% of NAFLD patients.

PS-201

External validation in NAFLD cohorts of the FibroScan-based FAST score combining liver stiffness, controlled attenuation parameter and AST to identify patients with active NASH (NAS ≥ 4) and significant fibrosis (F ≥ 2)

Jerome Boursier[1], Ming-Hua Zheng[2,3,4], Vincent Wai-Sun Wong[5], Sophie Michalak[6], Yang-Yang Li[7], Anthony Wing-Hung Chan[8], Grace Lai-Hung Wong[5], Xiao-Yan Pan[9], Paul Cales[1]. *[1]Angers University Hospital, Department of Hepato-Gastroenterology, Angers, France; [2]The First Affiliated Hospital of Wenzhou Medical University, NAFLD Research Center, Department of Hepatology, Wenzhou, China; [3]Wenzhou Key Laboratory of Hepatology, Wenzhou, China; [4]Institute of Hepatology, Wenzhou Medical University, Wenzhou, China; [5]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, China; [6]Angers University Hospital, Department of Pathology, Angers, France; [7]The First Affiliated Hospital of Wenzhou Medical University, Department of Pathology, Wenzhou, China; [8]The Chinese University of Hong Kong, Department of Anatomical and Cellular Pathology, Hong Kong, China; [9]The First Affiliated Hospital of Wenzhou Medical University, Department of Endocrinology, Wenzhou, China*
Email: jeboursier@chu-angers.fr

Background and aims: Given the upcoming market release of drugs for at risk NASH patients, Echosens have developed a score to identify patients with active NASH (NAS ≥ 4) and significant fibrosis (F ≥ 2) combining FibroScan liver stiffness measurement (LSM), controlled attenuation parameter (CAP) and AST. The objective was to perform an external validation of this score in several independent cohorts of biopsy-proven NAFLD patients.
Method: Patients from three centers (Angers, Wenzhou, Hong-Kong) who underwent FibroScan (LSM and CAP) and a clinically indicated liver biopsy (LB) for suspected NAFLD were included. In each cohort, all LB were read by a single expert pathologist using the NASH CRN scoring system and the FLIP definition for NASH. FibroScan-based score performance to identify NASH + NAS ≥ 4 + F ≥ 2 was assessed using area under the receiver operating characteristics (AUC).

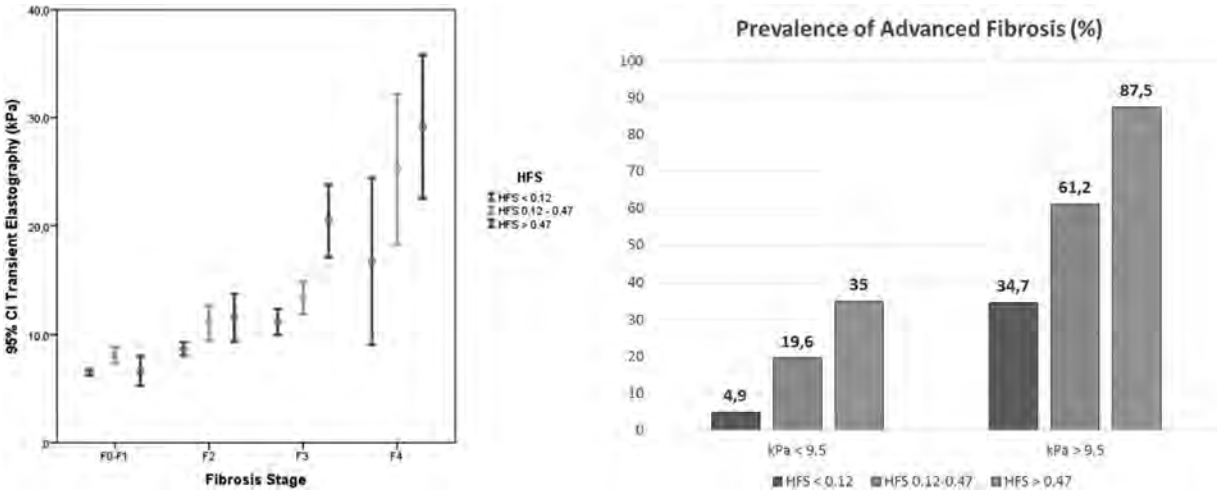

Figure: (abstract PS-200)

Table 1: (abstract: PS-201)

Cohort	Angers			Wenzhou			Hong-Kong			Pooled		
N	182			111			102			395		
Age (y)	58 [17]			40 [20]			55 [17]			53 [20]		
Female	36%			26%			47%			36%		
BMI (kg/m^2)	31.6 [8.6]			25.7 [4.3]			28.9 [5.3]			28.9 [6.9]		
AST (IU/L)	36 [22]			35 [28]			41 [31]			37 [26]		
ALT (IU/L)	48 [45]			51 [63]			68 [62]			53 [54]		
LSM (kPa)	7.9 [5.6]			5.9 [2.4]			9.2 [5.3]			7.4 [5.3]		
CAP (dB/m)	326 [72]			316 [50]			318 [61]			320 [62]		
Fibrosis F0F1	40%			85%			35%			51%		
F2	25%			9%			24%			20%		
F3	29%			5%			25%			21%		
F4	5%			0%			22%			8%		
NASH	67%			63%			60%			64%		
Fibrotic NASH	78 (43%)			12 (11%)			47 (46%)			137 (35%)		
Score LSM + CAP + AST	**0.80** (0.74–0.87)			**0.81** (0.69–0.93)			**0.86** (0.79–0.93)			**0.82** (0.78–0.87)		
AUC (95% CI)												
Performance	<0.40 N = 41% Se = 0.86 Sp = 0.61 NPV = 0.85	[0.40;0.76[N = 34%	>0.76 N = 26% Sp = 0.89 Se = 0.46 PPV = 0.77	<0.40 N = 58% Se = 0.75 Sp = 0.62 NPV = 0.95	[0.40;0.76[N = 28%	>0.76 N = 14% = 0.90 Se = 0.50 PPV = 0.38	<0.40 N = 31% Se = 0.96 Sp = 0.55 NPV = 0.94	[0.40;0.76[N = 38%	>0.76 N = 30% Sp = 0.89 Se = 0.53 PPV = 0.81	<0.40 N = 43% Se = 0.88 Sp = 0.60 NPV = 0.91	[0.40;0.76[N = 33%	>0.76 N = 24% Sp = 0.90 Se = 0.49 PPV = 0.71

Distribution: Median [IQR] or figure (%)

Diagnostic performance in each cohort were calculated using cutoffs determined in the score's derivation cohort: 0.40 for a sensitivity (Se) ≥ 0.90 and 0.76 for a specificity (Sp) ≥ 0.90.

Results: A total of 395 patients were analyzed. Characteristics of each cohort and pooled patients are given in Table 1 together with the score performances. Performance was good in each cohort with AUC above 0.80. Pooled AUC was 0.82 (0.78–0.87).

Conclusion: The simple score based on FibroScan LSM, CAP and AST showed good performance in all NAFLD cohorts. It could be used in liver units to efficiently screen patients with active NASH (NAS ≥ 4) and significant fibrosis (F ≥ 2) for drugs trials as well as identifying patients eligible for treatment when drugs will be on the market.

PS-202

Genome-wide association studies of abdominal MRI scans identifies loci associated with liver fat and liver iron in the UK Biobank

Henry Wilman[1,2], Constantinos Parisinos[3], Matt Kelly[2], Stefan Neubauer[4], Louise Thomas[1], Jimmy Bell[1], Rajarshi Banerjee[2], Hanieh Yaghootkar[5]. *[1]University of Westminster, Life Sciences, London, United Kingdom; [2]Perspectum Diagnostics Ltd, Oxford, United Kingdom; [3]University College London, London, United Kingdom; [4]University of Oxford, Oxford, United Kingdom; [5]University of Exeter, Exeter,*
Email: henry.wilman@perspectum-diagnostics.com

Background and aims: Liver fat and iron accumulation (e.g. hereditary haemochromatosis (HH), dysmetabolic iron overload syndrome) have been implicated in liver disease pathogenesis, but little is known about the genetic factors influencing these heritable traits. Multiparametric MRI is a fast, non-invasive and accurate method of measuring intra-hepatic fat and iron content. Here we aim to find genetic variants influencing liver fat and liver iron, using data from the UK Biobank.

Method: Data was acquired from UK Biobank (application 9914). Liver phenotypes were calculated from MRI data by trained analysts using LiverMultiScanTM Discover. Genetic data (UK Biobank Axiom Array) in unrelated individuals of European Ancestry, (n = 6758) were extracted. GWAS was performed with PLINK v1.90 and GEMMA. Linear additive models were used, controlling for age, sex, BMI, genotyping array, and population structure.

Results: Significant associations were seen between liver iron and variants within the HFE gene (rs1800562 (C282Y), p = 2.2 * 10–66) and TMPRSS6. The product of both genes regulate the production of hepcidin, which is the "master" iron regulatory hormone which determines how much iron is absorbed from the diet. Liver fat associations were seen with variants in PNPLA3 (e.g., rs738409, p = 2 * 10–41), TM6SF2 (rs58542926, p = 4.3 * 10–40), APOE, GCKR, GPAM, and NCAN. The same alleles at these loci are also associated with other traits, e.g., GCKR (associated with type 2 diabetes, lipid traits and cardiovascular disease), TRIB1 (lipid traits and heart disease), GPAM (lipid traits), NCAN (type 2 diabetes and lipid traits), APOE (type 2 diabetes, lipid traits and heart disease) and PNPLA3 (lipid traits and non-alcoholic fatty liver disease).

Conclusion: This is the first GWAS using MRI determined liver fat and iron content to date, which provides insights into the biology of liver disease pathogenesis and its link to other metabolic diseases. The replication of known loci provides genetic validation of the utility of MRI for the non-invasive assessment of the above measures. As more imaging data becomes available (planned for 100, 000 individuals in UK Biobank), larger GWAS will allow detection of more susceptibility loci for both liver fat and iron.

PS-203

Dietary risk factors for non-alcoholic fatty liver disease by cirrhosis status: The US multiethnic cohort

Mazen Noureddin[1], Jacqueline Porcel[2], Shira Zelber-Sagi[3], Loic Le Marchand[4], Veronica Wendy Setiawan[2]. *[1]Cedars Sinai Medical Center, Los Angeles, United States; [2]University of Southern California, Los Angeles, United States; [3]University of Haifa and The Tel-Aviv Medical Center, Haifa, Israel; [4]University of Hawaii, Hawaii, United States*
Email: mazen.noureddin@cshs.org

Background and aims: Epidemiological data on dietary risk factors for NAFLD from population-based studies are scarce. Here, we examined dietary factors in relation to NAFLD by cirrhosis status in African Americans, Japanese Americans, Latinos, Native Hawaiians, and whites from the Multiethnic Cohort (MEC).

Method: A nested case-control analysis was conducted within the MEC, a large prospective study with >215, 000 participants in Hawaii and California. NAFLD cases were identified between 1999 and 2015 using Medicare claims. Controls were selected among participants without liver disease and individually matched to cases (10:1) by birth year, sex, ethnicity, and length of Medicare enrollment. Diet was assessed at baseline via a validated quantitative food frequency questionnaire. The association between dietary factors and NAFLD by cirrhosis status was quantified by odds ratios (ORs) and 95% confidence intervals (CIs) using multivariable conditional logistic

regression stratified by matched sets and adjusted for body mass index, smoking status, and total calories.
Results: The study consisted of 2, 567 NAFLD cases (489 with cirrhosis; 2078 without cirrhosis) and 25, 579 controls. Men, African Americans, Latinos, and individuals who were obese or had diabetes were more likely to have NAFLD with cirrhosis than NAFLD without cirrhosis. Dietary factors associated with NAFLD-cirrhosis included: red meat (OR quartile 4 vs. quartile 1 = 1.36; 95% CI: 1.02–1.82), processed red meat (OR = 1.32; 95% CI: 1.00–1.74), saturated fat from meat and processed meat (OR = 1.43; 95% CI: 1.02–2.00), and cholesterol (OR = 1.59; 95% CI: 1.19–2.11). For NALFD without cirrhosis, carbohydrate (OR = 1.26; 95% CI: 1.01–1.57) and soda consumption (OR = 1.15; 95% CI: 1.00–1.32) were associated with risk.
Conclusion: Dietary risk factors for NAFLD seem to vary by cirrhosis status. Red meat, processed red meat, and cholesterol were associated with NAFLD with cirrhosis, while carbohydrates and soda intake were associated with NAFLD without cirrhosis.

PS-204
The relationship between FIB-4 progression and liver outcome among patients with type 2 diabetes mellitus: A population based hospital study
Lucia Parlati[1], Anais Vallet Pichard[1], Samir Bouam[2], Jean François Meritet[3], Alain Hernvann[3], Helene Fontaine[1], Marion Cororuge[1], Clemence Hollande[1], Philippe Sogni[1], Pol Stanislas[1], Emmanuel Tsochatzis[4], Vincent Mallet[1]. *[1]Assistance Publique — Hôpitaux de Paris (AP—HP), Hôpital Cochin, Hepatology Service and CERTIM group, PARIS 14E ARRONDISSEMENT, France; [2]Assistance Publique — Hôpitaux de Paris (AP—HP), Hôpital Cochin, Department of medical information, Paris, France; [3]Assistance Publique — Hôpitaux de Paris (AP—HP), Hôpital Cochin, Biology Service, Paris, France; [4]Sheila Sherlock Liver Unit and UCL Institute for Liver and Digestive Health, Royal Free Hospital and University College London, London, United Kingdom*
Email: lucia.parlati85@gmail.com

Background and aims: The FIB-4 index is a simple non-invasive fibrosis test developed for the diagnosis of advanced fibrosis. We evaluated the risk of liver disease progression, a composite outcome of primary liver cancer and decompensated cirrhosis, at different FIB-4 cut-offs (1.45 and 3.25) in a large cohort of patients with type II diabetes.
Method: We conducted a retrospective cohort study among consecutive adult patients with at least one hospital stay at Cochin University Hospital (Paris, France) between 2010 and 2018 and with a ICD-10 diagnostic code for diabetes mellitus (N = 39, 700). We selected all patients with type 2 diabetes mellitus without cancer, connective tissue disorder, solid-organ or bone marrow transplantation, HIV infection and chronic liver disease other than alcohol and non-alcoholic steatohepatitis. All repeated measures of liver function tests, platelet levels and glycated haemoglobin were retrieved from the biological database of the institution and merged with the clinical dataset. Outcome measure was liver disease progression. We measured the risk associated with the onset of a FIB-4 index ≥ 1.45, > 1.45- < 3.25 and ≥ 3.25 with time-dependent cox models adjusted for sex, HbA1c level and the presence of alcohol use disorders.
Results: The cohort comprised 19, 547 (49.7%) patients totalling 63, 854 FIB-4 measurements in 14, 307 (73.7%) individuals. There was 11, 259 (57.6%) men. At cohort inception, median (IQR) age, FIB-4 index and HbA1c level were 68 (58–74), 1.8 (1.2–2.8) and 7.6 (6.5–9.2), respectively. A total of 3038 (15.5%) patients were recorded with alcohol use disorders during the study period. Overall, 281 (1.4%) patients developed a liver-related complication over a median 3.6 (1.2–5.6) years. A total of 8110 (56.7%) and 2573 (18.0%) patients reached the 1.45 and 3.25 FIB-4 threshold during the observational period. The adjusted hazard ratio (95% CI) for liver disease progression was 0.6 (0.5–0.8) and 0.3 (0.2–0.5) when patients remained under the 1.45 and 3.25 thresholds; it was 8.1 (6.3–10.6) over the 3.25 threshold. The adjusted hazard ratio for liver disease progression was 8.1 (6.2, 10.6), 8.2 (6.2, 10.8) and 7.0 (5.4–9.3) for patients with alcohol use disorders and a FIB-4 index that remained under the 1.45 and 3.25 thresholds; it was 7.0 (5.4–9.3) for patients who reached the 3.25 index.

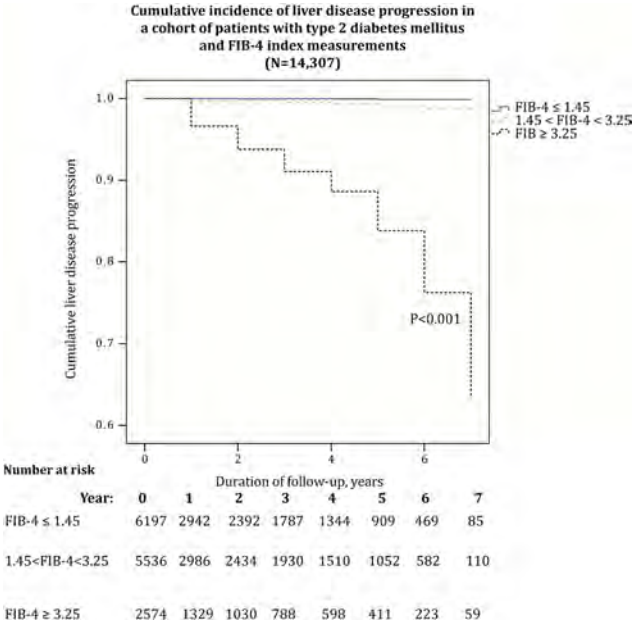

Figure: Cumulative incidence of liver disease progression in a cohort of patients with diabetes mellitus stratified on FIB-4 index (N = 19, 547).

Conclusion: The FIB-4 index progression to the 3.25 threshold is associated with chronic liver disease events among patients with type 2 diabetes mellitus. Alcohol use disorders are strongly associated with outcome.

PS-205
Longitudinal prognostic value of the most common algorithms for fibrosis in non-alcoholic fatty liver disease: An international study in non-cirrhotic, biopsy-proven patients
Ramy Younes[1], Chiara Rosso[1], Maria Jose Garcia Blanco[2], Salvatore Petta[3], Luca Miele[4], Antonio Liguori[4], Paolo Francione[5], Anna Ludovica Fracanzani[5], Luca Valenti[6], Quentin Anstee[7], Elisabetta Bugianesi[1]. *[1]University of Turin, Department of Medical Sciences, Division of Gastroenterology and Hepatology, Torino, Italy; [2]University Hospital of La Princesa, Department of Internal Medicine, Madrid, Spain; [3]University of Palermo, Sezione di Gastroenterologia, Di. Email: ramy.younes@unito.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a global health concern since it may progress to Steatohepatitis (NASH) and ultimately cirrhosis. As fibrosis is the main determinant of progressive disease, an important unmet need is to establish a defined set of biomarkers that enable detection of fibrotic NASH and can predict liver-related morbidity and mortality. We aimed at validating the long-term prognostic value of the most currently used non-invasive fibrosis scores in a cohort of biopsy-proven NAFLD patients.

Method: 918 prospectively recruited patients underwent a liver biopsy for clinical suspicion of NAFLD in main referral tertiary centres in Italy (Turin, Milan, Rome, Palermo) and the United Kingdom (Newcastle). Clinical and biochemical data were collected at the time of biopsy and throughout the follow-up. The following non-invasive fibrosis scores were calculated: NAFLD Fibrosis Score (NFS), APRI, FIB-4, BAAT and BARD

Results: At baseline, 593 patients (65%) presented non-alcoholic steatohepatitis (NASH) and 220 (24%) had moderate or advanced fibrosis. After a median follow-up of 85 months (9–336), 75 patients developed liver-related events (ascites, oesophageal varices or hepatic encephalopathy), 15 patients developed hepatocellular carcinoma (HCC) while 91 patients presented cardiovascular events. Among the non-invasive scores, NFS and FIB4 had the highest potential to predict both liver events and HCC (AUROC Liver Events 0, 76 for both NFS and FIB4; AUROC HCC 0, 82 and 0, 80 for NFS and FIB4 respectively). Despite all the scores did not show a high impact on the prediction of the cardiologic outcome, patients with a BAAT of 4 or a BARD score ≥ 2 presented a higher risk of developing cardiovascular events (OR 8, 82 and 2, 175 respectively). The survival analysis demonstrated that patients who presented a NFS > 0, 675, a FIB4 > 2, 67, an APRI > 1 or a BARD score ≥ 2 reported a worse survival outcome (Log Rank <0, 001 for NFS, FIB4 and APRI; 0, 006 for BARD). No additional value was obtained when the different scores were combined together.

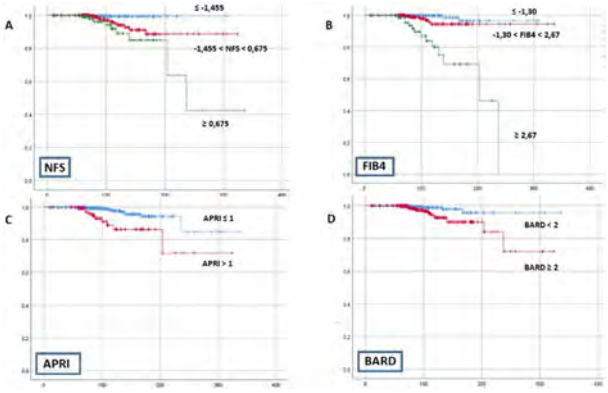

Figure: Survival curves of A) NFS B) FIB4 C) APRI D) BARD in our cohort

Conclusion: The lack of a prognostic biomarker for NAFLD and the ability of these algorithms to predict long-term NAFLD outcomes suggest the use of these scores in routine clinical practice may represent a tool to stratify patients at risk and to select patients for targeted therapies or pharmaceutical trials.

Email: brian.lee6@ucsf.edu

Background and Aims: The American Consortium of Early Liver Transplantation for Alcoholic Hepatitis (ACCELERATE-AH) is a multi-center consortium studying early liver transplant (LT) for alcoholic hepatitis (AH). To inform surveillance and intervention strategies for post-LT alcohol use, we sought to identify pre-LT factors associated with early versus later post-LT alcohol use, and if these patterns were associated with post-LT survival.

Method: In this multi-center longitudinal analysis, 11 US sites provided detailed pre-LT psychosocial, clinical, post-LT alcohol use, and survival data. Consecutive patients with clinically-diagnosed severe AH, no prior diagnosis of liver disease or AH, who received LT from 2006 to 2018, were included. Alcohol use post-LT was defined as *any* evidence of alcohol use post-LT: by clinical interview, biochemical testing, including ethyl glucuronide (ETG) and/or phosphotidylethanol (PEth). Alcohol use was categorized by date of first drink post-LT: none, early (≤1 year post-LT), later (>1 year post-LT) alcohol use. To evaluate factors associated with early vs. later post-LT alcohol use, Cox regression was performed, with LT recipients with no post-LT alcohol use as reference group, adjusting for center clustering.

Results: 140 LT recipients for AH survived to home discharge (69% male, median pre-LT abstinence 55 days, MELD-Na 39, Lille 0.79, 49% overt encephalopathy), with median post-LT follow-up of 2.5 years (IQR 1.5–4.4). Post-LT alcohol use was as follows: 91 (65%) none, 32 (23%) early use, 17 (12%) later use. The proportion with sustained alcohol use among early (11/32; 34%) versus later (4/17; 24%) alcohol use was similar (p = 0.43). Probability of any alcohol use post-LT at 1-, 3-, 5- years was 24% (95%CI: 18–32), 37% (95%CI: 29–46), 42% (95%CI: 33–53). In adjusted models, predictors of early alcohol use post-LT were younger age (HR 1.06, 95% CI 1.02–1.09, p < 0.001) and overt encephalopathy at LT (HR 1.75, 95% CI 1.05–2.91, p = 0.03), and of later alcohol use post-LT were female sex (HR 1.96, 95% CI 1.31–2.94, p = 0.001), >10 drinks/day pre-hospitalization (HR 2.45, 95% CI 1.05–5.73, p = 0.04) and prior failed rehabilitation attempt (HR 2.12, 95% CI 1.23–3.68, p = 0.007). After adjusting for MELD in separate bivariate models, both early (HR 6.36, 95% CI 2.18–18.5, p = 0.001) and later (HR 2.27, 95% CI 0.87–5.92, p = 0.09) alcohol use were associated with increased risk of post-LT death, though the association with later alcohol use did not reach statistical significance.

Conclusion: Pre-LT factors associated with early versus later post-LT alcohol use are different, which may inform surveillance strategies for post-LT alcohol use. Early (versus later) post-LT alcohol use appears to be more harmful as evidenced by the higher mortality risk. This highlights the first year post-LT as an especially important period to target interventions to prevent and treat alcohol use.

PS-207
Molecular classifier for T-cell-mediated and antibody-mediated rejection after liver transplantation

Email: hoefer.anne@mh-hannover.de

Background and aims: Long-term management after liver transplantation (Ltx) is complicated by a low sensitivity of liver enzymes for detecting subclinical graft injuries, atypical histological features of T cell-mediated rejection (TCMR) and limited knowledge about antibody mediated rejection (AMR). Graft gene expression analysis has shown superiority over histopathological assessment in detecting graft injury after kidney transplantation. The aim of this study was to generate a molecular classifier for various rejection types after Ltx.
Method: Cryo-conserved liver biopsies were collected for RNA isolation since 2008. We performed next generation transcriptome sequencing (NGS) to identify molecular pattern of rejection. Therefore, three cohorts were used: A screening cohort of 71 biopsies with no histological rejection (NHR), subclinical (subTCMR) and clinical TCMR (cTCMR) or possible chronic AMR (pcAMR) for NGS. An identification cohort of 110 biopsies with the same entities was used for qPCR of candidates from NGS and designing and validation of the rejection classifier. An application cohort of 97 liver biopsies with ambiguous histological findings was used.
Results: For identification of the four entities 85 transcript candidates were identified with NGS in the screening cohort. Candidates were tested with qPCR in the identification cohort consisting of the same entities. A rejection classifier consisting of 40 transcripts (RC40) was designed and validated in this qPCR data set. RC40 reached low sensitivities, but moderate to high specificities and total accuracies for the identification of the four entities (Table 1). When applied in the cohort with ambiguous histological findings, RC40 identified 80% of subTCMR and cTCMR features within these ambiguous findings correctly. Graft hepatitis with elevated liver enzymes mostly had molecular phenotype of cTCMR (80%) or pcAMR (10%), while subclinical graft hepatitis mostly had a molecular phenotype of subTCMR (80%) or NHR (10%). The molecular phenotype of portal inflammation was mostly subTCMR or NHR.

Table 1: RC40 in identification cohort (n = 110; NHR = 31; subTCMR = 43; cTCMR = 18; cAMR = 18):

	NHR	subTCMR	cTCMR	pcAMR
Sensitivity	68%	65%	44%	39%
Specificity	86%	73%	90%	91%
Accuracy	81%	70%	83%	83%

Conclusion: This is the first approach to generate a gene expression classifier after Ltx incorporating more than TCMR. After further validation such a rejection classifier could help to retrieve more information from allograft biopsies and facilitate individualized immunosuppression.

PS-208
Impact of successful DAA therapy at 3 years of follow-up in liver transplant recipients with hepatitis C recurrence and moderate/severe fibrosis

Silvia Martini[1], Marco Sacco[1], Giulia Testa[1], Federica Calvo[1], Stefano Mirabella[2], Donatella Cocchis[2], Giorgio Maria Saracco[1], Renato Romagnoli[2]. Email: sivima21@hotmail.com

Background and aims: Data on the long-term impact of direct-acting antivirals (DAAs) in patients with moderate/severe hepatitis C virus (HCV) recurrence after liver transplant (LT) are still lacking. In 2014, we treated in our center a cohort of patients with post-LT hepatitis C recurrence and moderate/severe fibrosis, and we observed an improvement in clinical outcome and non-invasive markers of fibrosis at 1 year (y) after viral eradication. In the same group of patients, who were prospectively followed up in our center, we aimed to evaluate the impact of viral eradication on hepatic fibrosis and liver function tests at 2 and 3 y of follow-up.
Method: This prospective, monocentric study included 102 liver transplant recipients successfully treated with DAAs between June 2014 and December 2014. At the beginning of the treatment, 72 were affected by cirrhosis (Group A; F4 according to Metavir), 30 by moderate fibrosis (Group B, F3 according to Metavir) assessed by liver biopsy and/or transient elastography (TE). At 2 and 3 y after the end of DAAs, we evaluated liver function tests, AST to Platelet Ratio Index (APRI), Fibrosis-4 (FIB-4) index and liver stiffness (LS) by TE.
Results: Patients were mostly male (77%) with a median age of 63 y; the median time between LT and viral eradication was 52 months (range 8–179). Three y after viral eradication the survival rate was 95% (97/102 patients).
Group A patients showed stable liver function tests at 2 and 3-y of follow-up (Child score A5 and MELD score 10) and platelet count significantly increased (from 112 × 10^9/L at 1-y to 131 × 10^9/L at 2-y to 135 × 10^9/L at 3-y, both $p < 0.001$). FIB-4 and APRI significantly decreased from the first to the second y (3.12 *vs* 2.86, p = 0.02; and 0.5 *vs* 0.4, p = 0.006 respectively). At the third y, these scores settled (2.69 and 0.4, respectively), compared with the second year (both p = 0.5) (Figure 1).
LS decreased from 14 Kilopascal (kPa) to 13 kPa at 2-y (p = 0.08), to 10.3 kPa at 3-y (p = 0.049) (Figure 1). One case of hepatocellular

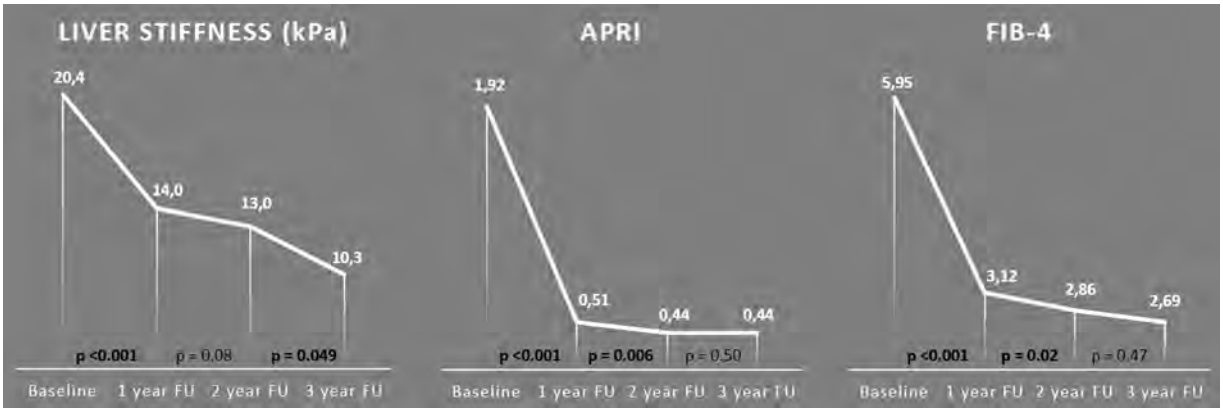

Figure: (abstract PS-208): Non-invasive markers of fibrosis after DAA therapy in cirrhotic patients.

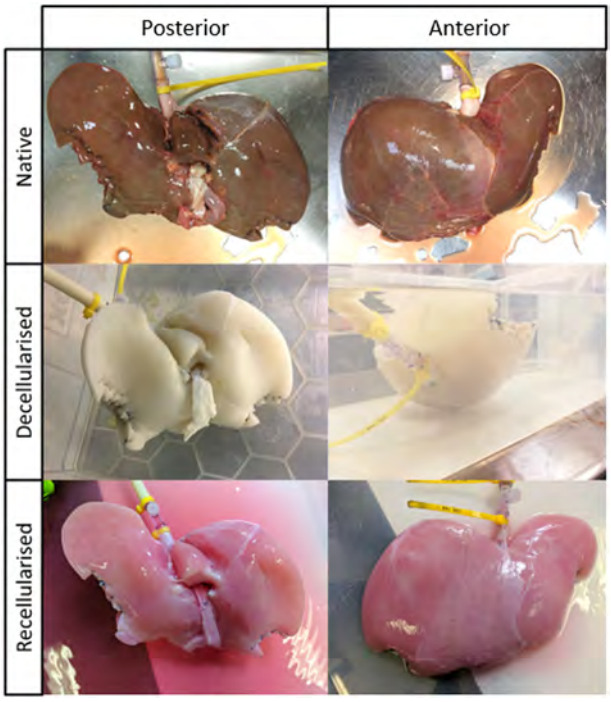
carcinoma was observed in group A, 36 months after the end of DAAs. In group B we observed a trend in reduction of non-invasive markers of hepatic fibrosis (FIB-4, APRI and LS: at y-1: 2.08, 0.4, 7.8 kPa; at 2-y 1.76, 0.3, 7.1 kPa; at 3-y 1.78, 0.3, 6.7 kPa, respectively; no significant p values).
Conclusions: Viral eradication with DAAs contributed to stabilize liver function tests of our patients affected by post-LT hepatitis C with moderate/severe fibrosis. The improvement of platelet count and the progressive reduction of indirect markers of fibrosis in group A patients may reflect a favorable remodeling in the hepatic architecture and an initial reduction of portal hypertension.

PS-209
Whole Human liver decellularisation-recellularisation for future liver transplantation and extracorporeal device application
Walid Al-Akkad[1], Eric Felli[1], Bettina M Buchholz[2], Joerg-Matthias Pollok[2], Tariq Al-Akkad[1], Toby Proctor[1], Luca Frenguelli[1], Simone Canestrari[1], Domenico Bagordo[1], Gabriele Spoletini[2], Domenico Tamburrino[2], Maria Giovanna Vilia[1], Krista Rombouts[1], Massimo Malago[2], Paolo De Coppi[3], Etienne Sokal[4], Massimo Pinzani[1], Giuseppe Mazza[1]. *[1]UCL Institute for Liver and Digestive Health, Division of Medicine, London, United Kingdom; [2]Royal Free Hospital, Department of HPB and Liver Transplant Surgery, London, United Kingdom; [3]UCL Great Ormond Street Institute of Child Health, London, United Kingdom; [4]Institut de recherche expérimentale et clinique, Université Catholique de Louvain, Brussels, Belgium*
Email: walid.al-akkad@ucl.ac.uk

Background and aims: An estimated 29 million people in the European Union (EU) suffer from a chronic liver condition, with liver transplantation still remaining the only treatment for end-stage hepatic disease. Currently, there are approximately 6700 people awaiting liver transplantation in the EU. Considering that 15–25% of donated organs are discarded, whole human liver regeneration represents a novel approach to overcome current organ shortages. One possible approach is the use of native extracellular matrix (ECM) as a suitable environment for cells to restore tissue function. Therefore, the aim of this project was to demonstrate, for the first time, the recellularisation of a decellularised whole human liver for future transplantation and extracorporeal device applications.



Method: A paediatric human liver explant (840 g), diagnosed with Crigler-Najjar syndrome, was decellularised using a well-established method, previously characterized for cellular material elimination and preservation of ECM proteins and micro-architecture. Temperature, pH, oxygen and pressure sensors were incorporated into the Harvard Apparatus' ORCA system, as well as compressed air, O_2 and CO_2 reservoirs. The whole human liver scaffold was recellularised by retrograde IVC infusion with 2×10^9 HepG2 cells. The liver was maintained in 6 L of complete media with a flow-rate of 400 ml/min. The media was changed by replacing 3L of existing media with fresh complete media after 48 hours. Albumin secretion was measured using an ELISA kit at 0, 24 and 72 hours. The liver was fixed in 4% formaldehyde at 72 hours and sectioned into 21 parts to investigate repopulation by Haemotoxilin and Eosin (HandE) stating.
Results: Histological analysis using HandE staining showed that the infused cells have infiltrated all liver segments, excluding segment one. HepG2 cells were seen microscopically to have been migrating from the central vein towards the portal triad, including penetrating into the parenchymal space. Oxygen content in the media decreased from 20% to 10% during the course of three days. Additionally, pH was reduced by 0.4. Finally, albumin present in the media increased from 0 ng/ml on day 0, to 200 ng/ml on day 1, and to 1500 ng/ml on day 3.
Conclusion: This is the first report describing the recellularisation of a whole human liver ECM scaffold with a human hepatocyte cell line. This is a key advance in the development of a bioengineered human liver for future liver transplantation and extracorporeal device applications.

PS-210
Repeated hepatic regeneration stimuli promoted biliary decompression via formation of extrahepatic biliary collaterals
Beate Richter[1], Hubert Scheuerlein[1,2], Utz Settmacher[1,2], Uta Dahmen[1]. *[1]Experimental Surgery, General, Visceral and Vascular Surgery, Jena, Germany; [2]University Jena, General, Visceral and Vascular Surgery, Jena, Germany*
Email: berichter@gmx.net

Background and aims: Patients with tumour related biliary obstruction seem not to benefit from a modern therapy concept like "two-stage hepatectomy." Therefore we designed a novel "two-stage hepatectomy" model in rats with complete or selective biliary occlusion to investigate the postoperative course. Despite transsection of the common bile duct, we observed formation of biliary collaterals leading to complete biliary decompression in 3/5 animals after subjecting them to two consecutive regeneration stimuli (selective portal vein ligation, extented liver resection)
Method: We performed two experiments: In the first experiment, rats (n = 45) were randomised into three groups (each n = 15). Groups were defined by extent of biliary obstruction: no obstruction as control group with no transection of the bile duct (Sham), 70% biliary obstruction mimicking Klatskin III° by transecting the left bile duct (sBDT), 100% biliary obstruction mimicking Klatskin IV° by transecting the common bile duct (BDT). "Two-stage hepatectomy" consisted of selective left portal vein ligation (sPVL, 70% liver volume) at postoperative day (POD) 14 to enlarge the future liver remnant (FLR) followed by a 70% partial hepatectomy (70%PHx) at POD 21. Animals were sacrificed at POD 14, 21 and 28 to assess the severity of systemic cholestasis (bilirubin levels), hepatic injury (transaminases), synthetic function (albumin and prothrombin time) and the alterations of the hepatic architecture and proliferation index (HandE, BrdU). In experiment 2 another 25 animals were subjected to BDT, sPVL and 70%PHx to visualize biliary collateral formation by µCT-examination of the explanted liver.
Results: Despite the challenging sequence of three consecutive hepatobiliary procedures within three weeks, animals tolerated surgery well with a survival of 96.7% (68/70). Signs of complete biliary obstruction (bilirubin level, histological bile duct convolutes) decreased after sPVL, and even more after the subsequent 70%PHx

leading to the suspicion of biliary collateral formation. Upon injection of blue radiopaque silicon rubber compound we visualized collateral formation in totally 6 out of 25 (~24%) animals: in 2 out of 10 (20%) animals after BDT (n = 1 at POD 21 and 28) and in 1 out of 10 (10%) animals subjected to one regeneration stimulus (BDT+sPVL: n = 0 and BDT+70PHx: n = 1) and in 3 out of 5 (60%) animals subjected to "two-stage hepatectomy." 3D-reconstruction of the samples and histological work up revealed the formation of biliary collaterals.
Conclusion: The regenerative pressure due to two regeneration stimuli fostered biliary collateral formation after biliary transection in rats. This phenomenon was so far only observed in biliary obstruction model with bile duct ligation, but not in models with bile duct transection, calling for further investigation of extrahepatic bile duct remodelling.

PS-211
Liver transplantation for HCC: Applicability and performance of the AFP score in real life. The French organization for organ sharing (ABM) experience

Email: mathildepetiet@gmail.com

Background and aims: The composite AFP model was adopted in France in January 2013 as a nationwide selection tool for HCC pts candidates to LT. The aim of this study was to evaluate in the real life applicability and performance of this model in HCC patients listed during the 1rst year of implementation
Method: Adult patients listed and subsequently transplanted for HCC in 15 French transplant centers between March 1st, 2013 and March 1st, 2014 were studied.
Data prospectively collected in the national data base of the French OSO ABM were studied. Primary end point was 3-year recurrence rate. Secondary end points were % of transplanted patients within AFP criteria, 3-year survivals, overall and in subgroups meeting or not AFP criteria, and same end points in patients transplanted after down-staging within the AFP score ≤ 2.
Agreement for extracting the ABM-centralized data was obtained from each center. Data were extracted anonymously and quality-controlled for recurrence and death.
Statistical analysis were performed with cumulative incidence functions and competing risk analysis taking into account graft lost, death from non recurrence and recurrence as competing risks
Results: 341 patients consecutively listed for HCC were included (Milan in/out: 246/79 (75.7%/24.3%), MELD 10.4). 335 patients (95%) had assessment of AFP score at listing. Among those patients, 275 (80.7%), 11 (3.2%) and 24 (7%) were transplanted with a final AFP score of ≤ 2, > 2 or after down-staging, respectively. AFP score was not reassessed before LT in 31 pts (9.1%). 3-year recurrence rate was 10.88% (95%CI 7, 63–14, 78) overall, and 10.34% (95%CI 6.84–14.65), 27.27% and 20.00% in patients transplanted with AFP score ≤ 2, > 2 or after down-staging, respectively. Median time between downstaging and LT was 38 days (IQR [20–66]). 3-year overall survival was 79.74% [95%CI: 75.02–83.67].
Conclusion: In the real life, overall survival and recurrence rates in HCC patients transplanted with AFP score ≤ 2 were in strict agreement with those predicted by the AFP model. The higher incidence of recurrence in the down-staged patients prompted a quick revision of allocation rules, by introducing a test of time of 3 months and emphasized the importance of periodical assessment of new indication systems. Adherence of centres was good at listing but quaterly reassessment deserved a reinforced control. The new AFP score-based French indication system complies with EASL 2018 CPG on HCC and can be adopted as a new model to expand Milan criteria.

PS-212
Liver transplantation in patients with grade 3 acute-on-chronic liver failure: Pre-transplant risk factors of post-transplant mortality
Thierry Artzner[1], Baptiste Michard[1], Emmanuel Weiss[2], Louise Barbier[3], Zaid Noorah[4], Jean-Claude Merle[4], Tasneem Pirani[5], Catherine Paugam-Burtz[2], Claire Francoz[2], francois durand[2], Eleni Theocharidou[5], John O'Grady[5], William Bernal[5], Nigel HEATON[5], Ephrem Salamé[3], Petru Bucur[3], Helene Barrault[3], François Lefebvre[1], Lawrence Serfaty[1], Camille Besch[1], Francis Schneider[1], Eric Levesque[4], François Faitot[1]. *[1]Hôpitaux Universitaires Strasbourg, Strasbourg, France; [2]AP-HP Hôpital Beaujon, Clichy, France; [3]Centre Hospitalier Universitaire de Tours, Tours, France; [4]AP-HP Hôpital Henri Mondor, Créteil, France; [5]King's College Hospital, London, United Kingdom*
Email: thierry.artzner@gmail.com

Background and aims: Liver transplantation (LT) in patients with cirrhosis and multiple organ failure (MOF) is a rare and controversial procedure given the ongoing organ shortage. The benefit of LT has been established for these patients in terms of individual survival but there have been diverging results concerning their post-LT outcomes as a group, which leaves uncertain the fairness of allocating organs to them in terms of collective utility. We report the post-LT results of a multicentre cohort and identify pre-LT criteria to help predict post-LT outcome.
Method: Patients who received LT with grade 3 acute-on-chronic liver failure (ACLF) between 2007 and 2017 in 5 transplant centres were retrospectively included and divided into a determination cohort (Strasbourg) and a validation cohort (Beaujon, Mondor, Tours and King's College). Immediate pre-LT one-year mortality risk factors were screened in the determination cohort and a multivariate logistic regression analysis was conducted. A predictive model was derived from these risk factors and evaluated in both cohorts by using the area under the receiver operating characteristic (AUROC) curve.
Results: One hundred and fifty-two patients met the inclusion criteria (76 in the determination cohort and 76 in the validation cohort). The overall one-year survival rate was 67.1%, with no significant difference between the two cohorts. In multivariate analysis, older age (OR = 1.092, 95% CI = 1.003–1.19, p = 0.0416), respiratory failure (not intubated vs. intubated vs. intubated with PaO_2/FiO_2 < 200mmHg: OR = 4.34, 95% CI = 1.02–18.49, p = 0.047), lactate levels > 4 mmol/l (OR = 8.04, 95% CI = 1.56–41.51, p = 0.0128) and lower leukocyte count prior to LT (OR = 0.86, CI 95% = 0.76–0.97, p = 0.014) were independent risk factors of one-year mortality. A predictive model derived from these factors was tested by comparing its AUROC curve in the determination and in the validation cohorts (0.87 vs. 0.80 respectively, p = 0.296). In addition, survival significantly differed according to the number of risk factors at the time of LT (p < 0.001).
Conclusion: We have identified four simple and clinically relevant factors that can be used to estimate the post-transplant outcome of cirrhotic patients with MOF and assist in the decision-making process with regards to the allocation of livers to such patients.

In NAFLD, alcohol drinking habits and genetics predict progression to advanced liver disease: follow-up of population surveys

Fredrik Åberg[1,2], Pauli Puukka[3], Perttu Sahlman[4], Markku Nissinen[4], Veikko Salomaa[3], Satu Männistö[3], Annamari Lundqvist[3], Liisa Valsta[3], Markus Perola[3], Antti Jula[3], Martti Färkkilä[4]. *[1]Helsinki University Hospital, Helsinki University, Transplantation and Liver Surgery Clinic, Helsinki, Finland; [2]Transplant Institute, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]National Institute for Health and Welfare, Helsinki, Finland; [4]Helsinki University and Helsinki University Hospital, Clinic of Gastroenterology, Helsinki, Finland*
Email: fredrik.aberg@helsinki.fi

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is highly prevalent in the population, but only a few patients progress to advanced liver disease. We analyzed risk factors for the development of such advanced liver disease in the general population with NAFLD.
Method: From several Finnish health-examination surveys (FINRISK 1992-2012 or Health 2000), we included individuals with NAFLD, defined as a fatty-liver index >30 and alcohol use <30 g/day for men and <20 g/day for women, with available genome-wide SNP data. Subjects with baseline clinical liver disease or viral hepatitis (baseline or follow-up) were excluded. Data were linked with national registers for liver-related admissions, mortality, and liver cancer until 2013, using ICD-codes reflecting liver cirrhosis or liver dysfunction. Age, sex, waist-hip ratio (/1SD), non-HDL and HDL cholesterol, triglycerides, diabetes, hypertension, alcohol use (g/day), wine fraction (percentage of total alcohol intake), binge drinking (5 drinks per occasion once/wk, once/month, or less often), PNPLA3 (rs738409), TM6SF2 (rs58542926), exercise (at least 2x/wk, 2-4x/month, or less often), smoking (current, former, never), and cigarettes/day were entered into backward stepwise Cox regression analysis with incident liver disease as the outcome.

	HR	95% CI	P
Age	**1.05**	**1.02-1.07**	**<0.001**
Waist-hip ratio (/1SD)	**1.80**	**1.32-2.44**	**<0.001**
HDL cholesterol	**2.09**	**1.08-4.04**	**0.03**
Alcohol use (10 g/day)	**1.43**	**1.12-1.82**	**0.004**
Binge drinking			
Less often	**Reference**		
Monthly	**2.69**	**1.27-5.69**	**0.01**
Weekly	**1.48**	**0.61-3.58**	**0.39**
TM6SF2 carrier	**2.18**	**1.12-4.24**	**0.02**
PNPLA3 carrier	**1.88**	**1.09-3.26**	**0.02**

Results: Complete data were available for 6462 NAFLD subjects (men 60%, mean age 53 yrs, diabetes 10%, lifetime abstainers 10%, mean alcohol intake 11 g/day). During 70401 person-years of follow-up, we observed 58 incident liver events. In the final Cox regression model, age, waist-hip ratio, HDL cholesterol, alcohol intake, binge drinking habits, PNPLA3, and TM6SF2 were significant independent predictors of liver events (Table). There was a 43% rise in the risk of liver events per each additional alcohol drink/day (1 drink = 10 g ethanol). We found no significant interaction effects between age or sex and the independent predictors.
Conclusion: Our findings highlight the role of alcohol drinking habits and genetics in the progression of NAFLD in the population. These data help identify patients at risk of developing complicated liver cirrhosis, in whom more intensive liver evaluation may be warranted.

LBP-02

Association between HBsAg loss and long-term clinical outcome in chronic hepatitis B: a systematic review and meta-analysis analysis

Hannah S.J. Choi[1], Ryan Anderson[2], Oliver Lenz[3], Marion Peters[4], Harry Janssen[1], Veronica Miller[2], Bettina Hansen[5]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]University of California, Berkeley, Forum for Collaborative Research, Washington, United States; [3]Janssen, Research and Development, Antwerp, Belgium; [4]University of California, San Francisco, San Francisco, United States; [5]University of Toronto, IHPME, Toronto, Canada*
Email: randerson@forumresearch.org

Background and Aims: Seroclearance of HBsAg is the recommended primary treatment goal for chronic hepatitis B (CHB) virus infection according to the current guidelines. It is of great interest to assess whether HBsAg loss translates into improved patient outcomes. This could further inform drug development and regulatory decision-making. We report on a systematic literature review and metaanalysis evaluating the strength of association between HBsAg seroclearance and long-term clinical outcomes.
Method: A systematic literature review was conducted in PubMed, EMBASE, and Cochrane Library databases for articles published between January 1990 - November 2018. Included studies had > 50 CHB patients, measured for the presence of serum HBsAg at baseline and during follow-up, and reported data on the incidence of hepatocellular carcinoma (HCC), liver decompensation, liver transplantation (LT), and/or all-cause mortality. A meta-analysis of risk ratios (RR) using a random effects model was performed independently for each endpoint and for a composite endpoint where only the first clinical event reported was used. Reciprocal continuity correction factors were used for studies reporting 0 events. Sensitive analyses were conducted to determine the robustness of the results.
Results: Our initial search strategy identified 3503 articles, of which 92 were assessed for eligibility and 27 articles were included in the quantitative synthesis: 24 reporting data on HCC, 5 on liver decompensation, and 10 on LT and/or all-cause mortality. The meta-analysis of the clinical endpoints produced pooled RRs for the HBsAg seroclearance group equal to 0.34 (0.17 – 0.68, $p < 0.01$) for hepatic decompensation, 0.76 (0.58 – 1.01, $p = 0.019$) for LT and/or all-cause mortality, 0.39 (0.25 – 0.61, $p < 0.01$) for HCC, and 0.40 (0.26 – 0.59, $p < 0.01$) for the composite endpoint, indicating significantly improved clinical outcome following the loss of HBsAg. The composite event rates were 39/100,000 person-years for the HBsAg-loss group and 152/100,000 person-years for the HBsAgpersistent group. Sensitivity analyses through stratification of

ELSEVIER

studies by treatment/natural history, HBV genotype, follow-up duration, and presence of coinfections showed that none of these factors significantly influence the RR for the composite endpoint ($p<0.05$).

Conclusion: The results of our analysis support the use of HBsAg seroclearance as a surrogate marker for improved clinical outcome in CHB patients.

LBP-03

LPCN 1144, an Androgen Receptor Agonist Targeted for NASH, Reduces Liver Fat and Key Serum Biomarkers

Jonathan Baker[1], Kilyoung Kim[1], Burke Byrne[1], Nachaippan Chidambaram[1], Arun Sanyal[2], Michael Charlton[3], Mahesh Patel[1]. *[1]Lipocine, Salt Lake City, United States; [2]Virgina Commonwealth University, Richmond, United States; [3]University of Chicago, Chicago, United States*
Email: innoventiusip@gmail.com

Background and aims: Androgen receptor signaling has been shown to be involved in fibrosis, inflammation, and steatosis pathways in NASH. Here we report results from clinical trials with LPCN 1144, an orally bioavailable prodrug of testosterone, an androgen receptor agonist, on liver disease biomarkers in adult hypogonadal males.

Method: The Liver Fat Study (LFS) is a 16-week open-label, multi-center, single arm study with LPCN 1144 treatment in subjects (n = 36) with liver fat (LF) changes assessed by Magnetic Resonance Imaging-Proton Density Fat Fraction (MRI-PDFF).

The Study of Androgen Replacement (SOAR) trial was an active controlled randomized multicenter 52-week study with LPCN 1144.

Results: In the LFS, NAFLD (liver fat ≥5 %) prevalence was 58% at baseline (BL), with increased prevalence in obese males.

At the 8-week interim visit (16 week to be presented), subjects having BL liver fat ≥1 0% had mean absolute and relative liver fat reductions of 7.6% and 38%, respectively. Increasing BMI was associated with increased response (absolute liver fat change): BMI 30-40 kg/m2 (−5.2%); BMI ≥4 0 kg/m2 (−9.4%). The responder rate, based on absolute LF reduction of at least 4.1%, for subjects with LF BL ≥1 0% was 86%. 28% of NAFLD confirmed subjects experienced NAFLD resolution with LPCN 1144.

In the SOAR trial, subjects with elevated baseline ALT, GGT, TG, and Lp-PLA2 experienced significant reductions. Significant normalization rates for above-normal levels of liver enzymes (ALT = 52%, GGT = 31%) and lipids (TG = 34%, and LDL-C = 56%) were observed post LPCN 1144 therapy. ALT responder rate (ALT normalization with at least 30% reduction) as a potential indicator of liver histological improvement was 43%.

Additionally, improvements were observed with LPCN 1144 in sexual and mental domains.

LPCN 1144, with up to 52 weeks exposure, exhibited no adverse drug reaction in the Hepatobilliary System Organ Class (e.g., peliosis hepatitis, hepatic neoplasms, cholestatic hepatitis and jaundice), no major adverse cardiac events (MACE), no signs of increased skeletal fragility or nephrotoxicity, and good gastrointestinal tolerability.

Conclusion: Our results indicate androgen deficiency is strongly associated with NAFLD/NASH in males. LPCN 1144 therapy meaningfully reduces liver fat in hypogonadal males, suggesting utility as a NAFLD/NASH therapy.

LBP-04

Investigation of synbiotic treatment in non-alcoholic fatty liver disease (NAFLD): Results of the INSYTE study

Chris BYRNE[1], Eleonora Scorletti[1]. *[1]University of Southampton, Southampton, United Kingdom*
Email: C.D.Byrne@soton.ac.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD), is characterised by abnormal accumulation of triglycerides in the liver. Recent evidence suggests that altered gut microbiota can play a role in the pathogenesis of NAFLD. A synbiotic is a combination of a pro- and prebiotics. Our aim was to investigate the effect of synbiotic treatment on: a) liver fat; b) liver fibrosis bio-markers and c) gut microbiota in patients with NAFLD.

Method: In a phase 2 double-blind placebo-controlled trial (INSYTE-Investigation of synbiotic treatment in NAFLD), participants with NAFLD were randomised to 10-14 months intervention with either synbiotic (fructooligosaccharides; 4 g/day+*Bifidobacterium animalis* subsp. *lactis* BB-12) (n = 55) or placebo (n = 49). Liver fat was measured by magnetic resonance spectroscopy (MRS), and change in gut microbiota composition was measured by a 16S rRNA sequencing in stool samples. The effect of the synbiotic intervention was tested in regression models.

Results: Mean and standard deviation (SD) for age and BMI were 50.8 (12.6) years and 33.1 (5.2) kg/m^2 respectively. 65% were men and 37% of participants had diabetes. Mean and (SD) of baseline and end-of-study MRS liver fat percentage was 32.3 (24.8) and 28.5 (20.1) (synbiotic) and 31.3 (22) and 25.2 (17.2) (placebo). In the unadjusted intention to treat (ITT) analyses, there was no evidence of a difference between groups ($\beta = 2.8$; 95% CI: −2.2, 7.8; $p = 0.3$). In a fully adjusted model (adjusted for baseline measurement of the outcome plus age, sex, weight difference, baseline weight), weight loss was significantly associated with an improvement in MRS liver fat percentage at the end of the study ($\beta = 2.0$; 95% CI: 1.5, 2.6; $p = 0.03$). Synbiotic consumption fostered the growth of *Bifidobacterium* and *Faecalibacterium* at the expense of *Oscillibacter* and *Alistipes*.

Conclusion: Synbiotic treatment was effective in changing the gut microbiota in patients with NAFLD. However, this pro- and prebiotic combination was ineffective in modifying liver fat and fibrosis biomarkers.

LBP-05

classification and mutation prediction based on liver cancer hisopathological images using deep learning

Mingyu Chen[1,2], jiasheng cao[1], bin zhang[1], hepan zhu[1], Xiujun Cai[1,2]. *[1]Sir Run Run Shaw hospital, Zhejiang University, general surgery, hangzhou, China; [2]Key Laboratory of Endoscopic Technique Research of Zhejiang Province and Engineering Research Center of Cognitive Healthcare of Zhejiang Province, hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and aims: HCC is the most common subtype of liver cancer, and assessing its grade requires visual inspection by experienced pathologist. We aim to use HandE image to automatically classify them into well, moderate, poor or normal liver tissue, even predict the fifteen most commonly mutated genes in HCC using deep learning.

Method: We used 188 HCC whole-silde HandE Images with 16700 tiles at magnification of 60 X from the Genomic Data Commons databases to train a deep convolution neural network (inception v3, Easy DL) for classification and mutation prediction. The performance of this model, which is evaluated by receiver operating characteristic curve, is comparable to that of pathologists. Moreover, our models were validated on independent datasets of 94 whole-silde HandE images with 9400 tiles at magnification of 60 X from our center.

Results: Compared to pathologist, it demonstrated better accuracy (94.7%) and sensitivity (94.9%) for classifying its grade in the training cohort. The values of AUC in the internal and external validation cohorts were up to 0.95 and 0.93, respectively. Furthermore, we trained the network to predict the fifth most commonly mutated genes in HCC. We found that five of them, including TP53, CTNNB1, ALB, TERT and APOB, can be predicted from pathology images, with internal and external AUCs from 0.71 to 0.89.

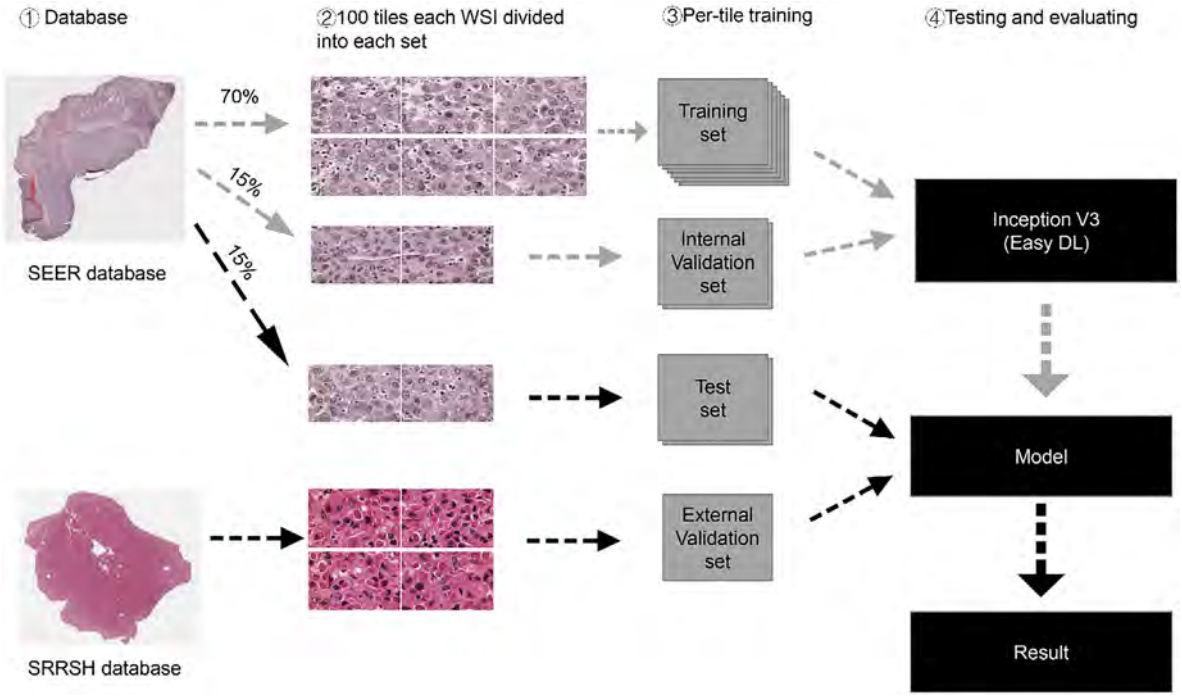

Figure (abstract: LBP-05): Strategy for training and validation.

Conclusion: Our novel models using deep learning can assist pathologists in the detection of liver cancer grade and gene mutations.

LBP-06

High Seroprotection Rates Achieved with Two Doses of Sci-B-Vac, a Third Generation Hepatitis B containing PreS1, PreS2 and S Antigens.

Francisco Diaz-Mitoma[1], Johanna Spaans[2], Nathalie Machluf[1], David Anderson[2], Avi Mazaltov[2]. [1]*VBI Vaccines Inc., Clinical Department, Cambridge, United States;* [2]*VBI Vaccines Inc., Cambridge, United States*
Email: fdiazmitoma@vbivaccines.com

Background and aims: Acute hepatitis B virus (HBV) infection may develop into a chronic disease, leading to a carrier state, chronic hepatitis, cirrhosis and liver cancer. Although licensed HBV vaccines are safe and effective in controlling HBV in healthy people younger than 40 years of age, vaccine efficacy decreases with age, in diabetics or smokers, in people with compromised immunity, or because of non-compliance with the required regimen. In both the US and Europe, there have been significant decreases in the incidence rates of acute HVB, however, the prevalence of chronic HBV and HBV carriers has actually remained constant or even increased. Europe, more so than the US, faces an increased risk of HBV due to the higher numbers of migrants and refugees. Thus, a more potent vaccine that is safe and protects faster or with fewer doses may address both public health and compliance needs. We tested the ability of SciBVac, a third generation HBV vaccine containing the Pre-S1, Pre-S2 and S components of HBV surface antigen (HBsAg) to elicit robust seroprotection after two or three immunizations.
Method: We analyzed the seroprotection rates (SPR or Anti-HBs of >10 IU/ml) after the second and third doses of Sci-B-Vac in three clinical studies, a phase 4 study conducted in Israel, a single arm open study (SciBVac n = 83) and two phase 3 studies; a single-blind comparative, controlled, randomized study conducted in Vietnam (SciBVac n = 120 and Engerix n = 117) and a comparative randomized study conducted in Russia (SciBVac n = 47 and Engerix n = 47). The three studies were conducted according to good clinical practice in healthy volunteers 18-45 years of age. Blood for Hepatitis B antibody testing was collected before and after each immunization. Standard diary cards were collected to determine vaccine reactogenicity and safety. Volunteers were followed for a total of 12 months.
Results: The SPR after two immunizations with SciBVac (day 180) was 98.8% (82/83) in the single arm Israeli study. The SPR after two immunizations with SciBVac or Engerix (day 180) was 98.3% (118/120) vs 81.2% (95/117, p = <0.001) in the Vietnamese study and 100% (47/47) vs 89% (42/47, p = 0.06), respectively in the Russian study. SPR post third immunization with SciBVac was 100% and 98% for Engerix in both phase 3 studies. Both vaccines had a similar reactogenicity and safety profile with no safety signals detected during volunteer follow-up.
Conclusion: Three separate SciBVac clinical studies demonstrate that the vaccine is well tolerated and that most individuals under the age of 45 achieve seroprotection with two doses of SciBVac.

LBP-07

Association of pharmacogenomics and pharmacokinetics with antiviral activity of Pradefovir for treatment of chronic hepatitis B infection

Hong Zhang[1], hong chen[1], qingmei li[1], junqi niu[1], yanhua ding[1]. [1]*The First Hospital of Jilin University, Jilin, China, changchun, China*
Email: lqmandy@163.com

Background and aims: Pradefovir, a liver-targeting oral prodrug of PMEA (active ingredient of adefovir), developed by using HepDirect TM patented technology, could be converted efficiently to PMEA by cytochrome P450 isozyme 3A4 (CYP3A4). The aim of this study was to evaluate the association of pharmacogenomics and pharmacokinetics with antiviral activity of pradefovir for treatment of chronic hepatitis B infection (CHB).

Method: 50 CHB patients were divided into five groups (10 for each group) and randomized within each group in the ratio 6:2:2 to receive an ascending dose of 30, 60, 75, 90, or 120 mg of pradefovir, adefovir dipivoxil 10 mg or tenofovir disoproxil 300 mg once a day for twenty eight days. The plasma pradefovir and PMEA concentrations were measured using LC-MS/MS, and pharmacokinetic parameters were determined by non-compartmental methods. Genetic analyses of absorption, distribution, metabolism and excretion were carried out by the Drug Metabolizing Enzymes and Transporter Affymetrix PharmacoScan Array.
Results: 50 patients (10 per group) were admitted and completed the study. Pradefovir has been well tolerated in CHB patients, and most of the adverse events (AEs) were mild, and there were no dose-limiting toxicities. AEs or laboratory abnormalities ≥G rade 2 were infrequent (40 times, 42% (21/50)), and 94% (47/50) patients experienced ≥1 AE on treatment. Pradefovir effectively inhibited HBV DNA for both HBeAg+ and HBeAg- patients. The mean decline in HBV DNA were −2.77 to −3.44IU/Ml at after pradefovir treatment, which were more than that at adefovir dipivoxil group, and the decline in HBV DNA of high dose group were also more than that at tenofovir disoproxil group. Tmax and t1/2 of pradefovir were obtained at about 0.25 to 1.5 hour and 1.91 to 2.95 h after administration. Conversion of pradefovir to PMEA was rapidly, the Tmax and t1/2 of PMEA were obtained at about 0.25 to 1.5 hour and 9.4 to 11.63 h after administration. Rs2517474 G, rs2517448 T or rs6457327 A allele were significantly associated with the higher exposure of pradefovir ($AUC_{0\text{-}24hour}$). However the relationship between the gene polymorphism with the decline in HBV DNA was not significant. Rs6939511 G allele was significantly associated with the higher exposure of PMEA ($AUC_{0\text{-}24hour}$), and the mean decline in HBV DNA was higher at G allele group after 28 days treatment (−3.37 and −3.06 IU/ml at A/G and A/A genotype, respectively).

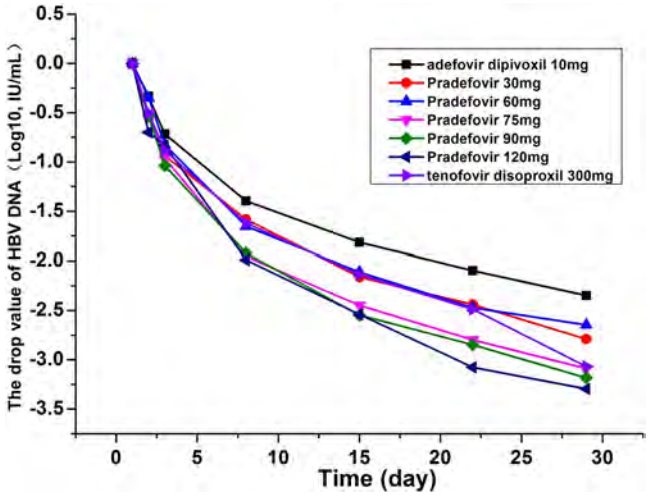

Figure 1: The drop value of HBV DNA (Log 10, IU/ml).

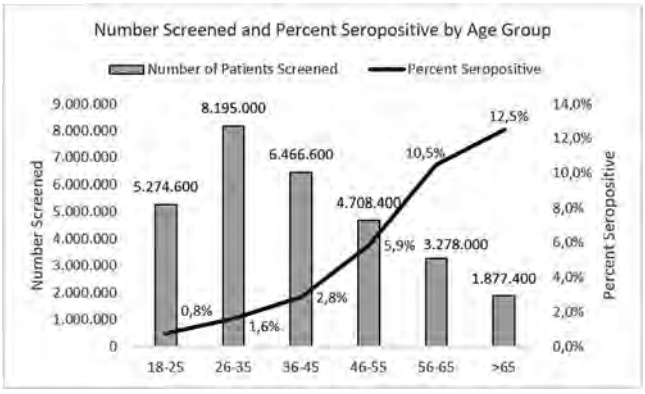
Conclusion: Pradefovir was found to be well tolerated and effectively inhibit hepatitis B virus in this study. Drug Metabolizing Enzymes and Transporter gene polymorphism was associated with the exposure of PMEA and antiviral effect. On the basis of these results, The gene polymorphism should be explored in phase II-III trials of treating CHB patients.

LBP-08

The World's Largest Hepatitis C Screening Program in Egypt

Wael Abdel-Razek[1], Mohamed Hassany[2], Dr Khaled Kabil[3], Islam Ammar[4], Hany Dabous[5], Wahed Doss[6], Manal Hamdy El-Sayed[7], yehia elshazly[8], Gamal Esmat[6], Imam WAKED[1], Magdi El-Serafy[6]. *[1]National Liver Institute, Menoufiya University, Hepatology Department, Shebeen El-Kom, Egypt; [2]National Hepatology and Tropical Medicine Research Institute, Tropical Medicine Department, Cairo, Egypt; [3]New Pediatric Children Hospital, Cairo University, Cairo, Egypt; [4]Faculty of Medicine, Al-Azhar University, Tropical Medicine Department, Cairo, Egypt; [5]Faculty of Medicine, Ain Shams University, Tropical Medicine Department, Cairo, Egypt; [6]Kasr Al-Aini School of Medicine, Cairo University, Hepatology and Tropical Medicine Department, Cairo, Egypt; [7]Faculty of Medicine, Ain Shams University, Pediatrics Department, Cairo, Egypt; [8]Faculty of Medicine, Ain Shams University, Internal Medicine Department, Cairo, Egypt*
Email: wabdelrazek@liver-eg.org

Background and aims: With the highest prevalence of HCV and 5.5 Million viremic patients, HCV elimination became a national health priority in Egypt. The national HCV treatment program with DAAs began in 2014, and by September 2018, about 2.5 million patients had been evaluated for and started treatment. These represented most patients who had been living with the diagnosis, and by mid 2018, the rate of patients registering for evaluation and treatment markedly decreased.
Methods: To augment treatment flow and meet disease elimination targets, a national population screening program was initiated in October 2018 aiming at screening all adults above the age of 18 (61 million), and all school children between the ages of 12 and 18 if their parents signed a letter of approval (15 million) within two years. The country was divided into three geographic sections of 17 to 23 million adults each, and the mass screening program is being implemented in three phases, with screening for adults lasting two to three months in each section, followed by screening school children. Screening is totally free and includes testing for anti-HCV, diabetes, hypertension and obesity. The cost of 12 weeks' treatment with locally produced generics was negotiated down to US$ 45. Preparation for each phase includes training ~1000 trainers who train more than 18, 000 healthcare workers (physicians, nurses, data entry personnel), and preparing screening sites in many Ministry of Health hospitals, rural health units, schools, sports facilities and youth centers. Each phase includes 5, 000 to 7, 000 screening sites, which work 12-hour days seven days a week. These screening sites are augmented by specially outfitted vehicles, which target crowds in mosques on Fridays, churches on Sundays, sports clubs, factories, and subway stations. Results are immediate, and data are transmitted instantaneously to a central database through handheld devices and cellular networks. Appointments are set for HCV seropositive individuals through the web-based registration system at a treatment center nearest to their residence, where further evaluation and treatment are free at the expense of the state.
Results: In the first 4.5 months of the program, turnout was massive, 29.8 Million persons were screened (78.5% of the target population in the areas where screening is still ongoing). Of these, 1.2 million were seropositive (4%), were referred for further evaluation, of whom 75% were viremic. Those who test positive and fail to show for their evaluation appointments are contacted to identify the cause of the "no show." The figure shows the number screened and percent seropositive in each age group.



Conclusion: With this screening program and the mass treatment effort that has been the largest in the world so far, Egypt is on a fast track to HCV elimination, and has the potential to be the first country to achieve the WHO disease elimination targets.

LBP-09

Liver humanization of Fah −/−/Rag2 −/−/Il2rg −/−andnbsp;NOD mice with human hepatocytes homozygous for M148I PNPLA3 allows the assessment of specific genotype contribution to NASH development in vivo.

Lander Foquet[1], Rob Copenhaver[1], Leslie Wakefield[2], Bin Li[2], John Bial[1], Markus Grompe[1,2]. *[1]Yecuris, Tigard, United States; [2]Oregon Health and Science University, Portland, United States*
Email: landerfoquet@yecuris.com

Background and aims: Current preclinical rodent models of NASH are inadequate and do not represent the full pathology of human NAFLD/NASH. This is reflected by the difficulties in the clinic, where observations from animal models failed to predict clinical trial outcomes.
Building on the liver humanized FRG KO model, we set out to establish an in vivo model, that recapitulates dyslipidemia/NAFLD/NASH with only high fat diet and without additional chemical inducers. To study hepatocytes from human donors with known genotypes of importance in the development of NAFLD and NASH, we assessed a PNPLA3 homozygous mutant donor in the model system.
Method: Fah −/−/Rag2 −/−/Il2rg −/− NOD (FRG KO/NOD) mice were transplanted with human hepatocytes from a donor homozygous for the G allele of rs738409 in PNPLA3. The M148I variant is significantly associated with high risk of NASH development. After near complete repopulation of the liver with human hepatocytes, the mice received either standard chow or a high fat diet (HFD) with fructose and cholesterol. The diets were 10% v 45% fat by kcal, respectively. Control murinized FRG KO/NOD animals (transplanted with murine NOD hepatocytes) were treated similarly (standard vs HFD chow). Animals from the four groups were bled every other week and sacrificed on weeks 8, 12, 16, and 20 after the start of the experiment.
Results: Lipidomics: Liver humanized mice on a regular diet show a lipid chemistry profile similar to humans (LDL/HDL ratio of ~1.5) whereas wildtype mice have low levels of circulating LDL (LDL/HDL ratio of ~0.3). After four weeks, the humanized animals on HFD had cholesterol levels 10-fold higher than control humanized animals. After eight weeks, the VLDL metabolic pathway started to fail, which is typical of a clinical NASH phenotype. Histology: By week sixteen, key NASH characteristics were detectable in the HFD group: hepatocyte ballooning, evidence of fibrosis, and a blood profile similar to that seen in patients with NASH. Liver histology of liver murinized mice did not exhibit similar features of human non-alcoholic fatty liver disease (NAFLD). Compared to animals transplanted with mouse hepatocytes, the liver humanized mice did not become obese, but did show an increase of liver to body weight ratio (control: 12% vs HFD: 15%).

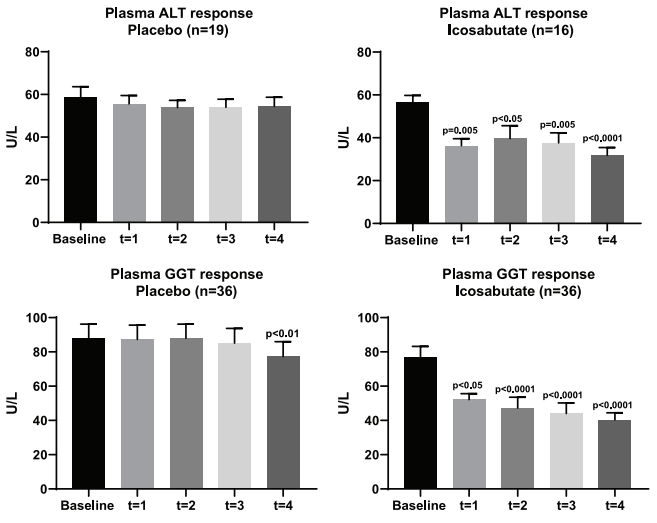
Conclusion: The liver humanized FRG KO model adds significant human relevance to an animal model system and will be of high value in studying the efficacy of novel treatments against NAFLD and NASH in an in vivo setting. Moreover, the flexibility of transplanting human hepatocytes from different donors allows us to study the development of NASH in human hepatocytes with specific mutations like M148I PNPLA3. After successful transplantation, these mice can either be used for in vivo studies on drug metabolism and efficacy against liver disease, or the human hepatocytes can be plated fresh for use in high throughput in vitro studies.

LBP-10

A structurally engineered fatty acid, icosabutate, rapidly normalises elevated plasma ALT and gamma-glutamyl transferase (GGT) concentrations in a study population at high risk of NAFLD/NASH

David A. Fraser[1], Xiao-Yu Wang[2], Marta Iruarrizaga-Lejarreta[3], Ditte Denker Thorbek[4], Tore Skjaeret[1], Michael Feigh[4], Cristina Alonso[3], John Kastelein[5], Detlef Schuppan[2]. *[1]Northsea Therapeutics, Goomier, Netherlands; [2]Johannes Gutenberg University of Mainz, Mainz, Germany; [3]OWL (One Way Liver S. L.), Derio, Spain; [4]Gubra, Hørsholm, Denmark; [5]Academic Medical Centre, Amsterdam, Netherlands*
Email: david.fraser@northseatherapeutics.com

Background and aims: Excessive plasma and mitochondrial membrane polyunsaturated fatty acid peroxidation contributes to the pathology of steatohepatitis, making supplementation with cardioprotective omega-3 supplementation potentially counterproductive in NAFLD patients. We have recently shown that in contrast to eicosapentaenoic (EPA), icosabutate (structurally modified EPA that avoids membrane incorporation) markedly reduces hepatic oxidative stress and plasma alanine aminotransferase (ALT) in rodent models of NASH. As reductions in plasma ALT have shown to be predictive of histological responses to therapy in NASH, we assessed time-course changes in abnormal baseline ALT and gamma-glutamyltransferase (GGT) from clinical trials in 3 study populations with a high risk of NAFLD/NASH (hyperlipidemic, overweight/obese, high prevalence of diabetes) treated for up to 12 weeks with 600 mg/day oral icosabutate or placebo.
Method: Subjects with abnormal baseline ALT (>40 U/L) or GGT (>38 U/L females, >51 U/L males) from 3 clinical trials were identified. Plasma ALT and GGT were assessed over 5 time points: 0, 1, 2, 3 and 4 weeks (study end) in NCT02364635 (phase 1b) and 0, 2, 4, 8 and 12 weeks (study end) in NCT01893515 and NCT01972178 (both phase 2a studies). Sequential time points were characterized as baseline, t = 1, t = 2, t = 3 and t = 4 and differences versus baseline were assessed via Friedman's ANOVA with Dunn's correction.



Results: From a total of 115 icosabutate- and 106 placebo-treated subjects, 36 subjects in each group had abnormal baseline GGT whereas 16 and 19 had abnormal ALT respectively. Icosabutate induced a rapid (within 1-2 weeks) and significant 45% reduction in mean plasma ALT (56 baseline vs 31 U/L study end, $p < 0.0001$), with 14/16 (88%) subjects achieving a normal ALT at study-end. Plasma GGT was also rapidly reduced by icosabutate, achieving a 48% decrease vs. baseline (77 baseline vs 40 U/L study end, $p < 0.0001$). In the icosabutate treated arm 29/36 (81%) had normal GGT at study end (see Figure). Plasma ALP (subjects >70 U/L baseline) and AST (subjects >34 U/L baseline) were also significantly reduced at all time points in icosabutate treated, but not in placebo treated subjects.
Conclusion: Oral icosabutate (600 mg) rapidly reduces both plasma ALT and GGT within 1-2 weeks, with >80% of subjects achieving normal levels within 12 weeks. Absolute decreases are comparable/superior to those that have been associated with histological responses in NASH intervention trials. An upcoming phase 2b trial with icosabutate will confirm whether reductions in liver enzyme in a study population with a high prevalence of NAFLD/NASH are also predictive of decreases in patients with biopsy confirmed NASH.

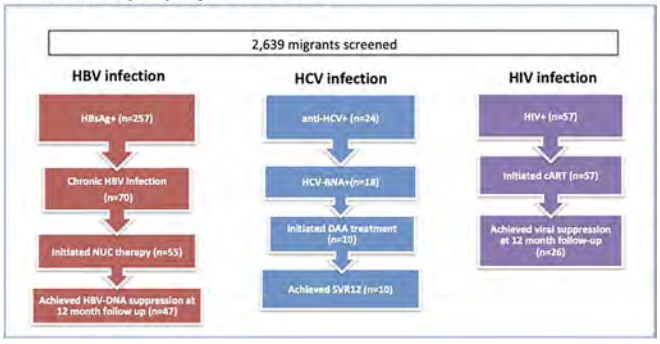
LBP-11

Is it possible to successfully link migrants from low-income countries to HBV, HCV, and HIV services upon arrival in the European Union?

Tullio Prestileo[1], Vito Di Marco[2], Ornella Dino[3], Adriana Sanfilippo[1], francesco Di Lorenzo[1], Marco Tutone[4], Maurizio Milesi[5], Camila Picchio[6], Antonio Craxi[2], Jeffrey Lazarus[6]. *[1]ARNAS Civico-Benfratelli Hospital, Infectious Diseases Unit and Centre for Migration and Health, Palermo, Italy; [2]University of Palermo, Gastroenterology and Hepatology Unit, PROMISE Department, Palermo, Italy; [3]Migrants Health Assistance Unit, ASP 6 Palermo, Palermo, Italy; [4]University of Modena, Infectious Diseases Clinic, Modena, Italy; [5]University of Torino, Unit of Infectious Diseases, Department of Medical Sciences, Torino, Italy; [6]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain*
Email: Jeffrey.Lazarus@isglobal.org

Background and aims: European Union/European Economic Area (EU/EEA) countries are not effectively addressing many public health challenges associated with the flow of migrants. We report HBV, HCV and HIV prevalence, risk factors and therapy outcomes in migrants crossing through Libya and arriving in Sicily.
Method: All migrants who arrived at 41 Immigrant Take Care Advocacy (ITaCA) centres in 2015-2017 were screened for HBsAg, anti-HCV Ab, and anti-HIV Ab within 6 weeks followed by confirmatory tests if positive. Patients with HBV and/or HCV infection were evaluated for liver fibrosis by transient elastography. HBV vaccination was offered to those negative. Patients with HBV, HCV and HIV infection received nucleos (t)ide analogs (NA), direct-acting antivirals (DAAs) and combination antiretroviral therapy (cART), respectively, from the regional healthcare system free of charge. Chi-square tests, odds ratios (OR) and adjusted odds ratios (aOR) were used for statistical analysis.
Results: 2, 639/2, 751 (96%) migrants (72% men) agreed to undergo viral screening. HBsAg was present in 257 (9.7%) migrants and 70 of these had chronic hepatitis. Of these latter, 55 (78.5%) started NA therapy and 47 (67.1%) achieved HBV-DNA suppression. Twenty-four (0.9%) were anti-HCV positive; 10 received DAAs and achieved SVR12. Fifty-seven (2.2%) had confirmed HIV infection and were offered cART. (Figure) The mean time crossing through Libya in 2015-16 was 10 weeks and 50 weeks in 2017. The probability of HBV and/or HIV infection was associated with having suffered sexual violence ($OR = 3.2$, $p < 0.001$ and $OR = 5.8$, $p < 0.001$) and was higher in women than men ($OR = 2.5$, $p < 0.001$ and $OR = 5.4$, $p < 0.001$). The prevalence of HIV infection was higher in men ($OR = 3.1$, $p = 0.01$) and women ($OR = 8.6$, $p < 0.001$) who had spent more time in Libya. Reported sexual violence ($aOR = 6.7$, $p < 0.001$) and a longer stay in Libya ($aOR = 4.7$, $p = 0.02$) were associated with higher risk for HIV infection in both genders and reported sexual violence ($aOR = 3.9$, $p < 0.001$) was associated with higher risk for HBV infection in women.

Figure. Proportion of migrants successfully retained in care in Italy 12 months after initiation of HBV, HCV, and/or HIV treatment



Conclusion: The Italian healthcare service is able to provide early screening for HBV, HCV, and HIV infection, linkage to care, and treatment in migrants arriving from Africa. Policy-makers should consider the ITaCA model in other European settings with large numbers of newly arrived migrants.

Phase 1a Study of the Safety, Tolerability and Pharmacokinetics of ABI-H2158, a Novel Second-Generation HBV Core Inhibitor, in Healthy Volunteers

Edward Gane[1,2], Christian Schwabe[1], Marc Evanhcik[3], Eric Ruby[3], Sandy Liaw[3], Katia Alves[3], Richard Colonno[3], Uri Lopatin[3]. *[1]Auckland Clinical Studies, Auckland, New Zealand; [2]Auckland City Hospital, New Zealand Liver Transplant Unit, Auckland, New Zealand; [3]Assembly Biosciences, Inc, South San Francisco, United States*
Email: urilopatin@gmail.com

Background and aims: Chronic Hepatitis B (CHB) infection remains a major cause of morbidity and mortality worldwide. Standard of care (SOC) nucleos (t)ide HBV polymerase inhibitors can maintain profound on-treatment viral suppression, but this is rarely sustained following treatment withdrawal. ABI-H2158 (2158) is a novel 2nd generation core protein inhibitor with enhanced antiviral potency and pharmacokinetic (PK) properties in preclinical models (*in vitro* EC_{90} of 70 and 290 ng/ml against HBV replication and cccDNA establishment, respectively). Here we report Phase 1a results from the first-in-human Phase 1a/1b dose ranging study of 2158.
Method: Safety, tolerability and PK were assessed in 48 healthy volunteers, ages 19-50 (88% Male, 73% Caucasian). Five sequential single ascending dose cohorts of 8 subjects (6:2 active:placebo) received single doses of 2158 at 5, 25, 100, 300 and 500 mg orally (PO) under fasted conditions After washout, the 100 mg cohort subjects repeated a 100 mg dose following a high fat meal. A multiple dose cohort of 8 subjects (6:2 active:placebo) was given 300 mg once daily for 10 days. Safety evaluations included physical exams, adverse event (AE) monitoring, ECGs, and clinical safety labs. Intensive PK plasma sampling was conducted for all cohorts.
Results: 2158 was well tolerated. All patients completed dosing and evaluations. Treatment Emergent AEs (TEAE) were mild. Treatment emergent laboratory abnormalities were grade 1 or 2, infrequent, transient, and deemed not clinically significant. Single dose PK results demonstrated ABI-H2158 is rapidly absorbed, with an elimination half-life ranging from 10-18 hr. After single doses, area under the curve (AUC_{0-inf}) exposures and C_{24hr} values were dose proportional between 5 and 500 mg, with mean exposures ranging between 1, 610

to 146, 000 ng*hr/ml and 20 and 2, 420 ng/ml, respectively. Mean-maximum concentrations (C_{max}) were less than dose proportional, ranging from 174 to 6, 810 ng/ml. A high fat meal showed no significant food effect on either C_{max} or AUC. Multi-dose PK results will be presented.
Conclusion: Oral dosing of 2158 in healthy volunteers demonstrated favorable safety and PK properties supportive of PO QD dosing. Oral ABI-H2158 achieved systemic exposures that exceed those predicted to inhibit cccDNA establishment in CHB patients. ABI-H2158 is expected to enter Phase 1b studies in CHB patients.

LBP-13
Effect of treatment of hepatitis B patients with tenofovir disoproxil or entecavir on risk of hepatocellular cancer death in a U.S. Cohort
Stuart C Gordon[1], Yueren Zhou[1], Jia Li[1], Loralee B Rupp[1], Joseph A. Boscarino[2], Yihe G Daida[3], Mark A Schmidt[4], Sheri Trudeau[1], Mei Lu[1]. *[1]Henry Ford Hospital, Detroit, United States; [2]Geisinger Commonweath School of Medicine, Scranton, United States; [3]Kaiser Permanente Center for Health Research, Honolulu, United States; [4]Kaiser Health, Portland, United States*
Email: sgordon3@hfhs.org

Background and aims: Both entecavir (ETV) and tenofovir disoproxil fumarate (TDF) are recommended as first-line treatment in patients with chronic hepatitis B (CHB). A recent study from Asia showed that treatment-naïve patients who started treatment with TDF had significantly lower risk of HCC compared to those who received treatment with ETV (HR = 0.61 and 95% confidence interval [CI] were 0.54-0.7). We used data from the longitudinal Chronic Hepatitis Cohort Study (CHeCS) to validate these findings in a US population that included both Asian and non-Asian patients.
Method: After excluding patients with liver transplant, HIV, or history of treatment with both ETV and TDF, we followed 822 CHB patients treated with either TDF (n = 407) or ETV (n = 415) for incidence of HCC and all-cause mortality. Cox regression was used to compare treatment effects and inverse probability treatment weighting (IPTW)—which included index age, sex, race, Fibrosis-4 score, and cirrhosis—was used to adjust for treatment selection bias. Death was considered a competing risk for HCC. The analysis was stratified by race (Asian or non-Asian). A subgroup analysis was conducted among previously treatment-naïve patients.
Results: Among 822 included CHB patients, 164 (20%) had previously received other antiviral treatment before starting TDF or ETV, 151 (18%) had cirrhosis, and 517 (63%) were Asian. Median follow-up was 3 years. The p value for race-by-treatment interaction was 0.17 for HCC and 0.30 for mortality. In the Asian group, the adjusted Hazard Ratios (aHR) for TDF versus ETV (95%CI) were 0.70 (0.29, 1.68) for HCC and 0.86 (0.48, 1.53) for mortality. In the non-Asian group, aHRs (95% CI) were 1.87 (0.60, 5.87) for HCC, and 1.25 (0.81, 1.92) for mortality. Results were similar in the treatment naïve patients (n = 677): among Asians, aHRs (95% CI) were 0.73, (0.29, 1.84) for HCC and 0.94 (0.51, 1.73) for mortality; in the non-Asian group, aHR (95% CI) were 1.21 (0.37, 3.98) for HCC and 1.17 (0.72, 1.90) for mortality.
Conclusion: We observed that risk of HCC among patients treated with TDF compared to those treated with ETV may vary by race group. Among Asian patients in our cohort, an adjusted hazard ratio = 0.70 (TDF vs. ETV) suggests a trend toward HCC risk reduction, consistent with the results published from Asia. There was no treatment-related difference in mortality risk between the two race groups. These findings need to be validated in a larger cohort.

Magnetic Resonance Biomarkers for Early Phase Steatohepatitis Clinical Trials: Short Term Evaluation in Adolescents, Transitoriness or Stability in Steatosis (STEATOSIS)
Nidhi Goyal[1,2], Catherine Sawh[1,2], Jorge Angeles[1], Particia Ugalde-Nicalo[1], James Proudfoot[3], Kimberly Newton[1,2], Michael Middleton[4], Claude Sirlin[4], Jeffrey Schwimmer[1,2]. *[1]University of California, San Diego, School of Medicine, Department of Pediatrics, Division of Gastroenterology, Hepatology, and Nutrition, San Diego, United States; [2]Rady Children's Hospital San Diego, Department of Gastroenterology, San Diego, United States; [3]University of California, San Diego, Clinical and Translational Research Institute, San Diego, United States; [4]University of California, San Diego School of Medicine, Department of Radiology, San Diego, United States*
Email: npandhoh@ucsd.edu

Background and aims: Early-phase paediatric non-alcoholic fatty liver disease (NAFLD) clinical trials are designed with non-invasive parameters to assess potential efficacy. Increasingly, these parameters include MRI-derived proton density fat fraction (PDFF) and MR elastography (MRE)-derived shear stiffness as biomarkers of hepatic steatosis and fibrosis, respectively. Understanding fluctuations in these measures is essential for calculating trial sample sizes and interpreting study results. These are critical data needed by the European Medicines Agency and the USA Food and Drug Administration to plan clinical drug trials in children with NAFLD and the lack of such data in children comprises a critical knowledge gap. Therefore, the primary aim of this study was to assess whole-liver MRI-PDFF change in adolescents with non-alcoholic steatohepatitis (NASH) over 12 weeks. Secondary aims included assessing changes in hepatic MRE-shear stiffness, per-segment MRI-PDFF changes, serum aminotransferases activity, and anthropometrics.
Method: Adolescents 12-19 years with biopsy-proven paediatric NASH undergoing standard-of-care treatment were enrolled. Baseline and week-12 assessments of anthropometrics, AST, ALT, GGT, MRI-PDFF, and MRE-stiffness were obtained.
Results: Fifteen adolescents with NASH were included (mean age 15.7 [SD 2.9] years, mean BMI 34.6 [SD 4.6] kg/m^2). Hepatic MRI-PDFF was stable over 12 weeks (mean *absolute* change −0.8%, p = 0.24) (Figure 1). The correlation between individual baseline and week-12 values of MRI-PDFF was high (ρ = 0.97, 95% CI 0.90-0.99). Additionally, the MRE-stiffness was also stable (mean percentage change 2.7%, p = 0.44) with a moderate correlation between individual baseline and week 12 values (ρ = 0.50; 95% CI: −0.11, 0.84). The changes in weight (+0.97 kg) and BMI (+0.14 kg/m^2) were not significant (p = 0.45). Similarly, the changes in aminotransferases were not significant (ALT −18 U/L p = 0.19, AST −8 U/L p = 0.23, GGT −4 U/L p = 0.45).
Conclusion: In adolescents with NASH, fluctuations in hepatic MRI-PDFF and MRE-stiffness over 12 weeks of standard-of-care were small. These data on the natural fluctuation in quantitative imaging biomarkers can serve as a reference for interventional trials in paediatric NASH and inform the interpretation and planning of clinical trials.

Urinary Liver Fatty-Acid-Binding Protein (uL-FABP) improves accuracy of MELD score to predict short-term mortality in patients with decompensated cirrhosis
Adria Juanola[1], Isabel Graupera[1,2,3], Salvatore Piano[1], Chiara Elia[1], Patricia Huelin[1,2,3], Cristina Solé[1,2,3], Octavi Bassegoda[1], Marta Carol[2,3,4], Gloria De Prada[1,2,3], Núria Fabrellas[2,3,4], Marta Cervera[2,3,4], Martina Perez[2,3,4], Laura Napoleone[1,2,3], Martin Bonacci[1,2,3], Elisa Pose[1,2,3], Elsa Solà[1,2,3], Pere Ginès[1,2,3]. *[1]Liver Unit, Hospital Clínic de Barcelona, Barcelona, Catalonia, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona,*

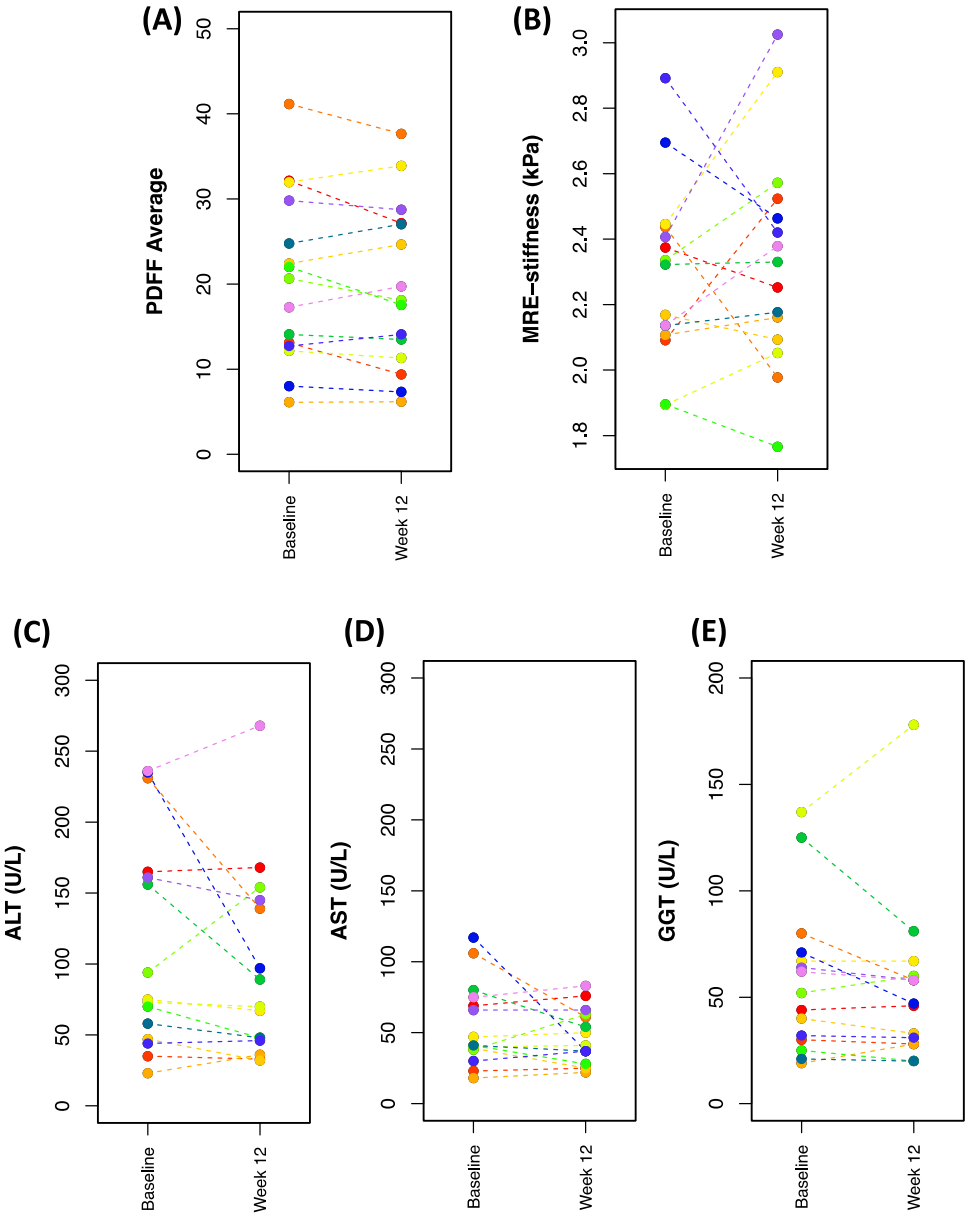

Figure: (abstract: LBP-14)

Catalonia, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEReHD), Barcelona, Catalonia, Spain; [4]Faculty of Medicine and Life Sciences. University of Barcelona., Barcelona, Catalonia, Spain
Email: esola@clinic.cat

Background and aims: Model for end-stage liver disease (MELD) is the best scoring system currently available to predict short-term prognosis in cirrhosis. However, it is known that MELD score has limitations and different attempts have been made to improve its prognostic accuracy with limited results. L-FABP is a small protein is highly expressed in the liver after tissue injury but is also expressed in other organs such as the kidney. We hypothesized that L-FABP could act as prognostic biomarker in patients with decompensated cirrhosis by reflecting multiorgan dysfunction. The aim was to investigate the usefulness of urinary L-FABP as a prognostic biomarker in patients with decompensated cirrhosis, and compare its accuracy to that of other biomarkers and MELD score.

Method: uL-FABP, urinary neutrophil gelatinase-associated lipocalin (uNGAL) and urinary kidney injury molecule 1 (uKIM1) were measured at the time of admission in a prospective cohort of patients with cirrhosis admitted to the hospital for complications of the disease. Clinical outcomes and survival were assessed over a 3-month period.

Results: a total of 310 patients were included (mean MELD score 20 ± 9). At the end of the 3-month follow-up, 207 (67%) patients were alive, 85 (27%) patients had died and 17 (5%) had been transplanted. Patients who died had significantly higher baseline levels of uL-FABP, uNGAL and uKIM1 compared to those who were alive: uL-FABP (median[IQR]) 52[24-107] vs 22[13-56]ug/gr creat, $p < 0.001$; uNGAL 84[37-265] vs 38[17-100]ug/gr creat, $p < 0.001$; and uKIM1 4.4[2.9-8.7] vs 3.6[2.0-6.6]ug/gr creat $p = 0.023$. Among all biomarkers, uL-FABP was the only one independently associated to 3-month mortality in the multivariate analysis, together with MELD score, serum sodium, leukocyte count and presence of hepatic encephalopathy. Predictive accuracy of uL-FABP was independent of the

presence of AKI or acute-on-chronic liver failure (ACLF) at admission. Interestingly, when patients were stratified according to median MELD score and median uL-FABP levels of the whole cohort, results showed that for the same MELD score value, those with high uL-FABP had significantly lower probability of 3-month survival compared to those with low uL-FABP levels (41% if MELD ≥ 20 and uL-FABp > 30 vs 62% if MELD ≥ 20 and uL-FABP < 30 vs; p < 0.001).
Conclusion: urinary L-FABP is an excellent biomarker to predict prognosis in patients with decompensated cirrhosis. Urinary L-FABP levels improve prognostic accuracy of MELD score to predict short-term mortality.

LBP-16
Phase II trial to evaluate immunogenicity and safety of a new adjuvanted HBAI20 Hepatitis B vaccine in non-responders: BE RESPONDER.
Özgür Koc[1,2,3], Philippe de Smedt[4], Geert Robaeys[2,3,5], Pierre Van Damme[4], Jorge Almeida[6], Frank Falkenberg[6,7], Paul H.M. Savelkoul[1,8], Astrid Oude Lashof[1]. *[1]Maastricht UMC+, Maastricht, Netherlands; [2]Ziekenhuis Oost-Limburg, Genk, Belgium; [3]Hasselt University, Hasselt, Belgium; [4]Antwerp University, Antwerp, Belgium; [5]KU Leuven, Leuven, Belgium; [6]CyTuVax BV, Maastricht, Netherlands; [7]CIRES GmbH, Bochum, Germany; [8]Amsterdam University Medical centers, VUmc, Amsterdam, Netherlands*
Email: a.oudelashof@mumc.nl

Background and aims: Approximately 5-15% of the general adult population respond inadequately to the licensed recombinant hepatitis B vaccines. A new hepatitis B vaccine (HBAI20) was formulated wherein the adjuvant AI20, containing 20 µg recombinant human IL-2 attached to 20 µg aluminum hydroxide, was added to HBVaxPro©-10 µg.
Method: In a double-blind randomized controlled phase II trial, we compared the immunogenicity and safety of the new adjuvanted HBAI20 vaccine with that of the licensed recombinant HBVaxPro©-10 µg vaccine. Both vaccines were given in a 0, 1, 2 months schedule in 18-59 years old non-responders (hepatitis B surface antibody (anti-HBs) level <10 mIU/ml after three or more hepatitis B vaccinations).
Results: Out of 1, 076 persons invited, 133 adults were enrolled and randomized (3:1 ratio) to receive either HBAI20 or HBVaxPro©-10 µg vaccine. Two individuals withdrew informed consent and another 15 individuals were excluded from the per-protocol analysis. Eight weeks following the last vaccination, the seroprotection rate (≥1 0 mIU/ml) in the HBAI20 group (92.0%) was substantially higher than in the HBVaxPro©-10 µg group (79.3%), p = .087. In a sub-analysis for which the study was not powered, we observed a seroprotection rate of 83.1% and 68.8% among subjects 40 years or older, respectively (p = .318), and among individuals with more than one hepatitis B vaccination schedule this was 81.8% and 66.7%, respectively (p = .236). Rates of any adverse events were low and similar between the trial arms. There were two serious adverse events, both unrelated to the study vaccine.
Conclusion: In this group of hepatitis B vaccine non-responders, the HBAI20 vaccine demonstrated a higher seroprotection rate compared to the licensed recombinant HBVaxPro©-10 µg vaccine. The safety profile of HBAI20 vaccine was comparable to that of the licensed recombinant vaccine.

LBP-17
Robust Mucosal-associated invariant T (MAIT) cell activation in response to interactions with primary human liver cell subsets
Martin Lett[1], Adrian Keogh[2], Tina Jaeger[1], Isabel Fofana[3], Markus Heim[3,4], Deborah Stroka[2], Magdalena Filipowicz Sinnreich[1,5]. *[1]University Hospital Basel and University Basel, Liver Immunology, Department of Biomedicine, Basel, Switzerland; [2]University Hospital Bern, Clinic of Visceral Surgery and Medicine, Department of Clinical Research, Bern, Switzerland; [3]University Hospital Basel and University Basel, Hepatology, Department of Biomedicine, Basel, Switzerland; [4]University Hospital Basel, Department of Gastroenterology and Hepatology, Basel, Switzerland; [5]Basel University Medical Clinic, Gastroenterology and Hepatology, Liestal, Switzerland*
Email: magdalena.filipowicz@unibas.ch

Background and aims: Mucosal-associated invariant T (MAIT) cells represent the most abundant T cell type in human liver. MAIT cells respond to bacterial metabolites presented by MHC-like molecule MR1 on antigen (Ag)-presenting cells (APCs). A metabolic study in mice suggested that the MAIT cell Ag precursor 5-amino-6-D-ribitylaminouracil (5-A-RU) is able to cross the intestinal barrier to reach both the circulation and the liver. In mouse models, activated liver MAIT cells were described as profibrogenic and, similarly, human MAIT cells from patients with liver cirrhosis show a pro-fibrogenic phenotype. It remains poorly understood which cells in the liver are involved in MAIT cell activation, and, consequently, how their profibrogenic function could be prevented.
Methods: We assessed Ag-presentation capacities of primary human liver cell subsets to human blood- and liver-derived MAIT cells. Responses were evaluated by defining activation markers and cytokine expression profiles of MAIT cells upon stimulation with synthetic Ag 5- (2-oxopropylideneamino)-6-D-ribitylaminouracil (5-OP-RU) or bacterial lysate from *E. coli*. To assess MR1-dependence and reversibility of the activation process, APCs were pretreated with MR1-blocking antibodies, and non-stimulatory MR1 ligands. To define tissue localization of MAIT cells, immunofluorescence staining was performed on cryopreserved human liver biopsies derived from healthy and diseased livers.
Results: Both parenchymal and non-parenchymal cells, including hepatocytes, hepatic myofibroblasts, sinusoidal endothelial cells and billary epithelial cells (BECs) were found to have the capacity to present Ag to MAIT cells. Presentation occurred in response to bacterial lysate and pure synthetic Ag. Importantly, human polyclonal liver-derived MAIT cells produced large amounts of IL-17, a cytokine with prominent profibrotic properties. MAIT cell activation was MR1-dependent and prevented by the presence of non-activating MR1 ligand 6-Formylpterin and acetylsalicylic acid derivative 5-formylsalicylic acid. The presentation capacities differed markedly among the investigated liver cell types, with BECs being the least efficient liver-derived APCs. Liver cells exposed to Ag precursor 5-A-RU had the capacity to generate active Ag endogenously. MAIT cells localized in the immediate proximity of specific liver cell subtypes when analysed *in situ*.
Conclusions: Our results provide new insights to the understanding of intrahepatic MAIT cell activation. By using both primary liver-derived APCs and liver-derived MAIT cells, and applying naturally occurring antigens as opposed to artificial T cell stimuli, we show the large *in vivo* interaction potential of this abundant intrahepatic cell type. Occupancy of MR1 with non-stimulatory ligands creates a therapeutic opportunity to prevent pro-fibrogenic properties of MAIT cells.

LBP-18
Effect of Obeticholic Acid on Liver Function in Patients with Fibrosis due to NASH
Naim Alkhouri[1], Gregory Everson[2], Steve Helmke[2], Jianfen Chen[3]. *[1]Texas Liver Institute, University of Texas Health, San Antonio, United States; [2]HepQuant, Greenwood Village, United States; [3]Intercept Pharmaceuticals, San Diego, United States*
Email: alkhouri@txliver.com

Background and aims: Obeticholic acid (OCA), a potent and selective FXR agonist, has been shown to improve fibrosis in NASH patients in a pivotal Phase 3 study (REGENERATE). As part of the OCA development program, a study in patients (pts) with NASH evaluated the effect of OCA on liver function improvement using the HepQuant methodology. HepQuant measures the hepatic extraction of exogenously administered labeled cholate as a marker of liver function, which has been correlated to clinical outcomes using a Disease Severity Index

(DSI). Based on prior studies of the relationship of DSI to probability of varices, a 2-point decrease in DSI is considered clinically meaningful. The aim of this analysis was to measure liver function in NASH patients with fibrosis after 3 months of OCA treatment.

Method: 51 pts were randomized 1:2:2 to placebo, OCA 10 mg, or OCA 25 mg QD for 85 days. Labeled cholate was administered intravenously and orally on Day −1 (baseline), 8, and 85 for HepQuant assessment.

Results: 50 pts, primarily white with median age 55yrs and BMI 35 kg/m2 completed Day 85. 45 pts had a DSI at baseline (27% F1, 62% F2/3, 11% F4); 43 pts had both a baseline and Day 85 DSI assessment. The mean baseline DSI±SD (n) was for F1 16.4 ± 3.8 (n = 12), F2/3 19.0 ± 4.6 (n = 28), and F4 22.1 ± 6.7 (n = 5). The mean baseline DSI score for all pts (F1-F4) was consistent with an increased likelihood for varices based on previous results in NASH and HCV pts1. OCA treatment improved hepatic function as evidenced by the number of responders (>2-point decrease) and median decrease in DSI at Day 85 (Table). No unexpected safety findings were observed.

	Placebo	OCA 10 mg	OCA 25 mg
		F2/F3	
Responders	0% (0/5)	36% (4/11)	73% (8/11)
ΔDSI (Median)	-0.65	0.78	-3.81
		All (F1-F4)	
Responders	10% (1/10)	44% (7/16)	59% (10/17)
ΔDSI (Median)	-1.07	-1.17	-2.78

Conclusion: This is the first demonstration of OCA eliciting a dose-dependent clinically significant improvement in liver function in NASH. These results are consistent with the dose-dependent reversal of fibrosis observed in REGENERATE and further support the efficacy of OCA treatment in pts with fibrosis due to NASH.

NGM282 Promotes HDL Biogenesis and Transhepatic Cholesterol Efflux to Prevent Atherosclerosis in Mice

Lei Ling[1], Mei Zhou[1], Marc Learned[1], Hui Tian[1], Alex DePaoli[1]. [1]*NGM Biopharmaceuticals, South San Francisco, United States*
Email: lling94080@yahoo.com

Background and aims: FGF19, an endocrine hormone produced in the gut, acts in the liver to control bile acid synthesis. NGM282, an engineered FGF19 analogue, reduces liver fat, liver injury, inflammation and fibrosis in patients with non-alcoholic steatohepatitis. However, NGM282 increases cholesterol levels, and the molecular mechanisms that integrate the FGF19 signaling with cholesterol metabolic pathways are incompletely understood. Here we investigate these mechanisms using a combination of pharmacological, bioinformatics, metabolomics and biochemical approaches.

Method: *db/db*, *Abca1*$^{fl/fl}$*Abcg1*$^{fl/fl}$, *Apoe*$^{-/-}$ and *Fgfr4*$^{-/-}$ mice received an intravenous injection of adeno-associated virus carrying FGF19, NGM282, caMEK1, caSTAT3 or GFP. Tissues were collected for transcriptome profiling, metabolomics and histological analysis. Serum levels of cholesterol, HDL-C and LDL-C were measured on a clinical analyzer. *Apoe*$^{-/-}$ mice were placed on a high-fat, high-cholesterol Western diet to induce atherosclerosis for *en face* analysis.

Results: Administration of FGF19 or NGM282 resulted in elevations in total cholesterol, HDL-C and LDL-C in *db/db* mice. Transcriptome profiling and pathway analysis revealed that FGF19 and NGM282 selectively modulate LXR signaling without causing steatosis. Metabolomics analysis uncovered an increase in intrahepatic hydroxysterols, natural ligands for LXR. FGF19 and NGM282 promote HDL biogenesis through the induction of *Abca1* and *Apoa1*, and cholesterol efflux from the liver by upregulating *Abcg5, Abcg8* and *Scarb1,* all LXR target genes. FGF19- or NGM282-associated cholesterol increases were blunted in mice deficient in ABCA1 or FGFR4. A constitutively active MEK1, but not a constitutively active STAT3, mimics the effect of FGF19 and NGM282 on cholesterol change. Furthermore, in dyslipidemic *Apoe*$^{-/-}$ mice fed a Western diet, treatment with NGM282 significantly reduced atherosclerotic lesion area in aortas (Figure 1).

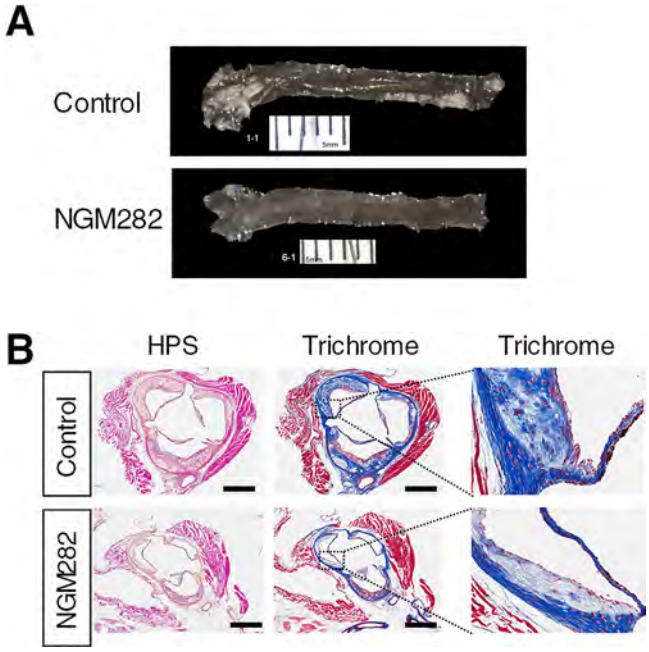

Figure 1: NGM282 protects against atherosclerosis in Apoe−/− mice.

Conclusion: The endocrine hormone FGF19 and its analogue NGM282 have a hitherto unsuspected intrinsic role in promoting transhepatic cholesterol efflux and HDL biogenesis through selectively activating LXR signaling, while ameliorating steatosis and atherosclerosis. Given that LXR agonists produce substantial increase in LDL-C in humans, the selective modulation of LXR by NGM282 may provide additional mechanism to the observed cholesterol increases in humans.

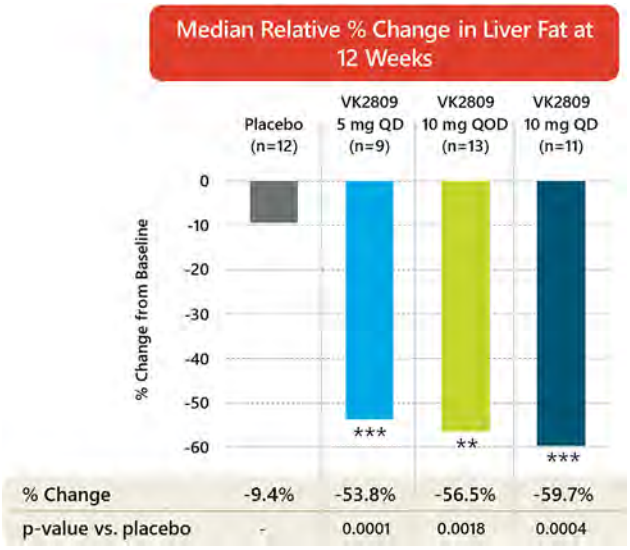
LBP-20

VK2809, a Novel Liver-Directed Thyroid Receptor Beta Agonist, Significantly Reduces Liver Fat with Both Low and High Doses in Patients with Non-Alcoholic Fatty Liver Disease: A Phase 2 Randomized, Placebo-Controlled Trial

Rohit Loomba[1], Joel Neutel[2], Rizwana Mohseni[3], David Bernard[4], Randall Severance[5], Michael Dao[6], Satinder Saini[7], Carmen Margaritescu[2], Ken Homer[2], Brian Tran[8], Marianne Mancini[8], Hiroko Masamune[8], Brian Lian[8]. [1]*NAFLD Research Center, University of California, San Diego, San Diego, United States;* [2]*Orange County Research Center, Tustin, United States;* [3]*Catalina Research Institute, Montclair, United States;* [4]*CHEAR Center, Bronx, United States;* [5]*Radiant Research, Chandler, United States;* [6]*SC Clinical Research, Garden Grove, United States;* [7]*Avant Research Associates, Crowley, United States;* [8]*Viking Therapeutics, San Diego, United States*
Email: roloomba@ucsd.edu

Background and aims: Thyroid hormone is an important regulator of lipid metabolism, particularly acting via the beta isoform of the hepatic T3 receptor. VK2809 is a small molecule prodrug of a potent thyroid beta receptor agonist. VK2809 is selectively cleaved in hepatic tissue by the action of cytochrome P450 isozyme 3A4, to release a pharmacologically active metabolite. We report herein new results

from a 12-week study of low-dose (5 mg) VK2809 in patients with NAFLD. The aim of this study was to examine the safety, tolerability and efficacy of oral VK2809 at three different doses (low-dose, 5 mg; high-dose, 10 mg; or 10 mg QOD) versus placebo in reducing liver fat content and LDL-C over a 12-week period in patients with NAFLD.
Method: This was a multi-center, randomized, double-blind, placebo-controlled, Phase 2a trial. Patients having liver fat content ≥8 % as assessed by magnetic-resonance-imaging, proton-density-fat-fraction (MRI-PDFF), LDL-C ≥ 110 mg/dL, and triglycerides ≥ 120 mg/dL were randomized to receive either oral VK2809 doses of 5 mg QD, 10 mg QOD, 10 mg QD, or placebo for 12 weeks.
Results: Patients receiving VK2809 experienced statistically significant reductions in liver fat content by MRI-PDFF, relative to placebo. Mean absolute change from baseline in liver fat content was 8.7% for VK2809 5 mg QD (p = 0.0014), 8.9% for VK2809 10 mg QOD (p = 0.013), and 10.6% for VK2809 10 mg QD (p = 0.0030), vs. 1.1% for placebo. Median relative change from baseline in liver fat content was 53.8% for VK2809 5 mg QD (p = 0.0001), 56.5% for VK2809 10 mg QOD (p = 0.0018), and 59.7% for VK2809 10 mg QD (p = 0.0004), vs. 9.4% for placebo. The proportion of patients who had ≥3 0% reduction in MRI-PDFF was 100% for VK2809 5 mg QD (p = 0.0002), 76.9% for VK2809 10 mg QOD (p = 0.0048) and 90.9% for VK2809 10 mg QD (p = 0.0006), vs. 16.7% of placebo patients (see graphic). Among all patients receiving VK2809 therapy, 70% demonstrated a ≥5 0% reduction in MRI-PDFF (p = 0.014). VK2809 was shown to be well-tolerated in this study; no SAEs were reported in any cohort.



Conclusion: These novel data demonstrate that a 12-week treatment with low-dose VK2809 produced significant and robust improvements in liver fat content in patients with NAFLD that were similar to the high dose (10 mg). These data provide strong rationale for further development of VK2809 as well potential use of low-dose liver-targeted thyroid receptor beta agonist therapy as a treatment for patients with biopsy-proven NASH with fibrosis.

Effect of NGM282, an FGF19 Analogue, on Pruritus in Patients with Primary Sclerosing Cholangitis: Analysis of a Phase 2, Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial

Marlyn J. Mayo[1], Lei Ling[2], Stacie Hudgens[3], Kathline H. Kim[2], Gideon Hirschfield[4], Alex DePaoli[2], Ulrich Beuers[5]. [1]*University of Texas Southwestern, Dallas, United States;* [2]*NGM Biopharmaceuticals, South San Francisco, United States;* [3]*Clinical Outcomes Solutions, Tucson, United States;* [4]*Toronto General Hospital, University Health Network, Toronto, Canada;* [5]*Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*
Email: lling94080@yahoo.com

Background and aims: PSC is an inflammatory, cholestatic and progressively fibrotic liver disease devoid of effective medical interventions. Approximately 50% of patients experience pruritus, a symptom that can reduce quality of life. NGM282 is a non-tumorigenic FGF19 analogue in development for chronic liver diseases in which bile acid dysregulation is involved in disease pathogenesis. We report here the effect of NGM282 on pruritus after 12 weeks of treatment.
Method: Sixty-two patients, with PSC by EASL criteria and an elevated ALp > 1.5xULN at Baseline (BL), were randomized to NGM282 1 mg, 3 mg or placebo (PBO) as a daily SC injection for 12 weeks. 5D-itch pruritus questionnaires (scores range from 5 to 25) were collected, and patients also recorded pruritus intensity on a numeric rating scale (NRS) ranging from 0 to 10. Higher numbers indicate more severe itch on both scales.
Results: At W12, changes from BL were +0.60, +0.30 and – 1.52 for 5D-itch score, +0.36, +0.01 and – 0.32 for pruritus NRS, in the PBO, 1 mg and 3 mg groups, respectively (Table 1). Pruritus was reported as a treatment emergent adverse event in 10% (PBO), 5% (1 mg) and 5% (3 mg) of patients. There were no discontinuations due to pruritus. Changes from BL to W12 in pruritus NRS correlate with changes in pruritus degree (r = 0.43, p < 0.01), direction (r = 0.43, p < 0.01), disability (r = 0.30, p < 0.05) and distribution (r = 0.33, p < 0.05), but not pruritus duration. Changes from BL to W12 in PIIINP correlate with changes in pruritus distribution (r = 0.42, p < 0.001), degree (r = 0.26, p < 0.05) and direction (r = 0.27, p < 0.05).

Table 1: Pruritus-Related PRO Measures

	PBO **(n = 20)**	NGM282 1mg **(n = 21)**	NGM282 3mg **(n = 21)**
5D-Itch Score (BL)	10.70 (4.60)	11.14 (3.79)	9.50 (3.87)
Δ 5D-Itch Score at W12, LS mean	**0.60**	**0.30**	**−1.52**
P value (W12 vs BL)	0.45	0.70	0.06
***NGM282 vs Placebo,** difference between means (95% CI)*		**−0.50 (−3.17 to 2.17)**	**−1.60 (−4.30 to 1.10)**
P value (NGM282 vs Placebo)		0.78	0.06
Pruritus NRS (BL)	1.50 (1.79)	2.29 (2.35)	0.90 (1.25)
Δ Pruritus NRS at W12, LS mean	**0.36**	**0.01**	**−0.32**
P value (W12 vs BL)	0.38	0.98	0.48
***NGM282 vs Placebo,** difference between means (95% CI)*		**−0.47 (−1.93 to 0.99)**	**−0.52 (−1.96 to 0.92)**
P value (NGM282 vs Placebo)		0.60	0.56

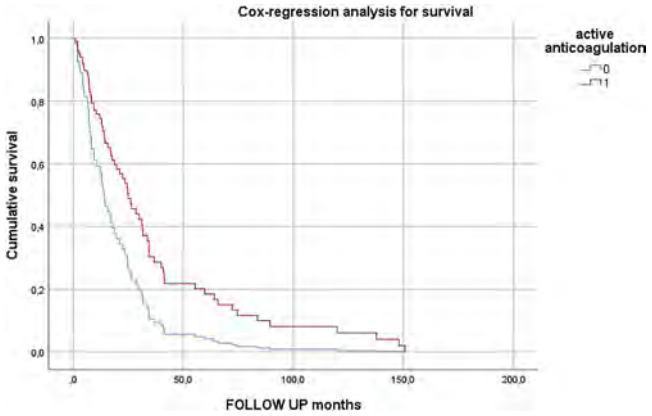
Conclusion: In this population of patients with PSC, treatment with NGM282 was not associated with drug-induced pruritus, but was associated with a trend of improvement in pruritus. These clinically relevant, patient-reported outcome measures should be evaluated in future trials.

LBP-22

Outcome of 119 cirrhotic patients with splanchnic thrombosis: a single center real-life experience

Giuseppe Tarantino[1], Giorgia Micucci[2], Serena Rupoli[2], Gianluca Svegliati-Baroni[1], Alessandro Fiorentini[2], Alessio Ortolani[1], Laura Schiadà[1], Marco Marzioni[1], Massimo Offidani[2], Irene Federici[2], Attilio Olivieri[2], Antonio Benedetti[1]. *[1]Ancona, Clinic of Gastroenterology and Hepatology, Polytechnic University of Marche Region, Ancona, Italy., Ancona, Italy; [2]Ancona, Clinic of Hematology, Polytechnic University of Marche Region, Ancona, Italy*
Email: giutar77@gmail.com

Background and aims: Splanchnic venous thrombosis (SVT) frequently affects patients with liver cirrhosis. Although being crucial for SVT, the benefit/risk ratio of anticoagulant treatment remains uncertain. Aims of this study were to evaluate the safety and efficacy of anticoagulant therapy (AT) in cirrhotic ST and to investigate outcomes.
Method: A cohort of 119 cirrhotic patients with ST, incidentally diagnosed during surveillance, were prospectively followed from 2000 to 2018 in our Hospital. Demographic, risk factors, clinical, laboratory, therapeutic and outcome data were collected. In patients with no active bleeding, a patient-tailored management with low-molecular-weight heparin (LMWH) or antivitamin-K (AVK) was started as soon as possible, associated to beta-blockers or endoscopic prophylactic treatments of variceal hemorrhages. The outcomes evaluated were major bleeding events (MB), recurrent thrombosis, recanalization and survival.
Results: Portal vein was the most common site of thrombosis (55%). Ninety-one patients (77%) had esophageal varices. Median Child Pugh Score was 8. Ninety-two patients (89%) were treated with AT: 69% with intermediate or full dose of LMWH and 23% with AVK. Twenty patients (22%) suspended AT due to clinical complications or decreased platelet counts. The median duration of therapy was 9 months, the median follow-up was 15 months. During AT, the incidence rates were 2.5 per 100 patient-years for major bleeding and 8.0 for all-cause mortality. Follow-up imaging, available for 91 patients, showed complete recanalization in 40 patients (44%), partial recanalization in 15 patients (16%), stable thrombosis in 27 patients (30%), progression or recurrent thrombosis in 9 patients (10%). Child Pugh score was improved in 27 patients (38%), stable in 31 patients (43%) and worsened in 14 patients (19%). At multivariate analysis, recanalization emerged as variable independently associated to Child Pugh improvement (Odds ratio 4.25; 1.3-14 95% CI; p = 0.02) while long-term AT resulted independently associated with a higher overall survival according to Cox-Regression analysis, adjusted for albumin levels, Child-Pugh score, HCC and recanalization (Odds ratio 1.88; 1.02-3.45, 95% CI; p = 0, 04).



Conclusion: AT appears to be safe and effective in our cohort of patients with cirrhosis affected by ST. Recanalization of ST is associated with improvement of liver function parameters. Moreover, long-term AT is correlated with higher overall survival.

LBP-23

Prognostic Impact of Peritumoral Neutrophil Infiltration on Hepatocellular Carcinoma Recurrence Following Liver Transplantation

Marc Najjar[1], Karim Halazun[2], Ayush Srivastava[1], Michael Moore[1], Donian Chyong[1], Robyn Gartrell[1], Emanuelle Rizk[1], Evan Lieberman[1], Olivia Perez[1], Shelief Robbins-Juarez[1], Charles Drake[1], Ladan Fazlollahi[1], Helen Remotti[1], Jean Emond[1], Yvonne Saenger[1]. *[1]Columbia University Irving Medical Center, New York, United States; [2]Weil Cornell Medical Center, New York, United States*
Email: mn2594@cumc.columbia.edu

Background and aims: Peritumoral neutrophil (PMN) infiltration has been associated with poor clinical outcomes in various tumors; however, its role in hepatocellular carcinoma (HCC) remains understudied. Moreover, novel methods to analyze tumor microenvironments are needed in HCC, an immune responsive tumor. We sought to use quantitative multiplex immunofluorescence (qmIF) in HCC to better study the immune milieu and detect cellular predictors of clinical outcomes.
Method: Patients without hepatitis viral infection and with available clinical follow-up from a single center cohort of 634 consecutive patients who underwent liver transplantation (LT) for HCC between 1998 and 2018 were included in a pilot analysis. The expression of MPO (PMNs), CD3 (T cells), CD8 (CTL), CD68 (Macrophages), Hep-Par1 (Hepatocytes) and HLA-DR was assessed on each tissue sample using qmIF. Tumor sections were pre-selected by a pathologist and visualized using Vectra (Akoya). Using an artificial intelligence-capable software (Inform, Akoya) and RStudio, cell densities were calculated by dividing over the total number of nuclear cells as defined by DAPI staining (Nuclei).
Results: A preliminary cohort of 10 patient samples was stained and tissue integrity allowed for data to be interpreted in 8 patients, 3 of whom recurred at a median of 3.5 years while the other 5 remained recurrence-free at a median of 12 years post-LT. We found that MPO+ PMN densities are significantly higher in patients who suffered from post-LT HCC recurrence as compared to those who remain recurrence-free, and that this difference is primarily driven by PMNs located within the peritumoral stroma. (Median [IQR] 2.9 [2.1–3.1] vs 0.9 [0.7–1.9], p = 0.037). PMN infiltration within the tumor was not associated with outcome, densities were equal in tumors of patients who had recurrence and those who did not (Median [IQR] 1 [0.4–1.7] vs 1.1 [0.5–1.4], p = 0.882).
Conclusion: Higher densities of peritumoral PMNs are associated with post-LT HCC recurrence in this preliminary cohort of 8 patients. This work, the first reported application of qmIF in HCC, is ongoing and will be validated within a larger cohort of patients. Updated results will be presented at the conference.

Email: mpalmer@shire.com

Background and aims: Apical sodium-dependent bile acid transporter inhibitors (ASBTi) reduce serum low-density lipoprotein cholesterol, improve insulin resistance, change bile acid pool and decrease NAFLD activity score (NAS) in murine models of fatty liver disease. This study aimed to assess the safety, tolerability and efficacy of volixibat, a selective ASBTi, in adults with non-alcoholic steatohepatitis (NASH).
Method: In this double-blind, placebo-controlled, dose-finding study across 68 sites in the USA, UK and Canada, adults with NASH were randomized (1:1:1:1; stratified by presence of type 2 diabetes mellitus [T2DM] and baseline NAS) to treatment with once-daily volixibat (5 mg, 10 mg or 20 mg) or placebo (PBO) for 48 weeks. Primary outcome measure was a 2-point reduction in NAS without worsening in fibrosis from baseline to end-of-treatment. Analyses were done using intention-to-treat. An interim analysis (IA), based on absolute change in steatosis on MRI proton density fat fraction (PDFF) and percentage change of ALT, was planned after 80 participants received 24 weeks' treatment. ClinicalTrials.gov identifier NCT02787304.
Results: Between 24 October 2016 and 5 June 2018, 197 subjects were randomized to volixibat or PBO. Mean (SD) age of participants was 53.1 ± 12.8 years, 60.2% were women, 89.3% were Caucasian, mean BMI was 34.5 ± 6.3 kg/m^2 and 43.4% had T2DM. Mean baseline NAS was 5.2 ± 1.1 and MRI-PDFF was 18.5 ± 8.2%. At the IA, mean absolute change (±SEM) from baseline to week 24 in MRI-PDFF was not different for any volixibat dose (5 mg – 0.4 ± 1.3%, 10 mg – 0.2 ± 1.8% or 20 mg – 1.3 ± 1.1%) vs PBO (+0.2 ± 1.1%). Similarly, percentage changes in serum ALT were not different for any dose of volixibat (5 mg + 17.1 ± 10.6%, 10 mg + 14.1 ± 10.1% or 20 mg + 2.4 ± 9.2%) vs PBO (0.0 ± 5.6%). Subgroup analysis by sex, presence of T2DM, NAS and stage of fibrosis did not reveal any significant improvement with any volixibat dose. Review of 43 participants with paired liver biopsies did not reveal numerical differences in instances of a 2-point reduction in NAS or NASH resolution (both without worsening fibrosis) between PBO and volixibat dose groups. The most common adverse event was diarrhoea (volixibat 73.5%; placebo 20.4%). There were no deaths or serious adverse events related to volixibat.
Conclusion: Volixibat treatment for 24 weeks did not improve MRI-PDFF, serum ALT or histology in adults with NASH. (Funding: Shire, a Takeda company)

LBP-25

a phase 1 clinical trial of therapeutic vaccine t101 in chronic hepatitis b (chb) patients: a randomized, double-blind, placebo-controlled, single and multiple injections, dose escalation study

Yue Hu[1], Xiaomin WANG[2], zhiming wang[3], dong gao[3], lan zhang[3], min wu[1], hong zhang[1], zhongyu hu[4], shaohui qiu[4], hong chen[1], meng wang[1], xiaojiao li[1], YANHUA DING[1], Junqi Niu[5]. *[1]Phase 1 Clinical Research Center, The First Hospital of Jilin University, Changchun, China; [2]Transgene Tasly (Tianjin) Biopharmaceutical Co., LTD, Tianjin, China; [3]Transgene Tasly (Tianjin) Biopharmaceutical Co., LTD, Tianjin, China, Tianjin, China; [4]National Institutes for Food and Drug Control, Beijing, China; [5]The First Hospital of Jilin University, Changchun, China*
Email: junqiniu@aliyun.com

Background and aims: Hepatitis B virus (HBV) infection is a worldwide health problem. It has been proved that the persistence of HBV is associated with the failure to stimulate an efficient HBV-specific immune response. T101, the Chinese counterpart of TG1050, is a replication-defective adenovirus serotype 5 (Ad5) expressing multiple HBV-specific antigens (polymerase, core and envelope) and it is used as a therapeutic vaccine for CHB patients. The application of T101 aims at inducing a broad HBV-specific T cell immune response and ultimately eliminating HBV infection.
Method: A total of 36 CHB patients with negative HBV DNA after NUC therapy were enrolled into the single dose (SD) cohorts and multiple dose (MD) cohorts. Patients were randomized to receive single subcutaneous injection of T101 (1.0E+9VP, 1.0E+10VP, 1.0E+11VP) or placebo at the ratio of 3:1, and 4 patients were enrolled for each dose in the SD cohort. For the MD cohort, patients were randomized to receive three weekly subcutaneous injections of T101 (1.0E+10VP, 1.0E +11VP) or placebo at the ratio of 3:1 and 12 patients were enrolled each dose. The aim of the trial is to evaluate the safety, immunogenicity and preliminary antiviral activity (the decrease of HBsAg level). T-cell responses were monitored by INFγ ELISPOT on PBMCs and the levels of anti-Ad5 neutralizing antibodies (NAd5) were also detected.
Results: T101 was well tolerated both in SD and MD cohorts. All of the adverse events were grade 1 or 2. No ALT flare, no SAE and no signs of immune-related AEs were observed. The most common AEs are

Flu-like symptoms and injection site reaction (induration, pain and pruritus), and most of them disappeared in 1~3 days after the administration. The administration of the T101 can rapidly induce HBV-specific (POL, Core or ENV) T cell immune response as early as 2 weeks after vaccination in CHB patients and last at least 12 weeks after vaccination. T101 can stimulate the body to produce NAD5 and reach peak concentration at 4th week after administration, and the titer decreased at the 12th weeks after administration. The preliminary antiviral effect was also observed. The HBsAg level had an average decrease about 22% at 1.0E+10VP dose group at the 4th weeks after administration and the maximal decrease reached 1.14 Log.

Conclusion: Subcutaneous injections of T101 are safe and tolerated in CHB patients. T101 can break the immune tolerance and stimulate HBV-specific (POL, Core or ENV) T cell immune response in CHB patients, at the same time the HBsAg level decreased. Data support future trials to explore the antiviral activity and safety of T101 in more CHB patients.

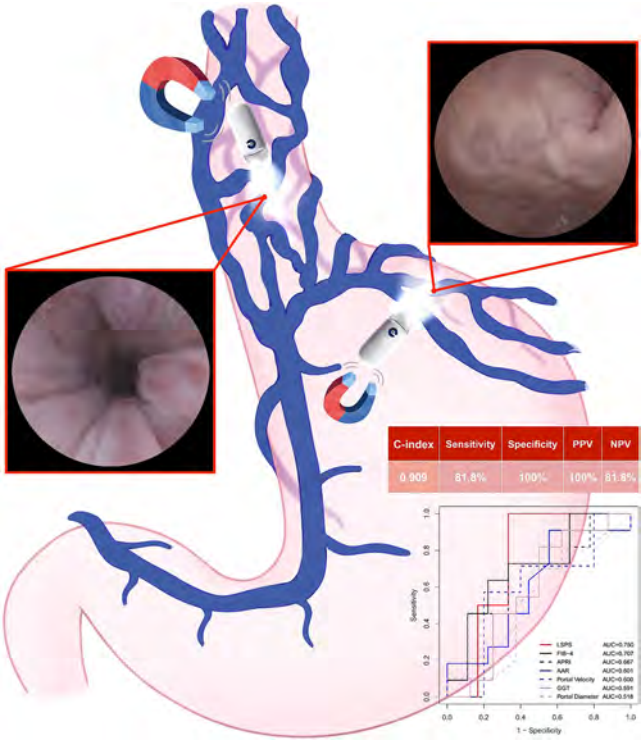
Background and aims: Variceal hemorrhage is a lethal complication in liver cirrhosis. The assessment of at-risk gastroesophageal varices (GOV) is of great therapeutic implications that once varices at risk for rupture are found, the primary prophylaxis of variceal hemorrhage is recommended. Therefore, an accurate non-invasive tool is needed to improve the risk stratification of GOV. The study aims to evaluate the performance of magnetically controlled capsule endoscopy (MCCE) for at-risk GOV in compensated cirrhosis.

