Results: In 2019, 161 hospitals were surveyed, and 129 (80,1%) responded, vs 90/160 (56,3%) who responded in 2017 (p < 0,001). Reflex testing is now implemented in 89% of Spanish hospitals (115/129); in 2017 only 31% (28/90; p < 0,001) performed reflex testing. The number of hospitals that implemented alert systems to communicate HCV active chronic infection rose from 68,9% (2017) to 86,0% (2019) (p = 0,002). Access to dried blood spot (DBS) and/or point of care testing in 2019 in Spain was: 10,9% for antibody testing from DBS; 15,5% for RNA testing from DBS; 36,4% for point of care (POC) RNA testing; 0,85% for antibody POC testing. Overall, 43,4% of Spanish hospitals has access to at least one of DBS/POC testing strategies.
Conclusion: In Spain, the proportion of hospitals that perform reflex testing for chronic HCV infection has significantly increased to 89% in 2019. Recommendations, training and dissemination measures performed since 2017 may be responsible for this increase. However, in 2019 new screening strategies such as DBS and POC testing are poorly implemented in Spanish hospitals.

THU356

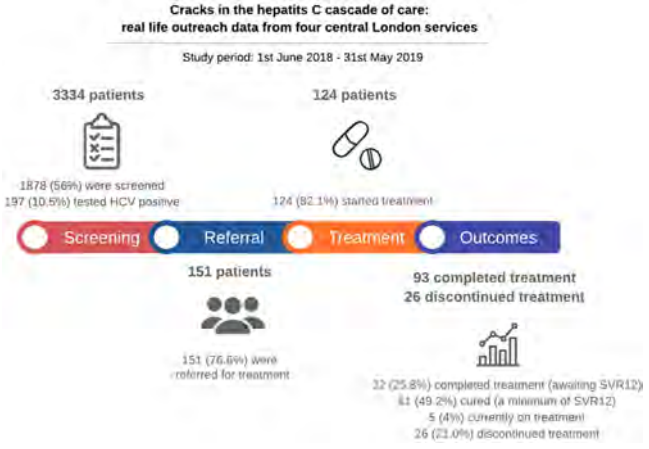
Cracks in the hepatitis C cascade of care: real-life outreach data from four Central London services

Hui Mei Wong[1], Yura Shin[1], Caroline Nelson[2], Ellen Rumgay[3], Claire Smith[4], Brigid Hamilton[2], Kate O'Brien[5], Stuart Flanagan[6], Indrajit Ghosh[6]. [1]*University College London, Medical School, United Kingdom;* [2]*The Grove, United Kingdom;* [3]*Camden Health Improvement Practice, United Kingdom;* [4]*Royal Free Hospital, United Kingdom;* [5]*Camden Specialist Drug Services- Margarete Centre, United Kingdom;* [6]*Mortimer Market Centre, United Kingdom*
Email: h.wong.15@ucl.ac.uk

Background and Aims: The standard Hepatitis C (HCV) care pathway incorporates multiple appointments for screening, referral, treatment and post-treatment follow up. However, at-risk patient populations often have multiple factors complicating treatment engagement, such as concurrent mental health diagnoses, no fixed abode, substance misuse and incarceration. Hence patients fall through cracks even before reaching the treatment stage. We reviewed data from four outreach clinics which target the at-risk patient population and aim to identify the main gaps where patients are lost in the cascade of care.

Method: We retrospectively analysed data from four outreach clinics in central London, collecting data from electronic patient records systems for patients attending from 1st June 2018 to 31st May 2019. Variables measured included numbers tested for HCV, referred for direct-acting antiviral (DAA) therapy, started on treatment and treatment outcomes.

Results: 3334 patients presented to these four outreach clinics over the one year period. 1878 (56%) patients were screened for HCV. 339 (18.1%) patients tested positive for anti-HCV and 197 (10.5%) were HCV viraemic. Of these 197, 151 (76.6%) were referred for treatment and 124 (62.9%) were started on therapy. At the end of the one-year period, 93 (75%) patients had completed treatment and achieved SVR12 (61, 49.2%) or were awaiting SVR12 (32, 25.8%). 5 (4%) were on continuing treatment. 26 (21%) patients discontinued treatment. Testing methods and time of testing differed between the four services, which offered venepuncture and opt-out testing (91.6% uptake), dried blood spots at triage (71.1% uptake), and venepuncture if clinically indicated (44.1% and 28.3%).



Conclusion: Opt-out testing at registration delivered the highest uptake (91.6%). Lower uptakes were seen at services where venepuncture testing was offered depending on clinical assessment. 10.5% of tested patients in this high-risk cohort were HCV viraemic. However, 44% were not tested and 23.4% of viraemic patients were not referred for treatment as they lacked baseline diagnostics. A further 13.7% did not attend to start treatment. Of those who began treatment, >75% were cured or await cure confirmation. Therefore, to improve outcomes and reduce cracks in the cascade for this marginalised population, a same-day testing and treatment approach would potentially improve overall care.

THU357

Seroprevalence of hepatitis B virus co-infection among HCV infected patients screened during the national campaign for HCV eradication in Egypt

Hadeel Gamal Eldeen[1], Mohamed Hassany[2], Wafaa El-Akel[1], Mohamed AbdAllah[3], Wael Abdel-Razek[4], Yehia Elshazly[5], Hesham Dabbous[5], Manal Hamdy El-Sayed[6], Magdi El-Serafy[1], Imam Waked[4], Gamal Esmat[1], Wahed Doss[1]. Email: hgamal@kasralainy.edu.eg

Background and Aims: Viral hepatitis is a major health problem in Egypt meanwhile, little is known about the true prevalence of hepatitis B virus (HBV) co-infection in Hepatitis C virus (HCV) patients and its risk factors. This multicenter nationwide study aimed to assess the seroprevalence of HBV among Egyptian patients with HCV and its possible risk factors.

Method: This is a cross section, multicentre, nationwide study. Data was extracted from database of the National Network of Treatment Centres (NNTC) affiliated to National Committee for Control of Viral Hepatitis (NCCVH), Ministry of Health, Egypt. Baseline data of patients screened and proved to be infected with HCV (by positive antibody) and viremic (by HCV RNA PCR) during the national campaign for HCV eradication (October 2018-April 2019) was retrieved. The data collected included: demographic data, laboratory investigations including (HBsAg, complete blood count, liver biochemical profile, serum creatinine, AFP, HBA1c, viral load), FIB-4 calculation and abdominal ultrasound results. Statistical analysis was done.

Table 1: Demographics and laboratory results of HBV/HCV co-infection versus HCV mono-infection

	HBsAg positive (n = 2,347)	HBsAg negative (n = 295,618)	P value
Age (years)	51.08 ± 13	51.57 ± 14	0.08
BMI (kg/m^2)	29.2 ± 7.6	29.6 ± 7.2	0.95
ALT (U/L)	47.48 ± 29.7	47.43 ± 45.5	0.34
AST (U/L)	44.78 ± 31.27	44.48 ± 34.41	0.84
AFP (ng/ml)	3.75 ± 3.68	3.7 ± 3.8	0.19
Albumin (g/dL)	4.28 ± 0.44	4.24 ± 0.46	0.10
Total Bilirubin (mg/dL)	0.68 ± 0.73	0.67 ± 0.43	0.39
WBC (×10^3)	7.09 ± 4.86	7.31 ± 6.34	0.30
Hb (gm/dl)	13.66 ± 2.03	13.62 ± 1.77	0.34
Platelets (×10^3)	227.70 ± 85.5	226.85 ± 149.07	0.78
INR	1.10 ± 0.2	1.08 ± 0.14	0.13
Creatinine (mgdL)	0.94 ± 0.7	0.87 ± 0.53	0.33
HbA1c (%)	7.36 ± 7.98	6.29 ± 3.35	<0.01*
FIB-4	1.78 ± 3.50	1.80 ± 2.31	0.64
HCV_RNA_log10	5.64 ± 0.98	5.62 ± 0.92	0.59

*Statistically significant (≤0.05).

Results: Available results of 297,965 patients who underwent HBsAg testing showed that HBsAg was positive in 2,347 patients (0.8%). Patients with HBV/HCV; mean age: 51 ± 13 years, 57.1% females, and mean BMI 29.2 ± 7.6 kg/m^2 with. Tobacco consumption, IV drug abuse, hypertension and diabetes were more reported in HBsAg +ve patients ($p < 0.01$). HBsAg +ve patients showed less advanced fibrosis by FIB-4 ($p < 0.01$). Only 14% of those with HBsAg +ve had liver cirrhosis by ultrasound with 2 patients had HCC. HbA1c level showed

statistically significant difference between both groups ($p < 0.01$), being higher in HBV/HCV group. No significant difference in HCV viremia or FIB-4 score between patients with HCV mono infection versus HBV/HCV co-infection (P value = 0.592, 0.64) respectively (Table 1).
Conclusion: Although Egypt has heavy burden of HCV, yet, the overall prevalence of HBV/HCV co-infection is low among HCV-infected patients.

THU358
Risk of liver and non-liver-related mortality among hepatitis C virus and human immunodeficiency virus co-infected persons in a cohort of Brazilian blood donors: a twenty-year study
Helio Ranes Filho[1,2], Ligia Capuani[2], Ana Luiza Bierrenbach[3], Alfredo Medroni Junior[4], Adele Benzaken[5], Soraia Machado[2], Ester Cerdeira Sabino[2], Steven Witkin[6,7], Maria Cassia Mendes-Correa[2,6]. *[1]Federal University of Jatai, Department of Health Sciences, Jatai, Brazil; [2]University of São Paulo, School of Medicine, Department of Infectious Diseases, São Paulo, Brazil; [3]Hospital Sírio-Libanês, Instituto de Ensino e Pesquisa, São Paulo, Brazil; [4]Fundação Pró-Sangue, Hemocentro de São Paulo, São Paulo, Brazil; [5]Tropical Medicine Foundation Heitor Vieira Dourado, Manaus, Brazil; [6]University of São Paulo, Institute of Tropical Medicine, LIM-52, São Paulo, Brazil; [7]Weill Cornell Medicine, Department of Obstetrics and Gynecology, New York, United States*
Email: hranesfilho@gmail.com

Background and Aims: Hepatitis C virus (HCV) infection is a major health problem associated with an increased risk of morbidity and mortality. However, among HCV and human immunodeficiency virus (HIV) co-infected individuals, studies on of non-liver-related mortality have yielded inconsistent results. The purpose of this study was to investigate the contribution of HCV and HIV co-infection on liver and non-liver-related mortality, in a large cohort of blood donors in Brazil.
Method: This is a retrospective cohort study of blood donors from 1994 to 2013, at Fundação Pró-Sangue - Hemocentro de São Paulo (FPS). This cohort included 36 HCV and HIV antibody seropositive (HCV/HIV co-infected), 5,782 HCV and HIV antibody seronegative and 2,652 HCV antibody seropositive (HCV mono-infected) blood donors respectively. Records from the FPS database and the Mortality Information System (SIM: a national database in Brazil) were linked through a probabilistic record linkage (RL). Mortality outcomes were defined based on ICD-10 (10th International Statistical Classification of Diseases and Related Health Problems) codes listed as the cause of death on the death certificate. Hazard ratios (HRs) were estimated for outcomes using Cox multiple regression models.
Results: When all causes of death were considered, RL identified 14 deaths among HCV/HIV co-infected donors, 190 among HCV/HIV seronegative donors and 209 among HCV mono-infected donors. HCV/HIV coinfected donors had 6.63 times higher risk of death due to all causes when compared to HCV mono-infected donors (95% CI: 3.83–11.48; $p < 0.001$) and 14.57 times higher risk of death due to all causes when compared to seronegative donors (95% CI: 8.42–25.22; $p < 0.001$). When only liver-related causes of death were considered, RL identified 3 deaths among HCV/HIV coinfected donors, 6 among seronegative and 73 among HCV mono-infected. HCV/HIV coinfected donors had a 95.76 times higher risk of liver related death when compared to HCV/HIV seronegative donors (95% CI: 23.54–389.52; $p < 0.001$) and a 4.16 times higher risk of death when compared to HCV mono-infected donors (95% CI: 1.3–13.34; $p = 0.016$).
Conclusion: Our data suggests that among HCV/HIV coinfected blood donors, even after specific treatment and sustained virologic response, specific interventions are urgent and necessary, in order to avoid both liver and non-liver related complications and death.

THU359
Emergency department screening for hepatitis C carriers does not improve linkage to care - a single-center prospective study
Inbal Houri[1], Noyah Horwitz[1], Helena Katzman[1,2], Yael Weksler[1], Ofer Miller[1,2], Liat Deutsch[1,2], Oren Shibolet[1,2]. *[1]Tel Aviv Medical Center, Department of Gastroenterology and Hepatology, Tel Aviv, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel*
Email: inbalhourio@gmail.com

Background and Aims: Hepatitis C virus (HCV) infection is a leading cause of chronic liver disease worldwide. New treatments for HCV revolutionized management and prompted the world health organization (WHO) to set the goal of viral elimination. To achieve this goal, better screening is needed, in order to identify asymptomatic carriers prior to development of chronic liver disease and its complications. Our aim was to identify HCV carriers among high risk emergency room attendees in order to link them to care and facilitate anti-viral treatment.
Method: Persons visiting the emergency department (ED) were screened for HCV by risk factor-specific questionnaire. Those with at least one risk factor were tested for HCV by serum for HCV antibodies, a novel oral test from saliva (OraQuick®) or both.
Results: Five hundred and forty-one participants had at least one risk factor and were tested for HCV. 3.1% (17/541) had a positive result as compared to the local population incidence of 1.96%. Of these, 82% were current or former intravenous drug users (IVDU), and 64% served time in prison. One patient had a negative HCV-PCR, and two patients died from non-HCV related reasons. At 1-year follow-up none of the remaining 14 patients had completed HCV-RNA testing, visited a hepatology clinic or received anti-viral treatment.
Conclusion: Targeted high-risk screening in the ED identified undiagnosed and untreated HCV carriers, but did not

	Univariate regression		logistic	Multivariate regression		logistic

improve treatment rates. Other strategies need to be developed in order to improve linkage to care in high risk populations attending the ED.

THU360

Treating patients with DAAs helped to save €1 billion in France - a budget impact model from 2014 to 2018

Henri Leleu[1], Ingrid Rodriguez[2], Martin Blachier[1], Olivier Lada[2], Stanislas Pol[3], Françoise Roudot-Thoraval[4]. [1]*Public Health Expertise, Paris, France;* [2]*Gilead Sciences, Boulogne-Billancourt, France;* [3]*Hospital Cochin, Paris, France;* [4]*Hôpital Henri-Mondor Ap-Hp, Créteil, France*
Email: ingrid.rodriguez@gilead.com

Background and Aims: New Direct Acting Antivirals (DAA) constituted a breakthrough innovation in chronic hepatitis C (CHC) treatments. Sustain virologic response rates (>90% vs 54%–70% previously) allowed cure in shorter treatment times with a fewer adverse events (AE) compared to treatment available prior to 2014. Studies have demonstrated new DAAs cost-effectiveness. With an estimated 72,000 patients treated in France from 2014 to 2018, this study assessed the economic impact of DAA launch.
Method: A budget impact (BI) model was constructed to estimate the BI of CHC between 2014 and 2018 and to extrapolate long-term (up to 40y) direct and indirect costs for treated CHC patients. Extrapolation was based on a Markov model that simulated the natural history of CHC. Real-world data was used for treatment patterns and patients' characteristics. Prices included published rebates and taxes. The model compared the real-world scenario (DAA) to a hypothetical scenario (no-DAA) where treatment patterns prior to 2014 were used for 2014–2018. No-DAA included lower number of treated patients and use of pegylated interferon, ribavirin, boceprevir and telaprevir only. Results compared direct costs (treatments, AEs, complications [HCC, decompensation, transplantation]) and indirect costs (loss of productivity) for both scenarios.
Results: Only 48,500 patients would have been treated in no-DAA between 2014 and 2018 compared to 72,000 with DAA with a respective treatment cost of 1 billion euros (B€) vs B€ 3.4. Long-term extrapolation shows an estimated B€ 1.9 vs 0.9 spending in other direct costs, and 2.4 in indirect costs for no-DAA; total cost was estimated to B€ 5.4 vs 4.3, over a billion saving for DAA.
Results will be provided regarding direct costs complications and deaths for the conference.
Conclusion: These results support that treating patients with DAAs will allow to save over a billion euros and was a good investment from a collective and patients perspective.

THU361

Outcomes of community and prison-based hepatitis C treatment using an eHealth model of care

Email: james.haridy@mh.org.au

Background and Aims: eHealth technologies may provide a scalable, patient-centred model of care to address barriers preventing non-specialist initiation of direct-acting antiviral (DAA) therapy for chronic hepatitis C (CHC). In 2016, Australia introduced unrestricted access to DAA therapy allowing for prescription by any medical practitioner, however treatment rates have declined. We aimed to investigate the efficacy, acceptability and feasibility of an online eHealth system to connect community-based clinicians and patients with specialist teams for community and prison-based DAA treatment.
Method: A multicentre quasi-experimental pre-post study utilising a hybrid effectiveness-implementation design was conducted with referring community and prison-based clinicians in consultation with eight tertiary centres in Australia. The pre-intervention control group was treated through existing paper, fax or remote consultation methods between 1 March 2016–28 February 2017. The eHealth model of care (using the HealthElink system) was prospectively implemented from 1 August 2017–30 April 2019. Key elements of the web-based eHealth model include CHC specific clinical decision support (incorporating automatic calculation of drug interactions and fibrosis assessment), secure electronic messaging, task management, email alerts and a patient portal. The primary outcome was sustained virological response at twelve weeks following treatment (SVR12), including all subjects intended for treatment. Secondary outcomes include implementation analysis, usability, acceptability, safety and uptake measures.
Results: In total, 236 subjects (174 community, 62 prison) were treated in the eHealth group and 681 (588 community, 87 prison) in the control group. On interim analysis, 150/236 (64%) of the eHealth cohort have completed follow-up. Sixty-one general practitioners, 13 specialists, 17 nurses and 4 prison systems registered to use the eHealth system. To date, in the community-based group SVR12 was confirmed in 81/122 (66%) compared to 383/588 (65%) in the control group, and 21/28 (75%) v 61/87 (70%) in the prison-based group. Completion of repeat liver biochemistry at the time of SVR12 testing (89% v 56%) and adherence to guideline-based treatment (100 v 98%) were higher in the eHealth group.
Conclusion: An integrated, patient-centred eHealth model of shared care is feasible for chronic disease management and may improve clinical outcomes in CHC. We anticipate final results to be presented at the conference, incorporating further qualitative data and final results.

THU362

Testing and linkage to treatment programme for hepatitis C in different homeless locations in Greater Manchester, UK

F Javier Vilar[1], Linda Borkin[1], Catherine Pat McLaughlin[1], Jill Delaney[1], Madeline Brodie[1], Grace Newbold[1], Benjamin Brown[2], Nicholas Machin[2], Andrew Ustianowski[1]. [1]*North Manchester General Hospital, Infectious Diseases, Manchester, United Kingdom;* [2]*Manchester Medical Microbiology, Virology, Manchester, United Kingdom*
Email: javier.vilar@pat.nhs.uk

Background and Aims: Greater Manchester has a high prevalence of hepatitis C virus (HCV). There is a well-developed programme of clinics in prisons, Primary care, hospitals and Drug services but a significant amount of patients still do not engage.
Method: We started a test and treat programme in 3 different type of locations: emergency night shelters- "a bed for every night" programme (ABEN), homeless hostels (HH) and day centres (DC) for the homeless. All locations were visited by our secondary care team to provide testing in a limited number of sessions (2–4) by a 2

people team (a nurse and a HCW). Dried blood spot samples were tested for Anti-HCV and HCV RNA. The test use was a dry blood spot from Virology Department at Manchester NHS Foundation Trust with a sensitivity of 660 copies.

Results: Overall 114 patients were tested in this programme. Of those 71 (49%) reported substance misuse and 2 declined to answer. Six patients reported having previously been treated and cured with 1 of those being PCR positive (reinfection rate 20%). 28 of the total were antibody positive for HCV (25%) with 13 HCV PCR positive (11%). Excluding those 6 who received therapy 10 patients out of 22 (45%) were antibody positive and PCR negative.

Seven emergency centres from the Greater Manchester ABEN programme were visited 12 times in total with 44 patients tested. Six were antibody positive (2 had previous therapy) and 4 PCR positive for HCV (14% prevalence for Abs and 9% for PCR positive, one of those was a reinfection). Three patients were referred to treatment centres in drug services clinics (none attended) and 1 was treated (and cured) in the shelter.

Four hostels were visited 6 times in total with 29 patients tested. Six were antibody positive (one previously treated) and 2 PCR positive (21% prevalence for Abs and 7% for PCR positive). One patient was referred to a clinic at his GP practice and 1 is undergoing treatment in a hostel.

Two community centres were visited 7 times in total with 41 patients tested. Sixteen were found antibody positive (3 received previous therapy) and 7 PCR positive (prevalence 39% for antibody positive and 17% for PCR). Three patient have started therapy (one has completed), two did not come back to start and 2 are due to start within a week.

Conclusion: Emergency shelters and hostels have a relative low frequency of HCV PCR positive in Greater Manchester with the highest prevalence found in day centres although also with the lowest acceptability. This might be due to some degree of self-selection and might explain the higher prevalence in this setting. On going referrals to a treatment clinic is associated with lack of treatment initiation and it is not a valid strategy for this population, whilst local treatment works well when accepted, although in a day centre it is more difficult as patients use the facilities for a limited period of time and not always daily.

THU363

Achieving micro elimination of hepatitis C across a network of prisons in the north-west of England covered by a single treatment provider

F Javier Vilar[1], Sandra Bell[1], Marie White[1], Jayne Dodd[1], Clare Van Halsema[1], Diane Fiefield[2], Morgan Burguess-Crane[3], Karren Pavey[4], Andrew Ustianowski[1]. *[1]North Manchester General Hospital, Department of Infectious diseases, Manchester, United Kingdom; [2]Public Health England, PHE, United Kingdom; [3]HMP Forest Bank, Health Care, Pendlebury, United Kingdom; [4]HMP Styal, Health Care, Styal, United Kingdom*
Email: javier.vilar@pat.nhs.uk

Background and Aims: Prisons are a critical part in the elimination of the hepatitis C virus (HCV). We provide HCV care for 6 prisons in the North West of England. In January 2018 the secondary care responsible for providing HCV therapy increased their workforce from 1 to 2 nurses and a health care worker to increase testing and faster treatment.

Method: Our network serves a population of around 4097 inmates. HMP Forest Bank (FB Male local prison - population 1501), HMP Manchester (M category A male- 933 males), HMP Lancaster Farms (LF category C male - 552), HMP Buckley Hall (BH category C Male-450), HMP Styal (S female - 446) and HMP Haverigg [H category C re-rolling currently to category D male – 215 (higher on the first year of network at 500+)]. Two prisons in the network take "on remand prisoners" (awaiting sentence): FB for males and S for females. These two prisons have a very large turnover of prisoners (3973 and 1430 new arrivals respectively in 2017).

Over a 12 month period this network had 9,980 new arrivals. All prisoners are offered testing when they arrive. This offer is then repeated usually once.

Besides this, secondary care nurses organised with the prison staff weekend testing events on the wings. Then target events for untested prisoners. Testing figures prior to the arrival of the extra secondary care staff and the testing events were- 2.5% for FB, 34% for M, 40% for LF, 56% for BH, 9% S, 56% for H. There were 251 referrals for therapy and 64 started therapy (25.5% of all referrals)

Results: In 2018 the secondary team provided 1137 (28% of total population) additional tests with 62 patients HCV PCR positive (5.5%). In 2019 (data to early November 2019) 1394 tests (34% of total population) were performed with 21 patients positive (1.5%).

Overall in October 2019 there were 410 prisoners declining a test out 4097 inmates (90% tested) whilst in November 2019 there were 261 out of 3871 inmates (93% tested). Three prisons achieved over 95% testing at both time points (BH 98 and 97% respectively, H 99 and 100%, LF 99% at both points). The other 3 prisons were above 80% at both points (M 81–93% respectively, FB 88–93% and S 92–81%).

In 2018 there were 391 referrals (56% increase) of whom 186 who started therapy (48% of all referrals) whilst in 2019 (to November) they were 342 referrals with 272 starting therapy (80%). During part of this period a HCV PCR Cepheid® machine was in use at HMP Styal allowing a rapid treatment start. Even if we exclude the 83 people tested through this project, we had 259 referrals with 193 starting on therapy (75% of referrals).

Conclusion: This project shows the success of supplementing prison testing efforts with special events to manage to test missing inmates to achieve microelimination (consistently testing of 90% of the inmates). Facilitating this with secondary care staff increases testing in this study but also increases very significantly patients starting on therapy whilst in prison.

THU365

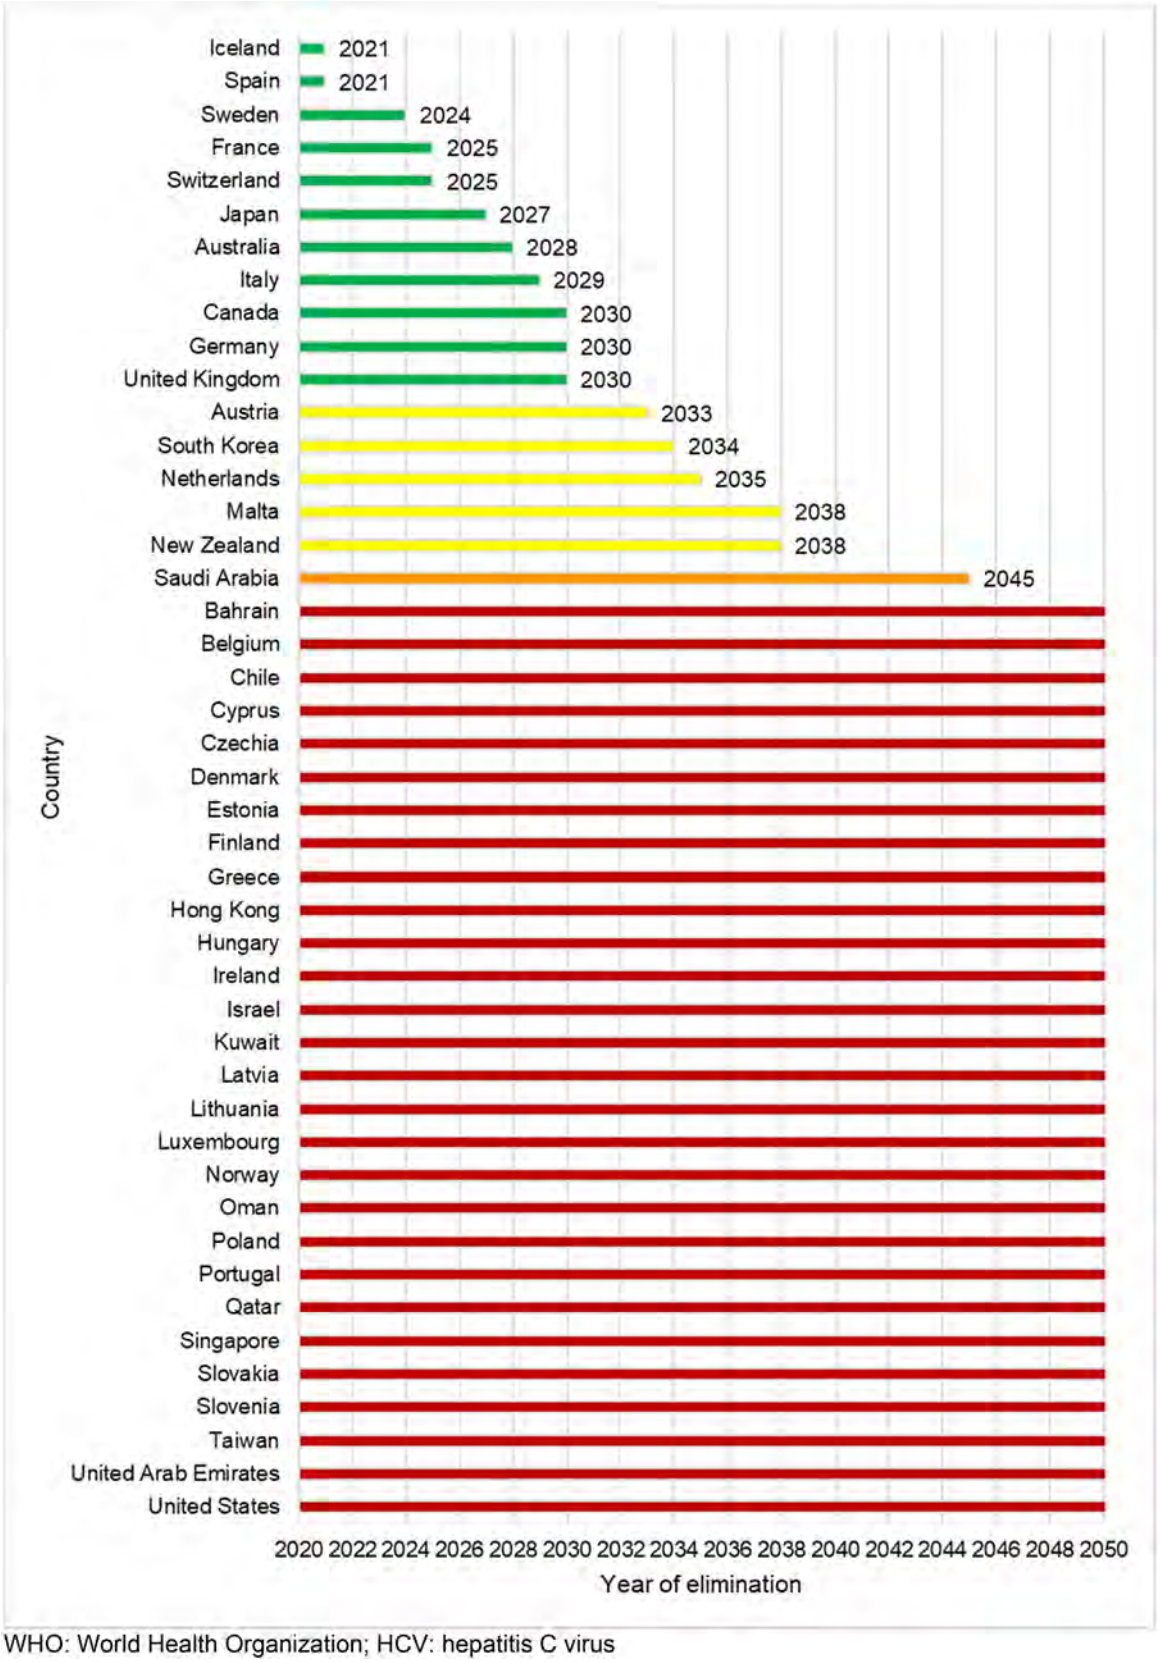
Global timing of hepatitis C virus elimination in high-income countries: an updated analysis

Homie Razavi[1], Jean-Michel Pawlotsky[2], Jeffrey Lazarus[3], Jordan Feld[4], Carol Bao[5], Ana Gabriela Pires dos Santos[5], Yuri Sanchez[5], Stefan Zeuzem[6]. *[1]Center for Disease Analysis, Lafayette, United States; [2]Hôpital Henri-Mondor Ap-Hp, Créteil, France; [3]University of Barcelona, Barcelona, Spain; [4]University of Toronto, Toronto, Canada; [5]AbbVie, North Chicago, United States; [6]University Hospital Frankfurt, Frankfurt am Main, Germany*
Email: yuri.sanchezgonzalez@abbvie.com

Background and Aims: Elimination of hepatitis C virus (HCV) by 2030 as set out by the World Health Organization (WHO) may be attainable with the availability of highly efficacious HCV therapies. This study updates a previously published analysis on the timing of HCV elimination in 45 high-income countries based on WHO's targets for incidence, mortality, diagnosis, and treatment.

Method: Previously published Markov disease progression models of HCV infection for 45 high-income countries were calibrated to the latest available data on chronic HCV prevalence, and updated with number of annual new diagnoses (with reported data over 2017–2018) and treatments (with reported and projected data over 2017–2019). The latest reported or projected levels of diagnosis and treatment were defined as baseline and optimistically assumed constant in the future. Modeled outcomes until 2050 were analyzed to determine the year in which each country would meet WHO's HCV elimination targets for reduction in incidence (80%) and mortality (65%), and diagnosis (90%) and treatment (80%) coverage relative to 2015 levels. Earliest year in which all targets were met was defined as the year of elimination.

Results: Of 45 high-income countries studied, 11 (Australia, Canada, France, Germany, Iceland, Italy, Japan, Spain, Sweden, Switzerland,



WHO: World Health Organization; HCV: hepatitis C virus

Figure: (abstract: THU365) Year of elimination per WHO's 2030 HCV elimination targets.

and the United Kingdom) are on track to meet WHO's HCV elimination targets by 2030; five (Austria, Malta, Netherlands, New Zealand, and South Korea) by 2040; and one (Saudi Arabia) by 2050. The remaining 28 countries are not expected to achieve HCV elimination before 2050. Of countries previously considered on track to eliminate HCV by 2030, one (South Korea) is now off track; of countries previously off track towards HCV elimination by 2030, three (Canada, Germany, and Sweden) are now on track. Most (29) countries saw no change since the previous analysis, with nine expecting an earlier time to HCV elimination, and seven expecting a later one. The incidence target, followed by mortality, remains the target fewer countries are expected to meet.

Conclusion: Assuming high-income countries will maintain their current levels of diagnosis and treatment, only 24% are on track to eliminate HCV by 2030 and 62% are off track by at least 20 years. If current levels of diagnosis and treatment continue falling, achieving WHO's 2030 targets will be even more challenging. With ten years remaining to meet these targets, expansion of screening and treatment is crucial to make HCV elimination possible.

THU366
Anticipated timing of elimination of hepatitis C virus in Canada's four most populous provinces

Jordan Feld[1], Yasmine Rahal[2], Catherine Robert[2], Yuri Sanchez[3], Homie Razavi[4]. *[1]University of Toronto, Toronto, Canada; [2]AbbVie, Montréal, Canada; [3]AbbVie, North Chicago, United States; [4]Center for Disease Analysis, Lafayette, United States*
Email: yuri.sanchezgonzalez@abbvie.com

Background and Aims: While direct-acting antiviral therapy for hepatitis C virus (HCV) infection has made HCV elimination an attainable goal, current diagnosis and treatment levels in many high-income countries are insufficient to reach World Health Organization's (WHO) 2030 elimination targets. This study examines timing of HCV elimination in Canada's four most populous provinces which account for 86% of total population.
Method: A previously published model of HCV progression was populated with reported data for Alberta (AB), British Columbia (BC), Ontario (ON), and Quebec (QC). For BC, chronic prevalence and diagnosis data from 2018, and average annual treatments over 2015–2018 were used. For AB, ON, and QC, prevalence and diagnosis data from 2007 and 2011, respectively, and peak number of treatments in Canada, prorated for each province, were used. As base case, diagnosis (from 2017) and treatment levels were assumed constant, optimistically, to determine year of achieving WHO's 2030 HCV elimination targets for reduction in incidence (80%) and mortality (65%), and diagnosis (90%) and treatment (80%) coverage. Impact of 5% and 10% annual reductions in diagnoses and treatments were explored as less optimistic scenarios. The minimum annual reduction in diagnoses and treatments for delaying HCV elimination beyond 2050 was also calculated.
Results: Under base case, BC would reach WHO's HCV elimination targets by 2028, ON by 2030, AB by 2031 and QC by 2035. At 5% annual reduction in diagnoses and treatments, BC would be on track to eliminate by 2030, AB and ON by 2040, and QC by 2050; at a 10% reduction, only BC and ON would eliminate by 2050. At 14% annual reduction in diagnoses and treatments, no province would eliminate HCV by 2050.
Conclusion: Assuming that current levels of diagnosis and treatment are maintained, only BC and ON are on track towards WHO's 2030 HCV elimination targets among Canada's four most populous provinces. With many of the currently diagnosed already being treated, increasing and maintaining diagnosis levels is critical for achieving the treatment levels that would make timely HCV elimination a reality in Canada.

THU367
Acute hepatitis C virus infection: a prospective ten-year observational study of HCV-mono and HCV/HIV-coinfected patients

Christiana Graf[1], Lutz Thomas[2], Gaby Knecht[2], Christoph Stephan[3], Peter Gute[2], Kai-Henrik Peiffer[1], Johannes Vermehren[1], Stefan Zeuzem[1], Julia Dietz[1], Christoph Sarrazin[1,4]. *[1]Goethe University Hospital, Department of Internal Medicine I, Frankfurt; [2]Infektiologikum, Frankfurt, Germany; [3]Goethe University Hospital, HIVCENTER, Department of Infectious Diseases, Frankfurt, Germany; [4]St. Josefs-Hospital, Wiesbaden, Germany*
Email: julia.dietz@em.uni-frankfurt.de

Background and Aims: An ongoing epidemic of acute hepatitis C (aHCV) infections has been observed in HIV-infected men who have sex with men (MSM) in several metropolitan areas worldwide. High SVR (sustained virologic response rates) have been reported in patients with acute hepatitis C using DAAs. However, repeated HCV infections have been observed in MSM after successful treatment. This study aimed to investigate parameters of epidemiological, clinical and phylogenetic evolution of acute hepatitis C over a time period of ten years.
Method: In this prospective, ongoing observational study, n = 167 patients with acute hepatitis C infection were included at three centers in Frankfurt between 2009–2019. Thereof, n = 24 were HCV monoinfected and n = 143 had a HCV/HIV coinfection (MSM).
Results: During the first 5 study years, the prevalence of HCV genotypes (GT) was: GT1a, 72% (n = 76/106); GT1b, 7% (n = 7/106); GT2, 3% (n = 3/106); GT3, 4% (n = 4/106); GT4, 12% (n = 13/106) and GT undetermined, 3% (n = 3/106). However, during the last 5 years higher frequencies of GT4 infections (20%, n = 12/61) were detected, while GT1a (77%, n = 47/61) and GT3a (3%, n = 2/61) infections stayed stable and no GT1b or GT2 infections were observed. The overall number of patients annually included decreased during the

Province	Anticipated year of HCV elimination			Annual treatments needed over 2020–2030 for HCV elimination by 2030
	Base case (0% reduction*)	5% reduction*	10% reduction*	
Alberta	2031	2035	-	1,300
British Columbia	2028	2030	2033	3,900
Ontario	2030	2033	2044	5,300
Quebec	2035	2043	-	2,100

* Reduction in HCV screening and treatment
- No HCV elimination before 2050

Figure: (abstract: THU366) Progress towards HCV elimination targets

last 5 study years (Figure 1). Spontaneous clearances rates were higher in HCV-mono- compared to HCV/HIV-coinfected patients (37%, n = 7/19 versus 13%, n = 18/135 patients with follow-up (FU) data available). Out of the initial population, 65% (n = 109/167) had completed antiviral treatment and FU. The median time between aHCV diagnosis and treatment initiation was 23.6 weeks. Overall, n = 60 individuals were treated with pegylated-interferon/ribavirin (P/R) with or without a direct acting antiviral (DAA). Further n = 49 patients received an interferon-free DAA treatment and all achieved SVR. The only two virologic failures observed had failed to P/R. During the 10 years observation period, n = 27/167 (16%) HCV/HIV-coinfected patients had acquired one or multiple acute HCV reinfections after spontaneous clearance of initial infection or achievement of SVR.

Conclusion: During the last 5 study years the prevalence of GT4 infections increased, while annual acute hepatitis C incidences decreased. Spontaneous clearance rates were higher in HCV-mono- compared to HCV/HIV-coinfected patients. Overall, 16% of HCV/HIV-coinfected patients had a HCV reinfection which may have implications for HCV elimination in MSM.

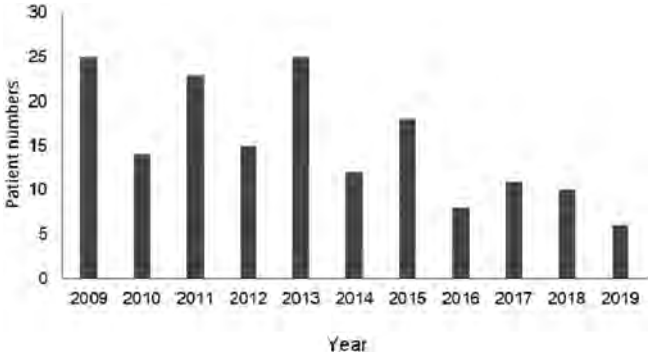


Figure 1: Numbers of patients annually included.

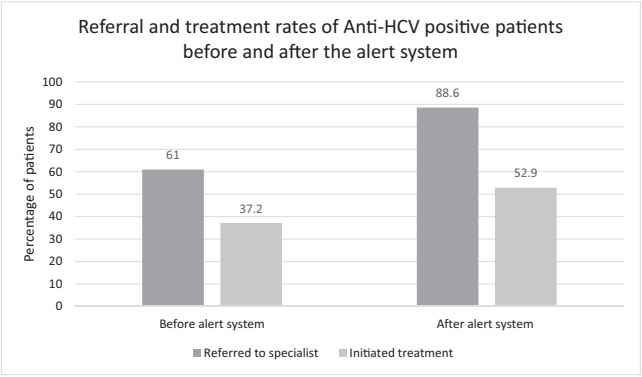
THU368

Improving the referral of hepatitis C virus positive patients to specialists through an electronic "pop-up" alert system

Süleyman Sayar[1], Gupse Adali[1], Oğuzhan Öztürk[1], Levent Doğanay[1], Kamil Ozdil[1]. [1]*Health Sciences University Umraniye Training and Research Hospital, Gastroenterology, İstanbul, Turkey*
Email: gupseadali@gmail.com

Background and Aims: Hepatitis C virus screening tests are often ordered as a part of medical check-up, preoperative or before transfusion. However, patients with Anti- HCV positive results are not sufficiently referred to specialists to receive treatment or for follow-up. Direct-acting antivirals (DAAs) offer a highly effective treatment response in short periods and it leads to decreased morbidity and mortality due to HCV infection. We introduced a simple "pop-up" alert system to increase the referral of Anti-HCV positive patients to gastroenterologists or infectious disease specialist through their electronic medical records. We investigated referral rates to specialists before and after the introduction of the "pop-up" alert system.

Method: From an area representing approximately 3 million population in Istanbul (North Anatolian Side), 5 reference and 7 district hospital medical records were searched for Anti-HCV and HCV RNA positivity. The referral rate to specialists was compared before (from January 2014 to January 2018) and after the introduction of the "pop-up" alert system (from January 2018 to May 2019). The "pop-up" alert system has been automatically integrated to the hospital electronic health records and it appears whenever the patients' medical records are viewed. It is activated with the positive Anti-HCV results and contains a comment to the physician for referral of the patient to a specialist.



Results: From January 2014 to May 2019 Anti-HCV antibody was tested in 601832 patients. Of these, 7410 (1.2%) patients were found to have positive Anti-HCV, and 1775 (0.29%) patients had positive HCV RNA. The referral rate to gastroenterologists after the "pop-up" alert system has improved from 61% to 88.6% and patients who received treatment increased from 37.2% to 52.9%. Admission to a specialist as an in-patient or immediately after discharge increased from 21.8% to 54.6%.

Conclusion: The electronic "pop-up" alert system increased the referral and treatment rates of patients with HCV. This approach could be an important strategy to detect and treat patients with chronic HCV infection.

THU369

Predictors of disengagement or delay after hepatitis C assessment

Kathleen Bryce[1], Douglas Macdonald[2,3]. [1]*Royal Free London NHS Foundation Trust, Hepatology, London, United Kingdom;* [2]*UCL Institute for Liver and Digestive Health;* [3]*Royal Free London NHS Foundation Trust, Hepatology, London, United Kingdom*
Email: kathleenbryce@doctors.org.uk

Background and Aims: Models of hepatitis C elimination in the directly-acting antiviral (DAA) era often assume that patients will progress to cure after assessment with minimal attrition or delay. We aimed to quantify disengagement or delay between assessment and treatment and determine the patient- and pathway-based factors that predict them.

Method: We analysed a cohort of 2762 patients assessed and approved for DAA treatment in North Central London between July 2014 and March 2019. A bespoke patient management system allowed quantitative attribution of any delay to patient or system factors. Multivariate analysis of disengaged versus treated (or delayed versus non-delayed) cohorts was performed against a number of patient, disease and setting characteristics.

Results: A total of 197 patients (7.1%) have not progressed to treatment, of which 90 have disengaged. Of 2565 treated patients, 517 (20%) had pre-treatment patient-attributable delays that exceeded treatment duration and in 206 (8%) this delay exceeded 6 months. Multivariate analysis revealed that those assessed in prisons had the highest risk of disengagement before treatment (OR 11.9, 95% CI 5.9–23.79, $p < 0.0001$). In all settings, UK-born patients had a 2-fold increased risk of disengagement compared with non-UK born (OR 1.95, CI 1.121–3.391, $p = 0.018$) and HIV positive patients were 7.8 times less likely to disengage before treatment (OR 0.128, CI 0.03–0.544, $p = 0.006$). Gender, injected drug use (IDU), treatment experience, excess alcohol or treatment in community drug services had no significant impact on disengagement risk after assessment. However, in the treated cohort, delays >6 months were more likely to be incurred by those with a history of IDU (OR 1.62, CI 1.1.6–2.256, $p = 0.005$).

Conclusion: Prisoners and those with a history of IDU have high onward transmission risks which are exacerbated by their greater likelihood of disengagement and delay after assessment. In all settings, multiple patient factors can predict progress arrest and

these may guide targeted preventative interventions. However, these account for the minority of variation in patient behaviour in this model (Nagelkerke R square = 0.17). Qualitative research examining patient motivation, knowledge, skills and opportunities may better predict and prevent disengagement.

THU370

Predictors of workload in a hepatitis C treatment pathway

Kathleen Bryce[1], Douglas Macdonald[1,2]. [1]*Royal Free London NHS Foundation Trust, Hepatology, London, United Kingdom;* [2]*UCL Institute for Liver and Digestive Health, London, United Kingdom*
Email: kathleenbryce@doctors.org.uk

Background and Aims: The workload of treatment pathways for hepatitis C is determined not only by caseload but also the number of contacts required per patient to plan and monitor treatment. Progress towards elimination will require agile and efficient pathways that can allocate resources according to predicted individual need. We aimed to identify factors that significantly impact the pathway workload from assessment to end of treatment.
Method: We analysed a cohort of 1499 patients undergoing directly-acting antiviral (DAA) treatment in North Central London between April 2016 and April 2019. These patients were managed using a bespoke system which allowed quantitative attribution of any pathway progress delay to patient or system factors. Pathway workload (PW) was calculated as the total number of pathway coordinator (PC) contacts and treatment monitoring (TM) encounters recorded between approval for treatment and end of treatment for each patient. Multivariate linear regression analysis was used to determine if specific patient, disease and setting factors independently correlated with PW.
Results: A mean of 2.72 (95% CI 2.587–2.848) PC contacts and 9.1 (CI 8.89–9.30) TM encounters were required between treatment approval and end of treatment. PW was positively correlated with patient factors including patient-attributable delay (B = 0.021, CI 0.019–0.022, p < 0.0001), ex or current intravenous drug use (B = 0.722, CI 0.246–1.197, p = 0.003) and age (B = 0.033, CI 0.016–0.051, p < 0.0001) and disease factors including cirrhosis (B = 2.141, CI 1.552–2.731, p < 0.0001), post-liver transplant (B = 1.933, CI 0.532–3.334, p = 0.007 and ribavarin-inclusive treatment (B = 1.789, CI 1.305–2.272, p < 0.0001). HIV positive patients required significantly fewer contacts/encounters (B = –4.252, CI – 5.064–3.440, p < 0.0001), as did patients monitored in prisons (B = –5.4,CI –7.9–2.9, p < 0.0001) or community drug services (B = –1.3, CI –2.591–0.044, p = 0.04).
Conclusion: These data demonstrate the significant impact of poorly-engaged patients on increased pathway workload (Figure 1) and would justify pre-emptive interventions to reduce patient-attributable delay or disengagement. Incorporating hepatitis C treatment into existing care pathways (e.g. HIV treatment, drug addiction services) with which patients are already well-engaged significantly reduces pathway workload.

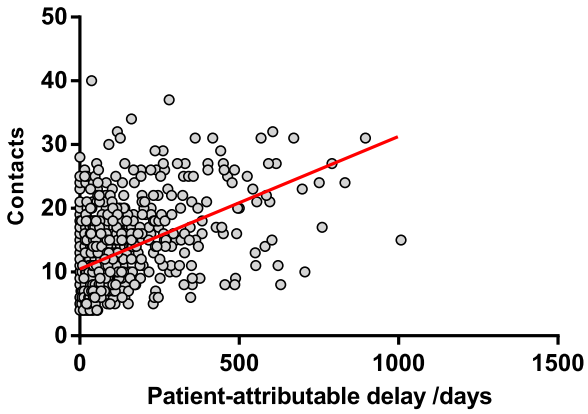


Figure: Patient delay and pathway workload.

THU371

Micro-elimination of hepatitis C in mental health care settings

Kristen McKee[1], Amy Chu[1], Monica Robotin[2], Geoff McCaughan[3,4], Janice Pritchard-Jones[3], Beth Kotze[5], Carolyn Fozzard[6], Antoni Yesudoss[6], Jacob George[1,4]. [1]*Westmead Hospital, Storr Liver Centre, Westmead, Australia;* [2]*The University of Notre Dame, Sydney, Australia;* [3]*Royal Prince Alfred Hospital, A.W Morrow Gastroenterology and Liver Unit, Sydney, Australia;* [4]*University of Sydney, Sydney, Australia;* [5]*Western Sydney Local Health District, Mental Health Services, Westmead, Australia;* [6]*Western Sydney Local Health District, Community Mental Health Services, Westmead, Australia*
Email: kristen.mckee@health.nsw.gov.au

Background and Aims: Marginalised populations including people with mental illness are disproportionally affected by chronic hepatitis C (CHC). The estimated prevalence of CHC in Western Sydney is 0.81%. Among people with mental illness, ~50% population report a history of substance misuse, 14% having injected drugs and half admit to sharing injecting equipment. We sought to achieve inpatient and community mental health CHC micro-elimination in Western Sydney, Australia.
Method: Systematic screening was introduced across 9 community mental health teams and 1 inpatient psychiatric facility. Testing was offered to all clients, partnered with harm reduction and education delivered by study specific nurses and appropriately trained mental health nurses. Patients who had viremia progressed to clinical assessment, case discussion and treatment. Nurse led end of treatment and 12 weeks post assessment was undertaken. Screening and treatment was delivered in the mental health setting.
Results: To date, 640 patients have been screened, 46% (n = 294) were inpatients while 54% (n = 346) were within the community mental health setting. During the latter half of the project, the availability of a pathology collector at community clinics reduced the time between initial contact and blood collection and increased likelihood of consent to testing.
Of the 294 inpatients and 346 community patients, 7.4% (n = 22) and 3.1% (n = 11) respectively, were found to be hepatitis C virus PCR positive. Ten inpatients commenced treatment; 3 achieved a sustained virological response (SVR), 6 are awaiting week 12 results and there was 1 treatment failure. Five others are awaiting treatment, 3 were discharged and require further follow up, and 4 refused treatment. Of the 11 patients assessed for treatment within the community setting, 3 commenced treatment; 2 completed and await SVR and 1 continues on treatment. Of the remaining 8, 6 refused treatment, 1 spontaneously cleared, and 1 patient was diagnosed with hepatocellular carcinoma and referred for further investigations and treatment, their CHC treatment was deferred.
Conclusion: CHC prevalence rates are higher in mental health settings compared to the overall population. Collaborating with and educating stakeholders across the mental healthcare sector resulted in significant numbers of patients being screened for CHC. Screening likelihood increased when venipuncture was offered at initial contact. While treatment uptake remains a challenge, with appropriate support, progress toward treatment initiation is achievable.

THU372

Triple E (engagement, education and eradication) for patients with chronic hepatitis C infection: >2 years of results of a successful, collaborative US model for improving education, screening and linkage to care in an underserved population

Marcelo Kugelmas[1], Andrew Talal[2], Mark Taglienti[3], Maxine Kugelmas[3], Jane Ranagan[3]. [1]*South Denver Gastroenterology P.C., Gastroenterology, Englewood, United States;* [2]*Jacobs School of Medicine and Biomedical Sciences, Center for Research and Clinical Care in Liver Disease, Buffalo, United States;* [3]*Chronic Liver Disease Foundation, Clark*
Email: Kugelmas@gutfeelings.com

Background and Aims: The United States (US) opioid epidemic has led to increases in hepatitis C viral (HCV) infections. Despite HCV being recognized as prevalent in individuals with substance use disorders (SUDs), the vast majority of substance abuse treatment facilities in the US do not screen for HCV. Lack of clinical staff and/or access to knowledgeable HCV experts' limits screening and disease management.
In 2017 the Chronic Liver Disease Foundation (CLDF), a non-profit educational organization dedicated to increasing awareness of the effects of chronic liver disease in the US, designed and implemented an integrated HCV program to improve the care of individuals with SUDs.
Method: This program provided 4 fundamentals to substance abuse centers: staff education, patient education/counselling, antibody (Ab) screening/HCV RNA testing (if Ab positive) and linkage to care. Linkage to care linked HCV RNA positive individuals directly to hepatitis specialists onsite or via telemedicine in areas where HCV providers are limited. A CLDF healthcare counsellor or local collaboration expert was involved in on-site patient education. Screening and linkage to care data were measured and the results of over two years of data are reported here.
Results: This began with substance abuse centers in 3 states and expanded to 8 states. Results from a smaller cohort were reported at EASL 2019. Results from a larger cohort are summarized here. Overall, 1131/2713 (42%) of SUD individuals, unaware of their HCV status, tested positive for HCV Ab. Of the 825 HCV Ab positive individuals who were tested for HCV RNA, 67% (552/825) tested positive. Some individuals could not complete a blood draw for various reasons and were referred for further confirmatory testing opportunities.
Conclusion: Direct-acting antiviral drug regimens offer the possibility of eradication of HCV but patient and provider HCV education, screening and linkage to care are necessary to effectively integrate treatments into disease management. Extending this program for an additional year resulted in substantially more patients who are now aware of their HCV status and have been effectively linked to care. Further broadening the reach of this self-sustaining, comprehensive HCV education, screening and treatment model could result in recovery center-focused eradication of HCV. This will have an invaluable effect on public health. This initiative was supported by educational grants from AbbVie and Gilead Sciences.

THU373

Prevalence of hepatitis C in a gastrointestinal endoscopy unit. An active search for asymptomatic subjects

Laura Gomez-Escolar Viejo[1], María Salud Sánchez Reyes[1], Verónica Pascual Climent[1], Laura Llobregat Carrasco[1], Cristina Quilez Ivorra[1], Elisenda Martín Fernández[1], Isabel López Martín[1], Antonio Garcia Herola[1]. [1]*Villajoyosa, Alicante, Villajoyosa, Spain*
Email: agherola@gmail.com

Background: A national cross-sectional, population-based survey carried out in Spain recently estimated HCV seroprevalence (0.85%) and viremia prevalence (0.22%) in the general population. The identification of asymptomatic subjects allows establishment of effective treatment and contributes to the elimination of the disease.
Aims: 1) To estimate seroprevalence and prevalence of HCV infection in a gastrointestinal endoscopy unit of a public hospital in Spain. 2) To describe epidemiological characteristics and known risk factors of HCV infection. 3) To asses acceptance and feasibility of an HCV screening program in a digestive endoscopy unit.
Method: Design: Observational, cross-sectional study.

- Population: All consecutive patients attended in the Gastrointestinal Endoscopy Unit between February and October 2019.
- Variables: 1) outcome: HCV serology, HCV viremia and genotype. 2) descriptive: id number, age, sex, nationality, known risk factors for HCV infection.
- Data collection: all subjects were invited to participate and sign in the study informed consent form. Information on descriptive variables was obtained from the Valencian Health Service database. An epidemiological survey was performed to all the participants were HCV risk factors were collected.

  HCV serology was obtained using a rapid anti-HCV finger stick blood test (Core HCV) amongst those who agreed to participate. An attempt to determine HCV viremia and genotype was done using PCR in seropositive subjects. All anti-HCV positive subjects were evaluated through personal interviews where clinical and analytical data were collected. Liver assessment of all anti-HCV positive subjects was carried out using abdomen ultrasound and transitional elastography.

Results: Anti-HCV test were performed in 3395 out of 3462 subjects invited to participate (98.1%) who underwent the following explorations: colonoscopy 1643, upper endoscopy 1373, both 314, ERCP 65. In all, 68 subjects (mean age 58, range: 38–85) were anti-HCV positive, resulting in an estimated prevalence of 2% (95%CI: 1.53%–2.47%). Of those, 11 were not aware of their condition and 64 (94%) reported one or more HCV risk factors. 12 subjects showed positive RNA-VHC viremia, with an HCV infection prevalence of 0.35%. 56 anti-HCV positive subjects (82.3%) were born between 1950 and 1979.
Conclusions: 1. The anti-HCV seroprevalence in the gastrointestinal endoscopy unit was 2%, higher than that reported in general population in Spain but HCV infection prevalence (0.35%) was similar. 2. Most anti-HCV positive patients were born in 1950 to 1979. 3. The majority of anti-HCV positive subjects were aware of this condition and had one or more HCV risk factors. 4. Digestive endoscopy units may be suitable areas for HCV screening.

THU374

Why didn't I see you in my clinic? Patients with HCV positive serology but never a confirmed infection. A retrospective analysis at 10 years

Matias Estevez[1], Ignacio Aguilar Martin[2], Matilde Palanca Gimenez[3], Beatriz Martinez Larios[2], Juan Jose Valverde Romera[2], Isabel Llamas Bellido[1], Katherine Gomez Torres[1], Francisco Javier Gallego Rojo[1]. [1]*APES Hospital de Poniente, Hepatology, El Ejido, Almeria, Spain;* [2]*Distrito Sanitario Poniente de Almería., Centro de Salud Ejido Norte, El Ejido, Almeria, Spain;* [3]*APES Hospital de Poniente, Microbiology, El Ejido, Almeria, Spain*
Email: matiasesteveze@gmail.com

Background and Aims: Although it is estimated that 29.4% of patients with active infection in Spain are unaware of their situation, there are few data on the profile of patients with positive serology but not well established viral status. Our aims was to evaluate the epidemiological and clinical profile of patients with positive HCV serology (HCVAb+) in our hospital, with special interest in patients without subsequent microbiological confirmation.
Method: Descriptive cross-sectional study on all those patients who presented any non-negative HCVAb serology between the years 2008–2017. After approval in the Ethics Committee, the patients were subclassified according to analytical evolution and the clinical digital reports.
Results: 14496 analytical codes containing "non-negative" HCV were extracted, after which analysis allowed to identify 2012 patients HCVAb+, 282 of whom had no RNA determination. Of these, 184 patients (65.2%) came from Primary Care (PC) and 98, from hospital and attached centers (mental health and drug dependence center). Among the patients from PC, 123 were not referred by their General Practitioner (66.8%) and 61 (33.2%) were, although they did not go to the specialist. The platelet count <150 × 109/L (60% referred vs. 30.6% not, p = 0.009) and ALT > = 35U/L (42.5% referred vs. 25.9% not, p = 0.021) were associated with higher referral rate to the Hepatologist. Among the patients who did not come from PC, most of the serologies were requested by Internal Medicine (30.6%), followed by General

Gastroenterology (23.5%) and Pneumology (14.3%), as shown in Table 2. 36 of 98 patients (36.7%) were referred, of whom 28 attended the consultation (77.7% of the derivatives) but none of them extracted the analytical with RNA requested from specialist. The only variable associated with the derivation rate was the origin of Gastroenterologist vs. other specialties (p = 0.014). Platelets <150 × 109/L and alcohol consumption >30gr/d were not related with higher referral but were close to statistical significance (p = 0.069 and p = 0.097, respectively).

Conclusion: Of the patients HCVAb+ who have not confirmed active HCV infection, approximately 2/3 are subjects who were not referred by the serology petitioner. In the case of Primary Care, thrombocytopenia and hypertransaminasemia are variables associated with a greater referral rate. In the rest of sources, only the origin of the analytical request was related with the appropriate derivation (greater if the petitioner was Gastroenterologist).

THU375

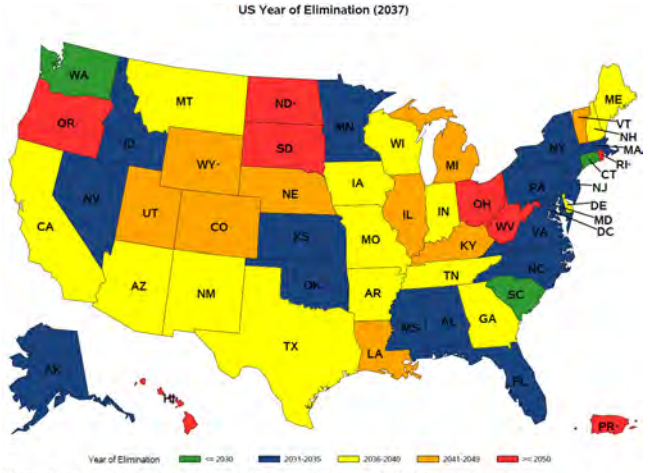
Timing of hepatitis C elimination in the United States: estimating the year each state will meet the World Health Organization's elimination targets

Mark Sulkowski[1], Wei-Han Cheng[2], Steven Marx[2], Yuri Sanchez[2], Nancy S Reau[3]. [1]*The Johns Hopkins University School of Medicine, Baltimore, United States;* [2]*AbbVie, North Chicago, United States;* [3]*Rush University Medical Center, Chicago, United States*
Email: yuri.sanchezgonzalez@abbvie.com

Background and Aims: Short-duration, pan-genotypic curative therapies can accelerate the path to HCV elimination. This study assesses the progress and timeline of US states to achieve the 2030 HCV elimination targets set by the World Health Organization (WHO) for incidence, mortality, diagnosis, and treatment.

Method: A previously published disease-progression model was utilized to project the path to HCV elimination based on national and state-specific population, mortality, and HCV prevalence statistics. Data from two US large laboratory companies were used to estimate HCV prevalence from 2013 to 2017, including the diagnosed HCV population, newly diagnosed HCV cases and number of patients receiving antiviral treatments in 2017. Fibrosis-stage restrictions for treatment reported in 2017 for each state were also considered. The model then estimated the annual HCV-infected population by stage of liver disease, and HCV-related deaths. To inform the path towards HCV elimination, the model estimated the year each state would meet the WHO targets for: diagnosing 90% of the HCV-infected population; treating 80% of the eligible population; and reducing new HCV infections by 80% and HCV-related deaths by 65% relative to 2015 benchmark levels. We also calculated the minimum number of annual treatments necessary to achieve the treatment target for HCV elimination, over the course of 2020 to 2030.

Results: Overall in the US, the estimated year of achieving WHO elimination targets is 2037, with 2037 being the year the target for incidence reduction will be met, 2020 for reducing liver-related mortality, 2027 for diagnosis coverage and 2033 for treatment coverage. Only three of 50 states (Connecticut, South Carolina and Washington State, 6%) are on track to eliminate HCV by 2030. An additional 16 states (32%) were projected to eliminate HCV by 2035, 15 (30%) by 2040, 10 (20%) by 2050, and 8 (16%; Hawaii, North Dakota, Ohio, Oregon, Puerto Rico, Rhode Island, South Dakota, and West Virginia) not before 2050.



*The estimation might be less accurate due to small number of HCV patients in the area

Conclusion: Our study suggests that the US is not on track to meet the WHO goals for HCV elimination by 2030 since only 6% of states are on track and 36% are off track by 10 years or more. As the year when all US states are expected to achieve HCV elimination targets is beyond 2050, strategies must be implemented to reduce HCV incidence, which include increased rates of screening, linkage to care, and unfettered access to curative therapy.

THU376

Managing hepatitis C in people who inject drugs (PWID) using the internist-addiction medicine-hepatology (IAHC) model to achieve Hep C micro-elimination

Naren Srinath Nallapeta[1], Anthony Martinez[2], Robin Jindal[1], Jason Edwards[1]. [1]*University at Buffalo, Internal Medicine, Buffalo, United States;* [2]*University at Buffalo, Hepatology, Buffalo, United States*
Email: narennal@buffalo.edu

Background and Aims: 2.5 million people in the United States are living with hepatitis C (HCV) with 80% of new infections occurring among People Who Inject Drugs (PWID). Rates of acute HCV among

people age 18–29 have increased 400%. In order to achieve the World Health Organization's target to eliminate HCV by 2030 improved screening, linkage to care and treatment among PWID is essential. This study describes the internist- addiction medicine-hepatology colocalization model (IAHC), an integrated, co-located program in which an internist-addiction medicine specialist evaluated opiate dependent patients for HCV infection in the hepatology clinic.

Method: Our clinic site applied the IAHC model to target PWIDs with HCV by partnering with community substance abuse clinics. Each site was educated on HCV screening and IAHC based social workers rotated among the referral sites on a weekly basis. The social work team collected the referrals, scheduled patients within thirty days and delivered the appointments directly to the referral sites the following week. The social work team remained in close contact with patients and provided weekly reminders as well as a call the day prior to the appointment. Upon being seen in the hepatology clinic, patients underwent HCV evaluation and medication-assisted treatment (MAT) for opiate dependency was offered if the patients were not already on therapy.

Results: 321 PWID were evaluated for HCV. 258 individuals completed direct acting antiviral (DAA) therapy of whom 168 achieved SVR (98.8%). 96 patients remain on treatment. 45 individuals failed to complete therapy due to various reasons, 4 had spontaneous resolution, 4 were unable to get treatment (pregnant, drug interactions, insurance issues). Overall adherence among PWID was 85.4%. 5 re-infected patients were identified and retreated.

Out of 379 general population, non-PWID patients who initiated HCV treatment, 236 completed treatment and 55 remain on therapy. 88 failed to complete treatment (incarcerated, insurance lapse, deceased, side effects, lost to care). Overall adherence was 73%.

We compared adherence amongst patient in the IAHC model (175/205) vs adherence in the regular model (236/324) and upon calculating the Chi-Square analysis, X2 = 5.71 and p-value was 0.016 which is clinically significant. The IAHC model was found to result in improved adherence.

Conclusion: The IAHC model of care is an effective strategy for HCV micro-elimination resulting in improved treatment uptake among PWID and high SVR rates. Early treatment of HCV can also result in increased treatment uptake for opiate dependency.

THU377

Testing and treatment for hepatitis C in the community pharmacy setting: an opportunity not to be missed?

Nicki Palmer[1], Paul John[2], Kerry Rockey[3], Rhys Oakley[2], Brendan Healy[1]. [1]*Public Health Wales, Microbiology University Hospital of Wales, Cardiff, United Kingdom;* [2]*Cardiff and Vale University Health Board, Pharmacy, Cardiff, United Kingdom;* [3]*Cardiff and Vale University Health Board, Hepatology/Infectious Diseases, Cardiff, United Kingdom*
Email: nicki.palmer@wales.nhs.uk

Background and Aims: To deliver against the World Health Organisation (WHO) Hepatitis C elimination agenda it is vital that services are developed that enable clients in high prevalence settings to be diagnosed and treated in an environment that is convenient and appropriate for them. This project was developed to investigate whether testing and treating clients for hepatitis C was feasible and successful in a community pharmacy setting.

Method: A national service specification acceptable to all pharmacies across Wales was agreed. Pharmacies with a high turnover of clients using enhanced services; needle exchange and opiate substitution therapy (OST) were approached to take part in the project. Pharmacy staff were trained on site in carrying out consent and dried blood spot testing (DBST) and all clients attending for enhanced services were offered DBST. 16 pharmacies across 3 Health Boards were enrolled. Positive results were followed up with a visit by a member of the liver team and treatment was subsequently prescribed in line with the All Wales guidelines.

Results: 500 clients were approached. 56 (11%) agreed to a test. The uptake of testing was much lower than anticipated, seemingly driven by 2 linked factors: a reluctance amongst the clients to accept the offer of a test (requests sometimes met with aggressive refusals) resulting in hesitancy amongst pharmacy staff to offer the test. Of the first 130 clients approached reasons for declining the test were given as no time (41%), no incentive to take the test (18%) and recently tested (41%). Of the 56 clients tested, 16 tested antibody positive on DBST with 4 testing RNA positive. Details of the barriers in testing that were encountered will be explored in the poster.

Conclusion: Uptake of testing in the community pharmacy setting was very low. The project experienced a number of unexpected barriers to testing. Alternative methods for enhancing engagement are needed to increase testing uptake in this setting. Ongoing education for pharmacy staff is also vital. Despite the disappointing uptake of testing, the interactions with pharmacy teams has been positive with increased awareness and understanding of the blood borne viruses. Development of the testing pathway in this setting continues as approximately 50% of at risk clients only access community pharmacy services. In rural areas delivery of treatment in this setting is likely to be crucial in achieving the WHO elimination targets.

THU378

Hepatitis C virus antigen detection as a tool for diagnosis of acute hepatitis C in patients with negative hepatitis C virus antibody

Rajneesh Kumar[1], Kwai Peng Chan[2], Victoria Ekstrom[1], Sheryl Gan[3], Sobhana Thangaraju[3], Terence Kee[3], Shi Min Woo[1], Marjorie Foo[3], Kian Sing Chan[4], Kun Lee Lim[5], Lynette Oon Lin Ean[4], Wan Cheng Chow[1]. [1]*Singapore General Hospital, Gastroenterology and Hepatology, Singapore, Singapore;* [2]*Singapore General Hospital, Pathology, Singapore, Singapore;* [3]*Singapore General Hospital, Renal Medicine, Singapore, Singapore;* [4]*Singapore General Hospital, Molecular Pathology, Singapore, Singapore;* [5]*Singapore General Hospital, Molecular Laboratory, Singapore, Singapore*
Email: rajneeshkrs@gmail.com

Background and Aims: World Health Organisation has named the elimination of Hepatitis C virus (HCV) as one of its key goals; hence early diagnosis remains key for effective prevention and treatment. Current HCV antibody (Ab) tests as a screening tool has limited utility in acute Hepatitis C, especially in subjects who are immunocompromised. As HCV antigen (Ag) can be useful in this clinical scenario, this study is aimed to study utility of HCV Ag testing as a screening tool.

Method: This study cohort comprises of nineteen samples from patients with acute hepatitis C who were HCV Ab negative, but HCV RNA positive and eighty-nine subjects who have been treated or having chronic Hepatitis C were all checked for HCV Ag.

The Abbott ARCHITECT HCV Ag assay Abbott architect kit was used to check test for the presence of HCV antigen Ag a, value of >3.00 fmol/L was considered as positive. HCV titre was measured by real-time quantitative PCR from Roche COBAS® AmpliPrep/COBAS® Taqman® HCV Quantitative Test v2.0.

Results: HCV Ag was positive in 19/19 plasma of subjects with acute HCV who had detectable HCV RNA, but not HCV Ab. In the plasma of 44 subjects with HCV RNA positive - HCV Ag was positive in 43/44 subjects. In the patients who had treated HCV with HCV Ab positive and HCV RNA negative, the HCV Ag was negative in all the 37 subjects

Conclusion: HCV Antigen is useful for diagnosis of acute hepatitis C infection with shorter turn over time. This is especially useful in patients on hemodialysis or who are immunocompromised where the utility of HCV Ab test is limited.

Characteristics of Acute HCV infection

Subjects with Acute HCV

	HCV RNA positive	HCV Ab detected
HCV Antigen positive	19	0

Subjects with chronic HCV, HCV Ab and HCV RNA positive

	HCV RNA positive
HCV antigen positive	43
HCV Antigen negative	1

Patient with negative HCVAntigen test had HCV RNA of 3049 IU/ml

Subjects with treated HCV , HCV Ab positive and RNA negative

	HCV RNA negative
HCV Antigen positive	0
HCV Antigen negative	37

Screening for chronic liver diseases in the general population reveals an unexpectedly high prevalence of hepatitis C and advanced NAFLD

Sebastian Bachmayer[1], Georg Semmler[1], Sarah Wernly[1], Eva-Maria Weilnböck[1], Bernhard Wernly[2], David Niederseer[3], Geja Oostingh[4], Karin Schwenoha[4], Ursula Huber-Schönauer[1], Elmar Aigner[5], Christian Datz[1]. *[1]General Hospital Oberndorf, Teaching Hospital of the Paracelsus Medical University Salzburg, Department of Internal Medicine, Oberndorf bei Salzburg, Austria; [2]Paracelsus Medical University of Salzburg, Clinic of Internal Medicine II, Department of Cardiology, Salzburg, Austria; [3]University Heart Centre, University Hospital Zurich, Department of Cardiology, Zürich, Switzerland; [4]Salzburg University of Applied Sciences, Biomedical Sciences, Puch bei Hallein, Austria; [5]Paracelsus Medical University Salzburg, First Department of Medicine, Salzburg, Austria*

Email: bachmayer@live.at

Background and Aims: Hepatitis C virus (HCV) infection and non-alcoholic fatty liver disease (NAFLD) are common causes for chronic liver disease and are associated with an increased risk for advanced liver disease as well as cardiovascular disease (CVD). Data on the prevalence of liver diseases such as chronic viral hepatitis or fatty liver disease in particular are limited. The cost-effectiveness of population-based HCV screening to achieve WHO goals for eradication of HCV infection is under debate. Here, we provide preliminary data of a population-based combined Hepatitis C and NAFLD screening program in Austria.

Method: As part of a colorectal carcinoma colonoscopy screening program (SAKKOPI), we investigated 661 asymptomatic subjects (median age 58.8 years [53.3–64.4], 56% males). The diagnosis of fatty liver disease was established by abdominal ultrasound and transient elastography-based controlled attenuation parameter (CAP) ≥ 280 dB/m after exclusion of autoimmune or hereditary liver diseases, excess alcohol consumption and previously diagnosed viral hepatitis. Assessment of fibrosis using transient elastography (≥7 kPa for significant fibrosis [≥F2] and ≥ 10 kPa for cirrhosis [F4]) as well as biochemical and metabolic parameters, including liver enzymes, oral glucose tolerance test, insulin resistance (HOMA-IR) and HbA1c was performed. In addition, a detailed questionnaire of dietary habits and physical activity was completed. If serologic testing was positive for HCV antibodies, HCV infection was confirmed by PCR.

Results: In 661 patients, median BMI was 25.9 (23.4–29.0). 200 patients (30%) had elevated liver enzymes (GGT/ALT) and 246 (37%) had (pre-) diabetes. Mean Fib4 score was 1.07; 527 patients (80%) had Fib4 scores <1.45, while 123 (19%) and 11 (2%) had scores between 1.45–3.25 and >3.25 (indicative for advanced fibrosis), respectively. 42% of patients showed increased echogenicity on ultrasound examination. On transient elastography, mean CAP-value was 265 dB/m (221–311), whereas 269 (42%) patients had CAP-values above 280 dB/m. 63 (10%) of NAFLD patients had significant fibrosis (≥F2) and 16 (2.5%) had liver cirrhosis.

Furthermore, 6 patients (0.9%) had detectable HCV antibodies. 5 of them (0.8%) had chronic HCV infection confirmed. Notably, two patients with chronic HCV infection had completely normal laboratory, ultrasound and transient elastography findings.

Conclusion: We show an unexpectedly high prevalence of chronic HCV infection and advanced NAFLD in a large, well-characterized cohort of asymptomatic patients. Especially the high prevalence of undetected HCV infections (0.8%) emphasizes the need for HCV screening in a population-based manner. Importantly, 40% of individuals with unknown HCV infection did not show any evidence for chronic liver disease, which would leave them without diagnosis and treatment.

THU380

Does additional information obtained from multiple visits change the timing of HCV treatment decisions

Shawn Greenan[1], Deepti Kalani[2], Cory Ramsay[3], Merissa Mitchell[1], Lisa Barrett[4]. *[1]Health PEI, Public Health and Childrens Developmental Services, Charlottetown, Canada; [2]Xavier School of Medicine; [3]University of Prince Edward Island; [4]Dalhousie University, Department of Infectious Disease*

Email: sagreenan@ihis.org

Background: PEI has a comprehensive jurisdiction-wide HCV elimination program. Past data suggests multiple visits and delayed treatment starts may be barriers to HCV care and elimination. Improved HIV health care has been demonstrated with rapid, same day treatment starts facilitated by simplified pre-treatment workup.

Aim: We evaluated the impact of standard of care workup on HCV treatment eligibility and decision making to determine the minimal data required for safe and timely HCV treatment starts.

Method: Patients were referred to the HCV program through Public Health, community providers, or “bring a friend” strategies. Four pre-visit steps were completed: 1. baseline blood work including APRI, FIB-4 and HCV viral load; 2. drug-drug interaction (DDI) checks; 3. patient-informed health-history; and 4. book a first appointment. Patient treatment eligibility and provider treatment choice was assessed at each of the four steps. Treatment naïve patients without contraindications were offered glecaprevir/pibrentasvir treatment start at the first visit.

Results: 236 patients were referred and assessed between February 2018–October 2019. 229 (97.03%) were considered treatment eligible before step 1–4 workup (6 adolescents excluded). All 197 individuals

with APRI <1.5, and detectable HCV viral load were deemed eligible for HCV treatment on the first visit and moved to step 2. 23/197 (12%) patients had a step 2 DDI screen identifying them as needing co-medication (statin, ethyl-estradiol, high dose quetiapine) adjustment before treatment start in step 2. All step 2 patients had a health history completed in step 3, and no treatment decisions were altered based on the health history. Of the 224 (94.92%) people dispensed medication at step 4 first visit, 100 (44.64%) achieved SVR12, 90 (40.18%) are pending SVR12, 26 (11.61%) are currently on treatment. In total, 5 (2.23%) treatment failures occurred and no individuals have been lost to follow-up. No serious adverse events or liver related decompensation occurred. failures occurred. No significant safety issues were noted.

Conclusions: APRI, HCV viral load, and DDI are key to deciding rapid treatment starts, and further information did not alter treatment timing or choice. Rapid treatment starts are safe and effective in the vast majority of HCV referrals, and facilitated high follow-up and cure even in difficult to engage populations. A streamlined, rapid treatment start approach may be an effective HCV elimination tool as part of a comprehensive program.

THU381

Missed linkage to care for patients with chronic hepatitis C virus infection in a tertiary care center: results of the telepass project

Francesca Ponziani[1], Francesco Santopaolo[1], Massimo Siciliano[1], Antonio De Belvis[2], Annalisa Tortora[1], Vincenzina Mora[2], Caterina Fanali[2], Alisha Morsella[2], Fulvio Balducci[2], Giuseppe Vetrugno[2], Maria Elena D'Alfonso[2], Andrea Cambieri[2], Roberto Cauda[2], Rocco Bellantone[2], Maurizio Sanguinetti[2], Maurizio Pompili[1], Antonio Gasbarrini[1]. *[1]Fondazione Policlinico Agostino Gemelli IRCS, Internal Medicne, Gastroenterology and Hepatology, Rome, Italy; [2]Fondazione Policlinico Agostino Gemelli IRCS, Rome, Italy*
Email: santopaolofrancesco@gmail.com

Background and Aims: Italy is one of the twelve countries worldwide considered on track to eliminate hepatitis C virus (HCV) by 2030. To achieve this goal, continuous effort is required in designing efficient case finding and linkage to care strategies. In this scenario, health-care facilities are crucial to seek infected patients who have not yet been treated, but the absence of specific management policies can hinder their linkage to care. We investigated the prevalence of HCV infection in a large cohort of patients and the effectiveness of a recall strategy for patients diagnosed with chronic HCV infection in a tertiary care center but not linked to care.

Method: The Telepass project, called "Telepass" from the name of the preferential lanes on the highway, was structured in: 1) a retrospective phase, aimed at identifying all anti-HCV positive subjects among patients who underwent pre-operative assessment between March 2017 and March 2018 in a tertiary care center in Central Italy (case finding) and 2) a prospective phase, finalized to the recall of all patients requiring further diagnostic tests (i.e. HCV-RNA) or treatment (linkage to care).

Results: A total number of 12246 records of patients tested for anti-HCV antibodies was reviewed. The overall prevalence of anti-HCV positive subjects was 1.83% (224/12246), which was significantly higher in men than in women (110/3890, 2.82% vs. 114/8356, 1.36%; p < 0.00001). No patient under the age of 25 was found anti-HCV positive and the prevalence increased from 0.85% in subjects aged 25 to 49 to 4.73% in those over 80. No information on the HCV-RNA test was available for 123 (54.91%) of these anti-HCV positive patients. Twenty-six out of them (21.13%) were referred for hepatological evaluation, 10 (38.46%) resulted HCV-RNA positive and started treatment with direct-acting antivirals (DAAs).

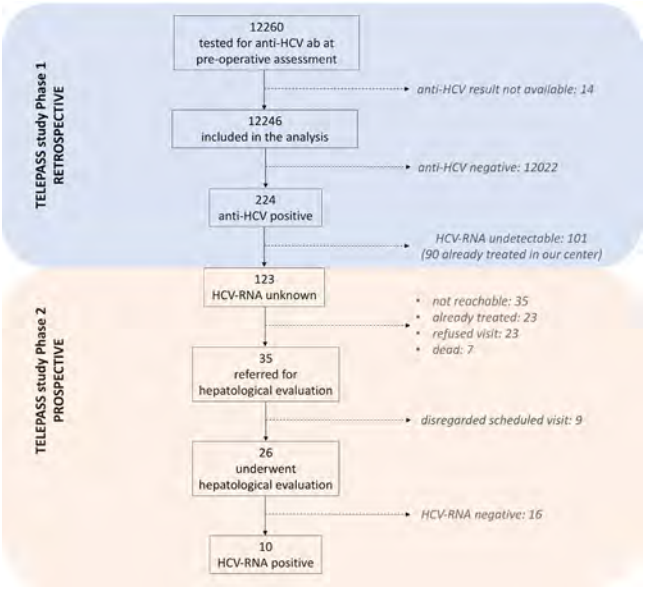

Figure: Flow diagram of patients' recruitment in the Telepass study.

Conclusion: The Telepass study highlights that a recall strategy starting from internal hospital databases is mandatory to link to care hidden patients with chronic HCV infection. Furthermore our study provides an epidemiological insight on the prevalence of HCV infection in Italy in the late DAAs era in order to plan targeted campaigns for screening and to program economic resources for treatment.

THU382

Epidermal growth factor gene polymorphism in hepatitis C virus patients with hepatocellular carcinoma

Sara Asar[1], Ayman Elshayeb[2], Doaa Elwazzan[3], Nehal Bahnasy[4]. *[1]Faculty of Medicine of Alexandria, Medical Microbiology and Immunolgy, Alexandria, Egypt; [2]Faculty of Medicine of Alexandria, Tropical Medicine, Alexandria, Egypt; [3]Faculty of Medicine of Alexandria, Tropical Medicine, Alexandria, Egypt; [4]Alexandria, Faculty of Medicine of Alexandria, Alexandria, Egypt*
Email: sara.asar@alexmed.edu.eg

Background and Aims: Hepatocellular carcinoma (HCC) is the fifth most common cancer worldwide and develops predominately in individuals with liver cirrhosis. Insights into the biology of HCC have demonstrated that accumulations of genetic abnormalities can play an essential role in liver carcinogenesis. Epidermal growth factor receptor (EGFR) is highly expressed in the liver and is upregulated in many cancers. The EGF +61A/G polymorphism (rs4444903) is a common single nucleotide polymorphism (SNP) in the 5′-untranslated region of the EGF gene, modulating the transcription of EGF gene. There is limited number of studies conducted to examine the association between EGF +61A/G polymorphism and HCC susceptibility. Our aim was to asses this association to highlight the benefit of molecular biomarkers predictive of individual HCC susceptibility, to improve guidelines for genetics-based patient screening and preventive strategies.

Method: This study included 90 subjects grouped as follows: 30 cirrhotic HCV patients with HCC, 30 cirrhotic HCV patients without HCC and 30 healthy controls. Detailed examination and routine laboratory investigations were performed. DNA extraction was done for peripheral blood samples from all cases and controls, using Qiagen DNA extraction kit. Genotyping assay was done for the EGF 61A > G polymorphisms using the fluorogenic 5′-nuclease assay according to the allele-specific primers, detecting SNP rs444903 by TaqMan Genotyping Assay Applied Biosystems ThermoFischer kit.

Results: Our study showed a statistically significant increased expression of 61*G allele of the EGF gene in the group of cirrhotic patients and group of HCC patients, in comparison to the control group, p = 0.003, p = 0.027 respectively. Genotypes AG and GG show higher incidence (36% and 33% respectively) among HCV patients with HCC.

	HCV+HCC (n = 30)		HCV (n = 30)		Control (n = 30)			
	No.	%	No.	%	No.	%	χ^2	p
Genotype								
AA	9	30.0	4	13.3	11	36.7	13.886*	0.008*
AG	10	33.3	16	53.3	18	60.0		
GG	11	36.7	10	33.3	1	3.3		
Sig.bet.Groups	$p_1 = 0.187$, $p_2 = 0.004^*$, $p_3 = 0.005^*$							
Allele								
A	28	46.7	24	40.0	40	66.7	9.249*	0.010*
G	32	53.3	36	60.0	20	33.3		
Sig.bet.Groups	$p_1 = 0.461$, $p_2 = 0.027^*$, $p_3 = 0.003^*$							

Figure: Comparison between the three studied groups according to genotype
p_1: p value for comparing between the **HCV+HCC** group and **HCV** group.
p_2: p value for comparing between the **HCV+HCC** group and **Control** group.
p_3: p value for comparing between the **HCV** group and **Control** group.

Conclusion: The HCC surveillance programs that could lead to early cancer detection and effective treatment are based on heterogeneous scoring systems that require costly measures. Our study revealed that it is of clinical benefit to identify genetic traits as EGF +61 A/G polymorphism, that can modify liver carcinogenesis, and potentially be used to improve preventive and therapeutic strategies in HCC management.

THU383

Impact of dysmetabolism on liver damage severity and evolution in a real-life cohort of patients treated for chronic hepatitis C

Luca Valenti[1,2], Serena Pelusi[1,2,3], Sara Gritti[4], Barbara Funaro[5], Alberto Ferrari[4], Daniele Prati[2], Stefano Fagiuoli[5]. *[1]Università degli Studi di Milano, Milano, Italy, Department of Pathophysiology and Transplantation, Milan, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Milano, Milano, Italy, Translational Medicine, Department of Transfusion Medicine and Hematology, Milan, Italy; [3]Università degli Studi di Milano, Milano, Italy, Department of Pathophysiology and Transplantation, Milan, Italy; [4]Papa Giovanni Hospital, Bergamo, Italy, Fondazione Ricerca Ospedale di Bergamo – FROM, Bergamo, Italy; [5]Papa Giovanni Hospital, Bergamo, Italy, Department of Gastroenterology and Hepatology, Bergamo, Italy*
Email: serenapelusi@libero.it

Background and Aims: Aim of this study was to examine the impact of dysmetabolism on liver disease in a real-life region-based registry of patients, who recently underwent therapy for chronic hepatitis C virus (HCV) infection with direct antiviral agents (DAAs).
Method: From the NAVIGATORE-Lombardia Network database, we extracted the records of 7,009 patients, for whom age, sex, body mass index, baseline severity of liver fibrosis (by liver histology and/or Fibroscan), diagnosis of treated diabetes, hypertension and hyperlipidemia were available. In 748 patients, liver stiffness measurement by Fibroscan at 24 weeks after the end of therapy was available.
Results: Mean age was 61.3 ± 12.7 years, 42.4% were females, 14.8% HIV+, 50.0% had cirrhosis. 8.3% were underweight (BMI < 25), 49.3% had normal weight (BMI 20–25), 31.7% were overweight (BMI 25–30), and 10.7% obese (BMI > 30); 33.3% had hypertension, 10.3% diabetes, and 4.3% treated dyslipidemia.
Higher BMI and type 2 diabetes were independently associated with fibrosis stage and baseline LSM (p < 0.0001 for all). The association remained significant after excluding cirrhotics. Diabetes and hypertension were associated with higher FIB-4 (p < 0.001). Those treated for dyslipidemia had less severe liver damage (p < 0.001). Severe fibrosis was independently associated with older age, male sex, HIV coinfection, HCV genotype, BMI and the presence of diabetes. The impact of higher BMI was larger in those without than in those with diabetes (p = .003).
Sustained virologic response (SVR) was achieved by 97.7% participants. SVR was negatively impacted by male sex, cirrhosis, and infection by genotype 3-HCV, but not metabolic cofactors. Among those who did not achieve SVR, diabetes and obesity were associated with FIB-4 worsening at 12 weeks after the end of therapy.
In the subset of patients for whom follow-up LSM evaluation was available, at multivariate generalized linear model LSM improvement was independently associated with higher baseline levels (p < 0.001), SVR achievement (p = .025), and absence of diabetes (p = .001).
Conclusion: We detected a high rate of metabolic comorbidities, except for dyslipidemia, in particular in subjects with severe fibrosis. We confirmed a strong association of diabetes and adiposity with liver damage severity. Diabetic patients remain at high risk of progression after HCV eradication. We are currently evaluating the impact of dysmetabolism and fatty liver on clinical events during follow-up.

THU384

Direct-acting antivirals have substantially modified the profile of patients with cirrhosis who require hospitalization in Spain

Sergio Rodríguez-Tajes[1,2], Anna Pocurull[1], Joaquin Andrés Castillo[1], Gherzon Simon Casanova[1], Laia Vega[1], Sabela Lens[1,2], Zoe Mariño[1,2], Xavier Forns[1,2]. *[1]Hospital Clínic de Barcelona, IDIBAPS, University of Barcelona, Liver Unit, Barcelona, Spain; [2]Ciberehd*
Email: sergio.tajes@gmail.com

Background and Aims: In 2015 the Spanish government set a goal of eliminating hepatitis C. Since then, more than 130.000 patients have been treated with direct-acting antivirals (DAAs). Our aim was to evaluate the impact of DAAs on the profile of patients with liver cirrhosis (LC) admitted to a liver unit of a referral hospital.
Method: Review of electronic health records of all patients admitted to a referral Liver Unit from 2011 to 2019. Patients hospitalized due to acute hepatitis, liver transplantation or a diagnosis different from LC were excluded. Demographic variables, causes of admission, days of admission, intensive care requirement, and clinical outcomes (discharge, death) were recorded. The aetiology of LC was reviewed individually and validated by a physician.
Results: Data for 2011, 2014, 2017 and 2018 have been obtained so far. 6449 admissions (corresponding to a total of 3742 patients) have been analysed. After applying the exclusion criteria, 4354 admissions corresponding to 2451 patients with LC, were included. There was a significant decrease in the number and proportion of admissions of patients with HCV-LC (2011: 47%, 2014: 53%, 2017: 36% and 2018: 30%, p < 0.01). Similarly, we found a significant decrease in the number and proportion of patients admitted for HCV-LC (2011: 50%, 2014: 48%, 2017: 35% and 2018: 32%, p < 0.01). Excluding patients with hepatocellular carcinoma, admissions due to HCV-LC dropped from 36% in 2011 to 19% in 2018, and the number of admissions due to acute decompensation in HCV-LC declined a 50% within the same period. Regarding HCV infection markers, the proportion of HCV-LC patients with positive HCV-RNA decreased from 94% in 2011 to 35% in 2018, p <0.01. Overall, the proportion of total days of admission per year due to HCV-LC dropped significantly (2011:44%, 2014: 50%, 2017: 33% and 2018: 25%, p < 0.01) as well as the number of episodes requiring intensive care support (from 46% in 2011 to 24% in 2018, p < 0.01). Most importantly, hospital mortality due to HCV-LC decreased from 51% in 2011 to 24% in 2018, p < 0.01). Interestingly, hospitalization episodes due to LC caused by NASH increased significantly (from 1.7% in 2011 to 10.2% in 2018), as well as those due to autoimmune LC (1.2% in 2011 to 4.4% in 2018).
Conclusion: The efficacy of interferon-free therapy has modified the profile of patients with LC undergoing hospitalization, by reducing the weight of HCV-LC. Moreover, during the last few years there has

Baseline Characteristics

been a significant reduction in hospital morbidity and mortality attributable to patients with HCV-related LC.

THU386

Patients with hepatitis C (Redpath): a randomised controlled trial of telephone contact or offer of an incentive, in addition to a standard letter

Stephen Barclay[1,2], Erica Peters[3], Natasha McDonald[3], Matthew Priest[3], Stuart Kirkwood[3], Jacquelyn McGinley[3], Shouren Datta[3], Judith Morris[3], David Goldberg[2], Sharon Hutchinson[2]. [1]*Glasgow Royal Infirmary, Gastroenterology, Glsagow, United Kingdom;* [2]*Caledonian University, Department of Life Sciences, Glasgow, United Kingdom;* [3]*NHS Greater Glasgow and Clyde, Glasgow*
Email: stephenbarclay@nhs.net

Background and Aims: Meeting the goals of hepatitis C (HCV) elimination requires the re-engagement of those diagnosed but no longer in clinical care. Limited evidence exists on how best to approach to such patients. We sought to establish the effectiveness of a letter combined with either a follow up phone call, or the offer of an incentive, compared to a standard letter inviting the patient to re-engage.

Method: Patients on the Greater Glasgow & Clyde (NHS GG&C) copy of the Scottish HCV database, with a community health index (CHI) number were identified. Those untreated, treated unsuccessfully, or with unknown outcome were selected. Cross checking with the CHI database identified and excluded patients who were deceased or no longer resident in GG&C. Patients were randomised to receive one of three letters. Group A (control): a letter outlining the consequences of untreated hepatitis C, the availability, tolerability and efficacy of new treatments, and a contact number to arrange an appointment. Group B (phone): additional text indicating an attempt to contact the patient by phone would be made if no response within 4 weeks, Group C (incentive): additional text offering a £20 (~€23) shopping voucher if contact made within 4 weeks. For Group B, 2 attempts to contact the patient by phone were made if they had not made contact by week 4, with a standard message left if voicemail in use. The primary outcome measure was attendance at hospital or outreach clinic for assessment of liver disease within 4 months of the letter. The secondary outcome was commencement of treatment within 6 months. We present an interim analysis of attendance at 3 months. Categorical variables were analysed using Fisher's exact test, continuous variable using student's t-test, comparing each intervention arm to the control.

Results: 1059 patients met the inclusion/exclusion criteria. The majority of patients were male, with a history of intravenous drug use, and were naïve to treatment (table 1). No significant differences in baseline characteristics were seen between groups. At 3 months 135 (12.7%) of patients had attended for assessment, 38 (10.6%) control, 57 (15.5%, p = 0.048) phone, 73 (12.0%, p = 0.55) incentive.

Conclusion: Interim results suggest that a letter with follow up phone call is more likely to reengage patients lost to follow up with HCV than a letter alone, or a letter plus offer of incentive. Full results on attendance and initiation of treatment according to intervention group will be presented.

THU387

Overdose events among active drug users successfully treated for HCV: the impact of homelessness

Tianna Magel[1], Kelli Wuerth[1], Lauren Jones[1], Letitia Chu[1], Rossitta Yung[1], David Truong[1], Brian Conway[1]. [1]*Vancouver Infectious Diseases Centre, Vancouver, Canada*
Email: tianna.magel@vidc.ca

Background and Aims: Since 2015, the opioid crisis has led to over 5,000 overdose deaths in British Columbia, Canada. Previous studies have demonstrated increases in risky drug use behaviour among individuals with unstable housing, a finding that may be mitigated by engagement in care, which may occur in the provision of HCV treatment to this priority population. We sought to evaluate the interaction of homeless and overdose events in a group of drug users having received HCV therapy in the context of a multidisciplinary system of care.

Method: We conducted a retrospective analysis of active drug users engaged in HCV treatment at our centre from 01/15–10/19, as a function of their housing status. All patients were enrolled in multidisciplinary care addressing their medical, social, psychological, and addiction needs. The primary endpoints of this analysis are correlates and occurrence of medically significant overdose events, including mortality.

Results: We compared 211 (74%) well-housed and 75 (26%) homeless active drug users engaged in HCV care at our centre. Of these, 25 remain on HCV therapy and 243/261 (93%) others achieved a cure of their infection and remain in care. Mean age among well-housed active drug users was 53 years, 25% female, 55%/30%/39% opioid/amphetamine/cocaine use, 53% on opioid substitution therapy (OST), 50% psychiatric comorbidities. Among homeless active drug users, mean age was 52 years, 13% female, 76%/48%/45% opioid/amphetamine/ cocaine use, 56% on OST, 64% psychiatric comorbidities. Among well-housed active drug users, 18 individuals experienced medically significant overdose events and there were 7 deaths (12% event rate). Among homeless active drug users, 13 individuals experienced medically significant overdose events and there were 3 deaths (21% event rate).

Conclusion: Among HCV-infected active drug users engaging in care at our centre, one quarter were homeless, who were more often male, more active poly-substance users and with a higher prevalence of psychiatric co-morbidities. Overdose events (including mortality) were twice as frequent in this population. Although engagement in care served to reduce the occurrence of opioid-related events by over 50% compared to the overall population of active drug users in the community, homelessness remains associated with a higher risk of events even in the setting of provision of HCV care in a multidisciplinary setting. This setting will provide the ideal setting to evaluate additional interventions to reduce opioid-related events, particularly in the homeless population.

THU388

Micro-elimination in prisons: a high-intensity test and treat (HITT) programme

Tracey Stirrup[1], Diane Williams[1], Samantha Sharman[1], Joan Williamson[1], Mark Aldersley[1]. [1]*Leeds Teaching Hospitals NHS Trust, Hepatology, Leeds, United Kingdom*
Email: markaldersley@hotmail.co.uk

Background and Aims: If countries are to meet the WHO target of elimination of HCV, all patients at risk of HCV must be identified and treated. Prisons are a high prevalence site with high throughput of people who in inject drugs. A High Intensity Test and Treat (HITT) initiative is one potential approach to try and micro-eliminate HCV in prisons. Leeds is a medium secure local prison and was chosen as a site to trial this approach. The aim was to test and treat as many prisoners as possible over a two weeks period.
Method: Prior to testing commencing a publicity campaign was conducted by peers within the prison and prisoners were incentivized to be tested by providing chocolate bars and telephone access cards. Over the course of a weekend period in July 2019 an attempt was made to test all inmates in the prison for HCV, Hepatitis B (HBV) and Human Immunodeficiency Virus (HIV) with a point of care Matrix test. Positive antibody tests were further tested with capillary blood PCR tests performed in the local laboratory with test result turnaround of 24 hours. Prisoners testing PCR positive were immediately informed of the diagnosis and a review of their current drug history made to check for drug drug interactions. If a genotype was already available on their medical record they were treated with an appropriate genotype specific drug or if no genotype was available they were treated with the pan-genotypic drug Maviret.
Results: There were 1022 in Leeds prison during the course of the testing weekend. 757 prisoners were tested but 47 refused to be tested and 218 could not be accessed within the prison to be tested. Only 1 prisoner with HIV and 1 prisoner with HBV were identified and these were already known to treatment services. 59 of 757 tested prisoners were HCV antibody positive (7.8%) and 36/757 (4.8%) were PCR positive. 9/36 were already on or about to start treatment and 8/36 were released or transferred to another prison in the week between testing and commencing treatment. One prisoner died during this period. 15 new patients started treatment during the course of the two weeks project. Treatment completion and sustained virological response rates are awaited.

Outcome	No	Outcome	No
Started treatment	15	Started treatment prior to HITT	7
Retreatment	3	Pending treatment	2
Transferred	1	Released lost to follow up	7
Deceased	1	Total	36

Figure: Treatment Starts for HCV RNA Positive Prisoners.

Conclusion: HITT is an effective approach to micro-eliminate HCV in prisons. Not all prisoners identified by this program are new diagnoses. Due to the high throughput of prisoners it is essential that treatment is commenced immediately after diagnosis or prisoners may be lost to follow up.

THU389

Oncogenic implications of sofosbuvir on the development of hepatocellular carcinoma

Wei-Lun Tsai[1,2], Jin-Shiung Cheng[1,2], Chih-Wen Shu[3]. [1]*Kaohsiung Veterans General Hospital, Division of Gastroenterology and Hepatology, Kaohsiung, Taiwan;* [2]*National Yang-Ming University, Shool of Medicine, Taipei, Taiwan;* [3]*I-Shou University, School of Medicine for International Students, Kaohsiung*
Email: tsaiwl@yahoo.com.tw

Background and Aims: Hepatitis C virus (HCV) is a major cause of liver cirrhosis and hepatocellular carcinoma (HCC) in Taiwan. Direct-acting antivirals (DAAs) have achieved a sustained virological response (SVR) rate around 95–98% in treating HCV. Several studies suggested that treatment with DAAs may be associated with increased risk of developing HCC in the first 6–12 months. The aim of the study is to investigate the oncogenic implication of sofosbuvir (SOF) on the development of HCC.
Method: OR-6 (harboring full length genotype 1b HCV) and Huh 7.5.1 cells were used in the study. We'll examine the effects of SOF on cell proliferation, migration and invasion assay in hepatoma cells. We also will inspect the potential molecules involved in tumorigenesis effects of SOF in OR-6 cells treated with SOF using next generation sequencing (NGS). After selection of the candidate genes significantly up-regulated by SOF in OR-6 cells by NGS analysis, we'll correlate the clinical significance of these candidate genes using The Cancer Genome Atlas (TCGA) data base.
Results: We found that SOF increased cell proliferation and migration in hepatoma cells. Using NGS we have identified several genes significantly up-regulated by SOF in OR-6 cells. Among these genes, we discovered that TRIM39, TSNAX-DISC1, RPP21 and another four genes are more significantly expressed in the tumor part of HCC than non-tumor part in the TCGA data base. These genes are significantly associated with the development of HCC in the TCGA data base. Besides, siRNA mediated knock-down of TRIM39, TSNAX-DISC1 and RPP21 reduced the increased cell proliferation and migration by SOF in OR-6 and Huh 7.5.1 cells.
Conclusion: SOF up-regulated several genes associated with the development of HCC in the TCGA data base. Knock-down of these genes reduced the increased cell proliferation and migration by SOF in hepatoma cells.

THU390

Epidemiological evolution of viral hepatitis in uremic patients in Taiwan - the Formosa like group

Yu-Ju Wei[1], Jia-Jung Lee[2,3], Chung-Feng Huang[1,3], Ching-I Huang[1,3], Ming-Lun Yeh[1,3], Szu-Chia Chen[2,3], Sheng-Wen Niu[2], Lii-Jia Yang[2], Chia-Yen Dai[1,3], Jee-Fu Huang[1,3], Shang-Jyh Hwang[2,3], Wan-Long Chuang[1,3], Yi Wen Chiu[2,3], Ming-Lung Yu[1,3]. [1]*Kaohsiung Medical University Hospital, Division of Hepatobiliary, Department of Internal Medicine, Kaohsiung, Taiwan;* [2]*Kaohsiung Medical University Hospital, Division of Nephrology, Department of Internal Medicine, Kaohsiung, Taiwan;* [3]*Kaohsiung Medical University, Faculty of Internal Medicine, College of Medicine, Kaohsiung, Taiwan*
Email: fish6069@gmail.com

Background and Aims: Hepatitis B virus (HBV) and hepatitis C virus (HCV) are leading causes of chronic liver disease in hemodialysis patients in Taiwan. The treatment of HCV may be underappreciated even in the era of directly acting antivirals. Evolution of the seroprevalence of viral hepatitis and HCV treatment rate in this special population is elusive. We aimed to address the issue by performing consecutive surveillances upon the population.
Method: The Formosan Coalition for the study of Liver Disease in Chronic Kidney Disease (FORMOSA-LIKE group) consisted of 18 hemodialysis centers in 2012 and expanding to 22 centers in 2019. A total of 490 uremic patients participated both of the first mass screen in 2012 and second mass screen in 2019. All subjects were tested for HBV and HCV serology and virology.
Results: The seropositive rates of anti-HCV, HBsAg and both HBsAg/anti-HCV were 15.7% (n = 77), 14.3% (n = 70) and 2.5% (n = 12), respectively, in 2012, and 16.3% (n = 80), 13.3% (n = 65), and 3.1% (n = 15), respectively, in 2019. The HCV viremic rate among anti-HCV seropositive patients decreased significantly from 71.4% (55/77) in 2012 to 52.5% (42/80) in 2019 (p = 0.015). Thirty-nine of the 55 HCV viremic patients in 2012 had persistent viremia in 2019, whereas 16 patients became HCV RNA undetectable. Of them, 12 patients were due to HCV eradication by antivirals ([interferon [IFN]-based (n = 1), IFN free-directly acting antivirals (n = 11)] and the other 4 experienced spontaneous HCV clearances. Seven patients got new HCV

infection, including one anti-HCV seropositive patient without viremia in 2012 became viremic in 2019, and 6 anti-HCV seronegative patients became anti-HCV seropositive in 2019 (five had viremia and one was with spontaneous HCV clearance). The annual incidence of new HCV infection was 0.24% (7/490). The HCV treatment rate was 5.2% (3/58) and 21.1% (12/57) in 2012 and 2019, respectively (p = 0.01). Two patients had new HBsAg seropositivity (0.07%/year) and 7 HBsAg antigemic patients experienced HBsAg loss (0.23%/year).
Conclusion: Viral hepatitis prevails with new infection occurrence in uremic patients. The treatment of HCV infection is underutilized. Link-to-care and outreach onsite treatment are mandatory to increase the treatment uptake of HCV in the highly contagious population.

THU391

Safety and efficacy of an all-oral interferon-free regimen of seraprevir, an NS3/4A protease inhibitor and sofosbuvir in patients with chronic hepatitis C virus (HCV) genotype 1: an open-label,multicentre, phase 3 trial

Xiaoyu Wen[1], Fei Kong[1], Xiaofeng Wen[2], Xiaozhong Wang[3], Shide Lin[4], Guicheng Wu[5], Li Wang[6], Huichun Xing[7], Xuebing Yan[8], Sujun Zheng[9], Qin Ning[10], Zheng Wang[11], Liaoyun Zhang[12], Jianmei Li[13], Zhaowei Tong[14], Minghua Su[15], Lixin Tong[16], Chengyu Huang[17], Ji-Dong Jia[18], Yongning Xin[19], Qingjing Zhu[20], Jing Wang[21], Yuexin Zhang[22], Guangming Li[23], Junqi Niu[1]. *[1]The first Hospital of Jilin University, Hepatology, China; [2]Liuzhou People's Hospital; [3]Xinjiang Uygur Autonomous Region Traditional Chinese Medicine Hospital; [4]Affiliated Hospital of Zunyi Medical College; [5]Chongqing Three Gorges Central Hospital; [6]Chengdu Public Clinical Health and Medical Center; [7]Beijing Ditan Hospital, Capital Medical University; [8]Affiliated Hospital of Xuzhou Medical University; [9]Beijing Youan Hospital, Capital Medical University; [10]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology; [11]Fifth Hospital of Wuxi; [12]The first Hospital of Shanxi Medical University; [13]Sichuan Province People's Hospital; [14]Huzhou City Central Hospital; [15]The first Hospital of Guangxi Medical University; [16]The first Hospital of Hebei Medical University; [17]Chongqing Public Clinical Health and Medical Center; [18]Beijing Friendship Hospital,Capital Medical University; [19]Qingdao City Central Hospital; [20]Jinyintan Hospital of Wuhan; [21]Traditional Chinese Medicine Hospital, Southwest Medical University; [22]The first Hospital of Xinjiang Medical University; [23]Zhengzhou Sixth People's Hospital*
Email: junqiniu@aliyun.com

Background and Aims: This phase 3, single-arm, open-label, multi-center study was conducted to evaluate the safety and efficacy of an all-oral interferon-free regimen of **Seraprevir**, an NS3/4A protease inhibitor and sofosbuvir for 12weeks in patients with chronic hepatitis C virus (HCV) genotype 1.

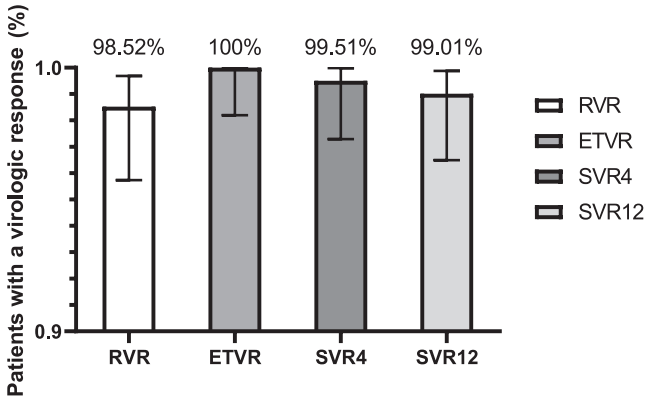

Figure 1. Efficacy of Seraprevir and sofosbuvir in patients with HCV genotype 1 infection.

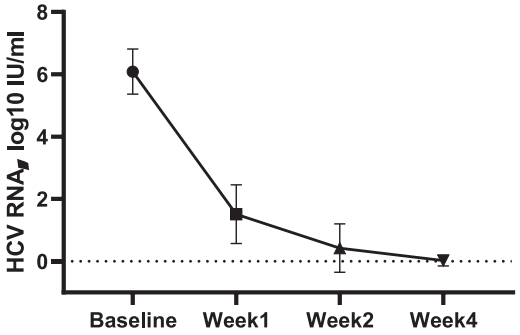

Figure 2. Changes in viral load from baseline to week 4.

Method: In this multicenter ongoing trial, 205 patients wererecruited from 23 sites in China. Eligible participants were aged 18–75 years with non-cirrhotic, chronic HCV genotype 1 infection and were 86.8% HCV treatment-naïve (178/205) or 13.2% treatment-experienced (27/205). Patients received once-daily sofosbuvir (400 mg) plus twice-daily **Seraprevir** (100 mg) for 12 weeks. The primary efficacy endpoint was sustained virological response, defined as HCV RNA less than 15 IU/mL at 12 weeks after the end of treatment (SVR12), assessed in all patients who received study drug. The primary safety endpoint was the proportion of adverse events leading to premature discontinuation of study drug. This trial is registered with ClinicalTrials.gov, number 2017L00637, and is completed.
Results: Between 17. Oct. 2018, and 17. Jan. 2019, a total of 205 patients were enrolled in the study, of whom 203 completed the full treatment course and two discontinued treatment. Overall, 45.4% were male, 2.4% had GT1a, 97.6% GT 1b HCV infection. The mean (range) age of enrolled patients was 46.9y (24–73). 13.2% had ever treated by IFN. The rate of SVR12 was 99.01% in Full Analysis Set. The overall SVR4 rate was 99.51%. One subject relapsed after 4 weeks of follow-up, and 1 subject relapsed after 12 weeks of follow-up. The most common adverse events were upper respiratory tract infection (32 [15.6%] patients). There was one discontinuation due to adverse events. Serious adverse events were reported in eight (3.9%) patients, none of which was judged to be related to sofosbuvir-**Seraprevir** treatment.
Conclusion: Treatment with the single-tablet sofosbuvir-**Seraprevir** was highly effective and well tolerated in GT1 chronic HCV infected population without cirrhosis.

THU392

Expansion of a multidisciplinary support program for patients with addictions and hepatitis C: strategies for an effective approach

Carrión[1,3], Marc Batlle[1], Susanna Coll[1,2,3], Santiago Grau Cerrato[2,3,4], Marta Torrens[2,3,13], Xavier Bessa[1,2,3]. *[1]Hospital del Mar, Liver Section, Gastroenterology Department, Barcelona, Spain; [2]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; [3]Universitat Autònoma de Barcelona, Bellaterra, Spain; [4]Hospital del Mar, Pharmacy Department, Barcelona, Spain; [5]Neuropsychiatric and Addictions Institute (INAD), Barcelona; [6]Centre d'Atenció Primària Drassanes (EAP Raval Sud), Barcelona, Spain; [7]CAS Baluard, Barcelona, Spain; [8]CAS Barceloneta, Barcelona, Spain; [9]CAS Fòrum, Barcelona, Spain; [10]CAS La Mina, Sant Adrià de Besòs, Spain; [11]Neuropsychiatric and Addictions Institute (INAD), Barcelona, Spain; [12]Cecas, Barcelona, Spain; [13]Neuropsychiatric and Addictions Institute (INAD), Barcelona, Spain*
Email: 97235@parcdesalutmar.cat

Background and Aims: In June 2018 we created a multidisciplinary support program (MSP ADIC C) at the addiction center of our hospital

to improve screening, evaluation and treatment of patients with addictions and hepatitis C. The aim of the study was to expand the experience of MSP ADIC C to the entire reference area of our hospital.
Method: we created a collaborative network of addiction centers from our reference area since February 2019. The MSP expansion has been based on: a) Screening of HCV infection at every addiction center and a fast-track referral to our MSP located in the hospital premises; b) Implementation of social educators who accompanies patients to the scheduled visits; c) Simplification of the evaluation and treatment process ("all-in-one" visit); d) Outsourcing Hospital Pharmacy; e) Coordination and evaluation. Variables related to sociodemographic and clinical aspects have been collected prospectively. We defined the impact of the MSP expansion as the increase of patients included monthly. Antiviral regimen depended on the potential drug-to-drug interactions. Treatment adherence has been analyzed in patients who have completed antiviral therapy. Follow up visits have been scheduled after achieving sustained virological response (SVR) in order to detect reinfection.
Results: We have included 56 patients from 5 addiction centers from February 2019. The expansion of the MSP has increased the number of new patients from 1,5 to 4 new patients/month (60%). The majority were men (37/56, 66%) with a median (range) age of 46 years (25–66) and 23/56 (41%) coinfected with HIV. Twenty-three out of 56 (41%) had been referred to the Hepatologist in the past but never attended the scheduled appointments. Twenty-one out of 56 (37.5%) had no stable housing. Thirty-five out of 56 (62.5%) presented recent/active drug consumption and 51/56 (91%) were under opioid substitution therapy. Thirteen patients (23.2%) were naive and 13/56 (23.2%) presented advanced fibrosis. So far, 42 patients have completed treatment with a median (range) adherence of 98% (85–100). Nineteen out of 20 (95%) patients have achieved the SVR. Nine patients (16%) were lost during follow up. To date we have not detected any reinfection
Conclusion: The expansion of the MSP ADIC C has increased significantly the number of patients with addictions that benefits from the Program and has proved to be an effective approach for achieving HCV elimination in our reference area.

THU393

Improvement of all HCV care cascade steps in IVDU treated with DAAs within a dedicated program

Alessandra Mangia[1], Fausto Campanozzi[2], Rosanna Santoro[1], Valeria Piazzolla[1], Maria Franca Rina[3], Maria Maddalena Squillante[1], Rosa Cotugno[1], Antonio Canosa[4], Massimiliano Copetti[5]. *[1]Liver Unit, IRCCS "Casa Sollievo della Sofferenza", Medical Sciences, San Giovanni Rotondo, Italy; [2]ASL Foggia, SUD Department, Torremaggiore, Italy; [3]SUD Department Policoro; [4]SUD Department Termoli; [5]Biostatistics, IRCCS "Casa Sollievo della Sofferenza", San Giovanni Rotondo*
Email: a.mangia@tin.it

Background and Aims: Screening, linkage to care and HCV treatment of past and recent intravenous drug users (IVDU) remain one of the most challenging topics in HCV eradication. In Italy, outpatients services for substance use disorders (SERDS) disseminated on the region's territory are not allowed to prescribe direct acting antivirals (DAAs). Puglia is a Southern Italian region 400 km long, and public transportation represents an additional barrier to treatment for IVDU needing to reach prescribing centres. The estimated number of IVDU in our region is 4500, the screening rate is lower than 50%. During 2018, a total of 218 IVDU have been linked to care and treated at our centre.
To improve HCV care cascade we designed a dedicated one-year program starting on June 30th, 2019 for IVDU in our geographical area, including "ad hoc" transportation.
Method: In this prospective study, 15 SERDS are connected with our Unit. The service at our Unit offers a daily fast track program of diagnosis and linkage to care to patients screened by OraQuick HCV (OraSureTechnologies Inc) at their SERDS. Patients evaluated at baseline at our centre were treated with DAAs as per physician clinical judgement. The study completed the first three months of enrollment.
Results: Of 450 patients screened at 15 SERDS, 219 HCVAb+ve were identified. Of them 109 resulted HCV RNA+ve and 109 were linked to care as compared to 73 during the previous year. Baseline characteristics of patients included in the Table. Of treated patients 89 (82%) completed treatment and follow-up wk4. Overall, SVR4 was 99% without difference between active or past IVDU. No significant DDI limited treatment. According to these preliminary results an increase of about 70% in the number of treatments was registered.

	HCV RNA+ve N=109	HCV RNA-ve N=110	HCV Ab+ve N=219
Median age (yrs) range	47.9 (22-71)	49.5 (29-69)	48.5 (22-71)
Male gender n,%	96 (88)	90 (81)	186 (85)
Mean BMI (range)	26.7 (18-49)	27.0 (18-40)	26.8 (17-49)
Diabetes n, (%)	16 (15)	6 (5)	22 (10)
Mean HCV RNA IU/ml range	2.060.000 (39-10^7)	na	2.060.000 (39-10^7)
Genotype n, (%) 1 2 3 4 Mixed Not detected	 52 (48) 4 (3.9) 45 (41) 7 (7) 1 (0.1)	110 (100)	na
PLT <100.000/mm^3 n, (%)	7 (6)	2 (2)	9 (4)
Liver stifness >12.5 Kpa n, (%)	38 (35)	10 (9)	48 (22)

Figure: (abstract: **THU393**): Baseline characteristics of HCVAb+ve patients

Conclusion: Treatment programs based on "ad hoc" services for IVDU are associated with significant improvement in all HCV care cascade steps. Despite substance use, a single patient was lost to follow-up.
Funding: This work was supported by Gilead for the study "The Puglia microelimination" NCT03923595.

Real-life efficacy and safety of direct-acting antivirals in patients with liver cirrhosis and history of hepatic decompensation: EPI-TER2 Study

Background and Aims: The aim of this study was to assess the real-life efficacy and safety of DAAs in patients with cirrhosis and history of hepatic decompensation compared to those with compensated cirrhosis, and to identify predictors of adverse events during treatment.

Method: Data of patients with chronic hepatitis C treated in Poland with DAAs and included in the EpiTer-2 database (N = 10,152) were collected retrospectively. A total of 316 patients with decompensated cirrhosis and 2397 patients with compensated cirrhosis were selected. The efficacy endpoint was sustained viral response (SVR) at 12 weeks posttreatment.

Results: The overall SVR rate was 91.4% in the intent to treat (ITT) analysis and 95.2% in the modified ITT (mITT) analysis ($p < 0.001$). Patients with decompensated liver disease had lower SVR rates in ITT analysis (86.4% vs 92.0%, $p < 0.001$) compared to those with compensated cirrhosis, while in the mITT analysis the difference was not significant (92.9% vs 95.5%, $p > 0.05$). Genotype 3 (OR 7.7; 95% CI 2.7–21.9) and BMI $\geq$ 28 kg/m^2 (OR 3.8; 95% CI: 1.4–10.4) were predictors of treatment failure. Adverse events occurred in 31.2% of patients, accounting for 144/316 (45.6%) and 702/2397 (29.3%) in patients with decompensated cirrhosis and compensated cirrhosis, respectively ($p < 0.001$). Patients with decompensated cirrhosis were at higher risk of death (5.4% vs. 0.9%; OR 6.4; 95% CI 3.4–12.3; $p < 0.0001$) or liver decompensation (21.5% vs. 1.3%; OR 25.9; 95% CI 16.8–39.8; $p < 0.0001$) during treatment/follow-up compared to those with compensated cirrhosis. Age $\geq$ 65 years (OR 2.2; 95% CI: 1.2–4.0; $p = 0.007$) and low albumins (OR 2.9; 95% CI: 1.6–5.4; $p = 0.001$) were associated with hepatic decompensation, while treatment with protease inhibitors was not (OR 0.7; 95% CI: 0.4–1.3; $p = 0.3$). Only 82.6% of patients with decompensated cirrhosis completed DAA treatment (versus 92.8% in compensated cirrhosis group; $p < 0.0001$), and were at higher risk of treatment discontinuation/modification.

Conclusion: Despite higher frequency of adverse events and treatment modifications, once completed, DAA therapy yields comparable results for decompensated and compensated cirrhosis patients.

THU395

Concomitant use of direct-acting antivirals (DDAs) and central nervous system drugs in current chronic hepatitis C patient profile

Antoni Sicras[1], Ramón Morillo Verdugo[2]. [1]*Health Economics & Outcomes Research Real Life Data, Barcelona, Spain;* [2]*Hospital Universitario Virgen de Valme, Seville, Spain*
Email: antoni.sicras@rlifedata.com

Background and Aims: High rate of comorbidity and comedication have recently been reported in Spanish population with hepatitis C. We evaluated the potential impact of concomitant use of central nervous system (CNS) drugs and new pangenotypic DAAs (pang-DAAs).

Method: Subanalysis of an observational, multicenter and retrospective study, done during 2017, in which 3,430 Spanish patients with hepatitis C and their associated concomitant medications were identified. In this subanalysis those who were receiving as a concomitant medication one of the following therapeutic groups with action on the CNS were identified: anticonvulsants, opioid analgesics, antidepressants, anxiolytics, antipsychotics, sedatives or hypnotics. A descriptive analysis of the most common CNS drugs used in our country in this population was done. These data were crossed for drug-drug interactions (DDIs) by the tool of the University of Liverpool with the pang-DAAs available in Spain (GLE/PIB, SOF/VEL and SOF/VEL/VOX).

Results: We identified 1,170 patients (34%) with hepatitis C who were receiving concomitant medication with CNS action (ATC N group): 744 (28%) patients with psycholeptic-anxiolytics, 679 (20%) with psychoanaleptics-antidepressants, 494 (14%) antiepileptics and 429 (13%) analgesics. Among the active principles belonging to these therapeutic groups and that showed potential DDIs with a panG DAAs included (>10 patients): quetiapine (n = 117), fentanyl (79), paliperidone (79), buprenorphine (51), oxycodone (38), aripiprazole (33), oxcarbamazepine (32) and clotiapine (19). The magnitude of the DDIs is labelled in Liverpool as contraindicated medication/red (oxcarbazepine), weak Interaction/yellow (buprenorphine and clotiapine) and significant Interaction/orange (the rest). With GLE/PIB seven of the eight CNS drugs showed potential DDIs (1 contraindication and 6 significant Interaction), three with SOF/VEL/VOX (1 contraindication, 1 significant Interaction and 1 weak Interaction), and two with SOF/VEL (1 contraindication and 1 weak Interaction) [see figure].

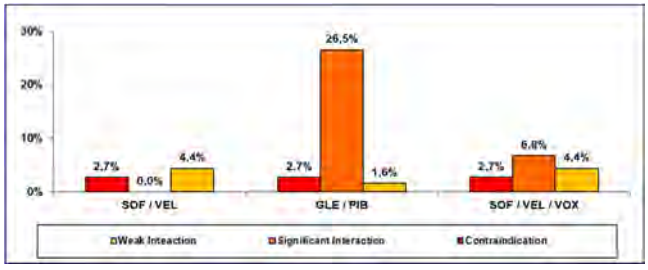

Figure: Potential DDIs between PanG-DAAs and CNS drugs (n = 1,170).

Conclusion: This analysis shows that one in three patients with hepatitis C has concomitant use of CNS drugs. Selection of a pang-DAAs with no interactions with this class of drugs is important to simplify HCV treatment. The presence of protease inhibitors in pang-DAAs may increase the number of CNSs DDIs. SOF/VEL has a lower level of interactions than other pang-DAAs.

THU396

Glecaprevir/pibrentasvir for the treatment of hepatitis C virus infection among active drug users: the grand plan study

Brian Conway[1], David Truong[1], Dorothy Rhee[1], Leo Yamamoto[1], Priya Sian[1], Robyn Parsons[1], Lauren Jones[1], Tianna Magel[1], Kelli Wuerth[1]. [1]*Vancouver Infectious Diseases Centre, Vancouver, Canada*
Email: bconway5538@gmail.com

Background and Aims: In order to achieve the WHO objective to eliminate HCV infection as a public health concern by 2030, specific strategies to identify active drug users who are infected and to engage them in care will be required. The availability of shorter course treatment regimens may allow for more efficient use of available resources and better adherence to the entire course of medications. We describe a program for the identification of vulnerable inner-city residents living with HCV infection and their engagement in a multidisciplinary program for the administration of antiviral therapy with glecaprevir/pibrentasvir (G/P).
Method: Using a community-based recruitment program (weekly outreach clinics on the Downtown Eastside of Vancouver), we identified individuals with a prior diagnosis of chronic HCV who were disengaged from care. Other individuals presented to our center by self-referral, referral from a corrections facility, or direct recruitment by existing participants in our program. All subjects were offered a broad-based intervention to address medical, social, psychiatric and addiction-related needs. Cirrhotic patients were excluded. HCV therapy was delivered in this context, with G/P dispensed on a daily, weekly or monthly basis (8 week course of treatment) to support adherence as required. The endpoint of this analysis is the achievement of a cure of HCV infection, defined as an undetectable HCV RNA 12 or more weeks after the end of treatment (SVR12).
Results: To date, 50 patients have been enrolled (mean age 47 years, 80% male, 50%/30%/46% fentanyl/cocaine/amphetamine use and 40% with an active psychiatric comorbidity, with 64% on opioid agonist therapy and 62% unstably housed at treatment start). Twenty-five patients have completed therapy, with no premature treatment discontinuations. Post-treatment, all patients (25/25) remain in follow-up, with 6 having reached the SVR12 time point and all 6 achieving SVR (SVR12 rate 100% for eligible patients). There have been no deaths in this population at high risk of opioid overdose. Treatment outcome in all patients will be available by March 2020.
Conclusion: When delivered within the context of a multidisciplinary program of care, HCV therapy with G/P for 8 weeks is highly effective in a vulnerable and marginalized population with a high prevalence of HCV infection. Approaches such as this will be an important part of HCV elimination over the next decade.

Direct-acting antiviral treatment in patients infected with a non-epidemic hepatitis C genotype in the Netherlands: results from a nationwide cohort study

Cas Isfordink[1], Thijs van der Laar[2], Els Wessels[3], Richard Molenkamp[4], Marjolein Knoester[5], Bert Baak[6], Bart Van Hoek[7], Sylvia Brakenhoff[8], Hans Blokzijl[9], Marc van der Valk[1], Janke Schinkel[10]. [1]*Amsterdam Infection & Immunity Institute Amsterdam UMC, University of Amsterdam, Division of Infectious Diseases, Amsterdam, Netherlands;* [2]*Sanquin Research, Department of Blood-borne infections, Amsterdam, Netherlands;* [3]*Leiden University Medical Centre, Department of Medical Microbiology, Leiden, Netherlands;* [4]*Erasmus MC, Department of Viroscience, Rotterdam, Netherlands;* [5]*University Medical Centre Groningen, Department of Medical Microbiology, Groningen, Netherlands;* [6]*Onze Lieve Vrouwe Gasthuis locatie Oost, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands;* [7]*Leiden University Medical Centre, Department of Gastroenterology and Hepatology, Leiden, Netherlands;* [8]*Erasmus MC, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands;* [9]*University Medical Centre Groningen, Department of Gastroenterology and Hepatology, Groningen, Netherlands;* [10]*Amsterdam UMC, University of Amsterdam, Department of Medical Microbiology, Laboratory of Clinical Virology, Amsterdam, Netherlands*
Email: c.j.isfordink@amsterdamumc.nl

Background and Aims: The majority of HCV infections are found in low- and middle-income countries (LMIC), with many region-specific endemic HCV subtypes. Nevertheless, trials with current direct-acting antivirals (DAA) were almost exclusively executed in high-income countries, where mainly global epidemically spread HCV subtypes are present. Recently, both clinical trials from LMIC and real-world studies from the Western world showed a sub-optimal DAA efficacy in certain HCV subtypes, which could hamper the global elimination of HCV. Therefore, the aim of this study was to investigate real-world efficacy of DAA treatment in all patients with a non-epidemic HCV genotype treated in the Netherlands.
Method: We performed a nationwide retrospective cohort study. All Dutch laboratories performing HCV genotyping participated. Patients infected with a non-epidemic HCV genotype and treated with an interferon-free DAA regimen were included. Non-epidemic HCV genotypes were defined as genotypes other than 1a, 1b, 2a, 2b, 3a, 4a or 4d. Genotype was determined by phylogenetic analysis of a 386 bp fragment of the NS5B region. Primary endpoint was SVR-12.
Results: We identified 122 patients. Most patients originated from either Northern Africa (31, 25%), South America (28, 23%), Sub-Saharan Africa (21, 17%) or South-East Asia (19, 16%). Cirrhosis was reported in 27 (22%) patients. SVR-12 data was available for 111 (91%) patients, of whom 100 (90%) reached SVR-12. Genotypes and SVR-percentage per genotype is shown in table 1. Remarkably, only 65% of patients with genotype 3 infection reached SVR-12, due to three failures in genotype 3b infections.

Genotype (n, %)	Subtypes (n)	SVR-12 (%, n/n)
1 (14, 13%)	c(6), d(1), g(7)	93% (13/14)
2 (44, 40%)	c(3), d(1), e(2), f(2), i(6), k(1), unassigned(29)	91% (40/44)
3 (8, 7.2%)	b(6), k(2)	63% (5/8)
4 (35, 32%)	c(2), f(2), h(5), k(4), l(2), n(6), o(6), q(1), r(3), t(1), v(1), unassigned(3)	94% (33/35)
5 (1, 0.9%)	a(1)	100% (1/1)
6 (9, 8.2%)	a(4), e(1), unassigned(4)	89% (8/9)

Figure: (abstract: THU397): non-epidemic HCV genotypes with SVR-12 result

Conclusion: DAA treatment results in most non-epidemic genotypes in the Netherlands seem reassuring. However, the low SVR-12 rate in genotype 3 infections is alarming, especially as this genotype is common in certain countries with high HCV prevalence. Together with earlier published results, these results show that one of the remaining challenges for global HCV elimination is confirmation and monitoring of DAA treatment effectiveness in non-epidemic genotypes.

THU398

A real-world study of treating advanced liver cirrhosis due to chronic HCV infection genotype 1b with sofosbuvir+ ledipasvir with or without ribavirin: results from a cohort of 349 patients

Carmen Monica Preda[1], Liana Gheorghe[1], Doina Istratescu[1], Mircea Mănuc[1], Corina Pop[2], Grigore Andreea[1], Speranta Iacob[1], Teodora Manuc[1], Letiția Țugui[1], Cristian Tieranu[3], Mircea Mihai Diculescu[1], Elena Laura Iliescu[4]. *[1]Fundeni, Gastroenterology&Hepatology, București, Romania; [2]Spitalul Universitar de Urgență București, Gastroenterology&Hepatology, București, Romania; [3]Spitalul Universitar de Urgență Elias, Gastroenterology&Hepatology, București, Romania; [4]Fundeni, Internal Medicine Department, București, Romania*
Email: carmenmonica.preda@gmail.com

Background and Aims: Sofosbuvir+Ledipasvir±Ribavirin showed good results in terms of efficacy and safety in clinical trials in advanced liver cirrhosis, but real life data are still needed in order to confirm this profile.
Method: We analyzed a multicentric prospective cohort enrolling 349 patients with liver cirrhosis (210 decompensated, 139 compensated) due to chronic hepatitis C who received Sofosbuvir + Ledipasvir ± Ribavirin for 12/24 weeks (301/48). Patients were included between september 2018- september 2019 and all of them had genotype 1b. Main inclusion criteria were liver cirrhosis and detectable HCV RNA. The cases were followed-up monthly during therapy and then at 12 weeks after the end of therapy.

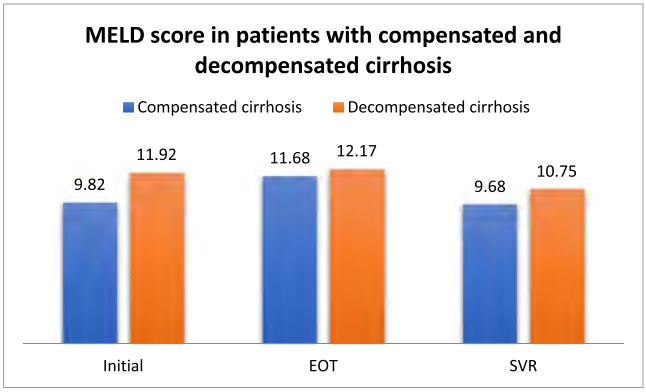

Figure: The evolution of MELD score in patients with compensated and decompensated cirrhosis and HCV infection treated with Sofosbuvir + Ledipasvir ± Ribavirin.

Results: 6 patients were lost during follow-up and in 16 patients (4.6%) treatment was interrupted due to adverse events: 9 with worsening hepatic decompensation (4.3%), 4 patients had cardiovascular events, 1 severe alergy and 2 bacterial infections. This cohort had 60% females with a median age of 61 years (37÷83), 12.4% IFN pre-treated, 50% with co-morbidities, 7% with Child Pugh C, 5% with virus B co-infection and 7% with treated HCC. Mean initial MELD score was 10.92 ± 3.01 (7.1÷24.5). Sustained viral response in intention to treat was reported in 175/210 (83.3%) in patients with decompensated cirrhosis and 122/139 (87.8%) in cases with compensated cirrhosis. The evolution of MELD score is depicted in figure. Predictive factors of SVR in decompensated cirrhosis were: decreased bilirubin ($p = 0.01$), absence of ascites ($p = 0.008$) and lower Child Pugh score ($p = 0.01$). In compensated cirrhosis female sex ($p < 0.001$), advanced age ($p = 0.001$), absence of ascites at therapy initiation ($p = 0.018$), no history of variceal bleeding ($p = 0.05$) predicted SVR.
Conclusion: Sofosbuvir+Ledipasvir±Ribavirin proved to be highly efficient in our difficult to treat population with 83.3% SVR in decompensated cirrhosis and 87.8% in compensated cirrhosis. Serious adverse events were reported in 16/349 (4.6%), most of them due to severe liver decompensation (9/16). Predictors of SVR in decompensated cirrhosis were: decreased bilirubin, absence of ascites, low Child Pugh score, while in compensated cirrhosis female sex, advanced age, absence of ascites and no history of variceal bleeding predicted a good response.

THU399

Alcohol use does not influence treatment uptake or outcomes in the DAA era

Curtis Cooper[1], Marie-Louise Vachon[2], Brian Conway[3], Alexander Wong[4], Alnoor Ramji[5], Sergio Borgia[6], Edward Tam[7], Lisa Barrett[8], Daniel Smyth[8], Jordan Feld[9], Samuel Lee[10]. *[1]University of Ottawa; [2]Université Laval; [3]Vancouver Infectious Diseases Centre, Vancouver, Canada; [4]University of Saskatchewan, Saskatoon, Canada; [5]The University of British Columbia, Vancouver, Canada; [6]McMaster University, Hamilton, Canada; [7]Liver Health Centre, Vancouver; [8]Dalhousie University, Halifax, Canada; [9]Toronto General Hospital Research Institute, Toronto; [10]University of Calgary, Calgary, Canada*
Email: ccooper@toh.ca

Background and Aims: Alcohol use is well recognized for accelerating liver disease in the context of HCV and often led to delayed initiation of interferon-based treatment. To successfully eliminate HCV, it is important to treat all persons living with HCV, including those in difficult to treat individuals. However, there are limited data on the influence of alcohol use on treatment initiation and outcome in the DAA era.
Method: The Canadian Network Undertaking against Hepatitis C (CANUHC) Cohort contains prospectively collected demographic information and HCV DAA treatment information collected at 10 Canadian sites. Self-reported alcohol (define as: (a) any use, (b) number of drinks per day/week/month) and other recreational substance use is collected. Characteristics and outcomes (SVR) were compared by past and present alcohol use.
Results: Since January 2016, 725 HCV-infected patients under assessment for DAA therapy were enrolled in CANUHC (mean age: 53 (SD 12.7); 66% male; 78% White, 5% Indigenous, 4% South East Asian, 4% South Asian, 3% Black). Any past and present alcohol use was reported by 37% and 30%, respectively. Mean age was older in those with [54.5 (SD 11.9)] vs without current alcohol use [51.9 (SD 12.9), $p < 0.01$]. A similar proportion of males (31%) and females (27%) reported current alcohol use ($p = 0.27$). The overall mean (10.8 kPa (SD 10.0) vs 10.9 kPa (SD 9.2)] and median (F2) baseline fibrosis measures were similar in current alcohol users. Treatment initiation during the period of evaluation was similar in current alcohol (42%) vs non users (39% in both groups, $p = 0.52$). SVR rates of 92.3% and 92.0% were similar in those with and without current alcohol use ($p = 0.93$).
Conclusion: DAA antiviral therapy is successful irrespective of past or current self-reported alcohol use. There is no evidence of diminished SVR in those concurrently using alcohol. These findings provide support from the Canadian context to recommend treatment of all people living with HCV, particularly in the context of alcohol use, in HCV elimination efforts.

THU400

Influence of baseline resistance on treatment outcome in patients treated for chronic hepatitis C in Denmark: a nationwide study

Ulrik Fahnøe[1,2], Martin Schou Pedersen[1,2,3], Christina Sølund[1,2,4], Sofie Hallager[4], Anja Ernst[5], Henrik Krarup[5,6,7], Birgit Thorup Røge[6,8], Peer Brehm Christensen[6,9,10], Alex Laursen[6,11], Jan Gerstoft[6,12,13], Peter Thielsen[6,14], Lone Madsen[6,13,15], Anders Gorm Pedersen[16], Kristian Schønning[3,13], Nina Weis[4,6,13], Jens Bukh[1,2,6]. *[1]Copenhagen University Hospital, Hvidovre, Copenhagen Hepatitis C Program (CO-HEP), Department of Infectious Diseases, Hvidovre, Denmark; [2]Copenhagen University, Department of Immunology and Microbiology, Faculty of Health and Medical Sciences, Copenhagen N, Denmark; [3]Copenhagen University Hospital, Hvidovre, Department of Clinical Microbiology, Hvidovre, Denmark; [4]Copenhagen University Hospital, Department of Infectious Diseases, Hvidovre, Denmark; [5]Aalborg University Hospital, Department of Molecular Diagnostics, Aalborg, Denmark; [6]The Danish Database for hepatitis B and C (DANHEP); [7]Aalborg University Hospital, Department of Medical Gastroenterology, Aalborg, Denmark; [8]Lillebaelt Hospital, Department of Medicine, Kolding, Denmark; [9]Odense University Hospital, Department of Infectious Diseases, Odense, Denmark; [10]University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense, Denmark; [11]Aarhus University Hospital, Skejby, Department of Infectious Diseases, Aarhus N, Denmark; [12]Copenhagen University Hospital, Rigshospitalet, Department of Infectious Diseases, Copenhagen Ø, Denmark; [13]University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen N, Denmark; [14]Copenhagen University Hospital, Herlev, Department of Gastroenterology, Herlev, Denmark; [15]Zealand University Hospital, Køge, Department of Medical Gastroenterology, Køge, Denmark; [16]Technical University of Denmark, Lyngby, DTU Bioinformatics, Lyngby, Denmark*
Email: jbukh@sund.ku.dk

Background and Aims: Direct acting antivirals (DAAs) have proven highly effective against chronic hepatitis C virus infection. However, some patients experience treatment failure, frequently associated with resistance associated substitutions (RASs). Our aim was to investigate the complete viral open reading frame (ORF) in hepatitis C patients with treatment failure, in order to detect RASs and the effects of treatment on the viral population.

Method: Chronic hepatitis C patients in the Danish Database for hepatitis B and C, who initiated DAA treatment between 1st January 2014–1st May 2015 were included and 21 patients with treatment failure were identified. We selected 22 patients with sustained virologic response (SVR) to match the 21 treatment failure patients in relation to genotype (GT), DAA regimen, liver cirrhosis and previous treatment experience. Data on viral titers were compared between the two patient groups and full-length ORF RT-PCR was performed to analyse the entire coding sequence, including identification of RASs.

Results: The proportion of NS5A RASs at baseline were significantly higher in treatment failure patients (82%) than in the matched SVR (25%) patients ($p = 0.0063$). In addition, treatment failure could be associated to slower declines in viremia titers. Viral population heterogeneity did not differ at baseline between SVR and treatment failure patients, but a bottleneck effect was observed post failure related to RASs selection. The substitution 150 V in the NS5B region at baseline was found in 4 (80%) out of 5 GT3a patients with treatment failure compared to only 1 out of 5 (20%) GT3a patients with SVR. Six retreated patients (35%) experienced 2nd treatment failure. RASs against the used DAA regimen in retreated patients were present prior to initiation of retreatment in 4 (67%) out of 6 patients compared to 2 (20%) out of 10 patients who achieved SVR after retreatment.

Conclusion: Baseline resistance to NS5A inhibitors was associated with treatment failure indicating that RAS at baseline may affect treatment outcome. The substitution 150 V in the NS5B region at baseline was associated with treatment failure to sofosbuvir in GT3a patients. The lower viral titer decline in the treatment failure group was associated with RAS present against the used DAA regimen at baseline. We found that successful DAA retreatment in patients with treatment failure was hampered by previously selected RASs. We recommend resistance testing in patients with previous DAA treatment failure before DAA retreatment in order to increase the chance of cure and prevent development of multi-resistant viruses in the future.

THU401

Inadvertent "off label" DAA treatment in the real-world and importance for virologic outcome - data from the German hepatitis C-Registry (DHC-R)

Peter Buggisch[1], Annika Schmitt[2], Stefan Mauss[3], Klaus Boeker[4], Hartwig Klinker[5], Albrecht Stoehr[1], Renate Heyne[6], Markus Cornberg[7], Christoph Sarrazin[2,8], German Hepatitis C-Registry[9]. *[1]ifi-Institute for Interdisciplinary Medicine, Hamburg, Germany; [2]St. Josefs-Hospital, Medical Clinic 2, Wiesbaden, Germany; [3]Center for HIV and Hepatogastroenterology, Düsseldorf, Germany; [4]Center of Hepatology, Hannover, Germany; [5]University Hospital Würzburg, Würzburg, Germany; [6]Leberzentrum am Checkpoint, Berlin, Germany; [7]Hannover Medical School, Hannover, Germany; [8]University Hospital Frankfurt, Frankfurt am Main, Germany; [9]Leberstiftungs-GmbH Deutschland, Hannover, Germany*
Email: csarrazin@joho.de

Background and Aims: Correct selection of DAA regimens and treatment duration for patients with chronic hepatitis C depend on clinical and virologic features. Frequency and potential reduced SVR rates for off-label use are not well known.

Method: The DHC-R (German Hepatitis C-Registry) is a national multicenter real-world registry including about 16,500 patients recruited by more than 250 centers. For the present analysis, data were analyzed as of Jan 20, 2019. All patients who received Glecaprevir/Pibrentasvir (G/P), Ledipasvir/Sofosbuvir (LDV/SOF), Velpatasvir/Sofosbuvir alone (VEL/SOF), with Voxilaprevir (V/V/S) and Grazoprevir/Elbasvir (GZR/EBR) were included. Data were analyzed with respect to in-label or off-label use of the given DAA regimen according to package insert and guidelines.

Results: For pangenotypic regimens (G/P, VEL/SOF, V/V/S) off-label use was observed infrequent (4.1–5.2%) while for LDV/SOF and GZR/EBR many patients were treated outside of the label or guidelines (27.3–36.3%).

Most frequent deviations from the label for G/P and VEL/SOF were shorter or longer treatment duration and not approved pre-treatment. Unnecessary addition of RBV was never used for G/P and VEL/SOF but was the only non-approved deviation for V/V/S.

SVR rates in "off-label" patients for G/P, VEL/SOF and V/V/S were 97% (37/38), 100% (10/10) and 100% (3/3), respectively.

For LDV/SOF the most frequent deviation to the label was unnecessary extension of treatment duration. However, for HCV GT 1, 4–6 infected patients irrespective of the cause of off-label use and other predictors like cirrhosis SVR rates remain high with 96–97% in comparison to 96–99% in patients treated in-label. For non-recommended use of LDV/SOF in HCV GT 2 and 3 infected patients SVR rates were low overall (88%) and in patients with shortened treatment duration (76%).

For GZR/EBR the most frequent deviation was not allowed pre-treatment. However, comparable SVR rates were observed for patients treated in- and off-label (98% versus 97%). No differences were observed with respect to the reason of off-label use, HCV subtype 1a versus 1b, baseline viral load and baseline RASs.

Conclusion: Most likely due to simplicity off-label administration of pangenotypic DAA regimen like G/P, VEL/SOF and V/V/S is rare and not associated with reduced SVR rates. Despite frequent inadvertent off-label use for LDV/SOF and GZR/EBR no reduced SVR rates were observed with exception to the use of LDV/SOF in HCV GT 2 and 3.

THU402

Real-world retreatment of HCV-infected patients with prior failure to direct acting antiviral therapy using sofosbuvir, velpatasvir and voxilaprevir

David A Smith[1], Daniel Bradshaw[2], Jean Mbisa[2], Carmen Manso[2], David Bibby[2], Josh Singer[3], Emma Thomson[3], Anna da Silva Filipe[3], Elihu Aranday-Cortes[3], Azim Ansari[1], Anthony Brown[1], Emma Hudson[1], Jennifer Benselin[4], Brendan Healy[5], Phil Troke[6], John Mclauchlan[3], Eleanor Barnes[1], William Irving[4]. *[1]University of Oxford, Peter Medawar Building for Pathogen Research, Nuffield Department of Medicine, Oxford, United Kingdom; [2]Public Health England, National Infection Service, London, United Kingdom; [3]University of Glasgow, MRC-University of Glasgow Centre for Virus Research, Glasgow, United Kingdom; [4]University of Nottingham and Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [5]Public Health Wales, Microbiology Cardiff, University Hospital of Wales, Cardiff, United Kingdom; [6]Gilead Sciences Ltd, London, United Kingdom*
Email: david.smith@ndm.ox.ac.uk

Background and Aims: Sustained viral response (SVR) rates to first-line Direct Acting Antiviral (DAA) therapy routinely exceed 95%. However, a small number of patients require retreatment. Sofosbuvir, velpatasvir and voxilaprevir (SOF/VEL/VOX) is a potent DAA combination primarily used for the retreatment of patients failed by first line DAA therapies. Bourliere, et al showed in the POLARIS-1 phase 3 retreatment study of NS5A-experienced patients, SOF/VEL/VOX showed a very high SVR rate in genotype (GT)1 infected patients (97% SVR12; 0.7% virologic failure (VF)); however a higher virologic failure rate in GT3 patients was observed (95% SVR12; 5% VF). Here we evaluate virologic outcomes and the effects of resistance associated substitutions (RAS) in the largest real-world cohort of GT3 infected patients, retreated with SOF/VEL/VOX to date.
Method: Full-length genome, next-generation sequencing using target enrichment was performed on 215 patients following virologic failure with DAA treatment regimens in the UK. All patients were retreated with 8–24 weeks of SOF/VEL/VOX. HCV subtypes were assigned and RAS relevant to each genotype were identified (15% read cut-off) using a bespoke pipeline based on HCV-GLUE (hcv-glue.cvr.gla.ac.uk).

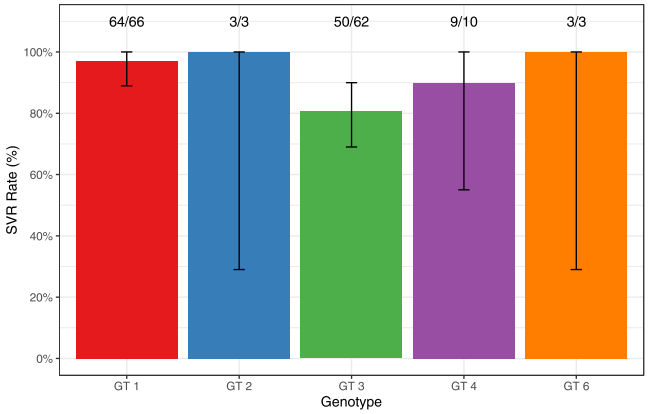

Figure 1: SVR12 rates for SOF/VEL/VOX against each HCV genotype. 95% confidence intervals shown by black lines.

Results: Of 215 patients, 35% were GT1a, 35% were GT3a, 5% GT1b, 2.5% GT4r, 2.5% GT3b, whilst 17 other subtypes were identified from genotypes 1,2,3,4 and 6. RAS against NS5A inhibitors were the most common (68%, n = 147) with the Y93H RAS being identified in 25% (n = 54) of sequences. Treatment outcomes are not currently known for 67 patients and 4 patients were lost to follow up, leaving 144 with known treatment outcomes. Of these, 40% (n = 58) had liver cirrhosis with 7% (n = 4) diagnosed as decompensated, 10% (n = 14) had HCC and 8% (n = 12) had received liver transplant prior to retreatment. The overall re-treatment SVR12 rate was 90% (129/144). The SVR rate for non-gt3 infected patients was 96% (79/82) whereas the SVR for GT3 infected patients was significantly lower 81% (50/602) ($p = 0.002$) (Figure 1). On univariate analysis, HCV GT3 ($p = 0.004$), cirrhosis ($p = 0.01$) and Y93H ($p = 0.03$) RAS were significantly associated with retreatment failure. However, in multivariate analysis only viral GT3 was associated with virologic failure ($p = 0.05$).
Conclusion: Although the overall rates of SVR in non-GT3 patients following retreatment with SOF/VEL/VOX are high, we show that in a large cohort of GT3 infected patients retreated with this regimen, SVR was only 81%. This may have important implications for elimination strategies in regions where GT3 dominates.

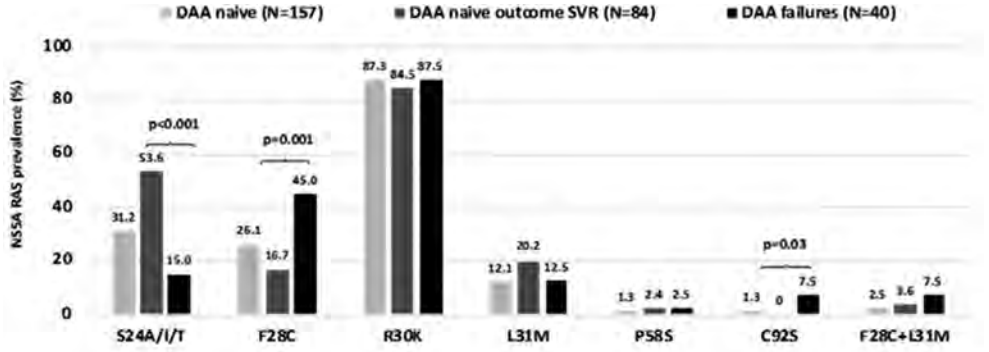
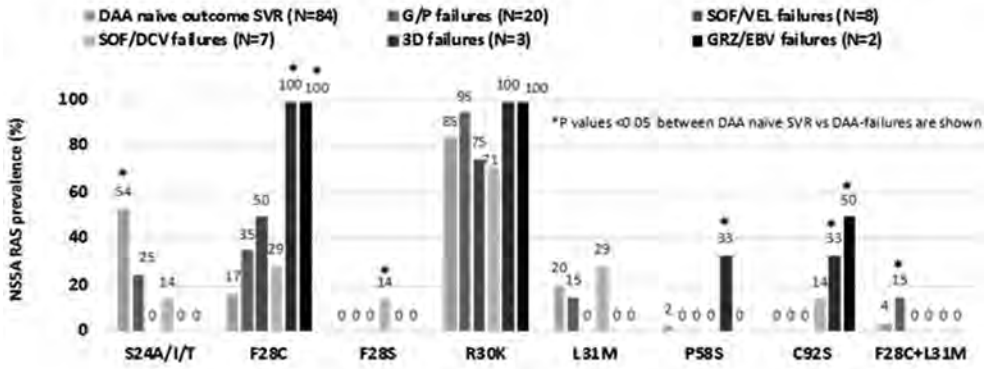
Background and Aims: HCV genotype 2 (GT2), particularly subtype c, is the second most prevalent GT in Italy after GT1b. Few data are available regarding the resistance-associated-substitutions (RASs) to direct acting antivirals (DAA) in GT2c. Therefore, the aim of this study





HCV GT2c clusters

Figure: (abstract: **THU403**): Prevalence of NS5A resistance associated substitutions in DAA-naïves and DAA-failed & phylogenetic clusters in GT2c infected patients.

was to investigate the prevalence and role of RASs and presence of phylogenetic clusters in GT2c, in Italy.
Method: Within the Italian VIRONET-C network, a total of 248 GT2 infected patients (pts) (204 DAA-naïve and 44 NS5A-failed), were analyzed. Sanger-sequencing of NS3/NS5A/NS5B was performed following home-made protocols. RAS and polymorphisms in NS3 (N = 167) and NS5A sequences (N = 197) were analysed. Cluster analysis was performed on NS5A sequences by Bayesian analysis (posterior probability ≥ 0.98).
Results: The majority of pts were Italians (92%), males (56%) with a median (IQR) age of 69 years (54–78); 2.5% were HIV co-infected and 25% cirrhotics. Phylogenetic analysis classified sequences as GT2a-2b-2c (4%-<1%-96%), respectively. Interestingly, a total of 11 transmission clusters (7 with 2 sequences and 4 with >3 sequences) were identified among GT2c infected pts. In particular, 9 clusters involved 23 pts from Northern Italy (all SVR, except one), 1 pair from Center (both SVR) and 1 pair from Northern-Southern (both DAA-failed; Fig). 84 DAA-naïve pts with SVR and 40 DAA-failed with GT2c infection were treated with the following recommended regimens: glecaprevir (G)/pibrentasvir(P) (18/20), sofosbuvir(SOF)/velpatasvir (VEL)±ribavirin (RBV) (54/8), SOF/daclatasvir±RBV (12/7), while suboptimal regimens for misclassified genotype were Paritaprevir/r+Ombitasvir +Dasabuvir±RBV (N = 0/3), grazoprevir/elbasvir (N = 0/2).
Notably, a different distribution of specific NS5A RASs was found among DAA-SVR pts versus DAA-failed, particularly among those exposed to suboptimal regimens (Fig). Only the pattern F28C+L31M was statistically significant associated with G/P failures. No naïves nor no failed with GT2c infection showed Y93FHNRS RASs. Considering NS3, >95% of DAA-naïves and DAA-failed showed 80G and 56F. Notably, 4/25 (16%) GT2c NS3-failures showed D168A/V and/or F56H/Y never detected in DAA-naïve pts.
Conclusion: In this large Italian cohort of GT2 infected pts, the most prevalent subtype was the unusual subtype c. The majority of GT2c failures with recommended regimens did not show specific HCV RAS at failure. Further structural and phenotypic analyses should investigate the role of the common polymorphisms observed in GT2c.

Grazoprevir/elbasvir for treatment of hepatitis C virus genotype 4 post kidney transplant

Faisal Abaalkhail[1,2], Hazem Hasan[3], Hussien Elsiesy[4], Waleed Alhamoudi[3,5]. [1]*King Fahd Specialist Hospital Dammam, Liver Transplant, Saudi Arabia;* [2]*Alfaisal University, Riyadh, Saudi Arabia;* [3]*King Faisal Specialist Hospital Riyadh, Riyadh, Saudi Arabia;* [4]*Baylor Scott & White All Saints Medical Center-Fort Worth, Fort Worth, United States;* [5]*King Saud University, Riyadh, Saudi Arabia*
Email: docabaalkhail@yahoo.com

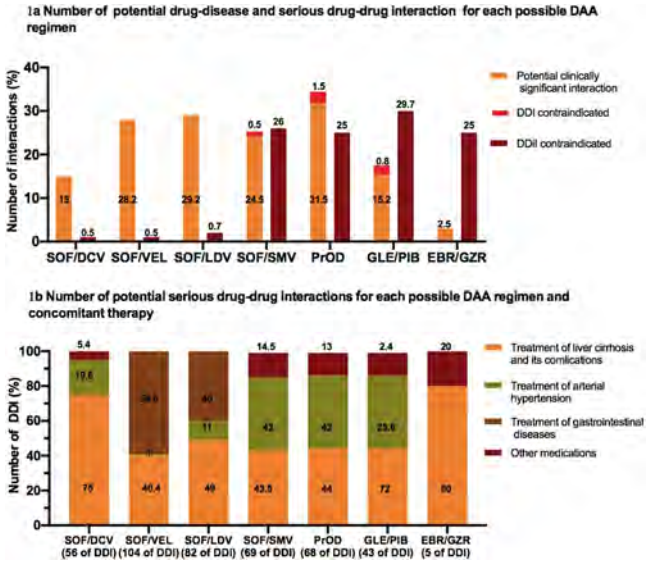
Background and Aims: Hepatitis C virus (HCV) infection affects about 150 million individuals worldwide and is a major cause of chronic hepatitis C, hepatocellular carcinoma, and liver cirrhosis leading to liver transplant or death. The overall prevalence of HCV in Saudi Arabia is estimated to fall between 0.3 to 1.1 percent. HCV genotype 4 was identified as the most prevalent genotype followed by genotype 1. Renal transplant recipients have a HCV infection rate of 5 to 15% in the developed countries, with higher rates reported in the developing world. Evidence suggests that the long-term graft and patient survival rates of HCV positive renal transplant recipients were significantly lower than that of HCV negative patients. There is however very limited data on the use of direct acting antivirals in patients with HCV genotype 4 post renal transplant. Our objective is to study the efficacy and safety of Grazoprevir/Elbasvir combination treatment without ribavirin in patients with HCV genotype 4 post renal transplant.
Method: It is a prospective, single arm, interventional, cohort study at King Faisal Specialist Hospital Riyadh that included all adult HCV genotype 4 infected patients post renal transplant with stable graft function. Patients received Grazoprevir/Elbasvir combination without ribavirin daily for 12 weeks. Patients co-infected with Hepatitis B Virus, Human Immunodeficiency Virus or has evidence of decompensated liver disease were excluded. Response was defined by sustained virologic response 12 weeks after completion of therapy (SVR 12).
Results: Nine patients with HCV genotype 4 infection post renal transplant were treated in our center. Three patients had mixed genotype 4 and 1 (33%). All patients (100%) were naïve to therapy. 2 had fibrosis score 0 (22%), 3 had Fibrosis score 1 (33%), 1 had Fibrosis score 2/3 (11%), and 3 had Fibrosis score 4 (33%). Week 4 HCV Polymerase chain reaction (PCR) was negative in all patients out of 9 with a treatment response of 100%. All patients completed the treatment period. SVR 12 was achieved in 100% of patients with no treatment failure or relapse. There was no any major or minor side effects during treatment. Renal function was stable during and after treatment period with no deterioration of graft function. The over all SVR 12 was 100%.
Conclusion: Grazoprevir/Elbasvir combination without ribavirin is an effective and safe treatment option for patients with HCV infection genotype 4 in the post renal transplant setting.

THU405
Drug - drug and drug - disease interactions in the treatment of hepatitis C in patients with liver cirrhosis: a single-center experience

Ekaterina Nabatchikova[1], Dzhamal Abdurakhmanov[1], Teona Rozina[1,2], Elena Nikulkina[1], Elena Tanashchuk[1], Sergey Moiseev[1,2]. [1]*Sechenov First Moscow State Medical University, Moscow, Russian Federation;* [2]*Lomonosov Moscow State University, Moscow, Russian Federation*
Email: e.nabat4ikova@gmail.com

Background and Aims: Direct acting antivirals (DAAs) have a high rate of SVR with little side effects and short treatment duration. However, these agents can be involved in drug-drug (DDI) and drug-disease (DDiI) interactions, that can adversely impact the effectiveness and safety of treatment. The aim of study was to assess the prevalence of comorbidities, concomitant medications and the frequency of potential DDIs and DDiIs in patients with hepatitis C virus (HCV) related liver cirrhosis.
Method: Our observational non-interventionist study included 192 patients with HCV-related cirrhosis. Median patients age was 54 [29–72] years, 47% were male, 70.3% had a genotype 1 and 29.7% - Child - Pugh class B/C. We described predicted drug interactions with the concomitant drug and diseases based on data available at www.hep-druginteractions.org and prescribing information.
Results: Overall, 159 (83%) of patients in the study had comorbidities with mean number 2.6. Most common comorbidities were arterial hypertension (37.7%), gastritis (36.5%) and diabetes mellitus (24.5%). Two (1%) patients had a glomerular filtration rate <30 ml/min. Overall, 144 (75%) patients took at least one concomitant medication, ranging from 1 to 9 per patient. Beta-blockers (18.6%), gastrointestinal agents (18%), diuretics (15%) were most frequently used. Overall, 369 medications were prescribed, 30.5% of them - for management of liver cirrhosis and its complications (non-selective beta-blockers, diuretics, anticoagulants, antimicrobials). Protease inhibitors-containing regimens have shown a high frequency of dangerous DDiIs due to the presence of decompensated liver cirrhosis in a third of our patients (figure a). Overall, 44% of prescribed medications have demonstrated clinically significant or dangerous interactions with at least one of the DAA regimens (figure a). The contraindicated drugs

count for up 1.6% of the predicted interactions and included calcium channel blockers, statins, antimicrobials and direct oral anticoagulants. Other drugs induced clinically significant DDIs and also included beta-blockers, diuretics, angiotensin converting enzyme inhibitors, steroids. Proton pump inhibitors were responsible for many clinically relevant interactions with velpatasvir and ledipasvir due to high incidence of acid-related disorders in the patients in our cohort (figure b).



Conclusion: The majority of patients with liver cirrhosis are at risk for clinically relevant drug interactions due to high incidence of comorbidities and concomitant therapy. The potential for DDIs and DDIls is still an important consideration in determining an optimal DAA regimen and the adjustment of concomitant medications.

THU406

Integrated efficacy and safety analysis of GT1-6 treatment-naive, non-cirrhotic and compensated cirrhotic patients who received 8 weeks of glecaprevir/pibrentasvir

Eli Zuckerman[1], Julio Gutierrez[2], Doug Dylla[3], Victor de Lédinghen[4,5], Andrew Muir[6], Michael Gschwantler[7,8], Massimo Puoti[9], Jihad Slim[10], Frederik Nevens[11], Linda Fredrick[3], Ana Gabriela Pires dos Santos[3], Lino Rodrigues, Jr.[3], John Dillon[12]. *[1]Liver Unit, Carmel Medical Center, Faculty of Medicine, Technion Institute, Haifa, Israel; [2]St. Vincent Medical Center, Los Angeles, CA, United States; [3]AbbVie Inc., North Chicago, IL, United States; [4]Bordeaux University Hospital, Centre d'Investigation de la Fibrose Hépatique, Pessac, France; [5]Bordeaux University, INSERM U1053, Bordeaux, France; [6]Duke Clinical Research Institute, Durham, NC, United States; [7]Wilhelminenspital, Department of Internal Medicine IV, Vienna, Austria; [8]Sigmund Freud University, Vienna, Austria; [9]Niguarda ca Grande Hospital, Milan, Italy; [10]St. Michael's Medical Center, Infectious Disease Division, Department of Internal Medicine, Newark, NJ, United States; [11]University Hospitals Leuven, Department of Gastroenterology and Hepatology, KU Leuven, Belgium; [12]University of Dundee, Division of Molecular and Clinical Medicine, School of Medicine, Dundee, United Kingdom*
Email: elizuc56@gmail.com

Background and Aims: The once-daily, all-oral, fixed-dose direct-acting antiviral combination glecaprevir (developed by AbbVie and Enanta) and pibrentasvir (G/P) is approved for chronic hepatitis C virus (HCV) infection in adults with genotypes (GT) 1–6. In the US, G/P is approved for an 8-week duration in HCV GT1–6, treatment naïve (TN), non-cirrhotic (NC) and cirrhotic patients (CC). In Europe, 8 weeks is indicated for HCV GT1–6 TN NC, and TN CC with GT1, 2, 4–6. In GT3 TN CC, 12 weeks is still recommended. This integrated analysis of label-consistent data evaluates the efficacy and safety of G/P for 8 weeks in NC and CC, TN patients.
Method: Data were pooled from TN patients with HCV GT1–6, receiving current label-consistent
8-week G/P across 8 Phase 2 and 3 clinical trials. Analyses were in intention-to-treat (ITT) and modified ITT (mITT; excluding non-virologic failures) populations.
Results: The table shows baseline demographics. Rates of sustained virologic response at Post-treatment Week 12 (SVR12) for NC patients with HCV GT1–6 were 97.6% (883/905) in the ITT and 99.2% (883/890) in the mITT populations. In NC and CC patients with HCV GT1–6, SVR12 rates were 97.6% (1218/1248) in the ITT and 99.3% (1218/1226) in the mITT populations. The SVR12 rates for NC and CC patients with HCV GT 1–6, excluding CC GT3 patients, were 97.6% (1157/1185) and 99.4% (1157/1164) in the ITT and mITT populations, respectively. Across all 3 groups, SVR12 rates remained high regardless of GT (94.3–100%); the GT3 ITT SVR rate was 95.4% for each group. The percentage of patients experiencing adverse events (AEs) was similar for all 3 groups (58–62%). The 3 most frequent AEs in each group were headache, fatigue, and nausea. In all groups, serious AEs were reported in <3% of patients and AEs led to study drug discontinuation in <1% of patients.
Conclusion: These data support 8-week treatment with G/P in TN GT1–6 patients, regardless of cirrhosis status, thus simplifying pre-treatment assessments for the selection of one short duration for most patients.

Table: (abstract: THU406): Baseline demographics

n (%) or mean ±SD	G/P for 8 weeks		
	GT1–6, TN, NC (n = 905)	US Label GT1–6, TN, NC/CC (n = 1248)	EU Label GT1–6, TN, NC/CC (excl. CC GT3) (n = 1185)

Hepatitis C micro-elimination pilot strategy in Pakistani migrants in Catalonia through the implementation of a community intervention: interim results of the HepC-link study

Jordi Gómez i Prat[1], Hakima Ouaarab[1], Tahir Rafi[1], Verónica Saludes[2,3], Sara González-Gómez[2], Adrian Antuori Torres[2], Maria Buti[4,5], Mar Riveiro Barciela[4,5], Luisa Roade[4,5], Blanca Borrás[1,6], Laia Egea-Cortés[7], Laia Ferrer[3,7], Juliana Reyes-Ureña[3,7], Xavier Major[8], Elisabeth Buira[8], Joan Colom[9], Jordi Casabona[3,7], Elisa Martró[2,3]. *[1]Vall Hebrón-Drassanes International Health Unit, Barcelona, Spain; [2]Germans Trias i Pujol University Hospital and Research Institute (IGTP), Microbiology Department, Clinical Laboratory North Metropolitan Area, Badalona, Spain; [3]Instituto de Salud Carlos III, Biomedical Research Networking Centre in Epidemiology and Public Health (CIBERESP), Madrid, Spain; [4]Vall Hebrón University Hospital, Hepatology Department, Barcelona, Spain; [5]Instituto de Salud Carlos III, Biomedical Research Networking Centre in Hepatic and Digestive Diseases (CIBEREHD), Madrid, Spain; [6]Vall Hebrón University Hospital, Department of Preventive Medicine and Epidemiology, Barcelona, Spain; [7]Centre for Epidemiological Studies on Sexually Transmitted Infections and HIV/AIDS of Catalonia (CEEISCAT), Catalonia Public Health Agency (ASPCAT), Badalona, Spain; [8]Catalonia Public Health Agency (ASPCAT), Barcelona, Spain; [9]Program for the Prevention, Control and Care of HIV, Sexually Transmitted Infections and Viral Hepatitis, Catalonia Public Health Agency (ASPCAT), Barcelona, Spain*
Email: emartro@igtp.cat

Background and Aims: Subjects from Pakistan living in Catalonia could have a high rate of hepatitis C virus (HCV) infection, and may have limited access to the health system. Therefore, it is necessary to design and evaluate strategies specifically targeting this collective to achieve HCV micro-elimination. The aim of this study was to implement and evaluate a community intervention that brings together education, screening and simplified access to treatment in this population.

Method: HepC-link is a prospective study with opportunistic sampling of 500 migrants from Pakistan in Barcelona city and metropolitan area. Recruitment was carried out in the community through individual or group strategies based on an educational game (HEPARJOC). Epidemiological data were collected and, if accepted, on-site rapid testing for HCV antibodies was performed. In the anti-HCV positive cases, a dried blood spot (DBS) sample was also collected on site for HCV-RNA testing in the laboratory. This result was delivered in a medical visit scheduled at the International Health Unit where a venous blood sample was obtained for analysis (including the HCV viral load and the FIB-4 fibrosis index). Viremic participants received antiviral treatment in the same Unit and were followed according to the standard of care until the sustained virological response. The degree of acceptability, prevalence (anti-HCV and HCV-RNA), detection of new cases, and referral and adherence to the healthcare system were evaluated.

Results: From March to October 2019, 373 participants (66.1% men, median age of 36 years (range, 18–66) and median of 6 years of residence in Spain (range, 0–28)) were recruited. Among all participants, 139 (37.3%) did not know what hepatitis C was. Thirty-six participants (9.7%) had previously been screened for HCV (17/36 in Spain); 11/373 (3.0%) reported a previous positive result, 7/11 had been treated and two were being followed up. The acceptability rate of the rapid test was 98.1% (366/373), 4.4% (16/366) had a positive result, and 43.8% (7/16) were unaware of having been infected with HCV. Of the total of anti-HCV positive cases, 93.8% (15/16) accepted the collection of the DBS sample, with 33.3% (5/15) of them being viremic cases (2/5 newly diagnosed), which represents a prevalence of viremic infection of 1.4% (5/366). Among the viremic cases, two have already started treatment within the intervention, one through routine care, and one has been lost to follow-up.

Conclusion: This community intervention has had an excellent acceptability among Pakistani migrants, and has reached both males and females with a limited awareness about hepatitis C, and most of whom had not been screened for HCV infection. The high prevalence observed so far (4.4% for antibodies and 1.4% for HCV-RNA), and the limited self-knowledge of their serological and viremic status against HCV justify a targeted screening in this group.

Figure: (abstract: THU408): Sociodemographic, epidemiologic, and clinical characteristics of participants with HCV GT4r and GT non-4r (n = 300)

Background and Aims: In sub-Saharan Africa (SSA), there exist distinct HCV genotype (GT) subtypes that frequently harbour resistance associated substitutions to commonly used NS5A inhibitor-based DAA regimens. GT4r subtype, highly prevalent in Eastern and Central Africa and SSA immigrants, has demonstrated high rates of treatment failure. In a prospective trial of SOF/LDV in Rwanda, only 56% of participants with GT4r achieved SVR12. Without routine viral sequencing in SSA, it is important to identify sociodemographic, epidemiologic, and clinical characteristics that may predict GT4r infection and predict treatment failure.
Method: A secondary analysis was performed on data from 300 adults with HCV GT4 enrolled in a prospective trial assessing the safety and efficacy of SOF/LDV in Rwanda from February 6, 2017-September 18, 2017. GT subtype was determined by PCR amplification. Association between characteristics at enrolment and GT subtype were assessed by chi-squared analysis.
Results: Participants with GT4r had no significantly different sociodemographic characteristics, geographical origin, or HCV risk factors compared to non-GT4r participants (Table 1). Participants with GT4r were more likely to have baseline cirrhosis by APRI >2 or ultrasound (p = 0.006), viral load >1,000,000 IU/mL (p = 0.001), and ALT>40 IU/mL (p = 0.002).
Conclusion: Rwandan adults with GT4r were more likely to have high viral load or advanced liver disease compared to other GT4 subtypes. In the absence of advanced diagnostics to assess GT subtype, patients with these characteristics may warrant closer monitoring for treatment failure or alternative DAA regimens. More treatment experience with diverse DAA regimens is urgently needed for GT subtypes particular to this region.

THU409

The importance of medical specialists and services coordination to effectively treat hepatitis C infection in patients who inject drugs: the Trieste model of care

Mauro Giuffrè[1], Mirko Santi[2], Anna Colombo[1], Ivo Crosato[3], Ariadna Celeste Baez[2], Flora Masutti[4], Roberta Balestra[2], Roberto Luzzati[3], Saveria Lory Croce'[1,4,5]. *[1]Dipartimento Universitario Clinico di Scienze Mediche, Chirurgiche e della Salute, Università degli Studi di Trieste, Italy; [2]Dipartimento delle Dipendenze, Azienda Sanitaria Universitaria Integrata di Trieste; [3]Malattie Infettive, Azienda Sanitaria Universitaria Integrata di Trieste; [4]Clinica Patologie del Fegato, Azienda Sanitaria Universitaria Integrata di Trieste; [5]Fondazione Italiana Fegato*
Email: gff.mauro@gmail.com

Background and Aims: According to Italian data, people who inject drugs (PWID) have high prevalence of Hepatitis C Virus (HCV) infection (30–60%). PWID have potential inadequate access to directly acting antivirals (DAA) due to mistrust towards the healthcare specialists and services and their lack of coordination.
Method: Universal and free-of-charge infective screening is offered to PWID by the addiction treatment service (SERD). Patients are introduced to counseling where HCV risk behaviors and harm reduction policies are carefully explained. HCV antibody detection represents the first-line of screening. Antibody-positive patients were offered further testing to determine HCV-RNA and genotype. Besides, they were evaluated by abdominal ultrasound and liver elastography and then referred to: (1) the Infective Disease Department (adults and/or HIV-coinfected patients) or (2) the Liver Clinic (teenagers, young adults, and/or patients with higher degree of liver fibrosis) – where the medical specialist prescribes DAA.
Results: Between January 2015 and December 2018, 2475 PWID were screened, of which 1655 resulted positive for HCV-antibodies. Around 90% of HCV-antibody positive patients agreed to further testing, which resulted in detection of HCV-RNA in blood samples of 367 individuals. The most prevalent genotypes were 3 (51%, subtype 3a in 61%) and 1 (40%, subtype 1b in 57%). 255 individuals resulted eligible for DAA treatment, in particular 45 patients were referred to the liver clinic, whereas 210 to the infective disease department. 177 patients (69%) presented fibrosis F0-2 at the beginning of therapy, 30 (12%) had F3, and 29 (11%) had F4. 249 (97.6%) patients had a sustained viral response at 12 weeks (SVR12), while 2 were non-responders, 2 had relapsing infection, and 2 presented with reinfection.
Conclusion: Our HCV care model demonstrated how an effective addiction treatment service is fundamental in the delivery and supervision of HCV treatment in PWID. The goal of the system is to create a personalized and straightforward care process that appoints the complexity and vulnerability of these patients. Simplified, integrated, and more flexible plans that promote the therapeutic relationship between the patients with the medical and nursing personnel, allow (1) quicker access to treatment, (2) increased adherence to therapy, and (3) changes in risk behaviors, thus reducing reinfection rate and progressively decreasing virus prevalence in the target population.

THU410

The outcome of re-treatment of relapsed hepatitis C virus infection after direct acting antiviral treatment failure in resource-limited settings

Gina Naguib[1], Tari George Michael[1], Yehia Elshazly[1], Maha Magdy Wahdan[1], Aya Mostafa[1], Ossama Ahmed[1], Hany Dabbous[1], Heba Aly[1], Mohamed Kamal Shaker[1], Magdi El-Serafy[2], Wahid Doss[2], Mahmoud Elmeteini[1], Manal Hamdy El-Sayed[1]. *[1]Faculty of Medicine, Ain Shams University, Egypt; [2]Tropical Department Cairo University*
Email: gina_gamal@med.asu.edu.eg

Background and Aims: Hepatitis C virus infection (HCV) is a public health concern. The mass scale up and uptake of treatment in Egypt with direct acting antiviral agents (DAAs) led to the identification of some treatment failures.
The aim of this study is to compare efficacy and safety of different combination regimens in re-treatment of HCV after failure of previous treatment and inaccessible resistance testing.
Method: This real-life prospective study included 86 chronic HCV infected patients who experienced failure of treatment out of 3000 who received DAAs at the viral hepatitis and research centre (Faculty of Medicine Ain shams Research Institute (MASRI) since 2018. 64% of the patients were males, with median age 50.2. Six patients were child B cirrhosis. They were re-treated using 3 combinations of DAA regimens. One group received PAR/OMB/SOF/RBV for 12 weeks, another group received SOF/DAC/SIM/RBV for 12 weeks and a third received SOF/DAC/RBV combinations for 24 weeks.
Response to different regimens was assessed by comparing sustained virologic response (SVR) of each group and also the effect of the previous failed regimen was observed as a possibility of being a risk factor. Safety was also assessed by monitoring the occurrence of adverse events.
The regimens used in this study were due to unavailability of other combination regimens as sofosbuvir, velpatasvir and voxilaprevir.
Results: Overall, SVR was achieved in 96.5% of the patients, 100% in those who received PAR/OMB/SOF/RBV, 98.1% in the SOF/DAC/SIM/RBV group and 71.4% among the SOF/DAC/RBV regimen group. Only three patients failed to achieve SVR, one of them had severe degree of fibrosis while two of them had moderate degree of fibrosis according to Fib 4 score. In general, all treatment regimens had comparable adverse events were mostly related to RBV as anaemia and hyperbilirubinemia.
Previous treatment used was a significant predictor to achieve to SVR. Patients who did not achieve SVR were previously treated with either SOF/INF or SOF/DAC.
Conclusion: In the absence of resistance testing, Sofosbuvir based combinations remain to be effective and safe alternative treatment regimens for retreating hepatitis C virus-infected patients who experienced previous failure of treatment. Additionally, the choice

of the first line of treatment has a significant role in treatment response.

THU411

Resistance-associated variants conferring quite a high level of resistance to all approved NS5A inhibitors in genotype 2 hepatitis C virus

Goki Suda[1], Kenichi Morikawa[1], Naoya Sakamoto[1]. [1]*Hokkaido University, Gastroenterology and Hepatology*
Email: gsudgast@pop.med.hokudai.ac.jp

Background and Aims: Development of direct-acting antivirals (DAAs) has made anti-hepatitis C virus (HCV) treatment highly safe and effective. However, the emergence of resistant-associated variants (RAVs) after failure of DAA therapy affects retreatment outcomes. In particular, genotype 1 HCV with P32deletion has been reported to be highly resistant to all approved NS5A inhibitors. However, analysis of RAVs in genotype 2 HCV has been limited. Accordingly, in this study, we evaluated the roles of genotype 2 HCV variants in antiviral drug efficacy.
Method: We utilized HCV-2b/2a (JFH-1) chimeric virus (genotype 2a), which replicates more robustly than JFH-1. We constructed various genotype 2a JFH-1-based HCV cell culture systems with NS3 (D168E), NS5A (F28S, F28S/M31I, P32deletion, andY93H), and NS5B (S282 T) RAVs and analyzed the replication ability and sensitivity to various anti-HCV reagents.
Results: Genotype 2a-based HCV with NS5A-P32deletion could not replicate even in long-term cultures. Genotype 2a-based HCV with NS5A-F28S/M31I showed significantly higher replication ability than the wild-type strain, and replication could not be suppressed, even with high concentrations of NS5A inhibitors, including pibrentasvir and velpatasvir (<1000–10000 fold-resistance compared with the wild-type strain). However, genotype 2a-based HCV with NA5A-F28S/M31I was sensitive to HCV protease inhibitor, NS5B inhibitor, interferon-α, and ribavirin. Genotype 2a-based HCV with NS5B-S282 T was resistant to sofosbuvir, but was highly sensitive to ribavirin compared with the control.
Conclusion: When performing retreatment for genotype 2a HCV-infected patients who fail to respond to DAAs, the optimized retreatment should be chosen according to the sensitivity of the emerging RAVs to anti-HCV drugs.

THU412

A phase 2, open-label study of pan-genotype regimen of SH229 plus daclatasvir in Chinese patients with chronic hepatitis C virus infection

Rui Hua[1], Fei Kong[1], Guangming Li[2], Yuexin Zhang[3], Xiaofeng Wen[4], Qingfang Xiong[5], Jiayu Chen[6], Chenxin Meng[7], Hong Ma[8], Youwen Tan[9], Yan Huang[10], Yongfang Jiang[11], Yujuan Guan[12], Xiaorong Mao[13], Jiefei Wang[14], Yongning Xin[15], Hainv Gao[16], Bin Xu[17], Cheng Li[2], Xian Zhang[18], Zhiqiang Wang[18], Yanhua Ding[1], Junqi Niu[1]. [1]*The First Hospital of Jilin University, Changchun, China;* [2]*Zhengzhou Sixth People's Hospital, Zhengzhou, China;* [3]*The First Hospital Affiliated to Xinjiang Medical University, Urumchi, China;* [4]*Liuzhou People's Hospital, Liuzhou, China;* [5]*The Second Hospital of Nanjing, Nanjing, China;* [6]*The 940th Hospital of Joint Logistics Support Force of PLA, Lanzhou, China;* [7]*The Sixth People's Hospital of Shenyang, Shenyang, China;* [8]*Beijing Friendship Hospital Affiliated with Capital Medical University, Beijing, China;* [9]*The Third People's Hospital of Zhenjiang, Zhenjiang, China;* [10]*Xiangya Hospital, Central South University, Changsha, China;* [11]*The Second Xiangya Hospital of Central South University, Changsha, China;* [12]*Guangzhou Eighth People's Hospital, Guangzhou, China;* [13]*The First Hospital of Lanzhou University, Lanzhou, China;* [14]*Shanghai Public Health Clinical Center, Shanghai, China;* [15]*Qingdao Municipal Hospital, Qingdao, China;* [16]*Shulan (Hangzhou) Hospital, Hangzhou, China;* [17]*Beijing You'an Hospital Affiliated with Capital Medical University, Beijing, China;* [18]*Nanjing Sanhome Pharmaceutical Co., Ltd., Nanjing, China*
Email: junqiniu@aliyun.com

Background and Aims: SH229 is a novel potent, pan-genotypic HCV NS5B polymerase inhibitor in development for the treatment of chronic HCV infection. During a 3-day monotherapy study in patients with HCV infection, SH229 was well-tolerated and resulted in median maximum HCV RNA reductions >3.8 $\log_{10}$ IU/mL at doses of 400, 600 and 800 mg once daily. Here we evaluate the efficacy and safety of SH229 in combination with daclatasvir (an HCV NS5A inhibitor) in Chinese patients infected with HCV genotype 1, 2, 3, or 6.
Method: In this open-label study, patients with chronic HCV infection were randomly assigned into three cohorts with a 1:1:1 ratio to receive 12 weeks of daclatasvir at a standard dose of 60 mg daily plus SH229 at a dose of 400 mg (Cohort A), 600 mg (Cohort B) or 800 mg (Cohort C) daily. Randomization was stratified by HCV genotype (1, 2, 3, and 6) and the presence or absence of cirrhosis at screening. Plasma samples were collected for HCV RNA quantification using Roche COBAS® AmpliPrep®/COBAS® TaqMan® HCV v2.0 test, which has a reported lower limit of quantification (LLOQ) of 15 IU/mL. The primary endpoint was a sustained virologic response 12 weeks after the end of treatment (SVR12).
Results: 124 patients were enrolled in the study, including 64 (51.6%) with HCV genotype 1, 31 (25.0%) with HCV genotype 2, 14 (11.3%) with HCV genotype 3, and 15 (12.1%) with genotype 6. 8.9% of patients had cirrhosis at baseline, 6.5% failed prior interferon-based therapy, and 88.7% had the IL28B CC allele. The median baseline HCV RNA was 6.3 log10 IU/mL, and 50.8% of patients had a baseline HCV RNA ≥ 200,000 IU/mL. The baseline disease characteristics are comparable among the treatment groups and no major differences are noted. As of Nov 19, 2019, 122 patients were available for post-treatment Week 12 assessments at this cut-off time. SVR12 was achieved in 92.5% (37/40), 95.2% (40/42), and 100% (40/40) of patients in Cohort A, B, and C, respectively. The overall SVR12 rate was 100% (62/62) among patients with HCV genotype 1, 100% (31/31) with genotype 2, 71.4% (10/14) with genotype 3, and 93.3% (14/15) with genotype 6. A similar number of patients experienced adverse events across three cohorts, and the majority of adverse events were mild to moderate in intensity. There were no discontinuations due to adverse events, and no treatment-related serious adverse events were reported.
Conclusion: Once-daily oral administration of SH229 plus daclatasvir were highly effective and safe in Chinese patients infected with HCV genotype 1, 2, 3, or 6, suggesting SH229 could be a promising drug candidate for HCV treatment in China irrespective of genotype.

THU413

Health-related quality of life (HRQOL) before and after treatment of genotype 1 (GT1) infection with elbasvir/grazoprevir (EBR/GZR): results from the German hepatitis C registry (DHC-R)

Dietrich Hüppe[1], Albrecht Stoehr[2], Hartwig Klinker[3], Renate Heyne[4], Christine John[5], Karl-Georg Simon[6], Manfred Bilzer[7], Veronika Guenther[8], Vanessa Witte[8], Markus Cornberg[9]. [1]*Gastroenterologische Gemeinschaftspraxis, Herne;* [2]*Institute for Interdisciplinary Medicine, Hamburg;* [3]*University Hospital Würzburg, Würzburg;* [4]*Leberzentrum am Checkpoint, Berlin;* [5]*Private Practice of Internal Medicine, Berlin;* [6]*MVZ Dres. Eisenbach, Simon, Schwarz GbR, Leverkusen;* [7]*Bilzer Consulting, München;* [8]*MSD Sharp & Dohme GmbH, Haar;* [9]*Hannover Medical School, Hannover*
Email: veronika.guenther@msd.de

Background and Aims: Recent studies show that HRQOL improve during and after direct-acting antiviral (DAA) therapies for HCV infection. However, it remains unclear whether these findings can be generalized to patients (pts) treated in real-world as clinical trials enroll highly selected pts and typically under-represent important subgroups of the HCV population. The present analysis investigated

the impact of the regimen with EBR/GZR on HRQOL in pts treated for GT1 infection in German real-world.

Method: From 09/2016 until 06/2019, 1408 pts with GT1 infection were treated with EBR/GZR +/– RBV for 12 to 16 weeks in 130 medical practices and hospital outpatient departments. Pts were documented in the German Hepatitis C Registry (DHC-R). HRQOL was assessed by the 36-item short form health survey (SF-36). The present analysis was restricted to 257 pts with documented SF-36 data at baseline and 24 weeks of follow-up (FU) after end of treatment.

Results: 257 pts included in the present analysis showed the following characteristics: mean age 55 years, female gender 43%, GT1a 32%, GT1b 68%, BMI 26, elevated ALT 69%, elevated gamma-GT 54%, liver cirrhosis 21%. Overall, 98.4% (249/253) of pts infected with GT1 achieved a sustained virologic response (SVR) at 12/24 weeks post treatment with EBR/GZR. In all pts, all mean scores of the eight SF-36 domains improved slightly at 24 weeks of FU compared to baseline. However, pts experiences before and after treatment were heterogeneous in subgroups of interest. At baseline drug users under opioid substitution (OST), pts with chronic alcohol use and pts >70 years had lower scores than pts without any of these comorbidities. At 24 weeks of FU improvements in the SF-36 domains were more pronounced in OST pts and pts with chronic alcohol use and less pronounced in pts >70 years. While pts with alcohol use showed distinctive increases in role physical and mental health together with slight declines in other functions, OST pts had improvements in all domains, most distinctly in role physical, bodily pain, social functioning and role emotional (table).

Table: Mean SF-36 score changes before and after treatment

SF-36 domains	All pts N = 257	Pts without comorbidities N = 44	OST pts N = 31	Pts with alcohol use N = 9	Pts >70 N = 30
Physical functioning	74–78	84–90	76–83	79–77	59–63
Role physical	63–69	81–89	58–76	39–69	47–46
Bodily pain	70–76	85–87	66–84	77–74	57–68
General health	56–63	69–72	51–61	52–57	51–57
Vitality	47–55	55–64	41–50	44–52	45–49
Social functioning	75–80	86–88	64–79	69–75	72–74
Role emotional	69–76	86–87	59–76	52–59	54–59
Mental health	65–69	70–74	54–65	53–63	62–64

Conclusion: GT1 infected pts treated with EBR/GZR in German real-world show slight improvements in SF-36 domains post therapy. Heterogeneous experiences are observed in subgroups, ranging from less distinct changes in elderly pts to some notable score increases in pts with alcohol use and great improvements in OST pts.

THU414

Second-generation DAAs for HCV: real-life efficacy in the resist-HCV cohort

Irene Cacciola[1,2], Salvatore Petta[3], Vincenza Calvaruso[3], Marco Distefano[2], Gaetano Scifo[2], Francesco Di Lorenzo[2], Adriana Sanfilippo[2], Maria Antonietta Di Rosolini[2], Antonio Davì[2], Francesco Benanti[2], Bruno Cacopardo[2], Anna Licata[2], Lydia Giannitrapani[2], Maria Rita Cannavò[2], Maurizio Russello[2], Salvatore Madonia[2], Maria Grazia Bavetta[2], Antonio Digiacomo[2], Alfonso Averna[2], Licia Nunzia La Rocca[2], Gaetano Bertino[2], Fabrizio Bronte[2], Luigi Guarneri[2], Ignazio Scalisi[2], Carmelo Iacobello[2], Pietro Colletti[2], Fabio Cartabellotta[2], Giuseppe Alaimo[2], Portelli Vincenzo[2], Teresa Pollicino[2], Francesca Ceccherini Silberstein[4], Giovanni Squadrito[1], Giovanni Raimondo[1], Antonio Craxi[3], Vito Di Marco[3]. *[1]University of Messina, Messina; [2]Rete Sicilia Selezione Terapia - HCV; [3]University of Palermo, Gastroenterology and Hepatology Unit, Department of Health Promotion Sciences Maternal and Infantile Care, Internal Medicine and Medical Specialities, PROMISE, Palermo; [4]University of Rome Tor Vergata, Department of Experimental Medicine, Rome*
Email: vincenza.calvaruso@unipa.it

Background and Aims: RESIST-HCV (Rete Sicilia Selezione Terapia–HCV) registers all patients in Sicily with chronic HCV infection undergoing treatment with DAAs. This analysis aims to evaluate SVR rates of DAA-naïve patients to. second-generation regimens (Sofosbuvir plus Velpatasvir: SOF/VEL; Glecaprevir plus Pibrentasvir: GLE/PIB; Elbasvir/Grazoprevir: EBV/GRZ), in order to evaluate

Methods: We analyzed 4,087 patients who received treatment between March 2017 and December 2018 whose SVR12 data were available in the RESIST-HCV database by June 2019. Cirrhosis was diagnosed by liver stiffness ≥ 12 KPa (Fibroscan) and/or by presence of esophageal varices at endoscopy and/or by a liver biopsy with METAVIR stage 4 fibrosis.

	DAA regimes	Chronic hepatitis	Cirrhosis
Genotype 1a (436 patients)	SOF/VEL	203/205 (99%)	70/71 (98.6%)
	GLE/PIB	93/93 (100%)	7/7 (100%)
	EBV/GRZ	43/43 (100%)	11/11 (100%)
Genotype 1b (2,434 patients)	SOF/VEL	519/520 (99.8%)	297/303 (98%)
	GLE/PIB	408/410 (99.5%)	26/26 (100)
	EBV/GRZ	873/910 (95.9%)	251/265 (94.7%)
Genotype 2 (577 patients)	SOF/VEL	350/352 (99.4%)	72/72 (100%)
	GLE/PIB	147/148 (99.3%)	5/5 (100%)
Genotype 3 (332 patients)	SOF/VEL	175/179 (97.7%)	35/35 (100%)
	SOF/VOL + ribavirin	12/12 (100%)	27/27 (100%)
	GLE/PIB	63/64 (98.4%)	15/15 (100%)
Genotype 4 (171 patients)	SOF/VEL	65/65 (100%)	30/31 (96.7%)
	GLE/PIB	39/39 (100%)	1/1 (100%)
	EBV/GRZ	28/30 (93.3%)	8/8 (100%)

Results: By ITT analysis 95.1% of patients (3,878/4,078) achieved SVR. Overall, 125 patients (3.1%) did not complete the assigned therapy. Of them, 11 patients (0.3%) died for liver-related (5 patients) or unrelated (6 patients) causes while on treatment. Twenty patients (0.5%) discontinued treatment due to adverse events and 94 patients (2.2%) did not have virology available at end of therapy (ETR) or for SVR evaluation. Seventy-five patients (1.8%) did not achieve SVR: of them, 14 were still HCV-RNA positive at the end of therapy and 61 showed a virological relapse after ETR. By PP analysis 98.1% of patients (3878/3953) obtained an SVR. The rates of PP SVR according to HCV genotype (Gt) and stage of disease are reported Table 1. Patients with chronic hepatitis and Gt 1a, 1b, 2 or 4 obtained SVR rates higher than 99% when treated with pangenotypic regimes (SOF/VEL or GLE/PIB). SVR rates above 96% were obtained in patients with cirrhosis and Gt 1a,1b, 2 or 4 treated with SOF/VEL or GLE/PIB. Adding ribavirin to SOF/VEL in genotype 3 patients with chronic hepatitis or cirrhosis did not enhance the rate of SVR. Genotype 1b patients with chronic hepatitis or cirrhosis, when treated with EBV/GRZ had an SVR in 95.9% and 94.7% of cases, respectively, mostly due to post-ETR relapses.

Conclusions: Current DAA regimens, especially if pangenotypic, obtain response rates of at least 95% in a real-life situation. Adding ribavirin to SOF/VEL seems unnecessary in Gt3 patients, regardless of fibrosis.

THU415

Use of sofosbuvir based direct acting antiviral regimens is associated with reduced mortality in liver transplant candidates with hepatitis C

Jeffrey Wang[1], Anne Sexter[2], W. Ray Kim[3], Ajay Israni[4]. *[1]Hennepin Healthcare, University of Minnesota, Medicine, Minneapolis, United States; [2]Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, United States; [3]Stanford University, Medicine, Stanford, United States; [4]Hennepin Healthcare, University of Minnesota, Medicine, Minneapolis, United States*
Email: isran001@umn.edu

Background and Aims: The role of sofosbuvir (SOF) based direct acting antivirals (DAAs) in waitlisted liver transplant candidates with Hepatitis C virus (HCV) is controversial, because of the concern that DAA use may disadvantage patients under the MELD system. Waitlist outcome data to date has been limited to select centers. The purpose of this study was to determine the prevalence of SOF containing DAA regimen use in liver transplant candidates in a nationwide registry and the associated impact on outcomes.
Method: Using the Scientific Registry of Transplant Recipients database, we examined all adult candidates on the national liver transplant waitlist from January 1, 2014 to December 31, 2017 waiting for their first transplant with HCV as the primary or secondary indication for listing. This cohort was linked to a national database of pharmacy claims, to identify patients treated with SOF containing regimens (sofosbuvir, sofosbuvir/ledipasvir, sofosbuvir/velpatasvir) during the study period. Subjects were followed from listing date or January 1, 2014 if they were listed before the study period until the first occurrence of removal from the waitlist, transplant, death, or December 31, 2017. The final cohort consisted of 1420 subjects. The SOF treated group was compared to a matched historical cohort of candidates waitlisted from January 1, 2010 to December 31, 2013 who were not treated with SOF based regimens. The groups were matched on several factors using incidence density without replacement sampling of 1 case up to 3 controls. Both univariate Cox proportional hazards models and cumulative incidence curves were done using competing risks methodology.

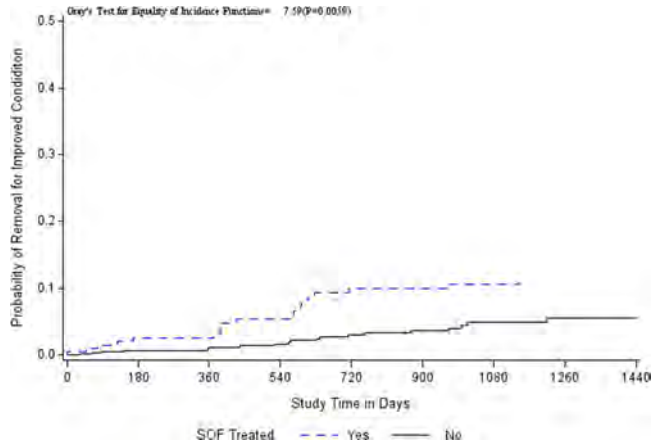

Figure: Removal from the liver transplant waiting list due to condition improved, according to exposure to SOF containing DAA.

Results: During the study period, 208 patients (14.6%) were treated with a SOF containing DAA regimen during liver transplant listing. There were 787 subjects in the matched cohort. Treatment with SOF based regimens was associated with a lower risk of all-cause mortality compared to non-treatment (HR 0.47, 95% CI 0.26–0.83, P = 0.0094). Patients treated with SOF based regimens were more likely to be removed from the waitlist due to improved condition compared to untreated subjects (HR 2.65, 95% CI 1.41–4.99, P = 0.0025). Liver transplant incidence (HR 1.02, 95% CI 0.78–1.34, P = 0.8719) and removal from the waitlist due to worsened condition (HR 0.84, 95% CI 0.50–1.40, P = 0.4941) did not differ between SOF treated and untreated groups.
Conclusion: In a contemporary national cohort, only a minority of waitlisted HCV positive liver transplant candidates were treated with SOF containing DAAs. However, SOF use was associated with reduced all-cause mortality and increased removal from the waitlist due to improved condition which suggests that HCV treatment should be considered in all HCV infected liver transplant candidates.

THU416

Factors associated with efficacy of retreatment with grecaprevir/pibrentasvir therapy in prior DAA failed patients - nationwide multicenter study in Japan

Jun Itakura[1], Masayuki Kurosaki[1], Namiki Izumi[1]. *[1]Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Tokyo, Japan*
Email: jitakura@musashino.jrc.or.jp

Background and Aims: To identify factors associated with the efficacy of retreatment with grecaprevir/pibrentasvir (GLE/PIB) therapy in patients who failed prior DAA therapy.
Method: This was a nation-wide multicenter study involving 83 regional core centers for the treatment of liver disease and related hospitals. A total of 526 patients who failed prior DAA therapy and retreated with GLE/PIB were registered. Serum was obtained before GLE/PIB therapy and the RAS in NS3/NS5A region was determined by population sequencing. Factors associated with SVR12 were analyzed.
Results: The overall SVR12 rate was 96.5%; the SVR12 rate of genotype 1a, 1b, 2a, 2b patients was 100%, 96.5%, 100% and 100%, respectively. Among the genotype-1b patients, the SVR12 rate in 4 patients with P32deletion RAS in NS5A region was 25%, which was significantly lower than 97% of patients without this unique RAS ($p < 0.01$). Among patients without P32deletion RAS, presence of A92 K RAS in NS5A (odds ratio 15.3, 95% confidence interval 2.3–101, $p < 0.01$), R30H in NS5A (OR 9.1, 95%CI 1.8–46, $p < 0.01$), prior failure of multiple DAA regimens (OR 8.3, 95%CI 1.9–37, $p < 0.01$), and age over 76 (OR 4.5, 95% CI 1.2–17, $p = 0.03$) independently affected SVR. The SVR12 was 99% in 193 patients who had none of the above four factors, whereas it was 97% in 92 patients who had only one factor, and 76% in 21 patients who had 2–3 factors.
Conclusion: This nation-wide study revealed high rate of SVR by retreatment with GLE/PIB. The unique RAS P32deletion in NS5A significantly attenuated the efficacy. Other than this unique RAS, R30H RAS in NS5A, Y92 K in NS5A, prior failure of multiple DAA regimens, and age were factors to lower SVR rates. In patients without these factors, the rate of SVR was 99%.

THU417

Impact of the universal access to direct-acting antivirals in the profile of hepatitis C treated patients

Jordi Llaneras[1], Mar Riveiro Barciela[1,2], Eulalia Pericas[3], Nuria Boixareu[1], Jordi Navarro[4], Juan Ignacio Esteban[1], Lluis Castells[1], Cristina Marcos[1], Maria Buti[1,2], Rafael Esteban[2,5]. *[1]Vall Hebron Hospital, Internal Medicine, Barcelona, Spain; [2]CIBERehd; [3]Vall Hebron Hospital, Information Management and Innovation, Barcelona, Spain; [4]Vall Hebron Hospital, Infectious Diseases, Barcelona, Spain; [5]Vall Hebron Hospital, Internal Medicine, Barcelona*
Email: jllaneras@vhebron.net

Background and Aims: Treatment with direct-acting antivirals (DAAs) was limited to patients with advanced fibrosis until 2017. Since then, access to DAAs was allowed to all subjects with chronic hepatitis C (CHC), regardless of the degree of fibrosis. Our aim was to analyse the impact of universal access to DAAs in the profile of subjects treated for CHC.
Method: Retrospective study based on the pharmacy register of all patients with CHC treated during two periods: restrictions (2014–2016) and universal access (2017–2019). Baseline clinical and virological characteristics, type of therapy and Sustained Virological response (SVR) were collected.
Results: 2,384 combinations of interferon-free oral DAAs were administered to 2,327 patients with CHC within these periods. The percentage of patients with advanced fibrosis (F3-F4) receiving therapy significantly decreased over time, although 23% of treated subjects in 2019 had significant fibrosis and 2% were decompensated. Baseline characteristics of subjects treated during each period are shown in the table. An increase in treated HIV-infected patients was observed, probably due to lower interactions with the new DAAs

Table: (abstract: THU417)

	Period with restrictions 2014–2016 (n = 1094)	Universal Access Period 2017–2019 (n = 1290)	Total (n = 2384)	
Male	613 (56%)	716 (56%)	1329 (56%)	p = 0.8
Age (years)	61 ± 13	57 ± 14	59 ± 14	p < 0.001
Fibrosis				p < 0.001
F0-F1	60 (6%)	538 (42%)	598 (25%)	
F2	241 (22%)	405 (31%)	646 (27%)	
F3	253 (23%)	154 (12%)	407 (17%)	
F4	540 (49%)	193 (15%)	733 (31%)	
Decompensated cirrhosis	38 (4%)	25 (2%)	63 (3%)	p = 0.2
Hepatocarcinoma	17 (2%)	4 (0.3%)	21 (1%)	p < 0.001
Liver transplant	52 (5%)	21 (2%)	73 (3%)	p < 0.001
HIV Coinfection	116 (11%)	238 (19%)	354 (15%)	p = 0.002
Genotype 1b	693 (63%)	558 (43%)	1251 (53%)	p < 0.001
Non- pangenotypic DAAs	1094 (100%)	605 (47%)	1709 (71%)	
Pangenotypic DAAs	–	675 (53%)	675 (29%)	
SVR 12	782/820 (95%)	983/1015 (97%)	1765/1835 (96%)	p = 0.1

Median, SD; n (%).
DAAs, Direct-Acting Antivirals. SVR12, Sustained virological response at week 12.

combinations. Genotype 1b was the most prevalent (53%) in the first period and decreased in the second period, due to an increase of patients infected by GT 1a, 3 and 4. Seven patients relapsed after DAA and were retreated with SOF/VEL/VOX, all of them achieving SVR. Pangenotypic regimens used in the second period slightly increased SVR rates.
Conclusion: Despite universal access to high efficacy pangenotypic DAAs combinations, 23% of patients treated in 2019 still had advanced fibrosis. This result highlights the need to improve and increase screening and linkage to care in order to eliminate HCV infection.

Email: johannes.wiegand@medizin.uni-leipzig.de

Background and Aims: Grazoprevir/elbasvir (EBR/GZR) and glecaprevir/pibrentasvir (G/P) are the two licensed treatment options with direct antiviral agents (DAA) for patients with chronic hepatitis C virus (HCV) infection and a baseline glomerular filtration rate (GFR) <30 ml/min. Real world data in this special patient population is sparse so far. Thus, we analyzed safety and effectiveness data within the German Hepatitis C-Registry (DHC-R).
Method: The DHC-R is a prospective national real-world registry including about 16,500 chronic hepatitis C patients recruited by more than 250 centers. Data were analyzed as of Jun 30, 2019. The analysis is based on 2,773 patients with documented GFR at baseline treated with EBR/GZR (N = 1,041), EBR/GZR + ribavirin (N = 53) and G/P (N = 1,679), respectively. For the per protocol analysis, non-adherent patients, patients with missing data and patients lost to follow-up were excluded.
Results: The baseline characteristics of the total study cohort were as follows: (70%/4%/21%/5% HCV-genotype 1/2/3/4; 64.7% male; age 50 ± 14 years, 96% Caucasian, 83% treatment-naïve,12% cirrhosis). 94 (3.4%) patients with baseline GFR <30 ml/min initiated antiviral therapy with EBR/GZR (N = 57), EBR/GZR + ribavirin (N = 4), or G/P (N

	End of treatment GFR			
Baseline GFR	**0-15**	**>15-30**	**>30-60**	**>60**
0-15 (n=79)	97.5% (n=77)	1.3% (n=1)	0	1.3% (n=1)
>15-30 (n=7)	14.3% (n=1)	57.1% (n=4)	14.3% (n=1)	14.3% (n=1)
>30-60 (n=83)	0	3.6% (n=3)	65.1% (n=54)	31.3% (n=26)
>60 (n=1,894)	0	0	2.4% (n=46)	97.6% (n=1,848)

Patients with documented GFR at baseline and end of treatment were considered in this analysis (N=2,063).

Figure: (abstract: **THU418**): Comparison between baseline and end-of-treatment glomerular filtration rate.

= 33). They suffered significantly more frequent from diabetes mellitus, hypertension, and coronary heart disease than individuals with GFR >30 ml/min and showed the following baseline characteristics: 78%/3%/13%/5% HCV-genotype 1/2/3/4; 13% cirrhosis; 81% treatment-naïve. Antiviral therapy was associated with a GFR improvement in 30/2,063 (1.5%) individuals, a deterioration to GFR <30 ml/min occurred in in 3/2,063 (0.1%) patients (Table 1). Adverse events (AE) occurred in 32.3% of patients with GFR <30 ml/min vs. 30% of cases with GFR >30 ml/min. Serious adverse events were significantly more frequent in individuals with GFR < 30 ml/min (7.5% vs. 1.4%), but unrelated to antiviral therapy in six cases. One patient suffered from a cholestatic hepatitis possibly related to EBR/GZR. Treatment discontinuation due to (serious) AE occurred in no patient with GFR <30 and in 0.1% of patients with GFR >30 ml/min. Per-Protocol overall sustained virologic response rates (SVR12) did not differ significantly between cases with GFR < 30 vs. >30 ml/min (99% vs. 99%).

Conclusion: EBR/GZR and G/P show a favorable safety profile and high antiviral efficacy in patients with chronic hepatitis C and a GFR < 30 ml/min.

THU419

HCV in the Australian primary care setting: real-world effectiveness of 12 weeks of sofosbuvir/velpatasvir for the treatment of chronic hepatitis C

Joss O'Loan[1,2], Anne Balcomb[3], David Baker[4], Joseph Doyle[5], Daniel Godfrey[6], Michael Kozminsky[7], Michael Mertens[8], Kim Vanstraelen[8], Matt Young[1,2]. *[1]Medico Clinic, Inala, Australia; [2]Kombi Clinic, Brisbane, Australia; [3]The Prince Street Clinic, Orange, Australia; [4]East Sydney Doctors, Darlinghurst, Australia; [5]The Alfred and Monash University, Department of Infectious Diseases, Melbourne, Australia; [6]Gilead Sciences Pty Ltd, Melbourne, Australia; [7]Genesis Medical Centre, Brighton, Australia; [8]Gilead Sciences Ltd, London, United Kingdom*
Email: jossoloan@gmail.com

Background and Aims: The World Health Organization has set HCV elimination targets to be achieved by 2030. The availability of pangenotypic, panfibrotic direct-acting antiviral drugs, simplification of treatment and management, and decentralization of patient care are key to reaching these targets. In phase 3 clinical trials and multiple large real-world data cohorts, sofosbuvir/velpatasvir (SOF/VEL) is a simple pangenotypic, panfibrotic, single tablet regimen, showing high sustained virologic response (SVR) rates across all genotypes and fibrosis stages with favorable safety and tolerability. In Australia, over 39% of HCV treatment are initiated in primary care but limited clinical outcome data are available in this setting. This real-world data cohort assesses the effectiveness of a 12-week SOF/VEL regimen in treating chronic HCV patients exclusively in primary care.

Method: Data from seven primary care clinic cohorts are included. Patients enrolled in the cohorts were treated according to local standards of clinical care. Data on HCV patients who were treated with 12 weeks of SOF/VEL before July 2019 were extracted from each cohort database, excluding patients with a history of decompensation, prior exposure to an NS5A inhibitor, treatment duration >12 weeks or concomitant ribavirin use. Demographics, reasons for non-SVR and model of care utilized were assessed. SVR (≥12 weeks after end-of-treatment) was assessed for all patients with virologic outcome data available at the time of abstract submission.

Results: SOF/VEL treatment initiation was identified for 301 patients, with a median age of 43 (range 19–67) years. 42% of patients reported recent injecting drug use, 2% were treatment-experienced and 7% had compensated cirrhosis. All patients were initiated on SOF/VEL in primary care by a mixture of general practitioner (GP)-led and nurse-led clinics. SVR results were available for 159 patients, with a SVR of 97%. For 142 patients, SVR was not available due to non-virological reasons including loss to follow-up (LTFU). Detailed analyses of the virological and non-virological reasons for not achieving SVR will be available for the full cohort at the conference

Conclusion: A 12-week pangenotypic and panfibrotic treatment regimen of SOF/VEL offers a simple treatment regimen with high SVR12 rates of 97% in chronic HCV patients treated in GP or nurse-led clinics in Australia. However, measures should be taken to decrease LTFU of patients. This multi-center cohort is one of the first to show the feasibility and effectiveness of treating chronic HCV patients with SOF/VEL in the primary care setting, in line with the recent AASLD/APASL/EASL/ALEH call to action for HCV elimination.

Email: jturnesv@gmail.com

Background and Aims: Glecaprevir/pibrentasvir (G/P) is a pangenotypic antiviral regimen that allows hepatitis C virus infection (HCV) cure rates above 95%. The recommended duration of treatment in naive patients with compensated liver cirrhosis was 12 weeks. Recently, the Expedition-8 study showed that in this subgroup of patients, G/P treatment can be reduced to 8 weeks without losing efficacy (Brown RS et al, J Hepatol 2019), but results are unknown under real clinical practice conditions.

Method: Multicenter observational study of consecutive HCV patients treated with G/P under real clinical practice conditions in the Spanish HepaC registry between September 2017 and March 2019, who reached 12 weeks follow-up assessment of sustained virological response (SVR12). Inclusion criteria were genotype (GT) 1-6, treatment-naïve and compensated liver cirrhosis. Patients with HIV-HCV coinfection were excluded. Baseline characteristics of the patients and SVR12 were assessed according to the duration of treatment (8 or 12 weeks).

Table: (abstract: THU420): Baseline characteristics of patients treated with G/P for 8 vs. 12 weeks

		G/P treatment duration				
		8 weeks		12 weeks		p

Platelet count (x10^9)		14	155 (128.63–181.37)	99	148.31 (135.09–161.53)	NS

Results: 114 naive patients with cirrhosis received G/P treatment, 14 for 8 weeks and 100 for 12 weeks. 60.5% were males, with a mean age of 59 (31–89) years and 26% were infected with GT3. 69.3% had an A5 Child-Pugh score, 9.6% A6 and 1.76% B7. No differences in baseline characteristics were observed among patients treated 8 or 12 weeks (table). SVR12 was achieved in the 14 patients treated 8 weeks and in 98/100 treated 12 weeks. The two virological failures, both GT1, were due to viral relapse and a non-responder, respectively.
Conclusion: Preliminary results of the HepaC cohort show a high effectiveness of G/P treatment for 8 weeks in HCV treatment-naïve patients with compensated liver cirrhosis, being similar to that observed in patients treated for 12 weeks.

THU421

Baseline features of hepatitis C patients associated to prescription of pangenotypic antiviral treatments: results from the real-world Spanish Hepa-C registry

Email: jturnesv@gmail.com

Background and Aims: Glecaprevir/pibrentasvir (G/P) and sofosbuvir/velpatasvir (SOF/VEL) are the first line pangenotypic regimens available to treat hepatitis C virus infection (HCV). In Spain, the choice of SOL/VEL vs G/P relies on the physician, since costs are similar and access to care is universal. We investigated how patient baseline characteristics may influence the decision process leading to indicate

a pangenotypic HCV treatment in the real-world setting, and their impact on SVR.

Method: we performed a retrospective analysis of patients with hepatitis C who started treatment with G/P or SOF/VEL between April 2017 and September 2019, and were included at the multicenter Spanish registry HepaC. We developed a multivariable logistic regression analysis, including clinical and virological variables, predicting the antiviral treatment of choice. A second model was developed to evaluate the potential impact of this choice on SVR.

Results: 4093 patients were included, 2402 received G/P and 1691 SOF/VEL. Different prescription patterns were found. Liver cirrhosis, former/current drug use, asian ethnicity, treatment with proton pump inhibitors or oral anticoagulants, and HCV genotype (GT) 2 and 3 were associated to the use of SOF/VEL; GT1, caucasian ethnicity and glomerular filtration rate below 45 ml/min, including hemodialysis, were associated to G/P (table).

Table:: Factors associated to the use of G/P vs. SOF/VEL

		OR	CI 95%
Race	Caucasian (n = 3358)	1.0	
	Afrocaribbean (n = 14)	0.9	0.3–2.7
	Asian (n = 20)	0.3	0.1–1
	Arab (n = 37)	1.4	0.7–3
	Latino (n = 44)	1.2	0.6–2.3
	Hindu (n = 25)	2.1	0.9–5
	Other (n = 49)	2.0	1–3.9
	Unknown (n = 546)	2.0	1.2–3.4
Haemodialysis	No (n = 4073)	1.0	
	Yes (n = 20)	6.3	1.3–31
MDRD4	>45 (n = 3399)	1.0	
	≤ 45 (n = 78)	7.3	3.7–14.5
	NA (n = 616)	1.0	0.6–1.7
PWIDs	No (n = 3145)	1.0	
	Yes (n = 948)	0.7	0.6–0.8
Liver decompensation	No (n = 4006)	1.0	
	Yes (n = 87)	0.1	0–0.3
Cirrhosis	No (n = 3525)	1.0	
	Yes (n = 568)	0.5	0.4–0.6
Oral antiacoagulation	No (n = 4017)	1.0	
	Taking (n = 76)	0.4	0.2–0.6
Proton Pump Inhibitor	No (n = 3563)	1.0	
	Taking (n = 530)	0.6	0.5–0.8
Liver elastography	F1–2 (n = 3086)	1.0	
	F3–4 (n = 887)	0.5	0.4–0.6
	NA (n = 161)	0.5	0.4–0.8
Genotype	1 (n = 2455)	1.0	
	2 (n = 249)	0.3	0.2–0.3
	3 (n = 929)	0.2	0.2–0.2
	Other (n = 460)	0.9	0.7–1.2

Overall, SVR was 90.9% in G/P patients (virological failure 1%, lost to follow-up 8.1%) and 90.0% in SOF/VEL (virological failure 1.8%, lost to follow-up 8.2%). The independent predictors of virological failure were male gender (OR = 2.9 CI95% 1.4–6.2), cirrhosis (OR = 2.1, CI95% 1.1–3.8), GT2 (OR = 3.1, CI95% 1.1–8.7) and GT3 (OR = 3.4, CI95% 1.7–6.5); but not the specific antiviral treatment

Conclusion: in the setting of an unrestricted access to HCV therapies, baseline characteristics of patients may influence the selection of the antiviral regimen. SVR rates were very high and independent of treatment regimen; non response was associated to male gender, liver cirrhosis and HCV genotypes 2 and 3.

THU422

The English hepatitis C registry shows only a modest effect from non-completion of directly-acting antivirals for hepatitis C: SVR rates over 80% in genotype 1, 2 or 3 HCV if more than one third of planned treatment is completed

Kate Drysdale[1], Yevedzo Ntuli[1], Jonathan Bestwick[2], Ceri Townley[3], Faizel Mahomed[4], Graham Foster[1]. *[1]Queen Mary University of London, Barts Liver Centre, Blizard Institute, London, United Kingdom; [2]Queen Mary University of London, Wolfson Institute of Preventive Medicine, London, United Kingdom; [3]NHS England, Specialised Services National Support Team, United Kingdom; [4]Arden & GEM Commissioning Support Unit, Leicester, United Kingdom*
Email: k.drysdale@qmul.ac.uk

Background and Aims: Until late 2019, DAA treatment funded by NHS England was limited to one treatment course per patient unless virological failure occurred.

The English national hepatitis C registry contains demographic, clinical and therapeutic data on every person in England known to have been treated for hepatitis C.

We aimed to quantify the effect of non-completion of a planned course of directly acting antiviral treatment.

Method: Sustained virological response (SVR) rates for patients who received a valid treatment for their genotype and were scheduled to finish treatment by 22 August 2018 were calculated from anonymised data. Odds ratios for SVR when treatment was completed or not were calculated using multivariable logistic regression to allow for confounding factors including age, gender, ethnicity, disease stage, treatment regimen and presence of HCC.

Results: Actual and planned treatment durations were recorded for 98.54% (14,391/14,603) of patients with an outcome 12 weeks after treatment. 4.38% (631/14,391) of these patients did not complete treatment.

Overall, patients who did not complete the planned treatment duration had a significantly lower SVR rate (80.67% (95% CI 77.45% to 83.60%)) than those who did (96.47% (95%CI 96.15% to 96.78%)). There was a trend for increasing SVR rate with increased proportion of treatment completed. If at least one third of treatment was completed, SVR rates for genotypes 1, 2 or 3 were over 80% and 69.23% for genotype 4.

Significantly more patients treated for genotype 1 HCV with 16 weeks of Elbasvir/Grazoprevir and Ribavirin did not complete treatment than in any other regimen (17.66% cf 1.90% to 4.85%, n = 145/821, p < 0.001). Adjusted odds ratios for SVR for genotype 1 and genotype 3 for non-completion of planned treatment compared to completion of planned treatment were 0.149 (95% CI 0.107 to 0.209) and 0.102 (95% CI 0.062 to 0.168) respectively.

Conclusion: Rates of treatment non-completion were low apart from patients with genotype 1 HCV treated with Elbasvir/Grazoprevir and Ribavirin for 16 weeks. Non-completion of the planned treatment duration was associated with significantly lower SVR rates overall. However, a plateau effect was seen with SVR rates over 80% in patients with genotype 1 or 3 who completed at least one third of planned treatment.

THU423

Evolution of hepatitis C virus genotype 1a vs 1b distribution reflects profound changes in HCV epidemiology in Germany - analysis of 17,093 patients from five consecutive registries including the German hepatitis C-registry (DHC-R)

Karl-Georg Simon[1], Yvonne Serfert[2], Peter Buggisch[3], Stefan Mauss[4], Klaus Boeker[5], Hartwig Klinker[6], Tobias Müller[7], Uta Merle[8], Dietrich Hüppe[9], Michael P. Manns[10], Heiner Wedemeyer[2,11], German Hepatitis C-Registry[2]. *[1]MVZ Dres. Eisenbach, Simon, Schwarz GbR, Leverkusen, Germany; [2]Leberstiftungs-GmbH Deutschland, Hannover, Germany; [3]Ifi-Institute for Interdisciplinary Medicine, Hamburg, Germany; [4]Center for HIV and Hepatogastroenterology, Düsseldorf,*

Email: k.-g.simon@t-online.de

Background and Aims: Hepatitis C virus (HCV) genotype (GT) 1 is the most common HCV GT in Western and Central Europe. Overall, HCV GT 1a is found more frequently in persons who have acquired HCV by drug use while HCV GT 1b has frequently been transmitted by transfusion of blood products before 1992. HCV GT 1 subtypes show different responses to some of the approved direct acting antivirals which still has relevance as, e.g. elbasvir/grazoprevir is widely used in some European countries. A more detailed knowledge on the evolution of HCV GT 1a vs. 1b would lead to a better understanding of HCV epidemiology which could have consequences for HCV elimination strategies.
Method: The present analysis is based on five German non-interventional registry studies and comprises data on 17,093 HCV-GT1 patients documented between 2004 and 2018 [ML17071, ML19464, ML21645, ML25724 (Peginterferon alfa-2a® non-interventional study, PAN) and the German Hepatitis C-Registry (DHC-R)]. ML17071, ML19464, ML21645 and PAN were initially sponsored by Roche Pharma AG. In 2014, these data were transferred in anonymous form to the German Liver Foundation. Leberstiftungs-GmbH Deutschland initiated the DHC-R which currently includes about 16,500 patients.
Results: Overall, 7,662 patients were infected with HCV GT 1a and 9,431 patients with HCV GT 1b. GT 1a patients were younger (46.5 years vs. 51.2 years) and more often male (70% vs. 52%). Previous or ongoing drug abuse was documented more frequently for GT1a patients throughout the study periods with highest frequencies in the most recent period (2017–2018; 44% for GT1a and 10.3% for GT1b). Until 2013, more GT1b than GT1a infected patients were obese and had diabetes mellitus while the proportion of patients with liver cirrhosis did not differ between these subgenotypes. A significant change in the GT1a/1b ratio was observed over time in men with less than 40% being infected with GT1a in 2004–2007 and about 60% in 2017/2018. In contrast, only 28–38% of women had GT1a infection throughout all study periods. There were no regional differences within Germany in HCV GT1a/1b distribution despite a higher proportion of GT1b infected women in eastern Germany in 2004–2007 (86%).
Conclusion: A marked increase of GT1a infection associated with drug use was observed in men but not women in Germany between 2004 and 2018. Metabolic comorbidities such as overweight and diabetes mellitus were associated with HCV GT 1b infected women.

The quetiapine question: management strategies for drug-drug interactions with antipsychotics and direct acting antivirals; a multicentre review

Katherine Davidson[1], Alison Boyle[2,3], Stephen Barclay[4], Elspeth Boxall[5], Cecilia Fleming[3], Peter Gossman[6], Janice McAvennie[3], Elaine Reilly[3], Elaine Sheridan[7], Andrew Sommerville[3], Fiona Marra[2,3]. *[1]NHS Lothian; [2]University of Liverpool; [3]NHS Greater Glasgow and Clyde, Gartnavel General Hospital; [4]NHS Greater Glasgow and Clyde, Glasgow Royal Infirmary; [5]NHS Fife; [6]NHS Ayrshire and Arran; [7]NHS Grampian*
Email: katherine.davidson@nhslothian.scot.nhs.uk

Background and Aims: Patients with mental illness are known to have higher prevalence of hepatitis C Virus (HCV). Direct Acting Antivirals (DAA) have enabled treatment for patients previously excluded due to psychiatric co-morbidities. However, some DAA may result in Drug Drug Interactions (DDI) with antipsychotics (AP) predominantly due to mild CYP3A4 or Pgp inhibition. Although many DAA/AP combinations are classed as green (no interaction expected) by University of Liverpool www.hep-druginteractions.org quetiapine, paliperidone and aripiprazole are as classed amber suggesting use with caution. This may result in increased levels of AP with subsequent toxicities, eg prolonged QTc interval, extrapyramidal or sedation. These could be further potentiated in presence of cirrhosis. The clinical significance of these DDI based on predictive pharmacokinetics is unknown. Management may include dose adjustment/change of AP, change to DAA or clinical monitoring, including ECG. We sought to describe characteristics of the patient cohort and management strategies of this DDI.
Method: Patients treated with DAA and co-prescribed quetiapine, aripiprazole or paliperidone from April 17-March 19 were identified in 5 treatment centres in Scotland. Data was collected on drugs prescribed, presence of cirrhosis, Adverse Drug Reactions (ADR) and virologic outcome. DAA choice was led by national guideline. Management of DDI was coded as: no action needed (NO), continue AP with clinical monitoring (CM), continue AP with dose reduction (DR), switch to alternative AP or DAA (SA/SD), or continue combination with ECG monitoring (ECG).
Results: 183 patients were identified, mean age 42.7 years (SD 9.4), male 123 (67.2%), F4 25 (13.7%). 72 (39.3%) patients had DDI categorised as green, therefore no action needed (NO). Of 111 (60.7%) amber DDI, management was; CM 67 (60.3%), DR 3 (3.3%), SD 26 (23.4%), ECG 15(13.5%) and ADR were reported in 8 patients (7.2%). Per protocol SVR12 was 97.6% (excluding 17 lost to follow up). Co-prescription of other QTc prolonging drugs was seen in 74 patients. Further breakdown will be presented.
Conclusion: Clinical monitoring was the most common strategy and minimal ADR were reported. Excellent virologic results were achieved. This data supports the use of all DAA regimens in the majority of patients prescribed these combinations. An individual approach can identify those few patients who require additional input such as use of high dose antipsychotics, other QTc prolonging drugs or cirrhosis. This data should reassure prescribers and ensure patients in this vulnerable group have access to safe and effective treatment.

THU425

Identification of patients with compensated cirrhosis who can safely use protease inhibitor-based therapy for HCV infection

Lisette Krassenburg[1,2], Raoel Maan[1], Alnoor Ramji[3], Michael P. Manns[4], Markus Cornberg[4], Heiner Wedemeyer[5], Robert De Knegt[1], Robert De Man[1], Harry Janssen[2], Bettina Hansen[2,6], Adriaan Van der Meer[1], Jordan Feld[2]. *[1]Erasmus MC University Medical Center Rotterdam, Department of Gastroenterology & Hepatology, Rotterdam, Netherlands; [2]Toronto General Hospital, University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [3]University of British Columbia, Department of Medicine, Division of Gastroenterology, Vancouver, Canada; [4]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [5]Essen University Hospital, Department of Gastroenterology and Hepatology, Essen, Germany; [6]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada*
Email: l.krassenburg@erasmusmc.nl

Background and Aims: Direct-acting antivirals (DAAs) are now widely used as treatment for chronic HCV in patients with compensated and decompensated cirrhosis. Based on reported decompensation events during treatment, advisories about use of protease inhibitors (PI) have been issued. Simple identification of patients with cirrhosis with a very low risk of decompensation during treatment who can safely use PI-based therapy would be very helpful.

Method: Retrospective cohort study including all consecutively chronic hepatitis C (HCV) patients treated with DAAs in 4 international hepatology clinics. Baseline was defined as the initiation of treatment. Primary endpoint was liver decompensation (ascites, variceal bleed or encephalopathy), with a follow-up until SVR12. ROC analyses were used to define cut-offs for continuous variables.
Results: 432 patients were included, 318 with Child-Pugh A cirrhosis (CP-A) and 114 Child-Pugh B/C cirrhosis (CP-B/C). Median (IQR) age was 58 (53–63) years and 73 (17%) had genotype 3. 107 (34%) patients with CP-A were treated with PIs and 23 (20%) patients with CP-B/C. SVR was attained in 263 (83%) CP-A patients 86 (75%) CP-B/C patients. Decompensation occurred in 50 (12%) patients, 8 with CP-A and 42 with CP-B/C in a median time of 8 (3–15) weeks. Factors significantly associated with experiencing no decompensation in univariate logistic regression were non-genotype 3 (G3), higher albumin, lower bilirubin, higher ALT, higher platelet (plt) count, lower INR and lower MELD. Among patients without baseline decompensation (no ascites, encephalopathy and normal bilirubin) (n = 266), albumin>38 and platelet count >130 accurately predicted no risk of decompensation. Of patients with baseline albumin>38 and plt count>130, 0 of 68 experienced decompensation. With albumin>38 but plt<130, the risk of decompensation was 3 of 77 (4%) similar to those with albumin<38 and plt>130 (2 of 36 (5.6%)). Of patients with albumin<38 and plt<130, 6 of 85 (7.1%) experienced a decompensation event with treatment. These thresholds were robust in those who received PIs and those who do not.

	Alb<38	Alb>38	Total
Plt<130	6/85 (7.1%)	3/77 (3.9%)	9/162 (5.6%)
Plt>130	2/36 (5.6%)	0/68 (0%)	2/104 (1.9%)
Total	8/121 (6.6%)	3/145 (2.1%)	11/266 (4.1%)

Figure: Risk of decompensation among patients with compensated cirrhosis starting DAA therapy

Conclusion: Patients with cirrhosis who have no evidence of decompensation at baseline and albumin>38 and plt count>130 can safely be treated with DAAs including PI-based therapy with minimal or no risk of decompensation.

THU426
Virological patterns of HCV-patients with failure to second generation direct-acting antivirals

Laura Occhiello[1], Mario Starace[1], Mariantonietta Pisaturo[1], Carmine Minichini[1], Stefania de Pascalis[1], Margherita Macera[1], Alessandra di Fraia[1], Loredana Alessio[2], Vincenzo Messina[2], Ernesto Claar[3], Tiziana Ascione[4], Aldo Marrone[5], Ivan Gentile[6], Giuseppe D'Adamo[7], Giovanni Battista Gaeta[1], Nicola Coppola[1].

Umberto I Nocera Inferiore
Email: laura.occhiello@gmail.com

Background and Aims: Direct-acting antivirals (DAA)-regimens are associated with failure in about 5% of cases. Aim of this work is to characterize the virological patterns and the resistant-associated substitutions (RASs) in the patients(pts) with failure to second-line DAA-regimen. It may help to identify the best approach of new line DAA-regimen.
Method: All the consecutive 63 HCV pts naive with failure to IFN-free regimen observed at the laboratory of infectious diseases of University of Campania, Naples from January 2018 to February 2019 were enrolled. All the pts had been treated with second DAA-regimens (Sofosbuvir+Velpatasvir, Glecaprevir+Pibrentasvir, Grazoprevir/Elbasvir) according HCV genotype, international guidelines and local availability. Sanger sequencing of NS3 (for genotypes 1 and 4), NS5A and NS5B (for all genotypes) was performed at failure by home-made protocols.
Results: Pts enrollerd were mainly males (60%) with median age 67.5 years (range 42–81). HCV RNA, IU/ml median value was 2.27E + 06 (range: 9.08E + 00–1.10E + 07), 33.3% of pts had a diagnosis of cirrhosis. 5 patients were HCV genotype 1a, 41 1b, 5 2a/2c, 9 3a/3 h and 3 were genotype 4. According to therapeutic outcome, 90.5% were relapse, 4.7% were breakthrough and 4.7% were non-response. Among the 63 pts failed at three therapeutic regimens, 19 (30.1%) were been treated with Sofosbuvir + Velpatasvir, 11 (17.4%) with Glecaprevir + Pibrentasvir and 33 (52.4%) with Elbasvir/Grazoprevir. The duration of DAA in months, median (range) 12 (8–24), the timing of resistence test in months at the end of treatment, median (range) 5 (1–19). The NS5A-RASs were more frequent in Sofosbuvir +Velpatasvir (17/19, 89.5%) and in Grazoprevir/Elbasvir (32/33, 97%) failed patients than in Glecaprevir/Pibrentasvir (2/11, 18.2%) failed pts (p = 0,002 and 0,000 respectively). Moreover NS3-RAS were more often detected in pts with failure to Grazoprevir/Elbasvir regimen (10/33, 30.3%) compared to Glecaprevir/Pibrentasvir (1/11, 9.1%) (p = 0,002) and Sofosbuvir + Velpatasvir regimen (2/19, 5.3%) but in this case without statistic significantly. While the NS5B-RAS were infrequent. According to Sofosbuvir + Velpatasvir regimen 36.4% pts showed at least 2 RASs in at least two HCV region including NS5A and 70.3% pts showed at least 2 RASs only in NS5A region. Considering Grazoprevir/Elbasvir regimen 27.3% pts showed at least 2 RASs in at least two HCV region including NS5A and 88% pts showed at least 2 RASs only in NS5A region. (p = 0.00)
Conclusion: Pts can fail also with second-line therapeutic regimens. These pts frequently show mutations above all in the NS5A region, in particular in pts experienced Sofosbuvir/Velpatasvir and in Grazoprevir/Elbasvir regimen than in pts experienced Glecaprevir/Pibrentasvir failure probably due to short lasting of the last cited therapy.

THU427
Global real-world evidence of sofosbuvir/velpatasvir (SOF/VEL) as a highly effective treatment and elimination tool in underserved patient populations experiencing mental health disorders, incarceration or homelessness

Email: lisa.barrett@nshealth.ca

Background and Aims: Successful HCV elimination will require care and cure of difficult to reach populations, including patients with mental health disorders, incarcerated, or homeless. While the WHO guidelines focus on the necessity of engaging these key populations, limited real world effectiveness data (RWD) exist. Simple curative regimens with high sustained virologic response (SVR) rates are key to successful HCV elimination in underserved populations. SOF/VEL is a simple protease inhibitor-free, pangenotypic, panfibrotic, single duration, single tablet regimen, to be taken without regards to food and with limited drug-drug interactions.

This RWD analysis evaluates the effectiveness and tolerability of SOF/VEL for 12 weeks in a worldwide HCV population with mental health disorder, incarcerated or homeless.

Method: 1731 patients from 32 clinical cohorts across Australia, Canada & Europe were managed per local standards of care. Adults were included if SOF/VEL for 12 weeks started before November 2019 and completed while experiencing a mental health disorder, being incarcerated or homeless, irrespective of genotype (GT), presence of compensated cirrhosis (CC) or treatment experience. Exclusion criteria were history of decompensation, prior NS5A-inhibitor exposure, treatment duration >12 weeks or addition of ribavirin. SVR and tolerability were assessed.

Results: Preliminary analysis includes 1143 (71.9% male) patients (51 ± 13.1 years): 691 with a mental health disorder, 341 incarcerated, 111 homeless. 48.9% (559/1143) of patients were taking antipsychotic medication and 55.9% had former or current injecting drug use. 44.6% patients had HCV GT1, 10.9% GT2, 35.0% GT3, 6.7% GT4–6, and 2.8% mixed/unknown GT. 15.5% patients had CC and 13.9% were treatment-experienced.

99.3% (n = 1005/1012) of patients achieved SVR, with SVR between 98.9% and 100% in all 3 priority populations. SVR was 99.6% in non-cirrhotic and 97.5% in CC patients. 131/1143 patients (11.5%) did not have documented SVR, due to non-virological or unknown reason; 95 (72.5%) of whom lost to follow-up. Full analysis will be available at the conference.

Conclusion: SOF/VEL for 12 weeks is a simple, well-tolerated regimen with high cure rates across key patient populations traditionally considered difficult to engage in care across a global context. It allows a test and treat strategy and decentralisation of care, as outlined in the AASLD/ALEH/APASL/EASL joint call to action, enabling reduction of LTFU and implementation of elimination programs.

THU428

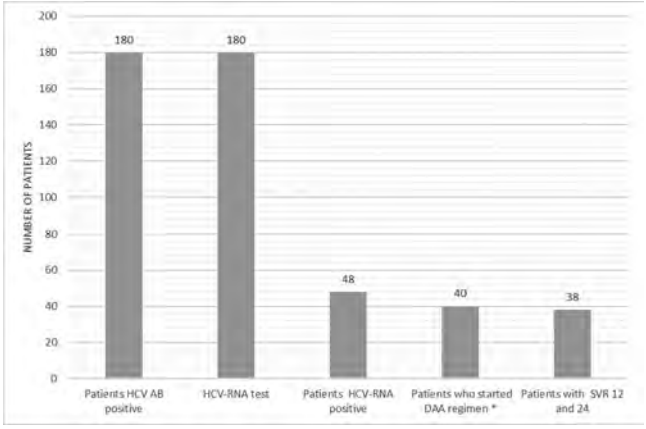
Innovative procedures for micro-elimination of HCV infection in a high-risk population of undocumented migrants and low-income refugees

Lorenzo Onorato[1,2], Nicola Coppola[3,4], Loredana Alessio[4,5], Stefania de Pascalis[3], Vincenzo Messina[4], Caterina Sagnelli[3,6], Evangelista Sagnelli[3], Giovanni Di Caprio[4,5], Margherita Macera[3,5], Mariantonietta Pisaturo[2,3]. *[1]University of Campania "L.Vanvitelli", Department of Mental Health and Public Medicine, Section of Infectious Diseases, Second University of Naples, Italy, Naples, Italy; [2]Medical Center, Centro di Accoglienza "La tenda di Abramo," Caserta, Italy; [3], Department of Mental Health and Public Medicine, Section of Infectious Diseases, Second University of Naples, Italy; [4]InfectiousDiseases Unit, AORN Sant'Anna e San Sebastiano, Caserta, Italy; [5]Medical Center, Centro Sociale ex Canapificio, Caserta, Italy; [6]Medical Center, Centro Suore Missionarie della Carità, Naples, Italy*
Email: lorenzoonorato@libero.it

Background: Because of the intermediate HCV endemicity in immigrant populations and of the high efficacy of DAA therapy, programs should be undertaken to eradicate the infection in this difficult-to-manage setting. The aim of the present study was to evaluate an innovative model to eliminate HCV infection in this population, who generally show an anti-HCV positivity rate 3-time higher than that of citizens of the host country.

Method: A prospective, multicenter, collaborative study, based on the active long-term cooperation between five 1st level clinical points and two corresponding 3rd level units of Infectious Diseases (ID) was performed in Campania, southern Italy.

A screening to identify the subjects with HCV infection, free of charge and without bureaucratic procedures, was proposed to all undocumented migrants and low-income refugees prospectively observed by a physician and a cultural mediator at one of the first-level clinical centres from June 2018 to March 2019. All migrants received correct information and illustrated brochures on transmission and prevention of HCV infection, related diseases and available treatments. All anti-HCV positive subjects were addressed at one of the two ID units for further clinical investigation including HCV-RNA determination and, if positive, HCV-genotyping (GT). HCV-RNA positive patients were treated with sofosbuvir plus velpatasvir + ribavirin for 12 weeks and followed up untreated for 12 weeks after treatment withdrawal



Results: Of the 3,401 migrants observed in the study period, 3,286 (96.6%) accepted to be screened. They were young (median age 27 years), predominantly male (83.3%) and came from North Africa (4%), from Sub-Saharan Africa (67.1%), from Eastern Europe (9.3%), from Indo-Pakistan (16.4%) and from other countries (3.2%). Of the

3,286 enrolled subjects, 180 (5.4%) resulted anti-HCV positive. The Figure shows the HCV-cure cascade. All the 180 anti-HCV-positive subjects were linked to care at 3rdIDand tested for HCV RNA and 48 (26.6%) resulted HCV-RNA positive. Of these, 40 (83.3%) started DAA regimen (14 withGT 1b, 21 with 1a, 18 with 3, 4 with 4 and 2 with 2): 38 completed the follow-up with a SVR rate of 100% and 2are still pending. No subject had adverse neither was drop-out.

Conclusion: This innovative procedures for micro-elimination of HCV infection seems to be effective in undocumented migrants and low-income refugees with rates of diagnosis, linkage to care and cure in line with the WHO goals

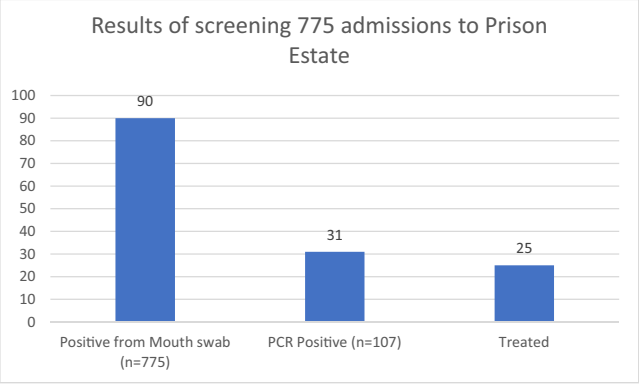
THU429

Elimination of hepatitis C in a remand prison using a rapid point of care driven test and treat pathway

Louise Davies[1], Brendan Healy[1], Gary Matthews[2], James Plant[2], Stephen Edwards[2], Lisa Hughes[3], Helen Thompson-Jones[3], Hayley Edwards[3], Sally Kneath[4], Cathryn Richards[2], RIchard Evans[4], Chin Lye Ch'ng[3]. *[1]Public Health Wales, Microbiology Department, Cardiff, United Kingdom; [2]Swansea Bay University Health Board, HM Prison, Swansea, United Kingdom; [3]Swansea Bay University Health Board, Gastroenterology, Swansea, United Kingdom; [4]Swansea Bay University Health Board, Pharmacy, Swansea, United Kingdom*
Email: Louise.Davies14@wales.nhs.uk

Background and Aims: Micro-elimination in high prevalence settings such as prison estates is seen as an effective strategy for meeting the WHO Hepatitis C elimination targets. We report the successful implementation of a streamlined point of care testing pathway with a rapid treatment strategy that has delivered elimination of hepatitis C in a UK remand prison. The prison has a capacity of 500, receives 45 new admissions week (175/month). Average stay is 6–8 weeks

Method: Individuals were screened on admission with a two-tiered point of care testing strategy. All admissions were first screened for hepatitis C antibodies using a mouth swab (OraSure, OraQuick). Antibody reactive individuals were then tested for hepatitis C PCR using a capillary blood sample (Cepheid, GeneXpert). PCR positive individuals were immediately referred for treatment with a pan-genotypic therapy (Glecaprevir/Pibrentasvir). The strategy was designed to deliver micro-elimination/all prison elimination of hepatitis C, declared when all residents had been tested and all positive residents had started treatment.



Results: The project started on the 8th May. Frontline screening was carried out by HMP nursing staff on secondary health screen (day 2 of arrival). Elimination was declared on 5th September 2019 and has been maintained since. 775 individuals were tested by mouth swab. 90 (12%) patients were hepatitis C reactive. 107 individuals were tested for PCR (17 known to be antibody positive prior to admission). 31 tested positive. 26 started treatment in the prison system. 6 were treated in the community after discharge. 10 (32%) started treatment on the same day that they were diagnosed and 23 (74%) were treated within 8 days. Positive outcomes included reduced stigma, individuals encouraging other residents to be tested, high acceptability of the testing pathway (very few individuals declined the mouth swab screen), provision of a positive health experience and reduction in the burden of the long-term effects of undiagnosed Hepatitis C.

Conclusion: A two-tiered point of care testing strategy with rapid access to treatment using pan-genotypic agents has high acceptability to individuals at risk of hepatitis C, reduced stigma in a prison setting and led to the first ever elimination of hepatitis C in a UK remand prison within 5 months. This test and treat strategy should be tested in other areas of high prevalence where micro-elimination is deemed appropriate.

Submitted on behalf of the All Wales Blood Borne Virus Network

Dermatological manifestations in the era of new direct acting antivirals: a single-center experience

Mohamed Talkhan[1], Khaled Raafat[1], Nouran Said[1], Ossama A Ahmed[1], Gina Naguib[1], Hany Dabous[1], Mohamed Kamal Shaker[1], Yehia Elshazly[1], Manal Hamdy El-Sayed[2], Mahira El Sayed[2]. *[1]Ain Shams University Faculty of Medicine, Hepatogastroenterology and Endoscopy Department, Egypt; [2]Ain Shams University Faculty of Medicine, Dermatology Department, Egypt*
Email: m.gamal.work@gmail.com

Background and Aims: Limited data exist regarding skin disease after introduction of direct acting antivirals (DAAs). When encountering skin lesions in HCV-infected patients treated with DAAs, both HCV related skin manifestations and drug-induced cutaneous adverse effects should be considered. The aim of this study was to analyse possible incidence of dermatological manifestations in patients treated with different DAAs protocols retrospectively.

Method: This case series study included 24 patients (median age 47.5 years) of 9200 patients with chronic HCV recruited from Ain Shams University viral hepatitis and research centre between January 2017 and June 2019. All patients received treatment with DAAs for HCV in conformity with the national protocols. Patients were followed up monthly during the treatment period for liver functions and any clinical complications and three monthly after end-of-treatment. Also, patients were routinely examined during treatment and the follow up period for skin manifestations. All Patients (n = 24) in this study achieved SVR at week 12 and week 24.

Results: Only 24/9200 patients developed dermatologic manifestations. Five of those patients had diabetes mellitus and 15 patients were cirrhotic. Treatment protocols received by affected patients included: Sofosbuvir (SOF) plus Daclatasvir (DAC) (n = 5), SOF plus Simeprevir (SIM) (n = 4) and SOF, DAC and ribavirin (n = 15). Frequency of skin manifestations observed before, during and after DAAs regimen is shown in table (1). All types of lesions showed complete response to standard medical therapies. Conclusion: DAAs can cause different self-limiting dermatologic side effects. Our findings suggest patients treated with DAA may remain at risk for various dermatologic lesions development. Larger prospective studies of patients treated with DAA are needed to better describe the relationship between DAAs and incidence of various skin manifestations, as well as the prognosis of pre-existing lesions after DAA treatment.

Table (1): (abstract: THU430): Frequency of different dermatologic findings in the studied group in different treatment protocols.

THU431

Hepatitis C treatment outcomes among people who inject drugs accessing harm reduction services in Kenya

Matthew Akiyama[1], John Lizcano[2], Helgar Musyoki[3], Peter Cherutich[3], Ann Kurth[2]. *[1]Albert Einstein College of Medicine/ Montefiore Medical Center, Medicine, Bronx, United States; [2]Yale University, School of Nursing, Orange, United States; [3]Kenya Ministry of Health, Nairobi, Kenya*
Email: makiyama@montefiore.org

Background and Aims: Sub-Saharan Africa has among the highest global hepatitis C virus (HCV) prevalence. To meet the WHO's goals for HCV elimination, treatment is needed as part of a comprehensive strategy; however, access to direct-acting antiviral (DAA) therapy has been limited in many low- and middle-income countries (LMICs). HCV treatment among people who inject drugs (PWID) is of particular importance to prevent forward transmission of HCV. Since PWID are a hard to reach population, medication-assisted treatment (MAT) and needle syringe programs (NSP) are potential access points where HCV treatment can be delivered. However, little is known about the feasibility and effectiveness of HCV treatment among PWID in LMICs in MAT and NSP settings.
Method: This study was part of a supplement to the Testing and Linkage to Care for Injection Drug Users (TLC-IDU) Kenya study. The TLC-IDU study was a stepped wedge cluster-randomized trial evaluating the effectiveness of a "seek, test, treat, and retain" approach to HIV community viral load suppression among PWID accessing NSP service sites in Nairobi, Coastal and Western Kenya. Participants from the TLC-IDU study were screened with rapid HCV antibody tests. Those who were antibody-positive were confirmed with HCV RNA tests and genotyped if viremic. We offered DAAs under directly observed therapy (DOT) to 95 participants. All participants had clinical exams and AST to platelet ratio (APRI) scores prior to treatment with sofosbuvir/ledipasvir. The primary endpoint was the proportion of participants with a sustained virological response 12 weeks after therapy (SVR12).
Results: Of the 95 participants who were offered HCV treatment for this sub-study, 51 were genotype 1a, 41 were genotype 4a, and 3 were genotype 1a/4a. Twelve were cirrhotic, 65 were treated in MAT, and 30 were treated in NSP. Of 95 participants, 5 (5.3%) were lost to follow-up after initiating treatment (2 from MAT, 3 from NSP). The other 90 (94.7%) participants were retained. Of those who were retained, 82/90 (91.1%) achieved SVR12–82/95 (86.3%) overall. Two participants had undetectable HCV RNA at the end of treatment (EOT), but were detectable 12 weeks following treatment; SVR12 results were unknown for 3 participants (2 refused blood draw, and the assay could not be performed for 1); 2 discontinued treatment; 1 died before EOT.
Conclusion: HCV treatment in MAT and NSP sites appears to be feasible with high SVR12 rates. These results need to be interpreted with caution given those who were most interested were retained for HCV treatment in this sub-study. Additional studies will be required to assess optimal models of care for HCV treatment among PWID in LMICs given DOT may be infeasible when resources are not sufficient. Additionally, reinfection following successful HCV treatment will need to be evaluated.