Method: The prospective multicentre study (NCT03749954) was performed after local institutional review board approvals. Written informed consents were obtained. We recruited 20 well-characterized participants with compensated cirrhosis from 6 independent centres between November 2018 and January 2019. All participants were scheduled to receive both non-invasive MCCE (Ankon) and conventional endoscopy for assessing at-risk GOV. High-risk varices were defined as medium-large varices (>5 mm) or small varices (≤5 mm) with red wale sign and/or nipple sign. A thin and hollow detachable string was attached on the MCCE so that the technicians could observe the esophagus by controlling the string. The capsule was released from the string once it entered the stomach and then manually controlled by the guidance magnet robot as previously reported. Experienced physicians who were blinded to MCCE results performed conventional endoscopy as reference standard on the same day of capsule ingestion. All MCCE frames were uploaded to the cloud MCCE reading platform and evaluated by at least two independently experienced capsule endoscopists who were blinded to the endoscopy results. Prior to and after completing the MCCE and conventional endoscopy, participants were requested to complete a questionnaire regarding their perceptions and satisfaction.

Results: For the risk stratification of GOV, the C-index, sensitivity, specificity, positive predictive value, and negative predictive value of MCCE were 0.909, 81.8%, 100%, 100%, and 81.8%, respectively. The overall agreement on management decisions between MCCE and endoscopy was substantial at 90.0% with kappa score of 0.800. The diagnostic performance of MCCE for at-risk GOV was statistically higher than other non-invasive models including LSPS (liver stiffness × spleen size/platelet count score), FIB-4, APRI, AAR, portal velocity, GGT and portal diameter with the area under the curves of 0.750, 0.707, 0.667, 0.601, 0.600, 0.591, and 0.518, respectively. The preprocedure perception and postprocedure satisfaction score of MCCE was significantly higher than that of conventional endoscopy without sedation (11.2 vs. 4.2, $p < 0.001$).



Conclusion: MCCE could be used as a non-invasive screening tool for risk stratification of GOV with better preprocedure perception and postprocedure satisfaction in compensated cirrhosis.

Background and aims: The elimination of Hepatitis C (HCV) requires greater access to testing and treatment for at-risk groups. People prescribed Opioid Substitution Therapy (OST) are at high risk of HCV infection. Community pharmacists see this group frequently to provide OST. We report the interim results from 34 of 55 pharmacies undertaking this cluster randomised trial of a pharmacy-led test and treat pathway where pharmacists completed the assessment for treatment on-site.

Method: 34 community pharmacies from Tayside, Scotland took part in a cluster randomised trial providing either conventional or pharmacy-led care. Patients were recruited to the study if they were HCV PCR positive by dried blood spot test. For conventional care, pharmacists referred participants to a local centre for assessment. In the pharmacy-led arm, patients underwent one set of conventional bloods, based on this and patient history pharmacists assessed participants for treatment with Direct Acting Anti-Virals (DAAs) using a standard protocol, drug prescribing was by pharmacist prescribers (pharmacy-led arm). The study used sofosbuvir/ledipasvir to treat genotype 1 HCV infection and daclatasvir/sofosbuvir to treat genotype 3 infection. Treatment was delivered as daily modified directly observed therapy (DOT) in a pharmacy. The primary trial outcome was sustained viral response 12 weeks (SVR12) after treatment completion. The study is now closed and in follow-up.

Results: 251 HCV positive participants were recruited from a total pool of 1393 OST recipients attending the pharmacies. (99 conventional, 152 pharmacy-led $p < 0.01$). No significant differences were detected for gender, age or Fib-4 assessment between the groups. More genotype 3 participants were detected in the pharmacy-led arm ($p < 0.01$). A total of 187 new DBST were taken (88 conventional, 99 pharmacy led $p < 0.5$). From recruited participants, 138 commenced treatment with DAAs (45 conventional, 93 pharmacy-led ($p < 0.01$) and 113 achieved SVR 12 (35 conventional, 78 pharmacy-led $p < 0.01$). In the conventional arm, 2 participants failed at SVR12, 2 withdrew voluntarily and 7 were lost-to follow-up. In the pharmacy-led arm 3 participants failed SVR12, 1 withdrew voluntarily, 4 were lost-to-follow-up, 2 died prior to SVR12 and 2 participants had a rejected SVR12 sample.

Conclusion: Preliminary analysis suggests that the pharmacy-led treatment pathway increased both HCV testing and initiation of, treatment. The offer of testing, assessment and treatment with DAAs in a pharmacy increased HCV treatment uptake in people on OST. The delivery of treatment within the familiar setting of the community pharmacy was central to the success of the model.

LBP-29

BIO89–100, a novel PEG-FGF21 analogue, is efficacious following weekly and every 2-week subcutaneous dosing in spontaneous diabetic cynomolgus monkeys

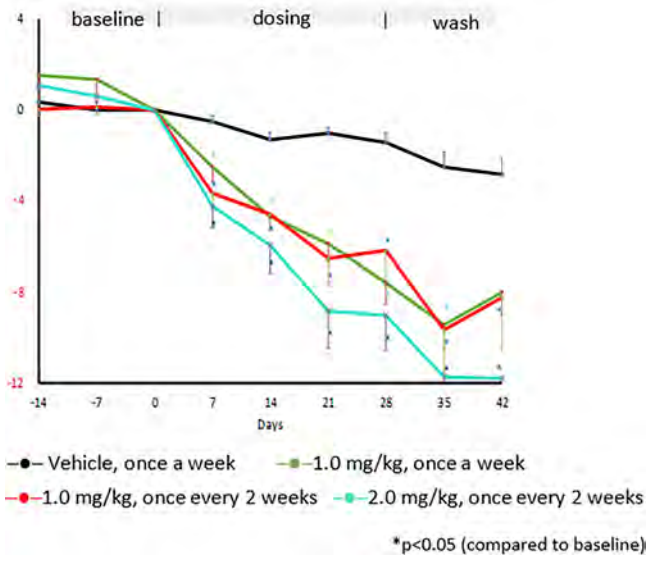
Moti Rosenstock[1], Michal Ayalon[2], Hank Mansbach[3], Yongqiang Liu[4], Maya Margalit[3]. *[1]89bio LTD., Department of Preclinical Development, Herzliya, Israel; [2]89bio LTD., Herzliya, Israel; [3]89bio LTD., Department of Clinical Development, Herzliya, Israel; [4]Crown-Bio, Suzhou, China*
Email: moti.rosenstock66@gmail.com

Background and aims: BIO89-100, a novel site-specific glycoPEGylated analogue of fibroblast growth factor 21 (FGF21), is under evaluation for the treatment of non-alcoholic steatohepatitis (NASH), a chronic fatty liver disease associated with obesity and type 2 diabetes mellitus. In previous study 89bio demonstrated efficacy of BIO89-100 (0, 0.1, 0.3 and 1 mg/kg) subcutaneous (sc) every week (qWk) in spontaneously diabetic cynomolgus monkeys. The objective of the current study was to compare the pharmacokinetics (PK) and pharmacodynamics (PD) of BIO89-100 following qWk and every 2-week (q2Wk) sc administration of 1 mg/kg qWk and 1 or 2 mg/kg q2Wk in the same monkey model.

Method: Spontaneously diabetic cynomolgus monkeys (mean age 17 years, mean body weight 8.4 kg) were administered BIO89-100 sc at doses of 0, 1 mg/kg qWk, 1 mg/kg q2Wk or 2 mg/kg q2Wk over a 4-week period. Blood samples were collected for PK analysis on the first and last days of dosing. PD profiles were determined for each group during the pretreatment and treatment periods, and for 2 weeks following the last dose. PD parameters included body weight, food intake, clinical chemistry (triglycerides, total cholesterol, high-density-lipoprotein, low-density lipoprotein, alanine aminotransferase, glucose), serum insulin, HbA1c, oral glucose tolerance test (OGTT) and adiponectin.

Results: Half-life was approximately 50 hrs. The exposure profile of the qWk dose was similar to the q2Wk curve, except for a higher trough levels on Day 14 and Day 28 than with the qWk dose. Exposure to BIO89-100 (AUC and C_{max}) increased approximately in proportion to the increase in dose from 1 mg/kg q2Wk to 2 mg/kg q2Wk. Statistically significant reductions were observed in body weight (Figure 1), food intake, glucose, insulin, HbA1c, and serum lipids, along with increased adiponectin levels and improvement in oral glucose test results in all BIO89-100-treated groups vs. the vehicle group. The magnitude of the different effects varied somewhat between doses; however, the results were generally comparable among the dosing groups.

Figure1 - Body Weight Change (%)



Conclusion: The PK and PD profiles following qWk and q2Wk sc administration of BIO89-100 to diabetic cynomolgus monkeys demonstrate potential utility of this long-acting FGF21 analogue for patients with NASH. Clinical studies are underway to confirm the prolonged half-life and PD properties which may show potential utility of qWk and/or q2Wk dosing.

LBP-30

Changes in Serum Bile Acids Correlate with 7alpha-Hydroxy-4-Cholesten-One and Fibrogenesis Biomarker Pro-C3 with NGM282 Therapy in Patients with Non-alcoholic Steatohepatitis

Arun Sanyal[1], Lei Ling[2], Mark Jaros[3], Bryan Baxter[2], Kris V. Kowdley[4], Alex DePaoli[2], Stephen Harrison[5]. [1]*Virginia Commonwealth University, Richmond, United States;* [2]*NGM Biopharmaceuticals, South San Francisco, United States;* [3]*Summit Analytical, Denver, United States;* [4]*Swedish Medical Center, Seattle, United States;* [5]*Pinnacle Clinical Research, Live Oak, United States*
Email: lling94080@yahoo.com

Background and aims: The presence and severity of NASH is associated with elevated circulating levels of bile acids (BA). NGM282, a non-tumorigenic FGF19 analogue, significantly reduced 7alpha-hydroxy-4-cholesten-3-one (C4, a marker of BA synthesis), ameliorated steatosis and improved hepatic inflammation and fibrosis in patients with NASH. To identify potential biomarkers of NGM282 therapy in NASH, we sought to evaluate the correlation of individual BA species with C4 and Pro-C3 (a marker of fibrogenesis) using pooled data from phase 2 trials.

Method: 157 subjects received NGM282 0.3 mg, 1 mg, 3 mg, 6 mg or placebo daily for 12 weeks. Key inclusion criteria included biopsy-proven NASH with NAS ≥4 (at least 1 point in each component), stage 1-3 fibrosis, and absolute liver fat content by MRI-PDFF ≥8 %. Serum levels of C4 and BA species were determined by mass spectrometry (Mayo Clinic). Serum Pro-C3 was measured by an ELISA method (Nordic Bioscience). Correlation coefficients were calculated using Spearman's method.

Results: At W12, serum levels of C4 were significantly reduced in NGM282-treated patients (−51%, −77%, −93%, −79% and +43% from baseline in the 0.3 mg, 1 mg, 3 mg, 6 mg and the placebo groups, respectively). Individual BA, and those previously associated with histological features of NASH in particular, were decreased by NGM282 treatment. Ratios of primary to secondary BA were increased with NGM282 therapy. Reductions from baseline in both C4 and Pro-C3 were strongly associated with reductions in glyco-conjugated as well as unconjugated BA, but less strongly associated with tauro-conjugated BA (Table 1).

Table 1: Correlation of %Change in Individual BA with %Change in C4 and Pro-C3 at W12

	Δ C4%		Δ Pro-C3%	
	r	P	*r*	P
Conjugated primary BA				
Δ GCA%	0.48	<0.0001	0.34	<0.0001
Δ TCA%	0.08	0.29	0.18	0.020
Δ GCDCA%	0.34	<0.0001	0.31	<0.0001
Δ TCDCA%	−0.13	0.10	0.12	0.13
Conjugated secondary BA				
Δ GDCA%	0.38	<0.0001	0.38	<0.0001
Δ TDCA%	0.12	0.15	0.30	0.0001
Unconjugated primary BA				
Δ CA%	0.36	<0.0001	0.29	0.0002
Δ CDCA%	0.41	<0.0001	0.24	0.0025
Unconjugated secondary BA				
Δ DCA%	0.48	<0.0001	0.42	<0.0001
Total BA				
Δ TBA%	0.41	<0.0001	0.39	<0.0001

Conclusion: Changes in circulating levels of BA highly correlated with changes in Pro-C3 in NASH patients treated with NGM282, consistent the notion that BA may be a molecular trigger of hepatic fibrogenesis. NGM282 demonstrated significant and robust activity on lowering serum BA and Pro-C3, signifying potential disease-modifying activity in reversing fibrosis.

LBP-31

AXA1665, a novel composition of amino acids restores the dysregulated amino acid profile, lowers ammonia, and improves body composition and function in Child-Pugh class A and B subjects

Manu Chakravarthy[1], Scharmen Confer[1], Joel Neutel[2], William Comb[1], Michael Hamill[1], Sean Carroll[1], Raffi Afeyan[1], Arun Sanyal[3]. [1]*Axcella Health, Inc., Cambridge, United States;* [2]*Orange County Research Center, Tustin, United States;* [3]*Virginia Commonwealth University, Richmond, United States*
Email: mchakravarthy@axcellahealth.com

Background and aims: Sarcopenia has emerged as an independent risk factor for important clinical outcomes in cirrhosis, including hepatic encephalopathy (HE). It is closely linked to protein-malnutrition and perturbation in amino acid metabolism. A late evening snack (LES), considered part of routine care, appears to improve quality-of-life parameters in cirrhotic patients. While protein supplementation is advised, it carries the risk of worsening ammonia and HE in these patients. We designed a novel amino acid composition, AXA1665, to maximize anabolic activity and minimize ammoniagenesis to support liver health. We investigated its impact on safety, and markers of structure and function in a population of compensated, well-nourished Child-Pugh class (CPC) A and B subjects.

Method: Two amounts of AXA1665 were orally administered three times a day (TID) for 15d each to 16 CPC A-B subjects in a 2-period cross-over study. One group (n = 7) received only LES (control) in Period 1 followed by AXA1665 4.9 g TID (14.7 g/d) in Period 2; another group (n = 9) received AXA1665 14.7 g TID (44.1 g/d) in Period 1 followed by LES only (control) in Period 2. There was a 14d washout between periods. Subjects were domiciled in the research unit for the study duration; all meals/exercise were standardized. Plasma amino acids, albumin, body composition, and liver frailty index (LFI, composite marker of functional status as assessed by strength, speed, and balance) were measured on d1, d8, and d15 of each period. A standardized 35 g protein shake was provided 1 hour prior to the administration of AXA1665 or control on d1 and d15 of each period, and plasma ammonia levels were serially measured over the subsequent 5 hours to determine area under the curve ($AUC_{0\text{-}5h}$).

Results: AXA1665 was safe and well-tolerated at both doses. AXA1665 44.1 g/d, but not the 14.7 g/d or control groups, increased the fasted Fischer's ratio (FR; plasma branched chain to aromatic amino acid ratio) by 40.1% on both d8 and d15 vs. d1. Despite the provision of additional nitrogen via amino acids within AXA1665, the mean plasma ammonia $AUC_{0\text{-}5h}$ decreased by 12.8% and 24.5% on d15 compared to d1 in 44.1 g/d and 14.7 g/d AXA1665 groups, respectively. By contrast, the control group only had a 7.4% mean decrease in plasma ammonia $AUC_{0\text{-}5h}$ on d15 vs. d1. Plasma albumin trended upward in both AXA groups vs. control. By d15, the AXA1665 44.1 g/d, but not the 14.7 g/d or control groups, manifested a leaner phenotype (+2.8% mean increase in dry lean mass, -2.5% mean decrease in fat mass) with a 20.5% improvement in LFI vs. d1.

Conclusion: Within a 15d period, AXA1665 meaningfully improved the FR, lean mass and LFI, which are all surrogate markers of liver-related health and outcomes, while decreasing plasma ammonia. Future studies over longer durations are warranted to assess whether AXA1665 impacts cirrhosis-related sarcopenia and HE.

LBP-32

The Natural History of Ferroportin Disease-First Results of the International, Multicenter EASL non-HFE Registry

Benedikt Schaefer[1], André Viveiros[1], Elena Corradini[2], Massimo Fiorini[2], Stefania Scarlini[2], Raffaela Rametta[3], Sara Pelucchi[4], Fabiana Busti[5], Hansi Weissensteiner[6], Sebastian Schoenherr[6], Lukas Forer[6], Nathan Subramaniam[7], Edouard Bardou-Jacquet[8], John Ryan[9], Olivier Loreal[10], Dorine Swinkels[11], Mayka Sanchez[12], Martina Muckenthaler[13], Alexander Drakesmith[9], Herbert Tilg[1], Günter Weiss[6], Igor Theurl[6], Florian Kronenberg[6], Domenico Girelli[5], Alberto Piperno[4], Antonello Pietrangelo[2], Luca Valenti[3], Graca Porto[14], Heinz ZOLLER[1].

Email: heinz.zoller@i-med.ac.at

Background and aims: Ferroportin (FPN) disease and hemochromatosis (HH) type 4 are phenotypically distinct diseases caused by mutations in *SLC40A1*. Both traits are characterized by high serum ferritin and hepatic iron overload. Transferrin saturation and splenic/macrophage iron overload distinguish FPN disease from HH type 4. Prognosis and management of patients with *SLC40A1* mutations has been inferred from HFE associated HH (type 1), despite distinct phenotypic presentation in patients with a FPN disease phenotype. The aim of the present study was to define the clinical and biochemical characteristics and management of patients with *SLC40A1* mutations in comparison to HFE HH.
Method: The EASL non-HFE registry study collect structured information on the clinical presentation, biochemistry, radiology, genetics and histology of patients with FPN disease. Data were compared with an age and sex matched cohort of patients diagnosed with HFE HH.

Table: Demographic and biochemical parameters of patients with FPN disease and HFE hemochromatosis.

	SLC40A1 mutation	HFE HH	p
N (females)	77 (41)	91 (47)	0.479
Age at diagnosis [years]	42.1 (±15.6)	40.5 (±13.5)	0.590
Serum iron [µg/dL]	74.2 (±46.1)	34.9 (±9.8)	<0.001
Ferritin [µg/L]	798 (505.6-1284)	427 (299.8-653)	<0.001
Transferrin [mg/dL]	216 (189-257)	167 (157.2-195)	<0.001
Transferrin saturation [%]	28 (21.5-37.5)	79 (60.5-84.5)	<0.001
Transferrin saturation >50%	11%	89%	<0.001
Liver iron content [µmol/g]	135.5 (±82.7)	123.2 (±107.1)	0.405
Median follow-up [years]	9.7 (±4.4)	7.6 (±5.6)	0.042
HCC incidence	1.3% (1/77)	1.1% (1/91)	1.000

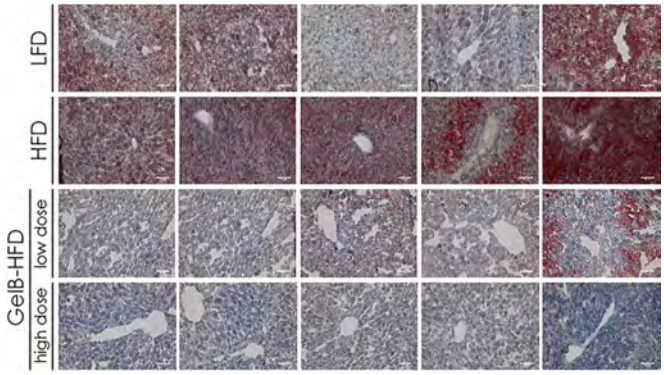
Results: As of January 2019, 77 patients (41 female) with genetically confirmed FPN disease have been registered, representing the largest cohort of patients with disease-associated *SLC40A1* mutations. Seventeen different mutations were reported. Eleven percent of patients presented with a HH type 4 phenotype. Demographic and biochemical parameters are shown in the Table. Patients with FPN disease had significantly lower serum iron, ferritin, and transferrin saturation when compared with HFE HH patients. Hepatic iron concentration determined by MRI was 135.5 (±82.8) µmol/g in the FPN disease group as compared 123.2 (±107) µmol/g in the HFE HH group ($p = 0.405$). Five-year survival rate was 95.6% in HFE HH patients as compared to 100% in individuals with SLC40A1 mutations. In the FPN group 45% of patients received regular phlebotomies (mean treatment duration 9.2 years, 0.85 phlebotomies/month).
Conclusion: Although serum ferritin indicates more severe iron overload in patients with *SLC40A1* mutations than in HFE associated HH, both groups show comparable hepatic iron concentration. In contrast, lower serum iron and transferrin saturation are associated with better outcome in FPN disease, despite low rate of iron reduction therapy in patients with *SLC40A1* mutations.

LBP-33

Gelesis superabsorbent hydrogel prevents hepatic steatosis in a high fat diet-induced NAFLD pre-clinical model

Alessandra Silvestri[1], Alessandro Sannino[2], Milena Vitale[1], Juliette Mouriès[1], Ilaria Spadoni[1], Christian Demitri[2], Elaine Chiquette[2], Maria Rescigno[1]. *[1]Humanitas University, Department of Biomedical Sciences, Milan, Italy; [2]Gelesis, Boston, United States*
Email: alessandra.silvestri@ieo.it

Background and aims: Obesity, insulin resistance and disrupted gut homeostasis are major contributors to the pathophysiology of NAFLD and its progression to NASH. The Gelesis novel hydrogel platform technology is based on crosslinked modified cellulose that can be orally administered. Based on previous preclinical work, Gel-B was designed to restore gut barrier function. Our aim was to evaluate whether Gel-B can prevent hepatic steatosis by repairing gut barrier function, reducing insulin resistance, affecting gut dysbiosis and weight loss, all mechanisms involved in NAFLD.
Method: C57BL/6J *wild type* male mice were fed with either isocaloric low fat diet (LFD: 10% lard) or HFD (45% lard), control groups, for 18 weeks. In parallel, 2 groups of mice were fed with the HFD supplemented with a low or high dose of Gel-B (GelB-HFD). Changes in body weight, glucose, insulin tolerance, GLP-1, and epididymal adipose tissue (EAT) were measured. Oil red O staining was performed to quantify triglyceride accumulation in the liver. Expression of zonula occludens-1 (ZO-1) and circulating levels of bacterial lipolysaccharides (LPS) were assessed to characterize the gut barrier function. Feces were collected and total genomic DNA was extracted. Bray-Curtis dissimilarity analysis was used to generate a principal coordinate analysis (PCoA).
Results: GelB-HFD significantly decreased EAT and blunted weight gain compared to HFD ($p < 0.05$); no difference in weight was observed in LFD alone. All mice on high dose (9/9) and (8/10) on low dose maintained healthy fat-free liver on HFD (Fig). In contrast, the LFD could not prevent hepatic steatosis while keeping the same weight range of GelB-HFD groups. A significant HOMA IR reduction was observed in the GelB-HFD (−18%; $p < 0.05$) compared to HFD, driven by reduction in fasting insulin ($p < 0.01$) and consistent with the improvement of glucose and insulin tolerance tests. Total GLP-1 increased in both GelB-HFD groups (low and high dose, $p < 0.05$, $p < 0.01$ compared to HFD and LFD). These findings in GelB-HFD were linked with improvement in gut barrier function by increasing ZO-1 and preventing an increase in LPS translocation. The PCoA revealed a clear and pronounced compositional separation of microbiomes after therapy with GelB.



Conclusion: These results support the role of GelB as a potential therapeutic option to target pathogenic mechanisms involved in NAFLD/NASH: excess weight, insulin resistance, gut barrier function and gut dysbiosis.

LBP-34

Effect of Resistance Associated Substitutions on Retreatment of HCV infected patients with prior failure to Direct Acting Antiviral Therapy

David Smith[1], Daniel Bradshaw[2], Jean Mbisa[2], Carmen Manso[2], David Bibby[2], Josh Singer[3], Emma Thomson[3], Ana Filipe[3], Elihu Aranday-Cortes[3], Azim Ansari[1], Anthony Brown[1], Emma Hudson[1], Jennifer Benselin[4,5], Brendan Healy[6], John Mclauchlan[3], Eleanor Barnes[1], William Irving[4,5]. *[1]University of Oxford, Peter Medawar Building for Pathogen Research, Nuffield Department of Medicine, Oxford, United Kingdom; [2]Public Health England, National Infection Service, Colindale, London, United Kingdom; [3]University of Glasgow, MRC Centre for Virus Research, Glasgow, United Kingdom; [4]University of Nottingham, Nottingham, United Kingdom; [5]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [6]Public Health Wales, Microbiology, Cardiff, United Kingdom*
Email: david.smith@ndm.ox.ac.uk

Background and aims: 5-10% of HCV-infected patients are not cured with interferon free Direct Acting Antiviral (DAA) regimes. These patients are now being retreated with pan-genotypic regimes such as sofosbuvir, velpatasvir and voxilaprevir, (SOF/VEL/VOX), SOF/VEL with ribavirin (RBV), or glecaprevir and pibrentasvir (GLE/PIB). Here, we present the first real world re-treatment data from the UK.

Method: Blood samples were collected from 282 patients about to begin HCV retreatment. Next generation, deep, whole genome sequencing (WGS) was performed using target enrichment. HCV subtypes were assigned and NS3, NS5A and NS5B resistance associated substitutions (RAS) relevant to each genotype were identified (15% of reads cut off) using a bespoke pipeline developed for HCV-GLUE (hcv.glue.cvr.ac.uk).

Results: Pre-retreatment WGSs were generated from 260 patients. Of these, 87% had previously received an NS5A inhibitor, 30% a protease inhibitor and 50% sofosbuvir. 64% of patients had cirrhosis with 26% decompensated, 11% had hepatocellular carcinoma and 9% had previously received a liver transplant. Subtypes 1a (41%, n = 106) and 3a (39%, n = 102) were the most common; the remaining sequences included 19 subtypes within genotypes 1, 2, 3, 4 and 6. RAS to NS5A inhibitors were the most common polymorphisms, identified in 64% (n = 167) of patients. RAS to Protease Inhibitors were found in 30% (n = 78) and to NS5B Inhibitors in 5% (n = 14). Retreatment outcomes are currently available for 53 patients (the remaining outcomes will be available by April 2019). 53% (n = 28) of patients were retreated with SOF/VEL/VOX, 26% (n = 14) received GLE/PIB and 21% (n = 11) received SOF/VEL+RBV. The overall re-treatment SVR12 rate was 85% (45/53) ITT and 92% (49/53) PP; re-treatment failures included 1 non-responders and 3 relapsers

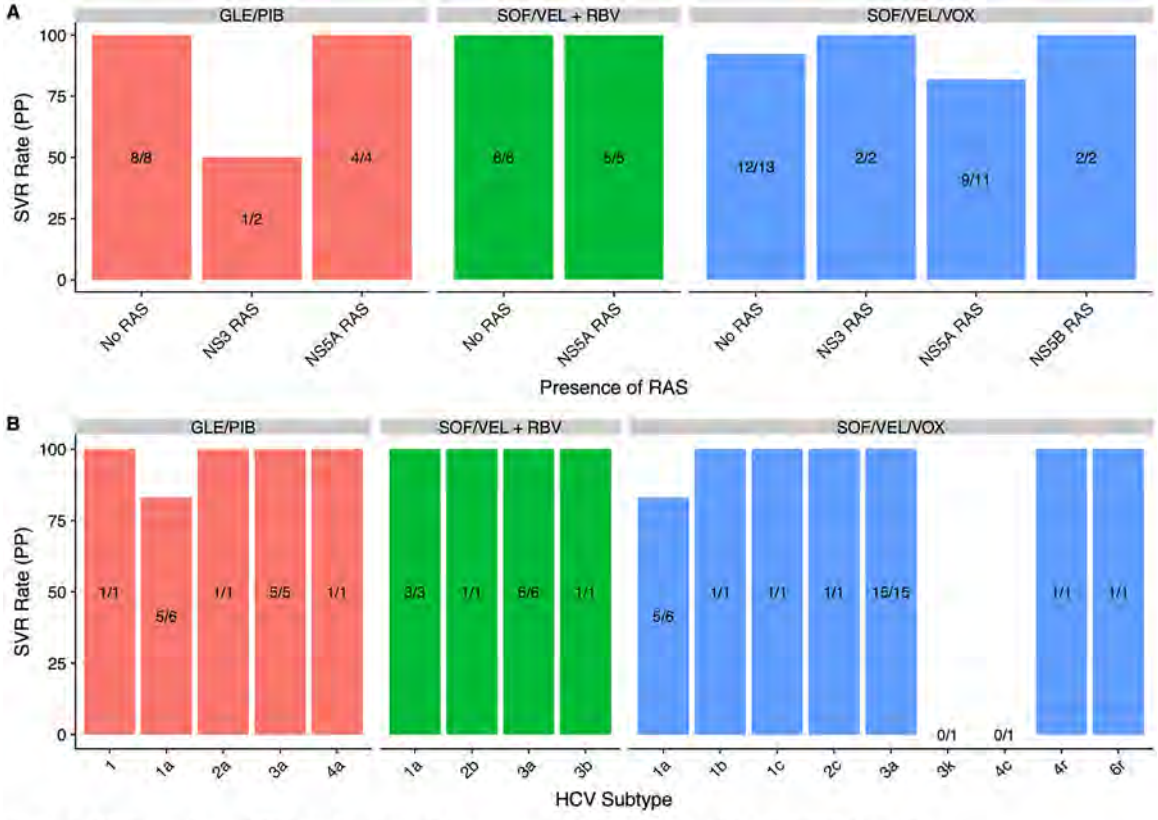


Figure 1: SVR12 rates for each DAA combination split by presence of RAS in each gene (A) or by HCV Subtype (B).

(4 cirrhotic, gt 1a, 3k, 4c), 2 patients lost to follow-up, 1 was re-infected, 1 discontinued. SVR rates by re-treatment regime, subtype and presence of RAS pre-retreatment is shown (Figure 1). At the time of retreatment initiation, 37% of patients had RAS to the NS5A inhibitor they received as retreatment, 8% had RAS to the NS3 Inhibitor and 4% had RAS to sofosbuvir. There was no association with the presence of RAS and outcome (p = 0.35).
Conclusion: The SVR rate for the retreatment of patients with prior DAA therapy failure is high. Pre retreatment RAS are common but do not associate with re-treatment outcomes. Interestingly the two SOF/VEL/VOX failures were subtypes rarely found in the UK (3k and 4c).

Kupffer cell development: A link between Notch signaling and LXRandalpha;
Bonnardel Johnny[1,2], Wouter T'jonck[1,2], Browaeys Robin[2,3], Martens Liesbet[2,3], Vanneste Bavo[1,2], De Prijck Sofie[1,2], Saeys Yvan[2,3], Guilliams Martin[1,2]. *[1]VIB Center for Inflammation Research, Laboratory of Myeloid Cell Ontogeny and Functional Specialization, Ghent, Belgium; [2]Ghent University, Department of Biomedical Molecular Biology, Ghent, Belgium; [3]VIB Center for Inflammation Research, Data Mining and Modeling for Biomedicine, Ghent, Belgium*
Email: martin.guilliams@ugent.vib.be

Background and aims: Macrophages form a heterogeneous group of immune cells which contribute to tissue-homeostasis by performing functions fitting with the requirements of their specific tissue of residence. These tissue-specific functions are acquired through induction of transcription factors (TFs) which control the expression of a number of tissue-specific genes. Expression of these TFs is regulated by a combination of tissue-specific signals produced by the local environment of the macrophage or "macrophage niche." Using a Kupffer cell (KC) specific depletion model, we aim to investigate the signals produced by the KC niche and the TFs they induce which drive KC development.
Method: To study KC development and the KC niche, we used multi-parameter flow cytometry, (sc)RNA-seq, KC-specific mouse models, prediction algorithms and *in vitro* systems.
Results: To identify the distinct TFs required for KC development, we first performed transcriptomic analysis of developing KCs. This identified a set of KC-specific TFs, including LXRα, that are upregulated during the initial stages of KC development. Focussing on LXRa, we generated a KC-specific LXRα knockout mice. Upon loss of LXRα, KCs lose 30% of their identity genes and die within weeks. Having identified LXRα as a crucial TF for KC identity, we next sought to identify the signal (s) inducing expression of LXRα. To this end, we first cocultured bone-marrow monocytes with hepatic stellate cells, liver sinusoidal endothelial cells (LSECs) and hepatocytes, the cells we hypothesise to constitute the KC niche. Expression of LXRα was induced exclusively in the monocytes cocultured with LSECs. To narrow down the potential LSEC ligands inducing LXRα we profiled the transcriptome of LSECs. Using this information paired with the transcriptomic analysis performed on developing KCs, we employed an algorithm, called NicheNet, to predict intercellular communication by linking ligands with target genes. The top predicted interaction was between the notch ligand DLL4 produced by LSECs and NOTCH1/2, expressed by liver-infiltrating monocytes. To validate this prediction, we cocultured monocytes and DLL4 expressing OP9-cells. This induced expression of LXRα and KC-identity genes.
Conclusion: We have studied the development of monocytes into KCs and identified DLL4 expressed by LSECs as a tissue-derived signal inducing the expression of LXRα and KC-identity genes during KC development.

LBP-36
Inhibition of glutamine synthetase in monocytes from patients with Acute-on-Chronic Liver Failure resuscitates their antibacterial and inflammatory capacity
Hannelie Korf[1], Johannie Du Plessis[1], Jos van Pelt[1], Sofie De Groote[1], David Cassiman[1], Len Verbeke[1], Bart Ghesquière[1], Sarah-Maria Fendt[1], Matthew Bird[1], Ali Talebi[1], Matthias Van Haele[1], Rita Feio-Azevedo[1], Lore Meelberghs[1], Tania Roskams[1], Rajeshwar Mookerjee[2], Gautam Mehta[2], Rajiv Jalan[2], Thierry Gustot[3], Wim Laleman[1], Frederik Nevens[1], Schalk van der Merwe[1]. *[1]KU Leuven, Leuven, Belgium; [2]University College London, London, United Kingdom; [3]Universite Libre de Bruxelles, Brussels, Belgium*
Email: hannelie.korf@kuleuven.be

Background and aims: Acute-on-chronic liver failure (ACLF) is associated with dysfunctional circulating monocytes whereby patients become highly susceptible to bacterial infections. Here we identify the pathways underlying monocyte dysfunction in ACLF and investigate whether metabolic rewiring reinstates their phagocytic and inflammatory capacity.
Method: Following phenotypic characterization, we performed RNA sequencing on $CD14^+CD16^-$ monocytes from ACLF and decompensated alcoholic cirrhosis patients. Additionally, an *in vitro* model mimicking ACLF patient-derived features was implemented to investigate the efficacy of metabolic regulators on monocyte function.
Results: Monocytes from ACLF patients featured elevated frequencies of IL-10-producing cells, reduced HLA-DR expression and, impaired phagocytic- and oxidative burst capacity. Transcriptional profiling of isolated $CD14^+CD16^-$ monocytes in ACLF revealed upregulation of an array of immunosuppressive parameters and compromised antibacterial- and antigen presentation machinery. In contrast, monocytes in decompensated cirrhosis showed intact capacity to respond to inflammatory triggers (1). Culturing healthy monocytes in ACLF plasma mimicked the immunosuppressive characteristics observed in patients, inducing a blunted phagocytic response and metabolic program associated with a tolerant state (1). Metabolic rewiring of the cells using a pharmacological inhibitor of glutamine synthetase, partially restored the phagocytic and inflammatory capacity of *in vitro*-generated- as well as ACLF patient-derived monocytes. Highlighting its biological relevance, the glutamine synthetase/glutaminase ratio of ACLF patient-derived monocytes positively correlated with disease severity scores (1).
Conclusion: In ACLF, monocytes feature a distinct transcriptional profile, polarized towards an immunotolerant state and altered metabolism. We demonstrated that metabolic rewiring of ACLF monocytes partially revives their function, opening up new options for therapeutic targeting in these patients.

Evaluation of Hepatitis C Virus Rapid Diagnostic Test in HCV mono- and HCV/HIV co-infected patients from Low and Middle Income Countries
Beatrice Vetter[1], Elena Ivanova Reipold[1], Rosemary Audu[2], Maia Alkhazashvili[3], Anja De Weggheleire[4], Stefano Ongarello[1], Katrien Fransen[4]. *[1]Foundation for Innovative New Diagnostics, Geneva, Switzerland; [2]National Institute of Medical Research, Lagos, Nigeria; [3]Lugar Centre, NCDC, Tbilisi, Georgia; [4]Institute of Tropical Medicine, Antwerp, Belgium*
Email: beatrice.vetter@finddx.org

Background and aims: Performance evaluations of Rapid Diagnostic Tests (RDT) for Hepatitis C Virus (HCV) antibody detection are mostly conducted in HCV-mono infected patients, often located in High

Income Countries. Although HIV is a commonly found co-infection in HCV-infected individuals, substantial data on RDT performance in HCV/HIV co-infected patients are lacking.
In the present study, we evaluated sensitivity and specificity of thirteen RDTs on 1'800 HCV mono- or HCV/HIV co-infected samples collected in different geographic regions, to fill the data gap in Low and Middle Income Countries (LMICs) and particularly the HIV-infected population.
Method: This is an observational, retrospective multicentre diagnostic accuracy study on archived EDTA plasma samples from Nigeria (42%), Cambodia (30%), Georgia (21%) and Belgium (7%).
Sensitivity and specificity were evaluated in each of 400 HCV mono- and HCV/HIV co-infected samples and each of 500 HCV-uninfected or HIV mono-infected samples. Results were compared to a composite reference standard combining two Enzyme Immuno Assays and a Line Immunoassay.
Each sample was tested on two lots per RDT and each result was read by three independent readers.
Results: Across all HCV RDTs and samples, the overall performance for sensitivity and specificity ranged from 91-99% and 90-100%, respectively. In the HCV-mono infected samples, both, sensitivity and specificity ranged from 98-100%. In the HCV/HIV co-infected samples, RDT performance was more variable, ranging from 80-99% for sensitivity and 88-100% for specificity.
False negative (FN) results were found across all genotypes, with a slightly higher proportion among genotype 4 and 6. For many samples there was no apparent relationship between CD4 counts and FN results in the HCV/HIV co-infected samples, though compromised immune status cannot be excluded as cause for FN results.
Conclusion: This is the first study assessing performance of frequently used HCV RDTs in a large sample set collected in diverse regions and with a focus on performance in the HIV infected population.
While RDT performance in the HCV-mono infected samples was overall good, it was variable in the presence of HIV infection, the reason for which could either be the immune-compromised status in HIV infection or the geographical origin of the HIV infected cohort.
Overall, these findings provide important insights for HCV RDT performance and should be taken into consideration when deciding on the most suitable RDT for screening in a particular setting or population.

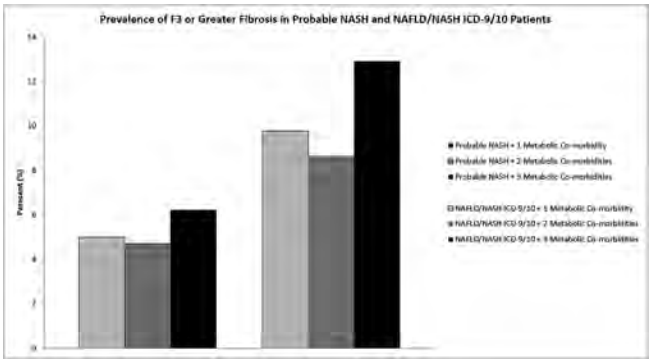
Increasing Number of Metabolic Co-Morbidities are Associated with Higher Risk of Advanced Fibrosis in Patients with Non-alcoholic Steatohepatitis

Robert Wong[1], Tram Tran[2], Harvey Kaufman[3], Justin Niles[3], Robert G. Gish[4]. *[1]Alameda Health System, Oakland, United States; [2]Gilead Sciences, Inc., Foster City, United States; [3]Quest Diagnostics Corporate Headquarters, Secaucus, United States; [4]Stanford Health Care, Palo Alto, United States*
Email: rowong@alamedahealthsystem.org

Background and aims: Accurate estimates of non-alcoholic steatohepatitis (NASH) prevalence are lacking, particularly the subset of patients with advanced fibrosis. We aim to evaluate prevalence and predictors of advanced fibrosis among patients with probable NASH using national clinical laboratory data.
Method: Clinical laboratory data from October 1, 2017-September 30, 2018 were collected using Quest Diagnostics database, which tests ~30% of U.S. adults annually. Adults with negative hepatitis B surface antigen, negative hepatitis C antibody, and elevated alanine aminotransferase (ALT) (>25 U/L women, >35 U/L men) were evaluated for prevalence of ≥F 3 fibrosis using fibrosis-4 score (FIB-4)>2.67. Patients were grouped by presence of one, two, or three concurrent metabolic co-morbidities (decreased high density lipoprotein (<40 mg/dL in men, <50 mg/dL in women), elevated triglycerides (≥1 50 mg/dL), or elevated hemoglobin A1C (≥6 .5%)). We further evaluated patients specifically with NAFLD/NASH ICD-9/10 codes from October 1, 2013-Septebmer 30, 2018 (n = 243, 050). Multivariate logistic regression models evaluated for predictors of ≥F 3 fibrosis.
Results: Among 20, 593, 077 patients (42.6% male, mean age 54.5), 9.4 million had available results to assess ALT and metabolic co-morbidities. Overall prevalence of ≥F 3 fibrosis was 3.34% (95% CI 3.33-3.34), which increased from 4.72% (95% CI 4.63-4.82) in patients with one metabolic co-morbidity to 6.24% (95% CI 6.06-6.42) in patients with three metabolic co-morbidities. Among patients with NAFLD/NASH ICD-9/10 codes, prevalence of ≥F 3 fibrosis was 9.07% (95% CI 8.95-9.18), which increased from 9.77% (95% CI 9.18-10.36) in patients with one metabolic co-morbidity to 12.91% (95% CI 11.79-14.03) in patients with three metabolic co-morbidities. On multivariate regression, significantly higher odds of ≥F 3 fibrosis was observed in men vs. women (OR 1.24, 95% CI 1.19-1.29), every 10-year increase in age (OR 2.02, 95% CI 1.99-2.06), and concurrent metabolic abnormalities (OR for three metabolic abnormalities vs. none: 1.31, 95% CI 1.23-1.40).



Conclusion: Among a large national sample of U.S. adults, estimated prevalence of ≥F 3 fibrosis among NASH patients ranged from 3.34-9.07%, representing 2.5-6.8 million individuals. Concurrent metabolic co-morbidities are associated with significantly higher odds of advanced fibrosis with estimated prevalence as high as 12.91% in patients with NASH and three metabolic co-morbidities.

LBP-40

Development of Oligonucleotide-Based miR-132 Antagonists for the Treatment of NASH

Romeo Papazyan[1], Garth Kinberger[1], Danling Wang[1], Graham Lang[1], Kathy Gogas[1], Timothy Wright[1], Shoutian Zhu[1]. *[1]Regulus Therapeutics Inc, San Diego, United States*
Email: szhu@regulusrx.com

Background and aims: MicroRNAs are small regulatory RNAs that play critical roles in animals and plants by regulating target gene expression at the post-transcription level. Many miRNAs are dysregulated in disease states including NASH, which indicates potential therapeutic targets for oligonucleotide-based drug development. Previous studies have shown that miR-132 is upregulated in livers of NASH patients and is involved in the development of NASH in rodent models. This study sought to validate miR-132 as a potential therapeutic target and to develop antagonists of miR-132 for the treatment of NASH
Method: Quantitative RT-PCR and Nanostring technologies were used to assess hepatic miR-132 levels from NASH patients as well as from several diet-induced mouse models of NASH. Over 250 oligonucleotide antagonists of miR-132 were synthesized and

analyzed for activity, safety and physicochemical properties. Efficacy of a lead compound was demonstrated in multiple mouse models of NASH. Global gene expression profiling was performed to unveil the underlying mechanisms of the lead compound.
Results: miR-132 was upregulated 2 to 4-fold in liver tissues of NASH patients compared to those of healthy donors. In several mouse models of NASH, treatment with a miR-132 antagonizing lead compound reduced liver triglyceride levels by up to 50%, neutralized serum liver enzyme levels (ALT and AST), enhanced glucose tolerance, and improved histopathological scores. Global gene expression profiling revealed significant increase in favorable metabolic genes and decrease inflammatory and fibrotic genes. The lead compound exhibited favorable pharmacological properties as only 2-4 weekly doses were sufficient to rescue NASH phenotypes. These therapeutics effects were sustained for up to 6 weeks following the final dose. The lead compound was well tolerated through intravenous and subcutaneous administration without any obvious drug-related adverse effects.
Conclusion: miR-132 is a promising therapeutic target for the treatment of NASH. Oligonucleotide-based antagonists of miR-132 exhibited excellent potency and pharmacological properties that warrant further development. Lead optimization is currently ongoing to generate drug candidate for first-in-human clinical studies.

Autoimmune and chronic cholestatic liver disease: Experimental and pathophysiology

THU-001
Identifying intrahepatic lymphocyte permutations in active untreated, resistant and treated autoimmune hepatitis

Gautham Appanna[1,2], Tom Pembroke[1,2], Kristin Ladell[1], Awen Gallimore[1], Andrew Godkin[1,2]. *[1]Cardiff University, Division of Infection and Immunity, Cardiff, United Kingdom; [2]University Hospital of Wales, Department of Gastroenterology and Hepatology, Cardiff, United Kingdom*
Email: gautham.appanna@doctors.net.uk

Background and aims: Autoimmune Hepatitis (AIH) is an inflammatory disease associated with elevated transaminases, immunoglobulin G, autoantibodies (e.g. antinuclear antibody) presence and interface hepatitis with a lymphocytic infiltrate histologically. Standard of care is long term immunosuppression therapy and there is not a clear consensus for treatment withdrawal once biochemical and histological remission has been achieved.
We performed serial intrahepatic fine needle aspiration (FNA) on patients with AIH before and after establishing immunosuppression to investigate the intrahepatic immune response to successful therapy.
Method: 16 patients with AIH were recruited. 10 patients had active disease (5: new diagnosis, 5: refractory to treatment) and 6 were in remission. Biochemical remission was achieved in 5 patients with active disease by six months with prednisolone monotherapy. Peripheral blood mononuclear cells and intrahepatic aspirates were analysed using multicolour flow cytometry.
Results: Serial FNA was well tolerated and no complications were observed. Within the intrahepatic compartment, treated/controlled disease is associated with a significant increase in the proportion of CD4+ lymphocytes ($p = 0.045$), and with a reduction in both CD4+ end-stage effector frequency (CD45RA+, CCR7-) and CD8+ frequency ($p = 0.051$). A significant decrease in B cells are seen in both peripheral blood and the liver ($p = 0.043$ and $p = 0.002$ respectively) in those in remission.
Conclusion: Our data suggests that a distinct intrahepatic inflammatory pattern is present which then resolves with immunosuppression. Understanding key lymphocyte phenotypes may provide early biomarkers of successful therapy and even indicate patients in whom immunosuppression may be withdrawn.

THU-002
Macrophage activation marker neopterin predicts liver transplantation-free survival in primary sclerosing cholangitis

Amandeep K Dhillon[1,2], Christian Rupp[3], Mette Vesterhus[4,5], Robert Voitl[3], Marius Trøseid[2,6], Øyvind Midttun[7], Per Ueland[7,8], Tom Hemming Karlsen[1,2], Martin Kummen[1,2], Johannes R. Hov[1,2]. *[1]Oslo University Hospital, Rikshospitalet, Norwegian PSC Research Center, Oslo, Norway; [2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway; [3]University Hospital of Heidelberg, Department of Internal Medicine IV, Heidelberg, Germany; [4]Haraldsplass Deaconess Hospital, Department of Medicine, Bergen, Norway; [5]University of Bergen, Department of Clinical Science, Bergen, Norway; [6]Oslo University Hospital, Rikshospitalet, Section of Clinical Immunology and Infectious diseases, Oslo, Norway; [7]Bevital AS, Bergen, Norway; [8]Haukeland University Hospital, Laboratory of Clinical Chemistry, Bergen, Norway*
Email: j.e.r.hov@medisin.uio.no

Background and aims: Circulating biomarkers of fibrosis and inflammation may be of clinical utility in primary sclerosing cholangitis (PSC). Some of the biomarkers reflect macrophage activation, which has been linked to disease severity in experimental PSC models. Upon activation with interferon gamma, macrophages produce neopterin, which has been associated with disease activity and severity in several other conditions. In the present study we aimed to investigate the role of neopterin in two independent PSC cohorts.
Method: A discovery panel of 191 PSC patients (79% male, median 41 (range 16–72) years old) and 100 healthy controls from Norway (59% male, 40 (28–56) years), and a validation panel of 150 PSC patients (63% male, 43 (18–74) years) from Germany were included. Neopterin was analyzed using LC-MS/MS. Primary end point was liver transplantation or death. Survival from time of sampling was analyzed by Kaplan-Meier plots and Cox regression. Optimal cut-off was calculated using ROC-curve.
Results: Neopterin was elevated in PSC patients compared with controls in the discovery panel (median 11.9 vs. 10.6 nmol/L, $p < 0.001$), and higher in PSC patients reaching an end point (n = 87, 46%) than those who did not (median 13.6 vs 11.2, $p < 0.001$), with 11.8 as the optimal cut-off. Neopterin divided into quartiles strongly predicted liver transplantation-free survival with estimated mean survival ranging from 3.5 (highest quartile) to 6.6 years (lowest quartile) from time of sampling, $p < 0.001$. PSC patients with high neopterin (>11.8), showed a mean survival of 4.1 years, compared to 6.1 years in the low group ($p < 0.001$). PSC patients in the validation panel had less advanced disease (Mayo risk score mean 0.06 vs. 0.56, $p = 0.001$), and also here, patients reaching an end point during follow-up (n = 16, 11%) showed higher neopterin levels compared to patients without ($p = 0.006$). Neopterin > 11.8 was also associated with reduced liver transplantation-free survival in the validation panel ($p = 0.003$). When correcting for Mayo risk score, neopterin > 11.8 was independently associated with survival in the discovery panel ($p = 0.04$) but not in the validation panel ($p = 0.09$). A combined analysis of all patients including center and Mayo risk score as covariates yielded a hazard ratio of 1.8 (95% CI 1.1-2.7), $p = 0.01$ for high neopterin (>11.8).
Conclusion: Neopterin associates with liver transplantation-free survival in PSC, highlighting a possible role of this macrophage activity marker as a measure of prognosis and disease activity.

European multicenter validation of autoantibodies against huntingtin-interacting protein 1-related protein for the diagnosis of autoimmune hepatitis in adults

Bastian Engel[1], Jana Diestelhorst[1,2], Maciej K. Janik[3], Zachou Kalliopi[4,5], Christoph Schramm[6,7], Maria Carlota Londoño[8], HABES Sarah[9], Claudine Lalanne[10], Simon Pape[11], Joost Ph Drenth[11], Luigi Muratori[10], Amédée Renand[12], Isabel Graupera[8], Ansgar W. Lohse[7], George Dalekos[4,5], Piotr Milkiewicz[3], Michael P. Manns[1], Elmar Jaeckel[1], Richard Taubert[1]. *[1]Department of Gastroenterology, Hepatology and Endocrinology, Hanover Medical School, Hannover, Germany; [2]Clinic for Paediatric Nephrology, Hepatology and Metabolic disorders, Hanover Medical School, Hannover, Germany; [3]Liver and Internal Medicine Unit, Medical University of Warsaw, Warsaw, Poland; [4]Institute of Internal Medicine and Hepatology, Larissa, Greece; [5]Department of Medicine and Research Laboratory of Internal Medicine, University Hospital of Larissa, Larissa, Greece; [6]Martin Zeitz Centre for Rare Diseases, University Medical Centre Hamburg-Eppendorf (UKE), Hamburg, Germany; [7]1st Medical Department, University Medical Center Hamburg Eppendorf (UKE), Hamburg, Germany; [8]Liver Unit, Hospital Clínic, IDIBAPS, CIBEREHD, Barcelona, Spain; [9]Service Hépato-Gastro-entérologie et Assistance Nutritionnelle, University Hospital of Nantes, Nantes, France; [10]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [11]Department of Gastroenterology and Hepatology, Radboud University Medical Center, Nijmegen, Netherlands; [12]Centre de Recherche en Transplantation et Immunologie UMR1064, INSERM, Nantes University Faculty of Medicine, Nantes, France*
Email: Engel.Bastian@mh-hannover.de

Background and aims: Autoantibodies are major components for the diagnosis of autoimmune hepatitis (AIH). Currently, common autoantibody testing is hampered by lack of either high specificity or sensitivity. We discovered antibodies against huntingtin-interacting protein 1-related protein (HIP1R) in AIH single center cohorts with a better overall accuracy and specificity compared to antinuclear antibodies (ANA) and smooth muscle antibodies (SMA) (abstract PS-006; ILC 2018). We now validated anti-HIP1R antibody testing in a large European multicenter AIH cohort.
Method: IgG antibodies against HIP1R were measured via ELISA in cryo-conserved serum samples of 177 patients with untreated AIH, 57 patients with AIH on therapy and 303 patients with non-AIH liver diseases (100x PBC, 100x PSC, 13x toxic hepatitis, 4x genetic liver disease, 86x NAFLD/NASH).
Results: Anti-HIP1R antibody concentrations were elevated in serum samples of untreated AIH patients compared to non-AIH liver diseases ($p < 0.001$). Anti-HIP1R antibody concentrations declined under immunosuppressive treatment in AIH patients to values as seen in non-AIH liver diseases. Applying the same cut-off values as in our single center training cohort, anti-HIP1R antibodies were equally sensitive ($p = .075$), more specific ($p < .001$) and more accurate (95% confidence interval (CI): 68.7–76.8 (anti-HIP1R) vs. 52.9–62.1 (ANA)) to diagnose AIH compared to ANA (Table 1). SMA performed similar to anti-HIP1R antibodies in terms of specificity ($p = .477$) and sensitivity ($p = .728$) and trended towards lower overall accuracy (CI: 63.3–72.9) (Table 1). The majority of patients with untreated AIH but non-diagnostic ANA and SMA titers (12/177; 6.8% of patients with untreated AIH) had diagnostic anti-HIP1R antibody concentrations (8/12; 66.7%).

Table 1: Test criteria to diagnose untreated AIH.

	Anti-HIP1R	ANA	SMA
Sensitivity	63.3%	70.3%	72.4%
Specificity	78.5%	49.1%	63.6%
Accuracy	72.9%	57.6%	68.3%

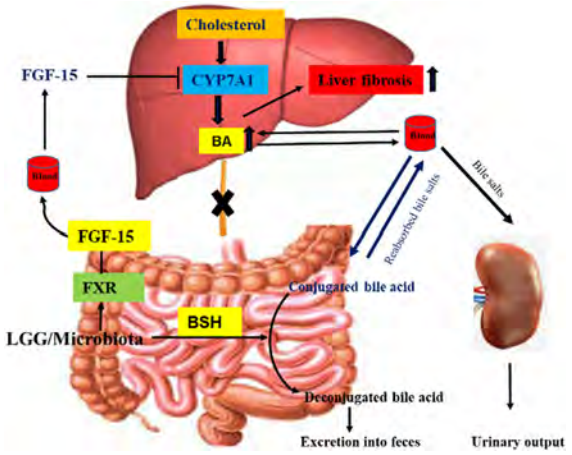
Conclusion: This European multicenter study confirmed that anti-HIP1R antibody testing serves to distinguish AIH from other liver diseases with the highest overall diagnostic accuracy. Anti-HIP1R antibodies can help to facilitate the diagnosis of AIH even when ANA and SMA titers are low and non-diagnostic. Finally, anti-HIP1R antibodies can be determined much easier with a single ELISA compared to the conventional gold standard of autoantibody-diagnostic using immunofluorescence.

THU-004

Lactobacillus rhamnosus GG prevents liver fibrosis through intestinal FXR/FGF15-mediated inhibition of bile acid synthesis and the increase of bile acid excretion in mice

Wenke Feng[1], Yunhuan Liu[1], Craig McClain[1]. *[1]University of Louisville, Medicine, Louisville, United States*
Email: wenke.feng@louisville.edu

Background and aims: Gut microbiota play a critical role in liver disease. The purpose of this study is to examine the effect of probiotics *Lactobacillus rhamnosus* GG (LGG) in the prevention of liver injury and fibrosis induced by bile-duct ligation (BDL) and to understand the underlying mechanisms.
Method: Liver fibrosis was induced in mice by BDL for 11 days. LGG was given to mice by oral gavage at a dose of 109 CFU/day/mouse. Bile acid level and compositions of liver, serum, feces and serum were determined. Liver fibrosis and injury were assessed by histology analysis, liver fibrotic gene expression and serum biochemistry analysis. Intestinal microbiota were determined by pyrosequencing and gut lumen bile salt hydrolase (BSH) activity was determined. FXR activity was analyzed by a reporter system. Global and intestinal specific FXR inhibitors were used to dissect the role of FXR.
Results: LGG treatment significantly decreased hepatic total bile acid level, liver injury and fibrosis in BDL mice. Metabolomics profiling showed a distinct bile acid composition in serum, liver and feces among Sham, BDL and BDL-LGG groups. Hepatic concentration of T-βMCA, a FXR antagonist, were markedly elevated in BDL mice and reduced in LGG treated BDL mice. While CDCA, a FXR agonist, was decreased in BDL mice and normalized in LGG-treated mice. LGG significantly increased the expression of serum and ileum FGF-15 (19), which is a FXR target and suppressor of hepatic bile acid synthesis through gut-liver axis. As a result, hepatic expression of key enzymes in bile acid synthesis, CYP7A1 and CYP27A1 was significantly reduced by LGG. Fecal BSH activity was significantly increased by LGG in BDL mice, which was accompanied by increased gut BSH-producing bacteria population and de-conjugated bile acid content in feces. In addition, LGG treatment increases urine bile acid excretion. The beneficial effects of LGG were attenuated by global and intestinal FXR inhibition. Furthermore, we showed that LGG attenuate T-βMCA-suppressed FXR activity and FGF-19 (15) and SHP expression in intestinal epithelial cells.



Conclusion: LGG treatment prevents liver fibrosis in a mouse model of cholestatic liver disease. The beneficial effect of LGG is mediated by intestinal FXR/FGF-15 (19) signaling activation leading to an inhibition of liver bile acid synthesis and increasing of fecal and urine bile acid excretion. Probiotic LGG may be used to prevent/treat cholestatic liver disease.

THU-005

Activation regulators of peripheral blood and intrahepatic T effector cells in autoimmune hepatitis

Pamela Filpe[1], Sören Alexander Weidemann[2], Christina Weiler-Normann[1], Ansgar W. Lohse[1], Christoph Schramm[1,3], Johannes Herkel[1], Marcial Sebode[1]. [1]*University Medical Centre Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany;* [2]*University Medical Centre Hamburg-Eppendorf, Department of Pathology, Hamburg, Germany;* [3]*University Medical Centre Hamburg-Eppendorf, Martin Zeitz Centre for Rare Diseases, Hamburg, Germany*
Email: p.filpe@uke.de

Background and aims: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease with unknown aetiology. T effector cells seem to play a crucial role in the pathogenesis of AIH by mediating the hepatic inflammation. Altered expression of activation regulators may account for enhanced T effector cell immune responses in AIH. We investigated regulators of T cell co- stimulation and co-inhibition in liver and blood of patients with AIH in comparison to healthy individuals and patients with other immune-mediated liver diseases such as primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC), and to immune-mediated drug- induced liver injuries (DILI).
Method: A total of 63 AIH patients (29 treatment-naïve and 34 under immunosuppressive treatment) were examined. Gene expression levels of *CBL-B, CTLA-4, GRAIL, ICOS, ITCH, NEDD4, OX40, PD-1, PKCϴ* and *TRAF6* were analysed by quantitative PCR of liver samples or isolated peripheral T cells of AIH patients and control subjects. Moreover, RNA in-situ hybridization with selected probes was performed on liver samples of AIH and DILI patients.
Results: Quantitative PCR screening revealed that peripheral blood T cells of AIH patients and healthy control subjects had similar gene expression levels of *CBL-B, CTLA-4, GRAIL, ICOS, ITCH, NEDD4, OX40, PD-1, PKCϴ* and *TRAF6*. In contrast, in livers of treatment-naïve AIH patients as compared to healthy control subjects, *CBL-B* (2-fold expr., $p = 0.009$), *PD-1* (10-fold expr., $p = 0.006$), *ICOS* (16-fold expr., $p < 0.001$) and *CTLA-4* (20-fold expr., $p < 0.001$) were significantly elevated. Intrahepatic expression of *CBL-B* and *ICOS* in AIH patients correlated positively with the modified hepatic activity index of these patients (mHAI, mean = 9; Spearmans R_s: 0.6, $p = 0.005$). RNA in-situ hybridization revealed that expression of *CBL-B* (57% positive cells in AIH vs. 20% positive cells in DILI; $p < 0.005$), *CTLA-4* (33% vs. 22%; $p < 0.02$) and *PD-1* (24% vs. 14%; $p = 0.03$) was elevated in liver-infiltrating cells (T cells and $CD3^-$ cells) in AIH patients as compared to DILI patients.
Conclusion: Expression of *CBL-B*, *CTLA-4*, *PD-1* and *ICOS* was significantly increased in livers of treatment-naïve AIH patients, whereas the expression levels in AIH patients under immunosuppressive treatment were not significantly different compared to healthy subjects. Therefore, altered expression of these activation regulators could be relevant for pro-inflammatory processes in AIH.

THU-006

Aberrant DNA methylation in bile accurately detects cholangiocarcinoma in patients with primary sclerosing cholangitis

Hege Marie Vedeld[1], Trine Folseraas[2], Kim Andresen[1], Heidi D. Pharo[1], Tom H. Karlsen[2,3], Marit Mæhle Grimsrud[2,3], Vemund Paulsen[2], Marine Jeanmougin[1], Lars Aabakken[2,3], Kirsten M. Boberg[2,3], Guro E. Lind[1]. [1]*Department of Molecular Oncology, Institute for Cancer Research and K.G. Jebsen Colorectal Cancer Research Centre, Oslo University Hospital, The Norwegian Radium Hospital, Oslo, Norway;* [2]*Norwegian PSC Research Centre and Section of Gastroenterology, Department of Transplantation Medicine, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo University Hospital Rikshospitalet, Oslo, Norway;* [3]*Institute of Clinical Medicine, University of Oslo, Oslo, Norway, Oslo, Norway*
Email: trine.folseraas@medisin.uio.no

Background and aims: Patients with primary sclerosing cholangitis (PSC) have up to 20% lifetime risk of developing cholangiocarcinoma (CCA). Current strategies for identifying CCA in patients with PSC are suffering from low diagnostic accuracy. Consequently, the majority of patients are diagnosed at an incurable stage of disease, highlighting the need for novel early detection methods that could qualify more patients for curative treatment. We aimed at establishing robust DNA methylation biomarkers in bile for improved detection of CCA in PSC.
Method: By using highly sensitive droplet digital PCR (ddPCR) 100 µl of bile collected during endoscopic retrograde cholangiopancreatography or liver transplantation from 261 patients with PSC, CCA with and without PSC and other non-malignant liver diseases were analyzed for promoter methylation of *CDO1*, *CNRIP1*, *SEPT9* and *VIM*.
Results: Receiver operating characteristics (ROC) curve analyses revealed high area under the ROC curves (AUCs) for all four markers (0.87–0.97) for CCA detection. AUCs increased (0.92–0.98) when only CCA patients with underlying PSC were included. Combining the markers (≥1 of 4 markers positive for methylation) achieved both high sensitivity (100%) and specificity (94%) for CCA detection in patients both with and without PSC. In PSC patients who were diagnosed with CCA after bile sampling at least one marker was positive in all of the samples (100% sensitivity) taken up to 27 months prior to established CCA diagnosis.

	AUC (95% CI)	*P* value	Cutoff	Sensitivity %	Specificity %
CDO1	0.95 (0.88–1.02)	<0.0001	>1.545	88	97
CNRIP1	0.98 (0.95–1.00)	<0.0001	>0.455	100	93
SEPT9	0.98 (0.95–1.00)	<0.0001	>0.572	75	98
VIM	0.92 (0.77–1.06)	<0.0001	>0.399	75	97

AUCs, *P* values, cutoff value used for positive methylation, sensitivity and specificity values for the four individual DNA methylation biomarkers measured in bile in patients with CCA with underlying PSC (n = 8) vs. PSC controls (n = 210).

Conclusion: By using highly sensitive ddPCR to analyze robust epigenetic biomarkers CCA was accurately detected in small volumes of bile, even before standard detection modalities. These findings suggest that measurements of aberrant DNA methylation in bile may complement current detection methods and improve surveillance algorithms for CCA in PSC.

THU-007

Absence of BSEP (ABCB11) protects MDR2 (ABCB4) KO mice from cholestatic liver and bile duct injury through anti-inflammatory bile acid composition and signaling

Claudia Fuchs[1], Veronika Mlitz[1], Matteo Tardelli[1], Jelena Remetic[1], Moritz Menz[1], Gustav Paumgartner[1], Susanne Wolfrum[2], Annika Wahlström[3], Marcus Ståhlman[3], Tatjana Stojakovic[4], Christian Wolfrum[5], Hanns-Ulrich Marschall[3], Michael Trauner[1]. Email: michael.trauner@meduniwien.ac.at

Background and aims: Bsep KO mice are protected from acquired cholestatic injury by metabolic preconditioning with a hydrophilic bile acid (BA) pool with formation of tetrahydroxylated bile acids (THBAs). We aimed to explore whether increased BA detoxification alters inflammatory signaling, thereby improving liver injury in the Mdr2 KO mouse.
Method: Cholestatic liver injury, hepatic inflammation and fibrosis in Mdr2/Bsep DKO and Mdr2 KO mice was studied for comparison. BDL WT and Mdr2 KO mice were treated with a THBA. Gene expression profile of inflammatory/fibrotic markers were investigated. RORγt+ and FOXP3+ T cells from liver were quantified by FACS. In vitro, the impact of THBA on chenodeoxycholic acid (CDCA) induced inflammatory signaling in IHH cells and RORγt as well as NFκB signaling in Jurcat cells (stably transfected with GFP -NFκB) were analyzed.
Results: In contrast to Mdr2 KO, DKO mice displayed increased BA hydroxylation and lacked histological features of sclerosing cholangitis. 67% of serum BAs in DKO mice were polyhydroxylated, (THBAs were most prominent), while Mdr2 KO mice had no such BAs. In contrast to profoundly increased gene expression of inflammatory/fibrotic markers (F4/80, Tnfα, Mcp1, Desmin, Col1a1; $p < 0, 05$) in Mdr2 KO, no increases were seen in DKO. Increased levels of PHBAs were associated with reduced RORγt+ (regulator of TH17 cell differentiation) cells but increased FOXP3+ (Treg differentiation) cell within the CD4 + CD3+ T cell population (50% RORγt+;5% FOXP3+ in Mdr2 KO vs 10% RORγt+;30% FOXP3+ cells in DKO). THBA feeding reduced inflammation (IL1b, Cxcl1 by 50%) and fibrosis (Col1a2 by 80%) in Mdr2 KO. In WT BDL mice, bile infarct size and inflammatory gene expression (F4/80 −50%, Cxcl1 −55% and Cxcl2 −75%; $p < 0, 05$) were also profoundly reduced by THBA. In IHH cells, THBA reduced CDCA induced mRNA expression of inflammatory markers (IL8, Icam, Cxcl2; $p < 0, 05$) and attenuated CDCA-induced NFκB activation in GFP-NFκB transfected Jurcat cells. Also in Jurcat cells, THBA attenuated RORγt signaling at mRNA levels (IL23 −55%, TGFβ-25%; TH17 related cytokines).
Conclusion: Increased formation of THBA (due to absence of Bsep) or THBA administration represses key pro-inflammatory signals such as NFκB and RORγt in hepatocytes and immune cells, protecting Mdr2 KO mice from cholestasis-associated inflammation and fibrosis. Therefore, THBA and their downstream targets may be a new potential treatment strategy for cholestatic liver diseases.

THU-008
Circulating fibroblast growth factor 21 regulates bile acids homeostasis in cholestatic patients

Chiara Gabbi[1], Claudia Anzivino[1], Enrica Baldelli[1], lucia carulli[1], Marco Bertolotti[1]. [1]*University of Modena and Reggio Emilia, Modena, Italy*
Email: chiara917@gmail.com

Background and aims: Cholestatic disorders are a class of liver conditions where the production and/or flow of bile is impaired resulting in intracellular retention of toxic bile components, that in the long term leads to fibrosis, cirrhosis and liver failure.
To overcome the cholestatic toxic damage, there are protective compensatory pathways promoting bile acids (BA) transport into the systemic circulation and reducing liver BA production. Three mechanisms contribute to inhibit BA synthesis: i. BA activation of the Farnesoid×Receptor (FXR) that, by inducing the transcription of SHP (Small Heterodimer Partner), reduces the expression of *cyp7a1*, the rate-limiting enzyme in BA synthesis; ii. intestinal BA induction of the Fibroblast Growth Factor 19 (FGF19) that, after activating its receptor FGFR4, suppresses BA synthesis; iii. post-transcriptional reduction of CYP7A1 activity.
The growth factor FGF21, known to be a metabolic regulator, has been shown, in a rodent model, to diminish *cyp7a1* expression and therefore BA synthesis. However, FGF21 signaling pathway is specie-specific, being for instance FGF21 mRNA expressed in liver and adipose tissue in rodent, while apparently only in liver in humans. In this study we aimed at investigating whether in humans, FGF21 is involved in regulating BA homeostasis.
Method: 33 subjects undergoing abdominal surgery were investigated. Among them, 9 subjects were affected by obstructive cholestasis and 24 were non-cholestatic controls. Liver biopsies and serum samples were collected. Expression of the main nuclear receptors involved in transcriptional regulation of bile acid synthesis/transport and of biliary transporters was analysed by real time qRT-PCR. Circulating levels of FGF21, FGF19 were measure with commercial ELISA kit. Circulating total bile acids levels were assessed with HPLC.
Results: Circulating levels of FGF21 were significantly increased in cholestatic patients ($p < 0.05$) but no differences were detected regarding its hepatic mRNA expression. In the liver, expression of *cyp7a1* was significantly reduced during cholestasis, together with an increased mRNA expression ($p < 0.01$) of the short heterodimer partner (SHP). Expression of genes coding for canalicular biliary transporters, such as ABCB4 and ATP8B1 ($p < 0.05$) were also increased. Circulating levels of FGF21 directly correlated with hepatic FXR and SHP expression and inversely with CYP7A1 expression. Also, FGF21 serum levels positively correlated with FGF19 levels and circulating total bile acids.
Conclusion: In human obstructive cholestasis, circulating FGF21 is markedly increased and correlates with hepatic expression of nuclear receptors and hepatobiliary transporters involved in bile acids metabolism. Such findings provide insight into a cross talk FGF21/bile acids, suggesting FGF21 as possible circulating factor regulating bile acids homeostasis.

High throughput RNA sequencing unravels pathways associated with cognitive deficit in primary billiary cholangitis

Lucy Gee[1], Marco Youssef[2], William Zaki[2], Graham Smith[1], Claire Richardson[3], Saimir Luli[1], Fiona Oakley[1], David Jones[1]. [1]*Newcastle University, Institute of Cellular Medicine, Newcastle Upon Tyne, United Kingdom;* [2]*Newcastle University, Northern Institute of Cancer Research, Newcastle Upon Tyne, United Kingdom;* [3]*Newcastle University, Institute of Neuroscience, Newcastle Upon Tyne, United Kingdom*
Email: l.m.gee@ncl.ac.uk

Background and aims: Primary Billiary Cholangitis (PBC) is an autoimmune disease of the bile duct and liver. Biliary epithelial cell injury causes cholestasis, fibrosis and systemic circulation of toxic bile acids. PBC patients frequently experience significant central fatigue with associated cognitive symptoms Including impaired short-term memory and problems with concentration. Likened by patients to "brain fog" this under-recognised complex of CNS symptoms is a major contributor to poor quality of life and is currently untreatable. This study aims to investigate the mechanistic basis of cholestasis-induced memory impairment in mice and if these changes are ameliorated by the FDA approved drug Obeticholic Acid (OCA) using high-throughput RNA sequencing.
Method: C57BL/6 mice underwent either Bile Duct Ligation (BDL) or sham surgery. A sub-group of BDL were treated prophylactically with OCA. Animals were humanely killed at day 10 and brains removed for hippocampal biopsy. RNA was isolated from each biopsy sample and processed for RNA sequencing using an Illumina NextSeq 500 system. Differentially expressed genes were analysed using Qiagen's Ingenuity Pathway Analysis (IPA) software.
Results: 869 genes were differentially expressed (DE) comparing BDL with sham controls. Number of DE genes was decreased to 162 genes in BDL animals treated with OCA versus sham animals. Analysis of DE genes in the untreated BDL vs sham group displayed a decrease in gene expression related to synaptic long-term potentiation and cAMP signalling pathway (neuronal plasticity), a pathway whose inhibition is associated with memory impairment. S-adenosyl methionine (SAMe) biosynthesis, which has important implications in the liver

and in cholestatic fatigue, was also decreased. In addition, genes related to apoptosis signalling were upregulated.
In contrast, treatment of mice with OCA has restored all of the above deregulated pathways concurrently with up-regulation of neuronal differentiation and outgrowth genes (GATA3, Gli1, LEF1). Immunofluorescent analysis of the hippocampus revealed an increase in the protein expression of SOX2, a marker of neuronal proliferation. DE genes were further validated by RT-PCR.
Conclusion: Our results show that OCA treated animals have a hippocampal transcriptome similar to sham animals. Cholestasis correlates with reduced neuronal plasticity and SAMe biosynthesis, plus an increase apoptosis; which are reversed with OCA therapy.

THU-010
Shedding light on the X chromosome contribution to the genetic architecture of primary biliary cholangitis
Alessio Gerussi[2], Elvezia Paraboschi[1], Marco Carbone[2], Vincenzo Ronca[2], Laura Cristoferi[2], Federica Malinverno[2], Stefano Duga[1], Pietro Invernizzi[2]. [1]*Humanitas University, Department of Biomedical Sciences, Pieve Emanuele (Milano), Italy;* [2]*University of Milano-Bicocca, Division of Gastroenterology and Centre for Autoimmune Liver Diseases, Monza, Italy*
Email: alessiogerussi@gmail.com

Background and aims: Genome-wide association studies (GWAS) in primary biliary cholangitis (PBC) failed to find X chromosome genetic variants associated with the disease. However, these studies analyzed the X chromosome applying methods designed for autosomes, without accounting for the analytical problems arising from X unique mode of inheritance. Aim of our study was to explore the contribution of the X chromosome to the genetic architecture of PBC, a highly sexually dimorphic complex disease with an autoimmune etiology, by performing a chromosome X-wide association study (XWAS).
Method: The study included data derived from 5 GWAS studies (cohorts from Italy, United Kingdom, Canada, China, Japan), for a total of 5, 244 cases and 11, 875 controls. Genotype data were quality checked, corrected for population stratification, and imputed using the IMPUTE2 software. A total of 110, 000 SNPs, common to all cohorts, were then used for association analyses. These were performed by using the PLINK-XWAS software by: 1) assuming uniform and complete X-inactivation in females and a similar effect size for males and females; and 2) considering separately males and females and then by combining p values (taking into account: differential effect-size/direction between males and females, and the weight of each study). A subsequent meta-analysis was performed using METAINTER.
Results: In the single-SNP association analysis we found 11 population-specific loci associated with PBC at a suggestive $p < 5*10^{-5}$, the most significant being a signal mapping within the OTUD5 gene ($p = 4.80*10^{-6}$; OR = 1.39 CI = 1.03–1.58; Japanese cohort). This gene codes for a protein that was demonstrated to suppress the type-I interferon-dependent innate immune response. The subsequent meta-analysis was performed separately for Caucasian and East Asian populations, and revealed a novel complex locus (containing GRIPAP1, PIM2, OTUD5, LL0XNC01, and KCND1 genes) below the threshold for genome-wide significance.
Finally, we performed a gene-ontology analysis, evidencing a significant enrichment for genes involved in immune system ($p = 8.4*10^{-11}$).
Conclusion: By applying a XWAS analysis, we were able to evidence novel association signals with PBC risk, shedding light on the genetic contribution of the "neglected" X chromosome to this immune-mediated disorder.

Cholecystectomy causes worsening of primary sclerosing cholangitis features in Abcb4 knockout mice
Ester Gonzalez-Sanchez[1], Marie Clavel[2], Haquima El Mourabit[1], Dominique Rainteau[3], Chantal Housset[1,4]. [1]*Sorbonne Université, INSERM, Centre de Recherche Saint-Antoine (CRSA), and Institute of Cardiometabolism and Nutrition (ICAN), Paris, France;* [2]*Inovarion, Paris, France;* [3]*Sorbonne Université, INSERM, ERL U1157, Paris, France;* [4]*Assistance Publique-Hôpitaux de Paris, Hôpital Saint-Antoine, Department of Hepato-Gastroenterology, Paris, France*
Email: ester.glezsan@gmail.com

Background and aims: Patients with primary sclerosing cholangitis (PSC) commonly undergo cholecystectomy for gallbladder abnormalities. Experimental studies have provided evidence indicating that the gallbladder provides protection against hepatic bile acid overload. The aim of this study was to determine the consequences of cholecystectomy in Abcb4 knockout mice, a widely used model of PSC.
Method: Seven weeks old male and female *Abcb4* knockout mice underwent cholecystectomy or sham operation. Serum tests, immunohistochemical and reverse transcription-quantitative polymerase chain reaction (RT-qPCR) analyses of the liver tissue, were performed in all animals five weeks after surgery. Bile acid composition in the liver and plasma was analysed at that time, using high-performance liquid chromatography coupled to tandem mass spectrometry.
Results: Cholecystectomized *Abcb4* knockout male mice and to a lesser extent female mice had more severe fibrosis, assessed by sirius red staining, as compared to sham-operated animals of the same gender. Following cholecystectomy, males developed a significant increase in ductular reaction, ascertained by cytokeratin 19 immunostaining, and in total bile acid concentrations in the liver. They also displayed a significant decrease in the mRNA expression of sodium-coupled taurocholate transport protein (Ntcp) and a trend towards lower hepatic expression of cytochrome P450 Cyp7a1. Following cholecystectomy, females showed a significant increase in bilirubinemia, in hepatic concentration of the secondary bile acid taurohyodeoxycholic acid (THDCA) and in the hepatic expression of the organic solute transporter β (Ostβ).
Conclusion: Ablation of the gallbladder causes an aggravation of cholestatic and PSC features in *Abcb4* knockout male mice. Cholecystectomy also has a negative impact although less dramatic in *Abcb4* knockout female mice. These findings suggest that cholecystectomy may aggravate the liver status of patients with PSC and other cholestatic liver diseases.

THU-012
Prevalence of autoimmune liver disease related autoantibodies in various non autoimmune liver diseases
Rakesh Kumar Jagdish[1], Shiv Kumar Sarin[1], Ashok Choudhury[1], Rakhi Maiwall[1], Manoj Kumar[1], Guresh Kumar[1]. [1]*Institute of liver and biliary sciences, Hepatology, Delhi, India*
Email: dr.rkj.kapil@gmail.com

Background and aims: The prevalence of autoimmune liver disease related autoantibodies has not been defined in patients with non autoimmune liver diseases and therefore need to be studied and the relevance defined. The aim of this study was to explore the prevalence of autoimmune liver disease related autoantibodies in various non autoimmune liver diseases.
Method: A total 8, 213 patients were enrolled, 351 were excluded due to autoimmune aetiology and hepatocellular carcinoma, 7862 patients with non autoimmune related liver diseases were analysed retrospectively, in hospital based study from 2012 to 2018. We aimed to investigate clinical profile, diagnosis, pattern of autoantibodies in various liver diseases.
Results: Mean age of the study population was 49.95 ± 14 years, with 78% being males. Age was also significant among the diseases ($p < 0.001$), with Wilsons diseases group being younger (34 ± 10.5 years)

as compared to others (44 ± 14.7 to 58 ± 10.1). Distribution of diseases group as per aetiology were as most common with alcohol liver diseases (ALD) 28.4%, followed by hepatitis B related (HBV)19.1%, hepatitis C related (HCV) 19%, non-alcoholic steatohepatitis (NASH) 17.1%, Drug-induced liver injury (DILI) 3.6%, Hepatitis E related (HEV) 5.9%, hepatitis A (HAV) 2%, and Wilson were least 0.8% common. The prevalence of antinuclear antibody (ANA) was 28.2%, Anti-smooth muscle antibody (ASMA) was 19.8%, perinuclear anti-neutrophil cytoplasmic antibodies (p ANCA)7.6%, anti-liver-kidney microsomal antibody (Anti-LKM) was 4.2%, Antimitochondrial antibodies (AMA) was 2.1%, Anti-soluble liver antigen (*SLA*) *a*ntibodies 1.8%. Average IgG level was 17.18 g/l and CRP was 8 mg/l and both were not found significant. ANA was predominately present in 38.9%, 36.5%, 25.3% and 15.1% in HBV, HCV, ALD, and NASH respectively. LKM −1 was present in 11.6% HCV patients as compared to others. pANCA was positive in 14.4% HCV patients, SLA was not found significant in any of the group. AMA was predominantly positive in DILI (5.8%) which was not significant. Gender wise, ANA was predominant in females in 44.8% as compared to males (5.9%) (p value < 0.001). Similarly, ASMA, LKM, pANCA, SLA, AMA were more prevalent in females in 34%, 11.5%, 23.7%, 3.6%, 5.6% respectively, all of which were clinically significant in females (p < 0.001). Acute-on-chronic liver failure (ACLF) was seen in 18.8% patients, male predominance was seen. Most common co-morbidity was hypothyroidism in 14.33% patients with female predominance.

Conclusion: All the autoimmune markers were more common in females. ANA was predominately present in HBV, HCV, ALD, and NASH respectively while AMA was common in patients with DILI. LKM −1 and pANCA were common in HCV patients while SLA was not found significant in any of the group. These findings suggest the need of further investigations to confirm or rule out the diagnosis of autoimmune liver diseases.

Investigating the potential immunomodulatory role of mesenchymal stromal cells in primary sclerosing cholangitis

Ashnila Janmohamed[1], Evaggelia Liaskou[1], Samita Patel[1], Philip. N. Newsome[1], Gideon. M Hirschfield[1,2]. *[1]NIHR Biomedical Research Centre and Centre for Liver and Gastrointestinal Research, University of Birmingham, Birmingham, United Kingdom; [2]Toronto Centre for Liver Disease, University Health Network, University of Toronto, Toronto, Canada*
Email: ashnilaj@yahoo.com

Background and aims: Liver-infiltrating T lymphocytes and high levels of TNF are implicated in the destruction of bile ducts in primary sclerosing cholangitis (PSC). Mesenchymal stromal cells (MSC) possess immunomodulatory properties suggesting a potential therapeutic role in PSC. We studied the effect of MSC and MSC derived conditioned media (CM) on T cells from PSC patients.

Method: Peripheral blood mononuclear cells (PBMC) were isolated from PSC patients (n = 6) and healthy controls (n = 4). $CD4^+$ and $CD8^+$ T cells were purified using negative-bead selection kits from explant livers of PSC (n = 6) and primary biliary cholangitis (PBC) patients (n = 3). Cells were labelled with cell trace violet and co-cultured with MSC at ratios; 1:1, 1:4, 1:16, 1:64 1:256 (MSC:PBMC/T cells) in the presence of anti-CD3/CD28. MSC effect on $CD4^+$ and $CD8^+$ T cell proliferation and activation (TNF-alpha, IFN-gamma, IL2 expression) was studied by flow cytometry. Experiments were repeated using CM at concentrations; 100%, 90%, 80%, 70%, 60%, 50%.

Results: MSC suppressed the proliferation of circulating $CD4^+$ (28%, p = 0.0001) and $CD8^+$ (38%, p < 0.0001) T cells at ratios up to 1:16 compared to stimulated PBMC only (90% and 92% respectively). No significant differences in the MSC effect on suppression of T cell proliferation was seen between PSC patients and healthy controls. MSC reduced circulating $CD4^+$TNF-apha$^+$ (38%, p < 0.05) at 1:1 and $CD4^+$IFN-gamma$^+$ (2%, p < 0.05) expressing cells at ratios up to 1:4 compared to stimulated PBMC only (73% and 28% respectively) (n = 4 PSC). MSC suppressed intrahepatic $CD4^+$ (23%, p < 0.05) at ratios up to 1:16 and $CD8^+$ (20%, p < 0.01) T cell proliferation at 1:1 compared to stimulated $CD4^+$ and $CD8^+$ T cells only (83% and 85% respectively) (n = 6 PSC). MSC reduced intrahepatic $CD4^+$TNF-alpha$^+$ (38% vs 79%, p < 0.05), $CD4^+$IFN-gamma$^+$ (6% vs 29%, p < 0.01) and $CD4^+$IL2$^+$ (20% vs 61%, p < 0.01) expressing cells at ratios up to 1:16, 1:4, 1:4 respectively compared to stimulated $CD4^+$ T cells only (n = 5 PSC). Similarly, MSC suppressed intrahepatic $CD4^+$ (54%, p < 0.01) and $CD8^+$ (12%, p < 0.01) T cell proliferation compared to stimulated $CD4^+$ and $CD8^+$ T cells only (89% and 84% respectively) in PBC livers. Addition of up to 80% CM suppressed circulating $CD4^+$ (46% vs 84%, p < 0.01) and $CD8^+$ (50% vs 86%, p < 0.01) T cell proliferation compared to stimulated PBMC only (n = 8 PSC). Addition of 100% CM reduced circulating $CD4^+$IFN-gamma$^+$ (11% vs 29%, p < 0.01) expressing cells compared to stimulated PBMC only (n = 6 PSC).

Conclusion: MSC suppress the proliferation and activation of PSC patient derived circulating and intrahepatic T cells. MSC act directly and indirectly via release of soluble factors on circulating T cells. Our results support efforts to assess *in vivo* the immunomodulatory effects of MSC in PSC patients.

THU-014

Primary sclerosing cholangitis-associated biliary neoplasia demonstrates a high inter- and intratumour heterogeneity

Eline Kamp[1], Dinjens Winand[2], Doukas Michael[2], Verheij Joanne[3], Bruno Marco[1], Groot Koerkamp Bas[4], Peppelenbosch Maikel[1], de Vries Annemarie[1]. *[1]Erasmus Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands; [2]Erasmus Medical Center, Pathology, Rotterdam, Netherlands; [3]Amsterdam UMC, University of Amsterdam, Pathology, Amsterdam, Netherlands; [4]Erasmus Medical Center, Surgery, Rotterdam, Netherlands*
Email: e.j.c.a.kamp@erasmusmc.nl

Background and aims: Tumour heterogeneity in primary sclerosing cholangitis (PSC)-associated cholangiocarcinoma (CCA) may attribute to the diagnostic limitations of cytology and fluorescence in situ hybridization of biliary brushes. In addition, these tumours are remarkably resistant to widely different chemotherapeutic drugs. A possible explanation may lie in that PSC-CCA is made up of divergent clones, each with their own genetic defence mechanisms to counteract therapeutic agents. We aimed to assess tumour heterogeneity through p53 and p16 protein expression analysis in PSC-associated biliary neoplasia.

Method: Formalin-fixed paraffin-embedded tissue samples from resection material of PSC patients with CCA and/or dysplasia were selected. Sections with CCA and foci with dysplasia were identified by two independent liver pathologists. Staining with p53 and p16 monoclonal antibodies was performed. Two investigators independently scored protein expression, p53 null mutation/wildtype/overexpression and p16 negative/heterogeneous/positive.

Results: A total of 18 resection specimens of PSC-CCA and 1 PSC-explant with dysplasia were included, and 37 tumour and 13 dysplasia sections were selected. P53 protein expression was classified as null mutation, wildtype and overexpression in 3/22/11 CCA and 2/7/3 dysplasia, respectively. In 5 patients, 7 CCA and 2 dysplasia samples showed null mutation or overexpression surrounded by neoplastic cells with wildtype expression. In one patient, 1 CCA and 1 dysplasia showed p53 overexpression with an abrupt transition to null mutation. Next generation sequencing (NGS) in this patient showed different patterns of genomic instability of *TP53* in overexpression compared to null mutation.

P16 protein expression was scored as negative, heterogeneous and positive in 13/18/6 CCA and 6/5/2 dysplasia, respectively. In four patients intratumour heterogeneity of the morphological aspect of p16 protein expression was observed.

Conclusion: PSC-associated biliary neoplasia is characterized by a high inter- and intratumour heterogeneity of p53 and p16 protein expression, indicating that such cancers consist of multiple clones

with substantially different genetic makeup. By using NGS genetic intratumour heterogeneity of *TP53* has been detected. These observations may explain the difficulty encountered to reliably diagnosis of PSC-CCA and provides a rational explanation for poor response to a large spectrum of chemotherapeutic agents.

THU-015

Mutational signatures during the neoplastic cascade towards cholangiocarcinoma in primary sclerosing cholangitis

Eline Kamp[1], Dinjens Winand[2], van Marion Ronald[2], Doukas Michael[2], Verheij Joanne[3], Bruno Marco[1], Groot Koerkamp Bas[4], Peppelenbosch Maikel[1], de Vries Annemarie[1]. *[1]Erasmus Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands; [2]Erasmus Medical Center, Pathology, Rotterdam, Netherlands; [3]Amsterdam UMC, University of Amsterdam, Pathology, Amsterdam, Netherlands; [4]Erasmus Medical Center, Surgery, Rotterdam, Netherlands*
Email: e.j.c.a.kamp@erasmusmc.nl

Background and aims: Primary sclerosing cholangitis (PSC) is associated with an increased risk of cholangiocarcinoma (CCA). Carcinogenesis and involved molecular processes are poorly understood. As PSC-related CCA (PSC-CCA) presumably follows the inflammation-dysplasia-carcinoma cascade, genetic aberrations might be detected at premalignant stage. We aimed to identify genetic alterations in PSC-related dysplasia and CCA by multiregional targeted sequencing.
Method: A total of 19 PSC-patients with biliary dysplasia and/or CCA after surgical resection were included. Resection specimens of 18 patients contained CCA±dysplasia, and one only dysplasia. DNA was extracted from sections of formalin-fixed paraffin-embedded tissue blocks. Targeted sequencing of a custom made cancer panel, consisting of 28 genes, was performed on 37 tumour and 6 dysplasia samples. Amplicons included in the gene panel were investigated in order to detect genomic imbalance of 13 genes of interest. In addition, copy number variations of *CDKN2A, EGFR, MCL1* and *MYC* were examined by fluorescence in situ hybridization (FISH).
Results: *TP53* mutations were the most common aberration observed in PSC-CCA (13 samples/8 patients), other mutations observed are in *KRAS* (7 samples), *GNAS* (3), *ERBB2* (2), *APC* (1) and *PIK3CA* (1). In addition, mutations in *TP53* (4) and *ERBB2* (3) were identified in four dysplasia samples. *CDKN2A* loss was seen in both tumour (7) and dysplasia (1), *SMAD4* and *TP53* loss only in tumour (10 and 1). Gain of *MYC, ERBB2, EGFR* and *PIK3CA* was found in 7/7/4/1 tumour and 3/2/1/1 dysplasia samples, respectively. Genomic imbalance assessment showed *MCL1*, *KRAS* and *FGFR3* amplification only in tumour samples (3/3/5). In one patient high level amplification of *EGFR* was found in dysplasia, while tumour did not show *EGFR* amplification. Strikingly, both loss and gain of *POLD1* were seen in tumour and dysplasia. We were able to confirm *CDKN2A* loss and gain of *MCL1, MYC* and *EGFR* in half of the samples by performing FISH. One or both of the analyses gave inconclusive results in the other half.
Conclusion: PSC-CCA exhibits multiple genetic alterations, including mutations and chromosomal imbalance. *TP53* mutations and genomic instability of *CDKN2A, MYC, ERBB2*, *EGFR* and *PIK3CA* seem to occur early in the multistep process since these alterations were observed at premalignant stage. These genetic alterations seem promising for development of sequencing guided diagnostic strategies of PSC strictures.

THU-016

Loss of signaling through the G-protein coupled bile acid receptor Tgr5 confers protection from fibrosis in the progressive cholangiopathy of Mdr2-/- mice

Nelson Matuschek[1], Ramesh Kudira[1], Mary Mulen[1], Alexander Miethke[1]. *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, United States*
Email: alexander.miethke@cchmc.org

Background and aims: Macrophages are chief cytokine producers in the liver under cholestatic conditions. They sense bile acids (BA) via the G-protein coupled receptor Tgr5 (Gbar1). Activation of Tgr5 has been associated with anti-inflammatory responses in models of acute cholestasis and in metabolic liver disease. Here we examine the role of Tgr5 in $Mdr2^{-/-}$ mice, in which biliary BA and cholesterol-microcrystals cause chronic inflammation and progressive fibrosis.
Method: Double knockout mice (DKO) were generated from $Mdr2^{-/-}$ and $Tgr5^{-/-}$ mice in C57BL/6 background and liver injury was characterized in 60-day-old male mice of both genotypes by determining serum liver biochemistries (colorimetric assays), percent area fibrosis on Sirius Red stained liver sections, and qPCR. Liver mononuclear cell (MNC) populations were enumerated by flow cytometry.
Results: Compared with $Mdr2^{-/-}$ mice, lack of Tgr5 activation in DKO mice reduced serum ALT (mean ± SEM: 197 ± 36 vs 359 ± 29 IU/L in DKO vs Mdr2-/-; $p < 0.01$) and ALP levels (70 ± 2 vs 83 ± 4 IU/L, $p = 0.01$). The liver-to-body weight ratios were significantly reduced in DKO ($p < 0.01$) and similar to wild type mice. Liver fibrosis was reduced (% area fibrosis: 4.2 ± 0.5 vs 6.3 ± 0.5%, $p < 0.05$) which was corroborated by downregulation of mRNA expression for Col1a2 ($p < 0.05$), and reduced number of periportal, desmin+ activated hepatic stellate cells in DKO mice. Serum BA concentrations were elevated and similar between both genotypes. Searching for mechanisms by which Tgr5 deletion conferred protection, we found that the pro-inflammatory cytokines TNFα and IL-1β were downregulated in whole liver ($p < 0.05$) and in hepatic MNC from DKO mice. While frequency of hepatic TNFα+ macrophages (MP) was reduced in DKO mice (%TNFa+/CD11b + F4/80+: 23 ± 3 vs 65 ± 3; $p < 0.01$), $Foxp3^{+}CD25^{+}$ regulatory T cells (Tregs) were expanded in these mice (%Tregs/CD4+: 4.4 ± 0.4 vs 2.7 ± 0.7; $p = 0.06$). When Tregs were cultured in media conditioned with supernatant collected from MP from WT or Tgr5-/- mice exposed to chenodeoxycholic acid, only the supernatant from WT mice repressed Foxp3 in Tregs.
Conclusion: In chronic cholestasis, bile acids induce pro-inflammatory cytokine production in hepatic MP in Tgr5-dependent manner which repress Treg responses and promote liver fibrosis. Whether the protective effects of Tgr5-deficiency in a genetic model can be reproduced in a pharmacological rescue approach in sclerosing cholangitis requires further investigations.

THU-017

Glucagon like peptide-2 treatment improves liver and bile duct injury in the Mdr2-/- mouse model of sclerosing cholangitis

Moritz Menz[1], Lorenz Hinterleitner[1], Philipp Königshofer[1], Emina Halilbasic[1], Victoria Kunczer[1], Tatjana Stojakovic[2], Thomas Reiberger[1], Claudia Fuchs[1], Michael Trauner[1]. *[1]Medical University of Vienna, Department of Gastroenterology and Hepatology, Vienna, Austria; [2]Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria*
Email: michael.trauner@meduniwien.ac.at

Background and aims: Glucagon like peptide (GLP)-1 has anti-apoptotic effects on cholangiocytes, thereby counteracting ductopenia and possibly cholestasis. GLP-2, deriving from the same precursor molecule proglucagon, exerts potent intestinotrophic endocrine and paracrine actions stimulating growth and repair of intestinal epithelium. However, its impact on liver, specifically on cholangiocytes, is poorly understood. Therefore, we aimed to test our hypothesis that the GLP2 analogue teduglutide has cholangioprotective and thereby anti-cholestastic effects in the Mdr2/Abcb4 KO mouse as a model of sclerosing cholangitis with profound hepatic inflammation and fibrosis
Method: Mdr2 (Abcb4) KO mice were injected daily for 2 weeks with a GLP-2 analogue (teduglutide). Liver RNA profiling was performed by RT-PCR. Liver histology/immunohistochemistry (IHC) and hepatobiliary bile flow were assessed.

Results: Inflammation was ameliorated as reflected by reduced mRNA levels of inflammatory markers (F4/80 (−35%), Mcp1 (−60%); iNos (−40%) $p \leq 0, 05$) in GLP-2 treated mice. Biliary fibrosis was improved by GLP-2 treatment as reflected by reduced Col1a2 mRNA expression (60%; $p \leq 0, 05$) and 3fold reduced ($p \leq 0, 05$) fibrotic areas in Sirius red stainings of GLP-2 treated Mdr2 KO mice. In addition, GLP-2 treatment reduced expression of profibrogenic and apoptotic markers Tgfβ (60%; $p = 0, 07$), Caspase3 (60%; $p \leq 0, 05$) as well as Chop (40%; $p \leq 0, 05$). CK19 mRNA and protein levels (IHC) showed a trend for an increase of about 1, 6fold at mRNA level ($p = 0, 06$) and 2fold at protein level ($p = 0, 6$) after GLP-2 treatment. In line, proliferation of cholangiocytes (and to lesser degree also hepatocytes) was increased in the GLP-2 treatment group reflected by increased KI67 protein levels ($p \leq 0, 05$, for both cell types). Despite elevated bile duct mass, expression of osteopontin (marker for reactive cholangiocyte phenotype, indicating a proinflammatory/profibrogenic status of cholangiocytes) was reduced 3fold ($p \leq 0, 05$) by GLP-2. Of note, this improvement of inflammatory and fibrotic markers by GLP2 was achieved without changes in bile flow, HCO3- output and serum biochemistry (ALT, AST, AP and bile acids) suggesting direct rather than indirect effects by improvement of cholestasis.
Conclusion: Our data show that GLP-2 treatment has a pro-regenerative, anti-inflammatory and anti-fibrotic effect on cholangiocytes in the Mdr2/Abcb4 KO mouse model of sclerosing cholangitis independent of cholestasis. Thus, targeting GLP-2 could be an interesting addition to the therapeutic armamentarium for cholangiopathies such as PSC and PBC.

THU-018

c-Jun N-terminal kinases act synergistically in hepatocytes to protect mice from cholestatic liver injury

Mohamed Ramadan Mohamed[1,2], Francisco Javier Cubero[1,3,4], Gang Zhao[1], Yulia A. Nevzorova[1,4,5], Nikolaus Gassler[6], Roger J. Davis[7], Christian Trautwein[1]. [1]*Department of Internal Medicine III, University Hospital, RWTH Aachen, Aachen, Germany;* [2]*Department of Therapeutic Chemistry, National Research Centre, Cairo, Egypt;* [3]*Department of Immunology, Ophtalmology and ORL, Complutense University School of Medicine, Madrid, Spain;* [4]*12 de Octubre Health Research Institute (imas12), Madrid, Spain;* [5]*Department of Physiology, Genetics and Microbiology, Faculty of Biology, Complutense University, Madrid, Spain;* [6]*Institute of Pathology, University Hospital, Braunschweig, Germany;* [7]*Howard Hughes Medical Institute and University of Massachusetts Medical School, Worcester, Massachusetts, United States*
Email: ctrautwein@ukaachen.de

Background and aims: c-Jun N-terminal kinase 1 (JNK1) and JNK2 are predominantly expressed in all mammalian cells including liver cells. JNKs are activated in response to cholestatic liver injury (CLI). Our previous study showed that JNK1 is responsible for hepatic stellate cells (HSCs) activation in liver fibrosis. Moreover, we showed that JNK1 and JNK2 have combined effects in protecting mice from carbon tetrachloride (CCl4)- and acetaminophen-induced liver injury. However, the overlapping functions of both JNK genes during CLI is unknown. Here we aimed to define the overlapping function of JNKs in hepatocytes after bile duct ligation (BDL).
Method: Chronic liver injury was induced in $Jnk^{f/f}$ wildtype (WT), $Jnk2^{-/-}$ and $JNK^{\Delta hepa}$ (complete deletion of JNK1 and 2 in hepatocytes) mice via BDL. Liver injury as well as inflammatory parameters and cell infiltration were investigated. Fibrogenesis was assessed by immunoblotting, immunofluorescence and immunohistochemical analysis. Finally, bone marrow transplantation experiments were included.
Results: Combined JNK1 and JNK2 deletion in hepatocytes exacerbated liver damage markers-liver transaminases- and histological analysis exhibited increased hepatic injury and compensatory proliferation after BDL compared to $Jnk2^{-/-}$ and WT mice. TUNEL and cleaved caspase 3 staining indicated significantly increased apoptosis in hepatocytes of $JNK^{\Delta hepa}$ animals. Consequently, BDL significantly increased hepatic fibrosis in $JNK^{\Delta hepa}$ livers as assessed by Sirius Red staining as well as Collagen IA1, TIMP1 and MMP2 in WT mice. Concomitantly, immune cell infiltration and inflammatory cytokines measured by CD11b, F4/80, TNF, TGF β, IL-6, IL-1α/β were strongly up-regulated in WT mice but no alterations was evident between $Jnk2^{-/-}$ and $JNK^{\Delta hepa}$ BDL-treated livers. Moreover, BDL treated chimeric $JNK^{\Delta hepa}$ mice reconstituted either with WT BM (WT to $JNK^{\Delta hepa}$) or $JNK^{\Delta hepa}$ BM ($JNK^{\Delta hepa}$ to $JNK^{\Delta hepa}$) revealed significantly higher liver damage and liver fibrogenesis after BDL than WT mice reconstituted with either with WT BM (WT to WT) or $JNK^{\Delta hepa}$ BM ($JNK^{\Delta hepa}$ to WT)
Conclusion: Combined JNK function is protective in hepatocytes during cholestatic liver injury. This JNK-dependent effect is directly mediated by inhibiting caspase 8-dependent apoptosis during CLI.

THU-019

Impact of metabolic stress on the pathogenesis of autoimmune liver disease in subjects bearing missense variant of negative immune regulator Lnk/Sh2b3

Taizo Mori[1], Sachio Yoshio[1], Michitaka Matsuda[1], Sakamoto Yuzuru[1], Tomonari Shimagaki[1], Hironari Kawai[1], Yosuke Osawa[1], Tatsuya Kanto[1]. [1]*National Center for Global Health and Medicine, Department of liver diseases, the research center for hepatitis and immunology, Chiba, Japan*
Email: kantot@hospk.ncgm.go.jp

Background and aims: Lnk/Sh2b3 (Lnk) is an adaptor protein that negatively regulates cytokine signaling in immune cells and hematopoietic stem cells. GWAS has revealed that a missense variant of Lnk gene increases a risk for hepato-biliary autoimmune diseases, including primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC) and autoimmune hepatitis (AIH). However, the causal relationship between Lnk gene and the pathogenesis of liver autoimmunity is undisclosed. We sought to test the hypothesis that metabolic stress to the liver could enhance the risk of disease phenotypes in patients who possess genetic predisposition, by using Lnk deficient mice model.
Method: Recently we reported that Lnk deficient mice showed glucose intolerance and insulin resistance, which is accompanied by adipose inflammation with hyper-reactivity of IL-15 (Cell Reports, 2018). We examined Lnk deficient mice fed with high fat and high cholesterol diet (HF/HCD). In addition, we prepared Lnk deficient bone marrow chimeric mice and analyzed phenotypes of the liver.
Results: $Lnk^{-/-}$ chimeric mice showed no sign of liver inflammation with normal diet. However, AST and ALT levels from 6 week were significantly elevated with HF/HCD feedings in $Lnk^{-/-}$ chimeric mice. Histological analysis showed that accumulation of inflammatory immune cells is observed in $Lnk^{-/-}$ HF/HCD mice. In addition, analysis of intra-hepatic lymphocytes showed that $CD19^{+}$ $CD138^{+}$ plasmacytes were profoundly increased compared to the other type of cells. Moreover, overproduction of IgG and IgM and autoantibodies were detected from 6 week in serum of $Lnk^{-/-}$ chimeric mice.
Conclusion: Metabolic stress may be one of the triggers of pathogenesis of autoimmune liver diseases in subjects who have genetic predisposition to autoimmunity, or possessing Lnk/Sh2b3 variant.

Postprandial changes in the hepatic bile acid transport in healthy human subjects measured by 11C-CSar PET/CT

Nikolaj Worm Orntoft[1], Susanne Keiding[1,2], Ole Lajord Munk[2], Lars Christian Gormsen[2], Michael Sørensen[1], Peter Ott[1]. [1]*Aarhus University Hospital, Dept. of Hepatology and Gastroenterology, Aarhus, Denmark;* [2]*Aarhus University Hospital, Dept. of Nuclear Medicine and PET Centre, Aarhus, Denmark*
Email: norntoft@gmail.com

Background and aims: PET/CT with the tracer ^{11}C-CSar, a synthetic sarcosine conjugate of cholic acid, provides new possibilities for in

vivo studies of hepatic handling of conjugated bile acids, which are essential for digestion, excretion of metabolites and regulation of metabolism. We previously quantified hepatic uptake and secretion kinetics of ^{11}C-CSar in fasting healthy human subjects. It is unknown whether the postprandial changes in bile acids homeostasis leads to changes in the hepatic transport kinetics. The aim of the present study was therefore to quantify the postprandial changes in hepatic ^{11}C-CSar kinetics in healthy human subjects.

Method: Six healthy subjects underwent two subsequent 60-min dynamic liver ^{11}C-CSar PET/CT scans: one before (fasting) and one 15 minutes after ingestion of a standard liquid meal (4291 kJ; 33% protein, 32% fat, and 35% carbohydrates). Arterial and hepatic venous blood ^{11}C-CSar concentrations were measured during both scans as was hepatic blood flow using constant infusion of Indocyanine green/Fick's principle. Kinetic constants for exchange of ^{11}C-CSar between blood, hepatocytes and bile were calculated and are presented as mean (95% CI). Data were normally distributed and tested for statistically significance using a paired *t*-test.

Results: In the postprandial state, hepatic blood perfusion increased from 0.92 ml blood/min/ml liver tissue (0, 76; 1.07) to 1.23 ml blood/min/ml liver tissue (1.00; 1.45) ($p < 0.01$). In agreement with a high capacity for transport of ^{11}C-CSar from blood to hepatocytes, PS_{mem} was significantly higher than perfusion; mean fasting PS_{mem} was 3.72 ml blood/min/ml liver tissue (2.21; 5.22) and did not change ($p = 0.51$). Rate constant for backflux from hepatocyte to blood did not change ($p = 0.55$), whereas the rate constant for transport from hepatocytes to bile increased from 0.40 min^{-1} (0.25; 0.54) to 0.67 min^{-1} (0.36; 0.98) ($p < 0.05$) in agreement with an increase in the flow-independent intrinsic clearance from 1.82 ml blood/min/ml liver tissue (1.59; 2.05) to 2.13 ml blood/min/ml liver tissue (1.75; 2.50) ($p < 0.05$). Accordingly, mean hepatic residence time for ^{11}C-CSar decreased from 2.8 min (1.6; 4.0) to 1.9 min (0.6; 3.2) ($p < 0.05$). Rate constant for bile flow increased from 0.07 min^{-1} (0.05; 0.10) to 0.10 min^{-1} (0.08; 0.12) ($p < 0.05$).

Conclusion: Both the transport capacity from hepatocyte to bile and bile flow increased significantly in all subjects. Accordingly, the mean residence time in hepatocytes decreased in spite of increased influx of tracer from blood. The increased secretion could be due to recruitment of transporters at the apical membrane.

Loss of bile salt export pump (Bsep/Abcb11) aggravates lipopolysaccharide induced hepatic inflammation in mice

Jelena Remetic[1], Veronika Mlitz[1], Victoria Kunczer[1], Hubert schargl[2], Tatjana Stojakovic[2], Claudia Fuchs[1], Michael Trauner[1]. [1]*Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria;* [2]*Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria*
Email: michael.trauner@meduniwien.ac.at

Background and aims: Bile salt export pump (Bsep) is the main canalicular transporter for biliary bile acid (BA) secretion. Although lack of BSEP causes severe cholestasis in human, Bsep KO mice are protected from acquired cholestasis because of metabolic preconditioning with a hydrophilic BA pool. This study aims to investigate whether presence of a hydrophilic BA pool may counteract development of hepatic inflammation.

Method: Wild-type (WT) and Bsep knockout (KO) mice were challenged with lipopolysaccharide (LPS) to induce hepatic inflammation. Serum biochemistry and liver histology were assessed. Hepatic markers of inflammation were analyzed by qPCR and Western blotting. Immunohistochemistry was used to determine inflammation.

Results: Bsep KO mice developed more severe LPS-induced liver inflammation than WT mice. LPS treatment increased serum levels of transaminases (ALT, AST) in Bsep KO mice compared to corresponding control group ($p \leq 0.05$), but remained unchanged in WT mice. AST, ALT and AP were elevated 6fold, 3fold, 3fold in LPS treated Bsep KO mice compared to challenged WT mice, respectively ($p \leq 0.05$). NF-kB, a main target of LPS-induced proinflammatory signaling, was significantly higher in LPS treated Bsep KO mice compared to WT mice at mRNA (1.7fold; $p \leq 0.05$) and protein level (1.8fold; $p = 0.052$). Increased inflammation was also reflected by elevated mRNA expression of proinflammatory cytokines Vcam (1.3fold), Icam (1.7fold), IL1b (2fold), Mcp1 (2.5fold), Tnfa (2.7fold), IL6 (3.2fold) and iNos (5fold) ($p \leq 0.05$). Immunohistochemistry of MAC2 showed increased immune cell number in livers of Bsep KO compared to those of WT mice. Ppara and Nrf2 (key regulators of inflammation) were both significantly reduced upon LPS challenge in Bsep KO mice at RNA level (60%; 40%, respectively; $p \leq 0.05$). Fxra, main regulator of BA metabolism and also known for its anti-inflammatory properties, was down-regulated in Bsep KO mice at mRNA level (53%; $p \leq 0.05$). Of note Cyp2b10, BA-detoxifying enzyme, was reduced by 53% ($p \leq 0.05$) in Bsep KO LPS treated mice compared to Bsep KO controls and by 40% compared to WT LPS challenged mice.

Conclusion: Absence of Bsep aggravates hepatic inflammation upon LPS stimulation, potentially by reduction of anti-inflammatory signaling via Fxra, Ppara and Nrf2 as well as by reduction of BA detoxification usually protecting these mice.

THU-022

CM-101- a Novel anti CCL24 monoclonal antibody reduces cholangiocytes proliferation in experimental cholestasis models

Michal Segal[1], Neta Barashi[1], Avi Katav[1], Victoria Edelshtein[1], Arnon Aharon[1], Sharon Hashmueli[1], Massimo Pinzani[2], Douglas Thorburn[2], Jacob George[3], Adi Mor[1]. [1]*Chemomab, Tel Aviv, Israel;* [2]*Sheila Sherlock Liver Centre, Royal Free London NHS Foundation Trust, London, United Kingdom;* [3]*Heart Center, Kaplan Medical Center, Rehovot, Affiliated to the Hebrew University, Jerusalem, Israel, Rehovot, Israel*
Email: michal@chemomab.com

Background and aims: Abnormal bile duct hyperplasia and cholangiocytes proliferation are two main features of primary sclerosing cholangitis (PSC). ChemomAb previous studies showed robust expression of CCL24 in cholangiocytes in liver biopsies from PSC patients. In this study we aimed to characterize the relevance of CCL24 in the abnormal cholangiocyte proliferation and to test the ability of CM-101, an anti CCL24 monoclonal antibody (mab), to reduce bile duct proliferation using two cholestatic animal models.

Method: Expression of CCL24 in mouse cholangiocytes was tested by immunohistochemistry in liver tissues. CM-101, a CCL24 blocking mab, was evaluated in two animal models: chronic α-naphthylisothiocyanate (ANIT) induced cholestasis in mice and bile duct ligation (BDL) in rats. In the chronic ANIT model mice were fed with ANIT diet (0.05%) for 4 weeks and treated with 5 mg/kg CM-101 or vehicle. In BDL model, rats were treated with either 10 mg/kg CM-101 or vehicle for two weeks following bile duct ligation. Cholangiocytes proliferation and hyperplasia were characterized using pan-CK, Ki67 and HandE staining.

Results: Similar to our previous observations in human liver biopsies, CCL24 was found to be expressed in mice cholangiocytes.

In the ANIT chronic treatment model, CM-101 treatment led to a significant improvement of several histopathological features. Significant reduction of fibrosis and complete abolishment of liver necrosis were observed in the CM-101 treated groups compared to vehicle treated group that was accompanied by reduction of bile acid serum levels. Biliary hyperplasia was decreased by 60%, together with reduction of Pan-CK staining further supporting a specific inhibition of cholangiocyte proliferation.

BDL induced massive cholangiocyte proliferation as seen by increased PAN-CK and Ki67 staining. Treatment with CM-101 decreased staining in the ductular area indicating a significant reduction of proliferation. Moreover, CM-101 led to down regulation of vascular endothelial growth factor (VEGF), a major regulator of cells proliferation in the liver.

Conclusion: Our finding reveals abundant expression of CCL24 in cholangiocytes implying its potential role in cholestatic diseases progression. Blocking of CCL24 by CM-101, led to significant reduction in cholangiocyte proliferation and bile duct hyperplasia, suggesting its potential therapeutic effect in PSC. CM-101 is therefore being tested in a Phase 2 clinical trial in PSC patients.

THU-023

Monoacylglycerol lipase inhibition protects from hepatic inflammation and fibrosis in mouse models of sclerosing cholangitis

Matteo Tardelli[1], Francesca Bruschi[1], Thierry Claudel[1], Claudia Fuchs[1], Nicole Auer[1], Victoria Kunczer[1], Tatjana Stojakovic[2], Onne Ronda[3], Henkjan Verkade[3], Sophie Lotersztajn[4], Michael Trauner[1]. *[1]Medical University of Vienna, Vienna, Austria; [2]Medical University of Graz, Graz, Austria; [3]University of Groningen, Groningen, Netherlands; [4]Centre de Recherche sur l'Inflammation, Paris, France*
Email: matteo.tardelli@meduniwien.ac.at

Background and aims: Lipid partitioning modulates cholestatic liver injury by providing ligands for nuclear receptors. Monoacylglycerol lipase (MGL) is the last enzymatic step in triglyceride degradation, hydrolyzing monoglycerides into glycerol and fatty acids (FA) and 2-arachidonoylglycerol into arachidonic acid (AA). We aimed to explore the role of MGL in the development of cholestatic liver and bile duct injury in mouse models of sclerosing cholangitis (SC).
Method: We analyzed the effects of 3, 5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC) feeding in wild type (WT) and knock out ($MGL^{-/-}$) mice and pharmacological inhibition with JZL184 in the $Mdr2^{-/-}$mouse model of SC. Cholestatic liver injury and fibrosis were assessed by serum biochemistry, liver histology, and expression of bile acid (BA) synthesis/transport. FAs were measured by gas chromatography. Transfection and silencing were performed in vitro.
Results: $MGL^{-/-}$ mice were protected from liver injury with lower serum levels of ALT, AST (−50%), reduced ductular proliferation (CK19 −50% mRNA) and attenuated reactive cholangiocyte phenotype (OPN, VCAM). BA transporter protein and gene expression were increased for Mrp2/3, Ostα (+40%) and Mrp4 (+60%) without changes in Ntcp/Oatp1. Inflammation was suppressed as reflected by F4/80 IHC and Cox2 mRNA (−60%). Importantly fibrosis (Sirius red), hepatic hydroxyproline content (−50%), Col1a1/Col1a2 genes (−60%) were reduced. Intestinal gene expression revealed diminished inflammation (TNFα −70%, F4/80 −40%), while FXR target genes were reduced (FGF15, iBABP-50%) in line with increased BA synthesis (Cyp7a1 + 50%) in liver. Importantly, $Mdr2^{-/-}$ fed JZL184 showed reduced serum levels of ALT, AP and BA (−50%) as well as diminished fibrosis and Col1a1/Col1a2 genes (−60%). Ductular proliferation was attenuated (CK19 −40% mRNA) along with inflammation-F4/80 (−60%) and MCP1 (−50%) mRNA in liver and intestine (TNFα −70%, F4/80 −40%). Intestinal FXR target genes were again reduced (FGF15, iBABP-50%). Interestingly, FA analysis showed accumulation of AA in DDC-fed $MGL^{-/-}$ and in JZL184 treated $Mdr2^{-/-}$ mice. When MGL was silenced in Caco2, cells became unresponsive to FXR agonism by CDCA (iBABP −60%, FGF19 −50%). In vitro, retinoid X receptor (RXR) agonism induced by AA diminished FXRE luciferase activity (−70%).
Conclusion: Inhibition of MGL protects against hepatic inflammation and biliary fibrosis despite intestinal competition as a result of AA-mediated RXR agonism

THU-024

Methylation signatures in blood show accelerated epigenetic aging in patients with primary sclerosing cholangitis compared to healthy controls

Michael Trauner[1], Yevgeniy Gindin[2], Zhaoshi Jiang[2], Chuhan Chung[2], Mani Subramanian[2], Robert Myers[2], Aliya Gulamhusein[3], Kris V. Kowdley[4], Cynthia LEVY[5], Zachary Goodman[6], Michael P. Manns[7], Christopher Bowlus[8], Andrew Muir[9]. *[1]Medical University of Vienna, Vienna, Austria; [2]Gilead Sciences, Inc., Foster City, United States; [3]University of Toronto, Toronto, Canada; [4]Swedish Organ Transplant and Liver Center, Seattle, United States; [5]University of Miami, Miami, United States; [6]Inova Fairfax Hospital, Falls Church, United States; [7]Hannover Medical School, Hannover, Germany; [8]University of California at Davis, Sacramento, United States; [9]Duke University School of Medicine, Durham, United States*
Email: yevgeniy.gindin@gilead.com

Background and aims: A DNA methylation (DNAm) signature derived from 353 CpG sites (the Horvath clock) has been proposed as an epigenetic measure of human chronological and biological age. This epigenetic signature is accelerated in diverse tissue types in various disorders, including non-alcoholic steatohepatitis (Loomba, et al. JCI Insight 2018), and is associated with mortality. Here, we assayed whole blood DNAm to explore epigenetic age acceleration (AA) in patients with primary sclerosing cholangitis (PSC).
Method: Using the MethylationEPIC BeadChip (850 K) array, DNAm signatures in whole blood were analyzed in 44 patients with PSC enrolled in a 96-week, Phase 2 trial of simtuzumab (Ishak F0-1, n = 22; F5-6, n = 22). AA, defined as the difference between DNAm age and the prediction based on a sex-adjusted linear model derived using a healthy reference population (n = 650), was calculated. Comparisons between patients with high and low AA (≥vs <median AA) were made using Mann-Whitney tests and Kaplan-Meier analysis was used evaluate the association between AA and PSC-related clinical events (e.g. decompensation, ascending cholangitis, cholangiocarcinoma, transplantation, death).
Results: The epigenetic model accurately predicted the chronological age of PSC patients (Spearman $\rho = 0.84$; $p = 9.7\times10^{-13}$) with a median difference of 4.4 years (IQR 5.25 years). Compared to healthy controls, significant AA was observed in PSC patients (median difference, 8.29 years; $p < 2.2\times10^{-16}$ [Figure A]). No significant differences in age, sex, race, BMI, use of UDCA, or presence of IBD were observed between PSC patients with low versus high AA. However, compared with patients with low AA, those with high AA had greater median serum ALP (193 vs 410 U/L; p = 0.007), GGT (221 vs 437 U/L, p = 0.05), ELF (9.1 vs 10.5, p = 0.007), and hepatic collagen content (4.3% vs 9.1%, p = 0.06) and α-SMA expression (3.9% vs 11.3%, p = 0.01). Cirrhosis (Ishak F5-6) was associated with significant AA (9.6 vs 6.9 years in F0-1; p = 0.015 [Figure A]) and PSC patients with high AA had a greater risk of PSC-related clinical events (log-rank p = 0.038 [Figure B]).

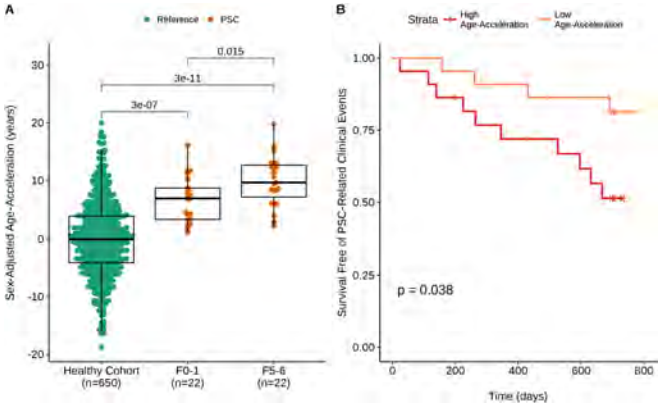

Figure: (A) Age acceleration in controls and PSC subjects according to fibrosis stage. (B) Survival free of PSC-related clinical events according to low versus high (relative to median) age acceleration.

Conclusion: This analysis of blood DNAm profiles suggests that compared with healthy controls, patients with PSC-particularly those with cirrhosis-exhibit significant acceleration of epigenetic age. Future studies are required to evaluate the effect of therapies on global methylation patterns and age acceleration in PSC.

THU-025

Pathway-analysis using datasets of GWAS and microarray identified IFNG as the most significant upstream-regulator in primary biliary cholangitis

Kazuko Ueno Ueno[1], Yoshihiro Aiba[2], Shinji Shimoda[3], Yuki Hitomi[1], Olivier Gervais[4], Yosuke Kawai[1], Minae Kawashima[1], Nao Nishida[1], Kaname Kojima[4], Seigo Abiru[2], Shinya Nagaoka[2], Atsumasa Komori[2,5], Hiroshi Yatsuhashi[2,5], Atsushi Tanaka[6], Masao Nagasaki[4], Katsushi Tokunaga[1], Minoru Nakamura[2,5,7], PBC-GWAS consortium in Japan[7]. *[1]Department of Human Genetics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan; [2]Clinical Research Center, National Hospital Organization (NHO) Nagasaki Medical Center, Omura, Japan; [3]Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan; [4]Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan; [5]Department of Hepatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; [6]Department of Medicine, Teikyo University School of Medicine, Tokyo, Japan; [7]Headquarters of PBC-GWAS consortium in Japan, Omura, Japan*
Email: ueno-k@m.u-tokyo.ac.jp

Background and aims: Genome-wide association studies (GWAS) in European descents and East Asian populations have identified more than 40 disease-susceptibility genes in primary biliary cholangitis (PBC). However, the disease-pathways and their upstream-regulators remain to be elucidated. The aim of this study is to objectively identify them in PBC by integrated analysis of GWAS and mRNA microarray in the Japanese population.

Method: We performed the analysis of disease-pathways and their upstream-regulators by Ingenuity Pathway Analysis (IPA) using the dataset 1 of GWAS (1920 PBC cases and 1770 controls) which included 261 annotated genes derived from 6760 SNPs ($p < 0.00001$), dataset 2 of mRNA microarray of liver biopsy specimens (15 PBC cases and 5 normal controls) which included 1506 genes with fold expression change >2 as compared to controls ($p < 0.05$), and dataset 3 of public mRNA microarray of peripheral blood mononuclear cells (PBMC) (2 PBC cases and 4 normal controls) which included 397 genes with fold expression change >2 as compared to controls ($p < 0.05$). Hierarchical cluster-analysis was performed using dataset 2 and the correlation of the genes with disease activity (AST, ALT and ALP levels) was analyzed.

Results: There were 34 genes (HLA, IKZF3, PRKCB, etc.) that were overlapped between the datasets 1 and 2, while there were 17 overlapped pathways (Th1, Th2 pathways, etc.) and 144 overlapped upstream regulators between the datasets 1 and 2. Among these 144 upstream regulators, 10 upstream-regulators showed fold expression change >2 in the micro array. Among these 10 upstream regulators, IFNG, CD40LG, SPIB, CD2, FASLG and B2M belonged to the cluster 1 which showed the strongest correlation with serum AST, ALT and ALP levels among 4 distinct clusters (cluster 1, 1-2, 2 and 2-2 containing 387, 308, 49 and 762 genes, respectively). PBC patients were also grouped into two distinct types, high and low disease-activity, by hierarchical clustering. Furthermore, the meta-analysis of upstream regulators using 3 datasets revealed that IFNG was the most significant upstream regulator associated with PBC ($p = 5.02E-49$).

Conclusion: Our hypothesis free integrated analysis using GWAS and microarray datasets predicted that IFNG is the most significant upstream-regulator in PBC. This is consistent with the previous reports demonstrating the importance of IFNG pathways in humans and mouse- model of PBC. Further studies focusing on IFNG -pathway are needed to identify the new molecular targets for PBC in humans.

THU-026

Natural killer T cells promote cholestatic liver disease in bile duct ligated mice

Laura Valestrand[1,2,3], Natalie L. Berntsen[1,2,3], Fei Zheng[1,2,3], Bjarte Fosby[4], Tom H. Karlsen[1,2,3,5], Pål Dag Line[3,4], Jiang Xiaojun[1,2], Espen Melum[1,2,3,5]. *[1]Norwegian PSC Research Center, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo University Hospital, Rikshospitalet, Oslo, Norway; [2]Research Institute of Internal Medicine, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo University Hospital, Rikshospitalet, Oslo, Norway; [3]Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [4]Department of Transplant Medicine, Oslo University Hospital, Rikshospitalet, Oslo, Norway; [5]Section of Gastroenterology, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo University Hospital, Rikshospitalet, Oslo, Norway*
Email: lauravalestrand@gmail.com

Background and aims: Natural Killer T (NKT) cells are a subset of lymphocytes with immune regulatory properties. NKT cells consist of an invariant (iNKT) and a non-invariant subgroup both responding to lipid antigens presented by the non-classical MHC molecule CD1d. We have previously demonstrated that CD1d on cholangiocytes presents lipid antigens to NKT cells. In this project we investigated the role of NKT cells in the pathophysiology of cholestasis by ligating the common bile duct in CD1d knockout ($Cd1d^{-/-}$) and wild type (WT) mice.

Method: We performed bile duct ligation (BDL) of the common bile duct of $Cd1d^{-/-}$ and WT mice. Sham operated mice underwent an identical surgical procedure without BDL. Weight was monitored daily. The mice were sacrificed after 3 or 5 days, and serum, spleens and livers were collected. Isolated lymphocytes from liver and spleen were stained with monoclonal antibodies and analysed by flow cytometry. Serum was analysed for alkaline phosphatase (ALP) and bilirubin.

Results: WT mice undergoing BDL had a decreased hepatic NKT cell population indicating activation at day 5 (33% vs. 15%, $P = 0.02$), corroborated by increased CD69 expression at day 3 (median fluorescence intensity (MFI) 709 vs. 1458, $P < 0.001$) and day 5 (599 MFI vs. 1229 MFI, $P < 0.001$). In both liver and spleen there was no change in the percentage of the remaining $TCR\beta^+$ cells, nor did they have an activated phenotype. $Cd1d^{-/-}$ mice undergoing BDL were protected against disease compared to WT mice. This was demonstrated by reduced weight loss at day 1; (7% vs. 11%, $P = 0.002$), day 2; (8% vs. 16%, $P = 0.003$) and at day 3; (7% vs. 15%, $P = 0.0003$). $Cd1d^{-/-}$ mice also had lower serum levels of ALP; (345 U/L vs. 511 U/L, $P = 0.036$) and bilirubin; (115 μmol/L vs. 224 μmol/L, $P = 0.003$).

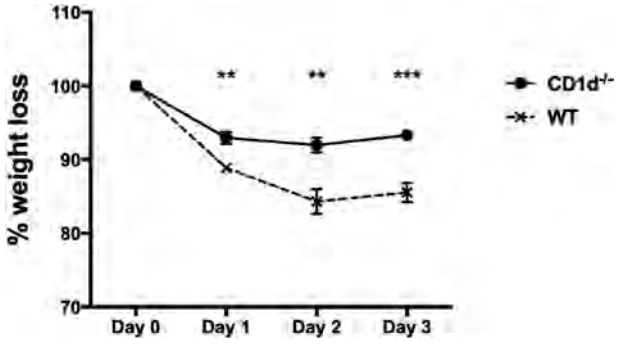

Figure: Daily percent weight for $Cd1d^{-/-}$ and WT mice after bile duct ligation.

Conclusion: We observed a clear activation of hepatic NKT cells in a mouse model of cholestasis. $Cd1d^{-/-}$ mice depleted of both invariant and non-invariant NKT cells were protected from cholestatic liver damage. Our findings contrast previous reports in $J\alpha18^{-/-}$ mice

lacking only iNKT cells. This suggests a potential detrimental role of the non-invariant NKT cells during cholestasis.

THU-027

The human apical sodium dependent bile salt transporter (ASBT) activates a bile salt-induced defense in human cholangiocytes

Jorrit van Niekerk[1], Dagmar Tolenaars[1], Jesús María Banales[2], Ronald Oude Elferink[1], Stan van de Graaf[1], Ulrich Beuers[1]. [1]*Amsterdam University Medical Centres Location AMC, Gastroenterology and Hepatology, Tytgat Institute for Liver and Intestinal Research, Amsterdam Zuid-Oost, Netherlands;* [2]*Biodonostia Research Institute, Liver disease, Donostia/Gipuzkoa, Spain*
Email: j.b.vanniekerk@amc.uva.nl

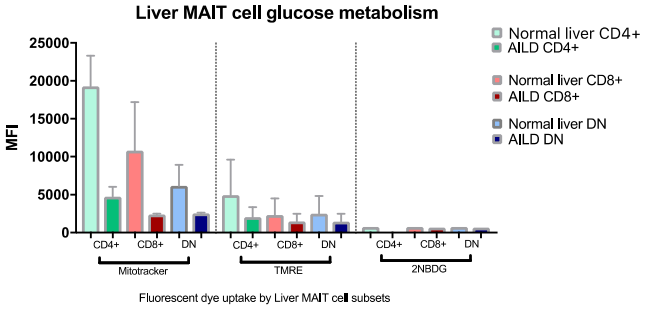
Background and aims: We previously proposed the "biliary HCO_3^- umbrella" hypothesis as a protective mechanism of human cholangiocytes against potentially toxic hydrophobic bile salts present in human bile. This apical barrier of bicarbonate (HCO_3^-) might keep biliary bile salt monomers such as glycochenodeoxycholate (GCDC) in a deprotonated, negatively charged, membrane-impermeable state. Uptake of large amounts of hydrophobic bile salts by ASBT could be deleterious for human cholangiocytes. Therefore, we speculated that ASBT in human cholangiocytes may serve as mediator for the activation of defense mechanisms by trace amounts of biliary bile salts, but not as high capacity bile salt transporter. Here we studied ASBT-mediated uptake and signaling of bile salts in human and rodent cholangiocytes affecting cellular viability, apoptosis, and bile salt-sensitive defense mechanisms.
Method: Normal human (NHC) and mouse cholangiocytes (NMC) and ASBT-overexpressing human immortalized H69 cholangiocytes ($ASBT^+$-H69) were exposed to radiolabeled ^{3}H-taurocholate to determine functional bile salt uptake. Cholangiocyte apoptosis and viability were determined by caspase-3/-7 and WST assays. Intracellular signaling response to bile salts was analyzed mainly by RT-qPCR, WB and ELISA.
Results: NMC expressed *Asbt* mRNA at higher levels than NHC. Accordingly, taurocholate uptake was 100-fold higher in murine than human cholangiocytes. Overexpression of ASBT in H69 cholangiocytes increased Na^+-dependent bile salt uptake from 0.1 to 49.3 pmol/mg protein/min. Exposure to GCDC induced caspase-3/-7 activity in $ASBT^+$-H69 compared to controls, whereas TCDC had no effect. In NHC and $ASBT^+$-H69, both mRNA and protein expression of farnesoid x receptor (FXR) and fibroblast growth factor (FGF19) were positively correlated with ASBT-dependent bile salt uptake. In NHC, ASBT-dependent bile salt uptake led to increased membrane expression of anion exchanger 2 (AE2), cystic fibrosis transmembrane conductance regulator (CFTR) and transmembrane member 16a (TMEM16a), crucial for adequate apical Cl^-/HCO_3^- secretion.
Conclusion: Human compared to murine cholangiocytes have a markedly reduced capacity to take up conjugated biliary bile salts via ASBT. ASBT-mediated bile salt dependent intracellular defense mechanisms may stabilize the "biliary HCO_3^- umbrella" and, thereby, protect human cholangiocytes against uncontrolled ASBT-independent entry of potentially toxic human hydrophobic bile salts.

THU-028

Gut derived bacteria, presented by liver dendritic cells can activate liver MAIT cells in primary sclerosing cholangitis

Suzan Warner[1], Deirdre Kelly[2], Ye Htun Oo[1]. [1]*University of Birmingham, Centre of Liver Research, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom;* [2]*Birmingham Children's Hospital, The Liver Unit, Birmingham, United Kingdom*
Email: S.Warner@bham.ac.uk

Background and aims: Mucosal-associated invariant T (MAIT) cells are the most abundant invariant T cell subset in the human liver. Their unique T cell receptor Vα7.2 is restricted by MR1, a MHC Class-1 like molecule. MAIT cell activation, via MR1 by microbial vitamin B metabolites or cytokines e.g. Interleukin 12 or 18, induces rapid release of Interferon gamma (IFNγ), Tumour necrosis factor alpha (TNFa), Granzymes and Perforin. Liver MAIT cells are emerging as significant players in autoimmune liver disease (AILD) but their biology is relatively unexplored. We aim to 1) investigate the functional profile of human liver MAIT cells activated by E.coli primed human liver dendritic cells (DCs) and 2) assess liver MAIT cell subset immunometabolism in AILD.
Method: 1) Cell Sorted liver DCs (HLADR+, CD123+, CD11c+) from human explanted PSC liver were stimulated with E.coli (200 E.coli/cell) or Control (Media with no E.coli) for 12hours, followed by addition of Cell Sorted CD3+ T cells from the same liver into this co-culture for 4hours. Expression of IFNy, TNFa and CD107a (degranulation marker) by MAIT cells (defined as CD3, Va7.2 TCR and CD161) were examined. 2) Glucose catabolism in MAIT cell subsets from AILD explants (n = 3, 1AIH, 1PSC, 1PBC) and normal liver (n = 2 donor livers) were explored using fluorescent dyes to assess a) Oxidative phosphorylation (mitochondrial mass (Mitotracker), mitochondrial membrane potential (TMRE, tetramethylrhodamine ethyl ester) and b) Glycolysis (2NBDG, 2- (*N*- (7-Nitrobenz-2-oxa-1, 3- diazol-4-yl) Amino)-2-Deoxyglucose) (n = 1 AIH, n = 1 donor liver). Co-culture and immunometabolism results were analysed with FlowJo V.10 and GraphPad Prism 6.
Results: 1) Functional assessment of liver derived MAIT cells activated by E.coli primed liver DCs revealed highest expression of IFNy 20.1% (TNFa 3.9%, CD107a 4.72%) compared to controls. 2) A marked difference in fluorescent dye Mitotracker uptake is seen between AILD and normal liver (Figure). Amongst AILD, slightly higher Mitotracker and TMRE (mitochondrial membrane potential) uptake was noted in CD4 compared to CD8 or DN MAIT cells. There was low 2NBDG uptake overall but none seen in CD4 MAIT cells.



Conclusion: We have shown for the first time that human liver MAIT cells can be activated by E.coli primed liver DCs in the PSC liver. Our preliminary data suggests CD4 liver MAIT cells in AILD and all normal liver MAIT cell subsets are metabolically quiescent compared to CD8 and DN liver MAIT cells in AILD, which may be utilizing Glycolysis or an alternative metabolic pathway.

THU-029

Interleukin 23 produced by hepatic monocyte-derived macrophages is essential for the development of primary biliary cholangitis

Debby Reuveni[1], ayelet kaminitz[1], Patrick Leung[2], Oren Shibolet[1], Eric Gershwin[2], Ehud Zigmond[1]. [1]*Tel Aviv Sourasky Medical Center, The Research Center for Digestive Tract and Liver Diseases, Tel Aviv, Israel;* [2]*University of California, Division of Rheumatology, Allergy and Clinical Immunology, Davis, CA, United States*
Email: zigmondu@gmail.com

Background and aims: Primary Biliary Cholangitis (PBC) is a chronic autoimmune liver disease characterized by non-suppurative cholangitis resulting in progressive cholestasis. Mononuclear phagocytes (MNPs), comprise of monocyte, dendritic cells and macrophages, constitute major arm of the innate immune system and were shown to be involved in the pathogenesis of autoimmune disorders. Interleukin 23 (IL-23) is a pro-inflammatory cytokine belongs to

the IL-12 family. IL-23 positive cells were detected around bile ducts in patients with advanced stage of PBC and IL-23 serum levels were found to be in correlation with PBC disease severity. Our overall goal was to assess the involvement of IL-23 derived from MNPs in the pathogenesis of PBC, and specifically addresses the subset of cells responsible for IL-23 secretion in this pathology.

Method: We took advantage of transgenic mice systems enabling us to achieve MNPs restricted IL-23 deficiency ($CD11c^{cre}P19^{flox}$ and $CX3CR1^{cre}P19^{flox}$) and subjected them to inducible xenobiotic model of PBC by immunization with 2-octynoic acid conjugated to bovine serum albumin. In addition, specific hepatic MNPs populations were sorted from livers of affected animals and assessed for IL-23 expression. Analysis included histology assessment by HandE and Sirius red staining, anti mitochondrial (AMA) serum titers, flow cytometry for hepatic non-parenchymal cells, and hepatic cytokine expression profile by RT PCR.

Results: Both $CD11c^{cre}P19^{flox}$ and $CX3CR1^{cre}P19^{flox}$ mice exhibited significant amelioration of disease severity as manifested by reduced extent of portal inflammation and peri-portal collagen deposition assessed by liver histology, and decreased hepatic expression levels of the pro-inflammatory cytokines TNFα and IFNγ. In addition, Flow cytometry analysis revealed a decreased CD8/CD4 hepatic T cell ratio in MNPs restricted IL-23 deficient mice accompanied by a significant reduction in the incidence of hepatic IL-17A producing CD4+ T cells. No significant difference in AMA titers was observed. Real time PCR analysis done on sorted hepatic cells demonstrated unique high expression of IL-23 mRNA by monocyte-derived macrophages a specific MNPs population expressing both CD11c and CX3CR1.

Conclusion: Our results indicate a major role for IL-23 produced by hepatic monocyte-derived macrophages in the pathogenesis of PBC. These results may pave the road for the development of new immune-based and cell specific therapeutic modalities.

Cirrhosis: ACLF and Critical illness

Hemorrhagic and thrombotic complications in critically patients with cirrhosis

Tsai-Wing Ow[1], Evangelia Fatourou[2], liane rabinowich[1], Lara Roberts[3], Roger Williams[2], Georg Auzinger[1], Mark J W McPhail[1], Julia Wendon[1], William Bernal[1]. *[1]Kings College Hospital, Liver Intensive Therapy Unit, London, United Kingdom; [2]Institute of Hepatology, London, United Kingdom; [3]Kings College Hospital, Haematology, London, United Kingdom*
Email: william.bernal@kcl.ac.uk

Background and aims: Altered haemostatic parameters are ubiquitous in patients with cirrhotic chronic liver disease (CLD), with changes in pro- and anti-coagulant processes that may result in haemorrhagic (HC) or thrombotic (TC) complications. In hospitalised patients with acutely decompensated (AD) CLD, indications are of increased risk of thrombotic complications, but that in acute on chronic liver failure (ACLF) is unknown. In a large cohort of critically ill patients with AD and ACLF we determined the prevalence and clinical associations of HC and TC.

Method: We studied consecutive patients with AD and ACLF admitted to a specialist Intensive Care Unit (ICU) 2009–2016. Demographics, clinical and standard laboratory findings and MELD and CLIF-C OF scores were determined. Using standard definitions, prevalence and timing of HC and TC were determined. Multi-variable analysis utilised logistic regression.

Results: The study cohort was 623 patients of median age 52 years, 61% male, 47% alcohol aetiology. Median MELD and CLIF-C OF scores were 26, and 11 respectively. 30% of patients had AD and 12%, 23%, and 35% had ACLF grades of 1, 2 and 3 respectively. 77 patients (12%) had hepatocellular carcinoma (HCC). Overall hospital mortality was 43%.

HC occurred in 332 (53%) patients, 67% with variceal bleeding. HC occurred on admission in 249 (40%) and as later episodes in 83 (13%) at median 9 (4–16) days later. Later HC were associated with greater ACLF severity ($p < 0.01$), prolonged APTR ($p < 0.01$) and increased mortality (Adjusted Odds Ratio 2.8 (95% CI 1.78–4.7) < 0.001).

TC occurred in 124 patients (20%), with 42 (7%) with pre-existing TC and 82 (13%) newly identified after ICU admission. New TC included 57 portal vein (PVT), 14 deep vein (DVT) 28 other venous and 5 arterial thromboses. Both pre-existing and new TC were independently associated with presence of hepatocellular carcinoma (AOR 3.7 (2.3–6.2), $p < 0.001$) but not coagulation status measures, ACLF severity or with administration of fresh frozen plasma, though new TC showed association with cryoprecipitate use ($p < 0.04$). TC on or after admission were not independently associated with increased hospital mortality.

Conclusion: In CLD patients admitted to ICU Haemorrhagic complications predominate and impact on mortality. Thrombotic complications are common and associated with concurrent HCC and may precipitate ACLF but are difficult to predict and do not show independent association with hospital mortality.

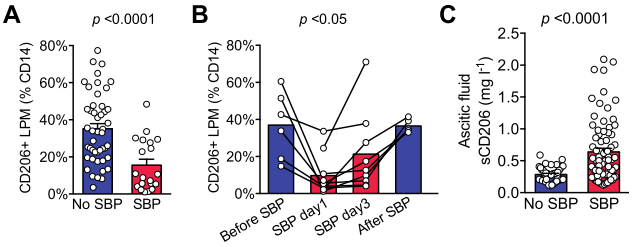
THU-032

Peritoneal CD206 links macrophage heterogeneity in decompensated cirrhosis with outcome of spontaneous bacterial peritonitis

Sven Stengel[1], Stefanie Quickert[1], Oluwatomi Ibidapo-obe[1], Arndt Steube[1], Nilay Köse[1], Melina Yarbakht[1,2], Philipp Reuken[1], Sachin Deshmukh[2], Andreas Stallmach[1], Tony Bruns[1,2]. *[1]Jena University Hospital, Department of Internal Medicine IV, Jena, Germany; [2]Jena University Hospital, The Integrated Research and Treatment Center for Sepsis Control and Care, Jena, Germany*
Email: tonybruns@gmail.com

Background and aims: Peritoneal macrophages (PM) are thought to regulate peritoneal inflammation and control bacterial infections in decompensated cirrhosis. The aim of this study was to characterize human PM heterogeneity and to link PM activation with the outcome of spontaneous bacterial peritonitis (SBP).

Method: 186 patients with decompensated cirrhosis were included, of which 89 had SBP. Human PM were characterized by flow cytometry (n = 67), transcriptome-wide gene-level expression analysis (n = 4) and *ex vivo* experiments. The soluble form of the mannose receptor CD206 was determined in ascitic fluid by ELISA (n = 120).



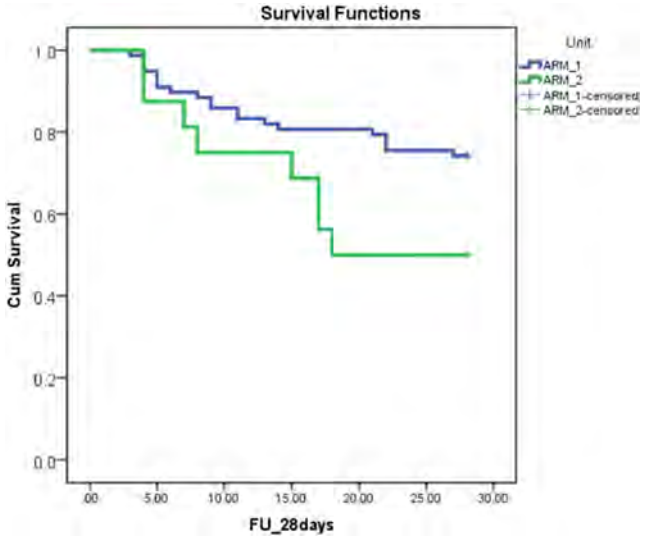
Results: Employing CD206 surface expression, we identified subsets of human large (LPM) and small PM (SPM), which differed in granularity and maturation states. FACS-sorted LPM from patients with decompensated cirrhosis revealed discrete transcriptome clusters, comprising more than 4000 differentially regulated genes involved in cell cycle, metabolism, and immune signaling. In contrast to SPM, LPM displayed a resident inflammatory phenotype, released higher levels of TNF after stimulation and were more resistant to inducing LPS tolerance. CD206 expression and sCD206 release from LPM could be manipulated by incubating PM with TLR2/TLR6 and

TLR4 agonists *in vitro*. Serial clinical samples revealed a depletion of LPM in the early phase of SBP followed by a recovery after successful treatment (Figure 1A-B). Higher ascitic fluid concentrations of sCD206 identified patients with SBP (Figure 1C) and indicated poor survival after 90 days ($p < 0.003$, in log rank test).
Conclusion: CD206 expression indicates a sub set of mature, resident, inflammatory human PM. Ascitic fluid concentrations of its soluble form predicts poor outcome of SBP.

THU-033
Impact of early Hemodynamic correction of AKI in acute on chronic liver failure patients with large ascites
Gaurav Pande[1], Shreya Butala[1], Alok Kumar[1], Manjunath Durgappa[1], Arun Singh Bhadauria[1], Samir Mohindra[1], Vivek Saraswat[1]. *[1]SGPGIMS, Gastroenterology, Lucknow, India*
Email: drgauravpandey@yahoo.com

Background and aims: Renal failure is the most important predictor of mortality in patients with Acute on chronic liver failure (ACLF). Early initiation of therapy to correct hemodynamics, improves renal blood flow and may improve survival.
Aim of the study was to assess survival in ACLF patients with AKI (Creatinine >2) with continuous slow infusion of furosemide, albumin, with Terlipressin [SAFI (T)] administered according to a response-guided protocol as compared with Standard Medical Therapy (SMT) for Hepato-renal Syndrome (HRS).
Method: ACLF patients with AKI (defined by ICA-AKI Criteria) with Creatinine >2 and large ascites were included. Within 12 hrs of admission 2D-ECHO for cardiac indices and Systemic vascular resistence (SVR), Doppler for Renal artery resistive indices (RARI) and IVC diameter with respiratory variability and Urine sediments were examined to rule out pre-renal AKI and ATN respectively. Excluding pre-renal AKI and ATN, 78 patients in ARM 1 were managed with SAFI (T) and 16 patients in ARM 2, were managed with SMT. Patients in ARM 1 were given infusions of Furosemide at 2 mg/hr, albumin at 2gm/hr (20–40gm/d) and Terlipressin infusion at 2 mg/24 hrs. If 24-hr Urine Na persisted below 80meq, response guided increase in terlipressin (1 mg/24hrly) and Furosemide (2 mg/12hrly) was done after correcting anaemia (≥8 g/dl) and excluding cardiac conduction anomalies with baseline ECG (and repeated 12 hrly) till reduction/normalization of S. creatinine.
Results: Baseline Characteristics were comparable in both arms ARM1 [SAFI (T)] (N-78) v/s ARM2 [SMT] (N-16): CTP-12.3 ± 3.6 vs 12.3 ± 1.6, CLIF-SOFA- 10.9 ± 1.8 vs 11.5 ± 2.2, MELD- 33 ± 8.3 vs 34 ± 9.1, Creatinine- 2.8 ± 0.76 vs 3.3 ± 1.3, U Na day 0- 28.9 ± 21 vs 35.9 ± 6. Urinary Na improved to 126 ± 101 in ARM1 as compared to 86 ± 44 in ARM-2. Overall survival was 75% in ARM1 vs 50% in ARM-2. There was significant improvement in systemic hemodynamic parameters in ACLF patients in ARM 1.
Conclusion: Early correction of systemic hemodynamics with aggressive therapy leads to improved survival in ACLF patients with AKI.

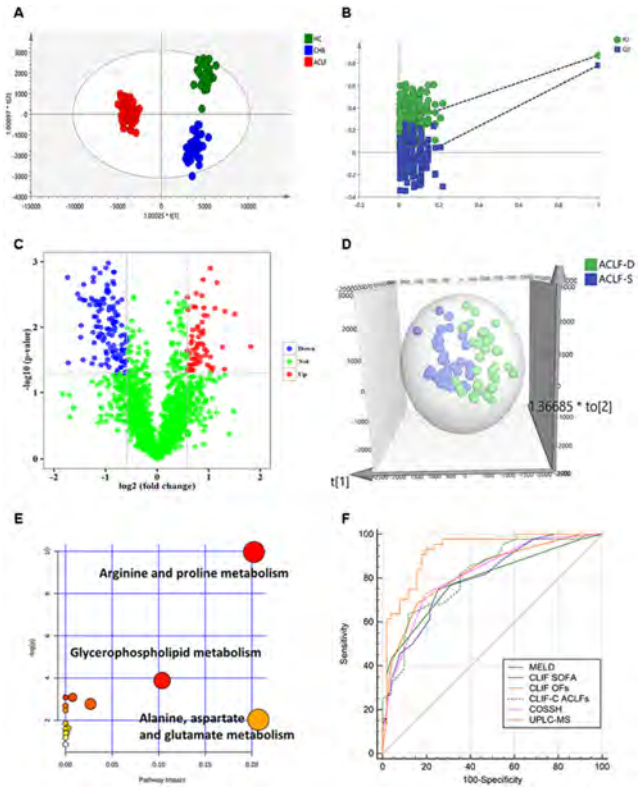
Variable	Admission	End of therapy	p value
Heart rate (bpm)	97.2 ± 8.3	81.9 ± 8.9	.000
SV (ml/beat)	92.1 ± 25.1	72.5 ± 24.4	.000
SVI (ml/m^2/beat)	50.9 ± 13.9	43.4 ± 15.4	.001
Cardiac output (L/min)	8.9 ± 2.6	6.0 ± 2.3	.000
Cardiac index (L/min/m^2)	4.9 ± 1.4	3.6 ± 1.4	.000
MAP (mmHg)	81.6 ± 6.5	93.9 ± 4.9	.000
SVR (dynes-sec/cm^{-5})	668.8 ± 234.1	1299.5 ± 531.5	.000
SVRI (dynes-sec/cm^{-5}/m^2)	1206.8 ± 398.8	2192.7 ± 907.6	.000



THU-034
Serum metabolite profiling predicts survival in patients with hepatitis B virus related acute-on-chronic liver failure
Ermei Chen[1,2], Zhongyang Xie[1,2], Daxian Wu[1,2], Lanjuan Li[1,2]. *[1]State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, hangzhou, China; [2]Collaborative Innovation Center for Diagnosis and Treatment of Infection Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, hangzhou, China*
Email: ljli@zju.edu.cn

Background and aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is characterized by acute deterioration of liver function, organ failure and high short term-mortality. Predicting survival in these patients is meaningful to allocate resources for liver transplantation. The study was to investigate whether the metabolic profiling can predict the 28-day survival.
Method: 95 HBV-ACLF patients, who met the APASL ACLF criteria from December 2016 to January 2018, were recruited and followed for 28 day. 48 chronic hepatitis B patients (CHB) and 30 healthy controls (HC) with no history of liver disease were also enrolled. All serum aliquots were analyzed by Ultra-performance liquid chromatography-mass spectrometry (UPLC-MS) in both positive and negative mode. Multivariate analysis was performed by SIMCA P software.
Results: 51 subjects of the ACLF patients spontaneously survived. The age, hepatic encephalopathy grade, total bilirubin, blood urea nitrogen, international normalized ratio (INR), white blood cell count and platelet were associated with mortality. The non-survivors group show a higher Child-Pugh, MELD, CLIF-SOFA, CLIF-OFs, COSSH score ($p < 0.001$).The UPLC-MS metabolic profiling accurately discriminated not only ACLF patients from HC and CHB, but also survivors and non-survivors. Base on volcano plot and the VIP, 24 potential metabolites were selected. Elevated amino acid, bile acid, fatty acid and decreased phosphatidylcholines were found in non-survivors group. Metabolic pathways show these metabolites mainly contribute to the arginine and proline metabolism, glycerophospholipid metabolism and alanine, asparatate and glutamate metabolism. A new prognostic model based on the combination of lysophosphatidylcolines (16:0), argininic acid, blood urea nitrogen, INR and platelet can accurately predict survival. The area under the receiver operating curve (AUROC) for 28-day mortality was 0.923, which was significantly higher than that of the MELD, CLIF-SOFA, CLIF-OFs, CLIF-C ACLF, COSSH (all $p < 0.05$).
Conclusion: Serum metabolic differences could distinguish ACLF patients from CHB and HC. Amino acid dysregulation and lipid metabolism abnormality are associated with the severity of disease.

A new prognostic model combining metabolites with clinical indicators could predict mortality in HBV-ACLF patients but needs further validation.



THU-035

A shorter period of a subsequent episode of acute decompensation of cirrhosis predicts worse outcome: A single center experience

Po-sung Chu[1], Nobuhiro Nakamoto[1], Takanori Kanai[1]. [1]*School of Medicine, Keio University, Gastroenterology and Hepatology, Tokyo, Japan*
Email: posungchu0928@yahoo.co.jp

Background and aims: Acute decompensation (AD) of liver cirrhosis is sometimes fatal and impairs quality of life. The dynamic change, e. g. recovery/deterioration of organ function, along with recurrent episodes of AD, is frequently encountered in clinical settings. The natural history of patients who survived without liver transplantation (LT) after their first episode of AD is still not elucidated.
Method: In this single liver transplant centre observation study approved by local institutional IRB, we retrospectively recruited 768 consecutive admissions to our liver unit from Apr 2015 to Apr 2018. After exclusion of admissions for planned procedures, 166 cases (254 admissions) with AD of cirrhosis were extracted. Patients with active HCC over Milan criteria, advanced malignancy of other organs, HIV, or patients undergo chronic dialysis were further excluded. Transplant-free survival (TFS, followed for at least 6 months) and various prognostic clinical parameters, including MELD and simplified CLIF-SOFA scores were evaluated. Acute-on-chronic liver failure (ACLF) was assessed according to the criteria suggested by EASL-CLIF Consortium.
Results: Totally, 120 cirrhotic patients (58% male; aged 63.5 ± 15 years) with 184 times of AD were analysed. Of the first episode of AD, 30% were of ACLF Gr 1–3. The TFS for 30 days was 85.8%. Patients who survived without LT for the first 30 days could be categorized as Group A: patients who recovered without a recurrent episode of AD (46%); Group B: patients who recovered once but with a subsequent episode (s) of AD (43%); Group C: patients who deteriorated without recovery (11%). Compared to Group A, patients in Group B were significantly older in age ($p = 0.03$), higher percentage of NASH and cirrhosis due to cholestasis, less active drinking. Group B patients were significantly more thrombocytopenic ($p < 0.01$), less leukocytic ($p < 0.01$), and of more frequent hypoalbuminemia ($p < 0.01$). However, patients of Group A and B didn't differ in Child-Pugh scores, MELD, simplified CLIF-SOFA scores, and percentage of higher grades of ACLF. Of patients of Group B who had shorter periods of subsequent ADs within 90 days, decreased 180-day ($p = 0.02$, log-rank) and 1-year ($p = 0.08$) TFS were noticed, compared to those beyond 90 days, even though MELD or CLIF-SOFA did not differ between the two groups.
Conclusion: The prognosis of transplant-free survivors within 30 days after the first episode of AD might be heterogeneous, and may not be predicted with widely used prognostic systems. Shorter periods of subsequent AD (within 90 days) might be prognostic for TFS in AD of liver cirrhosis.

THU-036

First description of the immune checkpoint receptor landscape in decompensated cirrhosis and ACLF

Douglas Corrigall[1,2,3], Nicola Harris[1], Dhruti Devshi[1], Sarah Fairclough[2], Gavin Wright[2], Jonel Trebicka[4,5], Carlo Alessandria[6], Paolo Angeli[7], Rajiv Jalan[8], Joan Claria[9], Richard Moreau[10], Vicente Arroyo[5], Roger Williams[1,3], Antonio Riva[1,3], Shilpa Chokshi[1,3]. Email: s.chokshi@researchinliver.org.uk

Background and aims: Acute-on-chronic liver failure (ACLF) is characterised by a supra-inflammatory state that coexists with profound immune paralysis. Individual immunoregulatory check-point receptors (CR) can direct functional activation and/or inhibition of both innate and adaptive immunity. Neutralisation of inhibitory-CRs including PD1 (Nivolumab) and CTLA4 (Ipilimumab) has revolutionised cancer treatment via restoration of anti-tumour immunity. We have shown that bacterial translocation drives hyperexpression of inhibitory-CRs in Alcoholic Hepatitis but their role in ACLF is unknown.
Method: We measured serum levels of 15 known stimulatory and inhibitory CRs (including PD1, PDL1, CTLA4), bacterial translocation (D-lactate; DLac) and gut barrier integrity (Zonulin1; ZO1) by ELISA in 511 patients with decompensated cirrhosis included in the CANONIC Study; 334 with acute decompensation (AD) and 177 with ACLF at inclusion. Group comparisons, cut-off identification and survival analyses were performed in SPSS and R.
Results: Both soluble immune-activatory-CR CD40 ($p < 0.001$) and immunosuppressive-CR BTLA (B and T-cell Lymphocyte-Associated; $p = 0.004$) increased significantly with presence of ACLF and ACLF grade, but we saw no changes in PD1, PDL1 and CTLA4. Serum CD80, which can act as both inhibitory and stimulatory, also increased with ACLF grade ($p = 0.002$), in particular between ACLF1 and ACLF2 or 3 ($p < 0.02$). This was correlated with bacterial translocation; DLac ($p < 0.001$) and gut permeability; ZO1 ($p = 0.01$) across ACLF

grades, with DLac also discriminating between AD and ACLF ($p < 0.001$). Bacteremia during admission for all patients was also associated with increases in both DLac ($p = 0.005$) and ZO1 ($p = 0.009$). One-year transplant-free survival analysis demonstrated that increased survival was associated with lower serum BTLA (<862.31pg/ml; $p = 0.0002$), CD40 (<3.47pg/ml; $p < 0.0001$) and CD80 (<1654.28pg/ml; $p = 0.002$).

Conclusion: We demonstrate for the first time the association of both inhibitory and stimulatory immune checkpoints with the paradoxical "hyperinflammatory immunodeficient" state observed in ACLF reflecting the coexistence of a primed, hyper-activated, pro-inflammatory immunity whose antibacterial functions are switched off. Our analysis also reveals that intestinal permeability and bacterial translocation are related to ACLF severity and together with serum levels of checkpoint receptors may discriminate between clinical outcomes.

THU-037

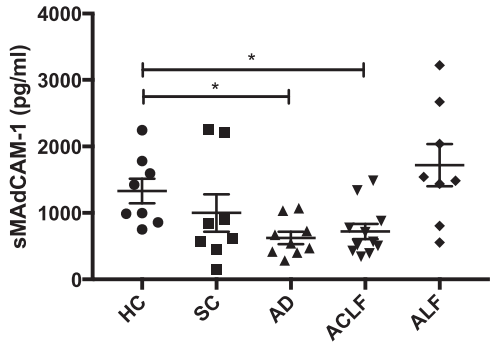
Soluble MAdCAM-1 as a novel marker of hepatic endothelial dysfunction in acutely decompensated cirrhosis

Jonathon Graham[1], Francesca Trovato[1], Davide Erminelli[1], Xiaohong Huang[1], Rodrigo Liberal[1], Diego VERGANI[1], Giorgina Mieli-Vergani[1], Yun Ma[1], Bu Hayee[1], Mark J W McPhail[1].
[1]*King's College Hospital NHS Foundation Trust, London, United Kingdom*
Email: jonathon.graham@kcl.ac.uk

Background and aims: Mucosal addressin cellular adhesion molecule 1 (MAdCAM-1) is an endothelial adhesion molecule expressed on high endothelial venules of the gut lymphoid tissue, with aberrant expression observed on the hepatic endothelium in cirrhosis. Associations between response to therapy and soluble (s)MAdCAM-1 concentrations have been shown in patients with inflammatory bowel disease (IBD). *In vitro* data suggests Th1 inflammatory responses induce, whereas nitric oxide signalling can depress, MAdCAM-1 expression. However, the pattern of sMAdCAM-1 induction in syndromes where systemic inflammation and endothelial dysfunction coexist, such as acute-on-chronic liver failure (ACLF), are unknown.

Method: Plasma samples were obtained from patients with stable cirrhosis (SC, n = 8), acute decompensation (AD, n = 10), ACLF (n = 11), acute liver failure (ALF, n = 8), IBD (n = 4) in and healthy controls (HC, n = 8) with sequential samples taken at day 7 for ACLF patients (n = 9). sMAdCAM-1 was quantified using enzyme-linked immunosorbent assay (ELISA). Immunohistochemistry was conducted on cirrhotic explanted liver tissue (n = 21) and healthy donor tissue (n = 6) and stained with anti-MAdCAM-1 antibody.

Results: Liver histology of 17/21 (81%) patients with cirrhosis demonstrated positive MAdCAM-1 staining compared to 0/5 in the control group ($p = 0.001$), predominantly on the portal venous endothelium and peripheral lymphoid aggregates. sMAdCAM-1 was analysed in 19 patients diagnosed with alcoholic liver disease (ALD), 5 non-alcoholic steatohepatitis, 7 primary sclerosing cholangitis and 4 IBD. Compared with HC, ALD patients showed a significant reduction in sMAdCAM-1 (1330 vs 656 pg/ml, $p < 0.05$) with no differences observed when comparing other aetiologies to HC. Between AD and ACLF there was no difference in sMAdCAM-1 expression (700.8 vs 721.2 pg/ml), however, when comparing to HC both groups showed significantly lower concentrations (700.8 and 721.2 vs pg/ml 1330 pg/ml, $p < 0.05$). In contrast, for patients with ALF, sMAdCAM-1 concentration did not differ from HC (1729 vs 1330 pg/ml, $p = 0.99$). Furthermore, sMAdCAM-1 accurately predicted decompensated disease in this combined cohort (AUROC 0.845 95% CI 0.663-0.952, sensitivity 67%, specificity 100%, $p < 0.001$). Sequential ACLF samples revealed a trend towards recovery of sMAdCAM-1 concentration at day 7 compared to baseline (668.8 vs 890.1 pg/ml, $p = 0.054$).



Conclusion: MAdCAM-1 is a marker of endothelial activation in decompensated cirrhosis, independent of the presence of concurrent IBD. Soluble MAdCAM-1 expression is paradoxically depressed during the development of ACLF and strongly predicts decompensation and progression to multi-organ failure. This may represent the development of endothelial dysfunction. The role of MAdCAM-1 in promoting abnormal endothelial responses requires further investigation.

Fungal pneumonia in critically ill cirrhotics: Spectrum and outcomes

Pratibha Ramchandra Kale[1], vikas khillan[2], Shiv Kumar Sarin[3].
[1]*Institute of liver and biliary sciences, Clinical Microbiology, New Delhi, India;* [2]*Institute of liver and biliary sciences, Clinical Microbiology, New Delhi, India;* [3]*Institute of liver and biliary sciences, Hepatology, New Delhi, India*
Email: drpratibhapgi@gmail.com

Background and aims: Liver cirrhosis causes immune dysregulation and increased susceptibility to fungal infections. We studied the epidemiology, spectrum, risk factors, and compared the rapid diagnostic methods and biomarkers for fungal pneumonia in critically ill cirrhotics admitted to intensive care unit (ICU).

Method: Single-center, prospective cohort study of 100 critically ill cirrhotics with fungal pneumonia between January to September 2018. Comparative analysis was done for culture, real time polymerase chain reaction (PCR) and biomarkers; bronchoalveolar lavage (BAL) and serum Galactomannan, and serum procalcitonin (PCT) measured on day 1, 3 7. Mortality within one month of diagnosis or discharge was analyzed.

Results: *Aspergillus flavus* was the most common species (70/100, 70%). Risk factors for fungal pneumonia included neutropenia (p 0.03), steroids prior to ICU admission (p 0.02), prolonged (>21 days) hospitalization ($p < 0.05$). Culture positivity was 80%. Culture was not inferior to real time PCR for diagnosis of fungal pneumonia. BAL Galactomannan was early prognostic marker with median rise >3.5 over the index value. Median PCT level was higher from day 1in the fungal pneumonia non-survivor than survivor group (3.29 vs. 0.8 ng/ml), with higher 30-day mortality (72%). Baseline PCT at admission to ICU was higher in non- survivors; levels on day 3 and day 7 were persistently higher. Higher PCT level was associated with bacterial co-infection (48%), antibiotic (74%) and antifungal therapy and renal failure and mortality.

Conclusion: Cirrhotics who are neutropenic, have prolonged hospitalization and exposed to steroids have a high risk of fungal pneumonia. High serum procalcitonin level is an independent prognostic biomarker of mortality risk in fungal pneumonia which reaches nearly 70%, high index of suspicion and early detetction is required in advanced cirrhosis.

LPS-induced upregulation of RANTES in a new mouse model of bacterial infection related acute-on-chronic liver injury

Ersin Karatayli[1], Susanne N Weber[1], Rabea Hall[1], Senem C. Karatayli[1], Steven Dooley[2], Frank Lammert[1]. [1]*Saarland University, Department of Medicine II, Saarland University Medical Center, Homburg, Germany;* [2]*Heidelberg University, Department of Medicine II, Medical Faculty Mannheim, Mannheim, Germany*
Email: Ersin.Karatayli@uks.eu

Background and aims: Bacterial infection (BI) is the second most common acute trigger leading to acute-on-chronic liver failure (ACLF) in humans. Here we aim to establish a novel BI-related ACLF model by intraperitoneal lipopolysaccharide injection to a knock-out mouse with well characterized chronic liver injury (*Abcb4*$^{-/-}$ mice) to mimic the disease conditions of ACLF and study the inflammatory events in this preclinical model.
Method: Fifteen week-old C57BL/6J (N = 16) (wild type, wt) or *Abcb4*$^{-/-}$ (N = 12) (knock-out, ko) were treated with IP injections of either LPS (4 mg/kg) or sterile saline solution (0.9% NaCl). Six hours after injection, mice were sacrificed, and plasma and liver tissue samples were collected. Liver-specific steady-state mRNA levels (relative to *Gapdh*) of interleukin-6 (*IL6*), C-reactive protein (*Crp*), Tumor necrosis factor-alpha (*Tnf-α*), regulated on activation, normal T cell expressed and secreted (*Rantes*, a.k.a. *Ccl5*), Toll like receptor 4 (*Tlr4*) and Monocyte chemoattractant protein-1 (*Mcp1*, a.k.a. *Ccl2*) were evaluated using the $2^{-\Delta\Delta Ct}$ method. Variables were evaluated with paired t-tests and $p < 0.05$ was considered as significant.
Results: LPS challenge resulted in rapid upregulation in hepatic expression of *Crp* (9-fold) and *Tlr4* (10-fold), while leading to a dramatic change in *IL6*, *Mcp1*, *Tnf-α* and *Rantes* mRNA levels with approximately 230-, 150-, 80- and 64-fold increases in wt control mice, respectively. Corresponding effects were also observed in the *Abcb4*$^{-/-}$ knock-out mice with no significant differences in terms of liver specific expressions of *IL6*, *Tnf-α*, *Tlr4* and *Mcp1* compared to wt mice. Of note, LPS resulted in a more profound upregulation of *Rantes* expression in *Abcb4*$^{-/-}$ mice with pre-existing liver injury (64-fold vs. 126-fold increase, $p = 0.037$), while *Mcp1* induction was comparable and *Crp* increase was more moderate (9-fold vs 4-fold, $p = 0.026$) in the knock-out mice compared with their wt counterparts.
Conclusion: In this dual hit model, high expression levels of hepatic cytokines and chemokines after intraperitoneal LPS injection suggest a novel promising approach to model BI-ACLI in Abcb4$^{-/-}$ mice. While excessive inflammatory responses might be dampened in this model after acute insult (LPS), we speculate that Rantes could specifically trigger inflammatory cascades with harmful consequences on further disease cause and prognosis.
This study was supported by BMBF LiSyM (031L0051).

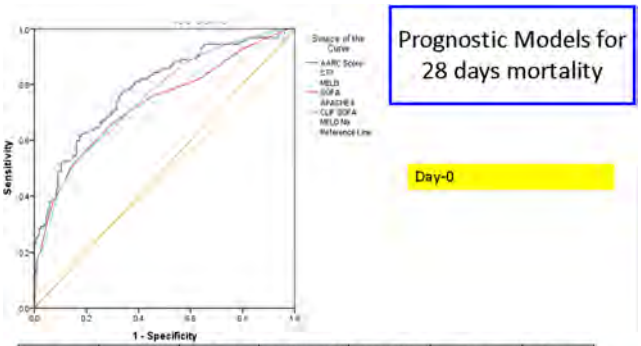
Email: karanbjmc93@gmail.com

Background and aims: Acute on Chronic Liver Failure (ACLF) is a syndrome characterized by acute and severe hepatic abnormalities resulting from different types of insults, in patients with underlying chronic liver disease or cirrhosis with a high short-term mortality. Various score have been developed to determine severity of ACLF. APASL-AARC research consortium (AARC) have developed an AARC score to determine Prognosis of ACLF patient. In this study we tried to revalidate the score over a cohort of ACLF patients and evaluated the dynamicity of AARC score
Method: A total of 2324 ACLF patients, enrolled in the APASL-ACLF Research Consortium (AARC) with 90-day follow-up, were analyzed. AARC score (range 5–15) determined by 5 variables (Total bilirubin, Creatinine, Serum Lactate, Hepatic Encephalopathy and INR) was calculated and patients were divided into 3 grades- Grade A (score 5–7) Grade B (score –8–10) Grade C (score 11–15). Calculated AARC score was than validated over the entire cohort for goodness of fit and concordance by using Harrell's C and Somers D. It was also compared with other severity score like CTP, MELD and CLIF SOFA
Results: Mean age of patients was 47.35 years±13.35 years with 64.6% male.The overall survival of ACLF patients at 28 days was 40.6%, with a median of 29.7 days. The cumulative mortality in the first week in grade -A, B and C were 0, 11 and 45% respectively AARC-ACLF score (range 5–15) was found to be superior to MELD and CLIF SOFA scores in predicting mortality with an AUROC of 0.70.A score ≥ 11 at any time in 1st week was a predictor of mortality. The mortality risk could also be dynamicallyalculated as, with each unit increase in AARC-ACLF score above 10, the mortality risk increases by 20% whereas each unit increase in score within 7 days raises the 28 days mortality by 5.2%



Score	Area	CUT OFF	SENSITIVITY	SPECIFICITY	PPV	NPV
AARC Score	.78	10.5	64.1	75.9	70.7	70
MELD	.76	30	65.3	74.4	63.1	76.1
SOFA	.73	9.5	63.8	69.5	62.2	70.9
APACHE II	.70	15.5	57.9	68.8	56.8	69.8
CLIF SOFA	.69	11.5	52.2	74.9	66.8	61.9
CTP	.65	11.5	72.4	53	50.4	74.4

Conclusion: AARC-ACLF score is simple, easy and dynamic score to use in clinical practice which can reliably predict outcome in ACLF patient.

Immune-metabolism disorder in progression of hepatitis B virus-related acute-on-chronic liver failure characterized by transcriptomics

Jun Li[1], Jiang Li[1], Xi Liang[2], Lingling Yang[1], Jiaojiao Xin[1], Jing Jiang[1], Jianing Zhang[2], Dongyan Shi[1], Tianzhou Wu[3], Suwan Sun[1], Yinyun Lu[1], Beibei Guo[1], Xingping Zhou[1], Hozeifa Mohamed Hassan[1], Xin Chen[2]. [1]*The first affiliated hospital, Zhejiang university school of medicine, State key laboratory for diagnosis and treatment of infectious diseases, Hangzhou, China;* [2]*Zhejiang university school of mdicine, Institute of pharmaceutical biotechnology, Hangzhou, China;* [3]*The First People's Hospital of Wenling, The Infectious Disease Department, Taizhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: The pathophysiological etiology of hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) remains

unclear. This study aims to characterize the molecular basis of HBV-ACLF using transcriptomics.
Method: Peripheral blood mononuclear cells (PBMCs) from patients with HBV-ACLF (n = 20) and acute-on-chronic hepatic dysfunction (ACHD), liver cirrhosis (LC), chronic hepatitis B (CHB) and heathy control groups (n = 15/group) were selected from a prospective multi-center cohort (Chinese Group on the Study of Severe Hepatitis B, COSSH-ACLF) for RNA-sequencing. Quantitative real-time polymerase chain reaction (qRT-PCR) was used to confirm marker genes in the validation groups (n = 80 in ACLF group, n = 35/each other group).
Results: Principle component analysis (PCA) shows that HBV-ACLF patients with or without cirrhosis were positioned together, and clearly separated from the ACHD, LC and CHB patients, demonstrating the effectiveness of COSSH-ACLF criteria to diagnose HBV-ACLF. Functional synergy analysis of the differentially expressed genes identified 8 groups of biological processes (immune, inflammation, metabolism, virus, etc.) that contribute to HBV-ACLF progression, suggesting that excessive immune response triggered by HBV reactivation was a potential cause of progression from ACHD to ACLF grade 1. Subsequently, multiple organ failures induced by inflammation and metabolism disorder were developed in patients with ACLF grade 2/3. Comparison between the survived and deceased patients showed multiple physiological dysfunctions, e.g., metabolism disturbances of nitric oxide and ammonia, which consequently induced renal dysfunction and hepatic encephalopathy. Four differentially expressed genes, MERTK, PPARG, SEMA6B and THBS1 were functionally associated with those eight biological processes and showed increased expressions with the progression of CHB, LC, ACHD and ACLF. The qPCR validation within external patient groups confirmed their potential for use as HBV-ACLF biomarkers.
Conclusion: This study highlights immune-metabolism disorder as an important axis that drives HBV-ACLF progression, which differs from the systemic inflammatory response syndrome (SIRS) route in the patients with alcoholic liver disease-related ACLF in Western populations. This insight may help to develop more effective intensive treatment strategies to reduce the high mortality rate of HBV-ACLF.

THU-042
Hypoxia aggravates acute on chronic hepatitis through MIR-210 mediated macrophage autophagy impairment

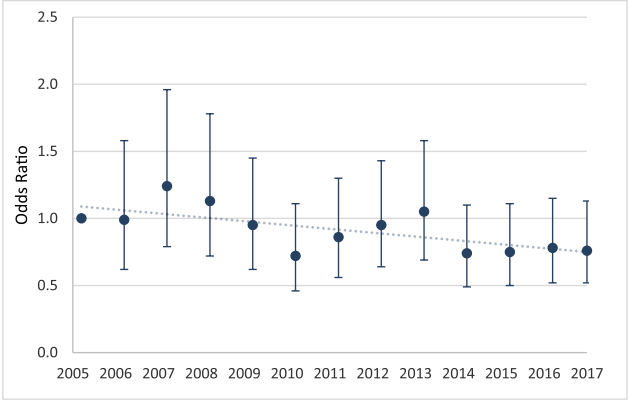
Feifei Liu[1], Yanning Liu[1], zhi chen[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*
Email: zjuchenzhi@zju.edu.cn

Background and aims: Patients with chronic hepatitis are prone to serious liver inflammation and contract Acute on Chronic Liver Failure (ACLF), when they are triggered by liver damage factors, but the mechanisms remain unclear. Different degrees of hypoxia exist in the liver tissue of chronic hepatitis, which contribute to poor prognosis. We aimed to study the role of hypoxia in mechanisms of ACLF.
Method: Expression of hypoxia inducible factor-1α (HIF-1α) in liver tissue of ACLF mouse was determined by Western Blot. Pretreating THP-1-derived macrophages (THP-M) in hypoxia condition and then exposing THP-M to LPS, the concentration of IL-1β in supernatant was measured by ELISA assay. The relative expression level of miR-210 was determined by qRT-PCR assay. The expression level of autophagy related molecules was detected by Western Blot.
Results: We found that HIF-1α was unregulated in liver tissue of ACLF mouse, indicating existence of hypoxia. Pretreating THP-M in hypoxia condition increased LPS-induced IL-1β secretion. Hypoxia increased miR-210 expression in macrophages apparently, and transfection of miR-210 agomir also increased LPS-induced IL-1β secretion. We further investigated the role of autophagy in hypoxia mediated excessive activation of macrophages. We found that hypoxia impaired macrophage autophagy, and upregulated miR-210 also impaired macrophage autophagy by targeting ATG7. Interference of miR-210 abrogated hypoxia-induced autophagy impairment and relieved hypoxia mediated excessive activation of macrophages.
Conclusion: Hypoxia impairs macrophage autophagy through miR-210, further leading to excessive activation and inflammatory cytokines secretion of macrophages in liver tissue of chronic hepatitis, which results in ACLF.

THU-043
Declining mortality of cirrhotic patients requiring admission to intensive care units for serious infections: A bi-national cohort study

Ammar Majeed[1], Michael Bailey[2], Avik Majumdar[3], William Kemp[1], Rinaldo Bellomo[2], David Pilcher[2], Stuart Roberts[1]. [1]*The Alfred Health, Department of Gastroenterology, Melbourne, Australia;* [2]*Australian and New Zealand Intensive Care Research Centre (ANZIC RC), Department of Epidemiology and Preventive Medicine, Melbourne, Australia;* [3]*Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Sydney, Australia*
Email: a.majeed@alfred.org.au

Background and aims: Epidemiological data on the outcomes of cirrhotic patients admitted to the intensive care unit (ICU) for serious infections are lacking. We aimed to describe changes over time in admissions and outcomes for such patients and to compare the results with the outcomes of those with and without cirrhosis admitted to ICU with other causes.
Method: We retrospectively analysed data from consecutive admissions of patients with cirrhosis to 183 ICUs between January 1st, 2005 and December 31st, 2017 as prospectively recorded by the Australian and New Zealand Intensive Care Society Centre for Outcome and Resource Evaluation Adult Patient Database.
Results: Admissions for cirrhotic patients with infections accounted for 4, 645 (0.6%) of all 813, 189 non-elective ICU admissions. The proportion of ICU admissions for cirrhotic patients with infections remained stable over the study period (0.6% per year). The median hospital and ICU stay were 12.1 (6.3–23.1) and 3.5 (1.7–7.2) days, respectively. Hospital mortality rate was significantly higher in patients with cirrhosis and infections compared to both cirrhotic patients admitted to ICU for other reasons and all other non-elective ICU admissions (35.5% vs 28.5 vs 15.2%, p < 0.0001). Mortality in cirrhotic patients with infections increased with the number of failing organs (15% in the absence of organ failure, 26% with one failing organ, 40% with two, 61% with three failing organs, 80% with four and 89% with five or more failing organs).



After adjustment for underlying severity of illness at admission to ICU, mortality in cirrhotic patients with infections decreased significantly over the study period (annual decline odds ratio, 0.97; 95% confidence interval; 0.95-0.99) (figure 1). The reduction in

mortality over time in the cirrhotic group with infections was comparable to cirrhotic patients with other indications for ICU admission (p value 1.0) and all other non-cirrhotic emergency ICU admissions (p value 0.14). There was no difference in the reduction in mortality over time in cirrhotic patients with infections admitted to ICUs between liver transplant and non-transplant centres (p = 0.12).
Conclusion: The mortality of cirrhotic patients admitted to ICU with infections is higher than for patients admitted with other indications but has declined over the past 13 years in line with a reduction in overall mortality of cirrhotic patients admitted to.

THU-044

Cystatin C as a predictive biomarker of ACLF development and mortality on the liver transplant waiting list

Ezequiel Mauro[1], Gonzalo Crespo[2], Agustina Martinez Garmendia[1], Maria Nelly Gutierrez Acevedo[1], Juan Manuel Diaz[1], Carla Bermudez[1], Jorge Ortiz Patron[1], Lucrecia Garcia Olveira[1], Fernanda Zalazar[1], Adrian Narvaez[1], Juan Carlos Spina[3], Salvatore Piano[4], Sebastián Marciano[1], Adrian Gadano[1]. *[1]Hospital Italiano de Bs. As., Liver Unit, Buenos Aires, Argentina; [2]Hospital Clinic i Provincial de Barcelona, Liver Unit, Barcelona, Spain; [3]Hospital Italiano de Bs As, Radiology Department, Buenos Aires, Argentina; [4]University of Padova, Liver Unit, Padova, Italy*
Email: ezequiel.mauro@hospitalitaliano.org.ar

Background and aims: Renal failure is the most common organ failure in patients with decompensated cirrhosis who develop acute-on-chronic liver failure (ACLF), and has a dreadful prognosis. The use of creatinine as an estimator of renal function has serious limitations in patients with cirrhosis. Cystatin C (CysC) is an early biomarker of renal dysfunction. However, its prognostic value in patients in the waiting list (WL) for liver transplantation (LT) has not been evaluated. We aimed to assess the capacity of CysC to predict both survival and development of ACLF in patients with cirrhosis in the WL.
Method: Retrospective cohort of patients with cirrhosis listed for LT at the Hospital Italiano from Buenos Aires (Argentina) between January 2014 and December 2017. Data was collected from the inclusion in the WL to death, LT or last date of follow-up. In all patients, CysC was measured at the time of pre-LT evaluation. The ability of liver-, kidney- and global status-related variables recorded at the time of WL inclusion to predict WL mortality and the development of ACLF (according to CLIF-SOFA definition) was evaluated with competing risk regression analysis (with LT as the competing risk of mortality in WL and LT or death as the competing risk of development of ACLF).
Results: A total of 180 patients with cirrhosis listed for LT were included: 40% female, median age 59 years, main etiologies of liver disease alcohol, HCV and NASH. The main indication of LT was decompensated cirrhosis (88%). The median values of MELD-Na, creatinine and CysC were 16 (13–21), 0.8 mg/dL (0.6–1.07) and 1.46 mg/L (1.13–2.05) respectively. The median follow-up for mortality and ACLF outcomes were 12.8 (6.59–24.55) months and 11.7 (4.45–22.62) months, respectively. During follow-up in the WL, 56 (31%) patients developed ACLF, 54 (30%) underwent LT and 35 (19%) died. After adjusting for possible confounders (MELD-Na, albumin, encephalopathy, gender and subjective global nutritional assessment) CysC ≥ 1.5 mg/L was an independent predictor of the development of ACLF (sHR 2.68; 95% CI 1.43–5.00; p = 0.002). Similarly, CysC ≥ 1.5 mg/L was an independent predictor of mortality in the WL (sHR 3.58; 95% CI 1.47–8.73; p = 0.005) after adjustment for MELD-Na, albumin and ACLF.
Conclusion: Higher levels of CysC are strongly associated with the development of ACLF and mortality in WL, regardless of MELD-Na, albumin or history of ACLF. CysC may help to identify patients at high risk of short-term mortality in the LT WT.

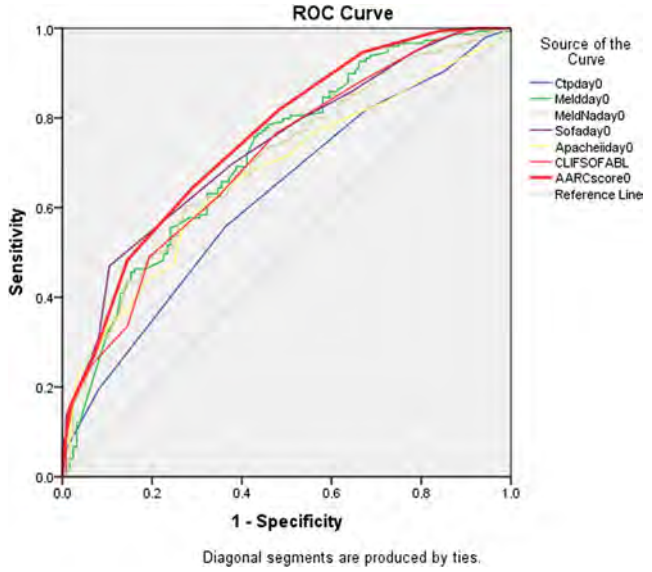
Background and aims: Acute on chronic liver failure (ACLF) is a serious clinical syndrome and carries a high overall mortality, especially those who are critically ill requiring intensive care unit (ICU) admission. We analyzed the natural history of sepsis and organ dysfunction or organ failure in patients with critically ill ACLF (CI-ACLF).
Method: Consecutive ACLF patients, fulfilling the APASL definition of ACLF and prospectively enrolled in the APASL-ACLF Research Consortium (AARC) were included. CI-ACLF patients requiring ICU admission at baseline or within 48 hours of hospitalisation were followed over next 30 days. Organ failure (OF) and organ dysfunction (OD) were defined as per AARC score for renal, coagulation and cerebral organs.
Results: A total of 632 patients with CI-ACLF were admitted to the ICU and complete 30 day data was available for 351 patients. Sepsis was seen in 47% of patients at baseline and in comparison to non-septic patients, carried a higher Day 7 (28.5% vs. 15.6%, p = 0.003) and Day 30 (57.6% vs. 40.3%, p = 0.001) mortality. New onset sepsis developed at day 4 and 7 in 30.3% and 38.7% respectively. Second-hit sepsis was seen in 37% of baseline septic patients. Patients with cerebral (No HE-No OF/Grade I and II HE-OD/Grade III and IV HE, OF- 35.8%/60.7%/75.6%, p = <0.001), renal failure (No OF/OD/OF-34.7%/45.1%/70.3%, p = <0.001) and circulatory failure (No OF/OD/OF-25.6%/60.5%/85.7%, p = <0.001) had significantly higher Day 30 mortality. Age, gender, total leukocytes count, platelet level, ammonia, creatinine, bilirubin, INR, lactate at baseline and presence of acute kidney injury (AKI) and hepatic encephalopathy (HE) were predictors of Day 30 mortality but on regression analysis age (HR, 95%CI-1.04, 1.02–1.06, p = <0.001), (log)INR (2.22, 1.25–3.95, p = 0.007), (log)Bilirubin (1.73, 1.11–2.70), lactate at baseline (1.24, 1.09–1.49, p = 0.001), HE at baseline (1.54, 1.10–1.75, 0.02) and AKI at baseline (2.11, 1.44–3.11, p < 0.001) were significant. AARC-ACLF score for CI-ACLF patients performed best with AUROC of 75% (Cut-off- 10.5, Sensitivity–64.4%, Specificity–71%, p < 0.001) for 30 day mortality.



Conclusion: Sepsis and organ failures as well as organ dysfunctions carry a high 30 day mortality in critically ill ACLF patients. AARC score is a useful tool for risk stratification in this sicker sub-group of ACLF patients.

THU-046

Implementation of acute kidney injury criteria to patients with acute-on-chronic liver failure: Characteristics of effect on outcomes

Laura Napoleone[1,2,3], Cristina Solé[1,2,3], Elisa Pose[1,2,3], Marta Carol[1,2,3], Adrià Juanola[1], Patrícia Huelín[1,2,3], Glòria De Prada[1,2,3], Marta Cervera[1,2,3], Martín Bonacci[1,2,3], Núria Fabrellas[1,2,3,4], Isabel Graupera[1,2,3], Elsa Solà[1,2,3], Pere Ginès[1,2,3]. Email: pgines@clinic.cat

Background and aims: The diagnostic criteria used to define acute-on-chronic liver failure (ACLF) uses serum creatinine as indicator of kidney failure. However, currently there is general consensus that assessment of acute impairment of kidney function in cirrhosis should be based on acute kidney injury (AKI) criteria and not on a single measurement of serum creatinine. Therefore, the relationship between kidney failure defined using AKI criteria and ACLF is not known. This study was aimed at investigating the characteristics of AKI in patients with and without ACLF and its relationship with outcomes.
Method: Prospective, single-center study of 639 consecutive admissions in 518 patients with decompensated cirrhosis. Patients were classified into 4 groups: 1)NoAKI-NoACLF (265 episodes); 2)NoAKI-ACLF (18); 3)AKI-NoACLF (142) and 4)AKI-ACLF (214). Demographic, clinical and analytical data as well as urinary biomarkers (NGAL, IL-18 and albumin) were assessed.
Results: AKI and ACLF occurred in 356 (55.7%) and 232 (36.3%) admissions, respectively. As expected, AKI stage 1A was more common in the AKI-NoACLF group compared to the AKI-ACLF group (53% vs 12%, p < 0.001) while AKI stage 3 was more common in the AKI-ACLF group (16% vs 1%, p < 0.001). With respect to the cause of AKI, acute tubular necrosis was more common in patients with ACLF compared to those without (13% vs 0%, p < 0.001). Interestingly, hepatorenal syndrome was more common in patients with AKI-NoACLF than in those with AKI-ACLF (32% vs 25%, p < 0.001). Resolution of AKI was observed in 89% of cases in AKI-NoACLF vs 54% in AKI-ACLF (p < 0.001). By contrast, progression of AKI occurred more frequently in AKI-ACLF (28% vs 4%, p < 0.001).
There was a striking difference in mortality between AKI-ACLF and AKI-NoACLF groups, both during hospitalization (38% vs 4%, p < 0.001, respectively) and at 3 months (49% vs 14%, p < 0.001). Mortality in AKI-NoACLF was slightly higher than that in NoAKI-NoACLF (14% vs 7%, p = 0.04).
Mortality was strongly associated with urinary biomarker levels, particularly NGAL. In multivariate analysis, presence of ACLF and urinary NGAL at day 3 were independent predictors of 3-month survival.
Conclusion: Characteristics and outcome of AKI are strongly dependent on the presence of associated ACLF. AKI without associated ACLF has good kidney and patient outcomes. Presence of ACLF and increased urinary levels of NGAL are associated with poor outcome.

Recalbration of the CLIF-C ACLF score after weighting by organ and by the presence of TIPS in patients with acute-on-chronic liver failure

Enric Reverter[1], Adrià Carpio[1], Pol Olivas[1], Adria Juanola[1], Gerhard Jung[1], Gabriel Mezzano[1], Karina Botana[1], Julieta Santillán[1], Maria Hernandez-Tejero[1], Fatima Aziz[1], Angels Escorsell[1], Javier Fernandez[1]. [1]*Hospital Clínic de Barcelona., Liver and Digestive ICU, Liver Unit., Barcelona, Spain*
Email: ereverte@clinic.cat

Background and aims: Acute-over-chronic liver failure (ACLF) assciates a high short-term mortality. The most accurate prognostic score is CLIF-C ACLF score, which includes leukocytes blood count, age and organ failures according to CLIF-SOFA (semi-quantitative 1–3 points). The model equally scores each organ failure though they have different prognostic weights. Our study assesses, in a contemporary cohort of ACLF patients, whether CLIF-C ACLF score may be improved by weighting the type of organ failure and by incorporating other variables.
Method: Retrospective inclusion (2008-16) of 344 patients admitted to the ICU with ACLF. The coefficients of the CLIF-C ACLF score on day 3 were recalibrated by survival analysis at days 28 and 90 (transplantation as competitive event). Other variables not included in the original model were studied. Predictions of the original model were compared with predictions after recalibration: discrimination (AUR, Delong for comparison) and calibration (Hosmer-Lemeshow) were assessed.
Results: 25% of patients had grade 1 ACLF, 41% grade 2 and 34% grade 3. Alcohol was the predominant etiology of cirrhosis (66%), and sepsis (35%) and bleeding (21%) were the main precipitants of the ACLF. Recalibration of CLIF-C ACLF score showed different weights for each organ failure coefficient: liver 0, 529, coagulation 0, 515, circulation 0, 490, respiration 0, 417, kidney 0, 296 and brain 0, 295. At univariate analysis variables included in CLIF-C ACLF, serum sodium, ALT and the presence of TIPS were prognostic factors. At multivariate analysis, TIPS (HR 0.260, p = 0.001) remained in the model along with CLIF-C ACLF variables. Mean values of the new model were higher than original ones (60 ± 14 vs. 49 ± 12).
Discrimination of the original model was correct at 28 and 90 days: AUROC 0.831 and 0.804, respectively. The recalibrated model was superior with AUROC of 0.858 (28d) and 0.845 (90d) ($p < 0.05$). Calibration of both original and recalibrated models was correct (n.s. H-L test).
CLIF-C ACLF score ≥ 70 (proposed for futility) occurred in 21 patients, 20 of whom died at 28–90 days. At recalibrated model, values > 76 (49 patients) and >74 points (61 patients) had a 100% mortality at 28 and 90 days, respectively.
Conclusion: The type of organ failure has a differential prognostic weight in ACLF. Recalibration of CLIF-C ACLF score by weighting the type of organ failure and the presence of TIPS may improve its predictive capacity and limits to define futility.

Email: j.g.rozga@gmail.com

Background and aims: AKI-HRS carries significant risk of morbidity and mortality due to lack of effective therapies. We report the results of a cohort, retrospective, single-center study to investigate the effects of continuous venovenous hemodialysis (CVVHD) coupled with intermittent high-flux single-pass albumin dialysis (SPAD) on survival and clinical and laboratory parameters in patients with ACLF and AKI-HRS.
Method: 16 patients (11 male), age 48 + 12 yrs, with severe decompensation of cirrhosis and AKI-HRS (n = 13) received extracorporeal therapy. The Ultraflux® Ci-Ca®CVVHD EMiC®2 kit (Fresenius MC) was used to improve middle molecule clearance. Each SPAD lasted 8 hrs and was followed by the CVVHD with no change of the dialyzer. Each subsequent SPAD/CVVHD was performed using a newly installed EMiC®2 kit. Fluid extraction rates ranged from 50 to 200 ml/h, depending on the urine output and fluid balance status. Data at the initiation of the first SPAD/CVVHD were compared with early morning data after termination of the treatment phase. Data are shown as mean + SD and were analyzed by ANOVA, Wilcoxon signed rank test, or binomial NPar Tests, where appropriate.
Results: All patients had markedly elevated plasma bilirubin levels and coagulopathy, 13 were oliguric or anuric, 14 had encephalopathy. All patients with alcoholic liver disease (n = 11) were actively drinking prior to admission. 5/16 patients were transplanted. Infection was a likely trigger of acute decompensation of cirrhosis in 4 pts. 37 SPAD/CVVHD treatments were performed [2.31 ± 1.40]; therapy was continued for 74.7 ± 51.8 hrs. Baseline MELD-Na score was 37.6 ± 6.6 and after SPAD/CVVHD treatment it was 33.4 ± 8.7 ($p < 0.001$). In parallel, the CLIF-C ACLF Grade, OFs, and estimated 1- and 3-mo mortality improved ($p = 0.003–0.032$). Clinically these changes were associated with improvement in AKI-HRS Stage and HE Grade ($p < 0.001$) and key blood tests (total bilirubin, NH_3, INR, creatinine). A 30-day and 90-day survival was 56.3%. Survival in the subgroup of AKI-HRS (n = 13) was 53.9%. Survival in patients after transplantation (n = 5) was 75.0%. Survival in patients not transplanted (n = 11) was 45.5%.
Conclusion: In this cohort of severely ill patients, SPAD/CVVHD improved a number of key clinical and laboratory parameters, including renal function, encephalopathy, blood coagulation indices, bilirubin and ammonia levels, MELD-Na, ACLF grade, CLIF-C OFs, and estimated 1- and 3-month survival. It is reasonable to postulate that survival may be further improved with earlier intervention (patients with lower MELD-Na score and ACLF Grade) and more SPAD treatments per patient.

Impaired adaptive immunity is an early event in liver cirrhosis preceding acute-on-chronic liver failure

Sabrina Rueschenbaum[1,2], Sandra Ciesek[3], Alexander Queck[2], Marek Widera[3], Katharina Schwarzkopf[2], Bernhard Brüne[4], Christoph Welsch[2], Stefan Zeuzem[2], Andreas Weigert[4], Christian Lange[1,2]. Email: sabrina.rueschenbaum@uni-due.de

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by high levels of systemic inflammation and parallel suppression of the innate immune system. In contrast, little is known about changes of the adaptive immune system in ACLF. Therefore, we aimed to display an overview of prominent cell populations from both innate and adaptive immune system in order to find changes in

immune cell frequencies responsible for immunosuppression and susceptibility to infections in patients.
Method: Patients with compensated liver cirrhosis, decompensated liver cirrhosis, or ACLF were recruited from a prospective cohort study. Comprehensive immunophenotyping of relevant innate and adaptive immune cell populations was performed using high dimensional multicolour flow cytometry on peripheral blood mononuclear cells. In addition, replication of Torque teno (TT) virus as a marker of immunosuppression was quantified in serum.
Results: A high frequency of detectable TT virus was observed already in patients with compensated liver cirrhosis compared to healthy controls (>50% vs. 19%, p = 0.0003), suggesting early occurrence of immunosuppression in the course of liver cirrhosis. In line, profoundly impaired cellular immune responses were observed, deduced by reduced numbers of important cell populations of the adaptive and innate immune system like CD4+ T cells and CD8+ T cells-especially the naïve (CD45RA+ CD197+) subpopulations-, B cells, NK cells, and dendritic cells. Importantly, most of the observed changes were already evident in patients with compensated liver cirrhosis and were fully developed in patients with acutely decompensated liver cirrhosis, while ACLF was associated with only few additional changes in immune cell frequencies like a diminished compartment of Vdelta2 gamma-delta T cells. The frequency of T cells correlates inversely with the presence of TT virus displaying the contribution of reduced T cell numbers to the immunosuppression in patients.
Conclusion: Impaired innate and-in particular-adaptive cellular immunity occurs early in the pathogenesis of liver cirrhosis and precedes ACLF. This may contribute to the development of ACLF by increasing the risk of infections in patients with liver cirrhosis. This study also sheds light on the adaptive immune system as a potential distinct target of immunological therapy in liver cirrhosis and ACLF.

THU-050

Genetic variants of innate immunity receptors are associated with mortality but not with bacterial infections in liver cirrhosis

Jelte Schaapman[1], Amoros Alex[2], Johannes van der Reijden[1], Wim Laleman[3], Stefan Zeuzem[4], Rafael Bañares[5], Rajiv Jalan[6], Vicente Arroyo[2], H.w. Verspaget[1], Minneke Coenraad[1]. *[1]Leiden University Medical Center (LUMC), Leiden, Netherlands; [2]European Foundation for the study of chronic liver failure, Barcelona, Spain; [3]UZ Leuven, Leuven, Belgium; [4]Universitätsklinikum Frankfurt, Frankfurt am Main, Germany; [5]Gregorio Marañón Hospital, Madrid, Spain; [6]University College London Hospital, London, United Kingdom*
Email: j.j.schaapman@lumc.nl

Background and aims: Acute on chronic liver failure (ACLF) is characterized by the presence of acute decompensation of cirrhosis (AD), organ failure (s) and a high risk of short term mortality. Bacterial infections are among the most frequently observed precipitating events for development of ACLF. The lectin pathway of complement activation is crucial to the innate immune (IM) response to pathogens. Single-nucleotide polymorphisms (SNPs) in the lectin pathway genes determine their liver-derived protein level and/or functional activity. Multiple other components are also involved in IM signalling against pathogens, among which TLR2, TLR4, MYD88 and NOD2. The aim of the present study was to investigate whether SNPs in IM genes for pathogen recognition are associated with the occurrence of bacterial infections or mortality in patients with cirrhosis hospitalized for AD or ACLF.
Method: All patients hospitalized for AD or ACLF from the CANONIC study of whom we had DNA available were included. Twenty-one IM genes variants with known functional implications on protein level and/or functionality were genotyped in 826 patients. Associations between baseline characteristics of the patients, the occurrence of bacterial infections and survival rate at 90 days of follow-up in relation to the IM gene variants were analysed.
Results: None of the analysed SNPs was significantly associated with the occurrence of acute bacterial infections in general or spontaneous bacterial peritonitis (SBP) alone. However, in both univariate and multivariate logistic regression analyses the NOD2-G908R gene risk variant (OR 2.25, 95% CI 1.30–3.91, P = 0.004) was found to be a strong independent predictor of mortality along with age (OR 1.03, 95% CI 1.02–1.05, P < 0.001) and Model For End-stage Liver Disease (MELD) Score (OR 1.15, 1.12–1.17, P < 0.001). In a predefined subgroup analysis in patients with bacterial infections (n = 331) the same association with mortality was observed for NOD2-G908R (OR 2.78, 95% CI 1.74 –4.44, P < 0.001).
Conclusion: In patients with AD or ACLF, single nucleotide polymorphisms in the lectin complement pathway and innate immune signalling components for pathogen recognition were not associated with increased risk of bacterial infection or SBP alone. NOD2-G908R gene risk variant is independently associated with increased risk of short-term mortality in patients with AD or ACLF, particularly those with bacterial infections.

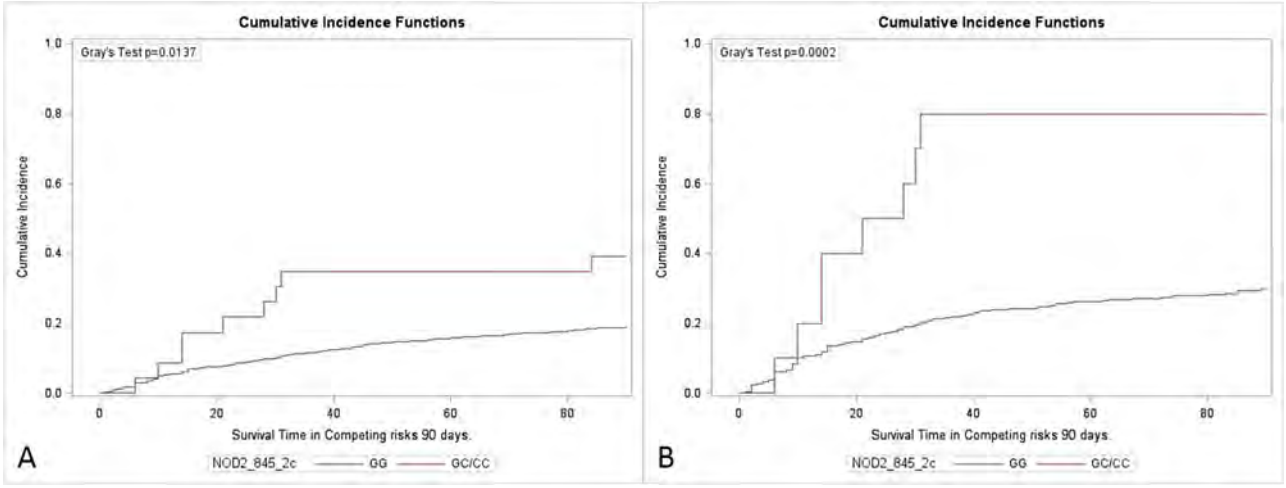

Figure 1A. Survival with competing risk analysis of NOD2-G908R gene risk variant in all patients at 90 days. Figure 1B. Survival with competing risk analysis of NOD2-G908R gene risk variant in patients with bacterial infections at 90 days.

Establishment of a new animal model for the acute-on-chronic liver failure

Katharina Schwarzkopf[1], Sabrina Rüschenbaum[2], Marcus Maximilian Muecke[1], Sina Fuchs[3], Marie Messmer[3], Monika Bayer[3], Edith Hintermann[3], Stefan Zeuzem[1], Urs Christen[3], Christian Lange[2]. *[1]Universitätsklinikum Frankfurt am Main, Medizinische Klinik I, Frankfurt, Germany; [2]Universitätsklinikum Essen, Essen, Germany; [3]Johann Wolfgang Goethe Universität, Pharmazentrum Frankfurt/ZAFES, Frankfurt, Germany*
Email: katharina.schwarzkopf@kgu.de

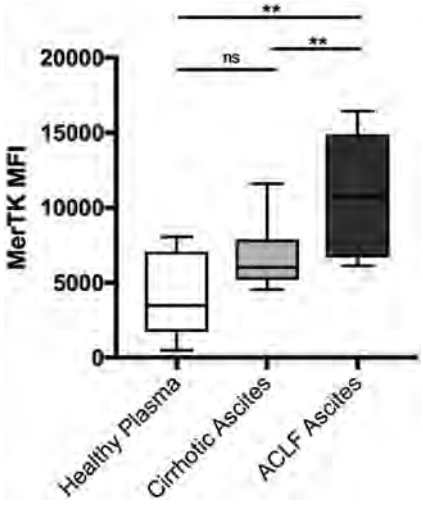
Background and aims: Acute-on-chronic liver failure (ACLF) is a severe complication of liver cirrhosis characterized by hepatic and extrahepatic organ failures. Established precipitating events of ACLF include infections, excessive alcohol consumption, exposure to toxins and bleeding episodes. ACLF is associated with a very high mortality rate and targeted therapy options are not available yet. The aim of this study was to develop a new animal model for the evaluation of target-oriented therapy options for ACLF.
Method: C57BL/6 mice were infected with an Adenovirus expressing the major AIH autoantigen cytochrome P450 2D6 (hCYP2D6) and developed autoimmune hepatitis with resulting liver fibrosis 4 weeks after injection of the virus. On top of the chronic liver damage an acute trigger (paracetamol overdose for toxic liver damage or cecal slurry for induction of sepsis) for the development of ACLF was applied. As control groups served naïve C57BL/6 mice (control group 1) as well as C57BL/6 mice with chronic liver damage (CYP2D6 infected, control group 2) and C57BL/6 mice exposed to an acute trigger only (paracetamol or cecal slurry injection, control group 3). Serum and tissue samples were harvested at different points of time and lymphocytes were isolated. Serum parameters including IL-6 and ALT were analyzed and immunohistochemical stainings as well as FACS analyses were performed.
Results: C57BL/6 mice with ACLF showed significantly higher liver damage (e.g. ALT 12h: paracetamol vs. ACLF $p = 0.0046$; ALT 24h: sepsis vs. ACLF $p = 0.0009$; necrotic area: paracetamol vs. ACLF $p = 0.047$) as well as higher systemic inflammation (e.g. IL6 24h: sepsis vs. ACLF $p = 0.038$, paracetamol vs. ACLF $p = 0.2366$) when compared to mice of control groups. FACS analyses revealed significantly reduced CD4- ($p = 0.0095$) and CD8-T-cells ($p = 0.0095$) in mice with ACLF when compared to mice with chronic liver damage only (control group 2). Additionally kidneys of mice with ACLF showed a relevant damage of the distal tubule in histological staining which could not be detected in the control groups.
Conclusion: We present a new animal model for ACLF which is characterized by enhanced liver damage, significantly increased systemic inflammation as well as dysfunction of the immune system in comparison to control groups. Additionally ACLF mice develop kidney damage as a characteristic feature of extrahepatic organ involvement. Based on this model, targeted therapy options for ACLF can be evaluated.

THU-052

Immunometabolic profiling of ascites from patients with acute-on-chronic liver failure reveals increased MerTK+ immunosuppressive myeloid cells and cell death markers with preferential lipid metabolism compared to cirrhosis without organ failure

Arjuna Singanayagam[1,2,3], Davide Erminelli[2], Evangelos Triantafyllou[1], Christine Bernsmeier[2], Enes Tunc[1], Marigona Krasniqi[1], Vishal Patel[2], Fanny Lebossé[1], Rooshi Nathwani[1], Andrew Atkinson[4], Ameet Dhar[1], Michael Heneghan[2], Georg Auzinger[2], Wafa Khamri[1], David Adams[3], Julia Wendon[2], Mark Thursz[1], Mark J W McPhail[2], Harry Antoniades[1,2]. *[1]Imperial College London, Division of Integrative Systems Medicine and Digestive Disease, London, United Kingdom; [2]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [3]University of Birmingham, NIHR Birmingham Liver Biomedical Research Unit, Birmingham, United Kingdom; [4]King's College London, NMR Facility, London, United Kingdom*
Email: asinganayagam@yahoo.co.uk

Background and aims: Acute-on-chronic liver failure (ACLF), characterized by rapid development of organ failure (OF) and high mortality, is associated with increased susceptibility to infection such as spontaneous bacterial peritonitis (SBP). Increased monocyte expression of pro-restorative marker Mer tyrosine kinase (MerTK) has been linked to dampened innate immune responses in ACLF. To investigate its potential role in SBP susceptibility, we sought to comprehensively phenotype the immunometabolic environment of ascites in patients with cirrhosis and ACLF.
Method: Plasma, ascites and ascitic cells (ACs) were obtained from cirrhotic patients on hospital admission. Healthy peripheral blood mononuclear cells (PBMCs) were cultured for 48hrs in 50% ascites derived from patients with and without ACLF. Healthy plasma was used as control. SBP cases were excluded. Monocyte immunophenotype (CD14, CD16, HLA-DR, MerTK) was determined by flow cytometry. Cell death markers (M30/M65) were measured using enzyme-linked immunosorbent assay, cytokines by multi-array immunoassay and metabonomic profile by ^{1}H nuclear magnetic resonance (NMR) spectroscopy. LPS-stimulated *ex-vivo* AC TNF-α production was determined by intracellular staining. Transcriptomic profile of CD14+ ACs was analysed after FACS-sorting of MerTK+ vs. MerTK- subsets.
Results: MerTK expression (Median Fluorescence Intensity) was significantly increased in PBMCs exposed to ACLF ascites compared to cirrhosis without OF and healthy plasma ($p < 0.01$, figure 1). Ascitic M30 and M65 levels were greater than plasma ($p < 0.05$). In ACLF vs. cirrhosis, ascitic M30, M65 and TNF-α concentrations were elevated ($p < 0.05$). Ascitic M65 positively correlated with MerTK MFI and TNF-α ($p < 0.05$). However, LPS-stimulated TNF-α production of CD14+ ACs was attenuated compared to healthy PBMCs ($p < 0.05$). In ACLF, ^{1}H NMR revealed a markedly altered ascitic metabolic environment compared to cirrhosis without OF, with higher lactate, acetone, 3-hydroxybutyrate and lipid concentrations. In contrast, lipids in ACLF plasma were significantly depleted. Transcriptomic profiling revealed that CD14 + MerTK+ ACs upregulated the lipid-metabolic *ApoE* gene ($p < 0.05$), 40-fold change compared to CD14 + MerTK- ACs.



Conclusion: In ascites from ACLF patients profound immunometabolic disturbances are evident with upregulated MerTK expression, impaired pro-inflammatory responses to LPS, preferential lipid metabolism and evidence of epithelial cell death. The impact of these perturbations on bacterial clearance requires further exploration.

THU-053

Usefulness of lactate-free Asian Pacific Association for The Study of Liver acute-on-chronic liver failure research consortium ACLF score for predicting short-term mortality in patient with alcoholic liver disease

Email: shivsarin@gmail.com

Background and aims: Asian Pacific Association for the Study of Liver (APASL) acute-on-chronic liver failure (ACLF) Research Consortium (AARC) proposed new prognostic scoring system of ACLF including lactate. However, lactate is not routinely checked in clinical practice of patient with ACLF in Korea. Therefore, we aimed to investigate the predictive accuracy of lactate-free AARC-ACLF score for predicting short-term mortality in patients with alcoholic liver disease
Method: A total of 749 ALD patients who had liver failure (bilirubin ≥ 5 mg/dL and INR ≥ 1.5) in AARC database were investigated. Diagnostic performances for short-term mortality were compared according to the area under receiver operating characteristic (AUROC) curve. Predictive accuracy of lactate-free AARC-ACLF score were compared with other prognostic scores in 143 ALD patients with liver failure and 65 ALD patients with ACLF according to AARC definition in Korean ACLF cohort.
Results: Among 749 patients, 28-day and 90-day mortality were 40.3% and 51.5%. There were no significant differences in AUROC for predicting 28-day and 90-day mortality between AARC-ACLF score and lactate-free AARC-ACLF score (28-day mortality: 0.758 vs. 0.759, P = 0.938, 90-day mortality: 0.747 vs. 0.740, P = 0.383). In Korean ACLF cohort, the AUROCs of lactate-free AARC-ACLF score for predicting 28-day and 90-day mortality were 0.861 and 0.846 in ALD with liver failure, and 0.865 and 0.873 in ALD patients with ACLF according to AARC definition, respectively. In Korean ALD patients with liver failure and ACLF according to AARC definition, diagnostic performance of lactate-free AARC-ACLF score for predicting 28-day and 90-day mortality was comparable to those of Model for End-stage Liver Disease (MELD), MELD-Na, Chronic Liver Failure-Sequential Organ Failure Assessment score.
Conclusion: Lactate-free AARC-ACLF score is as excellent as AARC-ACLF score in predicting short-term mortality in ALD patients with liver failure of AARC database and Korean ACLF cohort.

THU-054

Acute variceal bleed leads to acute on chronic liver failure like syndrome in a small proportion of cirrhotic patients: an analysis of 3845 patients from AARC data base

Harsh Vardhan Tevethia[1], Ashok Choudhury[2], Rakhi Maiwall[2], Manoj Kumar[2], Vikram Bhatia[2], Ankur Jindal[2], Shasthry Sm[2], Vinod Arora[2], V Rajan[2], Guresh Kumar[2], Priyanka Jain[2], Irene Paulson[2], Y K Joshi[2], Shiv Kumar Sarin[2]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: hershey4686@gmail.com

Background and aims: Acute on chronic liver failure patients have variable hemodynamic profiles, depending on the stage of underlying chronic liver diseases. These patients have high baseline hepatic venous pressure gradients (HVPG), which predisposes them to high risk of variceal bleed. However, it is not known, what proportion of patients with different Child's score develop post-bleed hepatic decompensation and ACLF like presentation. We investigated the spectrum, development of ACLF-like syndrome and mortality in patients with ACLF.
Method: Patients diagnosed to have chronic liver disease were recruited from Institute of liver and biliary sciences, New Delhi.This data was retrospectively collected on a predefined format from October 2009 to July 2018.A total of 3845 patients who had had the first episode of variceal bleed were analyzed. Of these, the patients who developed ACLF (APASL Definition) were also analysed.
Results: Out of the 3845 patients with first episode of Acute variceal bleed, Child A cirrhotics were 29.1% (n = 1118), Child B-30.1% (1172), Child -C-40.5% (1555).Males were 83.2% with mean age of 47.2 ± 11.25 years.Alcohol was the most common etiology in these patients. Among the Cirrhotics there was higher mortality in Child C Cirrhotics-35.7% (557) (p < 0.01). All Child A cirhotics with baseline bilirubin < 5/INR < 1.5/without encephalopathy/ascitis were then analysed for the development of ACLF post acute variceal bleed.A total of 1118 patients were analysed which showed the development of 3.6% (n = 39) of ACLF like syndrome
Conclusion: Variceal bleed can trigger ACLF like syndrome in a very small proportion (3.6%) of well compensated cirrhoticpatients. Prevention of acute variceal bleed should be incorporated even in well compensated cirrhotics to prevent development of ACLF.

THU-055

Improved stratification of liver failure syndromes using broad-panel bile acid LCMS phenotyping demonstrates novel pathways of dysregulation in tertiary bile acids in acute-on-chronic liver failure

Background and aims: Acute and acute-on-chronic liver failure (ALF; ACLF) are characterised by hyperbilirubinemia, systemic inflammation and high mortality. Differential metabolism of bile acids (BA) in ALF and ACLF is poorly understood. We sought to comprehensively phenotype the BA profile in ALF and ACLF via a novel LCMS method including tertiary BAs, and compare with commercial assays.
Method: Plasma samples from 106 subjects (ACLF n = 27, acute decompensation (AD) n = 31, ALF n = 35, HC n = 9, stable cirrhotic (SC) n = 5) were profiled using both a commercially available fully quantified clinical assay of 15 BA and a novel broad panel (BP) semi-quantitative UPLC-MS method with extended coverage of secondary BA (including conjugated) and sulphated BAs (tertiary BAs). Data were analysed using principal components analysis (PCA) and partial least squares discriminant analysis (PLSDA) and correlated with clinical severity scores and outcome.
Results: 12 BAs were represented on both panels with high levels of agreement on correlation analysis for 10 of the 12 (average rho 0.75, average $p < 0.01$). The BP illustrated robust differences in BA metabolism between patient groups. BA profiles from the BP demonstrated variance in PCA models associated with total bilirubin and MELD but individual BA measurements did not correlate directly with these measures. 30-day mortality was associated with an increase in BA sulfation, and reduced secondary bile acids, implying a role of gut microbiota activity. Ursocholanic acid concentration discriminated ACLF from non-ACLF (AUROC = 0.79, $p < 0.01$). ACLF patients could only be distinguished from AD patients by increases in BAs from the BP, including glycoursodeoxycholic acid sulfate, conjugates of hyodeoxycholic acid and murocholic acid sulfate (PLS-DA: $R^2X = 0.449$, $R^2Y = 0.533$, $Q^2 = 0.428$). ALF patients exhibited increased conjugates and sulfates of deoxycholic acid, lithocholic acid, and 5-cholenic acid-3β-ol compared with ACLF patients (PLS-DA for overall model: $R^2X = 0.523$, $R^2Y = 0.292$, $Q^2 = 0.19$, robust to permutation testing).
Conclusion: Wider BA coverage of tertiary BAs give new insight into BA metabolism in liver failure, particularly the progression from AD to ACLF and differentiating ALF from ACLF. While likely to represent metabolic manifestations of gut dysbiosis and reduced renal clearance of sulphated BA, validation in larger cohorts with correlation to immunological phenotypes is required.

Artificial liver support system improves short-term survival of patients with hepatitis B virus-related acute-on-chronic liver failure: A propensity-score matched analysis

Jun Li[1], Lingling Yang[1], Tianzhou Wu[2], Jiang Li[1], Jing Jiang[1], Jiaojiao Xin[1], Dongyan Shi[1], Yinyun Lu[1], Xingping Zhou[1], Jiaxian Chen[1], Jiaqi Li[1], Jianing Zhang[3], Keke Ren[1], Beibei Guo[1], Tan Li[1], xu xiaowei[1], Xin Chen[3]. *[1]The first affiliated hospital, Zhejiang university school of medicine, State key laboratory for diagnosis and treatment of infectious diseases, Hangzhou, China; [2]The first people's hospital of wenling, The infectious disease department, Taizhou, China; [3]Zhejiang university school of mdicine, Institute of pharmaceutical biotechnology, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is a complex syndrome with a high short-term mortality; in the meantime, liver transplantation is the only available treatment. This study aims to observe the effectiveness of the artificial liver support system (ALSS) as an alternative therapy on patients with hepatitis B virus-related ACLF (HBV-ACLF).
Method: The clinical data of 924 patients with HBV-ACLF receiving ALSS (n = 507) and standard medical treatment (SMT, n = 417) from Chinese Group on the Study of Severe Hepatitis B ACLF (COSSH-ACLF) open cohort from June 2013 to December 2017 were used in this study. The short-term (day 7, 14, 21, 28 and 90) mortality and cumulative survival rate were analyzed between ASSL and SMT groups. Propensity-score matched analysis was used to reduce bias in comparing these study outcomes.
Results: Among the patients assessed using the COSSH-ACLF criteria, the transplant-free mortality rate in ALSS patients' group at day 7, 14, 21 and 28 were significantly lower ($p < 0.001$) than those in SMT group (13.1-, 21.9-, 28.1-, 32.5% vs 22.1-, 33.9-, 41.7-, 45.2%, respectively), whereas the 90-day mortality rate has no significant difference ($p = 0.074$) between the two groups. Furthermore, the 7, 14, 21, 28 and 90-day cumulative survival rates were higher in ALSS patients' group compared to SMT group ($p < 0.001$). One-to-one paired cohorts were obtained following propensity-score matched analysis (172 pairs in ACLF-1, 101 pairs in ACLF-2 and 21 pairs in ACLF-3, totally 294 pairs). The 7, 14, 21, 28 and 90-day mortality rate were lower in ALSS group compared to SMT group ($p < 0.01$ at day 7, 14, 21, 28, $p = 0.055$ at day 90). The non-significance at day 90 might be associated with the limited patient cases. The cumulative survival rate of patients in ALSS group at day 7, 14, 21, 28, 90 were significantly higher than those in SMT group ($p < 0.01$). A lower mortality rate were observed in ACLF-1 ($p < 0.01$) and ACLF-2 ($p < 0.05$) in ALSS group compared to SMT group. Although several adverse events, including phlebothrombosis, plasma allergy response, bleeding from puncture site, hypotension and catheter-related infections were observed during ALSS therapy, they have no impact on patients' survival.

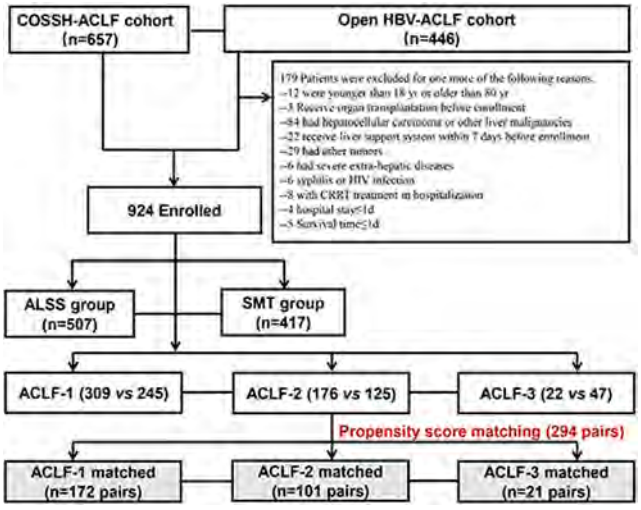

Figure: Patients select flow.

Conclusion: ALSS can improve short-term patients' survival in HBV-ACLF compared to SMT. Early application of ALSS helps to reduce short-term mortality rate especially in ACLF-1 and ACLF-2 grades.

THU-057

The homeostasis imbalance of autophagy in acute-on-chronic liver failure patients caused by acute exacerbation of chronic hepatitis B

Xiangying Zhang[1], Huijuan Wang[1], Ling Xu[1], Hongbo Shi[1], Yu Chen[1], Zhongping Duan[1], Feng Ren[1]. *[1]Beijing Youan Hospital, Capital Medical University, Beijing, China*
Email: renfeng7512@hotmail.com

Background and aims: Although autophagy is critical in various liver diseases, its role in acute-on-chronic liver failure (ACLF) caused by acute exacerbation of chronic hepatitis B (CHB) is still elusive. The aims were to (1) analyze the changes in autophagic response in CHB

and ACLF and (2) correlate expression of autophagy pathways with liver histology.
Method: Normal liver tissues (n = 10), liver tissues of CHB (n = 15) and HBV-related ACLF patients (n = 22) are included. Electron microscopy of the ultrastructure of the autophagy was carried out on liver specimens. Messenger RNA (mRNA) and protein expression were measured by quantitative real-time PCR, Western blot, and immunofluorescent staining, respectively. We further analyzed the correlation between the expression levels of autophagy-related molecules and liver injury.
Results: Electron microscopy identified that, compared with normal subjects, the numbers of autophagy, ERphagy and mitophagy were increased in liver of CHB subjects and further increased in liver of ACLF subjects, which confirmed by measurement of immunofluorescence double staining. The results of RT-PCR showed that, compared with CHB patients, the ER-phagy receptors including SEC62, RTN3 and CCPG1 were upregulated and the mitophagy markers including PINK1, FUNDC1 and Nix were upregulated in liver of ACLF subjects. For autophagic markers, the genes and proteins of LC3, Atg-5, Atg-7, and Atg-12 were slightly up-regulated in liver of CHB subjects and significantly down-regulated in liver of ACLF subjects; furthermore, the expression of Lamp-1 was not increased in CHB or ACLF, but p62 was slightly increased in CHB and significantly increased in ACLF, showing a positive correlation with serum ALT, AST and TBIL; whereas the expression of Beclin-1 was gradually decreased from CHB to ACLF, showing a negative correlation with serum ALT, AST and TBIL. Importantly, the autophagic markers were gradually decreased from the early stage of ACLF to the later stage of ACLF.
Conclusion: The homeostasis imbalance of autophagy may play a complicated role in the pathogenesis of ACLF, and an autophagy response may predict the occurrence of ACLF caused by acute exacerbation of CHB.

THU-058

Gene profiling of toll-like recepter signaling pathways in patients with acute-on-chronic liver failure

Ruihong Zhao[1], Wei Wu[1], Yu Shi[1], Jifang Sheng[1]. [1]*The first affiliated hospital of Zhejiang University, Hangzhou, China*
Email: jifang_sheng@zju.edu.cn

Background and aims: Toll-like receptors (TLRs) play a crucial role in detecting pathogen and organ/tissue injury. The aim of the study is to investigate the alteration of TLR signaling pathways in peripheral immune cells of patients with acute-on-chronic liver failure (ACLF).
Method: A total of 27 patients including 9 cases with compensated cirrhosis, 9 with de-compensated cirrhosis and 9 with ACLF, were enrolled in the study. Peripheral immune cells were isolated and alteration of TLR signaling pathways was evaluated using a RT² Profiler™ PCR Array. The fold change for each gene ($2^{(-\Delta\Delta CT)}$) was compared between the groups. Genes with fold change ratio ≥ 2 or ≤ 0.5 along with P value < 0.05 was considered to be differentially expressed.
Results: Neutrophils showed a broader gene adaptation than PBMCs in cirrhosis. A total of 17 genes were up-regulated in neutrophils from compensated cirrhosis, mainly distributing in adaptors, TLR interacting protein and downstream pathways. And 6 of 17 were seen in de-compensated cirrhosis. In contrast, no significant alteration of gene expression was found in PBMCs from cirrhosis. A trend towards down-regulation of the TLR signaling pathway was observed in both PBMCs and neutrophils from cirrhosis to ACLF. TLR3, IFNG, IL1B, TBK1, CCL2 and LTA were down-regulated in neutrophils, and TLR3, TLR9, TLR10, SIGIRR, IFNG, CCL2, CXCL10, PTGS2, IFNB1, LTA, IL2, IL12A and IRAK2 in PBMCs. On the other hand, CD14 and IL10 were up-regulated both in PBMCs and neutrophils of ACLF patients.
Conclusion: TLR signaling pathway genes is differentially regulated in PBMCs and neutrophils from cirrhosis to ACLF. A defective TLR3 and IFN expression, along with enhanced CD14 and IL10 expression, is a common hallmark of ACLF in peripheral immune cells.

Statins reduces liver fibrosis progression and promotes fibrosis regression in mice

Rola Al-Sayegh[1,2], Santia Diab[1], Ghewa El-Achkar[1], Wared Nour-Eldine[1], Eva Hamade[3], Sophie Lotersztajn[2], Aida Habib[1,2]. *[1]American University of Beirut, Biochemistry and Molecular Genetics, Beirut, Lebanon; [2]INSERM-U1149, Centre de Recherche sur l'Inflammation, Paris, France; [3]Lebanese University, Faculty of Sciences I, Laboratory of Cancer Biology and Molecular Immunology, Hadath, Lebanon*
Email: ah31@aub.edu.lb

Background and aims: Statins impede cholesterol and isoprenoid synthesis and have many pleiotropic beneficial roles including antioxidant and anti-inflammatory effects. In the present study, we investigated the effects of statin treatment on liver inflammation, fibrosis and regression in a carbon-tetrachloride (CCl_4) model of chronic liver injury.
Method: Liver fibrosis was induced by CCl_4. Pitavastatin (3 and 10 mg/kg) were administered. Fibrosis was assessed by sirius red staining, alpha-smooth muscle actin (αSMA) and expression of fibrotic genes. Inflammatory genes and proteins were assessed. Phenotyping of subtypes of intrahepatic leukocytes was performed by flow cytometry. *In vitro* studies were performed using bone-marrow derived macrophages.
Results: C7BL/6J mice treated with pitavastatin demonstrated a resistance to fibrosis after a chronic treatment with CCl_4 as evidenced by decrease sirius red staining and α-SMA. Hepatic fibrogenic and IL-6 gene expression were decreased. Pitavastatin accelerated the regression of fibrosis 3 days after CCl_4 cessation, as evidenced by a lower expression of sirius red, α-SMA and fibrogenic genes in pitavastatin-treated mice. This enhanced regression was associated with a decreased influx of Ly-6C^{high} macrophages into the liver. Accordingly, LPS-treated macrophage displayed a significant reduction in IL-6 and TNFα.
Conclusion: Our results demonstrate that pitavastatin attenuates the development of liver fibrosis, and accelerates its regression. Additional experiments are required to decipher the mechanisms by which pitavastatin modulates both liver regression and fibrosis and to elucidate the role of macrophages.
Funding: This study is funded by the National Council for Scientific Research in Lebanon (AH, EH 01-10-17).

THU-062

Exploring the immune environment in chronic hepatitis C associated fibrosis by examining the portal vein

Rabab Oun Ali Anwar Ali[1,1], Ohad Etzion[1], Grace Zhang[1], Elizabeth Townsend[1], Gabriella quinn[1], kareen hill[1], Christopher Koh[1], kimberly romito[2], Joseph Monsale[2], jennifer stoddard[2], Shakuntala Rampertaap[2], Elliot Levy[3], David E Kleiner[4], Sergio Rosenzweig[2], Theo Heller[1]. *[1]National Institutes of Health, Liver Disease Branch, Bethesda, United States; [2]National Institutes of Health, Immunology Service, Bethesda, United States; [3]National Institutes of Health, Diagnostic Radiology Department, Bethesda, United States; [4]National Institutes of Health, Laboratory of Pathology, Bethesda, United States*
Email: rabab.ali@nih.gov

Background and aims: Liver serves as an immunological barrier between portal and systemic circulation. Hepatitis C infection (HCV) results in immunological alterations in the setting of chronic inflammation and fibrosis in the liver. The aim was to assess the link between portal and peripheral immune markers and HCV associated fibrosis.
Method: 29 HCV patients underwent liver biopsy with portal vein cannulation. Portal and peripheral blood was obtained. Ishak fibrosis (IF) was used to score fibrosis. Flow cytometry and complete blood count assessed T, B- cells, and leukocytes, respectively. ELISA assessed cytokines grouped as proinflammatory (IL-6, IL-8, IL-18, TNF-α, TNF-β), type 1 helper T cell (Th1) cytokines (IFN-γ, IL-12p40, IL-12p70, CXCL9, CXCL10), and type 2 helper T cell (Th2) cytokines (IL-4, IL-5, IL-10, IL-13, CCL22, CCL11, CCL26). All reported correlations spearman $r > 0.35$, and $p < 0.05$.
Results: Portal and peripheral CD8+ T cells showed no correlation with fibrosis or cytokines. Among CD4+ T cells, higher portal (not peripheral) CD25+ and central memory CD4+ subsets were linked to fibrosis. Among proinflammatory cytokines, portal (not peripheral) IL-8 and TNF-α correlated positively with fibrosis and with portal CD4+ T and B cells. Among portal and peripheral Th1 cytokines, only IL-12p40 and IL-12p70 correlated with CD4+ T cells. In contrast, majority of the portal and peripheral Th2 cytokines i.e. IL-4, IL-5, IL-13, CCL22, and CCL26 correlated with CD4+ T cells. Portal CD4+ T cells were also linked to higher circulating eosinophils, cells of type 2 immunity. Similar to CD4 T cells, portal B cells were associated with Th2 cytokines IL-5, IL-13, and CCL22; and not with Th1 cytokines. Lastly, fibrosis and clinical markers of liver disease i.e. ALT, AST, ALP, AFP, and PT-INR, displayed associations with portal and peripheral sCD163, a type 2 polarized macrophage marker (M2).
Conclusion: Liver fibrosis showed associations with distinct CD4+ T cells and proinflammatory cytokines exclusively in the portal vein, which may be relevant to liver disease pathogenesis. Circulating immune cells displayed a predominant link to Th2 cytokines suggesting a possible shift in the type of immune responses in chronic HCV. The relationship of Th2 linked CD4+ T cells and M2 macrophage marker with increasing fibrosis and worsening liver disease suggests an importance of type 2 immunity in the pathogenesis of HCV associated fibrosis.

THU-063

Synergistic antifibrotic effect of rapamycin and zoledronic acid in advanced murine biliary fibrosis

Misbah Aslam[1,2], Muhammad Ashfaq-Khan[2], Asif Qureshi[3], Marcel Senkowski[2], Mirko nick[2], Yong Ook Kim[2], Leonard Kaps[2], Detlef Schuppan[2,4]. *[1]Shaheed Benazir Bhutto Women University, Peshawar, Pakistan; [2]Institute of Translational Immunology and Research Center for Immunotherapy, Mainz, Germany; [3]Dow university of medical sciences, Karachi, Pakistan; [4]Division of Gastroenterology, Beth Israel Deaconess Medical Centre, Boston, Germany*
Email: misbahmmg@gmail.com

There is no effective antifibrotic therapy for biliary fibrosis. The *in vivo* microenvironment, especially profibrotic monocyte-macrophages, are central modulators of hepatic stellate cell/myofibroblast activation and represent a promising drugable target. We assessed the antifibrotic potential of a combination of two clinically used drugs, Zoledronic acid (ZA) and Rapamycin (RA) that affect macrophage polarization and their putative fibrogenic potential.
Methods: Mdr2-knockout (Mdr2KO) mice that had received one dose of diethylnitrosamine (DEN) at day 5 after birth were treated from month 5-6 (stage of advanced fibrosis with emerging HCC) with 1) ZA alone (100 µg/kg body weight i.p., three times per week), 2) RA alone (5 mg/kg body weight orally three times per week), 3) the combination of both drugs. A fourth group served as vehicle treated control. The degree of biliary fibrosis and extent of inflammation was quantified histologically using morphometry of HandE, Sirius Red, alpha-SMA, CK-19 and CD68 stained sections. Collagen deposition was confirmed by hydroxyproline determination. Real time PCR was performed to analyze hepatic expression of fibrosis-related (Col1a1, Col3a1, aSMA), macrophage-specific (TNFa, CCL2, TGFb1, HIF1a and several MMPs), and angiogenic (VEGF) genes.
Results: Compared to vehicle treated controls and to mice treated with the single drugs alone, Mdr2KO mice that received the ZA/RA combination at peak fibrosis and for only one month demonstrated a

twofold reduced collagen deposition, with elimination of bridging fibrosis ($p < 0.0001$). This was accompanied by a similar reduction of the cholangiocyte-specific marker CK19 and the HSC activation (aSMA) and a significant suppression of profibrogenic transcripts including Col1a1, Col3a1, aSMA, TNFa, and markers of M2-type macrophages, including HIF1a and MMP9. Moreover, the number of YM1+ (M2-type) relative to CD68+ (total) macrophages was significantly reduced by combination treatment vs all other groups.
Conclusions: The combination of RA and ZA, two agents with macrophage modulating activity, induces a remarkable regression of even advanced biliary fibrosis. This antifibrotic effect goes along with a marked reduction of HCC formation. Since both drugs are used in the clinic for other indications, with a reasonable safety profile, their clinical testing should be considered in patients with fibrotic and (pre) cancerous PSC and other liver diseases.

THU-064
Identification of new epigenetic targets in hepatic fibrosis

Marina Bárcena-Varela[1], Hannah Paish[2], Laura Alvarez[1], Julen Oyarzabal[3], Felipe Prosper[4], Giuseppe Mazza[5], Krista Rombouts[5], Fiona Oakley[2], Jelena Mann[2], Carmen Berasain[1,6], Matías A Avila[1,6], Maite G Fernandez-Barrena[1,6]. [1]*CIMA.Universidad de Navarra, Hepatology Program, Pamplona, Spain;* [2]*Newcastle University, NFRG, Newcastle, United Kingdom;* [3]*CIMA.Universidad de Navarra, Molecular Therapies Program, Pamplona, Spain;* [4]*CIMA.Universidad de Navarra, Oncohematology Program, Pamplona, Spain;* [5]*Liver and Digestive Health-University Collage London, London, United Kingdom;* [6]*CIBERehd, Madrid, Spain*
Email: mbarcena.1@alumni.unav.es

Background and aims: Liver fibrosis is an essential component of chronic liver disease (CLD) and hepatocarcinogenesis. Hepatic cirrhosis, the most advanced stage of CLD, is becoming a worldwide health problem, with high mortality rates and no effective antifibrotic therapies available. Several molecular mechanisms implicated in the activation of hepatic extracellular matrix (ECM) producing cells have been identified. These include epigenetic mechanisms involving changes in DNA and histone methylation regulating the expression of key genes. Therefore, the enzymes responsible for these epigenetic events, such as DNA and histone-methyltransferases, would be attractive therapeutic targets. We have recently demonstrated that histone methyltransferase G9a and DNA methyltransferase DNMT1, forming a gene expression regulatory complex, play a key role in hepatocarcinogenesis. We have developed first-in-class dual inhibitors of these enzymes with therapeutic potential and significant antitumoral effects. The present study evaluates G9a as a possible therapeutic target in hepatic fibrosis and examines the antifibrotic potential of CM-272, our lead compound dual inhibitor of G9a/DNMT1.
Results: G9a is overexpressed in the fibrotic liver and is induced during the activation process of hepatic stellate cells (HSCs) in culture. We observed that G9a plays a very important role in the response of these cells to TGFβ, the main pro-fibrogenic cytokine, as G9a knockdown impaired TGFβ-mediated signaling and gene regulation. Treatment with CM-272 significantly modified the gene expression profile induced by TGFβ in human HSCs, prevented their profibrogenic response and the metabolic adaptation of these cells to hypoxia. We observed a potent antifibrotic effect of CM-272 in *ex vivo* models of precision-cut liver slices obtained from rats and patients subjected to profibrogenic stimuli (PDGF + TGFβ). Finally, the antifibrotic effect of CM-272 was corroborated in mouse models of hepatic fibrosis, such as the CCl_4 administration and bile duct ligation, where a very significant antifibrotic effect of CM-272 was observed without signs of hepatic or systemic toxicity.
Conclusion: G9a plays an important role in the activation of HSCs. We have demonstrated the antifibrotic potential of a dual G9a/DNMT1 inhibitory molecule, tested in *ex vivo* and *in vivo* models without apparent toxic effects. Our data suggest a new strategy for the development of effective therapies against fibrosis.

THU-065
Metformin reverses liver fibrosis via AMPK/PGC-1α mediated mitochondrial metabolic switch

Jianye Cai[1], Jia Yao[1], Jun Zheng[1], Liang Chen[1], Tongyu Lu[1], HuaXin Chen[2], Yingcai Zhang[1], Yang Yang[1]. [1]*Organ Transplantation Institute, Department of Hepatic Surgery and Liver Transplantation Center of the Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China;* [2]*Cell-Gene Therapy Translational Medicine Research Center, The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*
Email: yysysu@163.com

Background and aims: Liver fibrosis is pathological phenomena of dysfunctional repair response to chronic liver injury, which is characterized by the activation of hepatic stellate cells (HSCs). Cellular metabolic phenotype, which is regulated by a critical sensor AMPK, is closely related to cell fate. However, the roles of AMPK signaling pathway-mediated metabolic switch in liver fibrosis have not been well demonstrated.
Method: Immunofluorescence staining and q-PCR analysis were performed to identify the AMPK activity and the expression of metabolic genes in liver samples of patients with cirrhosis and mice following administration of CCl_4. Glucose uptake ability, oxygen consumption rate, lactate accumulation and ATP production, as well as HIF-1α activity, PGC-1α expression were measured in primary HSCs during transdifferentiation and after metformin administration, respectively. PGC-1α vectors were constructed and overexpressed in activated myofibroblasts to determine the effects of glycolytic and pro-fibrotic activities. Furthermore, mice with established liver fibrosis were administrated with metformin to measure the improvement of fibrotic status.
Results: We found that AMPK was inactivated in fibrotic regions in both patients with cirrhosis and mice following administration of CCl_4, which is associated with the increasing expression of pro-glycolytic proteins, such as Glut1, HK2, PKM2 and LDHA. Consistently, primary HSCs isolated from fibrotic models or myofibroblasts transdifferentiated from cultured, quiescent HSCs exhibited pro-glycolytic switch from oxidative phosphorylation, which could be rescued by activation of AMPK agonist, metformin. Mechanically, lower AMPK activity inhibited PGC-1α expression, an important transcription factor of mitochondrial biogenesis, but activated HIF-1α signaling. Enhancement of mitochondrial biogenesis and oxidative phosphorylation by overexpression of PGC-1α converted myofibroblasts to quiescent HSCs. In addition, metformin therapeutically alleviated CCl_4-induced liver fibrosis in an AMPK-dependent manner in mice.
Conclusion: This study clarified that AMPK activity-dependent pro-glycolytic switch drove the activation of HSCs and progress of liver fibrosis. AMPK agonist metformin might be expected to reverse established liver fibrosis by improvement of mitochondrial biogenesis.

Email: arieirace@yahoo.com.mx

Background and aims: Dozens of non-invasive models composed of blood biochemical biomarkers have been proposed to detect liver fibrosis, including aspartate aminotransferase to platelets ratio index (APRI). The latest research has shown that ultrasound elastography can measure the hardness of liver tissue to determine the degree of

hepatic fibrosis with features of non-invasiveness, simplicity, speed and repeatability. Non-invasive methods including ultrasound elastography have emerged within the past decade and are increasingly replacing liver biopsy for liver fibrosis assessment, avoiding the risks and discomforts of this invasive method.
It is important to know the correlation that exists with two non-invasive methods of fibrosis. Determine if there is an association with the APRI and the measurement by hepatic elastography. Calculate the APRI for patients who underwent hepatic elastography by shear wave elastography.
Method: Cohort study, retrospective, analytical. The clinical records of the 2017–2018 period were reviewed of patients who attended the outpatient Gastroenterology and elastography was performed by shear wave. The liver test was analyzed and APRI was calculated, to later make a comparison with both. Patients who did not have data in the electronic file were excluded. Average and standard calculation were calculated for the continbes and association by means of Pearson. Statistical analysis was performed through the SPSS program, 19 version.
Results: One hundred and twenty-one shear wave elastography were performed in a year, the average age of the patients was 59.57 ± 12.64 years, predominant gender was the female 70 (57.8%), etiologies of liver diseases: PBC 4, Overlap syndrome (PBC + AIH) 2, NASH cirrhosis 16, cryptogenic cirrhosis 14, alcoholic cirrhosis 22, AIH cirrhosis 5, alcohol cirrhosis plus chronic hepatitis C, HVC cirrhosis 9, DILI 1, NAFLD 33, AIH 4, HVC 10. Of these patients, only patients with liver cirrhosis were 68 (56%), gender men 36 (52.9%) and women 32 (47.1%), we obtained the mean and standard deviation: APRI = 0.58 ± 0.59, Child Pugh = 5.5 ± 1.0, MELD = 10.5 ± 3.0, Elastography = 8.35 ± 3.83 Kpa, platelets = 142161 ± 76380, albumin = 3.67 ± 0.54. Sixteen (23.5%) patients presented with esophageal varices. Pearson's association coefficient with the variables of APRI and platelets was obtained obtaining p = 0.000, Elastography and platelets with p = 0.046. APRI and elastoscopy with p = 0.068.
Conclusion: There is no correlation with the rate of APRI and hepatic elastography, but liver elastography correlates with the number of platelets.

THU-067

Selective targeting of GLI1 suppresses the differentiation of hepatic progenitor cell towards fibrogentic cholangiocyte and fibrosis progression

Jiamei Chen[1], Yonghong Hu[1], Long Chen[1], Yongping Mu[1], Ping Liu[1]. [1]*Shuguang Hospital affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China*
Email: cjm0102@126.com

Background and aims: Although the role of canonical Hedgehog pathway has been well established in liver fibrosis, how Gli1 is regulated in a smoothened (SMO)-independent manner is still a puzzle. We studied the role of Gli1 in hepatic progenitor cell (HPC) differentiation and liver fibrosis progression.
Method: Liver samples of 144 chronic hepatitis B patients were obtained from biopsy. Masson staining and cytokeratin19 (CK19) immuno-staining were performed to observe the collagen deposition and ductular reaction. Fibrosis was induced in F-344 rats via subcutaneous injection of 30% carbon tetrachloride (CCl_4) twice a week for 6 weeks. Then, CCl_4 was administered in conjunction with intragastric 2-acetylaminofluorine (2-AAF) for 3 weeks to induce activation of HPCs *in vivo*, meanwhile, GANT61, a Gli1 inhibitor was intraperitoneal injected to investigate the therapeutic efficacy on ductular reaction and liver fibrosis progression. *In vitro* WB-F344 cells, the HPC line were treated with sodium butyrate (SB) to provide direct evidence for differentiation towards cholangiocytes, meanwhile with or without GANT61 or Gli1 siRNA.
Results: 144 Patients were divided into four groups (S1, S2, S3, S4) according to fibrosis stage. Interestingly, expression of CK19 was notably enhanced with the severity of liver fibrosis and closely correlated with the increase in the percent of positive area ratio of collagen ($r = 0.31$, $p < 0.001$). The results *in vivo* showed that expressions of OV6 and Epcam and ductual cell markers (CK19 and CK7) were increased significantly in CCl_4/2-AAF treated group compared to the CCl_4 only treated group. Double staining showed that OV6 was largely colocated with CK19 positive cells, and the number of OV6 (+)CK19 (+) cells was obviously increased after administration of 2-AAF. The hydroxyproline content, the positive area of collagen and expressions of α-smooth muscle action, collagen type I, collagen type IV, Ki67, Dhh and Gli1were significantly increased, While these datas were remarkably decreased in the GANT61 group compared to CCl_4/2-AAF treated group. These results suggested that a large number of HPC were activated and proliferated, and differentiated to cholangiocyte to promote the fibrosis progression after administration of 2-AAF, while inhibiting the Gli1 expression suppressed ductular reaction and fibrosis progression. *In vitro*, expressions of CK19, CK7, Ki67, Dhh and Gli1 were significantly increased after treatment with SB for 4 days. Interestingly, expressions of CK19, CK7, Ki67 and Gli1 were significantly down-regulated in the GANT61 group and Gli1 siRNA group.
Conclusion: Gli1 directs differentiation of HPC to fibrogenic cholangiocyte and promotes liver fibrosis progression, blocking Gli1 inhibits ductular reaction and accelerates fibrosis reversal, suggesting that Gli1 may be a potential treatment target to treat liver fibrosis.

THU-068

Alcoholic and non-alcoholic fatty liver disease and liver-related mortality: A cohort study

Yong Kyun Cho[1], Keonhwa Kim[1], Yoosoo Chang[1], Juhee Cho[1], Hyun-Suk Jung[1], Kyung Eun Yun[1], Jiin Ahn[1], Seungho Ryu[1]. [1]*Kangbuk Samsung Hospital, Sungkyunkwan University, School of Medicine, Seoul, Korea, Rep. of South*
Email: choyk2004.cho@samsung.com

Background and aims: We compared liver-related mortality by fibrosis severity between two types of fatty liver disease (FLD), non-alcoholic FLD (NAFLD) and alcoholic FLD (AFLD) in a large cohort of non-obese and obese individuals.
Method: A cohort study was performed with 437, 828 Korean adults who were followed for up to 14 years. Steatosis was diagnosed based on ultrasonography; fibrosis severity was determined by the fibrosis-4 score (FIB-4). Vital status and liver-related deaths were ascertained through linkage to National Death records.
Results: The prevalence of NAFLD and AFLD were 20.9%, and 4.0%, respectively. During 3, 145, 541.1 person-years of follow-up, 109 liver-related deaths were identified (incidence rate of 3.5 per 10^5 person-years). When changes in fatty liver status, FIB-4, and confounders during follow-up were updated as time-varying covariates, compared with the reference (absence of both excessive alcohol use and FLD), the multivariable-adjusted hazard ratios (HRs) with 95% confidence intervals (95% CIs) for liver-related mortality among those with low, intermediate, and high FIB-4 scores were 0.43 (0.19–0.94), 2.74 (1.23–6.06), and 84.66 (39.05–183.54), respectively, among patients with NAFLD, whereas, among patients with AFLD, the corresponding HRs (95% CIs) were 0.67 (0.20–2.25), 5.44 (2.19–13.49), and 59.73 (27.99–127.46), respectively. The associations were more evident in non-obese individuals than in obese individuals (P for interaction = 0.004).
Conclusion: In this large cohort of young and middle-aged individuals, NAFLD and AFLD with intermediate to high fibrosis scores wereassociated with an increased risk of liver-related mortality in a dose-dependent manner, especially among non-obese individuals.

Human adipose derived stem cells exhibit enhanced liver regeneration in liver fibrosis model by controlled releasing hepatocyte growth factor

Ja Sung Choi[1], Sung-Whan Kim[2]. [1]*Catholic Kwandong University College of Medicine, International St. Mary's Hospital, Internal Medicine, Incheon, Korea, Rep. of South;* [2]*Catholic Kwandong University College of Medicine, Gangneung, Korea, Rep. of South*
Email: cjs0123@hanmail.net

Background and aims: Although mesenchymal stem cells (MSCs) provide effective therapy for liver fibrosis, there are conflicting data regarding their marginal therapeutic effects. This study aimed to enhance the potential of hepatocyte regeneration in human adipose mesenchymal stem cells (ASCs) and investigate whether they have robust therapeutic efficacy in experimental liver fibrosis.
Method: ASCs were cultured with four cytokines (ASC-C), the expression of hepatogenic factors was detected by microarray, and the effects of conditioned medium (CM) from ASC-C on the activation of hepatic stellate cells were analyzed. The therapeutic effects and mechanism of liver fibrosis induced by thioacetamide (TAA) were determined after cell transplantation. ASC-C exhibited high levels of hepatogenic (HGF, G-CSF), anti-apoptotic (IGFBP-2), and chemokine (IL-8) genes and increased expression of hepatocyte specific proteins.
Results: ASC-C CM inhibited the activation of hepatic stellate cells *in vitro*, and injection of ASC-C significantly delayed TAA-induced liver fibrosis and improved liver function and regeneration *in vivo*. In addition, human albumin-expressing ASC-C were observed in the livers of recipient animals. High levels of expression of HGF and its downstream signaling molecules, including p-38, were detected in the ASC-C-injected livers. Transplantation of ASC-C exerts anti-fibrotic effects and accelerates liver regeneration.
Conclusion: Thus, ASC-C may be a novel candidate for the enhanced treatment of liver cirrhosis in clinical settings.

Email: mmoralesruiz@gmail.com

Background and aims: Chronic liver diseases are related with the increase in collagen I production and deposition in the liver. This protein is synthesised in the endoplasmatic reticulum after the assembly of two peptides of procollagen alpha 1 (COL1A1) and one peptide of procollagen alpha 2 (COL1A2). The expression of both genes is regulated by different transcription factors such as SP1 and Ets. Accordingly, it has clinical interest to search for regulators of both transcription factors. In this context, the nuclear factor TCF20 acts as a co-activator of a variety of transcription factors, including SP1 and Ets. However, its function has not previously been studied in fibrogenic processes. Therefore, the objective of this study was to determine the role played by TCF20 in liver fibrosis through the generation of a mouse model of TCF20 gene deficiency.
Method: TCF20 knock-out mice were generated by microinjecting mouse embryonic stem cells $D09^{tm1\ (KOMP)Mbp}$ (KOMP Repository) to blastocytes C57Bl/6J.Ola.Hsd. Liver fibrosis was induced by the administration of carbon tetrachloride (CCl_4) three times a week during four weeks. The proteome from embryonic livers (E18.5) was analyzed by Label-free nLC MS/MS (Thermo Fisher Scientific). Mouse hepatic stellate cells (GRX) were transfected with plasmids that express a specific shRNA to silence TCF20 expression.
Results: TCF20 knock-out mice ($TCF20^{-/-}$) showed to be newborn-lethal. Liver proteomic analysis from $TCF20^{-/-}$ mice embryos (n = 5) revealed alterations in the aminoacid synthesis pathway and the oxidative phosphorilation. In contrast, heterozygous mice ($TCF20^{\pm}$) resulted to be viable without any apparent abnormality. After the CCl_4 treatment, $TCF20^{\pm}$ mice showed a significant increase in fibrotic area when compared to $TCF20^{+/+}$ (3.2 ± 0.1 vs 2.1 ± 0.1%, respectively; $p < 0.001$); as well as increased levels of ALT (2145 ± 1367.7 vs 690.4 ± 215.9 U/L, $p < 0.01$), AST (1413 ± 142.7 vs 562.4 ± 146.9 U/L, $p < 0.01$) and BUN (21 ± 2.5 vs 14.4 ± 1.0 mg/dL, $p < 0.05$). Seventy percent of TCF20 gene silencing in GRX cells was associated with an over-expression of COL1A1 when compared to control ($p < 0.05$).
Conclusion: TCF20 total deficiency is lethal in newborn mice. TCF20 partial deficiency is associated to increased fibrosis and liver injury *in vivo* and to an overexpression of collagen I in mouse HSC. Our results show a new function for TCF20 as a regulator of the severity of liver fibrosis after tissue damage.

THU-071

Matrix modulation in chronic liver injury and resolution

Marika Crescenzi[1], Chiara Frasson[2], Annalisa Stefani[3], Valentina Bertazzo[3], Patrizia Burra[4], Francesco Paolo Russo[4]. [1]*University of Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy;* [2]*Fondazione Città della Speranza, Istituto di Ricerca Pediatrica, Padua, Italy;* [3]*Istituto Zooprofilattico delle Venezie, Padua, Italy;* [4]*University Hospital Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy*
Email: Marikacrescenzi@hotmail.com

Background and aims: A sexual dimorphism in liver inflammation and repair was previously demonstrated in a mouse model of acute liver injury. The aim of our study was to verify if hepatic matrix is differently modulated according to gender
Method: A chronic hepatic injury was established in Balb/cJ mice intra-peritoneally injected with CCl4 and sacrificed at week 2, 6, 12 and after 8 weeks of self-healing (recovery group). Fibrosis was evaluated. Collagen III and TIMP-1 were evaluated by Western Blot. The expression of MMP9 and MMP13 mRNAs was evaluated by qRT-PCR. The amount of Kupffer cells was investigated by flow-cytometry on liver single cell suspension.
Results: The amount of fibrosis in the recovery group was higher in females with respect to males (mean±ds females vs males: 4.48 ± 1.39 vs 2.46 ± 0.53 p = 0.032). Collagen III was found lower in females than in males at week 2, with a significant increase along the treatment, but only in female mice. TIMP-1 protein showed a progressive accumulation from week 2 to 12 only in females, with a significant decrease during the recovery period. The analysis of MMP9 revealed a down modulation (68%) of mRNA in males from week 6 to the end of the recovery period; moreover MMP9 mRNA was found higher (60%) in females than in males of the recovery group. MMP13 mRNA was found higher in males than in females at week 12 showing a progressive down modulation in females from week 6 to the end of the recovery period. Kupffer cells were abundant in both female and male mice in the early chronic liver damage and significantly decreased over time, albeit in the recovery group female mice showed a significant higher amount of this cell population, in comparison with males.
Conclusion: During fibrosis resolution, female livers failed to properly regenerate compared to males. An imbalance in MMPs-TIMP-1 homeostasis was apparent in chronically-injured female livers. Modulations of MMP9 mRNA are in line with fluctuations observed in fibrosis amount. MMP13 mRNA modulations agree with the observed flows of Kupffer cells but suggest that other cells than Kupffer are responsible for MMP13 mRNA variations.

Email: fcubero@ucm.es

Background and aims: The *Ras* genes (*H-ras*, *K-ras* and *N-ras*) encode for the RAS proteins with pivotal roles in the regulation of cell survival, differentiation, growth and apoptosis. Apart from their oncogenic properties, little is known on the context and cell-dependent phatophysiological roles of RAS proteins. In particular, N-RAS is critically involved in immune cell function. Hepatic fibrogenesis develops in response to inflammatory cytokines, cellular interactions with immune cells and morphogenic signals. In the present work, we hypothesized that N-RAS plays a pivotal role in the pathophysiology of liver fibrogenesis.
Method: N-ras deficient (*N-ras*$^{-/-}$) and wildtype (*N-ras*$^{+/+}$) mice bred in a C57BL/6 background were subjected either to perifibrilary or periportal fibrosis using 28 days (i) bile duct ligation (BDL) and (ii) CCl_4-induced liver fibrosis, respectively. Sham-operated and corn-oil-injected mice were included as controls. Histopathological examination of livers, immunofluorescence and immunohistochemistry, Western Blot and Real time (RT)-qPCR studies and gene array analysis were performed.
Results: Histopathological examination of *N-ras*$^{-/-}$ mice showed rupture increased presence of necrotic foci associated with significantly elevated markers of liver damage in serum compared with *N-ras*$^{+/+}$, 28 days after BDL and CCl_4. *N-ras*$^{-/-}$ livers exhibited increased cell death and compensatory cell proliferation markers such as PCNA and Ki-67. Futhermore, CD11b^{+}, F4-80^{+} and CD45^{+} cells were significantly increased in *N-ras*$^{-/-}$ compared with *N-ras*$^{+/+}$ animals, 28 days after treatment. Moreover, Collagen I and III deposition and α-smooth muscle actin (αsMA) mRNA and protein expression were significantly elevated. Mechanistically *N-ras*$^{-/-}$ livers showed activation of cleaved Caspase 8, RIPK1/3 and pMLKL together with decreased cleaved Caspase-3. Additionally, *N-ras* deficiency triggered overexpression of pAKT and pJNK1/2.
Conclusion: Our results indicate that N-ras plays a pivotal role in liver fibrogenesis. N-ras deficiency triggered cleaved Caspase 8, RIPK1/3 and pMLKL-dependent cell death, exacerbated compensatory proliferation, increased inflammation and immune cell infiltration and hepatic fibrogenesis. These findings suggest that N-RAS modulation could be a novel therapeutic approach for the treatment of chronic liver injury.

The use of APRI and FIB-4 scores versus transient elastography for the assessment of liver fibrosis stage in patients with chronic hepatitis C: Is it possible to reduce the need for elastography?

Nikolaos Papadopoulos[1], Sofia Vasileiadi[2], Stavroula Michalea[2], Pinelopi Antonakaki[2], Maria Papavdi[2], Erminia Dellaporta[2], Emmanouel Koullias[2], Evaggelia Koutli[2], Spilios Manolakopoulos[2,3], Ioannis-Georgios Koskinas[2], Melanie Deutsch[2]. [1]*417 Army Share Fund Hospital, 1st department of Internal Medicine, Athens, Greece;* [2]*Hippokration Hospital, 2nd Department of Internal Medicine, Athens University Medical School, Athens, Greece;* [3]*Laiko General Hospital, Academic Gastroenterology Department, Athens, Greece*
Email: nipapmed@gmail.com

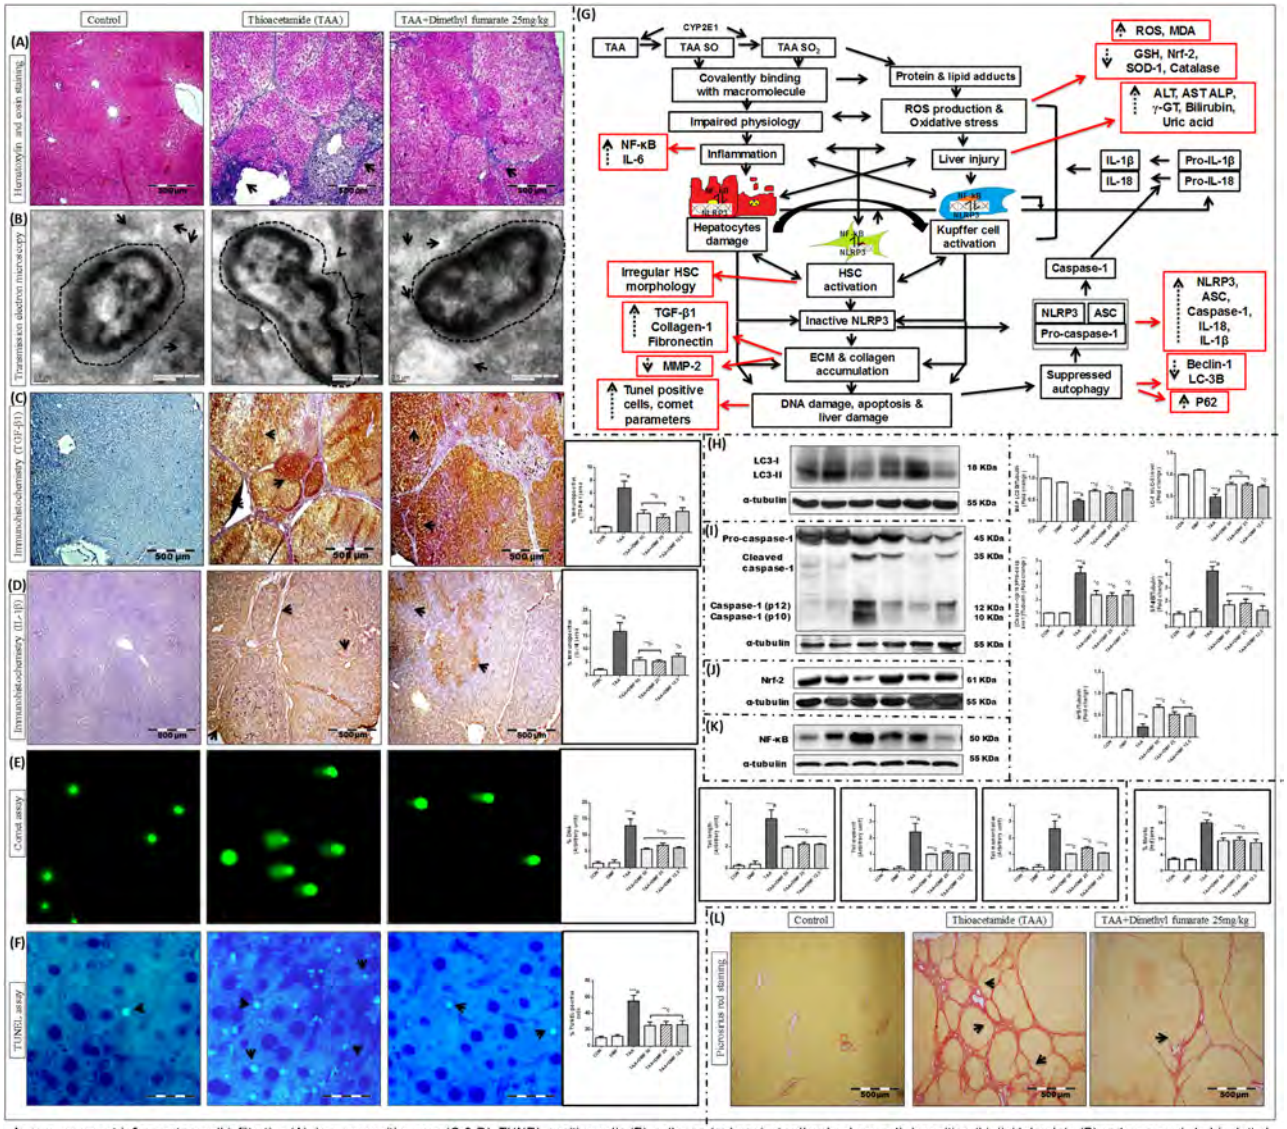
Background and aims: Liver fibrosis staging, based especially on liver stiffness measurement (LSM) with TE, represents an important step during the management of chronic hepatitis C (CHC). However, TE is not widely available and there is a need for less expensive and simpler non-invasive approaches especially in terms of the hepatitis C elimination strategy worldwide. In this context the use of scoring systems such as APRI and FIB-4 has been suggested but their validation in several populations is emerging. In this study the diagnostic performance of APRI and FIB-4 to detect significant fibrosis (F3) or cirrhosis (F4) compared to TE have been evaluated in a Greek CHC cohort.
Method: We retrospectively enrolled 589 patients admitted to our tertiary liver center with CHC who underwent TE [males: 370 (64.5%), mean age: 51.8 ± 12.2 years] between May 2014 and September 2018. The results of APRI and FIB-4 scores were compared to LSM.
Results: 117/589 (19.9%) patients had LSM values between 9–11.9 kPa and were classified as F3, while 249/589 (42.3%) were classified as F4. APRI (AUC = 0.735, p = 0.021) and FIB-4 (AUC = 0.769, p = 0.02) scores predicted F4 patients adequately. Cut-off values were determined as 0.66 (sensitivity 70%, specificity 66%) for APRI and 1.82 (sensitivity 72%, specificity 69%) for FIB-4. However, both scores were ineffective in predicting F3 patients. Cut-off values of 0.65 for APRI and 1.46 for FIB-4 predicted F3/F4 patients as one group of patients (sensitivity 65% and 74.5% respectively, specificity 75.5% and 70% respectively). Additionally, the use of APRI/FIB-4 as a combination marker with these cut-off values (0.65/1.46) adequately predicted F3/F4 patients (sensitivity 60%, specificity 83.5%, PPV 86%, NPV 55%). Furthermore, we determined that the same APRI/FIB-4 combination marker predicted adequately patients with low grade fibrosis F0-F2 (sensitivity 83.5%, specificity 60%, PPV 55%, NPV 86%) and could be used in order to reduce the need for LSM.
Conclusion: APRI and FIB-4 performed well in predicting advanced fibrosis. A proposed APRI/FIB-4 cut-off value of 0.65/1.46 as a combination marker could be used as a screening tool instead of LSM which is not widely available, especially in determining low grade fibrosis. Further prospective validation studies are required to confirm this finding.

THU-074

Anti-fibrotic effect of dimethyl fumarate on rat liver fibrosis induced by thioacetamide: Role of NF-kappa B, NLRP3, Nrf2 and autophagy

Durgesh Dwivedi[1], G. B. Jena[1]. [1]*National Institute of Pharmaceutical Education and Research, Facility for Risk Assessment and Intervention Studies, Department of Pharmacology and Toxicology, S A S Nagar, India*
Email: durgeshdubey111@gmail.com

Background and aims: Fibrosis is the most common pathway involved in acute and chronic liver diseases, which ultimately leads to the end-stage liver cirrhosis. World Health Organisation in 2018 reported that cirrhosis is at 9th position in top 10 causes of death in lower-middle income countries. Liver injury activates hepatic stellate cell (HSC) that releases extracellular matrix proteins, facilitates the deposition of collagen at the site of injury and results fibrosis. Thioacetamide (TAA) is one of the most widely known hepatotoxicants, precisely mimics the initiation and progression of human liver damage in experimental animal models. Dimethyl fumarate (DMF) used for the treatment of multiple sclerosis and selected as a pharmacological intervention agent in the present investigation. The aim is to evaluate the hepatoprotective as well as anti-fibrotic potential of DMF against TAA-induced hepatic damage in rat.
Method: Male Wistar rats (250 ± 20 g) were exposed to TAA (normal saline) intraperitoneally at the dose of 200 mg/kg, twice weekly, while DMF (0.5% sodium CMC) was administered everyday by oral



Arrows represent inflammatory cell infiltration (A), immunopositive area (C & D), TUNEL positive cells (F), collagen (red against yellow background) deposition (L), lipid droplets (B) and area encircled in dotted lines showing HSCs (B). Comet assay (E). Immunoblots of selected targets (H, I, J &K). Schematic presentation of TAA-induced possible hepatic damage and subsequent protection with DMF at different targets. Dashed arrow represents either decrease or increase in respective expression/level in red boxes (G).

gavage at the doses of 12.5, 25 and 50 mg/kg for 6 consecutive weeks. Several parameters like biochemical, histopathological, transmission electron microscopy (TEM), immunohistochemical and immunoblotting were evaluated.

Results: TAA exposure significantly reduced the body weight, increased liver weight while DMF treatment did not restore the same. TAA-induced significant increase in the liver weight and profuse nodular appearance might be due to collagen deposition, new angiogenesis, and deposition of other fibrotic components. DMF intervention significantly ameliorated TAA-induced increase in AST, ALT, gamma GT, bilirubin, uric acid, MDA and decrease in reduced glutathione. TAA-induced significant increase in plasma transaminases (AST, ALT) level was might be due to damage of hepatocyte membrane results release of transaminases. Moreover, DMF treatment significantly normalised TAA-induced alterations in histopathological findings such as severe degree of lymphocyte infiltration, collagen deposition, necrosis, bridging fibrosis. Further, TAA exposure increased the TUNEL positive cells, %DNA, tail length, olive tail moment and activated HSCs, whereas DMF intervention normalised the same. Furthermore, DMF treatment significantly restored the TAA-induced alterations in inflammatory cascade (NLRP3, ASC, caspase-1, NF κappa B, IL-6), fibrogenic (TGF beta1, fibronectin, collagen1, MMP2), anti-oxidant (Nrf2, SOD-1, catalase), and autophagy markers (beclin-1, MAP LC-3B, p62).

Conclusion: Present investigation confirmed the anti-fibrotic effect of DMF as mediated by the restoration of TAA-induced oxidative stress, inflammatory cascade, DNA damage, histopathological changes, autophagy and anti-oxidant levels.

2d- shear wave elastography for the spleen stiffness evaluation: A non-invasive marker for predicting high risk varices in patients with compensated liver cirrhosis

Renata Fofiu[1,1], Ioan Sporea[1], bende felix[1], Mirela Danila[1], Alina Popescu[1], Roxana Sirli[1]. *[1]Timișoara, Department of Gastroenterology and Hepatology, University of Medicine and Pharmacy "Victor Babeș" Timișoara, Romania, Timișoara, Romania*
Email: renata.fofiu@yahoo.com

Background and aims: Ultrasound based elastographic methods and biological markers can be used as non-invasive tools for predicting

the presence of high risk varices (HRV), defined as grade II, III esophageal and gastric varices, in patients with compensated liver cirrhosis. The **aim** of the study was to determinate the utility of spleen stiffness (SS) values measured by 2D-SWE as non-invasive marker for prediction of HRV, in patients with compensated liver cirrhosis.
Method: A prospective study was performed in 55 subjects with compensated liver cirrhosis, who underwent both spleen stiffness measurements (SSM) with a 2D-SWE technique (General Electric LOGIQ E9 XD clear 2.0) and upper endoscopy in the same admission. Spleen stiffness was performed with the patient in supine position and the SWE evaluation box was placed in the middle of the spleen, avoiding large vessels. Reliable SSM were defined as the median value of 10 measurements acquired in a homogenous area and an interquartile range/median (IQR/M) <0.30. Compensated liver cirrhosis was diagnosed based on clinical, biological and elastographic criteria (FibroScan > 12, 5 kPa)
Results: We obtained reliable SSM in 53/55 subjects (96.4%). 28/55 (51%) subjects had HRV. The mean SS values for patients with HRV were significantly higher as compared to those with first grade or no varices (18.6 ± 4.3 kPa vs. 15.7 ± 2.8 kPa with p = 0.0056). The best SS cut-off value measured with 2D-SWE-GE for predicting the presence of HRV in our study group was: 17.2 kPa (AUROC-0.80; sensitivity-67.8%; specificity-92%; PPV-91%; NPV-71, 9%).
Conclusion: Using the SS cut-off value > 17.2 kPa obtained by means of 2D-SWE we can rule in the presence of HRV, with a positive predictive value of 91%.