THU432

Real-life experience of direct acting antiviral treatment for chronic hepatitis C infection in adolescent patients in a low prevalence setting

Mary Flanagan[1], Michelle Goode[1], Annette Rochford[1], Sinead McDonagh[1], Maura O'Connor[2], Aisling Rafferty[3], Karina Butler[1,4], Patrick Gavin[1,4]. *[1]Children's Health Ireland, Crumlin, Rainbow Paediatric Infectious Diseases, Dublin, Ireland; [2]Children's Health Ireland, Crumlin, Pharmacy, Dublin, Ireland; [3]Children's Health Ireland, Temple Street, Pharmacy, Dublin, Ireland; [4]Children's Health Ireland, Temple Street, Rainbow Paediatric Infectious Diseases, Dublin, Ireland*
Email: marflanagan@gmail.com

Background and Aims: The global prevalence of hepatitis C virus infection (HCV) is estimated to be 177 million people (2.5%). Chronic HCV infection is associated with cirrhosis and hepatocellular carcinoma. Direct acting antivirals (DAT) for HCV have been licensed for use in adults since 2011 and have a cure rate of >95%. In 2018 the European Society of Paediatric Gastroenterology, Hepatology And Nutrition gave guidance on the use of DAT in children >12 years of age and >35 kg in weight. Currently 2 DATs are licensed to treat HCV in adolescents including; a 12 week course of Ledipasvir/Sofosbuvir and an 8 week course of Glecaprevir/Pibrentasvir.
Method: All children with chronic HCV in Ireland are treated in the rainbow paediatric infectious disease clinic. In 2017, the National HCV Treatment Programme agreed to extend access to DAT to our

paediatric cohort. The aim of our study was to evaluate DAT in our paediatric cohort.
Results: 31 adolescents have been eligible for DAT in our service, of which 26 (84%) have commenced and completed DAT, 3 patients were lost to follow up and 2 patients have deferred treatment until next summer. All patients completed therapy, no patient reported serious adverse drug reactions and 7 patients reported adherence issues. Median age at commencing DAT was 15.6 years (range 12.9–19.6years). 12 patients (46%) lived with their biological parent/s, a further 35% lived with extended family members and 19% were in foster/residential care. All patients with HCV genotype 1 received Ledipasvir/Sofosbuvir (n = 24), whilst the remaining 2 patients with genotype 3 received Glecaprevir/Pibrentasvir. Median pre-treatment HCV Viral Load (VL) was Log 5.87 (range Log 4.27–7). 23 of 26 patients had undetectable VL at treatment end, 2 had a VL below the limit of detection and 1 failed to attend for testing. 20 patients achieved a SVR 3 months from end of treatment, 5 have SVR results pending and 1 patient was lost to follow up.
Conclusion: Our study reaffirms the successful cure rate with DAT for adolescents with chronic HCV. Challenges with DAT in our patient cohort included; 1) adherence with treatment protocol 2) complex social backgrounds and 3) coordination of DAT monitoring with educational examinations. To ensure optimal success of DAT in a non clinical trial setting we suggest careful patient selection, advanced patient preparation, ongoing patient follow up and parental/guardian support from a multidisciplinary team.

THU433

Treatment of hepatitis C at the Stockholm needle syringe program - treatment success, reinfection rates and challenges for HCV elimination

Martin Kåberg[1,2], Ann-Marie Lang[1]. [1]*Stockholm Needle Exchange, Stockholm Centre for Dependency Disorders, Stockholm, Sweden;* [2]*Karolinska Institutet, Department of Medicine, Huddinge, Stockholm*
Email: martin.kaberg@sll.se

Background and Aims: The Stockholm Needle Syringe Program (NSP) has since the start in 2013 enrolled over 3,500 participants. Annually, around 1,800 persons make 26,000 visits at the Stockholm NEP. 43% inject mainly heroin and 43% amphetamine. Mean age is 39 years and mean duration of injection drug use is 18 years. 21% are homeless. The viremic HCV prevalence is 55%. Although injection risk behaviors decrease significantly over time among participants, HCV incidence remains high with an incidence rate of 22/100 person years.
Method: Since January 1st 2018, participants at the Stockholm NSP are HCV treated without reimbursement restrictions. Patients were HCV RNA tested at EOT, SVR12 and every 6 months post SVR.
Results: So far 124 participants (>75% amphetamine users) have initiated HCV treatment. 100/114 (88%) were HCV RNA negative at end of treatment (EOT), 10 participants dropped out 1–2 weeks after treatment initiation and two after 6–7 weeks. Another two participants were lost to follow-up. Thus, all participants who completed treatment, with a follow-up HCV test (n = 100), were HCV RNA negative at EOT. Overall, 73/95 (77%) reached SVR12 (12 drop-outs and 10 lost to follow-up). All with a follow-up test at SVR12 + (n = 73) were HCV RNA negative. 5 reinfections post-SVR occurred, corresponding to a reinfection rate of 10.6/100 PY. One reinfection was spontaneously cleared, leaving a persistent reinfection rate of 8.5/100 PY. On a parallel level, there were 146 new HCV infections

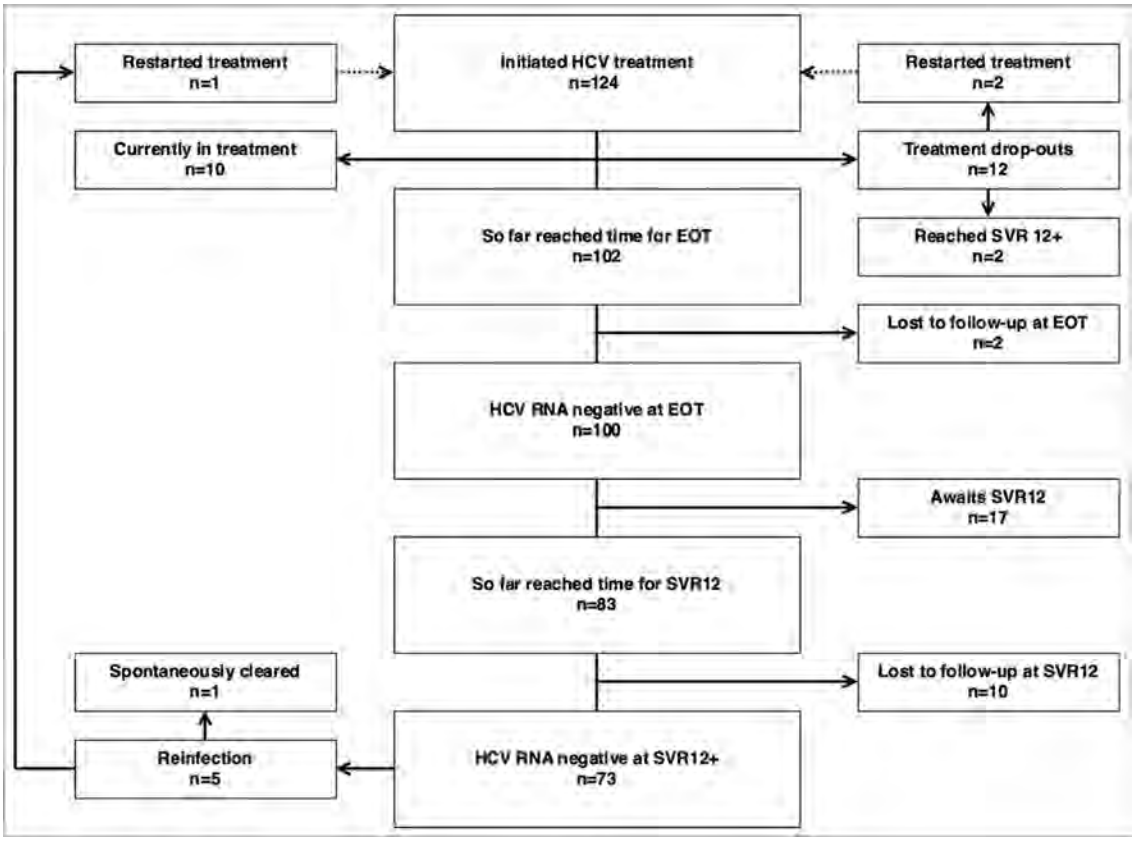

Fig 1: (abstract: THU433): Flowchart of HCV treated patient at the Stockholm Needle Syringe Program. "SVR 12+" refers to an SVR test at week 12 or later.

(seroconversions/reinfections) in the non-treated cohort during the study period.
Conclusion: Even though 8–10% of the HCV viremic patients were treated annually at the Stockholm NSP, the number of new HCV infections were higher than the total number treated. A high prevalence of HCV and amphetamine use (not eligible for effective substance use disorder treatment) thus constitutes a great challenge for HCV elimination.
Further treatment data and reinfection data is pending and will be presented at ILC 2020.

THU434
Epidemiological and clinical analysis of foreign patients treated with direct antivirals for hepatitis C in a high immigration area

Matias Estevez[1], Isabel Moreno Moraleda[2], Carmen Molina Villalba[1], Marta Casado[2], Leticia Miras Lucas[1], Carolina Molina Maldonado[1], Cristina Viñolo-Ubiña[1], Francisco Javier Gallego Rojo[1]. *[1]APES Hospital de Poniente, Gastroenterology and Hepatology, El Ejido, Almeria, Spain; [2]Hospital Universitario Torrecardenas, Gastroenterology and Hepatology, Almeria, Spain*
Email: matiasesteveze@gmail.com

Background and Aims: Although Spain has a low prevalence for hepatitis C (HCV) (0.85% seropositivity and 0.22% active infection), in the immigrant population this seroprevalence is estimated at 1.3–1.6%, with important differences according to origin. Our aims were to analyze the epidemiological and clinical characteristics of immigrants treated since the appearance of direct-acting antivirals (DAA) for HCV in our geographic area, and their possible differential features.
Method: Descriptive cross-sectional study on all HCV monoinfected immigrant patients treated with DAA (without Interferon) in two hospitals. Medical records and epidemiological data collected in Primary Care were reviewed.
Results: 149 immigrant patients were treated (89 Poniente, 60 Torrecárdenas), out of a total of 1314 treatments (11.3% from total). They came from 27 different nationalities, mostly from Eastern Europe and former USSR (EEu 55.4%), Sub-Saharan Africa (SubS 18.9%) and Maghreb (Mgb 15.5%). They presented an average of 12.6 +/– 8.2 years in Spain, being the EEu and Mgb who showed a greater median stay (14–16 years vs 9–10 years in other origins, $p = 0.035$). The viral load expressed in Log10 was 5.74 +/– 0.94, ALT 63.43 +/– 54.83 U/L and platelets 201 +/– 69 × 109/L. Most of them had absent or minimal fibrosis (54.1%). The genotypic distribution was the only infection-related variable that showed differences according to origin ($p < 0.001$), since the SubS had 84.0% of G2-G3, compared to a predominance of G1 in the rest. There are no SVR12 data from 24 patients (6 losses, 18 pending SVR). The overall SVR of the remaining 125 was 95.7% with 4 incidences of adherence: 2 dropouts, 1 dose failure (1 pill t.i.d. instead of 3 pills together daily, no SVR) and a suspension due to error (resumed after 2 weeks and obtained SVR).
Conclusion: The majority of immigrants treated with DAA in our health area come from Eastern Europe, have low fibrosis and only show differences in their genotypic distribution according to origin. The SVR12 is similar to that recorded in real-life cohorts, with little impact on therapeutic adherence.

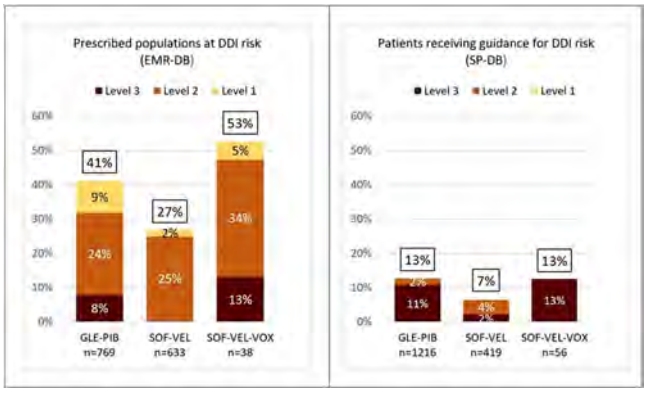
THU435
Drug-drug interactions (DDIs) with pangenotypic direct-acting antivirals (DAAs) in patients with hepatitis C; understanding the populations at risk and real-world care management

Michael Curry[1], Naoky Tsai[2], Bruce Bacon[3], Steven Flamm[4], Zobair Younossi[5], Scott Milligan[6], Nicole Wick[7], Nezam Afdhal[1]. *[1]Beth Israel Deaconess Medical Center; [2]University of Hawaii, Honolulu, Hawaii, USA; [3]Saint Louis University School of Medicine, St. Louis, Missouri, USA; [4]Division of Hepatology, Northwestern University, Feinberg School of Medicine; [5]Center for Liver Diseases and Department of Medicine, Inova Fairfax Hospital, Falls Church, VA, United States; [6]Trio Health Analytics, La Jolla, CA; [7]Trio Health Analytics, La Jolla, CA, La Jolla, United States*
Email: nicole.wick@triohealth.com

Background and Aims: Several studies have assessed the frequency and nature of DDIs with DAAs, but few have assessed care management for identified DDIs. We used two complementary data sources to initially identify DDI risk for DAAs and a second source to describe healthcare providers actions in care of HCV patients with potential DDIs.
Method: To assess DDI risk, data for patients prescribed DAAs in 2018 were collected from a propriety US EMR database (EMR-DB) covering 21 healthcare organizations and 26MM patients and possible interacting drugs identified. Per the Hepatitis Drug Interaction Database from The University of Liverpool, DDIs were considered potential weak interaction (level 1), potential interaction (level 2), or contraindicated (level 3). Real-world recommendations and resultant actions regarding DDIs were obtained from a specialty pharmacy database (SP-DB) and were specific for patients prescribed glecaprevir-pibrentasvir (GLE-PIB), sofosbuvir-velpatasvir (SOF-VEL), or SOF-VEL-voxilaprevir (SOF-VEL-VOX).
Results: The EMR-DB study population consisted of 2214 DAA-prescribed HCV patients of which 35% (769) were prescribed GLE-PIB, 29% (633) SOF-VEL, and 2% (38) SOF-VEL-VOX. Potential DDIs were identified in 41% (317/769) GLE-PIB prescribed patients, 27% (170/633) SOF-VEL, and 53% (20/38) SOF-VEL-VOX. [Figure] Top DDI drug classes for GLE-PIB were level 2 analgesics (139/317, 44%); for SOF-VEL were level 2 PPIs (83/170, 49%); and for SOF-VEL-VOX were level 2 PPIs (6/20, 30%). The SP-DB study population consisted of 1691 HCV patients. Potential DDIs that resulted in guidance to the physician were observed in 12% (151/1216) GLE-PIB prescribed patients, 7% (28/419) SOF-VEL, and 13% (7/56) SOF-VEL-VOX. [Figure] Recommendations varied by DDI, patient, and disease characteristics and consisted of "hold interacting drug," "modify dose of interacting drug," "switch interacting drug," or "proceed but monitor." The recommended guidance was not followed for 10% (15/155) GLE-PIB prescribed patients, 36% (10/28) SOF-VEL, and 43% (3/7) SOF-VEL-VOX.

Variable		EastEurope (n=82)	SubSahara (n=28)	Mgb/MEast (n=23)	Others (n=15)	p
Age		43,6 (36,8-51,0)	46,5 (31,2-52,5)	50,0 (45,0-59,0)	53,3 (44,0-57,0)	p=0,003
Time in Spain (years)		14,0 (11,0-16,0)	9,0 (2,2-13,7)	16,0 (10,0-20,0)	10,0 (4,0-14,0)	p=0,035
Viral load log10		5,68 (5,07-6,35)	5,94 (5,01-6,80)	5,74 (5,54-6,30)	6,03 (5,68-6,67)	ns
Genotype n(%)	1	58 (76,3%)	4 (16,0%)	14 (63,6%)	10 (66,7%)	p<0,001
	2-3	18 (23,7%)	21 (84,0%)	8 (36,4%)	5 (33,3%)	
Fibrosis n(%)	F0-F1	46 (57,5%)	17 (63,0%)	11 (50,0%)	6 (42,9%)	ns
	F2-4	34 (42,5%)	10 (37,0%)	11 (50,0%)	8 (57,1%)	
Platelets <150x10^9/L n(%)		19 (23,5%)	4 (14,3%)	7 (30,4%)	7 (46,7%)	ns
ALT≥35U/L n(%)		54 (66,7%)	19 (67,9%)	12 (52,2%)	13 (86,7%)	ns

Figure: (abstract: THU434)



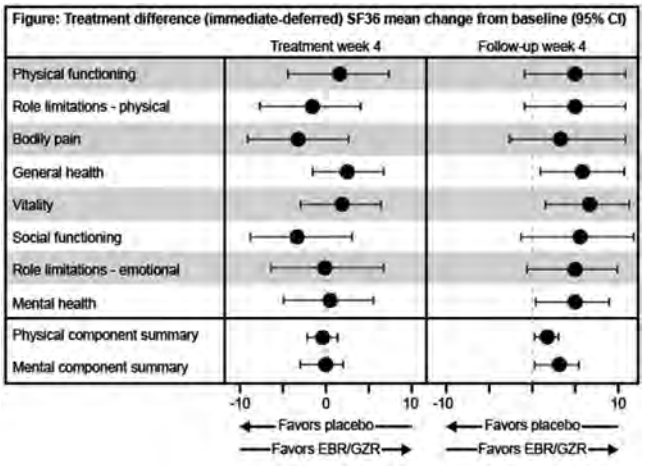
Conclusion: Prevalence of DDI is very common for HCV treatment and more frequent in protease-containing regimens and associated with common medications. Recommendations for identified DDIs in real-world care are given for level 2 and 3 DDIs and physician response is highly variable.

THU436

Patient-reported outcomes among people receiving opioid agonist therapy and treatment for hepatitis C virus infection: results from CO-STAR

Olav Dalgard[1], Alain Litwin[2], Gregory Dore[3], Oren Shibolet[4], Jason Grebely[3], Ronald Nahass[5], Frederick Altice[6], Brian Conway[7], Edward Gane[8], Anne Luetkemeyer[9], Cheng-Yuan Peng[10], David Iser[11], Isaias Noel Gendrano[12], Michelle M. Kelly[12], Barbara Haber[12], Heather Loryn Platt[12], Amy Puenpatom[12]. *[1]Institute of Clinical Medicine, Akershus University, Oslo, Norway; [2]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, United States; [3]The Kirby Institute, UNSW Sydney, Sydney, NSW, Australia; [4]Tel Aviv Medical Center and Tel Aviv University, Liver Unit, Department of Gastroenterology, Tel Aviv, Israel; [5]ID Care, Hillsborough, NJ, United States; [6]Yale University, New Haven, CT, United States; [7]Vancouver Infectious Diseases Centre, Vancouver, BC, Canada; [8]Auckland City Hospital, Liver Unit, Melbourne, VIC, Australia; [9]University of California, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, CA, United States; [10]China Medical University Hospital, Taichung, Taiwan; [11]The Alfred Hospital, Infectious Diseases Unit, Melbourne, VIC, Australia; [12]Merck & Co., Inc., Kenilworth, NJ, United States*
Email: Michael.Winterrowd@apothecom.com

Background and Aims: The CO-STAR study evaluated the safety and efficacy of elbasvir/grazoprevir (EBR/GZR) administered for 12 weeks in participants with hepatitis C virus (HCV) infection receiving opioid agonist therapy (OAT). Sustained virologic response was achieved by 96% of participants. The aim of this analysis was to evaluate changes in health-related quality of life (HRQOL) in the study population.
Method: Participants on OAT were randomized to receive the fixed-dose combination of EBR/GZR (50 mg/100 mg daily) or placebo once daily for 12 weeks. Participants remained blinded until follow-up week (FW) 4, after which those randomized to placebo initiated deferred treatment with EBR/GZR. HRQOL was measured at baseline, treatment week (TW) 4, end of treatment (EOT), and FW4 before any study-related procedures using the Short Form-36v2 survey. Difference in mean change from baseline scores >5% for individual domains or >2%–3% for physical/mental component summary (PCS/MCS) scores were considered clinically meaningful.
Results: Participants were primarily white (80%) and male (76%) with HCV genotype 1a infection (76%); 59% had a positive urine drug screen at baseline. At baseline, mean MCS and PCS scores for EBR/GZR (n = 198) and placebo (n = 98) treatment groups were 44.4 (standard deviation [SD] 11.4) vs 43.4 (SD 11.6) and 48.6 (SD 8.7) vs 49.1 (SD 9.6), respectively. At TW 4 and EOT, the differences in mean change from baseline MCS and PCS scores (EBR/GZR – placebo) suggested no clinically meaningful difference between EBR/GZR and placebo. The difference in mean change from baseline at FW4 in general health (6.0%; 95% CI 1.4–10.6), vitality (6.8%; 95% CI 1.9–11.8), and mental health (5.2%; 95% CI 0.5–9.8) domains suggests clinically meaningful improvements in participants receiving EBR/GZR compared with those receiving placebo (Figure). The difference in mean change from baseline scores (EBR/GZR – placebo) for the MCS was also considered clinically meaningful (2.8%, 95% CI 0.3–5.4). Significant differences at FW4 were not observed in physical functioning, role limitations (physical), bodily pain, or the PCS.



Conclusion: Post-treatment improvement in HRQOL was observed in participants on OAT receiving EBR/GZR compared with those receiving placebo. Clinically meaningful improvements were noted in the general health, vitality, and mental health domains. Improvement in general and mental health adds to the benefits of HCV therapy among people who inject drugs.

THU437

Real-world effectiveness of sofosbuvir/velpatasvir/voxilaprevir as a hepatitis C virus infection salvage treatment

Naveed Janjua[1,2], James Wilton[1], Darrel Cook[1], Stanley Wong[1], Zahid Butt[1,3], Sofia Bartlett[1], Dr. Margo Pearce[1], Alnoor Ramji[4], Eric Yoshida[4], Amanda Yu[1], Maria Alvarez[1], Mawuena Binka[1], Mel Krajden[1,5]. *[1]British Columbia Centre for Disease Control, Vancouver, Canada; [2]University of British Columbia, School of Population and Public Health, Vancouver, Canada; [3]University of Waterloo, School of Public Health and Health Systems, Waterloo, Canada; [4]University of British Columbia, Department of Medicine, Division of Gastroenterology, Vancouver, Canada; [5]University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada*
Email: naveed.janjua@bccdc.ca

Background and Aims: First-line direct acting antiviral agents (DAAs) are highly effective (90%–95%), yet some hepatitis C (HCV) patients do not achieve sustained virologic response (SVR). In patients previously treated with DAAs, sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) has shown high SVR rates in clinical trials. We assessed the effectiveness of SOF/VEL/VOX in treating treatment-experienced patients with HCV genotype 1 (GT1) to genotype 6 (GT6) infection in a large population-based Canadian cohort.
Method: This analysis included individuals in the British Columbia (BC) Hepatitis Testers Cohort who had virological failure after prior DAA therapy, initiated SOF/VEL/VOX for retreatment of GT1-GT6 on or prior to June 30, 2019, and had at least one HCV RNA test after treatment initiation. SVR was assessed from treatment start until Oct 9, 2019. The primary outcome was SVR at 12 weeks following end of HCV treatment based on modified intention-to-treat, where

individuals with a negative HCV RNA test after treatment end but no SVR assessment were excluded.
Results: Overall, 191 people treated with SOF/VEL/VOX (n = 153) or SOF/VEL/VOX+ribavirin (RBV; n = 38) were included in the analysis. The majority of were infected with GT1 (n = 104, 54.5%) or GT3 (n = 62, 32.5%), followed by GT2 (n = 17, 8.9%). Most individuals were male (82.2%) and aged ≥ 50 years (92.1%). The largest proportion of patients received SOF/ledipasvir (SOF/LDV; 37.2%), followed by SOF/VEL (14.1%) and SOF+RBV (13.6%) and as their last treatment. The overall SVR rate with SOF/VEL/VOX salvage treatment was 95.3% (182/191). SVR for GT1, GT2 and GT3 was 96.2%, 100%, and 91.9%, respectively. SVR was lower (but not statistically significant) for those with cirrhosis vs. no cirrhosis – overall (88.0% vs 96.4%) and across previous treatment regimens: SOF/VEL (75.0% vs 91.3%), SOF/LDV (85.7% vs 96.5%), SOF-containing (87.0% vs. 96.2%) and NS5A + SOF (84.2% vs. 95.1%).

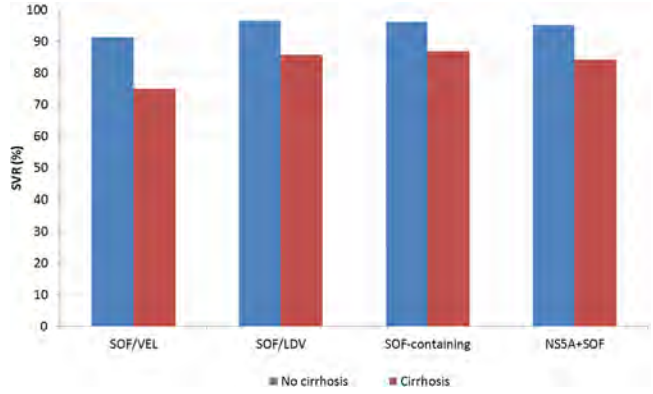


Figure: SVR among patients treated with SOF/VEL/VOX by cirrhosis status and previous treatment regimen

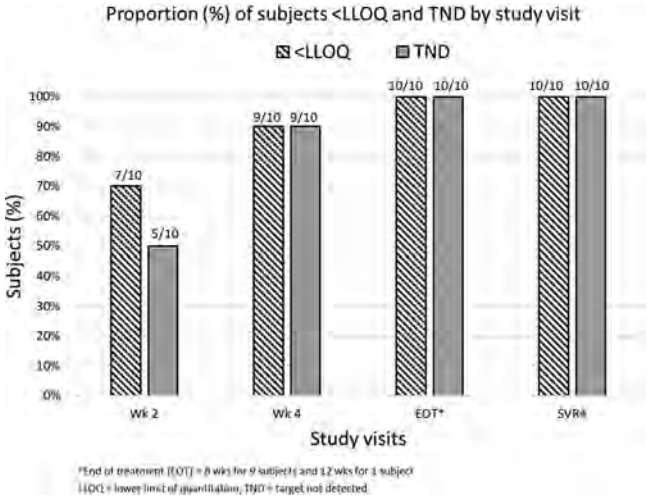
Conclusion: In this real-world cohort of patients with virological failure after prior DAA therapy, retreatment with SOF/VEL/VOX resulted in SVR rates of more than 90% across all genotypes; however, SVR was lower for those with underlying cirrhosis. Comparisons were limited by small sample sizes.

THU438

A combination of AT-527, a pan-genotypic guanosine nucleotide prodrug, and daclatasvir was well-tolerated and effective in HCV-infected subjects

Ounisha Mungur[1], Elina Berliba[2], Stefan Bourgeois[3], Marine Cardona[1], Alina Jucov[2], Steven Good[4], Adel Moussa[4], Keith Pietropaolo[4], Xiao-Jian Zhou[4], Nathaniel Brown[4], Jean-Pierre Sommadossi[4]. *[1]CAP Research, Phoenix, Mauritius; [2]ARENSIA Exploratory Medicine, Republican Clinical Hospital, Chișinău, Moldova; [3]ZNA Stuivenberg, Antwerpen, Belgium; [4]Atea Pharmaceuticals, Inc., Boston, United States*
Email: zhou.xj@ateapharma.com

Background and Aims: AT-527 is a novel modified guanosine nucleotide prodrug inhibitor of the hepatitis C virus (HCV) NS5B polymerase, with a highly differentiated profile compared to sofosbuvir. AT-527 exhibited profound pan-genotypic antiviral activity after 550 mg once daily (QD) dosing for 7 days in HCV-infected patients with or without cirrhosis. The current pilot phase 2 study was conducted to evaluate the long-term safety, viral kinetics and efficacy of AT-527 in combination with daclatasvir, the only approved stand-alone NS5A inhibitor.
Method: A cohort of 10 treatment-naïve, genotype (GT) 1-infected subjects without cirrhosis received 550 mg AT-527 and 60 mg daclatasvir QD. The protocol allowed subjects who achieved HCV RNA < lower limit of quantitation (LLOQ) by wk 4 to stop treatment after 8 wks. Otherwise, subjects were to receive 12 wks of treatment. Safety assessments included adverse events (AEs), vital signs, electrocardiograms (ECGs) and standard safety laboratory tests. Viral kinetics were evaluated by monitoring plasma HCV RNA using the Roche Cobas® quantitative test on the Cobas® 6800/8800 system (LLOQ = 15 IU/mL).
Results: The 10 enrolled subjects (5 African origin and 5 European origin) had the following demographic characteristics: mean age 39 yrs (range: 26–57), 8 male/2 female, mean HCV RNA 6.8 $\log_{10}$ IU/mL (range: 6.0–7.5), 6 GT1a/4 GT1b, mean ALT 72 U/L (range: 22–181). All subjects (100%; 10/10) achieved SVR4. Nine subjects received 8 wks of treatment, and one subject received 12 wks of treatment. The study drugs were well tolerated with no discontinuations or serious AEs. AEs were generally mild and transient. ALT decreased rapidly with dosing and normalized by wk 2. There were no clinically significant changes in vital signs or ECGs. Viral load declined rapidly with 7/10 (70%) subjects achieving HCV RNA < LLOQ by wk 2 (5 had non-detectable HCV RNA at wk 2). SVR12 data will be presented at the meeting.



Conclusion: AT-527 in combination with an HCV NS5A inhibitor (daclatasvir) was well-tolerated and highly effective. All subjects achieved SVR4. Very rapid early clearance of HCV RNA supports continued evaluation of AT-527 in short treatment regimens of 8 wks or less.

THU439

Frequency and characteristics of DAAs failure in hepatitis C therapy

Pablo Florez Díez[1], Noelia Rodríguez Ferreiro[1], Susana Rojo-Alba[2], Victor J Beltrán[1], Carmen Rosado[2], Marta E Alvarez-Argüelles[2], M Luisa Gonzalez-Dieguez[1], Mercedes Rodríguez[2], Carmen Álvarez-Navascués[1], Manuel Rodríguez[1]. *[1]Hospital Universitario Central de Asturias, Liver Unit, Division of Gastroenterology & Hepatology, Oviedo, Spain; [2]Hospital Universitario Central de Asturias, Pharmacy Department, Oviedo, Spain*
Email: pabloves@hotmail.com

Background and Aims: Since the introduction of DAAs there have been advances in its effectiveness and changes in the characteristics of treated patients. To know the evolution in the rate of therapeutic failures (TF) and their characteristics in a series of patients with hepatitis C treated with DAAs without IFN.
Method: 1149 patients treated with DAAs between Jul/14 and Mar/19 divided into 2 time periods (PI: Jul/14–Jun/17; n = 755 and P-II: Jul/17–Mar/19; n = 394) were analyzed. TF were classified as virological (V) and non-virological (NV). Discontinuation of treatment for any reason that led to a lack of SVR, death between the end of the treatment and +12 weeks control, as well as no attendance to that control were classified as NV.

Results: Globally TF was observed in 53/1149 (4.6%) patients [36/755 (4.7%) in P-I and 17/394 (4.3%) in P-II; p = 0.72]. Compared to P-I, P-II patients were younger [53.0 (46.7–59.6) vs. 55.1 (49.9–64.0) p < 0.001], most often immigrants (7.8% vs. 3.9%; p = 0.001), with more frequent history of PWID (48.5% vs. 36%; p < 0.001), anti-psychotic treatment (11.4% vs. 7.5%; p = 0.029), GT-3 infection (21% vs. 11.9%; p < 0.001) and naive (75% vs. 63%; p < 0.001). In contrast, the proportion of patients with cirrhosis was higher in P-I (46.6% vs. 14.4%; p < 0.001). 56% of P-II patients versus 4.5% of P-I received pangenotypic DAAs (p < 0.001). There were no differences between the two groups in sex (p = 0.35), treatment with methadone (p = 0.098) or anti-depressants (p = 0.31) or excessive alcohol consumption (p = 0.15). Of the 36 TF of P-I, 23 (63.8%) were V, while 16/17 (94.2%) that occurred in P-II were NV (p < 0.001). The most frequent cause of NV failure in P-II was the non attendance to the control in week +12 without apparent cause (12/16; 75%). In the univariate, NV failure was associated with age ≤ 55 years (p < 0.001), methadone treatment (p < 0.001), immigration (p = 0.004), history of PWID (p = 0.042) and treatment on P-II (p = 0.016); in the multivariate only methadone treatment (OR: 5,069; 95% CI: 2,338–10,989; p < 0.001) and being an immigrant (OR: 5,536; 95% CI: 1,946–15,774; p = 0.001) were associated with NV failure.

Conclusion: Despite the better profile of patients and drugs, the rate of TF remains stable along the study period. However, the type of failure has changed, being the NV the most important one since 2017. It is necessary to make an effort aimed at improving patients adherence to treatment and clinical visits, especially in immigrants and those on methadone treatment.

THU440

Real-world clinical practice outcomes in hepatitis C-infected patients with psychiatric and substance use disorders treated with glecaprevir/pibrentasvir for 8 or 12 weeks: a pooled analysis across nine countries

Pietro Lampertico[1], Robert Flisiak[2], Nuno Marques[3], Olivier Clerc[4], Ioannis Goulis[5], Mark Bondin[6], Ariel Porcalla[6], Zhenzhen Zhang[6], Yves Horsmans[7], Harald Hofer[8], Ella Veitsman[9,10], Georges-Philippe Pageaux[11]. *[1]1st Gastroenterology Unit at the Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [2]Medical University of Białystok, Department of Infectious Diseases and Hepatology, Białystok, Poland; [3]Infectious Diseases Service, Hospital Garcia de Orta EPE, Almada, Portugal; [4]Pourtalès Hospital, Department of Internal Medicine and Infectious Diseases, Neuchâtel, Switzerland; [5]Aristotle University of Thessaloniki, 4th Department of Internal Medicine, Thessaloniki, Greece; [6]AbbVie Inc, North Chicago, IL, United States; [7]Cliniques Universitaires Saint-Luc, UCL, Brussels, Belgium; [8]Klinikum Wels-Grieskirchen, Department of Internal Medicine, Gastroenterology and Hepatology, Wels, Austria; [9]Liver Unit, Rambam Health Care Campus, Haifa, Israel; [10]The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel; [11]Centre Hospitalier Universitaire (CHU) de Montpellier, Département Hépato-gastro-entérologie, Montpellier Cedex 5, France*
Email: pietro.lampertico@unimi.it

Background and Aims: Barriers to treatment with DAAs still exist in patients with dual pathologies (ie, psychiatric and substance abuse disorders). Real world data are critical to inform clinical decisions and achieve WHO elimination targets. Glecaprevir/pibrentasvir (G/P) is approved for treatment of chronic hepatitis C virus (HCV) genotypes 1–6. In treatment-naïve patients, G/P was recently approved for shorter treatment duration (8 weeks) in patients with or without cirrhosis. We evaluated real-world effectiveness, safety, and patient-reported outcomes (PROs) of G/P in marginalized HCV-infected patients in ongoing post-marketing observational studies.

Method: Data were pooled from Austria, Belgium, France, Greece, Israel, Italy, Poland, Portugal, and Switzerland (13 Nov 2017–02 Oct 2019). Treatment naïve or experienced patients aged ≥ 18 years with or without cirrhosis were included. Patients received G/P consistent with local label and/or at treating physician's discretion (1608 [84%] received G/P for 8 weeks). Percentage of patients in the core population with sufficient follow up (CPSFU) who achieved sustained virologic response at post-treatment Week 12 (SVR12) was assessed overall and for each subgroup. The mean (SD) change in PROs (36-Item Short Form Health Survey [SF-36] mental [MCS] and physical component summary [PCS] scores) from baseline to SVR12 visit was reported (minimally important difference ≥ 2.5). Safety was assessed in patients receiving ≥ 1 dose of G/P.

Results: Of 1922 patients receiving ≥ 1 dose of G/P, 640 (34%) had used illicit substances, 184 (10%) had psychiatric disorders, 300 (18%) had a history of alcohol use, and 768 (44%) were unemployed or had low to no education. In the CPSFU population, the SVR12 rate was 98.4% (1510/1535) overall, 98.3% (1332/1355) in treatment-naïve patients, 98.9% (175/177) in treatment-experienced patients, and

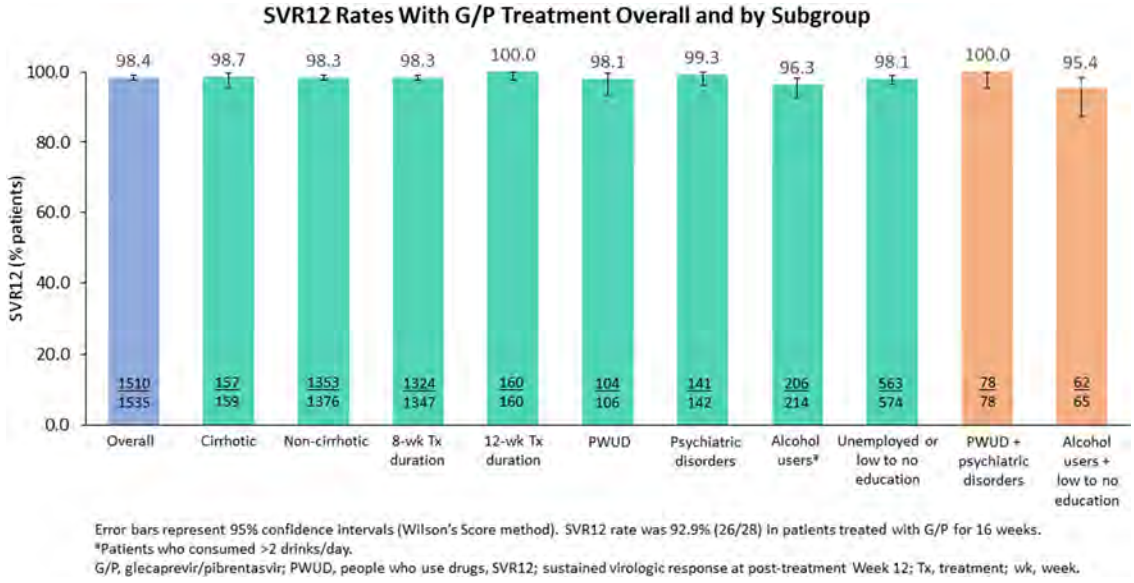


Figure: (abstract: THU440)

high (>95%) across all subgroups (Figure). Overall, mean change from baseline in MCS and PCS was 3.4 (10.5) and 2.1 (7.9), respectively, at SVR12 visit. In the total population (N = 1922), 1 G/P-related serious adverse event (pericarditis) was reported; 6 patients (0.3%) discontinued G/P due to drug-related adverse events. The most common adverse events were asthenia (2.2%), fatigue (2.0%), and headache (2.0%).

Conclusion: The 8- or 12-week G/P regimen was highly effective and well tolerated in marginalized patients with single or dual pathologies infected with chronic HCV in the real world.

THU441

Fast-track-consultation protocol: an interdisciplinary and useful tool for treating drug user hepatitis C infection in addiction out-patient units

Silvia Acosta-López[1], Luz Goretti Santiago Gutiérrez[2], Juan Carlos Fernández Molina[3], Teresa De La Rosa Vilar[2], Magdalena Lara[4], Pilar Díaz Ruiz[5], Ana Laserna Ramos[2], Angelina Rodriguez Perez[2], Ruth Suarez Darias[1], Carmen Alfonso Castillón[1], Antonio González Rodríguez[1], Teresa Santana Rodríguez[2], Cristina Cabrera Hernández[2], David Rodríguez Galloway[2], Andrés Estévez Tejera[2], Julia Alcoba-Florez[4], Francisco Javier Merino Alonso[5], Francisco Andrés Pérez Hernández[1]. *[1]Hospital Universitario Nuestra Señora de Candelaria, Liver Unit, Spain; [2]San Miguel Adicciones, Spain; [3]Asociación Norte de Tenerife de Atención A las Drogodependencias, Spain; [4]Hospital Universitario Nuestra Señora de Candelaria, Microbiology Department, Spain; [5]Hospital Universitario Nuestra Señora de Candelaria, Pharmacy Department, Spain*
Email: sacostalopez9@gmail.com

Background and Aims: Hepatitis C (HCV) infection treatment in high-risk of transmission patients (e.g. persons who injected drugs) should be a priority. However, adherence to direct acting antiviral therapy (DAA) may be low in this population. The aim of this study is to analyze the results of using a fast-track-consultation protocol in terms of adherence and response to HCV treatment in addiction out-patient units.

Method: A prospective observational study has been conducted. Addiction out-patient units' users with positive HCV-RNA by dried blood spot (DBS) were included from March to September 2019.

A specific protocol was used. The patients included were referred to fast-track-consultation with the help of addiction units' workers. In a sole appointment, all patients were seen by an hepatologist, a complete analysis and a liver fibrosis assessment by transient elastography were performed and finally, treatment was started. Addiction units' workers supervised and encouraged patients during the treatment. They also provided DBS at the end of the treatment and twelve weeks after treatment cessation. If a patient lose follow-up, the hepatologist sent an encrypted email to addiction unit´s workers to localized and gave him a new appointment.

Results: One-hundred and two patients were included in this analysis (9 women; mean age 49.3 years [SD = 7.0]). Most of the patients (45.1%) presented genotype 1 HCV and 91.2% were naïve to treatment. Seventeen patients (16.7%) suffered from mental disorder diagnosed by a psychiatrist and 16 had an unstable housing during treatment. Almost all patients (97.1%), received Sofosbuvir-Velpatasvir.

By this moment, sixty-nine patients have completed the treatment plan and 26 have the treatment ongoing. The HVC-RNA from 64/69 patients (92.8%) at the end of the treatment and 18/20 patients (90%) at twelve weeks post-treatment is available. They were all negative.

Seven patients (6.9%) did not finish the first DAA treatment. Most of them (6 patients) lose follow-up, but four of them, thanks to the protocol, were rescued and finally completed the treatment.

Conclusion: The interdisciplinary fast-track-consultation protocol is a useful method to achieve high rates of treatment adherence and sustained viral response in HCV patients from addiction out-patient units.

THU442

Achieving hepatitis C elimination in people who inject drugs - interim results of an innovative screen-and-treat program in Austria

Caroline Schmidbauer[1,2,3], Raphael Schubert[4], Angelika Schütz[4], Cornelia Schwanke[4], Enisa Gutic[1], Roxana Pirker[1], Tobias Lang[1], Thomas Reiberger[2,3], Hans Haltmayer[4], Michael Gschwantler[1,5]. *[1]Wilhelminenspital, Department of Internal Medicine IV, Vienna, Austria; [2]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; [3]Vienna HIV & Liver Study Group, Vienna, Austria; [4]Suchthilfe Wien gGmbH, Ambulatorium Suchthilfe Wien, Vienna, Austria; [5]Sigmund Freud University, Vienna, Austria*
Email: michael.gschwantler@wienkav.at

Background and Aims: To achieve the WHO goal of hepatitis C virus (HCV) elimination by 2030, strategic and tailored screening and treatment projects are essential. In Austria, people who inject drugs (PWIDs) represent the most important high-prevalence population. In Vienna there are about 6.500 PWIDs on opioid substitution therapy (OST). Our aim was to eliminate HCV in this population by a combined screen-and-treat strategy.

Method: Study part 1: According to our experience a considerable subgroup of PWIDs with HCV are reluctant to attend tertiary care centers who provide direct-acting antiviral (DAA) therapy. Next to poor adherence, they are unlikely to maintain a regular drug intake if provided with DAAs for self-administration at home. Therefore, HCV treatment was performed as "directly observed therapy" (DOT) since the end of 2014: Patients received DAA together with OST under direct supervision of medical staff at a pharmacy or a low-threshold facility.

Study part 2: In Vienna, every PWIDs on OST has to renew their long-term OST at one of the nine health authority centers once a month – rendering these health authority centers as an ideal interface for HCV screening. In our project all PWIDs are offered saliva-based testing for anti-HCV antibodies (OraQuick®) - followed by HCV-RNA PCR in case of a positive anti-HCV result. HCV-RNA(+) PWIDs are then referred to a low-threshold facility for initiation of DAA therapy.

Results: Study part 1: Using the concept of DOT, only 0.3% of scheduled dates for DAA intake together with OST were missed by the n = 409 included patients. So far, 289 of 290 (99.7%) PWIDs who finished treatment and 12 weeks of follow-up have achieved SVR12; one patient with genotype 3 HCV infection showed nonresponse. Reinfection was recorded in 18/289 (6.2%) patients. 89/409 (21.8%) patients are still on treatment and n = 30/409 (7.3%) were lost to follow-up.

Study part 2: Screening at health authority centers was well accepted by PWIDs. So far, 2810 patients were included: 34.6% of patients already knew about their HCV-status and were sent to the low-threshold facility for further evaluation and treatment. Of the tested population 46.5% showed anti-HCV(+), of whom 34.4% were viremic.

Conclusion: The concept of DOT is highly effective in PWIDs on OST with a high risk of non-adherence to DAA therapy. HCV-screening of PWIDs at public institutions is well accepted and has the potential to identify a considerable number of unknown HCV cases.

THU443

Directly observed therapy for hepatitis C with sofosbuvir/velpatasvir alongside opioid substitution as a tailored microelimination strategy in PWIDs with a high risk of non-adherence - real-world data from Vienna, Austria

Caroline Schmidbauer[1,2,3], Raphael Schubert[4], Angelika Schütz[4], Cornelia Schwanke[4], Enisa Gutic[1], Roxana Pirker[1], Tobias Lang[1], Thomas Reiberger[2,3], Hans Haltmayer[4], Michael Gschwantler[1,5].
[1]Wilhelminenspital, Department of Internal Medicine IV, Vienna, Austria; [2]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; [3]Vienna HIV & Liver Study Group, Vienna, Austria; [4]Suchthilfe Wien gGmbH, Ambulatorium Suchthilfe Wien, Vienna, Austria; [5]Sigmund Freud University, Vienna, Austria
Email: michael.gschwantler@wienkav.at

Background and Aims: Directly acting antivirals (DAA) against hepatitis C virus (HCV) infection have facilitated sustained virologic response (SVR) rates >90% in clinical studies. Yet, real life data regarding DAA treatment in people who inject drugs (PWIDs) are scarce. We evaluated the effectiveness of sofosbuvir/velpatasvir (SOF/VEL) in difficult-to-treat PWIDs with a presumed high risk for non-adherence to antiviral therapy using an innovative concept involving their opioid substitution therapy (OST) facility.
Method: N = 250 patients (m/f: 186/64; median age: 45.1 years (IQR 16.9); HCV-genotype (GT) 1/2/3/4/unknown: 119/5/109/10/7, GT3: 43.6%; cirrhosis: n = 88; 35.2%) treated with SOF/VEL were included. PWIDs at high risk for non-adherence to DAA therapy (n = 145) received HCV treatment alongside their OST under the supervision of medical staff ("directly observed therapy", DOT). The effectiveness of SOF/VEL given as DOT in PWIDs with presumed high risk for non-adherence to antiviral therapy was compared to patients with presumed "excellent compliance" in the "standard setting" (SS) of SOF/VEL prescription at a tertiary care center and self-managed SOF/VEL intake at home (n = 105). Treatment duration was 12 weeks according to the SOF/VEL drug label.
Results: DOT-patients (n = 145/250; 58.0%) were younger than SS-patients (median age: 41.6 years (IQR 12.3) vs. 53.8 years (IQR 14.7)), all had psychiatric co-morbidities and most had a poor socio-economic status. 91/145 (62.8%) reported ongoing intravenous drug use. So far, SVR has been achieved in 100% according to mITT analysis (n = 79/79) with n = 11/145 (7.6%) patients being lost to follow-up (FU) and n = 55/145 (37.9%) currently on treatment. 5 patients showed HCV reinfection after achieving SVR12.
SS-patients achieved SVR in 93.8% according to mITT analysis (n = 76/81) with n = 8/105 (7.6%) patients being lost to FU and n = 16/105 (15.2%) currently on treatment. 3 patients experienced HCV relapse after treatment with SOF/VEL and n = 2 died for reasons not related to therapy. No reinfections were recorded in the SS-group.
Conclusion: SOF/VEL given as DOT along with OST in PWIDs with a high risk of non-adherence to antiviral therapy resulted in excellent SVR rates (100% according to mITT) similar to patients with presumed "excellent compliance" under standard drug intake. Thus, HCV treatment with DAA using the concept of DOT seems to be an effective HCV-elimination strategy among the high-prevalence population of PWIDs on OST.

THU444

Externalized HCV linkage-to-care cascade in the biggest harm reduction center in Barcelona: approaching a high-risk PWID population

Sabela Lens[1,2,3], Anna Miralpeix[1,2], Mont Gálvez[1,2], Elisa Martró[4,5], Noemi Gonzalez[6], Sergio Rodriguez-Tajes[1,2,3], Zoe Mariño[1,2,3], Núria Ibáñez[7], Verónica Saludes[4,5], Juliana Reyes[5,8], Xavier Major[7], Joan Colom[7], Xavier Forns[1,2,3]. *[1]Hospital Clínic, Liver Unit, Barcelona, Spain; [2]IDIBAPS; [3]Consorcio de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD); [4]Institut d'Investigació Germans Trias i Pujol (IGTP), Microbiology Department, Badalona, Spain; [5]Consorcio de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP); [6]REDANLa Mina. Parc de Salut Mar. Barcelona, Institute of Neuropsychiatry and Addictions, Barcelona, Spain; [7]Public health Agency of Catalonia (ASPCAT). Government of Catalonia, · Program on Substance Abuse, Barcelona, Spain; [8]Center for Epidemiological Studies on HIV/AIDS and STIs of Catalonia (CEEISCAT), Barcelona, Spain*
Email: slens@clinic.cat

Background and Aims: Significant scale-up of treatment among people who inject drugs (PWID) is necessary to achieve WHO hepatitis C virus (HCV) elimination targets. PWID with ongoing high risk practices are the most difficult-to-reach population. We tested whether active PWID could be recruited and treated successfully through a externalized hepatology outpatient clinic at the biggest harm reduction center (HRC) in Barcelona.
Method: On site HCV point-of-care screening for HCV-IgG antibody and HCV-RNA (GenXpert®), liver stiffness measurement (LSM), antiviral therapy delivery and sustained virological response (SVR12) assessment were performed at the HRC. Dried blood spot (DBS) was collected at baseline, SVR12 and every 6 months in order to differentiate relapse vs reinfection. Adherence was assessed by daily or weekly visits. The program included educative and harm-reduction interventions.
Results: So far 443 individuals have been prospectively enrolled. Of these, 265 (58%) accepted HCV screening, of whom 172 (65%) were HCV-RNA positive. Of the 112 (65%) individuals who have already started treatment, median (P_{25}-P_{75}) age was 42 years (35–47), 87% were male, 34% foreigners, 37% homeless, 73% unemployed and 62% had been imprisoned before. At enrolment, 67% injected daily (51% more than once a day) although 39% were also on opiate substitution therapy. In regard to high risk practices, 30% reported either needle or paraphernalia sharing and 44% unprotected sexual relationships. Concomitant alcohol consumption was reported in 37% [4(2–8) units/day]. Baseline LSM values were 6.3 (4.9–7.8) kPa with 14% patients having advanced fibrosis (>9.5 kPa). All patients received pan-genotypic antiviral therapy either 8 or 12 weeks. Preliminary results showed >80% treatment adherence in the majority of patients (71%) and SVR12 rate of 70% with no difference regarding type or duration of antiviral therapy. Preliminary reinfection rate was 12%. Active injecting persisted in 90% of treated individuals, but the injecting frequency decreased from a daily to a weekly basis (or less) in 40% of them. Interestingly, unemployment rate decreased significantly (>50%) in treated individuals.
Conclusion: This patient-centered circuit demonstrates that HCV treatment can be successfully delivered to active PWID with high-risk practices. Besides HCV elimination, therapy might have a benefit on drug consumption habits and social inclusion, supporting the role of educative interventions.

THU445

In-depth molecular characterization of inherently resistant African HCV genotype 1, subtype 1l, in patients failing DAA-based therapy

Slim Fourati[1,2], Christophe Rodriguez[1,2], Alexandre Soulier[1,2], Lila Poiteau[1,2], Demontant Vanessa[1,2], Melissa N Debi[1,2], Stéphane Chevaliez[1,2], Hezode Christophe[2,3], Jean-Michel Pawlotsky[1,2]. *[1]Henri Mondor Hospital, Créteil, France; [2]INSERM U955, team 18, Créteil, France; [3]Henri Mondor Hospital, Hepatology*
Email: slim.fourati@aphp.fr

Background and Aims: So-called "unusual" HCV genotype 1, subtype 1l (GT-1l) is common among HCV-infected patients of African origin. GT-1l has recently been suggested to be less responsive to NS5A inhibitor-containing regimens than GT-1a or GT-1b. Here, we used shotgun metagenomics based on deep sequencing to generate full-length HCV genome sequences and characterize amino acid substitutions present at baseline and selected by DAA therapy in

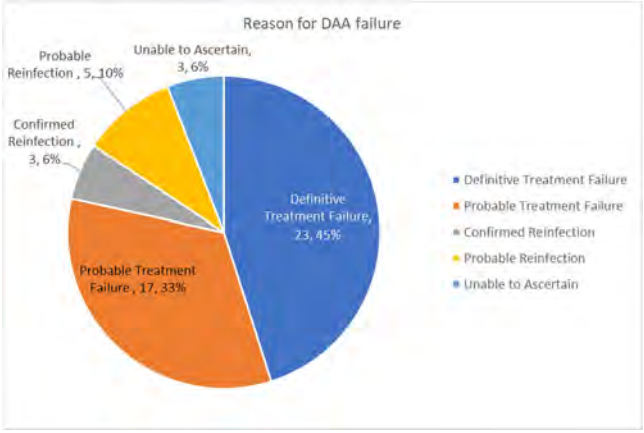
regions targeted and not targeted by DAAs in GT-1l infected patients who failed to achieve SVR.
Method: Shotgun metagenomics were used to generate full-length HCV GT-1l genome sequences. Briefly, library preparation was performed using Total RNA and Nextera XT kit (Illumina). Deep sequencing was performed by means of NextSeq500 (Illumina). Full-length HCV sequences were analyzed using our original in-house MetaMIC® software (1% cutoff).
Results: Among 771 patients with HCV infection, treated with DAAs who experienced a virological failure and were referred to our center between 2015 and 2019, 316 (41.0%) were infected with genotype 1, and 20 of them (6.3%) with GT-1l. All GT-1l-infected patients were of African origin. Deep sequencing of full-length HCV GT-1l genomes was performed in 10 patients who failed SOF/LDV±RBV (n = 8, 80%), SOF/VEL (n = 1, 10%) and SOF/SIM (n = 1, 10%).
At baseline, all of the 10 GT-1l patients had ≥ 3 dominant NS5A resistance-associated substitutions (RASs), including K24G/S (>99%), L31M (>99%) and H58P (>99%). Additionally, baseline NS5A-Q30R was present in 3 patients (>99% in 2 patients; 25% in 1 patient). Sequential analysis of full-length HCV genome sequences showed enrichment of NS5A-Q30R in one patient at failure (>99%) and the selection of NS5A RASs in other patients: baseline K24S (8% and 40%, respectively) replaced by K24G (>99%) in 2 patients; selection of Y93F and Y93H RASs at failure in 2 other patients (20% and 40% respectively).
No NS5B RASs were detected. NS3 R155K was selected in a patient failing SOF/SIM (30%). No particular amino acid changes were observed between baseline and failure in genome regions other than those targeted by the HCV DAAs administered.
Two patients were retreated with SOF/VEL/VOX and both achieved SVR.
Conclusion: We report the largest cohort of African GT-1l-infected patients failing DAAs thus far. The large number of NS5A RASs present at baseline explains lower SVR rates with NS5A inhibitor-based therapies in these patients. Our results emphasize the need for identification of this subtype and other "unusual" subtypes (e.g. GT-4r) in Africa where they are common, and the requirement for equity of access to last-generation DAA therapies in Africa.

THU446

Reasons for direct acting antiviral failure in patients referred for multi-disciplinary team discussion and virological outcomes of retreatment

Igor Starinskij[1], Stephen Barclay[2], Alison Boyle[3], Amanda Bradley[4], Fiona Marra[3], Erica Peters[1], Emma Thomson[5], Raymod Fox[1].
[1]Gartnavel General Hospital, Brownlee Centre for Infectious Diseases, Glasgow, United Kingdom; [2]Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom; [3]Gartnavel General Hospital, Brownlee Pharmacy, Glasgow, United Kingdom; [4]Glasgow Royal Infirmary, West of Scotland Specialist Virology Centre, Glasgow, United Kingdom; [5]Centre For Virus Research, Bearsden, United Kingdom
Email: starinskij@gmail.com

Background and Aims: NHS (National Health Service) Greater Glasgow and Clyde HCV (Hepatitis C virus) DAA (Direct Acting Antivirals) Treatment Failure MDT (Multi-Disciplinary Team meeting) provides regional advice service for retreatment of patients who previously failed DAA therapy and were not obviously re-infected. This is a service evaluation study to establish the reasons for DAA treatment failure, whether MDT advice was followed, and the virological outcome of retreatment.
Method: All referrals made to the HCV DAA Failure MDT service between April 2017 and March 2019 were retrospectively evaluated. Patients' pre- and post-treatment HCV Genotype, resistance-associated variants (RAVs) tested by population-based sequencing, risk of reinfection defined by documented history of intravenous drug abuse, and compliance with initial treatment regimen were all taken into account when deciding on the reason for DAA failure. Referred cases were categorized into 5 groups: Definitive Treatment Failure (DTF), Probable Treatment Failure (PTR), Confirmed Reinfection (CRI), Probable Reinfection (PRI), and Unable to Ascertain (UA).



Results: After excluding one case due to a pre-analytical diagnostic error, and seven cases due to a lack of documentation, a cohort of 51 eligible patients was identified. The majority of patients discussed had either DTF (45%) or PTF (33%) with relatively few cases of suspected reinfection (figure 1). New RAVs were identified in 22 (96%) of DTF cases. The MDT provided retreatment recommendations for 49 patients and advised against retreatment in 2 cases, both of whom subsequently died. Of the 49 patients, 42 (86%) received a second DAA course, 5 (10%) were lost to follow-up, 2 (4%) died prior to starting retreatment. MDT recommendations were followed in 37 (88%). At the time of writing, 23 (55%) patients had a test for sustained virological response (SVR) at week 12 or later and 21 (91%) of them remained negative for HCV. A further 14 (33%) had not yet been tested for SVR at week 12, and 4 (10%) were still undergoing retreatment.
Conclusion: Most cases referred to the HCV DAA Failure MDT service in NHS Greater Glasgow and Clyde are considered to have definitively or probably failed their treatment. The majority of patients received retreatment in line with the MDT advice. Successful retreatment can be achieved in a very high proportion of these patients.

THU447

Microelimination beyond prison walls: subjects sentenced to non-custodial sentences, screening and immediate assisted treatment with "navigator" figure and telemedicine

Susana Llerena[1,2], Joaquin Cabezas[1,2], Miguel Mateo[3], Rocio Alvarez[3], Maria del Mar Fernandez[3], Carmen Cobo[4], Antonio Cuadrado[1,2], Javier Crespo[1,2]. *[1]Marqués de Valdecilla University Hospital, Digestive Disease Department, Santander, Spain; [2]Health Research Institute Marques de Valdecilla, IDIVAL, Santander, Spain; [3]Medical Service. Center for Social Insertion "José Hierro," Santander, Spain; [4]Medical Service. El Dueso Penitentiary Centre, Santoña, Spain*
Email: susanallerena@hotmail.com

Background and Aims: The Spanish prison population includes two groups: inmates admitted in prison and those who are serving non-custodial sentences. The latter has not yet been studied. The aims of this study are: 1.- To describe this population at social, educational, medical levels and psychiatric comorbidities. 2.- To systematically screen and to treat HCV infection in this population. 3.- To engage this people with health care programs for the management of medical, psychiatric and social conditions.

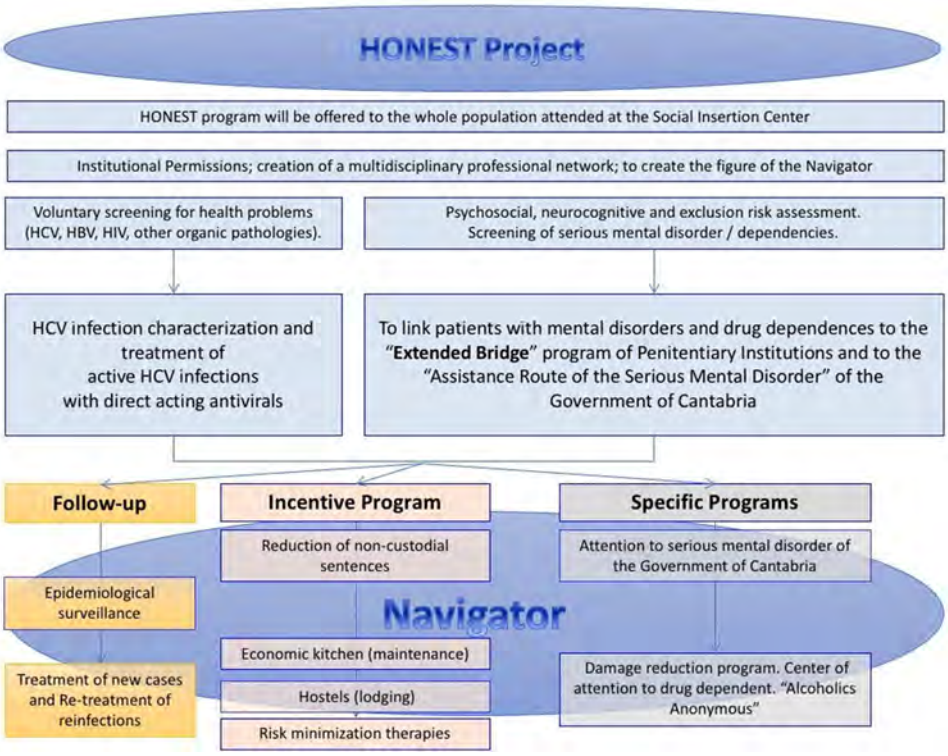


Figure: (abstract: THU447)

Method: Prospective observational study, including all subjects sentenced to non-custodial sentences attended at the Center for Social Insertion "José Hierro" (Santander) from June 2019 to June 2021, between 18 and 79 years and who gave signed informed consent. Assisted by the medical team and the center's "Navigator," systematic screening of HCV is performed by detection of antibodies by Oraquick®, those that are positive, viral load is determined by GeneXpert® in capillary blood. All cases with detectable viral load are evaluated by the hepatology staff by telemedicine and then antiviral treatment is prescribed. Thus, active HCV infection detection, disease evaluation and treatment are all done in the same day. The Navigator figure facilitates continuity for medical care and social assistance of these individuals (accompaniment to the hospital, adherence to treatment etc.)

Results: So far, 327 people have been invited to participate, 308 of them have been screened for HCV (94.2% acceptance). The prevalence of anti-HCV + has been 7.8% (24), which represents 5 times the general population. The prevalence of detectable viral load is 3.2% (10), above 10 times the prevalence of viremia in the community. All patients have initiated antiviral treatment either in the hepatology or infectious unit in case of HIV co-infected. Regarding comorbidities: problems related to substance abuse were detected in 148 (48%), suspected serious mental disorder in 25 (8.1%), previous stay in prison in 60 (19.5%). Currently, navigator is monitoring 54 (16.5%) patients regarding HCV treatment and their comorbidities.

Conclusion: The population serving non-custodial sentences is a challenging group, difficult to approach and with a high prevalence of HCV infection. Microelimination programs such as this, using rapid diagnostic tests, telemedicine and "the Navigator" figure are necessary in these vulnerable and hard to reach populations.

Email: tianna.magel@vidc.ca

Background and Aims: Current all-oral regimens offer the promise of cure for nearly all Canadians living with chronic HCV infection. This is particularly true with the availability of simple pan-genotypic regimens such as sofosbuvir/velpatasvir (S/V), administered as one tablet once a day for 12 weeks for the treatment of all HCV genotypes and all levels of fibrosis. Clinical trial results suggest these regimens are associated with very high cure rates, even in the setting of sub-optimal adherence. There is limited real-world evidence to substantiate these findings.

Method: Accessing the national observational Canadian Network Undertaking Against Hepatitis C (CANUHC) database, we evaluated

all patients receiving S/V for the treatment of chronic HCV infection. The endpoint of this analysis was the achievement of a cure of HCV infection (undetectable HCV RNA levels 12 or more weeks after the end of therapy, SVR12) as a function of the reported level of adherence to therapy that was achieved.

Results: A total of 152 individuals were included in this analysis, with an overall SVR12 rate of 98.7% (150/152). Overall adherence >90% was reported in 142 (93.4%) participants, with 10 (6.6%) reporting adherence below 90%, 3 of which (2%) were below 75%. Of those with <90% adherence, all achieved SVR12. Subjects with sub-optimal adherence (n = 10) differed slightly from the entire cohort by mean age (46.5 vs 50.4 years), sex (30% vs. 41% female), HCV genotype (50% vs. 45% GT3) HIV co-infection status (20% vs. 14%), history of injection drug use (70% vs. 47%) and mean fibrosis score (10.9 vs. 9.3 kPa). Two individuals did not achieve SVR12 (both virologic relapses), both within the >90% adherence group. Non-SVR subjects were 69 and 44 years old, both were female, fibrosis scores were 4.5 kPa and 8.2 kPa, one each GT2 and GT3. One individual had a history of injection drug use and neither had any documentation of treatment interruption >7 days or premature treatment discontinuation.

Conclusion: Within the CANUHC cohort, self-reported adherence was generally high, as was the rate of achievement of SVR12 with the use of S/V. Suboptimal adherence was rare and not associated with treatment failure nor with any specific demographic profile. These data endorse the relative robustness of the S/V regimen in clinical practice and is reassuring as the use of S/V is expanded into populations facing multiple obstacles to treatment adherence.

Email: alexander.thompson@svha.org.au

Background and Aims: In clinical trials, salvage therapy including Sofosbuvir/Velpatasvir/Voxilaprevir (SOF/VEL/VOX) achieved an SVR12 rate of 96% in NS5A-experienced participants. An extended access program (EAP) for SOF/VEL/VOX was sponsored by Gilead Pharmaceuticals for Australian patients with advanced liver disease or prior liver transplantation (LT), who had relapsed. We determined the real-world efficacy and safety of this regimen in this cohort with advanced liver disease.

Method: In this Australian multicentre EAP study, adult patients with chronic HCV infection genotype(GT)1–6 with prior failure on a DAA NS5A inhibitor containing regimen were eligible to access 12 weeks of SOF/VEL/VOX 400 mg/100 mg/100 mg. Other eligibility criteria included compensated liver disease with at least one of the following i) Child Pugh (CP)A cirrhosis with clinically significant portal hypertension or platelets $<100 \times 10^9$/L, ii) prior LT, or iii) severe extra hepatic manifestations. Hospitals with >1 EAP recipient were invited to participate. Clinical characteristics and treatment outcomes were recorded at baseline, end-of-treatment (EOT) and SVR12. HCV NS5A RAS testing was performed prior to retreatment, where serum was available. The primary outcomes was SVR12 rate.

Results: To date, baseline data is available for 89 patients from 24 participating hospitals. 85 have reached end-of-treatment (EOT), and 80 have SVR12 data available for analysis. Four patients have incomplete data due to early discontinuation of therapy (n = 2), loss to follow up (n = 1) and death (n = 1). 74 (83%) were male and the median age was 53. GT3 was the most common (n = 64), then GT1a (n = 18), GT1b (n = 4), GT6 (n = 2) and GT4 (n = 1). The median platelet count was 127. 68 (75%) had cirrhosis and of these, 35 (51%) had portal hypertension. 14 (16%) had prior hepatoma and 15 (17%) prior LT. All participants were NS5A-experienced and 8 (9%) had received >1 DAA course (1–4). Three participants were treated with a "lead-in" regimen of SOF + NS5A-inhibitor to optimise liver function before switching to SOF/VEL/VOX. SVR12 rates are shown in table 1. Treatment was generally well tolerated with mild AEs (n = 13/80, 16%), however two participants with CPA cirrhosis at baseline experienced hepatic decompensation. One *de novo* and two recurrent hepatomas were identified. Data collection is ongoing.

Table 1	Overall	GT3	GT1a	GT1b	GT6
Cirrhotic	89% (56/63)	89% (42/47)	100% (10/10)	50% (2/4)	100% (2/2)
LT/non cirrhotic	94% (16/17)	92% (11/12)	100% (5/5)		

Conclusion: This is the first Australian study to assess the real-world efficacy and safety of SOF/VEL/VOX amongst patients with advanced liver disease. SVR12 rates were good, but data suggests there remain a small number of very hard to cure patients, particularly those with GT3 and advanced disease, suggesting a need to explore strategies to optimise SVR in these groups.

Email: tt@aidscenter.ge

Background and Aims: In April 2015, with a partnership with Gilead Sciences and technical assistance from U.S. CDC, Georgia launched the world's first hepatitis C elimination program. By August 30, 2019, more than 60 thousand persons initiated treatment, achieving >98% cure rates. Broad access to direct acting antivirals (DAAs) resulted in rapid increase in treatment uptake in 2016, which has since declined due to barriers in diagnosis and linkage to care. To address this issue Georgia initiated service decentralization in 2018 by integrating hepatitis C virus (HCV) screening and treatment in primary healthcare centers (PHCs). We report preliminary results of an integrated model of HCV care in PHCs from August 2018 through August 2019.
Method: By August 31 2019, a total of 10 PHCs provided HCV care services throughout the country. The integrated model was based on a "one stop shop" approach, by which patients received all HCV screening, treatment and care services at the PHCs. PHCs provided care to HCV treatment-naïve patients with no or mild fibrosis (FIB-4 score<1.45) using simplified diagnostics and a treatment monitoring approach, while persons with advanced liver fibrosis/cirrhosis were referred to specialized clinics. Patients received Sofosbuvir/Ledipasvir and/or Sofosbuvir/Velpatasvir for 12 weeks. Sustained virological response (SVR) was defined as undetectable HCV RNA 12–24 weeks after end of therapy. The Extension for Community Healthcare Outcomes (ECHO) telemedicine model was utilized to train and support primary healthcare providers. Regular teleECHO videoconferencing was conducted to provide primary care providers with advice and clinical mentoring.
Results: Among persons diagnosed with active HCV infection, 639 were evaluated for FIB-4 score. Of these, 436 (68.2%) had FIB4 score<1.45; of them 355 (81.4%) initiated treatment. A total of 241 patients completed treatment. Of 146 patients within the 12–24 week window of SVR eligibility, 108 had been tested at the time of analysis, and 107 achieved SVR (99.1% cure rate).
Conclusion: Our study reported the feasibility and effectiveness of integrating a simplified HCV diagnostic and treatment model in PHCs. Countrywide expansion of this model is warranted to bridge the gaps in the HCV care continuum and ensure high rates of treatment uptake towards achieving elimination targets.

THU451

HCV DAA treatment failure is associated to hepatocellular carcinioma presence

Ubaldo Visco Comandini[1], Raffaella Lionetti[1], Chiara Taibi[1], Mauro Zaccarelli[2], Maria Rosaria Capobianchi[3], AnnaRosa Garbuglia[3], Giampiero D'Offizi[1]. [1]*National Institute for Infectious Diseases Lazzaro Spallanzani, POIT Department, Rome, Italy;* [2]*National Institute for Infectious Diseases Lazzaro Spallanzani, Clinical Department, Rome, Italy;* [3]*National Institute for Infectious Diseases Lazzaro Spallanzani, Virology Department, Rome, Italy*
Email: ubaldo.viscocomandini@inmi.it

Background and Aims: Sustained Virological Responses (SVR) are nowaday obtained in real life settings, in almost 98–99% of HCV-infected patients using 8 or 12W schedules and 2nd generation DAAs (glecaprevir/pibrentasvir, sofosbuvir/velpatasvir and elbasvir/gazoprevir). Clinical or virological predictors of viral failures with both 1st and 2nd generation DAAs are poorly understood.
Method: Between April 2015 and April 2019, 2508 patient received DAAs for HCV at our Institution. A retrospective analysis of the Virology Laboratory Database was performed to identify all the patients who completed the DAA treatment schedule, having HCV-RNA detectable 24 weeks or later after end-of treatment (EOT). Such cases were considered as viral failures (VF). Clinical features of the subjects with VF were recorded in a dataset: demographic, BMI, HCV genotype, basal Viral load, HIV status, Metavir stage, previous HCV treatment experience, type of DAA and presence of HCC (Li-RADS 4 or 5, identified before DAA, or during the 18 months following EOT). Several parameters were compared between 1st and 2nd generation DAA VF, and between subjects with VF or SVR. This latter group included 519 consecutive subjects with SVR, treated at our Unit during the same interval of time.
Results: The global SVR24 rate at our Institution was 97.1% (73/2508). Fifty-nine patients experienced failure with first generation DAA, and 14 with 2nd generation DAAs (Table 1). Viral relapses occurred in 49.4% of the cases already at post treatment (PT)W4 (n.36), 37.0% between PTW4 and PTW12 (n.27), 6.8% between PTW12 and PTW24 (n.5) and 6.8% (n.5) after PTW24.
Sixty out of the 73 subjects with viral relapse where submitted to a second DAA course with 100% of SVR12. Patients with VF showed high association (35.6%) to a concomitant HCC, reaching high statistical significance when compared to patient with SVR observed during the same time period at our Unit (Table 2). Significance persisted even when VFs were compared with only cirrhotic patients with SVR (n 175, p = 0.04).

	Pts with Virological Failure n. 73		Pts with Sustained Virological Response n. 519		p
Age (mean, SD)	56.8 yrs	8.9	59.4 yrs	10.4	0.524
Male Gender (n, %)	65	89.0%	319	61.4%	**0.0001**
HCV Genotype 1a or 3 (n, %)	46	63.0%	281	54.1%	0.168
HCC diagnosis (n, %)	26	35.6%	39	7.5%	**0.0001**
Liver Cirrhosis (F4)	49	67.1%	230	44.3%	**0.0003**

Conclusion: The presence of HCC and cirrhosis independently increase the risk of HCV treatment failure with DAAs.

Figure: (abstract: THU452)

Background and Aims: Hepatitis C therapy with directly-acting antiviral agents (DAA) (especially pangenotypic regimens) in a real-world setting is associated with sustained virological response (SVR) >95% with almost no adverse events. The World Health Association published a strategy to eliminate hepatitis C by 2030, but in daily practice this can be difficult to achieve in some patients, especially in people who inject drugs (PWIDs). The **aim** of this study was to investigate the adherence to treatment, SVR rate, and reinfection rate in hepatitis C patients with and without intravenous drug use.
Method: Our retrospective study included patients with hepatitis C, which were evaluated in our Hepatology outpatient's clinic between 01/2014–08/2019.
The following information were extracted from patients file: presence of positive viral load, active and recent (in the last six months) use of i. v. drugs, HCV genotype, treatment regimen, SVR, reinfection with hepatitis C virus, HIV coinfection, ongoing opioid substitution therapy (OST).
Results: We included 431 hepatitis C patients (234 PWIDs and 197 non-PWIDs).
PWIDs were younger as compared with non-PWIDs: 31 ± 9.6 vs 58.8 ± 13.8 years, p < 0.0001. The percentage of men was higher in the PWIDs as compared with non-PWIDs group: 71.8% vs. 55.4%, p = 0.0006.
HIV coinfection rate was similar between the two cohorts: 0.8% vs. 1%, p = 0.76.
Positive viral load rate was lower in the PWIDs group. Genotype 1b was predominant in patients without iv drug use, while genotype 3 was more common in the PWIDs group. Most of the patients were treated with DAAs only (Figure).
The proportion of patients not starting therapy was significantly higher in the PWIDs cohort: 19.4% vs. 8.9%, p = 0.003. Non-compliance (did not show up to start therapy) rate or refusal of therapy was also significantly higher in the PWIDs cohort: 15% vs. 6.7%, p = 0.01.
In the PWIDs cohort, younger age and recent (in the last 6 months) or ongoing i.v. drug use was associated with non-compliance: 31.1 ± 8.4 vs. 35.8 ± 10.6 years, p = 0.02 and 33.3% vs. 12.8% respectively, p = 0.0008.
Ongoing OST was associated with better compliance: 61.1% vs. 46.1%, p = 0.04.
Conclusion: To achieve hepatitis C elimination, better strategies especially regarding PWIDs are needed. In our cohort, around 14% of all the patients with positive viral load (and around 20% of PWIDs) were not able to be treated and still pose an ongoing risk for infection to the community.

THU453

Reasons for hepatitis C direct acting antiviral failure: experience from the field

Juliette Besombes[1], Charlotte Pronier[2], Caroline Jezequel[3], Dominique Guyader[3], Vincent Thibault[4]. *[1]CHU Rennes, Virology, Rennes, France; [2]Rennes, Virology – IRSET INSERM_U1085, Rennes, France; [3]CHU Rennes, Hepatology Unit, Rennes, France; [4]CHU Rennes, Virology – IRSET INSERM_U1085, Rennes, France*
Email: vincent.thibault@chu-rennes.fr

Background and Aims: Since HCV direct acting antiviral (DAA) disposal, successive national recommendations have been regularly published to optimise treatment efficacy and to homogenise practices. Adhesion to these guidelines led to an overall success of 97.4% in our university hospital setting, in line with other recently reported cure rates elsewhere. The aim of this study was to analyse the reasons for the rare observed treatment failures.
Method: A retrospective study based on data mining of 962 treatment lines started between January 2014 and April 2019 and leading to 937 (97.4%) sustained viral responses was conducted. Demographic and clinical characteristics of 23 (2.4%) patients who relapsed (RR) and 2 (0.2%) who presented a viral breakthrough were analyzed and compared to cured patients (SVR). HCV population sequencing was used to document genotype and resistance associated substitutions (RAS).
Results: Relapses were statistically more frequent before 2017 (3.4%) than after (1.2%; p = 0.033), and the unique failure observed in 2019 was attributed to a genotyping error leading to an inadequate treatment choice. Severe fibrosis was more frequent (56.5%) in RR than in SVR (27.7%; p = 0.004), however, cirrhotic patients were more frequently treated before 2017. Hepatocellular carcinoma was also linked to relapse (p = 0.03). Previous treatments with IFN +/– RBV did not influence treatment response, neither gender, age nor baseline viral load. Genotype 3 was not associated with relapse. By contrast, non-a/non-d genotype 4 subtypes (n = 29, 4r, p and k) were more

often found in relapsers (4/23; 17.3%) than in SVR (25/937; 2.7%; p = 0.015). In relation with these findings, to be of African ancestry was also associated with a 4 fold reduced rate of SVR (p = 0.0083). While poor compliance or reinfection could not be formally excluded, sequencing data performed on available viral strains (19/23) identified solely NS5A RAS but unremarkable NS3 and NS5B sequences. Noteworthy, only one patient (1/274; 0.36%) has relapsed since pangenotypic regimens have become available.
Conclusion: Despite an impressive overall efficacy in real-life setting, DAA treatments may present suboptimal response in rare situations that need to be finely characterized. As suggested in recent publications, infrequent HCV subtypes should be particularly scrutinized and could benefit from closer monitoring. Pangenotypic combinations are certainly the only choice to be recommended in these cases.

THU454

Effectiveness of new generation DAAs for HCV infection in a large cohort of Italian people who use drugs (PWID): the cleo-grecas real-world experience

Email: marcomax@tin.it

Background and Aims: HCV-infected people who use drugs (PWUD) is characterized by a low therapy adherence and often lost to follow-up when treated with directly acting antivirals (DAAs). Aim of our study was to evaluate the effectiveness of DAAs therapy in term of adherence and sustained virological response in a real-world setting as Italian PWUD, most of them strictly followed within a continuous interdisciplinary program with hepatologists included inside the Italian Centres for Drug Addicts (SerDs) widely distributed throughout the whole Italian territory.
Method: From July 2015 to April 2019, all consecutive HCV infected PWID were enrolled in a prospective observational real practice study (CLEO platform and RESIST Network); substances used were heroin 35.2%, cocaine 10.3%, opiates 8.6%; 44.8% were contemporary cocaine and heroin users. The majority of PWUD (80.9%) were routinely followed inside the Italian SerDs and on opiate substitution therapy (OST) with methadone 59.6%, buprenorphine 8.8%, naloxone plus buprenorphine 6.5%, naltrexone 20%. Treatments were often beginning inside the SerD Centres under strict prescription by the hepatologists, according the Italian national guidelines.
Results: One thousand three hundred eighty five patients, male 87.8%, mean age 49 (+/–9.47), 31% with liver cirrhosis, median basal HCV-RNA 122000 IU/ml completed treatment and were evaluated for the Sustained Virological Response at week 12 post-treatment (SVR-12); HCV genotypes: 1a = 34%, 1b = 11.28%, 2 = 2.88%, 3 = 42.3%, 4 = 9.3%, 7 = 0,17%. DAAs regimens: SOF/VEL 37.4%, GPR/PBR 36%, SOF/DCV14.4%, SOF/LDV 7,1%, EBR/GZR 5.1%. The overall SVR-12 rate was 95.51%; 2.63% relapsed; 0.77% were non responders; 0.70% dropped out, 0.39% stopped because of side effects. Patients undergoing treatment with 3rd generation DAAs (SOF/VEL, GPR/PBR,EBR/GZR) showed a SVR-12 rate higher than 2nd wave DAAs (97,5% vs 92,1%, p = 0.0002). HIV co-infected patients were 10% of total with a similar SVR-12 rate to that of HCV mono infected.
Conclusion: In this real-world setting of Italian HCV infected PWUD, a very high SVR-12 rate was observed, mostly due to the close cooperation between the healthcare workers in Italian SerDs and the hepatologists in the context of the interdisciplinary team. Low rate of drop-out was mainly due to the continuum of care programme inside SerDs. Our results launch this model as best practice to manage this kind of patients worldwide.

Hepatitis C positive organ transplantation to negative recipients at a multi-organ Canadian transplant centre: ready for prime time

Waleed Alghamdi[1], Karim Qumosani[1], Paul Marotta[1], Mayur Brahmania Brahmania[1], Anton Skaro Skaro[2], Anouar Teriaky[1]. *[1]London Health Sciences Centre – Western University, Gastroenterology Division, Department of Medicine, London, Canada; [2]London Health Sciences Centre – Western University, Division of General Surgery and Multi-Organ Transplant, Department of Surgery, London, Canada*
Email: walghamd@uwo.ca

Background and Aims: Organ transplantation offers better survival for patients with end stage organ disease compared to no transplant. Hepatitis C virus (HCV) positive donor organ transplantation to negative recipients is a novel adopted strategy that may potentially increase the donor pool. The aim of this study is to evaluate our multiorgan transplant centre experience with transplanting HCV positive organs.
Method: This study was conducted at London Health Sciences Centre in London, Ontario, Canada. All transplants with HCV nucleic acid testing (NAT) positive and negative organs were included from 2018 to present. Our primary outcome was the rate of sustained virologic response at 12 weeks after the end of treatment (SVR12) in patients that developed viremia. Secondary outcomes were the rate of transmission of HCV in both NAT positive and negative recipients, treatment adverse events, and graft failure rate.
Results: A total of 27 organ transplantations with hepatitis C positive organs were performed including 19 kidneys (70.4%), 4 livers (14.8%), 2 kidney-pancreas (7.4%),1 liver-kidney (3.7%), and 1 heart (3.7%). The mean age of recipients was 48 ± 12 years. 54% of them were male. NAT positive HCV organs were 20 (74%) of the organs used and viremia was transmitted in 90% of these patients while no transmission occurred in NAT negative HCV organs. HCV genotype was 1a in 76%, 1b in 6%, 2 in 6%, and 3 in 12%. The most common direct acting antiviral (DAA) used for treatment was Ledipasvir/Sofosbuvir in 13%, Velpatasvir/Sofosbuvir in 62%, and Glecaprevir/Pibrentasvir in 25%. SVR12 was 100% in all patients that completed HCV therapy. Treatment was tolerated by all patients, there were no significant treatment adverse events, and there were no graft failures.

Conclusion: Using HCV positive organs is safe and may further expand the donor pool. In patients that have HCV transmission post-transplant DAAs are efficacious with no significant adverse events, intolerance, or graft failure.

Liver tumours: Clinical aspects except therapy

Neutrophil-lymphocyte ratio predicts the risk of developing hepatocellular carcinoma in cirrhotic patients with chronic hepatitis B under antiviral therapy

Xian-bo Wang[1], Ke Shi[1], Yao Liu[1], Yuxin Li[1], Xiaojing Wang[1], Ping Li[2], Ying Hu[1]. [1]*Beijing Ditan Hospital, Center of Integrative Medicine, Beijing, China;* [2]*Tianjin Second People's Hospita, Center of Integrative Medicine, Tianjin, China*
Email: wangxianbo638@163.com

Background and Aims: The relationship between neutrophil-lymphocyte ratio (NLR) and hepatocellular carcinoma (HCC) development in cirrhotic patients with chronic hepatitis B is inadequately clarified. The objective of this study was to validate the predictive value of baseline NLR for HCC development in cirrhotic patients with chronic hepatitis B within three-year under antiviral therapy.

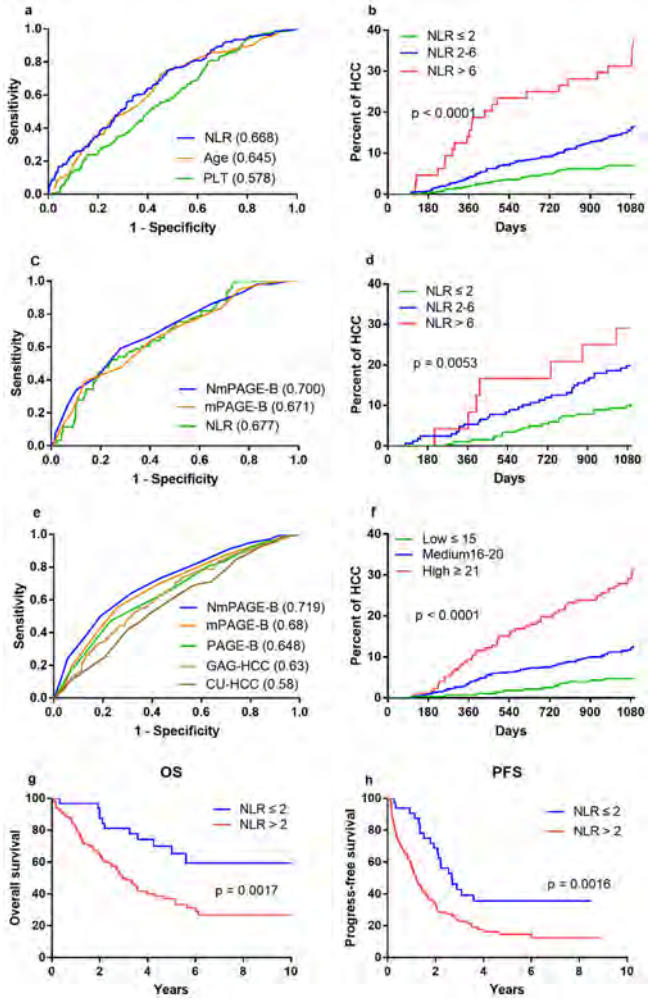

Figure: (a) AUROCs of the predictive value of the variables on HCC development during the 3-year follow-up in the derivation cohort. (b) Risk stratification of HCC development according to NLR with different cut-off (≤2, 2–6 and >6) in the derivation cohort ($p < 0.0001$). (c) AUROCs of NLR and risk models for the prediction of HCC development within 3 years in the validation cohort. (d) Risk stratification of HCC development according to NLR scores ($p = 0.0053$) in the validation cohort. (e) AUROCs of new model and other models for prediction of HCC in the derivation cohort ($p < 0.05$ for all, by log-rank test). (f) Cumulative incidence rates of HCC in the derivation cohort according to new model ($p < 0.0001$). (g) Kaplan-Meier curve analysis showing OS in HCC patients. (h) Kaplan-Meier curve analysis showing PFS in HCC patients. AUROC, time-dependent area under receiver operating characteristic; HCC, hepatocellular carcinoma; NLR, neutrophil-lymphocyte ratio; OS, overall survival; PFS, progress-free survival.

Method: In the retrospective analysis, a total of 1049 patients in the derivation group and 396 patients in the verification group were recruited. The independent factors of HCC development were determined using univariate and multivariate analyses. Optimal cut-offs were identified by calculating the Youden Index. Time-dependent area under receiver operating characteristic (AUROC) curve analysis was performed. The predictive value of NLR was assessed by Kaplan–Meier curves.
Results: The three-year cumulative HCC incidence rates were 13.5% and 15.4% in the derivation and validation group, respectively. Multivariate analyses showed that age, NLR and platelets were associated with HCC development. The AUROC for NLR was 0.668 (95% CI 0.622–0.713). Baseline NLR ≤ 2 predicted lower HCC development and NLR >6 is higher incidence of HCC ($p < 0.0001$). Moreover, NLR >2 was related to worse overall survival (OS) ($p = 0.0017$) and progress-free survival (PFS) ($p = 0.0016$) compared to those with NLR ≤ 2 in HCC group. Incorporation of NLR into a modified PAGE-B (mPAGE-B) model improved the predictive value for HCC development within three years (AUROC = 0.719).
Conclusion: Baseline NLR, an inexpensive blood count and routinely accessible inflammatory biomarker, may be a novel predictive marker of the three-year HCC risk in cirrhotic patients with chronic hepatitis B under antiviral therapy.

THU459

Differentiation and management of hepatobiliary mucinous cystic neoplasms: a single-center experience for 10 years

Junhao Zheng[1], Jingwei Cai[1], Junjie Xu[1], Mubarak Kirih[1], Yangyang Xie[1], Liye Tao[1], Xiao Liang[1]. [1]*Zhejiang University, School of Medicine, Sir Run Run Shaw Hospital, Department of General Surgery, Hangzhou, China*
Email: 21818381@zju.edu.cn

Background and Aims: Hepatobiliary mucinous cystic neoplasms (H-MCNs) are quite rare cystic neoplasms of the liver. The management and outcome of the hepatic simple cyst (HSC) and H-MCNs are really different. However, the differential diagnosis of H-MCNs remains big challenging. Our aim is to present our experience and provide a preoperative H-MCNs risk prediction nomogram for differentiating H-MCNs from HSC.
Method: A retrospective study included 29 patients diagnosed with H-MCNs in pathology and 75 patients with HSC from June 2011 to June 2019 in Zhejiang University, School of medicine affiliated Sir Run-Run Shaw Hospital. Preoperative clinical data and outcome of surgery in H-MCN and HSC patients were analyzed.
Results: US, CT and MRI could accurately diagnose only 3.4%, 46.1% and 57.1% of H-MCNs, respectively. After univariate analysis and multivariate logistic regression analysis, the preoperative variables associated with H-MCNs were "enhancement after contrast" ($p = 0.009$), "located in the left lobe" ($p = 0.02$) and "biliary ductal dilation" ($p = 0.027$). A H-MCN risk predictive nomogram constructed by those factors and serum CA199 level showed an excellent discrimination (areas under the receiver operating characteristic curve were 0.940) and agreement calibration between predicted and actual probability.
Conclusion: Among patients with the H-MCNs, location of the tumor, enhancement in CT scan and biliary ductal dilation are significantly

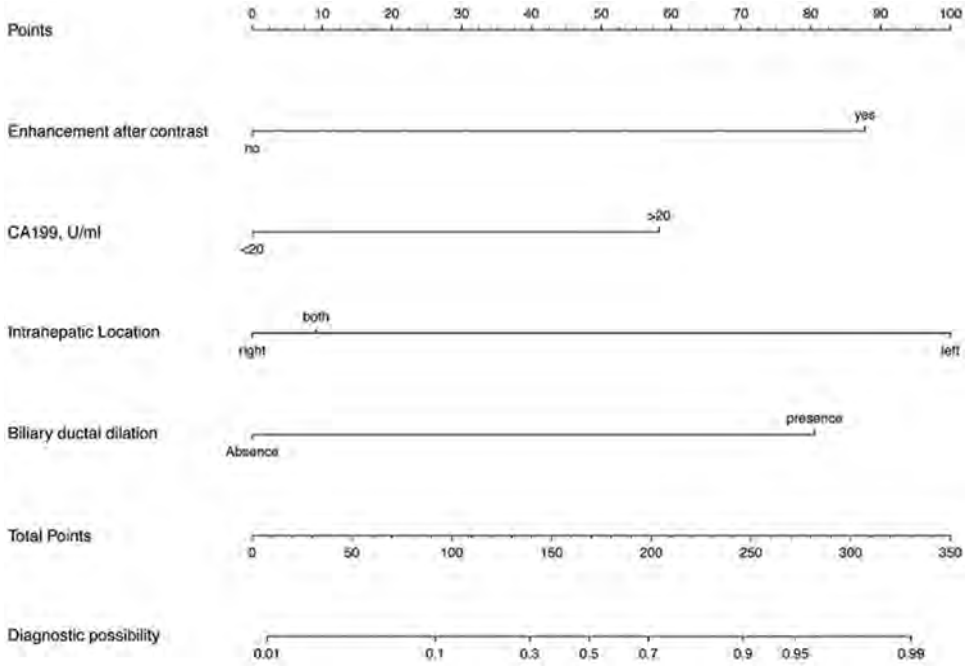

Figure 1. **A nomogram to estimate the possibility of H-MCN in liver cystic lesion.** To use this nomogram, find the position of the variables on the corresponding axis, draw a vertical line to the points axis to get the points of the variable. Calculate the total points of all variables and draw a line from corresponding total points axis to the possibility axis to get the probability of the H-MCNs.

independent risk factors. The reasonable treatment of H-MCNs are radical resection. Using of our nomogram could facilitate screening and identification of patients with liver cystic lesions.

THU460

Prognostic significance of systemic immune-inflammation index in patients with intrahepatic cholangiocarcinoma undergoing hepatic resection

Hui Li[1], Genshu Wang[2], Jinjiu Wang[1], Jiaxin Li[1], Lin Xu[1], Hong Wu[1].
[1]West China Hospital, Liver Surgery & Liver Transplantation, Chengdu, China; [2]The Third Affiliated Hospital of Sun Yat-sen University, Hepatic Surgery, Guangzhou, China
Email: 445613487@qq.com

Background and Aims: The systemic immune-inflammation index (SII) is an index which incorporates platelets, neutrophils and lymphocytes, calculating by multiplying platelet counts by NLR. No data exists until now, evaluating the prognostic value of SII for ICC. This study aimed to investigate the prognostic effect of SII to predict long-term outcomes in patients with intrahepatic cholangiocarcinoma (ICC) undergoing hepatic resection.
Method: Consecutive ICC patients who underwent initial hepatectomy with curative intent from January 2009 to September 2017 were retrospectively reviewed. Receiver-operating characteristic (ROC) curves were used to determine the optimal cut-off values of SII. Kaplan-Meier curves and Cox proportional hazards regression were performed to evaluate the discriminative ability of preoperative SII in predicting overall survival (OS) and recurrence-free survival (RFS).
Results: A total of 530 patients were included and randomly divided into derivation (n = 265) and validation cohort (n = 265). The optimal cut-off value for SII was 450. At a median follow-up of 18 months (range, 1–115.4 months), 317 (59.8%) patients died and 381 (71.9%) patients experienced tumor relapse. Low SII level was associated with better OS and RFS (both $p < 0.05$). Multivariate analyses identified multiple tumors, node invasion and high SII level as independent risk factors for OS, while multiple tumors, node invasion and high SII level were identified as independent risk factors for RFS. Validation cohort confirmed the findings of derivation cohort.
Conclusion: The present study demonstrated the feasibility of preoperative SII as a prognostic indicator for ICC. Patients with increased SII level were associated with worse OS and earlier tumor recurrence. The SII level was an independent risk factor for OS and RFS in patients with ICC after hepatectomy. In the future, the SII could help stratifying patients with ICC, thus guiding therapeutic choices, especially in immunotherapy.

THU461

Serum and urine extracellular vesicles contain specific RNAs with diagnostic capacity for cholangiocarcinoma, being possibly involved in disease pathogenesis

Ainhoa Lapitz[1], Pedro Miguel Rodrigues[1], Ander Arbelaiz[1], José Luis Lavin[2], Colm O Rourke[3], Marcin Krawczyk[4,5], Alvaro Santos-Laso[1], María Jesús Perugorria[1,6,7], Adelaida La Casta[1], Raul Jimenez-Aguero[1], Cesar Ibarra[8], Alberto Sanchez-Campos[8], Juan Pablo Jimeno[9], Ioana Riaño[1], Esperanza Gonzalez[10], Frank Lammert[11], Marco Marzioni[12], Rocio IR Macias[13], Jose Marin[13], Tom Hemming Karlsen[14], Luis Bujanda[1,6], Juan Falcon-Perez[6,7,10], Jesper Andersen[3], Ana María Aransay[2], Jesus M. Experimental Hepatology and Drug Targeting (HEVEFARM), Salamanca, Spain; [14]*Norwegian PSC Research Center, Division of Cancer Medicine, Surgery and Transplantation, Oslo, Norway*
Email: ainhoa.lapitz@biodonostia.org

Background and Aims: Cholangiocarcinoma (CCA) represents a heterogeneous group of biliary cancers with poor prognosis. The etiology of the majority of CCAs is unknown, but there are some risk factors that predispose to its development, such as the presence of primary sclerosing cholangitis (PSC). Simultaneously, around 80% of patients with PSC have concomitant inflammatory bowel disease, mainly ulcerative colitis (UC). Up to now, there are no specific and sensitive biomarkers for the non-invasive diagnosis of CCA. In this sense, extracellular vesicles (EVs) have been postulated as a source of biomarkers and possible pathogenic mediators of various diseases. Therefore, we propose to determine the potential value of serum and urine EVs as carriers of RNA biomarkers for the diagnosis of CCA and their possible involvement in CCA pathogenesis.

Method: Serum and urine EVs were isolated by differential ultracentrifugation from patients with UC (n = 8 and 12), PSC (n = 4 and 4) and CCA (n = 10 and 17) and from healthy individuals (n = 9 and 5). EV characterization was carried out through transmission electron microscopy (TEM), nanoparticle tracking analysis (NTA) and

immnunoblot. The content of EVs was determined by mRNA microarray-based transcriptomics (Illumina). The diagnostic value of identified transcripts [AUC, sensitivity, specificity, etc.] was calculated using IBM SPSS statistics. Finally, the expression of the selected candidates was evaluated in human CCA tumor and surrounding healthy tissue from two independent cohorts (TCGA and Copenhagen), as well as in cell cultures of normal human (NHC) and tumor cholangiocytes (EGI-1 and TFK-1) and in EVs released from those cell lines.

Results: Both isolated serum and urine EVs showed a rounded morphology (TEM), similar size (~180 nm in diameter, NTA) and typical EV markers (CD9, CD63 and CD81) by immunoblot. The transcriptomic analysis of these EVs showed a differential profile of RNAs in patients with CCA compared to healthy individuals or patients with other diseases (PSC and UC), with some of them presenting a high diagnostic value (AUC = 1). In patients with CCA, a total of 268 transcripts in serum and 50 in urine presented a differential abundance, and particularly 179 and 28 were found differentially expressed in CCA tumors (TCGA and Copenhagen), respectively. In addition, the expression of those transcripts also had altered RNA expression in CCA cells (49 mRNA) and in CCA cell-derived EVs (27 mRNA), presenting high diagnostic capacity (AUC = 0.92 CCA vs Ctrl) and possible being involved in the pathogenesis of the disease (e.g. cell growth, cell cycle, DNA repair, protein metabolism).

Conclusion: Serum and urine EVs of patients with CCA contain specific transcriptomic signatures with high diagnostic capacity, reflecting their potential use as non-invasive accurate biomarkers.

THU462

Novel protein biomarkers in serum extracellular vesicles for the diagnosis of cholangiocarcinoma (CCA) in patients with primary sclerosing cholangitis (PSC)

Ainhoa Lapitz[1], Mikel Azkargorta[2,3], Colm O Rourke[4], Ander Arbelaiz[1], Adelaida La Casta[1], Mette Vesterhus[5], Piotr Milkiewicz[6], Raul Jimenez-Aguero[1], Ioana Riaño[1], Ana Landa[1], Cesar Ibarra[7], Javier Bustamante[7], María Jesús Perugorria[1,3,8], Luis Bujanda[1,3], Pedro Miguel Rodrigues[1], Jesper Andersen[4], Felix Elortza[2], Trine Folseraas[5], Tom Hemming Karlsen[5], Jesus M. Banales[1,3,8].
[1]Biodonostia Health Research Institute, Liver and Gastrointestinal Diseases, San Sebastian, Spain; [2]CIC bioGUNE, Proteomics Platform, Derio, Spain; [3]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd), Madrid, Spain; [4]Biotech Research and Innovation Centre (BRIC), Department of Health and Medical Sciences, Copenhagen, Denmark; [5]Norwegian PSC Research Center, Department of Transplantation Medicine, Division of Surgery, Inflammatory Medicine and Transplantation, Oslo, Norway; [6]Medical University of Warsaw, Department of General, Transplant and Liver Surgery, Warsaw, Poland; [7]Hospital of Cruces, Bilbao, Spain; [8]Ikerbasque, Basque Foundation for Science, Bilbao, Spain
Email: ainhoa.lapitz@biodonostia.org

Background and Aims: Cholangiocarcinoma (CCA) includes a heterogeneous group of biliary malignancies with very poor prognosis. Its etiology is generally unknown, although primary sclerosing cholangitis (PSC) constitutes a well-known risk factor. Currently, there are no non-invasive, early and accurate diagnostic methods for the diagnosis of CCA. In this sense, extracellular vesicles (EVs), biomolecule holders which are found in biological fluids, have recently emerged as a potential source of biomarkers for several diseases. Therefore, we aimed to characterize the protein content of serum EVs and determine the diagnostic value of EV-proteins as non-invasive biomarkers for CCA of unknown etiology and for patients who developed CCA on a PSC background.

Method: Serum EVs were isolated from patients with PSC (n = 39), CCA (n = 30; unknown etiology), PSC-CCA (n = 25) as well as from healthy individuals (n = 41) by differential ultracentrifugation. The characterization of the EV fraction was performed by transmission electron microscopy (TEM), nanoparticle tracking analysis (NTA, Nanosight) and immnunoblot. The protein content of these vesicles was determined by mass spectrometry-based proteomics. The diagnostic efficacy of the identified proteins was evaluated in two patient cohorts (analysis of ROC curves with IBM SPSS statistics). In addition, the expression (mRNA) of candidate biomarkers was evaluated in two independent cohorts of CCA tumor tissue and surrounding liver (TCGA and Copenhagen), as well as in CCA cell lines and normal cholangiocytes.

Results: Isolated EVs presented a round morphology (TEM), a similar diameter (180 nm; NTA) and typical markers of EVs such as CD9, CD63 and CD81 (immunoblot). By mass spectrometry, a total of 635 proteins were identified and proteomic analysis revealed a differential protein profile in patients with PSC, PSC-CCA, CCA, and healthy individuals. Certain identified proteins showed a high diagnostic value for CCA (increased PIGR: AUC 0.96, decreased HEP2: AUC 0.865), and for the diagnosis of CCA in patients with PSC (increased FIBG: AUC 0.859 and decreased HEMO AUC 0.859). Some of these proteins showed similar changes in CCA tumor tissue compared to surrounding liver, as well as in CCA cells compared to normal cholangiocytes.

Conclusion: Serum EVs contain accurate protein biomarkers for the diagnosis of CCA; with some of them being common for general CCAs and others specific for those with PSC etiology. The differential abundance of certain proteins in serum EVs constitute a promising non-invasive diagnostic tool and correlates with gene expression in tumor tissue and CCA cells, potentially playing a role in the pathogenesis of the disease.

THU463

Investigating the impact of extrahepatic metastasis in patients with HCC: does location matter?

Roman Klöckner[1], Marie-Theres König[1], Felix Hahn[1], Christoph Düber[1], Peter Galle[2], Arndt Weinmann[2], Aline Maehringer-Kunz[1]. *[1]University Medical Center Mainz, Diagnostic and Interventional Radiology, Mainz, Germany; [2]University Medical Center of the Johannes Gutenberg University, Department of Internal Medicine – Hepatology, Mainz, Germany*
Email: roman.kloeckner@gmail.com

Background and Aims: Extrahepatic metastatic disease (EMD) in patients with hepatocellular carcinoma (HCC) leads to classification into advanced stage in which systemic therapy is recommended. However, data on the prognostic impact of EMD on overall survival (OS) in these patients is rare, especially when taking into account the exact location of extrahepatic metastases. Therefore, aim of this study was to determine the prognostic impact of EMD in general and with a focus on different EMD sites using a longitudinal approach.

Method: As the work-up of patients is still ongoing, so far 642 patients with HCC treated between 01/2005–01/2019 were extracted from the clinical registry of our tertiary referral center in order to reevaluate the impact of EMD. All cross sectional imaging studies were re-reviewed by a board certified radiologist specialized in HCC-imaging in order to determine date and location of EMD-development. Locations were classified into six categories: lymph nodes, peritoneum, lung, bone, adrenal gland, and others. Furthermore, the status of macrovascular invasion was determined.

Results: Of the 642 patients, 35 patients could not be evaluated due to concurrent malignant disease. Overall 124/607 patients developed EMD: 58 (47%) patients presented with EMD synchronous to initial HCC diagnosis, 66 (53%) patients had metachronous EMD. Median OS after initial diagnosis was 20.5 months for patients without and 11.7 months for patients with EMD ($p < 0.001$). The most common metastatic sites were: lymph node (n = 65), lung (n = 67), bone (n = 31), peritoneum (n = 26), adrenal gland (n = 18), and others (n = 12). Residual median OS after detection of lymph node, lung, bone, peritoneal, adrenal, brain, and other metastases was 6.2, 5.6, 4.8, 4.3, 4.7, and 5.6 months respectively. None of the sites were significantly

different. The incidence of macrovascular invasion in patients with EMD was significantly higher compared to the subgroup of patients without EMD (p < 0.001).

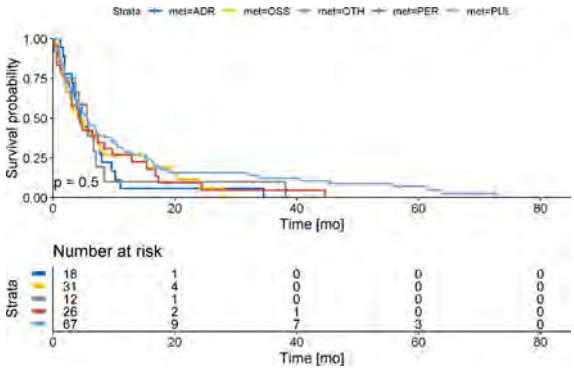

Figure: Overall survival of the different metastatic sites. ADR = adrenal; OSS = osseous; OTH = others; PER = peritoneal; PUL = pulmonary.

Conclusion: EMD had a significant impact on OS. However, there was no discernible difference in OS between metastatic sites. Therefore, under systemic treatment, the exact site is rather of secondary importance regarding OS. As EMD showed very strong correlation with macrovascular invasion, diagnosis of macrovascular invasion should prompt additional imaging in such patients.

THU464

Combination of AFP, AFP-l3 and PIVKA-II levels improves diagnostic accuracy of hepatocellular carcinoma (ALPS score)

Han Ah Lee[1], Tae Hyung Kim[1], Young-Sun Lee[1], Young Kul Jung[1], Ji Hoon Kim[1], Hyung Joon Yim[1], Jong Eun Yeon[1], Kwan Soo Byun[1], Soon Ho Um[1], Yeon Seok Seo[1]. [1]*Korea University School of Medicine, Internal Medicine, Seoul, Korea, Rep. of South*
Email: gandorie@gmail.com

Background/Aims: We investigated the diagnostic performances of serum AFP, AFP-L3, PIVKA-II level, and the combination of these tumor markers for diagnosis of hepatocellular carcinoma (HCC).
Methods: Total 526 patients who underwent AFP and AFP-L3 tests were enrolled. We calculated the serum AFP-L3 level using the formula as follows: serum AFP-L3 level = serum AFP level (ng/mL) × serum AFP-L3 fraction (%) × 0.01. New diagnostic model, ALPs (**A**FP, AFP-**L**3 fraction, and **P**IVKA-II) score was developed as follows: ALP-II level = 1.7 × [serum AFP level (ng/mL) × AFP-L3 fraction (%) × 0.01] + 0.2 × PIVKA-II level (mAU/mL).
Results: 317 patients (60.3%) had chronic liver disease and 185 patients (35.2%) had liver cirrhosis. Most common cause of chronic liver disease was chronic hepatitis B in 185 patients (35.2%). HCC was diagnosed in 131 patients (24.9%). BCLC stage was stage 0 in 6 patients (4.6%), stage A in 64 patients (48.9%), stage B in 32 patients (24.4%), stage C in 29 patients (22.1%).
The AUROCs for the diagnosis of HCC of serum AFP level, AFP-L3 fraction, and PIVKA level were 0.772, 0.801, and 0.829, respectively. Diagnostic accuracy did not differ among these markers (all P > 0.05). The optimal cutoff values of serum AFP level, AFP-L3 fraction, and serum PIVKA-II levels were 4.0 ng/mL, 5.7%, and 35.0 mAU/mL, respectively. The AUROC of AFP-L3 level was 0.816. It was significantly higher than AUROC of serum AFP level (P < 0.001), while it did not differ with AUROCs of AFP-L3 fraction (P = 0.210) and serum PIVKA-II level (P = 0.682). The optimal cutoff value of AFP-L3 level was 0.26 ng/mL with sensitivity 72.5% and specificity 79.7%. The AUROC of ALPs score for the diagnosis of HCC was 0.877, which was significantly higher than those of serum AFP level (P < 0.001), AFP-L3 fraction (P < 0.001), PIVKA-II level (P = 0.005), and AFP-L3 level (P = 0.004). The optimal cutoff value of ALPs score was 5.05 with 82.4% of sensitivity and 82.8% of specificity. AUROCs for the diagnosis of early stage HCC of serum AFP level, AFP-L3 fraction, AFP-L3 level, PIVKA-II level, and ALP-II level were 0.689, 0.738, 0.754, 0.735, and 0.815, respectively. AUROC of ALPs score was significantly higher than those of serum AFP level (P < 0.001), AFP-L3 fraction (P = 0.034), and serum PIVKA-II level (P = 0.007), while there was a trend of higher AUROC of ALPs score than that of AFP-L3 level (P = 0.060). AUROC of ALPs score was significantly higher than that of serum AFP level (P < 0.001), while it did not differ with AFP-L3 fraction (P = 0.470) and serum PIVKA-II level (P = 0.748).
Conclusions: Diagnostic accuracy for the diagnosis of HCC was significantly improved with ALPs score, calculated using serum AFP level, AFP-L3 fraction, and serum PIVKA-II level. ALPs score was also very accurate for the diagnosis of early stage HCC. To confirm these results, validation study is needed.

THU465

The PNPLA3 G-allele is common in patients with HCC but does not affect tumor characteristics and tumor biology

Benedikt Schaefer[1], Elisabeth Schönherr[2], André Viveiros[1], Herbert Tilg[1], Bernhard Glodny[2], Heinz Zoller[1]. [1]*Medical University of Innsbruck, Internal Medicine I, Gastroenterology, Hepatology and Endocrinology, Innsbruck, Austria;* [2]*Medical University of Innsbruck, Department of Radiology, Innsbruck, Austria*
Email: benedikt.schaefer@i-med.ac.at

Background and Aims: The G-allele of the of patatin-like phospholipase domain-containing protein 3 (*PNPLA3*) is an established risk factor for hepatic lipid accumulation and the development of advanced liver disease and HCC. This study explores a possible link between the *PNPLA3* G-allele and HCC tumor characteristics and biology.
Method: Patients referred for *PNPLA3* genotyping to the Hepatology Laboratory at the Medical University of Innsbruck were retrospectively assessed and included if the diagnosis HCC was made with multiphasic CT and/or dynamic contrast-enhanced MRI (n = 197). Tumor characteristics were assessed independently by two radiologists. An unselected *PNPLA3* genotyped cohort of cirrhotic patients without HCC (n = 1489) was used as a control group. Demographic, clinical and biochemical parameters were extracted from patient records.
Results: Of 197 (31 women) unselected HCC patients the G-allele prevalence was 70.6% (46.2% homozygous and 24.4% heterozygous). The allele frequency was not significantly different in an unselected cohort of cirrhotic patients (64.6%, p = 0.137) but far more frequent as in the general European population (allele frequency 0.228). At baseline (time of genotyping) age, median MELD scores and BMI did not differ between groups. When patients were grouped according to *PNPLA3* genotype no significant difference was observed in BCLC tumor stage, mRECIST defined tumor progression, tumor diameter and number, vascular tumor invasion and occurrence of extrahepatic metastasis. No association between *PNPLA3* and the combined endpoint death/liver transplantation was found. All before mentioned endpoints did also not differ between heterozygous and homozygous carriers.
Conclusion: Although G allele carriers in rs738409 of *PNPLA3* are known to be at increased risk of developing advanced fibrosis and HCC, no association between *PNPLA3* genotype and tumor characteristics, tumor biology or treatment response were found.

THU466

Long-term risk of HCC in persons with cirrhosis: national, population-based cohort study of 7,322 individuals

Bonnie Bengtsson[1,2], Linnea Widman[3], Staffan Wahlin[1,2], Per Stal[1,2], Niklas Björkström[2], Hannes Hagström[1,2,4]. Background and Aims: Cirrhosis is the major risk factor for development of hepatocellular carcinoma (HCC). Most estimates on HCC risk derive from smaller cohorts and tertiary centres. We aimed to investigate the risk for incident HCC in individuals in Sweden with a new diagnosis of cirrhosis in a population-based study.
Method: We identified all individuals with a new diagnosis of cirrhosis in Sweden between 2001–2016 based on administrative coding during outpatient visits. We ascertained incident HCC until the end of 2016 by record linkage to national registers. Cirrhosis etiology was defined by pre-specified coding algorithms. Persons with multiple etiologies were excluded. Each person with cirrhosis was compared with up to ten general population reference individuals free of cirrhosis, matched by age, sex and living location. Cox regression was used to estimate hazard ratios (HR) with censoring for non-HCC related mortality.
Results: We identified 7 322 persons with cirrhosis, of which 2 511 (34.3%) had viral hepatitis, 2 248 (30.7%) alcohol-related liver disease (ALD), 125 (1.7%) metabolic disease other than NAFLD, 597 (8.2%) autoimmune liver disease, and 1 841 (25.1%) NAFLD or other causes of cirrhosis. These were compared to 67 382 reference individuals.
During 419 236 person-years of follow-up, there were 801 (11%) cases of HCC in patients with cirrhosis compared to 49 (0.07%) in the reference population. This corresponded to an HR of 282 (95%CI = 189–420). Risk estimates differed across etiologies of cirrhosis. HRs for HCC development compared to reference individuals together with incidence rates are presented in Table 1.
Conclusion: Patients with cirrhosis have a high risk of HCC development. The risk differs significantly across etiologies of cirrhosis. These data support an individualized approach in determining HCC risk in patients with cirrhosis.

Serum cytokeratin-19 fragments (CYFRA 21–1) for the prediction of overall survival in patients with hepatocellular carcinoma

Gian Paolo Caviglia[1], Antonella Olivero[1], Michela Ciruolo[2], Patrizia Carucci[2], Emanuela Rolle[2], Chiara Rosso[1], Maria Lorena Abate[1], Alessandra Risso[2], Ramy Younes[1], Antonina Smedile[1], Giorgio Maria Saracco[1], Elisabetta Bugianesi[1], Silvia Gaia[2]. *[1]University of Turin, Department of Medical Sciences, Turin, Italy; [2]Città della Salute e della Scienza University-Hospital, Division of Gastroenterology, Turin, Italy*
Email: antonella.olivero@unito.it

Background and Aims: Cytokeratin-19 (CK-19) is a cancer stem cell marker expressed by a subpopulation of hepatocellular carcinomas (HCCs) associated with tumor aggressiveness. It has been shown that serum levels of CK-19 fragments (CYFRA 21-1) correlate with the HCC expression of CK-19; hence we evaluated the prognostic value of serum CYFRA 21-1 compared to alpha-fetoprotein (AFP) and protein induced by vitamin-K absence-II (PIVKA-II) in patients with HCC.
Method: A total of 160 patients (28F/132M; age 65 [44–86] years) with a new diagnosis of HCC achieved between Nov-2012 and Jan-2018 were retrospectively analyzed. All patients had cirrhosis and the main underlying etiology was viral (118/160, 73.8%). Barcelona Clinic Liver Cancer (BCLC) staging system was adopted for patients classification and therapies allocation (18 stage 0, 77 A, 39 B, 23 C, 3 D). Radiological response to treatment was assessed by modified Response Evaluation Criteria in Solid Tumors (mRECIST). Serum

samples were collected at HCC diagnosis; CYFRA 21-1, AFP and PIVKA-II were measured on Lumipulse® G600 II (Fujirebio Inc, Japan).
Results: The median overall survival (OS) after HCC diagnosis was 35.1 (95%CI 27.1–35.1) months. At HCC diagnosis, median CYFRA 21–1, AFP and PIVKA-II levels were 1.3 (95%CI 1.2–1.5) ng/mL, 12.6 (95%CI 8.6–16.9) ng/mL and 199 (95%CI 146–316) mAU/mL, respectively. CYFRA-21 showed a poor correlation with BCLC staging (rs = 0.157, p = 0.048) and PIVKA-II (rs = 0.163, p = 0.039) but no correlation with AFP (rs = 0.072, p = 0.368). At univariate analysis, CYFRA 21-1 >2.7 ng/mL resulted a significant factor for poor prognosis (Log-rank test, p < 0.001). Multivariate Cox regression showed that CYFRA 21-1 >2.7 ng/mL (HR = 3.45, 95%CI 1.84–6.46), AFP > 20 ng/mL (HR = 2.20, 95%CI 1.24–3.90), PIVKA-II >200 mAU/mL (HR = 2.38, 95%CI 1.29–4.39), BCLC stage (HR = 1.61, 95%CI 1.20–2.16) and radiological response (HR = 0.21, 95%CI 0.08–0.55) were independent predictors of 3-year OS, while only CYFRA 21-1 >2.7 ng/mL (HR = 3.46, 95%CI 1.69–7.10), BCLC stage (HR = 2.00, 95%CI 1.36–2.95) and radiological response (HR = 0.09, 95%CI 0.01–0.72) were independent predictors of 1-year OS.
Conclusion: Among investigated biomarkers, CYFRA 21-1 resulted the strongest independent predictor of OS. The determination of baseline serum CYFRA 21-1 may be a useful prognostic factor.

THU468
Contrast-enhanced ultrasound using sonazoid in liver imaging reporting and data system category 3 and 4 observations on gadoxetate-enhanced magnetic resonance imaging

Yeun-Yoon Kim[1], Ji Hye Min[1], Jeong Ah Hwang[2], Dong Ik Cha[1], Woo Kyoung Jeong[1], Hyo Keun Lim[1]. [1]*Samsung Medical Center, Department of Radiology and Center for Imaging Sciences, Seoul, Korea, Rep. of South;* [2]*Soonchunhyang University Cheonan Hospital, Department of Radiology, Cheonan, Korea, Rep. of South*
Email: minjh1123@gmail.com

Background and Aims: Contrast-enhanced ultrasound (CEUS) using perfluorobutane microbubble agent (Sonazoid) may have additional value for evaluating indeterminate focal liver lesions on gadoxetate-enhanced magnetic resonance imaging (MRI). We aimed to compare imaging features of gadoxetate-enhanced MRI and CEUS using Sonazoid in Liver Imaging Reporting and Data System (LI-RADS) v2018 category 3 (LR-3) and 4 observations, and to investigate the usefulness of CEUS to predict follow-up outcomes.
Method: We identified 136 LR-3 or LR-4 observations on gadoxetate-enhanced MRI which were subsequently evaluated with CEUS using Sonazoid in 131 patients (102 men and 29 women; mean age, 60.5 ± 9.3 years) with liver cirrhosis or chronic hepatitis B from 2013 to 2015. The presence of arterial phase hyperenhancement (MR-APHE), washout, and hepatobiliary phase (HBP) hypointensity on MRI, and the presence of APHE (CEUS-APHE) and Kupffer phase defect on CEUS were compared. In the subgroup of 53 observations which were not managed with ablation therapy, the follow-up outcomes were classified into high-risk group (pathologic proof of hepatocellular carcinoma, compact Lipiodol uptake after transarterial chemoembolization, or progression to LR-5 category within 6 months) and non-high-risk group. Logistic regression analysis was performed to identify imaging and clinical features associated with high-risk group.
Results: Thirteen (44.8%) of 29 observations without MR-APHE showed CEUS-APHE. Kupffer phase defect was demonstrated in 76 (81.7%) of 93 observations without washout and 6 (50.0%) of 12 observations without HBP hypointensity on MRI. In a subgroup analysis, 70.6% of high-risk group observations showed both CEUS-APHE and Kupffer phase defect at baseline, while 47.4% of non-high-risk group observations exhibited none of these features. Observations in the high-risk group tended to exhibit MR-APHE, washout, HBP hypointensity, CEUS-APHE, and Kupffer phase defect more frequently than those in the non-high-risk group. Multivariable analysis revealed that CEUS-APHE (OR, 8.38; 95% CI, 1.02–69.17; p = 0.048) and Kupffer phase defect (OR, 11.00; 95% CI, 1.52–79.86; p = 0.018) were independently associated with high-risk group.

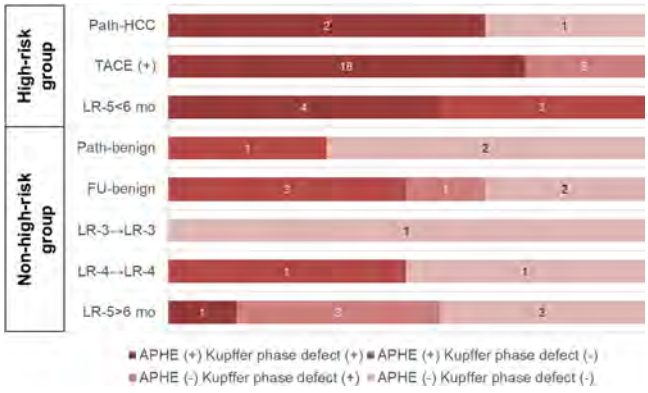

Figure: Baseline CEUS features according to follow-up outcomes.

Conclusion: The use of CEUS using Sonazoid can demonstrate additional imaging features, such as CEUS-APHE and Kupffer phase defect, in LR-3 or LR-4 observations on gadoxetate-enhanced MRI, which are independently associated with high-risk outcomes.

THU469
Active chronic hepatitis B increases the risk of liver metastasis - a retrospective observational study of 7,187 consecutive newly diagnosed colorectal cancer

Yue Yang[1], Lei Zhao[1]. [1]*Shandong Cancer Hospital and Institute, Shandong First Medical University, HBP Surgery, Jinan, China*
Email: drzhaolei@hotmail.com

Background and Aims: Worldwide, colorectal cancer (CRC) is the fourth leading cause of cancer mortality and is increasing in medium to highly-developed countries especially in Asia and Europe. China has the highest number of new cases, accounting for about 28% of global CRC cases [1]. Asia also has a high burden of viral hepatitis B, many CRC patients in Asia also have chronic hepatitis B (CHB) infection. The effect of concomitant CHB infection on the risk of colorectal liver metastasis (CRLM) has not been definitively elucidated.
Method: We performed this retrospective, cross-sectional study of 7187 consecutive newly diagnosed CRC cases in three hospitals. All patients were hospitalized during the period between January 2010 and January 2016 and had pathological confirmation of their CRC. Patients were divided into different groups depending on the status of HBsAg ($HBsAg^+$ *vs.* $HBsAg^-$) or HBeAg ($HBeAg^+$ *vs.* $HBeAg^-$). The prevalence of synCRLM and baseline clinicopathological parameters were compared between these groups.
Results: The overall prevalence of synCRLM was 8.72% (627/7187) and was significantly higher in $HBsAg^+$ patients (43/368) than $HBsAg^-$ patients (576/6742) (11.68% *vs.* 8.54%, $P = 0.037$; χ^2 test; Table 1).
6074 patients had HBeAg test performed, and HBeAg positivity was noted in 1.14% patients (69/6074). In 368 $HBsAg^+$ patients, 365 patients also had HBeAg information, 19 $HBsAg^+/HBeAg^+$ patients and 40 $HBsAg^+/HBeAg^-$ patients showed elevated ALT, while only 2 of them were under the anti-HBV treatment. There were other 7 patients with normal ALT are under or had a history of anti-HBV treatment.
In further sub-group analysis, synCRLM was also more prevalent in $HBsAg^+/HBeAg^+$ patients (13/69) compared to $HBsAg^+/HBeAg^-$ patients (30/296) (18.84% *vs.* 10.14%, $P = 0.043$; χ^2 test). If 9 patients with anti-HBV treatment were excluded, synCRLM remained more prevalent in $HBsAg^+/HBeAg^+$ patients (13/67) compared to $HBsAg^+/HBeAg^-$ patients (30/289) (19.40% *vs.* 10.38%, $P = 0.032$; χ^2 test).

In univariate logistic regression analysis (Table 3), HBeAg positivity had the highest odds ratio (OR) [OR: 2.920, 95% confidence interval (CI): 1.558–5.371, $P = 0.001$] and was more than twice that of HBsAg positivity (OR: 1.417, 95% CI: 1.019–1.969, $P = 0.038$). In the subsequent multivariate analysis with other significant factors, HBeAg positivity was still the strongest predictor of synCRLM (OR: 2.473, 95% CI: 1.081–5.661, $P = 0.032$) (table 4), the OR of HBsAg positivity was 1.671 (95% CI: 1.060–2.633, $P = 0.027$) (table 5).
Conclusion: HBeAg positivity is a clinical risk factor for CRLM that can be readily identified and addressed. It is yet unclear if antiviral treatment can decrease the risk of liver metastasis in CRC patients, but future studies with carefully designed prospective trials will be needed to better define this.

THU470
Identification and etiology-dependent evaluation of diagnostic algorithms for early detection of hepatocellular carcinoma
Magdalena Swiatek-de Lange[1], Henry Chan[2], Teerha Piratvisuth[3], Tawesak Tanwandee[4], Satawat Thongsawat[5], Wattana Sukeepaisarnjaroen[6], Juan Ignacio Esteban Mur[7], Marta Bes[8], Bruno Köhler[9], Marcus-Rene Lisy[1], Christine Anna Belz[1], Vinzent Rolny[1], Ying He[1], Dave Morgenstern[10]. *[1]Roche Diagnostics GmbH, Penzberg, Germany; [2]Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, China; [3]Prince of Songkla University, NKC Institute of Gastroenterology and Hepatology, Hat Yai, Thailand; [4]Mahidol University, Division of Gastroenterology Siriraj Hospital, Bangkok, Thailand; [5]Maharaj Nakorn Chiang Mai Hospital, Department of Internal Medicine, Chiang Mai, Thailand; [6]Srinagarind Hospital, Department of Medicine, Khon Kaen, Thailand; [7]Universitat Autónoma de Barcelona, Hospital Vall d'Hebrón, Barcelona, Spain; [8]Banc de Sang i Teixits, Facultativa Laboratori de Seguretat Transfusional, Barcelona, Spain; [9]National Center for Tumor Diseases University Hospital Heidelberg, Department of Medical Oncology, Heidelberg, Germany; [10]Roche Diagnostic Operations, Inc., Indianapolis, United States*
Email: magdalena.swiatek-de_lange@roche.com

Background and Aims: Hepatocellular carcinoma (HCC) has limited treatment options when diagnosed late so early detection is crucial to reduce mortality. Multiple factors associated with cirrhosis, e.g. HBV, HCV or steatohepatitis are involved in the etiology of HCC and have an impact on disease course, diagnosis and therapy. Ultrasound is used for the surveillance of at-risk patients, but has limitations in the setting of NASH and severe liver disease. Alpha-fetoprotein (AFP) improves HCC detection but lacks sensitivity for small tumours. With the aim to improve early diagnosis of HCC in different at-risk populations, we identified biomarker panels with high sensitivity and specificity for early HCC and analysed their performance in context of liver disease etiology.
Method: Over 60 biomarkers were evaluated in a panel composed of 308 HCC cases including 125 early stages (BCLC 0 and A) and demographically matched 734 chronic liver disease controls (CLD) from a prospective multi-center study. Univariate and multivariate analysis were performed to distinguish early stage HCC and all HCC from CLD. Performance of the selected panels was compared to GALAD score (Gender, Age, AFP-L3, AFP, DCP). Impact of cirrhosis, HBV, HCV and non-viral etiology on clinical performance was investigated for each biomarker panel.
Results: In over 100.000 analyzed combinations AFP and PIVKA-II were the strongest features, but with limited sensitivity toward early stages. Addition of a 3rd biomarker: AFP-L3, IGFBP3, COMP or MMP3 together with gender and age further increased accuracy. Performance of the biomarkers was influenced by disease etiology: AFP showed robust performance in HBV, HCV and NASH/ASH; PIVKA-II had limited performance in ASH, while IGFBP3, MMP3 and COMP were affected by ASH/NASH. AFP-L3 performed well in HCV and NASH/ASH groups. Compared to other scores, GALAD showed superior robustness and clinical performance with AUC of 95% for all- and 90% for early HCC for viral- and non-viral etiologies. Performance in the cirrhosis cohort was 4% lower with AUC of 92% for all HCC and 87% for early HCC.
Conclusion: Analysis of over 100.000 biomarker combinations identified panels for early diagnosis of HCC with differential impact of etiology on their performance. None of the candidates showed sufficient performance as single marker and none of the identified scores was superior to GALAD. GALAD score showed robust diagnostic performance in both viral and non-viral etiologies and was only slightly affected by cirrhosis.

THU471
Optimisation and qualification of tumour mutational burden (TMB) by targeted next-generation sequencing (TNGS) as a clinically applicable biomarker in hepatocellular carcinoma (HCC)
Ching Ngar Wong[1], Kathy Dominy[2], Francesco Mauri[1], Takahiro Kaneko[3], Persephone Du Parcq[2], Jamshid Khorasad[2], Pierluigi Toniutto[4], Robert D. Goldin[5], Claudio Avellini[6], David J. Pinato[1]. *[1]Imperial College London, Surgery and Cancer, London, United Kingdom; [2]Hammersmith Hospital, Molecular Pathology Laboratory, London, United Kingdom; [3]Tokyo Medical and Dental University, Medicine, Tokyo, Japan; [4]University of Udine, Medical Area (DAME) Hepatology and Liver Transplantation Unit, Udine, Italy; [5]Imperial College London, Centre of Pathology, London, United Kingdom; [6]Institute of Histopathology, Azienda Ospedaliero-Universitaria "Santa Maria della Misericordia", Udine, Italy*
Email: david.pinato@imperial.ac.uk

Background and Aims: Higher levels of somatic non-synonymous mutations associate with improved response and survival following immune-checkpoint inhibitors. In this pilot study, we aimed to optimise tNGS as a method to provide a reliable estimate of patients' TMB in HCC.
Method: Following macrodissection and DNA purification, 48 samples derived from an international biorepository (21 fresh-frozen [FF] and 27 formalin-fixed paraffin-embedded, [FFPE]) underwent tNGS by OncomineTM Tumour Mutation Load Assay (1.5 Megabase exome coverage) on an Ion S5TM sequencer. We performed uracil-DNA glycosylase (UDG) pre-treatment in a group of 11 FFPE samples to verify its effect on fixation-induced cytosine deamination. In total, 30/48 samples satisfied post-sequencing quality control and were included for clinicopathological correlation. We classified samples as high/low TMB based on median number of mutations/Mb (Mut/Mb), testing different minimum allele frequency (MAF) thresholds (≥ 0.05, ≥ 0.1 and ≥ 0.2) in relationship with clinicopathological features including Overall (OS) and Recurrence-Free survival (RFS).
Results: Eligible patients (n = 30) were mostly male, cirrhotic (84%) secondary to alcohol (48%) and Hepatitis C infection (45%). Median dominant tumour size was 4 cm with most patients being staged as TNM stage I-II (75%). Median OS was 12.3 months and median RFS was 12.1 months. FFPE samples displayed significantly higher TMB (median 958.39 vs 2.51 Mut/Mb, $p < 0.0001$), estimated deamination counts (median 1335.50 vs 0, $p < 0.0001$) and percentage C > T transition at CpG sites (median 60.3% vs 9.1%, $p = 0.002$) compared to FF. UDG-treated FFPE samples carried significantly lower TMB (median 4019.92 vs 353 Mut/Mb, $p = 0.041$), estimated deamination counts (median 6393.5 vs 328.5, $p = 0.041$) compared to untreated FFPE. Adjustment of MAF to 0.1 and 0.2 reduced deamination counts ($p < 0.05$), with a 0.2 threshold allowing for a reduction of TMB values within the interpretable range of <100 Mut/Mb in all samples. At a 0.2 MAF threshold with UDG treatment, the median number of non-synonymous mutations/Mb was 5.48 (range 1.68–16.07) and did not correlate with salient pathologic features of HCC including OS or RFS.
Conclusion: This pilot study highlights the challenges of TMB testing in archival tissue, where UDG pre-treatment and MAF adjustment to 0.2 allows for an improved assessment of TMB. Whilst tNGS on fresh

HCC samples appears the optimal source of somatic DNA, the low median TMB values observed here may limit the role of TMB as a predictive correlate of response to immunotherapy in HCC.

Peters VA Medical Center, Bronx, NY and Icahn School of Medicine at Mount Sinai, New York, United States*
Email: david.pinato@imperial.ac.uk

Background and Aims: HIV-seropositivity shortens survival in patients with hepatocellular carcinoma (HCC), a leading cause of mortality in people living with HIV (PLHIV) and hepatitis. Whether HIV pre-conditions cancer immune tolerance is unknown in HCC. This is a point of greater consequence given PLHIV are excluded from trials of immune checkpoint inhibitors. We intended to verify whether HIV status influences anti-tumour immunity by evaluating the functional characteristics of the T-cell infiltrate in tumour, peri-tumoral tissue and background cirrhosis.

Method: From an international biorepository of 55 HIV-associated HCCs from 4 centres in Europe and North America, we evaluated the expression of programmed cell death ligands 1 and 2 (PD-L1/2) in tumour and immune cells at a 1% cut-off. We explored their relationship with functional characteristics of the T-cell infiltrate (cytotoxic, regulatory and helper T-cell function) in tumoral, peritumoral and cirrhotic tissue. Immuno-pathologic features were correlated with patients' characteristics including markers of HIV infection.

Results: Of the 55 patients, 41 (85%) were male and had a median age of 52 years (range 41–64). Hepatitis C virus co-infection was the leading risk factor for HCC (n = 46, 90%). Most patients were of Barcelona Clinic Liver Cancer (BCLC) stage 0/A (n = 40, 85%), Child-Pugh A (n = 44, 86%), had median alfa-fetoprotein (AFP) values of 11 ng/ml (range 2–6536), undetectable HIV viral load (n = 31, 84%), and a median blood CD4+ cell count of 428 cells/mm^3. Patients were treated with liver transplantation (n = 39, 71%) or resection (n = 12, 22%). We observed tumoral PD-L1 expression in 24/55 (52%) and PD-L2 expression in 13/55 (28%) patients respectively. PD-L1 was frequently co-immunoexpressed in CD4 + FoxP3+ (49.0 vs. 8.2 cells/mm^2, p = 0.002) and CD8 + PD-1+ (40.8 vs. 12.3 cells/mm^2, p = 0.016) in tumour-infiltrating lymphocytes (TILs). This was not the case in PD-L2. PD-L1$^+$ HCCs had higher CD4$^+$FoxP3$^+$ TIL density compared to PD-L1$^-$ tumours (40.8 vs. 12.3 cells/mm^2, p = 0.014). PD ligands expression, CD4$^+$FoxP3$^+$ and CD8$^+$PD-1$^+$ cell density were independent of parameters reflective of HIV infection severity including peripheral blood CD4$^+$ count and HIV viral load. Peripheral CD4$^+$ counts positively correlated with CD4$^+$FoxP3$^-$ T-helper density in tumoral (r = 0.38, p = 0.032) and peri-tumoral cores (r = 0.45, p = 0.009), but not in surrounding cirrhosis. PD-L1 or PD-L2 expression was independent of patients' Child-Pugh class, AFP levels and did not predict for survival.

Conclusion: PD-L1 expression drives anti-tumour tolerogenesis in PLHIV with HCC, where prevalence of PD-L1 positivity (52%) is two-fold higher compared to historical HIV-negative controls (17%). Peripheral CD4$^+$ count is an appealing surrogate for effective T-helper infiltration in tumour and may guide the development of immunotherapy in HIV-associated HCC.

THU474

The burden of percutaneous liver biopsy use in hepatocellular carcinoma

Ahmad Khan[1], Raseen Tariq[2], Nida Khalid[2], Kamesh Gupta[3], Khadija Naseem[4], Shailendra Singh[5]. *[1]West Virginia University Charleston Division, Charleston, United States; [2]Rochester General Hospital, Rochester, United States; [3]Baystate Medical Center, Springfield, United States; [4]Services Institute of Medical Sciences, Lahore, Pakistan; [5]CAMC Memorial Hospital, Charleston, United States*
Email: drahmadk83@gmail.com

Background and Aims: The role of percutaneous liver biopsy (PLB) for the diagnostic workup for hepatocellular carcinoma (HCC) has become limited due to advancements in non-invasive diagnostic techniques. However, liver biopsy is still warranted under certain circumstances. We aimed to investigate the burden of PLB use for the diagnosis of HCC.

Method: We identified all the HCC related hospitalizations and PLB procedures using ICD 9-CM codes from the National Inpatient Sample (NIS) 2004 between 2014. Primary outcomes included the rate of LB procedures with secondary outcomes were in-patient mortality, length of stay (LOS), total hospitalization charges associated with these procedures. We also performed a univariate and multivariate regression analysis to account for confounding factors to predict the factors that can influence mortality and resource utilization in these patients.

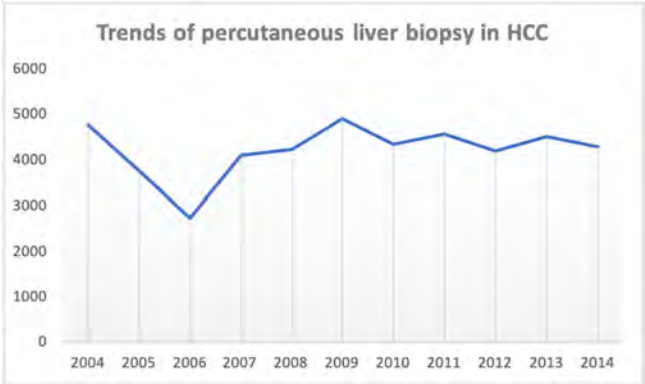

Figure: Number of percutaneous liver biopsy procedures performed through 2004 to 2014 in patients with hepatocellular carcinoma.

Results: A total of 390,393 HCC related hospitalizations with mean age 64 years and 31.74% of females were recorded. In total, 46,421 (11.89%) percutaneous liver biopsies were performed during hospitalizations between 2004 to 2014. A total of 38,687 (9.91%) of HCC related deaths occurred during the same admission, and 2,399 (5.1%) had PLB biopsies. Mean LOS was higher in patients who underwent

PLB 8.81 vs. 5.7 days, mean total hospitalization charges 69,840$ vs. 49,128$, mean total hospitalization cost 20,628$ vs. 14,449$. On univariate and multivariate regression analysis, black race (adj OR 1.26, p < 0.01), high charlson comorbidity index (adj OR 1.36, p < 0.01) transfusions (adj OR 1.41, p < 0.01, acute kidney injury (adj OR 2.5, p < 0.01) and sepsis (adj OR 3.2, p < 0.01) were found to be independent predictors of mortality in patients with HCC who underwent PLB. There was a significant downward trend noticed in the number of procedures performed in 2004 (4,777) as compared to 2014 (4,280).
Conclusion: Our study showed that a substantial number of patients with HCC still require PLB for the diagnostic workup, which adds to overall increased resource utilization. Large prospective studies are required to formulate validated diagnostic algorithm to further decrease the use of PLB in the diagnostic workup of HCC.

THU475

Epidemiological trends of hepatocellular carcinoma in patients with non-alcoholic fatty liver disease in Italy. On behalf of the ITA.LI.CA study group

Fabio Farinati[1], Alessandro Vitale[1], Alessio Ortolani[2], Luca Miele[3], Rafael Ramirez Morales[1], Franco Trevisani[4], Gianluca Svegliati-Baroni[2]. *[1]Padua University Hospital, Padova, Italy; [2]Polytechnic University of Marche, Ancona, Italy; [3]Policlinico Gemelli, Università Cattolica del Sacro Cuore, Rome, Italy; [4]Alma Mater Studiorum – University of Bologna, Bologna, Italy*
Email: alessandro.vitale@unipd.it

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is projected to become the leading cause of hepatocellular carcinoma (HCC) in Western countries within 2025. The Italian Cancer Liver (ITA.LI.CA) database, that has collected over the last 20 years data of a huge western population of HCC patients, offers the ideal possibility to depict the epidemiological trends of NAFLD-associated HCC in the last years.
Method: We analysed 6,485 consecutive HCC patients diagnosed and enrolled from 2002 to 2017 in this multicenter Italian database. To describe epidemiological trends, the study period was divided in eight consecutive biennials (2002–2003 to 2016–2017). We analysed trends in liver disease severity, HCC stage and treatment strategies according to the HCC aetiologies.

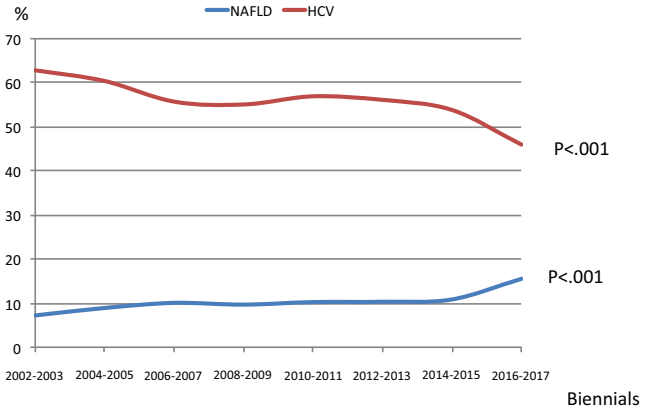

Figure 1: Epidemiological trends of NAFLD and HCV aetiologies in ITA.LI.CA patients with HCC, period 2002–2017.

Results: The proportion of NAFLD-HCC patients significantly increased in the study period from 7.19% in the first biennium, to 15.53% in the last (p < 0.001). Conversely, the proportion of hepatitis C related-HCC patients significantly decreased from 62.83% to 45.96% (p < 0.001). The proportion of hepatitis B related–HCC similarly decreased from 18.94% to 12.20% (p < 0.001), with a sharp decrease the overall of viral aetiology (p < 0.001). The proportion of HCC related to alcohol abuse remained stable around 16% (p = 0.183). Cirrhosis was present in about 75% of NAFLD-HCC patients, in contrast to the near totality of other HCC patients (p < 0.001). In addition, the proportion of cirrhosis in NAFLD-HCC patients slightly decreased from 86.67% in the first biennium to 74.7% in the last (p = 0.03). NAFLD-HCC patients showed less often a clinically significant portal hypertension and an early tumor stage, but these differences did not impact in their potential for radical therapies and overall survival (median survival 42 vs. 44 months in NAFLD vs other HCC patients, p = 0.77). Moreover, considering the different treatments and the ITA.LI.CA staging subgroups, no differences in overall survival were observed between NAFLD and other HCC patients.
Conclusion: The proportion of NAFLD-HCC in Italy has significantly increased from 2002 to 2017, with a progressive reduction of the association with cirrhosis (absent in about 1 out of 4 NAFLD-HCC patients). The outcome of NAFLD-HCC patients does not differ from that of the other HCC cases.

THU476

Circulating microRNA-21 and microRNA-122: prognosis prediction and correlation with HIF-1alpha in hepatocellular carcinoma patients treated with transarterial chemoembolization

Filippo Pelizzaro[1], Romilda Cardin[1], Milena Minotto[1], Chiara Carlotto[1], Angela Imondi[1], Anna Sartori[1], Barbara Penzo[1], Ambra Sammarco[1], Giulia Peserico[1], Camillo Aliberti[2], Alessandro Vitale[3], Fabio Farinati[1]. *[1]University of Padua, Department of Surgery, Oncology and Gastroenterology, Gastroenterology Unit, Padua, Italy; [2]AOP – University of Padua, Department of Radiology, Padua, Italy; [3]University of Padua, Department of Surgery, Oncology and Gastroenterology, Hepatobiliary Surgery and Liver Transplant Unit, Padua, Italy*
Email: filippo.pelizzaro@gmail.com

Background and Aims: MiR-21 and miR-122 have been identified as promising circulating biomarkers in hepatocellular carcinoma (HCC). We aimed to evaluate the prognostic role of their determination in HCC patients treated with transarterial chemoembolization (TACE), a treatment that induces liver ischemia, and the link, if present, with an angiogenesis biomarker (HIF-1alpha).
Method: Whole blood levels of miR-21 and miR-122 were evaluated in 40 HCC patients, 18 cirrhotics and 10 healthy volunteers, with a second determination in HCC 4 weeks after treatment (at the time of the imaging control). The miRNA level before TACE and the miRNA ratio (miRNA after/before TACE) were evaluated as potential progression-free survival (PFS) predictors. The Spearman's rank correlation coefficient was used to correlate miRNAs with HIF-1alpha. MiRNA levels were evaluated with qRT-PCR and expressed as $2^{-\Delta\Delta Ct}$; an ELISA method was used to measure HIF-1alpha levels.
Results: Both miR-21 and miR-122 were detectable in the blood of HCC patients at significantly higher levels as compared to healthy controls, with no significant differences with cirrhotics. A trend towards a decline in miR-21 after TACE (p = 0.056) was observed; miR-122 levels, despite being higher after TACE, were not significantly different. MiR-122 was higher in HCC patients with underlying viral liver disease (p = 0.03). High miR-21 levels before TACE (> median value) predicted favorable radiological response (chi-squared = 4.8; p = 0.03). MiR-21 ratio and miR-122 before TACE proved to be prognostic predictors: patients with levels of miR-21 ratio and miR-122 below the respective cut-off had a longer PFS (p = 0.0001 and p = 0.009, respectively) (see Figure). MiR-21 ratio, miR-122 and radiological response (mRECIST), were independent predictors of PFS at the Cox multivariate analysis. Moreover, miR-21 ratio and miR-122 were able to sub-stratify patients with complete or partial response in two groups, at favorable or poor PFS. MiR-21, but not miR-122, positively correlated with HIF-1alpha both before (r = 0.34, p = 0.049) and after TACE (r = 0.42, p = 0.01).

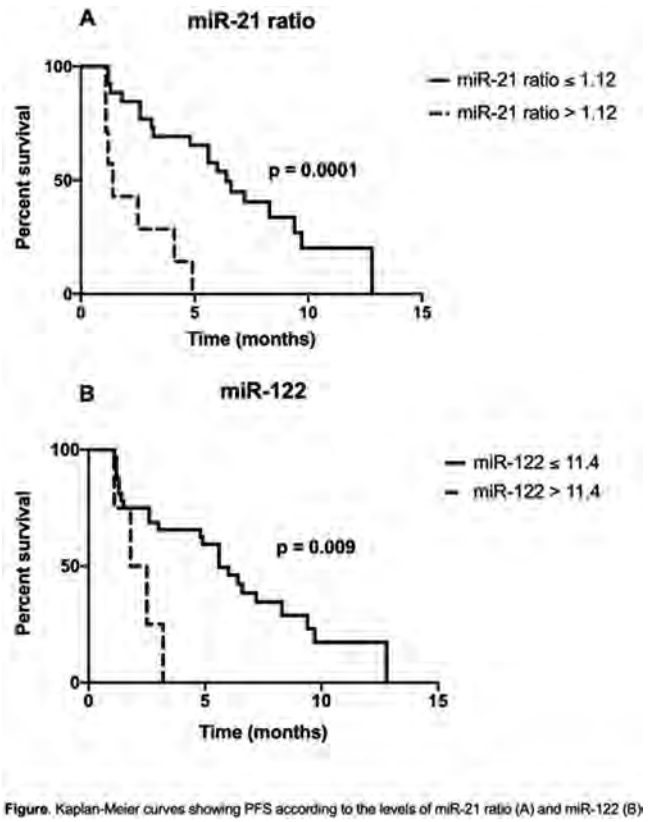

Figure. Kaplan-Meier curves showing PFS according to the levels of miR-21 ratio (A) and miR-122 (B)

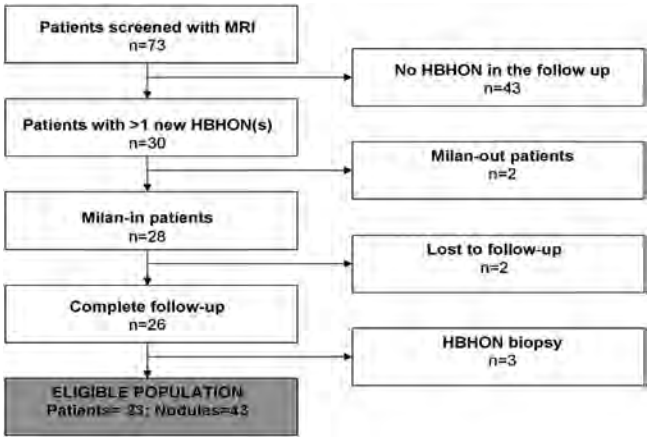
Conclusion: MiR-21 and miR-122 are independent predictors of PFS in TACE-treated HCC patients and are able to identify, in patients with favorable radiological response, those with an early tumor progression after the treatment. The finding of a link between circulating miR-21 and HIF-1alpha in HCC indicate a potential role of miR-21 in angiogenesis.

THU477

Natural history of hepatobiliary-hypointense only nodules found at magnetic resonance imaging with Gd-EOB-DTPA: time-dependent effects of dimensional increase and diffusion weighted imaging alterations

Luca Ielasi[1], Matteo Renzulli[2], Francesco Tovoli[1], Irene Pettinari[2], Francesca Benevento[1], Alessandro Granito[1]. [1]*University of Bologna, Department of Medical and Surgical Sciences, Italy;* [2]*Bologna Authority Hospital S.Orsola-Malpighi Bologna, Radiology Unit, Bologna, Italy*
Email: luca.ielasi.kr@gmail.com

Background and Aims: HB hypointense-only nodules (HBHONs) are frequently found in cirrhotic patients performing magnetic resonance imaging. Some HBHONs can transform into overt hepatocellular carcinoma (HCC) overtime. Studies including only de novo HBHON (i.e. which were absent at previous MRI examinations) and using rigorous time-dependent analyses are still lacking.
Method: We evaluated consecutive patients performing MRI in the surveillance programs of HC due to a poor ultrasound visualization of the liver, analyzing only HBHONs appearing during the program (availability of a previous MRI performed no more than 6 months before the appearance of HBHONs to confirm that the nodule was not previously present). To better define the clinical repercussion of the detection of HBHONs, we excluded patients for which this finding would not have altered the clinical decision-making process (i.e patients with a concurrent Milan-out HCC at the time of the HBHON detection). The time-to-transformation (TTT) to HCC was correlated with the baseline characteristics of HBHON and with time-dependent modifications during the follow-up.
Results: Twenty-three patients and 43 nodules were included. After a median follow-up of 31.7 months, 19 nodules (45.2%) transformed into HCC. The 1-year and 2-year transformation rates were 11.9 and 31.0%, respectively. The median TTT was 17.8 months (95% CI 15.4–20.2). At the multivariable Cox regression with time-dependent covariates, the risk of evolution was 4-time increased after a dimensional increase >2 mm for the baseline and 5-time increased after the appearance of diffusion-weighted imaging (DWI) alterations. The median TTT shortened to 12.1 months (range 3.1–12.1) following the appearance of DWI alterations and to 4.9 months (range 3.1–34.3) after the first dimensional increase. Diameter of the nodule at its first appearance, previous/concurrent HCC, baseline T1 and T2 parameters were no related to an increased risk of transformation.



Conclusion: Examining only de novo HBHON, we provided for the first time relevant information about the natural history of these nodules. If confirmed in collaborative studies with larger populations, our data would pave the way for important policy-making decisions about the follow-up of HBHONs.

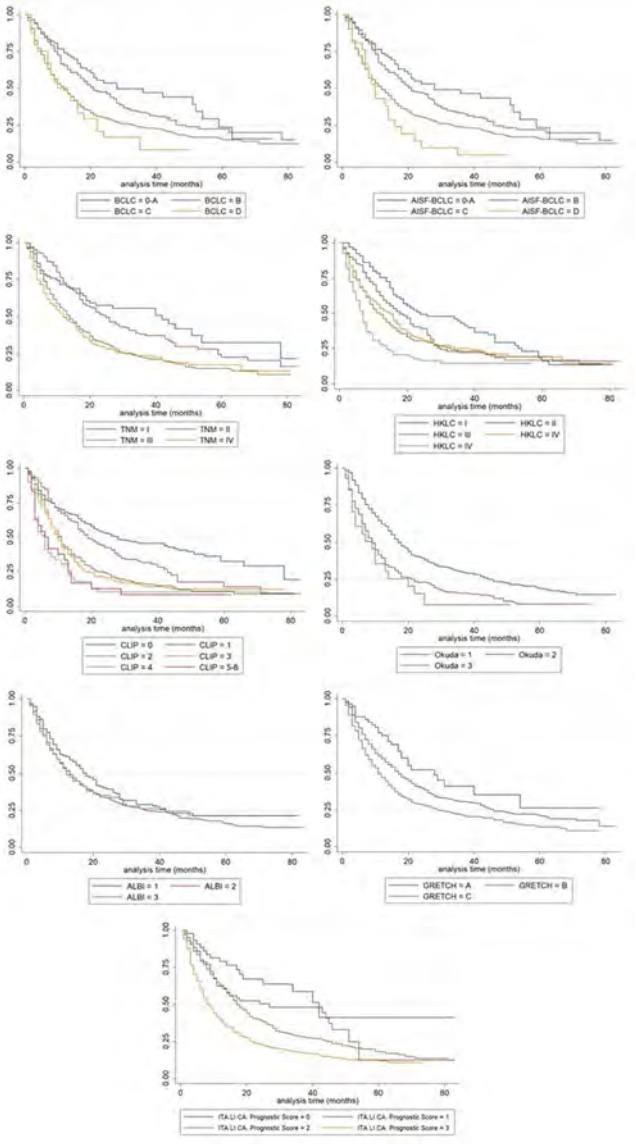
THU478

Comparison of prognostic models in predicting survival of patients with advanced hepatocellular carcinoma undergoing sorafenib treatment: a multicenter cohort study

Giovanni Marasco[1], Antonio Colecchia[2], Maria Letizia Bacchi Reggiani[1], Elton Dajti[1], Federico Ravaioli[1], Francesca Avanzato[1], Franco Trevisani[1], Davide Festi[1]. [1]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy;* [2]*Borgo Trento Hospital, Gastroenterology Unit, Verona, Italy*
Email: giovannimarasco89@gmail.com

Background and Aims: Currently Sorafenib treatment is the gold standard therapy for patients with advanced hepatocellular carcinoma (HCC). To date, no widely validated scores are available to predict the overall survival of these patients. Thus, the aim of our study is to evaluate the accuracy of the current available prognostic scores for HCC to predict the overall survival of patients with advanced HCC treated with Sorafenib.
Method: We included all patients undergone Sorafenib treatment belonged to the prospective multicenter cohort of the Italian Liver Cancer (ITA.LI.CA.) database. We selected clinical data from the visit before treatment administration. Patients lost at follow-up were excluded. We assessed the performance of several prognostic scores [Barcelona Clinic Liver Cancer- BCLC, Italian Liver Association (AISF)-BCLC, TNM, Hong-Kong Liver Cancer- HKLC, Italian Liver Cancer score- CLIP, ITA.LI.CA. Prognostic score, Okuda score, Albumin-Bilirubin (ALBI) score, GRETCH score] through a univariate Cox regression model evaluating the C-index (Harrell's C) and the Akaike Information Criterion (AIC) of each prognostic score. A high C-index and a low AIC were indicator of good accuracy of the score.

Results: One-thousand and one-hundred and twenty-nine (1129) patients were included. The mean age of the patients was 61.6 years. A total of 80.8% of the patients enrolled were male. Seven-hundred and eighty-nine patients died during a median follow-up period of 15 months. The median period of Sorafenib administration was 4 months. During the follow-up 63.1% of the patients experienced a HCC progression. All the prognostic scores were able to independently predict the overall survival ($p < 0.001$) at univariate analysis, except for ALBI score ($p = 0.152$). The CLIP score yielded the higher accuracy (C-index: 0.608, AIC: 6565) followed by the ITA.LI.CA. prognostic score (C-index:0.594, AIC:8569) and the Okuda score (C-index 0.579, AIC 7257) among the scores evaluated.



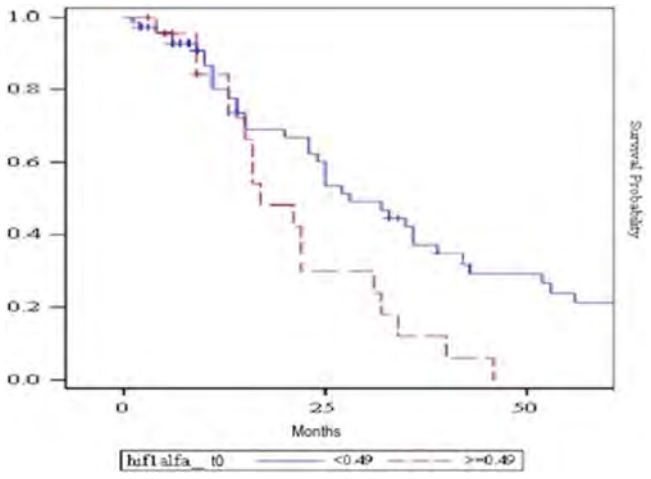
Conclusion: The overall survival of patients included in ITA.LI.CA. database undergoing Sorafenib treatment is slightly higher than that reported in the current literature. To date, the CLIP score and the ITA.LI.CA. Prognostic score showed the highest accuracy in predicting the overall survival of these patients, although it remains poor. Further studies are needed to investigate the prognostic role of other clinical variables.

THU479

Prognostic and diagnostic role of angiogenesis biomarkers in hepatocellular carcinoma treated with chemoembolization

Giulia Peserico[1], Elisa Pinto[1], Anna Sartori[1], Angela Imondi[1], Filippo Pelizzaro[1], Barbara Penzo[1], Umberto Cillo[2], Alessandro Vitale[2], Franco Trevisani[3], Fabio Farinati[1]. [1]*University of Padova, Department of Surgical, Oncological and Gastroenterological Sciences, Gastroenterology Unit, Padova, Italy;* [2]*University of Padova, Department of Surgical, Oncological and Gastroenterological Sciences, Hepatobiliary Surgery and Liver Transplant Unit, Padova, Italy;* [3]*Alma Mater Studiorum-University of Bologna, Department of Medical and Surgical Sciences, Semeiotica Medica Unit, Bologna, Italy*
Email: giulia88.fish@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the most common primary liver cancer, a tumor characterized by almost equal incidence and mortality, due to late diagnosis, insufficient and inadequate availability of therapies and with complex mechanisms of development and progression. Neo-angiogenesis plays an important role in HCC, to such an extent that it is considered as a possible therapy-target. We aimed to analyze the prognostic role of circulating VEGF-A and HIF-1α in patients treated by chemoembolization (TACE), the most used treatment for HCC whose mechanism of activity is, at least in part, based on its ischemia-inducing activity.
Method: We selected 163 consecutive patients classified as BCLC A/B treated by TACE and measured the two angiogenesis biomarkers concentration in sera and plasma from blood samples by ELISA tests before chemoembolization (t0) and after 4 weeks (t1) from the treatment. At t1 the patients' response to the treatment was assessed by CT scanning and mRECIST criteria. Statistics was applied as appropriate.
Results: Significant correlations between VEGF-A and the key tumoral and clinical features were documented [BCLC ($p = 0.009$), number of lesions ($p = 0.0001$) and complications ($p < 0.0001$)]. VEGF-A levels predicted treatment response by mRECIST criteria ($p = 0.014$). Patients with progressive disease (mRECIST PD) had significantly higher VEGF levels at t0 than those with complete response or disease control (mRECIST complete or partial response CR, PR, or stable disease, SD). On the other hand, HIF-1α t0 was significantly correlated only with lesions size ($p = 0.04$) and complications ($p = 0.002$). Finally, we analyzed the prognostic role of the two angiogenenesis biomarkers with a cut-off chosen on the basis of ROC curves. We found a statistically significant correlation ($p- = 0.01$) between HIF-1α t0 and survival, with a cut-off of 0.49 ng/mL. At Cox multivariate regression analysis, HIF-1α was confirmed as independent predictor of survival, together with Child-Pugh (p-value < 0.0001), etiology (p-value = 0.0028), lesion size (p-value = 0.004) and mRECIST (p-value = 0.0016).



Conclusion: Our findings suggest the potential use of VEGF-A and HIF-1α as additional prognostic criteria, possibly to be included in new staging systems, and support the everlasting search of molecules targeting angiogenesis to be used in the adjuvant or neo-adjuvant setting in HCC patients treated by TACE, an ischemia-inducing treatment.

THU480

Risk of hepatocellular carcinoma in hepatitis D co-infected patients compared to hepatitis B mono-infected patients: a systematic review and meta-analysis

Habiba Kamal[1], Fornes Romina[2], Simin Johanna[2], Nele Brusselaers[2], Soo Aleman[1]. [1]*Karolinska Universitetssjukhuset Huddinge, Infectious Diseases, Sweden;* [2]*Karolinska Institute, Centre for Translational Microbiome Research (CTMR), Department of Microbiology, Tumor and Cell Biology (MTC), stockholm, Sweden*
Email: habiba.khodir@ki.se

Background and Aims: Hepatitis D virus (HDV) infection is considered to cause the most severe viral hepatitis, with accelerated risks for cirrhosis and liver decompensation. However, whether it causes higher risk for hepatocellular carcinoma (HCC) is debated. We aimed therefore to evaluate the risk for HCC in patients with hepatitis B virus (HBV)/HDV co-infection compared to those with HBV mono-infection in a systematic review and meta-analysis.
Method: Ovid MEDLINE, PubMed, Embase and the Cochrane Library were systematically searched for studies reporting data on HCC risk among HBV/HDV co- infected patients and comparison group of HBV mono-infected patients, from inception until August 2019. Additionally, a comprehensive manual search was conducted. Only cohort studies with more than 20 patients in each group with minimum follow-up of 6 months were included. Two investigators independently extracted data, and data analysis was performed separately. Odds ratios were calculated and pooled together in a random-effects meta-analysis, generating pooled risk estimates with 95% confidence intervals (CI). Heterogeneity was assessed with I^2 and Q-test. Egger's test was used to assess publication bias and small-study effect.
Results: Of 3035 articles, 10 observational studies met inclusion criteria. Studies included 911 HBV/HDV co-infected patients with anti-HDV positivity and 14,694 with chronic HBV mono-infection. Overall, 11.96% (95% CI 10.01%–14.23%) of HBV/HDV co-infected patients developed HCC, whilst 3.41% (95% CI: 3.13%–3.72%) of HBV mono-infected developed HCC. The pooled analysis revealed an increased risk of HCC among patients with HBV/HDV co-infection (Effect size [ES] = 2.62, 95% CI 1.55–4.44, I^2 34.6%, P = 0.003). The association remained when excluding a study with high bias according to funnel plot visualization (ES = 2.76, 95% CI 1.77–4.30, I^2 29.5%, P < 0.001).

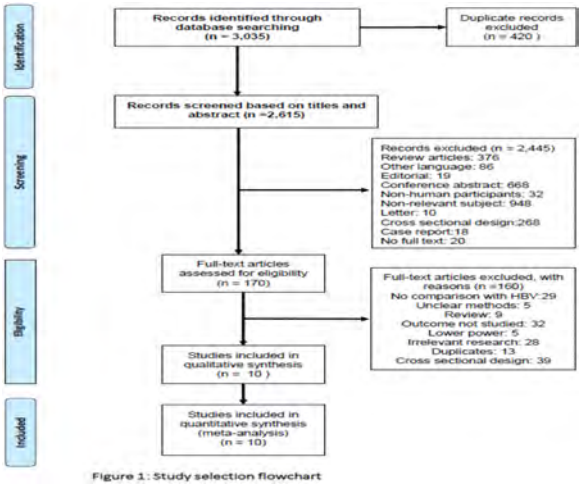


Figure 1: Study selection flowchart

Conclusion: These results suggest that HDV co-infection is associated with a 2.6 fold higher risk to develop HCC than HBV mono-infection, implying for a possible carcinogenic role of HDV. Better treatment options than currently available ones are needed, in order to cure HDV infection and minimize this risk.

THU481

The combination of EpCAM-positive circulating tumor cells and serum AFP/AFP-L3/DCP predicts outcome after curative resection of hepatocellular carcinoma

Johann von Felden[1], Martin Schoenlein[1], Berit Behrends[1], Christian Casar[1], Thorben Fruendt[1], Carolin Jung[1], Jenny Krause[1], Harald Ittrich[1], Munif Haddad[1], Thomas Renne[1], Asmus Heumann[1], Jun Li[1], Lutz Fischer[1], Ansgar Lohse[1], Klaus Pantel[1], Sabine Riethdorf[1], Henning Wege[1], Kornelius Schulze[1]. [1]*University Medical Center Hamburg Eppendorf*
Email: j.von-felden@uke.de

Background and Aims: Early hepatocellular carcinoma (HCC) has a limited prognosis due to recurrence rates of more than 50% after liver resection. As reported earlier, EpCAM-positive circulating tumor cells (CTC) have a high predictive value for presence of micro-metastases and early HCC recurrence after resection, however, sensitivity remains low (22%) (von Felden, Schulze et al., Oncotarget 2017). The serum biomarker-triplet alpha-fetoprotein (AFP), lectin-reactive AFP (AFP-L3), and des-gamma-carboxy prothrombin (DCP) are well-known diagnostic and prognostic markers for HCC. The objective of this study was to evaluate a composite panel of CTC and the biomarker-triplet to identify patients with high risk of early recurrence after liver resection.
Method: We prospectively enrolled patients undergoing curative intended resection for HCC at a single institution between 2011 and 2015. Blood specimens were obtained prior to resection and processed with the CellSearchTM system, detecting EpCAM-positive CTC, and serum levels of AFP, AFP-L3, and DCP were measured with the µTASWako™ system. The primary endpoints were early recurrence within two years after resection, recurrence-free survival (RFS), and overall survival (OS).
Results: A total of 66 patients were prospectively enrolled (86% male, age 66 years, 84% early disease with one or two nodules). A positive test was defined as detection of CTC or any serum marker AFP, AFP-L3, or DCP above the local thresholds, and significantly associated with shorter RFS (7 vs. 20 month, p = 0.011) and OS (21 vs. not reached, p = 0.036). Multivariate regression analysis for early recurrence including the composite biomarkers, vascular invasion (V0 vs. V1/2), and status of resection margins (R0 vs. R1/2), revealed hazard ratios of 2.12 (95% confidence interval [95%-CI] 0.9–5.0, p = 0.084), 2.01 (95%-CI 0.92–4.4, p = 0.081), and 0.95 (95%-CI 0.3–3.0, p = 0.925), respectively. The sensitivity for the composite biomarkers to detect patients who will develop an early recurrence after surgery was 73%.
Conclusion: An easy to use blood-based composite test for detection of EpCAM-positive CTC and biomarkers AFP, AFP-L3, and DCP improved the sensitivity for the prediction of early recurrence, likely due to the presence of micro-metastasis at time of resection, and was able to discriminate outcome following curative-intended liver resection. Thus, the combination potentially identifies patients with more aggressive tumors who might benefit from adjuvant treatment.

THU482

Intratumoral EpCAM-positive cancer stem cell heterogeneity in patients with hepatocellular carcinoma and its impact on clinical outcome

Jenny Krause[1], Johann von Felden[1], Christian Casar[1,2], Thorben Fruendt[1], Johanna Galaski[1], Caroline Jung[3], Harald Ittrich[3], Sören Alexander Weidemann[4], Till Krech[4], Asmus Heumann[5], Jun Li[5], L Fischer[6], Ansgar W. Lohse[1], Henning Wege[1], Kornelius Schulze[1]. [1]*University Medical Center Hamburg-Eppendorf, Department of Internal Medicine 1, Hamburg;* [2]*University Medical Center Hamburg-Eppendorf,*

Bioinformatics Core, Hamburg, Germany; [3]University Medical Center Hamburg-Eppendorf, Department of Diagnostic and Interventional Radiology and Nuclear Medicine, Hamburg, Germany; [4]University Medical Center Hamburg-Eppendorf, Institute of Pathology, Hamburg, Germany; [5]University Medical Center Hamburg-Eppendorf, Department of Surgery, Hamburg, Germany; [6]University Medical Center Hamburg-Eppendorf, Department for Hepatobiliary Surgery and Transplant Surgery, Hamburg, Germany
Email: je.krause@uke.de

Background and Aims: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death. The genomic and histopathological heterogeneity among and within HCC tumours is of increasing interest. Dismal prognosis is often linked to invasiveness and metastatic potential of HCC harbouring cancer stem cell (CSC)-features (e.g. EpCAM-expression). However, knowledge on intratumoral EpCAM-expression and its impact on recurrence after curative-intended resection remains limited. This study aimed to investigate the spatial heterogeneity of EpCAM-expression within early HCC, and to identify its potential impact for the risk stratification of recurrence.
Method: We screened our biobank for suitable tissue from patients undergoing liver resection or transplantation between 2011 and 2017 to design a tissue microarray (TMA). Tumour specimens for TMA construction were sampled at multiple locations (n = 3–8). EpCAM-positivity was assessed for intensity and proportion to derive a score dividing three groups: EpCAM-negative (E−/−), heterogeneous-positive (E−/+), homogeneous-positive (E+/+). EpCAM score was correlated with the major clinical primary endpoints time to recurrence (TTR) and recurrence free survival (RFS).
Results: Overall we included 341 tumour spots from 75 patients (77% male, median age 66 years, liver cirrhosis 40.3%, liver fibrosis 34.3%). Aetiology consisted of alcoholic liver disease in 24.1%, NASH 16.5%, HBV 14.3%, HCV 17.6% and others 27.5%, representing a typical Western cohort. EpCAM score resulted in 32 E−/−, 36 E−/+, and 7 E+/+. E+/+ patients experienced significantly shorter TTR and RFS compared to E−/− and E−/+ patients (TTR 5 vs. 19 vs. 19 months, p = 0.03; RFS 5 vs. 14 vs. 15 months, p = 0.028, respectively). Interestingly, homogeneous EpCAM-positivity correlated with AFP levels >400 ng/ml, p = 0.034. A single spot had a positive predictive value for homogenous EpCAM-positivity of 45.7%, a negative predictive value of 100%, a specificity of 87.4% and a sensitivity of 100%.
Conclusion: Intratumoral EpCAM-expression has a high spatial heterogeneity. Only homogeneous positivity is significantly correlated with worse outcome, identifying patients in urgent need for adjuvant treatment. Additionally, our study demonstrates the importance of multiple sampling, which should be considered to identify patients for targeted treatment.

Email: john.connell@perspectum.com

Background and Aims: The future liver performance (FLP) of an individual undergoing surgical liver resection to remove cancer is critical for their survival and recovery. We report the development and clinical testing of a novel magnetic resonance image (MRI) post-processing tool that combines quantitative multiparametric MRI with anatomical liver segmentation to estimate FLP. This is intended to inform the assessment of individualised operative risk and augment patient and surgeon decision making prior to liver resection.
Method: This software combines iron-corrected T1 (cT1) mapping, previously demonstrated to correlate with fibroinflammation and predict clinical outcomes in chronic liver disease, with a 3D U-net pipeline to automatically delineate the liver volume prior to defining Couinaud segments based on anatomical landmarks. Interactive removal of these segments, along with any interactively-defined virtual wedge resections, allows accurate estimation of the future liver remnant (FLR) volume, which when combined with quantitative cT1 mapping, provides a prediction of FLP, termed the "HepaT1ca score." The ability of this score to predict post-operative morbidity, length of stay and regenerative capacity was evaluated in a prospective clinical trial (ClinicalTrials.gov NCT03213314).
Results: Of the 143 patients recruited, 135 underwent liver resection. 84% of participants had liver metastases from colorectal cancer, with the remaining having primary liver cancer or other secondary cancers. 21% of participants had cT1 values above the upper limit of normal (795 ms) indicating increased risk of background liver disease. The HepaT1ca score showed a significant linear correlation with the modified Hyder-Pawlik score, an indicator of post-operative morbidity (adjusted $R^2 = 0.26$, $P < 0.001$), and liver regenerative performance (adjusted $R^2 = 0.46$, $P < 0.001$). Furthermore, in patients with an FLR below 90%, a high mean cT1 (>795 ms) was associated with a longer duration of hospital stay (median (IQR) of 6.5 (5.3–12) vs. 5 (4–7.1); P = 0.0053). cT1 also correlated with histological measures of inflammation and ballooning.

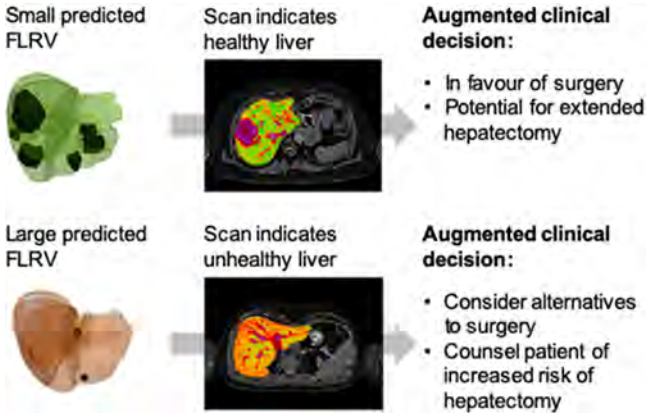

Figure: Concept diagram showing use of quantitative MRI in a clinical workflow highlighting exemplar case from the HepaT1ca study.

Conclusion: We demonstrate the utility of a non-invasive quantitative MRI approach for predicting post-operative liver performance. This has the potential to transform surgical decision-making and augment individualised risk assessment for patients undergoing liver resection for cancer.

THU484

Care pathway for patients with hepatocellular carcinoma in France in 2017: management overview, description of nurse coordinators' role and its impact

Background and Aims: Nurse coordinators (NC) were implemented in several French units to manage care pathways of patients with hepatocellular carcinoma (HCC). Their missions, not clearly defined, may vary according to the hospital they work in. The aims of the study were to describe: 1) HCC management overview in France in 2017; 2) NC's role and impact on patients' management.
Method: A questionnaire-based survey collected online declarative data from 72 French units' physicians or NC between August and November 2018. It included a description of units' activity and NC's missions over 2017. We performed descriptive statistics and a bivariate correlation test according to NC's presence or not and delay in taking care of patients, length of stay (LOS) and diagnostic disclosure.
Results: Forty-two units (58%) replied, declaring a cumulative activity in 2017 of 9079 patients with HCC, including 4331 new cases (representing 40% of French annual incident cases).
More than 90% of these units performed hepatic surgery, percutaneous ablation, chemoembolization and systemic treatment. Conversely, radioembolization and liver transplantation were available only in 52% and 31% of units. Accessibility to clinical trials was proposed in 74% of them. Between 5 and 8 different specialists participated in multidisciplinary tumour board (MTB). NC actively participated in MTB in 24% of units. MTB occurred in less than 1 week and between 1 to 2 weeks in 25% and 58% of units, after the first contact with the patient.
For scheduled treatments, the expected LOS for chemoembolization, percutaneous ablation and radioembolization were 3.3, 2.2 and 3 days, respectively. Patients were hospitalised mostly in hepatology units (89%), less in digestive surgery (28%) or oncology (18%). Among these 42 units, 13 (31%), including 11 university hospitals, had 1 or 2 NC (10 and 3 units respectively). NC's main missions were providing information to patients (100%), monitoring side effects (85%), psychological support, intra and extra-hospital coordination (77%), organisation of treatments and monitoring (70%). NC's presence was associated in bivariate analysis with the number of patients treated per unit ($p < 0.1$). There was no difference in terms of delay in taking care or LOS in units. Conversely, there was a correlation between nurse's presence and a more comprehensive diagnosis disclosure according to the national cancer recommendations ($p < 0.05$).
Conclusion: Patients with HCC have a complex and heterogeneous care pathway. These declarative data show no difference in terms of delay in taking care or LOS in units with or without NC. However, their presence seems to be associated with a more comprehensive diagnostic disclosure. This pilot study is a first step to assess NC implication's impact on patients' management. A second study will analyse objective patients' cases data analysis.

THU485

Predicting survival after hepatocellular carcinoma resection using deep-learning on histological slides

Charlie Saillard[1], Benoit Schmauch[1], Oumeima Laifa[1], Matahi Moarii[1], Sylvain Toldo[1], Mikhail Zaslavskiy[1], Elodie Pronier[1], Alexis Laurent[2], Giuliana Amaddeo[2], Helene Regnault[2], Daniele Sommacale[2], Marianne Ziol[2], Jean-Michel Pawlotsky[2], Sebastien Mulé[2], Alain Luciani[2], Gilles Wainrib[1], Thomas Clozel[1], Pierre Courtiol[1], Julien Calderaro[2]. *[1]Owkin Lab; [2]Assistance Publique-Hôpitaux de Paris*
Email: charlie.saillard@owkin.com

Background and Aims: The development of computational pathology and artificial intelligence promises to improve and standardize histological analyses, and may facilitate the extraction of "hidden" morphological features of potential clinical relevance. In this study, we used two deep-learning algorithms based on digitized histological slides, to build models for predicting the survival of patients with hepatocellular carcinoma (HCC) treated by surgical resection.
Method: Two independent series of patients were investigated: a discovery set (Henri Mondor Hospital, number of patients = 194, total of 390 whole image digitized slides (WSI)) used to develop our algorithms with cross-validation and an independent validation set (TCGA, number of patients = 328, total of 342 WSI).
The WSI were first divided into small squares, called "tiles", and features were extracted from these tiles with a pretrained convolutional neural network during the preprocessing step. During model development, the tiles were fed into the networks architectures. The first deep-learning based algorithm (designated as "SCHMOWDER") uses an attention mechanism on tumoral areas annotated by a pathologist while the second does not require human expertise.
Results: In the discovery set, c-indexes for survival prediction of SCHMOWDER and CHOWDER reached 0.78 and 0.75, respectively. Both models outperformed a composite score incorporating all baseline clinical, biological and pathological variables associated with survival. The prognostic value of the models were further valdiated in the TCGA dataset (c-indexes of 0.70 and 0.68 for SCHMOWDER and CHOWDER, respectively). As observed in the discovery series, both models had a higher discrimatory power than a score combining all relevant baseline variables associated with survival. Finally, pathological review showed that the tumoral areas most predictive of poor survival were characterized by vascular spaces, the macrotrabecular architectural pattern and a lack of immune infiltration.
Conclusion: Our study shows that artificial intelligence-based models using digitized histological slides predict overall survival after hepatocellular carcinoma resection more accurately than classical clinical, biological and pathological features. The analysis of areas classified as "low-risk" and "high-risk" by our model provides insight into the biological features that underly tumor aggressiveness.

Deep learning for cost-effective accurate diagnosis of liver tumor based-on magnetic resonance imaging and clinical information: a retrospective study

Shihui Zhen[1], Ming Cheng[2], Yubo Tao[2], Sarun Juengpanich[1], Zhiyu Jiang[1], Hai Lin[2], Xiujun Cai[1]. *[1]Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, General Surgery Hangzhou 310000, Zhejiang Province, China, Hangzhou, China; [2]Zhejiang University, State Key Laboratory of CAD&CG, Hangzhou, China*
Email: k123jing@126.com

Background and Aims: Early-stage diagnosis and treatment can improve survivals of liver cancer patients. However, short of ideal cost-effective screening tools and high cost burden of contrast agents calls for a new diagnostic strategy, in which deep learning may play a significant role. We aimed to develop and verify deep-neural-network models for accurate diagnosis of liver tumors with cost-effectiveness by analyzing MR images and clinical information.
Method: We derived a primary cohort of 1210 patients with liver tumors from Hepatic Focal Lesions Database of Sir Run Run Shaw Hospital affiliated Zhejiang University with linked MRI and medical records (N = 31608 images). The diagnosis-classification models were developed using enhanced images, unenhanced images, text and laboratory test results to get seven-way classifiers, binary classifiers and three-way malignancy-classifiers (Model A-Model G). Models

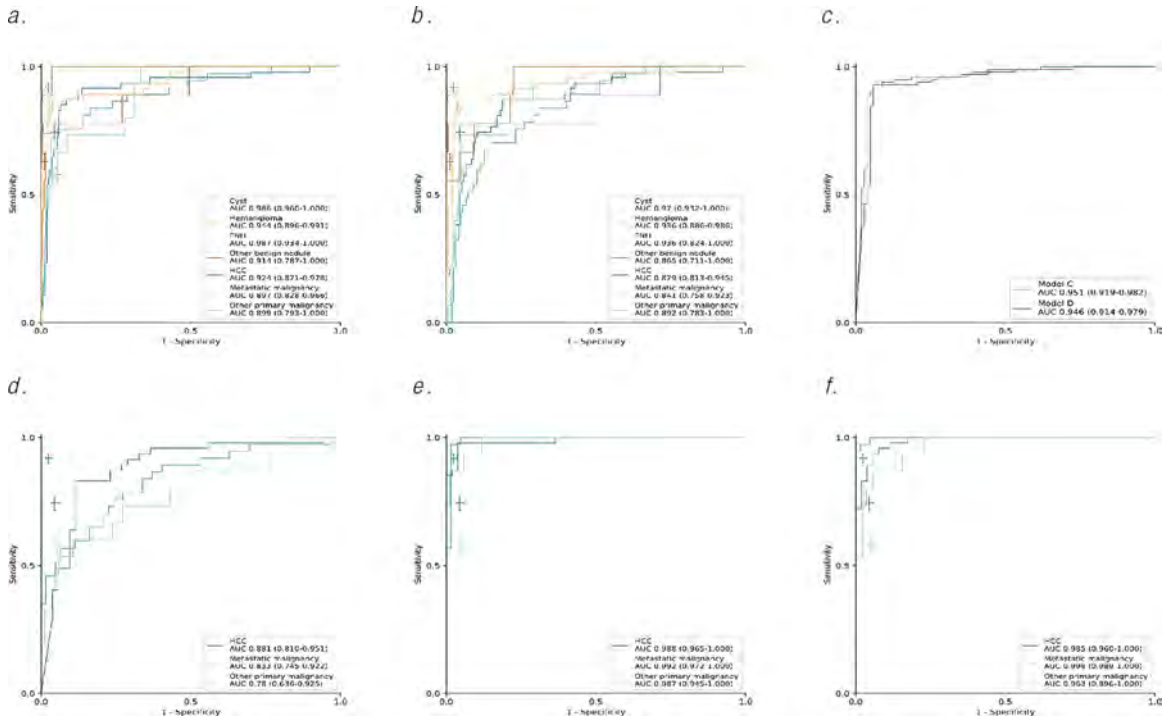

Figure: (abstract: THU486) **Performance of CNN models and radiologists in external validation set**. Receiver operating characteristic (ROC) curves for Model A-G. The crosses indicate the performance of average radiologists for each liver tumour category, the length of the cross represents the confidence Interval (CI).

were validated in an external independent extended cohort of 201 patients (N = 6816 images). Area under receiver operating characteristic (ROC) curve (AUC) were compared across different models. We also compared sensitivity and specificity compared with that of three experienced radiologists.

Results: Deep learning achieved competitive performance on par with experienced radiologists on seven-way classifier. Binary classifier using un-enhanced images achieved diagnostic performance similar to that using enhanced images (0.94 [95% CI 0·91–0·97] vs 0.95 [0.92–0.98], p = 0.66). New network combining unenhanced images with clinical data greatly improved the performance of classification for malignancy (AUCs of 0.98(0.96–1.00) for hepatocellular carcinoma, 0.99 (0.98–1.00) for metastatic tumors and 0.96 (0.89–1.00) for other primary malignancy). The agreement with pathology was 93.9%. These models mined diagnostic information in unenhanced images and clinical data by deep-neural-network, which were different with previous method that utilized enhanced images. The sensitivity and specificity of almost every category in these models reached the same high level compared to the consensus of experienced radiologists.

Conclusion: The current study is unprecedented in terms of disease diversity and diagnostic performance in absence of contrast agents. Models were trained with data in a various acquisition condition and new approach effectively integrated multimodal data. These are suitable for practical environment. It is potentially valuable and practical for non-invasive accurate diagnosis of liver tumors with cost-effectiveness.

THU488

The risk of hepatocellular carcinoma recurrence following resection or ablation is dependent on underlying etiology

Laura Telep[1], Chuhan Chung[1], Heribert Ramroth[1], Darren Huber[1], Pankaj Bhargava[1], Anuj Gaggar[1], Robert Myers[1], Anand Chokkalingam[1]. [1]*Gilead Sciences, Inc., Foster City, United States*
Email: laura.telep@gilead.com

Background and Aims: Recurrence of hepatocellular carcinoma (HCC) following resection or ablation is a major clinical problem. However, the influence of underlying etiology on rates of HCC recurrence is not well understood. We sought to characterize the risk of HCC recurrence based on known risk factors following potentially curative therapies.

Method: From a large commercial US administrative claims database, we identified adults with a diagnosis of HCC accompanied by a potentially curative procedure (resection or ablation, but not transplantation) and no evidence of treatment failure within the next 90 days. All patients had ≥ 1 year of continuous insurance enrollment prior to cohort entry during which time no curative procedures occurred. Major HCC risk factors were identified at cohort entry including hepatitis B (HBV) and C (HCV), metabolic liver disease (i.e. non-alcoholic fatty liver disease, non-alcoholic steatohepatitis, or metabolic syndrome), alcoholic liver disease (ALD), and cirrhosis/fibrosis. Patients were followed from end of curative procedure until the first of HCC recurrence, insurance enrolment end, or last date of data availability (March 2019). Absolute HCC recurrence rates per 100 person-years (PY) were calculated with exact 95% Poisson confidence intervals (CIs), and Cox regression was used to characterize risk of HCC recurrence according to etiology.

Results: Among 2,324 eligible patients, 108 had HBV, 276 had HCV, 560 had metabolic liver disease, 275 had ALD, and 640 had cirrhosis/fibrosis; 500 had more than one risk factor, and 1,149 had none. After a median follow up of 1.01 years (IQR: 0.46–2.36), absolute rates of HCC recurrence were highest among HCC patients with ALD, HCV, and cirrhosis/fibrosis. Among patients with HCV, 98% (270/276) had no evidence of DAA treatment at cohort entry. In multivariate analysis, significant independent risk factors for HCC recurrence included cirrhosis/fibrosis (hazard ratio [HR]: 1.35), ALD (HR 1.33), and HCV (HR 1.29). Metabolic liver disease and HBV were not associated with an increased risk of recurrence. Risks of recurrence were similar between antiviral-treated and untreated HBV patients (HR: 0.79 vs 0.78).

Table: Influence of Underlying Etiologies on HCC Recurrence Risk Following Resection or Ablation

Etiology	N Patients *	N Events*	Absolute Rate (95% CI)	Adjusted HR (95% CI)**	P-value
HBV	108	30	17.8 (12.0 – 25.5)	0.78 (0.54 – 1.13)	0.19
HCV	276	109	29.8 (24.5 – 36.0)	1.29 (1.04 – 1.60)	0.02
Alcoholic LVD	275	117	32.4 (26.8 – 38.9)	1.33 (1.08 – 1.64)	0.01
Metabolic Liver Disease	560	170	18.0 (15.4 – 20.9)	0.93 (0.78 – 1.10)	0.40
Cirrhosis/Fibrosis	640	258	26.4 (23.3 – 29.9)	1.35 (1.14 – 1.60)	<0.01

*Etiology categories are not mutually exclusive
** Mutually adjusted, including age group and sex

Figure: (abstract: THU488)

Conclusion: In this analysis of real-world data, HCC recurrence among patients treated with potentially curative procedures was common and differed by underlying HCC etiology. Cirrhosis, ALD, and untreated HCV infection were independently associated with increased recurrence risk. These results may have implications for surveillance of HCC recurrence in at-risk populations.

THU489

High subcutaneous tissue density correlates negatively with survival in patients with hepatocellular carcinoma

Pompilia Radu[1,2], Leona von Koeckritz[1], Marie Camille Roumet[3], Martin Maurer[4], Helen L. Reeves[5,6], Jean-François Dufour[1,2].
[1]University of Bern, Hepatology, Department of Clinical Research, Bern, Switzerland; [2]Inselspital Bern, University Clinic for Visceral Surgery and Medicine, Bern, Switzerland; [3]University of Bern, Clinical Trials Unit Bern, Department of Clinical Research, Bern, Switzerland; [4]Inselspital, University of Bern, Department of Radiology, Bern, Switzerland; [5]Newcastle University, The Northern Institute for Cancer Ressubvearch, Newcastle-upon-Tyne, United Kingdom; [6]Freeman Hospital, Newcastle-upon-Tyne Hospitals NHS Foundation Trust, The Liver Unit, Newcastle upon Tyne, United Kingdom
Email: jean-francois.dufour@dbmr.unibe.ch

Background and Aims: Prognostic stratification in patients with hepatocellular carcinoma (HCC) is based on parameters such as tumor burden, liver function and functional status of the patient. Body composition assessed by imaging techniques has been reported to contribute prognostic information in patients with various cancers. However, morphomics data in HCC is limited.
To assess the association between different body composition parameters measured on abdominal computed tomography (CT) scans and overall survival (OS) in two cohorts with newly diagnosed HCC in various stages.
Method: The area (cm^2) and density (Hounsfield Units) of skeletal muscle (SM), adipose tissue (subcutaneous (SAT), visceral (VAT) and intramuscular (IMAT)) were measured on CT scans at the level of the third lumbar vertebra in two cohorts of HCC patients (Bern, Switzerland n = 187 and Newcastle, United Kingdom n = 216). Univariate and multivariate Cox regressions analyses were used to assess the crude and adjusted association of body composition features with OS.
Results: In both cohorts, we found a significant variation of VAT density across Child Pugh classes and of SAT density among BCLC stages. Both body parameters tend to increase across Child Pugh classes and BCLC stages, respectively.
By univariate analysis, in both cohorts, only high SAT density (HR: 1.35; 1.12–1.62, p < 0.001 and 1.44; 1.27–1.63, p < 0.001, respectively) and high VAT density (HR: 1.38; 1.1–1.72, p = 0.005 and HR: 1.53; 1.3–1.81, p < 0.001, respectively) correlated negatively with survival. After model adjustment for potential baseline confounders (gender, age, diabetes, cirrhosis (yes/no), MELD score and BCLC stage) in a

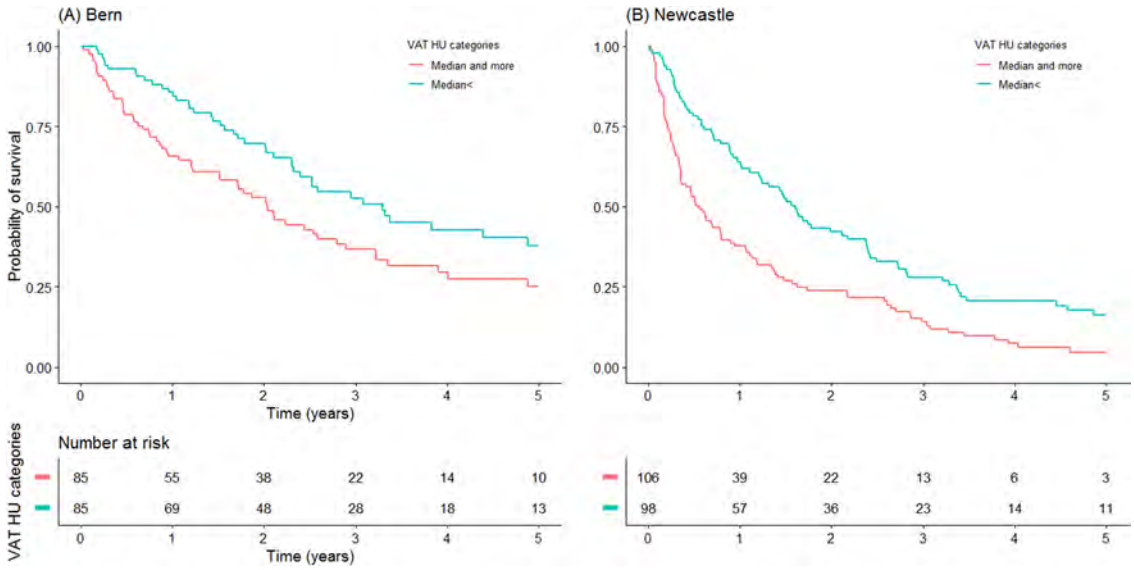

Figure 1: (abstract: THU489) Kaplan-Meier survival curves in groups of patients with low and high subcutaneous adipose tissue (SAT) density at the level of the third lumbar vertebra as determined by median - 97 HU for Bern cohort and -98 HU for Newcastle cohort. Log rank test in Bern, P = 0.042; in Newcastle, p = 0.003.

multivariate analysis, SAT density remained significantly associated with survival in both cohorts (Bern: HR: 1.27; 1.04–1.57, p = 0.022 and Newcastle: HR: 1.23; 1.03–1.48, p = 0.022) and VAT remained significantly associated with survival only in Bern cohort (HR: 1.31; 1.05–1.65, p = 0.019). Neither SM index nor SM density correlated with survival.
Conclusion: Based on two different HCC cohorts, our data show for the first time that a high SAT density assessed on CT scans correlates negatively with OS in HCC patients. Since HCC patients have CT scans for staging this new prognostic parameter can easily be obtained.

THU490
The protective role of urea-containing cream on sorafenib-associated hand-foot skin reaction in patients with hepatocellular carcinoma

Young-Sun Lee[1], Ji Hoon Kim[1], Young Kul Jung[1], Yeon Seok Seo[1], Hyung Joon Yim[1], Do Young Kim[2], Moon Young Kim[3], Ki Tae Yoon[4], Jeong-Hoon Lee[5], Hyun Woong Lee[6], Byoung Kuk Jang[7], Eun Sun Jang[8], Jae Young Jang[9], Sung Bum Cho[10], Sang Youn Hwang[11].

Email: kjhhepar@naver.com

Background and Aims: Sorafenib has recommended as first line treatment in patients with advanced hepatocellular carcinoma (HCC) patients. Although sorafenib increase overall survival in patients with HCC, it has many side effects such as fatigue, diarrhea, vomitting, nausea, pruritus, depilation, Hand-Foot Skin Reaction (HFSR). Among them, HFRS is the most common side effect and it is main reason for dose de-escalation or discontinuation of sorafenib in patients with HCC. In this study, we aimed that investigate the role of urea cream in preventing the occurrence of HFRS or ameliorating severity of HFRS.
Method: Total 288 patients with HCC at 13 hospitals in Korea were randomly assigned from May 2016 to May 2018. Patients were treated with placebo cream and urea cream at the same time as starting the treatment of sorafenib. Patients were followed up for up to 12 weeks. HFSR, score for Hand-Foot Skin Reaction and Quality of Life (HF-QoL) questionnaire, and adverse event were assessed at 2, 4, 8, and 12 weeks.
Results: After exclusion of 41 patients, 247 patients with 117 patients in placebo control group and 130 patients in urea cream group were analyzed. Urea cream group showed lower cumulative incidence of any grade of HFRS (Log-rank, p = 0.247) and severe HFRS of 2 or more grade Log-rank, p = 0.394) without statistical significance. In the incidence by time point, development of severe HFRS of 2 or more grade were significant lower in urea cream group compared to placebo control group (13.8% vs. 23.9%, p = 0.042). Urea cream group showed significant improved score of HF-QoL questionnaire comparing with placebo control group (11.8 vs. 19.7, p = 0.014) at 12 weeks. There was no significant difference for overall survival (Log-rank, p = 0.748) between two groups. Tumor response were also not significantly different between two groups, which objective response rate was 6.2% in placebo control group and 6.0% in urea cream group (p = 0.957), and disease control rate was 44.3% in placebo control group and 42.0% in urea cream group (p = 0.741).

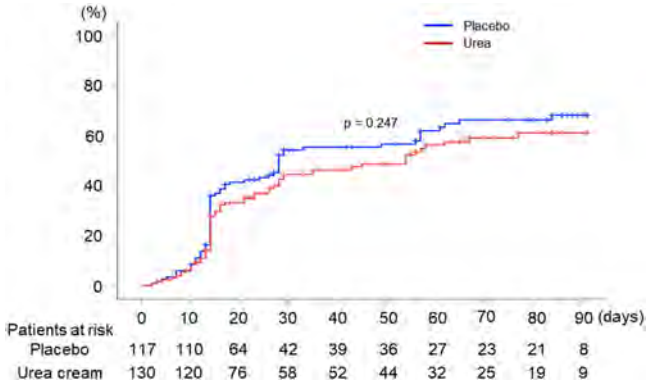

Figure: Cumulative incidence of any grade hand-foot skin reaction.

Conclusion: Treatment of urea cream showed decreased incidence of severe sorafenib-induced HFRS at 2 weeks and decreased tendency of development of HFRS in patients with HCC. Therefore, treatment of urea cream might be considered in patient that treated with sorafenib for HCC.

THU491
Applicability of the "six and twelve model" in patients with hepatocellular carcinoma treated with DEB-TACE

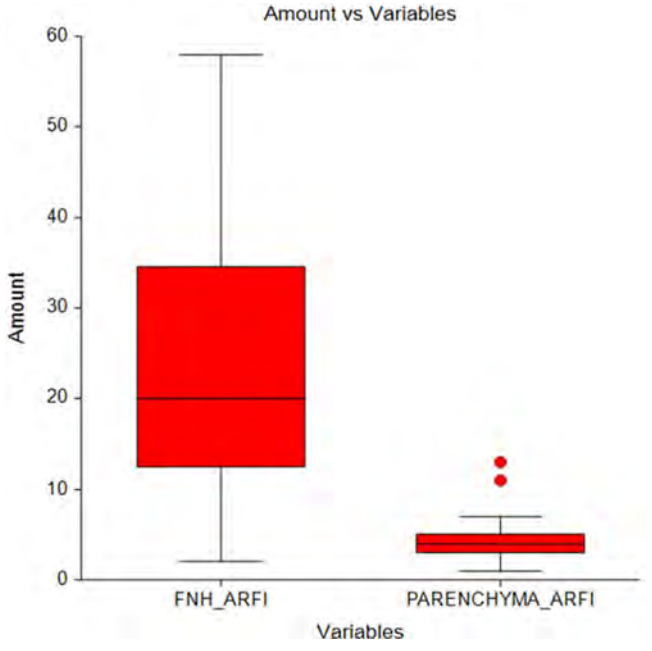
Maria Pipa Muñiz[1], Andrés Castano-Garcia[2], Maria Luisa Gonzalez Dieguez[2], Carmen Álvarez-Navascués[2], Valle Cadahía-Rodrigo[2], Susana Sanmartino[3], Alicia Mesa[4], Manuel Rodríguez[2,5], Maria Varela[2,6]. *[1]Hospital de Cabueñes, Gastroenterology and Hepatology Department, Gijón, Spain; [2]Hospital Universitario Central de Asturias, Liver Unit, Oviedo, Spain; [3]Hospital Universitario Central de Asturias, Interventional Radiology, Oviedo, Spain; [4]Hospital Universitario Central de Asturias, Radiology, Oviedo, Spain; [5]Universidad de Oviedo, Medicine, Oviedo, Spain; [6]IUOPA, Oviedo, Spain*
Email: maria.varela.calvo@gmail.com

Background and Aims: The effectiveness of transarterial chemoembolization (TACE) in hepatocellular carcinoma (HCC) depends on the selection of suitable patients. The "Six-and-Twelve" model [Wang Q et al, J Hepatol. 2019; 70(5): 893–903] has been developed and validated in an Asian cohort of ideal TACE candidates, and it distinguishes three groups with different overall survival (group 1, <6 points; group 2, 6–12; group 3, >12). This stratification based on the sum of number and size of tumors may impact in clinical practice and trials design. The score has been recently validated in a multicentric French cohort of patients treated with conventional TACE (n = 127) [Bourlière M et al. J Hepatol. 2019;71(5):1051–1052]. The aim of this study is to evaluate de usefulness of the "Six-and-Twelve" model in a cohort of HCC patients treated with DEB-TACE.
Method: observational retrospective study with consecutive HCC patients treated with DEB-TACE from October/2008 to October/2017; end of follow-up October 24th 2019. Exclusion criteria were Child-Pugh not available or ≥8, patients awaiting liver transplantation.
Results: 225 patients made up the study cohort: 187 men; 107 alcohol etiology, 70 HCV; Child A-5 n = 165, A-6 n = 43, B-7 n = 17; BCLC-0 n = 10, BCLC-A n = 102, BCLC-B n = 113. Median diameter of main nodule: 3.5 cm (IQR 2.5–4.8); median number of nodules 2 (IQR 1–3). Median overall survival (OS) was 27 months (95% CI 24.042–29.958), without differences in OS (25 months, 95% IC 20.734–29.266 vs 27 months, IC 95% 23.458–30.542, p = 0.586, respectively) between those with / without prior history of cirrhosis decompensation 34% (n = 77) and 66% (n = 148), respectively. OS was different between BCLC-0-A vs B: 32 vs 24 months, p = 0.004, and in Child-Pugh A5 compared to A6-B7: 30 vs 27 months, p = 0.005. The median value of

the "Six-and-Twelve" score was 6 (P_{25}-P_{75} 4.5–7.4). OS was different by stratifying through "Six-and-Twelve" model: group 1, n = 123, 32 months (95% CI 25.893–36.107) vs group 2, n = 101, 24 months (95% CI 19.576–28.424) vs group 3, n = 1, 27 months (p = 0.048).
Conclusion: The "Six-and-Twelve" model is a useful prognostic tool in patients with cirrhosis and HCC treated with DEB-TACE. As well as in the French cohort only few patients are included in the third group (score >12), therefore, the applicability of this model in our region is limited.

THU492
Application of acoustic radiation force impulse elastography in non-invasive diagnosis of focal nodular hyperplasia
Mariana Forlino[1], Irene Spinelli[1], Elio Pietro Perrone[1], Martina Carbone[1], Daniela Maggi[1], Emanuele La Gaetana[1], Ignazio Gerardi[1], Adriano De Santis[1]. [1]*Rome – Umberto 1 Policlinico, Clinical and Translational Medicine, Rome, Italy*
Email: mariana.forlino@gmail.com

Background and Aims: Focal nodular hyperplasia (FNH) is a benign pseudotumoral lesion of the liver, result of a hyperplastic process due to limited alterations of the arterial vasculature. Its identification is usually incidental, but diagnosis is not always easy and may require multiple tests including invasive ones, such as liver biopsy. In last years the role of elastometry is emerging also for studying focal liver lesions. In two pilot studies on stiffness by acoustic radiation force impulse (ARFI) of focal lesions (Park, 2013, WJG; Zhang, 2013, HPDI), some FNH were included (4 and 14 pts respectively) and showed a higher stiffness than the other benign lesions. Our study aims to confirm, within a larger sample of patients, the diagnostic hypothesis that FNH has a higher stiffness than surrounding liver parenchyma.
Method: From November 2011 to November 2019, 61 patients with FNH coming to our Center underwent upper abdomen ultrasound with ARFI (results in kPa). Examinations were performed with Sonoline Antares (Siemens) with probe PHA 2–4.1 MHz and convex 2.5–5 MHz, from the same operator.



Results: Our population is composed of 46 women (75.4%) and 15 men (24.6%). The average age at observation is 38.9 + 9.02 y. Two patients (3.2%) were affected by Budd Chiari Syndrome (BCS) and only one (1.6%) by HCV cirrhosis. Other pts were not affected by any liver disease. 48 pts (78.6%) presented a single FNH vs 13 pts (21.4%) multinodular. The average diameter of the lesions was 49.5 + 22.4 mm. The diagnosis of FNH was made in 37 cases (60.6%) by radiological contrast imaging (34 MRI, 3 CT scan), in 4 cases (6.5%) by biopsy and in 20 cases (32.7%) by ultrasound for typical features. Among the 20 pts with ultrasound diagnosis there were 16 (26%) in which CT and MRI failed diagnosis.
The medium stiffness of FNH was 23.1 + 13.4 kpa vs 3.9 + 2 kpa of liver parenchyma (p.0001, Figure).
We calculated a ratio between FNH stiffness value and hepatic stiffness (ARFI ratio) for each patient: the average value was 6.8 + 3.7. In 59 pts (96.7%) ratio was >1.5. The only two cases with a lower value were two pts with liver disease: one with BCS and the cirrhotic. In both cases diagnosis was made by liver biopsy.
Conclusion: within our study FNH was showing significantly higher values than liver parenchyma in 96.7%, with an ARFI FNH/parenchyma ratio >1.5. The introduction of elastometric measurement in routine ultrasound can facilitate the diagnostic process and excessively expensive or invasive methods can be avoided.

THU493
Diagnostic and prognostic roles of circulating miRNA-223-3p in hepatitis B virus-related hepatocellular carcinoma
Natthaya Chuaypen[1], Pornpitra Pratedrat[1], Nutcha Pinjaroen[2], Boonchoo Sirichindakul[3], Pisit Tangkijvanich[1]. [1]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, Bangkok;* [2]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, Department of Radiology, Bangkok;* [3]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, Department of Surgery, Bangkok*
Email: pisittkvn@yahoo.com

Background and Aims: Circulating microRNAs (miRNAs) have been shown to dysregulate in many cancer types including hepatocellular carcinoma (HCC). The purpose of this study was to examine the potential diagnostic or prognostic roles of circulating miRNAs in patients with hepatitis B virus (HBV)-related HCC.
Method: Paired cancerous and adjacent non-cancerous liver tissue specimens of patients with HBV-related HCC were used as a discovery set for screening 800 miRNAs by a Nanostring quantitative assay. Differentially expressed miRNAs were then examined by SYBR green quantitative RT-PCR in a validation cohort of serum samples obtained from 70 patients with HBV-related HCC, 70 HBV patients without HCC and 50 healthy controls.
Results: The discovery set identified miR-223-3p, miR-199a-5p and miR-451a significantly lower expressed in cancerous tissues compared with non-cancerous tissues. In the validated cohort, circulating miR-223-3p levels were significantly lower in the HCC group compared with the other groups. The combined use of serum alpha-fetoprotein and miR-223-3p displayed high sensitivity for detecting early HCC (85%) and intermediate/advanced stage HCC (100%). Additionally, serum miR-223-3p had a negative correlation with tumor size and BCLC stage. On multivariate analysis, serum miR-223-3p was identified as an independent prognostic factor of overall survival in patients with HCC. In contrast, circulating miRNA-199a-5p and miR-451a did not show any clinical benefit for the diagnosis and prognostic prediction of HCC.
Conclusion: Our results demonstrated that miR-223-3p was differentially expressed in cancerous compared with paired adjacent non-cancerous tissues. In addition, circulating miRNA-223-3p could represent a novel diagnostic and prognostic marker for patients with HBV-related HCC.

Email: nicola.personeni@humanitas.it

Background and Aims: Factors leading to immune-checkpoint inhibitors (ICI)-related hepatotoxicity in hepatocellular carcinoma (HCC) remain poorly understood. We sought to assess: (i) incidence and predictors of immuno-related hepatitis during ICI, (ii) relationship between hepatitis grade and time to treatment failure (TTF), (iii) clinical and morpho-pathological factors linked to hepatitis.
Method: 58 patients with advanced/unresectable HCC received anti-programmed cell death protein 1 (PD-1)/PD ligand 1 (PD-L1) antibodies. Hepatitis was categorized according to National Cancer Institute's Common Terminology Criteria for Adverse Events. Tumor necrosis, intratumoral tertiary lymphoid structures (TILs), expression of CD34, Glutamine Synthase (GS), CD3 and CD79 were evaluated on 27 pretreatment tumor biopsies and were fitted into an Immune or an Exclusion class.
Results: 20 patients received anti-PD-1/PD-L1 antibodies alone and 38 in combination with anti- cytotoxic T-lymphocyte-associated protein 4 antibodies and/or tyrosine kinase inhibitors. After a median time of 0.9 months, 9 (15.5%) developed grade ≥ 3 hepatitis, which was not associated to any etiologic nor clinical parameter, except baseline ALT levels (p = 0.037). Steroids were administered in 3 patients and ICI were safely resumed in 6 out of 9 patients. No significant differences in TTF were seen with grade ≥ 3 hepatitis vs lower grades (3.25 vs 3.91 months, respectively; p = 0.81). Immunoreactivity to GS, absence of TILs, and necrosis were more frequent in patients developing grade ≥ 3 hepatitis (p = NS; Table).

Table: HCC morpho-phenotypical features according to the severity of ICI-related hepatitis

Tumor features	Grade ≥ 3 Hepatitis (N = 7)	Grade 0–2 Hepatitis (N = 20)	p
GRADE ≥ 3	2 (28%)	7 (35%)	1
NECROSIS	3 (42%)	3 (15%)	0.290
TILs	0	3 (15%)	0.545
VETC	5 (71%)	13/19 (68%)	1
EXCLUSION CLASS	7 (100%)	16 (80%)	1
IMMUNE CLASS	0	4 (20%)	0.545
AFP >400 ng/ml	2/5 (40%)	3/15 (20%)	0.545

Conclusion: Holding ICI and sporadically using steroids allow to safely reintroduce treatment with no detrimental effect on TTF. Though no predictor could be identified, preliminary analyses suggest that some biomarkers could be linked with onset of high-grade hepatitis.

Email: coskun_demirtas10@hotmail.com

Background and Aims: Toronto Hepatocellular Carcinoma Risk Index (THRI) is developed to stratify cirrhotic patients according to 10-year Hepatocellular Carcinoma (HCC) risk. We aimed to validate the performance of THRI in a large Turkish cohort.
Method: We retrospectively reviewed the database of 1287 cirrhotic patients followed-up in a 10-year period (February 2008–January 2018). All patients were stratified into three groups based on the THRI score as follows; low-risk: <120, intermediate risk: 120–240 and high risk: >240. Area under the curve (AUC) and optimal cut-off value of THRI was obtained from receiver operator curve (ROC). To reveal the parameters related with HCC development, logistic regression analysis was conducted. The cumulative incidences of HCC were calculated using Kaplan-Meier method, and the curves were compared using the log-rank test.
Results: Out of 403 enrolled patients, 57 developed HCC. The median THRI value was higher in HCC (+) group comparing to HCC (–) group (267 (70–366) vs 224 (36–366), p < 0.001). Out of 57 detected HCCs, 45 (78.9%) were high risk, 11 (19.3%) were intermediate risk and only one (1.8%) was low risk at the entry. The AUC of the THRI to predict HCC was 0.750(%95 CI 0.683–0.817, p < 0.001). The optimal cut-off value of THRI was 239.5, giving a sensitivity of 78.9% and specificity of 62.7%. As a result, THRI remained to be the only significant parameter that has an affect on HCC development (adjusted-OR:1.016 (95%CI 1.007–1.024), p < 0.001).
Conclusion: The present study validated the performance of THRI in cirrhotic patients to predict HCC risk, which can be considered as a tool for personalized surveillance.

Figure: (abstract: THU495)

advanced hepatocellular carcinoma (HCC) following sorafenib. REACH-2 limited enrolment to pts with alpha-fetoprotein (AFP) ≥ 400 ng/mL, and met its primary overall survival (OS) endpoint, consistent with the prespecified REACH subgroup with baseline AFP ≥ 400 ng/mL. Analysis of pooled individual pt data from REACH (AFP ≥ 400 ng/mL) and REACH-2 showed improved OS with RAM versus (vs) PL for pts with hepatitis B virus (HBV) aetiology (7.7 vs 4.5 months [mos]; hazard ratio [HR] 0.74, 95% confidence interval [CI] 0.55, 0.99). Here we investigate survival and liver function in REACH-2 pts with HBV aetiology tested for serum HBV DNA.

Method: Pts had advanced HCC, Child-Pugh A, ECOG PS 0/1, AFP ≥ 400 ng/mL, prior sorafenib treatment, and were randomized (2:1) to receive RAM 8 mg/kg or PL Q2W. Pretreatment serum HBV DNA was quantified by HBV-specific PCR (Roche) by a central lab. HBV DNA >15 IU/mL was detectable (HBV DNA+), <15 IU/mL was undetectable (HBV DNA-). OS in pooled treatment arms was evaluated by Kaplan-Meier method and Cox proportional hazards model. Liver function was assessed at baseline and before each cycle with the ALBI linear predictor. Outcomes were assessed by concomitant antiviral therapy. Adverse events (AEs) were graded by NCI-CTCAE v4.0.

Results: Of 107 REACH-2 pts with HBV aetiology, 106 had available PCR samples and were included in a pooled analysis (70 RAM and 36 PL pts). 48 pts were HBV DNA+ and 58 pts were HBV DNA-. HBV DNA+ pts had poorer median OS vs HBV DNA- pts (5.3 vs 10.1 mos, unstratified HR 1.45, 95% CI 0.93, 2.28). HBV DNA+ pts taking concomitant antiviral therapy (n = 36) had numerically improved OS compared with those without (n = 12) (5.8 vs 4.0 mos). No difference in OS was noted for HBV DNA- pts by antiviral therapy use (n = 39 antiviral; n = 19 no antiviral) (10.2 vs 9.7 mos for yes vs no antiviral). In pts taking antiviral therapy, regardless of HBV DNA serology, liver function was improved and liver injury/failure related AEs were less frequent.

Conclusion: Our data reinforce the use of antiviral therapy to improve outcomes in pts with advanced HBV-associated HCC and elevated AFP.

THU497

AFP is elevated more than 10 years before hepatocellular carcinoma development is detected: this observation leads to a practical risk stratification strategy

Philip Johnson[1], Sarah Berhane[2], Emily de Groot[3], Hidenori Toyoda[4], Toshifumi Tada[4], Takashi Kumada[5], Shinji Satomura[6], Yukio Osaki[7], Masatoshi Kudo[8], Naoshi Nishida[8], Toru Kimura[9], Ruwanthi Kolamunnage-Dona[10], Thomas Bird[11], Ruben Amoros[12], Marta Garcia-Finana[10], David M Hughes[10]. *[1]University of Liverpool, Molecular and Clinical Cancer Medicine, Liverpool, United Kingdom; [2]University of Birmingham, Applied Health Research, Birmingham, United Kingdom; [3]St. Andrew's University, Economics, St. Andrews, United Kingdom; [4]Ogaki Municipal Hospital, Hepatology and Gastroenterology, Ogaki, Japan; [5]Gifu Kyoritsu University, Nursing, Ogaki, Japan; [6]Osaka University Graduate School of Medicine, Molecular Biochemistry & Clinical Investigation, Osaka, Japan; [7]Meiwa Hospital, Internal Medicine, Nishnomiya, Japan; [8]Kindai University, Gastroenterology and Hepatology, Osaka, Japan; [9]Osaka Red Cross Hospital, Gastroenterology and Hepatology, Osaka, Japan; [10]University of Liverpool, Biostatistics, Liverpool, United Kingdom; [11]The Queen's Medical Research Institute, MRC Centre for Inflammation Research, Edinburgh, United Kingdom; [12]University of Edinburgh, School of Mathematics, Edinburgh, United Kingdom*
Email: philip.johnson@liverpool.ac.uk

Background and Aims: Screening patients with chronic liver disease for HCC is supported by all clinical guidelines. We aimed to develop a practical risk -stratification tool which would permit optimal use of resources within screening programs.

Method: Longitudinal discriminant analysis was applied to serial AFP changes to develop a risk model for the development of HCC. Internal and external validations were conducted.

Results: We analysed 3450 prospectively accrued patients from a single centre ('the primary cohort') with chronic liver disease (median follow-up = 8.83 years). 413 developed HCC (median follow-up = 6.60 years), within a rigorous HCC surveillance program (median HCC diameter at diagnosis = 1.8 cm). The model achieved an AUC of 78.4% and was able to correctly identify 74.3% of patients who would go on to develop HCC, and 72.9% of patients who would not.

Overall, 73.1% of patients were correctly classified. The model identifies high and low-risk groups (27.5 and 4.9 HCCs/1000 patient-years respectively). Similar results were found when the model was confined to patients with cirrhosis and in validation cohorts from Eastern and Western populations (Fig.).

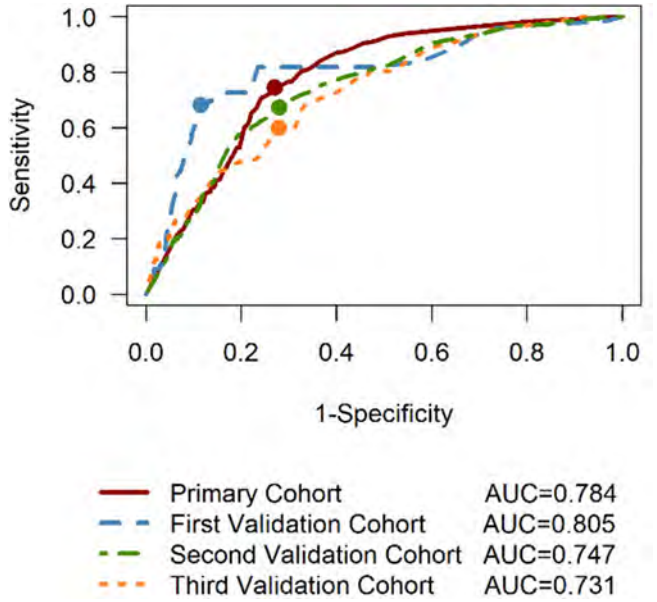

Figure: Receiver Operator Characteristic (ROC) curves for the primary and validation cohorts.

Conclusion: Our validated risk-stratification model assesses temporal changes in AFP and uses these to identify patients with chronic liver disease who are at high-risk of HCC development.

THU498

The prognostic and diagnostic significance of the neutrophil to lymphocyte ratio in hepatocellular carcinoma: a prospective controlled study

Philip Johnson[1], Sofi Dhanaraj[2], Yuk Ting Ma[3], Laura Bonnett[4], Sarah Berhane[5]. *[1]University of Liverpool, Molecular and Clinical Cancer Medicine, United Kingdom; [2]Queen Elizabeth Hospital, Liver Unit, Birmingham, United Kingdom; [3]University of Birmingham, Institute Immunology and Immunotherapy, Birmingham, United Kingdom; [4]University of Liverpool, Biostatistics, Liverpool, United Kingdom; [5]University of Birmingham, Applied Health Research, Birmingham, United Kingdom*
Email: philip.johnson@liverpool.ac.uk

Background and Aims: The neutrophil-lymphocyte ratio (NLR), a presumed measure of the balance between neutrophil-associated pro-tumor inflammation and lymphocyte-dependent anti-tumor immune function, has been suggested as a prognostic factor for patients with HCC. However, supporting studies have severe limitations including their retrospective nature, small numbers, lack of a relevant control group (chronic liver disease patients without HCC - CLD) and a rigorous statistical analysis that allows for potential confounding factors.
Method: A prospectively accrued cohort of 781 patients (493 HCC and 288 CLD) were followed up for more than 6 years. NLR levels between HCC and CLD patients were compared, and the effect of baseline NLR on overall survival amongst HCC patients was assessed via multivariable cox regression analysis.
Results: At baseline, there was no clinically significant difference in NLR between CLD and HCC patients. Amongst HCC patients, NLR levels closest to last visit/death were significantly higher compared to baseline. Multivariable cox regression analysis showed that NLR (along with AFP, bilirubin and BCLC stage) was an independent prognostic factor, even after adjustment for HCC stage.
Conclusion: In a prospectively accrued dataset, NLR was a significant independent factor influencing survival in HCC patients, hence offering an additional dimension in prognostic models.

THU499

Quantitative assessment of the impact of viral state on the rate of tumour progression in patients receiving sorafenib for advanced hepatocellular carcinoma

Philip Johnson[1], Sarah Berhane[2], Ruwanthi Kolamunnage-Dona[3]. *[1]University of Liverpool, Molecular and Clinical Cancer Medicine, Liverpool, United Kingdom; [2]University of Birmingham, Applied Health Research, Birmingham, United Kingdom; [3]University of Liverpool, Biostatistics, Liverpool, United Kingdom*
Email: philip.johnson@liverpool.ac.uk

Background and Aims: Although sorafenib remains the standard of care for patients with advanced hepatocellular carcinoma (aHCC), the tumour progression rate cannot be objectively assessed because of shorter survival amongst those who progress, so-called 'informative censoring'. We aimed to objectively quantify the rate of tumour progression and relate this figure to survival, both overall and in relation to viral status.
Method: Records from 502 patients receiving sorafenib for aHCC were analysed in a joint model that combines survival and change in tumour size, AFP and liver function over time. This permits an objective estimate of the rate of tumour burden growth and the impact of treatment on liver function in relation to viral status. The results were then tested for generalisability in a second analogous dataset of 588 patients.
Results: High tumour burden at baseline is associated with a significantly increased risk of death. The rate of increase in tumour burden was 12% (95% CI 10, 14) and the median doubling time (DT) was 665 days (95% CI 616, 735). The median survival amongst those who progressed was 237 days (95% CI 213, 281) compared to 449 days (95% CI 399-) among those who did not. The rate of tumour growth and serum AFP rise was significantly lower in HCV seropositive (as opposed to HBV or HCV negative patients) as was the rate of decline in liver function (Fig.). These results were replicated in the second dataset.

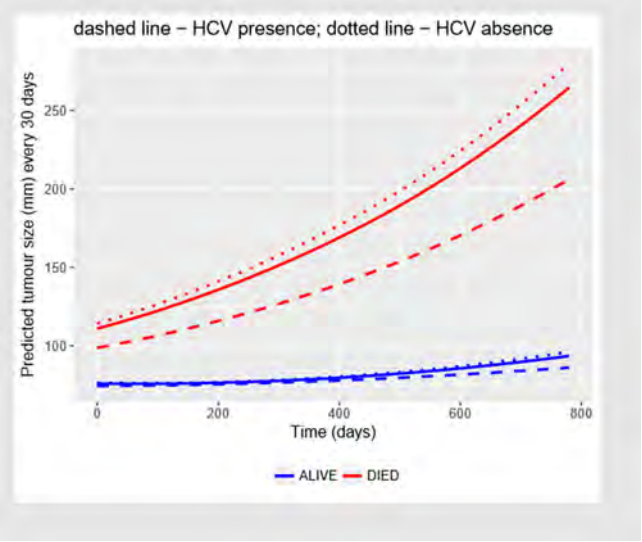

Figure: Change in tumour burden over time according to survival and viral status.

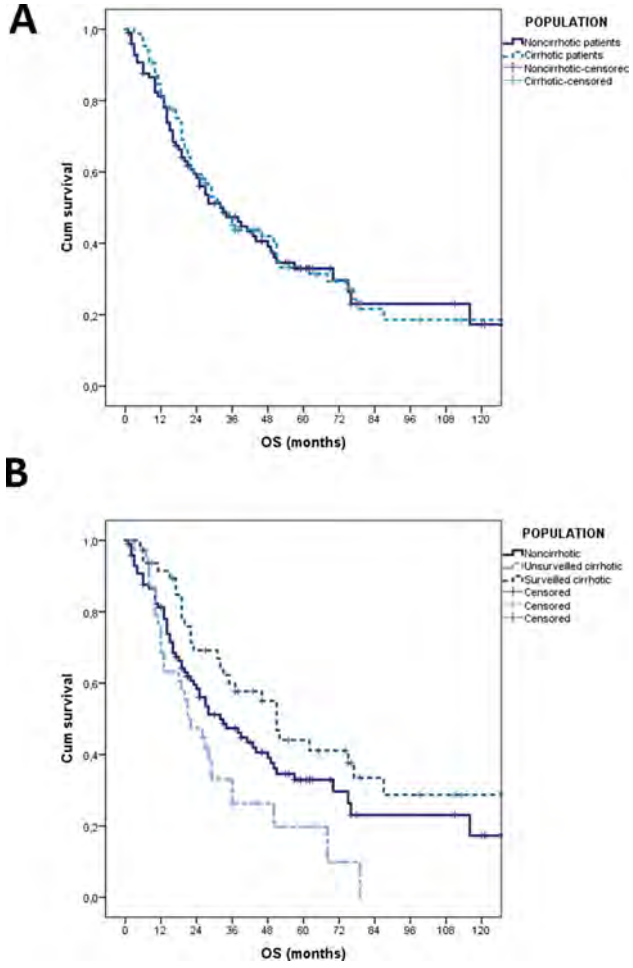
Conclusion: Our analysis suggests that sorafenib treatment benefits survival mainly by decreasing the tumour growth rate and improving liver function in patients with HCV.

THU500

Surveillance improves survival of intrahepatic cholangiocarcinoma arisen in liver cirrhosis

Francesco Tovoli[1], Pietro Guerra[1], Massimo Iavarone[2], Letizia Veronese[3], Matteo Renzulli[4], Stefania De Lorenzo[5], Giovanni Brandi[5], Federico Stefanini[1], Fabio Piscaglia[1]. *[1]University of Bologna, Department of Medical and Surgical Sciences, Italy; [2]University of Milan, Fondazione IRCCS Ca' Granda Maggiore Hospital, Milan, Italy, AM& A Migliavacca Center for Liver Disease, Division of Gastroenterology and Hepatology; [3]IRCCS – Policlinico San Matteo Foundation, Pavia, Italy, III Medical Clinic, Department of Internal Medicine; [4]Bologna Authority Hospital S.Orsola-Malpighi Bologna, Unit of Radiology, Italy; [5]University of Bologna, Unit of Oncology, Department of Medical and Surgical Sciences*
Email: francesco.tovoli2@unibo.it

Background and Aims: Due to its poor survival, intrahepatic cholangiocarcinoma (iCCA) is held to be a much more aggressive cancer than hepatocellular carcinoma (HCC), but in most series patients were diagnosed when symptomatic. However, iCCA is now increasingly being discovered during the surveillance for HCC in cirrhosis. Whether earlier detection of iCCA in cirrhosis is associated nonetheless with a dismal prognosis or not is unknown.
Method: Multicenter retrospective study of consecutively enrolled patients with histological diagnosis of iCCA. Patients were statified into subgroups according to the absence/presence of cirrhosis. A propensity score matching was performed to reduce the potential iases deriving form different baseline characteristic. Cirrhotic patients were further stratified according to their surveillance status. The lead-time bias was estimated and effects of the surveillance on the survival were adjusted accordingly.



Results: Data from 185 patients were gathered. Eighty-five patients (46.2%) were cirrhotic. Liver cirrhosis was not related to a worse overall survival (33.0 vs 32.0 months, p = 0.800) even after the propensity score analysis (36.0 vs 43.0 months, p = 0.227). Amongst the cirrhotic population,47 (55.3%) patients had received a diagnosis of iCCA during a surveillance program. The two subgroup differed in the tumour dimensions at the diagnosis (30 vs 48 mm in surveilled and nonsurveilled patients, respectively). As a result, surveilled patients were more likely to be treated surgically (59.8 vs 28.9%, p = 0.003). OS was significantly different between surveilled and nonsurveilled patients (median overall survival 51.0 vs 21.0 months, p < 0.001). The benefit of surveillance was confirmed after correction for the lead-time bias (adjusted hazard ratio 0.464–95% confidence interval 0.271–0.796).
Conclusion: Cirrhotic patients have a different clinical presentation and disease course of iCCA according to their surveillance status, significantly influencing the chance of receiving curative surgery and therefore of obtaining satisfactory long-term outcomes. The discrepant results of previous studies evaluating the prognostic role of cirrhosis might be at least partly justified by this aspect. In our series, cirrhosis (compensated in the majority of cases) was not associated with worse outcomes, and therefore cirrhosis itself should not discourage neither surgical nor and locoregional and systemic treatments.

THU501

Refining the immune class of hepatocellular carcinoma

Email: rpinyol@clinic.cat

Background and Aims: Immune checkpoint inhibitors have elicited unprecedented responses in several cancers, including hepatocellular carcinoma (HCC): nonetheless, only 15–20% of HCCs respond. A pre-existing inflamed tumour microenvironment (TME) may be essential for the activity of immunotherapy while specific oncogenic mechanisms have been reported to create a non-inflamed TME leading to ineffective clinical responses. Our study aims to characterize the HCC-TME and further define the Inflamed (described in Sia et al. Gastroenterology 2017) and non-Inflamed immune profiles of HCC.
Method: We assessed the presence of immune infiltration and tertiary lymphoid structures (TLS ≥ 5 foci, 10X) in haematoxylin eosin-stained slides, performed immuno-phenotyping (multiplex of CD8, PD1, and PDL1 and immunostaining for CTLA4, TIM3, LAG3 and TIGIT) and genomic analyses (RNA and whole-exome sequencing) in 240 HCCs encompassing the most common aetiologies (HCV = 90, HBV = 75, and non-infected = 75). T cell receptor sequencing (TCR-seq) was conducted in a subset of 40 samples.

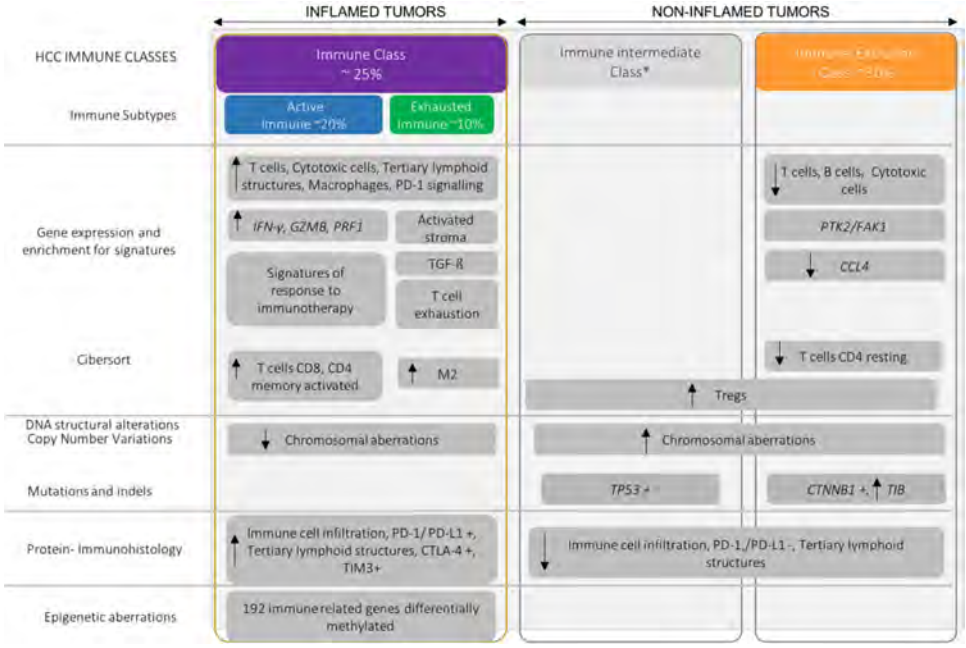

Figure 1: (abstract: THU501) Graphic representation of the three Immune classes and their molecular and histopathological features.

Results: High immune infiltration (15% of cohort) was associated with presence of TLS, higher intensity of CD8 and expression of immune checkpoints. LAG3 (29%), TIM3 (48%), CTLA4 (25%) and TIGIT (4%) showed no association with tumour mutational burden, aneuploidy or outcome. The recently described HCC Immune class or Inflamed profile was identified in 23% of patients, with no differences across aetiologies. The Immune class was linked to higher immune infiltration, CTLA4 and TIM-3 positive cases and higher CD8 and PDL1 intensities ($p < 0.05$). Patients with CTNNB1 activation (called Excluded class, 29% of tumours) displayed lower intensities of CD8, PD-1 and PD-L1, enrichment of Tregs and lower frequency of T CD4 resting ($p < 0.05$). The rest of the cohort was classified as Intermediate class, with a higher frequency of TP53 mutations (50% vs 26%, $p < 0.005$). The Immune class carried a significantly lower burden of chromosomal aberrations (broad and focal) compared to the rest. TCR-seq confirmed a higher fraction of T cells in the Immune Active class suggesting a more diverse and rich T cell repertoire in these tumours. Finally, while there was no difference in the tumour mutational burden, the Excluded class contained higher number of indels compared to the Immune class (Figure 1).
Conclusion: The characterization of the immune-TME of HCC has unveiled the existence of Inflamed (Immune class) and "non-inflamed" profiles (Intermediate and Excluded classes). The non-inflamed profiles show lower immune infiltration accompanied by the presence of oncogenic mechanisms associated with resistance to immunotherapy (i.e. mutations in CTNNB1) and immune evasion (high aneuploidy and TP53 loss).

Email: miroslawkornek@web.de

Background and Aims: Large extracellular vesicles (EVs) are cell-derived membrane vesicles that express the same surface antigens as their parental cells. To improve hepatobiliary cancer screening and differentiation, we investigated the feasibility of EV phenotyping in distinguishing biliary cancer (CCA and GbCa) from HCC and other cancer entities. Furthermore, we explored if combining the serum tumor marker AFP with EV populations increased the diagnostic benefit.
Method: The presence of $gp38^+$, $CD133^+$, $EpCAM^+$ and $CD44v6^+$ cells and their combination was confirmed in human CCA and HCC cell lines *in vitro* and in various organs of wild type C57Bl/6J mice *in vivo* by FACS. EVs from patients' sera were isolated by sequential ultracentrifugation at 2,000 and 20,000×g. To identify EV populations FACS was applied with AnnexinV (AnnV) serving as EV marker. In total, 106 biliary cancer, 67 HCC, 32 NSCLC, 20 CRC patients and 48 healthy subjects were enrolled in the study.
Results: i) CD133 and CD44v6 were differentially expressed in CCA and HCC cell lines, indicating their potential for differential diagnosis. ii) $gp38^+CD133^+$, $EpCAM^+gp38^+CD133^+$, $CD44^+$ and $CD44^+CD133^+$ cells were found in murine liver, gallbladder, lung and colon, confirming possible parental cell populations for EVs. iii) All four surface antigen combinations on EVs ($AnnV^+gp38^+CD133^+$,

AnnV$^+$EpCAM$^+$gp38$^+$CD133$^+$, AnnV$^+$CD44v6$^+$ and AnnV$^+$CD44v6$^+$ CD133$^+$) allowed a significant distinction of biliary cancer from HCC, NSCLC, CRC and healthy subjects. AUC values for biliary cancer vs. HCC ranged from 0.68 to 0.81. iv) When combining EV populations with the serum tumor marker AFP, diagnostic values could be improved. AnnV$^+$gp38$^+$CD133$^+$ and AnnV$^+$EpCAM$^+$gp38$^+$CD133$^+$ EVs achieved 100% sensitivity (sens) and positive predictive value (PPV) for biliary cancer vs. HCC, while AnnV$^+$CD44v6$^+$CD133$^+$ EVs reached 100% sens and negative predictive value (NPV), respectively, with 97% specificity (spec) and 98% PPV. Remarkably, together with AFP AnnV$^+$CD44v6$^+$ EVs achieved a perfect separation of biliary cancer from HCC with 100% sens, spec, PPV and NPV, respectively.

Conclusion: Our results provide evidence that AnnV$^+$gp38$^+$CD133$^+$, AnnV$^+$EpCAM$^+$gp38$^+$CD133$^+$, AnnV$^+$CD44v6$^+$ and AnnV$^+$CD44v6$^+$ CD133$^+$ EVs, especially in conjunction with AFP, serve as a clinically relevant screening biomarker for biliary cancer and might clearly distinguish it from HCC. Thus, this method represents a minimal-invasive, accurate liquid biopsy screening tool for early and differential detection of hepatobiliary cancers.

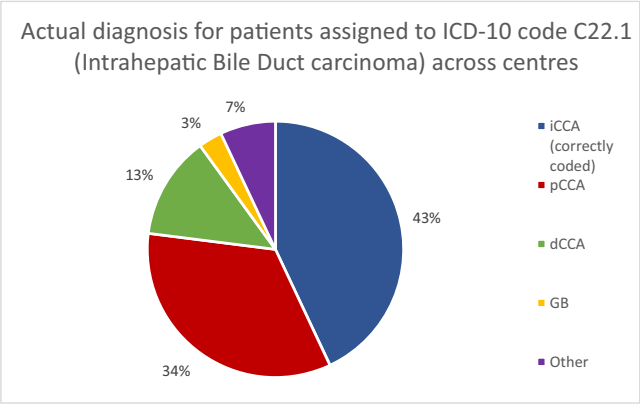
Cholangiocarcinoma miscoding in hepatobiliary centres

Shaun Selvadurai[1], Kulbir Mann[2], Sanjina Mithra[3], John Bridgewater[3], Hassan Malik[2], Shahid Khan[1]. [1]*Imperial College London and Imperial College Healthcare NHS Trust, Liver Unit, Division of Digestive Diseases, 10th Floor, QEQM Wing, St Mary's Hospital Campus, London, United Kingdom;* [2]*Aintree University Hospital Foundation Trust;* [3]*University College London Hospitals NHS Trust*
Email: shaun.selvadurai@nhs.net

Background and Aims: Cholangiocarcinomas (CCA) are sub-divided into intrahepatic (iCCA) or extrahepatic (eCCA). eCCA are further subdivided into perihilar (pCCA) and distal (dCCA) cholangiocarcinoma. Current and previous versions of the WHO International Coding of Disease and Oncology (ICD, ICD-O) classifications, ICD-10 and ICD-O-3, have separate topography codes for iCCA and eCCA, but none for pCCA. Over recent decades, multiple studies have reported rising incidence rates of iCCA with declining rates of eCCA, without reference to pCCA. We hypothesised that the lack of a specific code for pCCA has led to errors in the coding of CCA, specifically with miscoding of pCCA as iCCA.

Method: Clinical and radiological notes of cases coded as hepatobiliary carcinoma using ICD-10 criteria (C22.1/Intrahepatic Bile Duct carcinoma, C24.0/Extrahepatic Bile Duct carcinoma, C23X/Malignant Neoplasm Gall Bladder, C22.0/Malignant Neoplasm Liver Cell Carcinoma) over a 2 year period (2015–2017), were reviewed by two independent clinicians at three independent UK regional HepatoPancreatoBiliary (HPB) centres. The final diagnosis was compared to the originally allocated ICD-10 code.



Results: Of 744 CCA cases reviewed, 119 were excluded due to insufficient data. Of the remaining 625 cases, 226 were coded as C22.1/iCCA. 98 (43%) of these were true iCCA and coded correctly, while 76 cases (34%) were actually pCCA. 92% all pCCA cases were incorrectly coded as iCCA.

Conclusion: CCA coding misclassification in UK HPB centres is common, particularly the miscoding of pCCA, which is extrahepatic and the commonest form of CCA, as iCCA. This may be contributing to apparent rising incidence rates of iCCA reported over recent decades. This confirms the importance of implementing separate topographical codes for iCCA, pCCA and dCCA in ICD-11 and future iterations of ICD-0.

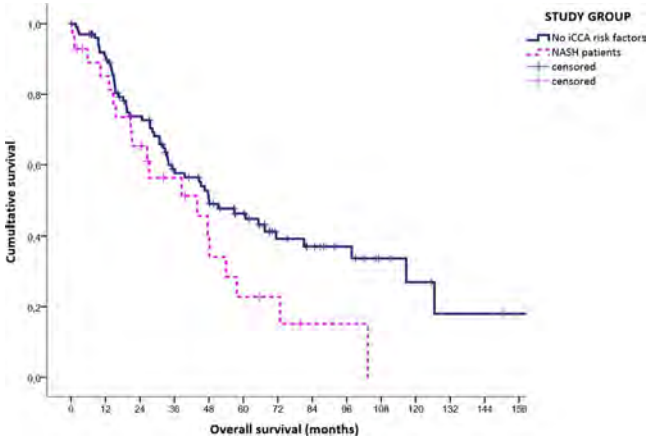
Non-alcoholic steatohepatitis is a risk factor for intrahepatic cholangiocarcinoma and affects its long-time outcome: results from a multicenter international case-control study

Stefania De Lorenzo[1], Francesco Tovoli[2], Alessandro Mazzotta[3], Francesco Vasuri[4], Deborah Malvi[4], Maria Antonietta D'Errico[4], Karim Boudjema[3], Bruno Turlin[5], Astrid Lievre[6], Giovanni Brandi[1]. Addarii" Institute of Oncology and Transplantation Pathology, Bologna, Italy;* [5]*Centre Hospitalier Universitaire (CHU) Pontchaillou, Pathology Department, Rennes, France;* [6]*Centre Hospitalier Universitaire (CHU) Pontchaillou, Gastroenterology, Rennes, France*
Email: stefania.delorenzo@libero.it

Background and Aims: The prevalence of intrahepatic cholangiocarcinoma (iCCA) is rising worldwide, for reasons not fully elucidated. The current epidemics of non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) might be partly responsible for this trend. Last year we reported preliminary monocentric data providing a rationale for larger studies about the pathogenic and prognostic role of NASH in iCCA. We intended to validate our results in a larger multicenter international study, verifying whether NASH is over-represented in iCCA patients (primary aim) and whether it affects iCCA outcome (secondary aim).

Method: Case-control study comparing the prevalence of histology-confirmed NASH in the peritumoral liver of resected iCCA patients (cases) and pre-explant biopsies of liver donors (controls). Controls were matched 1:1 for age and sex. In the iCCA cohort, patients with no known risk-factors for iCCA were stratified according to the presence/absence of NASH. Correlates between NASH, tumor characteristics and overall survival (OS) were subsequently explored.



Results: Between 2004 and 2017, 181 ICC patients were resected in two European centers [Bologna (Italy) and Rennes(France)]. Among

the study population, 130 patients (71.8%) had no apparent risk factors for iCCA. In this group, the prevalence of NAFLD and NASH was 45.4% and 21.5%,respectively, compared to 38.5 and 6.2% in the matched liver donors (p = 0.343 and p < 0.001, respectively). The prevalence of NASH was similar in the two centers. Among patients without established risk factors for iCCA, main tumor size (HR 1.009, 95%CI 1.003–1.014, p = 0.003), multinodular disease (HR 1.767, 95%CI 1.092–2.861, p = 0.020) and NASH (HR 2.009, 95%CI 1.158–3.484, p = 0.013) were independent predictors of the OS at the multivariate Cox regression. The median OS was 43.9 vs 48.1 months, with the two survival curves significantly diverging after the first 36 months (Figure). Instead, NASH was not related to an earlier recurrence of iCCA (p = 0.748).

Conclusion: This multicenter study confirmed that NASH (but not NAFLD) acts as a risk factor for iCCA and affects its long-term outcome. The absence of significant differences in the time to recurrence and the late divergence of the OS curves suggest that difference in mortality is probably not attributable to a greater biological aggressiveness of NASH-related iCCA but rather to the liver- and nonliver-related complications of NASH.

THU505

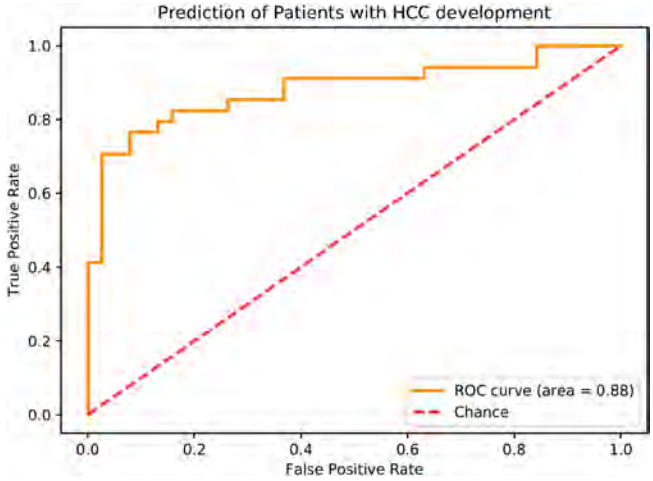
Transcriptome profiling of liver biopsies before antiviral treatment start can predict HCC development 8.3 years before clinical diagnosis in chronic hepatitis B and C patients

Stijn Van Hees[1,2], Bart Cuypers[3,4], Stefan Bourgeois[1,5], Kim Kreefft[6], Dirk Sprengers[7], Geert Robaeys[8,9,10], Pieter Meysman[4], Luisa Vonghia[1,2], Peter Michielsen[1,2], Sven Francque[1,2], Robert De Man[6], Ann Driessen[11], Andre Boonstra[6], Kris Laukens[4], Thomas Vanwolleghem[1,2,6]. *[1]Antwerp University Hospital, Department of Gastroenterology and Hepatology, Antwerp, Belgium; [2]Antwerp University, Laboratory of Experimental Medicine and Paediatrics, Antwerp, Belgium; [3]Institute of Tropical Medicine, Department of Biomedical sciences, Antwerp, Belgium; [4]Antwerp University, Department of Mathematics and Computer Sciences, Antwerp, Belgium; [5]ZNA Stuivenberg, Department of Gastroenterology and Hepatology, Antwerp, Belgium; [6]Erasmus Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [7]GZA Antwerp, Department of Gastroenterology and Hepatology, Antwerp, Belgium; [8]Hospital Oost-Limburg, Department of Gastroenterology and Hepatology, Genk, Belgium; [9]Hasselt University, Faculty of Health and LIfe Sciences, Hasselt, Belgium; [10]University Hospitals KULeuven, Department of Gastroenterology and Hepatology, Leuven, Belgium; [11]Antwerp University Hospital, Department of Pathology, Antwerp, Belgium*
Email: stijn.vanhees@uantwerpen.be

Background and Aims: An accurate prediction of Hepatocellular Carcinoma (HCC) development in Chronic Hepatitis B (CHB) and C (CHC) patients is currently impossible. In this study we explored pre-antiviral treatment liver transcriptome profiles of CHB and CHC patients with and without HCC development during long-term follow-up and investigated their potential to predict future HCC development.

Method: HCC developing cases (n = 34) were identified through retrospective chart review of all CHB and CHC patients with an available pre-antiviral treatment liver biopsy from 5 large Hepatology clinics. Cases were split in 4 subgroups based on infecting virus (HBV/HCV) and cirrhosis status (yes/no) at baseline liver biopsy. Each subgroup of cases was matched for different demographic (e.g. gender and age at biopsy) and clinical (e.g. cirrhosis at biopsy and infecting virus) factors to a group of controls without HCC development during an equal or longer follow-up time. RNA derived from baseline biopsies (total n = 72) was sequenced. Differentially Expressed Genes (DEG; FC >1.5 and q <0.2) were called in each subgroup and a random forest classifier was trained to predict HCC development.

Results: The total cohort consisted of 72 patients, of whom 34 developed a HCC at a median of 8.3 years after liver biopsy. Despite perfect matching for clinical and demographic characteristics, at least 452 DEG were found between cases and controls in each subgroup. Among the top 20 up- and down-regulated genes in each subgroup, 40–75% has previously been linked to oncogenesis, underlining the biological relevance. Ingenuity Pathway Analysis showed an enrichment for the "Wnt-bèta catenin signaling" pathway in the cirrhotic CHB group and the "molecular mechanisms of cancer" pathway in the non-cirrhotic CHC group. These results strongly suggest a genetic imprint for HCC development several years before clinical diagnosis. A random forest classifier tested with leave-one-out-cross-validation was able to predict HCC development with an accuracy of 84.7% (Figure 1), a Negative Predictive Value of 92.1% and a Positive Predictive Value of 75.8% based on the subgroup and baseline expression levels of 20 genes, of whom several have previously been linked to hepatocarcinogenesis.



Conclusion: Pre-antiviral treatment liver biopsies of chronic hepatitis B and C patients show a genetic imprint for future HCC development that allows to accurately predict HCC development 8.3 years before clinical diagnosis.

THU506

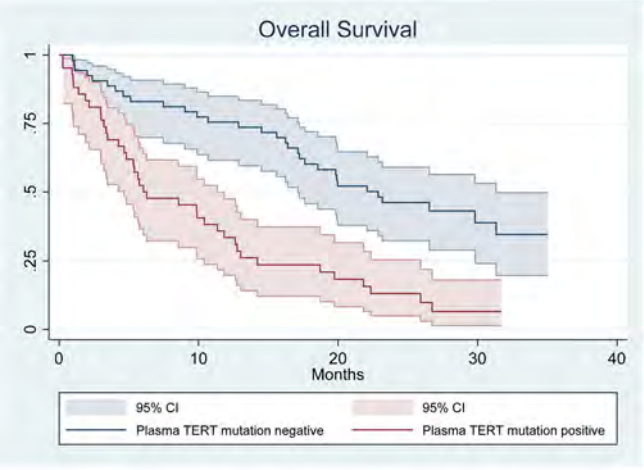
TERT mutated circulating tumor DNA is a useful biomarker and predicts prognosis in Danish HCC patients

Stine Karlsen[1], Michelle Simone Clement[2], Britta Weber[3], Niels Kristian Aagaard[1], Gerda Elisabeth Villadsen[1], Henning Grønbæk[1], Stephen Hamilton-Dutoit[4], Boe Sandahl Soerensen[2], Jens Kelsen[1]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark; [2]Aarhus University Hospital, Department of Clinical Biochemistry, Aarhus N, Denmark; [3]Aarhus University Hospital, Department of Clinical Oncology and Danish Centre of Particle Therapy, Aarhus N, Denmark; [4]Aarhus University Hospital, Department of Pathology, Aarhus N, Denmark*
Email: stinkarl@rm.dk

Background and Aims: No biomarker is able to diagnose hepatocellular carcinoma (HCC) with high sensitivity and specificity or provide clinically useful prognostic guidance. Circulating tumor DNA (ctDNA) with tumor-specific mutations is an attractive biomarker. The *Telomerase Reverse Transcriptase* (TERT) C228T promotor mutation is the most prevalent tumor-associated mutation in HCC.