THU-076

SPP1 gene knockout in human hepatic stellate cells decreased profibrogenic cytokines and collagen gene expression

Joseph George[1], Takashi Saito[1], Nobuhiko Hayashi[1], Kazuaki Ozaki[1], Mikihiro Tsutsumi[1], Mutsumi Tsuchishima[1]. [1]*Kanazawa Medical University, Hepatology, Uchinada, Japan*
Email: georgej@kanazawa-med.ac.jp

Background and aims: Secreted phosphoprotein-1 (SPP1) is a stress sensitive multifunctional cytokine involved in innate immunity, cell proliferation, invasion, and metastasis. It was observed that SPP1 promotes activation and transformation of resting hepatic stellate cells into myofibroblast like cells and drives collagen synthesis. The purpose of the study was to evaluate the role of SPP1 on activation and transformation of human hepatic stellate cells and subsequent production of profibrogenic cytokines and collagen gene expression.
Method: Primary human hepatic stellate cells were isolated from pieces of surgically resected human liver tissue after pronase and collagenase digestion and purified using density gradient centrifugation. The isolated and purified stellate cells were cultured with appropriate medium for 48 h. The cultures were then divided into two sets and one set was treated with SPP1 CRISPR guide RNA sequences that efficiently knockout SPP1 gene without significant binding of Cas9 elsewhere in the genome. The second set of cultures without SPP1 CRISPR gRNA treatment served as control. The cultures were maintained for another 7–10 days. The cells were fixed and stained for α–smooth muscle actin (α–SMA) to examine the activation of stellate cells. Western blotting was carried out for SPP1, PDGF-B, TGF-β1, and collagens type I and type III. qPCR was performed to quantify mRNA of α-SMA, and collagens type I and type III.
Results: Immunocytochemical staining showed that the isolated quiescent stellate cells were positive for glial fibrillary acidic protein (GFAP) and negative for α-smooth muscle actin (α-SMA). Western blotting demonstrated complete knockout of SPP1 after treatment with CRISPR/Cas9 gRNA. Knockdown of SPP1 in primary hepatic stellate cells prevented activation and transformation of over 50% hepatic stellate cells into myofibroblast like cells and depicted marked decrease in the staining intensity of α-SMA. Western blotting for PDGF-B, TGF-β1, and collagens type I and type III showed significant decrease in the protein levels in SPP1 knockout cells. qPCR demonstrated marked reduction in the expression of α-SMA and collagens type I and type III mRNA indicating decreased activation of stellate cells and reduced synthesis of collagens after deletion of SPP1 gene.
Conclusion: The results of the present study demonstrated that SPP1 regulates profibrogenic cytokines and activation of stellate cells contributing to the pathogenesis of hepatic fibrosis. Furthermore, blocking of SPP1 has potential therapeutic implications to arrest hepatic fibrosis and related events.

Fibro-protective molecular and cellular mechanisms emerge during resolution from thioacetamide-induced fibrosis

Francis Gratte[1,2], Jully Gogoi-Tiwari[2], Xiao Liu[3,4], Tatiana Kisseleva[4], David Brenner[3], John Olynyk[1,5,6], Janina Tirnitz-Parker[2,7]. [1]*Murdoch University, School of Veterinary and Life Science, Perth, Australia;* [2]*Curtin University, School of Pharmacy and Biomedical Sciences, Curtin Health Innovation Research Institute, Perth, Australia;* [3]*University of California San Diego, School of Medicine, La Jolla, United States;* [4]*University of California San Diego, Department of Surgery, La Jolla, United States;* [5]*Fiona Stanley Hospital, Murdoch, Australia;* [6]*Edith Cowan University (ECU), School of Medical and Health Sciences, Mount Lawley, Australia;* [7]*The University of Western Australia, School of Medicine and Pharmacology, Perth, Australia*
Email: francis.gratte@curtin.edu.au

Background and aims: The reported dynamic nature of hepatic stellate cells (HSCs) during fibrosis and resolution highlights that little is known of the fate of their co-migratory partner, liver progenitor cells (LPCs). Manipulating the known co-regulatory relationship between LPCs and HSCs during specific phases of fibrosis to alter their dynamic phenotypes may represent a new therapeutic target. Here we investigate thioacetamide (TAA) pre-treatment and recovery in mice, and the role and mechanism of resulting cell populations in the fibro-dynamic microenvironment of the liver after reintroduction of TAA.
Method: Tissue and sera were collected from C57BL/6 mice of two study groups (n = 5–9 per group): (a) pre-treated; 6-week TAA (300 mg/L drinking water), 4-week recovery, 6-week TAA and (b) naïve; 10-week control diet and 6-week TAA. Liver injury and fibrosis was characterized by extensive biochemical, histological and transcriptional analysis. Inflammatory, LPC and HSC subpopulations were identified by immunofluorescent staining. Primary isolated HSCs from healthy, fibrotic, and recovering mouse liver were co-cultured with the clonal bipotential murine oval liver (BMOL) LPC line prior to qPCR analysis of fibrotic transcriptional regulation.
Results: Phenotypically distinct inactivated desmin^{+}, aSMA^{-}, GFAP^{-} HSCs and CK19^{+} LPCs were confirmed in livers of pre-treated mice at d0, but not in naïve mice by immunofluorescence. TAA treatment induced early CD45^{+} inflammatory cell proliferation in naive mice typical to this model, which was notably absent in pre-treated mice. Elevated serum ALT levels and profibrogenic (aSMA, TGFb1, Col1A1 and TIMP1) transcription during early TAA treatment indicated a severe damage response in naïve mice. Incomplete resolution of fibrosis in pre-treated mice remained static throughout subsequent treatment, whereas naïve mice progressed to cirrhosis after 6 weeks of TAA. Primary HSCs isolated from fibrotic mice exhibit significantly reduced aSMA, Col1A1 and TGFb1 expression after co-culture with BMOL progenitor cells, suggesting anti-fibrotic regulation of HSCs through LPCs in this setting.
Conclusion: Contrary to the carbon tetrachloride model used in other recovery studies, TAA pre-treatment stimulates compensatory mechanisms, moderating the effects of a subsequent hepatic insult. As revealed through direct HSC-LPC coculture, LPCs may play a role in anti-fibrotic regulation of HSCs and could represent a mechanistic key to stabilising fibrosis for therapeutic benefit in patients with recurrent fibrotic pathology.

THU-078

PBI-4050 inhibits hepatic stellate cell activation, restores autophagy, and reduces CCl4-induced liver fibrosis

Brigitte Grouix[1], François Sarra-Bournet[1], Lilianne Geerts[1], Kathy Hince[1], Mikaël Tremblay[1], Alexandra Felton[1], Alexandra Blais[1], Jugurtha Ouboudinar[1], Jean-Christophe Simard[1], Pierre Laurin[1], Lyne Gagnon[1]. [1]*Prometic Biosciences Inc., Laval, Canada*
Email: b.grouix@prometic.com

Background and aims: Hepatic fibrosis is a major cause of morbidity and mortality for which there is currently no effective therapy. PBI-4050 is a dual GPR40 agonist/GPR84 antagonist with antifibrotic, anti-inflammatory and antiproliferative activities. We investigated the mechanism of action of PBI-4050 on human hepatic stellate cells (HSCs), the prominent cell type producing ECM and involved in liver fibrosis, and its antifibrotic activity in the CCl_4 mouse model.
Method: Primary human HSCs were stimulated with transforming growth factor (TGF)-β1 (10 ng/ml) or platelet-derived growth factor (PDGF)-BB (10 ng/ml) in the presence or absence of PBI-4050. Cell viability was assessed by the Resazurin fluorescence assay and cell cycle by flow cytometry. Phospho- and Total-AMPK, LKB1, mTOR, ULK1, and LC3A were detected by Western blot, and gene expression by qPCR. Liver fibrosis was induced in C57BL/6 mice by 10% CCl_4 in olive oil at 2 ml/kg, twice a week for 8 weeks, and mice were treated with PBI-4050 (200 mg/kg) or vehicle. The degree of fibrosis in the liver was evaluated by histopathology and gene expression analysis.
Results: Cell proliferation of HSCs treated 24 h with either TGF-β1 or PDGF-BB was inhibited by PBI-4050 without cytotoxicity. To confirm these results, cell cycle analysis was performed by flow cytometry on activated HSCs. PBI-4050 dose-dependently arrested HSC at the G0/G1 phase without inducing apoptosis. Subsequent analysis demonstrated that PBI-4050 decreased intracellular ATP concentration and signaled through the activation of LKB1/AMPK and the inhibition of mTOR phosphorylation. Furthermore, Ser555-ULK1 phosphorylation was increased and LC3A-II/LC3A-I ratio decreased suggesting a restoration of autophagy in these cells. In addition, we demonstrated reduced protein and mRNA levels of α-SMA and CTGF, and restoration of PPARγ mRNA expression. In CCl_4 mice, treatment with PBI-4050 reduced liver fibrosis as shown by a reduction of collagen (histological analysis and hydroxyproline content). PBI-4050 also significantly decreased gene expression of fibrosis, ECM remodeling, and epithelial to mesenchymal (EMT) markers (α-SMA, CTGF, MMP2, TIMP-1).
Conclusion: PBI-4050 inhibited HSC activation through reduction of intracellular ATP and the LKB1/AMPK/mTOR signaling pathway, resulting in restoration of PPARγ and autophagy. These results translate in reduction of liver fibrosis in the CCl_4 mouse model.

THU-079

Study of anti-fibrotic activity of human umbilical-cord tissue-derived mesenchymal stromal cells during fibrogenesis or resolution in murine models of liver fibrosis

Debashis Haldar[1,2,3], Richard Wilkin[4], Ditte Hedegaard[5], Mohammed Alfaifi[2], Vasanthy Vigneswara[2], Nguyet Luu[2], Lisa O'flynn[6], Steven Elliman[6], Madhu Gargesha[7], Debashish Roy[7], Neil Henderson[8], Gideon Hirschfield[1,2,9], Philip Newsome[1,2,3]. Email: debashishaldar1983@gmail.com

Background and aims: Substantial uncertainty exists from pre-clinical liver fibrosis models as to whether mesenchymal stromal cells (MSC) are anti-fibrotic, and yet clinically they have been proposed as a putative anti-fibrotic therapy for patients. Using two rigorous murine models, we aimed to determine the therapeutic effects of CD362-selected (S2+) umbilical-cord tissue-derived MSCs (UCT-MSC) on hepatic fibrogenesis and resolution.
Method: Peak fibrosis and resolution was delineated in C57Bl/6 mice using two models of chronic hepatic injury: 6 weeks of 2 µl/g body-weight intraperitoneal carbon tetrachloride (CCl_4), and 16 weeks of oral thioacetamide (600 mg/L) (TAA) in drinking fluid taken *ad libitum*. Intervention experiments were statistically powered to a 25% difference in picrosirius red (PSR) collagen proportional area (CPA) (N = 20/group). Human unselected or S2+ UCT-MSC from two donors were injected by tail vein (TV) ($2\times7.5\times10^5$ MSCs in each experiment) during either injury, or recovery in both models. Fibrosis outputs were PSR, hepatic hydroxyproline (HYP), quantitative polymerase chain reaction (qPCR) for collagen-1, -3, transforming growth factor-beta 1, matrix metalloproteinase-2, –9, and tissue inhibitor of metalloproteinase-1. Stellate cell activation was verified by qPCR and immunohistochemistry (IHC) for alpha-smooth muscle actin, inflammation by CD45, F4/80 IHC and flow cytometry. CryoViz of whole mice determined the bio-distribution and quantification of injected Q-Dot-labeled MSCs.
Results: Peak fibrosis was greater ($p < 0.05$) in the TAA (CPA 10.45% ± 1.62) than the CCl_4 (CPA 2.57% ± .51) model. Fibrosis persisted up to 21 days (CPA 1.48% ± .58) and 28 days (CPA 6.92% ± 2.29) after recovery respectively, albeit with a wide variance. MSCs injected during recovery or fibrogenesis in both models had no effect on fibrosis or hepatic stellate cell activation, compared to saline injection ($p > 0.05$ for all outputs). Use of unselected MSCs did not influence results ($p > 0.05$). CryoViz analysis in the CCl_4 model found 4.90% of TV injected cells in the liver after 24 hours and 0.78% after 8 days.
Conclusion: In two robust, adequately powered, murine models of liver injury and fibrosis, umbilical-cord-tissue-derived mesenchymal stromal cells, when given intravenously, were safe, had limited hepatic bioavailability, and no meaningful anti-fibrotic properties.

THU-080

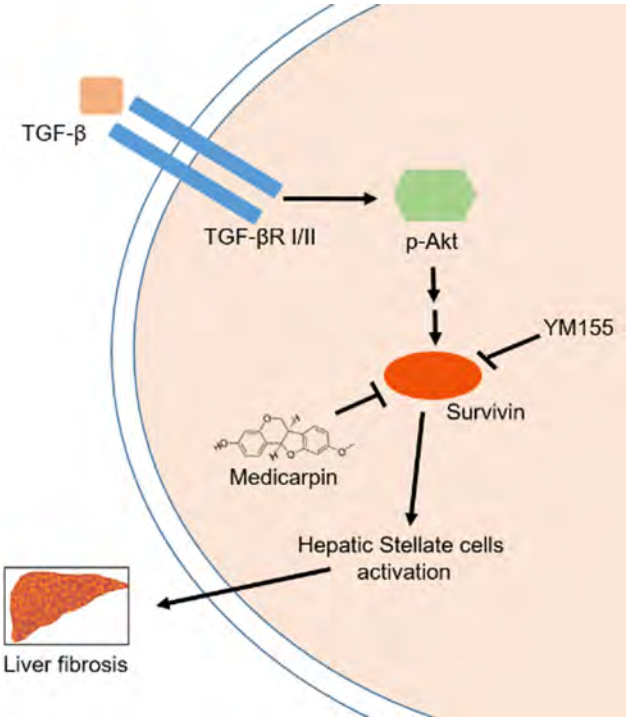
Survivin aggravates fibrogenecity of hepatic stellate cells via mediating TGF-beta/PI3 K/Akt pathway

Arun kumar jajoriya[1], Jaspreet bagga[1], Abhishek nirwan[1], Durga prasad mishra[1]. [1]*CSIR-Central Drug Research Institute, Endocrinology, Lucknow, India*
Email: dpm@cdri.res.in

Background and aims: Liver fibrosis is scarring of hepatic parenchymal tissue due to excessive deposition of extracellular matrix (ECM) by activated myofibroblastic cells, predominantly hepatic stellate cells (HSCs). If the condition remains unmanaged, it leads to cirrhosis and liver cancer. Because the activation of HSCs is the principal mechanism leading to liver fibrosis, understanding the process of their activation could open new avenues to cure the condition. Survivin has a vital role in chronic liver diseases. However, its relationship in context to HSCs activation is unknown. Since surviving inhibitor YM155 has been shown to have moderate anticancer effects in clinical trials, therefore, we tried to position another molecule to target survivin. Previously we have reported that a small molecule medicarpin (phytoalexin) can reduce survivin in leukemia. In present study, we aim to evaluate survivin as potential therapeutic target for liver fibrosis.
Method: Wild-type C57BL/6 mice were fed with methionine choline deficient (MCD) diet (*ad libitum*) for eight weeks to induce biliary liver fibrosis. For non-biliary liver fibrosis model, C57BL/6 mice were

fed with high fat diet and administered 0.5 ml/kg dose of carbon tetra chloride (CCl4) for six weeks on every third day. Effects of survivin inhibitor YM155 and medicarpin were evaluated in TGF-β activated hepatic stellate cell line LX-2 for 48hrs. *In vivo* antifibrotic effects of medicarpin were assessed by treating CCl4 induced liver fibrotic mice with medicarpin for six weeks.

Results: Here we show that survivin is highly expressed in activated HSCs and correlates with the expression of p-Akt. Treatment of HSCs with survivin inhibitor YM155 abolishes HSCs activation, and TGF-β pathway inhibitor SB431542 in combination with YM155 potentiates this effect. Treatment of HSCs with medicarpin and observed a decrease in expression of survivin and activation of HSCs. Moreover, Administration of medicarpin (10 mg/kg), reduced the expression of HSCs activation markers αSMA, Col1a1.



Conclusion: Collectively these results indicate that survivin has an essential role in progression of liver fibrosis by regulating activation of hepatic stellate cells and molecules targeting survivin could be helpful in managing the liver fibrosis.

THU-081

Saracatinib, a Src family kinase inhibitor, decreases liver fibrosis

Hye-Young Seo[1], So-Hee Lee[1], Ji-Ha Lee[1], Jae-Seok Hwang[1], Mi-Kyung Kim[1], Byoung Kuk Jang[1]. [1]*Keimyung University School of medicine, Daegu, Korea, Rep. of South*
Email: jangha106@dsmc.or.kr

Background and aims: The SRC family kinase belongs to a family of non-receptor tyrosine kinase and expressed ubiquitously in all cell types. When SRC phosphorylated, various membrane transcription receptor proteins, STAT3, AKT, and EGFR, are phosphorylated and activated to regulate various biological activities. Although inhibition of SRC activation has been reported to inhibit lung or renal fibrosis, little is known about the effet of inhibiting hepatic fibrosis. Here, we examined whether saracatinib, a SRC family kinase inhibitor, has the protective effect on liver fibrosis in vitro and in vivo.

Method: Liver fibrosis was induced by thioacetamide (TAA)-injection for 8 weeks in C57BL/6 mice and saracatinib was administered orally premixed with the pellet. We cultured AML12, LX2 and mouse primary hepatocytes. The effect of saracatinib on liver fibrosis was determined by Sirius red, immunohistorchemistry, real-time RT PCR and western blot analysis.

Results: Expression of SRC was upregulated at the mRNA and protein levels in liver of TAA-injected mice. In addition, we confirmed that phosphorylation of SRC was increased in TAA-injection mice. The SRC inhibitor saracatinib reduced TAA-induced collagen, αSMA and CTGF expression. In vitro studies also showed that TGF-β induces SRC phosphorylation and saracatinib inhibited TGF-β-stimulated CTGF and PAI-1 expression. In addition, saracatinib inhibited TGF-β-stimulated phospho-Smad3 and STAT3 expression.

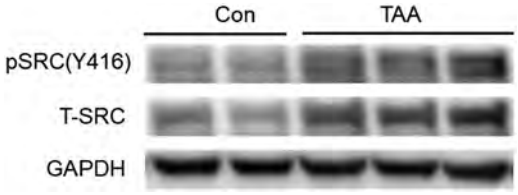


Figure 1: SRC is upregulated in TAA induced liver.

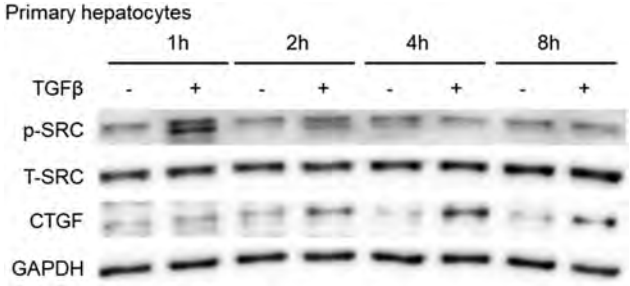

Figure 2: TGF-β increased SRC phosphorylation.

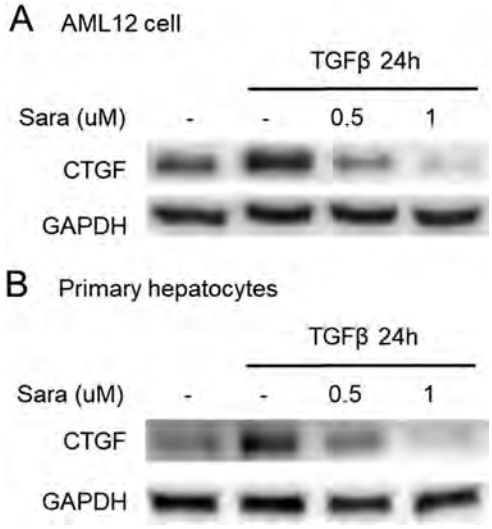

Figure 3: Saracatinib inhibits TGF-β induced CTGF expression.

Conclusion: The results of this study show that the SRC kinase is involved in TGF-β pathway and TAA-induced liver fibrosis. In addition, the SRC inhibitor saracatinib decreased TAA-induced collagen, αSMA and CTGF expression and inhibited TGF-β-stimulated CTGF expression. Furthermore, the inhibitory effect of saracatinib on liver fibrosis was associated with downregulation of TGF-β-stimulated phospho-Smad3 and STAT3.

THU-082

Thymosin beta 4 is a potential regulator of radiation-induced liver fibrosis

Jieun Kim[1], Youngmi Jung[1]. [1]*Pusan National University, Biological Sciences, Pusan, Korea, Rep. of South*
Email: y.jung@pusan.ac.kr

Background and aims: Radiation-induced liver disease (RILD) is a major limitation of radiotherapy for the treatment of liver cancer. Activation of hepatic stellate cells (HSCs), the most prominent feature of liver fibrosis, is commonly observed in the livers of patients with RILD. Thymosin beta 4 (Tb4) is expressed by activated HSCs in fibrotic liver and regulates activation of HSCs via Hedgehog (Hh) signaling by modulating integrin linked kinase (ILK) and glycogen synthase kinase 3 beta (GSK-3b). Herein, we hypothesized that Tb4 might be associated with radiation-induced liver fibrosis.
Method: Male C57BL/6 wild-type (WT) and Tb4-overexpressing transgenic (Tb4-Tg) mice were exposed to hepatic irradiation (IR) with 6 Gy in five weekly fractions and sacrificed at one week after fifth IR. CRISPR/Cas9 system was employed to delete Tb4 gene in LX-2 cells, the activated human HSC line, and these cells were exposed to IR with 2 Gy and harvested at 48 hours after IR.
Results: Only 25% of Tb4-Tg mice survived after 5th IR, whereas all WT mice survived during IR. The ratio of liver weight to body weight (LW/BW) and the serum level of bilirubin were elevated in Tb4-Tg mice compared to WT mice after IR. Livers of Tb4-Tg mice had more Tb4-positive-HSC looking cells than livers of WT mice at baseline and after IR, as assessed by immunostaining. Protein levels of profibrotic markers, TGF-b, a-SMA, vimentin, desmin, col1a1, were significantly upregulated in Tb4-Tg compared with WT mice. Sirius red staining also supported more deposition of collagen fibrils in Tb4-Tg than WT mice. Furthermore, expression of ILK, GSK-3b, and Hh activators, smoothened and glioblastoma 2, increased in the irradiated livers of Tb4-Tg mice compared to WT mice. In addition, Tb4 deletion by CRISPR/Cas9 system induced downregulation of ILK, GSK-3b, smoothened, glioblastoma 2, and profibrotic genes in irradiated LX-2 cells.
Conclusion: Our findings demonstrate that Tb4 influences development of radiation-induced liver fibrosis, suggesting that Tb4 might be a potential regulator of radiation-induced liver fibrosis.

THU-083

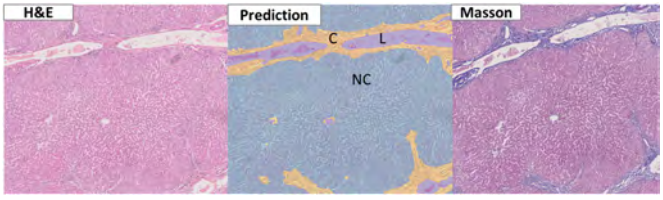
Predicting advanced liver fibrosis using deep learning based biopsy image analysis

Sergey Klimov[1], Alton B. "Brad" Farris[2], Hao Chen[1], Yaobing Chen[3], Yi Jiang[1]. [1]*Georgia State University, Mathematics and Statistics, Atlanta, United States;* [2]*Emory University Hospital, Department of Pathology, Atlanta, United States;* [3]*Tongji Hospital, Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China*
Email: yijianggsu@gmail.com

Background and aims: Liver fibrosis results from chronic liver damage and has been a strong clinical indication for liver health. Identifying the progression of liver fibrosis is vital for therapy recommendation and management. Liver fibrosis staging this analysis is often performed by expert pathologists using stains that target extracellular matrix components such as collagen; such analysis may be hindered by staining and interpretation variability. This study aimed to provide a more accurate and automated fibrosis classifier by machine learning analysis of features obtained from full slide HandE images.
Method: High-resolution, stage-annotated, HandE images (n = 115) were analyzed using a two-fold classification pipeline. First, a trained (through matched Masson's trichrome slides) pixel-based deep learning classifier (LinkNet) was used to perform sematic segmentation to annotate practical domains (collagen (C), lumen (L), non-collagen (NC)) (Fig. 1). Next, 58 full-slide features stemming from these annotations, which represented quantitative fibrotic descriptors such as fibrotic branching, envelopment, and fiber alignment, were developed and compared between patients with cirrhosis (S4) and all others (S0-S3). Finally, 10-fold cross-validated feature and machine learning algorithm selection was used to identify the optimal cirrhosis classifier, which was compared against the Masson trichrome stain's positive pixel count.
Results: On 51 million ground truth pixels, the pixel-based classifier leveled off at a prediction accuracy of over 99%. Individual full-slide features varied significantly in stage discrimination, with AUC's ranging between 0.70 and 0.93. Using only 3 whole slide HandE features, an optimized Support Vector Machine (SVM) model produced a cross validated sensitivity of over 95% and a 95% specificity for S4 (as compared to 52% and 96% respectively, using the trichrome stained positive pixel count) (Table 1).

Table 1: Performance Metrics for Stage 4 Prediction using the Proposed ML Model or the Trichrome Positive Pixel Count.

	Proposed Model	Trichrome Positive Predicted Pixels
Sensitivity	0.95	0.52
Specificity	0.95	0.96
Accuracy	0.98	0.88
AUC	0.98	0.83



Conclusion: Our novel, two-fold, HandE-based classification model provides an almost perfect degree of confidence in cirrhosis prediction for liver biopsies, showing superior prediction compared to Masson trichrome-based metrics. Thus, our model can be used to both supplement current pathological analysis and be used confidently for rapid biopsy staging where only HandE slides may be available.

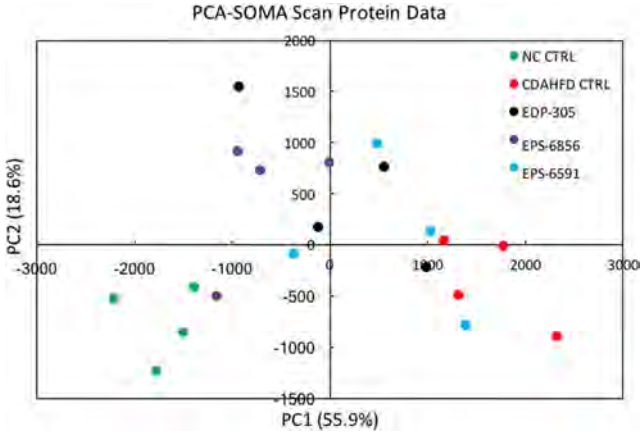
Email: skrishnan6@partners.org

Background and aims: Cirrhosis is the common end point of all chronic liver diseases, including non-alcoholic steatohepatitis (NASH). Several therapeutics are currently under clinical investigation for the treatment of NASH cirrhosis and they target key features of the disease including lipogenesis, inflammation, and fibrogenesis. Effective biomarkers to assess the efficacy of these therapeutics are urgently needed and could also provide insights into shared mechanisms of action. Here, we investigate three anti-fibrotic therapeutics in a pre-clinical model of NASH cirrhosis: two ASK1 inhibitors, EP-026856 and selonsertib, and one FXR agonist, EDP-305.
Method: Male Wistar rats (175–200 g) were fed either normal chow (NC) or a choline-deficient, L-amino acid-defined, high fat diet with

60 kcal% fat and 0.1% methionine (CDAHFD) for 12 weeks. Animals were randomized to receive daily oral gavage of either vehicle (0.5% methylcellulose (MC)), 30 mg/kg EDP-305, 30 mg/kg EP-026856, or 30 mg/kg selonsertib at the first signs of fibrosis (5 weeks, n = 8 per group). At 12 weeks, animals were sacrificed and serum samples, collected via cardiac puncture, were sent for proteomics analysis using SOMAScan.

Results: CDAHFD rats developed bridging fibrosis by 6 weeks that progressed to nodular cirrhosis by 12 weeks reminiscent of late-stage human disease. All three drugs were effective at inhibiting fibrosis as assessed by histological staining and hydroxyproline analysis (NC 208 ± 53 µg/g, MC 840 ± 269 µg/g, EDP-305 349 ± 112 µg/g, EP-026856 449 ± 212 µg/g, selonsertib 484 ± 197 µg/g). Utilizing SOMAscan, we quantitatively assessed 1305 proteins with high specificity. Principle component analysis (PCA) revealed highest similarity between normal chow rats and CDAHFD rats treated with EP-026856. These two groups separated across principle component 1 (PC1) from all other treatment groups. Utilizing ingenuity pathway analysis (IPA), we identified and placed discriminatory proteins along protein networks to visualize pathway enrichments in each of the animal groups. Pathway analysis revealed that the EP-026856 discriminatory proteins enriched the greatest number of distinct protein-protein interaction pathways. While only the ASK1 inhibitors enriched Akt, FoxO, and TGF-beta signaling pathways, EDP-305 uniquely enriched the ErbB signaling pathway.



Conclusion: By utilizing SOMAScan, we were able to identify non-invasive biomarkers of treatment response and potential pathways activated by different drugs currently in clinical trials. While all three drugs were effective in inhibiting fibrosis development in this rat model of NASH cirrhosis, PCA analysis identified EP-026856 has having the greatest effect on returning non-invasive serum markers back to baseline.

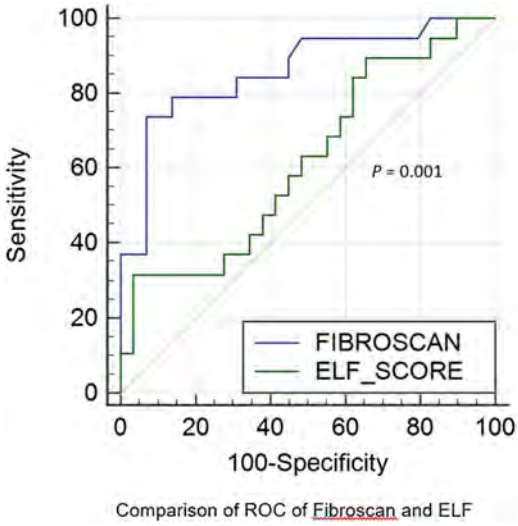
Efficacy of enhanced liver fibrosis score and transient elastography for assessment of severity of fibrosis in chronic hepatitis C

Manish Kumar[1], amarender singh puri[1], ajay kumar[1], sanjeev sachdeva[1], Amol Dahale[1], puja sakhuja[2]. [1]*Govind Ballabh Pant institute of postgraduate medical education and research, Gastroenterology, New Delhi, India;* [2]*Govind Ballabh Pant institute of postgraduate medical education and research, Pathology, New Delhi, India*
Email: amarender.puri@gmail.com

Background and aims: Chronic hepatitis C (CHC) patients with Genotype 3 infection having advanced fibrosis or cirrhosis need a longer duration of therapy and sustained virological response rate is lower with currently available directly acting antiviral therapy. Enhanced liver fibrosis (ELF) score and transient electrography (TE) are non-invasive methods for ruling out cirrhosis, have not been compared in Indian CHC patients. Aim is to compare TE and ELF for ruling out significant fibrosis (≥F2) CHC patients.

Method: Consecutive CHC patients who attended OPD at GIPMER from Sept. 2016 to May 2018 were included in the study. Patients with decompensated cirrhosis, BMI ≥ 30 kg/m2 or additional aetiology for liver disease were excluded. The liver biopsy was used as a gold standard; The METAVIR scoring system was used for grading fibrosis in liver biopsy. The TE by using fibroscan 430 mini and ELF were done on the same day in fasting state.

Results: Total of 50 patients were included, 30 were male and mean age was 35.02 ± 10.2 years. Genotype 1 and 3 found in 42 (84%) and 8 (16%) patients respectively. TE, ELF score calculation and liver biopsy was done in all patients. Median ELF score and TE score for patients were 9.46 and 5.95 kPa respectively. Significant fibrosis (≥F2) in biopsy, fibroscan and ELF score were 19 (38%), 14 (28%) and 47 (94%) patients respectively. The area under the receiver operator characteristic curve (AUROC) of TE was 0.860 [95% confidence interval (CI), 0.74-0.97], with the sensitivity and specificity of 79% and 86% for significant fibrosis and AUROC for ELF, was 0.619 [95% CI, 0.45-0.78], with the sensitivity and specificity of 74% and 42% respectively using liver biopsy as gold standard for diagnosing significant fibrosis. Using the proposed cut-offs, ELF overestimated fibrosis in 56% (28/50) of cases. We found statistically significant difference when comparing the AUROC of TE and ELF for diagnosing significant fibrosis (≥F2), ($p = 0.001$).



Comparison of ROC of Fibroscan and ELF

Conclusion: TE, as compared to ELF, is a better non-invasive method for diagnosing significant fibrosis (≥F2) in CHC patients. However, revised cut-off ELF score need to be established in CHC patients to improve its performance.

THU-086

Clinical study on plasma golgi protein 73 and the progression of viral hepatitis C-induced hepatic fibrosis

Liu Lingdi[1], Xiwei Yuan[1], Luyao Cui[1], Yuemin Nan[1]. [1]*Third Hospital of Hebei Medical University, Department of Traditional and Western Medical Hepatology, shijiazhuang, China*
Email: nanyuemin@163.com

Background and aims: To explore the correlation between plasma Golgi protein 73 (GP73)and the progression of Hepatitis C viral (HCV)-induced hepatic fibrosis.

Method: 232 cases of chronic hepatitis C (CHC) were included in our hospital from 2010.01 to 2018.09, which were diagnosed by serovirology and histopathological examination. And 31 healthy controls were enrolled. Clinical datas were collected. The plasma

GP73 level was detected by ELISA. Liver biopsy histopathological observation was based on liver inflammation grade (G1~3), fibrosis stage (S1~4) and "Beijing Classification" (P-I-R). The correlations were compared between GP73 and the stages of liver inflammation and fibrosis, disease progression and reversion. In addition, ROC of the subjects were performed to analyze the GP73 and APRI/FIB-4 in the diagnostic efficiency of fibrosis degrees and progression.

Results: The GP73 level of CHC patients was significantly higher than the healthy controls (94.82 ng/ml vs 172.90 ng/ml, $P < 0.0001$), and there were significant differences of the GP73 in mild and notable inflammation, 151.30 (113.70~174.75) and 172.15 (142.65~204.85) ng/ml in grade 1 and grade 2 to 3 respectively, $p = 0.004$). Particularly, GP73 levels were increasing with progression of liver fibrosis, these were in following: 151.30 (123.10~170.10), 157.90 (132.00~172.60), 181.70 (149.43~219.05), 208.50 (164.44~324.73) ng/ml in S1, S2, S3 and S4 respectively, and they are 189.16 (163.65~221.70) and 232.50 (174.60~335.65) ng/ml ($p = 0.023$) in the patients with compensated and decompensated liver cirrhosis. According to Beijing Classification, there was a significant difference of GP73 level in the Progression and Regressive/Indeterminate group, they are 177.08 (149.35~205.58) and 154.00 (121.95~178.05) ng/ml, $P = 0.004$. Furthermore, the AUC for the diagnosis in liver fibrosis of GP73, APRI and FIB-4 were 0.73, 0.78 and 0.81, respectively ($p < 0.0001$). And the AUC of GP73 for the diagnosis of Progressive fibrosis was 0.69 ($p = 0.011$), but ARRI and FIB-4 had no predictive significance.

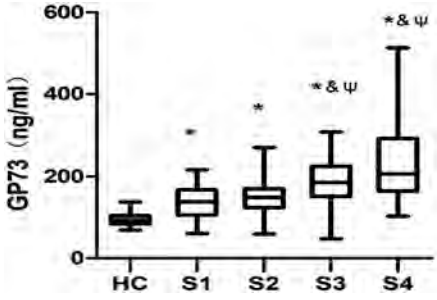


Figure 1: the GP73 levels in different statges. *:compared to HC, P<0.05; &:compared to S1, P<0.05; Ψ:compared to S2, P<0.05.

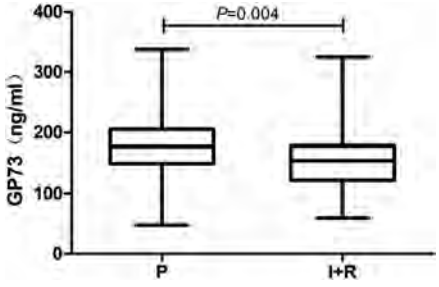

Figure 2: GP73 in P and I+R group.

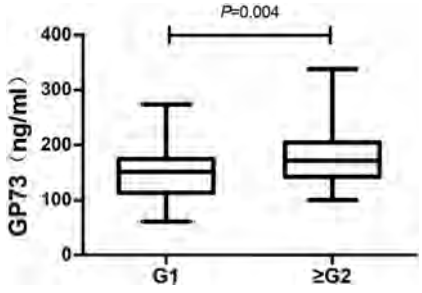

Figure 3: GP73 with different inflammation.

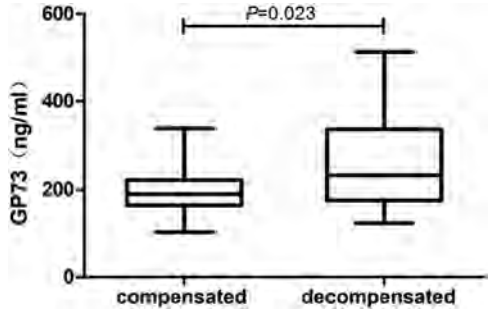

Figure 4: GP73 in different cirrhosis stages.

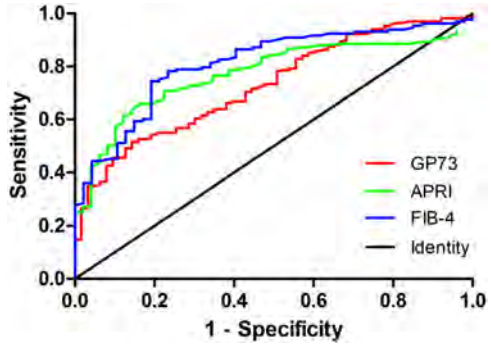

Figure 5: the ROC of GP73/APRI/FIB-4 in the diagnosis of fibrosis.

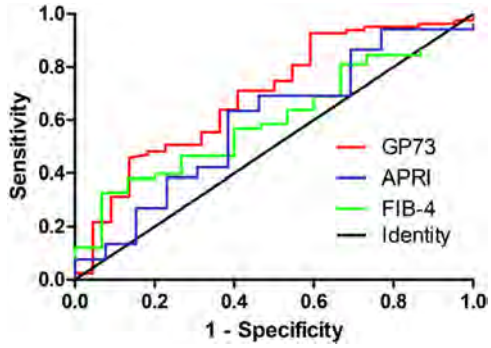

Figure 6: the ROC of GP73/APRI/FIB-4 in the diagnosis of "Beijing Classification"-P.

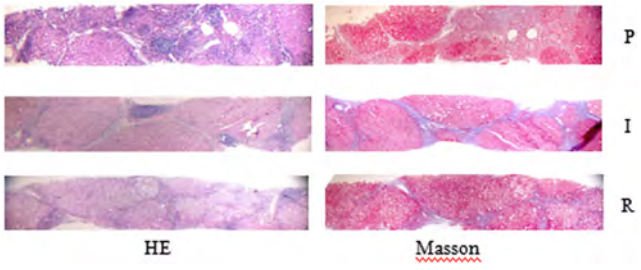

Figure 8: Beijing Classification "P-I-R".

Conclusion: The GP73 might be a potential biomarker for diagnosis of chronic HCV infection and the development of liver inflammation and liver fibrosis. Especially high level of the GP73 indicated progressive hepatic fibrosis.

Table 1: (abstract: THU-086): Analysis of basic data of patients with chronic hepatitis C in different fibrosis stages.

Variables	Fibrosis staging				F/X^2	P

Email: claire.mcquitty@researchinliver.org.uk

Background and aims: The extracellular matrix (ECM) is a complex network of structural and functional proteins. It acts as an architectural scaffold with mechanical properties and is a reservoir for cell signaling molecules. In the liver, cross-talk between the liver cells, the ECM and the circulating immune system is involved in both maintaining homeostasis and driving disease. A better understanding of these complex interactions will allow us to explore the driving factors behind fibrosis, leading to the identification of novel therapeutic targets. Current culture and animal models do not accurately recapitulate the complexity of liver fibrosis. We used a tissue engineering approach to create a 3D-dynamic, humanized model of liver fibrosis incorporating the ECM, native liver cells and immune cells circulating in a custom-made perfusion bioreactor.
Method: Liver scaffolds were produced by decellularization of whole rat liver to remove cellular content, whilst maintaining overall organ architecture, ECM and vasculature intact. Hepatic stellate cells (HSC) were isolated from patient liver biopsy and peripheral blood mononuclear cells (PBMC) from matched patient whole blood or from healthy controls. Decellularised scaffolds were re-seeded with either PBMCs or HSCs and cultured in static or dynamic conditions. Scaffolds were analysed up to 7 days of culture by histology and immunofluorescence. PBMCs in dynamic culture were profiled by FACs to determine leukocyte subpopulations.
Results: Whole livers were successfully decellularized to remove native cells and DNA, while ECM and vasculature were conserved. In static culture conditions, scaffolds supported engraftment of certain PBMC subsets including specifically localised clusters of macrophages and CD3+ cells. The custom-made bioreactor was able to support PBMC viability in the dynamic system, allowing circulation of PBMCs in the vasculature of the decellularized scaffold. Bioreactor-guided serial seeding of HSCs produced re-populated liver scaffolds with cell-ECM interaction where fibrosis can be induced and PBMC can be continuously circulated through the system.
Conclusion: Decellularized whole liver scaffolds were repopulated with HSCs using a custom-made bioreactor. The bioreactor supports circulation of matched PBMCs and will allow us to explore ECM-HSC-immune cell interactions in the context of liver fibrosis.

THU-088

Serum markers of interstitial matrix formation (PRO-C3) and basement membrane remodeling (PRO-C4 and C4M) predict recurrence of fibrosis and survival in post-liver transplanted patients

Mette Juul Nielsen[1], Ida Villesen[1], Natasja Gudmann[1], Diana Leeming[1], Aleksander Krag[2], Morten Karsdal[1], Rambabu Surabattula[3], Tim Zimmermann[4], Detlef Schuppan[3,5].
[1]Nordic Bioscience A/S, Herlev, Denmark; [2]University of Southern Denmark, Department of Gastroenterology and Hepatology, Odense, Denmark; [3]University Medical Center Mainz, Institute of Translational immunology, Mainz, Germany; [4]University Medical Center Mainz, Department of Medicine I, Transplant Hepatology, Mainz, Germany; [5]Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Gastroenterology, Boston, MA, United States
Email: mju@nordicbio.com

Background and aims: Following liver transplantation, 10–30% of patients rapidly progress to cirrhosis. There is an urgent need for predictive non-invasive markers of recurrent cirrhosis for a better risk management and for the monitoring of potential anti-fibrotic therapies. We therefore studied a panel of four defined serum biomarkers of interstitial matrix formation and basement membrane remodeling as predictors of recurrent cirrhosis after liver transplantation.
Method: Forty-seven liver transplatation patients were retrospectively divided into equally sized groups of fast, intermediate, or non-progressors towards recurrent cirrhosis according to the time from transplantation to cirrhosis; recurrent cirrhosis within 1 year, within 3–5 years, or no fibrosis within 5 years post liver transplantation, respectively. Fibrosis evolution was confirmed by liver biopsy. Markers of interstitial matrix type III and V collagen formation (PRO-C3 and PRO-C5), and basement membrane type IV collagen

formation (PRO-C4) and degradation (C4M) were assessed in serum samples using specific ELISAs. Blood samples were taken at 3, 6, and 12 months post-liver transplantation from all groups.
Results: PRO-C3, PRO-C4 and C4M were significantly elevated in fast progressors compared to non-progressors ($p < 0.05$-$p < 0.01$) at measurements taken three months after liver transplantation. Additionally, C4M and PRO-C4 differentiated between intermediate and fast progressors ($p < 0.001$ and $p < 0.05$, respectively). ROC curve analysis identified PRO-C4 and C4M as the best markers to discriminate fast progressors from non-progressors with AUROCs of 0.902 and 0.886, respectively. PRO-C3 was the best predictor post-liver transplantation survival with patients in the highest PRO-C3 tertile having significantly shorter post-liver transplantation survival compared to patients in the lowest tertile ($p < 0.01$) as well as predicting progressors towards cirrhosis with odds ratio of 28 ($p < 0.05$). When dividing the levels of C4M and PRO-C4 into tertiles, patients in the highest tertiles had an odds ratio of 21 or 85, respectively, of being progressors towards recurrent cirrhosis compared to patients in the lowest tertiles ($p < 0.05$-$p < 0.01$).
Conclusion: The study shows that elevated PRO-C3 levels are associated with both fibrosis progression and death, whereas markers of basement membrane remodeling is only associated with fibrosis progression. Thus, markers originating from different sites in the extracellular matrix may be used to monitor patients at risk of clinical events.

THU-089
Characterization of CDAA mouse model for non-alcoholic steatohepatitis at various time-points

Larissa Pfisterer[1], Jochen Huber[1], Andre Broermann[1]. [1]*Boehringer Ingelheim Pharma GmbH and Co. KG, 88397 Biberach, Germany*
Email: Larissa.Pfisterer@boehringer-ingelheim.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is defined by an increased storage of triglycerides and oxidation of fatty acids in hepatocytes. This can promote an elevated production of reactive oxygen species and necrosis leading to a severe hepatic inflammatory response and thereby progress to non-alcoholic steatohepatitis (NASH), which can result in fibrosis and ultimately cirrhosis. The pathologic onset and progression can be induced by a plethora of factors such as an imbalanced energy homeostasis, diabetes or obesity, whereas the impact of certain risk factors varies among patient groups depending on age, gender, genetic predispositions and lifestyle. The current treatment routine for NASH suggests diet and lifestyle adaptations, weight loss and -if indicated- diabetes therapy. Up until now there is no FDA approved drug to treat NASH and its consequences.
Method: Consequently, there is a high need for identification and development of specific therapeutic concepts, supported by a validated and disease-related animal model mimicking the pathologic onset and progression. Here, we analyze a mouse model based on a cholesterol-enriched, methionine-reduced, choline-deficient and amino acid defined diet (CDAA), leading to an attenuated VLDL production. The hereby promoted fat storage in hepatocytes leads to cellular damage, inflammation and fibrosis, while the animals do not suffer from reduced body weight as it is observed for classical methionine- and choline-deficient diets.
Results: Based on this diet composition we present an easy applicable model, which reveals the first symptoms of liver steatosis in a wild-type genetic background within two weeks of diet. In further detail, we characterize the time-dependent progression of pathological symptoms and plasma biomarker levels over 12 weeks in C57BL/6 mice upon cholesterol-enriched CDAA diet. Employing biomarkers such as TIMP1 and ProCollagen III, we are able to correlate their abundance in plasma samples with the severity and disease burden based on liver histology. Thereby document individual disease pro- or regression throughout the study and moreover minimize animal numbers.
Conclusion: In summary, we analyze a NASH mouse model showing a disease morphology that is comparable to patients -including steatosis, inflammation and fibrosis- within a relatively short period of time to further elucidate therapeutic concepts in NASH. Moreover the progression and therapeutic potential of various compounds can be monitored by defined biomarkers.

THU-090
Non-invasive fibrosis scores (APRI, FIB4 index, BARD): Useful tools for evaluating fatty liver disease

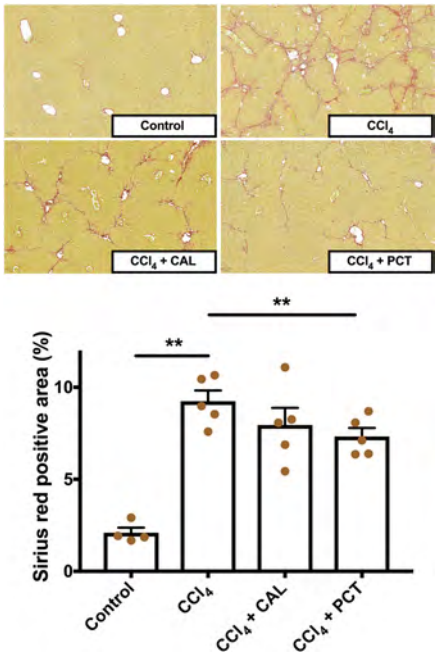
Alina Popescu[1], Ioan Sporea[1], Camelia Foncea[1], radu cotrau[1], Alexandra Christa Sima[2], Adina Braha[2], Roxana Sirli[1], Mirela Danila[1], Nistorescu Silviu[1], Raluca Lupusoru[1], Diana Gherhardt[1], Romulus Timar[2]. [1]*"Victor Babes" University of Medicine and Pharmacy, Gastroenterology and Hepatology, Timisoara, Romania;* [2]*"Victor Babes" University of Medicine and Pharmacy, Diabetes and Nutrition Department, Timisoara, Romania*
Email: alinamircea.popescu@gmail.com

Background and aims: Several non-invasive fibrosis assessment tests were developed in order to replace liver biopsy. Our goal was to assess the correlation between APRI, FIB 4 Index and BARD score with transient elastography (TE) in diabetic patients with fatty liver disease.
Method: We conducted a prospective study which included 469 diabetic patients out of which 454 with steatosis (mean age 61 ± 9.3 years, 55.1% females, 44.9% males) evaluated both by serum markers (TGO, TGP, platelets) as well as by TE-Fibroscan (Echosense, Paris, France, with incorporated CAP function). Based on specific formulas we calculated APRI, FIB 4 index and BARD score. Liver stiffness (LS) measurement was considered reliable only if 10 valid values were obtained, with an IQR < 30% and a success rate >60%. For differentiation between stages of liver fibrosis, the following cut-off values were used: F2-F3: 7–10.2kPa, F4 ≥ 10.3 kPa, and for steatosis we considered: S1 (mild)-232.5 db/m, S2 (moderate) –255 db/m, S3 (severe) –290 db/m.
Results: Severe steatosis according to CAP measurements prevailed: 69.5% of patients. Out of the 454 patients, 27.3% of them were overweight, whereas 62.5% were obese.
We tried to rule out cirrhosis by using APRI < 2 (98.5% patients) among which 368 patients (82.1%) had LS < 10.3 kPa, NPV = 82.6%. We found a moderate, but significant correlation between LS assessed by TE and LS predicted by APRI (Pearson r = 0.5, p = 0.001).
Regarding FIB 4 score, we found out that 94% patients had FIB4 < 2.6, thus ruling out advanced liver fibrosis (LS < 10.3kPa), NPV = 85%. The correlation between them was weak, but statistically extremely significant (r = 0.23, p = 0.0001). Patients with BARD score < 2 have a strong negative predictive value for advanced hepatic fibrosis, NPV = 86.1%. Among them, 97.5% had LS < 10.3 kPa
Conclusion: An APRI score < 2 and FIB 4 score < 2.6 can rule out advanced fibrosis when correlated with LS <10.3 kPa by TE. These two simple scores could be used as first line test to rule out patients without advanced fibrosis.

THU-091
Acalcemic vitamin D analogues show antifibrotic effects in vitro while paricalcitol prevents progression of established fibrosis in the CCl4 mouse-model

Florian Paul Reiter[1], Liangtao Ye[1], Florian Bösch[2], Ralf Wimmer[1], Renate Artmann[1], Andreas Ziesch[1], Veronika Kanitz[3], Mayr Doris[3], Michael Trauner[4], Ivonne Regel[1], Alexander Gerbes[1], Julia Mayerle[1], Simon Hohenester[1], Enrico de Toni[1], Denk Gerald[1]. [1]*University Hospital, LMU Munich, Department of Medicine II, Liver Center Munich, Munich, Germany;* [2]*University Hospital, LMU Munich, Department of General, Visceral and Transplantation Surgery, Munich, Germany;* [3]*Institute of Pathology, University of Munich, Munich, Germany, Munich, Germany;* [4]*Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*
Email: florian.reiter@med.uni-muenchen.de

Background and aims: Liver fibrosis due to chronic liver diseases leading to liver cirrhosis is a highly prevalent life-threatening condition. So far, no cause independent antifibrotic agent has been established in clinical practice, despite of a high medical need. Vitamin D (VD) and its analogue calcipotriol demonstrated anti-fibrotic potency in preclinical models of liver fibrosis. Head to head comparison of calcitriol (CAL) to VD-analogues is pending. In this study we investigated the antifibrotic efficacy of clinically available VD-analogues in comparison to CAL *in vitro*. Paricalcitol (PCT), a systemically available VD-analogue approved for the treatment of secondary hyperparathyroidism, with a lower risk of hypercalcemia compared to CAL, demonstrated promising effects *in vitro*. We therefore analyzed the hepatoprotective effects of PCT in a head to head comparison with CAL in the CCl_4 mouse model.
Method: Murine hepatic stellate cells (HSC) and human LX-2 cells were treated with CAL and clinically available VD-analogues. HSC behavior was investigated using immunoblotting, collagen gel contraction assay, migration assay, real-time PCR, and immunofluorescence-microscopy. Proliferation was studied using a BrdU-assay. The CCl_4 mouse model was used to investigate effects *in vivo*. Therapy with CAL and the equipotent dosage of PCT in parallel to CCl_4 was initiated when a significant fibrosis (F2 to F3) was evident after 4 weeks. Efficacy was evaluated using serum-biochemistry, sirius-red staining and quantification of fibrosis with image analysis of sirius-red staining.
Results: Vitamin D agents reduced α-smooth muscle actin (α-SMA) protein-expression, an indicator for HSC activation, in murine HSC. Human LX-2 cells, when activated by tissue-growth-factor-β (TGF-β), showed a lower α-SMA protein- and ACTA2- and TGF-β mRNA-expression under PCT stimulation. TGF-β induced platelet-derived growth factor-receptor (PDGF-R) protein-expression and TGF-β mediated HSC contractility was reduced under stimulation with alfacalcidol. CAL and PCT showed hepatoprotective effects *in vivo* as indicated by reduced ALT levels compared to CCl_4 controls. PCT treated animals had significant lower calcium and bilirubin levels compared to the CAL group. The CAL group showed a pronounced weight loss. PCT but not CAL significantly inhibited the progression of established liver-fibrosis in CCl_4-model indicated by lower fibrotic area in image-analysis of sirius-red staining (Figure).



Conclusion: VD analogues show antifibrotic properties *in vitro*. PCT was superior to CAL in regard to prevention of hypercalcemia and side effects. PCT but not CAL significantly inhibited progression of established fibrosis in the CCl_4 mouse model. Acalcemic VD-analogues should be considered routinely in the investigation of VD for the treatment of liver fibrosis in future studies.

THU-092
Role of endothelial mitophagy during endothelial dysfunction and liver fibrosis
Maria Ruart[1], Nuria Suárez-Herrera[1], Genís Campreciós[1,2], Claudia Berbel[1,2], Anna Baiges[1,2], Juan Carlos Garcia-Pagán[1,2], Virginia Hernandez-Gea[1,2]. *[1]Hospital Clínic-Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS). University of Barcelona., Barcelona Hepatic Hemodynamic Laboratory, Liver Unit, Barcelona, Spain; [2]Centro de Investigación Biomédica Red de enfermedades hepáticas y digestivas., Madrid, Spain*
Email: vihernandez@clinic.cat

Background and aims: Maintenance of healthy endothelial phenotype is essential to achieve an adequate cellular response against liver injury. The loss of liver sinusoidal endothelial cell (LSEC) phenotype known as endothelial dysfunction (ED) is a key event in the onset and progression of fibrosis since dysfunctional LSEC contribute to the activation of hepatic stellate cell (HSC). Defects in endothelial autophagy exacerbate ED and aggravate fibrosis due to, at least in part, an inefficient antioxidant response and accumulation of dysfunctional mitochondria worsening oxidative stress (OS). Mitophagy is a process that selectively removes damaged mitochondria (mainly oxidative damaged) and alleviates OS, however its role in ED and hepatic fibrosis is unknown. Our hypothesis is that mitophagy potentiation, would alleviate OS after injury by removing dysfunctional mitochondria, improving LSEC phenotype and consequently liver fibrosis.
Method: LSEC from control rats were cultured up to 48 hours to induce *in vitro* dysfunction. In addition, we isolated LSEC from CCl_4 treated rats (*in vivo* dysfunction). In dysfunctional LSECs, we evaluated mitophagy by markers of the PINK1/Parkin signaling pathway, the presence of dysfunctional mitochondria (Mitosox) and OS through the levels of reactive oxygen species (ROS). On the other hand, to evaluate the impact of OS on mitophagy, LSEC were treated with H_2O_2 and mitophagy levels were evaluated. Finally, in mouse LSEC (TSEC), autophagy was genetically inhibited (siAtg7) and potentiated with spermidine and evaluated their impact on OS, endothelial viability and mitophagic activity.
Results: Dysfunctional LSEC (*in vitro* and *in vivo*) showed an increase in ROS, an accumulation of dysfunctional mitochondria and a reduction in PINK1/Parkin signaling pathway. Exogenous OS caused mitochondrial damage that was accompanied by mitophagy upregulation. Autophagy inhibition in TSEC (siAtg7) was associated with accumulation of dysfunctional mitochondria and high levels of OS. Mitophagy enhancement using spermidine improved endothelial response to OS by increasing viability and reducing ROS, altogether contributing to an improvement of the endothelial phenotype.
Conclusion: Mitophagy potentiation improves endothelial response to oxidative stress by selectively removing damaged/dysfunctional mitochondria (mitophagy) and improves endothelial phenotype. Mitophagy enhancement could be a new antifibrotic strategy.

THU-093
The calpain inhibitor, BLD-2660, has robust anti-fibrotic activity in a rat model of non-alcoholic steatohepatitis
Mozhdeh Sojoodi[1], Smitha Krishnan[1], Allen A. Razavi[1], Michael R. Day[1], Gunisha Arora[1], Sarani Goshal[1], Shen Li[1], Derek J. Erstad[1], Peter Caravan[1], Kenneth K. Tanabe[1], Maria E. Fuentes[2], Bryan C. Fuchs[1]. *[1]Massachusetts General Hospital, Harvard Medical School, Boston, United States; [2]Blade Therapeutics, Inc, South San Francisco, United States*
Email: bfuchs@mgh.harvard.edu

Background and aims: Calpains are non-lysosomal Ca2+ dependent cysteine proteases, which modulate different cellular pathways and

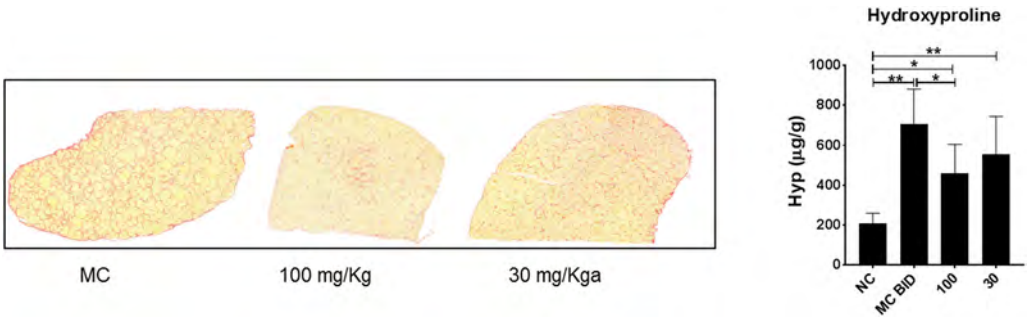


Figure: (abstract: THU-093)

have been involved in various inflammatory diseases. Calpains have also been shown to play a role in fibrosis development in mouse models of lung, skin, and myocardial fibrosis. Their role in liver fibrosis has yet to be explored. Here, we evaluated the effects of the small molecule inhibitor of calpain 1, 2, and 9, BLD-2660, provided by Blade Therapeutics Inc., in a rat model of non-alcoholic steatohepatitis (NASH).
Method: Adult male Wistar rats (175–200 g) were fed either normal chow (NC) or a choline-deficient, L-amino acid-defined, high fat diet with 60 kcal% fat and 0.1% methionine (CDAHFD) for 12 weeks. After 5 weeks, rats were randomized to receive either vehicle control (0.5% methylcellulose (MC), 100 mg/kg BLD-2660, or 30 mg/kg BLD-2660 by BID gavage (n = 8 per group). At the end of the study, liver tissue and serum were collected for further analysis.
Results: Rats fed CDAHFD developed liver fibrosis (F3) after 5 weeks of CDAHFD diet, which progressed to cirrhosis (F4) by 12 weeks. Expression of Calpain1 and 2 increased in rats fed CDAHFD. Treatment with BLD-2660 significantly decreased fibrosis development as assessed by morphometric quantification of the collagen proportional area on Sirius red stained sections (NC 3.02 ± 1.98%, MC 13.2 ± 4.4%, 100 mg/kg BLD-2660 6.0 ± 1.6%$p < 0.001$, and 30 mg/kg BLD-2660 8.8 ± 6.6% $p < 0.05$). These results were verified by measuring liver hydroxyproline (NC 207.7 ± 52.77 µg/g, MC 702 ± 173 µg/g, 100 mg/kg BLD–2660 458.2 ± 146 µg/g $p < 0.05$, and 30 mg/kg BLD-2660 554.6 ± 190.3 µg/g).
Conclusion: In a rat model of NASH cirrhosis that more closely resembles the histology of human disease increased expression of calpain 1 and 2 was observed. Therapeutic treatment with BLD-2660 reduces fibrosis progression further supports that calpain inhibitors have broad anti-fibrotic effects.

THU-094
Simple prediction score to predict fibrosis in type 2 diabetes mellitus patients

Ioan Sporea[1], Raluca Lupusoru[1], Ruxandra Mare[1], Nistorescu Silviu[1], Alina Popescu[1], Roxana Sirli[1], Diana Lungeanu[2]. *[1]Victor Babes University of Medicine and Pharmacy, Gastroenterology and Hepatology, Timișoara, Romania; [2]Victor Babes University of Medicine and Pharmacy, Medical Informatics and Biostatistics, Timișoara, Romania*
Email: isporea@umft.ro

Background and aims: Non-alcoholic fatty liver disease is becoming the most common cause of chronic liver disease. The aim of this study was to identify factors associated with advanced liver disease in a cohort of type 2 diabetes patients and to make a prediction score.
Method: Patients were recruited prospectively in the study. Every first 6 patients who were referred to the Metabolic Disease Outpatient Clinic on a consultation day. Evaluation of liver fibrosis was made using Transient Elastography (FibroScan), performed in fasting conditions, with M and XL probes. Each patient was evaluated biologically for the presence of viral hepatitis (B and C) and an AUDIT-C score was performed to exclude alcohol abuse. Variables tested for the association with advanced liver fibrosis were: age, body mass index (BMI), abdominal circumference, hypertension, years after diagnosis of diabetes, glycemia, glycosylate hemoglobin, AST, ALT. Logistic regression was used for multivariate model to assess the association between advanced liver fibrosis and other variables. The cut-off value for advanced fibrosis was >8.4 kPa (Petta S et al. 2015).
Results: The total number of diabetics evaluated was 641. After the exclusion of others conditions, 468 patients with NAFLD were included. We randomly assign patients in the model development set-344 patients (mean age 60.1 ± 9.1, 54.4% females) and 123 in the validation set (mean age 60.6 ± 9.6, 54.3% women and 45.7% men). Advanced fibrosis was found in 28.7% (99/344) patients. To assess the advanced fibrosis predicting score, all clinical variables associated with advanced fibrosis, with $p < 0.05$ in the univariate analysis were considered in a multivariate regression model. Predicting score for advanced fibrosis was given by age, BMI, glycosylate hemoglobin and AST: 0.26*age (years) + 0.01*BMI (kg/m²) + 0.03* glycosylate hemoglobin (mmol/L) + 0.0004*AST (U/L)-0.9. The model gave us an accuracy of 92.1%, AUROC = 0.99, 95% CI (0.97-0.99). The best cut-off value for rule out advanced fibrosis was >16.4, Se = 100%, NPV = 100%. On the validation set we obtained an accuracy of 91.3%, Se = 92.1% and NPV = 87.5% for ruling out advanced fibrosis.
Conclusion: In our group, 28.7% of diabetic patients had advanced fibrosis. Body mass index (BMI), age, glycemia, glycosylate hemoglobin, AST, ALT were associated with advanced liver fibrosis. For ruling out advanced fibrosis, the new predicting score had 91.3% accuracy.

THU-095
Short and long-term evaluation of liver fibrosis and outcomes in patients with chronic hepatitis C after INF-free antiviral treatment

Cristina Stasi[1], Sinan Sadalla[1], Eleonora Carradori[1], Monica Monti[1], Luisa Petraccia[1], Francesco Madia[1], Laura Gragnani[1], Anna Linda Zignego[1]. *[1]Interdepartmental Hepatology Center MaSVE, University of Florence, Department of Experimental and Clinical Medicine, and Research and Innovation Center CRIA-MASVE, AOU Careggi, Florence, Italy*
Email: cristina.stasi@unifi.it

Background and aims: The evolution of chronic hepatitis C into liver cirrhosis is correlated with an extensive accumulation of extracellular matrix, leading to the formation of large amounts of fibrotic tissue. The new direct-acting antiviral drugs (DAAs) can eradicate HCV infection in over 90% of patients. According to recent studies, the use of DAAs reduces the risk of complications even in advanced fibrosis. Therefore the aims of this study were to evaluate 1) changes in fibrosis during and after antiviral treatment; and 2) the incidence of hepatocellular carcinoma (HCC) and related mortality in various stages of fibrosis.
Method: This is a longitudinal monocentric prospective study. Laboratory and instrumental examinations were evaluated at baseline, at the end of therapy, and after 1 and 2 years following

treatment. The assessment of liver fibrosis was performed by transient elastography.
Results: Two hundred and ninety-six patients with chronic liver disease were enrolled, of whom 115 patients were treatment experienced, 181 naïve, including 2 with previous HCC. At baseline, the stiffness values were 13.46 ± 9.97 kPa. When the patients were divided by stiffness groups according to the fibrosis staging, the F0-F2 group and the F3-F4 one had stiffness of 6.07 kPa±1.68, and 17.93 ± 10.23, respectively. No statistically significant difference was found between stiffness values at baseline compared to end of treatment (EOT), while statistically significant differences were found between baseline and 1 year ($p = 0.05$) and the 2-year follow-up ($p < 0.01$). When the patients were divided into two groups (F0-F2 and F3-F4), no significant differences were found between the baseline and the EOT, or after 1 and 2 years from EOT in the F1-F2 group. On the contrary, statistically significant differences were found between the baseline and EOT, as well as 1 and 2 years after the end of treatment ($p < 0.001$) in the F3-F4 group. Five out of 67 patients with baseline cirrhosis developed HCC during post-treatment follow-up, 1 of whom died.
Conclusion: Non-invasive methods provide important prognostic information, particularly about regression of fibrosis or the occurrence of liver cirrhosis complications, despite the fibrosis regression after antiviral treatment. They may result very useful for the correct approach to patients with long life expectancies after direct-acting antiviral treatment.

THU-096
Development and validation of true serum biomarkers of liver fibrogenesis ans fibrolysis
Rambabu Surabattula[1], Erika Monguzzi[1], sudha rani myneni[1], Towia Libermann[2], Tim Zimmermann[3], Detlef Schuppan[1,4].
[1]University medical center Mainz, Institute of translational Immunology, 55131, Mainz, Germany; [2]harvard medical school, bidmc and dana-farber proteomics core, Boston, United States; [3]University medical center Mainz, First department of medicine, 55131, Mainz, Germany; [4]harvard medical school, Beth israel deaconess medical center, Boston, United States
Email: detlef.schuppan@unimedizin-mainz.de

Background and aims: Better serum biomarkers to assess the progression of liver fibrosis and especially fibrosis reversal are urgently needed. We aimed to identify novel extracellular matrix derived serum biomarkers of fibrogenesis and fibrolysis using well defined cirrhotic sera and follow-up sera of patients post liver transplant (LTx) with rapid fibrosis progression (cirrhosis within 1–5 years) and of patients before and after highly effective antiviral therapy for chronic hepatitis C (CHC), with sustained viral response (SVR).
Method: Matricellular fibrosis markers A9, T2, T4, I7 and I3 were identified by SOMAScan proteomics of sera of patients with rapid fibrosis progression, and based on their mechanistic role in ECM remodeling. Follow-up sera of patients with well-defined course post LTx and cirrhosis and pre/post-antiviral therapy with SVR were used to confirm fibrosis marker plausibility. Sera of 40 healthy controls served as comparators. Serum concentrations of A9, T2, T4, I3 and I7 were measured via in-house developed sandwich ELISAs.
Results: Normal serum levels of A9, T2, T4 and I7 were in a narrow range (10 ± 6, 54 ± 20, 84 ± 23, 182 ± 30 ng/ml resp.). Serum levels of A9, T2, T4 and I7 were significantly higher (42 ± 37, 178 ± 77, 135 ± 44 and 303 ± 48 ng/ml resp.), in LTx and cirrhotic patients with rapid fibrosis progression compared to healthy or patients with mild fibrosis. Serum A9, T2, T4 and I7 differentiated between Child-Pugh groups. The AUC values of ROC curves to distinguish fibrosis F2-4 from F0-1 were >0.95 for T2 and I7, and >0.85 for T4 and A9. In patients with CHC before and after effective antiviral therapy, levels of A9, T2, T4 and I7 fell from 71 ± 58, 134 ± 68, 121 ± 55 and 147 ± 22 to 28 ± 31, 86 ± 31, 86 ± 32 and 141 ± 22 ng/ml after the antiviral therapy, whereas another marker, I3 increased significantly from 350 ± 179 to 407 ± 79. The underlying biochemistry as well as the results support a prominent role of A9, T2, T4 and I7 in liver fibrogenesis, and of I3 in liver fibrolysis. There was a significant correlation between the markers T2, T4 and I7.
Conclusion: We identified and validated 4 novel ECM derived serum marker of liver fibrogenesis and one putative marker of liver fibrolysis. Two fibrogenesis markers showed the currently highest predictive value for detecting significant fibrosis. Studies are ongoing to evaluate large prospective and follow-up cohorts of patients with NASH and other chronic liver diseases, including comparisons with current fibrosis markers.

THU-097
Serum infrared spectral profile is predictive of the degree of hepatic fibrosis in chronic hepatitis C patients
Gérard Thiéfin[1,2], Dominique Bertrand[3], Valérie Untereiner[2], Roselyne Garnotel[2,4], Marc Offroy[5], Jean-Pierre Bronowicki[6], Ganesh Sockalingum[2]. *[1]Reims University Hospital, HepatoGastroenterology Unit, REIMS, France; [2]Reims Champagne Ardenne University, EA 7506 BiospecT unit, Reims, France; [3]DataFrame, Nantes, France; [4]Reims University Hospital, Biochemistry Department, REIMS, France; [5]Lorraine University, LIEC UMR 7360, Vandoeuvre les nancy, France; [6]Nancy University Hospital, HepatoGastroenterology Unit, Vandoeuvre les Nancy, France*
Email: gthiefin@chu-reims.fr

Background and aims: Assessment of liver fibrosis is crucial to guide the therapeutic strategy in patients with chronic liver disease. In this study, we investigated the potential of serum Fourier transform infrared (FTIR) spectroscopy for assessing the degree of fibrosis in a series of patients with chronic hepatitis C (CHC).
Method: Serum samples from 94 CHC patients at different histological stages of fibrosis were selected : Metavir F0 (n = 20), F1 (n = 17), F2 (n = 20), F3 (n = 20) et F4 (n = 17). Infrared spectra (ten replicates per sample) were acquired in the transmission mode using an FTIR spectrometer (tensor 27, Bruker Optics GmbH, Ettlingen, Germany) coupled to a high-throughput system (HTS-XT, Bruker Optics GmbH). Each spectrum was recorded in the wavenumber range from 400 to 4, 000 cm^{-1}, at a nominal physical resolution of 4 cm^{-1} and averaged over 32 scans. Spectra that passed the quality test were converted to second derivatives using the Savitsky-Golay algorithm and *normalized* using the *SNV* procedure. Twenty wavelengths were selected by genetic algorithm according to their diagnostic performance as assessed by a PLS model with 5 components. The diagnostic performance was measured by the area under the ROC curve (AUROC) using a training set (n = 76) and a validation set (n = 18) to differentiate patients with fibrosis at stages F0F1F2 and those with fibrosis at stages F3F4 and then to differentiate patients with fibrosis at stages F0F1F2F3 and those with fibrosis at stage F4. To take into account the sample error, 1000 iterations were performed with the final set of 20 wavelengths in order to calculate the mean AUROC. Matlab-based algorithm was built for automatic spectral analysis and classification.
Results: After quality tests and spectral pre-processing, analysis was performed on the mean spectra (1849 variables per spectrum) from the 94 patients. The PLS model with 5 components allowed to differentiate F3F4 patients and F0F1F2 patients with AUROC of 0.89 ± 0.084 (mean±SD for 1000 iterations). Among the 1000 iterations, only 0.46% had AUROC < 0.70. For the comparison of stages F0F1F2F3 vs F4, the PLS model with 5 components also had a good diagnostic performance with AUROC of 0.90 ± 0.051. Only 0.34% of 1000 iterations had AUROC < 0.70.
Conclusion: Serum FTIR spectroscopy appears to have a strong potential of development as a new diagnostic tool in clinical practice for assessing the degree of fibrosis in patients with chronic liver disease. The algorithm developed in CHC patients is intended to be tested and validated in other chronic liver diseases. This innovative

technique enables data acquisition in a simple, rapid, reagent-free and high-throughput mode.
This study was funded by Société d'Accélération de Transfert de Technologie SATT Nord.

Changes in liver stiffness measurements following DAA treatment among HIV/HCV-coinfected individuals: Does HIV contribute to liver disease after HCV cure?

Daniela van Santen[1], Jennifer Hoy[2], Paul Agius[1], David Iser[2,3], Mark O'reilly[4], Joe Sasadeusz[2,5], Mark Stoove[1], Janine Roney[1], Richard Moore[6], Tee Bk[7], Nick Medland[8,9], Christopher Fairley[9], Edward Gane[10], Gail Matthews[11], Maria Prins[12], Margaret Hellard[1,2,8], Joseph Doyle[1,2,8]. *[1]Burnet Institute, Melbourne, Australia; [2]Alfred Hospital, Melbourne, Australia; [3]St. Vincent's Hospital Melbourne, Fitzroy, Australia; [4]Prahran Market Clinic, Prahran, Australia; [5]The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; [6]Northside Clinic, Fitzroy North, Australia; [7]The Centre Clinic, Saint Kilda, Australia; [8]Monash University/Wellington Road, Clayton, Australia; [9]Melbourne Sexual Health Clinic, Melbourne, Australia; [10]The University of Auckland, Auckland, New Zealand; [11]The Kirby Institute, Kensington, Australia; [12]GGD Amsterdam, Amsterdam, Netherlands*
Email: daniela.vansanten@burnet.edu.au

Background: HIV-coinfection is known to accelerate liver fibrosis progression in HCV-infected individuals. Treatment with direct-acting antivirals (DAA) has the potential to reverse liver fibrosis, but evidence of fibrosis regression among HIV/HCV-coinfected populations in the DAA era is limited. We aimed to assess changes in liver stiffness measurements (LSM) after HCV cure in HIV/HCV-coinfected individuals, and to determine the role of HIV disease and other predictors of liver fibrosis.
Method: Data from individuals participating in the co-EC study were used. The co-EC study is an ongoing (March 2016–) non-randomised trial of DAA therapy among HIV/HCV-coinfected individuals. LSM before and after treatment were obtained using transient elastography. To evaluate changes in LSM values following treatment, univariable and multivariable linear mixed regression models were used. Potential predictive factors of LSM were determined a priori. Subsequently, we tested the interactions between selected potential predictors and time since initial TE assessment. A p value of <0.05 was considered statistically significant.
Results: Of 200 included participants, 179 had at least one LSM available and 96 participants had two LSM results. Median time between pre- and post-DAA elastography assessments was 1.2 years [Interquartile range = 0.9–2.1]. In univariable analysis, successfully treated patients had a decrease of 0.95 kilopascal (kPa) (95%CI: −0.91, −0.99 kPa) in LSM value per year, becoming non-significant in multivariable analysis (LSM change −0.97 kPa; 95%CI: −0.92, 1.01). Longer duration of known HIV infection (1.01 kPa per year since HIV diagnosis; 95%CI: 1.00, 1.02) and a lower CD4 count (lowest v highest CD4 count tertile: 1.32 kPa; 95%CI: 1.04, 1.64) at initial elastography assessment were significantly associated with higher LSM. However, changes in LSM after HCV cure did not differ by CD4 count or HIV known duration. Hazardous alcohol consumption, HCV genotype and body mass index were not significantly associated with changes in LSM values in multivariable analysis.
Conclusion: Consistent with data on HCV-monoinfection, we observed a decrease in LSM following HCV cure among HIV/HCV-coinfected individuals. Markers of more advanced HIV infection did not seem to impact changes in LSM values after HCV cure. The finding that individuals with more advanced HIV have on average higher LSM needs longer follow-up to determine the clinical importance following DAA treatment.

Collagen is not just collagen: Differential matrix expression induced by TgF-beta and PDGFs

Ida Villesen[1], Alexander Lynge[1], Federica Genovese[1], Morten Karsdal[1]. *[1]Nordic Bioscience, Herlev, Denmark*
Email: arp@nordicbio.com

Background and aims: Accumulation of extracellular matrix (ECM) proteins is a hallmark of fibrosis. It leads to altered tissue homeostasis and ultimately organ failure. This occurs as fibroblasts are activated in interplay with many different cell types and growth factors that leads to increased synthesis and accumulation of extracellular matrix (ECM) proteins. We hypothesized that platelet-derived growth factor (PDGF)-AB, PDGF-BB and transforming growth factor (TGF)-β1 each induce synthesis profiles of different ECM proteins relevant for fibrogenesis.
Methods: The effect of PDGFs (AB and BB) and TGF-β1 on ECM protein synthesis was assessed in a "scar-in-a-jar" (SiaJ) cell model using primary human fibroblasts from a healthy donor. Cells were seeded in 48-well plates at the density of 30.000 cells/well and incubated for 24 h in DMEM + 10% FBS. This was followed by 24 h incubation in serum starvation media (DMEM + 0.4% FBS). Fresh culture media were then added (this day was referred to as day 0) consisting of starvation media in addition to 225/150 mg/ml Ficoll 70/400 and 1% ascorbic acid, and containing 0.04 nM TGF-β1, 4-, 0.4-, or 0.04 nM PDGF-AB or -BB or no stimulants (vehicle control). Culture media were changed and collected at day 3, 6, 10 and 13. Biomarkers of collagen type I (PRO-C1), III (PRO-C3), VI (PRO-C6) and fibronectin (FBN-C) formation were assessed by competitive ELISAS measured in the supernatants.
Results: TGF-β1 induced significant higher PRO-C1, PRO-C3 and FBN-C compared to PDGFs or the vehicle. Levels were 50-fold higher for PRO-C1 and FBN-C and 10-fold for PRO-C3 compared to vehicle. PDGFs resulted in higher concentrations of FBN-C and PRO-C1 but not PRO-C3 compared to the vehicle, and with lower potency than TGF-β1. PRO-C6 was inhibited by TGF-β1, but dose-dependently stimulated by PDGFs. FBN-C and PRO-C1 peaked after 6 days of TGF-β1 treatment. PRO-C3 peaked after 10 days of TGF-β1 or PDGF stimulation, respectively and PRO-C6 peaked after 10 days of stimulation of PDGF.
Conclusion: These data provide insight in the complex regulation of fibroblast induced ECM protein synthesis in response to different signalling molecules. The presented findings clearly indicate that different growth factors lead to different protein synthesis profiles. Thus, the SiaJ fibroblast model combined with biomarkers of ECM formation may be a useful tool for further investigation of the unique interplay between growth factors and fibroblasts.

FGL2 regulates liverfibrosis progression and reversal by promoting profibrotic infiltrating macrophages maintenance

Ran Tao[1], Wei Yuan[1], Fang Xiao[1], meiqi liu[1], Hongwu Wang[1], Di Wu[1], Peng Wang[1], Jiaquan Huang[1], Xiaoping Luo[1], Xiaoyang Wan[1], Qin Ning[1]. *[1]Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*
Email: qning@vip.sina.com

Background and aims: Hepatic macrophages (HMs) are a heterogeneous population and hold central position in liver fibrosis progression and reversal. Fibrinogen-like protein 2 (Fgl2), expressed on macrophages in response to pathogens challenge, has been associated with severity of chronic hepatitis B. In this study, we aimed to investigate the role and the potential mechanisms of Fgl2 during liver fibrosis in vivo and in vitro.
Method: FGL2 levels were examined in patients of hepatitis B-related fibrosis. Murine model of liver fibrosis was established in wild type and *fgl2* mutant mice by intraperitoneal injection CCl_4. Liver fibrosis were detected by Sirius red or immunohistochemical staining against α-MSA. Resident and infiltrating macrophages were analysed by flow

cytometry. Cytokines of liver homogenate were assessed using ELISA. Pharmacological administration of muramyl dipeptide (MDP) by intraperitoneal injection was carried out to facilitate macrophage transition from profibrotic into restorative property. Bone marrow derived macrophages from wild type and *fgl2*$^{-/-}$ mice were co-cultured with were wild type hepatic stellate cells (HSC) to evaluate impact of Fgl2 expression on profibrotic macrophages.
Results: Fgl2 expression was associated with high grade of liver fibrosis in chronic Hepatitis B patients and experimental models in response to liver damage. Genetic ablation of the Fgl2 alleviated fibrosis in the chronically injured liver and promoted reversal during the resolution. Such effect was linked to a switch of macrophage from profibrotic into restorative phenotype in *fgl2*$^{-/-}$ mice in response to liver damage. Moreover, Pharmacological administration of MDP alleviated fibrosis in wild type mice and more profoundly in *fgl2*$^{-/-}$ mice. Such effect was associated with coordinated increased switch of infiltrating macrophages from Ly6C^{high} into Ly6C^{low} phenotype. On cellular levels, Fgl2 depletion in macrophages significantly dampened the activation of primary HSCs in response to macrophage-dependent stimulation.
Conclusion: Our data demonstrates that Fgl2 regulates liver fibrosis by maintaining profibrotic phenotype in resident and infiltrating macrophages. Target remodelling of infiltrating macrophages from proinflammatory Ly6C^{high} into restorative Ly6C^{low} ameliorates liver damage and fibrosis progression, thereby providing novel insights into therapeutic strategy for fibrosis treatment.

THU-101
Artery density in human liver: A valuable measure for staging of chronic liver disease

Ian Wanless[1], Yameng Sun[2], Bingqiong Wang[2], Hong You[2], Ji-Dong Jia[2], Shuyan Chen[2], Xiaoning Wu[2], Jialing Zhou[2], Xiaojuan Ou[2], Priyanka Ravi[1], Ashley Stueck[1]. [1]*Dalhousie University, Pathology, Halifax, Canada;* [2]*Beijing Friendship Hospital, Liver Research Center, Beijing, China*
Email: iwanless@eastlink.ca

Background and aims: Human chronic liver disease has classically been staged by density of collagen as estimated by the presence of collagen-containing septa (METAVIR, Ishak, Laennec systems) or by quantitative image analysis expressed as collagen proportionate area (sirius red or dual harmonic generation = qFibrosis). Recently, we have shown that severe cirrhosis is accompanied by 8-fold collapse of tissue revealed by increased portal tract number/mm^2, via duct density as well as artery density (AD). The present study demonstrates the value of AD as the basis of a new staging system.
Method: Preliminary measures of AD were performed on large excised liver specimens with variable etiology and stages (Laennec 0 to 4C, and regressed cirrhosis) to determine an optimal method. This method was applied to needle biopsies obtained in the course of a previously published therapeutic trial of entecavir in patients with chronic hepatitis B (Sun Y et al, Hepatology 2017;65:1438). 20 pairs of biopsies, obtained before and after 78 weeks of therapy, were evaluated by 3 methods. Stage was recorded blindly with the Laennec system. Collagen was quantified by qFibrosis (courtesy HistoIndex, Singapore). Artery profiles 12–20 microns diameter were counted on sections stained to identify smooth muscle actin.
Results: Artery density correlated closely with the other staging methods (qFibrosis vs AD, r = 0.60, p = 0.0002; Laennec vs AD, ANOVA F = 8.4, P = 0.0001) (Fig. 1). Laennec stage was improved at 78 weeks in 14 of the 20 pairs; those with an improved stage had a mean decrease in AD of 39% from baseline, consistent with repopulation of tissue with hepatocytes.

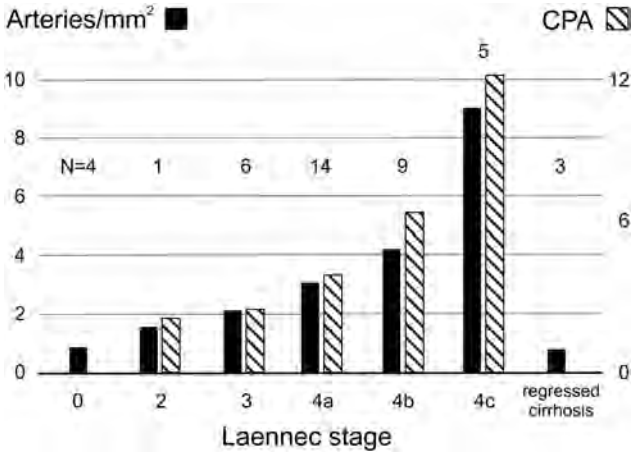

Figure: All data from needle biopsies in the hepatitis B trial, except stage 0 and regressed cirrhosis (hemochromatosis post-phlebotomy) tissue obtained at surgery. N = number of samples. Arteries 12–19.9 µm (solid bars). Collagen proportionate area (Total-CPA) by second harmonic generation (qFibrosis, hatched bars).

Conclusion: The close correlation among AD and other accepted staging systems indicates that this simple metric provides the basis for a new staging system. Minimal training is required to achieve less interobserver error compared to semiquantitative methods and does not require specialized equipment. The method can also be applied accurately to HandE slides if they are thin and well-prepared.
Artery density, as a measure of tissue collapse after disease-related hepatocyte loss, is fundamentally different from collagen measurement, providing insight into the pathogenesis of cirrhosis. Some increase of collagen density in cirrhosis is caused by collapse of preformed portal tract collagen. Comparison of these measures, standardized with appropriate controls, allows liver collagen to be subdivided into collapsed stroma and actively acquired collagen.

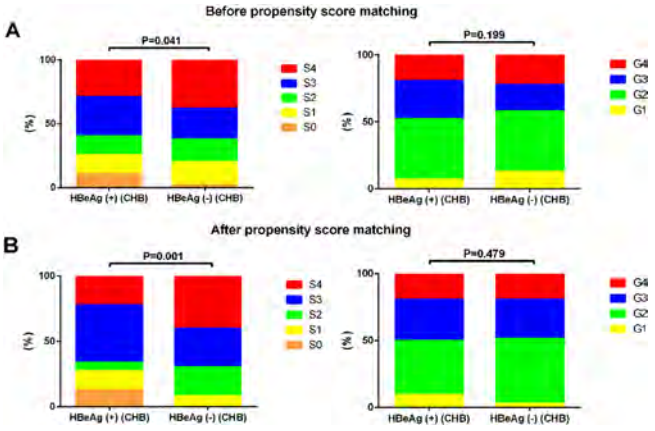
HBEAG negative CHB patients is associated with more severe liver fibrosis than hbeag positive CHB patients: A propensity score matching analysis

Jian Wang[1], Rui Huang[1], Yong Liu[2], YuXin Chen[2], Xiaomin Yan[1], Weimao Ding[3], Chao Wu[1]. [1]*Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Infectious Diseases, Nanjing, China;* [2]*Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Laboratory Medicine, Nanjing, China;* [3]*Huai'an No. 4 People's Hospital, Department of Hepatology, Huai'an, China*
Email: dr.wu@nju.edu.cn

Background and aims: Serum hepatitis B e antigen (HBeAg) plays an important role in the progression and prognosis of hepatitis B virus (HBV) related liver diseases. However, few studies reported whether HBeAg status is related with the degree of liver injury in patients with chronic hepatitis B (CHB). We aimed to investigate the relationship between hepatitis HBeAg status and liver pathological stages in CHB patients using propensity score matching (PSM).
Method: A total of 286 treatment-naïve CHB patients with alanine aminotransferase (ALT) > upper limit of normal (ULN) who had undergone liver biopsy were enrolled in this study. PSM was performed to adjust for the imbalance of baseline confounders between HBeAg-positive CHB patients and HBeAg-negative CHB patients.
Results: Of these 286 CHB patients, 62 patients were included in each group after PSM. HBeAg-negative CHB patients (n = 100) exhibited a significantly severity of liver fibrosis than HBeAg-positive CHB patients (n = 186) before PSM (p = 0.041). However, there were no significant differences of the distribution of each inflammation grade

between HBeAg-positive CHB patients and HBeAg-negative CHB patients (p = 0.199). After propensity matching, CHB patients with HBeAg-negative (n = 62) still showed a significantly severity of liver fibrosis as compared with HBeAg-positive CHB patients (n = 62) (p = 0.001). Furthermore, the distribution of liver inflammation grade was comparable between HBeAg-positive CHB patients and HBeAg-negative CHB patients (p = 0.479).



Conclusion: HBeAg negative CHB patients may have more serious degree of liver fibrosis than HBeAg positive CHB patients in the propensity score matching (PSM) analysis.

Email: detlef.schuppan@unimedizin-mainz.de

Background and aims: Fibroblast activation protein (FAP) is a surface protein with prolyl endopeptidase activity expressed on activated (myo-) fibroblasts. Its functional role in liver fibrosis and desmoplastic cancer is limited. Targeting FAP in liver fibrosis could be a novel antifibrotic strategy in fibrogenesis, but there exist no studies on pharmacological FAP inhibition due to the lack of a specific, small molecule inhibitor. Cpd 60, a new FAP inhibitor based on a 4-quinolinoyl-Gly-cyanoPro scaffold, shows a potent and selective inhibition with a promising pharmacokinetic behavior. Here, we investigated the effects of this new FAP inhibitor in murine liver fibrosis models.
Method: 3 liver fibrosis models were employed and mice received Cpd60 at 15 or 50 mg/kg/day orally, or vehicle: 1) Parenchymal progression: C57BL/6-WT mice were subjected to 6 weeks of escalating doses of CCl4 by oral gavage and received Cpd60 or vehicle in the last 2 weeks; 2) parenchymal regression: fibrosis was induced by 6 weeks of CCl4 and allowed to reverse for 2 weeks with Cpd60 or vehicle; 3) Mdr2−/− mice or their FVB wildtype controls received Cpd60 or vehicle from week 5 to week 7 of age. Collagen determinations, histological studies, serum and enzyme activity determinations, and molecular biology techniques were carried out to assess liver fibrosis and inflammation.
Results: In CCl4 induced progression Cpd60 reduced Sirius red stained collagen area by 44% and 37% (15 and 50 mg/kg/day) (p < 0.05, compared to vehicle), total liver hydroxyproline by 33% and 22% (p < 0.01), aSMA+ myofibroblasts by 35% and 52% (p < 0.001) and YM1+ (M2-type) macrophages by 63% and 68% (p < 0.001). This was accompanied by a decrease of serum ALT and AST, as well as a significant downregulation of key transcripts related to fibrogenesis (acta2, col1a1, col3a1, timp1, spp1, pdgfrb, mmp2, mmp9 and mmp13) and inflammation (ccl2, ym1) transcripts. However, FAP inhibition was ineffective in decreasing these parameters in the regression model of CCl4 induced fibrosis and in the model of biliary fibrosis in Mdr2−/− mice. FAP inhibition regulated TGFb1 but not TGFb2 expression that is mainly produced by activated cholangiocytes.
Conclusion: We describe for the first time the effect of an oral FAP inhibitor (Cpd60) in 2 models of liver fibrosis progression and in one model of spontaneous regression. Pharmacological FAP inhibition suppresses parenchymal fibrogenesis, but does not affect fibrosis resolution or biliary fibrogenesis. Antifibrotic effects of FAP inhibition may be dependent on TGFb1 but not TGFb2. FAP inhibition may be useful in rapidly progressive liver fibrosis.

THU-105

Modulation of G protein alpha inhibiting activity polypeptide 2 in hepatocytes regulate liver fibrosis

Amar Deep Sharma[1,2], Qinggong Yuan[1,3], Hsin-Chieh Tsay[1,2,3], balakrishnan asha[1,3], Michael Ott[1,3]. [1]*Medizinische Hochschule Hannover, Gastroenterology, Hepatology, and Endocrinology, Hannover, Germany;* [2]*Medizinische Hochschule Hannover, Cluster of Excellence, REBIRTH, Hannover, Germany;* [3]*Twincore, Zentrum für Experimentelle und Klinische Infektionsforschung GmbH, Hannover, Germany*
Email: sharma.amar@mh-hannover.de

Background and aims: Fibrosis significantly contributes to the mortality due to end-stage chronic liver diseases. The cross-talk, between hepatocytes and hepatic stellate cells, is suggested to play a key role in fibrosis progression. While major efforts have been devoted to elucidate hepatic stellate cells' functions during liver fibrosis, the regulatory functions of hepatocytes remain elusive.
Method: We co-cultured primary hepatocytes with hepatic stellate cells and investigated the ability of hepatocytes to regulate fibrosis by modulating the expression of G protein alpha inhibiting activity polypeptide 2 (Gnai2). The in vivo functional analyses were performed in hepatocytes using adeno-associated virus in carbon-tetrachloride- and 3, 5-di diethoxycarbonyl-1, 4-dihydrocollidine-induced liver fibrosis.
Results: We found that overexpression of Gnai2 in hepatocytes suppresses expression of fibrogenic genes in co-cultured hepatic stellate cells. Further, we demonstrate that Gnai2 modulation regulate secretion of C-C motif chemokine ligand 2 (CCL2), a key molecular regulator of liver fibrosis.
Conclusion: Our findings revealed that molecular changes, which cause overexpression of Gnai2 in hepatocytes, leads to suppression of liver fibrosis via reduction in CCL2 levels. Hence, modulation of Gnai2 in hepatocyte, an easy-to-target cell type in the liver, may serve as a potential therapeutic approach for liver fibrosis.

Viral hepatitis C: Therapy and resistance

THU-111

High efficacy and safety of the combination HCV regimen elbasvir and grazoprevir for 8 weeks in treatment-naive non-severe fibrosis HCVGT1b-infected patients: Final results of the STREAGER study

Armand Abergel[1], Christophe Hezode[2], Tarik Asselah[3], Dominique Larrey[4], Jérôme Gournay[5], Veronique Loustaud-Ratti[6], vincent di martino[7], Isabelle Fouchard Hubert[8], Pol Stanislas[9], Francois Bailly[10], Didier Samuel[11], Tran Albert[12], Brigitte Chanteranne[1], Marie Dodel[1], Frederic Faure[1], Bruno Pereira[1], Géraldine Lamblin[1], Leon Muti[1], Cecile Campos[1], Maud Reymond[1], Camille Teilhet[1], Benjamin Buchard[1]. *[1]Chu Estaing, Clermont-Ferrand, France; [2]Hôpital Henri-Mondor Ap-Hp, Créteil, France; [3]Hospital Beaujon Ap-Hp, Clichy, France; [4]Hospital Gui De Chauliac, Montpellier, France; [5]University Hospital of Nantes, Nantes, France; [6]Limoges Dupuytren University Hospital Center, Limoges, France; [7]Regional University Hospital of Besançon Jean Minjoz, Besançon, France; [8]Centre hospitalier universitaire d'Angers, Angers, France; [9]Hospital Cochin, Paris, France; [10]Hopital De La Croix Rousse, Caluire-et-Cuire, France; [11]Hôpital Paul-Brousse Ap-Hp, Villejuif, France; [12]Hospital L'archet 2, Nice, France*
Email: aabergel@chu-clermontferrand.fr

Background and aims: Genotype 1b is the most common HCV genotype globally, accounting for the largest proportion of infections in Europe, Latin America, Russia, Turkey, and East Asia. Reducing treatment duration can improve adherence and reduce drug exposure. L. Serfaty *et al.* have previously shown in a cohort of 56 patients that grazoprevir and elbasvir ± ribavirin for eight weeks can obtain an SVR12 higher than 90% (AASLD 2015). Accordingly, we evaluated the efficacy of eight weeks fixed dose single tablet combination of an NS5A inhibitor elbasvir 50 mg/d (EBR) and protease inhibitor grazoprevir 100 mg/d (GZR) in treatment-naïve patients, with non-severe fibrosis (F0-F2).
Method: Analysis included 112 treatment-naïve (TN), with non-severe fibrosis (Fibroscan® < 9.5 kPa and Fibrotest® < 0.59), HCV GT1b-mono-infected patients enrolled in the STREAGER trial, a study which included 117 patients. Historic labs were used for enrollment. Subsequent genotyping by sequencing during the course of the study identified five patients with non-1b genotype (2 GT1a, 1 GT1e, 1 GT1 h and 1 GT1 l). Thus, we will include in the final analysis 112 GT1b patients. The primary end point was the proportion of patients with HCV RNA below the lower limit of quantification (LLOQ) 12 weeks after treatment (SVR12).
Results: Mean age was 54 ± 13 years, 31% were male, viral load higher than 800.000 IU/ml: 70/112 (62.5%); ALT higher than the upper limit of normal: 51/112 (46%). Using Fibrotest® (FT), 69 had a F0-F1 fibrosis score (FT < 0.32); by Fibroscan® (FS) 100 had F0–1 fibrosis score (FS < 7.1 kPa). FIB-4 lower than 1.45 and APRI less than 1 was found in 74/112 (66%) and 107/112 (95.5%) patients respectively. By the end of treatment (EOT), 94.6% (106/112) of patients had HCV RNA < LLOQ. No adverse event grade III or IV related to treatment was observed. Relapse occurred in 3 patients. Viral loads before treatment of these 3 patients were as follows: 14, 16.4, 8.3 millions IU/ml. RAS (resistance associated substitutions) at relapse were respectively: Y93H; L31M, Y93H; L31M, Y93H. Then, mITT (modified intention-to-treat) SVR12 for patients with genotype 1b (after exclusion of the 5 patients with genotype non 1b) was 109/112 (97.3%). Two other patients relapsed 24 weeks after EOT (SVR24) despite reaching SVR12 and 1 patient is lost to follow-up. SVR24 results was 95.5% (106/111) in mITT. Further data related to the 112 patients will be available at the EASL meeting.
Conclusion: High SVR12 (109/112, 97.3%) was achieved in a TN non-severe fibrosis GT1b-infected patients treated for 8 weeks by the combination of elbasvir and grazoprevir.

THU-112

Real-world health care resource utilization and quality of life with G/P treatment: A pooled analysis from post-marketing observational studies

Alessio Aghemo[1], Stefan Bourgeois[2], Michael Gschwantler[3], Yuri Sanchez[4], Lois Larsen[4], Mark Bondin[4], Lorenzo Magenta[5], Tarik Asselah[6]. *[1]Humanitas University and Research Hospital, Rozzano, Italy; [2]ZNA Antwerp, Antwerp, Belgium; [3]Wilhelminenspital, and Sigmund Freud University, Vienna, Austria; [4]AbbVie, Inc, North Chicago, United States; [5]Epatocentro Ticino, Lugano, Switzerland; [6]Hopital Beaujon and INSERM UMR 1149, Clinchy, France*
Email: alessio.aghemo@hunimed.eu

Background and aims: To inform HCV treatment guidelines, it is important to understand healthcare resource utilization (HCRU) and treatment outcomes in routine clinical practice. As limited HCRU and quality of life data have been reported with direct acting antivirals, we present a pooled analysis across multiple countries of real-world HCRU and patient-reported outcomes (PROs) for patients receiving the pangenotypic regimen of glecaprevir (NS3/4A protease inhibitor; developed by AbbVie and Enanta) and pibrentasvir (NS5A inhibitor; co-formulated as G/P) in ongoing post-marketing observational studies (PMOS).
Method: Data were pooled from six countries (Austria, Belgium, France, Israel, Italy, and Switzerland) thus far participating in this prospective PMOS. Patients with chronic HCV genotypes 1-6 were eligible for the PMOS if they were receiving G/P at the treating physician's discretion according to local clinical practice, international recommendations and/or local label. HCRU was determined by the number of PMOS visits for patients within their local clinical setting. The study protocol recommended 5 visits per patient regardless of treatment duration. SF-36 and fatigue severity PROs and sustained virologic response at 12 weeks post-treatment (SVR12) were also assessed for patients with available data. The proportion of patients achieving significant improvement in PROs were reported for SF-36 and fatigue severity score (FSS) based on literature definitions of improvement.
Results: Among 238 patients, 227 (95%), 10 (4%), and 1 (<1%) received G/P for 8, 12, or 16 weeks, respectively. Overall, the number of HCRU visits (mean ± SD) was 4.2 ± 0.8. Percentages of patients attending each visit and achieving SVR12 are shown in the Table for subgroups of interest. In the PRO analyses at SVR12 visits, 54/159 (34%), 77/159 (48%) and 6/49 (12%) patients demonstrated significant improvement in their SF-36 physical (≥2.5 increase) and mental component scores (≥2.5 increase), and FSS (≥0.7 increase), respectively.

Subgroup, (%)	Baseline	During treatment	EOT	Post-treatment	SVR12 visit	SVR12 rate*
Cirrhotic (N = 10)	100	90	80	40	100	100
Non-cirrhotic (N = 228)	100	78	98	41	100	99
PWUD (-) (N = 164)	100	78	97	41	100	99
PWUD (+) (N = 68)	100	78	97	44	100	99
< 65 years (N = 171)	100	77	97	37	100	99
≥ 65 years (N = 67)	100	82	97	49	100	99

EOT, end of treatment; PWUD, person who uses drugs
*Among patients with follow-up in SVR12 window

Conclusion: G/P treatment demonstrated significant PRO improvement and high effectiveness, while the average number of HCRU visits was less than recommended in the protocol. Updated HCRU, PROs and SVR12 data will be presented at the Congress including all patients who reached SVR12 from these and additional countries as enrollment, treatment, and follow-up are currently ongoing.

THU-113

Comparison between safety and efficacy of two treatment regimens for pediatric patients with chronic hepatitis C virus: Sofosbuvir/ledipasvir versus sofosbuvir/daclatasvir regimen

Mohamed Ahmed[1], Abdelfattah Hanno[1], Soraya Hamouda[1], Manal Abdelgawad[2], Hossam Abouelkhier[1]. [1]*Alexandria Main University Hospital, Tropical Medicine Department, Alexandria, Egypt;* [2]*Alexandria, Pediatrics, Alexandria, Egypt*
Email: mohamedfayez1991@gmail.com

Background and aims: It is estimated that 11 million children under the age of 15 are infected by Hepatitis C virus (HCV), of whom 5 million are viremic. In the Egyptian children population (1- 14 years old), the prevalence of HCV antibody and HCV RNA are estimated to be 0.4% and 0.2% respectively, with genotype 4 being the most prevalent. Paucity of treatment options available for children with HCV infection fails to reflect the huge advances in adult's treatment regimens. The treatment regimen that is currently approved for children is a combination therapy of Ledipasvir/sofosbuvir (LDV/SOF) for genotype1, 4, 5 and 6, while genotype 2 or 3 can be treated cautiously with regimens approved for adults, as per European association for study of liver disease (EASL) guidelines. The aim of this study is to assess and compare the efficacy and safety of the standard regimen LDV/SOF against Daclatasvir/sofosbuvir (DCV/SOF) in Egyptian patients aged 10-17 years.
Method: Forty treatment naïve and experienced patients aged 10 to 17 years with PCR confirmed chronic HCV infection were enrolled and randomly assigned to two groups. Both groups were matched to age, sex and BMI. Inclusion criteria included subjects aged 10-17 years old, a positive PCR for HCV and Fibroscan result of F3 or less, while exclusion criteria included patients not meeting all inclusion criteria, those with hepatitis B virus, autoimmune hepatitis, and/or cirrhotic patients. Patients in group I received LDV/SOF 90 mg/400 mg once daily for 12 weeks while group II received DCV/SOF 60 mg/400 mg once daily for the same period. For patients in group I under 35 kg, and under 40 kg in group II, half the mentioned dose was given. Efficacy (in terms of a sustained virologic response-SVR) was assessed using PCR for HVC at week 4, week 12 (end of treatment) and 12 weeks after end of treatment (SVR 12) while safety was evaluated using close clinical follow-up and weekly laboratory investigations at three different intervals; weekly during the first month of treatment, monthly until end of treatment, and at 12 weeks from the last dose.
Results: All patient (n = 40) in our study achieved SVR 12 (100%). A significant decrease in ALT and AST was observed. No major side effects necessitating termination of treatment were observed in either group. The most common side effects were abdominal pain (40%) and fatigue (40%) in group I, and headache (45%) and abdominal pain (35%) in group II. There was no statistically significant difference between the two groups regarding the incidence or severity of side effects.
Conclusion: A 12-week regimen of LDV/SOF and DCV/SOF appear to achieve the same results in regards to efficacy and safety in the young population. More research should be targeted towards expanding treatment options of HCV for young patients to parallel those in the adult population, given the high prevalence of the disease among this age group.

THU-114

A comparison of currently available direct acting antiviral HCV therapy in Canada: On the path to elimination

Arshia Alimohammadi[1], Tianna Magel[1], Letitia Chu[1], Rossitta Yung[1], David Truong[1], Julie Holeksa[1], Brian Conway[1]. [1]*Vancouver Infectious Diseases Centre, Vancouver, Canada*
Email: arshia.alimohammadi@vidc.ca

Background and aims: Over 300, 000 Canadians are living with HCV infection. Specific populations like people who use drugs (PWUD) are disproportionally affected by this epidemic. To meet the World Health Organization (WHO) goals for the elimination of HCV as a public health concern by 2030, special attention needs to be paid to these vulnerable populations. The most prescribed HCV treatment regimens in Canada include elbasvir/grazoprevir (EG), sofosbuvir/ledipasvir (SL), and sofosbuvir/velpatasvir (SV). While clinical trials have highlighted the efficacy of these regimens, real world data is required to confirm these results, especially among PWUD.
Method: A retrospective analysis was performed on all HCV-infected PWUD (positive urine drug screen in the previous 6 month) initiating HCV treatment (rx) at our centre between 06/15-10/18. All subjects were enrolled in a multidisciplinary model of care, addressing medical, psychologic, social and addiction-related needs. The primary outcome was achievement of SVR12 (undetectable HCV RNA 12 or more weeks after the completion of HCV therapy).
Results: A total of 216 individuals (58% heroin/62% cocaine) have initiated therapy with one of the regimens of interest. The EG cohort (n = 50) includes 7 HIV+, 34 on opiate substitution therapy (OST), 38 Rx naïve, and 4 cirrhotic. To date, 40 individuals are eligible for SVR12 evaluations (34/40 SVR12), with no virologic failures (6 LTFU). The SL cohort (n = 68) includes 12 HIV+, 22 on OST, 48 Rx naïve, and 19 cirrhotic. To date, 58 are eligible for analysis (53/58 SVR), with 4 LTFU and one unrelated opioid overdose death. The SV cohort (n = 98) includes 12 HIV+, 49 on OST, 85 Rx naïve, 20 cirrhotic. To date, 64 are eligible for SVR12 analysis (54/64 SVR, 8 LTFU, 2 relapse).
Conclusion: The currently available regimens for the treatment of HCV appear to be equally efficacious among PWUD populations. The main reason for not achieving SVR is LRFU, occurring in 8% of individuals. Our data provide support for expanded access to HCV treatment, even in the setting of active drug use. Focus must now be shifted to mitigate losses to follow-up and recurrent viremia. Given these results, health care providers have three excellent options to provide HCV treatment to PWUD engaged in care, in support of the WHO's global elimination targets.

Effects of health-related quality of life of interferon-free antiviral therapy for chronic hepatitis C infection-Results from the GermanhHepatitis C-Registry (DHC-R)

Schäfer Arne[1], Stefan Christensen[2], Renate Heyne[3], Uwe Naumann[4], Ralph Link[5], Christoph Herold[6], Willibold Schiffelholz[7], Rainer Guenther[8], Markus Cornberg[9], Yvonne Serfert[10], Heiner Wedemeyer[10,11], Michael R. Kraus[12], Deutsches Hepatitis C-Register[10]. [1]*Diabetes-Klinik Bad Mergentheim, Bad Mergentheim, Germany;* [2]*CIM Münster, Münster, Germany;* [3]*Leberzentrum am Checkpoint, Berlin, Germany;* [4]*UBN/Praxis, Berlin, Germany;* [5]*MVZ-Offenburg GmbH/St. Josefs-Klinik, Offenburg, Germany;* [6]*Internisten am Ring, Nürnberg, Germany;* [7]*Gastroenterologische Schwerpunktpraxis, Augsburg, Germany;* [8]*Universitätsklinikum Schleswig-Holstein (UKSH), Campus Kiel, Department of Internal Medicine I, Kiel, Germany;* [9]*Hannover Medical School, Hannover, Germany;* [10]*Leberstiftungs-GmbH Deutschland, Hannover, Germany;* [11]*Essen University Hospital, University of Duisburg-Essen, Essen, Germany;* [12]*Kreiskliniken Altötting-Burghausen, Burghausen, Germany*
Email: arne.schaefer@me.com

Background and aims: Only limited data are available so far, regarding the influence of interferon-free, DAA-mediated therapy on patient reported outcomes (PROs) and clinical symptoms in patients with chronic hepatitis C infection. Especially, the time course of measures of quality of life (QoL) associated with interferon-free antiviral therapy and potential predictors of QoL improvement have not been thoroughly investigated so far. Therefore, we longitudinally assessed Short-Form 36 (SF-36) scores in HCV patients antivirally treated in a real life setting and focused on the identification of subgroups especially profiting from DAA regimens with respect to self-reported QoL.
Method: The DHC-R (German Hepatitis C-Registry) is a national real-world cohort including about 14, 500 patients recruited by more than 250 centers (approx. 90% physicians in private practice). We

evaluated the influence of DAA medication on the time course of PROs (basically SF-36 scores) at the end of treatment (EOT) and at follow-up 12 to 24 weeks after EOT (FU12/24) compared to baseline (BL) levels. Antiviral treatment started on or after Feb 1, 2014, and data were analysed as of Feb 9, 2018. Potential predictors of QoL improvement were identified using multivariate linear regression models (considering predictor candidates such as age, comorbidities, use of ribavirin (RBV), pre-treatment status, aminotransferases, BL SF-36 scores).

Results: A total of 1, 180 patients with complete PRO-data were considered for this analyses (684 males, 496 females, mean age 53.4 years). In line with reports from registration trials, both SF-36 physical component summary scale (PCS) ($p < 0.001$) and mental component summary scale (MCS) ($p < 0.001$) increased significantly at EOT and FU12/24 when compared to BL levels. These increases were associated with SF-36 BL levels (BL PCS < 50: $P < 0.001$; BL mental summary score < 43: $P = 0.022$). Other potential factors (such as GPT, RBV, presence of cirrhosis, comorbidities) were not relevant in this context. Further sub-analyses demonstrated that the increase in the SF-36 subscale "social functioning" was associated with the absence of HIV infection ($p = 0.045$) and the absence of RBV containing treatment ($p = 0.002$). Of note, despite the overall improvement, worsening in SF-36 PCS was reported for 43.6 (EOT) and 38.0% (FU12/24) of the patients when compared to SF-36 BL level. SF-36 MCS worsened in 41.7 (EOT) and 31.9% (FU12/24) of the patients.

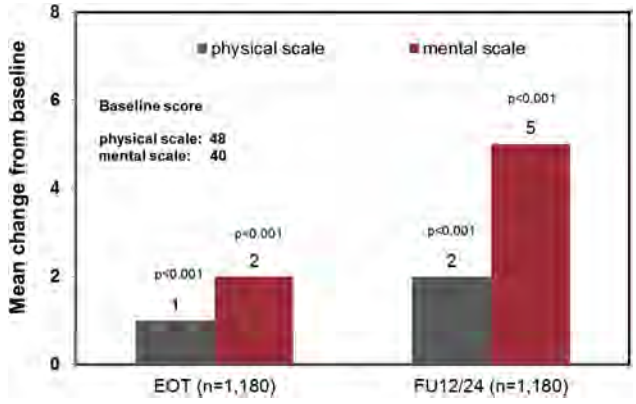

Figure: Mean change in physical and mental component summary score.

Conclusion: Hepatitis C patients undergoing DAA-based antiviral treatment significantly improve their self-reported QoL. The improvement in terms of increase in SF-36 scores is best predicted by BL levels of QoL. However, more than one third of patients do not improve in PCS and MCS. Longer follow-up is required to determine the extent of improvement in QoL after clearance of HCV infection.

THU-116

Effectiveness of the salvage therapy sofosbuvir-velpatasvir-voxilaprevir (SOF-VEL-VOX) in chronic hepatitis C: Clinical practice experience from the TRIO Network

Bruce Bacon[1], Michael Curry[2], Steven Flamm[3], Scott Milligan[4], Naoky Tsai[5], Nicole Wick[4], Zobair Younossi[6], Nezam Afdhal[2]. *[1]Saint Louis School of Medicine, St. Louis, United States; [2]Beth Israel Deaconess Medical Center, Boston, United States; [3]Northwestern University Feinberg School of Medicine, Chicago, United States; [4]Trio Health Analytics, La Jolla, United States; [5]University of Hawaii, Honolulu, United States; [6]Center for Liver Diseases, Inova Fairfax Hospital, Department of Medicine, Fairfax, United States*
Email: scott.milligan@triohealth.com

Background and aims: Although direct-acting antivirals (DAAs) failure is rare in clinical practice, SOF/VEL/VOX for 12-weeks is an FDA approved salvage therapy for patients that previously failed an NS5A inhibitor for any genotype (GT) or sofosbuvir without an NS5A inhibitor for GT1A or GT3. We report real world data from the TRIO network on the utilization and efficacy of SOF/VEL/VOX in US patients.

Method: Data from 196 patients who initiated SOF/VEL/VOX treatment between July 2017 to April 2018 were collected from providers and specialty pharmacies through Trio Health's disease management program. The primary outcome assessed was Per Protocol (PP) sustained virologic response at 12 weeks post treatment (SVR12). Comparisons were conducted using chi-square or Fisher Exact tests (categorical variables) or Student t test (continuous variables).

Results: 196 patients initiated SOF/VEL/VOX and although not indicated in the label, 4% (7/196) also received RBV. Intended duration was 12 weeks for 99% (195) with 1 patient receiving more than 12 weeks. By genotype: 78% (151) GT1, 3% (5) GT2, 16% (32) GT3, and 3% (6) GT4-6. Treatment status was reported for 194 of the 196 patients and only 21 (11%) were treatment naive (TN) indicating significant utilization for experienced patients. The top five prior therapies for the TE group included LDV/SOF ± RBV 53% (92/173), SOF/VEL ± RBV 12% (20/173), EBR/GZR ± RBV 11% (19/173), other SOF-based regimens 10% (17/173), and PrOD 6% (11/173). Physician-reported fibrosis score indicated cirrhosis for 42% (82) patients, consistent with baseline FIB-4 >3.25 for 40% (71/177) of patients with sufficient measures for calculation. Outcomes were: 0.5% (1/196) completed but were lost to follow-up, 4% (8/196) discontinued, 0.5% (1/196) died (cause unknown), 93% (183/196) achieved SVR12, and 2% (3/196) completed therapy but did not achieve SVR. Per protocol SVR12 rate was 98% (183/186) and the Intent-To-Treat SVR12 rate was 93% (183/196).

Conclusion: SOF/VEL/VOX in clinical practice is highly effective in prior treatment failures and treatment naïve patients with overall SVR12 rates of 98% (183/186) per protocol and 93% (183/196) in the Intent-To-Treat population.

THU-117

Evaluation of risk factors associated with failure to a first-line NS5A-containing regimen in HCV-infected patients naive to direct acting antivirals: Particular focus on natural resistance

Email: s.barbaliscia@gmail.com

Background and aims: This study aimed to evaluate the presence of natural resistance-associated-substitutions (RASs) and other pre-treatment risk-factors for failure in a large group of HCV-infected patients (pts) naive to direct-acting-antivirals (DAA) with an available outcome after their first-line NS5A inhibitor-containing regimen in Italy.

Method: RASs in NS3/NS5A/NS5B (N = 1685/1497/1175) were analysed in 1947 DAA-naïve pts. Of them, 705 had an available outcome after a first-line NS5A-containing regimen recommended by the 2016/18 guidelines, with a baseline (BL) NS5A-test. HCV Sanger-sequencing was performed by home-made protocols. Potential differences between the sustained-virological-response (SVR) and virological-failure (VF) group were evaluated by Fisher's exact test. A multivariable logistic-regression analysis was performed to define risk-factors associated to treatment-response.

Results: Overall, 579/1947 (29.7%) pts showed at least one natural RASs, particularly NS5A-RAS was observed in 18.9% of pts. 705 pts (GT1a/b/g[200/214/1]-GT2a/c[84]-3a[141]-4a/d[65]) had an available outcome (656 with a SVR and 49 with a VF) after the following recommended NS5A-containing regimen: daclatasvir (DCV)/ledipasvir (LDV)/velpatasvir (VEL)+sofosbuvir (SOF) ± ribavirin (RBV) (N = 125/130/161), 3D/2D (paritaprevir/ritonavir+ombitasvir ± dasabuvir) ± RBV (N = 125/44), grazoprevir (GZR)+elbasvir (EBR) ± RBV (N = 70), glecaprevir+pibrentasvir (G/P) (N = 50). By analysing retrospectively the BL samples, a higher prevalence of natural NS5A-RASs was observed before treatment in DAA-failures (18/49, 36.7%) *vs* SVR-pts (94/656, 14.3%; P < 0.001). Notably, ≥ 2 risk factors for failure were more frequently observed at BL among pts who experienced a VF to a DAA treatment (37/49, 75.5%) compared to those achieving SVR (295/656, 45.0%, P < 0.001). By multivariable logistic-regression high HCV-RNA, natural RAS, cirrhosis, previous IFN-failure were negatively associated with SVR (see figure). Interestingly, all 32 GT1-3 pts treated with G/P achieved SVR, with the exception of 1 GT3, who had a breakthrough and had at BL the NS5A RAS A30 K and HCV-RNA >800.000 IU/ml. All others were without (or only 1) risk-factor: notably none of them showed BL RASs regimen-related.

Variables	Univariate		Multivariate	
	Adjusted odds ratio (95% C.I.)	P Value	Adjusted odds ratio (95% C.I.)	P Value
At least 1 RAS specific for regimen	0.312 (0.172-0.565)	<0.001	0.468 (0.231-0.949)	0.035
Baseline NS5A-RASs	0.289 (0.155-0.537)	<0.001	0.422 (0.199-0.892)	0.024
HCV-RNA >800,000 IU/ml	0.292 (0.136-0.627)	0.002	0.422 (0.199-0.892)	0.002
Previous IFN-treatment	0.386 (0.214-0.697)	0.002	0.391 (0.197-0.776)	0.007
Cirrhosis	0.440 (0.245-0.790)	0.006	0.432 (0.217-0.859)	0.017
HCV genotype				
1b*	1		1	
1a	0.997 (0.479-2.073)	0.993	0.990 (0.398-2.465)	0.983
1g	1.30*10^{8} (0)	1.000	6.3*10^{7}(0)	1.000
2a	1.30*10^{8} (0)	0.999	9.0*10^{7}(0)	0.999
2c	1.30*10^{8} (0)	0.997	5.8*10^{7}(0)	0.997
3a	0.733 (0.346-1.554)	0.418	0.518 (0.212-1.265)	0.149
4a	0.808 (0.173-3.770)	0.786	0.587 (0.066-5.224)	0.633
4d	1.657 (0.367-7.483)	0.512	0.883 (0.172-4.519)	0.881

Figure summarize a multivariable logistic-regression analysis adjusted for cirrhosis, previous IFN-treatment, baseline HCV-RNA, at least one RAS regimen-related, NS5A RASs regimen-related, and genotype (GT). IU: international unit, C.I: confidence interval, IFN: interferon *dummy

Conclusion: The presence of specific pre-treatment risk-factor, such as RAS regimen-related, BL HCV-RNA > 800.000 IU/ml, cirrhosis and previous IFN-failure were associated with virological failure for some specific regimens and GTs.

THU-118

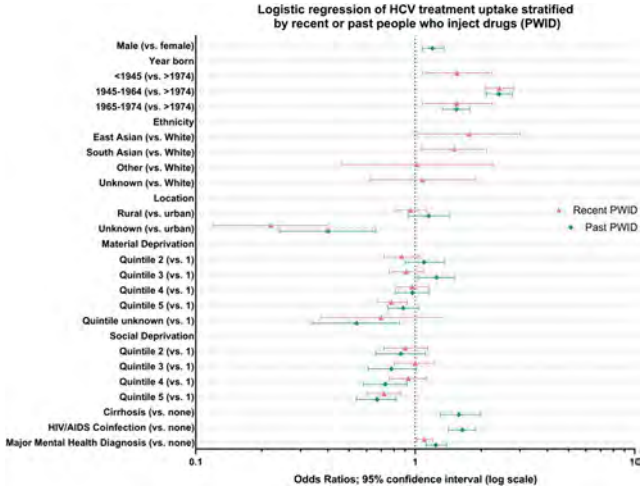
Factors associated with hepatitis C treatment uptake among people who inject drugs in a population based data linkage study

Sofia Bartlett[1,2,3], Stanley Wong[1], Amanda Yu[1], Maria Alvarez[1], Terri Buller-Taylor[1], Zahid A Butt[1,4], Maryam Darvishian[1,4], Carmine Rossi[1,2], Mawuena Binka[1,2], Dr. Margo Pearce[1,4], Dr. Jason Wong[1,4], Dr. Mark Gilbert[1,4], Mark Tyndall[1,4], Mel Krajden[1,2], Naveed Janjua[1,4]. [1]BC Centre for Disease Control, Vancouver, Canada; [2]University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada; [3]The Kirby Institute, University of New South Wales, Sydney, Australia; [4]University of British Columbia, School of Population and Public Health, Vancouver, Canada
Email: sofia.bartlett@bccdc.ca

Background and aims: Previous studies showed lower hepatitis C virus (HCV) treatment uptake among people who inject drugs (PWID) compared to people with no injecting drug use (IDU). Identifying factors associated with PWID receiving HCV treatment could inform strategies to improve treatment uptake among this group. We identified factors associated with treatment uptake among HCV diagnosed people with recent or past IDU in British Columbia (BC), Canada.

Method: For these analyses, we used the BC Hep Testers Cohort (BC-HTC), which includes all individuals tested for HCV in BC since 1990, linked to all prescription drugs, medical visits, hospitalizations and mortality data. People diagnosed HCV RNA positive were stratified by history of IDU (recent PWID; IDU ≤ 3 years; past PWID, IDU > 3 years ago) and factors associated with treatment uptake (direct acting antiviral and interferon based) assessed using multiple logistic regression.

Results: Among 43, 266 individuals who were HCV RNA positive in BC from 1990-2015, 22% (9, 384/43, 266) were recent PWID and 16% (7, 084/43, 266) were past PWID. Among recent PWID, 34% (3, 181/9, 384) received treatment, compared to 31% (2, 198/7, 084) among past PWID, and 49% (13, 057/26, 798) among those with no history of IDU. Having a major mental health diagnosis and being born before 1974 was associated with increased treatment uptake among both recent and past PWID (Figure). For past PWID, male sex, HIV coinfection and cirrhosis were also associated with increased treatment uptake (Figure). Within both groups, factors associated with decreased treatment uptake included belonging to the most materially and most socially deprived quintiles, and those with unknown residential location (Figure).



Conclusion: The association between major mental health diagnosis and HIV infection, with increased treatment uptake among recent and past PWID may be due to improved engagement with social or health services among people with these diagnoses. The association between material and social deprivation and lower treatment uptake among recent and past PWID suggests additional support and services may be required to facilitate HCV treatment uptake among highly marginalized people. Further investigation in to the association between unknown residential location and lower treatment uptake among recent and past PWID should be undertaken to assess if this is related to homelessness or stigma related to marginalization.

THU-119

Direct-acting antiviral regimens without protease inhibitors may help maintain a healthy lipid profile after hepatitis C eradication

Vanesa Bernal Monterde[1,2], Diego Casas-Deza[2], Eva Fernandez Bonilla[2], Silvia Espina[1,2], Marta Fernández Esgueva[3], Ana Martinez-Sapiña[3], Javier Fuentes[1,2], Jose M Arbones Mainar[1,4,5]. *[1]Instituto de Investigación Sanitaria (IIS) Aragón, Zaragoza, Spain; [2]Hospital Miguel Servet, Gastroenterology and Hepatology, Zaragoza, Spain; [3]Hospital Miguel Servet, Microbiology, Zaragoza, Spain; [4]Instituto Aragonés de Ciencias de la Salud (IACS), Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet., Zaragoza, Spain; [5]Instituto de Salud Carlos III, CIBEROBN, Madrid, Spain*
Email: vbernalm@gmail.com

Background and aims: Low VLDL- and LDL-cholesterol levels are characteristic of chronic HCV infection although this apparently healthy profile is associated with increased steatosis and augmented risk of cardiovascular disease (CVD). Additionally, HCV eradication with direct-acting anti-viral agents (DAAs) may result in increases in serum cholesterol and LDL, which might aggravate early CVD. Protease inhibitors (PI), now part of some DAA regimens, have previously shown a direct impact on lipid metabolism. It is, therefore, of paramount importance to determine to what extent these DAA-associated lipid changes are influenced by the eradication regimen chosen or by the underlying HCV disappearance.
Method: The study took place in the Hospital Universitario Miguel Servet (Zaragoza) from January/2018 to October/2018. All treatment-naive subjects with HCV were offered to join the study before DAA treatment. Exclusion criteria were the use of lipid lowering medications, HIV co-infection or decompensated cirrhosis. The lipoprotein and apolipoprotein (APO) profiles were studied prospectively by comparing pre and post-DAA regimens with and without PIs.
Results: HCV-infected DAA-naive subjects (n = 99, 52 women) were assigned to 4 different regimens according to clinical guidelines; sofosbuvir/ledipasvir (Harvoni, n = 5), sofosbuvir/velpatasvir (Epclusa, n = 40), glecaprevir/pibrentasvir (Maviret, n = 39), and grazoprevir/elbasvir (Zepatier, n = 15), being the last two PI-based therapies. All individuals had similar lipid profile at the baseline. HCV eradication regimen markedly increased their concentrations of APOB, as well as LDL and total cholesterol, irrespective of what treatment they were assigned. However, a PI-specific effect emerged in regards to subjects' high density lipoprotein (HDL) profile. Compared to PI-treated individuals, those upon non-PI regimens had at the end of the treatment an increased HDLc (mean[95% confidence interval: 61[56-66] *vs.* 50 mg/dl [46-53] for non-IP and IP, respectively, p = 0.001) and did not reduce their APOAI concentration (160 [150-170] *vs.* 140 mg/dl [130-150], for non-IP and IP, respectively, p < 0.001). This favorable effect on HDL concentration led to a decreased total cholesterol/HDL ratio (3.7 [3.4-4] *vs.* 4.2 [3.9-4.5], for non-IP and IP, respectively, p = 0.02), being lower ratios a surrogate of decreased risk of cardiovascular disease.
Conclusion: Our data suggest that the elimination of HCV with DAAs raises LDL-cholesterol and APOB. Those effects seem to be intrinsic to HCV eradication. However, this unfavorable lipid profile may be partially mitigated by using non-IP DAA therapy which increases HDL-cholesterol and prevents APOAI reduction. Given the many DAA-regimens available today, it is worth considering those which help maintain a healthy lipid profile, especially in those individuals with HCV and increased CDV-risk.

THU-120

Hepatitis C In children: Clinical profile and outcomes In the era of directly-acting antivirals in a tertiary centre in North India

Sadhna Bhasin Lal[1], Jagadeesh Menon[1], Vybhav Venkatesh[1], Ashim Das[2], Rishi Kumar Bolia[1]. *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, Paediatric Gastroenterology, Hepatology and Nutrition, Chandigarh, India; [2]Post Graduate Institute of Medical Education and Research, Chandigarh, Histopathology, Chandigarh, India*
Email: sadhnalal2014@gmail.com

Background and aims: Hepatitis C is an important cause of chronic liver disease in adults with onset in pediatric age group. We analysed the profile and outcome of these children managed at our center, especially focusing on the treatment response with the newly available directly acting antiviral agents.
Method: A retrospective descriptive study was done to analyse the clinical profile and outcome of infants vertically exposed to hepatitis C (VE) and those with chronic hepatitis C (CHC), from year 2007 to 2018.
Results: Among the 52 subjects, 16 were vertically exposed (VE) infants and 36 were horizontally transmitted chronic hepatitis C (CHC).The mean age group of VE was 5.3 months (2 weeks-12 months) and that of CHC was 9.7 years (1-15 years).The possible route of transmission was hematogenous in 55% of CHC because of transfusion dependency (85% thalassemics, and 5% each sideroblastic anemia, immune thrombocytopenia and blood transfused for other cause). In 45% cases was because of unsafe injection practices. None was co infected with hepatitis B and none had extra hepatic manifestations. Follow-up was available in 9 (56%) of VE group and 26 (72%) of CHC group. All infants initially positive (N = 9) and followed up at 2 years age had either a negative HCV RNA or negative anti HCV antibody. Among the CHC group (N = 36), genotype was available in 21 patients with genotype 3 being most common (62%), followed by genotype 1 (28.5%) and 4 (9.5%).Follow-up was available in 26 patients. Spontaneous clearance was seen in 10 (38.4%) cases. Liver biopsy was done in 14 (87.5%) patients who were planned for treatment. Advanced fibrosis (F3 or more) was seen in 29% cases and 71% had early (F2 or less) or no fibrosis. 14 patients underwent anti HCV treatment. Peg IFN based regimen was used in 8 and among them 6 (75%) achieved an SVR. 2 (25%) non-responders had genotype 3 infection. In the DAA group (N = 6), mean age 8.8 years (5-11years), treated with Sofosbuvir + Daclatasavir or Ledipasvir or Ribavirin, all had achieved SVR (100%).Two patients are pursuing DAA therapy. No major drug related adverse effect was seen in treatment cohort.

Conclusion: CHC in children in India is mainly due to unsafe blood products and injection practices. Spontaneous clearance of chronic hepatitis C is seen in upto 1/3 children. Treatment with the newer DAA has 100% cure rate irrespective of genotype, is cost effective, more patient friendly and free of major adverse effects.

THU-121

Real world outcomes from NS5a treatment failures undergoing therapy with sofosbuvir/velpatasvir/voxilaprevir and sofosbuvir/glecaprevir/pibrentasvir

Alison Boyle[1], Fiona Marra[1], Raymod Fox[1], Rory Gunson[2], Amanda Bradley[2], Emma Thomson[1], Erica Peters[1], Stephen Barclay[3]. *[1]Gartnavel General Hospital, Brownlee Centre for Infectious Diseases, Glasgow, United Kingdom; [2]West of Scotland Specialist Virology Centre, Glasgow, United Kingdom; [3]Glasgow Royal Infirmary, Walton Liver Clinic, Glasgow, United Kingdom*
Email: stephenbarclay@nhs.net

Background and aims: Patients infrequently fail first line hepatitis C therapy. For those who do, second line therapy options include Sofosubuvir/Velapatasvir/Voxilaprevir (S/V/V) and Sofosbuvir/Glecaprevir/Pibrentasvir (S/G/P) (± ribavirin (RBV) for difficult-to-cure patients as per EASL 2018 treatment guidelines). We sought to examine the efficacy of treatment with these regimens in patients previously failing NS5a containing regimens.
Method: Patients commencing treatment with S/V/V or S/G/P were identified from the Scottish HCV database, and baseline data on age, sex, cirrhosis, genotype and prior treatments identified. Baseline resistance, where available, was recorded from laboratory records. Testing for NS5a resistance associated substitutions (RAS) was performed using in house population sequencing. Sustained Viral Response (SVR) was obtained from the database where available.
Results: 16 patients received 17 second line treatments (12 S/V/V, 5 S/G/P) post NS5a failure (see table). 6 were also Interferon (IFN) experienced, and 3 had failed a (non NS5a) Sofosbuvir based regimen. 4 were post transplant and 3 HIV co-infected. 11 had baseline RAS. To date 2 S/V/V patients have failed to achieve SVR, 1 following premature discontinuation due to side effects and 1 relapse in a post transplant GT1a patient with 3 prior treatment failures. The latter has initiated treatment with S/G/P/RBV for 24 weeks.3 S/V/V patients have achieved SVR12, the remainder of the cohort are pending SVR.
Conclusion: To date, 3/5 prior NS5a failures have achieved SVR with Sofosbuvir/Velpatasvir/Voxilaprevir, 3/4 excluding premature discontinuation. Further SVR data for this regimen and for Sofosbuvir/Glecaprevir/Pibrentasvir from this heavily pre treated cohort will be presented.

THU-122

Sofosbuvir/velpatasvir ± ribavirin for retreatment of patients with chronic hepatitis C virus infection and advanced fibrosis failing to a previous DAA combination regimen

Email: p.brancaccio@alice.it

Background and aims: Failure to treatment of CHC virus infection with direct antiviral agents (DAA) occurs in about 2% of patients. Rescue therapy is still a cumbersome issue. We present data on retreatment with sofosbuvir+velpatasvir (SOF/VEL) ± ribavirin (RBV) in failures to DAA combination regimens.
Method: This was a multicenter study, based on an compassionate program for retreatment of patients with advanced liver disease who failed a previous treatment with DAA. SOF/VEL fixed dose ± weight based RBV was administered daily for 24 weeks. The end point was sustained virological response (SVR) at week 12 post-treatment. Resistance associated substitutions (RASs) were sought at baseline by Sanger method.
Results: The main characteristics of the patients are in Table 1. Thirty-four patients were enrolled and completed the follow-up (median age 56; 91% males; 73, 5% with cirrhosis; 26, 4% OLT recipients); most of the patients had RASs at NS5A and Y93H/C RAS was the the most

frequent; 28/34 received RBV. Previous treatments (± RBV) were dasabuvir/ombitasvir/r-paritaprevir (2/5.9%); daclatasvir/sofosbuvir (19/55.8%); ledipasvir/sofosbuvir (12/35.4%); simeprevir/sofosbuvir (1/2.9%). Overall, 28 patients (82.3%) achieved SVR12. SVR by genotype were: 75%; 71%; 100%; 87.5%; 83.0%, respectively, for genotypes 1a; 1b; 2; 3; 4. SVR was achieved in 14/18 (77.8%) patients with Y93H/C RAS and in 6/8 (75%) in those with L31F/I/M RAS. Simultaneous presence of RAS at L31 and Y93 sites led to SVR in 2/4 (50%) patients. Among 9 patients with cirrhosis and ascites, 8 achieved SVR (88.9%); all had riceived RBV. All patients completed treatment with DAA; 1 patient stopped RBV due to anemia.
Conclusion: Rescue therapy with SOF/VEL ± RBV was safe and effective for patients who failed a previous DAA treatment, particularly in patients with genotype 3, even in the presence of RAS or decompensated cirrhosis.

THU-123

No effect of alcohol consumption or dependence on treatment outcome in chronic hepatitis C patients treated with Elbasvir/Grazoprevir in a real-world setting

Email: Jeremy.SKRZYPSKI@icta.fr

Background and aims: The efficacy and safety of direct acting antivirals have been evaluated in different real-world settings, however patient reported outcomes (PROs) evaluating alcohol consumption are scarce. The study aims to assess the association between alcohol consumption, and clinical outcomes, including sustained virological response (SVR12), using AUDIT-C, a validated PRO assessing alcohol habits.
Method: Zephyr is a French multi-center, prospective, observational study on Elbasvir/Grazoprevir (EBR/GZR) utilization in a real-world setting. PROs, including AUDIT-C, were collected in routine care. All the patients received the PROs and were free to fill them at the inclusion, end of therapy (EOT) and at follow-up week 12 and 48. This analysis is based on patients included between January and September 2018. Data will be updated by the time of the meeting.
Results: 183 patients with chronic hepatitis C were included. The mean age was 56.0 years old, with 52% of males and a BMI of 25.6 ± 5.0 kg/m². 162 (89%) were HCV treatment naïve. 26 (14%), 117 (64%) and 36 (20%) patients were infected by HCV Genotype 1a, 1b and 4, respectively. 132 (72%), 24 (13%) and 23 (13%) patients had fibrosis METAVIR stage F0-F2, F3 and F4, respectively. According to the investigators, 95 (52%), 67 (37%) and 19 (10%) patients were abstinent for alcohol consumption, consumed < 3 and ≥ 3 units/day, respectively. At inclusion, AUDIT-C was fully completed by 134 patients. Respectively, 92 (69%) and 43 (31%) patients consumed < 3 and ≥ 3 units/day. The mean value of AUDIT-C score was 2.4 (CI 95%: 2.0-2.9), 85 (63%) and 49 (37%) had an AUDIT-C score < 3 and ≥ 3. At the end of therapy, the AUDIT-C score was < 3 and ≥ 3 in 46/67 (69%) and 21/67 (31%). At the time of the abstract submission, 32/183 patients reached week 12 of follow-up and had available AUDIT-C score. The SVR12 rate was 95.4% (21/22) and 100% (10/10) in patients with an AUDIT-C score < 3 and ≥ 3, respectively. Final SVR12 results and PROs related to drug use, sexual behaviour, life habits (employment, housing and working conditions) will be added to the analysis at the time of the meeting.
Conclusion: The ZEPHYR study reports for the first time, in real world setting, efficacy and the effect of PROs following the use of EBR/GZR. In the set of 32 patients with available SVR12 and AUDIT-C score, alcohol consumption along with alcohol abuse or dependence does not impact EBR/GZR treatment efficacy.