The mutational landscape of HCC depends on the etiology of any underlying liver disease. The aims of this study is to evaluate TERT mutation in plasma as a prognostic marker and evaluate presence of TERT mutation in a Danish patient cohort primarily consisting of patients with alcoholic cirrhosis.

Method: We analyzed plasma DNA from Danish patients, 95 with HCC and 44 with liver cirrhosis without HCC for the TERT promotor mutation using droplet digital PCR. In 34 HCC cases we also analyzed DNA from the corresponding primary tumors, and calculated the concordance rates. We investigated the association between presence of TERT mutation in plasma and tumor DNA and survival.
Results: Plasma TERT mutation was detected in 42/95 HCC patients (44%), but in none of the non-HCC patients. Moreover, TERT mutation was detected in 23/34 tumor samples (68%). In HCC patients, TERT mutation was associated with increased mortality when detected in plasma ctDNA (HR 2.27, P = 0.005, adjusted for BCLC stage and sex), but not in tumor DNA (HR 1.39, P = 0.52, adjusted for BCLC stage and sex). For HCC patients with BCLC stage C, we observed a difference in median survival of 10.4 months depending on plasma TERT mutational status (p = 0.024).
Analysis of TERT mutations in plasma and tumor DNA from the same patient was concordant in 21/34 cases (62%; kappa value 0.31, P = 0.014), 11 being double-positive and 10 double-negative. In the 13 non-concordant cases, TERT mutation was found in tumor DNA from 12 patients (92%) but not in the corresponding plasma DNA.



Conclusion: Plasma TERT mutation was found in 44% of Danish HCC patients and was associated with increased mortality. Moreover, plasma TERT mutation was specific for HCC patients, not being identified in non-HCC cirrhotic patients. We suggest TERT C228T mutation in ctDNA as a promising biomarker in HCC for both diagnosis and prognosis.

THU507

Comparison of hepatocellular carcinoma between the current decade and the past - a study of 3,013 cases

Miao-Shan Lim[1], Boon Bee George Goh[1], Pik Eu Jason Chang[1], Jee-Keem Low[2], Vishalkumar Grishchandra Shelat[2], Wei-Huey Terence Cheong[2], Yock-Young Dan[3], Alfred Kow[4], Shridhar Iyer[4], Poh-Seng Tan[3], Sameer Padmakumar Junnarkar[2], Chee-Kiat Tan[1]. *[1]Singapore General Hospital, Department of Gastroenterology and Hepatology, Singapore; [2]Tan Tock Seng Hospital, Department of General Surgery, Singapore; [3]National University Health Service, Division of Gastroenterology and Hepatology, Singapore; [4]University Surgical Cluster, National University Hospital, Department of Hepatobiliary and Pancreatic Surgery, Singapore*
Email: tan.chee.kiat@singhealth.com.sg

Background and Aims: Hepatocellular carcinoma (HCC) is a significant global problem for many decades. In view of changing disease patterns and advances in HCC diagnosis and therapy, our hypothesis is that there are significant differences in the clinical characteristics and treatment of HCC in the current decade compared to the past.

Method: Patients with HCC from 3 major tertiary hospitals in Singapore (Singapore General Hospital, Tan Tock Seng Hospital and National University Hospital System) were enrolled into a Research Electronic Data Capture (REDCap) database between 1980 and 2018. Clinical characteristics and treatment of HCC diagnosed in the current decade i.e. from 2008 were compared with those diagnosed before 2008. IRB approval for the study was obtained.
Results: There were 3,013 patients. Mean age of HCC diagnosis was significantly older in the current decade (68.6 vs 61.2 years, p < 0.001). Overall, majority were males (80.5%) and Chinese (84.6%). There were significantly more foreigners in the current decade (6.7% vs 4.3%, p < 0.007). Although the most common etiology remained as chronic hepatitis B (CHB) infection, the proportion due to CHB was significantly less in the current decade (46.6% vs 57.2%, p < 0.0001). Concurrently, cryptogenic/nonalcoholic steatohepatitis (NASH) has become significantly more important in the current decade (27.1% vs 18.6%, p < 0.0001). More patients received curative therapy in the current decade (43.7% vs 27.1%, p < 0.0001).
CHB is diminishing in lieu of cryptogenic/NASH as an etiology of HCC. This is in line with our nationwide hepatitis B vaccination program since 1985 coupled with the improved socioeconomic status of our population and ensuing increase in prevalence of NAFLD/NASH. The significant rise in the age of diagnosis of HCC in the current decade may be due to better treatment of CHB infection. There are more foreigners in the current decade due to the growth of Singapore as a regional medical hub. The proportion of patients who received curative therapy is significantly higher in the current decade, likely due to early diagnosis from more inclusive HCC surveillance programs together with advances in the diagnosis and therapy of HCC.
Conclusion: In this largest collection of 3,013 cases of HCC in Singapore accrued over more than 3 decades, patients are diagnosed at an older age and NASH is becoming more important as an aetiology of HCC in the current decade. It is heartening that more patients are amenable to curative therapy in the current decade.

THU508

Cholangiocarcinoma in England - a national study examining changes in incidence, diagnostic routes and overall survival

Tracey Genus[1], Daniela Tataru[2], Helen Morement[3], Mireille Toledano[4], Shahid Khan[5]. *[1]Public Health England, National Cancer Registration and Analysis Service, Birmingham, United Kingdom; [2]Public Health England, National Cancer Registration and Analysis Service, London, United Kingdom; [3]AMMF – The Cholangiocarcinoma Charity, Enterprise House, London, United Kingdom; [4]Imperial College London, Faculty of Medicine, School of Public Health, London, United Kingdom; [5]St Mary's Hospital, Imperial College London, Department of Hepatology, London, United Kingdom*
Email: tracey.genus@phe.gov.uk

Background and Aims: Cholangiocarcinoma (CCA) incidence rates have been rising internationally for several decades. The causes are unclear. It is not known if there have been changes to diagnostic routes, patterns of presentation or overall survival.
AMMF in partnership with the National Cancer Registration and Analysis Service (NCRAS) in Public Health England (PHE) calculated incidence and mortality rates for England during 2001–2017, the first national survival study 2001–2017, and Routes to Diagnosis (RTD) statistics (Elliss-Brookes *et al.* 2012) between 2006–2016.
Method: Age-standardised incidence and mortality rates, Kaplan-Meier overall survival (OS) estimates and the distribution by RtD for CCA (ICD-O-3: C22.1; C24.0; C24.8; C24.9; and C22 [excluding C22.1] with morphology code 8160) were determined using data from the PHE NCRAS population-based cancer registry.
Results: There were 29,653 CCAs diagnosed between 2001–2017, 51.6% were female, and the median age of diagnosis was 75 years (IQR 66–82).

The incidence rate increased on average by 0.8 per million per year from 2.9 per 100,000 in 2001 to 4.4 in 2017 whilst the mortality rate increased by 1.3 per million. Rates increased more rapidly in the most socio-economically deprived population, 1 per million for incidence and 1.5 per million for mortality.
Between 2001–2017, 1-year OS increased from 20% to 25%, and median survival from 7.1 to 9.5 months. The 5-year OS remained below 5%.
The RtD data showed that the proportion of patients diagnosed following an emergency presentation fell from 51% in 2006 to 47% in 2016.

Figure: Incidence, Mortality and Survival of Cholangiocarcinoma in England.

Conclusion: Incidence and mortality rates of CCA in England are increasing. The more pronounced increase in rates observed for the most deprived group is similar to findings from an NCRAS study of primary liver cancer (Konfortion *et al.* 2014), and are suggestive of an association between increased deprivation and increased exposure to known risk factors for CCA.
The median survival for CCA is poor, lower than that reported for primary liver cancer (Maluccio *et al.* 2017). Just under half of CCA patients present through an emergency route which previous studies have shown is associated with a worse clinical outcome (McPhail *et al.* 2013).
These findings emphasize the need to clarify risk factors and develop tools for earlier diagnosis, improving outcomes in this patient group in line with the NHS Long Term Plan.

THU509

Reduced incidence of hepatobiliary cancers in helicobacter pylori infected persons in a population-based cohort study

Linda Skibsted Kornerup[1], Peter Jepsen[1,2], Lars Erik Bartels[3], Jens Frederik Dahlerup[1], Hendrik Vilstrup[1]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark;* [2]*Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus N, Denmark;* [3]*Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark*
Email: lindajen@rm.dk

Background and Aims: *Helicobacter pylori* (*H. pylori*) infection is known to be involved in intestinal cancer carcinogenesis. As regards hepatobiliary cancers, *H. pylori* DNA/RNA has been isolated from liver tissue from patients with hepatobiliary cancer, but no direct association has been established.
This large cohort study investigated *H. pylori* infection and its association with the incidence of hepatobiliary cancers. The cohort's appropriateness for the purpose was gauged by its ability to identify the established risk relation to gastric cancer.

Method: This historical study was performed in the Central Denmark Region. Patients were included from the primary health care after being tested for *H. pylori* infection with a urea breath test (UBT) and followed for a median of 4.6 years. Patients' diagnoses, country of birth, and gender were obtained from national Danish administrative registries. Cox regression was used to compare incidences of hepatobiliary and gastric cancer between *H. pylori* positive and *H. pylori* negative persons, adjusting for confounding variables.
Results: A total of 53,633 persons were included and 10,553 were tested positive for *H. pylori*. We found a markedly lower incidence of hepatobiliary cancers (equally for both hepatocellular- and cholangiocarcinoma) in *H. pylori* positive persons; HR = 0.27 (95% CI 0.11–0.68). The increased incidence of gastric cancer was confirmed (HR = 1.99 (95% CI 1.35–2.94)).
Conclusion: This cross-sectional study, which is the first, large historical cohort study on this topic, showed that *H. pylori* infection may protect against hepatobiliary cancer. However, our data offer no mechanistic explanation of this protective effect or whether *H. pylori* infection is merely a proxy for other protective factors.

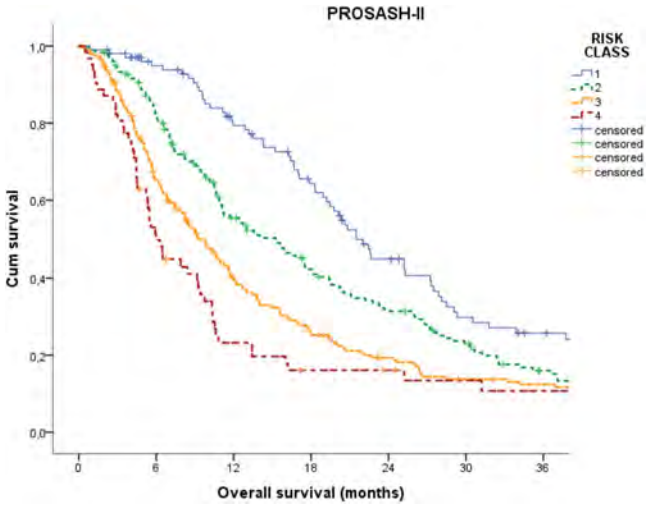
Email: francesco.tovoli2@unibo.it

Background and Aims: Prognostic classifications for patients treated with sorafenib for hepatocellular carcinoma (HCC) can be an useful tool to facilitate stratification in trials and inform clinical decision making. Very recently, Labeur and colleagues developed the PROSASH-II model, which performed better than other existing models in predicting the overall survival (OS) of sorafenib-treated patients. As this study included a 4-center training set and a single-center validation, further validation in multicenter cohorts are needed to understand the full potential of the PROSASH-II model. Aim of our study was to verify the stratification performance of the PROSASH-II and comparing with other existing prognostic models.
Method: We analyzed a large retrospective-prospective database gathering the clinical data of 552 patients from 7 Italian centres, who were prescribed with sorafenib between 2008 (date of licence in Italy) and 2017. The PROSASH –II score was calculated as proposed by its creators [(–0.0337 × albumin in g/l) + (0.315 × Ln(bilirubin in µmol/l) + (0.295 × macrovascular invasion, where 0 = No and 1 = Yes) + (0.181 × extrahepatic spread, where 0 = No and 1 = Yes) + (0.0336 × Largest tumour size in cm) + (0.0703 × Ln(AFP U/L)). It was subsequently categorized as follows: ≤-0.0760 (risk group 1), > –0.0760 to ≤ 0.355 (risk group 2), >0.355 to ≤ 0.858 (risk group 3) and >0.858 (risk group 4). The performance of the PROSASH-II was compared with those of BCLC, ALBI, HAP score and SAP score.
Results: The PROSASH-II stratification significantly discriminated patients, with a median OS of 21.5 months for risk group 1, 15.3 months for risk group 2, 9.3 months for risk group 3, and 5.9 months for risk group 4. Using risk group 1 as a reference, the hazard ratio was 1.52, 2.04, and 3.0 for risk groups 2,3, and 4, respectively. PROSASH-II

showed improved discrimination (C-index 0.61) compared with existing prognostic scores (C-index ≤ 0.57).



Conclusion: Our results validate the PROSASH-II as an effective prognostic classification model in a large Italian population of sorafenib-treated patients. We also confirm a slightly better performance of the PROSASH-II compared with the HAP and SAP scores.

THU512

Use of a novel thyroid-stimulating hormone model for predicting the progression of hepatocellular carcinoma

ZhiYun Yang[1], Lihua Yu[1], Xiaoli Liu[1], Yuyong Jiang[1], Xinhui Wang[1], Xian-bo Wang[1]. [1]*Beijing Ditan Hospital Capital Medical University, Center of Integrative Medicine, Beijing, China*
Email: yangzhiyun2016@163.com

Background and Aims: Individuals with hepatocellular carcinoma (HCC) are at risk of tumor recurrence after surgical resection, which affects their survival. The present study aimed to establish a model for predicting tumor progression in patients with HCC.
Method: To develop and validate the efficacy of a novel prognostic model, a retrospective cohort with HCC (n = 1,005) at Beijing Ditan Hospital was enrolled from January 2008 and June 2017. Furthermore, a prospective cohort (n = 77) was recruited to validate the association between thyroid-stimulating hormone (TSH) levels and tumor progression in patients with HCC.
Results: The model used in predicting the progression of HCC included four variables (namely, Barcelona Clinic Liver Cancer [BCLC] stage, presence of portal vein tumor thrombus, alpha-fetoprotein level, and TSH level). The AUROC of the 1-year progression-free survival (PFS) model were 0.755 and 0.753 in the deriving cohort and validation cohort, respectively, and these values were significantly higher than those of the Child–Pugh score, Model for End-stage Liver Disease (MELD), tumor–lymph node–metastasis (TNM) staging system, Okuda classification, and CLIP score. A simple assessment using a nomogram showed the 1-year PFS rate of patients with HCC. In the prospective cohort, the KM curve showed that the high TSH level group had a shorter PFS than the low TSH level (p = 0.001).

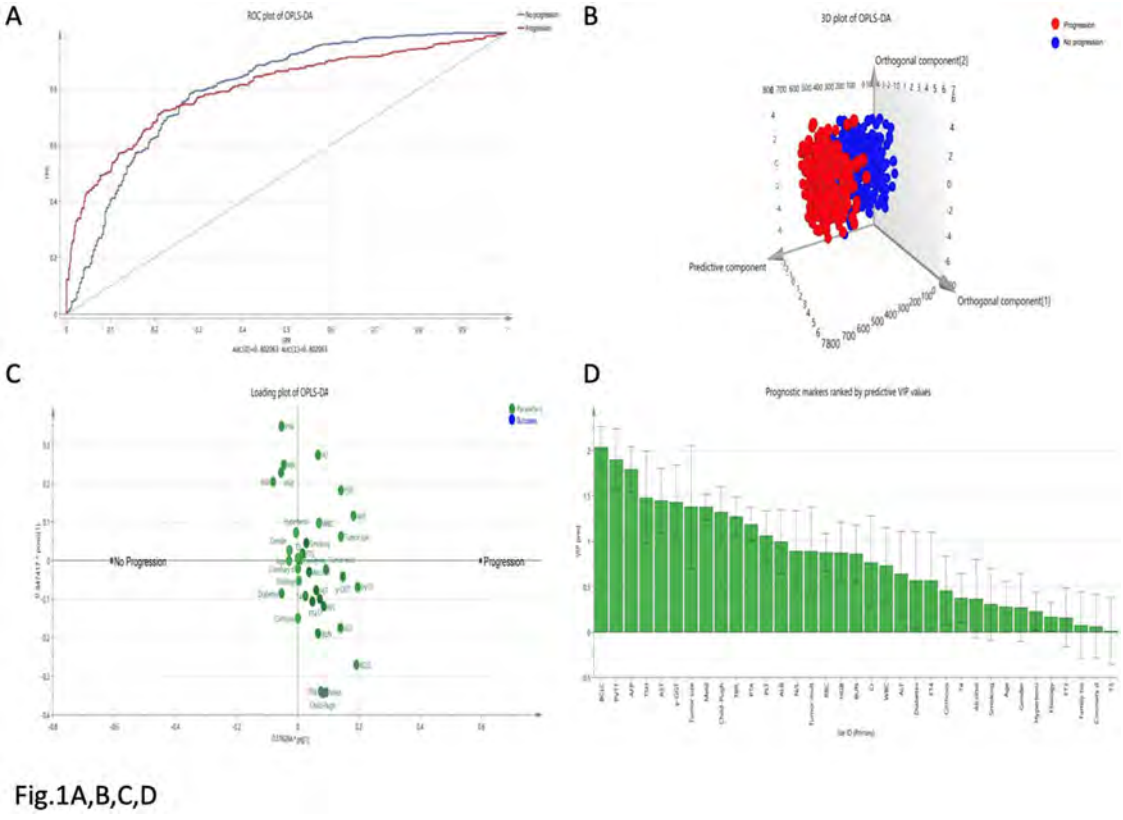


Fig. 1: (abstract: THU512) Orthogonal partial least squares discriminant analysis (OPLS-DA) of the prognosis of HCC. (A) Receiver operating characteristic (ROC) curve of OPLS-DA. (B) The OPLS-DA 3D plot of progression and no progression was distinguished using the predictive component: blue dots representing no progression and red dots indicating rogression. (C) Loading plot from the OPLS-DA of the progression and no progression groups. (D) When the predictive VIP (VIP-pred) value is higher, the ability to predict the progression of HCC is stronger.

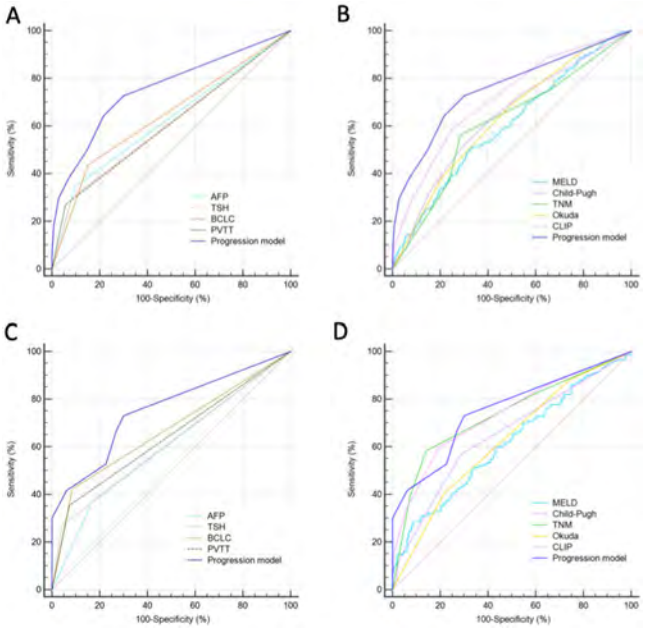

Fig. 2: (abstract: THU512): Receiver operating characteristic curves of the different models in predicting the 1-year PFS of patients with hepatocellular carcinoma. (A-B) Separate prognostic variables and other models in the deriving cohort. (C-D) Separate prognostic variables and other models in the validation cohort.

Conclusion: The prognostic model of HCC progression was superior to other well-known classical tumor scoring systems. A high TSH level was correlated to poor outcome, particularly those with advanced HCC.

THU513

A scoring system based on artificial neural network for predicting progression in HBV-related hepatocellular carcinoma

Xiaoli Liu[1], Li Jiang[2], Yixin Hou[1], Xinhui Wang[1], Lihua Yu[1], Xian-bo Wang[1], ZhiYun Yang[1]. [1]*Beijing Ditan Hospital Capital Medical University, Center of Integrative Medicine, Beijing, China;* [2]*Beijing Ditan Hospital Capital Medical University, Surgical, Beijing, China*
Email: yangzhiyun2016@163.com

Background and Aims: Disease progression is an important factor affecting the long-term survival in hepatocellular carcinoma (HCC). This study aimed to explore the prognostic factors that affect the progression of HCC and establish an individualized prediction model.
Method: We included 2,890 patients with hepatitis B-related HCC hospitalized at Beijing Ditan Hospital, Capital Medical University and randomly divided into training and validation cohort. Cox multivariate regression was used to analyze independent risk factors affecting the 1-year progression of HCC, and an artificial neural network model was constructed. C-index, calibration curve, and decision curve analysis were used to evaluate the performance of the model.
Results: Cox multivariate regression showed smoking history, a tumor number ≥ 2, tumor size ≥ 5 cm, portal vein tumor thrombus, WBC, NLR, γ-GGT, ALP, and AFP ≥ 400 ng/mL were risk factors for 1-year progression-free survival (PFS), while albumin and CD4T cell counts were protective factors in HCC patients. The AUROC of 1-year PFS in HCC patients was 0.866 (95% CI 0.848–0.884), which were higher than predicted by TNM, BCLC, Okuda, CLIP, CUPI, JIS, and ALBI scores ($P < 0.0001$). All patients were divided into high-, medium-, and low-risk groups, according to the ANNs model scores. Compared with the hazard ratios (HRs) of PFS in low-risk group, those in the high-risk group were 26.42 (95% CI 18.74–37.25; $P < 0.0001$) and 6.13 (95% CI 4.28–8.79; $P < 0.0001$) in the training and validation cohorts, respectively.

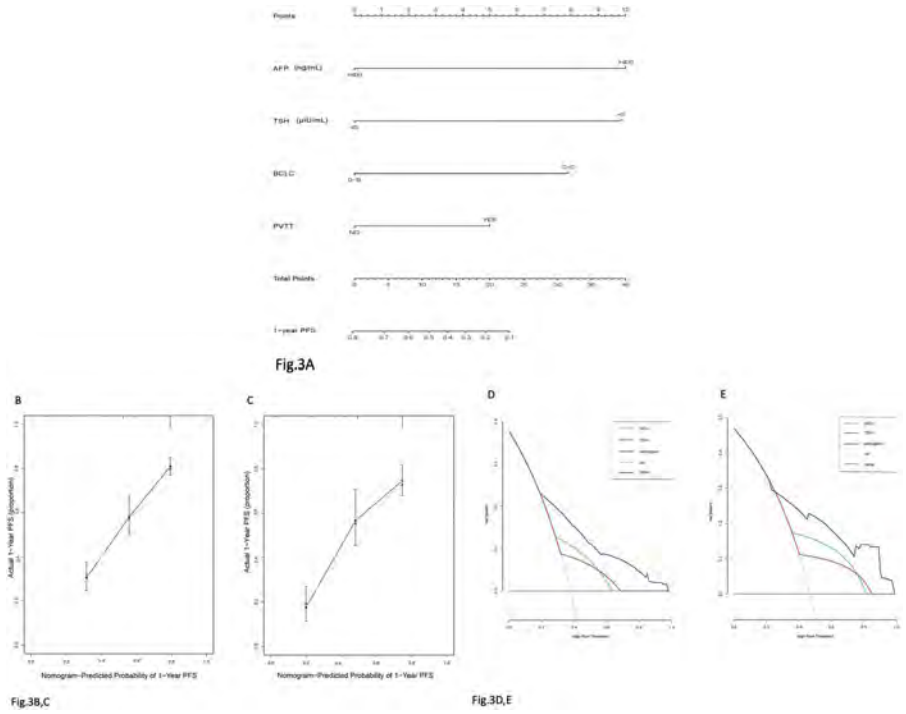

Fig. 3: (abstract: THU512): Prognostic nomogram and calibration curves and decision curve analysis. Nomogram predicted progression-free survival (PFS) (A) for HCC patients. The calibration curves for 1-year PFS (B, C) in the deriving and validation cohorts were identified. The nomogram-predicted probabilities of 1-year PFS (D, E) in the deriving and validation cohorts are compared with BCLC stage and TSH level.

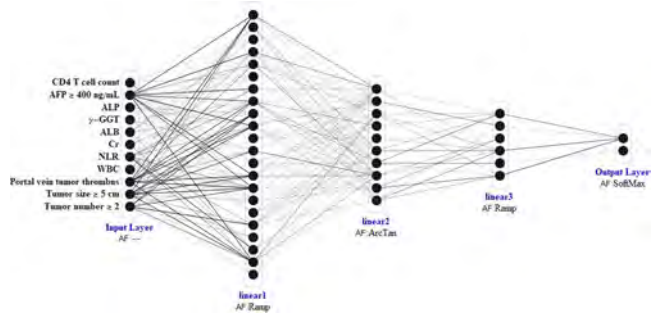

Fig. 2 ANN analysis of 1-year progression in patients with HBV-HCC.

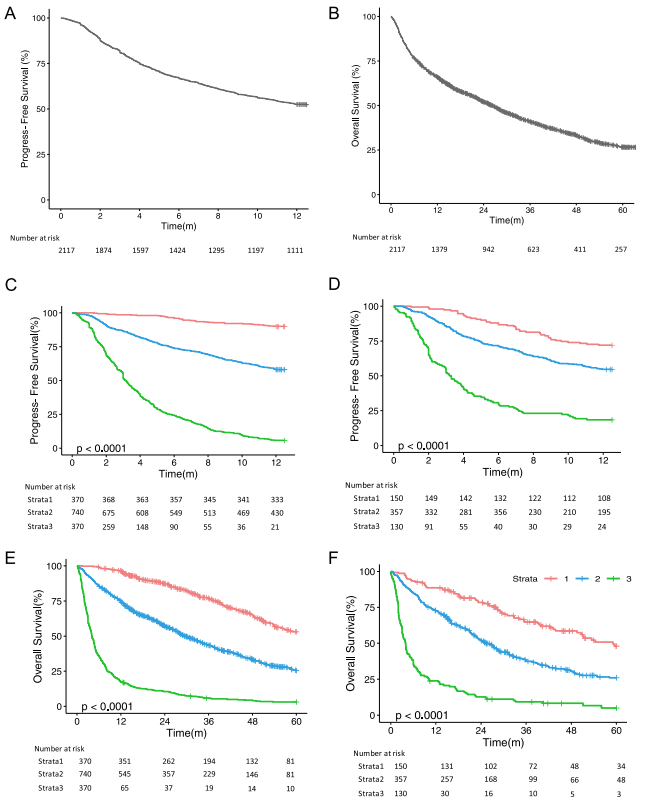

Fig. 4 The Kaplan-Meier survival curves of progress-free survival and overall survival in all HCC patients (A-B), training cohort (C-D), and validation cohort (E-F). C-F, comparison of survival distributions by ANNs model.

Conclusion: The ANNs model has good individualized prediction performance and is helpful to evaluate the disease progression of HCC in clinical practice.

THU514

Prediction of long-term survival of patients with hepatocellular carcinoma based on NK cells count novel model

ZhiYun Yang[1], Lihua Yu[1], Xiaoli Liu[1], Xinhui Wang[1], Huiwen Yan[1], Xian-bo Wang[1], Yuyong Jiang[1]. [1]*Beijing Ditan Hospital Capital Medical University, Center of Integrative Medicine, Beijing, China*
Email: yangzhiyun2016@163.com

Background and Aims: Among all immune cells, NK cells, as the first line of defense against tumor, play a vital role. The purpose of our study is to observe whether the number of NK cells can predict the survival of patients with hepatocellular carcinoma (HCC).
Method: To develop a novel model, a retrospective cohort with HCC (n = 121) at Beijing Ditan Hospital was enrolled from January 2012 and June 2014. Furthermore, a prospective cohort (n = 58) was recruited to validate the association between NK cells count and survival in patients with HCC.
Results: The model used in predicting survival of HCC included four variables (namely, NK cells count, tumor size, tumor number, and AFP level). A simple assessment using a nomogram showed the 5-year OS rate of patients with HCC. The nomogram was divided into high, intermediate and low risk groups to predict the 5-years survival risk of HCC patients (p < 0.001), and there were significant differences in BCLC stage 0-B and BCLC stage C-D (p = 0.002, p = 0.0042). The decision tree showed that the 5-years death risk of HCC with low NK count (≤124.5) was 61.2%. In the prospective cohort, the contour line shows that low NK counts and high AFP level have more death of HCC. NK cells count in patients with advanced HCC was significantly lower than that in patients with early.
Conclusion: Our study emphasises the utility of NK cells count for exploring interactions between long-term survival and predictor variables.

Chronological improvement in long-term outcomes of surgical resection for patients with hepatocellular carcinoma: two large-volume center studies

Yun Bin Lee[1], Jeonghoon Lee[1], Hyo Young Lee[1], Cheol-Hyung Lee[1], Minseok Albert Kim[1], Heejoon Jang[1], Hyunwoo Oh[1], Sun Woong Kim[1], Suk Kyun Hong[2], Eun Ju Cho[1], Su Jong Yu[1], Nam-Joon Yi[2], Kwang-Woong Lee[2], Jong Man Kim[3], Yoon Jun Kim[1], Kyung-Suk Suh[2], Jung-Hwan Yoon[1]. [1]*Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South;* [2]*Seoul National University College of Medicine, Department of Surgery, Seoul, Korea, Rep. of South;* [3]*Samsung Medical Center, Sungkyunkwan University College of Medicine, Department of Surgery, Seoul, Korea, Rep. of South*
Email: pindra@empal.com

Background and Aims: As the treatment for underlying liver diseases developed, clinical outcomes of patients with hepatocellular carcinoma (HCC) has been improved. We investigated whether long-term outcomes following surgical resection in HCC patients were changed over time according to the etiology of liver disease.
Method: In this study, 1,579 consecutive patients who underwent surgical resection for HCC as an initial treatment between 2016 and 2013 at two large-volume centers in Korea (Seoul National University Hospital and Samsung Medical Center) were included. Study patients were divided into two groups by the year of operation: late-2000s (2006–2009: n = 612) or early-2010s group (2010–2013: n = 967). Primary and secondary endpoints were recurrence-free survival (RFS) and overall survival (OS), respectively.
Results: Median follow-up duration was 5.7 years in the late-2000s group and 5.0 years in the early-2010s group. Both RFS and OS were significantly longer in the early-2010s group among entire cohort (both log-rank p < 0.001) (panel A and B). Multivariable Cox analyses revealed that the early-2010s group was an independent predictor of both prolonged RFS (adjusted hazard ratio [aHR] = 0.81, 95% CI = 0.69–0.96, p = 0.01) and OS (aHR = 0.33, 95% CI = 0.24–0.45, p < 0.001) compared to the late-2000s group. When patients were categorized into the two subgroups according to underlying liver disease (hepatitis B virus [HBV], n = 1,230; and others, n = 349), the aHR of RFS was similar between two subgroups (HBV subgroup: aHR = 0.83, 95% CI = 0.69–0.99, p = 0.04; other subgroup: aHR = 0.83, 95% CI = 0.55–1.25, p = 0.36) (panel C and D). OS of early-2010s group was also significantly improved in both subgroups (HBV subgroup: aHR = 0.32, 95% CI = 0.22–0.45, p < 0.001; other subgroup: aHR = 0.29, 95% CI = 0.16–0.56, p < 0.001) (panel E and F). HRs were maintained after balancing baseline characteristics using inverse probability weighting.
Conclusion: Long-term clinical outcomes of surgical resection for the treatment of HCC were improved over time with approximately 30% decreased risk of recurrence or death.

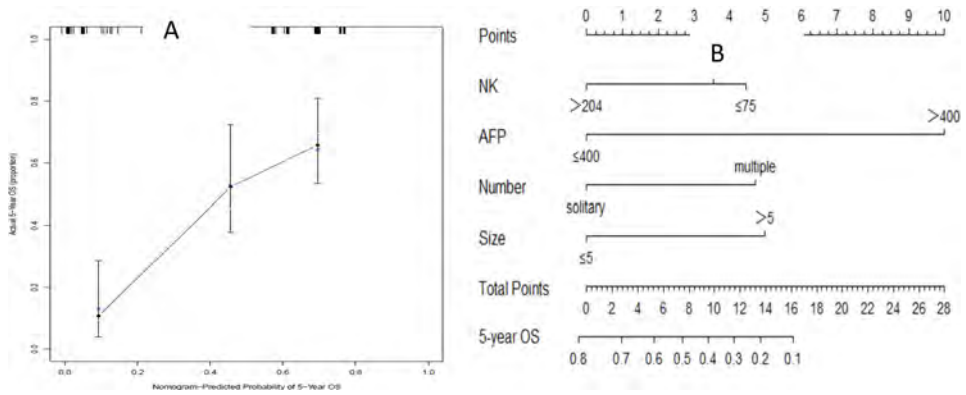

Figure 1: (abstract: THU514): Prognostic nomogram and calibration curves. Nomogram predicted overall survival (OS) (A) for HCC patients. To use the nomogram, the value of an individual patient is located on each variable axis, and a line is drawn upward to determine the number of points received for the value of each variable. The sum of these numbers is located on the total point axis, and a line is drawn downward to OS axes to determine the likelihood of 5-year OS. The calibration curves for 5-year OS (B) in the deriving cohorts were identified.

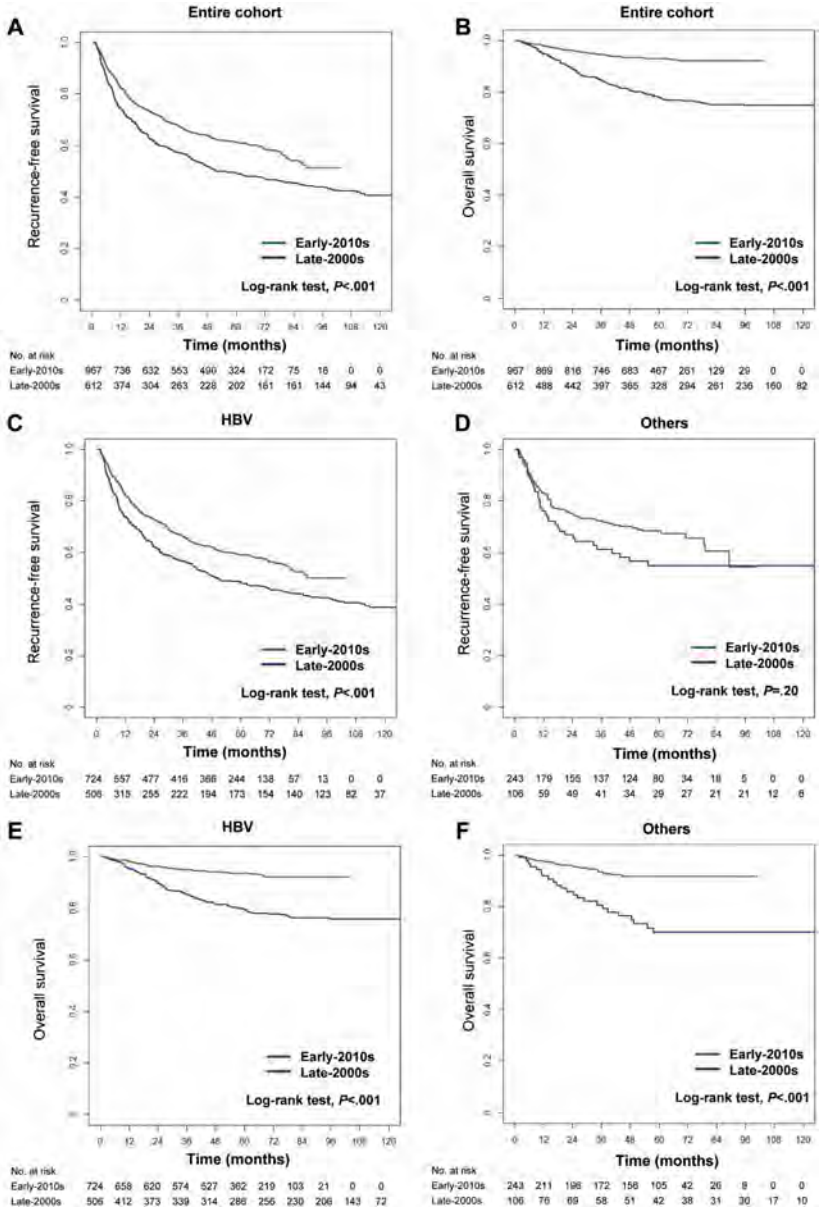

Figure: (abstract: THU515)

THU516

Glucose variability and risk of hepatocellular carcinoma in diabetic patients: a nationwide population-based study

Jeong-Ju Yoo[1], Eun Ju Cho[2], Su Jong Yu[2]. [1]*Soonchunhyang University Bucheon Hospital, Internal Medicine, Bucheon, Korea, Rep. of South;* [2]*Seoul National University, Internal Medicine, Seoul, Korea, Rep. of South*
Email: puby17@naver.com

Background and Aims: Although it is well known that diabetes is a significant risk factor for hepatocellular carcinoma (HCC), exactly which metabolic parameters of diabetes are associated with HCC remains unexplored. The aim of this study was to investigate the relationship between glucose variability (GV) and HCC in diabetic patients through a nationwide population-based study.
Method: A population-based cohort study including 674,178 diabetic subjects participating in more than 3 health examinations within 5 years from the index year (2009–2010) were followed until the end of 2017. The coefficient of variation (CV), standard deviation, and variability independent of the mean were calculated as GV indices.
Results: During a median follow-up of 6.7 years, there were 5,494 cases of HCC. When we classified groups according to glucose level, the highest risk for HCC was observed when the basal blood glucose level was 180 mg/dL or greater [adjusted hazard ratio [aHR] 1.19, 95% confidence interval (CI), 1.08–1.31]. We observed increasing trends for the relationship between GV and HCC in multivariable Cox proportional analyses. The risk of HCC increased by 27% (aHR 1.27, 95% CI, 1.17–1.38) for the highest quartile of GV relative to the lowest quartile. These findings were consistent regardless of the presence of chronic viral hepatitis or cirrhosis, alcohol consumption, or body mass index. Subgroup analysis also yielded similar results.
Conclusion: GV is an independent predictor of HCC, even after adjusting for confounding factors. There was a linear relationship between increase in GV and prevalence of HCC. These results suggest that GV is helpful for identifying diabetic patients at high risk of HCC.

Estimation of hepatocellular carcinoma risk after hepatitis B surface antigen seroclearance

Yewan Park[1], Joo Hyun Oh[1], Myungji Goh[1], Dong Hyun Sinn[1], Jihye Kim[1], Geum-Yon Gwak[1], Seung Woon Paik[1], Wonseok Kang[1], Yong-Han Paik[1], Moon Seok Choi[1], Minseok Albert Kim[2], Jeonghoon Lee[2]. [1]*Samsung Medical Center, Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Seoul National University Hospital, Internal Medicine, Seoul, Korea, Rep. of South*
Email: yewanish@gmail.com

Background and Aims: The available evidence suggests that hepatocellular carcinoma (HCC) can develop after hepatitis B surface antigen (HBsAg) loss. However, whether HCC risk differs between antiviral therapy (AVT)-induced or spontaneous cases, and ways to identify at risk population remains unclear. We compared.
Method: A retrospective cohort of 1174 patients (median age: 56 years; 809 males; 151 with cirrhosis; 200 antiviral therapy (AVT)-induced cases) who achieved HBsAg seroclearance were analyzed for the development of HCC after HBsAg seroclearance.
Results: During a median 4.5 years of follow-up (range: 1.0–17.8 years), HCC was developed in 18 patients (1.5%). AVT-induced patients showed higher incidence of HCC than spontaneous cases (5-years HCC incidence rate of 0.7% vs. 3.9%, $p < 0.001$). No HCC cases were identified among patients who achieved HBsAg seroclearance at <50 years of age, either spontaneously (n = 780) or by AVT (n = 116). For those who achieved HBsAg seroclearance after 50 years of age, the 5-year cumulative incidence rate of HCC was higher for AVT-induced cases (0.9% vs. 6.8%, $p < 0.001$), with higher hazard ratio (4.99, 95% confidence interval, 1.78–14.01) for HCC in multivariable adjusted analysis.
Conclusion: Patients who achieved HBsAg seroclearance by AVT showed higher risk for HCC, especially for those who achieved HBsAg seroclearance after 50 years. This imply that clinical benefit of HBsAg secoclearance by AVT can be more beneficial when induced at early age.

THU518

Indeterminate nodules in hepatocellular carcinoma surveillance: an analysis of the frequency, outcomes and costs

Yu Meng Li[1], Nowlan Selvapatt[1], Claire Kelly[1], Shahid Khan[1]. [1]*Imperial College London, Department of Hepatology, St Mary's Hospital, London, United Kingdom*
Email: yml15@ic.ac.uk

Background and Aims: Current guidelines recommend biannual hepatocellular carcinoma (HCC) surveillance with ultrasound scan (USS) for patients with cirrhosis. However, USS is not diagnostic for HCC, therefore USS-detected nodules are deemed indeterminate (INs), which require further investigation to confirm whether these are benign (INb) or HCCs. We investigated the frequency and outcomes of INs in a single-centre HCC surveillance programme and the downstream costs associated with IN detection.
Method: Retrospective data were collected from electronic records of adult cirrhotic patients attending St Mary's Hospital, London between 01/01/2014 and 01/01/2019. Relevant data were extracted for all liver imaging, patient demographics, baseline laboratory results and clinical evidence of liver decompensation. Cost of scans were calculated based on NHS tariffs and Public Health England guidance. SPSS was used for analysis.
Results: We identified n = 302 patients in total (Fig. 1). The mean follow-up was 3.3 years, median age was 60 years, 69% were male and 57% Caucasian. Less than 30% of patients adhered to 6-monthly surveillance for the whole follow-up period. 19% (n = 58) of patients were found to have INs. Upon further investigation, 9% (n = 28) were diagnosed with HCCs and 9% (n = 28) were diagnosed with INbs. 1% (n = 2) were still undergoing investigation at the end of the study period.

Table 1: (abstract: THU517): Factors associated with hepatocellular carcinoma development among overall patients (n = 1174) and patients aged over 50 years (n = 896)

	Overall (n = 1174)				Age ≥ 50 years (n = 896)			
	Univariable HR (95% CI)	*p*-value	Multivariable HR (95% CI)	*p*-value	Univariable HR (95% CI)	p-value	Multivariable HR (95% CI)	*p*-value
Age (per year)	1.04 (0.99–1.10)	0.104			0.99 (0.92–1.06)	0.762		
Male (vs. female)	7.15 (0.95–53.7)	0.056			7.02 (0.93–52.80)	0.058		
Cirrhosis (vs. no)	7.08 (2.80–17.8)	<0.001			6.92 (2.75–17.45)	<0.001		
Platelet count ($m^3/\mu l$)	0.99 (0.99–1.00)	0.202			1.00 (0.99–1.00)	0.268		
Elevated ALT* (vs. no)	1.55 (0.51–4.74)	0.438	4.62 (1.70–12.52)	0.003	1.91 (0.63–5.82)	0.255	3.79 (1.35–0.63)	0.011
AVT (vs. no)	6.03 (2.36–15.4)	0.001	3.57 (1.31–9.72)	0.013	8.48 (3.34–21.51)	<0.001	4.99 (1.78–4.01)	0.001

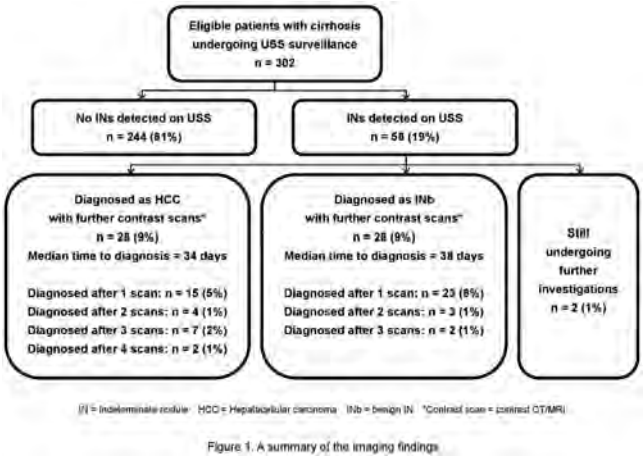

Figure 1. A summary of the imaging findings

On average, an additional 1.3 contrast scans were performed per patient with INb, which adds £175 to the cost per patient over a five-year period. Overall, this amounts to 4.4% of the total HCC surveillance cost in this study. Extrapolated nationally, NHS spending is estimated to be £972,000 for additional scans diagnosing INbs over a five-year period.

The median time to diagnose or exclude HCC was over 1 month. 71% of HCCs were detected at a potentially curable stage. Patients with HCC were significantly more likely to have varices (p = 0.02) and lower serum albumin (p = 0.01) than those with INbs. Older age was independently associated with HCC risk.

Conclusion: Although most HCCs diagnosed on surveillance are at a potentially curative stage, adherence to surveillance is poor. The percentage of INs that are eventually diagnosed as HCC or INb are similar. More severe liver disease and older age are associated with HCC. Substantial delays can occur before INs are definitively diagnosed; the burden on patients and resource implications of reducing diagnostic delays require further study.

Serum creatinine/cystatin C ratio has a potential as a useful surrogate marker for evaluation of muscle mass volume in patients with hepatocellular carcinoma

Kazufumi Kobayashi[1], Sadahisa Ogasawara[1], Hirotaka Oura[1], Kengo Kanayama[1], Hiroaki Kanzaki[1], Keisuke Koroki[1], Susumu Maruta[1], Naoya Kanogawa[1], Soichiro Kiyono[1], Masato Nakamura[1], Takayuki Kondo[1], Tomoko Saito[1], Eiichiro Suzuki[1], Yoshihiko Ooka[1], Shingo Nakamoto[1], Akinobu Tawada[1], Tetsuhiro Chiba[1], Makoto Arai[1], Tatsuo Kanda[2], Hitoshi Maruyama[3], Jun Kato[1], Naoya Kato[1]. *[1]Graduate School of Medicine, Chiba University, Department of Gastroenterology, Chiba, Japan; [2]Nihon University School of Medicine, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Tokyo, Japan; [3]Juntendo University School of Medicine, Department of Gastroenterology, Tokyo, Japan*
Email: z3m1034k@yahoo.co.jp

Background and Aims: Sarcopenia is considered a poor prognostic factor for many diseases and malignancies, including hepatocellular carcinoma (HCC). Muscle mass volume (MMV), which is required for sarcopenia diagnosis, is generally measured by computed tomography (CT) and bioelectrical impedance analysis. Due to their complicated methodologies and medical costs for examinations, more convenient and universal approaches for MMV are required. Recently, the ratio between serum creatinine (Cre) and cystatin C (CysC) (Cre/CysC) was reported to potentially be a new surrogate marker for MMV in several diseases. The present study aimed to clarify the relationship between Cre/CysC and MMV in HCC patients and explore the possibility of easy MMV evaluation.

Method: We identified consecutive newly diagnosed and initially treated HCC patients from our institutional database between June 2009 and December 2016. We excluded patients who lacked even one of the following parameters: abdominal CT image for assessing MMV, serum Cre level, and CysC level. MMV was expressed by the skeletal muscle index at L3 (L3-SMI) on CT. The correlation of Cre/CysC with L3-SMI was analyzed. A prediction model for L3-SMI was created using multiple regression analysis. Furthermore, we collected the measurement data of Cre/CysC and L3-SMI obtained more than 6 months after the initial measurement and validated the model.

Results: The study included 614 patients (age, 70.1 ± 9.5 years; 428 males). We found a significant correlation between Cre/CysC and L3-SMI (r = 0.307, p < 0.001). In patients with serum Cre levels higher than the upper normal limit, the correlation was not significant (r = 0.121, p = 0.252). However, in those with normal serum Cre levels, the correlation was strong (r = 0.356, p < 0.001). We attempted to develop a new prediction model in the normal serum Cre population (n = 522) (Figure). The model showed significant R-square in the original cohort (0.637) and internal validity by using bootstrap verification (0.633, 95%CI: 0.628–0.638). Of the 522 patients, 376 had datasets of abdominal CT, serum Cre, and CysC at different time points. Our prediction model was validated in the normal serum Cre population (n = 297, R-square: 0.46).

L3-SMI =

12.6*Cre/CysC + 1.40*BMI + 0.54*Alb – 0.14*Age + 10.4 (male)

12.6*Cre/CysC + 1.40*BMI + 0.54*Alb – 0.14*Age + 3.96 (female)

Conclusion: Our model, which was based on Cre/CysC, had the potential to estimate L3-SMI. Monitoring sarcopenia in HCC patients closely by using these two simple parameters will change daily practice. Our model should be validated in other patient cohorts of not only HCC but also other diseases.

NAFLD: Diagnostics and non-invasive assessment

FRI001

The development of the NAF3 score to accurately predict the presence of active NASH with advanced fibrosis

Naim Alkhouri[1], Allison Sachiko Harrington[1], Phuc Le[2], Ibrahim Hanouneh[3], Mangesh Pagadala[4], Edward Mena[5], Mazen Noureddin[6]. [1]*Texas Liver Institute and University of Texas Health San Antonio;* [2]*Cleveland Clinic;* [3]*Minnesota Gastroenterology;* [4]*Methodist Dallas;* [5]*California Liver Research Institute;* [6]*Cedars-Sinai Medial Center*
Email: alkhouri@txliver.com

Background and Aims: Several pharmacologic agents that target patients with advanced NASH are in development. Phase 3 clinical trials included patients with evidence of active disease defined as NAFLD activity score (NAS) of 4 or higher AND fibrosis stage 2–3 (F2-F3). Given potential for side effects and relatively low efficacy, clinicians are likely to restrict the use of new agents to patients with NAS = />4 with F3; therefore, noninvasive identification of those patients is urgently needed to optimize the use of new agents. The aim of this study was to develop a new noninvasive score using readily available clinical data and liver stiffness measure by transient elastography (TE) to predict NAS ≥ 4 + F3 in patients with biopsy-proven disease.
Method: Patients from 5 U.S. major centers who underwent liver biopsy, laboratory assessment, and TE measurements within 6 months were included. Liver histology was assessed by experienced pathologists blinded to clinical data. The grade of steatosis, hepatocyte ballooning, and inflammatory activity was measured by Kleiner's criteria and the stage of fibrosis was recorded (F0-F4). Multivariable backward stepwise logistic regression was used to build a model to identify patients with NAS ≥ 4 + F3 and C-statistics with AUROC were used to assess the accuracy of the model.
Results: Our cohort consisted of 282 patients with biopsy-proven disease with a mean age of 56.4 ± 11.8 years and mean BMI of 33.7 ± 7.7 kg/m^2. The mean platelet count was 228.8 ± 78.9 k/uL, mean AST of 45.5 U/L and ALT of 58.3 U/L. The M probe was used in 152 patients and the XL probe in 97 patients to measure liver stiffness with a mean of 12.5 ± 9.9 kPa. NASH was present in 67% (n = 159) and 24.8% (n = 70) of patients had NAS ≥ 4 + F3. We developed a model called NAF3 score to predict the presence of NAS ≥ 4 + F3 on liver biopsy using the following variables: Age, sex, AST, liver stiffness, bilirubin, HDL cholesterol, and the presence of diabetes. The AUROC for the new score was 0.836 (95% CI 0.754–0.918). Internal cross validation of the model revealed mean AUROC of 0.7772 (95% CI: 0.6792, 0.8240).
Conclusion: In a large multi-center cohort of patients with the full spectrum of NAFLD, the NAF3 score using liver stiffness and clinical variables can accurately identify patients with NAS ≥ 4 + F3. This score is a promising tool for selecting patients for pharmacologic agents. Further validation is needed.

Advanced transcriptomics identifies the tweak receptor as a novel biomarker in non-alcoholic steatohepatitis: biomarker discovery from gene expression signature to plasma protein

Anja Bengtsson[1], Kristoffer Rigbolt[2], Denise Oro[2], Helene Ægidius[2], Pia Steen Petersen[2], Niels Vrang[2], Jacob Jelsing[2], Lisbeth N Fink[3], Sanne Veidal[2]. [1]*Gubra Aps, Hørsholm;* [2]*Gubra Aps, Hørsholm, Denmark;* [3]*Gubra Aps, Hørsholm, Denmark*
Email: anb@gubra.dk

Background and Aims: Obesity and diabetes are major risk factors for non-alcoholic steatohepatitis (NASH). There is no specific clinical phenotype that permits diagnosis of NASH. Hence, there is an immediate need for validated and robust clinical biomarker assays to identify disease stages and direct treatment intervention strategies.
Method: Genes regulated in diet-induced obese (DIO)-NASH mice were identified using hepatic RNA sequencing datasets from DIO-NASH mice (AMLN diet; 40% fat, 20% fructose, 2% cholesterol) as compared to standard high-fat diet (60% high fat diet) and lean chow fed mice. Several novel NASH specific biomarker candidates were identified, including tumor necrosis factor receptor superfamily member 12A (tnfrsf12a), encoding the TWEAK receptor (TWEAKR), a candidate biomarker not previously related to NASH progression. TWEAKR levels were determined by ELISA (R&D Systems) in plasma from C57Bl/6J and ob/ob mice fed AMLN diet for 58 and 20 weeks, respectively.
Results: Single-cell sequencing of liver cells revealed expression of the lead biomarker candidate gene encoding TWEAKR, tnfrsf12a, to be confined to epithelial cells in chow mice, and upregulated in both these cells and in specific immune cell subsets in DIO-NASH mice. To verify translatability, expression of tnfrsf12a was compared to gene expression profiles in liver biopsies from healthy human individuals and NAFLD/NASH patients, showing excellent correspondence. Plasma TWEAKR levels were significantly increased in DIO-NASH mice compared to chow-fed control mice (189 ± 14 vs. 91 ± 4 ng/mL, $p < 0.001$). Returning mice to chow diet for 8 weeks normalized plasma levels (105 ± 6 ng/mL). The same pattern was observed in the more severe ob/ob DIO-NASH mouse model (ob/ob DIO-NASH 353 ± 25; ob/ob DIO-NASH reversal 178 ± 9, ob/ob chow 158 ± 10 ng/mL, $p < 0.001$). Plasma TWEAKR levels correlated to histological findings of inflammation and liver fibrosis.
Conclusion: We identified a panel of novel NASH-specific biomarker candidate genes by combining multiple hepatic RNA sequencing datasets in mouse and man. A lead biomarker candidate gene, tnfrsf12a, was subsequently identified to be elevated also at the protein level in plasma from two validated DIO-NASH mouse models. The data demonstrate methodological proof of concept and is considered of high value for the development of clinical biomarkers enabling patient stratification for future NASH treatment options and clinical trials.

Machine learning models identify novel histologic features predictive of clinical disease progression in patients with advanced fibrosis due to non-alcoholic steatohepatitis

Harsha Pokkalla[1], Kishalve Pethia[1], Amaro Taylor[1], Benjamin Glass[1], Hunter Elliott[1], Ling Han[2], Catherine Jia[2], Ryan Huss[2], Chuhan Chung[2], Mani Subramanian[2], Robert Myers[2], Stephen Harrison[3], Zachary Goodman[4], Murray Resnick[1], Aditya Khosla[1], Andrew Beck[1], Ilan Wapinski[1], Arun Sanyal[5], Zobair Younossi[4,6]. [1]*Path AI, Boston, United States;* [2]*Gilead Sciences, Foster City, United States;* [3]*Pinnacle Clinical Research, San Antonio, United States;* [4]*Inova Fairfax Hospital, Falls Church, United States;* [5]*Virginia Commonwealth University, Richmond, United States;* [6]*Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States*
Email: ryan.huss@gilead.com

Background and Aims: Fibrosis is the primary determinant of disease progression in patients with nonalcoholic steatohepatitis (NASH), but the prognostic impact of other histological features is unclear. We used a machine learning (ML) approach and biopsy images to identify novel morphologic features and associations with disease progression in patients with advanced fibrosis due to NASH.
Method: Biopsies from 644 patients screened for a phase 3 trial of selonsertib (STELLAR-4) were scored by a central pathologist (CP) according to the NASH CRN and Ishak staging systems. The PathAI research platform (PathAI, Boston, MA) was applied to train a convolutional neural network (CNN) with >68,000 annotations (e.g. steatosis, ballooning, lobular/portal inflammation) collected from 75 board-certified pathologists on images of H&E and trichrome (TC)-stained slides. For staging fibrosis, CNN models were trained using slide-level pathologist scores to recognize unique patterns associated with each stage within fibrotic regions of TC images. These region-based scores were summarized for each slide. In total, 202 features were extracted from biopsy images from NASH patients (F3-F4) enrolled in the STELLAR trials. Cox regression was used to identify associations between these features with progression to cirrhosis in F3 patients, and liver-related events (e.g. decompensation, transplantation, death) in those with cirrhosis (F4).
Results: 1526 NASH patients with F3-F4 fibrosis (median age 59 yrs, 73% diabetic, 52% F4) were included. During a median follow-up of 16.5 mos, 14.5% (105/726) of F3 patients progressed to cirrhosis, and over 15.9 mos, 2.8% (22/800) of F4 patients had liver-related events. Progression to cirrhosis was associated with greater proportions of all Ishak scored area consistent with Ishak 6 fibrosis and greater proportions of total tissue area consistent with portal inflammation (Figure). Similar associations with clinical events was observed in F4 patients, with hepatocellular ballooning also associated with clinical events. In F3, a greater proportion of Ishak scored area consistent with Ishak 1 fibrosis and of total tissue area consistent with steatosis were associated with a reduced risk of progression. In F4 patients, a greater proportion of total tissue area consistent was steatosis was similarly protective, while proportion of Ishak Stage 1 Fibrosis over Ishak scored area trended towards protective.

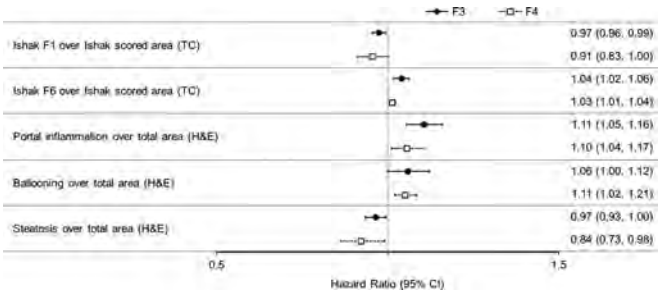

Figure: Associations Between ML-Based Morphological Features with Disease Progression in Patients with Advanced Fibrosis Due to NASH.

Conclusion: Liver histological evaluation using this automated, ML approach identified novel features associated with progression in NASH patients with advanced fibrosis. These data support the utility of ML approaches to evaluation of liver histology as endpoints in NASH clinical trials.

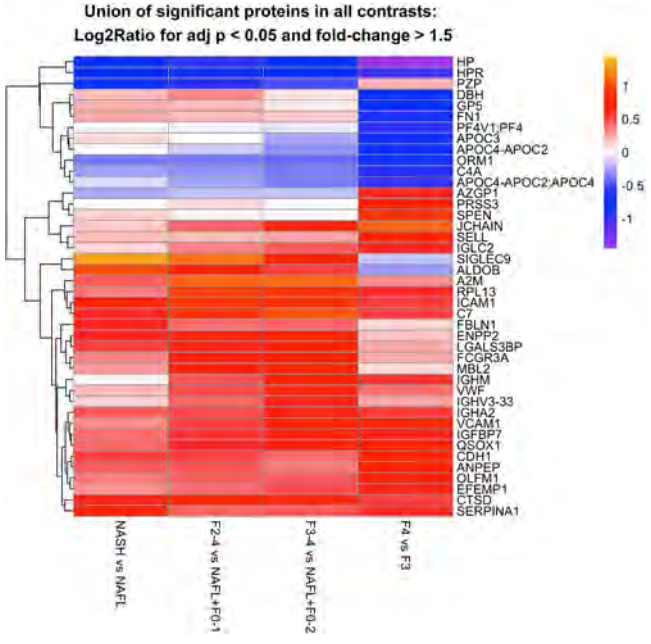
Email: christina.ebert@bms.com

Background and Aims: Non-alcoholic steatohepatitis (NASH) affects 3–12% of the US population and can progress to cirrhosis, liver failure and hepatocellular cancer. There is a strong need for noninvasive alternatives to liver biopsy. In this study we sought to identify serum biomarkers that associate with more advanced fibrosis severity in NASH.
Method: Sera from 420 biopsy-proven NASH (F0-F4) and NAFL (fatty liver) patients were randomized into 6 × 96-well plates. We analyzed samples by nano-liquid chromatography mass spectrometry (LCMS) using data-independent acquisition (DIA), and processed raw data in Spectronaut (Biognosys AG). Of 522 total detected proteins, 272 proteins were present in >75% of samples for analysis. We used limma to model how log2, quantile-normalized protein data associate with NASH (F0-F4 vs NAFL), significant fibrosis (F2-F4 vs NAFL and F0-F1), advanced fibrosis (F3-F4 vs NAFL and F0-F2), and NASH F4 vs F3. In parallel, 58 potential fibrotic biomarkers were assayed from the same patient sera using the Luminex platform, a multiplexed ELISA assay. Data were Arcsinh-transformed and locally-estimated-scatterplot-smoothing (LOESS)-normalized prior to limma modeling. All data were corrected for multiple testing using Benjamini-Hochberg.



Results: We identified many proteins associated with NASH compared to NAFL, and with fibrotic severity (Figure). We found 31 proteins associated with NASH, 84 with significant fibrosis, 100 with advanced fibrosis, and 79 with NASH F4 vs F3 (adjusted p = 0.05).

These include novel and reported biomarkers of fibrosis, cirrhosis, and NASH. In addition, 9 proteins were assayed in both the LCMS and Luminex data. For the advanced fibrosis contrast 4 proteins were significant by both LCMS and Luminex, 1 was significant by only Luminex with concordance of direction, and 4 were never significant.
Conclusion: Using a large bank of NASH and NAFL sera, we identified proteins that associate with fibrotic severity of NASH, which comprise both novel and previously known biomarkers. Some of these we confirmed by other assays, including several immunoglobulins. Importantly, signatures distinguishing NASH F4 from NASH F3 may help diagnose asymptomatic F4 patients who are at high risk to develop end stage liver disease. These biomarkers may aid in the development of novel non-invasive models to classify disease stages and enable patient stratification. Further investigation is warranted to confirm the findings using independent quantitative assays.

FRI005

Performance of non-invasive fibrosis tests among non-alcoholic fatty liver disease (NAFLD) patients with normal alanine aminotransferase (ALT): data from a large North American primary care NAFLD pathway

Abdel-Aziz Shaheen[1], Stephen Congly[1], Wendy Schaufert[1], Kelly Burak[1], Alexandra Medellin[2], Deepak Bhayana[2], Mark G Swain[1]. [1]*University of Calgary, Department of Medicine, Division of Gastroenterology and Hepatology, Canada;* [2]*University of Calgary, Department of Radiology*
Email: azshaheen@me.com

Background and Aims: Recent studies risk stratifying NAFLD patients within primary care have focused on patients with elevated transaminases (alanine aminotransferase [ALT] and aspartate aminotransferase [AST]). Therefore, we used data from the Calgary NAFLD clinical care pathway (CNCCP) to compare performance of non-invasive liver fibrosis tests FIB-4, NAFLD fibrosis score (NFS), and 2-dimensional shearwave elastography (SWE) in NAFLD patients based on having elevated baseline ALT levels.
Method: The CNCCP was developed as a partnership to enable primary care physicians (PCP) to risk-stratify NAFLD patients within primary care. PCPs can directly access the CNCCP for their patients with any of the following conditions: overweight, obesity, diabetes mellitus, elevated liver enzymes, or fatty liver detected by prior imaging. Patients with suspected NAFLD (i.e. other causes of chronic liver disease excluded) were then assessed by SWE, ordered directly by PCPs. NAFLD patients with liver stiffness by SWE ≥ 8 kPa (or inconclusive result) were referred to hepatology, and those with SWE <8.0 kPa were managed by their PCPs using a standardized CNCCP management pathway. ALT of 30 U/L for men and 25 U/L for women were considered the upper limit of normal.
Results: 1,944 NAFLD patients were enrolled in the CNCCP between March-October 2018. Within this patient cohort there were 577 (29.7%) patients with a normal ALT at enrollment in the CNCCP (baseline). NAFLD patients with normal ALT were likely older (median age: 57 vs. 54, $p < 0.001$) than patients with elevated ALT. Patients with normal and abnormal baseline ALT levels were similar according to sex, body mass index (BMI), having diabetes mellitus or hypertension. Patients with elevated ALT levels had similar FIB-4 scores as those patients with normal ALT levels (median 1.01 vs. 0.97, $p = 0.117$), but had lower NFS scores (median: −1.24 vs. −0.71, $p < 0.001$) and higher SWE results (4.5 vs. 4.3 kPa, $p < 0.001$). 26.6% of patients in the normal ALT cohort had FIB-4 >1.30, compared to 33.6% in the elevated ALT cohort ($p = 0.016$). 69.2% of patients with normal ALT levels had NFS >−1.45, compared to 54.7% with elevated ALT ($p = 0.001$). In addition, 3.3% of patients with normal ALT had elevated liver stiffness (SWE ≥ 8 kPa), compared to 3.5% with elevated ALT ($p = 0.809$). In adjusted logistic regression analyses, elevated ALT was an independent predictor of FIB>1.30 (adjusted OR 2.09, 95%CI: 1.51–2.91) and NFS >−1.45 (aOR: 0.51: 0.35–0.76), but was not a predictor of SWE>8.0 kPa (aOR: 1.44, 0.87–2.39).
Conclusion: In a large primary care-driven NAFLD pathway, 1/3 of patients had normal ALT levels (within recommended sex-based cutoffs). Elevated ALT associated inconsistently with serum-based fibrosis markers and liver stiffness. Therefore, risk-stratification of NAFLD patients within primary care should not be limited to patients with elevated transaminases.

FRI006

Non-invasive detection of NASH and significant fibrosis in NAFLD patients with low FIB-4

Stephanie Liebig[1], Simon Hohenester[2], Michael P. Manns[1], Heike Bantel[1]. [1]*Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*University of Munich, Department of Internal Medicine II, Munich, Germany*
Email: bantel.heike@mh-hannover.de

Background and Aims: Non-alcoholic steatohepatitis (NASH) and fibrosis play critical roles for the prognosis of patients with non-alcoholic fatty liver disease (NAFLD). Non-invasive methods to identify patients at risk for NASH or fibrosis are therefore crucial for disease management. The FIB-4 score, which is based on widely available and simple parameters (age, transaminases and platelets), has a high negative predictive value for advanced fibrosis (>90%) and has been therefore suggested as initial diagnostic approach. However, there is increasing evidence that also patients with NASH and early fibrosis are at significant risk of disease progression and complications, emphasizing the need for improved non-invasive risk stratification in NAFLD. Because hepatocyte apoptosis plays an early role in NASH pathogenesis, we evaluated whether the apoptosis biomarker M30, a neo-antigen generated by caspase-mediated keratin-18 cleavage, might identify NAFLD patients who are at risk of NASH and fibrosis despite low FIB-4 values.
Method and Results: Serum M30 levels were assessed by ELISA in combination with FIB-4 in a cohort of 103 patients with histological confirmed NAFLD. The majority of patients with low FIB-4 (cut-off value <1.3) revealed increased M30 levels (>200 U/L) and more than 80% of those had NASH, mostly with histological signs of fibrosis (43% of them with F2/F3 fibrosis). Importantly, most patients with FIB-4 <1.3 who revealed histological NASH despite non-elevated M30 levels showed no fibrosis. NASH was also detected in all patients with an intermediate FIB-4 score, i.e. between the low and high cut-off value (1.3 to 2.67), and elevated M30 levels, from which 81% showed fibrosis (F2-F4 fibrosis in almost half of cases). Similar results were obtained when considering a FIB-4 cut-off range of 1.3 to 3.25.
Conclusion: The combination of the M30 biomarker with FIB-4 enables a more reliable identification of patients with increased risk of progressed NAFLD and might be helpful for deciding which patient should be referred to a hepatologist and considered for liver biopsy.

Predictive modelling to identify and characterize fast progressors among patients with non-alcoholic steatohepatitis (NASH)

Brenda Reinhart[1], Matt Docherty[2], Maria Magdalena Balp[3], Stephane Régnier[3], Andreas Tietz[3], Jennifer Cai[4], Sanchita Porwal[5], Marcos Pedrosa[3], Jörn M. Schattenberg[6]. [1]*ZS Associates, Zurich, Switzerland;* [2]*ZS Associates, Princeton, United States;* [3]*Novartis Pharma AG, Basel, Switzerland;* [4]*Novartis Pharmaceuticals Inc, East Hanover, United States;* [5]*ZS Associates, Pune, India;* [6]*University Medical Center Mainz, Metabolic Liver Research Program, I. Department of Medicine, Mainz, Germany*
Email: brenda.reinhart@zs.com

Background and Aims: A subset of patients with non–alcoholic fatty liver disease (NALFD) and non-alcoholic steatohepatitis (NASH) progress more rapidly to cirrhosis or hepatocellular carcinoma (HCC) than typical patients. The purpose of this study was to develop a machine learning model to predict the progression risk to

end-stage liver disease using data available from standard clinical care and electronic health care records.

Method: The study was conducted in the Optum Electronic Health records (2007–2018 data from the United States). The study cohort was defined as patients with a diagnosis of cirrhosis or HCC (based on International Classification of Diseases codes ICD-9/ICD-10) most likely due to NAFLD/NASH after excluding any other causes of liver disease. Time of progression was established retrospectively from the date of cirrhosis or HCC to the first evidence of disease (index date), which was the first diagnosis of either NASH, NAFLD, or one of several comorbidities (e.g. type 2 diabetes, obesity) used as proxies. Patients were grouped by time to progression from the first evidence of disease to cirrhosis or HCC: fast progressors (<3 years), intermediate progressors (3 to 6 years), standard progressors (6–10 years). Each class of the cohort was profiled and statistical testing to identify differences between these classes was performed. A model to predict fast progressors class was developed and main covariates that separate fast and standard progressors were determined. Multiple machine learning classification techniques were tested and the best performing model selected. Covariates included: laboratory tests and observations; comorbidities; treatments for comorbidities; and rate of change of laboratory tests and observations.

Results: The study included 4,419 patients with cirrhosis (96.1%) or HCC (3.9%) due to NAFLD/NASH. Mean (standard deviation) age was 63.0 (12.6), BMI 34.9 (7.3), 65% were female, and the most common comorbidities were hypertension (59%), hyperlipidemia (54%), and type 2 diabetes (43%). Among these patients, 1,087 fast progressors, 2,070 intermediate progressors, and 992 standard progressors were identified. These three classes exhibited significantly different clinical and laboratory features with 55 out of 112 tested covariates separating fast progressors from standard progressors. These include age at cirrhosis/HCC, platelet count, albumin, aspartate aminotransferase, and triglycerides.

Conclusion: These results suggest that patients with different progression rates to end-stage liver disease could be identified in real-world medical records and support the finalization of a predictive algorithm for identification of NAFLD/NASH patients with the highest risk of progression.

FRI009

Non-invasive tests for assessing fibrosis in patients with non-alcoholic fatty liver disease: an evaluation of combining test results

Catherine Vick[1], Andrew Joyce[1], Amy Law[2], Molly Sherwood[1], Essy Mozaffari[2], Bruce Wong[2]. [1]*Venebio Group, LLC, Richmond, United States;* [2]*Intercept Pharmaceuticals Inc, New York, United States*
Email: catherine.vick@venebio.com

Background and Aims: Fibrosis in non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) is often assessed histologically. However, liver biopsy is expensive, invasive, and can be associated with sampling variations. Multiple non-invasive tests (NITs) have been developed to assess hepatic fibrosis but have suboptimal performance characteristics when used individually. The aim of this analysis is to provide a construct to assess the potential utility of combining NITs based on literature and identify key issues when developing a multi-test testing strategy.

Method: Primary literature in English on 7 NITs, including NAFLD Fibrosis Score (NFS), Fibrosis-4 (FIB-4) index, aspartate aminotransferase-to-platelet ratio index (APRI), enhanced liver fibrosis (ELF) panel, FibroSURE, transient elastography (TE), and magnetic resonance elastography (MRE), for fibrosis assessment in NAFLD and NASH patients was reviewed. Study characteristics, NIT attributes and test performance measures (e.g., sensitivity, specificity) were abstracted. Sensitivity and specificity were combined in probabilistic calculations to approximate parallel (i.e., simultaneous) or serial (i.e., sequential) test strategies. Pairwise test combinations were limited to those within specific studies to reduce spectrum bias.

Results: Data from 61 full text publications were abstracted, yielding 750 records on test performance for various subpopulations and NITs. Combinations in which both tests must be positive reduced sensitivity, but increased specificity; the opposite was true with testing in which only one of the tests was required to be positive. Results varied depending on the study from which combinations were calculated, individual study populations, and level of fibrosis detected. Amongst all pairwise combinations explored in this limited pilot - APRI or NFS, and Fibroscan or NFS - had both sensitivity and specificity greater than 80% for detecting fibrosis greater than or equal to stage 2.

Conclusion: This exploratory examination based on probabilistic calculations of the literature on NITs and fibrosis in NASH/NAFLD found the test performance of combinations to be variable. Pairwise combinations of NITs in which either test can be positive via a parallel or serial process could increase sensitivity for accurately staging fibrosis, reducing the need for liver biopsy. Additional research is needed to account for spectrum bias and multiple threshold cutpoints.

FRI010

^{13}C-Octanoate breath test in a predictive score for the diagnosis of non-alcoholic steatohepatitis

Carmen Fierbinteanu Braticevici[1], Moldoveanu Alexandru[1], Vlad Enciu[1], Roxana Sararu[1]. [1]*"Carol Davila" University of Medicine and Pharmacy Bucharest, Gastroenterology Department, University Hospital Bucharest, Bucharest, Romania*
Email: cfierbinteanu@yahoo.com

Background and Aims: Many studies have highlighted the importance of identifying the Nonalcoholic Steatohepatitis (NASH) subgroup, which carries a higher risk of morbidity/mortality with important prognostic implications. Hepatic mitochondrial dysfunction has been involved in progression of Nonalcoholic Fatty Liver to NASH especially by oxidative stress. The ^{13}C-Octanoate breath test (OBT), enables mitochondrial activity evaluation, as a source of oxidative stress, implicated in the development of nonalcoholic steatohepatitis. The aim is to develop a non-invasive score for identifying NASH among patients diagnosed with NAFLD.

Method: 68 patients with histological proven NAFLD were included in the study. Liver biopsy was performed for abnormal liver function tests and suspected NAFLD by greyscale ultrasonography. All patients underwent standard biochemistry as well as stable isotope breath tests with ^{13}C-Octanoate (OBT). The relevant parameters were determined using Independent Samples T test and incorporated into a formula using logistic regression. The formula was calculated as (74 X [C13-Octanoate Dose/h at 30 min] + 15 X [Cholesterol] + 7 X [Triglycerides] – 35)/100. The accuracy of the score was evaluated using the area under the ROC curve and its ability to establish diagnosis using a predetermined cutoff (35) was evaluated using chi-square test

Results: Patients were divided in two groups according to the histologic characteristics: 32 patients with steatosis and 36 patients with NASH. Patients with steatohepatitis had significantly increased 13C-Octanoate results (23.54 vs 18.29, $p < 0.001$), increased cholesterol (202.92 vs 172.45 $p = 0.030$) and increased triglycerides (178.95 vs.124.84 $p = 0.005$). The score had an area under the ROC curve of 0.953 (95%CI 0.863–1.000, $p < 0.001$). Using a cutoff value of 35, the score had significant results in the chi-squared test ($p < 0.001$) and presented with a sensitivity of 100% (95%CI 92.13%–100%), specificity of 95.65% (95%CI 78,05%–99.89%), PPV of 97.83% (95%CI 86.87%–99.67%) and NPV of 100%. Overall accuracy was 98.53% (95%CI 92.08–99.96%).

Conclusion: A non-invasive score containing the main parameters associated with NASH pathogenesis, may be useful for diagnosis, avoiding the need for many liver biopsies.

FRI011

Interplay between metabolic derangement, biomarkers of collagen remodeling and macrophage activation in non-diabetic patients with non-alcoholic fatty liver disease

Chiara Rosso[1], Ramy Younes[1], Diana Leeming[2], Rambabu Surabattula[3], Gian Paolo Caviglia[1], Melania Gaggini[4], Angelo Armandi[1], Antonella Olivero[1], Maria Lorena Abate[1], Amalia Gastaldelli[4], Detlef Schuppan[3], Elisabetta Bugianesi[1].

Email: chiara.rosso@unito.it

Background and Aims: The pathogenesis of Non-Alcoholic Fatty Liver Disease (NAFLD) and steatohepatitis (NASH) is likely due to the interaction between a deranged metabolic milieu and local mediators of hepatic inflammation and fibrosis. We investigated a panel of serum non-invasive biomarkers of collagen remodelling and explored their association with metabolic derangements and liver damage to elucidate their complex interplay in a well-characterized cohort of non-diabetic NAFLD patients.
Method: We enrolled 52 non-diabetic subjects with biopsy proven NAFLD who underwent a double tracers oral glucose tolerance test. Using tracers data we measured endogenous glucose production (EGP) and lipolysis by glycerol rate of appearance (GlycRa) and we calculated indexes of IR in the liver (Hep-IR = EGP × insulin) and in the adipose tissue (Lipo-IR = GlycRa × insulin and AT-IR = free fatty acids × insulin). Fasting c-peptide (CP) levels were measured using a chemiluminescence assay. Fibrogenesis biomarkers PRO-C3 and PRO-C6 as well as macrophage activation biomarker sCD163, were measured by ELISA. Histology was scored according to Kleiner.
Results: Overall, fasting CP, PRO-C3, PRO-C6 levels directly correlated with BMI and waist circumference (all $p < 0.03$). Among IR indexes, PRO-C3 and PRO-C6 correlated with Hep-IR ($r_S = 0.32$, $p = 0.025$; $r_S = 0.38$, $p = 0.006$), adipo-IR (both Lipo-IR [$r_S = 0.36$, $p = 0.010$; $r_S = 0.37$, $p = 0.007$] and AT-IR [$r_S = 0.36$, $p = 0.010$; $r_S = 0.37$, $p = 0.008$]) as well as with basal insulin ($r_S = 0.3$, $p = 0.005$ and $r_S = 0.34$, $p = 0.013$) and CP levels ($r_S = 0.51$, $p < 0.001$; $r_S = 0.55$, $p < 0.001$). On the opposite, sCD163 levels did not correlate with insulin levels but increased proportionally with adipo-IR (both Lipo-IR [$r_S = 0.28$, $p = 0.05$] and AT-IR [$r_S = 0.30$, $p = 0.032$]). Concerning the ability to discriminate hepatic fibrosis, CP and PRO-C6 levels were able to distinguish F0/F1 from F2 ($p = 0.013$; $p = 0.05$, respectively) while PRO-C3 and sCD163 levels discriminated F2 from F3/F4 ($p = 0.009$; $p = 0.002$, respectively). By biomarkers combination, the best performance for the identification of F3/F4 was obtained with CP and sCD163 with an area under the receiver operating curve (AUROC) of 0.91 (PPV = 83%; NPV = 91%).
Conclusion: In non-diabetic patients with NAFLD, the combination between CP and sCD163 provides the best performance for the assessment of severe fibrosis (F3/F4) yielding both a high positive and negative predictive value.

Comparison of diagnostic accuracy of magnetic resonance ideal-iq sequence and controlled attenuation parameter for detecting liver steatosis

Xiaoling Chi[1], Meijie Shi[1], Huanming Xiao[1], Yubao Xie[1], Pengtao Zhao[1], Junmin Jiang[1], Gaoshu Cai[1], Shuduo Wu[1], Yingxian Li[1], Chaozhen Zhang[1], Sheng Li[1], Yupin Liu[2], Yu Yang[3]. *[1]Guangdong Provincial Hospital of Chinese Medicine, The Second Affiliated Hospital of GuangzhouUniversity of Chinese Medicine, Hepatology, Guangzhou, China; [2]Guangdong Provincial Hospital of Chinese Medicine, The Second Affiliated Hospital of GuangzhouUniversity of Chinese Medicine, Radiology, Guangzhou, China; [3]Guangdong Provincial Hospital of Chinese Medicine, The Second Affiliated Hospital of GuangzhouUniversity of Chinese Medicine, Pathology, Guangzhou, China*
Email: chixiaolingqh@163.com

Background and Aims: It is well known that quantitative detecting liver steatosis is an essential step before treating Non-alcoholic Fatty Liver Disease (NAFLD). Magnetic resonance iterative decomposition of water and fat with Echo asymmetry and the Least Squares Estimation Quantification sequence (MR IDEAL-IQ) and Controlled Attenuation Parameter (CAP) are two noninvasive methods for quantitative detecting liver steatosis. No data reported that whether MR IDEAL-IQ or CAP is more accurate for detecting liver steatosis in NAFLD patients. So, the aim of this study was to compare the diagnostic accuracy of MR IDEAL-IQ sequence and CAP for detecting liver steatosis in NAFLD patients.
Method: One hundred thirty four patients with biopsy-proven NAFLD from Octorber 2016 to November 2019 were enrolled in this study and all of them were performed with MR IDEAL-IQ and CAP at the same period. Steatosis grade was defined according to the percentage of affected hepatocytes: S1 5–33%, S2 34–66%, S3 >67%. Area under receiver-operator curve (AUC) was used to calculate the diagnostic accuracy of these above two noninvasive tests.

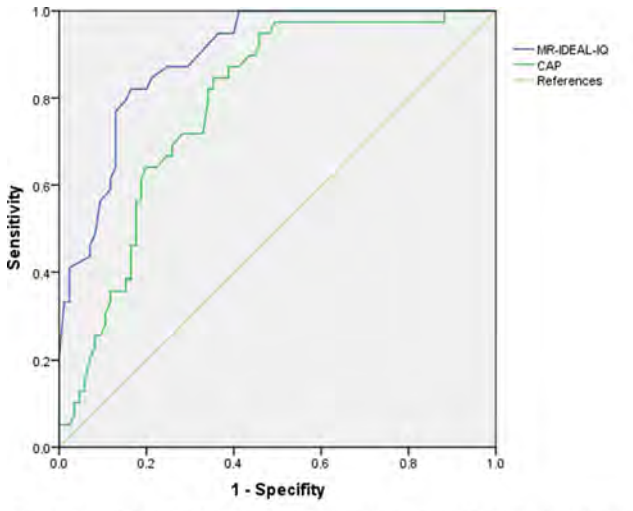

Fig.1 RCO curves for MR-IDEAL-IQ and CAP in detecting liver steatosis S≥3 in NAFLD patients

Results: Among the 134 NAFLD patients, 36, 52, 46 patients showed S1, S2, S3 respectively. The summary AUROC values using MR IDEAL-IQ and CAP for detecting steatosis $S \geq 2$ were 0.900 vs. 0.845 ($P = 0.229$) and $S \geq 3$ were 0.895vs. 0.785 ($P = 0.025$), respectively. The pooled sensitivity and specificity using CAP for the diagnosis of steatosis $S \geq 2$ and $S \geq 3$ were 71.4% and 87.9%, 84.6% and 64.7%, respectively. The pooled sensitivity and specificity using MR IDEAL-IQ for the diagnosis of steatosis $S \geq 2$ and $S \geq 3$ were 79.1% and 87.9%, 82.1% and 83.5%, respectively.

Conclusion: MR IDEAL-IQ is more accurate than CAP in diagnosing liver steatosis in patients with NAFLD, especially in diagnosing steatosis S ≥ 3.

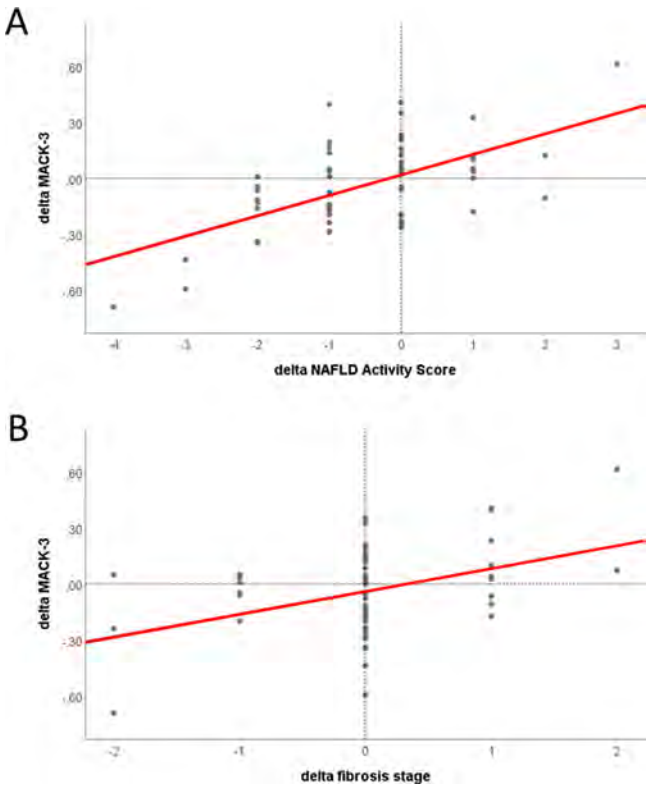
FRI013

MACK-3: an accurate blood test for the diagnosis of fibrotic NASH and a candidate biomarker to monitor disease progression

Clémence Canivet[1,2], Valérie Moal[3], Floraine Zuberbuhler[1,2], Lannes Adrien[1,2], Sophie Michalak[4], Marine Roux[1], Frédéric Oberti[1,2], Isabelle Fouchard[1,2], Paul Cales[1,2], Jerome Boursier[1,2]. *[1]Université d'Angers, Laboratoire HIFIH, Angers, France; [2]Centre Hospitalier Universitaire, Service d'Hépato-Gastroentérologie, Angers, France; [3]Centre Hospitalier Universitaire, Département de Biochimie et Génétique, Angers, France; [4]Centre Hospitalier Universitaire, Département de Pathologie Cellulaire et Tissulaire, Angers, France*
Email: jeboursier@chu-angers.fr

Background and Aims: MACK-3 is a blood test combining AST, HOMA and CK18 for the diagnosis of fibrotic NASH (NASH + NAS ≥ 4 + F ≥ 2), which is the inclusion criteria in NASH therapeutic trials. We aimed to validate the accuracy of MACK-3 in NAFLD.

Method: Cross-sectional study: 152 biopsy-proven NAFLD patients were prospectively included in our centre. Liver biopsies were scored by an expert pathologist using the NASH CRN classification. MACK-3 thresholds to rule-out and rule-in fibrotic NASH were, respectively, <0.135 and >0.549 (PMID 29577364). Longitudinal study: 57 additional patients with paired liver biopsies were retrospectively recruited to evaluate the ability of MACK-3 to monitor disease evolution.



Results: Cross sectional study. Mean age was 57.8 ± 11.4, male gender: 61%, BMI: 33.4 ± 6.2 kg/m^2, diabetes: 48%, fibrotic NASH: 41%. AUROC of MACK-3 for fibrotic NASH was 0.80 ± 0.04. At the lowest MACK-3 threshold (<0.135), sensitivity was 95% and negative predictive value was 93%. At the highest threshold (>0.549), specificity was 87% and positive predictive value was 68%. Among the 12 patients with false-positive result, 3 had advanced F3-4 fibrosis, 1 had NASH + F2, 2 had ballooning + F2, and 2 had NASH + NAS4. Longitudinal study: At baseline, 63% of patients had fibrotic NASH, mean NAFLD activity score (NAS) was 4.5 ± 1.3, and fibrosis stage were: F1: 16%, F2: 30%, F3: 46%, F4: 9%. Median follow-up was 2.5 years (1st quartile: 1.7; 3rd quartile: 4.7). The evolution of MACK-3 well correlated with the evolution of NAS (Rs = 0.48, p < 0.001; Figure A) and with the evolution of fibrosis stage (Rs = 0.31, p < 0.001; Figure B).

Conclusion: MACK-3 is an accurate blood test for the diagnosis of fibrotic NASH. It can be used to select patients for therapeutic trials and, once the new drugs for NASH will be approved, to identify patients who need to be treated in clinical practice. Because it well correlates with the evolution of liver lesions, MACK-3 is a candidate biomarker to monitor disease progression and assess treatment response.

Arrais de Souza[2], Jose Tadeu Stefano[3], Sebastián Marciano[4], Erika Yvamoto[2], Matheus Truccolo Michalczuk[5], Denise Siqueira Vanni[2], Hernan Rodriguez[6], Flair Jose Carrilho[3,7], Mario Reis Álvares-da-Silva[5], Marco Arrese[6], Adrian Gadano[4], Adelina Lozano Miranda[1], Claudia Oliveira[3,7]. *[1]Hospital Nacional Arzobispo Loayza, Lima, Peru; [2]Departamento de Gastroenterologia e Hepatologia do Hospital das Clínicas HCFMUSP da Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brasil; [3]Laboratório de Gastroenterologia Clínica e Experimental (LIM-07) do Departamento de Gastroenterologia e Hepatologia do Hospital das Clínicas HCFMUSP da Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brasil; [4]Hepatología Departamento de Investigación Hospital Italiano de Buenos Aires; [5]Division of Gastroenterology, Hospital de Clinicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [6]Departamento de Gastroenterología Escuela de Medicina, Pontificia Universidad Católica de Chile Santiago, Chile; [7]Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brasil*
Email: cpm@usp.br

Background and Aims: Several non-invasive scoring systems have been developed and validated to predict the risk of significant fibrosis in nonalcoholic fatty liver disease (NAFLD) in different scenarios over the world. However, it is scarce in Latin America and needs better validation in different countries in this region. Our aim was to evaluate the performance of three non- invasive fibrosis scores [Hepamet Fibrosis Score, Fibrosis-4 (FIB-4) and NAFLD Fibrosis Score (NFS)] in a mixed Latin America population.

Method: We conducted a retrospective cross-sectional study of 419 biopsy-proven NAFLD patients attending tertiary medical centers in Latin America. The diagnosis of NAFLD was based on histological criteria and fibrosis stages were determined according to using NASH CRN criteria. Clinical and laboratorial data were collected in the interval between three months before and three months after liver biopsy. According to liver biopsy results, histological fibrosis stages were classified as: significant fibrosis (F2-F3-F4); advanced fibrosis (F3-F4); and cirrhosis (F4). We calculated three non-invasive fibrosis scores: Hepamet, FIB-4 and NFS. Each score performance was evaluated through measurements of accuracy, sensibility, specificity, positive predictive value, negative predictive value and area under the ROC curve (AUROC).

Results: A total of patients with NAFLD were evaluated, being 240 (Brazil) 159 (Peru) 61 (Argentina). Among them the majority of patients were female (77%, 74%, 62,2%) respectively, with a mean age lower in Peru 38.96 (±10.38), than Brazil, 54.55 (±10.22), Argentina, 57.7 (+12.22). The mean body mass index (BMI) was 30.86 (±5.51) in Brazil, 38.36 (±6.07) in Peru, 30.80 (+4.66) in Argentina. The sample distribution of fibrosis stages on liver biopsies were as follows: Brazilian population: 17.1% F0, 38.8% F1, 9.1% F2, 26.8% F3 and 8% F4;

Peru population 55.3% F0, 18.2% F1, 1.2% F2, 21.3% F3 and 3.7% F4; Argentina population 27.8% F0, 36% F1, 22.9% F2, 8.1% F3 and 4.9% F4. The Hepamet AUROC for the detection of significant and advanced fibrosis was significantly higher than NFS in all three populations (Brazil, Peru and Argentina with $p = 0.03$; $p < 0,001$; $p = 0.004$, respectively and it was similar to FIB4 in all cohort.
Conclusion: The performance of both, FIB-4 and Hepamet scores, were satisfactory and similar to detect significant and advanced fibrosis in NAFLD Latin America population. This is the first study that validated Hepamet score in a mixed Latin America Population and compared with two validated scores.

FRI015
Identification of significant fibrosis in patients with non-alcoholic steatohepatitis using non-invasive tests: determination of optimal thresholds based on cross-sectional analyses of patients screened for a phase 3 randomised controlled trial
Darshini Shah[1], Xiaomeng Niu[1], Jalpa A. Doshi[2], Steve Marcus[3], Gerardo Rodriquez[4], Elliot Tapper[5]. *[1]Allergan plc, Madison, United States; [2]Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States; [3]School of Social Policy & Practice, University of Pennsylvania, Philadelphia, United States; [4]Allergan plc, Irvine, United States; [5]Division of Gastroenterology and Hepatology, University of Michigan, Michigan, United States*
Email: Darshini.Shah@allergan.com

Background and Aims: Few patients receive liver biopsies for diagnosis and staging of nonalcoholic steatohepatitis (NASH) in clinical practice. Where biopsy data are lacking, non-invasive tests (NITs) could identify patients with NASH fibrosis. However, whereas the performance and diagnostic cutoffs for NITs have been conditioned on fibrosis stages 3–4, there are limited data for stage ≥ F2. As NASH therapies in development seek to target people with ≥ F2, capacity to conduct real-world research in such patients is hindered. Using the screening database for entry into AURORA (Phase 3 trial to assess efficacy and safety of cenicriviroc for treatment of NASH fibrosis) we sought to determine the optimal thresholds on NITs for identifying significant fibrosis.
Method: The AURORA screening database included 2056 subjects with NASH who underwent screening liver biopsy and 3 NITs: FIB-4, NFS, and APRI. Liver biopsy was the gold standard and subjects were dichotomised as significant (NASH Clinical Research Network [CRN] F2-F4) or non-significant (NASH CRN F0-F1) fibrosis. Receiver operating characteristic (ROC) curves determined thresholds based on 3 NITs. The predictive accuracy of each NIT was evaluated using logistic regression. We selected 2 thresholds to maximise classification accuracy: a low threshold below which subjects were unlikely to have significant fibrosis (optimised for sensitivity ≥ 90%) and a high threshold above which subjects were likely to have significant fibrosis (optimised for specificity ≥ 90%).

Test	Cut-off	Sensitivity (%)	Specificity (%)	NPV (%)	PPV (%)	Total (n)
FIB-4	≥1.79	31	91	34	90	488
	≤0.62	93	21	55	75	223
APRI	≥0.8	27	92	33	90	447
	≤0.2	96	12	55	74	155

Results: Distribution of subjects by fibrosis stage was F0 = 118 (6%), F1 = 459 (22%), F2 = 605 (29%), F3 = 765 (37%), F4 = 109 (5%). Area under the ROCs to discriminate significant fibrosis were acceptable for FIB-4 (0.71; 95% CI: 0.68–0.73) and APRI (0.69; 95% CI: 0.66–0.71). The thresholds determined on FIB-4 and APRI were ≥ 1.79 and ≥ 0.8 (likely to have significant fibrosis) and ≤ 0.62 and ≤ 0.2 (unlikely to have significant fibrosis), respectively (see Table).
Conclusion: This study is the first to identify optimal thresholds for NITs to identify significant fibrosis among NASH patients. FIB-4 and APRI can be used to identify significant fibrosis with an acceptable level of accuracy. Future research using other clinical trial and real-world cohorts should be conducted to further validate these results.

Patients with non-alcoholic fatty liver disease referred from primary care have a significant serum fibrosis marker and liver stiffness measurement discordance
David Harman[1], Oliver Duncan[1], Nicola Slatter[2], Jeremy Tomlinson[3], Nishan Guha[3], Tim James[3], Jeremy Cobbold[1]. *[1]Oxford University Hospitals NHS Foundation Trust, Hepatology, Oxford, United Kingdom; [2]Oxford University Hospitals NHS Foundation Trust, Diabetes and Endocrinology, Oxford, United Kingdom; [3]Oxford University Hospitals NHS Foundation Trust, Clinical Biochemistry, Oxford, United Kingdom*
Email: david.harman13@gmail.com

Background and Aims: The utilisation of serum and imaging biomarkers for diagnosis of liver fibrosis in non-alcoholic fatty liver disease (NAFLD) has increased. Understanding the concordance of serum fibrosis markers and Transient Elastography (TE) may help further optimise primary care referral pathways. In NAFLD this has had limited study. We present analysis from our primary care NAFLD algorithm of factors associated with serum fibrosis marker and TE concordance.
Method: A primary care NAFLD stratification pathway introduced by Oxford University Hospitals NHS Foundation Trust and Oxfordshire Clinical Commissioning Group was established in November 2017. Investigations are requested electronically by primary care. Patients with high risk FIB-4 (>2.67), or intermediate FIB-4 (1.30–2.67) with elevated ELF score (>= 9.5) are referred to a specialist Metabolic liver clinic. Patients aged <35 years directly undergo ELF testing, with a high risk threshold of >= 9.0. TE is performed routinely in clinic. Liver stiffness measurement (LSM)>= 8 kilopascals (kPa) is considered indicative of significant fibrosis. Results were considered concordant if patients with high risk FIB-4 or ELF scores had LSM>=8 kPa, and discordant if <8 kPa. Factors associated with biomarker concordance were assessed.
Results: Between November 2017 and May 2019, 670 patients were investigated on the pathway. Of 139 referred to liver clinic (110 with high risk ELF score and 29 with high risk FIB-4), valid LSM was obtained in 119 patients. Elevated LSM results were seen in 63.4% of patients with high FIB-4 and 56% of patients with high ELF. With a revised ELF threshold of 10, 54.2% of patients had elevated LSM. Overall, 28 patients with concordant results underwent liver biopsy; >=F3 fibrosis was seen in 17 (60.7%). Only 4 patients with discordant results underwent liver biopsy, of whom 1 (25%) had >=F3 fibrosis. Diagnoses of advanced fibrosis and cirrhosis were given in 54.3% and 31.4% of patients with concordant results, but only 1 patient (2%) with discordant results. Patients with concordant results were more likely to have type 2 diabetes (50.7% vs. 14%; $p < 0.01$) or obesity (72.6% vs. 51.1%; $p = 0.02$). No factors, including joint disease or Age, were associated with discordant results.
Conclusion: A significant percentage of NAFLD patients with elevated FIB-4 or ELF scores referred from primary care have normal liver stiffness. This impacted on both liver biopsy utilization, and diagnosis of advanced fibrosis and cirrhosis. No factors could be identified to predict discordant serum and LSM results.

FRI017

Comparison of point-shear wave elastography (ElastPQ) and fibroscan transient elastography (F-TE) for liver fibrosis staging in patients with NAFLD

Davide Roccarina[1], Laura Iogna Prat[1], Giada Pallini[1], Marta Guerrero[1], Elena Buzzetti[1,2], Francesca Saffioti[1,3], Francesco Aricó[1,4], Anna Mantovani[1,5], Matteo Rosselli[1], Massimo Pinzani[1], Emmanuel Tsochatzis[1]. *[1]UCL Institute for Liver and Digestive Health, Royal Free Hospital and UCL, London, United Kingdom; [2]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences SMECHIMAI, Division of Medicine and CeMEF, Modena, Italy; [3]University of Messina, Department of Clinical and Experimental Medicine, Division of Clinical and Molecular Hepatology, Messina, Italy; [4]University Hospital and School of Medicine of Messina, Department of Internal Medicine, Messina, Italy; [5]Azienda Ospedaliera Universitaria Integrata, University of Verona, Division of General Medicine and Hypertension, Department of Medicine, Verona, Italy*
Email: davideroccarina@gmail.com

Background and Aims: ElastPQ is a point shear wave elastography technique used to non-invasively assess liver fibrosis. We compared liver stiffness measured by both ElastPQ and Fibroscan Transient Elastography (F-TE) in a cohort of consecutive patients with NAFLD. We further evaluated the performance of ElastPQ in a subgroup of patients with available liver histology.

Method: Anthropometric parameters (weight, height, BMI and waist circumference (WC)) were measured on the same day of routine bloods tests. Elastography measurements were carried out using F-TE (Echosens, Paris) and ElastPQ (Affiniti 70G, Philips) in all recruited patients. We considered liver biopsies performed within one year of the non-invasive assessment.

Results: We enrolled 546 consecutive patients with NAFLD, mean age 56 ± 13 y, BMI 31.9 ± 6.4 kg/m^2, WC 107.6 ± 15.5 cm, 57% male; 42% had diabetes, 55% hypertension, 72% hyperlipidaemia.

ElastPQ showed a good correlation with F-TE (CCC Lin's = 0.91, 95%CI 0.90–0.93, p < 0.001), which was better for mild and moderate stages of fibrosis. A ≥ 2 kPa difference between the two techniques was found in 128 (23.4%) patients. On multivariate analysis, the only independent predictor of such difference was F-TE ≥ 10 kPa (OR: 6.93, 95% CI 4.04–11.90, p < 0.001).

	ElastPQ				FIBROSCAN				
	Cut-off (kPa)	Sensitivity (%)	Specificity (%)	AUC	Cut-off (kPa)	Sensitivity (%)	Specificity (%)	AUC	P value*
F ≥ 2	7.8	77	77	0.80	7.8	84	78	0.82	0.515
F ≥ 3	8.9	81	76	0.86	9.8	78	76	0.83	0.741
F 4	13.4	90	90	0.97	13.5	84	85	0.91	0.637

In the subgroup of 142 patients with available histology, the distribution of fibrosis was as follow: F0 = 20 (14%), F1 = 48 (34%), F2 = 26 (18%), F3 = 29 (21%), F4 = 19 (13%).

The optimal cut-off values of ElastPQ for individual stages of fibrosis were similar to those obtained for F-TE. ElastPQ showed the same diagnostic performance of F-TE in all stages of fibrosis (Table 1).

Conclusion: ElastPQ and F-TE showed an excellent correlation in patients with NAFLD, which is better for low values of liver stiffness. The optimal cut-off values of ElastPQ are similar to those of F-TE for individual stages of fibrosis. ElastPQ has similar diagnostic accuracy to F-TE for all stages of fibrosis. ElastPQ, as well as F-TE, performs better to diagnose the presence of liver cirrhosis.

FRI018

Digital image analysis for quantitative evaluation of fibrosis, steatosis, inflammation and iron overload in patients with non-alcoholic fatty liver disease

David Marti-Aguado[1,2,3], Alejandro Rodríguez-Ortega[2], Claudia Mestre[4], Monica Bauza[5], Elena Valero-Pérez[6], Judith Pérez[5], Antonio Ferrández[4,7], Salvador Benlloch[8], Desamparados Escudero-García[1,7], Miguel Serra[7], Angel Alberich-Bayarri[2], Luis Marti-Bonmati[2,7,9]. *[1]Clinic University Hospital, Hepatology Department, Valencia, Spain; [2]Hospital Universitario y Politécnico de La Fe, Biomedical Imaging Research Group (GIBI230), Valencia, Spain; [3]Instituto Salud Carlos III, Rio Hortega, Madrid, Spain; [4]Clinic University Hospital, Pathology Department, Valencia, Spain; [5]Hospital Universitario y Politécnico de La Fe, Pathology Department, Valencia, Spain; [6]Hospital Universitario y Politécnico de La Fe, Hepatology Department, Valencia, Spain; [7]University of Valencia, Faculty of Medicine, Valencia, Spain; [8]Hospital Arnau Vilanova, Hepatology Department, Valencia, Spain; [9]Hospital Universitario y Politécnico de La Fe, Radiology Department, Valencia, Spain*

Background and Aims: Liver biopsy is frequently used for the assessment of liver disease severity in patients with non-alcoholic fatty liver disease (NAFLD). Interpretation of biopsies is based on semiquantitative scoring systems, carrying a risk of misclassification. In the present study, we evaluate the relationship between biopsy grading scores and the corresponding amount of collagen, fat, inflammation and iron quantified by computer-assisted digital image analysis (DIA).

Method: Prospective, multicenter, comparative study of digital pathology for the quantification of histologic features in liver biopsies of subjects with suspected-NAFLD. Samples were stained with: Picrosirius red for fibrosis detection, Perl's stain for iron, immunohistochemistry with adipophilin for fat and CD45 for inflammation. Grading scores included: METAVIR for fibrosis, Nonalcoholic Steatohepatitis Clinical Research Network (NASH-CRN) for steatosis and inflammation, and Deugnier for iron deposits. Stained tissue sections were scanned (Ventana iScan HT®) for DIA. Quantitative variables were expressed as proportional areas (%) of collagen (CPA); fat (FPA); inflammation (IPA); and iron (FePA). Statistical analysis was performed using ANOVA test for comparisons of DIA data among corresponding semiquantitative groups (METAVIR, NASH-CRN); and Spearman's co-efficient for correlation of quantitative data (Deugnier).

Results: The study included 80 patients (58% women; median age, 55 years; range, 48–63) with a median body mass index of 29 (range, 24–32). Median length and portal tracts of biopsies were 21 mm (range, 17–24) and 10 (range, 7–13) respectively. CPA values increased significantly with fibrosis stages (7.4 ± 1.9, 8.7 ± 1.3, 8.8 ± 1.3, 10.1 ± 2.4 and 13.5 ± 2.3, F0-F4 respectively, p < 0.001). FPA values increased significantly with steatosis stages (3.5 ± 2.2, 9.1 ± 5.0, 13.0 ± 4.2, and 20.3 ± 9.4, S0-S3 respectively, p < 0.001). IPA values were significantly different between inflammation stages (5.1 ± 1.7, 6.2 ± 1.8, 7.2 ± 3.3, and 9.9 ± 4.3, I0-I3 respectively p = 0,001). FePA correlated significantly with Deugnier's score (r = 0.84; p < 0.001). Results are represented in Figure 1.

Conclusion: Computational DIA provides an accurate evaluation of histological features in NAFLD, showing a high correlation with current semiquantitative scores. DIA measurements should be now validated towards in vivo non-invasive biomarkers.

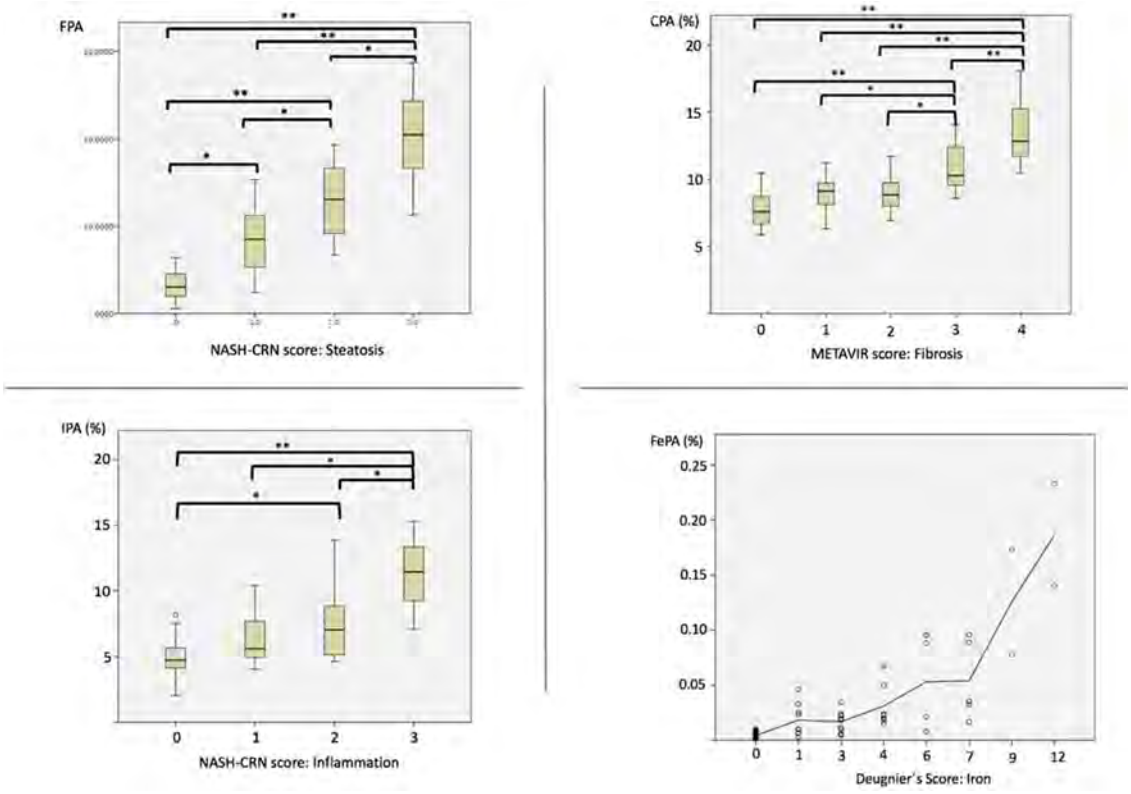

Figure: (abstract: FRI018): Distribution of DIA data across semiquantitative histologic scores.

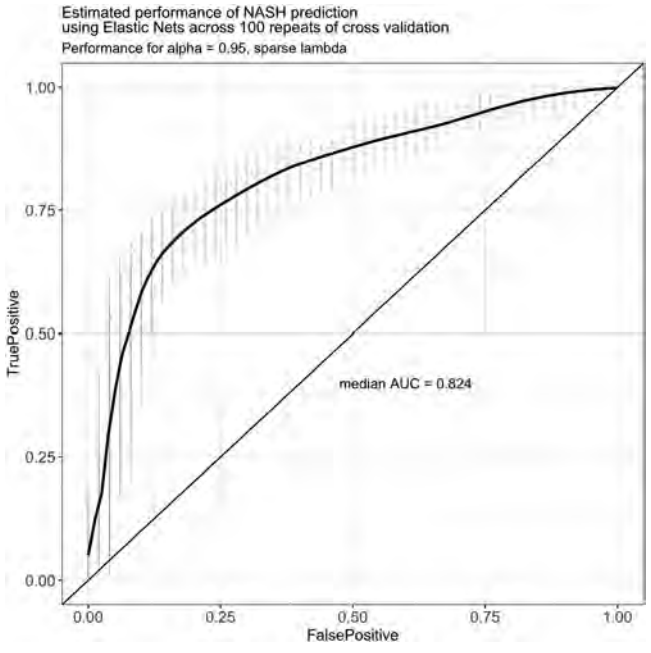
Metabolomics composite biomarkers selected by machine learning predicts NASH

Elizabeth Brown[1], Azza Karrar[2], Samuel Hellings[1], Maria Stepanova[3], Bethane Warrack[1], Brian Lam[2], Joelle Onorato[1], Sean Felix[2], Abraham Apfel[1], Thomas Jeffers[2], Bijal Rajput[2], Edgar Charles[1], Fatema Nader[2], Yi Luo[1], Michael Reily[1], Lei Zhao[1], John Thompson[1], Zachary Goodman[4], Zobair Younossi[2,4]. *[1]Bristol-Myers Squibb, Lawrence Township, United States; [2]Betty and Guy Beatty Centre for Integrated Research, Inova Health System, Falls Church, United States; [3]Centre for Outcomes Research in Liver Diseases; [4]Centre for Liver Disease, Department of Medicine, Inova Fairfax Medical Campus, Falls Vhurch, United States*

Email: zobair.younossi@inova.org

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) affect about 25% of the US population. Additionally, 1.5–6.5% have the progressive form of NAFLD or non-alcoholic steatohepatitis (NASH). Currently the diagnosis of NASH requires a liver biopsy and a serum based non-invasive test will be highly desirable. Here we use broad metabolic profiling of biopsy-proven NAFLD patients' serum samples to discover potential metabolite biomarkers of NASH and develop predictive composite biomarkers to diagnose it.

Method: Serum samples were obtained from 100 biopsy-proven NASH (F0-F4) and 50 NAFLD patients without NASH (simple steatosis or NAFL). We used liquid-chromatography mass-spectrometry (LCMS) to characterize metabolite fluorescent intensities. For 235 metabolites detected in >50% of the samples, we log2 and quantile normalized the data. Controlling for plate, age, sex, and diabetes, we applied limma to model metabolite associations with all NASH (F0-F4) vs NAFL, NASH with significant fibrosis (F2-F4) vs NAFL and early NASH (F0-F1), advanced NASH (F3-F4) vs NAFL and early NASH, and NASH F4 vs NASH F3 with Benjamini-Hockberg multiple testing correction. We also used the glmnet package in R to conduct the Elastic Nets algorithm with cross-validation to reduce the number of biomarkers and clinical predictors, and obtain two models to predict all NASH and advanced fibrosis. We applied repeated loops of cross-validation to predict out-of-sample performance of our selected models by area under the curve (AUC) of the receiver operating characteristic (ROC).



Results: We detect substantial signatures of metabolites associated with NASH (52 for adjusted p < 0.1) and advanced stages of NASH. In particular, we see strong down-regulation of many dicarboxylic acids and broad upregulation of secondary bile acids. Applying elastic nets with cross-validation, we find that 12 metabolites plus patient diabetes status classify NASH vs NAFL patients with predicted out-of-sample power AUC = 0.824. In addition to dicarboxylic and bile acids, predictors include lipid and microbiome-derived metabolites.
Conclusion: Using broad metabolomic profiling, we have discovered many potential biomarkers associated with NASH and advanced NASH. In particular, we have strong predicted performance to use composite metabolic biomarkers to distinguish NASH patients from those with NAFL, an unmet clinical need for NASH diagnostics. This should be validated in independent cohorts.

FRI021

Diagnostic accuracy of acoustic radiation force impulse elastography for the staging of hepatic fibrosis in non-alcoholic fatty liver disease: a systematic review and meta-analysis

Emmanuel Selvaraj[1,2,3], Hadi Zamarfand[4], Ferenc Mozes[1], Arjun Jayaswal[1], Christina Levick[1,2], Naaventhan Palaniyappan[5], Chang-Hai Liu[6], Guruprasad Aithal[5], Manuel Romero Gomez[6], Stefan Neubauer[1,3], Stephen Harrison[1], Quentin Anstee[7], Patrick Boussy[4], Michael Pavlides[1,2,3]. *[1]Oxford Centre for Clinical Magnetic Resonance Research (OCMR), Radcliffe Department of Medicine, University of Oxford, United Kingdom; [2]Translational Gastroenterology Unit, Nuffield Department of Medicine, University of Oxford, United Kingdom; [3]Oxford NIHR Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust and the University of Oxford, United Kingdom; [4]Amsterdam Public Health Research Institute, Academic Medical Center, University of Amsterdam, Department of Clinical Epidemiology and Biostatistics; [5]NIHR Nottingham Biomedical Research Centre, Nottingham University Hospitals NHS Trust and the University of Nottingham, United Kingdom; [6]Digestive Diseases Unit Virgen del Rocío University Hospital, SeLiver group at Institute of Biomedicie of Seville (IBIS), University of Seville, Spain; [7]Institute of Cellular Medicine, Newcastle University, United Kingdom*
Email: emmanuel.selvaraj@cardiov.ox.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) has become the most common chronic liver disease in the world, affecting almost one-third of the population in Western countries. There is an unmet need for non-invasive biomarkers to replace liver biopsy and ultrasound-based elastography techniques have shown promising results. The aim of this systematic review and meta-analysis was to evaluate the diagnostic performance of acoustic radiation force impulse (ARFI) elastography for staging hepatic fibrosis in patients with NAFLD.
Method: An electronic search of PubMED, EMBASE and Cochrane Library was conducted for full-text papers and conference abstracts examining the diagnostic test accuracy of ARFI. Studies reporting on adults with biopsy-proven NAFLD using the NASH CRN histological scoring system and ARFI within 6 months of biopsy were included. Contingency tables for each fibrosis group were constructed from reported diagnostic accuracy for each study. Summary sensitivities, specificities and area under the receiver operating characteristic curve (sAUROC) were produced using a bivariate model. Risk of bias was assessed using the QUADAS-2 tool.
Results: Nine studies (n = 1218 patients, 52% male) provided sufficient data for meta-analysis. Two studies were conducted in France, the USA and South Korea, respectively, one in Germany and one in Romania. Seven studies reported the proportion of obese participants (mean prevalence 63%) and 6 studies reported the proportion of patients with diabetes (mean prevalence 39%). Experienced radiologists performed ARFI using either Siemens Acuson S2000 or S3000 with a mean technical failure rate of 8%. Summary statistics for diagnosing stages of fibrosis are given in the accompanying table. All 9 studies were judged as having high risk of bias in the index test domain as none of them used predefined cut-off values or included patients with failed or unreliable test for diagnostic accuracy analysis.

Target condition	Number of patients	Prevalence, %	Number of studies	Cut-off range, kPa	sAUROC	Sensitivity, %	Specificity, %
F ≥ 1	249	49	3	1.11–1.81	0.77	60	76
F ≥ 2	641	58	6	1.17–1.81	0.89	77	90
F ≥ 3	1170	29	8	1.34–4.24	0.93	81	89
F = 4	720	16	6	1.50–2.54	0.93	73	92

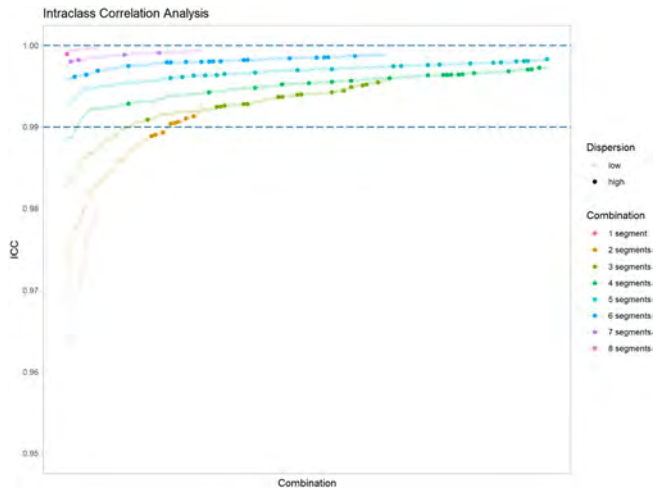
Conclusion: In patients where liver stiffness can be successfully measured using ARFI, the test has excellent diagnostic accuracy for fibrosis. However, "intention to diagnose" analyses and validation of pre-specified cut-offs are lacking from the literature and these areas should be the focus of future studies.

FRI022

Three is enough: optimization of regions of interest selection for accurate estimation of proton density fat fraction in liver from magnetic resonance images

Florent Roche[1], Fabrice Vincent[1], Jérémy Mary[1], Salvatore Zabbatino[2], Scott Holland[2]. *[1]Medpace, Lyon, France; [2]Medpace, Cincinnati, United States*
Email: f.roche@medpace.com

Background and Aims: Proton Density Fat Fraction (PDFF) measured by magnetic resonance imaging (MRI) is now widely accepted as a biomarker for liver fat fraction in non-alcoholic fatty liver disease (NAFLD) and steato-hepatitis (NASH), correlating highly with both MR spectroscopy and histology of liver biopsies. Here we demonstrate that average PDFF from a subset of widely dispersed regions of interest (ROI) correlates highly with a set of ROIs placed in each of the 9 Couinaud segments of the liver. We propose that PDFF based on the average of a subset number of ROIs with a high dispersion, provides an accurate estimate of liver fat fraction that compares favourably with more complicated, time-consuming and artefact-prone methods.
Method: PDFF maps (N = 96) were randomly extracted from an anonymous data registry of clinical trials for NAFLD. Liver PDFF maps were generated using the method of Zhong, et al. (2014), to estimate water and fat components. A 3 cm^2 ROI was placed in each Couinaud segment and average PDFF was then calculated over these 9 ROIs and over all combination of 1 to 8 ROIs. A dispersion score was constructed to represent the physical separation between ROIs in each set. Average PDFF values for each combination of ROIs was compared to the value calculated for all 9 ROIs using statistical measures of intraclass correlation coefficient (ICC), absolute error (AE) and limits of agreement (LOA). These statistics were examined as a function of dispersion score.
Results: For ICC, AE and LOA the average PDFF value computed from more ROIs leads to increased correlation with the 9 ROIs strategy. ROI combinations with higher dispersion score (best 25% combination for each number of ROIs selected) also results in higher, stable values of ICC, AE and LOA metrics (except for 2 ROIs selection): ICC > 0.99, AE < 0.9% and LOA < 2.7%.



Conclusion: Close agreement between average liver PDFF values suggests that selecting at least 3 ROIs with the greatest dispersion over the Couinaud segments produces a valid and reliable alternative to using 9 ROIs. Fewer ROIs can be placed more efficiently and reliably across the liver, taking care of avoiding vessels and any potential artefacts, compared to defining 9 ROIs in the Couinaud segments. We demonstrate quantitatively for the first time, that more complex and time-intensive approaches to liver segmentation and ROI selection yield little improvement in the quality of the resulting PDFF measurements compared with 3 or 4 widely dispersed ROIs.

FRI023

Diagnostic accuracy of magnetic resonance elastography for the staging of fibrosis and diagnosis of steatohepatitis in patients with non-alcoholic fatty liver disease: a systematic review and meta-analysis

Ferenc Mozes[1], Hadi Zafarmand[2], Arjun Jayaswal[1], Emmanuel Selvaraj[1], Christina Levick[3], Naaventhan Palaniyappan[4], Chang-Hai Liu[5,6], Stefan Neubauer[1], Manuel Romero Gomez[6], Guruprasad Aithal[4], Quentin Anstee[7], Stephen Harrison[1], Patrick Bossuyt[2], Michael Pavlides[1]. *[1]University of Oxford, OCMR, RDM Cardiovascular Medicine, Oxford, United Kingdom; [2]University of Amsterdam, Department of Clinical Epidemiology, Biostatistics and Bioinformatics, Amsterdam UMC, Amsterdam, Netherlands; [3]University of Oxford, Translational Gastroenterology Unit, Oxford, United Kingdom; [4]University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; [5]Sichuan University, Center of Infectious Diseases, West China Hospital, Chengdu, China; [6]University of Seville, UCM Digestive Diseases, Virgen del Rocío University Hospital, Liver Group at Institute of Biomedicie of Seville (IBIS), Seville, Spain; [7]Newcastle University, Liver Research Group, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom*
Email: ferenc.mozes@cardiov.ox.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease in Western countries. Histology is used for diagnosis and follow-up but has limitations. There is a need for non-invasive biomarkers to replace biopsy, therefore we evaluated the diagnostic accuracy of magnetic resonance elastography (MRE) for staging fibrosis and diagnosing non-alcoholic steatohepatitis (NASH) in NAFLD patients.
Methods: An electronic search of PubMED, EMBASE and Cochrane Library was conducted for full-text papers and conference abstracts examining the diagnostic test accuracy of 2D MRE. Studies reporting on adults with biopsy-proven NAFLD using the NASH CRN histological scoring system and MRE within 3 months of biopsy were included. Contingency tables were reconstructed from reported diagnostic accuracy measures. Risk of bias was assessed using the QUADAS-2 tool.
Results: Ten studies (one conference abstract and nine research papers, n = 990 patients, 40% male) provided sufficient data for meta-analysis. Eight studies were conducted in the USA, one in Japan and one in Brazil; only one study reported the proportion of obese participants (57%), although nine studies reported a mean or median BMI > 30 kg/m^2, and seven studies reported on patients with diabetes (average prevalence 38%). Nine studies did not use predefined cut-off values. Six studies did not report on the technical failure rates and none of the studies reported on rates of subjects excluded due to contra-indications to MR. Summary statistics for diagnosing stages of fibrosis and NASH are given in the accompanying table. Only one study, that used predefined cut-offs, was scored as having low risk of bias in all four domains (patient selection, index test, reference standard, flow and timing). The rest of the studies had high risk of bias in at least one domain.

Target condition	Total number of patients	Prevalence, %	Number of studies	Cut-off range, kPa	sAUROC	Sensitivity, %	Specificity, %
F ≥ 1	536	58	5	2.50–3.14	0.861	68.6	86.3
F ≥ 2	536	30	5	2.86–4.14	0.901	77.2	90.1
F ≥ 3	932	19	9	2.99–4.80	0.925	82.9	89.6
F = 4	536	8	5	3.35–6.70	0.916	83.5	90.8
NASH	376	69	4	2.53–3.26	0.826	65.3	82.4

Conclusion: When MRE could be successfully performed the test had a high diagnostic accuracy for fibrosis. Data on intention to diagnose analysis and validation of pre-specified cut-offs are lacking from the literature and should be the focus of future prospective studies. Further evaluation is also needed in specific populations especially those with obesity.

FRI024

Investigation of a composite imaging biomarker for identification of non-alcoholic steatohepatitis (NASH) patients in a Japanese population

Filza Aslam[1], Sofia Mouchti[1], Matt Kelly[1], Andrea Dennis[1], Kento Imajo[2], Atsushi Nakajima[2]. *[1]Perspectum Diagnostics, Oxford, United Kingdom; [2]Yokohama City University, Yokohama, Japan*
Email: filza.aslam@perspectum.com

Background and Aims: NASH pathogenesis is complex and composite biomarkers can improve identification of patients who are at risk of poor clinical outcomes. Liver*MultiScan*® uses multiparametric MRI to measure proton density fat fraction (PDFF) and iron-corrected T1 (cT1). PDFF quantifies hepatic steatosis while cT1 correlates with key histopathological features of NASH – ballooning, inflammation and fibrosis, and predicts clinical outcomes in patients with chronic liver disease. Herein, we report the performance of cT1 and PDFF in composite with non-imaging biomarkers, for the stratification of patients with suspected NASH in a prospective Japanese study cohort.
Method: Patients suspected of NASH underwent a 15-minute, contrast-free multiparametric MRI (Liver*MultiScan*, Perspectum Diagnostics). Liver biopsy was assessed using the NAFLD activity score (NAS) with NASH diagnosed as NAS ≥ 4 (ballooning ≥ 1, inflammation ≥ 1); fibrosis stage was assessed according to the Kleiner-Brunt criteria (F0-F4). The ability of the biomarkers to identify patients with (i) NASH and (ii) high-risk NASH (NAS ≥ 4 and F ≥ 2) was evaluated using area under receiver operating curve (AUROC) analysis, with logistic regression used to combine biomarkers.

Results: 97 patients were screened and underwent liver biopsy. Mean age was 60.1 years [28–82], mean BMI (±SD) was 29.0 (±4.7) kg/m^2, 38% were female and 54% had NASH. 23% were F1, 25% F2, 33% F3, and 16% F4 fibrosis; 45% were high-risk NASH. cT1 correlated with histological grading of fibrosis ($r_s = 0.34$, $p < 0.001$), inflammation ($r_s = 0.47$, $p < 0.001$), and ballooning ($r_s = 0.45$, $p < 0.001$); PDFF correlated with histological grading of steatosis ($r_s = 0.68$, $p < 0.001$). For identifying NASH, respective AUROCs for cT1 and PDFF were 0.76 (95% CI 0.66–0.86) and 0.77 (95% CI 0.68–0.87). For identifying high-risk NASH, respective AUROCs for cT1 and PDFF were 0.72 (95% CI 0.61–0.82) and 0.66 (95% CI 0.56–0.77). The optimal combination of cT1, PDFF, age and AST yielded a higher AUROC of 0.85 (95% CI 0.77–0.93) and 0.79 (95% CI 0.70–0.88) for identifying NASH and high-risk NASH, respectively (Figure 1).

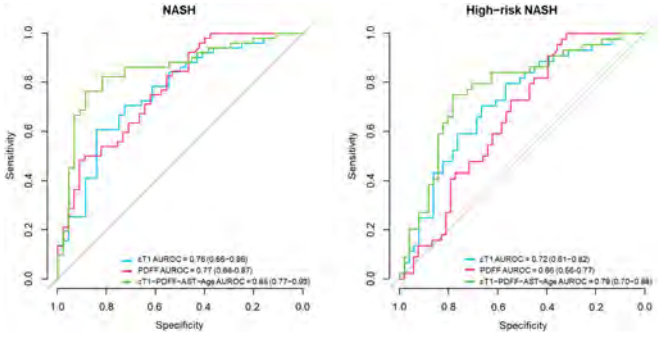


Figure 1: ROC curves to discriminate patients with NASH (left), and high-risk NASH (right).

Conclusion: In Japanese patients, cT1 outperformed PDFF for identification of high-risk NASH. Performance of cT1 was enhanced in combination with PDFF, age and AST for identification of NASH patients as well as those with significant fibrosis.

Background and Aims: NAFLD is the most common cause of chronic liver disease. The gold standard for determining hepatic fat deposition is a liver biopsy, but it is invasive and has the disadvantages of limited sampling and high cost. Therefore, in real clinical world, hepatic sterilization is assessed using ultrasound or estimated hepatic steatosis formulae. However, the currently used calculated steatosis formula uses a ultrasound which has low sensitivity and misses patients in the gray zone. Therefore, we compared the diagnostic performance of sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of conventional estimated hepatic steatosis formulas through MRI-PDFF which is used as gold standard with liver biopsy.
Method: The subjects of this study were those aged 18 years or older who visited Gangbuk Samsung Health Examination Center (Seoul, Suwon) from January 2015 to May 2018 and underwent intrahepatic fat measurement using MRI test. MRI was used 1.5 T MRI without contrast media and hepatic fat fraction percentage was measured by chemical shift technique. Diagnostic performances were compared using analytical methods such as Mann-whitney test, Independent t-test, Chi-square test, Spearman correlation, logistic regression, and AUROC.
Results: Among 1301 patients, ultrasound diagnosed NAFLD was 25.5% (549/2149), and MRI diagnosed NAFLD was 18.2% (392/2149). The sensitivity of fatty liver diagnosis using ultrasound was 71.9% (282/392), specificity was 67.1% (549/817), positive predictive value (PPV) was 51.1% (281/549), and negative predictive value (NPV) was 81.9% (549/670). AUROC of fatty Liver index (FLI), Hepatic Steatosis index (HSI), and NAFLD liver fat score were 0.68, 0.70, 0.72, respectively. NAFLD liver fat score showed the best diagnostic ability, but overall AUROC was low. Intermediate zones between high cut off and low cut off were the lowest in FLI (28.9%) and 43.3% and 50% in HSI and ZJU, respectively.
Conclusion: The performance of fatty liver diagnosis using the estimated hepatic steatosis formulae was slightly lower, ranging from 0.68 to 0.72. There is a need for further development of non-invasive diagnostic methods for the diagnosis of fatty liver.

FRI026

The prevalence of non-alcoholic fatty liver disease in type 2 diabetes mellitus

Leen Heyens[1], Geert Robaeys[1,2,3], Rob Bielen[1,2], Yves Kockaerts[4], Dana Busschots[1,2]. *[1]Hasselt University, Health and Life Sciences, Diepenbeek, Belgium; [2]Ziekenhuis Oost-Limburg A. V., Gastroenterology, Genk, Belgium; [3]UZ Leuven, Gastroenterology and Hepatology, Leuven, Belgium; [4]Ziekenhuis Oost-Limburg A. V., Endocrinology, Genk, Belgium*
Email: leen.heyens@uhasselt.be

Background and Aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is becoming an important cause for chronic liver disease worldwide and is one of the leading causes for hepatocellular carcinoma. In patients with type 2 diabetes mellitus (T2DM), NAFLD is reaching epidemic dimensions. Insulin resistance is a key contributor to the development of NAFLD and T2DM. Therefore, patients with T2DM have a higher chance of developing NAFLD. Nevertheless, little to no epidemiologic data is available about the presence of NALFD in T2DM patients. Our aim is to determine the prevalence of NAFLD and fibrosis in a cohort of T2DM patients followed at Ziekenhuis Oost-Limburg (ZOL), Belgium.
Method: In a retrospective, cohort study in ZOL, a large regional hospital in Limburg, Belgium the prevalence of NAFLD was determined by means of non-invasive score calculations in 1,000 of 2,910 T2DM patients. The Fibrosis-4 (FIB-4) score was used to determine liver fibrosis and the Fatty Liver Index (FLI) to determine the fat content of the liver.
Results: Thirty-seven of the 1,000 analysed patients were excluded due to reported other liver diseases, a history of bariatric surgery, or age 35 years or younger. In 218/972 (22.4%) T2DM patients, values for the FLI score were available and 525/972 (54.0%) patients had values for the FIB-4 score. In relation to steatosis, little to no steatosis was found in 14/218 (6.4%) patients, a moderate amount of liver fat was found in 31/218 (14.2%) patients, and a serious amount of liver fat in 173/218 (79.4%) of the cases. In relation to fibrosis, 63/525 (12.0%) patients had liver cirrhosis, 125/525 (23.8%) had significant fibrosis, and 337/525 (64.2%) had little to no fibrosis.

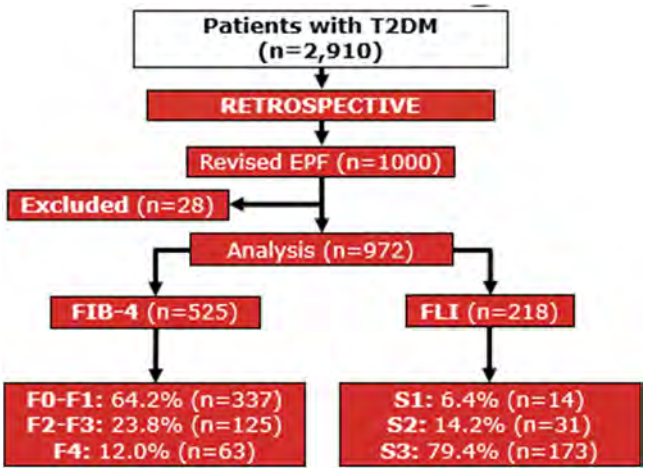

Figure 1: **The prevalence of NAFLD in the total cohort of T2DM patients followed at ZOL**. S1: little to no steatosis, S2: mild steatosis, S3: severe steatosis, F0-F1: little to no fibrosis, F2-F3: significant fibrosis and F4: cirrhosis, EPF: electronic patient file, T2DM: type 2 diabetes mellitus, FIB-4: fibrosis-4 score, FLI: fatty liver index.

Conclusion: One out of ten T2DM patients has evolved to liver cirrhosis. More than a quarter has significant fibrosis and are therefore eligible for anti-fibrotic/steatotic therapy. Four out of five patients has significant steatosis or NAFLD.

FRI027

Validation of interleukin-32 as a new circulating fatty liver biomarker

Email: guido.baselli@unimi.it

Background and Aims: Efforts to manage nonalcoholic fatty liver disease (NAFLD) are limited by the absence of accurate noninvasive biomarkers. The I148M variant in *PNPLA3* is a major determinant of the development and progression of NAFLD associated with a distinct disease pathophysiology. Aim of the study was to identify novel candidate NAFLD biomarkers by examining the hepatic transcripts associated with severe NAFLD in obese individuals in patients stratified by the presence of the PNPLA3 I148M variant.

Method: Hepatic transcriptomic analyses were conducted in 125 liver-biopsied severely obese individuals. "Severe NAFLD" was defined as the presence of steatohepatitis, or NAS ≥ 4, or fibrosis stage ≥ 2. RNA was isolated from liver biopsies and sequenced (HiSeq4000). After reads alignment (STAR software) and count (RSEM), differential expression was investigated at gene (DESeq2) and pathway (GSEA) level. Plasma IL32 was measured in other 71 liver-biopsied obese patients (Biomarker cohort) by ELISA (R&D), in an independent validation cohort of 44 individuals with metabolic disorders in which steatosis was evaluated by coefficient attenuation parameter (CAP) and in a further validation cohort of 174 liver-biopsied patients at risk for NAFLD.

Results: Principal component analysis revealed that carriage of the PNPLA3 I148M variant was one of the most important determinant of transcriptome variability. Indeed, carriage of the variant highly correlated with the first two principal component of transcriptome variability ($p < 0.001$, both). Consistently, differential gene expression analysis revealed overexpression of inflammatory genes together with a downregulation of metabolic genes in PNPLA3 I148M carriers. Conversely, severe NAFLD patients overexpressed genes involved both in inflammatory response and oxidative metabolism. Importantly, IL32 showed the strongest association with severe NAFLD (adjusted $p = 1^{*}10^{-6}$).

In the biomarker cohort, plasma IL32 levels were associated with both NAFLD and severe NAFLD ($p < 0.01$ for both). In our first validation cohort ($n = 44$), circulating IL32 positively correlated with CAP value ($p = 0.03$). Importantly, in a further validation set of 174 liver-biopsied patients we confirmed serum IL32 association with both NAFLD ($p = 9^{*}10^{-5}$) and severe NAFLD ($p = 0.008$).

Conclusion: This work highlights PNPLA3 148M allele as the major determinant of transcriptome variability and IL32 as a novel potential biomarker for noninvasive NAFLD diagnosis.

FRI028

Simple non-invasive prediction of advanced fibrosis in NAFLD - a stepwise approach and external validation study to reduce indeterminates and biopsy

Heather M Kosick[1], Aline Keyrouz[2], Giada Sebastiani[2], Keyur Patel[1]. *[1]UHN Toronto, Toronto, Canada; [2]McGill University Health Centre, Division of Gastroenterology and Hepatology, Montreal, Canada*
Email: keyur.patel@uhn.ca

Background and Aims: Advanced hepatic fibrosis predicts liver-related mortality in NAFLD. Simple Non-invasive Tests (NIT) designed to rule-in or rule-out advanced fibrosis in NAFLD are limited by 'indeterminate' (IND) results, necessitating liver biopsy. Our aim was to determine whether sequential or parallel combinations of serum-based NIT and elastography (VCTE) can accurately predict advanced NAFLD fibrosis (AF), reduce IND and misclassifications (MIS), and thus decrease need for liver biopsy.

Method: Biopsy-proven NAFLD patients were retrospectively identified between 2010–2018 from two Canadian tertiary centres to represent derivation and external validation cohorts for sequential algorithms. Cohorts were combined for parallel analysis. FIB-4, APRI, NFS, BARD, AST/ALT scores were calculated based on blood work performed within 6 months of biopsy. VCTE was available in $n = 172$, and liver stiffness measurement (LSM) ≤ 7.2 kPa was considered as F0-2. AF was defined as F3-4 fibrosis stages. Areas under the ROC curve (AUC) and weighted Obuchowski measures (OB) were determined for binary outcomes.

Table 1:

	Derivation					Validation				
Sequential NIT	Sens	Spec	AUC (OB)	IND	MIS	Sens	Spec	AUC (OB)	IND	MIS
FIB-4	0.66	0.94	0.83 (0.74)	27%	17%	0.88	0.61	0.81 (0.74)	34%	26%
NFS	0.64	0.90	0.78 (0.71)	25%	23%	0.64	0.85	0.78 (0.72)	40%	25%
FIB-4 + NFS	0.60	0.95	0.77 (0.71)	8%	20%	0.56	0.82	0.67 (0.65)	15%	30%
FIB-4 + VCTE	0.69	0.93	0.81 (0.72)	0%	17%	0.67	0.66	0.66 (0.64)	0%	34%
FIB-4 + NFS + VCTE	0.62	0.94	0.78 (0.71)	0%	20%	0.62	0.74	0.68 (0.64)	0%	31%

Results: 541 cases of NAFLD were identified (407 derivation, 134 validation). Characteristics of derivation/validation cohorts included: males 54%/59%; mean age 48.5/52.5 yrs; mean BMI 32.3/33.6; diabetes 30%/34%; AF 48%/43%. For single serum NITs, AUC for AF

were 0.70–0.83, and 0.68–0.81 for derivation and validation cohorts, with IND rates of 25%–39%, and 34%–45%. Concordance between FIB-4 and NFS for both cohorts was 71–73%. Sequential combinations of NIT reduced IND while maintaining diagnostic accuracy (Table 1). For the overall cohort, parallel FIB-4 + NFS had similar accuracy (AUC = 0.81) but was limited by a 38% IND rate. In our overall cohort, liver biopsy for AF was avoided in 27–30% of patients using sequential algorithms, representing an additional 6–9% biopsies avoided compared to using FIB4/NFS/VCTE alone.

Conclusion: Sequential combinations of NIT predict advanced fibrosis in NAFLD with good accuracy, while reducing IND. Use of sequential algorithms reduce need for liver biopsy compared to individual NIT. Parallel combined algorithms are limited by high rates of IND. In our tertiary cohorts, sequential FIB-4 + NFS performed with similar accuracy to VCTE-containing algorithms, and if validated in low prevalence cohorts, highlights potential use in resource-limited clinical settings as a means of risk stratification for advanced NAFLD fibrosis.

FRI029

Adherence to established process measures in the evaluation of hepatic steatosis on imaging in a large tertiary care network

Hersh Shroff[1], Lisa VanWagner[1], Dyanna Gregory[1], Sophia Damman[1], Rajesh Keswani[1], Mary Rinella[1]. *[1]Northwestern Memorial Hospital, Chicago, United States*
Email: hersh.shroff@northwestern.edu

Background and Aims: Hepatic steatosis (HS) is a common finding on imaging studies. Clinical practice guidelines propose several process measures for risk stratification and referral of non-alcoholic fatty liver disease (NAFLD) cases. Adherence to process measure guidelines are not well known. We sought to assess rates of process measure completion among patients with a new imaging finding of HS in a large tertiary care network.

Method: Using natural language processing, we identified an inception cohort of patients aged 18–79 years with HS on abdominal imaging between 1/1 2015 and 12/31/2018. Using manual chart review, we excluded patients with known chronic liver disease (including NAFLD) and patients not receiving primary care at our institution (defined as no visits in the year prior to the imaging study). We assessed the following NASH risk factors: age > 50, persistent elevation in ALT, or 1+ metabolic syndrome (MetS) comorbidities; we calculate FIB-4 and NAFLD fibrosis scores (NFS) where possible. For FIB-4 and NFS, low risk was defined <1.3 or <−1.455 and high risk as >2.67 or >0.676, respectively. The primary outcomes were completion of the following process measures within one year of identifying HS: liver chemistry measurement, assessment of MetS comorbidities (hemoglobin A1C, HDL-C, triglycerides, and blood pressure), fibrosis risk assessment (NFS, FIB-4, vibration controlled transient elastography [VCTE], acoustic radiofrequency imaging [ARFI] or magnetic resonance elastography [MRE]) or referral to hepatology where appropriate.

Results: We identified 385 patients with new HS. 61% of imaging tests were ordered for non-liver-related indications and 48% by primary care physicians. Nearly all (95%) patients had >=1 NASH risk factor, and 14% were high risk for fibrosis using at least one risk score. 92% of patients had liver chemistries measured within 1 year of imaging, but only 48% of patients had a complete assessment for MetS. No provider documented calculation of a fibrosis risk score. Only 9% of patients (n = 35) underwent non-invasive testing for fibrosis (VCTE, ARFI or MRE). 16% (12/75) of patients classified as low risk on *both* scores were referred to hepatology, and only 13% (6/48) with >=1 high-risk score were referred to hepatology for further risk stratification or biopsy.

Conclusion: Significant room for improvement exists in the identification and evaluation of patients with IHS by imaging. These results highlight the need to redesign systems of care to facilitate guideline-recommended evaluation and referral among high-risk NAFLD patients.

FRI030

Value of FIB-4 and NAFLD fibrosis scores for screening of liver fibrosis in the general population

Isabel Graupera[1], Miquel Serra-Burriel[2], Maja Thiele[3], Llorenç Caballeria[4], Dominique Roulot[5], Grace Lai-Hung Wong[6], Núria Fabrellas[7], Neil Guha[8], Anita Arslanow[9], Carmen Expósito[4], Rosario Hernández[10], Guruprasad Aithal[8], Peter Galle[9], Vincent Wai-Sun Wong[6], Frank Lammert[11], Pere Ginès[1], Castera Laurent[12], Aleksander Krag[3]. *[1]Hospital Clinic of Barcelona, IDIBAPS, University of Barcelona, Liver Unit, Barcelona, Spain; [2]University Pompeu Fabra, Centre for Research in Health and Economics, Barcelona, Spain; [3]University of Southern Denmark, Center for Liver Research, Odense, Denmark; [4]Institut Universitari d'Investigació en Atenció Primària (IDIAP Jordi Gol), ICS Metropolitana Nord, Mataro, Spain; [5]Hopital Avicenne - APHP, Bobigny, France; [6]Chinese University of Hong Kong, Hong Kong; [7]University of Barcelona, School of Nursing, Barcelona, Spain; [8]University of Nottingham University Hospitals, Queen's Medical Centre, Nottingham, United Kingdom; [9]University Medical Center of the Johannes Gutenberg University Mainz, Medical Klinik II, Mainz, Germany; [10]Institute de Cat Salut, CAP LA MARINA, Barcelona, Spain; [11]University Clinic of Saarland, Faculty of medicine, Homburg, Germany; [12]Hôpital Beaujon, Hepatologie, Clichy, France*
Email: pgines@clinic.cat

Background: Serum biomarkers of liver fibrosis such as the fibrosis-4 (FIB-4) score and the NAFLD fibrosis score (NFS) have been proposed as first step for the identification of subjects with suspected liver fibrosis in primary care. These scores have a high negative predictive value (>90%), leaving more specific non-invasive tools such as transient elastography (TE) as second step. However, the diagnostic value of FIB-4 and NFS is mainly based on cohorts from secondary and tertiary care where the prevalence of fibrosis is high (20–30%). The performance of both tests for screening of the general population (with low fibrosis prevalence <5%) is unclear. Therefore we aimed to evaluate the bivariate relation between liver stiffness measurement (LSM), assessed using TE, vs. FIB-4 and NFS in the general population without known liver disease.

Patients and Methods: Data from a consortium-wide database of 4,255 adults (Age 53.53 (sd 12.11), 2,439 female (57.3%), BMI 27.1 (sd 5.16) without known liver disease who underwent screening for liver fibrosis with TE and NITs was included. The distributions of LSM, FIB-4 and NFS at different cutoffs were evaluated. LSM>8 kPa was chosen as cutoff for suspected advanced fibrosis, according to findings from recent studies. FIB-4 and NFS cutoffs below 1.3 and −1.45 were used for defining subjects at low-risk of having advanced fibrosis whereas cutoffs above 2.67 and 0.676 were used for defining high-risk subjects. Subjects with values in between were considered at intermediate risk.

Results: The mean FIB-4 score was 1.16(sd 0.59), NFS −2.04(sd 1.32), and LSM 4.91 kPa(sd 2.28). Out of 4,255 patients included, 235 (5.5%) patients had LSM >8 kPa. FIB-4 values were distributed as follows: <1.3 n = 2,733(68.3%), 1.3 < < 2.67 n = 1,198(29.9%) and >2.67 n = 69 (1.7%); NFS values were distributed as follows: <−1.45 n = 2,700 (68.5%), −1.45 < < 0.676 n = 1,168 (29.6%) and >0.676 n = 74 (1.9%). Among the 2,733 patients with FIB-4 < 1.3, 140 (5.1%) had LSM >8 kPa while among the 2,700 patients with NFS <−1.45, n = 104 (3.9%) had LSM >8 kPa. Among patients with FiB-4 >2,67 and NFS >0.676, 11 (15.9%) and 19 (25.7%) had LSM >8 KPa, respectively.

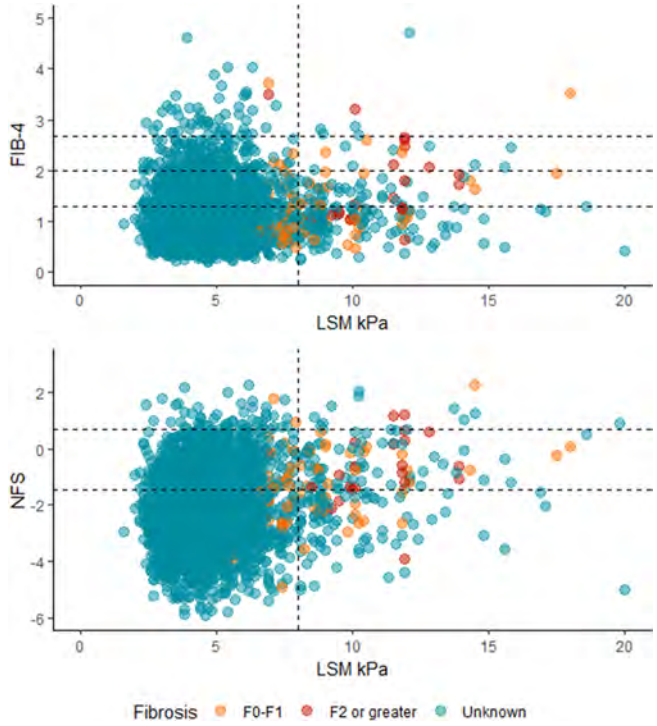

Figure 1. Scatterplots of LSM using TE and FIB_4 and NFS.

Conclusions: A significant fraction of patients with FIB4 or NFS values suggesting the absence of advanced fibrosis have elevated LSM above the 8 kPa cutoff. This raises the question regarding the utility of FIB-4 and NFS as the first step in the screening for liver fibrosis in the general population.

FRI031

Utilizing pre-existing imaging and data lake technology in the search of clinically neglected non-alcoholic fatty liver disease (NAFLD)

Iiro Karhiaho[1], Helka Parviainen[2], Antti Rantala[3], Martti Färkkilä[4], Niina Matikainen[1], Tiinamaija Tuomi[4]. *[1]Helsinki University Hospital, Abdominal Center, Endocrinology, Helsinki, Finland; [2]Helsinki University Hospital, Medical Imaging Center, Radiology, HUS, Finland; [3]Helsinki University Hospital, IT-services, A.I.-unit, Helsinki, Finland; [4]Helsinki University Hospital, Abdominal Center, Gastroenterology, HUS, Helsinki, Finland*
Email: iiro.karhiaho@hus.fi

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a major cause of liver morbidity and an independent risk for cardiovascular events, type 2 diabetes and mortality. However, it is rarely diagnosed when reported as an incidental observation when abdominal diagnostic imaging is performed for other clinical purposes. The aim of our study was to identify patients with clinically unrecognized fatty liver disease – and the proportion of it associated with insulin resistance and/or diabetes - in the Helsinki University hospital district utilizing data lake technology to mine the electronic health care records.
Method: We used a phrase recognition script to analyse all radiological reports for patients with any abdominal imaging (US, CT, MRI) performed during the last 6-year period in the Helsinki University Hospital electronic data lake, which contains radiology reports, laboratory data and ICD codes for a catchment area of 1.6 million people. We analysed all available glucose laboratory data for the patients with fatty liver disease (FLD) on imaging or with the ICD-10 code K76.0 to identify patients with diabetes: fasting plasma glucose >7, random glucose >11.1 or 2 h glucose during OGTT >11.1 mmol/l. or HbA1c >48 mmol/mol. The script utilised word stems and phrases indicative for FLD or excluding it (e.g."echog* liver," "fatty liver," etc). For validation, a set of 1000 randomly sampled radiological reports were manually read and a subspecialist in abdominal radiology reanalysed the original imaging studies constituting 10% of the validation set (33 US, 33 MRIs and 33 CTs).
Results: A traditional search found 360 patients with the ICD-10 code K76.0 while the phrase recognition script recognized 23 425 patients with radiologically reported FLD. In the validation, only 16/1000 radiology reports were found to be false positive in the script recognition and 2/99 imaging studies were found to be false positive in reanalysis of the images. Altogether, 4425 (19%) patients with fatty liver on imaging had diabetic glucose and/or HbA1c values.
Conclusion: Radiological FLD is a clinically neglected condition. Even when FLD is suspected the clinical diagnosis is not recorded in 98% of cases. Only 19% of the subjects found to have FLD had diabetic laboratory values suggesting associated co-morbidity, but the true prevalence of diabetes is unknown. Data lake technology and phrase recognition data mining provide a tool to discover undiagnosed NAFLD patients.

FRI032

Factors associated with NAFLD and advanced liver fibrosis and accuracy of liver biopsy in patients with diabetes mellitus type 2: a cross sectional study

Ivana Mikolasevic[1,2], Viktor Domislovic[3], Željko Krznarić[3,4], Nadija Skenderević[1], Ana Mijić[2], Marija Matašin[4], Tajana Stevanović[2], Božena Delija[2], Mia Klapan[2], Toni Jurić[2], Anđela Lukić[2], Petra Dinjar Kujundžić[1], Ana Ostojic[1], Petra Puž[5], Tajana Filipec Kanizaj[1,4]. *[1]Clinical Hospital Merkur, Department of Gastroenterology and Hepatology, Zagreb, Croatia; [2]University of Rijeka, School of Medicine Rijeka, Rijeka, Croatia; [3]Clinical Hospital Centre Zagreb, Department of Gastroenterology and Hepatology, Zagreb, Croatia; [4]University of Zagreb, Zagreb, Zagreb School of Medicine, Zagreb, Croatia; [5]General Hospital Dr. Tomislav Bardek Koprivnica, Department of Gastroenterology, Koprivnica, Croatia*
Email: viktor.domislovic@gmail.com

Background and Aims: NAFLD is commonly found in obese patients and with conditions that may be related to obesity, such as insulin resistance, dyslipidemia, hypertension and type 2 diabetes (T2DM). The prevalence of NAFLD in T2DM patients is high and the two conditions often coexist. The aim of our study was to assess the prevalence and to estimate the risk factors of NAFLD and liver fibrosis (LF) in patients with T2DM, as well as to explore accuracy of liver biopsy.
Method: This is a cross-sectional study of adult patients with T2DM. All patients had transient elastography (TE) after overnight fasting using Fibroscan®. Patients were considered to have hepatic steatosis as CAP ≥ 238 dB/m. LF was considered as LSM >7 kPa and advanced fibrosis (ALF) as LSM ≥ 9.6 kPa or ≥ 9.3 kPa according to the M or XL probe, respectively. Suitable patients underwent a percutaneous liver biopsy. ALF was defined as biopsy fibrosis stage ≥ F3.
Results: A total of 679 patients were included in this cross-sectional study, mean age 65.2 ± 11.6, 54.3% (n = 369) males, BMI 30.75 ± 5.15 kg/m^2 and prevalence of obesity and central obesity was 52.5% (n = 357) and 73.9% (n = 502), respectively. The prevalence of NAFLD was 83.6% (n = 568). Independent factors associated with NAFLD were higher BMI, longer T2DM duration, higher serum triglyceride, lower levels of vitamin D, higher CRP and higher HOMA-IR. The prevalence of LF was 27% (n = 183) and ALF 13% (n = 86). On multivariate analysis independent factors associated with ALF were female gender, higher BMI, higher levels of ALT, GGT and CRP, and lower levels of cholesterol. Liver biopsy was performed in 105 patients. F3-4 disease was detected in 38 (36.1%). The sensitivity, specificity, PPV and NPV of increased LSM to detect histological F3-4 disease were 41.03% (95%CI 25.6–57.9), 74.24% (95%CI 62–84.2), 48.5%

(95%CI 35–62.1), and 68% (95%CI 61.3–74.1), respectively, with AUC of 0.58. Sixty-six patients were misclassified (62.85%).
Conclusion: In patients with T2DM there is high proportion of NAFLD, liver fibrosis and advanced liver fibrosis according to TE. Risk factors can help in early identification of NAFLD, LF and ALF. TE is practical and convenient, and can help in identifying patients in which the liver biopsy would be beneficial. However, there, low accuracy in T2DM patients could be disadvantage. This study points out the complexity disease-specific factors and impact of T2DM on the risk factors and TE accuracy.

FRI033

FIB-4 first strategy for non-alcoholic fatty liver disease might not be appropriate for ruling-out advanced liver fibrosis with current cut-off values in patients with type 2 diabetes mellitus

Ivica Grgurevic[1], Tomislav Bokun[2], Sanda Mustapic[2], Dr. Vladimir Matic[2], Dario Rahelic[3], Dr. Tomas Matic[2], Prof. Srecko Marusic[4], Dr. Kristian Podrug[5], Dr. Darko Brnić[5], Nermin Salkic[6]. *[1]University Hospital Dubrava, University of Zagreb School of Medicine, Department of Gastroenterology, Hepatology and Clinical Nutrition, Zagreb, Croatia; [2]University Hospital Dubrava, Department of Gastroenterology, Hepatology and Clinical Nutrition, Zagreb, Croatia; [3]University Hospital Dubrava, Department of Endocrinology, Diabetes and Metabolic Diseases, Zagreb, Croatia; [4]University Hospital Dubrava, University of Zagreb School of Medicine, Department of Endocrinology, Diabetes and Metabolic Diseases, Zagreb, Croatia; [5]University Hospital Centre Split, Department of Gastroenterology, Split, Croatia; [6]University Hospital Tuzla, University of Tuzla School of Medicine, Department of Gastroenterology and Hepatology, Tuzla, Bosnia and Herzegovina*
Email: ivica.grgurevic@zg.htnet.hr

Background and Aims: There are proposals to implement "FIB-4 First" strategy to triage patients entering a Non-alcoholic fatty liver disease (NAFLD) assessment pathway with FIB-4 threshold of 1.3 as acceptable for reliably ruling-out advanced liver fibrosis. We intended to test this strategy in patients with type 2 diabetes mellitus (T2DM), known of having increased risk of liver fibrosis.
Methods: Retrospective analysis of prospectively enrolled cohort of patients with T2DM at diabetes clinic who all underwent liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) by transient elastography (TE) in addition to standardized laboratory work-up sufficient to calculate FIB-4 score. We used LSM cut-off value of 7.9 kPa to rule-out and 9.6 kPa to rule-in advanced fibrosis respectively. Patients were followed until death or censored date.
Results: A total of 454 DM patients (236; 52% males) with mean age (SD) of 62.5 (12) years were recruited. In patients with FIB-4 <1.3 (N = 268) there were 45 (16.8%) patients with LSM>7.9 (of them 21 (7.8%) had LSM>9.6 kPa indicative of advanced fibrosis/cirrhosis). During the median follow up time of 25 months (interquartile range: 9–39), a total of 106 (23.3%) patients experienced an adverse event: cardiovascular in 50 (11%) patients, infection-related in 31 (6.8%), diabetes-related in 22 (4.8%), oncological in 16 (3.5%), whereas there were no liver-related complications. Seventeen (3.7%) patients died during the follow up (all deaths non-related to liver disease). In Cox regression analysis only age (OR = 1.05; 95%CI = 1.027–1.073; p < 0.001) and with borderline significance HbA1c levels (OR = 1.008; 95%CI = 1.000–1.017; p = 0.059) were significant predictors of any morbidity or mortality at follow-up, but not gender, smoking, statin use, BMI, FIB-4, LSM nor CAP.
Conclusion: FIB-4 threshold of 1.3 in T2DM population might not be appropriate for ruling-out advanced liver fibrosis, although in short term it doesn't pose particular clinical issue since most of the complications in 2-year period are related to DM and not to liver. This conclusion is hampered by the lack of liver biopsy to confirm noninvasive results obtained in this study.

FRI034

Accuracy of cytokeratin-18 (M30 and M65) in detecting non-alcoholic steatohepatitis and fibrosis: a systematic review and meta-analysis

Jenny Lee[1], Yasaman Vali[1], Quentin Anstee[2], Kevin Duffin[3], Patrick Bossuyt[1], Mohammad Hadi Zafarmand[1]. *[1]Amsterdam University Medical Center, Department of Clinical Epidemiology, Biostatistics and Bioinformatics, Amsterdam, Netherlands; [2]Newcastle University, Institute of Clinical & Translational Research, Newcastle upon Tyne, United Kingdom; [3]Eli Lily and Company Ltd, Indianapolis, United States*
Email: j.a.lee@amsterdamumc.nl

Background and Aims: The association between elevated cytokeratin 18 (CK-18) levels and cell death in the liver has made circulating CK-18 a candidate biomarker to differentiate non-alcoholic fatty liver (NAFL) from non-alcoholic steatohepatitis (NASH). However, there is high variability among study results. We aimed to provide summary estimates with increased precision on the accuracy of CK-18 antigens (M30, M65) for detecting NASH, fibrotic NASH and fibrosis among NAFLD adults.
Method: We searched five electronic databases to retrieve studies evaluating CK-18 against a liver biopsy as the reference standard in NAFLD adults. Reference screening, data extraction and quality assessment (QUADAS-2) were independently conducted by two authors. Reported sensitivities, specificities, sample size and prevalence were utilized to construct 2 × 2 tables. Meta-analyses were performed for five groups based on the CK-18 antigens and target conditions, using one of two methods, based on availability of data: a linear mixed-effects multiple thresholds model and a bivariate logitnormal random-effects model.
Results: A wide range of disease prevalence was observed (Table 1). Most studies (86%; 32/37) had included patients with mean BMI <35. No study reported a pre-defined cut-off value. Twenty-nine out of 37 studies provided sufficient data for inclusion in any of the meta-analyses. The highest summary area under the receiver operating characteristic curve (AUC) was observed for M65 in diagnosing NASH (0.82; 95% CI: 0.69–0.91), all others had AUC <0.80. Thirteen studies used CK-18 as an ingredient of a biomarker panel, with higher reported AUC for these panels.

Table: Summary of meta-analysis results.

Target condition	CK-18 antigen	No of studies	No of patients	Prevalence of target condition, % mean (range)	AUC (95% CI)	No of unique cut-offs	Range of cut-off values (U/L)
NASH	M30	21	3,403	57 (21–85)	0.74 (0.67–0.81)	40	111–670
NASH	M65	6	414	53 (32–75)	0.82 (0.69–0.91)	11	340–1183
Fibrotic NASH	M30	3	1,271	27 (21–62)	0.73 (0.57–0.85)	7	113–464
Significant fibrosis	M30	5	1,155	48 (18–59)	0.68	5	122–285
Advanced fibrosis	M30	5	1,513	21 (19–36)	0.75	5	216–396

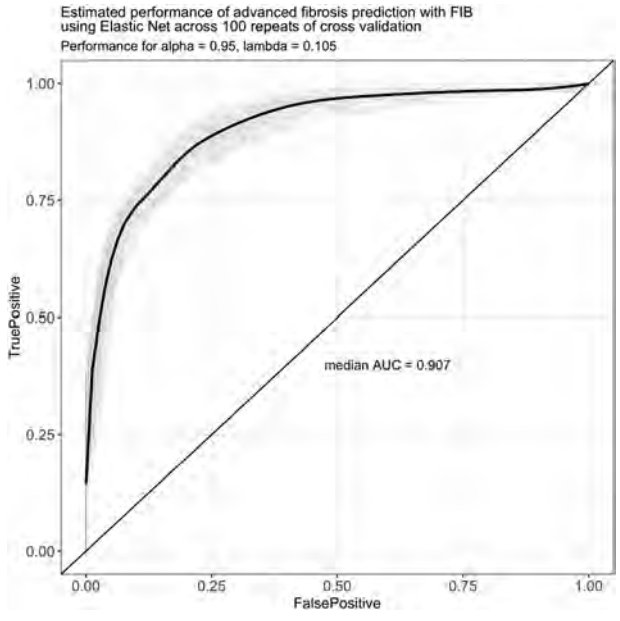
Conclusion: Our results show limited ability for CK-18 as a stand-alone test for identifying NASH and fibrosis staging. The M65 antigen and biomarker panels including CK-18 showed improved performance, but further external validation studies are needed to obtain credible estimates of the diagnostic accuracy of these panels.

FRI036

Composite biomarkers selected by machine learning predict severe fibrosis in NASH

Elizabeth Brown[1], John Thompson[1], Christina Ebert[1], Abraham Apfel[1], Jennifer Koenitzer[1], Thomas Spires[1], Mary Ellen Cvijic[1], Edgar Charles[1], Yi Luo[1], Lei Zhao[1], David Gordon[1], Raymond Chung[2,3], Kathleen Corey[2,3]. *[1]Bristol-Myers Squibb, Lawrenceville, United States; [2]Massachusetts General Hospital, Boston, United States; [3]Harvard Medical School, Boston, United States*
Email: john.thompson@bms.com.

Background and Aims: Distinguishing patients with more advanced stages of liver fibrosis in non-alcoholic steatohepatitis (NASH) is critical for patient stratification, treatment, and prognosis. However, published models based on circulating biomarkers lack discriminatory power and replicability across cohorts; thus current diagnosis of fibrotic stage still requires invasive liver biopsies. Here we employ a machine learning technique called Elastic Nets with cross-validation to train and test novel composite serum biomarker models in a cohort of 420 patients from the Harvard Fibrosis Network (HFN) to distinguish advanced stages of NASH.
Method: Sera from 420 biopsy-proven NASH (F0-F4) and non-alcoholic fatty liver (NAFL) patients were analyzed. With samples randomized into 6 × 96-well plates we conducted 2 multiplexed ELISA assays of 58 fibrotic (FIB) and 76 immune-related (IMM) biomarkers apiece, using the Luminex platform. We used the glmnet package in R to conduct the Elastic Net algorithm with cross-validation to reduce the number of biomarkers and clinical features, and obtain models to predict significant (F2-F4), advanced (F3-F4), and F4 fibrotic stages of NASH (resulting in 6 models total). We also applied repeated loops of cross-validation to predict out-of-sample performance of our selected models by area under the curve (AUC) of the receiver operating characteristic (ROC).
Results: The best performing model is able to predict NASH with advanced fibrosis in our sample using 9 biomarkers and patient age with cross-validated median AUC = 0.907 predicted for performance in an independent cohort. Our other models could predict significant fibrosis (NASH F2-F4) and NASH F4 using combinations of just 3–11 biomarkers, patient BMI, and age, all with cross-validated predicted performance of AUC >0.85. Our models consist of common subsets of biomarkers, both novel and previously reported. The predicted out-of-sample performance of these models exceeds that of standard clinical models in this cohort (AUCs for BARD = 0.7, NAFLD score = 0.76, FIB-4 = 0.84 compared to cross-validated AUC = 0.91).



Conclusion: In a large cohort of NASH and NAFLD patients, we successfully used machine learning to develop predictive models to classify the severity of fibrosis in NASH. These outperform standard non-invasive clinical models. Importantly, we identified composite biomarker panels that can distinguish NASH F4 from NASH F3, an unmet need in clinical diagnostics. These cross-validated models should be further validated in independent cohorts.

FRI037

Low transient elastography score appropriately identifies patients that can stay within primary care practice

Jaspreet Suri[1], Hirsh Trivedi[1], Jeffrey Schwartz[2], Idriss Rajab[1], Daniela Goyes[1], Christopher Danford[1], Michelle Lai[1], Michael Curry[1]. *[1]Beth Israel Deaconess Medical Center (BIDMC), Liver Center, Department of Gastroenterology and Hepatology, Boston, United States; [2]Beth Israel Deaconess Medical Center (BIDMC), Department of Internal Medicine, Boston, United States*
Email: JSSURI@BIDMC.HARVARD.EDU

Background and Aim: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disorder in western countries. Transient Elastography (TE) is a convenient, non-invasive test to screen NAFLD patients for fibrosis thereby selecting patients who need evaluation for progressive disease and complications of portal hypertension. Given the high prevalence of NAFLD, referral of all patients to specialist care is not feasible. Therefore, we created an open access TE referral system with primary care providers (PCPs) to stratify based on TE score. Aim: To determine referral trends for low risk patients using open access TE.

Characteristics of study population (n = 212)			
	Not referred to hepatology (n = 160)	Referred to hepatology (n = 52)	p value
Age (years)	**54.3 (12.1)**	**50.2 (14.3)**	**0.04**
Sex (% female)	69 (43.1)	19 (36.5)	0.5
Race (%)			0.43
Caucasian	100 (65.4)	31 (60.8)	
Hispanic	24 (15.7)	9 (17.6)	
African-American	12 (7.8)	8 (15.7)	
Asian	16 (10.5)	3 (5.9)	
Other	1 (0.7)	0 (0)	
BMI (kg/m^2)	31.3 (6.8)	32.7 (7.4)	0.23
ALT (IU/L)	**43 (30.8)**	**73.4 (67.7)**	**<0.001**
DM2 (%)	34 (23.8)	11 (21.2)	0.85
PLT (K/uL)	248.1 (71.1)	261.2 (66.1)	0.29
A1C (%)	6.5 (4.6)	6.1 (1)	0.55
Alcohol abuse (%)	15 (10.9)	8 (15.7)	0.52
Fibroscan score (kPa)	**5.0 (1.1)**	**5.4 (1)**	**0.03**
CAP score (dB/m)	296.99 (53.3)	294.22 (61.1)	0.76
FIB-4	1.23 (1.1)	1.24 (1.2)	0.97
NFS	-2.31 (4.1)	-2.27 (1.5)	0.96
FIB-4 ≥ 2.67 (%)	6 (5.2)	2 (4.7)	1
NFS ≥ 0.676 (%)	7 (13)	1 (3.2)	0.27
CAP score ≥ 280	68 (81)	30 (85.7)	0.72
Steatosis on ultrasound (%)	68 (81)	30 (85.7)	0.72
Splenomegaly (%)	8 (9.6)	4 (11.4)	1
Portal hypertension (%)	4 (6.2)	4 (14.8)	0.35

Methods: In August 2017, an open access program was established whereby PCPs order TE for fibrosis assessment on NAFLD patients. A TE score < 7 kilopascals (kPa) was considered low-risk and would recommend management by the PCP. TE scores ≥ 7 kPa were considered high-risk and prompted a hepatology evaluation. Data were collected on each referral including demographics, practice type of the ordering physician, TE score, CAP score, serological testing, comorbidities, imaging and patient follow up with hepatology.
Results: Seventy percent (212/303) of those initially referred using the open access TE system had a score of <7 kPa. Despite this score, 25% (52/212) of these patients were still referred and evaluated by hepatology. Those were referred for evaluation tended to have a higher TE score (5.4 kPa vs 5.0 kPa, p = 0.03), ALT values (73.4 IU/L vs 43 IU/L, p < 0.001) and were slightly younger (50.2 y/o vs 54.3 y/o, p = 0.04). There was no statistically significant difference in race, BMI, A1c, FIB-4 score, NFS score, CAP score, or findings of steatosis and portal hypertension on imaging between the group eventually seen by hepatology and those referred back to PCP.

Conclusion: Use of screening TE in the primary care setting is a useful tool to risk stratify NAFLD patients, allowing efficient utilization of healthcare resources by referring low risk patients back to the PCP for lifestyle modifications. Patients with TE score <7 kPa had concordantly low FIB-4 and NFS scores demonstrating that our open access TE program and referral algorithm was able to appropriate risk stratify patients. Still, higher ALT values tend to trigger appropriate hepatology evaluations in this group. Linkage to care remains an important part of this process and clear communication between primary care and hepatologists is paramount.

FRI038

Phenome-wide association study of the FIB-4 index in a large, populational-based study in the United States

Karen Schlauch[1], Gai Elhanan[1], Robert Read[1], Jim Metcalf[1], Daniel Kiser[1], Marianne Camargo[2], Andrew N. Billin[3], Anand Chokkalingam[2], Scott Patterson[3], Robert P. Myers[2], Joseph J. Grzymski[1]. *[1]Desert Research Institute, Reno, United States; [2]Gilead Sciences, Liver Disease Therapeutic Area, Foster City, United States; [3]Gilead Sciences Inc., Biomarker Sciences, Foster City, United States*
Email: joe.grzymski@dri.edu

Background: The fibrosis-4 index (FIB-4) is a noninvasive test that has been validated in patients with nonalcoholic fatty liver disease (NAFLD), but is increasingly utilized to identify at-risk patients in the general population. We report a large-scale analysis of associations between FIB-4 and diagnostic phenotypes (PheCodes) in a general electronic health record (EHR).
Method: Using the EHR database of the Renown Health system in Reno, Nevada, 57,764 individuals aged 40–65 years were identified with any high or always low FIB-4 scores, based on standardized lab values across the last four years. After application of stringent exclusion criteria for hepatic comorbidities unrelated to NAFLD such as alcohol and drug abuse and viral hepatitis, 41,326 individuals remained eligible (the curated cohort). ICD9/10 codes were extracted and mapped to 1,757 PheCodes. On average, an individual had 17 PheCodes assigned. Linear regression was used to evaluate associations between the incidence of each phenotype group containing at least 250 participants, adjusted for age and gender, using a modification of the PheWAS program in R. A standard correction for the false discovery rate was performed, and all adjusted p-values less than 10^{-5} were considered for statistically significant associations.
Results: In the non-curated cohort, FIB-4 scores were significantly associated with numerous expected phenotypes with large effect size (>8) including chronic liver and hematologic conditions ($p < 10^{-320}$). In total, 366 phenotype codes ($p < 10^{-5}$) were identified. In contrast, the curated cohort generated fewer significant PheCodes associated with FIB-4 (98 codes, $p < 10^{-5}$) and a much lower effect sizes (mean effect size, 0.45 vs 1.92 in the non-curated cohort). These notable differences in significant associations and effect sizes between the non-curated and curated cohorts suggest that the predictive value of FIB-4 decreases drastically when eliminating hepatic comorbidities unrelated to NAFLD. In the curated cohort, the phenotypes significantly associated with FIB-4 with the largest effect sizes (all < 1) were related to cardiac and respiratory disorders.
Conclusion: These findings from a large general population EHR database suggest that elevated FIB-4 scores are often strongly associated with a variety of phenotypes unrelated to NAFLD even after application of exclusion criteria. Thus, careful cohort selection is necessary when utilizing FIB-4 in such populations to assess the epidemiology and outcomes of NAFLD.

FRI039

A combined and sequential non-invasive approach to diagnosing non-alcoholic steatohepatitis in patients with non-alcoholic fatty liver disease and persistently normal alanine aminotransferase levels

Kenneth I. Zheng[1], Wen-Yue Liu[2], Xiao-Yan Pan[3], Hong-Lei Ma[1], Pei-Wu Zhu[4], Xi-Xi Wu[5], Giovanni Targher[6], Chris Byrne[7], Xiao-Dong Wang[1,8], Yong-Ping Chen[1,8], Fengmin Lu[9], Ming-Hua Zheng[1,8,10]. *[1]The First Affiliated Hospital of Wenzhou Medical University, NAFLD Research Center, Department of Hepatology, Wenzhou, China; [2]The First Affiliated Hospital of Wenzhou Medical University, Department of Endocrinology, Wenzhou, China; [3]The First Affiliated Hospital of Wenzhou Medical University, Department of Endocrinology, Wenzhou, Chile; [4]The First Affiliated Hospital of Wenzhou Medical University, Department of Clinical Laboratory, Wenzhou, China; [5]The First Affiliated Hospital of Wenzhou Medical University, Department of Gastroenterology, Wenzhou, China; [6]University and Azienda Ospedaliera Universitaria Integrata of Verona, Section of Endocrinology, Diabetes and Metabolism, Department of Medicine, Verona, Italy; [7]University Hospital Southampton, Southampton General Hospital, Southampton National Institute for Health Research Biomedical Research Centre, Southampton, United Kingdom; [8]Wenzhou*

Email: zhengmh@wmu.edu.cn

Background & Aim: Liver disease severity is often not investigated further in patients with imaging-confirmed non-alcoholic fatty liver disease (NAFLD), who have normal alanine aminotransferase (nALT) levels. Early diagnosis of non-alcoholic steatohepatitis (NASH) is needed for preventing further progression in NAFLD patients. We aim to test whether serum Golgi protein 73 (GP73) levels predicts NASH in patients with biopsy-confirmed NAFLD and nALT levels, and develop a non-invasive model to diagnose NASH in this group of patients.

Methods: Serum GP73 and cytokeratin 18 M30 fragments (CK18-M30) levels were measured in 345 patients with biopsy-proven NAFLD. We have developed a new G-NASH model (that included serum GP73 concentration) and combined it with serum CK18-M30 measurement in a sequential non-invasive approach to accurately identify NASH among patients with NAFLD and persistently nALT levels.

Results: 105 (30.4%) patients had persistently nALT, 53 (50.5%) of which had histologically-confirmed NASH. Both serum GP73 and CK18-M30 levels alone had poor diagnostic accuracy for identifying NASH (55.2% and 51.6% respectively) in patients with NAFLD and persistently nALT. In contrast, the newly developed G-NASH model

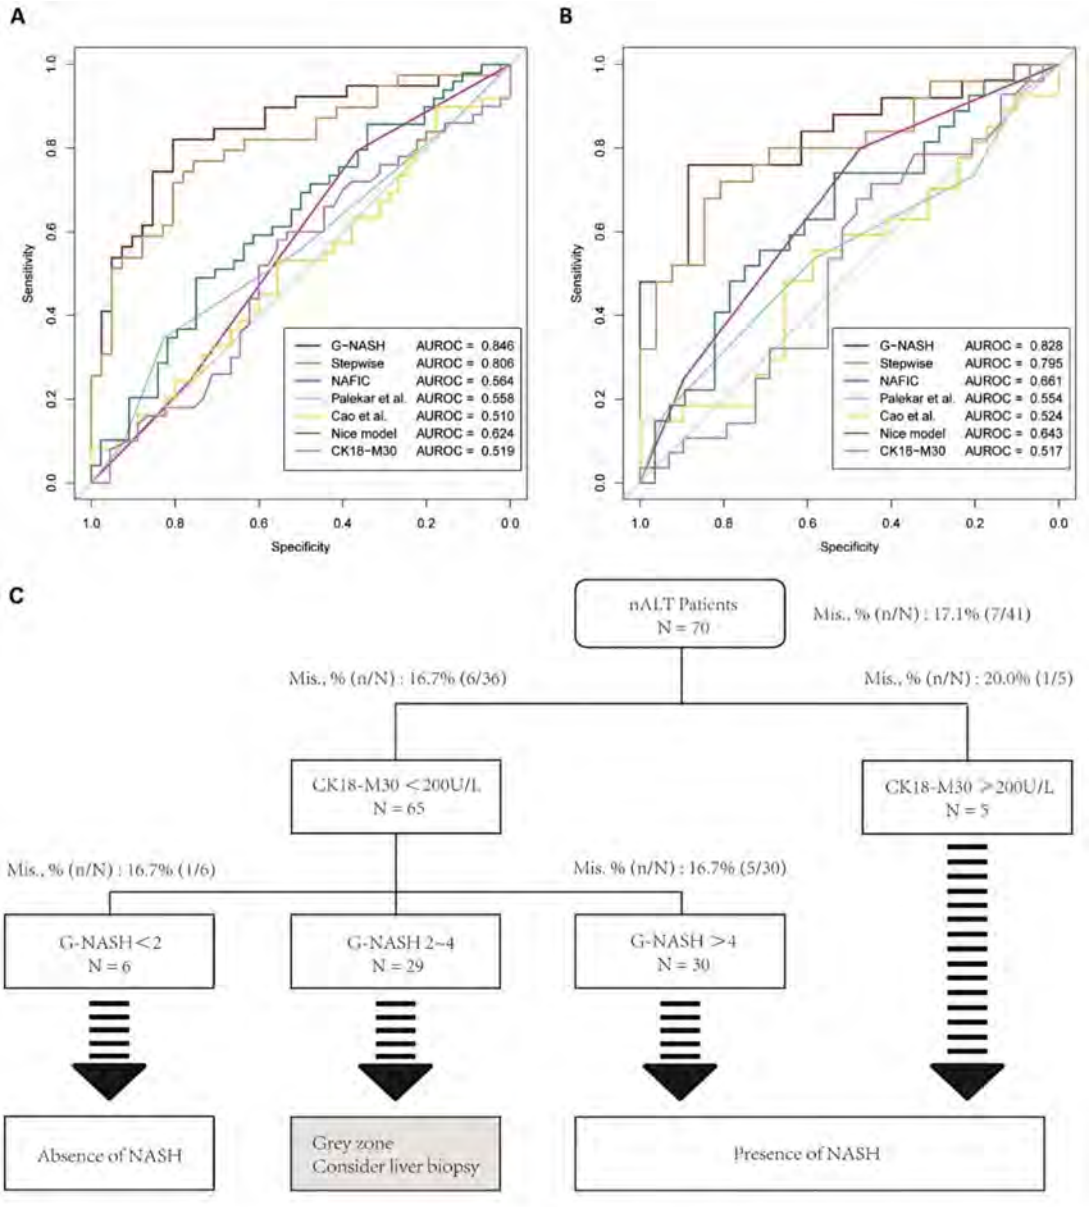

Figure 1. A&B. Receiver operating characteristic curves of various non-invasive clinical scoring systems for the prediction of NASH among NAFLD patients with persistently nALT. C. Combined and sequential non-invasive approach to predict NASH among NAFLD patients with persistently nALT levels by using serum CK18-M30 levels and the G-NASH model.

(A) using a cut-off of serum ALT levels <40 U/L for both sexes. (B) using a lower cut-off of serum ALT ≤35 U/L in men (n = 48) and ≤23 U/L in women (n = 16). (C) Mis.: misdiagnosis.

Figure: (abstract: FRI039)

performed best when compared to other established non-invasive scoring systems (area under the receiver operator characteristic curve [AUROC] 0.846, 95% confidence intervals 0.757 to 0.934). Moreover, by using our proposed combined and sequential non-invasive approach, 82.9% (34 out of 41) of patients with NASH were correctly identified.

Conclusions: NASH is highly prevalent in NAFLD patients with persistently nALT levels. The G-NASH model can accurately identify NASH in this patient group.

FRI040

Macrophage markers do not add to the prediction of liver fibrosis by transient elastography in patients with non-alcoholic fatty liver disease

Konstantin Kazankov[1], Chiara Rosso[2], Ramy Younes[2], Hannes Hagström[3,4], Holger Jon Møller[5], Per Stal[6,7], Elisabetta Bugianesi[2], Henning Grønbæk[1]. Email: konskaza@rm.dk

Background and Aims: Fibrosis staging by non-invasive tests is essential in non-alcoholic fatty liver disease (NAFLD). Measurement of liver stiffness by transient elastography (TE) is a well-established method for liver fibrosis assessment in NAFLD. We have previously shown that macrophage marker sCD163 is an independent predictor for fibrosis in NAFLD, and that combining sCD163 with e.g. NAFLD Fibrosis score improves the precision. In the present study we tested whether the combination of macrophage markers and TE improves fibrosis prediction compared to the individual parameters.

Method: We measured macrophage markers soluble CD163 (sCD163) and mannose receptor (sMR) using in-house ELISA assays in two independent cohorts from Italy (n = 141) and Sweden (n = 70) with biopsy-proven NAFLD and available TE.

Results: In the Italian cohort, TE and sCD163 showed similar moderate associations with liver fibrosis (rho = 0.56, p < 001 and rho = 0.45, p < 0.001, respectively). TE had an area under the Receiver Operating Characteristics curve (AUROC) (with 95% CI) for F2 fibrosis: 0.79 (0.72–0.87), F3: 0.81 (0.73–0.89), F4: 0.95 (0.90–1.0). sCD163 also predicted fibrosis well [F2: 0.71 (0.63–0.80), F3: 0.82 (0.74–0.90), F4: 0.89 (0.76–1.0)]. However, combining sCD163 and TE did not improve the AUROCs significantly [F2: 0.79 (0.72–0.87), F3: 0.85 (0.78–0.92), F4: 0.97 (0.93–1.0)]. In the Swedish cohort, TE showed a closer association with fibrosis (rho = 0.73, p < 0.001) than sCD163 (rho = 0.42, p < 0.001) and sMR (rho = 0.39, p < 0.001). TE predicted fibrosis well [F2: 0.88 (0.80–0.97), F3: 0.90 (0.83–0.97), F4: 0.87 (0.78–0.96)], whereas sCD163 did not (best AUROC 0.75). sMR showed a better prediction [F2: 0.68 (0.56–0.81), F3: 0.82 (0.71–0.92), F4: 0.79 (0.66–0.93)], but the addition of sMR did not further improve the prediction of fibrosis by TE.

Conclusion: In these cohorts of NAFLD patients, TE was superior to macrophage markers for fibrosis prediction and in contrast to our hypothesis the addition of these markers to TE did not improve its predictive capability.

FRI041

Diagnostic accuracy of controlled attenuation parameter compared to ultrasound for detecting steatosis in children with obesity

Jurgen Runge[1], Jet van Giessen[1], Laura Draijer[2], Eline Deurloo[1], Anne Smets[1], Marc Benninga[2], Bart Koot[2], Jaap Stoker[1]. [1]*Amsterdam UMC, Location AMC, Radiology and Nuclear Medicine, Amsterdam, Netherlands;* [2]*Amsterdam UMC, Location AMC, Pediatric Gastroenterology and Nutrition, Amsterdam, Netherlands*
Email: l.g.draijer@amsterdamumc.nl

Background and Aims: Current screening tools, alanine amino-transferase (ALT) and ultrasound (US), have insufficient accuracy for detecting Non-alcoholic Fatty Liver Disease (NAFLD) in children with obesity. The aim of this study is to determine the diagnostic accuracy of Controlled Attenuation Parameter (CAP) in detecting and grading steatosis in a screening setting and perform a head-to-head comparison with US.

Method: Sixty children (57% male) with severe obesity (median BMI z-score 3.37; median age 13.7 years) were evaluated. All underwent CAP measurement and US using a standardized 4-item scoring system. Magnetic Resonance Spectroscopy Proton Density Fat Fraction (MRS-PDFF) was used as reference standard. ROC curve analyses were performed to determine diagnostic performance and optimal screening cutoffs.

Results: Steatosis was present in 36/60 (60%) children. The areas under the ROC (AUROC) of CAP for the detection of grade ≥ S1, ≥ S2 and ≥ S3 steatosis were 0.79 (95% CI:0.67–0.89), 0.75 (95% CI:0.62–0.85) and 0.79 (95% CI:0.67–0.89), respectively. The AUROC of US for the detection of grade ≥ S1 steatosis was 0.68 (95% CI:0.55–0.80) and was not significantly different from CAP (p = 0.11). For detecting ≥S1 steatosis, CAP had a sensitivity of 75% and a specificity of 75% at its optimal cutoff of 277 dB/m. US had a sensitivity of 61% and a specificity of 71% for detecting ≥ S1 steatosis at its optimal cutoff (US steatosis score ≥ 2). When using echogenicity of liver parenchyma as only scoring item, US had a sensitivity of 70% and specificity of 54% to detect ≥S1 steatosis. The difference in specificity of CAP and US

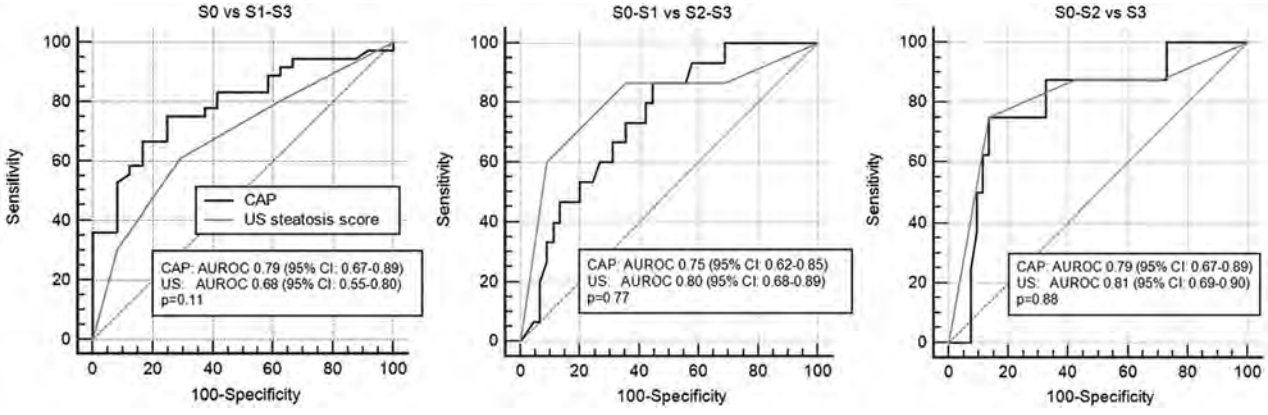

Figure: (abstract: FRI041)

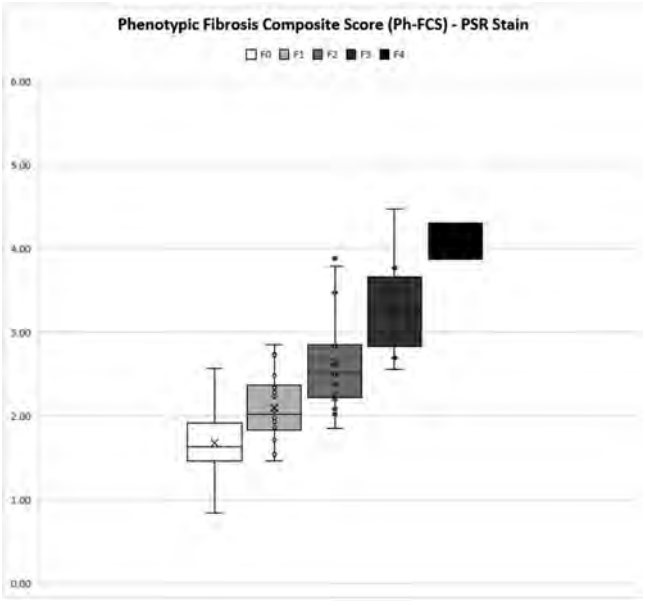
when using only echogenicity of liver parenchyma of 21% was significant (p = 0.04).
Conclusion: The overall performance of CAP is not significantly better than US in detecting steatosis in children with obesity, provided that standardized scoring of US features is applied. When US is based on liver echogenicity only, CAP outperforms US in screening for any steatosis (≥S1).

FRI042
ELF test should be used concurrently with elastography in NAFLD to maximize diagnostic accuracy
Laura Iogna Prat[1], Marta Guerrero[1], Elena Buzzetti[1,2], Anna Mantovani[1,3], Mona Ismail[1], Atul Goyale[1], Davide Roccarina[1], Emmanuel Tsochatzis[1]. *[1]UCL Institute for Liver and Digestive Health, Royal Free Hospital and UCL, London, London, United Kingdom; [2]Department of Medical and Surgical Sciences SMECHIMAI, Division of Medicine and CeMEF, University of Modena and Reggio Emilia, Modena, Italy; [3]Division of General Medicine and Hypertension, Department of Medicine, Azienda Ospedaliera Universitaria Integrata, University of Verona, Verona, Italy, Verona, Italy*
Email: laura.iognaprat@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the leading cause for secondary care referrals in most western countries. Despite its high prevalence, only a minority of patients develops fibrosis and subsequent liver-related outcomes. The ELF test is a validated tool for non-invasive assessment of liver fibrosis and is recommended by the National Institute for Clinical Excellence (NICE) in the UK for screening NAFLD patients for advanced fibrosis. We explored the concordance of ELF with FibroScan® and its diagnostic accuracy compared to liver biopsy in consecutive patients referred because of a high ELF score.
Method: We selected all patients referred from 2014 to 2019 according to local referral pathways because of a suspicion of NAFLD and an ELF test ≥9.5. Clinical and laboratory data were collected. ELF test was compared to liver biopsy and/or liver stiffness assessed with FibroScan®.
Results: 292 patients fulfilled our inclusion criteria. Characteristics of the population were: 50% male, mean age 64 ± 10 years, mean BMI 32 ± 6 Kg/m^2, 47% had diabetes, 66% dyslipidaemia, 68% hypertension. Liver biopsy was available for 80 (27%) patients and FibroScan® measurements for 233 (80%) patients. 24 (30%) liver biopsies showed advanced fibrosis and 57 (71%) showed NASH. Liver stiffness values were ≥ 8 kPa in 69 (30%) patients and ≥ 10 kPa in 45 (19%). Therefore, the concordance of FibroScan® and ELF for advanced fibrosis (cut-off 10 kPa) was 19% and there was a significant discordance (FibroScan® <6 kPa) in 105 (45%) of the cases. Forty-eight (60%) patients with a high ELF score had no or minimal fibrosis (F0-F1) on liver biopsy; only eight and four of these patients had FibroScan® values above 8 kPa and 10 kPa respectively. All patients with biopsy proven advanced fibrosis had FibroScan® values >8 kPa. We could not identify independent predictors of advanced fibrosis in our cohort.
Conclusion: The ELF test has a poor concordance with liver stiffness for the diagnosis of advanced fibrosis. When ELF is used as a screening tool, the use of a confirmatory second non-invasive test is warranted for positive results, in order to better stratify patients needing a liver biopsy.

FRI043
Evaluation of a novel histology-based fibrosis phenotypic composite score and its correlation with NASH-CRN fibrosis scores in patients with NASH
Li Chen[1], Michael Lung[2], Mathieu Petitjean[1], Cynthia Behling[3], Arun Sanyal[4]. *[1]PharmaNest, Princeton, United States; [2]Pacific Rim Pathology, San Diego, United States; [3]University of California, Department of Pediatrics, San Diego, United States; [4]Virginia Commonwealth University, Richmond, United States*
Email: mathieu.petitjean@pharmanest.com

Background and Aims: We have previously shown that the Phenotypic Fibrosis Composite Score (Ph-FCS) calculated by the FibroNest image analysis platform from second harmonic generation (SHG) images correlates with the NASH-CRN fibrosis scores. Ph-FCS is a novel continuous phenotypic scoring and quantifier of fibrosis. In this study, the same slides imaged non-destructively by SHG have been stained, digitized and then quantified with FibroNest. This study evaluates the performance of the Ph-FCS obtained from stained slides and its relationship with NASH-CRN fibrosis scores.
Method: This retrospective study comprised a cohort of 77 patients with NASH diagnosed by histologic assessment of liver biopsy according to NASH CRN criteria by pathologists (F0(21), F1(17), F2 (20), F3(15), F4(4)). FFPE sections (3–4 microns) of biopsies were stained with picro sirius red (PSR, Abcam Kit ab150681) and imaged at 20X in white light with an Aperio AT2 Digital Pathology system. Using FibroNest© for image analysis, the fibrosis phenotype is described for its collagen content and structure (12 traits), the morphometric traits of the collagen fibers (12), and fibrosis texture traits (7). Each morphometric and texture trait is quantified with 7 parameters (qFPs) to account for severity, progression, distortion and variance for both fine and assembled collagens, resulting in a total of 315 qFPs. Meaningful qFPs are combined to calculate the normalized Ph-CFS. The sensitivity of the Ph-CFS to the PSR process is also evaluated on a separate group of 5 biopsies (thickness: 2–5 micron; bath time: 10–60 min).
Results: The Ph-CFS correlates with fibrosis stages (p < 0.00001) and differentiates between fibrosis F1 to F4 stages. In the development of the score, non-adequate biopsies (<10 mm long) limited the performance of the computerized method and were removed from the final analysis. In order to obtain a Ph-FCS of similar performance as the one obtained using SHG, we doubled the amount of meaningful qFPs (from 30 to 70) to generate a higher image analysis signal to noise capable to offset any loss in collagen detection (vs SHG). The Ph-FSC appears to be very robust as it varies less than 5% when the thickness of the section varies within 1 micron and the staining bath time varies within 10 mins.



Conclusion: The Ph-CFS calculated with FibroNest© from histopathology stained sections is a valuable and reliable evaluation of fibrosis severity and progression in patients with NASH.

FRI044

Serum exosomal miRNA-4668-5p as potential biomarker for advanced fibrosis in non-alcoholic fatty liver disease

Young-Sun Lee[1], Eunjung Ko[1], Yoonseok Lee[1], Ji Hoon Kim[1], Jong Eun Yeon[1], Kwan Soo Byun[1]. [1]*Korea University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: jeyyeon@hotmail.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is becoming leading cause of chronic liver disease. As fibrosis is the main prognostic factor in patients with NAFLD, it is important to identify advanced fibrosis. In this study, we analyzed serum exosomal miRNA and tissue miRNA from biopsy-proven NAFLD patients and identified the role of miRNA in progression of fibrosis.
Method: Sera and tissue were collected from 41 patients with biopsy-proven NAFLD without other chronic liver disease between November 2016 and January 2018. Sera were stored at −80°C and thawed for isolation of the exosome. Exosomes were isolated from sera using an exosome isolation kit. Total RNA was extracted from exosomes and microarray was performed. Liver tissues were stored at −80°C and subjected to real-time PCR. Overexpression and inhibition of miRNA were achieved by transfection of miRNA mimic and miRNA inhibitor in hepatic stellate cell line (LX-2), respectively.
Results: Mean age and BMI were 53.5 ± 12.3 years and 29.9 ± 4.6 kg/m^2, respectively. Female was dominant (n = 34, 82.9%). In microarray analysis, total 2,578 miRNAs were identified. We classified patients into non-advanced fibrosis group (F0-2, n = 25) and advanced fibrosis group (F3-4, n = 16). 40 miRNAs expression were significantly increased in advanced fibrosis group comparing with non-advanced fibrosis group. Among them, miRNA4668 were increased more than 8 times in advanced fibrosis group comparing with non-advanced fibrosis group. In tissue, the expression of miRNA 4668-5p (miR-4668-5p) were significantly decreased in advanced fibrosis group comparing with non-advanced fibrosis group. Overexpression of miR-4668-5p increased expression of profibrotic genes (TGF-β1, collagenase 1a1, and α-SMA) in LX-2, whereas inhibition of miR-4668–5p decreased expression of profibrotic genes in LX-2. (Figure).

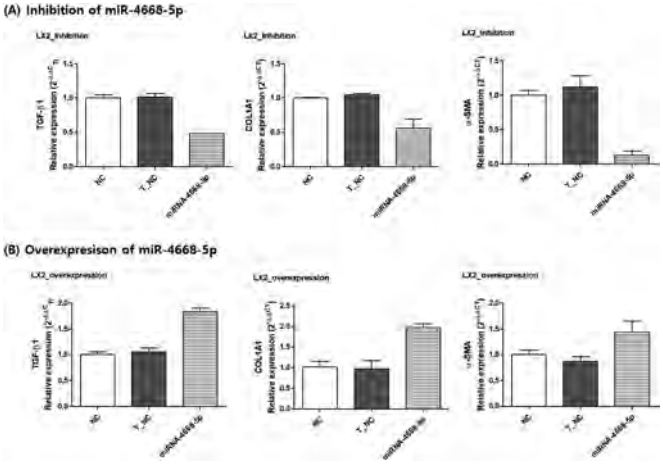


Figure: Profibrotic gene expression in LX-2 after inhibition of miR4668-5p (A) and overexpression of miR-4668-5p (B).

Conclusion: miR-4668-5p expression was significantly increased in exosome from patients with advanced fibrosis compared to non-advanced fibrosis group. miR4668-5p could be useful biomarker and might be therapeutic target for advanced fibrosis in NAFLD.

Patient-reported symptoms and impact in non-alcoholic steatohepatitis: an evaluation of the NASH-check, a novel prom in NASH

Diane Whalley[1], James Twiss[1], Lynda Doward[1], Maria Magdalena Balp[2], Clifford Brass[3], Juergen Loeffler[4], Patricia Lopez[4], Jennifer Cai[5], Donna Cryer[6], Quentin Anstee[7], Arun Sanyal[8]. [1]*RTI-Health Solutions, Patient-Centered Outcomes Research, Manchester, United Kingdom;* [2]*Novartis Pharma AG, Immunology & Dermatology Franchise, Basel, Switzerland;* [3]*Novartis Pharmaceuticals Corporation, Hepatology & Dermatology Development Unit, East Hanover, United States;* [4]*Novartis Pharma AG, Dev B&SS IHD, Basel, Switzerland;* [5]*Novartis Pharmaceuticals Corporation, East Hanover, United States;* [6]*Global Liver Institute, Washington, United States;* [7]*Newcastle University Medical School, Institute of Cellular Medicine, Newcastle-Upon-Tyne, United Kingdom;* [8]*Medical College of Virginia, Pharmacology and Molecular Pathology, Richmond, United States*
Email: ldoward@rti.org

Background and Aims: NASH-CHECK is a newly developed patient-reported outcome measure (PROM) assessing symptoms and health-related quality of life (HRQOL) in nonalcoholic steatohepatitis (NASH). The aim of the study was to conduct an evaluation of the preliminary dimensional structure of this PROM. The evaluation was guided by a conceptual model prepared during the initial development of NASH-CHECK, from which items were categorised into logical groupings comprising 10 symptoms items and 21 HRQOL items (activity limitations = 8 items; emotions and lifestyle issues = 13 items).
Method: Data from a randomised, double-blind, placebo-controlled phase 2 trial of tropifexor in adult patients with NASH were used for the evaluation. Analyses included item correlations, exploratory factor analysis and Rasch analysis.
Results: The analysis sample included 104 patients with NASH fibrosis grades 1 to 3 (54.8% female; mean [standard deviation] age = 51.2 [12.7] years; mean [standard deviation] body mass index = 32.5 [6.1]). Type 2 diabetes was present for 60 (65.4%) patients. Figure 1 shows a summary of the preliminary structure of NASH-CHECK resulting from the analyses. The results supported a 4-item cognitive symptoms subscale with the remaining symptoms items (e.g. pain, bloating, fatigue, itch) as individual items. For HRQOL, analysis supported the distinction between activity limitations and emotions & lifestyle. Analysis supported an overall activity limitations summary score which can be further divided into two activity limitations subscales (daily activities; ambulation). For emotions & lifestyle, production of an overall psychosocial summary was supported along with two subscales (emotions and social). Some items were highly correlated with each other (>0.80) suggesting potential content overlap (e.g. single symptoms items fatigue and need to rest, ambulatory items within the activity limitations subscales). In addition, one item (food restriction) showed a lack of association with other HRQOL items.

Figure: Preliminary dimensional structure of NASH-CHECK.

Conclusion: The results provide evidence for a preliminary dimensional structure for NASH-CHECK that is in line with the proposed logical groupings in the conceptual model. Further analyses using new trial data are planned to confirm the dimensional structure of NASH-CHECK.

FRI047

The FGF19 analogue aldafermin improves non-invasive tests in patients with non-alcoholic steatohepatitis

Marno Ryan[1], Stuart Roberts[2], Manal Abdelmalek[3], James F. Trotter[4], Angelo Paredes[5], Guy Neff[6], Andrew Yan[7], Alex DePaoli[7], Lei Ling[7], Hsiao Lieu[7], Stephen Harrison[8]. *[1]St. Vincent's Hospital, Department of Gastroenterology, Melbourne, Australia; [2]Alfred Hospital, Melbourne, Australia; [3]Duke University, Durham, United States; [4]Liver Consultants of Texas, Dallas, United States; [5]Brooke Army Medical Center, San Antonio, United States; [6]Florida Digestive Health Specialists, Lakewood Ranch, United States; [7]NGM Biopharmaceuticals, South San Francisco, United States; [8]Pinnacle Clinical Research, San Antonio, United States*
Email: lling94080@yahoo.com

Background and Aims: Nonalcoholic steatohepatitis (NASH) represents an epidemic health crisis with broad impact on public health. Developing therapeutics for NASH poses a vexing challenge, which requires invasive procedures such as liver biopsy. Several inexpensive, simple, commonly used non-invasive tests (NITs), such as AST to platelet ratio index (APRI) and FIB-4 index, can predict liver-related outcomes and have been used to identify high-risk NASH patients from primary care settings. Aldafermin (previously known as NGM282), a non-tumorigenic FGF19 analogue, significantly inhibited bile acid synthesis, reduced steatosis, hepatic inflammation and fibrosis in patients with NASH. Here we report the effect of aldafermin on NITs in phase 2 studies in patients with NASH.
Method: In part 1 of the study, 82 subjects were randomized to aldafermin 3 mg (n = 27) or 6 mg (n = 28) vs. placebo (n = 27) as a daily SC injection for 12 weeks. In part 2 of the study, 94 subjects received open-label aldafermin 0.3 mg (n = 23), 1 mg (n = 49) or 3 mg (n = 22) for 12 weeks for dose-range finding. Key inclusion criteria included biopsy-proven NASH with NAS ≥ 4 (at least 1 point in each component), Stage 1–3 fibrosis and absolute liver fat content (LFC) by MRI-PDFF ≥ 8%. APRI, FIB-4, fatty liver index (FLI) and ratio of triglyceride and HDL (TG/HDL) were evaluated at baseline (BL) and week 12 (W12).
Results: At BL, mean APRI, FIB-4, FLI and TG/HDL values were similar across all groups. At W12, aldafermin-treated patients showed reductions in NITs of fibrosis (APRI and FIB-4) and fatty liver (FLI) (Table 1). In contrast, no improvement was seen with placebo-treated subjects. Improvements were observed as early as 2 weeks on aldafermin and were maintained throughout treatment duration. TG/HDL ratio decreased significantly with aldafermin treatment.

Table 1: Change from baseline to week 12 in non-invasive tests.

	APRI	FIB-4	FLI	TG/HDL
Part 1: Double-Blind, Placebo-Controlled				
PBO	0.03	0.08	0.3	−0.7
Aldafermin 3 mg	−0.24***	−0.14	−1.2	−0.9
Aldafermin 6 mg	−0.17***	−0.01	−2.2	−1.3**
Part 2: Open-Label				
Aldafermin 0.3 mg	−0.14*	−0.04	−2.2	−0.9
Aldafermin 1 mg	−0.38***	−0.22**	−3.1***	−1.4***
Aldafermin 3 mg	−0.44***	−0.35**	−2.7	−1.7***

***p < 0.001, **p < 0.01, *p < 0.05 vs baseline.

Conclusion: Aldafermin therapy produced improvements in several simple and inexpensive NITs of liver fibrosis, steatosis and cardiovascular risk. These NITs may be useful for monitoring early treatment response to aldafermin.

Evaluating the patient-perceived impact of non-alcoholic steatohepatitis with compensated cirrhosis

Matthew Breckons[1], Lynda Doward[2], Lorraine McSweeney[1], Maria Magdalena Balp[3], James Twiss[2], Yemi Oluboyede[1], Luke Vale[1], Laura Ternent[1], Clifford Brass[4], Arun Sanyal[5], Quentin Anstee[6,7]. *[1]Newcastle University, Population Health Sciences Institute, Newcastle upon Tyne, United Kingdom; [2]RTI-Health Solutions, Manchester, United Kingdom; [3]Novartis Pharma AG, Basel, Switzerland; [4]Novartis Pharmaceutical Corporation, East Hanover, United States; [5]Virginia Commonwealth University School of Medicine, Dept. of Internal Medicine, Div. Of Gastroenterology, Hepatology and Nutrition, Richmond, United States; [6]Newcastle University, Institute of Clinical & Translational Research, Faculty of Medical Sciences, Newcastle-upon-Tyne, United Kingdom; [7]Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle NIHR Biomedical Research Centre, Newcastle-upon-Tyne, United Kingdom*
Email: Matthew.Breckons@newcastle.ac.uk

Background and Aims: NASH-CHECK is the first patient-reported outcome measure (PROM) developed specifically for patients with non-cirrhotic non-alcoholic steatohepatitis (NASH; fibrosis F1-F3) in accordance with the US Food and Drug Administration guidance for PROMs supportive of drug labelling claims. It contains items assessing symptoms and health-related quality of life (HRQOL; activity limitations, emotions and lifestyle items). The current study assessed the symptom burden and HRQOL impacts experienced by patients with compensated cirrhotic NASH and compared them to the concepts covered by NASH-CHECK.
Method: A qualitative study with concept elicitation interviews was conducted with compensated cirrhotic NASH patients attending hepatology clinics in the United States and United Kingdom. Thematic analysis identified key symptoms and HRQOL impacts. These were compared with the key concepts encompassed by NASH-CHECK. New symptom items identified were discussed with an international group of clinicians to gain consensus on their relevance to compensated cirrhotic NASH.
Results: Thirty-three patients were interviewed, 61% female, mean (SD) age = 64.5 (7.8) years, body mass index = 34.5 (4.1). Comorbidities included type II diabetes 81.8%, obesity 87.9%, and hypertension 39.4%. Saturation was reached during the thematic analysis. Key symptoms identified in NASH-CHECK (pain, bloating, itch, fatigue, sleep, cognitive) were all reported. Key HRQOL concepts identified in NASH-CHECK (activity limitations, emotional, social, relationships, and work impacts) were also frequently reported and found to be comprehensive in relation to patients' experience of NASH with compensated cirrhosis. Additional symptoms reported included muscle cramps 54.6%, generalised pain 42.4%, shortness of breath 42.4%, and heartburn 39.4%. On clinical review, these additional symptoms identified were deemed to be related to co-morbidities or medication side-effects and so not directly related to compensated NASH cirrhosis or appropriate for inclusion in a PROM.
Conclusion: NASH patients with compensated cirrhosis experience similar symptoms and HRQOL impacts to patients with earlier stages of disease but may experience them more severely. These data suggest that NASH-CHECK is likely to be applicable in the compensated NASH cirrhosis population. Cognitive debriefing interviews are being conducted to further evaluate NASH-CHECK in cirrhotic patients.

FRI049

Systematic review and meta-analysis of FIB-4 for the diagnosis of advanced fibrosis due to non-alcoholic steatohepatitis

Mazen Noureddin[1], Amber L. Martin[2], Samantha Martel[2], Robert Myers[3], Angela Nitka[3], Meghna Mehta[3], Kavita Juneja[3], Arun Sanyal[4]. [1]*Cedars-Sinai Medical Center, Los Angeles, United States;* [2]*Evidera, Waltham, United States;* [3]*Gilead Sciences, Inc., Foster City, United States;* [4]*Virginia Commonwealth University VCU Medical Center, Richmond, United States*
Email: amber.martin@evidera.com

Background and Aims: Liver biopsy is the current standard for the staging of fibrosis in patients with nonalcoholic fatty liver disease (NAFLD)/nonalcoholic steatohepatitis (NASH). However, biopsy is expensive, invasive, and not ideal for monitoring of fibrosis. Due to these limitations, noninvasive tests (NIT) have been developed, including the fibrosis-4 index (FIB-4), which includes age, platelets, and serum ALT and AST. Our objective was to summarize the evidence regarding the diagnostic performance of FIB-4 for staging fibrosis in NAFLD/NASH using a systematic literature review (SLR) and meta-analysis (MA).
Method: Searches were conducted in MEDLINE and Embase to identify studies published in English from 1/1/1945–3/21/2019, that evaluated the diagnostic performance of FIB-4 to stage fibrosis in patients with NAFLD/NASH. Methods followed the PRISMA guidelines. Random effects meta-analyses (restricted maximum likelihood approach) were conducted on diagnostic odds ratios (DOR) in terms of the logit of sensitivity and specificity with a focus on biopsy-confirmed advanced fibrosis (F3-4 vs F0-2) at the FIB-4 cut-points of <1.30 and ≥ 2.67.
Results: The SLR identified 42 studies including 31,309 patients with NAFLD/NASH. FIB-4 cutoffs ranging from 1.30 to 3.25 yielded the best performance to stage fibrosis (AUROCs 0.80–0.95, n = 25 studies). Except for five studies with poor to moderate performance (AUROCs 0.52–0.65), FIB-4 showed good to excellent accuracy for diagnosing any fibrosis (biopsy-confirmed F1-4 vs F0, AUROCs 0.70–0.95, n = 34). FIB-4 performed best at predicting advanced fibrosis (F3-4 vs F0-2; AUROCs 0.80–0.95, n = 17) or cirrhosis (F4 vs F0-3, AUROCs 0.78–0.92, n = 4), compared with significant fibrosis (F2-4 vs F0-1, AUROCs 0.62–0.84, n = 8). MA results from nine studies including 8,155 patients (Figure) suggest that FIB-4 was a strong predictor of advanced fibrosis using both cut-points with slightly higher DOR for the cut-point ≥ 2.67 in comparison with <1.30 (DOR of 9.93 vs. 8.04).

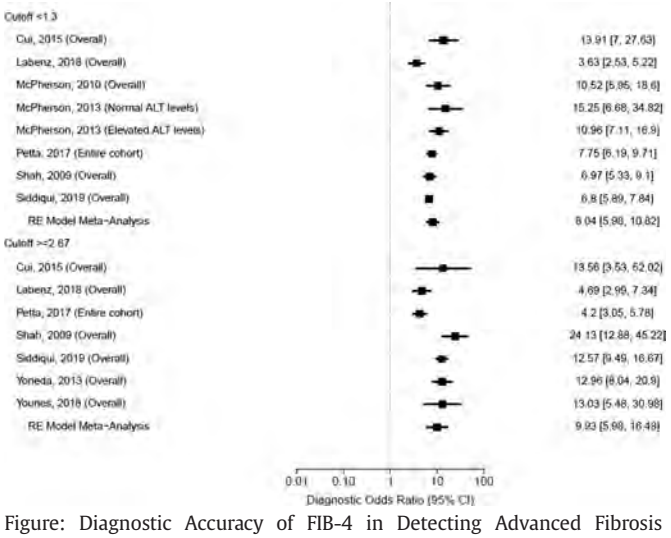

Figure: Diagnostic Accuracy of FIB-4 in Detecting Advanced Fibrosis by Cutoff. Abbreviations: CI = confidence interval; FIB-4 = fibrosis-4 index; RE = random-effects.

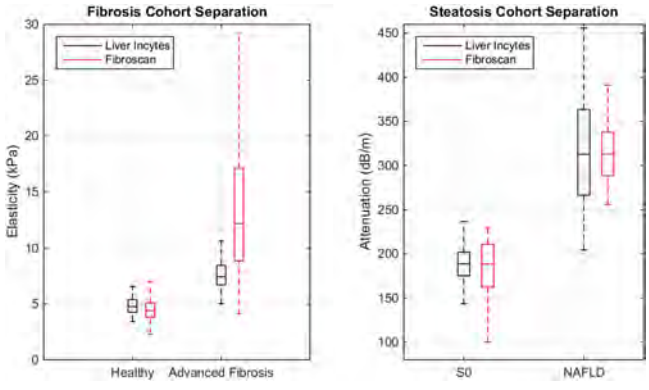
Conclusion: This SLR and MA shows that FIB-4 is an accurate NIT of advanced fibrosis in patients with NAFLD/NASH. MA results show that diagnostic accuracy may be best at the FIB-4 cut point ≥2.67 for advanced fibrosis. Further research is needed to determine what patient and setting characteristics that may impact the accuracy of FIB-4.

FRI050

Liver incytes: assessment of fibrosis and steatosis in patients and healthy volunteers

Michael Curry[1], Edward Tam[2], Tarek Hassanein[3], Caitlin Schneider[4], Fatma Barakat[3], Nezam Afdhal[1]. [1]*Beth Israel Deaconess Medical Center;* [2]*LAIR Centre;* [3]*Southern California Research Center;* [4]*Sonic Incytes*
Email: mcurry@bidmc.harvard.edu

Background and Aims: Non-invasive liver fibrosis and steatosis measurements have been shown to allow better disease staging and clinical management and are correlated to patient outcomes. Here we present initial fibrosis and steatosis measurement results using Liver Incytes, a volumetric ultrasound elasticity and attenuation measurement system. The aim was to evaluate the ability of Liver Incytes to discriminate between healthy volunteers (HV) and those with clinically diagnosed non-alcoholic fatty liver disease (NALFD) or previous Hepatitis C virus (HCV).
Method: Liver Incytes is a steatosis and elasticity measurement system (Sonic Incytes, BC, Canada) comprising an ultrasound transducer and a vibration device to generate multi-frequency (40–70 Hz) steady state shear waves in the patient. The ultrasound elasticity and attenuation is measured over a volume of the liver, using an intercostal approach. Volumes are collected in a fan of 30 degrees, at a depth of 15 cm. Patients and HV were recruited from three clinical sites in the United States and Canada. HV had no history of liver disease. Patients were enrolled with either NALFD or HCV. Patients had a FibroScan® (FS) of greater than 8 kPa. FS was completed on the same day for comparison. The ability of Liver Incytes to discriminate HV from those with advanced fibrosis or steatosis was measured using Area Under the Receiver Operating Curve (AUROC). A subset of patients also had Magnetic Resonance Elastography (MRE) and Proton Density Fat Fraction (MR-PDFF).
Results: A total of 50 HV and 48 patients were recruited. The mean [range] age of the volunteers was 27 [19–58] years and 61 [31–75] for patients. 27 of the patients had clinically diagnosed NAFLD and 21 had HCV post SVR. Median [IQR] stiffness for the HV was 4.8 [1.1] and 7.5 [1.7] kPa for patients on Liver Incytes and 4.4 [1.3] and 12.5 [9.0] kPa when measured with FS. Mean attenuation for the HV and patients was 200 [61] and 298 [98] respectively on Liver Incytes and CAP score was 210 [59] and 295 [96] on FS respectively. The AUROC for Liver Incytes was 0.964 for fibrosis and 0.985 for steatosis, using FS as the gold standard.
Seven patients participated in the MR sub-study. When looking at elasticity, the concordance correlation coefficient was 0.80 for Liver Incytes and 0.20 for FS. The Pearson's coefficient between attenuation and MR-PDFF was 0.98 for Liver Incytes and 0.73 for FS.



Conclusion: Initial results show that Liver Incytes is able to discriminate HV from patients with advanced fibrosis and steatosis. Initial concordance and correlation with MRE and MR-PDFF were superior for Liver Incytes compared to FS although numbers are small. Larger clinical trials should be undertaken.

FRI051

Analysis of the prevalence of metabolic syndrome components and other factors as predictors of disease progression among an urban population with NAFLD and/or NASH

Anish Jammu[1], Hamed Dallali[1], Justin Lee[1], Sirajuddaula Kausar[1], Muhammad Khurram[1], Silva Cortez[1], Marzena Magnes[1], Magdy Elkhashab[1]. [1]*Toronto Liver Centre, Toronto, Canada*
Email: melkashabmd@yahoo.ca.

Background and Aims: The incidence and prevalence of NAFLD/NASH is rising globally, as is the incidence of metabolic syndrome. The spectrum of NAFLD ranges from simple steatosis to non-alcoholic steatohepatitis with variable degrees of liver fibrosis, cirrhosis and HCC. Current literature illustrates an association between NAFLD and comorbid conditions such as diabetes, obesity and dyslipidaemia. The aim is to determine whether the components of metabolic syndrome and other relevant comorbid conditions/factors can predict a disease progression of NAFLD and/or NASH in an urban population.
Method: Retrospective review of 2764 patient charts at the Toronto Liver Centre with an indicated NAFLD and/or NASH diagnosis. 1968 patient charts with complete demographic information and comorbid condition history were included. Four components of metabolic syndrome: diabetes, obesity, dyslipidemia, hypertension and other factors/comorbid conditions including elevated liver enzymes, coronary artery disease (CAD) and AST:ALT ratio (>0.8) were examined.
Results: Of the 1968 patient charts, 1140 male patients (58%) and 828 female patients (42%). In terms of age distribution: <30–37, 30 to 39–168, 40 to 49–409, 50 to 59–612. 60–69–460, 70 to 79–206, 80 to 89–69, 90 to 99–7. The components of metabolic syndrome and other comorbid condition/diagnostic measures were examined individually across the fibrosis stage scale *(see* Figure 1*)*. In addition, they were assessed collectively to determine whether an association exists between disease progression and the number of components. The mean number of factors that patients had at each fibrosis stage was: F0: 1.77; F0-F1: 2.03; F1: 2.30; F1-F2: 2.35; F2: 2.70; F2-F3: 2.51; F3: 2.70; F3-F4: 3.06; F4: 3.32. The most commonly observed number of factors (mode) at each fibrosis stage was as follows: F0: 1; F0-F1: 2; F1: 2; F1-F2: 2; F2: 2; F2-F3: 2; F3: 3; F3-F4: 4; F4: 4.

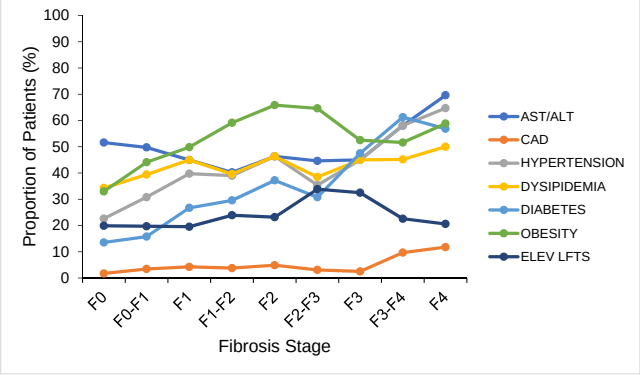


Figure 1: Proportion of patients with each individual component of metabolic syndrome/relevant study factor at defined fibrosis stages (n = 1968).

Conclusion: There is a relatively strong positive correlation between disease stage and the proportion of patients diagnosed with diabetes and hypertension. To a lesser degree, a positive correlation was also observed for obesity and dyslipidaemia (Figure 1*)*. Individually, these factors appear to be good predictors of disease progression. Most people with severe fibrosis (F4) have diabetes, diabetes (56.9%), obesity (58.8%), dyslipidaemia (50.0%) and hypertension (64.7%). On average, there is some indication that advanced fibrosis is associated with a greater number of components of metabolic syndrome/relevant study factors compared to lower stage fibrosis when only considering the extreme ends of fibrosis (F0 and F3 to F4) and not the intermediate stages.

FRI052

The impact of ethnicity on incidence of NAFLD/NASH among patients referred to the Toronto liver centre for non-invasive evaluation with transient elastography

Justin Lee[1], Anish Jammu[1], Hamed Dallali[1], Sirajuddaula Kausar[1], Muhammad Khurram[1], Silva Cortez[1], Marzena Magnes[1], Magdy Elkhashab[1]. [1]*Toronto Liver Centre, Toronto, Canada*
Email: melkashabmd@yahoo.ca.

Background and Aims: The prevalence of NAFLD/NASH is rising in North America and worldwide. The etiology of NAFLD is multifactorial with environmental factors and dietary habits considered as major contributing factors. Genetic factor and ethnicity play a major role as well. We sought to investigate the impact of ethnicity on prevalence of NAFLD among a cohort of patients with multiple ethnic backgrounds, referred to the Toronto Liver Centre for evaluation with transient elastography (Fibroscan®).
Method: 2219 patients referred for evaluation of liver stiffness were reviewed. All patients had fatty liver disease with no other underlying liver condition. Each patient was labeled with their closest ethnic origin. Fibrosis scores were average to eliminate ambiguity in judgment for scores that lie between two numbers (F1-2 = 1.5). An age range of 5 years was used incrementally for each cluster, starting from 1939–1998. As such, only individuals over age 21 were considered in this retrospective study.
Results: Of the total 2199 viable patients, 673 patients were of Asian descent, 207 were of Hispanic origin, 304 of East European background, 722 West European and 293 Middle Eastern. The level of fibrosis was particularly elevated for those of Hispanic/Latino origin in older age. As a general observation, the West European cohort had greater average fibrosis scores than any other ethnicity over the 50 year. A spike in fibrosis scores in the 1945–1950 age range was also noted for all ethnicities. However, this was especially pronounced in East European, Middle Eastern and Asian groups. It was apparent that those groups only developed greater fibrotic severity once the certain age is reached. This is indicated by the sharp incline in the 1945–1950 age groups. On the contrary, the West European population demonstrated a positive linear slope starting from the earlier age groups. Although the greatest number of NAFLD patients stem from the 1959–1962 age groups, the average fibrosis scores collected from this group led to a trough rather than a crest in the graph (Figure 1).

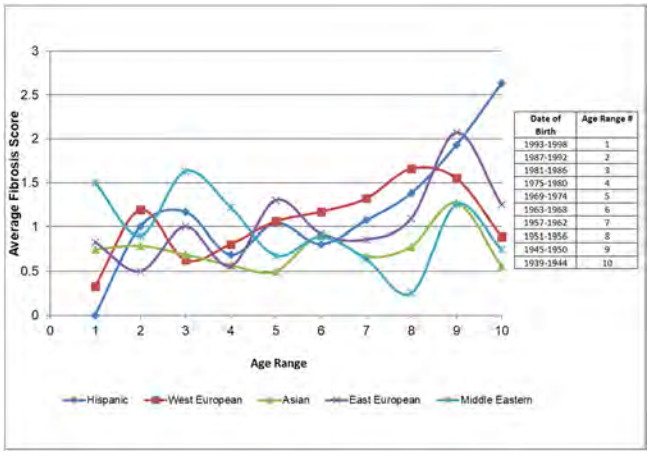

Figure 1: Average fibrosis scores relative to closest ethnic background.

Conclusion: There is probable indication to suggest a relation between ethnicity and the level of fibrosis at certain age ranges. This is particularly reflected in the Hispanic patient cohort, in which only patients in the 1957–1962 age range and above began to develop significant fibrosis. As for Asian and East European groups, although there is deviation in the actual fibrosis score values, the general trends were similar. This indicates that the difference between these two groups lie in the overall average fibrosis score itself, rather than the trend of development.

FRI053

Drivers of diagnosis and referral decisions in non-alcoholic fatty liver disease patients

Michael Roden[1], Branko Popovic[2]. [1]*Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, Germany;* [2]*Sanofi Consumer HealthCare, Sanofi Aventis Deutschland GmbH, Frankfurt, Germany*
Email: branko.popovic@sanofi.com.

Background and Aims: Non-alcoholic fatty liver disease (NAFLD), including non-alcoholic steatohepatitis (NASH), is an increasing cause of chronic liver disease. NAFLD patients frequently suffer from metabolic syndrome and are at higher risk of NAFLD progression and cardiovascular mortality. The aim of this focused review was to assess the current state of awareness of specialists and general practitioners (GPs) on the epidemiology of NAFLD in adults and to identify the factors responsible for the diagnosis and treatment of NAFLD.
Method: Two independent reviewers conducted a search via PubMed, Embase, and DynaMed on studies published between 2005–2019, following a pre-defined Patient, Intervention, Comparison, Outcome (PICO) model. Final accepted studies were summarized and applied to pre-determined research questions related to the study aim.
Results: Twenty-two systematic reviews and network meta-analyses of randomized clinical trials were included. Physician and patient awareness: Many GPs seem to lack knowledge of NAFLD and underestimate its prevalence, e. g. 70% in Italy and 84% in USA. Similarly, patient awareness of NAFLD is also very low, even among those with relevant risk factors such as obesity (19% in an USA study). Likewise, 94% of diabetes specialists in UK report that their patients are not aware of NAFLD and 66% are concerned about missing a diagnosis of severe NAFLD. Diagnosis and screening: More than half of GPs do not test their NAFLD patients for other common causes of fatty liver. In USA, specialists, but not GPs, are more likely to screen patients with diabetes for NAFLD and NASH (68% vs. 44%), but less likely to screen patients with abdominal pain (7% vs. 24%, respectively). Additionally, endocrinologists and cardiologists report greater clinical concern regarding NAFLD and are more likely to refer patients than GPs (67% vs. 33%).
Conclusion: Many patients at risk of NAFLD are currently missed due to inadequate screening and uncertainties surrounding diagnostic tests and treatment options, along with lack of knowledge related to screening and management.

FRI054

Validation of the accuracy of the fast score for detecting non-alcoholic steatohepatitis patients at high risk of becoming cirrhotic in a North American cohort

Mariana Lazo[1], Mark Van Natta[1], Arun Sanyal[2], James Tonascia[1], Naga Chalasani[3], Samer Gawrieh[3], Mohammad Siddiqui[2], Cynthia Behling[4], Srinivasan Dasarathy[5], Anna Mae Diehl[6], Kris V. Kowdley[7], Rohit Loomba[8], Arthur McCullough[5], Norah Terrault[9], Brent Tetri[10], Raj Vuppalanchi[3]. [1]*Johns Hopkins University;* [2]*Virginia Commonwealth University;* [3]*Indiana University;* [4]*Sharp Health Care;* [5]*Cleveland Clinic Foundation;* [6]*Duke University;* [7]*Washington State University;* [8]*University of California, San Diego;* [9]*University of Southern California;* [10]*St. Louis University*
Email: mlazo@jhu.edu.

Background and Aims: Management of patients with nonalcoholic steatohepatitis liver disease who are at elevated risk of progressing to cirrhosis (at risk NASH) would be enhanced by an accurate noninvasive diagnostic test. The new FAST™ score, a mix of FIBROSCAN™ and aspartate aminotransferase (AST), has shown moderate diagnostic accuracy for at-risk NASH (area-under-the-Receiver-Operating-Characteristic [AUROC] = 0.80) in European cohorts. Our aims were to validate the FAST™ in a North American cohort and show how its accuracy might vary by patient mix.
Methods: We studied 585 adults with biopsy-confirmed NASH from the multicenter NASH Clinical Research Network (CRN) cohort. At-risk NASH was defined as definite NASH, NAFLD Activity Score (NAS) ≥ 4 and a fibrosis stage ≥ 2. We used the echosens® formula for FAST™ from liver stiffness (E kPa), steatosis (controlled attenuation parameter [CAP] dB/m), and AST (U/L); the FAST™-based Rule-Out (FAST™<0.35, sensitivity = 90%) and Rule-In (FAST™ >0.67, specificity = 90%) zones. The diagnostic performance measures used were AUROC, sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV); these were calculated for the total sample and by subgroups of patients and by FIBROSCAN™ exam features.
Results: The NASH CRN population was 38% male, 79% white; 73% obese; with means for age = 51 years, ALT = 66 U/L, and AST = 50 U/L. The prevalence of at-risk NASH was 37% vs. 50% in the Derivation population. The AUROC of FAST™ for at-risk NASH in the NASH CRN was 0.81 (95% CI: 0.77, 0.84), very similar to the AUROC in the Derivation population: 0.80. The Se, Sp, PPV and NPV are shown in the Table. The performance of FAST™ was better in non-whites vs. whites (AUROC: 0.91 vs 0.78; p = 0.0002) and inversely related to obesity status (AUROC: 0.94 in normal, 0.84 in overweight, and 0.78 in obese; p = 0.04). No differences were observed by other patient characteristics, or FIBROSCAN™ exam features.
Table: Diagnostic accuracy of FAST™.

Populations	Prevalence of at- risk NASH	Rule-Out Zone Zone intervals FAST™ <0.35	Gray Zone FAST™ 0.35–0.67	Rule-In Zone FAST™ >0.67
Derivation	50% (174/350)	% patients: 31% Se = 0.90 Sp = 0.53 NPV = 0.85	% patients: 40%	% patients: 29% Se = 0.48 Sp = 0.90 PPV = 0.83
NASH CRN	37% (214/585)	% patients: 35% Se = 0.91 Sp.0.50 NPV = 0.90	% patients: 38%	% patients: 27% Se = 0.51 Sp = 0.87 PPV = 0.69

Conclusion: FAST™ for diagnosing at-risk NASH was validated in large, multi-racial population from North America. Diagnostic performance varies by subgroups of NASH patients, including race, obesity, and prevalence of at-risk NASH.

FRI055

Serum lipidomic landscape of non-alcoholic fatty liver disease progression to hepatocellular carcinoma in a Caucasian population

Email: jesper.andersen@bric.ku.dk.

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a highly prevalent (24% of population globally) and progressive liver disorder emerging as a leading risk factor for hepatocellular carcinoma (HCC). The molecular mechanisms behind the progression from NAFLD to HCC (NAFLD-HCC) remain elusive, and surveillance of 'at risk' NAFLD patients constitutes a clinical challenge. In this study, we elucidate the deregulated metabolic serum landscape of NAFLD-HCC patients and individual lipids diagnostic utility.
Method: We have performed comprehensive ultra-high-performance liquid chromatography mass spectrometry (UHPLC-MS), investigating 1,295 metabolites in 196 serum samples from Caucasian patients with biopsy-proven diagnosis stratified into healthy and obese (CTRL = 44), metabolic disease (NAFLD = 93), NAFLD-HCC (n = 27) and alcohol or viral-associated HCC (AV-HCC = 32).

	CTRL vs NAFLD-HCC	NAFLD vs NAFLD-HCC	AV-HCC vs NAFLD-HCC
Model	0.989	0.997	0.999
AFP	0.786	NA	0.613
ALT	0.776	0.733	0.570

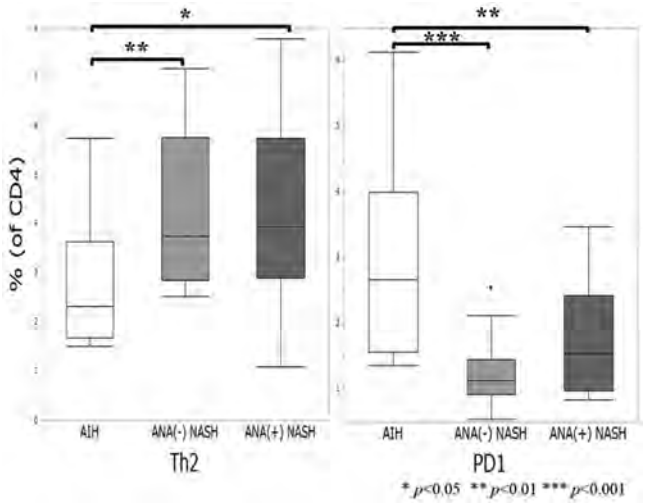
Results: In total, we detected 470 metabolites, including amino acids, their derivatives and lipids. We identified two major metabolic events in NAFLD-HCC. The initial metabolic rearrangement occurs in the onset of NAFLD (healthy liver; obese to NAFLD), characterized by differential expression (FDR $p < 0.05$) of 232 metabolites (DEMs). The most prevalent metabolites impaired within the first metabolic step include amino acids, acylcarnitines (AC), bile acids, cholesteryl esters, and glycerophosphocholines. Contrary, the significantly augmented metabolic program covers mostly free fatty acids (FFA), as well as diglycerides and triglycerides (TG). The second metabolic rearrangement was observed at the neoplastic conversion from NAFLD to NAFLD-HCC. The late metabolic switch included major metabolic aberrations covering 334 DEMs with significant changes in AC, ceramides and FFA. The progressive change (Spearman, $p < 0.05$) of metabolites showed gradual TG increase, progressive loss of AC and complete deterioration of FFA as the main perturbed metabolite subclasses. Multivariate analysis discriminated NAFLD-HCC patients from CTRL, NAFLD and HCC with a different etiology (AV-HCC) (Q2 = 0.51, R2 = 0.57). We generated ROC curves for DEMs and built a discriminator model including the top 5 metabolites, reaching a predictive accuracy >90%. The predictive power of the panel is superior to alpha-fetoprotein (AFP) and biochemical marker alanine transaminase (ALT) for the liver function:
Conclusion: Serum metabolomics revealed a specific perturbation of the lipid biology during the progression from healthy liver and morbidly obese, through NAFLD to malignant onset of NAFLD-HCC. Our metabolite panel can be clinically exploited in surveillance of patients at risk for developing HCC (morbidly obese, diabetic and NAFLD patients), and can distinguish NAFLD-HCC from AV-HCC.

FRI056

Difference between antinuclear antibody-positive non-alcoholic steatohepatitis and autoimmune hepatitis based on differential patterns of peripheral T lymphocytes

Akira Kado[1], Takeya Tsutsumi[2], Kazuhiko Ikeuchi[2], Kazuya Okushin[3], Kenichiro Enooku[1], Hidetaka Fujinaga[1], Kyoji Moriya[3], Hiroshi Yotsuyanagi[2], Kazuhiko Koike[1]. *[1]The University of Tokyo, Gastroenterology, Japan; [2]Medical Science, The University of Tokyo, Infectious Diseases, Advanced Clinical Research Center, Japan; [3]The University of Tokyo, Infection Control and Prevention, Japan*
Email: monteruterubest@gmail.com.

Background and Aims: About 15–45% of nonalcoholic steatohepatitis (NASH) has been reported to be seropositive for antinuclear antibody (ANA), and may be misdiagnosed as autoimmune hepatitis (AIH). Clinically, pathological diagnosis by liver biopsy is useful to discriminate ANA-positive NASH from AIH, but on some clinical situations, urgent medication by steroids without pathological diagnosis is needed, which may exacerbate the pathogenesis of NASH. NASH is known to involve immunological mechanism which is probably different from AIH, therefore it is possible that there are some differences in patterns of peripheral lymphocytes. The aim of this study is to determine differential patterns of peripheral T lymphocytes between ANA-positive NASH and AIH.
Method: Peripheral blood mononuclear cells (PBMCs) were obtained from 38 patients pathologically diagnosed as NASH (ANA negative: positive = 21: 17) by liver biopsy, and also from 15 patients pathologically diagnosed as AIH, based on diagnostic criteria of AIH (Hennes EM, et al. Hepatology 2008). For flow cytometry analysis, we used several subset markers of T lymphocytes to select target T lymphocytes. All T cells were selected from PBMCs through CD3 gating, and helper T cells (Th) and cytotoxic T cells (CTL) were selected through CD4 and CD8 gating, respectively. To further separate Th, we used CXCR3+CCR4-CCR6- (Th1), CXCR3-CCR4-CCR6+ (Th2), CXCR3-CCR4+CCR6+ (Th17), and CD25+CD127- (Treg) as Th subset markers. Furthermore, PD1 and CTLA4, recently focused as immune tolerance, were also examined. T lymphocyte percentages were calculated as standardized by CD3, CD4, and CD8 positive cells with each gating.



Results: We found no differences in the percentages of all T cells, Th and CTL between ANA-positive NASH and AIH patients. Among Th cells, ANA-positive NASH patients showed a significant higher percentage of Th2 compared to AIH patients, but we found no differences in the percentages of Th1, Th17 and Treg. Concerning PD1 and CTLA4, ANA-positive NASH patients showed a significant lower percentage of CD4+PD1+ T cells compared to AIH patients. On the

other hand, we found no differences in the percentages of CD8+ PD1+ and CTLA4+ T cells.
Conclusion: This study suggests that ANA-positive NASH is different from AIH in patterns of peripheral T lymphocytes, in particular, Th2 and CD4 + PD1 + T cells. The underlying mechanism for this difference remains to be elucidated, but this differential pattern may be useful to noninvasively discriminate ANA-positive NASH from AIH.

Utility of metabolomic biomarkers to identify non-alcoholic fatty liver disease in liver transplant recipients
Christopher Mowry[1], Josh Levitsky[2], Cristina Alonso[3], Marta Iruarrizaga-Lejarreta[3], Ortiz Pablo[3], Mary Rinella[2].
[1]Northwestern University Feinberg School of Medicine, Chicago, United States; [2]Northwestern University Feinberg School of Medicine, Department of Gastroenterology and Hepatology, Chicago, United States; [3]OWL Metabolomics, Derio, Spain
Email: mary.rinella@nm.org.

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is a rising indication for liver transplantation (LT) worldwide. Diagnosis of recurrent NASH after LT requires liver biopsy, which is invasive, costly, and impractical for serial monitoring. Our aim was to use an unbiased, noninvasive metabolomics approach to identify biomarker profiles for nonalcoholic fatty liver (NAFL) and steatohepatitis (NASH) in LT recipients.
Method: This cross-sectional pilot study included 39 LT recipients who underwent liver biopsy and had simultaneous plasma samples collected and analyzed using ultra-high-performance liquid chromatography – mass spectrometry (UHPLC-MS) to elucidate metabolomic profiles. The resulting profiles were compared between patients with recurrent NAFL/NASH vs. normal liver (negative control) and acute rejection (positive control).
Results: Univariate analysis revealed 22 metabolites that were differentially and significantly ($p < 0.05$) altered in patients with recurrence of NAFLD compared to patients with normal liver histology on biopsy. Three metabolites (triglyceride (44:1), triglyceride (53:0), and arginine) were identified as potential specific markers of NAFLD vs. both normal and rejection biopsies. Within participants with NAFLD, 15 metabolites were identified as divergent between NAFL and NASH. Among patients transplanted for NASH cirrhosis, 18 metabolites were significantly altered between those with fibrosis vs. without fibrosis on liver biopsy.

Conclusion: In conclusion, we were able to identify a number of potential metabolic biomarkers that could be used in the clinical setting to noninvasively identify recurrent NAFL and NASH. Further investigation with a larger sample size is warranted to validate these preliminary results.

Background and Aims: Non-alcoholic fatty liver diseases at risk of advanced fibrosis is underdiagnosed out of hepatology clinics. Strategies based on education, tools and communication with primary care could impact on the management of this entity. The main aim was to compare the effectiveness of several non-invasive test son detection and referral of patients with NAFLD at risk of advanced fibrosis.
Method: Peer-to-peer sessions were scheduled with all primary care centres from Virgen del Rocio University Hospital. Hepamet Fibrosis Score (HFS), NAFLD Fibrosis score (NFS) and FIB4 were available to be requested from primary care. Combined score was defined as gold standard for advanced fibrosis risk detection. Combined score was

Class	Metabolite	Code OWL	NASH *vs.* NAFL

built adding 0,1 or 2 points from each NIT when under or over lower or higher cut-off from 0–6 points. Patients at risk of advanced fibrosis were defined when combined score was ≥3 points. Diagnostic accuracy and cost-effectiveness was calculated. Confidence intervals and Odds ratio were also calculated.

Results: Eight-hundred and fifty requests from primary care. T2DM 23%; Obesity 47%; Normal ALT 40%; females 40%. Patients at risk of advanced fibrosis were: NFS: 37.9% (322/850); FIB4: 39.6% (337/850) y HFS un 17.5% (197/850). CS was suggestive of advanced fibrosis (CS ≥ 3) in 116/850 cases (13.6%). Referral rate was lower with HFS in comparison with NFS (OR:0,35, IC95%:0,28–0,44) and FIB4 (OR:0,32, IC95%:0,26–0,40). Cost of these three analyses were: 0,70€ in diabetics and 1.85€ in non-T2DM. Besides, average cost of hepatology clinics attendance of a patient with NAFLD has been calculated around 570.78€ (Sánchez-Torrijos et al. 2019). The cost of the management of this cohort could be 485.163€, but referring based on HFS >0.12 (N = 149) Cost: 85.046€ (IC95%:72.645–97.448); NFS > −1.455 (n = 322) Cost: 183.791€ (IC95%:167.969–199.613); FIB4>1.30 (n = 337) Cost: 192.353€ (IC95%:176.398–208.308).

Conclusion: Implementation of a detection and referral strategy based on Hepamet fibrosis score increased diagnostic accuracy and is cost-effective saving a half of the budget.

Prediction of advanced fibrosis with transient elastography is superior to gut microbiota-based approaches in non-alcoholic fatty liver disease

Sonja Lang[1,2], Fedja Farowski[3,4,5], Anna Martin[1], Hilmar Wisplinghoff[6,7,8], Maria J.G.T. Vehreschild[3,4,5], Marcin Krawczyk[9,10], Angela Nowag[6], Anne Kretschmar[6], Claus Jürgen Scholz[6], Philipp Kasper[1], Christoph Roderburg[11], Frank Lammert[9], Tobias Goeser[1], Hans-Michael Steffen[1], Münevver Demir[1,11]. *[1]University of Cologne, Faculty of Medicine, and University Hospital Cologne, Department of Gastroenterology and Hepatology, Cologne, Germany; [2]Department of Medicine, University of California San Diego, La Jolla, CA, USA; [3]University of Cologne, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Cologne, Germany; [4]German Centre for Infection Research (DZIF), partner site Bonn/Cologne; [5]Department of Internal Medicine, Infectious Diseases, Goethe University Frankfurt, Frankfurt am Main, Germany; [6]Wisplinghoff Laboratories, Cologne, Germany; [7]Institute for Virology and Medical Microbiology, University Witten/Herdecke, Witten, Germany; [8]University of Cologne, Faculty of Medicine, Institute for Medical Microbiology, Immunology and Hygiene, University Hospital of Cologne, Cologne, Germany; [9]Department of Medicine II, Saarland University Medical Center, Homburg, Germany; [10]Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland; [11]Department of Hepatology and Gastroenterology, Campus Virchow Clinic, Charité University Medicine, Berlin, Germany*
Email: slang@ucsd.edu.

Background and Aims: The presence of liver fibrosis is the major determinant of future liver related complications in patients with non-alcoholic fatty liver disease (NAFLD). Several studies identified associations between gut bacterial dysbiosis and liver fibrosis. Based on these findings, microbiome signatures have been explored as prediction models for advanced fibrosis in NAFLD. The aim of this study was to validate and directly compare the diagnostic performance of gut microbiota-based machine learning approaches to other simple and widely used non-invasive tools for the prediction of advanced fibrosis.

Method: 16S rRNA gene sequencing was performed in a well-characterized cohort of 96 biopsy-proven NAFLD patients. Random Forest models based on clinical data and sequencing results were compared to transient elastography, the NAFLD fibrosis score and the FIB-4 index.

Results: A Random Forest model containing clinical features and gut bacterial taxa achieved an area under the curve (AUC) of 0.87 for the prediction of advanced fibrosis (Fig. 1a). The model was only marginally superior to a similar model without microbiota features (AUC 0.85). The model that aimed to validate a published algorithm that used whole genome sequencing, achieved an AUC of 0.71 with less than half of species being resolved based on 16S rRNA gene sequencing (Fig. 1b). AUCs for the NAFLD fibrosis score and FIB-4 index were 0.86 and 0.85, respectively (Fig. 1c). Transient elastography performed best with an AUC of 0.93 (Fig. 1c).

Conclusion: A gut microbiota signature might help to predict the presence of advanced fibrosis. However, transient elastography, which is a fast and convenient method, achieved the best diagnostic performance for the detection of NAFLD patients at risk for disease progression.

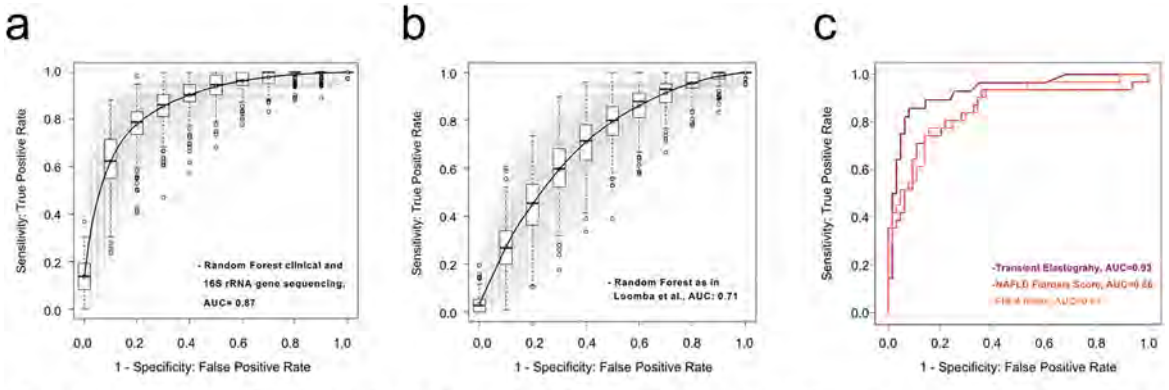

Figure legend: (a) Area under the curve (AUC) for our Random Forest model based on 14 features that were identified by Random Forest feature elimination. Light grey lines represent the 300 training runs, the black line and AUC represent the median over these. (b) AUC for the validation in approximation of the Random Forest model by Loomba et al. (c) Performance of the FIB-4 index, NAFLD fibrosis score and transient elastography. In a-c, 65 patients were staged as F0-F2 and 31 as F3-F4.

The accuracy of the fast score in predicting NASH with significant fibrosis

Mazen Noureddin[1,2], Nabil Noureddin[3], Edward Mena[4], Kimberly Ramirez[1], Fabiana Pacheco[4], Aileen Alon[1], Allison Sachiko Harrington[5], Mangesh Pagadala[6], Ibrahim Hanouneh[7], Naim Alkhouri[8]. *[1]Cedars Sinai Medical Center; [2]University of Nevada at Las Vegas; [3]University of Nevada at Las Vegas; [4]California Liver Research Institute; [5]University of Texas San Antonio; [6]The Liver Institute at Methodist, Dallas; [7]MNGI Digestive Health, Minneapolis; [8]Texas Liver Institute*
Email: mazen.noureddin@cshs.org.

Background and Aims: Vibration controlled transient elastography (VCTE) is useful in assessing steatosis via its controlled attenuated parameter (CAP) and fibrosis measured as liver stiffness. Recent data showed that the FAST score which uses a formula that contains the CAP, stiffness and Aspartate Aminotransferase values is highly accurate in predicting non-alcoholic steatohepatitis (NASH) patients who have NAS score of ≥ 4 and Fibrosis ≥ 2 (NAS4F2). We aimed to validate the FAST score and assess its performance in various patients' subgroups.

Method: This is a cross-sectional analysis from tertiary care center in the U.S. NAFLD was diagnosed based on society guideline recommendations. NASH was assessed via Kleiner's histology score. Liver biopsy was done within 6 months from VCTE (FibroScan, Echosens, France) and patients were excluded if they had >5% change in body weight. M and XL probes were chosen based on the automated machine recommendation.

Results: To date, 101 patients have been enrolled with an average age of 57.2 years and body mass index (BMI) of 31.0 kg/m^2. Of those 55% had NASH,21% had F0, 24% had F1, 16% had F2, 12% had F3 and 27% had F4. The average FAST score for the entire cohort was 0.5. The FAST score was accurate in predicting NAS4F2 with a corresponding AUC of 0.74. We then analyzed the FAST score by various sensitivity and specificities cut offs as well as the Youden's index (Table 1). Finally, we assessed if there are any differences in the FAST score in predicting NAS4F2 by diabetes status or BMI. We found no difference in the accuracy for the FAST score in predicting NAS4F2 in diabetic's vs non-diabetics (AUC = 0.71 vs 0.73; p = 0.8182). We found no difference in the accuracy of the FAST score in predicting NAS4F2 in patients with BMI ≤ 30 kg/m^2 vs those >30 kg/m^2 (AUC = 0.73 vs 0.74 p = NS), but the accuracy varied between very good in patients with BMI ≤ 32 kg/m^2 (AUC = 0.73) to excellent in those >32 kg/m^2 (AUC = 0.82) and similarly in those with BMI ≤ 35 kg/m^2 (AUC = 0.73) and >35 kg/m^2 (AUC = 0.81).