THU-124

Efficacy and safety of glecaprevir/pibrentasvir for the pangenotypic treatment of chronic hepatitis C in former intravenous drug users: Subanalysis from a Spanish real-world cohort (Hepa-C)

Email: 95565@parcdesalutmar.cat

Background and aims: Glecaprevir and pibrentasvir (G/P) are direct-acting antiviral agents with pangenotypic activity against hepatitis C virus (HCV). Integrated analysis of nine clinical trials in patients with chronic hepatitis C (CHC) treated for 8 or 12 weeks showed sustained virological response (SVR12) of 98% and 99%, respectively[1]. Similarly, analysis of four clinical trials in patients with compensated cirrhosis treated for 12 or 16 weeks showed SVR of 96%[2]. Studies evaluating G/P in former i.v. drug users (IDUs) in clinical practice are scarce. **Aim:** To assess the efficacy and safety of G/P in a real-world cohort of former IDUs with CHC.
Method: Multicenter observational study from a Spanish real-life cohort including patients from 32 Spanish centers. Patients with CHC who received G/P for 8, 12 or 16 weeks (September 2017 to May 2018) were included and categorized according to the previous IDU. Primary end point was the rate of patients with undetectable HCV-RNA 12 weeks after end of treatment (RVS12, ITT). Patients lost during follow-up were excluded (mITT). Safety was assessed by collecting the reported adverse effects (AEs) (clinical and laboratory).

Quantitative variables are expressed as medians and 25th/75th percentiles. Qualitative variables are expressed as percentages.
Results: A total of 1, 581 patients were included, 294 (18.6%) with prior IDU. Median age was 50 (44-54) years, with BMI (kg/m2) of 25.3 (22-27.1). 84% were males, 97.8% Caucasians, and 85% naive. Compared to the remaining, IDUs were younger (50 vs. 55 years), had higher alcohol consumption (27.2% vs. 4.7%), were more frequently infected by genotype 1a, 3 or 4 (43.8%, 22.1% and 19.3% vs. 23%, 11.1% and 8.9%, respectively), and showed more advanced liver fibrosis by transient elastography (TE > 9.6 kPa) (23% vs. 11.6%) (all p < 0.001). Among IDUs, 199 (67.7%) have completed treatment and follow-up, and 190 (95.5%) achieved SVR12. Three (1.5%) were relapsers and 6 (3%) lost during follow-up. mITT SVR12 rates were 98.4% (190/193). No differences were observed in SVR12 comparing gender, genotype, fibrosis stage, or treatment duration. No significant adverse events were observed and no treatments discontinuations were needed.
Conclusion: Our preliminary real-world data confirm that G/P is an effective and save pangenotypic therapy for patients with chronic hepatitis C and prior IDU, similarly to the general population.

High real-world effectiveness of elbasvir/grazoprevir in PWID on opioid substitution therapy with HCV genotype 1 infection: Results from the German hepatitis C registry (DHC-R)

Stefan Christensen[1], Albrecht Stoehr[2], Markus Cornberg[3], Hartwig Klinker[4], Renate Heyne[5], Christine John[6], Karl-Georg Simon[7], Manfred Bilzer[8], Veronika Guenther[9], Vanessa Witte[9], Jens Reimer[10,11]. [1]*CIM Muenster, Muenster, Germany;* [2]*ifi-Institute for Interdisciplinary Medicine, Study Centre St. Georg, Hamburg, Germany;* [3]*Hannover Medical School, Hannover, Germany;* [4]*University Hospital Wuerzburg, Wuerzburg, Germany;* [5]*Leberzentrum am Checkpoint, Berlin, Germany;* [6]*Private Practice of Internal Medicine, Berlin, Germany;* [7]*MVZ Dres. Email: veronika.guenther@msd.de

Background and aims: In most high-income countries, people who inject drugs (PWID) are the major population affected by chronic HCV infection with an estimated HCV prevalence of 60-80%. In clinical studies direct-acting antiviral (DAA) therapy has proven high efficacy in PWID on opioid substitution therapy (OST), even with ongoing drug use if treated with EBR/GZR. Until now, the effectiveness of EBR/GZR in PWID has not been investigated in detail in real-world. This was aimed by the present analysis of a large GT1 real-world cohort of the German Hepatitis C Registry.
Method: From September 2016 until July 2018, 992 patients (pts) with GT1 infection were treated at physician discretion's with EBR/GZR ± ribavirin (RBV) for 12 to 16 weeks in 130 medical practices and hospital outpatient departments. The present analysis was restricted to 613 pts who completed 12 or 24 weeks of follow-up or discontinued the treatment early; the demographic data are shown for this ITT population. Sustained virologic response (SVR) data were available and are shown for 599 pts (Per Protocol (PP) population).
Results: Demographics of 499 pts without former drug use (Non-OST/NDU) were compared with 67 PWID on OST therapy (OST) and 47 former/current drug users not receiving OST (Non-OST/DU): mean age was 56 vs. 45 vs. 47 years, male gender 54 vs. 81 vs. 72%, GT1a 23 vs. 74 vs. 70%, baseline viral load >800, 000 IU/ml 56 vs. 52 vs. 53%, cirrhosis 18 vs. 18 vs. 13%, HIV co-infection 3 vs. 6 vs. 19%, cardiovascular diseases 40 vs. 13 vs. 13% and psychiatric disorders 10 vs. 13 vs. 28%. NS5A RAS at baseline were tested in 15 vs. 37 vs. 34% while RAS were detectable in 12 vs. 0 vs. 13%. EBR/GZR treatment was used in 96 vs. 78 vs. 85% of pts and EBR/GZR+RBV in 4 vs. 22 vs. 15%. ITT and PP SVR rates were 96.2% and 98.6% in Non-OST/NDU pts, 89.6% and 98.4% in OST and 93.6% and 95.7% in Non-OST/DU pts (table). 7 reinfections occurred. 6 were observed in Non-OST/NDU and 1 in OST and were counted as therapy success in the PP analysis. Comparative statistics for the ITT and PP SVR results demonstrated a significant difference (p = 0.025) in SVR for Non-OST/NDU vs. OST in the ITT analysis, which was mainly due to LTFU.

	Non-OST/NDU	OST	Non-OST/DU
ITT SVR-n/N (%)			
Total	480/499 (96.2)	60/67 (89.6)	44/47 (93.6)
GT1a	107/115 (93)	45/49 (91.8)	31/33 (93.9)
GT1b	369/380 (97.1)	15/17 (88.2)	13/14 (92.9)
PP SVR-n/N (%)			
Total	484/491 (98.6)	61/62 (98.4)	44/46 (95.7)
GT1a	108/112 (96.4)	45/46 (97.8)	31/32 (96.9)
GT1b	372/375 (99.2)	16/16 (100)	13/14 (92.9)

Conclusion: Despite the controversy concerning HCV treatment in PWID, this analysis demonstrates a high real-world effectiveness of EBR/GZR treatment regimens in pts on OST as well as in Non-OST pts with a history of drug use. A significant difference among groups was only observed in ITT SVR for OST vs. Non-OST/NDU pts. Nevertheless, these findings suggest that reservations to initiate DAA therapy in these groups are unwarranted.

THU-126

HCV treatment outcomes among current and remote injection drug users: Real- life data

Brian Conway[1], Tianna Magel[1], Julie Holeksa[1], Astou Thiam[1], Rossitta Yung[1], Letitia Chu[1], David Truong[1]. [1]*Vancouver Infectious Diseases Centre, Vancouver, Canada*
Email: tianna.magel@vidc.ca

Background and aims: A number of clinical trials (CO-STAR, D3FEAT, SIMPLIFY) have suggested that HCV treatment outcomes among active injection drug users (IDUs) is identical to that observed in other populations. It has been suggested that these data may not pertain to IDUs who would not be enrolled in such trials. Despite the recent publication of a meta-analysis on this subject, there is a need for more comparative data among current and remote IDUs treated for HCV under similar circumstances.
Method: A retrospective cohort analysis was performed on all HCV infected patients who were treated with Direct Acting Antivirals (DAAs) at our centre with a history of current or remote IDU between 04/14- 10/18. All participants had access to a multidisciplinary model of care addressing their medical, social, psychological, and addiction-related needs. The primary end point of this analysis was the achievement of SVR12 and its correlates, with a view to demonstrating whether active IDU was a correlate of treatment outcome when care was delivered to current and remote IDUs within the same setting.
Results: In this analysis, we compared 141 active and 88 remote IDUs who were evaluated at the SVR12 time point. Baseline demographic and disease characteristics for active and remote IDU, respectively: mean age 51.7/55.8 years, 78%/70% male, 53%/25% opiate substitution therapy, 36%/25% alcohol use, 22%/7% homelessness, 17%/16% cirrhotic, 14%/10% HIV co-infected. All oral HCV treatment for active and remote IDUs, respectively: 27%/18% SOF/VEL, 17%/23% SOF/LED, 13%/15% ELB/GRAZ and 23%/23% PrOD. Of the active IDUs that reached the SVR timepoint, 138/141 (98%) achieved SVR12 vs. 88/88 (100%) amongst remote IDUs by mITT analysis. Two active IDUs relapsed and one individual discontinued treatment due to medical complications unrelated to therapy. Four cases of reinfection have been identified, all amongst active IDUs at a rate of 1.6 per 100 person-years. Reinfection occurred at a mean of 50 weeks post SVR12 date.

Conclusion: Within a multidisciplinary care model, high SVR12 rates were achieved in both active and remote IDUs. Therapeutic failure and re-infection events occurred infrequently, but only among active IDUs. This supports the need to develop interventions to maintain these individuals in care during and after treatment to mitigate these risks and ensure that proper harm reduction interventions can be applied.

Background and aims: In the continued evolution of DAA therapies, pan genotypic drugs GLE-PIB and SOF-VEL offer a simplification of HCV treatment. In this study we examine use of these agents to describe real-world use profiles and outcomes.
Method: Data specific to patients who initiated GLE-PIB (n = 1131) or SOF-VEL (n = 777) between Aug 2017 to April 2018 were collected from providers and specialty pharmacies through Trio Health's disease management program. Variable comparisons between treatment groups were conducted using chi-square, exact tests, or z-test for proportions. Multivariate analyses were performed using forward stepwise logistic regression (LR).
Results: In the TRIO data set, GLE-PIB patients had more 8-week therapy (75% v. 2%), were younger (29% v. 21% < 50), mostly GT1 (71% v. 22%), more CKD Stage 4-5 (7% v. 1%), and less cirrhosis (16% v. 27%) compared to SOF-VEL. Outcomes in the intent to treat (ITT) population receiving GLE-PIB were 93% (1049/1131) achieved SVR12, 2% (17/1131) completed therapy but did not achieve SVR12, 2% (21/1131) completed but were lost to follow-up (LTFU), 3% (38/1131) discontinued, and 1% (6/1131) died. ITT outcomes with SOF-VEL were 90% (701/777) achieved SVR12, 2% (15/777) completed therapy but did not achieve SVR12, 2% (14/777) LTFU, 5% (40/777) discontinued, and 1% (7/777) died. Nearly half of patients (45%) who discontinued SOF-VEL were with GT3 HCV compared to 5% for GLE-PIB. For GLE-PIB, 16% of patients who discontinued had severe renal impairment compared to 2% for SOF-VEL discontinues. Virologic failure with GLE-PIB was associated with treatment experience (TE) (OR: 0.14 (0.05-0.36), $p \leq 0.001$), cirrhosis (OR: 0.29 (0.11-0.80) p = 0.017), and VL > 6MM in GT3 (OR: 0.14 (0.03-0.60) p = 0.008). The presence of +RBV was significantly associated with virologic failure with SOF-VEL (0.16 (0.04-0.60) p = 0.007), likely representing a confounding factor not accounted in the LR. Per protocol (PP) SVR12 rates for subgroups defined by genotype, fibrosis, prior treatment experience, and baseline viral load were not significantly different by treatment except for cirrhotic GT3 which were 88% (22/25) for GLE-PIB and 98% (57/58) for SOF-VEL (p = 0.044).
Conclusion: 59% of study patients were treated with GLE/PIB ± RBV and 41% SOF/VEL ± RBV. In general, GLE-PIB treated patients were younger, had less fibrosis, and higher frequency of CKD Stage 4-5 compared to SOF-based regimens. Overall outcomes between regimens differed in ITT populations with a higher rate of discontinuations in patients receiving SOF/VEL (5% v 3% for GLE-PIB), possibly reflecting patients with more difficult to treat HCV. In the PP population, SVR12 rates for both therapies were 98%. Virologic failure in the GLE-PIB group was associated with TE, cirrhosis, and GT3*VL > 6MM. For SOF-VEL, virologic failure was associated with +RBV.

Background and aims: The use of Sofosbuvir (SOF)-based regimens has been associated with renal function worsening in hepatitis C virus (HCV) patients with impaired (≤45 ml/min/1.73 m^2) estimated glomerular filtration rate (eGFR), but it has never been further investigated. We therefore investigated renal safety of any direct-acting antivirals (DAA) in a large cohort of HCV patients, including patients with moderate to severe chronic kidney disease (CKD).
Method: All HCV patients treated with DAA in Lombardy between December 2014 and November 2017 with available kidney function tests at baseline, end of treatment (EOT) and 12 weeks after treatment completion (SVR) were included. Data were extracted from the NAVIGATORE-Lombardia web-based Platform. eGFR was estimated according to the MDRD formula, and CKD stage was defined according to the KDIGO classification.
Results: Among 3, 264 DAA treated patients included (65% were males, 67% cirrhotics, 61% HCV-1, 30% diabetics), median eGFR was 88 (9-264), and CKD stage was 4-5 in 23 (0.7%). SOF-based and RBV-containing regimens were used in 79% and 73% patients, respectively. During DAA treatment, eGFR values significantly declined in patients

with CKD-1 ($p < 0.0001$) and CKD-2 ($p = 0.0002$), with correspondent rates of CKD stage reduction of 25% and 8%, respectively. Rates of CKD improvement were 17% in CKD-2 patients. Conversely, DAA led to eGFR improvement in patients with eGFR < 60 ml/min/1.73 m2 ($p < 0.0001$ in CKD-3a, $p = 0.0007$ in CKD-3b and $p = 0.024$ in CKD-4/5). Among them, rates of CKD worsening were 8-17% (vs. improvement in 33-45%), at EOT. Changes in eGFR and CKD distribution remained stable at SVR. Predictors of worsening CKD at EOT were age > 75 years ($p = 0.05$), preserved baseline renal function ($p < 0.0001$) and diabetes ($p = 0.04$); predictors of worsening CKD at SVR were age > 75 years ($p = 0.005$), preserved baseline renal function ($p < 0.0001$), arterial hypertension ($p = 0.0006$) and on-treatment renal worsening ($p < 0.0001$).

Conclusion: In patients with preserved baseline renal function, DAA treatment led to statistically significant eGFR decline that was not reverted upon drug discontinuation. This detrimental effect was not observed in those with moderate to severe kidney dysfunction.

New antiviral therapy and the quality of life in patients with HCV infection

Claudia Monica Danilescu[1], Ion Rogoveanu[2], Daniela Larisa Sandulescu[2], Victor Gheorman[3], Monica Laura Cara[4], Mihail Cristian Pirlog[5]. *[1]University of Medicine and Pharmacy Craiova, Doctoral School, Craiova, Romania; [2]University of Medicine and Pharmacy Craiova, Gastroenterology Department, Craiova, Romania; [3]University of Medicine and Pharmacy Craiova, Psychiatry Department, Craiova, Romania; [4]University of Medicine and Pharmacy Craiova, Public Health Department, Craiova, Romania; [5]University of Medicine and Pharmacy Craiova, Medical Sociology Department, Craiova, Romania*
Email: claudiamonica.danilescu@gmail.com

Background and aims: The effects of the infection with the hepatitis C virus (HCV) are not limited to the medical dimensions, but also apply to psychological and social areas. Our study aims to assess the influence of treatment with DAA-based therapies on the quality of life and on the level of stress perceived by the patients.

Method: The study was done on subjects diagnosed with HCV infection, F3-F4 METAVIR score, and detectable HCV-RNA viral load, treated with Ombitasvir/Paritaprevir/Ritonavir/Dasabuvir for 12 weeks. All patients were clinically and biologically evaluated at the start of the treatment (SoT), at weeks 4, 8, 12 (end of treatment-EoT), respectively 12 weeks after therapy (sustained viral response-SVR). Quality of life (QHO-QOL Bref), level of perceived stress (PSS scale), and presence of depression and/or anxiety screening (HADS scale) were consecutively assessed at SoT, EoT and SVR. Statistical analysis was realized using SPSS software and Friedman test for consecutively data recorded.

Results: The study sample included 73 subjects (75.3% females, 50.7% urban area) with minor adverse events present in 30.37% of patients (asthenia, pruritus, insomnia), and none discontinued treatment. There were recorded: a high level of perceived stress in 20.5% (SoT), respectively moderate stress 78.1% (SoT), but during the treatment it was significantly improved ($\chi2\ (2) = 18.33$, $p < 0.0001$). Depression as assessed through HADS was present in 17.8% (SoT), and only in 1.4% at SVR ($\chi2\ (2) = 24.86$, $p < 0.0001$), similar situation being observed for anxiety: 45.2% (SoT), 9.6% (EoT), 5.5% (SVR) ($\chi2\ (2) = 33.95$, $p < 0.0001$). Patients under DAA therapy had statistically significant improvements in physical health ($\chi2\ (2) = 35.289$, $p < 0.0001$), psychological ($\chi2\ (2) = 39.42$, $p < 0.0001$), social relationships ($\chi2\ (2) = 54.10$, $p < 0.0001$), environment ($\chi2\ (2) = 41.52$, $p < 0.0001$).

Conclusion: DAA-based therapies lead to good outcomes not only related to the evolution of the liver disease, but also for the social functioning and quality of life of the affected individuals. Additionally, during the treatment and after it, the level of perceived stress, and the associated depression and anxiety with the medical condition were significantly reduced

THU-130

Management strategies for drug drug interactions between direct oral anticoagulants and hepatitis C directly acting agents: A multi-centre review

Alison Boyle[1], Katherine Davidson[2], Caroline Cassidy[1], Aniqa Afzal[1], Anthony Pratt[3], Sally Midgley[4], Jacqueline Swabe[5], Paul Selby[6], Sital Shah[7], Aisling Considine[7], Louise Mcgivern[4], Joan Mackintosh[8], Elaine Sheridan[9], Fiona Marra[1]. *[1]Gartnavel General Hospital, Glasgow, United Kingdom; [2]Western General Hospital, edinburgh, United Kingdom; [3]York Teaching Hospital, york, United Kingdom; [4]Leeds General Infirmary, leeds, United Kingdom; [5]Southampton University Hospital, southampton, United Kingdom; [6]Addenbrooke's Hospital, cambridge, United Kingdom; [7]King's College Hospital, london, United Kingdom; [8]Raigmore Hospital, inverness, United Kingdom; [9]Aberdeen Royal Infirmary, aberdeen, United Kingdom*
Email: fmarra@liverpool.ac.uk

Background and aims: Direct oral anticoagulants (DOACs) are increasingly prescribed as alternatives to warfarin. Predictable pharmacokinetics mean blood monitoring is not routinely required. However, risk of bleeding remains an important adverse drug reaction (ADR). DOACs, such as apixaban, rivaroxaban, edoxaban, and dabigatran, are substrates of CYP3A4 and/or P-glycoprotein making them susceptible to drug-drug interactions (DDIs) with Hepatitis C (HCV) Direct Acting Antivirals (DAAs). This may result in increased DOAC exposure and bleeding risk. Some DOAC/DAA combinations are contraindicated but the majority are classed as "amber" by University of Liverpool DDI website (www.hepdruginteractions.org) suggesting use with caution. Management of this DDI includes assessment of individual risk of bleeding, consideration of switching medicines to low molecular heparin (LMWH) or an alternative DAA, clinical monitoring for ADRs or, where available, plasma monitoring of anti-Xa activity. We gathered data from UK centres to describe the patient cohort and explore optimum strategies for management of this potentially serious DDI.

Method: A data collection form was sent to HCV pharmacists within the British Hepatology Pharmacy Group (BHPG) for patients co-prescribed DAAs and DOACs from June 17-May 18. Data on DAA and DOAC regimen prescribed, presence of cirrhosis, illicit drug use, treatment setting, and any ADRs reported was obtained. Management of the DDI was categorised as: clinical monitoring (CM), blood monitoring of anti-Xa activity (BM), switch to LMWH (SL), switch DAA (SD) or wait until DOAC completed (W) for short courses.

Results: 54 patients were identified. Baseline characteristics are outlined below. Management of DDIs was as follows: CM 24 (44.4%), BM 13 (24.1%), SL 9 (16.7%), SD 7 (13%), or W 1 (1.9%). Of 13 patients planned for BM, 6 had 0 or only 1 available result, 2 had increased levels and 5 had decreased levels on treatment. No treatment changes were made. 6/7 patients who switched DAAs were originally planned for a DAA which was contraindicated with the prescribed DOAC. ADRs were reported in 12 patients (22.2%); 1 mild bruising and 1 haemoglobin drop (patient with known varices). No serious bleeding ADRs were reported.

Baseline Characteristics	n = 54
Mean age (± SD)	46 (12.5)
Male (%)	43 (80)
Injecting drug use (within 3 months) (%)	13 (24.1%)
Genotype (%)	
1A	24 (44.4)
3	21 (38.9)
Other (1B, 2, 4)	9 (16.7)
Fibrosis Stage (%)	
F0-2	30 (55.6)
F3	5 (9.3)
F4 (CPA)	17 (31.5)
F4 (CPB/C)	2 (3.7)

Conclusion: Reassuringly, no serious ADRs were reported in this small cohort. However, only a third of patients were cirrhotic and further study is needed in this group with increased bleeding risk. BM was difficult to interpret in practice, in part due to sampling times. A case by case approach is needed in managing these patients with individual assessment of risk used to plan management of interaction.

THU-131

Effectiveness and safety of sofosbuvir/velpatasvir/voxilaprevir for retreatment of chronic hepatitis C patients with a previous failure to direct-acting antivirals: A real-life study from the NAVIGATORE Lombardia and Veneto Networks

Email: elisabetta.degasperi@unimi.it

Background and aims: Sofosbuvir/Velpatasivr/Voxilaprevir (SOF/VEL/VOX) is approved for retreatment of hepatitis C (HCV) patients with a previous failure to direct-acting antivirals (DAA), however real-life data are still limited. Aim of the study was to assess effectiveness and safety of SOF/VEL/VOX combination in an Italian real-life setting.

Methods: All consecutive HCV patients starting SOF/VEL/VOX treatment from 31 May 2018 in 27 centers were enrolled. Bridging fibrosis and cirrhosis were diagnosed by liver stiffness measurement (LSM): >10 kPa for F3 and >13 kPa for F4. Sustained virological response (SVR) was defined as undetectable HCV-RNA 4 (SVR4) or 12 (SVR12) weeks after the end of treatment (EOT).

Results: 179 patients were included in the analysis: median age was 56 (18-88) years, 73% males, BMI 24 (16-45), ALT 54 (13-387) U/L. Fibrosis stage was F0-F1 in 18%, F2 in 16%, F3 in 21%, F4 in 45%. 1% and 4% of patients were HBV or HIV coinfected, respectively. HCV genotype was 1 in 58% (1b 33%, 1a 25%), 2 in 10%, 3 in 24% and 4 in 8%. Median baseline HCV-RNA was 1, 012, 277 (482-25, 590, 000) IU/ml. Previous DAA ± ribavirin (RBV) treatments included combination of nNS5B + NS5A or NS3 inhibitor in 61%, NS3 + NS5A in 21%, NS3 + NS5A ± nnNS5B in 18%. First DAA course was optimal according to EASL recommendations in 88%. Testing for resistance associated substitutions (RAS) at DAA failure was available in 48% of patients. RAS were detected in the NS3 region in 26%, NS5A in 74% (Y93H in 61%) and NS5B in 20%; combined NS5A + NS5B or NS3 RAS were detected in 32%. Overall, patients received SOF/VEL/VOX for 12 weeks, and RBV was added in 21% of treatment schedules. Undetectable HCV-RNA at week 4 was achieved by 63% of patients, while EOT response by 91%. Rates of EOT response did not differ according to baseline HCV-RNA (<800, 000 vs. 800, 000-6, 000, 000 vs. >6, 000, 000: 85% vs. 88% vs. 80%, p = 0.8), fibrosis stage (F0-3 vs. F4: 82% vs. 94%, p = 0.1) or presence of RAS (yes vs. no: 78% vs. 88% p = 0.5). Treatment was discontinued in 2 (1%) patients, one due to virological failure at week 4 and the other for non-virological reasons. Most frequent adverse events were anemia, fatigue and nausea, reported in 3%, 5% and 2%, respectively. No severe adverse events were reported. Complete SVR data will be presented at the meeting.

Conclusion: SOF/VEL/VOX combination is an effective and safe retreatment for HCV patients failing a first DAA course in a real-life setting.

THU-132

Decentralised care with generic direct antivirals is effective in the management of patients with hepatitis C in a public health care setting: The Punjab model

Radha Krishan Dhiman[1,2,3], Gagandeep Singh Grover[4], Madhumita Premkumar[5], Sunil Taneja[5], Ajay Duseja[5], Sanjeev Arora[6], Sahaj Rathi[5], Sandeep Satsangi[5], Akash Roy[5]. *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, Hepatology, Chandigarh, India; [2]Health Department, Punjab Government, Technical Consultant, Mukh-Mantri Punjab Hepatitis C Relief Fund (MMPHCRF), Chandigarh, India; [3]Heath Ministry, Government of India, Chairman, Technical Resource Group-National Viral Hepatitis Control Program (NVHCP), New Delhi, India; [4]Health Department, Punjab Government, Program Officer, Hepatitis C Virus Infection, Chandigarh, India; [5]Post Graduate Institute of Medical Education and Research, Chandigarh, Hepatology, Chandigarh, India; [6]ECHO Institute University of New Mexico, USA, New Mexico, United States*
Email: rkpsdhiman@hotmail.com

Background and aims: The prevalence of hepatitis C virus infection (HCV) infection in Punjab, India is 3.29%, with an estimated burden of around 650, 000 viremic chronic HCV (CHC) patients. The Mukh-Mantri Punjab Hepatitis C Relief Fund (MMPHCRF) was launched in June 2016 to eliminate HCV from Punjab and provides no cost treatment to all CHC patients. We assessed the feasibility, safety and efficacy of decentralized care and treatment of CHC with12 or 24 weeks of sofosbuvir (SOF) + ledipasvir (LDV) or SOF + daclatasvir (DCV) ± ribavirin (RBV) in a public health care setting.

Method: ***Decentralized care:*** All patients were evaluated and treated at 3 University Hospitals (tertiary level healthcare) and 22 District Hospitals (secondary level); they were followed up to 12 weeks post-treatment to look for sustained viral response (SVR-12). ***Health care worker capacity building:*** All medical specialists were trained in a 4-hr course, followed by telehealth PGIMER-INASL-Punjab Extension for Community Healthcare Outcomes (ECHO) Clinics conducted fortnightly. 25 pharmacists from each of the 25 centres dispensed medicine. ***Data Management:*** 25 trained data entry operators and Clinton Health Access Initiative (CHAI) managed epidemiological data. ***Monitoring:*** Medical alerts were used for drug compliance

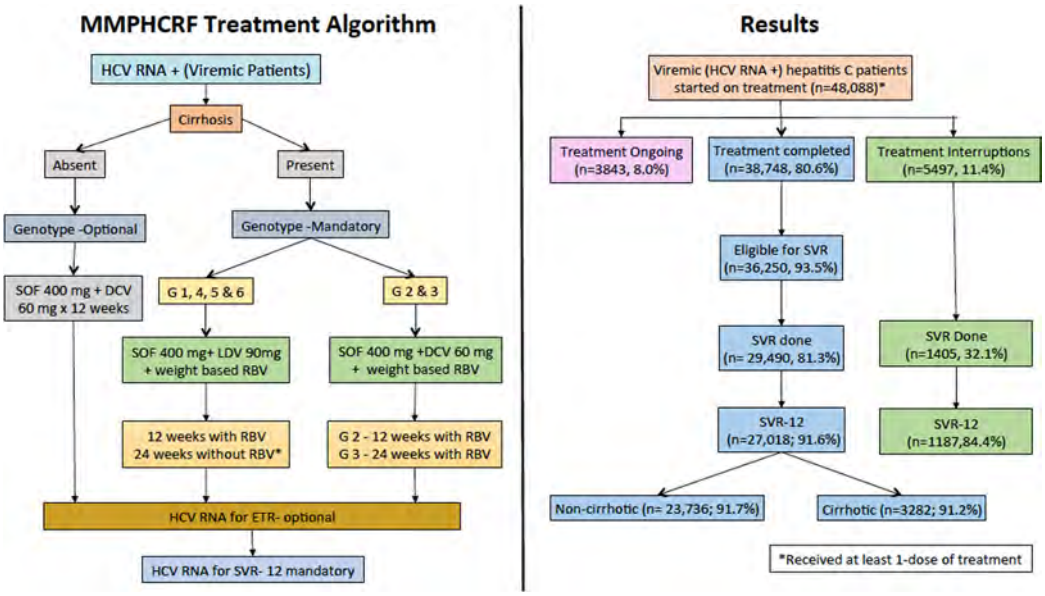

Figure: (abstract: THU-132)

monitoring. ***Study design:*** A cost-effective algorithm was developed using SOF-based regimens to treat all patients (Figure). The diagnosis of cirrhosis was based on clinical evidence, AST-to-platelet ratio index (≥ 2.0) or FIB-4 score (>3.25) or on liver stiffness measurement ≥ 12.5 kPa on fibroscan.
Results: We enrolled 48, 088 patients (63.9% male; mean age 42.1 years; 80.5% rural) during the period from 18thJune 2016 to 31stJuly2018; While 38, 748 (80.6%) patients completed the desired treatment, 5497 (11.4%) had treatment interruptions and 3843 (8.0%) patients are currently on-going treatment. SVR-12 was achieved in 91.6% of patients who had completed the treatment and in 84.4% of patients who had treatment interruptions (Figure). The predominant genotype (G) was G3 (69.9%) and 14.8% were cirrhotics. SVR-12 rates in cirrhotics versus non-cirrhotics and G3 versus non-G3 were comparable. Amongst 21, 753 patients who were interviewed for risk-factors, unsafe medical practices (11, 877; 54.6%), injection drug use (1640; 7.5%), unsafe dental practice (948; 4.3%), prior surgery (1420; 6.5%) and unprotected sex (112; 0.5%) were the main suspected modes of virus transmission. There were no major adverse events.
Conclusion: Decentralized care of HCV in Punjab India with generic all oral DAA regimens is a safe and effective regardless of genotype or presence of cirrhosis.
ClinicalTrials.gov number: NCT01110447.

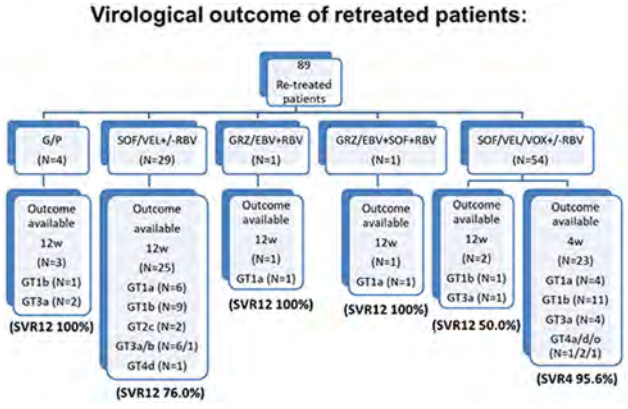
Email: Di.Maio@med.uniroma2.it

Background and aims: This study aimed to analyze Italian real-life data of patients (pts) who experienced a failure to a recommended NS5A inhibitor containing regimen and their retreatment.
Method: Within the Italian VIRONET-C network, 361 NS5A-failing pts infected with different HCV genotypes (GT) (GT1a/1b/2a-c/3a-b-g-h/4a-d-n-o-v = 84/118/17/106/36) were analyzed. Retreatment of 89 failures was investigated. HCV resistance test was performed by Sanger-sequencing.
Results: Failures following seven different NS5A containing regimens were studied: 3D/2D (paritaprevir/ombitasvir ± dasabuvir) ± ribavirin (RBV) (N = 69/4), daclatasvir/ledipasvir/velpatasvir (VEL) +sofosbuvir (SOF) ± RBV (N = 102/123/18), grazoprevir (GRZ)/elbasvir (EBV) ± RBV (N = 27), glecaprevir/pibrentasvir (G/P) (N = 18). Notably, 13.6% of NS5A-failing pts did not show any resistance associated substitutions (RAS), while 83.6% showed at least one NS5A-RAS and 46.6% at least one NS3-RAS, with multiclass-resistance in 37.7%. NS5A-RAS patterns were observed more frequently in G/P failures (GT1a 80%: Y93H+Q30H/D or +H58D; GT3a: 83.3% Y93H+A30 K/G or +L31I) compared to SOF/VEL (GT1a 20%: Y93H+Q30H, p = 0.2; GT3a 22.2%: Y93H/N+A30 K/T, p = 0.04).



To date, 89 failures have started a retreatment: SOF/VEL ± RBV (N = 29), SOF/VEL/voxilaprevir (VOX) ± RBV (N = 54), G/P (N = 4), GRZ/EBV ± SOF+RBV (N = 2) (see figure). The majority of pts were cirrhotic (56.2%) and relapser (87.6%). The overall prevalence of NS5A-RASs before retreatment was 86.5%, with multiclass resistance in 29.2% of pts. Among those completing post-retreatment follow-up, a sustained viral response at week 12 (SVR12) was observed in 25/32 (78.1%). Among those with ongoing follow-up, SVR4 was documented in 46/53 (86.8%).
SVR12 was 76% with SOF/VEL ± RBV (N = 25) and 100% with G/P for 8/12/16 wks (N = 3) or GRZ/EBV ± SOF+RBV for 12/24 wks (N = 2) despite the presence of NS5A RASs.
Until now, 54 pts have been started SOF/VEL/VOX ± RBV retreatment for 12 wks. 48/54 (88.8%) showed at least one baseline NS5A RAS, 21/54 (38.8%) multiple NS5A RASs, and 38/54 (70.3%) multiclass resistance. Of 23 pts with available outcome, 95.6% had SVR4. Only 1 GT1b infected patient failed as non-responder, but RASs were not detected before retreatment.
Conclusion: In this real-life setting, NS5A-RASs were frequently detected at failure, and multiclass resistance was close to 30%. SVR4 data with the recommended retreatment regimen SOF/VEL/VOX ± RBV was >95%. Our results show how HCV resistance test at failure may be useful to optimize retreatment strategies.

Email: julia.dietz@em.uni-frankfurt.de

Background and aims: Failure to treatment of chronic hepatitis C virus (HCV) infection with direct acting antivirals (DAAs) is rare and is associated with the selection of resistance-associated substitutions (RASs). For a retreatment, a DAA combination regimen consisting of a second generation NS3 protease (voxilaprevir) and NS5A inhibitor (velpatasvir) plus sofosbuvir is approved. Only limited data is available of single VOX/VEL/SOF treatment failures from the approval studies. This study investigated the characteristics of VOX/VEL/SOF failure patients in real world.
Method: Samples were obtained from resistance databases in Germany, Spain and Italy containing samples of overall 2530 DAA failure patients. Population sequencing of NS3, NS5A and NSB5 was conducted and RASs conferring a >2-fold increased DAA susceptibility were analyzed. Limited clinical parameters were collected retrospectively.
Results: Altogether ten patients had a virologic treatment failure to VOX/VEL/SOF. Eight patients were male (80%) with a mean age of 60 years (54-70). The majority of patients was infected with genotype (GT) 3a (n = 5, 50%), while two individuals had GT1a and three were infected with GT1b. A cirrhosis was detected in five patients and another patient had a HCC and liver transplantation. Regarding the previous treatment, seven patients failed to one DAA combination

treatment, further two individuals had received two subsequent DAA treatments and an additional patient even failed to three DAA regimens. All patients had a history of at least one NS5A inhibitor regimen and NS5A RASs were common prior to VOX/VEL/SOF retreatment (89%, n = 8/9; thereof Y93 variants in n = 6/9 with available data), while NS3 D168 RASs were not observed. After virologic failure to VOX/VEL/SOF for 12 weeks, the NS5A resistance profile was identical compared to before retreatment in most of the patients (89%, n = 8/9 with available data). However, NS3 D168 RASs reached moderate frequencies only (33%, n = 3/9 with available data). Regarding NS5B SOF RASs, L159F was observed in one GT1b individual before and after VOX/VEL/SOF failure, other NS5B RASs were not detected. One patient had no NS3, NS5A or NS5B RASs, neither before nor after VOX/VEL/SOF failure.

Conclusion: Failure to VOX/VEL/SOF was mainly observed in patients infected with genotype 3a, but also in those infected with 1a and 1b. NS3 and NS5B RASs were uncommon, while NS5A RASs were frequent with a resistance profile maintained from previous treatments.

Figure: (abstract: THU-0135)

Background and aims: Per AASLD-IDSA guideline, HCV treatment should be prioritized in HCV-HIV coinfected patients (pts). We evaluated access to direct-acting antiviral agents (DAAs).
Method: Trio Health HIV network consists of 10 treatment centres providing care for 34, 000 HIV pts from 50 states, DC, and Puerto Rico in the US. We evaluated and verified Rx for pts with HCV-HIV on HIV regimens in Jan 1, 2016-Oct 31, 2018 at 5 sites. Pts with < 6 months follow-up or on clinical trials were excluded. Subgroups were compared using descriptive statistics, predictors of Rx and fill were evaluated via logistic regression.
Results: Of 1452 pts, 51% were prescribed DAAs, of those prescribed 87% filled Rx, therefore 44% of the pts ultimately received a DAAs. Differences were found in characteristics of Rx and Fill groups (Table). Rx were more likely to smoke, have higher BMI, Charlson comorbidity index (CCI), cirrhosis, less control of HIV, less likely to be black; Fill were less likely to use alcohol, had lower ALT values, and longer follow-up.
Conclusion: Despite guideline recommendations, less than half of HIV-HCV coinfected pts on HIV Rx were treated for HCV. Unlike HCV monoinfected pts, once prescribed, coinfected pts do not appear to face significant access barriers to DAAs from payers and the key care access issue is under prescribing.

THU-136
Ledipasvir/sofosbuvir for 8 weeks cures genotype 4 chronic hepatitis C in non-cirrhotic children and adolescents

Manal Hamdy El-Sayed[1,2], Mohamed Hassany[3], Fatma S El Sayed Ebeid[4], Ahmed Zeidan[5], Noha Asem[6]. [1]*Faculty of Medicine Ain Shams University Research Institute (MASRI), Clinical Research Centre, Cairo, Egypt;* [2]*Ain Shams University, Department of Paediatrics, Cairo, Egypt;* [3]*National Hepatology and Tropical Medicine Research Institute (NHTMRI), Department of Tropical Medicine, Cairo, Egypt;* [4]*Ain Shams University, Department of Paediatrics, Cairo, Egypt;* [5]*National Hepatology and Tropical Medicine Research Institute (NHTMRI), Department of Tropical Medicine, Cairo, Egypt;* [6]*Cairo University, Department of Public Health and Community Medicine, Cairo, Egypt*
Email: manalhelsayed@yahoo.co.uk

Background and aims: Globally, it is estimated that 6 million children may be HCV viremic with at least 100, 000 viremic adolescents in Egypt and limited access to treatment. Shortening of DAA therapy is cost-effective and may improve access and adherence of children and adolescents to HCV therapy. Ledipasvir/sofosbuvir (LDV/SOF) for 8 weeks in real world clinical settings achieved sustained virological response at 12 weeks (SVR12) in adults with hepatitis C viral (HCV) genotype 1 and 4 infections. We aimed to evaluate the efficacy, defined as SVR12, of 8 weeks LDV/SOF in HCV genotype 4 pediatric and adolescent population in a real-world setting.
Methods: Forty three (M:F 27:16; median age 12.5 yrs; range 10-17 yrs) children and adolescents >12 and < 18 years or ≥ 35 kg (median: 35.0 kg; range: 35-70.0 kg) with HCV-RNA positivity for at least 6 months and no evidence of cirrhosis were consecutively enrolled to receive ledipasvir 90 mg/sofosbuvir 400 mg fixed dose combination single tablet daily for 8 weeks. All patients had their laboratory and HCV-RNA tests assessed before DAA therapy (baseline) and at 4, 8 and 20 weeks (SVR12) after starting treatment. Fibroscan was assessed at baseline and at 20 weeks.
Results: The median baseline ALT and AST were 40.0 (interquartile range: 28.0-55.0) IU/L and 34.0 (interquartile range: 29.0-48.0) IU/L respectively and HCV viral load 297, 000 (interquartile range: 84519-1, 060, 000) IU/ml. All patients had an HCV-RNA below detection limit (<15 IU/ml) at week 4, 8 and 20 with 100% SVR12. Median percent change of fibroscan was −5.26% (interquartile range: −14.49% to −2.86%). Four patients had a CAP score of S1-S2 (steatosis >10%, to ≤ 30%); all had normal CAP (S0) at week 20. No serious adverse events were reported while all patients/legal guardians reported improved activity and sleeping pattern. Following therapy, one child exhibited at least 40% improvement in neuropsychiatric manifestations reported by his physician while another recovered from long term severe myalgia and bone aches starting week 4.
Conclusion: Shortened LDV/SOF 8 weeks' therapy cured 100% of non-cirrhotic children and adolescents in a real-world clinical setting and could offer a cost-effective therapy protocol to improve access to treatment in this special population.

THU-137
DAA therapy in women of child bearing age: Accidental conception during therapy and pregnancy outcome

Manal Hamdy El-Sayed[1,2], Wafaa Elakel[3], Aisha Elsharkawy[3], Rasha Eletreby[3], Kadry Elsaees[4], Yehia Elshazly[4], Magdi El-Serafy[3], Wahid Doss[3]. [1]*Faculty of Medicine Ain Shams University Research Institute (MASRI), Clinical Research Centre, Cairo, Egypt;* [2]*Ain Shams University, Department of Paediatrics, Cairo, Egypt;* [3]*Cairo University, Department of Endemic Medicine and Hepatology, Cairo, Egypt;* [4]*Ain Shams University, Department of Internal Medicine, Cairo, Egypt*
Email: manalhelsayed@yahoo.co.uk

Background and aims: The prevalence of HCV antibody and HCV-RNA among Egyptian females aged 15-59 years is 8.1% and 5.5% respectively. Treatment of women of childbearing age (WoCBA) should be prioritized to minimize the risk of mother to child transmission (MTCT). Although pregnant females are excluded from DAAs treatment protocols, a minority may accidentally become pregnant while on treatment despite vigilant contraception. We aimed to assess the pregnancy outcome in WoCBA with chronic HCV who accidentally got pregnant while receiving DAA therapy.
Methods: This retrospective study included 58059 females in the childbearing period (18-45 years) enrolled to receive DAA therapy through the national treatment program between October 2014 and March 2016. Patients were included according to the approved standard inclusion and exclusion criteria. Demographic, clinical and laboratory baseline data were collected in addition to, ultrasound assessment of the liver. Pregnancy test was done for all WoCBA before starting therapy.
Results: The mean age of the studied group was (37.16 ± 6.31 years), 93.1% were treatment naiive and 10.7% were cirrhotic. Sofusbuvir and daclatasavir with or without ribavirin was the main treatment regimen in this group (80.6%) with 96.7% sustained virological response. We report 11 of the WoCBA who commenced DAAs and discontinued treatment for accidental pregnancy. Seven women could be contacted and 4 were unreachable. They were all naïve patients with median baseline HCV viremia of 441500 IU/ml and all were treated with SOF/DAC regimen for 12 weeks; 6 discontinued therapy at week 4 while one discontinued SOF/DAC at week 8. The later was HCV-RNA negative and sustained virological response. Six of those women reported full term non interventional deliveries of normal weight newborns with no congenital anomalies. One woman reported postpartum hemorrhage and received blood transfusion. All seven infants were tested for HCV antibodies at 18 months, only one was positive with low viremia. All those women were advised to check HCV-RNA and restart treatment if proved positive.
Conclusion: WoCBA with HCV infection should be prioritized in the cascade of care and treatment, while more data on the safety of DAAs during pregnancy is required to prevent MTCT.

Background and aims: The ASTRAL-4 study demonstrated the efficacy and safety of sofosbuvir/velpatasvir plus ribavirin (SOF/VEL+RBV) for 12 weeks in patients with CPT B decompensated cirrhosis. The current study is the first to evaluate the efficacy and safety of SOF/VEL+RBV for 12 weeks in patients with CPT C decompensated cirrhosis.

Method: This was an open-label, single-arm study conducted in France and the US. Patients had CPT score 10-12 at screening and infected with any HCV genotype. Patients with a portosystemic shunt, variceal bleeding in the 6 months prior to screening, HIV or HBV co-infection, or HCC were excluded. All subjects were treated with SOF/VEL (400 mg/100 mg) and RBV (starting dose of 600 mg/day regardless of weight) for 12 weeks. The primary efficacy end point was SVR12. Safety end points included tolerability of the regimen.

Results: Of the 32 patients enrolled, 26 (81%) were male and 28 (88%) were treatment naïve. The mean age (range) was 55 (39-77) years. Eighteen patients (56%) had genotype 1, 5 (16%) had genotype 2, and 7 (22%) had genotype 3. Genotype could not be determined for 2 patients. At baseline, CPT score ranged from 8-13, with 9 (28%) and 23 (72%) having CPT B and CPT C cirrhosis, respectively. MELD scores ranged from 10-25, with the majority (19 patients, 59%) having scores >15. SVR12 was achieved in 78% of patients (25/32), with no virologic failures. Among those who did not achieve SVR12, 1 discontinued study drugs on Day 17 due to coadministration of amiodarone for an SAE of ventricular tachycardia that was considered unrelated to study drugs, and 6 others died due to AEs expected in a population with advanced liver disease, including liver failure, sepsis, and variceal hemorrhage. Three patients received a liver transplant during the study. Among the 21 patients who achieved SVR12, who did not receive a liver transplant and who had CPT score evaluated, 48% (10/21) improved in CPT class from baseline to post-treatment Week 12. SOF/VEL+RBV was well-tolerated with no Grade 3-4, SAEs, or deaths considered related to study drugs.

Conclusion: This study demonstrates that treatment with SOF/VEL+RBV for 12 weeks was well tolerated and resulted in high rates of SVR12 that were associated with clinical benefit, as measured by improvement in CPT class. The high rates of mortality and liver transplant are consistent with the advanced liver disease of patients with CPT C cirrhosis.

Real world experience of chronic hepatitis C retreatment with genotype specific regimens in non-responders to previous interferon-free therapy

Robert Flisiak[1], Dorota Zarębska-Michaluk[2], Pawel Pabjan[2], Iwona Orłowska[3], Simon Krzysztof[3], Magdalena Tudrujek[4], Ewa Janczewska[5], Dorota Dybowska[6], Marek Sitko[7], Witold Dobracki[8], Jerzy Jaroszewicz[9], Klapaczynski Jakub[10], Łukasz Laurans[11,12], Wlodzimierz Mazur[13], Łukasz Socha[12], Tronina Olga[14]. *[1]Uniwersytet Medyczny w Białymstoku, Białystok, Poland; [2]Voivodship Hospital and Jan Kochanowski University, Kielce, Poland; [3]Wrocław Medical University, Wrocława, Poland; [4]Medical University of Lublin, Lublin, Poland; [5]School of Public Health in Bytom, Medical University of Silesia, Katowice, Poland; [6]Faculty of Medicine, Collegium Medicum Bydgoszcz, Nicolaus Copernicus University Toruń, Bydgoszcz, Poland; [7]Jagiellonian University Collegium Medicum, Kraków, Poland; [8]MED-FIX Medical Center, Wrocława, Poland; [9]Medical University of Silesia in Katowice, Bytom, Poland; [10]Central Clinical Hospital of the Ministry of Internal Affairs and Administration, Warszawa, Poland; [11]Multidisciplinary Regional Hospital in Gorzów Wielkopolski, Gorzów Wielkopolski, Poland; [12]Pomeranian Medical University, Szczecin, Poland; [13]Specialist Hospital in Chorzów, Medical University of Silesia, Katowice, Poland; [14]Medical University of Warsaw, Warszawa, Poland*
Email: robert.flisiak@umb.edu.pl

Background and aims: The development of interferon (IFN)-free all-oral regimens substantially improved efficacy of antiviral treatment for HCV, but despite excellent effectiveness the failures still occur. The aim of our study was to evaluate the efficacy of retreatment with genotype specific direct acting antivirals (DAA)-based regimens in non-responders to previous IFN-free therapy.

Method: Studied population consisted of 31 non-responders to IFN-free regimen, which received second IFN-free rescue therapy, selected from 6228 patients included in a large national database EpiTer-2.

Results: Age, gender and genotype distribution in the studied group were similar to the whole population, but patients included in this analysis demonstrated much more advanced fibrosis. Primary therapy was discontinued in 12 patients, which were recognized as non-virologic failures, whereas virologic failure was recognized in 19 patients which completed therapy. Overall SVR rate was 81% and 86% in intent-to-treat (ITT) and modified ITT analysis, respectively (74% and 78% in virologic failures, 92% and 100% in non-virologic failures). There were no significant differences in SVR rate after the rescue therapy related to the type of administered primary or rescue regimen. All non-responders to rescue therapy were cirrhotics resulting with SVR of 62% in virologic and 89% in non-virologic failures, whereas SVR rate in non-cirrhotics achieved 100%. Resistance associated substitutions (RAS) testing was carried out in 8 virologic non-responders and three of them had potential risk for failure of rescue therapy due to NS5A association, but two of them finally achieved SVR.

Conclusion: Rescue therapy with genotype specific regimens can be considered in non-cirrhotics if more potent regimens are not available, but should be avoided in cirrhotics. RAS testing does not seem to be helpful to select optimal rescue therapy among genotype specific therapeutic option.

Background and aims: Aim was to follow the profile and effectiveness of treatment in patients with chronic hepatitis C in real world experience during 4 years of access to interferon-free therapy
Method: Study included 8737 patients treated in Poland between 2015–2018 from the EpiTer2 database. Analysis was carried-out as an comparison of three periods A: 2015-2016 (n = 2879) with data published recently (J.Viral.Hepat.2018;25:661), B: 2017 (n = 3349), C: 2018 (n = 2509).
Results: Gender distribution was similar in periods, but we observed significant reduction of age (A:55 ± 13, B:53 ± 15, C:50 ± 15 years), overweight (A:62%, B:55%, C:52%), accompanying diseases (A:69%, B:67%, C:40%), concomitant medications (A:65%, B:63%, C:23%). Genotype 1b was predominant, but decreased from 87% to 78%. Increasing proportion of treatment naïve (A:47%, B:66%, C:84%) and F0-F2 fibrosis (A:35%, B:53%, C:76%) was noticed. We observed reduced number of cirrhotics (A:44%, B;26%, C:15%), decompensation history (A:7.6%, B:1.6%, C:0.8%), Child-Pugh >A (A:6.0%, B:3.0%, C:1.1%), MELD >15 (A:4.4%, B:3.8%, C:2.2%), history of liver transplantation (A:3.5%, B:1.3%, C:0.1%). During B/C periods more HIV coinfected patients were treated (3.9% vs 1.4% in A). Ombitasvir/paritaprevir/ritonavir ± dasabuvir ± ribavirin (OPrDR) was the most frequent regimen untill 2017 (A:64%, B:44%, C:23%), followed by ledipasvir/sofosbuvir ± ribavirin (LSR; A:27%, B:38%, C:33%), but in 2018 the leading became grazoprevir/elbasvir ± ribavirin (GER; A:0, B:12%, C:36%). SVR of OPrDR (n = 3905) was higher (97%) than LSR (95%; n = 2402) and GER (95%, n = 1266). SVR of 96% in 6222 non-cirrhotics was significantly higher than in 2382 cirrhotics (92%). Pangenotypic regimens became available in mid 2018, administered to 273 patients, data will be available for presentation at the meeting.
Conclusion: Patients treated currently for HCV are younger and demonstrate less advanced liver disease compared to the beginning of interferon-free era. Effectiveness of novel regimens in this large real world study reached up to 97%.

Background and aims: The efficacy and safety of Elbasvir/Grazoprevir (E/G) among patients with Hepatitis C Virus (HCV) chronic infection have been mainly investigated in clinical trials, and scarce real-life data are available yet. The aim of the study was to investigate efficacy and safety of Elbasvir/Grazoprevir in a large Italian real-life cohort.
Method: All HCV-infected patients consecutively treated with E/G within the Lombardia-Veneto web-based NAVIGATORE HCV Network were analysed. E/G was administered for 12 or 16 weeks, usually according to drug label. Fibrosis stage was determined histologically or non-invasively, through liver stiffness measurement (LSM). Sustained Virological Response 12 (SVR12) was defined as undetectable HCV-RNA 12 weeks after the end of treatment (EOT).
Results: Between 4/2017 and 7/2018, 1799 patients (47, 6% male, mean age 61 yrs) were treated with E/G. Genotype (G) 1a, 1b and 4 were 14% (n = 258), 77% (n = 1380), 9% (n = 161), respectively. HIV co-infection in 7, 8%. Mean GFR 92.9 ml/min, CDK stages: 48.1%CKD1, 37.0%CKD2, 11.8%CKD3, 1.0%CKD4 and 2.1%CKD5. Cirrhotic patients were 19% (n = 312). Mean LSM, MELD, APRI was 10 kpa, 7.5, 0.9, respectively. SVR12 rate in both cirrhotic and non-cirrhotic patients was independent on Genotype, treatment duration, albumin level, PLT count, MELD, APRI, LSM, HIV co-infection, CKD stage and gender. Only in non-cirrhotic patients, SVR12 was influenced by mean baseline HCV viral load (3.987.778 IU/ml in non-SVR vs 2.104.418 IU/ml in SVR, p = 0.011). No treatment-related discontinuation was reported. Adverse events were reported in 1.1% in non-cirrhotic vs 2.2% in cirrhotic patients (p = 0.14). Results of the 1260 patients who have currently reached SVR12 are reported in the table.

Results of the 1260 patients who reached SVR12

	GT 1a		GT 1b		GT 4	
Schedule	12w	16w	12w	16w	12w	16w
No cirrhosis						
SVR12 n (%)	81/81 (100%)	75/76 (98.7%)	724/744 (97.3%)	9/9 (100%)	57/58 (98.3%)	24/24 (100%)
Overall	99.4%		97.3%		98.8%	
Cirrhosis						
SVR12 n (%)	20/21 (95.2%)	16/17 (94.1%)	206/211 (97.6%)	1/2 (50%)	10/10 (100%)	7/7 (100%)
Overall	94.7%		97.2%		100%	

Conclusion: in a large real-life Italian cohort of patients with HCV infection, virological responses and safety profile of E/G 12 or 16 weeks were excellent across G 1a, 1b, 4, and liver fibrosis stages. The complete SVR data will be available for ILC2019.

Background and aims: The combination sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) is approved for 12 weeks as a single tablet, once daily regimen, based on the phase 3 POLARIS studies for HCV patients who failed with DAA-containing regimens. Few data from real-world cohorts exist. We report the efficacy and safety of SOF/VEL/VOX ± RBV in DAA failure patients with cirrhosis included in the French compassionate use program.

Method: A total of 46 patients (33 males; mean age 58.7 years) were treated with SOF/VEL/VOX with RBV for 8 (n = 1) or 12 weeks (n = 9) or SOF/VEL/VOX for 12 weeks without RBV (n = 36). Patients were chronically infected with HCV genotype 1 (1a n = 10; 1b n = 3; 1e n = 2), 2 (n = 4), 3 (3a n = 17; 3b n = 1), 4 (n = 8), 5 (n = 1) and 41 had cirrhosis (Median FibroScan 16 kPa, [13.5-24.9]). Among the 46 patients, 3 were liver transplant recipients, and 5 were co-infected with HIV. Previous treatment was SOF/LDV (n = 16), SOF/DCV (n = 23), 2D/3D (n = 5), GZR/EBR (n = 2). Baseline resistance testing was performed in 39 (85%) patients and NS5A, NS3, and NS5B RASs were present in 34, 8, and 0 patients, respectively.

Results: All patients (n = 44) who achieved the end of treatment had undetectable HCV RNA. Among the 44 patients with available results at SVR4 and SVR12, SVR4 and SVR12 were observed in 43 (97.7%) patients and in 42 (95.5%) patients, respectively. Two patients (genotype 1a and 3a) experienced a relapse at SVR12. At baseline, Y93H was observed in the genotype 3a patient and, both NS3 and NS5A RASs were identified in the genotype 1a patient. Resistance testing at the time of the relapse is pending. To date, 3 serious adverse events were reported in 2 patients. One liver decompensation, and one HCC were reported in one patient with Child B8 score at the initiation of antiviral treatment. One HCC was observed in one patient classified Child A6 at baseline.

Conclusion: In a real-world cohort, the combination SOF/VEL/VOX ± RBV for 12 weeks is effective in patients with cirrhosis who failed with DAA combination containing 1st generation NS5A inhibitor and/or protease inhibitor. This strategy is safe in patients with compensated cirrhosis

THU-143

High effectiveness of elbasvir/grazoprevir treatment in patients with HCV genotype 1a infection in German real-world: Results from the German hepatitis C registry (DHC-R)

Holger Hinrichsen[1], Albrecht Stoehr[2], Markus Cornberg[3], Hartwig Klinker[4], Renate Heyne[5], Christine John[6], Karl-Georg Simon[7], Manfred Bilzer[8], Veronika Guenther[9], Vanessa Witte[9], Stefan Zeuzem[10]. *[1]Gastroenterology-Hepatology Center Kiel, Kiel, Germany; [2]ifi-Institute for Interdisciplinary Medicine, Study Centre St. Georg, Hamburg, Germany; [3]Hannover Medical School, Hannover, Germany; [4]University Hospital Würzburg, Würzburg, Germany; [5]Leberzentrum am Checkpoint, Berlin, Germany; [6]Private Practice of Internal Medicine, Berlin, Germany; [7]MVZ Dres. Eisenbach, Simon, Schwarz GbR, Leverkusen, Germany; [8]Bilzer Consulting, Munich, Germany; [9]MSD Sharp and Dohme GmbH, Haar, Germany; [10]Johann Wolfgang Goethe University, Frankfurt, Germany*
Email: veronika.guenther@msd.de

Background and aims: For treatment of HCV GT1a infection with EBR/GZR German guidelines recommend a differentiated approach depending on baseline viral load (BVL). For low BVL ≤ 800, 000 IU/ml treatment with 12 weeks EBR/GZR should be considered, whereas for high BVL >800, 000 IU/ml a 12 weeks regimen of EBR/GZR is only recommended in the absence of NS5A RAS. In the presence of NS5A RAS or when RAS-testing is not available, treatment with EBR/GZR + ribavirin (RBV) for 16 weeks is preferred. Therefore, the present analysis investigated the adherence to these recommendations and the real-world effectiveness of EBR/GZR regimens in a large GT1a cohort of the German Hepatitis C Registry.

Method: From 09/2016 until 07/2018, 992 patients (pts) with GT1 infection were treated with EBR/GZR ± RBV for 12 to 16 weeks in 130 medical practices and hospital outpatient departments in Germany. The present analysis was restricted to 195 pts with GT1a infection who completed follow-up. The primary outcome was per protocol sustained virologic response at 12 or 24 weeks post treatment (SVR12 or SVR24).

Results: 88 pts (45%) with low baseline viral load (BVL) ≤ 800, 000 IU/ml and 107 pts (55%) with high BVL >800, 000 IU/ml showed comparable characteristics: mean age 49 vs. 51 years, female gender 30 vs. 33%, cirrhosis 22 vs. 17%, opioid substitution 26 vs. 24%, HIV co-infection 11 vs. 10% and treatment-naïve 74 vs. 70%. RAS at baseline were tested in 49% vs. 42% of pts with high/low BVL. 4 pts with high BVL (8%) and 2 pts with low BVL (5%) had NS5A RAS of which 50% were treated with EBR/GZR+RBV, respectively. In total, 65% of GT1a pts with high BVL and 94% of pts with low BVL were treated with EBR/GZR in the absence of RBV. Per protocol SVR rates stratified by low vs. high BVL were 85/86 (98.8%) vs. 97/102 (95.1%). All pts with NS5A RAS achieved SVR. When SVR rates were additionally stratified by age, pts with low BVL achieved high SVR rates across all age groups (table). Interestingly, in pts with high BVL younger than 50 years SVR was 100% but this rate decreased with higher age (table). A multivariate analysis will be presented to investigate the significance of these findings.

	SVR Rates, n/N (%)		
	Age < 50 years	Age 50-70 years	Age > 70 years
GT1a ≤ 800, 000 IU/ml	43/43 (100)	40/41 (97.6)	2/2 (100)
GT1a > 800, 000 IU/ml	46/46 (100)	46/49 (93.9)	5/7 (71.4)

Conclusion: In German real-world, 94% of GT1a infections with low BVL and 65% with high BVL are treated with EBR/GZR for 12 weeks. SVR rates are consistently high. While a decrease in SVR rates in pts with high BVL >800, 000 IU/ml can be observed, this seems to be limited to pts older than 50 years. Pts younger than 50 years achieve SVR rates of 100% independent of BVL.

Background and aims: Approved HCV treatments for patients on dialysis are associated with complexities including drug-drug interactions, baseline resistance testing, use of ribavirin, and risk of hepatotoxicity. Despite higher concentrations of the primary circulating sofosbuvir (SOF) metabolite, GS-331007, in severe renal impairment, real-world case series demonstrated substantial use of SOF-based regimens in this population with no safety concerns identified. This study evaluated the safety, efficacy, and pharmacokinetics (PK) of ledipasvir (LDV)/SOF for 8, 12 or 24 weeks in patients with HCV infection on dialysis.

Method: Treatment-naïve or interferon-experienced patients, with or without compensated cirrhosis undergoing hemodialysis or peritoneal dialysis, were enrolled to receive open-label LDV/SOF (90 mg/400 mg daily) fixed-dose combination once daily. Eligible patients had HCV genotype 1, 2, 4, 5, or 6 infection. Treatment-naïve patients without cirrhosis infected with HCV genotype 1 received treatment for 8 weeks, patients with cirrhosis received treatment for 24 weeks, all other patients received 12 weeks of treatment. The primary efficacy end point was the proportion of patients with sustained virologic response 12 weeks after treatment (SVR12). The primary safety end point was the proportion of patients who discontinued therapy due to adverse events (AEs). Secondary end points included safety, viral resistance, and PK.

Results: 95 patients were enrolled at 21 sites in Taiwan, Italy, Germany, the USA, and Belgium. The median age was 61 years (range 32-84), 59% were male, 64% Asian, 22% treatment-experienced, and 20% had cirrhosis. Most patients had HCV genotype 1 (72%) or 2 (22%) infection. Most (92%) were on hemodialysis with a mean (range) dialysis duration of 11.5 years (0-43). Treatment was well tolerated; there were no discontinuations due to AEs. To date, 87/95 (92%) of patients achieved SVR12; with no virologic failures. Four (4%) patients died during therapy, two (2%) additional patients died during the posttreatment period after achieving SVR4, and two (2%) patients achieved SVR4 but have not yet attended their post-treatment week 12 visit. None of the deaths were considered related to LDV/SOF. The most frequent AEs were muscle spasms (13%), nasopharyngitis (12%), and headache (8%). Serious AEs (SAEs) occurred in 13% of patients, none was assessed as related to LDV/SOF.

Conclusion: Treatment with LDV/SOF single tablet regimen in patients with and without cirrhosis undergoing dialysis resulted in a 92% SVR12 rate with no virologic failures. The regimen was safe and well-tolerated with no treatment related discontinuations or treatment-related SAEs.

THU-145

High real-world effectiveness of elbasvir/grazoprevir in a HCV genotype 1 population with a migration background and predominant subtype 1b infection: Results from the German hepatitis C registry (DHC-R)

Dietrich Hüppe[1], Albrecht Stoehr[2], Markus Cornberg[3], Hartwig Klinker[4], Renate Heyne[5], Christine John[6], Karl-Georg Simon[7], Manfred Bilzer[8], Veronika Guenther[9], Vanessa Witte[9], Claus Niederau[10]. Email: veronika.guenther@msd.de

Background and aims: Approximately 71 million individuals worldwide are chronically HCV-infected. Dependent on the geographical area stark differences regarding prevalence and genotype/subtype distribution can be observed. With an increasingly interconnected world due to migration, infectious diseases such as HCV do not remain geographically isolated. Therefore, the aim of the present study was to investigate the proportion of GT1 patients (pts) with a migration background undergoing treatment with EBR/GZR in a German real-world setting and to estimate its effectiveness in this patient population.

Method: From September 2016 until July 2018, 992 pts with GT1 infection were treated at the physiciańs discretion with EBR/GZR ± ribavirin (RBV) for 12 to 16 weeks in 130 medical practices and hospital outpatient departments. The present analysis was restricted to 613 pts who completed 12 or 24 weeks of follow-up or discontinued the treatment early; the demographic data are shown for this ITT population. Sustained virologic response (SVR) data were available and are shown for 599 patients (Per Protocol (PP) population).

Results: From the overall 613 pts, 360 (59%) were German natives and 253 (41%) had a migration background. Among the migrants, pts from the former Soviet Union (GUS countries) represented the largest population (51%). Demographics of native Germans, all migrants, and migrants from GUS countries differed markedly: mean age was 58 vs. 50 vs. 48 years, GT1b 58 vs. 81 vs. 91%, elevated gammaGT 59 vs. 49 vs. 45%, cirrhosis 19 vs. 16 vs. 12% and co-morbidities 90 vs. 84 vs. 78%, respectively. EBR/GZR treatment was used without RBV in 93 vs. 94 vs. 99% of pts and EBR/GZR+RBV in 7 vs. 6 vs. 1%, respectively. PP SVR was 97.7% in German natives, 99.2% in all migrants, and 99.2% in migrants from GUS countries. SVR rates according to GT1 subtypes and treatment regimens are summarized in the table.

	German natives	All Migrants	Migrants from GUS countries
PP SVR-n/N (%)			
Total	347/355 (97.7)	242/244 (99.2)	125/126 (99.2)
GT1a	141/147 (95.9)	43/43 (100)	11/11 (100)
GT1b	203/205 (99.0)	198/200 (99.0)	114/115 (99.1)
EBR/GZR	323/330 (97.9)	229/231 (99.1)	124/125 (99.2)
EBR/GZR + RBV	24/25 (96.0)	13/13 (100)	1/1 (100)

Conclusion: 41% of GT1 patients treated with EBR/GZR in a German real-world setting have a migration background. These patients show a much higher frequency of GT1b infections than German natives. In the migrant population treatment with EBR/GZR based regimens yields high SVR rates of 100% in GT1a and 99% in GT1b infected pts. These results are comparable to the high SVR rates achieved in German natives of 96% in GT1a and 99% in GT1b. This data strongly suggests that treatment adherence is excellent in HCV infected migrants.

THU-146

LDV/SOF/RBV is an effective first-line DAA regimen as well as re-treatment option for RF1_2k/1b patients within Georgian national hepatitis C elimination program

Marika Karchava[1,2], Nikoloz Chkhartishvili[1], Lali Sharvadze[1,2,3], Akaki Abutidze[1,2,3], Natia Dvali[1], Lana Gatserelia[1,2], Lela Dzigua[1], Natalia Bolokadze[1,3], Adam Kotorashvili[4], Paata Imnadze[4], Amiran Gamkrelidze[4], Tengiz Tsertsvadze[1,2,3]. [1]*Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia;* [2]*Hepatology Clinic- Hepa, Tbilisi, Georgia;* [3]*Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia;* [4]*National Center for Diseases Control and Public Health, Tbilisi, Georgia*
Email: kmarika79@yahoo.com

Background and aims: HCV RF1_2k/1b patientsmake up to 76.0% among HCV genotype 2 patients receiving care at the Georgian national hepatitis C elimination program. These patients are treated with either Sofosbuvir/Ribavirin (SOF/RBV) or Ledipasvir/Sofosbuvir/Ribavirin (LDV/SOF/RBV) since 2015 within this program. Our aim was to evaluate baseline and retreatment outcomes among HCV genotype 2 patients receiving HCV care within national hepatitis C elimination program.
Method: Study included 401 adult patients with HCV genotype 2 as determined by 5'UTR/Core genotyping assay. NS5B sequencing was also performed for genotype clarification. Confirmation of breakpoint positions among selected RF1_2k/1b patients was performed by whole genome sequencing. Study patients were treated with either Sofosbuvir/Ribavirin (SOF/RBV) or Ledipasvir/Sofosbuvir/Ribavirin (LDV/SOF/RBV regimens) from September, 2015 to August, 2018. Re-treatment was done with LDV/SOF/RBV for 24 weeks.
Results: Of total 401 patients enrolled 305 (76.1%) had RF1_2k/1b strain and 96 (23.9%) had HCV 2a, 2k, or 2c subtypes. Of total patients, 354 (88.3%) were males with a median age of 49.9 years (IQR-42.1-55.5%), and 88 (21.9%) had liver cirrhosis. As of August 2018, sustained virologic response (SVR) was available for 304 individuals. SVR rate was 97.3% (72/74) among genotype 2 and 89.1% (205/230) among RF_2k/1b patients (p = 0.05), with an overall SVR rate of 91.1% (277/304). Highest SVR rate was observed among patients treated with LDV/SOF/RBV among both genotypes (99.5%). For patients with cirrhosis SVR was 94.1% (16/17) among genotype 2 compared to 83.7% (41/49) among RF1_2k/1b (p = 0.43) patients. Among non-cirrhotic patients, SVR was 98.2% [56/57] among genotype 2 as compared to RF1_2k/1b (SVR 90.6% [164/181]) (p = 0.08). Statistically significant difference was observed in response rates among patients treated with SOF/RBV (94.4% for genotype 2 vs. 64.6% for RF1_2k/1b, p = 0.02). Among patients with RF1_2k/1b LDV/SOF/RBV had higher SVR rate (100% [147/147%) vs. SOF/RBV (SVR 64.6% [42/65], p < 0.0001). All 27 failing patients were re-treated with LDV/SOF/RBV for 24 weeks yielding SVR rate of 100%.
Conclusion: LDV/SOF/RBV was found to be highly effective both as first-line regimen as well as retreating option for HCVRF1_2k/1b patients within Georgian national hepatitis C elimination program.

THU-147

Improvement of neutrophil function in hepatitis C patients under direct acting anti-viral treatment is associated with hemolysis parameters

Irina Komarova[1], Bettina Leber[2], Angela Horvath[1,3], Andreas Posch[1], Andrea Streit[1], Walter Spindelböck[1], Philipp Stiegler[2], Rudolf E. Stauber[1], Vanessa Stadlbauer[1]. [1]*Medical University of Graz, Department of Gastroenterology and Hepatology, Graz, Austria;* [2]*Medical University of Graz, Department of Transplantation Surgery, Graz, Austria;* [3]*Center of Biomarker Research in Medicine (CBmed), Graz, Austria*
Email: irina.komarova@medunigraz.at

Background and aims: Hepatitis C (HCV) patients were shown to have impaired neutrophil function, which increases their risk of bacterial infections and worsen their prognosis. We showed before that direct-acting anti-viral (DAA) treatment improves neutrophil function in these patients and influences hemolysis. HCV infection is associated with increased hemolysis. Our aim is to study if there is a relationship between changes in neutrophil function and hemolysis parameters.
Method: Neutrophil function parameters (phagocytosis (phagocytic capacity (PC) and non-phagocyting cells (NPC)) and respiratory burst (burst without stimulus-resting burst (RB), burst after stimulation with fMLP-priming (P), burst after stimulation with E.Coli-full burst)) and hemolysis parameters (hemoglobin (Hb), bilirubin (Bili), hematocrit, haptoglobin (Hapto) and heme) were obtained from 85 HCV patients (mean age 57 ± 11 years, 40% female) before, after 12 weeks and 12 weeks after DAA treatment. To study the relationship between parameters Spearman correlation with Benjamini-Hochberg correction, simple linear regression (SLR), linear mixed model (LMM) with likelihood ratio test (LR) and ROC curve analysis were applied. Results of analysis were independent of liver function, ribavirin treatment, presence of sustained virologic response, age and sex. The analysis was performed using R and SPSS Statistics 23.
Results: There was a negative partial correlation between Hapto and RB (GMFI and %) and P (GMFI) and positive partial correlation between Hb and PC at baseline. SLR showed significant associations of Hb and PC. LMM showed that the increase in Hapto was associated with an increase in PC, a decrease in RB (GMFI) and a decrease in NPC. ROC curve analysis showed that the changes in Hapto over time were predictive for the changes in NPC, RB (GMFI) and P (GMFI). Changes in Bili over time were predictive for the changes in RB (%) (Table 1).

	Partial correlation	LMM (LR)	ROC curve
HaptoandRB (%)	R = -0.218 p = 0.046		
HaptoandRB (GMFI)	R = -0.243 p = 0.026	χ2 (1) = 4.66 p = 0.031	AUC = 0.652 p = 0.050
HaptoandP (GMFI)	R = -0.234 p = 0.032		AUC = 0.664 p = 0.023
HaptoandPC		χ2 (1) = 5.65 p = 0.017	
HaptoandNPC		χ2 (1) = 4.59 p = 0.032	AUC = 0.692 p = 0.013
HbandPC	R = 0.262 p = 0.016		
BiliandRB (%)			AUC = 0.635 p = 0.034

Conclusion: Improvement in neutrophil function in HCV patients after DAA treatment was significantly associated with decreased hemolysis. DAA therapy therefore has beneficial effects beyond viral clearance.

THU-148

Variability of selected extracellular matrix proteins concentrations in HCV infected patients treated with sofosbuvir and ledipasvir

Agata Kozłowska[1], Krzysztof Tomasiewicz[1], Joanna Krzowska-Firych[1]. [1]*Medical University of Lublin, Department of Infectious Diseases, Lublin, Poland*
Email: agata.h.kozlowska@gmail.com

Background and aims: It is known that in most of patients with chronic hepatitis C (CHC) successfully treated with antiviral therapy, reduction in liver stiffness is observed. However, there is lack of data assessing treatment-related changes occurring in the concentration of direct fibrosis biomarkers. Therefore, our study aimed to assess the levels of laminin (LN), hyaluronic acid (HA) and collagen type IV (Col IV) and transient elastography (TE) in patients with chronic hepatitis C treated with direct acting antivirals (DAA).
Method: A total of 52 patients were enrolled to this study. 42 patients with CHC were treated with sofosbuvir and ledipasvir (all achieved

SVR), 10 healthy volunteers formed control group. In all patients TE was performed at baseline (BL) and SVR24, and serum concentrations of laminin, hyaluronic acid and type IV collagen were determinated by ELISA at BL, End of Treatment (EOT), SVR24.

Results: Baseline **c**oncentrations of HA and Col IV were significantly higher (p = 0, 012, p = 0, 002) in cirrhotics, and LN was notably lower in the control group than in HCV infected patients (p = 0, 003). A significant decrease of HA, LN and Col IV at SVR24 was observed in cirrhotics (p = 0.005, p = 0.009, p < 0.001). In patients without cirrhosis significant increase of LN, HA, Col IV was observed at EOT. However, at SVR24 HA and Col IV decreased to BL level, only LN remained significantly higher than at BL.

Conclusion: DAA treatment changes the concentrations of LN, HA, Col IV and its dynamics depends on the severity of liver disease. Assessment of direct fibrosis biomarkers and liver stiffness may have prognostic value in the course of liver disease after achieving SVR.

THU-149

Efficiency and safety of direct acting antivirals in chronic hepatitis C patients infected with genotype 2 and 3 in Turkey

Behice Kurtaran[1], Figen Sarıgül[2], Mehmet Çabalak[3], Sibel Kaya[4], Nagehan Didem Sarı[5], Hasan Karsen[6], Esra Zerdali[7], Rahmet Güner[8], Kamuran Türker[9], Nevin İnce[10], Fehmi Tabak[4], Hepcturkey Study Group[4]. *[1]Cukurova University Faculty of Medicine Department of Infectious Diseases, Adana, Turkey; [2]Antalya Training and Research Hospital Department of Infectious Diseases, Antalya, Turkey; [3]Mustafa Kemal University Faculty of Medicine Infectious Diseases Department, Hatay, Turkey; [4]Istanbul University Faculty of Medicine Infectious Diseases Department, İstanbul, Turkey; [5]Istanbul Training and Research Hospital Department of Infectious Diseases, İstanbul, Turkey; [6]Harran University Faculty of Medicine Infectious Diseases Department, Şanlıurfa, Turkey; [7]Haseki Training and Research Hospital Department of Infectious Diseases, İstanbul, Turkey; [8]Yıldırım Beyazıt University Faculty of Medicine Infectious Diseases Department, Ankara, Turkey; [9]Bağcılar Training and Research Hospital Department of Infectious Diseases, İstanbul, Turkey; [10]Düzce University, Düzce, Turkey*
Email: behicekurtaran@gmail.com

Background and aims: Genotypes 2 and 3 chronic hepatitis C (CHC) patients are less frequently seen than genotype 1 in Turkey. While these genotypes have had favorable treatment outcomes with interferon-based regimens, response rates are lower with direct acting antivirals (DAAs).

We aimed to evaluate efficiency and safety of DAAs in CHC patients infected with genotype 2 and 3.

Method: Between April 2017 and September 2018, 37 centers recorded 2230 patients. All patients >18 years with CHC under DAAs were enrolled in this observational study. Those infected with genotype 2 and 3 were analyzed for end of treatment response (EoTR) and response at week 12 (SVR12).

Results: Among 2230 patients recorded into the database; 267 (12%) were infected with genotype 2 or 3, 73 (27%) were female and mean age was 41.7 ± 17 years (range 18-84 years). The genotypes were 3 in 189 (71%) and 2 in 78 (29%). 25 (9.4%) had cirrhosis; 24 had compensated (Child-Pugh A) and 1 had decompensated (Child-Pugh B-C) cirrhosis.

Liver biopsy was available in 151 (57%, G3: 107, G2: 44) patients; mean histologic activity index (HAI) was 7.4 and fibrosis score was 2.4. HAI was mild (1-6) in 37%, moderate (7-12) in 59%, and severe (13-18) in 4%. Fibrosis was mild in 49% moderate in 47%, and advanced in 4%. While 200 (79%) patients were treatment-naïve, 57 (21%) were previously treated with pegylated interferon+ribavirin: 74% relapse and 26% non-responder. Baseline viral load was 5.3 x10^6 copies/ml. Ledipasvir + Sofosbuvir, Ledipasvir + Sofosbuvir + Ribavirin and Sofosbuvir + Ribavirin were given to 8, 15, and 154 patients, respectively. The drugs were tolerated well. Severe adverse events were not reported. SVR was evaluated in 134 patients, shown in Table 1. Response rate at week 4 was 119/147 (81%), EoTR 143/144 (% 99.3%) and SVR12 128/134 (95.5%).

Drugs	G3	SVR12	G2	SVR12
Ledipasvir + Sofosbuvir	4/4	100%	1/1	100%
Ledipasvir + Sofosbuvir + Ribavirin	11/12	91.7%	3/3	100%
Sofosbuvir + Ribavirin	67/69	97%	42/45	93, 3%
Overall	**82/85**	**96.5%**	**46/49**	**93.9%**

Table 1. Direct Acting Antivirals and Response Rates in Patients Infected with Genotype 2 and 3 Chronic Hepatitis C.

Conclusion: This study represents the largest study of genotypes 2 and 3 CHC in Turkey. Genotype 3 is much commoner than genotype 2 (71% vs 29%). Rate of male gender was higher (73%) and mean age was 42 years. Liver histology showed moderate to higher activity in more than half of the patients and fibrosis was moderate to severe in half. Sofosbuvir and ribavirin containing regimens provided a SVR of more than 90%. The response rate in genotype 2 (94%) was lower than that in genotype 3 (96.5%). DAAs containing sofosbuvir and ribavirin have found efficient and safe among genotype 2 and 3 CHC patients in Turkey.

*This study was supported by Gilead Sciences İlaç Ltd. Şti. (Istanbul, Turkey). Company was not involved to the content of the study/publication; no involvement to the decision to submit for publication.

Factors associated with treatment failure with SOF+RBV in patients with genotype 2 chronic hepatitis C and consideration of retreatment with GLE+PIB in patients not responding to SOF+RBV

Atsunori Kusakabe[1], Masayuki Kurosaki[2], Jun Itakura[2], Kouji Joko[3], Takehiro Akahane[4], Haruhiko Kobashi[5], Tetsuro Sohda[6], Keiji Tsuji[7], Hiroyuki Matusawa[8], Hiroyuki Kimura[9], Ryoichi Narita[10], Koichiro Furuta[11], Namiki Izumi[2]. *[1]Japanese Red Cross Nagoya Daini Hospital, Gastroenterology, Nagoya, Japan; [2]Musashino Red Cross Hospital, Musashino, Japan; [3]Matsuyama Red Cross Hospital, Matsuyama, Japan; [4]Japanese Red Cross Ishinomaki Hospital, Ishinomaki, Japan; [5]Japanese Red Cross Okayama Hospital, Okayama, Japan; [6]Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; [7]Hiroshima Red Cross Hospital and Atomic-bomb Survivors Hospital, Hiroshima, Japan; [8]Osaka Red Cross Hospital, Osaka, Japan; [9]Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan; [10]Oita Red Cross Hospital, Oita, Japan; [11]Masuda Red Cross Hospital, Masuda, Japan*
Email: atsunori-ku@nifty.com

Background and aims: This study aims to elucidate factors associated with treatment failure with sofosbuvir (SOF) + ribavirin (RBV) in patients with genotype 2 (GT2) chronic hepatitis C and to examine the efficacy and safety of glecaprevir (GLE) + pibrentasvir (PIB) as a retreatment regimen in patients not responding to SOF + RBV.

Method: 915 patients with GT2 chronic hepatitis C were treated with SOF + RBV in 24 nationwide centers of Japanese Red Cross Hospitals. By comparing data of patients who achieved sustained viral response at post-treatment week 12 (SVR12) with those with unsuccessful responses to the therapy (non-SVR12), we investigated factors associated with treatment failure. Regarding the treatment failure cases, the presence of NS5B resistance-associated variants was also examined. Next, we investigated the rates of SVR and side effects in patients who received GLE + PIB as a retreatment regimen.

Results: Of the 915 patients administered SOF + RBV, 34 were non-SVR12. Multivariate analysis revealed that “a history of interferon (IFN) treatment” (odds ratio: 2.97, $p < 0.005$) and “a history of hepatocellular carcinoma (HCC) treatment” (odds ratio: 7.27, $p < 0.0001$) were associated with non-SVR12. In 19 of the non-SVR patients, we were able to investigate the presence of NS5B resistance-associated variants at the time of treatment failure, but S282 T mutation was not detected in any of these patients. The mean age of 29 patients who underwent GLE + PIB therapy as a retreatment regimen was 67.7 years. Of the 29 patients, 21 were men and 14 had

genotype 2a. Advanced liver fibrosis was noted in many; 20 patients had FIB-4 index of 3.25 or higher. The duration of therapy was 12 weeks in all patients. At week 4 of therapy, serum hepatitis C virus (HCV) RNA levels were below the limit of detection in all patients (26/26). At the completion of the therapy, a negative HCV RNA status was achieved in all patients (21/21). The SVR4 rate was 100% (20/20), and the SVR12 rate 100% (13/13). No patient has had a relapse, to date. The side effects noted included itchy skin in 5 patients and fatigue in 3, all of which were mild in severity. There were no discontinuations of the therapy.

Conclusion: A history of IFN treatment and HCC treatment were identified as factors associated with treatment failure with SOF + RBV therapy in patients with GT2 chronic hepatitis C. However, the involvement of NS5B resistance-associated variants was not observed. GLE + PIB therapy as a retreatment regimen in patients not responding to SOF + RBV was considered to be safe and highly effective.

THU-151

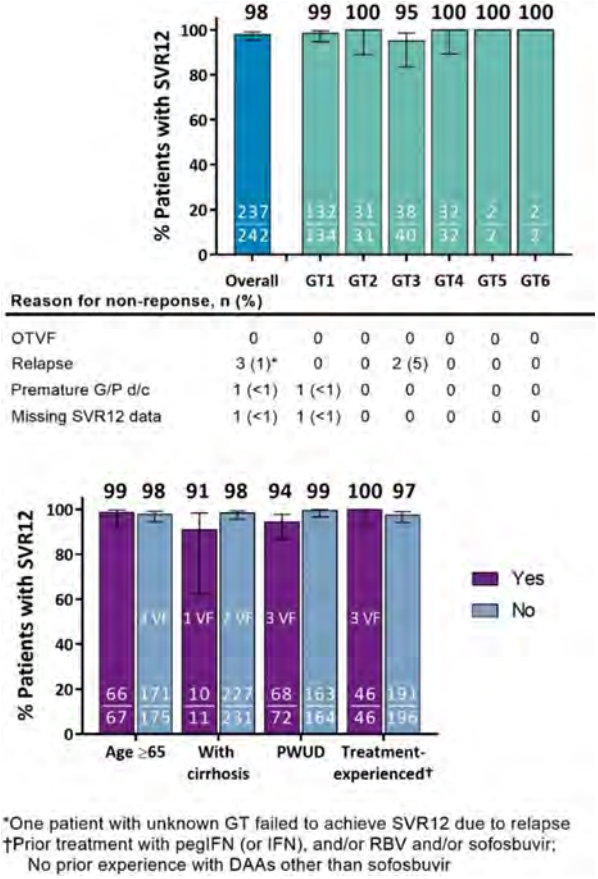
Real-world effectiveness and safety of glecaprevir plus pibrentasvir in HCV: A multi-country analysis of postmarketing observational studies

Pietro Lampertico[1], Markus Peck[2], Mark Bondin[3], Yves Horsmans[4], Nasser Semmo[5], Sadhana Sonparote[3], Zhenzhen Zhang[3], Ariel Porcalla[3], Dominique Thabut[6]. *[1]CRC "AM e A Migliavacca" Center for Liver Diseases, Milan, Italy; [2]Klinikum Klagenfurt am Wörthersee, Klagenfurt, Austria; [3]AbbVie, Inc, 1 N Waukegan Rd, North Chicago, United States; [4]Cliniques Universitaires Saint-Luc, UCL, Brussels, Belgium; [5]University of Bern, Bern, Switzerland; [6]Paris Sorbonne Université, Paris, France*
Email: pietro.lampertico@unimi.it

Background and aims: Across different countries, there is significant heterogeneity in DAA access and types of patients treated, thus real-world safety and effectiveness data in the era of pangenotypic regimens is crucial to better understand such treatment patterns. Here we report a pooled analysis across multiple countries of real-world effectiveness and safety from ongoing post-marketing observational studies (PMOS) using the recently approved, pangenotypic regimen of glecaprevir (NS3/4A protease inhibitor; developed by AbbVie and Enanta) and pibrentasvir (NS5A inhibitor; coformulated as G/P).

Method: Data were pooled from six countries (Austria, Belgium, France, Israel, Italy, and Switzerland) thus far participating in this prospective PMOS. Patients were receiving G/P at the treating physician's discretion according to local clinical practice, international recommendations and/or local label. Patients eligible for the PMOS had HCV GT1-6 infection, were HCV treatment-naïve or interferon, ribavirin and/or sofosbuvir-experienced, and either had compensated cirrhosis or were without cirrhosis. Cirrhosis status was most often assessed using transient elastography or non-invasive measures. Baseline characteristics and safety were summarized for all patients who received ≥ 1 dose of G/P. Effectiveness was assessed both overall and by subpopulations of interest as the percentage of patients achieving sustained virologic response (SVR) in all treated patients who have reached post-treatment week 12.

Results: Of 815 patients dosed, 89% were non-cirrhotic and 84% were treatment-naïve. As a result, most (86%) were assigned to 8-week G/P treatment, while 13% and 1% were assigned 12- or 16-weeks G/P treatment, respectively. Common prescribed and/or non-prescribed drugs included antithrombotic agents (9.2%), anxiolytics (8.3%), beta blocking agents (8.2%), antidepressants (8.0%), and drugs used in addictive disorders (7.2%). To date, for those reaching end of treatment and SVR12 visits, the SVR rates were 100% (546/546) and 97.9% (237/242; 3 virologic failures all due to relapse), respectively. SVR12 rates and reasons for non-response are reported both overall and by subpopulations of interest in the Figure. G/P was well-tolerated with no G/P-related serious adverse events (SAEs) and a low rate of AEs leading to premature G/P discontinuation (<1%). The most common AEs were fatigue (3%), asthenia (2%), headache (1%), and nausea (1%). Enrollment, treatment, and follow-up are currently ongoing.



*One patient with unknown GT failed to achieve SVR12 due to relapse
†Prior treatment with pegIFN (or IFN), and/or RBV and/or sofosbuvir; No prior experience with DAAs other than sofosbuvir

Conclusion: Effectiveness and safety of G/P in this study were consistent with that seen in registrational trials. Updated baseline characteristics, safety, and SVR data will be presented at the Congress to include all patients who have enrolled and reached SVR12 from these and additional enrolling countries.

Email: dom-larrey@chu-montpellier.fr

Background and aims: France is one of the first european countries engaged on HCV eradication. Since 2013, DAAs were initially prescribed to very severe patients (F3/F4, Liver transplant, HCV/HIV

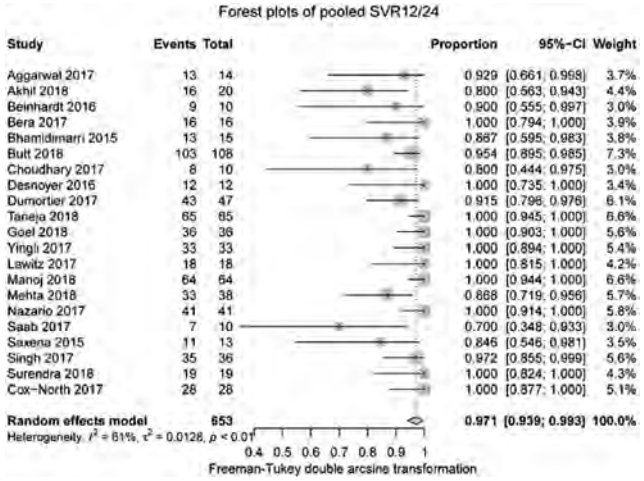
co-infected), then extended to historically difficult to treat patients (GT3) and F2. In 2017 DAAs reimbursement was finally extended to all HCV-patients, including F0/F1.
HELIOS is a study cohort aimed to assess real-world effectiveness and safety of sofosbuvir-based therapy in patients with HCV chronic infection in France. Patients were recruited in two periods (Oct15-Jul16 and Oct17-Jul18). The analysis objective was to assess patient characteristics changes within 4 years and to put into perspectives therapeutic strategies as recommended by guidelines.
Method: 1020 HCV-patients who started SOF-based therapy were prospectively enrolled in a real-world cohort in 46 French centers. SVR12 was defined as HCV-RNA < 25 IU/ml 12 weeks after the end of treatment.
Results: Baseline characteristics were: mean age 55 ± 11 years, 60% male, 84% Caucasian, 23.1% F4, 23.4% F3, 11.5% HIV-HCV co-infected. 27.6% significant clinical medical history. SOF-based therapies distributed as follows: SOF/LDV ± RBV (n = 570), SOF+RBV (n = 22), SOF+DAC or SIM (49), SOF/VEL (379). The profile of HCV-patients treated in France between 2015 and 2018 has slightly evolved. HCV treatment experienced (39.2% to 22.7%), F0/F1 (39.5% to 55.6%), HIV-HCV co-infected (15.3% to 4.5%), extrahepatic manifestation (20.3% to 12.7%), illicit drug use (12.6% to 20.7%), excessive alcohol consumption (11.4% to 18.4%). Treatment discontinuation was reported on 6 patients: 2 lost of FU, 2 AEs not related, 2 AEs related to therapy (asthenia, general physical condition).On a per protocol analysis, total SVR12 was 98.5% (196/200 SOF/LDV, 140/140 SOF/VEL). No major safety issues were reported. The most common AE were asthenia (n = 71), headache (n = 49), nausea (n = 16), anemia (n = 14) and insomnia (n = 9). There was one treatment-emergent AE leading to death (hepatorenal syndrome).
Conclusion: This analysis demonstrates that the profile of HCV-patients treated in France has changed between 2015–2016 and 2017-2018 driven by treatment access recommendations. All patients have now access to potent pan-genotypic HCV-treatment. High SVR rates were reported with Sofosbuvir/Velpatasvir in this cohort. SVR were in accordance with clinical studies and other real-world cohorts. SOF-based therapy presented a favorable safety profile.

THU-153

Is sofosbuvir-based regimen safe and effective in hepatitis C virus-infected patients with stage 4-5 chronic kidney disease? A systematic review and meta-analysis

Mingshu Li[1], Jun Chen[2], Zhixiong Fang[3], Yi Li[2], Qian Lin[1]. [1]*Central South University, Xiangya School of Public Health, Changsha, China;* [2]*The Second Xiangya Hospital of Central South University, Changsha, China;* [3]*XiangTan City Central Hospital, Xiangtan, China*
Email: linqian@csu.edu.cn

Background and aims: Whether sofosbuvir is suitable for hepatitis C virus (HCV) infected patients with severe renal impairment is inconclusive. The goal of the present study is to evaluate the safety and effectiveness of SOF-based regimen in the setting of stage 4 and 5 chronic kidney disease (CKD) by summarizing all available evidence.
Method: Two investigators independently searched PubMed, Web of Science, EMBASE and Google Scholar from inception through August 2018. Eligible studies were those that applied SOF-containing therapy to treat HCV infected patients living with comorbidity of stage 4 or 5 CKD (eGFR < 30 ml/min/1.73 m^2). SVR12/24 and SAE rate were aggregated via random effects model. The relative risk (RR) with 95% confidence interval (CI) was used to assess the impact of cirrhosis status to sustained virological response. Comparison was made between studies that adopted full dose and decreased dose of sofosbuvir in subgroup analysis.
Results: 21 studies with 717 patients (58.4% receiving dialysis) were included in the final meta-analysis. HCV genotypes ranged from GT1 to GT6 among these studies. GT1 was the predominant genotype (67%), followed by GT3 (20%) and GT2 (8%). 14 studies recruited cirrhotic patients, with varied proportion (11%-83%). SOF-based regimen included: SOF/LDV ± RBV, SOF+DCV ± RBV, SOF+SMV ± RBV, SOF+RBV, and SOF+PR, under different administration of sofosbuvir: 400 mg daily (full dose), 400 mg/48 h (decreased dose), 400 mg three times a week (decreased dose). Pooled SVR12/24 (per protocol) was 97.1% (95% CI 93.9%-99.3%, I^2 = 61%), and SAE rate was 4.8% (95% CI 2.1%-10.3%, I^2 = 60%). Patients with or without cirrhosis achieved comparable SVR12/24 (RR 0.93, 95% CI 0.85-1.02). There was no significant difference between studies applying full and decreased dose of sofosbuvir in terms of safety (SAE: 8.8% vs 2.9%, p = 0.13) and effectiveness (SVR12/24: 97.1% vs 96.2%, p = 0.72). 4 studies provided information about the kidney function before and after treatment. None of these studies reported significant change of eGFR/serum creatinine during treatment.



Conclusion: Our study suggests SOF-based regimen might be used safely and effectively in patients living with HCV infection/stage 4-5 CKD, with normal and reduced dose of sofosbuvir. Prospective and well-controlled trials are needed to confirm these findings.

THU-154

Low rate of hepatitis B reactivation among patients with chronic hepatitis C during direct acting antiviral therapy

Seng Liem[1,2], Ahmad Samer Alawad[3], Varun Takyar[3], Wayel R. Zanjir[1], Harvey Alter[4], Jordan Feld[1,5], Harry Janssen[1], Marc Ghany[3]. [1]*University Health Network, Toronto Centre for Liver Disease, Toronto, Canada;* [2]*Erasmus Medical Center University, Department of Hepatology and Gastroenterology, Rotterdam;* [3]*NIH/NIDDK, Liver Diseases Branch, Bethesda, United States;* [4]*NIH, Bethesda, United States;* [5]*McLaughlin-Rotman Centre for Global Health, Toronto, Canada*
Email: k.s.liem@erasmusmc.nl

Background and aims: Hepatitis B Virus (HBV) reactivation has been reported in patients with chronic hepatitis C (CHC) with prior HBV exposure (HBsAg negative/anti-HBc positive) during direct acting antiviral (DAA) therapy. This led the US FDA to issue a black box warning on all DAA drug labels to recommend measuring HBV DNA and monitoring for HBV reactivation during and after treatment. Prior studies have looked at single time points either during or after treatment and may have underestimated HBV reactivation incidence. We aimed to conduct a more comprehensive evaluation of HBV reactivation with multiple time points during and after treatment.
Method: Patients with CHC from two North American sites were included who were treated with DAAs, had prior exposure to HBV (HBsAg negative/anti-HBc positive) and had sera from multiple time points pre-, during and post-treatment. Samples were tested for HBV DNA (Roche COBAS® Assay) and HBsAg at each time point. We defined HBV reactivation as detectable HBV DNA, if initially negative or quantifiable HBV DNA, if initially detectable (<20 IU/ml) ± HBsAg

seroreversion. We also evaluated the occurrence of ALT flares (≥2x ULN).

Results: Of 79 patients (44 at site 1; 35 at site 2), mean age was 62 years, 66% was male and 66% was Caucasian. Treatment regimens included LED/SOF ± RBV, SOF/VEL, SIM/SOF, SOF/RBV, PAR/RIT/OMB/DAS ± RBV for 12-24 weeks. Of 375 serum samples, 51 had insufficient volume to measure HBV DNA. Reactivation, observed in 8/79 (10%) patients, occurred in 6 at on-treatment week 4-8 and in 2 at off-treatment week 14/15 (Table). HBV DNA was detectable but < 20 IU/ml in 5 patients and quantifiable in 3, ranging from 33-184 IU/ml. An ALT flare or HBsAg seroreversion was not observed in patients with HBV reactivation. Detectable/quantifiable HBV DNA was transient in 4/8 while the duration could was unknown in 4/8 due to lack of follow-up samples but ALT flares did not occur in these patients.

Patient	HBV DNA (IU/ml)		
	Baseline	On-treatment	Off-treatment
1	Neg	Wk 4 < 20; Wk 12 < 20	Wk 14 < 20
2	Neg	Wk 4 Neg; Wk 8 Neg	Wk 15 33
3	Neg	Wk 4 < 20; Wk 8 Neg	Wk 13 Neg
4	Neg	Wk 4 Neg	Wk 1 Neg; Wk 14 < 20
5	Neg	Wk 4 52	Wk 2 Neg; Wk 17 Neg
6	Neg	Wk 4 < 20; Wk 8 184	
7	Neg	Wk 4 Neg; Wk 8 < 20	Wk 4 Neg; Wk 12 Neg
8	Neg	Wk 4 < 20; Wk 8 Neg	Wk 4 Neg; Wk 8 < 20; Wk 12 Neg

Figure HBV DNA results in patients with HBV reactivation.

Conclusion: The risk of HBV reactivation was low in CHC patients with recovered HBV. No ALT flares or HBsAg seroreversion was observed. These data suggest that monitoring for HBV reactivation among CHC patients undergoing DAA therapy is probably not warranted. We recommend only testing for HBV DNA in selected patients with ALT flares or failure of ALT normalization during DAA treatment.

THU-155

Polymeric, metallic nanoparticles, and curcumin as inhibitors of hepatitis C virus genotype 4a replication in vitro

samah loutfy[1], Hanaa Alam Eldin[2], Mostafa Hamed Elberry[3], Khaled Farroh[4], El-Chaimaa B. Mohamed[3], Ahmed Hassan Ibrahim Faraag[5], Reham Dawood[6], Mostafa EL Awady[7].

Email: samah.loutfy@gmail.com

Background and aims: Despite the remarkable progress in treating HCV4a, there is still some serious concern on adverse side effects and viral resistance to treatment. Discovery of more effective and less toxic agents are still needed. In the current study, we evaluated the inhibitory effect of nanomaterials formulations and curcumin against replication of HCV4a in HCV-human hepatoblastoma cell line (huh7.5) harboring ED- 43/SG-Feo (VYG) replicon of HCV4a, both In *silico* and in vitro.

Method: Initial, *in-silico* screening using ligand-receptor docking against NS3 protease, NS5A and NS5B polymerase of HCV-4a with MolDock were done. The four materials with the highest antiviral activity; namely, chitosan, silver and gold nanoparticles (CNPs, AgNPs and AuNPs, respectively) as well as curcumin were used in the subsequent experiments. For the *in vitro* study, we treated the HCV Huh7.5 replicating system with the non toxic concentrations of all tested materials. The CC50 doses were determined using MTT assay and the efficacy concentrations (EC50) were also determined. The therapeutic index was calculated as CC50/EC50. Sofosbuvir (the polymerase inhibitor) was used as a positive control. Antiviral activity was evaluated by HCV real time RT-PCR and HCV core protein expression by western blot assay.

Results: MolDock showed binding affinity score with NS3 protease, NS5A and NS5B polymerase of −131.044, −149.498 and −133.494 for curcumin, −156.512, −131.875 and 154.603 for CSNPs, and −127.581, −167.192 and −131.535 for sofosbuvir, respectively. Chitosan nanoparticles were prepared with minor modifications (patent **1120-2018**) and was controlled to size of 29 nm and charges of 33 mV but AgNPs and AuNPs were controlled to sizes of 21.03 and 14.67 nm, with charges of −26.3 and −37.7 mV, respectively. Cytotoxicity assay by MTT revealed that CC50 concentrations were at 185 µg/ml, 50 µM, 300 µM for chitosan, silver, gold nanoparticles but was at 21.5 µg/ml and 50 µg/ml for curcumin and sofosbuvir compounds. We determined the EC50 of 15 µg/ml, 10.5 µM, 25 µM for chitosan, silver, gold nanoparticles respectively, but of 7 µg/ml and 5 µg/ml for curcumin and sofosbuvir respectively, as effective concentrations could dramatically inhibit HCV4a replication. HCV core protein expression ratio was at 0.79 ± 0.005, 0.87 ± 0.0042, and 1.16 ± 0.05 for CNPs, AgNPs and curcumin, respectively, but at 1.875 ± 0.04 for sofosbuvir versus positive infected cells of 5.66± 0.4. These data are the first description for CNPs and nanoparticles possessing antiHCV-4a activity.

Conclusion: Chitosan and silver nanoparticles showed desirable therapeutic index at 12.3 and 7 respectively that can be considered newly developed candidate for further drug delivery system and subjected to in vivo studies.

THU-156

Real world outcomes for Genotype 3 patients treated with glecaprevir/pibrentasvir: Real world outcomes from an unselected cohort

Fiona Marra[1], Alison Boyle[1], Erica Peters[1], Jude Morris[2], Matthew Priest[3], Natasha McDonald[4], Stephen Barclay[5]. *[1]Gartnavel General Hospital, Brownlee Centre for Infectious Diseases, Glasgow, United Kingdom; [2]Queen Elizabeth University Hospital, Gastroenterology, Glasgow, United Kingdom; [3]Gartnavel General Hospital, Gastroenterology, Glasgow, United Kingdom; [4]Royal Alexandra Hospital, Gastroenterology, Paisley, United Kingdom; [5]Glasgow Royal Infirmary, Walton Liver Clinic, Glasgow, United Kingdom*
Email: fionamarra@nhs.net

Background and aims: Glecaprevir/Pibrentasvir (G/P) is a potent pan genotypic Direct Acting Antiviral (DAA). In registration trials SVR rates for GT3 were good, but did not match those of non-GT3 patients. Real world results are required to confirm efficacy amongst unselected patients, who may not meet rigorous clinical trial requirements. Clinician choice of DAA may introduce unexpected bias at a patient level in the context of other available GT3 regimens. In our treatment centres, in line with national guidelines, clinicians are restricted to prescribing a designated 1st line regimen unless there is an insurmountable drug -drug interaction (requiring independent review by a specialist pharmacist) eliminating physician choice as a confounder. In this context we sought to ascertain the real world outcomes of unselected genotype 3 patients receiving G/P.

Method: GT3 patients commencing G/P prior to 01/11/2018 in Glasgow treatment centres were identified from the Scottish HCV database. Data on age, gender, opiate replacement therapy (ORT) status, liver stiffness measurement (LSM)/fibrosis stage, prior treatment and HIV status were obtained along with treatment outcome. Fibrosis stage was defined by FIB-4 or LSM (F0-2), LSM (F3) and LSM, imaging or biopsy (F4) respectively.

Results: 382 patients met the inclusion criteria, 96 (25.1%) with advanced (F3/4) fibrosis, and 22 (5.8%) with prior treatment

(see figure for other baseline characteristics). Patients received 8/12/16 weeks of treatment in line with the license. To date, 270 (70.3%) have completed treatment, with low rates of premature discontinuation (2 (0.5%)). Of those reaching SVR12, 153/156 (98.0%) achieved SVR including 22 patients with cirrhosis (2 treatment experienced). Of the 3 not achieving SVR 2 relapsed and 1 died following completion of treatment. Further SVR data will be presented.

Baseline Characteristics	n = 382
Mean age (± SD)	45.7 (8.4)
Male (%)	269 (70.4)
HIV co-infected (%)	15 (3.9)
ORT (%)	200 (52.4)
Treatment experienced	22 (5.8) (19 IFN/RBV, 1 boceprevir/IFN/RBV, 1 Sof/Gras/Elb, 1 Sof/IFN/RBV
Fibrosis Stage	
F0-2	286 (74.9)
F3	24 (6.3)
F4	72 (18.8)
Mean LSM F0-3 (n = 298)	6.3 (1.9)
Mean LSM F4 (n = 70)	25.9 (15.4)

Conclusion: G/P is well tolerated in clinical practice, with low rates of premature discontinuation. Preliminary SVR results indicate a high efficacy amongst a GT3 cohort with significant rates of advanced fibrosis.

THU-157

Shortened duration pan-genotypic therapy with glecaprevir-pibrentasvir for six weeks among people with acute and recent HCV infection

Marianne Martinello[1,2,3], Chloe Orkin[4], Graham Cooke[5], Sanjay Bhagani[6], Edward Gane[7], Ranjababu Kulasegaram[8], David Shaw[9], Elise Tu[1], Ecaterina Filep[1], Kathy Petoumenos[1], Pip Marks[1], Tanya Applegate[1], Jason Grebely[1], Gregory Dore[1,2], Mark Nelson[10], Gail Matthews[1,2]. *[1]The Kirby Institute, Sydney, Australia; [2]St Vincent's Hospital Sydney, Sydney, Australia; [3]Blacktown Hospital, Sydney, Australia; [4]Queen Mary University of London, London, United Kingdom; [5]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [6]Royal Free Hospital, London, United Kingdom; [7]Auckland Hospital, Auckland, New Zealand; [8]St Mary's Hospital, London, United Kingdom; [9]West Terrace, Adelaide, Australia; [10]Chelsea and Westminster Hospital, London, United Kingdom*
Email: mmartinello@kirby.unsw.edu.au

Background and aims: Glecaprevir-pibrentasvir for eight weeks is approved for treatment of chronic HCV infection in treatment-naïve individuals without cirrhosis. The aim of this study was to assess the efficacy of glecaprevir-pibrentasvir for six weeks in people with acute or recent HCV infection.
Method: In this open-label study conducted in Australia, New Zealand and England, adults with recent HCV (duration of infection < 12 months) received glecaprevir-pibrentasvir 300 mg/120 mg daily for six weeks. Primary infection was defined by first positive anti-HCV antibody (Ab) and/or HCV RNA within 6 months of enrolment and either acute clinical hepatitis within the past 12 months (symptomatic seroconversion illness or ALT >10x upper limit of normal [ULN]) or documented anti-HCV Ab seroconversion within 18 months. Reinfection was defined as new positive HCV RNA within 6 months of enrolment and evidence of prior clearance (positive anti-HCV Ab and negative HCV RNA on ≥ 2 occasions). The primary end point was sustained virologic response at 12 weeks post treatment (SVR12) with efficacy end points reported in the intention-to treat (ITT) and per-protocol (PP) populations.
Results: Thirty men (median age 43 years, 90% men-who-have-sex-with-men) received treatment, of whom 77% (n = 23) were HIV-positive, 33% (n = 10) had ever injected drugs and 13% (n = 4) had HCV reinfection. The majority were infected with HCV genotype 1 (80%, n = 24), followed by genotype 4 (10%, n = 3), 3 (7%, n = 2) and 2 (3%, n = 1). Median maximum ALT in the preceding 12 months was 381 U/L (range 26, 3087). Acute clinical hepatitis with ALT >10xULN was reported in 73%; five (17%) had jaundice. At end of treatment, HCV RNA was below the limit of quantitation in 97% (n = 29); one participant had quantifiable HCV RNA (21 IU/ml) and achieved SVR12. Of those who have reached post treatment week four (n = 28), SVR4 ITT and PP were 93% and 100%, respectively (loss to follow-up, n = 2). Of those who have reached post treatment week 12 (n = 24), SVR12 ITT and PP were 79% and 95%, respectively (detectable HCV RNA, n = 1; death after SVR4, n = 1; loss to follow-up, n = 3); sequencing is awaited to determine if recurrent viraemia represents relapse or reinfection. There were no treatment-emergent serious adverse events.
Conclusion: Shortened duration pan-genotypic therapy with glecaprevir-pibrentasvir for six weeks was highly effective among HIV-positive and HIV-negative individuals with acute and recent HCV infection.

THU-158

High efficacy of sofosbuvir and velpatasvir regardless of patients' clinical characteristics

Vitor Hugo Martins[1], Giulia Troshina[1], Giulia Verzon[1], Michela Ciruolo[1], Felice Rizzi[1], Claudia Chialà[1], Ludovica Venezia[1], Pablo Cortegoso Valdivia[1], Stefano Rizza[1], Giorgio Maria Saracco[1], Alessia Ciancio[1]. *[1]University of Turin, Department of Medical Sciences, Turin, Italy*
Email: vitorhugomartins@gmail.com

Background and aims: Second generation direct antiviral agents are characterized by very high SVR rates and good safety profiles. Real-life data are essential to further improve the care of the patients in our daily clinical practice.
Method: We conducted a prospective analysis of a representative Italian cohort involving untreated and previously treated patients with chronic HCV genotype 1, 2, 3, 4 or 5 infection, including those with compensated cirrhosis. The patient records were collected in the Department of Medical Science Gastroenterology Unit of the Molinette Hospital, University of Turin and we analysed the efficacy and safety of antiviral therapy under real-life conditions. All patients received the combination sofosbuvir (SOF) + velpatasvir (VEL) in a once-daily fixed-dose for 12 weeks. Of the 478 patients who received SOF+VEL treatment, 12.6% had HCV genotype 1a, 44.8% genotype 1b, 17.4% genotype 2, 17.2% genotype 3, 6.5% genotype 4 and 1% genotype 5. A total of 17.2% had cirrhosis, 31.4% had been previously treated for HCV and 78.5% had at least one comorbid condition.
Results: The primary end point was SVR at 12 weeks after the end of therapy. In 474 patients, we could document SVR12 data and found an overall SVR rate of 99.2% (470/474). All patients with HCV genotype 1a (61/61), genotype 4 (31/31) and genotype 5 (5/5) achieved SVR12. In HCV genotype 1b patients SVR rate was 99.5% (210/211), in genotype 3 and genotype 2 was 98.8% (79/80) and 97.6% (81/83), respectively. SVR12 rate was 97.5% in cirrhotic patients and 99.4% in non cirrhotic (p = 0.079). The great majority of patients (68.6%) was naive and they achieved SVR12 in 99.5% of the cases. The corresponding SVR rate in the subpopulation that had experienced a previous antiviral treatment was 98.6% (p = 0.416). SVR12 rates were not significantly different in patients with comorbidities (99.2%) and patients without any comorbid condition (99.0%, p = 0.873). Serious adverse events were reported in 10 patients (2.1%). No association between patients' characteristics and SVR was observed.
Conclusion: Treatment with SOF+VEL for 12 weeks provided high SVR rates in real-life conditions among both previously treated and untreated patients with HCV genotypes 1, 2, 3, 4, or 5, including those with cirrhosis or associated comorbidities.

THU-159

Real-world efficacy of elvasvir and grazoprevir for hepatitis C virus (genotype 1): A nationwide, multicenter study by the Japanese Red Cross Hospital Liver Study Group

Toshie Mashiba[1], Kouji Joko[1], Hironori Ochi[1], Ryo Yano[1], Kaori Sato[1], Yusuke Okujima[1], Michiko Aono[1], Nobuaki Azemoto[1], Tomoyuki Yokota[1], Masayuki Kurosaki[2], Namiki Izumi[2]. [1]*matsuyama Red Cross Hospital, Center for Liver-Biliary-Pancreatic Disease, Matsuyama city, Japan;* [2]*Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Musashino city, Japan*
Email: koujijoko@matsuyama.jrc.or.jp

Background and aims: The purpose of this study is to determine the real-world efficacy and safety of the nonstructural protein (NS)5A inhibitor elbasvir (EBR) combined with NS3/4A protease inhibitor grazoprevir (GZR) in patients with hepatitis C virus (HCV) genotype 1 (GT1) infection in actual clinical practice.
Method: This study by the Japanese Red Cross Liver Study Group retrospectively evaluated the sustained viral response (SVR12) rate and safety of 12-week EBR/GZR treatment. This study also assessed factors associated with the SVR12 rate.
Results: Study patients included 159 men and 194 women with a median age of 72 years. Patient characteristics were as follows: 19.1% (67/351 patients) had a history of interferon therapy; 4.7% (16/342 patients) had a history of direct-acting antiviral (DAA) therapy; 20.5% (68/331 patients) had cirrhosis; 10.5% (37 patients) had a history of hepatocellular carcinoma treatment; 6.0% (18/297 patients) had an NS5A-L31 resistance-associated substitution (RAS) mutation; and 16.2% (48/297 patients) had an NS5A-Y93 RAS mutation. The overall SVR12 rate was 97.2% (343/353 patients). Treatment failure occurred in merely 2.9% (10/353 patients); however, eight of these patients had a history of DAA therapy, and the two other patients had NS5A-L31, -Y93 double RAS. The SVR rate was 50% (8/16 patients) in patients with a history of DAA therapy, and it was extremely poor, at 18.2% (2/11 patients), in patients with NS5A-L31, -Y93 double RAS. On multivariate logistic regression analysis, NS5A-Y93 RAS (odds ratio [OR] 19.6; 95% confidence interval [CI] 2.25-440.8; p = 0.0061) and NS5A-Y31 RAS (OR 114.8; 95% CI 14.74-2518.2; p < 0.0001) were identified as independent predictors of treatment failure. No serious adverse events were observed with EBR/GZR therapy, nine patients discontinued treatment due to complications such as liver disorders. Nonetheless, SVR was achieved in all patients who discontinued treatment.
Conclusion: The treatment outcomes of EBR/GZR were favorable in DAA-naïve patients, of whom 99.4% achieved SVR. However, the EBR/GZR response was poor in patients with a history of DAA therapy and NS5A-Y93, -L31 double RAS even when they were DAA-naïve. The SVR rate of EBR/GZR would have been 100% in patients with neither a history of DAA therapy nor a double RAS. This combination of drugs could also be given safely to patients and was, therefore, considered to be a highly useful first-line treatment for DAA-naïve patients with HCV.

THU-160

Outcomes of the national strategy on hepatitis C treatment with direct acting antivirals in a real-life setting: Results from a national survey in Slovenia

Email: mojca.maticic@kclj.si

Background and aims: Treatment of hepatitis C virus (HCV) infection with direct acting antivirals (DAAs) has proved excellent efficacy, as well in previously difficult to treat patients. In Slovenia, management of HCV infection has been organized systematically for over two decades with the second generation DAAs representing a standard of care since January 2015, at first restricted to patients with advanced liver disease and afterwards used with no restrictions. The aim of this study was to evaluate the strategy and efficacy of DAA treatment in a real-life setting at national level.
Method: All HCV-infected patients from Slovenia that started treatment with DAA combinations (simeprevir, sofosbuvir, paritaprevir/ombitasvir ± dasabuvir, sofosbuvir/ledipasvir, elbasvir/grazoprevir, and sofosbuvir/velpatasvir) between January 2015 and December 2017 were included prospectively on intention to treat (ITT) and modified ITT (mITT) analyses. Demographic, epidemiological, virological and clinical data were collected from all the hospitals performing HCV treatment in Slovenia and analysed.
Results: Overall, 383 patients were included, 67% were males, average age was 50 years. Among them, 45% reported intravenous drug use (IDU). Genotypes 1a, 1b, 1, 2, 3, and 4 were present in 34%, 32%, 2%, 3%, 26% and 3%, respectively. 18/383 (5%) were HIV coinfected. Fibrosis stage F3 was detected in 24% and F4 in 44%; 7% experienced Child-Pugh B or C decompensated cirrhosis and 8% presented hepatocellular carcinoma. 137/383 (36%) were interferon-based treatment experienced. Sustained virological response (SVR) rates were 90% (344/383) in ITT and 97% (344/354) in mITT analyses. In the latter, among those with no SVR, 9 patients experienced relapse and one was a complete non-responder; patients with genotypes 1, 1a, 2 and 4 presented 100% SVR, whereas those with genotypes 1b and 3 achieved 98% and 91% SVR, respectively; among patients with F3 and F4, SVR was reached in 99% and 97%, respectively; SVR was significantly more common in treatment naive (99%) compared to treatment experienced patients (94%) (CI = 99%, p = 0.0039); 97% of IDUs and 94% of HIV-positive patients gained SVR.
Conclusion: This study demonstrates excellent SVR rates of DAA treatment in a real-life setting in Slovenia achieved as a result of a national strategy and availability of new treatments which is in line with the global strategy towards viral hepatitis elimination.

Email: stefan.mauss@center-duesseldorf.de

Background and aims: Elevated liver function tests (ALT, GGT) in chronic hepatitis C not always normalize after successful elimination of HCV by DAAs, indicating concomitant additional liver diseases. We analysed the factors determining biochemical response (normal ALT or GGT) of DAA therapy in a large real-world cohort.
Method: The DHC-R (German Hepatitis C-Registry) is a national multicenter real-world cohort including about 14, 500 patients recruited by more than 250 centers (approx. 90% physicians in private practice). Normal ALT (at 37°C) was defined as (i) ≤ 35 U/l for females and ≤ 50 U/l for males and or (ii) according to AASLD as ≤ 19 U/l for females and ≤ 30 U/l for males. Normal GGT (at 37°C) was defined as ≤ 40 U/l (female) and ≤ 60 U/l (male). Variables selected were HCV genotype (GT), sex, BMI, HIV coinfection, opioid substitution (OST), age, liver cirrhosis, alcohol, co-morbidities, co-medication, ethnicity, country of birth, HCV therapy. Statistical analysis was performed using univariate and multivariate logistic regression analysis.
Results: At baseline, we found elevated ALT in 3705/4946 (74.9%), elevated ALT (AASLD) in 4669/4946 (94.4%) and elevated GGT in 3018/4906 (61, 5%). 97% of patients achieved SVR12. At week 12 after end of therapy, we found elevated ALT in 451/4946 (9.1%) or ALT (AASLD) in 1906/4946 (38.5%) and GGT in 863/4879 (17.7%). A higher ALT at baseline was associated with HCV GT1 compared to GT3 (OR 2.42), male sex (OR 1.68), higher BMI (<18 vs 18-25 vs 25-30 vs >30; OR 2.04, 3.44, 3.25), liver cirrhosis (OR 1.90), being on OST (OR 2.13), being German vs. European or Russian (OR 1.46, 1.36). With the stricter ALT AASLD definition, liver cirrhosis and being of Russian origin dropped out and GT2 had a higher risk (OR 1.98). Higher GGT at baseline was associated with HCV GT3 and 2 compared to GT1 (OR 2.52, 1.37), higher BMI (<18 vs 25-30 vs >30, OR 1.84, 2.28), age >50 years (OR 1.28) and liver cirrhosis (OR 3.22).
At week 12 after end of therapy, a higher ALT was associated with higher BMI (<18 vs 18- < 25, 18- 25- < 30; OR 4.25, 2.91), age < 70 years (OR 1.54), liver cirrhosis (OR 2.55), alcohol consumption (OR 2.27) and non-SVR12 (OR 28.57). The same variables were selected using the AASLD criteria except age < 70 years, which fell out and a history of GT1a versus GT1b infection which was associated with a higher ALT (OR 2.56). Higher GGT at week 12 was associated with higher BMI, age > 70 years (OR 1.61), liver cirrhosis (OR 3.34), alcohol consumption (OR 3.83), non-SVR (OR 8.33). Co-medication, diabetes and HIV-coinfection were not identified as risk factors.
Conclusion: Successful HCV therapy can demask additional hepatic morbidities. In particular, risk factors already present at baseline like obesity, liver cirrhosis and alcohol consumption are associated with elevated liver function tests after SVR, indicating that these patients warrant further hepatological follow-up.

THU-162

The combination of sofosbuvir and daclatasvir is well tolerated and extremely effective in treating patients with hepatitis C with severe renal impairment including hemodialysis patinets

Shahin Merat[1], Amir-Houshang Sharifi[1], Ali Akbar Shayesteh[2], Mohammad Minakari[3], Mohammad Reza Fattahi[4], Maryam Moini[4], Fatemeh Roozbeh[5], Fariborz Mansour-Ghanaei[6], Behrooz Afshar[7], Marjan Mokhtare[8], Taghi Amiriani[9], Masomeh Sofian[10], Mohammad-Hossein Somi[11], Shahram Agah[8], Iradj Maleki[12], Maryam Latifnia[13], Ahmad Hormati[14], Masoud Khoshnia[9], Masoud Sohrabi[8], Reza Malekzadeh[1]. Email: shahin.merat@gmail.com

Background and aims: Many of the treatments available for hepatitis C include sofosbuvir. Sofosbuvir has not been cleared for use in patients with eGFR under 30 ml/min leaving these group of patients with few options. Nevertheless, there are some reports in which patients with renal failure have been treated with sofosbuvir-containing regiments without any important adverse events. This study aims at determining the safety and effectiveness of a sofosbuvir-based treatment in patients with severe renal impairment.
Method: We enrolled subjects with severely impaired renal function infected with hepatitis C from 13 centers. Patients were treated for 12 weeks with a single daily pill containing 400 mg sofosbuvir and 60 mg daclatasvir (Sovodak, Rojan Pharma, Tehran, Iran). Patients with cirrhosis were treated for 24 weeks. Response to treatment was evaluated 12 weeks after end of treatment (SVR12).
Results: By the time of this report 79 patients had finished the follow-up period. 58 patients were on hemodialysis. 33 had cirrhosis, 8 decompensated. 40 were genotype 1 and 23 genotype 3. 22 patients had history of previous failed interferon-based treatment. Three patients died in which cause of death was not related to treatment. The remaining 76 patients all achieved SVR12.
Conclusion: The combination of sofosbuvir and daclatasvir is an extremely effective and safe treatment for patients infected with all genotypes of hepatitis C who have severely impaired renal function, including hemodialysis patients.

THU-163

Efficacy and safety of direct-acting antivirals for hepatitis C in elderly patients: a systematic review and meta-analysis

Marcus Mücke[1], Eva Herrmann[2], Victoria Therese Mücke[1], Christiana Graf[1], Stefan Zeuzem[1], Johannes Vermehren[1]. [1]University Hospital Frankfurt, Department of Internal Medicine 1, Frankfurt am Main, Germany; [2]University Hospital Frankfurt, Institute of Biostatistics and Mathematical Modeling, Frankfurt am Main, Germany
Email: marcus.m.muecke@gmail.com

Background and aims: Historically, age has been a major limitation of interferon-based antiviral therapy for hepatitis C. Since the introduction of direct-acting antivirals (DAAs) several studies have reported high efficacy and safety in elderly patients yet concerns were raised in some studies among different subgroups. Aim of this systematic review and meta-analysis was to assess and compare the efficacy and safety of DAA therapy among elderly (≥65 years or ≥ 75 years) and younger (<65 years or < 75 years) patients with chronic HCV infection.
Method: The PubMed MEDLINE and Embase databases were searched through July 2018. Two independent researchers extracted data and assessed quality and risk of bias. To account for different study populations between studies and heterogeneous study designs/protocols risk ratios for non-SVR (not mere SVR rates) were calculated and pooled using either fixed or random effects models, and group comparisons were performed. The primary outcome was efficacy of DAA therapy assessed by the RR for non-SVR among patients aged < 65 years vs. ≥ 65 years. This study was registered with PROSPERO (CRD42018104392).
Results: Overall, we identified 63 studies including 34, 082 patients treated with different DAAs. Risk for non-SVR was lower in patients ≥ 65 years of age (RR 0.91, 95% CI 0.83-0.99; p = 0.037) in the whole data set and in a subgroup analysis of cirrhotic patients (RR 0.54, 95% CI 0.36-0.82, p = 0.032). A trend towards a lower risk for non-SVR was observed in the elderly when applying age categories < 75 years vs. ≥ 75 years (RR 0.82, 95% CI 0.65-1.03; p = 0.086). Risk for non-SVR was

comparable between age groups in all other subgroup analyses including HCV genotype, treatment experience, therapy regimen or the additional use of ribavirin. Elderly patients (≥65 years) had a significantly increased risk of adverse events (RR 1.30, 95% CI 1.11-1.52, p = 0.001), but not for serious adverse events (p = 0.43) or treatment discontinuation (p = 0.15). Risk for anemia if treated with additional ribavirin was 2.84 (95% CI 1.73-4.66, p < 0.001) in elderly patients compared to patients < 65 years.

Conclusion: Our results show that DAAs are highly effective and safe in elderly patients. Ribavirin should be avoided in the elderly, as more AEs, and particularly anemia is observed. Further cost-effectiveness analyses are needed to evaluate the socio-economic benefit of treating elderly people without advanced liver disease.

THU-164

High cure rates of hepatitis C in a genotype 3 predominant Pakistani community using generic direct acting antivirals

Ammara Naveed[1,2], Amjad Khan[3], Asif Butt[1], Ahmad Karim Malik[1], Farooq A. Khan[1,4], Khurram Anis[1], Nauman Zakir[1], Amer Yar Khan[1], Saeed Akhter[1], Naveed Janjua[5,6], Abdul Nadir[1]. *[1]Pakistan Kidney and Liver Institute and Research Center, Lahore, Pakistan; [2]University of Illinois at Chicago, Chicago, United States; [3]Hepatitis Prevention and Treatment Program, Pakistan Kidney and Liver Institute and Research Center, Lahore, Pakistan; [4]University Hospitals of Leicester, NHS Trust, Leicestershire, United Kingdom; [5]British Columbia Centre for Disease Control, Vancouver, Canada; [6]School of population and public health, University of British Columbia, Vancouver, Canada*
Email: ammara.naveed@gmail.com

Background and aims: Pakistan Kidney and Liver Institute and Research Center (PKLIandRC) is running a 24-site Hepatitis Prevention and Treatment Program (HPTP) with government funding. The largest clinic in Lahore opened in March, 2017. Generic sofosbuvir (SOF) based regimens are used. Until daclatasvir (DCV) became available, Genotype (GT) 3, non-cirrhotics received SOF with ribavirin (RBV) for 24 weeks (w), while all GT-1 and only GT-3 cirrhotics were offered peg-interferon (peg)/SOF/RBV for 12w. GT testing was stopped with DCV availability. Patients are now treated with SOF/DCV ± RBV for 12w vs 24w depending on degree of fibrosis. Those with ≥ 3 months remaining on SOF/RBV were switched to SOF/DCV (cross over). We assessed rates of Sustained Virological Response (SVR) 12 and its predictors in HCV treated patients.

Method: All patients who received their last refill of SOF until April 30, 2018 were recruited from a single clinic. Those who either did not complete treatment or did not show up for SVR12 were excluded. A complete set analysis was run to assess SVR12 and factors potentially affecting it.

Results: SOF-based treatment was initiated on 5, 060 patients. 20% were cirrhotic (n = 1024) and 3% (n = 154) co-infected with hepatitis B. 80% (n = 4069) completed treatment and SVR12 was available on 73% (n = 3708). Among mono-infected patients, 26% (n = 913) received SOF/RBV, 45% (n = 1603) received SOF/DCV ± RBV and 2% (n = 84) received peg/SOF/RBV. 26% (n = 929) crossed over from SOF/RBV to SOF/DCV. The overall SVR12 was 97.5% with all regimens combined. SVR12 was higher in treatment naïve vs treatment experienced patients (98.1% vs 97.1%, p value 0.02) and in non-cirrhotics compared to cirrhotics (98.1% vs 95.2%, p value < 0.05). SVR12 for SOF/RBV, SOF/DCV and cross overs was 98.1%, 97% and 98.5% respectively. GT data was available in 1790 patients. SVR12 rates was not statistically significant based on GT, nor was it significant in those with and without GT data (GT-3 98.5% vs GT-1 97.6%, vs all others 100% p value >0.05, GT available 97.8% vs no GT 97.2%, p >0.05). Presence of DM lowered SVR12 rates (93.8% vs 97.9%, P value < 0.05), while age, HBV co-infection and HTN had no impact.

Conclusion: A large database of HCV patients, treated with generic SOF based regimen suggests high SVR12, even in the absence of GT testing at baseline when scaling up treatment, leading to cost-savings. Co-infection does not appear to impact cure rates.

THU-165

The risk of HBV reactivation among HBV/HCV co-infected patients treated with direct-acting antiviral agents: A single center experience

Young Joo Park[1], Hyun Young Woo[1], Jeong Heo[1]. *[1]Pusan National University Hospital, Busan, Korea, Rep. of South*
Email: sodium@korea.com

Background and aims: As the number of reports of hepatitis B virus (HBV) reactivation increases in patients with HBV/HCV co-infection with direct-acting antiviral (DAA) agents, the US Food and Drug Administration has issued warnings about the potential risk of HBV reactivation in these patients. So far, there are very limited clinical data. We report the experience of DAA treatment in patients with HBV/HCV co-infection and factors affecting HBV reactivation during and after treatment with DAA.

Method: We conducted a retrospective observational study of 62 patients with HBV/HCV co-infection between January 2005 and April 2018 at the Pusan National University Hospital.

Results: Of the 62 patients, 25 patients were interferon (IFN) based therapy only, 15 patients were DAA alone, and 9 patients were DAA-treated after failure of IFN based treatment. SVR of IFN only treated group and DAA experienced group was 61.8% and 80.0%, respectively. The rate of HBV reactivation was higher in the patients with experience of DAA than the patients treated with IFN only (IFN only vs. DAA experienced 8.0% vs. 37.5%). In univariate analysis, HBV reactivation during or after anti-HCV treatment was more frequent in patients with experience of DAA (no vs. yes; 2 vs. 9, $p = 0.013$), in women (male vs. female; 3 vs. 8, $p = 0.037$) and in genotype 1b (1b vs. 2 vs. 3; 9 vs. 1 vs. 1, $p = 0.039$). The experience of DAA ($p = 0.016$) and women ($p = 0.020$) were significant predictors of HBV reactivation according to multivariate analysis. HBV reactivation was occurred at 50.5 weeks (range 4-173 weeks) from the start of anti-HCV treatment and time to HBV reactivation from the start of anti-HCV treatment was shorter in the DAA experienced group than IFN only treated group (157.5 ± 21.9 vs. 26.6 ± 27.7 weeks, $p = 0.036$). The mean peak elevation of ALT after HBV reactivation was 41.3 IU/L (range 11-113 IU/L), and the biochemical breakthrough did not occurred. At HBV reactivation, HBV DNA levels did not rise further and remained at similar levels or were not detected during 817 days.

Conclusion: HBV reactivation occurs more frequently in HBV/HCV co-infected patients who were treated with DAAs compared with IFN-based therapy. However, biochemical breakthrough was not occurred.

Background and aims: Real life data on the treatment of HCV-related genotype 3 cirrhosis are needed to assess the efficacy of the combination Sofosbuvir and Velpatasvir (SOF/VEL). Indeed, the recent EASL recommendations define this combination as suboptimal in Genotype 3 patients with compensated (CPT A) cirrhosis. Starting from May 2017, 33 Prescribing-Centers Italy started to use SOF/VEL and collected data prospectively in a Network-database to explore the real life outcome of genotype 3pts with compensated cirrhosis treated with SOf/VEL+Riba.
Method: We retrospectively/prospectively analyzed the treatment outcome of **320 G3** patients, with compensated or decompensated cirrhosis.The pts were treated for 12weeks: 59, 8% with SOF/VEL and 40, 2% with SOF/VEL+RBV.

Figure

Baseline data

LSM (mean-SD)		APRI (mean-SD)		CTP=5		CTP>5	
RBV	No RBV	RBV	No RBV	RBV	No RBV	RBV	No RBV
24.0 (14.9)	19.9 (12.7)	2.7 (2.8)	2.0 (1.4)	59/121 (48.8)	62/121 (51.2%)	40/71 (56.3%)	31/71 (43.7%)

	RBV	No RBV	RBV	No RBV	RBV	No RBV	RBV	No RBV	RBV	No RBV	RBV	No RBV	RBV	No RBV
SVR 12	62/66	63/64	10/11	6/6	47/51	58/58	32/34	20/23	7/7	7/9	18/18	19/20	50/56	57/60
p=	0.366		1.000		0.045		0.384		0.475		1.000		0.311	
SVR 12%*	93.9	98.4	90.9	100	92.2	100	94.1	87.0	100	77.8	100	95.0	89.3	95.0
Overall SVR	125/130 (96.1%)		16/17 (94.1%)		105/109 (96.3%)		52/57 (91.2%)		14/16 (87.5%)		37/38 (97.4%)		107/116 (92.2%)	
p=	0.528				0.277				0.333					

Results: Decompensated cirrhosis was present in 10, 2% of the pts (CHILD B). Baseline data are reported in table. No difference were observed between SOF/VEL and SOF/VEL+riba groups. 240 patients could be evaluated for SVR12. By ITT analysis, the overall SVR12 was 92, 4%. 5 pts discontinued for non liver-related causes; PP SVR is 96, 5%. No differences in SVR rates were observed by stratifying patients according to: platelets, albumin and creatinine. SVR 12 in CHILD > 5 pts (92.2%) were not statistically different from compensated patients (96, 3%) (p = 0.277) and among CPT > 5 pts were not statistically different from SOF/VEL (87%) and SOF/VEL+Riba (94.1%) (p = ns). Among CPT5 pts SVR 12 were statistically higher in SOF/VEL (100%) compared with SOF/VEL+Riba (92, 2%) (p = 0, 045).
Conclusion: In our cohort, the overall SVR12 in G3 patients with compensated cirrhosis is 96, 5% In patients with decompensated cirrhosis, the efficacy of SOF/VEL appears to be reduced in patients with both albumin < 3, 5 or PLT < 100.000. In these patients the use of ribavirin appears to improve the response rate but the size of the study population is too small to draw conclusions. Overall SOF/VEL is highly effective in genotype 3 patients with compensated cirrhosis.