Prevalence of NASH +NAS ≥ 4 +F ≥ 2	AUC [95% CI]	Description	Cut-off	Sensitivity	Specificity	PPV	NPV	Accuracy
30%	0.74 [0.63;0.84]	80%-Sensitivity	0.41	80%	52%	41%	86%	61%
		90%-Sensitivity	0.28	90%	37%	38%	91%	53%
		80%-Specificity	0.74	49%	81%	52%	79%	71%
		90%-Specificity	0.84	30%	90%	60%	76%	72%
		Max. of Yourdon's index	0.62	65%	69%	47%	82%	68%

Conclusion: The FAST score is an accurate score in predicting NAS4F2. FAST doesn't vary by diabetes status and its accuracy ranges between very good to excellent depending on BMI.

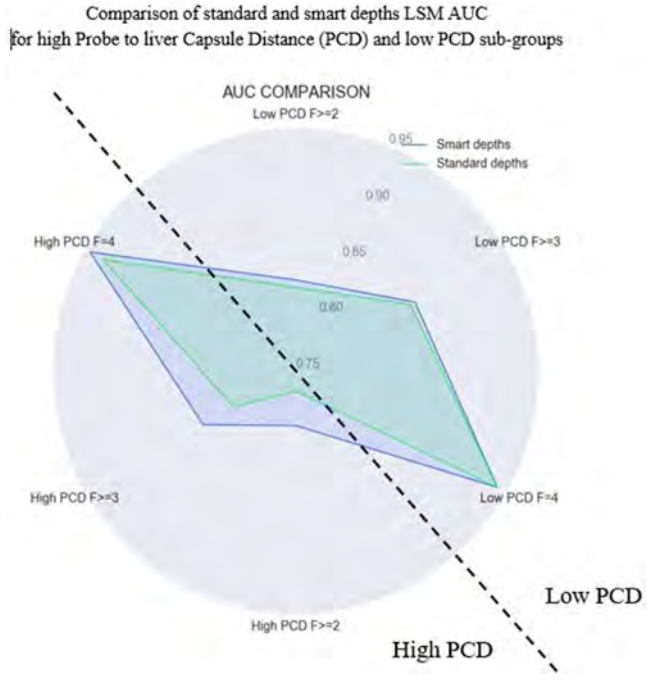
Email: p.n.newsome@bham.ac.uk

Background and Aims: The XL probe significantly expanded the applicability of VCTE (FibroScan), yet there are still challenges in morbidly obese (body mass index, BMI >40 kg/m²) patients when the probe to liver-capsule distance (PCD) is larger than the current maximum measurement depth (35–75 mm). Our objective was to evaluate a new automated adaptive measurement depths algorithm called 'smart depths' allowing Liver Stiffness Measurement (LSM) with the XL probe up to 45–85 mm and from 25–65 mm to 30–70 mm M probe in three pooled cohorts of patients investigated for suspicion of NAFLD.

Method: Patients underwent LSM and liver biopsy (LB). LB was scored in a blinded manner by two expert pathologists using the NASH CRN scoring system. To be included patients needed an interpretable LB as well as a valid FibroScan examination (defined as at least 8 valid measurements) with both Standard and 'Smart Depths' stiffness measurement. To avoid spectrum bias when comparing patients with high and low PCD, median PCD determined for each fibrosis stage were used to split the cohort into two groups; low PCD and high PCD. Diagnostic performance was assessed using area under the ROC curves (AUC) and compared using Delong test.

Results: 669 patients (348 UK, 202 USA, 119 France) were included (BMI = 36 ± 7 kg/m², age = 52 ± 12 years, 52% male, PCD 23 ± 5: mm). For each fibrosis stage, patient distribution and median PCD were as follows: F0: [40%; 20.6 mm], F1: [26%; 24.1 mm], F2: [14%; 22.6 mm], F3: [15%; 21.9 mm] and F4: [5%; 23.3 mm]. Sub-groups consisted of 339 (BMI: 39 ± 7.2 kg/m²) and 330 patients (BMI: 32 ± 5.6 kg/m²) with high and low PCD, respectively. In low PCD sub-group, diagnostic performances of standard stiffness versus Smart Depths were equivalent, with respective AUCs as follows: F ≥ 2AUC = 0.819/0.825 (p = 0.006); F ≥ 3AUC = 0.859/0.863 (p = 0.008) and F = 4 AUC = 0.941/0.941 (p = 1). In the high PCD sub-group, diagnostic performance was significantly improved by the Smart Depths with: F ≥ 2AUC = 0.767/0.795 (p = 0.0001); F ≥ 3AUC = 0.809/0.838

(p = 0.00008) and F = 4 AUC = 0.933/0.946 (p = 0.007) for standard/Smart Depths, respectively (Figure). Moreover, LSM applicability increased by 13% in the high PCD sub-group using the Smart Depths.



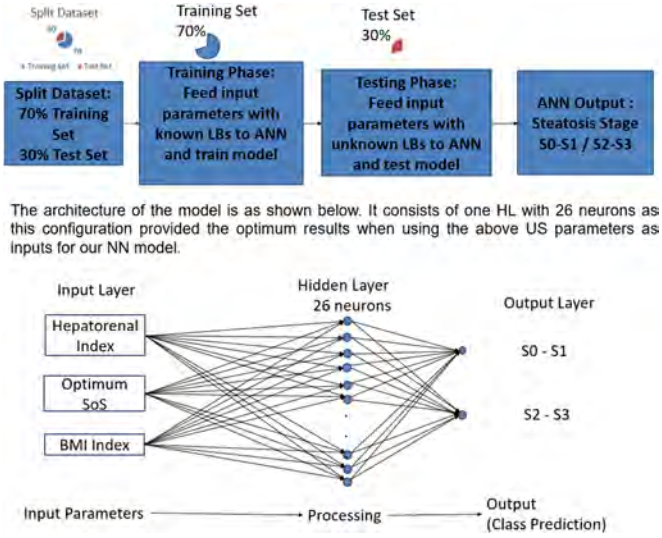
Conclusion: The performance of LSM as a fibrosis surrogate marker is improved in high PCD patients by automatically adjusting the depth of measurement to the patient morphology. This will need to be confirmed in a prospective study.

FRI063

A diagnostic approach of non-alcoholic fatty liver disease with a machine learning model using parameters derived from ultrasound B-mode examination

Petros Drazinos[1], Ilias Gatos[1], Ioannis Theotokas[1], Spyros Yarmenitis[1], Emmanouel Koullias[2], Ioannis-Georgios Koskinas[2], Pavlos Zoumpoulis[1]. [1]*Diagnostic Echotomography, Kifissia, Greece;* [2]*National and Kapodistrian University of Athens Hippokration Hospital, Department of Internal Medicine, Athens, Greece*
Email: p.drazinos@echomed.gr

Background and Aims: Non-Alcoholic Fatty Liver Disease (NAFLD) may lead to Non- Alcoholic Steatohepatitis (NASH) and to cirrhosis and liver failure. Ultrasound (US) is widely used for the disease diagnosis and staging. The aim of this study is to build a Neural Network (NN) model to evaluate the impact of B-Mode US examination parameters for Steatosis assessment.
Method: 195 liver biopsy-validated for Steatosis patients (117 S0-S1 and 78 S2-S3) were included in our study. To calculate the Hepatorenal Index (HI) a B-Mode US examination was performed by an expert radiologist on each patient's right lobe, including view of the right kidney at the same depth. The examiner provided a diagnostic impression of each patient's Steatosis (0–3). The input features selected were the Body Mass Index (BMI), the HI and optimum speed of sound index (SSI), calculated from a US B-Mode image showing each patient's liver parenchyma. These parameters were used as input to a NN classifier. Our dataset was divided into training and testing sets (70%-30% of whole dataset). For the training process a three-fold cross validation (CV) was used. In order to have a robust estimation of the model's performance the split of the dataset and training-testing process was repeated 30 times.
Results: The classifier had a mean CV accuracy of 87.53% with 95% confidence interval (CI) 87.44% –87.62%. The mean accuracy of test sample was 89.44% (95% CI: 89.31%–89.56%). The mean Area Under Curve (AUC) for test sample was 0.953 (95% CI: 0.944–0.962). The radiologists' diagnostic impression accuracy against the liver biopsy for the whole dataset was 80%.



Conclusion: The NN classifier performance was superior to the radiologists' estimation and can be used as a supplementary tool in liver steatosis assessment.

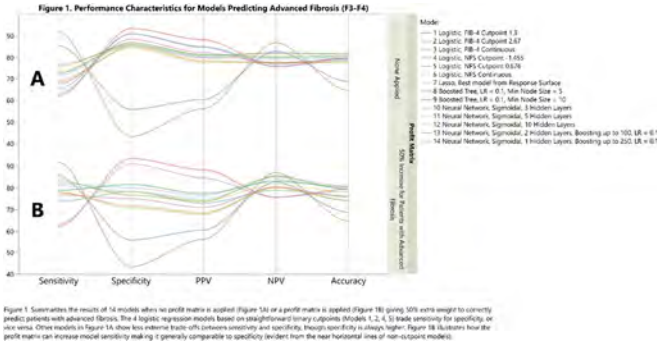
Predicting advanced fibrosis using non-invasive clinical tests and modern machine learning methods in TARGET-NASH

Peter Mesenbrink[1], A. Sidney Barritt[2], Rohit Loomba[3], Philip N Newsome[4], Arun Sanyal[5], Richard Zink[6]. [1]*Novartis Pharmaceuticals Corporation, East Hanover, United States;* [2]*University of North Carolina at Chapel Hill, Chapel Hill, United States;* [3]*University of California at San Diego, san diego, United States;* [4]*University of Birmingham, Institute of Biomedical Research, Birmingham, United Kingdom;* [5]*Virginia Commonwealth University, Division of Gastroenterology, Hepatology and Nutrition, Department of Internal Medicine, Richmond, United States;* [6]*TARGET Pharmasolutions, Inc., Durham, United States*
Email: rzink@targetpharmasolutions.com

Background and Aims: Liver biopsy is the reference standard for fibrosis staging, but is an invasive procedure with limitations and potential complications. There is an unmet need for readily-available noninvasive tests (NITs) to identify patients with advanced fibrosis. The aim of this study is to describe the performance characteristics of NITs in predicting advanced fibrosis using modern machine learning methods and real-world data from TARGET-NASH.
Method: TARGET-NASH is a longitudinal observational study that includes patients with NAFLD defined by biopsy or pragmatic case definitions. NITs, including the Fibrosis-4 (FIB-4) index and the Non-Alcoholic Fatty Liver Disease Fibrosis Score (NFS) that were calculated within 6 months of liver biopsies were analyzed in predictive models. Individual variables of the FIB-4 and NFS were considered for the models: age, BMI, diabetes, albumin, platelets, ALT, AST, as well as composite FIB-4 and NFS scores. Performance characteristics were calculated for predictive models including logistic regression, lasso, boosted trees, and neural networks. A profit matrix was then applied to the models, prioritizing the diagnosis of advanced fibrosis.
Results: 859 adult patients with a liver biopsy and both FIB-4 and NFS were included in this analysis. Median age was 57 and 60% of the patients were female. 86% of the subjects were Caucasian, 60% had diabetes and median BMI was 33 kg/m^2. Median ALT and AST were 49 IU/L and 41 IU/L, respectively. Median platelet count was 201 × 10^3

and median albumin was 4.2 g/dL. Median FIB-4 score was 1.66 and NFS score −0.29. Performance characteristics based on a validation sample of 25% of the patient cohort are in Figure 1A. Figure 1B shows that defining a profit matrix is effective at increasing sensitivity. Most neural network models provide a good balance between sensitivity and specificity for predicting advanced fibrosis, with 3 of these models (Models 10, 11, 14) providing sensitivity and specificity ≥ 78%. The lasso model has similar performance with greater interpretability for the impact of individual covariates.



Conclusion: Analyzing the individual component variables for commonly-used NITs provide a good balance between several performance characteristics for predicting advanced fibrosis using modern modeling techniques. However, this improved performance may come at the expense of less easily-interpretable models, or may require applications to classify patients based on their data.

FRI065

Liver derived apoptotic microparticles as biomarkers to detect transition from simple steatosis to steatohepatitis in non-alcoholic fatty liver disease

Rocio Munoz Hernandez[1], Ángela Rojas[1,2], Sheila Gato Zambrano[1], Raquel Millan[1], Rocio Gallego-Durán[1,2], Rocío Montero-Vallejo[1], Maria Giraldez-Jimenez[1], Javier Ampuero[1,2,3], Manuel Romero Gomez[1,2,3]. *[1]Instituto de Biomedicina de Sevilla (IBiS). Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Sevilla, España., Seliver group., Seville, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Spain; [3]UGC de Enfermedades Digestivas, Hospital Universitario Virgen del Rocío, España, Spain*
Email: mromerogomez@us.es

Background and Aims: Microparticles (MPs) are small membrane-derived vesicles that are shed from cells to act as biological messengers regulating biological processes. Liver derived MPs are ASGPR positive (Asialoglycoprotein receptor) alone or in combination with others markers such as EPCAM (Epithelial cell adhesion molecule) and CD133 (Prominin-1), both of them overexpressed in hepatic progenitor cells. The aim of the study was to analyze the role of liver derived MPs in non-alcoholic fatty liver disease (NAFLD) progression.

Method: Thirty-four patients with NAFLD proven liver biopsy were included; simple steatosis (n = 10) and steatohepatitis scored by SAF score (n = 24); F0-F1 (n = 12); F2 (n = 11) and F3-F4 (n = 11). MPs were determined in heparin plasma by Flow cytometry by size (0,2–1 µm-Megamix Plus SC protocol, BD) and phosphatidylserine measured by Annexin V+. Cellular origin was determine using ASGPR, EPCAM and CD133.

Results: Patients with steatohepatitis (n = 24) showed significantly higher levels of MPs expressing AV+ASGPR+ (561.7 ± 88.9 vs. 1593.7 ± 393.2; p = 0.025), AV+EPCAM+ (318.4 vs. 1149 ± 195.3; p = 0.007), AV ± EPCAM+ASGPR+ (18.3 ± 12.4 vs. 70.1 ± 19.6; p = 0.025), AV +EPCAM+CD133+ (130.7 ± 33.3 vs. 834.2 ± 147.6; p < 0.001 and triple markers combination AV+EPCAM+ASGPR+CD133+ (3.1 ± 1.9 vs. 33.7 ± 13.4; p < 0.001). Triple markers combination reached the highest diagnostic accuracy segregating simple steatosis from steatohepatitis [AUROC = 0.917; (IC95%: 0.797–1); p = 0.001, sensitivity; 0.947 and specificity: 0.714]. There were no differences between MPs quantification and fibrosis stage. Quantification of liver-derived microparticles were also significantly different in patients with or without lobular inflammation and with or without ballooning.

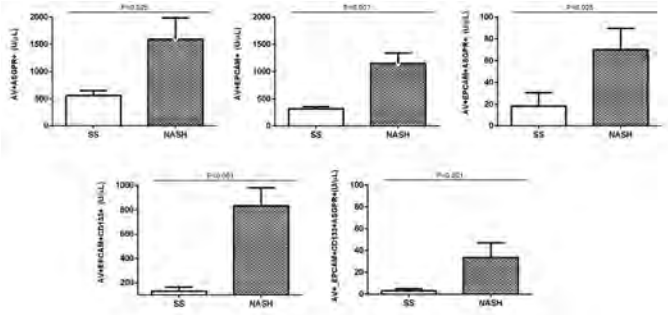


Figure 1: Levels of MPs (Data are represented as Means± SE)

Conclusion: Liver-derived microparticles increased in patients showing inflammation, ballooning and steatohepatitis irrespective of fibrosis stage. Identification and quantification of liver-derived microparticles could be a useful biomarker to detect the transition from simple steatosis to steatohepatitis in non-alcoholic fatty liver disease.

FRI066

Obeticholic acid improves hepatic fibroinflammation as assessed by multiparametric magnetic resonance imaging: interim results of the regenerate trial

Rohit Loomba[1], Quentin Anstee[2], Stephen Harrison[3], Arun Sanyal[4], Vlad Ratziu[5], Zobair Younossi[6], Zachary Goodman[6], Pierre Bedossa[7], Rajarshi Banerjee[8], Michael Stenkilsson[8], Reshma Shringarpure[8], Luna Zaru[8], Aditya Venugopal[8], Leigh MacConell[8], Mary Rinella[9]. *[1]University of California San Diego, La Jolla, United States; [2]Newcastle University, United Kingdom; [3]Pinnacle Clinical Research Center, San Antonio, United States; [4]Virginia Commonwealth University, Richmond, United States; [5]Sorbonne Université, Paris, France; [6]Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; [7]Hôpital Beaujon, Clichy, France; [8]Intercept Pharmaceuticals, Inc., San Diego, United States; [9]Northwestern University Feinberg School of Medicine, Chicago, United States*
Email: quentin.anstee@newcastle.ac.uk

Background and Aims: A month-18 interim analysis of REGENERATE showed that treatment with OCA improved fibrosis and steatohepatitis based on liver histology in patients with NASH.[1] However, liver biopsy has several limitations and development of noninvasive tools for diagnosis and monitoring of NASH is warranted. Here, we evaluate the effects of OCA on multiparametric magnetic resonance imaging (MRI)-derived iron-corrected T1 (cT1) mapping which is thought to correlate with hepatic fibroinflammatory disease (Wilman 2017) and has been shown to predict clinical outcomes (Jayaswal 2018).

Method: Multiparametric MRI by Liver *MultiScan* (Perspectum Diagnostics, UK) was performed in a subset of REGENERATE NASH patients with fibrosis stage 2 or 3 (N = 20) randomized 1:1:1 to placebo (n = 7), OCA 10 mg (n = 6) or OCA 25 mg (n = 7). Change in cT1, a standardized imaging biomarker of hepatic fibroinflammatory disease, as well as change in liver fat content was evaluated following 18 months of treatment.

Results: At baseline, mean (SD) cT1 was similar across all 3 treatment groups (856.7[106.8]ms; 943.2[116.11]ms; and 882.1 [94.75]ms in placebo, OCA 10 mg and OCA 25 mg groups, respectively), with values in the elevated range reflective of a population with definite

steatohepatitis and significant fibrosis. Following 18 months of treatment, a dose dependent reduction in cT1 was observed with a mean change from baseline of –91.7 ms in the OCA 25 mg group and –59.6 ms in the OCA 10 mg group, compared to –1.4 ms in the placebo group. Mean liver fat content at baseline was 16.29% (placebo), 19.27% (OCA 10 mg) and 15.3% (OCA 25 mg). Modest reduction (–7.9%) in fat content was noted in the OCA 25 mg arm as early as 6 months following treatment, and was generally sustained through Month 18.

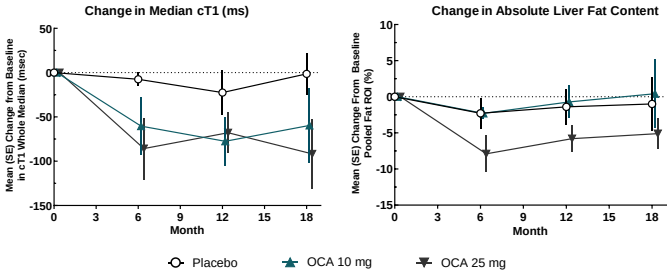

Figure: Fibroinflammatory Disease and Fat Content by Multiparametric MRI.

Conclusion: Treatment with OCA resulted in dose-dependent improvements in cT1 and liver fat content measured noninvasively by multiparametric MRI, that may be consistent with histologic improvements in steatohepatitis and fibrosis, as well as in serum-based noninvasive markers of steatohepatitis and fibrosis. (Anstee 2019)

1. The REGENERATE month 18 interim analysis results are based on surrogate endpoints considered reasonably likely to predict clinical benefit and longer term OCA treatment effect on clinical outcomes has not yet been demonstrated: the study is ongoing through outcomes to characterize OCA's clinical benefit

FRI067

Liver stiffness measurement by fibroscan predicts the occurrence of liver-related events and death in patients with NAFLD-related compensated advanced chronic liver disease

Email: salvatore.petta@unipa.it

Background and Aims: Patients with advanced fibrosis related to nonalcoholic fatty liver disease (NAFLD) are at risk of developing hepatic and extrahepatic complications. Liver stiffness measurement (LSM) by FibroScan has a good diagnostic accuracy for advanced fibrosis in patients with NAFLD, and can also predict the occurrence of liver-related events in patients with chronic hepatitis C. Data about the accuracy of LSM in the prediction of events in NAFLD, especially in patients with NAFLD and F3-F4 fibrosis, are scarce. We investigated whether, in a large cohort of patients with NAFLD and compensated advanced chronic liver disease (cACLD), LSM at baseline, at follow-up, and its variations are accurate for the prediction of hepatic and extrahepatic events.

Method: We retrospectively evaluated consecutive individuals with NAFLD with histological diagnosis of F3-F4 fibrosis and/or LSM >10 KPa, and prospectively followed-up for at least 6 months. LSM was measured by FibroScan using M or XL probe, and recorded at baseline and within 1 year from the last follow-up visit. Difference between follow-up and baseline LSM (delta LSM) was categorized as <–20%, –20% to +20%. >+20%. Hepatic (liver decompensation –ascites, encephalopathy, variceal bleeding and jaundice- and hepatocellular carcinoma (HCC)) and extrahepatic (cardiovascular and extrahepatic cancers) events, as well as overall and liver-related death were recorded during follow-up.

Results: 937 patients (56.5% males, mean age 60.2 years, mean BMI 32.5 Kg/m2, 61.1% with diabetes, 78.6% with cirrhosis) with a median follow-up time of 37.9 months (1st/3rd quartiles 22.6/64.8 months) were enrolled. 67 (7.2%) hepatic decompensation, 34 (3.6%) HCC, 56 (6%) all-cause deaths and 33 (3.5%) liver-related deaths were recorded. By Cox regression analysis and after adjusting for age, gender (only for HCC), serum albumin and platelets levels, baseline LSM was independently associated with occurrence of hepatic decompensation (HR 1.03, 95%C.I. 1.02–1.04, $p < 0.001$), HCC (HR 1.02, 95%C.I. 1.00–1.04, $p = 0.01$), and liver-related death (HR 1.03, 95% C.I. 1.02–1.04, $p < 0.001$). In a subgroup of 494 patients with available follow-up LSM, delta LSM was independently associated with hepatic decompensation (HR 1.54, 95%C.I. 1.04–2.48, $p = 0.04$), together with baseline LSM (HR 1.03, 95%C.I. 1.00–1.05, $p = 0.01$), and with liver related death (HR 1.87, 95%C.I. 1.05–3.34, $p = 0.03$).

Conclusion: In patients with NAFLD and F3-F4 fibrosis baseline LSM can predict the occurrence of hepatic decompensation, HCC and liver-related death. Moreover, changes in LSM during follow-up can further help to identify patients at higher risk of hepatic decompensation and liver-related death.

FRI068

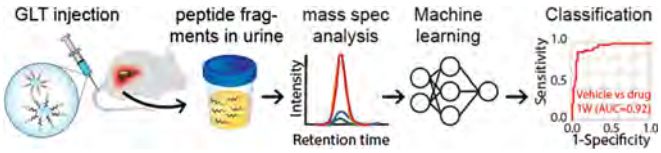
Glympse liver test for noninvasive monitoring of combination drug therapy in a rat model of non-alcoholic steatohepatitis (NASH)

Sophie Cazanave[1], Maciej Pacula[1], Anna Zagorska[2], Andrew Warren[1], Sarah Sherman[1], Eric Huang[1], Katie Walker[2], Kathy Liu[2], David Lopez[2], David Newstrom[2], Shiva Zaboli[2], Jamie Bates[2], John Liles[2], Grant Budas[2], David Breckenridge[2], Andrew Billin[2], Gabe Kwong[1]. *[1]Glympse Bio, Inc, Cambridge, United States; [2]Gilead Sciences, Inc, Foster City, United States*
Email: scazanave@glympsebio.com

Background and Aims: NASH diagnosis is limited by invasive procedures. Glympse Liver Test (GLT) is an injectable mixture of 19 sensors that measure the activity of proteases in NASH progression and regression. Here, we analyze GLT's performance to noninvasively monitor the efficacy of a combination drug therapy in a rat model of NASH.

Method: Male Wistar Han rats fed a choline-deficient high fat diet (CDHFD) for 6 weeks were administered vehicle (n = 15) or a triple drug combination (ACC inhibitor, FXR agonist and ASK1 inhibitor, or TRIPLE; n = 15) for 6 more weeks while on CDHFD diet. Control rats received chow diet (CD, n = 10). GLT was administered i.v. at weeks 2, 4, 6, 7, 8, 10 and 12; urine was collected 120–180 min post-injection and analyzed by tandem mass spectrometry. Liver histology and RNAseq of liver tissue were also analyzed. Regularized logistic

regression algorithm was used for disease classification using gene or urine signals (using 80% train, 20% validation splits).
Results: Rats fed a CDHFD developed a wide range of liver fibrosis from low stages at 6 W (4 F0, 4 F1, 1 F2, 1 F3) up to cirrhosis at 12 W (5 F3 and 10 F4). In parallel, CDHFD rat had increased expression in 10 out of 13 human NASH proteases whose expression positively correlated with fibrosis stage (Pearson $\rho = 0.36–0.73$; padj <0.05). TRIPLE treatment significantly prevented fibrosis progression (3 F0, 9 F1, 2 F2, 1 F3) and reduced protease mRNA upregulation upon CDHFD. Training a classifier using biopsy-derived NASH protease gene expression allowed for discrimination of TRIPLE-treated animals with a perfect AUC = 1.00 and prediction of F2 and above (F2+) from F0-F1 with an AUC = 0.94. When testing GLT in this model, we efficiently predicted TRIPLE response non-invasively as early as 1 week after treatment initiation (AUC = 0.92) and staging of F2+ fibrosis over F0-F1 with an AUC = 0.90 (95% CI 0.79–0.97), outperforming biomarkers ALT, AST and PIIINP (AUROCs $\leq$ 0.77) in accuracy. GLT-predicted output probability of having F2+ also correlated with fibrosis stage. Urinary signal of probe 7, a cathepsin sensor, markedly increased in CDHFD rat at 6 and 12 W and decreased back to normal in TRIPLE-treated rats. Removing probe 7, decreased GLT performance to predict F2+ (AUC = 0.76) indicating that cathepsins are key contributors to disease classification.



Conclusion: GLT multiplexed sensors enable accurate staging of fibrosis in NASH and early monitoring of treatment response without the need for biopsy.

FRI069

Too many to refer? FIB-4 scores in primary care patients with abnormal liver tests

Andrew Schreiner[1], Jingwen Zhang[1], Valerie Durkalski-Mauldin[2], Sherry Livingston[2], Justin Marsden[1], Patrick Mauldin[1], William Moran[1], Don Rockey[1]. *[1]Medical University of South Carolina, Medicine, Charleston, South Carolina, United States; [2]Medical University of South Carolina, Public Health Sciences, Charleston, South Carolina, United States*
Email: schrein@musc.edu

Background and Aims: The Fibrosis-4 (FIB-4) Index has been proposed as a tool to improve the diagnosis and management of non-alcoholic fatty liver disease (NAFLD) in primary care patients at risk.[1–5] Our aim was to examine the FIB-4 score and its relationship with clinical components of metabolic syndrome (MetS) in a primary care population with abnormal liver tests and no other liver disease diagnoses.
Method: A retrospective study of electronic record data from a primary care clinic from 2007–2018 analyzed adult patients with abnormal liver tests for: (1) patient-level FIB-4 scores and the proportion of patients with values concerning for liver fibrosis (FIB-4 > 1.3) and cirrhosis (FIB-4 > 2.67); (2) demographic and clinical factors associated with a mean FIB-4 above these thresholds. Abnormal liver tests included any elevation in: bilirubin, transaminases, or alkaline phosphatase. Multivariable logistic regression models for the dependent variables of mean FIB-4 > 1.3 and mean FIB-4 > 2.67 were developed. Objective measures of MetS components served as independent variables: BMI (continuous), A1c > 6.5%, triglycerides >150 mg/dL, HDL < 50 mg/dL for women (<40 mg/dL for men), and blood pressure (BP) > 130/85 mm Hg.[2,3]
Results: 9,657 patients with 116,237 FIB-4 scores were included, with a median of 7 (IQR: 3–14) values per patient. Of these patients, 97.2% had at least one component of MetS, 8.4% had all five components, and 1.0% had an ICD-9/10 code for NAFLD. Using patient-level mean FIB-4 scores, 3,544 (36.7%) patients had values >1.3, and 555 (5.8%) >2.67 (Table 1). The logistic regression model identified male gender, Black race, elevated transaminases, elevated BP, hyperglycemia, hypertriglyceridemia, and hypothyroidism positively associated with a mean FIB-4 score >1.3. Similar results were found for the cirrhosis threshold.

Table 1: Proportion of patient-level FIB-4 scores exceeding clinical thresholds and odds ratios from regression models for the dependent variables of (1) mean FIB-4 >1.3 and (2) mean FIB-4 >2.67.

FIB-4 N = 9,657	% >1.3			% >2.67		
Mean	36.7%			5.8%		
Median	32.0%			3.8%		
Maximum	60.0%			20.8%		
Minimum	14.4%			1.3%		
	Mean FIB-4 >1.30 N = 3,547			**Mean FIB-4 >2.67 N = 564**		
	OR	**95% CI**	**p-value**	**OR**	**95% CI**	**p-value**
Male	1.76	1.61–1.92	<0.01	1.63	1.37–1.95	<0.01
Black	1.31	1.20–1.43	<0.01	1.77	1.48–2.13	<0.01
Transaminase abnormality	1.74	1.57–1.92	<0.01	3.09	2.73–4.03	<0.01
BP >130/85	1.71	1.47–1.99	<0.01	1.47	1.08–2.02	0.02
A1C > 6.5%	1.25	1.12–1.39	<0.01	0.96	0.77–1.19	0.69
Low HDL	0.84	0.76–0.92	<0.01	1.36	1.12–1.65	<0.01
Triglycerides >150	1.15	1.05–1.27	<0.01	0.83	0.68–1.01	0.06
BMI	0.97	0.96–0.97	<0.01	0.96	0.94–0.97	<0.01
Hypothyroidism	1.26	1.11–1.42	<0.01	1.04	0.80–1.37	0.75

Conclusion: Many primary care patients with risk factors and clinical signals of NAFLD have FIB-4 scores concerning for advanced fibrosis. Future work is needed to validate the performance of FIB-4 in this setting.

FRI070

Circulating PCSK9 levels correlated with advanced disease in patients with biopsy-proven non-alcoholic fatty liver disease

Sheila Gato Zambrano[1], Rocio Munoz Hernandez[1,2], Rocio Montero-Vallejo[1], Ángela Rojas[1], Douglas Maya[1], M. Carmen Rico[1,3], Javier Ampuero[1,2,3], Manuel Romero Gomez[1,2,3]. *[1]Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío, CSIC, Universidad de Sevilla, SeLiver Group, Sevilla, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Spain; [3]Hospital Universitario Virgen del Rocío, UGC Enfermedades Digestivas, Sevilla, Spain*
Email: mromerogomez@us.es

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) has been associated with cardiovascular events, mainly in presence of NASH and fibrosis. Proprotein convertase subtilisin/kenin type 9 (PCSK9) is secreted into the plasma by the liver and regulates lipid homeostasis by promoting degradation of the LDL receptor and possibly lipogenesis, disrupting cholesterol homeostasis. In the present study we examined the effect of circulating PCSK9 levels on hepatic steatosis.
Method: Sixty-nine NAFLD biopsy-proven patients were recruited. Liver biopsies were classified by SAF score as Non-alcoholic fatty liver (NAFL) (n = 26) or as non-alcoholic steatohepatitis (NASH) (n = 43). Levels of circulating PCSK9 were evaluated by ELISA in 50 µl of serum samples.
Results: The half of NAFL group were males and 51% in the NASH (p = 0.588). Mean age was 48 ± 14 in the NAFL group and 55 ± 10 in the NASH group (p = 0.027). According to fibrosis stage; 43% of patients were F0, 16.5% were F1, 12.4% F2, 19.6% F3 and 7.2% F4. Levels of triglycerides were significantly higher in NASH compared to NAFL (109.73 ± 53.92 vs. 170.90 ± 77.61; p < 0.001) and levels of HDL cholesterol were higher in NAFL in comparison with NASH patients (59.06 ± 11.88 vs. 45.19 ± 11.69; p < 0.001), while levels of LDL

cholesterol (121.44 ± 28.54 vs. 105.46 ± 30.26) and total cholesterol (196.69 ± 34.54 vs. 180.26 ± 31.13) were similar between both groups (0.067 and 0.225 respectively). As shown in figure 1, PCSK9 in NASH patients was significantly higher than in NAFL group (p < 0.001). Patients without lobulillar inflammation (n = 6; 11.8%) had lower levels of PCSK9, than those with mild (n = 29, 56.9%) or moderate grade of inflammation (n = 16; 31.3%) (p = 0.014). On the other side, PCSK9 was lower in patients without ballooning (n = 21, 42%) than in those with mild (n = 24; 48%) or significant ballooning (n = 5; 10%, p = 0.001). Indeed, patients with fibrosis had higher levels of PCSK9 than those without (p = 0.004).

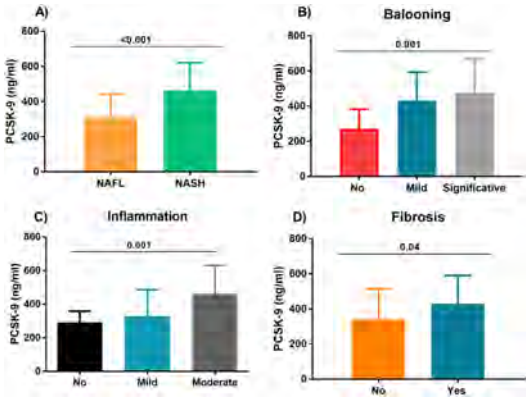


Figure 1: Data are shown as mean±SD. Circulating PCSK9 levels are increase in patients with NASH (a) ballooning (B), inflammation (C) and fibrosis (D).

Conclusion: Circulating PCSK9 levels correlated positively with fibrosis stage, ballooning and inflammation degree in patients with biopsy-proven NAFLD. Modulation of PCSK9 synthesis and release might be involved in NAFLD pathogenesis. PCSK9 could be a link between advanced NAFLD and cardiovascular risk.

FRI071

Non-invasive liver fibrosis markers, FIB-4, PRO-C3 and ADAPT, are significantly elevated in biopsy confirmed NAFLD patients at high risk of developing coronary heart disease and cardiovascular disease and are promising clinical decision making tools

Samuel Daniels[1], Mette Nielsen[1], Mohammed Eslam[2], Morten Karsdal[1], Leon Adams[3], Jacob George[2]. [1]*Nordic Bioscience Biomarkers and Research, Fibrosis Research, Herlev, Denmark;* [2]*Westmead Institute for Medical Research, University of Sydney and Westmead Hospital, Storr Liver Centre, Westmead, Australia;* [3]*University of Western Australia, Medical School, Nedlands, Australia*
Email: sjd@nordicbio.com

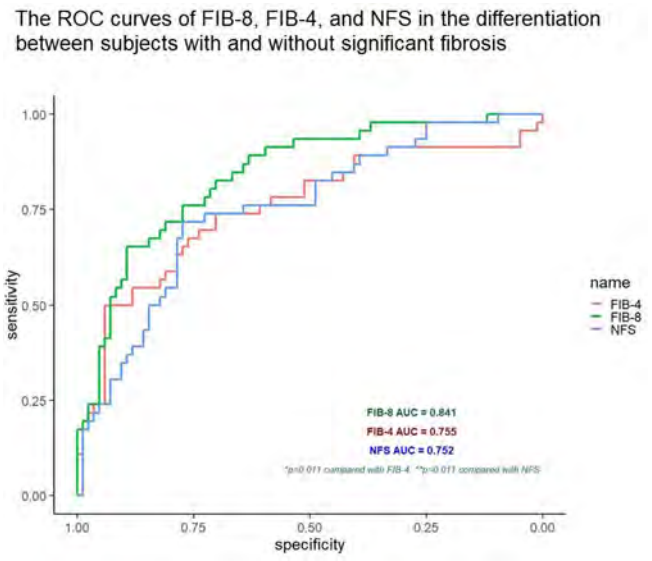
Background and Aims: A bidirectional association between NAFLD and cardiovascular disease (CVD) exists; as such CVD is the primary cause of mortality in NAFLD. Patients with advanced fibrosis (F3–4) are most at risk of clinical events and mortality. Currently, liver biopsy is used to diagnose and monitor patients. However, this is not suitable for mass screening. Hence, there is an urgent need for non-invasive markers. We aimed to investigate the association of non-invasive liver fibrosis tests and risk of developing atherosclerotic CVD (ASCVD) and coronary heart disease (CHD) over 10 years.
Method: Biopsy confirmed NAFLD patients had their risk of developing ASCVD and CHD estimated using ASCVD risk estimator and the Framingham Risk Score (FRS), respectively. Serum markers were determined at time of biopsy with PRO-C3 quantified by competitive ELISA. Patients were stratified into risk groups, patients with an ASCVD risk estimate and FRS ≥ 20% were considered high risk. Comparisons between high risk and low-moderate risk were assessed by t-test, area under receiver operating characteristic (AUROC) and logistic regression.
Results: 170 patients (mean age was 52, n = 72 male, n = 72 diabetic) were included. Those with F3–4 (n = 36) had significantly higher ASCVD and CHD risk estimates compared to patients with F0–2 (p < 0.0001 and p < 0.001 respectively). PRO-C3 correlated to both ASCVD and FRS risk estimates (Rho 0.36, p < 0.0001 and Rho 0.26, p < 0.001). Patients at high risk for ASCVD had significantly higher PRO-C3 levels compared to low-borderline risk (p < 0.002) with an odds ratio (OR) 1.04; PRO-C3 showed good discriminative ability (AUROC 0.73). High CHD risk patients had higher PRO-C3 levels compared to low risk (p < 0.02), AUROC 0.67 and OR 1.02. FIB-4 was significantly higher in those at high risk for ASCVD compared to low-borderline (p < 0.0001), AUROC 0.84 and OR 3.18. High CHD risk patients had greater FIB-4 levels than low risk (p < 0.0001), AUROC 0.75 and OR 1.28. ADAPT was greater in those at high ASCVD risk compared to low-intermediate risk (P < 0.0001), AUROC 0.88, OR 1.92. High risk CHD patients had greater levels of ADAPT compared to low- intermediate risk (p < 0.0001), AUROC 0.81 and OR 1.58.
Conclusion: NAFLD patients with a high risk of CHD and ASCVD have high levels of non-invasive fibrosis markers such as PRO-C3, ADAPT and FIB-4. PRO-C3 and ADAPT show promise as clinical decision-making tools and may have prognostic value.

FRI072

The FIB-8 score: validation of a model to screen patients with non-alcoholic fatty liver disease for significant fibrosis

Pimsiri Sripongpun[1,2], Donghee Kim[1], Ajitha Mannalithara[1], W. Ray Kim[1]. [1]*Stanford University, Division of Gastroenterology and Hepatology, Redwood City, United States;* [2]*Prince of Songkla University, Gastroenterology and Hepatology Unit, Hat Yai, Thailand*
Email: wrkim@stanford.edu

Background and Aims: Noninvasive fibrosis assessment is essential in the screening and diagnosis of non-alcoholic fatty liver disease (NAFLD). We have recently developed and validated (AASLD 2019 abstract #1723) a new model, FIB-8, optimized to detect clinically significant fibrosis (fibrosis stage 2, F2 or higher). In this study, we refine, field-test and validate the score in a real world cohort of NAFLD patients.
Method: FIB-8 was constructed to include four additional variables to FIB-4, namely, body mass index (BMI), albumin/globulin (A/G) ratio, gamma-glutamyl transferase (GGT), and diabetes (DM). The final FIB-8 model was as the following formula.
FIB-8 = FIB4 + 0.042*(BMI; if >40, use 40) - 1.314*(A/G ratio; if >1.5, use 1.5) + 0.004*GGT + 0.819*(DM; 1 if present)
In validating the model further, we analysed data in NAFLD patients who underwent magnetic resonance (MR) examination of the liver in our unit. Eligible patients had hepatic steatosis (proton density fat fraction>5%) without an alternate cause for the steatosis (e.g. heavy alcohol use). Liver stiffness ≥ 3.4 kPa was used to determine clinically significant fibrosis. Area under the receiver operating characteristic (AUROC) curve was used to evaluate the diagnostic accuracy of FIB-8, in comparison to FIB-4 and NAFLD fibrosis score (NFS).
Results: A total of 130 NAFLD patients were eligible for this validation. The mean age was 52.4 years, 53.1% were women, the mean BMI was 31.47 kg/m^2, and 34% had diabetes. Significant fibrosis was found in 35.4%. All had complete data for DM and for the calculation of FIB4, BMI, and A/G ratio. GGT was missing in 93 patients in whom linear imputation was used to render the data complete. In the Figure, the AUROC of FIB-8 was 0.84 with imputed data (n = 130) and 0.91 when only patients with complete data without imputation were included (n = 31). Either version of FIB-8 outperformed FIB-4 and NFS. The previously determined thresholds to rule out and rule in F ≥ 2(<0.72 and ≥ 1.92, respectively) had 97.8% sensitivity, 76.2% specificity, and 96.6% negative predictive value. When FIB-8 was used to diagnose advanced fibrosis (F3, liver stiffness ≥ 4.8 kPa), it also outperformed FIB4 and NFS (AUROC = 0.86 vs 0.80 and 0.77, respectively).



Conclusion: The new model (FIB-8) incorporating BMI, A/G ratio, GGT and DM into FIB4 yields higher accuracy to diagnose significant (F ≥ 2) and advanced (F ≥ 3) fibrosis compared to FIB-4 and NFS, when applied to real world patients undergoing MR evaluation. This simple score based on commonly available data may be used to select patients for further hepatological evaluation.

FRI073

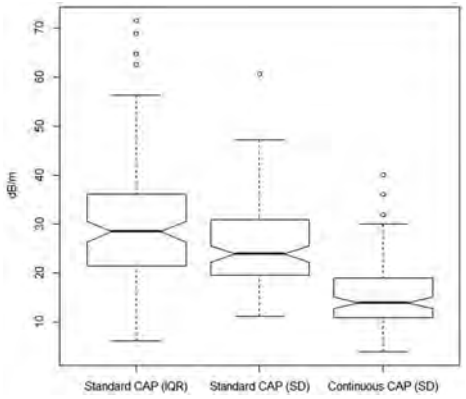
Continuous CAP algorithm: reduced variability in a prospective cohort

Stéphane Audière[1], Véronique Miette[1], Céline Fournier[2], Jennifer Whitehead[3], Angelo Paredes[3,4], Laurent Sandrin[1], Stephen Harrison[5]. *[1]Echosens, Research and Development, Paris, France; [2]Echosens, Medical Affairs, Paris, France; [3]Brooke Army Medical Center, San Antonio, United States; [4]Uniformed Services University of the Health Sciences, Bethesda, United States; [5]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom*
Email: stephenharrison87@gmail.com

Background and Aims: Controlled Attenuation Parameter (CAP) is a surrogate marker of liver steatosis measured with FibroScan (FS) which was improved (named 'Continuous CAP') to reduce the variability. The aim is to evaluate the improvement on data collected during a clinical study in San Antonio, TX. Diagnostic performances of both (standard and continuous) CAP algorithms were assessed comparatively to the proton density fat fraction estimated by magnetic resonance imaging (MRI-PDFF).

Method: Patients referred for a routine cancer screening with no prior history of liver disease or alcohol abuse were offered participation in a prospective prevalence study. 113 consecutive patients (BMI = 30 ± 5 kg/m², age = 56 ± 8 years, 44% male) were enrolled with MRI-PDFF done within 86 days of FS examinations (78 with M and 35 XL FS probe). FS exams were performed by expert users. Continuous CAP results were obtained after reprocessing the raw ultrasonic data. Standard deviation and coefficient of variations were calculated and compared. Spearman's rank correlations and area under receiver operating characteristic (AUC) analysis of CAP versus MRI-PDFF were performed.

Results: For standard CAP, the reported values are median and interquartile range (IQR) (skewed distribution), while for continuous CAP we use mean and Standard Deviation (SD) (Gaussian distribution). In order to compare the variability between the two versions of the CAP, SD was also computed for standard CAP (Figure). The variability is improved by 61% (26 ± 9 dB/m and 16 ± 7 dB/m, standard and continuous CAP SD respectively). Coefficients of variation of less than 10% were obtained in 58% and 91% of exams for standard and continuous CAP, respectively. The correlation coefficients of MRI-PDFF versus CAP are 0.69 (standard) and 0.73 (continuous), which demonstrates an increased trueness of continuous CAP versus MRI-PDFF. AUC for CAP versus MRI-PDFF ≥ 5% (prevalence 31%) are respectively 0.889 [0.827–0.953] (standard)/0.900 [0.838–0.961] (continuous) with a p-value = 0.55). Cutoff are respectively 279 dB/m and 285 dB/m.



Conclusion: Continuous CAP demonstrates a reduced variability and increased correlation with the MRI-PDFF. These first results must be confirmed in a larger cohort of patients.

FRI074

Ultrasound small vessel imaging and deep learning; a novel approach to FLD screening

Tim Hoogenboom[1], Adrian Lim[2], Rohini Sharma[3], Elsa Angelini[2]. *[1]Imperial College London, Metabolism, Digestion and Reproduction, London, United Kingdom; [2]Imperial College London, Metabolism, Digestion and Reproduction; [3]Imperial College London, Surgery and Cancer*
Email: t.hoogenboom13@imperial.ac.uk

Background and Aims: Fatty liver disease (FLD) affects approximately 30% of the global population and is associated with increased risk of developing hepatocellular carcinoma (HCC). Although primarily identified in patients with advanced liver disease, HCC is increasingly reported in non-fibrotic FLD. There is no effective screening for these patients. Hypoxia-driven neoangiogenesis and vascular changes play a key role in progression of both FLD and HCC, independent of fibrosis. We aimed to develop a method for non-invasive automated assessment of FLD and HCC based on intrahepatic vascular structures only.

Method: 95 participants were enrolled including: healthy volunteers (n = 19), early stage liver disease (n = 28), significant fibrosis (n = 27), and HCC (n = 21). Among those, 57 participants had FLD as underlying cause for their liver disease. All participants were subjected to an ultrasound-based method for visualising sub-millimetre intrahepatic vasculature using clinically available technology (contrast enhanced ultrasound and Doppler). A Deep learning classifier was trained on vascular images to differentiate healthy from diseased cases based on vascular features alone. Findings were correlated with clinical measures including liver stiffness measurements (LSM), controlled attenuation parameter (CAP), body mass index (BMI), plasma analysis of neoangiogenic factors, and an image quality score.

Results: The ultrasound-based vascular imaging was applied successfully in all cases, without any adverse event. The Deep learning classifier correctly labelled 88% of cases. Four healthy cases were mislabelled as diseased, two of which had raised CAP which could indicate early stage FLD. Seven diseased cases were mislabeled as healthy, these cases had lower LSM, CAP, and BMI compared to the correctly labelled cases, usually within the normal ranges, independent of image quality.

Figure: Image showing intrahepatic vascular structures with sub-millimeter resolution, segmentation, and skeletonisation.

Conclusion: Deep learning of ultrasound vascular imaging is able to correctly detect the majority of diseased cases, including early stage liver disease, suggesting that hypoxia-associated vascular changes occur in early stages of disease before fibrotic change. This method can be further developed to identify patients most at risk for FLD progression and HCC, without relying on fibrotic changes.

FRI075

Individual patient data meta-analysis on controlled attenuation parameter for the XL probe in obese patients

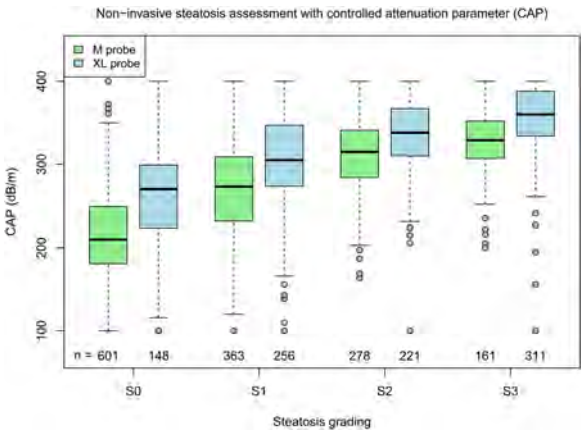
Email: thomas.karlas@medizin.uni-leipzig.de

Background and Aims: Effective screening tools are important for detecting NAFLD and ruling out advanced fibrosis in obese patients. Ultrasound-based vibration controlled transient elastography (VCTE) with controlled attenuation parameter (CAP) is a promising tool that has been studied extensively in leaner patients of various aetiology. In the last few years, CAP has been included for the VCTE probe designed for use in overweight and obese patients (XL probe). CAP-XL has been tested in a number of studies, but consensus regarding cut-offs and diagnostic performance has not yet been reached. We, the international CAP-XL study group, performed an individual patient data meta-analysis to establish optimal cut-offs.

Method: A structured literature search yielded 15 papers that fulfilled the criteria of histology-controlled CAP analyses including the XL probe. We received data from 13 papers and finally included individual data from 2339 patients in the current analysis. Probe selection was based on automated probe selection tool, BMI or skin-to-liver-capsule distance, depending on the study. ROC analyses with optimization according to the Youden method were performed. For further details see the registered protocol (CRD42018099284).

Results: Patients (age 46 ± 14, 49% female) came from 20 centres in 9 countries and 3 continents. 29%, 23%, 47% were normal weight, overweight and obese, respectively. 52% had NAFLD/NASH, 12% ALD, 1% HBV, 9% HCV and 15% had other aetiologies. After taking appropriate probe selection into account, median CAP-XL values (n = 936) were higher than those from the M probe (n = 1403) at each steatosis grade, see Figure 1. This difference arises from higher prevalence of obesity in the XL probe population. The area under the curve (AUC) for distinguishing no steatosis (S0) from any steatosis (S1-S3) using the XL probe was 0.83 (95% CI 0.79 to 0.86). At the optimal cut-off of 294 dB/m sensitivity and specificity were 80% and 73% respectively. The corresponding AUC for S0–S1 vs S2–S3 was 0.78 (95% CI 0.75–0.81) and at the optimal cut-off of 306 dB/m sensitivity and specificity were 86% and 60%. Results in NAFLD patients alone are very similar.



Conclusion: For non-invasive grading of hepatic steatosis, median and optimal CAP values with the XL probe are higher than established ones for the M probe. The effects of covariates and implications for clinical practice have to be explored.

FRI076

Metabolomics approaches to identify biomarkers of non-alcoholic fatty liver disease

Aidan McGlinchey[1], Dawei Geng[1], Olivier Govaere[2], Vlad Ratziu[3], Elisabetta Bugianesi[4], Jörn M. Schattenberg[5], Ann K Daly[2], Tuulia Hyötyläinen[1], Quentin Anstee[2], Matej Orešič[1]. *[1]Örebro University, Sweden; [2]Newcastle University, United Kingdom; [3]Paris Diderot University, Paris, France; [4]University of Turin, Torino, Italy; [5]University Medical Center Mainz, Metabolic Liver Research Program, I. Department of Medicine, Mainz, Germany*
Email: matej.oresic@oru.se

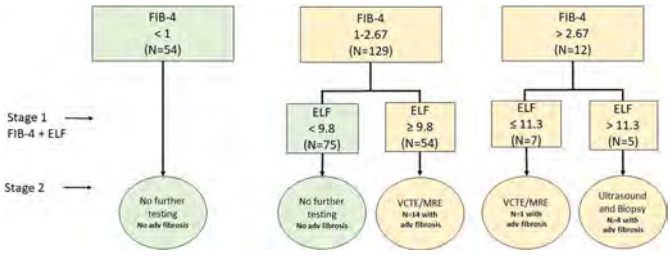
Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is a progressive liver disease that is strongly associated with type 2 diabetes. Accurate, non-invasive diagnostic tests to deliniate the different stages: degree of steatosis, grade of nonalcoholic steatohepatitis (NASH) and stage fibrosis represent an unmet medical need. In our previous studies, we successfully identified specific serum molecular lipid signatures which associate with the amount of liver fat as well as with NASH. Here we report underlying associations between clinical data, lipidomic profiles, metabolic profiles and clinical outcomes, including downstream identification of potential biomarkers for various stages of the disease.
Method: We leverage several statistical and machine-learning approaches to analyse clinical, lipidomic and metabolomic profiles of individuals from the European Horizon 2020 project: Elucidating Pathways of Steatohepatitis (EPoS). We interrogate data on patients representing the full spectrum of NAFLD/NASH derived from the EPoS European NAFLD Registry (n = 627). We condense the EPoS lipidomic data into lipid clusters and subsequently apply non-rejection-rate-pruned partial correlation network techniques to facilitate network analysis between the datasets of lipidomic, metabolomic and clinical data. For biomarker identification, random forest ensemble classification and neural network machine learning approaches were used to both search for valid disease biomarkers and to assess the relative improvement over clinical-data-only classification versus addition of our lipidomic and metabolomic datasets.
Results: We found that steatosis grade was strongly associated with (1) an increase of triglycerides with low carbon number and double bond count as well as (2) a decrease of specific phospholipids, including lysophosphatidylcholines. In addition to the network topology as a result itself, we also present lipid clusters (LCs) of interest to the derived network of proposed interactions in our NAFLD data from the EPoS cohort, along with our proposed biomarkers for various disease outcomes, as put forward by our current machine learning analyses.
Conclusion: Our findings suggest that dysregulation of lipid metabolism in progressive stages of NAFLD is reflected in circulation and may thus hold diagnostic value as well as offer new insights about the NAFLD pathogenesis. Using this cohort as a proof-of-concept, we demonstrate current progress in tuning the accuracy of neural network and random forest approaches with a view to predicting various subtypes of NAFLD patient using a minimal set of lipidomic and metabolic markers. A detailed network-based picture emerges between lipids, polar metabolites and clinical variables. Lipidomic/metabolomic markers may provide an alternative method of NAFLD patient classification and risk stratification to guide therapy.

FRI077

Optimal non-invasive screening strategy for non-alcoholic fatty liver disease in a prospective cohort of patients with type 2 diabetes

Veeral Ajmera[1,2], Jinho Jung[2], Keshin Purohit[2], Scarlett Lopez[2], Egbert Madamba[2], Sonia Bajwa-Dulai[3], Richele Bettencourt[2], Lisa Richards[2], Kathryn Fowler[4], Claude Sirlin[4], Rohit Loomba[1,2]. *[1]University of California San Diego, Medicine-Gastroenterology and Hepatology, La Jolla, United States; [2]University of California San Diego, NAFLD Research Center, La Jolla, United States; [3]University of California San Diego, Medicine, La Jolla, United States; [4]University of California San Diego, Radiology, La Jolla, United States*
Email: v1ajmera@ucsd.edu

Background and Aims: Type 2 diabetes (T2DM) is associated with higher prevalence and severity of nonalcoholic fatty liver disease (NAFLD), therefore EASL guidelines recommend screening older patients with T2DM for NAFLD and advanced fibrosis. However, the optimal screening strategy is unknown. We hypothesized that the combination of FIB-4 and ELF would reduce the need for liver stiffness measurement (LSM), which is not typically available in primary care practices and aimed to define the optimal non-invasive screening strategy in T2DM patients.
Method: This interim cross-sectional analysis of a prospective cohort study included T2DM patients, age ≥ 50 years without an existing diagnosis of NAFLD. Exclusion criteria included other causes of chronic liver disease or hepatic steatosis including excessive alcohol use. Participants included in this study underwent a clinical history, physical exam, laboratory work-up including ELF, VCTE, MRI-PDFF and MRE. The primary outcome was the number of T2DM patients needing additional risk stratification with LSM after FIB-4 alone compared to a staged approach of FIB-4 and ELF.
Results: One-hundred ninety-five consecutive patients (42% men) with T2DM were included. The mean (±SD) age and BMI were 63.9 (±8.1) years and 30.5 (± 5.5) kg/m2, respectively. The prevalence of NAFLD (MRI-PDFF ≥ 5%) was 65% and 10% had advanced fibrosis (MRE >3.62 kPa). In a subset of 48 patients who underwent liver biopsy MRE accurately classified advanced fibrosis status in 42 (88%) patients. FIB-4 values of <1, 1–2.67 and >2.67 were present in 54 (28%), 129 (66%), and 12 (6%) of patients respectively. ELF scores of <9.8, 9.8–11.3 and >11.3 were present in 122 (63%), 61 (31%) and 12 (6%) patients respectively. Significantly fewer patients required LSM when combining FIB-4 and ELF (N = 61, 31%) compared to FIB-4 alone (N = 141, 72%), p < 0.001 (Figure) without misclassification of any patients with advanced fibrosis. In addition, the FIB-4 and ELF combination identified five high-risk patients with FIB-4 >2.67 and ELF >11.3, four of whom had advanced fibrosis on MRE and 1 with stage 2 fibrosis on liver biopsy.



Conclusion: The combination of FIB-4 and ELF is superior to FIB-4 alone in identifying low- and high-risk patients for NAFLD with advanced fibrosis in a screening cohort with T2DM and, if validated, the outlined approach to screening will increase the feasibility of screening T2DM patients for NAFLD and advanced fibrosis.

FRI079

Use of the fibrosis-4 score to estimate fibrosis stage for patients with non-alcoholic fatty liver disease/non-alcoholic steatohepatitis in retrospective real-world datasets: a targeted literature review and feasibility assessment

Ying Qiu[1], Yuexi Wang[2], Clare Byrne[2], Jackson Tang[2], Joel Myers[1]. [1]*Bristol-Myers Squibb, Lawrence Township, United States;* [2]*STATinMED Research, Ann Arbor, United States*
Email: ywang@statinmed.com

Background and Aims: It is not possible to classify patients with non-alcoholic fatty liver disease/non-alcoholic steatohepatitis (NAFLD/NASH) by fibrosis stage in retrospective real-world datasets using International Classification of Diseases codes, because there are currently no specific codes to distinguish between different stages. The Fibrosis-4 (FIB-4) score could be used for retrospective staging because it requires variables that are available for most patients with liver disease in real-world datasets. A targeted literature review was performed to assess the evidence on the use of the FIB-4 score for staging fibrosis in NAFLD/NASH and to determine the optimal cut-off level(s) for stage 3 (F3) and stage 4 (F4) fibrosis.
Method: All published studies including use of FIB-4 score to assess fibrosis in adults with NAFLD/NASH, as well as select hepatitis C virus (HCV) publications, were reviewed.
Results: A total of 167 studies qualified for inclusion. Most concluded that FIB-4 is effective for detecting patients with NAFLD/NASH and advanced fibrosis (F3/F4) and most used cut-offs to identify these patients. The cut-off ≥ 2.67 was the most common and most validated, with an AUROC of ≥ 0.80 for predicting a high risk of advanced fibrosis in retrospective data in multiple studies. The next most common cut-off was ≥ 3.25, which was originally validated in patients with HCV. Very few studies classified patients into separate F stages prior to 3 recent studies that used 4 sets of cut-offs to distinguish between F3 and F4 patients (>2.67 or ≥ 3.25 for F3; >3.15, >3.5, or >4.12 for F4). The F4 cut-offs could not be traced to the NAFLD/NASH literature but >3.5 and >4.12 were identified as cut-offs for cirrhosis in 2 large HCV studies. These sets of cut-offs each selected significantly different populations in the NAFLD/NASH studies. Thus, currently, the 4 potential sets of cut-offs with the best rationale for identifying F3 and F4, respectively, are as follows: ≥ 2.67 and >3.5; ≥ 2.67 and >4.12; ≥ 3.25 and >3.5; ≥ 3.25 and >4.12.
Conclusion: FIB-4 score ≥ 2.67 is well-validated for identifying patients with advanced fibrosis. In terms of distinguishing between F3 and F4, the evidence is less strong. Studies aiming to classify patients into separate stages using FIB-4 are recommended to use more than one set of criteria as sensitivity analyses. Future validation studies to determine the optimal FIB-4 score cut-off/range for each stage would be welcomed.

Background and Aims: NASH patients typically are overweight or obese, which may negatively impact health-related quality of life (HRQOL). Weight loss may reverse NASH and may also improve HRQOL. We aimed to determine whether improvements in fibrosis and steatohepatitis with OCA were associated with improvements in Obesity-specific HRQOL in the month 18 interim analysis of REGENERATE.
Method: Obesity-specific HRQOL was assessed in non-cirrhotic NASH patients at baseline, 6, 12, and 18 months using Impact of Weight on Quality of Life (IWQOL) in REGENERATE. IWQOL is a validated self-reported questionnaire including five domains: Physical Function, Self-Esteem, Sexual Life, Public Distress, and Work, which range from 0–100 (higher score is better) and are averaged to calculate the total IWQOL score.
Results: 1,218 patients [age (mean ± SD) 54.1 ± 11.5 years, 57% female, 34% fibrosis (N = 411) stage 2 and 43% (N = 520) stage 3] were randomized to receive 10 mg (N = 407) or 25 mg (N = 404) of OCA or Placebo (N = 407). Balanced across 3 treatment groups and fibrosis stages, mean body weight and BMI were 95 ± 19 kg and 34.0 ± 5.6 kg/m^2, respectively; 75% and 37% of patients had a BMI>30 kg/m^2 and >35 kg/m^2, respectively. Baseline IWQOL scores were impaired in all domains, with a mean total score of 83.3 ± 17.4, similar in all groups. Treatment with OCA 25 and 10 mg was associated with a mean reduction from baseline to month 18 in body weight and BMI compared to Placebo: −2.17,−1.78,−0.68 kg and BMI −0.78, −0.63, −0.26 kg/m^2, respectively. Mean total IWQOL score showed a significant increase at month 6 (mean ± SD +1.4 ± 0.3), month 12 (+2.14 ± 0.35) and month 18 (+2.12 ± 0.40) compared to baseline ($p < 0.01$), driven by improvement of physical function, self-esteem and sexual life. Improvement was comparable across treatment groups and fibrosis stages over time (all $p > 0.05$), except for sexual life in OCA 25 mg at month 18 ($p < 0.02$). Achieving REGENERATE endpoints at month 18 was associated with greater mean IWQOL improvement: Fibrosis improvement 4.15+/−0.83 vs 1.7+/−0.45; NASH resolution 3.76+/−1.04 vs 1.86+/−0.43 (both $p < 0.05$)
Conclusion: Quality of life measured by IWQOL was impaired at baseline and improved in dose-dependent manner across treatment groups. To what extent these results are attributable to weight loss and to dose-dependent beneficial effects of OCA on fibrosis and NASH will be examined at the end of the study. The REGENERATE study remains ongoing and will continue through clinical outcomes for verification and description of clinical benefit

FRI081

Significant knowledge gap about non-alcoholic fatty liver disease (NAFLD) in real-world practices: a global survey of hepatologists, gastroenterologists, endocrinologists and primary care physicians

Zobair Younossi[1,2,3], Yusuf Yilmaz[4,5], Mohammed El Kassas[6], Vincent Wai-Sun Wong[7], Ajay Kumar Duseja[8], Nahúm Méndez-Sanchez[9], Jacob George[10], Wah-Kheong Chan[11], Laurent Castera[12], Marco Arrese[13], Khaled Alswat[14], Hirokazu Takahashi[15], Manuel Romero Gomez[16], Janus Ong[17], Mariam Ziayee[18], Issah Younossi[18], Andrei Racila[1,2,3], Maria Stepanova[18,19]. *[1]Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; [2]Center for Liver Diseases-Department of Medicine, Falls Church, United States; [3]Inova Health Systems; [4]Institute of Gastroenterology, Marmara University, Istanbul, Turkey; [5]Department of Gastroenterology, School of Medicine, Marmara University, Istanbul, Turkey; [6]Endemic Medicine Department/Faculty of Medicine, Helwan University, Cairo, Egypt; [7]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong; [8]Department of Hepatology, Postgraduate Institute of Medical Education and Research, Chandigarh, India; [9]Liver Research Unit Medica Sur Clinic and Foundation, National Autonomous University of Mexico, Mexico City, Mexico; [10]The University of Sydney Westmead Hospital, Sydney, NSW, Australia; [11]Gastroenterology and Hepatology Unit, Gastroenterology Endoscopy Unit, Department of Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia; [12]Department of Hepatology, Hopital Beaujon, Clichy, France; [13]Departmento de Gastroenterologia, Pontificia Universidad Catolica de Chile, Santiago, Chile; [14]College of Medicine, King Suad University, Riyadh, Saudi Arabia; [15]Department of Internal Medicine, Faculty of Medicine, Saga Medical School, Saga, Japan; [16]Digestive Diseases Department, Ciberehd,Virgen Del Rocio University Hospital, Seliver Group, IBIS, University of Seville, Seville, Spain; [17]University of the Philipines, College of Medicine, Manila, Philippines; [18]Center for Outcomes Research in Liver Diseases, Washington DC, United States; [19]on behalf of the Global NASH council*
Email: zobair.younossi@inova.org

Background: Despite being one of the most common causes of chronic liver disease, health-care providers' knowledge about NAFLD, its risk factors and management may vary across specialties. Our aim was to assess knowledge about NAFLD among 4 medical specialties, globally.

Methods: Surveys with 66 items divided in 4 domains (1. Practice Characteristic Domain: 10 items, 2. Knowledge of Disease Domain: 28 items, 3. Knowledge of Diagnostics Domain: 13 items, 4. Knowledge of Intervention and Management Domain: 15 items) were developed to assess physicians' knowledge (Table). For validity and accuracy, all questions and answers were reviewed by 8 hepatology experts. The IRB-approved survey was completed electronically by hepatologists (HEP), gastroenterologists (GE), endocrinologists (ENDO) and primary care/internists (PCP).

Results: 818 physicians (HEP = 264, GE = 297, ENDO = 69, and PCP = 188) from 14 countries completed the survey; practice duration 10 years (IQR 5–19); 72% hospital-based. HEPs saw the largest number of NAFLD patients/year, while PCPs saw the lowest: [HEP 140 (IQR 60–350), GE/ENDO 100 (50–300), PCP 20 (8–90), $p = 0.001$]. Disease knowledge (accurate classification of obesity/central obesity, importance of raised ALT, excessive alcohol threshold and the most common cause of death) were correctly identified more by GE/HEP than ENDO/PCP ($p < 0.001$). The role of diagnostic tests (ultrasound, transient elastography, and liver biopsy) was more accurately identified by GE/HEP than ENDO/PCP as was treatment management with life style modification and medications ($p < 0.01$). The use of practice guidelines was the most common method of acquiring new knowledge for all specialties (36% to 41%) followed by data from national/international conferences (HEP/GE/ENDO) while for PCP's Internet ranked second for knowledge (17%).

Table: Representative Questions Included in the Survey

1. Practice Characteristic Domain:
Primary practice setting (5 options)
Number of years in practice (write in option)
2. Knowledge of Disease Domain:
What is the prevalence of NAFLD in the general population in your country? (5 options)
Threshold of daily alcohol intake is used to rule out NAFLD in men (5 options)
Normal BMI and normal waist circumference in Asians (5 options)
The main mechanisms underlying the physiopathology of NAFLD (4 options)
3. Knowledge of Diagnostics Domain:
Which one of these non-invasive methods do you use to diagnose NAFLD? (6 options)
How do you make the diagnosis of NASH related cirrhosis in the absence of liver biopsy? (4 options)
4. Knowledge of Intervention and Management Domain:
Initial option to treat patients with NAFLD (4 options)
Do you use pharmacotherapy only in patients with NASH? (2 options)

Conclusion: Despite growing burden of NAFLD, there is a significant knowledge gap. Better implementation of NAFLD guidelines and conferences by different societies may improve this gap.

NAFLD: Therapy

FRI082

A randomized, double blind, placebo-controlled trial of htd1801 (berberine ursodeoxycholate, budc) in patients with hypercholesterolemia: implications for its use in non-alcoholic steatohepatitis (NASH)

Adrian Di Bisceglie[1], Gerald Watts[2], Bao-Van Linberg[3], Li Yu[3], Meng Yu[3], Philip Lavin[4], Liping Liu[3]. *[1]Saint Louis University School of Medicine, Internal Medicine, St. Louis, United States; [2]The University of Western Australia, Cardiology, Crawley, Australia; [3]HighTide Therapeutics, Rockville, United States; [4]Boston Biostatistics Research Foundation, Framingham, United States*
Email: adibisceglie@hightidetx.com

Background and Aims: NASH is often associated with hyperlipidemia and diabetes. BUDC is an ionic salt of berberine (BBR, a plant-extracted compound with anti-oxidant and anti-microbial properties, commonly used for diabetes and heart disease) and UDCA (a secondary bile acid used in cholestatic liver disease which lowers serum aminotransferases in a variety of liver diseases, including NASH. We assessed pharmacokinetics, safety and tolerability of ascending doses of HTD1801 in overweight/obese patients with hypercholesterolemia and measured its effects on serum lipids, HbA1C and aminotransferases.

Method: We enrolled pts with serum LDL >2.59 mmol/L and BMI between 25 and 40 kg/m^2. Pts were excluded if they had recently been on lipid lowering agents, had a history of cardiac disease or severe, uncontrolled diabetes. Pts were randomized to receive ascending doses of HTD 1801 in 3 sequential groups: Group I. 500 mg/day of HTD1801 or matching placebo in a ratio of 3:1. Group II. 1,000 mg/day of HTD1801 or placebo, 3:1. Group III. 2,000 mg/day HTD1801 or placebo, 3:1. Study medication or placebo were given in 2 equal doses daily for 28 days. Disease markers were measured at baseline and day 28. Serum levels of BBR and UDCA were measured after single and multiple doses for PK profile of HTD1801.

Results: 50 subjects were enrolled, including 30 females, equally distributed across the 3 dosing groups, 38 receiving HTD1801 and 12 placebo. Only 2 had a history of diabetes. Half life of BBR in serum was about 8–10 hrs and for UDCA approximately 7 hrs. After repeated

dosing, accumulation was about 4x in BBR and 2x in UDCA. Serum lipids decreased in a dose-dependent fashion (see Table). HbA1C and ALT levels did not decrease significantly. The frequency of treatment-related adverse events was similar with placebo (66%) and active drug (67%), the most frequent complaint in both groups being headache; no study drug-related were reported.

	500 mg (n = 12)		1000 mg (n = 12)		2000 mg (n = 14)		Placebo (n = 12)	
Mean (μmol/L)	Baseline	28d	Baseline	28d	Baseline	28d	Baseline	28d
Total Cholesterol	6.13	5.88	5.81	5.54	5.91	5.42*	6.23	6.59
LDL	4.01	3.72	3.68	3.51	3.85	3.44**	3.91	3.85
Non-HDL cholesterol	4.85	4.71	4.48	4.31	4.62	4.14***	4.66	5.18
Triglycerides	2.11	2.27	1.76	1.86	1.60	1.54*	1.91	2.58

*p < 01; **p = 08; ***p < 0002.

Conclusion: HTD1801 was well tolerated for 28 days. Serum half life for both BBR and UDCA supported twice daily dosing. Dose-dependent lowering of serum lipid levels was observed, statistically significant for the highest dose group. A Phase 2 study of HTD1801 is currently underway in NASH.

FRI083

Weight loss and change in alanine aminotransferase (ALT) among patients with non-alcoholic fatty liver disease (NAFLD) receiving standard care in real world clinical practice: TARGET-NASH

Andrew Moon[1], Stephanie Watkins[2], Miguel Malespin[3], Cheryl Schoen[2], L. Michael Weiss[4], Rohit Loomba[5], Paul J. Thuluvath[6], Rajender Reddy[7], A. Sidney Barritt[1], Arun Sanyal[8], Brent Tetri[9].
[1]University of North Carolina at Chapel Hill; [2]TARGET Pharmasolutions; [3]Tampa General Hospital; [4]GastroFlorida; [5]University of California San Diego; [6]Mercy Medical Center; [7]University of Pennsylvania; [8]Virginia Commonwealth University; [9]Saint Louis University
Email: malespinm@gmail.com

Background and Aims: Weight loss of 7% has been associated with improvement in liver histology among patients with non-alcoholic fatty liver disease (NAFLD). We estimated the association between weight loss and change in ALT among patients enrolled in TARGET-NASH.

Method: Patients enrolled in TARGET NASH between August 2016 and October 2019 with two or more weight measurements and an elevated ALT level (>30 U/L for males and >19 U/L for females) at the first weight measurement were included in the analysis. Patients with decompensated cirrhosis, bariatric surgery, weight loss medication, or a cancer diagnosis were excluded. Weight loss was defined as the difference between the baseline weight and the lowest measured weight over the follow-up study period. Weight loss was then categorized into ≥ 7% or <7% loss. Mean change in ALT was determined by using ALT values closest to the baseline and follow-up weights (within 3 months). The average change in ALT and the 95% CI were estimated among patients with an a priori goal weight change ≥ 7% and <7% using linear regression. Age at enrollment, race, gender, follow up time, insurance status, and body mass index (BMI) were thought a priori to be associated with weight loss and ALT and controlled for in the model.

Results: The study population included 1,006 patients. At enrollment, the median age was 56 years, 58% female, 70% white, 29% overweight, 31% obese class I and 33% obese class ≥ II, 13% had cirrhosis, and 37% had a history of diabetes. During a median follow up of 18.4 months, 24% of patients lost ≥ 7% weight, 57% of patients remained within 7% of baseline weight, and 19% patients gained >7% weight. Mean ALT level decreased by −24.05 IU/L (95% CI:−42.75, −5.42) among patients with ≥ 7% loss compared to patients whose weight loss was <7%.

Table: Estimated mean change in ALT by patient characteristics among patients who had a maximum weight loss ≥ 7% compared to patients who lost <7%*,#

Parameter	Estimate	Standard Error
Weight Loss ≥ 7% vs <7%	−24.08	9.52
Age at enrollment: ≥ 56 vs <56	16.56	6.20
Race: White vs Non-White	−8.10	6.80
Gender: Female vs Male	11.56	5.93
Months of Follow Up	0.43	0.23
Insurance Status at enrollment		
Private	−18.19	18.54
Medicare	−18.42	19.34
Medicaid	−20.96	19.62
Other	reference	reference
BMI category at baseline weight		
Underweight	17.17	65.72
Lean	−21.54	16.50
Overweight	−14.21	9.68
Obesity Class 1	−18.88	9.77
Obesity Class 2 and 3	reference	reference

*Interaction terms between BMI and weight change not shown.
#Estimates are adjusted for other patient characteristics shown in the table.

Conclusion: Weight loss of ≥ 7% may clinically improve ALT levels among patients with NAFLD receiving care in standard practice. These findings support results from randomized trials suggesting improvement in ALT among patients with NAFLD who participated in weight loss interventions.

FRI084

Gw9662, a peroxisome proliferator-activated receptor gamma antagonist, attenuates the development of non-alcoholic fatty liver disease

Anja Baumann[1], Annette Brandt[1], Dragana Rajcic[1], Finn Jung[1], Anika Nier[1], Ina Bergheim[1]. *[1]University of Vienna, Department of Nutritional Sciences, Vienna, Austria*
Email: ina.bergheim@univie.ac.at

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is by now one of the most common liver disease worldwide. Besides a genetic predisposition, overweight and insulin resistance are among the main risk factors in the development of NAFLD. Peroxisome proliferator-activated receptor gamma (PPARγ), which belongs to a class of nuclear receptors, plays a pivotal role in the regulation of the expression of genes involved in lipid and glucose metabolism. Several studies suggest that hepatic expression of PPARγ is induced in NAFLD patients and experimental models while intervention studies suggest that targeting PPARγ activity with specific agonists may be beneficial. However, it has been reported that the PPARγ antagonist GW9662 may improve insulin sensitivity in settings of type 2 diabetes. Here, we determined the effects of a treatment with this antagonist of PPARγ on the development of NAFLD and molecular mechanisms involved.

Method: Female C57BL/6J mice were pair-fed either a liquid control diet (C) or a fat-, fructose- and cholesterol-rich (FFC) diet for 8 weeks. In addition, mice were treated with the PPARγ antagonist GW9662 (1 mg/kg body weight) i.p. 3 times per week. Indices of liver damage and inflammation, parameters of glucose metabolism and portal endotoxin levels were determined.

Results: Despite similar caloric intake and weight gain, mice fed a FFC diet showed marked signs of steatosis with beginning inflammation and elevated liver transaminase activity in plasma. Indices of liver damage including macrovesicular fat accumulation and numbers of inflammatory foci were significantly lower in FFC-fed mice concomitantly treated with GW9662 compared to FFC-fed mice. Alanine transaminase activity and area under the curve of glucose tolerance test were both significantly lower in FFC-fed mice treated with GW9662 when compared to FFC-fed mice. Furthermore, bacterial

endotoxin levels in portal plasma were higher in both FFC-fed groups than in controls, respectively, while concentrations were similar between FFC- and FFC+PPARγ-treated mice.
Conclusion: In summary, our data suggest that a treatment with the PPARγ antagonist attenuates the development of a diet-induced NAFLD and that this is not associated with changes of intestinal barrier function (DFG FKZ: BE2376/6-3).

FRI085
Obesity management during the rise of NAFLD: real world outcomes of the medical weight loss approach using a very low energy diet
Ann Farrell[1,2], Hayden Green[2], James Williams[1], Alexander Thompson[1,2], Marno Ryan[1,2]. [1]*St Vincent's Hospital Melbourne, Gastroenterology, Melbourne, Australia;* [2]*University of Melbourne, Parkville, Australia*
Email: Ann.Farrell@svha.org.au

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a rapidly growing cause of liver disease, with approximately a quarter of the global population now thought to be affected. It is more common in overweight and obesity, and at present loss of weight is the key treatment for NAFLD. Weight loss improves steatosis, and a loss of ≥ 10% of total body weight (TBW) can result in fibrosis regression. Despite this, weight loss is difficult to achieve and maintain, resulting in the need for effective, real world medical weight loss strategies. Medical weight loss often includes; Very Low Energy Diets (VLED), which induce ketosis to suppresses appetite, alongside the use of Appetite Suppressing (AS) medications. Here we aim to review the real world outcomes of a medical weight management clinic, which utilises this approach.
Method: We performed a single centre retrospective analysis of an outpatient weight management clinic at a tertiary referral centre between July 2015 and February 2019. All patients were offered a ketogenic VLED in order to achieve their target weight, with AS medications used to assist with weight loss or weight maintenance as required. The primary outcome was weight loss achieved at 3 and 6 months.
Results: 411 patients attended the clinic during this period, with the majority (92%) of patients commenced on the VLED. The median loss of weight was 8.2 kg (2.8–12.9) or 6.7% (2.4–10.9) of baseline TBW at 3 months (n = 227), and 11.8 kg (4.4–19.8) or 9.37% (3–15.8) of TBW at 6 months (n = 153). At 3 months 30% of the cohort were able to achieve ≥ 10% loss of TBW, which increased to 48% at 6 months. 35% of patients were also prescribed AS medications, with Topiramate the most commonly prescribed, followed by phentermine, then GLP-1 agonists. Those treated with pharmacotherapy more likely to achieve ≥ 10% loss of TBW at both 3 (30% vs 21%, p = 0.006) and 6 months (57% vs 34%, p = 0.005). There was some loss to follow up within the cohort, however patients who were more likely to remain in the clinic had previously tried pharmacotherapy (OR 0.57, 95%CI 0.3–0.96, p = 0.04), or other dietary methods of weight loss in the past (OR 0.44, 95%CI 0.3–0.7, p = 0.00).

Baseline cohort characteristics

	Overall	Female	Male	P-value
N	411	275 (67%)	136 (33%)	<0.0001
Age	47 ± 12	45 ± 12	50 ± 11	0.0001
Weight (kg)	129.8 ± 29	122.9 ± 25	144.2 ± 30	<0.0001
BMI (kg/m^2)	46.5 ± 8	46.7 ± 9	46.1 ± 7.7	0.5057
Waist circumference (cm)	129.6 ± 17	124.5 ± 16	140.5 ± 16	<0.0001
Waist Hip Ratio	0.9 ± 0.1	0.9 ± 0.1	1.0 ± 0.1	<0.0001

Conclusion: An outpatient based ketogenic VLED program is an effective method of achieving weight loss, particularly in combination with pharmacotherapy. This is an effective real world approach to weight loss which should be considered in the management of obese patients with NAFLD.

FRI086
Supplementing diet with olive oil does not prevent the progression of non-alcoholic fatty liver disease
Annette Brandt[1], Dragana Rajcic[1], Cheng Jun Jin[2], Victor Sánchez[1], Anna Janina Engstler[1], Finn Jung[1], Anika Nier[1], Anja Baumann[1], Ina Bergheim[1]. [1]*University of Vienna, Department of Nutritional Sciences, Vienna, Austria;* [2]*Friedrich-Schiller University of Jena, Institute of Nutrition, Jena, Germany*
Email: ina.bergheim@univie.ac.at.

Background and Aims: Besides general overnutrition the intake of certain macronutrients like fructose as well as the type of dietary fat intake and fatty acid composition seems to be of importance during development of non-alcoholic fatty liver disease (NAFLD). Indeed, it has been recommended that patients with NAFLD should follow a 'Mediterranean diet' being rich in vegetables, fruits but also olive oil. Findings regarding the addition of olive oil to the diet in settings of NAFLD and insulin resistance are still contradictory. Here, we evaluate the effect of exchanging dietary fat source from butterfat to olive oil on progression of an already existing diet-induced NAFLD in mouse model.
Method: Female C57Bl/6 mice were either fed a liquid fat-, fructose and cholesterol-rich diet (FFC, 25 E% from butterfat) or control diet (C) for 8 weeks. Some FFC- and C-fed mice were then switched on FFC- or C-diets containing olive oil for 5 more weeks (FFC+OO, 25 E% from olive oil, C+OO, 12 E% from OO), while other groups continuously received butterfat-containing diets (C, FFC). FFC and FFC+OO, as well as C and C+OO-fed mice were pairfed. One week prior to the end of the trial, glucose tolerance test (GTT) was performed and markers of liver damage and glucose metabolism were assessed at the end of the trial.
Results: After 8 weeks of feeding, FFC-fed mice had developed marked signs of NAFLD and insulin resistance which progressed after 13 weeks of feeding. Surprisingly, exchanging dietary fat source for last 5 weeks had no preventive effect on markers of liver damage. Indeed, NAFLD activity score and liver: to body weight ratio was similar between FFC and FFC+OO-fed mice. Furthermore, markers of lipid metabolism like sterol regulatory element-binding transcription factor-1c (Srebp1c) and fatty acid synthase (Fas) mRNA expression were also similarly induced in livers of FFC and FFC+OO-fed mice. Exchanging fat source in FFC diet also had no effect on the significantly higher fasting glucose levels as well as area under the curve during GTT. Also no differences regarding insulin receptor (Ir) or insulin receptor substrate-2 (Irs2) mRNA expression in muscle tissue were found between FFC-groups.
Conclusion: Taken together, our data suggest that exchanging butterfat with similar amounts of olive oil has no effect on the progression of diet-induced NAFLD as well as impairments of glucose metabolism in mice. (funded in parts by UFOP e.V.).

FRI088
Single doses of TERN-201, a novel selective semicarbazide-sensitive amine oxidase (SSAO) inhibitor, are safe, well-tolerated, and result in sustained reduction of SSAO activity in healthy participants
Christopher Jones[1], Pengfei Guo[2], Qiong Zhang[2], Yujin Wang[1], Martijn Fenaux[1], Diana Chung[1], Erin Quirk[1]. [1]*Terns Pharmaceuticals, Foster City, United States;* [2]*Terns China Biotechnology, Shanghai, China*
Email: cjones@ternspharma.com.

Background and Aims: SSAO contributes to non-alcoholic steatohepatitis (NASH) by increasing oxidative stress through deamination of primary amines (e.g. methylamine, MMA) to aldehyde, ammonium, and H_2O_2 and by recruitment of inflammatory cells to the liver, exacerbating hepatic inflammation and injury. SSAO levels are

elevated in NASH and correlate with fibrosis stage. TERN-201 is a novel, selective, covalent SSAO inhibitor that decreases liver inflammation and fibrosis in a rat model of NASH. We conducted a single-ascending dose clinical trial of TERN-201 and report the first pharmacokinetic (PK) and pharmacodynamic (PD) target engagement data for an SSAO inhibitor in humans.

Method: Four groups of 8 healthy participants were randomized to receive TERN-201 capsule or matching placebo in a 3:1 ratio. Plasma levels of TERN-201 and PD biomarkers were determined at pre-dose and various timepoints post-dose. SSAO inhibition was determined by measuring relative reductions in plasma H_2O_2 generation after addition of an exogenous substrate (benzylamine). Endogenous methylamine (MMA) levels, predicted to increase upon SSAO inhibition, were measured in plasma. Safety was assessed for 7 (±3) days after dosing.

Results: 32 healthy human participants (100% male, 63% Black, 19% Asian, 13% Caucasian) were enrolled and received a single oral dose of TERN-201 (1, 3, 6, and 10 mg, n = 6 each) or placebo (n = 2). TERN-201 plasma PK exposure increased in a greater than dose proportional manner between the 3 and 10 mg dose levels. The mean half-life of TERN-201 ranged from 1–3 hours. At 4 hours post-dose, near complete inhibition of plasma SSAO activity was seen in all dose cohorts and continued suppression was detected for up to 1 week after a single dose of TERN-201. Maximum plasma MMA levels increased with TERN-201 dose. No clinically relevant adverse events or laboratory abnormalities were reported.

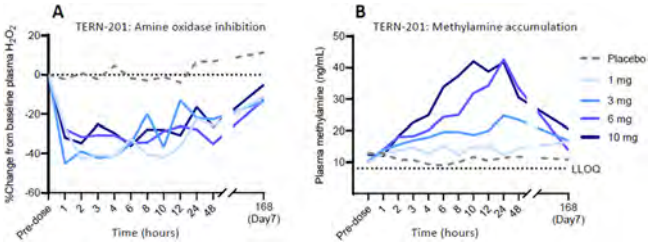

Figure Inhibition of total amine oxidase levels (A) and accumulation of methylamine (B) in the plasma of healthy participants receiving a single dose of TERN-201 or placebo.

Conclusion: Inhibition of plasma SSAO amine oxidase activity and dose-dependent increases in plasma MMA were sustained up to 1 week after single doses of TERN-201, suggesting potent, covalent target engagement and supporting once daily dosing despite a short plasma half-life. All TERN-201 dose levels were well-tolerated. Additional studies are warranted to further investigate TERN-201 for the treatment of NASH.

FRI089

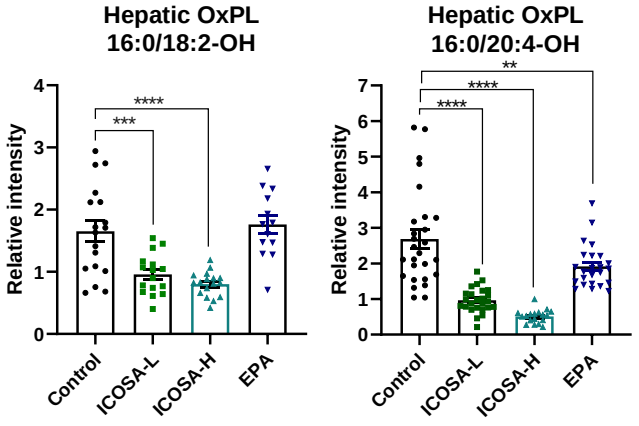
Decline in NASH and atherosclerosis-associated oxidised phospholipids and 7-ketocholesterol in response to icosabutate therapy

David A. Fraser[1], Detlef Schuppan[2,3], Yong Ook Kim[2], Cristina Alonso[4], Marta Iruarrizaga-Lejarreta[4], Xiaoyu Wang[2], John Kastelein[5], Tore Skjaeret[1]. *[1]NorthSea Therapeutics, Naarden, Netherlands; [2]Institute of Translational Immunology, University Medical Center, Mainz, Germany; [3]Division of Gastroenterology, Beth Israel Deaconess Medical Center, Boston, United States; [4]OWL Metabolomics, Parque Tecnológico de Bizkaia, Derio, Spain; [5]Department of Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands*
Email: david.fraser@northseatherapeutics.com.

Background and Aims: Oxidative stress plays a central role in the pathology of both non-alcoholic steatohepatitis (NASH) and atherosclerosis. We have recently shown that icosabutate, a structurally engineered omega-3 fatty-acid (EPA) derivative resistant to β-oxidation and membrane incorporation, significantly reduces markers of hepatic oxidative stress (oxidised glutathione) in multiple murine NASH models and systemic oxidative stress (plasma gamma-glutamyltransferase) in hyperlipidemic humans. To investigate if these findings extend to pathology-associated oxidised lipids, we assessed hepatic concentrations of oxidised phospholipids (oxPLs) in mice and plasma concentrations of 7-ketocholesterol (7-KC) in humans treated with icosabutate.

Method: 9-week old C56BL/6J mice were fed a moderately high-fat diet (31% fat) for 6 weeks, then continued with the diet but received treatment with either low (56 mg/kg, ICOSA-L) or high (112 mg/kg, ICOSA-H) dose icosabutate or EPA (equimolar to ICOSA-H) for 6 weeks (9 mice per group). Changes in hepatic concentrations of oxPLs (16:0/18:2-OH and 16:0/20:4-OH isomers) were measured and differences versus baseline assessed via ANOVA with Dunnet's correction. In hyperlipidemic subjects (n = 15) temporarily withdrawn from statins (NCT02364635), plasma concentrations of 7-KC were assessed at day 0 (baseline), 7 and 28 (study end) in response to either 600 mg/d icosabutate (n = 15) or placebo (n = 5) and differences versus both baseline and placebo were assessed via ANOVA as a univariate procedure.

Results: Icosabutate, but not EPA, reduced hepatic 16:0/18:2 oxPL concentrations (−43%, $p < 0.01$ and.
−53%, $p < 0.001$ for low- and high-dose respectively). Both icosabutate and EPA reduced hepatic 16:0/20:4 oxPL concentrations, with the most pronounced decrease occurring in response to icosabutate (−57% and −71% for low- and high-dose respectively, both $p < 0.001$) versus −18% for EPA, ($p < 0.01$). In humans, icosabutate markedly reduced plasma concentrations of 7-KC by −54% at day 7 ($p < 0.01$) and −42% at day 28 ($p < 0.05$) versus baseline and −37% at day 7 and −39% at day 28 versus placebo (both $p < 0.01$). The reductions in 7-KC exceeded the −23% (day 7) and −35% (day 28) reductions in LDL-C versus baseline (both $p < 0.01$).



Conclusion: Icosabutate effectively reduces pro-inflammatory oxidised lipids in both liver and plasma. Marked decreases in hepatic oxPLs were observed in mice despite icosabutate's resistance to membrane incorporation whilst decreases in plasma 7-KC exceeded the decreases in plasma LDL-C in humans. These findings support the therapeutic potential of icosabutate for the treatment of both NASH and atherosclerosis via a reduction in pathology-associated oxidised lipids.

Background and Aims: Arachidyl amido cholanoic acid (Aramchol) is a potent downregulator of hepatic SCD1 protein expression that reduces liver triglycerides (TG) and fibrosis in animal models of steatohepatitis. In a phase IIb clinical trial, Aramchol improved the histological features of non-alcoholic steatohepatitis (NASH) and reduced blood levels of hemoglobin A1c (HbA1c). We aimed at assessing lipid and glucose metabolism in mouse hepatocytes and in a mouse model of NASH (0.1MCD, 0.1% methionine and choline deficient diet) after treatment with Aramchol.
Method: Mouse hepatocytes were incubated with 20 μM Aramchol for 48 hours. C57BL/6 mice fed a control diet or 0.1MCD diet for 4 weeks received Aramchol (1 or 5 mg/kg/day) or vehicle by gavage for the last 2 weeks.
Results: Proteomics and Western blot analysis showed that the activity of AMP activated protein kinase (AMPK) was increased while the activity of nutrient sensor mammalian target of rapamycin complex 1 (mTORC1) was decreased by Aramchol in hepatocytes. This translated into changes in the content of their downstream targets including proteins involved in fatty acid (FA) synthesis and oxidation (SCD1, P-ACCα/β(S79), CPT1a/b, HADHA and HADHB), oxidative phosphorylation (NDUFA9, NDUFB11, NDUFS1, NDUFV1, ETFDH and UQCRC2), tricarboxylic acid (TCA) cycle (MDH2, SUCLA2 and SUCLG2), P-p70S6K(T389), and P-S6(S235/S236). The protein content of HMGCR and FDPS, two rate-limiting steps in the synthesis of cholesterol was unchanged. Flux experiments with ^{13}C-uniformely labeled glucose showed that TCA cycle cataplerosis was reduced by Aramchol in hepatocytes. Finally, liver metabolic analysis showed that glucose homeostasis is improved by Aramchol in 0.1MCD fed mice in a dose-dependent manner.
Conclusion: Our study shows that hepatocytes respond to Aramchol treatment by activating AMPK and inhibiting mTORC1, which in turn activate FA β-oxidation and oxidative phosphorylation inhibiting de novo lipogenesis, gluconeogenesis and cataplerosis. These results offer a possible explanation for downregulation of HbA1c as well as for the reduction in hepatic TG observed in NASH patients treated with Aramchol.

FRI091
Saroglitazar for the treatment of NAFLD patients: a single- center observational study at 52 weeks follow up

Santosh D. Hajare[1], Sandesha S. Ghorpade[2]. [1]*Jawaharlal Nehru Medical College, Department of Gastroenterology, Belgaum, India;* [2]*KLES Dr. Prabhakar Kore Hospital & M.R.C, Department of Gastroenterology, Belgaum, India*
Email: drsantoshhajare@gmail.com.

Background and Aims: Saroglitazar a dual PPAR alpha and PPAR gamma agonist is approved for management of Diabetic Dyslipidemia and Hypertriglyceridemia in India. Considering the association between insulin resistance, dyslipidemia and the development of NAFLD/NASH, Saroglitazar could potentially benefit patients with NAFLD including those with borderline NASH. Therefore, the purpose of the present study was to examine the efficacy of saroglitazar in patients with NAFLD.
Method: This study was Single Center, Single arm, Prospective Observational study conducted in Southern India. A total of 52 patients Diabetic and Non-Diabetic diagnosed as fatty liver on USG and with Liver Stiffness Measurement (LSM) >6 kPa were prescribed Saroglitazar 4 mg once daily. The Males (71.15%) and Females (28.84%) with Mean age of 45.8 ± 11.6 years and Mean Body Mass Index 28.1 ± 6.0 Kg/m^2 were followed up for the period of 52 weeks for body weight, ALT (Alanine Aminotransferase), AST (Aspartate Aminotransferase), Serum triglycerides and LSM. Statistical analysis was done using Paired sample student t -test.
Results: In this study 28.8% were Diabetic and 17.3% were hypertensive. Patients were Normal (21.15%), Overweight (11.54%), Obese I (32.69%) and Obese II (34.62%) as per WHO Asian criteria based on BMI. Saroglitazar treatment was associated with significant reduction in ALT (56.1 ± 30.9 to 33.5 ± 16.7IU/L) and AST (46.7 ± 22.3 to 29.4 ± 11.1 IU/L), Serum triglycerides reduced significantly from (193 ± 56.75 mg/dL to 133.11 ± 37.04 mg/dL) and Liver Stiffness Measurement at baseline 12.3 ± 9.9 kPa was significantly reduced to 9.6 ± 4.5 kPa at 52 weeks follow up. Percentage reduction in the above parameters are summarized in Table 1. There was slight variation in weight (75.2 ± 13.8 to 73.9 ± 13.5 kg). Overall, Saroglitazar was well tolerated during the study.

Table 1: Change in efficacy endpoints from baseline to week 52.

Parameters	Percentage Reduction	P Value at 95% CI
ALT	40.3%	<0.001
AST	36.9%	<0.001
Serum Triglycerides	31.0%	<0.001
Liver Stiffness Measurement	21.0%	0.02
Body Weight	1.7%	0.005

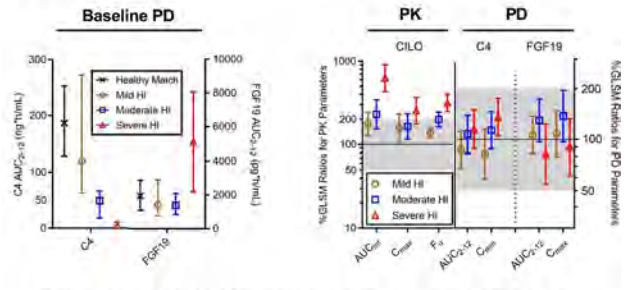
Conclusion: Saroglitazar 4 mg once daily improved the liver enzymes, serum triglycerides and Liver Stiffness measurement. Further studies are needed to substantiate the efficacy and safety of Saroglitazar.

FRI092
The pharmacokinetics, pharmacodynamics, and short-term safety of cilofexor, a nonsteroidal farnesoid X receptor agonist, in subjects with hepatic impairment

Chia-Hsiang Hsueh[1], Andrew Billin[1], Shirley Li[1], Stephen Lin[1], Deqing Xiao[1], Chuhan Chung[1], Robert Myers[1], Elijah Weber[1], Cara Nelson[1]. [1]*Gilead sciences, inc.*
Email: cara.nelson@gilead.com

Background and Aims: Cilofexor (CILO) is a selective, oral, nonsteroidal farnesoid X receptor (FXR) agonist in development for the treatment of nonalcoholic steatohepatitis (NASH) and primary sclerosing cholangitis (PSC). This Phase 1 study evaluated the short-term safety, pharmacokinetics (PK), and pharmacodynamics (PD) of CILO in subjects with mild, moderate, or severe hepatic impairment (HI) to support development of CILO in patients with cirrhosis.
Method: Subjects with stable mild, moderate, or severe HI (Child-Turcotte-Pugh [CTP] A, B, or C, respectively, [n = 10/group]) and healthy matched controls with normal hepatic function (by sex, age, and BMI) underwent intensive PD sampling on Day-1 and received a single, oral dose of CILO (30 mg CTP-A, -B; 10 mg CTP-C) on Day 1 with intensive sampling for PK (96 hr) and PD (24 hr). Safety was monitored and the effect of HI on PK parameters (AUC, Cmax, free fraction [f_u]) of CILO and its major circulating metabolites (GS-716070 and GS-156765), as well as PD parameters (C4 and FGF19), were evaluated. Geometric least square mean ratios (GLSM ratios) and 90% confidence intervals (CIs) relative to controls are reported.
Results: Treatment-emergent adverse events (AEs) were generally mild. Two subjects (with moderate and severe HI), both with histories of esophageal varices, experienced serious AEs of GI hemorrhage, considered unrelated to study drug. Preliminary data summarizing the effect of varying degrees of HI on PK and baseline-corrected PD are presented in the Figure. Systemic/free exposures of CILO and its major circulating metabolite GS-716070 were increased, whereas GS-1056756 exposure was decreased with increasing severity of HI. Whereas PD response to CILO was similar in subjects with mild or moderate HI compared to controls, subjects with severe HI had reduced response, likely due to baseline activation of the FXR pathway (Figure).

Figure 1 Effect of HI on the PD, and PK/PD of CILO



C4, 7α-hydroxy-4-cholesten-3-one; FGF19, fibroblast growth factor 19; GLSM ratio, geometric least square mean ratio (HI/healthy matched control); AUC, area under the curve; Cmax, maximum plasma concentration; F_u, free fraction; grey shaded area represents the 50% - 200% boundary

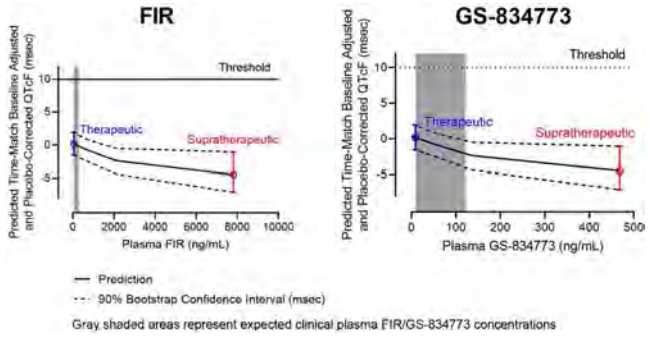
Conclusion: CILO was generally well tolerated in this study. The moderate (<2-fold) changes in CILO PK in subjects with mild HI is unlikely to be clinically relevant and support administration without dose modification in this population. Reduced PD response in severe HI is likely related to baseline activation of the FXR pathway.

FRI093

Concentration-QT analysis of firsocostat, a liver-targeted acetyl-coa carboxylase inhibitor

Chia-Hsiang Hsueh[1], Mun Sang Yue[1], Victoria Millward[1], Darren Huber[1], Chuhan Chung[1], Robert Myers[1], Elijah Weber[1], Cara Nelson[1]. [1]*Gilead sciences, inc.*
Email: cara.nelson@gilead.com

Background and Aims: Patients with nonalcoholic steatohepatitis (NASH) have an increased risk of cardiovascular disease. Firsocostat (FIR) is a potent, oral, liver-targeted inhibitor of acetyl-CoA carboxylase (ACC) in development for the treatment of NASH. In animals, no electrocardiographic (ECG) abnormalities have been observed at a dose providing a >300-fold exposure margin relative to the human clinical dose (20 mg daily). In this first-in-human, placebo-controlled, single ascending dose study, intensive ECG monitoring was conducted to evaluate the potential pro-arrhythmic risk of FIR.
Method: High quality, intensive, time-matched 12-lead ECGs were obtained from healthy subjects administered single doses of FIR up to 1000 mg. Effects of FIR, GS-834773 (primary metabolite of FIR produced by UDP-glucuronosyltransferases (UGTs)), and their interaction on baseline-adjusted Friedrich's correction QT(ΔQTcF) were modelled using linear mixed-effects models. Bootstrapping was used to obtain 90% confidence intervals (CIs) of predicted placebo-corrected ΔQTcF (ΔΔQTcF) to evaluate the potential risk of QT prolongation.
Results: C_{max} at FIR 1000 mg provided a supratherapeutic concentration that was at least 3-fold higher than the maximal expected concentrations of FIR and GS-834773 in subjects with moderate hepatic impairment co-administered UGT inhibitors. Figure 1 shows the relationships between ΔΔQTcF and concentrations of FIR and GS-834773. The upper bounds of the 90% CIs for predicted ΔΔQTcF were <10 msec, indicating the absence of QT prolongation at therapeutic and supratherapeutic concentrations of FIR and GS-834773.



Gray shaded areas represent expected clinical plasma FIR/GS-834773 concentrations

Figure: Association between predicted ΔΔQTcF and plasma FIR/GS-834773 concentrations

Conclusion: This concentration-QT study showed that FIR does not cause QT prolongation at the highest exposures expected in the clinical setting. These data formed the basis of a waiver that obviated the requirement for a thorough QT (TQT) study by the US FDA. The cardiovascular safety of FIR will be confirmed in ongoing and future studies of patients with NASH.

FRI094

The safety and pharmacokinetics of fenofibrate in patients with advanced fibrosis including those with non-alcoholic steatohepatitis (NASH)

Elijah Weber[1], Cara Nelson[1], Ann Qin[1], Ryan Huss[1], Marianne Camargo[1], Robert Myers[1], Shirley Li[1], Jie Zhang[1], Brian Kirby[1]. [1]*Gilead Sciences, Inc., Foster City, United States*
Email: elijah.weber@gilead.com

Background and Aims: Fenofibrate (FENO), a lipid-lowering PPAR-α agonist, is contraindicated in patients with advanced hepatic fibrosis due to lack of prior studies. FENO has shown promise for mitigating hypertriglyceridemia observed in NASH patients treated with the acetyl-CoA carboxylase (ACC) inhibitor firsocostat (FIR). Here, we describe Ph 1 and 2 studies that evaluated the pharmacokinetics (PK) and safety of FENO in patients with advanced fibrosis to support coadministration with FIR.
Method: In the Ph 1 study, subjects with mild hepatic impairment (HI) (Child-Turcotte-Pugh [CTP]-A) and healthy matched controls (n = 10/group) received a single, oral dose of FENO 48 mg with intensive PK sampling. In the Ph 2 study, 31 patients with hypertriglyceridemia (TGs >150 and <500 mg/dL) and advanced fibrosis (F3-F4) due to NASH were randomized (1:1) to treatment with FENO 48 mg (n = 15) or 145 mg (n = 16) orally once daily for 2 weeks, followed by the combination of FENO+FIR 20 mg daily for 24 weeks (NCT02781584); an optional PK substudy was included (n = 16). Safety was monitored throughout both studies. Plasma concentrations of fenofibric acid (the active moiety of fenofibrate) were determined by validated LC-MS/MS methods. Geometric least squares mean ratios (GLSMRs) and 90% confidence intervals (CIs) of FENO AUC and C_{max} were constructed for subjects with mild HI vs healthy matched controls. PK parameters in NASH patients were dose-normalized for comparison.
Results: In the Ph 1 HI study, no treatment-emergent adverse events (TEAEs) or ≥ Grade 3 laboratory abnormalities were reported in patients with CTP-A cirrhosis. In NASH patients with F3-F4 fibrosis, there was no evidence of hepatotoxicity, or difference in frequency of TEAEs (no Grade 3–4) or laboratory abnormalities between dose groups. No clinically meaningful differences in fenofibric acid AUC_{inf} (GLSMR 1.25 [90% CI 89, 174]) or C_{max} (GLSMR 1.09 [90% CI 81, 146]) were observed between subjects with mild HI and healthy matched controls. In patients with NASH, dose-normalized fenofibric acid exposures were similar between those with F3 (n = 12) and F4 (n = 4) fibrosis and similar to mild HI.
Conclusion: In patients with mild HI or NASH with advanced fibrosis, FENO was well tolerated and the PK of fenofibric acid was unaltered. These data suggest that FENO may be a safe option for the management of hypertriglyceridemia in patients with advanced fibrosis and represent a meaningful contribution to our understanding of the PK of FENO in a previously unevaluated population.

FRI096

A randomized, double-blind, placebo-controlled, first-in-human single ascending dose, multiple ascending dose, and food effect study to evaluate the safety, tolerability, and pharmacokinetic profile of FM101 in healthy volunteers

Seon-Ah Ha[1], Mi Ri Kim[1], Saehan Kang[1], Mira Yu[1], Chong-Woo Park[1], Jiyoun Lee[1], Jiyeon Kang[1], Ji-Young Kim[1], Seong Wook Seo[1], Seohyun Son[1], Hyeon Deok Cho[1], Hyuk Woo Lee[1], Lak Shin Jeong[1,2].
[1]Future Medicine Co., Ltd., Seongnam, Gyeonggi-do, Korea, Rep. of South; [2]Seoul National University, College of Pharmacy, Seoul, Korea, Rep. of South
Email: hsa387@futuremedicine.co.kr

Background and Aims: FM101 is a highly potent modulator of human A_3 adenosine receptor (A_3AR) over-expressed in inflammatory cells. We have previously shown anti-inflammatory and -fibrotic activities of FM101 in non-alcoholic steatohepatitis (NASH) animal models including the Stelic animal model (STAM) and Fast Food Diet (FFD). To explore the potentiality of FM101 as a therapeutic, this first-in-human (FIH) study was performed by evaluating the safety, tolerability, and pharmacokinetic (PK) profile of FM101 in healthy subjects.

Method: This was a randomized, double-blind, placebo-controlled, first-in-human (FIH) study consisting of three parts: a single ascending dose (SAD) part, a single dose of food effect (FE) part, and a multiple ascending dose (MAD) part. The primary objectives of the study were to evaluate the safety/tolerability and the pharmacokinetics (PK) of FM101 after single and multiple oral dose administration to healthy volunteers. The secondary objective was to evaluated the food effect on the single dose PK of FM101 in healthy volunteers. As exploratory, we investigated the PKs of FM101 and its major metabolite M6 in the urine after MAD administration. Fifty subjects were entered onto this study. A single dose of FM101 was escalated from 75 mg to 2400 mg per patient in SAD study. A single dose of 300 mg was administered in FE study. A multiple dose of FM101 for a period of one week was escalated from 150 mg QD to 450 mg QD and 600 mg BID, respectively.

Results: No clinically relevant safety and tolerability findings were observed in all safety variables such as laboratory values, vital signs, or electrocardiograms. All adverse events (AEs) reported during the study were mild of intensity and local toxicities in the gastrointestinal tract were most frequently observed in the forms of nausea and diarrhea. The FM101 was rapidly absorbed and plasma concentrations declined with a mean terminal half-life of approximately 18 h.

Table 1. Summary of Related TEAEs by Treatment, SOC and PT

Figure: (abstract: FRI096)

Steady-state levels were achieved within a week. The FM101 area under the curve from time 0 to infinity and peak or maximum FM101 concentration seemed to increase with escalating dose, which suggests that FM101 has linear pharmacokinetics.
Conclusion: The prevalence of NASH gradually increases over time due to the epidemics of obesity and metabolic diseases including diabetes. There is no standard of care for this chronic type of disease so far. In this study, we demonstrated that FM101, a potential drug for treating NASH was generally well-tolerated up to 2400 mg (QD) and 600 mg (BID) in SAD and MAD studies, respectively. It also had a linear PK profile without significant inter-individual variations in healthy subjects. Based upon the obtained results, FM101 is considered as a suitable drug candidate for future evaluation in patients with inflammatory and fibrotic diseases including NASH.

FRI097

Direct access lifestyle training improves liver biochemistry and causes weight loss but uptake is suboptimal in patients with NAFLD

Lili Molnar[1], Katherine Akerboom[2], Jayne Wilkie[2], Roxanne Gore[2], Tehreem Chaudhry[2], Katie Lane[1], Imran Patanwala[2,3]. *[1]Liverpool John Moores University, United Kingdom; [2]Royal Liverpool and Broadgreen University Hospitals NHS Trust, Gastroenterology and hepatology, Liverpool, United Kingdom; [3]University of Liverpool, Liverpool, United Kingdom*
Email: ipatanwala@gmail.com

Background and Aims: EASL NAFLD guidelines recommend a comprehensive and pragmatic individualised approach to lifestyle modification. Delivery of such interventions in busy clinics in the United Kingdom is challenging due to organisational pressures borne out in a recent survey where only 1 in 5 practices polled were able to offer adequate access to multidisciplinary weight management services.(1) Evidence on the acceptability, uptake and efficacy of direct access intensive lifestyle training program offered in secondary care where adequately provided is lacking. We aimed to assess the uptake of lifestyle training and its impact in patients with NAFLD.
Method: All patients attending a dedicated NAFLD clinic from April 2018 to March 2019 were offered referral to a lifestyle trainer program funded by Liverpool Council via a representative present in clinic. The program involves the patient seeing a health trainer in community hubs or GP practices close to the patient's home on a weekly or fortnightly basis for 12 weeks. Personalised advice and support is offered to complete objectives set out in a Personalised Health Plan based on Public Health England guidelines. We compared weight loss and changes in ALT between patients who completed the program versus age and sex matched patients who did not.
Results:167 patients with fatty liver disease were offered lifestyle training during the study period. Median age of patient was 58 yr; Only 16 (9.58%, 95% CI 6%–15%) patients completed the program. Weight loss in the intervention group was significantly higher compared to the control group (–2.79 Kg vs + 0.95 Kg, p = 0.007). A drop in ALT was noted in both groups though this was not statistically significant (–20.6 IU/L vs –15.75 IU/L p = 0.579). Completing the program was not associated with improvement in lipid profiles but was associated with an improvement in self rated emotional wellbeing (56.25% to 75%), an increase in fruit intake by 61.7%, reduction in the use of fried food and snacking by 13% and 21% respectively.
Conclusion: Dedicated direct access health trainer input resulted in significant weight loss but had no impact on liver biochemistry or lipid profile over 3 months. Only 1 in 10 patients offered the opportunity completed the program, reasons for which should be a focus for further research

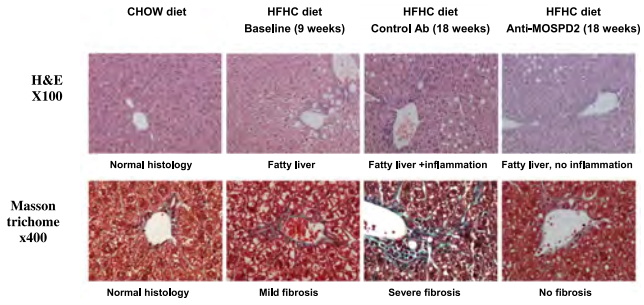
Motile sperm domain-containing protein 2: a novel therapeutic target for the treatment of non-alcoholic steatohepatitis

Itzhak Mendel[1], Niva Yacov[1], Yaniv Salem[1], Eyal Breitbart[1]. *[1]VBL Therapeutics*
Email: itzhak@vblrx.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is a major cause of liver-related morbidity and mortality worldwide with no effective treatment currently available. In the absence of circulating monocytes or treatment with Ceniciviroc, an oral CCR2/5 antagonist that inhibits monocyte migration, Nonalcoholic steatohepatitis (NASH) and liver fibrosis were shown to be reduced. These findings indicated that inhibiting monocyte migration could have a therapeutic benefit in NASH. We previously identified MOSPD2 (Motile sperm domain–containing protein 2) as a protein which is predominantly expressed on the surface of human monocytes and is essential for their migration. In this study, the potential of MOSPD2 as a target for treating NASH was assessed. The efficacy of anti-MOSPD2 monoclonal antibody (mAb) compared with Ceniciviroc to inhibit monocyte migration in-vitro was tested.
Method: MCP-1 and RANTES were used to induce migration of primary human monocytes through a trans-well plate. MOSPD2 knockout (KO) mice were generated by homologous recombination. Anti-MOSPD2 mAbs were prepared by immunizing mice with the extracellular region of human MOSPD2 and isolating hybridoma producing antibodies. NASH was induced in mice by using a High-Fat High-Carbohydrate (HFHC) diet.
Results: Anti-MOSPD2 mAb significantly inhibited MCP-1 and RANTES-induced migration of monocyte and was superior to Ceniciviroc in-vitro. In a NASH model induced by HFHC diet, MOSPD2 KO mice showed significant decrease in liver inflammation and fibrosis compared with wild type controls. Furthermore, employing anti-MOSPD2 mAb in the HFHC model after fibrosis was initiated halted and reversed the disease.



Conclusion: The results indicate that MOSPD2 is playing a role in NAFLD pathogenesis, and that targeting MOSPD2 using mAbs may hold promise as a treatment for NASH and liver fibrosis through inhibition of monocytes accumulation in the liver.

The efficacy of vitamin D supplementation on NAFLD: a randomized, double-blind, placebo-controlled 12- month trial on 311 patients

Ivana Mikolasevic[1,2], Viktor Domislovic[3], Vladimir Trkulja[4], Željko Krznarić[3,4], Nadija Skenderević[1], Ana Mijić[2], Marija Matašin[4], Tajana Stevanović[2], Božena Delija[2], Mia Klapan[2], Toni Jurić[2], Anđela Lukić[2], Petra Dinjar Kujundžić[5], Ana Ostojic[5], Petra Puž[6], Tajana Filipec Kanizaj[4,5]. *[1]Clinical Hospital Merkur, Department of*

Gastroenterology and Hepatology; [2]University of Rijeka, School of Medicine Rijeka; [3]Clinical Hospital Centre Zagreb, Department of Gastroenterology and Hepatology, Zagreb, Croatia; [4]University of Zagreb, Zagreb School of Medicine, Zagreb, Croatia; [5]Clinical Hospital Merkur, Department of Gastroenterology and Hepatology, Zagreb, Croatia; [6]General Hospital Dr. Tomislav Bardek, Department of Gastroenterology, Koprivnica, Croatia
Email: viktor.domislovic@gmail.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is common cause of liver disease worldwide which can eventually cause chronic liver damage. Current studies suggest that vitamin D supplementation may have a favorable effect on the management of NAFLD. The aim of the present randomized controlled trial and was to evaluate potential impact of vitamin D supplementation on the transient elastography indices of liver steatosis (CAP) and fibrosis (LSM) as primary outcome and AST, ALT and GGT as secondary outcomes in adult patients with NAFLD.
Method: This randomized, double-blind, placebo-controlled 12-month trial was conducted at a single tertiary center in Rijeka, Croatia. Eligible patients were randomized (2:1) to vitamin D3 oral solution (1000 IU/day; 5 drops) or a matching placebo. Eligible for inclusion were adult patients with NAFLD on ultrasound and with at least one clinical marker of the metabolic syndrome. Excluded were patients with any other potential cause of liver steatosis/fibrosis. Patients were evaluated at baseline and after 6 and 12 months of treatment with transient elastography FibroScan® to assess CAP and LSM and blood analysis.
Results: A total of 311 pts were enrolled and randomized, 201 to vitamin D 1000 IU/day and 110 to placebo. There appeared a clear decreasing trend in CAP over time in vitamin D-treated patients and a slight increasing trend in the placebo arm (Figure 1). No such trends were apparent regarding LSM and liver enzymes. There was vitamin D – placebo difference in change vs. baseline of –22.1 dB/m (95% CI –32.2, –12.0) after 180 days and of –49.4 dB/m (95% CI –59.6, –39.3) after 360 days of treatment (95% CI adjusted for multiplicity). The treatment*visit interaction was significant ($P < 0.001$), i.e., between-treatment difference in change vs. baseline was greater after 360 days than after 180 days of treatment (difference in between-treatment difference = –27.4 dB/m, 95% CI –36.0, –18.7). The vitamin D - placebo difference in change vs. baseline was –0.89 kPa (95% CI –1.60, –0.17) after 180 days, and –0.72 kPa (95%CI –1.43, –0.00) after 360 days of treatment (95% CI adjusted for multiplicity).
Conclusion: Our study suggest the efficacy of vitamin D supplementation on CAP reduction, while this was not the case for LSM, AST, ALT and GGT. Since there are still no FDA approved drugs for NAFLD so far, vitamin D may be a good therapeutic option, esspetially due to the safety and favorable cost/benefit ratio.

FRI100

Molecular, cellular, and pharmacological characterization of beta-selective partial agonists of human thyroid hormone receptor for the treatment of non-alcoholic steatohepatitis

Jerome Deval[1], Sarah Stevens[1], Xuan Luong[1], Andreas Jekle[1], Tse-I Lin[2], Kusum Gupta[1], Dinah Misner[1], Sushmita Chanda[1], Jyanwei Liu[1], Caroline Williams[1], Antitsa Stoycheva[1], Leonid Beigelman[1], Julian Symons[1], Pierre Raboisson[2], Koen Vandyck[2]. *[1]Aligos Therapeutics, South San Francisco, United States; [2]Aligos Belgium, Leuven, Belgium*
Email: jdeval@aligos.com

Background and Aims: Thyroid hormone receptor (THR) agonists currently in clinical trials for the treatment of nonalcoholic steatohepatitis (NASH) have demonstrated potential to reduce liver fat and restore liver function. These beneficial effects are attributed to an intra-hepatic activation of the beta (B) receptor isoform. Activation of the alpha (A) isoform in the heart with non-selective THR agonists has previously been reported and is considered detrimental for NASH patients. The aim of our project is to characterize novel THR agonists with no activation potential against THR-A.
Method: Binding between small molecule agonists and THR-A or -B resulting in coactivator recruitment was assessed in a FRET-based biochemical assay. The primary cell-based assay relied on HEK293 T cells transiently transfected with a luciferase reporter and a THR-A or -B expression plasmid. Activation of THR in Huh-7 hepatic cells was measured by qPCR. Compounds with favorable in vivo pharmacokinetics were evaluated for efficacy in High Fat Diet (HFD) rats.
Results: We discovered a series of novel THR agonists that were evaluated in a panel of in vitro functional assays. In a biochemical assay, the compounds activated THR-B with an EC_{50} of around 40–60 nM, and a maximum effective amplitude (E_{max}) of ~25–50% compared to the natural thyroid hormone T3. The same compounds did not significantly activate THR-A at concentrations up to 10 µM. In a HEK293T-based reporter assay, we observed a similar behavior of E_{max} value at ~55% compared to T3, with no measurable activation of the A-receptor, resulting in a selectivity index of more than 90-fold. The selective partial agonism effect on THR-B was confirmed for these compounds by measuring changes in gene expression in hepatocytes. These results are in contrast with all other known thyromimetic agents reported to date. In the cellular reporter assay, the B/A selectivity index of GC-1, MGL-3196 and VK-2809 (active form) ranged between 1- to 3.4-fold. In a HFD rat efficacy model, single doses of these highly B-selective THR partial agonists induced reduction in atherogenic lipids, but at lower levels compared with full agonists.

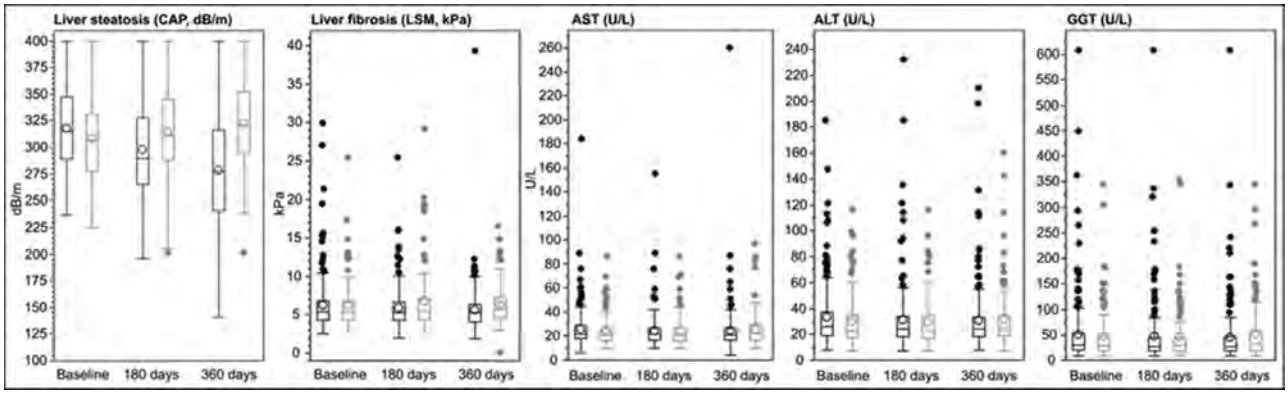

Figure 1: (abstract: FRI099): Primary and secondary outcomes of the study.

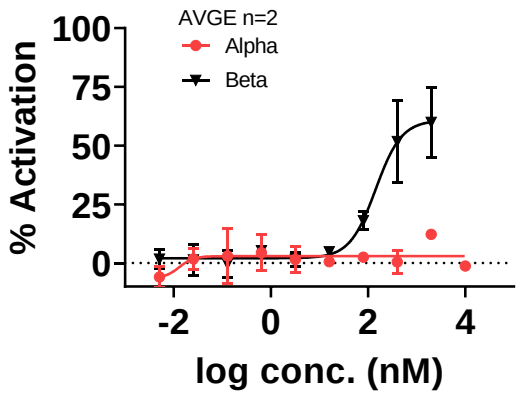

Conclusion: We discovered a novel series of B selective THR partial agonists. As described for other nuclear receptors, selective partial agonists of THR hold the promise of lowering liver fat with minimum risk of inducing the side effects described with non-selective full agonists.

FRI101

The first double-blind randomized placebo-controlled phase 2 study to assess the efficacy and safety of insulin sensitizer in patients with non-alcoholic steatohepatitis in Asia- an interim report

Ming-Lun Yeh[1,2], Chung-Feng Huang[1,2,3], Pei-Chien Tsai[2], Ching-I Huang[1,2,3], Chia-Yen Dai[1,2,3], Shinn-Chern Chen[1,2], Jee-Fu Huang[1,2,3,4], Ming-Lung Yu[1,2,4], Wan-Long Chuang[1,2].

Email: jfliver@kmu.edu.tw

Background and Aims: Non-alcoholic steatohepatitis (NASH) is the leading liver disease globally. Insulin sensitizer has been demonstrated the efficacy in lowering liver fat and inflammation of NASH patients. We conducted the randomized trial aiming to investigate the efficacy and safety of insulin sensitizer in Asian NASH patients.
Method: A total of 90 biopsy-proved NASH patients was consecutively randomized into receiving either oral Pioglitazone 40 mg/day or placebo for 24 weeks and another 12 weeks post-treatment follow up. Biochemistry profiles, liver biopsy and magnetic resonance imaging (MRI) were collected before and after the intervention, respectively. The histological severity of NASH was evaluated and the primary endpoint was the efficacy of pioglitazone in liver biochemistry and fat accumulation.
Results: Among the 90 NASH patients recruited, 66 (73.3%) were male and the mean age was 44.1 ± 12.7 years old. Diabetes, dyslipidemia, and metabolic syndrome were found in 21 (23.3%), 55 (61.1%), and 52 (57.8%) of the patients. The mean body mass index (BMI) was 28.9 ± 3.9 kg/m^2 and 29 (32.2%) patients of obesity. The mean AST, ALT, glucose, total cholesterol, HDL-cholesterol, LDL-cholesterol, triglyceride, and uric acid were 52 ± 23 U/L, 90 ± 39 U/L, 103.8 ± 16.2 mg/dl, 215.1 ± 33.7 mg/dl, 44.0 ± 10.6 mg/dL, 141.1 ± 35.2 mg/dL, 165.6 ± 116.0 mg/dL, and 6.8 ± 1.4 mg/dL, respectively. The mean HOMA-IR was 2.82 ± 2.74. The 2nd MRI at 6 months after first dosing showed a significantly decreased liver fat content from 19.6 ± 8.9% to 15.7 ± 7.6%. ($p = 0.001$). More than half (52.4%) of the patients had improvement of liver fat content and only 19.0% of the patients had worsening liver fat content on the 2nd MRI. Further analysis demonstrated initial higher liver fat content as the only independent factor associated with improvement of liver fat content at 2nd MRI. (OR: 1.22, 95% CI: 1.082–1.369, $p = 0.001$). For histology changes, most of the patients showed none change or improvement in steatosis, NASH grade and stage. Only a few patients (<10%) showed a worsening change in histology.
Conclusion: The preliminary results of the first-in-Asia randomized trial demonstrated insulin sensitizer improved liver fat on MRI and NASH severity on histopathology. Further analysis upon the study deblinding is mandatory to evaluate the efficacy and safety.

FRI102

Efficacy and feasibility of a very low calorie diet to achieve 10% weight loss in patients with advanced non-alcoholic fatty liver disease

Jadine Scragg[1], Leah Avery[2], Sophie Cassidy[1], Laura Haigh[3,4], Marie Boyle[3,4], Quentin Anstee[3,4], Stuart McPherson[3,4], Kate Hallsworth[1,3]. *[1]Population Health Sciences Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK; [2]School of Health & Life Sciences, Teesside University, Tees Valley, UK; [3]Liver Unit, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, UK; [4]Institute of Clinical and Translational Research, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK*
Email: kate.hallsworth@ncl.ac.uk

Background and Aims: NAFLD is the most common liver condition worldwide and is directly linked to chronic excess calorie consumption, lack of physical activity and overweight/obesity. In the absence of approved drugs, lifestyle modification promoting weight loss, is the primary recommended therapy for NAFLD. A weight loss goal of ~10% has been recommended for patients with NAFLD as this has been shown to improve liver fat, inflammation and fibrosis. However, only 10–20% of patients achieve this level of weight reduction with standard dietary approaches. This pilot study aimed to determine whether an 8–12 week very low calorie diet (VLCD) is an acceptable therapy to achieve a target weight loss of 10% in patients with advanced NAFLD.

Subject Characteristics	Baseline (n = 30)	Post-VLCD (n = 27)	P-Value
Age (years)	56 ± 12		
Sex (n) male/female	18/12		
Time since NAFLD Diagnosis (months):			
Mean	28.4 ± 31.7		
Median (range)	13.5 (1–113)		
Anthropometry			
Weight (kg)	119 ± 25	104 ± 21	0.000**
BMI (kg/m^2)	42 ± 8	37 ± 8	0.000**
Body fat (%)	45 ± 6.9	40 ± 9.1	0.001**
Blood pressure: Systolic (mmHg)	144 ± 15	133 ± 14	0.003**
Diastolic (mmHg)	86 ± 11	81 ± 9	0.018*
Blood samples			
Total cholesterol (mmol/L)	4.3 ± 0.9	4.3 ± 1.1	0.652
Triglycerides (mmol/L)	2.1 ± 1.8	2.0 ± 1.4	0.156
HDL (mmol/L)	1.2 ± 0.3	1.6 ± 1.9	0.270
AST (IU/L)	35 ± 18	25 ± 9	0.004**
ALT (IU/L)	47 ± 30	31 ± 16	0.003**
GGT (IU/L)	82 ± 74	52 ± 72	0.000**
Fasting glucose (mmol/L)	7.5 ± 2.3	6.1 ± 1.1	0.002**
Hba1c (mmol/mol)	50 ± 13	42 ± 9	0.000**
Insulin (pmol/L)	135 ± 85	92 ± 91	0.018*
Fibroscan			
Stiffness (KPa)	13.0 ± 6.6	8.0 ± 2.9	0.022*
IQR (KPa)	3.5 ± 3.0	2.5 ± 2.8	0.183
Non-invasive scores			
FIB-4	1.5 ± 1.0	1.2 ± 0.7	0.206
QRISK2	15.6 ± 14.2	11.9 ± 9.8	0.030*

Values are means (SD). *significant difference Baseline vs. Post-VLCD ($p < 0.05$); **significant difference ($p < 0.01$).

Method: 30 patients with advanced NAFLD were recruited to an 8–12 week VLCD (~800 kcal/day) using meal replacement products (Optifast, Nestlè Health Science). Anthropometrics, blood tests (liver enzymes, lipid profile, glucose, HbA1c, insulin), liver stiffness and cardiovascular disease risk were measured at baseline and after the VLCD intervention.
Results: Of the 45 patients approached to take part in this study, 30 consented to enrol. This study was fully recruited at a single site within 6 months and 27/30 retained post VLCD.
68% of patients reached the weight loss target of 10%; mean weight loss was 13 kg.
Weight loss through an 8–12 week VLCD significantly improved liver health (liver enzymes and liver stiffness), cardiovascular disease risk (blood pressure and QRISK2) and metabolic health (fasting glucose, HbA1c and insulin). BMI and body composition also improved (See Table 1).
Conclusion: A VLCD is a feasible way of achieving 10% weight loss in patients with advanced NAFLD. Patients were willing to undertake the strict dietary intervention and significant improvements in liver, metabolic and cardiac health were observed.

IDL-2965: a selective, highly potent, clinical-stage integrin antagonist for treatment of non-alcoholic steatohepatitis

Karl Kossen[1], Caralee Schaefer[1], Sharlene Lim[1], Marshall Michener[1], Dave Griggs[2], Peter Ruminski[3], Ramachandran Radhakrishnan[1], Christopher Rubino[4], Tonya Marmon[1], Ari Gershman[1], Roxann Hanning[1], Renee Jones[1], Watiri Kamau-Kelley[1], Scott Seiwert[1]. *[1]Indalo Therapeutics, Cambridge, MA, United States; [2]Saint Louis University, Saint Louis, MO, United States; [3]Washington Universtiy, Saint Louis, MO, United States; [4]Institute for Clinical Pharmacodynamics, Schenectady, NY, United States*
Email: kossen@indalotherapeutics.com

Background and Aims: Clinical outcome in NASH is associated with the stage of liver fibrosis. RGD-binding integrins are attractive therapeutic targets for the treatment of fibrosis. IDL-2965 is a potent antagonist of integrins αvβ1, αvβ3, and αvβ6 that is being evaluated in a Ph1/1b clinical study. The present work characterizes the antifibrotic activity of IDL-2965 in animal models of liver fibrosis at exposures attained following oral dosing in clinical studies.
Methods: The effects of oral IDL-2965 on liver fibrosis and fibrosis-related plasma biomarkers were assessed in mouse and rat carbon tetrachloride (CCl_4)-induced liver fibrosis models, a mouse choline-deficient, amino acid-defined, high-fat diet (CDAHFD) model, and a diet-induced obesity (DIO-NASH) model in ob/ob mice. Clinical safety and pharmacokinetics (PK) of IDL-2965 in healthy volunteers were evaluated in single- and multiple-ascending dose studies.
Results: At exposures attained clinically, IDL-2965 strongly inhibits fibrosis in multiple animal models. In a rat model of CCl_4-induced fibrosis, prophylactic treatment with IDL-2965 significantly reduced liver fibrosis (via histopathology). In a mouse CCl_4 model, therapeutic treatment with IDL-2965 provided a greater therapeutic effect than an αvβ1-specific compound. In a mouse CDAHFD model, therapeutic treatment with IDL-2965 significantly reduced fibrosis scores (via histopathology), liver hydroxyproline, and plasma CK-18. In a mouse DIO-NASH model, a comparison of morphometric measures of collagen and αSMA in biopsies taken pre- and post-treatment demonstrated that IDL-2965 reduced pre-existing fibrosis. Pharmacodynamic studies in the DIO-NASH model further demonstrated that IDL-2965 reduced plasma CK-18 and TIMP-1 within one week, with reductions in hyaluronic acid by week 4. In Ph 1 clinical studies in healthy volunteers, once-daily oral administration of IDL-2965 for up to 14 days was safe and well tolerated and achieved robust dose proportional plasma PK that exceeded the maximal efficacious exposure in preclinical fibrosis models at a dose of 45 mg.
Conclusions: At exposures attained following oral administration and associated with a favorable safety profile in healthy volunteers, IDL-2965 exhibits robust antifibrotic effects in multiple models of liver fibrosis. IDL-2965-mediated reductions in liver fibrosis are accompanied by changes in relevant plasma biomarkers. These data support evaluating IDL-2965 in NASH patients.

The effectiveness of Mediterranean diet versus calorie restriction in non-alcoholic fatty liver disease (NAFLD): a systematic review with clinical implications

Laura Haigh[1,2], Colette Kirk[2], Jenny Gallacher[1,2], Linda Errington[3], John Mathers[4], Quentin Anstee[1,2]. *[1]Institute of Translational and Clinical Research, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Newcastle NIHR Biomedical Research Centre, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [3]Institute of Academic Services, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [4]Institute of Population Health Sciences, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom*
Email: l.haigh3@newcastle.ac.uk

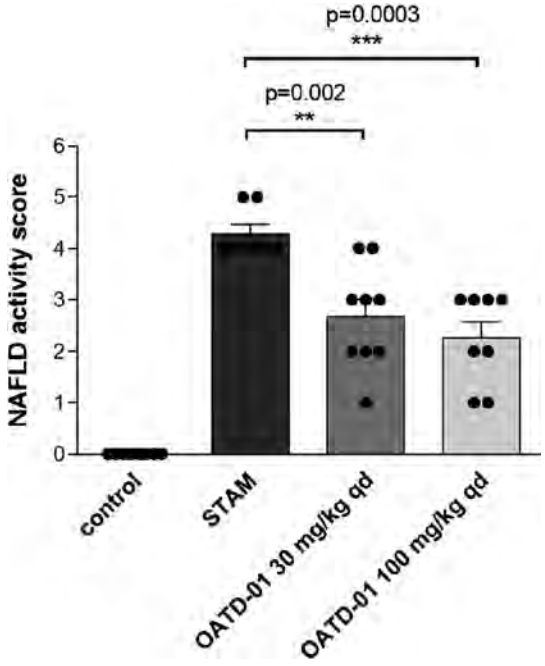
Background and Aims: Lifestyle interventions that focus on reduced energy intake and improved dietary pattern are the cornerstone of NAFLD management. However, it remains unclear whether a Mediterranean diet (MD) is more beneficial than other diets, or confers benefits beyond weight loss.
Method: A systematic review of trials investigating the effects of MD and calorie-restricted interventions (CRI), on NAFLD was conducted. In February 2019, we searched MEDLINE, Embase, Scopus, WoS, and CENTRAL databases using key words for NAFLD, controlled trials, MD and weight loss. The Cochrane Handbook and risk of bias tools (Rob 2.0/Robin I) were used to assess study quality.
Results: 2173 publications were identified; from these 15 trials with 1725 participants met the inclusion criteria. Study characteristics included: 59% male; mean BMI 30.1 kg/m^2 at baseline, mean follow-up 33 weeks (range 2–104 weeks). Nutritional intake using self-report instruments was described in 8 studies. Hepatic Steatosis (HS) was assessed using histology (n = 1), MRS/MRI-PDFF (n = 5), USnd (n = 7) and FLI (n = 4). Compared with standard care (SC), CRI (n = 10; 1492 participants) improved ALT levels, MRS/USnd/FLI HS and fibrosis markers and resulted in greater weight loss (6.3% (CRI) vs. 0.4% (SC)). Weight loss of ≥ 7% tended to improve HS, lobular inflammation, ballooning injury and NAS, but not a reduction in fibrosis. AST levels decreased in both CRI and SC groups. All CRI produced similar weight losses of 5.2%–6.0% and improved ALT, AST, and USnd HS. However, interventions with specific dietary change components beyond calorie restriction, such as olive oil enrichment, reported larger improvements. MD (n = 5; 233 participants) produced bigger improvements in USnd/FLI HS and fibrosis markers when compared with SC and resulted in greater weight loss of 5.7% vs. 1.1%. ALT levels improved in both MD and SC groups. MD and low-fat diets both improved ALT and MRS/MRI-PDFF HS, with greater HS reductions in MD groups (35.7% vs. 16%), independent of weight loss.
Conclusion: Dietary changes are clinically beneficial for NAFLD. Calorie restriction is effective with a dose-response relationship between effects on liver function and weight loss. Based on the limited evidence available, MD appears to be the diet of choice, with or without weight loss. The mechanisms by which MD exerts its NAFLD-specific effects are poorly understood and need clarification in further experimental studies.

FRI105

Therapeutic efficacy of the chitotriosidase inhibitors in STAM model of non-alcoholic steatohepatitis

Michal Mlacki[1], Barbara Dymek[1], Agnieszka Zagozdzon[1], Marzena Mazur[1], Robert Koralewski[1], Adam Golebiewski[1], Karolina Dzwonek[1], Pawel Dobrzanski[1]. [1]*OncoArendi Therapeutics SA, Warsaw, Poland*
Email: p.dobrzanski@oncoarendi.com

Background and Aims: NASH (non-alcoholic steatohepatitis) is a chronic liver disease characterized by steatosis, inflammation, hepatocytes death, metabolic disfunction and, in severe cases, fibrosis. One of the key players in progression of NASH are Kupffer cells (KCs) – liver resident macrophages. When activated, they initiate cascade of events resulting in canonical pathologies of NASH. Chitotriosidase (CHIT1), a member of the glycosyl hydrolase family 18, is highly and specifically induced in KCs from patients with NASH but not these with simple steatosis. CHIT1 expression significantly correlates with the stage of disease, inflammation and fibrosis. These results prompted us to evaluate therapeutic potential of chitotriosidase inhibition in the STAM model of NASH with OATD-01, a potent, oral, small molecule chitinase inhibitor currently in Ph1 clinical trials for inflammatory and fibrotic lung diseases.
Method: STAM mouse model of NASH was induced by a subcutaneous injection of streptozotocin to 2-day-old mice and following continuous high fat diet. After pathology has developed, animals were treated with a vehicle or OATD-01 at 30 and 100 mg/kg/day. At the end of the study serum and liver samples were collected for biochemical and histological evaluation. Comprehensive histological NAS score (NAFLD activity score – combined scores of hepatocytes ballooning, inflammation, steatosis) was used as a main read-out of severity of NASH.
Results: In the pilot studies we confirmed significant induction of the chitinolytic activity in plasma and expression of CHIT1 in KCs-like cells in livers of the STAM mice. Administration of OATD-01 in the therapeutic scheme significantly decreased the NAS score with a reduction of all 3 pathological parameters, including a strong improvement in hepatocytes ballooning. Additionally, OATD-01 alleviated morphometrically measured fibrosis and a number of F4/80 macrophages. The therapeutic efficacy of OATD-01 in the STAM model correlated with a strong inhibition of the chitinolytic activity (pharmacodynamic marker).



Conclusion: Therapeutic efficacy of OATD-01 in the STAM model represents a preclinical proof-of-concept for the pathological role of CHIT1 in NASH. These results together with the documented clinical correlation of CHIT1 expression with NASH progression provide a rationale for the further development of OATD-01 as a novel therapy for the disease.

FRI106

Endoscopic gastric plication (endosleeve) improves hepatic steatosis and liver fibrosis in patients with grade 1-2 obesity, preliminary results at 6 months

Michel Ble Caso[1], Román Turró[1], Mercedes Rosinach[1], Javier Michelena Escudero[1], Rocío Temiño[1], Alfredo Mata Bilbao[1], Hugo Uchima[1], Sonia Ruiz[1,2], Mireia Cabrera Cárdenas[1,2], Jorge Carlos Espinós[1]. [1]*Teknon Medical Center, Quirónsalud, Barcelona, Spain, Gastrointestinal Endoscopy Unit, Barcelona, Spain;* [2]*Teknon Medical Center, Quirónsalud, Barcelona, Spain, Bariatric Endoscopy Nutrition Unit, Barcelona, Spain*
Email: michelble@gmail.com

Background and Aims: There is a higher prevalence of non-alcoholic steatosis/steatohepatitis in patients with obesity. The intragastric balloon is the endoscopic treatment of choice for short-term weight loss. However, endoscopic gastric plication (Endosleeve) may offer better long-term results. Fibrosis and hepatic steatosis (HS) can be estimated non-invasively with transition elastography (TE) and the controlled attenuation parameter (CAP).
Method: Prospective and multicenter pilot study aimed at 1) assessing the safety and efficacy of Endosleeve and 2) its effect on hepatic fibrosis and steatosis (subcohort of patients from Teknon Medical Center (TMC). We included patients with grade I-II obesity and without diabetes mellitus. We use the endoscopic Incisionless Operating Platform™ (USGI Medical, San Clemente, CA, USA), with a defined pattern of transmural plication arrangement with g-Cath™ EZ suture, to reduce gastric volume/distensibility in order to slow down gastric emptying. TE + CAP (Fibroscan®) and blood analysis were evaluated at baseline and at 2 and 6 months (m).
Results: 39 patients were included; 17/39 (44%) patients from TMC were analyzed. At baseline, 88% had grade II obesity with a mean age of 46 ± 7 years (59% women). There were no serious adverse effects related to the endoscopic technique. At baseline, 29% had liver stiffness values compatible with risk zone for fibrosis (ET >8 kPa; mean 9 ± 2) and 71% had HS >10% (CAP >248 dB/m; mean 320 ± 37). At 2 and 6 m there was a media decrease of the total excess weight (TEW) (37 ± 11 and 53 ± 20%, respectively) with amelioration in fibrosis (ET <8 vs >8 kPa, p = 0.01) and HS (CAP <248 vs>248, p = 0.001). In addition, at 6 m there was a decrease in levels of triglycerides (p = 0.01) with an increase in HDL cholesterol (p <0.01).

Total Excess Weight (%)	Body Mass Index (BMI)			Excess Weight Loss (%)		Liver stiffness (kPa)			Liver steatosis (dBm)		
Baseline	Baseline	2 months	6 months	2 months	6 months	Baseline	2 months	6 months	Baseline	2 months	6 months

65	40	32	30	52	61	12,3	11,3	11,1	364	250	160

> 50%	Overweight	25-30	15 - 29	Risk of fibrosis	kPa		dBm	% Steatosis
< 50%	Obesity type I	30-35	30 - 50	No	< 8	S0	< 248	< 10
	Obesity type II	35-40	>50	Yes	> 8	S1	249 - 268	10 - 33
						S2	269 - 280	33 - 66
						S3	> 280	> 66

Conclusion: The Endosleeve offers promising preliminary results at 6 months. It is safe, reduces TEW in a media of 53% ± 20% and is associated with amelioration of fibrosis, HE and dyslipidemia. Long-term follow-up is necessary.

FRI107

Use of GLP-1 receptor agonists (GLP1A) and/or SGLT-2 inhibitors (SGLT2I) in populations with NASH or at risk of NASH in US clinical practice

Michelle Lai[1], Jeremy Broestl[2], Kavita Juneja[3], Scott Milligan[2], Janna Radtchenko[2], Zobair Younossi[4,5], Nezam Afdhal[1]. [1]*Beth Israel Deaconess Medical Center (BIDMC), Boston, United States;* [2]*Trio Health Analytics, San Diego, United States;* [3]*Gilead Sciences, Inc., Foster City, United States;* [4]*Inova Fairfax Hospital, Center for Liver Diseases, Department of Medicine, Falls Church, United States;* [5]*Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States*
Email: scott.milligan@triohealth.com

Background and Aims: Currently, no drugs are FDA approved for the treatment of NASH. However, some success has been observed with GLP1a in histological resolution of NASH without worsening of fibrosis and with SGLT2i in reduction of body weight, ALT, and FIB4 compared with baseline values. Here, we examined data from type II diabetic (T2DM) and non-T2DM patients with or at risk of NASH to determine use of these therapies in clinical practice.

Method: Data collected from a proprietary US EMR database were limited to adult patients with diagnosed NAFLD without NASH (ICD10 K76 and ICD9 equivalent without evidence of NASH), NASH (ICD10 K75.81) or with a risk profile (RISK) of Age >50 + ALT >30 U/L + [BMI >30 or T2DM] and without viral hepatitis or evidence of alcohol abuse. Index date was assigned at the first calculable FIB4 between Jul 2015 to Jun 2017 and for which >1 year history and >2 years follow-up or to death was available.

Results: Of 30MM adult patients, 81108 met all study criteria with 22% (17582) NAFLD without NASH, 1% (914) NASH, and 77% (62612) RISK (without NAFLD or NASH) [Figure]. At index, 50% (40194/81095) male, 84% (65121/77635) white, 73% BMI >30 (44190/60882), 43% (34730) T2DM, 11% (9210) FIB4 ≥ 2.67, and median (IQR) age 60 (55–65). Use of SGLT2i and GLP1a at index was 2% and 3% respectively overall, but higher in the T2DM subset (4% and 7%) compared to non-T2DM (<1%, $p < 0.001$). Among 105 non-T2DM on SGLT2i, 54% received canagliflozin, 41% dapagliflozin, and 35% empagliflozin. Among 188 non-T2DM on GLP1a at index, 64% received liraglutide, 30% dulaglutide, and 22% exenatide. Non-T2DM patients receiving SGLT2i and/or GLP1a (n = 279) differed from those not on these therapies (n = 46099) in age (mean 57.0 v. 60.5 not treated (NT), $p < 0.001$), Charlson CI (0.9 v. 1.7 NT, $p < 0.001$), AST>30 IU/L (43% v. 36% NT, $p = 0.014$), blood glucose ≥ 1.1 g/dL (66% v. 27% NT, $p < 0.001$), HbA1c ≥ 5.6% (91% v. 72% NT, $p < 0.001$), triglycerides ≥ 150 mg/L (35% v. 25% NT, $p < 0.001$), LDL cholesterol ≥ 100 mg/dL (22% v. 33% NT, $p < 0.001$), and eGFR ≥ 90 (41% vs. 31% NT, $p = 0.001$).

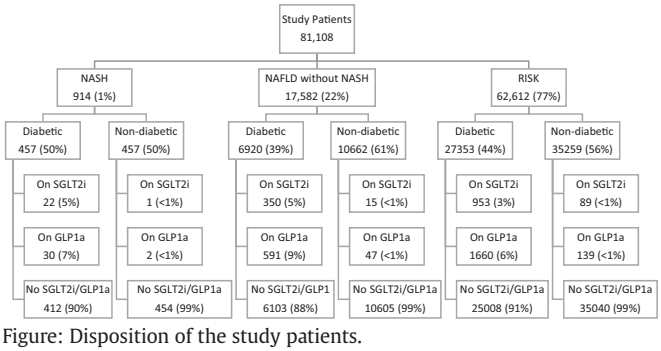

Figure: Disposition of the study patients.

Conclusion: Despite evidence suggesting benefits with GLP1a and SGLT2i in patients with NASH or risk of NASH, real-world use of these therapies in patients with T2DM was relatively low at 4–7% despite higher rates of insurance drug coverage for this population. Use in non-T2DM patients was <1% overall and more common in younger patients with fewer comorbidities and with lab measures similar to T2DM patients.

FRI108

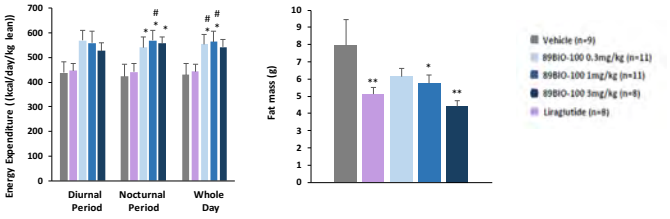
BIO89-100, a novel glycopegylated FGF21 analog, reduces body weight and fat mass in naive CD-1 mice through an increase in energy expenditure despite an increase in food consumption

Moti Rosenstock[1], Thais Rouquet[2], Bruno Bariohay[2], Hank Mansbach[1], Maya Margalit[1]. [1]*89bio Ltd.;* [2]*Biomeostasis*
Email: moti.rosenstock@89bio.com

Background and Aims: BIO89-100, a novel glycoPEGylated analog of FGF21, is being developed for the treatment of nonalcoholic steatohepatitis (NASH) and cardiometabolic diseases. In CD-1 mice, BIO89-100 reduces body weight (BW) despite increased food consumption (FC). To better understand these findings, we investigated the effect of BIO89-100 on energy expenditure and body composition.

Methods: Naïve mice were treated subcutaneously (SC) for 4 weeks at ambient temp. with BIO89-100 at doses of 0, 0.3, 1.0 and 3.0 mg/kg (3qW × 4 weeks) or with liraglutide at 0.2 mg/kg (BID × 4W; SC). BW and FC were measured daily throughout the treatment period. To investigate the impact of BIO89-100 on energy expenditure, the respiratory exchanges (VO_2 and VCO_2) were recorded during 3 distinct sessions of METABOpack™, a multiparametric approach allowing an automated and simultaneous recording of FC, water intake, respiratory exchanges and spontaneous activity. Meal pattern analysis was conducted on the high-resolution recordings of FC. The body composition (fat, lean and fluid masses) was analyzed 3 times during the study by the mean of Time-Domain Nuclear Magnetic Resonance (TD-NMR).

Results: Dose-dependent decrease in BW (up to −13.8%) and increase in FC (up to +94%) were observed in BIO89-100-treated mice. Increased FC was related to an increase in mean meal number, with no change in mean meal size. There was no evidence of change in basal metabolism or total spontaneous activity in studied animals, thus the increase in energy expenditure is presumed to be through increased thermogenesis. BIO89-100-treated mice had a marked decrease in fat mass (measured both by TD-NMR during the study and by weighing the epididymal white adipose tissue (eWAT) at sacrifice), without affecting lean masses and body fluid. Liraglutide induced a significant decrease in BW when compared with controls resulting in a final 10% reduction, associated with a decrease in fat mass. However, liraglutide did not affect the energy expenditure or food consumption.



Mean ± SEM. * $p < 0.05$, significantly different vs. Vehicle group; # $p < 0.05$, significantly different vs. Liraglutide group.

Conclusion: Naïve CD-1 mice treated with BIO89-100 had a dose-dependent reduction in BW and increased FC. Our results suggest that this BW loss is due, at least in part, to an increase in energy expenditure, resulting in a marked decrease in fat mass, including the eWAT weight, without affecting lean masses and body fluid. If these effects translate to humans, they could be beneficial in patients with metabolic diseases.

FRI109

EDP-297, a novel and potent fxr agonist, exhibit robust anti-fibrotic effects with significant liver function in a rat model of non-alcoholic steatohepatitis

Mozhdeh Sojoodi[1], Yongtao Wang[1], Derek J. Erstad[1], Peter Caravan[2], Michael Lanuti[3], Motaz Qadan[1], Bryan C. Fuchs[1], Khanh Hoang[4], Yat Sun Or[4], Lijuan Jiang[4], Kenneth K. Tanabe[1]. *[1]Massachusetts General Hospital, Harvard Medical School, Surgical Oncology, Boston, United States; [2]Massachusetts General Hospital, Harvard Medical School, The Institute for Innovation in Imaging, A. Email: msojoodi@mgh.harvard.edu

Background and Aims: Farnesoid X receptor (FXR) is a nuclear receptor that has emerged as a key regulator in the maintenance of bile acid homeostasis. FXR agonists are currently under clinical investigation for the management of various liver diseases such as primary biliary cholangitis (PBC) and nonalcoholic steatohepatitis (NASH). However, most preclinical studies have examined the effects of FXR agonists in mouse models where fibrosis progression to cirrhosis does not resemble that observed in humans. Here, we investigate the anti-fibrotic effects of the FXR agonist EDP-297 in a rat model of NASH cirrhosis.
Method: Adult male Wistar rats (175–200 g) were fed either normal chow (NC) or a choline-deficient, L-amino-acid-defined, high-fat diet with 60 kcal% fat and 0.1% methionine (CDAHFD) for 12 weeks. Rats were randomized to receive either vehicle control (0.5% methylcellulose (MC)), 0.1 mg/kg EDP-297, or 0.3 mg/kg EDP-297 by once-daily oral gavage at the first signs of fibrosis (5 weeks, n = 8 per group).
Results: Treatment with EDP-297 significantly reduced fibrosis progression as assessed by morphometric quantification of the collagen proportional area using Sirius Red staining (NC 3.0 ± 0.9%; MC 18.4 ± 4.1%; EDP-297 0.1 mg/kg 12.2 ± 3.7% with $p < 0.001$ compared to MC; and EDP-297 0.3 mg/kg 11.9 ± 3.8% with $p < 0.001$ compared to MC). EDP-297 at 0.1 mg/kg also significantly decreased the fat content quantitated by H&E staining (MC 36.1 ± 3.5% vs EDP-297 0.1 mg/kg 26.8 ± 5.0%, $p < 0.001$). Moreover, EDP-297 improved significantly liver function measured by key biomarkers (Table 1).

Table 1: EDP-297 improved significantly liver function measured by key biomarkers

Key Biomarkers	Vehicle Control	EDP-297	Reduction (%)	*p*-value
Alanine Transaminase (ALT, U/I)	547.6 ± 190.7	115.8 ± 37.4	78.9% ↓	$p < 0.001$
Aspartate Aminotransferase (AST, U/I)	1309.0 ± 551.9	347.0 ± 103.5	73.5% ↓	$p < 0.001$
Total Bilirubin (U/I)	0.74 ± 0.32	0.18 ± 0.07	75.7% ↓	$p < 0.001$

Conclusion: In a rat model of NASH cirrhosis that more closely resembles the human disease progression, EDP-297 at a low dose significantly reduced fibrosis progression and improved liver function. These results suggest that EDP-297 may have a potent anti-fibrotic effect in NASH patients, including those with late-stage F3/4 fibrosis.

Characterization of EYP001 a novel, potent and selective FXR agonist in in vitro 3D human liver models of NASH

Pauline Radreau - Pierini[1], Stéphane Joly[1], Jacky Vonderscher[1], Pietro Scalfaro[1], Meldrum Eric[1], Raphaël Darteil[1]. *[1]ENYO Pharma SA, Lyon, France*
Email: prp@enyopharma.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a condition defined by excessive fat accumulation (steatosis) in the liver that currently affects 20–40% of the general population. Non-alcoholic steatohepatitis (NASH), the most severe form of NAFLD, is characterized by steatosis, hepatocyte ballooning, inflammation, and fibrosis. It may also lead to complications such as cardiovascular disease, cirrhosis, liver failure or liver cancer. 10–20% of NAFLD patients develop NASH, thus making NASH a significant health burden with currently no approved pharmacological treatments. The Farnesoid X receptor (FXR), a nuclear receptor, controls bile acid homeostasis and is a promising target for the treatment of NASH. EYP001, a novel non-steroidal, selective, potent, second generation FXR agonist, is currently in a phase 2 NASH clinical trial. With this study we aimed to investigate the effects of EYP001 in *in vitro* 3D human liver models of NASH.
Method: Cytotoxicity in 3D InSightTM human liver microtissues was assessed upon exposure to EYP001 and OCA (0.03 to 30 µM) for 7 days. Bile acid secretion profiles were analyzed at day 2 by LC/MS. EYP001 effects predictive of protection against NASH were assessed in 3D bioprinted ExVive human liver tissues following 21 days of daily treatments. PLIN2 and αSMA positive areas were digitally quantified via ImageJ, and ballooning was semi-quantitatively assessed.
Results: EYP001 was found not to be cytotoxic to 3D InSightTM human liver microtissues (as measured by LDH and cellular ATP) throughout the 7 day treatment. Unlike EYP001, OCA showed cytotoxicity at 3 and 10 µM at day 2. Both compounds showed a dose-dependent decrease in secretion of the bile acids GCA and GCDCA within days 0–2. Maximal inhibitory effect on bile acid release was reached at 0.1 and 1 µM for EYP001 and OCA respectively. In 3D bioprinted ExVive human liver tissues, EYP001 reduced PLIN2 (steatosis marker) positive area in a dose dependent manner compared to the untreated NASH control thereby suggesting a decreased presence of lipid droplets with EYP001. Also, EYP001 significantly reduced αSMA (fibrosis marker) positive areas, suggesting potent inhibition of stellate cell activation.
Conclusion: The non-steroidal FXR agonist EYP001 was shown to be well tolerated by 3D human liver tissues *in vitro* and to be more potent than OCA on reduction of bile acid secretion. EYP001 reduced PLIN2 and αSMA, two parameters linked to lipid accumulation and fibrosis respectively, strongly suggesting an improvement of NASH parameters in this 3D *in vitro* human liver model. Based on these preclinical efficacy findings, and safety, tolerability, pharmacokinetics and pharmacodynamics data obtained in Phase 1 clinical trials, EYP001 has now entered a Phase 2 clinical trial examining benefit in NASH patients.

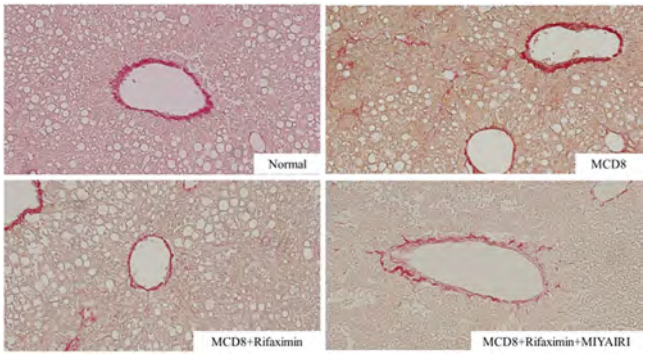
FRI111

Synergistic effect of clostridium butyricum miyairi on rifaximin in mice model of non-alcoholic steatohepatitis by methionine choline-deficient diet

Ryo Yamauchi[1], Hidetoshi Takedatsu[1], Keiji Yokoyama[1], Eri Yamauchi[1], Motoko Kawashima[1], Naoaki Tsuchiya[1], Kazuhide Takata[1], Takashi Tanaka[1], Daisuki Morihara[1], Yasuaki Takeyama[1], Satoshi Shakado[1], Shotaro Sakisaka[2], Fumihito Hirai[1]. *[1]Fukuoka University, Gastroenterology, Fukuoka, Japan; [2]Fukuoka University, Medical Science Research Center, Fukuoka, Japan*
Email: r_christinue2017@yahoo.co.jp

Background and Aims: Nonalcoholic steatohepatitis (NASH) is increasing and recent studies reveled gut microbiota was associated with liver damage. Rifaximin is an anti-absorbable antibacterial agent and widely used as a therapeutic agent for minimal hepatic encephalopathy. We investigated whether the administration of rifaximin and Clostridium butyricum Miyairi (MIYAIRI) improve the hepatic inflammation and fibrosis by NASH.
Method: C57BL/6J mice were fed standard chow or Methionine choline-deficient (MCD) diet for 8 weeks. We divided into four groups (1) standard chow, (2) MCD, (3) MCD + rifaximin, and (4) MCD + rifaximin + MIYAIRI. Mice were followed for 8 weeks while rifaximin was administered at 0.012 mg/kg/day and/or MIYAIRI

0.024 mg/kg/day from 5 to 8 weeks. Inflammation and fibrosis were evaluated in liver, intestine, and mesenteric lymph node (MLN).
Results: In the MCD diet group, the expressions of IL- 6 and TNF-alpha increased in small intestine, MLN and liver. The expression of TGF-beta in liver was also upregulated. The administration of rifaximin alone did not improve the hepatic inflammation and fibrosis in NASH models. However, the use of rifaximin + MIYAIRI significantly suppressed the hepatic inflammation and fibrosis compared with rifaximin alone. The expression of IL- 6 and TNF-alpha MLN and liver, TGF-beta liver and CLDN1 in small-intestine was downregulated in rifaximin +MIYAIRI group than rifaximin.



Conclusion: Our results suggested that the gut microbioma was involved in the pathogenesis of NASH and hepatic inflammation and fibrosis could be more suppressed by Butyrate-producing bacteria as MIYAIRI in addition to anti-absorbable antibacterial agent.

FRI112

Methylnaltrexone and rifaximin treatments significantly improve chronic "leaky gut" in a diet-induced mouse model of non-alcoholic fatty liver disease

Rebecca Caffrey[1], William Jo[2], Nicole Deng[2], Madhavi Bhat[1], Arun Sanyal[3]. [1]*Sanyal Biotechnology LLC, Norfolk, United States;* [2]*Bausch Health Companies Inc., Bridgewater, United States;* [3]*Virginia Commonwealth University, Richmond, United States*
Email: rebecca@sanyalbio.com

Background and Aims: Increased gut permeability (GP, "leaky gut") occurs in the progression of numerous diseases, such as nonalcoholic fatty liver disease/nonalcoholic steatohepatitis (NAFLD/NASH) and hepatic encephalopathy. These conditions are partially driven by proinflammatory bacterial products leaking from the gut into the bloodstream. The aim of this study was to evaluate the mu-opioid receptor antagonist methylnaltrexone (MNTX) and the nonsystemic antibiotic rifaximin for improving GP in a diet-induced animal model of nonalcoholic fatty liver disease (DIAMOND), which develops chronic leaky gut and progressive NASH when fed a Western diet (WD).
Method: Four groups of 8 DIAMOND mice were initially fed a WD (Teklad 42% kcal from fat and 4% sugar water) for 8 weeks then continued on a WD with concomitant oral gavage administration of aqueous vehicle, MNTX 25 mg/kg, rifaximin 400 mg/kg, or pioglitazone 30 mg/kg 5 times per week for 12 weeks. GP was assessed at Weeks 12 and 20 by administering 4 kDa dextran 600 mg/kg orally, and followed by dextran quantitation in serum using a competitive ELISA; increased gut permeability correlates positively with serum dextran concentration. Results between groups were compared using Student's 2-tailed t-test, and pair-wise analysis was performed on serial measurements at Weeks 12 and 20 to assess drug treatment effect on GP.
Results: Mean serum dextran concentrations of vehicle WD mice at Week 12 (corresponding to NASH F0) averaged 247 mcg/mL. In the MNTX group, mean serum dextran concentration at Week 12 (4 weeks of treatment) was 90.9 mcg/mL, a 2.7-fold reduction compared with the vehicle group ($p \leq 0.046$). At Week 20 (12 weeks of treatment), mean serum dextran concentrations were 2-fold lower vs the vehicle group for MNTX and rifaximin ($p \leq 0.014$ and $p \leq 0.017$, respectively). Pioglitazone, the active comparator, also improved GP vs vehicle at Week 20. By pair-wise analysis, rifaximin treatment continued improving the leaky gut induced by diet over time; Week 20 serum dextran in the rifaximin-treated group averaged 85.9 mcg/mL compared to the 12-week average of 154.0 mcg/mL. Thus, rifaximin improved leaky gut by 45% in the 8 weeks between the first and second measurement ($p \leq 0.053$).
Conclusion: This preclinical study showed that MNTX and rifaximin treatments dramatically improved WD-induced GP, suggesting that these compounds may have broad utility in treating inflammatory diseases exacerbated by "leaky gut." Further dose optimization studies are needed to determine if these compounds could be effective in NASH. These results support the biological rationale for further testing for efficacy in NASH, particularly in combination with drugs that target other mechanistic drivers of NASH, such as insulin sensitivity and inflammation.

Recombinant glutamine synthetase (AM-535): a novel therapeutic approach for the treatment of hyperammonaemia and its deleterious effects on multiple systems

Antria Siakalli[1], Annarein Kerbert[1], Abeba Habtesion[1], Andrew Hall[1], Tamara Nicolson[2], Rajiv Jalan[1], Jane Macnaughtan[1]. [1]*UCL Institute for Liver and Digestive Health, London;* [2]*Thoeris GmBh, Vienna, Austria*
Email: tamara.nicolson@thoeris-therapeutics.com

Background and Aims: Hyperammonaemia is central to the development of hepatic encephalopathy in a spectrum of disorders from liver failure to urea cycle disorders (UCD) but its deleterious effect on the kidneys, lipids and lipids is unknown. We have recently shown that AM-535 directly reduces ammonia in models of cirrhosis, UCD and NAFLD. We developed a new model of diet-induced hyperammonaemia in healthy mice and aim to evaluate the effect of AM-535 on ammonia levels and its end organ effects in this 'pure' model.
Method: Male C57BL mice were fed daily with an isoleucine deficient amino acid mixture (AA), hyperammonaemic diet for two weeks (10 mg/kg) and administered a single dose of vehicle (AAv) or AM-535 (AAGS) (30 mg/Kg), or sodium phenylacetate (SP; 0.3 mg/Kg) (n = 5/group); Controls (C): n = 8. Animals were sacrificed 3 h after a single treatment. Arterial plasma ammonia (NH3), liver and renal function, glucose and lipid profile were assessed. Distribution of AM-535 to the brain and liver was assessed using immunohistochemistry.
Results: Significantly higher ammonia concentrations were observed in AA group compared with controls and this was significantly reduced with AM-535 (AAv: 167 ± 71.64 vs C: 49 ± 9.18 vs AAGS: 70 ± 17.47 μmol/L) ($p < 0.005$). Ammonia concentrations were restored in presence of SP (124.2 ± 37.9 μmol/L; $p < 0.005$) (Figure 1). The reduced AM-535 ammonia levels were also associated with significantly lower urea, creatinine, glucose, HDL cholesterol and albumin (Table 1). No effect of GS was observed in levels of ALT and AST. Liver immunohistochemistry for GS showed perivenular distribution of AM-535 and absence of increased GS brain expression.

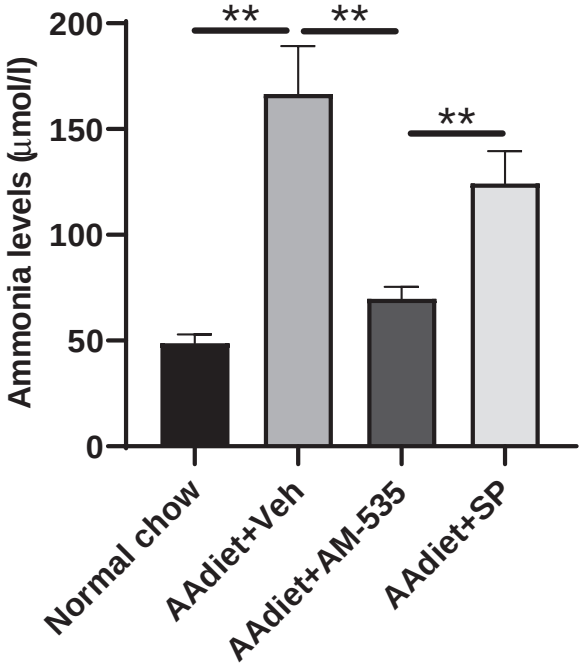

Figure 1: Ammonia levels under controls, recombinant glutamine synthetase (AM-535) and sodium phenylacetate (SP) treatments.

Table 1: Summarised Liver function test analysis

	Normal chow	AAdiet +Veh	AAdiet +AM-535	AAdiet +SP	p value (Normal chow vs AAdiet +Veh)	p value (AAdiet +Veh vs AAdiet +AM-535)	p value (AAdiet +AM-535 vs AAdiet +SP)
Urea (mmol/L)	7.7 ± 0.7	12.1 ± 0.8	8.0 ± 0.8	11.7 ± 1.7	<0.0001	<0.0001	0.0001
Creatinine (µmol/L)	9.2 ± 1.1	8.6 ± 1.0	7.1 ± 1.8	9.6 ± 1.1	ns	0.0380	0.0183
Albumin (g/L)	20.8 ± 2.8	21.9 ± 3.9	21.6 ± 2.8	22.2 ± 3.3	ns	<0.0001	0.0004
Glucose (µmol/L)	16.8 ± 2.3	19.8 ± 1.2	13.4 ± 1.4	13.2 ± 0.6	0.0050	<0.0001	ns
HDL-C (mg/dL)	80.4 ± 3.9	36.7 ± 4.1	45.8 ± 3.9	47.0 ± 4.9	<0.0001	<0.0001	ns

Conclusion: The results of this study show for the first time that induction of hyperammonaemia in an otherwise healthy mouse results is hyperglycemia, hypoalbuminemia and lipid abnormalities. Administration of AM-535 led a rapid reduction in ammonia levels and this was associated with improvement glucose levels, lipid profile, ureagenesis and in renal function. Taken together, these data confirm the safety and efficacy of AM-535 and, provides the rationale for development of this agent for clinical trials.

FRI114

Co-administration of PF-05221304 and PF-06865571 delivers robust whole liver fat reduction and mitigation of acetyl-coa carboxilase inhibitor induced hypertriglyceridemia in patients with NAFLD

Roberto Calle[1], Sudeepta Aggarwal[2], Jessica Mancuso[3], Arthur Bergman[3], Veena Somayaji[2], Trenton Ross[1], William Esler[1].

[3]*Pfizer WRD, Early Clinical Development, Groton, United States*
Email: roberto.a.calle@pfizer.com

Background and Aims: Disordered lipid metabolism contributes to the pathogenesis of NAFLD/NASH. Acetyl-CoA carboxylase (ACC) and Diacylglycerol acyl transferase 2 (DGAT2) play critical and complementary roles in hepatic lipid metabolism. PF-05221304 (ACCi), a liver directed ACC1/2 inhibitor, and PF-06865571 (DGAT2i), a DGAT2 inhibitor are in clinical development for NASH. Co-administration of ACCi and DGAT2i has potential to re-balance the elevated lipogenic tone in NAFLD/NASH by inhibiting de novo fatty acid synthesis, promoting fatty acid oxidation, inhibiting triglyceride (TG) formation and by down-regulating expression of lipogenic genes. This clinical study was designed to test the hypothesis that co-administration of ACCi and DGAT2i may lead to increased clinical efficacy in the treatment of NASH and mitigation of ACCi-induced TG elevations.
Method: 99 subjects with NAFLD (>8% Whole Liver Fat [WLF] by MRI-PDFF) were randomized and 85 subjects completed the trial. Subjects were stratified by presence or absence of diabetes and baseline WLF. Randomized participants received placebo (N = 14), ACCi 15 mg (N = 29), DGAT2i 300 mg (N = 28) or ACCi 15 mg + DGAT2i 300 mg (N = 28) every 12 hrs for 6 weeks.

	Week 6 Percent Change from Baseline [LS Mean (90%CI)]			
	Placebo	ACCi	DGAT2i	ACCi + DGAT2i
WLF PDFF	N = 12 8.14 (−8.56, 27.89)	N = 22 −40.01 (−47.00, −32.09)	N = 24 −30.14 (−37.97, −21.33)	N = 26 −40.13 (−46.58, −32.90)
Serum TG	N = 12 7.38 (−8.06, 25.41)	N = 22 58.17 (41.76, 76.48)	N = 24 −1.89 (−11.94, 9.32)	N = 26 13.83 (2.27, 26.69)
ALT	N = 12 −3.01 (−11.76, 6.61)	N = 22 −12.41 (−18.24, −6.18)	N = 24 −4.15 (−10.30, 2.42)	N = 24 −7.91 (−13.80, −1.61)
HDL-Cholesterol	N = 12 −3.19 (−9.87, 3.98)	N = 22 −15.56 (−19.70, −11.20)	N = 24 −13.43 (−17.62, −9.03)	N = 26 −18.21 (−22.13, −14.09)
LDL-Cholesterol	N = 12 2.04 (−9.52, 15.09)	N = 22 −19.74 (−26.24, −12.67)	N = 24 −5.22 (−12.81, 3.02)	N = 26 −9.45 (−16.68, −1.59)

Results: Incidence of treatment emergent adverse events was similar across all active treatment groups. No treatment-related SAEs were reported. Pharmacodynamic observations are summarized below.
Conclusion: Co-administration of ACCi+DGAT2i for 6 weeks resulted in greater reductions in WLF than DGAT2i monotherapy and was safe and well-tolerated in adults with NAFLD. ACCi-induced TG elevation was observed and was mitigated by co-administration with DGAT2i after 6 weeks. Decreases from baseline were observed in alanine aminotransferase (ALT), HDL-Cholesterol and LDL-Cholesterol in the ACCi+DGAT2i group, relative to placebo. Aspartate aminotransferase (AST) and alkaline phosphatase were unchanged at 6 weeks (data not shown). These results suggest that additional studies are warranted to assess the potential of ACCi+DGAT2i for the treatment of NASH.

FRI115

A randomized, double-blinded, placebo-controlled single ascending dose study to assess safety, tolerability, immunogenicity, and pharmacokinetics of a novel long-acting GLP-1/GIP/glucagon triple agonist (hm15211) in healthy obese subjects

JaeDuk Choi[1], Youngmin Kim[1], Kahee Eun[1], Linda Morrow[2], Marcus Hompesch[2], Seungjae Baek[1]. [1]*Hanmi Pharmaceutical Co., Ltd., Seoul, Korea, Rep. of South;* [2]*ProSciento, Inc., CA, United States*
Email: seungjae.baek@hanmi.co.kr

Background and Aims: HM15211 is a novel long-acting GLP-1/GIP/Glucagon triple-receptor co-agonist with extended half-life through reduced renal clearance. HM15211 has shown therapeutic potential in animal models of obesity and NASH.
Method: This study was a randomized, double-blind, placebo-controlled First-In-Human trial designed to assess safety, pharmacokinetics, pharmacodynamics, and immunogenicity of a single subcutaneous dose of HM15211 in obese but otherwise healthy adult subjects (Total 41 subjects were randomized, the mean age was 45.7 years, 51.2% were males, and the mean BMI was 33.6 kg/m^2). Subjects were randomized to one of 5 sequential ascending doses of either HM15211 or matching placebo.
Results: HM15211 was safe and well-tolerated in this population without significant changes in physical exams, CV parameters (HR, BP, ECG), and clinical laboratory tests. The most common adverse events were gastrointestinal disorders, reported by 9 out of 31 (29.0%) active subjects. There was no subject who discontinued the study and

there were no serious adverse events due to study medication. A total of 12 out of 31 (38.7%) active subjects tested positive for anti-drug antibodies (ADAs), however, no dose-related trend or relationship between immunogenicity and pharmacokinetic or safety outcomes were observed. Plasma concentration of HM15211 reached its peak level (T_{max}) in 31.20 to 68.08 hours. Plasma $AUC_{0\text{-}inf}$ and C_{max} increased in a dose-proportional manner and the terminal half-life ($t_{1/2}$) was 72.09 to 142.10 hours.
Conclusion: In conclusion, single doses of HM15211 were safe and well-tolerated, and the majority of adverse events were mild and transient. Pharmacokinetic profiles were suitable for weekly administration. Clinical studies in patients with NAFLD/NASH are following.

Email: ahmad.al-mrabeh2@ncl.ac.uk

Background and Aims: Saturated fatty acids and related lipid intermediates contribute to the pathogenesis of NAFLD. Palmitic acid, the most abundant saturated fatty acid, has reported to have toxic effects on insulin signaling and beta cell function. We aimed to assess the change in hepatic output of palmitic acid following weight loss and remission of type 2 diabetes.
Method: 54 participants from the Tyneside cohort of DiRECT: The Diabetes Remission Clinical Trial were studied over 2 years (25/29 F/M, 53.1 ± 1.0 years, and 101.0 ± 2.4 kg). Hepatic palmitic acid production rate (hepatic output) was assessed from the increment in plasma VLDL-TG concentration by a competitive non-isotopic method. Palmitic acid was quantified by GC-MS using FAME method. Liver fat was quantified by 3-point Dixon MRI.
Results: At baseline, liver fat was elevated in this cohort with early diabetes compared with a group of non-diabetic controls (16.4 ± 1.4 v 4.4 ± 1.1%, $p < 0.0001$). After weight loss, liver fat was normalized (3.2 ± 0.5%, $p = 0.65$ vs. control). Hepatic VLDL-TG production rate was also higher (9.7 ± 0.45 vs. 7.9 ± 0.48 mg/L/min, $p = 0.011$), but this was also decreased after intervention (7.8 ± 0.41 mg/L/min; $p < 0.0001$).
Palmitic acid content of fasting plasma VLDL was high in diabetes (11.3 ± 0.8 vs. 7.7 ± 0.8 mg/l, $p = 0.002$). However, hepatic output of VLDL palmitic acid was not different (140.9 ± 7.9 vs. 130.3 ± 8.8 µg/L/min; $p = 0.59$). Fasting plasma VLDL- palmitic acid decreased after weight loss (to 9.4 ± 1.0 mg/l, $p = 0.027$), and as did hepatic output of palmitic acid (to 108.9 ± 6.5 µg/L/min, $p = 0.005$). The change in fasting VLDL-palmitic acid was only significant in those who achieved remission of diabetes whereas hepatic VLDL palmitic acid output decreased irrespective of remission ($p < 0.05$). At 24 months, those who initially achieved remission of diabetes then returned to diabetic state were characterized by higher fasting VLDL-palmitic acid than those in remission (17.1 ± 2.4 vs. 7.6 ± 1.1 mg/l, $p = 0.002$; $p = 0.004$ compared with non-diabetic controls). Paradoxically, hepatic output of palmitic acid was not different between relapsers and those who remained in remission (104.4 ± 19.3 vs.134.2 ± 15.9 µg/L/min, $p = 0.40$).
Conclusion: These data highlight the importance of clearance of plasma VLDL palmitic acid rather than hepatic output in the pathogenesis of this disease. Further work is required to define why clearance of VLDL- derived palmitic acid is impaired in type 2 diabetes.

FRI117
GLP-1/glucagon dual receptor agonist ALT-801 is superior to semaglutide in improving NASH endpoints in a biopsy-confirmed DIO mouse model
John Nestor[1], Kristoffer Rigbolt[2], Michael Feigh[2], David Parkes[3], M. Scott Harris[1]. [1]*Altimmune, Inc., Gaithersburg, United States;* [2]*Gubra, Hørsholm, Denmark;* [3]*DGP Scientific, Del Mar, United States*
Email: sharris@altimmune.com

Background and Aims: Body weight loss of approximately 10% improves the metabolic derangements and liver disease in the majority of NASH patients, suggesting metabolic modulators may be effective in the control of the disease. GLP-1 agonists show promise for NASH, but weight loss associated with these agents has been modest. Glucagon receptor activation has direct effects on lipolysis, basal energy expenditure and liver lipid metabolism, so may act synergistically with GLP-1 in the treatment of NASH. To evaluate this hypothesis, we compared ALT-801, a balanced and long-acting GLP-1/glucagon receptor dual agonist, and semaglutide, a GLP-1 agonist, in a biopsy-confirmed DIO NASH mouse model.
Method: Male C57BL/6J mice were fed an AMLN diet high in trans-fat, fructose and cholesterol for 32 weeks. Animals with biopsy-confirmed steatosis (score ≥ 2) and fibrosis (stage ≥ 1) received ALT-801 (10 nmol/kg; SC), semaglutide (10 nmol/kg; SC), or vehicle (SC) for 12 weeks while maintained on the diet. Study endpoints included body and liver weight, liver and plasma total cholesterol (TC) and triglycerides (TG), plasma alanine aminotransferase (ALT), and histological analysis of liver inflammation (galectin-3) and fibrosis (Collagen1a1). Furthermore, within-subject evaluation of changes in composite NAFLD Activity Score (NAS) were performed. Finally, liver RNA sequencing analysis was performed to evaluate the regulation of genes involved in NASH pathways.
Results: ALT-801 demonstrated statistically superior reductions ($p \leq 0.05$) in body weight, liver weight, plasma ALT, liver TG and TC, and plasma TC compared to semaglutide, with only the ALT-801 group returning to normal lean mouse body weight, liver weight and ALT levels. Reduction in the inflammation marker galectin-3 was also superior to semaglutide, with a numerically greater reduction in the fibrosis marker COL1a1. In addition, all animals treated with ALT-801 improved composite NAS driven by reduction in steatosis, lobular inflammation and hepatocellular ballooning scores. Principal component analysis of the 500 most variable genes differentially clustered genes regulated by ALT-801 from those regulated by semaglutide consistent with a unique gene regulatory signature associated with glucagon receptor activation. ALT-801 also resulted in suppression of archetypal genes involved in de novo lipogenesis and fatty acid uptake (FASN, GPAT2, CD36), inflammation (jun, fos, p38, TLR4), hepatocellular death (AIM2, CASP1, IPAF, RIP3), fibrosis (collagens, TIMPs, MMPs) and stellate cell activation (A-SMA, CD146, PDGF, TGF-β).
Conclusion: This study provides evidence for the beneficial effects of glucagon receptor activation in the therapeutic treatment of NASH. The return of body weight to lean normal and metabolic improvement with improvement of liver pathology highlights ALT-801 as a new candidate for the treatment of NASH.

FRI118
Long-term safety profile of cenicriviroc in adults with non-alcoholic steatohepatitis: rollover study
Sven Francque[1], Alex Hodge[2], Jerome Boursier[3], Sam Moussa[4], Ziad H. Younes[5], Grace S. Park[6], Gerardo Rodriquez[6], Karen Lai[6], Eduardo Bruno Martins[7], Naim Alkhouri[8], Manal Abdelmalek[9]. Email: lai_karen@allergan.com

Background and Aims: Pharmacologic treatments for nonalcoholic steatohepatitis (NASH) need to display a good long-term safety and tolerability profile. Cenicriviroc (CVC), a novel, oral and potent inhibitor of C-C chemokine receptor types 2 and 5, is currently being evaluated for the treatment of liver fibrosis in adults with NASH. In the Phase 2b CENTAUR study (NCT02217475), CVC treatment resulted in a significant antifibrotic benefit over placebo in the Year 1 primary analysis with an excellent safety profile. The aim of this analysis was to assess the long-term safety profile of CVC in subjects from CENTAUR included in the Rollover study (NCT03059446).
Method: Rollover is an ongoing, open-label, multicentre global study of CENTAUR completers as well as subjects who have met pre-specified adjudicated events in the ongoing Phase 3 AURORA study (NCT03028740). CENTAUR completers were analysed by total treatment duration across CENTAUR and the Rollover study. The safety endpoints include clinical laboratory assessments of interest and adverse events (AEs). AEs were coded using the Medical Dictionary for Regulatory Activities version 22.0. Treatment relatedness was assessed by the investigator.
Results: As of 7 October 2019, a total of 147 subjects have been enrolled in the Rollover study, 106 of whom were previously on CVC in CENTAUR. Over time, the incidence rates of treatment-related AEs and serious AEs (SAEs) did not increase with longer treatment durations (Table). In subjects treated for 24 to <36 months and 36 to <48 months, no differences in gastrointestinal AEs (38.9% and 40.8%, respectively) and AEs of infections/infestations (38.9% and 38.8%, respectively) were observed. Only one subject discontinued CVC due to liver biochemistry elevations, which was adjudicated as not related to CVC by an external expert panel.
Table: Summary of AEs

n (%)	All AEs	Treatment-related AEs	SAEs
Overall (N = 106)	84 (79.2)	11 (10.4)	18 (17.0)
0–24 mos (n = 6; 5.7%)	3 (50.0)	0	1 (16.7)
24 – <36 mos (n = 36; 34.0%)	29 (80.6)	5 (13.9)	4 (11.1)
36 – <48 mos (n = 49; 46.2%)	38 (77.6)	5 (10.2)	9 (18.4)
48 – <60 mos (n = 15; 14.2%)	14 (93.3)	1 (6.7)	4 (26.7)

Conclusion: This is the first presentation of safety data beyond 36 weeks for NASH treatment. These data suggest that CVC's safety and tolerability profile in patients with NASH and liver fibrosis remained favourable with chronic exposure beyond 2 years. Writing assistance by Complete HealthVizion.

FRI119
Novel autophagy inducer, a4368 improves non-alchoholic steatohepatitis in mice

Hyun Jin Jung[1], Seungho Choi[1], Ming Li Jin[1], Sundaramurthy Pasupathi[1], Min Woo Kim[1], Ju-Hee Kang[1], Hyeon Gwan Choi[2], Sung-Won Song[2], Seung-Woo Yeon[2], Jung Ju Kim[2], Jae Hyun Kim[3], Gyoonhee Han[3], Hwan Mook Kim[1], Kwang Won Jung[1], Seung Hyun Oh[1]. *[1]Gachon University, College of Pharmacy, Incheon, Korea, Rep. of South; [2]Autophagy Sciences, Seoul, Korea, Rep. of South; [3]Yonsei University, College of Pharmacy, Incheon, Korea, Rep. of South*
Email: eyeball@gachon.ac.kr

Background and Aims: Recently, impaired autophagy has been reported to be critically associated with the progression of non-alcoholic steatohepatitis (NASH). Here, we investigated whether A4368, an autophagy inducer, has a therapeutic effect on NASH.
Method: A4368 was selected from a focused chemical library as an effective autophagy inducer. After A4368 treatment in Hep3B cells, LC3-II formation and the expression of inflammatory genes were monitored by western blotting and RT-qPCR. The efficacy of A4368 was investigated in high-fat diet (HFD) and STAMTM mice models. In HFD model, C57BL/6N mice were fed with high-fat diet (HFD, 40% Fat + 20% fructose + 2% cholesterol) for 35 weeks to induce NASH and were orally administered with 10, 25, or 50 mg/kg of A4368 for 8 weeks. In STAMTM model, C57BL/6N mice were subcutaneously injected with 0.2 mg streptozotocin 2 days after birth and fed with high fat diet (57kcal% fat) from 4 to 9 weeks of age. A4368 was orally administered for 4 weeks. We evaluated the therapeutic potential of A4368 by testing steatosis, fibrosis, and elevated liver enzymes such as ALT and AST and cholesterol levels in blood. To evaluate pharmacokinetics and tissue distribution, A4368 was orally administered in ICR mice. The concentration of A4368 was quantitatively analyzed in plasma and tissues by LC-MS/MS.
Results: A4368 increased autophagy flux in Hep3B. In addition, the expression of inflammatory genes was significantly suppressed by A4368 treatment. In HFD model, histological analysis revealed that A4368 treatment markedly decreased hepatic steatosis in a dose-dependent manner and reduced lobular inflammation and hepatocyte ballooning (25 mg/kg). Based on these observations, A4368 treatment improved NAS score (NAFLD activity score). However, increased body weights of HFD-fed mice were not reduced by A4368 treatment. To further evaluate the therapeutic activity in fibrosis, collagen deposition was evaluated using Sirius red staining, and hydroxyproline assay. The treatment of A4368 significantly decreased the fibrosis area and the amount of hydroxyproline. A4368 also showed comparable NAS score and reduction of fibrosis area with OCA in STAMTM mice. In a pharmacokinetic study, A4368 showed selective liver-targeting PK profile and only trace amounts were detected in other tissues.

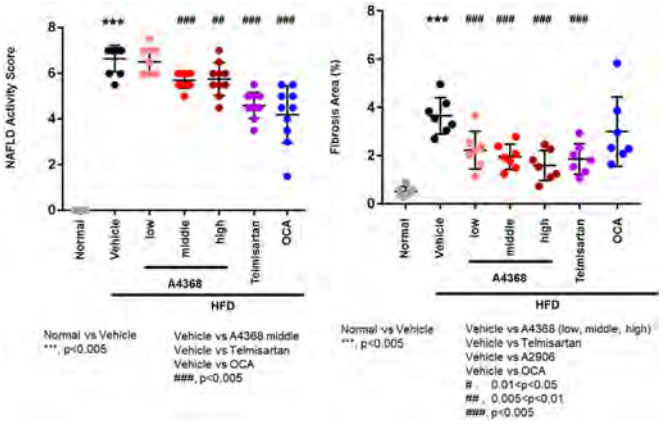

Figure: Improvements of NAS score and fibrosis by A4368 in HFD model.

Conclusion: Taken together, A4368 has therapeutic effect in NASH with selective liver targeting.

FRI120
Intrahepatic microcirculation disorders and increased blood ammonia at the chronic liver diseases with initial stage of liver fibrosis

Tatiana Ermolova[1]. *[1]North-Western State Medical University named after I.I.Mechnicov, Internal Medicine, St.-Petersburg, Russian Federation*
Email: t.v.ermolova@mail.ru

Background and Aims: ammonia is new therapeutic target for chronic liver diseases. Some experimental studies demonstrated effect of hypoammoniemic drugs for decrease of activity of hepatic stellate cells, improvement of endothelial function, liver microcirculation and prevention of liver fibrogenesis. Aims of our study are to estimate blood level of ammonia, intrahepatic microcirculation and

efficacy of Hepa-Merz (L-ornithine-L-aspartate) for correction of such disorders at the chronic liver diseases.
Method: We investigated 26 nonalcoholic steatohepatitis (NASH) and 35 HCV patients with initial fibrosis 0–2 stages. Level of ammonia was estimated by biochemical method (PocketChem BA, Arcray, Japan) in capillary blood at the patients and 19 healthy individuals (control). Intrahepatic hemodinamics are determined by polyhepatography (PHG) - modificated hepatic impedansometry, non-invasive method for integral estimation of intrahepatic blood flow by checking of tissue resistance to weak electric current. PHG registers a blood flow in projection of zone of hepatic right, left lobes and spleen, integral body impedansography. For verification of functional disorders in during PHG we use test with deep respiration and nitrates. For correction of blood flow disorders we used hypoammoniemic drug Hepa-Merz in dosage 3 grams 3 times daily 4 weeks. Efficacy of LOLA we looked in 2 and 4 weeks via the control PHG and control of ammonia.
Results: Analysis of PHG demonstrated, that at all patients we revealed a liver microcirculation disorders - increased blood resistance, abnormal forms and amplitude of waves in sinusoidal level (out flow zone) at NASH patients and presinusoidal level (inflow zone) at viral patients. Level of ammonia was higher in the patients compared with control group ($p < 0.001$), and hyperammoniemia was higher at the NASH patients ($p < 0.01$). Analysis of efficacy of Hepa-Merz showed, that it was effective for correction of hepatic hemodinamic disorders, in 2 weeks of the treatment we observed normalization or improvement of the wave form, in 4 weeks – wave amplitude. Level of ammonia was decreased in 2 weeks.
Conclusion: chronic liver diseases with initial liver fibrosis, especially NASH, are characterized by hyperammoniemia, disorders of intrahepatic microcirculation. LOLA improved liver microcirculation and decreases of blood ammonia level at the NASH and HCV patients.

FRI121
Composite targeting of nuclear receptors protects against diet-induced NAFLD

Tawhidul Islam[1], Pedro Miguel Rodrigues[1,2], Helena Ignacakova[1], Marta B. Afonso[1], André Simão[1], Cecília M. P. Rodrigues[1], Rui E. Castro[1]. [1]*Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal;* [2]*Department of Liver and Gastrointestinal Diseases, Biodonostia Health Research Institute, Donostia University Hospital, University of the Basque Country (UPV/EHU), San Sebastian, Spain, Spain*
Email: tislam@ff.ulisboa.pt

Background and Aims: As key regulators of hepatic metabolism, bile acid-activated receptors impact on non-alcoholic fatty liver disease (NAFLD) pathogenesis, supporting the use of selected agonists to treat disease. To this end, ligands of the farnesoid X receptor (FXR) and G protein-coupled receptor 5 (TGR5) are promising, although their efficacy is still limited and accompanied by side effects. Here, we aimed to elucidate whether INT-767, a dual FXR and TGR5 agonist, alone or in combination with miR-21 silencing, could synergize in ameliorating NAFLD and its progression towards hepatocellular carcinoma.
Method: C57BL/6N mice were fed a high-fat choline-deficient (HFCD) diet for 14 or 24 weeks, supplemented with or without INT-767, and/or injected with antagomiR-21 or a scrambled antagomir (control). Liver and serum samples were collected and processed for histological and molecular assessment. Expression of genes and proteins involved in NAFLD signalling circuits, as well as those lying downstream of activation of nuclear receptors were investigated through qRT-PCR and immunoblotting.
Results: 14-week HFCD-fed mice developed non-alcoholic steatohepatitis (NASH) with minimal fibrosis, whereas 24-week-fed animals already displayed significant fibrosis and, notably, pre-neoplasic nodules. Noteworthy, INT-767 and antagomiR-21, alone or in combination, prevented disease progression at both time points. Particularly, HFCD diet-induced upregulation of liver pro-inflammatory genes and proteins, as well as pro-fibrogenic markers, were significantly reverted by either INT-767 or antagomiR-21 alone, and even more so, by both treatments combined. Similar results were observed in histological examinations. Further, HFCD diet-induced downregulation of lipid metabolism genes/proteins (FXR, SHP-1, PPAR-α, CPT-1, MCAD and TGR5, FGF-21) was also rescued upon treatments. Finally, HFCD diet-induced overall mitochondrial dysfunction, as observed through the upregulation of DRP-1 and FIS-1 expression, concomitantly with downregulation of MFN2, OPA-1, NRF1, NRF2 and TFAM, was also inhibited by either INT-767 or antagomiR-21 alone, as well as both combined, at both timepoints
Conclusion: In conclusion, either INT-767 or antagomiR-21 alone prevent NAFLD triggering and progression, with both treatments combined more effectively ameliorating the NAFLD phenotype at distinct disease stages. These effects are mediated through modulation of multiple inflammatory-, fibrogenic-, insulin resistance-, mitochondrial function-, lipid and cholesterol metabolism-related genes, in overlapping and complementary signalling cascades. Hence, the multiple targeting of selected bile acid-activated receptors may embody a novel putative therapeutic approach in preventing NAFLD. SAICTPAC/0019/2015, PTDC/MED-PAT/31882/2017, EU H2020 Marie Sklodowska-Curie 722619.

FRI122
Patient-reported benefits for future non-alcoholic steatohepatitis therapy: a global real-world study among 1,035 patients across 12 countries

Victoria Higgins[1], Nathan Williams[1], Jessica Jackson[1], Rhys Williams[1], James Piercy[1]. [1]*Adelphi Real World, Metabolic Franchise, Bollington, United Kingdom*
Email: nathan.williams@adelphigroup.com.

Background and Aims: Non-alcoholic steatohepatitis (NASH) is estimated to increase 63% by 2030. Published evidence highlights a lack of patient understanding and long-term consequences linked to NASH. Health Technology Assessment (HTA) decisions, including UK-based National Institute for Health & Clinical Excellence (NICE), are increasingly requesting patient statement questionnaires around disease experience. This analysis aims to explore most important benefits patients seek from future NASH drug treatments.
Method: Data were derived from the 2018/19 Adelphi NASH Disease Specific Programme, a real-world, cross-sectional chart review in Europe (EU; France, Germany, Italy, Portugal, Spain, UK), North America (NA; US, Canada), Middle East (ME; Saudi Arabia, UAE), Australia (AU) & Japan (JP). Physicians completed questionnaires describing 2–8 NASH patients. Patients completed a voluntary questionnaire answering: Other than cure your fatty liver, what is the most important benefit your drug treatment could provide? 62 grouped responses generated 6 themes: diet and weight (DW), activities of daily living (ADL), feelings (F), reduce disease-related risks (RDR), treatment-specific benefits (TSB) and don't know (DK).
Results: 687 physicians (28% Hepatologist, 49% Gastroenterologist, 21% Diabetologist, 2% PCP) provided data on 3434 patients. Of these, 1035 patients (EU 600; NA 244; ME 102; AU 34; JP 55) provided a response, with 78 patients providing >1 response. Grouped responses reported DW 26%, ADL 17%, F 9%, RDR 17%, TSB 22% and DK 17%. NA patients were most concerned with DW (33% vs 9–26%) and RDR (26% vs 14–18%), AU/ME were most concerned with TSB (50% & 37% respectively vs 19–25%) and ADL (38% & 28% respectively vs 12–17%) and JP/EU most likely DK (25% & 24% respectively vs 5–7%). All $p < 0.05$. Minimal statistical differences across BMI, age, sex, disease duration, diagnostic tests, patient engagement/knowledge of disease.
Conclusion: Patient-reported expectations for NASH treatment benefits vary the most across regions suggesting cultural influence may drive expectations. However, lack of differentiation across other demographic, clinical and engagement factors could suggest a degree of homogeneity across NASH patients regarding treatment

expectations. This supports the notion that NASH patients, regardless of patient type, lack disease understanding and awareness supporting a need for enhanced patient education and engagement.

FRI123

Effects of kaempferol on CFLAR-JNK pathway in mice with non-alcoholic steatohepatitis

Yue Shen[1], Siqi Wang[1], Wei Jiang[1]. [1]*Zhongshan Hospital, Fudan University; Shanghai Institute of Liver Diseases, Department of Gastroenterology and Hepatology, Shanghai, China*
Email: jiang.wei@zs-hospital.sh.cn.

Background and Aims: Non-alcoholic steatohepatitis (NASH), characterized by metabolic syndrome, hepatic steatosis, and liver inflammationmay, may progress to liver fibrosis, cirrhosis, and hepatocellular carcinoma. Without approved pharmacotherapy, the need to find appropriate therapeutic targets is more urgent than ever before. Recently, Fas-associated protein with death domain-like apoptosis regulator (CFLAR) has been proposed as a promising suppressor of steatohepatitis. Kaempferol (KAM), a natural flavonoid found in fruits and vegetables, has raised concern for its anti-oxidant, anti-inflammatory, and anti-apoptotic effects. The hepatoprotective effect of KAM has been indicated in drug-induced liver injury, alcoholic liver injury and acute liver failure, while its role against NASH remains unclear. The study aims to investigate the effect of KAM on CFLAR-JNK pathway and its downstream target genes concerning lipid metabolism, oxidative stress and inflammatory response in NASH models both *in vivo* and *in vitro*.
Method: *In vivo* study was performed on C57BL/6 male mice kept on a methionine/choline-deficient (MCD) diet or control methionine/choline-sufficient (MCS) diet from the age of 8 weeks to 12 weeks. Treatment with vehicle (0.5% carboxymethyl cellulose), KAM (50 mg/kg/d) was given for another 4–6 weeks via daily gavage (group size = 10). For *in vitro* study, oleic acid plus palmitic acid treated L02 cells were applied to establish the steatosis model. Key indicators involved in CFLAR-JNK pathway reflecting lipid metabolism, oxidative stress and hepatic injury were determined.
Results: Compared to the MCD models, treatment with KAM significantly improved the histological changes via decreasing parameters of steatosis, inflammation and fibrosis. CFLAR was activated while the pJNK was inhibited. KAM treatment could also improve the indicators as follows: (1) decreased the level of serum ALT, AST and TC, TG; (2) up-regulated hepatic transcript levels reflecting lipid metabolism, including *PPARα, FABP5, CPTLα, Acox, SCD-1, GPAT and MTTP* while suppressed lipid synthesis related genes including *SREBP-1c* and *PNPLA3*; (3) increased the level of NRF2 and the activities of oxygen radical scavenging enzymes (GSH-Px, CAT and HO-1) while reduced the expression of oxygen free radical generating enzymes (CYP2E1 and CYP4A). The regulation role of KAM in NASH was also confirmed by *in vitro* experiments.
Conclusion: Our results suggested that KAM can ameliorate NASH via activating CFLAR-JNK pathway. By targeting its downstream genes involved in the process of hepatic lipid synthesis (SREBP-1c, PNPLA3), β-oxidation (PPARα, FABP5, CPTLα, Acox) and transport (SCD-1, GPAT, MTTP) as well as hepatic oxidative stress (GSH-Px, CAT, HO-1, CYP2E1, CYP4A), KAM shows promising hepatoprotective property against NASH and may be a new therapeutic approach for NASH treatment.

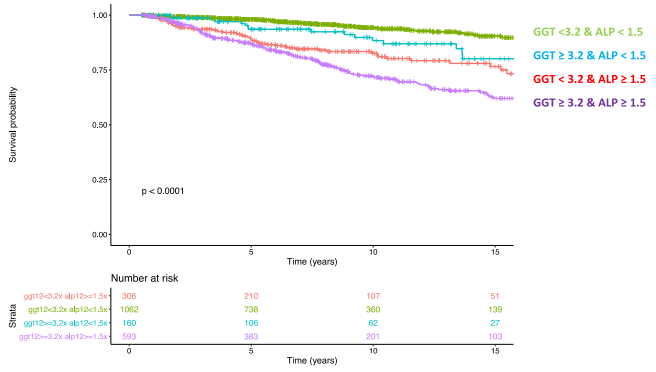
Background and Aims: Gamma-glutamyltransferase (GGT) is a serum marker of cholestasis. Its prognostic meaning in primary biliary cholangitis (PBC) is however unknown. We aimed to explore whether GGT is a prognostic marker in PBC.
Method: Data on patients from 14 centers from the Global PBC Study Group were included in the analysis. All patients with available GGT values at 12 months were selected. Levels of GGT were analyzed in different sub-populations at different time frames in relation to clinical endpoints of interest, i.e. liver transplantation (LT) or liver-related death.
Results: We identified 2129 patients, 281 (13%) experienced a liver-related clinical endpoint. Mean age at diagnosis was 53 years and 91% of patients were females. Patients treated with UDCA were 1983 (93%). Correlation between GGT and alkaline phosphatase (ALP) was strong (r = 0.71). When evaluated at baseline and yearly up to 5 years, higher GGT levels translated in lower transplant-free survival. When evaluated at 12 months since study enrollment, levels of GGT higher than 3.2 × upper limit of normal (ULN) best predicted the outcome at 10 years (AUC 0.70). The risk of liver-related death or LT in patients

with GGT higher than 3.2 × ULN despite ALP lower than 1.5 × ULN was higher compared to those with GGT lower than 3.2 × ULN and ALP lower than 1.5 × ULN (Figure). The GGT threshold of 3.2 × ULN confirmed its prognostic value in several subgroups, like young individuals (hazard ratio (HR) 3.52, confidence interval (CI) 2.15–5.77), male sex (HR 2.05, CI 1.06–3.96), and advanced histological stages (HR 2.53, 1.64–3.89). All findings were confirmed when patients not treated with UDCA were excluded. The trend of GGT/total bilirubin over time in patients who experienced LT or death decreased before the endpoint.



Conclusion: Serum GGT can predict liver transplantation or death of patients with PBC and enhances risk stratification based on ALP only. It might be used as surrogate end points in clinical trials. Moreover, GGT might replace ALP in patients with conditions that may spuriously alter levels of ALP, such as bone disease.

FRI125

Ursodeoxycholic acid and/or ciprofibrate for treating patients with presumptive diagnosis of low phospholipid cholelithiasis, a clinical spectrum of progressive familial intrahepatic cholestasis type 3

Fernanda S. Linhares[1], Ana Cardoso[1], Debora Terrabuio[1], Michelle Harriz[1], Laura Guedes[1], Flair Jose Carrilho[1], Eduardo Luiz Rachid Cançado[1]. [1]*Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Gastroenterology and Hepatology, São Paulo, Brazil*
Email: linhares.fs@gmail.com.

Background and Aims: Low phospholipid-associated cholelithiasis (LPAC) is a clinical spectrum of progressive familial intrahepatic cholestasis type 3 (PFIC3) in which biliary phosphatidylcholine levels are reduced. Ursodeoxycholic acid (UDCA) is often effective. Fibrates may also be used theoretically due to their effects on peroxisome proliferator-activated alpha receptor activation, inducing bile secretion of phosphatidyl choline. The aim of the study was to retrospectively evaluate the safety and efficacy of fibrate in 29 patients (23 females) diagnosed with LPAC/PFIC3.
Methods: Diagnosis of PFIC3 was based on the detection of mutations in the ABCB4 gene. LPAC diagnosis was suggested by the presence of 2 of the following criteria: cholestasis in patients with cholelithiasis before age 40, recurrence of symptoms after cholecystectomy, intrahepatic lithiasis; cholelithiasis in first degree relatives; intrahepatic cholestasis of pregnancy or contraceptive-induced cholestasis. It was excluded other etiologies of chronic cholestasis. Liver enzymes and function and pruritus were analyzed after 3, 6 and 12 months of UDCA use and after ciprofibrate 100 mg/day by the Wilcoxon test; a p value <0.05 was considered statistically significant.
Results: Two patients (7%) were diagnosed with PFIC3 and 27 (93%) had clinical data compatible with LPAC. The mean age at onset of symptoms was 26.7 ± 13.6 years. Twenty-three patients (80%) had a family history of biliary diseases; 22 (76%) cholelithiasis before 40 years; 7 (24%) intrahepatic lithiasis. UDCA was given at a median dose of 13.4 mg/kg/day and ciprofibrate was added after a median time of 2.06 years of UDCA in 78% (22). During UDCA therapy, there was a significant decrease in aminotransferases, alkaline phosphatase and gamma-glutamyl transferase levels, without significant improvement in liver function. After addition of fibrate, pruritus resolved in all 7 patients, and there was improvement of the canalicular enzymes and albumin (only in the third month), with no significant worsening in renal function. Fibrate was stopped in 8 patients because liver transplantation (1), irregular use (2), side effects (5). The most common side effect was myalgia (2). Twenty-seven patients are in still in follow up.
Conclusion: Fibrate may be a safe and effective option to improve pruritus and laboratory tests in patients with LPAC/PFIC3 who were incompletely treated with UDCA. These findings should be confirmed by other centers.

FRI126

Comparative effects of second-line therapy with obeticholic acid or fibrates in primary biliary cholangitis patients

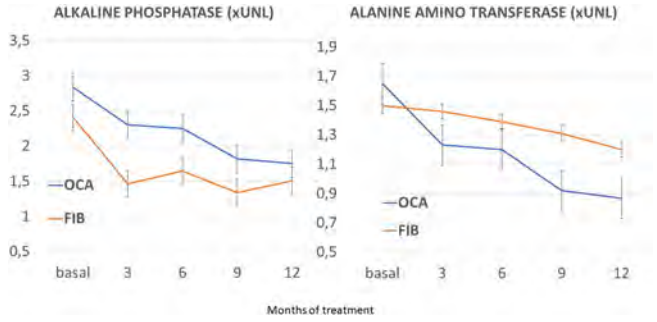
Background and Aims: Obeticholic acid (OCA) and fibrates are proposed as the second-line therapy in patients with primary biliary cholangitis (PBC) and suboptimal response to ursodeoxycholic acid (UDCA), but there is no definite data about their results in real life. Therefore, the aim has been to evaluate the comparative efficacy and adverse effects of OCA and fibrates.
Method: 355 patients (30 centres, Col-Hai registry) without optimal response to UDCA initiated therapy with fibrates, OCA or both. Biochemical changes during one year were analysed in patients

treated ≥ 3 months. Adverse effects and treatment discontinuation were recorded.
Results: 277 patients treated ≥ 3 months: 65 with OCA (5 mg/d), 201 with fibrates (84% bezafibrate 400 mg/d; 16% fenofibrate 200 -IQR 160–299- mg/d) and 11 with both OCA and fibrates. 90.9% women, 55 ± 1 year-old, 98.4% treated with UDCA for 7.5 ± 0.3 years, 11,8% with cirrhosis or portal hypertension and 13% with autoimmune hepatitis overlap. Baseline characteristics were similar between OCA and fibrates regimens, as well as in prognostic scores (UK-PBC and Globa-PBC). Both treatments decreased significatively alkaline phosphatase (AP), γ-glutamyl transferase (GGT) and transaminases. Fibrates improved the Global score (p = 0.01) and both treatments increased the percentage of patients with good prognosis according to this score. AP decrease was higher with fibrates (p = 0.002), while OCA has better on transaminases decrease (p = 0.05) (figure). Overlap syndrome (36% vs 9.2%, p < 0.01), and baseline hypertransaminasemia and biochemical cholestasis were higher in the 11 patients receiving OCA and fibrates concurrently. No significant changes were observed after 6 months of treatment in these patients.



Second-line treatment was discontinued in 9% of patients with OCA (2.2% no response; 2.2% intolerance) and 9.8% with fibrates (1.8% no response; 4% intolerance). Adverse events were reported in 10,1% with OCA and 3,6% with fibrates, mainly pruritus (3,5% with OCA). One patient with fibrates presented a severe adverse event.
Conclusion: Second-line therapy with obeticholic acid or fibrates improve hepatic biochemistry with infrequent adverse events in patients with primary biliary cholangitis non-responders to UDCA. Fibrates are associated with higher decrease in alkaline phosphatase while obeticholic acid with higher transaminases improvement.

FRI127

Histological features of non-alcoholic steatohepatitis are common in patients with autoimmune hepatitis who have advanced fibrosis at diagnosis

Ashleigh Lima[1], James Truell[1], Annie Dixey[1], Michael Patrick Johnston[1], Janisha Patel[1]. [1]*University Hospital Southampton NHS Foundation Trust, Department of Hepatology, Southampton, United Kingdom*
Email: michael.johnston1@nhs.net.

Background and Aims: Given the growing prevalence of obesity and non-alcoholic fatty liver disease (NAFLD) it is likely that we will begin to see coincident NAFLD in patients with other liver conditions, such as autoimmune hepatitis (AIH). We aimed to evaluate the prevalence of histological features of non-alcoholic steatohepatitis (NASH) in patients presenting with AIH. We hypothesized that baseline fibrosis stage in patients with AIH is associated with histological features of NASH.
Method: We identified all adult patients who attended the liver clinic between 2013–2019 with a diagnosis of AIH. We used a cross-sectional design to analyse baseline characteristics of all patients including age, sex, body mass index (BMI), presence of type 2 diabetes (T2DM), hypertension and dyslipidaemia. We reviewed index biopsy reports for fibrosis stage, presence of steatosis, hepatocyte ballooning and lobular inflammation. We calculated odds ratios for the presence of histological features of NASH based on baseline fibrosis stage.
Results: 71 patients had a diagnosis of AIH and baseline biopsy data. 16/71 (22.5%) were male. Mean age (SD) was 60.7 years (16.3). 45/71 (63.4%) were overweight (BMI ≥ 25 kg/m^2) and 17/71 (23.9%) were obese (BMI ≥ 30 kg/m^2). At the time of diagnosis 7/71 (9.9%) had hypertension, 5/71 (7.0%) had T2DM and 4/71 (5.6%) had dyslipidaemia. 16/71 (22.5%) were cirrhotic at diagnosis. The prevalence of obesity was similar in patients with F3-F4 and F0-F2 fibrosis (25.0% vs 23.5%). Patients with F3-F4 fibrosis had an increased prevalence of steatosis (25.0% vs 15.7%), lobular inflammation (20.0% vs 0%) and ballooning (35.0% vs 5.5%), compared to patients with F0-F2. With F0-F2 as the reference, the crude odds ratio (OR) for presence of steatosis in F3-F4 was OR 1.8 [95% CI 0.51–6.3]). Crude OR for presence of ballooning in F3-F4 was OR 8.6 [95% CI 2.0–38.0]. Age adjusted OR for presence of ballooning in F3-F4 was aOR 1.75 [95% CI 0.11–27.6].
Table: Baseline characteristics in patients with AIH

	All patients with AIH n = 71		
Fibrosis stage at diagnosis	F0 – F2	F3 – F4	
Total number (%)	51 (71.8)	20 (28.2)	
Age (years) (± S.D.)	58.2 ± 17.7	67.0 ± 10.1	P < 0.05
Male sex (%)	12 (18.2)	4 (20.0)	
BMI (kg/m^2)	26.8 (23.4–30.2)	27.3 (25.0–31.0)	
Overweight ≥ 25 kg/m^2 (%)	30 (58.8)	15 (75.0)	
Obese ≥ 30 kg/m^2 (%)	12 (23.5)	5 (25.0)	
T2DM (%)	4 (7.8)	1 (5.0)	
Dyslipidaemia (%)	3 (5.9)	1 (5.0)	
Hypertension (%)	7 (13.7)	0 (0)	
Features of NASH on baseline biopsy			
Steatosis (%)	8 (15.7)	5 (25.0)	P = 0.361
Lobular inflammation (%)	0 (0)	4 (20.0)	P < 0.05
Ballooning (%)	3 (5.5)	7 (35.0)	P < 0.05

Conclusion: Obesity is encountered frequently in patients presenting with AIH. In patients with advanced fibrosis at diagnosis there is a high prevalence of histological features of NASH compared to patients without advanced fibrosis. However, after adjusting for age, fibrosis does not appear to be associated with a higher prevalence of histological features of NASH.

Background and Aims: The Swiss primary biliary cholangitis (PBC) cohort, established in 2017, includes also subjects with positive anti-mitochondrial antibody (AMA) and/or PBC-specific anti-nuclear antibody (ANA) and normal alkaline phosphatase (AP) serum

levels. We report the subgroup of subjects with isolated PBC-serology who have undergone a liver biopsy within one year of autoantibody testing.

Method: Preliminary report of the Swiss PBC cohort describing biochemical, serological and histological features of patients with isolated positive PBC-serology. Liver biochemistry was assessed before UDCA start in all patients.

Results: 66 patients with isolated PBC-serology have been included so far in the Swiss PBC cohort study, of whom 33 underwent a liver biopsy; six were excluded from data analysis for AIH-overlap, one for liver biopsy >1 year before serology test. 24 were female, median age 50 years, all Caucasian; 23 were AMA-positive, two were anti-centromere-positive, one ANA rim-like positive, confirmed by anti-gp210-positivity. PBC-compatible or -typical histological changes were seen in 22 patients, coexisting with NASH in one, the remainder showing steatosis (n = 2), NASH and normal histology (n = 1 each). Both subjects with isolated anti-centromere-positivity showed bile duct damage with granulomatous portal tract inflammatory infiltration (Figure). Two subjects had advanced fibrosis. While PBC histological changes were found in 16/17 (94%) of subjects with elevated GGT levels, only 6/9 (67%) subjects with normal GGT levels had PBC-compatible histology. Five subjects were on UDCA at the time of biopsy, median time on UDCA was two months.

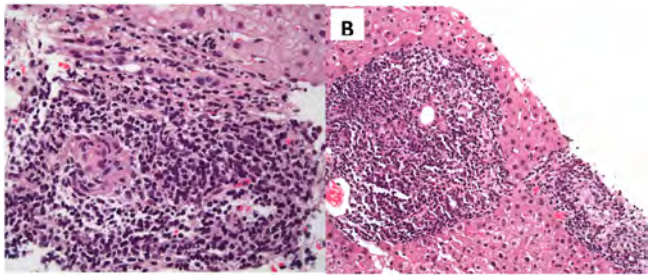

Figure: **A.** Liver histology of a 53-year old AMA-positive female patient with normal AP and GGT levels showing an epithelioid cell granulomatous reaction surrounding a bile duct (H&E 400x). **B**. Liver histology of a 44-year old AMA-negative, anti-centromere positive female patient with normal AP and normal GGT levels showing a portal tract with mixed chronic inflammatory cell infiltration surrounding a bile duct (H&E 200x).

Conclusion: these preliminary data not only confirm the frequent presence of PBC histological changes in patients with isolated AMA-positivity, but also demonstrate PBC-characteristic histology in patients with isolated anti-centromere antibody. Our data also suggest that GGT serum levels may be a novel disease marker in PBC.

FRI129

Ursodeoxycholic acid response in primary biliary cholangitis is associated with a significant reduction in decompensation and mortality in compensated cirrhosis

Binu John[1], Nidah Shabbir Khakoo[2], Gabriella Aitcheson[2], Cynthia Levy[3], David Goldberg[3], Kalyan Ram Bhamidimarri[3], Maria Hernandez[1], Bassam Dahman[4], Yangyang Deng[4], Paul Martin[3], Tamar Taddei[5,6], David Kaplan[7,8]. *[1]Bruce W Carter VA Medical Center, Department of Gastroenterology and Hepatology, Miami, United States; [2]Jackson Memorial Hospital/University of Miami, Department of Internal Medicine, Miami, United States; [3]University of Miami, Department of Gastroenterology and Hepatology, Miami, United States; [4]Virginia Commonwealth University, Department of Health Behavior and Policy, Richmond, United States; [5]VA Connecticut Healthcare System, West Haven, United States; [6]Yale School of Medicine, Section of Digestive Diseases, New Haven, United States; [7]University of Pennsylvania, Department of Gastroenterology and Hepatology, Philadelphia, United States; [8]Corporal Michael J. Crescenz VA Medical Center, Philadelphia, United States*

Email: binu.john@va.gov

Background and Aims: Most natural history studies of primary biliary cholangitis (PBC) have a relatively small number of patients with cirrhosis and little is known about the benefit of ursodeoxycholic acid (UDCA) in compensated cirrhotics. Therefore, the aim of this study is to compare UDCA responders and non-responders among PBC patients with compensated cirrhosis for the outcomes of hepatic decompensation and mortality (liver and non-liver related).

Method: This was a multicenter retrospective cohort study of 953 adult Veterans with PBC, diagnosed with compensated cirrhosis between 2008 and 2016 with follow up to June 2019. Entry date was defined as the first date of cirrhosis diagnosis. Patients who had decompensation at the time of cirrhosis diagnosis or follow-up of less than six months were excluded. UDCA was initiated at the time of PBC diagnosis and response was defined as alkaline phosphatase less than 1.67 times the upper limit of normal after one year of therapy. The associations of UDCA response and risk of decompensation and mortality were estimated using competing risk time-updating Cox proportional hazards models adjusted for age, sex, race-ethnicity, time-dependent AUDIT-C–defined alcohol use, diabetes, cirrhosis co-morbidity index, BMI, and Child Pugh score.

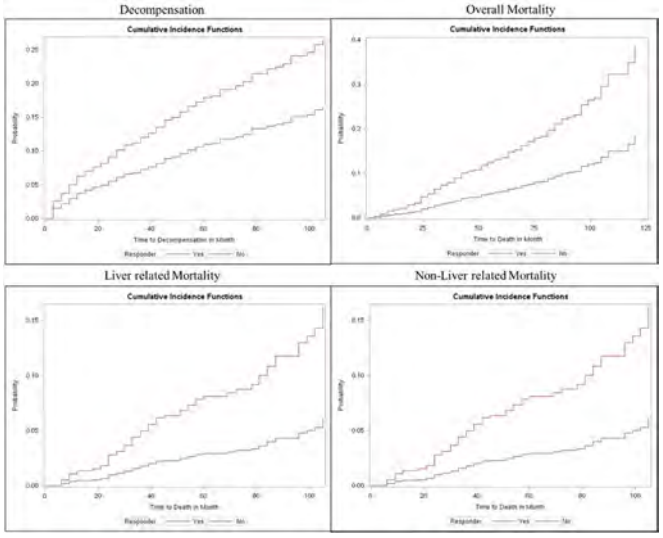

Figure: Cumulative Incidence of Decompensation, Death, Liver and Non-Liver related Death over Time, by UDCA response.

Results: A total of 953 patients with PBC and compensated cirrhosis with a follow-up of 4758 person-years were included in this study. Of these, 628 were UDCA responders. In comparison to non-responders, responders were less likely to develop decompensation (14% vs 21.9%, $p < 0.002$), including ascites (6.2% vs.13.5%, $p < 0.001$), encephalopathy (11.0% vs 12.9%, $p < 0.001$), variceal bleeding (11.0% vs. 12.9%, $p < 0.001$), and spontaneous bacterial peritonitis (1.6% vs 3.7%, $p < 0.001$). Further, responders were less likely to develop hepatocellular carcinoma (2.9% vs. 5.2%, $p < 0.001$). Responders also had significantly delayed median time to decompensation compared to non-responders (63 versus 49 months, $p < 0.002$). On adjusted multivariable analysis, UDCA response was associated with a 41% decrease in decompensation (HR 0.59, 95% CI 0.42–0.83), a 58% decrease of overall mortality (HR 0.42, 95% CI 0.29–0.61), a 65% decrease in liver-related mortality (HR 0.35, 95% CI 0.20–0.62), and a 54% decrease in non-liver related mortality (HR 0.46, 95% CI 0.27–0.77).

Conclusion: In a large cohort of patients with PBC and compensated cirrhosis, UDCA response is associated with a significant reduction in hazards of hepatic decompensation and mortality (liver and non-liver related).

FRI130

Male gender is associated with a high rate of decompensation and mortality in primary biliary cholangitis with well compensated cirrhosis

Binu John[1], Nidah Shabbir Khakoo[2], Gabriella Aitcheson[2], Cynthia Levy[3], David Goldberg[3], Kalyan Ram Bhamidimarri[3], Maria Hernandez[1], Bassam Dahman[4], Yangyang Deng[4], Paul Martin[3], Tamar Taddei[5,6], David Kaplan[7,8]. *[1]Bruce W Carter VA Medical Center, Department of Gastroenterology and Hepatology, Miami, United States; [2]Jackson Memorial Hospital, Department of Internal Medicine, Miami, United States; [3]University of Miami, Department of Gastroenterology and Hepatology, Miami, United States; [4]Virginia Commonwealth University, Department of Health Behavior and Policy, Richmond, United States; [5]Yale School of Medicine, Section of Digestive Diseases, New Haven, United States; [6]VA Connecticut Healthcare System, West Haven, United States; [7]University of Pennsylvania, Department of Gastroenterology and Hepatology, Philadelphia, United States; [8]Corporal Michael J. Crescenz VA Medical Center, Philadelphia, United States*
Email: binu.john@va.gov

Background and Aims: Most natural history studies of primary biliary cholangitis (PBC) have a relatively small number of male patients, particularly with cirrhosis. A recent study from the Global PBC study cohort of 4355 patients found that male gender was not associated with Ursodeoxycholic acid (UDCA) response or transplant free survival, but this cohort had only 59 males with portal hypertension at baseline. Other studies have shown that males have a delayed diagnosis and worse prognosis. The aim of this study was to identify the association of male gender with decompensation and mortality in a cohort of patients with PBC cirrhosis with a large proportion of males.
Method: This was a multicenter retrospective cohort study of 1167 Veterans with PBC who were diagnosed with compensated cirrhosis between 2008 and 2016 with follow up to June 2019. Cohort entry date was defined as the first date of cirrhosis diagnosis. Patients who had evidence of decompensation at the time of diagnosis of cirrhosis or who had a follow-up of less than six months were excluded. Response to UDCA was defined as alkaline phosphatase less than 1.67 times the upper limit of normal after 12 months of therapy. The associations of male gender and risk of decompensation, overall mortality as well as liver and non-liver related mortality were estimated using competing risk time-updating Cox proportional hazards models adjusted for age, sex, race–ethnicity, response to UDCA, and time-dependent AUDIT-C–defined alcohol use, diabetes, cirrhosis co-morbidity index, BMI and Child Pugh Score.

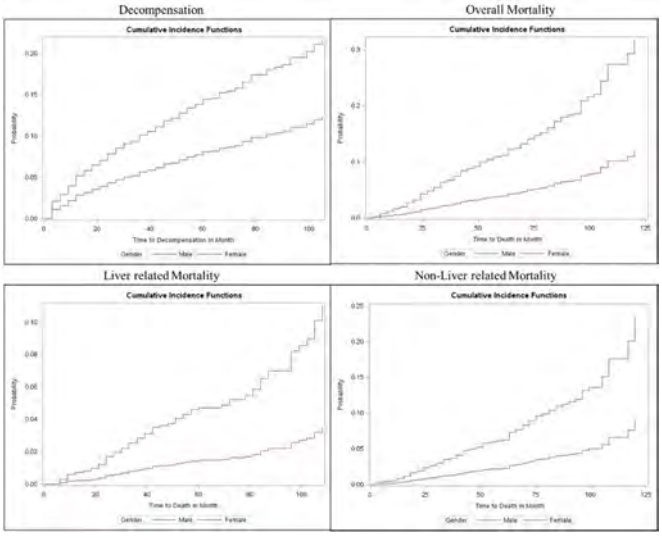

Figure: Cumulative Incidence of Decompensation, Death, Liver and Non-Liver related Death over Time, by Gender

Results: Of the 1167 patients with PBC, 924 were males. In comparison to women, men were older at diagnosis of cirrhosis (66.2 vs. 56.5 years, $p < 0.0001$), more likely to be white (71 vs. 65%), be diabetic (37 vs. 21%, $p < 0.0001$), and have an AUDIT score ≥ 4 at diagnosis of cirrhosis (7 vs. 3%, $p = 0.001$) and less likely to be UDCA responders (52 vs. 60%, $p = 0.04$). A total of 204 patients developed decompensation (19% of males vs. 10% of the females) with no significant difference in the median time to decompensation from diagnosis of cirrhosis (60 months in males vs. 62 months, $p = 0.12$). On adjusted Cox proportional hazard regression model, male gender was associated with higher hazard of decompensation (HR 1.85, 95% CI 1.16, 2.98), overall mortality (HR 2.98, 95% CI 5. 1.41–6.3), including liver (HR 3.26, 95% CI 1.13–9.45), and non-liver related mortality (HR 2.85, 95% CI 1.00–8.11).
Conclusion: In this large cohort of patients with PBC and compensated cirrhosis with a predominant male population, male gender was associated with a significant increase in hazards of hepatic decompensation and mortality.

FRI131

Psychometric evaluation of the adult itch reported outcome tool, a worst-itch numeric rating scale in adults with cholestatic liver disease

Brandon Foster[1], David Andrae[1], Pamela Vig[2], Andrew McKibben[2], Christopher Bowlus[3]. *[1]Endpoint Outcomes, Boston, United States; [2]Mirum Pharmaceuticals, Foster City, United States; [3]University of California Davis School of Medicine, Division of Gastroenterology and Hepatology, Sacramento, United States*
Email: brandon.foster@endpointoutcomes.com

Background and Aims: Cholestasis often leads to severe pruritus, which may significantly impair quality of life. The Adult Itch Reported Outcome (ItchRO) is a single-item, numeric rating scale (NRS) measure that assesses the severity of pruritus with an 11-point scale (0 = no itch to 10 = worst possible itch). The measure was originally developed using qualitative methods and cognitive debriefing with primary biliary cholangitis (PBC) patients. This study aimed to validate the Adult ItchRO for pruritus in adult patients with either primary sclerosing cholangitis (PSC) or PBC.
Method: During two clinical studies of the apical sodium-dependent bile acid transporter (ASBT) inhibitor maralixibat: a 13-week randomized double-blind, placebo-controlled study in PBC and a 14-week pilot open-label study in PSC patients, the Adult ItchRO was completed twice daily (morning [AM] and evening [PM]) along with other co-validating measures. Analyses for the exchangeability of the AM and PM ratings were used to establish a score. Scores were examined for reliability and validity. A patient impression of change (PIC) was completed by the PBC study patients and used to establish the minimal clinically important change (MCIC) of the Adult ItchRO. To accommodate different designs, analyses were conducted within both trials.
Results: Data from 61 PBC and 27 PSC patients were eligible for analysis. No differences were observed in patients' AM and PM ratings of the Adult ItchRO, thus a weekly average score of the daily worst itch rating was calculated to align with other NRS. Test retest reliability estimates using a one-week lag and the two-way random intra-class correlation coefficient were 0.93 and 0.98. Convergent validity of the scores in both studies was established with the 5D-Itch Total Score ($r = 0.59$ to 0.95) and PBC-40 Itch domain ($r = 0.51$ to 0.85). The distribution-based analysis of the PBC study to establish a change score that reflected true underlying change in pruritus showed that the MCIC = –1.86. The anchor-based analysis of the PBC study using the PIC showed that the average scores between those rating "No change" versus "A little better" showed that the MCIC = –1.86.
Conclusion: Results from the present analyses demonstrate that the Adult ItchRO is a reliable and valid measure able to detect small changes in pruritus, which are clinically meaningful in patients with cholestatic liver diseases.

Email: cfernandez@fhalcorcon.es

Background and Aims: Obeticholic Acid (OCA), a potent farnesoid X receptor agonist was recently approved for patients with primary biliary cholangitis (PBC) and suboptimal response/intolerance to ursodeoxycholic acid (UDCA). There is limited information on the OCA effectiveness and safety in the real practice setting. Here we present a real world cohort of PBC patients with incomplete response to UDCA therapy. The primary outcomes were the rate of patients achieving response (Paris-2 criteria) and reduction in GLOBE and UK-PBC scores from baseline. Secondary outcome was the OCA effect in non-invasive fibrosis score aspartate transaminase to platelets ratio index score (APRI).

Method: Open-label real practice multicenter study from 19 centers from Spain and Portugal, to assess OCA effectiveness and safety in patients with inadequate response to UDCA (Paris 2 criteria). Data are presented are mean ± standard deviation or median (interquartile range).

Results: One hundred and two patients were included, age 57.1 ± 10.8, females (94.1%), time since PBC diagnosis 11 ± 6.8 yrs., 81 and 59 were AMA and ANA positive (79.4% and 57.8%), respectively. The median F-U: 7.2 months. (IQR: 4.4–12.5). Thirty five patients completed 1 year of OCA treatment (34.3%), alkaline phosphatase (AP) decreased from 273 (IQR: 209–388) to 203 (IQR: 178–266) IU/L ($p < 0.001$), ALT decreased from 42 (IQR: 25–63) to 26 (IQR: 21–38) IU/L ($p < 0.001$). Twenty percent of patients achieved optimal response (Paris 2 criteria), with an alkaline phosphatase decrease of 30%. However, alkaline phosphatase also decreased a 20% in incomplete responders (Figure). APRI score improved from 0.58 (IQR: 0.41–1.01) to 0.49 (IQR: 0.36–0.82) ($p = 0.005$). The UK PBC score improved at 5, 10 and 15 years, from 1.7 (IQR:1.1–4.4), 5.6 (IQR:3.5–14) and 10.1 (IQR:6.4–24.5) to 1.8 (IQR:0.8–3.5), 5.9 (IQR:2.5–11.2) and 10.7 (IQR:4.6–19.7). respectively ($p < 0.01$). However, the GLOBE-PBC score reduction did not reach significance ($p = 0.14$). During OCA treatment, 34.3% developed adverse effects and six patients discontinued OCA treatment (5.9%). At univariate analysis, older age 63 (IQR: 59–69) vs.53 yrs. (IQR: 43–63); $p = 0.03$, lower baseline serum AP 210 (IQR: 163–296) vs. 289 (IQR: 227–454) IU/mL and bilirubin 0.5 (IQR: 0.32–0.52) vs. 0.82 (IQR: 0.5–1.45) mg/dL were associated to complete response (Paris 2 criteria).

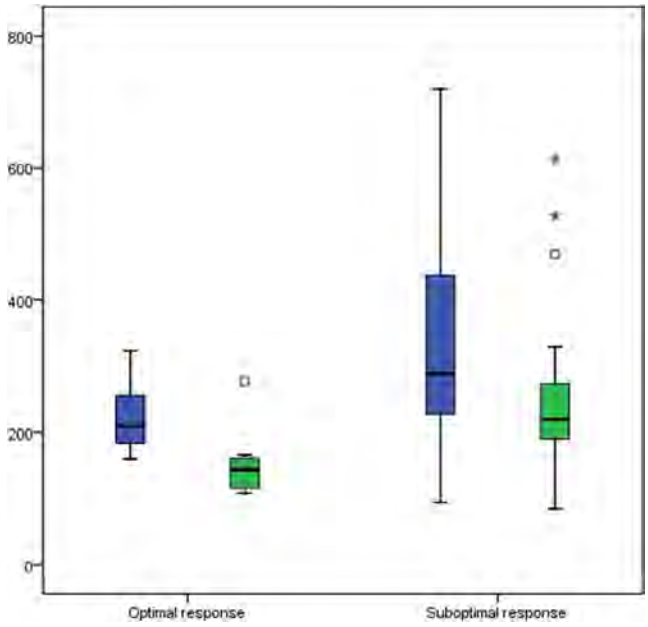

Figure: Values of serum Alkaline Phosphatase in responders and non-responders (Paris-2 criteria) the decrease of AP was a 31% from baseline in responders and a 20% in incomplete responders.

Conclusion: OCA treatment significantly improved the UK-PBC and APRI Scores. In addition, this drug increased the rate of patients who achieved Paris-2 complete response, older age and lower baseline serum bilirubin and AP were significantly associated to complete response. The rate of OCA discontinuation due to adverse effects was low.

FRI133

Durability of treatment response after 1 year of therapy with seladelpar in patients with primary biliary cholangitis (PBC): final results of an international phase 2 study

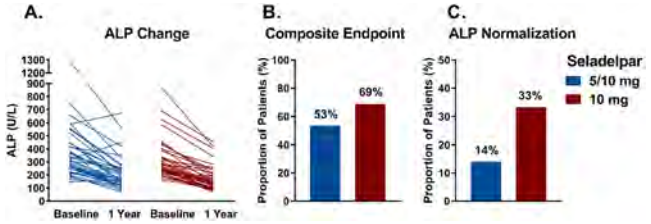
Background and Aims: Seladelpar is a potent and selective peroxisome proliferator activated receptor-delta agonist that has shown improvement in markers of cholestasis in PBC patients. We evaluated the efficacy, safety, and tolerability of seladelpar during 1 year of treatment in patients with PBC.

Method: This was a 1-year, Phase 2, open label uncontrolled dose-finding study in PBC patients with an inadequate response or intolerance to ursodeoxycholic acid (UDCA). Eligible patients had alkaline phosphatase (ALP) ≥ 1.67 × ULN, alanine aminotransferase (ALT) and aspartate aminotransferase (AST) ≤ 3 ULN and total bilirubin (TB) ≤ 2 mg/dL. Patients received oral daily doses of 2, 5 or 10 mg seladelpar; after 12 weeks, doses could be increased up to 10 mg based on biochemical response. The primary endpoint was percent change in ALP. After 1 year, patients were offered a long-term study.

Results: Of 119 PBC patients treated with seladelpar, 112 were evaluated for efficacy [2 mg (N = 11), 5 mg (N = 49) and 10 mg (N = 52)]. At 1 year, no patients remained on 2 mg and no results are presented for this group.

Patients were predominantly female (95.5%), with a mean age of 57.5 ± 9 years, mean duration of PBC 10 ± 7 years, and mean UDCA dose of 15 ± 4 mg/kg/day. Mean baseline values in the 5/10 mg and 10 mg dosage groups were: ALP 353 U/L and 301 U/L, TB 0.76 mg/dL and 0.83 mg/dL, GGT 244 U/L and 239 U/L, and ALT 46 U/L and 46 U/L. After 1 year of treatment, nearly all patients decreased ALP (Figure 1A) with mean decreases of 40% in 5/10 mg and 45% in 10 mg groups. The composite endpoint (ALP < 1.67 × ULN and −15% and TB < ULN) was met in 53% patients in 5/10 mg and 69% in 10 mg (Figure 1B). 14% of patients in 5/10 mg and 33% in 10 mg normalized ALP (Figure 1C). TB was stable over the year. GGT decreased by −34% in 5/10 and −32% in 10 mg. ALT decreased by 31% in both groups. Over 1 year, seladelpar appeared safe, well tolerated, and did not induce pruritus. 14 patients experienced SAEs, all unrelated to the drug. 4 patients discontinued seladelpar due to adverse events, 2 were considered related to the drug (heartburn, Grade 1 and ALT/AST elevation, Grade 2). 98% (104) of eligible patients enrolled in the long-term follow-up study.



Conclusion: In patients with PBC treated for 1 year, seladelpar resulted in a substantial and sustained biochemical response with a good tolerability and safety profile. Seladelpar is being further evaluated in PBC in the Phase 3 ENHANCE study.

FRI134

Hepatocellular carcinoma in patients with autoimmune hepatitis: prevalence and risk factors

Nayana Fonseca Vaz[1], Julia Fadini Margon[1], Bruna Damasio Moutinho[1], Michele Harriz Braga[1], Claudia Megumi Tani[2], Regiane Saraiva de Souza Melo Alencar[2], Lisa Rodrigues da Cunha Saud[2], Denise Cerqueira Paranaguá Vezozzo[1], Marta Deguti[1], Natally Horvat[2], Eduardo Luiz Rachid Cançado[1,3], Flair Jose Carrilho[1,2], Aline Lopes Chagas[1,2], Débora Terrabuio[1]. [1]Hospital das Clínicas da FMUSP, Department of Gastroenterology, São Paulo, Brazil; [2]Instituto do Câncer do Estado de São Paulo, São Paulo Clinicas Liver Cancer Group, São Paulo, Brazil; [3]Institute of Tropical Medicine of São Paulo, Immunopathology and zoonoses, São Paulo, Brazil
Email: nayanafvaz@gmail.com

Background and Aims: The prevalence and risks factors for hepatocellular carcinoma (HCC) occurrence in autoimmune hepatitis (AIH) are unclear. The aims of this study were to describe HCC prevalence in AIH in a tertiary referral hospital as well as clinical, laboratorial and radiological features and treatment outcomes.

Method: Retrospective cohort of AIH patients followed from 2003 to 2019. HCC-free survival was defined as the time interval between AIH and HCC diagnosis or the end of follow up. The hazard ratios (HR) and their respective 95% confidence intervals (CIs) were estimated using the simple Cox regression. A multivariate regression model was fitted using relevant covariates for HCC occurrence. P values < 0.05 were considered significant.

Results: 355 patients, 84.5% female, 85% AIH-1, mean age at diagnosis of AIH 27 ± 18 years, 65% with cirrhosis. Sixteen cases of HCC were diagnosed (4.5%), all of them in cirrhotic patients, 81.3% female, mean age of 49 ± 20 years, 83% overweight (mean BMI 34 ± 5 kg/m^2) and 3 with steatohepatitis. The pooled incidence rate for HCC in patients with AIH was 3.2 per 100 patient-years. The pooled incidence of HCC in patients with cirrhosis at AIH diagnosis was 4.5 per 100 patient-years. The median time between AIH diagnosis and HCC was 9 years (1-42). At univariate analysis the factors associated with HCC risk were age at diagnosis of AIH, platelet count <100 × 10^6/mm^3 (HR,4.77; 95%CI, 1.73–13.17;p = 0.003), presence of portal hypertension at diagnosis, diabetes (HR,3.89; 95%CI, 1.18–12.7;p = 0.025) and disease remission at any time of follow up. At multivariate analysis the factors associated with HCC risk were age at diagnosis (HR,1.05; 95%CI, 1.027–1.083;p < 0.001) and portal hypertension at diagnosis (HR,4.88; 95%CI, 1.49–15.92;p = 0.009). The occurrence of disease remission during follow up was associated with lower risk of HCC occurrence (HR,0.128; 95%CI, 0.043–0.38;p < 0.001). At diagnosis of HCC 62.5% were unique, mean diameter of the largest lesion of 3.5 cm, 50% BCLC 0-A, 37.5% BCLC B and 12.5% BCLC C. Survival at 1 year was 43.7% and at 5 years 6%.

Conclusion: The prevalence of HCC in this cohort was 4.5%. Advanced age at diagnosis, diabetes, platelet count <100 × 10^6/mm^3, presence of portal hypertension at diagnosis and absence of disease remission during treatment were associated with greater risk of HCC. Our study

have the limitations of a retrospective analysis and our findings should be confirmed in other populations.

FRI135

Safety, tolerability, pharmacokinetics and pharmacodynamics of a novel farnesoid x receptor (FXR)-TQA3526 in healthy Chinese volunteers: a double-blind, randomized, placebo-controlled, dose-escalation, food effect phase? study

Jia Xu[1], Hong Zhang[1], Hong Chen[1], Xiaoxue Zhu[1], Zhong-Nan Xu[2], Dandan Huo[2], Haiyan Jia[3], Yanhua Ding[1], Junqi Niu[3]. *[1]The First Hospital of Jilin University, Department of Phase I Clinical Trail, Changchun, China; [2]Chia Tai Tianqing Pharmaceutical Co.Ltd.; [3]The First Hospital of Jilin University, Department of Hepatology, Changchun, China*
Email: dingyanhua2003@126.com

Background and Aims: TQA3526, a novel farnesoid X receptor (FXR)-selective high affinity agonist. The concentration for 50% of maximal effect of TQA3526 for FXR cytoactive is 100 times higher than that of OCA in vitro (3.1 VS 385.0 nM). This Phase I first-in-human study was designed to evaluate the safety, tolerability, PK and PD of TQA3526 in healthy volunteers.

Method: Healthy volunteers aged 18–55 years were enrolled in this study. Part 1 and part 2 were single ascending dose (SAD) (1 mg 2 mg 5 mg and 10 mg) and multiple ascending dose (MAD) (0.2 mg 0.5 mg 1 mg for 10 consecutive days in a titration way) under fasted conditions, and part 3 was a food effect study (10 mg) with 10 days washout period.

Results: TQA3526 was well tolerated in 1 mg 2 mg 5 mg 10 mg fasted SAD group and 0.2 mg 0.5 mg 1 mg MAD group, the most common treatment emergent adverse events (TEAEs) was pruritus, liver ingury and abdominal disorders, which were expected based on its mechanism, and showed a dose-related trend. Fed conditions showed less tolerance compared with fasted conditions.

AUC0-∞ (158.9–2490 h*ng/ml) and Cmax (10.925–120 ng/ml) exhibited a linear increase. Plasma TQA3526 concentrations peaked 2 to 5 hours postdose, median t1/2 ranged from 8.93–16.69 hours, supported QD dosing. The fed group AUC0-∞ (2600.47 h*ng/ml) increased almost 43% compared to the fasted group AUC0-∞ (1817.78 h*ng/ml). Accumulation of TQA3526 was low with accumulation ratios (RAUC) of 1.4. In the MAD study, steady-state conditions were achieved after 5 days of daily dosing.

C4 levels reduced approximately 90% in 24 hours in 1 mg TQA3526 SAD and showed a proportional linear decrease. The MAD result of C4 haven't came out. FGF19 levels increased approximately 2.5-fold in 0.5 mg TQA3526 MAD versus 8.3% 2 degree pruritus, and increased approximately 5-fold in 1 mg TQA3526 MAD versus 33.3% 3 degree pruritus.

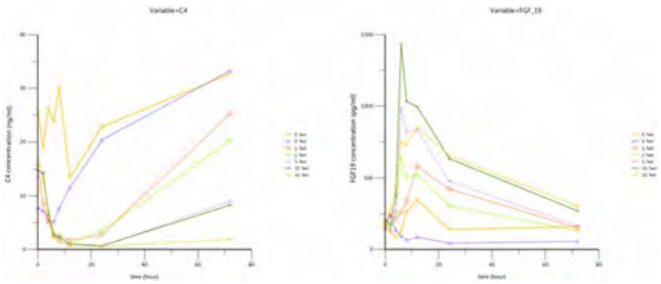


Figure: mean C4 (ng/ml) and FGF19 (pg/ml) plasma concentration-time profiles for the SAD.

Conclusion: TQA3526 was well tolerated at single dose up to 10 mg/d, multiple dose up to 1 mg/d, with a linear pharmacokinetic and pharmacodynamics profile among all subjects, which proved efficient since 0.5 mg.

FRI136

Temporal trends of autoimmune hepatitis related hospitalizations: a descriptive study

Ahmad Khan[1], Nasir Saleem[2], Kamesh Gupta[3], Khadija Naseem[4], Shailendra Singh[5]. *[1]West Virginia University Charleston Division, Charleston, United States; [2]University of Tennessee Health Science Center-Health Sciences Library, Memphis, United States; [3]Baystate Medical Center, Springfield, United States; [4]Services Institute of Medical Sciences, Lahore, Pakistan; [5]CAMC Memorial Hospital, Charleston, United States*
Email: drahmadk83@gmail.com

Background and Aims: Autoimmune hepatitis (AIH) is caused by circulating autoantibodies that result in chronic, inflammatory disease of the liver, which manifests as acute hepatitis and progresses to chronic liver disease and cirrhosis. Our study aims to perform a nationwide survey of the hospitalization trends for AIH through large database analysis.

Method: The National Inpatient Sample (NIS) is the US largest publicly available database to analyze different hospital-related outcomes. We queried NIS from 2008 to 2014 to identify all the hospitalization related to AIH identified with ICD-9 CM code "571.42" as a primary diagnosis and secondary diagnosis. Our primary outcome of interest was to measure the yearly hospitalization rate associated with AIH as a primary and secondary diagnosis. Secondary outcomes included inpatient mortality, length of stay (LOS), inflation-adjusted total hospitalization charges, and complications associated with AIH related hospitalizations such as acute liver failure, acute kidney injury, portal hypertension, need for mechanical ventilation, liver biopsy, and liver transplant.

Results: A total of 11,621 and 78,165 nonelective hospitalizations for adults age above 18 years were recorded between 2008 and 2014 for AIH as a primary diagnosis and secondary diagnosis, respectively. The outcomes were analyzed separately for primary and secondary diagnoses. The prevalence of hospitalizations for AIH increased significantly over the years, from 0.19 to 0.91 for primary diagnosis, and from 1.08 to 5.68 for secondary diagnosis group per 100,000 patients. Mean age was recorded 50 years for primary AIH and 57 in secondary AIH, with the majority comprising of females (81%) in both the groups. A total of 513 (4.41%) patients in the primary and 3,144 (4.02%) in the secondary group died within the same admission. Mean LOS was recorded 6.7 in the primary vs. 5.7 days in the secondary group. Mean total hospitalization charges were found to be higher in the primary group 62,729$ vs. 49,886$). Comparison of major complications in these two groups is as follows, acute kidney injury 1,241 (10.67%) vs. 10,832 (13.85%); acute liver failure 778 (6.69%) vs. 2,180 (2.79%); portal hypertension 2,009 (17.2%) vs. 11,927 (15.25%); mechanical ventilation, 417 (3.5%) vs. 3,470 (4.43%); liver biopsy 3,963 (34.10%) vs. 3,838 (4.9%); liver transplant 394 (3.33%) vs. 476 (0.6%) underwent liver biopsies and liver transplant respectively in the primary AIH group.

Figure: Temporal Trends of AIH related hospitalization rate as a primary and secondary diagnosis

Conclusion: Our study showed that the hospitalization rate of AIH as a primary as well as the secondary diagnosis is on the rise. This can be explained either by improved diagnostic techniques or a real increase in the autoimmune disorders in the general population, which needs to be further evaluated through large prospective cohort studies.

FRI137

Ursodeoxycholic acid reduces cholestatic hepatitis and maternal bile acid levels in intrahepatic cholestasis of pregnancy

Madhumita Premkumar[1], Akash Roy[1], Rohit Mehtani[1], Syed Ahmed[1], Vanita Suri[2], Neelam Aggarwal[2], Radha Krishan Dhiman[1]. *[1]Post Graduate Institute of Medical Education & Research, Chandigarh, Hepatology, Chandigarh, India; [2]Post Graduate Institute of Medical Education & Research, Chandigarh, Obstetrics and Gynaecology, Chandigarh, India*
Email: drmadhumitap@gmail.com

Background and Aims: Intrahepatic cholestasis of pregnancy (ICP) is the commonest pregnancy-related liver disorder, characterized by pruritus without rash and increased serum bile acids (BA) >10 mmol/L. We reviewed the management and outcomes of patients with ICP over a period of 1 year when managed with UDCA.

Table: Maternal characteristics of women with ICP n = 375.

Variable	Entire Cohort (n = 375)	Mild ICP (n = 341)	Severe ICP (n = 34)	Gestational Pruritus (n = 68)*
Maternal Age (years, median/IQR)	26.7 (21.3–33.6)	26.5 (21.6–32.4)	27.4 (22.1–34.3)	26.9 (21.2–32.1)
Gestational age at presentation (weeks)	32 (24–34)	32 (31–35)	26 (24–30)†	29 (25–31)
Prior ICP	161 (42.9%)	143 (41.9%)	18 (26.4%)†	0
Maternal history of ICP	45 (12%)	29 (8.5%)	16 (47%)†	0
Highest bile acid concentration mmol/L (median, IQR)	25 (18–34)	18 (14–29)	98 (49–85)†	5 (2–8)
Medication Usage				
UDCA	375 (100%)	341 (100%)	34 (100%)	54 (79.4%)
Cholestyramine	14 (3.7%)	4 (1.1%)	10 (29.4%)	0
Dexamethasone	33 (8.8%)	24 (7.0%)	9 (26.4%)†	0
Onset of Labour				
Spontaneous	347 (92.5%)	319 (93.5%)	28 (82.3%)	56 (82.3%)
Induced Labour	28 (7.5%)	22 (6.4%)	6 (17.6%)†	12 (17.6%)
Mode of Delivery				
Vaginal	289 (77.0%)	267 (78.2%)	24 (74.8%)	64 (94.1%)
Caesarian section	86 (22.9%)	74	12 (35.2%)†	4 (5.9%)
Neonatal Outcome				
Neonatal Distress	31 (8.2%)	16 (4.6%)	15 (44.1%)†	6 (8.8%)
Still Birth	8 (2.4%)	5 (1.4%)	3 (8.8%)†	0

Abbreviations: IQR, interquartile range, ICP, intrahepatic cholestasis of pregnancy.
†p < 0.05 when mild ICP is compared with severe ICP.

Method: All pregnancies associated with ICP (defined as pruritus with serum bile acids) were prospectively included with analysis of demographics, maternal/perinatal outcomes co-morbidities and treatment response. Mild and severe ICP were diagnosed when serum BA was always <40 mmol/L, and ≥ 40 mmol/L respectively. Patients with gestational pruritus were taken as controls.

Results: Of 643 screened pregnant women, 375(mean age 29 years; 45.8% primigravida) of these patients met diagnostic criteria for ICP. In ICP, incidences of pregnancy induced hypertension (PIH; 10.3%; OR4.8, 95%CI 2.6–9.7, P = 0.043), gestational diabetes (12.5%; OR2.6, 95%CI 2.3–4.1, P = 0.029), and spontaneous preterm labour (15.1%; OR1.8, 95%CI 1.3–2.9, P = 0.034) were higher than in the general pregnant population. Response to UDCA (median daily dose 900 mg; 600–1800 mg) was seen in 79% patients with resolution of pruritus and normalization of liver enzymes. Patients with severe ICP (serum BA>40 mmol/L) presented earlier (26 vs. 32 weeks, P = 0.036), required induction (12%; OR2.1 95%CI 1.8–4.3, p = 0.045) with increased foetal distress than those with mild ICP. (Figure). There were 8 stillbirths.

Conclusion: Our study showed safe maternal outcomes with mild ICP but with persistent risk for stillbirths, pre-term labour, and need for induction in severe ICP. UDCA ameliorated symptoms of cholestasis in 79% patients.

FRI138

Poor diagnostic accuracy of blood igG4/igG RNA ratio for discriminating igG4-related disease from pancreatic or biliary cancer (DIPAC): a prospective cohort study

Elsemieke de Vries[1], Floor Tielbeke[1], Lowiek Hubers[1], Jeltje Helder[1], Nahid Mostafavi[1], Joanne Verheij[2], Jeanin van Hooft[1], Paul Fockens[1], Marc Besselink[3], Niek de Vries[4], Ulrich Beuers[1]. *[1]Amsterdam University Medical Centers, location AMC, Gastroenterology and Hepatology, Amsterdam, Netherlands; [2]Amsterdam University Medical Centers, location AMC, Pathology, Amsterdam, Netherlands; [3]Amsterdam University Medical Centers, location AMC, Surgery, Amsterdam, Netherlands; [4]Amsterdam University Medical Centers, location AMC, Clinical Immunology and Rheumatology, Amsterdam, Netherlands*
Email: e.s.devries@amsterdamumc.nl

Background and Aims: IgG4-related disease (IgG4-RD) of the pancreas and biliary tract is difficult to distinguish from pancreato-biliary cancer. Misdiagnosis may result in unnecessary major surgical interventions or chemotherapy. The blood IgG4/IgG RNA ratio determined by quantitative polymerase chain reaction (qPCR) was reported by us to discriminate IgG4-RD from PSC or biliary and pancreatic cancer with high accuracy[1]. This study aimed to assess prospectively the diagnostic accuracy of blood IgG4/IgG RNA ratio for the differentiation between IgG4-RD and cancer in a cohort of patients with suspicion of pancreatobiliary malignancy.

Method: In this prospective, observational study, all patients presenting at a specialized hepato-pancreato-biliary clinic with suspicion of pancreatobiliary malignancy were included between February and August 2019. The IgG4/IgG RNA ratio was determined in addition to standard diagnostic procedures (threshold 5.0%[1]). In all patients, clinical and laboratory data were collected. Histo- or cytopathological findings were analyzed in patients who underwent a biopsy, brush or surgery of the pancreas or biliary tract and liver. For the diagnosis of IgG4-RD, the HISORt criteria were used as reference standard. Malignancy was defined by the presence of neoplastic cells at histo- or cytopathological examination.

Results: In this interim analysis, 213 consecutive patients were investigated of whom 104 (48.8%) were male and 109 (51.2%) were female with an age of 68 ± 11 years. Three patients were diagnosed with IgG4-RD, in two of these, serum IgG4 was markedly elevated (>14.0 g/L; upper limit of normal 1.4). 175 patients were diagnosed with a malignancy of whom 163 patients with malignant disease of the pancreas or biliary tract (108 pancreatic cancer, 37 cholangio-carcinoma, 11 carcinoma of the papilla of Vater, 7 gallbladder carcinoma). In 3 patients (1.6%), the qPCR test was true positive and in 87 (40.7%) false positive. In 123 (57.5%) patients the test was true negative. The sensitivity of the IgG4/IgG RNA qPCR was 100%, the specificity 59%, the positive predictive 3.3%.

Conclusion: An elevated IgG4/IgG RNA ratio did not accurately discriminate pancreatic and biliary cancer from IgG4-RD as illustrated by low specificity and concordant low positive predictive value. We decided to stop the trial and advise against the use of this test for discrimination of IgG4-RD from pancreatic and biliary malignancies outside a research setting.

Glucuronidation directs systemically available norursodeoxcholic acid (norUDCA) to the kidney

Emina Halilbasic[1], Michael Trauner[1], Peter Fickert[2], Markus Proels[3], Kirsten Hauswald[3], Roland Greinwald[3], Bernhard Tewes[3]. [1]*Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria;* [2]*Medical University of Graz, Division of Gastroenterology and Hepatology, Graz, Austria;* [3]*Dr. Falk Pharma GmbH, R&D, Freiburg, Germany*
Email: bernhard.tewes@drfalkpharma.de

Background and Aims: *Nor*UDCA is a chemically modified bile acid with clinically proven therapeutic potential in cholestatic and metabolic liver diseases. Due to shortening of the side chain, *nor*UDCA is evading the natural bile acid metabolism resulting in a unique pharmacokinetic profile.
Method: Six healthy male volunteers were treated with a single oral dose of 1500 mg [14C]-labelled *nor*UDCA. Plasma pharmacokinetics and excretion of radioactivity in urine and faeces were followed over a period of 264 h. Metabolites found in plasma, faeces and urine were identified and quantified by a combination of radio-chromatography and liquid chromatography with tandem mass spectrometry (LC-MS/MS).
Results: Following oral administration of [14C]-*nor*UDCA, 64% of the radioactivity was excreted with the urine while approximately 30% was recovered from the faeces. *Nor*UDCA accounted for 56% of the circulating plasma total radioactivity and showed maximal plasma concentrations of 37 µg/mL at a Tmax of 4 h and an elimination half-life of 27 h. NorUDCA-23-acylglucuronide (*nor*UDCA-AG) was the main metabolite of norUDCA in plasma and demonstrated similar pharmacokinetics as its parent compound *nor*UDCA. Other metabolites found in plasma resulted from isomerisation of *nor*UDCA and from a combination of glucuronidation and sulfation. The main drug-related compound found in urine was *nor*UDCA-AG, while fecal samples contained mainly unchanged *nor*UDCA.
Conclusion: *Nor*UDCA is absorbed with a high oral bioavailability resulting in a relatively high systemic exposure in plasma. The study demonstrates predominant *nor*UDCA glucuronidation with subsequent urinary elimination. The high systemic exposure suggests that *nor*UDCA could have extrahepatic effects, in particular in the kidney. This could be of potential clinical relevance for jaundiced patients with cholemic nephropathy, in line with pre-clinical evidence (Norursodeoxycholic acid ameliorates cholemic nephropathy in bile duct ligated mice, Krones et al. *J Hepatol* 2017; 67(1):110–119).

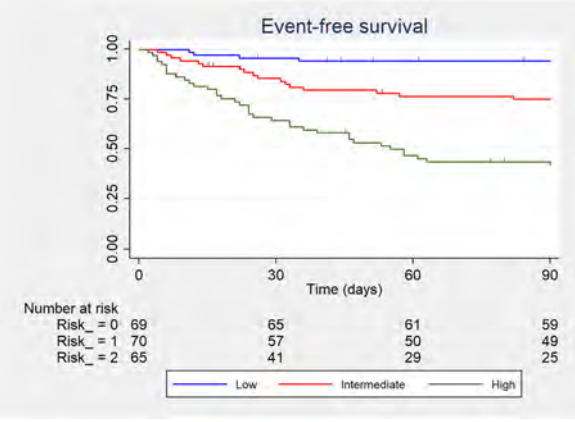
Background and Aims: Acute severe autoimmune hepatitis (AS-AIH) is a disease poorly characterized, with weak evidence-based criteria to guide diagnosis and treatment. The usefulness of corticosteroids in this setting as well as the predictors of response to these drugs remain controversial. In consequence, AS-AIH represents a challenge for liver transplant (LT) clinicians. Aim: To identify predictive factors of response to corticosteroids in patients with AS-AIH.
Method: Multicenter and retrospective study including patients with AS-AIH, defined as an acute presentation of AIH with INR ≥ 1.5 at any time, between 01/01/2002–31/12/2018 at 13 tertiary centers in Spain. A multivariable survival analysis using Cox´s regression model was performed to identify those variables associated with a poor outcome (90 day -overall and -transplant-free survival) and a predictive model was developed to predict response to corticosteroids.
Results: (mean ± SD). 242 consecutive patients were enrolled (female 74,4%), mean age 49,68 ± 16,81 years. 90 days -overall and -transplant-free survival rate was 62,8%. Corticosteroid therapy was significantly associated with a better outcome (adjusted HR: 0.18, IC 95%: 0.11–0.29%). This treatment failed in 59/205 (28.8%) patients (90-day mortality: 15.1%; LT: 15.6%). Factors associated with treatment failure were age, MELD, presence of ascites and hepatic encephalopathy. Based on these data, a **predictive model** was developed: age in years*0.02 points + MELD >25 (1 point) + ascites (0,5 points) + hepatic encephalopathy (EH, 0,25 points). Obtaining <1 point predicted a high probability of response to steroids (90 day – overall and transplant-free survival was 88%), whereas >1.7 points implied a low probability of response (figure 1).



Conclusion: Corticosteroids are a useful treatment for patients with AS-AIH. Older age, MELD and the presence of ascites and hepatic encephalopathy are early predictors of poor response to corticosteroids.

FRI141

Antibodies against glycoprotein 2 and anti-neutrophil cytoplasmic antibodies targeting the serine proteinase 3 are markers of severe primary sclerosing cholangitis (PSC) and progression to cholangiocarcinoma (CCA)

Ewa Wunsch[1], Dirk Roggenbuck[2,3,4], Gary L. Email: ewa.wunsch@gmail.com

Background and Aims: Anti-glycoprotein 2 (anti-GP2, also called anti-MZGP2) and anti-neutrophil cytoplasmic antibodies to serine proteinase 3 (PR3 ANCA) have been linked with inflammatory bowel disease and PSC. In PSC, anti-GP2 IgA has been suggested as a marker of disease severity and poor outcome related to CCA and PR3 ANCA as a marker of disease severity. In this study we assessed the value of anti-GP2 IgA and PR3 ANCA as predictors of progressive disease course and poor outcome in a large cohort of PSC patients.
Method: 338 patients with PSC (age range 17–73, 65% male, 26% cirrhotic, 3.8% developed CCA during follow-up) were prospectively evaluated. Anti-GP2 IgA (isoforms 1 and 4) were detected by ELISAs (GA Generic Assays, Germany) and PR3 ANCA by chemiluminescence immunoassay (Inova Diagnostics, San Diego; using optimized cut-off of 10 units). Poor disease outcome was defined as liver transplantation and/or liver-related death during a median follow-up of 14 months.

	Anti-$GP2_1$ IgA			Anti-$GP2_4$ IgA			PR3 ANCA		
Feature (median)	Neg	Pos	p	Neg	Pos	p	Neg	Pos	p
PLT (ths/ul)	256	209	**0.007**	247	210	NS	229	255	NS
BIL (mg/dl)	0.9	1.6	**<0.001**	0.9	1.7	**0.02**	0.8	1.1	**0.02**
ALP (IU/L)	216	317	**<0.001**	242	225	NS	197	294	**<0.001**
GGT (IU/L)	197	200	NS	204	140	**0.02**	150	213	**0.005**
ALT (IU/L)	76	81	NS	79	68	NS	65	87	**0.007**
AST (IU/L)	57	77	**0.03**	63	62	NS	55	70	**0.003**
ALB (g/dl)	4.2	3.9	**<0.001**	4.2	4.0	**0.001**	4.2	4.1	NS
INR	1.0	1.1	**<0.001**	1.0	1.1	**0.005**	1.0	1.1	**0.01**

Results: Anti-$GP2_1$ IgA occurred in 79 (23%), anti-$GP2_4$ IgA in 58 (17%), and anti-$GP2_1$ and/or anti-$GP2_4$ IgA in 103 (30%) patients. PR3 ANCA positivity rate was 54.5%. Anti-GP2 IgA and PR3 ANCA were associated with poor liver function (Tab. 1). Cirrhosis was associated with anti-$GP2_4$ IgA ($p = 0.003$). CCA occurred more often in patients with anti-$GP2_1$ IgA ($p = 0.04$) and PR3 ANCA ($p = 0.008$). 100% of CCA patients were positive for PR3 and/or anti-GP2 IgA. Significant associations between anti-$GP2_1$ IgA, anti-$GP2_4$ IgA, PR3 ANCA and poor outcome were found ($Chi^2 = 11.2$, HR = 2.1, 95%CI = 1.4–4.2, $p = 0.0008$; $Chi^2 = 7.8$, HR = 2.4, 95%CI = 1.3–4.5, $p = 0.005$; $Chi^2 = 6.87$, HR = 1.8, 95%CI = 1.2–2.8, $p = 0.009$; respectively). Cox proportional-hazards regression indicated anti-$GP2_1$ IgA and lower albumin level as independent variables of poor outcome ($p < 0.0001$), while anti-$GP2_4$ IgA and PR3 ANCA were independent risk factors of CCA ($p = 0.0019$).
Conclusion: Anti-GP2 IgA/PR3 ANCA identify a subgroup of PSC patients at risk of poor outcome, more aggressive course, and biliary cancer. These antibodies may be of prognostic value in PSC.

Analysis of 1,776 patients with primary sclerosing cholangitis from a laboratory database

Friedrich Mittermayer[1], Stephen Jones[2], Michelle Jones[3], Claudia Filozof[4]. [1]*Covance GmbH, Science/Medicine, Vienna, Austria;* [2]*Covance Clinical and Periapproval Services Limited, Operational Strategy&Planning, Maidenhead, United Kingdom;* [3]*Covance Clinical and Periapproval Services Limited, Clinical Informatics, Maidenhead, United Kingdom;* [4]*Covance Clinical Development SA, Science/Medicine, Madrid, Spain*
Email: friedrich.mittermayer@covance.com

Background and Aims: The ICD-10 is an international standard for defining and reporting diseases and health conditions. Most of the epidemiologic data available in Primary Sclerosing Cholangitis (PSC), a rare cholestatic liver disease, originate from a period before the new ICD 10 code K83.01 was available. The aim of the current analysis was to evaluate laboratory and comorbidities data from patients with this PSC specific ICD 10 code.
Method: A clinical laboratory database maintained by LabCorp® was utilized to assess laboratory data of 1776 PSC patients from the United States who were seen by a health care provider between 1 Oct 2018 and 31 Aug 2019. The earliest complete assessment per patient was included in the analysis if more than one was present.
Results: The mean age of the patients was 49 years (0–92 yrs, SD 18), 44.1% were female. Alkaline phosphatase (ALP) levels were elevated in 69.7% and were >1.5 × ULN in 52.7% of the patients. Inflammatory bowel disease was reported in 25.7% (ulcerative colitis 19.0%, Crohn's disease 6.7%). Other concomitant diagnoses with a frequency >5% were fibrosis and cirrhosis of the liver (10%), abnormal serum enzyme levels (6.4%), other inflammatory liver disease (IBD, 6.1%) and abnormal results of function studies (5.7%). A comparison between female and male patients (mean age 51 vs. 47 years) revealed a higher prevalence of ulcerative colitis in males (21.6% vs. 15.7%) and a slightly higher rate of reported fibrosis and cirrhosis of the liver in males (10.8% vs. 8.9%). ALP and other laboratory parameters were comparable between the sexes. Patients with IBD had a lower rate of reported fibrosis and cirrhosis of the liver (7.2 vs. 10.9%). This was mainly attributable to a lower rate in patients with Crohn's disease compared to patients without Crohn's disease (4.2 vs. 10.4%). The highest prevalence of fibrosis and cirrhosis of the liver was seen in patients with concomitant autoimmune hepatitis (16.3 vs. 9.6%).
Conclusion: A lower rate of fibrosis and liver cirrhosis in PSC patients with concomitant Crohn's disease is consistent with previous reports. Additional analysis of the reasons for a higher proportion of women with PSC in this database than the one reported in other studies is warranted. Availability of a large clinical laboratory database may add value when assessing PSC patient characteristics.

FRI143

The treatment response and corticosteroid therapy was predicted by GGT, chol, and fibrosis in patients of PBC-AIH overlap syndrome: a real-world study

Xiaoli Fan[1], Ruoting Men[1], Zhichao Hu[1], Yi Shen[1], Tinghong Ye[1], Li Yang[1]. [1]*West China Hospital, Sichuan University, Chengdu, Sichuan 610041, China, Department of Gastroenterology & Hepatology, chengdu, China*
Email: menruoting@wchscu.cn

Background and Aims: The aim of this study was to elucidate the response to corticosteroid therapy and the associated factors in

primary biliary cholangitis- autoimmune hepatitis (PBC–AIH) overlap syndrome.
Method: A cohort study was performed to evaluate the treatment response to immunosuppressive therapy and ursodesoxycholic acid (UDCA) combination in this unique group. This cohort study was performed by a retrospective analysis of prospectively documented data between October 2013 and January 2019 and included 101 patients. The primary endpoints were treatment response at 6 months. Logistic regression analysis was performed to identify factors significantly associated with treatment response.
Results: 55.4% of patients did not respond to treatment. The baseline values of serum total bilirubin, alkaline phosphatase, gamma-glutamyl transpeptidase (GGT), globulin, IgG, cholesterol (CHOL) and positivity for anti-mitochondrial antibody differed significantly between the responders and non-responders ($P < 0.05$). After multivariate analysis, high GGT levels ($P = 0.036$; odds ratio = 1.003), high CHOL levels ($P = 0.005$; odds ratio = 1.639) and presence of cirrhosis ($P = 0.005$; odds ratio = 6.424) were associated with lack of response to corticosteroid therapy. The responders have a better liver-related adverse event-free survival, compared with non-responders according to the Kaplan-Meier estimate (Log-Rank: $p < 0.001$). Second-line immunosuppressive agents (mainly mycophenolate mofetil and tacrolimus) led to biochemical remission in 65.0% of patients who did not respond to initial immunosuppression.

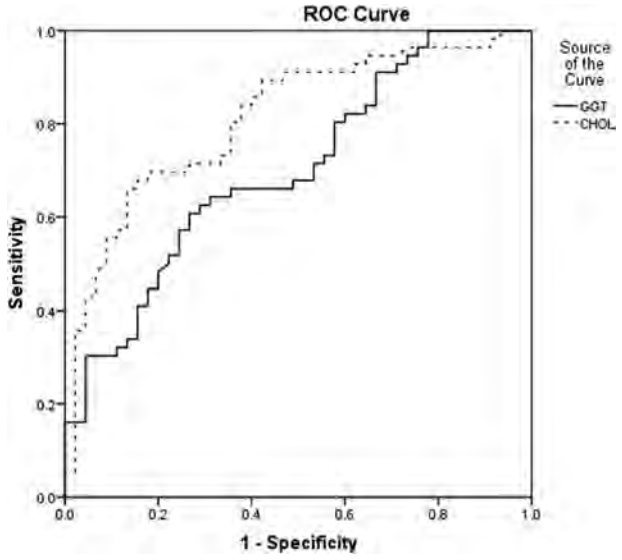

Figure 1: GGT and CHOL values showed high predictive accuracy of non-response (AUROC 0.701, 95% CI: 0.600, 0.802; AUROC 0.812, 95% CI: 0.728, 0.896; respectively), with the optimal cutoff at entry as 398 umol/L and 6.225 g/L, respectively.

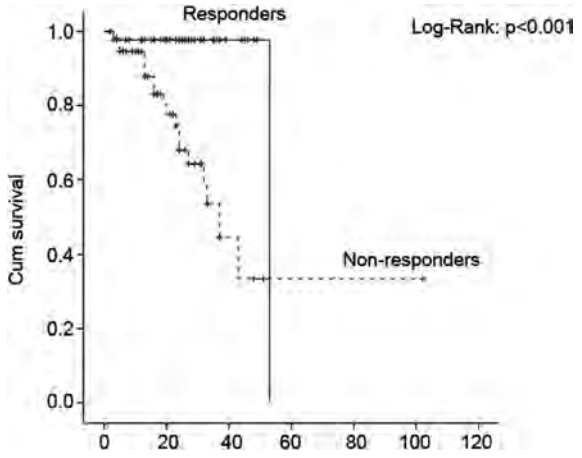

Figure 2: Kaplan–Meier analysis revealed that responders had a significantly higher liver-related adverse events-free survival rate than non-responders (Log-Rank: $p < 0.001$).

Conclusion: 55.4% of patients of PBC-AIH overlap showed poor response to corticosteroid therapy in a university hospital, and high GGT levels, high CHOL levels, and presence of cirrhosis were associated with lack of response to corticosteroid therapy. Early identification of no-response may allow timely intervention to prevent clinical deterioration. Second-line immunosuppressive agents lead to 65.0% of response.

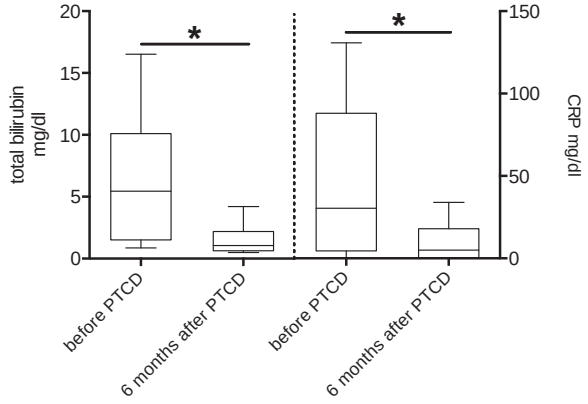
Risks and benefits of percutaneous transhepatic cholangiodrainage in patients with primary sclerosing cholangitis

Gustav Buescher[1,2], Christina Villard[3], Annika M Bergquist[4], Taotao Zhou[5], Tobias Weismüller[5], Miriam Wiestler[2,6], Hanno Ehlken[7], Thomas Rösch[7], Samuel Huber[1,2], Ansgar W. Lohse[1,2], Christoph Schramm[1,2,8], Marcial Sebode[1,2]. *[1]University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany; [2]European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Hamburg, Germany; [3]Karolinska University Hospital, Division of Liver Surgery, Department of Upper GI Diseases, Stockholm, Sweden; [4]Karolinska Institutet, Department of Medicine Huddinge, Unit of Gastroenterology and Rheumatology, Stockholm, Sweden; [5]University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany; [6]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [7]University Medical Center Hamburg-Eppendorf, Department of Interdisciplinary Endoscopy, Hamburg, Germany; [8]Martin Zeitz Centre for Rare Diseases, University Hospital Hamburg-Eppendorf, Hamburg, Germany*
Email: g.buescher@uke.de

Background and Aims: Endoscopic retrograde cholangiography (ERC) is the method of choice to treat biliary strictures in patients with primary sclerosing cholangitis (PSC). However, in a subgroup of PSC patients, biliary stenoses are complex and endoscopic biliary drainage cannot be established using ERCP. There is no generally accepted recommendation how to proceed in this situation, highlighting a severe lack of data. The aim of this study was to investigate in a multicentre study the risks, benefits and clinical outcomes of PSC patients after percutaneous transhepatic cholangiodrainage (PTCD).
Method: In this retrospective study medical records were reviewed for clinical data including laboratory results, previous endoscopic interventions and intervention-related complications.
Results: A total of 37 PSC patients who underwent PTCD were identified. Strictures were localised in the common bile duct (CBD) in most of the cases (CBD = 51.4%; bifurcation = 16.2%; left = 13,5%; right = 2,7%; multiple = 16.2%). Liver cirrhosis was present in 14 patients (37.8%) with a median MELD score of 16 at the time of first PTCD. In most cases jaundice (51.2%) was the indication for PTCD, followed by recurrent bacterial cholangitis (16.3%), suspected cholangiocarcinoma (CCA, 16.3%) and pruritus (11.6%). Mild periinterventional complications occurred in 20 patients (54%; 19x bacterial cholangitis, 1x pancreatitis). Severe complications in three patients (bile duct perforation, dislocation of catheter, pleural puncture) resolved without sequelae. Overall total bilirubin and CRP levels significantly decreased six months after PTCD (Fig. 1). Pruritus improved in four of five patients after PTCD.



Conclusion: To our knowledge, this is the first multicentre study investigating clinical outcomes of PSC patients undergoing PTCD. The procedure was generally safe and mild complications prevailed. PTCD for PSC patients is effective by amending jaundice and pruritus and by improving biochemical signs of cholestasis and inflammation. These results indicate that PTCD should not be withheld from PSC patients lacking endoscopic options for biliary drainage.

Email: gatselis@me.com

Background and Aims: Antimitochondrial antibodies (AMA) are specific for primary biliary cholangitis (PBC) diagnosis but can also be found in patients with autoimmune hepatitis (AIH). The present large multicenter study assessed the prevalence and significance of AMA in AIH-patients.

Method: 191 AMA (+) AIH-patients were investigated compared to 699 age- and sex-matched AMA (−) AIH-patients. The total number of AIH-patients followed at each center was used for evaluation of AMA prevalence. A subgroup of 774 patients with available liver biopsy was classified according to AMA and PBC histological characteristics: group A: 441 AMA (−)/Hist. (−); group B: 164 AMA (−)/Hist.(+); group C: 83 AMA (+)/Hist.(−); group D: 86 AMA (+)/Hist. (+).

Results: AMA prevalence in AIH-patients was 10.5% (range 3.7%–16.3%). Comparison of 4 groups revealed that itching was mainly associated with the presence of PBC histological characteristics (14.5% vs 32.3% vs 27.7% vs 26.7%, respectively, $p < 0.001$). Alkaline phosphatase levels (xULN) were higher in AIH-patients with PBC histological characteristics irrespective of AMA presence [1.1 (0.8) vs 1.3 (1.3) vs 1.3 (1) vs 1.4 (2), respectively, $p < 0.001$]. Anti-sp100 (3.3% vs 11.4% vs 8% vs 28%, $p < 0.001$) and anti-gp210 positivity (1.3% vs 2.9% vs 8.3% vs 21.7%, respectively, $p < 0.001$) were significantly higher in AMA (+) AIH-patients with PBC histological characteristics. AMA positivity was associated with the presence of florid duct lesions (OR 5.1, 95%CI 2.8–9.2, $p < 0.001$) and ductopenia (OR 3.3, 95%CI 1.5–8.1, $p < 0.01$). Response to immunosuppression or UDCA was similar among groups. Progression to cirrhosis during follow-up was associated only with the presence of PBC histological characteristics (HR 2.1, 95%CI 1.2–3.5, $p < 0.01$ group B; HR 1.5, 95%CI 0.7–3.2, $p = 0.3$ group C; HR 3.2, 95%CI 1.8–5.7, $p < 0.001$ group D, compared to group A respectively), while similar survival rates were found among groups. During follow-up, AMA (+) AIH-patients had higher risk to develop PBC histological characteristics (HR 3.6, 95%CI 1.4–9.3, $p < 0.01$), while resolution of PBC histological characteristics was not associated with AMA presence ($p = 0.3$).

Conclusion: AMA presence is common among AIH-patients, but their clinical significance appears to be important only when they co-exist with characteristics of PBC at the histological level. Therefore, a careful evaluation of liver biopsy for cholestatic lesions seems of outmost importance in these patients. [on behalf of International AIH Group]

FRI146

Durability of biochemical improvements through six years of open label treatment with obeticholic acid in patients with primary biliary cholangitis who did not achieve the poise criteria

Gideon Hirschfield[1], Marco Carbone[2], David Jones[3], Bettina Hansen[1], Andreas E Kremer[4], Michael Trauner[5], Alexander Liberman[6], Elizabeth Smoot Malecha[6], Leigh MacConell[6]. *[1]Toronto General Hospital, Toronto Centre for Liver Disease, Toronto, Canada; [2]University of Cambridge, Academic Department of Medical Genetics, Cambridge, United Kingdom; [3]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; [4]Friedrich-Alexander-University Erlangen-Nürnberg, Department of Medicine I, Erlangen, Germany; [5]Medical University of Vienna, Vienna, Austria; [6]Intercept Pharmaceuticals, Inc., San Diego, United States*
Email: gideon.hirschfield@uhn.ca

Background and Aims: In various clinical studies and in daily clinical practice, response to primary biliary cholangitis (PBC) treatment has been assessed using dichotomous biochemical response criteria. While achieving these response criteria may be associated with improved clinical outcomes, they may underestimate the benefit in patients who have an incomplete response to treatment. The objective of this analysis was to assess the extent and durability of obeticholic acid (OCA) in patients with PBC who did not achieve the dichotomous primary endpoint criteria in the phase 3 POISE study through 72 months of OCA treatment.

Method: Key inclusion criteria included PBC diagnosis, alkaline phosphatase (ALP) ≥ 1.67 × upper limit of normal (ULN) and/or total bilirubin >ULN to <2 × ULN, and on a stable dose of—or intolerant of—UDCA. During the 12 month double-blind phase, 216 patients were randomized to daily placebo, OCA 5–10, or OCA 10 mg. This analysis pooled double-blind placebo (OCA baseline was OLE day 0) and double-blind OCA patients to evaluate the efficacy and safety of up to 72 months of OCA treatment. This analysis excludes subjects who

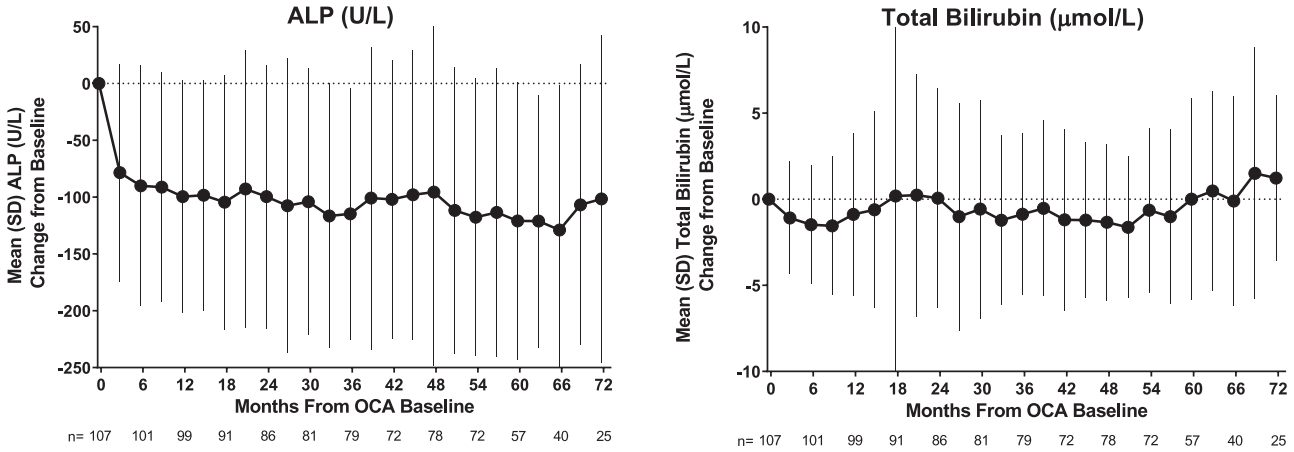

Figure 1: (abstract: FRI146): Change From Baseline in ALP and Total Bilirubin through 72 Months of OCA Treatment

achieved the POISE primary endpoint (ALP <1.67 × ULN, with a reduction of ≥ 15% from baseline, and total bilirubin ≤ ULN) 12 months from OCA Baseline. Values shown are mean (SD) unless otherwise specified. P-values were based on paired t-tests.

Results: One hundred and ninety-three patients enrolled in the OLE of which 107 patients (55%) did not achieve the POISE criteria after 12 months of OCA treatment. Patients were 93% female, 91% Caucasian, 56 (10) years of age at baseline and 91% received UDCA (15 [4] mg/kg/day). At baseline, ALP was 356 (138) U/L and total bilirubin was 13 (8) µmol/L (elevated above ULN in 18 patients [17%]). Despite not achieving the POISE criteria after 12 months of OCA, a significant and durable reduction was observed in ALP ($p < 0.01$ at all time points) through the duration of 72 months of treatment (figure 1). Total bilirubin levels remained stable and near baseline values within the normal range through the duration of treatment. Through the 6-year study period, the most commonly occurring adverse events were pruritus (92 patients [86%]) and fatigue (33 patients [31%]) consistent with previous reports from POISE and expected PBC symptoms.

Conclusion: Despite the fact that these patients did not achieve the POISE primary endpoint, significant and sustained biochemical improvements were observed.

FRI147

Enhanced liver fibrosis test and liver stiffness variation over time in a prospective cohort of primary sclerosing cholangitis patients

Guri Fossdal[1,2,3], Kristine Wiencke[1,4,5], Ida Bjørk[6], Lasse Gil[3], Trine Folseraas[1,4,5], Tom Hemming Karlsen[1,4,5], William Rosenberg[7], Mette Vesterhus[1,2,3]. *[1]Norwegian PSC Research Center, Department of Transplantation Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [2]Department of Clinical Science, University of Bergen, Bergen, Norway; [3]Department of Medicine, Haraldsplass Deaconess Hospital, Bergen, Norway; [4]Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [5]Research Institute of Internal Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [6]Department of Radiology, Oslo University Hospital Rikshospitalet, Oslo; [7]UCL Institute for Liver and Digestive Health, University College London & Royal Free London NHS Foundation Trust, London, United Kingdom*
Email: mette.namdal.vesterhus@haraldsplass.no

Background and Aims: The clinical presentation, liver biochemistry fluctuations and progression of primary sclerosing cholangitis (PSC) is highly variable and there is a need to establish prognostic tools. The Enhanced Liver Fibrosis (ELF) test and liver stiffness measurements (LSM) have both demonstrated strong predictive abilities/association with transplant-free survival in PSC, which was validated in independent studies; however, whether ELF and LSM fluctuate and how they vary over time is not well described. We aimed to characterize ELF and LSM variation over time in a prospective PSC cohort.

Method: We included 120 non-transplant PSC patients (90 males [75%]; mean age 43.7+/−15.4 years; n = 87 [72.5%] had inflammatory bowel disease [IBD]) followed prospectively at annual study visits between 2013 and 2019 in the Norwegian PSC Research Center prospective cohort. ELF test, clinical data, liver biochemistries and liver stiffness measurement (LSM) by point shear wave elastography were included from all available visits. Revised Mayo risk score was calculated using the published algorithm. We performed statistical analysis using a generalized mixed model in STATA version 16.0.

Results: At baseline, PSC patients were characterized by mean ELF of 9.46+/−1.17 and median LSM of 1.25 m/s (range 0.66–3.04 m/s). ELF score was significantly higher (10.67 vs 9.11; $p < 0.001$) in patients with advanced (F3-F4; LSM >1.79 m/s; n = 24) compared to mild-moderate fibrosis (n = 92) as defined by LSM applying published cutoff values for transient elastography. ELF increased significantly over time (0.06 per year, CI [0.01, 0.10], $p = 0.013$), with an intraclass correlation (ICC) of 0.76, indicating that 76% and 24% of ELF variation was explained by between- and within-patient effects, respectively. LSM increased over time ($p = 0.04$) with a larger influence of within-patient effects (ICC 0.53). ELF, but not ALP, was associated with LSM variation. In multivariate analysis of longitudinal data, ELF test was more strongly associated with Mayo risk score than ALP and LSM.

Conclusion: ELF test and LSM increased during 5-year follow-up in PSC, with a stronger effect of between-patient variation for ELF than for LSM. Both between- and within-patient effects of ELF were associated with Mayo risk score and ELF test was more strongly associated with Mayo risk score compared to LSM and ALP. Our results may indicate that ELF is a more robust predictor in PSC compared to LSM.

FRI148

An international perspective on cholestatic pruritus in primary biliary cholangitis (PBC)

Helen Smith[1], April Thompson[2], Megan McLaughlin[3], Fabrice Dussol[4], Lauren Quast[4], Claire Macchia[4], Caroline Mathie[4]. *[1]GSK R&D, London, United Kingdom; [2]GSK R&D, North Carolina, United States; [3]GSK R&D, Collegeville, United States; [4]The Planning Shop, London, United Kingdom*
Email: helen.t.smith@gsk.com

Background and Aims: This survey of physicians treating patients with PBC and cholestatic pruritus aimed to provide information about the presentation and severity of pruritus and its management in clinical practice and the broader symptom burden of PBC internationally.

Method: This was a multinational survey of 68 Gastroenterologists and Hepatologists across US, Germany, China and Japan (funded by GSK). Participating physicians were asked to complete 3 patient record forms (PRFs) for patients with PBC and cholestatic pruritus, including ≥ 1 receiving a second line PBC treatment.
Results: Completed PRFs were provided for 164 patients; 83 in the US, 33 in Germany, 29 in China and 19 in Japan. The majority of patients (81%) were over 40 yrs. Patients in Japan were notably older than in other countries.
Overall 69% of patients were reported to have intermittent pruritus and 31% chronic pruritus. The proportion with chronic pruritus was highest in China (38%) and lowest in Japan (16%). Patients with chronic pruritus tended to be younger. The majority of patients had mild (48%) or moderate (46%) pruritus with only 6% reported to have severe pruritus. Patients with severe pruritus were younger than those with mild or moderate pruritus; in this sample no patients over 60 yrs had severe pruritus and older patients (71+ yrs) all had mild pruritus.
Fatigue was consistently the most reported other symptom in this sample of patients (70%). The reported symptom profile was similar in US and Germany. Fewer symptoms were reported for Japanese patients and the China symptom profile was notably different with a higher report of jaundice (76%) compared to other countries (11–21%). Presence of other symptoms tended to be higher in patients with more severe pruritus, in particular; dry eyes, emotional stress, jaundice, sleeping difficulties and dry mouth.

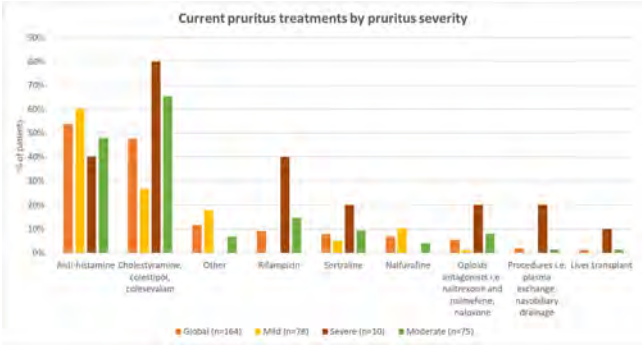

Figure: Current pruritus treatment by pruritus severity.

Overall cholestyramine and anti-histamines were the most common pruritus treatments; except in Japan where patients were prescribed nalfurafine or anti-histamine. Patients with mild pruritus were more commonly treated with anti-histamine and to a lesser extent cholestyramine (Figure), whereas more severe patients were more likely to receive all the treatments (except anti-histamine) and receive multiple treatments. The mean number of treatments (class) concurrently prescribed per patient by pruritus severity was 1.22 mild, 1.59 moderate, and 2.30 severe, and by country 1.59 US, 1.12 Germany, 1.72 China and 1 Japan.
Conclusion: This international survey of physicians identified notable differences in both the presentation and the management of cholestatic pruritus in patients with PBC internationally. These data underscore the burden of cholestatic pruritus in PBC, particularly for those patients with severe pruritus. Regardless of pruritus severity most patients with pruritus also suffer with fatigue.

FRI149
Magnetic resonance imaging features of primary biliary cholangitis
Ilkay S. Idilman[1,2], Sandeep Venkatesh[3], John Eaton[4], Candice Bolan[5], Karim Osman[4], Daniel Maselli[4], Christine Menias[6], Sudhakar Venkatesh[2]. [1]*Hacettepe University, School of Medicine, Radiology, Turkey;* [2]*Mayo Clinic, Radiology, United States;* [3]*Sengkang General Hospital, Radiology, Singapore;* [4]*Mayo Clinic College of Medicine, Division of Gastroenterology and Hepatology, United States;* [5]*Mayo Clinic, Radiology, Jacksonville, United States;* [6]*Mayo Clinic, Radiology, Scottsdale, United States*
Email: venkatesh.sudhakar@mayo.edu

Background and Aims: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease characterized by slow progression of cholestasis and the development of liver fibrosis. Imaging features described in the literature were nonspecific till the first specific imaging finding "periportal halo sign" was described. In this study, we aimed to evaluate MRI features of the liver in PBC patients in a large cohort and also correlate the features in a subgroup of patients with histological findings on liver biopsy performed within 6 months of MRI studies.
Method: We conducted a multicenter retrospective review on 283 patients with PBC who underwent an MRI. MRI studies were reviewed by two abdominal radiologists in consensus for liver morphology, signal intensity, post-contrast enhancement and signs of decompensation. Liver and spleen volumes and normalized liver apparent diffusion coefficient (nlADC) were also calculated. MRI features were correlated with fibrosis stage among a subset of patients who had a liver biopsy within 6 months (n = 72).
Results: The study population comprised of 253 (89%) females and a mean ± SD age of 59.4 ± 11.8 years. Lymphadenopathy (78.1%), periportal hyperintensity (36.7%), and periportal halo sign (27.6%) were most common features. A positive correlation was found between fibrosis stage and spleen size ($r = 0.457$, $p < 0.001$), spleen volume ($r = 0.557$, $p < 0.001$) and portal vein diameter ($r = 0.287$, $p = 0.013$) and a negative correlation with nlADC ($r = -0.332$, $p = 0.011$). Fibrosis stage also correlated with presence of surface nodularity ($p < 0.001$), periportal halo sign ($p = 0.04$), collaterals ($p = 0.033$) and splenomegaly ($p = 0.002$). No significant differences in nlADC values were found in different fibrosis stages. The periportal halo sign was present in only patients with significant fibrosis. None of the MRI features significantly correlated with inflammation grade.
Conclusion: In PBC, presence of periportal halo sign correlates with significant fibrosis. Heterogeneous T2W intensity, heterogeneous post-contrast enhancement, spleen size, spleen volume correlate with fibrosis stages and may be useful for predicting advanced fibrosis.

FRI150
Comparison of liver stiffness measurement with MRE and liver and spleen volumetry for prediction of disease severity and hepatic decompensation in patients with primary sclerosing cholangitis
Ilkay S. Idilman[1,2], Hsien Min Low[3], Zeinab Bakhshi[4], John Eaton[4], Sudhakar Venkatesh[2]. [1]*Hacettepe University, School of Medicine, Radiology, Turkey;* [2]*Mayo Clinic, Radiology, United States;* [3]*Tan Tock Seng Hospital, Radiology, Singapore;* [4]*Mayo Clinic College of Medicine, Division of Gastroenterology and Hepatology, United States*
Email: venkatesh.sudhakar@mayo.edu

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic liver disease characterized with bile duct inflammation and fibrosis leading to cholestasis and parenchymal injury. The aim of this study was to evaluate liver stiffness measures (LSM) with magnetic resonance elastography (MRE) and volumetry measurements of liver and spleen and their correlation with disease severity and prediction of hepatic decompensation.
Method: This retrospective study was approved by the institutional review board. Magnetic resonance imaging (MRI) and MRE studies were reviewed and mean liver stiffness of entire liver, right lobe and left lobe, total liver, right lobe, left lobe, caudate lobe and spleen volumes were calculated. Qualitative evaluation of lobar atrophy or hypertrophy and presence of macronodular regeneration (MNR) was recorded. Univariate and multivariate analyses were performed to predict hepatic decompensation.

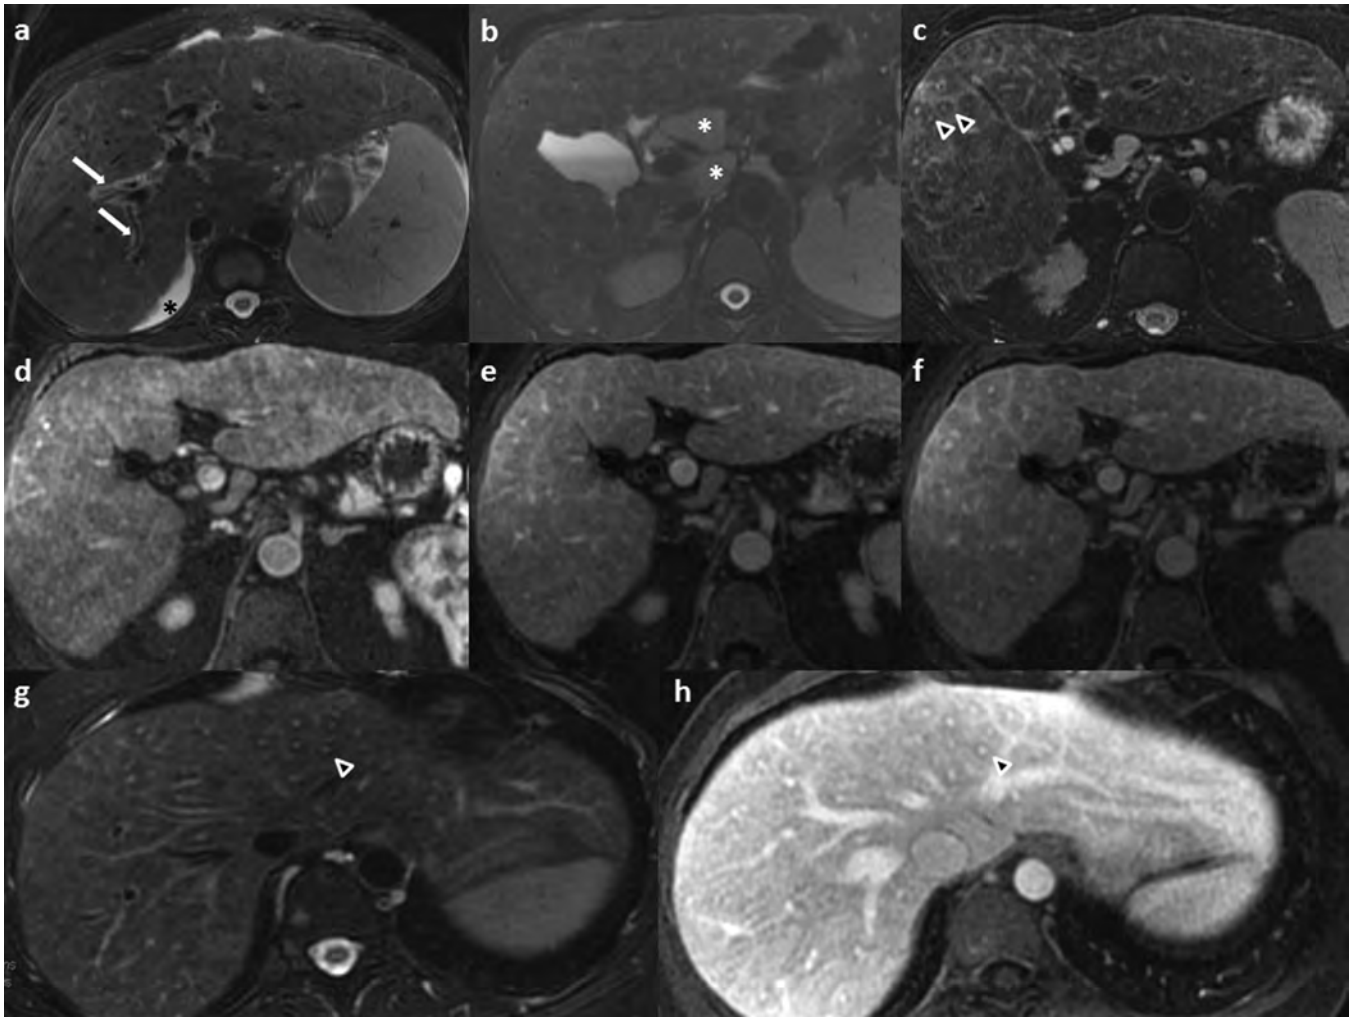

Figure 1: (abstract: FRI149): Typical MRI findings in PBC illustrated with examples from different patients. (a) A T2W image in a patient with stage 4 fibrosis shows periportal hyperintensity and T2 signal heterogeneity of the liver parenchyma. Ascites (*) and surface nodularity is also seen. (b) Enlarged lymph node (*) in the portal hilum is seen on T2W image of a different patient with stage 3 fibrosis. Images from another patient with stage 4 fibrosis demonstrating heterogeneity and periportal halo sign (arrow-heads) on T2W image (c), heterogeneity on post-contrast arterial phase (d), portal venous phase (e) and delayed phase images (f). A patient with periportal halo sign on T2W image (g) and post-contrast venous phase image (h) (arrow heads).

Results: A total of 266 patients with PSC were included in the study. Lobar stiffness measures were higher in the presence of relative lobe atrophy. Mean LSM was higher in the presence of MNR. Significant correlations were observed between mean LSM and volumetry measurements with a fair correlation between LSM and spleen volume ($rs = 0.526$, $p < 0.0001$). Among the measurements, the best correlation was observed between mean LSM and Mayo risk score ($rs = 0.646$, $p < 0.0001$). In the multivariate analyses, mean LSM and Mayo risk score were significantly associated with the liver decompensation (hazard ratio, 1.18; 95% CI, 1.02–1.36 and hazard ratio, 1.65; 95% CI, 1.08–2.53, respectively).
Conclusion: LSM with MRE performs significantly better than liver and spleen volumes for prediction of both disease severity and hepatic decompensation.

FRI151

The inter-relationship between primary sclerosing cholangitis and socioeconomic status

Jessica Dyson[1,2], Alasdair Blain[3], Mark Shirley[4], Mark Hudson[1,2], Steven Rushton[4], David Jones[1,2]. *[1]Newcastle upon Tyne Hospitals NHS Foundation Trust, Liver Unit, Newcastle upon Tyne, United Kingdom; [2]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; [3]Newcastle University, Wellcome Centre for Mitochondrial Research, Institute of Neuroscience, Newcastle upon Tyne, United Kingdom; [4]Newcastle University, School of Natural and Environmental Sciences, Newcastle upon Tyne, United Kingdom*
Email: jessicadyson@doctors.org.uk

Background and Aims: Disease clustering in primary sclerosing cholangitis (PSC) is seen in less socioeconomically deprived areas. This study aimed to explore which components of socioeconomic status either drive disease or may protect against it.
Method: All patients with PSC ($n = 472$) in a defined geographical region within England were identified using multi-source case-finding methodology. Besag-York-Mollie models were used to estimate relative risk in postcode districts and fitted with measures of social deprivation. A greater Townsend Score implies greater deprivation. A lower Index of Multiple Deprivation (IMD),

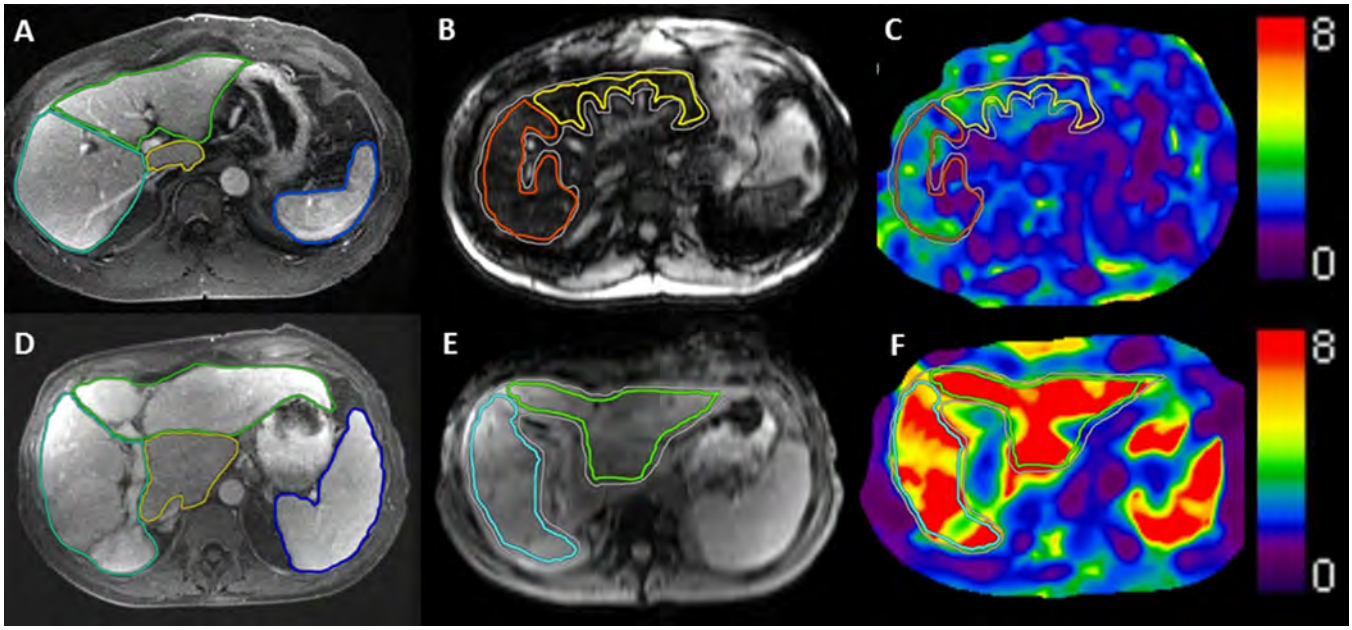

Figure 1: (abstract: FRI150): Axial post contrast T1 weighted image in the portal venous phase and MRE sequences showing the morphological and elastogram differences between 2 patients. The top row shows a 45 year old female patient with mild PSC (Mayo risk score –0.25) with right lobe volume (turquoise outline) was 986 ml, left lobe volume (green outline) was 409 ml and the caudate lobe volume (yellow outline) was 33 ml. The spleen volume (dark blue outline) measured 205 ml (Figure 1A). Figure 1B shows the magnitude image of the elastogram with ROIs for the total liver stiffness (white line), right lobe stiffness (orange line) and the left lobe (green line). The corresponding ROIs on the elastogram (Figure 1C) yielded the stiffness values as follows LSM = 1.99 kPa, RLSM = 2.12 kPa, LLSM 1.79 kPa. The bottom row shows a 65 year old patient with severe PSC (Mayo risk score 2.75). The right lobe volume was 290 ml, left lobe volume was 1364 ml and the caudate lobe was 362 ml. The spleen volume was 870 ml. The liver showed increased liver stiffness with the LSM measuring 9.47 kPa, RLSM measuring 11.82 kPa and the LLSM measuring 8.99 kPa.

constructed from 7 domains, equates to more deprivation. A change in Deviance Information Criterion (DIC) >2 indicates significant improvement in model performance.

Results: A higher risk of PSC was seen in significantly less deprived areas:

- Townsend score –3.27 to –0.46 (–2.205) in 'highest' risk areas vs –3.12 to 10.87 (4.615) in 'lowest' (p = 0.0002)
- IMD 13340 to 27960 (18685) in 'highest' risk vs 68 to 29070 (8220) in 'lowest' (p = 0.0099)

Disease risk was associated with more affluent areas with a healthier population, less crime and more expensive housing (Table 1). 'Health' refers to years of potential life lost, emergency hospital admissions and prevalence of mood disorders.

Table 1: DIC scores for null model, Townsend score and IMD domains

	2.50%	median	97.50%	DIC	Significant model improvement	Change in DIC
Null				577.2		
Townsend Score	–0.119	–0.063	–0.012	574.4	YES	2.78
Income	–2.816	–1.458	–0.057	575.2	YES	1.95
Employment	–3.676	–1.659	0.207	577.1	NO	0.07
Health	–0.455	–0.240	–0.048	573.5	YES	3.60
Education	–0.015	–0.006	0.001	576.2	NO	0.96
Crime	–0.382	–0.202	–0.020	574.4	YES	2.78
Housing	0.008	0.022	0.033	573.8	YES	3.33
Environment	–0.014	0.002	0.019	577.5	NO	–0.34

Conclusion: This work identifies particular components of socio-economic status that may be relevant to disease risk. They may be surrogate markers for disease mechanisms that reflect environmental factors linked to PSC. The association with crime may be a third party phenomenon (or not at all related) i.e. a surrogate marker for less affluent areas. It could also be that factors associated with more deprivation are protective. For example, smoking is reported in some studies to be less prevalent in PSC patients or only those with associated inflammatory bowel disease. It would also be valuable to investigate for associations between deprivation, timing of diagnosis and class mobility.

FRI152

Change in risk of primary biliary cholangitis is associated with the evolution of coal mining

Jessica Dyson[1,2], Alasdair Blain[3], Mark Hudson[1,2], Steven Rushton[4], David Jones[1,2]. *[1]Newcastle upon Tyne Hospitals NHS Foundation Trust, Liver Unit, Newcastle upon Tyne, United Kingdom; [2]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; [3]Newcastle University, Wellcome Centre for Mitochondrial Research, Institute of Neuroscience, Newcastle upon Tyne, United Kingdom; [4]Newcastle University, School of Natural and Environmental Sciences, Newcastle upon Tyne, United Kingdom*
Email: jessicadyson@doctors.org.uk

Background and Aims: Disease clustering in primary biliary cholangitis (PBC) is associated with coal-mining activity. In the UK, there were marked changes in the type of coal mined throughout the 20th century with development of the National Coal Board (NCB) with associated safety legislation in 1950 and a revolution in the technology used in the 1960s. This study aimed to explore which aspect of coal mining is specifically related to PBC risk.

Method: All patients with PBC (n = 2150) in a defined geographical region within England were identified using multi-source case-finding methodology. Besag-York-Mollie models were used for area-based modeling to estimate relative risk in postcode districts and fitted with the number of coal-mines open in 1920, 1950, 1960 and 1970 (data from the BRITPITS database). A change in Deviance Information Criterion (DIC) >2 indicated significant improvement in model performance. Structural equation modelling (SEM) was used to explore relationships between eras of coal-mining and disease risk.

Root Mean Square Error of Association (RMSEA) <0.05 with covariates significant at the 95% level and comparative fit index (CFI) were used to assess model fit.

Results: All eras of coal-mines were associated with an increased risk of PBC. Using area-based analyses, the best model was using 1950 coal-mines. When using SEM to assess multivariate relationships, coal-mines contributed up to 45% of the variation in disease risk for PBC (Table 1).

Table 1: Summary of results of area-based modelling and SEM

			Area-based modelling		SEM
	Number of open mines	Key change in coal mining	DIC score	Change in DIC	Contribution from mines
Null model			799.755		
1920 mines	1311	Peak coal production	793.508	6.247	38%
1950 mines	727	NCB opened	791.525	8.23	41%
1960 mines	501	Change in mines technology	792.797	6.958	45%
1970 mines	163	End of coal mining	802.838	−3.083	37%

Conclusion: Anthropogenic disturbance of the landscape may take years to have a detectable, clinical effect with the impact of more polluting coal-mining techniques in the early 20th century being seen decades later. It may be that long-term, low-level exposure to xenobiotics associated with coal-mining activity is implicated in disease risk. The decline in disease risk seen with 1970 coal-mines may reflect decreasing exposure to pollutants as coal-mining activity dropped and safety legislation had led to improved coal-mine administration and cleaner processing methods. There is a need to explore whether it is coal itself, mining processes or local environmental contamination that are relevant in disease development.

FRI153

The simple cholestatic complaints score is a valid and reliable questionnaire for cholestatic symptoms in PSC patients

Kim N. van Munster[1], Marcel Dijkgraaf[2], Ulrich Beuers[1], Cyriel Ponsioen[1]. [1]*Academic Medical Centre - Location AMC, Gastroenterology and hepatology, Amsterdam, Netherlands;* [2]*Academic Medical Centre - Location AMC, Public health, Amsterdam, Netherlands*
Email: k.n.vanmunster@amc.uva.nl

Background and Aims: Patients with primary sclerosing cholangitis (PSC) often suffer from cholestatic symptoms such as pruritus, fatigue and abdominal pain. There is an important unmet need for reliably measuring symptoms and disease burden in clinical trials and daily practice. The Simple Cholestatic Complaints Score (SCCS) is a 4-item questionnaire measuring pruritus, right upper quadrant pain, fatigue, and fever in PSC patients. The aim of this study is to evaluate the reliability and validity of the SCCS.

Method: The study population consists of 212 patients from the Dutch prospective PSC registry. Data were collected via digital surveys. The FDA guideline for Patient Reported Outcome (PRO) development was followed. Reliability was evaluated by internal consistency (Cronbach's-alpha) and test-re-test reproducibility (intraclass correlation coefficient (ICC)). Cronbach's-alpha >0.7 and ICC >0.7 are considered as good internal consistency and reproducibility, respectively. Face and content validity was assessed by an expert panel and based on literature. The SCCS items were compared to corresponding gold-standard measurements to determine criterion validity. A correlation >0.7 is considered as good criterion validity. Construct validity was assessed by evaluating a priori hypothesized correlations with other relevant questionnaires. If more than 75% of all correlations were as hypothesized construct validity is considered good. Discriminant and convergent validity were assessed by comparing SCCS scores in clinically different (i.e. SD-PSC vs LD-PSC) and clinically comparable (PSC-IBD vs PSC) groups. The ability to detect change was evaluated in a cohort with patients that underwent endoscopic intervention.

Results: A total of 153 patients (72%) completed the questionnaire. Demographics were representative of the general PSC population. Internal consistency was moderate and increased to 0.708 after removal of the fever item. The test-re-test reproducibility was high (ICC = 0.96). Criterion validity was good (all >0.82). Construct validity was in line with a priori hypothesized correlations in 80%. SCCS scores were different in clinically different groups and the same in patients with and without IBD. Scores of individual questions and the sum score decreased after endoscopic intervention in successfully treated patients.

Conclusion: The SCCS is a valid and reliable instrument to measure cholestatic symptoms in PSC patients. Because of its quick and easy to use properties it is highly suitable for frequent monitoring of symptoms in clinical trials and daily practice.

FRI154

The clinical significance of programmed cell death-1 rs11568821 and interleukin-28b rs12979860 polymorphisms in autommune hepatitis

Kalliopi Azariadi[1,2], Nikolaos Gatselis[1,2], Angeliki Lyberopoulou[1,2], Pinelopi Arvaniti[1,2], Asterios Saitis[1,2], Eleni Exarhou[1,2], Stella Gabeta[1,2], Kalliopi Zachou[1,2], Eirini Rigopoulou[1,2], George Dalekos[1,2]. [1]*University Hospital of Larissa, Department of Medicine and Research Laboratory of Internal Medicine, National Expertise Center of Greece in Autoimmune Liver Diseases, Larissa, Greece;* [2]*Institute of Internal Medicine and Hepatology, Larissa, Greece*
Email: kazariadis@hotmail.com

Background and Aims: Autoimmune hepatitis (AIH) is a chronic liver disease of unknown aetiology characterized by dysregulation of T-cell immunity. Programmed cell death-1 (PD1) protein is involved in immunotolerance by down-regulating effector T-cells. The single nucleotide polymorphism (SNP) PD1.3 (rs11568821, G > A) is associated with susceptibility to systemic lupus erythematosus. Furthermore, the coincidence of non-alcoholic liver disease (NAFLD) in AIH is 20–30%. The polymorphism interleukin-28B (IL-28B) rs12979860 (T > C) is associated with steatosis in HCV infection and lobular inflammation and fibrosis in NAFLD. Our aim was to investigate the prevalence and clinical significance of PD1.3 rs11568821 and IL28B rs12979860 SNPs in AIH.

Method: 125 patients followed in our Centre with AIH according to the EASL Clinical Practice Guidelines were evaluated. 100 healthy subjects were used as controls (HC). Polymorphisms were assessed with in-house allelic discrimination end-point PCR.

Results: 2/125 (2%) AIH patients were PD1.3 homozygotes AA and 22/124 (18%) heterozygotes GA vs 2/100 (2%) AA and 27/100 (27%) GA in the HC group (p = 0.2). The AA/GA genotypes were not associated with the mode of presentation of AIH, the histological grade/stage, the presence of cirrhosis, decompensation risk, response to treatment and prognosis (p > 0.1 each). Furthermore, 47/125 (38%) AIH patients were IL28B CC, 62/125 (49%) CT and 16/125 (13%) TT vs 42/100 (42%) CC, 42/100 (42%) CT and 16/100 (16%) TT in the HC group (p = 0.5). 32/125 (26%) AIH patients had concomitant NAFLD (25 steatosis and 7 steatohepatitis). NAFLD coexistence was not related to any genotype (p = 0.7). In a subgroup of 118 patients with available baseline liver biopsy, CC/CT genotype was more likely to present with advanced fibrosis (F3/F4) at baseline: 37/102 (36%) in CC/CT vs 1/16 (6%) in TT, p = 0.03. In addition, TT homozygotes were more likely to achieve complete response on treatment [10/16 (62.5%) in TT vs 38/105, (36%) in CC/CT, p = 0.04], although no difference was found between the two groups in regard to achievement of complete treatment withdrawal (p = 1.0). Survival free of liver transplantation was not affected by either genotype (p = 0.3).

Conclusion: Although the PD1.3 variant was not related to AIH susceptibility and prognosis, the IL28B rs12979860 CC/CT genotypes were associated with advanced fibrosis and lower rates of response during treatment, suggesting a potential new biomarker for AIH.

FRI155

Histological characteristics of primary biliary cholangitis with an incomplete response to ursodeoxycholic acid

Kenichi Harada[1], Yuko Kakuda[2], Atsushi Tanaka[3], Masanori Abe[4], Tadashi Namisaki[5], Shinji Shimoda[6], Mikio Zeniya[7], Akio Ido[8], Hitoshi Yoshiji[5], Hiromasa Ohira[9], Atsushi Umeda[10], Yuki Kamiya[10], Yukari Higashine[11], Seiichiro Hojo[11], Toshio Imai[12], Tetsu Kawano[12], Hirohito Tsubouchi[13], Yasuni Nakanuma[14]. *[1]Kanazawa University Graduate School of Medical Sciences, Department of Human Pathology; [2]Shizuoka Cancer Center, Division of Pathology; [3]Teikyo University School of Medicine, Department of Medicine; [4]Ehime University Graduate School of Medicine, Department of Gastroenterology and Metabology; [5]Nara Medical University, Third Department of Internal Medicine; [6]Kyushu University Graduate School of Medical Sciences, Department of Medicine and Biosystemic Science; [7]International University of Health and Welfare, Gastroenterology; [8]Kagoshima University Graduate School of Medical and Dental Sciences, Digestive and Lifestyle Diseases; [9]Fukushima Medical University School of Medicine, Gastroenterology; [10]EA Pharma Co., Ltd; [11]Eisai Co., Ltd.; [12]Kan Research Institute; [13]Kagoshima City Hospital; [14]Fukui Saiseikai Hospital, Department of Pathology*
Email: kenichih@med.kanazawa-u.ac.jp

Background and Aims: Ursodeoxycholic acid (UDCA) is used as the first-line therapy for primary biliary cholangitis (PBC); it is effective for most patients. Although approximately 20% patients are incomplete response to this treatment, the clinicopathological features of these patients are unknown. A clinical trial in patients with PBC with an incomplete response to UDCA examined their liver histology to clarify predict findings for UDCA-unresponsiveness.

Method: Liver biopsy specimens from 33 patients with PBC elevated alkaline phosphatase of at least 1.67 times the upper normal limit despite UDCA were collected and classified as per the classical classification (Scheuer classification, stages 1–4). Disease activity and staging were characterized using our grading and staging system (Nakanuma classification). Chronic cholangitis with periductal lymphoplasmacytic infiltration, including chronic non-suppurative destructive cholangitis and combined activity of interface hepatitis and lobular hepatitis, were categorized into 4 grades as per the degree and distribution (CA0-3 and HA0-3, respectively). For staging, 3 criteria (fibrosis, bile duct loss, and orcein-positive granules) were independently scored (0–3) as per their degrees; a final stage score was created from the sum.

Results: Bile duct loss and hepatitis activity on HE stain and orcein-positive granules on orcein stain were relatively prominent compared with those of the general PBC population in our routine practice. CA0/1/2/3 cases were distributed as 55%, 15%, 3%, and 27%, respectively. CA0 cases were prominent because of marked bile ducts loss. HA0/1/2/3 cases were 0%, 27%, 48%, and 24%, respectively, with a prominence of cases categorized with moderate hepatic activity. The distribution of stages 1–4 as per Nakanuma classification considerably differed from that as per Scheuer classification. Although with Scheuer classification, stage 1/2/3/4 cases were distributed as 36%, 24%, 30%, and 9%, respectively, with Nakanuma classification, they were distributed as 0%, 3%, 15%, and 82%, respectively, indicating that most were advanced cases. Among 3 criteria defining stage, particularly, the scores of bile duct loss and orcein-positive granules were higher than that of fibrosis.

Conclusions: The histology of PBC with an incomplete response to UDCA was characterized by marked hepatitic activity, bile duct loss, and orcein-positive granules. The Scheuer classification could not reflect these features, but the Nakanuma classification accurately showed the pathological condition of PBC, including prognostic prediction of UDCA treatment.

Nakanuma classification							
CA0	55%	HA0	0%

Maternal and foetal outcomes, biochemistry and immunology changes during pregnancy in patients with autoimmune hepatitis

Kathryn Olsen[1,2], James Hodson[2], Vincenzo Ronca[1], Jennifer Hayden[2], Grace Wootton[1], Ellen Knox[3], Omar El-Sherif[2], Matthew Armstrong[2], Tracey Johnston[3], James Ferguson[2], Fiona Thompson[2], David Adams[1,2], Ye Oo[1,2]. *[1]University of Birmingham, United Kingdom; [2]University Hospital Birmingham, United Kingdom; [3]Birmingham Women's Hospital, United Kingdom*
Email: klm112@student.bham.ac.uk

Background and Aims: Autoimmune hepatitis (AIH) is an immune mediated liver disease predominantly affecting women. It is challenging to manage, especially during pregnancy. Our aim was to observe the clinical outcomes, biochemistry and immunology changes occurring during pregnancy and in the six months following delivery in patients with AIH.

Method: We reviewed the records and collected data for 16 women (26 pregnancies) with well-defined AIH who had experienced a pregnancy (including miscarriages and stillbirths) while under the care of our unit over a 10 year period. Rates of change in blood markers over the antenatal period were assessed using general linear models or log-linear models where appropriate. The models were then extended to assess post-natal trends using an interrupted time series approach, comparing ante- and postnatal blood markers, rates of change and any step-changes occurring immediately after delivery.

Results: Data were available for N = 26 pregnancies in N = 16 patients (with data for 5 further pregnancies in the process of being collected). The majority of pregnancies were Type 1 AIH (N = 21). Ten pregnancies occurred in the presence of liver cirrhosis. The majority of pregnancies resulted in a live birth (N = 20), while two resulted in miscarriage and one in a still-birth (three pregnancies ongoing). Of live births, 30% were premature and 65% were delivered via caesarean section. A total of N = 64 blood samples were taken during the antenatal period. ALT, AST, Bilirubin, IgG and INR decline significantly during pregnancy (all $p < 0.001$). Using data from live births (N = 20), trends in blood markers over the ante and post-natal periods were assessed. ALT and IgG declined significantly across the antenatal period by an average of 9.1% and 4.6% per month respectively ($p = 0.033$ and $p < 0.001$). Following delivery, ALT levels showed a step-change increase of 124% ($p = 0.007$), while IgG showed a 34.2% ($p < 0.001$) step-change increase (see Figure). Post-partum flare occurred in 52% of pregnancies.

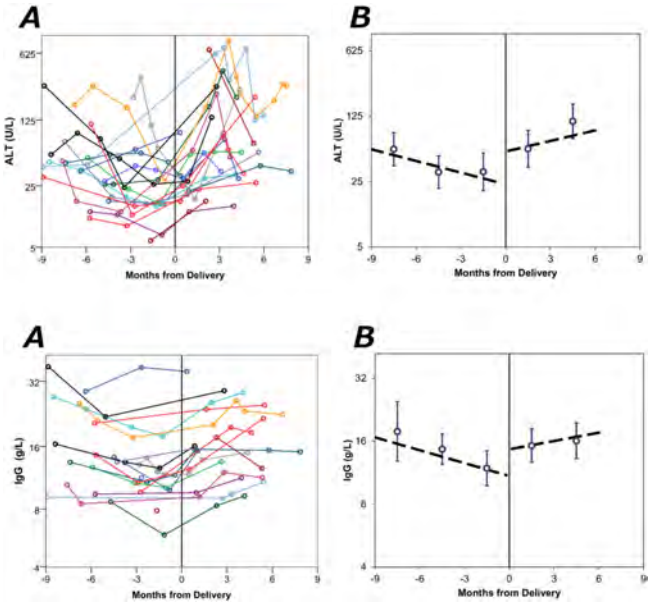

Figure: Trends in blood markers during ante- and post-natal periods: y-axis uses a logarithmic scale. Negative values are antenatal and positive are postnatal. Figure A shows the trajectories for each pregnancy (live births). In Figure B, points represent the geometric mean ALT/ IgG within three-monthly intervals, which are plotted at the midpoint of the interval (whiskers represent 95% confidence intervals). Broken lines represent interrupted time series models.

Conclusion: Biochemical and immunological remission occurs during pregnancy. Post-partum flare is common, being observed in half of the pregnancies. Pre-pregnancy counselling and management of this unique patient cohort with obstetric-liver multi-disciplinary team is crucial. Additionally, dissecting the immune mechanism is crucial to understanding and preventing post-partum flare ups.

FRI157

Impaired sulfation capacity may deteriorate clinical course in patients with primary sclerosing cholangitis (PSC)

Karolina Maria Wronka[1,2], Ewa Wunsch[3], Beata Kruk[4], Piotr Milkiewicz[1,2,3]. *[1]Medical University of Warsaw, Liver and Internal Medicine Unit; [2]European Reference Network on Hepatological Diseases (ERN RARE-LIVER); [3]Pomeranian Medical University, Translational Medicine Group; [4]Medical University of Warsaw, Laboratory of Metabolic Liver Diseases, Centre for Preclinical Research, Department of General, Transplant and Liver Surgery*
Email: p.milkiewicz@wp.pl

Background and Aims: Chronic cholestasis induces pregnane-X-receptor (PXR) which orchestrates various detoxifying processes. These include activation of sulfotransferase 2A1 (SULT2A1), an enzyme which facilitates sulfation, a critically important mechanism of elimination of endo and exotoxins. It has been previously shown that SULT2A1 activation is specifically impaired in PSC but not in another cholestatic condition, namely PBC. In this study we analyzed serum levels of dehydroepiandrostendione sulfate (DHEA-S), a marker of sulfation capacity in a large cohort of patients with PSC and correlated it with various clinical features.
Method: We included 307 patients with PSC (215 males, median age 32 years). Seventy one subjects had additional features of autoimmune hepatitis (AIH/PSC). Health-related quality of life (HRQoL) in PSC patients was evaluated with SF-36/PBC-40. Control group comprised of 104 patients with HCV (83 males, median age 41 years). Mann-Whitney, Spearman correlation and Fisher exact tests were applied as appropriate. Stepwise logistic regression analysis was used to indicate independent variables determining decreased DHEA-S
Results: Eighty three (27%) PSC patients had decreased DHEA-S, as compared to 10 (9.6%) in controls ($p = 0.0002$). Patients with PSC and decreased DHEA-S levels had significantly worse laboratory parameters including lower albumin/bilirubin ($p < 0.001$ for both); higher MELD scores ($p < 0.01$), and INR ($p < 0.001$). They also had significantly impaired PBC-40 Social Emotional (PBC-40) and Physical Functioning (SF-36) domains. Decreased DHEA-S level was associated with younger age at diagnosis ($p < 0.001$); female gender ($p < 0.05$), the presence of cirrhosis ($p < 0.01$) and PSC/AIH ($p < 0.0001$). No association between decreased DHEA-S and the presence of concomitant inflammatory bowel disease ($p = 0.65$) was seen. In multivariate analysis, higher MELD (OR = 1.219, 95% CI 1.09–1.363, $p < 0.001$), female gender (OR = 3.122, 95% CI 1.60–6.11, $p < 0.005$), younger age (OR = 3.12, 95% CI 1.60–6.11, $p < 0.01$) and AIH/PSC ($p < 0.0001$) but not liver cirrhosis were found as independent risk factors for decreased DHEA-S level.
Conclusion: Significant proportion of patients with PSC presents with low levels of DHEA-S reflecting impaired sulfation processes. These patients have significantly worse course of their disease. Impaired sulfation could be considered as one of contributing factors in a clinical progression of PSC.

FRI158

Accuracy of liver stiffness measurement in assessing liver fibrosis in naive patients with primary biliary cholangitis

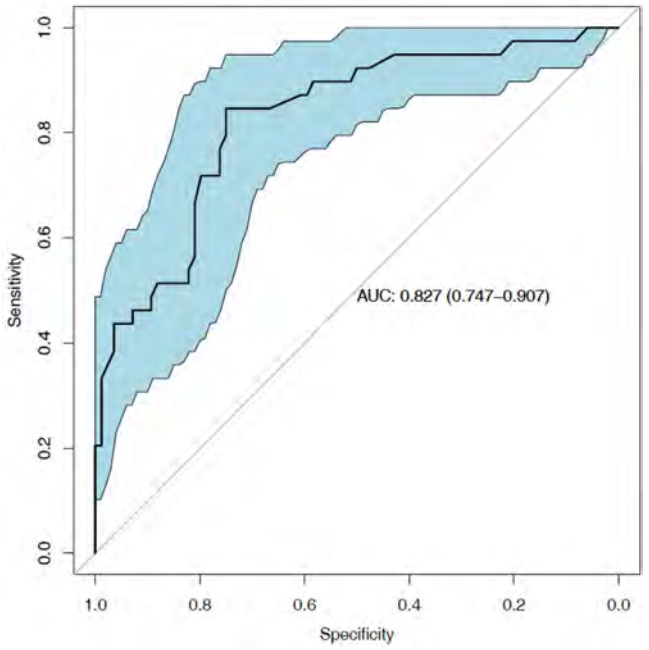
Email: laura.cristoferi@unimi.it

Background and Aims: Non-invasive evaluation of liver fibrosis in primary biliary cholangitis (PBC) with Liver Stiffness Measurements (LSM) by Transient Elastography (TE) is routinely undertaken at diagnosis for disease staging and risk stratification. However, evidence on correlation between LSM and liver fibrosis is based on cross-sectional studies in PBC-treated patients. Moreover, the impact of potential confounders, e.g. cholestasis and steatosis, is unclear.
Aim of our study was to investigate the accuracy of LSM to predict moderate to severe fibrosis in newly diagnosed PBC patients naïve to therapy.

Method: We collected data from 182 adult patients who underwent liver biopsy (LB) for PBC at diagnosis in five Italian liver centers from Jan 2006 through Aug 2019. TE examinations within 3 months from LB were included. LB were scored centrally by two expert pathologists, blinded to clinical data and disease stage, according to Ludwig staging system. In all patients Fibrosis-4 (FIB-4) and aspartate aminotransferase [AST]/platelet ratio (APRI) score have been calculated. Diagnostic accuracy of LSM, FIB-4 and APRI score was estimated using the area under the receiver operating characteristic curves (AUROCs) for fibrosis. The effects of liver biochemistry and histological parameters were appraised using multivariable logistic model.
Results: 123 PBC patients had adequate LB (≥9 portal tracts) and valid LSM values. According to histological assessment, Ludwig stage distribution was as follows: stage I = 38 (30.9%), stage II = 46(37.4%), stage III = 27 (21.9%), stage IV = 12 (9.8%). TE identified patients with Ludwig stage III/IV with an AUROC of 0.83 (95% confidence interval [CI] (0.74, 0.90)) (Figure). The optimal threshold was identified at 6.75 kPa (CI (6.55, 7.50)), with 85% of sensitivity, 75% of specificity, 78% of accuracy and 6 false negative. TE was superior to APRI and FIB-4 having AUROC of 0.638 (CI = (0.535, 0.740)) and 0.641 (CI = (0.516, 0.766)), respectively. At multivariable analysis only LSM was associated with liver fibrosis and no significant effect of biochemical measures and steatosis was found.



Conclusion: LSM is accurate to predict moderate to severe liver fibrosis at diagnosis in PBC naïve patients using a threshold of 6.75 kPa with an AUROC of 0.83. TE outperformed FIB-4 and APRI score and is not confounded by liver biochemistry and steatosis. These data can inform strategies for patient surveillance and trial design in PBC.

FRI159

Ciprofibrate: a new option of fibrate for primary biliary cholangitis with incomplete response to ursodeoxycholic acid

Laura Guedes[1], Michele Harriz Braga[1], Bruna Damasio Moutinho[1], Flair Jose Carrilho[1], Eduardo Luiz Rachid Cançado[2]. [1]*Clinical Hospital, Gastroenterology and Hepatology, Sao Paulo, Brazil;* [2]*Clinical Hospital, Gastroenterology and Hepatology, São Paulo, Brazil*
Email: lauvguedes@gmail.com

Background and Aims: Bezafibrate and fenofibrate both have substantial evidence of anticholestatic properties in patients with primary biliary cholangitis (PBC). Ciprofibrate, one of the most potent peroxisome proliferators, had never been studied in this scenario. Our goal was to describe an experience with ciprofibrate in PBC with incomplete response to UDCA.
Method: A retrospective study was conducted with 40 patients (38 women) with cholestasis and anti-mitochondrial antibody reactivity with incomplete UDCA response (Paris II criteria). Ciprofibrate was combined at a daily dose of 100 mg between 2013 and 2017, and patients were followed until May 2019. Blood samples were obtained at diagnosis, after 12 months of UDCA use and at 3, 6, and 12 months after combination with ciprofibrate. We compared laboratory tests by paired two-tailed T-test, and $p < 0.05$ was considered significant.
Results: Mean age at diagnosis was 44.8 years; 3 patients (9.4%) had cirrhosis and 23 (57.5%) had moderate to severe pruritus. UDCA reduced the levels of alkaline phosphatase (ALP), gamma glutamyl transferase (GGT), aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin (TB) and reduced partially pruritus in 23 patients (74.2%), and completely in 8 (25.8%). Association with ciprofibrate reduced ALP and GGT at 12 months, 83.9% had complete response and after one year 37.5% of patients had ALP, GGT, AST, ALT, TB, albumin and prothrombin index normalized. It also fully eliminated itching in 81% of patients who still had itching under UDCA. The ciprofibrate dose was reduced to 100 mg every other day in 14 patients (35%) after an average of 12 months and was withdrawn in 14 (35%) after an average of 13 months. The main side effects were myalgia, hepatitis, dyspepsia, increased creatinine, creatine phosphokinase, TB levels. Among non-cirrhotic patients, 7 (17.5%) evolved to cirrhosis, 4 of them had withdrawn fibrate. One patient died 18 months after fibrate withdrawal and another one progressed to liver transplantation due to refractory itching despite the use of UDCA and ciprofibrate for 24 months.
Conclusion: Ciprofibrate appears to be as effective as other fibrates as adjunctive treatment of PBC. However, there were a large number of side effects. Randomized controlled trials are needed to compare the efficacy and safety of different fibrates.

FRI160

Utility of thiopurine metabolite testing in autoimmune hepatitis: defining an optimal therapeutic range for disease management and measurement may avert relapse and adverse drug reactions

Lena Susanna Candels[1], Mussarat Rahim[2], Andrew Yeoman[2], Guan Wee Wong[2], Michael Heneghan[2]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom;* [2]*Institute of Liver Studies, King's College Hospital, London, United Kingdom*
Email: michael.heneghan@nhs.net

Background and Aims: Patients with autoimmune hepatitis (AIH) receive maintenance therapy with thiopurines, e.g. azathioprine (AZA) at 1–2 mg/kg/day. Genetic polymorphisms in the metabolism of AZA lead to variation in levels of metabolites, thioguanine nucleotide (TGN) and 6-methylmercaptopurine (6-MMP) which is associated with adverse drug reactions (ADR). For inflammatory bowel disease, a therapeutic range of TGN 235–450 pmol/8×10^8 erythrocytes has been identified to optimize effectiveness. We aim to elucidate the benefits of metabolite monitoring in patients with AIH.
Method: 109 patients with AIH were identified as having thiopurine metabolite levels between 1999–2019. In addition, 105 AIH patients on a weight-based dose of thiopurine, who had never had metabolite levels, were also identified. Charts were reviewed retrospectively. Chi squared test was used for statistical analysis.
Results: In those that had TGN monitoring, 73% (80/109) were female and the mean age at presentation was 35 yrs (range 4–82). In those that had no TGN monitoring, 74% (78/105) were female and the mean age at presentation was 37 yrs (range 7–70). In the TGN and non-TGN groups, 73% and 81% had type 1 AIH, 6% and 5% had type 2 AIH and 21% and 14% had auto-antibody negative AIH (respectively).
Patients with metabolite measurements had less loss of remission compared to those without metabolite levels (13% vs. 24%, p = 0.045). TGN levels within the therapeutic range predicted more stable

disease with fewer flares at 6 and 12 months post testing compared to patients with levels outside the therapeutic range (6 months: $p < 0.0001$; 1 year: $p = 0.0032$). Patients with normal TGN levels and normal TGN/6MMP ratio had more stable disease compared to patients with normal TGN levels and elevated TGN:MMP ratio ($p = 0.021$). High TGN:MMP ratios were related to more ADR compared to patients with normal TGN levels and TGN:MMP ratios ($p < 0.0001$). Average dose of AZA for patients in remission at 6 months post metabolite testing was 1.2 mg/kg/day. The remission group had an average baseline TGN level of 282 pmol/8 × 10^8 RBC (range 19–1009). The lowest number of ADR was observed in the group with subtherapeutic TGN levels. Interestingly, this group did not have the highest rate of relapse.

Conclusion: Measuring metabolite levels can help optimize treatment regimens in AIH patients with less ADR and relapses. It may be possible to define an alternative therapeutic range of TGN levels more specific to AIH.

FRI161

Correlation of serum bile acids and pruritus with aldafermin (NGM282) therapy in patients with primary sclerosing cholangitis

Marlyn J. Mayo[1], Lei Ling[2], Alex DePaoli[2], Gideon Hirschfield[3], Ulrich Beuers[4]. [1]*University of Texas Southwestern, Dallas, United States;* [2]*NGM Biopharmaceuticals, South San Francisco, United States;* [3]*Toronto General Hospital, Toronto, Canada;* [4]*University of Amsterdam, Amsterdam, Netherlands*
Email: lling94080@yahoo.com

Background and Aims: Pruritus is a common symptom in patients with cholestatic liver diseases, including PSC, an inflammatory and progressively fibrotic liver disease devoid of effective medical interventions. The pathogenesis of pruritus is poorly understood, and proposed pruritogens include bile acids (BA) and autotaxin/lysophosphatidic acid. Recently, BAs have been shown to activate the MRGPRX4 receptor located in the sensory neurons to induce itch. Aldafermin (NGM282), a non-tumorigenic FGF19 analogue, potently inhibited BA synthesis, improved hepatic inflammation, and decreased fibrosis markers in patients with PSC. To determine whether certain BA species may be related to pruritus, we correlated changes in individual serum BAs with patient-reported outcome measures of pruritus from a phase 2 aldafermin trial in patients with PSC.

Method: 62 subjects, with PSC by EASL criteria and an elevated ALP>1.5 × ULN at baseline (BL), were randomized to daily aldafermin 1 mg, 3 mg or placebo (PBO) for 12 weeks (W12). 5D-itch pruritus questionnaires (scores from 5 to 25) and fatigue severity numeric rating scale (NRS, from 0 to 10) were collected; higher numbers indicated more severe symptoms. Serum concentrations of BA species were determined by mass spectrometry. Scores were compared with the use of a mixed-effect model repeated measures analysis. Correlations between pruritus and serum BAs were assessed with a clinical anchor threshold of $r > 0.30$ and $p < 0.05$ as significant.

Results: At BL, pruritus severity by 5D-itch correlated with serum concentrations of GCA ($r = 0.35$, $p < 0.01$) and TCA ($r = 0.36$, $p < 0.01$), but not C4, GCDCA, TCDCA, ALP, ALT, AST or ELF. At W12, changes from BL were +0.6, 0, −1.3 for 5D-itch total score, −0.1, −0.2, −0.5 for pruritus direction, +0.1, −0.1, −0.3 for pruritus disability, 0.1, 0, −0.2 for pruritus degree, 0.5, 0.1, −0.1 for pruritus distribution, and 0, −0.4, −0.7 for fatigue NRS, in the PBO, 1 mg and 3 mg groups, respectively. Reductions from BL in GCA ($p < 0.001$) and GCDCA ($p < 0.001$) were observed in the aldafermin groups, but not in PBO. Change in pruritus severity from BL to W12 correlated with changes in GCA ($r = 0.39$, $p < 0.01$) and GCDCA ($r = 0.35$, $p < 0.01$). Change in fatigue severity did not correlate with BA levels.

Conclusion: Reductions in serum GCA and GCDCA correlated with reductions in 5D-itch score in PSC patients treated with aldafermin, suggesting that these BA species may serve as markers of pruritus response to aldafermin treatment.

FRI162

Higher prevalence of hepatitis E virus in autoimmune hepatitis: the role of false positive antibodies

Laura Patricia Llovet[1], Jordi Gratacós-Gines[1], Oswaldo Ortiz[1], Sergio Rodriguez-Tajes[1], Sabela Lens[1], Enric Reverter[1], Estibaliz Ruiz-Ortiz[2], Josep Costa[3], Odette Viñas[2], Xavier Forns[1], Albert Parés[1], Maria Carlota Londoño[1]. [1]*Hospital Clinic Barcelona, Liver Unit;* [2]*Hospital Clinic Barcelona, Immunology Department;* [3]*Hospital Clinic Barcelona, Microbiology Department*
Email: mlondono@clinic.cat

Background and Aims: Recent studies have found an increase in the seroprevalence of hepatitis E virus (HEV) infection in patients with autoimmune hepatitis (AIH) suggesting that the virus could play a role in the pathogenesis of the disease. However, the presence of false positive anti-HEV antibodies could explain the higher HEV seroprevalence observed in previous studies. Therefore, we aimed to assess the prevalence of positive anti-HEV IgM and IgG, and HEV-RNA in a cohort of patients with AIH, to determine the impact of positive HEV serology on patient outcome, and to evaluate the role of hypergammaglobulinemia and positive autoantibodies in the presence of positive anti-HEV serology.

Method: One hundred five patients tested for HEV infection (anti-HEV IgG, anti-HEV IgM and HEV-RNA) between 2014–2018 were included in the study: 50 with chronic AIH (more than 1 year on treatment), and 55 with an acute hepatitis (30 patients with acute AIH and 25 with non-autoimmune acute hepatitis). Clinical and laboratory data were analyzed.

Results: The seroprevalence of HEV infection was found to be higher in patients with acute AIH (17% vs. 10% in patients with chronic AIH and 8% in patients with non-autoimmune acute hepatitis). Only one patient from with the last group had HEV-RNA positive and was diagnosed with an acute HEV infection. Patients with acute AIH and positive anti-HEV IgG were older (58 vs. 40; $p = 0.006$), had higher IgG levels (27 g/dL vs. 13 g/dL; $p = 0.03$) and ASMA titres (1:160 vs. 1:80; $p = 0.045$), and were more likely to have another autoimmune disease (60% vs. 16%; $p = 0.03$). At the time of HEV testing, anti-HEV IgG positive patients had significantly higher serum IgG levels (17 g/L vs. 11 g/L; $p = 0.009$), ANA (1:160 vs. 1:60; $p = 0.026$) and ASMA titres (1:80 vs. 1:40; $p = 0.021$).

Conclusion: Despite the use of chronic immunosuppression, the seroprevalence of HEV infection in patients with AIH in Catalonia do not differ from that of the general population. The higher HEV seroprevalence in patients with acute AIH with higher levels of gammaglobulins and high antibody titres suggest the presence of cross-reactivity between HEV and liver antigens.

[11]AZ Maria Middelares, Gastroenterology and Hepatology, Gent, Belgium; [12]University Hospital Antwerp, Gastroenterology and Hepatology, Edegem, Belgium; [13]UZ Leuven, Gastroenterology and Hepatology, Leuven, Belgium
Email: m.biewenga@lumc.nl

Background and Aims: No prognostic risk score is currently available to predict long term survival in autoimmune hepatitis (AIH) patients. The aim of this study was to develop and validate a risk score for AIH patients.
Method: The prognostic index was developed using uni- & multivariate Cox regression in a derivation cohort and validated in an independent cohort. A landmark analysis was used to assess biochemical remission as a baseline variable.
Results: In the derivation cohort 19 liver transplantations and 18 liver related death occurred in 396 patients (median follow-up 118 months; range: 1–560 months).
In multivariate analysis age (HR 1.023; p = 0.008), non-caucasian ethnicity (HR 2.633; p = 0.013), cirrhosis (HR 10.568; p < 0.001) and ALT level (HR 0.667; p = 0.010) were significant independent predictors for long term survival (C-statistic 0.866; 95% CI 0.822–0.910). In the validation cohort 39 of the 408 patients had liver transplantation or liver related death and median follow-up was 74 months (range: 1–496 months). Predicted 5-year event rate did not differ from observed event rate (high risk group 11.0% vs 10.4% (95% CI: 3.3%–17.0%); moderate risk group 1.3% vs 3.0% (95% CI: 0.0%–7.0%); low risk group 0.6% vs 3.4% (95% CI: 0.0%–8.0%); C-statistic 0.741 (95% CI 0.595–0.887)). Complete remission at 12 months after diagnosis was an additional independent predictor (HR 0.276; p = 0.040).
Conclusion: the newly developed prognostic index can predict long term survival free of liver transplantation and liver related death in AIH patients. Reaching biochemical remission within 12 months after diagnosis is the only identified modifiable independent risk factor.

FRI164
Safety and efficacy of temporary placement of fully covered metallic stent for dominant stricture among primary sclerosing cholangitis patients

Amir Mari[1], Baker Mahamid[1], Eran Goldin[2], Tawfik Khoury[3], Mahmud Mahamid[2]. [1]EMMS Nazareth Hospital, Israel; [2]Shaare Zedek Medical Center, Jerusalem, Israel; [3]2-Department of Gastroenterology, Galilee Medical Center, Nahariya, Israel
Email: mahmudmahamid@yahoo.com

Background and Aims: when dominant stricture (DS) is diagnosed either prior to ERCP or during ERCP, there are multiple therapeutic options available to the endoscopist including dilation and stenting, each with their own benefits and drawbacks. The aim of the current study is to assess the safety and efficacy of fully-covered self-expandable metal stent (FCSEMS) in management of DS among PSC patients.
Method: we include PSC patients with refractory DS, defined as strictures resistance to conventional therapy (balloon dilatation, or and plastic biliary stent insertion) longer than three months. FCSEMS was placed for 3 months.
The primary outcome was the DS resolution at stent removal. And the secondary outcome was the DS recurrence as well as development of cholangitis, jaundice, and elevation of liver functions test and or refractory pruritus.
Results: 15 patient were enrolled between January 2016 to May 2018, FCSEMS was placed in all the 15 patients with DS, one patients need premature removal of the FCSEMS due to cholangitis on day 46 from the stent placement. Overall 14 patients complete planned 3 months, and after 90 days all the stents were softly removed.
The rate of DS resolution was, 43.7%. And recurrence occurred in 17.8 during median follow-up of 12 months. Improvement on liver function test, pruritus and weakness were observed in 28.5%, 57%, and 64.2% respectively. In all 14 patients MAYO score was improved by median 26%.
Adverse event was observed in 28.5% during 12 months follow-up, 1 case of cholangitis, 2 cases of biliary pancreatitis, 1 stent partially migrated to duodenum.
Conclusion: temporary FCSEMS was feasible, safe and effective treatment option among refractory DS PSC patients

FRI165
Understanding of central and peripheral fatigue in primary biliary cholangitis

Naw April Phaw[1], Jessica Dyson[1], George Mells[2], David Jones[3]. [1]Newcastle University and Newcastle upon Tyne Hospital NHS foundation Trust, Institute of Cellular Medicine, Newcastle Upon Tyne, United Kingdom; [2]Cambridge University Hospitals NHS Foundation Trust, Department of Hepatology, Cambridge, United Kingdom; [3]Newcastle University and Newcastle upon Tyne Hospital NHS foundation Trust, Institute of Cellular Medicine, Newcastle Upon Tyne, United Kingdom
Email: david.jones@newcastle.ac.uk

Background and Aims: Fatigue is the commonest symptom in patients with primary biliary cholangitis (PBC). It significantly impairs quality of life in approximately 20% of PBC patients (1, 2, 3). The pathogenesis of fatigue in PBC is multi-factorial and it is thought to be driven by both peripherally- and centrally-mediated processes. The aim of the study is to identify endotypes of fatigue in PBC to allow targeting of therapy in appropriate subgroups in future clinical trials of fatigue-modifying agents and approaches.
Method: Further analysis of data from patients from the UK-PBC Research Cohort recruited between 2008 and 2011. The PBC-40, Hospital Anxiety and Depression Scale (HADS) and Epworth Sleepiness Scale (ESS) assessment tools were used for symptoms assessment. Significant fatigue and significant cognitive symptoms were defined as moderate or severe symptoms using PBC-40 cut-offs. Symptom correlations between fatigue and cognitive symptoms were performed.
Results: There were 2002 patients included. 1203 (60%) had significant fatigue and 730 (36%) had significant cognitive symptoms. Of the 1203 patients with significant fatigue, 55% had significant cognitive symptoms; a combination we have named **"central-type fatigue."** The remaining patients with significant fatigue did not have significant cognitive symptoms and we named this group "**peripheral-type fatigue."** In central-type fatigue there was a strong linear association between fatigue and cognitive symptom severity ($p < 0.0001$, $r^2 = 0.22$) whilst the association was weak in peripheral-type fatigue. Patients with central-type fatigue were younger and experienced a greater level of perceived quality of life impairment, worse depression and worse sleep disturbance. Interestingly, significant cognitive symptoms without fatigue were very uncommon (3%) in our study but the converse was not true.

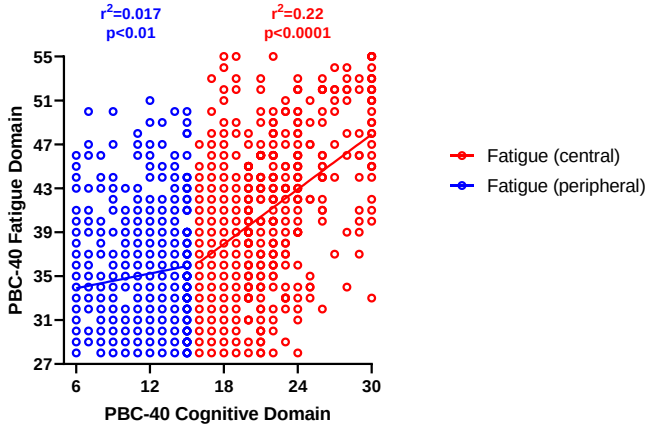

Figure: Correlation between cognitive and fatigue symptoms

Conclusion: The findings in the study have helped us to characterise fatigue endotypes in PBC. The strong association between the severity of cognitive symptoms and severity of fatigue in the subgroup of patients with the worst quality of life impairment suggests that the mechanisms underpinning the 2 symptoms are closely related. The greater impact on quality of life in those with central-type fatigue suggests that this group should be prioritized in future trials of symptom-modifying agents.

Email: marcin.krawczyk@uks.eu

Background and Aims: Liver scarring is a consequence of chronic liver diseases (CLD). Transient elastography (TE) threshold of 9.1 kPa has been recently demonstrated to have the best accuracy for the prediction of significant liver fibrosis (i.e. stages ≥F2, Serra-Burriel et al. *J Hepatol* 2019). The common *PNPLA3* (adiponutrin) p.I148M variant is associated with liver cirrhosis and carriers of the procholestatic *ABCB4* c.711T allele, who are also positive for the *PNPLA3* variant, might be at risk of progressive liver injury. Here, we investigate the relation between this common *ABCB4* polymorphism and liver stiffness as well as the interaction of both *ABCB4* and *PNPLA3* on fibrosis in a mouse model of chronic cholestasis (*Abcb4*$^{-/-}$ mice).
Method: n total, we investigated a cohort of 712 prospectively recruited patients with CLDs (278 women, age 50 ± 13 years) whose liver stiffness was measured non-invasively using TE. *ABCB4* and *PNPLA3* genotypes were determined by PCR-based assays. *Pnpla3* expression and liver injury were analysed in *Abcb4*$^{-/-}$ mice and wild-type controls.
Results: The frequency of the *ABCB4* c.711 minor allele in our cohort was 0.18. Median liver stiffness value was 6.7 kPa, and 226 individuals (32%) presented with TE ≥9.1 kPa. Carriers of the *ABCB4* variant presented significantly (P = 0.02, OR = 1.33) more frequently with liver stiffness ≥9.1 kPa. In a multivariate regression model including the *ABCB4* variant (P = 0.047, OR = 1.43) as well as non-genetic profibrogenic factors such as BMI (P = 0.043, OR = 1.04) and age (P < 0.01, OR = 1.02), all proved to be independent risk factors for fibrosis stage ≥F2. *Abcb4* knockout in mice led to enhanced liver injury (reflected by increased *Col1a2* expression and elevated collagen contents), which was coupled with significantly (P < 0.05) lower hepatic expression of *Pnpla3* as compared to wild-type mice.
Conclusion: The procholestatic *ABCB4* c.711T allele might represent a new genetic risk factor for clinically relevant liver fibrosis. Lower expression of adiponutrin in fibrotic livers of *Abcb4*$^{-/-}$ mice alludes to the interaction between altered phospholipid metabolism and *PNPLA3* in progressive liver injury. Our results suggest that *Abcb4* knockouts might represent a model to further dissect the role of *PNPLA3* in liver fibrosis.

Response to treatment in autoimmune hepatitis determines the health-related quality of life

Maurice Michel[1], Francesca Spinelli[1], Christian Labenz[1], Yvonne Huber[1], Nagel Michael[1], Leonard Kaps[1], Peter Galle[1], Marcus-Alexander Woerns[1], Jörn M. Schattenberg[1]. [1]*Metabolic Liver Disease Research Program, Department of Medicine I, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany*
Email: schatten@uni-mainz.de

Background and Aims: Autoimmune hepatitis (AIH) is a rare chronic liver disease resulting from inflammation and eventual destruction of hepatocytes. Incomplete response to treatment can lead to disease progression and end-stage liver disease. Frequently the health-related quality of life (HRQL) is impaired in AIH. In this prospective study we assessed the impact of the response to treatment on HRQL using the validated chronic liver disease questionnaire (CLDQ) in AIH.
Method: A total of 116 patients with AIH (n = 89) or AIH/PSC/PBC overlap (n = 27) were prospectively enrolled in this study at an outpatient hepatology clinic in Germany starting in July 2018. The CLDQ was used to assess HRQL and clinical and laboratory assessment was performed at baseline. The CLDQ is a validated tool and reports a scale from 1 to 7, with 1 indicating worst and 7 indicating best HRQL in five domains and a total score.
Results: The mean CLDQ overall score was 5.3 ± 1.3 with the lowest score in the subscale fatigue (4.3 ± 1.7) and the highest score for activity (5.8 ± 1.3). The score for activity was significantly lower in female than in male (5.7 ± 1.4 vs. 6.4 ± 0.9; p < 0.05). Patients with a complete response to immunosuppressive therapy defined as normalization of ALT, AST and IgG had a significantly higher CLDQ overall score compared to patients with incomplete response, respectively (5.7 ± 1.2 vs. 5.1 ± 1.3; p < 0.05). The scores of the subscales abdominal symptoms (6.1 ± 1.4; p < 0.05), activity (6.2 ± 1.2; p < 0.05), emotional functioning (5.44 ± 1.40; p < 0.05) and worry (5.8 ± 1.5; p < 0.05) were also significantly higher in patients with complete response. Interestingly, the subscale fatigue, which showed the lowest score overall, was independent of treatment response (4.7 ± 1.6 vs. 4.1 ± 1.7; p = 0.104). There was a negative correlation between the level of gGT and the CLDQ total value (r = –0.276; p < 0.01). A negative correlation was also observed for other cholestatic parameters including bilirubin and ALP with the subscales fatigue (bilirubin: r = –0.218; p < 0.05), systemic symptoms (ALP: r = –0.241; p < 0.05) and activity (ALP: r = –0.222, p < 0.05).
Conclusion: Overall, AIH is associated with a high symptom burden. A complete response to treatment is associated with a significant higher HRQL. In addition, cholestatic patterns of liver injury showed a negative impact on the subscales symptoms and activity of the CLDQ. Achieving a complete treatment response will therefore be beneficial for all aspects of relevance – feeling, function and survival.

Background and Aims: PSC is a cholestatic disorder characterized by abnormal serum bile acid (BA) levels, but there are limited data regarding individual BA species. Our aim was to evaluate associations

between BA species, liver histology, and disease progression in patients with PSC.

Method: Levels of 15 BAs and the BA intermediate, 7α-hydroxy-4-cholesten-3-one (C4), were quantified by LC-MS/MS (Agilent 1290/Sciex, Metabolon) in fasting serum samples from patients with compensated large-duct PSC at baseline (BL) in a 96-week, phase 2 trial of simtuzumab (NCT01672879). Ursodeoxycholic acid (UDCA) and conjugates were removed as potential confounders in this analysis. Fibroblast growth factor 19 (FGF19) was measured by ELISA in fasting plasma samples and liver fibrosis at BL was staged according to the Ishak classification. Associations between BA species, Ishak fibrosis stage, and clinical parameters (e.g. liver biochemistry, Enhanced Liver Fibrosis [ELF] test), as well as their prognostic utility for PSC-related events (e.g. decompensation, cholangitis, transplantation) and progression to cirrhosis were determined.

Results: 115 patients were included (mean age 44 yrs, 62% male, 59% with IBD, 63% on UDCA, 54% with advanced [Ishak F3-F6] fibrosis). Median total BAs at BL were 2383 ng/mL (IQR 1204, 7406); conjugated primary BAs (glycocholic acid [GCA], taurocholic acid [TCA], glycochenodeoxycholic acid [GCDCA], and taurochenodeoxycholic acid [TCDCA]) contributed to more than 70% of the total BA pool. Total and primary BAs were highly correlated with ELF and its components (Spearman $\rho = 0.56–0.71$), serum ALP ($\rho = 0.58–0.60$), ALT ($\rho = 0.57–0.60$), and direct bilirubin ($\rho = 0.68–0.71$), and Ishak fibrosis stage ($\rho = 0.51$; all $p < 0.05$), while correlations between secondary BAs and these markers were weaker ($|\rho| < 0.20$). Compared with patients with no to mild (F0-F2) fibrosis, those with advanced fibrosis (F3-F6) had higher total (1537 vs 4313 ng/mL [$p < 0.001$]; AUROC 0.77) and primary BAs (1245 vs 4100 ng/mL [$p < 0.001$]; AUROC 0.77), and lower C4 (13.7 vs 6.46 ng/mL [$p < 0.001$]; AUROC 0.69). Levels of all four conjugated primary BAs were significantly higher in patients with advanced fibrosis (all $p < 0.001$, AUROCs 0.76–0.79). By week 96, 23 patients (20%) developed a PSC-related event (cholangitis, n = 15; jaundice, n = 4; cholangiocarcinoma, n = 1; decompensation, n = 3). Higher BL total BAs, primary BAs, GCA, GCDCA, TCA, and TCDCA, but not secondary BAs, FGF19, or C4, were associated with an increased risk of PSC-related events (Table). Similar factors predicted progression to cirrhosis (15%).

Table: Associations between baseline BAs, C4, and FGF19 with PSC-related clinical events

Marker	With PSC-Related Event (N=23)	Without PSC-Related Event (N=92)	Wilcoxon P-value	Hazard Ratio[§] (95% CI)	HR P-value
Total BAs*	4152.87 (2392.37, 10096.84)	2148.8 (1082.29, 6579.8)	0.0083	1.39 (1.06, 1.81)	0.017
Total primary BAs	3357.39 (2131.78, 10074.4)	1810.84 (774.37, 5354.4)	0.0076	1.36 (1.06, 1.74)	0.014
Total secondary BAs*	338.7 (109.63, 771.9)	259 (126.29, 630.89)	0.793	1.03 (0.76, 1.39)	0.866
GCA	1140 (503, 3180)	498 (157, 1515)	0.012	1.36 (1.07, 1.72)	0.012
GCDCA	1090 (689, 3330)	725.5 (356, 1870)	0.028	1.4 (1.05, 1.86)	0.021
TCA	476 (225, 1540)	106 (29.8, 594)	0.002	1.29 (1.08, 1.54)	0.004
TCDCA	421 (244, 1180)	182 (53.7, 661)	0.006	1.33 (1.08, 1.62)	0.007
FGF19	99 (70, 214)	111 (61, 177)	0.928	1.34 (0.82, 2.19)	0.247
C4	10.6 (3.0, 15.5)	11.9 (5.4, 23.8)	0.168	0.74 (0.49, 1.12)	0.159

Unless indicated, data are median (Q1, Q3) and measurement units are ng/mL.
* UDCA and conjugates removed from total and secondary BAs.
§ Hazard ratio from Cox proportional hazards model for PSC-related clinical event-free survival based on log-transformed marker.

Conclusion: In patients with compensated PSC, total serum BAs, as well as conjugated primary BAs, are markers of liver fibrosis and predict clinical disease progression. These data support ongoing evaluation of therapies that reduce BA levels (e.g. FXR agonists) for the treatment of PSC.

FRI169

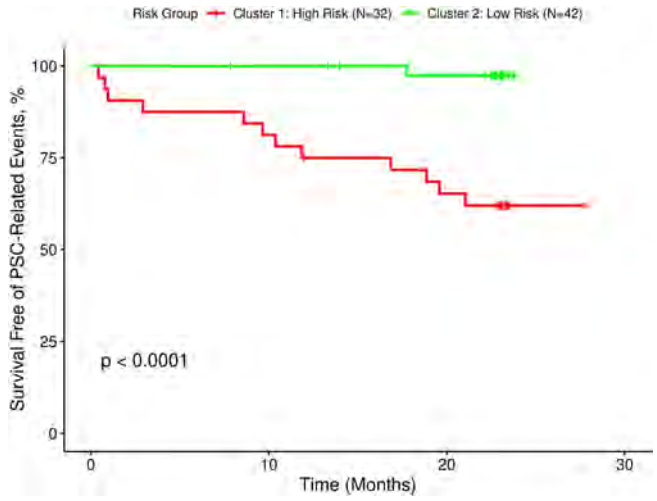
Removal of fibrosis-related genes identifies a hepatic gene expression signature that identifies canonical signaling pathways and is correlated with clinical outcomes in patients with primary sclerosing cholangitis

Michael Trauner[1], Yevgeniy Gindin[2], Jing Zhu Zhou[2], Ryan Huss[2], Chuhan Chung[2], Mani Subramanian[2], Robert Myers[2], Zachary Goodman[3], Andrew Muir[4], Christopher Bowlus[5], Aldo J Montano-Loza[6], Palak Trivedi[7], Cynthia LEVY[8]. *[1]Division of Gastroenterology and Hepatology, Medical University of Vienna, Austria; [2]Gilead Sciences, Inc., Foster City, CA, USA; [3]Inova Fairfax Hospital, Falls Church, VA, USA; [4]Duke Clinical Research Institute, Durham, NC, USA; [5]University of California Davis, Davis, CA, USA; [6]University of Alberta, Edmonton, AB, Canada; [7]NIHR Birmingham BRC, University of Birmingham, United Kingdom; [8]University of Miami, Miami, FL, USA*
Email: michael.trauner@meduniwien.ac.at

Background and Aims: Primary sclerosing cholangitis (PSC) is a heterogeneous cholangiopathy that leads to progressive biliary fibrosis. In this study, RNA sequencing (RNA-Seq) of liver tissue from PSC patients was performed to identify associations between biological pathways and clinical events independent of fibrosis stage.

Method: RNA-Seq (SureSelect protocol) was performed on baseline FFPE biopsies from 74 PSC patients enrolled in a 96-week clinical trial (NCT01672853). RNA quality was assessed by DV200 and gene expression quantified using Salmon. A semi-supervised approach was used to identify in-tissue, fibrosis-independent gene expression signatures associated with time to first PSC-related clinical event (e.g. cholangitis, decompensation, cholangiocarcinoma). The effect of fibrosis was subtracted from gene expression using the "removeBatchEffect" function in R package limma. Patient clustering, using genes associated with clinical events as input, was carried out using Consensus Clustering algorithm. Differential expression based on the identified risk groups was performed by Limma-Voom and pathway analysis by Ingenuity Pathway Analysis (IPA). All P-values were corrected for multiple testing.

Results: The median age was 48 yrs, 71% were male, 49% had IBD, 68% were prescribed UDCA, and 44% had Ishak F3-F6 fibrosis. The first principle component of RNA-Seq data accounted for 18% of variance and correlated with fibrosis stage ($\rho = –0.80$; $P < 0.001$). After removing the effect of fibrosis on gene expression data, PC1 was no longer associated with fibrosis ($\rho = –0.19$; $P = 0.11$). The patient clustering approach identified two distinct PSC patient clusters with differential risk of time to first PSC-related clinical event (log-rank $P < 0.0001$; Figure). These PSC patient clusters were not significantly different in terms of fibrosis stage ($P = 1.0$), enhanced liver fibrosis score ($P = 0.25$), hepatic α-SMA expression ($P = 0.87$), or serum concentrations of ALP ($p = 0.48$), ALT ($p = 0.97$), or GGT ($p = 0.74$). The top pathways identified by IPA were eIF2 signaling and regulation of eIF4/p70S6K signaling. Genes involved in the unfolded protein response (UPR), *ATF6* and *eIF2*, were among the transcripts differentially expressed between the PSC clusters (down-regulated in the high-risk group by log-fold-changes of –0.18 [$P = 0.02$] and –0.16 [$P = 0.02$], respectively).



Conclusion: After removing the influence of fibrosis-related pathways, this hepatic transcriptomic analysis identified canonical biological pathways, such as the UPR, that are associated with prognosis in PSC.

FRI170

Hepatic transcriptomic analysis identifies a mast cell gene expression signature that correlates with fibrosis stage and is prognostic in patients with primary sclerosing cholangitis

Michael Trauner[1], Yevgeniy Gindin[2], Jing Zhu Zhou[2], Jun Xu[2], Andrew Billin[2], Chuhan Chung[2], Mani Subramanian[2], Robert Myers[2], Atsushi Tanaka[3], Zachary Goodman[4], Andrew Muir[5], Douglas Thorburn[6], Christopher Bowlus[7], Cynthia Levy[8], Kris V. Kowdley[9]. *[1]Division of Gastroenterology and Hepatology, Medical University of Vienna, Austria; [2]Gilead Sciences, Inc., Foster City, CA, USA; [3]Teikyo University School of Medicine, Tokyo, Japan; [4]Inova Fairfax Hospital, Falls Church, VA, USA; [5]Duke Clinical Research Institute, Durham, NC, USA; [6]UCL Institute of Liver and Digestive Health, Royal Free Hospital, London, UK; [7]University of California Davis, Davis, CA, USA; [8]University of Miami, Miami, FL, USA; [9]Liver Institute Northwest, Seattle, WA, USA*
Email: michael.trauner@meduniwien.ac.at

Background and Aims: PSC is a heterogeneous cholangiopathy of unclear pathogenesis. Experimental and clinical data suggest roles for mast cell infiltration and senescence in the pathogenesis of PSC. We hypothesized that a mast cell gene expression profile would be increased in advanced PSC and explored associations with senescence-related gene expression.

Method: RNA sequencing (RNA-Seq, SureSelect protocol) of baseline FFPE liver biopsies from 75 patients with PSC enrolled in a clinical trial (NCT01672853) was performed to identify mast cell (Nakajima) and senescence (Reactome; both Broad Institute, GSEA C2 collection) gene expression signatures. RNA quality was assessed by DV200 and gene signature expression was quantified using a modified z-score approach (Plage method). Associations between these gene expression signatures and fibrosis stage, clinical parameters (e.g. IBD, UDCA use, liver biochemistry, ELF score, serum IL-8 and total bile acids, pruritus by Visual Analog Scale), and PSC-related clinical events (e.g. cholangitis, decompensation, cholangiocarcinoma) were evaluated.

Results: The median age was 48 yrs, 71% were male, 49% had IBD, 68% were on UDCA, and 44% had bridging fibrosis or cirrhosis (Ishak stages F3-F6). The mast cell gene expression signature was associated with increasing fibrosis stage (Figure) and correlated with ELF score (Pearson r = 0.63; p < 0.001), serum alkaline phosphatase (r = 0.44; p < 0.001), ALT (r = 0.36; p = 0.002), bilirubin (r = 0.40, p < 0.001), IL-8 (r = 0.39, p < 0.001), and total serum bile acids (r = 0.54, p < 0.001) but not IBD status, UDCA use, or pruritus severity. A significant inverse correlation was observed between the mast cell and senescence-related signatures (r = –0.90; p < 0.001), which contain no common genes. During a median follow-up of 23 months, 14 patients (19%) had a PSC-related event. In univariate Cox regression analysis, higher scores (≥the median) for the mast cell signature (hazard ratio [HR] 2.62; 95% CI 0.92, 7.49) and lower scores (< the median) for the senescence signature (HR 5.06; 95% CI 1.76, 14.51) were associated with an increased risk of events.

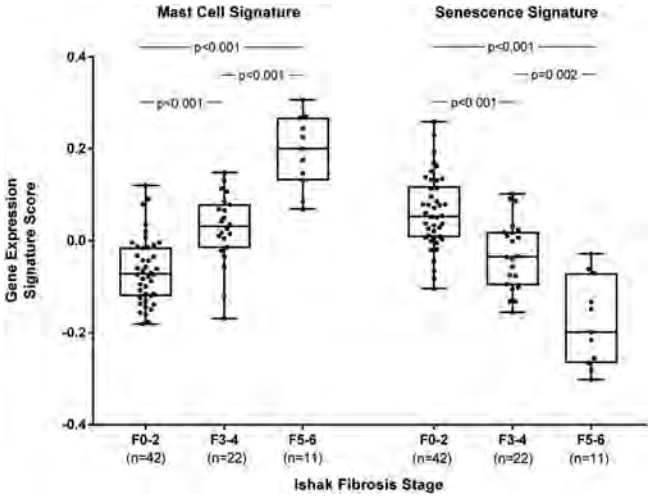


Figure: Associations Between Mast Cell and Senescence-Related Hepatic Gene Expression Signatures and Ishak Fibrosis Stage in PSC.

Conclusion: In patients with PSC, hepatic expression of mast cell-related genes is associated with increasing fibrosis stage, is prognostic, and is inversely correlated with expression of senescence-related genes. These data support experimental findings that suggest inhibition of mast cell infiltration and activation as potential therapeutic targets in PSC.

FRI171

Simultaneous liver and spleen stiffness measurements as complementary methods for fibrosis quantification in autoimmune hepatitis

Maciej K. Janik[1,2], Beata Kruk[3], Benedykt Szczepankiewicz[4], Konrad Kostrzewa[5], Raszeja-Wyszomirska Joanna[1,2], Barbara Górnicka[4], Frank Lammert[6], Piotr Milkiewicz[1,2,7], Marcin Krawczyk[3,6]. *[1]Medical University of Warsaw, Liver and Internal Medicine Unit, Poland; [2]European Reference Network on Hepatological Diseases (ERN RARE-LIVER); [3]Medical University of Warsaw, Laboratory of Metabolic Liver Diseases, Centre for Preclinical Research, Department of General, Transplant and Liver Surgery; [4]Medical University of Warsaw, Department of Pathology; [5]Warsaw School of Economics; [6]Saarland University Medical Centre, Department of Medicine II; [7]Pomeranian Medical University, Translational Medicine Group*
Email: p.milkiewicz@wp.pl

Background and Aims: Liver stiffness measurement (LSM), commonly performed using transient elastography (TE), is widely applied to assess liver fibrosis, but results can be biased by active hepatitis. This bias might be lower in spleen stiffness measurement (SSM), however, there is limited data concerning SSM in patients with autoimmune hepatitis (AIH). Here, we compare LSM-SWE and SSM-SWE (both performed by 2D-shear wave elastography) to LSM-TE and liver biopsy (LB) in prospectively recruited patients with AIH.

Methods: At first, LSM-SWE and SSM-SWE were compared to LSM-TE in 90 patients (80% women, median age 31 years, 21% with liver cirrhosis) treated for AIH for ≥6 months. Then, SWE and LB were performed in 57 patients with AIH (77% women, median age 37 years, 60% therapy-naïve, 37% with liver cirrhosis, 44% with histological signs of flare), with a median interval of 12 days between procedures.

The optimal SWE cut-offs were calculated in relation to fibrosis stages according to Batts & Ludwig. Finally, SWE changes during 18 months follow-up were evaluated in a cohort of 74 outpatients with AIH (80% women, median age 37 years, 28% with cirrhosis).

Results: LSM-SWE and SSM-SWE strongly correlated with LSM-TE ($P < 0.001$), however LSM-SWE was superior ($P < 0.01$) to SSM-SWE in identifying cirrhosis in treated patients. LSM-SWE and SSM-SWE correlated significantly ($P < 0.001$) with fibrosis in LB ($r = 0.74$, $r = 0.79$, respectively), but only LSM was associated with histopathological inflammatory score ($r = 0.39$, $P < 0.05$). When compared to LB, the optimal cut-offs for cirrhosis by LSM-SWE and SSM-SWE were 16.1 kPa (AUROC 0.92, $P < 0.001$, PPV = 0.76, NPV = 0.94) and 29.8 kPa (AUROC 0.95, $P < 0.001$, PPV = 0.88, NPV = 0.94), respectively. During follow-up, substantial improvements of LSM-SWE, ALT, and MELD (all $P \leq 0.01$), but neither of SSM-SWE nor markers of portal hypertension (PLT and PLT-to-spleen ratio) were detected. In subgroup analysis of patients with flares at baseline ($n = 14$) a significant ($P < 0.005$) reductions of LSM-SWE, SSM-SWE, and MELD was noted.

Conclusions: LSM-SWE and SSM-SWE might serve as complementary tools for the assessment of cirrhosis in patients with AIH. In patients with AIH flare and active hepatitis, SSM-SWE might provide more accurate estimation of liver fibrosis as compared to LSM-SWE alone.

FRI172

Pregnancy outcomes for women with primary sclerosis cholangitis and primary binary cholangitis

Email: mrc100@ic.ac.uk

Background and Aims: To determine maternal, obstetric and neonatal outcomes in a cohort of women with primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC)

Method: Retrospective cohort study of 10 UK specialist centres managing pregnant women with liver disease. Women with a diagnosis of PBC and PSC and a pregnancy of ≥20 completed weeks' gestation were included. Adverse outcomes were defined as maternal: development of ascites, variceal bleeding, encephalopathy and jaundice; obstetric events: gestational hypertension, pre-eclampsia and postpartum haemorrhage; and neonatal: stillbirth, preterm delivery, and admission to neonatal unit. The relationship of alanine transferase (ALT) and bile acid levels with gestation at delivery was studied.

Results: The first recorded pregnancies of 34 women with PSC and 27 with PBC were analysed. There were 60 livebirths and one intrapartum stillbirth that did not occur in the context of maternal cholestasis. Overall median gestation of delivery was 38 weeks, but the rate of preterm birth was 28% (17/61 deliveries) of which 76% (13/17) were spontaneous. Gestation at birth negatively correlated with maternal serum ALT concentration at booking ($p = 0.017$) and serum bile acid concentration during pregnancy ($p = 0.016$). There were no other significant correlations and maternal and neonatal outcomes were good.

Conclusion: Pregnancy in PBC and PSC is well tolerated, but women should be counselled regarding the increased risk of preterm birth. Measurement of maternal ALT and bile acids may help identify women at risk of preterm delivery.

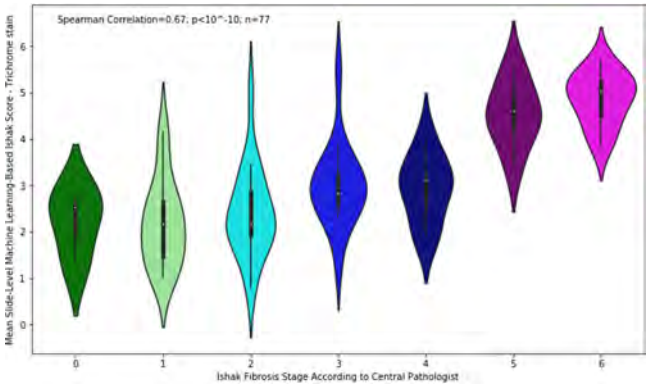
Email: chuhan.chung@gilead.com

Background and Aims: Variability in histological evaluation in patients with PSC may hinder disease staging and confound clinical trial results. Our aim was to develop machine learning (ML) models to accurately and automatically interpret PSC histology.

Method: ML models were developed using whole slide images of biopsies from 141 PSC patients enrolled in a trial of simtuzumab. Fibrosis was staged at baseline (BL) and weeks 48 and 96 by a central pathologist (CP) according to the Ishak classification using trichrome (TC)-stained slides. Using an ML platform (PathAI, Boston, MA), convolutional neural networks (>20 layers and 8 million parameters) developed for NASH (Pokkalla, AASLD 2019) were further trained using 44,000 annotations (eg. fibrosis, lobular/portal/interface inflammation, bile ducts/ductules) from 29 board-certified pathologists on images from 252 H&E, 254 TC, and 330 picrosirius red (PSR)-stained slides. The model was trained to recognize and summarize these features at slide-level. For fibrosis, models were trained on TC and PSR images using slide-level CP Ishak stages to recognize patterns associated with each stage. These region-based scores were used to generate a slide-level ML fibrosis score. Correlations between these scores and CP-derived fibrosis stage were evaluated on test images excluded from model training (77 TC, 88 PSR), and associations between ML-derived features with clinical parameters, PSC-related events (e.g. decompensation, cholangitis, transplantation), and progression to cirrhosis were determined.

Results: ML fibrosis scores were strongly correlated with Ishak stage by the CP ($\rho = 0.67$ [PSR and TC images]; both $p < 10^{-10}$; Figure), serum ELF ($\rho = 0.68$–0.72; both $p < 10^{-11}$), and serum alkaline phosphatase (ALP) ($\rho = 0.49$–0.56; both $p < 10^{-5}$). During a median follow-up of 23 months (IQR 18.9, 23.1), 21% of patients (29/141) developed a PSC-related event. Events were associated with higher ML Ishak fibrosis score at BL (HR per unit: 1.74 [95% CI 1.18, 2.59]) and greater area of interface inflammation and remodeling (HR per 1%: 1.39 [95% CI 1.14, 1.70]) (both on TC images). Discrimination of the ML Ishak fibrosis score (TC) was similar to CP-derived Ishak stage, ELF, and serum ALP (c-statistics 0.68–0.69), and area of interface inflammation and remodeling (c-statistic 0.65). The ML Ishak fibrosis scores were also predictive of progression to cirrhosis at week 48 or 96 (AUROCs 0.86 for TC and 0.76 for PSR). By comparison, AUROCs for CP-derived Ishak stage, ELF, and ALP were 0.73, 0.81, and 0.74, respectively.



Conclusion: ML models demonstrated high concordance with pathologist assessment of PSC-related fibrosis, and ML-derived metrics were associated with the risk of disease progression. These data highlight the potential of ML for automated and quantitative assessment of liver histology and risk stratification in PSC.

FRI174

CCL24 modulates fibrosis development in primary sclerosing cholangitis: correlation of human serum CCL24 levels with fibrosis markers and data from the Mdr2−/− mouse model.

Neta Barashi[1], Michal Segal[1], Arnon Aharon[1], Avi Katav[1], Adi Mor[1], Inbal Mishalian[2], Devorah Olam[2], Amnon Peled[2], Francesca Saffioti[3], Douglas Thorburn[3]. [1]*ChemomAb Ltd., Israel;* [2]*Genetic Therapy Institute, Hadassah Medical Center, Jerusalem, Israel;* [3]*Royal Free London NHS Foundation Trust, London, United Kingdom*
Email: neta@chemomab.com

Background and Aims: Primary sclerosing cholangitis (PSC) is a disease involving hepatic inflammatory, cholestatic liver damage and fibrosis, with no approved medical treatment. CCL24, a chemokine that was shown to be involved in the development of liver inflammation and fibrosis in several animal models is over expressed in liver biopsies of PSC patients. Blocking CCL24, was shown to diminish liver fibroblast activation and reduce liver fibrosis in both NASH and PSC models. Here we aim to study the correlation between CCL24 and fibrotic biomarkers in serum of PSC patients and to assess the anti-fibrotic effect of blocking CCL24 in the MDR2−/− mouse model.
Method: Serum CCL24 levels of PSC patients was quantified by ELISA and corelated with the serum levels of the fibrotic biomarkers TIMP-1 and ELF scoring. Cholestatic liver injury and fibrosis were studied in C57/bl MDR2−/− mice treated with either placebo or 5 mg/kg of the CCL24 blocking antibody CM-101(D8) by SC injections. Serum alkaline phosphatase (ALP) and bile acid (BA) levels were measured and fibrosis was evaluated by histopathological analysis of H&E and Sirius red stained liver sections. Expression of liver TIMP-1 and Col1a1 were tested by Real-time PCR.
Results: MDR2−/− mice developed severe ductular reaction accompanied by progressive fibrosis. CM-101 (D8) treatment diminished cholestatic injury manifested in normalization of ALP and significant reduction of BA levels (144 ± 15 vs.173 ± 27; $p \leq 0.05$ and 15 ± 7 vs. 34 ± 13, $p \leq 0.001$, respectively). Histological assessment of fibrosis by Sirius red staining revealed that CM-101(D8) treatment significantly attenuated fibrosis development. This was further supported by reduced liver expression of the profibrotic genes Col1a1 and TIMP-1. CCL24 levels in serum from PSC patients were corelated with serum levels of TIMP-1 ($R = 0.65$, $p \leq 0.005$), and ELF score ($R = 0.39$, $p = 0.06$) suggesting an association between CCL24 and PSC related fibrosis.

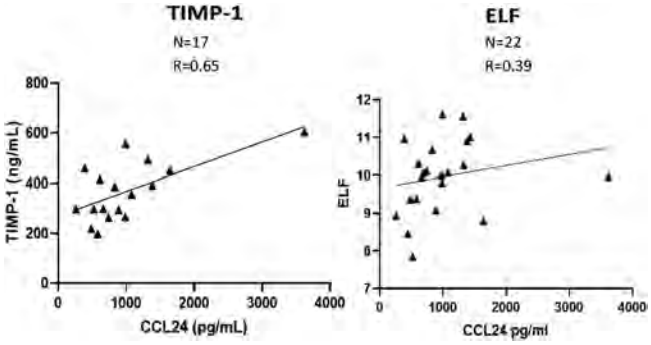


Figure: Correlation of CCL24 with fibrotic biomarkers in PSC patients.

Conclusion: CCL24 expression correlates with increased expression of TIMP-1 and ELF scoring in the serum of PSC patients. CCL24 blockade using CM-101(D8), a specific anti-CCL24 antibody, in an animal model of cholestasis, reduced TIMP-1 and Col1a1 expression in the liver reflecting significant attenuation of hepatic fibrosis. These findings support the potential of CCL24 as a therapeutic target in liver fibrotic diseases and the anti-fibrotic activity of CM-101.

FRI175

Belimumab: a promising third line treatment option for refractory autoimmune hepatitis

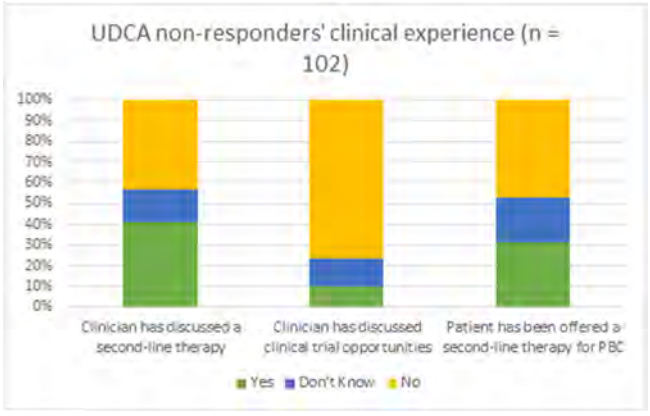
Pinelopi Arvaniti[1], George Giannoulis[1], Stella Gabeta[1], Kalliopi Zachou[1,2], George Dalekos[1,2]. [1]*University Hospital of Larissa, Department of Medicine and Research Laboratory of Internal Medicine, National Expertise Center of Greece in Autoimmune Liver Diseases, Larissa, Greece;* [2]*Institute of Internal Medicine and Hepatology, Larissa, Greece*
Email: peni.arvaniti@gmail.com

Background and Aims: Autoimmune hepatitis (AIH) is an autoimmune liver disease of unknown aetiology that may lead to end stage liver disease if untreated. In real world conditions, however, it appears that less than 50% of patients achieve complete response on standard immunosuppression. Serum B cell activating factor (BAFF) levels are high in AIH patients contributing probably to disease pathogenesis. As belimumab, a BAFF inhibitor, was proved effective in other autoimmune diseases, the aim of the present case-study was to investigate the safety and efficacy of belimumab as a third line treatment option in patients with AIH refractory to standard treatments.
Method: Belimumab (10 mg/kg iv) was administered as add on, third line treatment in two AIH patients who had partial response and multiple flares with conventional regimens. Belimumab was administered on days 0, 14, 28 and every 28 days thereafter according to previous publications. The outcome after 12 months of treatment was evaluated.
Results: Both patients (27 years old female and 58 years old male) had AIH-related compensated cirrhosis at diagnosis. The female patient had received treatment with prednisolone (PRED, 1 mg/kg/d) and azathioprine (AZA, 1.5 mg/kg/d) for 12 months during which she suffered multiple relapses and then mycophenolate mofetil (MMF, 2 g/d) for 54 months with partial response. The male patient received combination therapy with PRED and AZA for a short period due to severe myelotoxicity and then MMF for 46 months with initial complete response but flares in any attempt of PRED withdrawal. Therefore, add on third line therapy with belimumab was initiated at month 66 and 47 of follow-up. Both patients achieved complete response after the 1st and 5th belimumab infusion, respectively, and remained in remission during the next 12 and 8 months, respectively, while receiving low corticosteroids dose (<10 mg/d). Of interest, in the female patient sequential liver stiffness measurements were improved (from 14.6 kPa to 9 kPa) while second liver biopsy showed significant improvement (no inflammatory activity and moderate

fibrosis). No adverse events were observed and none of patients decompensated.
Conclusion: Belimumab could be an effective and safe third line treatment option for patients with refractory AIH and advanced liver fibrosis. However, long-term randomized control trials are needed in order to assess belimumab efficacy and safety in this difficult to treat subgroup of AIH patients.

FRI176
European Association for the Study of the Liver primary biliary cholangitis guideline clinical care standards: the patient experience as recorded by PBC Foundation app and International Patient Registry
Robert Mitchell Thain[1], Jessica Leighton[2], Vinod Hegade[3]. [1]*PBC Foundation, Edinburgh, United Kingdom;* [2]*Freeman Hospital, Liver Unit, Newcastle-upon-Tyne;* [3]*St James University Hospital, Hepatology, Leeds, United Kingdom*
Email: vinod.hegade@newcastle.ac.uk

Background and Aims: In 2017, EASL published practice guidelines for care in Primary Biliary Cholangitis (PBC), and set out clinical care standards. Using the PBC Foundation's smartphone App, linked to an international patient registry, we aimed to assess the patient experience, particularly in reference to the EASL clinical care standards. We focussed on ursodeoxycholic acid (UDCA) dose, response status, second-line therapy and symptoms.
Method: PBC Foundation's self-management App became available to use in May 2019. To date, the App has been downloaded by over 2500 service users. A survey was produced via the App, inviting patients to answer a series of "radio-style" questions, with only tick box options to answer. Members were invited to the survey in Oct 2019. Only patients with PBC were included.
Results: 153 patients with PBC (N = 153) responded to the survey. As compared to EASL's target of 90%, only 51% of respondents (n = 78) were on optimal UDCA dose (13–15 mg/kg/day). 18% (n = 28) received higher doses (>15 mg/kg/day). Short of EASL's target of 90%, only 66.7% respondents (n = 102) reported that their clinician had asked them about their PBC symptom burden in the last 12 months.



EASL set a target of 80%, yet only 62% respondents (n = 95) had been informed of their UDCA response status by their clinicians.
Of the 153 respondents, 102 (66.6%) were UDCA non-responders. Of these only 41.2% (n = 42) reported their clinicians had discussed second-line therapies with them and 15.7% (n = 16) reported they did not know. Only 31.4% (n = 32) had been offered a second-line therapy by their clinicians, with a further 21.6% (n = 22) not knowing if they had been offered a second-line therapy
Overall, 75.5% (n = 77) reported their clinician had not spoken to them about clinical trial opportunities with only 9.8% reporting such a discussion with their clinicians.

Conclusion: The PBC App is an effective way to capture treatment related information with a high level of patient engagement. The results of this survey are well below the clinical care standards proposed in the EASL PBC guidelines. Our study highlights the need for improved clinician education about the current best practice in the care and management of PBC.

Email: rory.peters@ndm.ox.ac.uk

Background and Aims: IgG4-related disease (IgG4-RD) is a complex multi-system fibro-inflammatory disorder that often manifests as autoimmune pancreatitis or sclerosing cholangitis. Challenges include diagnostic differentiation from malignancy and other inflammatory conditions, careful management to minimise gluco-corticoid-induced toxicity and prevention of progressive organ dysfunction. We describe the experience of the first multi-site specialist IgG4-RD multi-disciplinary meeting (MDM) incorporating a broad range of generalists and specialists and held via web-link between Oxford University Hospitals and University College London Hospital.
Method: Data from the IgG4-RD MDM was collected prospectively in real-time over a three-year period. We performed a review of patient electronic records with specific emphasis on diagnosis, management decisions and outcomes.

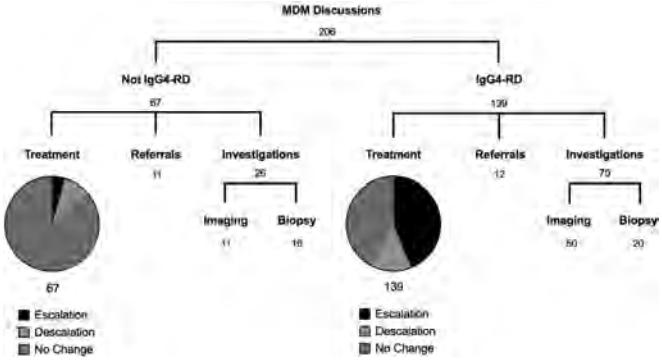

Figure 1: IgG4 MDM management recommendations.

Results: Over three-years, there were 206 discussions on 156 patients. Of these patients discussed, 97 (62%) were considered to have definite (60) (meeting defined diagnostic criteria) or possible (37) (considered most likely diagnosis at MDM) IgG4-RD. 67% had multi-organ involvement and 23% had a normal serum IgG4. Disease phenotype of these IgG4-RD patients was as follows: Systemic 47.4%, Hepatopancreatobiliary 37.1%, Ear Nose & Throat 12.4% and Retroperitoneal/Aortic 3.1%. The average number of specialist opinions sought prior to MDM was four. Management was changed in the majority of patients (74%) with the MDM recommending treatment escalation in 61 cases, including 19 recommendations for rituximab (Figure 1).
Conclusion: Our cross-discipline IgG4-RD MDM enhanced diagnostic clarity, a major concern for patients who may experience delays and misdiagnosis, often compounded by cross-speciality presentation of a rare disease. The pooled experience of our MDM provided consistency in complex decisions including management of multi-

system or sub-clinical disease. Our MDM based approach could be used as a model for IgG4-RD management at other centres.

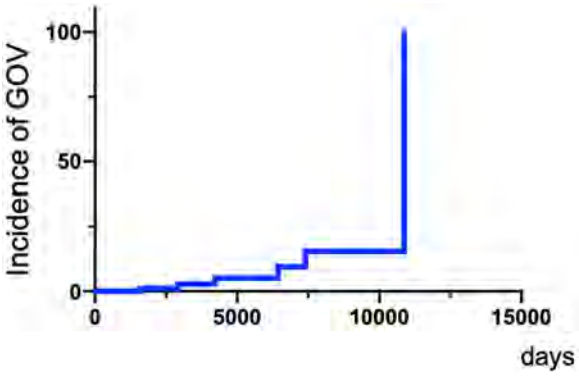
Long-term prevalence of gastro-oesophageal varices in early primary biliary cholangitis patients with good response to treatment

Toru Setsu[1,1], Junji Yokoyama[1], Masaaki Takamura[1], Shuji Terai[1].
[1]*Niigata university, division of gastroenterology and hepatology, Niigata, Japan*
Email: setsut@med.niigata-u.ac.jp

Background and Aims: Recent routine testing for anti-mitochondrial antibodies has increased the number of patients with early primary biliary cholangitis (PBC). Furthermore, most PBC patients respond to ursodeoxycholic acid, leading to good prognosis and an increased number of aged PBC patients. Since Gastro-oesophageal varices (GOV) is a life-threating complication in chronic disease patients, several clinical tools for the prediction of varices in chronic liver disease patients have been developed. However, in PBC patients, risks related to development of varices are still obscure. We sought to determine the long-term prevalence and clinical characteristics of GOV in PBC patients

Method: We retrospectively reviewed 392 PBC patients who had undergone oesophago-gastro-duodenoscopy (OGD) regularly from 1985 to 2018. Histopathological data were available in 160 patients. We divided the patients into two groups and explored the characteristics of patients with varices; early stage (Scheuer I and II) and advanced stage (Scheuer III and IV).

Results: Fifteen percent (59/392) of patients had GOV. Twenty-six patients had GOV at the time of diagnosis, and 32 patients developed GOV during the course. The median follow-up period was 7.1 years prior to the development of GOV. Multivariate analysis revealed that itching, reduced serum albumin level and decreased platelet count were significantly associated with GOV development. In histopathological analysis, advanced-stage PBC patients showed significantly higher incidence of GOV than early stage PBC ($p < 0.0001$, log-rank test). From the viewpoint of response to treatment, patients who had good response to UDCA and met Paris criteria showed significantly lower prevalence of GOV ($p < 0.0001$, log-rank test). Patients with GOV had a significantly higher GLOBE score than those without GOV (0.89 ± 0.30 vs. -0.06 ± 0.63, $p = 0.0006$). On the other hand, among early Scheuer stage PBC patients who met Paris criteria, 5.7% (6/105) of patients developed GOV during the long-term follow up (1.1–29.1 years, Figure). Laboratory findings in those patients were comparable to the early stage PBC patients without GOV.



Conclusion: Early PBC patients with good response to UDCA treatment can develop GOV. Since it's difficult to predict the development of GOV in early PBC patients, we should bear in mind that periodic endoscopic screening for varices is important even in steady PBC patients.

FRI179

Symptom burden in patients living with primary biliary cholangitis: indigenous Canadians report significantly higher PBC-40 quality of life scores

Surain Roberts[1,2], Gideon Hirschfield[1,2], Catherine Vincent[3], Lawrence Worobetz[4], Jennifer Flemming[5], Harry Janssen[2], Aliya Gulamhusein[1,2], Andrew L. Mason[6], Bettina Hansen[1,2].
[1]*University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada;* [2]*University Health Network, Toronto Centre for Liver Disease, Toronto, Canada;* [3]*University of Montreal, Department of Medicine, Montreal, Canada;* [4]*University of Saskatchewan, Department of Medicine, Saskatoon, Canada;* [5]*Queen's University, Department of Medicine, Kingston, Canada;* [6]*University of Alberta, Department of Medicine, Edmonton, Canada*
Email: surain.roberts@mail.utoronto.ca

Background and Aims: Primary Biliary Cholangitis (PBC) is a chronic liver disease that adversely impacts quantity and quality of life. We aimed to investigate differences in PBC-related quality of life by ethnicity in our multicentre Canadian cohort using the UK-derived PBC-40 questionnaire.

Method: The Canadian Network for Autoimmune Liver disease (CaNAL) is a multicentre registry including patients with PBC followed prospectively. Mixed-effects regressions with random intercepts were used to investigate the association of PBC-40 quality of life scores with ethnicity, in participants who completed at least one PBC-40 quality of life questionnaire.

Results: 318 patients were included from 5 centres in Canada with a mean of 1.2 measurements per patient. Mean (SD) age at first PBC-40 questionnaire was 59.4 (10.3) years, 94% (n = 299) were female, and mean duration of disease was 9.4 (7.7) years. 82% of the cohort were Caucasian (n = 262), 5.7% Asian (n = 18), 3.8% Indigenous Canadian (n = 12), 2.2% Black (n = 7), 2.2% Middle Eastern (n = 7), and 3.8% of various other ethnicities (n = 12). PBC-40 scores slightly lower than those previously published in the literature were identified: out of a maximum score of 200, mean (SD) total PBC-40 scores were 86 (32) for Caucasian patients, 100 (32) for Asian patients, 127 (22) for Indigenous Canadian patients, 69 (37) for Black patients, and 86 (31) for Middle Eastern patients.

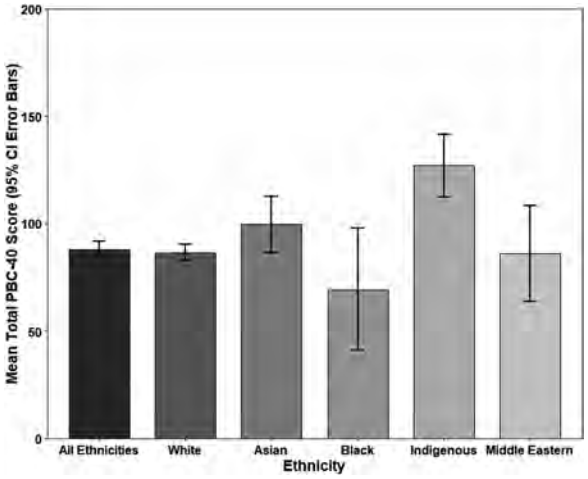


Figure: Mean Total PBC-40 Scores by Ethnicity

Indigenous Canadian ethnicity was associated with a mean total PBC-40 score that was 40 (95%CI 21–59) points higher than other Canadians ($p < 0.0001$). Indigenous Canadians were the only ethnicity whose mean total PBC-40 scores differed significantly from Caucasian patients ($p < 0.0001$). Investigation into which specific PBC-40 domains contributed to these worse scores revealed that Indigenous Canadians had significantly higher scores across all 5 domains of the PBC-40 compared to other Canadians (itch/symptom/

fatigue/cognitive/social-emotional: 3.1/4.8/11.7/8.2/12.3 additional points, p < 0.005 all domains). These differences in reported quality of life remained after adjusting for sex, age, centre, and duration of disease (itch domain p < 0.05, other domains p < 0.005).
Conclusion: When applying the PBC-40 in a multi-ethnic Canadian setting, quality of life burden among patients with PBC was substantially higher for Indigenous patients compared to other Canadians. Both the method of assessment, and approaches to improving quality of life in patients living with PBC, must be tailored to the population of patients served.

FRI180

Efficacy and tolerance of obeticholic acid in patients with primary biliary cholangitis and inadequate response to ursodeoxycholic acid in real life: interim analysis of the OCARELIFE study

Leroy Vincent[1], Christophe Corpechot[2], Jérôme Dumortier[3], Laurent Alric[4], Dominique Larrey[5], Sebastien Dharancy[6], Olivier Chazouillères[7], Alexandra Heurgue-berlot[8], Francois Boer[9], Aldo Trylesinski[9]. *[1]CHU Michallon, Department of Hepatology and Digestive Diseases, Grenoble, France; [2]Saint-Antoine Hospital, Paris, France, Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, Paris, France; [3]Hospices Civils de Lyon, Hôpital Edouard Herriot, Université Claude Bernard Lyon, Department of Hepatology and Digestive Diseases, Lyon, France; [4]Toulouse University Hospital, Department of Internal Medicine and Digestive Diseases, Toulouse, France; [5]Saint Eloi University Hospital, Department of Hepatology and Digestive Diseases, Montpellier, France; [6]Claude Huriez University Hospital, CHRU Lille, Hepatology Department, Lille, France; [7]Saint-Antoine Hospital, Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, Paris, France; [8]Robert-Debré University Hospital, Department of Hepatology and Digestive Diseases, Reims, France; [9]Intercept Pharmaceuticals, Paris, France*
Email: vincent.leroy2@aphp.fr

Background and Aims: Obeticholic acid (OCA), a selective farnesoid X receptor agonist, is currently the only approved second-line therapy for patients (pts) with primary biliary cholangitis (PBC) with inadequate response to ursodeoxycholic acid (UDCA). The objectives of the study were to evaluate the efficacy and the tolerability of OCA in the real-life setting in France.
Method: OCARELIFE is an observational, noninterventional, multi-site, ambispective study of pts with PBC who started OCA treatment in France between Oct 2016 and Dec 2017. Eligible pts had a diagnosis of PBC, an inadequate response to UDCA according to Paris II criteria, and had received at least 1 dose of OCA. The planned follow-up was 18 months (M). Clinical data and laboratory tests were collected at baseline (BL) and visits M1, M3, M6, M9, M12, and M18. Primary endpoint was the percentage of pts meeting Paris II criteria at M12.
Results: Interim analysis included 76 pts with consolidated data at BL. Most pts were female (87%) with a mean (standard deviation [SD]) age of 56 ± 11 years. Mean (SD) PBC disease duration was 10 ± 7 years. At BL, pruritus was present in 41% and considered severe in 7% of pts; mean (SD) total bilirubin and alkaline phosphatase (ALP) concentrations were 23 ± 33 µmol/L and 252 ± 201 IU/L, respectively. Liver biopsy was available in 84% of pts, and 41.5% of the pts had advanced fibrosis (METAVIR F3 or F4 or Scheuer stage 3 or 4) at BL. Transient elastography was available in 75% of pts: 50% had severe fibrosis defined as ≥9.6 kPa and 29% were >14.4 kPa. Seventy-two pts (95%) received UDCA at a median dose of 15.6 mg/kg, and 21 (28%) received fibrates. Efficacy was assessed in the 50 pts who temporally achieved M12 treatment period. Liver tests (mean) significantly improved after 12 months of treatment (Table). The percentage of pts with normal bilirubin increased from 61% at BL to 82% at M12. The primary endpoint of Paris II criteria was achieved by 40% (95% CI, 26.4–53.6) at M12. Liver stiffness did not change significantly. The main adverse events were fatigue (49%), pruritus (30%), and arthralgia (9%). Thirteen pts (17%) did not reach M12 due to pruritus. Three pts experienced serious adverse events, all of which were considered not related to therapy.
Conclusion: This real-life study including pts in severe condition demonstrated OCA efficacy and tolerability profile consistent with that observed in previous controlled trials.

FRI181

Lost in the system: identification of patients with undiagnosed primary biliary cholangitis

Jorge Yebra Carmona[1], Carla Amaral[2], Esther Molina[3], Maria Hernández Pérez[1], Carolina Suarez Cabredo[1], Isabel Spigarelli de Rábago[1], Cristina Julia Suárez Ferrer[1], Dalia Morales Arraez[2], Felicitas Diaz-Flores[4], Javier Fernandez[3], Pablo Eiras[5], Manuel Hernández Guerra[2], Antonio Olveira Martin[1]. *[1]Universitary Hospital La Paz, Gastroenterology, Madrid, Spain; [2]Universitary Hospital of the Canary Islands, Gastroenterology, Santa Cruz de Tenerife, Spain; [3]Universitary Hospital of Santiago de Compostela, Gastroenterology, Santiago de Compostela, Spain; [4]Universitary Hospital of the Canary Islands, Central Laboratory, Santa Cruz de Tenerife, Spain; [5]Universitary Hospital of Santiago de Compostela, Immunology, Santiago de Compostela, Spain*
Email: aolveiram@gmail.com

Background and Aims: There is a renewed interest in Primary Biliary Cholangitis (PBC). The existence of inadequately detected patients, so called patients lost in the system (PLS), has been shown in other liver diseases as Hepatitis C. We aimed to investigate this issue in PBC.
Method: Database analysis (Immunology, Biochemistry, Reports, Appointments) of three reference Hospitals in Spain covering 1565000 healthcare population. PBC was diagnosed if AMA ≥ 1:80, chronically elevated alkaline phosphatase (ALP), and absence of other liver disease. Classification: 1) Baseline-detected PBC (diagnosis and treatment since the beginning); 2) Baseline PBC-PLS (absence of reports diagnosing PBC, medical follow-up and/or treatment with bile salts); 3) PBC development (previously normal ALP with elevation during follow-up); 4) PBC development-PLS (previously normal ALP subsequently elevated without detection or treatment). In patients with detected PBC, the delay time (DT) between first elevation of ALP and first request of AMA was also analyzed. Variables were expressed in n (%); median (IQR25-75); differences were assessed by T-test/U-Mann-Whitney (quantitative) or Chi-square (categorical); statistical significance was considered if p < 0.05.

Table

	n	Baseline	Month 12	Difference	95% CI		p value*
AST, IU/L	45	61.3	49	−12.3	−23.35	−1.32	0.0075
ALT, IU/L	45	66.2	46.6	−19.6	−34.35	−4.9	0.0002
GGT, IU/L	43	323.4	153.4	−170	−243.06	−96.62	< 0.0001
ALP, IU/L	42	250.8	188.1	−62.7	−122.84	−2.44	0.0042
Bilirubin, µmol/L	40	17	16.47	−0.53	−4.15	3.08	0.0790

*Wilcoxon signed-rank test.
ALP, alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; CI, confidence interval; GGT, gamma-glutamyl transferase.

Figure: (abstract: FRI180)

Results: 1326 patients with AMA ≥ 1:80 (83.3% women, 56 years) between Jan/2010 – March/2019 were included: PBC 673 ([50.7%] 556 baseline-detected, 90 baseline-PLS, 18 development, 9 development-PLS), 653 with permanently normal ALP (49.3%). 99/673 (14.7%; CI95% 12–17.3) were identified as PLS. Of them, 26/99 have been contacted and retrieved for now (characteristics in Table 1). PBC has been confirmed and Ursodeoxycholic acid started in all. PBC development rate in patients with normal baseline ALP was 3.9% (27/680; median follow-up 2.96 ± 2.41 years). DT was 2.06 ± 3.89 years.

Table 1: Characteristics of retrieved patients

N = 26	(%)
Women	24 (92)
Other autoimmune disease	12 (46)
Pruritus	2 (7)
Fatigue	7 (26)
Elastography > 9.5 kPa	7/24 (29)
	Median (IQR)
Age (years)	70 (60–80)
Body Mass Index (kg/m^2)	27 (26–29.2)
ALP (UI/L)	185 (135–321)
GGT (UI/L)	101 (70–204)
Bilirubin (mg/dL)	0.6 (0.42–0.96)
Elastography (kPa)	7.1 (5.2–10)

Conclusion: Up to 14.7% patients (1 out of 7) with definitive diagnostic results of PBC remain undetected, preventing their monitoring and treatment. An effort to identify and retrieve these lost-in-the-system patients is necessary. The use of hospital databases is an appropriate tool.

Cirrhosis: ACLF and Critical illness

Low growth hormone levels predict poor outcome of hepatitis B virus-related acute-on-chronic liver failure

Zhongyang Xie[1], Lingjian Zhang[1], Xiaowei Xu[1], Lanjuan Li[1]. [1]*The First Affiliated Hospital, College of Medicine, Zhejiang University, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China*
Email: ljli@zju.edu.cn

Background and Aims: Hepatitis B related acute-on-chronic liver failure remains a serious entity with high mortality. Growth hormone

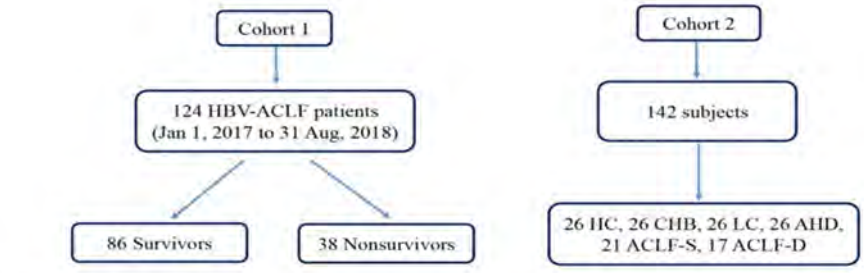

Figure 1 flow chart if enrolled cohorts.

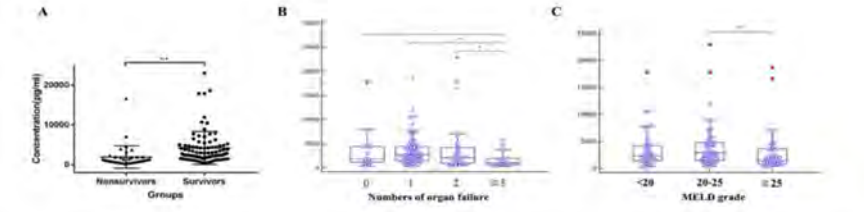

Figure 2 distribution of GH in HBV-ACLF cohort. (A) GH level was higher in survivors group than in nonsurvivors group. (B) Patients with 3 or more organs failure had lower GH levels than patients with 2, 1 or no organ failure. (C) Patients with MELD ≥ 25 had lower GH levels than patients with MELD between 20 and 25.*<0.05, **<0.01.

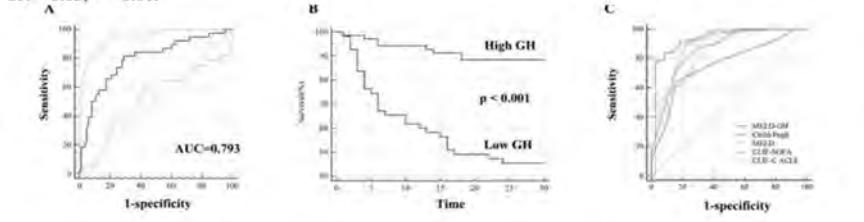

Figure 3 Performance of GH on predicting 30-day survival of HBV-ACLF patients. (A) the AUC of GH predicting the outcome was 0.793, and low GH(<2001ng/ml) group showed significantly worse 30-day outcome than high GH group. (C) MELD-GH score showed highest AUC than Child-Pugh, MELD, CLIF-SOFA and CLIF-C ACLF scores.

Figure: (abstract: FRI182)

(GH) is related to the liver metabolism and regeneration. The present study aimed to explore the changes and prognostic efficacy of GH on the outcome of HBV–ACLF.

Method: A prospective cohort of 124 patients and a cross-sectional cohort of 142 subjects were enrolled. History, complications, as well as image and laboratory measurements. Growth hormone (GH) and insulin-like growth factor-1(IGF-1) were detected by ELISA. 30-day survival was collected cirrhosis and the association between GH and the 30-day mortality of HBV-ACLF was analyzed.

Results: The mean age of the whole prospective cohort was 46.61 ± 12.71 years, and 19 (15.3%) patients were female. GH level was significantly higher in survivors than nonsurvivors of HBV-ACLF patients ($P < 0.001$), and it was correlated to white blood cell (WBC) count, albumin, blood urea nitrogen (BUN), etc. In the cross-sectional cohort, GH level was significantly higher in liver cirrhosis – acute decompensation group than liver cirrhosis group ($p < 0.001$). ACLF group didn't show any difference compared with liver cirrhosis- acute decompensation (LC-AD) group. The AUROC of GH for 30-day mortality was 0.793. Combining with MELD score, we built a new prognostic model, namely MELD-GH, which showed better predictive efficacy than Child-Pugh, MELD, CLIF-SOFA and CLIF-C ACLF scores.

Conclusion: Low GH predicted the poor outcome of HBV-ACLF patients. Combined with MELD, MELD-GH had better predictive accuracy when compared to Child-Pugh, MELD, CLIF-SOFA and CLIF-C ACLF scores. Pituitary function might play a role on ACLF, which need further research.

FRI183

Mesenchymal stem cells regulated DX5 – liver natural killer cells in rescuing acute-on-chronic liver failure murine

Jing Xiong[1], Bingliang Lin[2], Zhiliang Gao[3], Shi Qiu Xiong[4], Weizhen Weng[2], Dengna Lin[5], Jun-feng Chen[3], Hui Juan Cao[3], Shao Quan Zhang[3], Jing Zhang[3], Juan Gao[5]. *[1]The third affiliated hospital of Sun Yet-Sen university, the third affiliated hospital of Sun Yet-Sen university, Guangzhou; [2]Third seventh Hospital of Sun Yat-Sen University, Infectious Diseases, Shenzhen, China; [3]Third Affiliated Hospital of Sun Yat-Sen University, Infectious Diseases, Guangzhou, China; [4]National Measurement Lab, LGC, Cell Biology group, Cambridgeshire, United Kingdom; [5]the third affiliated hospital of Sun Yat-Sen University, GuangDong Provincial Key Laboratory of Liver Diseases, Guangzhou, China*
Email: lamikin@126.com

Background and Aims: Acute-on-chronic liver failure (ACLF) is a severe, life-threatening syndrome with high mortality. Transplantation of Mesenchymal Stem Cells (MSCs) have been shown their efficacy in reducing mortality of ACLF patients in our clinical trials, but the mechanism is not clear, so unveiling the underlying mechanism of action will improve clinical regime of ACLF.

Method: Flow cytometry was applied to characterize natural killer cell (NK) from HBV-ACLF patients and ACLF mouse, and MSC developed in vitro.

An acute-on-chronic liver failure mouse model was established by injection of carbon tetrachloride (CCL4) intraperitoneally. Confocal microscopy was used to investigate cell-cell contact. Hematoxylin and eosin stained specimens and Bromodeoxyuridine incorporated liver tissues were investigated under microscopes. Western blot was used for hepatocellular death assay.

Results: Frequency of peripheral blood NK cells and frequency of NKG2A and KIR3DL1 on NK cells from HBV-ACLF patients were upregulated by MSCs infusion. Frequency of NKG2D, perforin and FasL were suppressed, which correlated with the recovery of liver function. MSCs infusion improved survival rate of ACLF mice efficiently (Log-rank $X2 = 3.88$, $P < 0.05$), coinciding with hepatitis remission, liver regeneration and NK frequency increase both in blood and liver. Meanwhile, MSCs were proved to promote the proliferation and GM-CSF secretion of NKP46+ DX5- liver NK cells specifically, which may be owing to their higher cell-cell (MSC-NKP46+ DX5- liver NK cells) adhesion.

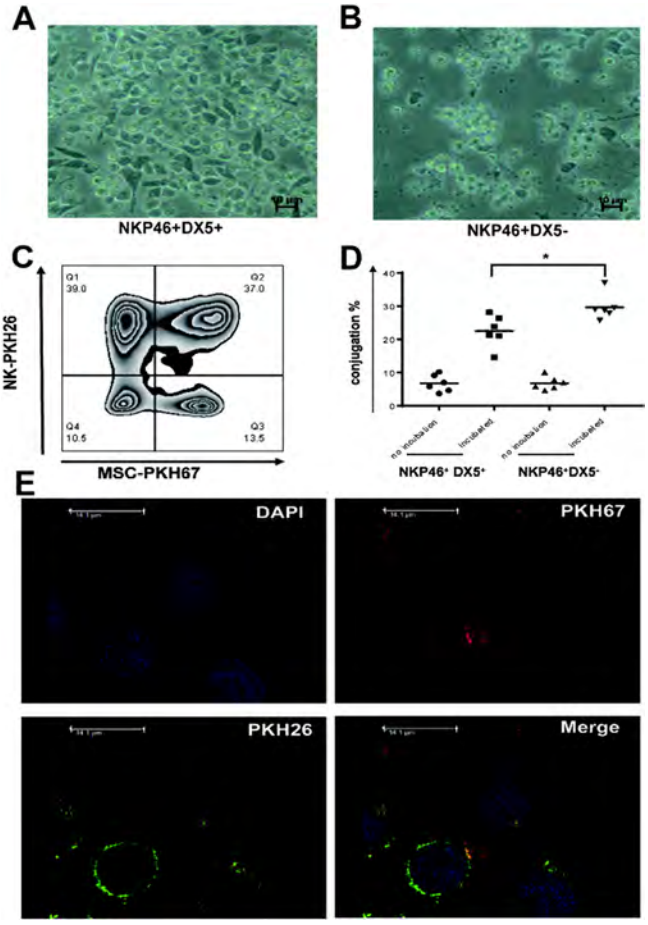

Figure: MSCs conjugated with NKP46+DX5- liver NK cells preferentially in vitro.

Conclusion: MSCs can rescue the ACLF patient and mouse by regulating NK cell. Promoting NKP46+ DX5- liver NK cells proliferation and secreting GM-CSF maybe the new machinery of MSCs' efficacy in ACLF.

Selecting patients with decompensated cirrhosis and acute-on-chronic liver failure (ACLF) admitted to the intensive care unit for liver transplantation

Sophie-Caroline Sacleux[1,2,3,4,5], Faouzi Saliba[1,2,3], Philippe ICHAI[1,2,3], Marc Boudon[1,2,3], Elise Lemaitre[1], Audrey COILLY[1,2,3], Valérie Caillez[1], Rodolphe Sobesky[1,2,3], Eleonora De Martin[1,2,3], Ilias Kounis[1], Gabriella Pittau[1,2,3,4,5], Oriana Ciacio[1,2,3,4,5], Cyrille Feray[1], Daniel Azoulay[1], Eric Vibert[1,2,3,6], Daniel Cherqui[1,3], René Adam[1,4,5], Jean-Charles Duclos-Vallée[1,2,3,6], Didier Samuel[1,2,3,6]. *[1]AP-HP, Hôpital Paul Brousse, Centre Hépato-Biliaire, Villejuif, France; [2]Univ Paris-Sud, UMR-S 1193, Université Paris-Saclay, Villejuif, France; [3]Inserm, Unité 1193, Université Paris-Saclay, Villejuif, France; [4]Univ Paris-Sud, UMR-S 935, Université Paris-Saclay, Villejuif, France; [5]Inserm, Unité 935, Université Paris-Saclay, Villejuif, France; [6]Hepatinov, Villejuif, France*
Email: caroline.sacleux@aphp.fr

Background: ACLF is a clinical concept defined in patients with chronic liver disease who presented organ failure(s) secondary to an acute decompensated event. Liver transplantation (LTx) in this indication showed good results in selected patients. The aim of this prospective study was to evaluate the outcome and the factors associated with a favorable selection to LTx in this population.

Method: All consecutive patients admitted to the ICU with cirrhosis and ACLF, were recruited. Patient with age <18 years or with

fulminant hepatitis (including acute manifestation of Budd-Chiari, Wilson and auto-immune disease) were excluded.
Results: Between July 2017 and February 2019, 155 cirrhotic patients were admitted to ICU. Mean age was 55.6 ± 11.3 years (71.6% Male). Cirrhosis was due to alcohol in 78.1% of the patients. ACLF grading at admission was: 44.5% ACLF3 (n = 60), 21.3% ACLF2 (n = 33), 14.8% ACLF1 (n = 23), and 19.4% ACLF0 (n = 30).
Of the 155 patients, 46.5% (n = 72) were considered to be eligible for a transplant project and were assessed for LTx. The main reasons were alcohol abuse (66.3%, n = 55), death within 7 days after admission (32.5%, n = 27) and rapid improvement of the liver disease and discharged. Of the eligible patients 47.2% (n = 34) were transplanted with a mean time between admission to ICU and LTx of 57.9 ± 72.9 days. Twelve patients died on the waiting list (24% of the listed patients), mainly of septic shock and the remaining 5 patients are still awaiting. Among those who were assessed for LTx but not listed (n = 21), 76.2% died before the listing (n = 16) and 23.8% were not listed because of severe comorbidities (n = 5). The 28 and 90 days mortality rates were respectively 42.9% and 56.2%. The overall 3-month patient survival was respectively 97% and 26% in the transplant and non-transplant group ($p < 0.001$) for the entire cohort. Among eligible patients, factors associated with the absence of LTx, in the multivariate analyses, were mechanical ventilation (HR 8.95; 95% CI [2.75; 29.06], $p < 0.001$) and age over 60 years (HR 3.32; CI 95% [1.04; 10.63], $p < 0.001$).
Conclusion: Cirrhotic patients admitted to the ICU should be evaluated for eligibility to LTx. Merely half of the patients were eligible/assessed and 23% patients were transplanted. Among those eligible, patients over 60 years and under mechanical ventilation during early ICU stay would less likely to survive and be selected for LTx.

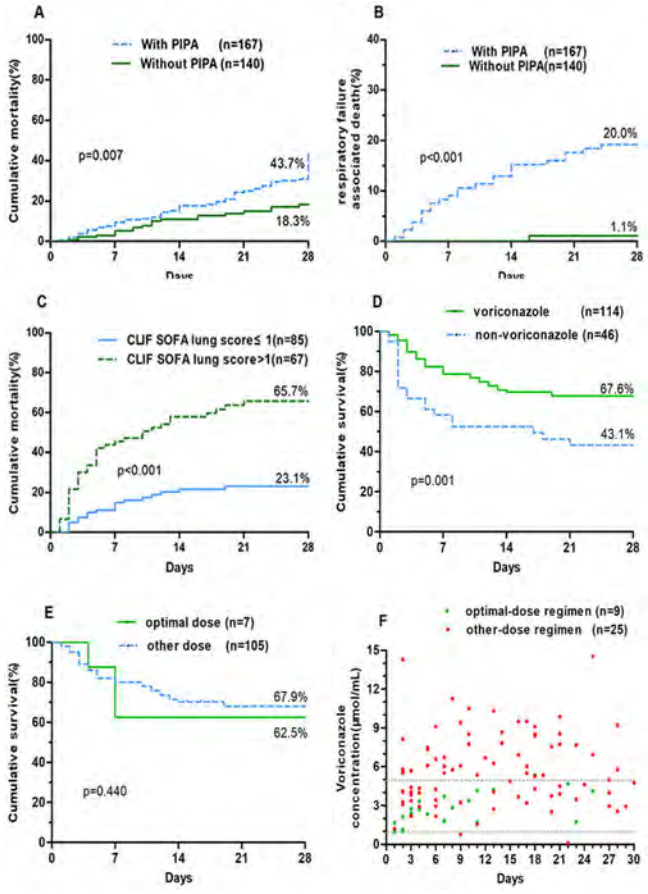
Email: chjj@smu.edu.cn

Background and Aims: Patients with critical liver diseases,especially acute-on-chronic liver failure (ACLF) are at high risk of developing infection. Fungal infection increases the mortality in ACLF patients. Data on invasive pulmonary aspergillosis (IPA) infection in ACLF patients is limited. This multicentre and retrospective study aimed to explore the prognosis and antifungal treatment in patients with IPA.
Method: This matched cohort study included ACLF patients from 15 tertiary hospitals in China between 2011 and 2018. In parallel, a control ACLF group in absence of IPA was enrolled at 1:1 ratio. Clinical features, laboratory data, micrological information, radiological findings, major causes of death,early prognostic indicators and antifungal options of patients with complicated IPA were recorded.
Results: We retrospectively analyzed 172 ACLF patients with IPA and 147 control patients. Respiratory failure was the main cause of death in patients with IPA. The 28-day mortality of IPA group was significantly higher than that of control group (43.7% vs 18.3%, $p < 0.001$) (Figure A). The 28-day mortality caused by respiratory failure in IPA group was significantly higher than in control group (20.0% vs 1.1%, $p < 0.001$) (Figure B). Furthermore, CLIF lung score >1 strongly predicted a short-term outcome of IPA patients (AuROC: 0.726). It was found that IPA patients with CLIF-SOFA lung score >1 had higher 28-day survival than those with lung score ≤ 1(65.7% vs 23.1%, $p < 0.001$) (Figure C). 164 of 172 (95.3%) patients received an antifungal therapy. Among multiple regimen, the voriconazole monotherapy was most common (42.1%, n = 69). Subsequently, the survival curves showed a significantly improved survival in those who received voriconazole-containing therapy (Figure D). There was no statistically significant difference in survival curves among an optimal voriconazole regimen (loading doses: 0.2 g twice daily; maintenance doses, 0.1 g once daily) (Figure E). Based on plasma voriconazole concentration measurement, an optimal voriconazole regimen was retrospectively validated, with optimal drug concentrations ranging from 1 to 5 μg/mL (Figure F).



Conclusion: IPA increases the mortality of ACLF patients and CLIF lung score predicts its outcome. An optimal voriconazole regimen might be safe and effective in ACLF patients with IPA.

Soluble immune checkpoints are involved in the immunopathogenesis of ACLF

Douglas Corrigall[1,2,3], Nicola Harris[1], Dhruti Devshi[1,3], Sarah Fairclough[2], Gavin Wright[2], Jonel Trebicka[4,5], Carlo Alessandria[6], Paolo Angeli[7], Rajiv Jalan[8], Joan Claria[9], Richard Moreau[10], Vicente Arroyo[5], Roger Williams[1,3], Antonio Riva[1,3], Shilpa Chokshi[1,3]. *[1]Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; [2]Basildon and Thurrock University Hospitals NHS Foundation Trust, Gastroenterology Department, Basildon, United Kingdom; [3]King's College London, London, United Kingdom; [4]Goethe University Clinic, Medical Department I, Frankfurt, Germany; [5]European Association for the Study of the Liver – Chronic Liver Failure (EASL-CLIF) Consortium and European Foundation for the study of Chronic Liver Failure (EF-CLIF), Barcelona, Spain; [6]San Giovanni Battista Hospital, Division of Gastroenterology and Hepatology, Torino, Italy; [7]University of Padova, Unit of Internal Medicine and Hepatology, Department of Medicine, DIMED, Padova, Italy; [8]University College London, Institute for Liver and Digestive Health, Royal Free Hospital, London, United Kingdom; [9]IDIBAPS, Hospital Clinic, Barcelona, Spain; [10]INSERM, Centre de Recherche sur l'Inflammation (CRI), Paris, France*
Email: s.chokshi@researchinliver.org.uk

Background and Aims: Acute on Chronic Liver Failure (ACLF) represents an immunological paradox. Patients exhibit a hyperinflammatory state at the clinical and molecular level that exists in parallel with a profound immunoparesis and increased susceptibility to bacterial infection. Immune checkpoints are key regulators of immune activation and their soluble forms have been shown in many contexts to modulate autoimmunity and responses to infection or malignancy. We therefore aim to explore their role in the initiation and propagation of the pathological immune response in ACLF.
Method: We quantified 17 soluble immune checkpoints by ELISA in the serum of 511 patients with decompensated cirrhosis included in the CANONIC Study; 334 with acute decompensation and 177 with ACLF at inclusion. Statistical analyses examined correlations with ACLF grade, clinical outcomes including survival and pro and anti-inflammatory cytokines.
Results: The soluble immune activatory checkpoints CD40 ($p < 0.001$), CD137 ($p = 0.009$) and CD27 ($p = 0.003$) increased significantly in the presence of ACLF and with increasing ACLF grade. The soluble immunosuppressive checkpoint BTLA (B and T-cell Lymphocyte-Associated) increased significantly in the presence of ACLF and with increasing ACLF grade ($p = 0.004$). Soluble CD80, which can be both inhibitory and stimulatory, also increased with ACLF grade ($p = 0.002$). Galectin 9 and Galectin 1, which have numerous immunomodulatory role showed similar increase. ($p < 0.0001$). Transplant-free survival at 28 days (CD40: $p < 0.001$, CD137: $p < 0.001$, CD80: $p = 0.035$, BTLA: $p = 0.035$, Galectin 9: $p = 0.027$, Galectin 1: $p = 0.027$) and 1 year (CD40: $p = 0.043$, CD137: $p < 0.001$, BTLA: $p < 0.001$, Galectin 9: $p < 0.001$, Galectin 1: $p < 0.001$) was also significantly associated with lower serum levels of certain immune checkpoints at presentation. Plotting the data as a heatmap demonstrates that levels of several checkpoint receptors increase in parallel in individual patients with increasing ACLF grades (Fig. 1).
Conclusion: We demonstrate increased levels of stimulatory and inhibitory soluble immune checkpoints with the presence of and increase in ACLF grade, and that higher levels of some of these factors associate with poorer clinical outcomes. We suggest that this activatory/inhibitory milieu is important in generating and maintaining the pathological hyperinflammatory hypoimmune state that is seen in patients with ACLF.

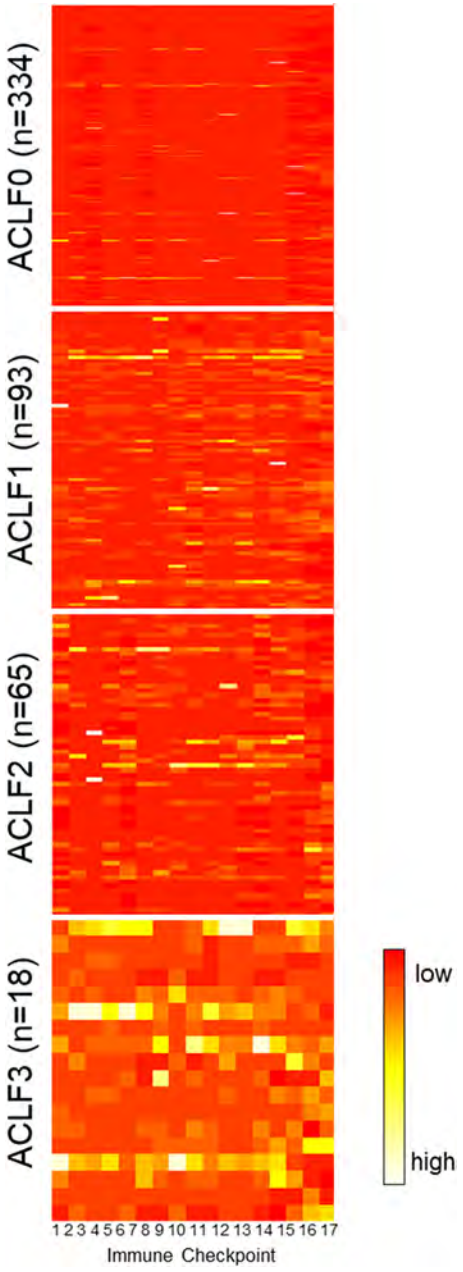

Figure: Levels of 17 soluble immune checkpoints by ACLF grade at presentation

FRI187

Prevalence, profile and predictors of invasive fungal infections in acute- on -chronic liver failure; analysis of Asia Pacific Association for Study of the Liver, Acute -on -Chronic Liver Failure Research Consortium (AARC) data base

Pratibha Ramchandra Kale[1], Ashok Choudhury[2], Shiv Kumar Sarin[2] and Asia Pacific Association for the Study of the Liver Acute on Chronic Liver Failure Research Consortium[3]. *[1]Institute of Liver and Biliary Sciences, Clinical Microbiology, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India; [3]Asia Pacific Association for the Study of the Liver, New Delhi, India*
Email: drpratibhapgi@gmail.com

Background and Aims: Acute on chronic liver failure (ACLF) causes immune dysregulation and increased susceptibility to fungal infections. We studied the epidemiology, risk factors associated with invasive fungal infections (IFI) in ACLF. We correlated the timing of

occurrence, predictors of development, role of biomarkers in the diagnosis, antifungal prophylaxis with the outcome of IFI.
Method: The demographic, clinical and laboratory characteristics of ACLF patients, admitted to our tertiary care hepatobiliary centre, developing IFI were studied retrospectively based on the Asia Pacific association for the study of the liver (APASL) ACLF Research Consortium (AARC) data base. The diagnosis of IFI was based on revised definitions of invasive fungal disease from the European organization for research and treatment of cancer/Invasive fungal infections cooperative group and the national institute of allergy and infectious diseases mycoses study group (EORTC/MSG) consensus group. We also measured the biomarkers bronchoalveolar lavage (BAL) and serum Galactomannan index (GMI).
Results: Amongst 1670 patient with ACLF analysed. 320 (19.16%) who had appropriate host factors including recent history of neutropenia, prolonged use of corticosteroids or immunosuppressive therapy, and sufficient clinical evidence consistent with IFD but no mycological evidence were classified as possible IFI.60 (3.6%) who had host factors, clinical features, and mycological evidence consisting of direct test (cytology, direct microscopy, or culture) and indirect test, positive Galactomannan assay, were classified as probable IFI. Amongst the probable IFI group, the most common site of infection was urinary tract (n = 42/60, 70%) followed by respiratory (n = 12/60, 20%) and blood (n = 6/60, 10%). On univariate analysis, prior antibiotic use, high total leucocyte counts (TLC), acute renal failure, hemodialysis, diabetes mellitus, multi-organ failure, were predictors for development of IFI ($p < 0.05$). On multivariate analysis, TLC >14.3 × 10^3/ml^3, multi-organ failure, hemodialysis and prior antibiotics use predicted the development of IFI ($p < 0.05$). IFI occurrence was associated with significantly high 30 and 90 day mortality ($p < 0.001$). 68.4% patients with IFI in first 7 days of enrolment died as compared to 47.9% in control group ($p = 0.002$). BAL GMI (cut off ≥1) was positive in 38/60 (63.33%) and serum GMI was positive in 11/60, (18.33%). BAL GMI above 3.25 was better predictor of IFI (sensitivity 72.7%, specificity 51.5%).
Conclusion: Invasive fungal infections cause high mortality in ACLF patients. High TLC at admission, multi-organ failure, hemodialysis, prior antibiotics use and high BAL GMI predict the development of IFI.

FRI188

Differential hepatic mRNA and miRNA expression patterns in a novel mouse model of bacterial infection related to acute-on-chronic liver injury

Ersin Karatayli[1], Susanne N Weber[1], Senem C. Karatayli[1], Maximillian Tessenyi[1], Rabea Hall[1], Steven Dooley[2], Frank Lammert[1]. *[1]Saarland University Medical Center, Department of Medicine II, Homburg, Germany; [2]Heidelberg University, Medical Faculty Mannheim, Department of Medicine II, Mannheim, Germany*
Email: Ersin.Karatayli@uks.eu

Background and Aims: Bacterial infection (BI) is a common acute trigger leading to acute-on-chronic liver failure in humans. Here we aim to establish a novel BI-ACLI model by LPS injection in a knock-out mouse with chronic hepatobiliary injury (*Abcb4*$^{-/-}$) to mimic disease conditions of ACLF.
Method: 15-weeks-old C57BL/6J (N = 16; wild-type, wt) and *Abcb4*$^{-/-}$ (N = 16; knock-out, ko) mice were treated with a single dose IP injection of either LPS (4 mg/kg) or saline (0.9% NaCl). qRT-PCR and stem-loop qRT-PCR were used to assess relative hepatic mRNA and miRNA expression. miRNAs 26a, 29a, 122, 143, 146, 192 m and Let7c, *Crp*, *Tnf-α*, *Rantes*, *Tgf-β*, *Tlr4*, *Mcp1* and interleukins (*IL*) 2, 6, 10, 17 and 22 were evaluated by $2^{-\Delta\Delta Ct}$ method.
Results: LPS resulted in a dramatic change in *Mcp1*, *IL-10*, *IL-6*, *Rantes* and *Tnf-α* expression with 200-, 63-, 45-, 38- and 31-fold increases in wt mice, and relatively moderate upregulation of *Crp* (4-fold), *IL-2* (5-fold), and *Tlr4* (6-fold). Corresponding effects were also observed in ko mice, whereby upregulation of *IL-6*, *IL-10*, *Tnf-α*, *Tlr4* and *Mcp1* was not significant. In line with the differential regulation of IL-22 and IL-17, where IL-6 alone is sufficient for IL-22 induction and high levels of IL-6 and Tgf-β are required for IL-17 upregulation, *Tgf-β and IL-17* did not differ among groups. More profound induction of *Rantes* (118-fold vs. 38-fold increase, $p = 0.037$), *IL-22* (75-fold vs. 5-fold, $p < 0.01$) and *Crp* (9-fold vs. 4-fold, $p = 0.026$) was present in ko mice as compared to wt. No *IL-22* was detected in NaCl-treated mice, whereas it was stimulated by LPS in both genotypes with a 7.3-fold higher upregulation ($p < 0.01$) in ko mice. Ko mice displayed higher basal expressions of miR-122 ($p = 0.029$), miR-192 ($p = 0.037$), and miR-143 ($p < 0.01$). Upregulation of miR-122 and miR-192 and repression of miR-143 and miR29a were evident upon LPS treatment without significant differences between genotypes. miR-26a, miR-146 and miR-Let7c, which were previously identified as markers for liver fibrosis and inflammation, were neither affected by *Abcb4* deficiency nor LPS challenge.
Conclusion: We propose a novel approach to model BI-ACLI in *Abcb4*$^{-/-}$ mice with differential expressions of hepatic cytokines, chemokines and miRNAs after LPS challenge. We speculate that *IL-2*, *IL-22* and *Rantes* could specifically trigger inflammatory cascades with harmful consequences on disease progression in chronic hepatobiliary diseases.
This study was supported by BMBF LiSyM (031L0051).

The prevalence of multi-resistant bacterial infections in patients with decompensated cirrhosis admitted to the intensive care unit

Fischer Petra[1,2], Pandrea Stanca Lucia[3], Ralica Hateganu[4], Adina Hadade[4], Simona Margarit[4], Horia Stefanescu[2,5], Marcel Tantau[1,5], Daniela Ionescu[4], Bogdan Procopet[1,2,5]. *[1]University of Medicine and Pharmacy 'Iuliu Hatieganu', Gastroenterology Department; 3rd Medical Clinic, Cluj-Napoca, Romania; [2]University of Medicine and Pharmacy 'Iuliu Hatieganu', Liver Research Club, Cluj-Napoca, Romania; [3]Regional Institute of Gastroenterology and Hepatology 'Octavian Fodor', Bacteriology Laboratory, Cluj-Napoca, Romania; [4]Regional Institute of Gastroenterology and Hepatology 'Octavian Fodor', Intensive Care Unit, Cluj-Napoca, Romania; [5]Regional Institute of Gastroenterology and Hepatology 'Octavian Fodor', Hepatology Department, Cluj-Napoca, Romania*
Email: bogdanprocopet@gmail.com

Background and Aims: Multiresistant bacterial infections (MRBI) are a significant health burden in patients with decompensated cirrhosis. We aimed to evaluate the prevalence and in-hospital mortality of MRBI in patients with decompensated cirrhosis admitted to the intensive care unit (ICU).
Method: Extensive infectious workup was performed at admission, and whenever worsening (further decompensation, new organ failure, acute kidney injury, or changes in infectious biomarkers) occurred. Child-Pugh, MELD, CLIF-C-ACLF, SOFA scores, ACLF grade, and in-hospital mortality were registered. MRBI were defined as bacterial infections with vancomycin-resistant enterococci (VRE), methicillin-resistant staphylococcus aureus (MRSA), extended-spectrum beta-lactamase (ESBL) and carbapenemase-producing organisms (CPO), including extensive drug-resistant (XDR) species.
Results: Seventy-six patients with decompensated cirrhosis (Child-Pugh, MELD, CLIF-C-ACLF, and SOFA scores were 12.3 ± 1.94, 27.8 ± 7.84, 11.6 ± 2.3, and 10.2 ± 3.31, respectively) were admitted to the ICU, mainly due to hepatic encephalopathy (39.5%). Fifty-one patients (67%) were infected, 19 (37%) had multiple infection sites, and 35 (68%) had sepsis. The respiratory origin was the most frequent (30%). There were 18 (25%) MRBI with the following etiologies: 4 VRE (22%), 4 ESBL (22%), and 10 CPO (55%). Thirty-nine patients had grade 3 ACLF

at admission. Among them, 28 (71%) were infected, of whom 10 (35%) had MRBI. Worsening occurred in 63 patients, the development of new organ failure (circulatory or respiratory) being the most frequent (39%). Among those who worsened 30 had a new or a second infection, of whom 16 patients (53%) had MRBI with 21 infection episodes (4 patients having more than one infection), as follows: 2 VRE, 1 MRSA, 2 ESBL, 12 CPO, and 4 XDR. Fifty-eight patients (76%) died during hospitalization, 41 (71%) of those being infected, of whom 18 where MRBI (44%). Sepsis-related multiorgan failure was the most frequent cause of death (44.8%). The median ICU stay was 9.8 ± 11.8 days. Median ICU stay, previous antibiotic therapy, and MELD score ≥20 at admission were associated with MRBI at worsening.

Conclusion: CPO was the most frequent etiology of MRBI in patients with decompensated cirrhosis admitted to the ICU. The development rate of a second infection with CPO increased with the length of ICU stay.

FRI190

Acute-on-chronic liver failure as defined by the European (EASL-CLIF) versus North American (NACSELD) diagnostic criteria in their prediction of short-term prognosis in patients with decompensated cirrhosis admitted into hospital

Florence Wong[1], Rajender Reddy[2], Puneeta Tandon[3], Jennifer Lai[4], Nishita Jagarlamudi[1], Beverley Kok[3], Sylvia Kalainy[3], Yanin Srisengfa[4], Somaya Albhaisi[5], Bradley Reuter[5], Chathur Acharya[5], Jawaid Shaw[5], Leroy Thacker[6], Jasmohan S Bajaj[5]. *[1]Medicine, Toronto, Canada; [2]Liver Transplantation, Philadelphia, United States; [3]Medicine, Edmonton, Canada; [4]University of California, Liver Transplant Program, San Francisco, United States; [5]Virginia Commonwealth University and McGuire VA Medical Center, Medicine, Richmond, United States; [6]Virginia Commonwealth University and McGuire VA Medical Center, Biostatistics, Richmond, United States*
Email: florence.wong@utoronto.ca

Background: Both the European (EASL-CLIF) and the North American (NACSELD) ACLF definitions, each describing a different number of organ systems and using different parameters to define organ failures (OF), are predictive of prognosis in decompensated cirrhosis.

Aims: To compare the CLIF-C-OF score (the Sequential Organ Failure Assessment score modified for patients with chronic liver disease) vs. the NASCELD score in the prediction of prognosis in ACLF.

Method: 5 NACSELD centres provided prospective demographic and clinical data on patients with cirrhosis admitted non-electively. Patients were followed for the development of organ failure, hospital course, and survival. Baseline models were derived using a backward elimination multivariable logistic regression including all admission variables significant at $p < 0.10$. To determine the impact of NACSELD vs CLIF definitions of ACLF on (a) ICU transfer & (b) inpatient mortality, we first compared CLIF OF (range 0–6) to NACSELD OF (range 0–4), and then CLIF ACLF Grades (range 0–3) to NACSELD ACLF (Yes/No).

Results: 1031 patients were included, aged 57 ± 11 ys, 66% men with mostly alcoholic cirrhosis (47%). Admission reasons were infection (25%), HE (17%), GI bleed (16%) and renal dysfunction (12%). Admission Child-Pugh score was 9.6 ± 2.2 and MELD was 20 ± 8. More patients had renal failure (28% vs 9% $p < 0.001$) using CLIF vs NACSELD, but respiratory (3% vs 4%, $p = 0.28$), circulatory (4% vs 4%, $p = 1.0$) & brain failure (12% vs 12%, $p = 1.0$) were similar.

ICU transfer: Compared to baseline models, CLIF and NACSELD models were significantly better in the prediction for ICU transfer whether using # OF or ACLF grade and presence. NACSELD # OF had better prediction for ICU transfer compared to CLIF # OF. No significant differences were found comparing NACSELD vs CLIF on ACLF grade or presence analyses.

Table: Baseline models for prediction

ICU transfer		In-hospital mortality	
Alcohol Etiology Refractory Ascites Admission β-blockers use Rifaximin use Heart rate Hemoglobin WBC MELD score		Age Admission WBC MELD score	
vs. Baseline model			
CLIF #OF, p = 0.006	CLIF grade, p = 0.003	CLIF #OF, p = 0.35	CLIF grade, p = 0.27
NACSELD #OF, p = 0.0002	NACSELD (Y/N), p = 0.001	NACSELD #OF, p = 0.09	NACSELD (Y/N), p = 0.05
CLIF vs. NACSELD #OF, p = 0.04	Grade/presence, p = 0.92	#OF, p = 0.16	Grade/presence, p = 0.31

In-hospital mortality: Compared to baseline models, using OF analyses, there was trend towards better prediction by NACSELD but not by CLIF. With the ACLF grade/presence analysis, NACSELD added significantly to the baseline model while CLIF did not. No significant differences were found comparing NACSELD vs CLIF on ACLF grade/presence analyses.

Conclusion: The NACSELD # OF score, using admission parameters easily obtainable at the bedside without the need for an App, is equally, if not more effective than the EASL-CLIF score in the prediction of prognosis in inpatients with cirrhosis.

Novel experimental animal models for acute decompensation and acute-on-chronic liver failure

Frank Uschner[1], Sabine Klein[1], Cristina Ortiz[1], Robert Schierwagen[1], Olaf Tyc[1], Christiana Graf[1], Alexander Queck[1], Marcus Maximilian Muecke[1], Victoria Mücke[1], Katharina Maria Schwarzkopf[1], Hans-Peter Erasmus[1], Martin Schulz[1], Stefan Zeuzem[1], Vicente Arroyo[2], Joan Claria[2,3], Jonel Trebicka[1,2,3,4]. *[1]Hospital of the Goethe University Frankfurt, Department of Internal Medicine I, Frankfurt am Main, Germany; [2]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain; [3]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]Odense University Hospital, University of Southern Denmark, Institute of Clinical Research, Odense, Denmark*
Email: frank.uschner@kgu.de

Background and Aims: The development of acute-on-chronic liver failure (ACLF) in patients with acute decompensation (AD) of chronic liver disease is associated with high short term mortality (up to 30–40%). Precipitating factors are known to induce AD and eventually lead to ACLF, which is defined by systemic inflammation, immune paralysis and organ failure. Still, the clinical picture of ACLF is largely variable, therefore different models are needed. The aim of this work was to characterise novel animal models for AD and ACLF to be used for drug development and testing.

Method: Cirrhosis was induced by bile duct ligation in rats (BDL; 28 days). They received either (i) a single intravenous injection of lipopolysaccharid (LPS) on day 21 (AD) or (ii) repeated injections on day 21 and 25 (ACLF). Portal and systemic hemodynamic changes were measured *in vivo*. Peripheral blood monocytes (PBMC), blood- as well as organ samples were collected at the end of the experiment. Markers of organ failure and systemic inflammation were characterized using cRNA Microarray, multiplex-based immuno-assay, western-blot and colorimetric assays.

Results: LPS significantly increased mortality in AD and ACLF rats (AD 15%; ACLF 50% at one week). The expression of inflammatory cytokines was induced in isolated PBMC from AD and ACLF rats and

in organs corresponding to the development of ACLF (liver, kidney, lung, brain, heart). Furthermore, circulating pro-inflammatory cytokines in peripheral blood were significantly increased, while anti-inflammatory cytokines were reduced. LPS injection induced hyperdynamic circulation in ACLF rats, demonstrated by increased portal pressure and cardiac output, as well as decreased systemic resistance. In line, intrahepatic and extrahepatic expression of endothelial cell function markers was dysregulated in ACLF rats. Bilirubin and creatinine levels were significantly increased in ACLF and renal perfusion was markedly reduced compared to untreated BDL rats.

Conclusion: The experimental models of LPS-induced AD and ACLF in BDL rats show the typical characteristics of human AD and ACLF (systemic inflammation, immune paralysis, hyperdynamic circulation, endothelial dysfunction and organ failure) and they could be suitable to investigate novel therapeutic strategies for patients in future.

FRI192

Artificial liver support system in hepatitis B virus-related acute-on-chronic liver failure patients

Tao Han[1,2,3,4,5,6], Hua Liu[1,2,4,5,6], Qian Zhang[2,4,5,6], Yingying Cao[1,4,5,6], Qing Ye[2,4,5,6], Fang Liu[2,4,5,6], Jing Liang[2,4,5,6], Ying Li[2,4,5,6]. *[1]The Third Central Clinical College of Tianjin Medical University, Hepatology, Tianjin, China; [2]The Third Central Hospital of Tianjin, Hepatlogy, Tianjin, China; [3]Tianjin Third Central Hospital Affiliated to Nankai University, Hepatology, Tianjin, China; [4]Tianjin Key Laboratory of Extracorporeal Life Support for Critical Diseases, Hepatology, Tianjin, China; [5]Artificial Cell Engineering Technology Research Center, Tianjin, China; [6]Tianjin Institute of Hepatobiliary Disease, Tianjin, China*
Email: hantaomd@126.com

Background and Aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is difficult to treat and carries a high risk of short-term mortality. Unfortunately, as the result of no worldwide uniform diagnostic criteria for ACLF, it remains unclear that the effect of artificial liver support system (ALSS) on the prognosis of HBV-ACLF. This study aimed to compare the survival rate of HBV-ACLF patients treated with ALSS and standard medical treatment (SMT) alone, thereby gaining insight into the future improvement of HBV-ACLF prognosis.

Method: We selected 132 patients hospitalized to HBV-ACLF according with the criteria of Chinese Group on the study of Sever Hepatitis B-ACLF (COSSH-ACLF) (Gut 2018; 67:1–11) from 425 ACLF patients who were diagnosed to meet APASL criteria at least and followed up for 90 days. Among HBV-ACLF patients, 78 patients receiving ALSS, in which plasma exchange was the majority, and 54 patients receiving SMT alone were compared in terms of prognosis.

Results: The baseline characteristics of 78 patients treated with ALSS was comparable to that of 54 patients treated with SMT. The proportion of ACLF Grade 1, 2, 3 was 57.69%, 37.18%, 5.13% in ALSS group, 51.85%, 35.19, 12.96% in SMT group, respectively. There was difference in Child-Turcotte-Pugh score between ALSS group and SMT group, but no statistical difference in other baseline characteristics. The 28-day and 90-day mortality in the ALSS group and SMT group were 23.08% *vs* 48.15%, $P = 0.005$, 33.33% *vs* 57.41%, $P = 0.007$, respectively. Using Kaplan-Meier survival curve analysis, the survival time of ALSS at 28-day and 90-day were significantly higher than SMT group ($P < 0.05$). Multivariate Cox regression modeling showed that ALSS independently reduced the risk of 28-day death (HR 0.397, $P = 0.003$), besids total bilirubin (TBIL), international normalized ratio (INR) and Model for end-stage liver disease score (HR 1.382, 1.488, 1.054, $P < 0.05$). In addition, TBIL, INR, CLIF-C ACLF score and ALSS were independent factors affecting the survival time during 90 days. In HBV-ACLF Grade-1 group, compared with SMT alone, ALSS has a more significant effect on reducing the 28-day and 90-day mortality.

Conclusion: Based on the criteria of COSSH-ACLF, ALSS could obviously improve the short-term survival rate of ACLF patients than SMT alone, especially in ACLF Grade-1 of HBV-ACLF patients.

FRI193

Global hemostatic status in patients with acute-on-chronic liver failure and patients with sepsis without underlying liver disease

Ton Lisman[1], Bethlehem Arefaine[2], Jelle Adelmeijer[1], Ane Zamalloa[3], William Bernal[3], Vishal C Patel[2,3,4]. *[1]University Medical Center Groningen, Surgery, Groningen, Netherlands; [2]Foundation for Liver Research, Institute of Hepatology, London, United Kingdom; [3]King's College Hospital NHS Foundation Trust, Institute of Liver Studies, London, United Kingdom; [4]King's College, School of Immunology and Microbial Sciences, Faculty of Liver Sciences and Medicine, London, United Kingdom*
Email: j.a.lisman@umcg.nl

Background and Aims: Patients with chronic liver disease (CLD) have substantial alterations in their hemostatic system. Remarkably, even in the sickest patients, such as those with acute-on-chronic liver failure (ACLF), the hemostatic system appears to remain in balance due to a concomitant decline of pro- and antihemostatic systems. It is, however, unknown whether the hemostatic status in ACLF is merely an exaggeration from the status in patients with compensated cirrhosis, or whether sepsis-associated hemostatic changes contribute.

Method: We performed extensive hemostatic profiling using functional tests and levels of markers of activation of hemostasis in 31 adult patients with ACLF, 20 with sepsis without underlying CLD, and 40 healthy controls (HC). Patients were longitudinally sampled over a 10 day period.

Results: Median MELD scores in ACLF patients on admission were 33 (IQR 26-40), and SOFA scores in sepsis patients were 6 (3–8). We found similarly elevated plasma levels of the platelet adhesive protein von Willebrand factor (VWF) and decreased levels of the VWF-regulating protease ADAMTS13 in both groups, compared to HC. In-vivo markers of activation of coagulation (TAT, D-dimer) were similarly elevated in both groups compared to HC, but ex-vivo

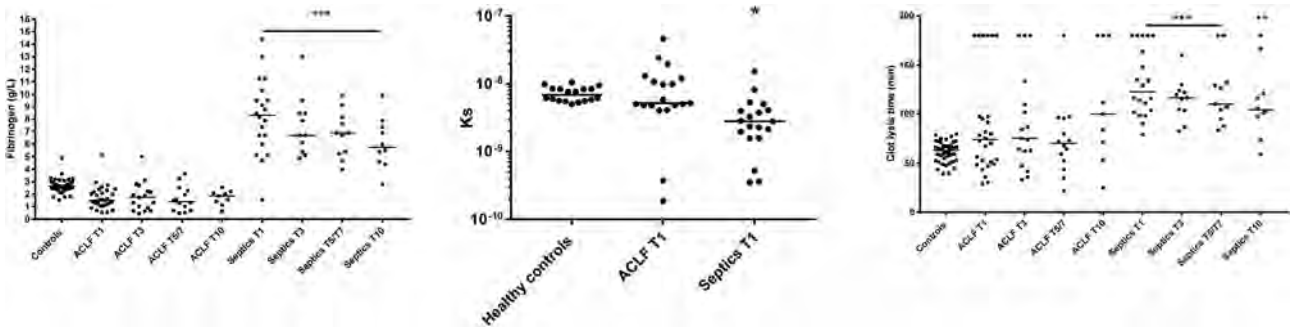

Figure: (abstract: FRI193): Fibrinogen levels, fibrin clot permeability, and plasma clot lysis time in plasma samples from healthy controls, patients with ACLF, and patients with sepsis without underlying liver disease sampled at various time points after admission.

thrombin generating capacity was similar between both patient groups and HC, despite a much more profound INR elevation in ACLF (INR of 2.4 [IQR 1.1–1.2] in ACLF vs 1.2 [1.1–1.2] in septics). Plasma fibrinogen levels were much higher in septics, which was accompanied by a decreased *ex-vivo* clot permeability and an increased in *ex-vivo* resistance to clot lysis (figure; * = significance vs controls). All hemostatic parameters were remarkably stable over the first 10 days after admission.

Conclusion: We have found hemostatic changes in ACLF to partially overlap with that of patients with sepsis, and evidence of preserved hemostatic capacity in both patient groups. The notable difference was a profound hyperfibrinogenemia with a thrombogenic clot structure and a profound *ex-vivo* resistance to fibrinolysis in patients with sepsis. A better understanding of the hemostatic status in both groups of acutely ill patients may facilitate a more rational approach to hemostatic management.

FRI194

Muscle quality as assessed by computed tomography-derived skeletal muscle density is associated with 28- day mortality in mechanically ventilated critically- ill patients with cirrhosis

Jaya Benjamin[1], Harshita Tripathi[1], Shalini Thapar[2], Varsha Shasthry[1], Rakhi Maiwall[3], Vijayraghavan Rajan[3], Vandana Saluja[4], Dr. Prashant Mohan Agarwal[4], Lalita Mitra[4], Guresh Kumar[5], Dr. Puneet Puri[6], Yogendrakumar Joshi[1,3], Shiv Kumar Sarin[3].

Email: jayabenjamin269@gmail.com

Background and Aims: Sarcopenia is known to adversly influence survival and transplant outcomes. Myosteatosis as assessed by computed tomography (CT) by analysing the skeletal muscle density (SMD), impacts the muscle quality. We investigated whether muscle quality is associated with 28 day mortality in critically ill cirrhotics.

Method: In this retrospective observational study of prospectively collected data of 117 mechanically ventilated patients admitted to the liver intensive care unit (LICU) between July 2018 to August 2019, 42 patients with a CT scan of the abdomen done 1 month prior or 4 days after ICU admissions were studied. The SMD was assessed for 80 mm^3 region of interest on the right and left psoas muscles and mean attenuation coefficient was expressed in HU. Skeletal muscle area (SMA), subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT) and intramuscular adipose tissue (IMAT) were analysed using the Slice-O-Matic software and expressed in cm^2. Multivariate stepwise (forward) logistic regression analysis was used to study the association between muscle quality and mortality.

Results: In 42 patients where complete data was available [M-36 (86%), age-48 ± 12.5 yrs; BMI-26.2 ± 4.9 Kg/m^2; diagnosis- cirrhosis 34(81%): ACLF 8(19%); etiology- Alcohol –22(52.4%): NASH-10 (23.8%): Viral-10(23.8%)], 28 day mortality was 71.4%. The survivors had more bleeders [4(33.3%) vs. 2(6.7%); p = 0.04)], lower prevalence of co-morbidities [3(25%) vs. 18 (60%)], lower CLIFSOFA score [8.9 ± 1.8 vs. 13.0 ± 4; p < 0.001], higher SMD [56.8 ± 5.1 vs. 48.6 ± 7.3; p = 0.001] and lower IMAT [3.8 ± 2.3 vs. 5.5 ± 2.1; p = 0.03] than non-survivors, though BMI, SMA, SAT and VAT were comparable. CLIFSOFA [OR (95% CI)]-1.55 (1.1–2.2);p = 0.019 and SMD 0.81(0.66–0.99);0.029 were the independent predictors of mortality also after adjustments for bleeding status and comorbidities. Mortality increased by 11% with every 1 unit increase in SMD. Cut-off of SMD <52.8HU would predict mortality (sensitivity = 75%, specificity = 76.7%, AUC = 80.8; p = 0.006).

Conclusion: Poor skeletal muscle quality as measured by SMD at ICU admissions is an independent predictor of 28 day mortality in mechanically ventilated patients with cirrhosis.

FRI195

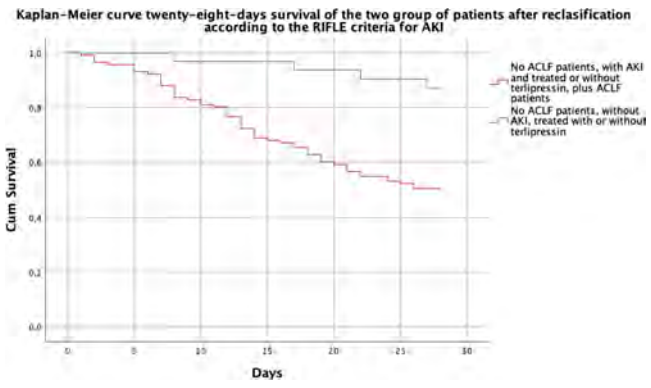
Refining the renal failure criteria of the EASL-CLIF diagnostic model for defining acute- on- chronic liver failure (ACLF)

Joana Calvão[1,2], Cornelius Engelmann[1], Rahul Kumar[1,3], Haqeeqat Gurm[1], Komal Ramsahye[1], Gautam Mehta[1], Raj Mookerjee[1], Noam Pinchas Gessler Roth[4], Banwari Agarwal[1,4], Rajiv Jalan[1].
[1]University College London, Royal Free Campus, Institute for Liver and Digestive Health, London, United Kingdom; [2]Centro Hospitalar de Trás-os-Montes e Alto Douro, Internal Medicine, Vila Real, Portugal; [3]Changi General Hospital, Gastroenterology and Hepatology, Singapore; [4]Royal Free London, Intensive Care Unit, London, United Kingdom
Email: joanacalvao@gmail.com

Background and Aims: Kidney function is estimated using serum creatinine (SCr). In cirrhosis, many factors affect values of SCr. The EASL-CLIF criteria for the diagnosis of ACLF uses static values of SCr to diagnose kidney failure. Recent changes in acute kidney injury (AKI) definitions would allow treatment of such patients earlier in their disease course, whilst application of existing SCr criteria (used to identify patients with a 28-day (28d) mortality of >15%) have been shown to have limitations by underestimating the presence of ACLF. The aims of this study were to evaluate whether the RIFLE classification, which has been extensively validated and stratifies AKI according to 3-classes of severity based on SCr or glomerular filtration rate (GFR), can be used instead.

Method: Retrospective analysis of prospectively collected data from 223 patients admitted to the ICU between 2005 and 2015, classified as having ACLF or no ACLF according to EASL CLIF criteria along with their 28-day mortality, was evaluated. Patients were then reclassified into different groups as having ACLF or not, with or without AKI using the RIFLE criteria and if they were treated or not with terlipressin. Mortality rate and survival analysis with Kaplan-Meier analysis were used.

Results: Patients with *no ACLF* (n = 69) had a high mortality rate (above the 15% threshold expected used for the EF-CLIF criteria) of 29%, which suggested that SCr criteria might under-diagnosed ACLF. Using the RIFLE criteria, patients with *no ACLF and no AKI* (n = 32) had 12.5% mortality at 28 d. Patients with *no ACLF but with AKI and not treated with terlipressin* (n = 11), and patients *with no ACLF but with AKI and treated with terlipressin* (n = 5) had a 28 d mortality of 63.6% and 20%, respectively. Reclassification using these new criteria to diagnose renal failure was applied and patients with high mortality risk (>15% at 28 d; those with *no ACLF and with AKI*), were allocated together with ACLF patients. When compared with *no ACLF and no AKI* patients, the 28 d survival was 20.6 days vs 26.8 days (p = 0.00) and 28 d mortality rate was 49.2% (odds ratio (OR) 6.77, p = 0.001; hazard ratio (HR) 1.65, p = 0.01) vs. 12.5% (OR 0.54, p = 0.04; HR 0.19, p = 0.001).



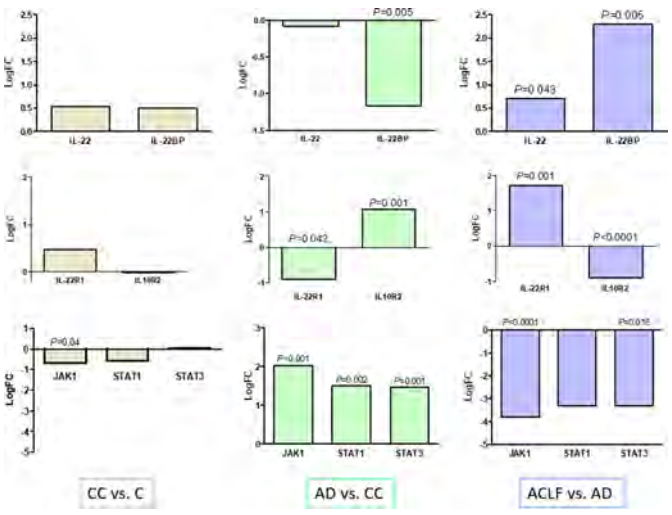
Conclusion: SCr underestimates kidney failure for the diagnosis of ACLF. Using the RIFLE criteria may more accurately identify 'kidney failure' within the EASL-CLIF criteria for ACLF. These data require further validation within larger patient cohorts.

FRI196

Regulation of IL-22 in a rat model for acute-on-chronic liver failure (ACLF)

Katharina Maria Schwarzkopf[1], Frank Uschner[1], Robert Schierwagen[1], Sabine Klein[1], Marcus Maximilian Muecke[1], Alexander Queck[1], Hans-Peter Erasmus[1], Christiana Graf[1], Martin Schulz[1], Stefan Zeuzem[1], Christoph Welsch[1], Vicente Arroyo[2], Joan Clària[2,3], Jonel Trebicka[1]. [1]*Goethe University Hospital Frankfurt, Department of Internal Medicine I, Frankfurt, Germany;* [2]*European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain;* [3]*Hospital Clínic, IDIBAPS and CIBERehd, Department of Biochemistry and Molecular Genetics, Barcelona, Spain*
Email: katharina.schwarzkopf@kgu.de

Background and Aims: Interleukin-22 (IL-22) may exert both hepatoprotective or hepatotoxic effects, as shown *in vivo* and *in vitro*. IL-22 binding protein (IL-22BP) is a soluble inhibitor of IL-22 signaling. Recently we were able to show that high levels of IL-22 and excessive secretion of IL-22BP are associated with ACLF and mortality of patients with cirrhosis. We investigated IL-22 signaling in rats with liver cirrhosis, acute decompensation (AD) and ACLF.
Method: Cirrhosis was induced in Sprague Dawley (SD) rats by bile-duct-ligation (BDL). Single administration of lipopolysaccharides (LPS) (6.25 µg i.v. on day 21; n = 5, group AD) lead to acute decompensation (AD) of liver disease with subsequent recovery of the animals. A second administration of LPS (6.25 µg i.v. day 21 and day 25, n = 4, group ACLF) induced ACLF with a mortality of 30%. Harvesting of organs and isolation of peripheral blood mononuclear cells (PBMCs) was performed on day 28 in all animals. The transcriptome was analyzed for changes in IL-22 signaling. As control groups served naïve SD rats (n = 5, group C) and cirrhotic rats with BDL (n = 5, group CC).
Results: IL-22 signaling was not altered in muscle, brain, duodenum, liver, heart, spleen, lung and kidney tissue. In PBMCs of rats with ACLF, IL-22 (ACLF vs. AD p = 0.043) and IL-22BP (ACLF vs. AD p = 0.005) were upregulated, whereas IL-22BP was downregulated in PBMCs of rats with AD (AD vs. CC p = 0.005). The IL-22R1 subunit of the IL-22 receptor complex was significantly upregulated in ACLF (ACLF vs. AD p = 0.001) while the IL-10R2 subunit of the IL-22 receptor was downregulated (ACLF vs. AD p = 0.0001). Comparison of AD vs. CC showed an opposite regulation of the receptor complex with a downregulation of IL-22R1 (AD vs. CC; p = 0.042) and upregulation of IL-10R2 (AD vs. CC; p = 0.001). Of note, GSK3B, a stabilizer of the IL-22R1/IL-10R2 complex was upregulated in AD (AD vs. CC; *P* = 0.022) but downregulated in ACLF (ACLF vs. AD p = 0.018). This resulted in a suppressed downstream signaling of IL-22 in ACLF (ACLF vs. AD; JAK1 p = 0.0001 and STAT3 p = 0.016) and an enhanced signaling in AD (AD vs. CC; JAK1 p = 0.005, STAT1 p = 0.002, STAT3 p = 0.001).



Conclusion: Our data suggest that IL-22 and IL-22 signaling are dysregulated in AD as well as ACLF and dependent on the severity of liver cirrhosis. Despite upregulation of IL-22 in rats with ACLF, downstream signaling is significantly decreased. A reason could be a reduced stability of the IL-22R1/IL-10R2 receptor complex.

FRI197

Thymosin alpha 1 for patients with hepatitis B virus-related acute-on-chronic liver falure: a randomized controlled trial

Jun-Feng Chen[1], Shu-Ru Chen[1], Zi-ying Lei[1], Hui-Juan Cao[1], Shao-Quan Zhang[1], Weizhen Weng[1], Jing Xiong[1], Wenxiong Xu[1], Ka Zhang[1], Zhiliang Gao[1], Bingliang Lin[1]. [1]*The Third Affilirated Hospital, Sun Yat-sen University, Department of Infectious Diseases, Guanghzhou, China*
Email: lamikin@126.com

Background and Aims: Mortality from hepatitis B virus (HBV)-related acute-on-chronic liver failure (ACLF) is high due to limited treatment options. The immunity of ACLF is like sepsis, and severe infection is the most important complication that affects the outcome of patients. As an immunoregulatory agent, we hypothesized that thymosin alpha 1 would improve the outcome of HBV-related ACLF.
Methods: From 2017 to 2019, 120 patients with HBV-related ACLF were enrolled in this open-label, nonblinded randomized controlled study (Clinical Trial ID: NCT 03082885). The control group (N = 58) was treated with standard medical therapy (SMT) only. The experiment group (N = 56) was injected 1.6 mg thymosin alpha 1 (THY) once a day for the first week and then twice a week for a total of 12 weeks subcutaneously.
Results: The 90-day cumulated survival rate of the THY group was 75.0% (95% confidence interval 63.3%–86.7%) versus 53.4% (95% confidence interval 40.2%–66.7%) for the SMT group (p = 0.03). There were no thymosin alpha 1 injection-related side effects. Compared with the control group, thymosin alpha 1 treatment markedly improved the international normalized ratio (INR) of patients. The incidences of new infection and hepatic encephalopathy in the THY group were much lower than that in the SMT group (25.0% vs 58.6%, p < 0.001; 8.9% vs 24.8%, p = 0.029, respectively). Mortality from severe infection in the SMT group was higher than in the THY group (24.1% vs 8.9%, p = 0.029).

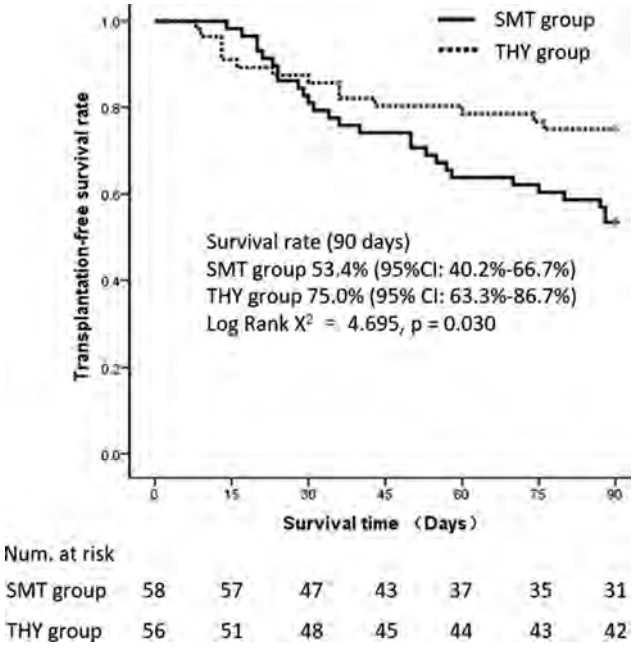


Figure: Kaplan-Meier survival curve of patients in SMT group and THY group

Conclusion: Thymosin alpha 1 is safe for patients with HBV-related ACLF and significantly improves the 90-day survival rate, due to decreasing the complications including severe infections and hepatic encephalopathy.

Email: lamikin@126.com

Background and Aims: Liver transplantation is the only therapy that has been proven beneficial for hepatitis B virus(HBV)-related acute-on-chronic liver failure(ACLF). It is necessary to establish a simple and optimized scoring system to evaluate the patients' condition, so that liver transplantation can be performed on patients with greatest needed. This study aimed to establish an effective prognostic nomogram for HBV-related ACLF patients.
Method: The nomogram was based on a retrospective cohort (derivation cohort) of 1353 HBV-related ACLF patients who underwent comprehensive medical treatment at The Third Affiliated Hospital of Sun Yat-sen University from Jan 2010 to Jun 2016. The predictive accuracy and discriminative ability of the nomogram were determined by a concordance index (C-index) and calibration curve and were compared with the current scoring systems. The results were validated using bootstrap resampling and an independent retrospective cohort (validation cohort) on 669 HBV-related ACLF patients consecutively enrolled from July 2016 to March 2018 at the same institution. All statistical tests were two-sided. This study is registered at ClinicalTrials.gov (NCT03992898).
Results: Independent factors derived from multivariable analysis of the derivation cohort to predict 90 days' survival were age, aspartate aminotransferase(AST), total bilirubin(TBil), international normalized ratio (INR), creatinine, alpha fetal protein(AFP), hepatic encephalopathy(HE), infection, pre-existing chronic liver diseases(PreLD), and hepatitis B virus (HBV) DNA, which were all assembled into the nomogram. The calibration curve for the probability of 90 days' survival showed that the nomogram-based predictions were in good agreement with actual observations. The C-index of nomogram for predicting 90 days' survival were 0.786, which was statistically higher than the C-index values for Child-Turcotte-Pugh (CTP) (0.573, $P < 0.001$), Model for End-Stage Liver Disease (MELD) (0.664, $P < 0.001$), and MELD Na score (0.673, $P < 0.001$) in derivation cohort. The results were confirmed in the validation cohort. Besides, in validation cohort, the C-index of nomogram (0.787) was also higher than Chronic Liver Failure Consortium Organ Failure (CLIF-C OF) (0.727, $P < 0.001$), CLIF-C ACLF(0.746,$P = 0.005$) and Chinese Group on the Study of Severe Hepatitis B(COSSH) ACLF scores (0.762, $P = 0.012$).
Conclusion: The proposed nomogram resulted in more accurate prognostic prediction for HBV- related ACLF patients in South China.

FRI199

Efficacy evaluation of artificial liver support system (ALSS) in treatment of HBV-ACLF patients based on metabolomics

Jie Wang[1], Lanjuan Li[1], Ermei Chen[1]. [1]*The First Affiliated Hospital, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China*
Email: ljli@zju.edu.cn

Background and Aims: Hepatitis B Virus-related acute on chronic liver failure (HBV-ACLF) is characterized by rapid development, poor treatment effect and high short-term mortality. Liver transplantation is an effective treatment but is difficult to carry out large scales due to the shortage of liver source and high cost. Artificial liver support

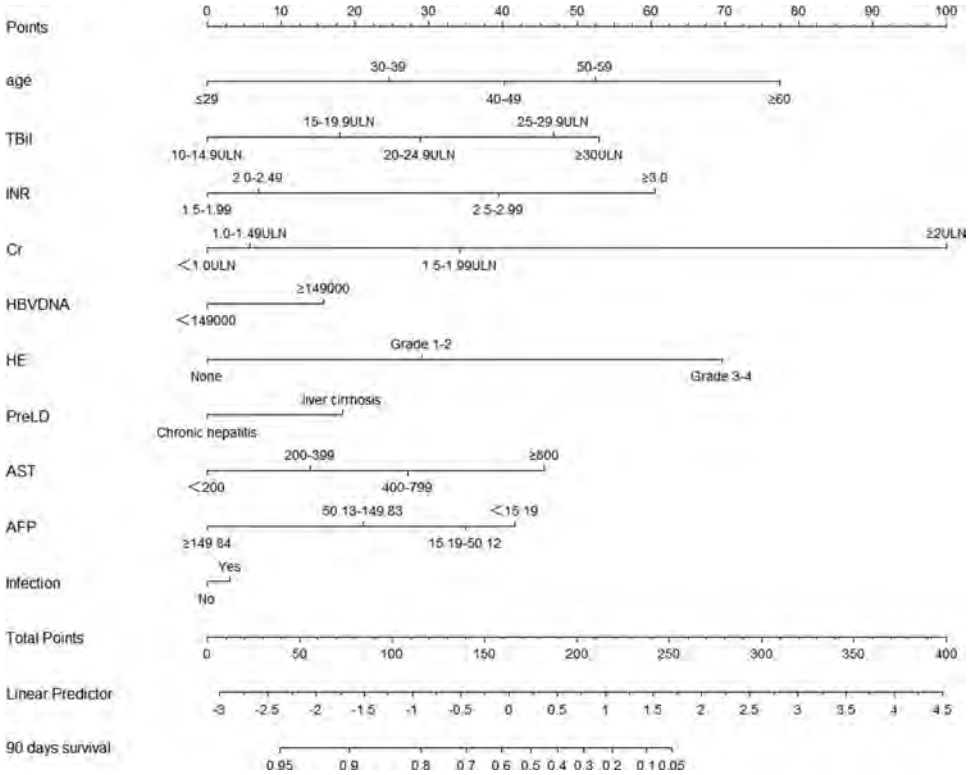

Figure: (abstract: FRI198): Nomogram for 90 days' survival in HBV-related ACLF patients.

system(ALSS) can effectively improve the survival rate of patients by temporarily replacing liver function. Liver is the main metabolic organ and the metabolic profiling could change during liver failure process. Analyzing the metabolites change is important to evaluate the efficacy of ALSS treatment of HBV-ACLF.
Method: Serum samples of HBV-ACLF patients were collected before and after ALSS treatment for three times. Multivariate analysis showed the metabolic trajectory changes before and after treatment. Based on serum samples acquired after the first treatment, the prognostic metabolites were screened out, and the trend difference between survival group and death group during the whole treatment process was investigated.
Results: Bilirubin and coagulation function improved significantly after ALSS treatment ($p < 0.001$). The OPLS-DA model of all samples revealed the metabolic trajectory changes before and after the ALSS treatment. Metabolite analysis showed a decrease in products of phenylalanine metabolism and an increase in glutamic acid, phenylpropionyl dipeptide and phospholipids after ALSS treatment. Phenylalanylphenylalanine and lysophosphatidylcholine were associated with disease severity and prognosis. Glutamyl substances were related to the prognosis of artificial liver treatment. Acylcarnitine substances and phenylalanyl-aspartate clearly differentiated between survival group and death group at the end of the treatment period.
Conclusion: ALSS therapy for HBV-ACLF can effectively remove excessive products of phenylalanine metabolism and supply phosphatidylcholine. Metabonomics provides new technique means to elucidate the pathological mechanism of HBV-ACLF.

FRI200
Mesenchymal stem cells regulate hepatocytes excessive autophagy and apoptosis through miR-125b/TRAF6 pathway in acute- on- chronic liver failure

Dengna Lin[1], Bingliang Lin[2], Jing Zhang[1], Jing Xiong[1], Juan Gao[1], Weizhen Weng[1], Jun-Feng Chen[1], Shao Quan Zhang[3]. *[1]The Third Affilirated Hospital, Sun Yat-sen University, Department of Infectious Diseases, Guangzhou, China; [2]The Third Affilirated Hospital, Sun Yat-sen University, Guangzhou, China; [3]The Third Affilirated Hospital, Sun Yat-sen University, Guangzhou, China*
Email: m15521015839@163.com

Background and Aims: Acute on chronic liver failure (ACLF) is a clinical syndrome with high mortality and lack of effective treatment. Previous clinical study confirm that mesenchymal stem cells (MSCs) can improve the prognosis of patients, but its mechanism remains elusive. Autophagy can be an adaptive response to provide energy and degrade the damaged intracellular components when the liver is subjected to varies injuries, however, in condition of ACLF, the cell necrosis is prolonged and more severe, the chronically activated autophagic process may lead to further cell death and worsen the disease. Recent lines of evidence indicate that the hepatoprotective effect of MSCs may through the regulation of autophagy, and the miR-125b, which is enriched in MSCs culture supernatant, play a major role to link autophagy and apoptosis, but whether and how it occurred during ACLF remains elusive.
Method: C57BL/6 mice were intravenously injected with carbon tetrachloride (CCL4) to generate a model of ACLF, and MSCs was transplanted through tail vein. The MSCs mediated autophagy and apoptosis in ACLF mouse and the role of miR-125b were examined in vivo and in vitro. The downstream target of miR-125b were identified in vitro and validated in vivo. Human liver tissues from ACLF patients and control individuals were obtained to evaluate the influence of miR-125b/TRAF6 on autophagy and apoptosis.
Results: The autophagic flux and hepatocytes apoptosis in ACLF mice were reduced by MSCs infusion, which were correlated with elevated miR-125b level. The anti-miR-125b oligonucleotide can make autophagy flux and hepatocyte death increase. TRAF6 was identified as a miR-125b target gene, knockdown of its expression in vitro can partially attenuated the effect of miR-125b inhibition via decreasing the inflammatory response in addition to reducing autophagy, which may be owing to repressing the activation of NF-κβ p65 and JNK. In human liver tissues, the expression of miR-125b was down-regulated in ACLF patients, both TRAF6 and autophagic flux were over-expressed in ACLF.
Conclusion: The hepatoprotective effect of MSCs may partially profit by miR-125b/TRAF6 mediating autophagy and apoptosis reduction, which may provide a new experimental basis for MSCs treating ACLF.

FRI202
Impact of acute-on-chronic liver failure and decompensated liver cirrhosis on psychosocial burden and quality of life of patients and their close relatives

Nagel Michael[1,2], Christian Labenz[1,2], Marcus-Alexander Woerns[1,2], Jens Marquardt[3,4], Jörn M. Schattenberg[5], Peter Galle[1,2], Marc Nguyen-Tat[1,2,6]. *[1]University Medical Center Mainz, First Department of Medicine, Mainz, Germany; [2]University Medical Center of the Johannes Gutenberg-University Mainz, Cirrhose Centrum Mainz, Mainz, Germany; [3]University Medical Center Lübeck, First Department of Internal Medicine, Lübeck, Germany; [4]University Medical Center of the Johannes Gutenberg-University Mainz, Lichtenberg Research Group for Molecular Hepatocarcinogenesis, Mainz, Germany; [5]University Medical Center Mainz, Metabolic Liver Research Program, I. Background and Aims: Patients with liver cirrhosis often suffer from complications such as ascites, gastrointestinal bleeding, and infections, resulting in impaired quality of life. Frequently, the close relatives of patients also suffer from a lower quality of life in chronic diseases. In recent years, acute-to-chronic liver failure has been defined as a separate entity with high mortality. Often several organs are affected which makes intensive care therapy necessary. Little is known about the influence of acute-on-chronic-liver failure (ACLF) on the quality of life of patients and the psychosocial burden on close relatives. The purpose of this non-randomized prospective study is to investigate the influence of decompensated liver cirrhosis and the onset of ACLF of the patient's' quality of life and the psychosocial burden of close relatives.
Method: A total of 63 patients with acute decompensation of liver cirrhosis and hospital admission were enrolled in the study. To assess the quality of life of patients, the disease specific CLDQ questionnaire was assessed. In addition. quality of life and psychosocial burden of first-degree relatives was measured using the generic SF-36 questionnaire as well as the Zarit Burden Score.
Results: 21 of the 63 patients suffered from ACLF. Patients with ACLF showed a lower quality of life in terms of worries compared to patients with only decompensated liver cirrhosis and increased systemic symptoms. The univariate analysis confirmed the link between the existence of an ACLF and the concerns of patients. The organ failure score was significantly associated with overall CLDQ scores, especially with worries and systemic symptoms of patients. Interestingly the psychosocial burden and quality of life of close relative correlates with patient's quality of life and was influenced by the onset of an acute-on-chronic liver failure.
Conclusion: Patients with decompensated liver cirrhosis suffer from impaired quality of life. In particular, patients with ACLF have a significantly reduced quality of life. The extent of the psychosocial burden on close relative correlates with poor quality of life in patients with decompensated liver disease and is influenced by the existence of ACLF.

Reversal of immune paralysis to immune homeostasis: effect of plasma exchange on monocyte merTK and HLA-DR expression in patients with acute- on- chronic liver failure

Siddharth Mittal[1], Meenu Bajpai[2], Pradeep Kumar[1], Ravinder Chaudhary[1], Gayatri Ramakrishna[1], Shiv Kumar Sarin[3], Nirupma Trehanpati[1]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Transfusion Medicine, New Delhi, India;* [3]*Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: trehanpati@gmail.com

Background and Aims: Acute on chronic liver failure (ACLF) is a clinical syndrome characterized by liver failure due to an acute hepatic insult on an underlying cirrhosis/chronic liver disease. MerTk negatively regulates immune cells and increases MerTk expression on monocytes in ACLF. It is associated with defective response to microbial challenge and decreased HLADR expression.
Plasma exchange (PE) by removing DAMPS, toxins and cytokines may readjust the immune system. We aimed to assess the impact of PE on HLADR and MerTK expression on monocytes in patients with ACLF.
Method: Whole blood samples from ACLF patients requiring plasma exchange (PE) (Gr.A; n = 12) and receiving standard medical therapy (SMT) (Gr.B; n = 10) were collected at baseline (Pre PE; Day 0), immediately Post PE (iPPE) and 24 hours Post PE (24hPPE) and Day 2 (D2) in SMT patients. Median fluorescent intensity of monocyte HLADR expression and frequency of MerTk expressing monocytes was assessed and compared with healthy controls (HC; n = 10) by flow cytometric analysis using FlowJo software. Biochemical parameters and clinical scores (MELD Na and AARC) were assessed in all patients.
Results: At baseline, Gr.A had significantly lower hematocrit (p = 0.04) and deranged PT/INR (p = 0.02) as compared to Gr.B. With PE in Gr.A, there was a significant drop in total bilirubin (p = 0.002), AST (p = 0.002), total protein & A/G ratio (p = 0.002) and PT/INR levels (p = 0.003) at iPPE. AARC and MELD Na scores also reduced significantly at iPPE (p = 0.004 and 0.008 respectively). There were no such differences in Gr.B on D0 and D2.
HLADR expression was significantly lower in ACLF patients in both groups compared to HC. However, monocyte HLADR expression increased significantly 24 hours after PE (p = 0.03) in Gr.A. However, in Gr.B, there was no difference in monocyte HLADR expression till D2. The frequency of MerTk expressing monocytes decreased significantly at iPPE in Gr.A (p = 0.01), as well as, on D2 in Gr.B (p = 0.02).
Conclusion: PE significantly improves liver function tests, indices of liver disease severity in ACLF patients. PE by abrogating the frequency of MerTk expressing monocytes and by restoring monocyte HLADR expression substantially restores immune homeostasis for a short interval. MerTk may act as a novel biomarker of monocyte function as well as a novel therapeutic target in sepsis.

Different transcriptome characteristics of peripheral blood mononuclear cells are associated with survival outcome in hepatitis B-related acute-on-chronic liver failure

Shanshan Ma[1], Zhongyang Xie[1], Xiaowei Xu[2], Lanjuan Li[1]. [1]*The First Affiliated Hospital, College of Medicine, Zhejiang University, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China;* [2]*The First Affiliated Hospital, College of Medicine, Zhejiang University, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Department of Infectious Diseases, Hangzhou, China*
Email: ljli@zju.edu.cn

Background and Aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is a specific syndrome involving the acute deterioration of liver function that could result in multisystem failure. The lack of knowledge of the exact molecular pathogenesis and broad-spectrum specific treatments contribute to the poor prognosis of HBV-ACLF. This study aims to find specific and sensitive biomarkers for predicting short-term mortality of HBV-ACLF using transcriptomics.
Method: It was a prospective cohort, in which all 16 HBV-ACLF patients met the Chinese Group on the Study of Severe Hepatitis B

Figure: (abstract: FRI204)

(COSSH)-ACLF criteria. Clinical characteristics and peripheral blood mononuclear cells (PBMCs) were collected at admission for transcriptome and bioinformatics analysis.

Results: Analysis of gene expression profile showed that survival group was different from non-survival group obviously. The volcano Plot indicated that 1032 probes were significantly differentially expressed in non-survival group compared with survival group, of which 626 were upregulated and 406 were downregulated. Functional analysis of the differently expressed genes suggested immune response and inflammatory response played important parts in disease progression. The result of microRNA (miRNA) expression profile was similar. There were 39 miRNAs significantly differentially expressed in non-survival group compared with survival group.

Conclusion: Different transcriptome characteristics of PBMCs are associated with severity of liver damage, in which there are potential biomarkers for poor outcomes in HBV-ACLF cases.

Granulocyte colony-stimulating factor in acute-on-chronic liver failure: systematic review and meta-analysis

Rosa Martin-Mateos[1,2,3,4], Rosario González Alonso[1], Alfonso Muriel[5], Noelia Álvarez[6], Alexandre Figueroa Tubio[1], Jesus Donate[1], Alejandro López Jerez[1], Agustin Albillos[1,2,3,4]. *[1]Hospital Ramón y Cajal, Gastroenterology, Madrid, Spain; [2]Universidad de Alcalá; [3]Instituto Ramón y Cajal de investigación sanitaria (IRYCIS); [4]Centro de Investigación Biosanitaria en Red Enfermedades Hepáticas y Digestivas (CIBERehd); [5]Hospital Ramón y Cajal, Biostatistics; [6]Hospital Ramón y Cajal, Library*
Email: agustin.albillos@uah.es

Background and Aims: Acute-on-chronic liver failure (ACLF) is characterized by an acute decompensation of cirrhosis, organ failure and high short-term mortality. A dysfunctional immune response underlies the pathogenesis of ACLF. The granulocyte colony-stimulating factor (G-CSF) mobilizes bone marrow-derived stem cells. It has been suggested that treatment with G-CSF may increase survival in patients with ACLF. The aim of the study is to assess the survival benefit associated with G-CSF administration compared to the standard of care in ACLF.

Methods: Systematic review and meta-analysis of randomized controlled trials. The primary outcome was long-term (60–90 days) survival. We searched PubMed from inception to October 2019. Manual searches of reference lists in relevant articles and conference proceedings from the European, North America and Asia associations for the study of the liver were also included (2009-present). GRADE system was used for quality and risk of bias analysis. Two independent investigators extracted the data and disagreements were solved by a third investigator.

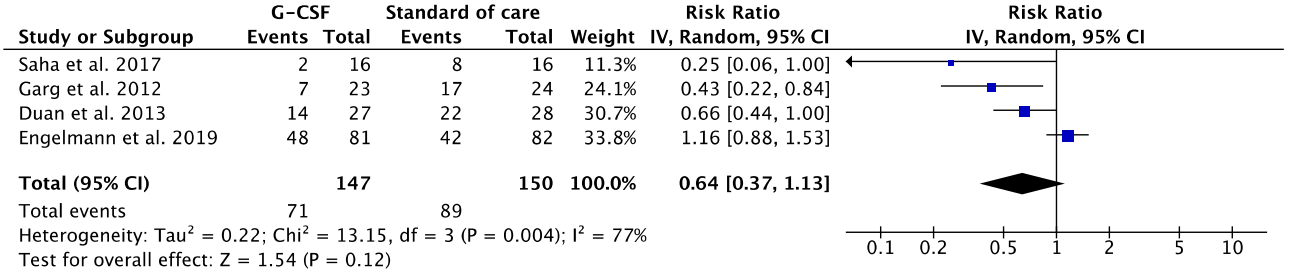

Figure: (abstract: FRI205)

Results: The initial search strategy identified 38 studies. Four randomized controlled trials were included for the quantitative analysis with a total of 297 patients (147 G-CSF and 150 standard of care). ACLF was defined by the Asian Pacific Association for the Study of the Liver criteria in all but one study (Engelmann et al 2019) which used the EASL-CLIF criteria. G-CSF regimens were 5 μg/kg/day for 6 consecutive days (Duan et al. and Saha et al.) and 12 doses of 5 μg/kg (Garg et al. and Engelmann et al.). Significant heterogeneity among studies was observed (I^2 = 77%, Chi^2 = 13.15, p = 0.004). Patients who received G-CSF did not show a significant overall survival benefit compared to the standard of care (random effects model, Risk Ratio = 0.64 [95% CI 0.37, 1.13]).
Conclusion: In a systematic review and meta-analysis, administration of G-CSF did not significantly improve transplant free survival in comparison with standard of care alone in patients with ACLF.

FRI206

Dysfunctional adaptive immunity in liver cirrhosis and acute-on-chronic liver failure is characterized by aberrant immune checkpoint expression and diminished cytokine secretion in T cells

Sabrina Rueschenbaum[1,2], Sandra Ciesek[3], Alexander Queck[2], Marek Widera[3], Katharina Maria Schwarzkopf[2], Bernhard Brüne[4], Christoph Welsch[2], Heiner Wedemeyer[1], Stefan Zeuzem[2], Andreas Weigert[4], Christian Lange[1,2]. *[1]University Hospital Essen, Department for Gastroenterology and Hepatology, Essen, Germany; [2]Goethe-University Hospital Frankfurt, Department of Internal Medicine 1, Frankfurt am Main, Germany; [3]University Hospital Essen, Institute of Virology, Essen, Germany; [4]Goethe-University Frankfurt, Institute of Biochemistry 1, Frankfurt am Main, Germany*
Email: sabrina.rueschenbaum@uni-due.de

Background and Aims: Liver cirrhosis and acute-on-chronic liver failure (ACLF) patients suffer from high levels of systemic inflammation and parallel suppression of immunity. This was mostly demonstrated for innate immune cells where regulatory receptors and cytokine expression were upregulated. Yet, phenotypic changes in the adaptive immune cell compartment are not understood. We therefore aimed to characterize the development of T cells regarding their co-stimulatory and inhibitory marker expression as well as cytokine production during the progression of liver cirrhosis to ACLF
Method: Patients with compensated/stable decompensated liver cirrhosis, acute decompensation of liver cirrhosis, or ACLF were recruited from a prospective cohort study. Peripheral blood mononuclear cells (PBMCs) underwent flow cytometric immunophenotyping for 23 co-stimulatory and inhibitory cell surface markers. In addition, PBMCs were treated with PMA/Ionomycin and stained intracellular for cytokine production, i.e. TNFalpha and IFNgamma.
Results: Previous results of our group showed higher frequencies of detectable TT virus in patients with compensated/stable decompensated liver cirrhosis compared to healthy controls suggesting immunosupression as an early phenomenon in liver cirrhosis. On a phenotypic level, CD8+ as well as CD4+ T cells demonstrated parallel upregulation of numerous co-stimulatory (e.g. CD40L, OX40, CD69, GITR, TIM-1) and inhibitory immune checkpoints (e.g. PDPN, PROCR, 2B4, TIGIT), which again preceded the development of ACLF. Whereas all T cell types – CD8+, CD4+ and regulatory T cells (Tregs, CD4+ CD25dim CD127-) – displayed higher frequencies of the death receptor CD95 and the inhibitory marker PDPN, many changes occurred prominently within one subgroup, such as an upregulation of KLRG1 on CD8+ T cells and CTLA-4 on Tregs. On a functional basis, the capacity of CD4+ and CD8+ T cells to produce pro-inflammatory cytokines upon stimulation was strongly diminished in patients with acute decompensation of liver cirrhosis and ACLF.
Conclusion: Occurrence of dysfunctional T cell responses is an early event in the pathogenesis of liver cirrhosis and precedes ACLF. As a mechanism, abnormal expression of co-stimulatory and inhibitory markers provides an explanatory link towards immunosuppression and higher death cell rates. This might contribute to the development of ACLF by elevating the risk of infections in patients with liver cirrhosis.

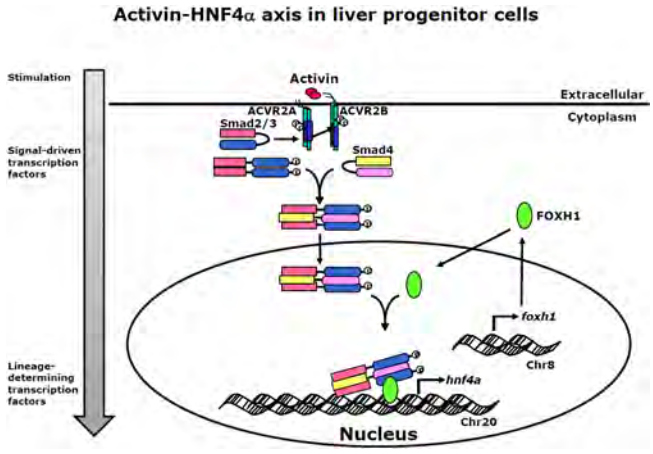
Functional activin-HNF4A-coagulation axis in liver progenitor cells determines MELD score and outcome of acute-on-chronic liver failure

Tao Lin[1], Shanshan Wang[1], Rilu Feng[1], Xiaodong Yuan[1], Hui Liu[2], Chen Shao[2], Wandrer Franziska[3], Alexander Marx[4], Matthias Ebert[1], Heike Bantel[3], Steven Dooley[1], Huiguo Ding[5], Honglei Weng[1]. *[1]Department of Medicine II, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany; [2]Department of Pathology, Beijing You'an Hospital, Affiliated with Capital Medical University, Beijing, China; [3]Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover; Germany; [4]Institute of Pathology, University Medical Centre Mannheim, Heidelberg University, Mannheim, Germany; [5]Department of Gastroenterology and Hepatology, Beijing You'an Hospital, Affiliated with Capital Medical University, Beijing, China*
Email: Tao.Lin@medma.uni-heidelberg.de

Background and Aims: Given the shortage of donors, only patients with MELD score ≥15 are on the waiting list for liver transplantation (LTx). Impressively, a lot of patients e.g. those with acute-on-chronic liver failure (ACLF) display successful hepatic regeneration in the explanted livers. This raises a controversial issue whether these patients should obtain donor livers. Liver progenitor cells (LPCs) are major cell source running hepatic function when a liver suffers from massive hepatic necrosis, a histological feature of ACLF. This study shows that LPCs in irreversible ACLF lose intact Activin-FOXH1-HNF4α regulatory axis, and thus cannot provide sufficient coagulation function, which results in high MELD scores and poor prognosis.
Method: Twenty-five ACLF patients (17 received LTx and 8 recovered) were enrolled. Clinical, blood biochemical and histological parameters were analyzed. The molecular mechanisms of how Activin-FOXH1-HNF4α axis exerted function were investigated in rodent LPCs.



Results: In vitro study showed that LPCs produce key hepatocyte functional genes/proteins, including coagulation factors and albumin. Expression of these genes was controlled by a lineage determination transcription factor HNF4α. Knockdown of HNF4α remarkably reduced expression of coagulation factor V (f5) and albumin. ChIP analysis confirmed the binding of HNF4α on the promoter of f5 and albumin genes. Further analyses showed that disruption of Activin specific receptor ALK4, downstream substrates (SMAD2, SMAD3 and SMAD4) and transcription factor FOXH1 significantly decreased HNF4α expression. Activin induced HNF4α expression. Co-IP analysis showed that Activin-induced p-SMAD2

formed a complex with SMAD4 and FOXH1. In most irreversible ACLF patients, immune positivity of p-SMAD2, FOXH1 and HNF4α was undetectable by immunohistochemistry. However, 8 recovered ACLF patients demonstrated robust expression of HNF4α in nuclei of LPCs and remaining hepatocytes. There was closed association between high levels of HNF4α expression, low INR and high MELD scores in ACLF.

Conclusion: These results revealed that Activin provides a key signal stimulating HNF4α to govern expression of coagulation factors in ACLF. Impairment of Activin-HNF4α axis causes high MELD scores. Even if these patients complete LPC-mediated regeneration, LPC-derived hepatocytes still are not capable of running intact hepatic function. LTx is the only option to rescue these patients.

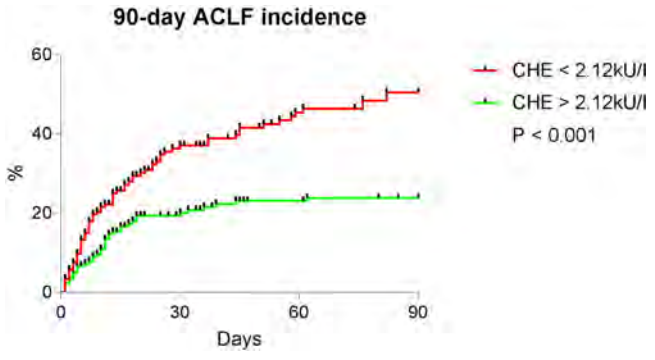
FRI208

Serum cholinesterase, an underestimated marker in the prediction of acute-on-chronic liver failure, organ failure and LTx-free survival in patients with liver cirrhosis?

Tammo Lambert Tergast[1], Abdul-Rahman Kabbani[1], Marie Schultalbers[1], Michael P. Manns[1,2,3], Markus Cornberg[1,2,3], Benjamin Maasoumy[1,2,3]. [1]*Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*German Centre for Infection Research (Deutsches Zentrum für Infektionsforschung DZIF), Partner-site Hannover-Braunschweig, Hannover, Germany;* [3]*Centre for Individualised Infection Medicine (CIIM), c/o CRC Hannover, Hannover, Germany*
Email: tergast.tammo@mh-hannover.de

Background and Aims: Acute-on-chronic liver failure (ACLF) is associated with a high short-term mortality and defined as the combination of acute decompensation and organ failure (OF) in patients with liver cirrhosis. In clinical practice, it is often challenging to determine which patients will develop OF and ACLF. Serum cholinesterase (CHE) is closely associated with the synthetic function of the liver. However, its prognostic value in patients with liver cirrhosis, in particular in terms of ACLF development, remains unclear. Thus, we aimed to investigate the prognostic value of CHE in these patients.