THU-167

Prevalence, linkage to care and treatment of hepatitis C virus in person who inject drugs under opioid substitution therapy in a Spanish area

Ylenia Pérez Castaño[1], Alexandra Gomez Garcia[1], Jose Manuel Chouza Pérez[2], Vanesa Sanz Largo[2], Sandra Arranz Diaz[1], Itxaso Urtasun Lugea[1], Francisco Javier Esandi Gonzalez[1], Agustin Castiella Eguskiza[1], Edurne Almandoz Cortajarena[1], Maria Jose Sanchez Iturri[1], Juan Arenas Ruiz Ruiz[1]. [1]*Hospital Universitario Donostia, San Sebastián, Spain;* [2]*Red de Salud Mental de Guipuzcoa, San Sebastián, Spain*
Email: ylenia_perez@hotmail.com

Background and aims: PWIDs have high prevalence of HCV infection and limited access to health care, forming a risk group that explains most of transmissions. The treatment of PWIDs is a priority for the elimination of the HCV. Bitarte is the opioid substitution program that follows up all the methadone consumers in Guipuzcoa (Spain). The purpose of this project is to simplify the care circuit, approaching the resources to Bitarte, effectively treating the infection.
Method: All methadone consumers positive for HCV antibodies are monitored by the same psychiatrist. The hepatologist moves to the clinic, where a clinical assessment and a fibroscan are made. The antiviral therapy sent from the hospital pharmacy is dispensed together with the methadone by the nursery from de clinic, previously trained. We analyse prospectively the following outcomes: prevalence, genotype, viral load (VL), fibrosis degree, previous access to hepatologist, drug consumption, psychiatric comorbidity (before and after the treatment) and project effectivity (acceptance, efficacy, adherence and reinfections).
Results: Bitarte follows up 660 individuals in methadone program. 470 (71%) are HCV + antibodies. We excluded HIV coinfected (113) and individuals who lost contact with methadone programme in the last year (38). From the 319 HCV seropositive, 38.2% had never been examined by an hepatologist. Among those who had previously been examined, 68.1% failed in the follow-up. At current date, 146 have been treated and 1 refused treatment. 2 HCC have been diagnosed. The predominant genotype is GT1a (42%), followed by GT3 (29%). Regarding to fibrosis, 42% are F3 or F4. Before starting treatment, 38% have consumed heroine, 36% cocaine, 20% amphetamines and 50% cannabis in the last 6 months (measured in urine). We know the VL after treatment in 92 patients, all negative. 54 have reached the12th week after treatment with 1 relapser. Details of efficacy and adherence will be presented in the meeting.
Conclusion: 1) The HCV seroprevalence PWIDs in the north of Spain is 71%. 2) It is a population with a poor previous follow-up and advanced liver disease (F3-4). 3) The simplification of the care circuit

and the multidisciplinary team working is effective for the follow-up and treatment of this population.

Real-life effectivness and safety of glecaprevir/pibrentasvir in HCV infected patients with chronic kidney disease

Marcello Persico[1], Andrea Aglitti[1], Rosa Caruso[1], Gemma Calvanese[1], Pasqualina Di Siervi[1], Nuzzo Maria Grazia[1], Marie Francoise Tripodi[1], Mario Masarone[1]. [1]*University of Salerno, Department of Medicine and Surgery, Salerno, Italy*
Email: marcello.persico@sangiovannieruggi.it

Background and aims: Poor real-life data of Glecaprevir/Pibrentasvir (G/P) combination in the cure of HCV-infected patients with chronic kidney disease (CKD)are currently available. Aim of the present study was to evaluate the efficacy and safety of G/P in HCV-infected patients with CKD in a real-life scenario.
Method: Patients with compromised renal function (eGFR < 60 ml/min/1, 73m^2) were included. Sustained virologic response (SVR) was defined as an undetectable serum HCV-RNA after 12 weeks from end of therapy. An adverse event (AE) was defined as any unfavorable sign (including an abnormal laboratory finding) or symptom, during the drug administration and which does not necessarily have a causal relationship with treatment. If an AE caused death, hospitalization or therapy discontinuation, was defined as serious adverse event (SAE).
Results: Onehundredtwentytwo patients were enrolled: 30.3% had an end stage renal disease (ESRD), 46, 7% were male, median age 69 ± 13 yrs, 16, 4% were cirrhotics. Genotype 2 was the most frequent (53.3%), genotype 1b (33.6%), 3 (7.4%), 1a (4.1%), 4 (1.6%). Most of the patients (76.2%) were treated for 8 weeks. Currently107/109 reached a SVR (98.2%).There was no difference between ESRD patients and all the others (96.4% vs 98.8% p = 0.427). There were no virologic failures, 2 discontinuations for no drug-related SAEs. Thirteen pts reported pruritus as the most frequent AE and 3 SAE (death for car accident, jaundice and cryoglobulinemic syndrome) were reported. Full data will be shown at the EASL meeting.
Conclusion: Real-life G/P therapy confirms an excellent efficacy and safe profilein HCV-infected patients with CKD also in those with ESRD.

Email: s.popping@erasmusmc.nl

Background and aims: Worldwide approximately 20 million people are infected with a genotype (GT)4 hepatitis C virus (HCV). GT4 is highly variable, with 17 confirmed subtypes. It is the most common genotype in the middle east and norther-equatorial Africa, however, several cases have been observed in Europe. Although GT4 patients respond very well to direct-acting antivirals (DAA) in clinical trials, virological failure still occurs. Virological failure is often related to resistance associated substitutions (RAS). Due to the underrepresentation of GT4 in clinical trials and lack of real-life data, there is limited knowledge about RAS profiles. We used real-life GT4 data from the HepCare cohort (Hepatitis C antiviral therapy failure registry), to gather resistance data to assess the RAS at baseline and failure of European GT4 patients.
Method: We extracted data of patients with a GT4 confirmed HCV infection. Subtypes were provided by submitters and mostly based on in-house assays. As a quality control subtypes were re-assessed using the COMET tool. All sequences were aligned and trimmed to equal length with their reference strain using Aliview. We assessed RAS in the NS3, NS5A and NS5B at positions recommended by EASL guidelines and in addition identified all variation that occurred in paired (baseline -failure) sequences.
Results: We analysed sequences of 166 GT4 patients (80 baseline and 86 failures) of which five had paired baseline and failure samples. GT4 patients were submitted by five different European countries (Spain, Italy, Germany, Israel, and the Netherlands). The majority of the subtypes were *4d (77%)*, but also *4a (20%), k (1%), t (1%) and n (1%)* occurred in our cohort. NS3 baseline RAS are uncommon among all subtypes. However NS3-RASs at position 168 occurred in 22% of *4d* PI-failures. 80% of DAA failures have at least one NS5A RAS and 30% two or more (*4a/4d*). At baseline and failure, NS5A-polymorphisms at position 58 were frequent (56 and 58%, respectively) mostly in *4d*. In 5% of failures the E62Q/M RAS was detected, even though this RAS is not reported by EASL guidelines for GT4. In baseline NS5B sequences (n = 22) no RAS were detected, however, among failures the S282 T prevalence was 15% (n = 28).
Conclusion: GT4 has low numbers of baseline RAS, apart from polymorphisms at position 58. Almost all patients fail with at least one NS5A RAS, and potential new RAS at NS5A-position 62 was identified. Importantly, a high (15)% prevalence of the S282 T RAS at failure was detected among GT4 patients, which can challenge further retreatment with sofosbuvir.

THU-170

Real-world effectiveness of elbasvir/grazoprevir in patients with hepatitis C virus genotype 4 infection: Results from a Veterans Affairs population

Jennifer Kramer[1,2], Amy Puenpatom[3], Yumei Cao[1], Hashem El-Serag[1,2], Fasiha Kanwal[1,2]. [1]*Center for Innovations in Quality, Effectiveness and Safety (IQuESt), Michael E. DeBakey VA Medical Center, Houston, TX, United States;* [2]*Baylor College of Medicine, Department of Medicine, Houston, TX, United States;* [3]*Merck and Co., Inc., Kenilworth, NJ, United States*
Email: puenpatom.amy@merck.com

Background and aims: Elbasvir/grazoprevir (EBR/GZR) administered for 12 weeks is a highly effective treatment option for patients with hepatitis C virus (HCV) genotype (GT) 4 infection, achieving sustained virologic response rates (SVR) of 96% in an integrated analysis of participants from phase 2 and 3 clinical trials. This study assessed the real-world effectiveness of EBR/GZR in patients with HCV GT4 infection.
Method: We conducted a nationwide retrospective observational cohort study of patients with chronic HCV GT4 infection in the US Department of Veterans Affairs. Patients were required to have received EBR/GZR with or without ribavirin (RBV) for ≥ 11 weeks, initiated between January 28, 2016, and August 31, 2017. Patients previously treated with an NS5A inhibitor-containing treatment regimen or undetermined regimens were excluded. SVR was defined as undetectable HCV RNA at ≥ 4 weeks after the end of treatment.
Results: A total of 125 patients were included, of whom 112 received EBR/GZR without RBV for 12 weeks and 13 received other EBR/GZR-based regimens. The majority were male (96.8%) and black (45.6%), and mean age was 62.4 years (SD, 5.2 years). Baseline viral load was < 800, 000 IU/ml in 51 (41%) patients, ≥ 800, 000 IU/ml in 67 (54%) patients, and unknown in 7 (6%) patients. The majority of patients (n = 119, 95%) were treatment-naive, of whom 62 (52%) had a

baseline viral load ≥ 800, 000 IU/ml and 9 (8%) had a baseline viral load ≥ 6, 000, 000 IU/ml. Overall, SVR was achieved by 123 of 125 patients (98%), with high SVR rates in the subgroups who received EBR/GZR without RBV for 12 weeks (110/112, 98%), who had diabetes (39/39, 100%), were receiving concomitant proton pump inhibitor therapy (38/38, 100%), with a baseline viral load ≥ 800, 000 IU/ml (66/67, 99%), or with cirrhosis (23/23, 100%). SVR rates among subgroups of patients with GT4 infection who received EBR/GZR without RBV for 12 weeks are shown in the Figure.

SVR rates in patients with GT4 infection

Baseline variable	EBR/GZR for 12 weeks N = 112	All patients N = 125
Treatment history, n/N (%)		
Treatment-experienced	2/2 (100)	6/6 (100)
Treatment-naive	108/110 (98)	117/119 (98)
Cirrhosis, n/N (%)	19/19 (100)	23/23 (100)
Baseline viral load, n/N (%)		
<800,000 IU/mL	48/49 (98)	50/51 (98)
≥800,000 IU/mL	56/57 (98)	66/67 (99)
<6,000,000 IU/mL	95/97 (98)	106/108 (98)
≥6,000,000 IU/mL	9/9 (100)	10/10 (100)
Unknown	6/6 (100)	7/7 (100)

EBR, elbasvir; GT, genotype; GZR, grazoprevir; SVR, sustained virologic response.

Conclusion: In this real-world population, EBR/GZR was highly effective in patients with HCV GT4 infection. SVR rates were consistently high regardless of treatment history, baseline viral load, advanced fibrosis, diabetes, or concomitant proton pump inhibitor therapy.

THU-171

Effectiveness of elbasvir/grazoprevir in patients with hepatitis C virus genotype 1 infection receiving dialysis

Jennifer Kramer[1,2], Amy Puenpatom[3], Yumei Cao[1], Hashem El-Serag[1,2], Fasiha Kanwal[1,2]. [1]*Center for Innovations in Quality, Effectiveness and Safety (IQuESt), Michael E DeBakey VA Medical Center, Houston, TX, United States;* [2]*Baylor College of Medicine, Department of Medicine, Houston, TX, United States;* [3]*Merck and Co., Inc., Kenilworth, NJ, United States*
Email: puenpatom.amy@merck.com

Background and aims: In the phase 3, placebo-controlled C-SURFER study, the combination of elbasvir and grazoprevir (EBR/GZR) was safe and highly effective in a population of participants with hepatitis C virus (HCV) genotype (GT) 1 infection and chronic kidney disease (CKD) stages 4-5, including those receiving dialysis. This study assessed the effectiveness of EBR/GZR in patients with HCV GT1 infection receiving dialysis in a large real-world clinical setting.
Method: We conducted a nationwide retrospective observational cohort study of patients with chronic HCV infection in the US Department of Veterans Affairs (VA). The study population included persons with chronic HCV GT1 infection who were receiving hemo- or peritoneal dialysis or with a diagnosis of end-stage renal disease identified by procedure and diagnosis codes in the VA Corporate Data Warehouse. Patients were required to have received EBR/GZR for ≥ 11 weeks, initiated between January 28, 2016, and August 31, 2017. Patients with acute kidney injury 1 year prior to treatment initiation or who had previously received an NS5A inhibitor-containing treatment regimen or kidney transplant were excluded. Sustained virologic response (SVR) was defined as undetectable HCV RNA at ≥ 4 weeks after the end of treatment.
Results: A total of 533 patients who received EBR/GZR for ≥ 11 weeks were included in the per-protocol population (cirrhosis, n = 239 [45%]; diabetes, n = 353 [66%]; depression, n = 294 [55%]; CKD 3, n = 16 [3%]; CKD 4-5, n = 486 [91%]). At baseline, the mean age was 64 years (SD, 4.99), and the mean estimated glomerular filtration rate was 16.4 ml/min/1.72 m^2 (SD, 59.7). Overall, SVR was achieved by 514 of 533 (96.4%) patients. SVR rates by GT1 subtype for various patient subgroups are shown in the Figure. Ninety percent of the patients received EBR/GZR without ribavirin for 12 weeks in this cohort. Of these patients, SVR rates were 281/290 (97%) in those with GT1a infection, 169/173 (98%) in those with GT1b infection, and 466/479 (97%) in those with any GT1 infection.

SVR rates in the per-protocol population

SVR	HCV genotype GT1a (n = 331)	GT1b (n = 182)	All (N = 533*)
All, n/N (%)	318/331 (96)	177/182 (97)	514/533 (96)
CKD stage 3	9/9 (100	7/7 (100)	16/16 (100)
CKD stage 4–5	293/305 (96)	57/162 (97)	468/486 (96)
History of alcohol abuse	151/158 (96)	91/93 (98)	261/270 (97)
History of drug abuse	157/163 (96)	85/88 (97)	253/263 (96)
Baseline viral load ≥800,000 IU/mL	179/186 (96)	82/86 (95)	270/282 (96)

CKD, chronic kidney disease; GT, genotype; HCV, hepatitis C virus; SVR, sustained virologic response.

*Includes 20 patients with unknown HCV GT1 subtype.

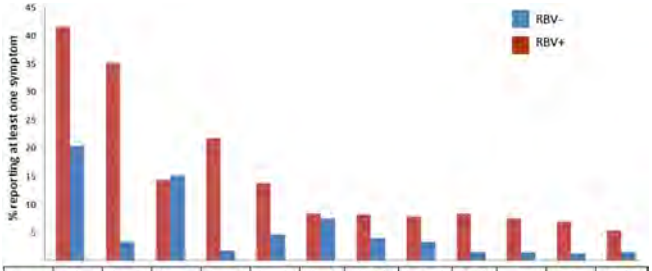
Conclusion: EBR/GZR was highly effective in patients with HCV GT1 infection receiving dialysis in the US VA population.

THU-172

It's the ribavarin, stupid: an analysis of >10, 000 hepatitis C treatment monitoring encounters and the factors associated with side-effects and non-adherence

Adelaide Randazzo[1], Damien Leith[1], Shirin Demma[1], Douglas Macdonald[1]. [1]*Institute of Liver and Digestive Health, UCL, London, United Kingdom*
Email: douglasmacdonald@nhs.net

Background and aims: The England hepatitis C commissioning policy mandates selection of directly-acting antiviral (DAA) treatments for hepatitis C by lowest cost. This has pseudorandomised treatment such that the impact of different DAA regimens on side-effects and adherence between large, otherwise well-matched cohorts can be compared.
Method: We analysed 10273 treatment monitoring episodes in 1793 hepatitis C patients treated with DAAs at The Royal Free Hospital between July 2015 and July 2018. Reported side-effects were categorised into 58 symptoms and rated on severity. The frequency and severity of side-effects were compared across ribavarin (RBV)-containing and non-RBV DAA regimens. The impact of RBV, DAA regimen, age, gender, disease-stage, treatment-experience, daily dosage frequency and route of transmission was assessed on side-effects, adherence and treatment outcome by separate multivariate analyses (MVA).
Results: RBV-inclusive regimens were associated with between a 2 to 11-fold increased risk of 10 of the 12 most commonly reported side-effects (Figure 1). The addition of RBV to Sofosbuvir-based regimens also increased the mean severity score of symptoms (1.036 vs 1.523, p = 0.01). The use of RBV was the only parameter associated with both significant side-effects during treatment and non-adherence on MVA of the parameters above. The total frequency of side-effects during treatment was independently associated with non-adherence on MVA, as were the specific side-effects of insomnia and nausea. Importantly, we also found documented non-adherence was associated with an increased risk of failing to achieve SVR 12 (OR = 2.009, P = 0.0384). Significant differences in side-effect frequency were seen between RBV-free DAA regimens but these did not seem to impact on adherence.



Symptom	Fatigue	Anaemia	Headache	Dyspnoea	Insomnia	Nausea	Abdo Pain	Low mood	Dry Skin	Rash	Pruritus	Irritability
Relative Risk RBV+	2.05	10.28	0.94	11.7	2.846	1.121	2.069	2.299	All dermatological 5.113			3.473
P-value	<0.0001	<0.0001	ns	<0.0001	<0.0001	ns	0.0003	<0.0001	<0.0001			<0.0001

Conclusion: Adherence is of increasing importance as we treat increasing numbers of difficult-to-engage patients in community settings. These data clarify the markedly increased side-effect burden of RBV-inclusive compared with RBV-free regimens and show how this impacts significantly on adherence whilst controlling for multiple other factors.

THU-173

Sofosbuvir based anti-HCV therapy: Safe in hemodialysis

Adnan Salim[1], Omer Farooq[1], Kashif Malik[2]. [1]*Shaikh Zayed Medical Complex, Gastroenterology and Hepatology, Lahore, Pakistan;* [2]*Shaikh Zayed Medical Complex, Gastroenterology and Hepatology, Lahore, Pakistan*
Email: adnansalim1147@gmail.com

Background and aims: The prevalence of hepatitis C among patients undergoing hemodialysis for end stage renal disease (ESRD) is much higher than the general population, ranging from 1-84.6%, with 38% being the figure for patients in Pakistan. It contributes to significant morbidity and mortality if left untreated. Sofosbuvir is an essential component of anti-HCV therapy available worldwide and assessing its safety in this population is vital.
Method: 23 patients undergoing regular hemodialysis for ESRD with HCV infection and not candidates for renal transplantation within the following 6 months, were included in the study. All patients received sofosbuvir 400 mg once daily, used in different combinations with daclatasvir, ledipasvir and ribavirin (ribavirin was used in fixed dose of 400 mg on alternate days). The duration of treatment was 12 to 24 weeks, depending on state of liver disease, previous treatment history and combination of DAAs used. All patients underwent check-up of viral response at end of treatment and 12 weeks after completion of therapy.
Results: 23 patients, 18 male and 5 female, average age 41.5 ± 14.5 years, were enrolled. All patients were undergoing hemodialysis two to three times per week. 21 (91.3%) were GT 3 and 2 (8.7%) GT 1. 8 (34.7%) patients had liver cirrhosis (5 Child A, 3 Child B). 3 (13%) were previous relapsers to sofosbuvir plus ribavirin and 1 (4.3%) was relapser to interferon therapy. 4 (17.3%) patients were treated with sofosbuvir plus ribavirin, 11 (47.8%) with sofosbuvir plus daclatasvir, 4 (17.3%) with sofosbuvir plus daclatasvir and ribavirin, 3 (13%) with sofosbuvir plus velpatasvir and one (4.3%) with sofosbuvir plus ledipasvir. 14 (61%) patients received antiviral therapy for 12 weeks and 9 (39%) for 24 weeks.
1 patient died during therapy due to myocardial infarction. 21 (91.3%) patients achieved viral clearance at end of therapy. 19 out of 22 (86.4%) patients showed sustained response at 12 weeks after end of therapy. 2 (8.7%) patients relapsed, evidenced by detectable viral RNA 3 months after ending therapy. No significant drug-related adverse effects were noted. Mild, occasionally reported, effects were slight lethargy, mild anorexia and dry cough.
Conclusion: Sofosbuvir is safe for use in HCV infected patients with end stage renal disease undergoing maintenance hemodialysis, with favourable viral response rates.

THU-174

Efficacy of L-Carnitine on the ribavirin induced hemolytic anemia for patients with HCV infection

Shinya Sato[1], Kei Moriya[1], Tadashi Namisaki[1], Kosuke Kaji[1], Hiroaki Takaya[1], Takemi Akahane[1], Hideto Kawaratani[1], Yasuhiko Sawada[1], Yukihisa Fujinaga[1], Masanori Furukawa[1], Hitoshi YOSHIJI[1]. [1]*Nara Medical University, Kashihara, Japan*
Email: shinyasato0624@yahoo.co.jp

Background and aims: In the field of clinical practice, L-carnitine have been recently reported not only to alleviate hyperammonemia and reduce muscle cramps in patients with liver cirrhosis, but also improve anemia in patients with chronic hepatitis and renal dysfunction. Although chronic hepatitis C therapy has been dramatically changed with the recent appearance of direct acting antivirals (DAAs), some existing DAAs regimens using ribavirin has been mainly selected for patients with decompensated cirrhosis and who relapsed after prior DAAs monotherapy. In this study, we prospectively evaluated the preventing effect of L-carnitine supplementation during antiviral treatment using ribavirin on a hemolytic anemia in hepatitis C virus (HCV)-related chronic liver disease patients.
Method: This study, designed as a prospective and randomized clinical trial, was conducted at the third department of internal medicine in Nara Medical University Hostital between July 2015 and August 2016. A total of forty-one patients with chronic hepatitis was consecutively enrolled. Twenty-two patients received sofosbuvir plus ribavirin (group A) for three months, while nineteen patients were treated with sofosbuvir, ribavirin, and L-carnitine (group B). We analyzed the changes of hemoglobin concentration, the effects of antiviral treatment and the healthy status levels of patients assessed by the SF-8 questionnaires in the both groups.
Results: The decreased level of hemoglobin concentration in the group B was significantly smaller than that in the group A at every time point. Consistently, the serum lactate dehydrogenase (LDH) level of patients in the group A was significantly higher than that in the group B at both eight and twelve weeks after the beginning of treatment. Moreover, the prescribed dose intensity of ribavirin in the group B was higher than that of group A (100% vs 91.2%), resulting in that the ratio of sustained virological response (SVR) 24 in the group B was higher than the group A (100% vs 90.9%). Additionally, the physical functioning of patients in the group B was significantly better than that in the group A at the end of antiviral treatment.
Conclusion: O L-carnitine supplementation actually alleviates the ribavirin induced hemolytic anemia in patients with HCV and might relieve the physical burden of patients during the treatment of the ribavirin included regimen. These advantages would increase the opportunity of achieving SVR.

THU-175

Eligibility and feasibility of hepatitis C treatment in the era of direct-acting antiviral agents: Our experience in real-world practice

Monica Schiavini[1], Simona Landonio[1], Carlo Magni[1], Simone Passerini[1], Fosca Niero[1], Alessandro Luciano Croci[1], Matteo Passerini[1], Matteo Bolis[1], Guido Gubertini[1], Elena Angeli[1], Annalisa Mainini[1], Riccardo Giorgi[1], Stefania Vimercati[2], Giuliano Rizzardini[1]. [1]*ASST-FBF-SACCO, L. Sacco Hospital, I Department of Infectious Diseases, Milan, Italy;* [2]*ASST-FBF-SACCO, L. Sacco Hospital, Pharmacy Unit, Milan, Italy*
Email: monica.schiavini@asst-fbf-sacco.it

Background and aims: In pre-DAAs era, some categories of patients (with HIV co-infection, intravenous drug users (IVDUs), psychiatric, with cirrhosis and elderly), were reported as "special" populations. This definition was based on limited feasibility and effectiveness of interferon-based HCV treatment, low compliance, potential drug-drug interactions and higher risk of adverse events. The aim of this study is to verify eligibility, feasibility and effectiveness of DAAs in "special" populations in our cohort.

Method: We studied 1278 pts who were referred to 1^ Department of Infectious Diseases of L. Sacco Hospital, Milan, Italy, for evaluation hepatitis C treatment, since 30/6/2013 to 31/12/2017.
Results: To date, out of 1278 pts, 1228 (95.5**%)** underwent DAAs treatment and completed follow-up of 12 weeks post-treatment. Among them, 348 pts were HIV co-infected, 262 IVDUs, 481 had diagnosis of cirrhosis, 35 pts were psychiatric, 372 elderly (>65 years old: 49 of them were >80 years old). Sustained virological response (SVR) was obtained as follows: 95.4% in HIV co-infected pts, 100% in IVDUs pts, 97.7% in cirrhotic pts, 100% in psychiatric pts, 97.5% and 100% in elderly (>65 and >80 years old respectively). Discontinuation for adverse events occurred only in 0.7% of 1228 pts: 4 HIV co-infected, 2 elderly and 3 pts with cirrhosis.
50 pts (3.9%) were excluded from treatment: 24/50 pts were HIV co-infected with active IVDU and poor compliance; whereas, in HCV mono-infected population, 16/26 pts refused therapy and 10/26 had serious co-morbidities.
Conclusion: In our experience, only a small number of patients (3.9%) resulted not eligible for DAAs treatment. SVR >95% was observed even in all "special" populations and only in a small percentage of cases (0.7%) therapy was discontinued for adverse events. These data confirm in real life the effectiveness, feasibility and safety of DAAs for all patients and the possibility to achieve HCV cure in almost all our patients.
In this setting, further efforts should be made by clinicians to reconsider also "difficult to treat" pts as suitable for therapy.

THU-176

Weight gain after interferon-free clearance of chronic hepatitis C: Results from the German hepatitis C registry (DHC-R)

Bernhard Schlevogt[1], Klaus Boeker[2], Stefan Mauss[3], Hartwig Klinker[4], Renate Heyne[5], Ralph Link[6], Karl-Georg Simon[7], Christoph Sarrazin[8,9], Michael P. Manns[10], Heiner Wedemeyer[10,11,12], Deutsches Hepatitis C-Register[12]. *[1]Münster University Hospital (UKM), Department of Medicine B, Münster, Germany; [2]Center of Hepatology, Hannover, Germany; [3]Center for HIV and Hepatogastroenterology, Düsseldorf, Germany; [4]University Hospital Würzburg, Würzburg, Germany; [5]Leberzentrum am Checkpoint, Berlin, Germany; [6]MVZ-Offenburg GmbH/St. Josefs-Klinik, Offenburg, Germany; [7]MVZ Dres. Email: bernhard.schlevogt@ukmuenster.de

Background and aims: Hepatitis C Virus (HCV) infection can be associated with a variety of extrahepatic manifestations including metabolic alterations. Few single center studies reported substantial weight gain during and after interferon-free treatment of chronic hepatitis C which has been considered as a potential concern. The aim of this study was to investigate short- and long-term weight changes of patients followed in a large, real-world multicenter cohort.
Method: The DHC-R (German Hepatitis C-Registry) is a national multicenter real-world cohort including about 14, 500 patients recruited by more than 250 centers (approx. 90% physicians in private practice). Patients are treated at the discretion of the physician. Data are collected by a web-based system. Data quality is analyzed by plausibility checks and on site monitoring. This analysis is based on 5, 111 patients who were documented until July 15th 2018 and who were observed for up to 3 years after completion of antiviral treatment.
Results: At the end of antiviral treatment the proportion of patients with weight gain of at least 1 kilogram was 21.1% which constantly increased to 47.8% at 3 years after DAA treatment (Fig. 1). Mean weight change compared to baseline was −0.2 kg (SD 4.3) at end of treatment whereas weight increased significantly to 1.6 kg (SD 6.6) and 1.7 kg (SD 8.0) at follow-up year 2 and 3. Multivariate regression analysis at FU2 revealed body mass index and sex as significant predictors of weight change. Patients with BMI ≤ 30 had a mean weight gain of 1.9 kg whereas patients with BMI > 30 showed no significant weight changes (0.1 kg). Male patients had a mean weight gain of 1.9 kg which was higher than observed in female patients (1.1 kg, p = 0.014).

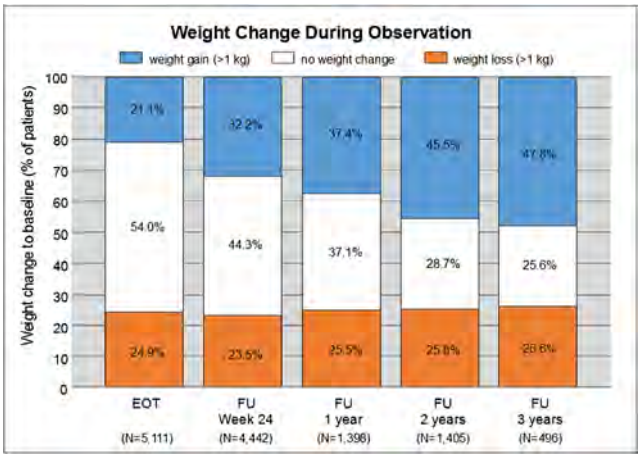

Figure: Weight change after interferon-free antiviral HCV treatment.

Conclusion: DAA treatment is followed by a substantial weight gain in almost half of the patients during long-term follow-up. Male patients were particularly vulnerable to weight gain. However, obese patients did not further gain weight which possibly could be explained by improved metabolic situation after HCV cure.

THU-177

Interim results of an ongoing project to eliminate chronic hepatitis C in people who inject drugs with ongoing intravenous drug use and a high risk of non-adherence to direct-acting antivirals in Vienna

Caroline Schmidbauer[1], Angelika Schütz[2], Cornelia Schwanke[2], Raphael Schubert[2], Julian Luhn[2], Enisa Gutic[1], Roxana Pirker[1], Tobias Lang[1], Hans Haltmayer[2], Michael Gschwantler[1]. *[1]Wilhelminenspital, Department of Internal Medicine IV, Vienna, Austria; [2]Suchthilfe Wien gGmbH, Ambulatorium Suchthilfe Wien, Vienna, Austria*
Email: michael.gschwantler@wienkav.at

Background and aims: An important subgroup of people who inject drugs (PWID) receiving opioid agonist therapy (OAT), cannot be treated in the setting of a hepatologic center and would not regularly ingest their medication when handed to them for self-administration. Our hypothesis was that chronic hepatitis C in these patients could be ideally managed if care was provided at a low-threshold facility and direct-acting antivirals (DAA) were administered together with OAT under direct observation of a pharmacist, physician or nurse at a pharmacy or a low-threshold facility.
Method: 267 PWID on stable OAT with chronic hepatitis C and high risk for non-adherence to DAA-therapy (male/female: 203/64; mean age: 38.0 ± 8.3 years; genotype (GT) 1/2/3/4/: 158/3/97/6 (unknown: n = 3); HIV-coinfection: n = 17; liver cirrhosis: n = 53) started antiviral treatment. Patients received antiviral therapy together with OAT under direct observation of a pharmacist, physician or nurse at a pharmacy or low-threshold facility. The DAA-regimen was selected according to GT, fibrosis stage, pretreatment and current reimbursement policy of insurances.
Results: Following this concept of directly observed therapy, adherence to antiviral therapy was excellent: Only 0.15% of scheduled dates for ingestion of the antiviral therapy in combination with OAT were missed by the 267 patients. Till now, 190 patients have

completed treatment and a 12-week follow-up period. Virological cure of hepatitis C infection (sustained virologic response, SVR12) could be confirmed in 189/190 patients (SVR12 rate: 99.5%; 95% CI: 97.1-99.9). One patient died 8 weeks after end of therapy for reasons not related to treatment. During follow-up reinfections occured in 12/190 (6.3%) patients. The cumulative rate of reinfection 24 and 48 weeks after end of therapy was 5.5% and 9.9%, respectively.

Conclusion: Directly observed therapy of chronic hepatitis C at a pharmacy or a low-threshold facility is highly effective in PWID with ongoing intravenous drug use and a high risk for non-adherence to DAA. By this new concept, a group of difficult-to-treat patients can be cured, who could not have been treated in settings of studies published so far.

Drug-drug interactions in HCV therapy: Still relevant for clinical practice?

Benjamin Schulte[1], Maximilian Wübbolding[1], Kerstin Port[1], Michael P. Manns[1], David Back[2], Fiona Marra[2], Markus Cornberg[1], Benjamin Maasoumy[1], Christoph Hoener zu Siederdissen[1]. [1]*Hannover Medical School, Hannover, Germany;* [2]*University of Liverpool, Liverpool, United Kingdom*
Email: schulte.benjamin@mh-hannover.de

Background and aims: With direct-acting antivirals (DAA) drug-drug interactions (DDI) have emerged as a new challenge in the treatment of hepatitis C virus infection (HCV). In the present study we aim to i) assess if the frequency of DDI has changed over time, ii) identify patients with an increased risk for DDI and iii) identify drugs most commonly involved.

Method: All consecutive HCV patients treated at Hannover Medical School from January 2014 to July 2018 were evaluated for their concomitant medication and assessed for DDI with the prescribed antiviral regimen. DDI were classified as follows: 1) no interaction expected 2) potential weak interaction 3) potential significant interaction and 4) do not coadminister. The assessment was based on data from hep-druginteractions.org and in case of missing information an expert opinion of a pharmacist. To evaluate changing frequencies of DDI over time with various DAA regimens, periods were defined as follows: A) January 2014-November 2014, B) November 2014-August 2016 and C) August 2016-July 2018, based on new approval of key DAA.

Results: Overall, 670 patients were included in the study with a mean age of 55.5 years (18-85). 44.9% of patients were female, 42.2% had cirrhosis, 6.6% were older than 74 years. 350 different medications were used in the cohort. The median number of medications used per patient was 3 (0-19). Over time, the frequency of patients without interactions remained stable (A: 63.0%, B: 51.2%, C: 61.5%) but the frequency of contraindications doubled between period A and B and remained elevated in period C (A: 2.5%, B: 5.1%, C: 4.0%). On average, cirrhotic patients took significantly more medications with category 3 interactions (figure). Patients aged 65-74 were also more likely to suffer from category 3 interactions. Patients aged >74 years had similar risks for interactions as patients aged 65-74 (figure). The medications most frequently involved in category 3 and category 4 interactions with the modern DAA regimens sofosbuvir/velpatasvir, glecaprevir/pibrentasvir and elbasvir/grazoprevir were proton pump inhibitors, metamizole, statins and carvedilol.

Conclusion: DDI remain common and affect about 40% of patients treated with DAA. Cirrhotic patients and patients aged >64 years were identified to have an increased risk for DDI. The most common drugs involved in significant interactions in our cohort are proton pump inhibitors, metamizole, statins and carvedilol.

Never too old to be direct acting antiviral treated for hepatitis C virus

Stephen Shafran[1], Sergio Borgia[2], Karen Doucette[1], Chrissi Galanakis[3], Curtis Cooper[4]. [1]*University of Alberta, Infectious Diseases, Edmonton, Canada;* [2]*William Osler Health System, Infectious Diseases, Brampton, Canada;* [3]*Ottawa Hospital Research Institute, Ottawa, Canada;* [4]*University of Ottawa, Infectious Diseases, Ottawa, Canada*
Email: ccooper@toh.ca

Background and aims: Elderly patients were seldom treated for HCV in the IFN era due to treatment side effects. IFN-free DAA therapy has minimal side effects making treatment feasible for many more patients, including the elderly. We report demographic and outcome data on all patients over 75 years of age who were treated for HCV with DAA therapy in 3 Canadian clinics.

Method: All HCV-infected patients greater than 75 years treated with DAAs without IFN were included. Information on demographics, treatment and outcomes were collected at 3 Canadian sites (Ottawa, Edmonton and Brampton). Fibrosis score was determined by transient elastography.

Results: 78 patients were included in the analysis. Patients were female (63%) with a mean age of 79 (SD 3.5, range 75-88 years; 36% were ≥ 80 years) and Caucasian (56%). 90% were treatment naïve. Genotypes included: G1a = 18%, G1b = 35%, G2 = 22%, G3 = 6%, and G4 = 9%. The mean METAVIR fibrosis score was 2.8 (SD 1.2) with 78% having fibrosis scores ≥ F2. 41% had cirrhosis. The main HCV treatments included: SOF/VEL = 33%, SOF/LDV = 32% and EBR/GZR = 17%. 13 of 78 (17%) received ribavirin (RBV) containing regimens with daily doses of 400 mg (n = 1), 600 mg (n = 1), 800 mg (n = 3), and

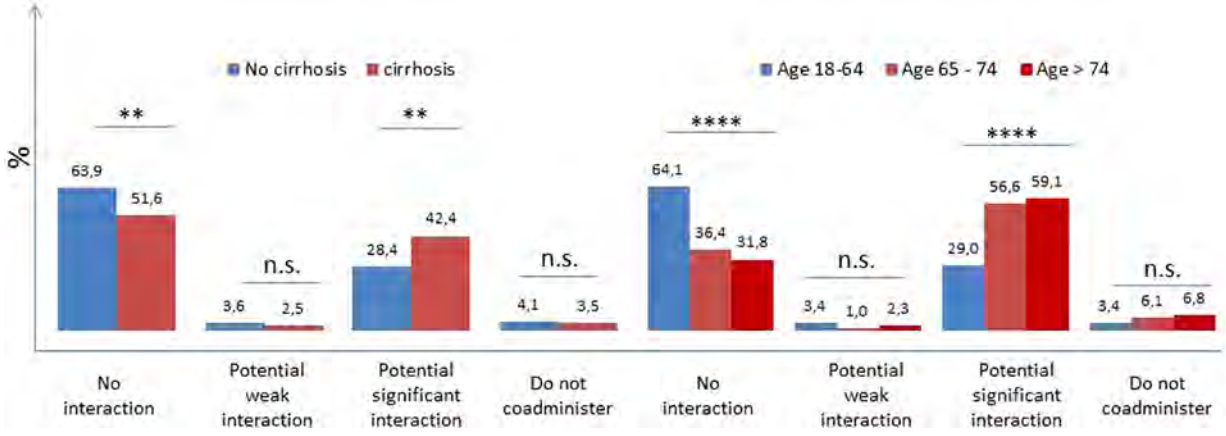

Figure: (abstract: THU-178): Drug-drug interactions in different subpopulations.

1000 mg (n = 8). 92% (57/62) with outcome results achieved SVR. No virologic failures occurred. SVR was 98% (n = 48/49) with non-RBV regimens and 69% (9/13) for RBV-recipients. Two deaths (ESLD, HCC), 1 discontinuation of all HCV medications at week 2, and 1 lost-to-follow-up occurred in RBV recipients. Mean on-treatment nadir hemoglobin in RBV recipients was 95 g/L (SD 22.1, range 57-128). RBV dose was reduced in 3 of 13 cases and was later discontinued in 2 of these 3 patients. Three received on-treatment PRBC transfusions.
Conclusion: Safety and efficacy of RBV-free DAA therapy is similar to that of younger adults. RBV-specific complications are frequent and without evidence of improved SVR in the elderly.

Email: soria.alessandro@gmail.com

Background and aims: In the direct acting antiviral (DAA) era, treatment of genotype 3 HCV (HCV-G3) is still challenging. The currently recommended treatment options are: sofosbuvir (SOF) + daclatasvir (DAC), SOF/velpatasvir (VEL), and glecaprevir/pibrentasvir (G/P). These recommendations are based on small, non-randomized trials or on comparisons with suboptimal and currently dismissed regimens, with HIV coinfection and cirrhosis being often under-represented. Direct comparisons of the 3 regimens are lacking, and real-life data are scarce on this issue. Temporal shifts in Italian prescription rules, alternating single regimens for HCV-G3, favour comparisons, reducing the risk of indication biases.
Method: All HCV-G3 patients consecutively treated within the Lombardia web-based Navigatore HCV Network were analysed. The primary end point was sustained virologic response 12 weeks after end of treatment (SVR12). Cirrhosis was defined by Fibroscan liver stiffness > 13 KPa. Uni- and multivariable logistic regression analyses were run to assess differences in SVR12 among regimens.
Results: Among 1535 patients treated for HCV-G3 with DAA, 271 were excluded from subsequent analyses as they had received suboptimal therapy (i.e. SOF+RBV ± pegylated interferon). Of the remaining 1264 patients, 27% were females, 53% cirrhotic and 31% had HIV coinfection; median (IQR) age was 53 (49-56) years, 41% had previous exposure to interferon. Overall, SVR12 was 95% (1202/1264): 94% (768/817) for SOF+DAC, 97% (319/327) for SOF/VEL, 96% (115/120) for G/P, P = 0.039, likely reflecting different prevalence of cirrhosis among the 3 groups (69%, 27%, 12%, respectively). At univariate analysis, treatment with SOF/VEL was associated with a higher likelihood of SVR12 (OR 2.54, 95%CI 1.19-5.43 P = 0.016). However, at multivariable analysis, when adjusted for gender, age, HIV status, presence of cirrhosis, baseline HCVRNA, the association lost statistical significance: OR 1.84 95%CI 0.78-4.35, P = 0.163. No other covariates were associated with treatment response.
Conclusion: In a large real-life setting of HCV-G3-infected patients with a high proportion of cirrhosis, the success rate was remarkable. The slight advantage of the SOF/VEL regimen was not confirmed at multivariable analysis, where adjustment for cirrhosis likely rebalanced the current shift of using novel regimens (i.e. SOF/VEL and G/P) for easier-to-treat patients in this era.

Safety and efficacy of glecaprevir/pibrentasvir for the treatment of HCV genotype 1-6: Results of the HCV-TARGET study

Richard Sterling[1], Stefan Zeuzem[2], Tania Welzel[2], Michael P. Manns[3], Rajender Reddy[4], Norah Terrault[5], Ziv Ben Ari[6], Irine Vodkin[7], Arifa Toor[8], Monika Vainorius[9], Lucy Akushevich[9], Michael W. Fried[9], David R. Nelson[10], Mark Sulkowski[11]. *[1]Virginia Commonwealth University, Richmond, United States; [2]Goethe University Hospital, Frankfurt, Germany; [3]Hannover Medical School, Hannover, Germany; [4]University of Pennsylvania, Philadelphia, United States; [5]University of California, San Francisco, San Francisco, United States; [6]Sheba Medical Center, Ramat Gan, Israel, United States; [7]"University of California, San Diego" La Jolla, United States; [8]Dartmouth-Hitchcock Medical Center, Lebanon, United States; [9]University of North Carolina Chapel Hill, Chapel Hill, United States; [10]University of Florida, Gainesville, United States; [11]Johns Hopkins University School of Medicine, Baltimore, United States*
Email: richard.sterling@vcuhealth.org

Background and aims: Glecaprevir/Pibrentasvir (G/P) is approved for treatment of chronic hepatitis C virus (HCV) genotypes (GT) 1-6 infection in treatment naïve (TN) and experienced (TE) non-cirrhotic as well as compensated cirrhotic patients. It is not recommended in patients with moderate hepatic impairment. We report real-world safety and efficacy of G/P in HCV-TARGET participants.
Method: Patients enrolled in HCV-TARGET were treated according to the local standards of care at academic (n = 45) and community

medical centers (n = 19) in North America (n = 60) and Europe (n = 4). Detailed information on demographics, clinical course, and adverse events was abstracted from medical records into a unique centralized data core. Independent data monitors systematically reviewed data for completeness and accuracy. This analysis includes patients who started G/P before August 1 2018.

Results: Of 660 patients treated with G/P 393 (60%) were male, 171 (26%) Black, 108 (16%) cirrhotic and 19 (3%) with history of decompensating events. Patients were predominantly treatment naïve (577, 87%); of whom, 312 (54%) completed an 8 week regimen. Overall, SVR12 for G/P is 344/359 (96%, 95% CI 93%-98%); GT1 225/234 (96%, 95% CI 93%-98%); GT2 49/54 (91%, 95% CI 80%-96%); GT3 50/51 (96%, 95% CI 90%-100%); Other GTs 20/20 (100%, 95% CI 84%-100%); TN 293/305 (96%, 95% CI 93%-98%), including 191/201 (95%, 95% CI 91%-97%) in those who completed 8 ± 1 weeks of treatment); and TE 51/54 (94%, 95% CI 85%-98%). Three hundred and one patients' virological outcomes are pending at this time. There were no virologic failures reported in 62 cirrhotics with available SVR data. On treatment adverse events (>90% mild in severity) occurred in 44% of patients. Common adverse events included fatigue (16%), headache (11%) and nausea (8%). Six patients experienced liver related events. Eighteen patients (3%) reported a total of 24 SAEs. Two patients died while on treatment: one of Lung cancer and second of unknown cause.

Category	N	%
All Patients Treated with G/P	**660**	**100.0%**
Male	393	60%
Black	171	26%
HCV genotype		
1	442	66%
1a	332	50%
Non-1a	110	17%
2	81	12%
3	88	13%
Other	49	7%
Cirrhosis	108	16%
Prior history of hepatic decompensation	19	3%
Prior DAA Treatment failure	23	4%
-NS5A experienced	16	2%
-PI experienced	1	0%
On-treatment Adverse Event (s)	288	44%
Disposition		
Completed Treatment	535	81%
D/C treatment early	33	5%
-AE	7	1%
-Lost to follow-up	22	3%
-Other reasons	4	< 1%
Still on Treatment	92	14%
SVR12 available	359	54%

Conclusion: G/P-based regimens in this real-world cohort show overall high efficacy with 96% SVR12 rate. This study cohort consisted of predominantly GT1 and treatment-naïve patients. Safety and efficacy results for all 660 patients will be presented.

THU-182

The PRIORITIZE study: A pragmatic, randomized study of oral regimens for hepatitis C- transforming decision-making for patients, providers, and stakeholders

Mark Sulkowski[1], Juhi Moon[1], Kenneth E. Sherman[2], Jama Darling[3], Andrew Muir[4], Mandana Khalili[5], Dawn Fishbein[6], Federico Hinestrosa[7], Mitchell Shiffman[8], Adrian Di Bisceglie[9], Rajender Reddy[10], Brian Pearlman[11], Anna Lok[12], Michael W. Fried[3], Paul Stewart[3], Joy Peter[13], Summer Wadsworth[14], Monika Vainorius[3], Larry Michael[3], Donna Evon[3], Jodi Segal[1], David R. Nelson[13]. *[1]Johns Hopkins University School of Medicine, Baltimore, United States; [2]University of Cincinnati, Cincinnati, United States; [3]University of North Carolina Chapel Hill, Chapel Hill, United States; [4]Duke University, Durham, United States; [5]University of California San Francisco/ San Francisco General Hospital, San Francisco, United States; [6]Medstar Health Research Institute, Washington, D.C., United States; [7]Orlando Immunology Center, Orlando, United States; [8]Liver Institute of Virginia, Richmond, United States; [9]Saint Louis University School of Medicine, St. Louis, United States; [10]University of Pennsylvania, Philadelphia, United States; [11]WellStar Atlanta Medical Center, Atlanta, United States; [12]University of Michigan Health System, Ann Arbor, United States; [13]University of Florida, Gainesville, United States; [14]No Affiliation, Chapel Hill, United States*
Email: msulkowski@jhmi.edu

Background and aims: The PRIORITIZE Study was designed to evaluate the comparative effectiveness of recommended direct acting antiviral (DAA) treatment options for persons infected with HCV genotype 1 (GT1). The study also evaluated the multi-faceted outcomes that stakeholders identified as being most important to HCV treatment decisions. 1) rates of patients being cured and durability of cure, 2) drug side effects and other short and long-term treatment harms, and 3) patient-centered clinical benefits.

Method: This pragmatic, open-label, randomized trial of sofosbuvir/ledipasvir (SOF/LDV) (provided by commercial payer) vs elbasvir/grazoprevir (EBR/GZV) vs (paritaprevir/ritonavir-ombitasvir-dasabuvir (PrOD) (the latter 2 regimens provided via the study) enrolled GT1 DAA-naive participants. NS5a Resistance-Associated Substitutions (RAS) testing was offered prior to treatment initiations for all patients. Patient Reported Outcomes (PRO) surveys were collected at baseline, week 4, end of treatment (EOT), and year 1. Treatment duration and use of ribavirin was at the discretion of treating physician and patients were monitored per local standard of care. After the standard of care shifted in the U.S. (August 2017), randomization to PrOD was stopped and participants were randomized 1:1 to the remaining treatment arms. Comparison of outcomes with the PrOD regimen was restricted to participants enrolled prior to the amendment; the comparison of SOF/LDV and EBR/GZV was based on all participants. The primary outcome was SVR12 defined as HCV RNA < LLOQ at least 12 weeks after therapy completion.

Results: 1677 patients were screened, 1609 were randomized, and 1276 were dosed (429 of 726 randomized to SOF/LDV, 700 of 729 to EBV/GZR, 147 of 154 to PrOD). The primary reason for failure to dose after randomization was payer denial of SOF/LDV (n = 244). The enrolled population was 60% male, 42% Black, 68% noncirrhotic, 75% GT1a. The mean age was 55 years and 12% had confirmed baseline NS5A RASs. The most frequent adverse events (AEs) have been fatigue (25%), headache (15%) and nausea (20%). Serious AEs were reported by 46 participants; none was treatment-related. Overall, 111 participants (9%) discontinued treatment early due to: lost to follow-up, n = 61; AEs, n = 21; death, n = 6; non-adherence, n = 13; lack of efficacy, n = 1, withdrew consent, n = 4 and administrative, n = 5. Of these 111 participants, 25 had sufficient data to assess virologic outcome; 17 achieved SVR12. Of the remaining 1165 participants, 234 are pending SVR12 classification and 931 have final outcomes available; of whom 904 (97.1%) have achieved SVR12.

Conclusion: This pragmatic trial is the largest randomized study to evaluate the comparative effectiveness of recommended treatments for GT1 infection. Final SVR, safety and on-treatment PRO outcome data for this study will be presented.

THU-183

Prospective multicenter study of glecaprevir plus pibrentasvir combination therapy for patients with chronic hepatitis C

Akihiro Tamori[1], Motoo Iwasa[2], Kazuaki Inoue[3], Tatehiro Kagawa[4], Koichi Takaguchi[5], Masahito Minami[6], Yoshiaki Iwasaki[7], Kazuhiro Nouso[8], Hai Hoang[9], Masaru Enomoto[1], Norifumi Kawada[1]. *[1]Osaka City University Graduate School of Medicine, Hepatology, Osaka, Japan; [2]Mie University, Gastroenterology, Tsu, Japan; [3]Showa University,*

Yokohama, Japan; [4]Tokai University, Gastroenterology, Isehara, Japan; [5]Kagawa Prefectural Central Hospital, Takamatsu, Japan; [6]Aiseikai Yamashina Hospital, Kyoto, Japan; [7]Okayama University, Okayama, Japan; [8]Okayama City General Medical Center, Okayama, Japan; [9]Osaka City University Graduate School of Medicine, Osaka, Japan
Email: atamori@med.osaka-cu.ac.jp

Background and aims: The once-daily, ribavirin-free, pangenotypic, direct-acting antiviral (DAA) regimen glecaprevir + pibrentasvir has shown high and sustained virological response rates in phase 2 and 3 studies. We assessed the safety and efficacy of 8 and 12 weeks of this combination therapy for patients infected with hepatitis C virus (HCV) in real world.
Method: This single-arm, multicenter study involved eight centers in Japan. On October 31, 2018, 424 patients aged 26-89 years (n = 94 aged >75 years) infected with HCV genotype (GT) 1, 2, 3, or 4, of which 49 had undergone curative treatment for hepatocellular carcinoma (HCC), started the treatment. Oral glecaprevir (300 mg) + pibrentasvir (120 mg) was administered once daily for 8 weeks to 245 non-cirrhotic DAA-naïve patients with HCV GT-1 or –2, and for 12 weeks to 56 cirrhotic, 78 DAA-failure, 39 cirrhotic and DAA-failure, 6 GT-3, and 1 GT-4 patient. Anti-HCV efficacy was defined as a sustained virological response at 12 weeks post-treatment (SVR12) (HCV RNA < 15 IU/ml). The efficacy and safety analysis included all patients who received at least one dose of the study drugs (intention-to-treat population). This study is registered at UMIN (No. UMIN000030599).
Results: In all, 395 patients completed the treatment, including 225 (92%) of 245 patients on the 8-week regimen and 167 (93%) of 179 patients on the 12-week regimen. Three patients were dropped because they were given a different DAA regimen. SVR12 was evaluated in 288 patients (Table). All of the DAA-naïve patients with GT-1 achieved an SVR12. The 12-week regimen resulted in 100% SVR12 in patients with GT-2. Six patients did not achieve SVR12: one GT-2a patient, two GT-3b patients, and three GT-1b patients with past DAA failure. During treatment, severe adverse effects (SAE) occurred in five patients: esophageal varices rupture, cerebral bleeding, femur fracture, burn, and exacerbation of heart failure. Mild adverse effects were reported in 130 (33%) patients: itching was reported by 27 patients (6.8%), GI discomfort by 10 (2.5%), elevation of total bilirubin >2.0 mg/dL by 7 patients (1.8%), and hyperuricemia by 6 (1.5%), etc.

Table: SVR12 rate after DAA therapy for 8 and 12 weeks.

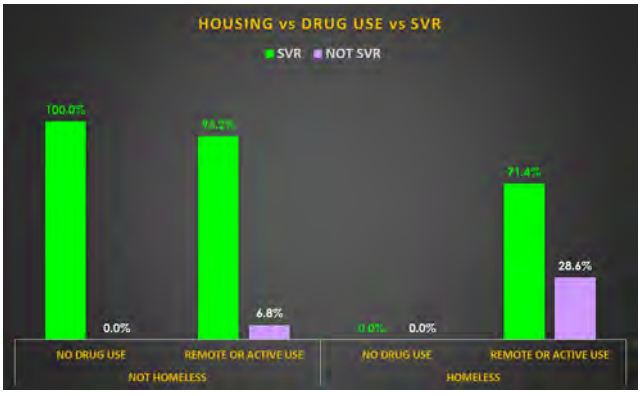
	8-Week Regimen	12-Week Regimen
Genotype 1	100% (77/77)	DAA naïve cirrhosis 100% (24/24) DAA retreatment 96% (68/71)
Genotype 2	99% (86/87)	DAA naïve cirrhosis 100% (15/15) DAA retreatment 100% (11/11)
Genotype 3	-	50% (2/4)

Conclusion: Glecaprevir + pibrentasvir for 8 or 12 weeks had a marked anti-HCV effect for GT-1 and GT-2 patients. The SVR rate was low in patients with GT-3. This combination therapy was reasonably safe, including in elderly patients.

THU-184
Correlates of unsuccessful hepatitis C virus therapy and recurrent viremia among active drug users: A mixed methods analysis

Astou Thiam[1], Julie Holeksa[1], Tianna Magel[1], Letitia Chu[1], Rossitta Yung[1], David Truong[1], Brian Conway[1]. *[1]Vancouver Infectious Disease Centre, Vancouver, Canada*
Email: astou.thiam@vidc.ca

Background and aims: People who use drugs (PWUD) have been identified as a prioritized population to receive hepatitis C virus (HCV) therapy. Numerous clinical trials have now shown that high cure rates can be achieved in this population. Concerns remain about the risk of unsuccessful therapy due to non-adherence as well as the risk of HCV reinfection. This study was conducted to determine the frequency and correlates of the inability to achieve and/or maintain a sustained viral response (SVR) in a target population of active PWUD receiving care.
Method: We undertook a retrospective mixed-methods analysis of patients receiving Direct Acting Agents (DAA) HCV treatment at our centre between 03/14-12/17. Statistical analyses were carried out using Chi square and logistic regression models with SPSS V24. Additionally, two focus groups were held (04-05/18) with participants asked to identify key factors affecting engagement in care. Qualitative data analysis was done using the Framework Approach with NVivo 11 software.
Results: A total of 215 patients eligible were included (74% male (n = 160), 39% active drug users (n = 83), 88% lifetime drug users (n = 189)). SVR was achieved in 91.2% (196/215) cases. During 282.7 patient-years of follow-up, no cases of recurrent viremia post-SVR were detected. Homelessness was the most important independent correlate of an inability to achieve SVR [OR: 7.08; CI: 95% (2.07-24.25); p = 0.002]. Moreover, 100% of the patients who did not use drugs during HCV treatment and were not homeless (n = 26) reached SVR. In the focus groups, most participants identified housing as the key social issue that needs to be addressed to improve their quality of life. Also, a number of comments suggested an awareness of the risk of HCV reinfection and an understanding of strategies to avoid it.



Conclusion: Homelessness was the main predictor of non-SVR among HCV-treated PWUD and was identified as the key factor affecting their quality of life. Multidisciplinary programs to address HCV infection in this population must include strategies to address unstable housing to enhance their success and impact. To date, we have not observed any cases of HCV reinfection in patients continuing to be enrolled in our multidisciplinary program, suggesting that they may have acquired and implemented strategies to avoid it.

Email: tomaskdr@poczta.fm

Background and aims: The aim of this study was to analyze efficacy and safety of HCV treatment of patients with severe CKD, including HD and kidney transplants recipients, in Poland in years 2015-2017 and registered in real-world EpiTer-2 database.
Method: Among 6229 patients in EpiTer-2 database we identified 334 patients with any kidney disease. In 77 patients eGFR was < 30 ml/min/1.73 m^2, that included 53 patients on hemodialysis (HD). All patients underwent IFN-free, anti-HCV therapy.
Results: Among 77 patients with CKD stage 4 and 5 there were 35 females (45.5%) and 42 males (54.5%) with mean age 49.0 ± 12.08 and 49.4 ± 14.55 respectively. HCV genotype distribution analysis revealed dominance of genotype 1b-63 pts (82%), genotype 1a in 3 pts (4%), genotype 3 in 1 pt (1.3%) and genotype 4 in 10 pts (13%). Only 14 (18%) were cirrhotic, 4 had previous liver decompensation and 3 had esophageal varices. The most prevalent comorbidities were hypertension (56%) and diabetes (18%). Three patients had liver and 20 (29%) kidney transplantation. The majority of patients (74%) were treatment-naïve. The most frequent treatment was OBV/PTV/r ± DSV- in 39 patients (51%), GZR/EBR was used in 26 (34%), ASV/DCV in 4 (5%), GLE/PIB in 1 (1%). Seven patients (16%) were treated with LDV/SOF, contraindicated in patients with GFR < 30 ml/min/1.73m^2. The main reason for choosing LDV/SOF were DDIs and liver decompensation. There were no safety issue with LDV/SOF including renal function.
All patients, but 1 who was lost to follow-up, achieved SVR12, so ITT SVR12 was 99% and mITT SVR12 was 100%, that was even better than in the general cohort (ITT SVR12-95%; mITT SVR12-97%)
Adverse events were reported in 24 patients (31%) with 3 SAE (2 liver decompensations and 1 esophageal bleeding) that led to 1 treatment discontinuation.
All HD patients completed treatment, achieved SVR and there was 1 episode of ascites, 4 cases of anemia, 2 pruritus and 2 bilirubin level elevation. None of them led to therapy modification.
Conclusion: Extremely high efficacy and few side effects allowed to use DAAs in severe and end-stage kidney disease. In this real-world study we confirmed that patients are no longer difficult-to-treat population. but some of them may still require special attention due to decompensated liver cirrhosis when selecting regimen or establish follow-up procedures.

THU-186

Progress towards achieving hepatitis C elimination in the country of Georgia, April 2015-August 2018

Tengiz Tsertsvadze[1,2], Amiran Gamkrelidze[3], Nikoloz Chkhartishvili[1], Akaki Abutidze[1], Lali Sharvadze[2,4], Vakhtang Kerashvili[1], Maia Butsashvili[5], David Metreveli[6], Lia Gvinjilia[7], Shaun Shadaker[8], Muazzam Nasrullah[8], Valeri Kvaratskhelia[9], Maia Lagvilava[9], Ekaterine Adamia[9], Stefan Zeuzem[10], Nezam Afdhal[11], Sanjeev Arora[12], Karla Thornton[12], Francisco Averhoff[8]. *[1]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia; [2]Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia; [3]National Center for Disease Control and Public Health, Tbilisi, Georgia; [4]Hepatology clinic HEPA, Tbilisi, Georgia; [5]Health Research Union, Tbilisi, Georgia; [6]Medical Center Mrcheveli, Tbilisi, Georgia; [7]CDC Foundation, Tbilisi, Georgia; [8]Centers for Disease Control and Prevention, Division of Viral Hepatitis National Center for HIV, Hepatitis, STDandTB Prevention, Atlanta, Georgia; [9]Ministry of Labour, Health and Social Affairs of Georgia, Tbilisi, Georgia; [10]Goethe University Hospital, Frankfurt, Germany; [11]Beth Israel Deaconess Medical Center Liver Center, Boston, United States; [12]ECHO Institute, University of New Mexico, Albuquerque, Georgia*
Email: tt@aidscenter.ge

Background and aims: In April 2015, Georgia with the support of U.S. CDC and Gilead Sciences, launched the world's first HCV elimination program. A key strategy is nationwide HCV screening, linkage to care, provision of treatment for all HCV persons and effective prevention interventions. A national serosurvey conducted in 2015 estimated 150, 000 persons with chronic HCV in the country. To achieve the elimination goal by 2020, a 90% reduction in prevalence of HCV, there are objectives including: diagnosing 90% of HCV-infected persons, treating 95% of those diagnosed and curing 95% of those treated. Progress towards the goal will be assessed by monitoring the HCV care continuum.
Method: A hepatitis C care cascade was constructed using data from the national HCV treatment program (Figure). The program collects data on all persons registered with the treatment program. Data on persons tested for chronic HCV infection through sustained virologic response (SVR) were extracted as of August 31, 2018. SVR rates were calculated using both per-protocol (PP) and intent-to-treat analysis (ITT).
Results: Among estimated 150, 000 adults living with chronic hepatitis C in Georgia, 61, 666 (41.1%) were diagnosed and registered with the treatment program. Among those registered in the program, 48, 871 (79.3%) have initiated treatment with either sofosbuvir or ledipasvir/sofosbuvir based regimens, of which 45, 088 (92.2%) have completed treatment. Among 41, 734 persons eligible for SVR assessment 32, 880 (78.8%) returned for final evaluation. In PP analysis SVR rate achieved was 98.2% (32, 297/32, 880) while 77.4% (32, 297/41, 734) of persons achieved SVR in ITT analysis. High cure rates were achieved for all HCV genotypes: 98.5% in genotype 1, 98.4% in genotype 2 and 97.7% in most challenging to treat genotype 3. Treatment effectiveness was comparable among persons with advanced fibrosis (F3 and F4) with 97.3% achieving SVR, and among patients with mild or no liver fibrosis (≤F2), SVR = 98.8%.

Figure: Hepatitis C care cascade as of August 31, 2018.

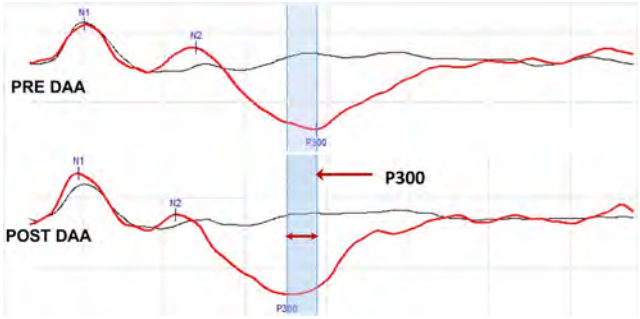
Conclusion: Georgia has made substantial progress towards eliminating hepatitis C, with over 40% of persons with HCV infection identified and registered for treatment. High cure rates have been achieved among those who received SVR testing. Efforts to identify and link to care persons with HCV infection, ensure SVR testing and implement prevention interventions are needed to achieve the elimination goals.

THU-187

Objective evidence of neurocognitive impairment associated with hepatitis C virus infection and of its regression after viral clearance with direct antivirals

Gloria Vaghi[1], Matteo Nazzareno Barbaglia[1], Benedetta Gori[2], Gionata Strigaro[2], Michela Emma Burlone[1], Giacomo Tondo[2], Rosalba Minisini[1], Roberto Cantello[1], Mario Pirisi[1]. *[1]Università del Piemonte Orientale, Translational Medicine, Novara, Italy; [2]AOU Maggiore della Carità Neurology, Novara, Italy*
Email: rosalba.minisini@med.uniupo.it

Background and aims: Neurocognitive impairment associated with Hepatitis C Virus (HCV) infection has a great impact on patients' quality of life. However, it is unclear whether it is due to viral infection per se (either directly for infection of brain cells or indirectly via neuroinflammation) or to other reasons, for example the mere awareness of having a chronic disease. This study was designed to investigate these issues.
Method: The study population included: N. = 23 HCV infected patients, N. = 15 patients with non-alcoholic fatty liver disease (NAFLD) and N. = 15 healthy controls. They were all matched for age, education and (limited to the 2 groups of patients) fibrotic stage. All subjects underwent a battery of 10 neuropsychological tests and measurement of the evoked potential P300. The 3 groups repeated testing six months apart; HCV patients were tested before and after therapy with Direct Antiviral Agents (DAA). For in vitro experiments, Human Brain Microvascular Endothelial Cells (HBMEC) were exposed to HCV strain JFH-1 cell cultured. The relative expression of intracellular viral RNA and inflammatory cytokines mRNA levels (Interleukin (IL)-1beta, IL-8, IL-18 and Transforming Growth Factor-beta) were then quantified.
Results: Only in the chronic HCV group a significant improvement was observed in the repeat examination in several cognitive fields, including verbal ability and logic thinking (Verbal judgments test $p < 0.001$), executive functions (phonological fluency $p = 0.001$), and P300 latency ($p = 0.003$) (Fig.1). Improvements occurred also in tests investigating episodic memory (Rey Auditory Verbal Learning Test immediate and differed tasks, $p < 0.001$ and $p = 0.001$ respectively), but being registered also in control groups were likely due to test-enhanced learning.
Moreover, at baseline patients showed significant deficits compared to both control groups in the tests mentioned above. *In vitro*, HMBEC exposed to viral inocula were negative for intracellular HCV RNA, however a striking rise in IL-1beta (8 fold $p < 0.0001$) and IL-8 (64 fold $p = 0.0005$) mRNAs was observed.



Conclusion: Neurocognitive deficits associated with HCV infection are demonstrable by neuropsychological tests and objective neurophysiologic tests, and regress after viral clearance. *In vitro* results suggest that the pathophysiological mechanism is more likely related to neuroinflammation induced by exposure to circulating virions, than to direct infection of brain cells.

Email: johannes.vermehren@kgu.de

Background and aims: Chronic hepatitis C virus (HCV) infection can be cured with all-oral direct-acting antivirals (DAAs) in >90% of patients. There are only few patients in whom DAA treatment fails. Re-treatment options for patients with DAA failure are limited. In Europe, the fixed dose combination of sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) given for 12 weeks is the only approved DAA regimen for patients in whom HCV NS5A inhibitor-based therapy has failed. Aim of the present analysis was to evaluate the efficacy and tolerability of SOF/VEL/VOX under real-world conditions.
Method: The DHC-R (German Hepatitis C-Registry) is a national multicenter real-world cohort including about 14, 500 patients recruited by more than 250 centers (approx. 90% physicians in private practice). For the present analysis, all consecutive patients enrolled in the DHC-R who were retreated with SOF/VEL/VOX were analyzed (as of 9 Feb, 2018). SVR data were updated as of 4 Nov, 2018.
Results: Retreatment with VOX/VEL/SOF with or without ribavirin (RBV) was initiated in 86 patients with prior DAA failure. Patients were infected with HCV genotypes (GT) 1, 3, and 4 in 64%, 31% and 5%, respectively. Prior DAA regimens included: LDV/SOF ± RBV (n = 26), PrO ± D ± RBV (n = 27), VEL/SOF ± RBV (n = 12), GZR/EBR (n = 6), DCV/SOF ± RBV (n = 12), SMV/SOF+RBV (n = 1), and SOF+RBV (n = 2). The median age was 52.5 years (range, 26-79), 86% were male and 24% had compensated cirrhosis. Four patients had received RBV (GT1b, n = 2; GT3, n = 2) as part of their treatment. At the time of data analysis, 56/56 (100%) had achieved SVR. There were no virologic failures. SOF/VEL/VOX was well-tolerated. The most frequent adverse events included fatigue (16%) and headaches (10.5%). There were two severe adverse events (pneumonia, urothelial carcinoma) that were considered unrelated to HCV treatment.
Conclusion: Retreatment with SOF/VEL/VOX was highly effective and well-tolerated in this real-world cohort.

THU-189

Role of comorbidites in sofosbuvir-based treatment response: Clinical experience from an Italian real life cohort

Vitor Hugo Martins[1], Giulia Troshina[1], Giulia Verzon[1], Michela Ciruolo[1], Felice Rizzi[1], Claudia Chialà[1], Ludovica Venezia[1], Pablo Cortegoso Valdivia[1], Federico Cravero[1], Stefano Rizza[1], Giorgio Maria Saracco[1], Alessia Ciancio[1]. [1]*University of Turin, Department of Medical Sciences, Turin, Italy*
Email: vitorhugomartins@gmail.com

Background and aims: Chronic hepatitis C (CHC) can be complicated with comorbidities conditions that may impact the treatment eligibility and outcomes. The aim of this study was to assess sustained virological response (SVR) rates in a real-world cohort of patients with HCV infection treated with sofosbuvir-based regimens.
Method: All naive and prior interferon-treated patients with genotypes 1, 2, 3, 4 or 5 who started sofosbuvir-based treatment at the Gastroenterology unit of the Molinette Hospital, University of Turin from June 2014 trought May 2018 were included. All consecutive patients received Sofosbuvir (SOF) in association with: ledipasvir (LDV), daclatasvir (DCV), simeprevir (SMV) or velpatasvir (VEL) in a once-daily fixed-dose. The characteristics of the CHC population were evaluated-with specific focus upon use of medications and comorbidities. The primary end point was SVR at 12 weeks after the end of therapy by modified intention-to-treat analysis.
Results: Among a chronic HCV cohort of 1061 patients, at least one comorbidity condition was seen on the great majority of the patients (75.4%). The most common categories of comorbidities were: endocrine (37.4%), gastrointestinal (19.8%), haematological (19.1%), cardiovascular (15.4%) and neurological diseases (7.4%). The three most frequent comorbidities were hypertension (36.3%), diabetes (14.2%) and depression (12.1%). 1049 patients reached week 12 of follow-up post-treatment given that 4 patients died (2 of septic shock while receiving treatment and 2 of HCC during follow-up), 2 discontinued treatment (1 patient's decision and 1 adverse event) and 6 were lost to follow-up. Overall SVR rate was 98.2% (1030/1049). Unexpectedly SVR rates were lower in patients without comorbidites (96.9%) versus the ones that had them (98.6%, p = 0.068). All of the patients (100% 127/127) diagnosed with depression achieved SVR12, followed by the ones with high blood pressure (98.7% 377/382) and diabetes (98.0%, 147/150). All of the patients (100%, 63/63) with 5 or more comorbidities achieved SVR12, followed by the ones with 2 (99.9%, 206/208), 3 (98.8%, 162/164), 4 (98.0%, 100/102) and just 1 comorbid condition (97.7%, 211/216). Prior HCV treatment (p = 0.043) and cirrhosis (p = 0.013) were associated with SVR. HCV genotype 1b (OR = 7.105^{-8}, 95% CI 2.316^{-8}-2.180^{-7}, p = 0.000), genotype 2 (OR = 5.104^{-8}, 95% CI 8.185^{-8}-3.183^{-7}, p = 0.000), genotype 3 (OR = 2.965^{-7}, 95% CI 3.379^{-8}-2.601^{-6}, p = 0.000) and male gender (OR = 0.224, 95% CI 0.063-0.804, p = 0.022) were predictors of relapse.
Conclusion: Our real-life results validate the efficacy and safety of sofosbuvir-based regimens suggesting that, patients' comorbidities and the correlate therapies taken during antiviral treatment were not significantly associated with SVR rates. Male gender and HCV genotype 1b, 2 and 3 were predictors of relapse.

THU-190

Characteristics associated with sustained virologic response in chronic hepatitis C patients who received an abbreviated course of direct-acting antiviral therapy

Kirsten Vest[1], Mei Chang[1], Troy Kish[1,2], Amy Horey[3], Mitchell Snyder[4], Kendra Vermeulen[4]. [1]*James J. Peters VA Medical Center, Bronx, United States;* [2]*Long Island University Pharmacy (Arnold and Marie Schwartz College of Pharmacy and Health Sciences), Brooklyn, United States;* [3]*VA Western New York Healthcare System, Buffalo, United States;* [4]*VA New Jersey Health Care System, East Orange, United States*
Email: kirsten.vest@va.gov

Background and aims: Treatment of chronic hepatitis C virus (HCV) with 8-12 weeks of direct-acting antivirals (DAA) results in sustained virologic response (SVR) rates > 95%. Limited data exists suggesting treatment durations of 3-6 weeks may also be curative. Shorter treatment durations can positively impact patient adherence and healthcare costs. Factors associated with SVR in patients receiving shorter courses include HCV viral load (VL) < 6 million copies/ml, absence of cirrhosis or resistance-associated substitutions (RAS), and HCV genotype. This project evaluated SVR rates in patients with chronic HCV who received abbreviated courses of DAA therapy and observed characteristics associated with SVR.
Method: A retrospective chart review was performed to identify all patients who received abbreviated courses of DAA-containing regimens for HCV from January 2014 to June 2018. Patients with incomplete documentation of treatment course or those treated with interferon, boceprevir, or telaprevir were excluded.
Results: A total of 2, 663 charts were reviewed and 87 patients met inclusion criteria. Fifty-three percent (n = 46) of patients achieved SVR. The median (interquartile range, IQR) percentage of treatment days completed was 66% (49-70%) for those who were cured vs. 17% (11-33%) for those who failed therapy. Median (IQR) baseline HCV VL was 1.2 million copies/ml (0.4-2.6 million copies/ml) vs. 2.2 million copies/ml (0.8-5.2 million copies/ml) for the SVR group and non-SVR group, respectively. More patients in the SVR group were genotype non-1a (50% vs. 27%, respectively), cirrhotic (28% vs. 20%, respectively), received an NS5B-contaning DAA regimen (76% vs. 68%, respectively), and had treatment interruptions (38% vs. 15%, respectively) when compared to the non-SVR group. Compared to the SVR group, more patients in the non-SVR group were HIV+ (4% vs. 10%, respectively), Hispanic (15% vs. 22%, respectively), and had RASs (2% vs. 17%, respectively).
Conclusion: Characteristics that appear to be associated with SVR in chronic HCV patients who received an abbreviated course of DAA therapy include genotype non-1a, therapy with an NS5B-containing regimen, and completion of at least 50% of the treatment course. Characteristics associated with treatment failure include HIV+ status, Hispanic ethnicity, and presence of RASs. Severity of liver disease, treatment interruption, and baseline HCV VL do not appear to impact the SVR rate in this patient population.

THU-191

The cost-effectiveness of an HCV outreach intervention for at-risk populations in London, UK

Zoe Ward[1], Linda Campbell[1], Julian Surey[2], Steven Platts[3], Rachel Glass[4], Matthew Hickman[1], Alistair Story[5], Peter Vickerman[1]. [1]*University of Bristol, Bristol, United Kingdom;* [2]*Find and Treat, NHS, London, United Kingdom;* [3]*Groundswell, London, United Kingdom;* [4]*Public Health England, London, United Kingdom;* [5]*University College London, London, United Kingdom*
Email: zoe.ward@bristol.ac.uk

Background and aims: Hepatitis C virus (HCV) disproportionately affects marginalised communities such as homeless populations and people who inject drugs (PWID), posing a challenge to traditional health services. The HepFriend initiative in London is a model of care utilising HCV outreach screening and peer support to link vulnerable individuals to HCV treatment in secondary care. The aim of the study is to assess the cost-effectiveness of the HepFriend initiative from a healthcare provider perspective, compared to standard-of-care pathways (consisting of testing in primary care and other static locations, including drug treatment centres, and linkage to secondary care).
Method: Cost-effectiveness analysis using a dynamic HCV transmission and disease progression model among PWID and those who have ceased injecting, including housing status and drug treatment service contact, parameterised using London specific surveillance and survey data, and primary intervention cost and effectiveness data (September 2015 to June 2018). Out of 461 individuals screened, 200

were identified as HCV RNA positive, 198 attended secondary care and 99 have commenced treatment to date. The incremental cost-effectiveness ratio (ICER) was determined using a 50-year time horizon.

Results: For a £20, 000 per quality adjusted life year (QALY) gained willingness-to-pay threshold, the HepFriend initiative was cost-effective, mean ICER of £8, 880 per QALY, and would become cost-saving at 45% (£17, 536 per treatment) of the current drug list price. Results are robust to variations in intervention costs and model assumptions.

Conclusion: New models of care that undertake active case-finding with enhanced peer-support to improve testing and treatment uptake amongst marginalised and vulnerable groups could be highly cost-effective and possibly cost-saving.

THU-192

All-oral, 12-week ravidasvir plus ritonavir-boosted danoprevir and ribavirin delivers 100% svr12 in treatment-naive non-cirrhotic hcv genotype 1 patients with resistance-associated substitutions of a phase 2/3 clinical trial in china

Email: weelai@163.com

Background and aims: Ravidasvir (RDV) is a pan-genotypic NS5A inhibitor with high barrier to resistance. As reported from phase 2 trial (NCT03020095), all-oral RDV and DNVr in combination with ribavirin achieved the SVR12 rate of 100% (38/38) in treatment-naïve non-cirrhotic patients with HCV GT1 infection in Taiwan. This s a subanalysis of phase 2/3 study of RDV and DNVr in combination with ribavirin regimen for treatment-naïve HCV genotype 1 (GT1) patients without cirrhosis in a large population in China Mainland.

Method: In this multi-center, randomized, double-blind, placebo-controlled phase 2/3 trial (NCT03362814), we enrolled 424 treatment-naïve, non-cirrhotic adult HCV GT1 patients from 42 sites in different provinces of China. These patients were randomized 3 : 1 to receive a combination of RDV 200 mg once daily plus DNVr 100 mg/100 mg twice daily and oral ribavirin 1000/1200 mg/day (body weight < 75/ ≥ 75 kg) (n = 318) or placebo (n = 106) for 12 weeks, then patients in the placebo group went on to receive 12 weeks' treatment with the above combination. The primary efficacy end point was the sustained virologic response rate 12 weeks after the end of treatment (SVR12) using the CAP/CTMHCV 2.0 assay (LLOQ = 15 IU/ml).

Results: Of the 424 patients (mean age 45yrs, range 21~73 yrs) enrolled, 47% were male, 82%(348/424) was IL-28B CC genotype, and most of the patients (305/424, 72%) had HCV RNA ≥ 800, 000 IU/ml at baseline. All patients had NS5A testing at baseline, with 76 patients (76/309, 25%, PPS) in the treatment group and 29 patients in the placebo group (29/101, 29%, PPS) having detectable RASs in the NS5A region. The most common NS5A RASs were R30Q (38/309, 12.3%), Y93H (21/309, 6.8%) and R30Q/Y93H (8/309, 2.6%) in the treatment group and R30Q (21/101, 20.8%), Y93H (6/101, 5.9%), R30Q/Y93H (1/101, 0.99%) in the placebo group. The overall SVR12 was 99.03% (306/309, 95%CI: 97.19%~99.80%, PPS)and 99.01% (100/101, 95%CI: 94.61%, 99.97%, PPS) respectively for the treatment group and the placebo group. All patients with baseline NS5A RAS from the treatment group (76/76, PPS) and the placebo group (29/29, PPS) achieved SVR12. 3 patients (3/309, 0.97%, PPS) in the treatment group experienced virologic breakthrough and 1 patient in the placebo group relapsed (1/101, 0.99%, PPS), none of them had RASs at baseline. No serious AE was assessed by the investigator as related to study drugs. Most of the abnormal laboratory tests of liver function were of mild or moderate severity (grade 1 and grade 2).

Conclusion: For Chinese treatment-naïve non-cirrhotic GT1 HCV adult patients, there was no significant impact of baseline NS5A RASs on SVR12 with 12-week ravidasvir plus ritonavir-boosted danoprevir and ribavirin.

4 week treatment for hepatitis C: A randomized controlled trial (4RIBC)

Lone Wulff Madsen[1], Anne Øvrehus[1], Jan Gerstoft[2], Nina Weis[3,4], Toke Seierøe Barfod[5], Alex Laursen[6], Henrik Krarup[7,8], Anja Ernst[8], Peer Brehm Christensen[1]. *[1]Odense University Hospital, Department of infectious diseases, Odense, Denmark; [2]Rigshospitalet, Clinic for Infectious Diseases, Copenhagen, Denmark; [3]Copenhagen University Hospital, Hvidovre, Department of infectious Diseases, Copenhagen, Denmark; [4]Faculty of Health and Medical Sciences, University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [5]Zeeland University Hospital Roskilde, Unit for Infectious Diseases, Deparmtment of Medicine, Roskilde, Denmark; [6]Aarhus University Hospital, Skejby, Department of Infectious Diseases, Aarhus, Denmark; [7]Aalborg University Hospital, Department of Medical Gastroenterology, Aalborg, Denmark; [8]Aalborg University Hospital, Section of Molecular Diagnostics and Clinical Biochemistry, Aalborg, Denmark*
Email: lone.wulff.madsen@rsyd.dk

Background and aims: Since the introduction of Directing Acting Antivirals (DAA) the cure rate of chronic hepatitis C has been over 90% which even includes difficult to treat patients as cirrhotic and treatment experienced patients. Shortening treatment duration

could reduce overall treatment cost and probably improve adherence. If 4 weeks of treatment could be used in a large proportion of hepatitis C virus infected patients it will be much more feasible to implement in treatment of HCV infected drug users where adherence and lost to follow-up is a concern.

We have previously shown that 4 weeks of ledipasvir/sofosbuvir plus weight based ribavirin gave a cure rate of 92% in young and easy to treat patients. However Ribavirin adds to side effects but the addition might be defensible if treatment can be shortened.

We hypothesize that patients under the age of 50 with no or minimal liver fibrosis could be cured receiving only four weeks of glecaprevir/pibrentasvir and aim to investigate whether ribavirin is necessary in this population.

Method: The study consists of two phases. Phase 1: comparing glecaprevir/pibrentasvir ± ribavirin in a single center study and hereafter in phase 2 conduct a multicenter study with 168 patients. Here we present the preliminary results of phase 1. The trial was conducted at the outpatient clinic at infectious disease department at Odense University Hospital in Denmark.

Main inclusion criteria: Treatment naive patients with chronic hepatitis C (all genotypes), age < 50 years and liver stiffness measurement of < 8 kPa.

Patients were stratified according to genotype 3/non genotype 3. Thirty two patients were randomized 1:1 to either glecaprevir/pibrentasvir or glecaprevir/pibrentasvir + ribavirin for 4 weeks. Ribavirin was dosed 15 mg/kg q.d. with an upper limit of 1400 mg. The study was sponsored exclusively by the Danish Health Authorities.

Results: From May to August 2018, 32 patients initiated treatment: 31 patients have reached week 4 post treatment and 13 have reached 12 week post treatment.

SVR4 in the ribavirin containing arm was 86% (13/15) and SVR12 71% (5/7). In the ribavirin free arm SVR4 was 75% (12/16) and SVR12 50% (3/6).

Conclusion: These preliminary results suggest that ribavirin will be necessary for a 4 week regime with glecaprevir/pibrentasvir. Full SVR12 result for phase one will be presented at the conference as well as baseline and treatment resistance associated variants in patients not achieving SVR 12.

THU-194

Efficacy and safety of glecaprevir/pibrentasvir in patients with HCV genotype 5 or 6 infection: An integrated analysis of phase 2 and 3 studies

Betty Yao[1], Tarik Asselah[2], Linda Fredrick[1], Gretja Schnell[1], Kris V. Kowdley[3], Paul Kwo[4], Fred Poordad[5], Kinh Nguyen[6], Samuel Lee[7], Federico Mensa[1]. *[1]AbbVie, Inc, North Chicago, United States; [2]Centre de Recherche sur l'Inflammation, INSERM UMR 1149, Université Paris Diderot, Department of Hepatology, Clichy, France; [3]Swedish Medical Center, Seattle, United States; [4]Stanford University School of Medicine, Palo Alto, United States; [5]The Texas Liver Institute, University of Texas Health, San Antonio, United States; [6]National Hospital for Tropical Diseases, Hanoi, Viet Nam; [7]University of Calgary, Calgary, Canada*

Email: betty.yao@abbvie.com

Background and aims: The pangenotypic direct-acting antivirals (DAAs) glecaprevir (identified by AbbVie and Enanta) coformulated with pibrentasvir (G/P) are approved for the treatment of chronic HCV genotype (GT) 1-6 infection. However, the efficacy and safety data of G/P are limited in patients infected with HCV GT5 and GT6.

Method: The data analysis integrated data from 10 Phase 2b, 3a (registrational) and 3b (post-registrational) studies. The patient population comprised adults with chronic HCV GT5 or GT6 infection and compensated liver disease (with or without cirrhosis) who were treatment-naïve or experienced with regimens containing interferon (IFN) or pegylated IFN (pegIFN) ± ribavirin or sofosbuvir + ribavirin ± pegIFN. Patients received 8 or 12 weeks of G/P (300 mg/120 mg) depending on the design of the original study. Efficacy was evaluated as the rate of sustained virologic response (SVR) at post-treatment week (PTW) 12 (SVR12). HCV subtype was identified by phylogenetic analysis.

Results: Data from 181 patients were included in this integrated analysis, including 56 (30.9%) with HCV GT5 and 125 (69.1%) with HCV GT6 infection. Overall, 102 (56.4%) patients were treated for 8 weeks and 79 (43.6%) for 12 weeks, irrespective of the presence of cirrhosis. Most patients were male (54.1%), Asian (64.6%), < 65 years of age (72.4%), treatment-naïve (87.8%), with F0-F1 fibrosis (68%), and non-cirrhotic (non-F4, 84.5%). One GT5 subtype (5a) and 17 GT6 subtypes were included, with the majority of GT6 subtypes being 6a (35.2%) or 6e (24%). In patients with HCV GT5 infection, 95.7% (22/23) on 8-week treatment and 100% (33/33) on 12-week treatment achieved SVR12. In GT6, 98.7% (78/79) patients on 8-week treatment and 97.8% (45/46) on 12-week treatment achieved SVR12. Overall, 1% (1/102) of patients on 8-week treatment and no (0/76) patient on 12-week treatment experienced relapse. SVR12 rates by cirrhosis status and treatment duration are shown in Fig 1. Treatment-emergent adverse events (AEs) were mostly mild or moderate in severity (175/181, 96.7%). Most common AEs in at least 10% of patients were fatigue (29/181, 16%) and headache (27/181, 14.9%). Seven patients (3.9%) had treatment-emergent serious AEs, none of which were related to G/P or led to study drug discontinuation.

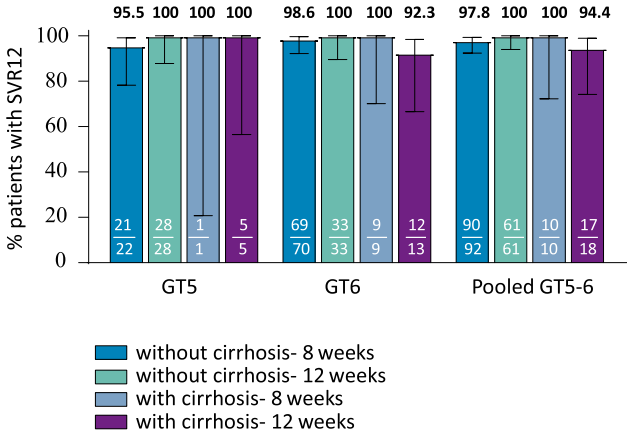

Figure 1: Efficacy with G/P in GT5/GT6 patients.

Conclusion: HCV GT5- and GT6-infected patients without cirrhosis or with compensated cirrhosis treated with G/P for 8 or 12 weeks achieved high rates of SVR12. There were no added efficacy benefits when treatment was extended from 8 to 12 weeks, even in patients with compensated cirrhosis. The G/P regimen was well-tolerated.

THU-195

An open-label, randomized, active control trial of 8 versus 12 weeks of elbasvir/grazoprevir for naive chronic hepatitis C genotype 1b patients with mild fibrosis (EGALITE): Impact of baseline viral loads and NS5A resitance-associated substitution

Email: fish6069@gmail.com

Background and aims: Grazoprevir/elbasvir achieved a high sustained virological response (SVR) rate (>95%) for patients with genotype 1 or 4 (HCV-1/4) infection. The current study aimed to evaluate the efficacy of truncated treatment period of 8-week grazoprevir/elbasvir for naïve, HCV-1b patients with mild fibrosis.
Method: EGALITE (NCT03186365), a randomized, open-label, active controlled trial, enrolled 82 treatment-naive HCV-1b patients with fibroscan < 9.5 kPa from 11 centers in Taiwan to receive 8 (n = 41) or 12 (n = 41) weeks of elbasvir/grazoprevir, stratified by baseline viral loads (VL, cut-off: 800, 000 IU/ml) and interleukin-28B genotype. The primary end point was SVR12 (HCV RNA < 12 IU/ml at posttreatment week 12). Resistance-associated substitution (RAS) was determined by next-generation sequencing.

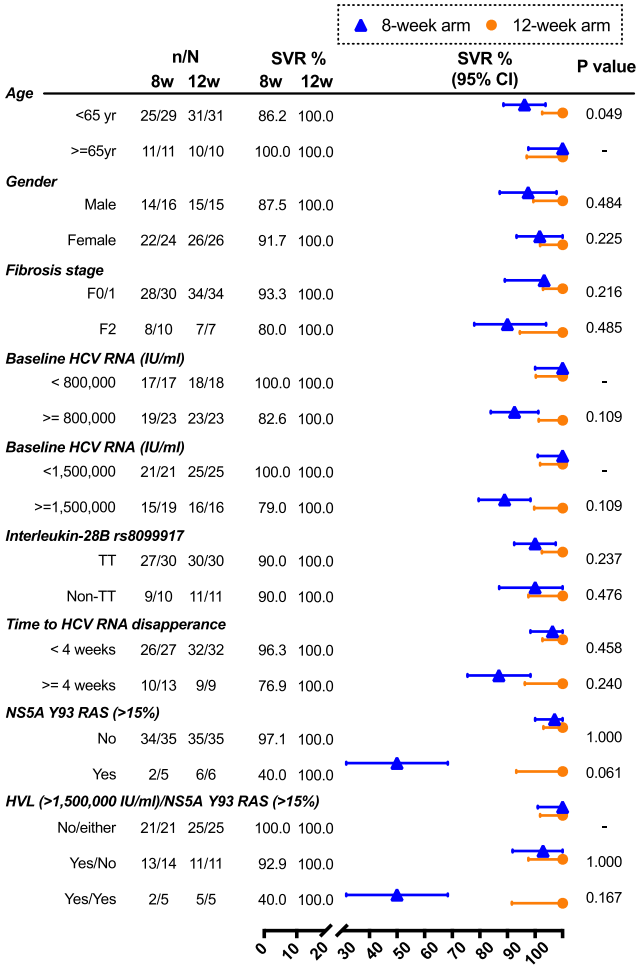

Figure 1: Rates of SVR12 stratified by subgroups between 8-week and 12-week arms among 81 naïve HCV genotype 1b patients with mild fibrosis.
Note: SVR, sustained virological response; CI, confidence interval; HCV, hepatitis C virus; NS5A, non-structural 5A protein; RAS, resistance-associated substitution; HVL, high viral loads.

Results: Overall, 50 (61%) were female; 46 (56.1%) with VL >800, 000 IU/ml and 22 (26.8%) interleukin-28B rs8099917 non-TT genotype. Both arms had comparable baseline characteristics/clinical features (Table 1). SVR12 was achieved by 87.8% (36/41, 95% confidence intervals [CI]: 81.4%-94.2%) and 100% (41/41, CI: 93.6%-100%) in full-analysis-set population and 90.0% (36/40, CI: 83.5%-96.5%) and 100% (41/41, CI: 93.6%-100%) in per-protocol population (excluding one HCV-6 patient) in 8-week and 12-week arms, respectively (both p = 0.055). In the 8-week arm, a significantly lower SVR12 rate was observed among patients with a high baseline VL (cut-off: 1, 500, 000 IU/ml, 79% [15/19] vs. 100% [21/21], p = 0.042) and those with baseline NS5A Y93H > 15% (40.0% [2/5] vs. 97.1% [34/35], p = 0.004). Between group analysis demonstrated patients with baseline VL > 1, 500, 000 IU/ml and NS5A RAS (Y93H > 15%) had a substantial lower SVR12 rate in 8-week (2/5 [40.0%, CI: 21.6%-58.4%]) than in 12-week arms (5/5 [100.0%, CI: 81.6%-100.0%] figure 1). All four HCV-1b relapsers in 8-week arm had NS5A RAS Y93H > 99% at posttreatment week 12. None experienced grade 3/4 adverse event, treatment-related serious adverse event and discontinuation.
Conclusion: Grazoprevir/elbasvir for 8-12 weeks was highly effective and safe in HCV-1b naïve patients with mild fibrosis, except for those with baseline high VL and significant NS5A RAS treated with 8-week regimen.

THU-196

Efficacy of 8 versus 12-weeks treatment with ledipasvir/sofosbuvir in chronic hepatitis C patients eligible for 8-weeks regimen in real world setting

Background and aims: Non-cirrhotic treatment-naive hepatitis C patients infected with genotype 1 can be treated with Ledipasvir/Sofosbuvir (LDV/SOF) for 8 weeks according to Summary of Product Characteristics, but in real world practice this regimen is frequently extended up to 12 weeks. The aim of our study was efficacy comparison of 8 and 12-weeks regimens in patients eligible for 8 weeks therapy.
Method: Data of HCV genotype 1 infected patients treated with LDV/SOF between 2015 and 2017 and included into the EpiTer-2 database were analysed in respect to patients characteristics and length of treatment.
Results: Among total of 1718 patients treated with LDV/SOF, 679 were included in the analysis and 238 (35%) received 8-weeks regimen, whereas 441 patients were treated for 12-weeks although fulfilled criteria for a shorter LDV/SOF course. Majority of patients were infected with genotype 1b (89%) and demonstrated minimal fibrosis (55%). Twelve weeks regimen was assigned significantly more frequently to patients with comorbidities (71% vs 45%), concomitant medications (69% vs 39%), advanced liver fibrosis (32% vs 1%), HIV coinfected (7.9% vs 2.5%) and HBV coinfected (13.4% vs. 4.6%). Sustained virologic response rate was similar after 8 (98%) and 12 (97%) weeks of therapy according to intent-to-treat analysis and reached 99% in both groups after exclusion of patients lost to follow-up.
Conclusion: We confirmed high and the same efficacy of 8 and 12-weeks regimens of LDV/SOF in non-cirrhotic chronic hepatitis C patients infected with genotype 1 which fulfilled criteria for 8 weeks regimen according to current label and expert guidelines. This real-world study confirmed no need of 12-weeks therapy with LDV/SOF in this population.

THU-197

Comparative effectiveness of 8 versus 12 weeks of ombitasvir/paritaprevir/ritonavir and dasabuvir in treatment-naive patients infected with HCV genotype 1b with non-advanced hepatic fibrosis

Background and aims: Since 2016 treatment-naïve patients with chronic hepatitis C virus genotype 1b infection with minimal or moderate fibrosis can be treated with ombitasvir/paritaprevir/ritonavir and dasabuvir (OprD) for 8 weeks according to Summary of Product Characteristics updated based on results of Garnet trial. The aim of our study was to assess the comparative efficacy of 8 and 12-week treatment duration of OPrD in patients with none, minimal or moderate fibrosis (F0-F2) treated in real-world setting.
Method: We analysed data of 3067 HCV genotype 1b infected patients treated with OPrD between 2015 and 2017 obtained from EpiTer-2 database.
Results: A total of 800 patients with non-advanced fibrosis were enrolled to the study, that included 223 (29%) treated for 8-weeks and 577 patients fulfilling criteria for shorter treatment but assigned to 12-weeks regimen. Majority of patients had no or minimal fibrosis, and they were more frequently treated for 8 weeks (82%) than 12 weeks (61%). Longer treatment duration was more often administered in patients with comorbidities (56% vs 31%), concomitant medications (45% vs 30%), HIV coinfected (0.7% vs 0%) and HBV coinfected (11.6% vs. 7.2%). SVR was achieved in 211 (95%) patients treated for 8 weeks and 561 (97%) for 12 weeks ($p = 0.09$). After exclusion of lost to follow-up patients, SVR rate reached 96% and 98%, respectively, and the difference was statistically significant according to the Fischer analysis ($p = 0.02$). All 10 non-responders from the 8 weeks group were naïve to DAA and demonstrated viral load below 6 million U/l. All except one demonstrated minimal fibrosis (F1) and 9 were males. We were not able to identify factors associated with non-response in this group.
Conclusion: We confirmed high effectiveness of 8 and 12-weeks regimens of OPrD in genotype 1b HCV infected patients with non-advanced fibrosis and supported no need of 12-weeks therapy in large majority of such patients. Further analysis of growing population treated for 8 weeks is necessary to identify possible factors responsible for non-response.

THU-198

Efficacy and safety of glecaprevir/pibrentasvir treatment for 8 weeks in treatment-naive patients with chronic hepatitis C virus infection without cirrhosis or with compensated cirrhosis: Analysis of data pooled from phase 2 and 3 studies

Eli Zuckerman[1], Julio Gutierrez[2], Andrew Ustianowski[3], Susanna Naggie[4], Florin Alexandru Caruntu[5], Natarajan Ravendhran[6], Samuel Sigal[7], Lisa Barrett[8], Stanley Cohen[9], Eric Crown[10], Doug Dylla[10], Linda Fredrick[10], Stanley Wang[10], Ariel Porcalla[10], Federico Mensa[10], Savino Bruno[11]. *[1]Carmel Medical Center, Hafia, Israel; [2]St. Vincent Medical Center, Los Angeles, CA, United States; [3]North Manchester General Hospital, Manchester, United Kingdom; [4]Duke University School of Medicine, Durham, NC, United States; [5]"Matei Bals" National Institute for Infectious Diseases, Bucharest, Romania; [6]Digestive Disease Associates, Cantonsville, MD, United States; [7]Montefiore Medical Center, New York, NY, United States; [8]Dalhousie University, Halifax, Nova Scotia, Canada; [9]UH Cleveland Medical Center, Cleveland, OH, United States; [10]AbbVie Inc., North Chicago, IL, United States; [11]Humanitas University and Humanitas Research Hospital, Milan, Italy*
Email: eric.crown@abbvie.com

Background and aims: The once-daily, all-oral, fixed-dose direct-acting antiviral combination glecaprevir (developed by AbbVie and Enanta) and pibrentasvir (G/P) is approved to treat adults chronically infected with hepatitis C virus (HCV) genotypes (GT) 1-6. In HCV treatment-naïve patients, G/P is currently approved for 8 weeks in non-cirrhotic patients and 12 weeks in patients with compensated cirrhosis. A recent post-approval study of G/P for 8 weeks in treatment-naïve cirrhotic patients with HCV GT1, 2, 4–6 showed a high rate of sustained virologic response at post-treatment Week 12 (SVR12) that was similar to the rate with 12 weeks of treatment. This integrated analysis evaluated the efficacy and safety of G/P for 8 weeks in treatment-naïve patients without cirrhosis or with compensated cirrhosis.
Method: Data were pooled from treatment-naïve patients with HCV GT1, 2, 4–6 without cirrhosis or with compensated cirrhosis who received G/P for 8 weeks across 8 Phase 2 and 3 clinical trials.
Results: Of 1163 patients, 280 (24%) had cirrhosis. Most patients were white (79%) and had HCV GT1 (63%) or GT2 (22%); mean age was 53 years. Liver disease characteristics for non-cirrhotic vs cirrhotic patients were: platelets < 100 × 109/L, 1% vs 17%; aspartate amino-transferase-to-platelet ratio (APRI) ≥ 2, 2% vs 34%; FibroScan ≥ 20 kPa, 0% vs 51%; FibroTest ≥ 0.72, 7% vs 69%; FIB-4 ≥ 3.25, 4% vs 52%. The SVR12 rate (intention-to-treat, ITT) was 98% (1139/1163) overall, and was 98% in both non-cirrhotic (865/883) and cirrhotic (274/280) patients. Excluding non-virologic failures, the modified ITT (mITT) SVR12 rate was 99.9% (1139/1140); one non-cirrhotic patient had virologic relapse (<0.1%; 1/1145). SVR12 rates by baseline laboratory thresholds are shown (Table). Treatment-emergent adverse events (AEs) occurred in 57% (662/1163) of patients. The most frequent AEs (>5%) were headache (11%), fatigue (10%), and nausea (7%). Serious AEs were reported in 3% (30/1163) of patients. AEs led to study drug discontinuation in 0.3% (4/1163) of patients.

Table: mITT SVR12 rates by baseline laboratory thresholds.

	Below threshold, SVR12% (n/N)	Equal to or above threshold, SVR12% (n/N)
Platelets 100 × 10^9/L	100 (52/52)	99.9 (1087/1088)
APRI 2*	99.9 (1020/1021)	100 (107/107)
FibroTest 0.72†	100 (572/572)	100 (222/222)
FIB-4 3.25‡	99.9 (945/946)	100 (172/172)

Missing patients: *n = 12; †n = 346; ‡n = 22.

Conclusion: G/P for 8 weeks was highly efficacious and well tolerated regardless of cirrhosis status in treatment-naïve patients with HCV GT1, 2, 4–6 infection.

THU-199

Awake the dormants: Barriers to access to care and cure in patients with chronic HCV infection

Orly Azulay[1], Eyal Ashkenazi[1], Yulia Kovalev[1], Eli Zuckerman[1]. *[1]Carmel Medical Center, Technion Faculty of Medicine, Liver Unit, Haifa, Israel*
Email: elizuc@clalit.org.il

Background and aims: Despite improved safety and efficacy of HCV treatment, challenges remain in referral to care and access to treatment. Failure to treat and cure eligible-for-treatment patients may prevent achieving the goal of HCV elimination in Israel by 2030. AIM: To assess the number of "dormants" HCV patients (HCV-positive patients eligible for anti-viral treatment and were not referred to liver clinics) and to identify the patients'- and providers barriers to referral to care and to cure.
Method: Data were obtained from the computerized records and database of Haifa and Western Galilee District of Clalit Health Services (CHS) (the largest CHS district responsible for 800, 000 insured individuals) at years 2000-2012. The database contains information regarding demographic parameters, laboratory tests and pharmacy records, hospitalization and primary care physician records and death-related data. 3800 HCV-Ab positive patients were identified of whom 2895 were thoroughly investigated. 745 patients were HCV-Ab "low-positive" (PCR negative), 590 have been previously treated and cured, 259 left CHS, 81 died, 156 were active drug users, 136 had severe illness, mainly psychiatric, and 104 lost to follow-up. For the remaining 824 potentially eligible-for -treatment patients, a letter (e-mail) was sent to the primary care physician (PP) requesting completeness of the work-up including complete liver function tests, quantitative HCV RNA, HCV genotype and shear-wave elastography (logistics was assisted by the Carmel MC Liver Unit).
Results: Out of these 824 potentially eligible for treatment patients HCV-positive, only 208 patients were treated and achieved SVR and 108 are candidate to initiate treatment soon (28%). Overall barriers to referral or treatment among 1116 HCV patients were of the following reasons: providers'-related 317 (28%): no response from the PP (214), no work-up was performed (103), patients'-related 483 (43%): active IDU (156), severe illness, mainly psychiatric (136), logistic problems (128, of whom 106 are receiving OST), not interested in treatment (56) and financial reasons (7).
Conclusion: 40% of the barriers to cure are provider-related and 60% are patient-related. Ways to overcome these barriers and improve access to care and cure will be presented.

THU-200

The Real-Eorld Israeli experience of treating mild and severe chronic hepatitis C patients with elbasvir/grazoprevir: A large multi-center cohort study

Eli Zuckerman[1], Eyal Ashkenazi[1], Yulia Kovalev[1], Oranit Cohen-ezra[2], Ella Veitsman[3], Tarek Saadi[3], Matthias Carlebach[4], Dr. Rawi Hazzan[5], Rifaat Safadi[6], Tova Goldberg[6], Ran Oren[6], Yaffa Ashur[7], Michal Carmiel[8], Yona Kitay[9], Ruthy Hadary[9], Saif Abu-Mouch[10], Rafael Bruk[11], Yoram Menachem[11], Helena Katchman[11], Oren Shibolet[11], Orly Sne Arbib[12], Haim Shirin[13], Ran Tur-Kaspa[14], Marius Braun[14], Michal Cohen-Naftaly[14], Amir Shlomai[14]. *[1]Carmel Medical Center, Haifa, Israel; [2]Sheba Medical Center, Ramat Gan, Israel; [3]Rambam Medical Center, Haifa, Israel; [4]Bnei Zion Medical Center, Haifa, Israel; [5]HaEmek Medical Center, Haifa, Israel; [6]Hadassah Medical Center, Jerusalem, Israel; [7]CHS, Liver Clinic, Southern District, Israel; [8]Western Galilee Medical Center, Nahariya, Israel; [9]Meir Medical Center, Kfar Saba, Israel; [10]Hillel Yaffe Medical Center, Hadera, Israel; [11]Tel Aviv Medical Center, Tel Aviv, Israel; [12]CHS, Talpiot Clinic, Jerusalem, Israel; [13]Assaf Harofeh Medical Center, Tzrifin, Israel; [14]Rabin Medical Center, Petach Tikva, Israel*
Email: elizuc@clalit.org.il

Background and aims: Elbasvir (EBR) and Grazoprevir (GZR) is a fixed dose combination regimen of Direct Antiviral Acting Agents (DAAs) that was approved in the USA and Europe for Chronic

Hepatitis C (CHC) patients with Genotype (GT) 1 and 4. In 2016, this regimen has been included in the Israeli Essential Drugs List (EDL) for F3-F4 CHC patients. F2 patients were included in 2017 EDL, and since January 2018 all CHC patients (F0-F4) are eligible for treatment. In this study we aim to characterize the real-world effectiveness and tolerability of EBR/GZR in CHC patients with all fibrosis stages.

Method: Data on demographics, clinical features, tolerability and virological response were collected from 15 centers in Israel in both hospitals and community clinics. Data would be presented for over 620 patients treated with EBR/GZR between June 2016 and March 2019.The primary efficacy end point was sustained virologic response at follow-up week 12 (SVR12); special attention was paid to co-morbidities, kidney function and drug-drug interactions (DDIs).

Results: This interim analysis includes 519 patients who were treated with EBR/GZR. Of the 519 patients, 46% had mild and 54% had advanced fibrosis (30% were cirrhotic patients). 52% of the patients were males. Mean age was 56.8 ± 14 years old. Patients with mild fibrosis were younger than patients with severe fibrosis (53 years old vs. 60 years old, P < 0.05). Most of the patients (84%) had GT1b. 12.7% (n = 51) of the patients had chronic kidney disease (CKD) stage 3-5 (stage 4/5- 6%), 14% (n = 74) had type 2 diabetes mellitus, 6% (n = 31) had HCV/HIV co-infection and 8 patients had symptomatic cryoglobulinemia. The most common concomitant medications included anti-hypertensive (31%), anti-acids (17%) and statins (13%).

Effectiveness: Interim analysis showed negative PCR at the end-of-treatment in 279 patients (99.3%) and SVR12 in 190/196 patients (97.4%). SVR12 was similar in patients with advanced- and with mild fibrosis (97.2% vs. 96.4%, respectively). Tolerability data which includes most common adverse events and SAEs will be presented.

Conclusion: CHC treatment with EBR/GZR in a real-world setting was associated with high SVR12 rates and good tolerability in both patients with mild as well as with advanced fibrosis.

Viral hepatitis B/D: Clinical aspects except therapy

Hepatitis D infection and risk of hepatocellular carcinoma: A systematic review and meta-analysis of observational studies

Dulce Alfaiate[1], Nicolas Goossens[2], Sophie Clément-Leboube[3], Francesco Negro[2,3]. [1]*University of Geneva, Department of Pathology and Immunology, Geneva, Switzerland;* [2]*Geneva University Hospital, Division of Gastroenterology and Hepatology, Geneva, Switzerland;* [3]*Geneva University Hospital, Division of Clinical Pathology, Geneva, Switzerland*

Email: francesco.negro@hcuge.ch

Background and aims: Hepatitis D virus (HDV) infection is the most severe form of chronic viral hepatitis, with a faster progression to cirrhosis and increased mortality compared with hepatitis B virus (HBV) monoinfection. However, the role of HDV in the development of hepatocellular carcinoma (HCC) remains debated.

We conducted a systematic review and meta-analysis of epidemiological studies to examine whether chronic HDV infection is associated with an increased risk of HCC compared to chronic HBV monoinfection.

Method: We searched Pubmed, Embase and Web of Science databases, with no date or language restriction. Search terms referred to chronic hepatitis D, liver disease progression and HCC.

We considered cohort, case-control and cross-sectional studies allowing the calculation of effect estimates for the association between chronic HDV infection and HCC, in comparison to chronic HBV infection, according to the definitions provided by the authors of each study.

Data extraction and quality evaluation were performed by two authors. Data were pooled using random-effects models and heterogeneity between studies was examined using the I^2 statistic.

Results: Eighty-eight studies (64 case-control studies including 20782 patients and 24 cohorts including 74822 patients), from 34 countries, were selected. Ten studies adjusted for confounders and 11 cohorts were prospective. The overall analysis showed a significantly increased risk of HCC in patients with chronic HDV infection (Figure),

Figure: (abstract: THU-203)

despite the presence of substantial study heterogeneity (OR 1.25; 95% CI 1.00-1.56; p = 0, 047; I^2 = 68%). The effect was higher in cohort studies (OR 1.68; 95% CI 1.23-2.22; p = 0.0009; I^2 = 64.31%), particularly in those with a prospective design, with reduced heterogeneity (OR 2.36; 95% CI 1.34-4.14; p = 0.0029; I^2 = 31.37%) It was also confirmed in studies excluding children and patients infected with hepatitis C or human immunodeficiency virus (HIV) and was particularly strong in cohorts of HIV-infected patients.
Conclusion: To our knowledge, this is the first meta-analysis showing a significant risk increase for development of HCC in chronic HDV infection. Despite important study heterogeneity, this association was stronger with increasingly robust study design, in particular in prospective cohorts and in studies with adjustment for confounders. These data suggest a carcinogenic role for HDV and justify the need for strict HCC screening procedures in chronic hepatitis D.

THU-204

Analysis of interleukin 28B rs12979860 polymorphism relationship with spontaneous clearance of hepatitis D virus infection in Mongolian population

Zaya Batsuuri[1], Purevjargal Bat-Ulzii[2], Anir Enkhbat[2], Naranbaatar Dashdorj[3], Ganzorig Chimed[1], Enkhbaatar Perenlei[4], Odgerel Oidovsambuu[1,2,5]. *[1]New Mongol Institute of Technology, Nano and Chemical Engineering Department, Ulaanbaatar, Mongolia; [2]Liver Center, Laboratory, Ulaanbaatar, Mongolia; [3]Onom Foundation, Head Office, Ulaanbaatar, Mongolia; [4]The University of Texas Medical Branch at Galveston, Anesthesiology, Galveston, United States; [5]National University of Mongolia, Genetic Engineering Department, Ulaanbaatar, Mongolia*
Email: zayaa217@gmail.com

Background and aims: Mongolia has the highest prevalence of hepatitis B (10.6%), C (11.1%) and D (7.2%) virus infections in the world that leads to highest mortality rate of the liver cancer.
Previous studies showed the single nucleotide polymorphism rs12979860 near the interleukin 28B (IL28B) is strongly associated with spontaneous clearance of hepatitis C virus and interferon treatment for this virus. But there is no adequate evidence of rs12979860 polymorphism near the 28B (IL28B) gene for spontaneous clearance of hepatitis D virus (HDV) using large number of statistically relevant samples.
The aim of our study is to investigate the association of rs12979860 polymorphism near the IL28B gene with spontaneous clearances of hepatitis D virus in Mongolian population.
Method: We have analyzed total of 374 participants (125 HDV spontaneously cleared people, 249 healthy people) for their rs12979860 polymorphism using restriction fragment length polymorphism (RFLP) assay and identified the association of spontaneously clearance of HDV and rs12979860 polymorphism. Randomly selected samples (96 samples) were Sanger sequenced for confirmation of RFLP results.
Results: The results of RFLP analysis showed that genotype frequencies of rs12979860 locus in healthy population (normal population) are following: 88.7% (221) for CC genotype, 11.245% (28) for CT genotype and 0.0 for TT genotype. In the HDV spontaneously cleared people group, the analysis showed that the genotype frequencies of rs12979860 locus are following: 84.8% (106) for CC genotype, 15.2% (19) for CT genotype and 0.0 for TT genotype. Statistical analysis by comparing the genotype frequencies of healthy group and HDV spontaneously cleared group showed that there is no significant difference between these two groups (p = 0.276, CI = 0.95).
Conclusion: There is no significant difference of genotype frequencies of rs12979860 locus near IL28B gene between the group of healthy population and group of HDV spontaneously cleared people.

THU-205

Evaluation of HBV outcomes after treatment discontinuation from 4 phase 3 studies

Maria Buti[1], Thomas Berg[2], Henry Chan[3], Vithika Suri[4], Hongyuan Wang[4], Anuj Gaggar[4], Edward Gane[5], Jörg Petersen[6], Sang Hoon Ahn[7], Patrick Marcellin[8]. *[1]University Hospital Vall d'Hebron, Barcelona, Spain; [2]Leipzig University, Leipzig, Germany; [3]Chinese University of Hong Kong, Hong Kong, Hong Kong; [4]Gilead Sciences, Inc., Foster City, United States; [5]Auckland City Hospital, New Zealand Liver Transplant Unit, Auckland, New Zealand; [6]University of Hamburg, Hamburg, Germany; [7]Yonsei University College of Medicine, Seoul, Korea, Rep. of South; [8]Hôpital Beaujon, Viral Hepatitis Research Unit, Clichy, France*
Email: vithika.suri@gilead.com

Background and aims: Current international guidelines recommend stopping Nucleot (s)ide analogue (NA) therapy in a select group of patients with the aim of promoting sustained off treatment response. However, the durability and effectiveness of stopping NA therapy appears to be poor with results from several studies reporting virologic remission response rates of ~50%. Here we evaluate 4 large phase 3 studies for responses following treatment discontinuation.
Method: Patients from 4 phase 3 studies of TDF with or without Peg-IFN in HBeAg negative and positive patients were followed for up to 144 weeks after discontinuing treatment. Multivariate logistic regression modeling with stepwise selections were used to evaluate baseline (BL) and post-treatment discontinuation predictors of off-treatment responses, including; HBsAg loss and ALT < ULN with HBV DNA <2000 IU/ml, each in 3 separate models
Results: Of the 1423 enrolled in the parent studies, 660 HBsAg positive patients entered treatment free follow-up (TFFU) with a mean follow-up duration of 34 weeks. Demographic and disease characteristics of patients at the time of withdrawal are shown in Table. At the end of the TFFU, 2% had HBsAg loss and 17% of patients had ALT < ULN with DNA <2000 IU/ml. For the virologic outcomes, a lower BL HBV DNA level (Odds Ratio (OR): 0.748, p < 0.001), an increased duration of HBV DNA suppression (OR: 1.003, p < 0.0001), HBeAg negativity (OR: 2.821, p = 0.0013), a smaller increase in HBV DNA off treatment (OR: 0.505, p < 0.0001) and NA treatment (OR (NA vs Peg IFN): 8.285, p < 0.0001) at the time of withdrawal were significant predictors of patients who remain ALT <ULN with HBV DNA <2000 IU/ml at the end of follow-up. Predictors of patients with HBsAg loss include low BL HBV DNA levels (OR: 0.342, p < 0.001) and low HBsAg levels (OR: 0.445, p < 0.001) at the time of withdrawal.

		N = 660
Median Age, y (range)		37 (18-69)
Male, n (%)		449 (68)
Asian, n (%)		435 (67)
Genotype, n (%)	**A**	72 (11)
	B	161 (24)
	C	243 (37)
	D	171 (26)
Median BL ALT, U/L (Q1, Q3)		84 (56, 132)
Median BL HBV DNA, log10 IU/ml (Q1, Q3)		7 (5.6, 8)
Median BL HBsAg, log10 IU/ml (Q1, Q3)		3.9 (3.4, 4.4)
Treatment n (%)	**NUC**	275 (42)
	Peg IFN	161 (24)
	NUC + Peg IFN	324 (49)
Mean TFFU Duration, weeks (SD)		33.7 (37.29)
Median BL ALT at treatment withdrawal, U, L (Q1, Q3)		32 (23, 48)
Median BL HBV DNA at treatment withdrawal, log10 IU/ml (Q1, Q3)		1.30 (1.15, 1.52)
Median BL HBsAg at treatment withdrawal, log10 IU/ml (Q1, Q3)		3.47 (2.83, 3.97)
HBeAg positive at treatment withdrawal, n (%)		251 (38)

Conclusion: Treatment discontinuation results in the majority of patients having recurrence of HBV viremia with low rates of HBsAg loss or maintenance of inactive carrier state. Predicting outcomes in a diverse population will be required for safe and effective treatment discontinuation.

THU-206

HBV DNA relapse after stopping nucleoside analogue therapy in patients with HBsAg loss: Detectable pre-genomic HBV RNA is a better predictor of relapse than ultra-sensitive HBsAg- 'implications for HBV cure'

Ivana Carey[1], Jeffrey Gersch[2], Christiana Moigboi[1], Matthew Bruce[1], Mary Kuhns[2], Gavin Cloherty[2], Geoffrey Dusheiko[1], Kosh Agarwal[1]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom;* [2]*Department of Infectious Diseases, Abbott Diagnostics, Chicago, United States*
Email: ivana.kraslova@kcl.ac.uk

Background and aims: Functional cure in chronic hepatitis B (CHB) is defined as a loss of HBsAg, undetectable HBV DNA and absence of ongoing liver damage. The EASL HBV guidelines recommend consolidation therapy with nucleos (t)ide analogue (NA) for at least 6 months after achieving HBsAg loss. HBV DNA or HBsAg re-activation is rare but markers predicting relapse are lacking. Serum pre-genomic (pg) HBV RNA reflects cccDNA transcriptional activity, and ultra-sensitive HBsAg assay (CLEIA HBsAgHQ Fujirebio) enables HBsAg detection at very low levels (0.5mIU/ml). We have evaluated the ability of pgHBV RNA, ultrasensitive HBsAg and anti-HBs antibody titre to predict HBV re-activation in patients who achieved HBsAg loss and stopped NA therapy
Methods: 19 CHB non-cirrhotic patients (61%males, median age 43.7 yrs) were treated for a median duration 8.5 yrs (1.6-12.2) with tenofovir (TDF) and achieved HBsAg loss after a median 7.5 yrs. Therapy with TDF was continued for median one year (0.5-2.7 yrs) after HBsAg loss. 12 weeks after TDF withdrawal 2 (11%) patients had detectable HBV DNA, but not HBsAg (qualitative). PgHBV RNA was measured by a novel real-time PCR research assay (Abbott Diagnostics [LLDQ 1.65 $\log_{10}$U/ml]), ultrasensitive HBsAg by CLEIA HBsAgHQ (Fujirebio) [LLDQ 0.5mIU/ml] and anti-HBs antibody titre on Abbott Architect [mIU/ml]. Levels were compared between patients according to re-activation status. In patients with re-activation TDF therapy was re-commenced and follow-up serum samples were available for test.
Results: Age, therapy duration overall and after achieving HBsAg loss, ALT activity and HBsAg levels by ultrasensitive test were similar at TDF withdrawal irrespective of re-activation. At the time of TDF withdrawal all patients had detected HBsAg by ultrasensitive test (median 1.23, range 0.6-190 mIU/ml). However, pgHBV RNA was exclusively detected in 2 patients with re-activation (median 2.12, range 2.01-2.23 $\log_{10}$U/ml, p = 0.02). Anti-HBs antibodies titres were lower in patients with re-activation (median 0.3 vs. 3.6 mIU/ml, p = 0.01). At the first visit after TDF withdrawal patients with re-activation had detectable HBV DNA (45600 and 12100 IU/ml), pgHBV RNA and HBsAg levels by ultra-sensitive assay increased from concentrations at therapy cessation. 12 weeks after re-commencing TDF, both HBV DNA and pgHBV RNA were not detected, HBsAg concentrations declined and anti-HBs antibodies levels increased.
Conclusion: Pre-genomic HBV RNA and anti-HBs antibodies are helpful makers to predict sustained loss of HBsAg without a HBV DNA increase after NA withdrawal in CHB patients who have achieved HBsAg loss on therapy. The HBsAg ultrasensitive assay provided a useful insight into dynamics of HBsAg changes after NA withdrawal but did not help to predict HBV re-activation. Larger studies assessing the utility of these markers to predict HBV re-activation after HBsAg loss are needed.

THU-207

A retrospective review of the incidence of hepatocellular carcinoma in patients with chronic hepatitis B attending the regional hepatitis clinic in Northern Ireland

Geraldine Carroll[1], Johnny Cash[1], Gemma Wasson[1], Conor Braniff[1], Neil McDougall[1]. [1]*Royal Victoria Hospital, Belfast, United Kingdom*
Email: gcarroll02@googlemail.com

Background and aims: Hepatocellular Carcinoma (HCC) is a major concern in patients with Chronic Hepatitis B (CHB) and may develop, even when a patient is adequately treated. Incidence of HCC is reported as being higher in patients with co-factors including cirrhosis, high viral load, family history of HCC, male sex and alcohol excess.
In Northern Ireland all Hepatitis B cases are managed at a single regional centre.
The aim of this study was to ascertain the incidence of HCC in the CHB cohort attending the regional viral hepatitis clinic.
Method: Data was analysed using the regional liver unit Hepatitis B database. This information was cross-referenced with the CHB treatment database and Northern Ireland Electronic Care Record.
Co-infected patient were not included in this review.
Results: 1126 patients attended the Liver Unit for management of Hepatitis B between 2009 and 2018.
15 (1.3%) were diagnosed with HCC. 12 (80%) were male. 10 patients (67%) had established cirrhosis.
3 (20%) received transartertial chemoembolization (TACE), 2 (13%) were transplanted and 2 (13%) underwent resection, 1 (7%) received Sorafenib therapy, 1 (7%) underwent resection, TACE and Sorafenib therapy, 1 (7%) received ablation therapy. 5 (33%) were not suitable for intervention.
11 (73%) are now deceased.
10 patients (67.5%) were South East Asian in ethnicity, 1 (6.5%) was from Northern Ireland with 1 (6.5%) each from Portugal, Nigeria, Spain and Lithuania. 4 of the 5 patients who developed HCC without underlying cirrhosis were South East Asian men, the remaining patient was Portuguese.
7 patients (47%) had significant viraemia of >20, 000 at the time of diagnosis.
12 (80%) were treated with nucleotide/nucleoside analogues while the remaining 3 (19%) were referred at an advanced stage and not commenced on treatment. 9 (69%) of those receiving antiviral therapy achieved complete viral suppression at their last recorded HBV DNA PCR.
In total, 147 patients received antiviral therapy, of whom 49 (33%) had cirrhosis. The incidence of HCC in this high risk group was 12 (8%).
Conclusion: The incidence of HCC in patients with CHB attending the regional viral hepatitis clinic is 1.3% but is much higher in the subgroup that have received antiviral therapy (8%). Significant cofactors include male sex and South East Asian ethnicity, high viral load and established cirrhosis.

THU-208

Characterization of a novel chemiluminescent enzyme immunoassay for the quantitation of antibodies to hepatitis B core antigen class IgG and correlation with intrahepatic HBV covalently-closed-circular DNA

Gian Paolo Caviglia[1], Francesco Tandoi[2], Giulia Troshina[1], Lucio Boglione[1], Chiara Rosso[1], Elisabetta Bugianesi[1], Alessia Ciancio[1], Renato Romagnoli[2], Mario Rizzetto[1], Giorgio Maria Saracco[1], Antonina Smedile[1], Antonella Olivero[1]. [1]*University of Turin, Department of Medical Sciences, Turin, Italy;* [2]*University of Turin, Department of Surgical Sciences, Turin, Italy*
Email: caviglia.giampi@libero.it

Background and aims: Non-invasive biomarkers for the cure and the management of chronic hepatitis B (CHB) infection are an unmet need. Our aim was to characterize a novel HBV assay for the quantitation of anti-HBc IgG and to assess the correlation between

serum anti-HBc IgG and intrahepatic HBV cccDNA, in comparison to quantitative hepatitis B surface antigen (qHBsAg) and hepatitis B core-related antigen (HBcrAg) in patients with CHB infection.
Method: Serum samples and liver specimens were collected from 35 CHB patients (26M/9F; median age 52 [20-70] years; 25 chronic hepatitis and 10 cirrhosis). Intrahepatic HBV cccDNA was measured by digital-droplet PCR (Bio-Rad, USA) following total DNA digestion with plasmid safe ATP-dependent DNase. Serum qHBsAg and HBcrAg were measured by CLEIA on Lumipulse® G600 II analyzer (Fujirebio, Japan). qHBsAg limit of sensitivity was 0.005 IU/ml. The lower limit of detection (LLoD) and the measurement range of HBcrAg were 2 Log U/ml and 3-7 Log U/ml, respectively. The WHO 1st International Standard for anti-HBc (NIBSC code 95/522) was used for the calibration of anti-HBc IgG assay (Lumipulse® G HBcAb-N, Fujirebio).
Results: The new assay for anti-HBc IgG quantitation showed a linear dynamic range ($R2 = 0.997$, $p < 0.001$); lower limit of detection (LLoD) and quantitation (LLoQ) were estimated at 0.5 IU/ml and 0.8 IU/ml, respectively. The coefficient of variation (CV) for repeatability was 3.1% whereas the CV for reproducibility was 4.0%. In liver specimens, mean HBV cccDNA levels were 3.11 ± 1.14 Log copies/105 cells; in serum samples, mean qHBsAg, HBcrAg and anti-HBc IgG values were 3.13 ± 1.31 Log IU/ml, 3.8 ± 1.9 Log U/ml and 3.68 ± 0.83 Log IU/ml, respectively. In 18/35 (51%) patients, HBcrAg was below the measurement limit of the assay (<3 Log U/ml). HBV cccDNA correlated significantly with qHBsAg ($r = 0.624$, $p < 0.001$), HBcrAg ($r = 0.734$, $p < 0.001$) and anti-HBc IgG ($r = 0.553$, $p < 0.001$). In patients with HBcrAg values <3.0 Log U/ml, intrahepatic HBV cccDNA correlated significantly with anti-HBc IgG ($r = 0.752$, $p < 0.001$) but not with qHBsAg ($r = 0.384$, $p = 0.116$).
Conclusion: Anti-HBc IgG quantitation by CLEIA was a sensitive and accurate assay. Among the investigated biomarkers, HBcrAg was confirmed as reliable surrogate marker of intrahepatic HBV cccDNA. In patients with low HBcrAg levels (<3.0 log), anti-HBc IgG quantitation by CLEIA may be proposed as alternative marker for intrahepatic HBV cccDNA measurement.

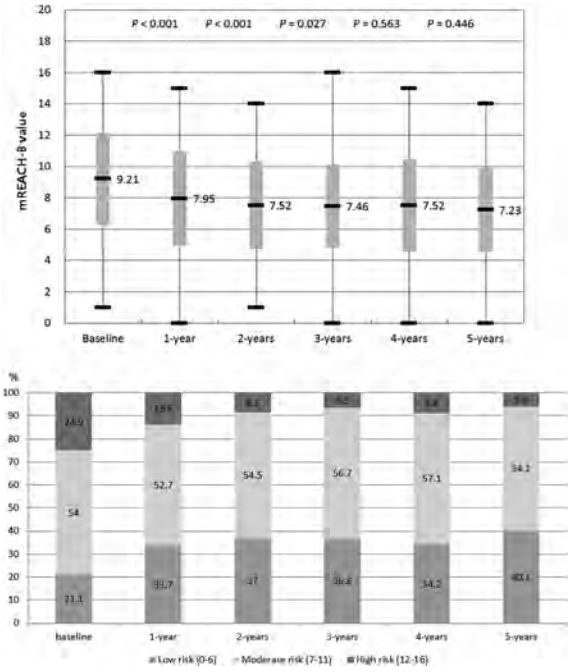
Email: ksukorea@yuhs.ac

Background and aims: The transient elastography (TE)-based risk prediction models such as mREACH-B and LSM-HCC are used to predict the risk of hepatocellular carcinoma (HCC) development. However, the influence of antiviral therapy (AVT) on these TE-based risk prediction models in patients diagnosed with chronic hepatitis B (CHB) is unknown.
Method: In this retrospective study, Patients with CHB who initiated AVT using entecavir or tenofovir were recruited from 13 referral Korean tertiary academic institutes. Of the existing TE-based risk prediction models, the mREACH-B model was selected.
Results: Between 2007 and 2015, 1, 034 patients with CHB (545 non-cirrhotic, 489 cirrhotic) who initiated AVT using entecavir ($n = 729$) or tenofovir ($n = 305$) were recruited. The mean age of the study population was 46.8 years, and 61.8% ($n = 639$) of the patients were male. In subgroup analyses, patients with cirrhosis and those with HCC showed higher mREACH-B scores at baseline compared with those of the counterparts (8.2 *vs.* 10.3 and 9.1 *vs.* 11.6, respectively, all $P < 0.05$). The mean mREACH-B study population score was 9.21 at baseline, and it decreased significantly to 7.46 by 3 years of AVT (mean 7.95 at year 1, 7.52 at year 2, and 7.46 at year 3, all $P < 0.05$) and was maintained until 5 years of AVT (mean 7.52 at year 4 and 7.23 at year 5, all $P > 0.05$). The proportion of high-risk patients (mREACH-B score ≥12) was 24.9% at baseline, and it decreased significantly to 8.5% by year 2 of AVT (13.6% at year 1 and 8.5% at year 2; $P < 0.001$) and was maintained until year 5 of AVT (6.5% at year 3, 8.8% at year 4, and 5.9% at year 5, all $P > 0.05$). The mREACH-B scores at baseline, year 1 of AVT, and year 2 of AVT independently predicted HCC development (hazard ratio = 1.123-1.262), together with evidence of cirrhosis and platelet count (all $P < 0.05$). The cumulative incidence rate of HCC was significantly higher in high-risk patients than in low- (mREACH-B score 0-6) and moderate-risk patients (mREACH-B score 7-11) from the baseline (10.39% *vs.* 1.42% at year 5), year 1 AVT (11.95% *vs.* 2.51% at year 5), and year 2 AVT (14.03% *vs.* 2.91% at year 5) (all $P < 0.05$, log-rank tests). Similar results were obtained in the subgroups with and without cirrhosis.



Conclusion: The mREACH-B score was decreased significantly by AVT, up to 3 years. In addition, the mREACH-B score at baseline, year 1 AVT, and year 2 AVT significantly predicted HCC development. Thus, repeated assessment of the mREACH-B score is required to predict the changing risk of HCC development in patients with CHB undergoing AVT.

THU-210

HBcrAg levels at baseline are not predictive for HBsAg and HBeAg loss in patients treated with adefovir and PEG-interferon

Robin Erken[1], Hans Zaaijer[2,3], Ed Bakker[3], Neeltje Kootstra[1], Henk Reesink[2]. [1]*Amsterdam University Medical Centers, location AMC, Experimental immunology, Amsterdam, Netherlands;* [2]*Amsterdam University Medical Centers, location AMC, Gastroenterology and hepatology, Amsterdam, Netherlands;* [3]*Sanquin Blood Supply, Amsterdam, Netherlands*
Email: r.erken@amc.uva.nl

Background and aims: Various studies indicated that Hepatitis B core related antigen (HBcrAg) levels are correlated with intrahepatic covalently closed circular DNA (cccDNA) activity and serum HBV-DNA and HBV-RNA. The association with HBsAg levels is less clear. With various new HBV direct acting antiviral compounds under development, HBcrAg may be a valuable marker for HBV replication when HBV surface antigen (HBsAg) and HBV DNA are targeted and no longer reflect the viral intrahepatic HBV replication. However, HBcrAg as a predictor for response to treatment is not known. Here we aimed to identify the predictive value of HBcrAg for treatment outcome in CHB patients treated with a combination of adefovir and pegylated interferon alpha-2a (PEG-IFN).
Method: 92 CHB patients with high HBV-DNA levels were treated with adefovir and PEG-IFN for 48 weeks in a prospective study described previously. HBsAg loss was seen in 11% (5/44) of the HBeAg positive and 17% (8/48) of the HBeAg negative patients, two years after start of the study. HBcrAg was measured in stored serum samples from these patients at baseline (BL) using the Lumipulse chemiluminecence enzyme immunoassay analyser (Fujirebio Inc., Tokyo Japan) with a lower limit of detection of 3 $\log_{10}$ U/ml. Treatment outcomes were: HBsAg loss (functional cure), HBeAg loss and virological response (HBeAg negative and HBV DNA $\leq$ 2, 000 IU/ml). Treatment outcomes were established previously at: EOT, week 72 and week 144 after start of therapy. A multivariable logistic regression analysis adjusted for HBV genotype, age, ethnicity and gender was used to determine the association between HBcrAg levels at BL and treatment outcome, p values of <0.05 were defined significant.
Results: HBcrAg levels at BL varied significantly between HBeAg positive (median 8 $\log_{10}$ U/ml, IQR 6.6-8.4) and HBeAg negative (median 4.5 $\log_{10}$U/ml, IQR 3.9-5.6) patients ($p < 0.001$). BL levels of HBcrAg did not differ between patients who reached HBsAg loss (median 6.1, IQR 3.7-8.2) and who did not (median 5.8, IQR 4.6-8.0). The same was seen in patients with HBeAg loss (median HBcrAg 8, IQR 6.4-8.5) and without HBeAg loss (median HBcrAg 8, IQR 6.6-8.4). Also, in patients with a virological response after treatment, no statistical difference in HBcrAg levels at BL was observed.
Conclusion: HBcrAg concentration at baseline was not predictive for HBsAg or HBeAg loss in CHB patients treated for 48 weeks with adefovir and PEG-IFN.

Evaluation of point shearwave elastography using acoustic radiation force impulse imaging for non-invasive assessment of liver fibrosis in HBeAg-negative chronic HBV infection: A prospective longitudinal study

Christiana Graf[1], Viola Knop[1], Antonia Mondorf[1], Kai-Henrik Peiffer[1], Stefan Zeuzem[1], Christoph Sarrazin[2], Johannes Vermehren[1]. [1]*University Hospital Frankfurt, Internal Medicine I, Department of Gastroenterology, Frankfurt, Germany;* [2]*St. Josefs Hospital Wiesbaden, Internal Medicine II, Department of Gastroenterology, Wiesbaden, Germany*
Email: christiana.graf@kgu.de

Background and aims: Transient elastography (TE) and point shearwave elastography (pSWE) using acoustic radiation force impulse (ARFI) imaging have been widely validated for the non-invasive diagnosis of significant fibrosis ($F \geq 2$) and cirrhosis in patients with chronic liver disease. Patients with chronic HBe-antigen-negative HBV infection with persistently normal ALT and HBV-DNA levels <2000 IU/ml represent a large group of patients with mostly F0/F1 fibrosis who generally do not require antiviral treatment. However, follow-up of these patients is crucial to early detect fluctuating HBV-DNA and/or ALT levels and possible fibrosis progression. The aim of this study was to prospectively assess, whether pSWE represents a comparable diagnostic tool to TE for non-invasive assessment of liver fibrosis progression in a longitudinal cohort of untreated patients with HbeAg-negative chronic HBV infection.
Method: 922 consecutive patients (302 males, mean age 42 ± 12 years) with HbeAg-negative HBV infection were prospectively followed-up for 6 years. TE, pSWE as well as laboratory fibrosis markers FIB-4 and APRI were performed at study inclusion and at yearly intervals for 6 years. Patients were classified into the following 3 groups: nALTnHBV (ALT within normal range, HBV DNA <2000 IU/ml, n = 679), nALTeHBV (ALT within normal range, elevated HBV-DNA between 2000 and 10^5 IU/ml, n = 95) and eALTnHBV (elevated ALT, HBV-DNA <2000 IU/ml, n = 148).
Results: In the present study, pSWE results were significantly correlated with TE ($r = 0.292$, $p < 0.001$) and APRI values ($r = 0.197$, $p < 0.001$). Median ARFI values did not differ between eALTnHBV, nALTeHBV and nALTnHBV ($p = 0.43$, $p = 0.14$, $p = 0.05$). However, considering TE results, eALTnHBV had signficantly higher values despite low HBV compared to nALTnHBV and nALTeHBV ($p < 0.001$). In the 6 years of follow-up, median TE and pSWE values as well as FIB-4 and APRI values did not differ significantly from baseline values (median intra-patient changes at the end of follow-up relative to Baseline in nALTnHBV patients, TE: 0.75, $p = 0.62$; ARFI: 2.0, $p = 0.62$; APRI: 0.5, $p = 0.28$; FIB-4: 0.17, $p = 0.90$).
Conclusion: This study shows that pSWE using ARFI imaging is a reliable ultrasound-based method for the follow-up and the assessment of liver fibrosis in HbeAg-negative chronic HBV infection.