Method: Overall, 521 hospitalized patients between 2012 and 2018 with liver cirrhosis were considered for this study. Patients with ACLF at admission were excluded, leaving 353 patients for further analyses. Study endpoints were 90-day (90d) incidence of ACLF, 90d incidence of distinctive OF (i.e. liver, kidney, cerebral, circulatory, respiratory, coagulation) and 90d liver transplant (LTx) free survival. ROC-analysis was used to determine optimal CHE cut-off values associated with ACLF. For survival analysis uni- and multivariate Cox-regression were conducted, adjusting for MELD, leukocyte count, age and serum-sodium.



Results: Overall, 132 (38%) patients were female, mean age was 57 years and the mean MELD score was 15.8. The optimal cut-off for CHE to determine 90d ACLF development was 2.12 kU/l ($p < 0.001$). CHE <2.12 kU/l was associated with a higher 90d-incidence of ACLF (HR:2.30; $p < 0.001$) (Figure 1). In the multivariate model only CHE <2.12 kU/l, age and MELD score were independently associated with 90d-ACLF development (HR:2.02; $p = 0.001$, HR:1.02; $p = 0.03$ and HR: 1.09; $p < 0.001$, respectively). Regarding specific OF, CHE <2.12 kU/l was independently associated with kidney failure, cerebral failure, circulatory failure and coagulation failure (HR:2.04; $p = 0.002$, HR:4.15; $p = 0.01$: HR:1.97; $p = 0.002$; HR:3.49; $p = 0.001$). Of note, liver failure and respiratory failure were not linked to CHE values <2.12 kU/l (HR:1.38; $p = 0.26$, HR:1.77; $p = 0.19$). However, CHE <2.21 kU/l was associated with lower LTx-free survival (HR:3.20; $p < 0.001$). Interestingly, in patients with MELD scores <15 only CHE <2.12 kU/l and leukocytes but not the MELD score were independently associated with 90d-survival (HR: 5.76; $p = 0.01$ and HR:1.11; $p = 0.04$).

Conclusion: In patients with liver cirrhosis CHE values may help to identify those with a high risk for ACLF, organ failure and mortality.

FRI210

Single- centre experience of implementing a hepatology outreach service to improve patient care for emergency admissions of acutely decompensated cirrhosis

Tomi Ashaye[1], Nicolas Omorphos[1], Paul Trembling[1], Richard Warburton[1]. [1]*Lister Hospital, Department of Gastroenterology, Stevenage, United Kingdom*
Email: tomi.ashaye@nhs.net

Background and Aims: Decompensated cirrhosis is a medical emergency associated with high in-patient mortality. Despite the introduction of the BASL/BSG care bundle in the UK, emergency admissions due to decompensated cirrhosis are often sub-optimally managed in non-specialist areas. In this study we reviewed patient care before and after introduction of a consultant- led hepatology outreach service to acute clinical areas.

Method: After our outreach service had been active for three months, we reviewed patient records for all emergency admissions due to decompensated cirrhosis and compared these to the same three-month period, three years before the induction of the outreach service. We recorded whether elements of the BASL/BSG care bundle were completed within 24 hours as well as the length of stay (LoS), intensive care unit (ICU) admissions, mortality and 90-day outcomes following discharge.

Chi-squared analysis was performed to identify any statistically significant results.

Results: 21 cases met the inclusion criteria and were included in the pre-intervention group and 28 cases in the post-intervention group. An improvement in compliance with the BASL/BSG bundle was noted within 24 hours of admission, with patients being more likely to receive blood cultures, abdominal ultrasound scans and paracentesis ($p < 0.05$). Once admitted, the proportion of patients receiving specialist reviews within 24 hours increased from 50% to 68% ($p < 0.05$). Post intervention a reduction in intensive care unit admissions and re-admissions within 90 days was noted. However, length of stay increased from 11 to 16 days. Despite improvements in care, mortality rates remained high (Figure 1).

Conclusion: Decompensated cirrhosis is an acutely life-threatening condition. Our results show that support of the acute medical team through early specialty review improves patient care during their initial admission and has resulted in reduced re-admissions.

These data, demonstrating improved patient care and outcomes, have resulted in adoption of a permanent in-reach service in our hospital, and a prospective analysis of the service will inform future service development.

	2016	2019	p-value

Background and Aims: Serum total bilirubin (TB) is the critical indicator to judge whether the patients with acute exacerbated chronic liver disease (CLD) are suffering from a hepatotropic insult and benefiting from expedited liver-specific treatments. However, definition is of hepatotropic insult blurry. We aim to explore the evidence-based TB cutoff value to define it.

Method: Two prospective, multicenter cohort studies were conducted in china. We consecutive enrolled 2600 (from Jan.2015 to Dec.2016) and 1370 (Sep.2018 to Jan.2019) patients with CLD hospitalized for acute decompensation (AD) or acute liver injury. Patients' characteristics at admission and their 90-day outcome were collected. TB value (mg/dL) was normalized by natural logarithm. We used local weighted scatter smoothing (LOWESS) model to visualized the relationship between TB and 90-day LT-free mortality (LTF-M). Rational equations were used to fit and calibrate the curves' functions. Second derivatives were used to describe the mortality's acceleration and calculated the cutoff of TB.

Results: Among all 3970 patients enrolled, 70.8% were HBV related, 71.2% were cirrhotic, and 81.1% were with AD. We found patients' 90-day LTF-M acceleratingly climbs as the TB increases. Therefore, we made a hypothesis that value of TB at the maximum acceleration point is the cutoff value of hepatotropic insult, then via a rational equation, we calculated it [ln (TB) = 2.49, TB = 12 mg/dL, Figure 1A, B]. 1168 patients (TB ≥12 mg/dL) and 2792 patients (TB<12 mg/dL) were compared. The group of patients with higher TB [20.7 (15.9 – 27.4) vs

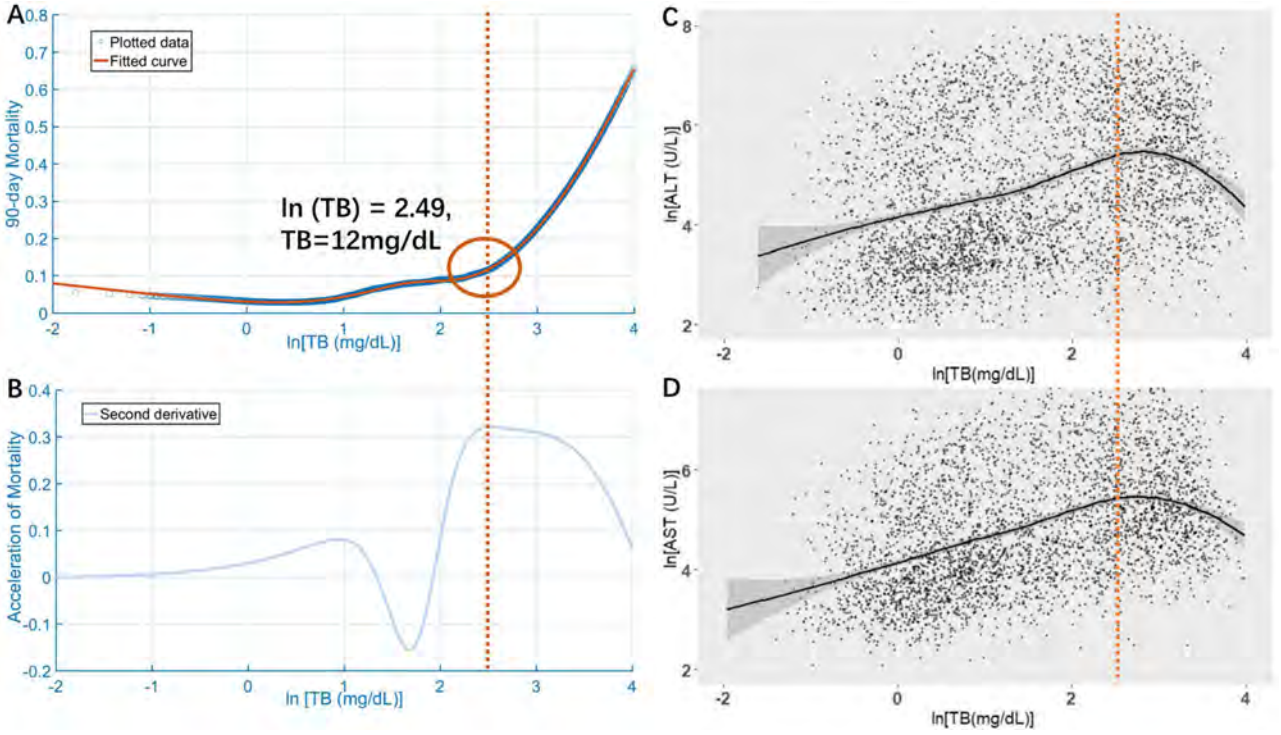

Figure: (abstract: FRI211): **Legend A** Relationship between TB and 90-day LT-free mortality; **B** the Second derivatives curve shows the mortality's maximum acceleration; **C, D** Relationship between TB and ALT; **D** Relationship between TB and AST.

2.3 (1.2 – 4.9), p < 0.001] show much higher 90-day LTF-M (31.2% vs 6.0%, p < 0.001), transaminase, INR and MELD score [25.0 (22.0 – 29.0) vs 12.0 (9.0 – 17.0), p < 0.001], but only slightly elevated creatinine [0.8 (0.6–1.0) vs 0.8 (0.6–0.9), p < 0.001] and lower rate of gastrointestinal bleeding (3.2% vs 19.3%, p < 0.001). Additionally, we found that when TB exceeds 12 mg/dL, its correlation with transaminase is reversed (Figure 1C, D).

Conclusion: First time hepatotropic insult is clearly defined as TB ≥ 12 mg/dl, which was obtained from large scale cohort data and mathematical model instead of expert consensus in HBV high-endemic region.

Clinical features and natural history of acute-on-chronic liver failure precipitated by any indeterminate factor: single-center observational study

Hitomi Hoshi[1], Po-sung Chu[1], Nobuhiro Nakamoto[1], Takanori Kanai[1].
[1]*Keio University, Shinjuku City, Japan*
Email: usako172000@yahoo.co.jp

Background and Aims: Acute decompensation (AD), along with subsequent acute-on-chronic liver failure (ACLF) of patients with liver cirrhosis (LC) may be fatal and impairs quality of life. How a precipitating factor (PF) of ACLF influences prognosis is still largely unknown. Studies from different regions of the world reported that about 10 to 40% of ADs/ ACLFs were precipitated by any acute insult that was not identifiable. In the current study, we aimed to clarify the clinical features and the natural history of AD/ACLF with any indeterminate PF.

Method: In this single liver transplant center observational study approved by local institutional IRB (no. 20170202), we retrospectively recruited 1532 consecutive admissions to our liver unit from Jan 2012 to Apr 2019. After exclusion of admissions for planned procedures, 220 cases (58% male; aged 62.8 ± 15 years) with AD were extracted for analysis. PFs of each AD were reviewed retrospectively. Transplant-free survival (TFS) within 180 days and clinical parameters were compared by PFs.

Results: The median observation period 380 days. Twenty cases (9%) underwent liver transplantation (LT), 52 (23%) suffered from liver-related death, 114 (51%) survived without LT, and the remaining deceased due to non-hepatic cause or lost follow-up (17%); 29% met the EASL CLIF-C criteria of ACLF grade 1–3, and 51% met the APASL criteria of ACLF. PFs included bacterial infection (INF-AD; 23%), GI bleeding (15%), active alcoholism (13%), superimposed/ exacerbated hepatic viral infection (3%), others (trauma or procedure-related, 9%), and indeterminate (IND-AD; 38%). By Kaplan-Meier analysis, patients of IND-AD demonstrated comparable 180-day TFS of that of INF-AD (p = 0.79), but significantly worse TFS than those of all the other PFs (p = 0.02). However, none of the known prognostic parameters including MELD, MELD-Na, CLIF-C OF scores, CLIC-C ACLF scores differentiated the 3 groups. Compared to cases of all the other PFs, those of IND-AD and INF-AD shared similar clinical features including a significant lower level of serum albumin (p = 0.07; 0.008, respectively) and tended to have higher baseline creatinine levels. Compared to cases of INF-AD, those of IND-AD tended to complicate with hepatic encephalopathy (p = 0.11), and to suffer from subsequent episodes of Grade 1–3 ACLF within 3 months (p = 0.09).

Conclusion: IND-AD shares similar clinical features with INF-AD, including worse 180-day transplant-free survival, lower serum albumin and more impaired renal function. Whether any infection that is not easily identifiable (such as fungal infection) or hypoalbuminemia might be therapeutic targets in decompensation of LC warrants more investigations in the future.

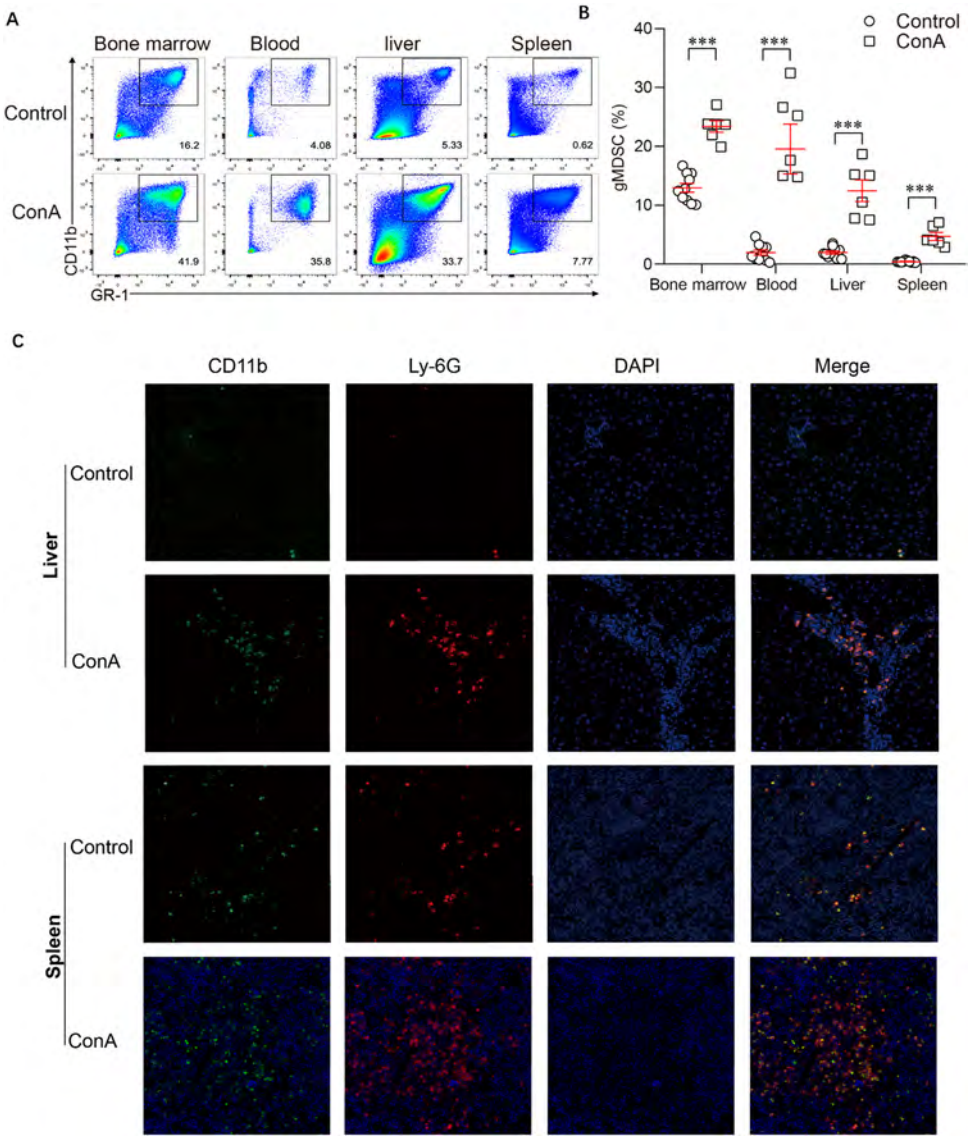

Figure 1: (abstract: FRI213): The percentage of gMDSC in peripheral blood, liver, spleen and bone marrow were markedly increased in ACLF mouse model induced by Concanavalin (n = 5) compare to the control group (normal saline, n = 10).

FRI213

Granulocytic myeloid-derived suppressor cells contribute to HBV-related acute-on-chronic liver failure infection and mortality by inducing T cell exhaustion

Xueping Yu[1,2], Feifei Yang[2], Richeng Mao[2], Songhua Yuan[3], Yu Yang[3], Haoxiang Zhu[2], Chao Qiu[2], Zhijun Su[1], Jiming Zhang[2]. *[1]The First Hospital of Quanzhou affiliated to Fujian Medical University, Infection Diseases, Quanzhou, China; [2]Huashan Hospital affiliated to Fudan University, Infection Diseases, Shanghai, China; [3]Shanghai Medical College, Fudan University, Shanghai Public Health Clinical Center and Institutes of Biomedical Science, Shanghai, China*
Email: jmzhang@fudan.edu.cn

Background and Aims: Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is characterized by susceptibility to infection and T-cell immune exhaustion. Studies have shown that granulocytic myeloid-derived suppressor cells (gMDSC) may lead to persistent HBV infection by suppressing T-cell function. However, it is unclear whether gMDSC could lead to T-cell immune exhaustion and infection in HBV-ACLF patients by inhibiting T-cell function.

Method: The blood and liver samples were collected from healthy subjects, chronic hepatitis B (CHB) and HBV-ACLF patients admitted to Huashan hospital and the first hospital of Quanzhou. ACLF mouse model was established by continuous injection of Concanavalin for 5 times (15 mg/Kg, every other day). The frequency of gMDSC in human peripheral blood mononuclear cells and intrahepatic immune cells, and in mouse peripheral blood, liver, spleen and bone marrow, were detected by flow cytometry and immunofluorescence. The expansion of gMDSC were detected by adding recombinant cytokines or corresponding inhibitors. The effects of gMDSC on proliferation and cytokines secretion of T-cells were observed upon co-culturing purified gMDSC and PanT cells. Anti-indoleamine 2,3-dioxygenase (IDO) was used to determine whether gMDSC could inhibit the function of T-cells through IDO signal pathway.

Results: The frequency of human gMDSC (HLA-DR$^-$CD33$^+$CD11b$^+$CD14$^-$CD15$^+$) in circulation and intrahepatic immune cells of HBV-ACLF patients were significantly increased and positively correlated with severity of disease, prognosis and infection. Moreover, the percentage of gMDSC (GR-1$^+$CD11b$^+$Ly6C$^-$Ly6G$^+$) in peripheral blood, liver, spleen and bone marrow of ACLF mouse model were also markedly increased compare to the control group.

Immunofluorescence results showed that the number of gMDSC cells in the liver tissues of HBV-ACLF patients and the liver and spleen tissues of ACLF mouse models were significantly increased. TNF-α facilitate to the expansion of gMDSC, while blocking or neutralizing TNF-α signalling pathways decrease the frequency of gMDSC. Importantly, HBV-ACLF patient-derived gMDSC inhibited T-cell proliferation and interferon-γ secretion. Mechanistically, neutralization of IDO blunted the inhibition effects of gMDSC on T-cell.
Conclusion: gMDSC were compensatory increased, leading to the gradual decline of T-cell function until exhaustion, which may weaken the ability of removing pathogen, and eventually contribute to infection and aggravate HBV-ACLF patients' death. This study is helpful to elucidate the pathogenesis of HBV-ACLF and provide a new drug target.

Baseline demographics and clinical characteristics of subjects enrolled in the phase 3 AURORA study of cenicriviroc for the treatment of liver fibrosis associated with non-alcoholic steatohepatitis

Naim Alkhouri[1], Vincent Wai-Sun Wong[2], Maciej Jablkowski[3], Alma Laura Ladrón de Guevara[4], Muhammad Sheikh[5], Alex Hodge[6], Magdy Elkhashab[7], Simone Strasser[8], Grace S. Park[9], Henrik Landgren[10], Bill Tan[11], Benedetta Massetto[11], Maria Lucia Pecoraro[11], Star Seyedkazemi[11], Eduardo Bruno Martins[11], Laurent Fischer[11], Manal Abdelmalek[12], Brent Tetri[13], Quentin Anstee[14]. *[1]Texas Liver Institute, University of Texas Health, San Antonio, United States; [2]The Chinese University of Hong Kong, Hong Kong, China; [3]Medical University of Łódź, Lodzkie, Poland; [4]Hospital Angeles Clínica Londres, Mexico City, Mexico; [5]Fresno Clinical Research Center, Fresno, United States; [6]Monash Medical Center, Monash University, Melbourne, Australia; [7]Toronto Liver Centre, Toronto, Canada; [8]A W Morrow Gastroenterology and Liver Centre, University of Sydney, Sydney, Australia; [9]Allergan PLC, Irvine, United States; [10]Allergan PLC, Marlow, United Kingdom; [11]Allergan PLC, South San Francisco, United States; [12]Duke University, Durham, United States; [13]Saint Louis University, St. Louis, United States; [14]Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom*
Email: benedetta.massetto@allergan.com

Background and Aims: Approximately 10–20% of subjects with NAFLD have nonalcoholic steatohepatitis (NASH) with varying degrees of fibrosis. The severity of liver fibrosis significantly increases the risks of liver-related and all-cause morbidity and mortality. No treatments are approved for fibrotic NASH. Cenicriviroc, a novel, once-daily, oral, potent inhibitor of C-C chemokine receptor types 2 and 5, is currently in development for the treatment of liver fibrosis in adults with NASH.
Method: AURORA (NCT03028740) is an ongoing, global, Phase 3, multicentre, randomised, double-blind, placebo-controlled trial to evaluate a surrogate histology endpoint (improvement in fibrosis by ≥1 stage per NASH CRN classification AND no worsening of steatohepatitis) in Part 1 (~1200 subjects) and clinical outcomes (time to first occurrence of any adjudicated events of mortality, histologic progression to cirrhosis or specified liver-related events) in Part 2 (~2000 subjects overall). Adults with histologic diagnosis of NASH and Stage 2 or 3 liver fibrosis per NASH CRN are enrolled. Subjects with cirrhosis or other causes of chronic liver disease are excluded. We aim to describe the baseline demographics and clinical characteristics of subjects enrolled in AURORA.
Results: Approximately 6000 subjects were screened by the analysis date and 1122 were randomised, with histology criteria being the primary reason for screen failure. The majority of the randomised subjects were female (63%), white (90%), with a mean age of 54 years (SD: 11). The mean BMI was 36 kg/m^2 (SD: 7). Fifty one percent had type 2 diabetes mellitus; most commonly used treatments were biguanides (84%) and sulfonylureas (23%). Hypertension was present in 61% of subjects, and 35% were on statins; 42% had Stage 2 and 56% had Stage 3 fibrosis. Table 1 shows baseline laboratory parameters, including non-invasive fibrosis markers.

Table 1: Baseline laboratory data

Laboratory parameter	Mean	SD
ALP* (IU/L)	86.2	34.2
ALT* (units/L)	57.7	38.2
AST* (units/L)	45.5	28.1
Total bilirubin* (μmol/L)	8.23	4.84
Platelet count* (×10^9/L)	240.4	66.6
FIB-4**	1.5	0.7
APRI**	0.6	0.5
NFS**	−0.9	2.0

*Available for 1097 subjects at data analysis date; **Evaluable for 1091 subjects

Conclusion: AURORA is one of the largest ongoing Phase 3 trials in subjects with fibrosis due to NASH. Description of the demographics and clinical characteristics of subjects screened and enrolled in this study will help to further characterise this population and inform the design of future trials. Editorial assistance by Complete HealthVizion.

FRI215

Diagnostic accuracy of a pocket-size ultrasound device in identifying liver surface nodularity for fibrosis staging in chronic liver disease

Andrea Costantino[1], Alessandra Piagnani[2], Marco Maggioni[3], Maria Francesca Donato[4], Pietro Lampertico[4], Maurizio Vecchi[1], Mirella Fraquelli[1]. *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Gastroenterology and Endoscopy, Milano, Italy; [2]Università degli Studi di Milano; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Pathology, Milano, Italy; [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Gastroenterology and Hepatology, Milano, Italy*
Email: andreascostantino@gmail.com

Background and Aims: In chronic liver disease fibrosis is the key prognostic factor. Liver biopsy, the reference standard for hepatic fibrosis assessment, is an invasive procedure with a small but significant risk of life-threatening complications. Many non-invasive tests have been evaluated as alternatives. Liver surface nodularity (LSN) is the highest-accuracy ultrasonographic sign to detect advanced liver fibrosis (F3-F4). Pocket-size Ultrasound Devices — with their small size, low cost and ease of use — have been assessed in several clinical settings, but never in CLD.
Our cross-sectional study evaluated PUD feasibility, reproducibility and accuracy in identifying LSN.
Method: Between September 2017 and January 2019 we enrolled all consecutive consenting adults referred for liver parenchymal biopsy. LSN was evaluated by 2 independent operators using PUD (Vscan® Dual Probe GE Healthcare, UK), and by an operator using standard GIUS. Transient elastography (TE) and liver biopsy were performed on all patients. PUD reproducibility was evaluated by κ coefficient.
PUD, GIUS and TE results were compared with histology (METAVIR). The estimated pre-test probability of severe fibrosis was 35%. Sensitivity, specificity, positive/negative likelihood ratios, and post-test probability were calculated
Results: For 72 patients (31 M, age 47 ± 28 years, NAFLD/NASH 35%, AIH 25%, PBC/PSC 14%, HBV/HCV 12%,, other 14%) PUD reproducibility (κ 0.82, 95% CI 0.68–0.96) and concordance between PUD and GIUS (κ 0.78, 95% CI 0.64–0.94) were excellent. In diagnosing F ≥ 3PUD achieved: 87% sensitivity, 91% specificity, LR+ 9.7, LR- 0.14, PPV 84%, NPV 93% against GIUS (95% sensitivity, 93% specificity, LR+ 13.5, LR-

0.05, PPV 88%, NPV 97%) and TE (67% sensitivity, 96% specificity, LR+ 16, LR- 0.35, PPV 89%, NPV 86%).

Variables	Cut off kPa	Sn %	Sp %	LR+	LR-	PPV %	NPV %	AUROC (95% CI)
Vscan	-	87	91	9.7	0.14	84	93	0.875 (0.78–0.94)
US	-	95	93	13.5	0.05	88	97	0.937 (0.85–0.98)
TE	10.3	67	96	16	0.35	89	86	0.967 (0-89–0.99)

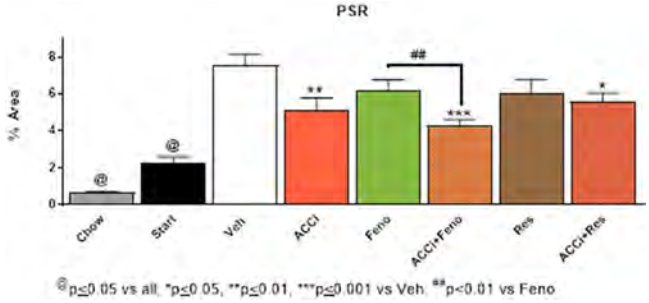
Conclusion: PUD proved feasible, with excellent reproducibility. PUD performed very well in diagnosing advanced compensated CLD, and comparably to GIUS and TE. PUD is deployable as first-line screening to select patients for more invasive techniques, thus shortening clinical decision times.

FRI216

Combination of an acetyl CoA carboxylase inhibitor with therapeutics that promote fatty acid oxidation moderately improves efficacy in a preclinical NASH model

Archana Vijayakumar[1], Isabel Olson[1], Sangeetha Mahadevan[1], Ting Wang[1], Shiva Zaboli[1], Maria Toteva[1], James Trevaskis[1], David Breckenridge[1], Jamie Bates[1]. [1]*Gilead Sciences, Inc., Foster City, United States*
Email: archana.vijayakumar@gilead.com

Background and Aims: Firsocostat, a liver-directed acetyl-CoA carboxylase inhibitor (ACCi) is currently being investigated in NASH patients with F3/F4 fibrosis. ACC simultaneously increases de novo lipogenesis and inhibits mitochondrial fatty acid oxidation (FAO) in hepatocytes. We have previously shown that ACC inhibition reduces fibrosis in a rat choline-deficient high-fat diet (CDHFD) model of NASH, partially via direct inhibition of hepatic stellate cell activation. In the current study, we assessed if increasing hepatocyte FAO, using either peroxisomal proliferator-activated receptor alpha (fenofibrate, Feno) or thyroid hormone receptor beta (Resmetirom, Res) agonists, could augment the anti-fibrotic efficacy of an ACCi.
Method: Male rats were fed CDHFD for 12 weeks and treated with Vehicle (Veh), 10 mg/kg ACCi, and 5 mg/kg Feno or 3 mg/kg Res, alone or in combination (combo) with ACCi, from week 6–12 (n = 15/group). Separate groups of rats were either maintained on normal chow or sacrificed after 6 weeks on CDHFD (Start). Hepatic fibrosis was assessed by quantitative morphometry of liver sections after picrosirius red (PSR) staining or alpha smooth muscle actin (αSMA) immunohistochemistry. Additional end-points measured included plasma non-invasive markers of fibrosis and total liver triglycerides (TG).
Results: CDHFD significantly increased hepatic PSR and αSMA area at 6 weeks (2.3 and 0.9% respectively) and 12 weeks (7.6 and 2.8% respectively) vs chow ($p < 0.05$). Among the monotherapy arms, ACCi reduced PSR and αSMA by 32% ($p = 0.01$) and 48% ($p = 0.001$), respectively vs Veh, while Res significantly reduced αSMA by 33% ($p = 0.04$) but not PSR. Compared to Veh, the ACCi/Feno combo reduced PSR and αSMA by 43% ($p = 0.0001$) and 59% ($p = 0.0001$), respectively, and the ACCi/Res combo by 26% ($p = 0.02$) and 57% ($p = 0.004$), respectively. The trend for improved efficacy in the combo groups compared to ACCi alone were not statistically significant. Similar treatment responses were observed in plasma markers of fibrosis with ACCi/Res combo reducing TIMP 1 and CK18 (M30) beyond ACCi alone ($p < 0.05$). None of the treatments (single agent or combo) changed total liver TG.



Conclusion: ACC inhibition reduced fibrosis progression in a preclinical model of NASH. Increased hepatocyte FAO with Res or Feno did not reduce fibrosis progression, however when used in combination with an ACCi, these therapeutics moderately increased anti-fibrotic efficacy.

FRI217

PBI-4050 promotes hepatic stellate cell deactivation by shifting energy metabolism

Brigitte Grouix[1], François Sarra-Bournet[1], Jean-Christophe Simard[1], Jean-Francois Thibodeau[1], Martin Leduc[1], Lyne Gagnon[1]. [1]*Liminal R&D BioSciences Inc.*
Email: b.grouix@prometic.com

Background and Aims: The establishment and progression of liver fibrosis is the best predictive factor of long-term outcome in NAFLD and NASH. One of the most important features in the establishment of liver fibrosis is unquestionably the activation of Hepatic Stellate Cells (HSCs). PBI-4050, a GPR40 agonist and GPR84 antagonist, and a lead drug candidate in the treatment of fibrotic-related diseases, has previously demonstrated strong anti-proliferative activity towards HSCs. In the present study, we investigated the mechanism by which PBI-4050 reverses HSCs proliferation and activation.
Method: *In vitro* culture of primary human HSCs were used to evaluate the effects of PBI-4050. A Seahorse XFe-96 analyzer was used to measure the effects of PBI-4050 on mitochondrial respiration and glycolysis. The expression profile of genes involved in glucose/fatty acid metabolism, fibrosis and inflammation was determined on HSCs activated by TGF-β1. The gene expression profile of PBI-4050-treated cells was compared to retinoic acid, an agent known to promote HSC deactivation.
Results: In the presence of glucose, levels of mitochondrial respiration and glycolysis were reduced, suggesting that PBI-4050 could shift the energy balance towards fatty acid oxidation (FAO). At the basal state, PBI-4050-treated HSCs harbored a quiescent-like energy phenotype characterized by a decreased level of intracellular ATP. Moreover, in TGF-β-activated HSCs, genes involved in FAO, such as CPT1, CPT2, ACLS1 and PDK4, were upregulated by PBI-4050, while genes involved in fibrosis and inflammation (α-SMA, CTGF, IL-8) were greatly reduced. Finally, expression of the lipid droplet marker perilipin-2, associated to HSC quiescent phenotype, was upregulated by PBI-4050.
Conclusion: These results indicate that PBI-4050 restores HSC quiescent-like phenotype by shifting energy metabolism towards FAO and could be a potential therapy for the treatment of liver fibrosis.

Email: bluefish010@naver.com

Background and Aims: Accurate evaluation of significant hepatic fibrosis is crucial for management of patient with chronic liver disease. We investigated the diagnostic performance of novel fibrosis glycobiomaker Wisteria floribunda agglutinin-positive Mac-2-binding protein (WFA+-M2BP) for evaluation of significant fibrosis diagnosed by MR elastography (MRE) in subjects with chronic liver disease and healthy subjects.
Method: A total of 490 subjects (mean age: 59, range: 33–80) who underwent serological tests for WFA+-M2BP were enrolled. 245 subjects with chronic liver disease underwent MRE and propensity score matched 245 healthy subject were analysed. The value of MRE 3.6 or above was considered as significant fibrosis. Clinical data were compared with other noninvasive markers (aspartate transaminase/alanine aminotransferase ratio (AAR), aspartate transaminase to platelet ratio index(APRI), fibrosis-4(FIB-4) index) for estimating significant fibrosis using receiver operating characteristic (ROC) analysis.
Results: Serum WFA+-M2BP level of health subjects, chronic liver disease without significant fibrosis and with significant fibrosis was 0.55 ± 0.32, 1.12 ± 0.76, 5.16 ± 5.39, respectively ($p < 0.001$). It was not significantly difference between sex, however, some difference between the cause of the chronic liver disease. The area under the ROC curves for significant fibrosis using cutoff value of 1.08 was 0.916 (95% CI: 0.888–0.939) was comparable to that using FIB-4 index of 0.885 (95% CI : 0.854–0.912) ($p = 0.202$), and superior to other surrogate marker, including AAR (0.793, $p < 001$) and APRI (0.870, $p = 0.045$).
Conclusion: WFA+-M2BP is a reliable noninvasive surrogate marker for predicting the significant hepatic fibrosis for chronic liver disease.

ZLN005, PGC-1? activator, induces oxidative phosphorylation and lipogenesis in myofibroblasts to reverse liver fibrosis

Jianye Cai[1], Yingcai Zhang[1], Jun Zheng[1], Jiebin Zhang[1], Liang Chen[1], Tongyu Lu[1], Yang Yang[1], Jia Yao[1]. *[1]Organ transplantation institution, Department of Hepatic Surgery and Liver Transplantation Center of the Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*
Email: yaojia6@mail.sysu.edu.cn

Background and Aims: Metabolic alterations are responsible for the activation of hepatic stellate cells (HSCs), which leads to liver fibrosis. PGC-1α, the central regulator of oxidative phosphorylation (OXPHOS) and lipogenesis, is closely related to cell fate. We aim to explore the mechanisms underlying therapeutic potentials of PGC-1α signaling in *mdr2* knockout-induced liver fibrosis model.
Method: Immunohistochemical staining and q-PCR analysis were performed to identify the expression of glucose and lipid metabolic genes, as well as PGC-1α in liver samples of patients with cirrhosis and $mdr2^{-/-}$ mice. Myofibroblasts were isolated from fibrotic liver tissues and administrated with PGC-1α vectors or PGC-1α activator, ZLN005, to determine the anti-fibrotic effects and the switch of glucose and lipid metabolism by measurement of glucose uptake ability, oxygen consumption rate, lactate accumulation and lipid staining, as well as expression of key metabolic enzymes. Moreover, $mdr2^{-/-}$ mice developed liver fibrosis spontaneously were administrated with ZLN005 to explore the therapeutic effects.
Results: PGC-1α was downregulated in fibrotic regions compared with normal liver tissues, accompanied with the increasing expression of glycolytic and fatty acid oxidation (FAO) enzymes. Furthermore, transfection of PGC-1α vectors or ZLN005 could reverse the fibrotic phenotype of myofibroblasts and promote the switch of glucose metabolism from glycolysis to OXPHOS and lipid metabolism from FAO to lipogenesis. Mechanically, PGC-1α overexpression increased NAD+/NADH ratio, subsequently activated sirtuin1 and deacetylated PGC-1α, which formed positive loop to constitutively activate PGC-1α signaling. In addition, ZLN005 therapeutically alleviated liver fibrosis in $mdr2^{-/-}$ mice models by modulating metabolic pathways.
Conclusion: This study demonstrated a two-arm mechanism on metabolic regulation by which PGC-1α accelerated fibrosis resolution. PGC-1α activator ZLN005 might be considered as a potential anti-fibrotic treatment.

Prevalence of significant hepatic fibrosis using magnetic resonance elastography in a health check-up clinic population

Kyung A Kang[1], Dae Won Jun[2], Joo Hyun Sohn[3], Jihyun An[3], Eileen Yoon[4], Jaeyoon Jeong[5], Sang Bong Ahn[6], Hyo Young Lee[6], Jinhwa Park[2], Yong Kyun Cho[7], Bo-Kyeong Kang[8], Mi Mi Kim[8]. *[1]Gangbuk Samsung Hospital, Radiology, Seoul, Korea, Rep. of South; [2]Hanyang university hospital, Internal Medicine, Seoul, Korea, Rep. of South; [3]Hanyang University Guri Hospital, Internal Medicine, Gyeonggi-do, Korea, Rep. of South; [4]Sanggye Paik Hospital, Inje University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of South; [5]National Medical Center, Internal Medicine, Seoul, Korea, Rep. of South; [6]Eulji Medical College Hospital., Internal Medicine, Seoul, Korea, Rep. of South; [7]Gangbuk Samsung Hospital, Internal Medicine, Seoul, Korea, Rep. of South; [8]Hanyang University Hospital, Radiology, Seoul, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and Aims: Significant hepatic fibrosis is associated with higher mortality. However, data on the prevalence of liver fibrosis in the general population are scarce, owing to the fact that liver biopsy is neither feasible nor ethical in the community setting. Using magnetic resonance elastography (MRE), we investigated the prevalence of significant fibrosis in a community-based cohort.
Method: We enrolled 2,170 participants at our health check-up clinic between 1/2015 to 5/2018, all of whom had MR with chemical shift technique and MRE. The primary study objective was the prevalence of liver fibrosis defined as F2 or F3 by MRE. For generalization, sex- and age-standardized prevalence estimates were calculated based on the Korean Statistical Information Service (KOSIS) in 2015–2018.
Results: The prevalence of F2 (≥3.0 kPa) and F3 fibrosis (≥3.6 kPa) in the overall cohort was 5.1% and 1.3%, respectively (sex-and age-adjusted prevalence of 3.8% and 1.3%). NAFLD prevalence (>5% fat fraction) was 20.8% in the average risk population (after excluding alcohol use and viral hepatitis), and the prevalence of significant and advanced fibrosis in NAFLD participants was 7.5% and 1.1%, respectively. The prevalence of DM was 7.7% in the overall cohort, with significant fibrosis in 13.7% and advanced fibrosis in 4.8%. In participants with fatty liver (of any etiology) plus diabetes, 27.5% had ≥F2 and 7.2% ≥F3. Multivariate analyses indicated that older age, lower platelet count, higher AST/ALT ratio, diabetes, and fatty liver were independently associated with significant fibrosis.

Table: Factors associated with significant hepatic fibrosis (≥F2, 3.0 kPa) using MRE (N = 2,170)

	Univariate		Multivariate	
	OR	95% CI	OR	95% CI
Male (%)	2.15	1.15–4.06	2.05	0.85–4.95
Age (years)	1.05	1.02–1.07	1.04	1.02–1.07
BMI (kg/m2)	1.08	1.02–1.15	0.95	0.82–1.09
Waist (cm)	1.03	1.01–1.06		
Platelet (10^9/L)	0.99	0.99–1.00	0.99	0.99–1.00
AST/ALT	1.03	0.60–1.77		
Triglycerides (mg/dL)	1.00	0.99–1.00		
Total cholesterol (mg/dL)	1.00	0.99–1.01		
HDL-cholesterol (mg/dL)	1.00	1.00–1.01		
LDL-cholesterol (mg/dL)	1.00	1.00–1.01		
Fat mass (kg)	1.04	1.01–1.07	1.03	0.96–1.11
Muscle mass (kg)	1.01	0.99–1.04		
ASM (kg)/height(m)2	1.17	1.00–1.37	1.07	0.85–1.36
Glucose (mg/dL)	1.02	1.01–1.03		
Insulin (μUmL)	1.08	1.05–1.11	1.07	1.03–1.12
Diabetes	3.49	2.14–5.70	2.83	1.67–4.81
Hypertension	1.52	1.03–2.26	1.07	0.69–1.66
Fatty liver on MR	2.46	1.67–3.62	1.77	1.12–2.80

Conclusion: In a health check-up clinic setting, the prevalence of significant and advanced fibrosis was 5.1% and 1.3% in (sex-and age-adjusted prevalence of 3.8% and 1.3%, respectively) and increased three- to four-fold with diabetes.

FRI221

GLI1, but not smoothened-dependent, signaling in hepatic progenitor cells promotes a ductular reaction, which aggravates liver fibrosis

Jiamei Chen[1], Yonghong Hu[1], Jing Fang[1], Long Chen[1], Yongping Mu[1], Wei Liu[1], Ping Liu[1]. [1]*Shuguang Hospital affiliated to Shanghai University of Traditional Chinese Medicine, Institute of liver disease, Shanghai, China*
Email: cjm0102@126.com

Background and Aims: Ductular reaction (DR) is pathologically recognized as bile duct hyperplasia and is commonly observed in various liver disorders. It is still unclear, however, whether DR promotes liver fibrosis via elevated bile duct mass and cholangiocyte activation, or DR protects the liver during injury by enhancing liver regeneration. We studied detailed mechanisms and the functional roles of DR in liver fibrosis.
Method: Liver samples of 144 chronic hepatitis B patients were obtained from biopsy. Masson staining and cytokeratin19 immunostaining were performed to observe the collagen deposition and ductular reaction. Fibrosis was induced in rats via two kinds methods, including carbon tetrachloride combined with 2-acetylaminofluorine and bile duct ligation *in vivo*. Meanwhile, GANT61, a Gli1 inhibitor was intraperitoneal injected to investigate the therapeutic efficacy on DR and liver fibrosis progression. *In vitro* hepatic progenitor cells (HPCs) were treated with sodium butyrate to provide direct evidence for differentiation towards cholangiocytes, meanwhile with or without GANT61, small interfering RNAs against Gli1 (siRNA-Gli1) or lentivirus vector overexpressing Gli1 (LV-Gli1).
Results: The results of patients' sample showed that DR was notably enhanced with the severity of liver fibrosis and closely correlated with collagen deposition. The results in both models *in vivo* showed that a large number of hepatic progenitor cells were activated and proliferated, and differentiated to cholangiocytes (DR) to promote the fibrosis progression, and upregulation of Gli1 was observed during a DR. While inhibiting the Gli1 expression suppressed DR and fibrosis progression. *In vitro*, we found that Gli1, but not Smoothened-dependent signaling was activated during differentiation of HPCs into fibrogenic cholangiocytes. And Gli1 knock-down can directly inhibit this process.
Conclusion: DR plays a key role in pathogenesis of aggravating liver fibrosis. Gli1, but not Smoothened-dependent, signaling directs differentiation of HPCs to fibrogenic cholangiocytes and promotes liver fibrosis progression suggesting that DR and Gli1 may be potential targets to treat liver fibrosis.

FRI222

Enigma proteins control YAP1 related mechano-transduction in hepatic stellate cells

Dina Abdelmottaleb[1], Karen Piper Hanley[2], James Pritchett[1]. [1]*Centre for Bioscience, Department of Life Science, Manchester, United Kingdom;* [2]*Faculty of Biology, Medicine & Health, Wellcome Centre for Cell-Matrix Research, Manchester, United Kingdom*
Email: d.abdelmottaleb@mmu.ac.uk

Background and Aims: Liver fibrosis is defined by dysregulated extracellular matrix (ECM) deposition by hepatic stellate cells (HSCs). In response to liver injury HSCs adopt an activated proliferative, migratory, and contractile myofibroblast phenotype. Increases in organ stiffness occur rapidly after liver injury[1 2], and are necessary for HSC activation. Mechano-transduction caused by the stiffened fibrotic ECM then drives further activation of HSCs. Yes Associated Protein (YAP) 1 is a key mechano-regulator of HSC activation and fibrotic gene expression[3]. It remains unclear how mechanical force from outside the cell triggers the nuclear translocation of YAP1, allowing YAP1 to drive fibrotic gene expression. We propose that mechano-activation of YAP1 in HSCs is regulated by the enigma protein family members PDLIM5 and PDLIM7[4].
Method: Human liver tissue was from the Manchester Biobank (ethical approval NW1260/22). Primary human or mouse HSCs were isolated using standard liver perfusion, digestion and density gradient centrifugation. Enigma family gene and protein expression was characterized in immortalized human HSCs (LX-2 cells) and primary HSCs by qPCR, western blot (WB) and immunocytochemistry (ICC). LX-2 s and primary HSCs were grown on hyrdrogel substrates of varying stiffness to model mechanical ECM changes. LX-2 cells were transfected with plasmids expressing flag tagged PDLIM5 or 7 for immunoprecipitation experiments. siRNA was used to disrupt Enigma protein expression in LX-2 cells and verified by qPCR, western blot and ICC.
Results: PDLIM5 and 7 expression was confirmed by PCR, western blot and ICC in LX-2 cells and primary HSCs. Lx-2 cells and primary HSCs grown on soft substrates had altered Enigma protein and YAP1 localization. Stimulation of LX2 cells with TGFβ (2 ng/ml) for 24 hrs significantly increased expression of PDLIM5 and PDLIM7. Immunoprecipitation experiments show that enigma proteins physically interact with YAP1 in LX-2 cells. siRNA knock down of *PDLIM5* or *PDLIM7* reduced the expression of fibrotic genes including *Acta2*, and was accompanied by increased cytoplasmic localization of YAP1.
Conclusion: The current study reveals a new mechanism for YAP1 activation in HSCs. The Enigma proteins PDLIM5 and PDLIM7 are expressed in LX-2 cells and culture activated primary human HSCs. Knockdown of Enigma protein expression reduced fibrotic gene expression and YAP1 activation. Understanding hippo independent mechanisms of YAP1 activation in HSCs may reveal novel targets for urgently needed anti-fibrotics.

Growth differentiation factor 11 attenuates liver fibrosis via expansion of liver progenitor cells

Zhen Dai[1], Guangqi Song[1,2], Asha Balakrishnan[1], Taihua Yang[1], Qinggong Yuan[1], Selina Möbus[1], Carina Weiss[3], Martin Bentler[4], Heike Bantel[1], Elmar Jaeckel[1], Andreas Kispert[3], Arndt Vogel[1], Anna Saborowski[1], Hildegard Büning[4], Michael P. Manns[1], Tobias Cantz[1], Michael Ott[1], Amar Deep Sharma[3]. *[1]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Zhongshan Hospital of Fudan University, Department of Gastroenterology, Shanghai, China; [3]Hannover Medical School, Institute for Molecular Biology, Hannover, Germany; [4]Hannover Medical School, Institute of Experimental Hematology, Hannover, Germany*
Email: sharma.amar@mh-hannover.de

Background and Aims: Liver fibrosis and cirrhosis resulting from long-standing liver damage represent a major health care burden worldwide. Members of the transforming growth factor β (TGF-β) family have been shown to play a pivotal role in fibrogenesis of the liver as well as multiple other organs. Growth differentiation factor (GDF) 11, a member of TGF-β family, has been recently investigated for its role in the rejuvenation of aging organs. However, the function of GDF11 in liver fibrosis has remained elusive. Here, we investigated the expression and function of GDF11 in chronic liver disease.
Method: We analyzed the expression of GDF11 in patients with liver fibrosis, in a mouse model of liver fibrosis and in hepatic stellate cells (HSCs) as well as in other liver cell types. The functional relevance of GDF11 in toxin- and cholestasis-induced mouse models of liver fibrosis was examined by *in vivo* modulation of *Gdf11* expression using adeno-associated virus (AAV) vectors. The effect of GDF11 on leucine-rich repeat-containing G-protein coupled receptor 5 (LGR5)+ liver progenitor cells was studied in mouse and human liver organoids culture. Furthermore, *in vivo* depletion of LGR5+ cells was induced by injecting AAV vectors expressing diptheria toxin A under the transcriptional control of *Lgr5* promoter.

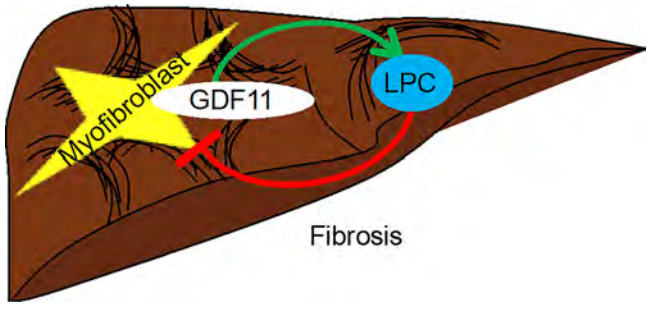

Figure: The expression of GDF11, mainly secreted by myofibroblasts, is enhanced upon chronic liver injury. The overexpression of GDF11 in injured liver promotes expansion of LGR5+ liver progenitor cells, which in turn attenuate liver fibrosis.

Results: We show that expression of GDF11 is upregulated in patients with liver fibrosis and in experimentally induced murine liver fibrosis models. Furthermore, we found that therapeutic application of GDF11 mounts a protective response against fibrosis by increasing the number of LGR5+ progenitor cells in the liver.
Conclusion: Collectively, our findings uncover a protective role of GDF11 during liver fibrosis and suggest a potential application of GDF11 for the treatment of chronic liver disease.

FRI224

The IL-17a and IL-22 cytokines like triggers of human liver fibrosis

Daria Kartasheva-Ebertz[1,2], Jesintha Gaston[1,2], Massault Pierre-Philippe[3], Gaujoux Sebastien[3], Olivier Scatton[4], Jean-Christophe Vaillant[4], Vladimir A. Morozov[5], Stanislas Pol[1,2,6], Sylvie Lagaye[2]. *[1]universite de Paris, Paris, France; [2]Institut Pasteur, INSERM U1223, Immunobiologie des Cellules Dendritiques, Paris, France; [3]AP-HP, Groupe Hospitalier Cochin, Service de Chirurgie digestive, Hépato-biliaire et Endocrinienne, Paris, France; [4]APHP, Groupe Hospitalier La Pitié-Salpétrière, Service de Chirurgie digestive et Hépato bilio pancréatique, Paris, France; [5]Robert Koch Institute, Berlin, Germany; [6]APHP, Groupe Hospitalier Cochin, Département d'Hépatologie, Paris, France*
Email: DARIA.KARTASHEVA@PASTEUR.FR

Background and Aims: IL-17A and IL-22 are both related to liver fibrosis. Their role is dual, depending on the type of the model that was used. IL-17A is considered to be a profibrotic cytokine while IL-22 shows anti-fibrotic properties in the mice models of acute liver diseases. Here, we analyzed IL-17A and IL-22 secretion in human liver tissue samples of different fibrotic stages, as well as their influence on fibrotic markers expression in the model of human liver slices culture.
Method: Human fibrotic liver samples (F0-F4 fibrosis stage) were collected after liver resection. Human precision-cut liver slices of 350 µm were stimulated with different cytokines (IL-17A, IL-22, TGF-beta) for 48 hours, fibrotic markers (alfa-SMA, MMP-2, MMP-9, TIMP-1) were assessed by western blotting and Elisa. **I**ntrahepatic liver infiltrating immune cells was extracted from post-surgery liver samples, stimulated and analyzed by flow cytometry. Thirty human liver samples after liver resection were analyzed for IL-17A, IL-22, TGF-beta expression.
Results: Here, we report an unexpected raise of IL-17A and IL-22 cytokine concentration in human liver tissue samples (F0-F1, F2) compared to advanced fibrosis (F3-F4), as well as their significant correlation. On the other side, the TGF-beta secretion was higher in advanced fibrotic stages. Liver infiltrating $CD3^+CD4^+$ lymphocytes and MAIT cells were the principal source of IL-17A and IL-22 among lymphoid cells. We identified much stronger secretion of INF-gamma in the liver tissue compared with blood samples of the same patient. In addition, the liver tissue from mild fibrotic samples had significantly greater infiltration by the $CD45^+CD3^+$TCRValfa7.2 cells than the liver samples with advanced fibrotic stages. In the second time, we stimulated human liver slices culture by IL-17A, IL-22 or TGF-beta. We observed that IL-17A promotes IL-6 production in the liver, as well as MMP-2, MMP-9 and TIMP-1 production. However, IL-22 didn't induce MMP-9 and TIMP-1 expression during 48 h of stimulation neither alone nor in presence of TGF-beta. IL-17A and IL-22 both were capable to stimulate alfa-SMA synthesis, the principal marker of stellate cells activation contributing either to liver regeneration or to liver fibrosis.
Conclusion: The strong expression of IL-17A and IL-22 in earliest fibrotic stages as well as the increased expression of fibrotic markers should highlight the importance of these cytokines to trigger human liver fibrosis.

FRI225

Fib-4 score for assessment of liver fibrosis is useful in general practice

Denis Ouzan[1], Mosnier Anne[2], Guillaume Penaranda[3], Daviaud Isabelle[2], Françoise Barat[2], Joly Helene[1], Monelle Muntlak[4], Cohen Jean Marie[2]. *[1]Institut Arnault Tzanck, Saint-Laurent-du-Var, France; [2]OpenRome, Paris, France; [3]Laboratoire Alphabio, Marseillz, France; [4]Blanc Vif, Paris, France*
Email: denis.ouzan@wanadoo.fr

Background and Aims: Chronic liver inflammation, mainly due to non-alcoholic fatty liver disease (NAFLD), leads to fibrosis which may progress to cirrhosis and cancer. Early detection of hepatic fibrosis is a challenge and should be performed by general practitioners (GP). The

FIB-4 score is a non-invasive fibrosis scoring test based on routine laboratory parameters and have been shown to rule in/rule out significant fibrosis (1).

Objectives: 1) Measure by FIB4 score the prevalence of significant liver fibrosis in adults consulting a GP; 2) compare this tests to others APRI, NAFLD Fibrosis Score (NFS), Fibrometer V3G; 3) explore the prevalence of main risk factors (obesity, diabetes, alcohol consumption, hypertension) and their link with fibrosis scores; 4) describe the causes of liver disease.

Method: Over a 6-month period, from 10/01/2018 to 03/31/2019, 40 GPs from the French Alpes Maritimes area offered all their 45 to 79-year-old primary care patients, without known liver pathology and outside emergency, liver fibrosis screen via simple blood test allowing calculation of the non-invasive fibrosis scores. New thresholds for FIB4 and NAFLD fibrosis score were used in patients aged >65 years (2).

Results: Among the 2121 patients included (sex ratio M/F 0.61, mean age 62 years), 54% had a BMI>25 kg/m², 13% alcohol consumption >100 g/week, 10% diabetes and 29% hypertension. Increased ASAT rate was found in 6.8%, ALAT in 6.1% and GGT in 15% of cases. The prevalence of significant hepatic fibrosis defined as a FIB4≥1.3 (for <65year) and ≥2 (for >65 years) was 19.1% [95%CI 17, 5–20.9%]. By comparison, prevalence was at 0.28% [0.09–0.65%] by the APRI test, 16.8% [15.0–18.5%] by the NFS score defined as NAFLD ≥−1.455 (for <65 years) and ≥0.12 (for ≥65 years), and 8.2% [6.9–9.6%] by the Fibrometer V3G. Significant correlation was found between the positivity of FIB4, NFS, Fibrometer V3G and hepatic risk factors (obesity, diabetes, alcohol). Among the 406 patients with significant FIB4 score, GPs defined the cause of liver damage in 65% of cases: NAFLD 97, alcohol 48, both 24, other 24 cases. Specialized advice was requested for 65/406 patients. At the time of writing this abstract, 62/65 patients had interpretable hepatic stiffness measurements: 13 (21%) had an elasticity score >7 Kpa with a fibrosis stage F2 for 9, F3 for 2 and F4 for 2. An hepatic risk factor was found in all patients with elasticity >7 Kpa and in only 42% of patients with elasticity <7 KPa ($p < 0.05$).

Conclusion: Liver fibrosis was suspected by FIB4 score in 19.1% patients without known hepatic pathology, who consulted a GP. A liver stiffness >7 KPa was found in 21% of the FIB4 identified patients. The detection of significant fibrosis by a simple blood test allowed the GP to recognize a chronic liver disease and to define its cause in 2/3 of cases.

Analysis of PNPLA3 SNP variants in human hepatic stellate cells in 3D human liver extracellular matrix scaffolds reveals key PNPLA3-dependent pro-fibrogenic features

Elisabetta Caon[1], Ana Levi[1], Dong Xia[2], Leo Ghemtio[3], Kessarin Thanapirom[1], Walid Al-Akkad[1], Giuseppe Mazza[1], Massimo Pinzani[1], Krista Rombouts[1]. *[1]University College London, Regenerative Medicine and Fibrosis Group, Institute for Liver and Digestive Health, London, United Kingdom; [2]Royal Veterinary College – Camden Campus, Comparative Biomedical Sciences, Royal Veterinary College, London, United Kingdom; [3]University of Helsinki, Drug Research Program, Division of Pharmaceutical Biosciences, Faculty of Pharmacy, Helsinki, Finland*
Email: k.rombouts@ucl.ac.uk

Background and Aims: The I148M variant of the Patatin-like phospholipase domain-containing 3 (PNPLA3) protein is the most robustly validated risk locus for the fibrogenic progression of chronic liver diseases. This study aimed to investigate a comprehensive genetic background of primary human Hepatic Stellate Cells (hHSC) genotyped for I148M PNPLA3 variants and its impact on hHSC profibrogenic behaviour.

Method: Primary hHSC were isolated (n = 23 donors) and cultured in 2D, then genotyped for PNPLA3(I148M) variants CG/GG. RNAseq data was analysed on 3 donors/genotype with Ingenuity pathway analysis (IPA). Cell behaviour of PNPLA3(WT) hHSC and PNPLA3(I148M) hHSC was evaluated in 3D decellularized scaffolds from human healthy and cirrhotic liver. Cells were cultured for 13 days and stimulated 3 × 48 h with TGFbeta1. QRT-PCR and RT Profiler array for human ECM and adhesion molecules was performed.

Results: IPA linked PNPLA3(I148M) hHSC variant to pathways related to cancer, gastrointestinal diseases and connective tissue disorders including "caveolar-mediated endocytosis," "triacylglycerol biosynthesis" and "corticotropin releasing hormone signalling." Comparing PNPLA3(I148M/CG) to PNPLA3(WT), the top dysregulated upstream effector was the oxidative stress-related kinase GSK3. A possible derangement of intracellular anti-oxidant response was also suggested by QPCR on 3D cultured hHSC, with decreased or absent expression of VARS2, a mitochondrial enzyme, GSTT1, a Glutathione-S-Transferase and CLEC3B (GSK3 downstream pathway) in PNPLA3 (I148M) hHSC compared to PNPLA3(WT) hHSC with/without TGFB1 treatment. RT profiler of 84 genes related to ECM and adhesion molecules showed an increased activation of PNPLA3(I148M) hHSC compared to PNPLA3(WT). Striking differences in the expression of integrin subsets, MMPs and ECM components was found comparing PNPLA3(148M) to PNPLA3(WT) hHSC cultured on healthy scaffolds, highlighting a more aggressive pro-fibrogenic phenotype of HSC carrying the mutation. The differences were more pronounced in hHSC cultured in cirrhotic scaffolds or stimulated with TGFB1.

Conclusion: This is the first study dissecting at the cellular level the profibrogenic mechanisms associated to PNPLA3 variants in hHSC employing an innovative 3D culture system recapitulating the ECM microenvironment of normal and cirrhotic human liver. The results indicate that hHSC carrying variants of PNPLA3(I148M) have a more aggressive profibrogenic phenotype also in reason of a dysregulated oxidative stress response.

Email: felix.hempel@med.jlug.de

Background and Aims: Bone marrow-derived fibrocytes, defined as spindle-shaped, $CD45^+/Col1^+$ cells, have been implicated in the pathogenesis of fibrotic diseases of the kidney, lung, heart, and liver. Previous studies demonstrated the specific proliferation and infiltration of fibrocytes into the injured liver. However, prior investigations were limited to cell culture or fate-tracing approaches. We aimed to establish a specific depletion of fibrocytes in a murine model to study their contribution to chronic-toxic liver fibrosis.

Method: Transgene C57BL/6 mice expressing a herpes simplex virus thymidine kinase (HSV-TK) under the control of a collagen type I promotor were generated. Bone marrow of transgene mice was transplanted into lethally irradiated wild type mice of the same

genetic background (n = 16 per group, controls received wild type bone marrow). After 4 weeks of reconstitution, thioacetamide (TAA, 300 mg/l) and valganciclovir (8.3 mg/l) were administered via drinking water for 18 weeks. Mice were sacrificed and RNA *in situ* hybridization was applied. Fibrocytes were identified in liver sections by the simultaneous expression of *Ptprc* (CD45) and *Col1a1* (collagen type I alpha chain) mRNA transcripts. Hepatic hydroxyproline content and serum alanine aminotransferase (ALT) levels were measured.

Results: RNA *in situ* hybridization visualized fibrocytes in mice which received wild type bone marrow. The transplantation of transgene bone marrow lead to a marked reduction of fibrocytes. The treatment was well tolerated presenting no signs of unwanted side effects. Mice of both groups gained weight steadily, liver histology showed a marked perilobular fibrosis comparable to preceding experiments involving TAA-induced liver fibrosis. Immunohistochemical stainings of CD68, F4/80, Ly6G, and myeloperoxidase demonstrated an unchanged pattern of distinct leucocytes in the liver. The expression of alpha-SMA^{+} myofibroblasts was unaffected by the fibrocytes depletion, indicated by western blot, RT-qPCR and immunohistochemistry, too. Both hepatic hydroxyproline content (381 vs. 413 µg/g liver; p = 0.033) and serum ALT levels (89 vs. 115 U/l; p = 0.049) were significantly reduced in consequence of the fibrocyte ablation.

Conclusion: The HSV-TK/Valganciclovir model allows for a specific depletion of bone marrow-derived fibrocytes, enabling new approaches to study this unique cell type. Our results, indicating an attenuation of fibrogenesis, emphasize the need to elaborate the biology of fibrocytes in liver fibrosis.

FRI228

Factors predicting liver histological changes under long-term follow-up chronic hepatitis C patients treated with pegylated-interferon-alpha plus ribavirin

Jung-Ta Kao[1], Ming-Han Hsieh[2]. [1]*Division of Hepato-Gastroenterology, Department of Internal Medicine, Taichung, Taiwan;* [2]*China Medical University, Taichung City, Taiwan*
Email: garrydarkao@gmail.com

Background and Aims: The study aims to evaluate whether sustained viral response (SVR) and other factors predict liver histological changes under long-term follow up in chronic hepatitis C (CHC) patients receiving pegylated interferon (pegIFN)-alpha and ribavirin.

Method: From December 2005 to February 2017 at our hospital, 102 non-previously treated CHC patients were prospectively enrolled to receive pegIFN-alpha plus ribavirin and undergo long-term follow-up thereafter. To assess hepatic histological status, all patients received liver biopsy at treatment initiation and were invited to undergo second biopsy at the end of follow up.

Results: Only 18 patients failed to receive follow-up biopsy. In patients receiving paired biopsies (n = 84), mean duration between biopsies is 6.71 ± 1.43 years. SVR does not predict fibrosis regression [odds ratio (OR) = 1.606, p = 0.335] or stabilization (OR = 1.266, p = 0.627) in univariate analysis and insignificantly correlates with fibrosis progression (OR = 0.664, p = 0.653) in multivariate analysis. Conversely, pretreatment fibrosis stage ≥2 (F ≥ 2) independently predicts fibrosis regression (OR = 5.135, p = 0.005) and correlates with fibrosis stabilization (OR = 0.191, p = 0.003). Besides, decreased or permanently absent necroinflammatory activity (defined as activity response) is independently associated with fibrosis progression (OR = 0.068, p = 0.003). As for predictors of activity response, baseline glucose ≤ 105 mg/dL is the only factor showing significance in multivariate analysis (OR = 9.525, p = 0.022).

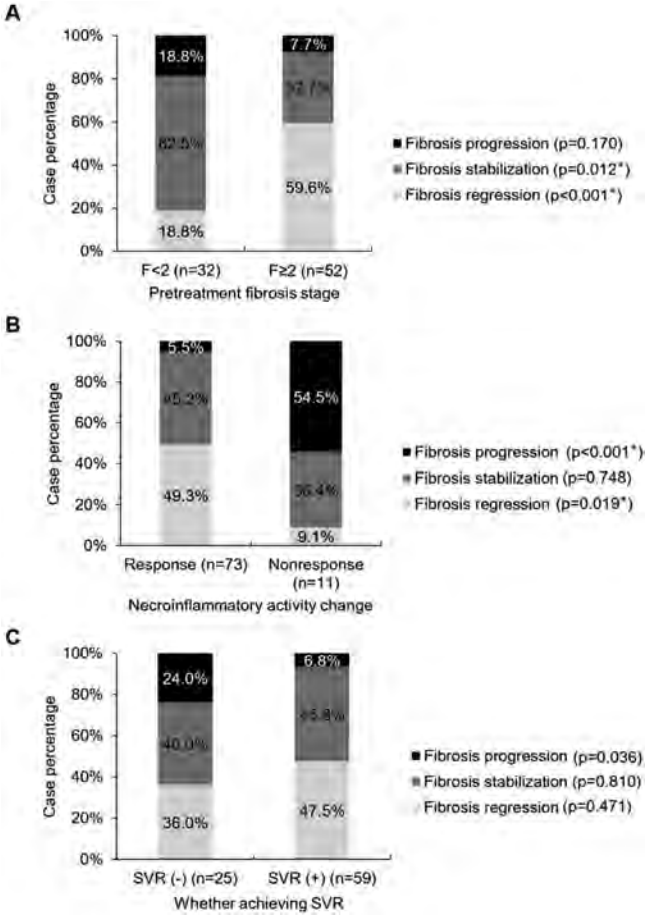

Figure: Percentage of cases presenting different fibrosis changes in hepatitis C patients (n = 84) divided by (A) pretreatment fibrosis stage (B) necroinflammatory activity change (C) whether achieving SVR.

Conclusion: Rather than SVR, pretreatment F ≥ 2 and activity response independently predict fibrosis changes under long-term follow up in CHC patients receiving pegIFN-alpha plus ribavirin. To achieve activity response, lowering serum glucose level before treatment is an effective method.

TGF-beta3 plays a prominent role in murine parenchymal liver fibrosis

Hiroyuki Abe[1,2], Yong Ook Kim[1], Kyoung-Sook Park[1], MariaCristina Giardino[1], Shuji Terai[2], Detlef Schuppan[1,3]. [1]*University Medical Center of the Johannes Gutenberg University Mainz, Institute of Translational Immunology, Research Center for Immune Therapy, Mainz, Germany;* [2]*Graduate School of Medical and Dental Sciences, Niigata University, Division of Gastroenterology and Hepatology, Niigata, Japan;* [3]*Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Gastroenterology, Boston, United States*
Email: detlef.schuppan@unimedizin-mainz.de

Background and Aims: TGF-beta1 is considered the central profibrogenic cytokine that drives hepatic stellate cell/myofibroblast (HSC) activation in liver fibrosis. Less is known about TGF-beta2, and at best some controversial data exist on TGF-beta3. We therefore aimed to assess the profibrotic vs potential antifibrotic effect of TGF-beta3 in vitro and in vivo, with comparisons between TGF-beta1, TGF-beta2 and TGF-beta3.

Method: In vitro, recombinant TGF-beta1, TGF-beta2 and TGF-beta3 were added to murine 3T3 fibroblasts and human LX-2 HSC, followed by qPCR for major fibrosis-related transcripts (col1a1, acta2, pai1, timp1, pdgfb, mmp13, alk1, alk5, smad1/2/3/5/7/8, id2, bglyc, endogl,

tgfbr2). In vivo, C57BL/6 mice were treated with escalating doses of CCl4 for 6 weeks. Other groups were allowed to spontaneously regress for 1 or 4 weeks after 6 weeks of CCl4. Liver fibrosis was assessed by Sirius Red morphometry and hydroxyproline quantification. The gene expression of fibrosis and inflammation-related genes was assessed by qPCR.

Results: The 3 isoforms of TGF-beta highly significantly upregulated the expression of col1a1 and acta2 in 3T3 fibroblasts and HSC, while smad3 and smad8 as downstream mediators of the Alk5 and Alk1 pathway, respectively, id2, and the transcripts for the TGF-beta type II and III receptors (tgfbr2, bglyc) were equally downregulated. In contrast, smad7 as antagonists of the Alk5 pathway, and profibrogenic pai1 and timp1 (but also mmp13) were highly upregulated by the 3 TGF-beta isoforms. The 3 isoforms of TGF-beta equally (auto) induced TGF-beta1 and TGF-beta3 but not TGF-beta2. Notably, TGF-beta3 enhanced cola1a and acta2 transcription significantly more potently than TGF-beta1. In vivo, after 6 weeks of CCl4, transcript levels of TGF-beta1, TGF-beta2 and TGF-beta3 were upregulated 2.59 ± 0.48, 11.2 ± 2.75, and 13.0 ± 3.92 fold, respectively, reaching normal levels for TGF-beta1 already after 1 week of reversal, but remaining elevated 2–3 fold for TGF-beta2 and TGF-beta3 even after 4 weeks of reversal.

Conclusion: 1. TGF-beta3 is the most highly expressed TGF-beta isoform in murine parenchymal liver fibrosis; 2. TGF-beta3 robustly modulates fibrogenic signaling, mainly through Alk5, and is an equipotent and in some aspects more potent fibrogenic cytokine than TGF-beta1 and TGF-beta2; 3. This qualifies TGF-beta3 as an attractive target for antifibrotic therapies.

FRI231

MUDENG (mu-2 related death-inducing gene) overexpression accelerates liver fibrosis in carbon tetrachloride-induced cirrhosis

Ju-Yeon Cho[1], JungHee Park[1], Ji-Hye Han[1], Seung-Hyun Myung[1], Tae-Hyoung Kim[1], Jung Hee Kim[2], Won Sohn[3], Chan Guk Park[1], Young Dae Kim[1], Man Woo Kim[1]. *[1]Chosun University, Korea, Rep. of South; [2]Sacred Heart Hospital, Hallym University Dongtan, Hwaseong-si, Korea, Rep. of South; [3]Kangbuk Samsung Hospital, Korea, Rep. of South*
Email: intelheal@gmail.com

Background and Aims: Liver fibrosis and its end-stage disease, cirrhosis, are major risk factors for hepatocellular carcinoma. MUDENG (Mu-2 related death-inducing gene, also known as AP5M1) is a gene which encodes a 490 amino acid protein initially reported to be involved in cell death of cytotoxic T cells, in tumor necrosis factor-related apoptosis-inducing ligand (TRAIL)-mediated anti-apoptotic signaling, and in trafficking of membrane vesicles. Recent advances in TRAIL signaling pathway presents a new target to achieve elimination of activated hepatic stellate cells, thereby reversing fibrosis. In this study, we developed a MUDENG transgenic mouse to further evaluate the role of MUDENG in inducing and potentially alleviating liver fibrosis.

Method: Eight 8-weeks-old male MUDENG transgenic mice and eight C57BL/6N male mice were injected with carbon tetrachloride (CCl_4) intraperitoneally twice weekly (40 μl/20–25 g, 50 μl/25–30 g body weight; 1:7 dilution with Olive oil). Livers were harvested at baseline for control and biweekly after intraperitoneal injection of CCl_4. The difference in the percent collagen area at baseline, 2, 4, and 6 weeks of the MUDENG transgenic mice and C57BL/6N mice was evaluated. Opensource software ImageJ (distributed by NIH) was used to calculate the collagen proportionate area of the liver after undergoing picoSirius red staining.

Results: The Ishak fibrosis grade of the MUDENG mice at baseline, week 2, 4, and 6 were 0, 1, 2, and 2, respectively. The Ishak fibrosis grade of the C57BL/6N mice at baseline, week 2, 4, and 6 were 0, 0, 1, and 1, respectively. The collagen proportionate area (CPA) at baseline in MUDENG and C57BL/6N mice were 0.36% and 0.38%, respectively ($p = 0.77$). The CPA at 2 weeks in MUDENG and C57BL/6N mice were 0.91% and 0.67%, respectively ($p = 0.03$). The CPA at 4 weeks in MUDENG and C57BL/6N mice were 2.51% and 1.29%, respectively ($p < 0.001$). The CPA at 6 weeks in MUDENG and C57BL/6N mice were 2.86% and 1.84%, respectively ($p < 0.001$). Greater expression of TGF-β throughout the life span in MUDENG transgenic mice compared to C57BL/6N was noticed.

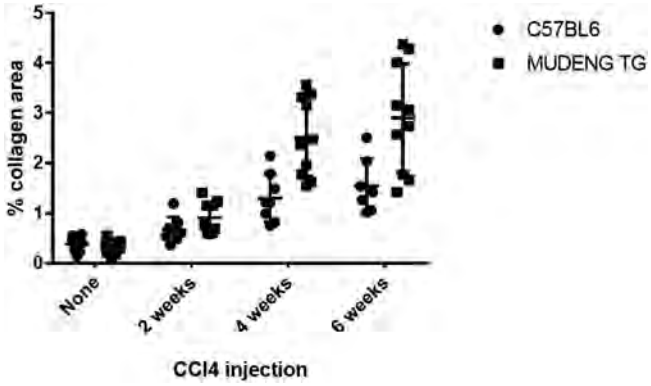

Figure 1: The collagen proportionate area between the MUDENG and C57BL/6N mice is significantly different starting at week 2 after intraperitoneal injection of CCl_4.

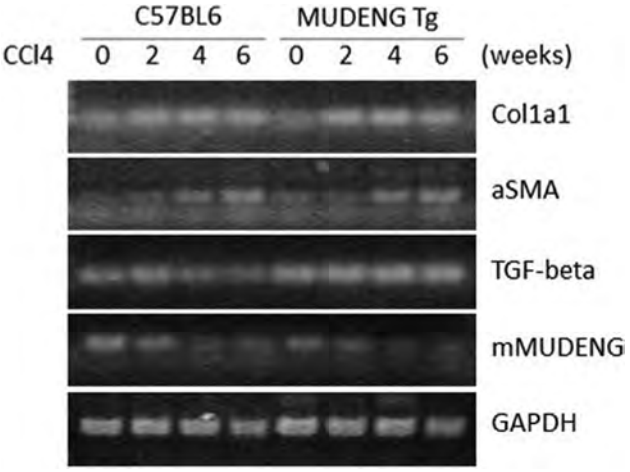

Fig 2. Greater expression of TGF-β throughout the life span in MUDENG transgenic mice compared to C57BL/6N was noticed.

Conclusion: MUDENG transgenic mice demonstrates rapid development of fibrosis compared to C57BL/6N mice. Further studies to evaluate the pathways altered by MUDENG overexpression inducing accelerated liver fibrosis should be done.

FRI232

Thrombofibrosis: inherited thrombophilia as a cause of significant liver fibrosis

Iranzu Ezcurra[1], Jose Ignacio Fortea[1], Angela Puente[1], Antonio Cuadrado[1], Ines García[1], Francisco Jose Gonzalez[2], Raul Pellon[2], Sara Sanchez[2], Juan Crespo[2], Mercedes Acebo[2], Marcos López-Hoyos[3], María del Rocío Pérez Montes[4], Amalia Cuesta[4], Emilio Fabrega[1], Javier Crespo[1]. *[1]Hospital Universitario Marqués de Valdecilla, Gastroenterology and Hepatology Service. IDIVAL, Santander, Spain; [2]Hospital Universitario Marqués de Valdecilla, Radiology Service, Santander, Spain; [3]Hospital Universitario Marqués de Valdecilla, Immunology Service, Santander, Spain; [4]Hospital Universitario Marqués de Valdecilla, Hematology Service, Santander, Spain*
Email: jifortea@gmail.com

Background and Aims: inherited hypercoagulable states can favor the progression of hepatic fibrogenesis in patients with chronic liver

disease of different etiologies and lead to vascular diseases of the liver. Moreover, it has been recently suggested that they are *per se* a cause of significant liver fibrosis. Our aim was to determine the prevalence of significant/advanced fibrosis and hepatic vascular disease in a cohort of patients with inherited thrombophilia.

Method: we performed a unicenter, cross-sectional study. Patients with inherited thrombophilia diagnosed by the Hematology Department between May 2013 and February 2017 were included. A complete laboratory analysis for liver disease, FibroScan® and abdominal ultrasound were performed. The FibroScan® threshold to consider fibrosis as significant was >8 Kpa. In those patients with suspected liver disease, a liver biopsy and/or computed tomography/magnetic resonance imaging were additionally performed according to clinical criteria.

Results: 241 patients with inherited thrombophilia (25.7% had combined thrombophilia) were included. The mean age was 46.2 ± 14.3 years, 61.4% were women and 99.6% Caucasian. The most frequent disorders were Factor V Leiden (36.1%) and Factor II Mutation (35.7%). Thrombotic complications and/or abortion had been experienced by 53.5% of patients. Anticoagulant and antiplatelet therapy had been prescribed in 27.8% (median time (IQR): 11.1 (5.1–35.9) months) and 25,3% (28.8 (13.5–47.9) months) of patients, respectively. Risk factors for liver disease were present in 54.8% of patients, the most important being dyslipidemia (27.4%), obesity (24.9%) and excessive alcohol consumption (10.4%). Eight patients (3.3%) had significant fibrosis, of whom 2 (0.8%) were cirrhotic. These 8 patients had at least one risk factor for liver disease. The only variables associated with the presence of significant fibrosis were a more advanced age (54.5 vs. 45.9 years, $p < 0.001$) and the presence of risk factors for liver disease (100 vs. 53.2%, $p = 0.009$). Regarding vascular disorders of the liver, nine patients (3.7%) had or had had a portal vein thrombosis, without diagnosing any case of Budd-Chiari syndrome or portosinusoidal vascular disease. No variable was associated with the development of non-cirrhotic portal vein thrombosis.

Conclusion: all patients with significant and/or advanced liver fibrosis had risk factors for liver disease and were older. These data do not support inherited thrombophilia as a cause of liver disease. The prevalence of vascular diseases of the liver was low and was not associated with any variable.

FRI234

An improved method for liver fibrosis assessment using magnetic resonance elastography

JunSheng Jaryl Cheng[1], Hsien Min Low[2], Jingkai Joel Liu[2], Cher Heng Tan[2], Kuo Chao Yew[1]. [1]*Tan Tock Seng Hospital, Gastroenterology and Hepatology, Singapore, Singapore;* [2]*Tan Tock Seng Hospital, Diagnostic Radiology, Singapore, Singapore*
Email: jchengjs@gmail.com

Background and Aims: Liver stiffness measurement (LSM) allows indirect measurement of liver fibrosis. Transient elastography (TE) is often selected over magnetic resonance elastography (MRE) due to costs and logistics. However, TE has similar limitations to liver biopsy in accuracy of assessment of general liver stiffness (LS) as each method only measures 1:500 and 1:50000 respectively of the whole liver volume. Hence, the current approach is suboptimal in ruling out significant fibrosis.

Method: This is a retrospective analysis on MRE images of 171 subjects at our hospital between April 2017- March 2019. Four planes of MRE images were selected as per standard protocol and region of interests (ROI) were drawn to measure LS. Blood vessels, bile ducts and areas near to the heart were excluded. Each plane consisted of ROIs selected at 12 different points within the right liver lobe which were arranged into outer, middle and inner bands (4 points within each band). Generalized measurements were also made of the 3 bands. We compared the differences of LS across different bands horizontally and vertically. The differences in LS between the bands and the mean of the 4 points in each corresponding band were also compared.

Results: The most common conditions were non-alcoholic fatty liver disease/steatohepatitis (48%) and chronic hepatitis B (20%). Patient demography was – Age (59 +/– 13), Chinese (83%, N = 141) and Male (64%, N = 109). There was significant difference in LSM between bands of each plane ($p < 0.01$) and vertically especially in the outer region of the right liver lobe.

Table: Differences between measured bands

Plane	Measured Mean		Difference (95% CI)	*p* value
	Band (1–4)	Band (9–12)		
A, Median (IQR)	3.46 (1.85)	2.81 (1.62)		**<0.001**[b]
B, Mean (SD)	3.95 (1.70)	3.39 (1.62)	0.56 (0.46, 0.66)	**<0.001**[a]
C, Mean (SD)	3.84 (1.65)	3.22 (1.43)	0.61 (0.51, 0.72)	**<0.001**[a]
D, Mean (SD)	3.83 (1.70)	3.26 (1.43)	0.58 (0.45, 0.71)	**<0.001**[a]

[a]Paired sample t test;
[b]Wilcoxon signed rank test

Conclusion: Systematic analysis of MRE images demonstrates differences in LS within the right liver lobe both vertically and horizontally. Perhaps TE should not be used as a precise method to exclude significant LS as it only measures the outer 3 cm^3 of the liver. This would underestimate the prevalence of advanced LS. Also, vertical differences of LS could explain TE report variability when LSMs are performed across different liver locations during the same assessment period.

FRI235

Expression of cyclin E1 and CDK2 in hepatic stellate cells is critical for initiation and progression of liver fibrosis in mice

Julia Hennings[1], Anna Hübbers[1], Christian Penners[1], Daniela Lambertz[1], Tobias Otto[1], Christian Trautwein[1], Roland Sonntag[1], Christian Liedtke[1]. [1]*University Hospital RWTH Aachen, Clinic for Gastroenterology, Metabolic Disorders and Internal Intensive Medicine (Medical Clinic III), Aachen, Germany*
Email: jhennings@ukaachen.de

Background and Aims: Liver fibrogenesis is a wound healing process characterized by the accumulation of extracellular collagen produced by Hepatic Stellate Cells (HSCs). Initiation of liver fibrosis involves cell cycle re-entry and thus activation and proliferation of normally quiescent HSCs. It is believed that the cyclin-dependent kinase 2 (Cdk2) together with its regulatory subunit Cyclin E in general controls cell cycle re-entry. We have recently shown that constitutive ablation of Cyclin E1 (CcnE1) in mice inhibited liver fibrogenesis. However, the effector cells of CcnE1 during fibrogenesis are not known so far and it has also not been clarified yet, whether the pro-fibrotic effect of CcnE1 depends on the kinase activity of Cdk2. Thus the aim of the present study was to evaluate the contribution of CcnE1 and Cdk2 specifically in HSCs for liver fibrogenesis.

Methods: We generated HSC-specific knockout mice for CcnE1 ($CcnE1^{\Delta HSC}$) and Cdk2 ($Cdk2^{\Delta HSC}$) by crossing floxed (*i.e.* $CcnE1^{f/f}$/$Cdk2^{f/f}$) mice with transgenic mice expressing cre-recombinase under the control of the L-rat promoter. Liver fibrosis was induced by treating mice with a combination of Diethylnitrosamin (DEN) and CCl_4 or with CCl_4 only according to established protocols. For

pharmacological inhibition of Cdk2 kinase activity the pan-Cdk inhibitor CR8 was applied *in vitro* on HSC cell lines (LX-2, human; GRX, murine) and in primary murine HSCs.
Results: Genetic ablation of Cdk2 specifically in HSCs significantly reduced collagen accumulation and fiber formation in the liver after CCl_4 treatment when compared to cre-negative littermates. Accordingly, $Cdk2^{\Delta HSC}$ mice showed a significantly reduced HSC activation in the liver. Similarly, $CcnE1^{\Delta HSC}$ mice revealed significantly reduced liver fibrosis in comparison to cre-negative littermates after DEN/CCl_4 treatment, which was however not associated with a reduced liver cancer incidence as initially hypothesized. In good agreement with these findings, treatment with CR8 inhibited kinase activity, proliferation, survival and pro-fibrotic activation of HSCs (*i.e.* primary cells and cell lines) *in vitro.*
Conclusion: The pro-fibrotic properties of HSCs depend on functional Cdk2 and CcnE1. This suggests that cell cycle re-activation of naïve HSCs *in vivo* requires functional CcnE1/Cdk2 kinase activity. We conclude that pharmacological inhibition of Cdk2 kinase activity in HSC could be an alternative approach to treat liver fibrosis.

Non-canonical autophagy in myeloid cells constrains hepatic and systemic inflammation and limits fibrosis

JingHong Wan[1,2], Emmanuel Weiss[1,2,3], Sanae Ben Mkadden[1,2], Morgane Mabire[1,2], Pushpa Hegde[1,2], Tristan Thibault-Sogorb[1,2,3], Marcelle Bens[1,2], Hélène Gilgenkrantz[1,2], Richard Moreau[1,2], Loredana Saveanu[1,2], Patrice Codogno[4,5], Renato C Monteiro[1,2], Sophie Lotersztajn[1,2]. *[1]Université de Paris, Laboratoire d'Excellence Inflamex, School of Medicine Bichat, Paris, France; [2]Inserm U1149 CRI, Inflammatory and Stress Responses in Chronic Liver Diseases, Paris, France; [3]Beaujon Hospital, Department of anesthesiology and intensive care, Clichy, France; [4]Inserm U1151 CNRS U8223, Institute Necker-Enfants malades, Paris, France; [5]Université de Paris, Site Necker Enfants-Malades, Paris*
Email: sophie.lotersztajn@inserm.fr

Background and Aims: Sustained hepatic and systemic inflammation, in particular originating from monocytes/macrophages, is a driving force for chronic liver disease progression to cirrhosis. Therefore, reprogramming monocyte/macrophage phenotype has emerged as a strategy to limit inflammation during chronic liver injury. LC3-associated phagocytosis (LAP) is a non-canonical form of autophagy that shifts monocyte/macrophage phenotype to an anti-inflammatory phenotype. This phagocytic process results in the recruitment of some, but not all, members of the autophagic machinery and is functionally and mechanistically distinct from the canonical macroautophagic process. Here, we investigated whether LAP is involved in the regulation of inflammation and fibrosis.
Method: LAPosome number were quantified in blood and liver monocytes from patients with cirrhosis and control subjects following incubation with either pHrodo^{TM} red *E. coli* Bioparticles or IgG latex beads and immunostained with an anti LC3 antibody. FcγRIIA expression and inflammatory profile were evaluated in human monocytes from patients with cirrhosis and healthy donors by flow cytometry. LysMCre $Rubicon^{flox/flox}$ mice (LAP-deficient in myeloid cells), human $FcγRIIA^{Tg}$ mice expressing the human $FcγRIIA^{R131}$ isoform and WT littermates were exposed to chronic carbon tetrachloride (CCl_4) administration or subjected to bile duct ligation (BDL).
Results: Recruitment of LC3 to pHrodo+phagosomes (LAPosomes) was minimal in blood and liver monocytes from healthy donors, and enhanced in cells from patients with cirrhosis, and in mice exposed to chronic administration of CCl_4 or BDL. Pharmacological inhibition of LAP components exacerbated the inflammatory signature in monocytes from patients with cirrhosis. Similarly, LysMCre $Rubicon^{flox/flox}$ mice showed enhanced hepatic inflammatory profile upon chronic exposure to CCl_4 or following BDL, resulting in enhanced liver fibrosis. Mechanistically, cirrhotic patients show increased monocyte expression of FcγRIIA and enhanced engulfment of monomeric IgG in LC3+ phagosomes. In keeping, mice overexpressing human FcγRIIA in myeloid cells show enhanced LAP in response to chronic liver injury, and were resistant to inflammation and liver fibrosis.
Conclusion: These data shed light on a novel role for LC3-associated phagocytosis as an anti-inflammatory pathway in monocytes that constrains both systemic and hepatic inflammation during cirrhosis, with potent antifibrogenic effects driven by monomeric IgG-FcγRIIA.

FRI237

Reduction in types I and III collagen gene expression by an alphavbeta1 integrin inhibitor correlates with a decrease in PRO-C1 and PRO-C3 levels in precision-cut liver tissue slices from cirrhotic non-alcoholic steatohepatitis patients

Johanna Schaub[1], Steve Ho[1], Vikram Rao[1], Megan Marlow[1], Eric Lefebvre[1], Diana Leeming[2], Mette Juul Nielsen[2], Natasja Gudmann[2], Morten Karsdal[2], Scott Turner[1]. *[1]Pliant Therapeutics, South San Francisco, United States; [2]Nordic Bioscience, Herlev, Denmark*
Email: jschaub@pliantrx.com

Background and Aims: The interactions of multiple cell types with the extracellular matrix involved in fibrogenesis is difficult to reproduce in cell cultures, thus translation of antifibrotics to clinical settings remains a challenge. Types I and III collagen are the most prominent fibrillar collagens of the fibrotic matrix produced by fibroblasts. Type III collagen formation, measured by the PRO-C3 neoepitope marker, has been shown to be useful for prognostic, diagnostic, and therapeutic assessment in liver diseases in humans. Integrin $\alpha_V\beta_1$ is a (myo)fibroblast-specific integrin that activates transforming growth factor (TGF)-β, promoting fibrogenesis. Inhibition of $\alpha_V\beta_1$ is antifibrotic in mouse models; however, data in human tissue are limited. The study aims were to use human precision-cut liver tissue slices (PCLivS) to 1) assess fibrogenesis through measurement of types I and III collagen gene expression and pro-peptides released into culture media and 2) evaluate the antifibrotic efficacy of $\alpha_V\beta_1$ inhibition.
Method: PCLivS were obtained from cirrhotic nonalcoholic steatohepatitis (NASH) patient tissue explants and cultured in the presence of a small-molecule, selective, $\alpha_V\beta_1$ inhibitor or a TGF-β receptor kinase (ALK5) inhibitor. After 2 days, tissue was harvested for gene expression analysis and culture medium for biomarker analysis. Gene expression was assessed using the NanoString platform, and biomarkers of types I (PRO-C1) and III (PRO-C3) collagen formation were assessed by enzyme-linked immunosorbent assay (ELISA; Nordic Bioscience).
Results: Treatment of PCLivS from NASH patients with an $\alpha_V\beta_1$ or ALK5 inhibitor reduced expression of pro-fibrogenic genes. *COL1A1* and *COL3A1* gene expression was reduced as was release of PRO-C1 and PRO-C3. There was a significant correlation between relative *COL1A1* and *COL3A1* gene expression and relative PRO-C1 and PRO-C3 biomarker levels.
Conclusion: Using PCLivS from cirrhotic NASH patient livers, a strong correlation was observed between types I and III collagen gene expression and their respective biomarker levels, both were reduced in response to antifibrotic treatment via $\alpha_V\beta_1$ integrin or ALK5 inhibition. Thus, these data confirm the validity of PRO-C1 and PRO-C3 as biomarkers of fibroblast collagen gene expression and, therefore, as suitable translational markers of fibrogenesis in PCLivS assays. Furthermore, the data support the evaluation of an $\alpha_V\beta_1$

integrin inhibitor for the treatment of advanced liver fibrosis associated with NASH.

FRI238

Active role of sphingosine-1-phosphate in promoting peripheral-dominant liver fibrosis in mice model of congestive hepatopathy

Hironari Kawai[1], Yosuke Osawa[1], Yuriko Tsutsui[1], Yuichi Yoshida[1], Taizo Mori[1], Shiori Yoshikawa[1], Taiji Yamazoe[1], Sachiyo Yoshio[1], Tatsuya Kanto[1]. *[1]National Center for Global Health and Medicine, Department of Liver Disease, Ichikawa-shi, Japan*
Email: kantot@hospk.ncgm.go.jp

Background and Aims: Congestive hepatopathy (CH) is an entity of non-viral chronic liver disease that often develops to liver fibrosis and liver cancer. As a prototype of CH, Fontan-associated liver disease (FALD) has been increasing in adults due to longer survival after Fontan procedure. Recently, European cohort study on FALD showed that majority of hepatic nodules were found in peripheral part of the liver, suggesting the close link between peripheral dominance of fibrosis and carcinogenesis. However, the underlying molecular mechanisms of liver fibrosis by CH remain largely undisclosed. Sphingosine-1-phosphate (S1P), mainly synthesized by sphingosine kinase 1 (SphK1), is one of lipid mediators in cellular proliferation or differentiation, thus involving in fibrosis or carcinogenesis. In this study, we sought to clarify the mechanisms of congestion-induced liver fibrosis, by focusing on the impact of S1P on regional fibrosis distribution.
Method: Congestive hepatic fibrosis was induced by partial ligation (0.6 mm) of the suprahepatic inferior vena cava (pIVCL) of C57BL/6J male mice (aged 8–12 weeks). After 6 weeks of the operation, liver fibrosis was evaluated by Sirius red staining and αSMA staining. To assess fibrosis distribution, we performed such quantification in both central (around large vessels) and peripheral (near liver surface) part of the liver. Liver S1P was quantified by liquid chromatography mass spectrometry. The expressions of fibrosis-related and S1P-related genes were evaluated by laser microdissection. To clarify the involvement of S1P in fibrosis, we treated pIVCL mice with antagonists for S1P receptor (S1PR) 1 (Ex26), S1PR2 (JTE013), or S1PR3 (CAY10444), respectively.
Results: After 6 weeks of pIVCL, congestive hepatic fibrosis were significantly induced in the peripheral rather than central part of the liver. Such regional disparities in fibrosis were not observed in other liver fibrosis models (CDD-induced NASH-like model/ CCl4-induced fibrosis model). Vascular extravasation, as a consequence of congestion, was mainly appeared in the peripheral part and tended to colocalize with fibrosis distribution. Liver S1P levels in the pIVCL mice were significantly elevated compared to the control. The expressions of SphK1 and fibrosis related genes were significantly elevated in the peripheral part than that in the central part of the liver. Blockade of S1P/S1PR2 axis by JTE013 alleviated fibrosis in the pIVCL mice, while blockade of S1PR1 and S1PR3 failed to do so.
Conclusion: In mice model of congestive hepatopathy, liver fibrosis accompanied by extravasation is more prominent in the peripheral part of the liver. The activation of SphK1-S1P-S1PR2 axis in this model supports for a possibility that, S1P pathway serves as a therapeutic target for the congestion-induced, peripheral-dominant liver fibrosis, such as FALD.

CRV431 decreases diet- and chemical-driven fibrosis in livers of mice

Joseph Kuo[1], Erika Cabrera[1], Patrick Mayo[2], Daren Ure[2], Robert Foster[2], Philippe Gallay[1]. *[1]The Scripps Research Institute, Immunology & Microbiology, La Jolla, CA, United States; [2]Hepion Pharmaceuticals, Edison, NJ, United States*
Email: gallay@scripps.edu

Background and Aims: Liver fibrosis is the prevalent pathological feature of chronic hepatic injuries. With limited treatment options available for fibrotic patients, identification of novel, effective antifibrotic compounds is crucial. We previously reported that CRV431, a potent pan-cyclophilin inhibitor, decreased collagen deposition in mice administered carbon tetrachloride (CCl_4). Moreover, similar results were observed in mice under high fat diet. Here, we examined whether CRV431 decreases diet- and chemical-induced fibrosis in mice.
Method: Male C57BL/6J mice were nourished with the Western diet that includes chow containing 21.1% fat, 41% sucrose, and 1.25% cholesterol by weight and high sugar solution (23.1 g/L fructose and 18.9 g/L glucose). 0.2 uL/g CCl_4 were administered intraperitoneally once weekly. After 6 weeks, mice (n = 8 to 10 per group) were randomly assigned to receive daily oral gavage with 50 mg/kg CRV431, 10 mg/kg obeticholic acid (OCA, a comparator), combination (COMBO) of CRV431 and OCA, or vehicle for 6 weeks until sacrifice. Negative control mice were included. Body weight and liver weight were recorded. Livers were histologically examined for inflammation, steatosis, and ballooned cells. Collagen was measured by Sirius Red staining of hepatic tissues. Glucose, cholesterol, alanine transaminase (ALT), aspartate transaminase (AST), and alpha fetoprotein (AFP) levels were detected from sera. Two-tailed Bonferroni's multiple comparison statistical analyses, with alpha value set at 0.05, were conducted with GraphPad Prism.
Results: A 65% reduction in hepatic collagen deposition was observed in CRV431 treated mice compared to control animals ($p < 0.0001$). OCA-treated animals demonstrated a 39% reduction in collagen deposition. The COMBO group demonstrated a 67% reduction in collagen deposition. This was not statistically different from CRV431 alone or from negative control with stained collagen. CRV431 and COMBO also lowered body weight compared to vehicle ($p = 0.0129$ and 0.0055, respectively), which was not observed with OCA alone. Glucose, AST, ALT, cholesterol, inflammation, steatosis, and ballooning were unaffected by treatment ($p > 0.05$).
Conclusion: CRV431 is a potent agent against diet- and chemical-driven fibrosis. This result is consistent with our previous findings and suggests that cyclophilin inhibition can protect the liver from induced injuries.

FRI240

Fibrosis progression in NASH: real- world data from the US population

Gabriel Pedra[1], Leonardo Ruiz Casas[1], Harpal Dhillon[1], Jörn M. Schattenberg[2], Manuel Romero Gomez[3]. *[1]HCD Economics, Warrington; [2]University Medical Center Mainz, Metabolic Liver Research Program, I. Department of Medicine, Mainz, Germany; [3]Universidad de Sevilla, Sevilla*
Email: leo.ruiz@hcdeconomics.com

Background and Aims: GAIN is a retrospective and cross-sectional study in which a sample of secondary care physicians (hepatologists, gastroenterologists, endocrinologists and diabetologists) recruited from public and private hospitals and practices provided clinical and resource use information on patients with NASH diagnosis via an online survey.
The aim of this analysis was to study fibrosis progression between clinical diagnosis and date of follow-up for the US patients (n = 1,221).
Method: Descriptive analysis of US patients' characteristics and of the fibrosis progression for patients. Chi squared and odds-ratios were used to test differences in proportions.
Results: Out of 1,221 patients recruited in USA, 52% were male, mean age was 50.9 (10.9), BMI 31.8 (13.2) and most frequent comorbidities were obesity (36.6%) Diabetes (21.1%); Dyslipidaemia (27.4%) and Hypertension (24.8%). Additionally, 3.1% had cardiovascular diseases (CV, including infarction, heart failure and angina). 554 had at least 1 drug prescribed for NASH at the time of the diagnosis. For those who had a NASH treatment, 33.6% were on Statins, 31.8% on Vitamin E, 30% were on Metformin, 12.5% on Omega-3 fatty acids, 9.2% on

Thiazolidinediones, 6.1% on other anti-diabetic medication and 27% other medications.
1,016 patients had measurements of fibrosis stage at both diagnosis and at follow-up, therefore fibrosis progression could only be evaluated for those individuals. Additionally, fibrosis evaluation was performed with biopsy for 54.8% of patients at diagnosis and 30.4% at follow up date, while non-invasive blood tests and imaging techniques where used when biopsy wasn't performed. At diagnosis, 201 (20%) were F0, 293 (29%) F1, 233 (23%) F2, 136 (13%) F3, 126 (12%) F4 Compensated cirrhosis and 27 (3%) F4 Decompensated cirrhosis.
Amongst patients who progressed to next stage or advanced stage (141 patients), 59% had obesity, 57% had either Hypertension, Dyslipidaemia, T2D or cardiovascular diseases. Amongst those who regressed (84 patients) to previous stage or were stable (791 patients), 42% had obesity, 55% had either Hypertension, Dyslipidaemia, T2D or cardiovascular diseases (p = 0.006).
Likelihood of progression is 1.75 times more than regression. Chance of progressing were higher for patients with Obesity (Odds ratio (95% CI) = 2.003 (1.158–3.467)) and CV.
Conclusion: Progression of fibrosis stage in NASH was more likely among obese. Further analysis is granted to understand the role of treatment on disease progression.

FRI241

Nanoparticular bisphosphonate induces an anti-fibrotic response by modulation of fibrosis associated genes and pathways in (non-) parenchymal liver cells in CCl4 fibrotic mice

Leonard Kaps[1,2], Lutz Nuhn[3], Niklas Choteschovsky[1], Friedrich Foerster[1,2], Mustafa Diken[4], Adrian Klefenz[1], Detlef Schuppan[1,5]. *[1]Institute of Translational Immunology, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany; [2]First Department of Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany; [3]Max Planck Institute for Polymer Research, Mainz, Germany; [4]TRON – Translational Oncology, University Medical Center of Johannes Gutenberg University, Obere Zahlbacher Str. 63, Germany; [5]Beth Israel Deaconess Medical Center, Division of Gastroenterology, Boston, United States*
Email: leonardkaps@googlemail.com

Background and Aims: Bisphosphonates, e.g. Alendronate (AL), inhibit osteoclasts, a specialized population of macrophages. AL showed an anti-fibrotic together with an anti-tumor effect via macrophage (re-)polarization in rat hepatocellular carcinoma [Rogers T et. al., J. Transl. Med. 2011]. However, after intravenous application, bisphosphonates are sequestered in bone and rapidly excreted by the kidneys. Therefore, we aimed to develop nontoxic nanohydrogel particles (NHP) with covalently linked Alendronate (AL-NHP) that primarily home to the liver.
Method and Results: Stable AL-NHP with diameters below 100 nm were synthesized by controlled-radical polymerization. In primary murine macrophages, AL-NHP induced no cytotoxic effect compared to free AL (up to 60 µM AL). AL-NHP (30 µM AL) repolarized M2-type macrophages towards anti-fibrotic and anti-tumorous M1-type macrophages, increasing macrophage expression of TNF-a and Interferon-g, as determined on the transcript and protein level via qPCR and FACS analysis. After intravenous (iv) injection in both healthy and CCl_4 liver-fibrotic Balb/c mice, more than 80% of near-infrared fluorescence labeled CS800-AL-NHP rapidly accumulated in the liver, whereas CS800 labeled AL was readily cleared via the kidneys. On the cellular level, CS800-AL-NHP were effectively taken up by liver macrophages (>90%), hepatocytes (>90%) and portal myofibroblasts (>90%) as determined by FACS. CS800-AL-NHP were well tolerated and showed no toxicity. Mice gavaged with escalating doses of CCl_4 over 5 weeks, were treated with iv AL-NHP (1.2 or 2.4 mg/kg AL) thrice weekly from week 4–5, while fibrotic controls received equal concentrations of AL or empty NHP. On sacrifice, liver collagen and alpha-SMA expressing myofibroblasts were significantly reduced to non-fibrotic control levels in AL-NHP treated vs. control mice, as determined by hepatic Sirius Red stained collagen and hydroxyproline content, while free AL and empty NHP were ineffective. Staining for alpha-SMA, and RNA-NGS-sequencing of livers from AL-NHP (2.4 mg/kg) revealed a significant downregulation of numerous fibrosis-related genes, and profibrotic pathways in both macrophages and myofibroblasts/hepatic stellate cells.
Conclusion: We have designed an AL-NHP as a biocompatible nanocarrier for the bisphosphonate Alendronate. In contrast to soluble AL, AL-NHP was almost exclusively sequestered by the liver, and efficiently taken up in all non-macrophages and activated myofibroblasts/hepatic stellate cells. In CCl_4 fibrotic mice, late-onset treatment with AL-NHP reduced liver collagen down to normal levels by beneficial of a broad range of fibrosis-relevant genes and pathways.

FRI242

Microscopy-based fibrosis phenotypic analysis of animal and human NASH cohorts reveal translational traits of fibrosis progression and severity

Li Chen[1], Anthony Azzara[2], Arun Sanyal[3], Mathieu Petitjean[1]. *[1]PharmaNest, Princeton, United States; [2]BMS, Hopewell, United States; [3]Virginia Commonwealth University, Richmond, United States*
Email: li.chen@pharmanest.com

Background and Aims: To date, no single rodent model can display the whole disease spectrum and metabolic features associated with human NASH but can only imitate characteristics. In this study, we focus on the phenotypic traits of fibrosis severity from three rodent fibrosis progression models and an adult human NASH progression cohort. In each model and for each progression stage, we quantify 31 different traits (145 parameters) of the fibrosis phenotypes. We identified the traits of fibrosis severity that are common to all the species.
Method: The rodent models include (1) a Bile Duct Ligation (BDL) fibrosis progression cohort (Sham, Day 5, 10, 14 and 20) (N = 5/grp), (2) a thioacetamide (TAA) induced fibrosis (ctrl, week 4 and 8 (N = 5/grp), and (3) a methionine and choline-deficient (MCD) fat diet (ctrl, week 8 and 12) (n = 4–10/grp). The clinical cohort is comprised of patients with NASH diagnosed by histologic assessment of liver biopsy according to NASH CRN criteria by pathologists (N = 98, F0(24), F1(24), F2(25), F3(20) and F4(5)). Unstained tissue slides were imaged at 20× with a Genesis200® Two- Photon microscopy system. FibroNest©, a novel cloud-based fibrosis image analysis platform, is used to quantify fibrosis phenotypes for the collagen content and structure (12 traits), the morphometric traits (12) of the collagen fibers, and fibrosis texture traits (7). Each trait is described by parameters (qFPs) to account for the mean, variance, and progression. AVenn Diagram is used to summarize the fibrosis progression (PqFP) that are common between animal and human models.
Results: Most of the PqFp identified for the TAA model are texture-based and only the Count of Tortuous fibers was translated to the other rodent models, but not to the NASH human model. The BDL model exhibited 6 PqFPs in common with the NASH model, but only 4 with the MCD model. The MCD model exhibited 3 PqFP in common with the NASH human model, including collagen area, density, and skeleton nodes.
Conclusion: We identified 3 significant fibrosis traits out of 31 that are translational to the BLD, MCD, and Adult NASH phenotypic models: Collagen Area Ratio, Collagen Fiber Density, and the qFPs

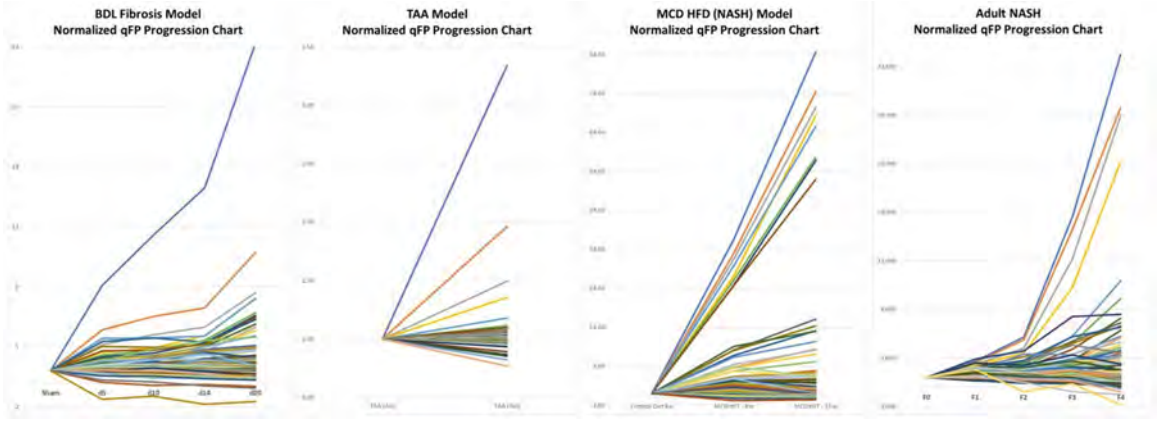

Figure: (abstract: FRI242)

associated with the skeleton of the collagen fibers (Skeleton Length, Skeleton nodes density). This result confirms that the phenotype of fibrosis in each model is fundamentally different. It also has the potential to improve the quality of translational drug discovery and development process and to yield specific biopsy-based diagnostic tools for fibrosis.

FRI243

Fibrosis phenotypic analysis of collagen stained liver histology sections discern anti-fibrotic agents in DDC- induced cholangitis mouse model

Li Chen[1], Richard Chen[2], Liangsu Wang[2], Mathieu Petitjean[1].
[1]*PharmaNest, Princeton, United States;* [2]*Morphic, Waltham, United States*
Email: li.chen@pharmanest.com

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic liver disease caused by progressive inflammation, fibrosis, and strictures of hepatic bile ducts, often leading to biliary cirrhosis. Transforming growth factor beta (TGF-b) and its activation by alpha v beta 6 (avb6) integrin are key players in the pathogenesis and exacerbation of fibrosis. Here, we assess the anti-fibrotic efficacy of SB30 (TGF-b receptor I (ALK5) inhibitor) and 3G9 (anti-avb6) in a chemically induced cholangitis mouse model with a focus on the phenotypic quantification of fibrosis.
Method: Mice (8 wks old, n = 8–10/grp) were fed with 0.1% DDC (3,5 diethoxycarbonyl- 1,4-dihydrocollidine)-diet for 20 days to induce biliary fibrosis and cholestasis. A small molecule ALK5 inhibitor, SB30) (30 mpk, PO, bid), and a blocking antibody against mouse avb6, 3G9 (10 mpk, IP injection, bid) were administered in DDC mice starting at diet initiation. Liver histology sections stained with Picro-Sirius Red were imaged with light microscopy. We developed a novel cloud-based image analysis platform to quantify fibrosis for the collagen content and structure, morphometric trait of each individual collagen fibers, and the fiber texture (relative arrangement of the fibers). Each morphometric and texture trait is described by several quantitative fibrosis parameters (qFPs) to account for mean, variance, and progression. qFPs were combined to generate a Composite Fibrosis Score (CFS), a continuous phenotypic quantifier of fibrosis.
Results: SB30 reduced liver collagen fiber area and fiber network structures (80% and 50%, respectively, compared to DDC-Vehicle), while 3G9 decreased it to a lesser degree (10% and 15%, respectively). The qFPs, reported on heat charts, show highest values for DDC-Vehicle, mid values for SG9, and lowest values for SB30. SB30 is more effective than 3G9 in improving fibrosis area and structure index, qFPs, and Composite Fibrosis Scores (SB30 40% and 3G9 20% reduction compared to DDC- Vehicle).
Conclusion: SB30 has higher anti-fibrotic effects compared to 3G9 in chronic DDC-induced PSC model for improving liver histopathology. These data show that phenotypic fibrosis analysis of collagen from stained histological images is an effective method to describe and quantify the severity and progression of liver fibrosis and may differentiate pharmacological agents.

FRI244

Dietary wheat amylase trypsin inhibitors activate myeloid cell toll-like receptor 4 to enhance chronic liver disease in murine liver fibrosis and hepatocellular carcinoma

Muhammad Ashfaq-Khan[1], Misbah Aslam[1], Marcel Senkowski[1], Yong Ook Kim[1], Detlef Schuppan[1]. [1]*Institute of Translational Immunology and Research Center for Immune Therapy, University Medical Center, Johannes Gutenberg University Mainz, Mainz, Germany*
Email: m.ashfaq_biotech@yahoo.com

Background and Aims: Specific bioactive nutritional components affect the intestinal immune system. The gut-liver axis is increasingly recognized as a central modulator of liver health and disease. We hypothesized that nutritional wheat amylase trypsin inhibitors, compact molecules that resist intestinal proteolysis and that activate intestinal myeloid cells via toll-like receptor 4 (TLR4), may promote murine liver fibrosis and hepatocellular carcinoma (HCC).
Method: The following murine models for liver fibrosis and HCC, respectively, were employed: 1) Male *Mdr2*(Abcb4)–/– mice that develop spontaneous biliary fibrosis resembling human PSC; 2) male *Mdr2*–/– mice were injected intraperitoneally with a single dose of diethyl-nitrosamine (DEN, 10 μg/g of bw at age 5 days old), followed by 0.05% phenobarbital in drinking water starting at the 3 weeks of age. Mice received a well-defined, wheat free and zein (non-inflammatory protein from corn) containing diet with or without 1.5% of the protein being replaced by ATI from age 4–10 weeks (fibrosis model), or from age 1–5 months (HCC model).
Results: 1) *Mdr2*–/– mice fed the ATI-containing diet developed significantly increased hepatic fibrosis (Sirius red staining and hydroxyproline content) and serum transaminases vs the ATI-free controls. Gene expression analysis (*il1b*, *tnfa*, *cd68*, *col1a1*, *asma*, *col3a1*, *mmp13*, *timp1* and *mmp9),* quantitative immunohistochemistry (CD68+macrophages, alpha-SMA+ myofibroblasts and CK19+ cholangiocytes), and FACS analysis (infiltrating inflammatory monocytes-macrophages) confirmed a significantly increased inflammation, ductular proliferation and fibrogenesis in the ATI-fed vs the control mice. 2) ATI feeding of the HCC bearing mice significantly increased tumour burden, and induced higher transcript levels of *vefg, hif1a, mmp9, arg1* compared to mice on the control diet. ATI-fed mice showed significantly increased numbers of hepatic M2-type macrophages ($CD11b^{high}$ $CD206^{high}$), myeloid derived suppressor cells ($Ly6c^{high}$, $Ly6G^{-}CD11b^{+}$), and $CD4^{+}$ Treg cells vs the ATI-free HCC

bearing mice. Furthermore, their numbers of Glypican-3, Ki67, CD68, and Ym-1 positive cells were significantly increased in parallel with the accelerated tumor growth, proliferation and tumor associated immune suppression.
Conclusion: Ingestion of dietary wheat ATI in amounts comparable to average daily human intake promote murine liver fibrosis and primary liver cancer.

FRI245
Epigenetic mechanism and metabolic reprogramming in fibrogenesis: dual targeting of G9a and DNA methyltransferase 1 for the inhibition of liver fibrosis

Marina Bárcena-Varela[1], Hannah Paish[2], Iker Uriarte[1,3], Maria U Latasa[1], Eva Santamaria[1,3], Alex Claveria-Cabello[1], Leticia Colyn[1], Maria Arechederra[1,4], Maria Iraburu Elizalde[5], Malgorzata Milkiewicz[6], Piotr Milkiewicz[7], Stuart Robinson[8], Jeremy French[8], Bruno Sangro[3,4,9], Julen Oyarzabal[10], Felipe Prosper[4,11], Krista Rombouts[12], Fiona Oakley[2], Jelena Mann[2], Carmen Berasain[1,3,4], Matías A Avila[1,3,4], Maite G Fernandez-Barrena[1,3,4]. *[1]CIMA – University of Navarra, Hepatology, Pamplona, Spain; [2]Institute of Cellular Medicine, Faculty of Medical Sciences, Newcastle University, Newcastle Fibrosis Research Group, Newcastle, United Kingdom; [3]CiberEHD, Instituto de Salud Carlos III, Madrid, Spain; [4]Instituto de Investigaciones Sanitarias de Navarra-IdiSNA, Pamplona, Spain; [5]University of Navarra, Biochemistry and Genetics, Pamplona, Spain; [6]Pomeranian Medical University, Medical Biology, Szczecin, Poland; [7]Medical University of Warsaw, Liver and International Medicine Unit, Department of General Transplant and Liver Surgery, Warsaw, Poland; [8]Newcastle upon Tyne Hospitals NHS Foundation Trust, Hepatobiliary Surgery, Newcastle, United Kingdom; [9]Navarra University Clinic, Hepatology Unit, Pamplona, Spain; [10]CIMA, University of Navarra, Molecular Therapies, Pamplona, Spain; [11]CIMA, University of Navarra, Oncohematology, Pamplona, Spain; [12]University College London, Liver and Digestive Health, London, United Kingdom*
Email: magarfer@unav.es

Background and Aims: Hepatic stellate cells (HSC) transdifferentiation into myofibroblasts is central to fibrogenesis. Epigenetic mechanisms, including histone and DNA methylation, play a key role in this process. Concerted action between histone and DNA-mehyltransferase like G9a and DNMT1 is a common theme in gene expression regulation. We aimed to study the efficacy of CM272, a first-in-class dual and reversible G9a/DNMT1 inhibitor, in halting fibrogenesis.
Method: G9a and DNMT1 were analyzed in cirrhotic human livers, mouse models of liver fibrosis and cultured mouse HSC. G9a and DNMT1 expression was knocked-down or inhibited with CM272 in human HSC (hHSC), and transcriptomic responses to transforming growth factor-β (TGFβ) and hypoxia were examined. Glycolytic metabolism and mitochondrial function were analyzed with Seahorse-XF technology. Gene expression regulation was analyzed by chromatin immunoprecipitation and methylation-specific PCR. Antifibrogenic activity and safety of CM272 were studied in mouse chronic CCl_4 administration and bile duct ligation (BDL), and in human precision-cut liver slices (PCLSs) in a new bioreactor technology.
Results: G9a and DNMT1 were detected in stromal cells in areas of active fibrosis in human and mouse livers. G9a and DNMT1 expression was induced during mouse HSC activation, and TGFβ triggered their chromatin recruitment in hHSC. G9a/DNMT1 knockdown and CM272 inhibited TGFβ fibrogenic responses and hypoxia adaptation in hHSC. TGFβ-mediated profibrogenic metabolic reprogramming was abrogated by CM272, which restored gluconeogenic gene expression and mitochondrial function through on-target epigenetic effects. CM272 inhibited fibrogenesis in mice and PCLSs without toxicity.
Conclusion: Dual G9a/DNMT1 inhibition by compounds like CM272 may be a novel therapeutic strategy for treating liver fibrosis.

FRI246
FIB-4 and APRI scores re-validation; a cohort study of 69106 chronic hepatitis C patients

Mahasen Mabrouk[1], Abubakr Awad[2], Hend Shousha[1], Wafaa Elakel[1], Tahany Awad[1], Ahmed Salama[1]. *[1]Cairo University, Faculty Of Medicine, Endemic Medicine and Hepatology Department, Cairo, Egypt; [2]University of Aberdeen, Computing Science, Aberdeen, United Kingdom*
Email: mahasen.mabrouk@gmail.com

Background and Aims: FIB-4 and APRI are simple, non-invasive, inexpensive scores however, its accuracy is questioned. The Egyptian National Committee for Control of Viral Hepatitis has provided a rich pool of electronic patients' records with liver biopsy results. So, we were motivated to have the chance to revise and validate the accuracy of FIB-4 and APRI scores, and to go further step to explore the potentials of developing an accurate prediction method using machine learning approach.
Method: This retrospective multi-center study included 69106 Egyptian patients with HCV for interferon-based antiviral therapy from 2010–2014 where liver biopsy was mandatory for fibrosis assessment. FIB-4 and APRI scores were calculated and its performance analysis was assessed versus to Metavir scoring system (F0-F4) as a gold standard of liver fibrosis. Machine learning (ML) was used for feature selection and reduction to the most relevant attributes (CfsSubseteval / best first).
Results: In this study, 57492 (83.2%) patients had F0- F2, and 11615 (16.8%) patients had F3-F4. Any score validation involves the evaluation of discrimination represented by AUC, and calibration to assess agreement between predicted and observed risks (correctly classified). The revalidation of FIB-4 and APRI showed low accuracy and high disagreement with biopsy results, with overall AUC 0.68 and 0.58 respectively (Table 1). FIB-4 diagnoses few cases (14%) of F3-F4 patients, the high specificity, and negative predictive values of FIB-4 and APRI just reflect the low prevalence of F3-F4 in the study population. The high disagreement between APRI, FIB-4 and biopsy provided the motivation to develop our ML approach. Out of 15 attributes machine learning has selected Age (>35 years), AFP (>6.5), and platelet (<150,000) as the most relevant risk attributes at these cut off values. Any patient with one or more of these risk factors will be considered as a possible F3-F4 with a classification accuracy up to 92% and ROC Area 0.74 (Table 1). This high sensitivity will ensure that high risk F3-F4 patients will not be missed to be assessed appropriately and to minimize fibrosis screening by 40% which is the percent of patients with no risk factors.

	FIB4 ≥ 1.45	FIB4 ≥ 3.25	APRI ≥ 1	ML approach
Sensitivity	57.5%	13.9%	32.7%	92%
Specificity	68.5%	96.5%	80.68%	49%
PPV	27.6%	45.2%	25.1%	34%
NPV	88.5%	84.3%	85.8%	95.5%
Disagreement with Metavir score	42.5%	86%	67%	8%
ROC area		0.69	0.58	0.74

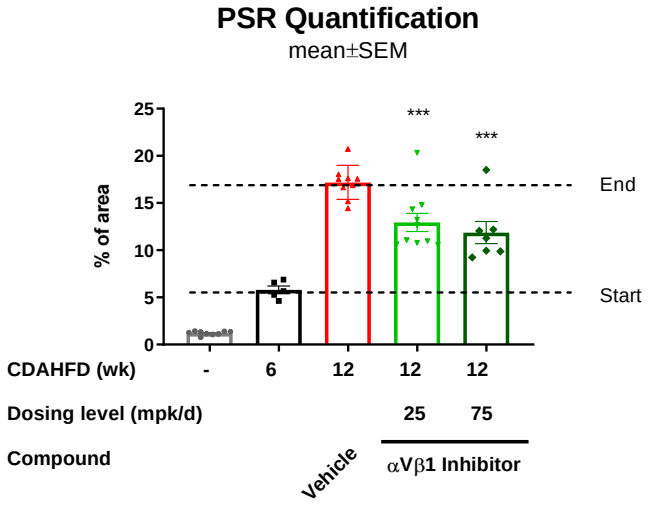
Conclusion: This revalidation study showed that the two popular FIB-4 and APRI scores are not accurate, and miss the diagnosis of most of F3-F4 patients. ML implementation helps the empowerment of medical decision and minimizes the dimensionality of clinical data to three risk factors (Age, AFP and Platelet). This approach does not need any calculation and provides an accurate F3-F4 diagnosis superior to APRI, FIB-4 scores.

FRI247

Integrin alphaVbeta1 inhibition ameliorates liver fibrosis in mice

Richard Chen[1], Parmita Saxena[1], Mayra Senices[1], Vinod Yadav[1], Bryce Harrison[1], James E. Dowling[1], Patrycja Nowakowski[1], Laura Cappellucci[1], Faith Finley[1], Andrew Sullivan[1], Angela Kennedy-Curran[1], Terence Moy[1], Albert Lin[1], Dan Cui[1], Adrian Ray[1], Blaise Lippa[1], Alex Lugovskoy[1], Bruce Rogers[1], Liangsu Wang[1], Min Lu[1]. [1]*Morphic Therapeutic Inc, Waltham, United States*
Email: min.lu@morphictx.com

Background and Aims: Integrins are heterodimeric membrane proteins composed of alpha and beta subunits that regulate cellular activity by integrating the extracellular and intracellular environments in a bidirectional manner. Integrin alphaVbeta1, found highly expressed in activated fibroblasts, has been implicated in fibrogenesis, by binding to latency-associated peptide (LAP) of pro-transforming growth factor beta (TGF-beta) to liberate active TGF-beta. However, given alphaVbeta1′s low affinity towards LAP, its exact mechanism of action in rodent fibrosis models and human translational systems remains to be fully elucidated.
Method: Integrin alphaVbeta1 heterodimer expression was determined by co-immunoprecipitation of the alphaV and the beta1 subunits. Activation of TGF-beta was determined by the luciferase activity in TGF-beta reporter cells, co-cultured with Chinese Hamster Ovary (CHO) cells over-expressing human alphaVbeta1 and pro-TGF-beta1. Active and total TGF-beta in conditioned media from LX-2 cells and primary human hepatic stellate cells (HSC) were measured by an enzyme-linked immunosorbent assay (ELISA). HSC migration was measured by Incucyte migration module. An orally bioavailable, selective small molecule alphaVbeta1 antagonist was identified. The in vivo effects of the molecule were examined in the choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD)-induced mouse nonalcoholic steatohepatitis (NASH) model.



***p<0.001 vs vehicle by One Way Anova and Dunnett's multiple comparisons

Results: While alphaVbeta1 modestly mediated TGF-beta activation in an engineered cell line, no appreciable level of TGF-beta activation by this integrin was detected in cultured HSC cell line and primary human HSCs. This is consistent with 100× lower affinity between alphaVbeta1 and LAP, compared to that between alphaVbeta6 and LAP. Nonetheless, we observed significantly attenuated HSC migration in vitro and dampened fibrosis in a CDAHFD-induced NASH model by alphaVbeta1 blockade. Deep sequencing analyses suggest that alphaVbeta1 blockade may regulate anti-oxidation, fibrolysis, and inflammatory pathways in CDAHFD mouse liver. Moreover, alphaVbeta1 inhibition modulated common gene signatures that are elevated in both mouse liver fibrosis and human NASH with advanced fibrosis stage (F3/F4). Finally, we assessed the expression of alphaVbeta1 in different human tissues and primary human fibroblasts and demonstrated the upregulation of alphaVbeta1 heterodimer in human fibrotic diseases.
Conclusion: Novel mechanisms have been unveiled for the role of alphaVbeta1 integrin in liver fibrosis. Inhibition of alphaVbeta1 impairs HSC migration in vitro and ameliorates fibrosis in a mouse NASH model. The genes modulated by the alphaVbeta1 inhibitor in animals share common signatures that are dysregulated in human NASH liver with advanced fibrosis. AlphaVbeta1 represents a promising target for liver fibrosis.

FRI248

AlphaVbeta6 inhibitor stabilizing the bent closed integrin conformation is effective in primary sclerosis cholangitis mouse model

Min Lu[1], Richard Chen[1], Bryce Harrison[1], Monica S. Montesinos[1], Lukasz Stawski[1], Vinod Yadav[1], Andrew Sullivan[1], Lia Luus[1], Patrycja Nowakowski[1], Laura Cappellucci[1], Sung Jo[1], Albert Lin[1], Qi Qiao[1], Eugene Nebelitsky[1], Meghan Monroy[1], Terence Moy[1], Dan Cui[1], Adrian Ray[1], Blaise Lippa[1], Alex Lugovskoy[1], Liangsu Wang[1], Bruce Rogers[1]. [1]*Morphic Therapeutic, Waltham, United States*
Email: min.lu@morphictx.com

Background and Aims: Integrins are heterodimeric membrane proteins composed of alpha and beta subunits that regulate cellular activity by integrating the extracellular and intracellular environments in a bidirectional manner. Integrins can undergo large conformational changes in response to mechano-biochemical signalling events, differing in intracellular or extracellular ligand affinity by up to 1000-fold. AlphaVbeta6, an integrin highly expressed in injured biliary ductular cells, binds to latency-associated peptide (LAP) of transforming growth factor beta (TGF-beta) as its principal ligand and activates mature TGF-beta that drives fibrogenesis. Understanding the impact of conformations of alphaVbeta6 integrin stabilized by its inhibitors on disease pathophysiology may have implications in the therapeutic potential of this target class.
Method: Small molecule oral inhibitors that stabilize the alphaVbeta6 integrin in a bent-closed conformation have been identified. The efficacy of the small molecule closing inhibitor, MR-cpd3, was evaluated in a 0.1% DDC (3,5-diethoxycarbonyl-1,4-dihydrocollidine)-diet-induced primary sclerosing cholangitis (PSC)-like biliary mouse model. Feeding with a DDC diet for 7 days [for acute pharmacodynamics (PD)] or 20 days (for chronic efficacy) in 8-wk old mice was used to induce biliary fibrosis and cholestasis. MR-cpd3 was orally administered at 10–60 mg/kg, b.i.d., in both the acute and chronic DDC models to evaluate its anti-fibrosis effects. mrationTo understand the differential effects of conformation specific alphaVbeta6 inhibition, a closing antagonist and an opening antagonist were dosed at 10 mg/kg in DDC mice.
Results: In the chronic DDC-induced PSC model, MR-cpd3 treatment dose dependently reduced cholestatic end points and hepatic collagen deposition. While the expression of some fibrotic genes and plasma cholestatic markers were equally reduced by both opening and closing inhibitors, other critical genes, such as CTGF, and plasma total bile acid levels, were differentially modulated by the closing and opening inhibitors. In the acute PD model, gene set enrichment analysis (GSEA) of the RNAseq results revealed that closing antagonism of alphaVbeta6 distinctively modulates lipid metabolism and epithelial cellular proliferation while the opening compound did not.
Conclusion: Our results suggest that alphaVbeta6 inhibition ameliorates biliary fibrosis and markedly improves liver function in DDC-induced PSC model. AlphaVbeta6 presents as a high potential target in cholestatic liver diseases. The development of new generation of

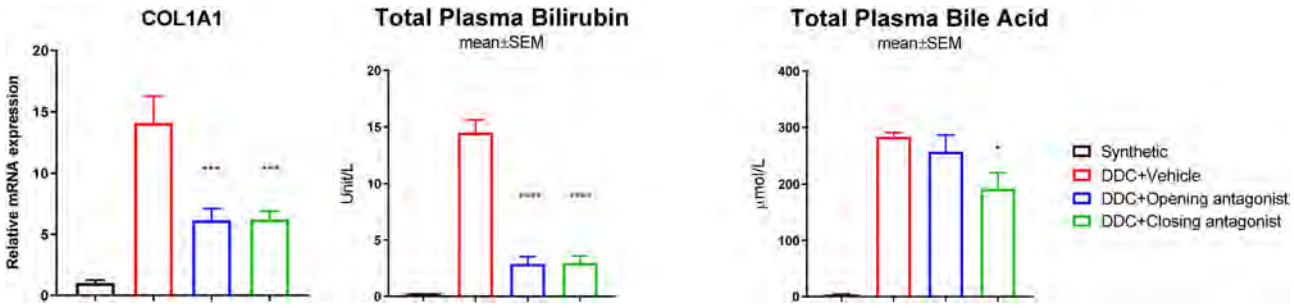


Figure: (abstract: FRI248)

oral drugs that stabilize the closed conformation of this integrin is desirable to realize this potential.

FRI249

Endotrophin, a hormone derived from type VI collagen, activates fibroblasts and drives fibrosis in the liver, lung, kidney, and heart

Morten Karsdal[1], Mette Juul Nielsen[1], Jannie MB Sand[1], Alexander Lynge[1], Daniel Guldager Kring Rasmussen[1], Federica Genovese[1], Anne Christine Bay-Jensen[1], Nicholas Willumsen[1], Diana Leeming[1]. *[1]Nordic Bioscience A/S, Biomarkers and Research, Herlev, Denmark*
Email: mju@nordicbio.com

Background and Aims: The type VI collagen pro-peptide, endotrophin (ETP), holds signaling properties in the extracellular matrix (ECM). Fibrosis may in some instances self-perpetuate in the absence growth factors such as transforming growth factor (TGF)-β and platelet-derived growth factor (PDGF). This suggests that ECM components produced by fibroblasts may drive fibrosis. We undertook a systemic screening approach to identify fragments of collagens that could induce fibrosis in fibroblasts to the same extent as TGF-β. In addition, we investigated serological collagen biomarkers and their association to fibrosis in prospective cohorts of liver, lung, kidney, and heart fibrosis in a meta-analysis.
Method: The effect of ETP, TGF-β and PGDF-DD was investigated on type III collagen formation in a scar-in-a-jar (SiaJ) cell model using human fibroblasts. Cells were exposed to 11.75 nM human recombinant ETP. In a meta-analysis, serum samples from patients with liver cirrhosis and hepatocellular outcome (HCC) (n = 200), acute-on-chronic liver failure (ACLF) (n = 150), chronic kidney disease (n = 500), heart failure (n = 350), idiopathic pulmonary fibrosis (IPF) (n = 300) were included. Biomarkers of type III formation (PRO-C3) and ETP (PRO-C6) were assessed in cell supernatants and patient sera by ELISAs developed at Nordic Bioscience.
Results: In SiaJ, PRO-C3 was increased 700% when induced by ETP ($p < 0.0001$) comparable to TGF-β and PDGF-DD induction. PRO-C6 was correlated to disease severity of liver, lung, and kidney fibrosis and SSC. Baseline PRO-C6 predicted 1) worsening of liver fibrosis in liver biopsies, progression from cirrhosis to HCC, liver related outcome, and outcome of ACLF; 2) progression of IPF defined by a decline in forced vital capacity (FVC) > 10% or death; 3) Kidney fibrosis and function loss defined as a decline in eGFR, progression to end-stage renal disease, and death; and 4) heart failure, hospitalization or death.
Conclusion: Here we show that ETP have a direct stimulating effect on fibroblasts. These data are the first to suggest that collagen peptides initiate and drive fibrosis, independent of TGF-β and PDGF. Moreover, ETP was prognostic for all fibrotic diseases tested, suggesting ETP to be a common denominator for progression of fibrosis and outcome. Further understanding of this signal may lead to novel treatments of fibrosis.

Hepatocytic C-jun NH2 terminal kinase activity confers protection against cholestatic liver injury in mice

Mohamed Ramadan Mohamed[1,2], Francisco Javier Cubero[1,3,4], Peter Boor[5], Johannes Haybäck[6], Mark Boekschoten[7], Roger J. Davis[8], Christian Trautwein[1]. *[1] University Hospital, RWTH Aachen, Department of Internal Medicine III, Aachen, Germany; [2]National Research Centre, Department of Therapeutic Chemistry, Cairo, Egypt; [3]Complutense University School of Medicine, Department of Immunology, Ophthalmology & ENT, Madrid, Spain; [4]12 de Octubre Health Research Institute (imas12), Madrid, Spain; [5]University Hospital, RWTH Aachen, Institute of Pathology & Department of Nephrology, Aachen, Germany; [6]Institute of Pathology, Medical University of Graz, Diagnostic and Research Center for Molecular BioMedicine, Graz, Austria; [7]Wageningen University, Nutrition, Metabolism and Genomics Group, Division of Human Nutrition, Wageningen, Netherlands; [8]Howard Hughes Medical Institute and University of Massachusetts Medical School, Worcester, United States*
Email: ctrautwein@ukaachen.de

Background and Aims: Chronic liver injury triggers death of parenchymal cells, followed by an inflammatory response activating myofibroblasts eventually leading to liver fibrosis. C-Jun NH2-terminal kinase (JNK) activation plays a crucial role during hepatic fibrosis progression. Previously, we showed that JNK1 in hepatic stellate cells (HSCs) mediates transactivation of HSCs during murine liver fibrosis. Moreover, JNK combined activities are fundamental for drug-induced liver injury. In the present work, we investigated the functional of Jnk1/2 in hepatocytes during cholestatic liver disease.
Method: The involvement of JNK in the pathogenesis of human and murine cholestatic liver diseases (CLD) was examined. Cholestatic liver injury was triggered through 28 days bile duct ligation (BDL) in $Jnk1^{f/f}/2^{f/f}$ (WT) and $Jnk1/2^{\Delta hepa}$ (hepatocyte-specific deletion of JNK1 and JNK2) mice. The states of liver injury, inflammation and fibrosis were investigated. Moreover, microarray analysis was performed.
Results: Analysis of liver sections from patients with primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) with varying degrees of hepatic fibrosis revealed strong JNK activation in both immune and parenchymal cells compared to healthy control livers correlating with disease activity. Additionally, JNK activation was characteristic in the livers of murine cholestasis ($Mdr2^{-/-}$ and BDL). After 28 days of BDL, $Jnk1/2^{\Delta hepa}$ compared to WT mice developed a significantly severer phenotype as characterized by exacerbated serum transaminases, increased ductular proliferation and dramatically increased areas of bile infarcts. Consistently, liver analysis revealed increased hepatic fibrogenesis, oxidative stress and inflammation in $Jnk1/2^{\Delta hepa}$ compared to WT mice, 28-days after BDL. Microarray analysis indicated that $Jnk1/2^{\Delta hepa}$ livers displayed increased transcripts of genes related to IL-6 signaling and mucosal and epithelium protection (Trefoil and Mucin).
Conclusion: JNK is strongly activated during human and murine cholestatic liver injury. Combined JNK function in hepatocytes

confers protection during cholestatic liver injury-induced liver fibrosis and thus our study defines a novel therapeutic target for CLD.

FRI252

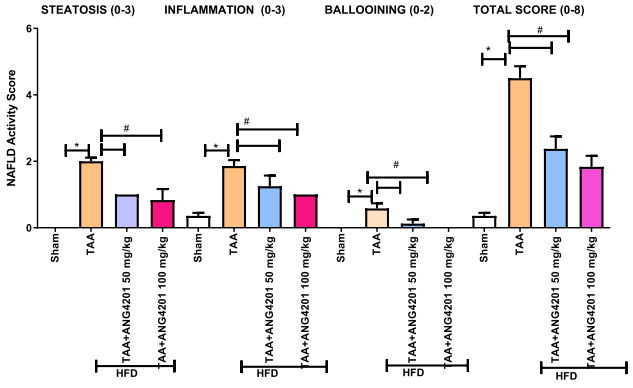
Novel Rho associated coiled kinase inhibitor improves hepatic fibrosis in mice model of non-alcoholic steatohepatitis (NASH)

Quaisar Ali[1], Natalia Prakash[1], Sony Dalapati[1], Jingsong Li[1], Itzhak Goldberg[1], Latha Paka[1]. [1]*Angion Biomedica Corp, Uniondale, United States*
Email: quaisar.ali@gmail.com

Background and Aims: Rho-associated coiled kinases 1 (ROCK1) and 2 (ROCK2) are involved in variety of cellular processes including tissue fibrosis. Recently, we demonstrated that hepatic ROCK2 and not ROCK1 is upregulated in mice model of NASH (thioacetamide + high fat diet). The present study was done to investigate if selective blocking of ROCK2 reduces hepatic fibrosis and improves liver function.

Method: Using core hopping and structure based drug design approach, we synthesized highly selective (>200 fold selective for ROCK2 vs ROCK1), orally bioavailable ROCK2 inhibitor (ANG4201). We evaluated the antifibrotic effects of ANG4201 in mice model (C57Bl/6) of NASH. Adult male and female mice were subjected to high fatty diet (FFD) for three months and thioacetamide (TAA, 100 mg/kg body wt) was administered thrice a week concomitantly to accelerate the progression of liver fibrosis. After three months, mice were randomized to vehicle or ANG4201 (50 & 100 mg/kg body wt, PO, BID) for two-months. Liver injury was analysed by measuring serum transaminases (AST/ALT). RNA was isolated from livers and panel of fibrotic and inflammatory markers were assessed by RT-PCR. Collagen quantification was performed on liver tissue using Bioquant software.

Results: Compared to control, ANG4201 treatment dose dependently reduced TAA + FFD induced liver fibrosis in mice, demonstrated by significant reduction in hepatic hydroxyproline, Masson Trichrome and Sirius red staining as well as alpha-SMA, collagen I, CTGF and TGF-beta mRNA expression and the inflammatory infiltration and myofibroblast activation associated-signalling (TNF-alpha, FN1 and MMP3). The reduction in fibrosis was associated with significant improvement in the ratio of liver wt and body wt and reduction in serum transaminases. ANG4201 treatment was associated with overall improvement in NAFLD activity score.



Conclusion: This study demonstrates that ROCK2 upregulation contributes to hepatic fibrosis and hepatic dysfunction in FFD+TAA mice model. ANG4201 is highly promising orally bioavailable therapeutic ROCK2 inhibitor with potential use in liver fibrosis.

Email: gerardaraujo_@hotmail.com

Background and Aims: In NASH patients, type 2 diabetes (T2D) is a driver of liver fibrosis progression and related complications. Pre-test probability of disease heavily influences the performance of non-invasive tests (NITs), so their predictive value may be degraded in T2D patients. Use of more advanced NITs (eg, transient elastography, ELF) to identify T2D patients with high fibrosis risk may not be economically and technically feasible. There are no cut-off points for NITs applicable solely to T2D populations to inform healthcare providers of the need for referral to a hepatologist and/or to a clinical trial. We aimed to identify cut-off points for simple NITs in patients with T2D with NASH at risk of liver fibrosis.

Method: Screening visit data from T2D patients with biopsy-confirmed NASH from the Phase 3 AURORA trial were analysed to determine the cut-off values for the target fibrosis stages (F3–F4, NASH CRN) based on FIB-4, APRI, and NFS. The predictive accuracy of each NIT was evaluated using logistic regression. Subjects were classified into binary responder groups: F3 and F4 were considered positive; F0 to F2 negative. Positive and negative predictive values (PPVs and NPVs) were obtained to identify cut-offs that had acceptable specificity and PPV to rule in advanced fibrosis. NPV ≥ 30% and PPV ≥ 80% were used to detect those cut-offs.

Results: The AURORA screening database included 2056 subjects with NASH who underwent liver biopsy; of those, 420 subjects with T2D were included in this analysis (17, 86, 121, 170 and 26 had fibrosis staging F0, F1, F2, F3 and F4, respectively). The AUROCs for FIB-4, APRI and NFS were 0.68, 0.67 and 0.56 for F3–F4, respectively. In NASH patients with T2D and F3–F4 liver fibrosis, cut-off value for FIB-4 was ≥2.31 (sens 0.21, spec 0.96, PPV 0.80, NPV 0.58) and for APRI was ≥1.03 (sens 0.20, spec 0.96, PPV 0.81, NPV 0.58).

Conclusion: The cut-off points for FIB-4 and APRI for F3–F4 derived from the large AURORA study screening cohort may serve to identify T2D patients who definitely need hepatologist referral and/or considered for enrolment in clinical trials. Further validation using other cohorts to refine predictive values in respect of varying pre-test probabilities and contexts of use is warranted. Editorial assistance by Complete HealthVizion.

What did we learn from a large cohort of more than 24,000 patients evaluated by transient elastography in a single- center?

Roxana Sirli[1], Ioan Sporea[1], Lazar Alin[1], Dan Isabel[1], Alexandra Elena Deleanu[1], Vernic Corina[2]. [1]*"Victor Babes" University of Medicine and Pharmacy, Department of Gastroenterology and Hepatology, Timisoara, Romania;* [2]*"Victor Babes" University of Medicine and Pharmacy, Department of Functional Sciences, Timisoara, Romania*
Email: lazaralin1990@yahoo.com

Background and Aims: In the last years, transient Elastography (TE) became one of the main tools for the non-invasive assessment of liver fibrosis. The aim of our study was to assess the feasibility of TE and fibrosis stage prevalence, evaluated by TE, in a large cohort of patients in a single study centre.
Method: We performed a retrospective study on 24,454 liver stiffness measurements (LSM) by mean of TE performed in our Department during a 12 years period (2007–2019). The study included patients with liver diseases of various etiologies and normal subjects. In each patient, 10 valid LSM were obtained using the M or XL probe, according to the body mass index (BMI) of each subject. If no valid LSM could be obtained, the evaluation was declared as failed. Reliable LSM were defined as median value of 10 measurements with Interquartile range/median (IQR/M) ≤ 30%, and a Success Rate (SR) ≥ 60%. To discriminate between liver fibrosis stages by TE we used the following cut-offs [1]: F2-7 kPa; F3-9.5 kPa and F4-12 kPa.
Results: Gender distribution was relatively equal, with 49.9% (11,223 female subjects), average age 54 years. LSM were obtained using the M probe in 72.2% (17,663) cases and by XL probe in 27.8% (6,791) cases. The feasibility in our cohort was 90.7%; 2,270 of the 9.3% LSM (24,454) were considered failed or unreliable. The etiology of chronic liver diseases evaluated by TE was: hepatitis C virus infection: 35%, hepatitis B virus infection: 20.6%, dual hepatitis virus infection: 1.4%, alcoholic liver disease: 5.4%, Non-Alcoholic Steatohepatitis (NASH): 6.8%, Both Alcoholic and Non-Alcoholic Steatohepatitis (BASH): 0.3% (81 patients), hepatocytolysis syndrome 4%, autoimmune hepatitis 0.8% (194 patients), normal subjects 2% (494 cases) and other etiologies: 23.7% (5,750 patients).
Based on TE cut-off values, the severity of liver fibrosis in our group was as follows: F < 2: 48.9% patients (10,851); F2: 15.5% patients (3,449); F3: 8.5% (1,886 patients) and F4: 27% patients (5,998).
Conclusion: Transient elastography had a feasibility of 90.7% in this large cohort, almost half of the patients (48.9%) having at most mild fibrosis, and a little bit over one quarter having cirrhosis (27%).

The impact of LOXL2 inhibition on fibrosis progression in-vitro and in-vivo

Sarah A Townsend[1], Clare J Thomas[1], Philip N Newsome[1], Chris J Weston[1]. [1]*University of Birmingham, Liver Research, Birmingham, United Kingdom*
Email: sarahanntownsend@yahoo.com

Background and Aims: Fibrosis is the final common pathway of chronic liver injury, and resultant cirrhosis accounts for >2.5% of deaths worldwide. Lysyl oxidase-like protein 2 (LOXL2) oxidises lysine residues in collagen/elastin leading to stabilisation of the extracellular matrix. The aim of this study was to investigate whether LOXL2 enzyme inhibition would reduce fibrosis in models of liver disease.
Method: Models of hepatic fibrosis in mice and rats (CCl_4, *Mdr2*$^{-/-}$, TAA) were used to evaluate the efficacy of LOXL2 enzyme inhibitors (Pharmaxis) as assessed by flow cytometry, immunohistochemistry, qPCR and assessment of blood markers of liver injury. LOXL2 inhibition was assessed *in vitro* using primary human fibroblasts.
Results: LOXL2 inhibition reduced CCl_4-induced liver fibrosis in rats (median % picrosirius red area following 2 weeks treatment, vehicle 2.84% vs high dose inhibitor 1.90%, p = 0.02; vehicle vs low dose inhibitor 1.92% p = 0.07; qPCR: median expression for *Col1a1* following CCl_4 injury was, vehicle 0.021 vs low dose inhibitor 0.009, p = 0.006, or high dose inhibitor 0.003, p = 0.001, for *Acta2* vehicle 0.010 vs low dose inhibitor 0.004, p = 0.001, or high dose inhibitor 0.001, p < 0.0001).
This effect was not observed in either the short murine *Mdr2*$^{-/-}$ model of liver injury following administration of LOXL2 inhibitor on alternate days (median % fibrosis, vehicle 4.64% vs inhibitor 4.61%, p = 0.46; median *Col1a1,* vehicle 0.11 vs inhibitor 0.84, p = 0.27, *Acta2,* 0.0006 vs 0.0005, p = 0.98) nor in the longer and more fibrotic TAA model with daily gavage of LOXL2 inhibitor (median % fibrosis, vehicle 9.4% vs inhibitor 8.4%, p = 0.46, median *Col1a1,* vehicle 0.08 vs inhibitor 0.078, p = 0.53, *Acta2,* 0.00006 vs 0.00007, p = 0.69). Daily provision of LOXL2 inhibitor following cessation of TAA dosing did not accelerate resolution of TAA induced fibrosis, and was not associated with altered intrahepatic immune cell infiltration (median % fibrosis, vehicle 3.9% vs inhibitor 5.6%, p = 0.13, median *Col1a1*, vehicle 0.04 vs inhibitor 0.06, p = 0.43, *Acta2*, 0.0006 vs 0.0005, p = 0.95; median % CD4+ cells, vehicle 9.1% vs inhibitor 8.9%, p = 0.46), median % CD8+ cells vehicle 7.0% vs inhibitor 8.3%, p = 0.60).
Notably, LOXL2 inhibition reduced human fibroblast contractility *in vitro*, implicating the LOX family of enzymes in fibrosis progression (% contraction, control 81.5% vs inhibitor 67.3%, p = 0.004).
Conclusion: Inhibition of LOXL2 enzyme showed differing effects in rat, mouse and human models of liver disease. This suggests that the timing and dose of the inhibitor are critical for effective targeting of LOXL2 in different species.

FRI256

Hydrophobic bile acids promote proliferation and activation of hepatic stellate cells by PI3K-dependent mechanisms

Sebastian Zimny[1], Ralf Wimmer[1], Florian Paul Reiter[1], Gerald Denk[1], Simon Hohenester[1]. [1]*University Hospital, LMU, Department of Medicine II, Munich, Germany*
Email: sebastian.zimny@med.uni-muenchen.de

Background and Aims: Chronic cholestatic liver diseases frequently progress to liver fibrosis. In this context, hydrophobic bile acids (BA) are assumed to exhibit pro-fibrotic effects. However, mechanisms of cholestasis-induced liver fibrosis are incompletely understood. It has been described that BA may induce pro-proliferative signals in murine hepatic stellate cells (mHSC). Functional consequences of such signalling, however, have not been explored and underlying signalling pathways are unknown. We therefore investigated effects of BA on HSC proliferation, cell expansion and collagen deposition as well as contributing signalling pathways.
Method: mHSC derived from female FVB mice were isolated, purified and incubated with hydrophilic and hydrophobic BA. Activation of signalling pathways was evaluated by western blotting. Cell proliferation was determined via BrdU assays. Total cell count was evaluated microscopically, DNA quantification served as alternative measure for cell mass. Collagen deposition was quantified photometrically. The human stellate cell line LX2 was incubated with TGF beta and activation was determined by alpha SMA quantification.
Results: The most relevant hydrophobic BA in human cholestasis, chenodeoxycholic acid (CDCA), but not cholic acid and ursodeoxycholic acid, led to an increased proliferation of mHSC in BrdU assays, which led to an increased cell count after 14 days of culture. HSC mass increased dose dependently to up to 1.90 ± 0.9-fold (0.25 mM CDCA, mean ± SD, p < 0.05). Accumulation of mHSC resulted in increased deposition of collagen. These effects were associated with phosphorylation of protein kinase B (PKB) after shortterm (2–4 h) and longterm (7–10 d) stimulation. Inhibition of the upstream target

PI3 K by LY294002 (0.01 mM) impeded CDCA induced phosphorylation of PKB and prevented BA-induced HSC cell expansion. Suggesting a role of this signalling pathway also in humans, TGF beta-induced activation of LX2 cells was abolished by LY294002.
Conclusion: Hydrophobic but not hydrophilic BA induce pro-proliferative signalling in murine HSC. We describe for the first time that such signalling is associated with consecutive cell mass expansion and collagen deposition. These pro-fibrotic effects may partially be mediated by PI3 K dependent signalling. Activation of human HSC, too, may be mediated by PI3 K.

Aldafermin (NGM282) reduces the cross-linked pro-peptides of type III collagen PRO-C3X, a novel biomarker, in non-alcoholic steatohepatitis and primary sclerosing cholangitis patients

Stephen Harrison[1], Lei Ling[2], James F. Trotter[3], Angelo Paredes[4], Andrew Yan[2], Ulrich Beuers[5], Gideon Hirschfield[6], Diana Leeming[7], Morten Karsdal[7], Alex DePaoli[2], Hsiao Lieu[2]. *[1]Pinnacle Clinical Research, San Antonio, United States; [2]NGM Biopharmaceuticals, South San Francisco, United States; [3]The Liver Consultants of Texas, Dallas, United States; [4]Brooke Army Medical Center, San Antonio, United States; [5]University of Amsterdam, Amsterdam, Netherlands; [6]Toronto General Hospital, Toronto, Canada; [7]Nordic Bioscience, Herlev, Denmark*
Email: lling94080@yahoo.com

Background and Aims: Cross-linking of collagen is a key contributor to tissue stiffness. Recent studies have shown that circulating concentrations of PRO-C3X are elevated in HCC patients, and are superior to PRO-C3 in predicting progression-free survival and overall survival independent of AFP (Jensen et al., 2019). Aldafermin (NGM282), a non-tumorigenic FGF19 analogue, is a potent regulator of bile acid synthesis with anti-fibrotic effects in clinical trials. We determined plasma levels of PRO-C3X in phase 2 trials of aldafermin in NASH and PSC.
Method: Fourty-three NASH subjects, with NAS ≥4 (at least 1 point in each component), stage 1–3 fibrosis and absolute liver fat content by MRI-PDFF ≥8%, received aldafermin 1 mg or 3 mg daily for 12 weeks (W12). 62 PSC subjects, with an elevated ALP>1.5xULN at baseline (BL), received aldafermin 1 mg, 3 mg or placebo daily for 12 weeks. The PRO-C3X sandwich ELISA only detects cross-linked type III collagen pro-peptides, whereas the PRO-C3 competitive ELISA quantifies the sum of single-stranded and cross-linked pro-peptides (Nordic Bioscience).
Results: At BL, circulating PRO-C3X concentrations were significantly lower in subjects with NASH than PSC (9.1 ng/mL vs 14.7 ng/mL, $p < 0.001$), while PRO-C3 levels were similar in NASH and PSC. PRO-C3X declined rapidly and significantly with aldafermin therapy in NASH (−2.7 and −2.8 at W6 and W12 in the 1 mg group, $p < 0.001$ vs BL for both comparisons) and PSC (−0.8 and −0.7 at W2 and W12 with aldafermin 1 mg; −2.8 and −3.1 at W2 and W12 with aldafermin 3 mg; $p < 0.01$ vs BL for all comparisons) (Table 1). In contrast, no significant change in PRO-C3X was observed with placebo (0 and +0.5 at W2 and W12 in PSC).
Conclusion: NASH patients had much lower type III collagen cross-linking than PSC patients, underlining the potential for rapid fibrosis reversal in a dynamic extracellular matrix environment in NASH. Aldafermin significantly reduces PRO-C3X, a novel noninvasive marker of cross-linked type III collagen, across metabolic and cholestatic liver disease. Given that liver fibrosis progression and HCC growth are associated with matrix stiffness and cross-linking of collagens, these results may support an anti-tumor activity, in addition to the anti-fibrotic activity, of aldafermin in chronic liver disease.

Table 1: Aldafermin reduced cross-linked type III collagen in NASH and PSC populations.

	PRO-C3X (ng/mL)				
	BL	W12	Change from BL at W12	P (vs BL)	P (vs Placebo)
NASH Population					
Aldafermin 1 mg	9.9	7.2	−2.8	<0.001	NA
Aldafermin 3 mg	7.9	6.7	−1.2	0.07	NA
PSC Population					
Placebo	15.8	16.1	0.5	0.62	
Aldafermin 1 mg	14.2	13.3	−0.7	0.004	0.008
Aldafermin 3 mg	14.3	10.9	−3.1	0.001	0.006

Background and Aims: The effect of γ-sEVs on macrophage polarization, motility, and phagocytosis were evaluated *in vitro*. To analyze the contents of γ-sEVs, proteomics and miRNA analyses were performed. To analyze the effects of γ-sEVs, hepatic stellate cells (HSCs) were cultured with sEVs. To evaluate the therapeutic effects, a cirrhosis mouse model was treated with MSCs and sEVs with or without IFN-γ. To assess the effects of sEVs in the liver, single-cell RNA sequencing of immune cells, including macrophages in the liver tissues, was performed.
Method: The effect of γ-sEVs on macrophage polarization, motility, and phagocytosis were evaluated *in vitro*. To analyze the contents of γ-sEVs, proteomics and miRNA analyses were performed. To analyze the effects of γ-sEVs, hepatic stellate cells (HSCs) were cultured with sEVs. To evaluate the therapeutic effects, a cirrhosis mouse model was treated with MSCs and sEVs with or without IFN-γ. To assess the effects of sEVs in the liver, single-cell RNA sequencing of immune cells, including macrophages in the liver tissues, was performed.
Results: γ-sEVs can effectively induce anti-inflammatory macrophages *in vitro* and enhance their motility and phagocytotic ability. Proteomics and miRNA analyses of MSC-derived exosomes revealed that some proteins, such as annexin-A1, and miRNAs were increased after IFN-γ stimulation. However, γ-sEVs did not inhibit the activation of HSCs *in vitro*, suggesting that γ-sEVs do not directly inhibit HSC activation. Furthermore, γ-sEVs contributed to a reduction in inflammation and fibrosis in the cirrhosis mouse model. The single-cell RNA sequencing analysis revealed a wide range of effects, such as induction of anti-inflammatory macrophages and regulatory T cell, which were observed in the liver.
Conclusion: γ-sEVs can act as "cargo" and induce anti-inflammatory macrophages with high migratory and phagocytotic abilities, thereby effectively reducing inflammation and fibrosis. Our results demonstrate that sEVs can be modified before treatment and can potentially be used to develop new therapeutic approaches for treating cirrhosis.

Aspirin induces autophagy and alleviates liver fibrosis by reducing oxidative stress and inflammation in mice model of chronic liver injury

Adil Bhat[1], Sudrishti Chaudhary[1], Gaurav Yadav[1], Anupama Parasar[1], Chhagan Bihari[2], Jaswinder Maras[1], Shiv Kumar Sarin[1,3]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine;* [2]*Institute of Liver and Biliary Sciences, Department of Pathology;* [3]*Institute of Liver and Biliary Sciences, Department of Hepatology*
Email: shivsarin@gmail.com

Background and Aims: Aspirin has potent anti-platelet activities and possibly helps regression of fibrosis. We investigated the potentials and putative mechanisms of antifibrotic effects of aspirin in the liver using integrated omics analysis.
Method: C57/B6 mice were treated with CCl_4 for 8 weeks, followed by aspirin treatment. The identified antifibrotic targets were validated subsequently in mice and human samples with increasing grade of fibrosis.
Results: Biochemical and histopathological changes and hepatic fibrosis was greater in the CCl_4-treated (Group A) compared to CCl_4-Aspirin (CCl_4-ASA, Group B) group ($p < 0.05$) or controls (Group C). The proteome (>450 up- and >340 downregulated proteins) and metabolome (>70 up- and >60 downregulated metabolites) of Group-A was distinctly different compared to Group B or C ($p < 0.05$). Aspirin treatment significantly induced proteins and metabolites linked to drug and fatty acid metabolism, glutathione metabolism, autophagy, energy metabolism and amino acid metabolism ($p < 0.05$). In Group A, mice displayed down-regulation of autophagy related proteins such as lysosomal membrane associated protein 1 (LAMP1; <1.5 FC) whereas aspirin treatment significantly increases the expression of autophagy related proteins in Group B mice (LAMP1; >1.5 FC). Inflammatory pathways; TNF-alpha, NFKB signaling, arachidonic acid metabolism, cholesterol metabolism, synthesis of ketone bodies and butanoate metabolism were significantly reduced in Group B ($p < 0.05$). Global cross-correlation and clustering analysis showed significant association of differentially regulated pathways with biochemical parameters and markers of fibrosis (Sirius red, TGF-β) ($r^2>0.5$, $p < 0.05$). Protein-metabolite network analysis identified urea cycle (Arginase-1; ARG1), leukotriene metabolism (Arachidonate 5-lipoxygenase; ALOX5), oxidative-stress (Ryanodine receptor 2; RYR2) and tryptophan metabolism (Kynurenine-3-Monooxygenase; KMO) pathways which correlated with α-SMA, PDGFR-β and the degree of liver fibrosis ($r^2>0.75$, $p < 0.05$) and were inhibited with aspirin.

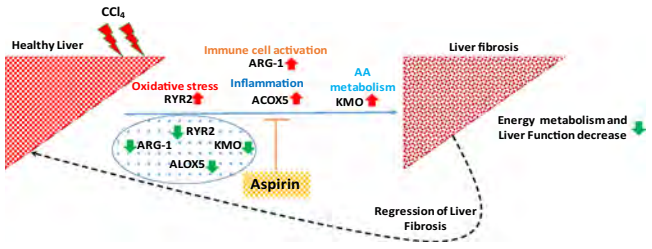

Figure 1 Aspirin mediated decrease in key marker proteins (RYR2, ALOX-5, ARG-1, and KMO) correlates with reduction of liver fibrosis and diseases severity.

Conclusion: Aspirin is effective in regression of hepatic fibrosis in the CCl_4 mouse model. It achieves this by enhancing autophagy and via inhibition of oxidative stress (RYR2), inflammation (ALOX5), urea cycle (ARG1) and tryptophan metabolism (KMO). Aspirin and targets for new identified molecules may serve as new therapeutic options for regression of hepatic fibrosis.

FRI261

Carabin deficiency promotes liver fibrosis via regulating RAS and calcineurin pathway in macrophage

Rong Xue[1], Xuhao Ni[2], Ling Lu[1,2]. [1]*Southeast University, Nanjing, China;* [2]*Nanjing Medical University, Nanjing Shi, China*
Email: xuhaoni@sina.cn

Background and Aims: Liver fibrosis a typical wound-healing response to chronic injury of variety etiologies, which can develop to cirrhosis and carcinoma. Carabin, an endogenous inhibitor of calcineurin (CaN) and Ras, its role in adaptive immune response has been documented, however, much less is known about its role in cells of the innate immune system such as macrophage.
Method: We induced experimental liver fibrosis in mice by intraperitoneal injection of 10% carbon tetrachloride (CCL4) twice a week for 8 weeks. To investigate the role of Carabin in the progression of liver fibrosis, we generated Carabinfl/fl LysMcre mice. Following the establishment of the fibrotic mouse model, hepatic macrophages were isolated.
Results: Carabinfl/fl LysMcre mice exposed to CCl4 were more susceptible to inflammation and fibrosis compared to wild-type counterparts. Carabin invalidation in myeloid cells is enhance inflammation and fibrosis progression. Cultured macrophages from Carabinfl/fl LysMcre mice displayed increased cytokine secretion and polarized toward to M1 or $Ly6^{hi}$ macrophage. Further studied demonstrated that Carabin regulatory macrophage polarization via inhibiting Ras and Calcineurin pathways.
Conclusion: Our findings suggest that Carabin plays a crucial proinflammatory role in liver fibrosis by regulating the Ras and Calcineurin pathways in macrophages and therefore may be a potential therapeutic target for immune-mediated liver fibrosis.

(pro)renin receptor knockdown attenuates liver fibrosis through inactivation of ERK/TGF- ?1/Smad3 pathway

Yun-Cheng Hsieh[1], Kuei-Chuan Lee[1], Keng-Hsin Lan[1], Teh-Ia Huo[1], Yi-Hsiang Huang[1], Ming-Chih Hou[1], Han-Chieh Lin[1]. [1]*Division of Gastroenterology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan*
Email: kclee2@vghtpe.gov.tw

Background and Aims: The (pro)renin receptor (PRR) activation upregulates the expression of profibrotic genes in kidney and heart. We aimed to investigate the role of PRR in hepatic fibrogenesis.
Method: Primary mouse hepatic stellate cells (HSCs) were isolated for PRR expression analysis. Human hepatic PRR levels were measured in patients with or without liver fibrosis. Experimental fibrosis was studied in thioacetamide (TAA)-treated or methionine choline-deficient (MCD) diet-fed C57BL/6 mice. Lentivirus-mediated PRR short hairpin RNA (shRNA) was used to knockdown hepatic PRR expression. A lentiviral vector expressing PRR shRNA from the α-smooth muscle actin promoter was used for HSC-specific gene knockdown.
Results: The PRR is upregulated in the mouse and human fibrotic livers and activated HSCs. Hepatic PRR knockdown reduced liver fibrosis with suppression of HSC activation and profibrotic genes expression in TAA-treated mice without significant changes in hepatic inflammation. The HSC-specific PRR knockdown also attenuated liver fibrosis in TAA or MCD diet-injured mice. Both the mice with HSC-specific and whole liver PRR knockdown down-regulated the hepatic ERK1/2-TGF-β1/Smad3 pathway. Renin or prorenin induced an increase expression of PRR and production of TGF-β1 in LX-2 cells and knockdown of PRR inactivated LX-2 cells with blocking production of TGF-β1 and Smad3 phosphorylation.
Conclusion: (Pro)renin receptor is upregulated in fibrotic livers and activated HSCs, and its downregulation attenuates liver fibrosis through inactivation of ERK1/2-TGF-β1/Smad3 pathway. Thus, PRR is a promising therapeutic target for liver fibrosis.

Diagnostic accuracy of liver stiffness measurement by fibroscan in liver transplant recipients

Zeynep Melekoğlu Ellik[1], Aysun Caliskan[1], Serkan Duman[1], Mesut Gümüşsoy[1], Abdullah Mübin Özercan[1], Ramazan Erdem Er[1], Atilla Halil Elhan[2], Ramazan Idilman[1]. *[1]Ankara University School of Medicine, Gastroenterology, Ankara, Turkey; [2]Ankara University School of Medicine, Biostatistic, Ankara, Turkey*
Email: zeynepmelekoglu33@hotmail.com

Background and Aims: Vibration-controlled transient elastography (TE), is a non-invasive technique, measure the controlled attenuation parameter (CAP) for hepatic steatosis and liver stiffness for liver fibrosis. However, increased body mass index, hepatic steatosis, low fibrosis stage (<2) and the degree of hepatic necroinflammation affect liver stiffness measurement. The aims of the present study were to evaluate utility of TE for assessment liver fibrosis in liver transplantation (LT) recipients and compare the TE and the FIB-4, the APRI results.

Method: Between September 10, 2019 and November 9, 2019, a total of 106 consecutive LT recipients (M/F: 59/47) who had at least 1-year follow-up period underwent liver stiffness measurement by FibroScan with M or XL probe (Echosens, Paris, France). At least ten valid measurements were obtained within 5–10 minutes. APRI and FIB-4 scoring systems were also performed for the evaluation of liver fibrosis in the same time.

Results: The median time interval between LT and FibroScan was 78 months. The cause of LT was HBV-induced cirrhosis in 51 patients (48.1%), cryptogenic cirrhosis in 13 patients (12.3) and HCV-induced cirrhosis in 7 patients (6.6%). Living donor LT was performed on 74 patients (70%) and the remaining 32 had cadaveric donor LT. At the time of the evaluation, the mean age was 55.8 ± 11.6 years, mean body mass index was 26.1 ± 4.5 kg/m^2, and 38% had diabetes mellitus, 26% hypertension, and 25% were current smoker. The median serum AST, ALT and GGT levels were 22 U/L, 18.5 U/L and 29 U/L, respectively.

A median prevalence of 10 valid measurements (IQR) was 14% (4%–36%). The median CAP and liver stiffness values were 252.2 dB/m (range: 100–399) and 5.45 kPa (range: 2.1–30.3 kPa). The median FIB-4, APRI score were 1.44 (range: 0.15–3.92), 0.24 (range: 0.08–1.53) and the median platelet count was 198.500 (range: 50.000–471.000 per/ml), respectively.

A significant correlation among FIB-4, APRI and platelet counts (FIB-4 - APRI: $r = 0.74$, $p < 0.001$ and FIB-4 – platelet count: $r = 0.62$, $p < 0.001$, whereas no correlation was found between liver stiffness at TE and biochemical fibrosis tests (FIB-4 – TE: $r = 0.36$, $p = 0.72$ and APRI – TE: $r = 0.18$, $p = 0.61$).

Conclusion: Based on the results of the present study, liver stiffness measurement by FibroScan seems not to accurately assess graft fibrosis in liver transplant recipients.

Background and Aims: The Enhanced Liver Fibrosis test (ELF) accurately stages fibrosis, is prognostic, and has potential for monitoring treatment response in patients with nonalcoholic steatohepatitis (NASH). Our objective was to evaluate changes in the hepatic transcriptome in patients with advanced fibrosis due to NASH according to improvement in the ELF test.

Method: Patients with advanced fibrosis (F3-F4) due to NASH (NAS ≥3) enrolled in two phase 3, placebo-controlled trials of selonsertib (STELLAR) were included. RNA was isolated from formalin-fixed paraffin-embedded (FFPE) blocks obtained from paired liver biopsies at baseline (BL) and week 48 (W48), sequenced using TruSeq® RNA Exome, and gene expression was quantified using Salmon. ELF was measured at BL and W48. Using Limma-Voom, we evaluated differential gene expression (adjusted p-value cutoff of 0.05) between patients with and without ELF response, defined as a ≥0.5-unit reduction from BL to W48. We overlapped differentially expressed genes with Hallmark gene sets curated by the Broad Institute (MSigDB Collection) and ascertained the significance of the overlap using hypergeometric distribution as implemented in the RITAN package.

Results: A total of 714 patients were included (median age 59 years, 60% female, 50% F4, median BL ELF 10.21 [IQR 9.59, 10.97]). An ELF response was observed in 17% (121/714) of patients (19% with F3 and 18% with F4), of whom 21 patients (17%) had a ≥1-stage improvement in fibrosis without worsening of NASH (histologic response). Differential expression of 486 genes was observed in patients with ELF response; 302 of these genes were also differentially-expressed in patients with histologic response. The cellular pathway that was enriched most significantly in patients with ELF response was related to pro-fibrogenic signaling ($q = 1.26 \times 10^{-20}$); additional enriched pathways are shown in the **Table**. The top differentially expressed genes in ELF responders (adjusted $p < 10^{-5}$) were *AKR1B10*, *LOXL4*, *THBS2*, *COL5A1*, *THY1*, *PDGFA*, *COL1A1*, *TIMP1* (all downregulated), *MT1E, MT1G,* and *GNMT* (all upregulated).

Table. Top differentially-enriched cellular pathways in patients with ELF response

Gene Pathway Enriched in ELF Responders (Number of Genes)	FDR q-value*	
	ELF Responders	Histologic Responders
Pro-fibrogenic signaling (37)†	1.26×10^{-20}	2.65×10^{-13}
Angiogenesis (8)	3.44×10^{-5}	9.25×10^{-9}
Myogenesis (18)	3.44×10^{-5}	2.84×10^{-2}
Apical junction (15)	8.44×10^{-4}	1.25×10^{-3}
KRAS signaling (15)	8.44×10^{-4}	--
p53 pathway (15)	8.44×10^{-4}	3.67×10^{-3}

* P-value adjusted for false discovery rate (FDR).
† Pathway referred to as epithelial to mesenchymal transition in Hallmark gene sets of the Broad Institute.

Conclusion: In NASH patients who experienced improvements in the ELF score, widespread changes in the hepatic transcriptome, particularly in pathways related to stellate cell biology and fibrosis, were observed. These data provide important insights into the pathogenesis of NASH and further support for the utility of the ELF test in monitoring treatment response in patients with advanced fibrosis due to NASH.

Email: barbara.schellhaas@googlemail.com

Background and Aims: Despite its high diagnostic accuracy for the non-invasive diagnosis of hepatocellular carcinoma (HCC) in high risk patients, standardisation of contrast-enhanced ultrasound (CEUS) is insufficient. This prospective multicentre study funded by the German Society for Ultrasound in Medicine (DEGUM) intended to improve standardisation of the CEUS examination procedure, and to assess the diagnostic value of CEUS and the new standardised CEUS-algorithms for non-invasive diagnosis of HCC.
Method: Patients at risk for HCC with histologically proven focal liver lesions upon B-mode ultrasound were prospectively assessed with CEUS following standardised examination protocols in 43 German centres. Clinical data, findings from B-mode ultrasound, CEUS, categorisation according to the CEUS algorithms ESCULAP and CEUS LI-RADS®, and histology were entered into online entry-forms. CEUS-based diagnosis was compared to histology as the reference standard.
Results: 395 patients (male/female = 329/66; mean age, 67.2 ± 10.5 years; liver cirrhosis, 76.5%) were enrolled. Mean tumour size was 57.6 mm (range, 5–200 mm; <2 cm, n = 42; 61.3% solitary). Histological diagnosis was HCC in 316 cases and intrahepatic cholangiocellular carcinoma (ICC) in 26 cases. 271 HCCs (85.8%) displayed arterial phase hyperenhancement; 255 (80.7%) showed contrast washout. The typical "hyper-hypo"-pattern was found in 72.2% of HCCs (positive predictive value, 87.4%), and the "hyper-iso"-pattern in 13.6% (positive predictive value, 86%). 33 HCCs (10.4%) showed late onset of washout after 4–6 minutes. Intensity of washout was mild in 54.7% and marked in 17.4% of HCCs. The highest sensitivity for the diagnosis of HCC was reached with the ESCULAP algorithm (94.2%) and subjective on-site interpretation of CEUS (90.2%). The CEUS LI-RADS® algorithm yielded the highest specificity (81.8%), but poorest sensitivity (61.8%) and negative predictive value (35.3%). The algorithms showed consensus in 67.1% of cases; 1/3 of the HCCs were correctly identified only with ESCULAP.
Conclusion: Arterial phase hyperenhancement is the key diagnostic feature of HCC in CEUS; positive predictive value of the hyper-iso-pattern is similar to that of the hyper-hypo-pattern. The standardised CEUS algorithms add little diagnostic benefit to conventional on-site interpretation of CEUS. Additional late phase assessment of washout after 4–6 minutes increases the diagnostic accuracy of CEUS for HCC and should be routinely performed.

FRI267

Evidence-based dilemma in the image-guided therapeutic management of uncomplicated amoebic liver abscess: a systematic review and meta-analysis

Ramesh Kumar[1], Alok Ranjan[2], Ruchika Narayan[3], Rajeev Priyadarshi[4], Utpal Anand[5]. *[1]AIIMS Patna, Gastroenterology, Patna, India; [2]AIIMS Patna, CFM, Patna, India; [3]Narayan Medical College & Hospital Dehri On Sone, Radiodiagnosis, Jamuhar, India; [4]AIIMS Patna, Radiodiagnosis, Patna, India; [5]AIIMS Patna, Surgical Gastroenterology, Patna, India*
Email: docrameshkr@gmail.com

Background and Aims: Amoebic liver abscess (ALA) continues to be a common problem in *tropical* countries. Role of adjunct ultrasound-guided percutaneous aspiration (PA) or percutaneous catheter drainage (PCD) in the treatment of uncomplicated ALA is still unclear. This systematic review and meta-analysis evaluated the available evidences with regard to image-guided treatment modalities in such patients.
Method: The database was searched for relevant randomized controlled trials (RCTs) comparing metronidazole alone versus metronidazole combined with PA or PCD, published till May 2019. All studies were assessed for risk of bias. The relevant data were pooled in a random or fixed-effect model to calculate the mean difference (MD) or relative risks.
Results: After the detailed screening, 570 patients from 10 RCTs comparing metronidazole alone with metronidazole combined with PA were included. Most studies had uncertain risk of biases. Days to resolution of abdominal pain (MD −1.59, 95% CI −2.77, −0.42, I^2 = 89%) and tenderness (MD −1.76, 95% CI −2.93, −0.58, I^2 = 72%) were significantly shorter in metronidazole + PA group. There was no significant difference in relation to the resolution of fever, abscess size and hospital stays. The beneficial effects of PA were seen with medium-to- large (>5 cm) ALA and not with small (<5 cm) ALA. Addition of PCD to metronidazole therapy was better than metronidazole alone in one low-quality RCT. Two RCTs found adjunct PCD to be better than PA for large ALA.
Conclusion: Metronidazole combined with PA, as compared to metronidazole alone, results in the early resolution of pain and tenderness in patients with medium-to-large ALA. PCD, as compared to PA, is better for drainage of larger ALA. However, discrepancies in RCTs create therapeutic dilemmas necessitating further efforts to generate more reliable data.

FRI269

Ph-responsive polymersomes for matrix metalloproteinase-1 delivery as a promising therapeutic strategy for the treatment of liver fibrosis

Eline Geervliet[1], Silvia Moreno Pinilla[2], Dietmar Appelhans[2], Ruchi Bansal[1]. *[1]University of Twente, Department of Medical Cell BioPhysics, Enschede, Netherlands; [2]Leibniz Institute for polymer research Dresden e.V, Bioactive and Responsive Polymers, Dresden, Germany*
Email: ekgeervliet@gmail.com

Background and Aims: Liver fibrosis is a growing health problem affecting millions of people worldwide. Chronic liver injury leads to the formation of scar tissue due to the excessive accumulation of extracellular matrix, mainly collagen-I and -III produced by activated hepatic stellate cells (HSCs). Currently, there are no therapies available for liver fibrosis. Matrix metalloproteinase-1 (MMP1) is an enzyme that degrades the scar tissue by degrading collagen-I and -III favoring liver regeneration. We hypothesized that liver-specific delivery of MMP1 to degrade collagen as a promising approach for

Table: (abstract: FRI267): Response to Combined Therapy compared to Drug Therapy alone on Qualitative Parameters

*NS: not stated

the treatment of liver fibrosis. Using state-of-the-art technologies, we synthesized innovative pH-responsive smart MMPsomes with the MMP1 decorated on the polymersome surface. Finally, we investigated the therapeutic efficacy of MMP1 and MMPsomes on human HSCs *in vitro* and on liver fibrosis mouse models *in vivo,* and *ex vivo* on fibrotic mouse livers.

Method: Polymersomes were fabricated using the pH switch method and MMP1 post-loading at pH 5–6 was performed to increase the interaction between MMP1 and the polymersome membrane. Physiochemical analysis and enzymatic assays were performed to characterize the attachment and functionalization of enzyme on polymersomes. *In vitro* studies were performed on TGF-beta-activated human HSCs to evaluate the effects of MMP1 and MMPsomes on the cell viability, gene and protein expression of collagen and HSCs activation marker alpha-SMA. Finally, the efficacy of MMP1 and MMPsomes was tested *in vivo* and *ex vivo* on CCl_4-induced liver fibrosis mouse models.

Results: Decoration of MMP1 on the surface of the polymersome was successfully established with an affinity of 30%, without inhibition of function. Synthesized MMPsome hybrid structures showed favorable size (~180 nm at pH 6 and ~140 nm at pH 8) and charge (positive at pH 6 and negative at pH 8). MMP1 and more significantly MMPsomes showed dose-dependent inhibition of collagen-I, -III and α-SMA gene expression, and collagen-I protein expression in TGFβ-activated human HSCs with no significant effects on cell viability. The studies on CCl_4-induced liver fibrosis mouse models have been performed, showed promising preliminary results with no *in vivo* toxicity however still under investigation.

Conclusion: In conclusion, we present an innovative approach of MMP1 delivery for the treatment of liver fibrosis.

FRI270

Diagnostic value of magnetic resonance elastography in cirrhotic portal hypertension

Yu Wang[1], Guanhua Zhang[1], Xuechun Mu[1], Hong Ma[1], Min Wang[1].
[1]*Beijing Friendship Hospital, Capital Medical University, Liver Research Center, Beijing, China*
Email: wangyuliver@126.com

Background and Aims: The liver and spleen stiffness may assess the severity of portal hypertension (PH) because of cirrhosis and

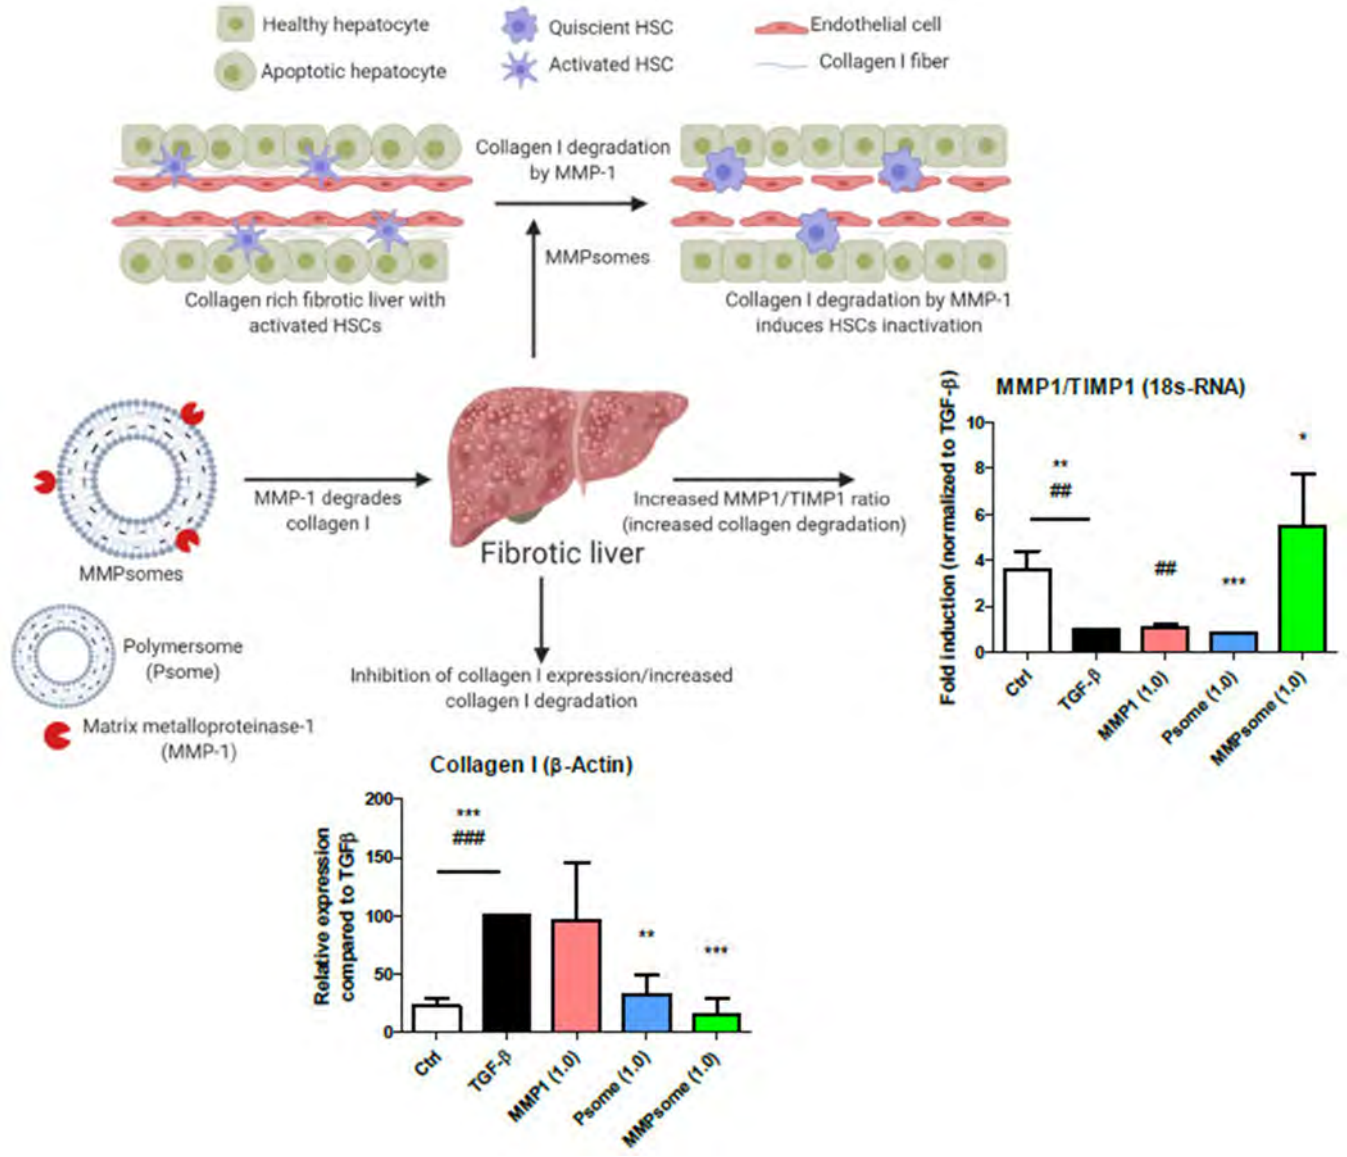

Figure: (abstract: FRI269)

splenomegaly. The aims of this study were to evaluate the diagnostic performance of magnetic resonance elastography (MRE) of the liver and spleen as a noninvasive tool for the severity of portal hypertension in cirrhosis.

Method: The patients with chronic liver disease who underwent hepatic vein pressure gradient (HVPG) measurements were consecutively enrolled in this study from November 2017 to October 2019 in Beijing Friendship Hospital, Capital Medical University. Liver stiffness (MLS) and spleen stiffness (MSS) were calculated by MRE within 1 week prior or inferior to HVPG measurement. The relationship between the liver or spleen stiffness values measured by MRE and the value of HVPG was assessed by using Spearman's correlation analysis. In addition, the diagnostic performances of MRE for predicting the presence of HVPG ≥ 12 mmHg, HVPG ≥ 16 mmHg and HVPG ≥ 20 mmHg were evaluated using area under the receiver operating characteristics curves (AUROCs).

Results: A total of 27 patients were included eventually (mean age: 53.3, 66.6% male). The main liver disease etiologies of the patients included in the study were Hepatitis B virus infection (25.9%)and alcohol (25.9%). There were five patients with HVPG < 12 mmHg and nine patients with HVPG ≥ 20 mmHg. MRE measurements of the liver and spleen stiffness was successfully performed on all patients. There was a significant correlation between spleen stiffness (r = 0.48, p = 0.012) and HVPG measurement. Liver stiffness-MRE was not significantly correlated with HVPG (r = 0.35, p = 0.076). The AUROC analysis is presented in the figure. To diagnose HVPG ≥ 12 mmHg using MSS, we observed AUROC of 0.782 (p = 0.006), sensitivity of 54.5%, and specificity of 100% (using cutoff ≥9.96). To diagnose HVPG ≥ 20 mmHg using MSS, we observed AUROC of 0.806(P < 0.001), sensitivity of 100%, and specificity of 63.2% (using cutoff ≥9.36).

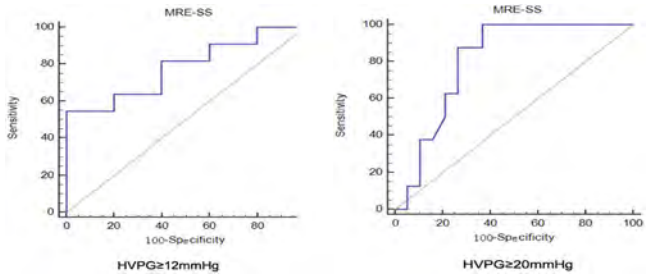

Figure The ROC curves of SS by MRE for the diagnosis of HVPG ≥ 12 and 20 mmHg.

Conclusion: MRE measurement of liver and spleen stiffness is feasible. MSS can diagnose HVPG ≥ 12 mmHg HVPG ≥ 20 mmHg well. But the sample size was small and our results need to be validated in a larger study.

FRI271

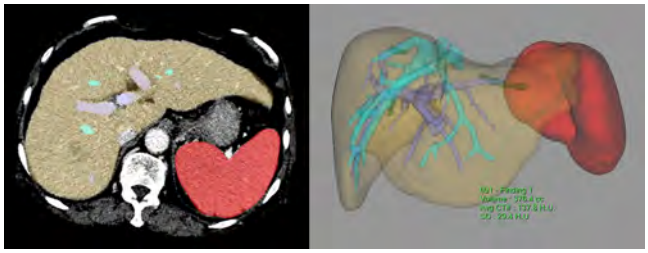
Prognostic value of spleen volume obtained from preoperative computed tomography images in patients with hepatocellular carcinoma

Jae Seok Bae[1], Dong Ho Lee[1]. [1]*Seoul National University Hospital, Radiology, Seoul, Korea, Rep. of South*
Email: jaeseok.bae@gmail.com

Background and Aims: Post-hepatectomy liver failure (PHLF) can occur as a major complication after hepatic resection (HR) for hepatocellular carcinomas (HCCs) and potentially affects the prognosis of patients. The development of PHLF is associated with portal hypertension and ensuing hepatic fibrosis, and portal hypertension is known to be associated with splenomegaly. Recently, it become possible to semi-automatically measure spleen volume using computed tomography (CT) images that are routinely obtained before HR in patients with HCC. However, the clinical importance of the spleen volume measured by using CT images has not been fully evaluated. Therefore, we aimed to assess whether spleen volume measured by using preoperative CT images could have a prognostic impact in patients who underwent HR for HCCs.

Method: We retrospectively enrolled 317 patients with very early or early HCCs who underwent preoperative CT and HR between January 2010 and December 2016. Spleen volume was semi-automatically measured by using the preoperative CT images. Receiver operating characteristics (ROC) curve and logistic regression analyses were performed to identify predictive factors for the development of PHLF. Cox proportional hazard model was used to determine prognostic factors for overall survival (OS).

Results: PHLF was observed in 72 patients (22.7%). The area under the ROC curve of spleen volume for the development of PHLF was 0.657 (p < 0.001). Multivariate logistic regression analysis revealed that operation time, extent of surgery, and spleen volume were associated with the development of PHLF. On survival analysis, serum prothrombin induced by vitamin K absence-II level, HCC size ≥8.6 cm, HCC differentiation, microvascular invasion, and spleen volume ≥214 cm^3 on preoperative CT were significant affecting factors for OS.



Conclusion: Spleen volume measured by using preoperative CT images was associated with the occurrence of PHLF and was a significant predictor for poor OS.

FRI272

Predicting prognosis of hepatocellular carcinomas according to treatments by using hepatobiliary phase images of gadoxetic acid-enhanced magnetic resonance imaging

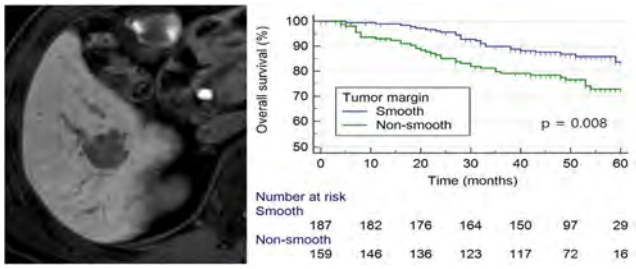
Jae Seok Bae[1], Jung Hoon Kim[1], Dong Ho Lee[1], Jae Hyun Kim[1], Joon Koo Han[1]. [1]*Seoul National University Hospital, Radiology, Seoul, Korea, Rep. of South*
Email: jaeseok.bae@gmail.com

Background and Aims: The prognostic value of hepatobiliary phase (HBP) images of gadoxetic acid-enhanced magnetic resonance imaging (MRI) in patients with hepatocellular carcinomas (HCCs) according to treatments has not been investigated. Therefore, we aimed to predict prognosis in patients with HCCs after different treatments by using HBP images of gadoxetic acid-enhanced MRI.

Method: In this IRB-approved, single-institutional study, we retrospectively enrolled patients with very early or early, treatment-naïve HCCs who underwent gadoxetic acid-enhanced MRI between January 2014 and December 2015. A final cohort comprised of 347 patients with 381 HCCs that were pathologically proven (n = 130) or radiologically diagnosed (n = 251). Two radiologists evaluated the imaging features of HCCs and liver function on HBP images in consensus. Clinical findings were collected as well. Univariate and multivariate Cox proportional hazard models were used to reveal the predictive HBP imaging features of overall survival (OS).

Results: Following treatments were performed: resection (n = 130), radiofrequency ablation (RFA) (n = 96), and transarterial chemoembolization (TACE) (n = 121). Median and mean follow-up periods were 50.0 months (0–66 months, range) and 45.7 ± 15.7 months, respectively. Both in total patients and the resection group, among the HBP imaging features, non-smooth tumor margin (hazard ratio (HR) 3.202, 95% confidence interval [CI]; 1.042–9.839), satellite nodules (HR 3.336, 95% CI; 1.078–10.321), and tumor size (HR 1.023, 95% CI; 1.011–1.036) were shown to be associated with poor OS. In the RFA

group, liver-to-portal vein contrast (slightly hyper, HR 0.016, 95% CI; 0.002–0.781; hyper, HR 0.007, 95% CI; <0.001–0.778), and peritumoral hypointensity (HR 10.627, 95% CI; 1.483–76.134) were associated with OS. In the TACE group, tumor size was a predictor of poor OS (HR 1.014, 95% CI; 1.004–1.023). Among clinical findings, bilirubin, prothrombin time, creatinine, and alpha-fetoprotein were associated with OS.



Conclusion: Non-smooth tumor margin, satellite nodules, and larger tumor size on HBP images were independently associated with poor OS in both total patients and the resection group. Better liver function was associated with better OS in the RFA group, and larger tumor size was associated with poor OS in the TACE group.

FRI273

Kahweol activates Nrf2/HO-1 by a pathway different from p62 and autophagy dependent degradation

Hye-Young Seo[1], So-Hee Lee[1], Ji-Ha Lee[1], Jae-Seok Hwang[1], Mi-Kyung Kim[1], Byoung Kuk Jang[1]. [1]*Keimyung University School of Medicine, Department of Internal Medicine, Daegu, Korea, Rep. of South*
Email: jangha106@dsmc.or.kr

Background and Aims: Kahweol is a coffee-specific diterpene found in coffee beans and present in unfiltered coffee drinks. Several studies demonstrated that kahweol induces Nrf2/HO-1 pathway. However, the mechanism by which kahweol increase Nrf2/HO-1 is unknown. Keap1 is one of the major regulators of Nrf2 expression and is known to be degraded mostly by autophagy. In this study, we investigated that kahweol is associated with a decrease in keap1 protein expression.

Method: Hepatocyte-specific ATG7 knockout mice were generated by crossing ATG7 Flox/Flxo mice with albumin Cre mice. We isolated and cultured ATG7K/O mouse primary hepatocyte, mouse primary hepatocyte and AML12 cells. The expression levels of HO-1, p62 and keap1 were measured by real-time RT-PCR analysis. The expression levels of HO-1, Nrf2, p62, keap1 and autophagye marker were measured by western blot analysis.

Results: Kahweol significantly increase HO-1, Nrf2 and p62 expression. In order to examine whether p62 mediates HO-1 expression because Nrf2- is activated by p62, siRNA targeting p62 was performed. Even if p62 is inhibited, kahweol still increases HO-1 expression. Next, we examined the effect of kahweol on keap1 expression. Kahweol decreased deap1 protein expression, but not decrease keap1 mRNA levels. To determine if kahweol degrades keap1, we examined ubiqutination and autophagy. Kahweol did not affect ubiqutination, but rather reduced autophagy-related proteins. In addition, kahweol also decreased keap1 protein expression in primary hepatocyte of ATG7 knockout mice.

Conclusion: This study shows that kahweol decreased keap1 protein expression in primary hepatocyte and AML12 cells. The keap1-Nrf2-pathway by p62 dependent autophagy is well known. However, it was confirmed that the reduction of keap1 by kahweol was not due to p62, ubiquitin and autophagy degradation. Further research is needed to determine whether kahweol regulates the translation of keap1.

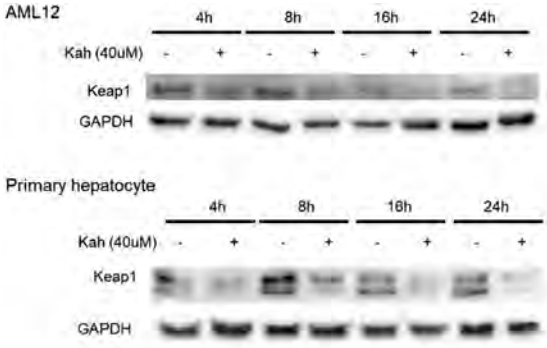


Figure. Kahweol reduces keap1 protein expression

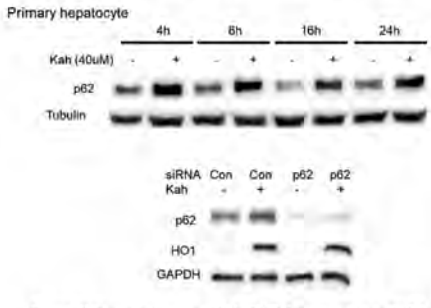

Figure. Kahweol increases p62, but HO-1 increase even if p62 decreases.

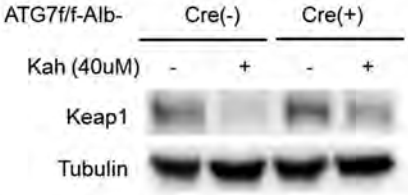

Figure. Kahwoel reduces keap1 in primary hepatocyte of ATG7 knockout mice.

Email: jeongwk@gmail.com

Background and Aims: The recently released contrast-enhanced ultrasonography Liver Imaging Reporting And Data System (CEUS LI-RADS) v2017 uses pure blood-pool agent only. This study aimed to evaluate CEUS feature using Sonazoid® for liver nodules with possibility for hepatocellular carcinoma (HCC) and to assess the diagnostic value of modified CEUS LI-RADS applied Kupffer phase image.
Method: This retrospective study included 228 patients at high risk for HCC who underwent CEUS using Sonazoid® between January 2013 and December 2016 in our tertiary institution. Total 235 nodules were classified as HCC group (n = 76) and indefinite HCC group (n = 159). HCC group is defined as pathologically proven HCC and/or CT/MRI LR-5; otherwise, classified into indefinite HCC group including LR-3/4 and LR-M. CEUS features were compared among two groups using t-test or Mann-Whitney test, and Chi-square or Fisher's exact test. And we have defined modified CEUS LI-RADS of which "Kupffer phase defect" is an alternative to "late and mild washout" of CEUS LI-RADS, and compared the diagnostic performance among two systems.
Results: The median nodule size on B-mode was 1.3 cm (range, 0.7–5 cm). Arterial phase hyperenhencement (88.2% vs. 73.0%, p = 0.009) were more frequent in HCC group than in indefinite HCC group. HCC group more frequently showed Kupffer phase defect (90.8% vs. 80.5%, p = 0.045) than indefinite HCC group, but there was no significant difference among two groups in late and mild washout (76.3% vs. 68.6%, p = 0.220). Modified CEUS LI-RADS showed higher sensitivity (80.3% vs. 69.7%), accuracy (70.2% vs. 68.1%), positive predictive value (52.6% vs. 50.5%), and negative predictive value (87.4% vs. 82.3%) compared to CEUS LI-RADS.
Conclusion: Kupffer phase defect could improve sensitivity for HCC diagnosis than late and mild washout and applying Kupffer phase defect in LI-RADS could aid in enhancing the diagnostic value.

Email: mikael.sawatzki@kssg.ch

Background and Aims: Colorectal carcinoma (CRC) is the second leading cause of cancer mortality in the world and up to 25% of patients with CRC have liver metastases (CRLM) at initial diagnosis. Early detection of CRLM is important for prognosis and therapeutic strategies. Contrast-enhanced CT may miss up to 30% of liver metastases. The objective of this prospective study was twofold: first, to assess the impact of contrast-enhanced ultrasound (CEUS) on the detection rate of CRLM compared to standard staging-CT; and second, to evaluate the resulting impact of CEUS on changes of therapeutic strategies.
Method: We prospectively analysed all patients with newly diagnosed CRC at our tertiary gastroenterological centre between December 2015 and May 2019. All patients with newly diagnosed

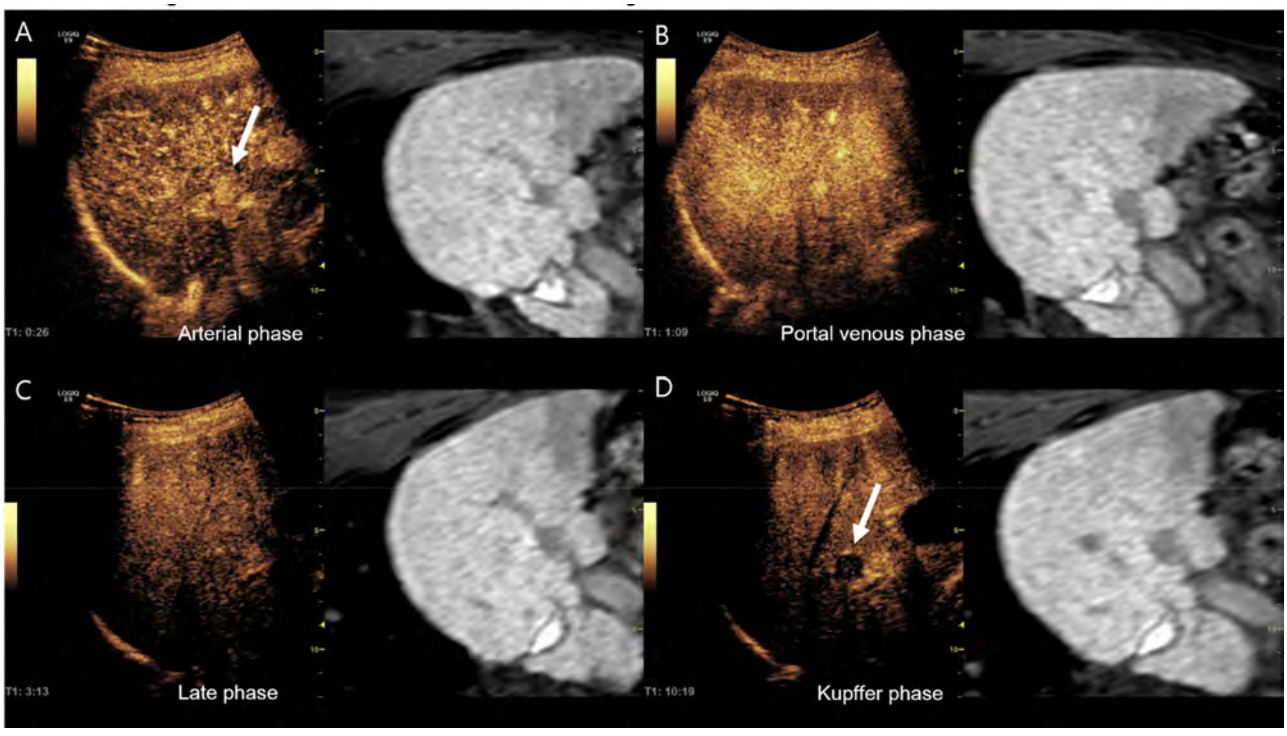

Figure: (abstract: FRI274): Sonazoid®-enhanced US with imaging fusion technique for CT/MRI LI-RADS LR-5 nodule in a 68-year-old woman with chronic viral hepatitis B. (A) Arterial phase image shows about 1.2 cm hyperenhancing liver nodule (arrow) in hepatic segment VII. (B-C) Portal venous and late phase images show no late and mild washout. (D) There is Kupffer phase defect (arrow). The liver nodule was assigned LR-5 according to modified CEUS, but LR-4 according to CEUS LI-RADS.

CRC by colonoscopy and histology without CRLM or with unclear (benign or malignant) focal liver lesions in CT were recruited. CEUS was performed by a single experienced hepatologist to avoid interobserver variation using renal-independent 0.8 to 1.5 ml intravenous contrast agent (SonoVue ®) with intermittent ultrasound scanning up to 5 minutes. Standard of reference (SOR) was obtained by MRI or histology (if CRLM was detected).

Results: We enrolled prospectively 296 patients (median age of 68 years) into this study. Eight additional CRLM were detected by CEUS (2.7%). CT had misdiagnosed these CRLM as hemangioma or as unclear focal liver lesions. The number needed to screen to detect one additional CRLM by CEUS was 37 patients. When results were reviewed by a board certified radiologist and oncologist, the therapeutic strategy changed in 6 of these 8 patients. All patients with CRLM detected by CEUS only were staged pT3 or pT4 CRCs. Among the 58 patients with focal liver lesion (FLL) of unknown dignity after CT, CEUS demonstrated benign FLL (hemangioma, cyst, focal liver (non)-steatosis and focal nodular hyperplasia) within 5 minutes in 90% of the patients.

Conclusion: In this study, CEUS detected 2.7% additional CRLM with a significant impact on the oncological therapeutic strategy for 75% (6/8) of these patients. Given a number needed to screen of 37 patients, CEUS may be cost-effective. Especially patients with CRC stage pT3 or pT4 seem to benefit from additional CEUS. Focal liver lesions of uncertain dignity after CT staging were determined as benign by CEUS in 90% of the cases.

Overall, CEUS appears to be a valuable and cost-effective diagnostic tool in patients with newly diagnosed CRC.

Rare liver diseases (including pediatric and genetic)

Email: a.felzen@umcg.nl

Background and Aims: Bile Salt Export Pump deficiency (BSEP-def), caused by mutations in *ABCB11*, frequently leads to end-stage liver disease and need for liver transplantation. Patients with homozygous (HO) p.D482G or p.E297G mutations have a relatively mild phenotype

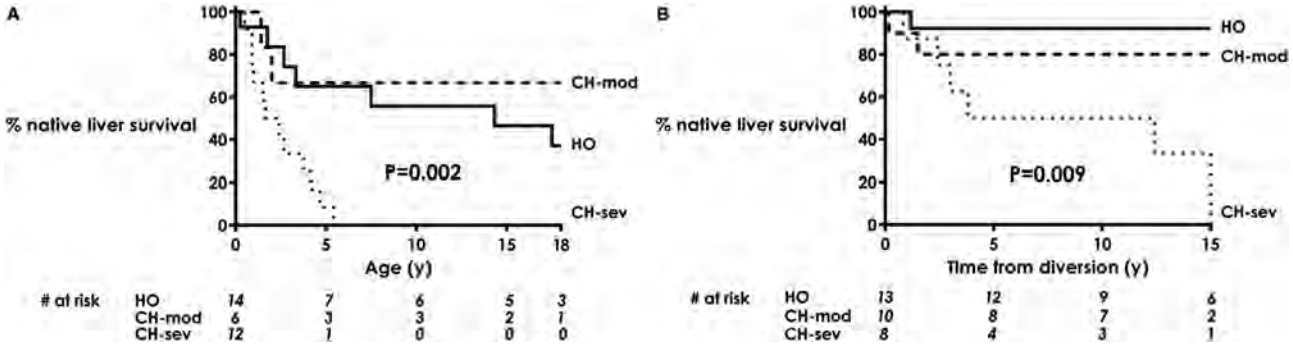

Figure: (abstract: FRI276): A: Native liver survival in patients with a homozygous (HO, solid line), compound heterozygous moderate (CH-mod, dashed line) or compound heterozygous severe (CH-sev, dotted line) genotype, without surgical biliary diversion. B: Native liver survival after surgical biliary diversion in patients with a homozygous (HO, solid line), compound heterozygous moderate (CH-mod, dashed line) or compound heterozygous severe (CH-sev, dotted line) genotype. Log-rank tests.

(Hep 2019;70:S1,48A). Serum bile acid (sBA) levels after surgical biliary diversion (SBD) allow prediction of subsequent survival with native liver (NLS, J Hep 2019;70:S1, e121). We aim to further specify genotype-phenotype relationships in compound heterozygous (CH) patients with one p.D482G or p.E297G mutation.

Method: From our global database we selected all HO p.D482G or p.E297G patients (n = 28) and CH patients in which one mutation was either p.D482G or p.E297G (n = 41). CH patients were further subdivided into two groups according to predicted genotypic severity: moderate (CH-mod; missense mutation, not p.D482G/p.E297G; n = 18) and severe (CH-sev; non-functional protein; n = 23). We compared biochemistry, SBD, post-SBD sBA levels and NLS. Continuous variables are expressed as median [IQR]. Appropriate non-parametric tests and log-rank tests were used.

Results: At presentation (median age < 1 y), liver tests were elevated, most pronounced in the CH-sev group (AST: 425 [170–762] IU/L in CH-sev; 218 [68–359] in HO; 169 [96–249] in CH-mod; P = 0.02). The groups did not differ in proportion of patients undergoing SBD (at age 5 y: 44–60%, P = 0.69). In patients without SBD, NLS was lowest in patients with a CH-sev genotype (NLS at age 15 y: 0% vs. 56% in HO and 67% in CH-mod; P = 0.002, Fig A). Post-SBD sBA levels were associated with NLS (NLS at 15y post-SBD: 95% at sBA <102 uM vs. 40% at ≥102 uM). The percentage of patients that obtained a post-SBD sBA <102 uM correlated with the severity of the second mutation (17% in CH-sev; 60% in CH-mod; 93% in HO; P = 0.001). NLS after SBD was markedly lower in CH-sev patients (NLS 15y post-SBD: 33% in CH-sev; 80% in CH-mod; 94% in HO; P = 0.004, Fig B). Mortality was comparable (0–7%, P = 0.25).

Conclusion: We were able to specify genotype/phenotype relationships in patients with compound heterozygous p.D482G or p.E297G *ABCB11* mutations. The severity of mutation on the second allele impacts the phenotype with regard to native liver survival and chance on long-term benefit of biliary diversion. Here we show, for the first time, that both alleles contribute and that the predicted total amount of residual function is critical to the phenotype.

FRI277

Proteostasis improvement in cystic cholangiocytes alleviates endoplasmic reticulum stress and halts polycystic liver disease

Email: jesus_banales@yahoo.es

Background and Aims: Polycystic liver disease (PLD) is a group of genetic disorders characterized by bile duct dilatation and/or progressive development of multiple intrahepatic biliary cysts (>10), which are the main cause of morbidity. Current surgical and/or pharmacological therapies exert modest benefits, and thus liver transplantation represents the only curative option. Recently, novel PLD-causative genes, encoding for endoplasmic reticulum (ER)-resident proteins involved in protein biogenesis and transport, were identified. Here, we hypothesized that PLD arises as a consequence of aberrant proteostasis in cystic cholangiocytes, representing a potential target for therapy.

Method: ER stress was assessed at transcriptional (qPCR), proteomic (mass spectrometry), morphological (transmission electron microscopy; TEM) and functional (20S proteasome activity) levels in different models of PLD (i.e., human and rat). Moreover, PCK rat (animal model of PLD) was employed to determine the effects of the ER stress inhibitor 4-phenylbutyric acid (4-PBA) and/or inducer tunicamycin (TM), in the progression of the disease. The impact of the aforementioned ER stress modulators was also analyzed on the expression of unfolded protein response (UPR) factors, the 20S proteasome activity, the mechanisms involved in the maintenance of ER proteostasis and the cell fate decisions (i.e., survival/apoptosis).

Results: The expression levels of the UPR factors were markedly upregulated in liver tissue from PLD patients and PCK rats, as well as in primary cultures of human and rat cystic cholangiocytes, compared to normal controls. Cystic cholangiocytes showed altered proteomic profiles, mainly related to proteostasis (i.e., synthesis, folding, trafficking and degradation of proteins), marked enlargement of the ER lumen (by TEM), and hyperactivation of the 20S proteasome. Notably, chronic treatment of PCK rats with 4-PBA decreased liver weight, as well as both liver and cystic volumes, of animals under baseline or TM administration compared to control groups. *In vitro*, 4-PBA downregulated the expression (mRNA) of UPR effectors, normalized proteomic profiles related to protein synthesis, folding, trafficking and degradation, and reduced the proteasome hyperactivity in cystic cholangiocytes, reducing their hyperproliferation and apoptosis.

Conclusion: Restoration of proteostasis in cystic cholangiocytes with 4-PBA halts hepatic cystogenesis, emerging as a novel therapeutic strategy.

Background and Aims: Oxaliplatin (OX) the most widely chemotherapeutic agent used in neo and adjuvant colon cancer (CRC), has been described as a potential etiologic agent for portosinusoidal vascular disease (PSVD). We aimed to describe the natural history of PSVD associated to OX (PSVD-OX) and identify risk factors for development.
Method: Multicenter, retrospective case-control study with patients diagnosed of PSVD-OX included in REHEVASC registry, with a history of exposure to OX and CRC. Baseline data (B), end of treatment (END-OX), years of follow up and end of follow up/diagnosis PSVD (F-PSVD) were collected and compared to 1.3 ratio controls (CRC without PSVD), matched by baseline characteristics, OX-dose and time of follow up.
Results: 41 cases were identified with a mean age of 56.6 ± 10.2 years, male sex 53.7%, rectum-sigma location (58.5%), liver metastases (26.8%), OX dose (median,range) = 1364.5 mg (705–17784 mg), anti-angiogenic agents (14.6%). The mean time to PSVD diagnosis after the end of OX was 33.7 ± 26.9 months, mostly asymptomatic, while 31.7% had complications of portal hypertension as first manifestation.15 patients presented gastrointestinal bleeding, 14 ascites and 9 thrombosis portal. In cases, platelet count (PLT) was markedly decreased from B to END-OX ($\times 10^9$/L): 269 ± 104 vs 120 ± 46; p = 0.0001 not recovering during follow-up and F-PSVD (269 ± 105 vs 102 ± 36; p = 0.0001). The 123 controls, PLT decrease was significantly lower and recovered during follow-up: B vs END-OX vs F-PSVD (274 ± 84 vs.142 ± 64, vs. 188 ± 73, p < 0.0001). At the first year post-OX, 29% of cases had <100 × 10^9 PTL vs 5% of controls (p < 0.001). Delta-PLT at END-OX and first year was significantly higher in cases (-149 ± 96 vs – 132 ± 93 × 10^9/L, p < 0.0001) and kept falling until F-EVPS Delta – 16 ± 6 × 10^9/L, while increased in controls +54 ± 71 × 10^9/L, p = 0.0001. Splenic longitudinal diameter (SLD) increased in cases respect B to END-OX and F-PSVD (cm) (10.7 ± 1.8 vs.12.8 ± 2.3 vs.14.8 ± 2.6; p <0.0001) and higher (p <0.001) than control group (END-OX 9.5 ± 1.5 and F-PSVD 9.8 ± 2.7, p < 0.001). Regarding markers of risk of PSVD development, SLD was the only variable that significantly persisted throughout the follow-up (multivariate analysis OR 0.596 (0.449–0.790); p < 0.0001), while PLT was only significant at END-OX OR 1.008 (1.000–1.016) p = 0.05. The increase in SLD was the strongest predictor of PSVD during treatment OR 43.94 (14.48–133.336) p < 0.0001, and Delta-SLD > 3.1 cm, at the first year post-OX had an AUROC = 0.855 S = 0,99 and E = 0.67, (p < 0.001) for PSVD; while Delta-PLT>-202 × 10^9, the AUROC = 0.653 with S = 0.92 E = 0.75 p < 0.007.
Conclusion: Low platelet count and the increase in SLD maintained after OX can be considered risk factors for PSVD and therefore, these patients could be candidates for a specific follow-up of portal hypertension complications.

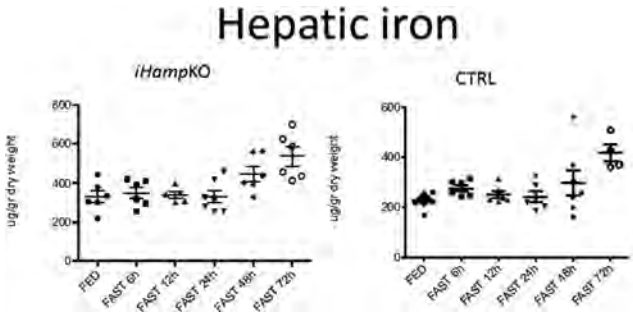
Cross-talk between regulation of iron homeostasis and gluconeogenesis in a murine model of hereditary hemochromatosis

Elena Buzzetti[1], Cinzia Garuti[1], Chiara Vecchi[1], Giuliana Montosi[1], Mauela Sabelli[1], Paolo Ventura[1], Andrew Armitage[2], Elena Corradini[1], Alexander Drakesmith[2], Antonello Pietrangelo[1]. *[1]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences SMECHIMAI, Division of Medicine and CeMEF, Modena, Italy; [2]University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom*
Email: buzzetti.elena@gmail.com

Background and Aims: The relationship between glucose homeostasis and iron metabolism has been increasingly studied over recent years. We have previously shown that hepcidin, the iron-hormone defective in hereditary hemochromatosis (HH), is up-regulated by glucogenic signals and its target-receptor, ferroportin, down-regulated, thus leading to liver iron overload and suggesting a defensive response, led by hepcidin, to metabolic stress. Since patients with HH may present diabetes and metabolic alterations, we wondered whether hepcidin deficiency per se might represent a pathogenic co-factor. We therefore studied adaptation to starvation, a model for insulin-resistance and activated gluconeogenesis, in murine HH.
Method: Eight to 10-week-old male conditional Hamp-/- (iHampKO) or control (CTRL) mice were first i.p. injected with tamoxifen, to induce hepcidin gene deletion in iHampKO, and then starved up to 72 hours or fed a standard diet. Biochemical, nutritional, serum and tissue iron parameters were determined. The expression of genes involved in iron metabolism and gluconeogenic response was assessed by qRT-PCR and western-blot analysis
Results: Starvation induced gluconeogenic genes Pepck and Pgc1a in CTRL mice, but such increase was delayed and less prominent in iHampKO mice. Mortality was not significantly different between groups. Serum glucose decreased gradually and equally in both iHampKO and CTRL mice with progression of starvation (p < 0.0001). In iHampKO mice serum iron decreased during starvation (p < 0.0001) whereas, in spite of hepcidin deficiency and consequent ferroportin up-regulation, hepatic iron progressively increased as compared to fed iHampKO mice, particularly at 72 hours (starved vs fed mice, p = 0.005), similarly to CTRL mice. Such hepatic iron accumulation was not due to upregulation of iron importers, as confirmed by unchanged levels of Tfr1 and Zip 14 mRNA expression and/or protein.



Conclusion: In murine HH, gluconeogenic gene response is partly blunted but preserved, and metabolic compensation or overall survival are not negatively affected. This indicates that hepcidin deficiency per se in HH does not impair metabolic adaptation.

Interestingly, hepatic iron overload during starvation seems due to iron retention, independent on the hepcidin-ferroportin axis,likely aimed at preserving iron for vital energetic functions. Studies are ongoing to dissect the molecular basis for this novel regulatory pathway.

Custom-designed next generation sequencing panel for genotype identification in cholestasis

Carola Dröge[1], Patrick Petzsch[2], Lena Peitzmann[2], Karl Köhrer[2], Dieter Häussinger[1], Verena Keitel[1]. *[1]University Hospital, Heinrich Heine University, Department of Gastroenterology, Hepatology, and Infectious Diseases, Düsseldorf, Germany; [2]Heinrich Heine University, Biological and Medical Research Centre (BMFZ), Genomics & Transcriptomics Laboratory, Düsseldorf, Germany*
Email: carola.droege@med.uni-duesseldorf.de

Background and Aims: Inherited cholestatic liver diseases of varying severity were linked to genetic variants in ATP8B1 (FIC1), ABCB11 (BSEP), and ABCB4 (MDR3) in the late nineties. Moreover, using next generation sequencing (NGS) techniques, genetic variants in further genes, such as NR1H4 (FXR), TJP2, and MYO5B were identified as molecular basis for intrahepatic cholestasis of varying severity. Genetic analysis represents an important tool not only to confirm clinical diagnosis but also for individual surveillance strategies and targeted therapeutic approaches.
Method: We created a custom-designed NGS panel comprising coding sequences and flanking intronic regions of more than 30 genes and over 16 specific hot spot regions. The panel includes genes known to be related to mono- and polygenetic cholestatic liver diseases as well as possible candidate genes involved in hepatobiliary transport and therefore cholestasis. The hot spots comprise specific genetic variants, which may affect progression of liver diseases acting as disease modifiers.
Results: Over 300 NGS analyses were performed for patients with intrahepatic cholestasis and a suspected genetic contribution. More than 100 different potentially pathogenic variants were detected in the cholestasis-associated genes ATP8B1, ABCB11, ABCB4, NR1H4, TJP2 and MYO5B including 18 novel variants. About one third of the analysed patients revealed at least two heterozygous variants in different cholestasis-associated genes suggesting that this complex genotype may be sufficient to elicit a cholestatic phenotype besides homozygous or compound heterozygous variants in one gene. Moreover, variants in TJP2 and MYO5B may also result in milder forms of cholestasis such as a benign recurrent intrahepatic cholestasis (BRIC)-like phenotype as described for ATP8B1 and ABCB11.
Conclusion: We created a custom-designed NGS panel to determine the genetic contribution in patients with cholestatic disorders. NGS analysis of cholestasis-associated genes underscores that multiple variants in different cholestasis-associated genes may cause a cholestatic phenotype. Furthermore, milder forms of cholestasis like BRIC may also be related to genetic variants in TJP2 and MYO5B.

FRI281

ABCB4/MDR3 gene mutations in young patients with symptomatic cholelithiasis

Catarina Gouveia[1], Margarida Flor de Lima[2], Flávio Pereira[3], Bruno Rosa[4], Maria Antonia Duarte[2], António Banhudo[3], José Cotter[4], Alexandre Ferreira[1], Marília Cravo[1], Joana Nunes[1]. *[1]Beatriz Ângelo Hospital, Gastroenterology, Lisboa, Portugal; [2]Divido Espirito Santo Hospital, Gastroenterology; [3]Amato Lusitano Hospital, Gastroenterology; [4]Senhora da Oliveira Hospital, Gastroenterology*
Email: catarinagouveia228@gmail.com

Background and Aims: Low phospholipid-associated cholestasis and cholelithiasis syndrome (LPAC) is characterized by recurrent symptomatic cholelithiasis in young adults and is associated with mutations of the *ABCB4/MDR3* gene. The **primary aim** of our study was to evaluate the prevalence of ABCB4/MDR3 mutations in patients with symptomatic cholelithiasis before 30 years of age.
Method: We conducted an interim analysis of a prospective study, since January 1, 2017, including patients with symptomatic cholelithiasis before 30 years of age from 4 Portuguese centers. Patients' clinic and demographic data was collected, and *ABCB4/MDR3* gene was analyzed by next generation sequencing including all exons and flanking regions. In addition, other intra-hepatic cholestasis associated genes (*ABCB11, ATP8B1*) were also analyzed in one center.
Results: We have included 30 patients, 23 of them women, mean age 28 ± 8 years (min 13, max 49). Mean age of symptoms onset was 23 ± 4 (min 11, max 30). Most frequent clinical presentation was biliary colic (n = 10), followed by choledocholithiasis (n = 8) and acute cholecystitis (n = 5). Seven patients had family history of biliary symptoms (1st degree relatives). Twenty-three patients were submitted to cholecystectomy, and thirteen (57%) had symptoms/complications recurrence after surgery. Two patients had liver echogenic foci suggestive of intrahepatic lithiasis or sludge in abdominal imaging. Eighteen (60%) patients met clinical criteria for LPAC syndrome – 7 of them (39%) had *ABCB4* mutations (2 in homozygosity, 4 in combined heterozygosity, 1 single *ABCB4* heterozygous missense variant) and 1 had a single heterozygous missense variant in the *ABCB11* gene. Of the 12 patients who didn't meet clinical criteria for LPAC syndrome – 1 had a single *ABCB4* heterozygous missense variant and 3 had missense variants in the *ATP8B1* gene (1 in homozygosity and 2 in heterozygosity). Fourteen patients had other risk factors for cholelithiasis (obesity, combined oral contraceptives, postpartum, dyslipidemia, diabetes) – 3 (21%) of them had gene mutations (2 in *ABCB4* and 1 in *ATP8B1*). We found a tendency for association of 1st degree relative family history and ABCB4 mutation (p = 0,06), in fact 3 patient relatives tested positive for the same mutation. Overall prevalence of ABCB4 gene mutations was 27% (8/30) and of cholestasis related gene mutations was 47% (8/17). Eleven patients were put on ursodeoxycholic acid (8–15 mg/Kg/day) and had no symptom recurrence since. Median follow up time was 25 months.
Conclusion: We found a high prevalence of mutations in *ABCB4/MDR3* and cholestasis associated genes in general in patients with symptomatic cholelithiasis before 30 years of age – 27% and 47%, respectively. This highlights the importance of these entities, often underdiagnosed and with available and effective therapy to prevent complications in these patients.

FRI282

Efficacy of zinc on human hepatic copper uptake depending on zinc type and dose regimen quantified with 64-CuCl2 PET/CTscan

Ditte Emilie Munk[1], Tea Lund Laursen[1], Hendrik Vilstrup[1], Peter Ott[1], Lars Gormsen[2], Thomas Damgaard Sandahl[1]. *[1]Aarhus University Hospital, Hepatology & Gastroenterology, Aarhus N, Denmark; [2]Aarhus University Hospital, Nuclear Medicine & PET-centre, Aarhus N, Denmark*
Email: dittmu@rm.dk

Background and Aims: Zinc is used in the treatment of Wilson's disease (WD) and works by blocking intestinal copper uptake. Current recommended dose is 50 mg thrice daily with a one hour fast before and after. Different types of zinc salts exist but only one, zinc acetate (Zn-ac), is approved as treatment of WD. Our aim was to investigate the effect of different zinc types and dose regimens on hepatic copper uptake.
Method: In an interim analysis, we included the first 15 healthy individuals in a randomized, non-blinded clinical trial. Hepatic copper uptake was determined with 64-Cu PET/CT scans before and after four weeks of treatment with either Zn-ac 50 mg × 3 daily, Zn-ac 150 mg × 1 daily or zinc gluconate (Zn-glu) 150 mg × 1 daily. The effect was quantified as the relative difference in mean standard uptake value in the liver.
Results: The effect on copper uptake varied substantially among the individuals, and 3/15 participants had no effect. The mean ratio was

0.39 (SD: 0.19) for Zn-ac 50 mg × 3, 0.60 (SD: 0.35) for Zn-ac 150 mg × 1, and 0.90 (SD: 0.23) for Zn-glu 150 mg × 1, indicating that all treatments lowered hepatic copper uptake. There was no significant difference in the effect on copper uptake between Zn-ac thrice or once daily (p = 0.26), or between Zn-ac and Zn-glu once daily (p = 0.15). There was a difference between Zn-ac thrice and Zn-glu once daily (p < 0.05).
Conclusion: The effect of zinc treatment on hepatic copper uptake is highly variable but quantifiable by 64-Cu PET/CT scan, indicating that efficacy evaluation by 64 Cu-PET/CT is advisable in WD. Zinc thrice daily was not significantly different than once daily as long as the zinc type was Zn-ac.

FRI283
High burden of future liver disease in intrahepatic cholestasis of pregnancy patients
Erica Monrose[1,1], Anthony Bui[1], Emma Rosenbluth[1], Tatyana Kushner[1].
[1]*Icahn School of Medicine at Mount Sinai, New York, United States*
Email: erica.monrose@gmail.co

Background and Aims: Intrahepatic cholestasis of pregnancy (ICP) occurs in 0.3% of all pregnancies and may be linked to future liver disease. There are currently no guidelines for liver follow up care for women with ICP. Using a cohort of women with ICP and controls, we investigated incidence, predictors, and time to future liver disease.
Method: We conducted a retrospective cohort study of pregnant women with and without ICP who delivered between 2005–2009 at a community hospital in New York City with a high prevalence of ICP (2.5% of all deliveries). Women returning for care with liver function tests at a minimum 6 months post-partum were included in the analyses. We examined prevalence and time to the development of two outcomes: (1) ALT > 25 U/L (the upper limit of normal) and (2) diagnosis of liver disease (through imaging or clinical evaluation). Analyses were performed using Kaplan Meier methods and we fit Cox regression models.
Results: We identified 255 women with ICP and 100 control patients who returned to care within the study period. Subjects in both groups were similar in median follow up time, median age at time of pregnancy, median pre-pregnancy body mass index (BMI) and 80% or more of women in both groups identified as Hispanic.
Adjusting for metabolic factors including ICP diagnosis, ethnicity, diabetes status, BMI, maternal age, ICP diagnosis and class A2 gestational diabetes (GDMA2) diagnosis are associated with increased incidence of ALT > 25 U/L postpartum (HR 2.7, p < 0.0001 & HR 1.6, p = 0.02). For ICP and control women with ALT > 25 U/L, the median time to ALT > 25 U/L was 4.4 & 11.9 years respectively (p < 0.0001).
60 (24%) ICP patients and 19 (19%) controls were diagnosed with liver disease, the most common disease diagnosis being NAFLD. Adjusting for metabolic factors listed above, ICP is associated 1.8 times increased incidence of liver disease (p = 0.031), advanced maternal age is associated with 2.0 times increased incidence (p = 0.026), and Hispanic ethnicity is associated with decreased incidence of liver disease (HR 0.61, p = 0.032).
Conclusion: ICP diagnosis was found to be an important predictor of risk of future liver disease and abnormal liver tests. Women with pregnancies complicated by ICP, particularly those with GDMA2, and older than 35 at the time of ICP diagnosis could possibly benefit from surveillance for post-partum liver disease.

Email: haaike.colemonts-vroninks@vub.b

Background and Aims: Hereditary tyrosinemia type 1 (HT1) patients are unable to fully break down L-tyrosine due to a deficient fumarylacetoacetate hydrolase (FAH) enzyme. Consequently, they suffer from a chronic loss of hepatocytes leading to cirrhosis and hepatocellular carcinoma. Nowadays, most patients are treated with the drug nitisinone that installs a metabolic roadblock by inhibiting the 4-hydroxyphenylpyruvate dioxygenase (HPD) enzyme upstream of FAH. In this study, we investigated the impact of nitisinone treatment and discontinuation on the serum metabolome of healthy wildtype (WT) and Fah-deficient mice by untargeted metabolomics.
Method: Fah^{5981SB} mice bear a single point mutation in the FAH gene, leading to an inactive protein that degrades. Serum was collected from Fah^{5981SB} and WT mice that received drinking water ad libitum supplemented with 8 mg/L nitisinone and from mice that were discontinued from nitisinone for seven consecutive days. Serum from untreated WT served as healthy control. On these samples, unbiased small molecule profiling was performed by high-resolution mass spectrometry using an Agilent 6550 QTOF-MS. Peak alignment, data normalization, compound identification and statistical analyses were performed using Progenesis QI software.

Table 1: (abstract: FRI283): Results of the Cox proportional hazards regression model

	Time to Liver disease				Time to ALT> 25 U/L		
Covariates	Hazard Ratio	95% CI	p value		Hazard Ratio	95% CI	p value
Hispanic ethnicity	0.61	0.39, 0.96	**0.032**		0.93	0.81, 1.1	0.25
Advanced Maternal Age (≥35 years)	2.0	1.1, 3.7	**0.026**		1.2	0.80, 1.8	0.40
GDMA2 diagnosis in current pregnancy	1.6	0.76, 3.3	0.22		1.6	1.1, 2.6	**0.02**
Overweight or higher (BMI >25 kg/m^2)	1.5	0.91, 2.5	0.11		1.1	0.81, 1.4	0.61
ICP diagnosis in current pregnancy	1.8	1.1, 3.2	**0.031**		2.7	1.9, 4.0	**<.0001**

Results: Treating healthy WT mice with nitisinone resulted in the accumulation of alternative tyrosine metabolites including acetyl-L-tyrosine, 4-hydroxyphenyllactic acid, 4-hydroxyphenylacetic acid and 4-hydroxybenzaldehyde. Conversely, key L-tryptophan metabolites of the kynurenine pathway were found to be decreased upon nitisinone treatment including kynurenine and picolinic acid. These metabolic changes were reversed upon discontinuation of the treatment. In addition, kynurenine and picolinic acid concentrations were found to be 2-fold higher in nitisinone-treated Fah^{5981SB} versus WT mice. Upon discontinuation of nitisinone treatment in Fah^{5981SB} mice, serum levels of ophthalmic acid, a glutathione analogue, raised by 3-fold.

Conclusion: Our study reports for the first time that L-tryptophan-related kynurenine metabolism is deregulated by nitisinone. This suggests that, besides HPD, nitisinone also inhibits a key enzyme involved in kynurenine metabolism. In addition, we propose ophthalmic acid as a potential biomarker to monitor the level of oxidative stress in HT1 patients due to hepatic glutathione depletion when nitisinone treatment is insufficient or discontinued.

Prognosis in persons with an HFE-mutation: population-based cohort study of 3,645 individuals

Hannes Hagström[1,2,2,3], Nelson Ndegwa[4], Mattias Ekstedt[5], Iris Posserud[6], Fredrik Rorsman[7], Nils Nyhlin[8], Daniel Klintman[9], Mårten Werner[10], Hanns-Ulrich Marschall[11], Johan Askling[3], Per Stal[2,12]. *[1]Karolinska University Hospital, Unit of Hepatology, Department of Upper GI Diseases, Sweden; [2]Karolinska Institutet, Department of Medicine, Huddinge, Stockholm, Sweden; [3]Karolinska Institutet, Unit of Clinical Epidemiology, Department of Medicine, Solna, Stockholm, Sweden; [4]Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden; [5]Linköping University Hospital, Sweden; [6]Gothenburg University, Sweden; [7]Akademiska University Hospital, Uppsala, Sweden; [8]Örebro University Hospital, Sweden; [9]Skåne University Hospital, Sweden; [10]Norrland University Hospital, Sweden; [11]Sahlgrenska University Hospital, Gothenburg, Sweden; [12]Karolinska University Hospital, Department of Medicine, Huddinge, Stockholm, Sweden*
Email: hannes.hagstrom@ki.s

Background and Aims: Mutations in the HFE gene can lead to hemochromatosis and cirrhosis and have been suggested to also increase the risk of extra-hepatic diseases, especially breast and colorectal cancer. Most previous studies in this field have been small. Here we investigated long-term outcomes of a large cohort of patients with the most common HFE mutations.

Method: We identified 3,645 patients with either a homozygous C282Y (68%) or a C282Y/H63D (32%) mutation from eight centers in Sweden between 1997 and 2017. These were matched 1:10 by age, sex and county of residence at the time of HFE testing to a reference population. We ascertained incident diagnoses until the end of 2017 by linkage to national registers on hospital-based care and prescribed drugs. Studied outcomes included hemochromatosis, cirrhosis, hepatocellular carcinoma (HCC), breast cancer (in women), colorectal cancer, type 1 and 2 diabetes, hypothyroidism, Parkinson's disease and overall mortality. Cox regression was used to estimate hazard ratios for the outcomes in patients with HFE mutations compared to the reference population.

Results: Median age at diagnosis was 52 years and 44% were females. During a follow-up of in mean 7.9 years, we found an increased risk for HCC, hemochromatosis, cirrhosis, type 2 diabetes, and death. No increased risk was seen for other outcomes (Table 1). Liver-related outcomes were rare, with a cumulative incidence of <1%.

Conclusion: In this large cohort study we found no increased risk for extra-hepatic malignancies in persons with verified HFE mutations.

Table 1: (abstract: FRI285)

Incident outcomes	N (%) HFE	N (%) controls	Incidence rate per 1000 person-years, cases with HFE (95%CI)	Incidence rate per 1000 person-years, controls (95%CI)	aHR	95%CI	P

Cracking the notch code in alagille syndrome: single-cell receptor-ligand interactions and outcomes in vivo, and an emerging role of immune cells

Jan Mašek[1], Simona Hankeova[1], Shao-Bo Jin[2], Urban Lendahl[2], Emma Andersson[1]. [1]*Karolinska Institute, Biosciences and Nutrition, Stockholm, Sweden;* [2]*Karolinska Institute, Stockholm, Sweden*
Email: emma.andersson@ki.s

Background and Aims: Alagille syndrome (ALGS) is a dominant multi-systemic disorder caused by mutation of either the Notch ligand *JAGGED1* or the receptor *NOTCH2*. Impaired JAG1/NOTCH2 signaling leads to developmental defects in heart, bones, eyes, and liver, where it can lead to bile duct paucity (*1*). Notch signaling also regulates haematopoiesis and immune cell maturation (*3*), and immunological features add to the complexity of ALGS (*2*). However virtually nothing is known about the interaction between blood cells and biliary cells during bile duct maturation, when these systems are in immediate contact. Does the altered profile of immune cells in ALGS patients reflect an immune response to the biliary failure, modify the biliary phenotype, or represent a separate Notch-dependent phenotype? Notch receptors and ligands are expressed throughout the embryonic liver (*4*), in both liver cells and hematopoietic cells. However, the parameters dictating the output of Notch receptor-ligand interaction - the "Notch code" – remains poorly understood.
Method: We investigated the Notch code, and the interaction of the biliary and hematopoietic system, in $Jag1^{Ndr/Ndr}$ mice, which carry a homozygous $Jag1^{H268Q}$ mutation, and faithfully mimic ALGS (*5*). 10X Genomics scRNAseq of early postnatal (P3) $Jag1^{Ndr}$ liver was used to identify cell types and Notch component expression. To test Notch signalling parameters in a clean system, we generated "Notch-clean" reporter cells using CRISPR (*6*). Notch receptor-ligand output was assessed using these reporter cells, in combination with high-throughput live imaging.
Results: We generated cell lines devoid of either all 4 Notch receptors ($NOTCH1/2/3/4^{-/-}$), multiple Notch ligands ($JAG1/2^{-/-}$, $DLL4^{-/-}$, $DLL1/3^{-/in\ frame}$), or both ($NOTCH1/2/3^{-/-}$, $NOTCH4^{+/+}$, $JAG1/2^{-/-}$, $DLL1/3^{-/in\ frame}$, $DLL4^{+/-n}$). We designed a library of Notch ligands (JAGGED1/2, DELTA-LIKE1/3/4), and Notch receptors (NOTCH1-4) with permanent (EGFP, HA), or transient T2A fused fluorescent tags (EGFP, RFP670-N1). Together with our new fluorescent Notch reporter (12 × CSL-H2B-m1RFP-PEST), this allows non-disruptive quantification of Notch signaling in individual cells using live cell imaging.
Single cell analysis of >40,000 randomly sampled cells from control and $Jag1^{Ndr/Ndr}$ P3 livers revealed a preponderance of haematological cells at this stage in both control and $Jag1^{Ndr/Ndr}$ liver, but with further enriched numbers, and altered characteristics, of specific immune cells and their precursors, in the $Jag1^{Ndr/Ndr}$ liver.
Conclusion: Immunological dysregulation in ALGS is detectable shortly after birth in the mouse model. How this interacts with the biliary phenotype is currently under investigation. Together with our new Notch reporter assays, we now aim to unravel the signalling and developmental mechanisms controlled by biliary-hematopoietic system interaction. (Refs on poster.)

FRI287

Real-world disease burden, treatment patterns, and outcomes of hospitalized patients with hepatic encephalopathy

Xingyue Huang[1], Sara Hovland[1], Jan Stange[2], Shivani Pandya[3], Li Wang[3]. [1]*Mallinckrodt Pharmaceuticals, Bedminster, United States;* [2]*University of Rostock, Internal Medicine, Rostock, Germany;* [3]*STATinMED Research, Plano, United States*
Email: jan.stange@mnk.co

Background and Aims: Hepatic encephalopathy (HE) is a serious clinical complication of cirrhosis and/or portosystemic shunting with a substantial economic burden. This study aimed to evaluate the characteristics of patients hospitalized with HE, treatment patterns, clinical outcomes, health care resource utilization (HCRU), and costs during hospitalization. It also evaluated readmission rates and mortality rates post-discharge.
Methods: This retrospective study using the nThrive Health System Data (US hospital encounter database from over 400 US hospitals) included adults with an incident inpatient HE diagnosis during 01FEB2014-30APR2018 (index hospitalization: the first inpatient stay with HE diagnosis) and a diagnosis for liver cirrhosis within 90 days prior to or during index hospitalization. Outcomes analyzed included comorbidities, medications, procedures, mortality rate, HCRU and costs during index hospitalization. It also analyzed readmission rate and mortality rate during 30 to 180 days after the discharge from index hospitalization. Standard summary statistics are presented for all outcomes.
Results: Among the 24,093 eligible patients (mean age: 59.1 years; 61.7% males), the most common comorbidities during the index hospitalization included cardiovascular disease (79.8%), electrolyte imbalance (61.0%), and acute/chronic kidney disease (50.7%). The most commonly used medications included lactulose and rifaximin (lactulose only: 45.5%; rifaximin only: 2.1%; combination: 30.0%). On average, patients had 1.1 procedure and a hospital stay of 8.1 days during the index hospitalization. The average total cost and charge of hospitalization was $18,297 ($2,180/day) and $79,439 ($9,538/day), respectively, with an 11.4% in-hospital mortality rate. During the 30 to 180 day period post-discharge from index hospitalization, there were increasing trends observed for all-cause readmission rate (16.5% to 34.7%), HE-related readmission rate (9.7% to 22.4%), and all-cause mortality rate (1.7% to 4.8%).
Conclusion: Results from this latest US hospital database study indicate that hospitalized HE patients have a substantial comorbidity burden with in-hospital mortality of 11.4%, length of stay of 8.1 days, and total in-hospital costs of $18,297. Increasing trends for mortality and readmission rates were also noted during 30 to 180 days post-discharge from the hospital. These findings underscore the need for new, more effective treatments to better control and manage HE.

FRI288

Liver ultrasonic transient elastometry (fibroscan (r)) in hepatic amyloidosis: results of a multicenter cohort of 26 cases

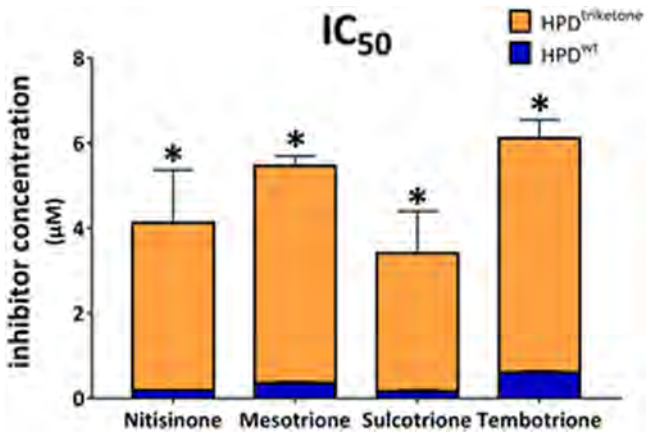
Jean-François Cadranel[1], Eric Nguyen Khac[2], Laurent Alric[2], Heng Ratmony[1], Honoré Zougmoré[1], Tristan Le Magoarou[3], Veronique Loustaud-Ratti[4]. [1]*GHPSO, Hepatology, Creil, France;* [2]*CHU Amiens, Hepatology, France;* [3]*GHPSO, Public Health, France;* [4]*CH Limoge, Hepatology, France*
Email: jeanfrancois.cadranel@ghpso.f

Background and Aims: Transient elastometry (E) (Fibroscan®) is a physical method that measures the stiffness of liver fibrosis. It was validated by HAS for its evaluation in patients with chronic hepatitis C, without comorbidity and in other indications. The hepatic elastometric values may be also elevated in other situations i.e: acute hepatic cytolysis, cardiac liver failure, and cholestasis syndrome. During amyloidosis with liver injury, the liver is hard without correlation with the degree of fibrosis. The purpose of this study is to report the results of elastometry values during liver amyloidoidosis in a multicenter study.
Method: 26 patients with amyloidosis followed in 5 centers were included. All patients had an evaluation of their E by Fibroscan according to the manufacturer's recommendations with at least 10 measurements; only results with an IQR < 30% and a success rate (TR) > 60% are interpretable. The statistics are presented in median and quartile.
Results: 9 women and 17 men with 62 years old median age (Q25 = 68 years, Q75 = 72 years) were studied. 24 had AL amyloidosis. The result of elastometry made possible diagnosis of liver amyloidosis in 3 among 26 cases (12%) in patients with unknown liver disease. 18 patients had cardiac failure (69%), 16 had renal impairment (64%), 26 (100%) had liver injury: hepatomegaly n = 21 (81%); splenomegaly n

= 8 (31%); Unintentional weight loss n = 11 (42%). 11 (42%) had ventricular dysfunction and 4 (15%) had inferior vena cava dilatation. All patients had remarkable anicteric cholestasis (median = 2.2 times the upper limit of normal, Q25 = 1.6N, Q75 = 2.8N). Transaminases were normal in 25 of the 26 patients, the median serum creatinine was 83 μmol/L (Q25 = 75 μmol/L, Q75 = 109 μmol/L).
The median of elastometry was 48 kPa (Q25 = 17 kPa, Q75 = 75 kPa), 50% of patients had an IQR of 0% elastometry. The median value of the IQR was 0.5 points, (Q25 = 0 pt, Q75 = 17 pts).
Fibroscan was interpretable in 100% of patients without cardiac involvement with a median value of 27 kPa (Q25 = 13 kPa, Q75 = 75 kPa) and a median IQR of 0 points (Q25 = 0 pt, Q75 = 2.5 pts), in patients with cardiac involvement the median of fibroscan was 59 kPa (Q25 = 27 kPa, Q75 = 75 kPa) and a median IQR of 7 points (Q25 = 0 pt, Q75 = 20 pts). The difference in median elastometry if there was cardiac involvement was 11 kPa (p = 0.42) and a median IQR difference of 11 points (p = 0.03); 22% of patients with cardiac involvement had uninterpretable fibroscan. 9 patients performed a transjugular liver biopsy to confirm the diagnosis of amyloidosis without extensive fibrosis.
Conclusion: Fibroscan makes possible diagnosis of amyloidosis in case of liver disease of undetermined etiology, which avoids invasive transparietal biopsy. These results suggest that the elastometric score during liver amyloidosis with or without cardiac involvement is very high and the accuracy of its measurement is reduced in case of cardiac involvement.

FRI289
Directed protein evolution as a tool to innovate gene therapy for hereditary tyrosinemia type 1
Jessie Neuckermans[1], Haaike Colemonts-Vroninks[1], Marcelis Lionel[2], Alan Mertens[3], Ulrich Schwaneberg[3], Joery De Kock[1]. *[1]Vrije Universiteit Brussel, In Vitro Toxicology and Dermato-Cosmetology (IVTD), Jette, Belgium; [2]Université libre de Bruxelles, Laboratoire de Pédiatrie, Brussels, Belgium; [3]Rheinisch-Westfälische Technische Hochschule, Lehrstuhl für Biotechnologie, Aachen, Germany*
Email: jessie.neuckermans@vub.b

Background and Aims: Hereditary tyrosinemia type 1 (HT1) is a life-threatening hepatorenal disorder characterised by a dysfunctional fumarylacetoacetase (FAH) enzyme. HT1 can be effectively treated with the drug nitisinone (NTBC), a potent inhibitor of 4-hydroxyphenylpyruvate dioxygenase (HPD), an enzyme upstream of FAH. Gene therapy with the wildtype version of FAH would require withdrawal of NTBC due to the upstream metabolic block. Nonetheless, a low transduction efficiency impedes normalisation of the patient's metabolome and due to the cell-autonomous pathophysiology of the disease, withdrawal of NTBC is unacceptable. As a first step to solve the foregoing problem, we aimed to engineer an HPD enzyme with a significantly decreased sensitivity towards NTBC (HPD^{NTBC}) by the use of directed protein evolution technology.
Method: First, we developed a colorimetric bacterial whole-cell screening system that allows the evaluation of HPD variants in a high-throughput and a robust fashion ($Z' = 0.93 \pm 0.02$). The principle of the screening system is based on the degradation of tyrosine through 4-hydroxyphenylpyruvate into homogentisate by human HPD expressed in *E. coli* and subsequent production of a soluble melanin-like pigment. Next, the KnowVolution approach was used to engineer a human HPD enzyme with a significantly decreased sensitivity towards NTBC. This comprised the identification and determination of beneficial amino acid positions, substitutions and their recombination. Technologies that were used in iterative rounds of evolution included error prone (ep) PCR, site saturation mutagenesis (SSM) and site-directed mutagenesis (SDM).
Results: EpPCR allowed to identify 12 amino acid substitutions that decreased the sensitivity of human HPD towards NTBC. Combination of 8 out of 12 individual beneficial amino acid substitutions by SSM and SDM into a single lead variant further decreased the sensitivity of the engineered human HPD^{NTBC} enzyme towards NTBC as well as other triketone inhibitors. More specifically, the engineered lead variant exhibited significantly increased IC_{50} values versus wild type human HPD for the triketone inhibitors nitisinone (20.2-fold), mesotrione (14.1-fold), sulcotrione (19.8-fold) and tembotrione (9.0-fold) (Fig).



Conclusion: This NTBC insensitive human HPD variant comprises the first step in the development of new gene therapeutic approaches for the treatment of HT1 that are functional under NTBC treatment.

FRI290
Hospitalization rates of Budd Chiari syndrome in the United States
Joseph Alukal[1], Talan Zhang[1], Paul J. Thuluvath[2]. *[1]Mercy Medical Center, Institute of Digestive Health & Liver Diseases, Baltimore, United States; [2]University of Maryland School of Medicine & Mercy Medical Center, Institute of Digestive Health & Liver Diseases, Baltimore, United States*
Email: thuluvath@gmail.co

Background and Aims: The current knowledge about the epidemiology of Budd Chiari Syndrome (BCS) in the United States is limited, and is based on data from case series and multi center studies that consisted of a relatively small number of patients. The primary objective of our study was to assess temporal trends in the prevalence of BCS among hospitalized patients in the US using the National Inpatient Sample (NIS) database and also to evaluate patient characteristics, risk factors and common presenting symptoms of BCS that required hospitalization. The NIS is the largest publicly available administrative database developed by AHRQ for the Health care cost and utilization project (HCUP) and represents approximately 20% stratified sample of discharges from the US hospitals.
Method: Data were extracted from the NIS to identify patients >18 years of age using all listed diagnosis (primary or secondary diagnosis) of BCS from 1998 to 2016. The diagnosis of BCS was captured using the codes 453.0 (ICD 9) and I82.0 (ICD 10).
Results: Between 1998 and 2016 we identified a total of 7,755 (unweighted) hospitalizations related to BCS and over the 18 year period, the hospitalization rate for BCS increased consistently from 4.96 per 1,000,000 US population in 1998 to 10 per 1,000,000 in 2016, with an annual percentage change (APC) increase of 4.25% (95% CI: 4.05% – 4.44%, $p < 0.0001$). Similarly, 5% increase was seen per 1,000,000 all cause hospitalizations (see figure). The mean age of the cohort was 50 years, 55.4% were female and 66.3% were white. The admission rate among Hispanics increased by 2.23% during this time period (p = 0.002). The underlying risk factors for BCS included myeloproliferative disorder (essential thrombocythemia or polycythemia vera) in 7.4%, a primary hypercoagulable state (protein C deficiency, factor 5 Leiden mutation, APLA or prothrombin gene mutation) in 6.8% and paroxysmal nocturnal hemoglobinuria in 1.7%. The most common manifestation of BCS among admitted patients

was ascites (30.2%) followed by acute kidney injury (18.1%). Other liver related complications of BCS included hepatic encephalopathy (9.3%), acute liver failure (5.4%), esophageal variceal bleeding (3.3%), IVC thrombosis (6.5%) and hepatorenal syndrome (3.3%).

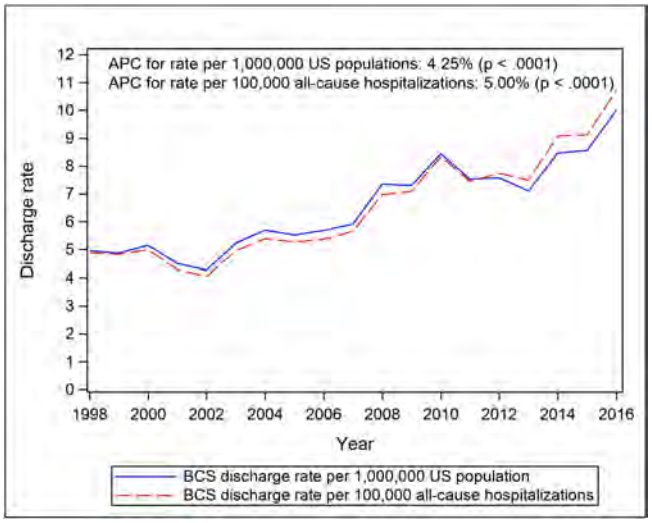


Figure: (abstract: FRI290)

Conclusion: This is the first and the largest population-based study in the United States to report increasing hospitalizations related to the Budd Chiari Syndrome.

FRI291

Health care burden and in-hospital mortality of BCS in the United States between 1998 and 2016

Joseph Alukal[1], Talan Zhang[1], Paul J. Thuluvath[2]. [1]*Mercy Medical Center, Institute of Digestive Health & Liver Diseases, Baltimore, United States;* [2]*University of Maryland School of Medicine & Mercy Medical Center, Institute of Digestive Health & Liver Diseases, Baltimore, United States*
Email: jjalukal@gmail.co

Background and Aims: The Budd Chiari Syndrome (BCS) is a rare and potentially fatal disease, but there is a paucity of data on the in-hospital mortality of BCS as well its economic burden on the health care system. In this study, using a large administrative database we evaluated the trends in mortality, length of stay and resource utilization among inpatient with BCS.

Method: The NIS (National Inpatient Sample) is the largest publicly available administrative database developed by AHRQ for the Health care cost and utilization project (HCUP) and represents approximately 20% stratified sample of discharges from community hospitals. Data were extracted from the NIS to identify patients >18 years of age using all listed diagnosis (primary or secondary diagnosis) of BCS from 1998 to 2016. The diagnosis of BCS was captured using the codes 453.0 (ICD 9) and I82.0 (ICD 10).

Results: Between 1998 and 2016 we identified a total of 7,755 (unweighted) hospitalizations related to BCS. The overall in-hospital mortality rate among BCS patients decreased significantly by 5% ($p < 0.0001$) from 18% in 1998 to 7% in 2016, with the mortality rate being the lowest in 2015 (5%) (see figure). On multivariate analysis, older age, higher comorbidity score, acute liver failure, acute kidney injury, acute respiratory failure, IVC thrombosis and hepatorenal syndrome were associated increased risk of mortality. The average of length of stay for the cohort was 9 days and this consistently decreased by 2% ($p < 0.001$) from 13 days in 1998 to 8 days in 2016.

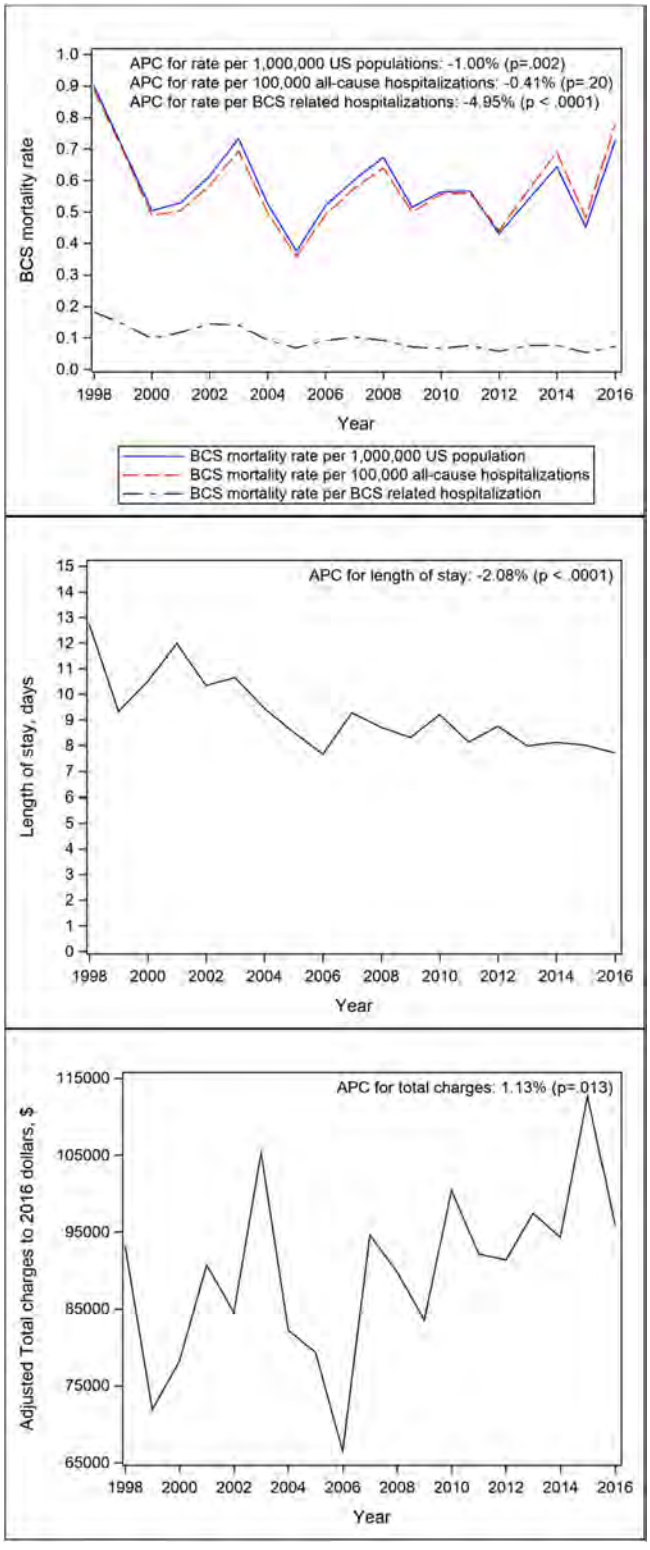

Figure: (abstract: FRI291):

During hospitalization, paracentesis was the most frequent procedure (18.6%) followed by upper endoscopy (10.7%), liver biopsy (6.3) and TIPS (3.7%). While total number of procedures performed remained stable during the study period, there was a significant and notable reduction in the number of liver biopsies (Annual

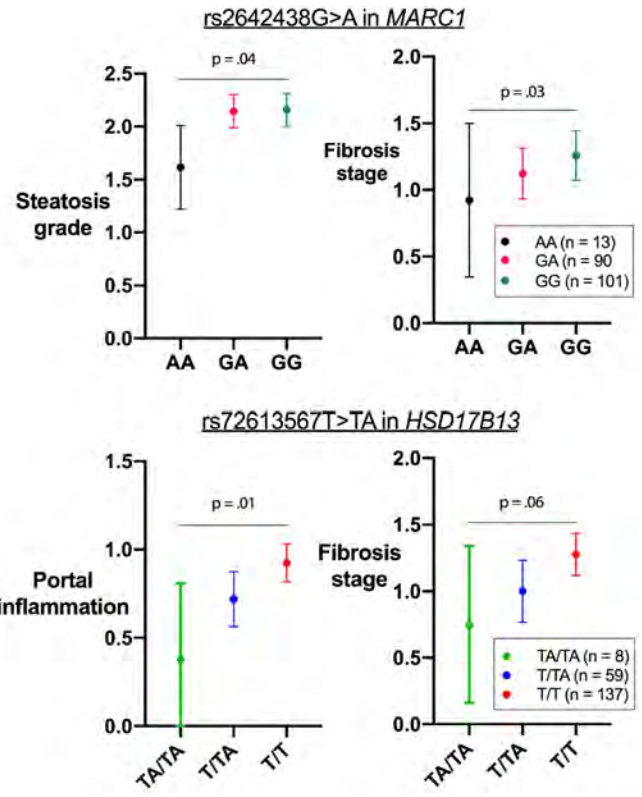
Percentage Change [APC]: −4.33%, P < 0.0001) and TIPS (APC: −5.41%, P < 0.0001).
The average total charges after adjusted for Medical Care Consumers Price Index to 2016 dollars during the time period was $91,280 and the annual percentage change (APC) increased by 1% (95% CI: [0.24%, 2.02%], p = 0.013) from $93,175 in 1998 to $95,822 in 2016. On multivariate analysis race, primary payer, number of procedures, length of stay, comorbidity score, hospital size, location and teaching status were associated with total charges. Important complications that had an effect on total charges included acute kidney injury, acute respiratory failure, IVC thrombosis and acute blood loss anemia.
Conclusion: The in-hospital mortality rate for patients admitted with BCS in the United States has reduced between 1998 and 2016. Despite the reduction in the length of hospital stay, total charges continue to rise.

FRI292

Genome-wide protective variants in MARC1 and HSD17B13 are associated with reduced inflammation and lower fibrosis stage on biopsy in children with NAFLD

Christian Hudert[1], Anna Alisi[2], Kylie Karnebeek[3], Laura Draijer[4], Bart Koot[4], Anita Vreugdenhil[3], Jake Mann[5]. [1]*Charité – Universitätsmedizin Berlin, Berlin, Germany;* [2]*Ospedale pediatrico Bambino Gesù, Roma, Italy;* [3]*Maastricht, MUMC, Maastricht, Netherlands;* [4]*Amsterdam UMC - locatie AMC, Amsterdam, Netherlands;* [5]*Institute of Metabolic Science, Cambridge, United Kingdom*
Email: jm2032@cam.ac.u

Background and Aims: Population-level coding data in adults has identified two common variants that are associated with protection against non-alcoholic fatty liver disease (NAFLD) and all-cause cirrhosis at genome-wide significance: rs72613567T > TA in HSD17B13 and, more recently, rs2642438G > A in MARC1. To date there is no histological data confirming the observation in MARC1 and neither have been studied in children. More generally, it is not entirely clear to what extent genetic influences are consistently shared in adults and children. Therefore we aimed to establish the effect these common variants had on histological features of NAFLD in children.
Method: Data from 204 children (<18 years) with biopsy-proven NAFLD were recruited from the European Paediatric NAFLD Registry and the Berlin paediatric NAFLD cohort. Histology was assessed according to the Non-Alcoholic Steatohepatitis Clinical Research Network scoring criteria. Participants were genotyped for rs72613567T > TA in HSD17B13 and rs2642438G > A in MARC1 using TaqMan genotyping. Expected genotype frequencies were tested using chi-squared analysis and histological differences between genotype were assessed using one-way ANOVA.
Results: The protective AA-genotype of rs2642438G > A in MARC1 was under-represented in this cohort compared to population prevalence (6% NAFLD vs. 9% population, p = .01). rs2642438G > A was associated with lower AST (p = 0.02), steatosis grade (p = 0.04), and fibrosis stage (p = 0.03).



The protective TA-allele of rs72613567T > TA in HSD17B13 was less prevalent in this cohort compared to population reference (18% NAFLD vs. 27% population, p = 0.002). The TA-allele was associated with lower portal inflammation (p = 0.01) and a trend towards lower fibrosis stage.

Conclusion: This is the first histological confirmation of the protective role of rs2642438G > A in *MARC1* in NAFLD, confirming the utility of coding data in identifying variants that influence NAFLD histology. Genome-wide significant protective variants have pervasive effects across adults and children, suggesting substantial genetic similarity between paediatric and adult NAFLD.

FRI293

Non-invasive screening for liver fibrosis by acoustic radiation force impulse in patients with ciliopathies

Johanna Bresch[1], Jens König[2], Sabine Kollmann[2], Martin Konrad[2], Hauke Heinzow[1], Hartmut Schmidt[1], Bernhard Schlevogt[1]. [1]*Muenster University Hospital, Department of Medicine B, Muenster, Germany;* [2]*Muenster University Hospital, Department of General Pediatrics, Muenster, Germany*
Email: johanna.bresch@uni-muenster.de

Background and Aims: Ciliopathies are a heterogenous group of diseases caused by inherited malfunction of primary cilia. These antenna-like structures on the cell surface are involved in multiple signaling pathways and their dysfunction is most often associated with renal impairment but also (among others) retinitis pigmentosa, brain anomalies and hepatic fibrosis. The broad spectrum makes it difficult to predict liver involvement in individuals, yet knowledge is crucial for affected patients as advanced fibrosis may lead to variceal bleeding due to portal hypertension (PH). Acoustic radiation force impulse (ARFI) imaging is an ultrasound based elastography used for measuring tissue stiffness and thereby detecting fibrosis as well as PH. The aim of this study was to evaluate ARFI as a screening tool for liver involvement in ciliopathies in order to identify patients who are in need of treatment or may benefit from closer monitoring.

Methods: In a prospective cohort of 42 patients from the NEOCYST registry with ciliopathies (aged 1 – 74 years) stiffness of the right liver lobe and spleen was measured via ARFI and results were then compared with alanine transaminase (ALT) and platelets (the latter being a marker of PH) as well as histologic findings in 7 patients. All patients were clinically and n = 35 genetically diagnosed; most commonly with NPHP1, NPHP11 and HNF1B.
Results: ARFI-screening of the liver identified 26 patients without fibrotic conversion, 7 with moderate fibrosis (F1-F3) and 10 with severe fibrosis (F4), of which 6 had PH (Fig. 1). All 7 patients with histologically confirmed fibrosis were substantiated with decreased liver elasticity. In comparison to patients with normal elastography results, in ones with fibrosis the median ALT was significantly higher (40 ± 67 vs 106 ± 72 U/l, p = 0.008). Thrombocytopenia occurred more often in F4 patients. Yet some patients who showed increased liver stiffness had normal laboratory parameters (n = 3) and some patients with elevated ALT did not show increased liver stiffness (n = 3) (Fig. 1).

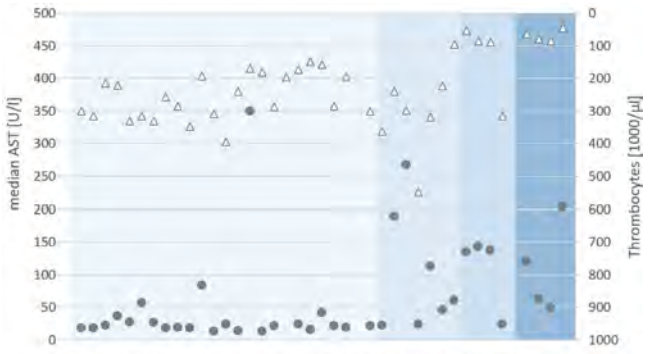


Figure 1: Platelet numbers (Δ) and median ALT values (•) visualized in ARFI-categories no fibrosis/F1-F3 fibrosis/F4 fibrosis without PH/F4 fibrosis with PH.

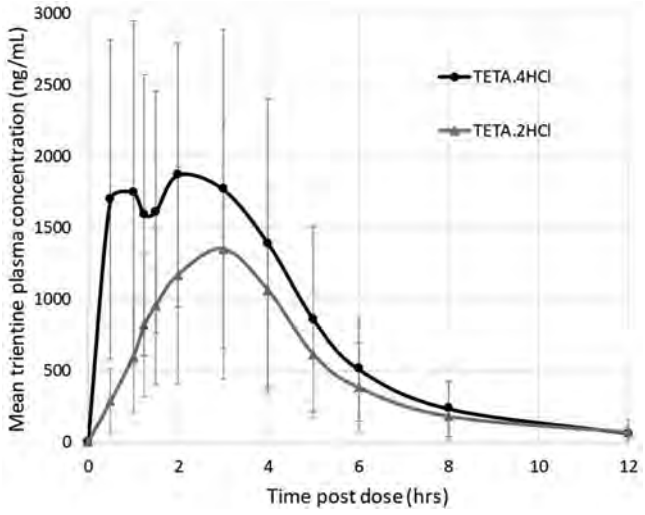
Conclusion: ARFI is an easy screening method that identifies a higher number of fibrotic patients than ALT and reliably identifies patients with severe PH. This study suggests integrating ARFI as a valuable non-invasive tool in evaluating patients with ciliopathies.

FRI294
Cholestatic phenotype of a mouse model for organic solute transporter? (OST?/SLC51B) deficiency suggest a role of the beta subunit beyond an OST? chaperone
Sandra Van de Wiel[1], Vanesa Muncan[1], Ronald Oude-Elferink[1], Stan van de Graaf[1]. [1]*Amsterdam UMC, AGEM, Tytgat Institute for Liver and Intestinal Research*
Email: k.f.vandegraaf@amsterdamumc.nl

Background and Aims: The organic solute transporter alpha-beta (OSTalpha-OSTbeta) facilitates bile acid efflux mainly in ileal enterocytes, liver and kidney which is expected to protect cells from an overload of bile acids. OSTα-OSTβ consists of two distinct subunits expressed on separate genes. Heterodimerization is essential for transporter stability, trafficking to the plasma membrane and bile acid transport. OSTbeta deficiency in humans leads to congenital chronic diarrhea with features of cholestatic liver disease. In contrast, *Ostα*$^{-/-}$ mice displayed attenuated cholestasis-induced liver injury, by increasing urinary bile acid excretion. To elucidate the consequence of OSTβ deficiency in mice, we generated *Ostβ*$^{-/-}$ mice and compared them with *Ostα*$^{-/-}$ mice and wild-type littermate controls under standard and cholestatic conditions.
Method: *Ostβ*$^{-/-}$ mice were generated using the CRISPR/Cas9 system. Ileal organoids were isolated and cultured from *Ostβ*$^{-/-}$ and *Ostα*$^{-/-}$ mice, as well as their wild-type littermates. To induce cholestatic liver injury, mice were subjected to common bile duct ligation. Histological and biochemical parameters for liver damage were assessed.
Results: *Ostβ*$^{-/-}$ mice displayed a trend towards modestly elevated ALT and ALP levels, without other signs of cholestasis or diarrhea. Both *Ostα*$^{-/-}$ and *Ostβ*$^{-/-}$ mice exhibited longer, heavier small intestines and altered ileal histology, including blunted villi, increased crypt depth and increased mucus at the top of the villi. Increased gene expression levels of ileal *Fgf15*, and decreased *Asbt* expression, indicate accumulation of bile acids in the enterocyte. Organoids from *Ostα*$^{-/-}$ and *Ostβ*$^{-/-}$ cultured in the absence of bile acids show a similar phenotype and gene expression pattern as the wild-type organoids. Challenged by ligation of the common bile duct, clear differences between *Ostβ*$^{-/-}$ mice, *Ostα*$^{-/-}$ and wild-type mice were observed. All *Ostα*$^{-/-}$ and wild-type mice survived, with even a hepatoprotective phenotype in *Ostα*$^{-/-}$ mice, whereas 40–100% of the *Ostβ*$^{-/-}$ mice died within 5 days. Remarkably, a clear reduction was observed in plasma bilirubin (42%), cholesterol (38%) and bile acid levels (62%) in surviving *Ostβ*$^{-/-}$ mice. The *Ostβ*$^{-/-}$ mice that died did not produce feces, and display blackened content of small intestine and stomach.
Conclusion: OSTβ is a pivotal subunit for bile acid transport *in vivo* and its deficiency leads to an intestinal phenotype similar to *Ostα*$^{-/-}$ mice. Challenging *Ostβ*$^{-/-}$ mice by BDL reveals an unexpected phenotype, beyond the isolated hepatoprotection seen in *Ostα*$^{-/-}$ mice, suggesting that the chaperone function of OSTβ is not restricted to OSTα.

FRI295
Comparative pharmacokinetic profile of two distinct trientine salt formulations used for treatment of Wilson's disease
Karl Heinz Weiss[1], Tim Morley[2], Catherine Thompson[2]. [1]*University Hospital Heidelberg, Internal Medicine IV, Heidelberg, Germany;* [2]*GMP-Orphan, Paris, France*
Email: KarlHeinz.Weiss@med.uni-heidelberg.de

Background and Aims: Wilson disease is an autosomal recessive inherited disorder of copper metabolism requiring life-long medical treatment to control copper levels. The copper chelator Trientine Dihydrochloride (TETA.2HCl) is an established treatment for Wilson disease patients intolerant to D-penicillamine. A new salt Trientine Tetrahydrochloride (TETA.4HCl) has been recently approved in Europe (EU) for the treatment of Wilson disease. TETA.4HCl is stable at room temperature, while TETA.2HCl formulations require refrigerated storage. This study is the first to provide comparative pharmacokinetics (PK) on these two different oral Trientine salt formulations.
Method: In a randomised, cross-over study, 23 healthy adults received a single oral dose of TETA.4HCl tablets (gmp-orphan SA) and TETA.2HCl capsules (Univar BV). Blood samples were taken pre-dose and 0.5, 1, 1.25, 1.5, 2, 3, 4, 5, 6, 8, 12, 16, 24, 30, 36, 42, 48 and 72 hours after dosing for analysis of plasma concentrations of Trientine and main metabolites using LC-MS/MS.
Results: Following the administration of a 600 milligram dose of active ingredient Trientine, there was significantly greater Trientine bioavailability with TETA.4HCl tablets versus (vs) TETA.2HCl capsules: Arithmetic mean (standard deviation, SD) for Cmax was 2340 (1170) vs 1490 (864) ng/mL and for AUC0-t was 10100 (5740) vs 6600 (3870) ng.hr/ml. Peak plasma levels were reached sooner with TETA.4HCl (median Tmax 2 vs 3 hrs). Arithmetic mean and SD of plasma levels of Trientine over first 12 hrs are shown in the figure.



Statistical comparisons of systemic Trientine exposure between the formulations following administration of the same oral dose gives the least square geometric mean ratios of 168 and 157 for Cmax and AUC0-t, giving an adjustment factor to the oral dose of approximately 0.6 (100/168 or 100/157) for comparable systemic exposure.
Conclusion: The recently approved TETA.4HCl salt provides a more rapid and extensive absorption of Trientine than the tested TETA.2HCl salt. A factor of approximately 0.6 can be applied to the oral trientine dose of the tested TETA.2HCl to provide comparable systemic exposure with TETA.4HCl.

FRI296

Differential expression of bile acid subspecies with maralixibat treatment in pruritus responders with bile salt export pump deficiency

Xueheng Zhao[1], Pamela Vig[2], Andrew Wardle[2], Kenneth Setchell[3].
[1]Cincinnati Children's Hospital Medical Center, Pathology and Laboratory Medicine, Cincinnati, United States; [2]Mirum Pharmaceuticals, Foster City, United States; [3]University of Cincinnati, College of Medicine, Cincinnati, United States
Email: kenneth.setchell@cchmc.org

Background and Aims: Maralixibat (MRX), a nonabsorbable apical sodium-dependent bile acid (BA) transport inhibitor, interrupts the enterohepatic circulation of BAs and is proposed as a treatment for pediatric cholestasis and associated pruritus by reducing the accumulation of circulating and hepatic BAs. The open-label phase 2 INDIGO trial (NCT02057718) enrolled patients with progressive familial intrahepatic cholestasis due to bile salt export pump (BSEP) deficiency.
Method: In patients with mild to moderate nontruncating BSEP mutations (n = 19), MRX doses of 280 micrograms/kilogram/day, and later 560 micrograms/kilogram/day, were administered. Total and individual serum BAs (sBA), and 7 alpha-hydroxy-4-cholesten-3-one (sterol-C4), a marker of BA synthesis, were measured by stable-isotope dilution tandem mass spectrometry. Changes in the composition of sBA associated with pruritus improvement were investigated at week 72 in this ongoing trial in pruritus responders, defined as ≥1 reduction in the Itch Reported Outcome Observer (ItchRO[Obs]) score, compared with nonresponders.
Results: Of the 19 patients, 11 met the pruritus-response criteria, which correlated with the percentage reduction from baseline in total sBA and was significantly greater than in nonresponders ($p < 0.05$). Changes were also observed in the individual BA subspecies. Despite continued long-term therapy with ursodeoxycholic acid, reductions in glycine and taurine-conjugated cholic acid (TCA) were the best predictors of pruritus reduction due to MRX and correlated with percentage ItchRO(Obs) score reduction (Pearson correlation coefficient: 0.58, 0.50, 0.53 for TCA, glycocholic acid, and total cholic acid [CA], respectively). A trend towards increased proportion of unconjugated BA in responders (9.84 ± 4.87%) was observed compared with nonresponders (0.61 ± 0.24%, $p = 0.09$). Concomitant increases in serum sterol-C4 were observed in pruritus responders, consistent with the biological action of MRX.
Conclusion: Pruritus response with MRX in children with nontruncating BSEP deficiency was associated with BA composition changes. Reductions in serum CA conjugates, with concomitant increases in sterol-C4, were the best predictors of cholestasis and pruritus reduction associated with MRX treatment. These findings offer further interpretation on BA subspecies associated with reductions in cholestasis and pruritus with MRX.

FRI297

Clinical, histological, and biochemical liver phenotype of European adults with heterozygous alpha-1 antitrypsin deficiency (Pi*MZ genotype)

Karim Hamesch[1,2], Carolin Victoria Heimes[2], Annika Gross[2], Mattias Mandorfer[3], Linda S. Moeller[4], Vítor Pereira[5], Monica Pons Delgado[6], Pawel Kuca[7], Matthias C. Reichert[8], Federica Benini[9], Georg Lurje[2], Joan Genesca[6], Frank Lammert[8], Aleksander Krag[4], Michael Trauner[3], Alexander Teumer[10], Nadine Gaisa[11], Helmut Denk[12], Christian Trautwein[1,2], Elmar Aigner[13], Pavel Strnad[1,2]. *[1]Coordinating center for alpha-1 antitrypsin deficiency-related liver disease of the European Reference Network (ERN) "Rare Liver" and the European Association for the Study of the Liver (EASL) registry group "Alpha-1 Liver", Aachen, Germany; [2]University Hospital RWTH Aachen, Medical Clinic III, Aachen, Germany; [3]Medical University Vienna, Vienna, Austria; [4]Odense University Hospital, Odense, Denmark; [5]Centro Hospitalar do Funchal, Madeira, Portugal; [6]Vall d'Hebron Hospital, Barcelona, Spain; [7]National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; [8]Saarland University Medical Center, Homburg, Germany; [9]Spedali Civili and University, Brescia, Italy; [10]Epidemiology, Greifswald, Germany; [11]Pathology, Aachen, Germany; [12]Pathology, Graz, Austria; [13]Paracelsus Medical University, Salzburg, Austria*
Email: khamesch@ukaachen.de

Background and Aims: The 'Pi*Z' variant of alpha-1 antitrypsin (AAT) causes AAT retention within hepatocytes giving rise to globular inclusions and proteotoxic stress. While homozygous Pi*Z carriage ('Pi*ZZ' genotype) causes liver disease on its own, heterozygous carriage ('Pi*MZ' genotype) emerged as a strong genetic risk factor for cirrhosis in individuals with concomitant liver disease. As up to 4% of Caucasians are Pi*MZ carriers, our aim was to characterize the liver phenotype of Pi*MZ carriers without pre-existing liver disease.
Method: Our multinational, prospective cohort consisted of 421 Pi*MZ carriers, 309 Pi*ZZ carriers, and 284 non-carriers from 10 European countries. All underwent a comprehensive work-up as well as liver stiffness measurements (LSM) and controlled attenuation parameter (CAP) via transient elastography. Liver biopsies from 30 Pi*MZ and 35 Pi*ZZ individuals with signs of liver disease were used to define the histological and biochemical consequences of Pi*Z carriage. Data were adjusted for age, sex, BMI, diabetes mellitus, and alcohol consumption.
Results: Compared to homozygous Pi*ZZ subjects and Pi*Z non-carriers, heterozygous Pi*MZ participants had intermediate gamma-glutamyl transferase (GGT) and LSM values (all comparisons $P < 0.05$). 10% of Pi*MZ carriers vs. 4% of non-carriers had LSM ≥ 7.1 kPa (adjusted OR = 3.4 [1.6–7.3]). Age ≥ 50 years, male sex, obesity, presence of diabetes, and elevated GGT values associated with LSM ≥7.1 kPa in Pi*MZ carriers. No difference in CAP and metabolic parameters were detected between Pi*MZ carriers and non-carriers. On liver biopsies, AAT inclusions were detected in only 41% of Pi*MZ carriers (vs. 97% of Pi*ZZ carriers; Figure 1 A-B) and were more numerous in higher liver fibrosis stages (Figure 1 C-E). Accordingly, AAT genotyping was the only reliable method to diagnose Pi*MZ

status. Pi*MZ carriers did not harbor increased hepatic AAT levels, whereas the amounts of insoluble AAT displayed strong inter-individual variations.

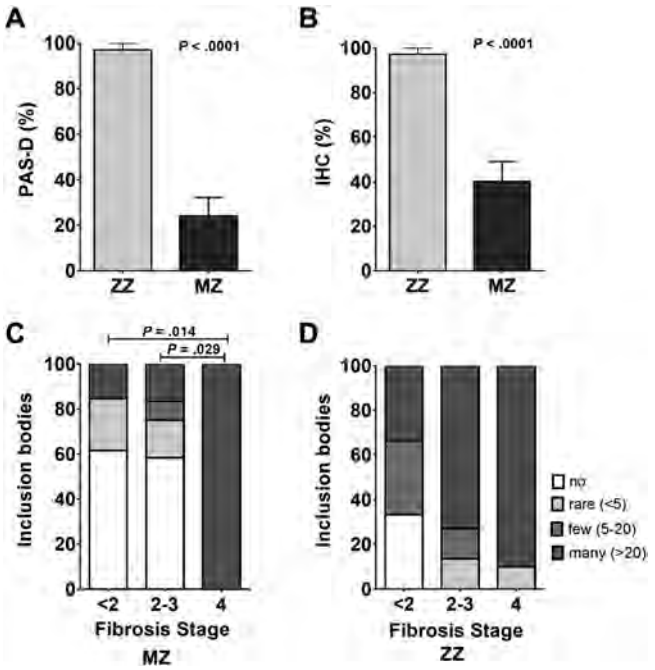


Figure: Histological features of Pi*MZ carriers vs. Pi*ZZ subjects. Histological analysis of liver biopsies from 30 Pi*MZ and 35 Pi*ZZ individuals with signs of liver disease. Rate of inclusion bodies seen on PAS-D staining (A) and immunohistochemistry (B) in Pi*ZZ (left) and Pi*MZ subjects (right). Rate of inclusion bodies depending on the fibrosis stage (as determined by the Kleiner classification) in Pi*MZ (C) and Pi*ZZ individuals (D).

Conclusion: This hitherto largest analysis of Pi*MZ carriers defines their clinical and biological consequences and demonstrates an intermediate clinical and histological liver phenotype compared to Pi*ZZ subjects and Pi*Z non-carriers. Our data should help in risk stratification and counseling of these individuals.

FRI298

Customized xenograft model development: liver repopulation of FRG® KO mice with primary hepatocytes from donors carrying specific genetic variants

Greg Bial[1], Lander Foquet[1], Markus Grompe[2], Rob Copenhaver[1].
[1]Yecuris, Portland, United States; [2]Oregon Health & Science University, Portland, United States
Email: landerfoquet@yecuris.com

Background and Aims: Liver-humanized mice have proven to be of great use for in vivo studies in many application areas including infectious diseases, NAFLD/NASH, gene editing/therapy, metabolism, regenerative medicine, and pharmacology/toxicology.
The FRG KO mice can be repopulated with hepatocytes from different species.
Similarly, hepatocytes from donors with specific mutations of interest can be transplanted into the FRG mouse model to enable research of the human disease in human hepatocytes in vivo.
Method: FRG KO mice were transplanted with hepatocytes from various sources. These include different species: mouse, rat, pig, non-human primate, or human.
To compare the efficacy of different human donors to humanize the liver of FRG KO mice, we selected donors with a wide variety of age, BMI, genetic background, metabolic disease state.
Results: Using a standardized protocol, we were able to generate FRG KO mice that were highly repopulated with a xenograft liver. On average, it takes approximately 12 weeks to repopulate the animal's liver. The percentage of repopulation was consistently above 90%. Once repopulated, the xenograft remains stable for the remainder of the animal's life.
The liver-xenograft mice show a metabolism profile of the original donor species. This allows the testing of novel compounds in a small animal model.
Murinized FRG KO mice are used frequently as a control for liver-humanized FRG KO mice. Transplantation with mouse hepatocytes from a specific genetic model generates animals with the mutation only present in the liver. FRG KO mice transplanted with non-human primate hepatocytes (NHP) can replace the use of some experiments with primates.
For example, delivery of gene therapy can be compared between murinized, monkeynized, or humanized FRG KO mice.
To study NASH in vivo, a donor was identified that is homozygous for the G allele of rs738409 in PNPLA3. This I148M variant is significantly associated with high risk of NASH development. FRGN KO mice repopulated with human PNPLA3-148M hepatocytes and fed HFD developed key aspects of NASH.
Repopulation efficiencies were overall lower when using donors with known metabolic diseases. This was expected since many of these diseases are severe and have a detrimental impact on the health of the animal. We have been successful in transplanting either ornithine transcarbamylase (OTC) deficient hepatocytes, or maple syrup urine disease (MSUD) hepatocytes into FRG KO mice. Liver-humanized mice with a specific disease state can be of great use to study novel therapies in vivo.
Conclusion: FRG KO mice can be repopulated with hepatocytes from different species, and with hepatocytes carrying specific genetic backgrounds of interest. These liver-xenograft mice can be used either for in vivo studies, or their hepatocytes can be harvested and used for in vitro applications.

FRI299

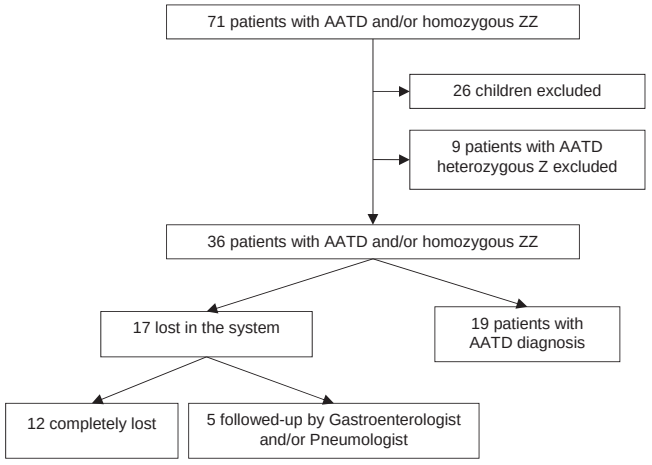
Alpha-1-antitrypsin deficiency liver disease: patients lost in the system

Maria Angeles Ruiz-Ramirez[1], Clara Urteaga[2], Antonio Diaz Sanchez[3], Carmen Prior de Castro[4], Concepcion Prados[5], Ester Zamarron De Lucas[5], Pilar Castillo[1], José Carlos Erdozaín[1], Araceli García-Sánchez[1], Miriam Romero[1], Francisco Javier Garcia-Samaniego Rey[1,6], Gloria Ruiz-Fernandez[1], Pedro Mora[1], Antonio Olveira Martin[1]. *[1]Hospital Universitario La Paz, Gastroenterology and Hepatology Department, Madrid, Spain; [2]Hospital Universitario Araba, Gastroenterology and Hepatology Department, Vitoria, Spain; [3]Hospital Universitario del Sureste, Gastroenterology and Hepatology Department, Madrid, Spain; [4]Hospital Universitario La Paz, Department of Genetics, Madrid, Spain; [5]Hospital Universitario La Paz, Pneumology Department, Madrid, Spain; [6]Centro de Investigacion Biomedica en Red de Enfermedades Hepaticas y Digestivas (CIBERehd), Madrid, Spain*
Email: m.angelesruiz92@gmail.com

Background and Aims: Alpha-1-antitrypsin deficiency (AATD) liver disease has a very low prevalence and is considered a Rare Disease. Patients lost in the system have been described in HBV, HCV and primary biliary cholangitis. We investigate whether this problem also occurs with AATD.
Method: We included patients from 2 hospitals with homozygous genetic studies for allele Z (PiZZ) and/or AAT values ≤0.6 g/L (sensitivity and specificity >90% for PiZZ) between 2012 and 2019. Clinical reports and laboratory results from Hospital and regional databases were reviewed. Patients without specific AATD diagnosis, follow-up, or treatment were contacted and offered analysis, abdominal ultrasound, elastography and genotype. Other liver diseases were excluded. According to recent publications, elastographic cut-off points were considered: 5.45 kPa ≥ F2, 8.45 kPa ≥ F3 (AUROC 0.69 and 0.92, respectively). Liver damage in ultrasound was

considered if hyperechoic appearance of hepatic parenchyma or liver surface nodularity. The study was approved by the Ethics Committee. Variables were expressed in n (%); median (IQR 25-75).

Results: We identified 71 patients (Figure 1). Of the 36 resulting patients, 17 (47%) were classified as lost in the system (median age 64 ± 16.6 years; 59% women; median AAT value 0.5 ± 0.1 g/L; permanently normal liver biochemistry: 65%). Of these 17 patients, 5 (29%) were under follow-up by Gastroenterology/Hepatology and/or Pneumology for other reasons (fatty liver disease, chronic obstructive pulmonary disease, others) without suspected AATD. 11 patients agreed to be studied (median ± SD): platelets 243 ± 48 × 10^3/μL; ALT 26 ± 29 UI/L; HOMA-IR index 1.75 ± 2.56, BMI 21.2 ± 3.8 (0% BMI ≥ 30). Ultrasound and elastography data in 10 patients: hyperechogenicity 50%; nodularity 10%; elastography: median 5.95 ± 1.5 kPa; ≥5.45 kPa: 70%; ≥8.45 kPa: 10%.



Conclusion: Almost half of the patients with AAT deficiency are lost in the system. Of them, one half have results suggestive of liver disease, occasionally at an advanced stage.

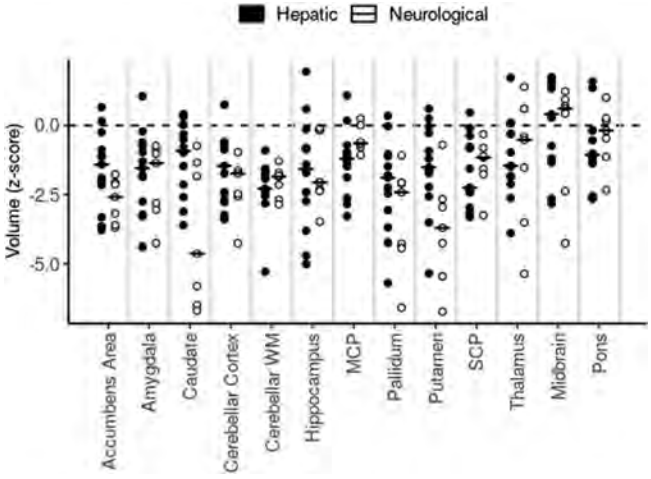
Neurodegenerative patterns in Wilson's disease with hepatic or neurological manifestation assessed by morphometric magnetic resonance imaging

André Viveiros[1], Marlene Panzer[1], Vincent Beliveau[2], Benedikt Schaefer[2], Christoph Scherfler[2], Heinz Zoller[1], Herbert Tilg[1].
[1]Medical University of Innsbruck, Internal Medicine, Innsbruck, Austria; [2]Medical University of Innsbruck, Neurology, Innsbruck, Austria
Email: andre.viveiros@i-med.ac.at

Background and Aims: Clinical presentation of Wilson disease (WD) is heterogeneous and includes hepatic and neurologic disease manifestations. Genotype-phenotype correlations failed to identify factors associated with disease expression. WD is known to cause specific qualitative neuroradiologic changes with hypo-intensities in basal ganglia known as the 'face of the giant panda' and 'eye of the tiger' signs. On neuropathological studies WD is a neurodegenerative disorder affecting the basal ganglia. The aim of the present study was to test if WD patients with predominantly hepatic or neurological phenotypic presentation show quantitative differences when magnetic resonance imaging results were analyzed by automated whole-brain segmentation procedure.

Method: Segmentation of subcortical regions from T1-weighted 3-D structural MRI data and estimation of structure volumes were carried out using the FreeSurfer tool kit (version 6.0, available at http://surfer.nmr.mgh.harvard.edu/). The volumes of the specific brain regions were expressed as Z-scores to correct for age and gender specific variations in the volume of specific segments of the brain. The study included 20 patients diagnosed with WD (13 patients with hepatic and 7 patients with neurologic WD). Liver transplant recipients were excluded. No significant differences were found when demographic genetic and baseline biochemical parameters were compared.

Results: Patients with predominantly neurological presentation showed a significant reduction in age and sex-adjusted volume of the caudate (z-score −4.64 vs −0.93, p = 0.024) and the putamen (z-score −3.72 vs −1.52, p = 0.014) when compared with the group of patients with predominantly hepatic disease manifestation. In contrast, the latter showed a significant reduction of the middle cerebellar peduncle volume (z-score −1.20 vs −0.65, p = 0.024). When all patients were compared with age and sex-matched controls, significantly reduced volumes in several brain regions could be identified, of which the most severe neurodegeneration was present in cerebellar white matter, the pallidum and cerebellar cortex. In most severely affected brain regions no difference between patients with hepatic and neurologic disease manifestations were noted.



Conclusion: This is the first study to quantitative evaluate segmentation of subcortical regions in patients with neurological and hepatic manifestation of WD. Although distinct changes were present in basal ganglia of patients with neurologic or hepatic WD, our findings indicate that WD is associated with more general pattern of neurodegeneration in patients with WD.

Email: mattias.lissing@ki.se

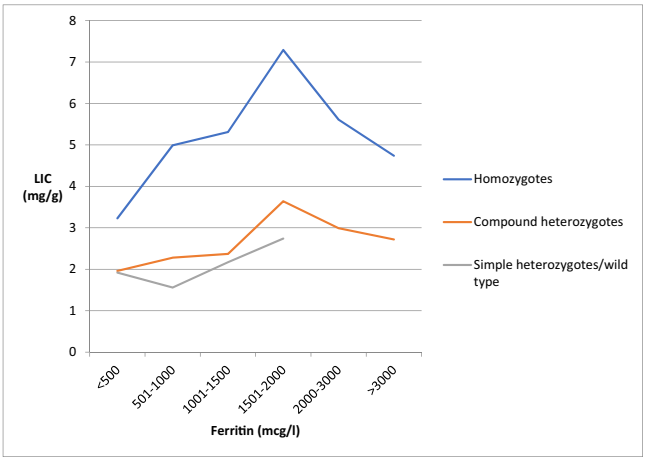
Background and Aims: Since the first report on liver transplantation (LT) for acute intermittent porphyria (AIP) in 2004, LT has become an established treatment option for patients with severe recurrent disease and poor quality of life. The outcomes after LT have been reported in an early case series and a few case reports. We aim to describe pre-transplant morbidity, transplant complications, outcomes and survival for all adult LTs for AIP in Europe.
Method: Cases were identified by searching the European Liver Transplant Registry (ELTR), previous publications and by personal communications. A questionnaire was sent to identified transplant centres or managing physicians. Data compilation focuses on 1) demographics & clinical porphyria characteristics, 2) transplant related factors and 3) post-transplant outcomes including survival, renal function and neurological impairment.
Results: The case search identified 40 AIP patients. We have data on 36 to date, 32 females and 4 males, from 12 countries who were transplanted in Europe 2002–2019. Median age at LT was 37 years (18–58) and median follow up time 5.2 years (0.2–14.5). Hepatic artery thrombosis occurred in 4 cases (12%). Two patients were retransplanted and 9 died during the follow-up period. The 1-year and 5-year overall survival rates were 91% and 81%. Renal impairment was identified as a risk factor for poor outcome. Neurological impairment improved after LT: e.g. mobility was impaired in 39% at LT compared to 14% at follow-up. Renal function was impaired in 55% at LT and improved in a minority of patients after LT but no improvement in the mean GFR was noticed. No patients had AIP symptoms after LT.
Conclusion: Liver transplantation is an important treatment option for patients with severe recurrent AIP. Survival is equal to other transplantation indications and all patients were cured from the AIP. Renal impairment is a risk factor for poor outcome and most patients show no improvement in GFR after LT. Neurological function improves after transplantation.

FRI302

Magnetic resonance iron quantification facilitates venesection decision making in iron overload

Meha Bhuva[1], Ilse Patterson[2], Edmund Godfrey[2], William Griffiths[1].
[1]Cambridge University Hospitals, Hepatology, United Kingdom; [2]Cambridge University Hospitals, Radiology, United Kingdom
Email: mehajb@aol.com

Background and Aims: Venesection is the standard treatment for hereditary haemochromatosis (HH) preventing morbidity and mortality however in some groups the clinical benefit of therapeutic venesection may be negligible. Furthermore the degree of ferritin elevation may overestimate the true extent of iron overload. In order to help inform practice we analysed magnetic resonance (MR) iron quantification data in a cohort investigated for HH.
Method: A cross-sectional study of 87 patients, without known liver or haematological disease, was undertaken. All subjects underwent HFE genotyping and MR imaging with hepatic iron quantification. Additional risk factors for liver disease were noted: alcohol excess, fatty liver, obesity (BMI > 30). Serum ferritin and transferrin saturation values were time-matched with MR liver iron concentration (LIC).
Results: The cohort comprised 39 C282Y homozygotes, 23 compound heterozygotes (C282Y/H63D) and 25 either simple C282Y heterozygote or wild-type. Of 39 C282Y homozygotes (17 females, 22 males, mean age 59), 15/39 (38%) had liver risk factors. Serum ferritin ranged 184–3000 mcg/l (mean 1062 mcg/l), transferrin saturation 43–100% (mean 81%), and LIC 1.27–9.97 mg/g (mean 5.02 mg/g, 1/39 in normal range). There was no difference between those with liver risk factors and those without regarding either serum ferritin (1131 vs 1021 mcg/l) or LIC (4.68 vs 5.23 mg/g).
Of 23 compound heterozygotes (5 females, 18 males, mean age 55), 21/23 (91%) had liver risk factors. Serum ferritin ranged 418–3016 mcg/l (mean 1033 mcg/l), transferrin saturation 29%–100% (mean 51%) and LIC 1.36–4.58 mg/g (mean 2.43 mg/g). 6/23 (26%) had LIC in the normal range with mean serum ferritin 659 mcg/l. A serum ferritin of 1000 mcg/l had 92% sensitivity and 50% specificity for the detection of significant iron overload (>2.5 mg/g).
In the remaining group (3 females, 22 males, average age 65), 15/25 (60%) had liver disease risk factors. Serum ferritin ranged 351–1957 mcg/l (mean 1113 mcg/l), transferrin saturation 21%–96% (mean 46%) and LIC 1.41–4.23 mg/g (mean 2.11 mg/g). 10/25 (40%) had LIC in the normal range with mean serum ferritin 1031 mcg/l. Those with liver risk factors had higher serum ferritin (1254 vs 901 mcg/l, $p < 0.05$) with comparable LIC (2.19 vs 1.97 mg/g).
LIC was significantly higher in homozygotes compared with the other groups for any given ferritin concentration (see figure).



Conclusion: Compared with C282Y homozygotes, liver risk factors are more common in other HFE genotypes, especially compound heterozygotes, and contribute to serum ferritin values. In non-homozygotes around 1/3 have LIC in the normal range despite significant hyperferritinaemia. Compound heterozygotes with serum ferritin >1000 mcg/l are more likely to benefit from venesection.

FRI303

Major depressive disorder in patients with Wilson's disease: relationship with liver disease, neurological disease and quality of life

Michelle Camarata[1,2,3], Aftab Ala[2,3,4], Uyen Kim To[1], Paula Zimbrean[5], Susan Rubman[5], Amar Patel[6], Anant Wadhwa[6], Kaitlin Maciejewski[7], Xuemei Song[7], Yanhong Deng[7], Ricarda Tomlin[1], Tugce Apdik[1], Ayse Coskun[1], Michael Schilsky[1]. *[1]Yale University, Digestive Diseases, Transplantation and Immunology, New Haven, United States; [2]Royal Surrey County Hospital, Gastroenterology and Hepatology, United Kingdom; [3]University Of Surrey, United Kingdom; [4]King's College Hospital, Hepatology, United Kingdom; [5]Yale University, Psychiatry, New Haven, United States; [6]Yale University, Neurology, New Haven, United States; [7]Yale University, Biostatistics, New Haven, United States*
Email: michellecamarata@gmail.com

Background and Aims: Mental health problems are underappreciated in Wilson disease (WD) (Schaefer et al. 2016. *Clin Res Hepatol Gastroenterol*, 40(3):349–356). We aimed to determine: i) the prevalence and clinical features of major depressive disorder (MDD) in adults with WD ii) whether MDD is related to liver and neurological disease and quality of life (QOL).
Method: A multi-site WD registry was initiated in December 2017. At enrollment adults (n = 55) were evaluated using questionnaires and

administered exams assessing cognition, mood, psychosis, substance use, anxiety, perceived stress, personality change and QOL. MDD was determined using the MINI-7. Patients underwent hepatology and neurological assessments (UWDRS). We reviewed depression at first presentation and diagnosis. Statistical analyses included Wilcoxon Rank Sum test, Chi-squared test or Fisher's exact test.

Results: Depression was self-reported in 25% at first presentation of WD (29% at diagnosis). At enrollment, 40% had a lifetime history of MDD, 9 with MDD took antidepressants; 10 reported historic use. Cirrhosis was present in 23% based on imaging, APRI and Fib4. We found no significant difference in MDD (36% vs 42% p = 0.74) or depression symptomology based on PHQ-9 score (median 2 vs 4, p = 0.08) in cirrhotics vs non-cirrhotics. Liver disease severity did not differ in cirrhotics with MDD and those without (median Child-Pugh 5 (5–9) vs 5 (5–9), p = 0.92; MELD-Na 7 (6–12) vs 8 (7–13), p = 0.18). Two patients (1 with MDD) took medication for hepatic encephalopathy. No significant difference in neurological UWDRS total scores was found in those with MDD vs without (median 8.5 (0–73) vs 5 (0–45), p = 0.22). A UWDRS total score >0 was not found to be associated with MDD (77.3% vs 81.8%, p = 0.74).

Patients with MDD had worse mental health QOL (median 42.3 vs 54.6 p < 0.01), more suicidal ideation (36% vs 3% p = 0.002), higher anxiety (median 3.5 vs 3 p = 0.049), higher perceived stress (median 19 vs 9 p < 0.001), and more neuroticism (median 7 vs 5, p = 0.005). We found no significant difference in physical health QOL in MDD (median 54 vs 56.7 p = 0.34).

Conclusion: MDD is highly prevalent in WD and associated with worse mental health QOL. The risk appears higher than other chronic liver diseases (Lee et al. 2013. *Psychosomatics*, 4:52–9). We did not find a statistically significant association between the severity of liver, neurological disease and MDD. Screening for depression should be considered in patients with WD.

FRI304

Mortality in patients with Wilson's disease in England: a national register-based study

Michelle Camarata[1,2,3], Osob Mohamed[1,2,3], Jeanette Aston[3], Mary Bythell[3], Sarah Stevens[3], Griffiths Bill[4], Aftab Ala[1,2,5], Graeme Alexander[6]. *[1]Royal Surrey County Hospital, Gastroenterology and Hepatology, United Kingdom; [2]University Of Surrey, Clinical and Experimental Medicine, United Kingdom; [3]Public Health England, National Congenital Anomaly and Rare Disease Registration Service, London, United Kingdom; [4]Addenbrooke's Hospital, Hepatology, Cambridge, United Kingdom; [5]King's College Hospital, Hepatology, United Kingdom; [6]University College London, Institute for Liver and Digestive Health, London, United Kingdom*
Email: michellecamarata@gmail.com

Background and Aims: Wilson Disease (WD) is a rare genetic disorder of copper metabolism. Without appropriate treatment it can progress to liver failure and death. The National Congenital Anomaly and Rare Disease Registration Service (NCARDRS), with support from the British Association for the Study of the Liver WD Special Interest Group, has established registration of WD in England. We aim to provide a descriptive study of mortality, including multiple cause of death and transplant status, of those with WD.

Method: Confirmed cases of WD were reported by 20 hospital trusts and registered with NCARDRS enabled by their legal permissions (CAG 10-02(d)/2015) to collect patient data without consent. Vital status of all cases were determined and linkage with Office of National Statistics (ONS) mortality data was undertaken to obtain death certificate data. Cases of *E83.0 Disorders of copper metabolism*, between 2008 and 2018, were extracted from ONS mortality data. Cause of death free text was manually searched to identify deaths that mentioned WD. All deaths were linked to Hospital Episode Statistics (HES) inpatient data to determine transplant status.

Results: Death records were identified for 52 patients, with a mean age of 45.5 years (range 17–82), 65% were male. Complications related to cirrhosis or liver failure were assigned as the underlying cause of death (UCOD) in 44%. Hepatocellular carcinoma (HCC) was the UCOD in 5.8%. Of the 21% of patients who were recorded as having a liver transplant, transplant complications or graft failure were recorded as a cause of death in 8%. Sepsis was mentioned on the death certificate in 42% and recorded as the UCOD in 21%.

Table: Underlying cause of death in WD.

UCOD	Assigned on death certificate (%)	Assigned by ONS (%)
WD	40	44
Transplant	8	2
Infection[a]	29	21
HCC	4	5.8
Bleeding	6	2
Liver disease (other)[b]	0	2
Chronic illness	0	5.8
Accident	0	5.8
Cancer	2	5.8
Other	11	5.8

[a]Includes cirrhosis, decompensated disease, liver failure.
[b]Includes spontaneous bacterial peritonitis, biliary, viral and fungal.

Conclusion: The contribution of WD to mortality in England will be underestimated unless multiple cause of death analysis is undertaken. The number of deaths resulting from complications related to cirrhosis or liver failure suggests that there might be missed opportunity for liver grafting. HCC was the cause of death in 5.8% of cases suggesting the prevalence of HCC in WD may be higher than previously thought. This project demonstrates the utility of the NCARDRS for WD in England.

FRI305

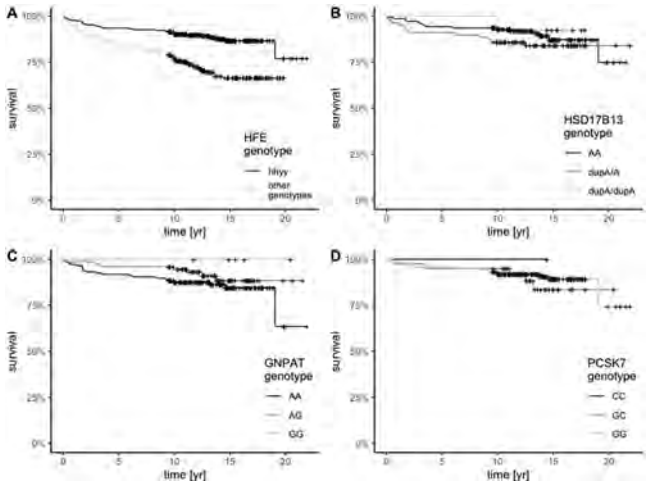
Survival in HFE hemochromatosis: influence of polymorphisms in HSD17B13, GNPAT, and PCSK7

Moritz Tobiasch[1], Benedikt Schaefer[2], André Viveiros[2], Herbert Tilg[2], Ivo Graziadei[1], Heinz Zoller[2]. *[1]LKH Hall in Tirol, Dept. of Medicine, Hall in Tirol, Austria; [2]Medical University Innsbruck, Dept. of Internal Medicine, Innsbruck, Austria*
Email: moritztobiasch@gmail.com

Background and Aims: Hereditary hemochromatosis, defined as homozygosity for the p.C282Y polymorphism in the HFE gene, is a condition of iron overload with variable penetrance. The polymorphism affects endogenous iron homeostasis by impairing transferrin receptor mediated hepcidin response. Various genetic modifiers have been postulated to modify the disease phenotype in persons with this genetic constellation, with conflicting results when serum iron parameters or the degree of liver disease were used as statistical endpoints. In a cohort of 438 patients presenting for workup of hyperferritinemia, survival was assessed in relation to the presence of polymorphisms in HSD17B13, GNPAT, and PCSK7, as well in relation to the HFE genotype.

Method: In a cohort of 438 patients having presented at LKH Innsbruck for genetic workup of hyperferritinemia, HFE genotyping was routinely performed. Serum iron parameters were recorded simultaneously, together with a staging of liver disease. Additionally, alcohol intake was recorded. Survival data were available for the entire cohort as of Oct 1, 2019. For this study, pseudonymized samples were additionally genotyped for polymorphisms rs72613567 in the HSD17B13 gene, rs11558492 in the GNPAT gene, and rs236918 in the PCSK7 gene. Principal component analysis (PCA), Kaplan-Meier survival estimates and Cox proportional hazard models were calculated in R in a manner of right-censored data. Stratification for iron overload was performed using EASL criteria, i.e., gender specific cutoffs for ferritin (FTN) of 300 µg/L and 200 µg/L as well as 50% and 45% in transferrin saturation, in male and female persons, respectively. Minor allele frequencies were compared to gnomAD Genomes (subset, european population).

Results: Out of 230 patients homozygous for the HFE p.C282Y polymorphism, 182 met EASL criteria of iron overload. Criteria for Hardy-Weinberg equilibria were met for all three polymorphisms studied, minor allele frequencies did not significantly differ in comparison to the general population. Serum iron parameters were not significantly different in dependence of polymorphisms. Survival was not different in any of the three polymorphisms studied. Results were similar in the subset with elevated serum iron parameters.



Conclusion: Iron overload syndrome caused by type I hereditary hemochromatosis has a better prognosis as compared to non-HFE iron overload. HSD17B13, GNPAT and PCSK7 showed no relevant effects on outcome.

FRI306

Analysis of survival and influence of genetic modifiers in HFE- and non-HFE-associated iron overload

Moritz Tobiasch[1], Benedikt Schaefer[2], André Viveiros[2], Herbert Tilg[2], Ivo Graziadei[1], Heinz Zoller[2]. *[1]Hall in Tirol, Dept. of Medicine, Hall in Tirol, Austria; [2]Medical University Innsbruck, Dept. of Internal Medicine, Innsbruck, Austria*
Email: moritztobiasch@gmail.com

Background and Aims: The most common form of hereditary iron overload is linked to homozygosity for the p.C282Y polymorphism in the HFE gene, resulting in an impaired hepcidin response. A large proportion of patients with clinically relevant iron overload, however, does not carry this genetic constellation, the iron overload then being classified as non-HFE hemochromatosis. Iron overload is one of many potential risk factors of chronic liver disease and is in itself influenced by both other genetic modifiers, concurrent diseases, and external factors. Survival as a potential end-point of iron overload syndromes is rarely reported.
Method: In a cohort of 438 patients having presented at LKH Innsbruck for genetic workup of hyperferritinemia, HFE genotyping was routinely performed. Serum iron parameters were recorded, together with a staging of liver disease, and alcohol intake. Survival data were available for the entire cohort as of Oct 1, 2019. For this study, samples were additionally genotyped for polymorphisms rs72613567 in HSD17B13, rs11558492 in GNPAT, and rs236918 in the PCSK7 genes. Principal component analysis (PCA), Kaplan-Meier survival estimates and Cox proportional hazard models were calculated in R in a manner of right-censored data. Stratification for iron overload was performed using EASL criteria, i.e., gender specific cutoffs for ferritin (FTN) of 300 µg/L and 200 µg/L as well as 50% and 45% in transferrin saturation, in male and female persons, respectively.
Results: Survival is markedly reduced in non-HFE hemochromatosis patients as compared to patients homozygous for HFE p.C282Y (hazard ratio, 2.75, $p < 0.001$). This difference is strongest in the subset of patients with elevated serum iron parameters (HR, 6.57, $p = 0.001$), further illustrated by PCA analysis. Alcohol intake (HR, 2.19, $p = 0.03$) and advanced liver disease (HR, 3.21, $p < 0.001$) additionally proved to be associated with mortality in non-HFE patients. Effects of putative genetic modifiers of iron homeostasis were stronger in the non-HFE subset.
Conclusion: Iron overload syndrome caused by type I hereditary hemochromatosis (homozygosity for HFE p.C282Y) has a better prognosis as compared to non-HFE hemochromatosis. This is most likely a consequence of the fact that significant iron overload in the absence of the strongest genetic modifier is most likely caused by multiple, less obvious concurrent risk factors that generally are more challenging to control.

FRI307

Validation of the new proposed histological criteria for the diagnosis of porto-sinusoidal vascular disease in a single tertiary center

Oana Nicoara-Farcau[1,2,3], Rusu Ioana[2,4], Iulia Flueraru[3], Horia Stefanescu[1,3], Marcel Tantau[1,2], Bogdan Procopet[1,2,3]. *[1]Regional Institute of Gastroenterology and Hepatology 'Octavian Fodor', Hepatology Department, Cluj-Napoca, Romania; [2]University of Medicine and Pharmacy 'Iuliu Hatieganu', Gastroenterology Department, 3rd Medical Clinic, Cluj-Napoca, Romania; [3]University of Medicine and Pharmacy 'Iuliu Hatieganu', Liver Research Club, Cluj-Napoca, Romania; [4]Regional Institute of Gastroenterology and Hepatology 'Octavian Fodor', Pathology Department, Cluj-Napoca, Romania*
Email: bogdanprocopet@gmail.com

Background and Aims: Recently, a new definition of porto-sinusoidal vascular disease (PSVD) has been proposed. An adequate liver biopsy is still mandatory for PSVD diagnosis. However, many histological features are also found in chronic portal vein thrombosis (PVT).
The study aims to validate the new proposed histologic criteria in a cohort of PSVD patients and to test these criteria in patients with PVT.
Method: Patients diagnosed with PSVD between 2016 and 2019 at our center were included. All liver biopsies were reviewed by an expert pathologist and were classified according to the new criteria: specific signs (obliterative portal venopathy-OPV, nodular regenerative hyperplasia-NRH, and incomplete septal fibrosis ISF), non-specific signs (portal tract abnormalities, architectural disturbances, non-zonal sinusoidal dilatation, and mild perisinusoidal fibrosis). Patients without clinical signs of portal hypertension (PHT) but who had a positive liver biopsy were also included. A small cohort of patients diagnosed with PVT that had liver biopsies performed was also included.
Results: Thirty-three patients (28 with PSVD and 5 PVT) were included. Mean age was 40.52 years [19–72], 48.5% females, MELD score of 9 [6–17]. Twenty-six (93%) patients with PSVD and all patients with PVT had PHT signs at diagnosis. The two patients without PHT signs at diagnosis performed liver biopsies for the alteration of liver enzymes. Twenty-three (82%) patients with PSVD and all patients with PVT had adequate biopsies: median length of 28.48 mm [7–49] and 36.8 mm [23–54], respectively, and the total number of portal tracts of 19.41 [8–40] and 23.8 [15–35], respectively. In the PSVD group, 22 (78.6%) patients had specific criteria (19-OPV, 10-NRH, and 1-ISF), and 24 (88.9%) patients had non-specific criteria (19-portal tract abnormalities, 1-architectural changes, 19-sinusoidal dilatation, and 14-mild perisinusoidal fibrosis). In the 2 PSVD patients without signs of PHT, the liver biopsies showed major criteria (2-OVP) as well as minor criteria. In the PVT group, all patients had major as well as minor criteria on liver biopsy.
Conclusion: The new proposed histologic criteria for the diagnosis of PSVD is feasible in patients with or without PHT. Although the present cohort was very small, in patients with PVT, the histological signs were very similar to that of PSVD. More studies should focus on the histological differentiation between the two entities.

FRI308

Non-invasive diagnostic tools in porto sinusoidal vascular liver disease. A pilot study

Oana Nicoara-Farcau[1,2], Crina Grigoras[1], Iulia Flueraru[2], Marcel Tantau[2,3], Bogdan Procopet[1,2], Horia Stefanescu[1]. [1]*Regional Institute of Gastroenterology and Hepatology 'O. Fodor', Hepatology Department, Hepatic Hemodynamic Laboratory, Cluj-Napoca, Romania;* [2]*University of Medicine and Parmacy 'Iuliu Hatieganu', Cluj-Napoca, Romania;* [3]*Regional Institute of Gastroenterology and Hepatology 'O. Fodor', Cluj-, Napoca, Romania*
Email: oana.farcau@gmail.com

Background and Aims: Porto sinusoidal vascular liver disease (PSVD) represents a cause of presinusoidal portal hypertension which can often lead to formation of oesophageal or gastric varices and portal hypertension related bleeding. In cirrhotic patients, liver stiffness measurement by transient elastography (LSM) < 20 kPa and platelets (PLT) count >150.000 are able to rule-out high risk oesophageal varices. However, in patients PSVD there is no non – invasive test that can predict the presence of varices. We aimed to investigate whether LSM, spleen stiffness measurement (SSM) and PLT count have a role in prediction of varices in patients with PSVD.
Method: Patients diagnosed with PSVD who were admitted at the RIGH 'Prof. dr. Octavian Fodor' and who had performed endoscopies prior to or at enrolment were included in the study. All patients had routine laboratory work out and performed liver and spleen measurements by transient elastography with a Fibroscan 502 Touch® (M or XL probe). The median of 10 measurements with an IQR < 0.3 was considered adequate. A control group of cirrhotic of various etiologies compensated patients was also included in the study.
Results: Nineteen patients with biopsy proven PSVD were included in the study. Mean age was 34.79 years [range 19–72] and included 57.9% of male patients. All patients were Child Pugh A and had a mean MELD score of 9.31 [range 6–17], mean PLT level was 120.000 [range 12.000–325.000]. Fifteen patients of the patients had varices, either esophageal (n = 11), gastric (n = 2) or both (n = 1). Mean LSM was 9.3 kPa [range 3–39.7] and mean SSM was 46.9 kPa [11.8–75]. The ratio between the difference of SSM and LSM and PLT count ((SSM-LSM)/PLT) was the best test to predict the presence of varices with an AUROC of 0.83 CI 95% (0.64–1), p = 0.04. If the (SSM – LSM)/PLT ratio was <0.06, the test had a sensitivity of 100%, specificity of 25%, a PPV of 83% and a NPV of 100% with a +L = 1.33 and a – LR = 0 in prediction of varices. The test had a diagnostic accuracy of 84.2% (16 / 19). If the (SSM – LSM)/PLT ration was > = 0.29, the test had a sensitivity of 66%, specificity of 100%, a PPV of 100% and a NPV of 44% with a + L = infinite and a – LR = 0.33 in prediction of varices. When this ratio was tested in the cirrhotic population, the AUROC was 0.32 CI 95% (0.13–0.53), p = 0.13.
Conclusion: The ratio of (SSM-LSM)/PLT has a high accuracy for predicting esophageal or gastric varices in patients with porto sinusoidal vascular liver disease, but not for patients with compensated cirrhosis. At a cut – off of 0.06, the test has a very large effect on ruling-out and at a cut-off of 0.29 the test has a very large effect on ruling-in the presence of varices in this disorder. In these patients, according to these cut-offs, endoscopies should be performed if the ratio is between 0.06 and 0.29. Due to small sample size and high prevalence of varices, these results need confirmation in a larger cohort.

Simplification of Wilson's disease maintenance therapy with a single daily dose: safety and efficacy in difficult to treat patients

Olivier Guillaud[1], Eduardo Couchonnal[1], Broussole Emmanuel[1], Chloé Laurencin[1], Laurence Lion-François[1], Belmalih Abdelouahed[1], Muriel Bost[1], Jérôme Dumortier[1], Alain Lachaux[1]. [1]*Hospices civils de Lyon, CRMR pour la madie de Wilson, Bron, France*
Email: olivier.guillaud@chu-lyon.fr

Background and Aims: Wilson's disease (WD) is a rare genetic disease responsible for deleterious accumulation of copper in different organs, mainly in the liver and brain. There are effective medications for the treatment of this affection but according to recommendations the drugs have to be taken 2 or 3 times a day all-lifelong, which may limit adherence to treatment and therefore therapeutic efficacy. Single daily dose (SDD) is a good way to improve adherence by simplification of therapy. In the French National Reference Center for WD of Lyon, some patients are currently on single daily dose of D-Penicillamine, Trientine of Zinc, either by personal choice or by physician choice. The goal of our study was to report the efficacy of single daily dose of treatment in WD patients.
Method: We reviewed the chart of all WD patients followed in our center. Patients with an history of SDD of WD treatment were included in this retrospective study. The treatment failure was defined as a composite criteria with the occurrence of at least one of the following criteria : death, transplantation, increase of transaminases >2 × ULN, hepatic decompensation, neurological aggravation, severe side effect related to treatment and/or discontinuation of treatment for more than a week. The rate and the time to first failure after SDD were reported.
Results: We identified 14 patients with a past history of non-adherence who received a SDD of WD therapy: 6 males and 8 females, with a mean age at diagnosis of 12,9 yrs. There were 6 hepatic, 6 extrahepatic and 2 presymptomatic forms. The switch to SDD was performed after a median delay of 151 months after diagnosis. Eight, five and one patients were respectively on SDD of Trolovol, trientine and Wilzin. Two patients were considered as non-stabilized before the switch: one patient had cytolysis >2 × ULN and one patient had neurological aggravation related to treatment discontinuation. After one year of SDD, only one patient (7%) met criteria for treatment failure with the occurrence of cytolysis >2 × ULN though the liver function tests (LFT) were initially normal. The two non-stabilized patients had clinical improvement (normalization of LFT, amelioration of UWDRS neurological score). After a median delay of 41 months on SDD, 3 patients (21%) had treatment failure (2 cytolysis and 1 treatment discontinuation). There were no death, no liver transplantation, no hepatic decompensation, no neurological deterioration and no severe side effects related to treatment during the follow-up. Moreover ALT, AST and exchangeable serum copper were not statistically different after one year of SDD and at last news compared to baseline.
Conclusion: Simplification of maintenance therapy with a single daily dose is an option to consider in difficult-to-treat Wilsonian patients. In this pilot study, SDD was effective in around 80% of patients without any concern regarding safety.

Email: p.stein@nhs.net

Background and Aims: Acute intermittent porphyria (AIP) is a rare genetic disease caused by an enzyme deficiency involved in heme biosynthesis. Induction of 5-aminolaevulinic acid synthase 1 (ALAS1) leads to accumulation of toxic heme intermediates, 5-aminolevulinic acid (ALA) and porphobilinogen (PBG), resulting in potentially life-threatening, neurovisceral attacks and chronic symptoms. Givosiran, an investigational RNAi therapeutic, specifically targets ALAS1 to reduce ALA and PBG levels.
Method: A Phase 1 study evaluated the safety, tolerability, and pharmacokinetics/pharmacodynamics of givosiran (NCT02452372). Part C of the study was conducted in AIP patients experiencing recurrent attacks and included clinical activity as an exploratory endpoint. Patients completing Part C were eligible to enroll in the Phase 1/2 open-label extension (OLE) study (NCT0294983).
Results: As of April 19, 2019 (median time on study 24.7 months), givosiran administered at 2.5 mg/kg monthly robustly lowered ALA and PBG from baseline by >85% at 18 months in a sustained manner (median follow-up 19.8 months). Patients on givosiran had substantial mean reductions of >90% in annualized attack rate (AAR) and annualized hemin use, relative to Phase 1 Run-in. Serious adverse events (10) were reported in six patients, with one case of anaphylaxis assessed as definitely related to study drug. Adverse events occurring in more than three patients included abdominal pain, fatigue, injection site erythema, nausea, nasopharyngitis, headache, myalgia, diarrhea, injection site pruritus, and international normalized ratio increased. Seven patients had injection site reactions, all mild to moderate. No clinically significant laboratory changes were observed, including liver function tests.
Conclusion: In an ongoing Phase 1/2 OLE study, givosiran has shown an acceptable safety profile and has been associated with marked and sustained reductions in both AAR and annualized hemin use. Updated data from this study will be presented.

Good clinical outcomes after direct intrahepatic portocaval stent (DIPS) insertion for Budd-Chiari syndrome

Abhishek Chauhan[1,2,3], Rosemary Faulkes[1], Homoyon Mehrzad[4], Salil Karkhanis[4], Frederick Chen[5], Hayder Hussein[5], Simon Olliff[4], Jo Grayer[1], Dhiraj Tripathi[1,2,3]. *[1]University Hospital Birmingham Liver Unit, United Kingdom; [2]NIHR Birmingham Biomedical Research Centre, UHB NHS Foundation Trust and University of Birmingham, Birmingham, UK, United Kingdom; [3]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, UK, United Kingdom; [4]University Hospital Birmingham Radiology Department, United Kingdom; [5]University Hospital Birmingham Haematology Department, United Kingdom*
Email: abhichauhan@mac.com

Background and Aims: Budd Chiari syndrome (BCS) is rare but potentially life-threatening condition. Recanalization using TIPSS or hepatic venous stenting is key to relieving hepatic congestion. These procedures are impossible in complete HV occlusion. Direct intrahepatic portocaval shunt (DIPS) is a new procedure where a stent is placed directly from the inferior vena cava, often through the caudate lobe to the portal vein bypassing the thrombosed HVs. We report our experience in using DIPS for recanalization in BCS.
Method: Single centre retrospective analysis from May 2015 to January 2019 comparing outcomes following a DIPS insertion compared to our centres previously published data*.
Results: 14 patients were referred for a DIPS procedure. M:F ratio 8:6; age 40.5 ± 13.2; follow up 23.1 ± 15.0 months. HV-BCS type in all. Aetiology: myeloproliferative neoplasm (MPN) in 7, all JAK2+ve with mutation load 17.3 ± 10.2%; PNH, 1; idiopathic, 6 (all –ve following next generation sequencing). Pre-DIPS: MELD 13.1 ± 3.2, UKELD 49.1 ± 13.35, BCS-TIPS PI score 4.45 ± 1.1**. Post DIPS portal pressure gradient was 6.9 ± 2.2 mmHg. Clinical indication: variceal bleeding and ascites (n = 1) or ascites (n = 13). Multidisciplinary consensus to undertake a DIPS insertion as a first line procedure was reached in 13 patients, in 1 patient a TIPSS insertion was initially attempted, when this failed a rescue DIPS was performed. One DIPS insertion (7%) was not successful, this patient is now on the waiting list for transplantation, all of the others patients were successful stent placement and none required escalation to transplantation. Ascites resolution was seen in 7 out of 11 patients at follow up (64%). 2 patients developed hepatic encephalopathy post DIPS (14%). Primary patency rates at 6 months, 1 year, and 2 years were 83%, 83%, 58% respectively. Secondary patency was 100%. Transplant free survival 100% to date. The outcomes are comparable to a previously reported series from the same institution, with similar BCS-TIPS PI but slightly lower MELD.*
Conclusion: Our data demonstrates that with technical excellence, multidisciplinary management, and careful patient selection, DIPS results in very good clinical outcomes in patients unsuitable for standard TIPSS. The outcomes are comparable to standard TIPSS from our historic data.* We strongly recommend early referral of all patients with BCS to multidisciplinary teams in centres that offer advanced interventional radiology and liver transplantation.

* Tripathi D, et al. Long-term outcomes following percutaneous hepatic vein recanalization for BCS. Liver Int. 2017 Jan;37(1):111–120.

Email: shannon.vandriel@sickkids.ca

Background and Aims: Alagille Syndrome (ALGS) is a rare multi-system disorder and one of the most common inherited causes of neonatal cholestasis. Prior ALGS studies largely come from tertiary liver centers and therefore select for the most severely affected cholestatic patients. As a result, the full spectrum of ALGS liver involvement remains unclear. Also, a comprehensive assessment of extrahepatic manifestations in a large cohort is missing. The Global ALagille Alliance (GALA) Study Group was established to overcome these limitations.

Method: Multicenter retrospective analysis of children with a clinically and/or genetically confirmed ALGS diagnosis, born between Jan-1997 and Aug-2019. Histopathological features in liver biopsies were compared with chi-square. Cox proportional hazards models were constructed to determine transplant-free survival (TFS) in ALGS patients who underwent a Kasai or biliary diversion (BD). TFS and overall survival were estimated using the Kaplan-Meier method.

Results: 1154 ALGS (58% male) patients from 25 countries were included (median follow-up 5.6 years, IQR 2.3–11.3). Of the 75% genetically confirmed patients, 93% have a mutation in *JAG1* and 4% in *NOTCH2* (69% *de novo*). Any cardiac anomaly was the most common extrahepatic manifestation (89%), followed by characteristic facies (88%), posterior embryotoxon (49%), butterfly vertebrae (44%), and renal anomalies (35%). MRI and CT reports revealed cerebral and intra-abdominal vascular anomalies in 34% and 31% of patients, respectively. Review of 497 baseline liver biopsy reports (Table) revealed an increasing frequency of bile duct paucity with age ($p = 0.01$) and features of biliary obstruction in 20% of biopsies <6-months. 10-and-18-year TFS rates in 911 ALGS patients presenting with neonatal cholestasis were 57% and 41%, respectively. ALGS patients who underwent a Kasai (n = 74, HR 3.3, 95% CI 2.4–4.5; $p < 0.001$) or BD (n = 46, HR 2.0, 95% CI 1.4–3.7; $p = 0.004$) had significantly lower rates of TFS. Overall 10-and 18-year survival rates were 90.9% and 88.6%, respectively.

Table: Histopathological features in 497 baseline liver biopsies.

	Biopsy <6 months	Biopsy ≥6 and <24 months	Biopsy ≥24 months	P-value
n	307	84	106	
Histopathologic Findings, % (*n*)				
Bile duct paucity	61 (188)	63 (53)	77 (82)	0.01
Giant cell transformation	40 (124)	12 (10)	4 (4)	<0.001
Bile duct proliferation	20 (62)	18 (15)	7 (7)	0.005
Duct/ductular bile plugs	7 (20)	5 (4)	2 (2)	0.20

Conclusion: We describe the largest global cohort of ALGS to date. Almost 60% of ALGS children with neonatal cholestasis will undergo liver transplantation by the age of 18 years. ALGS patients who underwent a Kasai procedure had significantly lower rates of TFS – it remains to be seen if this is due to a more severe hepatic phenotype in these patients, or if Kasai adversely affects hepatic natural history. This dataset provides a robust foundation for future clinical studies in ALGS.

FRI314

Wilson's disease: epidemiologic and therapeutic insights from German hospital and ambulatory invoicing data

Steffen Wahler[1], Simone Svea Janka[2], Karl Heinz Weiss[2]. [1]*St. Bernward GmbH, Hamburg, Germany;* [2]*Heidelberg University, Heidelberg, Germany*
Email: steffen.wahler@t-online.de

Background and Aims: Wilson's disease (WD) is an autosomal recessive inherited condition in which copper excretion via bile is diminished due to gene mutations in the ATP7B gene. Consequence is a toxic accumulation of copper in predominantly the liver and the brain leading to a variety of hepatic and neurologic symptoms. WD prevalence in Germany is often estimated around 1:30,000. Little is known about the medical treatment and hospitalization rate of patients in Germany. Here we used health insurance billing data to estimate the current number and care of WD patients.
Method: Inpatient care data from Federal Statistical Office 2005–2017 and ambulatory billing data from the federal physicians' organization and quality reports for 2009–2017 of all German hospitals were evaluated for WD encodings and treatment schemes. Analysis with IBM SPSS-25.
Results: In 2017 there were 1,368 patients in German statutory sick funds diagnosed with the fitting ICD E83.0 for WD and received a WD specific therapy. Thereof 828 (60.5%) D-penicillamine, 217 (15.9%) trientine, 174 (12.7%) zinc-acetate and 149 (10.9%) other zinc-salts. 46.4% of treated patients are women, they make 45.7% of all chelator and 48.1% of all zinc therapies. The prevalence related to diagnosed and treated patients was around 1:60.000. The relation of chelators to zinc therapy was very stable from 2009 to 2017. Patients younger than 24 years were treated relatively more frequently with chelators than adults. The number of diagnosed patients under 15 years hardly changed from 159 (2009) to 161 (2017). Regional distribution of WD diagnoses was rather similar throughout Germany.
186 patients were hospitalized with WD as main diagnosis in 2017. Thereof 45.1% female, who stay shorter in hospital (6.2 days) than men (8.5 days). 45.2% of cases are treated in neurologic departments, 29.0% in gastroenterological and 19.9 in pediatric departments; 3.2% in transplant units (2.7% other). Stays in neurologic departments take longer, such that more than half of hospital days are spent there. Regional distribution of hospitalization differs widely and is not related to ambulatory cases, from 4.9 per million in Rhineland to 11.8 per million in Pomerania. Mean age at hospitalization with main diagnosis WD is 30.1 years (m 29.9 y, f 30.3). Around 48% of patients are treated in university hospitals.
Conclusion: The German billing data allows for a quite exact estimation of diagnosed and treated patients with WD. From 2009 to 2017 treatment patterns did hardly change. Younger patients are treated more frequently with chelators than adults. Hospitalizations are partly driven by regional habits. Men stay more frequently and longer in hospital. A national registry would support further insights.

FRI315

The role of liver stiffness by ARFI elastography in the diagnosis of porto-sinusoidal vascular disease: comparison with patients with chronic portal vein thrombosis

Stefania Gioia[1], Silvia Nardelli[1], Francesca Aprile[1], Barbara Lattanzi[1], Lorenzo Ridola[1], Adriano De Santis[1], Manuela Merli[1], Oliviero Riggio[1]. [1]*Sapienza, Università di Roma, Dipartimento di Medicina Traslazionale e di Precisione, Roma, Italy*
Email: stensgioia@hotmail.com

Background and Aims: PSVD (porto-sinusoidal vascular liver disease) and PVT (portal vein thrombosis) are distinct vascular liver diseases characterized respectively by an intrahepatic and a pre-hepatic obstacle to the flow in the liver portal system. PVT may also occur as a complication of the natural history of PSVD, especially if a pro-thrombotic condition coexists.
The presence of PSVD should be suspected in patients with PVT and its active search be included in their diagnostic work-out. However, sometimes the diagnosis of pre-existing PSVD is very hard. Liver stiffness (LS) may help as it has been shown to be higher in PSVD than in "pure" PVT but this comparison is until now restricted to very limited series of patients. The aim of the study is to compare LS between the two groups of patients and to find a cut-off value of LS to discriminate the two diseases.
Method: Forty-six patients affected by histologically proven PSVD and fifty-five patients affected by chronic PVT were enrolled. Laboratory, endoscopic and ultrasonographic data were collected. LS was measured by ARFI (acoustic radiation force impulse).

Table: Comparison between patients with PSVD and chronic PVT.

	PSVD (n = 46)	Chronic PVT (n = 55)	P value
Age (mean ± SD)	49 ± 15	52 ± 14	NS
Sex (M/F)	31/15	27/28	NS
Bilirubin (mg/dl)	1.1 ± 0.6	1.2 ± 0.6	NS
Albumin (g/dl)	4.2 ± 0.6	4.6 ± 0.4	NS
Platelet ($\times 10^3/\mu l$)	133 ± 129	278 ± 178	0.0001
Esophageal Varices (absent/small/large)	16/14/16	19/19/17	NS
Previous Variceal bleeding (No/Yes)	29/17	35/20	NS
Ascites (No/Yes)	42/4	39/16	0.01
Spleen Diameter (cm)	18 ± 4	17 ± 5	NS
ARFI (KPa)	**7.4 ± 7**	**4.6 ± 2**	**0.005**

Results: The results of the comparison between the two groups of patients are summarized in the table. Liver stiffness was significantly higher in patients affected by PSVD than in patients with chronic PVT. Based on the results of ROC analysis, the best cut-off of LS to distinguish the two groups of patients was 7 KPa, with a sensitivity of 90% and specificity of 53%.
Conclusion: Our study showed that liver stiffness measured by ARFI is higher in patients with PSVD than in patients with chronic PVT. A cut-off value of 7 KPa has been identify but needs to be confirmed by more studies with a higher number of patients.
Even if still to strengthen, our findings may have clinical consequences, especially in the decision of performing a liver biopsy in patients with PVT and a higher liver stiffness and suspending the anticoagulation in patients with PVT and no detectable pro-thrombotic factors.

FRI316

Elevated serum bile acid and alanine aminotransferase concentrations in intrahepatic cholestasis of pregnancy are associated with increased fetal NT-proBNP which is ameliorated by ursodeoxycholic acid treatment

Tharni Vasavan[1], Jenny Chambers[1], Paul Seed[1], Peter Dixon[1], Jim Thornton[2], Lucy Chappell[1], Catherine Williamson[1]. [1]*King's College London, Women and Children's Health, United Kingdom;* [2]*University of Nottingham, Obstetrics & Gynaecology, United Kingdom.*
Email: tharni.vasavan@kcl.ac.uk

Background and Aims: Intrahepatic cholestasis of pregnancy (ICP), diagnosed by elevated maternal total serum bile acid (TSBA) concentrations and pruritus, is associated with fetal cardiac dysfunction that is thought to cause the increased rate of stillbirth observed in severe forms of the disease. We aimed to investigate the relationship between severity of deranged markers of liver function shown in ICP and fetal NT-proBNP, a marker of heart failure, at birth and assess the effect of ursodeoxycholic acid (UDCA) treatment.
Method: Serum samples were collected between 1 and 21 days before birth from 17 women with uncomplicated pregnancies (defined as controls) and 68 women with ICP (35 of whom were untreated and 33 UDCA-treated) from St. Thomas' and Queen Charlotte's and Chelsea Hospitals (London, UK). TSBA, alanine aminotransferase (ALT) and bilirubin concentrations were tested in-

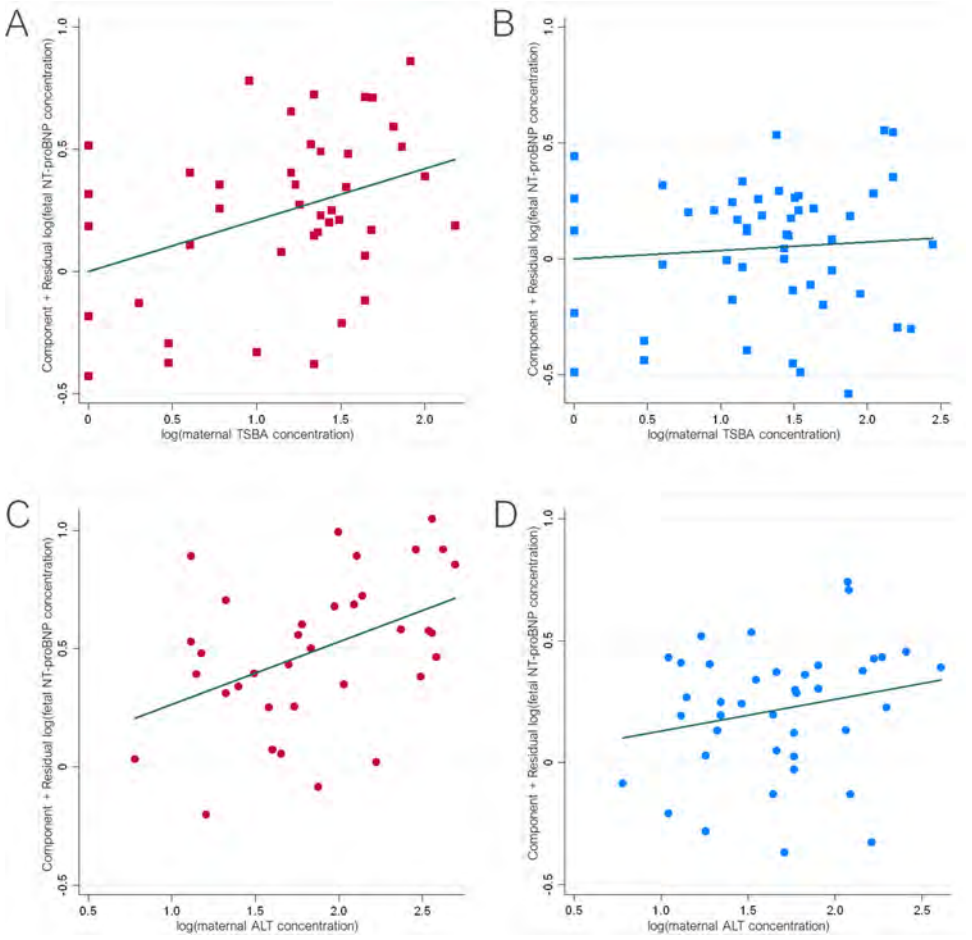

Figure 1: (abstract: FRI316)

house by pathology laboratories. Umbilical cord serum samples were collected immediately after birth and NT-proBNP was measured via a human proBNP enzyme linked immunosorbant assay kit. Maternal liver function and fetal NT-proBNP measurements were log transformed and the relationship between them analysed using linear regression models adjusted for the potential confounding variables of labour induction, mode of delivery and gestational age at delivery. Figure 1 contains partial residual plots and fitted regression lines from the above models which include control participant data.

Results: A 1% increase in maternal TSBA or ALT concentration resulted in a 0.24% or 0.26% increase in fetal NT-proBNP concentration respectively ($p = 0.0367$ and $p = 0.0260$, Figures 1A and 1C). No significant associations were observed in women who had UDCA treatment ($p = 0.1355$ and $p = 0.2072$, respectively, Figures 1B and 1D). Maternal bilirubin values did not have any significant associations with fetal NT-proBNP concentration in untreated participants ($p = 0.1065$) or UDCA-treated participants ($p = 0.0646$).

Conclusion: Fetal NT-proBNP concentration in untreated ICP increases with increasing maternal concentrations of TSBA and ALT; this is not observed in UDCA-treated ICP. This suggests that pregnancies complicated by untreated ICP may have a higher likelihood of fetal impaired ventricular function which is associated with severity of disease. UDCA treatment appears to have a protective effect. Further studies are required to assess the clinical impact of these data.

FRI317

Penetrance, cancer incidence and survival of hemochromatosis in a long-term follow-up and epidemiological modelling study

Thomas Kallab[1], Benedikt Schaefer[1], André Viveiros[1], Bernhard Pfeifer[2], Florian Kronenberg[3], Claudia Lamina[3], Herbert Tilg[1], Heinz Zoller[1]. *[1]University Hospital of Innsbruck, Internal Medicine I, Innsbruck, Austria; [2]Tirol Kliniken, Institute for Clinical Epidemiology, Innsbruck, Austria; [3]University Hospital of Innsbruck, Institute of Genetic Epidemiology, Innsbruck, Austria*
Email: heinz.zoller@i-med.ac.at

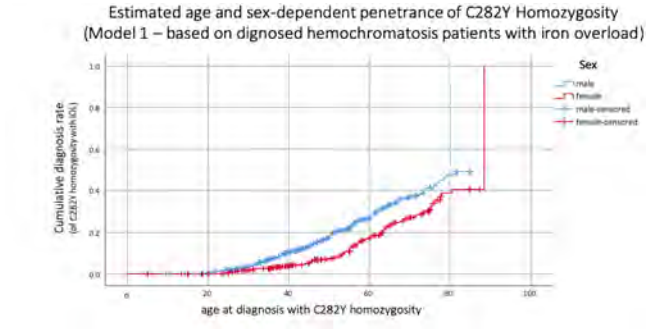
Background and Aims: Hereditary Hemochromatosis (HH) is associated with homozygosity for p.C282Y in *HFE* in 80% of patients, but disease penetrance occurs in only 14%, when HH is defined by presence of iron overload (IOL). Considering cirrhosis and hepatocellular carcinoma (HCC) as complications of HH, an even lower penetrance can be assumed, but the exact risk of this complications is unknown, especially in early diagnosed and treated patients.

The aim of the present study was to determine age- and sex-dependent penetrance of IOL in an epidemiological modelling study and assess the risk for cirrhosis and HCC during a long-term follow-up in a large cohort of HH patients from the geographical region of Tyrol in Austria.

Method: For this retrospective cohort study survival and cancer incidence data were extracted from national databases in 498 patients homozygous for p.C282Y between 1996 and 2018. HH was defined as homozygosity for p.C282Y and presence of provisional IOL (in males: Ferritin >300 + Transferrin saturation >50% and in females: Ferritin >200 + Transferrin saturation >45%) at the time of

genotyping. From the reported allele frequency of p.C282Y in the general population and the respective age distribution in Tyrol, an expected number of homozygous individuals was calculated. After correcting for mortality, age- and sex-specific estimates of disease penetrance were calculated based on patients diagnosed with HH and the expected number of homozygous individuals in 2008 and 2018. Crude incidence rates for HCC and prostate cancer as a control as well as survival status on 28 January 2019 were assessed to calculate age-standardized cancer incidence rates for HH patients and risk genotype carriers.

Results: Age- and sex-dependent estimates of HH penetrance for p.C282Y homozygous individuals are 28–40% in males and 18–25% in females aged 60 years or older (Figure). Among the 498 patients with homozygosity for p.C282Y, the crude penetrance estimate was 14% when only diagnosed patients alive with provisional IOL were considered in both sexes. In this group of p.C282Y homozygotes, 73% of patients presented with provisional IOL. Mean age at diagnosis of p.C282Y homozygotes was 47.8 years. In this group, the diagnosis of HCC was made in 5 patients, which represents an estimated risk for HCC of 1:60 by the age of 80. For comparison, in the general population from Tyrol the risk of having developed an HCC by the age of 80 is 1:77 in men and 1:333 in women. Hence, no increased HCC risk could be found in patients with p.C282Y homozygosity. Regression analysis shows that age and sex were independently associated with HH penetrance.



years of age	0-9	10-19	20-29	30-39	40-49	50-59	60-69	70-79	80-89
numbers at risk (males)	851	777	700	584	461	332	199	109	39
diagnosis HH with IOL	0	3	21	38	32	31	24	12	1
numbers at risk (females)	713	640	567	475	391	302	191	112	36
diagnosis HH with IOL	0	0	9	10	11	27	20	10	2

Figure: (abstract: FRI317)

Conclusion: Considering age and sex allows for a more accurate prognosis of hemochromatosis penetrance among p.C282Y homozygotes. Overall, no increased mortality or risk for the development of HCC could be identified in this long-term follow-up and epidemiological modelling study.

Prevalence and characteristics of cystic fibrosis associated-liver disease in a cohort of cystic fibrosis patients

Zaina Issa[1], Sophie Gohy[2], Bénédicte Delire[1], Géraldine Dahlqvist[1].
[1]*Cliniques Universitaires Saint-Luc, Hepato-Gastroenterology, Woluwé-Saint-Lambert, Belgium;* [2]*Cliniques Universitaires Saint-Luc, Pulmonology, Woluwé-Saint-Lambert, Belgium*
Email: zaina.issa@uclouvain.be

Background and Aims: Cystic fibrosis (CF) is the most common autosomal recessive disease in Caucasians and is caused by CF transmembrane conductance regulator (CFTR) gene mutation. CF-associated liver disease (CFLD) is the 3rd leading cause of death in CF patients. Its prevalence is controversial since the term CFLD is used to describe a wide range of manifestations. Therefore, it is important to distinguish CF-associated from CF-related liver disease. CFLD is thought to be a pediatric disorder although adult-onset CFLD (ad-CFLD) is being increasingly reported together with the arrival of new definition criteria using noninvasive liver fibrosis tests. We aim to determine the prevalence and characteristics of CFLD in a cohort of adult CF patients.

Method: We retrospectively studied a cohort of CF patients followed at our CF clinic. Inclusion criteria were age >18 years, a typical form of CF and at least 1 year of follow-up. We excluded pulmonary transplant patients. Data on baseline and CF characteristics were collected. CFLD was defined as having 2 out of 3 criteria: persistent elevation of transaminases and/or gamma-glutamyltransferase, abnormal ultrasound findings and/or abnormal transient elastography (cutoff >6.8 kPa). Noninvasive fibrosis markers were calculated in all CFLD patients. Ad-CFLD was defined as CFLD diagnosed >18 years. Severe CFLD (s-CFLD) was defined as CFLD with cirrhosis and/or portal hypertension.

Results: A total of 113 patients were included, median age was 29 years and 58 (51%) were male. Median age at CF diagnosis was 6 months, 17% had meconial ileus, 54% had deltaF508 homozygous mutation, and 83% had pancreatic exocrine insufficiency. Sixteen patients (14%) had isolated hepatic steatosis. Forty patients (35%) had CFLD including 28 (70%) male patients. Median age at CFLD diagnosis was 10 years. Twenty-one patients (19%) had s-CFLD with a median age of 13 years and median delay to s-CFLD diagnosis was 2 years. Two s-CFLD patients had nodular regenerative hyperplasia, 1 had hepatocellular carcinoma and 4 others underwent liver transplantation. Six patients (5.3%) had ad-CFLD with a median age of 42 years including 1 patient with s-CFLD.

Conclusion: Thirty-five percent of adult CF patients had CFLD in our cohort and 19% had s-CFLD. We used new definition criteria for CFLD and identified ad-CFLD in 6 patients. Better characterization of liver involvement in CF is crucial in order to better target medical care in this population.

FRI319

Liver cirrhosis development and value of transient elastography among a large cohort of Wilsońs disease patients with a long-term follow-up in Spain

Zoe Mariño[1], Antonio Olveira Martin[2], Anna Pocurull[1], Loreto Hierro[3], Concepció Bartres[1], Pilar Castillo[2], Virginia Hernandez-Gea[1], Francisco Javier Garcia-Samaniego Rey[2], Celia Badenas[4], Xavier Forns[1].
[1]*Liver Unit, Hospital Clinic Barcelona, CIBERehd, IDIBAPS, Universitat de Barcelona, Spain;* [2]*Liver Unit, Hospital Universitario La Paz, Madrid, Spain;* [3]*Liver Unit, Hospital Infantil La Paz, Madrid, Spain;* [4]*Biochemistry and Molecular Genetics Unit, Hospital Clínic de Barcelona. IDIBAPS, Universitat de Barcelona, CIBERER, Barcelona, Spain*
Email: xforns@clinic.cat

Background and Aims: Wilson's Disease(WD) is a rare congenital disorder of copper metabolism, with hepatic and neuropsychiatric symptoms. Due to its low prevalence(1/30.000), long-term follow up analysis of patients remains critical.

Method: Collaborative study of two Hospitals in Spain; retrospective evaluation of WD patients(clinical presentation, therapy and evolution). Acceptable therapeutical compliance was set in >80% of the planned doses. Variables were expressed in n(%); median (IQR_{25-75}); differences were assessed by T-test/U-Mann-Whitney (quantitative) or Chi-square (categorical) and statistical significance was considered if $p < 0.05$.

Results: One hundred and seven patients were included in the analysis after a median follow-up (FU) of 15 years. Age at diagnosis was 17 (12–29);55% were male. The main initial manifestation was ALT increase (55%) with ALT 92.5IU/L (41–178);11 cases (10.3%) already had liver cirrhosis (LC) at presentation. In 86.9% cases, WD diagnosis was established with Leipzig score ≥4 points. The most frequent phenotype was chronic liver disease (H2,72%);7 cases (6.5%) presented a fulminant liver presentation (H1) and required urgent liver transplantation (LT). The most common initial therapy was D-penicillamine (66.4%). During FU, treatment was modified in 49% of cases (due to adverse events 39.6%; protocol 26.4%; inefficacy 20.7%; other 13.3%); in most of cases (73.5%), chelator was replaced by zinc salts. Despite a good global compliance (65.4%) and ALT

normalization(57%), 21 patients(19.8%) developed LC during FU. LC development was not associated with initial therapy, changes in medication or worst adherence. Age at diagnosis was significantly higher in patients developing LC compared to non-LC [24.5 (11–34) vs 14.5 (12–24), p = 0.013]. The FU time in LC patients was significantly lower than in non-LC (9.3 vs 17.3, p < 0.01), due to higher rates of LT and death(31.3% and 15.6% in LC *vs*. 4.1% and 0% in non-LC) (p < 0.01). Transient elastography (TE) was available in 79 cases (73.8%) at a median time of 15 years; TE value was 6.1 (4.9–8.5) Kpa. TE was significantly higher among LC (9.1 Kpa) compared to non-LC (5.6 Kpa) (p < 0.01), but values for LC were lower than those reported for other liver diseases.

Conclusion: Progression to cirrhosis was significant in this large cohort of WD patients; a late diagnosis is associated with a worse prognosis. TE values in WD patients with LC were significantly lower than those established for other chronic liver diseases.

Employment after liver transplantation and contributing factors

Anna van den Burg[1], Robert De Man[1], Lara Elshove[1]. [1]*Erasmus Medical Center Rotterdam, Hepatology, Liver transplantation, Rotterdam, Netherlands*
Email: a.vandenburg@erasmusmc.nl

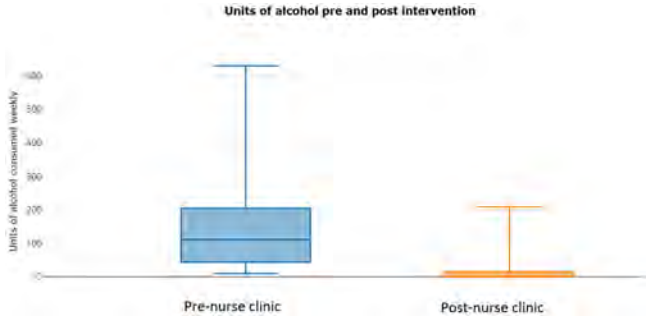
Background and Aims: Employment is important after liver transplantation. It has a positive effect on physical and mental health of the patient. Work related problems are regularly observed and discussed during follow up transplantation care. The extent of this problem in Erasmus MC is unknown.
Therefore we explored the employment rate of post-liver transplant patients in Erasmus Medical Center Rotterdam, as well as the contributing factors in employment reintegration.
Method: A retrospective cross-sectional single center study was performed. Included were patients who receive outpatient follow up in Erasmus Medical Center, aged between 18 and 65 at time of transplantation, and transplanted between 2006 and 2017. The data was collected with a questionnaire and supplemented with clinical information. Factors for resuming work known from the literature included age, gender, education level, household, liver disease, severity of liver disease, physical health, quality of life (RAND-36) and employment before transplantation. These were compared between the working and non-working patients after liver transplantation.
Results: Of the 185/378 (response rate 48,9%) patients who completed the questionnaire, 50,8% were working after transplantation. Of those who did not work after transplantation 21,1% indicate a disability which does not allow them to work and 9,2% did not work, because they (almost) reached retirement age.
Significant independent factors of employment after transplantation are: employment before transplantation (p < 0.001), age (p < 0.001), education level (p < 0.001), liver disease etiology (p 0.002) and physical health (p < 0.001). In a multivariable regression model, pre-transplant employment is the only predictive factor determining if patients return to work.
Conclusion: In this study we found that half (50,8%) of the patients are working after liver transplantation. Factors that can be influenced need more attention. Interventions aimed at (maintaining) better physical health and maintaining work are advised. Multidisciplinary interventions for transplant patients are advised to focus on maintaining employment status in the period on the waiting list for transplantation and should continue throughout the post-transplant period.

FRI321

Development of a district general hospital liver nurse service for patients with acute and chronic liver conditions

Amy Thatcher[1], Leyla Foden[1], Mary Haight[1], Rebecca Hawley[1], Vijay Grover[1]. [1]*Hillingdon Hospital, Gastroenterology, United Kingdom*
Email: amy.thatcher@nhs.net

Background and Aims: Liver disease is the third largest cause of premature mortality in the United Kingdom (UK). This quality improvement (QI) aims to evidence the effectiveness of the liver nurse service (LNS), primarily out-patients with chronic liver disease (CLD), to improve quality of life and outcomes in line with NICE guidelines. Hillingdon Hospital is a district general hospital serving an ethnically diverse population of 300,000.
Method: Two liver clinical nurse specialists were recruited from the wards, trained in-house and iteratively developed the service with mentorship of the Consultant Hepatologist. Patient alcohol consumption was analysed using a Wilcoxon signed-rank test.
Results: Face to face nurse appointments increased from 278 in 2015/ 2016 financial year, to 1812 in 2018/ 2019, including FibroScan® clinics, whereby nurses provide health promotion and education. 200 FibroScans® were performed between 13/03/2019–19/08/19, most prevalent aetiology being non-alcoholic fatty liver disease (NAFLD) 33%. If patients were non-fibrotic, their referral pathway ended; avoiding consultant review. Telephone clinics were established in response to increased demand for follow up appointments in CLD patients, with 1013 telephone consultations in 2018/ 2019. Telephone clinics support admission avoidance and safe early discharge of liver patients, with remote blood monitoring, medication management and multidisciplinary team working. Alcohol dependent patients are offered holistic care with opportunity to be seen by alcohol assistant psychologists. Alcohol consumption data analysed for 72 patients demonstrated a significant decrease in weekly alcohol units consumed pre and six months post liver nurse clinic, reducing from a mean of 136 to 19.5 units (Z = –7.4, p < 0.001). 97% of patients reduced alcohol intake, 51% achieved abstinence. Nurses also provide a focus on bone health in CLD ensuring patients had DEXA scans in accordance to NICE guidelines. 115 scans performed between 2018 and 2019, 71% patients had low bone density, 79% of whom had cirrhosis.



Conclusion: This QI project has demonstrated how the LNS has been developed to provide a high quality service and holistic care for patients with liver disease. The service aims to provide further focus on inpatients helping to manage and co-ordinate care to improve patient outcomes.

FRI322

Managing decompensated cirrhosis – the importance of multidisciplinary engagement

Dev Katarey[1]. [1]*Royal Free Hospital, London, United Kingdom*
Email: d.katarey@nhs.net

Background and Aims: Decompensated cirrhosis represents a paramount landmark in the disease progression of a cirrhotic. The index presentation of a decompensating event, or any subsequent decompensating event, requires swift investigation and management which can be guided by the "British Association for the Study of the Liver (BASL) Decompensated Cirrhosis Care Bundle". Many of the care items listed require support from the wider multidisciplinary team, however knowledge and utility of this care bundle may be limited within these groups. This qualitative study set out to determine the beliefs on managing decompensated cirrhosis held by members of the multidisciplinary team in a tertiary liver transplant unit in central London.
Method: A 10-point questionnaire mapped to individual care points within the BASL Decompensated Cirrhosis Care Bundle was created and distributed to members of the multidisciplinary team on a tertiary liver transplant unit. Following the questionnaire, interviews took place to discuss misconceptions/false beliefs regarding the care of decompensated cirrhosis and thematic analysis was performed. Post-hoc education was delivered where required.
Results: A total of 15 participants (uptake 100%) filled in the questionnaire and were interviewed: 7 were registered nurses (RNs), 6 junior doctors, 1 dietician, and 1 pharmacist. Thematic analysis revealed that, particularly amongst RNs, advanced liver disease was felt to be a contraindication to thromboprophylaxis in hospital. Another common misbelief seen in all participants aside from specialist-grade doctors was transfusion targets for gastrointestinal hemorrhage with most respondents targeting >90 g/L. A universal theme which was extracted from the interviews was that active involvement from multidisciplinary members of the team in delivering the BASL Decompensated Care Bundle would achieve higher real-world uptake, and help allied health professionals more readily identify sub-optimal standards of care, and thereby improve outcomes for our decompensated cirrhosis population.
Conclusion: The BASL Decompensated Cirrhosis Care Bundle should be delivered as front-line care with engagement from all members of the multidisciplinary team looking after these patients in order to deliver consistently high standards of care.

FRI323

The first step towards comprehensive nurse-led hepatology care: evolution of the Hull specialist liver nurse service (SLNS)

Dianne Backhouse[1], Lynsey Corless[1], George Abouda[1]. [1]*Hull University Teaching Hospitals NHS Trust, Hepatology, HULL, United Kingdom*
Email: dianne.backhouse@hey.nhs.uk

Background and Aims: A specialist liver nursing service (SLNS) was launched in April 2018 to improve quality of care for patients with chronic liver disease (CLD) in our Trust.
Method: The SLNS was delivered by an experienced senior nurse and comprised: A new day-case paracentesis service, nurse-led clinics providing hepatoma surveillance and rapid post-discharge reviews, and daily nurse-led in-reach to the acute medical unit (AMU), emergency department and non-specialist wards to initiate early management (e.g. use of the BASL/BSG decompensated CLD care bundle) and identify patients for transfer to specialist ward or early discharge. The service was reviewed at 1 year to measure impact.
Results: Average length of stay (LOS) for paracentesis reduced by 94% to 5 hours, with 36% of drains now conducted as day cases, resulting in 416 saved bed days and financial savings of £166,400. It has also led to greater consideration of long-term drain placement in patients with end-stage disease, with 6 placed in 2018/19 vs 1 in preceding year. Nurse-led clinics have been very successful, with waiting time beyond planned follow up date for hepatoma surveillance significantly reduced from 71 to 13 days ($p < 0.001$); and 42% of patients discharged following decompensation having nurse rather than consultant review. Mean waiting time for post-discharge review was just 4.9 days, enabling safe earlier discharge from hospital. The SLNS is highly valued by non-specialist areas for timely and informative reviews, and use of the cirrhosis care bundle is now well-established. Crucially, all aspects of the service receive excellent feedback from both patients and colleagues. The immediate and significant impact of the SLNS on patient care contributed to the Trust giving approval for a new enhanced alcohol care team and recruitment of alcohol specialist nurses, to improve quality of care for these patients. Importantly however, the SLNS has now reached capacity and yet there are many more patients who could benefit from the service, as well as clear potential to broaden the nurse-led model of care into community hepatology. We have therefore submitted proposals for additional recruitment to support a multi-skilled and resilient SLNS working across our hospital and community.
Conclusion: The SLNS has improved care for patients with CLD. The service has been recognised as innovative locally, nationally and internationally, and laid the foundations for comprehensive nurse-led hepatology care for our patients.

FRI324

Prospective study of therapeutic education (TE) designed with a multidisciplinary team and participation of patients to improve the adherence to treatment of the patients and their quality of life (QOL)

Dominique Larrey[1], Joséphine Vernet-Montagnac[1], Corinne Rotrou[1], Lucy Meunier[1]. [1]*Hôpital Saint Eloi, Département d'Hépato-gastroentérologie, Montpellier, France*
Email: dom-larrey@chu-montpellier.fr

Background and Aims: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease with variable severity and important consequences on the QoL. There is no specific study regarding therapeutic education (TE) for PBC. The association to other autoimmune hepato-biliary or extra-hepatic diseases and availability of new treatments strengthen the interest of TE.
Method: Prospective monocentric exploratory study of TE with a multidisciplinary team and patient participation aimed to improve the management of treatments and symptoms and the QoL of patients (pts) with PBC.
The participation/inclusion to the study was prospectively proposed during medical consultations in pts with PBC diagnostic criteria. The study was performed with a nurse experimented in TE and PBC care over one year. Questionnaires (QS) were given at each consultation (Month: 3,6,9,12): Analogic Visual scale (AVS) and PBC-40 score for the QoL, AVS and 5D-itch scale QS (analysis of Duration, Degree, Direction, Disability, Distribution within the 2 last weeks) for pruritus.
Results: 30/32 prospectively seen pts agreed to participate to the study (93,6%); 2 asymptomatic well-controlled pts denied (6,4%). The 30 included pts were 28 females/2 males (median 55 yrs). ***Baseline characteristics (number of pts):*** isolated PBC (n = 21), overlap syndrome with AIH (n = 9), extra-hepatic AI signs (n = 20); fibrosis: F0-F2 (n = 25), F3 (n = 2), cirrhosis (n = 3); pruritus (n = 2); treatment : UDCA (n = 25), fibrate (n = 6), budesonide (n = 4), azathioprine (n = 5). ***Adherence to the one-yr-TE-program*** : 26/30 pts (86.7%); lost of follow-up 4/30 (13.3%). ***New treatments after inclusion:*** UDCA (n = 2), obeticholic acid (n = 7), bezafibrate (n = 5). ***The effects of TE*** on the QoL and pruritus were analysed in the 26 pts who completed the whole study (Table 1).

Table 1: QoL and pruritus in the 26 pts who completed the study.

	Day 1	Month 12	P-value
QoL			
AVS mean/10	5.19	6.88	P = 0.0012
Improvement		19 (73.1%)	p = 0.004
Worsening		3 (11.5%)	
Stable		4 (15.4%)	
PBC-40 score	3.41	3.74	NS
Improvement		19 (73.1%)	p = 0.058 (NS)
Worsening		7 (26.9%)	
Pruritus			
AVS mean/10	3.42	1.27	P = 0.013
Improvement		12 (46.2%)	p = 0.044
Worsening		3 (11.5%)	
Stable		11 (42.3%)	
5D score (mean)	14.32	8.03	P = 0.025
Improvement		14 (53.8%)	p = 0.024
Worsening		3 (11.5%)	
Stable		9 (34.7%)	

This study was supported by a grant from the program Practice and Policy Program, Intercept, Canada.
The authors thank ALBI Association of patients for their help in the design of the study.

Conclusion: Patients with PBC exhibit a good adherence to a therapeutic education program which was associated with improvement in QoL and pruritus.

FRI325

Hepatitis B testing in Bcr-Abl tyrosine kinase inhibitor therapy

Fatema Jessa[1], James Lochrie[1], Douglas Macdonald[2], Sheetal Shah[1].
[1]Royal Free London NHS Foundation Trust, Pharmacy Department, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, Hepatology Department, London, United Kingdom
Email: fatema.jessa@nhs.net

Background and Aims: BCR-ABL TKIs are used in the treatment of haematological malignancies. An EU wide review found that in patients who are carriers of hepatitis B virus (HBV), reactivation can occur after receiving BCR-ABL TKIs. This may lead to acute liver failure resulting in liver transplantation or death. MHRA published guidance in April 2016 advising that all patients must be tested for HBV prior to starting BCR-ABL TKI therapy. All positive patients before and during treatment must be discussed with a hepatologist and all HBV carriers must be closely monitored during treatment for reactivation. The aim of this study was to investigate whether HBV screening takes place prior to, during and after stopping BCR-ABL TKIs and if practice has changed following the MHRA alert.

Method: All patients dispensed BCR-ABL TKIs from April to Sept 2019 from Royal Free London Hospitals were investigated. Using dispensing records, screening systems and clinic letters, treatment start dates were confirmed. Multiple hospital data sources were examined to determine if patients had a hepatitis B test prior to starting and during treatment. Data up to 10 years preceding treatment were analysed.

Results: A total of 50 patients received BCR ABL TKIs. The mean age was 47 years and M:F ratio was 30:20. The majority were on imatinib (64%) and no patients on ponatinib. The earliest start date was May 2010 and most recent was September 2019.

The table below shows the number of patients starting treatment before or after the MHRA alert and documentation of hepatitis B test prior to treatment.

Of 22 patients who had a documented HBV test prior to starting treatment, 1 patient was HBV core antibody (HbcAb) positive. This patient was monitored 3 monthly and remained HbcAb positive and HbsAg negative and was not given prophylactic HBV therapy. No other patients were retested post starting treatment.

	Total	Start date before MHRA alert n (%)	HBV test prior to treatment n (%)	Start date after MHRA alert n (%)	HBV test prior to treatment n (%)
Imatinib	32	9(28)	1	23(72)	10
Dasatinib	10	3(30)	2	7(70)	6
Nilotinib	7	6(86)	2	1(14)	1
Bosutinib	1	0(0)	0	1(100)	0
Ponatinib	0	0(0)	0	0(0)	0
Total	50	18(36)	5(28)	32(64)	17(53)

Conclusion: There was a 25% increase in HBV testing following the MHRA alert however testing rates remain low. Clinical pharmacists are well placed to prompt clinicians to order these tests as part of the clinical screening process for BCR-ABL TKIs.

FRI326

Impact of a nurse educational program for patient empowerment during sequential systemic therapy for hepatocellular carcinoma

Gemma Iserte[1], Neus Llarch[1,2], Víctor Sapena[1], Marco Sanduzzi Zamparelli[1], Sergio Muñoz Martinez[1], Alejandro Forner[1], Jordi Rimola[3], Anna Darnell[3], Ernest Belmonte[3], Carmen Ayuso[4], Jordi Bruix[1], María Reig[1]. *[1]Hospital Clínic de Barcelona, Unitat Oncologia Hepàtica. Liver Unit. BCLC Group. University of Barcelona.IDIBAPS. CIBERehd, Barcelona, Spain; [2]Generalitat de Catalunya. Departament de Salut, IPIF PERIS 2019 SLT0008/18/00182, Barcelona, Spain; [3]Hospital Clínic de Barcelona, BCLC group, Radiology Department, Hospital Clínic Barcelona, Barcelona, Spain; [4]Hospital Clínic de Barcelona, Radiology Department. BCLC group. Hospital Clinic Barcelona. University of Barcelona. CIBERehd, Barcelona, Spain*
Email: giserte@clinic.cat

Background and Aims: The BCLC Nurse Educational Program (BCLC-NEP; Llarch, ILC 2019) was designed for educational purposes. This program reduced on-site visits, optimized health resources and secured patient compliance, although 26% of the unscheduled phone calls visits (UPCVs) received during the early phase of treatment (ePT), which includes the first 60 days of sorafenib initiation, were related to administrative tasks. Other systemic treatments such as lenvatinib, regorafenib, cabozantinib and ramucirumab also require dose adjustments within the first 60 days of starting treatment, and the safety profile of each treatment is slightly different. The aim of this study is to evaluate the impact of the BCLC-NEP on regorafenib-treated patients and analyze whether the rate of administrative consultations differs in the second line setting.

Method: This is a retrospective study in regorafenib-treated patients in Hospital Clinic of Barcelona from 08/2016 to 12/2018. The BCLC-NEP includes an on-site educational appointment before starting regorafenib, on-site visits every month and UPCV. We collected the number, causes, type of issues raised by patients and the solution offered by the nurse team. UPCVs were divided according to their timing (early or late (lPT) after treatment start.

Results: The nurses received 170 UPCVs from all (n = 21) but 1 patient who started regorafenib. We excluded 46 calls (27%) due to their administrative nature and 24 health-related UPCVs due to lack of information: We analyzed the remaining 100 UPCVs related to clinical issues; 42 calls from 19 patients were received in the ePT and 58 calls from 13 patients were received in the lPT. Analyzing the regorafenib related and non-related reported issues: the nurses solved 49 of the 100 UPCVs on their own.

Fifty-one of these 100 UPCVs were considered regorafenib related-adverse events (AE). All in all, the nurses themselves solved 14 (28%) of the regorafenib-related AEs during the ePT and 27 (54%) during the lPT.
Of all UPCVs received (n = 170), 58 occurred during the ePT and 9 (15.5%) were related to administrative issues. Interestingly, this shows a 10.5% reduction as compared to the sorafenib population.
Conclusion: The BCLC Nurses Educational Program implemented for regorafenib-treated patient clearly shows the relevant role of nurses in this population (54% reforafenib-related AE calls were solved by nurses during the late phase). The dose-adjustments needed in the early phase and previous experience with sorafenib influence the nature of the calls received. The use of this educational tool during the systemic treatment sequence suggest a progressive empowerment of the patients and a more efficient use of resources.

FRI327
Treatment with sorafenib on hepatocellular carcinoma –10 years' experience in a nursing-led outpatient clinic
Gordana Grujcic[1], Pia Loqvist[2], Hannes Hagström[2]. [1]*Karolinska University Hospisal, Center for Digestive Diseases, Departement of Hepatology, Stockholm, Sweden;* [2]*Karolinska University Hospital, Center for Digestive Diseases, Departement of Hepatology, Stockholm, Sweden*
Email: gordana.grujcic@sll.se

Background and Aims: Sorafenib has been the standard of care treatment for advanced hepatocellular carcinoma (HCC) since many years. Side-effects are common and often leads to dose adjustments or treatment withdrawal. Here, we investigated the results of a nursing-lead outpatient clinic focused on Sorafenib-treated patients with HCC. We aimed to describe treatment side-effects and the feasibility of the programme.
Method: Single-center study in Sweden. We included 210 patients treated with Sorafenib between 2007 and 2017. Retrospective chart review was performed to extract data on clinical characteristics, treatment side-effects and mortality.
Results: Mean age was 66.7 years, 76% were men and the most common cause of HCC was viral hepatitis (42%). Mean MELD score was 9.3. Median treatment duration was 29 weeks for the full study but was shortened between 2007 (median 34 weeks) to 2017 (25 weeks). Side effects were common and included nausea (45%), fatigue (30%), diarrhea (20%), hand-foot syndrome (22%), and other skin-related side-effects (18%). Dose adjustments were made by nurses in 97/210 patients (46%) with around 50% of the initial dose. Treatment withdrawal due to side-effects was uncommon (6/210, 2.9%) There was no reduction in annual mortality while on active treatment during the study period.
Conclusion: A Sorafenib treatment program run by specialized nurses was not associated with a reduced mortality during the study period and led to frequent dose-adjustments of treatment. Side-effects were very common and often lead to dose adjustments, but complete withdrawal was uncommon. This suggests that the program was efficient and safe and associated with a high tolerability in the treated population. Nursing-led outpatient clinics could be a safe and cost-effective method for patients with HCC.

FRI328
Pilot of an advanced liver disease nurse education program and its intersection with emerging models of advanced hepatology nursing practice
Janice Prtichard-Jones[1], Simone Strasser[1], Janice Gullick[2]. [1]*Royal Prince Alfred Hospital, G&L, Camperdown, Australia;* [2]*The University of Sydney, Nursing School, Camperdown, Australia*
Email: hanajones97@gmail.com

Background and Aims: Advanced liver disease (ALD) and liver cancer are a growing public health issue. Burdensome treatments for Hepatitis C once consumed nursing resources. However, as new treatments shift Hepatitis C care from specialist to generalist practice, hepatology nurses are freed to diversify their skills to meet the growing burden of ALD and liver cancer. There are limited examples internationally of hepatology education programs that address and assess core ADL nurse capability.
Method: Phase 1 surveyed nurses' attitudes towards ALD training and identified their learning needs. This informed curriculum and assessments comprising nine months of formal hepatologist mentoring, face to face and online learning, hands-on skill development and clinical placement. Phase 2 evaluated relevance of, and satisfaction with the curriculum, nurse/hepatologist experience of mentorship, and local issues impacting course participation. Phase 3 used a descriptive, qualitative method. Analysis of semi-structured interviews with nurses and hepatologists was guided by Fawcett's nursing metaparadigm and Schuler's model of advanced practice.
Results: There was considerable demand for this program, which was rated as highly acceptable, feasible and relevant to ALD practice. Under mentorship, nurses developed education initiatives and local policies, and gave examples of nurse-led, patient-centred holistic models of advanced ALD practice. Participants revealed the *person* with ALD as socially disadvantaged, with substance use disorders and communication challenges. Their *health* embodied complex body needs. Their *environment* lacked ALD services, particularly in rural/regional settings, heightening stigma and discrimination. Emerging models of ALD *nursing* practice responded with listening to the whole story, being non-judgemental, being a lynch pin and building networks and lines of referral.
Conclusion: The program was acceptable, feasible and effective in building capability for advanced nursing practice. Further research could confirm the impact of education and advanced practice on ALD service access and outcomes.

FRI329
Diet lifestyle management of non-alcoholic fatty liver disease (NAFLD): a cross-sectional survey of clinicians
Laura Haigh[1,2], Stuart McPherson[1,2], John Mathers[3], Quentin Anstee[1,2]. [1]*Institute of Translational and Clinical Research, Faculty of Medical Sciences, Newcastle University, Newcastle Upon Tyne, United Kingdom;* [2]*Newcastle NIHR Biomedical Research Centre, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom;* [3]*Institute of Population Health Sciences, Faculty of Medical Sciences, Newcastle University, Newcastle, United Kingdom*
Email: l.haigh3@newcastle.ac.uk

Background and Aims: NAFLD is the most common liver disease in Europe, increasing in parallel with the obesity epidemic. Diet lifestyle intervention that induces weight loss (7–10%) prevents disease progression and is the standard of care recommended by International guidelines. We aimed to evaluate the status of diet lifestyle care for patients with NAFLD across Europe and Israel.
Method: In February-June 2019, clinicians with a NAFLD interest from 11 countries completed an e-survey to assess current practice and perceived barriers to the effective delivery of diet lifestyle interventions. Descriptive statistics and cross-tabulations were performed.
Results: 137 clinicians responded (86 gastroenterologists/hepatologists (GH), 31 dietitians/nutritionists (DN), 15 specialist trainees (ST) and 5 other); 50% specialist centres, 42% general hospitals and 8% primary care; mean age 42 years (range 25–69), 55% male. Two thirds responded that all patients with NAFLD would be eligible for diet lifestyle interventions. Despite this, 68% of respondents referred less than half their patients. Key barriers preventing referrals included no commissioned services (42%), short consultations/work overload (42%) and limited dietetic resources (32%). GH most frequently considered lack of services a barrier (50% vs. ST 27% vs. DN 23%) (p = 0.014). Access to multidisciplinary lifestyle services was reported by 23%; twice as many respondents from specialist centres used this option compared with general hospitals (31% vs. 14%) (p = 0.033).

Lifestyle advice delivered included impact of weight status on NAFLD outcomes (90%) and goal setting (64%) in brief/very brief interventions (43% vs. 34%). Only 52% advised weight loss of 7–10%. More DN and GH advised this target compared to ST (58% vs. 52% vs. 33%) (p = 0.003). Perceived obstacles to lifestyle advice delivery were short consultations/work overload (80%) and inadequate behavioural training (45%). More GH and ST reported inadequate training as an obstacle than DN (54% vs. 53% vs. 16%) (p = 0.001). Dietary approaches were face-to-face (94%) and Mediterranean diet (60%).

Conclusion: The survey highlights considerable variability in diet lifestyle care for NAFLD. Access to diet lifestyle interventions for eligible patients appears limited by a lack of commissioned services and resources. Given the high prevalence of obesity and NAFLD, these data suggest a need to improve training of clinicians to deliver diet lifestyle interventions.

FRI330

Development of clinical professional standards for liver transplant nursing

Michelle Clayton[1], Lynda Greenslade[2]. [1]*University of Leeds & St. James's University Hospital, Leeds, United Kingdom;* [2]*Royal Free Hospital, London*
Email: m.clayton@leeds.ac.uk

Background and Aims: Nurses are the largest group of health care professionals and are intergral in making an impact on liver disease and providing quality care. Following the publication of the Royal College of Nursing (RCN) *Caring for people with liver disease: a competence framework for nursing* (2015); it was recognised that the area of liver transplant nursing was under represented. There were no professional clinical standards in liver transplant nursing to demonstrate competence or educational resources needed to develop this practice. New clinical professional standards were developed to promote consistency and person centred care delivery in both specialist transplant and referral hospitals in the United Kingdom (UK). The competence framework aims to benefit practitioners, employers, patients and the public by providing quality, safety and effectiveness of liver and liver transplant practice.

Method: Liver recipient transplant co-ordinators, transplant nurses and specialist nurses in referral hospitals across all liver transplant centers in the UK were involved in this development. The clinical professional standards cover the continuum of referral, assessment, listing for transplant and options for those not suitable for transplant. They describe high quality care pre-, peri- and post-liver transplant, as well as staying healthy in the long term. The standards were reviewed by previously identified stakeholders and final review completed with the original members of the development group.

Results: In September 2019 the RCN *Caring for people with liver disease including liver transplantation: a competence framework* was published. This is a refreshed and updated document that reflects contemporary person centred liver nursing practice as well as the new section on liver transplant nursing. The competence framework will be audited in two years' time to review the quality of care delivery, consistency of nursing care across liver transplant centres and the impact on patient experience. Future developments include benchmarking liver and transplant nursing practice against other European countries.

Conclusion: By developing clinical professional standards in liver and liver transplant nursing, care delivery can be benchmarked to ensure that nurses are delivering and patients are receiving high quality, evidence based, and effective person centred care.

FRI331

Nurse assisted follow-up after admission with decompensation in cirrhosis: a systematic review and meta-analysis

Malene Barfod O'Connell[1], Flemming Bendtsen[1], Vibeke Nørholm[2], Anne Broedsgaard Madsen[3,4], Nina Kimer[1,5]. [1]*University Hospital Hvidovre, Gastro Unit, Medical Division, Hvidovre, Denmark;* [2]*University Hospital Hvidovre, Clinical Research Centre, Hvidovre, Denmark;* [3]*University Hospital Hvidovre, Department of Pediatrics and Adolescent Medicine, Hvidovre, Denmark;* [4]*Aarhus University, Department of Public Health, Section for Nursing and Health Care, Aarhus, Denmark;* [5]*The University of Copenhagen, Faculty of Health and Medical Sciences, Novo Nordisk Foundation Center for Basic Metabolic Research, København, Denmark*
Email: nina.kimer@regionh.dk

Background and Aims: Liver cirrhosis is a grave disease with nearly half of the patients decompensated at diagnosis and substantial complications causing a high risk of admission and readmissions. Evidence supporting structured rehabilitation after admission with decompensation or complications to cirrhosis is scarce. This systematic review and meta-analysis aimed to evaluate the effects of nurse-facilitated interventions to prevent readmissions in cirrhosis.

Method: We searched MEDLINE, EMBASE, Web of Science; Cinahl databases through September 2019 for studies that evaluated a nurse-facilitated or nurse involved intervention instituted to benefit

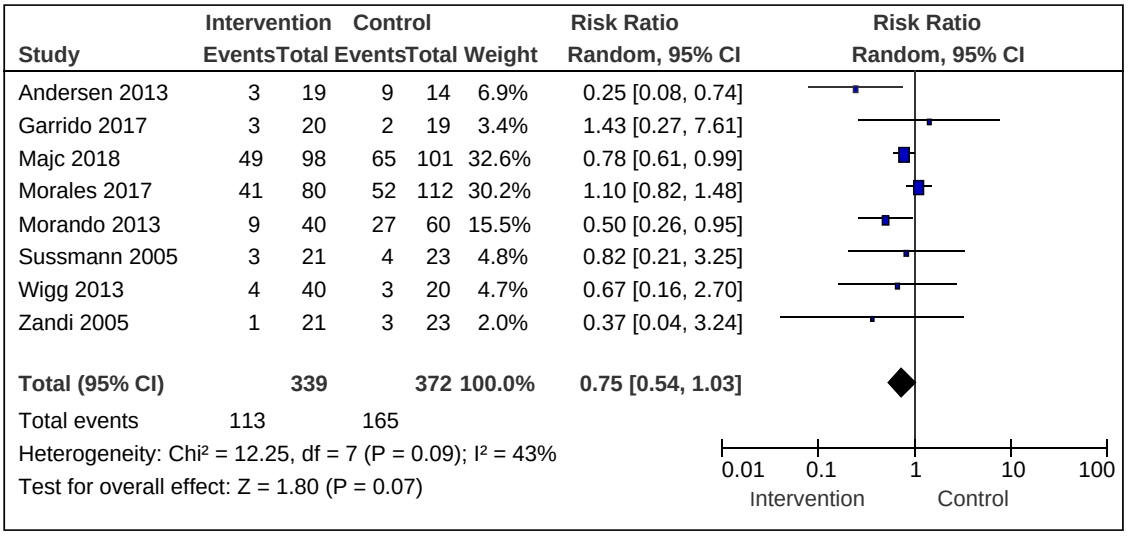


Figure: (abstract: FRI331)

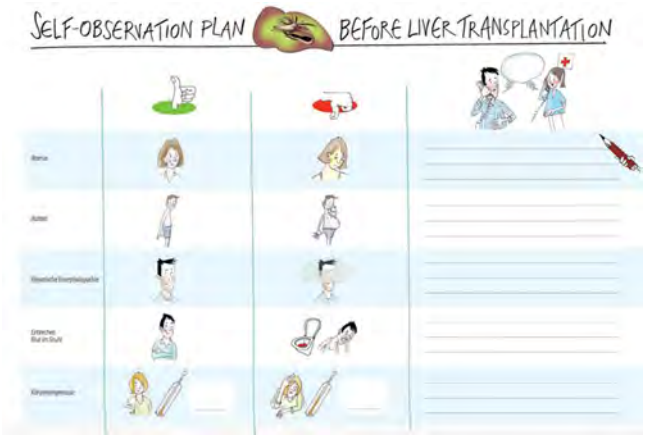
the patients. Primary outcomes of meta-analysis were mortality and readmission. Secondary outcomes were patient education, self-management and patient perception of the interventions. Bias assessment of randomized trials and quality assessment of controlled and prospective trials were conducted to assess overall quality of the evidence.
Results: Ten controlled studies and five cohort studies comprising 1164 participants assessed educational, case-management and standard nurse-driven hospital follow-up interventions. Meta-analysis of eight studies comprising 711 participants revealed beneficial effects of interventions on mortality in fixed effects analysis, Risk Ratio 0.69, 95% CI 0.67–0.95, but the effect was insignificant in random effects analysis (Figure). Nurse assisted intervention improved readmission rates in fixed affects analysis (five studies, 436 participants), Risk Ratio 0.76, 95% CI 0.63–0.92, but was insignificant in random effects analysis (Figure). Evidence was of low quality and the heterogeneity was significant. In a qualitative review, all interventions increased participants' perception of disease and self-management.
Conclusion: Nurse facilitated interventions to prevent admission and readmissions in liver cirrhosis are well tolerated by patients and may be effective in prevention of mortality and readmission. Protocolled and clearly defined nursing interventions compared to structured standard of care are in demand.

FRI332
Prospective evaluation of a non-alcoholic fatty liver disease assessment pathway; impact of clinical nurse specialist role
Marie McGrath[1], Suzanne Norris[1], Andie Stephens[1], Sara Naimimohasses[1]. [1]*St James's Hospital, Department of Hepatology, Dublin, Ireland*
Email: mmcgrath@stjames.ie

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a major health burden, affecting 1 in 4 across the EU and is the commonest cause of abnormal LFTs in primary care. 60% of Irish adults are overweight or obese. While the majority of patients will not develop clinically significant liver disease, patients with fibrosis who may benefit from early specialist intervention remain undetected in the absence of a national NAFLD care pathway. The **aim** of this project was to develop a NAFLD screening pathway to identify patients with no/minimal fibrosis to be managed in primary care.
Method: Referrals with suspected and/or ultrasound evidence of fatty liver were triaged by the NAFLD nurse specialist to the NAFLD assessment clinic. Assessment included blood tests for chronic liver disease screen, NAFLD and FIB-4 scores, and Fibroscan examination. Following bimonthly MDT meetings, patients were discharged to primary referrer or retained in specialist care.
Results: From Jan-Oct 2019, 126 individuals (M:49%, F:51%, mean age 54 years, mean BMI 32.4 kg/m^2, 63% BMI>30 kg/m^2) were assessed. 85% of patients met diagnostic criteria for NAFLD. Of 126 fibroscans performed, 52% of patients had LSM < 7.0 kPa, 23% had LSM > 7.1 kPa <9.9 kPa, and 25% LSM > 9.9 kPa, and 52% of patients were eligible for discharge to primary referrer.
Conclusion: These data support the implementation of a NAFLD nurse specialist role to identify NAFLD patients for early specialist intervention.

FRI333
Illustrations supporting patient counseling before and after liver transplantation
Patrizia Kuenzler-Heule[1,2], Andrea Pfister-Koch[3], Irina Bergamin[1], Nadine Stanek[4], Sonja Beckmann[2,5]. [1]*Cantonal Hospital St.Gallen, Gastroenterology/Hepatology, St. Gallen, Switzerland;* [2]*University of Basel, Institute of Nursing Science, Basel, Switzerland;* [3]*University Hospital of Zürich, Department of Abdomen and Metabolism, Zürich, Switzerland;* [4]*University Hospital of Zürich, Clinic for Gastroenterology/Hepatology, Zürich, Switzerland;* [5]*University Hospital of Zürich, Center for Clinical Nursing Science, Zürich, Switzerland*
Email: patrizia.kuenzler@kssg.ch

Background and Aims: Adherence to health relevant medical and behavioural recommendations before and after liver transplantation (LTx) improves clinical patient outcomes. Therefore, healthcare professionals should provide self-management support and education. Relying on oral counselling or written brochures only is sometimes challenging. We aimed to develop language-independent illustrations to support patient counselling before and after LTx.
Method: The participatory action research approach was led by two advanced practice nurses (APNs) and a nurse scientist. The interprofessional group from two liver clinics (5 nurses, 2 physicians) convened in two meetings and engaged in all four action research cycle phases: constructing, planning, acting, and evaluating. A professional illustrator participated in the second meeting.
Results: Constructing: In the first meeting, each participant presented three clinical practice situations in which illustrations would have facilitated patient counselling. Planning: All practice situations were discussed and three main themes for illustrations were identified: Understanding the disease (e.g. liver functioning), organizational aspects (e.g. preparing a hospital visit) and life after LTx (e.g. taking immunosuppressants, healthy behaviour). Acting: The illustrator presented four draft illustrations in the second meeting. The group used the "thinking aloud" technique to evaluate the drafts and discussed adaptations. The group agreed on a final set of twelve draft illustrations and two self-observation plans (fig. 1). Evaluation: To facilitate implementation, a group of additional healthcare professionals from both hospitals (n = 12) participated in cognitive debriefing interviews to evaluate the complete draft set using the "thinking aloud" technique. Overall, the drafts were clear and well accepted with high ratings in relevance and comprehensibility. However, it became obvious that the illustrations should not be a stand-alone tool, but must be integrated in counselling sessions provided by specialized liver nurses or physicians. The APNs finally tested the drafts during counselling and received good feedback from patients. Patients especially appreciated the visualization of complex relationships, which also helped them to better discuss and explain those issues with family members.



Conclusion: Early involvement of relevant stakeholders is key in practice development and the application of new tools. The detailed stakeholder and patient feedback was used to finalize the illustrations in view of specific content and layout. The illustrations have been implemented in patient counselling before and after LTx in both specialized liver clinics. This in turn, will hopefully not only improve counselling but also safety in deprived patient groups.
Astellas Pharma AG-financially supported the two meetings.

Soluble CEACAM1 induces regulatory T cells in vitro

Mareike Kellerer[1], Christoph Schramm[2], Gisa Tiegs[1], Andrea Horst[1].
[1]*University Medical Center Hamburg-Eppendorf, Inst. Experimental Immunology and Hepatology, Hamburg, Germany;* [2]*University Medical Center Hamburg-Eppendorf, Martin-Zeitz Center for Rare Diseases, Hamburg, Germany*
Email: ahorst@uke.de

Background and Aims: CEACAM1 (carcinoembryonic antigen-related cell adhesion molecule 1) is a checkpoint regulator that controls T cell activation. CEACAM1 binds heteroligands, for example T cell immunoglobulin and mucin-domain containing-3 (TIM-3), or it acts as a homophilic adhesion molecule engaged in self-ligation. In mice, CEACAM1 promotes IL-2-dependent regulatory T cell (Treg) induction and -stability, and *Ceacam1*$^{-/-}$ mice exhibit exacerbation and persistence in murine immune-mediated hepatitis (Concanavalin A–induced hepatitis) resulting from an imbalance of effector T cells and poor Treg expansion and stability. Originally, CEACAM1 has been discovered as *biliary glycoprotein* that was detected as a soluble form in the circulation of human patients with autoimmune liver diseases, tumors of the gastrointestinal tract and cholestasis. However, an immune-regulatory role for soluble CEACAM1 (sCC1) has not been demonstrated so far. Here, we intend to study a putative immune regulatory role for soluble CEACAM1 in the induction of Tregs.
Method: sCC1 in sera from humans and mice was analyzed in Westerns Blots. In cocultures from bone-marrow derived, FACS-purified dendritic cells (DCs) and MACS-purified T cells from CEACAM1-deficient and WT mice, cytokine production was monitored using bead-based immunoassays and ELISAs. Cell-surface marker expression was characterized in flow cytometry. Phosphorylation of intracellular proteins after stimulation of T cells and T cells and DCs in cocultures with sCC1 was analyzed in flow cytometry and Western Blots.
Results: sCC1 is detectable in the circulation of patients with advanced primary sclerosing cholangitis (PSC) and is prominently found in sera of *mdr2*$^{-/-}$ mice. In cocultures of CD4$^+$ T cells and DCs, sCC1 binds to activated (CD4$^+$CD25$^+$ T cells) only, but not to naïve CD4$^+$ T cells. In CD4$^+$CD25$^+$ T cells, sCC1 induces phosphorylation of STAT5 (pSTAT5), and upregulation of Foxp3, and expression of Bcl-2. In CEACAM1-deficient CD4$^+$ T cells, reduction of pSTAT5 and Bcl-2 are observed. Furthermore, sCC1 inhibited production of IL-12 by DCs.
Conclusion: sCC1 binds to activated T cells in a homophilic and heterophilic manner and induces STAT5 signaling and Foxp3$^+$ Tregs. In T cell-DC cocultures, sCC1 supports IL-2 signaling on WT T cells and enhances their stability. This is the first report of the involvement of sCC1 in the induction of regulatory T cells. In addition, sCC1 appears to suppress DC-related IL-12 production via a yet unknown receptor.

FRI337
The alarmin IL-33 drives a ST2+ Treg-mediated anti-inflammatory immune response during immune-mediated hepatitis

Katrin Neumann[1], Fabian Heinrich[1], Aaron Ochel[1], Gisa Tiegs[1].
[1]*University Medical Center Hamburg-Eppendorf, Institute of Experimental Immunology and Hepatology, Hamburg, Germany*
Email: kat.neumann@uke.de

Background and Aims: Elevated levels of the alarmin IL-33 were shown in patients with chronic liver disease, indicating an immunomodulatory function of IL-33 in hepatic inflammation. In Concanavalin (Con)A-induced immune-mediated hepatitis, IL-33 was released by necrotic hepatocytes and induced immune responses by signaling through the IL-33 receptor ST2. We have shown previously that IL-33 pre-treatment protected from immune-mediated hepatitis, suggesting an immunosuppressive role of the IL-33/ST2 axis in liver disease. Since regulatory T cells (Tregs) expressing ST2 respond to IL-33, we aimed at investigating the IL-33-driven ST2$^+$ Treg response in the inflamed liver.
Method: To induce immune-mediated hepatitis, mice received ConA and were analyzed 24 hours later. To address the immunosuppressive effect of IL-33 on disease pathology, mice were treated with IL-33 on three days before ConA challenge. The phenotype of hepatic Tregs was determined by flow cytometry. Tregs from IL-33-treated FIR-tiger mice were adoptively transferred into C57BL/6 mice, which received ConA one day later.
Results: In homeostasis, the frequency of ST2$^+$ Foxp3$^+$ Tregs was elevated in the liver compared to the spleen. Hepatic ST2$^+$ Tregs expressed higher levels of Foxp3 than ST2$^-$ Tregs and the frequencies of ST2$^+$ Tregs expressing ICOS, KLRG1, Ki-67, CTLA-4, TIGIT, CD39, CD73, and IL-10 were increased, indicating an activated, proliferative and anti-inflammatory phenotype of this Treg subset in steady-state. In immune-mediated hepatitis, the frequency of ST2$^+$ Tregs was enhanced, which up-regulated expression of inhibitory molecules. Moreover, ST2-deficient mice developed more severe immune-mediated hepatitis despite an elevated frequency of Foxp3$^+$ Tregs in the inflamed liver, underlining the importance of the IL-33/ST2 axis for hepatic immune regulation. IL-33 pre-treatment before induction of hepatitis increased the frequency of activated hepatic ST2$^+$ Tregs compared to ConA-treated mice, which was associated with protection from liver disease. Moreover, transfer of IL-33-activated Tregs before ConA challenge potently suppressed immune-mediated hepatitis by inhibiting the inflammatory immune response.
Conclusion: The immune regulatory function of IL-33 in liver inflammation might be driven by expansion and recruitment of a highly immunosuppressive Treg subset expressing ST2.

FRI338
Plasmacytoid dendrtic cells protect against acute liver injury via IL-35

Yuzo Koda[1], Nobuhiro Nakamoto[1], Po-Sung Chu[1], Aya Yoshida[1], Yohei Mikami[1], Toshiaki Teratani[1], Takanori Kanai[1]. [1]*Keio University School of Medicine, Department of Internal Medicine, Division of Gastroenterology and hepatology, Tokyo, Japan*
Email: kodayuzo0423@gmail.com

Background and Aims: Plasmacytoid dendritic cells (pDCs) are well known as a subset of anti-viral immune cells that produce type I interferons. Recently, it has become clear that pDCs also have immune suppressive functions in various diseases of human and mice. However, the role of pDCs in liver diseases, especially non-viral liver diseases, remains largely unknown.
Method: A total 22 patients with acute hepatitis and 21 healthy controls were enrolled, and their peripheral blood (PB) and liver sections was used to analyze the frequency and phenotype of pDCs. In a mouse study, C57BL/6 male mice were administered Concanavalin A (ConA) to induce acute liver injury. The immune phenotype and function of specific subsets of immune cells in the PB and liver were evaluated by flow cytometry and IHC.
Results: We initially found that the number of CD123+ BDCA-2+ pDCs in the PB and liver of patients with acute liver failure, including acute-onset autoimmune hepatitis, was significantly reduced compared to that of healthy controls, suggesting a contribution of pDCs to the pathogenesis of acute hepatitis. We further examined the specific role of pDCs in liver injury using a ConA-induced immune-mediated acute hepatitis mouse model. In general, CCR9+ Siglec H+ PDCA-1+ pDCs were more abundant in the liver and small intestine (SI) than other organs in steady state, and hepatic pDCs dramatically decreased following ConA-induced acute liver injury. Depletion of pDCs in Siglec-H-DTR transgenic mice exacerbated the severity of liver inflammation compared to that in wild-type mice. Conversely, adoptive transfer of Flt-3L-induced pDCs, but not conventional DCs,

significantly suppressed liver injury. These results suggest a protective role for pDCs against ConA-induced acute liver injury. Mechanistically, the serum levels of IL-35, an IL-12 family regulatory cytokine, were significantly increased in pDC-transferred mice, and IL-35 neutralization canceled the suppressive effect of pDCs. Depletion of regulatory T (Treg) cells using anti-CD25 antibody also canceled the suppression of acute liver injury by systemic IL-35 upregulation by pDCs. Together, these results suggest that the suppressive effect of pDCs on acute liver injury is mediated by IL-35 through interactions with Treg cells. Furthermore, we found that CCR9 deficient pDCs unidirectionally migrated to the inflamed liver with less migration to SI and exert stronger suppression compared to wild-type pDCs.
Conclusion: pDCs play a substantial role in regulating acute liver injury via the IL-35 axis. Adoptive transfer of pDCs with CCR9 inhibition might be a novel therapeutic option for severe acute liver failure.

Email: andrea.mayer@immatics.com

Background and Aims: Hepatocellular carcinoma (HCC) is the third leading cause of death from cancer globally with an extremely variable 5-year survival rate. Immunotherapy strategies for HCC may represent a key therapeutic tool to improve clinical outcome in HCC patients. HepaVac-101 (EudraCT Number: 2015-003389-10; NCT03203005), is a single-arm, first-in-man Phase I/II clinical trial evaluating a therapeutic cancer vaccine in patients affected by HCC. It is a highly innovative, novel approach based on a multi-peptide vaccine (IMA970A) combined with an RNAdjuvant® (CV8102).
Method: The IMA970A *off-the-shelf* vaccine includes 5 HLA-A*24 and 7 HLA-A*02 as well as 4 HLA-DR restricted peptides identified and selected from native human HCC tumor tissue by applying the XPRESIDENT® discovery platform. CV8102 is a novel ribonucleic acid (RNA) based immunostimulatory agent inducing a balanced Th1/Th2 immune response.
HLA-A*02 and/or A*24-positive patients with very early, early and intermediate stage HCCs have been enrolled to be treated with 9 intradermal vaccinations consisting of IMA970A plus CV8102 following a single pre-vaccination infusion of low-dose cyclophosphamide acting as an immunomodulator. Study drugs are applied without concomitant anti-tumor therapy aiming to reduce the risk of tumor recurrence/progression in patients who have received all indicated treatments according to the standard of care and remain without evidence of active disease that warrants further treatment. The primary endpoints of the HepaVac-101 clinical trial are safety, tolerability, and immunogenicity. Secondary/exploratory endpoints are additional immunological parameters in blood, infiltrating T-lymphocytes in tumor tissue, biomarkers in blood and tissue, disease-free survival/progression-free survival and overall survival.
Results: Patients were enrolled in 6 centers located in 5 European countries i.e. Italy (Naples and Negrar/Varese), Germany (Tübingen), UK (Birmingham), Spain (Pamplona) and Belgium (Antwerp). 82 HCC patients have been screened for suitable HLA haplotypes, 22 patients were put on study treatment (i.e. received at least the pre-treatment with cyclophosphamide). So far, the observed safety profile is as expected. Immunogenicity data will be available at time of the meeting.
Conclusion: The HEPAVAC-101 clinical trial is the achievement of the HEPAVAC Consortium supported by the European Commission's 7th framework program with contract No. 602893 (www.hepavac.eu).

FRI340

High somatic mutation and neoantigen burden do not correlate with decreased progression-free survival in HCC patients

Maria Tagliamonte[1], Angela Mauriello[1], Roberta Zeuli[2], Beatrice Cavalluzzo[1], Annacarmen Petrizzo[1], Maria Lina Tornesello[3], Franco M. Buonaguro[3], Michele Ceccarelli[2], Luigi Buonaguro[1]. *[1]Istituto Nazionale Tumori IRCCS Fondazione G. Pascale, Cancer Immunoregulation Unit, Cancer Experimental Dept, Napoli, Italy; [2]Dipartimento di Scienze e Tecnologie dell'Università degli Studi del Sannio, Benevento, Italy; [3]Istituto Nazionale Tumori IRCCS Fondazione G. Pascale, Molecular Biology and Viral Oncology Unit, Cancer Experimental Dept, Napoli, Italy*
Email: l.buonaguro@istitutotumori.na.it

Background and Aims: Cancer genome instability leads to accumulation of mutations which may result into tumor-specific mutated "neoantigens", not be affected by central T-cell tolerance. Such neoantigens are considered the optimal target for the patient's anti-tumor T cell immunity as well as for personalized cancer immunotherapy strategies. However, only a minor fraction of predicted neoantigens are relevant to the clinical outcome. A strategy for predicting mutated neoantigens relevant to survival in HCC patients is needed.
Method: In the present study, a prediction algorithm was applied using datasets of RNA sequencing from all 377 HCC patients available at The Cancer Genome Atlas **(TCGA),** to predict neoantigens to be presented by each patient's autologous HLA molecules. Training and validation sets were used to assess the validity of the analysis.
Results: Neither the somatic mutations nor the number nor the quality of the predicted neoantigens correlate as single parameter with survival of HCC patients who do not undergo immunotherapy treatment. Furthermore, the preferential presentation of such neoantigens in the context of one of the major MHC class I molecules does not have an impact on the survival. On the contrary, the expression of GZMA is significantly correlated with survival and, in the context of high GZMA, a direct correlation between number and quality of neoantigens with survival is observed.
Conclusion: This is in striking contrast to results described in cancer patients undergoing immunotherapy, in which a strong correlation between Tumor Mutational Burden, number of predicted neoantigens and survival has been reported (Mauriello et al., Cancers 2019).

FRI341

Myeloid derived suppressor cells enhance regulatory T cell suppressive activity via IL-10, iNOS and PDL-2 in cirrhotic patients with sepsis

Rashi Sehgal[1,2], Rakhi Maiwall[3], Navkiran Kaur[2], Vijayraghavan Rajan[3], Shiv Kumar Sarin[3], Nirupma Trehanpati[1].
[1]Institute of liver and biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Amity University, Amity Institute of Biotechnology, Noida, India; [3]Institute of liver and biliary Sciences, Hepatology, New Delhi, India
Email: trehanpati@gmail.com

Background and Aims: Decompensated cirrhotic patients are more prone to bacterial infections leading to sepsis. Myeloid derived suppressor cells (MDSC) do expand in sepsis patients and correlate with ICU stay. However, their role in decompensated cirrhosis (DC) patients is not known. We studied the impact of MDSCs on T cells, suppressive Tregs and Th17 cells in decompensated cirrhosis patients with sepsis.

Method: Frequency of both monocytic and granulocytic MDSC (M and G-MDSCs), T-cells and Tregs was analysed in peripheral blood of DC patients with sepsis (Gr. A, n = 45), without sepsis (Gr. B, n = 20), and healthy controls (HC, [Gr. C, n = 10]). Expression of Naïve T-cell markers (CCR7+CD45RA+), T-cell exhaustion markers (PD-1 and TIM3), IL-10 on Tregs and HLA-DR on monocytes were analysed. mRNA levels of IL-10, iNOS, arginase-1, PDL-2 and PDL-1 were assessed in sorted MDSCs and monocytes. *Ex-vivo* co-culture of FACS sorted MDSCs and adherent monocytes with T-cells was assessed for proliferation and apoptosis using PI/ANNEXIN and CFSE. Ex-vivo co-cultured cells were also assessed for Foxp3 and IL-17 under Th0 and Th17 condition.

Results: Percentage of total and G-MDSCs were significantly higher in Gr. A than B (p = 0.005, p = 0.02) and C (p = 0.05, p = 0.02); though there was no difference in the M-MDSCs between groups. CD4+ T-cells were lower in Gr. A (p = 0.027) and B (p = 0.023) patients but with enhanced expression of CCR7+CD45RA+, PD-1 and TIM3 in Gr. A than C (p = 0.034, p = 0.009). The CD4+CD25+FOXP3+ Tregs were also higher in Gr. A (p = 0.041) and B (p = 0.047) compared to Gr. C. Expression of HLA-DR on monocytes was significantly low in Gr. A (p = 0.005) and B (p = 0.005) compared to HC. IL-10, iNOS and PDL-2 were found increased in MDSCs of Gr. A. *EX-vivo* cultured T cells with MDSCs in Gr. A patients showed suppression in proliferation and marked increase in ANNEXIN+ve cells compared to T-cells cultured with monocytes and also compared to Gr. B and C. Ex vivo cultured T cells with MDSCs under Th0 and Th17 condition showed increased expression of FOXP3+ (p = 0.028) in Gr. A compared to B and C.

Conclusion: Our results highlight the cross talk of MDSCs with T-cells inducing expression of FoxP3 in sepsis. MDSCs leads to the expansion of Tregs and enhanced immune suppressive as well as immune exhaustion environment through IL-10, iNOS and PDL-2 perpetuate sepsis in cirrhosis patients.

Neutrophils are recruited at the periportal area in alcoholic liver disease and promote ductular reaction expansion

Silvia Ariño Mons[1], Beatriz Aguilar-Bravo[1], Mar Coll[2], Woo-Yong Lee[3], Paul Kubes[3], Pau Sancho-Bru[1,2]. *[1]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Barcelona, Spain; [3]Snyder institute of Chronic Diseases, University of Calgary, Calgary, Canada*
Email: psancho@clinic.cat

Background and Aims: Alcoholic hepatitis is characterized by the expansion of ductular reaction (DR), which is accompanied by a prominent infiltration of neutrophils. Previous results from our group

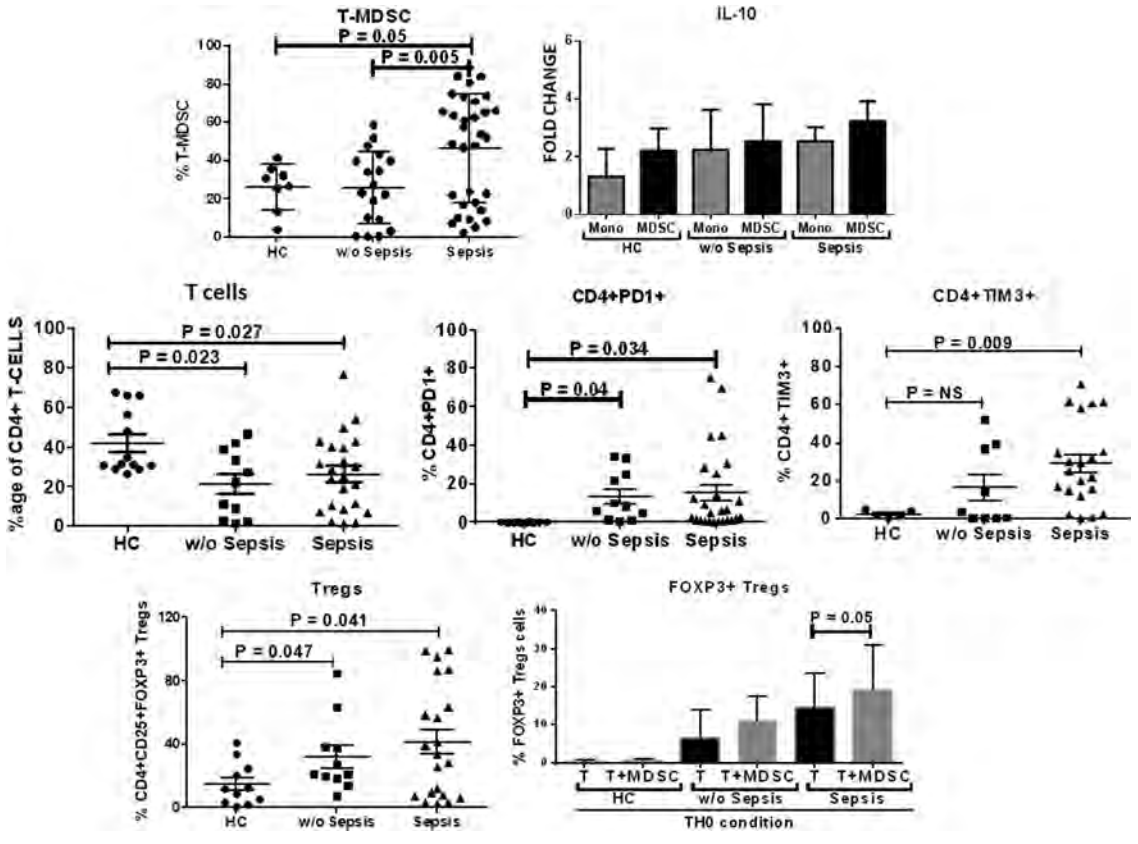

Figure: (abstract: FRI341)

revealed a proinflammatory profile of DR cells, suggesting their role in neutrophils recruitment to the periportal area. The aim of the present study was to investigate the recruitment of neutrophils around DR in chronic liver disease and explore their role in tissue repair.

Method: Infiltration of neutrophils was assessed by immunofluorescence and tissue clearing in stages of alcoholic liver disease progression. Intravital microscopy was performed in mice treated with DDC. Infiltrating mouse neutrophils were used for functional analysis by qPCR and FACS. In order to evaluate the impact of neutrophils on DR expansion, mice fed with DDC diet for 3 weeks were depleted of neutrophils by daily intraperitoneal administration of 1A8 antibody. Inhibition of neutrophil recruitment was performed by daily oral administration of CXCR1/2 receptor inhibitor.

Results: Histologically, DR was associated with neutrophil infiltration at the periportal area, as demonstrated in KRT7-MPO immunofluorescence. The number of infiltrating neutrophils increased with disease progression. Moreover, tissue clearing showed a direct contact of neutrophils with DR cells. Alongside, intravital microscopy in an experimental model of DR revealed a time-dependent infiltration of neutrophil, which were found in close contact with DR cells. Functionally, infiltrating neutrophils showed a lower phagocytic capacity and a reduced inflammatory response to LPS as compared with circulating neutrophils. Long-term inhibition of neutrophil recruitment with a CXCR1/2 inhibitor attenuated the expansion of DR and liver fibrosis. Likewise, treated animals showed a decreased hepatic gene expression of inflammatory markers fibrosis and DR. In addition, the chronic depletion of neutrophils by 1A8 antibody administration also showed a reduction in neutrophil recruitment and DR expansion both at histology and gene expression level.

Conclusion: Overall, our study shows that chronic liver disease progression is associated with increasing number of infiltrating neutrophils, which are found in close contact with DR cells. Infiltrating neutrophils show an altered functionality and their recruitment promote DR expansion. These results suggest that strategies targeting neutrophil recruitment may improve chronic liver injury.

FRI343

Obeticholic acid suppresses expansion of hepatic immune cell populations in a diet-induced obese and biopsy-confirmed model of non-alcoholic steatohepatitis

Sanne Veidal[1], Alba Manresa Arraut[1], Michael Feigh[1], Niels Vrang[1], Lisbeth N Fink[1]. [1]*Gubra ApS*
Email: ssv@gubra.dk

Background and Aims: Both hepatic and extrahepatic inflammatory mechanisms are considered important components in the development and progression of non-alcoholic steatohepatitis (NASH). The present study aimed to profile liver and epididymal white adipose tissue (eWAT) leukocyte populations by flow cytometry following treatment with obeticholic acid (OCA), an FXR agonist currently in clinical development for NASH, in a diet-induced obese (DIO) and biopsy-confirmed mouse model of NASH with fibrosis.

Method: Male C57Bl/6J mice were fed the AMLN diet (40% fat, 20% fructose, 2% cholesterol) for 30 weeks prior to liver pre-biopsy sampling. Only animals with histology-proven steatosis (score ≥2) and fibrosis (stage ≥F1) were included and stratified into treatment groups. DIO-NASH mice received vehicle (PO, QD) or OCA (30 mg/kg, PO, QD) for 8 weeks. Vehicle-dosed chow-fed mice served as lean controls. Single cell suspensions from liver lobular and eWAT samples were stained with two panels of fluorescently labelled antibodies to detect and quantify leukocyte subsets, including monocytes/macrophages, neutrophils, T-cells, B-cells, Natural killer (NK) and NK T-cells, and analyzed by flow cytometry.

Results: DIO-NASH mice displayed significant increases in the total number of hepatic (~4-fold) and eWAT (~3-fold) leukocytes compared to chow-fed controls. Hepatic leukocyte expansion was dominated by Ly6C^{++} infiltrating pro-inflammatory monocytes and resident-like F4/80^{+} macrophages as well as a 5-fold increase in CD8^{+} T-cells/mg liver. In contrast, the increase in eWAT leukocyte populations in DIO-NASH mice reflected the tissue expansion, with only minor changes in the proportions of infiltrating leukocyte subsets. OCA significantly reduced the total number of leukocytes in the liver but had no effect in eWAT. The pronounced hepatic anti-inflammatory effects of OCA were primarily driven by >50% reduction in the number of infiltrating pro-inflammatory monocytes and CD8^{+} T-cells.

Conclusion: DIO-NASH mice showed distinct changes in liver- and eWAT-associated immune cell populations. Accordingly, changes in liver leukocyte populations were characterized by large expansions in both infiltrating and resident monocyte/macrophage subsets and CD8^{+} T-cells, whereas all major cell types in eWAT expanded to the same extent. OCA treatment led to distinct reductions in hepatic pro-inflammatory monocytes and lymphocyte populations, demonstrating the utility of flow cytometry to define anti-inflammatory mechanisms of compounds profiled for therapeutic effects in a DIO mouse model of biopsy-confirmed NASH mouse model.

FRI344

Drug screening against complement disorders using human stem cell-derived endothelium and liver organoids

Yasunori Nio[1], Momoko Ohori[1], Eri Kawakami[1], Tadahiro Shinozawa[2], Norikazu Saiki[3], Takanori Takebe[4]. [1]*Takeda Pharmaceuticals, T-CiRA Discovery, Fujisawa, Japan;* [2]*Takeda Pharmaceuticals, Drug Safety Research Laboratories, Fujisawa, Japan;* [3]*Tokyo Medical and Dental University, Institute of Research, Bunkyo City, Japan;* [4]*Cincinnati Children's Hospital Medical Center, Cincinnati, United States*
Email: takanori.takebe@cchmc.org

Background and Aims: The liver is a main source of complement factor secretion, whereas endothelial overactivation in alternative pathway leads to life-threatening diseases such as atypical Hemolytic Uremic Syndrome (aHUS). Working with human liver organoid (HLO) model, we found that HLO synthesizes high levels of functional complement factors. The present study leverages HLO-derived complement proteins to study complement dysregulation on human endothelial cells with a goal to interrogate aHUS pathogenesis.

Method: We first differentiated human induced pluripotent stem cell (iPSC) into both HLO and endothelial cells (ECs). Complement factor related gene expression and secretion of them from HLO were confirmed by transcriptome analysis and ELISA. The deposition of membrane attack complex (MAC), the final product of complement pathways, on iPSC-EC and its effect on cell injury were observed by supernatant of HLO after lipopolysaccharide (LPS) stimulation. Using this our novel MAC deposition system on iPSC-EC and conventional hemolysis assay, we conducted compound screening on MAC deposition. For in vivo evaluation, aHUS model, complement factor H W1206R mutant, mice was generated.

Results: For the first compound screening, we established high-throughput (HTS) 384 well-based in vitro soluble MAC ELISA assay. Using this HTS MAC ELISA and hemolysis assay, screening was conducted with over 35000 compounds. We identified 21 hit compounds. For the second screening, our original MAC deposition system on iPSC-EC was conducted. We identified several chemotypes of compounds which showed IC50 for MAC deposition around 1 μM in iPSC-EC. These compounds also significantly suppressed LDH release after complement over activation induced by LPS. For in vivo compound evaluation, the phenotypes of aHUS model mice were confirmed. They showed significant reduction of platelet numbers, increase of LDH levels in blood, kidney and liver fibrosis and thrombosis in multiple tissues like aHUS patient. One of our hit compounds significantly improved their aHUS phenotypes.

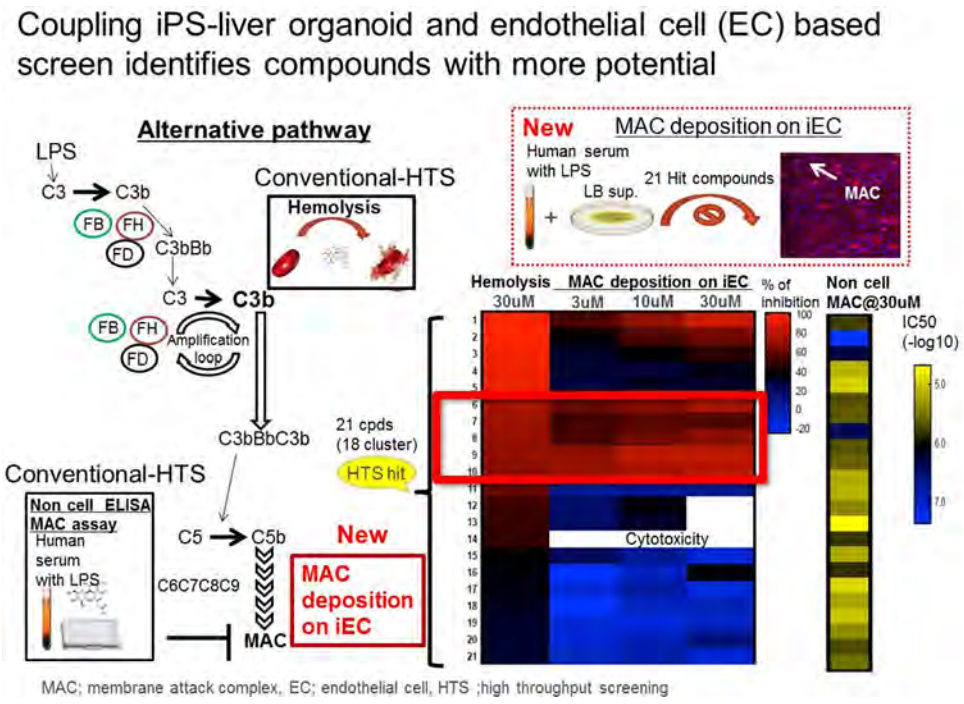

Figure: (abstract: FRI344)

Conclusion: Collectively, we developed new aHUS compound screening platform using iPSC-HLO and EC. Given that current approved therapy is limited to intravenous infusion of incredibly expensive monoclonal antibody, our approach paves the way to identify efficacious compounds against complement related diseases beyond current standard hemolysis screen assay.

FRI346

Immune cells restricted C/EBPbeta deficiency is associated with distorted hepatic mononuclear phagocytes composition, weight loss and spontaneous hepatitis

Debby Reuveni[1,2], Ayelet Kaminitz[1,2], Metsada Pasmanik Chor[2], Ehud Zigmond[1,2]. [1]*Tel Aviv Sourasky Medical Center, The Research Center for Digestive Tract & Liver Diseases, Tel Aviv-Yafo, Israel;* [2]*Tel Aviv University, Tel Aviv-Yafo, Israel*
Email: zigmondu@gmail.com

Background and Aims: CCAAT-enhancer-binding proteins (or C/EBPs) are a family of transcription factors with a leucine zipper (bZIP) domain that are enriched in the liver. C/EBPbeta is a known regulator of numerous physiological and pathological conditions including the regulation of development and function of macrophages. Our aim was to investigate the importance of immune system C/EBPbeta expression in the liver at steady state.
Method: We have generated chimeric mice by injecting C/EBPbeta$^{-/-}$ vs. WT bone marrow into irradiated WT recipients. Mice were assessed for body and liver weight, biochemical profile for liver enzymes and bile acids, prevalence of hepatic mononuclear phagocytes cell subsets by flow cytometry analysis and qPCR of whole liver tissue for expression of genes associated with inflammation and fibrosis. In addition, we performed cell sorting of hepatic mononuclear phagocytes populations from C/EBPbeta deficient and proficient mice and conducted RNA-seq transcriptomic analysis of sorted populations.
Results: C/EBPbeta$^{-/-}$ recipient mice displayed lower body weight as compared to WT recipients. Serum levels of liver enzymes and total bile acids were increased in C/EBPbeta$^{-/-}$ recipients. Liver histology assessment revealed inflammatory infiltrates and tissue damage in C/EBPbeta$^{-/-}$ but not in WT recipients. Flow cytometry analysis of hepatic immune cell populations showed the absence of Ly6c^{low} monocytes and revealed significant decrease in cell numbers of Ly6c^{high} monocytes and Kupffer cells and an increase in monocyte-derived macrophages and CD11b^{positive} dendritic cells in C/EBPbeta$^{-/-}$ mice. RT-PCR analysis discovered significant elevation in relative expression of TNFα, IL6 and IL10 in livers of C/EBPbeta$^{-/-}$mice. RNA-seq analysis of sorted hepatic mononuclear phagocyte populations revealed 50 highly significant differential expressed genes between CEBPbeta deficient and WT hepatic mononuclear subsets that where especially prominent for the Ly6c^{high} monocytes population. Enriched biological pathways include among others regulation of immune system, inflammatory response and response to stimulus.
Conclusion: Great knowledge was obtained using C/EBPbeta$^{-/-}$ mouse model at different pathological conditions. Our data demonstrate vast abnormalities in the same model, already at the naïve like, steady state. Based on our findings, we suggest that previous C/EBPbeta$^{-/-}$ data should be re-challenged with this novel point of view.

Platelet activation during chronic hepatitis B infection exacerbates liver inflammation and promotes fibrosis

Qirong Jiang[1], Richeng Mao[1], Zhongren Ding[2], Haoxiang Zhu[1], Jiming Zhang[1]. [1]*Huashan Hospital, Fudan University, Department of Infectious Disease, Shanghai, China;* [2]*School of Basic Medical Sciences, fudan university, Key Laboratory of Metabolism and Molecular Medicine, Shanghai, China*
Email: jmzhang@fudan.edu.cn

Background and Aims: Recurrent hepatitis activity during chronic hepatitis B virus infection (CHB) results in fibrosis and even hepatocellular carcinoma. It is still unclear what causes acute

exacerbation. As platelets have recently been identified a significant role in inflammation, we here investigated the role of platelets in mediating liver damage in patients with CHB.

Method: Platelet aggregation testing and flow cytometry were carried out to evaluate platelet activation status in 121 patients chronically infected with hepatitis B across different phases of the condition. The correlation between platelet aggregation rate and liver inflammation or liver fibrosis index was evaluated. To investigate the genesis of platelet activation, several serum cytokines were also assessed by MILLIPLEX microsphere-based multiplex cytokine assay.

Results: Active hepatitis patients showed a higher aggregation rate than others. Levels of CD62p, a marker of platelet activation, were also increased in this group of patients. Positive correlations between platelet aggregation rate and liver inflammation or liver fibrosis were also noted, indicating significant role of platelet in the progression of liver disease. The level of tumor necrosis factor alpha, which is known to trigger platelet activation, was markedly higher in the active hepatitis group ($p < 0.005$).

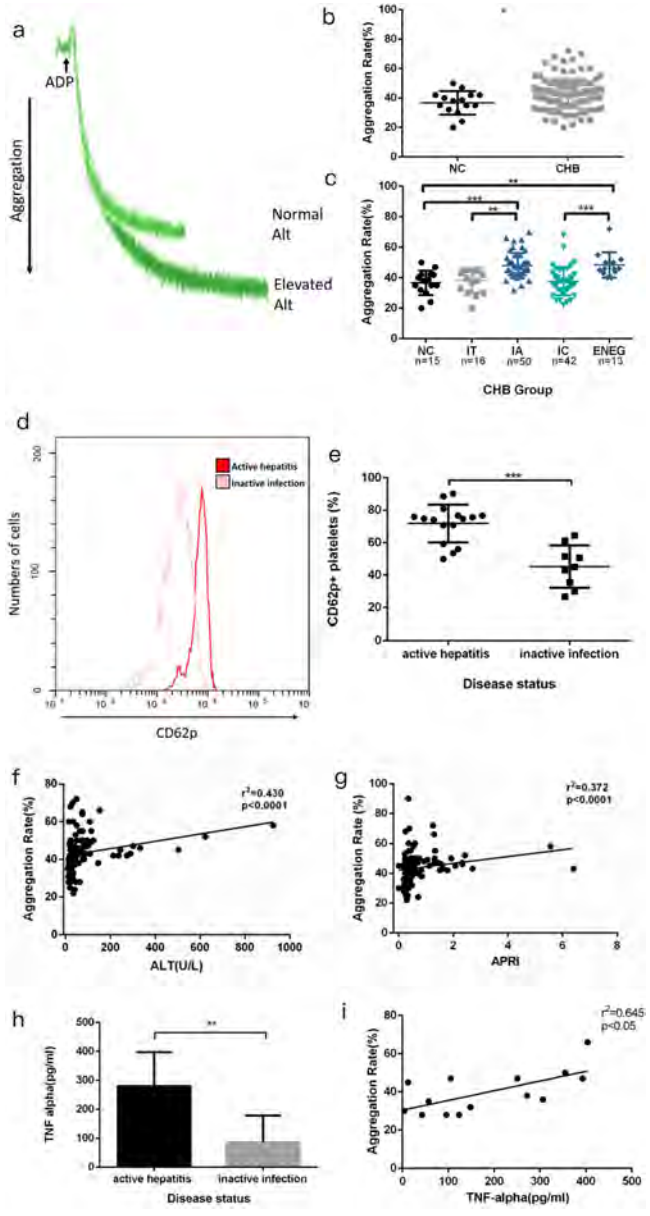

Figure: (abstract: FRI347)

Conclusion: Based on the findings in our study, platelet activation plays a vital role in the progression of CHB. Anti-platelet therapy may provide a new means of hepatitis B infection treatment.

FRI348

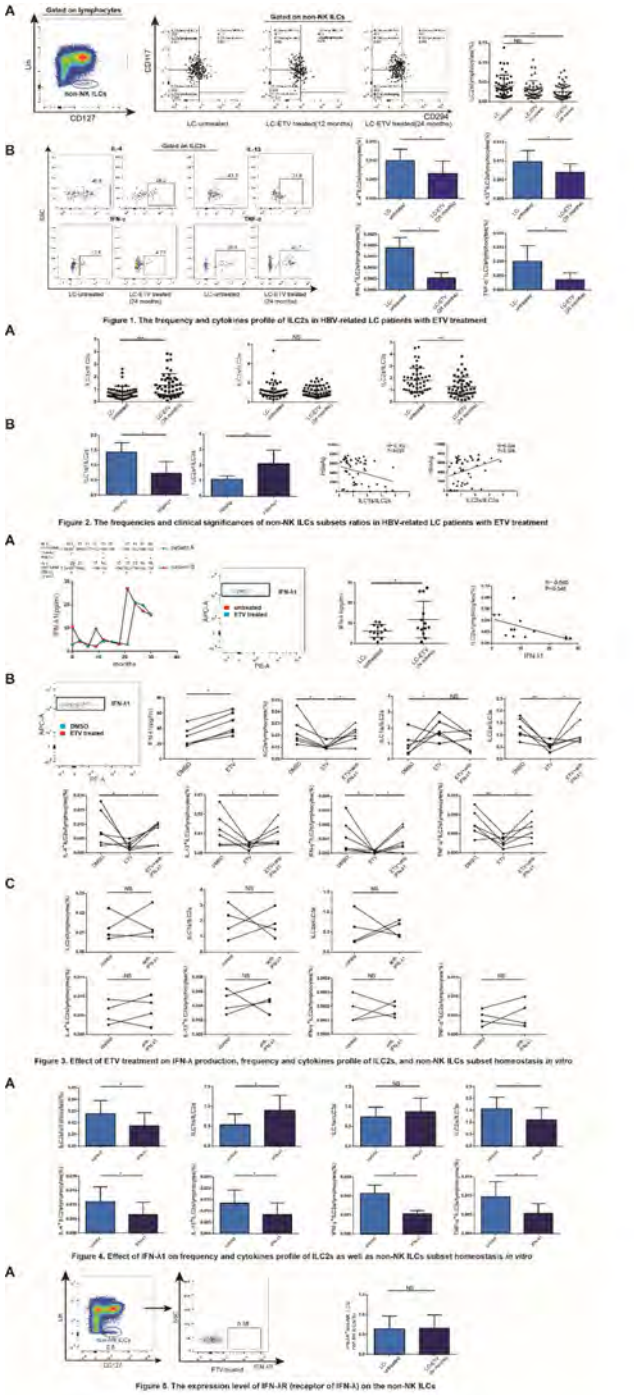
Entecavir-induced interferon-lambda 1 suppresses innate lymphoid cells 2 in patients with hepatitis B virus-related liver cirrhosis

Siqi Wang[1], Yue Shen[1], Wei Jiang[1]. [1]*Zhongshan Hospital, Fudan University, Department of Gastroenterology, Shanghai, China*
Email: jiang.wei@zs-hospital.sh.cn

Background and Aims: Entecavir (ETV) is widely used for its effective suppression on hepatitis B virus (HBV) replication, and its influences on immune microenvironment are observed but not clearly understood. This study aims to explore the immunoregulatory roles of ETV on non-natural killer innate lymphoid cells (non-NK ILCs) in HBV-related liver disease progression.

Method: We enrolled treatment-naïve chronic hepatitis B (CHB) (n = 45) and HBV-related liver cirrhosis (LC) (n = 47) patients, and followed them with ETV treatment for 24 months. The frequency, correlation, and clinical significances of non-NK ILCs and their subsets in addition with cytokines profile of ILC2s were determined before and after ETV therapy. Interferon-lambda (IFN-lambda) levels were compared before and after treatment, and its correlations with ILC2s were identified in ETV-treated LC patients. The IFN-lambda level in supernatants, the frequency and intracellular cytokines production of ILC2s as well as non-NK ILCs subsets ratios were calculated after *in vitro* application of ETV, IFN-lambda 1 neutralizing antibody, or IFN-lambda 1 to peripheral blood mononuclear cells (PBMCs). Additionally, the expression level of IFN-lambda receptor on non-NK ILCs was detected.

Results: In LC rather than CHB cohort, compared with treatment-naïve patients, the frequency and cytokines production of ILC2s (IL-4, IL-13, IFN-gamma, TNF-alpha) decreased with increased ILC1s/ILC2s and decreased ILC2s/ILC3s ratio after 24-month ETV treatment. During treatment, hepatitis B virus e antigen (HBeAg) serological conversion group was characterized with higher ILC1s/ILC2s and lower ILC2s/ILC3s than no serological conversion group. ILC1s/ILC2s had negative and ILC2s/ILC3s had positive correlation with hepatitis B virus surface antigen (HBsAg) level. Furthermore, IFN-lambda 1, which increased with ETV administration, had negative correlation with ILC2s and influenced the non-NK ILCs homeostasis *in vitro* and *in vivo*. *In vitro* experiments showed that additional IFN-lambda 1 had same effects with ETV on suppressing ILC2 s, and in the presence of ETV, IFN-lambda 1 neutralizing antibody could increase the frequency and cytokines production of ILC2s. However, IFN-lambda receptor on non-NK ILCs of LC patients was barely detected regardless of ETV treatment.



Conclusion: ETV suppresses the frequency and cytokines profile of ILC2s through increasing IFN-lambda 1 production in HBV-related LC patients.

FRI349

A new therapeutic candidate vaccine can overcome hepatitis B virus-induced immune tolerance in a mouse model of chronic infection

Babak Bayat[1], Clarisse Lorin[1], Ventzislav Vassilev[1], Lucile Warter[1].
[1]*GSK Vaccines, R&D, Rixensart, Belgium*
Email: babak.bayat@gsk.com

Background and Aims: Hepatitis B virus (HBV) infection is the leading cause of chronic liver disease and death worldwide representing severe public health concern. We have developed a novel vaccine regimen consisting in a prime-boost administration of ChAd155-hli-HBV (prime) and MVA-HBV (boost) viral vector vaccines, both encoding the hepatitis B core (HBc) and surface (HBs) antigens, followed by a recombinant protein vaccine containing HBc and HBs antigens adjuvanted with AS01 (HBc-HBs/AS01) administered either sequentially or concomitantly to the prime-boost.
Method: ELISA and Flow cytometry.
Results: The T-cell priming mediated by ChAd155-hli-HBV is enhanced by encoding of genetic adjuvant, hli. This vaccine regimen is intended to induce robust T-cells and antibodies against HBV antigens to overcome immune tolerance and to restore the immune control of HBV infection and ultimately to achieve hepatitis B functional cure, defined by loss of circulating HBs antigen, and sustained absence of HBV DNA detection. Our therapeutic HBV vaccine candidate has been tested in AAV-HBV *(adeno-associated virus expressing HBV genome)*-transduced HLA-A2/DR1 mice (transgenic for the human HLA-A2 and HLA-DR1 molecules). All AAV-HBV-transduced mice were positive for HBs antigen at 23 days post transduction and the HBs antigen concentrations were higher in sera from male than female HLA-A2/DR1 mice. Therefore, mice were randomized before vaccination according to both levels of HBs antigen and sex. The results showed that both tested vaccine regimens (*sequential or co-administration*) broke the tolerance established in this mouse model. The vaccine induced HBc- and HBs-specific $CD8^+$ T cell responses, as well as HBs-specific $CD4^+$ T cell responses in spleen and liver. In addition, high levels of HBc- and HBs-specific IgG responses were detected following the full vaccine regimens. We also evaluated inflammatory responses in the liver by measuring alanine and aspartate aminotransferase (ALAT and ASAT, respectively) levels in sera. These levels were not higher in sera from AAV-HBV-transduced and immunized mice than in sera from AAV-HBV-transduced non-vaccinated mice, suggesting the absence of liver-targeted cytotoxicity due to vaccination in this AAV-HBV-transduced mouse model.
Conclusion: Overall, the vaccine proved to be immunogenic despite the induced tolerance in this mouse model. These results strongly support the further clinical development of our vaccine candidates.

FRI350

Potential biomarkers of response in chronic hepatitis B patients who achieved HBeAg loss upon treatment with toll-like receptor 8 (TLR8) agonist selgantolimod

Diana Chen[1], Sam Kim[1], Anna Brooks[2], Liao Zhang[1], Ondrej Podlaha[1], Jenny Yang[1], Anuj Gaggar[1], P. Rod Dunbar[2], Jeffrey Wallin[1]. [1]*Gilead Sciences, Inc., Foster City, United States;* [2]*University of Auckland, Auckland, New Zealand*
Email: jenny.yang@gilead.com

Background and Aims: GS-US-389-2024 is a randomized, double-blinded, placebo-controlled Phase 2 study of selgantolimod, an oral selective small molecule agonist of TLR8 in virally suppressed CHB subjects on oral antivirals. Here we investigate potential biomarkers of HBeAg loss in CHB subjects after 24 weeks of selgantolimod treatment.
Method: Patients were randomized (2:2:1) to receive once weekly selgantolimod doses of 1.5 mg, 3 mg or placebo for 24 doses. Serum and peripheral blood mononuclear cells were collected at baseline and on-treatment and evaluated for soluble protein expression levels as well as proportions of myeloid, T-, B- and NK-cell subsets using multicolor flow cytometry. Association between HBeAg loss, biomarkers and clinical parameters was determined by regression analysis with generalized linear model and modular cytokine clustering.
Results: One HBeAg positive patient in the 1.5-mg dose group experienced HBeAg loss at week 12 of treatment and two in the 3-mg dose group at week 48 post-treatment. HBeAg loss was not associated with baseline viral parameters (ie. HBV-DNA, qHBsAg levels) or TLR8 SNP. Selgantolimod induced a dose-dependent increase of circulating

immune mediators such as interleukin (IL)-12, antiviral cytokines interferon (IFN)-γ, and various proinflammatory and anti-inflammatory cytokines (IL-1α, IL-1β, IL-6, and IL-1RA), peaking at 4 hours post-dose and returning to near baseline by 24 hours post-dose. HBeAg loss upon selgantolimod treatment was strongly associated with induction of VEGF [odds ratio (OR) 2.26, 95% confidence interval (CI) (1.56, 3.28); false discovery rate (FDR)-adjusted p-value = 3.1 × 10–4] as well as immune proteins IL-18 [OR 1.66 (1.19, 2.30); FDR = 0.016], CXCL7 [OR 1.74 (1.22, 2.50); FDR = 0.016], IL-12p40 [OR 1.73 (1.20, 2.51); FDR = 0.018] and eotaxin-1 [OR 1.51 (1.11, 2.24); FDR = 0.038]. Notably, selgantolimod induced a pronounced and progressive increase of IL-18 expression in HBeAg loss patients [median fold-change from baseline across all timepoints (IQR) = 1.32 (1, 1.55)] that was not observed in most other patients [1.01 (0.928, 1.22); Wilcoxon rank sum test p = 0.0034]. Transient expansion of CD4+CD57 +granzymeB+perforin+ T cells and CD57+ NK-cell subsets was also observed in these individuals. Studies are ongoing to determine the relationship between these immune cells and cytokine response.
Conclusion: Potential systemic biomarkers associated with TLR8 activation by selgantolimod were identified in CHB patients who achieved HBeAg loss. The biomarkers suggest a role for NK and cytolytic CD4+ T cells in TLR8 mediated immune response against HBV.

FRI351
Immunogenicity and efficacy of an HBV vaccine with an intrinsic checkpoint inhibitor
Mohadeseh Hasanpourghadi[1], Andrew Luber[2], Colin Magowan[2], Xiang Zhou[1], Hildegund Ertl[1]. *[1]The Wistar Institute, Philadelphia, United States; [2]Virion Therapeutics, Newark, United States*
Email: aluber@viriontx.com

Background and Aims: $CD8^+$ T-cells are critical for control of HBV infection, but their activity is hampered by low antigen immunogenicity and T-cell exhaustion. HSV-1 glycoprotein D (gD), when genetically expressed as a fusion protein with target antigens, serves as a checkpoint inhibitor of the B and T cell attenuator (BTLA)-herpes virus entry mediator (HVEM) pathway, which acts early during T cell activation. HSV-1 gD thereby augments antigen-driven $CD8^+$ T-cell responses. We describe the immunogenicity and antiviral activity of two distinct chimpanzee adenoviral vector (AdC) vaccines containing key HBV sequences fused into gD.
Method: Adenoviral vectors of chimpanzee serotypes AdC7 and AdC6 expressing three different HBV sequences, which are conserved between HBV strains and carry human T-cell epitopes, were generated in HEK 293 cells. Each vector was injected at different doses intramuscularly into different strains of mice – in some experiments mice were primed with AdC6 and boosted 6–8 weeks later with AdC7. Blood- or spleen-derived lymphocytes were tested 2–8 weeks after immunization for $CD8^+$ and $CD4^+$ T-cell responses upon a brief in vitro stimulation with peptide pools representing the HBV sequences and then stained for T-cell surface markers and intracellular IFN-gamma and analyzed by flow cytometry. Individual epitopes in different mouse strains were determined using peptide matrices. An adeno-associated virus (AAV) vector of serotype 8 expressing the 1.3 HBV genome was injected i.v. at doses ranging from 1×10^{10}–3×10^{11} genome copies (gc) into C57Bl/6 mice. Mice were vaccinated 4–8 weeks later or left untreated. HBV genome copies in serum were assessed before and after vaccination using a quantitative PCR.
Results: The vaccines were highly immunogenic and induced sustained T-cell responses. Multiple $CD8^+$ and $CD4^+$ epitopes were identified in different strains of mice including HLA-A2 transgenic mice. At low vaccine doses the response could be increased by a booster immunization with a heterologous AdC vector. Boosting furthermore increased the breadth of the T-cell responses. A single IM injection of the AdC6 vector produced sustained HBV DNA viral load declines of –2.0, –1.3 and –1.0 $\log_{10}$ mL through 8 weeks in animals injected with 1×10^{10}, 1×10^{11} and 1.5×10^{11} gc of AAV8-1.3HBV, respectively.
Conclusion: These HBV vaccines induced high immunogenicity and significant antiviral efficacy; a Phase 1b trial in HBV-infected patients is in development.

FRI352
Extracellular HBsAg clearance has minimal impact on CD8+ T cell responses in mouse models of HBV pathogenesis
Valeria Fumagalli[1], Pietro Di Lucia[1], Valentina Venzin[1], Robert Jordan[2], Christian Frey[2], Bill Delaney[2], Frank Chisari[3], Luca Guidotti[1], Matteo Iannacone[1]. *[1]San Raffaele Scientific Institute, Immunology, Milan, Italy; [2]Gilead Sciences, Foster City, United States; [3]The Scripps Ressearch Institute, La Jolla, United States*
Email: iannacone.matteo@hsr.it

Background and Aims: During the course of natural hepatitis B virus (HBV) infection, the clearance of HBV surface antigen (HBsAg) by specific antibodies – a phenomenon referred to as seroconversion – is often associated with increased HBV-specific T cell responsiveness. Therefore, it is widely believed that therapeutic strategies aimed at reducing HBsAg may directly improve the antiviral potential of HBV-specific CD8+ T cells. However, a causative link between circulating, extracellular HBsAg and impairment of $CD8^+$ T cell function has not been definitely established.
Method: Here we used HBV replication-competent transgenic (HBV Tg) mice that were depleted of extracellular circulating HBsAg – via either spontaneous seroconversion or by treatment with therapeutic monoclonal antibodies – as recipients of HBV-specific $CD8^+$ T cells.
Results: Surprisingly, we found that circulating HBsAg had no impact on the capacity of HBV-specific effector CD8+ T cells to induce liver immunopathology. Moreover, depleting extracellular HBsAg had only minimal effect on the expansion of HBV-specific naïve CD8+ T cells undergoing hepatocellular antigen recognition and it did not alter their differentiation into dysfunctional cells. Finally, a brief exposure to circulating HBsAg did not affect the functional restoration of intrahepatically primed CD8+ T cells by interleukin (IL)-2-based immunotherapeutic strategies.
Conclusion: In summary, our results reveal that transient extracellular HBsAg clearance has minimal impact on HBV-specific CD8+ T cells responses and may have important implications for the treatment of chronic HBV infection.

FRI353
Analysis of regulatory T cells frequency and phenotype in chronic hepatitis C patients undergoing interferon-free therapies
Elena Perpiñan[1], Ivana Jordan[1], Mireia García-López[1], Maria Carlota Londoño[1], Sabela Lens[1], Concepció Bartres[1], Sofía Pérez-del-Pulgar[1], Alberto Sanchez-Fueyo[2], Xavier Forns[1], George Koutsoudakis[1]. *[1]Hospital Clínic, IDIBAPS, CIBERehd, University of Barcelona, Liver Unit, Barcelona; [2]King's College London, Institute of Liver Studies, Faculty of Life Sciences, Medical Research Council Centre for Transplantation and Medicine, Division of Transplantation Immunology and Mucosal Biology, London, United Kingdom*
Email: gkoutsou@clinic.cat

Background and Aims: Chronic hepatitis C infection has been associated with elevated frequency of CD4+ regulatory T (Treg) cells. High Treg cells count contributes to antiviral immunity inhibition and promotes liver fibrosis. Direct-acting antiviral (DAA) therapies achieve high rates of sustained virological response (SVR) regardless the degree of fibrosis/cirrhosis state. Since the liver plays a major role in maintaining immune system homeostasis, we hypothesize that liver cirrhosis per se may have an impact on Treg cells frequency and phenotype, even after SVR. The aim of this study was to characterize the potential changes of Treg cells in HCV-infected patients stratified by the fibrosis/cirrhosis state during and post DAA therapies.
Method: Frequency and phenotype of peripheral CD4 + CD25 + Foxp3+ Treg cells were analyzed by flow cytometry in HCV-infected patients with (n = 21) and without (n = 31) cirrhosis, at baseline, week 4 during therapy (W4) and, weeks 12 and 48 after the end-of-

therapy (FU12 and FU48, respectively). Samples obtained from 12 healthy individuals and 19 cirrhotic patients from other aetiologies served as controls.

Results: At baseline, the frequency of Treg cells in HCV patients with cirrhosis was elevated in comparison to healthy controls (mean 3.49% vs. 1.03%, p = .0023) and to HCV patients without cirrhosis (3.49% vs. 0.83%, p < 0.0001), but without statistically significant difference to that of cirrhotics non-HCV controls (3.49% vs 2.05%, p = ns). Longitudinal analysis revealed that Treg cells frequency did not normalize in HCV patients with cirrhosis even at FU48. Phenotypical analysis of Treg cells showed elevated expression of the CD45RO (memory) and HLA-DR (activation) markers in HCV patients regardless cirrhosis status at all time-points.

Conclusion: The elevated expression of CD45RO and HLA-DR in Treg cells of HCV patients, regardless cirrhosis status, indicate that HCV may leave a sustained imprint in Treg cells phenotype towards activation. However, elevated frequency was only detected in patients with cirrhosis, which also persists post DAA therapies. Thus, such immune system alterations associated with cirrhosis may impede immune system restoration and modulate the course of liver disease in these patients after HCV eradication.

FRI354

Characterization of the HBV-specific T cell pool reveals shared epitope usage but different phenotypes of HBV-reactive T cells across patients

Hassen Kared[1], Jeffrey Wallin[2], Michael Fehlings[1], Diana Chen[2], Indrani Rebbapragada[2], Jenny Yang[2], Abishek Garg[2], Faris Kairi[1], Alessandra Nardin[1], Evan Newell[1], Anuj Gaggar[2]. *[1]ImmunoSCAPE, Singapore, Singapore; [2]Gilead Sciences, Inc., Foster City, United States*
Email: jeffrey.wallin@gilead.com

Background and Aims: Development of effective therapeutic strategies for HBV infection requires a better understanding of the nature and biology of CD8$^+$ T cell responses, including the epitopes driving the protective responses and the associated T cell phenotypes. HBV-specific T cell characteristics could be used as measure of clinical and biological activity of the candidate immunotherapy.

Method: Baseline and on-treatment PBMC samples from GS-US-330-1401, a study designed to evaluate the safety and efficacy of the T-cell vaccine GS-4774 in combination with Tenofovir Disoproxil Fumarate (TDF) in patients with chronic HBV infection were investigated by high-dimensional immune profiling. A mass cytometry-based highly multiplexed peptide-MHC (pMHC) tetramer staining strategy was applied to simultaneously screen over 100 HLA-A*11:01 and HLA-A*02:01-restricted HBV T cell candidate epitopes and to further phenotypically profile HBV-specific T cells in PBMC from HBV patients. Influenza- and EBV-specific CD8$^+$ T cells were tracked as controls and benchmarks in each sample. Peptide clusters were automatically generated grouping HBV peptide variants and virus-related epitopes. *Bona fide* antigen-specific T cells were identified by different objective statistical criteria, and phenotypes were assessed using high-dimensional analytical tools. Assessment of longitudinal changes in the HBV-specific CD8$^+$ T cell response and associations with clinical response were also performed.

Results: We detected HBV-specific CD8$^+$ T cells in the majority of patients analyzed as well as in longitudinal samples, with frequencies as low as 0.003% of the total CD8$^+$ T cell pool. Several epitopes were shared across patients including the previously reported epitopes HBV_{pol387} and $HBV_{core169}$. Phenotypes of HBV-specific T cells differed across patients and epitopes, with specific T cells ranging from naïve to terminally differentiated/exhausted profiles. Throughout the treatment period, no significant longitudinal changes in these phenotypes were observed among the patients evaluated. Correlations of measured parameters and clinical features and outcomes are ongoing.

Conclusion: The sensitivity and robustness of our antigen-specific T cell identification methodology enabled us to detect and profile rare HBV-specific CD8$^+$ T cells in a pilot trial cohort. The donor-dependent epitope reactivity and HBV-specific T cell phenotype provide insight into patient clinical history and/or outcome and may be leveraged as a biomarker to guide future HBV treatment strategies.

Hepatitis B virus kinetics after nucleos(t)ide-analogue withdrawal in chronic HBeAg(-) hepatitis correlates with HBV-specific CD8+ response and HBsAg level

Julia Peña Asensio[1,2], Eduardo Sanz-de Villalobos[1], Joaquín Míquel[1], Alejandro González Praetorius[1], Juan Ramón Larrubia[1,3]. *[1]Hospital Universitario de Guadalajara, Translational Hepatology Unit, Guadalajara, Spain; [2]Facultad de Medicina-UAH, Departamento de Biología de Sistemas, Alcalá de Henares, Spain; [3]Facultad de Medicina-UAH, Departamento de Medicina y Especialidades Médicas, Alcalá de Henares, Spain*
Email: juan.larrubia@uah.es

Background and Aims: Nucleos(t)ide-analogue (NA) treatment controls HBV replication in chronic hepatitis B (CHB) eAg(−) but must be taken indefinitely. Persistent viral inhibition could decrease

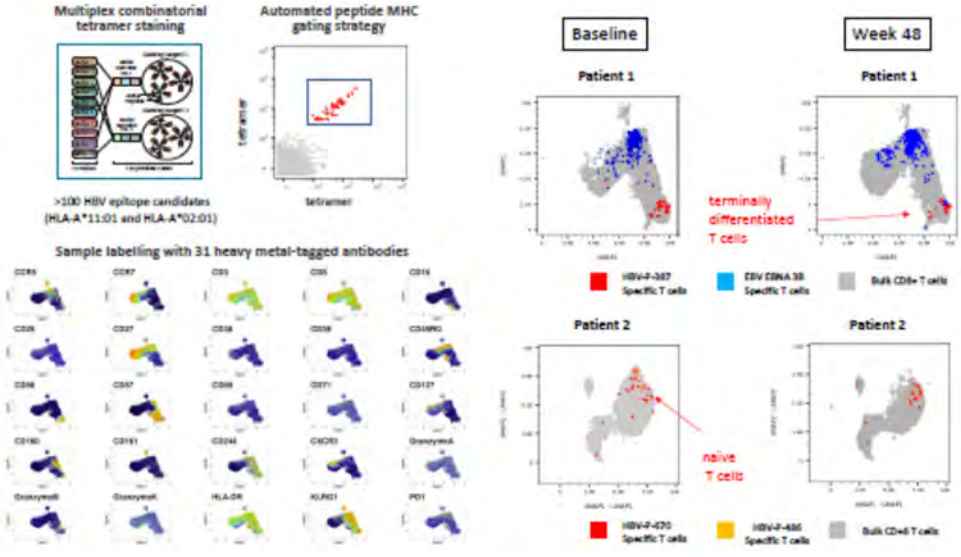

Figure: (abstract: FRI354)

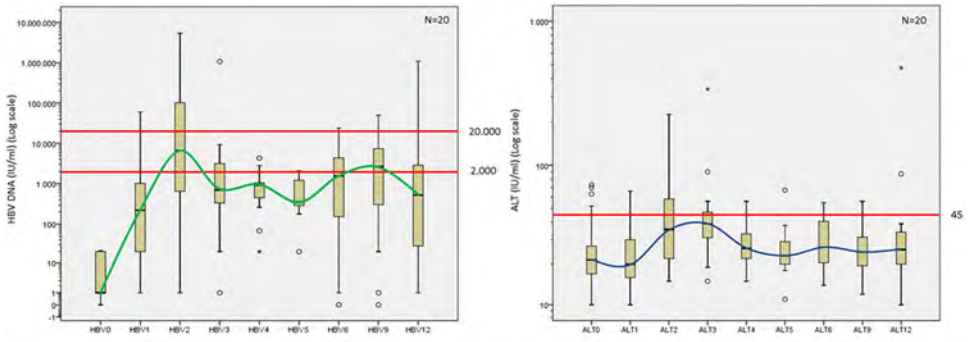

Fig. 1. HBV DNA and ALT dynamics during follow-up after NUC withdrawal in CHB eAg(-) cases with liver fibrosis <F3

Figure: (abstract: FRI355)

antigen load and favours adaptive immune response restoration and functional cure. The outcome after 12-month NA withdrawal was assessed. The role of HBsAg level and HBV-specific immune response was checked.

Method: 20 CHB eAg(−) cases with liver fibrosis <F3 and NA treatment duration >3.5 years were submitted to NA withdrawal. Patients were followed up for one year. Base-line ALT, HBV DNA and HBsAg level were tested. Monthly, HBV DNA and ALT, and quarterly, HBsAg was checked. In HLA-A2^{+} patients, base-line peripheral HBVcore$_{18\text{-}27}$ specific cytotoxic T lymphocytes (CTLs) were visualised directly ex-vivo and after specific proliferation by FACS analysis. After one-year follow-up, NA withdrawal outcome was assessed. Non-parametrical statistical analysis was carried out.

Results: During follow-up, nonpatient developed liver decompensation and only two flare-ups were detected without clinical consequences. Baseline HBsAg level negatively correlated with treatment duration ($r = -0.434$, $p < 0.05$). At month 2, a peak of HBV DNA level was observed (4.5 log, IQR 0.65) and it was followed by an ALT peak at month 3 (41 IU/mL, IQR: 35). At month 5, all cases had HBV DNA < 2000 IU/mL (2.6 log, IQR 0.6) and normal ALT (Fig. 1). At month 12, 60% of cases remained with HBV DNA < 2000 IU/ml, 30% <20.000 IU/mL and 15% had lost HBsAg; all of them with ALT into the normal range (Fig 1). HBV DNA level at month 12 positively correlated with baseline HBsAg ($r = 0.487$; $p < 0.05$). In fact, patients with baseline HBsAg <3.6 log had a lower HBV DNA at month 12 (<3.6log: 1.4 HBV DNA log[IQR: 2.16]; >3.6 log: 2.9 HBV DNA log[IQR: 1.4], $p < 0.05$) and more chance of HBsAg lost (<3.6log: 75%; >3.6 log: 0%, $p < 0.05$). Cases with HBsAg lost had a higher frequency of directly ex-vivo peripheral HBV core$_{18\text{-}27}$ specific CTLs out of total CD8 cells (HBsAg lost: 0.13%, HBsAg persistence: <0.02%, $p < 0.05$) and higher proliferation after specific in-vitro challenge (HBsAg lost: 30%, HBsAg persistence: <0.3%, $p = 0.08$).

Conclusion: NA withdrawal in non-advanced CHB eAg(-) is safe and leads to sustained virological response at month 12 in 90% of cases. Baseline HBsAg level negatively correlates with HBsAg lost and HBV DNA level at month 12. HBsAg lost positively correlates with a better HBV-specific CTL response.

Hepatitis B virus-specific CXCR5+ CD8+ T cells may be related to hepatitis B virus clearance in chronic hepatitis B patients treated with pegylated interferon alpha

Li Zhang[1], Qian Zhang[1], Xichen Pang[1], Xiaoqing Liu[1], Hong Ren[1], Peng Hu[1]. [1]*Institute for Viral Hepatitis, The Key Laboratory of Molecular Biology for Infectious Diseases, Chinese Ministry of Education, Department of Infectious Diseases,The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China*
Email: hp_cq@163.com

Background and Aims: Hepatitis B virus (HBV)-specific CD8+ T cells are the main force in eliminating HBV, however, the functional exhaustion of HBV-specific CD8+ T cells impedes HBV clearance in chronic HBV infection. So, we studied a unique CD8+ T cell subset expressing C-X-C motif chemokine receptor 5 (CXCR5) in patients with chronic hepatitis B (CHB) in this study.

Method: A total of 38 CHB patients were enrolled in this study. Among them, Group A: 16 hepatitis B e antigen (HBeAg) positive CHB patients with alanine aminotransferase (ALT) >2 × upper limit of normal (ULN); Group B: 12 HBeAg positive CHB patients with ALT < 2 × ULN; Group C: 10 HBeAg negative CHB patients with ALT < 2 × ULN. In addition, eight of the 16 CHB patients in Group A were treated with pegylated interferon alpha (PEG-IFN-alpha). Frequency of HBV-specific CXCR5 + CD8+ T cells and levels of surface molecules in CXCR5 + CD8+ T cells were measured through flow cytometry.

Results: The frequencies of HBV-specific CXCR5 + CD8+ T cells were highest in Group A, followed by patients in Group B, and lowest in Group C. While the levels of surface molecules, inducible costimulatory molecule, programmed death 1, CD40 ligands and T cell immunoglobulin and mucin domain 3 were highest in Group A, followed by patients in Group C, and lowest in Group B. In addition, the levels of the four surface molecules were significantly higher in CXCR5 + CD8+ T cells than that in CXCR5-CD8+ T cells. In the longitudinal studies, after 12 weeks of PEG-IFN-alpha therapy, the frequency of HBV-specific CXCR5 + CD8+ T cells in patients whose HBV DNA level decreased by more than 3 log values showed an upward trend, while the frequency of HBV-specific CXCR5 + CD8+ T cells decreased at week 12 relative to baseline in the other patients.

Conclusion: Compared to CXCR5-CD8+ T cells, CXCR5 + CD8+ T cells exhibit partially exhausted in chronic HBV infection. However, HBV-specific CXCR5 + CD8+ T cells may be related to HBV clearance in CHB patients treated with PEG-IFN-alpha.

FRI358

Hepatitis B virus-specific CXCR5+ CD8+ T cells shows stronger functional activity in a mouse model of acute hepatitis B virus infection

Li Zhang[1], Qian Zhang[1], Xichen Pang[1], Xiaoqing Liu[1], Hong Ren[1], Peng Hu[1]. [1]*Institute for Viral Hepatitis, The Key Laboratory of Molecular Biology for Infectious Diseases, Chinese Ministry of Education, Department of Infectious Diseases, The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China*
Email: hp_cq@163.com

Background and Aims: Cellular immune response plays an important role in hepatitis B virus (HBV) clearance. This study aimed to discuss the functional status of HBV-specific CD8+ T cells expressing C-X-C motif chemokine receptor 5 (CXCR5) in a mouse model of acute HBV infection.

Method: The model of acute HBV infection was established by hydrodynamically transfecting female C57BL/6J (B6) mice with pCDNA3.1-HBV1.3 plasmids which contained a supergenomic HBV1.3-length transgene. The frequencies and phenotypes of splenic HBV-specific CXCR5+ and CXCR5-CD8+ T cells were assessed using flow cytometry. The splenic lymphocytes of transfected mice were isolated and stimulated by HBc-derived peptides overnight and then the cytokine secretion of HBV-specific CXCR5+ and CXCR5-CD8+ T cells were detected by flow cytometry.
Results: The frequency of HBV-specific CXCR5+CD8+ T cells increased from day 1 to day 4, and then decreased at day 7 and day 10 after transfection. And the levels of surface molecules, inducible costimulatory molecule (ICOS), programmed death 1 (PD1), CD40 ligands (CD40L) and T cell immunoglobulin and mucin domain 3 (TIM3) were significantly higher in HBV-specific CXCR5 + CD8+ T cells than that in HBV-specific CXCR5-CD8+ T cells at each timepoint. However, the expression of PD1 and TIM3 showed a gradual decline in HBV-specific CXCR5 + CD8+ T cells after plasmid injection, but increased in HBV-specific CXCR5-CD8+ T cells from day 1 to day 4. What's more, the secretion of interleukin-21 (IL-21), interferon gamma (IFN-gamma) and tumor necrosis factor alpha (TNF-alpha) after stimulated by HBc-derived peptides overnight were significantly higher in CXCR5 + CD8+ T cells than secreted in CXCR5-CD8+ T cells at each timepoint.
Conclusion: Although HBV-specific CXCR5 + CD8+ T cells are partially exhausted, it possesses a stronger cytotoxic function by producing high levels of HBV-specific IFN-gamma and TNF-alpha in acute HBV infection. Also, this cell subset may have the same function as follicular helper T cells in assisting humoral immune response by expressing ICOS and CD40L and secreting IL-21.

Email: j.bockmann@uke.de

Background and Aims: While the relevance of CXCR3+ CD4T cell memory subsets has been demonstrated in different HIV and HCV infection settings, the role of CXCR3 receptor/ligand axis in chronic hepatitis B (CHB) and D (CHD) virus infection is yet unknown.
Method: FACS multicolour panels determined the expression of chemokine receptors on PBMCs of 29 CHB, 27 CHD patients and 14 healthy individuals. Intrahepatic RNA levels of CXCR3 receptor and corresponding ligands were determined using human-specific Taqman RT-qPCR assays in cryopreserved liver specimens of 19 CHB, 29 CHD patients and 14 uninfected individuals, as well as in uninfected, HBV mono- and HBV/HDV co-infected livers of chimeric uPA/SCID/beige (USB) mice. Serum levels of chemokines were analysed in the sera of patients and USB mice by Bead Conjugation Assay.
Results: Median frequency of CXCR3 + CD4+ T cells was higher in CHD compared to CHB patients ($p < 0.0001$), while frequency of CXCR3+ NK and CD8T cells did not differ between hepatitis B and D patients. Subtype analysis revealed that CXCR3 + CD4+ T cells in CHD were mainly effector memory T cells (CD4 + CXCR3 + CD45RA-CCR7-, 68.4%) and subtype analysis showed significantly enhanced Th1 cell (CD4 + CD45RA-CXCR3 + CXCR5-, $p = 0.003$) but significantly reduced circulating T follicular helper cell (CD4 + CD45RA-CXCR3-CXCR5+, $p < 0.0001$) frequencies in CHD compared to CHB. Intrahepatic RNA analysis showed higher expression of both CXCR3 ($p = 0.0084$, 2.8-fold) and corresponding ligand chemokines CXCL9 ($p = 0.004$, 3.6-fold), CXCL10 ($p = 0.0028$, 2.2-fold) and CXCL11 ($p = 0.0056$, 2.1-fold) in CHD compared to CHB patients. In line with these patient data, also HBV/HDV co-infected livers of chimeric USB mice revealed significantly higher expression levels of human chemokines CXCL9, −10 and −11 compared to HBV mono-infected mouse livers (CXCL10: $p < 0.0001$, 7.8-fold; CXCL9: $p = 0.009$, 3-fold and CXCL11: $p = 0.0002$, 43.9-fold). Intriguingly, such differences in chemokine levels appeared less pronounced in serum. While CXCL10 levels were modestly higher in sera of CHD patients (1.7-fold, $p = 0.0073$) and HDV infected mice (4.1-fold, $p = 0.028$) compared to CHB patients and HBV infected mice, serum amounts of CXCL9 and −11 did not differ significantly either in patients or mice.
Conclusion: Peripheral TH1 polarized CXCR3+CD4+ T cells rather than serum chemokines mirror substantial differences between CHD and CHB regarding the intrahepatic expression of pro-inflammatory chemokines CXCL9-11.

FRI360

Magnitude and functionality of HEV-specific CD8+ and CD4+ T cell responses in asymptomatic blood donors resemble those in acute and symptomatic patients

Janine Kemming[1,2], Benedikt Csernalabics[1], Marcus Panning[3], Markus Umhau[4], Robert Thimme[1], Tobias Böttler[1], Christoph Neumann-Haefelin[1]. *[1]University Hospital Freiburg, Department of Medicine II; [2]Albert-Ludwigs University Freiburg, Faculty of Biology; [3]University Hospital Freiburg, Institute of Virology; [4]University Hospital Freiburg, Institute for Transfusion Medicine and Gene Therapy*
Email: janine.kemming@uniklinik-freiburg.de

Background and Aims: Hepatitis E virus (HEV) infection is the main cause for acute viral hepatitis worldwide. In the large majority of immunocompetent individuals, HEV infection resolves asymptomatically, however severe courses with fulminant hepatitis and extrahepatic manifestations may occur. In order to clear infection an effective virus-specific CD4+ and CD8+ T-cell response is compulsory for other viral hepatitis viruses. For HEV infection, first evidence supports a critical role of HEV-specific CD4+ and CD8+ T-cell responses in order to achieve viral clearance. In acute symptomatic patients, elimination of HEV infection is accompanied by the occurrence of typical immune-related clinical symptoms such as fatigue, jaundice and ultimately, liver failure. The mechanisms of viral clearance in asymptomatic individuals with normal or only mildly elevated liver enzymes, however, remain obscure. In this study, we assessed the role of HEV-specific T-cell responses in asymptomatic infections without evidence for immunopathology.
Method: We comprehensively studied the HEV-specific CD8+ and CD4+ T-cell responses of 8 HEV RNA+ asymptomatic blood donors identified by routine screening of blood products with antigen-specific expansion, functional testing and pMHCI-tetramer stainings and compared them to a cohort of acute symptomatic HEV-infected patients.
Results: We identified functional and multi-specific CD4+ and CD8+ T-cell responses in all asymptomatic blood donors. In the 8 individuals, responses towards a total of 6 different HEV-specific CD8+ T-cell epitopes could be detected, that were restricted by HLA alleles HLA-A*02:01, B*07:02, and B*18:01. The 12 CD4+ T cell responses detected were restricted by HLA-DRB1*01:01 and DRB1*13:01. Magnitude and functionality of HEV-specific T-cell responses did not significantly differ between asymptomatic and symptomatic infections. Phenotypic characteristics of epitope-specific CD8+ T cells were also comparable in asymptomatic and symptomatic infections.
Conclusion: Our study found no difference between T-cell responses in symptomatic and asymptomatic HEV infections, implicating that

functional and multi-specific T-cell responses in HEV infection are not *per se* associated with immune-related pathogenesis. Why, in some cases, fulminant hepatitis occurs and whether this is caused by the HEV-specific T-cell response remains to be further elucidated.

Peripheral soluble protein, transcriptomic, and methylation biomarkers associated with HBsAg loss in patients with chronic hepatitis B

Jeffrey Wallin[1], Diana Chen[1], Ruidong Li[1], Sam Kim[1], Yevgeniy Gindin[1], Vithika Suri[1], Ondrej Podlaha[1], Li Li[1], Anuj Gaggar[1]. [1]*Gilead Sciences, Inc., Foster City, United States*
Email: jeffrey.wallin@gilead.com

Background and Aims: Immune mechanisms accompanying the clinical response to IFN-α in chronic hepatitis B (CHB) have not been fully characterized. Here, we utilized transcriptome, DNA methylation and multiplex soluble protein profiling to characterize the differential signals associated with clinical response in pegylated interferon alpha-2a (PEG-IFN) treated CHB subjects.
Method: GS-US-174-0149 evaluated PEG-IFN alone or in combination with tenofovir disoproxil fumarate. Whole blood transcriptome and DNA methylation, and soluble plasma protein analysis were performed on baseline and on-treatment samples for study subjects with HBsAg loss (n = 14) and without HBsAg loss (n = 16). Gene expression signatures and methylation profiles were compared between the two response groups (HBsAg loss vs. no HBsAg loss). Association between HBsAg loss and magnitude of cytokine response was determined by regression analysis with Generalized Linear Model and modular cytokine clustering.
Results: Immune signature analysis identified dendritic cells, macrophages, monocytes, memory CD4T cells and CD66+ granulocytes in baseline samples (FDR<0.1) and enrichment of additional immune signatures, i.e. IFN-α and IFN-γ response, activated CD4, exhausted CD4 and CD8, effector memory and cytolytic CD8, and NK were significantly enhanced (FDR<0.1) at on-treatment timepoints for HBsAg loss subjects. A corresponding decrease in DNA methylation was detected for IFN-α (FDR = 5.34 e^{-13}) and IFN-γ (FDR = 5.76 e^{-9}) response genes on-treatment for only the HBsAg loss group. Peripheral proteins associated with IFN activity were increased at baseline in HBsAg loss subjects including IL-18 (p = 0.02) and IP-10 (p = 0.03). On treatment, levels of cytokines and chemokines were higher in the HBsAg loss group, though fold increases across both treatment arms were generally similar. Taken together, these results may signify a greater capacity of some CHB subjects to respond to immunomodulatory agents such as PEG-IFN.
Conclusion: Transcriptome, DNA methylation and soluble plasma protein analysis identified immune pathway differences between PEG-IFN-treated subjects that experience HBsAg loss compared to those that did not. These results inform the type of immune pathway alternations that may be needed for an effective clinical response.

Email: robert.thimme@uniklinik-freiburg.de

Background and Aims: T-cell exhaustion with dysfunctional effector responses towards virally infected cells is a hallmark of chronic HBV infection, but also observed in many other chronic infections. However, the mechanisms controlling the differentiation of exhausted T cells are poorly understood. Recently, the transcription factor and epigenetic modifier TOX was identified as a master regulator of the T-cell exhaustion program in mice. However, the role of TOX in T-cell responses to HBV and different human viral antigens remains unclear.
Method: To address this important question, we analyzed the phenotype and function of HLA-A*02:01 restricted virus-specific CD8+ T cells from 23 HBeAg negative and 7 HBeAg positive chronically HBV-infected patients, as well as patients chronically infected with HCV, HIV, and healthy controls using flow cytometry and high-parametric mass cytometry.
Results: We found that TOX expression on virus-specific CD8+ T cells was strongly increased in persistent viral infections. Interestingly, TOX was significantly higher expressed on HBV-specific T cells facing high levels of antigen isolated from HBeAg positive patients compared to patients with HBeAg negative infection (inactive carrier) indicating that TOX is linked to the different clinical stages of HBV infection and to high antigen load. In agreement with this assumption, we found that virus-specific CD8+ T cells obtained from chronically HCV- and HIV-infected patients with high viral loads also expressed high levels of TOX. Functional analysis linked TOX to a diminished polyfunctionality of exhausted HBV-specific CD8+ T cells suggesting a TOX-dependent programming of CD8+ T-cell dysfunction.
Despite these clear links of TOX to severe T-cell exhaustion, we also observed a high TOX expression on memory CD8+ T cells, in particular senescent cells with irreversible arrest of cell proliferation and cell function in patients with chronic viral infection but also healthy individuals. Indeed, differential patterns of Eomes, T-bet and TCF1 co-expression with TOX were transcriptionally linked to exhaustion vs. senescence programs.
Conclusion: In sum, these results reveal a context-dependent role for TOX tied into differential antigen-dependent exhaustion and senescence programs in humans. The links between TOX and differential exhaustion of HBV-specific T cells during different clinical stages of HBV infection has implications for immunotherapeutic approaches in chronic HBV infection.

Distinct serum HBsAg levels show minimal effect on gene expression profiles of blood leukocyte subpopulations in non-viremic chronic HBV patients

Noé Axel Montanari[1], Nadia Neto[2], Jeroen Aerssens[2], Andre Boonstra[1]. [1]*Erasmus MC, Gastroenterology and Hepatology, Rotterdam, Netherlands;* [2]*Janssen Research and Development, Infectious Diseases Therapeutic Area, Beerse, Belgium*
Email: p.a.boonstra@erasmusmc.nl

Background and Aims: Functional cure in patients chronically infected with hepatitis B virus (HBV) is a rare event, and long-term treatment with nucleoside-analogues (NUC) alone or in combination with interferon-based strategies do not improve rates. It has been postulated that viral proteins, such as hepatitis B surface antigen (HBsAg), have immunomodulatory activities and may negatively impact immunity to HBV. However, limited data is available to support the importance of HBsAg as an immunomodulator. Here we compared whole genome transcriptome profiles of purified blood leukocyte populations obtained from chronic HBV patients with highly distinct HBsAg levels.
Method: By means of multicolour flowcytometry (FACS) and microarray (GO Screen) both PBMC frequencies and FACS-sorted PBMC populations (CD4, CD8 and NKT cells, NK cells, B cells, dendritic cells and monocytes) were analyzed and transcriptionally profiled. We included a total of 24 IC patients and 16 NUC-treated patients with minimal HBV replication (HBV DNA max 2,250 IU/ml), normalized ALT, minimal fibrosis, and predominantly HBeAg-negative. Yet

they displayed a wide range of serum HBsAg levels (0.5–26,000 IU/ml). Patients were classified as high (average 8,912 IU/ml and 7,244 IU/ml serum HBsAg in IC and NUC-treated, respectively) and low (average 83 IU/ml and 151 IU/ml serum HBsAg in IC and NUC-treated, respectively).
Results: FACS analysis of the different leukocyte populations were comparable in patients with high and low levels of circulating HBsAg in IC and NUC-treated. Whereas significant differences in gene expression profiles were found between the various FACS-sorted cell populations, no to minimal transcript modulation was observed within each of these cell type populations in IC and NUC-treated patients with high versus low HBsAg levels. In particular, the largest modulation was observed in monocytes where only 0,16% of genes, out of the 20,251 covered in the array, were found to be tuned by HBsAg.
Conclusion: Our comprehensive approach revealed minimal effects of serum HBsAg levels on frequencies and gene expression profiles of peripheral leukocyte subpopulations in non-viremic chronic HBV patients. It cannot be excluded that HBsAg might impact the intrahepatic compartment where immune signatures are exacerbated.

FRI365
Hepatitis C virus chronicity is associated with a tox-1(high), Eomes(high), T-bet(dim) and PD1(high) phenotype of HCV-specific CD8+ T cells
Nils Wildner[1], Franziska Brauneck[2], Ansgar Lohse[1], Christin Ackermann[1], Julian Schulze zur Wiesch[1]. *[1]University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, II. Department of Medicine, Hamburg, Germany*
Email: julianszw@gmail.com

Background and Aims: First highly published studies have identified the expression of the "transcription factor thymocyte selection-associated high mobility group box protein" (Tox-1) in virus-specific T cells as central regulator of T cell exhaustion in chronic viral infection. Here, we analysed the immune checkpoint phenotype and intracellular transcription factor expression of virus-specific CD8+ T cells at different stages of hepatitis c virus (HCV) infection in order to identify possible roles of T-box transcription factor TBX21 (T-bet), Eomesodermin (Eomes), and Tox-1 for T cell exhaustion and outcome of HCV infection.
Method: HCV and FLU MHC class I tetramer-associated magnetic bead enrichment technique and 16-colour flow cytometry were performed with peripheral blood mononuclear cells (PBMC) of patients with acute (aHCV; n = 5), chronic (cHCV; n = 4) and spontaneously resolved (rHCV; n = 3) HCV infection and compared with PBMCs of healthy donors (HD; n = 5) to assess the expression of different immune checkpoint molecules and intracellular transcription factor profile of virus-specific CD8+ T cells.
Results: We observed a significant increase of T-bet(dim)Eomes(hi) HCV-specific CD8+ T cells at all stages of HCV disease compared with FLU-specific CD8+ T cells and a significant increase of T-bet(dim) Eomes(hi) HCV-specific CD8+ T cells in cHCV compared with rHCV ($p = 0.0078$) and aHCV ($p = 0.0171$) in this small, expanding cohort. Next, we analysed the expression of Eomes and Tox-1 at different stages of HCV infection. Here, we found a significant increase of Tox-1+ Eomes+ HCV-specific CD8+ T cells ($p = 0.0009$) and Tox-1(hi)Eomes (hi) ($p < 0.0001$) in cHCV compared to rHCV patients. We found a significant increase of Tox-1(hi)PD1(hi) HCV-specific CD8+ T cells during cHCV compared to rHCV and HD ($p < 0.0001$). Whereas rHCV showed a significant increase of Tox-1(low)PD1(dim) HCV-specific CD8+ T cells compared with cHCV ($p < 0.0001$).
Conclusion: Our results demonstrate a unique transcription factor expression signature during the chronic stage of HCV infection compared to patients who spontaneously clear the virus. In summary, we see that virus-specific CD8+ T cells in cHCV are Tox-1 (hi), Eomes(hi), T-bet(dim) and PD1(hi). Tox-1 and Eomes induction are associated with the exhaustion phenotype of HCV-specific CD8+ T cells in chronic HCV infection. Thus, the induction of Tox-1 and Eomes during the acute stage of infection might be early key events in the development of HCV chronicity.

Profiles of expression of costimulatory molecules OX40 and OX40l in PBMCs and levels of soluble OX40/OX40l in plasma in chronic hepatitis B patients and health subjects
Mengru Zhan[1], Xiuzhu Gao[1], Zhijun Zhang[2], Fei Peng[1], Chang Wang[1], Mingyuan Zhang[1], Xiaoyu Wen[1], Qinglong Jin[1], Heming Ma[1], Xu Liu[1], Junqi Niu[1,3]. *[1]The First Hospital of Jilin University, Department of Hepatology, Changchun, China; [2]Zhimeng Biopharma Inc, Shanghai; [3]The First Hospital of Jilin University, Key Laboratory of Organ Regeneration & Transplantation of Ministry of Education, Changchun, China*
Email: junqiniu@aliyun.com

Background and Aims: Recent studies suggested that the costimulatory molecules OX40/OX40L, members of the tumor necrosis factor (receptor) superfamily, play pivotal roles in regulating HBV immunity. Here, we report our comprehensive study results on the expression levels of membrane OX40 and OX40L (mOX40 and mOX40L) and levels of soluble OX40 and OX40L (sOX40 and sOX40L) in plasma in hepatitis B(CHB) patients and health subjects (adults and children).
Method: Peripheral bloods were collected from 52 CHB patients, 24 health adults and 13 health children. Expression of mOX40 in T cells and mOX40L in APCs were detected by flow cytometry. Levels of sOX40 and sOX40L in plasma were measured by ELISA. The results were analysed.
Results: While the expression of mOX40 on $CD3^+CD4^+$ and $CD3^+CD8^+$ T cells in PBMCs were significantly reduced in CHB patients compared with health adults, the expression of mOX40L on $CD3^-CD19^+$ B cells and $CD14^+$ monocytes as well as sOX40/sOX40L in plasma in CHB patients were significantly higher than that in health adults. Interestingly, among CHB patients, while negative correlations between levels of HBV DNA ($r = -0.574$, $p < 0.001$) and HBsAg ($r = -0.634$, $p < 0.001$) with the frequency of $CD3^+CD8^+OX40^+$ T cells were observed, there were positive correlations between the levels of HBV DNA ($r = 0.528$, $p = 0.001$) and HBsAg ($r = 0.346$, $p = 0.045$) with the frequency of $CD14^+OX40L^+$ monocytes. Additionally, we observed that $CD14^+OX40L^+$ monocytes and $CD3^-CD19^+OX40L^+$ B cells were both positively correlated with levels of ALT($r = 0.441$, $p = 0.004$; $r = 0.456$, $p = 0.002$, respectively), AST ($r = 0.472$, $p = 0.002$; $r = 0.531$, $p < 0.001$, respectively), ALP ($r = 0.416$, $p = 0.008$; $r = 0.599$, $p < 0.001$, respectively), GGT ($r = 0.421$, $p = 0.007$; $r = 0.499$, $p = 0.001$, respectively). Further, the levels of sOX40/sOX40L in plasma also had a significant positive correlation with HBV DNA, HBsAg, HBeAg, ALT, AST, GGT. Furthermore, we found that the levels of mOX40 expressed on $CD3^+CD4^+$ and $CD3^+CD8^+$ T cells, mOX40L expressed on $CD3^-CD19^+$ B cells and $CD14^+$ monocytes, as well as the level of sOX40 in plasma in health children were all significantly lower than that in health adults. Finally, the frequency of $CD3^+CD4^+OX40^+$ T cells was positively correlated with the age in health subjects including children and adults.

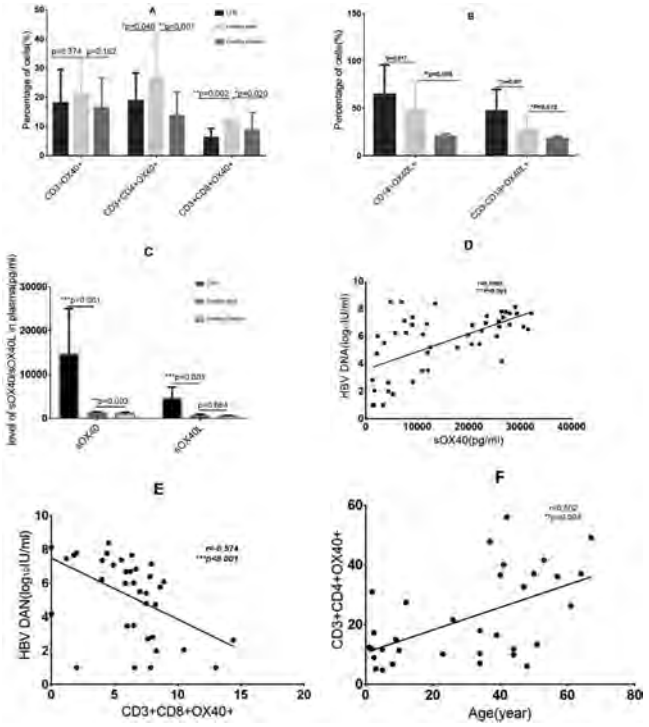

Figure: Frequency of mOX40+ and mOX40L+ cells and levels of sOX40 and sOX40L in CHB patients, health adults, and children.

Conclusion: These results suggest that the levels of cellular and soluble OX40/OX40L are both associated with the virologic status and pathogenesis of CHB patients, and therefore may be promising biomarkers for monitoring disease progression. Arguably, the reduced expression of OX40/OX40L in children suggests a vulnerable biological condition against HBV infection.

FRI368

Phenotypic variation among myeloid-derived suppressor cells (MDSC) in natural history phases of chronic HBV infection differentially impacts HBV-specific T cell response and homing: lack of functional normalization after anti-viral therapy

Sourina Pal[1], Debangana Dey[1], Madhuparna Nandi[1], Archi Goswami[1], Mousumi Khatun[1], Soma Banerjee[1], Amal K Santra[1], Sk. Mahiuddin Ahammed[1], Abhijit Chowdhury[1], Simanti Datta[1].

Email: sourina.pal@gmail.com

Background and Aims: Chronic HBV infection (CHI) is associated with diverse natural history that includes Immune-tolerant (IT), HBeAg-positive chronic hepatitis B (CHB) (EP-CHB), inactive carrier (IC) and HBeAg-negative CHB (EN-CHB) phases. A hallmark of CHI is HBV-specific T cell dysfunction that is mediated by multiple regulatory mechanisms and the nature of response is influenced by the disease phases. Myeloid-derived suppressor cells (MDSC) have emerged as key regulator of T cell and their properties are sculpted by the microenvironment. Here, we investigated the distinctive features of MDSC in various phases *of* CHI, the factors responsible for their functional discrepancies and the impact of diverse phenotypes of MDSC on the response pattern and homing of HBV-specific $CD8^+$/$CD4^+$T cells. Effect of Tenofovir on MDSC profile and T cell response was also assessed.
Method: Flow cytometry, ELISA, cell-sorting and co-culture assays were performed.
Results: MDSC in EP-/EN-CHB patients showed profound suppressive ability, expressing Arg1, iNOS, PD-L1, CTLA-4 and CD40 at significantly greater levels relative to healthy controls (HC). However, in IT, only Arg^+MDSC and in IC, $iNOS^+$ and $PD\text{-}L1^+$MDSC were markedly higher than HC and comparable to CHB. Correlation analysis indicated that high HBsAg titer in IT and CHB was associated with elevated Arg^+MDSC, whereas high serum IL-1β (in CHB/IC) and TNF-α (only in CHB) potentiated PD-L1/iNOS and CD40/CTLA-4 expression respectively on MDSC. Further, HBV-specific IFN-γ^+ and IL-2^+ $CD8^+$/$CD4^+$T cells were significantly high in IT as compared to CHB and IC, while the homing receptor, CCR5 was poorly expressed on T cells of IT and CHB than IC. To test whether diverse phenotypes of MDSC could reciprocally regulate HBV-specific T cell response, HLA-DR^-CD33^+-MDSC sorted from patients in different disease phases, were co-cultured with autologous T cells in presence of overlapping peptides of HBV core protein. MDSC from CHB/IC, greatly attenuated IL-2 and IFN-γ production by HBV-specific $CD8^+$/$CD4^+$T cells, the effect being more pronounced in CHB. In contrast, MDSC of IT minimally affected the cytokine production by T cells. However, MDSC from IT and CHB downregulated CCR5 on HBV-specific T cells and disrupted trafficking of these cells. Addition of Arg1 or iNOS inhibitor during co-culture restored only HBV-specific IFN-γ^+T cells while neutralizing PD-L1 recovered both IL-2 and IFN-γ producing abilities of T cells, implying PD-L1/PD-1 signalling to be the key MDSC-mediated immunosuppressive mechanism in CHI. One year of Tenofovir therapy failed to normalize MDSC phenotype, serum IL-1β/TNF-α/HBsAg levels and T cell functions despite reduction in HBV DNA.
Conclusion: Diversity of MDSC during CHI impacts HBV-specific T cell response and homing. Hence therapeutic targeting of MDSC could boost anti-HBV immunity.

Integrated analysis of serum immunological biomarkers in patients with chronic hepatitis C upon direct-acting antiviral treatment

Isabela Gomes Ribeiro[1], Ismael Artur Costa-Rocha[2], Andrea Teixeira-Carvalho[2], Luciana Diniz Silva[1], Ana Carolina Campi-Azevedo[2], Olindo Assis Martins-Filho[2], Rosângela Teixeira[1]. [1]*UFMG Faculty of Medicine, Internal Medicine, Belo Horizonte, Brazil;* [2]*Instituto René Rachou, Laboratório de Biomarcadores e de Diagnóstico, Belo Horizonte, Brazil*
Email: teixeira@medicina.ufmg.br

Background and Aims: The knowledge of timing of immune response remodeling upon DAAs can provide relevant evidences to support novel fields of clinical investigation. Important issues related to post-treatment has been recently raised. We sought to analyze the kinetics profiles of serum chemokines, pro-inflammatory/regulatory cytokines and growth factor in patients with chronic hepatitis C upon DDAs treatment.
Method: Fifty HCV patients, 33/50 (66%) males, mean age of 61 years (40–81 years), were enrolled in a longitudinal investigation carried out before (Baseline), during (2–4 and 8–12 weeks) and post-treatment (12–24 weeks) with sofosbuvir and daclatasvir or simeprevir. All patients had SVR. Serum biomarkers CXCL8, CCL11, CCL3, CCL4, CCL2, CCL5, CXCL10, IL-1β, IL-6, TNF-α, IL-12, IFN-γ, IL-15, IL-17, IL-1Ra, IL-4, IL-5, IL-9, IL-10, IL-13, FGF-basic, PDGF, VEGF, G-CSF, GM-CSF, IL-7 and IL-2 were quantified by Luminex™ platform. Twenty uninfected blood donors were control group (NI). Mann-Whitney test was used for comparison between HCV and NI groups and Kruskal-Wallis test for multiple comparisons followed by Dunn's post-test for sequential pairwise comparisons. The significance was considered at $p \leq 0.05$. The Prism GraphPad 8.0 software was used for statistical analysis and graphical arts. The study was approved by UFMG and FIOCRUZ-Minas ethical boards. All participants signed consent form.
Results: A clear biomarker storm was observed in HCV patients at the pre-treatment period, characterized by a massive increase levels of chemokines (CXCL8, CCL11, CCL3, CCL2, CXCL10), pro-inflammatory cytokines (IL-1β, IL-6, TNF-α, IL-12, IFN-γ, IL-17) and growth factors (FGF-basic, PDGF, GM-CSF, IL-7) with minor increase in regulatory cytokines (IL-9, IL-13) as compared to NI. The kinetics of baseline fold changes monitored during and after DAAs treatment revealed a early

decline in the levels of CXCL8, CCL4, IL-6, IL-15, IL-17, IL-9, GM-CSF and IL-7 observed at 8–12 weeks of treatment, and a later remodeling of CCL3, CCL2, CCL5, IL1β, TNF-α, IL-12, IFN-γ, IL1-Ra, IL-4, IL-10, IL-13, PDGF, VEGF, G-CSF that reached lower levels at 12–24 weeks post-treatment. Higher ALT levels (>69 mg/dL UNL) and compensated cirrhosis at baseline were factors related to delayed immune response as compared to the rapid immune remodeling observed in patients with lower ALT levels (<69 mg/dL) and non-cirrhotic status.

Conclusion: The HCV treatment with DAAs resulted in a clear remodeling of the serum biomarker storm, hallmark of untreated HCV patients. Regardless the SVR response observed in all patients, the kinetics of serum biomarkers during and after DDAs treatment was associated with the pre-treatment high ALT and cirrhosis status. These findings added novel evidences for the immunological remodeling process triggered by DDAs.

FRI370

Higher proportion of responders with hepatitis B antibody levels ≥ 100 miu/ml with the trivalent HepB vaccine, Sci-B-Vac, compared to Engerix-B: results from the phase 3 double-blind, randomized study comparing immunogenicity and safety (PROTECT)

Timo Vesikari[1], Joanne Langley[2,3], Nathan Segall[4], Brian Ward[5], Curtis Cooper[6], Guillaume Poliquin[7], Soren Gantt[8], Bruce Smith[9], Pierre Van Damme[10], Isabel Leroux-Roels[11], Geert Leroux-Roels[11], Nathalie Machluf[12], Johanna Spaans[13], Bebi Yassin-Rajkumar[13], David Anderson[14], Vlad Popovic[15], Francisco Diaz-Mitoma[13]. *[1]Vaccine Research Center, Tampere, Finland; [2]Canadian Center for Vaccinology, Halifax, Canada; [3]Departments of Pediatrics and Community Health and Epidemiology; [4]Clinical Research Atlanta, Atlanta, United States; [5]McGill University, Montreal, Canada; [6]The Ottawa Hospital, Ottawa, Canada; [7]Public Health Agency of Canada, Winnipeg, Canada; [8]BC Children's Hospital Research Institute, University of British Columbia, Division of Infectious Diseases in the Department of Pediatrics, Vancouver, Canada; [9]Dalhousie University, Department of Mathematics & Statistics, Halifax, Canada; [10]Vaccine & Infectious Disease Institute, Wilrijk, Belgium; [11]Ghent University Hospital, Gent, Belgium; [12]SciVac Ltd/VBI, Rehovot, Israel; [13]VBI Vaccines Inc., Nepean, Canada; [14]VBI Vaccines Inc., Cambridge, United States; [15]VBI Vaccines Inc., Nepean, Canada*
Email: fdiazmitoma@vbivaccines.com

Background and Aims: Sci-B-Vac®, a trivalent HepB vaccine with pre-S1/pre-S2/S antigens, may enhance immunogenicity in adults, compared to the monovalent (s-only) HepB vaccine, Engerix B®. HepB antibody (Ab) level >10 mIU/mL is accepted as a correlate of seroprotection (SPR), but higher levels (≥100 mIU/mL) and/or higher HepB Ab geometric mean concentration (GMC) may indicate a more robust immune response and be associated with longer duration of protection. The aim of PROTECT (Clinical Trials ID: NCT03393754) was to compare the immunogenicity and safety of a 3-dose regimen between Sci-B-Vac® and Engerix B® in adults.

Method: In a multinational, comparator-controlled, randomized, and double-blind study, 1607 adults in stable health (≥18 years, 80% ≥45 years), received either Sci-B-Vac® 10 µg or Engerix B® 20 µg, on days 0, 28, and 168. Immunogenicity, including SPR (% participants with HepB Ab level ≥10 mIU/mL), and safety outcomes were followed to day 336. Co-primary objectives were 1) non-inferiority of SPR in adults ≥18 years and 2) superiority of SPR in adults ≥45 years, 4 weeks after the 3rd dose. GMC and HepB Ab ≥100 mIU/mL were exploratory outcomes. GMC ratio was the fold change in GMC of Sci-B-Vac® compared to that of Engerix B®.

Results: Sci-B-Vac® was non-inferior to Engerix B® in participants ≥18 years old (SPR 91.4% *vs*. 76.5%) and superior in participants ≥45 years old (SPR 89.4% *vs*. 73.1%). The proportion of participants who achieved HepB Ab level ≥100 mIU/mL was 80.8% with Sci-B-Vac® compared to 60.7% with Engerix B® in adults ≥18 years (difference 20.1% [95% CI: 15.5,24.6%]), and 77.9% with Sci-B-Vac® compared to 56.5% with Engerix B® in adults ≥45 years old (difference 21.45% [95% CI: 16.2,26.6%]. The proportion of participants with HepB Ab level ≥100 mIU/mL was higher with Sci-B-Vac® compared to Engerix B® in key subgroups with co-morbidities, including BMI >30 (79.6% *vs*. 55.5%), current smokers (70.7% *vs*. 54.7%), and diabetics (59.3% *vs*. 45.0%). Sci-B-Vac® was well-tolerated with no safety signals with low rates of serious adverse events (SAEs) reported (Engerix B®: 2.6% and Sci-B-Vac®: 4.0%).

Conclusion: Sci-B-Vac® yielded a more robust immune response, reflected in high GMC ratios, compared to Engerix B® and met both co-primary immunogenicity endpoints—non-inferiority in adults ≥18 years and superiority in adults ≥45 years. Safety and tolerability were consistent with the known profile of Sci-B-Vac®.

FRI371

Hepatocyte-derived l-carnitine impedes HBsAg clearance in chronic HBV infection

Shuqin Gu[1], Libo Tang[1], Guofu Ye[1], Chengcong Chen[1], Jinlin HOU[1], Yongyin Li[1]. *[1]Nanfang Hospital, Southern Medical University, Department of Infectious Diseases, Guangzhou, China*
Email: yongyinli@foxmail.com

Background and Aims: The seroclearance of HBsAg is regarded as a functional cure of chronic HBV infection. An association between low levels of plasma L-carnitine (L-Cn) and treatment-induced HBsAg

	HepB Ab Geometric Mean Concentration one month after 3rd dose									
Engerix B®	192.616	720.591	142.28	260.916	109.979	41.297	221.419	161.88	106.603	273.477
Sci-B-Vac®	1148.224	4570.377	858.16	1343.013	883.965	222.34	1312.236	449.44	761.009	1498.189

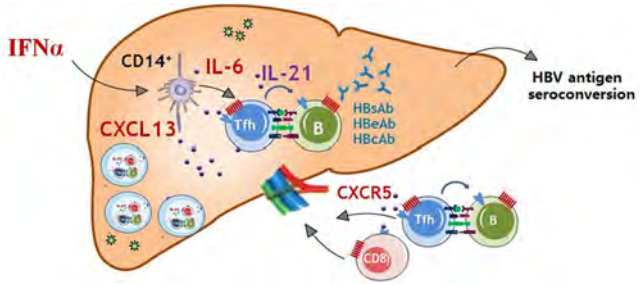
Figure: (abstract: FRI371)

loss in CHB patients has been documented. However, the underlying mechanisms are less well understood.
Method: Ninety-three patients with chronic HBV infection were defined as HBsAg positivity (≥100 IU/mL) or HBsAg loss (<0.05 IU/mL) group. HBeAg-positive CHB patients who participated in clinical trial with telbivudine treatment were classified into either a complete response (CR) group or a noncomplete response (NCR) group based on the status of HBeAg and HBV DNA at 48 weeks. Plasma levels of L-Cn were measured by ELISA. Flow cytometry and ELISPOT assay were performed to investigate the effect of L-Cn on lymphocytes. HepG2.2.15 cells were lysed and mouse model with acute liver injury was established by intraperitoneal injection of APAP to investigate the origin of L-Cn. In vivo effect of L-Cn was assessed by using an HBV mouse model with pAAV/HBV1.2 injection.
Results: Compared with patients with HBsAg loss, patients with HBsAg positivity had higher levels of L-Cn, and positive correlations between levels of L-Cn and the levels of HBsAg, HBeAg, and HBV DNA were observed. Interestingly, plasma levels of L-Cn were significantly decreased after telbivudine treatment, while the CR group showed lower levels of L-Cn than the NCR group at baseline (Figure A). Additionally, plasma levels of L-Cn were negatively correlated with the frequency of HBV-specific IFN-γ producing CD8+ T cells in patients with chronic HBV infection. In vitro assays revealed that L-Cn suppressed the proliferation and IFN-γ production of CD4+ and CD8+ T cells, and it also downregulated the proliferation and IgG production of B cells (Figure B). In contrast, L-Cn upregulated the frequencies of arginase-expressing gMDSC and IL-10-secreting regulatory T cells (Figure C). Additionally, plasma levels of L-Cn were positively correlated with ALT levels, and were significantly increased in patients with flare after the discontinuation of antiviral treatment. Moreover, lysates from HepG2.2.15 cells showed an ascending level of L-Cn in a cell-density-dependent manner. A transiently sharp increased levels of L-Cn accompanied by a gradually increased serum levels of ALT was observed in mouse model after the administration of APAP injection (Figure D). More strikingly, compared with HBV mice treated with normal saline (NS), HBV mice treated with L-Cn showed persistently elevated levels of serum HBsAg and HBeAg (Figure E).
Conclusion: L-Cn released from the injured hepatocytes displays immune suppressive properties and impedes HBsAg clearance, implicating that L-Cn may serve as a potentially therapeutic target for HBV infection.

FRI372
Interferon alpha-induced CXCL13 and IL-6 from intrahepatic monocytes facilitate HBV antigen seroconversion in chronic HBV infection
Yang Zhou[1], Shihong Zhong[1], Libo Tang[1], Jinlin HOU[1], Yongyin Li[1].
[1]*Nanfang Hospital, Southern Medical University, Department of Infectious Diseases, Guangzhou, China*
Email: yongyinli@foxmail.com

Background and Aims: It is well documented that interferon (IFN)α is superior to nucleos(t)ide analogs for the achievement of HBeAg/HBsAg seroconversion in chronic hepatitis B (CHB) patients, which indicates that IFNα could trigger effective humoral immunity in this setting; However, the underlying mechanism is not well understood.
Method: A total of 56 patients with chronic HBV infection were enrolled, including 24 patients with Peg-IFNα-2a treatment. Patients who achieved HBeAg seroconversion were defined as complete response (CR), the other patients were noncomplete response (NCR). The frequency of T cells, B cells, monocytes subsets and serum cytokines were detected. The effect of Peg-IFNα-2a on diverse immune cells were assessed. C57/BL6 WT mice were simultaneously administrated with pAAV-HBV1.2 and pIFNα plasmids by hydrodynamically injection of tail vein, levels of IL-6, CXCL13, HBsAb, and HBcAb were measured.
Results: A higher expression of IFNα-2a receptor was found in CD14+ monocytes and CD19+ B cells in treatment-naïve CHB patients. Although an increased frequency of plasmablasts was observed in patients with Peg-IFNα-2a treatment, in vitro assay revealed that Peg-IFNα-2a could not promote the proliferation and HBV-related antibodies production of B cell directly. Interestingly, Peg-IFNα-2a could promote the proliferation and cytokines production of monocytes, especially IL-6 and CXCL13. Notably, serum levels of IL-6 and CXCL13 were significantly higher in CR patients than that of NCR patients after Peg-IFNα-2a treatment. In vitro experiments showed that IL-6 triggered an enhanced production of IL-21 mainly from CXCR5 + CD4+ T cells, and IL-21 promoted the production of HBsAb and HBeAb from B cells. More importantly, an increased expression of intrahepatic CXCL13 and CXCR5+ cells were observed in the liver from HBV mouse model with exogenous IFNα injection, which can suppress HBV replication and promote the production of HBsAb.



Conclusion: IFNα-induced CXCL13 and IL-6 production from intrahepatic monocytes facilitate the recruitment of CXCR5+ cells and trigger IL-21 production from CXCR5 + CD4+ T cells, thus favoring potent B cell responses and HBV antigen seroconversion.

Viral hepatitis B/D: Clinical aspects except therapy

Email: gepapath@med.uoa.gr

Background and Aims: Chronic hepatitis B (CHB) patients, even under effective long-term oral antiviral therapy, may develop hepatocellular carcinoma (HCC) which is the only factor that affects their liver-related mortality. Therefore, the accurate prediction of HCC

in CHB patients under therapy remains of great interest. The aim of this study was to investigate whether different species of circulating cell free DNA (cfDNA) may be used as markers to predict the development of HCC in treated CHB patients.
Method: Serum samples were obtained from 37 CHB patients who developed HCC during the first 5 years of oral antiviral therapy (HCC cases) and 74 CHB patients who did not develop HCC during at least 5 years of oral antiviral therapy (controls). HCC cases and controls were matched 1:2 for age, sex and platelets. cfDNA quantity was evaluated (before HCC diagnosis in HCC cases) by performing quantitative real-time polymerase chain reaction (PCR) of the housekeeping gene GAPDH. The levels (genomic equivalent [GE]) of the Alu repeats of 115 and of 247 bases, the levels of RNAse P coding DNA and the copies of mitochondrial DNA were also assessed by quantitative real-time PCR.
Results: Median [IQR] cfDNA concentration and levels of Alu115 were similar between HCC cases and controls (65 [112] vs 55 [137] ng/mL and 246 [482] vs 233 [567] GE, $p > 0.290$). In contrast, the levels of Alu247 were significantly higher in patients who developed HCC (349 [292] vs 69 [251] GE, $p = 0.042$). However, the Alu 247/115 ratio, used as an index of DNA integrity, did not differ significantly between the two groups (0.74 [0.76] vs 0.57 [0.65], $p = 0.118$), which also had similar numbers of mitochondrial DNA copies (54 [55] vs 63 [68], $p = 0.535$). The median levels of RNAse P coding DNA were significantly higher in patients who developed HCC (68 [108] vs 15 [30] GE, $p < 0.001$). ROC curve analysis showed that the levels RNAse P coding DNA offered good prediction of subsequent HCC development (c-statistic: 0.80).
Conclusion: Serum levels of longer fragments (Alu247) of cfDNA and particularly those of the RNAse P coding DNA could be potentially used as non-invasive biomarkers for the prediction of the HCC risk in treated CHB patients.