THU-212

Reactivation of occult HBV infection in HIV treated for HCV: A retrospective study

Bianca Granozzi[1], Viola Guardigni[1], Lorenzo Badia[1], Silvia Galli[1], Giulia Piazza[2], Isabella Bon[1], Irene Zaghi[1], Pierluigi Viale[1], Gabriella Verucchi[1]. [1]*Alma Mater Studiorum -University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy;* [2]*S. Orsola Hospital, Bologna, Italy*
Email: bianca.granozzi@gmail.com

Background and aims: Occult hepatitis B (OBI) reactivation is widely studied in immunocompromised subjects. A risk has also been described with anti-HCV direct-acting antivirals (DAAs). Aim of this retrospective study was to determine the risk of OBI reactivation in HCV-HIV patients not receiving dual active anti-HBV/HIV antiretroviral therapy (daART), treated with DAAs.
Method: We retrospectively studied HCV-HIV individuals with evidence of previous HBV exposure (HBsAg-, HBcAb+), treated with DAAs from Nov 2014 to Sep 2017, not receiving daART with tenofovir, lamivudine or emtricitabine and with undetectable baseline plasma HBV DNA. We defined HBV reactivation as an increase in both HBV DNA and serum aminotransferase, with or without clinical signs of liver decompensation.
Results: We enrolled 24 subjects. Figure shows patients' baseline characteristics. 2/24 (8.3%) developed HBV reactivation during the observation period. Both patients had AIDS history. Their CD4 nadir

was <50/mmc. At baseline they had good immunovirological control. *Case 1* was treated with SOF/VEL for 12 weeks and had HBV reactivation during follow-up, with an increase in transaminases and signs of liver decompensation. *Case 2* was treated with DCV+SOF +RBV for 24 weeks and had hypertransaminasemia at week 20, without clinical signs. Both patients showed a recurrence of HBV DNA and were switched to a daART with virological response.

Baseline Characteristics	n = 24	Case 1	Case 2
Age (year), median [IQR]	53 [50.5-58.3]	59	51
Male, n (%)	20 (83.3)	Male	Male
Prior Peg-IFN/RBV, n (%)	12 (50.0)	Naive	Naive
HCV RNA, log_{10}, median [IQR]	6.2 [5.8-6.5]	6.5	6.4
Stiffness (kPa), median [IQR]	16.1 [10.1-32.8]	7.2	46.4
HCV Genotype, n (%) 1 3 4	 11 (45.8) 10 (41.7) 3 (12.5)	4	1a
HCV Treatment, n (%) LDV/SOF ± RBV VEL/SOF ± RBV DCV/SOF ± RBV EBV/GRZ	 5 (20.8) 6 (25.0) 11 (45.8) 2 (8.4)	SOF/VEL	SOF/DCV+RBV
ALT, U/L median [IQR]	55 [38-72]	50	56
HIV RNA < 50, n (%) CD4+ count, median [IQR] CD4+ nadir	22 (91.4) 577 [346-754] 248 [111-338]	Undetectable 694 3	Undetectable 696 4
HIV Treatment, n (%) PI+INI INI+NNRTI No HAART	 19 (79.1) 2 (8.4) 3 (12.5)	RAL+DRV/r	RAL+DRV/r

Conclusion: This is the first study analyzing the risk for OBI reactivation in HCV-HIV population treated with DAAs. Our findings suggest history of AIDS and low CD4 nadir as potential risk factors for OBI reactivation. Despite small sample size, the remarkable rate of OBI reactivation (8.3%) observed could lead to hypothesize that subjects with OBI and HCV-HIV infection should receive daART during DAAs treatment or be closely monitored for OBI reactivation.

THU-213

Distinct features of hepatitis delta in a Mediterranean setting

Helena Hernàndez-Èvole[1], marina berenguer-haym[1,2,3,4]. [1]*universitat De València, Valencia, Spain;* [2]*hospital Universitario Y Politécnico La Fe, Valencia, Spain;* [3]*ciberehd, Valencia, Spain;* [4]*instituto De Investigación Sanitaria La Fe, Valencia, Spain*
Email: hernandez.ievole@gmail.com

Background and aims: Hepatitis Delta is a rare but severe infectious disease caused by hepatitis D virus (HDV). Our aim was to establish the trend and profile of HDV-infected patients in a historically endemic mediterranean region and currently immigration receiving area.
Method: Retrospective evaluation of anti-HDV-IgG seroprevalence among HBV chronically infected patients followed in a reference Hepatology Unit. Demographic, clinical, analytic, serologic and virologic parameters were retrieved from chart review together with evolution events (cirrhosis, liver decompensation, liver transplantation and death).
Results: 70 HDV-HBV patients were included: 62, 9% were men and the median age was 52 years (interquartile range 12). Few were HBeAg positive at diagnosis (11.4%). Coinfection with other viruses (HIV 10%, HCV 11.4%), excessive alcohol consumption (34%) and overweight-obesity (50%) were common. Roughly 40% of patients were immigrants (table 1). Only 3., 4% had been treated with Interferon. Regarding HBV infection, 54.3% had received oral antiviral drugs, mostly tenofovir. Significant differences were found regarding the time between the diagnosis of infection and that of cirrhosis among patients diagnosed before and after 2000. Patients diagnosed after vs before the year 2000 were diagnosed within a median time frame of 2 vs 17 years, respectively, suggesting a late diagnosis in those recently diagnosed. The vast majority of patients developed cirrhosis (77.1%), liver decompensation (72.2%), need of transplantation (45.7%) and/5.7% patients died due to liver diseases.

Demographic parameters		*Total* *% (N)*	*Diagnosis pre- 2000* *57, 1% (N = 40)*	*Diagnosis post 2000* *42, 5% (N = 30)*
COUNTRY OF BIRTH BY REGION	*Spain*	67, 1% (47)	92, 5% (37)	33, 3% (10)
	Eastern Europe	24, 3% (17)	7, 5% (3)	46, 7% (14)
	Other	8, 6% (6)	0	20% (6)
DIABETES MELLITUS	*Non diabetic*	91, 4% (64)	97, 5% (39)	83, 3% (25)
	Diabetic	8, 6% (6)	2, 5% (1)	16, 7% (5)
ALCOHOL CONSUMPTION	*No alcohol use*	64, 3% (45)	70% (28)	58, 6% (17)
	Alcoholic	34, 3% (24)	30% (12)	41, 4% (12)
WEIGHT	*Underweight*	2, 9% (2)	2, 7% (1)	3, 8% (1)
	Normal weight	37, 1% (26)	32, 4% (12)	53, 8% (14)
	Overweight	32, 9 % (23)	37, 8% (14)	34, 6% (9)
	Obese	17, 1% (12)	27% (10)	7, 7% (2)
Serologic parameters				
HBe Antigen	*HBeAg +*	11, 4% (8)	20, 5% (8)	0
VIH	*VIH +*	10% (7)	17, 5% (7)	0
VHC	*VHC +*	11, 4% (8)	11, 4% (8)	0
Evolution events				
CIRRHOSIS PROGRESSION		77, 1% (54)	82, 5% (33)	72, 4% (21)
LIVER DECOMPENSATION		72, 2% (39)	77, 4% (24)	75, 0% (15)
TRASPLANTATION		45, 7% (32)	55, 0% (22)	33, 3% (10)
DEATH		5, 7% (4)	5% (2)	6, 7% (2)

Conclusion: Patients diagnosed in recent years are diagnosed late, possibly reflecting a late referral pattern among immigrants. We confirm a high rate of evolutive liver complications, probably related to HDV, although we cannot rule out the role of other etiologic agents such as alcohol, metabolic syndrome or hepatotropic virus coinfection.

THU-214

Annual average of integral FIB-4 index and HBV core-related antigen as an appropriate indicators for starting nucleoside analogues at an optimum timing

Shuhei Hige[1], Itaru Ozeki[1], Hirokazu Suii[1], Ryoji Tatsumi[1], Masakatsu Yamaguchi[1], Mutsuumi Kimura[1], Tomohiro Arakawa[1], Tomoaki Nakajima[1], Yasuaki Kuwata[1], Takumi Ohmura[1], Joji Toyota[1], Yoshiyasu Karino[1]. [1]*Sapporo-Kosei General Hospital, Hepatology, Sapporo,*
Email: shuhei.hige@ja-hokkaidoukouseiren.or.jp

Background and aims: Although nucleos (t)ide analogue (NA) has been reported to be useful for suppressing hepatocellular carcinoma (HCC) with hepatitis B patients, it is important not to miss an optimum timing of starting NA because not a few patients progress to HCC thereafter. Serum HBV core-related antigen (HBcrAg) is reported to correlate with intrahepatic cccDNA which may be related to viral activity and carcinogenic risk. In this study, we evaluated annual average of integral FIB-4 index (aaFIB-4) and serum HBcrAg for determining an adequate timing of NA and estimating the HCC risk during NA treatment.
Method: A total of 522 HBs antigen (HBsAg)-positive patients who did not have a history of HCC were followed from the start of NA [entecavir (ETV) 319, lamivudine (Lam) to ETV 76, Lam 28, Lam or ETV plus adefovir (ADV) 99 cases]. An aaFIB-4 was calculated from the integral value of each FIB-4 index during the same year. Serum levels of HBcrAg were measured by the Lumipulse® HBcrAg

Chemiluminescence Enzyme Immunoassay (Fujirebio, Tokyo, Japan). The dynamic range of the assay is 3.0 to 6.8 (log_{10} U/ml). Kaplan-Meier method was used to estimate the cumulative occurrence of HCC.

Results: During the median follow-up of 107 months, HCC was confirmed in 79 patients. Overall cumulative 5/10 year occurrence rate of HCC (5/10y-HCC rate) was 10.0/18.2%. The cut off value of aaFIB-4 and log_{10} HBsAg at the start of NA treatment for the occurrence of HCC during the treatment course was 3.00 and 3.2 (log_{10} IU/ml) by ROC analysis. 5y-HCC rate was 0/2.3/1.1/18.7/31.3 (%) for those whose pretreatment aaFIB-4 was <1.0/1.0-2.0/2.0-3.0/3.0-4.0/4.0 ≤ and 5.1/15.9/5.7 (%) for those whose pretreatment HBcrAg was <3.0/3.0-6.8/6.8 < .5/10y-HCC rate by the combined conditions is shown in Table. High aaFIB-4 was a significant predictive factor of HCC and high HBsAg/low HBcrAg indicated low risk of HCC. In cases of high aaFIB-4/low HBsAg, probability of HCC increased with increasing HBcrAg. 10y-HCC rate of cases whose HBcrAg remained <3.0 (Gr.1), decreased to <3.0 (Gr.2), remained ≥3.0 (Gr.3) was 5.1/11.9/17.8 (%). Among high aa FIB-4 cases, 5y-HCC risk of those whose aa FIB-4 declined below 3.00 during NA treatment was 17.2%, whereas those who did not show aaFIB-4 decrease was 29.5% (p = 0.04).

Table: 5y/10y-HCC rate (%) by the combined conditions of aaFIB-4 index, HBcrAg and HBsAg.

		Overall		aaFIB-4 <3.00		aaFIB-4 ≥3.00	
log_{10}HBsAg		<3.2	3.2 ≤	<3.2	3.2 ≤	<3.2	3.2 ≤
HBcrAg	<3.0	8.4/8.4	2.3/2.3	0/0	0/0	19.0/19.0	0/0
	3.0–6.8	17.6/30.2	11.9/19.6	5.0/14.7	2.4/5.1	22.9/48.0	24.6/39.2
	6.8 <	10.3/17.6	1.4/8.6	0/0	0/3.5	27.3/62.7	17.6/21.6

Conclusion: AaFIB-4 and HBcrAg at the start of NA treatment was correlated with occurrence of HCC afterwards. NA should be started before aaFIB-4 index reaches 3.00. The decrease of aaFIB-4 or HBcrAg after NA treatment may reduce the risk of HCC.

THU-215

Association between core mutations and annual decline rate of HBVDNA and HBsAg in chronic hepatitis B patients treated with nucleoside analogue

Takashi Honda[1], Masatoshi Ishigami[1], Takanori Ito[1], Yoji Ishizu[1], Teiji Kuzuya[1], Mitsuhiro Fujishiro[1]. [1]*Nagoya University Graduate School of Medicine, Gastroenterology and Hepatology, Nagoya, Japan*
Email: honda@med.nagoya-u.ac.jp

Background and aims: We have reported that measurement of core I97L mutation in addition to HBVDNA and ALT levels would be useful to predict subsequent clinical course in chronic hepatitis B (CHB) patients. We investigated differences in annual decline rate of HBVDNA and HBsAg between patients who treated with nucleoside analogue therapy (NA) therapy (Group NA) and patients who were observed in the natural history of the disease (Group N). Hepatitis B core-related antigen (HBcrAg) may serve as useful marker for virus replication and reflect intrahepatic cccDNA.

Method: One hundred thirty-eight CHB patients who were determined core I97 were enrolled in this study. Median age of patients was 42 (male/female = 67/71, Group NA/Group N = 42/96, all patients had genotype C virus). Median observational period was 7.0 years. 1) In Group N (n = 96) annual decline rate of HBVDNA and HBsAg were compared according to presence of core I97L mutation. 2) Among Group NA (n = 42) annual decline rate of HBVDNA and HBsAg were compared according to presence of core I97L mutation before NA therapy. Moreover, HBcrAg at final visit was also compared according to presence of core I97L mutation.

Results: 1) In Group N annual decline rate of HBVDNA in patients with I97L was significantly higher than that in patients with I97 wild-type (0.23 log copies/ml/year, 0.05 log copies/ml/year, respectively, p = 0.036). On the other hand, annual decline rate of HBsAg in patients with I97L was significantly higher than that in patients with I97 wild (0.10 IU/ml/year, 0.05 IU/ml/year, respectively, p = 0.003). Furthermore, the rate of HBsAg loss in patients with I97L was significantly higher than that in the patients with I97 wild (24.3% vs. 3.6%, respectively, p = 0.002). 2) Among Group NA there was no significant difference in annual decline rate of HBVDNA and HBsAg. However, HBcrAg of the patient with I97L was significantly lower than that of the patients with I97I/Fwild (3.0 logU/ml vs. 3.7 logU/ml, respectively).

Conclusion: In CHB patients, patients with I97L had significantly higher annual decline rate of HBVDNA and HBsAg. Patients with I97L before NA treatment showed significantly lower HBcrAg at final visit. These results suggest HBcrAg levels would be low in patients who have I97L mutation before NA therapy.

THU-216

Rapid turnover of HBV cccDNA in nucleoside-treated chronic hepatitis B patients during drug resistance emergence and breakthrough

Qi Huang[1], Bin Zhou[2], Dawei Cai[1], Yuhua Zong[1], Yaobo Wu[2], Shi Liu[2], Haitao Guo[3], Jian Sun[2], Jinlin Hou[2], Richard Colonno[1]. [1]*Assembly Biosciences, South San Francisco, United States;* [2]*Nanfang Hospital, Hepatology Unit and Department of Infectious Diseases, Guangzhou, China;* [3]*Indiana University School of Medicine, Department of Microbiology and Immunology, Indianapolis, United States*
Email: qi@assemblybio.com

Background and aims: Current low cure rates in patients chronically-infected with Hepatitis B Virus (HBV) using standard of care therapy are believed to be due to an inability to eliminate cccDNA reservoirs in patients. It remains unclear whether persistence is due to the longevity of cccDNA or its efficient replenishment by either *de novo* infection or intracellular amplification.

Method: Methodologies were optimized to enable analysis of distinct populations of cccDNA, pgRNA and viral DNA in both CHB patient sera and liver biopsies. Pan-genotypic primers were designed to amplify the HBV reverse transcriptase (RT) gene. HBV cccDNA from snap-frozen liver biopsies were extracted by a modified Hirt method, digested with T5 exonuclease, amplified by PCR. Intrahepatic rcDNA and HBV RNA were purified with QIAamp MinElute Virus kit from flow-through of Hirt extraction. HBV DNA and pgRNA were extracted from patient sera using a QIAamp MinElute Virus kit. Aliquots were digested by DNase I and used as a template for RT-PCR. Sanger sequencing results of PCR and RT-PCR fragments were analyzed using Sequencher™ software (Gene Codes) and the percentage of signature lamivudine/telbivudine resistance (Nuc^R) mutations was calculated by population sequencing or clone-based sequencing following TA-cloning.

Results: The emergence and disappearance of Nuc^R mutations was retrospectively monitored as a sensitive genetic marker of cccDNA turnover/evolution in a panel of patients with paired patient liver and serum samples from two clinical studies (EFFORT and ML18376). Critical to the success of this genetic approach, we found a strong relationship between the population sequences found in serum pgRNA, intrahepatic HBV RNA and cccDNA samples, validating serum RNA as a surrogate marker of cccDNA sequences at time points when liver biopsy samples were unavailable. The observed changes in Nuc^R viral variants (DNA) suggest the near complete turnover of wild-type pgRNA and cccDNA populations, with serum HBV DNA, pgRNA and cccDNA populations observed to switch between WT and Nuc^R populations in as little as 3-4 months in some patients. Compensatory mutations that affect fitness likely account for the range of timelines observed for complete viral genetic turnover in breakthrough patients. In all cases, turnover rates were measured in several months, not years, as previously predicted.

Conclusion: Serum pgRNA was validated as a surrogate genetic biomarker for cccDNA populations. Overall, cccDNA pools appear to

be dynamic, with rapid decay of existing populations and complete turnover in as little as 3-4 months. These findings support the potential for a finite treatment period for regimens that can fully suppress viral replication and inhibit regeneration of new cccDNA molecules.

THU-217

Low risk of HBV reactivation in a large European cohort of HBV/HCV coinfected patients treated with DAA

Jerzy Jaroszewicz[1], Maciej Piasecki[1], Beata Lorenc[2], Iwona Buczyńska[3], Simon Krzysztof[3], Dorota Zarębska-Michaluk[4], Dorota Dybowska[5], Waldemar Halota[5], Małgorzata Pawłowska[5], Aleksander Garlicki[6], Teresa Belica-Wdowik[7], Ewa Janczewska[8], Beata Dobracka[9], Magdalena Tudrujek[10], Krzysztof Tomasiewicz[10], Hanna Berak[11], Włodzimierz Mazur[12], Tronina Olga[13], Klapaczynski Jakub[14], Rafal Krygier[15], Agnieszka Czauż-Andrzejuk[16], Jolanta Citko[17], Łukasz Socha[18], Anna Piekarska[19], Deron Zbigniew[20], Jolanta Bialkowska-Warzecha[21], Robert Flisiak[16]. *[1]Medical University of Silesia in Katowice, Department of Infectious Diseases and Hepatology, Bytom, Poland; [2]Medical University of Gdansk, Pomeranian Center of Infectious Diseases, Gdansk, Poland; [3]Wrocław Medical University, Department of Infectious Diseases and Hepatology, Wrocław, Poland; [4]Voivodship Hospital and Jan Kochanowski University, Department of Infectious Diseases, Kielce, Poland; [5]Collegium Medicum Bydgoszcz, Nicolaus Copernicus University Toruń, Department of Infectious Diseases and Hepatology, Toruń Poland; [6]Jagiellonian University, Collegium Medicum, Department of Infectious and Tropical Diseases, Kraków, Poland; [7]John Paul II Hospital, Regional Center for Diagnosis and Treatment of Viral Hepatitis and Hepatology, Kraków, Poland; [8]Medical University of Silesia in Katowice, School of Public Health in Bytom, Department of Basic Medical Sciences, Bytom, Poland; [9]Medical Center, MEDFIX, Wrocław, Poland; [10]Medical University of Lublin, Department of Infectious Diseases, Lublin, Poland; [11]Warsaw Medical University, Hospital for Infectious Diseases, Warszawa, Poland; [12]Medical University of Silesia, Clinical Department of Infectious Diseases, Katowice, Poland; [13]Medical University of Warsaw, 13. Email: jerzy.jr@gmail.com

Background and aims: Several cases of HBV reactivation during direct acting antivirals (DAA) for HCV were described in both HBsAg (+) and HBsAg (-)/anti-HBc IgG (+) patients. The exact rate of HBV-reactivation in HBV/HCV coinfection is poorly defined, especially in European cohorts. The aim of study was to characterize HBV/HCV coinfection and evaluate the prevalence HBV-reactivation during DAA.

Method: Analyzed population consisted of 6228 chronic hepatitis C patients (52% female, mean age 54yo, 82% HCV-GT1b, 34% with liver cirrhosis) receiving therapy with DAA in 2016-2017 included in a large national database EpiTer-2. DAA combinations consisted mainly of OBV/PTV/r±DSV±RBV (53%) and LDV/SOF±RBV (28%). Prior to the DAA all subjects had HBsAg testing and ALT-activity evaluated every 4 weeks during DAA. Anti-HBc IgG testing was available in 742 patients without HBsAg.

Results: 70 of 6228 patients (1.1%) had detectable HBsAg. HBV/HCV patients were significantly younger and more often infected with HCV-GT3 and 4 than HCV-group. They were also less often diagnosed with arterial hypertension (26% vs 38%, P = 0.04), diabetes (6% vs 15%, P = 0.03) and had lower BMI (24.5 vs 26.0, P <0.01). On the other hand, proportion of liver cirrhotics, ALT activity, MELD and Child-Pugh were comparable. Prior of DAA only 21 (30%) of HBV/HCV required NA-therapy.

In both groups DAA-therapy was continued according to plan in 96% (HBV/HCV) vs 95% (HCV) and number of adverse events was comparable. SVR rates were similar in HBV/HCV and HCV in overall group (mITT 97% vs 95%, P = 0.7) and for specific HCV-genotypes.

Importantly, in HBsAg (+) subjects only 3 (4.3%) HBV reactivations were observed, while none occurred in HBsAg (-)/anti-HBc IgG (+) group (n = 742). All 3 subjects with reactivation were HBeAg (-), infected with HCV-GT1 and had advanced liver disease (F3-F4). One reactivation was clinically significant with HBV-DNA increase (from 1.3 to 7.6 log10 IU/ml at wk5) and ALT-flare (1337 IU/m) requiring DAA discontinuation and NA therapy, while 2 remaining were subclinical with HBV-DNA increase form negative to 1.3 (wk12) and 3.2 log10 IU/ml (wk8). All subjects with HBV-reactivation reached SVR.

Conclusion: Data form a large European cohort suggest that the risk of HBV reactivation during therapy with DAA seems to be low in HBsAg (+) HBV/HCV subjects (<5%), while probably neglectable in HBsAg (-)/anti-HBc IgG (+). Interestingly, subjects with HBV/HCV coinfection seem to less often present symptoms and complication of metabolic syndrome.

THU-218

Immune reconstitution inflammatory syndrome and CD4 lymphocyte count as predictive factors for HBsAg seroclearance in HBV/HIV patients treated with antiretroviral therapy

Yasuharu Kawamoto[1], Satoshi Tanaka[1], Akio Ishihara[1], Dai Watanabe[2], Tomoko Uehira[2], Hisashi Ishida[1], Takuma Shirasaka[2], Eiji Mita[1].
[1]National Hospital Organization Osaka National Hospital, Department of Gastroenterology and Hepatology, Osaka, Japan; [2]National Hospital Organization Osaka National Hospital, Department of Infectious Diseases, Osaka, Japan
Email: st0305@onh.go.jp

Background and aims: HIV infection has a great influence on the natural history of HBV infection, with enhanced risk of liver disease progression and increased liver-associated mortality compared with HBV mono-infection. Treatment of HBV infection in patients co-infected with HIV is commonly initiated with HBV-active antiretroviral therapy (ART), which includes two nucleoside/nucleotide reverse transcriptase inhibitors, usually either lamivudine or emtricitabine together with tenofovir disoproxil fumarate (TDF) or tenofovir alafenamide (TAF). The main goal of HBV treatment is HBsAg seroclearance both in HBV mono-infected patients and in HBV/HIV coinfected patients. However, little is known about factors predicting HBsAg seroclearance. The aim of this study is to identify predictive factors for HBsAg seroclearance in HBV/HIV coinfected patients treated with ART.

Method: This is a retrospective study at our hospital in Osaka, Japan. A total of 43 patients coinfected with HBV/HIV who started TDF/TAF-based ART between December 2012 and December 2017 were analyzed with a mean follow-up period of 31.0 months. Immune reconstitution inflammatory syndrome (IRIS), which is a common complication of ART initiation and associated with an inflammatory response toward microbial antigens, was diagnosed according to Shelburne's criteria (J Antimicrob Chemother. 2006). Predictive factors for HBsAg seroclearance were assessed by univariate and multivariate logistic regression analysis.

Results: The baseline characteristics of all patients at therapy initiation were as follows (continuous variables are expressed as mean): age, 37.0 years old; sex (male/female), 43/0; HBV genotype (A/B/C/D/unknown), 31/0/3/0/9; HBV-DNA level, 7.4 logCP/ml; HIV-RNA level, 4.9 logCP/ml and CD4 lymphocyte count, 250/μL. All patients achieved sustained viral suppression. HBsAg seroclearnce

occurred in 13 patients with HBV genotype A and was not observed in patients with HBV genotype C. Seven out of the 13 patients showed liver enzyme elevation associated with IRIS within 3 months after antiretroviral therapy initiation. Both univariate and multivariate analysis showed that IRIS onset (odds ratio = 6.770, P = 0.0236) and initial CD4 lymphocyte count (odds ratio = 8.710, P = 0.0121) were found to be statistically significant predictive factors for HBsAg seroclearance following ART.
Conclusion: This study indicated that IRIS onset and initial CD4 lymphocyte count can be independent predictive factors for HBsAg seroclearance in HBV/HIV coinfected patients treated with ART.

Long-term outcome in Caucasian patients with hepatitis B e antigen-negative chronic infection: An observational cohort study

Özgür Koc[1,2,3], Geert Robaeys[1,2,4], Rob Bielen[1,2], Dana Busschots[1,2], Ger Koek[3,5], Frederik Nevens[4]. *[1]Ziekenhuis Oost-Limburg, Genk, Belgium; [2]Hasselt University, Hasselt, Belgium; [3]Maastricht University Medical Centre, Maastricht, Netherlands; [4]University Hospitals KULeuven, Leuven, Belgium; [5]University Hospital of the RWTH, Aachen, Germany*
Email: ozgurmkoc@gmail.com

Background and aims: The long-term outcome and risk of hepatitis B virus (HBV) reactivation in the Caucasian population with hepatitis B e antigen (HBeAg)-negative chronic infection have rarely been studied before. In this study, we explored this issue by a long-term follow-up of patients with HBeAg-negative chronic infection.
Method: Out of 1, 081 patients with chronic HBV infection, we retrospectively identified 236 Caucasian patients with HBeAg-negative chronic infection who presented at the Outpatient Hepatology Department of University Hospitals KULeuven between 1 January 1968 and 31 July 2018. HBeAg-negative chronic infection was defined as low or undetectable HBV DNA (≤20, 000 IU/ml) and persistently normal alanine-aminotransferase levels (PNALT). Patients previously treated with HBV antiviral agents or corticosteroids were to be excluded as well as patients with cirrhosis at presentation and patients with co-existing chronic liver disease.

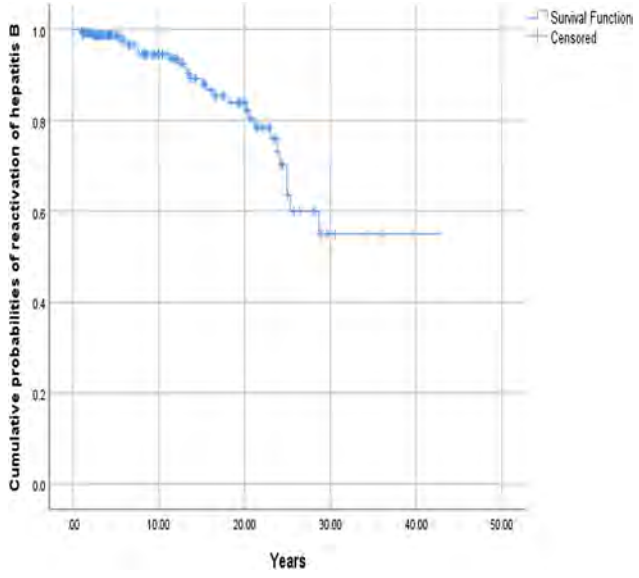

Figure 1: Cumulative probability of reactivation of hepatitis B in Caucasian patients with hepatitis B e antigen-negative chronic infection.
Results: During a median follow-up of 10 (interquartile range: 14.2) years, 208 (88%) of the 236 patients showed sustained remission, whereas the remaining 28 (12%) experienced reactivation of hepatitis B. The cumulative probabilities of reactivation of hepatitis B were 2% 8% and 27% at 5, 10 and 20 years follow-up, respectively (Fig. 1). In a multivariate analysis using Cox proportional hazards regression models, reactivation of hepatitis B was independently associated with advanced age at presentation (>40 years) (hazard ratio (HR) = 2.92; 95% confidence interval (CI) = 1.23-6.92; p = .015) and any HBV DNA level >2, 000 IU/ml (HR = 3.68; 95% CI = 1.53-8.82; p = .004). Significant fibrosis (liver stiffness >9 kPa) and cirrhosis developed in respectively 9/133 (7%) and 3/236 (1%) patients. Cox proportional hazard regression models showed that advanced age at presentation was the only factor significantly associated with a higher risk of significant fibrosis (HR = 4.90; 95% CI = 1.71-14.1; p = .003).
Conclusion: Antiviral treatment is not indicated in Caucasian patients with HBeAg-negative chronic infection since the prognosis of liver disease is favourable. However, the results from this study reinforce the need for clinical surveillance for the risk of HBV reactivation in patients older than 40 years and those with any HBV DNA level >2, 000 IU.

THU-220

Early steep decline of liver stiffness predicts histological reverse of fibrosis in chronic hepatitis B patients treated with entecavir

Yuanyuan Kong[1], Hong You[1], Jidong Jia[1], Regression of HBV-induced Liver Fibrosis Research Group China[2]. *[1]Beijing Friendship Hospital, Capital Medical University, Beijing, China; [2]Hospitals, Beijing, China*
Email: youhong30@sina.com

Background and aims: Whether dynamic changes of liver stiffness measurement (LSM) could predict the reversibility of fibrosis remains unknown. Therefore, we evaluated the utility of LSM declining for predicting histological changes of fibrosis in patients with chronic hepatitis B (CHB) on antiviral therapy.
Method: In a prospective cohort of CHB patients treated with entecavir, virology, biochemistry and LSM were measured at baseline and every 6 months. Liver biopsies were conducted at both baseline and 18-month treatment. Fibrosis regression was defined by two criteria: (1) Ishak decreasing ≥1 stage, (2) Ishak decreasing ≥1 stage or predominantly regressive by posttreatment P-I-R classification. Piecewise linear mixed-effects model and ROC analysis were used to evaluate the dynamic changes of LSM and its predictive value for histological reversibility.
Results: We found that at month 18 of antiviral therapy, liver fibrosis was reserved in 86 patients of 212 (40.6%) CHB patients by Ishak reversal criterion. Overall, LSM declining was associated with attenuation of Ishak stage. The rate of LSM declining in the first 6 months was significantly faster in patients with fibrosis reverse (ΔLSM%Ishak = −2.19%/month, p = 0.0025; ΔLSM%Ishak/PIR = −2.56%/month, p = 0.0004). The predictive model based on baseline FIB-4 and Ishak stage as well as baseline LSM, PLT, ALB and their changes during the first 6 months could predict the histological reverse (AUROCIshak = 0.74, 95% CI: 0.67-0.80; AUROCIshak/PIR = 0.81, 95% CI: 0.74-0.87).
Conclusion: We concluded that dynamic changes of LSM during the first 6 months of entecavir therapy could predict histological reversibility of liver fibrosis in CHB patients.

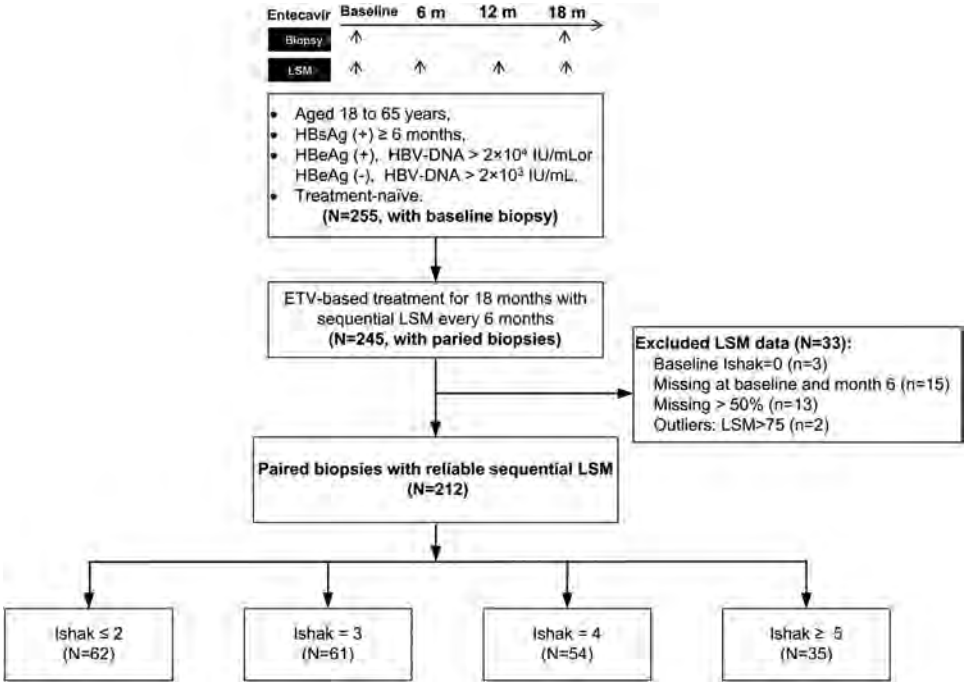

Figure 1: (abstract: THU-220): Flowchart of the selection of patients with paired liver biopsy and reliable sequential LSM.

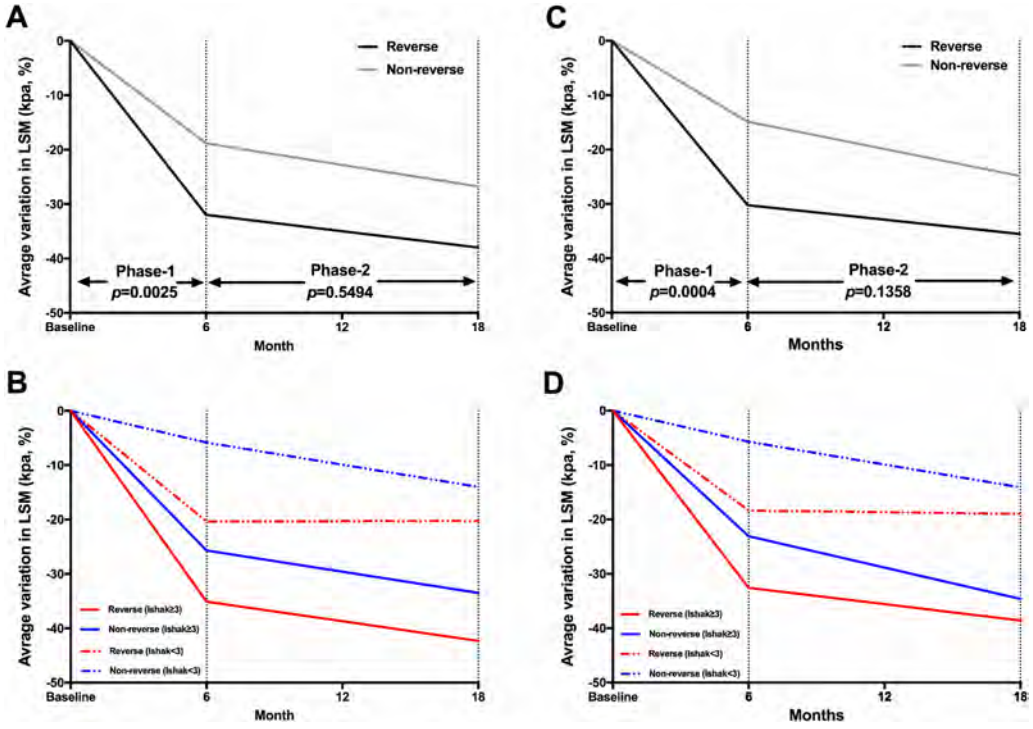

Figure 2: (abstract: THU-220): Biphasic pattern of LSM changes in CHB patients on antiviral therapy and LSM declining was associated with the fibrosis stage by the Ishak criterion (A and B) and by the Ishak/posttreatment P-I-R criterion (C and D). Under both criteria of fibrosis regression, dynamic changes of LSM consisted of a rapid phase of declining during the first 6 months of treatment and a slow phase of declining from month 6 to month 18. In patients with baseline Ishak stage ≥3, the first phase of LSM declining was significant faster in reverse group.

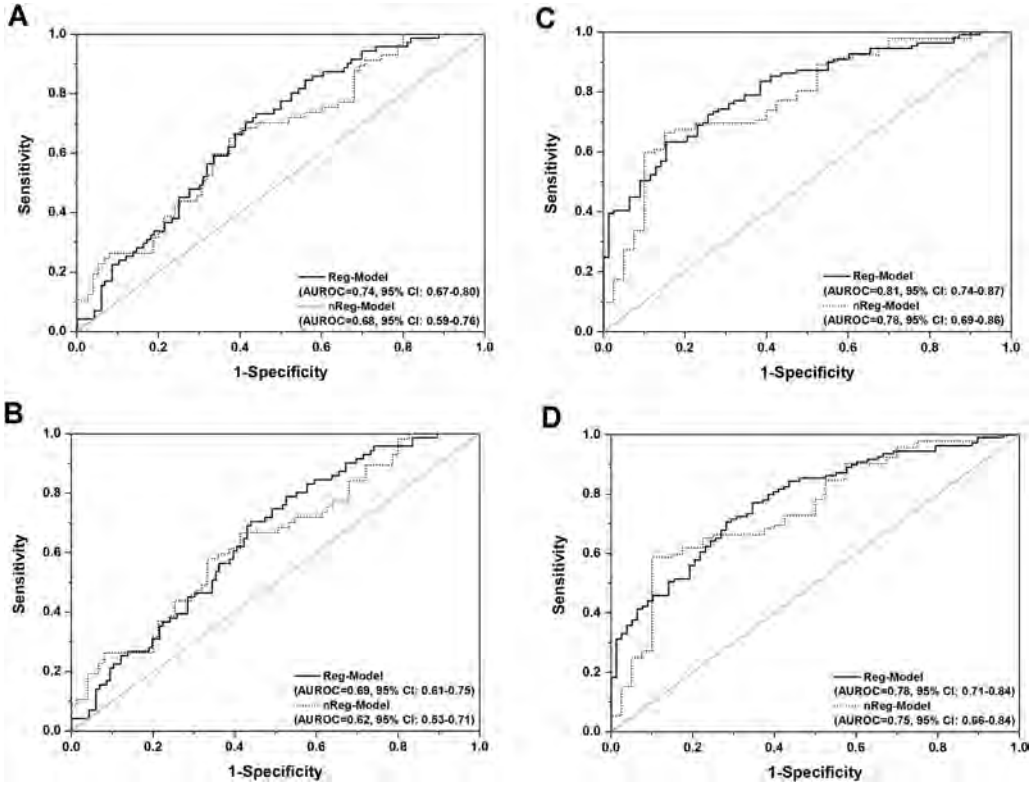

Figure 3: (abstract: THU-220): The performance of regression-predicting models for predicting histological reverse of liver fibrosis in patients with or without significant fibrosis in derivation set and validation set by the Ishak criterion (A and B) and by the Ishak/posttreatment P-I-R criterion (C and D). Reg-Models based on dynamic changes of LSM of first 6 months of treatment could predict histological reversibility of liver fibrosis in CHB patients. Reg-Model: prediction model in total CHB patients;nReg-Model: prediction model in CHB patients with significant fibrosis.

Xpert HBV VL, simplifying HBV viral load testing and disease management

Sara Uceda[2], Letizia Greco[2], Alessandro Loglio[1], Giovanna Lunghi[2], Pietro Lampertico[1]. [1]*Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy;* [2]*Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Virology Unit, Milan, Italy*
Email: sarauceda@outlook.com

Background and aims: Viral Load (VL) quantification plays a key role for the monitoring of patients affected by Hepatitis B virus. Recently Cepheid has developed a new cartridge-based HBV VL assay. The aim of this work was to compare the performance of the Cepheid Xpert HBV VL assay to the Abbott m2000 HBV VL assay, to assess the linearity, the inclusivity and the precision of Xpert HBV VL test. The workflow of the two assays has been evaluated.
Method: For the precision, 4 HBV specimen have been prepared by dilutions at different concentrations (0, 1.64, 6.09 and 7.92 log IU/ml) and tested on the Xpert HBV VL assay in duplicate for 10 runs over 10 days. For the method comparison (MC), 85 specimens from HBV infected patients were tested with both assays. Results were compared by a Passing Bablok and Bland-Altman analysis. The patient monitoring has been carried out on 80 serial plasma samples collected from 24 patients. Inclusivity has been assessed on 5 genotypes circulating in our region, genotype A, B, C, D and E. For linearity, one high viremic sample was diluted to several concentrations.The turn-around time (TAT), the hands on-time (HoT) have been determined on both assays.
Results: The MC showed a high correlation (R^2 = 0.99, slope = 1.04, intercept = –0.12, Passing Bablok) and a Mean Difference of –0.015 (CI 95% = –0.05-0.02 Bland Altman) between the assays. Linearity on the genotypes (A, B, C, D and E) shows an R^2 >0.95. Precision gave a standard deviation lower than 0.1 log IU/ml. Workflow has been analyzed on 1 week activity. Abbott method required 7h to process all the samples, Cepheid method provided all the results in 3h21min. The HoT required by Cepheid assay is significantly lower than the HoT for Abbott assay (36mn versus 54mn respectively). In our laboratory Abbott test is performed twice a week (two batches) and the mean TAT is 89h34mn. Cepheid assay showed a TAT of 3h21mn.
Conclusion: A good correlation was observed between both assays. Inclusivity and linearity showed very good performances with high R^2 values. The extraction, amplification and detection steps of Xpert HBV VL assay are all performed onto a single platform, GeneXpert system. It reduces consequently the complexity of the process and the labor time. Xpert HBV VL assay allows continuous loading of samples, which eliminates the need for batching, but it also allows urgent samples testing, leading to a significative improvement of our productivity.

THU-222

The application of novel HBV pgRNA assay to predict HBeAg clearance on long-term nucleos (t)ide analogues

Pir Ahmad Shah[1], Idriss Rajab[1], Saad Choudhry[1], Jeffrey Gersch[2], Vijayram Malladi[1], Rizwan Ishtiaq[1], Mary Kuhns[2], Gavin Cloherty[2], Daryl Lau[1]. [1]*Beth Israel Deaconess Medical Center, Gastroenterology, Medicine, Boston, United States;* [2]*Abbott, Infectious disease research, Chicago, IL, United States*
Email: pshah7@bidmc.harvard.edu

Background and aims: Nucleos (t)ide analogues (NAs) are associated with HBeAg loss in only approximately 40-50% of patients with prolonged therapy. The aim of the study is to identify the virological

profiles of patients who are unlikely to clear HBeAg with long term NA treatment so alternative therapy can be considered.
Method: HBeAg positive patients with baseline HBV DNA ≥ 5 $\log_{10}$ IU/ml on NAs for at least 20 months with available stored serial sera were included. HBV pgRNA was measured using the Abbott research assay [Sensitivity is 1.65 $\log_{10}$ U/ml with linearity from 2.5 to 7.5 $\log_{10}$ IU/ml (R^2 = 0.99)]. Clinical and virological parameters were compared between patients with and without HBeAg clearance on prolonged therapy.
Results: This predominantly Asian (86%) cohort included 17 and 11 patients with and without NA treatment-related HBeAg loss respectively. The duration of therapy, baseline HBV DNA, ALT levels were similar between the 2 groups [Table]. Patients with and without HBeAg loss achieved HBV DNA < 20 IU/ml at similar time line from start of therapy. Those with HBeAg loss, however, had significantly lower HBV pgRNA levels when HBV DNA became suppressed to < 20 IU/ml. With long term therapy more than 5 years, HBV RNA levels remained > 4 $\log_{10}$ IU/ml among those without HBeAg loss. Five of 17 (29%) patients with HBeAg loss had hepatitis flare (ALT > 100 U/L) associated with HBV RNA reduction (Mean 1.68 log) preceding HBeAg clearance. Their HBV pgRNA levels became <1.65 $\log_{10}$ IU/ml shortly after HBeAg loss. In contrast, 12 of 17 patients without hepatitis flare prior to HBeAg loss had significantly higher HBV pgRNA level (Average 3.12 $\log_{10}$ IU/ml) at time of HBeAg clearance. At last follow-up, the HBV pgRNA level was significantly lower among those with HBeAg loss [Table]. Ten of 17 (59%) patients with HBeAg clearance achieved HBV pgRNA < 1.65 $\log_{10}$ IU/ml.

[Mean, range]	HBeAg Loss (N = 17)	Without HBeAg Loss (N = 10)	P Value
Duration of therapy: Months	75 (22, 168)	84 (27, 184)	0.30
Baseline HBV DNA ($\log_{10}$ IU/ml)	7.2 (5.2, 8.2)	7.5 (5, 8.2)	0.28
Baseline ALT (U/L)	107 (18, 260)	84 (14, 268)	0.20
Time to HBV DNA <20 IU/ml (Months)	38.6 (10.6, 141)	46.9 (6, 159)	0.29
HBV pgRNA ($\log_{10}$ IU/ml) when HBV DNA <20 IU/ml	2.5 (*UD, 5.32)	5.6 (3.83, 6.72)	<0.00002
HBV pgRNA at last follow-up ($\log_{10}$ IU/ml)	1.62 (*UD, 3.33)	4.68 (3.29, 5.77)	<0.00001

*UD = undetectable

Conclusion: In this cohort, HBV pgRNA kinetics on therapy differentiated patients with and without HBeAg clearance on long term NA treatment. Those HBV pgRNA remained > 5.6 $\log_{10}$ IU/ml when HBV DNA was suppressed tended to have very gradual HBV pgRNA decline over prolonged therapy and were unlikely to achieve HBeAg loss. Hepatitis flare with ALT > 100 U/L was often associated with significant HBV pgRNA reduction and subsequent HBeAg clearance. These observations need to be carefully validated in a larger cohort of patients.

THU-223
Development of an optimized risk prediction model for hepatocellular carcinoma in chronic hepatitis B patients with well-controlled viremia by antivirals

Hye Won LEE[1], Beom Kyung Kim[1], Seung Up Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1], Kwang-Hyub Han[1]. [1]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: beomkkim@yuhs.ac

Background and aims: The risk of hepatocellular carcinoma (HCC) in patients with chronic hepatitis B has been substantially decreased in the era of antiviral therapy. We aimed to develop an optimized risk prediction model for HCC in patients with well-controlled viremia by nucelos (t)ide analogues (NUCs).
Method: This study included patients who achieved virological response (VR; serum HBV-DNA < 2, 000 IU/ml on two consecutive assessments) by NUCs. Liver stiffness (LS) was assessed by transient elastography at the time of confirmed VR in all patients. Patients with decompensated liver cirrhosis or HCC at baseline were excluded. Multivariate Cox-proportional hazards model were used to determine potential factors for a risk prediction model.
Results: Among a total of 1511 patients, 143 (9.5%) patients developed HCC during follow-up. Age (adjusted hazard ratio [aHR] 1.04, 95% CI 1.02-1.06), LS ≥ 11 kPa (aHR 6.09, 95% CI 3.89-9.55), cirrhosis on ultrasonography (aHR 2.47, 95% CI 1.35-4.53), male gender (aHR 1.9, 95% CI 1.2-2.8), albumin <4.5 g/dL (aHR 1.77, 95% CI 1.21-2.59) and platelet < 135, 000/uL (aHR 1.57, 95% CI 1.07-2.32) were potential variables to make a risk prediction model for HCC development (all p < 0.05). These 6 parameters were weighted to develop a novel nomogram ranging from 0 to 271 points; a total point of 180 means the probability of 10% and 30% for HCC development at 5- and 10-years, respectively. The overall c-index was 0.876 (95% CI 0.845-0.902).
Conclusion: A novel nomogram enabled the more accurate prediction of HCC development among patients with well-controlled viremia by NUCs.

THU-224
Validation of modified PAGE B in patients with chronic hepatitis B undergoing antiviral treatment

Hye Won Lee[1], Beom Kyung Kim[1], Seung Up Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1], Kwang-Hyub Han[1]. [1]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: beomkkim@yuhs.ac

Background and aims: A new risk prediction model for development of hepatocellular carcinoma (HCC), that is, modified PAGE-B (mPAGE-B) which includes age, gender, platelet count and albumin level as constituent variables, has recently been proposed in Asian chronic hepatitis B (CHB) patients undergoing antiviral therapy. We aimed to externally validate mPAGE-B model and compared its predictive performance with that of conventional risk prediction models in the independent cohort.
Method: CHB patients undergoing oral antiviral therapy between November 2005 and December 2014 were consecutively recruited. The predictive performance of mPAGE-B and five conventional risk prediction models including the Chinese University-HCC (CU-HCC), the modified guide with age, gender, HBV DNA, and cirrhosis-HCC (GAG-HCC), the risk estimation for hepatocellular carcinoma in chronic hepatitis B (REACH-B), PAGE-B and Toronto HCC risk index (THRI) were assessed with comparisons.
Results: A total of 1330 chronic hepatitis B patients (821 men, 61.7%) who were treated with oral antivirals were finally analyzed. The mean age was 48.1 years. During the follow-up period (median, 65.8 months), 101 (7.6%) patients developed HCC. For the prediction of HCC development at 5-years, mPAGE-B showed the highest c-index (0.792, 95% confidence interval [CI] 0.759–0.826), followed by GAG-HCC (0.772, 95% CI 0.732–0.813; vs. mPAGE, p > 0.05), PAGE (0.769, 95% CI 0.731–0.807; vs. mPAGE, p > 0.05), REACH-B (0.714, 95% CI 0.663–0.764; vs. mPAGE, p < 0.05), CU-HCC (0.623, 95% CI 0.571–0.675; vs. mPAGE, p < 0.05), and THRI (0.542, 95% CI 0.516–0.599; vs. mPAGE, p < 0.05). The cumulative risk of HCC development at 3- and 5-years were 0% and 0% in the low-risk group (mPAGE score ≤ 8), 4.1% and 6.1% at 5-years in the intermediate-risk group (mPAGE score 8–12) and 10.8% and 19.7% in the high-risk group (mPAGE score ≥ 13), respectively (p < 0.001 by log-rank test; low- vs. intermediate-risk group, p < 0.001 and intermediate- vs. high-risk group, p < 0.001).

Conclusion: Our study demonstrated that mPAGE-B is applicable with acceptable predictive performance in Asian CHB patients receiving oral antiviral therapy. mPAGE-B showed the similar predictive performance to PAGE-B and GAG-HCC and the better performance than REACH-B, CU-HCC and THRI.

THU-225

Risk prediction model for hepatocellular carcinoma after hepatitis b e antigen seroclearance in patients treated with entecavir or tenofovir

Tae Seop Lim[1,2], Mi Young Jeon[1,2], Beom Kyung Kim[1,2], Jun Yong Park[1,2], Do Young Kim[1,2], Sang Hoon Ahn[1,2], Kwang-Hyub Han[1,2], Seung Up Kim[1,2]. *[1]Yonsei University College of Medicine, Internal medicine, Seoul, Korea, Rep. of South; [2]Severance Hospital, Yonsei Liver Center, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Only one risk prediction model for hepatocellular carcinoma (HCC) after hepatitis B e antigen (HBeAg) seroclearance has been available. Therefore, we established and validated a risk prediction model for HCC development after HBeAg seroclearance in patients with chronic hepatitis B (CHB) treated with either entecavir or tenofovir.
Method: We recruited patients with CHB who experienced HBeAg loss during either entecavir or tenofovir treatment between March 2006 and December 2016. Patients with significant alcohol abuse or decompensated cirrhosis were excluded.
Results: A total of 777 patients were evaluated. The mean age was 46.6 years old, and 59.3% were male. At the time of HBeAg seroclearance, 473 (60.9%), 296 (38.1%), and 8 (1.0%) of these patients received entecavir, tenofovir, or a combined use of entecavir and tenofovir, respectively. Ultrasonographic cirrhosis was identified in 321 (41.3%) patients. In multivariate analysis, male gender (hazard ratio [HR] = 2.236; 95% confidence interval [CI], 1.242-4.028; P = 0.007), ultrasonographic cirrhosis (HR = 6.076; 95% CI, 2.905-12.707; P < 0.001), and FIB-4 > 3.25 (HR = 2.145; 95% CI, 1.252-3.675; P = 0.005) were independent risk factors for HCC development after HBeAg seroclearance. Based on these independent predictors, a HBE-HCC model was developed (1x [male 1, female 0] + 3x (ultrasonographic cirrhosis 1, non-cirrhosis 0) + 1x (FIB-4 > 3.25 1, ≤ 3.25 0). The area under receiver operating characteristics to predict HCC development at 1-, 3-, 5-, and 10-years after HBeAg seroclearance was 0.775 (95% CI, 0.687-0.863), 0.791 (95% CI, 0.724-0.858), 0.771 (95% CI, 0.708-0.834), and 0.790 (95% CI, 0.745-0.845), respectively (all P < 0.05).
Conclusion: We established a new risk prediction model for HCC development, which we called the HBE-HCC model. This model is based on three independent risk factors (male gender, ultrasonographic cirrhosis, and FIB-4 > 3.25) in patients with CHB treated with entecavir or tenofovir and here we reported that the accuracy which can predict HCC development until 10 years was acceptable. This model might be helpful in risk stratification even with evidence of HBeAg seroclearance. However, external validation is required.

THU-226

Concomitant diabetes mellitus increases risk of liver fibrosis in treatment-naive chronic hepatitis B with low viral loads: Results from a matched case-control study

Hei Chun Justin Ma[1], Lung-Yi Mak[1], Ka-Shing Cheung[1], Yan Yue James Fung[1], Ching Lung Lai[1], Man-Fung Yuen[1], Wai-Kay Seto[1]. *[1]The University of Hong Kong, Medicine, Hong Kong, Hong Kong*
Email: wkseto@hku.hk

Background and aims: >60% of the world's diabetic population are from Asia, and East Asia has a high prevalence of chronic hepatitis B (CHB). The presence of diabetes may affect disease outcomes in CHB, although this interaction is not well understood. We aim to determine the association between diabetes and CHB in terms of metabolic, virologic and transient elastography profiles.
Methods: We prospectively recruited CHB patients with concomitant type two diabetes mellitus, as defined by the International Diabetes Federation, for measurement of liver biochemistry, virologic profiles, metabolic parameters and transient elastography for liver stiffness (LS) and controlled attenuation parameter (CAP). This cohort was matched with non-diabetic CHB patients according to age, gender, nucleoside analogue treatment status and duration in a 1:1 ratio. Cirrhosis was defined following American Gastroenterological Association as LS ≥ 11.0kPa. Steatosis was defined as CAP ≥ 248 dB/m.
Results: 970 CHB patients, including 485 diabetic CHB (mean age 60.9 ± 8.4 years, 66.4% male, 68.2% treated with median treatment duration 79.1 months) and 485 non-diabetic CHB (mean age 60.5 ± 8.4 years, 66.4% male, 68.2% treated with median treatment duration 77.5 months) were recruited in this interim analysis. Among treatment-naïve patients, median HBV DNA level was 450 (IQR 56-6, 700) IU/ml and 67.2% had HBV DNA levels < 2, 000 IU/ml. Diabetic CHB patients, when compared to non-diabetic patients, had significantly higher median LS (6.7 vs 6.1 kPa, p = 0.001) and CAP (272 vs 240 dB/m, p < 0.001). Median LS measurements showed similar differences in treatment-naïve patients (6.3 vs 5.2 kPa, p < 0.001) but not in on-treatment patients (6.9 vs 6.9 kPa, p = 0.938). The prevalence of cirrhosis was also only significantly different in treatment-naïve patients (18.8% vs 5.8%, p = 0.001) but not in on-treatment patients (24.2% vs 23.3%, p = 0.784). By multivariate analysis, the presence of diabetes was independently associated with increased LS in treatment-naïve patients (OR 1.100, 95% CI 1.020-1.186, p = 0.013) but not in treated patients (p > 0.05).
Conclusion: With the concomitant presence of diabetes, the risk of liver fibrosis is increased in treatment-naïve CHB with low serum HBV DNA levels. Diabetic CHB patients, even when virological activity is quiescent, may need monitoring for cirrhosis-related complications.

NTCP S267F variant associates with decreased susceptibility to HBV infection and decelerated progression of related liver diseases

Thanh Binh Mai[1,2,3], Xuan Hoan Nghiem[1,2,3], Tong Hoang[1,2,4], Tien Sy Bui[2,3], Tat Trung Ngo[2,3], C.-Thomas Bock[5], Linh Toan Nguyen[2,4], Huu Song Le[2,3], Hong Bang Mai[3], Christian G. Meyer[1,2], Thirumalaisamy P. Velavan[1,2]. *[1]University of Tübingen, Institute of Tropical Medicine, Tübingen, Germany; [2]Vietnamese-German Center for Excellence in Medical Research, Ha Noi, Viet Nam; [3]108 Military Central Hospital, Hanoi, Viet Nam; [4]Vietnamese Military Medical University, Hanoi, Viet Nam; [5]Robert Koch Institute, Department of Infectious Diseases, Berlin, Germany*
Email: velavan@medizin.uni-tuebingen.de

Background and aims: The sodium taurocholate co-transporting polypeptide (NTCP), encoded by the *SLC10A1* gene, is the entry receptor for the hepatitis B (HBV) and the hepatitis D (HDV) into hepatocytes. We aimed to determine potential associations of the rs2296651 variant (c.800C > T, S267F) with HBV infection as well as with the progression of related liver diseases
Method: The S267F variant was genotyped by DNA sequencing in 620 HBV-infected patients and 214 healthy controls (HCs). Among the patients, 450 individuals were tested for HDV by a nested PCR assay. Logistic regression was applied to examine the association.
Results: The S267F variant (genotypes rs2296651 CT and TT) was found more frequently among HCs (16%) compared to HBV-infected (6%) (HBV patients vs HC: OR = 0.32, 95% CI = 0.19-0.54, P = 0.00002). The T allele was found less frequent in HBV patients (3%) compared to HCs (OR = 0.34, 95%CI = 0.2-0.57, adjusted P = 0.00003). S267F variant (genotype CT) was also associated with decreased risk of the development of liver cirrhosis (LC) and hepatocellular carcinoma (HCC) (OR = 0.32, adjusted P = 0.013 and OR = 0.34, adjusted P = 0.002, respectively). In addition, patients with the genotype CT had lower levels of AST, ALT, total and direct bilirubin as well as higher platelet

NTCP rs2296651 S267F	CHB n = 176 (%)	LC n = 144 (%)	HCC n = 300 (%)	All HBV n = 620 (%)	HC n = 214 (%)	HBV vs. HC OR (95%CI); *P* value	CHB vs. HC. OR (95%CI), *P* value	LC vs. HC. OR (95%CI); *P* value	HCC vs. HC. OR (95%CI); *P* value

Table: (abstract: THU-227): Association of NTCP S267F variant with HBV-related liver diseases. CHB, chronic hepatitis B; LC, liver cirrhosis; HCC, hepatocellular carcinoma; HC, healthy controls; n, numbers individuals; OR, Odd ratio. *P* values were calculated using binary logistic regression model adjusted for age and gender.

counts, indicating an association with a more favorable clinical outcome.

Conclusion: The NTCP S267F variant of the *SLC10A1* gene exhibits protective effects against HBV infection and is associated with a reduced risk of progression to infection-related advanced liver diseases such as LC and HCC.

THU-228

HBV RNA can influence HBV viral load results depending on the test used

Andre Frontzek[1], Ed G. Marins[2], Christian O. Simon[2], Jesse Canchola[2], Rafael Delgado[3]. [1]*Labor Stein, Mönchengladbach, Germany;* [2]*Roche Molecular Systems, Inc., Pleasanton, United States;* [3]*University Hospital 12 de Octubre, Madrid, Spain*
Email: ed.marins@roche.com

Background and aims: The aim of HBV treatment with nucleot (s)ide analogs (NAs) is complete HBV DNA suppression and EASL guidelines recommend monitoring HBV DNA.
NAs therapy blocks the viral polymerase preventing the formation of HBV DNA from the pre-genomic RNA template that can be released in particles.
The detection and quantification of HBV RNA in plasma has been previously described.
The aim of the study was to compare different technologies for HBV DNA quantification (real time PCR and TMA) and evaluate potential impact of the type of test on clinical decision making.

Method: Remnant samples from a clinical study that evaluated treatment response in lamivudine-resistant chronic HBV patients were tested with the Roche **cobas**® HBV test (cobas) for the **cobas**® 6800/8800 Systems, the Hologic Aptima HBV test (Hologic) and with a modified version of the cobas HBV test adding a reverse-transcription step to the PCR profile, intended to amplify HBV RNA in addition to HBV DNA resulting in a total nucleic acid amplification test (cobas RT). The results from the three methods were compared to the reference test used in the trial. A sub-set of individual patients were analyzed with all methods over time (baseline, Weeks 12, 24, 48, 72, 84 and 96) and the mean viral load per time point was compared across tests.

Results: In total, 346 samples from 50 patients were included in the study. The means from all tests were concordant at baseline. At week 12 of therapy, the mean results were significantly different across tests. From week 24 up to week 96, the cobas mean results were comparable to the reference test while cobas RT and Hologic remained significantly different. cobas RT and Hologic mean results were comparable at all time points (figure).

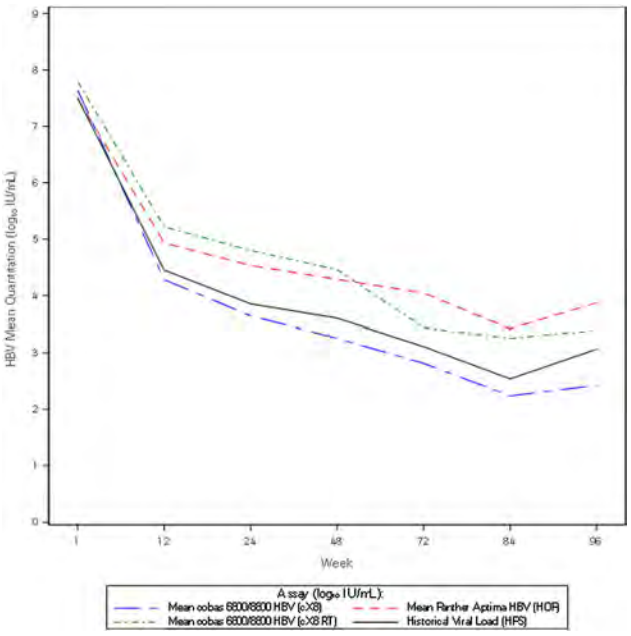

Figure: Longitudinal plot of mean viral load (across patients) from baseline to Week 96 for cobas HBV, Hologic HBV, cobas RT, and Historical HPS.

Conclusion: The presence of HBV RNA in plasma of subjects undergoing NAs treatment is suggested by the difference observed between viral load results of cobas vs cobas RT.
The results suggest cobas is specific for DNA, showing good correlation to the reference test while Hologic test results correlated

well with the cobas RT and were not comparable to the reference test during treatment with NAs suggesting lack of specificity for HBV DNA. The implications of RNA amplification can be misinterpretation of the clinical response and consequent additional interventions like adherence counseling, resistance testing and treatment modifications, all associated with incremental cost to the patient and health system which should be further evaluated.

THU-229

Increased gaps in hepatitis B pregnancy care identified among "low-risk" populations

Rena Mei[1], Meena Bansa[2], Tatyana Kushner[2]. [1]*Icahn School of Medicine at Mount Sinai, Medical Education, New York, United States;* [2]*Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, United States*
Email: rena.mei@icahn.mssm.edu

Background and aims: Although the United States (U.S.) is a low-endemic country with universal vaccination for the hepatitis B virus (HBV), about 1, 000 mothers still transmit HBV to their infants each year, making disease eradication difficult to attain. Pregnancy is a key time to intervene to decrease HBV transmission, as it is the only time for universal HBV screening in the U.S. However, recent studies demonstrate low rates of HBV DNA testing (<50%), initiation of antiviral therapy when indicated, and referral to specialty care (<60%) during pregnancy. These represent critical missed opportunities to prevent both vertical and horizontal transmission. We aimed to identify gaps in HBV pregnancy care and evaluate for predictors in an inner-city obstetrics care setting.
Method: We conducted a retrospective chart review of HBV-positive pregnant women at Mount Sinai Health System in NYC from 1/1/2015 to 6/30/2018. Adherence to care was defined as referral to specialist, HBV DNA testing, and antiviral initiation when indicated. Multivariable regression was performed to identify predictors of gaps in care. Causal inference analysis further delineated the causative impact of factors associated with adherence.
Results: 103 pregnancies in 96 patients were identified. Patients were 45.6% Asian, 31.1% African, and 7.8% White. 61 (59.2%) had private insurance and 42 (40.8%) had public (Medicaid) insurance. 14 (14%) were first diagnosed with HBV during the pregnancy. 86 (87%) had HBV DNA measured during pregnancy; of those, 46 (57%) had it checked at third trimester (weeks 25-30). 63 (69%) patients had not been following with a liver specialist prior to the pregnancy; of those, 46 (69%) were referred. Of the 15 who met criteria for antiviral therapy, 3 (20%) continued their pre-pregnancy treatment, 4 (27%) initiated therapy, and 8 (53%) were left untreated. Multivariable regression of insurance status, race, age, and provider type demonstrates a significant association between African ethnicity and increased adherence to care (OR = 3.28; 95% CI, 2.21-4.34). Causal inference demonstrates that having public (Medicaid) insurance causes increased adherence by an additional 16% from having private insurance.
Conclusion: Initiation of antiviral therapy when indicated during pregnancy remains low. Medicaid-insured and African-ethnic patients, considered underserved populations in the U.S., were more likely to receive the standard of care. Providers may selectively apply increased vigilance to certain "high-risk" groups, leaving others susceptible to gaps in care. As current efforts may be proportional to HBV prevalence, interventions (e.g., education and clinical decision support tools targeted to obstetrics care settings) in low endemic countries are necessary for global eradication of HBV.

THU-230

HBV and HDV confection trends in HIV+ patients in Vienna

Caroline Schmidbauer[1,2,3], David Chromy[1,2], David Bauer[1,2], Victor Schmidbauer[1,2], Mattias Mandorfer[1,2], Armin Rieger[4], Florian Mayer[5], Heidemarie Holzmann[6], Michael Trauner[2], Michael Gschwantler[3], Thomas Reiberger[1,2]. [1]*Vienna HIV and Liver Study Group, Vienna, Austria;* [2]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria;* [3]*Wilhelminenspital der Stadt Wien, Wiener Krankenanstaltenverbund, Department of Internal Medicine IV, Vienna, Austria;* [4]*Medical University of Vienna, Department of Dermatology, Vienna, Austria;* [5]*Medical University of Vienna, Division of Virology, Department of Laboratory Medicine, Vienna, Austria;* [6]*Medical University of Vienna, Center for Virology, Vienna, Austria*
Email: schmidbauer.c@gmail.com

Background and aims: Despite vaccination recommendations, hepatitis B (HBV) coinfections are common in HIV+ patients. Recent immigration trends and high-risk behaviour among men who have sex with men (MSM) have likely impacted on the epidemiology of HBV and delta (HDV) coinfection among HIV+ patients in Europe.
Method: N = 1874 HIV+ patients attending our clinic between 2014-2016 were assessed at HIV diagnosis (baseline, BL) and at last visit (follow-up, FU). We assessed HBV immunization status (anti-HBs (+)) as well as HBV (HBsAg (+)/HBV-DNA (+)) and HDV (anti-HDV (+)) coinfection rates at BL and at FU.
Results: N = 68 (3.6%) patients were never tested for HBV. At BL, n = 89/1793 (5.0%) HIV+ patients had HBV coinfection, while only n = 51/89 (57.3%) were tested for HDV. However, n = 11/51 (21.6%) had anti-HDV (+) and n = 3/7 (42.9%) showed HDV-RNA-viremia.
At BL, n = 417 (23.3%) had HBV-clearance (HBsAg (-)/anti-HBc (+)/anti-HBs (+)) and n = 1081 (60.3%) were HBV-negative (HBsAg (-)/anti-HBc (-)), however, only n = 377 (34.9%) had received vaccination and showed anti-HBs (+).
After a median FU of 9.4 years, n = 136/704 (19.3%) had received HBV-vaccination. Importantly, n = 8/1081 (0.7%) had acquired new HBV-infection (including n = 1/377 of initially vaccinated patients)-resulting in an overall number of n = 59/1607 (3.7%) HBV/HIV coinfected patients at FU: n = 21 (35.6%) HBeAg (+), n = 11 (18.6%) HBeAg (-), and n = 27 (45.8%) with unknown HBeAg status. From BL to FU, n = 22/80 (27.5%) cleared their HBsAg (-) while on HBV-active ART.
Among the total n = 97/1793 (5.4%) patients with HBV-coinfection, n = 56 (57.7%) underwent HBV-DNA PCR during FU with n = 42 (75%) achieving HBV-DNA-suppression. HDV-testing was performed in n = 19/59 (32.2%) HBV-patients during FU and HBV/HDV-coinfection was found in n = 6/19 (31.6%) of tested HBV/HIV+ patients.
Under HBV-active ART, n = 13/27 (48.1%) patients achieved normalization of their ALT values at FU and only n = 2/72 (2.8%) had advanced liver fibrosis according to FIB4 score (>3.25) at FU.
Conclusion: While HBV-testing is regularly performed in HIV+ patients, HBV-vaccinations have not been sufficiently implemented. HDV-testing is not systematically performed-although about one third of HBV/HIV+ patients may have HDV-co/superinfection. Suppression of HBV replication was achieved in 72.3% of HIV+ patients and 31/82 (37.8%) lost their HBsAg from BL to FU.

THU-231

Risk of hepatocellular carcinoma in patients with immune-tolerant chronic hepatitis B

Gyeol Seong[1], Dong Hyun Sinn[1], Wonseok Kang[1], Geum-Yon Gwak[1], Moon Seok Choi[1], Kwang Cheol Koh[1], Seoung Woon Paik[1], Yong Han Paik[1]. [1]*Samsung Medical Center, Seoul, Korea, Rep. of South*
Email: yh.paik@skku.edu

Background and aims: Recent studies have suggested that patients with immune-tolerant chronic hepatitis B (CHB), characterized by hepatitis b e antigen (HBeAg) positive patients with high serum hepatitis B virus (HBV) DNA but normal alanine aminotransferase

(ALT), may develop hepatocellular carcinoma (HCC). However, it is unclear how to stratify HCC risk in these patients.
Method: A retrospective cohort of 651 HBeAg positive, adult patients with high serum HBV DNA levels (>7 log IU/ml) but normal or mildly elevated ALT levels (<80 U/L) were analyzed. Age and FIB-4 index were used to categorize patients, and assessed HCC incidence rate in each subgroups. Normal ALT was defined as <35 U/L for males and <25 U/L for females.
Results: During a median 5.2 years of follow-up (range: 1.0-17.8 years), 24 (3.7%) patients developed HCC. Age and FIB-4 index were independent factors associated with HCC development. When stratified, 5 and 10-year cumulative HCC incidence rates were 0% and 2.0% for patients aged <40 years plus FIB-4 index <1.45, and were 5.9% and 32.7% for patients aged ≥ 40 years plus FIB-4 index ≥ 1.45, respectively ($p < 0.001$). In patients with normal ALT levels (n = 301), 10-year HCC incidence rate was 0% for patients aged <40 years plus FIB-4 index <1.45, while 5 and 10-years HCC incidence rate was 4.5% and 27.1% for patients aged ≥ 40 years plus FIB-4 index ≥ 1.45, respectively ($p < 0.001$).
Conclusion: In patients with immune-tolerant CHB, HCC risk was considerably high for aged patients with elevated FIB-4 index while HCC risk was very low for young patients with low FIB-4 index. These two factors could effectively stratify HCC risk, indicating that they may guide management plan for this population.

THU-232

Hepatitis B vaccination is effective among HIV-infected adults in Uganda

Emmanuel Seremba[1], Ponsiano Ocama[1], Richard Ssekitoleko[1], Harriet Mayanja-Kizza[1], Elly Katabira[1], Steven J Reynolds[2,3], Rose Nabatanzi[1], Corey Casper[4], Warren Phipps[4]. [1]*Makerere University College of Health Sciences, Kampala, Uganda;* [2]*Johns Hopkins School of Medicine, Baltimore, United States;* [3]*Division of Intramural Research, National Institute of Allergy and Infectious Disease, Bethesda, United States;* [4]*Fred Hutchinson's Cancer Research Center, Seattle, United States*
Email: eseremba@gmail.com

Background and aims: Coinfection with hepatitis B virus (HBV) and human immunodeficiency virus (HIV) is common in sub-Saharan Africa (SSA) and can lead to progression of liver disease, cirrhosis and hepatocellular carcinoma. Recent data demonstrate ongoing HBV transmission among HIV-infected adults in SSA, suggesting complications of HBV could be prevented with vaccination. Because HBV vaccine efficacy is poorly understood in HIV-infected persons in SSA, we sought to characterize the humoral response of HIV-positive Ugandan adults to the vaccine.
Method: We enrolled HIV-infected adults in Kampala, Uganda with no serologic evidence of prior exposure to HBV. Baseline socio-demographic variables, HBV and HIV history were obtained by participant interview and medical chart review. Three 20µg HBV vaccine doses were administered at intervals of 0, 1 and 6 months. Anti-HBs levels were measured at 4 weeks after the third vaccine dose. "Response" to the vaccine was defined as anti-HBs levels ≥ 10 IU/L and "high response" as ≥ 100 IU/L. Univariate and multivariate regression analysis were used to determine the predictors of vaccine response. **Results:** Of 251 HIV-positive adults screened, 132 (53%) had no prior HBV infection or vaccination and were enrolled. Most participants were women 89 (67%) and had a median (IQR) age of 32 years (27-41). 68 (52%) were on antiretroviral therapy >3 months. Median (IQR) CD4 count was 426 (261-583), and 64 (94%) of the 68 receiving ART had undetectable HIV RNA. Overall, 117 (92%) seroconverted to the vaccine (anti-HBs titres ≥10IU/L) with the majority 109 (86%) being high-level responders (anti-HBs ≥ 100IU/L). Eight (6.3%) were low-level responders (anti-HBs 10-100IU/L) and 10 (7.9%) non-responders (anti-HBs <10). In univariate analysis, only baseline CD4 >200 cells/mm3 was associated with both response (p = 0.02) and high-level response (p = 0.01). In multivariate analysis baseline CD4 was associated with "high response" with each unit increase in CD4 count corresponding to a 0.004 increase in vaccine response (p = 0.01, CI 0.001-0.008).
Conclusion: Half of the screened patients did not have immunity to HBV infection, suggesting a large "at risk" population for the infection among HIV-positive adults in Uganda. The vaccine was effective in eliciting a protective humoral immunologic response, particularly among those with higher CD4 counts. Our findings support routine HBV vaccination among HIV-positive adults at risk for HBV infection.

THU-233

Whole exome sequencing analysis of the role of rare human variation in chronic hepatitis B infection

Patrick R. Shea[1], Sarah Kleinstein[1], Nicholas Stong[1], Edward Gane[2], Kosh Agarwal[3], Zhaoshi Jiang[4], John F. Flaherty[4], Vithika Suri[4], Anuj Gaggar[4], Mani Subramanian[4], Maria Buti[5], Wan-Long Chuang[6], Scott Fung[7], David Goldstein[1]. Email: vithika.suri@gilead.com

Background and aims: To examine the role of rare human genetic variation in CHB, we performed whole exome sequencing (WES) on 1438 patients with CHB and 18776 population controls to test for genetic associations with baseline CHB phenotypes.
Method: DNA was isolated from 1438 CHB patients (Table 1) enrolled in phase 3 clinical trials of tenofovir disoproxil fumarate or tenofovir alafenamide. WES data was generated to an average depth of 81x coverage using the Illumina HiSeq2500 or NovaSeq DNA sequencing platforms. Genetic associations were assessed using single-variant tests and gene-based collapsing to detect rare variant associations with CHB phenotypes, including risk of CHB persistence and baseline viral quantitative traits. Fisher's exact test (FET) and linear regression were used for binary and quantitative traits, respectively. All tests were Bonferroni-corrected to adjust for multiple testing.

Table 1:

		N = 1438
HBeAg positive, n (%)		776 (54)
Median ALT U/L (Q1, Q3)		74.0 (47, 116)
Median HBV DNA log10IU/ml (Q1, Q3)		7.17 (5.53, 8.28)
HBV Genotype, n (%)	A	118 (8.2)
	B	240 (16.7)
	C	626 (43.5)
	D	375 (26.1)
	Other	31 (2.3)
	Not available	48 (3.2)

Results: The role of MHC class II haplotypes in HBV persistence was confirmed with an exome-wide significant association centered at the rs2308930 SNP in *HLA-DPA1* (p = 1.249E-7, OR = 1.41; logistic regression of CHB cases and controls). No single variant or gene was found to reach statistical significance (p < 2.65E-6 for collapsing analysis), however, several biologically relevant findings were identified. In a collapsing analysis of hepatitis B viral load (VL), the top result was the charged multivesicular body protein 7 (*CHMP7*) gene (p = 1.08E-4, linear regression of VL), a member of the ESCRT-III pathway that plays a critical role in the maturation of viral particles. In addition, a depletion of rare functional variation in the interferon alpha 2 (*IFNA2*) gene among HBeAg positive patients was identified (p = 2.99E-4, FET of HBeAg status). The *IFNA2* collapsing signal was primarily driven by a depletion of the A120T allele. Variation in *CHMP7* and *IFNA2* was also correlated with reduced levels of HBsAg (p = 0.001 and 0.02, respectively).
Conclusion: Here we present the results of largest WES study of patients with CHB reported to date. The findings suggest that rare

variation in *CHMP7* and *IFNA2* may influence clinically relevant phenotypes in CHB, however, given that these did not achieve statistical significance, additional confirmation is required.

THU-234

High body-mass index is associated with increased risk of alanine aminotransferase elevation and hepatocellular carcinoma in chronic hepatitis B patients with sustained viral control

Jian Sun[1], Weiyin Lin[2], Kaifeng Wang[2], Rong Fan[2], Xieer Liang[2], Jie Peng[2], Yabing Guo[2], Jinjun Chen[2], Zhihong Liu[2], Xiaoyun Hu[2], Jinlin Hou[3]. *[1]State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Nanfang Hospital, Southern Medical University, Department of Infectious Diseases, Guangzhou, China; [3]Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China*
Email: jlhousmu@163.com

Background and aims: Alanine aminotransferase (ALT) is a marker of liver damage that results from a range of etiologies. This study investigated whether high body-mass index (BMI) contributes to the risk of ALT elevation and hepatocellular carcinoma (HCC) in chronic hepatitis B (CHB) patients who achieved sustained viral control with antiviral treatment.
Method: This was a real-life, prospective cohort study which enrolled CHB patients receiving nucleos(t)ide analogues (NAs) treatment with sustained HBV DNA suppression (defined as HBV DNA undetectable on two consecutive visits 6 months apart). At study enrollment, logistic regression model was used to evaluate the association between high BMI (defined as BMI ≥ 25 kg/m^2) and the risk of ALT elevation (defined as ALT > 35 U/L in males and >25 U/L in females). Cox regression model was used to investigate the association between high BMI and the risk of HCC during follow-up. The impact of high BMI plus ALT elevation on the risk of HCC was also evaluated.
Results: A total of 2, 085 patients with sustained HBV DNA suppression were identified. At baseline, 494 (23.7%) patients had high BMI, the median ALT level was 23 U/L and ALT elevation was observed in 409 (19.6%) of patients. During a median follow-up of 2.27 years, 2011 patients finished at least two assessments of ALT, 578 (28.7%) patients had transient elevation of ALT (defined as ≥1 elevated ALT but some normal) and 139 (6.9%) patients had persistent elevation of ALT, 28 patients developed HCC with 3 years cumulative incidence of 1.85%. High BMI at baseline was associated with an increased risk of transient and persistent elevation of ALT (p < 0.001). The patients with high BMI at baseline had an increased risk of HCC, after adjustment by ALT, cirrhosis, age and sex [adjusted hazard ratio (aHR) and 95% CI: 2.40 (1.14-5.07), p = 0.021]. Compared to patients with BMI < 25 kg/m^2 and normal ALT at baseline, patients with BMI ≥25 kg/m^2 and ALT elevation were at the highest risk of HCC [aHR and 95% CI: 5.25 (1.87-14.73), p < 0.001].
Conclusion: High BMI is significantly associated with an increased risk of ALT elevation and HCC in CHB patients receiving NAs treatment with sustained viral control.

THU-235

Hepatitis B virus testing and cascade of care in a tertiary referral centre, Maastricht The Netherlands

Ozgur Koc[1,2,3], Eva van Oorschot[4,5], Dirk Posthouwer[1], Astrid Oude Lashof[1], Inge van Loo[1], Robin Ackens[6], Ger Koek[5,7]. *[1]Academic Hospital Maastricht, Department of Medical Microbiology, School of Nutrition and Translational Research in Metabolism, Maastricht, Netherlands; [2]St.Jan Hospital Genk, Department of Gastro-enterology and Hepatology, Genk, Belgium; [3]Universiteit Hasselt, Faculty of Medicine and Life Sciences, Hasselt, Belgium; [4]Faculty of Health, Medicine and Life Sciences-Maastricht University, Maastricht, Netherlands; [5]Academic Hospital Maastricht, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Maastricht, Netherlands; [6]Academic Hospital Maastricht, Department of Integrated Medicine, Maastricht, Netherlands; [7]University Hospital RWTH Aachen, Department of Surgery, Aachen, Germany*
Email: o.koc@mumc.nl

Background and aims: There are approximately 40, 000 people (0.2%) in the Netherlands chronically infected with the hepatitis B virus (HBV). Amongst this population, it is not clear how many have been linked to care and are still under follow-up in the hepatitis outpatient clinics. Therefore, in this study, we aimed to determine the cascade of care of all known chronic hepatitis B patients in our Maastricht UMC+.
Method: Based on laboratory and patient data, we retrospectively identified all people with a positive hepatitis B surface antigen (HBsAg) from 1st December 1996 to 30th September 2018. Demographic and viral factors (alanine-aminotransferase (ALT), HBV DNA and HBeAg status) were extracted within 6 months of a positive HBsAg, and it was identified if a specialist evaluation was conducted, from the hospital's database. Patients with a chronic HBV infection (positive HBsAg for >6 months) were observed until they started treatment or until their follow-up ended.
Results: In total, 644 HBsAg positive people with a median age of 35 years (interquartile range: 19) at the time of diagnosis were found. Out of 644 individuals with a positive HBsAg, 497/644 (77%) had ALT testing, 271/644 (42%) had testing for HBV DNA and 515/644 (80%) had HBeAg testing within six months after diagnosis. Overall, 75/644 (12%), 471/644 (73%) and 98/644 (15%) people were designated as acute hepatitis B, chronic hepatitis B and unknown cases respectively. A total of 421/471 people (89%) with a chronic HBV infection visited a specialist and 180/471 (38%) of them were eligible for antiviral treatment of whom 169/180 (94%) started treatment and 117/169 (69%) achieved HBV DNA suppression. At this moment, 79/169 (47%) chronic hepatitis B patients who started antiviral treatment are still under follow-up.

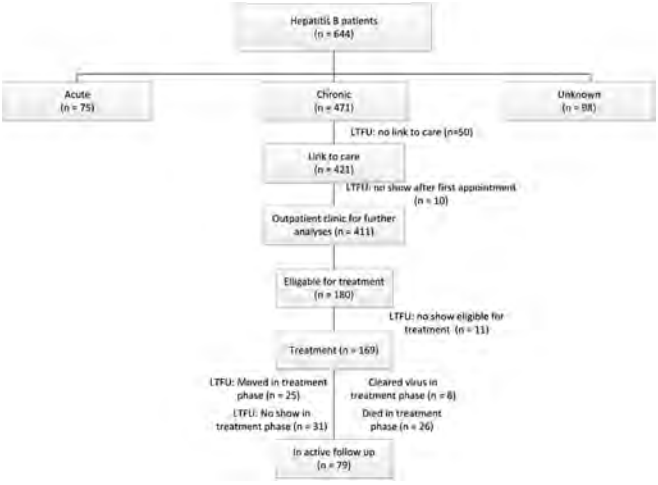

Figure 1: **Cascade of care for hepatitis B patients within the region of Maastricht, The Netherlands.** *LTFU, Loss to follow-up*

Conclusion: To a considerable amount of HBsAg positive individuals in the Maastricht region, the recommended laboratory testing and/or specialist evaluation is not given. Only half of the chronic hepatitis B patients who started antiviral treatment are still under follow-up. These results reinforce the need of continual public health efforts to re-evaluate chronic hepatitis B patients and to ensure adequate follow-up in order to eliminate viral hepatitis B by 2030.

THU-236

Integration of HBV DNA near cancer-related genes in HBsAg-negative hepatocellular carcinoma patients

Danny Wong[1,2], Ching Yan Serene Cheng[1], Lung-Yi Mak[1], Wai Pan To[1], Tan-to Cheung[2,3], Wai-Kay Seto[1,2], Yan Yue James Fung[1,2], Kwan Man[2,3], Ching Lung Lai[1,2], Man-Fung Yuen[1,2]. *[1]The University of Hong Kong, Medicine, Hong Kong, Hong Kong; [2]The University of Hong Kong, State Key Laboratory of Liver Research, Hong Kong, Hong Kong; [3]The University of Hong Kong, Surgery, Hong Kong, Hong Kong*
Email: dannykhwong@gmail.com

Background and aims: HBV DNA can integrate into host chromosomes, which may cause chromosomal instability and/or dysregulation of cancer-related genes, leading to HCC. We previously identified that HBsAg-negative HCC patients could have occult hepatitis B infection (OBI), based on their detectable HBV DNA in the liver tissues (Wong et al, J Hepatol. 2018;68:S474). In this study, we aimed to investigate the presence of HBV DNA integration in tumour and non-tumour tissues and identify the integration sites.
Method: Liver DNA was extracted from both tumour and non-tumour tissues of 62 HBsAg-negative HCC patients with OBI. HBV integration was detected by Alu-PCR sequencing, with one primer targeting to HBV (surface, core, polymerase, or X) and another primer targeting to the Alu-repeat regions in the human chromosomes.
Results: Of the 62 HCC patients with OBI, 43 (69%) were found to have HBV integration (35 found in tumour and 16 in non-tumour tissues, with 8 patients having integration in both tumour and non-tumour tissues). The majority (39/43; 91%) of OBI patients with HBV integration did not have histological evidence of cirrhosis. The common viral breakpoints of HBV integration were at the polymerase/preS1 region (18/35 tumour [51%] and 6/16 non-tumour [38%]) and the X/Enhancer II/precore region (15/35 tumour [43%] and 9/16 non-tumour [56%]). The most frequent identifiable integration sites in the tumour tissues were chromosome 5 (5 cases), chromosome 11 (3 cases) and chromosome 17 (4 cases), while the most frequent sites in the non-tumour tissues were chromosomes 3 and 4 (3 cases each). In the tumour tissues, integration near genes encoding the RING finger protein COP1 (negative regulator of p53), cyclin A2 (cell cycle-related), promoter region of TERT (regulator of telomerase activity) and lysine methyltransferase 2B (histone modification) were found. In the non-tumour tissues, integration near the coding regions of alpha-3-catenin (tumour suppressor in HCC) and CREB binding protein (transcription activator) were identified.
Conclusion: HBV integration was found in 69% of HBsAg-negative HCC patients with OBI. HBV integrations were identified mostly in the tumour tissues, but were also found in the non-tumour tissues. The majority of OBI patients with HBV integration did not have cirrhosis, suggesting that HBV integration, especially those near cancer-related genes, is a likely cause of HCC in OBI patients.

THU-237

Increasing prevalence of indications to choose bone/renal-friendly antiviral drug: A territory-wide study of 135, 414 patients from 2000 to 2017

Grace Lai-Hung Wong[1], Becky Wing-Yan Yuen[1], Yee-Kit Tse[2], Hester Wing-Sum Luk[1], Terry CF Yip[1], Henry Chan[1], Vincent Wai-Sun Wong[1]. *[1]The Chinese University of Hong Kong, Shatin, Hong Kong; [2]The Chinese University of Hong Kong, Shatin, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: The latest clinical practice guideline from European Association for the Study of the Liver (EASL) published in 2017 advocate the use of entecavir or tenofovir alafenamide (TAF) over tenofovir disoproxil fumarate (TDF) according to age, bone disease and renal alteration. As patients with chronic hepatitis B (CHB) are aging with improved survival under better healthcare, more patients may fulfil these criteria. We aimed to determine the prevalence of these criteria in the territory-wide CHB cohort in Hong Kong over 18 years from year 2000 to 2017.

Method: CHB patients who have been under the care at primary, secondary and tertiary medical centers in the public sector in Hong Kong were identified through the Clinical Data Analysis and Reporting System of the Hospital Authority. The demographics and prevalence of relevant bone and renal co-morbidities, and relevant laboratory parameters were determined according to patients' first appearance in four time periods: 2000-2004, 2005-2009, 2010-2013 and 2014-2017.
Results: 136, 414 CHB patients were included. The prevalence of the above criteria increased over the four periods: age >60 years 11.6%, 20.4%, 27.6% and 35.4%; Steroid/medications that worsen bone density 57.2%, 50.5%, 56.0% and 61.8% respectively; albuminuria 0.2% 0.4% 0.7% and 1.1% respectively, and low phosphate (<2.5 mg/dl) 3.9%, 4.0%, 5.1% and 7.0% respectively (all $P < 0.001$; Figure).

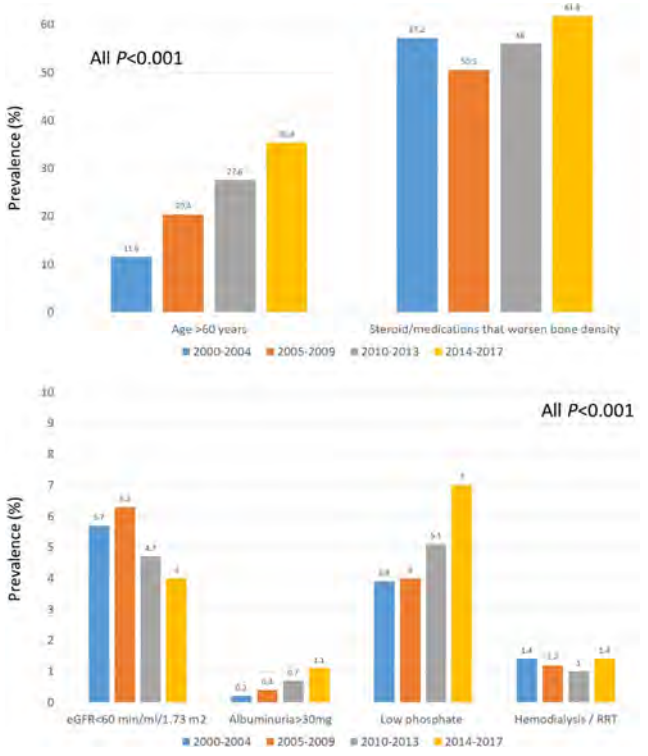

Figure: Prevalence of co-morbidities to choose entecavir or tenofovir alafenamide (TAF) over tenofovir disoproxil fumarate (TDF) over the four periods. eGFR = estimated glomerular filtration rate, RRT = renal replacement therapy.

Conclusion: CHB patients are getting older with increasing prevalence of indications to choose entecavir or TAF over TDF according to the latest EASL guidelines.
Funding: This work was supported by the Investigator Sponsored Research of Gilead Sciences (Reference: IN-US-988-5290).

THU-238

Low rates of antiviral therapy among treatment-eligible adults with chronic hepatitis B virus infection

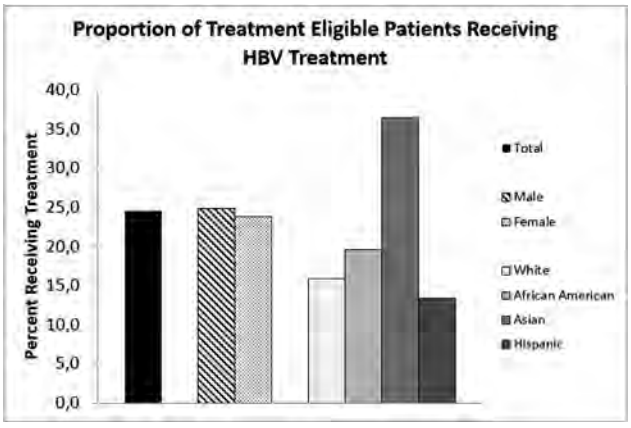
Robert Wong[1], Mamta Jain[2], Onkar Kshirsagar[3], Lakshmi Digala[1], Christopher Clark[4], Mae Thamer[3]. *[1]Alameda Health System, Oakland, United States; [2]UT Southwestern Medical Center, Dallas, United States; [3]Medical Technology and Practice Patterns Institute, Bethesda, United States; [4]Parkland Health And Hospital System, Dallas, United States*
Email: rowong@alamedahealthsystem.org

Background and aims: Timely initiation of hepatitis B virus (HBV) treatment among eligible patients contributes to viral suppression and reduces long term risk of disease progression to cirrhosis and hepatocellular carcinoma. However, overall HBV treatment rates are

sub-optimal, particularly among ethnic minority and immigrant populations, which are the highest risk groups for chronic HBV. We aim to evaluate treatment eligibility and treatment rates among a large ethnically diverse adult HBV population.

Method: We retrospectively evaluated adults with chronic HBV at two urban safety-net heath systems from January 1, 2010 to December 31, 2015, with a minimum of 2-years follow-up. Chronic HBV was identified with ICD-9/10 diagnosis coding and confirmed with laboratory data. HBV treatment eligibility was determined using American Association for the Study of Liver Diseases criteria, which included assessment of HBV E antigen (HBeAg) status, serum alanine aminotransferase (ALT), HBV viral load, and fibrosis stage. Comparison of HBV treatment eligibility and HBV treatment rates among eligible patients were performed using chi-square testing, and adjusted multivariate Cox proportional hazards models identified predictors of receiving HBV treatment among eligible patients. Statistical significance was met with $p < 0.05$.

Results: Among 2, 150 chronic HBV patients with available data to assess treatment eligibility (58.1% men, 25.8% white, 39.1% African American, 32.6% Asian, 12.4% Hispanic), 29.5% had cirrhosis, 5.3% had HCC. Overall, 28.4% were eligible for HBV treatment, with significantly higher rates of treatment eligibility among men compared to women (35.8% vs. 18.2%, $p < 0.01$) and similar eligibility across race/ethnicity groups. Among eligible patients, 24.5% received HBV treatment at any point during the study and only 8.0% received HBV treatment within 6 months of becoming eligible. While no sex-specific differences were observed, treatment-eligible Asians were significantly more likely to receive HBV treatment compared to whites (36.4% vs. 15.9%; HR 5.06, 95% CI 2.05-12.51, $p < 0.01$). Significantly higher likelihood of HBV treatment was also observed in patients with cirrhosis (24.9%; HR 1.81, 95% CI 1.07-3.09, $p < 0.03$).



Conclusion: Among an ethnically diverse cohort of HBV patients across 2 urban safety-net hospitals, only 24.5% of eligible patients received HBV treatment. While Asian HBV patients were significantly more likely to receive HBV treatment, over 60% of treatment-eligible Asian HBV patients did not did not receive treatment during the study period.

THU-239

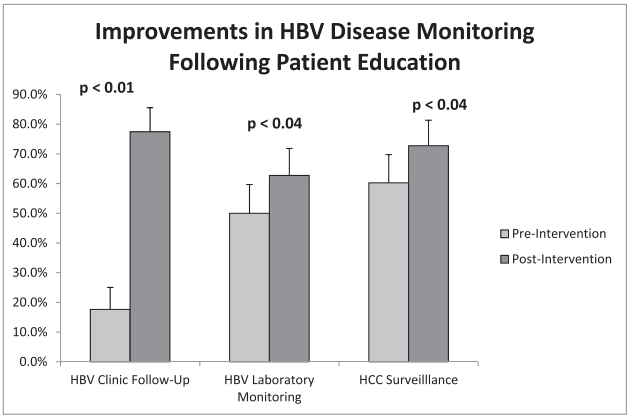
Improving patient knowledge about hepatitis B virus leads to improvements in HBV disease monitoring

Robert Wong[1], Mandana Khalili[2]. [1]*Alameda Health System, Oakland, United States;* [2]*Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, United States*
Email: rowong@alamedahealthsystem.org

Background and aims: Suboptimal patient knowledge and awareness of hepatitis B virus (HBV) contributes to barriers in effective HBV monitoring. We aim to evaluate the impact of a HBV patient educational intervention on improving HBV disease monitoring, with a focus on clinic follow-up, laboratory monitoring, and HCC surveillance.

Method: Consecutive chronic HBV adults at a safety-net gastroenterology clinic were recruited from July 2017-May 2018. Surveys assessing HBV Knowledge were conducted before and after a formal language-concordant HBV education session. Appropriate HBV clinic follow-up (≥1 visit/year), laboratory monitoring (≥1 HBV viral load and alanine aminotransferase test/year), and HCC surveillance (≥1 HCC imaging test/year in eligible patients) were assessed before and after education. Improvements in these parameters of HBV monitoring were assessed using chi-square testing and adjusted multivariate logistic regression models.

Results: Among 102 HBV patients (54.9% men, mean age 52.0 ± 13.8, 83.3% Asian, 89.2% non-US born, 42.2% non-English speaking, 23.5% less than high school education, 37.3% unemployed), HBV Knowledge score improved from 7.0 out of total 13.0 points (95% CI 5.98-8.01), to 9.67 points (95% CI 9.41-9.93), representing 38.1% improvement. Following educational intervention, appropriate HBV clinic follow-up improved from 17.7% to 77.5% of patients ($p < 0.01$), HBV lab monitoring from 50.0% to 62.8% ($p < 0.04$), and HCC surveillance from 60.3% to 72.7% ($p < 0.04$). Post-education HBV Knowledge score was the only significant predictor of improvements in HBV disease monitoring. On multivariate regression, compared to patients with HBV Knowledge score <10, those who achieved HBV Knowledge score of ≥10 after the educational intervention were significantly more likely to have appropriate HBV clinic follow-up (OR 4.07, 95% CI 1.27-13.01, $p = 0.02$) and HCC surveillance (OR 9.20, 95% CI 1.48-57.14, $p < 0.02$), demonstrating the ability to improve HBV disease monitoring through increasing patients HBV awareness and knowledge.



Conclusion: HBV disease monitoring among safety-net populations, as measured by clinic follow-up, laboratory monitoring, and HCC surveillance was sub-optimal. A patient-centered language concordant educational intervention successfully improved patients HBV Knowledge, which translated into significant improvements in HBV disease monitoring.

Glial cell line-derived neurotrophic factor is associated with fibrosis in patients with chronic viral hepatitis B

Liu Wu[1], Tao Le[1], Cheng Liu[1], Wenting Ma[1], Wei Zhang[1]. [1]*Putuo Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China*
Email: liucheng0082010@163.com

Background and aims: Liver biopsy is currently the most reliable way of evaluating liver fibrosis in patients. Its inherent risks limit its widespread use. Glial cell line-derived neurotrophic factor (GDNF) is a member of the transforming growth factor superfamily, whereas its

content and expression in liver fibrosis was never studied. The aim of this study was to assess GDNF in human serum comparison with liver fibrotic F stages. Meanwhile, we detected the liver GDNF mRNA expression in liver biopsy and comparison with liver fibrotic F stages and biochemical parameters.
Method: There were 319 (F0 = 30, F1 = 71, F2 = 115, F3 = 67, F4 = 36) serum samples for GDNF detection using ELISA from patients with clinically diagnosed chronic liver disease who underwent liver biopsy. The expression of GDNF mRNA was also detected in 212 (F0 = 15, F1 = 38, F2 = 89, F3 = 46, F4 = 24) patients using real-time PCR analysis.
Results: The serum GDNF level in F4 stage were significantly higher compared with each F0-3 stage patients ($p < 0.001$). GDNF was associated with fibrosis stage (risk ratio [RR] 0.544, 95% confidence interval [CI]: 0.334-0.885). GDNF showed areas under the receiver operating characteristics curve (AUROC) of 0.77 (95% CI: 0.71-0.83) and 0.79 (95% CI: 0.71-0.88), for liver injury and F4 stage, respectively. Compared to existing fibrosis scores, GDNF was significantly superior to the aspartate aminotransferase (AST) to platelet ratio index (APRI) and fibrosis 4 score (FIB-4) for F4 stage. Liver fibrosis progression was associated with GDNF level using multiple logistic regression ([RR] 0.176, 95% [CI]: 0.061-0.509). GDNF mRNA from liver biopsy could reflect the liver G stage and validate the serum results in some extent.
Conclusion: GDNF levels are increased in patients with chronic viral hepatitis, reflecting HSC activation. Increased GDNF is associated with the severity of disease and predicts fibrosis. Non-invasive tests can accurately predict hepatic F4 stage and may reduce the need for liver biopsy in the majority of HBV-infected patients.

THU-241
Influence of HBV genotype on the risk of hepatocellular carcinoma: mediating roles of different phase of viral infection and epigenetic modifications

Wan-Jung Wu[1], Yi-Chun Kuo[1], Wei-Yi Kao[1], Shu-Han Yang[1], Chih-Feng Wu[1], Chih-Lin Lin[2], Chun-Jen Liu[3], Yi-Wen Huang[4], Ming-Whei Yu[1]. *[1]National Taiwan University, Taipei, Taiwan; [2]Ren-Ai Branch, Taipei City Hospital, Taipei, Taiwan; [3]National Taiwan University Hospital, Taipei, Taiwan; [4]Cathay General Hospital Medical Center, Taipei, Taiwan*
Email: wendy1234599@gmail.com

Background and aims: Chronic hepatitis B (CHB) is a dynamic disease divided into several phases, depending on virus-host interaction. Duration of phases varies among CHB patients, and its association with hepatocellular carcinoma (HCC) remains inconclusive. HBV genotype is associated with timing of phase transition, but the underlying mechanisms are unclear. In vitro models suggest that HBV can alter host DNA methylation, affecting gene expression. We evaluated methylation status of leukocyte DNA to examine the significance of epigenetic variation in the interaction between virus and host immune system during phase transition and its associations with clinical outcomes.
Method: We used a case-cohort approach to investigate the long-term risks of HCC relating to phases of CHB and effect modification by HBV genotype in a longitudinal viral-load study of 1143 treatment-naive HBV carriers. We prioritized HCC-associated DNA methylation loci based on their correlation with viral replication and functional relevance with omics data and bioinformatics analysis. Mediating effects of distinct phases and epigenetic changes on genotype C-related HCC risk were assessed in 574 subjects using mediation analysis.
Results: Of 1116 subjects with ALT and viral markers data, 69 were immune-tolerant, 100 were immune-active (32 HBeAg positive), 505 were inactive, and 442 were phase indeterminate at baseline. The multivariate hazard ratios were 4.83 and 11.52, respectively, for the immune-tolerant and immune-active group, compared to the inactive group. HBV genotype modified this association. Integrative analysis of methylome with clinical data identified epigenetic changes associated with HCC and viral replication. We focused on methylation at CpGs in three immune genes (IFI44L, PRF1, and PRR5L) that demonstrated correlation with gene expression ($r = -0.34$–0.73; $p < 0.008$). IFI44L gene methylation was found to be strongly associated with immune-active phase ($p = 0.0015$) and genotype C infection ($p = 0.0190$). Mediation analysis indicated that prolonged immune-active phase accounted for 16.5% ($p = 0.0002$) of the effect of genotype C on HCC risk. IFI44L gene methylation was also identified as a mediator of the genotype C-related HCC risk through prolonged immune-active phase.
Conclusion: The association between HBV genotype and HCC was in part mediated through immune phases. We highlight a role of immune-specific gene methylation in phase transition and pathogenesis of virus-host interaction.

THU-242
Clinical non-invasive markers for hepatic inflammation and fibrosis assessment in chronic hepatitis B with normal alanine aminotransferase

Zhao Wu[1], Xiao-Qin Dong[1], Hong Zhao[1], Guiqiang Wang[1]. *[1]Peking University First Hospital, Beijing, China*
Email: john131212@sina.com

Background and aims: Liver biopsy is the reference method to assess hepatic inflammation and fibrosis and for antiviral therapy decision in chronic hepatitis B (CHB) with normal alanine aminotransferase (ALT). The study aims to explore non-invasive markers for assessing inflammation or fibrosis in CHB with normal ALT.
Method: 235 treatment naïve CHB patients with normal ALT underwent liver biopsy were analyzed in this prospective multi-center study. We analyzed data using univariate and multivariate analysis and receiver operating characteristic curve (ROC).

Table:

C-IV (pg/ml)	736.1 ± 321.5	947.3 ± 460.5	0.000	0.398
LSM (KPa)	6.7 ± 7.3	11.5 ± 6.7	0.000	0.000
qHBsAg, $\log_{10}$ (IU/ml)	3.8 ± 1.0	3.4 ± 0.6	0.001	0.201
Anti-HBc, $\log_{10}$ (IU/ml)	3.8 ± 1.0	4.4 ± 0.6	0.000	0.001
HBV DNA, $\log_{10}$ (IU/ml)	5.8 ± 2.2	5.3 ± 2.0	0.054	
HBeAg, Positive, n (%)	63(52.9)	59(50.8)	0.750	

Results: 84 (35.7%) cases had moderate inflammation (Histology activity index, HAI ≥5) and alpha fetoprotein (AFP) ($p = 0.025$), anti-hepatitis B virus core antibody (anti-HBc) ($p = 0.001$) and liver stiffness measurement (LSM) ($p = 0.031$) were independent variables. 78 (33.2%) cases had significant fibrosis and platelet (PLT) ($p = 0.009$), albumin (ALB) ($p = 0.006$), anti-HBc ($p = 0.003$) and LSM ($p = 0.000$) were independent variables. Furthermore, 116 (49.4%)

cases had moderate inflammation or significant fibrosis who were recommended to receive antiviral therapy and aspartate aminotransferase (AST) (p = 0.031), AFP (p = 0.044), anti-HBc (p = 0.001) and LSM (p = 0.000) were independent variables. Our novel AAL index [AAL index = exp (Y)/[1+exp (Y), Y = 0.344*AFP (ng/ml) +1.643*$\log_{10}$Anti-HBc (IU/ml)+0.526*LSM (kPa)-12.119] showed good performance for diagnosing moderate inflammation or significant fibrosis with AUROC of 0.889. A high cutoff value (>0.64) with PPV of 96.2% was chosen to diagnose moderate inflammation or significant fibrosis and a low cutoff value (≤ 0.22) with NPV of 87.3% was chosen to exclude. Finally, 108 (46.0%) of 235 patients could avoid liver biopsy based on AAL index.

Conclusion: AST, AFP, anti-HBc and LSM are related to antiviral therapy decision among CHB patients with normal ALT. The novel AAL index is a more reliable non-invasive model.

THU-243

Occult hepatitis B virus infection after haploidentical haematopoietic stem cell transplantation patients: incidence and characterization of HBV pres/s gene mutations

Haiying Zhang[1], Lai Wei[1], Jianghua Wang[1], Huiying Rao[1]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory for Hepatitis C and Immunotherapy for Liver Disease, Beijing, China*
Email: weilai@pkuph.edu.cn

Background and aims: Occult hepatitis B virus (HBV) infection (OBI) is found in allogeneic haematopoietic stem cell transplantation (HSCT) patients. However, incidence and characterization of HBV preS/S gene mutations in patients with OBI infection receiving haploidentical HSCT (haplo-HSCT) has not been prospectively studied. OBI has been associated with an increased risk for the development of hepatocellular carcinoma and cirrhosis.

Method: We retrospectively evaluate the incidence and characterization of HBV preS/S gene mutantions in haplo-HSCT patients. From January 2014 to September 2018, 227 patients who received haplo-HSCT at Peking University Institute of Haematology were screened for hepatitis B surface antigen (HBsAg), antibodies to HBV core (anti-HBc). Serum samples negative for HBsAg and positive for anti-HBc were subjected to nucleic acid extraction and HBV DNA detection by real-time PCR. PreS/S gene mutants were analyzed by clonal sequencing in cases with occult HBV infection and 30 control chronic carriers.

Results: 189/227 patients were HBsAg-negative. The 15/189 (7.94%) HBsAg-negative patients with haplo-HSCT tested positive for HBV-DNA in serum. A total 13 OBI-patients and 30 control patients were analyzed for the the preS gene and S gene through sequencing simultaneously. 45 preS/S gene mutations were cloned from 13 OBI sequential serum samples, including 10 mutations that were not previously documented. 26 preS/S gene mutations significantly correlated with OBI. 11/13 OBI-patients (84.6%) carried in median 3 mutations in the three regions labelled here as preS1, preS2, and S were significantly higher in chronically-infected patients. Of 13 OBI sequences, 9 harboured MHR mutations. The populations of variants harbouring the D49V, W56T, L75M, I84T, A90V, P41Q, N51T, P/T78A, M120I, R135K, F141P and T168I mutations in the preS region and the T/I126M/N, P127I, Q129H and P142L mutations in the "a" determinant region were detected more frequently in the occult subjects than in the carriers.

Conclusion: This is the first report demonstrating OBI after haplo-HSCT confirmed by molecular analysis. We found a high prevalence (7.94%) of OBI in haplo-HSCT patients suggesting that routine screening for HBV-DNA should be considered in haplo-HSCT population in our region. Our data suggest that preS mutations and "a" determinant mutations are associated with OBI. This has implications for HBV diagnosis and vaccine improvement.

THU-244

Virological and clinical characteristics of chronic hepatitis delta patients of Mongolia

Delgersaikhan Zulkhuu[1], Bekhbold Dashtseren[2], Myagmarjav Budeebazar[2], Maralmaa Enkhbat[2], Miriam Eichner[3], Purevjargal Bat-Ulzii[2], Zulkhuu Genden[2], Altankhuu Mordorjyn[2], Dahgwahdorj Yagaanbuyant[3], Naranbaatar Dashdorj[2,3], Andreas Bungert[3], Naranjargal Dashdorj[2,4]. [1]*Liver Center, Ulaanbaatar, Mongolia;* [2]*Liver Center, Ulaanbaatar, Mongolia;* [3]*Onom foundation, Ulaanbaatar, Mongolia;* [4]*Onom foundation, Ulaanbaatar, Mongolia*
Email: z.delgersaikhan@onomfoundation.org

Background and aims: Mongolia has the highest prevalence of chronic hepatitis B (HBV) and D (HDV) virus co-infection. HBV-HDV co-infection leads to rapid progression towards liver-related complications and is considered to be the most severe form of chronic viral hepatitis.

We here describe virological and clinical characteristics of chronic HDV patients in Mongolia.

Method: Data of 2303 HDV patients were collected for this retrospective study. We included individuals who tested positive for HBV surface antigen (HBsAg), HDV antibody (anti-HDV) and HDV-RNA any time between October 2015 to June 2018.

We summarized latest results for HDV-RNA, HBV-DNA, HBV envelope antigen (HBeAg), HBsAg, liver function tests, platelets (PLT) and fibroscan.

Patients were divided into groups according to HDV-RNA level (cleared (not detected), low (<10^4 IU/ml), medium (10^4 to 10^5 IU/ml) and high (>10^5 IU/ml)). Differences between this groups with respect to clinical markers and general biomarkers were analyzed by two-tailed t-test.

Results: Most individuals were HBeAg-negative (82.1%) and HDV-RNA positive (86.7%). 305 patients had cleared HDV-infection. Advanced liver fibrosis was found in 51.3% of the patients.

Table: (abstract: THU-244)

	patients tested	total n = 2303	cleared n = 305	low (<10^4IU/ml) n = 461	medium (10^4 to 10^5IU/ml) n = 336	high (>10^5IU/ml) n = 1201
mean age	2303	44.9	46	45.6	45.7	44.1
male%	2303	47.6	49.1	46.4	43.1	48.5
ALT±SDIU/L	897	71.2 ± 71.8	34.9 ± 27.8	49.5 ± 47.6	76.7 ± 81.7	86.4 ± 78.4
AST±SDIU/L	894	47.8 ± 41.5	27 ± 22.6	34.1 ± 24.4	51.5 ± 4.0	56.8 ± 46.7
ALB±SDmg/dL	891	42.2 ± 3.9	43.6 ± 3.9	43.5 ± 3.4	42.1 ± 4.3	41.4 ± 3.8
PLT±SD10^3/L	721	189.6 ± 56.9	202 ± 62.4	203.5 ± 64.0	176.3 ± 50.6	186.1 ± 53.4
HbeAg positive at serology%	712	17.9	7.2	7.4	8.5	26.1
HBV-DNA$\log_{10}$ IU/ml	1184	275-ND6.5 ± 7.6	6.9 ± 7.9	6.8 ± 7.7	5.3 ± 6.4	5.6 ± 6.6
HDV-RNA$\log_{10}$ IU/ml	2303	305-ND7.0 ± 8.1	0	3.2 ± 3.4	4.7 ± 4.4	6.9 ± 8.1
HBsAg$\log_{10}$ IU/ml	1228	3.9 ± 4.4	3.9 ± 4.8	3.7 ± 4.1	3.8 ± 3.8	4.0 ± 3.9
Fibroscan±SDkPa	720	10.9 ± 7.9	8.2 ± 6	10.1 ± 9.3	11.39 ± 7.19	11.5 ± 7.7

Fibroscan score was higher (p < 0.05) in patients with low, medium and high HDV-RNA levels versus patients who had cleared HDV-infection. We found no difference (p >0.05) between ALT and PLT levels in patients with low HDV-RNA versus patients with cleared infection. However, patients with medium and high HDV-RNA had elevated ALT and reduced PLT levels compared to patients who had cleared infection.

Conclusion: Mongolian chronic HDV patients are mostly young, HBeAg negative and have advanced liver fibrosis indicating rapid progression. Lower HDV-RNA level was indicative of less inflammation.

Alcoholic liver disease

THU-251

Metabolic risk factors for advanced liver disease among alcohol risk users in the general population

Fredrik Åberg[1,2], Pauli Puukka[3], Perttu Sahlman[4], Markku Nissinen[4], Veikko Salomaa[3], Satu Männistö[3], Annamari Lundqvist[3], Markus Perola[3], Antti Jula[3], Martti Färkkilä[4]. [1]*Helsinki University Hospital, Transplantation and Liver Surgery Clinic, Helsinki, Finland;,* [2]*Sahlgrenska university hospital, Transplant Institute, Gothenburg, Sweden;,* [3]*National Institute for Health and Welfare, Helsinki and Turku, Finland;,* [4]*Helsinki University and Helsinki University Hospital, Clinic of Gastroenterology, Helsinki, Finland*
Email: fredrik.aberg@helsinki.fi

Background and aims: 15–20% of alcohol risk users will develop liver cirrhosis. Metabolic factors may modify this risk for cirrhosis, but it remains unclear which metabolic factors are most important in alcohol risk users. We analyzed the role of several metabolic factors in predicting the development of advanced liver disease in alcohol risk users.

Method: Of 41243 participants in several Finnish health-examination surveys (FINRISK 1992-2012 or Health 2000), we included alcohol risk users, defined as weekly ethanol consumption > 210g for men and > 140g for women. Subjects with baseline clinical liver disease or viral hepatitis were excluded. Data were linked with national registers for liver-related admissions, mortality, and liver cancer until 2013. Metabolic factors (diabetes, body-mass index (BMI), waist circumference, waist-hip ratio, non-HDL and HDL cholesterol, triglycerides), hypertension, alcohol use, exercise, smoking, age and sex were analyzed for incident liver events by backward stepwise Cox regression analysis.

	HR	95% CI	P
Diabetes	3.42	2.07-5.63	< 0.001
Waist-hip ratio	241.0	14.9-3890	< 0.001
BMI	0.93	0.88-0.98	0.007
Hypertension	2.46	1.30–4.67	0.006
HDL cholesterol	2.09	1.34-3.24	0.001
Triglycerides	1.18	1.06-1.31	0.002
Exercise > once/wk	Reference		
Exercise 2-4x/month	0.99	0.64-1.54	0.96
Exercise less often	1.55	1.02-2.37	0.04
Alcohol use (g/wk)	1.001	1.00-1.001	0.003

Results: Among 2855 alcohol risk users with complete baseline and follow-up data (mean age 47 yrs, 70% male, mean alcohol use 370g/wk, diabetes 7%), there were 123 incident liver events. In the final backward Cox regression model (Table), diabetes, high waist-hip ratio, low BMI, HDL cholesterol, high triglyceride level and hypertension were independent metabolic predictors of incident advanced liver disease. Weekly alcohol use and inactive lifestyle were additional risk factors. Age and gender were non-significant, and adjustment for these in the final model did not alter results. There were no significant interactions between various metabolic factors and weekly alcohol use to the liver risk.

Conclusion: Diabetes, abdominal obesity, HDL cholesterol, triglycerides, and hypertension independently increased the risk for incident advanced liver disease among alcohol risk users in the general population. These findings may help to identify those alcohol risk users in whom more intensive interventions against metabolic factors are particularly important to prevent progression to advanced liver disease, and in whom more intensive liver evaluation may be warranted.

THU-252

Nursing staff volume is the most significant predictor of improved in-hospital mortality among alcoholic hepatitis patients admitted with ascites or hepatic encephalopathy: US nationwide population-based study

Hassan Azhari[1], Mark G Swain[1], Jacob Charette[1], Kelly Burak[1], Abdel-Aziz Shaheen[1]. [1]*University of Calgary, Gastroenterology and Hepatology, Calgary, Canada*
Email: azshaheen@me.com

Background and aims: Nursing care is associated with improved outcomes in many conditions. Alcoholic hepatitis (AH) patients have poor outcomes and require frequent monitoring during hospitalization. Therefore, our objective was to evaluate the association between nurse staffing and in-hospital mortality in patients with AH.

Method: We used the 2011 Nationwide Inpatient Sample (NIS) database to identify AH admissions in the United States. An AH admission was identified if the primary diagnosis was ICD-9: 571.1. Hospital-level nursing staff volume, which includes the volume of registered nurses, licensed practical nurses and nursing aids, was categorized into terciles (low [< 4.8], medium [4.8–6.4], and high-volume [> 6.4 nurse full-time equivalents per 1, 000 adjusted inpatient days]). Regression models assessed the impact of nursing volume on in-hospital mortality. We identified decompensated cirrhosis conditions based on validated ICD-9 codes. We adjusted for patient (e.g. demographics, insurance, and Elixhauser co-morbidities) and hospital characteristics, including hospital volume for cirrhosis-related admissions.

Results: We identified 2877 AH admission in 2011 corresponding to an estimated 31, 148 admissions in the United States. In our cohort, decompensated cirrhosis was prevalent (overall 37.6%; ascites = 28.4%; hepatic encephalopathy = 15.2%). Compared with patients admitted to hospitals with low nursing volume, patients hospitalized in high nursing volume centres were younger (median age: 46 vs. 48; P < 0.01) and more likely admitted to hospitals with high-volume of cirrhosis admissions (62.5% vs. 11.3%; P < 0.01). There was no difference between high and low nursing volume hospital admissions in relation to sex, insurance, or comorbidities. Although in-hospital mortality was similar across nursing volume groups (high vs. low: 3.3% vs. 4.2%; P = 0.52), patients with ascites or hepatic encephalopathy admitted to high nursing volume hospitals had lower mortality (high vs. low: 3.9% vs. 9.4%; P = 0.02). In our adjusted models, for AH patients without decompensated cirrhosis nursing volume was not a predictor of in-hospital mortality (high vs. low nursing volume: adjusted odds ratio aOR 3.76, 95% CI 0.82–17.21). However, among AH patients with decompensated cirrhosis, nursing volume was the only predictor of in-hospital mortality (high vs. low nursing volume: aOR 0.43, 95% CI 0.22–0.81).

Conclusion: High nursing staff volume significantly reduced in-hospital mortality among AH patients admitted with decompensated cirrhosis. Our findings suggest that altering admission pathways to

enhance nursing care for hospitalized decompensated AH cirrhotics may potentially improve in-hospital mortality.

THU-253

Equal efficacy of gastric and jejunal tube feeding in liver cirrhosis and/or alcoholic hepatitis: A randomised controlled trial

Palle Bager[1], Lene Kruse Olsen[1], Rikke Baltzer[1], Mette Borre[1], Niels Kristian Aagaard[1]. [1]*Aarhus University Hospital, Hepatology and Gastroenterology, Aarhus, Denmark*
Email: pallbage@rm.dk

Background and aims: Malnutrition is a frequent complication in decompensated liver cirrhosis (50%) and alcoholic hepatitis (almost 100%). Hospitalized patients who do not meet nutritional requirements are recommended to be enteral or parenteral feed (EASL eller ESPEN guidelines). No guidelines recommend a specific type of tube. However, jejunal feeding may result in the least discomfort and thus be more tolerable. We hypothesized that jejunal feeding, compared to gastric feeding, would be more efficacious in delivering the calculated amount of food and result in fewer accidental removals.
Method: 40 inpatients with liver cirrhosis and/or alcoholic hepatitis and a daily energy intake <75% of the calculated energy and protein demand was included consecutively. Patients were randomized 1:1 to nasogastric (NG)- or nasojejunal (NJ) tube feeding. All received Peptamen AF® as supplement to their oral intake. Participants were followed until discharge or death. The primary outcome was amount of food delivered. Secondary outcomes were number of tubes applied and bodyweight. Patients with HE 3 or 4 were excluded.
Results: 146 patients were screened, 40 were randomized (40% males, mean age 58 years, 70% cirrhosis, 10% alcoholic hepatitis, 20% both cirrhosis and alcoholic hepatitis. 30% were CP B, 70% CP C. A total of 33 fulfilled 7 days (6 discharged, 1 dead). Mean daily energy intake for 7 days were 6400kJ (NG) vs. 5900kJ (NJ) (p = 0.53). CP-B and NG: 6100kJ; CP-B and NJ: 5415kJ (p = 0.56); CP-C and NG: 5935kJ; CP-C and NJ: 5520kJ (p = 0.52).
The calculated caloric and protein requirement was not acquired in either of the groups. Mean deficit were 1650kJ for NG vs. 2322kJ for NJ. Tubes were accidently removed by the patients: once = 36; twice = 22; three times = 10, with, no differences between NG and NJ. There were no differences between group in the changes of bodyweight or albumin between baseline and day 7.
Conclusion: Jejunal feeding was not superior to gastric feeding in alcoholic hepatitis with or with out cirrhosis. In contrast, NG feeding tended to be more efficacious in patients with CP-B. Nutritional needs remained unmeet in both groups.

THU-254

Cumulative effects of western diet and alcohol abuse: A novel model of ASH/NASH-derived liver injury

Raquel Benedé[1], Olga Estévez[1], Laura Moran Blanco[2], Nuria López-Alcántara[2], Feifei Guo[1], Chaobo CHEN[2], Ricardo Macias-Rodriguez[3], Astrid Ruiz-Margain[3], kang Zheng[2,4], Pierluigi Ramadori[5], Francisco Javier Cubero[2,4], Yulia Nevzorova[1,4,5]. [1]*Faculty of Biology, Complutense University, Genetics, Physiology and Microbiology, Madrid, Spain;* [2]*Complutense University School of Medicine, Immunology, Ophthalmology and ORL, Madrid, Spain;* [3]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Gastroenterology, Mexico City, Mexico;* [4]*12 de Octubre Health Research Institute (imas12), Madrid, Spain;* [5]*University Hospital RWTH Aachen, Department of Internal Medicine III, Aachen, Germany*
Email: yulianev@ucm.es

Background and aims: The life style in the prosperous parts of the world often include the overlapping of the Western diet (WD) (high fat and high sugar diet) with alcohol intake. Current clinical studies showed a strong causative link between dietary habits and the onset of chronic liver disease. However, the mechanisms by which WD and alcohol synergistically trigger liver damage still remain unclear. In the present work, we aimed to develop an innovative experimental model which resembles the compound effects of WD and alcohol as observed in patients with non-alcoholic steatohepatitis (NASH) and alcoholic steatohepatitis (ASH).
Method: Female C57BL/6 mice received 10% alcohol in the drinking water together with a WD for 10 weeks (*ASH/NASH model*). Mice receiving only WD or alcohol were used as controls. Serum markers of liver damage, blood lipids and glucose tolerance test (GTT), liver and epididymal white adipose tissue (eWAT) histology, hepatic triglyceride content (HTC) and hepatic expression of pro-inflammatory and pro-fibrotic genes were analysed.
Results: Our novel experimental *ASH/NASH diet* recapitulated the compound effect of WD and alcohol consumption in humans, leading to obesity, significant hepatomegaly and exacerbated glucose intolerance after GTT. The *ASH/NASH*-feeding resulted in hypercholesterolemia, high HTC, hepatic macrosteatosis and ballooning degeneration of hepatocytes. Significant liver damage was characterized by elevated plasma ALT and positive TUNEL staining. Notable, mice treated with the *ASH/NASH diet* exhibited significant hepatic inflammation and intrahepatic accumulation of $CD11b^+$ and $F4/80^+$-positive immune cells accompanied by upregulated mRNA expression of TNFα. Importantly the *ASH/NASH diet* diet also resulted in increased hepatic fibrosis and remarkable collagen accumulation in perisinusoidal areas. Furthermore, *ASH/NASH*-fed mice developed profound eWAT inflammation characterized by adipocyte hypertrophy, macrophage infiltration and a dramatic increase in crown-like structures.
Conclusion: The novel *ASH/NASH-diet* is an excellent novel model for the characterization of patients with signs of NASH/ASH. Importantly, the compound effects of WD and alcohol synergistically enhanced obesity, glucose intolerance, liver damage, triggered prominent steatohepatitis and hepatic fibrosis, as well as inflammation in the eWAT tissue. This diet therefore is a suitable tool in the search for new therapeutic avenues to combat chronic liver disease.

THU-255

Long term outcomes of alcoholic patients without clinical evidence of liver disease: A 15 years follow-up study

sonia bernardo[1], Ricardo Crespo[1], Helena Cortez-Pinto[1], Mariana Machado[1]. [1]*Hospital de Santa Maria, CHLN, Lisbon, Portugal. Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, Gastroenterology and Hepatology Department, Lisbon, Portugal*
Email: mverdelhomachado@gmail.com

Background and aims: Data considering the impact of alcoholic consumption and abstinence in alcoholic patients without liver disease are scarce. We aimed to investigate long-term outcomes of alcoholic patients without clinical evidence of chronic liver disease (CLD), and to identify risk factors for mortality and for the development of CLD.
Method: Alcoholic patients from a rehabilitation center were prospectively enrolled in a clinical protocol performed in 2002 and revaluated at 2011 and 2018. Demographic, clinical and alcoholic consumption data were collected, and available blood tests and abdominal ultrasounds were also analysed. We investigated long-term outcomes in 123 patients with no evidence of CLD at the first evaluation. Of those 22 patients were lost for follow-up.
Results: 101 patients with no CLD were included; 81.2% were male. At the first evaluation, the median duration and amount of alcoholic consumption was 24.5 ± 12.9 years (4–50) and 315 ± 207 g/day (47.5–1128.3 g/day), respectively; 59.4% were abstinent, for a period of 6 ± 30 months. At 15 years of follow-up, 45.5% have returned alcohol intake for a median duration and amount of 5.7 ± 7.7 years (0–15) and 98 ± 177 g/day (0–1072), respectively. Six (5.9%) patients developed CLD during follow-up; of whom, 60% presented as ascites. During follow-up 26.7% died, and causes of death were: cancer in 54.2%, cardiovascular in 29.2%, liver disease in 8.3%, infections and car accident both in 4.2%. Development of CLD on follow-up positively

associated with total years with consumption (47 ± 5 vs. 29 ± 1 years, p = 0.003) and binge drinking on follow-up (OR 13.5 [1.5–121.9], p = 0.015) and negatively with duration of abstinence on follow-up (2.3 ± 1.4 vs. 9.6 ± 0.8 years, p = 0.001). Type of alcoholic beverage, gender or ethnicity did not associate with the risk for CLD. Abstinence for longer than 3 years associated with higher CLD-free survival (15.8 ± 0.1 vs. 14.8 ± 0.1, p = 0.027). Patients that drank beer showed decreased overall survival (63.6 ± 2.1 vs. 75.8 ± 1.0, p < 0.001).
Conclusion: Long-term alcoholics with no evidence of liver disease can still progress to CLD in 6%, which associates with total years of consumption and negatively with time of abstinence on follow-up. Beer consumption seems to associate with higher overall mortality.

THU-256

Alpha-1 antitrypsin ameliorates experimental alcoholic liver disease and predicts patient outcome

Grander Christoph[1], Benedikt Schaefer[1], Felix Grabherr[1], Timon Adolph[1], Georg Oberhuber[2], Heinz Zoller[1], Herbert Tilg[1].
[1]Medical University Innsbruck, Internal medicine I, Innsbruck, Austria; [2]InnPath, Innsbruck, Austria
Email: christoph.grander@i-med.ac.at

Background and aims: Alcoholic liver disease (ALD) is a substantial global health care problem, encompassing a broad spectrum of phenotypes including simple steatosis, steatohepatitis, liver fibrosis and cirrhosis or even HCC (hepatocellular carcinoma). Pro-inflammatory cytokines (TNF-α, IL-1β), gut-barrier dysfunction and toxicity of ethanol and its metabolites (namely acetaldehyde) have been suggested as critical factors in the development of ALD, resulting in hepatocyte damage and cellular infiltration of immune cells (e.g. neutrophils). Ultimately, these changes lead to liver fibrosis and cirrhosis. The acute-phase-protein Alpha-1 antitrypsin (A1AT) is a serin-proteinase inhibitor with anti-inflammatory properties (e.g. neutrophil elastase inhibition). In the present study we aimed to investigate the role of A1AT in ALD.
Method: In a cohort of 512 cirrhotic patients, biochemical and clinical parameters were compared between individuals with cirrhosis due to ALD and other etiologies, respectively. In a second step, the potential protective role of A1AT was evaluated in a murine binge-drinking model.
Results: Low A1AT serum concentrations (≤ 120 mg/dL) were significantly associated with poorer survival of cirrhotic ALD patients (p < 0.001), however, this finding could not be found in patients with liver disease of other etiologies (p = 0.18). Multivariate Cox-regression analysis revealed that low A1AT serum concentration (<120 mg/dL) was a NaMELD (Natrium model for end-stage liver disease)-independent predictor of transplantation/survival (HR = 2.17; 95% CI 1.20–3.92, p < 0.01). In a murine model of acute ALD a single ethanol gavage was associated with distinctive liver injury, inflammation and increased expression of hepatic *Serpina1* (p < 0.05). Moreover, simultaneous ethanol gavage and supplementation of A1AT ameliorated ethanol-induced hepatic injury exemplified by decreased *Tnfα* transcription (p < 0.05) and hepatic infiltration by MPO^+ cells (p < 0.001). Additionally, A1AT reduced hepatic microscopic steatosis (p < 0.05) upon acute ethanol exposure.
Conclusion: A1AT concentrations > 120 mg/dL are associated with increased survival in patients with alcoholic liver cirrhosis. A1AT supplementation might potentially serve as a novel therapeutic option in ALD.

THU-257

Fungal dysbiosis in alcoholic patients is associated with the severity of the liver injury

Dragos Ciocan[1,2], Laura Wrzosek[1], Cosmin Sebastian Voican[1,2], Cindy Hugot[1], Gabriel Perlemuter[1,2], Anne-Marie Cassard Doulcier[1].
[1]INSERM, U 996, Clamart, France; [2]APHP, Antoine Béclère Hospital, Hepato-Gastroenterology and Nutrition, Clamart,
Email: cassard.doulcier@u-psud.fr

Background and aims: Gut bacteria play an important role in alcoholic liver disease (ALD). Recently it has been showed that fungal dysbiosis is involved in disease severity in an animal model of ALD. The aim of this study was to characterize fungal dysbiosis in patients at different stages of ALD and its relationships with bacterial dysbiosis and clinical features.
Method: Gut bacterial/fungal profiles were analysed using 16s/ITS sequencing in healthy controls (HC) and alcoholic patients.
Results: A total of 133 patients were included: 28 HC and 105 alcoholic patients (with and without histologically proven alcoholic hepatitis). Alcoholic patients had an increase in Ascomycota and a decrease in Basidomycota phyla as compared to HC. Moreover, patients with severe alcoholic hepatitis (sAH) had a specific signature of fungal and bacterial dysbiosis as compared to cirrhotic patients without sAH. This dysbiosis included an increase in Candida and Xerochrysium levels in the mycobiota associated with an increase of the bacterial phyla, Proteobacteria, Fusobacteria and Actinobacteria. Candida levels were positively correlated to the sAH histological score. Also, the presence of serum anti-Saccharomyces cerevisiae IgG antibodies (ASCA), a marker of the immune response against fungi, was positively correlated to the fibrosis and alcohol hepatitis histological scores.
Conclusion: Overall, our study show that alcohol consumption induces a fungal dysbiosis that is correlated to ALD severity and to bacterial dysbiosis, supporting the role of fungal microbiota in ALD pathogenesis. Modifying fungal microbiota in patients with ALD could be a new therapeutic target in patients with ALD.

THU-258

Comparison of a fast corticosteroid tapering with the standard corticosteroid schedule in severe alcoholic hepatitis

Berta Cuyas[1], Elida Oblitas[1], Marc Batlle[2], Gerard Suris[3], Alberto Amador[3], Margarita Sala[4,5], Helena Masnou[4], José Castellote[3], Nuria Cañete[2], Eva Roman[1,5,6], Carlos Guarner[1,5], German Soriano[1,5], Maria Poca[1,5]. *[1]Hospital de la Santa Creu i Sant Pau, UAB, Department of Gastroenterology, Barcelona, Spain; [2]Hospital del Mar, IMIM, Department of Gastroenterology, Barcelona, Spain; [3]Hospital Universitari de Bellvitge, UB, IDIBELL, Department of Gastroenterology, Hospitalet de Llobregat, Spain; [4]Hospital Universitari Germans Trias i Pujol, UAB, Department of Gastroenterology, Badalona, Spain; [5]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, CIBERehd, Spain; [6]School of Nursing EUI-Sant Pau, Barcelona, Spain*
Email: bcuyas@santpau.cat

Background and aims: Corticosteroids reduce short-term mortality of patients with severe alcoholic hepatitis (AH). Prednisolone 40 mg/day for 28 days followed by tapering is the standard treatment. A shorter corticosteroid treatment could be useful to treat severe AH, reducing the risk for treatment-related complications. We aimed to compare the mortality between a fast corticosteroid tapering and the standard corticosteroid tapering schedule in patients with severe AH.
Method: We retrospectively reviewed a cohort of patients with severe AH (Maddrey score ≥ 32 and/or hepatic encephalopathy) who were responders based on Lille score, and treated with a fast corticosteroid tapering (prednisone 40 mg/day for 7 days followed by a reduction of 10 mg every week) between 2009 and 2017. Data were compared to an external cohort of patients from 3 other tertiary hospitals in the same area, treated with the standard schedule. We evaluated baseline characteristics, concomitant treatments, infection rate, and mortality.
Results: A total of 27 patients treated with the fast corticosteroid tapering and 52 with the standard schedule were included (mean MELD 22 ± 2 vs. 23 ± 2, respectively, p = 0.21). Corticosteroid treatment duration was significantly shorter in the first group (34 ± 9 vs. 45 ± 13 days, p < 0.001). Antibiotic prophylaxis was more frequent among patients treated with the fast corticosteroid tapering than in the standard schedule cohort (77.8% vs. 44.2%, p = 0.004). No significant differences were found in the use of nutritional

supplements, enteral nutrition or 180-day alcohol abstinence. The probability of death of patients treated with the fast corticosteroid tapering vs. the standard schedule was 0% vs. 3.8% at 30 days (p = 0.30), 0% vs. 7.8% at 90 days (p = 0.14), 7.4% vs. 11.8% at 180 days (p = 0.53), and 7.4% vs. 33% at one year (p = 0.02). We observed that 33.3% vs. 32.7% of patients, respectively, presented an infection at AH diagnosis (p = 0.95), and 29.6% vs. 40.4% developed infection after initiation of corticosteroids (p = 0.34). Multivariate analysis in the whole series showed that the fast corticosteroid tapering was a one-year independent predictive factor of survival, but antibiotic prophylaxis was not.
Conclusion: A fast corticosteroid tapering is not associated with a worse outcome than the standard schedule. This new regime could be a proper treatment strategy for severe alcoholic hepatitis, but randomized trials are needed to compare it to the standard schedule.

THU-259
The gene signature-MELD score and alcohol consumption determine long-term prognosis of patients with severe alcoholic hepatitis
Pierre Deltenre[1,2], Eric Trepo[3], Naoto Fujiwara[4], Nicolas Goossens[5], Astrid Marot[6], Margaux Dubois[7], Laurent Spahr[5], Jean Henrion[8], Christophe Moreno[3], Yujin Hoshida[9]. *[1]C.U.B. Hôpital Erasme, Department of Gastroenterology, Hepatopancreatology, and Digestive Oncology, Brussels, Belgium; [2]Clinique St-Luc, Department of Gastroenterology and Hepatology, Bouge, Belgium; [3]C.U.B. Hôpital Erasme, Brussels, Belgium; [4]Icahn School of Medicine at Mount Sinai, New York, United States; [5]Geneva University Hospital, Geneva, Switzerland; [6]CHU UCL Namur, Yvoir, Belgium; [7]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [8]Hôpital de Jolimont, Haine-Saint-Paul, Belgium; [9]University of Texas Southwestern Medical Center, Dallas, United States*
Email: pierre.deltenre01@gmail.com

Background and aims: Accurate prediction of long-term prognosis of patients with severe alcoholic hepatitis (AH) is mandatory to guide therapeutic strategy. The gene signature-MELD (gs-MELD) score, a combination of a gene signature and the MELD score, has been proposed as a new prognostic tool and showed better diagnostic accuracy than all other prognostic scores for assessing the risk of death at 6 months (Trepo *et al*. Gastroenterology 2018;154:965–75).
Aim: To assess the long-term prognostic value of the gs-MELD score among patients with severe AH.
Method: Patients with severe AH (Maddrey Discriminant Function > 32) treated with methylprednisolone orally at a dose of 32 mg/day for a maximum of 28 days were followed for 5 years from the date of corticosteroid therapy initiation. The primary end point was survival at 5 years. The gs-MELD score was generated as described previously. Patients with a gs-MELD greater than 2.66 were considered to have a poor prognosis. Patients were considered abstinent if they had no alcohol consumption during follow-up.
Results: 48 consecutive patients with histologically proven severe AH from 4 European centers were included (median age: 52 years [95% CI: 48–56], median Maddrey Discriminant Function: 50 [95% IC: 45–58]). None had active infection at the start of corticosteroids. Median gs-MELD score was 2.6 (95% CI: 2.2–3.0). 14 (30%) were considered non-responders to corticosteroids at day 7 according to the Lille score. During follow-up, 19 patients (40%) were abstinent, 24 (55%) died and 4 (8%) underwent a liver transplantation. At 5 years, rates of survival without death or liver transplantation were 57% (95% CI: 36–78) and 14% (95% CI: 0–30) in patients with favorable and with poor gs-MELD score (p < 0.001), and 61% (95% CI: 35–86) and 22% (95% CI: 6–39) in abstainers and in consumers (p = 0.001), respectively. In time-dependent multivariable proportional hazards models, the gs-MELD score (hazard ratio: 5.78, 95% CI:2.17–15.38, p < 0.001) and alcohol consumption (hazard ratio: 12.18, 95% CI:3.16–46.95, p < 0.001) were independently associated with 5-year mortality.
Conclusion: While only the gs-MELD score determines prognosis at short-term, both gs-MELD score and alcohol consumption are independently associated with the risk of death at 5 years. Therapeutic strategies should target alcohol consumption to improve long-term prognosis.

THU-260
Alcoholic cirrhosis is associated with higher in-patient mortality compared to non-alcoholic cirrhosis
Xiaowen Fan[1], Melissa Hershman[2], Ilan Weisberg[3]. *[1]Mount Sinai St. Luke's and Mount Sinai West, New York, United States; [2]Mount Sinai Beth Israel, Mount Sinai St. Luke's and Mount Sinai West, New York, United States; [3]Mount Sinai Beth Israel, Mount Sinai St. Luke's and Mount Sinai West, New York, United States*
Email: xiaowen.fan@mountsinai.org

Background and aims: Alcoholic liver disease represents a spectrum of alcohol related conditions that range from reversible steatosis to steatohepatitis, fibrosis, and cirrhosis. Alcohol is one of the most common causes of cirrhosis. Previous studies showed the high burden of alcoholic liver disease and higher rate of decompensation with alcoholic cirrhosis (AC), we aim to investigate mortality risk of AC among hospitalized patients with cirrhosis.
Method: We analyzed hospitalizations (age ≥ 18) with diagnostic ICD9 codes indicating cirrhosis in the National Inpatient Sample (NIS) 2014. An AC diagnosis was defined as a discrete AC diagnosis code or a non-alcohol related cirrhosis code plus either an alcohol use code or an alcohol related comorbidity (alcoholic hepatitis, alcoholic liver failure) code; all other cirrhosis codes excluding these criteria were defined as non-alcoholic cirrhosis (NAC). The primary outcome was the mortality odds ratio (OR) of AC vs NAC among all-cause hospitalizations with cirrhosis. Multivariate regression analysis was used to adjust for potential confounders.
Results: The total number of hospitalizations with AC included was 307, 215. The mean age was 55.8, 71.7% were male. Mortality among all-cause hospitalizations with AC was 6.6% (6.4%–6.8%) compared to 5.7% (5.5%–5.9%) with NAC (Table 1). AC was independently associated with higher mortality (OR 1.22; 1.15–1.29) compared to NAC among all-cause hospitalizations. Multivariate regression analysis was used to isolate variable including age, sex, race, insurance, hospital characteristics, disease complications, liver transplantation status, and Charlson Comorbidity Index. Among all-cause hospitalizations with cirrhosis, Hispanic race (0.89; 0.82–0.97), Medicare insured (0.83; 0.77–0.90) with primary insured as reference, urban hospital (0.86; 0.75–0.97), and liver transplantation during same hospitalization (0.32; 0.22–0.46) were associated with lower mortality; while older age (1.02; 1.018–1.024), uninsured (1.46; 1.31–1.62), higher Charlson Comorbidity Index (1.07; 1.06–1.09), and larger hospital bed sizes (medium/large with small as reference) were associated with higher mortality. All the comorbidities adjusted were associated with higher mortality (Table 2).

Table 1

Comparison of Alcoholic Cirrhosis vs. Non-alcoholic Cirrhosis

Characteristics	Alcoholic Cirrhosis	Non-alcoholic Cirrhosis
Total Number of Observations	307,215	314,600
Average Age (year)	55.8 (55.7-55.9)	63.0 (62.8-63.2)
Female (%)	28.3 (27.8-28.7)	50.4 (49.9-50.9)
HCV (%)	26.8 (26.2-27.4)	32.1 (31.4-32.8)
Ascites (%)	38.0 (37.4-38.6)	32.2 (31.5-32.8)
Spontaneous Bacterial Peritonitis (%)	3.7 (3.5-3.8)	2.6 (2.5-2.8)
Variceal Bleed (%)	7.0 (6.8-7.2)	3.8 (3.7-4.0)
Hepatic Encephalopathy (%)	21.8 (21.4-22.2)	15.0 (14.6-15.4)
Hepatocellular Carcinoma (%)	4.0 (3.8-4.3)	6.0 (5.6-6.4)
Septicemia (%)	10.7 (10.4-11.0)	11.1 (10.8-11.4)
Acute Kidney Failure (%)	24.1 (23.6-24.6)	25.9 (25.4-26.4)
Coagulopathy (%)	14.9 (14.4-15.5)	7.4 (7.0-7.8)
Liver transplant During Hospitalization (%)	0.5 (0.4-0.7)	1.0 (0.8-1.2)
In-hospital Mortality among All-cause Hospitalizations (%)	6.6 (6.4 -6.8)	5.7 (5.5-5 9)

Table 2

Mortality Risk Factors among Cirrhosis Patients

Factor	Odds Ratio (OR)	Lower 95% CI	Upper 95% CI	p-value
Age	1.02	1.018	1.024	**<0.01**
Female Sex	0.96	0.91	1.01	0.13
Alcoholic Cirrhosis	1.22	1.15	1.29	**<0.01**
Race				
White	Reference			
Black	1.04	0.95	1.13	0.41
Hispanic	0.89	0.82	0.97	**0.01**
Asian and Pacific Islander	1.01	0.85	1.20	0.92
Native American	0.93	0.75	1.15	0.52
Other	1.05	0.91	1.22	0.50
Primary Insurance				
Private	Reference			
Medicaid	0.95	0.87	1.04	0.27
Medicare	0.83	0.77	0.90	**<0.01**
Uninsured	1.46	1.31	1.62	**<0.01**
Hospital Bed-size				
Small	Reference			
Medium	1.21	1.09	1.34	**<0.01**
Large	1.26	1.15	1.39	**<0.01**
Teaching Hospital	1.02	0.95	1.10	0.52
Urban Hospital	0.86	0.75	0.97	**0.02**
Charlson Comorbidity Index	1.07	1.06	1.09	**<0.01**
Liver Transplantation	0.32	0.22	0.46	**<0.01**
Hepatocellular Carcinoma	1.41	1.27	1.57	**<0.01**
Variceal Bleed	1.91	1.73	2.11	**<0.01**
Hepatic Encephalopathy	1.35	1.26	1.43	**<0.01**
Septicemia	7.04	6.63	7.47	**<0.01**
Acute Kidney Injury	3.50	3.29	3.71	**<0.01**
Ascites	1.20	1.13	1.26	**<0.01**
Coagulopathy	2.06	1.92	2.22	**<0.01**

Conclusion: AC was associated with higher inpatient mortality compared to NAC. The pathophysiology behind it is multifactorial: nutritional deficiency in AC can cause higher rate of coagulopathy; low thiamine and phosphate depletion in AC can contribute to hepatic encephalopathy; alcohol interferes with immune functions and can increase the risk for infection; thus causing higher rate of complications and worse outcome. Alcoholic cirrhosis requires more aggressive intervention and systemic approach in the inpatient setting.

THU-261

Validation of the pre-treatment neutrophil-to-lymphocyte ratio to predict response to corticosteroids in severe alcoholic hepatitis

Ewan Forrest[1], Ashwin Dhanda[2], Dev Katarey[3], Jonathan Potts[3], Sumita Verma[4], Richard Parker[5], Peter Hayes[6]. *[1]Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom; [2]Derriford Hospital, Plymouth, Liver Unit, Plymouth, United Kingdom; [3]Brighton and Sussex University Hospital, Department of Gastroenterology and Hepatology, Brighton, United Kingdom; [4]Brighton and Sussex Medical School, Department of Clinical and Experimental Medicine, Brighton, United Kingdom; [5]St James' Hospital, Liver Unit, Leeds, United Kingdom; [6]Royal Infirmary of Edinburgh, Liver Unit, Edinburgh, United Kingdom*
Email: ewanforrest@hotmail.com

Background and aims: Previous analysis of the Neutrophil-to-Lymphocyte Ratio (NLR) in patients from the STOPAH trial identified patients with alcoholic hepatitis who have a survival benefit from corticosteroids. We aimed to validate this observation in an independent patient group.
Method: A validation group was derived from patients recruited from four United Kingdom centres (Leeds, Bristol, Brighton and Plymouth) treated for severe alcoholic hepatitis out with the STOPAH trial. All patients had a serum bilirubin greater than 80μmol/l and a discriminant function (DF) > 32. Treatment with prednisolone (40mg/day) and its continuation or discontinuation after 7 days was based on local clinical discretion. Kaplan-Meier analysis was used to assess survival. Log-Rank tests and *t*-tests were used for comparative analysis with 95% confidence intervals shown.
Results: There were 237 patients in the validation group, 138 of whom received prednisolone. The overall 90-day mortality was 26.3% *vs.* 32.6% for those treated and not treated with prednisolone respectively (p = 0.20; HR 0.73 (0.45, 1.19)). The mean NLR at baseline for all patients was 8.56 (7.23, 9.84). The NLR was greater in those who initially presented with AKI (10.22 *cf.* 7.37: p = 0.014; 0.57, 5.14) and infection (10.06 *cf.* 7.36: p = 0.023; 0.38, 5.01). There was no benefit with prednisolone treatment for those with NLR < 5 or > 8. There was an improvement in 28-day outcome with prednisolone if NLR 5–8 (Table). Those with a modified Glasgow Alcoholic Hepatitis Score (with incorporation of the NLR) ≥ 9 and NLR 5–8 had a reduction in 90-day mortality with Prednisolone treatment: 23.3% *vs.* 46.4%: p = 0.036; HR 0.268 (0.10, 0.71).

Table:

		NLR <5		NLR 5–8		NLR > 8	
		Untreatedn = 39	Treated n = 50	Untreated n = 35	Treated n = 37	Untreated n = 25	Treated n = 51
TOTAL n = 237	28 Day Mortality	5.1% P = 0.416 (0.44, 8.69)	10.0%	28.6% P = 0.0023 (0.026, 0.27)	2.7%	28.0% P = 0.469 (0.26, 1.91)	23.5%
	90 Day Mortality	18.4% P = 0.843 (0.32, 2.47)	16.3%	37.4% P = 0.097 (0.20, 1.14)	21.6%	48.0% P = 0.362 (0.34, 1.53)	39.2%

Conclusions: This real-life validation cohort confirms the observation that patients with severe alcoholic hepatitis and low (<5) or high (> 8) NLRs do not benefit from corticosteroids. Favourable outcome with corticosteroids is only seen in those with NLR 5–8.

THU-262

A modified Glasgow alcoholic hepatitis score incorporating the neutrophil-to-lymphocyte ratio is superior to other baseline scores of prognosis in alcoholic hepatitis

Ewan Forrest[1], Natasha Storey[1], Rohit Sinha[2], Stephen Atkinson[3], Nikhil Vergis[3], Michael Allison[4], Paul Richardson[5], Steven Masson[6], Mark Thursz[3], Peter Hayes[2]. *[1]Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom; [2]Royal Infirmary of Edinburgh, Liver Unit, Edinburgh, United Kingdom; [3]Imperial College, Liver Unit, London, United Kingdom; [4]Addenbrooke's Hospital, Cambridge Biomedical Research Centre, Cambridge, United Kingdom; [5]Royal Liverpool Hospital, Liver Unit, Liverpool, United Kingdom; [6]Freeman Hospital, Liver Unit, Newcastle, United Kingdom*
Email: ewanforrest@hotmail.com

Background and aims: The Neutrophil-to-Lymphocyte Ratio (NLR) has been shown to be prognostic in a variety of liver conditions. We assessed the role of NLR in the prognosis of alcoholic hepatitis and its performance when incorporated into the Glasgow Alcoholic Hepatitis Score (GAHS).
Method: The NLR was calculated from 789 patients who participated in the STOPAH trial. Area under the Receiver Operating Curve (AUC) analysis was performed. Kaplan-Meier analysis was used to assess survival. Log-Rank test was used for comparative analysis with 95% confidence intervals shown, and Pearson's correlation co-efficient (r) for correlations.
Results: The mean NLR at baseline for all patients was 6.51 (6.14, 6.88). Overall the baseline NLR had a modest discriminatory capacity with an AUC of 0.660 (0.626, 0.693) with an optimal cut-point of 5 (*J* = 0.247) for 90-day mortality. Mortality at Day 90 was 16.1% for those with a NLR < 5 and 33.6% for those with a NLR ≥ 5 (p < 0.0001; HR 2.39 (1.81, 3.15)). There was a strong correlation between the total white blood cell count (WCC) and NLR: r = 0.564 (0.52, 0.60); p < 0.0001. In view of this, the NLR was incorporated into the GAHS with an NLR threshold of 5 replacing the WCC threshold of 15, creating a modified GAHS (mGAHS). The AUCs for mGAHS for 28-day and 90-day outcomes were 0.783 (0.752, 0.812) and 0.739 (0.706, 0.770) respectively. For 28-day outcome the mGAHS AUC was superior to that of the DF (0.684: p < 0.0001; 0.05, 0.14), the original GAHS (0.763: p = 0.027; 0.002, 0.04) and the MELD (0.739: p = 0.0014; 0.009, 0.08). A mGAHS ≥ 9 was present in 460 patients (58.6%) with a

90-day mortality of 35.4% compared with a mortality of 10.8% for those with mGAHS < 9 (p < 0.0001 HR 3.91 (2.96, 5.17)).
Conclusion: The incorporation of the NLR into the GAHS improved the AUC and this mGAHS was superior to other baseline scores for predicting 28-day outcome.

THU-263

The demonstration of antibodies to histone 2B of the IgA-type helps to differentiate between alcoholic liver disease and non-alcoholic fatty liver disorder

Amelie Frank[1], Beate Preuss[1], Christoph Berg[2], Reinhild Klein[1].
[1]*Department of Internal Medicine II, Tuebingen, Germany;* [2]*Department of Internal Medicine I, Tuebingen, Germany*
Email: reinhild.klein@med.uni-tuebingen.de

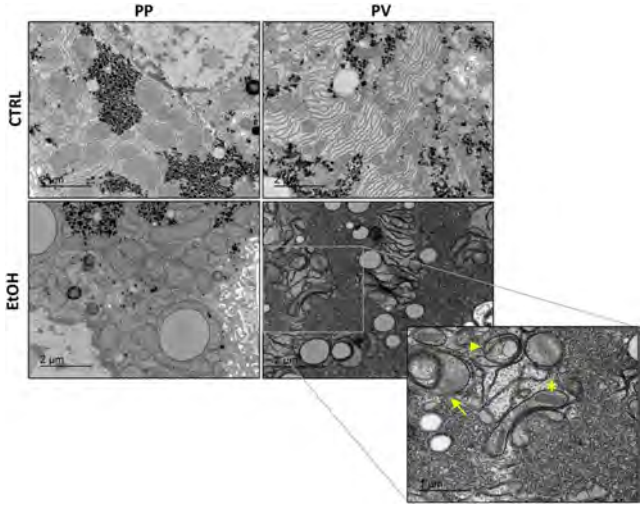
Background and aims: Re-analysing the clinical relevance of antibodies to histones for the serological diagnosis of systemic lupus erythematosus (SLE) we accidentally found that these antibodies-especially those to histone 2B-showed a strong association also with alcoholic liver disorders (ALD) when they were of the IgG-type and that IgA-antibodies were only found in ALD but not SLE. We, therefore, wanted to analyse the specificity and clinical relevance of abs to histone 2B of the IgA-type in more depth in order to see whether they occur also in patients with other chronic liver disorders.
Method: Sera from patients with clinically defined ALD (n = 58), non-alcoholic fatty liver disease (NAFLD; n = 52), drug-induced liver disease (n = 8), storage diseases (Wilson's disease, hemochromatosis; n = 9), and autoimmune liver disorders (AILD; autoimmune hepatitis [AIH] n = 353; primary biliary cholangitis [PBC] n = 255; primary sclerosing cholangitis [PSC] n = 41) as well as from 85 healthy individuals were analysed by ELISA using histone 2B as antigen. Peroxidase conjugated anti-human IgA-antibodies were used as secondary antibodies.
Results: Anti-histone 2B antibodies of the IgA-type were found in 62% of the patients with ALD and 38% of patients with drug-induced liver disorders but only 10% of patients with NAFLD, up to 14% of patients with AILD or storage diseases and 5% of healthy individuals (p < 0.001). Also antibody reactivity was significantly higher in patients with ALD than in the other groups of patients (p < 0.001).
Conclusion: These data indicate that antibodies to histone 2B of the IgA-type may be a helpful marker for the diagnosis of ALD and especially for its differentiation to NAFLD. Their presence in pts with drug-induced liver disorders indicates that the antibodies may be induced by a toxic process in general, not just alcohol. It still remains to be seen by which mechanism these antibodies are induced and whether gut barrier leaking may play a role.

THU-264

Transmission electron microscopy reveals dramatic hepatic zonal changes upon chronic alcohol feeding

Raquel Fucho[1,2], Estel Solsona-Vilarrasa[1,2,3], Carlos Enrich[3], M. Carmen Garcia-Ruiz[1,2,4], José Fernandez-Checa[1,2,4]. [1]*IIBB-CSIC, Cell death and proliferation, Barcelona, Spain;* [2]*IDIBAPS-CIBEREHD-Liver Unit Hospital Clínic Barcelona, Barcelona, Spain;* [3]*Universitat de Barcelona, Barcelona, Spain;* [4]*USC Research Center for the Liver Diseases, Los Angeles, United States*
Email: checa229@yahoo.com

Background and aims: Alcoholic liver disease (ALD) is a leading cause of liver-related mortality. Ethanol (EtOH) induces changes in hepatocytes including lipid droplet (LD) accumulation, ER and oxidative stress, and mitochondrial dysfunction that can lead to cell death. Periportal (PP) and perivenous (PV) hepatocytes exhibit specialized metabolic functions due, in part, to exposure to different oxygen gradient and nutrients along the liver sinusoid. As the PV area is the most affected in ALD, we aimed to characterize the structural changes induced by ETOH in PP and PV hepatocytes using transmission electron microscopy (TEM).
Method: 8 week-old C57BL/6J male mice were fed a control (CTRL) or 5% EtOH Lieber-DeCarli diet (EtOH) for 30 days. Livers were washed via portal vein with Hanks I buffer and fixed with 3% glutaraldehyde in phosphate buffer. Semifine sections were observed with light microscopy to define PP and PV areas. Images from ultrathin sections containing both areas were taken using a TEM JEOL JEM-1010. Changes in mitochondrial number/length were estimated using Image J software.
Results: In CTRL diet both areas presented high glycogen content and few small LD. However, PV hepatocytes contained more RER and mitochondria than PP hepatocytes. Furthermore, PV mitochondria presented higher length/width ratio compared to PP mitochondria. Chronic EtOH intake induced a strong decrease in glycogen content in both areas, especially in the PV. EtOH increased LD number in both populations. While PP LD sizes ranged from small to very large, PV LD remained small. EtOH increased mitochondrial number and length in PP hepatocytes with the largest mitochondria surrounding LDs. In contrast, EtOH decreased mitochondrial size in PV areas while maintaining the high length/width ratio. The biggest effect of EtOH in PV area was a dramatic change in mitochondrial shape: concave forms with thick edges and a thin matrix in the center (arrowhead), and donut-like forms with bent shapes shrinking into a ring with a lumen containing cytoplasm (arrow). Some of these mitochondria presented unusual parallel cristae (*). Moreover, EtOH caused a shift from RER to SER in PV areas.



Conclusion: These data reveal that PP and PV areas are different in basal states. EtOH induces differential changes in both populations, pooling them further apart. ETOH predominantly induces structural changes in mitochondria from zone 3, which may account for the prevailing injury seen in this area in ALD.

THU-265

In severe alcoholic hepatitis, serum transferrin indicates impaired HNF4a signaling and predicts mortality independently of disease severity

Karim Hamesch[1], Stephen Atkinson[2], Igor Spivak[1], Nurdan Gueldiken[1], Igor Theurl[3], Heinz ZOLLER[4], Josepmaria Argemi[5], Ramon Bataller[5], Christian Trautwein[1], Mark Thursz[2], Pavel Strnad[1]. Innsbruck, Austria; [5]University of Pittsburgh Medical Center, Pittsburgh Liver Research Center, Pittsburgh, United States
Email: khamesch@ukaachen.de

Background and aims: Severe alcoholic hepatitis (AH) confers substantial mortality but the underlying pathogenesis remains incompletely understood. Deranged iron parameters are common in liver disease patients and constitute attractive outcome predictors. Since alcohol suppresses the production of the iron-regulatory hormone hepcidin, we analysed the role of iron parameters in patients with severe AH.
Method: Ferritin, transferrin, iron, transferrin saturation (TSAT), non-transferrin bound iron (NTBI), soluble transferrin receptor (sTfR), and hepcidin were measured in sera from 828 patients with severe AH recruited prospectively via the STOPAH trial. Potential regulators of the established negative acute-phase protein (APP) transferrin were assessed in primary mouse hepatocytes.
Results: AH patients had diminished serum transferrin (median 93 mg/dl), but increased ferritin (median 625 ng/dl) and TSAT (median 70%). Among iron parameters, baseline transferrin was the best predictor of 28-day (AUROC 0.72, 95% CI 0.67–0.78) and 90-day survival (AUROC 0.65, 95% CI 0.61–0.70). Transferrin's predictive ability was comparable to the established scores MELD, GAHS, or DF and was independently associated in multivariable analysis. In contrast, NTBI and sTfR as the markers of excess unbound iron and functional iron deficiency, respectively, did not have an obvious prognostic importance. Hepatic transcriptome analysis revealed a strong positive relationship with the nuclear factor HNF4α and negative association with cytokines TGFß1, IL1ß, TNF or IL6. In primary hepatocytes, treatment with TGFβ1 or the HNF4α inhibitor BI6015 suppressed the production of the negative APP transferrin, while exposure to TNFα, IL1β, and IL6 had no effect.
Conclusion: Serum parameters of iron metabolism, particularly transferrin as a negative acute phase reactant, are strongly associated with outcome in severe AH. Accordingly, serum transferrin predicts 28- and 90-day mortality with a performance comparable to commonly used scoring systems. Transferrin′s decrease may reflect an impaired HNF4α axis.

THU-266

Comparison of clinical features and prognosis in different types of severe alcoholic hepatitis: Is it time to classify?

ping zhu[1], Tao Han[1]. *[1]Third Central Hospital of Tianjin, Tianjin, China*
Email: hantaomd@126.com

Background and aims: Severe alcoholic hepatitis (SAH) is a clinical syndrome amongst people with with very poor prognosis. Various prognostic scores are available for predicting outcome in SAH.We evaluated the clinical characteristics of SAH with different underlying liver disease and compared the available prognostic models as predictors of outcome in patients with SAH.
Method: Patients which were diagnosed as alcoholic hepatitis with a Maddrey discriminant function (MDF) ≥ 32 were included. Enrolled patients were divided into 3 groups: type SAH-A (patients with underlying non-cirrhotic chronic liver disease), type SAH-B (patients with previous compensated cirrhosis) and type SAH-C (patients with previous decompensated cirrhosis). Biochemical parameters were collected at baseline. Complications and mortality were assessed during a 28-day follow-up period. The difference of 3 types of SAH upon survival was assessed by Kaplan-Meier analysis and tested using the log-rank test. MDF, age, model for end-stage liver disease (MELD), bilirubin, international normalized ratio (INR), and creatinine (ABIC), Glasgow alcoholic hepatitis score (GAHS), chronic liver failure-sequential organ failure assessment (CLIF-SOFA), were calculated 48 hours after admission and correlated with patient outcome after 28 days. Receiver operator characteristic (ROC) curves were plotted for all prognostic scores.
Results: 170 patients were included. 27 (15.9%) were defined as SAH-A, 52 (30.6%) as SAH-B, and 91 (53.5%) as SAH-C, respectively. Whereas age, prothrombin time, urea nitrogen, blood creatinine, INR, encephalopathy rate, infection rate, and 28-day death rate, were higher in patients with SAH-C ($p < 0.05$), and white blood cell, platelet count, albumin, γ-glutamyltransferase, total bilirubin, were higher in patients with SAH-A ($p < 0.05$). The Kaplan-Meier survival probability in patients with SAH-C (51.6%) was different from those with SAH-A (88.9%) and SAH-B (80.8%) ($p < 0.001$), Figure1. The CLIF-SOFA score, compared with other scores, most accurately predicted 28-day mortality, with an area under the ROC of 0.796 (MELD, 0.584, $p < 0.0001$; GAHS, 0.644, $p = 0.0035$; MDF, 0.681, $p = 0.0324$), Figure2. ABIC showed similar prediction level to CLIF-SOFA (0.745 VS. 0.791, $p = 0.2266$). The MELD score has poor sensitivity and specificity for early identification ($p = 0.073$).Underlying liver disease ($p = 0.002$) and CLIF-SOFA score ($p = 0.008$) were independent predictors of 28-day mortality.

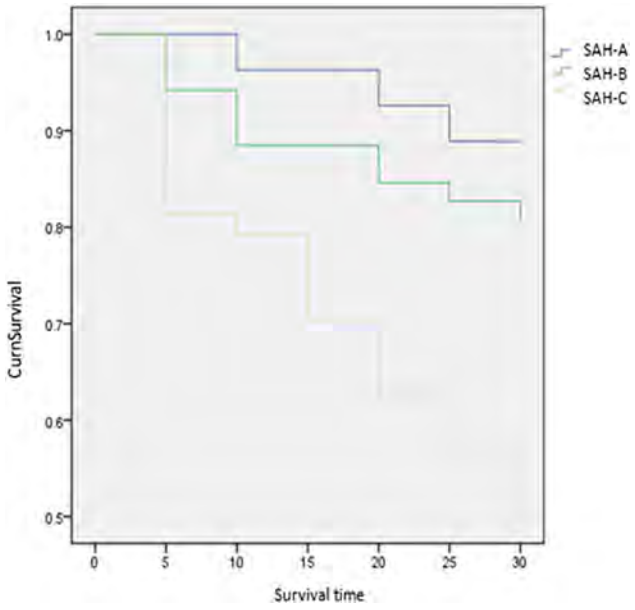

Figure 1: Kaplan-Meier survival probability for patients in 28 days

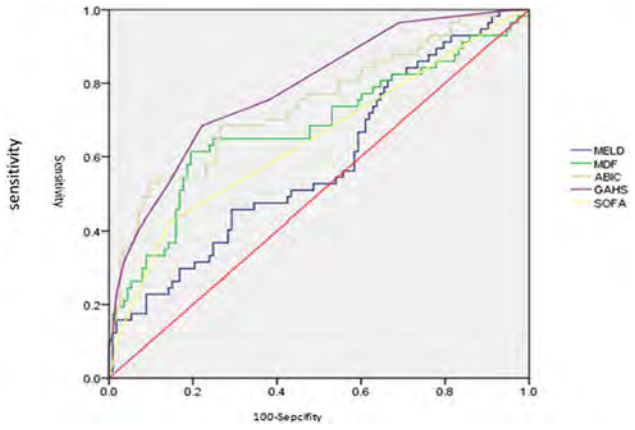

Figure 2: the receiver operator characteristic curves of various prognostic indicators for predicting 28-day mortality

Conclusion: There are significant differences in biochemical parameters, complication rates, and prognosis in SAH patients with different underlying liver disease. CLIF-SOFA is superior to the others in SAH.

THU-267

The increasing burden of alcohol related liver disease: A single tertiary centre experience

Arif Hussenbux[1], ian liew[1], Jeremy Cobbold[1], Jane D. Collier[1], John Ryan[1]. [1]*University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom*
Email: arif.hussenbux@hotmail.co.uk

Background and aims: Alcohol-related liver disease accounts for 60% of all liver disease and approx. 80% of liver-related deaths. In the UK, the high levels of alcohol-related health burden show no signs of subsiding, with over 10 million adults drinking excessively each week. Unless the trends are reversed, it is projected that over the next five years, £17 billion in costs to the NHS will be incurred.
Method: Data on all adult patients admitted with alcohol related liver disease were collected retrospectively over a 5 year period at a single tertiary centre hospital which serves a catchment of 800, 000 individuals.
Using the Trust database, the number of admissions, gender, diagnosis, number of deaths, length of stay and cost of admission were recorded. Comparative analyses were carried out to assess hospitalisation trends of major indicators over time.
Results: Data collection period was from 01/01/2013 to 31/12/2017 yielding 1196 patients with alcohol related liver disease, accounting for a total of 5859 admissions over 5 years. The average number of admissions per patient were 4.9 (± 2.3). The mean age was 61 years (±13), and 69% of the cohort were male. During the study period there was a 44% increase in admissions for alcohol related liver disease and a 75% increase in admissions for alcohol related cirrhosis. This was at an estimated total cost of admissions of £5.2 million in 2017, a 48% increase from 2013. Despite the increase in disease burden, the average length of stay (6.5 days vs 5.3 days) and inpatient mortality (23.4% vs 19.6%) fell during the study period.
Conclusion: This study demonstrates the increasingly detrimental impact of alcohol related liver disease on health services in the UK. Substantial increases in health care cost and utilisation among hospitalised patients were observed, while a possible improvement in disease management was noted. This highlights the urgent need to allocate resources so that effective prevention strategies can be implemented.

Human microfibrillar-associated protein 4 expressed in the liver and serum in alcoholic liver disease predicts liver fibrosis severity with accuracy similar to transient elastography and enhanced liver fibrosis test

Bjørn Madsen[1,2,3], Maja Thiele[1], Sönke Detlefsen[4,5], Maria Kjærgaard[1], Linda Sevelsted Møller[1], Ditlev Nytoft Rasmussen[1], Anders Schlosser[6], Uffe Holmskov[6], Jonel Trebicka[5,7,8,9], Grith Lykke Sorensen[6], Aleksander Krag[1]. [1]*Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark;* [2]*Odense University Hospital, OPEN: Odense Patient Data Exploratory Network, Odense, Denmark;* [3]*Odense Universitets Hospital, FLASH: Fibrosis, Fatty Liver and Steatohepatitis elite research center, Odense, Denmark;* [4]*Odense Universitetshospital, Department of Pathology, Odense, Denmark;* [5]*Odense University Hospital, Institute of Clinical Research, Odense, Denmark;* [6]*University of Southern Denmark, Institute of Molecular Medicine, Odense, Denmark;* [7]*University Clinic Frankfurt, Department of Internal Medicine, Frankfurt, Germany;* [8]*European Foundation for the Study of Chronic Liver Failure-EF Clif, Barcelona, Spain;* [9]*Institute for Bioengineering of Catalonia, Barcelona, Spain*
Email: ozomalo@hotmail.com

Background and aims: Alcoholic liver disease (ALD) is a public health concern and responsible for half of all cirrhosis-related deaths. Early detection of fibrosis, ideally in the pre-cirrhotic stage, is a key strategy for improving ALD outcomes and for preventing progression to cirrhosis. We investigated the utility of human microfibrillar-associated protein 4 (MFAP4) as a serological biomarker for the early detection of alcoholic liver fibrosis.
Method: To evaluate the diagnostic accuracy of MFAP4 to detect ALD-induced fibrosis, we performed a prospective liver biopsy-controlled study involving 266 patients with prior or current alcohol overuse. All patients were evaluated with a) liver biopsy, b) transient elastography (TE), c) Enhanced Liver Fibrosis test (ELF) and d) serum MFAP4 level. All measurements and investigations were performed on the same day. Patients were split into a training (n = 153) and a validation (n = 113) cohort. Blood samples from 50 healthy gender- and aged-matched participants were used to determine the concentration of MFAP4 in healthy individuals. MFAP4 expression in liver biopsies was semiquantitatively evaluated by immunostaining of MFAP4 in 116 liver biopsies distributed across the full spectrum of Kleiner fibrosis stages. Patients with cirrhosis were followed until a hepatic decompensation episode developed.
Results: The distribution of Kleiner fibrosis stage in the cohort was F0 = 32; F1 = 93; F2 = 79; F3 = 17; F4 = 45. MFAP4 expression in liver tissue and serum MFAP4 levels increased with fibrosis stage until the development of advanced fibrosis (Spearman's $\rho = 0.66$, $p < .000$). The area under the receiver operating characteristic curve (AUROC) for detection of cirrhosis was 0.91 (95% CI 0.85–0.96) in the training cohort and 0.91 (95% CI 0.79–1.00) in the validation cohort. For detection of advanced fibrosis, the AUROC was 0.88 (95% CI 0.81–0.94) in the training cohort and 0.92 (95% CI 0.83–1.00) in the validation cohort. Sensitivity was 89% and specificity was 86% for detection of cirrhosis in the training cohort and respectively 59% and 99% in the validation cohort. The sensitivity was 76% and specificity was 90% for the detection of advanced fibrosis in the test cohort. Sensitivity was 55% and specificity was 100% for the detection of advanced fibrosis in the validation cohort. The diagnostic accuracy did not differ between MFAP4 and the ELF test or TE in an intention-to-diagnose analysis. The median follow-up was 452 days. MFAP4 did not predict hepatic decompensation in a time-to-decompensation analysis in the subgroup of 45 patients with cirrhosis.

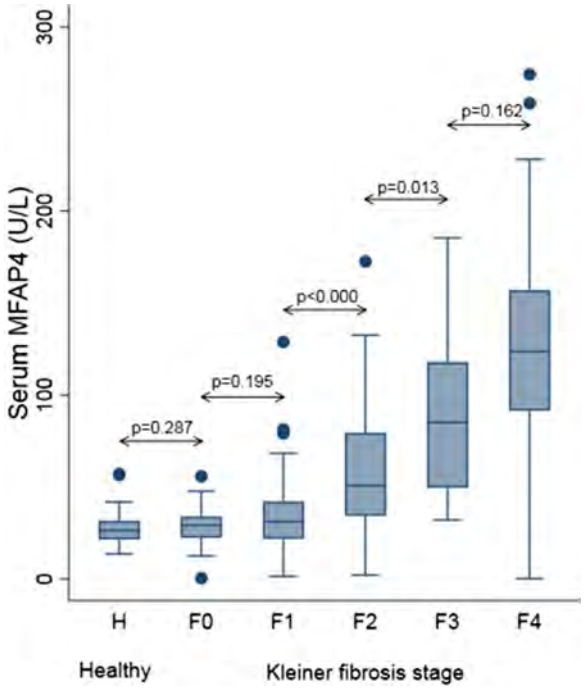

Figure: Boxplot of the serum concentration of MFAP4 in the healthy population group and in the cohort of patients with current or prior alcohol overuse distributed according to the Kleiner fibrosis stage.

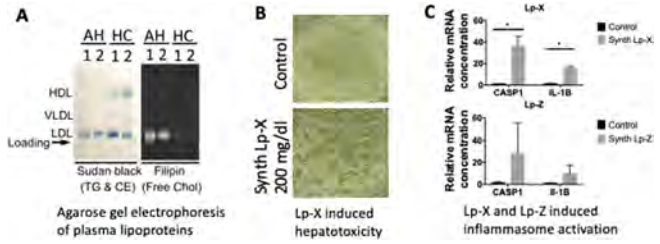
Conclusion: MFAP4 is a novel serological biomarker that can detect ALD-related liver fibrosis with high accuracy.

THU-269

Abnormal lipoproteins in alcoholic hepatitis cause hepatocellular injury via inflammasome activation

Maria Perez-Matos[1], Stephanie Tran[1], Shilpa Tiwari-Heckler[1], James McKnight[1], Esther Bullitt[2], Z. Gordon Jiang[1]. [1]*Beth Israel Deaconess Medical Center, Division of Gastroenterology and Hepatology, Boston, United States;* [2]*Boston University, Boston, United States*
Email: mcperezmatos1704@gmail.com

Background and aims: Alcoholic hepatitis (AH) is a severe acute manifestation of alcoholic liver disease with a mortality up to 30–50%. It has been shown that profound changes in circulating lipoproteins occur in severe alcoholic hepatitis. We aim to characterize the lipoprotein profile in AH and investigate the impact of abnormal lipoproteins on hepatocellular function.
Method: Patient samples were derived from an alcoholic hepatitis registry at Beth Israel Deaconess Medical Center. Human plasma was analyzed by agarose gel electrophoresis and stained by Sudan Black for neutral lipids and Filipin for free cholesterol. Serum lipoproteins were isolated by a Superose 12 10/300 GL size exclusion column and analyzed by negative stain electron microscopy. Synthetic Lp-X and Lp-Z were reconstituted using membrane extrusion *in vitro* and administered to HepG2 cells to evaluate cell viability and inflammasome activation.
Results: Lipoprotein profile in AH is characterized by the disappearance of normal circulating lipoproteins, including very low density lipoprotein (VLDL), high density lipoprotein (HDL), and a significant elevation of Lp-Z, a low density lipoprotein (LDL)-like particle that is enriched by free cholesterol and triglyceride, but deficient in cholesterol ester (A). Lp-X, a phospholipid and cholesterol-rich vesicle, is found in some patients. Reconstituted Lp-X- and Lp-Z-like emulsion particles were structurally similar to lipoproteins isolated from AH patients based on cholesterol content and electron microscopy images. Both Lp-X and Lp-Z-like emulsion particles demonstrate dose-dependent toxicity to HepG2 cells. Upon incubation with 200 mg/dl of Lp-X-like particles, HepG2 cells developed cellular swelling in 2 hours. Incubation with 200 mg/dl of Lp-X- and Lp-Z-like particles resulted in peak cell death at 2 hours and 6 hours, respectively (B). An increase in inflammasome gene expression, including CASP1 and IL-1β, was observed, a pattern that is consistent with changes associated with pyroptosis (C).



Conclusion: The accumulation of Lp-X and Lp-Z in the circulation is a characteristic disease feature in severe AH. These abnormal lipoproteins demonstrate hepatotoxicity through inflammasome activation *in vitro*. Our data suggest that Lp-X and Lp-Z are both biomarkers and potential therapeutic targets in severe AH.

THU-270

Severe alcoholic hepatitis has no influence on prognosis of variceal bleeding in patients with alcoholic cirrhosis

Petra Fischer[1], Andreea Fodor[1], Adelina Horhat[1], Daniela Matei[1], Maria Imbuzan[1], Ingrit Iuhasz[1], Oana Nicoara-Farcau[1], Andreea Bumbu[1], Zeno Sparchez[1], Marcel Tantau[1], Horia Stefanescu[1], Bogdan Procopet[1]. [1]*University of Medicine and Pharmacy "Iuliu Hatieganu", Regional Institute of Gastroenterology and Hepatology "O. Fodor, 3rd Medical Clinic, Hepatology Department, Cluj-Napoca, Romania*
Email: bogdanprocopet@gmail.com

Background and aims: Frequently, severe alcoholic hepatitis (AH) is manifested by portal hypertension related complications. Moreover, AH is associated with very high portal pressure, which is a risk factor for failure to control bleeding or low survival. The prognostic of variceal bleeding in these patients is not very well known.
The aim of the study was to evaluate the prognostic of patients with severe AH presenting with variceal bleeding.
Method: 128 patients with alcoholic cirrhosis and variceal bleeding recorded in our prospective variceal bleeding register (11.2013–03.2015 and 07.2017-present) were considered for inclusion. Among those with clinical criteria of severe AH (n = 51) transjugular liver biopsy was performed and confirmed the condition in 16 patients. Due to uncertain diagnosis of AH, the remaining patients with clinical criteria and no liver biopsy were excluded.
Results: Finally, 98 patients were included: 16 with severe AH and 77 with alcoholic cirrhosis. The median HVPG was 21 (14–30) mmHg in AH group (70% had > 20 mmHg). The age was significantly lower in AH group, 53 (35–65) vs. 59 (36–79), p = 0.004 and, as expected, bilirubin, AST and INR were significantly higher in AH. The AH and cirrhotic groups had similar outcomes regarding failure to control bleeding (12.5% vs. 9.1%, respectively, p = 0.48), the rate of infections during admission (20% vs. 17.8%, respectively, p = 1) or rebleeding within 42 days (0% vs. 10.8%, respectively, p = 0.594). However, the hospitalization length was longer in AH group in comparison with cirrhosis group, 14 (6–30) days vs. 9 (4–44) days, respectively (p = 0.006).
Mortality at 42 days was also not different: 3 (21.4%) patients in the AH, and 10 (14%) in the cirrhosis group, respectively (p = 0.44).
Conclusion: Patients with severe AH and variceal bleeding seems to have similar short-term prognosis with patients with alcoholic induced cirrhosis.

THU-271

Metabolic syndrome increases the risk of hepatic fibrosis in subjects with increased alcohol consumption: Results from a population-based cohort

llorenç caballeria[1], ELISA POSE[2], guillem pera[1], Isabel Graupera[2], carmen exposito[1], mónica sabater[3], José-María Moreno[3], Elsa Solà[2], José-Manuel Fernández-Real[3], pere toran[1], Pere Ginès[2]. [1]*USR Metropolitana Nord, IDIAP, Barcelona, Spain;* [2]*Liver Unit, Hospital Clínic de Barcelona, Barcelona, Spain;* [3]*Endocrinology Unit, Hospital Josep Trueta, Girona, Spain*
Email: lcaballeriarovira@gmail.com

Background and aims: Increased alcohol consumption and metabolic syndrome (MS) are two of the most common etiologies of chronic liver diseases worldwide. There is very little information about the interaction between alcohol consumption and MS. Although MS may theoretically increase the intensity of alcohol-induced liver damage, there is no conclusive data to support this hypothesis. Therefore, the aim of the present study was to investigate the effect of MS on hepatic fibrosis in subjects with increased alcohol consumption from a large population-based cohort.
Method: 275 of the 3, 014 (9.1%) subjects in the cohort had increased alcohol consumption, defined as > 14 units per week in women and > 21 units per week in men (average 29 ± 14 units per week). Demographic, clinical and analytical variables, including various pro-inflammatory cytokines, were obtained in all the subjects included. Liver fibrosis was estimated by transient elastography (TE).
Results: The frequency of significant fibrosis (TE > 8kPa) in subjects with increased alcohol consumption was 10.2%, a value significantly higher than that of the remaining subjects of the cohort without increased alcohol consumption (5.3%, p < 0, 001). The existence of significant fibrosis was associated with the intensity of alcohol consumption as well as with several metabolic factors, particularly

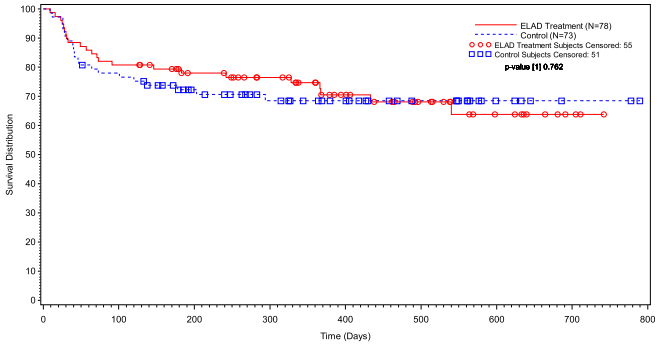
body mass index, abdominal circumference, type 2 diabetes, MS, glycaemia and glycosylated hemoglobin. In a multivariate analysis, independent predictors of significant fibrosis were the intensity of alcohol consumption and MS (age- and sex-adjusted OR 3.5 (IQR 1.5–8.1)). In subjects with MS the frequency of fibrosis was 18.6%, compared with only 6.3% in subjects without MS ($p = 0.003$). Subjects with significant fibrosis had higher serum levels of interleukin-6 (IL-6) and soluble receptor II of TNFα (sTNFRII) with respect to subjects without significant fibrosis, suggestive of an increased systemic inflammatory activity (IL-6: 4.8 vs 2.1 pg/ml; sTNFRII: 5.6 vs 5.0 ng/ml; $p < 0.001$ and 0.013, respectively).
Conclusion: In patients with increased alcohol consumption, the existence of MS is associated with a markedly higher risk of significant hepatic fibrosis. This higher risk may be related to the systemic inflammatory activity characteristic of MS. This interaction between alcohol and MS should be taken into account especially for the implementation of measures to prevent chronic liver diseases among the general population.

THU-272

A study investigating the effect of extracorporeal cellular therapy with C3A cells on the survival of alcoholic hepatitis designed along the guidelines of the NIAAA

Nikolaos T. Pyrsopoulos[1], Tarek Hassanein[2], Ram Subramanian[3], Julie Thompson[4], Stephen Caldwell[5], Ali Al-Khafaji[6], David Reich[7], Cyril Sieberhagen[8], Jan Stange[9]. *[1]Rutgers University, New Jersey, United States; [2]Southern California Liver Centers, Coronado, United States; [3]Emory, Atlanta, United States; [4]University of Minnesota, Minneapolis, United States; [5]University of Virginia, Charlottesville, United States; [6]University of Pittsburgh, Pittsburgh, United States; [7]Drexel, Philadelphia, United States; [8]Aintree, Liverpool, United States; [9]University of Rostock, 308 Study Group* Rostock, Germany*
Email: pyrsopni@njms.rutgers.edu

Background and aims: Alcoholic Hepatitis (AH) is a form of Acute on Chronic Liver Failure in Alcoholic Liver Disease (ALD). In 2016, the National Institute on Alcohol Abuse and Alcoholism (NIAAA) Alcoholic Hepatitis Consortia published guidelines on the design of clinical studies investigating acute AH (Crabb DW et. Al. Gastroenterology 2016; 150:785–790).
Based on those guidelines and on a pre-specified group analysis of a phase II/III trial (Thompson et al. Liver Transplantation 2018 (24):380–393) enrolling 203 subjects, a sub-population was identified to be enrolled in the pivotal trial VTL 308 to investigate the efficacy and safety of extracorporeal C3A cellular therapy (ELAD) in AH.
Method: 151 subjects with AH, <50 yo, MELD < 30, INR < 2.5, creatinine <1.3 mg/dl, bilirubin > 16mg/dl were randomized 1:1 in 50 sites in the EU and the US to either SOC or SOC in combination with 5 days of ELAD therapy. The primary end point was survival.



Results: 78 subjects were randomized to ELAD and 73 to SOC. Mean (range) values for age was 39.3 (23–49), for MELD (25.14 (19-29), for Bilirubin 24.93 (16–44.7) mg/dl, for INR 1.82 (0.95-2.5), for creatinine 0.73 (0.3–1.27) mg/dl. There were no differences in age, ethnicity, sex, race, height, weight, MELD, time from hospital admission to randomization, ascites, liver volume, Child-Pugh Score, renal function, HE grade, coagulopathy, pulmonary function and CLIF SOFA at baseline.
The study failed its primary end point as depicted in figure 1.
There were 116 treatment emergent serious adverse events in 76 subjects receiving ELAD and 113 in 75 subjects receiving SOC (safety population), therefore treatment in this population appeared safe.
Conclusion: In its current version ELAD could not demonstrate a significant survival difference in this sample size.

THU-273

Role of PNPLA3 rs738409 and MBOAT7 rs626283 during alcohol detoxification: Indication of different mechanisms for fibrosis development

Vanessa Rausch[1], Mueller Johannes[1], Silva Ines[1], Elshaarawy Omar[1], Peccerella Teresa[1], Seitz Helmut Karl[1], Mueller Sebastian[1]. *[1]Center for Alcohol Research and Salem Medical Center, University of Heidelberg, Heidelberg, Germany*
Email: vanessa.rausch@uni-heidelberg.de

Background and aims: The PNPLA3 rs738409 and MBOAT7 rs626283 polymorphisms have been identified as genetic risk factors for ALD progression; however, their molecular mechanisms are still poorly understood. We here study the impact of these two variants on various important clinical parameters in response to alcohol withdrawal.
Method: We prospectively enrolled heavy drinkers primarily presenting for alcohol withdrawal (n = 516). Mean alcohol intake was 184 g/day and the mean duration of detoxification was 6.3 days. All patients were genotyped for PNPLA3 rs738409 and MBOAT7 rs626283. In addition, inflammation, fibrosis and steatosis were non-invasively characterized in all patients using laboratory markers including M30 levels, CAP, LS and ultrasound before and after detoxification. In addition, in a subgroup of ALD patients (n = 105) liver biopsy was obtained and histologically analyzed.
Results: The PNPLA3 genotype frequencies were 41% 50% and 9% for CC, CG and GG and for MBOAT7 18% 52% and 30% for CC, CG and GG. Both genotypes (MBOAT7 CC and PNPLA3 GG) showed a strong and combined effect on fibrosis development in the overall cohort (ANOVA, $P < 0.05$). However, we observed striking differences between both genetic polymorphisms with regard to inflammation, fibrosis and steatosis in response to alcohol withdrawal. While inflammation showed no difference with a significant decrease during detoxification in all MBOAT7 genotypes, PNPLA3 GG showed significantly increased signs of liver injury after detoxification and a delayed resolution of inflammation (M30 and AST, $P < 0.001$). In contrast, inflammation resolved equally in all MBOAT7 genotypes (AST, $P < 0.001$) after detoxification. Finally, steatosis resolved in both polymorphisms and all genotypes to the same extent and no differences prior and after detoxification have been observed. In the histology cohort, PNPLA3 GG was significantly associated with inflammation (steatohepatitis, $P < 0.001$; ballooning, $P < 0.01$ and lobular inflammation, $P < 0.05$)), steatosis ($p < 0.05$) and microgranulomas ($p < 0.05$). Both variants were significantly associated with the presence of megamitochondria ($p < 0.001$).
Conclusion: While both variants showed a significant and combined effect on fibrosis progression, the response of steatosis and liver injury to alcohol withdrawal suggests important mechanistic differences. While PNPLA3 is primarily associated with liver injury and steatosis, MBOAT7 seems to sensitize directly for fibrosis development without affecting liver injury. Interestingly, both genetic polymorphisms did not affect the resolution of steatosis during alcohol withdrawal.

THU-274

Utility of quantitative CD64 expression on neutrophils in differentiating between bacterial Infection and inflammation in severe alcoholic hepatitis

Vivek Saraswat[1], Gaurav Pande[2], Alok Kumar[3], Samir Mohindra[3], Vikas Agarwal[4], Durga Prasanna Misra[4]. *[1]SGPGI, Gastroenterology, Lucknow, India; [2]SGPGI, Gastroenterology, Lucknow, India; [3]SGPGI Rae Bareilly Road, Gastroenterology, Lucknow, India; [4]SGPGI Rae Bareilly Road, Clinical Immunology, Lucknow, India*
Email: profviveksaraswat@gmail.com

Background and aims: It is vital to differentiate infection from inflammation in patients with severe alcoholic hepatitis (SAH; MDF > 32: MELD > 20) since steroids may exacerbate sepsis. Fc receptor (FcγR1 or CD64) expression on neutrophils is a potential biomarker of bacterial infections.
Aim: To assess clinical usefulness of measuring quantitative CD64 expression on neutrophils in differentiating bacterial infection from inflammation in patients of SAH.
Method: In a cross sectional observational study from March 2016 to June 2018, neutrophil CD64 expression using flow cytometry and procalcitonin levels were studied in consecutive patients with SAH. CD64 expression on neutrophils was analyzed over 10, 000 counted cell on BD FACS Canto flow cytometer (BD biosciences). Full work up for infection was done in all patients including microbiological cultures twice in 72 hours, repeated at onset of new fever episodes. Patients were categorized into those with (SAH-I) and without infection (SAH). SAH-I included those with "definite" (pathogen isolated on culture) or "probable" infection (negative cultures but obvious symptoms eg. pus discharge or radiological findings eg. lung abscess on CT chest). Patients with bacterial infection (SAH-I; n = 63), without proven infection (SAH; n = 72), and healthy controls (n = 20) were included.
Results: The percentage of neutrophils with CD64 expression and their mean fluorescence intensity in patients with infection [76.2% (56.9–86.5) and 1431 (229–1828)] were significantly ($p < 0.05$) higher as compared to those without infection [16% (12.6-23.1), and 853 (20-968)] and in controls [7.05% (1.4–9.5) and 99.5 (54.7–140.7)]. Using a cut off value of 27%, sensitivity and specificity of CD64 expression on neutrophils to diagnose bacterial infection was 94% and 78% respectively. Sensitivity and specificity for procalcitonin was 83% and 72% at cut-off of 2.91ng/ml. Combining procalcitonin with CD64 increased the sensitivity to 98.3%.

Table 1: Descriptive Statistics

	Groups	N	Mean	Std. Deviation	P value
CD 64 (%)	Infection	63	76.66	22.60	< 0.001
	No Infection	72	16.02	18.96	
CRP mg/L	Infection	63	6.20	4.84	< 0.001
	No Infection	72	3.11	3.57	
Procalcitonin	Infection	63	4.38	2.40	< 0.001
	No Infection	72	1.85	1.28	
TLC	Infection	63	11108.19	6911.99	0.001
	No Infection	72	7402.50	4166.63	

Independent sample t test used, $p < 0.05$ significant

Conclusion: Quantitative measurement of CD64 on neutrophils can distinguish between systemic infection and inflammation in the setting of SAH.

THU-275

Blood transcript modules differentiate steroid responders from non-responders at baseline in severe alcoholic hepatitis

Shvetank Sharma[1], Jaswinder Maras[1], Sukriti Sukriti[1], S Muralikrishna Shasthry[2], Richard Moreau[3], Shiv Kumar Sarin[2]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India; [3]Inserm U1149, Centre de Recherche sur l'Inflammation (CRI), Paris, France*
Email: shvetanks@gmail.com

Background and aims: Steroid therapy is effective in severe alcoholic hepatitis (SAH) in about 60% of patients with high 1-month mortality. Baseline clinical and laboratory features do not differentiate responders from non-responders at baseline. We aimed to determine the variability in blood cells as a marker to identify non-responders at baseline.
Method: Baseline and day-7 blood samples were drawn from SAH patients (16 each responders and non-responders), total RNA from PBMCs isolated and subjected to whole blood transcriptome analysis by RNA-seq. Gene expression profiles were grouped into 346 blood transcription modules (BTM). Activity of each module was taken as mean of the expression of all genes in a BTM. The BTMs were further regressed and correlation networks drawn within each study group. These networks were used to compare between the groups to determine BTMs associated with immune cell types and their functions that could distinguish non-responders (Fig1: each node is a network of significantly regressed BTMs in a group).
Results: RNA-seq revealed a total of 19806 protein coding genes. 346 BTMs could be drawn from all these genes. Responders had unique BTMs at day-0 and day-7 (11 vs 43), whereas non-responders had 48 and 144 BTMs at same time points. There were 9 BTMs that persisted. Top 25 BTMs that differentiated the study groups at baseline are presented in the figure. Amongst these, BTMs related to T and B cell types were significantly ($p = 0.02$) over expressed (>2-fold) in non-responders at baseline. Other BTMs that could differentiate the study groups at baseline were NK and select chemokines (CCL1, 4, 5, 7, 8; CXCL10, 11, 12, 13; IL8) and receptors (CCR1 and 5).

Figure: (a) Heatmap of top 25 differentiating BTMs, (b) Differentiating modules related to immune cells

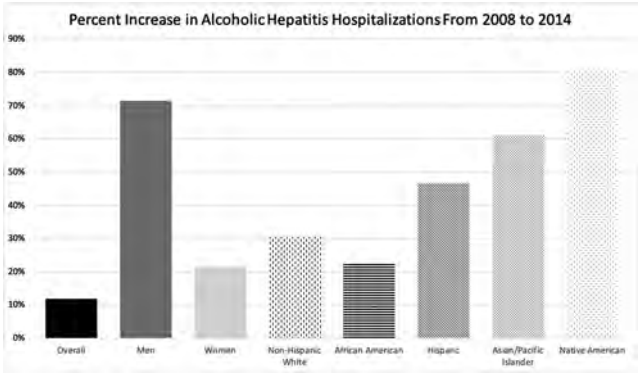
Conclusion: Baseline blood transcriptome analysis can be used as an effective method for determining the underlying immune cell profile without going into detailed cell specific analysis.

THU-276

Women, Native Americans, and Asians experience the greatest increase in alcoholic hepatitis hospitalizations: An analysis of the 2008-2014 U.S. nationwide inpatient sample

Farah Shirazi[1], Robert Wong[2]. [1]*California Pacific Medical Center, Department of Medicine, San Francisco, United States;* [2]*Alameda Health System-Highland Hospital, Division of Gastroenterology and Hepatology, Oakland, United States*
Email: fshirazi00@gmail.com

Background and aims: Excessive alcohol use remains a concerning issue contributing to significant morbidity and mortality, among which alcoholic hepatitis (AH) is one severe complication. To better understand the clinical and economic impact of AH, we aim to evaluate overall trends in AH-related hospitalizations and the increasing associated inpatient healthcare resource utilization.
Method: Using the 2008-2014 National Inpatient Sample, the largest all-payer inpatient database of hospital discharges in the U.S., AH-related hospitalizations among adults (age >18) were identified using ICD-9 codes. Survey-weighted annual hospitalization trends were stratified by sex, age, and race/ethnicity. Year-specific hospitalization rates were compared using chi-squared testing. Survey-weighted AH-related hospitalization charges were compared between years using adjusted Wald tests. Charges were inflation adjusted to 2014 U.S. dollars. Statistical significance was established with $p < 0.05$.
Results: Among 126, 268 AH-related hospitalizations representing a national estimate of 2.33 million hospitalizations (mean age 48.29 ± 11.3, 69.2% male, 64.5% non-Hispanic white, 10.3% African American, 9.7% Hispanic), 8.6% had concurrent hepatitis C, 16.1% ascites, 1.2% spontaneous bacterial peritonitis, and 11.0% hepatic encephalopathy at time of hospitalization. From 2008 to 2014, overall AH hospitalizations increased by 11.8% (16, 845 to 18, 837). During this same period, AH hospitalizations increased by 21.6% among women compared to 7.1% among men, $p < 0.01$. When stratified by race/ethnicity, the greatest proportional increases in AH hospitalizations were observed in Native Americans (+81%) and Asians (+61.3%), both significantly greater than African Americans (+22.8%, $p < 0.01$) and non-Hispanic whites (+30.6%, $p < 0.01$). When stratified by age, the greatest increase in AH hospitalizations was seen in those ages 60–69 years (+25.5%), whereas hospitalizations among patients <50 years decreased by 12% from 2008 to 2014. From 2008 to 2014, the estimated national economic burden of AH hospitalizations increased from $1.77 billion to $2.54 billion.



Conclusion: From 2008 to 2014, AH hospitalizations in the U.S. increased by nearly 12%, with the greatest increases seen among women, Native Americans, and Asians. Increasing healthcare resource utilization was also observed, and in 2014 total national AH-hospitalization related charges was $2.54 billion.

THU-277

Significant differences in alcoholic hepatitis related mortality in the United States by sex, race/ethnicity, and insurance: An analysis of the 2008-2014 nationwide inpatient sample

Farah Shirazi[1], Robert Wong[2]. [1]*California Pacific Medical Center, Department of Medicine, San Francisco, United States;* [2]*Alameda Health System-Highland Hospital, Division of Gastroenterology and Hepatology, Oakland, United States*
Email: fshirazi00@gmail.com

Background and aims: Excessive alcohol consumption leading to alcoholic hepatitis (AH) is associated with significant morbidity and mortality. Whether certain populations affected by AH are at particularly higher risk of mortality is not well studied. We aim to evaluate disparities in in-hospital mortality among adults hospitalized for AH with a focus on sex, race/ethnicity and insurance-specific disparities.
Method: Using the 2008-2014 National Inpatient Sample, the largest all-payer inpatient database of hospital discharges in the U.S., AH-related hospitalizations among adults (age > 18) were identified. Survey-weighted in-hospital mortality rates were evaluated between groups using chi-square methods and adjusted multivariate logistic regression models that included age, sex, race/ethnicity, primary insurance, household income, hospital characteristics, liver-related complications, and All Patient-Refined Diagnosis Related Group (APR-DRG) risk of mortality score. P value <0.05 indicated statistical significance.
Results: Among 126, 268 AH hospitalizations representing a national estimate of 2.33 million hospitalizations (mean age 48.29 ± 11.3, 69.2% male, 64.5% were non-Hispanic white) 8.6% had concurrent hepatitis C, 16.1% ascites, 1.2% spontaneous bacterial peritonitis, 11.0% hepatic encephalopathy at time of hospitalization. Overall in-hospital mortality was 3.33%. Compared to women hospitalized for AH, men had significantly lower in-hospital mortality (OR 0.87 95% CI 0.80–0.94; $p < 0.001$). When stratified by race/ethnicity, Asian/Pacific Islanders had significantly higher in-hospital mortality compared to non-Hispanic whites (OR 1.70; 95% CI 1.18-2.43; $p = 0.004$). When evaluating insurance-specific mortality, compared to Medicare insured patients, those who were self-pay/uninsured had significantly higher in-hospital mortality (OR 1.25; 95% CI 1.08–1.44, $p = 0.002$), whereas there was a trend towards higher mortality in Medicaid patients (OR 1.13; 95% CI 0.99–1.29, $p = 0.069$).

Multivariate logistic regression evaluating predictors of in-hospital mortality

	Odds Ratio	95%CI	P value
Gender			
Female	1.000	Reference	
Male	0.867	0.80-0.94	.001
Race/Ethnicity			
Non-Hispanic White	1.000	Reference	
African American	0.943	0.82-1.09	.418
Hispanic	0.973	0.86-1.10	.678
Asian/Pacific Islander	1.700	1.18-2.43	.004
Native American	1.064	0.81-1.41	.661
Primary Insurance			
Medicare	1.000	Reference	
Medicaid	1.129	0.99-1.29	.069
Private/Commercial	1.017	0.90-1.16	.789
Self-pay/Uninsured	1.250	1.08-1.44	.002

Conclusion: Among adults hospitalized for AH in the U.S., overall in-hospital mortality was 3.33%. Significant sex, race/ethnicity and insurance-specific disparities in in-hospital mortality were observed, with the greatest in-hospital mortality observed in women, Asians, and patients who were uninsured or Medicaid insured.

THU-278

Increasing hospitalizations and resource utilization for alcohol associated liver disease and acute on chronic liver failure in young american adults

Ashwani Singal[1], page axley[2], Patrick S. Kamath[3]. *[1]Birmingham, Birmingham, United States; [2]University of Alabama at Birmingham, Birmingham, United States; [3]Mayo clinic, Rochester, United States*
Email: ashwanisingal.com@gmail.com

Background and aims: Alcohol associated liver disease (AALD) is associated with significant morbidity, mortality and financial burden. Data are scanty examining trends on disease burden in young adults hospitalized with AALD. A proportion of these patients develop acute on chronic liver failure (ACLF) with multiorgan failure and high short-term mortality. Our aim is to assess trends in prevalence, in-hospital mortality, resource utilization associated with AALD and with ACLF in young adults.

Method: National Inpatient Sample (2006–2014) was queried for hospitalizations with discharge diagnosis of cirrhosis using ICD-09 codes. ACLF was defined with ≥ 2 organ failures (OF) and its severity stratified to 1, 2, 3 with 2, 3, and > 3 OF. Hospitalizations were stratified by age: young (≤ 35 yrs.) and old (> 35 yrs.).

Results: Of 447, 078 patients, admissions with discharge diagnosis of AALD between 2006 and 2014, 16, 114 (3.7%) were ≤ 35 years. The proportion of young patients with AALD increased from 3.4% in 2006 to 4.2% in 2014. A total of 29, 594 (6.6%) admissions developed ACLF, 1138 (7.1%) admissions in young. Young admissions compared to older had more severe ACLF (34 vs. 25% grade 2–3, P < 0.0001). Proportion of ACLF admissions in young increased from 2.8% in 2006 to 5.2% in 2014, P < 0.001 = 01. Compared to older, admissions in young were more female (35 vs. 29%), obese (11 vs. 7.6%), Hispanic (29 vs. 18%), and admitted with alcoholic hepatitis (41 vs. 17%) p < 0.0001 for all. Proportion of admissions with discharge diagnosis of AH increased in young from 24 to 42% from 2006 to 2014, P < 0.0001. Despite similar frequency of esophageal varices, young adults were more likely to have variceal bleeding (11 vs. 8%), hepatic encephalopathy (72.7 vs. 68.3%) and hepatorenal syndrome (28.5 vs. 19%), with increased use of mechanical ventilation (79 vs. 76%) and dialysis (31.9 vs. 27.9%), p < 0.001 for all. Compared to young, admissions in old had higher in-hospital mortality (7.4 vs. 5.5%, p < 0.0001). Similarly, ACLF admissions in young had longer hospitalizations (16.6 vs. 13.5 days) and higher hospital charges ($197, 199 vs. $154, 816), p < 0.0001. In-hospital mortality among admissions with AALD decreased from 9% in 2006 to 6.9% in 2014), but remained stable in young (5.9% to 5.8% respectively). Similarly trend on in-hospital mortality in ACLF admissions declined from 54 to 45% in young and from 52% to 43% in older patients. AH and non-AH related ACLF had similar in-hospital mortality (47.2 vs. 46.2%, P = 0.2).

Conclusion: AALD related hospitalizations are increasing in young adults in the US, and is mainly due to increasing frequency of AH. Further, this disease burden in young is increasing with higher frequency of admissions with more severe ACLF and is associated with consumption of hospital resources. Studies are needed to develop preventive strategies to reduce burden in young adults related to AALD and ACLF.

THU-279

The prognostic stratification using acute-on-chronic liver failure scoring systems for predicting short-term mortality in patients with alcoholic hepatitis

Email: shivsarin@gmail.com

Background and aims: To compare the existing various prognostic scoring models and newly proposed scores for acute-on-chronic liver failure (ACLF) and evaluate usefulness of stratification for the prediction of short-term morality in patients with alcoholic hepatitis (AH).

Method: A total of 705 clinical AH patients, enrolled in the APASL-ACLF Research Consortium (AARC) with 90-day follow-up, were analyzed. AARC-ACLF score, Maddrey discrimination function (DF) score, age, bilirubin, international normalized ratio and creatinine score (ABIC), Glasgow Alcoholic Hepatitis Score (GAHS), Child-Turcott-Pugh (CTP) score, model for end-stage liver disease (MELD), and MELD-Sodium (Na) scores were used to compare the performance for predicting 30-day and 90-day mortality. AARC-ACLF scores were categorized into three grades (Gr I: 5–7; II: 8–10; and III: 11–15 points) and survival curves by the Kaplan-Meier method were created and compared using log-rank test.

Results: Of 708 patients, 286 (40.4%) and 363 (51.3%) patients died within 30 days and 90 days, respectively. The area under receiver operating characteristics curve (AUC) of AARC-ACLF, DF, ABIC, GAHS, CTP, MELD, and MELD-Na was 0.752 (0.705–0.799), 0.630 (0.575–0.685), 0.658 (0.604–0.711), 0.577 (0.523–0.631), 0.641 (0.589–0.694), 0.705 (0.653–0.756), 0.703 (0.651–0.755), respectively, for 30-day mortality. The AUC of various prognostic scores for the prediction of 90-day mortality is similar. The performance of AARC-ACLF was superior to that of DF, ABIC, GAHS, CTP, while comparable to that of MELD and MELD-Na in predicting short-term mortality. According to AARC-ACLF grades, short-term cumulative survivals was statistically different (30-day, 82.4, 70.4, and 35.3% p < 0.001; 90-day, 76.9, 56.0, and 26.4% p < 0.001).

Conclusion: Compared to the previous AH prognostic scores, AARC-ACLF score and grades are simple and useful for predicting the short-term mortality in patients with AH. Further studies are needed to confirm these implications.

THU-280

Quantitative fibrosis assessment independently predicts outcome in alcoholic liver disease

Rudolf E. Stauber[1], Patrick Käferböck[2], Walter Spindelböck[1], Philipp Douschan[1], Florian Rainer[1], Carolin Lackner[2]. [1]*Medical University of Graz, Department of Internal Medicine, Graz, Austria;* [2]*Medical University of Graz, Institute of Pathology, Graz, Austria*
Email: rudolf.stauber@medunigraz.at

Background and aims: Semiquantitative assessment of hepatic fibrosis in conventional histopathology is prone to intra- and inter-observer variation. Digital image analysis provides an objective tool for quantitation of total fibrosis (TF) and, specifically, for discrimination of septal fibrosis (SF) and pericellular fibrosis (PCF). We have previously shown that conventional assessment of fibrosis stage and semiquantitative scoring of PCF has a differential impact on outcome in alcoholic liver disease (ALD), with stage F ³ 3 predicting worse outcome in compensated but presence of PCF predicting better outcome in decompensated ALD. The aim of the present study was to evaluate the prognostic value of quantitative assessment of TF, SF and PCF along with routine clinical and biochemical parameters in compensated and decompensated ALD.
Method: We investigated consecutive patients with ALD who underwent liver biopsy for staging or differential diagnosis. Clinical and biochemical parameters and date of liver-related death were collected. Median follow-up time was 4.3 years. After staining with sirius red, SF and PCF were manually segmented using digitized slides and collagen proportionate areas for TF, SF, and PCF were quantified using Definiens ™ software. Multivariable Cox regression was used to assess the prognostic value of clinical, biochemical and histological parameters for the prediction of 5-year liver-related mortality.
Results: Our cohort comprised 166 patients with ALD (compensated, n = 50; decompensated, n = 116). In compensated ALD, TF, ASH, ductular reaction, alcohol abstinence, INR, albumin, and platelet count were identified as prognostic variables; on multivariable analysis, TF (p = 0.002) and alcohol abstinence (p = 0.050) remained as independent predictors of outcome. In decompensated ALD, PCF/SF ratio, ASH, canalicular cholestasis, ductular cholestasis, sex, alcohol abstinence, bilirubin, INR, sodium, albumin, WBC, and platelet count were identified as prognostic variables; on multivariable analysis, PCF/SF ratio (p = 0.037), canalicular cholestasis (p = 0.014), bilirubin (p < 0.001), INR (p = 0.001), and sodium (p = 0.017) remained as independent predictors of outcome.
Conclusion: On multivariable analysis of clinical, biochemical and histological parameters, quantitative fibrosis types measured by digital image analysis showed independent prognostic value for 5-year survival in ALD.

THU-281

Single nucleotide polymorphisms associated with no interferon lambda 4 production are associated with reduced mortality in alcoholic hepatitis

Sidsel Støy[1], Ewa Terczynska-Dyla[2], Sanne Skovgård Veidal[3], Kristoffer Rigbolt[3], Hendrik Vilstrup[1], Henning Grønbæk[1], Rune Hartmann[2], Thomas Damgaard Sandahl[1]. [1]*Aarhus University Hospital, Hepatology and Gastroenterology, Aarhus, Denmark;* [2]*Aarhus University, Molecular Biology and Genetics, Aarhus, Denmark;* [3]*Gubra, Hørsholm, Denmark*
Email: sidsel.stoy@clin.au.dk

Background and aims: Single nucleotide polymorphisms (SNPs) in the genomic region encoding interferon lambdas (IFNλ) influence liver inflammation and fibrosis progression. This effect appears aetiology-independent as the association is observed in both chronic viral hepatitis and in non-alcoholic fatty liver disease. As alcoholic hepatitis shares many genetic risk factors and pathogenic features with non-alcoholic fatty liver disease, we investigated if *IFNL* genetic variants could influence severity and progression of alcoholic hepatitis.
Method: Fifty-eight patients with severe alcoholic hepatitis were genotyped for the *rs368234815* and *rs11768444 IFNL4* SNPs. SNP association with mortality, infection risk, inflammatory markers and IFN signalling were explored.
Results: Alcoholic hepatitis patients with a non-functional *IFNL4* gene have improved survival (p = 0.03) compared with those encoding the IFNλ4 protein. These patients also have lower plasma sCD163 (p = 0.05) and lower circulating monocyte counts (p = 0.01) and tend to have fewer infections at diagnosis (p = 0.15). We observe no differences in GAHS and MELD between the genotypes. The *IFNL4* genotype distribution between patients with alcoholic hepatitis and heathy controls is the same. However, patients with alcoholic hepatitis have a reduced expression of *IFNLR* in the liver (p = 0.01) and on circulating leukocytes and lower expression levels of IFN stimulated genes in circulating leukocytes than healthy controls. This however is not related to *IFNL4* genotype within patients with alcoholic hepatitis.
Conclusion: SNPs associated with no ability to express IFNλ4 seem to reduce mortality from alcoholic hepatitis, possible boosting infection resistance through effects on the monocyte/macrophage compartment.

THU-282

Augument of liver regeneration protects against ethanol-induced acute liver injury by promoting autophagy

Yuan Wu[1], Ping Xie[1], Limin Liu[1], Wen Li[1], Wei An[1]. [1]*Capital Medical University, Beijing, China*
Email: anwei@ccmu.edu.cn

Background and aims: Alcoholic liver disease (ALD) is associated with high morbidity and mortality, and treatment options are very limited to date. Augmenter of liver regeneration (ALR) may protect against hepatic injury caused by chemical poisons, including ethanol (EtOH). Autophagy appears to positively influence survival in cases of liver dysfunction. Although ALR-mediated protection of mitochondrial morphology and function has been investigated extensively, the effects of ALR on mitophagy are less well understood to date. Our study is aiming to determine whether ALR-mediated protection against alcoholic liver injury is associated with changes in autophagy, particularly mitophagy.
Method: In this study, we investigated the impact of ALR-induced autophagy *in vitro* and *in vivo* in an ethanol-induced model of acute liver injury. ALT and AST and reduced histological lesions were measured to reveal the liver damage in mice overexpressing or knockdown *ALR*. The survival rates, improved maintenance of mitochondrial membrane potential and ATP levels were detected in *ALR*-transfected HepG2 cells following EtOH treatment. The expression of autophagy-markers including LC3-II, Beclin-1, and Atg5 were characterized by western blot and quantitative reverse transcription PCR. Liver transcriptome profile analysis was performed Ad-*ALR* (or $ALR^{\pm}$) and WT mice in response to EtOH treatment.
Results: Our study showed that hepatic overexpression of ALR alleviates EtOH-induced liver injury in mice, which is in line with its ability to protect the liver from a variety of other toxic insults. Furthermore, we could show that the protection conveyed by ALR expression may be mediated by promoting mitophagy and activating the mTOR signaling pathway. We confirmed an association of ALR overexpression with increased LC3II conversion and p62 degradation both *in vivo* and *in vitro*. Compared with control cells, ALR overexpression also upregulated Atg5 and beclin-1 expression, and increased Parkin translocation to mitochondria following ethanol stimulation. These results indicate that ALR induction enhances autophagy and mitophagy in response to EtOH-induced liver injury. In addition, SOD is decreased by ethanol intoxication and that is prevented by ALR. Our results showed that ALR promotes the mitochondrial SOD at transcriptional level to combat ethanol-induced hepatocyte injury.

Conclusion: ALR protected the liver from EtOH injury by enhancing autophagy, and the protection was mediated by mTOR signaling. Our results suggest the possibility that intravenous injection of ALR maybe a feasible clinical therapy to combat with ALD. The identifcation of ALR as a novel inducer of autophagy may not only serve as a new lead for developing new therapeutic agents for ALD, it may additionally serve as a novel molecular probe for studying the regulation of autophagy.

FGF15 deficiency aggregates experimental alcoholic steatohepatitis in mice: A critical role for lipocalin 2 signaling

Zhou Zhou[1], Ting Jie Ye[1,2], Elizabeth DeCaro[1], Brian Buehler[1], Zachary Stahl[1], Gregory Bonavita[1], Min You[1]. *[1]Northeast Ohio Medical University, Pharmaceutical Sciences, Rootstown, United States; [2]Shanghai University of Traditional Chinese Medicine, 2Department of Biology, School of Basic Medical Science, Shanghai, China*
Email: myou@neomed.edu

Background and aims: Fibroblast growth factor (FGF) 15 (human homolog, FGF19) is a pivotal endocrine hormone largely expressed in the small intestine of rodents. Our group has previously demonstrated that ethanol administration to mice inhibits ileum Fgf15 synthesis, decreases circulating Fgf15, and causes hepatic dysfunctions.
Method: The present study assessed the causal role of Fgf15 and its hepatic signaling in development and progression of experimental alcoholic steatohepatitis by utilizing the Fgf15 knockout (FGF15KO) mouse model. Gender and age matched wild-type (WT) and FGF15KO mice were pair-fed with either an ethanol-containing diet or an ethanol-free diet (control) using a chronic-binge ethanol feeding protocol.
Results: Ethanol-administrated FGF15KO mice exhibited substantial hepatic triglyceride accumulation, exacerbated oxidative stress, and markedly augmented elevation of serum liver enzymes compared to ethanol-fed WT mice. Mechanistic studies revealed that removal of FGF15 in mice drastically augmented the ethanol-induced circulating level of lipocalin 2, a prominent regulator of lipid metabolism and inflammation in the pathogenesis of alcoholic liver disease. In cultured mouse AML-12 hepatocytes, treatment with recombinant FGF19 protein blocked the ability of ethanol or lipopolysaccharides (LPS) to induce lipocalin 2. Furthermore, knocking down FGFR4, a FGF15/19 receptor, abolished FGF19's ability to suppress lipocalin 2 levels in AML-12 hepatocytes exposed to either ethanol or LPS, indicating that FGF19 directly downregulates lipocalin 2.
Conclusion: Our present study illustrates a crucial role of FGF15/19-lipocalin 2 axis in alcoholic liver injury and suggests that ameliorating the FGF15/19-lipoalin 2 axis-mediated signaling could be of great value for the treatment of human alcoholic steatohepatitis.

THU-284

Hepatocyte-specific deletion of splicing factor SRSF3 exacerbates experimental alcoholic steatohepatitis in mice

Zhou Zhou[1], Ting Jie Ye[1,2], Elizabeth DeCaro[1], Brian Buehler[1], Zachary Stahl[1], Gregory Bonavita[1], Min You[1]. *[1]Northeast Ohio Medical University, Pharmaceutical Sciences, Rootstown, Ohio, United States; [2]Shanghai University of Traditional Chinese Medicine, Department of Biology, School of Basic Medical Sciences, Shanghai, China*
Email: myou@neomed.edu

Background and aims: The RNA-binding protein Serine/arginine-rich splicing factor 3 (Srsf3) (also known as SRp20) plays critical roles for maintaining liver metabolic function. Liver-specific SRSF3 deficiency in mice caused spontaneous progressive liver damage, including steatohepatitis, fibrosis, and hepatocellular carcinoma (HCC) with aging, similar to the progression of human liver disease. Here, utilizing a hepatocyte-specific SRSF3 knockout mouse model (SRSF3HKO), we investigated the role of SRSF3 in the development and progression of alcoholic steatohepatitis.
Method: Gender and age matched SRSF3HKO mice and littermate loxP control (WT) mice were pair-fed with either an ethanol-containing diet or an ethanol-free diet (control) with the chronic-binge ethanol feeding protocol. Liver and serum samples were collected after 10 days of pair-feeding. We measured mRNA and protein expression levels of SRSF3 in the mouse samples as well as in liver samples from patients with alcoholic steatohepatitis and healthy individuals (controls).
Results: On the ethanol-containing diet, the SRSF3HKO mice displayed greater hepatic lipid accumulation, and augmented elevation of alanine aminotransferase and aspartate aminotransferase, markers of liver injury, compared with WT mice. Remarkably, the fatty livers of SRSF3HKO mice progressed to fibrotic liver in response to ethanol challenge. Accordingly, liver samples from patients with alcoholic steatohepatitis had significantly reduced SRSF3 gene and protein expression levels and displayed abnormality in pre-mRNA splicing of E-selectin, a pivotal neutrophil infiltration mediator, compared with healthy controls.
Conclusion: Our novel findings demonstrate that hepatocyte-specific SRSF3 deficiency in mice exacerbates the development and progression of alcoholic steatohepatitis in mice. Dysregulation of the hepatic SRSF3 and its signaling during ethanol exposure may represent an important mechanism that contributes to progression of human alcoholic steatohepatitis.

Loss of X-Box Protein-1 in intestinal epithelial cells promotes the development of alcoholic liver disease in the liver

kang Zheng[1,2], Hui Ye[1,2], Yulia Nevzorova[2,3,4], Beatriz Martin[1,2], Iris Asensio[5,6,7], Javier Vaquero[5,6,7], Manuel Gómez del Moral[8], Rafael Bañares[5,6,7], Eduardo Martínez-Naves[1,2], Francisco Javier Cubero[1,2]. *[1]Complutense University School of Medicine, Immunology, Ophthalmology and ORL, Madrid, Spain; [2]12 de Octubre Health Research Institute (imas12), Madrid, Spain; [3]Faculty of Biology, Complutense University Madrid, Genetics, Physiology and Microbiology, Madrid, Spain; [4]University Hospital RWTH Aachen, Department of Internal Medicine III, Aachen, Germany; [5]Hospital Universitario Gregorio Marañón, Servicio de Aparato Digestivo, Madrid, Spain; [6]Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Madrid, Spain; [7]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain; [8]Complutense University School of Medicine, Department of Cell Biology, Madrid, Spain*
Email: fcubero@ucm.es

Background and aims: In the context of alcoholic liver disease (ALD), the gut- liver axis has become a focus of major attention in the last few years. Increased gut permeability and intestinal flora alternation are increasingly recognized as major factors in ALD. Intestinal epithelial cells (IECs), play a pivotal role in maintaining gut permeability and intestinal microbiota homeostasis. The transcription factor *XBP1* is a key component of the endoplasmic reticulum (ER) stress response. In the present study, we hypothesized that deletion of *XBP1* in IECs might promote ALD development in the liver.
Method: Mice with specific deletion of *XBP1* in IECs ($XBP1^{\Delta IEC}$) and *XBP1*-floxed wildtype ($XBP1^{f/f}$) mice were subjected to acute ethanol (EtOH) intoxication and a diet model of ALD by performing either: (i) 3x PBS (3GP) or EtOH gavages (3GE) or (ii) Lieber-DeCarli control (LDC) and ethanol (LDE) diet for 4 weeks plus a single PBS or EtOH gavage, respectively. Upon sacrifice, organs were extracted, and markers of liver damage, histopathological examination and transmission electron microscopy (TEM) were performed.
Results: Serum markers of liver damage (e.g.: AST) were statistically increased in $XBP1^{\Delta IEC}$ compared with $XBP1^{f/f}$ after both models of

ALD: 3GE and LDE. Concomitantly, HandE staining of XBP1$^{\Delta IEC}$ livers displayed macrovesicular ballooning accompanied by significantly elevated inflammation and immune cell infiltration (CD45, F4/80) after LDE and to a lesser extent after 3GE. Furthermore, Oil Red O (ORO), Toluidine Blue staining and the content of intrahepatic triglycerides revealed significantly increased lipid deposition in XBP1$^{\Delta IEC}$ compared with XBP1$^{f/f}$ after LDE and 3GE feeding. Specifically, the TEM studies revealed lipid accumulation in hepatocytic cytoplasm, mitochondria and nuclei of XBP1$^{\Delta IEC}$, whilst XBP1$^{f/f}$ livers exhibited lipids in the cytosolic compartment. Since our mice had loss of XBP1 in IECs, we also evaluated the ileum of these mice. Importantly, presence of autophagic vacuoles, decreased lysozyme granules and dilation of the Golgi cisterns associated with loss of Paneth cells was characteristic of XBP1$^{\Delta IEC}$ compared with XBP1$^{f/f}$ ilea, after both models of EtOH intoxication.

Conclusion: Our results clearly suggest that loss of XBP1 in IECs triggers significant damage in the liver, opening a new avenue for research in the gut-liver axis in the context of ER stress and ALD, using two well-established models of EtOH intoxication.

THU-286

Activation of the NLRP3 inflammasome correlates with the severity of alcoholic liver disease

Zijian Sun[1], Ying Sun[2], Binxia Chang[2], Ang Huang[2], Ning Li[2], Ji-yuan Zhang[3], Zhengsheng Zou[1]. [1]*Peking University 302 Clinical Medical School, Center of Non-infectious Liver Diseases, Beijing, China;* [2]*Beijing 302 Hospital, Center of Non-infectious Liver Diseases, Beijing, China;* [3]*Beijing 302 Hospital, Treatment and Research Center for Infectious Diseases, Beijing, China*
Email: zszou302@163.com

Background and aims: Alcoholic liver disease (ALD) is a common liver disease in China but lack of definitive treatment. Aggravated inflammation with increased expression of proinflammatory cytokines is an important feature of ALD. Inflammasomes are cytosolic multi-protein complexes that are essential effectors for sterile inflammatory response, in which nucleotide-binding oligomerization domain-Like Receptor with a pyrin domain 3 (NLRP3) inflammasome is the most studied by far. NLRP3 inflammasome has been shown to be required for a wide range of liver diseases. However, the characteristic of NLRP3 inflammasome in human ALD remains unclear. The aim of our study is to investigate the characteristic of NLRP3 inflammasome during ALD.

Method: Blood samples were collected from healthy controls (HCs, n = 20) and ALD patients (n = 38) and the plasma levels of IL-1 beta were measured by enzyme-linked immunosorbent assay. The expression of NLRP3 inflammasome associated molecules in liver tissues from HCs (n = 4) and ALD patients (n = 5) were performed through qPCR and immunohistochemistry.

Results: As an indicator of activation of NLRP3 inflammasome, plasma levels of IL-1 beta were significantly elevated in ALD patients as compared to HCs ($p = 0.0075$), especially in patients with severe alcoholic hepatitis (Maddrey's DF > 32). The levels of NLRP3, ASC, Caspase-1 and IL-1 beta mRNA were significantly increased in ALD patients ($p = 0.0159$). Further Immunohistochemical staining showed that NLRP3 inflammasome was expressed in macrophages. Mechanically, mitochondrial DNA in microparticles of hepatocyte origin activated NLRP3 inflammasome in macrophages through TLR-9.

Conclusion: These data demonstrate that activation of the NLRP3 inflammasome increases significantly in ALD patients and closely associates with liver damage.

NAFLD: Clinical aspects except therapy

THU-291

Is non-alcoholic fatty liver disease a risk factor for chronic kidney disease?

Takemi Akahane[1], Tadashi Namisaki[1], Kei Moriya[1], Hideto Kawaratani[1], Kosuke Kaji[1], Hiroaki Takaya[1], Naotaka Shimozato[1], Shinya Sato[1], Yasuhiko Sawada[1], Keisuke Nakanishi[1], Masanori Furukawa[1], Yukihisa Fujinaga[1], Yuki Tsuji[1], Hitoshi YOSHIJI[1]. [1]*Nara Medical University, Third Department of Internal Medicine, Kashihara, Japan*
Email: stakemi@naramed-u.ac.jp

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is thought to increase the risk of chronic kidney disease (CKD). This is because the risk factors for both conditions include obesity, diabetes, and hypertension. However, the evidence clarifying the independent role of NAFLD on CKD progression is lacking. Therefore, we investigated whether NAFLD is independently associated with CKD.

Method: In this study, 3, 725 Japanese individuals [1, 751 males, 1, 974 females; mean age, 53.4 ± 9.1 (17-89) years] who underwent medical examination at the Nara Health Promotion Center in 2012 were assessed. Patients with hepatitis B or C infection, other hepatobiliary diseases, or males and females consuming >30 and >20 g/day of alcohol, respectively, were excluded. Fatty liver was diagnosed based on abdominal ultrasonography (hepatorenal echo contrast and liver brightness); CKD was defined as an estimated glomerular filtration rate < 60 ml/min per 1.73 m^2. The prevalence of CKD was compared between participants with and without NAFLD in obese and non-obese subjects, subjects with and without hypertension or subjects with and without fasting hyperglycemia. Independent predictors of CKD were determined by logistic regression analysis.

Results: The prevalence of CKD was significantly higher in participants with NAFLD than in those without NAFLD. However, the prevalence of CKD in the participants with obesity was not significantly different between those with and without NAFLD. Similar results were obtained regarding the prevalence of CKD in participants with hypertension and those with fasting hyperglycemia. In non-obese participants, there was no difference in the prevalence of CKD between those with and without NAFLD. Similar results were obtained for participants without hypertension and those without fasting hyperglycemia. Logistic regression analysis demonstrated that obesity and hypertension were independent predictors of CKD but NAFLD was not independently associated with CKD.

Conclusion: The findings conclude that NAFLD is not an independent risk factor for CKD, but obesity and hypertension, which are complications of NAFLD, are independently associated with CKD.

THU-292

The natural history of NASH-induced advanced fibrosis in a large cohort of patients with type-2 diabetes

Naim Alkhouri[1,2], Amandeep Singh[3], Mazen Noureddin[4], Mary Barbara[2], Eric Lawitz[1,2]. [1]*Texas Liver Institute, San Antonio, TX, United States;* [2]*University of Texas (UT) Health San Antonio, San Antonio, TX, United States;* [3]*Cleveland Clinic, Cleveland, OH, United States;* [4]*Cedars-Sinai Medical Center, Los Angeles, CA, United States*
Email: alkhouri@txliver.com

Background and aims: Non-alcoholic steatohepatitis can lead to advanced fibrosis (AF) and cirrhosis especially in patients with type-2 diabetes (T2D). Large cohort studies on AF progression and regression in diabetics are lacking. The aim of this study was to assess the transition of AF in a large cohort of diabetics and define factors associated with worsening or improvement in fibrosis.

Methods: Using ICD-9 codes, all T2D with the diagnosis of fatty liver in a large U.S. healthcare system were identified. Baseline demographics, clinical characteristics, and laboratory data were collected. Non-invasive scores to assess AF were calculated at baseline (BL) and then recalculated using last follow-up (LF) laboratory values to assess for the transition using the following cutoffs (AST/ALT >1.4, APRI >1.5, FIB-4 >2.67, NFS >0.676). Patients were divided into 4 groups as follows: No AF either times (BL and LF), AF both times, transition from no AF at BL to AF at LF, transition from AF to no AF. A univariable and a multivariable logistic regression analysis were done to further assess which clinical factors are associated with transition in AF status. A p value < 0.05 was considered statistically significant.
Results: A total of 50, 695 patients were included. The mean age at BL was 51.2 ± 11.6 years and at LF was 59.6 ± 11.6 years with median duration between 1st and last available labs was 84.4 (24 –199) months. 55.3% were females, 71% were Caucasians, and 42.6% had family history of T2D. Baseline mean platelet count was 251 [208, 299] and mean HbA1c was 6.6[6.0, 7.9]. Interestingly, the prevalence of obesity, HTN, CKD, hyperlipidemia and CAD increased during this period (p < 0.001 for all). During this period, 25.8% of subjects transitioned from no evidence of AF to AF (progression), 6.4% transition from AF to no AF (regression) and, the rest stayed stable. Clinical factors associated with transition from no AF to AF (progression) were female gender, African-American race, and the presence of baseline obesity, CKD or CAD. In terms of T2D medications, the use of insulin was associated with progression to AF whereas the use of oral hypoglycemic agents was protective. Interestingly, the use of statins was associated with increased odds of AF regression (OR (95% CI) = 1.12 (1.00, 1.25), corrected p value of 0.045.
Conclusion: The natural history of AF transition in patients with T2D is bidirectional and certain baseline characteristics predict progression. The effects of commonly used medications in diabetics on AF progression need further analysis.

THU-293

Increased risk of advanced liver disease independently of classic metabolic risk factors or drug induced hepatotoxicity in patients with psoriasis

María Teresa Arias Loste[1,2], Paula Iruzubieta[1,2], Laura Rasines[2], Juan Carlos Rodriguez Duque[1], Jose Ignacio Fortea[1,2], Agustin Garcia[2], Angela Puente Sanchez[1,2], Susana Armesto[3], Javier Crespo[1,2].
[1]Hospital Universitario Marqués de Valdecilla, Gastroenterology and Hepatology, Santander, Spain; [2]Instituto de Investigación Marques de Valdecilla. IDIVAL, Infection, Immunity and Digestive Diseases Group., Santander, Spain; [3]Hospital Universitario Marqués de Valdecilla, Dermatology, Santander, Spain
Email: ariasloste@gmail.com

Background and aims: Patients with psoriasis (Ps) frequently present with liver disease due to concomitant medication and/or coexistence of metabolic syndrome. However, the role that psoriasis plays as an immune-mediated disease, its phenotype, severity and treatment in the development of chronic liver disease, regardless of the presence of factors associated with the metabolic syndrome, are not well known.
Method: cross-sectional case-control study. Patients with Ps come from a consecutive cohort of patients with Ps in which other chronic liver diseases were discarded and variables associated with cardiovascular risk factors, metabolic syndrome, as well as those related to the severity, phenotype and treatment of the Ps were recorded. NAFLD was established by liver ultrasound and controlled attenuation parameter (CAP) measured with transient elastography (TE). Liver fibrosis was estimated by liver stiffness measurement (LSM) with TE. Controls come from a general population random sample and were matched by age, sex, BMI and presence of type 2 DM, hypertension and dyslipidemia, at a ratio of 1: 2.
Results: 57 cases of Ps were included (mean age 54.63 [12.06], 40 [70.2%] men) and 100 controls. It was detected a harmful consumption of OH in 10 patients (17.5%) and other causes of chronic liver disease were not identified. Fifteen patients were diabetic (26.3%), 25 had hypertension (43.9%) and 30 were dyslipemic (52.6%). The average PASI was 3.76 (± 3.27) and 36.8% of the cases were accompanied by joint involvement. 10 patients (17.5%) were receiving treatment with MTX, 17 with anti-TNF agents (29.8%) and 10 with other biological agents. Patients with Ps present an absolute value of TE and CAP significantly higher than controls (ET: 7.16 kPa [±3.25] vs 5.72 [±3.80], p < 0.0001) (CAP: 295.51 db/s [±65.17] vs 274.97 [±68.25], p = 0.042). In the univariate analysis, we found as predictor variables of fibrosis the diagnosis of Ps (crude OR 4, 01 [1, 961-8, 187], p < 0, 0001), obesity (1, 17 [1, 092-1, 268]; p < 0.0001), altered fasting blood glucose and alterations in liver function tests (GPT, GOT, GGT, albumin and platelets). We have not found differences according to treatment, phenotype or severity of Ps, the presence of metabolic syndrome components or OH consumption. In the multivariate analysis, Ps was found as an independent and the strongest predictor of fibrosis (3.94 [1.787-8.706]; p = 0.001), together with obesity (adjusted OR 1, 179 [95 CI: 1, 086-1, 280], p < 0.0001).
Conclusion: Ps patients have an increased risk of significant fibrosis. This risk appears independently of classical factors of metabolic syndrome or concomitant medication with potential hepatotoxicity. These data point to a possible role of the immune-mediated chronic inflammation underlying the cases of Ps and the existence of a dermo-hepatic axis.

THU-294

Non-invasive measures of liver fibrosis in NAFLD is associated with cardiovascular risk

David Niederseer[1,2], Sebastian Bachmayer[2], Andreas Stadlmayr[2], Ursula Huber-Schönauer[2], Dieter Lederer[2], Christian Schmied[1], Sabrina Hammerl[2], Elmar Aigner[3], Martin Plöderl[3], Wolfgang Patsch[3], Christian Datz[2]. *[1]University Hospital Zurich, Zurich, Switzerland; [2]General Hospital Oberndorf, Teaching Hospital of the Paracelsus Medical University, Department of Internal Medicine, Oberndorf, Austria; [3]Paracelsus Medical University Salzburg, Salzburg, Austria*
Email: david.niederseer@usz.ch

Background and aims: Many patients with non-alcoholic fatty liver disease (NAFLD) simultaneously suffer from cardiovascular diseases and often carry multiple cardiovascular risk factors. Several cardiovascular risk factors are known to drive the progression of fibrosis in NAFLD. It was the aim of this study to investigate whether established cardiovascular risk scores such as the Framingham risk score (FRS) and the Heart Score of the European Society of Cardiology (HS) are associated with the degree of fibrosis in NAFLD.
Method: We screened 2138 asymptomatic subjects (59.6 ± 10.2 years, 50% males, BMI 27.2 ± 4.6 kg/m²). The diagnosis of NAFLD was labeled if 1. (Areas of significant increased echogenicity in relation to the renal parenchyma present in right upper quadrant ultrasound) and 2. (Exclusion of viral, autoimmune, hereditary [Wilson`s disease, HFE-associated hereditary hemochromatosis, alpha-1 antitrypsin deficiency] liver disease and excess alcohol consumption evaluated by a questionnaire) was fulfilled. The FRS (estimates the ten-year risk of developing coronary heart disease) and HS (estimates ten-year risk of fatal cardiovascular disease) were calculated for each subject, as were NAFLD Fibrosis Score (NFS) and Fibrosis 4 Score (Fib4). Subsequently, NFS, Fib4, FRS and HS were correlated.
Results: Of 2138 subjects, 829 (38.7%) had NAFLD. Patients with NAFLD had a significantly higher cardiovascular risk: FRS: no NAFLD: 5.5 ± 5.2%; NAFLD: 8.8 ± 6.5% (p < 0.001); HS: no NAFLD: 2.9 ± 3.8%; NAFLD: 3.7 ± 4.1% (p = 0.002). Patients with NAFLD were grouped into three groups according their NFS: F0-F2 (n = 663); indifferent (n = 155); F3-F4 (n = 11). In patients with F0-F2 according to NFS, FRS was 8.0 ± 6.1%; with indifferent NFS, 10.8 ± 6.4%; and in F3-F4

(NFS): 11.5 ± 5.2%, respectively. HS showed a similar pattern: F0-F2 (NFS): 3.0 ± 3.4%; with indifferent NFS, 5.4 ± 4.5%, and in F3-F4 (NFS): 7.0 ± 5.7%, respectively. NFS correlated significantly with FRS ($r = 0.18$, $p < 0.001$) and HS ($r = 0.27$, $p < 0.001$). Likewise, patients with NAFLD were grouped into three groups according to their Fib4: F0-F1 (n = 589); indifferent Fib4 (n = 411); F3-F4 (n = 58). In patients with F0-F1 according to Fib4, FRS was 7.3 ± 5.8%; with indifferent Fib4, 11.1 ± 6.7%; and in F3-F4 (Fib4): 11.1 ± 6.9% respectively. HS did not change with respect to Fib4 estimated degree of fibrosis: F0-F1 (Fib4), 3.2 ± 3.6%; with indifferent Fib4, 3.3 ± 3.8%, and in F3-F4 (Fib4): 2.9 ± 3.9%, respectively. Fib4 correlated with FRS ($r = 0.25$, $p < 0.001$), but not with HS ($r = 0.02$, $p = 0.55$).

Conclusion: In this large asymptomatic screening cohort, subjects with non-invasive indicators of advanced stages of NAFLD had an increased risk of coronary heart disease and cardiovascular outcomes. A multidisciplinary approach including hepatologists and cardiologists is important to ensure optimal care for these patients at high risk of CVD and liver-related end points.

THU-295

Non-alcoholic fatty liver disease is associated with QTc lengthening in the general population

Bubu Banini[1], Danny Issa[1,2], Mulugeta Seneshaw[1], Mohammad Siddiqui[1], Abdul Oseini[1], Faridoddin Mirshahi[1], Sofanit Dessie[1], Puneet Puri[1,3], Ehimen Aneni[4], Michael Blaha[5], Matthew Budoff[6], Mahmoud Al Rifai[7], Moyses Szklo[8], Khurram Nasir[4], Arun J Sanyal[1]. *[1]Virginia Commonwealth University, Internal Medicine, Richmond, United States; [2]New York Prebyterian Hospital, New York, United States; [3]Hunter Holmes Mcguire VA Medical Center, Richmond, United States; [4]Yale New Haven Hospital, New Haven, United States; [5]Johns Hopkins Medicine, Lutherville, United States; [6]University of California Los Angeles, Torrance, United States; [7]University of Kansas School of Medicine, Wichita, United States; [8]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States*
Email: bububanini@yahoo.com

Background and aims: Cardiovascular disease is the leading cause of mortality in the general population. Prolonged heart rate corrected QT (QTc) interval is a risk factor for cardiac death. We aimed to determine: (1) if underlying non-alcoholic fatty liver disease (NAFLD), a common disease in the population, is associated with QTc length and (2) if the histological severity of NAFLD is associated with more severe QTc prolongation.

Method: Two cohorts were studied: (1) The Multi-Ethnic Study of Atherosclerosis (MESA), a population-based prospective cohort study of 6814 adult men and women free of cardiovascular disease at enrollment, and (2) A biopsy-proven non-cirrhotic NAFLD cohort (n = 52) and age/gender matched non-NAFLD controls (n = 67) at Virginia Commonwealth University (VCU). NAFLD was identified by a Liver to spleen attenuation ratio (L/S) >1 on CT scan. Severity of NAFLD in the general population was graded as: no NAFLD (Hounsfield Units (HU) ≥ 55), mild NAFLD (HU 40-54) and moderate to severe NAFLD (HU < 40). Liver histology was scored by Non-alcoholic steatohepatitis Clinical Research Network (NASH CRN) criteria. Patients with alcohol consumption >2 units/day, viral hepatitis, cardiac arrhythmias, or patients taking antiarrhythmic medications or systemic steroids were excluded from the analyses. QTc was determined by Bazett formula using electrocardiograms performed at the time of initial enrollment. Data are presented as mean ± standard deviation (SD). The odds ratio (OR) with confidence interval (CI) of having a clinically significant QTc prolongation in NAFLD vs non-NAFLD individuals was determined.

Results: (1) MESA cohort: A subset of 3892 individuals met eligibility criteria; 666 individuals (17%) had NAFLD. Those with NAFLD had longer QTc than those without NAFLD (424 ± 22.7 ms vs 418 ± 21.2 ms; $p < 0.0001$). There was a step-wise increase in the mean QTc interval in association with NAFLD severity ($p < 0.0001$ for trend). Moreover, NAFLD was associated with higher likelihood of clinically significant QTc prolongation of >450 ms in men (OR 2.24; 95% CI 1.4 to 3.6) and >460 ms in women (OR 1.8; 95% CI 1.2 to 2.7) (2) VCU cohort: Mean QTc for grade 1, 2 and 3 steatosis was 422 ± 7 ms, 435 ± 8 ms, and 466 ± 19 ms, respectively; $p < 0.03$. Aside from steatosis, other histological features of NASH, NAFLD activity score and fibrosis stage were not significantly related to QTc.

Conclusion: The presence and severity of hepatic steatosis is associated with lengthening of the QTc interval.

THU-296

Hepatic and visceral adipose tissue expression of vitamin D receptor and vitamin D hydroxylases in relation to non-alcoholic fatty liver disease and adipose tissue inflammation

Ilaria Barchetta[1], Flavia Agata Cimini[1], Caterina Chiappetta[1], Claudio Di Cristofano[1], Gianfranco Silecchia[1], Frida Leonetti[1], Maria Gisella Cavallo[1]. *[1]Sapienza University, Rome, Italy*
Email: ilaria.barchetta@uniroma1.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common chronic hepatic disease worldwide and associated with increased cardiovascular mortality. Visceral adipose tissue (VAT) inflammation is a leading cause of NAFLD and steatohepatitis (NASH) in obesity. Besides, adipose tissue (AT) represents the main site of vitamin D accumulation in humans and a major target of action of this hormone; similarly, a direct role of vitamin D (VD)/vitamin D receptor (VDR) axis has been demonstrated in liver pathophysiology. However, no data are available on the relationship between VDR expression and vitamin D metabolism in liver and VAT in metabolic disease. This study aimed at investigating the expression of VDR and VD hydroxylases in liver and VAT from obese patients in relation to the presence of NAFLD and VAT inflammation.

Method: Forty consecutive obese individuals candidate to bariatric surgery for clinical purposes (M/F: 11/29, mean ± SD age: 43.7 ± 9.6 years) were recruited at Sapienza University of Rome, Italy. Liver and omental biopsies were obtained intra-operatively and VDR, CYP27A1, CYP2R1 and CYP27B1 expression was evaluated by immunohystochemistry and real-time PCR in both tissues. Circulating 25 (OH)VD levels were measured on sera by colorimetry (DiaSorin, LAISON).

Results: Simple steatosis was diagnosed in 50% and NASH in 25% participants; hepatocyte VDR expression positively correlated with the presence of NAFLD, greater NAS steatosis ($p = 0.02$) and inflammation ($p = 0.002$) scores. Greater VDR expression in the liver was positively associated with VAT VDR expression ($p = 0.01$) and presence of VAT inflammation, as indicated by increased macrophage infiltration ($p = 0.008$) and expression of inflammatory markers such as IL-8 ($p = 0.01$), MIP1α ($p = 0.04$), MIP2 ($p = 0.002$) and DPP4 ($p = 0.01$). No association was found between circulating 25 (OH)VD and either hepatic or VAT VDR expression; similarly hepatic VDR expression did not correlated with VD hydroxylases expression in liver or VAT.

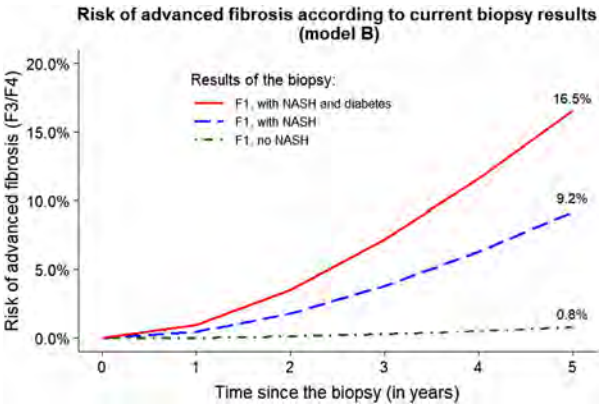
Conclusion: VDR is overexpressed in hepatocytes in the presence of NAFLD without showing further increase in more severe stages of the disease. VDR expression in hepatocytes may be likely induced by aberrant hepatic fat accumulation per se, representing a metabolic checkpoint in condition of chronic caloric excess and FFAs overload to the liver. The presence of a tight association between increased hepatic VDR expression, NAFLD and VAT inflammation, along with the novel finding of a correlation between VDR expression in liver and AT, point towards a central involvement of this receptor in metabolic disease, not necessarily mediated by its traditional ligand vitamin D.

THU-297

Prediction of NAFLD progression according to duration of exposure to obesity and diabetes: New approach to adapt therapeutic and research strategies

Pierre Bauvin[1], Lassailly Guillaume[1,2], Line Carolle Ntandja Wandji[2], Claire Delacôte[1], Flavien Dautrecque[2], Alexandre Louvet[1,2], Caiazzo Robert[3], Viviane Gnemmi[4], Violeta Raverdi[3], Francois Pattou[3], Sylvie Deuffic-Burban[1], Philippe Mathurin[1,2]. *[1]Univ. Lille, INSERM, CHU Lille, U995-LIRIC, Lille, France; [2]Hôpital Claude Huriez, CHRU Lille, Services Maladies de l'Appareil Digestif, Lille, France; [3]Univ. Lille, Inserm, CHU Lille, U1190-EGID, Lille, France; [4]Centre de Biologie Pathologie, CHRU Lille, Univ Lille, Department of Pathology, Lille, France*
Email: pierre.bauvin@inserm.fr

Background and aims: The identification of non-alcoholic fatty liver disease (NAFLD) patients with high-risk of disease progression is an unmet need. The "Atlas Biologique de l'Obésité sévère" (ABOS) database on severely obese patients, with available information on duration of exposure to disease progression cofactors, is a unique opportunity to develop a predictive tool. With such an approach, clinicians would be able to base their therapeutic decision according to the predicted risk of progression.
Method: 989 severely obese candidates to bariatric surgery, with systematic biopsy and reported history of obesity and diabetes, were prospectively included in the ABOS database.
Histological analysis was performed with Kleiner, NAFLD Activity and Brunt scores. From this data, two Markov models of NAFLD progression, based on the risk factors (sex, age, BMI at 20 years, presence of diabetes and its duration) and duration exposure to obesity, were developed assuming that all had normal liver (NL) at the onset of obesity: model A aims to assess the current risk of NASH or advanced fibrosis, knowing the duration of obesity; model B predicts disease progression over 5 years, in patients with histological data. Both models closely reproduced the observed dynamics of NAFLD (mean absolute error: 4.8% for model A, 5.3% for model B in the ABOS database; 9.9% and 9.2%, respectively, in an independent test cohort of 248 obese patients)
Results: Examples were provided to highlight the usefulness of the models.
Model A: a 50-years old woman, obese for 20 years, BMI 30 at 20 years-old, without diabetes, is predicted to have a 3.4% risk of being F3-F4 and 7.6% of having NASH. Patient with same risk factors but obese for 30 years would have 3.9% and 9.6% risks, respectively. The latter being diabetic for 10 years would have 9.1% and 16.6% risks, respectively.
Model B (Figure): a no-NASH F1, 50-years old woman, BMI 30 at 20 years-old, without diabetes, would have a 5-year risk of 0.8% to progress to F3-F4. This risk increases to 9.2% in a NASH F1 (without diabetes), and to 16.5% in a NASH F1 (with diabetes since 10 years), other cofactors being unchanged.



Conclusion: This work highlights the importance of exposure duration to obesity and diabetes to predict disease progression. It provides decision making tools that may be used for therapeutic strategy and help in the design of clinical studies by providing more accurate statistical hypothesis.

THU-298

Clinical characteristics of NAFLD/NASH patients from gastroenterology and endocrinology clinics

Rachel Botchlett[1], Gail Hinkson[1], Stephen Harrison[1]. *[1]Pinnacle Clinical Research, San Antonio, United States*
Email: rbotchlett@pinnacleresearch.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) and its more aggressive form, non-alcoholic steatohepatitis (NASH), are closely linked to obesity, diabetes, hypertension, and hypothyroidism. Screening for NAFLD/NASH primarily occurs at gastroenterology/hepatology (GI/Hep) clinics, potentially limiting the screening of at-risk populations. The purpose of this study was to compare the prevalence of NAFLD/NASH and clinical characteristics between endocrinology (Endo) and GI/Hep clinics.
Method: Data was collected as part of the NASH Registry Study, in which participants are identified based on abnormal fibroscan (kPa ≥ 7.0, CAP ≥ 270), NAFLD fibrosis score (NFS) >−1.455, and/or biopsy-confirmed NASH. Information from consenting adults including demographics, recent lab results, and comorbidities was collected. Participants with excessive alcohol consumption or concomitant liver disease were excluded. Participants were grouped by the clinic in which they were recruited; either as a GI/Hep or Endo patient. Mean differences between groups were analyzed by t-test (continuous variables) or Chi-square (categorical).
Results: 561 adult subjects (mean age 55yrs) were prospectively enrolled and included in analyses, of which there were 356 GI/Hep and 205 Endo. Overall, participants tended to be Hispanic White and female, and no demographic differences were observed between groups. However, metabolic syndrome ($p < .001$), hypothyroidism ($p < 0.05$), pre-diabetes ($p < 0.01$) and type 2 diabetes ($p < 0.001$) were more prevalent in Endo patients, whereas colon polyps ($p < 0.001$) and NASH ($p < 0.05$) were more abundant in GI/Hep patients. GI/Hep patients also had a slightly higher incidence of hypertension, although not statistically different from Endo patients. BMI, waist and hip circumference, CAP, platelets, WBC and HbA1C were significantly higher, while age, kPa, ALT, AST and alkaline phosphatase were significantly lower in Endo vs GI/Hep patients. Clinical indices of fibrosis were also significantly higher in GI/Hep patients.
Conclusion: NASH prevalence was higher in participants from GI/Hep clinics. Endo patients present with significantly more risk factors for NASH, namely higher BMI, waist and hip circumference, and T2DM, while exhibiting lower indicators of fibrosis. Interestingly, almost all laboratory tests were more frequently collected at Endo vs GI/Hep clinics. These findings collectively highlight the importance of screening for NAFLD/NASH at Endo practices and enhancing NAFLD/NASH awareness among endocrinologists. Perhaps targeting these clinics is the first step in preventing the progression of disease often seen by specialists.

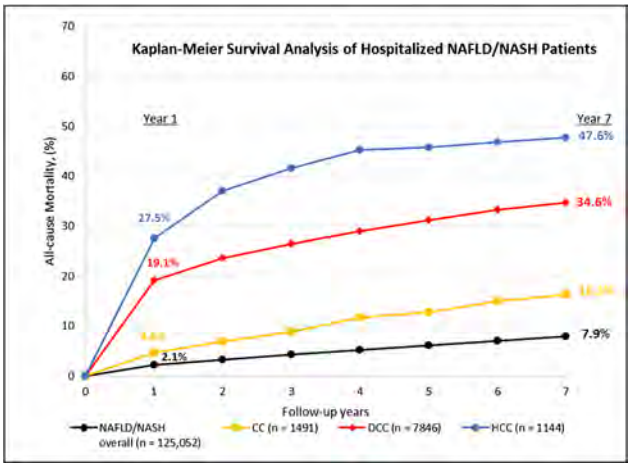
THU-299

Increased risk of mortality with liver disease progression in non-alcoholic fatty liver disease/non-alcoholic steatohepatitis patients: An analysis of French national hospital care

Jerome Boursier[1], Jeremy Fraysse[2], Antoine Lafuma[3], Cecile Fabron[3], Shreay Sanatan[2]. *[1]Angers Hospital University, Angers, France; [2]Gilead Sciences, Foster City, United States; [3]CEMKA, Bourg La Reine, France*
Email: jeboursier@chu-angers.fr

Background and aims: NAFLD/NASH can lead to compensated cirrhosis (CC), decompensated cirrhosis (DCC), and hepatocellular carcinoma (HCC), and is projected to be a major cause of liver-related mortality in the coming decades. However, limited data are available

on disease progression and mortality in French NAFLD/NASH patients. This study evaluated rates of disease progression and all-cause mortality in hospitalized NAFLD/NASH patients in France.
Method: Patients aged ≥ 18 years with NAFLD/NASH were identified from the French National Database on hospital care (PMSI) between 2009 and 2015, which captures all hospitalizations in France. Five study cohorts were identified via ICD-10-CM: (1) NAFLD/NASH overall, (2) CC, (3) DCC, and (4) HCC. Index date was defined as the earliest diagnosis date for each stage. Cohorts were not mutually exclusive. Survival analyses were performed via Kaplan-Meier curves for cumulative incidences of all-cause mortality occurring during hospitalization.
Results: Among 125, 052 NAFLD/NASH patients (mean age 55.9), 1, 491 (1.2%) were diagnosed with CC (1.2%), 7, 846 (6.3%) DCC, and 1, 144 (0.9%) HCC, with mean ages of 62.2, 65.0, and 70.1, respectively. The comorbidity burden was high for all cohorts: ≥ 43% had diabetes, ≥ 41% had cardiovascular disease, ≥ 21% had renal impairment, and ≥ 47% had hypertension. In 1 year of follow-up, 4-times as many NAFLD/NASH patients were diagnosed with DCC than CC (1200; 0.96% vs. 250; 0.20%), indicating under diagnosis of CC. In 7 years of follow-up, 5.6% of NAFLD/NASH patients progressed to more severe liver disease and 27.5% of diagnosed CC patients progressed to DCC. Mortality was high across cohorts and increased with liver disease progression: after 1 year mortality was 2-times higher in CC than NAFLD/NASH (4.6% vs. 2.1%) and almost 4-times higher DCC than CC patients (19.1% vs. 4.6%) (Figure). Overall mortality after 7 years in DCC was 34.6% CC, was 16.3%, and NAFLD/NASH was 7.9%.



Conclusion: Hospitalized NAFLD/NASH patients in France had high rates of comorbidities and high rates of liver disease progression (over 1 in 4 CC progressed to DCC). The overall NAFLD/NASH mortality rate of 7.9% was higher than the expected rate for the general similarly aged population of 4.6%, and increased with liver disease progression. Early identification and treatments to halt or reverse disease progression due to NAFLD/NASH may reduce the rate of mortality.

Prevalence of NAFLD in patients with a first episode of stroke and impact on the mortality and severity at 3 months

Teresa Broquetas[1,2], Elisa Cuadrado[2,3], Lidia Canillas[1], Susana Coll[1,2], Montserrat Garcia Retortillo[1,2], Nuria Cañete[1,2], Carlos Fernando Enriquez[1], Marc Puigvehí[1,2], Ricard Sola Lamoglia[1,2], Jose A. Carrión[1,2]. *[1]Hospital del Mar, Liver Section. Gastroenterlogy department, Barcelona, Spain; [2]Hospital del Mar Medical Research Institute, Barcelona, Spain; [3]Hospital del Mar, Neurology Department, Barcelona, Spain*
Email: 60578@parcdesalutmar.cat

Background and aims: non-alcoholic fatty liver disease (NAFLD) is associated with a higher prevalence of cardiovascular events and subclinical atherosclerosis. Previous studies suggest that the presence of NAFLD and significant fibrosis could be associated with a higher severity and mortality in patients with a stroke. The aim of the study was to determine the prevalence of NAFLD in a prospective cohort of patients with a first episode of stroke and the relationship between NAFLD and severity and mortality at 3 months after stroke.
Method: retrospective analysis of a prospective cohort of patients admitted for a first episode of stroke. NAFLD was defined as the presence of a Fatty Liver Index (FLI) >60 and significant fibrosis according to the values of FIB4 adjusted for age (FIB4 >1.4 if age < 65 years and >2 if age >65 years). Patients with known liver cirrhosis were excluded. Mortality and severity of stroke were assessed with the Rankin scale (RS) at 3 months after stroke.
Results: from January 2016 to May 2018, 481 patients were evaluated with a first episode of stroke. 14 (2.9%) patients with a previous diagnose of cirrhosis and 65 (13%) for missing values to calculate the FLI were excluded. Finally, 402 patients were included, 58% men with a median age of 76 years and a BMI of 27Kg/m^2. The prevalence of hypertension, diabetes mellitus, dyslipidemia and atrial fibrillation was respectively: 71%, 32%, 52% and 32%. The etiology of the stroke was cardioembolic (31%), lacunar (19%), hemorrhagic (13%) and atherothrombotic (12%). The overall prevalence of NAFLD was 43.5% (n = 175), higher in men than in women (48% vs. 37% p = 0.03). 34% of the patients presented significant fibrosis. At 3 months after stroke, no significant differences were observed in patients with and without NAFLD in mortality (8.6% vs. 8.0%, p = 0.8) or in the severity of stroke (RS0: 20% vs.17%, RS1: 19% vs. 16%, RS2: 17% vs. 18%, RS3 25% vs. 20%, RS4 15% vs. 14%, RS5: 1% vs. 2%, p = 0.9).
Conclusion: in patients with a first episode of stroke, the prevalence of NAFLD is very high. NAFLD affects almost half of men. One third of patients are at risk of significant fibrosis. Even thought, the presence of NAFLD does not seem to condition a worse prognosis in our cohort

THU-301
Weight loss significantly reduces the risk of chronic kidney disease development in patients with non-alcoholic fatty liver disease

Young Eun Chon[1], Seong Gyu Hwang[1], Mi Na Kim[1], Hana Park[1], Joo Ho Lee[1], Yeonjung Ha[1], Shin-Wook Kang[2], Hyung-Jong Kim[1], Yu Bum Choi[1], Mi Jung Lee[1]. *[1]CHA Bundang Medical Center, CHA University., Seongnam, Korea, Rep. of South; [2]Yonsei University College of Medicine, Seoul, Korea, Rep. of South*
Email: mjlee1203@chamc.co.kr

Background and aims: Weight loss is regarded as a pivotal treatment strategy in non-alcoholic fatty liver disease (NAFLD). However, there is a lack of data evaluating whether weight loss affects long-term kidney function in this population. Therefore, we investigated the impact of weight changes on adverse kidney outcomes in NAFLD patients using a community-based, prospective cohort with a 12-year follow-up.
Method: Among 10, 030 participants from the Korean Genome Epidemiology Study, 1, 774 NAFLD patients were included in this study. Patients were categorized into four groups according to the quartiles of time-averaged percent weight change (TA-%weight change). Study outcomes were development of chronic kidney disease (CKD) and rapid decline of kidney function.
Results: The median value of TA-% weight change was −1.3% (interquartile range, − 4.2 to 1.1). During a mean follow-up of 108.7 ± 44.5 months, CKD developed in 510 patients (28.7%). Patients in the first quartile (TA-%weight change < −4.2%) had a significantly lower risk of CKD development (hazard ratio [HR] = 0.531, 95% confidence interval [CI] = 0.409-0.690) and rapid decline of kidney function (HR = 0.598, 95% CI = 0.458-0.782), compared with patients with minimal changes. Decreased risk of CKD development in patients of the first quartile remained significant in the overweight (HR = 0.528, 95% CI = 0.372-0.751) and obese (HR = 0.482, 95% CI = 0.307-0.755) groups.

Table 2: (abstract: THU-301): Uni- and multivariable Cox regression analyses of TA-%weight change categories for CKD development in patients with NAFLD

	n (%)	Crude		[a]Model 1		[b]Model 2		[c]Model 3	
		HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P
TA-%weight change quartiles									
Q1 (<−4.2%)	96 (21.6%)	0.583 (0.450-0.756)	<0.001	0.543 (0.418-0.705)	<0.001	0.542 (0.417-0.704)	<0.001	0.531 (0.409-0.690)	<0.001
Q2 (−4.2 to −1.3%)	124 (27.9%)	0.812 (0.638-1.033)	0.90	0.873 (0.685-1.112)	0.31	0.872 (0.684-1.111)	0.27	0.843 (0.660-1.075)	0.17
Q3 (−1.3 to < 1.1%)	141 (31.8%)	1 (reference)		1 (reference)		1 (reference)		1 (reference)	
Q4 (≥ 1.1%)	149 (33.6%)	1.043 (0.828-1.313)	0.72	1.079 (0.856-1.360)	0.52	1.079 (0.856-1.360)	0.52	1.132 (0.896-1.430)	0.30
TA-% weight change (per 1 SD increase)	510 (28.7%)	1.234 (1.133-1.343)	< 0.001	1.256 (1.155-11.367)	< 0.001	1.257 (1.155-1.368)	< 0.001	1.291 (1.185-1.407)	< 0.001

[a]Model 1: adjusted for age, sex, education, income, smoking status, history of CVD, mean arterial pressure, and metabolic syndrome.
[b]Model 2: model 1 + serum albumin and CRP.
[c]Model 3: model 2 + BMI and baseline eGFR.
* TA-%weight change, time-averaged percent weight change.

Conclusion: In conclusion, this study is the first to demonstrate that weight loss, above an average of 4.2%, was associated with significant risk reduction of CKD development and rapid decline in kidney function. It suggests that significant and sustained weight loss may improve long-term kidney outcomes in patients with NAFLD.

THU-302

Association between advanced fibrosis in fatty liver disease and overall mortality in terms of body size and body fat distribution

Goh Eun Chung[1], Nam Ju Heo[1], Jeong Yoon Yim[1], Min-Sun Kwak[1], Joo Sung Kim[1], Aijaz Ahmed[2], Donghee Kim[2]. *[1]Seoul National University Hospital Gangnam Center, Internal Medicine, Seoul, Korea, Rep. of South; [2]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, California, United States*
Email: gohwom@hanmail.net

Background and aims: Association between fatty liver disease and overall mortality have yielded inconsistent results, from a strong association to no association. This study aimed to determine the association between fatty liver disease and advanced fibrosis and overall morality according to body size and abdominal fat distribution as measured by computed tomography (CT).
Method: We performed a prospective cohort study of 38, 647 subjects (mean age, 51.3 years; 58.3% men) who underwent abdominal ultrasonography and fat CT from 2007. Fatty liver was diagnosed by ultrasonography and advanced fibrosis was defined as having high probability for advanced fibrosis using three non-invasive methods such as aspartate aminotransferase to platelet ratio index, non-alcoholic fatty liver disease fibrosis score, and FiB-4 score. Body size was categorized based on body mass index: obese (≥ 25 kg/m^2) or non-obese (<25 kg/m^2). Multivariate proportional Cox hazard regression analyses were performed to determine independent predictor of overall mortality.
Results: The prevalence of fatty liver disease was 32.6%, while the prevalence of advanced fibrosis in fatty liver disease was 1.8%. During the median follow-up of 88 months (range, 1.2-138), there were a total of 352 deaths. Fatty liver disease was not associated with higher overall mortality (multivariable-adjusted hazard ratio [HR]: 1.02, 95% confidence interval [CI]: 0.77-1.34), while an increased subcutaneous adiposity was associated with decreased mortality (HR 0.72 95% CI 0.60-0.80), more prominent in non-obese population. Subjects with advanced fibrosis had 3.5 fold increase in overall mortality (adjusted HR 3.52, 95% CI, 1.86 – 6.65, $p < 0.001$) after adjustment for other known risk factors of mortality. This significant increased risk of overall mortality in advanced fibrosis was more pronounced in non-obese population.
Conclusion: Fatty liver disease was not associated with increased overall mortality, while subcutaneous adiposity was associated with decreased overall mortality, more pronounced in non-obese population. Advanced fibrosis was associated with increased risk of overall mortality, more pronounced in the non-obese population.

THU-303

Report from the trenches: Real-life challenges to recruitment and enrollment in NAFLD clinical trials

Christine Chen[1], Daniel Pang[1], Meredith Lewis[2], Ilan Weisberg[1], Douglas Dieterich[2], Amreen Dinani[3]. *[1]Mount Sinai Beth Israel, New York, United States; [2]Icahn School of Medicine at Mount Sinai, New York, United States; [3]Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, United States*
Email: amreen.dinani@mssm.edu

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is one of the most common causes of chronic liver diseases worldwide, associated with both liver and all-cause mortality and projected to be the leading indication for liver transplantation. To date there are no effective pharmacological therapies and hence a race to drug development is critical. Despite its abundant prevalence, multiple challenges exist that hinder the recruitment and enrolment of participants in NAFLD clinical trials. The purpose of this study is to describe the real-world experience and screen failure reasons for recruitment into NAFLD clinical trials.
Method: Retrospective chart review of all patients referred for participation in a NAFLD clinical trial was performed from June 2016 to October 2018. Descriptive data were collected; the incidence of screen failure and the causative reasons for exclusion were investigated. Screen failure was defined as those participants who consented to participate in a study but were found to be ineligible based on inclusion and exclusion criteria.
Results: All screen failures (n = 40) were included for evaluation (Table 1). The most common cause of screen failure was a discordance in liver fibrosis stage between transient elastography and liver biopsy (19 cases, 48%). 53% (10/19) cases down-staged by 1 stage of fibrosis, 33% (6/19) down-staged by 2 stages of fibrosis, 11% (2/19) down-staged by 3 stages of fibrosis and 5% (1/19) cases were found to have cirrhosis excluding from a non-cirrhotic trial. 8 cases did not meet the criteria of NAS ≥ 4; 3 of the cases were being considered for cirrhotic trials but did not fulfil requirement of steatosis or inflammation.

Reason for Screening Failure	Number of Patients (n = 40)
1) Did Not Meet Minimum Inclusion Fibrosis Stage	19
2) Fibrosis score too low	18
3) Fibrosis score too high	1
NAS Score < 4	8
Consent Withdrawn	4
Refused Liver Biopsy	2
• Exclusion criteria	2
• Thrombocytopenia	1
• Change in anti-diabetic medication within screening period	1
• History of Hepatocellular carcinoma	1
• Hypertriglyceridemia	1
Fragmented Biopsy (Unable to Stage)	2

Conclusion: The screen failure rate for NAFLD trials remains high despite the abundance of disease. Most cases are due to a discordance between our non-invasive tools to assess fibrosis and assessment of liver fibrosis by the central reader compared to our local expertise. In clinical practice, we err on the side of caution and overestimate the degree of fibrosis while in clinical trials the degree of fibrosis is conservative, which is not reflective of the real-world. Efforts should be made to broaden inclusion criteria for NAFLD trials and/or discuss each case where there is a discrepancy and understand that features of NAS are lost as fibrosis progresses.

THU-304
Modeling NAFLD-related disease progression among the PITER SVR12 cohort

Chris Estes[1], Loreta Kondili[2], Maria Giovanna Quaranta[2], Antonio Craxi[3], Salvatore Petta[3], Mario Masarone[4], Francesco Paolo Russo[5], Massimo Siciliano[6], Barbara Coco[7], Roberto Filomia[8], Homie Razavi[1]. *[1]Center for Disease Analysis Foundation, Lafayette, United States; [2]Istituto Superiore di Sanità, Rome, Italy; [3]University of Palermo, Palermo, Italy; [4]Salerno University, Salerno, Italy; [5]University of Padua, Padua, Italy; [6]Catholic University of Rome, Rome, Italy; [7]University Hospital of Pisa, Pisa, Italy; [8]University Hospital of Messina, Messina, Italy*
Email: cestes@cdafound.org

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is frequent among patients with chronic hepatitis C. The cured HCV population may be susceptible to worsening of NAFLD and development of non-alcoholic steatohepatitis (NASH), due to advancing age combined with high levels of obesity and metabolic risk factors. Modeling can help assess how continued liver disease progression due to NAFLD would alter the outcome of HCV cure.
Method: A model of NAFLD-related disease burden was applied to over 2, 000 participants in the Italian PITER cohort who achieved SVR12 to quantify disease progression and outcomes. Based on previously modeled prevalence among the general Italian population by age group and gender, 670 cohort participants during 2014-2018 were estimated to have NAFLD. This cohort entered the model by disease stage and data year and were followed over time. Over 80% of the cohort entered the model at fibrosis stage ≥ F2 and 65% were classified as F4. Progression through fibrosis stages varied by age group and gender. Disease burden and mortality were estimated through 2030.
Results: NAFLD cases peaked at 640 cases in 2017, declining 40% to 380 cases by 2030. In 2018, 86% of cases were classified as ≥ F2 fibrosis (530 cases), 77% as ≥ F3 fibrosis (480 cases) and 64% as F4 fibrosis (400 cases), reflecting the high burden of disease attributable to previous viral infection. By 2030, the proportion of cases classified as ≥ F2 fibrosis declined to 78% (300 cases) of total prevalent NAFLD, due to lower mortality among participants with no/mild fibrosis. Likewise, the proportion of cases estimated as ≥ F3 declined to 70% and F4 cases declined to 56% of the total. There were an estimated 140 incident decompensated cirrhosis and 15 incident liver cancer cases from 2014-2030. Median age was estimated at 66 years in 2018, increasing to 74 years by 2030. Half of the cohort was lost to mortality by 2030 (330 total deaths). Nearly half of deaths were classified as NAFLD-related (160 liver deaths).
Conclusion: In the presence of NAFLD, disease progression will continue among a portion of the cured HCV population. The post-SVR population will experience high rates of chronic disease and remain susceptible to liver morbidity and mortality. Additional research and improved diagnostic technologies are needed to quantify the probability of NASH and related disease progression among post-SVR cases with advanced fibrosis and metabolic risk factors.

THU-305
Comparing perceptions of illness among patients with chronic liver disease

Izza Sattar[1,2], Joel Karkada[1,2], Nechama Lipton[1,2], Harry Janssen[1,2], Bettina Hansen[1,2], Jordan Feld[1,2]. *[1]Toronto Centre for Liver Disease, Toronto, Canada; [2]University of Toronto, Toronto, Canada*
Email: izza.sattar@mail.utoronto.ca

Background and aims: When patients are diagnosed with a chronic disease, their understanding of the illness and its severity may influence the goals they set and the steps they take towards its management. Perception of disease severity may be particularly challenging in chronic liver disease due to its relative lack of attributable symptoms. In this study, we examined the relationship between disease perception and disease severity (as measured by degree of liver fibrosis) among patients with various chronic liver diseases.
Method: We administered the Brief Illness Perception Questionnaire (Brief IPQ) to patients at the Toronto Centre for Liver Disease who had been diagnosed with or were receiving treatment for non-alcoholic fatty liver disease (NAFLD), hepatitis B infection (HBV) or hepatitis C infection (HCV) including patients who had achieved sustained virological response (HCV-SVR). Patients were categorized by fibrosis stage as early (F0-2) versus late (F3-4). Increasing IPQ scores indicate perception of more severe illness. Individuals with HIV, liver cancer, decompensated cirrhosis or severe comorbidities were excluded.