FRI374
Immunological and virological markers during pegylated interferon therapy in HDV chronic hepatitis: any predictor of response?
Antonella Olivero[1], Gian Paolo Caviglia[1], Rossana Fontana[2], Maria Lorena Abate[1], Chiara Rosso[1], Giulia Troshina[1], Elisabetta Bugianesi[1], Giorgio Maria Saracco[1], Mario Rizzetto[1], Grazia Niro[2], Antonina Smedile[1], Alessia Ciancio[1]. *[1]University of Turin, Department of Medical Sciences, Turin, Italy; [2]CSS Hospital San Giovanni Rotondo, Gastroenterology, Italy*
Email: antonella.olivero@unito.it

Background and Aims: Although several new compounds are currently under investigation, therapy with pegylated interferon-alpha-2a (Peg-IFN) is still considered the standard of care for patients with HDV chronic hepatitis (CHD). This study investigates host and virological patterns during Peg-IFN treatment as feasible predictors of response.
Method: Eighty sequential serum samples from 16 CHD patients (HBV genotype D and HDV genotype 1) were tested. Serum HDV-RNA and HBV-DNA were detected by real-time quantitative PCR; HBsAg, HBcrAg and anti-HBc IgG levels were determined by chemiluminescence immunoassay (Lumipulse® G system, Fujirebio, Japan). Serum concentration of 12 soluble immune modulators (IL-1ra, IL2-ra, IL-6, IL-7, IL-10, IL-12p70, IL-13, IL-16, IP-10, INFgamma, TNFalfa e TNFbeta) were evaluated by LUMINEX-based multiplex technology. Virological and immunological markers were measured at baseline, 6, 12, 18 and 12 months after end of therapy (12MFU).
Results: Overall, 8 patients cleared HDV RNA during treatment and were still negative at 12MFU (responders, R), among them 2 cleared HBsAg and 1 became anti-HBs positive. Eight patients were not responders (NR). Except anti-HBc IgG,the other virological markers HDV-RNA, HBsAg and HBcrAg showed mean baseline levels significantly lower in R then in NR (Table). By combining baseline levels and reduction values at 6 months, HDV RNA, HBsAg and HBcrAg showed a high accuracy in distinguish R and NR (area under the curve [AUC] = 0.969, 0.958, 0.891, respectively). Compared to normal physiological levels, CHD patients had lower values of IL-7 and Il-13; conversely, IP-10 levels were distinctly higher (more than ten-fold). No difference was observed in basal cytokines levels between R and NR. In all patients, both R and NR, we observed an increase of IL-2 ($p = 0.017$), IL-6 ($p = 0.061$), IP-10 ($p = 0.078$), and a reduction of IL-1 ($p = 0.003$) and IL-16 ($p = 0.014$) from baseline to the end of therapy.

Baseline	R	NR	p
HDV-RNA (Log IU/mL)	4.01 ± 1.38	5.54 ± 0.77	0.016
HBsAg (Log IU/mL)	3.12 ± 0.98	4.13 ± 0.62	0.027
HBcrAg (Log U/mL)	2.9 ± 1.2	4.5 ± 1.1	0.017
Anti-HBc IgG (Log IU/mL)	2.48 ± 0.75	2.74 ± 0.50	0.435

Conclusion: Peg-IFN treatment induces in CHD patients specific cytokines response showing a modulation of the innate IFN system but not predictive of the response to therapy. Conversely, the combination of baseline and early on-treatment 6 months values of either HDV RNA, HBsAg, HBcrAg, may be useful to predict treatment efficacy.

FRI375
Comparison of the risk of hepatocellular carcinoma in nucleos(t)ide analogue-naive chronic hepatitis B patients treated with entecavir versus tenofovir : a systematic review and meta-analysis
Hyunwoo Oh[1], Yoon Jun Kim[1], Cheol-Hyung Lee[1], Minseok Albert Kim[1], Heejoon Jang[1], Sun Woong Kim[1], Yun Bin Lee[1], Eun Ju Cho[1], Jeonghoon Lee[1], Su Jong Yu[1], Jung-Hwan Yoon[1]. *[1]Seoul National University Hospital, Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South*
Email: yoonjun@snu.ac.kr

Background and Aims: Tenofovir (TDF) and entecavir (ETV) are nucleos(t)ide analogues (NAs) preferred as first-line treatments for chronic hepatitis B (CHB) patients. Recently, efficacy for reducing incidence of hepatocelluar carcinoma (HCC) has become a critical concern in treated patients due to the long-term use of these drugs. However, existing studies show conflicting results. This meta-analysis aims to assess the efficacy in reducing incidence of HCC comparing TDF monotherapy with ETV monotherapy among CHB patients by analyzing their long-term clinical outcomes with hazard ratios (HRs).
Method: Two investigators independently searched the Cochrane Library, MEDLINE, and Embase databases for randomized controlled trials and nonrandomized studies (NRSs) using the keywords “Hepatocellular carcinoma”, “Tenofovir”, and “Entecavir”, and additional references were obtained from the bibliographies of relevant articles published through october 2019. The quality of each study was assessed using the Newcastle-ottawa scale and the gading of recommendations assessment, development and ealuation criteria.
Results: Twelve NRSs enrolling 51,648 patients met the inclusion criteria, 9947 in TDF group and 41701 in ETV group. For meta analysis, the incidence of HCC seems significantly low among the TDF group than ETV group [HR (95% CI) of 0.67 (0.51, 0.87), P = 0.003]. However, using adjusted HRs or HRs of propensity score (PS) matched subcohort in each studies, a statistically significant difference disappeared [In adjusted HR analysis : HR (95% CI), from 0.64 (0.41, 0.98) P = 0.04 to 0.83 (0.66, 1.05) P = 0.12] [In PS matched subcohort analysis : HR (95% CI), from 0.64 (0.47, 0.92) P = 0.01 to 0.86 (0.64, 1.16) P = 0.29].
Conclusion: There was no statistical significant difference when using HR which reduce heterogeneity of the TDF and ETV groups. Each involved study has a different observation period, study enroll year, inclusion & exclusion criteria, and baseline characteristics of host/hepatic/viral risk factors between TDF and ETV treatment groups. And each cohort, derived from separate countries, reflects

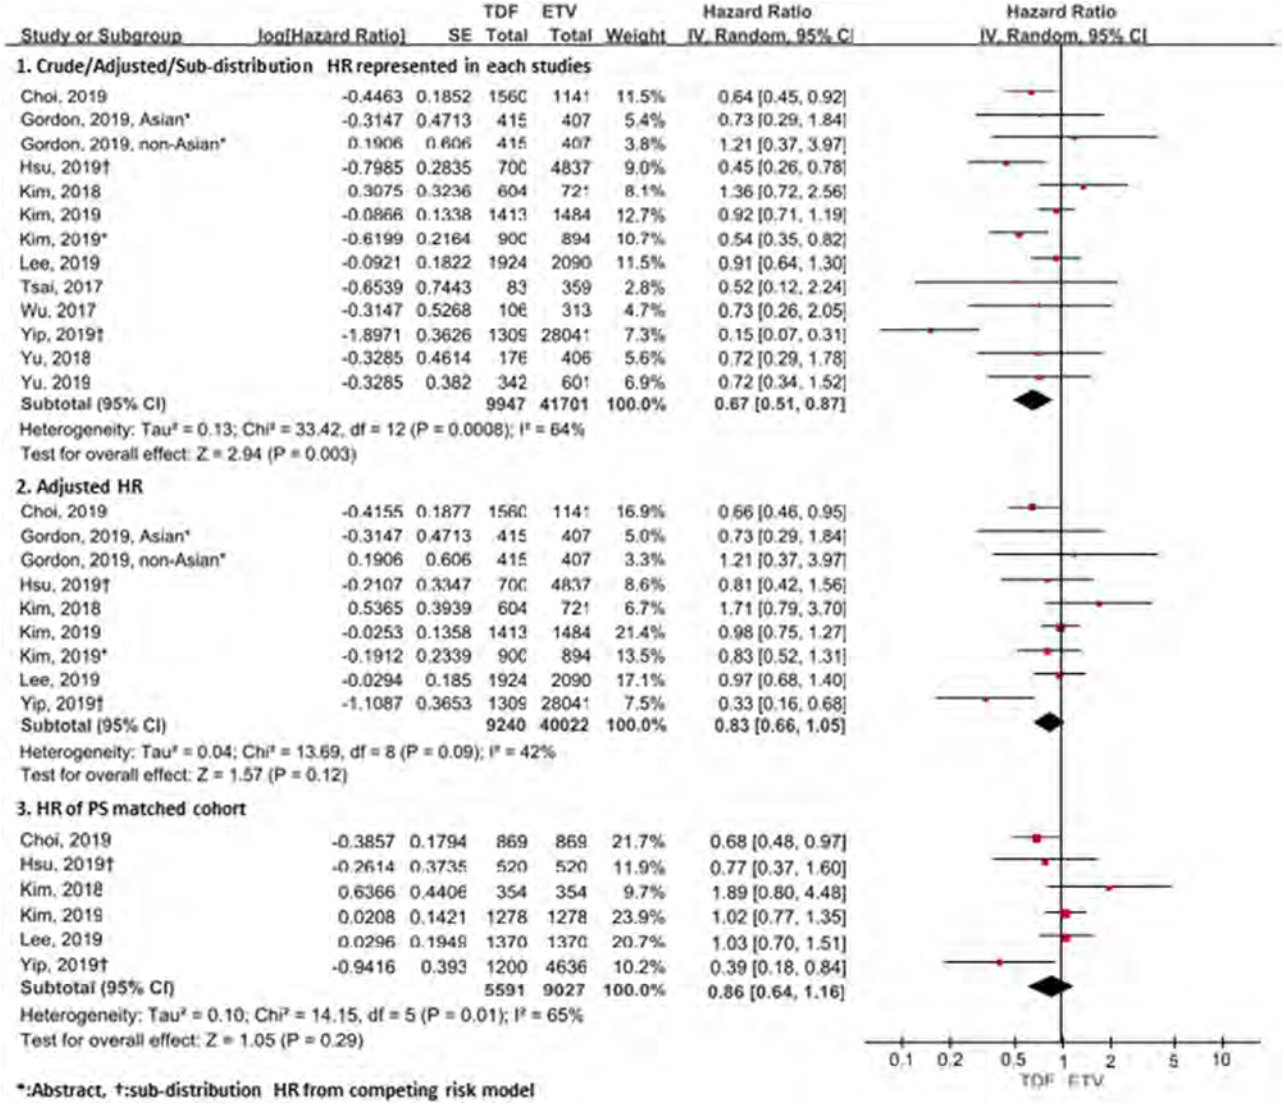

Figure: (abstract: FRI375)

different insurance, reimbursement policies, viral genotypes, and culture. We need further research comparing the efficacy of two drugs with standardized protocols reducing heterogeneity of treatment groups or large-scale randomized clinical trial to facilitate conclusive comparisons.

FRI376

Is it possible to stop nucleus(t)die analogue safely in patients with preemptive or preventive therapy for HBV reactivation?

Akihiro Tamori[1], Kiminori Kimura[2], Kiyohide Kioka[3], Sawako Uchida-Kobayashi[1], Masaru Enomoto[1], Norifumi Kawada[1], Mizokami Masashi[4]. *[1]Osaka City University Graduate School of Medicine, Hepatology, Osaka, Japan; [2]Tokyo Metropolitan Komagome Hospital, Hepatology; [3]Osaka City General Hospital, Hepatology; [4]National Center for Global Health and Medicine, Genome Medical Sciences Project*
Email: atamori@med.osaka-cu.ac.jp

Background and Aims: Preventing or preemptive therapy with nucleos(t)ide analogue (NA) could prevent severe hepatitis related to HBV reactivation. However, it is not clear if NA can safely be stopped in such patients after cytotoxic therapies or during immunosuppressive therapies.

Method: A retrospective study, conducted in multiple hospitals, was used to evaluate 131 patients who initiated NA therapy between December 2007 and October 2018. In details, 103 patients were positive for HBV surface antigen (HBsAg) at baseline measured by (Architect HBsAg QT; Abbott Japan Corp., Tokyo). Preventive therapy with NA was started before cytotoxic or immunosuppressive therapy. Twenty-eight patients with resolved HBV infection were treated with NA after HBV reactivation during a monitoring period; preemptive therapy. The NA therapy could prevent severe hepatitis related to HBV reactivation in both groups. We examined anti-HBs and HB core related antigen (HBcrAg) examined by chemiluminescence enzyme immunoassay (Fuji-Rebio, Tokyo), using reserved serum of the enrolled patients. The relapse risk score was calculated by HBsAg and HBcrAg, according to the guideline of Japanese Society of Hepatology (JSH) HBV management.

Results: NA was stopped in 13 (13%) of 103 HBsAg positive patients, and in 15 (54%) of 28 HBV reactivated patients. We confirmed that clinical conditions including serological HBV markers at NA cessation were matched the criteria of JSH*. After NA cessation, HBV DNA was

redetected in 6 (46%) of 13 HBsAg-positive patients. However, ALT flare did not occur without NA treatment. We compared clinical characters between recurrence and non-recurrence patients in HBsAg positive group. High HBV DNA levels at baseline, and high amount of HBsAg both at baseline and at NA stop were marginal relationship to HBV recurrence. Relapse risk score '0' was significant association with non-recurrence ($p = 0.02$). In preemptive group, HBV DNA was redetected in 5 (33%) of 15 patients. HBV recurrence was observed in only anti-HBs negative patients at NA cessation. NA re-administration was initiated in 4 of 5 patients. Anti-HBs titers were increased over 10 mIU/mL in 2 of 4 patients after NA re-administration. *Hepatol Res 2014, 44 Suppl. 1

Conclusion: The HBsAg and HBcrAg scores predicted HBV recurrence after NA cessation in HBsAg-positive patients. In patients with resolved HBV, anti-HBs could be a predictive marker for NA cessation.

FRI378

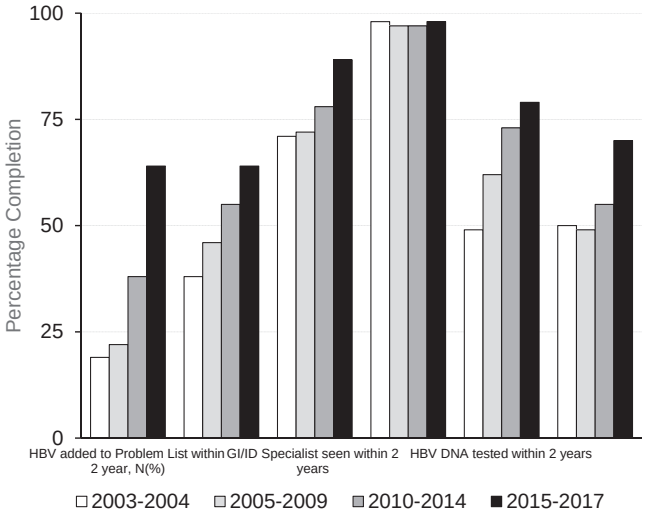
Evolution of care quality metrics for chronic hepatitis B in the hepatitis C direct-acting antiviral era

David Kaplan[1,2], Marina Serper[1,2]. [1]*University of Pennsylvania, Gastroenterology, Philadelphia, United States;* [2]*Corporal Michael J. Crescenz VA Medical Center, Medicine, Philadelphia, United States*
Email: dakaplan@pennmedicine.upenn.edu

Background and Aims: National efforts to eradicate chronic hepatitis C (HCV) infection utilizing direct-acting antiviral (HCVDAA) were initiated in the Veterans Affairs medical system in 2014. Testing to identify patients at risk for associated hepatitis B reactivation (HBVr) soon became necessary. The objective of this study was to investigate whether the all-oral HCVDAA era was associated with increased recognition and delivery of guideline-recommended care for chronic hepatitis B (cHBV). We hypothesized that as a consequence of widespread HCVDAA treatment, referrals to specialist increased for HBV resulting in increased adherence to guideline-recommended care for HBV compared to the pre-HCVDAA era.

Method: Retrospective cohort study of veterans with at least one positive HBsAg (HBsAg+) result from January 1, 2003 to December 31st, 2017 using the VA Corporate Data Warehouse (CDW) were analyzed by era (2003–2004, 2005–2009, 2010–2014, 2015–2017). HCV coinfection was determined with positive HCV RNA PCR, and relevant covariates such as age, race/ethnicity, cirrhosis, and baseline laboratory testing were obtained through previously validated approaches. Process outcomes measured within 2 years of HBsAg+ result included: specialty care referral (GI/Hepatology/ID); Testing rates for ALT, HAVAb (IgG), HBV DNA, HBeAg, HBeAb, HCVAb (or HCVRNA), HDVAb (or HDVRNA), HIVAb (or HIVRNA; vaccination for HAV and HBV; any liver imaging and percentage time up-to-date with surveillance (PTUDS) in surveillance candidates; antiviral therapy in appropriate candidates (ALT $\geq 2 \times$ ULN, HBV DNA $\geq$ 2000 IU/ml).

Results: 16,673 individuals had a first HBsAg+ test result during the study period; of these, 9,521 could be confirmed as cHBV. There was a progressive decline in HCV coinfection rates (31% 2003–2004 to 15% in 2015–2017) but marked utilization of HCVDAA in candidates in later eras. Time-related increases in the following process measures were observed: outpatient visits with a GI or ID specialist within 2 years of HBsAg+ testing (71% to 89%), any type of liver imaging within 2 years of diagnosis (58% to 83%), HBV DNA testing (49% to 79%), HDV testing (26% to 35%), HBV DAA utilization in patients with active hepatitis and elevated HBV DNA titers (50% to 70%). By contrast, adherence with liver cancer surveillance remained static (40% ± 38% to 43% ± 35%). There were no significant interactions of process outcomes with HCV infection or HCVDAA exposure, but HCVDAA therapy was associated with improved survival in multivariable models. We however identify specific markers of high-quality HBV-directed care, specifically testing for concomitant HDV, that strongly associates with reduced mortality (HR 0.73 95% CI 0.66–0.81).



Conclusion: Quality of care for chronic HBV has significantly improved over time concomitant with efforts to eradicate HCV.

FRI379

Excess body weight is associated with HBV-related HCC despite antiviral treatment

Kaifeng Wang[1], Li Chen[1], Yaobo Wu[1], Zhou Zhao[1], Qiuhong You[1], Sheng Shen[1], Weiyin Lin[1], Xiaoju Liu[1], Shi Liu[1], Wanying Li[1], Rui Deng[1], Jian Sun[1]. [1]*Nanfang Hospital, Southern Medical University, Department of Infectious Diseases, China*
Email: doctorsunjian@qq.com

Background and Aims: Antiviral treatment cannot eliminate hepatocellular carcinoma (HCC) risk in patients infected with hepatitis B virus (HBV). It is unclear whether excess body weight contributes to HBV-related HCC development despite antiviral treatment.

Method: From January 2015 to December 2017, newly diagnosed HCC patients with hepatitis B surface antigen (HBsAg) positive were identified in Nanfang Hospital in Guangdong, Southern China. Excess body weight was defined as body mass index $\geq$23 kg/m^2. Antiviral history was defined as any prescription for anti-HBV medication >6 months prior to the date of HCC diagnosis, including interferon and nucleos(t)ide analogues. Multivariate logistic regressions were used to estimate adjusted association between excess body weight and HCC development despite antiviral treatment. We used HCC patients without antiviral history as a reference.

Results: A total of 2324 HCC patients with HBsAg positive were identified, 334 (14.4%) patients were defined as having antiviral history. Frequencies of excess body weight in patients with and without antiviral history were 57.8% and 42.9%, respectively ($p < 0.001$). Compared to HCC patients without antiviral history, HCC patients with antiviral history were more likely to have excess body weight (adjusted odds ratio [aOR] 1.48, 95% confidence interval [CI] 1.15–1.89). This phenomenon was only observed in patients with elevated alanine aminotransferase (ALT), but not in those with normal ALT, and in those with age $\geq$50 years, but not in those with age <50 years, and in smokers but not in never smokers (Table 1).

Table 1: Subgroup analyses for the association between excess body weight and HBV-related HCC despite antiviral treatment.

Subgroups	Unadjusted OR (95% CI)	P	Adjusted OR* (95% CI)	P
Elevated ALT (n = 1415)	2.54 (1.76–3.65)	<0.001	2.28 (1.52–3.42)	<0.001
Normal ALT (n = 909)	1.43 (1.04–1.97)	0.028	1.25 (0.86–1.83)	0.236
Age≥50 years (n = 1265)	2.25 (1.64–3.08)	<0.001	2.06 (1.42–3.02)	<0.001
Age<50 years (n = 1059)	1.37 (0.96–1.96)	0.082	1.21 (0.81–1.81)	0.341
Smoker (n = 879)	3.66 (2.26–5.91)	<0.001	3.16 (1.89–5.28)	<0.001
Never smoker (n = 1445)	1.38 (1.05–1.82)	0.020	1.23 (0.89–1.72)	0.201

*: Smoking history, live cirrhosis, hypertension, diabetes, high HBV DNA (≥2000 IU/ml), elevated ALT and tumor size were adjusted.

Conclusion: Excess body weight is involved in HBV-related HCC development despite antiviral treatment, especially in smokers.

FRI380

Commonly used non-invasive markers do not reliably predict liver fibrosis in those patients of chronic hepatitis B who really need it: a prospective multi-centre study

Akash Shukla[1], Amit Gupte[2], Alisha Chaubal[1], Prashant Dhore[2], Suhas Udgirkar[3], Rahulkumar Jadhav[1], Abhishek Sadalage[2], Ravi Thanage[3], Prabha sawant[1], Pravin Rathi[3], Shobna Bhatia[2].

Email: drakashshukla@yahoo.com

Background and Aims: American Association for Study of Liver Diseases recommends liver biopsy in patients with Hepatitis B virus deoxy-ribonucleic acid (HBV DNA >2000 IU/ml) and alanine transaminase (ALT) levels between 1 and 2 X upper limit of normal (ULN), or age >40 years and normal ALT. European association of study of liver diseases recommends magnetic resonance elastography (MRE) or transient elastography (TE) for estimation of fibrosis. MR and TE are costly and not widely available, especially in resource limited settings. We did this study to assess performance of commonly used non-invasive markers in predicting liver fibrosis in patients with chronic hepatitis (CHB).
Method: Ethics committee approval was obtained. In a prospective multi-centric study in 3 university hospitals, from January 2016 to December 2018, 226 consecutive patients with asymptomatic CHB who did not fulfill the definitive criteria for therapy or no therapy as per AASLD guidelines underwent liver biopsy. Patients were classified in group A (Normal ALT and age >40 years, HBV DNA > 2000 IU/mL) and group B (ALT 1-2 X ULN, HBV DNA > 2000 IU/mL). The performance of simple non-invasive markers of fibrosis - Fibrosis 4 (FIB-4), Fibrofast 5 (FIB-5) and Aspartate transaminase platelet ratio index (APRI) to predict significant fibrosis [METAVIR stage > = 2] was evaluated. Significant inflammation was defined as Histology Activity Index > = 3.
Results: Out of the 226 patients (152 men, 40.0 ± 12.3 years), 107 (47.34%) had significant fibrosis and/or significant inflammation. Among group A, 15 (34%) patients had significant fibrosis and/or inflammation. In patients with group B, 26 (61.9%) HBeAg positive and 66 (47.14%) HBeAg negative patients had significant fibrosis and/or inflammation. Patients with ALT 1-2 X ULN were more likely to have significant inflammation than those with persistently normal ALT (60/81 Vs 21/81, p = 0.001).

Score	Cut off	Significant fibrosis (Mean ± SD)	Minimal/ no fibrosis (Mean ± SD)	AUROC	Sensitivity (%)	Specificity (%)
APRI	≥0.5	0.63 ± 0.44	0.46 ± 0.31	0.543	42	65.9
FIB-4	≥1.5	2.01 ± 0.92	1.88 ± 0.92	0.527	78.6	43
FIB-5	≤6.3	6.15 ± 0.35	6.29 ± 0.39	0.602	70	49.5

Conclusion: ALT of 1-2 X ULN is associated with significant inflammation. None of the non-invasive markers reliably predict liver fibrosis. Liver biopsy remains gold standard for detection of fibrosis and initiation of antiviral treatment with normal liver enzymes in resource limited settings where TE or MRE are not available.

FRI381

Evaluation of dried plasma spot on the cobas(r) plasma separation card as a sample type for hepatitis B virus load quantification on the cobas(r) 6800 system

Ariadna Rando[1], Fernando Rodrigo-Velásquez[1], Paula Salmerón[1], Mar Riveiro-Barciela[2,3], Rafael Esteban[2,3], Maria Buti[2,3], Ed G. Marins[4], Francisco Rodríguez-Frías[3,5]. *[1]Vall d'Hebron University Hospital, Department of Microbiology, Barcelona, Spain; [2]Vall d'Hebron University Hospital, Department of Hepatology, Barcelona, Spain; [3]Center for Biomedical Research in Network of Hepatic and Digestive Diseases (CIBERehd), Barcelona, Spain; [4]Roche Molecular Systems, Inc, Medical & Scientific Affairs, Pleasanton, United States; [5]Vall d'Hebron University Hospital, Liver Pathology Unit, Biochemistry and Microbiology Departments, Barcelona, Spain*
Email: mbuti@vhebron.net

Background and Aims: Improving access to diagnostic testing in resource limited settings is critical to achieving hepatitis elimination goals and expanding coverage in these regions. Nucleic acid testing (NAT) is an accurate way to aid in the management of patients with hepatitis B virus (HBV) and enabling sample transportation over longer distances and harsher environmental conditions than EDTA plasma is necessary. Alternative sample types can facilitate the utilization of HBV diagnostic testing by permitting testing to be performed in remote areas or environments where phlebotomy may not be available. The **cobas®** Plasma Separation Card (PSC) is a device uses finger-prick blood to prepare dried plasma spots that are stable under high temperature and humidity conditions, allowing for sample transportation without the need of cold-chain but it was never evaluated as a sample type for HBV viral load monitoring.
The aim of this study was to evaluate the performance of the PSC as alternative sample type for HBV viral load quantification compared to plasma.
Method: We recovered whole EDTA venous blood from 67 clinical samples with positive HBsAg and HBV viral load determination. PSC samples were prepared by spotting 140 µL of whole EDTA venous blood and drying it at room temperature over a minimum of 4 hours. One spot of each PSC was eluted by incubating at 56 degrees C with Specimen Pre-Extraction Reagent for 10 minutes at 1000 rpm on a preheated thermo-shaker. Plasma EDTA direct samples and PSC eluted samples were analyzed by **cobas®** HBV Test in the **cobas®** 6800 system and paired results were compared.
Results: Correlation between PSC and plasma samples was linear (slope = – 1.24, intercept = 0.83, R^2 = 0.89) (Figure 1). For these samples, the mean viral load difference between plasma and PSC samples was – 1.81 log10 IU/mL (95% CI, – 2.22 to – 1.40). Detection for PSC above 1000 IU/mL occurred in all samples tested with PSC.

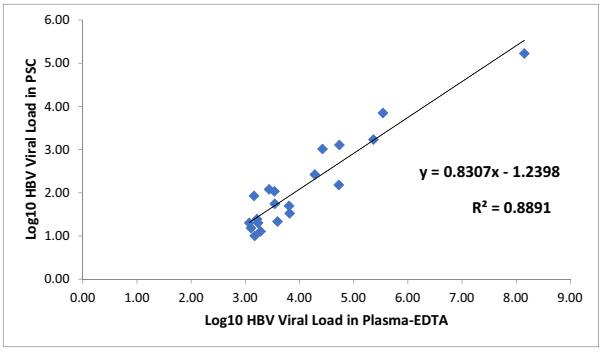

Figure: Comparison of results for PSC samples and Plasma-EDTA

Conclusion: Using PSC as an alternative sample type demonstrated a linear correlation to plasma viral load when tested with **cobas®** HBV Test, indicating that a correction factor could be applied to better align the PSC and plasma viral load. These results support the feasibility of PSC as an alternative sample type for detection and viral load monitoring of HBV.

FRI382

Genetic variants do not predict the development of hepatocellular carcinoma in cross-sectional and longitudinal studies including caucasian compensated HBV cirrhotics treated with NUC for 10 years

Enrico Galmozzi[1], Alessandro Loglio[1], Floriana Facchetti[1], Massimo Iavarone[1], Marta Borghi[1], Mauro Viganò[2], Riccardo Perbellini[1], Maria Grazia Rumi[2], Angelo Sangiovanni[1], Pietro Lampertico[1]. *[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, CRC "A.M. and A. Migliavacca" Certer for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy; [2]San Giuseppe Hospital, Università degli Studi di Milano, Hepatology Division, Milan, Italy*
Email: enrico.galmozzi@gmail.com

Background and Aims: Signal transducers and activators of transcription (STAT4), Epidermal Growth Factor 1 (EGF1), Tolloid like 1 gene (TLL1), Myeloid-epithelial-reproductive tyrosine kinase (MERTK) and for domain II (MERTK2), Patatin-like phospholipase-3 gene (PNPLA3) and Membrane Bound O-Acyltransferase Domain Containing 7 (MBOAT7) genetic variants have been associated with the development of hepatocellular carcinoma (HCC) in Asian and Caucasian HBV patients. Here we assess if these variants predict the HCC onset also in HBV cirrhotics long-term treated by NUCs.
Method: TDF or ETV-treated Caucasian HBV-monoinfected compensated cirrhotics were consecutively enrolled in a longitudinal (n = 258) as well as in cross-sectional (n = 111) studies. At baseline longitudinal cohort were: age 61 (43–77) year, 82% males, 88% HBeAg negative, 60% NUCs-experienced, BMI 25 (17–40) kg/m^2, 12% diabetics, spleen length 11 (7–20) cm, 14% with esophageal varices, when transverse were: age 64 (51–77) year, 87% males, 93% HBeAg negative, 76% NUCs-experienced, BMI 25.1 (17–33) kg/m^2, 19% diabetics, spleen length 11 (7–20) cm, 24% with esophageal varices. Seven SNPs mapping on genes above cited (*rs7574865, rs4444903, rs17047200, rs4374383, rs6726639, rs738409* and *rs641738*) were analyzed by TaqMan genotyping assay.
Results: In the cross-sectional study, there were no significant difference between HCC patients (n = 51) and controls (n = 60) in rate of minor allele carriers of each SNPs investigated: 24% vs 27% for STAT4 (p = 0.63), 52% vs 74% for EGF (p = 0.09), 33% vs 30% for TLL1 (p = 0.75), 75% vs 77% for MERTK (p = 0.80), 57% vs 63% for MERTK2 (p = 0.53), 52% vs 40% for PNPLA3 (p = 0.33), 67% vs 62% for MBOAT7 (p = 0.72). In univariate only correlation with HCC was spleen length (11 vs 11.5 cm, p = 0.04). In the longitudinal cohort of 258 HBV patients followed on therapy for 123 (20–158) months, 45 (17%) patients developed an HCC after 56 (18–129) months. The 10-year cumulative HCC incidence was 20% (yearly rate 2.2%). The 10-year cumulative incidence of HCC was similar across different genetic variants while the only independent baseline predictors of HCC were and age (HR 1.09, 95%CI 1.0–1.1, p < 0.001) and spleen length (HR 1.33, 95%CI 1.1–1.5, p < 0.001).
Conclusion: In Caucasian HBV compensated cirrhotics treated with NUC, age and severity of portal hypertension, but not any of the 7 different genetic signatures, predicted the development of HCC in both longitudinal and cross-sectional studies.

FRI383

PAGE-B score is simpler and has similar predictive performance with the new Asian hepatocellular carcinoma risk scores in Caucasian chronic hepatitis B patients treated with long-term entecavir or tenofovir disoproxil fumarate therapy

Email: gepapath@med.uoa.gr

Background and Aims: Hepatocellular carcinoma (HCC) risk scores developed in untreated Asian chronic hepatitis B (CHB) patients offer poor/modest predictability in treated Caucasian patients, for whom HCC prediction is currently based on PAGE-B score. Recently, new HCC risk scores were developed in cohorts of treated Asian patients mainly based on age, gender and a parameter of liver disease severity. We assessed the predictability and comparative utility of the recent Asian HCC risk scores in treated adult Caucasian CHB patients, with or without well documented compensated cirrhosis.
Method: We included 1951 patients treated with entecavir/tenofovir (age 53 ± 14 years, males 71%, HBeAg-positive 18%, cirrhosis 28%, follow-up 7.1 ± 3.0 years). C-index was used to estimate the predictive performance of CAMD (age, sex, cirrhosis, diabetes), AASL (age, sex, cirrhosis, albumin), modified PAGE-B (mPAGE-B: age, sex, platelets, albumin) and PAGE-B score (age, sex, platelets) for HCC development within the first 5 years of therapy. The low-risk group cut-off of each score was used for estimation of sensitivity, specificity and negative predictive value (NPV) and the high-risk group cut-off for estimation of positive predictive value (PPV).
Results: HCC developed in 103/1951 (5.3%) patients during the first 5 years; 3- and 5-year cumulative HCC rates were 3.3% and 5.9%, respectively. All scores offered good 5-year HCC prediction (c-statistic - CAMD: 0.79, AASL: 0.81, mPAGE-B: 0.82, PAGE-B: 0.80). The proportion of patients classified into low-risk groups were 30% for CAMD, 22% for AASL, 24% for mPAGE-B and 21% for PAGE-B. Sensitivity and NPV were 100% for CAMD, AASL, PAGE-B and 98% and 99.5% for mPAGE-B, respectively. Specificity was 32% for CAMD, 25% for mPAGE-B and 23% for AASL and PAGE-B. The proportion of patients classified into high-risk groups were 24% for CAMD, 19% for AASL, 36% for mPAGE-B and 31% for PAGE-B, while PPV for 5-year HCC development was 13%, 18%, 13% and 13%, respectively.

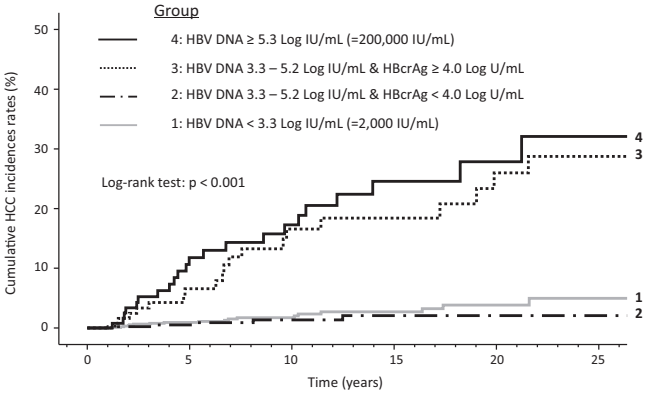
Conclusion: In treated Caucasian CHB patients, with or without compensated cirrhosis, all recent HCC risk scores developed in Asian treated patients offer good 5-year HCC predictability, similar to that of PAGE-B score. PAGE-B and mPAGE-B scores are simpler in clinical practice, as they do not require an accurate diagnosis of cirrhosis, while the addition of albumin in mPAGE-B does not seem to offer an advantage in patients with well compensated liver disease.

FRI384

Hepatitis B core-related antigen and viral loads status impacts on the risk of hepatocellular carcinoma in patients with HBeAg-negative chronic hepatitis B virus infection

Tetsuya Hosaka[1], Fumitaka Suzuki[1], Masahiro Kobayashi[1], Shunichirou Fujiyama[1], Yusuke Kawamura[1], Hitomi Sezaki[1], Norio Akuta[1], Yoshiyuki Suzuki[1], Satoshi Saitoh[1], Yasuji Arase[1], Kenji Ikeda[1], Mariko Kobayashi[2], Hiromitsu Kumada[1]. *[1]Toranomon Hospital, Hepatology, Tokyo, Japan; [2]Toranomon Hospital, Research institute for hepatology, Kawasaki, Japan*
Email: hosa-p@toranomon.gr.jp

Background and Aims: Serum hepatitis B core-related antigen (HBcrAg) has been known as surrogate markers of intrahepatic covalently closed circular DNA (cccDNA). HBcrAg also reflects intrahepatic transcriptional activities of hepatitis B virus (HBV). Hepatocellular carcinoma (HCC) is likely to occur in patients with serum high viral loads. We examined whether HBcrAg and HBV DNA levels would have the impact on HCC development in chronically HBV-infected patients treated with or without nucleos(t)ide analogue (NA) treatment.
Method: We conducted a retrospective cohort study of in 1724 HBe antigen (HBeAg)-negative patients who experienced no antiviral treatment (untreated cohort), and 502 HBeAg-negative patients who received entecavir (ETV), tenofovir disoproxil fumarate (TDF), or tenofovir alafenamide (TAF) for more than one year in our institute as a first-line drug (NA-treated cohort) (452 patients started with ETV and 50 with TDF or TAF). Serum HBcrAg levels at baseline were measured using a commercial assay (Fujirebio Inc.). We categorized these cohorts into four groups stratified by baseline HBcrAg and viral loads as shown in figure. Patients were followed until any confirmed HCC diagnosis 1 year after the start of follow-up or NA treatment (primary outcome). We examined whether the stratification of baseline HBcrAg and viral loads would predict HCC development.
Results: During follow-ups of median 9.8 years, 69 patients (3.9%) had developed HCC (3.96/1,000 person-years) in untreated cohort. 1025 patients were categorized into group 1, 438 into group 2, 129 into group 3, and 132 into group 4 in untreated cohort. Cumulative HCC incidence rates were significantly higher in group 3 and 4 than those in group 1 and 2 in untreated cohort (Figure). This finding was observed in subgroup of patients with baseline low ALT. Multivariate Cox regression analysis showed that untreated patients in group 3 and 4 were likely to develop HCC than those in group 1 and 2 (hazard ratio (HR) of group 3: 5.20 and HR of group 4: 2.67). During follow-ups of median 7.0 years, 26 patients (5.2%) had developed HCC (7.44/1,000 person-years) in NA-treated cohort. HCC incidence rates were also significantly higher in group 3 and 4 than those in group 1 and 2 in NA-treated cohort as well as untreated cohort. Next, we compared HCC incidences in each group between untreated and NA-treated cohort. Multivariate Cox regression showed that NA-treated patients in group 3 and 4 were less likely to develop HCC than untreated patients in the same groups (HR of NA treatment in group 3: 0.26 and HR of that in group 4: 0.39), adjusted for baseline factors. However, this finding was not observed in patients with or without NA treatment in both group 1 and 2.



Conclusion: Patients with high HBcrAg and intermediate viral loads had the high risk of HCC as well as those with high viral loads. NA treatment greatly reduced HCC incidence in both group 3 and 4.

Background and Aims: Nucleoside analogue therapy (NA) can lead to fibrosis regression in chronic hepatitis B (CHB). Nonetheless, emerging evidence is demonstrating the impact of metabolic parameters on the fibrogenic process in CHB. We aim to study the association between adipokine levels and fibrosis evolution in NA-treated CHB patients.
Method: NA-treated CHB patients were recruited for baseline and 3-year transient elastography. Fibrosis stages was defined based on EASL-ALEH guidelines. Fibrosis regression and progression were defined as decrease or increase of ≥1 fibrosis stages from baseline respectively. Steatosis was defined as controlled attenuation parameter (CAP) ≥248 dB/m. Plasma adipokines including adiponectin, adipocyte fatty acid-binding protein (AFABP) and fibroblast growth factor 21 (FGF21) were measured by enzyme linked immunosorbent assay at baseline (Antibody and Immunoassay Services, The University of Hong Kong).
Results: 404 patients were recruited (72% male; median age 58.6 years; median NA treatment duration 74.5 months). 92.3% and 93.9% of patients had undetectable HBV DNA (≤20 IU/mL) at baseline and reassessment. Median adiponectin, AFABP and FGF21 levels were 10.4 (6.7–17.1) μg/ml, 96.5 (28.4–172.3) pg/ml and 12.6 (7.2–37.0) pg/ml respectively. Patients with steatosis, when compared with non-steatotic patients, had higher AFABP (117.0 vs 85.4 pg/ml), higher FGF21 (15.4 vs 10.2 pg/ml) and lower adiponectin (8.6 vs 13.3 μg/ml) (all $p < 0.05$). Patients with advanced fibrosis/cirrhosis had lower FGF21 (11.3 vs 13.6 pg/ml, $p = 0.045$) and higher AFABP (123.1 vs 69.1 μg/ml, $p < 0.001$) when compared with non-fibrotic patients. 17.8% of patients had fibrosis progression, while 21.8% of patients had fibrosis regression. Baseline FGF21, body mass index and metabolic syndrome were not predictive of fibrosis evolution. Among patients with advanced fibrosis/cirrhosis at baseline, lower levels of AFABP were independently associated with fibrosis regression (odds 1.005, 95% CI 1.001–1.010). Change in liver stiffness over 3 years correlated

moderately with AFABP (r = 0.308, p < 0.001). In the diabetic subgroup, adiponectin was an independent predictor of fibrosis regression (odds 1.296, 95% CI, 1.108–1.516, p = 0.001).
Conclusion: Adipokines including AFABP and adiponectin have prognostic value as biomarkers of fibrosis evolution during the treatment course of CHB, further illustrating the influence of metabolic factors in CHB-related treatment outcomes.

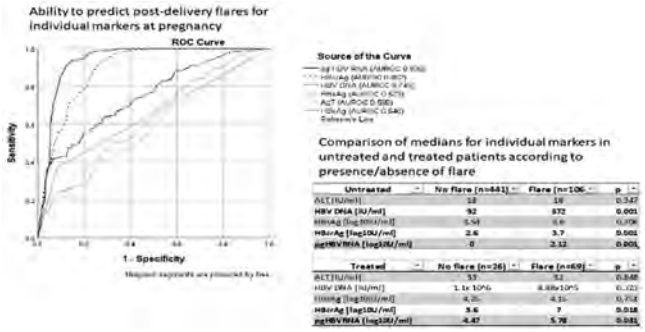
Higher pregnancy hbcrag and pg HBV RNA concentrations are observed in treated and untreated chronic hepatitis B mothers with post-partum alt flares

Ivana Carey[1], Jeffrey Gersch[2], Christiana Moigboi[1], Teresa Bowyer[1], Bo Wang[1], Gavin Cloherty[2], Geoffrey Dusheiko[1], Kosh Agarwal[1].
[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]Infectious Disease Laboratory, Abbott Diagnostics Laboratories, North Chicago, United States
Email: ivana.kraslova@kcl.ac.uk

Background and Aims: Post-partum ALT increases are observed in 30% of HBsAg-positive mothers and can also be noticed in mothers administered nucleoside analogues (NA) to prevent mother-to-child transmission (MTCT). As such flares may be injurious we have studied the utility of novel and sensitive markers of cccDNA transcriptional activity i.e. hepatitis B core-related antigen (HBcrAg) and pre-genomic (pg) HBV RNA to predict post-partum ALT flares in both NA treated and untreated HBsAg-positive mothers. We aimed to evaluate the role of serum levels of HBcrAg and pgRNA in pregnancy to predict post-delivery ALT flares, their severity and by inference, a preference to continue NA therapy.
Method: Plasma samples from 642 HBsAg-positive pregnant women (pangenotypic cohort) were collected during the 2nd & 3rd trimesters and at 6, 12, 18, 24, 36 and 48 weeks post-partum. 103 (16%) were HBeAg-positive; median age 31 years. Samples were tested for HBeAg, HBV DNA (TaqMan, Roche; IU/ml); quantitative HBsAg (Abbott Architect; log_{10}IU/ml), HBcrAg levels (CLEIA Fujirebio; log_{10}U/ml) and pgRNA concentrations (real-time PCR assay Abbott Diagnostic; log_{10}U/ml). 95/642 mothers with HBV DNA concentrations >200,000 IU/ml started tenofovir prophylaxis from 28 weeks of gestation to prevent HBV MTCT. The ALT flares incidence and severe flares (defined as >10 × ULN) was correlated with HBcrAg and pgRNA in treated and untreated mothers.
Results: *Untreated cohort:* 106/547 (19%) of untreated mothers developed a post-delivery flare, but none was severe. Higher pre-delivery HBV DNA, HBcrAg and pgRNA concentrations were observed in untreated mothers with post-partum ALT flares than in mothers without a flare. ALT and HBsAg concentrations were similar in flare vs. no flare patients (Figure). *NA treated cohort: S*imilarly, higher pre-delivery HBcrAg and pgRNA concentrations were observed in NA treated mothers with a post-partum flare. 80/95 treated mothers stopped NA therapy post-partum (median 4 weeks). However no difference in the incidence of flares was observed in mothers discontinuing treatment versus in mothers who continued NA: 56/80 (70%) vs 13/15 (87%). Seven HBeAg-negative treated patients who stopped NA developed a severe ALT flare within 12 weeks post-delivery. High pre-delivery levels of HBcrAg (>7 log_{10}U/ml) and pgRNA (>4 log_{10}U/ml) were noted in mothers with severe flare. The flares resolved after re-starting NA. Thirteen (13%) mothers lost HBeAg and 6 (1%) lost HBsAg spontaneously within 1 year post-delivery (all mild flares). No ALT flares were associated with hepatic synthetic dysfunction.



Conclusion: Post-partum ALT flares are more common in pregnant women with higher pregnancy HBcrAg and pg HBV RNA levels, in both NA treated and untreated mothers. However high pre-delivery levels could suggest that NA therapy should be continued post-partum to avoid severe and injurious ALT flares.

FRI387

Gender disparity in the association of interleukin-10 and interleukin-12 polymorphisms with the progression of hepatitis B virus infection in Caucasians

Janett Fischer[1], Long Shuang[1], Koukoulioti Eleni[1], Tobias Müller[2], Fueloep Balazs[3], Heyne Renate[4], Thomas Berg[1], Florian van Bömmel[1].
[1]University Clinic Leipzig, Division of Hepatology, Clinic and Polyclinic for Gastroenterology, Hepatology, Infectiology, and Pneumology, Leipzig, Germany; [2]Charité Campus Virchow-Klinikum (CVK), Department of Gastroenterology and Hepatology, Berlin, Germany; [3]HELIOS Klinikum Berlin-Buch, Department of Internal Medicine and Gastroenterology, Berlin, Germany; [4]Liver and Study Center Checkpoint, Berlin, Germany
Email: janett.fischer@medizin.uni-leipzig.de

Background and Aims: Interleukin-10 (IL-10) and interleukin-12 (IL-12) are pivotal immunoregulatory cytokines which can affect the immune response against hepatitis B virus (HBV) infection. Variations in the IL-10 and IL-12 genes might influence the level of cytokine production and subsequently the course of HBV infection. Therefore, we evaluated whether there is an association between four common polymorphisms (SNPs) in these genes with the disease progression.
Method: The study cohort included 614 Caucasian patients (mean age 56 ± 15 years, 59% male) with chronic hepatitis B (CHB) and 239 individuals with spontaneous HBV surface antigen (HBsAg) seroclearance (SC). In the CHB group, 50% of patients were inactive carriers and 84% were HBeAg negative. 89(15%) had liver cirrhosis and 41 (7%) hepatocellular carcinoma, respectively. Host genomic DNA extraction and genotyping of the IL-10 SNPs rs1800896 and rs3024490 and IL-12 SNPs rs4568408 and rs2243115 was done from peripheral blood samples.
Results: Differences in the genotype distribution of the IL-10 SNP rs1800896 were observed between females with CHB and SC (p = 0.042) and between female inactive carriers and patients with chronic hepatitis B (p = 0.028). In multivariate analysis, the AA genotype was significantly associated with a reduced likelihood of spontaneous SC (OR = 0.56, p = 0.037) and a reduced likelihood of the development of an inactive carrier state (OR = 0.39, p = 0.003) in females. In contrast, the AG/AA variants of IL-12 SNP rs4568408 were significantly more frequent in chronically infected male patients with liver cirrhosis than in patients without liver cirrhosis (46% vs. 28%, p = 0.004). In multivariate analysis, the AG/AA genotypes were independently associated with an increased risk to develop liver cirrhosis with an odds ratio of 2.84 (p = 0.001) in males.
Conclusion: We identified a gender-related association of the IL-10 SNP rs1800896 and IL-12 SNP rs4568408 with different stages of HBV infection and liver disease progression in Caucasians. We suggest that genetic variants in components modulating innate immunity and inflammatory processes might play a role in the sex-related variability in response to HBV.

FRI388

Association between quantitative hepatitis B virus core antibody levels and surface antigen in chronic low viraemic patients

Jing Li[1], Dong Wei[1], Jia Chen[1], Qi Ming Gong[2], Xinxin Zhang[1]. [1]*Research Laboratory of Clinical Virology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China;* [2]*Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China*
Email: xin-xin-zhang@163.com

Background and Aims: Hepatitis B virus (HBV) core antibody (Anti-HBc) is a marker of HBV core antigen-specific immune activity. Several studies have revealed that baseline quantitative Anti-HBc (qAnti-HBc) could predict the response of antiviral therapy. We performed a cross-sectional study to determine whether the total serum level of qAnti-HBc (immunoglobulins M and G) is associated with hepatitis B surface antigen (HBsAg) in low viraemic chronic HBV infected patients.
Method: Biochemical and virologic data were collected from 1493 HBsAg positive patients with HBV DNA < 500 IU/L and quantified qAnti-HBc at RuiJin Hospital, between August 2018 and September 2019. The association between qAnti-HBc and serum virologic markers was systematically analyzed.
Results: The mean qAnti-HBc level was 2.71 ± 0.69 log10IU/mL, which was higher in HBeAg negative patients of 2.86 ± 0.71 log10IU/mL than in HBeAg positive patients of 2.41 ± 0.52 log10IU/mL (p < 0.001). The correlation of the qAnti-HBc level and HBsAg was slightly positive in both HBeAg positive patients (pearson r = 0.10, p < 0.05) and negative patients (pearson r = 0.13, p < 0.001). Multivariate regression analysis revealed that HBsAg was independent factor associated with qAnti-HBc (beta = 0.10, p < 0.0001). Additionally, a nonlinear relationship was observed between qAnti-HBc and HBsAg. The qAnti-HBc level increased significantly only when HBsAg level above 512.86 IU/mL (log HBsAg 2.71) (adjusted beta = 0.19, 95% CI 0.04 to 0.12, p < 0.0001).
Conclusion: In chronic HBV infected patients with low viraemic, serum qAnti-HBc level was closely related to HBsAg in a nonlinear pattern. These findings suggest that monitoring qAnti-HBc level could serve as a useful marker for measuring host immune response against HBV.

Risk of hepatitis flare in inflammatory bowel disease patients with previous hepatitis B virus exposure - results from a territory-wide Hong Kong ibd registry study

Joyce Wing Yan Mak[1], Terry Cheuk-Fung Yip[1], Hon Man Lam[1], Tsz Yan Cheng[1], Sunny Hei Wong[1], Francis Ka Leung Chan[1], Siew Chien Ng[1], Vincent Wai-Sun Wong[1], Grace Lai-Hung Wong[1]. [1]*The Chinese University of Hong Kong, Medicine and Therapeutics, Shatin, Hong Kong*
Email: joycemwy@gmail.com

Background and Aims: Biologics, thiopurines and steroid are commonly used in inflammatory bowel disease (IBD) and may

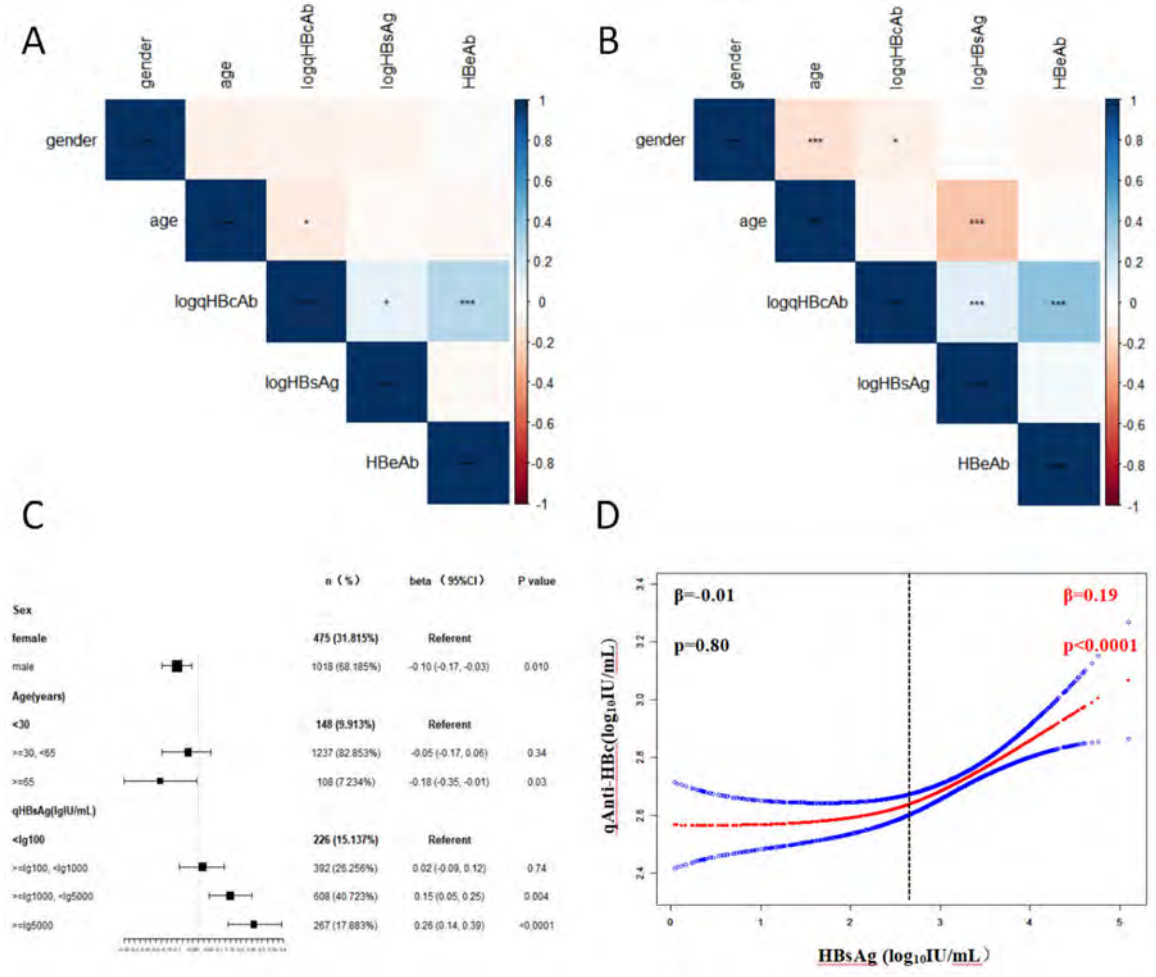

Figure: (abstract: FRI388) Heat map representation of correlation between qAnti-HBc and clinical parameters in HBeAg positive patients (A) and HBeAg negative patients (B). Forest plot for the multivariate analysis the association of clinical factors with qAnti-HBc adjusted for HBeAg status (C). Nonlinear pattern between qAnti-HBc and HBsAg adjusted for gender, age and HBeAg status (D).

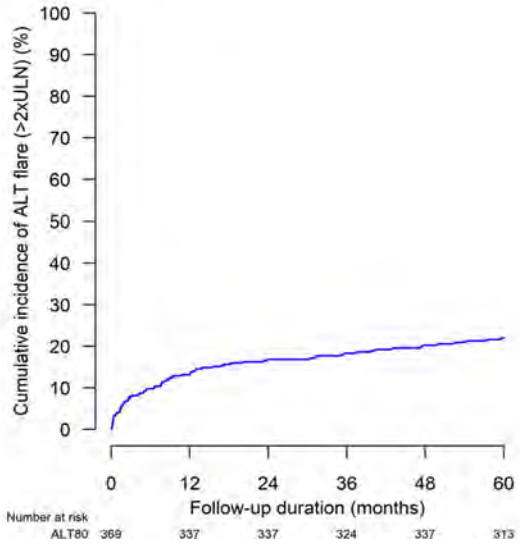
cause hepatitis B virus (HBV) reactivation. Their exact risk of hepatitis B flare in patients with previous HBV exposure is poorly defined. We aim to study risk of hepatitis flare in IBD patients with previous HBV exposure.

Method: Patients were identified from territory-wide Hong Kong IBD Registry. IBD patients who were negative for HBsAg and received biologics or thiopurines or steroids from 1 January 2000 to 30 June 2019 were included. Patients who were positive for total antibody to hepatitis B core antigen (anti-HBc) and/or hepatitis B surface antigen (anti-HBs) were defined to have previous HBV exposure. Primary endpoint was development of hepatitis flare (alanine Aminotransferase [ALT) >80 U/L).

Results: Total 369 patients fulfilled inclusion criteria and were classified into 3 groups: anti-HBs positive only (n = 246); anti-HBs and anti-HBc positive (n = 78) and anti-HBc positive only (n = 45). Median follow up duration was 60 months (Interquartile range: 32.7–60 months). Seventy-six IBD patients (20.6%) developed hepatitis flare. Cumulative incidence of hepatitis flare were 13.2%, 18.3% and 22% at 12 months, 36 months and 60 months respectively. Use of thiopurine [adjusted hazard ratio (aHR) 2.56; 95% Confidence Interval (CI) 1.54–4.26, p < 0.001] and ever exposure to steroid [aHR 2.73; 95% CI 1.30–5.72; p = 0.008] were risk factors for hepatitis flare after adjustment of baseline ALT level. Use of biologics was not associated with risk of hepatitis flare [aHR 1.79; 95% CI 0.79–3.99; p = 0.14]. Ever exposure to steroid was associated with increased risk of hepatitis flare irrespective of peak dose (<20 mg prednisolone daily, 20–40 mg daily or >40 mg daily) [aHR: 2.34–4.18]. Fifteen patients (4.1%) developed severe icteric hepatitis flare (ALT >120 U/L and bilirubin >38 mmol/L). Cumulative incidence of severe icteric hepatitis flare were 2.7%, 7.2% and 8.4% at 12 months, 36 months and 60 months respectively.

Cumulative incidence of hepatitis B flare (ALT >80U/L) in inflammatory bowel disease patients with previous hepatitis B virus exposure



Univariate and multivariable analysis for hepatitis flare amongst IBD patients with previous HBV exposure

	Univariate analysis			Multivariable analysis		
Parameters	HR	95% CI	*P* value	Adjusted HR	95% CI	*P* value
Biologics	1.93	0.88–4.23	0.102	1.83	0.81–4.09	0.144
Aza	1.61	1.01–2.58	0.047	2.70	1.57–4.64	<0.001
Age	1.01	0.99–1.02	0.356	1.00	0.99–1.02	0.486
Male sex	1.13	0.71–1.80	0.601	0.94	0.58–1.52	0.805
IBD type CD/UC/IBD-U	1.06	0.67–1.67	0.797	1.29	0.77–2.16	0.328
Exposure to steroid	1.69	0.84–3.39	0.139	2.73	1.30–5.72	0.008
ALT	1.03	1.02–1.05	<0.001	1.03	1.02–1.05	<0.001

Conclusion: Amongst IBD patients with previous HBV exposure who were on biologics, thiopurines or steroid, 20.6% developed hepatitis flare. Use of thiopurine and ever exposure to steroid were risk factors for hepatitis flare. Use of biologic was not associated with risk of hepatitis flare.

FRI390

Sarcopenia is associated with type 2 diabetes and sedentary lifestyle in patients with chronic hepatitis B

Cecy Maria de Lima Santos[1], Aline Marcos Pires[1], Nataly Lopes Viana[1], Emile Amador Sigales[1], Adriana Maria Kakehasi[2], Olivio Brito Malheiro[2], Maria Marta Sarquis Soares[3], Rosangela Teixeira[1], Gifone Aguiar Rocha[4], Tatiana Bering Bering[5], Luciana Diniz Silva[1,3]. *[1]Outpatient Clinic of Viral Hepatitis, Instituto Alfa de Gastroenterologia, Faculdade de Medicina, Universidade Federal de Minas Gerais (UFMG), Brazil; [2]Locomotor System Department, Faculdade de Medicina, Universidade Federal de Minas Gerais (UFMG), Brazil; [3]Internal Medicine, Faculdade de Medicina, Universidade Federal de Minas Gerais (UFMG), Brazil; [4]Laboratory of Research in Bacteriology, Faculdade de Medicina, Universidade Federal de Minas Gerais (UFMG), Brazil; [5]Department of Food and Nutrition, Universidade Federal de Mato Grosso (UFMT), Brazil*
Email: lucianadinizsilva@gmail.com

Background and Aims: Several evidences have shown that metabolic risk factors may play a role in sarcopenia. Of note, in cirrhotic patients, sarcopenia is common, and it is related to a poor prognosis. However, in chronic hepatis B (CHB) scenario, the relationship between sarcopenia, obesity, type 2 diabetes (T2D), hypertension and sedentary lifestyle has not yet been completely clarified. Thus, we aimed to evaluate the prevalence of sarcopenia and its association with metabolic risk factors in CHB.

Method: 121 patients [mean age, 48.5 ± 12.1 years; 56.5%, males; 80.2%, non-cirrhotic and 19.8%, with compensated cirrhosis; HBsAg/anti-HBe-positive, 91.7%; treatment-naïve, 57.0% and antiviral nucleos(t)ide analogues- (NUCs)- experienced, 43.0%] with CHB, prospectively, underwent scanning of the appendicular skeletal muscle mass (ASM), and fat mass by dual-energy X-ray absorptiometry. Muscle strength was assessed by dynamometry. Sarcopenia was defined by the presence of both low, ASM/height^2 (ASMI) and low muscle strength according to the European Working Group on Sarcopenia in Older People criteria. The cut-off points for low ASMI and low muscle strength, for women and men, were <5.45 and <7.26 kg/m^2 and <20 and <30 kg, respectively. The habitual physical activity was assessed using the International Physical Activity Questionnaire (IPAQ) short version. The data were analyzed by logistic regression models. The study was approved by the Ethics Committee of the UFMG.

Results: Pre-sarcopenia (low muscle mass), sarcopenia and sarcopenic obesity (sarcopenia and body fat percentage >27% and >38% for men and women, respectively) were observed in 18.2% (22/121), 8.3% (10/121) and 5.0% (6/121) of the patients, respectively. In multivariate

analysis, adjusted by age, body mass index, glomerular filtration rate and sex, sarcopenia is positively associated with T2D (OR = 4.70; 95%CI = 1.02–21.72; p = 0.05) and low physical activity (OR = 3.08; 95%CI = 1.08–8.75; p = 0.04) and, inversely associated with NUCs therapy (OR = 0.23; 95%CI = 0.06–0.94; p = 0.04).
Conclusion: Sarcopenia is associated with metabolic risk factors in patients with CHB, specifically those with obesity, T2D and sedentarism. Antiviral therapy is associated with preserved ASM. These findings may influence clinical decision-making and contribute to the development of effective strategies to screen skeletal muscle abnormalities in CHB patients, independently of the stage of the liver disease.

FRI392

Incidence and predictors of hepatitis B surface antigen clearance among people living with HIV and hepatitis B

Mamta Jain[1], Karen Vigil[2], Xilong Li[3], Paul Parisot[1], Gabriella Go[2], Trung Vu[4], Barbara Taylor[4]. *[1]UT Southwestern Medical Center, Internal Medicine, Dallas, United States; [2]University of Texas Health Science Center at Houston, Internal Medicine, Houston, United States; [3]UT Southwestern Medical Center, Population and Data Sciences, Dallas, United States; [4]University of Texas Health Science Center at San Antonio – UT Health San Antonio, Internal Medicine, San Antonio, United States*
Email: mamta.jain@utsouthwestern.edu

Background and Aims: Incidence of hepatitis B surface antigen (HBsAg) clearance is reported to be 0.7% to 1.02% per year among those with hepatitis B virus (HBV). Low HBV DNA or HBsAg levels and hepatitis B e antigen (HBeAg) negative status was associated with HBsAg loss. However, incidence and predictors of HBsAg loss among people living with HIV (PLWH) is not known.
Method: We conducted a retrospective multi-center analysis of PLWH coinfected with HBV. Data were collected from 3 HIV clinics in Dallas, San Antonio, and Houston, Texas. Chronic HBV was defined by: (1) hepatitis B core IgM negative and HBsAg+, HBeAg+, or HBV DNA+ or (2) HBsAg+, HBV DNA+, or HBeAg+ two times 6 months apart. Incident HBSAg loss was defined as loss of HBsAg >6 months after initial HBV diagnosis. Hazard risk ratio for HBsAg clearance was examined by univariate and multivariate analysis.
Results: We examined 567 PLWH with chronic HBV (86% Male; 61% Black and 15% Hispanic; 41% uninsured, 44% with AIDS at baseline) who had 4,127 years of follow-up. HBsAg loss occurred in 10.6% and among those with HBsAg loss, 62% developed anti-HBs. The incidence of HBsAg loss was 1.45% per year and anti-HBs developed 0.88% per year. We examined race, HIV risk factor, HBeAg-status at baseline, HBV DNA suppression at baseline, HIV RNA suppression at baseline, cirrhosis, hepatitis C, age, gender, insurance, and alcohol use. In a multivariable analysis, Hispanics (HR 3.00, 95% CI: 1.12–8.05),those with AIDS at baseline (HR 2.11, 95% CI: 1.26–3.54), injection drug use (IDU) as HIV risk factor (HR 2.74, 95% CI: 1.13–6.67) were at more likely to experience HBsAg loss, whereas those who were HBeAg+ at baseline (HR 0.36, 95% CI: 0.19–0.66) were less likely (Figure 1). Compared to those who had an increase in CD4 >300 cells/μL from baseline to end of follow-up, those with a decrease in CD4 cells were less likely to lose HBsAg (HR 0.31, 95% CI: 0.14, 0.68).

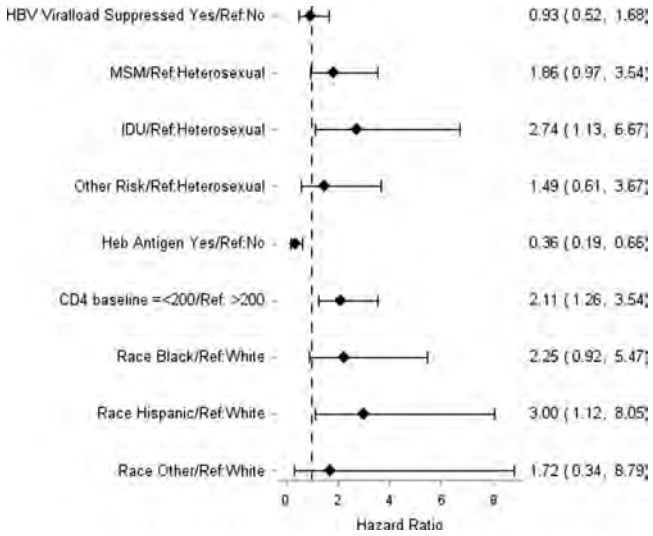


Figure 1: (abstract: FRI392)

Conclusion: HBsAg clearance occurs 70 to 200% times more frequently in PLWH compared to published incidence data in those with HBV alone. HBV surface antigen clearance in this cohort of PLWH is 3 times more likely in Hispanics than non-Hispanic Whites, and twice as likely in those with AIDS than those without. Those with HBeAg+ were 33% as likely to lose HBsAg compared to HBeAg-negative. Immune restoration may be a mechanism which increases likelihood of HBsAg clearance in HIV patients. Further studies are needed to understand why certain sub-groups have higher rates of HBsAg clearance.

FRI393

Rituximab monotherapy in anti-HBC positive patients with multiple sclerosis or neuromyelitis optica spectrum disorders is not associated with HBV reactivation

Blanca Marzo[1], Ángela Vidal-Jordana[2], Joaquim Castrilló-Justribo[2], Luisa Roade[1], Clara Oriol[2], Miguel Ángel Robles[2], Rafael Esteban[1,3], Mar Tintoré[2], Maria Buti[1,3], Mar Riveiro Barciela[1,3]. *[1]Vall d'Hebron University Hospital, Liver Unit. Internal Medicine Department, Barcelona, Spain; [2]Centre d'Esclerosi Mútiple de Catalunya (Cemcat), Neurology-Neuroimmunology Department. Neurorehabilitation Unit, Barcelona, Spain; [3]CIBERehd. Carlos III Health Institute, Centro de investigación biomédica en Red. Enfermedades hepáticas y digestivas., Madrid, Spain*
Email: mar.riveiro@gmail.com

Background and Aims: Immunosuppressant therapy in subjects with chronic hepatitis B virus infection (HBsAg) and resolved infection (antiHBc positive/HBsAg negative) may cause HBV reactivation. Anti-CD20 monoclonal antibodies are associated with greater risk of HBV reactivation, mainly in the context of hematological chemotherapy, although there are few data on the risk of monotherapy.
Method: All consecutive subjects with multiple sclerosis (MS) or neuromyelitis optica spectrum disorder (NMOSD) undergoing anti-CD20 monoclonal antibodies (rituximab, ocrelizumab) were included. Viral serologies were determined prior starting treatment. Those antiHBc+/HBsAg- not receiving other immunosuppressants, analytical follow-up was performed every 6 months (ALT, HBsAg, HBV-DNA, anti-HBs) without antiviral prophylaxis. HBV reactivation was defined by ≥2 log in HBV DNA or seroconversion to HBsAg+.

Results: 290 patients with MS or NMOSD underwent anti-CD20 agents: 260 (90%) rituximab and 30 (10%) ocrelizumab. Majority women (63%), Caucasian (97%), mean age 48 ± 10. All cases were HBsAg, anti-HCV and HIV negative. Anti-HBc antibodies were positive in 17 subjects (6%), and its prevalence was higher by 11% in subjects>50 years. Anti-HBc+ subjects were older (53.7 vs. 47.4, p = 0.015) and more frequently male (59% vs. 36%, p = 0.05) than anti-HBc-. Other immunomodulator drugs (59% interferon, 35% glatiramer acetate, 18% natalizumab), including corticosteroid bolus in disease relapses (a median of 10 bolus had previously received in 77% of anti-HBc positive). The median time between the diagnosis of neurological disease and starting anti-CD20 therapy was 18 years (0–37). All subjects presented undetectable HBV DNA at baseline, and median anti-HB titres were 35 mUI/mL (0–1000), being <10 mUI/mL in 5 (29%) of them. After a median follow-up of 12 months and 2 cycles of anti-CD20 (1–6 cycles), no cases of HBV reactivation or significant rise in anti-HBs levels were observed (p = 0.289). No subjects included in this study required corticosteroid bolus due to disease relapse, although 4 (23%) of them required dose adjustment due to toxicity or intercurrent infections.
Conclusion: Anti-CD20 monoclonal antibodies monotherapy in antiHBc positive subjects with multiple sclerosis or diseases of the spectrum of optic neuromyelitis does not seem to be associated with a higher risk of HBV reactivation, although longer follow-up is required to confirm these findings.

FRI394

Not uncommon: HBV genotype g co-infection in HBeAg-negative chronic HBV infected patients

Michael Basic[1,2], Alica Kubesch[1], Lisa Kuhnhenn[1], Gert Carra[2], Johannes Vermehren[1], Viola Knop[1], Christiana Graf[1], Julia Dietz[1], Stefan Zeuzem[1], Christoph Sarrazin[1,3], Eberhard Hildt[2,4], Kai-Henrik Peiffer[1,2]. *[1]Goethe University Hospital, Department of Internal Medicine I, Frankfurt, Germany; [2]Paul-Ehrlich-Institute, Virology, Langen, Germany; [3]St. Josefs Hospital, Gastroenterology, Wiesbaden, Germany; [4]German Center for Infection Research, Braunschweig, Germany*
Email: kai-henrik.peiffer@kgu.de

Background and Aims: A total of ten HBV genotypes (A-J) have been described. HBV genotype G (HBV/G) was mainly found in co-infections with other genotypes, predominantly with genotype A (HBV/A) and H (HBV/H). HBV/G is characterized by a 12 amino acid insertion in the core gene and two stop codons in the precore region that prevent HBeAg expression. We recently observed an impaired release of HBsAg and an accumulation of filamentous subviral particles in the ER and reduced activation of Nrf2 and cytoprotective genes in HBV/G expressing cells. In addition, *in vivo* reports suggest HBV/G as a risk factor for liver fibrosis in HBV/HIV co-infected patients. This study aimed to evaluate the prevalence and virologic characteristics of HBV/G in HBeAg-negative chronic infected patients.
Method: A total of 560 patients with HBeAg-negative chronic HBV infection were tested for HBV/G co-infection by a specific semi-nested PCR and direct sequencing of the core/precore and preS gene. Deep sequencing of HBV/G positive samples was performed to determine the percentage of HBV/G in the quasispecies. Co-infection was further correlated with clinical parameters and known basal core promotor (BCP) and precore (PC) mutations. Western blot analyses were performed using an SHBs-specific antibody.
Results: By direct sequencing, HBV/G was detected in 4% (7/161) and 8% (4/48) of patients infected with either HBV/A or HBV/E, respectively. Deep sequencing revealed that HBV/G was present as the major variant in the quasispecies of patients infected with HBV/A, while it was found only in low frequencies in patients co-infected with HBV/E. No significant impact of HBV/G co-infection on HBsAg or HBV-DNA levels was observed. In addition, co-infection with HBV/G was not associated with the presence of BCP (A1762T/G1764A) and PC (G1896A or G1896A/G1899A) mutations. Interestingly, the size of LHBs in serum samples from co-infected patients did not show the HBV/G-specific size difference in molecular weight.
Conclusion: A significant prevalence of HBV/G in co-infection with HBV/A and for the first time with HBV/E was detected in patients with HBeAg-negative chronic HBV infection. Interestingly, in HBV/A co-infected patients HBV/G represents the major variant in the quasispecies whereas in HBV/E co-infections HBV/G was found only as a minor variant. In contrast to recent in vitro data, HBV/G does not lead to a lower HBsAg level in the serum which might reflect HBsAg synthesis from integrated DNA in infected patients.

FRI395

Poor improvement of on-treatment FIB-4 index after initiation of nucleos(t)ide analogs is associated with development of hepatocellular carcinoma in both cirrhotic and non-cirrhotic chronic hepatitis B patients

Miyako Murakawa[1,2], Taro Shimizu[1], Eiko Takeichi[1], Jun Tsuchiya[1], Ayako Sato[1], Masato Miyoshi[1], Fukiko Kawai-Kitahata[1], Sayuri Nitta[1], Yasuhiro Itsui[1], Mina Nakagawa[1], Seishin Azuma[1], Sei Kakinuma[1,3], Yasuhiro Asahina[1,3]. *[1]Tokyo Medical and Dental University, Gastroenterology and Hepatology, Japan; [2]Tokyo Medical and Dental University, Clinical Laboratory; [3]Tokyo Medical and Dental University, Liver Disease Control*
Email: asahina.gast@tmd.ac.jp

Background and Aims: Development of hepatocellular carcinoma (HCC) in chronic hepatitis B (CHB) patients is not completely suppressed even under suppression of HBV replication by nucleos(t)ide analogs (NAs) treatment. While liver cirrhosis is known as the major risk factor for HCC, non-cirrhotic CHB patients often develop HCC. Although we previously reported HBV integration was responsible for HCC development during NAs therapy in such patients, clinically useful predictor for HCC development in non-cirrhotic patients is unclear. The aim of this study is to characterize the patients who develop HCC during NA treatment, and to clarify the risk factors for HCC especially in non-cirrhotic CHB patients.
Method: A total of 163 CHB patients who were treated with NAs were enrolled. Patients with previous history of HCC were excluded. All patients were followed up every 3 to 6 months, and pre- and on-treatment data were analyzed in patients with or without HCC development during follow-up.
Results: During median follow-up period of 6.8 years, the cumulative incidence of HCC at 10 years was 10.1%. In the univariate analysis of pre-treatment factors, cirrhosis (p = 0.020), lower platelet (PLT) counts (p = 0.028), and higher AFP levels (p = 0.043) were associated with HCC development. Of these, only cirrhosis was identified as the significant pre-treatment risk factor for HCC development by multivariate analysis (p = 0.021). Although levels of HBV DNA and serum inflammation markers such as ALT and AFP significantly improved after starting of NA therapy in most of the patients, changes of the fibrosis markers such as PLT, ALB, and FIB4 index were various among the patients. In the univariate analysis of on-treatment factors at 6 months and 12 months after the initiation of NAs, 6M-FIB4 index (p = 0.008), 12M-PLT (p = 0.047), 12M-ALB (p = 0.012), 12M-AFP (p = 0.022), and 12M-FIB-4 index (p = 0.010) were associated with HCC development. When changes in FIB-4 index during NAs therapy was

analyzed, 6M-/pre-FIB-4 ratio were significantly associated with HCC risk with a cutoff value of 1.0459 (p = 0.032), and the negative predictive values were extremely high at 0.980. In overall, 6M-/pre-FIB-4 ratio and cirrhosis were identified as the independent risk factors for HCC development by multivariate analysis. The cumulative incidence of HCC in 6M-/pre-FIB-4 ratio >1.0459 group was significantly higher in both non-cirrhotic and cirrhotic subgroups (p < 0.001).

Conclusion: Poor improvement of FIB-4 index even after initiation of NAs therapy predicts HCC development during NAs therapy both in non-cirrhotic and cirrhotic patients. Careful surveillance for HCC should be necessary in CHB patients without decrease in FIB-4 index during NAs treatment.

FRI396

The integrated use of accurate virological and serological HBV markers can help identifying HBsAg-negative/anti-HBC -positive patients at higher risk of HBV-reactivation and optimizing the duration of prophylaxis in oncohematological setting

Romina Salpini[1], Carlotta Cerva[2], Mohammad Alkhatib[1], Lorenzo Piermatteo[2], Arianna Battisti[1], Vincenzo Malagnino[2], Lavinia Fabeni[1], Maria Cantonetti[3], William Arcese[3], Francesca Ceccherini Silberstein[1], Carlo Federico Perno[4], Massimo Andreoni[2], Loredana Sarmati[2], Valentina Svicher[1]. *[1]Tor Vergata University, Department of Experimental Medicine, Rome, Italy; [2]Tor Vergata University, Clinical Infectious Disease, Department of System Medicine, Rome, Italy; [3]Tor Vergata University, Department of Hematology, Stem Cell transplant Unit, Rome, Italy; [4]University of Milan, Department of Oncology and Haemato-oncology, Milan, Italy*
Email: mohammad–alkhatib@hotmail.com

Background and Aims: Prevention of HBV-reactivation (HBV-R) in patients undergoing immunosuppressive therapy is still challenging. We investigate the role of HBV markers in predicting HBV-R in HBsAg-negative/anti-HBc-positive oncohematological patients.

Method: HBV-R rate is estimated in 107 HBsAg-negative/anti-HBc-positive patients (42 receiving rituximab [RTX], 40 hematopoietic stem cell transplantation [HSCT], 25 other chemotherapeutics [chemo]). All patients received lamivudine-prophylaxis for ≥18months after stopping immunosuppression (EASL guidelines) and were prospectively monitored every 3 months during and after prophylaxis completion. The role of HBV markers in predicting HBV-R is evaluated by testing 629 serum samples for highly-sensitive HBsAg (Fujirebio, HS-HBs; lower limit of quantification [LLOQ]: 5 vs 50 mIU/ml of routinely-used assays), HBV-DNA (Roche, LLOQ:20 IU/ml), quantitative anti-HBs and anti-HBc (Fujirebio, LLOQ:1.0COI). HBV-R is defined as serum HBV-DNA ≥ 20 IU/ml (Seto,2016).

Results: At baseline-screening, all patients have undetectable HBV-DNA and 67.3% is anti-HBs positive (median [IQR]:152[47–976]mIU/ml]. HBV-R occurs in 13/107 patients with the highest 5-year cumulative reactivation rate in HSCT (38% vs 21% for RTX and 10% for other chemo).

At HBV-R, median (IQR) HBV-DNA is 42(23–5831)IU/ml and ALT>ULN for 46%(median [IQR]:95[81–986]U/L). Among HBV-R cases, 5 develops HBV-R during and 8 after completing prophylaxis (median [min-max] months after prophylaxis completion:3[1–27]).

The analysis of serological markers during the entire monitoring reveals that an anti-HBc>3COI combined with anti-HBs persistently or declining to <50 mIU/ml correlates with a higher risk to develop HBV-R (46.2% of patients with anti-HBc>3COI+anti-HBs<50 mIU/ml vs 9.1% without this combination experiences HBV-R, P = 0.006, OR [95%CI]: 8.6[1.9–38.4]).

Furthermore, by monitoring virological markers, the positivity, confirmed in at least 2 time-points, to HS-HBs (detection failed by routinely used HBsAg-assays) and/or to HBV-DNA (detected below LLOQ) is another factor predicting HBV-R (45.5% of patients positive to HS-HBs and/or HBV-DNA vs 5.6% never positive to these markers experiences HBV-R, P < 0.001, OR [95%CI]: 14.2[3.2–62.9]).

Conclusion: HBV-R frequently occurs in anti-HBc-positive/HBsAg-negative oncohematological patients, particularly after completing antiviral prophylaxis. The combined usage of accurate HBV-markers can guide the identification of patients at higher HBV-R risk who need an extended prophylaxis.

FRI397

A comparative study of risks for hepatocellular carcinoma and mortality in chronic hepatitis B patients initially treated with entecavir or tenofovir

Hyo Young Lee[1], Eileen Yoon[2], Dae Won Jun[3], Hyunwoo Oh[4], Sang Bong Ahn[1], Jae Yoon Jeong[5], Sung Eun Kim[6], Soung Won Jeong[7], Hyoung Su Kim[8], Jae-Jun Shim[9], Joo Hyun Sohn[10], Yong Kyun Cho[11]. *[1]Nowon Eulji Medical Center, Eulji University, Department of Internal Medicine, Korea, Rep. of South; [2]Inje University College of Medicine, Sanggye Paik Hospital, Department of Internal Medicine; [3]Hanyang University Hospital., Department of Internal Medicine, Korea, Rep. of South; [4]Seoul National University Hospital, Department of Internal Medicine and Liver Research Institute, Korea, Rep. of South; [5]National Medical Center, Department of Gastroenterology and Hepatology, Korea, Rep. of South; [6]Kangdong Sacred Heart Hospital, Hallym University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [7]Soonchunhyang University College of Medicine, Soonchunhyang University Seoul Hospital, Department of Internal Medicine; [8]Hallym University Sacred Heart Hospital, Department of Internal Medicine, Anyang, Korea, Rep. of South; [9]Kyung Hee University School of Medicine, Korea, Rep. of South; [10]Hanyang University Guri Hospital, Department of Internal Medicine; [11]Kangbuk Samsung Hospital, Department of Internal Medicine, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and Aims: Risk evaluations of hepatocellular carcinoma (HCC) in entecavir (ETV) and tenofovir (TDF) treated chronic hepatitis B (CHB) patients have shown contradicting results in several retrospective cohort studies. Considerable “censored” data, insufficient “observation period”, and different “observation periods” between the drugs are unsolved issues in previous studies. We aimed to compare the incidence of HCC development between two oral nucelos(t)ide analogues over the same “observation period”.

Method: We examined retrospective data from treatment naïve CHB patients who were first treated with either ETV or TDF between 2011 and 2015 at nine academic hospitals in Korea. Clinical outcomes were observed for 4.7 ± 1.0 years and minimum observation duration was guaranteed for 3 years in both the groups.

Results: A total of 1,560 treatment naïve patients (753 in the ETV group and 807 in the TDF group) were included. In the entire cohort, mean and median “observation periods” were 4.6 ± 1.0 and 4.8 (Interquartile rage (IQR), 4.2–5.4) years, respectively. 92.4% of TDF and 92.7% of ETV treated patients were followed up during the observational period. In this cohort, 34 out of 753 patients (4.5%) in the ETV group and 45 out of 807 patients (5.6%) in the TDF group developed HCC under antiviral treatment during the follow up period; the incidences were not different between the groups. Moreover, these rates were not different between the drugs based on the 516-pair propensity score-matched population.

Conclusion: Incidence of HCC was similar between ETV and TDF treated patients over the same observation period (clinical trial No. KCT0003487).

Reverse transcriptase droplet digital PCR versus reverse transcriptase quantitative real-time pcr for serum HBV RNA quantification

Natthaya Chuaypen[1], Umaporn Limothai[1], Pisit Tangkijvanich[1].
[1]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, Bangkok, Thailand*
Email: pisittkvn@yahoo.com

Background and Aims: Serum hepatitis B virus (HBV) RNA is a novel marker reflecting the activity of intrahepatic covalently closed circular DNA (cccDNA). However, the optimal methodology for detecting HBV RNA has been a technical challenge and it is required to be applied in clinical setting.
Method: The performance of reverse transcription droplet digital PCR (RT-ddPCR) for quantifying HBV RNA was compared with that of reverse transcription quantitative real-time PCR (RT-qPCR) in serum samples collected from treatment-naïve patients with different phases of chronic hepatitis B (CHB). Serum HBV DNA and HBsAg quantifications were assessed by commercially available standard methods.
Results: A total of 417 serum samples, including 136 HBeAg-positive CHB and 281 HBeAg-negative CHB were examined. Serum HBV RNA levels measured by RT-ddPCR and RT-qPCR showed a high degree of linearity and quantitative correlation ($r = 0.929$, $P < 0.001$). The limit of detections of RT-ddPCR and RT-qPCR assays were approximately 10^2 and 10^3 copies/mL, respectively. Our results demonstrated that RT-ddPCR was superior to RT-qPCR in terms of its consistency for quantifying HBV RNA across all concentrations, particularly in the HBeAg-negative group with low HBV DNA levels. In the HBeAg-positive group, serum HBV RNA levels based on RT-ddPCR were moderately correlated with HBV DNA ($r = 0.591$, $P < 0.001$) and HBsAg ($r = 0.502$, $P < 0.001$). Among patients with HBeAg-negative CHB, serum HBV RNA levels were moderately correlated with HBV DNA ($r = 0.603$, $P < 0.001$) but had weak correlation with HBsAg ($r = 0.203$, $P = 0.001$).
Conclusion: The RT-ddPCR was more sensitive than RT-qPCR for measuring serum HBV RNA and could enhance the detection rate, particularly among the HBeAg-negative group with low viral loads. Thus, RT-ddPCR could serve as an optimal method for HBV RNA quantification in clinical practice.

Email: ozgurmkoc@gmail.com

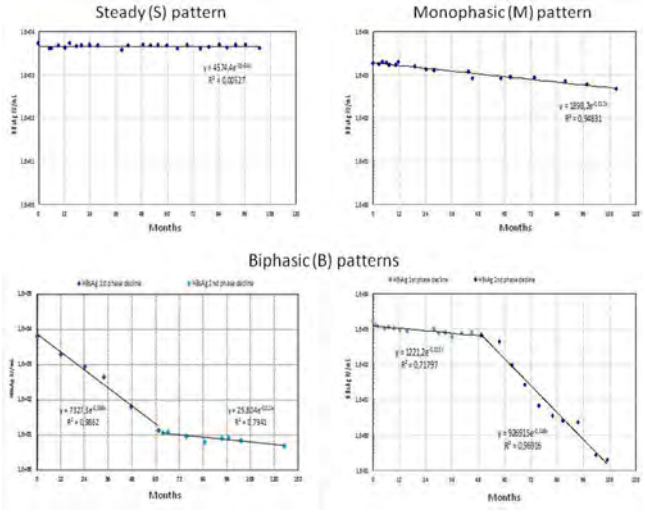
Background and Aims: Turkey is an intermediate hepatitis B virus (HBV) endemic country. However, prevalence among Turkish migrants in Belgium is unknown, especially in those born in Belgium with a foreign-born parent, i.e. second-generation migrants (SGM). This study evaluated the prevalence of HBV infection and associated risk factors in Turkish first-generation migrants (FGM), i.e. foreign-born, and SGM.
Method: Between September 2017 and May 2019, free outreach testing for hepatitis B surface antigen (HBsAg), hepatitis B core antibodies (anti-HBc) and antibodies against HBsAg was offered to Turkish migrants in Middle-Limburg, Belgium. Face-to-face questionnaire assessed HBV risk factors. HBsAg positive patients were referred and followed up. Turkish SGM were stratified into birth

cohort born before and after 1987, since those born after 1987 should be covered by the universal infant vaccination program.
Results: A total of 1,081/1,113 (97.1%) Turkish did go for HBV testing. Twenty-six (2.4%) were HBsAg positive; 11/26 were unaware of their status and 10/11 were successfully referred. HBsAg prevalence was 3.0% in FGM and 1.5% in SGM, $p = 0.070$. These numbers were 32.8% and 5.7% for anti-HBc, respectively, $p < 0.001$. Only one out of seven HBsAg positive SGM was born after 1987. Anti-HBc positivity in Turkish SGM born after 1987 was 1.1%, this was 9.1% for those born before 1987, $p < 0.001$.
Conclusion: Outreach testing was well-accepted and referral to specialist care was generally successful. National HBV screening should be implemented in the Turkish FGM population and might be considered in SGM not covered by primary prevention strategies.

FRI400
Three HBsAg kinetic profiles in HBeAg negative infection and chronic hepatitis are associated with different chances of HBsAg clearance

Piero Colombatto[1], Patrizia Bleve[1], Filippo Oliveri[1], Daniela Cavallone[1], Gabriele Ricco[1,2], Barbara Coco[1], Veronica Romagnoli[1], Antonio Salvati[1], Ferruccio Bonino[3], Maurizia Brunetto[1,2,3]. [1]*Pisa University Hospital, Hepatology Unit and Laboratory of Molecular Genetics and Pathology of Hepatitis Viruses, Pisa, Italy;* [2]*University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy;* [3]*National Research Council of Italy, Biostructure and Bio-imaging Institute*
Email: maurizia.brunetto@unipi.it

Background and Aims: Predictive markers of HBsAg clearance in HBeAg negative infection (ENI) and chronic hepatitis (CHB) treated with nucleos(t)ide analogues (NAs) remain an unmet need. We investigated whether the kinetic profile of HBsAg decline may predict this end point.
Method: HBV-DNA and HBsAg were measured at baseline (BL) and every 6 months thereafter in 89 ENI, 63 Low Viremic Carriers (LVC, HBV-DNA ≤ 20.000 IU/mL) and 90 CHB under NAs (55 with cirrhosis, CI). Individual HBsAg kinetics were plotted in semi-log scale and fitted with the exponential function y = a·exp^bx, with $-1 < b < 1$. Statistical analyses were performed by χ^2, Kruskal-Wallis, Spearman correlation test and logistic regression analysis.



Results: Median BL HBsAg (LogIU/mL) was lower in ENI vs LVC vs CHB [3.07 (−0.86/4.62) vs 3.36 (1.24–4.69) vs 3.52 (1.12/4.71); p = 0.003). The overall rate of HBsAg clearance was similar in ENI, LVC and CHB (9.0% vs 7.9% vs 6.7%, p = 0.846), however, median follow up was longer in CHB and LVC vs ENI [81.0 (11.6/204.6) vs 85.8 (33.1/226.7) vs 65.3 (25.2/155.9) mos., p = 0.004]. HBsAg < 100 UI/mL was reached within the end of follow up (EOF) in 63 (28.8%) of 219 cases with BL HBsAg>100 IU/mL: 15/72 (20.8%) ENI, 9/59 (15.3%) LVC and in 19/88 (21.6%) CHB (p = 0.608). Three HBsAg kinetic patterns were observed: Steady, S = 54 (22.4%); Monophasic, M = 146 (60.3%) and Biphasic, B = 42 (17.4%) decline (Figure). S was more frequent in ENI and LVC than in CHB (29.2% and 34.9% vs 6.7%); M was similarly distributed (57.3% vs 52.4% and 68.9%); B was more frequent in CHB than in ENI and LVC (24.4% vs 13.55% and 12.7%; p < 0.001). HBsAg clearance occurred in 9/146 (6.2%) with M and in 10/42 (23.8%) with B patterns (p < 0.001). In M the exponential decline was slower in LVC vs ENI vs CHB (median b = – 0.009 vs – 0.011 vs – 0.014; p = 0.016). In B, the 2nd phase exponential decline was faster in LVC vs ENI vs CHB (median b = – 0.108 vs – 0.087 vs – 0.040; p = 0.053). HBsAg clearance was independently associated with BL HBsAg Log IU/mL (OR = 0.521, 95%CI = 0.284–0.956, p = 0.035) and its Delta Log decline at 36 months (ΔLog36 m) (OR = 26.94, 95%CI = 4.386–165.481, p < 0.001). Overall, EOF HBsAg predicted by ΔLog36 m correlated with measured EOF HBsAg ($\rho = 0.897$), more strongly in ENI ($\rho = 0.964$) and CHB without CI ($\rho = 0.900$) than in LVC ($\rho = 0.883$) and CHB with CI ($\rho = 0.748$) and ΔLog36 m identified carriers who achieved EOF HBsAg<100 IU/mL with 78.7% Se, 99.4% Sp, 98.0% PPV, 93.0% NPV and 94.0% DA.
Conclusion: The lack of HBsAg decline was higher in untreated ENI and LV carriers (29.2% and 34.9%) than NAs treated CHB (6.7%). The monophasic exponential decline was predominant, and faster in CHB than in ENI and LV. HBsAg clearance occurred more frequently in biphasic (23.8%) than monophasic (6.2%) patterns, and was independently associated with BL HBsAg. The 36 months Delta Log decline identified carriers with EOF HBsAg<100 IU/mL with 98.0% PPV.

Email: paolo.fabris@aulss8.veneto.it

Background and Aims: Several small series have described the incidence of HBV reactivation during direct -acting antivirals (DAAS), so far. However, many key issues remain unresolved. Aims of the present study was to evaluate both the incidence and the clinical impact of HBV reactivation in a large cohort of HCVHBV co-infected-patients treated in North Italy.
Method: Between January 2015 and December 2018 data from a common web based program (NAVIGATORE), 16.161 patients treated with DAAs in Veneto and Lombardia were collected. After the first data extraction, centers were asked to provide further details on both the clinical course and outcome of HBV reactivation.
Results: Overall, the prevalence of HBV/HCV co-infection was 1.39% (226/16.161). HCV/HBV co-infection was more frequent in male ($p < 0.01$), and in HIV positive versus HIV negative patients (28.3% versus 12.7%, $p < 0.01$). HBV/HCV co-infected patients had more severe liver disease compared with HCV mono-infected (F3-F4 65.9% versus 57.1%, $p < 0.01$). HCV/HBV co-infected patients were comparable with HCV mono-infected in term of HCV baseline viral load, and SVR 12 (96.0% versus 96.6%). The incidence of HCC during follow-up was more frequent in HBV/HCV co-infected than in HCV mono-infected patients (2.2% versus 0.8%, $p < 0.05$). HBV-DNA was serially monitored during and after treatment with DAAS in 160 (70%) patients. HBV reactivation (increment of HBV-DNA > 2 log from baseline) was observed in 9 cases (5.6%). None of the patients in treatment with (Nucleoside/Nucleotide inhibitors) NUCs (as part of treatment of HIV infection or those treated prophylactically with tenofovir, entecavir or lamivudine) showed HBV reactivation during the follow-up period. Only one of the nine cases which reactivated HBV showed transient mild hepatitis (ALT > 2 normal value). In additional 2 cases HBV reactivation was observed after the withdrawal of NUCs at the end of DAAs treatment (lamivudine) and after 12 weeks from DAAs suspension (entecavir).
Conclusion: In a large series from Northern Italy HBV reactivation after DAAs in HCV/HBV co-infected patients appears to be lower than previously reported-Prophylaxis or therapy with NUCs can avoid reactivation. However, the timing of withdrawal of NUCs prophylaxis remains to be clarified. Moreover, HBV positive patients must be closely monitored for the increased residual risk of HCC, after HCV eradication.

FRI402
Quantitative HBeAg varies in the different phases of HBV infection, and can predict therapeutic outcome in the setting of immunosuppression driven HBV reactivation

Lorenzo Piermatteo[1], Romina Salpini[1], Mohammad Alkhatib[1], Ada Bertoli[1], Alessandra Iuvara[2], Maria De Cristofaro[3], Giuseppina Cappiello[3], Carlotta Cerva[4], Carmine Minichini[5], Mario Starace[5], Mariantonietta Pisaturo[5], Nicola Coppola[5], Carla Fontana[2], Loredana Sarmati[4], Massimo Andreoni[4], Angelico Mario[6], Sandro Grelli[1,2], Francesca Ceccherini Silberstein[1], Carlo Federico Perno[7], Valentina Svicher[1]. *[1]University of Rome "Tor Vergata", Experimental medicine, Rome, Italy; [2]University Hospital of Rome "Tor Vergata", Microbiology and Virology Unit, Rome, Italy; [3]"Sandro Pertini" Hospital, Microbiology Unit, Rome, Italy; [4]University Hospital of Rome "Tor Vergata" Infectious Diseases Unit, Rome, Italy; [5]University of Campania "Luigi Vanvitelli", Medical, Surgical, Neurological, Metabolic and Aging Sciences, Naples, Italy; [6]University Hospital of Rome "Tor Vergata", Hepatology Unit, Rome, Italy; [7]University of Milan, Oncology and Haemato-oncology, Milan, Italy*
Email: piermatteolorenzo@gmail.com

Background and Aims: Qualitative HBeAg is a marker of active HBV replication and HBeAg loss is an important clinical and therapeutic end-point. Here, we quantify HBeAg level in different phases of HBV infection, its correlation with virological/biochemical markers and its role in predicting virological response to anti-HBV therapy.
Method: This study includes 86 eAg+ patients (pts): 20 with acute infection (AI) (HBcIgM+, median [IQR] HBV-DNA:8.3[7.9–8.7]logIU/mL, ALT:1556[142–2027]U/L), 14 with eAg+ chronic infection (CI) (median[IQR] HBV-DNA:8.1[4.7–8.5]logIU/mL, ALT<40U/L), 23 with eAg+ chronic hepatitis (CH) (median[IQR] HBV-DNA:8[6.8–8.5]logIU/mL, ALT:85[62–179]U/L) and 29 pts with immunosuppression-driven HBV reactivation (HBV-R) (median[IQR] HBV-DNA:6.8[5.5–8]logIU/mL, ALT:143[40–528]U/L, pre-reactivation status HBcAb+/HBsAg-). 15/29 pts with HBV-R were monitored for >12months after starting TDF or ETV therapy (median[min-max] months of follow-up: 21[12–54]). Quantitative HBeAg (qHBeAg) is assessed by DiaSorin LIAISON assay. Association of qHBeAg at HBV-R with the achievement of HBeAg loss after starting anti-HBV therapy is assessed by Fisher exact test.
Results: qHBeAg is higher in pts with HBV-R and AI (median[IQR] 930 [206–1945] and 754[210–3379]PEIU/mL) and decreases in pts with CI and CH (median[IQR] 655[0.9–1773] and 412[17–1850]).
qHBeAg positively correlates with qHBsAg in all the subsets of pts (Rho = 0.61, P = 0.003 for HBV-R, Rho = 0.78, P < 0.001 for AI, Rho = 0.71, P = 0.023 for CI and Rho = 0.75, P < 0.001 for CH) and with HBV-DNA only in CH (Rho = 0.59, P = 0.005). Moreover, qHBeAg negatively correlates with ALT in AI and CH (Rho = –0.59, P = 0.035; Rho = –0.42, P = 0.044), reflecting a modulation in HBeAg production by immune response.
Focusing on 15 pts with HBV-R starting anti-HBV therapy for >12 months, ALT normalization is achieved in 93% of pts while virological suppression and HBeAg loss in 60% and 53.3%, respectively. The combination of qHBeAg > 2000 PEIU/mL + qHBsAg > 52000 IU/mL at HBV-R is the only factor predicting no HBeAg loss during anti-HBV therapy (HBeAg loss in 0% pts with qHBeAg > 2000 PEIU/mL + qHBsAg > 52000 IU/mL vs 72.7% pts without this combination, P = 0.01, result not significant considering qHBeAg and qHBsAg separately).
Conclusion: HBeAg levels differ during the natural history of HBV infection and according to the extent of immunological pressure. In the setting of HBV reactivation, HBeAg levels can be useful in predicting virological response to anti-HBV therapy under iatrogenic immunosuppression.

FRI403
Development of a highly sensitive multiplex platform assay to monitor low levels of HBV DNA and pgRNA in samples from patients with chronic hepatitis B

Qi Huang[1], Ran Yan[1], Dawei Cai[1], Xuman Tang[1], Xiang Xu[1], Richard Colonno[1]. *[1]Assembly Biosciences, South San Francisco, United States*
Email: richard@assemblybio.com

Background and Aims: HBV DNA levels, a surrogate of virus replication, and pregenomic RNA (pgRNA), a surrogate of cccDNA levels, are the strongest predictors of treatment response and clinical relapse. Current assays, such as the COBAS (AmpliPre/Cobas Taqman HBV test v2), quantitate HBV DNA levels ≥20 IU/mL, but are insufficient to monitor loss of residual virus in HBV patients on NrtI therapy. No commercialized assays are approved to detect plasma HBV pgRNA levels. More sensitive assays are clearly needed to guide treatment discontinuation decisions.

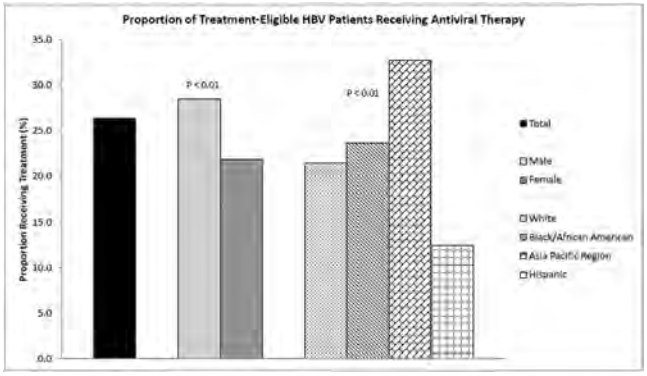
Method: Viral nucleic acids were purified from patient serum or plasma with a QIA Amp MinElute Viral Vacuum Kit. HBV DNA + pgRNA were quantified by RT-(q)PCR with the dual pan-genotypic primer probes. Highly sensitive PCR (HBV DNA) and RT-PCR (HBV DNA + pgRNA) assays were developed and calibrated against the WHO international standard for HBV DNA. Both PCR and RT-PCR products were sequenced for genotyping and resistance monitoring purpose.
Results: HBV DNA and pgRNA assay sensitivity and linearity were evaluated using an HBV GT B plasmid, AcroMetrix HBV GT E panel, and clinical samples containing a wide range of HBV DNA concentrations. For qPCR and RT-qPCR assays, the linear range was 2–9 $\log_{10}$ copies/mL, using 0.1 mL of serum/plasma. For the HBV PCR (DNA) and RT-PCR (DNA + pgRNA) "target detection" (TD) assays, pan-genotypic primers were designed to the conserved region of HBx and Core proteins. These protein regions were amplified by PCR and RT-PCR, respectively, separated by ethidium bromide agarose gels, and analysed by population sequencing. HBV nucleic acid TD was confirmed with sequence analysis aligned with pre-treatment sample sequences. Results from this dual probe qPCR assay were 5 times more sensitive than the COBAS assay, with HBV DNA detected in 22 additional samples from a panel of 69 clinical samples from NrtI-suppressed patients scoring "Target Not Detected" using the COBAS assay. These highly sensitive PCR (DNA) and RT-PCR (DNA + pgRNA) assays detected a single copy of HBV genome plasmid and HBV DNA down to 2–5 IU/mL.
Conclusion: The multiplex HBV nucleic acid assay platform allows simultaneous quantification and detection of HBV DNA and pgRNA with improved sensitivity and accuracy. Constant undetectable levels of total HBV nucleic acid level may be used for monitoring loss of key viral biomarkers on treatment and guiding discontinuation decisions.

FRI404

Very low rates of receiving antiviral therapy among treatment eligible chronic hepatitis B virus infected patients

Robert Wong[1], Mamta Jain[2], George Therapondos[3], Bolin Niu[4], Onkar Kshirsagar[5], Mae Thamer[5]. *[1]Alameda Health System Highland Hospital, Oakland, United States; [2]UT Southwestern Medical Center, Dallas, United States; [3]Ochsner Health System, New Orleans, United States; [4]Metrohealth Hospital, Cleveland, United States; [5]mtppi, Bethesda, United States*
Email: robertwong123@gmail.com

Background and Aims: Delays in initiation of antiviral therapy for chronic hepatitis B virus (CHB) patients contributes to continued disease progression to cirrhosis and development of hepatocellular carcinoma. CHB treatment rates are particularly sub-optimal among ethnic minority and immigrant populations, which are the highest risk groups for CHB. We aim to evaluate treatment eligibility and treatment rates among a large ethnically diverse multi-center adult CHB population.
Method: We retrospectively evaluated adults with CHB at four urban safety-net heath systems from January 1, 2010 to December 31, 2015, with a minimum 2-year follow-up. CHB was identified with ICD-9/10 diagnosis coding and confirmed with laboratory data. CHB treatment eligibility was determined using American Association for the Study of Liver Diseases criteria, which included assessment of hepatitis B virus (HBV) E antigen (HBeAg) status, serum alanine aminotransferase, HBV viral load, and fibrosis stage. Comparison of treatment eligibility and CHB treatment rates among eligible patients were performed using chi-square testing, and adjusted multivariate Cox proportional hazards models evaluated for predictors of receiving CHB treatment among eligible patients. Statistical significance was met with $p < 0.05$.
Results: Among 5,157 CHB patients (54.7% men, 35.7% white, 34.6% African American, 22.3% Asian, 7.7% Hispanic), 25.8% had cirrhosis,14.2% HIV co-infection, and 20.5% with HCV co-infection. Overall, 46.8% were eligible for CHB treatment, with significantly higher rates of treatment eligibility among men compared to women (58.2% vs. 32.9%, $p < 0.001$) and similar eligibility across race/ethnicity. Among treatment eligible patients, 26.4% received CHB treatment and only 10.0% received CHB treatment within 6 months of becoming eligible. Compared to men, women with treatment-eligible CHB were significantly less likely to receive therapy (21.8% vs. 28.5%; OR 0.72, 95% CI 0.58–0.91, $p < 0.01$) and Asians were significantly more likely to be treated compared to whites (32.7% vs. 21.4%; OR 1.51, 95% CI 1.12–2.04, $p < 0.01$).



Conclusion: Among a large, ethnically diverse multi-center cohort of CHB patients, only 26.4% of treatment eligible patients received CHB treatment. Women were the least likely to be treated, with nearly 80% of treatment-eligible not receiving therapy. Similarly, nearly 70% of treatment eligible Asians and 80% of treatment eligible whites and African Americans did not receive HBV treatment.

FRI405

Impact of hepatitis B virus-related immune reconstitution inflammatory syndrome on HBsAg loss in patients co-infected with human immunodeficiency virus

Sachiyo Yoshio[1], Shiori Yoshikawa[1], Taizo Mori[1], Hironari Kawai[1], Yuichi Yoshida[1], Yuriko Tsutsui[1], Taiji Yamazoe[1], Yosuke Osawa[1], Hiroyuki Gatanaga[2], Tatsuya Kanto[1]. *[1]National Center for Global Health and Medicine, Research Center for Hepatitis and Immunology, Chiba, Japan; [2]National Center for Global Health and Medicine, AIDs Clinical Research Center, Tokyo, Japan*
Email: sachiyo@hospk.ncgm.go.jp

Background and Aims: HBsAg loss, defined as functional cure, is an ideal therapeutic goal for chronic hepatitis B patients. In patients with HIV/HBV co-infection, liver-related mortality is higher than those with HIV or HBV mono-infection. It is thus strongly required to suppress HBV replication, or hopefully achieving HBsAg loss, to improve long-term prognosis in co-infected patients. After starting antiretroviral therapy (ART), HBV-related immune reconstitution syndrome (HBV-IRIS) occurs in some patients, which is clinically diagnosed as hepatic flare but without increase of HBV titers. However, it is yet to be determined the predictive markers of HBV-IRIS and its impact on the clinical course of HBV/HIV co-infection. We aimed to clarify these issues.
Method: We enrolled 56 HIV-infected subjects (median age, 41 years; $CD4^+$T cell count, 209 cells/μl). who had been HBsAg-positive for more than 6 months at the time of starting ART (HBeAg-positive/negative: 36/20). We observed patients for >3 years thereafter (median observational period, 9.1 years). Hepatic flare of HBV-IRIS was defined by an increase of ALT >5 × ULN, or ALT elevation of >200 IU/L from the baseline, which occurred within 12 months from the beginning of ART. We examined the correlation between clinical and viral markers and compared them between patients with and without HBV-IRIS.
Results: ourteen (25%) patients developed HBV-IRIS (average time to flare, 108 days; average ALT at flare, 592 IU/L). As predictors of HBV-

IRIS occurrence, younger age, increase of CD4 counts at one month after beginning ART (ΔCD4), and the regimens containing integrase inhibitors (INSTIs) were determined to be significant. Our new HBV-IRIS prediction model using age, ΔCD4 and INSTI (yes/no) distinguished HBV-IRIS patients from non-HBV-IRIS patients with an ROCAUC of 0.899, a sensitivity of 78.6%, and a specificity of 87.8%. The cumulative rate of HBeAg seroconversion in patients with HBV-IRIS was significantly higher than those in patients without HBV-IRIS (Log-rank, $p < 0.0001$, HR = 4.4). Furthermore, patients with HBV-IRIS subsequently achieved a significantly higher rate of HBsAg loss than those without HBV-IRIS (Log-rank, $p < 0.0001$, HR = 5.5). Uni-and multivariate analysis revealed that HBV-IRIS was the only contributing factor for HBsAg loss. All patients who showed >2 log reduction in HBsAg within one month after the onset of HBV-IRIS achieved HBsAg loss.

Conclusion: In HIV/HBV co-infected patients, age, an increase of CD4, and INSTI usage are predictors of HBV-IRIS occurrence. HBV-IRIS is associated with HBsAg loss, supporting the notion that immune reconstitution accompanying beneficial ALT flare is a key for attaining functional cure.

FRI406

Response to a double dose (40 mcg) and an accelerated schedule (0-1-2 months) of hepatitis B vaccine in patients with advance cirrhosis. A prospective study

Sergio Rodríguez-Tajes[1,2], Anna Pocurull[1], Sabela Lens[1,2], Zoe Mariño[1,2], Ana Alonso[1], Anna Vilella[3], Xavier Forns[1,2]. *[1]Hospital Clínic de Barcelona, IDIBAPS, University of Barcelona, Liver Unit, Barcelona, Spain; [2]Ciberehd; [3]Hospital Clínic de Barcelona, University of Barcelona, Preventive Medicine Unit, Barcelona, Spain*
Email: sergio.tajes@gmail.com

Background and Aims: The hepatitis B (HBV) vaccine is recommended in unvaccinated adults at high risk for HBV infection, including those with cirrhosis, to prevent HBV infection from triggering serious complications or death. However, the efficacy of HBV vaccine at a standard dose is low in patients with cirrhosis. Our aim was to evaluate the response to a double dose/accelerated schedule HBV vaccine in patients with decompensated cirrhosis.

Method: Prospective study including consecutive patients with liver cirrhosis admitted to the hepatology ward between March 2017 and April 2019. After assessing the immune status against HBV, all anti-HBs negative patients without exclusion criteria (HBsAg or antiHBc positive, age >75 years, hepatocellular carcinoma BCLC B-D, life expectancy <3 months) were offered HBV vaccination. The first dose of the HBVAXPRO 40mcg vaccine was administered during admission, and at month 1 and 2 in the Preventive Medicine Unit. After the first vaccination cycle patients with an anti-HBs <10 U/ml were offered a second vaccination schedule (40 mcg, 0-1-2 months).

Results: 496 patients were analysed; 91 (18.3%) were anti-HBs positive, and in 182 (45%) vaccination was not considered due to exclusion criteria. The vaccine was indicated to 207 patients. Ninety-nine (48%) completed the first cycle of vaccination, 28 died or were transplanted, 55 never attended and 25 did not complete the schedule due to their own decision or loss to follow-up. Thus, the acceptance rate was 56% (51% in alcohol consumers and 69% in the rest, $p < 0.05$). Of the 99 who completed the vaccine schedule, 63% were men, age 61 (54–67) years. The etiology of cirrhosis was alcohol (45%), hepatitis C (18%), NASH (14%) or autoimmune (8%). 72% were Child-Pugh (CP) B-C, 32% had diabetes, 33% were smokers and 23% alcohol consumers. By protocol, response (anti-HBs >10 U/ml) to the first cycle of vaccination was 22% and after the second schedule it increased to 61% (response to the second cycle 43%). 19% had a response greater than 100 IU/ml. The intention to treat response was 20.3% (42 out of 207 patients). No differences were found in the response according to the CP stage (68%, 62% and 50% for CP A, B and C respectively). The only predictor of non-response was autoimmune etiology (0% in the first cycle and 40% in the second cycle, per protocol).

Conclusion: This is the biggest prospective study evaluating HBV vaccination response in cirrhotic patients. More than 80% of patients with advanced cirrhosis admitted to a referral hepatology unit were unprotected against HBV. The response to a double dose and accelerated cycle of HBV vaccine was low (22%), but it improved significantly (61%) after a second cycle. Nevertheless, the low intention to treat response reinforces clinical guideline recommendation, which is HBV vaccination of patients with liver diseases before the development of cirrhosis.

FRI407

Presence of significant histopathology in HBeAg-positive chronic infection patients identified by four international guidelines: a Chinese multi-center study

Yidi Jia[1], Haoxiang Zhu[1], Xun Qi[2], Minhui Dong[1], Xueping Yu[3], Jingjing He[1], Jingwen Wu[1], Jing Li[1], Xueyun Zhang[1], Richeng Mao[1], Yanli Qin[1], Yuxian Huang[1], Jie Yu[1], Jiming Zhang[1]. *[1]Huashan Hospital Affiliated to Fudan University, Department of Infectious Diseases, Shanghai, China; [2]Shanghai Public Health Clinical Center, Department of Hepatitis Diseases, Shanghai, China; [3]The First Hospital of Quanzhou Affiliated to Fujian Medical University, Department of Infectious Diseases, Quanzhou, China*
Email: jmzhang@fudan.edu.cn

Background and Aims: HBeAg-positive chronic hepatitis B virus (HBV) infection, previously termed as "immune tolerant" phase, was defined with different threshold levels of HBV DNA and alanine aminotransferase (ALT) by international guidelines. In this study, we aimed to retrospectively analyze the performance of these guidelines in a Chinese multi-center cohort.

Method: From 2006 to 2018, a total of 1116 HBeAg-positive and treatment-naïve Chinese patients with liver biopsy samples were reviewed. We distinguished the HBeAg positive chronic infection patients from the others by ALT and HBV DNA threshold recommended by EASL (European Association for the Study of the Liver 2017), AASLD (American Association for the Study of Liver Diseases 2018), APASL (Asian-Pacific Association for the Study of the Liver 2015), and WHO (World Health Organization 2015). Among the patients with ALT ≤ 2 upper limit of normal (ALT ≤ 80 U/L, corresponding to EASL 2017), a liver biopsy with minimal or no liver necroinflammation or fibrosis ($G \leq 1$ and $S \leq 1$, Scheuer scoring system)was used as "gold standard" of a genuine HBeAg-positive chronic infection phase.

Results: The patients fulfilling each guideline criteria were grouped: EASL (ALT < 40 U/L and HBV DNA HBV DNA ≥ 107 IU/mL, n = 112), AASLD (ALT < 35 for men and 25 U/L for women and HBV DNA ≥ 106 IU/mL, n = 105), APASL (ALT < 40 U/L and HBV DNA ≥ 20000 IU/mL and age <30 y, n = 94), WHO (ALT <30 U/L for men and 19 U/L for women and HBV DNA ≥ 20000 IU/mL, n = 100). In applying the EASL, AASLD, APASL, and WHO criteria, the percentage of patients with significant histopathology ($G \geq 2$ or $S \geq 2$) was 35.7%, 30.5%, 45.7% and 42% respectively. The sensitivity and specificity values for HBeAg-positive chronic infection diagnosis were 75%, 67%, 15%, 62% and 95%, 94%, 96%, 94%, respectively. The EASL criteria (area under the receiver operating characteristic [AUROC] curve, 0.70; 95% confidence interval [CI], 0.65–0.74) performed better than AASLD criteria (AUROC, 0.66; 95% CI, 0.61–0.71), APASL criteria (AUROC, 0.64; 95% CI, 0.59–0.69) and WHO criteria (AUROC, 0.63; 95% CI, 0.58–0.68).

Conclusion: Though we couldn't deny the presence of significant histopathology in HBeAg-positive Chronic infection patients identified by the guidelines, ALT and HBV DNA threshold by EASL performed a better role in identifying HBeAg positive Chronic infection phase in Chinese Patients with Hepatitis B, compared with AASLD, APASL and WHO criteria.

Evaluation of page-b and modified page-b scores to guide hepatocellular carcinoma surveillance in chronic hepatitis B patients on antiviral therapy - a territory-wide study of 32,150 subjects

Terry Cheuk-Fung Yip[1], Grace Lai-Hung Wong[1], Vincent Wai-Sun Wong[1], Yee-Kit Tse[1], Yan Lilian Liang[1], Vicki Wing-Ki Hui[1], Hye Won Lee[2], Henry Chan[1]. [1]*The Chinese University of Hong Kong, Institute of Digestive Disease, Department of Medicine and Therapeutics, Hong Kong, Hong Kong;* [2]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South*

Email: hlychan@cuhk.edu.hk

Background and Aims: PAGE-B and modified PAGE-B (mPAGE-B) scores are developed to predict risk of hepatocellular carcinoma (HCC) in patients on nucleos(t)ide analogue therapy. However, how and when to use these risk scores in clinical practice is uncertain.

Method: Consecutive adult patients with chronic hepatitis B who had received entecavir or tenofovir for at least 6 months between January 2005 and June 2018 were identified from a territory-wide database in Hong Kong. Performance of PAGE-B and mPAGE-B scores on HCC prediction at 5 years was assessed by area under the time-dependent receiver operating characteristic curve (AUROC), and different cut-off values of these two scores were evaluated by survival analysis adjusted for competing risk of death and liver transplantation.

Results: Of 32,150 identified chronic hepatitis B patients, 20,868 (64.9%) were male. Their mean age was 53.0 ± 13.2 years; 4,625 (14.4%) had cirrhosis. At a median (interquartile range) follow-up of 3.9 (1.8–5.0) years, 1,532 (4.8%) patients developed HCC. The AUROC (95% confidence interval [CI]) of PAGE-B and mPAGE-B scores to predict HCC at 5 years was 0.77 (0.76–0.78) and 0.80 (0.79–0.81), respectively ($p < 0.001$). Patients were classified as low, intermediate, and high HCC risk by the suggested cut-off values of PAGE-B and mPAGE-B scores (Figure). 9,417 (29.3%) patients were classified as low HCC risk by either PAGE-B or mPAGE-B scores; their 5-year

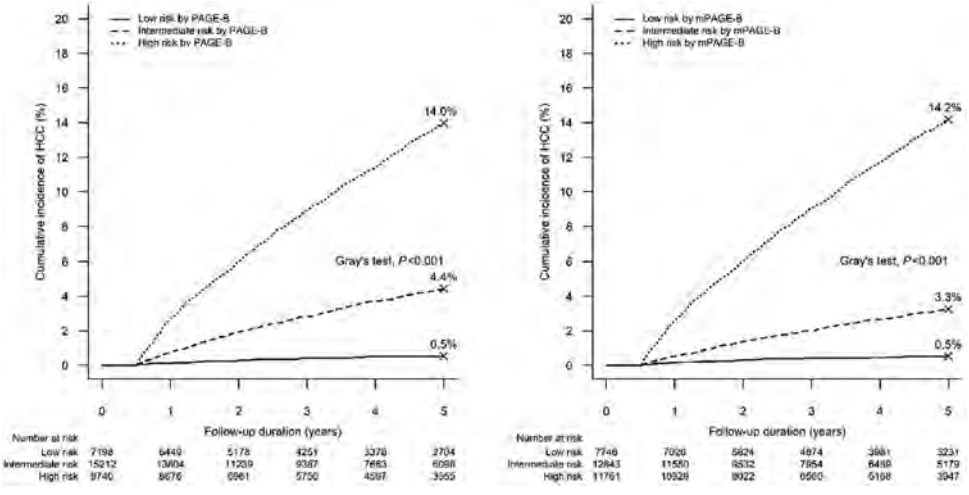

Figure: (abstract: FRI410)

cumulative incidence (95% CI) of HCC was 0.6% (0.4%–0.8%). This classification achieved a negative predictive value (NPV) (95% CI) of 99.5% (99.4%–99.7%) to exclude patients without HCC development in five years. The AUROC of PAGE-B and mPAGE-B scores at 2-year on-treatment to predict HCC was 0.78 (0.76–0.79) and 0.81 (0.79–0.82), respectively, which was comparable to that at baseline. Among 4,625 cirrhotic patients, 230 (5.0%) patients were classified as low HCC risk by either PAGE-B or mPAGE-B scores; their 5-year cumulative incidence (95% CI) of HCC was 5.6% (2.9%–9.5%). This classification achieved a NPV (95% CI) of 95.2% (91.4%–97.5%) to exclude patients without HCC development in five years.

Conclusion: PAGE-B and mPAGE-B scores can be applied to identify patients who have low risk of HCC development on antiviral therapy. These patients may be considered exemption from HCC surveillance due to their very low HCC risk. Caution should however be taken for patients who have liver cirrhosis.

FRI411

Clinical effectiveness of a newly developed and fully automated high-sensitive hepatitis B core-related antigen assay for monitoring nucleos(t)ide analogues therapy in hepatitis B envelope antigen-negative patients

Takako Inoue[1], Kentaro Matsuura[2], Etsuko Iio[2], Kei Fujiwara[2], Shintaro Ogawa[3], Chiharu Ohue[4], Shintaro Yagi[4], Katsumi Aoyagi[4,5], Yasuhito Tanaka[1,3]. *[1]Nagoya City University Hospital, Department of Clinical Laboratory Medicine, Nagoya, Japan; [2]Nagoya City University Graduate School of Medical Sciences, Department of Gastroenterology and Metabolism, Nagoya, Japan; [3]Nagoya City University Graduate School of Medical Sciences, Department of Virology and Liver Unit, Nagoya, Japan; [4]Advanced Life Science Institute, Inc., Research and Development Department, Hachioji, Japan; [5]Fujirebio Inc., Research and Development Division, Tokyo, Japan*
Email: tinoue@fg8.so-net.ne.jp

Background and Aims: Hepatitis B core-related antigen (HBcrAg) is one of important biomarkers that have an important role in chronic hepatitis B (CHB). A fully automated high-sensitive chemiluminescent enzyme immunoassay for detection of HBcrAg has been newly developing in Japan. Our aim is to demonstrate the clinical utility of the improved HBcrAg assay for monitoring the effect of nucleos(t)ide analogues (NA) therapy in hepatitis B envelope antigen (HBeAg)-negative patients.

Method: In this study, the performance of high-sensitive HBcrAg assay (HS-HBcrAg, Fujirebio, Inc.) was compared with that of conventional HBcrAg assay (Cv-HBcrAg, Fujirebio, Inc.) for monitoring NA treatment in HBeAg-negative patients. The sensitivity of HS-HBcrAg (2.1 Log IU/mL) is approximately 10-fold higher than that of Cv-HBcrAg assay (3 Log IU/mL). The total of 250 CHB patients treated with NA were enrolled, and 176 HBeAg-negative patients out of them were examined in our cohort. 1) In 93 NA-treated patients who have been undetectable for HBV-DNA, HS-HBcrAg was examined at the point before treatment and last visit. 2) In 40 naïve inactive carriers (IC), HS-HBcrAg was examined at first visit and last visit. The median durations of two groups were 14.8 [2.8–17.6] years and 7.3 [0.7–19.8] years, respectively. The study protocol was approved by the appropriate institutional ethics review committees.

Results: 1) In the sera from 93 patients undetectable for HBV-DNA, baseline HBcrAg was undetectable in the sera from 41.9% (39/93) patients by Cv-HBcrAg. Meanwhile, in the sera from 96.8% (90/93) patients, HBcrAg was detectable by HS-HBcrAg. The sera from 59.1% (55/93) patients showed HS-HBcrAg with ≥3 Log IU/mL, and 37.6% (35/93) patients had HS-HBcrAg with 2.1–3 Log IU/mL, which might be undetectable by Cv-HBcrAg. Note that the undetectable rates of HS-HBcrAg in NA-treated patients were only 1.1% at the point before NA-treatment and 4.3% at last visit. Meanwhile, those of Cv-HBcrAg were 16.1% at the point before NA-treatment and 41.9% at last visit (Table). 2) In naïve IC, undetectable rates of HS-HBcrAg were 15% at baseline and 25% at last visit. Meanwhile, those of Cv-HBcrAg were 65% at baseline and 82.5% at last visit (Table).

Conclusion: Compared with Cv-HBcrAg, HS-HBcrAg is much higher sensitive and could quantify HBcrAg for a long time regardless of NA-treatment. HS-HBcrAg assay would be more useful for the monitoring anti-HBV therapies in HBeAg-negative patients.

FRI412

Clinical efficacy of a newly developed high-sensitive hepatitis B core-related antigen assay for monitoring hepatitis B virus reactivation

Takako Inoue[1], Shigeru Kusumoto[2], Shintaro Ogawa[3], Chiharu Ohue[4], Shintaro Yagi[4], Katsumi Aoyagi[4,5], Yasuhito Tanaka[1,3]. *[1]Nagoya City University Hospital, Department of Clinical Laboratory Medicine, Nagoya, Japan; [2]Nagoya City University Graduate School of Medical Sciences, Department of Hematology and Oncology, Nagoya, Japan; [3]Nagoya City University Graduate School of Medical Sciences, Department of Virology and Liver Unit, Nagoya; [4]Advanced Life Science Institute, Inc., Research and Development Department, Hachioji, Japan; [5]Fujirebio Inc., Research and Development Division, Tokyo, Japan*
Email: tinoue@fg8.so-net.ne.jp

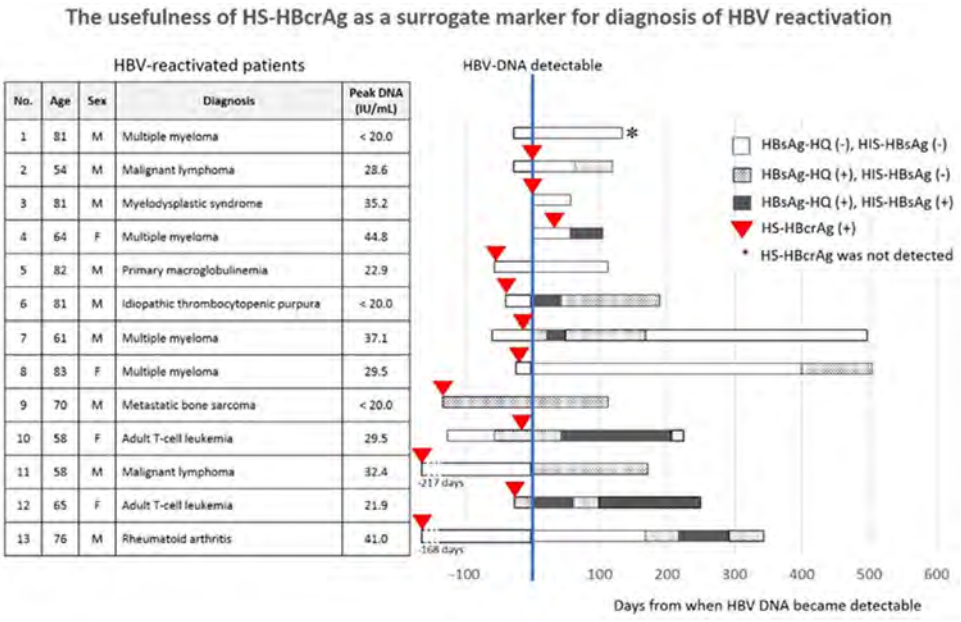
Background and Aims: Prevention and diagnosis of hepatitis B virus (HBV) reactivation is necessary for patients receiving systematic chemotherapy or immunosuppressive therapy. A fully automated high-sensitive chemiluminescent enzyme immunoassay for detection of HBcrAg has been newly developing in Japan. Our aim is to demonstrate the basic assessments of the new HBcrAg assay and present clinical utility of that for monitoring HBV reactivation to prevent the related hepatitis.

TABLE Undetectable rates of HBcrAg (%)

HBcrAg assay (Cut-off value, Log IU/mL)	Naïve IC (n=40)		NA-treated patients (n=93)	
	Baseline	Last visit	Baseline	Last visit
Cv-HBcrAg (< 3.0)	26 (65%)	33 (82.5%)	15 (16.1%)	39 (41.9%)
HS-HBcrAg (< 2.1)	6 (15%)	10 (25%)	1 (1.1%)	4 (4.3%)

Abbreviations: HBcrAg, hepatitis B core-related antigen; IC, inactive carriers; NA, nucleos(t)ide analogues; Cv-HBcrAg, conventional HBcrAg; HS-HBcrAg, high-sensitive HBcrAg.

Figure: (abstract: FRI411)



No.	Age	Sex	Diagnosis	Peak DNA (IU/mL)

13	76	M	Rheumatoid arthritis	41.0

Figure: (abstract: FRI412)

Method: A new high-sensitive HBcrAg assay (HS-HBcrAg, Fujirebio, Inc.) is more inexpensive than HBV-DNA test, and can measure HBcrAg within 30 minutes. The sensitivity of HS-HBcrAg (2.1 Log IU/mL) is approximately 10-fold higher than that of conventional HBcrAg assay (Cv-HBcrAg, Fujirebio, Inc.) (3 Log IU/mL). In this study, as fundamental examinations, specificity test for HS-HBcrAg, correlation analysis between HS-HBcrAg and Cv-HBcrAg, and linearity-of-dilution experiments of HS-HBcrAg were examined. After confirmation of the fundamental data, we enrolled 13 patients diagnosed as HBV reactivation during or after receiving systematic chemotherapy or immunosuppressive therapy. Their serial sera were examined by HS-HBcrAg, high-sensitive hepatitis B surface antigen (0.005 IU/mL, HBsAg-HQ, Fujirebio, Inc.) and conventional HBsAg (0.05 IU/mL) retrospectively to compare with the results of HBV-DNA (1.3 Log IU/mL). The study protocol was approved by the appropriate institutional ethics review committees.
Results: The specificity of HS-HBcrAg was 99.8% (494/495). Among 74 specimens positive for HBcrAg by both HS-HBcrAg and Cv-HBcrAg, correlation analysis between HS-HBcrAg and Cv-HBcrAg yielded the following values: $y = 1.00x + 0.10$, $r = 0.987$. Linearity-of-dilution experiments for HBcrAg-positive samples with high and low concentrations showed preferable results (% linearity for each: 99–101%). In our HBV-reactivated patients, the primary diseases were hematologic malignancies (10 patients), benign hematologic disease, autoimmune disease and solid cancer (1 patient each). Surprisingly, 9 of 13 patients with HBV reactivation showed earlier detection of HS-HBcrAg than HBV-DNA. Also, 9 HBV-reactivated patients showed earlier detection of HS-HBcrAg than HBsAg-HQ (Figure).
Conclusion: Fundamental and clinical examinations of HS-HBcrAg showed that HS-HBcrAg assay was reliable and useful as a surrogate marker for the monitoring HBV reactivation at early phase.

FRI413

Treatment advantage in HBV/HIV coinfection compared to HBV monoinfection in a South African cohort

Tongai Gibson Maponga[1], Anna Mcnaughton[2], Marije Van Schalkwyk[3], Susan Hugo[3], Chikezie Nwankwo[4], Jantjie Taljaard[3], Jolynne Mokaya[2], David Smith[2], Cloete Jansen van Vuuren[5], Dominique Goedhals[6], Shiraaz Gabriel[4], Monique Andersson[7], Wolfgang Preiser[1], Christo van Rensburg[4], Philippa Matthews[8]. *[1]Stellenbosch University, Division of Medical Virology, Cape Town, South Africa; [2]University of Oxford, Nuffield Department of Medicine, Oxford; [3]Stellenbosch University, Division of Infectious Diseases, Cape Town, South Africa; [4]Stellenbosch University, Division of Gastroenterology, Cape Town, South Africa; [5]University of The Free State, Division of Infectious Diseases, Bloemfontein, South Africa; [6]University of The Free State, Division of Virology, Bloemfontein, South Africa; [7]Oxford University Hospitals NHS Foundation Trust, Department of Infectious Diseases and Microbiology, Oxford, United Kingdom; [8]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom*
Email: philippa.matthews@ndm.ox.ac.uk

Background and Aims: Prompted by international targets for elimination of hepatitis B virus (HBV) infection, we performed a cross-sectional observational study of adults with chronic HBV (CHB) infection in Cape Town, South Africa. We characterised individuals with HBV monoinfection vs. those coinfected with HBV/HIV, to determine the effect of HIV coinfection, to evaluate the impact of current therapy and to shape improvements in clinical care as guidelines for antiviral therapy change over time.
Method: A cohort representing prevalent CHB was recruited at Tygerberg Hospital, Cape Town, South Africa, over one year (commencing July 2018). In this setting, antiviral therapy for HIV and HBV includes tenofovir disoproxil fumarate (TDF) as a first line agent. We recorded cross-sectional demographic, clinical and laboratory data. Ethical approval was provided by University of Oxford Tropical Research Ethics Committee and Stellenbosch University Human Research Ethics Committee.
Results: We prospectively recruited 112 adults with CHB; 55% were male, and 34% had HIV coinfection. Adults with HBV monoinfection were comparable to those with HBV/HIV coinfection in terms of age,

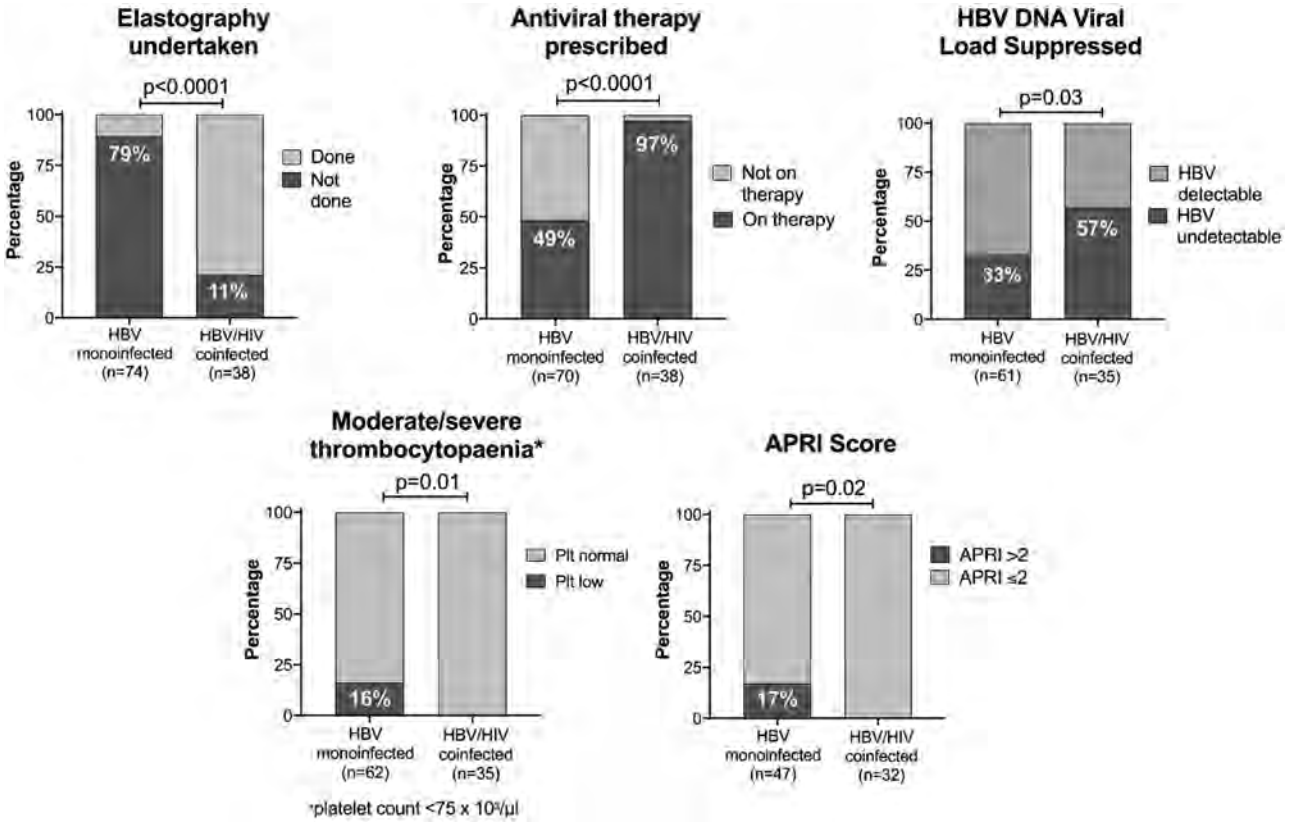

Fig 1: (abstract: FRI413): Comparison between HBV monoinfected and HBV/HIV coinfected adults.

sex, body mass and duration of antiviral therapy (p > 0.05 in each case). HBeAg-positive status was more common among those with coinfection (p = 0.01). However, compared to HBV/HIV coinfection, HBV monoinfected patients were consistently disadvantaged (Fig 1). HBV monoinfected patients were less likely to have been assessed by fibroscan (p < 0.0001), and less likely to be on antiviral therapy (p < 0.0001) compared to those with coinfection. The HBV monoinfected group were also more likely to have detectable HBV viraemia (p = 0.01), thrombocytopaenia (p = 0.01), elevated bilirubin (p = 0.002), and APRI score >2 (p = 0.02), compared to the coinfected group. Three cases of hepatocellular carcinoma were all in HBV monoinfection. Among 36 HBV monoinfected individuals not on therapy, 6 (17%) were treatment eligible based on local guidelines but had not been commenced on therapy.

Conclusion: Our results reflect systematic differences between management of HBV and HIV, and expose evidence of a consistent disadvantage for those with HBV monoinfection. This reflects late detection and referral to specialist services, and differences in guidelines. Enhanced advocacy, resources and infrastructure are required to optimise interventions for CHB.

FRI414

Clonal expansion of hepatocytes and state of hepatitis B virus DNA integration in patients with nucleos(t)ide analogue therapy

Ning Chow[1], Lung Yi Mak[1], Ching Lung Lai[1,2], Yan Yue James Fung[1,2], Wai-Kay Seto[1,2], Man-Fung Yuen[1,2], Danny Ka-Ho Wong[1,2]. *[1]The University of Hong Kong, Medicine, Hong Kong; [2]The University of Hong Kong, State Key Laboratory of Liver Research, Hong Kong*
Email: u3006113@connect.hku.hk

Background and Aims: HBV DNA integration and hepatocyte clonal expansion are possible mechanisms of hepatocarcinogenesis. While it has been suggested that nucleos(t)ide analogues (NUCs) treatment can reduce the risk of hepatocellular carcinoma, the effect of NUC on HBV DNA integration has not been examined. This study aimed to investigate the effect of 1 year of NUCs treatment on HBV DNA integration and hepatocyte clonal expansion.

Method: This study included 10 chronic hepatitis B patients with paired liver biopsies collected before treatment and after 1 year of NUCs treatment. HBV DNA integration was detected by inverse PCR. Hepatocyte clone size, which reflects the extent of HBV DNA integration, was measured using a semi-quantitative end-point dilution method.

Results: All 10 patients (7 males and 3 females; mean age 38 ± 10 years) received entecavir treatment. Six were hepatitis B e antigen (HBeAg)-positive and 4 were HBeAg-negative at baseline. HBV DNA integration was detectable in all 10 patients at baseline. The viral junctions of HBV DNA integration clustered at the HBV direct repeat regions (nucleotides 1698 to 1986), while integration junctions at human chromosomes 1, 7, 8, 11, 16, 20 and 21 were identified. HBV DNA integration was also detected after 1 year of treatment, and the site of HBV DNA integration remained unchanged in each of the patients at year 1. There was no significant association between hepatocyte clone size and patients' age at baseline. After 1 year of treatment, a significant reduction in hepatocyte clone size was seen (median hepatocyte clone size at baseline vs. at year 1: 1.17 × 106 vs 1.48 × 105; P = 0.005), with a median reduction of 78% (range 21%–95%) in clone size. At year 1, serum HBV DNA, intrahepatic total HBV DNA and covalently closed circular DNA were reduced by 5.2 log, 1.5 log and 0.5 log respectively, but their reductions did not significantly correlate with the magnitude of hepatocyte clone size reduction.

Conclusion: HBV DNA integration was detected in patients both before and after 1 year of entecavir therapy. However, hepatocyte clone size, which reflects the degree of HBV DNA integration, was significantly reduced after 1 year of treatment. This suggested that, in addition to reducing serum and intrahepatic HBV DNA, NUCs

treatment by reducing the extent of HBV DNA integration, may have an additional anti-oncogenic mechanism.

FRI415

Machine learning identifies immune profile to predict virological relapse after stopping nucleos(t)ide analogue therapy in HBeAg negative chronic hepatitis B

Maximilian Wübbolding[1,2,3], Juan Carlos Lopez Alfonso[2,4], Sebastian Binder[2,4], Christine Falk[5], Jennifer Debarry[2,6], Paul Gineste[7], Anke Kraft[1,2,3], Michael P. Manns[1], Benjamin Maasoumy[1], Heiner Wedemeyer[8], Michael Meyer-Hermann[2,4,9], Markus Cornberg[1,2,3,6], Christoph Hoener zu Siederdissen[1]. *[1]Hanover Medical School, Department of Gastroenterology, Hepatology, and Endocrinology, Hannover, Germany; [2]Centre for Individualised Infection Medicine (CiiM), Hannover, Germany; [3]German Center for Infection Research (DZIF), Hannover, Germany; [4]Helmholtz Centre for Infection Research, Department of Systems Immunology and Integrated Centre of Systems Biology, Braunschweig, Germany; [5]Hanover Medical School, Institute of Transplantation Immunology, Hannover, Germany; [6]TWINCORE, a joint venture of Helmholtz Centre for Infection Research and Hannover Medical School, Hannover, Germany; [7]Abivax, Paris, France; [8]University Hospital Essen, Department of Gastroenterology and Hepatology, Essen, Germany; [9]Technische Universität Braunschweig, Institute for Biochemistry, Biotechnology and Bioinformatics, Braunschweig, Germany*
Email: hoenerzusiederdissen.christoph@mh-hannover.de

Background and Aims: Discontinuation of nucleos(t)ide analogue (NA) treatment in HBeAg negative patients with chronic hepatitis B is associated with a significant risk for virological relapse (VR). Currently, the virological and immunological background for relapse is poorly understood and there is a lack of predictors. This study investigated the use of soluble immune markers (SIMs) in predicting virological relapse (HBV DNA > 2,000 IU/ml).

Method: In a post-hoc analysis of a prospective, multicenter therapeutic vaccination trial (ABX-203, NCT02249988) HBsAg, HBcrAg, and 47 SIMs were repeatedly determined before NA was stopped. Forty-three non-cirrhotic HBeAg negative non-vaccinated patients were included. To detect the highest predictive constellation of host and viral markers a supervised machine learning approach was used.

Results: VR (HBV DNA ≥ 2,000 IU/ml) occurred in 27 of 43 patients. The predictive value for VR of single SIMs at time point of NA stop was

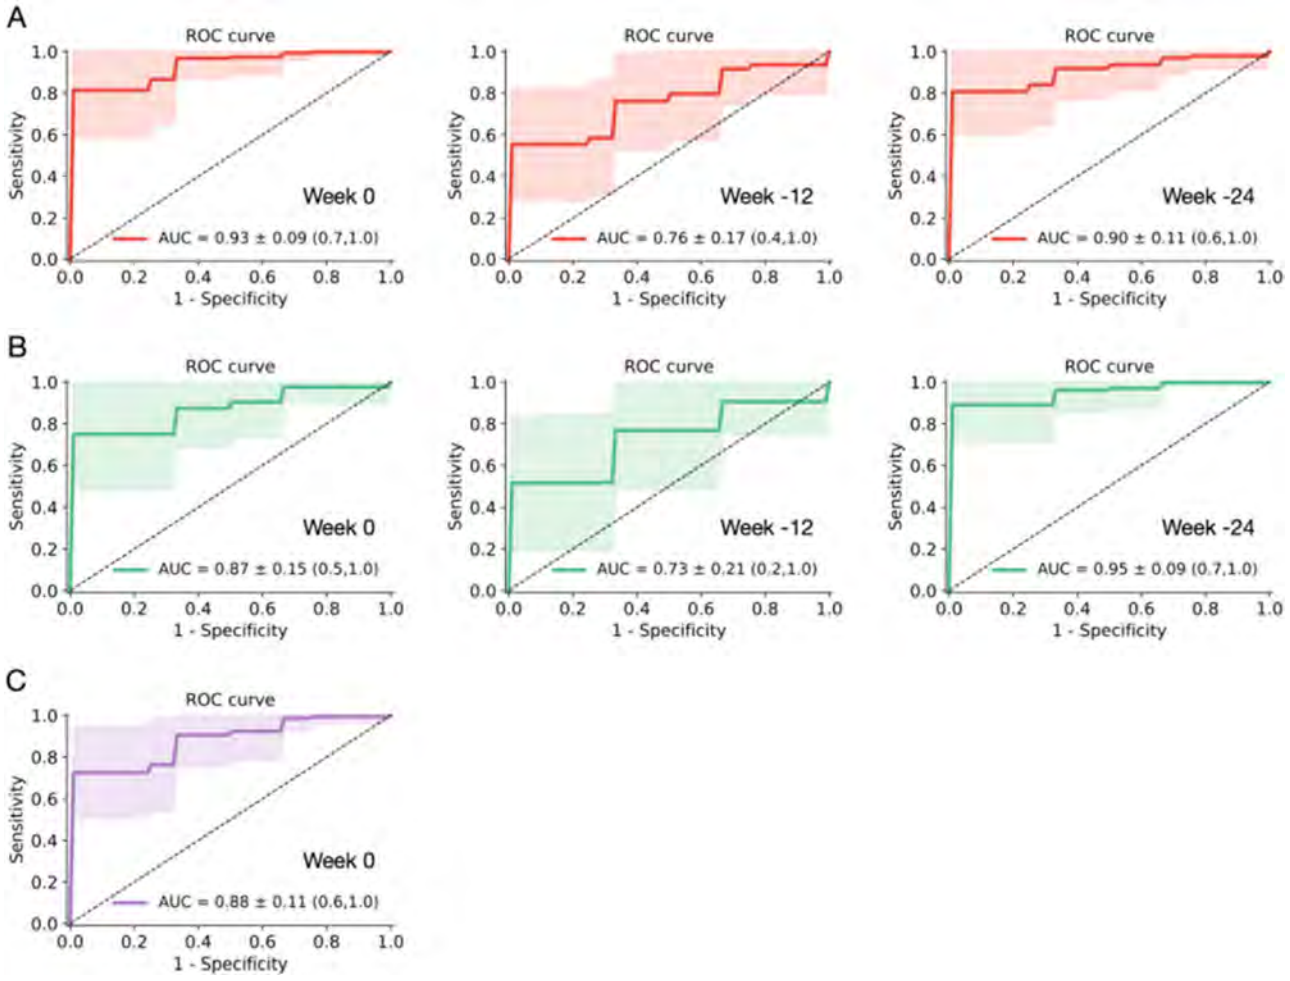

Figure: (abstract: FRI415): AUC values to predict virological relapse (HBV DNA ≥ 2,000 IU/ml) A) Sensitivity and specificity of 5 cytokines (IL-2, MIG, RANTES, SCF and TRAIL) at week 0, week -12 and week -24; B) Sensitivity and specificity of 4 cytokines and HBsAg (IL-2, RANTES, SCF, TRAIL and HBsAg) at week 0, week -12 and week -24; C) Sensitivity and specificity of 4 cytokines and HBcrAg (IL-2, RANTES, SCF, TRAIL and HBcrAg) at week 0, week -12 and week -24. IL-2: interleukin 2, MIG/CXCL9: monokine induced by gamma interferon, RANTES/CCL5: regulated on activation, normal T cell expressed and secreted; SCF: Stem cell factor, TRAIL: TNF-related apoptosis-inducing ligand.

best for IL-2, IL-17, and RANTES/CCL5 but with AUC of maximal 0.65. HBcrAg had a higher predictive power than HBsAg but lower than the SIMs. Applying a supervised machine learning algorithm allowed a remarkable improvement of relapse prediction. The combination of the five SIMs IL-2, MIG/CCL9, RANTES/CCL5, SCF, and TRAIL was highly reliable in predicting VR (0.93; 95% CI: 0.67–0.99). Predictive power of the cytokines remained high 12 and 24 weeks before treatment discontinuation (0.76, 0.48–0.99; 0.9, 0.56–0.99; respectively; Figure 1).

Conclusion: Host immune markers such as SIMs seem to be an underestimated marker for guiding treatment cessation in HBeAg negative CHB patients. Machine learning emerged as a valuable tool to predict SIM patterns that allow a precise identification of patients particularly suitable for NA cessation.

FRI416

Cessation of nucleos(t)ide analogues therapy in chronic hepatitis B: a systematic review and meta-analysis

Yandi Xie[1], Rui Jin[1], Guangjun Song[1], Hui Ma[1], Bo Feng[1], Lai Wei[2].
[1]*Peking University People's Hospital, Peking University Hepatology Institute, China;* [2]*Beijing Tsinghua Changgung Hospital, China*
Email: weelai@163.com

Background and Aims: To address the possibility of safe cessation of nucleos(t)ide analogues (NAs) therapy in chronic hepatitis B patients and to identify factors associated with off-NAs virological relapse (VR).

Method: A published work search was performed in order to identify all published studies including patients who discontinued NAs and were followed for ≥12 months. A systematic review and a meta-analysis were performed.

Results: Twenty-six studies involving 2573 patients who discontinued NAs were included. The pooled rate of off-NAs VR was 0,63, being lower in initially HBeAg-positive than HBeAg-negative patients (0.57 versus 0.62, P = 0.732). In view of the duration of follow up after NAs cessation, the pooled rates of VR were 0.47, 0.55, 0.61, 0.51, 0.73 and 0.64 at 6, 12, 24, 36, 48 and 60 months after NAs cessation, respectively, being relatively lower in initially HBeAg–positive (0.50, 0.55, 0.69, 0.57, 0.53, 0.68) than HBeAg-negative patients (0.31, 0.45, 0.55, 0.44, 0.48, 0.52) (P = 0.405). The pooled rates of biochemical relapse was 0.44, being lower in initially HBeAg-positive than HBeAg-negative patients (0.43 versus 0.48, P = 0.554). The pooled rates of hepatitis B surface antigen loss and seroconversion was 0.09 and 0.06, respectively. The pooled probabilities of VR at 12 months after NAs cessation were getting lower in studies defining VR by HBV DNA <200, <2000 and <20,000 IU/mL in all patients (0.80 versus 0.57 versus 0.39, P = 0.006) and initially HBeAg-negative patients (0.83 versus 0.68 versus 0.44, P < 0.001). The pooled rates of VR at 12 months after NAs cessation were significant different between duration of on-NAs virological response ≤24 months and >24 months in all patients (0.55 versus 0.41, P = 0.011), initially HBeAg-positive patients (0.59 versus 0.41, P = 0.031), and initially HBeAg-negative patients (0.53 versus 0.37, P = 0.025).

Conclusion: Safe cessation of NAs therapy seems to be feasible in a substantial proportion of CHB patients. On-NAs virological response >24 months reduces the risk of off-NAs VR.

FRI417

Prevalence of liver fibrosis in the natural course of chronic hepatitis B virus infection: a systematic review with meta-analysis

Yan Wang[1,2], Meihong Lin[1,3], Hai-Qiong Li[1,3], Lin Zhu[1,3]. [1]*Southern Medical University Nanfang Hospital, Institute of Hepatology, Department of Infectious Diseases and Hepatology Unit, Guangzhou, China;* [2]*Southern Medical University, Biomedical Research Center, Guangzhou, China;* [3]*Southern Medical University Zhujiang Hospital, The Second School of Clinical Medicine, Guangzhou, China*
Email: yanwang@i.smu.edu.cn

Background and Aims: There still lack systematic quantitative data on the risk of liver fibrosis across the natural course of chronic HBV infection (CHB). We conducted meta-analyses based on systematic literature review, aiming to determine the prevalence of different fibrosis status, including non-fibrosis (NF), significant fibrosis (SF), advanced fibrosis (AF), and cirrhosis, in the phases of viral infection defined by current clinical practice guidelines (CPG) (EASL2017, APASL2016, and AASLD2016).

Method: The review followed the MOOSE guidelines. We searched Cochrane library, EMBASE, PubMed, SCOPUS, and Web of Science from 1/1/1993 to 9/30/2018 for literatures with histologic data on liver fibrosis in CHB natural course. CHB course was defined based on current criteria for identifying infection phases as recommended by the CPGs, including the HBeAg-positive immune-tolerant (P1) and immune-active (P2), HBeAg-negative immune-inactive (P3) and immune-reactive (P4), and HBsAg-negative (P5) phases. A common fibrosis index was applied to translate the scores used in diverse histologic systems into stages from F0-F4. NF was then defined by F0, SF by F2-4, AF by F3-4, and cirrhosis by F4. Pooled prevalence rate was

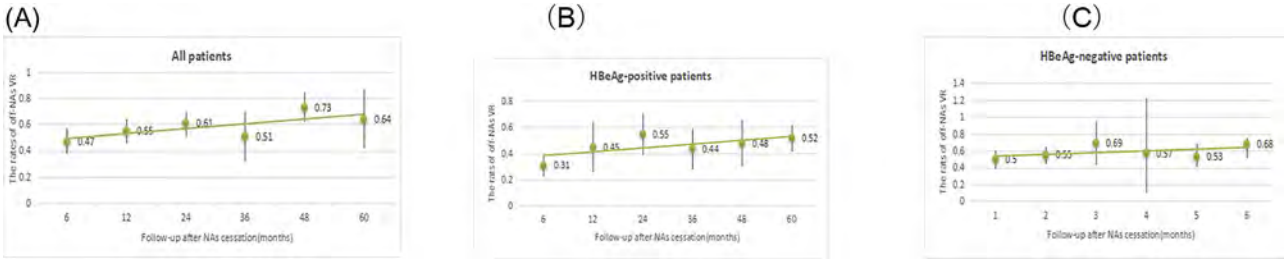

Figure: (abstract: FRI416): The rates of off-NAs virological relapse (VR) during follow-up after NAs cessation. Bars are 95% CI. Green lines are trend lines. (A) all patients,(B) HBeAg-positive patients, (C) HBeAg-negative patients.

Table 1: (abstract: FRI417): Estimated prevalence of fibrosis in CHB natural course

Phase	Patients number	Studies number	Basic characteristics				Fibrosis prevalence (%) (95% CI)			
			Age (years)	Male (%) (95% CI)	HBV DNA (IU/mL)	ALT (IU/L)	NF	SF	AF	Cirrhosis

[a]Without meta-analysis.

obtained from random-effects meta-analyses. Risks of bias were determined to identify quality of the studies.
Results: We identified 3,796 records by search strategy. A total of 41 eligible literatures were finally included. All had high-moderate quality. Of these, 9,718 adult participants from 13 countries were included in analyses, with 8,792 (90.1%) from Asia, 755 (7.8%) from Europe, 123 (1.3%) from US, and 82 (0.8%) from Africa. For each of the five phases, basic characteristics of participants and the estimated prevalence of NF, SF, AF, and cirrhosis were described in Table 1.
Conclusion: Fibrosis risk persists through CHB natural course. The present data can be used as supportive reference for clinical practice, guidelines complement, and investigation of non-invasive diagnosis.

FRI418
Estimating the clinical and economic burden of chronic hepatitis B (CHB) in the United States

Zobair Younossi[1,2], Radhika Tampi[1], Leyla Deavila[1], Rebecca Cable[1], Fatema Nader[3], Issah Younossi[3], Andrei Racila[1,3]. [1]*Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States;* [2]*Inova Health System, Department of Medicine, Center for Liver Diseases;* [3]*Center for Outcomes Research in Liver Diseases, Washington, DC*
Email: zobair.younossi@inova.org

Background and Aims: Hepatitis B virus (HBV) infection is a major cause of chronic liver disease and hepatocellular carcinoma worldwide. Over the past decade, new antiviral therapies have been developed which can lead to sustained HBV suppression, potentially improving clinical outcomes and patient-reported outcomes (PROs). Our aim was to estimate the clinical and economic burden of prevalent CHB in 10,000 50-year-old patients in the United States.
Method: We used a decision tree combined with Markov model with 1-year cycles and 20-year horizon to estimate the burden of CHB when treated with nucleos(t)ide analogs (NAs). The cohort entered the model in one of four sub-states of CHB – E antigen positive/negative (HBeAg +, –) and high and low serum HBV DNA. We included a recovered state (R), compensated and decompensated cirrhosis (CC & DCC), and hepatocellular carcinoma (HCC), first year post-liver transplant (oyPLT) and post-liver transplant (PLT). Patients could die from liver-related and background mortality (LRM & BM). Following AASLD 2018 treatment guidelines, we treated patients with high viral load, and assumed patients were treatment naïve, received monotherapy, with 100% adherence over model horizon. Transition probabilities were found through literature review. For treatment probability, we used the combined market share for the three major NAs utilized in HBV care which was 85% (Trio Health). We estimated health state costs by micro-costing and through literature review in 2019 USD with 3% annual discount. Average annual treatment costs and average reduction in HCC incidence were weighted by market share of the NAs. We conducted a univariate sensitivity analysis.
Results: At 85% treatment probability, economic burden of CHB is $149.7 million over 20 years, or $884 per person-year, and 1.4 thousand person-years spent with HCC. When reducing the probability of treatment to 10%, economic burden increased to $189.6 million or $1,254 per person-year and 3.5 thousand person-years spent with HCC. When increasing probability of treatment to 95%, economic burden increased to $151 million, or $887 per person-year and 1.2 thousand person-years spent with HCC.

	Deterministic Analysis	Univariate Sensitivity Analysis	
Treatment Probability	85%	10%	95%
Total Costs of CHB	$149,735,221	$189,612,355	$150,965,312
Costs per Person-Year	$884.31	$1,254.05	$887.33
Person-Years with HCC	1,412	3,498	1,247
Total Person-Years Accumulated	169,324	151,200	170,134

Conclusion: These data suggest that the burden of CHB in the United States is driven by the incidence and costs of HCC and LT. Sensitivity analysis demonstrates that lower costs of treatment with a 10% treatment probability are offset by the increased incidence of HCC and associated costs, increasing costs per-person year by 42% even with decrease in total person-years accumulated by 11% due to high mortality rate of HCC.

Viral hepatitis C: Post SVR and long term follow up

FRI419
Exaggerated risk of vitamin B12 deficiency after HCV eradication with direct-acting antivirals

Diego Casas Deza[1,2], Vanesa Bernal Monterde[1,2], Eva Fernandez Bonilla[1], Silvia Espina[3], Marta Fernández Esgueva[4], Ana Martinez-Sapiña[4], Javier Fuentes[1,2], Jose M Arbones Mainar[2,5]. [1]*Hospital Universitario Miguel Servet, Gastroenterology and hepatology, Zaragoza, Spain;* [2]*IIS Aragon. Unidad de Investigación Clínica HUMS;* [3]*Hospital Santa Barbara, Soria, Spain;* [4]*Hospital Universitario Miguel Servet, Microbiology, Zaragoza, Spain;* [5]*Hospital Universitario Miguel Servet, Unidad de investigación traslacional, CIBEROBN, Instituto Aragonés de Ciencias de la Salud (IACS), Zaragoza., Zaragoza, Spain*
Email: 630552@unizar.es

Background and Aims: Elevated vitamin B12 levels have been considered as a predictive marker of acute and chronic liver disease of different etiologies. However, no reports have investigated the variation of vitamin B12 after the treatment of the underlying hepatic disease. Objetive: To evaluate the changes in vitamin B12 levels and the prevalence of its deficiency (vitamin B12 <180 pg/ml) after the eradication of HCV with direct-acting antivirals (DAA).
Method: Longitudinal prospective study including all treatment naive patients with DAA therapy for HCV eradication during the year 2018 in the Gastroenterology Department at the University Hospital Miguel Servet (Zaragoza. Spain). Basal vitamin B12 and homocysteine levels were analyzed and then, at the end of treatment, SVR 12, and SVR 48. This study was approved by our Institutional Review Board and all participants signed informed consent forms.
Results: 167 patients with HCV were included: 93 (58.12%) F1, 21 (13.12%) F2, 24 (15%) F3 and 22 (13.75%) F4. 52.7% were women. The median age was 53 years (range 20–87). Vitamin B12 levels (median [interquartile range]) decreased significantly during follow-up (323 pg/ml [246; 388] at baseline *vs.* 282 pg/ml [213; 344] in SVR48, p = 0.004). In turn, homocysteine tended t to increase (9.95 μmol/l [8.35; 11.7] baseline *vs.* 10.6 [9.13; 12.8] SVR48, p = 0.085).
The prevalence of vitamin B12 deficit increased significantly (3.1% baseline, 13.33% in SVR and 12% in SVR 48, (p = 0.009), while folic acid levels did not show significant changes during the follow-up (8.15 ng/mL [6.06; 11.4] *vs.* 7.50 [5.34; 10.4], p = 0.117).

Table 1: Vitamin B12, folic acid and homocysteine along the follow up.

Variable	Basal	SVR 48	P *
Median [interquartilic range]			
Vitamin B12 (pg/ml)	323 [246;388]	282 [213;344]	**0.004**
Homocysteine (μmol/l)	9.95 [8.35;11.7]	10.6 [9.13;12.8]	0.085
Folic acid (ng/mL)	8.15 [6.06;11.4]	7.50 [5.34;10.4]	0.117
B12 deficit (%)	3.1	12	**0.009**

*p-value for the media comparation (t-Student) or proportions (Chi^2).

Conclusion: DAA-treated patients have a progressive decrease in vitamin B12 levels after HCV eradication, with an increase in the prevalence of B12 deficiency one year after treatment. The

relationship of this decrease with the improvement of hepatic damage in patients with SVR is still unknown. However, given the clinical repercussions of vitamin B12 deficiency, routine monitoring of B12 is advised after DAA treatment.

FRI420

Risk of hepatocellular carcinoma recurrence in patients treated with direct acting antiviral therapy

Shimaa Kilsny[1], Asmaa Gomaa[1], Aliaa Sabry[1], Inas Moaz[1], Sameera Ezzat[1], Mohamed Elwaraky[1], Gamal Badra[1], Imam Waked[1].
[1]*National Liver Institute, Egypt*
Email: aibrahim@liver-eg.org

Background and Aims: The impact of direct acting antiviral (DAA) therapy on recurrence of HCC is controversial. In this study, we assessed rate and pattern of hepatocellular carcinoma (HCC) recurrence among DAA treated patients.

Method: This study included 392 patients with HCV-related HCC and complete response to resection, local ablation or transplantation, of whom 92 received DAA therapy for HCV, and followed up at a single tertiary referral center up to 30 months. HCC recurrence rates were calculated in DAA treated and untreated patients. Cox's regression analysis was used to identify risk factors associated with recurrent HCC among patients, and the pattern of HCC recurrence was compared in both groups.

Results: Baseline Child Pugh score (CTP), BCLC stage, HCC treatment modality, alpha-fetoprotein (AFP) level and platelet count were similar between DAA treated and untreated groups ($p > 0.05$). Follow-up after complete ablation was 155.8 person-years (PY) for DAA treated patients and 319.3 PY for DAA untreated patients. HCC recurred in 38 DAA-treated patients (41.3%) and 93 untreated patients (31%). The recurrence rate per 100 PY was 24.38 (95% CI, 17.7–33.5) for DAA treated patients vs. 31.01 (95% CI, 25.5–37.8) for untreated patients. The 1- and 2- year cumulative recurrence rates in the DAA cohort were 17.6% and 30.3%, compared to 28.3% and 48.3% in untreated patients, $p = 0.34$. Multivariate analysis showed that DAA therapy was not associated with increased HCC recurrence (adjusted HR = 0.91; 95% CI, 0.61–1.36), after adjustment for age, gender, CTP, AFP level, initial tumor burden, and HCC therapy. No difference in pattern of recurrences was noticed between both groups regarding size of recurrent tumor (30.8% of DAA treated recurrence vs 35.9%, of recurrence in DAA untreated patients were within Milan criteria; $p = 0.57$) or treatment received for recurrence (28.2% and 36.6% received potentially curative HCC therapy for recurrent HCC, $p = 0.34$). In patients treated with DAA, initial tumor diameter >3 cm was the only significant predictor of recurrent HCC.

Conclusion: In patients with complete response to HCC treatment, DAA therapy was not associated with increased recurrence rate. HCC recurrence patterns were similar in DAA-treated and untreated patients.

FRI421

Evidence of declining HCV transmission in Australia following scale-up of direct acting antiviral therapy

Jisoo Amy Kwon[1], Gregory Dore[1], Behzad Hajarizadeh[1], Rebecca Guy[1], Richard T Gray[1]. [1]*The Kirby Institute, UNSW, Sydney, Australia*
Email: akwon@kirby.unsw.edu.au

Background and Aims: In Australia, DAAs have been funded by the Australian government since March 2016 for all adults living with chronic HCV. This unrestricted access has facilitated rapid uptake of treatment, with more than 70,000 people treated by the end of 2018 and with 50% coverage among people who inject drugs (PWIDs) who attended needle and syringe programs. Here we provide data that indicates this policy and rapid uptake of DAA therapy has led to a reduction in the number of new HCV infections in Australia.

Method: Since the early 1990s, it has been mandatory in Australia to notify any HCV diagnosis to state health departments who forward the information to the National Notifiable Disease Surveillance System (NNDSS). We extracted monthly HCV notification data from August 2009 to August 2019 from the NNDSS website and determined the existence of change points in trends using Poisson segmented regression. We report trends with a rate ratio (RR) and 95% confidence interval (95% CI). We used standard statistical methods to assess goodness-of-fit and evaluated the sensitivity of detected change points to outliers and the period of analysis.

Results: HCV notifications slowly increased from August 2009 followed by a sharp peak during 2016 and then a decline (Figure 1). We detected a changepoint in October 2016 (95% CI: July 2016, December 2016; $p < 0.001$) with the rate ratio changing from an increasing trend (RR 0·019; 95% CI 0·015–0·022; $p < 0.001$) before October 2016 to a declining trend (RR –0·086; 95% CI –0·10 to –0·072; $p < 0.001$) afterwards.

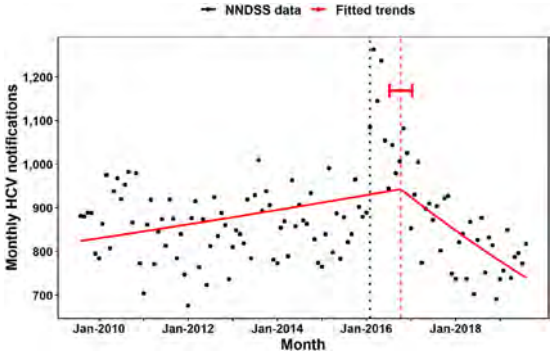

Figure: Monthly HCV notifications in Australia from August 2009 to August 2019 (black points: HCV notification data from National Notifiable Diseases Surveillance System (NNDSS), red line: segmented regression trend, vertical black-dotted line: subsidised DAA became available (1st March 2016), vertical red-dotted line: year of change point, red horizontal error bar: 95% CI for change point).

Conclusion: The short period of rapid increase in HCV notifications in early to mid-2016 is likely related to increased testing following the announcement in December 2015 of unrestricted DAA therapy access from March 2016. A degree of testing saturation among the at-risk population could be a contributor to the subsequent sharp decline, but we believe the continued decline indicates reduced new HCV infections. This is because the decline in notifications has coincided with continued high levels of HCV testing, and particularly high DAA uptake among PWID including people who are incarcerated.

Email: japineda@telefonica.net

Background and Aims: In patients with active HCV infection, HIV accelerates liver disease progression. After SVR, HIV co-infection seems no longer impact on the risk of emergence of liver complications, considered as a whole. However, information about the effect of HIV co-infection on risk of specific liver complications after SVR is very limited. The aim of this study was to assess the impact of HIV infection on the risk of developing hepatocellular carcinoma (HCC) in HCV-infected patients who achieve SVR with direct-acting antiviral (DAA).
Method: Multisite prospective cohort study, where HCV-monoinfected patients and HIV/HCV-coinfected individuals were included if they met: 1) SVR with DAA-based combination; 2) Liver stiffness (LS) ≥9.5 kPa previous to treatment; 3) LS measurement at the SVR timepoint. The primary endpoint was the emergence of HCC. The relationship between the time to endpoint and the other variables was assessed in a multivariate analysis using a Fine-Gray regression model for competing risks. Propensity score (PS) for HIV infection was calculated with a logit model including variables which were significantly different in HIV+ and HIV- at baseline.
Results: 1006 HCV-infected patients were included, 661 (66%) coinfected with HIV. HIV/HCV-coinfected patients were younger (52 vs 56 years; p < 0.001), more frequently males (87% vs 73%; p < 0.001), and injecting drug users (84% vs 36%; p < 0.001). At SVR, a lower proportion of HCV-monoinfected patients showed MELD >10 (3% vs 7%; p = 0.041). After a median (Q1-Q3) follow-up time of 37 (23–42) months, 19 (1.9%) patients developed HCC [10 (2.9%) HCV-monoinfected, 9 (1.4%) HIV/HCV-coinfected individuals; p = 0.021]. In the multivariate analysis, HIV co-infection was associated with a lower adjusted risk of developing HCC [sHR = 0.27, 95% IC (0.09–0.83); p = 0.024]. Predictors of HCC emergence were: HCV genotype 3 [sHR = 5.7 (1.7–19.3); p = 0.005], MELD score at SVR [sHR = 1.45 (1.01–2.08); p = 0.042] and LS value at SVR [sHR = 1.03 (1.01–1.05) for 1 kPa increase; p = 0.015]. After adjusting the model by PS for HIV infection, HIV co-infection remained associated with lower risk of HCC [sHR = 0.28 (0.09–0.85), p = 0.025]. Stratifying by the median of PS, the association between HIV and HCC showed the same trend in the two categories created.
Conclusion: In HCV-infected patients with advanced fibrosis, who achieve SVR with DAA, HIV-coinfection is associated with a lower risk of HCC emergence. The underlying causes for this finding need to be investigated.

FRI423

Statins use corrects the impact of direct acting antiviral agents on lipid profile in hepatitis C virus patients

Andrea Dalbeni[1,2], Anna Mantovani[1], Diego Faccincani[2], Michele Bevilacqua[1], Filippo Cattazzo[1], Donatella Ieluzzi[2], Veronica Paon[1,2], Laura Iogna Prat[2], David Sacerdoti[1,2]. *[1]University and Azienda Ospedaliera Universitaria Integrata of Verona, Division of General Medicine and Hypertension, Department of Medicine, Verona, Italy; [2]University and Azienda Ospedaliera Universitaria Integrata of Verona, Division of Liver Unit, Department of Medicine, Verona, Italy*
Email: annamantovani4@gmail.com

Background and Aims: Hepatitis C virus (HCV) infection is associated with an increased risk of atherosclerosis, linked with alteration of the lipid profile. To date, few data are available regarding the impact of HCV clearance obtained with direct acting antiviral agents (DAAs) on lipid profile. DAAs therapy seems linked to an increase in total cholesterol (TC), LDL cholesterol and triglycerides (TG) suggesting a higher cardiovascular (CV) risk. We evaluated lipid profile changes after sustained viral response (SVR) with DAAs in dyslipidemic compared to non-dyslipidemic patients.
Method: Prospectively collected data of SVR patients were analyzed, with the exclusion of diabetic patients.
Results: 361 patients were enrolled and evaluated for a mean follow-up period (T1) of 10.6 ± 3 months. Mean age was 59,3 ± 11,1 years, with 55% males. 79 patients (21.9%) were dyslipidemic (63 were F1-F3 according to METAVIR assessed by transient elastography with FibroScan and 16 were F4) while 282 patients (78.1%) were non-dylipidemic (166 patients F1-F3 and 116 patients F4). At baseline, HCV genotype 2 was significantly more present in the dylipidemic group (p < 0.001). In the dyslipidemic group hypertension was more prevalent (p = 0.020), with a higher CV risk (p = 0.001) assessed by the SCORE system, more past CV events (30.4% vs 14.9%, p = 0.003), significant lower liver stiffness (p < 0.001) and, as expected, a significant higher level of TC, LDL and TG. No differences were found in transaminases and glicemic profile.
At T1, a significant improvement in ALT, AST, GGT and liver stiffness was found in all subgroups. In linear regression, the absence of significant changes in lipid profile was associated with statins use (p < 0,001, β = 2,3) in the dyslipidemic group. Regarding the non-dyslipidemic group, in the F1-F3 subgroup a worsening in TC (at T1 175.3 ± 29 mg/dl, p < 0.001), LDL (at T1 100.6 ± 26 mg/dl, p < 0.001) and TG (at T1 93.1 ± 40 mg/dl, p = 0.031) was found, while in the F4 subgroup only LDL reached a significant increase (at T1 87.7 ± 23 mg/dl, p = 0.040). No significant impact on HDL and glicemic profile was recorded.
Conclusion: In our cohort an impact on lipid profile was proved only in the non-dyslipidemic group after the use of DAAs, in particular with lower degrees of fibrosis. Interestingly, this increase did not reach the cut-offs considered dangerous for a worsened CV risk, but a longer follow-up is needed to confirm these results.

FRI424

Medium-term outcomes of hepatitis C virus-infected patients with a sustained viral response according to albumin-bilirubin grade

Akihiro Tamori[1], Naoshi Odagiri[1], Kanako Yoshida[1], Kohei Kotani[1], Hiroyuki Motoyama[1], Etsushi Kawamura[1], Hideki Fujii[1,2], Atsushi Hagihara[1], Sawako Uchida-Kobayashi[1], Masaru Enomoto[1], Norifumi Kawada[1]. *[1]Osaka City University Graduate School of Medicine, Hepatology, Osaka, Japan; [2]Osaka City University Graduate School of Medicine, Premier preventive medicine, Osaka, Japan*
Email: atamori@med.osaka-cu.ac.jp

Background and Aims: Owing to the development of direct-acting antiviral agents (DAAs), the rate of a sustained viral response (SVR) has dramatically improved. However, the previous studies did not fully evaluate the long-term prognoses of patients who achieve an SVR. We examined the incidence of hepatocellular carcinoma (HCC) and the survival of patients who achieved an SVR using the albumin-bilirubin (ALBI) grade*, a hepatic-function classification system useful for therapeutic decision making.
Method: Among 1,164 patients treated with DAAs from 2014 to 2019, 1,010 patients who achieved an SVR were prospectively evaluated. The median age of the patients was 68 (26–90) years, and 465 (46%) were males, 188 (19%) had cirrhosis, and 115 (11%) had a history of HCC treatment. The median follow-up period was 745 (92–1,690) days. The patients were stratified by ALBI grade at initiation of DAA therapy (1/2a/2b, 639/227/144). The cumulative rates of HCC and survival were calculated by Kaplan–Meier analysis and differences were evaluated by log-rank test. *Johnson PJ. *et al.* J Clin Oncol. 2015. Hiraoka A. *et al.* Liver Cancer 2017.
Results: Among patients with and without prior HCC, the cumulative rates of HCC were 37/2% at 1 year, 44/3% at 2 years, 49/6% at 3 years, and 63/9% at 4 years (p < 0.01). The survival rates were 94/99% at 2 years and 92/95% at 4 years. HCC recurrence was associated with a baseline alpha-fetoprotein level of >7 ng/mL, cirrhosis, and non-

surgical treatment for HCC, but not with ALBI grade. No clinical factor was related to survival at 4 years in patients with a history of HCC treatment. Among patients without prior HCC of ALBI grade 1/2a/2b, the cumulative rates of HCC were 1/4/3% at 1 year, 1/4/7% at 2 years, 3/6/16% at 3 years, and 3/9/26% at 4 years, respectively ($p < 0.01$). The survival rates were 99/99/96% at 2 years and 98/96/86% at 4 years, respectively ($p < 0.01$).

Conclusion: In patients with a history of HCC treatment, the rate of cumulative recurrence was almost 50% at 3 years, even if an SVR was achieved. However, there was no association between HCC recurrence and the prognosis at 4 years. In patients without prior HCC, the ALBI grade was capable of predicting HCC development and the prognosis after achieving an SVR.

Identification of serum miRNAs whose expression were associated with and changed after HCV eradication

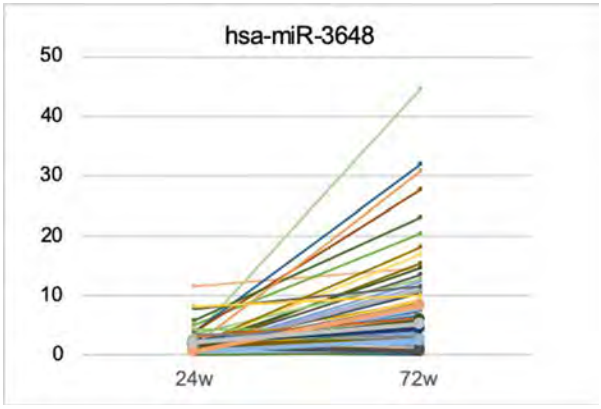
Atsumasa Komori[1], Shinji Katsushima[2], Kazuhiro Sugi[3], Hiroshi Kouno[4], Masaaki Shimada[5], Keisuke Ario[6], Hiroshi Yatsuhashi[1]. *[1]National Hospital Organization Nagasaki Medical Center; [2]National Hospital Organization Kyoto Medical Center; [3]National Hospital Organization Kumamoto Medical Center; [4]National Hospital Organization Kure Medical Center; [5]National Hospital Organization Nagoya Medical Center; [6]National Hospital Organization Ureshino Medical Center*

Email: atsuriko1027@yahoo.co.jp

Background and Aims: Molecular and cellular machinery of wound healing in the HCV eradicated liver likely exerts influence on the persisting risk of hepatocellular carcinoma (HCC). As serum or plasma miRNA have been recognized as potential non-invasive markers for the activity and staging in chronic hepatitis C, they might be utilized also as surrogate for the multicellular process in the liver after sustained viral response (SVR), especially for its temporal evaluation. The aim of this exploratory study is to identify serum miRNA pattern in SVR patients and to evaluate its longitudinal changes.

Method: We recruited 217 patients who achieved SVR, but not with concurrent HCC diagnosis by imaging, at 24 weeks after the end of anti-viral treatment: 32 patients were considered as cohort 1, and remaining 185 were as cohort 2. RNA were extracted from the serum of cohort 1 at SVR24W or from those of 8 healthy volunteers and microarray hybridization was performed on Human miRNA array (TORAY, Japan). Normalization of raw intensity values, followed by analysis of data were performed using GeneSpring (Agilent Technologies, U.S.A.). We first extracted differentially expressed miRNAs (DEmiRs) in SVR 24W serum in cohort 1, compared with those in healthy volunteers, whose expression had FDR corrected $p < 0.05$ and a fold change (≥ 2) in signal intensity (unpaired Welch test). Next, validation of DEmiRs were performed by quantitative RT-PCR, using RNA that were extracted from the serum of cohort 2 at SVR24W or at SVR72W ($n = 93$), which were pre-mixed with cel-miR-39 as spike-in control.

Results: 44.9% of patients were predicted to be in advanced fibrosis, by their greater than 3.25 pretreatment FIB4 index. Among DEmiRs in cohort 1, overexpressed miR-3648 ($p = 0.0025$) and underexpressed miR-223-3p ($p = 0.0026$) were validated in cohort 2 by qRT-PCR. Steady-state level of both serum miRNAs were significantly increased at SVR72W from those at SVR24W ($p < 0.0001$). No DEmiRs at SVR24W were associated with either pretreatment FIB4 index, AFP values, or interferon free regimen.



Conclusion: Post SVR wound healing process in the liver may be monitored by serum miRNA pattern.

FRI426

Impact of genetic variants on liver disease regression in HCV patients with advanced chronic liver disease who achieved SVR to IFN-free therapies

Bernhard Scheiner[1,2], Georg Semmler[1,2], Teresa Binter[1,2], Karin Kozbial[1], Philipp Schwabl[1,2,3,4], David Chromy[1,2], David JM Bauer[1,2], Benedikt Simbrunner[1,2,3,4], Theresa Bucsics[1,2], Albert Stättermayer[1,2], Matthias Pinter[1,2], Petra Munda[1], Michael Trauner[1], Peter Ferenci[1], Thomas Reiberger[1,2,3,4], Mattias Mandorfer[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Vienna, Austria; [3]Ludwig Boltzmann Institute for Rare and Undiagnosed Diseases, Vienna, Austria; [4]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria*

Email: bernhard.scheiner@meduniwien.ac.at

Background and Aims: Several single nucleotide variants (SNVs; including *PNPLA3 rs738409 C > G*, *TM6SF2 rs58542926 C > T*, *MBOAT7 rs641738 C > T*, and *HSD17B13 rs72613567 T > TA*) have been shown to promote or prevent progression to advanced chronic liver disease (ACLD) in patients with chronic hepatitis C (CHC). However, their influence on disease regression is unclear.

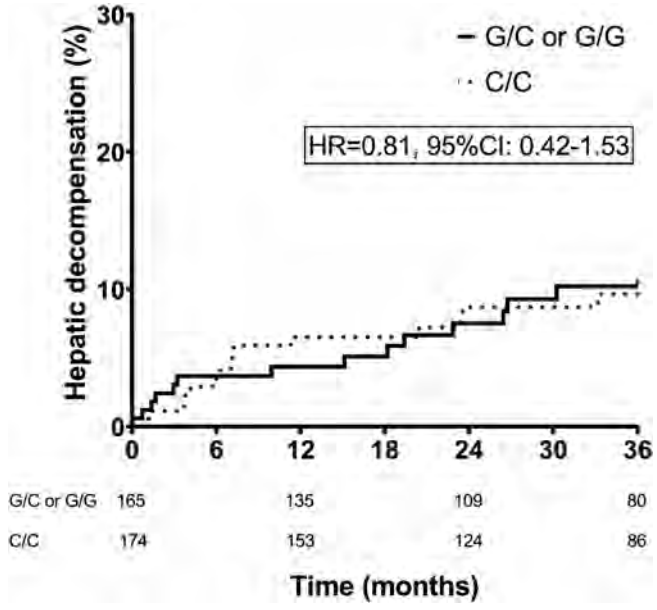
Therefore, we aimed to assess their impact on **(I)** the regression of portal hypertension, as assessed by hepatic venous pressure gradient (HVPG), **(II)** changes in non-invasive markers (transient elastography (TE) and von Willebrand factor (VWF)), and **(III)** clinical events in CHC patients with pre-treatment ACLD who achieved sustained virological response (SVR) to interferon (IFN)-free therapies.

Method: 339 CHC patients with pre-treatment ACLD (i.e., hepatic venous pressure gradient [HVPG]$\geq$6 mmHg and/or liver stiffness measurement [LSM]$\geq$10 kPa and/or advanced liver fibrosis/cirrhosis on histology) and information on the *PNPLA3 rs738409 C > G* variant were included into this retrospective analysis.

Results: Of 339 included patients, 49 (14.5%) had a history of hepatic decompensation (dACLD), while 290 (85.5%) had compensated ACLD (cACLD). Two hundred and ninety-seven (87.6%) patients were Child-Turcotte-Pugh (CTP) A. The mean MELD was of 8.8 ± 2.6 points, with a median LSM of 17.6 (11.8–28.0)kPa, median VWF levels of 243 (177–321)%, and a median VWF/platelet count ratio (VITRO) of 1.97 (1.13–3.38). Patients harboring the PNPLA3 *rs738409 G*-allele had more advanced liver disease prior to antiviral therapy, while liver disease severity was similar across the other SNVs.

In a subgroup of 88 patients with information on all SNVs and paired HVPG measurements, the distribution of *PNPLA3*, *TM6SF2*, *MBOAT7*, and *HSD17B13* genotypes was comparable between patients with vs. without an HVPG decrease.

In line with the observed changes in HVPG, treatment induced decreases in surrogates of portal hypertension (LSM, VWF, and VITRO) were comparable between carriers and non-carriers of the PNPLA3 *rs738409 G*-allele in the overall cohort.
Patients were followed for a median of 38 months after end of treatment. Interestingly, the PNPLA3 *rs738409 G*-allele did not impact hepatic decompensation or liver-related mortality in unadjusted analysis, or hepatic decompensation in an analysis adjusted for indicators of hepatic dysfunction and portal hypertension before treatment initiation.



Conclusion: Genetic variants in *PNPLA3, TM6SF2, MBOAT7, and HSD17B13* do not impact the regression of portal hypertension. After etiological cure (i.e., after SVR), the PNPLA3 *rs738409 G*-allele was also not associated with clinical events or mortality in our well-characterized cohort of ACLD due to CHC.

FRI428

HIV/HCV co-infected subjects show better thrombocytopenia improvement after sustained virologic response achievement than HCV mono-infected cirrhotics. Data from the hepaiCONA and PITER cohorts.

Roberto Rossotti[1], Alessandro Tavelli[2], Maria Giovanna Quaranta[3], Francesca Bai[4], Luigina Ferrigno[3], Antonella Cingolani[5], Francesco Barbaro[6], Marcello Dallio[7], Massimo Puoti[1], Martina Loi[8], Emanuela Zappulo[9], Antonella d'Arminio Monforte[4]. *[1]ASST Grande Ospedale Metropolitano Niguarda, Infectious Diseases, Milan, Italy; [2]ICONA Foundation, Milan, Italy; [3]Istituto Superiore di Sanità, Center for Global Health, Rome, Italy; [4]ASST Santi Paolo e Carlo, University of Milan, Health Sciences, Clinic of Infectious Diseases, Milan, Italy; [5]Fondazione Policlinico Agostino Gemelli IRCCS, Catholic University of the Sacred Heart, Infectious Diseases, Rome, Italy; [6]Azienda Ospedaliera di Padova, Infectious and Tropical Diseases, Padua, Italy; [7]University of Campania Luigi Vanvitelli, Precision Medicine, Naples, Italy; [8]University Hospital Monserrato, Liver Unit, Cagliari, Italy; [9]University of Naples Federico II, Clinical Medicine and Surgery, Naples, Italy*
Email: blixen79@hotmail.com

Background and Aims: Thrombocytopenia (TCP) is common in HCV-related liver cirrhosis with portal hypertension (PHT). In HIV/HCV co-infected subjects it is due to several factors, including immune activation. After sustained virologic response (SVR), PHT shows an improvement in approximately 85% of cases but only one third returns to normality. Aim of present study is to compare TCP trend and return to normal values in co- and mono-infected cirrhotics after SVR achievement.
Method: HepaICONA and PITER are observational cohort studies that enroll patients undergoing treatment with direct acting agents throughout Italy. Subjects with a platelets (PLT) count <150,000 cell/mmc before DAA start who achieved SVR were selected. Demographic, clinical and laboratory features were collected. PLT count during and after DAA treatment was analyzed. Descriptive statistics, paired t and non-parametric (Chi-square and Kruskal-Wallis) tests were applied; KM probability curves and multivariable Cox regression models for PLT increase were used.
Results: 3,808 subjects were enrolled: 1,739 HIV/HCV co-infected from HepaICONA and 2,069 HCV mono-infected from PITER. Co-infected individuals were younger (53 versus 62 years, $p < 0.001$), with a higher median PLT count (173,000 versus 157,000, $p < 0.001$) and lower presence of TCP (36.4% versus 45.9%, $p < 0.001$). In the overall population, 12 months after SVR HIV+ showed a larger median PLT increase (15,930 versus 8,832 cell/mmc, $p < 0.001$). Among those with TCP, PLT count returned within normal values more commonly in co- than in mono-infected (35.1% versus 20.9%, $p < 0.001$). Figure 1 shows the probability for PLT increase assessed by mean of KM analysis: HIV+ subjects exerted a more favorable kinetics. After adjusting for confounding factors, HIV co-infection, baseline PLT and AST values and HCV genotype 3 were independently associated with TCP recovery.

Conclusion: PLT count returned within normal ranges in one third of co-infected and only in one fifth of mono-infected cirrhotics. PLT increase was more rapid and robust in HIV+ individuals: these data suggest that in this setting HCV eradication could have a stronger impact on the inflammatory milieu with a consequent better evolution of TCP. Nevertheless, SVR achievement failed to resolve TCP in the large majority of study population underlying the need for a careful and ongoing monitoring in subjects with PHT.

FRI429

Long-term liver fibrosis and outcomes in HCV-infected solid organ transplant recipients after DASSs-induced viral eradication

Chiara Manuli[1], Alberto Zanetto[1], Alberto Ferrarese[1], Sarah Shalaby[1], Salvatore Sciarrone[1], Monica Pellone[1], Giacomo Germani[1], Marco Senzolo[1], Patrizia Burra[1], Francesco Paolo Russo[1], Martina Gambato[1]. *[1]Multivisceral Transplant Unit, Gastroenterology, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy, Italy*
Email: martina.gambato@gmail.com

Background and Aims: Hepatitis C virus (HCV) infection is associated with faster liver fibrosis progression and higher mortality in solid organ transplant (SOT) recipients compared to non-transplanted population. High safety and efficacy of direct acting antivirals (DAAs) after SOT were reported worldwide. The aim of this study was to evaluate the long-term impact of viral eradication on fibrosis progression and patient survival after SOT.
Method: All consecutive HCV-infected patients treated with DAAs after SOT between August 2014 and January 2019 in a single transplant center in Italy were considered. Patients were either included in the NAVIGATORE platform or treated within the Compassionate Use Program. Clinical and virological features were registered at baseline and during the follow-up, at monthly intervals during treatment and at 3, 6, 12 months and 2, 3 years after end of treatment (EoT). Liver fibrosis was assessed by liver biopsy and/or transient elastography (TE) at baseline and during the follow-up.
Results: Overall, 110 patients treated with DAAs at median time of 44.5 months (IQR 13–111) after SOT (liver = 93, kidney = 14, heart = 1, heart-kidney = 1, liver-kidney = 1) were included. 55% of patients (n = 61) showed F3-F4 liver fibrosis at baseline. Median follow-up after DAAs was 47 months (IQR 31–54). Sustained virological response rate (SVR12) was 80% and 96% after retreatment. Patients who achieved SVR12 showed a significant improvement in biochemical tests from

Figure 1. Kaplan-Meier curves of platelets increase: probability to achieve a normal count (≥150,000 cell/mmc) in the thrombocytopenic population (**A**) and probability to achieve a count ≥50,000 cell/mmc in the subgroup with severe thrombocytopenia (**B**). Univariate and multivariate analyses of factors associated with platelets increase are shown below.

PLT: platelets count; LD: liver decompensation; HCC: hepatocellular carcinoma; OLT: liver transplantation; RBV: ribavirin; DAA: direct-acting agents.

Figure: (abstract: FRI428)

baseline to SVR48: bilirubin ($p < 0.001$), ALT ($p < 0.001$) and platelet count ($p = 0.006$). Overall, patients who achieved SVR12 showed an improvement in liver fibrosis measured by TE ($p < 0.001$) and APRI ($p < 0.001$) during the follow-up; this result was confirmed in cirrhotic patients ($p = 0.001$, $p < 0.001$). Patient survival at 12, 24 and 36 months after DAAs was 96%, 91% and 86%, respectively. Patients with F3-4 fibrosis before DAAs who achieved SVR12 had similar survival compared to patients with F0-2 ($p = 0.087$). Patients with F3-4 fibrosis before DAAs who relapsed, showed lower survival compared to the other groups ($p < 0.001$). At multivariate analysis, no variable considered was an independent risk factor for mortality after SOT.

Conclusion: Treatment with DAAs was effective after SOT. Long-term follow-up data demonstrated that viral eradication was associated with an improvement in hepatic function, liver fibrosis and post-SOT survival, even in patients with F3-4 fibrosis before DAAs.

FRI430

Development of hepatocellular carcinoma by patients aged 75 years or over after HCV elimination by all-oral DAA therapy: results from a large-scale, multicenter cohort study

Email: eogawa@gim.med.kyushu-u.ac.jp

Background and Aims: Antiviral HCV therapy with direct-acting antivirals (DAAs) has become much easier than ever even for elderly patients. However, as much data as possible on the development of hepatocellular carcinoma (HCC) are needed to better manage HCC surveillance after HCV elimination. The aim of this study was to evaluate HCC development, including de novo and recurrence, and

the survival rate of Japanese chronic hepatitis C (CHC) patients aged 75–84 following the achievement of sustained viral response (SVR) by DAAs.

Method: This large-scale, multicenter cohort study included 726 consecutive patients with CHC aged 75–84 who achieved SVR by all-oral DAAs, divided into groups with (n = 578) or without previous HCC (n = 147). We excluded patients with decompensated cirrhosis, co-infection with HBV/HIV, or a history of organ transplantation. The Kaplan-Meier method and Cox proportional hazard analysis were used to calculate the cumulative HCC incidence and factors related to HCC.

Results: During the observational period (median: 38 months), the 1- and 3-year cumulative rates of de novo HCC were 2.3% and 6.2%, respectively. In multivariable Cox analysis, alpha-fetoprotein (AFP) at 12 weeks after the end of treatment (p12) (OR 1.01, P < 0.001) and high p12-FIB4 index (>3.25) (OR 2.08, P = 0.04) were extracted as predictors of de novo HCC. The 1- and 3-year cumulative rates of de novo HCC were 4.1% and 8.2% for patients with high p12-FIB4 index (>3.25), respectively (log-rank test: p < 0.01). For patients with prior HCC, the respective 1- and 3-year cumulative rates of HCC recurrence were 15.2% and 36.4% for patients treated with a curative procedure and 30.4% and 82.4% for patients treated with a non-curative procedure (log-rank test: both p < 0.001). The 3-year survival rates for the non-HCC, curative HCC, and non-curative HCC groups were 98.6%, 94.3%, and 67.3%, respectively. Liver-related complications, mainly HCC recurrence, were responsible for approximately 60% of all deaths for patients with previous HCC.

Conclusion: For older patients who achieved SVR, high p12-FIB4 index and p12-AFP were strongly associated with the development of de novo HCC. For patients with a prior history of HCC, HCC recurrence will commonly occur, even if curative HCC treatment has been received. However, the survival rates for the non-HCC and curative HCC groups were higher (over 90% in three years) than that of the non-curative HCC group.

FRI431

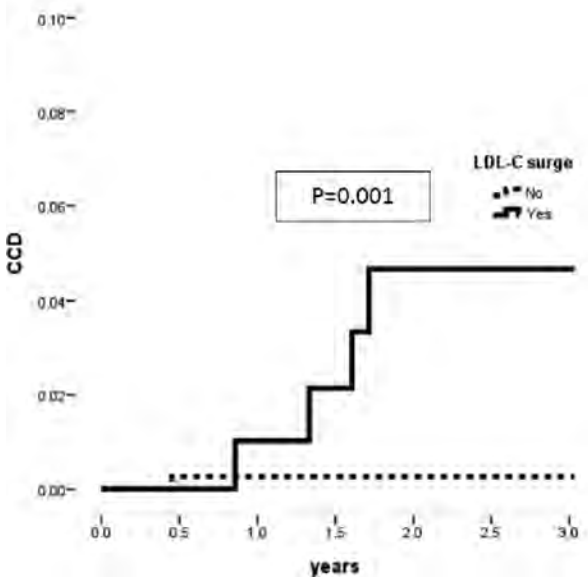
Deteriorated lipid profiles and cardio-cerebrovascular events after hepatitis C virus eradication

Chung-Feng Huang[1], Ming-Lung Yu[1], Chia-Yen Dai[1], Jee-Fu Huang[1], Wan-Long Chuang[1]. *[1]Hepatobiliary Division, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan*
Email: fengcheerup@gmail.com

Background and Aims: Chronic hepatitis C virus (HCV) infection is associated with lower levels of total cholesterol (T-CHOL) and low-density lipoprotein cholesterol (LDL-C). Whether viral eradication leads to dyslipidemia and increases the risk of cardio-cerebral disease is unclear among chronic hepatitis C (CHC) patients after therapy with direct-acting-antivirals (DAAs).

Method: Lipid profiles were measured throughout DAA therapy and annually thereafter in CHC patients with a sustained virological response (SVR, undetectable HCV RNA at posttreatment week 12). The primary end-point was the occurrence of the events.

Results: A total of 617 SVR patients were included, with a mean follow-up period of 26.8 months (range:1–65 months). T-CHOL and LDL-C levels increased significantly from treatment week-4 to 2 years after treatment. A significant increase in the triglyceride level was noted at/after the end-of-treatment, whereas a significant increase in high-density lipoprotein cholesterol was observed only until 12 weeks after the end-of-treatment. Logistic regression analysis revealed that factors independently associated with a significant cholesterol increase included age (odds ratio [OR]/95% confidence intervals [CI]:1.02/1.006–1.039, P = 0.007) and smoking (OR/CI:3.21/1.14–9.02, P = 0.027). Five patients developed cardio-cerebral diseases during the follow-up period (36 per 1000 person-years). Compared to patients without vascular events, a significantly higher proportion of those with vascular events experienced an LDL-C surge >40% (80% vs. 19.9%, log-rank test P = 0.001). Cox regression analysis revealed that an LDL-C surge >40% was the only factor predictive of vascular events (HR/CI: 15.44/1.73–138.20, P = 0.014).



Conclusion: Dyslipidemia occurred after HCV eradication, which was associated with the risk of cardio-cerebrovascular diseases. Attention should also be paid to the extrahepatic consequence beyond liver-related complications in the post-SVR era.

FRI432

Dynamic of cytokine profiles predicts risk of HCC among HCV patients with advanced fibrosis after successful antiviral therapy

Ming-Lung Yu[1,2], Ming-Ying Lu[2], Shu-Chi Wang[3], Ming-Lun Yeh[1,2], Chung-Feng Huang[1,2], Jee-Fu Huang[1,2], Chia-Yen Dai[1,2], Wan-Long Chuang[1,2]. *[1]Kaohsiung Medical University Hospital, Hepatobiliary Division, Department of Internal Medicine, Kaohsiung, Taiwan; [2]Kaohsiung Medical University, Faculty of Internal Medicine and Graduate Institute of Medicine, Kaohsiung, Taiwan; [3]Kaohsiung Medical University, Department of Medical Laboratory Science and Biotechnology, Kaohsiung, Taiwan*
Email: fish6069@gmail.com

Background and Aims: Successful HCV eradication did not eliminate HCC development among patients with advanced fibrosis. Clearance of HCV by DAA or IFN results in reconstitution of immune surveillance. We aimed to investigate the impact of differential cytokine expression on the development of HCC following antiviral therapy.

Method: 50 HCV patients with advanced fibrosis receiving pegIFN/RBV and 50 age-, sex- and fibrosis-matched HCV patients receiving DAA who achieved sustained virologic response (SVR) were enrolled in this study. The primary endpoint is the development of HCC. Cytokines profile were measured at baseline and SVR12 or SVR24 follow-up. A total of 64 cytokines was detected by the multiplex immunoassay.

Results: HCC developed in 12 (IFN group n = 11, DAA group n = 1) of the 97 patients over 459 person-years of follow-up after HCV eradication. In univariate analysis, the variation of tumor necrosis factors (TNF)-α and TWEAK (TNF-like weak inducer of apoptosis) after antiviral therapy were significantly associated with the development of HCC. The multivariate Cox regression model showed the reduction of TNF-α ($\triangle$ = –5.7 pg/ml) was the independent risk factor of HCC (HR = 11.54, 95% C.I. = 2.27–58.72, p = 0.003). We established an HCC predictive model as follows: Score = 5 × Gender (male = 1, female = 0) + 8 x$\triangle$TNF ($\leqq$–5.7, yes = 1, no = 0) + 11 x$\triangle$TWEAK ($\leqq$–70, yes = 1, no = 0). Time-dependent ROC analysis

revealed the 3-year, 5-year, 10-year, and 13-year AUC were 0.815, 0.836, 0.870, and 0.916, respectively.
Conclusion: Reduction of TNF-α after antivirals predicts HCC development in chronic hepatitis C patients with advanced fibrosis after successful viral eradication.

FRI433
Procoagulant imbalance in patients with non-cirrhotic chronic hepatitis C (CHC) improves six months after eradication with direct-acting antiviral agents (DAAs) and likely correlates with liver fibrosis

Giordano Sigon[1], Annalisa Cespiati[1], Giuseppina Pisano[1], Roberta D'Ambrosio[2], Marigrazia Clerici[3], Veena Chantarangkul[3], Pietro Lampertico[2], Roberta Sollazzi[1], Flora Peyvandi[4], Armando Tripodi[3], Rosa Lombardi[1], Silvia Fargion[1], Anna Ludovica Fracanzani[1]. *[1]Ca' Granda IRCCS Foundation, Policlinico Hospital, University of Milan, Italy, Department of Pathophysiology and Transplantation, Milan, Italy; [2]CRC AM e A Migliavacca Center for liver diseases, Gastroenterology and Hepatology. Email: gio.sigon@virgilio.it

Background and Aims: Chronic hepatitis C (CHC) is one of the most important causes of morbidity and mortality not only for the liver but also for cardiovascular diseases. A procoagulant imbalance, potentially responsible for cardiovascular disease and liver injury, has been reported in patients with CHC without cirrhosis. Aim: to assess whether HCV eradication by DAAs leads to a reduction in the procoagulant imbalance in CHC patients without cirrhosis and correlates with the improvement in hepatic histology.
Method: From 2017 to 2019, 122 patients with non-cirrhotic CHC (mean age 58.9 ± 10.5 years), were enrolled. Clinical and biochemical parameters, presence of steatosis (ultrasound), severity of liver damage [liver stiffness measurement (LSM) and non-invasive fibrosis scores (FIB-4 and NAFLD fibrosis score (NFS))] and coagulation balance through the evaluation of endogenous thrombin potential (ETP) with/without thrombomodulin and protein C (PC) – factor VIII ratio, were determined at enrollment and at 6 ± 1 months after sustained virological response (SVR) confirmation. Coagulation parameters of CHC patients at baseline were compared to those of 188 control subjects, enrolled among healthy hospital employers.
Results: Indexes of procoagulant imbalance were significantly higher in CHC patients than in controls (FVIII/PC ratio 1.7 + 0.7 vs 1.1 + 0.3; ETP ratio 0.8 + 0.1 vs 0.6 + 0.2, $p < 0.0001$). Pre-treatment indexes of procoagulant imbalance (FVIII/PC ratio) at analysis adjusted for sex, BMI, diabetes and GGT was significant associated with FIB4 (Coefficient 0.6, SE 0.2, $p = 0.003$) and NFS (coefficient 0.7 SE 0.1, $p < 0.0001$). Six months after SVR we observed a significant reduction in the procoagulant imbalance compared to what was observed before treatment (FVIII/PC 1.3 ± 0.5 vs 1.6 ± 0.6, ETP ratio 0.64 ± 0.11 vs 0.73 ± 0.1, $p < 0.0001$) and a decrease of liver fibrosis compared to pre-treatment (LSM 5.1 ± 1.7 vs 6.5 ± 5.5; NFS 0.1 ± 1.9 vs – 1.9 ± 1.2; $p < 0.0001$ and FIB4 1.9 ± 1.2 vs 1.6 ± 0.7, $p = 0.02$). At analysis adjusted for sex, BMI, diabetes, and GGT, the FVIII/PC was significantly associated with FIB4 (adjusted-coefficient 0.3, SE 0.14, $p = 0.01$) but not with LSM and NFS.
Conclusion: The viral eradication induced by DAA leads to a reduction in the procoagulant imbalance in non-cirrhotic patients with CHC. Whether this mechanism underlies the reported reduction of fibrosis after SVR needs to be confirmed in a larger cohort of patients with a longer follow up.

FRI434
Direct-acting antivirals improve treatment outcomes in patients with chronic hepatitis C-related hepatocellular carcinoma treated with transarterial chemoembolization: a nationwide, multi-center, retrospective cohort study

Email: ksukorea@yuhs.ac

Background and Aims: The influence of direct-acting antivirals (DAAs) for chronic hepatitis C (CHC) on hepatocellular carcinoma (HCC) is controversial. We investigated whether eradicating CHC using DAAs influenced treatment outcomes in patients with CHC-related HCC, treated with transarterial chemoembolization (TACE).
Method: In this nationwide, multi-center, retrospective cohort, patients with CHC-related HCC who were treated with TACE as the first anti-cancer treatment and who achieved a sustained virological response (SVR) using DAAs (DAA group) were recruited between 2006 and 2017. Patients with a SVR using the interferon-based treatment (IFN group) and those without treatment (Control group) were also recruited for comparison.
Results: In total, 425 patients were eligible for the study. Of these, 356 (83.8%), 26 (6.1%), and 43 (10.1%) patients were allocated into the Control, IFN, and DAA groups, respectively. A multivariate analysis showed that liver cirrhosis, segmental portal vein thrombosis, and larger maximal tumour size independently predicted an increased risk of progression (all $p < 0.05$), whereas the DAA group (vs. IFN and Control group) independently predicted a reduced risk of progression (hazard ratio = 0.630, 95% confidence interval 0.411–0.966, $p = 0.034$). The cumulative incidence rate of HCC progression in the DAA group was significantly lower than that in the IFN and Control groups ($p = 0.033$, log-rank test). In addition, the DAA group (vs. IFN and Control group) was independently associated with a reduced risk of mortality ($p = 0.042$).

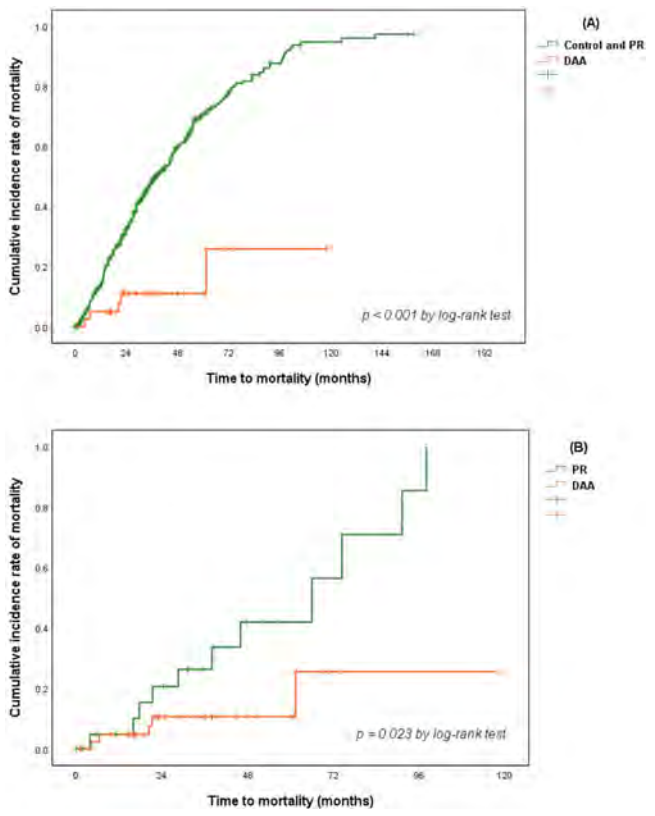

Figure 3 The cumulative incidence rate of mortality (A) Control and PR vs. DAA, (B) PR vs. DAA.

Conclusion: DAA treatment provided significantly prolonged progression-free survival in patients with CHC-related HCC treated with TACE, compared to IFN treatment or no treatment.

FRI435

Patients treated for hepatitis C: an observational study with the French administrative healthcare database (SNDS)

Stanislas Pol[1], Ingrid Rodriguez[2], Olivier Lada[2], Fayssoil fouad[3], Magali Lemaitre[3], Françoise Roudot-Thoraval[4]. *[1]Hospital Cochin, Paris, France; [2]Gilead Sciences, Boulogne-Billancourt, France; [3]IQVIA, Courbevoie, France; [4]Hôpital Henri-Mondor Ap-Hp, Créteil, France*
Email: ingrid.rodriguez@gilead.com

Background and Aims: In 2014 direct antiviral agents (DAA) became available for the treatment of chronic hepatitis C (CHC) for patients with severe fibrosis in France. In 2017, the universal access to DAA was adopted by the French health minister. The aim of this study is to evaluate the impact of DAAs on access to CHC treatment and HCV screening.
Method: All patients affiliated to the French national health insurance, screened or treated against CHC between 2015 and 2018 were included and followed. Different algorithms were developed to identify special populations: migrants, prisoners, HIV+ patients, psychiatric patients, and drug users.
Results: Over the study period 2015–2017, 51,478 patients were treated against CHC (mean age 55.5 years; min: 18 years; max: 95 years; q1: 49 years; q3: 62 years; CI 95%: 55.4–55.6 years, 59.8% of males). Between 2015 to 2017, the annual treated population increased by 30% (17,400 to 22,700 patients), the mean age decreased from 57 to 54 years and the percentage of female increased from 35% to 45%. The weight of HIV+ patients dropped from 18% to 8% of the patients treated with DAA, while for the populations, an increase or stabilization was observed: 3% to 5% for migrants, 1% to 5% for prisoners, 21% to 20% for psychiatric patients, and 16% to 19% for drug users. The population of screened patients increased by 11% between 2015 and 2017 (2.8 to 3.1 million patients). The median delay between the last screening test and the treatment initiation decreased from 187 days in 2015 to 86 days in 2017 and 43 days in 2018.
The results for the year 2018 will be presented at the conference, with the poster.
Conclusion: This study highlights the impact of providing universal access to DAA with an increase of patients treated in 2017, of the screened population and the reduction of time between screening and treatment initiation. This is also the first study from SNDS data using algorithms to identify special populations.

FRI436

Role of pre- and post-treatment transient elastography measurements in predicting hepatocellular carcinoma (HCC) among hepatitis C patients treated with direct acting antivirals (DAAs)

Jacob Charette[1], Mark G Swain[1], Abdel-Aziz Shaheen[1]. *[1]University of Calgary Liver Unit, Gastroenterology and Hepatology, Calgary, Canada*
Email: jacobcharette@gmail.com

Background and Aims: Current guidelines recommend regular lifelong HCC screening in HCV patients with advanced fibrosis or cirrhosis. However, no study has evaluated the impact of early changes in liver stiffness measurement (LSM) by transient elastography (TE), which may reflect DAA-induced improvement in liver inflammation, on subsequent HCC risk after successful eradication of HCV. Therefore, we evaluated the association between LSM measured by TE pre- and early post-DAA treatment, and HCC occurrence.
Method: All electronic medical records of HCV patients treated with DAA at the University of Calgary Liver Unit (UCLU) between January 2014 and December 2017 were reviewed (n = 1,161) to identify those patients who developed HCC after completing treatment. Patients were excluded if they were treated for HCV while having HCC, or developed HCC during or immediately after (within 3 months) therapy. Baseline LSM was defined as TE within 6 months before starting DAA therapy, and post-treatment LSM was defined as TE within 36 months post-DAA therapy. We used Cox regression analysis to evaluate the association between pre- and post-HCV treatment TE measurements and HCC occurrence. We adjusted for age, sex, HCV genotype, and Charlson comorbidity index in our models.
Results: We identified 524 patients with a valid TE assessment obtained both at pre- and post-DAA treatment. In our cohort, median TE pre-DAA treatment was 12.1 kPa (IQR: 8.3–21.1 kPa), while post-DAA TE was 8.4 kPa (IQR: 5.8–14.1 kPa), $p < 0.001$.Therefore, the majority of our cohort (65.1%, n = 341) had advanced fibrosis or cirrhosis (TE >9.5 kPa) pre-DAA treatment, compared to 43.5% (n = 228) post-treatment. Within a median follow-up of 26 months (IQR:14–36) 18 patients (3.4%) developed HCC. In our cohort, sustained viral response (SVR) was 98.6% and all HCC patients had achieved SVR. Patients who developed HCC were similar to those not developing HCC according to sex (male 72.2% vs. 61.0%), age (median: 61 vs. 59 year), HCV genotype (1a: 38.9% vs. 49.4%), and having >2 comorbidities (66.7% vs. 58.3%), respectively; $p > 0.05$ for all comparisons. However, patients who developed HCC had a higher median TE pre-treatment (29.2 vs. 12.0 kPa, $p < 0.001$) and post- treatment (15.8 vs. 8.1 kPa, $p < 0.001$), respectively. All patients who developed HCC had TE >9.5 kPa at pre-treatment, while one (5.6%) patient had a post-treatment TE <9.5 kPa. In our adjusted Cox regression models, pre-treatment TE >9.5 kPa accurately predicted HCC (all HCC patients had pre-treatment TE>9.5 kPa), while post-treatment TE of >9.5 kPa was a strong predictor for HCC (HR: 18.70, 2.46–141.92).
Conclusion: In our large DAA-treated HCV cohort, pre- and post-treatment TE indicating advanced fibrosis or cirrhosis were strong predictors for HCC development post-treatment. Future studies should examine utility and cost effectiveness of measuring LSM post-HCV therapy on HCC occurrence.

FRI437

Non-invasive tests predict the risk of hepatocellular carcinoma in hepatitis C patients after sustained virological response: impact on HCC surveillance

Javier Ampuero[1], Isabel Carmona[2], Jose Miguel Rosales Zabal[3], Marta Casado[4], Manuel De La Mata Garcia[5], Aida Ortega-Alonso[6], Yolanda Sánchez[1], Patricia Cordero Ruiz[2], Matias Estevez[7], Raul J. Andrade[6], Manuel Romero Gomez[1]. *[1]Hospital Universitario Virgen del Rocio, Sevilla, Spain; [2]Hospital Universitario Virgen Macarena, Sevilla, Spain; [3]Agencia Sanitaria Costa del Sol, Marbella, Spain; [4]Hospital Universitario Torrecárdenas, Almería, Spain; [5]Hospital Universitario Reina Sofía, Córdoba, Spain; [6]Hospital Universitario Virgen de la VIctoria, Málaga, Spain; [7]Hospital Universitario Poniente, El Ejido, Spain*

Email: javi.ampuero@gmail.com

Background and Aims: After achieving the sustained virological response (SVR), hepatitis C (HCV) patients showing cirrhosis or advanced fibrosis (>10 kPa) must be screened from hepatocellular carcinoma (HCC) twice a year (EASL CPG, 2018). We assessed the role of non-invasive tests (NITs) [FIB4 and APRI] on HCC prediction and need for surveillance after SVR in patients treated with direct-acting antivirals (DAA).

Method: Multicenter study including 1180 Hepatitis C patients reaching SVR after DAA therapy. Patients suffering HCC within six months from starting DAA therapy (n = 5), as well as HCC and liver transplant before treatment, were excluded. They were followed-up to 5 years (36 ± 15 months) or until HCC occurrence (liver transplant and death before HCC were competing events).

Results: The 76% (898/1180) of the cohort had EASL criterium for HCC screening (cirrhosis or >10 kPa after SVR). HCC occurred in 5% (63/1180) of patients, while 1% (12/1180) was transplanted and 5% (61/1180) died before HCC diagnosis. Male sex [sHR 1.84 (95%CI 1.02–3.29); p = 0.041], cirrhosis [sHR 4.91 (95%CI 1.69–14.3); p = 0.004], albumin [sHR 0.51 (95%CI 0.32–0.83); p = 0.007], FIB4>3.25 [sHR 2.58 (95%CI 1.38–4.81); p = 0.003] and APRI>1.5 [sHR 2.29 (95%CI 1.33–3.93); p = 0.003] predicted HCC. Figure shows HCC rate per 100 persons-year, and HCC and mortality cumulative incidence, depending on baseline FIB4 and APRI. Pre- and post-treatment FIB4>3.25 [OR 10.86 (95%CI 3.06–38.53); p < 0.0001] and APRI>1.5 [OR 18.78 (95%CI 4.97–70.95); p < 0.0001] showed the highest HCC risk.

Conclusion: Combination of NITs predicted HCC risk and mortality after SVR in hepatitis C patients showing cirrhosis and/or baseline transient elastography >10 kPa. Subjects with FIB4<3.25 and/or APRI<1.5 had a low HCC risk, so surveillance could be not cost-effective. By contrast, patients with FIB4>3.25 and APRI>1.5 belonged to a high-risk group and should be included in a routine surveillance program.

Reinfection with hepatitis C following cure: results from the TraP Hep C program in Iceland - a prospective nationwide, population-based study

Jon M Johannesson[1], Sigurdur Olafsson[2,3], Ragnheidur H. Fridriksdottir[2], Thorvardur J. Löve[3,4], Valgerdur Runarsdottir[5], Gudrun Sigmundsdottir[6], Arthur Löve[3,7], Magnús Gottfredsson[3,4,8]. *[1]Landspitali University Hospital, Department of Internal Medicine, Reykjavik, Iceland; [2]Landspitali University Hospital, Department of Gastroenterology and Hepatology, Reykjavik, Iceland; [3]University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland; [4]Landspitali University Hospital, Department of Science, Reykjavik, Iceland; [5]SAA National Center for Addiction Medicine, Reykjavik, Iceland; [6]Chief Epidemiologist, Directorate of Health, Reykjavik, Iceland; [7]Landspitali University Hospital, Department of Virology, Reykjavik, Iceland; [8]Landspitali University Hospital, Department of Infectious Diseases, Reykjavik, Iceland*
Email: sigurdol@landspitali.is

Background and Aims: The introduction of direct-acting antivirals (DAAs) has revolutionised treatment of hepatitis C but reinfections among those who share injection drug paraphernalia can jeopardize efforts to eliminate HCV infection as a public health threat. Risk of reinfection has been reported to be higher among younger patients and those who mainly use stimulants. The Treatment as Prevention for Hepatitis C in Iceland (TraP Hep C), was started in 2016 in Iceland, offering treatment with DAAs to all HCV-infected individuals. We sought to determine the incidence of HCV reinfections among patients in the program.

Method: Background clinical data was gathered prospectively. The study cohort was limited to patients who completed treatment and achieved sustained virological response (SVR) between January 11th 2016–November 20th 2018, and thus had >1 year of observation following cure. In addition, viral genotypes and viral deep sequencing results were reviewed. The observed follow-up time from confirmed SVR to the most recent HCV PCR was used to calculate the period for each individual and the reinfection rate/100 person- years (PYs) for the patient cohort. In addition, to account for low-risk patients in the cohort we also approximated the theoretical minimum reinfection rate, by the assumption that every patient with last HCV PCR listed as negative had remained negative until November 20th 2019.

Results: A total of 617 treatments of 597 patients (409 males, average age 44,5 years) were completed with confirmed SVR. During follow-up, 44 reinfections occurred in 42 patients (9 female, 33 male). The total follow-up was 494,7 PYs with an average time to a positive HCV PCR test of 380 days. History of IDU was reported by 508 (85%) and recent IDU with 205 (33%) treatments. Stimulants were the preferred iv drug among 85%. The observed overall reinfection rate was 8,9/100 PYs (95% CI 5.8–13.6). High reinfection rates were associated with homelessness (24,3/100 PYs), recent IDU (reinfection rate 18,1/100 PYs), concomitant IDU and use of non-intravenous stimulants (reinfection rate 26,2/100 PYs), and young age (20–24 years; reinfection rate 24/100 PYs). The theoretical (calculated) observation period for the total cohort was 1502 PYs and thus the lowest theoretical minimum reinfection rate in Iceland was 2,9/100 PYs (95% CI 1,9–4,5). Most reinfected patients have been successfully retreated.

Conclusion: The observed reinfection rate after successful DAA treatment in Iceland is high and seems to be segregated to young marginalized people who continue to use drugs and those who have unstable housing. The inherent bias towards repeat blood tests in high-risk patients may lead to an overestimate of reinfection rates. Further emphasis on people at the highest risk of reinfection is challenging, but essential in order to maintain the effectiveness of treatment and further reduce HCV transmission.

Background and Aims: Chronic hepatitis C (CHC) and non-alcoholic steatohepatitis (NASH) are major underlying etiologies for hepatocellular carcinoma (HCC), one of the fastest growing cause for cancer-related mortality. However, options for treating HCC are unsatisfactory with absent chemopreventive strategies. We have recently shown that chronic HCV infection results in epigenetic modifications that drive HCC development and persist after DAA cure in patients with CHC (Hamdane, Juehling et al. Gastroenterology 2019). Here we aimed to investigate hepatocyte chromatin readers and modifiers as targets for HCC chemoprevention in CHC and NASH-induced liver disease.

Method: Liver tissues samples from CHC and NASH patients with early and late stage disease were analyzed using genome-wide RNA-seq and ChIPmentation-based ChIP-Seq of the H3K27ac histone modification. CHC- and NASH-specific epigenetic modifications and transcriptional reprogramming were modeled in human liver cell culture systems and animal models. Perturbation studies combined with small molecule screens followed by *in vivo* and *ex vivo* validation were applied to identify chromatin modifiers and readers for HCC chemoprevention.

Results: CHC and NASH share a redundant set of epigenetic and transcriptional modifications inducing a transcriptional program driving carcinogenesis in the liver of patients. Using a cell-based system modeling the virus and NASH-induced epigenetic modifications in patients, we identified chromatin readers as targets to revert liver gene transcription driving clinical HCC risk. Proof-of-concept studies in a NASH-HCC mouse model showed that the pharmacological inhibition of chromatin reader BRD4 inhibited liver disease progression and hepatocarcinogenesis by restoring transcriptional reprogramming of the genes that were epigenetically altered in patients.

Conclusion: Our epigenetic and transcriptional analyses suggest that CHC and NASH share common mechanisms of disease progression and HCC risk. Our perturbation studies in cell culture and animal models uncover the functional relevance of metabolic and virus-induced epigenetic alterations for HCC risk. Our pharmacological *in vivo* studies identify chromatin readers are candidate targets for HCC chemoprevention in patients with chronic liver disease.

Simple blood test criteria for non-cirrhosis plus age and post-treatment AFP rule-out the risk of hepatocellular carcinoma development after SVR

Masayuki Kurosaki[1], Namiki Izumi[1], Jun Itakura[1], Kaoru Tsuchiya[1], Hiroyuki Nakanishi[1], Nobuharu Tamaki[1], Shun Kaneko[1], Yutaka Yasui[1]. [1]*Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Tokyo, Japan*
Email: kurosakim@gmail.com

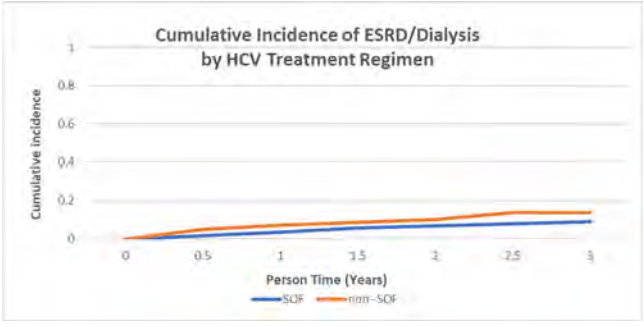
Background and Aims: The EASL guideline suggest that patients without advanced fibrosis or cirrhosis could be discharged after sustained virologic response (SVR). Simplified HCV treatment algorism for treatment-naive patients without cirrhosis by AASLD/IDSA also advised against liver-related follow-up after SVR for no-cirrhotic patients. In this algorism, any positive result with the cutoffs of the following was used to suggest cirrhosis: FIB-4 >3.25, Platelet count <150,000/mm^3, APRI >2.0, and Fibroscan stiffness >12.5 kPa. The aim of the present study was to validate these cutoffs in terms of hepatocellular carcinoma (HCC) risk after SVR, and to further refine the criteria of patients who could be discharged after SVR.
Method: A hospital cohort of 717 patients who had no prior history of HCC and achieved SVR by interferon-free DAA regimens were studied. The incidence of HCC development was analyzed after stratification by the number of positive test results for FIB-4 >3.25, Platelet count <150,000/mm^3, and APRI >2.0. In patients with no-cirrhosis, factors for HCC risk was analysed.
Results: The number of patients with 1, 2, and 3 positive tests was 125 (17.4%), 160 (22.3%), and 5 (0.7%), respectively. Thus, a total of 40.4% was regarded as cirrhosis. The remaining 427 patients (59.6%) with no positive results were regarded as no-cirrhosis. During the median observation of 2.3 years after SVR, HCC developed in 27 patients. The incidence of HCC in patients with cirrhosis was significantly high compared to no-cirrhosis: (4.1% vs. 2.0% at 1 year, 6.3% vs. 3.1% at 2 years, 8.4% vs. 3.1% at 3 years, p = 0.015). The incidence was higher in patients with 2 or more positive tests compared to those with only 1 test (HR 4.0, 95%CI 1.1–13.9, p = 0.03). Among patients with no-cirrhosis (no positive test), age older than 65 (HR 5.2, 95%CI 1.6–17.4, p < 0.001) and post-treatment AFP>6.0 (HR 9.1, 95%CI 4.2–19.7, p < 0.001) was significantly associated with HCC development. HCC did not develop in 182 patients (25% of the cohort) who fulfilled the following criteria: no-cirrhosis (no positive test), age under 65, and post-treatment AFP <6.0.
Conclusion: The number of positive tests suggestive of cirrhosis, as defined by AASLD-IDSA simple algorism, correlated with the risk of HCC after SVR. Among no-cirrhosis patients, older age and post-treatment AFP>6.0 was associated with HCC risk. Addition of age and post-treatment AFP to simple blood criteria for no-cirrhosis could define the true no-HCC risk patients who may be discharged after SVR.

FRI441

Risk of end-stage renal disease among hepatitis C patients with chronic kidney disease treated with and without sofosbuvir

Laura Telep[1], Meghan Sise[2], Lindsey Force[1], Anuj Gaggar[1], Anand Chokkalingam[1]. [1]*Gilead Sciences, Inc., Foster City, United States;* [2]*Massachusetts General Hospital, Boston, United States*
Email: laura.telep@gilead.com

Background and Aims: Sofosbuvir (SOF) is a prodrug inhibitor of the hepatitis C virus (HCV) NS5B polymerase. The predominant circulating metabolite of SOF, GS-331007, is renally eliminated. Whether SOF affects kidney function is not well described. Using administrative claims data, we sought to characterize the risk of end-stage renal disease (ESRD) or dialysis among patients with chronic kidney disease (CKD) and HCV treated with SOF- and non-SOF-containing direct acting antiviral (DAA) regimens.
Method: 2,359 adult patients with evidence of interferon (IFN) -free DAA-treated HCV infection and claims indicating diagnosis of CKD were identified from a large US administrative claims database. All included patients had at least 1 year of continuous enrolment prior to cohort entry. Exclusion criteria were 1) prior claim for ESRD, dialysis, or kidney transplant, 2) simultaneous exposure to SOF and non-SOF DAA regimens, and 3) concomitant receipt of IFN. Patients were observed from initiation of the most recent DAA regimen to the first of: a claim for ESRD or dialysis, kidney transplant, discontinuation of insurance enrolment, or last date of data availability (September 2018). Absolute rates per 100 person-years (PYs) were calculated with exact 95% Poisson confidence intervals (CIs) at all stages of CKD combined and stratified for those patients with staging identified. Adjusted hazard ratios (HRs) estimating ESRD/dialysis risk associated with SOF- vs non-SOF-containing DAA regimens were calculated using Cox proportional hazards methods, after adjustment for baseline health status and treatment propensity score weighting.
Results: Overall, the unadjusted incidence of ESRD or dialysis was 3.88 (95% CI, 3.24–4.62) per 100 PY, with rates highest for patients with severe CKD (18.26; 95% CI, 12.79–25.28 per 100 PY). For the 1,976 SOF and 383 non-SOF DAA regimens, the unadjusted rates of ESRD or dialysis were 3.53 (95% CI: 2.89–4.28) and 7.41 (95% CI: 4.65–11.22) per 100 PY respectively. After covariate adjustment and treatment propensity score weighting, there was no significant difference in risk of ESRD or dialysis with vs. without SOF (adjusted HR = 0.77, 95% CI: 0.43–1.36). Similar results were observed when stratified by CKD stage.



Conclusion: The results of this analysis of real world data indicate no difference in risk of ESRD or dialysis in HCV-infected CKD patients treated with SOF- vs. non-SOF-containing DAA regimens.

FRI442

The weight of pre-existing cofactors for liver disease progression in patients who successfully eradicated chronic hepatitis C viral infection: an interim analysis in the PITER cohort

Email: loreta.kondili@iss.it

Background and Aims: EASL clinical practice guidelines suggest that HCV patients who achieve an SVR need to be maintained on follow-up if pre-existing cofactors (CF) for liver disease progression such as excessive alcohol drinking, obesity and/or type 2 diabetes are present. In the PITER cohort, we evaluated the real life management of patients following HCV eradication according to liver disease stage and presence of these CF.
Method: Data of 4038 patients enrolled in PITER, who eradicated HCV were evaluated. Fibrosis stage was defined by elastometry and/or clinical evaluation for patients with cirrhosis.
Results: Of 1557 patients (mean age 57; SD: 13 years) with F1-F2 fibrosis stage, 77% had CF for liver disease progression. Of overall patients with F1-F2 stage, 30% had a follow-up (median 27 range: 19–34 months) after the SVR12. The prevalence of cofactors was 71% in those who continued follow-up versus 76% in those who interrupted it (p = 0.05). ALT remained elevated during the follow-up in 2% of patients with F1-F2 and CF compared to none of patient without. Of 473 patients (mean age 61;SD: 12 years) with F3 stage and a follow up (median 23; range 13–35 months) after the SVR, 89% had CF for disease progression. During the follow up, transaminase levels remained altered in 4% of patients with CF compared to none in those without CF (p = 0.02). In 3 (0.6%) patients with CF and F3 fibrosis stage at SVR, HCC was developed during the follow-up. Regarding the 2008 patients with cirrhosis, they were followed up for a median period of 33: range 26–41 months, the overall HCC incidence was 4.4% in those with CF and 3.9% in those without (p = 0.7). Factors independently associated to HCC occurrence were age (HR = 1.08; 95% CI 1.04–1.12), decreased albumin value (HR = 3.03 95% CI = 1.46–6.30) and genotype 3 (HR = 2.67 95% CI = 1.03–6.96). During the follow up, 3.2% of patients with decompensated cirrhosis, prior to antiviral treatment, had a new episode of decompensation whereas in 4.8% an incident decompensation episode was registered. Decompensation and worsening of Child Pugh class (found in 33%) were not associated with presence of CF for liver disease progression. Liver decompensation prior to treatment (HR = 7.13; 95% CI 4.51–11.27), platelets count lower than 100,000 (HR = 2.01; 95% CI 1.29–3.12) and decreased albumin values (HR = 1.65; 95% CI 1.08–2.54) were independently associated to liver decompensation.
Conclusion: The presence of cofactors for liver disease progression is common in patients with HCV who received antiviral therapy in Italy. Most physicians did not follow EASL recommendations and interrupted follow-up in F0-F2 patients regardless of the presence of CF. CF are associated with persistent post SVR ALT elevations in F0-F3 patients, but were not associated with higher incidence of HCC or liver related complications during a medium term follow up after HCV viral eradication.

FRI443
Clinical impact of direct-acting antiviral treatment on patients affected by hepatitis C virus-related oral lichen planus

Marco Di Petrillo[1], Dario Di Stasio[1], Riccardo Nevola[2], Luca Rinaldi[2], Luigi Elio Adinolfi[2], Rosario Serpico[1], Aldo Marrone[2]. *[1]University of Campania "Luigi Vanvitelli", Multidisciplinary Department of Medical-Surgical and Dental Specialties, Naples, Italy; [2]University of Campania "Luigi Vanvitelli", Advanced Medical and Surgical Sciences, Naples, Italy*
Email: aldo.marrone@unicampania.it

Background and Aims: Oral lichen planus (OLP) is a chronic inflammatory mucocutaneous disease, and it has been related to the hepatitis C virus (HCV) infection as one of the extrahepatic pathological manifestations. The current treatment for HCV infection with direct-acting antivirals (DAAs) is highly effective and safe. This study aimed to evaluate the impact of HCV eradication on OLP clinical manifestations.
Method: Patients (pts) with clinical and/or histological diagnosis of OLP and HCV chronic infection were recruited from the Oral Medicine and Internal Medicine Units of the University of Campania "Luigi Vanvitelli". All pts received DAAs treatment and were monitored at baseline, during, and after treatment for liver function and antiviral response. Patients received an oral clinical examination before DAAs (T0), 8 weeks after the end of treatment (T1) and were periodically followed. Statistical analysis was performed using Mann–Whitney and Wilcoxon tests, Chi-square, and Fisher's tests.
Results: Eighteen pts. (13 females and 5 males; median age years 75, range 44–87) with chronic HCV infection (10 pts. with 1b genotype; 7 pts with 2a/2c; 1 pt. with 3a) were enrolled. Fourteen pts. had chronic hepatitis and 4 liver cirrhosis. All pts. received DAAs as reported in Table 1. All pts. cleared HCV RNA and presented a sustained virologic response (SVR) at the follow-up (FU). No adverse events were reported. The median FU was 92 weeks at T2. At T0, five pts presented reticular and bilateral white lesions, 7 pts presented erosive OLP, and 6 presented a mixed form. The mean percentage of oral sites involved at T0 was 30% (±13.9), 20.8% (±12.9) at T1, and 16.2% (±15.2) at T2 showing a progressive improvement from T0 to T1 (p = 0.007) and T2 (p = 0.005). One patient developed oral cancer during the treatment and was excluded. Oral lesions have improved in 9 cases (52.9%) at T1 and in 10 cases (55.6%) at FU (T2); among these, 6 (60%) showed complete remission. However, statistical analysis did not reveal a significant correlation between oral improvement and HCV genotype (p = 0.64), viral load (p = 0.27), liver status (p = 0.60), isolated HBcAb positivity (p = 0.633) and type of DAA treatment received (p = 0.103).
Conclusion: DAAs treatment leading to HCV eradication can improve OLP symptoms. However, a causative relationship between HCV infection and OLP pathogenesis is difficult to establish. Further and larger studies are necessary.

FRI444
Identification of circulating microRNAs predictive of HCC in DAA-cured HCV-related cirrhosis

marie-laure plissonnier[1], Alessandro Loglio[2], Francesca Guerrieri[1], Floriana Facchetti[2], Claude Caron de Fromentel[1], Mirjam Zeisel[1], Pietro Lampertico[2], Massimo Levrero[1,3]. *[1]Cancer Research Center of Lyon, UMR Inserm 1052 - CNRS 5286 - Mixte CLB - UCBL1, Lyon, France; [2]University of Milan, IRCCS Policlinico, Milan, Italy; [3]Hospices Civils de Lyon, Service d'Hépatogastroentérologie/Hôpital Croix Rousse, Lyon, France*
Email: massimo.levrero@inserm.fr

Backround and aims: Treatment of patients with chronic hepatitis C (CHC) with Interferon (IFN)-based or DAA regimens leads to persistent viral eradication, i.e. sustained virological response (SVR). In CHC cirrhotic patient a successful antiviral therapy has been associated with the prevention of clinical decompensation and a strong reduction, but not the complete elimination, of the risk of developing HCC. The identification of those patients at higher risk of

Figure: (abstract: FRI443)

developing HCC among HCV-related cirrhosis patients reaching an SVR represents an important unmet clinical need.

Methods: We performed a retrospective analysis of circulating miRNAs using the NanoString nCounter® technology in selected patients from a prospective longitudinal cohort of 565 HCV cirrhotic patients treated with DAAs in a single clinical center. The study population comprised 12 cirrhotic patients treated with DAA reaching SVR who developed HCC (sera collected before starting DAA treatment (*HCV pre-DAA HCC*) and at HCC diagnosis (*HCV SVR HCC*)) and a case-control cohort of 12 DAA-treated patients who did not develop HCC over a comparable follow-up period after SVR (sera collected before starting DAA treatment (*HCV pre-DAA*) and at SVR (*HCV SVR*)).

Results: Principal component analysis of >800 circulating miRNA profiles from the 4 groups showed that DAA-treated patients who develop an HCC after SVR (*HCV SVR HCC*) cluster tightly together and are well separated from the DAA-treated patients who do not develop an HCC after SVR (*HCV SVR*). Unsupervised hierarchical clustering analysis shows that HCV eradication has a strong impact on circulating miRNAs and that HCC development is accompanied by a further reduction of the number of circulating miRNAs detected, supporting the notion that the profile of circulating miRNAs in the HCV SVR HCC patients is the result of both HCV eradication and HCC development. Four miRNAs were specifically detected in the *HCV pre-DAA HCC* patients who will develop HCC after DAAs treatment and SVR but not in the *HCV pre-DAA* patients who do not develop HCC.

Conclusion: Circulating miRNAs identifies miRNAs that are associated with a higher risk of developing HCC after DAA treatment and HCV eradication in patients with HCV-related cirrhosis. These miRNAs are canditates to be included in new clinical/biological scores to predict HCC in relevant populations of HCV-infected patients.

Impact on health perception, quality of life and labor productivity of antiviral treatment for hepatitis C in patients without significant fibrosis

Matias Estevez[1], Jose Miguel Rosales Zabal[2], Francisco Luis Bellido Muñoz[3], Marta Casado[4], Maria Angeles Lopez Garrido[5], Carmen Molina Villalba[1], Carolina Molina Maldonado[1], Cristina Viñolo-Ubiña[1], Francisco Javier Gallego Rojo[1]. *[1]APES Hospital de Poniente, Gastroenterology and Hepatology, El Ejido, Almeria, Spain; [2]Agencia Sanitaria Costa del Sol, Gastroenterology and Hepatologuy, Marbella, Malaga, Spain; [3]Hospital Universitario Virgen Macarena, Gastroenterology and Hepatology, Sevilla, Spain; [4]Hospital Universitario Torrecárdenas, Gastroenterology and Hepatology, Almeria, Spain; [5]Hospital Universitario Virgen de las Nieves, Gastroenterology and Hepatology, Granada, Spain*
Email: matiasesteveze@gmail.com

Background and Aims: Among the extrahepatic manifestations of chronic hepatitis C virus (HCV) infection, asthenia is estimated at up to 61% of those affected. Improvement in Patient Recorded Outcomes (PROs) related to quality of life has been described with obtaining a sustained viral response (SVR12) after the use of direct-acting antivirals (DAA) in registration studies, but to a lesser extent in real life, and on samples that also included patients with variable degrees of fibrosis. In our study, we treated to assess the effect of DAA treatment in patients with chronic HCV infection with low fibrosis

(F0-F1) on asthenia, perception of quality of life and work productivity.
Method: Multicenter prospective longitudinal case series, between May 2018 and April 2019. Monoinfected patients with low fibrosis (Elastography <7.1 kPa or Fib-4 <1.45) filled in FACIT-F validated questionnaires (assess asthenia and physical, social, emotional well-being and functional) and WPAI for hepatitis C (assesses absenteeism, presenteeism and deterioration in work and daily performance), prior to therapy and in visit of SVR12.
Results: 156 patients were included, 118 of whom completed the forms in both visits, in 5 hospitals. Only 1 did not obtain SVR12. Significant improvement was obtained in the FACIT-F scoring in SVR12 with respect to the baseline both globally and in each of the sub-spheres (Fig 1, up). In the analysis of the possible associated variables, an increase in the overall score ≥ 10% (obtained by 59 patients, 50.4%), only full-time employment was related to such improvement (54.2% vs. 43.4%, p = 0.033). In the figure (bottom), we show the variables associated with greater positive or negative changes in FACIT-F global score, analyzed by mixed effects model. In the WPAI questionnaire, there was no significant improvement in percentage of absenteeism, presenteeism, or performance deterioration in the employed patients, but a lower deterioration of non-work performance attributed to HCV, in the total sample (from 21% to 14%, p = 0.013).
Conclusion: The successful treatment of HCV with AA in patients with minimal or absent liver fibrosis results in an improvement in the physical, social, emotional and functional well-being of the subject, as well as in their subjective level of fatigue, especially in patients who work full time. In addition, it improves the performance capacity of daily activities, although it does not modify the indexes of labor productivity.

Sustained virologic response to direct-acting antivirals does affect the risk of portal vein thrombosis in patients with advanced chronic liver disease

Mattias Mandorfer[1,2], Fanny Turon[1,3,4], Sabela Lens[3,4,5], Anna Baiges[1,3,4], José Ferrusquia[1,3,4], Marta Magaz[1,3,4], David JM Bauer[2], Pol Olivas[1,3,4], Zoe Mariño[3,4,5], Xavier Forns[3,4,5], Virginia Hernandez-Gea[1,3,4], Juan Carlos Garcia Pagan[1,3,4]. *[1]Hospital Clínic, Barcelona Hepatic Hemodynamic Lab, Liver Unit, Barcelona, Spain; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [3]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; [5]Hospital Clínic, Liver Unit, Barclona, Austria*

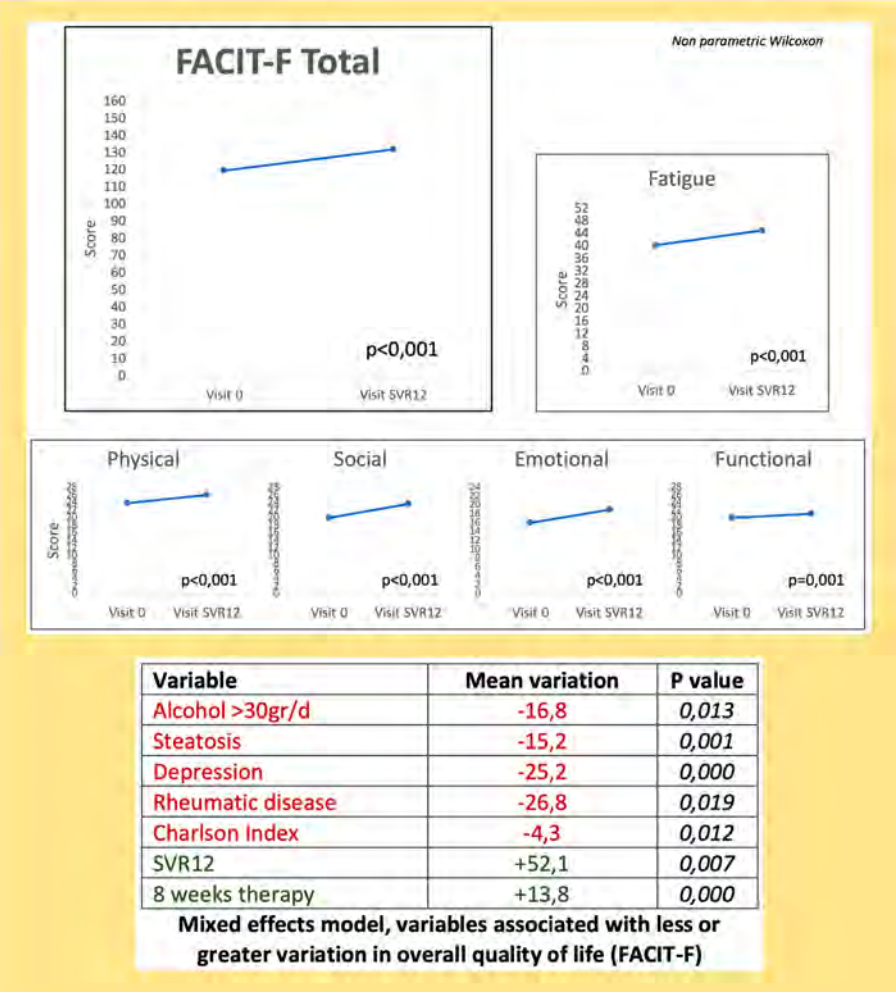
Background and Aims: Sustained virologic response (SVR) to direct-acting antivirals (DAA) ameliorates portal hypertension and improves hepatic function in HCV-related advanced chronic liver disease (ACLD). Studies performing thrombomodulin-modified thrombin generation assays reported no change or even a regression of the

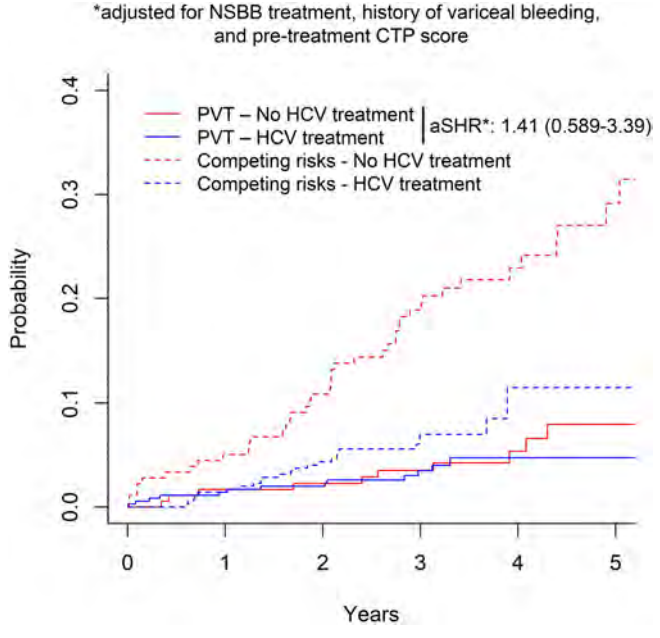


Variable	Mean variation	P value
Alcohol >30gr/d	-16,8	0,013
Steatosis	-15,2	0,001
Depression	-25,2	0,000
Rheumatic disease	-26,8	0,019
Charlson Index	-4,3	0,012
SVR12	+52,1	0,007
8 weeks therapy	+13,8	0,000

Mixed effects model, variables associated with less or greater variation in overall quality of life (FACIT-F)

Figure: (abstract: FRI445)

in vitro hypercoagulability that was observed pre-treatment. However, a worrisome incidence of portal vein thrombosis (PVT) immediately after antiviral therapy has recently been reported.
Therefore, we aimed to analyze the long-term impact of SVR on the development of PVT based on two independent, large, well-characterized cohorts of patients with chronic hepatitis C (CHC) and ACLD.
Method: All patients underwent standardized ultrasound every 6 months; PVT was confirmed by cross-sectional imaging.
Patients entered the time-to-event analyses at end of antiviral therapy ('**HCV treatment**' cohort**;** n = 358) or at the time of inclusion in a prospective study ('**No HCV treatment**' cohort; n = 179). The event of interest in the main analysis was PVT, while events hindering its observation (i.e., tumoral PVT, liver transplantation, or death) or modifying the risk (i.e., transjugular intrahepatic portosystemic shunt (TIPS) or anticoagulation) were considered as competing risks. '**No HCV treatment**' patients were censored at the start of antiviral therapy.
Results: At treatment initiation ('**HCV treatment**')/study inclusion ('**No HCV treatment**'), 18% of patients were Child-Turcotte-Pugh (CTP) stage B/C and the median MELD was 8 (interquartile range: 8–11). Thirteen (3.6%) patients in the '**HCV treatment**' cohort developed a PVT during a median follow-up of 3.1 years, while 10 (5.6%) patients in the '**No HCV treatment**' cohort were diagnosed with PVT during a median follow-up of 3.5 years. High pre- (per point; adjusted subdistribution hazard ratio (aSHR): 1.32 (1.08–1.82)) and post-treatment (aSHR: 1.94 (1.03–3.66)) CTP scores were the only independent risk factors for PVT development. HCV cure did not modify the risk of PVT in competing risk regression models adjusted for previous variceal bleeding, use of non-selective beta-blockers, as well as severity of hepatic dysfunction pre- (SVR vs. non-SVR; aSHR: 1.41 (0.589–3.39); Figure) or post-treatment (aSHR: 1.44 (0.588–3.54)). However, SVR was associated with a substantial reduction of adverse outcomes (a composite of TIPS, liver transplantation, or death; e.g., aHR: 0.204 (0.1–0.418)) and mortality (e.g., aHR: 0.162 (0.06–0.44)).



Conclusion: Although HCV cure reduces the risk of adverse outcomes, and in particular, mortality, it does not affect the risk of PVT in patients who have pre-treatment ACLD. Accordingly, ACLD patients achieving SVR remain at risk for PVT, and thus, should be carefully monitored for PVT. The risk for PVT is increased in patients with impaired hepatic function pre- or post-treatment.
